Identification of immune cell types within bodily fluids, including blood samples, plays a critical role in early detection and disease monitoring within public health initiatives. Although protein biomarkers present in blood samples are useful for clinical assessment, the process of sample preparation for immunostaining is time-consuming and costly. In this study, we present an efficient and rapid preparation procedure for affixing cells on a glass slide for downstream histological staining. Furthermore, using $CD3^+$ T cells as a paradigm, our study concurrently investigates if deep learning models can predict these cells from unlabeled brightfield images of these cell smears. The prediction models could potentially aid in the initial screening process of blood samples and identify samples that require further testing, therefore increasing the throughput of obtaining cell identification results.

Material and Methods

Buffy coat samples were separately processed and spread as monolayers across positively charged glass slides, where they were subjected to fluorescent IHC (fIHC) staining (CD3 and DAPI) using the automated clinical stainer Leica BondMax (Leica Biosystems, Australia). Whole slide fIHC and brightfield differential interference contrast (DIC) images were acquired concurrently with Axioscan 7 Slide Scanner (Zeiss, Germany).

Cell segmentation and guided thresholding of $CD3^+$ cells were performed on the fIHC image using HALO (Indica Labs, U.S.A.) to obtain cell centroids and cell-level ground truth labels. Next, each cell was extracted from the DIC image as a 56×56-pixel image patch, yielding 200,000 image patches (equal ratio of $CD3^+$:$CD3^-$ cells) that were split 80:20 for training and validation respectively. A held-out dataset consisting of 56,000 image patches was used for testing. The model architecture used is a custom ResNet18 convolutional neural network, and its performance was evaluated with metrics such as F1 score and area under the receiver operating characteristic curve (AUROC).

Results

Cell smear slides were successfully stained and imaged, where intact cell morphology was observed across all images. The $CD3^+$ prediction model attained an F1 score of 0.638 and AUROC of 0.87 when applied to the held-out test dataset, indicating that it can differentiate between the unstained brightfield images of $CD3^+$ and $CD3^-$ cells.

Conclusion

Our cell smear preparation procedure is straightforward and rapid, where the slides could be further processed in an automated staining and imaging pipeline. The acquired images can then be used for identification of protein biomarker expression via IHC. If prediction via DL models is applied, then immunostaining could be omitted. Future works include applying this workflow to all other samples of bodily fluids from patients to examine other disease-related biomarkers, and to build prediction models on other protein biomarkers.

#5088 Single cell-based elucidation and pharmacologic targeting of master regulator dependencies in small cell lung cancer (SCLC) subpopulations.

Lucas ZhongMing Hu[1], Anish Thomas[2], Andrea Califano[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]National Cancer Institute, Bethesda, MD

Small Cell Lung Cancer (SCLC) is a highly aggressive and deadly neuroendocrine lung cancer with no major effective treatments. SCLCs are usually detected after wide metastasis, which leads to extremely low five-year survival rate (around 7%). To address this challenge, we leveraged network-based computational approach to first dissect the heterogeneity of SCLC tumors and to discover Master Regulator (MR) proteins representing pharmacologically accessible, mechanistic determinants of molecularly distinct SCLC cell populations. Specifically, we first profiled transcriptomes of 182,189 cells from 41 fresh SCLC human tissue samples, acquired from 14 patients. Samples are collected from both primary site (lung) and metastases (Mediastinum, liver and adrenal gland). Built upon this dataset, we reverse-engineered single-cell based SCLC-specific regulatory networks through ARACNe algorithm. Using these networks, we then measured protein activity of over 6,000 regulatory and signaling proteins for all the cells via VIPER. To dissect intra-tumor heterogeneity of SCLC, protein activity-based analysis of tumor cells identified cell subpopulations representing distinct differentiation and proliferation stages. Our analysis helped identify cell populations presenting highly aberrant activity of proliferative MRs, which are termed as “Tumor Checkpoint” regulatory module. We then identified SCLC cell lines showing high protein activity similarity with the target tumor cell populations using rank-based statistics. Following perturbation of the selected cancer cell lines with hundreds of oncology drugs, we identified potent drugs that could invert the activities of the MRs of target tumor subpopulations using OncoTreat algorithm. The identified drugs are subsequently validated using *in vivo* mouse model. The outcome of this project is four-fold: First, the patient derived SCLC single-cell RNA-Seq dataset generated in this project represents the largest cohort of this kind up to date; Second, our analysis helps study SCLC intra-tumor heterogeneity from the protein activity angle, which is complementary to gene expression measurement alone; Third, our drug perturbation dataset is the first whole-genome based drug perturbation gene expression profile in SCLC cell lines. Fourth, our comprehensive analysis identifies drugs effectively induce tumor population demise in SCLC. Currently, we are working on the drug perturbation experiment on SCLC cell lines to finalize potent drug predictions.

#5089 Cross-platform comparison of snRNAseq, Visium, and Xenium on lung and breast cancer samples.

Mariia Bilous[1], **Daria Buszta**[2], Jonathan Bac[1], Yixing Dong[1], Sylvie Andre[2], Marina Alexandre-Gaveta[2], Senbai Kang[1], Krisztian Homicsko[2], Raphael Gottardo[1]

[1]Data Science Center, CHUV Lausanne University Hospital, Lausanne, Switzerland,[2]Oncology, CHUV Lausanne University Hospital, Lausanne, Switzerland

Background: Spatial transcriptomics is revolutionizing biology and pathology of cancer by enabling the spatial analysis of RNA profiles in formalin-fixed tissues. However, the comparative performance of different platforms and their potential complementarity remain unclear.
Methods: We conducted a comprehensive analysis of single-nuclei RNA sequencing (snRNAseq, n=15), full-transcriptome Visium v2 (n=10), and Xenium (n=40) on lung and breast cancer samples. This allowed a direct comparison between Visium and Xenium and an assessment of how snRNAseq can complement these spatial platforms.
Results: Our findings highlight that Xenium provides high-resolution spatial data with single-cell accuracy and robust performance on FFPE tissues. We demonstrate that snRNAseq enhances Xenium analysis by facilitating automated cell annotation, quality control, and imputing missing gene expression profiles. Although Visium's full transcriptome capabilities offer broader coverage, its resolution is limited and remains a challenge for interpretation, even when refined with super-resolution modeling (e.g., BayesSpace).
Conclusion: Xenium excels in resolution and single-cell spatial mapping, seamlessly integrating with snRNAseq without requiring additional normalization. While Visium offers full transcriptome data, its resolution restricts biological interpretation. Together, Xenium and snRNAseq provide a powerful framework for spatial transcriptomics, advancing insights into tissue biology and pathology.

#5090 Bioinformatics analysis of the role of asymmetric self renewal associated genes in the cancer progression.

S. Hwang, M. Lee, J. Cho, M. Kim, S. Lee, M. Noh;
Seoul National University, Seoul, Korea, Republic of

Adult stem cells possess a unique ability for asymmetric self-renewal, enabling the simultaneous production of non-stem cell progenitors and self-renewing stem cells, distinguishing them from symmetrical cell division. In cancer cells, the regulation of cell division is often disrupted to sustain proliferation. However, specific patterns might be essential for evading cell death and adapting to the tumor microenvironment. In this study, transcriptomic data from engineered p53-expressing and p53-null mouse fibroblasts were re-analyzed to identify expression signatures of asymmetric self-renewal associated (ASRA) and p53/IMPDH2-related self-renewal patterns associated (SRPA). Pathway analysis revealed that ASRA signatures were enriched in immune regulation and angiogenesis pathways, in addition to cell cycle regulation. Genomic analysis using The Cancer Genome Atlas (TCGA) database demonstrated correlations between ASRA signatures and survival outcomes, as well as molecular properties across various cancer types, including stomach adenocarcinoma (STAD). Additionally, public single-cell RNA sequencing (scRNA-seq) and clinical dataset analyses revealed the role of ASRA genes in the interactions between tumor cells and surrounding immune and stromal cells. These findings suggested that targeting ASRA signatures is a promising strategy for developing novel cancer therapies.

#5091 Exploration of conversion therapies target in pancreatic cancer with liver metastasis in single cell spatial transcriptomic levels.

Zijin Xu[1], Qiang Zhou[1], Ying Ying[1], Zeyuan Cao[2], Wenquan Wang[1], Huaxiang Xu[1], Liang Liu[1]

[1]Department of Pancreatic Surgery, Zhongshan Hospital Fudan University, Shanghai, China,[2]State Key Laboratory of Genetic Engineering, Fudan University Human Phenome Institute, Shanghai, China

Objectives: Multidisciplinary treatment drives conversion surgery of pancreatic cancer with liver metastatic clinical cases with unresectable features. The adjuvant regime included AG and FOLFIRINOX and partial cases exhibited no poor response for the treatment. We analyzed single cell spatial transcriptome data to explore biomarkers of therapy.
Materials and Methods: The GSE202051 and GSE199102 cohorts derived from GEO database. The quality control, analysis, and plotting of single cell spatial transcriptome rely on the R packages including R packages ISCHIA, robustbase, data.table, ggplot2, Seurat, dplyr, factoextra, cluster, showtext, gridExtra, and pdftools.
Results: Malignant biomarkers in liver metastatic samples We drew dim plots to display spatial distribution of various types cells in primary and liver metastatic pancreatic cancer samples. We selected subset of tumor epithelial cells to analyze clusters and displayed c0-c26 tumor epithelial clusters in primary and liver metastatic two groups with dim plots and bar plot. The clusters among c0(59.2%), c5(32.8%), c6(32.4%), and c10(21.9%) possessed more enrichment distribution in liver metastatic region. We used the function FindAllMarkers to analyze top differentiation expression genes in clusters and found three prominent genes including TNFSF14, CYP2E1, and LCN2(Fig1).Stromal microenvironment evolution driven liver metastatic biomarkers gene We calculated and settled each cell type proportion data in each sample based on spatial transcriptome information. Subsequently, we drew the correlation heatmap to discover the positive correlation of TNFSF14 expression levels in tumor epithelial cells with endothelial cells(R=0.64, pvalue=0.032) and negative correlation of CYP2E1 with CAF(R=-0.91, pvalue<0.001) in primary cell type proportion. We identify CYP2E1 driving myCAF changes in stromal microenvironment. For the purpose of exploring extinct myCAF subtypes in volution, we also displayed the correlation heatmap to discover the correlation results of c0-c14 myCAF clusters with CYP2E1 gene expression. Interestingly, only positive result demonstrated positive correlation between c5 cluster and CYP2E1 gene(R=0.76, pvalue<001). The heatmap displayed that CYP2E1 expressed prominently in c5 cluster myCAF. Simultaneously, we identified the expression tendency in samples with neoadjuvant therapy and displayed the positive correlation between CYP2E1 and poor response(Fig2).
Conclusion: Our study used single cell spatial transcriptome data with in-depth explaining spatial distribution and expression levels and explored vital biomarker CYP2E1 in pancreatic cancer with liver metastasis. A series of experiments and clinical trials would be designed and conducted by our team in future.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Pharmacokinetics and Pharmacodynamics of Cancer Therapeutics Poster Session

#6393 Patient selection, target engagement and pharmacodynamic markers of WRN inhibitor GSK4418959 (IDE275).

Yanhua Rao[1], Gabriele Picco[2], Diana M. Munoz[3], Susan Merrihew[1], Yang Lee[4], Anjana Srivatsan[3], Marya Liimatta[3], Yang Peng[1], Thomas E. Angel[1], Robert Silvers[1], Joshua E. Cottom[1], Matthew G. Rees[5], Melissa M. Ronan[5], Jennifer A. Roth[5], Raynold Shenje[1], Brian T. Jones[3], Edward J. Brnardic[1], Michael P. DeMartino[1], Geeta Sharma[4], Mathew J. Garnett[2], Joshua P. Taygerly[3], Michael A. White[3], Benjamin Schwartz[4]

[1]GSK, Upper Providence, PA,[2]Wellcome Sanger Institute, Cambridge, United Kingdom,[3]IDEAYA Biosciences, South San Francisco, CA,[4]GSK, Cambridge, MA,[5]Broad Institute of MIT and Harvard, Cambridge, MA

GSK4418959 (IDE275) is a clinical-stage WRN helicase inhibitor designed to treat MSI-H cancer. This compound phenocopies WRN genetic inactivation, with exquisite MSI-H selectivity in large panel of cell lines. Results from extensive cell line profiling indicate a strong correlation between MSI score and sensitivity to the compound. Interestingly, sensitivity to the compound also correlates with the TA-repeat prevalence of individual cell lines. There appears to be no bias toward specific genetic mutations in the dMMR panel, and the compound's sensitivity is not affected by the driver mutation status of the tested cell lines or models. These findings support the use of dMMR and MSI-H as patient-selection biomarkers for GSK4418959 (IDE275). A mass spectrometry-based target occupancy assay was developed to measure WRN target engagement by GSK4418959 (IDE275), using a covalent WRN inhibitor as a probe. GSK4418959 (IDE275) demonstrated dose-dependent target occupancy in cells, showing that over 90% target occupancy is required to inhibit growth. This assay was successfully applied to xenograft tumors, demonstrating dose-dependent WRN occupancy by GSK4418959 (IDE275) in vivo. GSK4418959 (IDE275) induced significant DNA damage selectively in MSI-H cells, but not in MSS cells. DNA damage markers such as gH2AX and pKAP1 were strongly induced both in vitro and in vivo. Immunohistochemistry (IHC) results suggested dose- and time-dependent induction of these markers in MSI-H xenograft models by GSK4418959 (IDE275), providing evidence to support their use in monitoring drug response in clinical settings.

IMMUNOLOGY: CAR-T Cells

#6395 Synthetic pathway activators enhance CAR-T functional persistence and prevent T cell exhaustion.

Lan Chen[1], Thomas Gardner[1], Beatriz Millare[1], Anzhi Yao[1], Josephine Giles[2], Ashley Cass[1], Suchismita Mohanty[1], Jeremy Chen[1], Alma Gomez[1], David DeTomaso[1], Aaron Cooper[1], Levi Gray-Rupp[1], John Wherry[2], Nicholas Haining[1]

[1]Arsenal Biosciences, South San Francisco, CA,[2]University of Pennsylvania, Philadelphia, PA

The emergence of T cell exhaustion in CAR-T cells used to treat solid tumors remains a barrier to clinical efficacy. T cell engineering approaches are increasingly used to enhance CAR-T cell function, but to date few approaches directly modulate the development of T cell exhaustion. We have used large scale screening of synthetic transmembrane signaling molecules to identify a class of SPA (Synthetic Pathway Activators) that result in constitutive STAT1/STAT3 activity with marked gains of CAR-T cell anti-tumor potency, expansion, and persistence both in-vitro and in-vivo. In vitro, CAR-T cells expressing SPA displayed higher proliferation in response to both TCR and tumor antigen stimulation, and secreted more Granzyme B and IL-10 cytokines, but did not show cytokine-independent proliferation. SPA-expressing CAR-T cells also retained superior function relative to control CAR-T cells in a repetitive stimulation assay that recapitulates T cell exhaustion. In vivo, SPA-expressing CAR-T cells showed greatly enhanced potency in both 786-O and A498 xenograft models of Renal Cell Carcinoma, and demonstrated increased T cell expansion followed by rapid contraction after tumor clearance. Mechanistic studies utilizing temporal RNAseq data and pseudotime analysis of SPA expressing cells throughout the 14-day RSA assay revealed a divergent trajectory of T cell differentiation in comparison to control CAR-T cells, with greater maintenance of memory marker expression. Importantly, SPA-expressing CAR-T failed to induce TOX - a canonical transcriptional regulator of exhausted T cells - compared to control CAR-T cells. ATAC-Seq analysis further confirmed that the TOX locus remains inactive in SPA cells following chronic antigen stimulation, while unmodified CAR-T cells develop characteristic open chromatin regions surrounding the TOX locus. Thus the SPA module is a T cell intrinsic enhancement that boosts CAR-T potency and persistence by limiting the development of exhaustion. Moreover, it suggests that persistent STAT3/STAT1 activation may provide a general approach to modulate the emergence of T cell exhaustion.

#6401 *In vivo* mRNA CAR-T cell engineering using peptide based targeted nanoparticles.

Gilles Divita[1], Audrey Grunenberger[2], Lea Cabrera[2], Julien Vollaire[3], Veronique Josserand[3], Neil Desai[1]

[1]Aanastra, Pacific Palisades, CA,[2]Divincell, Nimes, France,[3]Plateforme OPTIMAL, IAB, Grenoble, France

The Chimeric Antigen Receptor (CAR) T cell therapy has emerged as a ground-breaking immunotherapeutic approach in cancer treatment and demonstrated encouraging clinical results in autoimmune disease indications. However, personalized CAR T cell production is a bottleneck due to challenges in cell manufacturing, scalability, high production costs and the use of viral transduction. *In vivo* CAR T cell generation has been proposed to make this treatment immediately accessible to patients and applicable for broader use. However, efficient and highly selective gene delivery to target cells *in vivo* is challenging. To that end, we are developing a new peptide based (non-lipid) delivery platform (PEP-NP) to enable *in vivo* delivery of CAR mRNA to T-cells. The PEP-NP platform is based on short amphipathic peptides that form stable, scalable nanoparticles capable of efficiently packaging and delivering RNA to the target site. PEP-NPs have been designed to bypass the liver and to enhance mRNA expression in the spleen and T-cells *in vivo*. PEP-NPs were selected based on their efficiency to deliver functional Fluc-mRNA on Jurkat or THP-1 cells and primary human T cells from different donors. Efficiency of PEP-NP to deliver a mRNA encoding for αCD-19 protein was evaluated on human primary T cells. The cytotoxicity of CAR-PEP-NPs transfected T cells was evaluated by co-cultured with either Nalm6 (CD19+) or K651 (CD19-) cells. *In-vivo* efficacy of PEP-NP (0.5 and 1.0 mg/kg) to deliver mRNA in the spleen and in specific immune cells, was evaluated in C57BL/C6 mice using luciferase or eGFP encoding mRNA and analyze by flow cytometry. PEP-NPs carrying mRNA encoding luciferase showed a dose responsive transfection starting at 6 hr post treatment with more than 80% of treated cells expressing Luciferase after 72 hr. We validated transfection, translation and surface expression of a functional CD19 CAR protein by transfecting T cells with PEP-NPs mRNA encoding for αCD19 CAR protein. CAR expression was observed in more than 80% of the transfected T cells from different donors. CAR-PEP-NPs transfected T Cells showed a robust dose response specific cytotoxic effect, resulting in 65% to 92% killing of CD19+Nalm6 cells, while in contrast, no cytotoxicity was observed on K561 (CD19-) cells or with T cells transfected with PEP-NP eGFP mRNA . Then we demonstrated that IV administration of T cell targeted PEP-NPs resulted in a high Luciferase or GFP mRNA expression in the spleen. PEP-NPs carrying GFP mRNA showed a dose-dependent mRNA delivery to T cells in the blood as well as splenic T cells with 15-22% of GFP positive T cells after a single injection. No toxicity of PEP-NP was detected after single or repeat dosing. Our study provides a proof-of-concept that PEP-NP platform can be applied to directly target T cells for *in vivo* CAR T cell engineering. PEP-NP is a novel strategy for specific T cell reprogramming providing redosable, off the shelf T cell gene therapies for patients.

TUMOR BIOLOGY: Cancer Cell Heterogeneity, Evolution, and Trajectory Profiling

#6713 RB1 and TP53 restrict lineage plasticity in prostate cancer by regulating chromatin accessibility.
M. R. Flores, J. Jacobi, D. W. Goodrich;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Lineage plasticity has been widely recognized in various cancers as a driver of therapeutic resistance, but the molecular basis of this plasticity remains incompletely defined. Evidence from the literature reveals that the inactivation of RB1 and TP53 in prostate cancer (PC) results in the emergence of alternative lineage states that are resistant to androgen receptor (AR)-targeted treatment. How RB1 and TP53 loss cause this lineage plasticity is not clear. This study proposes that RB1 and TP53 help maintain heterochromatin in order to restrict chromatin accessibility and maintain the fidelity of lineage specific gene expression. To test this hypothesis, changes in chromatin accessibility (ATAC-seq) and lineage gene expression (RNA-seq) are monitored in single prostate organoid cells over time following deletion of PTEN (SKO) or PTEN/RB1/TP53 (TKO). Analysis of resulting data indicates that TKO organoids have increased transcriptional diversity and elevated expression pathways like JAK-STAT that have been functionally linked to lineage plasticity and resistance to AR-targeted therapies. These gene expression changes are preceded by increased chromatin accessibility at relevant gene promoters. Enrichment of neuroendocrine PC gene signatures is found in both SKO and TKO organoids likely driven by histone methyltransferase EZH2 as well as DNA methyltransferase DNMT1. TKO organoids also exhibit increased ability to adapt to changing growth conditions, likely facilitated by their increased transcriptional plasticity. Future directions for this study will assess the influence of EZH2 and DNMT1 on chromatin accessibility, gene expression, lineage plasticity, and therapeutic resistance following tumor suppressor deletion. Overall, results are consistent with the hypothesis that RB1 and TP53 loss in PC cells creates a more accessible chromatin state permissive for transcription. Findings may also reveal approaches to suppress therapeutic resistance in PC by therapeutic targeting of lineage plasticity.

TUMOR BIOLOGY: A Role for the Tumor Microenvironment in Progression

#5096 G2.2, a synthetic mimetic of heparan sulfate hexasaccharide, inhibits chemotherapy-induced dormancy.

Shoja M. Haneefa[1], Rio Boothello[2], Bharath Villuri[1], Rawan Fayyad[1], Priyanka Mishra[1], Sajni Vora[3], Umesh R. Desai[1], Bhaumik B. Patel[1]

[1]Virginia Commonwealth University, Richmond, VA,[2]Strand Therapeutics, Boston, MA,[3]Rutgers UMDNJ, New Brunswick, NJ

Background: Tumor cells can enter distant sites and persist as disseminating tumor cells (DTCs). DTCs are known to remain dormant, exhibiting reversible cell cycle arrest/quiescence and anti-cancer therapy resistance. We and others have shown that Insulin-like Growth factor 1 (IGF1) - Receptor (IGF1R) is critical in therapy resistance and cancer stem cell (CSC) phenotype. We have recently discovered a novel role of sulfated glycosaminoglycan (sGAG) oligosaccharides, particularly heparan sulfate hexasaccharide (HS06), in regulating IGF1R signaling through direct binding to its extracellular domain in competition with IGF1. A structurally specific non-saccharide mimetic of HS06, called G2.2, potently inhibits CSC phenotype in various cancers. These observations led us to explore the possible involvement of IGF1R in dormancy phenotype and G2.2 in targeting dormant cells.

Methods: HT-29, as well as HCT-116 (wild type, IGF1R KO (CRISPR), and IGF1R KO + GAG binding site mutant IGF1R (R107H) expressing) cells were studied. Cells were treated with clinically relevant oxaliplatin and 5-fluorouracil (FUOX) (5μM and 125μM, respectively) for 48 hours. They were reseeded in the presence and absence of IGF1 (20 ng/ml) or G2.2 (0→100 μM) to monitor growth and characterize dormancy - DEC2, p27, and Ki-67 (Flow and IF) as well as sGAG expression. Furthermore, FUOX-treated HT-29 cells were harvested on day 7 and implanted subcutaneously in nude mice (10^6 cells/mouse). Two weeks following s.c. injection, the animals were randomized to Vehicle or G2.2 (100 mg/kg, three times a week) for 10 weeks and monitored till euthanasia criteria were met.

Results: The growth curve showed three phases- the initial dormancy induction (phase 1) followed by a growth arrest/dormancy maintenance (phase 2), which was promptly followed by an exponential growth/dormancy escape (phase 3) representing the dormant cell cycle. Indeed, DEC2, p27 expression, and % of Ki-67 negative cells were higher during phase 2 and decreased before phase 3. Interestingly, sGAG and pIGF1R levels were significantly higher in Phase 1 and Phase 2. Consequently, in the presence of IGF-1, cells failed to enter phase 2. On the other hand, G2.2 treatment resulted in a prompt entry into phase 2 but failure to exit phase 3 in cells expressing wild-type IGF1R but not R107H mutant IGF1R. In the HT-29 DTC-induced xenograft model, we observed 100% inhibition of tumor recurrence in the G2.2 treated group, but all the animals in the treated group eventually succumbed to tumor regrowth (with a latent phase).

Conclusions: Our *in vitro* model is representative of therapy-induced tumor arrest followed by spontaneous recurrences observed in the clinic. sGAG-IGF1R interaction may be a critical regulator of DTC survival, and G2.2 represents a novel therapy for targeting DTC*, partially* through IGF1R inhibition.

#5097 Single cell analysis reveals upregulation of immune stimulatory pathways in quiescent metastatic castration resistant prostate cancer cells.

Kristina G. Ibrahim, Julie Boerner, Steven Zielske, **Frank C. 1394557 Cackowski**

Oncology, Wayne State University School of Medicine, Detroit, MI

Quiescent, or G_0 cell cycle phase, cells are common in most prostate cancer (PCa) cases, yet are relatively resistant to many treatments, especially cytotoxic chemotherapy. They also play key roles in tumorigenesis, and dormancy and recurrence after curative intent therapy, but are difficult to identify when viable. To identify characteristics of quiescent prostate cancer cells, we used previously published FACS methods to isolate cancer cells from bone or bone marrow of eight metastatic castration resistant prostate cancer (mCRPC) patient samples and generated single cell RNA sequencing (scRNA-seq) gene expression data of individually sorted cells. We also generated scRNA-seq data from six PCa cell lines and two normal (cancer free) bone marrow samples as positive and negative controls for cell identification. We eliminated *a priori* any potentially contaminating cells based on tSNE cluster location, expression of a 12 gene panel of PCa markers, and lack of expression of bone marrow markers (*PTPRC* / CD45, and *GYPA* / CD235a), leaving 297 high confidence PCa cells. To identify characteristics of G_0 cells, we separated the patient PCa cells into quiescent and cycling groups based on expression of *MKI67* (Ki67). GSEA analysis of KEGG pathways revealed enrichment of primarily immune related pathways in quiescent cells with the top 3 pathways; “allograft rejection,” “autoimmune thyroid disease,” and “intestinal immune network for IgA production.” Similarly, for GSEA analysis using gene ontology (GO) groups, “beta-2-microglobulin binding” was the second most enriched group in quiescent cells. Type 1 HLA genes, were common among multiple pathway groups suggesting potential differences in antigen presentation. In subsequent validation experiments, induction of quiescence in LNCaP, C4-2B, PC3, and RM1 PCa cell lines increased cell surface HLA class 1 or Mhc-1. Overall, these results suggest that antigen presentation is increased in quiescent PCa cells, which may be important for their elimination by the immune system, or useful for future immunotherapy approaches.

#5098 Targeting fatty acid dependency in hormone receptor positive HER2 negative drug tolerant persister bone metastases.

Abigail E. Goen[1], Jonathan D. Marotti[2], Todd W. Miller[3]

[1]MCB Cancer Biology, Dartmouth College, Lebanon, NH,[2]Molecular and Systems Biology, Pathology and Laboratory Medicine, Dartmouth College, Lebanon, NH,[3]Medical College of Wisconsin, Milwaukee, WI

The HR + subtype constitutes 65% of breast cancer (BC) cases with a 1/3 of patients eventually developing metastatic disease, most often in bone. This implicates a drug-tolerant persister cancer cell (DTP) population as a source of disease recurrence. Mouse models of primary and metastatic dormancy along with human tumor transcriptional profiles suggest preferential use of fatty acids (FA) by DTPs, offering fatty acid inhibition as a potential therapeutic vulnerability. HR+ BC cells were treated ± 1 nM 17b-estradiol (E2) for 14 d to provide growing and DTP cell populations. Cells were then treated ± inhibitors of fatty acid transporter CPT1a or fatty acid synthase (FASN). Assay endpoints included levels of proteins and transcripts associated with fatty acid metabolism. CD36 over-expressing, shRNA knock-down, and control cell lines were cultured with exogenous FA adipocytes, or treated with adipocyte-condition medium; assay endpoints included fatty acid uptake, growth response, and levels of fat metabolism proteins and stored lipid. Luciferase-labeled xenografts were induced in NSG mice with E2, which was removed for 90 d to induce tumor regression and yield DTP populations both orthotopically and intra-tibially. Mice were randomized to treatment with vehicle or CD36 mAb and assayed for DTP burden by imaging. Tumors were harvested and molecular endpoints were assessed. DTPs had increased lipid uptake compared to E2-treated controls. Estrogen deprivation increased levels of fatty acid metabolism-associated proteins, and FASN inhibition induced CD36 upregulation, indicating a potential compensatory mechanism between sources of fatty acids. In DTPs, culture with FA supplementation, adipocyte-conditioned media, or adipocyte co-culture rescued growth to levels observed with E2, suggesting the abundance of FA may push DTP cells out of dormancy. Functional metabolic assays showed inhibition of FASN, CPT1a, or CD36 reduced the ability of DTPs to use fatty acid oxidation to drive respiration. Xenografts showed model-specific upregulation of FASN or CD36 after 90 d of E2 deprivation compared to baseline. Treatment of mice bearing MCF-7 primary and metastatic xenografts with a CD36-neutralizing mAb decreased DTP burden compared to vehicle control. Preclinical modeling suggests that DTPs have an increased dependence upon fatty acids (e.g., mammary fat pad, bone associated adipocytes, co-culture of adipocytes, or FA supplementation) than their proliferative counterparts, offering fatty acid inhibition as a therapeutic vulnerability, particularly for bone-tropic DTPs.

#5099 Notch inhibition as a therapeutic approach to eliminate dormant cancer cells in multiple myeloma.

Hayley M. Sabol[1], Aric Anloague[1], Japneet Kaur[1], Sharmin Khan[1], Bethany Paxton[1], James Smith[2], Michelle McDonald[3], Peter Croucher[2], C. Lowry Barnes[1], Elena Ambrogini[1], Alison Frontier[4], Frank H. Ebetino[4], Jesus Delgado-Calle[1]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Garvan Institute of Medical Research, Sydney, Australia,[3]University of Sydney, Sydney, Australia,[4]University of Rochester, Rochester, NY

Multiple myeloma (MM) remains incurable due to disease relapses, thought to stem from the activation of dormant MM cells. Preventing the awakening or eliminating dormant MM cells is crucial to avoiding disease relapse. In this study, we sought to identify targetable vulnerabilities to eliminate or control dormant cells. First, we used a scRNAseq dataset of dormant MM cells and found that dormant MM cells exhibit upregulation of Notch pathway genes compared to proliferating MM cells. Based on this, we hypothesized that inhibiting Notch signals in the tumor niche should decrease dormant MM cells. To test this notion, we injected immunocompetent mice i.v. with murine 5TGM1 MM cells double-labeled with a fixed genetic reporter and a membrane dye (DiD) retained by non-dividing cells, allowing us to distinguish dormant (GFP^+DID^+) from proliferating cells (GFP^+DID^-). After 2wks, we randomized mice to groups receiving vehicle or a bone-targeted Notch inhibitor (BT-GSI). We detected a population of GFP^+DiD^+ dormant cells that expressed high levels of Axl and were growth arrested throughout the life span of the mice. Short-term treatment with BT-GSI (1wk) reduced tumor burden (75%) and decreased the number of dormant MM cells (70%) via apoptosis. Prolonged BT-GSI treatment (7 wks) eliminated all dormant MM cells and further reduced proliferating cells. These effects were replicated in immunodeficient mice injected with RFP^+DID^+ human OPM2 MM cells and in human bones infiltrated by OPM2 RFP^+DID^+ cultured ex vivo. Next, we explored if modulating the tumor niche could influence MM cell dormancy. Since dormant MM cells colocalize with osteoblasts in the endosteal bone surface, we assessed if increasing osteoblasts numbers and their activity prevents the awakening of MM dormant cells or enhances their engagement in dormancy programs. To test this, we injected GFP^+DiD^+ MM cells and, after two weeks, randomized mice to groups receiving vehicle or Scl-Ab, an anabolic agent that rapidly increases osteoblasts. Scl-Ab (2wks) increased osteoblasts but did not affect the proportion of proliferating or dormant MM cells. Similar results were observed in human bones infiltrated with human MM cells cultured ex vivo treated with Scl-Ab. Next, we pre-treated mice with Scl-Ab (2wks) to generate a microenvironment loaded with osteoblasts before MM cell injection. Despite the increase in osteoblasts, Scl-Ab did not impact the number of dormant or proliferating MM cells. Further, co-administration of Scl-Ab did not interfere with BT-GSI's ability to eliminate proliferating or dormant MM cells in any of these models. In conclusion, our findings show that 1) Notch signals promote the survival of dormant MM cells, 2) manipulating osteoblasts in the tumor niche does not affect MM cell dormancy, and 3) bone-targeted Notch inhibition is a promising approach to eradicate dormant tumor cells and potentially delay/prevent disease relapse in MM patients.

#5100 Mediator subunit *Med4* enforces metastatic dormancy in breast cancer.

S.-Y. Bae[1], H.-H. Ling[1], Y. Chen[1], H. Chen[2], D. Kumar[1], J. Zhang[1], A. Viny[1], R. A. DePinho[2], F. G. Giancotti[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Long term survival of breast cancer patients is limited due to recurrence from metastatic dormant cancer cells. However, the mechanisms by which these dormant breast cancer cells survive and awaken remain poorly understood. Our unbiased genome-scale genetic screen in mice identified *Med4* as a novel cancer-cell intrinsic gatekeeper in metastatic reactivation. *MED4* haploinsufficiency is prevalent in metastatic breast cancer patients and correlates with poorer prognosis. Syngeneic xenograft models revealed that *Med4* enforces breast cancer dormancy. Contrary to the canonical function of the Mediator complex in activating gene expression, *Med4* maintains 3D chromatin compaction and enhancer landscape, by preventing enhancer priming or activation through the suppression of H3K4me1 deposition. *Med4* haploinsufficiency disrupts enhancer poise and reprograms the enhancer dynamics to facilitate extracellular matrix (ECM) gene expression and integrin-mediated mechano-transduction, driving metastatic growth. Our findings establish *Med4* as a key regulator of cellular dormancy and a potential biomarker for high-risk metastatic relapse.

#5103 Digital spatial profling with GeoMx to identify differential protein expression in Non-Hispanic/Latino and Hispanic/Latino Patients with metastatic hormone sensitive prostate cancer.

Peter D. Zang, Joe Bonner, Alexander Chehrazi-Raffle, Lixin Yang, Natasha Garg, Swapnil Rajurkar, James Shen, Naveen Gupta, Amartej Merla, Sumanta Pal, Raju Pillai, Stephen Gruber, Tanya B. Dorff

City of Hope National Medical Center, Duarte, CA

Background: Emerging evidence suggests that there is a complex interplay between ethnicity and disease biology in metastatic hormone sensitive prostate cancer (mHSPC). We examined digital spatial profiling with GeoMx to evaluate differential protein expression between non-Hispanic/non-Latino (NHL) and Hispanic/Latino (HL) patients with mHSPC.
Methods: Pre-treatment prostate biopsy specimens were obtained from patients on a clinical trial as part of an IRB approved protocol. The GeoMx Digital Spatial Profiler (DSP) was used to evaluate protein expression in selected regions of interest (ROIs). Differential expression analysis was performed using R (v 4.4.2). To determine significant differences in protein expression, a false discovery rate (FDR)-adjusted q-value was applied and a Log2Fold change (Log2FC) with a q-value < 0.01 was considered significantly differentially expressed.
Results: A total of 8 patients (4 NHL and 4 HL) were enrolled at City of Hope including network sites and who had pre-treatment biopsy specimens that were available for digital spatial profiling analysis. We examined the Log2FC between protein expression in NHL and HL patients and filtered for q-values < 0.01. We identified multiple proteins that were significantly differentially expressed. Proteins that were more highly expressed (Log2FC > 1) in NHL patients included CD44, fibronection, and Ki-67. Proteins that were more moderately expressed (Log2FC < 1) in NHL patients included beta-2 microglobulin and. In contrast, HL patients were found to have higher expression in BCL6, CD68, CD80, Foxp3, PARP, and STING (Log2FC < 0).
Conclusions: Digital spatial profiling with GeoMx reveals significant differences in protein expression in NHL vs. HL patients with mHSPC. Notably, these include markers of cancer stem cells (CD44), DNA damage pathway proteins (PARP), and both immunoregulatory (Foxp3) and immunostimulatory (STING) proteins. This may have both prognostic and therapeutic implications.

#5104 Fibrosis activates pancreatic cancer Schwann cells in a non-canonical pathway through a nuclear mechanosensing mechanism.

Pavel Stupakov[1], Golbahar Sadatrezaei[1], Ines Velazquez Quesada[2], Lillian Boe[1], Efsevia Vakiani[1], Bojana Gligorijevic[2], Boris Reva[3], Richard J. Wong[1], **Sylvie Deborde**[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Temple University, Philadelphia, PA,[3]Mount Sinai, New York, NY

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive malignancies, with only 12% of patients surviving 5 years after diagnosis. Several elements of the PDAC tumor microenvironment (TME) including fibrosis and tumor innervation contributes to the malignancy, but how they affect each other is unstudied. Here we report a relationship between the stiff desmoplastic environment of PDAC and Schwann cell (SC) activation in nerves of the tumor. The activated SCs reprogram into cells that induce cancer cell spread via activation of the transcription factor c-Jun and the formation of tracks for cancer cells. We show how mechanical forces encountered by SCs in the stiff TME activate SC in a non-canonical manner. We use in vivo and in vitro live imaging, mechanobiology and computational analysis of transcriptomic data, as well as several models including human PDAC specimens, mouse models of pancreatic fibrosis and cells expressing live reporter for c-Jun phosphorylation. We report a positive correlation between c-Jun phosphorylation in SCs of nerves and stiffness of the stroma surrounding these nerves, suggesting a role for stromal stiffness in SC activation. To monitor c-Jun phosphorylation in live SCs, we express a c-Jun kinase translocation reporter (KTR), a fluorescent biosensor that translocates from the nucleus to the cytoplasm upon phosphorylation of a c-Jun motif, in the cell line HEI-286 SCs. Imaging of HEI-286 KTR SCs injected in murine fibrotic and non-fibrotic pancreas shows an association of activated cells with fibrosis. Intravital 4D multiphoton microscopy allows the observation of HEI-286 KTR SCs along collagen fibers and shows a concomitant change of nuclear shape with KTR translocation. Using three different in vitro models, we show that mechanical forces on HEI-286 KTR SCs induce KTR translocation. We show that this activation is associated with a cPLA2 activity and an increase of the AP1 transcription factor network molecules, but not with the expression of the conventional Jun kinase molecules. The results support a nuclear mechanical sensing mechanism inducing SC activation in PDAC through a non-canonical mechanism of c-Jun activation. Furthermore, we show that the SC cellular stress response differs from the cancer cell response. We propose that SCs is activated by two different mechanisms localized at the nucleus and at the plasma membrane. The findings reveal therapeutic opportunities to treat PDAC by indirect targeting of specific component of the TME.

#5105 Tumor treating fields (TTFields) alter nanomechanical attributes of cell-ECM complex in pancreatic ductal adenocarcinoma.

T. Kulkarni, H. Babiker, D. Mukhopadhyay, **S. Bhattacharya**;
Mayo Clinic Florida, Jacksonville, FL

Tumor treating fields (TTFields), a noninvasive anticancer treatment modality, has received FDA approval for pleural mesothelioma, metastatic NSCLC following platinum-based therapy, newly diagnosed and recurrent glioblastoma multiforme. TTFields have also demonstrated potential benefits in other cancer types, including pancreatic ductal adenocarcinoma (PDAC). Although the PANOVA trial yielded positive results in PDAC patients, the mechanisms underlying these beneficial effects remain unclear. Severe desmoplasia is a hallmark characteristic of PDAC due to accumulation of excess extracellular matrix (ECM) caused by activated fibroblasts and cancer cells. This dense ECM contributes to an immunosuppressive tumor microenvironment (TME) and drug resistance, which ultimately leads to poor 5-year survival in PDAC patients. Our previous work with atomic force microscopy (AFM) showed that the nanomechanical properties of the ECM change dynamically based on its composition and the presence of PDAC cells, and vice versa. Herein, we prepared an ECM complex comprising of collagen, fibronectin and laminin at physiological concentrations. Following which, we investigated the alteration of stiffness of both PDAC cells and the ECM in presence of TTFields using an AFM. A frequency-dependent analysis of TTFields showed that a frequency of 150 KHz led to consistent decreases ECM stiffness at 48 and 72 hours. Next, we evaluated the influence of TTFields in PDAC cells alone. In Panc-1 cells exposed to TTFields for 48 and 72 hours, we observed a more than 6-fold increase in membrane stiffness compared to untreated controls. Additionally, AsPC-1 cells subjected to TTFields exhibited a greater than 2-fold increase in membrane stiffness at these time points. Furthermore, we have investigated influence of TTFields on PDAC cells and ECM components in a co-culture model. In this co-culture scenario for Panc-1 cells, TTFields increase membrane stiffness by 5-fold compared to untreated at these time points. Also, AsPC-1 cells demonstrated a 1.5-fold increase in membrane stiffness in the presence of TTFields compared to the untreated. Lastly, we also evaluated the influence of cells on the ECM stiffness in the presence of TTFields. It significantly increased the ECM stiffness in presence of Panc-1 co-culture by 1.3-folds compared to control. We also observed 3- and 4-fold increase in ECM matrix stiffness when co-cultured with AsPC-1 for 48 and 72 hours from TTFields, respectively compared to control. In conclusion, TTFields significantly modulate the stiffness of PDAC cells and the ECM, both individually and in co-culture.

#5106 Cell crowding-induced TRPV4 inhibition and relocation to plasma membranes: Implications for a pro-invasive mechanotransduction pathway in DCIS progression.

Xiangning Bu[1], Nathanael Ashby[1], Teresa Vitali[1], Sulgi Lee[1], Ananya Gottumukkala[1], Kangsun Yun[1], Sana Tabbara[2], Patricia Latham[2], Christine Teal[3], **Inhee Chung**[1]

[1]Anatomy and Cell Biology, The George Washington University, Washington, DC,[2]Pathology, The George Washington University, Washington, DC,[3]Surgery, The George Washington University, Washington, DC

Cell crowding is a common microenvironmental factor influencing disease progression, yet its role in promoting cell invasiveness remains poorly understood. Here, we demonstrate that cell crowding enhances the invasiveness of high-grade ductal carcinoma in situ (DCIS) cells through pro-invasive cell volume reduction. High-grade DCIS cells showed significant volume reduction compared to hyperplasia-mimicking or normal cells under crowded conditions. Mass spectrometry revealed selective relocation of TRPV4, a calcium-permeant ion channel, to the plasma membrane in high-grade DCIS cells, a response absent in less aggressive or normal cells. We found that cell crowding inhibits TRPV4 activity in high-grade DCIS cells, reducing intracellular calcium levels and inducing volume reduction. This inhibition triggers TRPV4 relocation to the plasma membrane, priming it for subsequent activation to counterbalance calcium loss. Analyses of patient-derived breast cancer tissues confirmed TRPV4 association with the plasma membrane specifically in high-grade DCIS, correlating with increased cell invasiveness and motility. Moreover, hyperosmotic stress and pharmacologic TRPV4 inhibition replicated crowding-induced pro-invasive volume reduction, while TRPV4 activation reversed these effects. These findings uncover a novel, selective mechanotransduction pathway in high-grade DCIS that links cell crowding to enhanced invasiveness, shedding light on the biophysical mechanisms driving breast cancer progression. Our results highlight TRPV4 as a potential diagnostic and prognostic biomarker for high-risk DCIS and provide insights into therapeutic interventions targeting cell volume regulation.

#5107 Alterations in cancer-associated fibroblasts are associated with a dysfunctional T cell phenotype and antioxidant response in LKB1/KEAP1-mutant lung adenocarcinoma.

Amirali Karimi[1], Yu Qian[1], Ana Galan-Cobo[2], Fuduan Peng[3], Monique Nilsson[1], Linghua Wang[3], Ferdinandos Skoulidis[1], John V. Heymach[1]

[1]Department of Thoracic, Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Molecular Diagnostic, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX

Background: LKB1/*STK11* and *KEAP1* are the second and third most-commonly mutated tumor suppressor genes in lung adenocarcinoma. *STK11* and *KEAP1* mutations often co-occur together and with *KRAS* mutations and have been associated with an immunosuppressive microenvironment, lack of response to anti-PD-(L)1 therapy, and enhanced antioxidant response. Cancer-associated fibroblasts (CAFs) have been associated with tumor progression and worse survival in lung adenocarcinoma. However, the role of this cell population in promoting the phenotype of LKB1/KEAP1-mutant lung adenocarcinoma remains undefined.

Methods: We analyzed single-cell RNA sequencing (scRNAseq) data from syngeneic *Kras*^{MUT} models (LKR10 and LKR13) of lung adenocarcinoma with or without LKB1 or KEAP1 deficiency. *Stk11* and *Keap1* genes were knocked-out from LKR10K and LKR13K cell lines using CRISPR-Cas9 technology, and mice were injected subcutaneously with *Kras*^{MUT} (K), *Kras*^{MUT}/*Lkb1*^{MUT} (KL), *Kras*^{MUT}/*Keap1*^{MUT} (KK), and *Kras*^{MUT}/*Lkb1*^{MUT}/*Keap1*^{MUT} (KLK) tumor cells. CAF populations were analyzed by scRNAseq using R software packages.

Results: CAF proportion among non-tumor cells was increased in KL and KK populations compared to K, with the highest percentage observed in the KLK tumors. In the LKR10 model UMAP, KK CAFs clustered distinctly from other samples, showing their different phenotype from other three groups. This was not observed in the LKR13 model where differentially expressed genes (DEGs) from KK-vs-K and KL-vs-K comparisons had considerable overlap, indicating similarities in this population. Twelve genes overlapped in DEGs from LKR10 KL-vs-K and KK-vs-K, of which four were related to MHC class I antigen presentation (*B2m*, *H2-D1*, *H2-Q7*, *Psmb8*), suggesting a possible role of CAFs in antigen-presentation to CD8 T cells and their exhaustion, a phenomenon previously described in colorectal carcinoma. *Npc2*, a gene involved in CD1d-mediated lipid antigen presentation to NKT cells, was also upregulated in both groups. In the LKR10 model, classical and non-classical MHC class I genes had the highest expression in KK CAFs, and this was also observed for KL CAFs in the LKR13 model. However, MHC class I upregulation was not replicated in KLK models. *Sod3*, a secretory extracellular superoxide dismutase that generates an antioxidant response in the microenvironment, was upregulated in both LKR10 KL and KK CAFs. Concurrently, LKR13KLK CAFs also demonstrated increased *Sod3* expression compared to LKR13K CAFs.

Conclusions: Our analysis demonstrated that CAFs display distinct phenotypes in LKB1 and KEAP1 deficient tumors, indicating that these cells may in part contribute to the immunosuppressive tumor microenvironment and enhanced antioxidant response, hypothetically partly through the upregulation of MHC class I molecules and secretion of antioxidant protein *Sod3*.

#5108 Decoding tumor intrinsic and stroma-related drug resistance in EGFR mutant NSCLC.

Radhika Koranne[1], Aimee Gleason[2], Emily Hensley[2], Xiaodong Wang[3], Alba Font-Tello[3], Brian Rabe[3], Fayaz Seifuddin[3], Eugene Drokhlyansky[3], Kartik Subramanian[3], Martino Colombo[3], Jason Dobson[3], Mavrakis J. Konstantinos[3], Leila Dardaei[3], Aaron Hata[1]

[1]Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[2]Cancer Center, Massachusetts General Hospital Cancer Cente, Boston, MA,[3]Bristol Myers Squibb, Cambridge, MA

The presence of oncogenic driver mutations such as EGFR, ALK, or KRAS renders non-small cell lung adenocarcinomas sensitive to molecularly targeted therapies, however the inevitable emergence of acquired drug resistance remains an unsolved clinical problem. Osimertinib, a third-generation EGFR inhibitor that was initially developed to overcome the EGFRT790M resistance mutation, is now the standard first-line therapy. Although various mechanisms of acquired resistance to osimertinib have been identified, the specific drivers of resistance remain unexplained in over half of patients. Recent work from our group and others has suggested that cancer-associated fibroblasts may play a role in drug resistance to tyrosine kinase inhibitors (TKIs). Notably, we have observed that patient-derived cancer-associated fibroblast (PDF) cell lines established from TKI-resistant tumors display heterogeneous phenotypes with ability to rescue cancer cells from TKIs. To enable parallel discovery of both tumor cell-intrinsic and stroma-driven resistance mechanisms to osimertinib, we developed a genome-wide CRISPR sensitizer screening approach that incorporates osimertinib-resistant patient-derived EGFR-mutant NSCLC cell lines and conditioned media from matched immortalized PDFs. These studies aim to uncover intrinsic and extrinsic resistance pathways and nominate targets for next-generation therapies to overcome acquired resistance to osimertinib

#5109 ATF4 and SCD: Co-conspirators in promoting the progression of metastatic prostate cancer in bone.

Alexis R. Wilson, Shane Mecca, Mackenzie Herroon, Shrila Rajendran, Laimar Garmo, Izabela Podgorski

Wayne State University School of Medicine, Detroit, MI

Prostate Cancer (PCa) is predisposed to metastasize to bone, a hospitable environment abundant in adipocytes. Our previous studies have highlighted the critical role of marrow adipocytes in PCa progression and chemoresistance in bone. Bone marrow adipocytes are metabolic cells that interact with neighboring cells through the secretion of lipids and adipokines. Specifically, we have shown that interaction with adipocytes promotes lipid uptake by PCa cells and activates ER/oxidative stress pathways; however, the mechanisms behind the tumor-promoting effects of adipocytes are not clearly understood. *The main objective of this study* was to investigate the molecular mechanisms underlying lipid-induced stress during tumor cell-adipocyte crosstalk and its functional relationship to tumor progression in bone. Previously, we have demonstrated that adipocyte exposure increases expression of lipogenic enzyme stearoyl-CoA desaturase (SCD) and ER stress regulator ATF4 in PCa cells. Here, we show that SCD expression decreases with transient knockdown of ATF4. Also, through dual transient knockdown of SCD and ATF4, we determine that SCD deficiency leads to an increase of ER stress genes and demise of PCa cells only when expression of ATF4 is present. We also observe this phenomenon in PCa cells with a stable knockdown of ATF4 (shATF4), suggesting an interplay between SCD and ATF4. Additionally, we reveal that shATF4 PCa cells have decreased proliferation *in vitro,* reduced ER stress signaling, and increased lipid peroxidation levels. RNAseq analyses of shATF4 cells demonstrate the downregulation of inflammation-related pathways, such as NFkB. Notably, we observe that shATF4 cells have decreased expression of *protein tyrosine phosphatase receptor type D* (*PTPRD*) compared to control cells. PTPRD has been implicated in regulating inflammatory pathways but, to our knowledge, has not been shown to be regulated by ATF4. Curiously, shATF4 cells that undergo knockdown of SCD cannot induce pathways involved in apoptotic signaling and ER stress signaling compared to control cells with SCD knockdown. We also observe the induction of the NOTCH signaling pathway and increased expression of *p53 apoptosis effector* (*PERP*), a gene regulated directly by NOTCH, in shATF4 cells grown in co-culture with adipocytes. This is in contrast to control cells with SCD knockdown, where we observe a decrease in *PERP* expression. These results indicate that the downregulation of inflammatory pathways during ATF4 knockdown may be occurring through PTPRD. Also, the increase in NOTCH signaling, which may be due to the reciprocal activation of NFkB and NOTCH pathways, may be counteracting the anti-tumor effects of SCD inhibition on PCa cells. Overall, we demonstrate an interplay between ATF4 and SCD and the critical role of ATF4 in mediating the anti-tumor effects of SCD, which may have therapeutic complications for bone metastatic PCa.

#5110 Solid stress reduces synaptic density and neuronal activity via hypoxia-induced reactive gene expression programs in glioblastoma.

Maksym Zarodniuk, Anna Wenninger, Julian Najera, Jihaeng Lee, Jack Markillie, Cameron Mackenzie, Bianca Batista, Megna Panchbhavi, R'nld Rumbach, Alice Burchett, Hailey Sallaberry, Bradley Smith, Meenal Datta, Christopher Patzke

University of Notre Dame, Notre Dame, IN

Mass effect in central nervous system pathologies poses a significant clinical challenge. This phenomenon, characterized by the compression and deformation of neural tissue from space-occupying lesions, can lead to debilitating neurological symptoms. In glioblastoma, we have shown previously that compressive solid stresses from the growing tumor are correlated with significantly worse neurological performance and survival in patients. While edema is often measured as a prognostic biomarker, it fails to consistently predict neurological deficits; conversely, solid stress correlates with functional impairments and reduced cerebral blood flow. In this study, we explored the direct effects of solid stress on human induced pluripotent stem cell (hiPSC)-derived neurons using an in vitro compression system. Our results reveal that solid stress decreases synaptic puncta and neuronal excitability by activating hypoxia response and pro-apoptotic programs in neurons. We further show that compression upregulates reactive gene expression programs in astrocytes and microglia, contributing to neuroinflammation. These findings illuminate the critical role of solid stress in glioblastoma, offering new insights into its potential contribution to neurodegeneration.

#5111 Targeting the dysadherin/CA9 axis inhibits colorectal cancer adaptation and growth within the acidic tumor microenvironment.

Jeong-Seok Nam, Choong-Jae Lee, Hyeon-Ji Yun

School of Life Sciences, Gwangju Institute of Science & Technology, Gwangju, Korea, Republic of

The tumor microenvironment (TME) has a significant impact on colorectal cancer (CRC) progression by promoting tumor survival and aggressive behavior. A key player in this process is the tumor-associated glycoprotein dysadherin, which is highly expressed in aggressive CRC cells and facilitates their adaptation to the TME. In this study, we conducted a comprehensive bioinformatics analysis of clinical genomic data from CRC patients, integrated with studies on dysadherin-knockout CRC cells. We also examined the downstream effects of dysadherin in human CRC cells, patient tissue samples, and a xenograft mouse model. Through bioinformatics and pathological analysis, we found that increased tumor acidity is a prominent feature of CRC progression and is positively associated with high dysadherin expression. Overexpression and silencing studies of dysadherin in CRC cells further confirmed that high dysadherin levels enhance malignant traits, especially under acidic conditions within the TME. Mechanistically, dysadherin activates the Integrin/FAK/STAT3 signaling pathway, leading to upregulation of carbonic anhydrase 9 (CA9). CA9 helps cancer cells survive in acidic environments by maintaining intracellular pH balance. By buffering the acidic TME, CA9 enhances CRC cell adaptation and resilience in an otherwise hostile environment. Notably, the deletion of dysadherin in xenograft models led to reduced tumor growth, while the reintroduction of CA9 restored malignancy, underscoring the essential role of the dysadherin/CA9 axis. This pathway is crucial for CRC cell survival in acidic TME, positioning dysadherin and CA9 as promising prognostic markers and therapeutic targets. Targeting this axis could disrupt CRC progression, offering new therapeutic avenues and potentially more effective interventions for inhibiting disease advancement

#5112 Tumor cell expression of a distinct TME gene signature defines differential drug sensitivities to EGFR/MEK/SRC targeted agents.

Mingli Yang[1], Michael V. Nebozhyn[2], Lance Pflieger[3], Ramani Soundararajan[1], Michelle Maurin[1], Heiman Wang[1], Andrey Loboda[2], W. Jack Pledger[4], Timothy J. Yeatman[1]

[1]University of South Florida, Tampa, FL,[2]Merck Research Laboratories, Boston, MA,[3]Phenome Health, Seattle, WA,[4]Tampa General Hospital Cancer Institute, Tampa, FL

Recently, we serendipitously identified a pair of distinct 10-gene signatures, one associated with epithelial cells (EPI^S) and one the tumor microenvironment(TME^S). When we classified 2373 colorectal cancer (CRC) tumors into the consensus molecular subtypes (CMS1-4), the EPI^S signature score was predominantly related to the TME-poor CMS2/CMS3 classes and was highly predictive of EGFRi outcomes in two clinical trial datasets and a large, real-world clinico-genomics dataset. By contrast, the TME^S signature score was strongly associated with the immune/stromal CMS1/CMS4 subtypes and was highly correlated with the gene expression signature scores portending EMT, SRC activation and MEK inhibitor resistance (MEKi-R). To understand the cellular features underpinning the TME^S correlation, we further analyzed the cellular origins of 61 SRC signature genes and 13 MEKi-R signature genes, as well as 8 EMT genes using an independent public scRNASEQ dataset (n=62). All of the 13 MEKi-R genes and all of the 8 EMT genes, as well as most of the SRC activation genes, were predominantly expressed in various immune/stromal TME cells, supporting a key role of the TME gene expression. Remarkably, when the signature scores were analyzed in a dataset of ~150 heterogenous CRC cell lines that do not have a TME, a similar strong correlation among the TME^S, EMT, SRC activation and MEKi-R scores was also observed. These data suggest that the CRC epithelial cells may have adopted the TME gene expression features important in modulating the drug sensitivities. Spatial transcriptomics of 8 CRC samples confirmed that the EPI^S genes were predominantly expressed in epithelial cells. By contrast, the signature genes of the TME^S linked to EMT/SRC activation/MEKi-R were diffusely expressed across epithelial/invasive cancer mixed with the TME, indicating an interactive tumor-TME cellular feature. Our data suggest that the TME through its impact on epithelial cell gene expression may define drug sensitivities to targeted therapies.

#5113 Elucidating the biological effects of platinum adduct-containing cell-free DNA.

Sri Meghana Yerrapragada, M. Alexandra Carpenter, Michael G Kemp

Pharmacology and toxicology, Wright State University, Dayton, OH

Cisplatin is a widely used chemotherapeutic agent for cancers such as lung, breast, esophageal, ovarian, and pancreatic. However, its effectiveness is constrained by its cytotoxicity to healthy tissues and the rapid development of cancer cell resistance. Cisplatin binds to the N7 position of purines in DNA, forming intra- and inter-strand crosslinks, which are potentially mutagenic and lethal if not removed by the nucleotide excision repair (NER) system. When DNA repair mechanisms are overwhelmed, cisplatin-DNA adducts can trigger caspase-dependent apoptosis, leading to degradation of the damaged DNA. Interestingly, the ultimate fate of this damaged DNA remains unclear. Our study, using differential centrifugation and DNA immunoblotting, has identified that cisplatin-adduct-containing DNA are released into extracellular spaces upon treating with lethal doses of cisplatin. Notably, caspase inhibition blocks this release, while inhibition of NER enhances it. Further, our research demonstrates that non-damaged bystander cells can uptake the cisplatin-DNA adducts, potentially activating DNA damage checkpoints or innate immune responses. This process can also alter the sensitivity of bystander cells to cisplatin. Given the role of cell-free DNA (cf-DNA) in intercellular communication, our findings suggest that damaged DNA could be transferred to distant organs, contributing to cisplatin resistance, toxicity, and systemic side effects. Understanding the mechanism by which cisplatin-DNA adducts influence cell signaling and treatment outcomes could open new avenues for using cf-DNA as biomarkers to monitor therapeutic responses and minimize long-term genomic risks associated with chemotherapy.

#5114 Investigating the novel role of the protease A Disintegrin And Metalloprotease (ADAM)-17 in small cell lung cancer.

M. I. Saad[1], K. Hon[1], J. Solujic[2], T. Weng[3], A. Badiei[2], C. Young[4], S. Dusterhoft[5], D. Gough[6], S. Rose-John[7], P. Hoffmann[4], P. Nguyen[2], B. Jenkins[1];

[1]University of Adelaide, Adelaide, Australia, [2]Royal Adelaide Hospital, Adelaide, Australia, [3]Monash University, Victoria, Australia, [4]University of South Australia, Adelaide, Australia, [5]RWTH Aachen University, Aachen, Germany, [6]Hudson Institute of Medical Research, Victoria, Australia, [7]Kiel University, Kiel, Germany

Lung cancer is the most lethal and common cancer worldwide, which comprises two main subtypes, non-small cell lung cancer and small cell lung cancer (SCLC), accounting for ~85% and ~15%, respectively, of all diagnoses. SCLC is a highly aggressive neuroendocrine malignancy which is detected in two thirds of SCLC patients at a late stage with a dismal 5-year survival rate of less than 5%. This poor outcome is largely due to the stagnated clinical management of SCLC over the last 3 decades, comprising first-line platinum-based chemotherapy with etoposide, which, despite initial high response rates, is associated with rapid disease relapse due to acquired chemoresistance. Therefore, there is a pressing clinical need to identity new molecular drivers of SCLC which can serve as therapeutic targets. In this regard, A Disintegrin And Metalloprotease 17 (ADAM17) is the major “sheddase” for >80 membrane-tethered pro-tumourigenic substrates, including epidermal growth factor receptor ligands, notch receptor and tumour necrosis factor-α, which control many cellular processes (e.g. inflammation, proliferation) in immune and non-immune cells. Therefore, ADAM17 modulates key physiological and pathophysiological cellular processes. Despite the large body of data implicating ADAM17 in lung cancer, the pathological role of ADAM17 in SCLC is unknown. Using our unique highly relevant and well-established clinical and preclinical models, including SCLC patient biopsies, the *Rb1*$^{fl/fl}$*;Trp53*$^{fl/fl}$ (RP) and *Rb1*$^{fl/fl}$*Trp53*$^{fl/fl}$*Myc*$^{LSL/LSL}$ (RPM) genetic mouse models, patient-derived xenografts and human SCLC cell lines, as well as proteomics pipeline and a suite of biochemical and molecular biology techniques, we aim to define the role of ADAM17 in SCLC. ADAM17 expression, interactome and substrate repertoire was investigated while the anticancer activity of ADAM17 inhibitors in SCLC was assessed. This research therefore could pave the way for the development of novel therapeutic and biomarker avenues for SCLC.

#5115 Engineered TIMP-1 for selective MMP-9 inhibition: A novel strategy to suppress breast cancer invasiveness.

A. Shoari, A. Hockla, M. A. Coban, A. M. Dimesa, D. C. Radisky, E. S. Radisky;
Mayo Clinic, Jacksonville, FL

Tissue inhibitors of metalloproteinases (TIMPs) are endogenous inhibitors that regulate the function and activity of matrix metalloproteinases (MMPs), enzymes that are known for their involvement in cancer progression. MMP-9, also known as gelatinase B, plays a crucial role in tumorigenesis of several cancers including triple negative breast cancer (TNBC); tumor cell-produced MMP-9 promotes malignant progression and metastasis of basal-like TNBC. Here, we have used full-length TIMP-1 as a scaffold for engineering inhibitors that bind with higher selectivity to MMP-9, for potential therapeutic applications. We previously developed a yeast surface display library of human TIMP-1, with diversity incorporated at 17 residues within five loops; mutation burden was tuned to 3-5 mutations per clone. Here, we have screened the TIMP-1 library for affinity toward recombinant MMP-9 by using fluorescence-activated cell sorting (FACS). Yeast cells were incubated with an incrementally decreasing concentration of biotinylated MMP-9 (400 nM to 25 nM) in successive rounds of sorting. Samples were analyzed using flow cytometry and highest affinity populations were selected using FACS. Among the TIMP-1 variants with highest enrichment, we identified the TIMP-1-C15 variant that showed 12-fold enhanced binding with improved selectivity toward MMP-9 compared with wild type TIMP-1 (WT TIMP-1). We next expressed and purified soluble recombinant TIMP-1-C15 and conducted inhibition studies using a fluorogenic substrate to evaluate inhibitory potency towards MMP-9 activity. These experiments showed that TIMP-1-C15 inhibits MMP-9 activity with an inhibition constant (K_i) of 0.61 nM, more than 5-fold stronger than WT TIMP-1; these studies also corroborated the improved selectivity towards MMP-9 over other MMPs. Additionally, we further evaluated the functional impact of the TIMP-1-C15 variant on cancer cell invasiveness using TNBC cell lines in cellular invasion assays. The TIMP-1-C15 variant markedly reduced the invasive capabilities of TNBC cells to a greater extent than WT TIMP-1. Currently, we are working to isolate additional TIMP-1 variants from our library that exhibit enhanced selectivity for MMP-9, with MMP-8 included in the sorting process as a competitive target to ensure specificity. Selective inhibition of MMP-9 over MMP-8 is particularly important in breast cancer therapy, as MMP-8 has been shown to have anti-tumorigenic properties, and its inhibition could counteract therapeutic efforts aimed at reducing cancer invasiveness. Our findings suggest that engineered TIMP-1 variants could serve as potent inhibitors of MMP-9, offering a novel approach to reducing the invasiveness of breast cancer cells and potentially limiting the progression of metastatic disease.

#5116 Alpha-2-macroglobulin in the tumor microenvironment of pancreatic ductal adenocarcinoma to regulate versican proteolysis.

Somak Chaudhuri, Yousef Gadalla, Katherine A. Johnson, Philip B. Emmerich, Sean G. Kraus, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin-Madison, Madison, WI

Background: Versican (VCAN), a large chondroitin sulfate matrix proteoglycan is upregulated in the pancreatic ductal adenocarcinoma (PDAC) stroma and plays an immunosuppressive role. In contrast, the VCAN V1 isoform can be cleaved by ADAMTS proteases 1, 4, 5, 9, 15 and 20 into the fragment versikine which is known to be immunostimulatory. PDAC displays poor VCAN proteolysis and CD8+ T-cell infiltration, but interestingly overexpresses ADAMTS 1, 4, 5 and 9. Alpha-2-macroglobulin (A2M) has been shown to inhibit ADAMTS 4 and 5 and may be overexpressed in the PDAC tumor microenvironment (TME). This complex interplay is currently not well understood and is investigated here.

Methods: The PDAC TCGA PanCancer Atlas dataset was used to compare relative levels of ADAMTS protease expression at the bulk RNA seq level. A TNM plot was used to compare levels of ADAMTS proteases between normal adjacent (NA) and tumor tissues. Patient-derived tissue microarrays (TMAs) (n=66) were used to correlate VCAN proteolysis, ADAMTS 4 and 5 as well as A2M expression. To explore the causative link between A2M and VCAN proteolysis, a major drawback of the well-studied Pan02 injectable model of PDAC is the lack of intense desmoplasia seen in the TME of human PDAC. To overcome this limitation, KPC tumor organoids and cancer-associated fibroblasts (1:10) were co-allografted into the flanks of B6 mice, followed by validation of cytokeratin-17/19 and alpha-smooth muscle actin expression using immunohistochemistry.

Results: ADAMTS 1, 4 and 9 have similar relative levels of expression in PDAC; ADAMTS 5 and 15 slightly lower [median RSEM $\log_2$(value+1) = 10.2, 9.91, 9.54, 7.25, 5.33] and ADAMTS 20 is almost absent. ADAMTS 4, 5, 9 and 15 have significantly higher expression in PDAC tumor tissue versus (vs) normal adjacent (NA) pancreas tissue ($\log_2$FC= 2.16, 1.9, 1.57, 1.4, p-values <0.05). In patient-derived TMAs, PDAC tumors show higher levels of ADAMTS 4 expression vs. NA pancreas tissue (58.42% vs 44.12% of samples are ADAMTS 4^{hi}). ADAMTS 5 expression is high in both tumor and NA tissue (90.5% vs 90%) which may be attributed to residual tumor tissue in the NA samples. Both ADAMTS 4 and 5 correlate with poor VCAN proteolysis. A2M RNA ($\log_2$FC= 2.09, p-value <0.05) and protein levels are significantly higher in tumor tissue vs. NA pancreas (67.41% vs 33.33% of samples are $A2M^{hi}$) and correlate with poor VCAN proteolysis. The murine co-allograft model resembles the human PDAC TME closely as evidenced by the pattern of cytokeratin-17/19 staining on epithelial cells and alpha-smooth muscle actin on cancer-associated fibroblasts.

Conclusions: High A2M expression correlates with high ADAMTS 4/5 expression and poor VCAN proteolysis, indicating a potential for A2M to aid in VCAN accumulation in the TME. The co-allograft model will be used to explore the role of A2M further in the PDAC TME.

#5118 Ectopic expression of cathepsin G in mammary tumor cells and its role in tumor growth and osteolytic bone metastasis.

Ridhi Bhola, Reegan Sturgeon, Rakesh K. Singh

University of Nebraska Medical Center, Omaha, NE

Breast cancer has a high propensity to metastasize to the bone microenvironment. The resulting lesions are predominantly osteolytic and are associated with patient morbidity and mortality. We have demonstrated that tumor-bone interaction plays an important role in osteolytic bone metastasis mediated by the dysregulation of a unique set of genes. Among these genes, several proteases are up-regulated at the tumor-bone interface, including Cathepsin G, a serine protease. These proteases act as mediators between the tumor and stroma. Previously, we have shown that both malignant cells and osteoclasts at the TB interface express higher levels of Cathepsin G, which is critical for osteolytic bone metastasis. The precise role of tumor and/or host-derived Cathepsin G in osteolytic bone metastasis is unknown. In this report, we examined the contribution of tumor-derived Cathepsin G by testing the hypothesis that ectopic expression of Cathepsin G modulates malignant cell phenotype, osteoclast recruitment and activation, and osteolytic metastasis. We generated stable mammary tumor cell lines constitutively expressing Cathepsin G (Cl66-CTSG). Cathepsin G-expressing tumor cells showed diminished *in vitro* cell proliferative potential and *in vivo* mammary fat pad tumor growth as compared to vector control transfected Cl66-CMV cells. We demonstrated that Cathepsin G-overexpressing tumor cells induced osteoclast activation and differentiation *in vitro* and tumor-induced osteolysis *in vivo*. To observe the morphological changes in tumor cells by CTSG, we performed phalloidin staining and live cell imaging using CTSG-treated tumor cells. We observed that CTSG induced the formation of homotypic aggregations of tumor cells. We found that increasing the concentration of CTSG decreases tumor cell proliferation and increases cell cycle arrest. Our data suggest that tumor-derived Cathepsin G might have distinct tumor-modulating activities in the bone microenvironment by regulating cell proliferation and osteoclast recruitment and activation.

#5119 Serine proteases modulate neutrophil survival and contribute to immunosuppression.

R. Sturgeon[1], S. Maram[2], A. Meyerson[3], R. Bhola[1], E. Johnson[1], R. K. Singh[1];
[1]University of Nebraska Medical Center, Omaha, NE, [2]Millard North High School, Omaha, NE, [3]University of Michigan, Ann Arbor, MI

Tumor-promoting inflammation is a hallmark of cancer, contributing to malignant cells' survival and proliferation. Infiltrating leukocytes and pro-inflammatory cytokines released into the tumor microenvironment (TME) often cause this inflammation. We have previously shown that increased infiltrating neutrophils are associated with pancreatic ductal adenocarcinoma (PDAC) disease progression, which correlates with increased inflammation and neutrophil accumulation. Prolonged neutrophil accumulation has been linked to chronic inflammation, which in turn is thought to contribute to tumor progression, therapy resistance, and metastasis. In the present study, we examined how neutrophil-PDAC interaction enhances the survival of neutrophils dependent on serine proteases and their inhibitors. Previous reports suggest that serine proteases, such as cathepsin G, can contribute to inflammation and induce caspase-independent neutrophil apoptosis. We examined the role of serine proteases and their inhibitors on neutrophil survival using defined cellular models. We observed an association between increased serine protease and neutrophil survival. Moreover, this survival was modulated by cellular aggressiveness and therapy resistance. In addition, we observed increased survival of neutrophils associated with inhibition of serine proteases and increased expression of serpins to proteases in neutrophils upon PDAC cancer cell conditioned media treatment. In summary, these studies point to neutrophil serine proteases and their inhibitors as versatile mediators that modulate neutrophil survival, leading to an immunosuppressive microenvironment and identifying them as potential targets for therapeutic interventions.

TUMOR BIOLOGY: Molecular Regulation of EMT
Poster Session

#5123 Up-regulation of KRT14 promotes EMT in basal muscle-invasive bladder cancer through IGF2BP1/FTO dependence on methyladenosine-modified SNAI1.

C. Huang;
Wenzhou Medical University, Wenzhou, China

Basal muscle-invasive bladder cancer (BMIBC) is considered one of the subtypes of BC with the highest metastatic rate and the poorest prognosis. Therefore, elucidating the mechanisms underlying BMIBC metastasis and identifying novel precision therapeutic targets are current research hotspots and challenges to the cancer researchers. Through a series of *in vitro* and *in vivo* functional experiments, we have identified the crucial role of KRT14 in the high invasiveness and adverse prognosis of BMIBC. We found that the K294 site within the IGF2BP1-KH2 domain is responsible for reading the conserved genetic information carried by D226/E227 in the KRT14 nuclear export signal (NES). Activation of the KRT14-IGF2BP1 signaling axis is essential for IGF2BP1-mediated stabilization of SNAI1 mRNA through FTO modification. Additionally, IGF2BP1 forms a positive feedback loop by stabilizing its own mRNA, thereby accelerating the invasion and metastasis of BMIBC. Collectively, our study identifies the KRT14/IGF2BP1/FTO/Snail signaling axis as an essential regulatory mechanism associated with poor prognosis in BMIBC, providing a theoretical basis for KRT14 and its downstream regulated molecules as therapeutic targets for BMIBC and the development of corresponding targeted therapies.

Keywords: Basal muscle invasive bladder cancer; KRT14; IGF2BP1; m^6A methylation; Nuclear translocation

#5124 Dynamic subcellular localization of the EMT-associated lncRNA lncX in pancreatic cancer.

Shu Hirako[1], Keiko Shinjo[1], Miho Suzuki[1], Tatsunori Nishimura[1], XingXing Wang[1], Yoshiteru Murofushi[1], Shinji Mii[1], Reo Maruyama[2], Kohei Kumegawa[2], Atsushi Enomoto[1], Yutaka Kondo[1]

[1]Nagoya University, Nagoya, Japan,[2]Japanese Foundation for Cancer Research, Tokyo, Japan

Long non-coding RNAs (lncRNAs) are non-coding RNAs that are longer than 200 nucleotides. These RNAs play essential regulatory roles in processes such as chromatin modification, transcriptional regulation, and protein localization, depending on their subcellular distribution in the nucleus or cytoplasm. These functions have attracted considerable attention in cancer research. LncX, highly expressed in various cancers, has been implicated in promoting tumor malignancy by influencing processes such as proliferation, epithelial-mesenchymal transition (EMT). It has been reported that lncX regulates mRNA by acting as a competing endogenous RNA through binding to miRNAs. However, the subcellular localization of lncX and its interactions with specific proteins in pancreatic ductal adenocarcinoma (PDAC) remain poorly understood. We investigated the localization of lncX in the PDAC cell lines using RNA fluorescence in situ hybridization (RNA-FISH) and super-resolution microscopy. Under conditions where cells were tightly adhered to one another, lncX was localized at the cell membrane. Interestingly, when cell adhesion was disrupted and the cells entered a suspended state, lncX predominantly localized in the nucleus and cytoplasm. A similar localization pattern was observed in PDAC samples from a PDAC mouse model (KPC) and human PDAC tissues. Notably, lncX co-localized with CDH1 at the cell membrane and translocated to the nucleus following specific stimuli. These findings suggest that lncX may play distinct roles depending on its localization, potentially contributing to cancer malignancy.

#5125 Low-density lipoprotein receptor-related protein 1 as a negative regulator in epithelial-mesenchymal transition and metastasis of colorectal cancer: Targeting the Wnt/β-Catenin signaling pathway.

Zhihong Zhang[1], Dingwen Zhong[2], Tanxing Cai[1], Ze Li[1], Yufeng Chen[1], Xiaojian Wu[1], Xiaobin Zheng[1]

[1]the Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China, China,[2]Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China, China

Background and aim: Low-density lipoprotein receptor-related protein 1 (LRP1) is a multifunctional receptor involved in various cellular processes, including cancer progression. Its role and the underlying mechanisms in the metastasis of colorectal cancer (CRC) remain to be fully elucidated.

Methods: LRP1 expression in CRC was assessed by immunohistochemistry in a cohort of 400 tissue samples, with subsequent Kaplan-Meier survival analysis. In vitro studies included real-time PCR, western blot, colony formation assays, immunofluorescence assays, wound healing assays, and migration and invasion experiments to explore LRP1's impact on epithelial-mesenchymal transition (EMT), cell migration, and invasion. In vivo, mouse xenograft and metastasis models were employed to assess tumorigenicity and metastatic potential, with immunohistochemistry, real-time PCR, and western blot used to evaluate protein expression levels. Luciferase reporter assays were conducted to investigate LRP1's influence on the Wnt/β-catenin signaling pathway.

Results: LRP1 was found to be highly expressed in 68.2% of the CRC specimens and was significantly associated with membranous E-cadherin expression and cytoplasmic β-catenin localization. Elevated LRP1 levels, in conjunction with reduced Wnt/β-catenin signaling activity, correlated with decreased nuclear accumulation of β-catenin and predicted better prognosis. LRP1 suppressed cell proliferation, migration, and invasion both in vitro and in vivo, and hindered the nuclear translocation of β-catenin. Wnt/β-catenin signaling could counteract LRP1's effects on EMT and enhance the expression of vimentin, a mesenchymal marker. Restoring vimentin expression mimicked the effects of LRP1 knockdown without altering Wnt/β-catenin activity.

Conclusions: LRP1 appears to be a significant negative regulator in the EMT, invasion, and metastasis of CRC, potentially acting upstream of the Wnt/β-catenin signaling pathway. Therefore, the combined targeting of LRP1 and the Wnt/β-catenin pathway may offer a novel and promising therapeutic strategy for CRC patients.

#5126 Time-series single-cell RNA sequencing uncovers PLAU enhancing early lung metastatic seeding of esophageal squamous cell carcinoma.

Yingchen Lyu, Ching Ngar Wong, Hongyu Zhou, Songna Wang, Xinyuan Guan

The University of Hong Kong, Pokfulam, Hong Kong

Background: Metastasis continues to be the primary cause of cancer death even with recent advancements in cancer treatment. The initiating ability of metastatic growth bottlenecked in cancer development and could be a promising target. We have successfully captured the distinctive features of early metastatic cells through time-series scRNA-seq using the pulmonary metastatic model.
Methods: To characterize the early metastatic tumor microenvironment (TME), we looked into the highly expressed genes encoding the secreted protein in early metastasis performing GO and KEGG pathway analysis. Clinical implication of PLAU overexpression was studied in ESCC patients. Multiplex immunohistochemistry staining of PLAU and previously identified metastatic initiating genes in ESCC patient samples were completed. Functional assays, including cell migration, invasion, wound healing, and foci formation were undertaken to evaluate the metastatic ability. PLAU knockdown ESCC cells were injected intravenously and subsequent in vivo lung imaging was obtained.
Results: Through GO and KEGG pathway analysis of the single-cell profiling, the genes highly expressed in early metastatic lung exhibited a significant enrichment in processes related to coagulation and fibrinolysis (F3, THBS1, PLAU, SEPRINE1 and ANXA2). Among these genes, PLAU increased greatly in 6 hours and was maintained at a relatively high level during the early metastatic phase. We further explored the implications of PLAU. The analysis of the TCGA database reveals that PLAU is significantly upregulated in tumor tissues compared to non-tumor tissues .Multiplex immunohistochemistry staining of both ESCC cell lines and clinical samples demonstrated co-expression of PLAU and the previously identified metastatic initiating signature CD44 and TACSTD2. Knockdown of PLAU greatly impaired the ability of migration, invasion, wound healing and foci formation ($p<0.05$). In addition, the knockdown of PLAU led to significantly fewer surviving cancer cells in mice lungs in the early phase of metastasis ($p<0.05$).
Conclusions: In all, the finding indicated that PLAU co-expressed with previously identified metastatic initiating genes and increased early dissemination of ESCC lung metastasis. Targeting PLAU could offer a promising approach to limit early metastatic progression in ESCC.

#5127 Metastatic organotropism in small cell lung cancer.

M. Krishnamurthy[1], A. Dhall[2], C. W. Schultz[2], M. Baird[3], P. A. Desai[2], J. Odell[4], S. Sahoo[5], N. Takahashi[6], M. Nirula[2], S. Zhuang[2], Y. Huang[2], B. Schroeder[2], Y. Zhang[2], C. Redon[2], C. Robinson[2], L. Thang[2], L. Ileva[2], N. L. Patel[2], J. D. Kalen[2], A.-A. Varlet[4], N. Zuela-Sopilniak[4], A. Jha[3], D. W. Zong[7], D. Butcher[2], T. Morgan[2], A. Afzal[2], R. [1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]National Cancer Institute, Bethesda, MD, [3]National Heart, Lung, and Blood Institute, Bethesda, MD, [4]Cornell University, Ithaca, NY, [5]Indian Institute of Science, Bengaluru, India, [6]National Cancer Center East Hospital, Kashiwa, Japan, [7]National Center for Advancing Translational Sciences, Bethesda, MD, [8]Cancer Genomics and Epigenetics Core Group, Szeged, Hungary

Metastasis is the leading cause of cancer-related deaths, yet its regulatory mechanisms are not fully understood. Small-cell lung cancer (SCLC) is the most metastatic form of lung cancer, with most patients presenting with widespread disease, making it an ideal model for studying metastasis. However, the lack of suitable preclinical models has limited such studies. We utilized well-annotated rapid autopsy-derived tumors to develop xenograft models that mimic key features of SCLC, including histopathology, rapid and widespread development of metastasis to the liver, brain, adrenal, bone marrow, and kidneys within weeks, and response to chemotherapy. By integrating in vivo lineage selection with comprehensive transcriptomic, epigenomic, and single cell multi-omic analyses, we identified critical cellular programs driving metastatic organotropism to the liver and brain, the most common sites of SCLC metastasis. Our findings reveal the key role of nuclear-cytoskeletal interactions in SCLC liver metastasis. Specifically, the loss of the nuclear envelope protein lamin A/C, encoded by the *LMNA* gene, increased nuclear deformability and significantly increased the incidence of liver metastasis. Human liver metastases exhibited reduced *LMNA* expression compared to other metastatic sites, correlating with poorer patient outcomes and increased mortality. This study introduces novel preclinical models for SCLC metastasis and highlights pathways critical for organ-specific metastasis, offering new avenues for the development of targeted therapies to prevent or treat metastatic disease.

#5128 Role of adherent-to-suspension transition in melanoma metastatic dissemination and circulating tumor cell dynamics.

Dong Ki Lee[1], Jongwook Oh[1], Soyeon Lee[1], Hyun Woo Park[2], Heon Yung Gee[1]

[1]Department of Pharmacology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Biochemistry, Yonsei University College of Life Science and Biotechnology, Seoul, Korea, Republic of

Background: Melanoma is the most fatal form of skin cancer, presenting significant therapeutic challenges due to its high metastatic potential. Once melanoma spreads to distant sites, prognosis declines sharply, underscoring the need to uncover the mechanisms driving metastasis. This study investigates the role of transcriptional regulators in melanoma metastasis, focusing on how primary tumor cells undergo “Adherent-to-Suspension Transition” (AST) to reprogram their anchorage dependency and disseminate into the bloodstream.
Methods: Using fluorescent protein-tagged melanoma cells, we developed an orthotopic melanoma metastasis mouse model and performed single-cell RNA sequencing (scRNA-seq) on melanoma cells isolated from the primary footpad tumor, blood, and lung metastases. Publicly available spatial transcriptomics data were analyzed to identify the cells undergoing AST within the primary tumor. Doxycycline-inducible AST-overexpressing melanoma cell lines were generated for functional validation.
Results: We identified three AST factors—IKZF1, IRF8, and NFE2—known hematopoietic transcriptional regulators that reprogram adherent cells into suspension cells. Induction of these AST factors upregulated hemoglobin genes while downregulating extracellular matrix (ECM)-integrin genes, leading to cell-matrix dissociation and anoikis resistance. During metastasis, AST factor expression was induced in circulating tumor cells (CTCs) but reversed in metastatic niches. Notably, AST factor expression was independent of epithelial-mesenchymal-like transition (EMT-like transition). Phylogenetic analysis of scRNA-seq data revealed that AST-positive clones exhibited greater aggressiveness and metastatic potential.
To evaluate AST factors as therapeutic targets, we performed an intervention study using lenalidomide, an IKZF1 inhibitor. Treatment significantly reduced the number of CTCs and metastatic burden without affecting the primary tumor. Spatial transcriptomics analysis demonstrated an inverse correlation between AST factor expression and proximity to blood vessels, further implicating AST in early metastatic processes.
To explore AST-mediated regulation of anchorage dependence, we subjected B16F10-3AST^{TetR} cells to repeated cycles of doxycycline treatment. Doxycycline induction caused cell detachment, which was reversed upon withdrawal, highlighting the dynamic nature of AST. RNA sequencing revealed that AST-induced cells were depleted of the Hallmark EMT pathway, suggesting that AST reprograms anchorage dependency through distinct mechanisms.
Conclusion: AST represents a novel, EMT-independent mechanism driving melanoma metastasis by reprogramming anchorage dependency. These findings position AST factors as actionable therapeutic targets for preventing metastatic progression in melanoma.

#5130 DNA methylation profiling reveals epigenetic dynamics across epithelial-mesenchymal transition states in the triple-negative breast tumor microenvironment.

Hanxu Lu[1], Fred W. Kolling[1], Lucas A. Salas[1], Diwakar R. Pattabiraman[1], Todd W. Miller[2], Brock C. Christensen[1]

[1]Dartmouth Geisel School of Medicine, Lebanon, NH,[2]Medical College of Wisconsin, Milwaukee, WI

Epithelial-mesenchymal transition (EMT) is a dynamic, reversible process that facilitates tumor invasion and metastasis. Tumors often exhibit intermediate EMT states with co-expression of epithelial and mesenchymal markers. DNA methylation can regulate the expression of EMT-related genes, influencing the stability of epithelial and mesenchymal cell states. However, DNA methylation changes during the dynamic process as cells transition through intermediate EMT states are not well understood. This study integrated single-cell RNA sequencing (scRNA-seq) and DNA methylation profiling to investigate dynamic DNA methylation changes across the EMT spectrum. Single-cell-derived clonal populations from the heterogeneous 4T1 murine triple-negative breast cancer cell line were isolated for five states representing the spectrum of EMT: an epithelial-like clone (E), three intermediate clones (EM1, EM2, EM3), and a mesenchymal-like clone (M). These clones were orthotopically transplanted into the mammary fat pads of mice, and tumors were harvested to isolate CD45- and CD45+ cell populations for DNA methylation profiling at over 285,000 CpG sites throughout the mouse genome using an Illumina mouse methylation array. Previous scRNA-seq revealed significantly higher expression of *Epcam* in the epithelial-like clone and *Gpnmb* in the mesenchymal-like clone. Consistent with the changes in gene expression, methylation shifts were observed across EMT states in the *Epcam* and *Gpnmb* promoter regions, both *in vitro* and *in vivo*. Notably, immune cell proportions estimated using DNA-based deconvolution exhibited trends consistent with scRNA-seq data, highlighting the potential of multi-omics approaches to comprehensively study the EMT process. To further investigate the progressive increase in mesenchymal transition, we employed a linear model using the CD45- fraction. Hypomethylated CpGs in mesenchymal states were enriched in EMT-related transcription factors, such as FOXC1 and HOXA6. Compared with DNA methylation data from the tumor CD45+ cell fraction, principal component analysis (PCA) of CD45- samples showed separation by EMT states, suggesting fewer DNA methylation changes in tumor infiltrating immune cells. This study highlights epigenetic alterations as cells transition from epithelial to mesenchymal states, with methylation patterns aligning closely with gene expression profiles. Furthermore, these findings emphasize the opportunity to use DNA-based cell type deconvolution to accurately assess and investigate immune cell infiltration within the tumor microenvironment in association with cancer cell plasticity and immune response in tumor progression.

#5131 Dysregulated cholesterol metabolism facilitates epithelial-to-mesenchymal transition and tumor progression in colorectal cancer.

Blake M. Arciga[1], Van Nguyen[2], Jussuf T. Kaifi[3], Satyanarayana Rachagani[4]

[1]Roy Blunt NextGen Precision Health Institute, University of Missouri-Columbia, Columbia, MO,[2]Department of Clinical Pathology and Anatomical Sciences, University of Missouri-Columbia, Columbia, MO,[3]Department of Surgery, University of Missouri-Columbia, Columbia, MO,[4]Department of Veterinary Medicine and Surgery, University of Missouri-Columbia, Columbia, MO

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related death in the United States, and its development is closely correlated with lifestyle factors, including a high cholesterol “Western” diet. In our novel study, we investigated the etiology of dysregulated cholesterol homeostasis in CRC and characterized its systemic effects on tumor progression.

Methods: Expression of DHCR7, the rate-limiting enzyme of cholesterol biosynthesis, in CRC was analyzed *in silico* using TCGA-COAD data. A human tissue microarray (n=208 cores) with samples from normal colon, local colon tumors, and lymph node metastases was stained for DHCR7 using IHC. Stained tissue cores were scored blindly by a clinical pathologist based on our histological scoring system, which accounted for the percentage of positive cells and the intensity of staining. We generated an APCCDX-Cre^{ER} CRC mouse model and collected colonic tissue samples for analysis. Tissues were stained for DHCR7 and scored. To assess the impacts of high diet cholesterol on epithelial-to-mesenchymal transition (EMT) *in vivo*, we developed an APC model which was divided into three diet groups of equal size: a control group (fed a 0 ppm cholesterol diet), a low cholesterol group (186 ppm), and a high cholesterol group (880 ppm). Colonic tissue samples were stained for claudin-1, a classical marker of epithelial barrier integrity. MTT assays were used to measure the *in vitro* proliferation of SW620 human CRC cells incubated in 0, 5, 10, 15, 20, and 25 µM cholesterol.

Results: *In silico* data analysis indicated that DHCR7 is broadly overexpressed in CRC patients. Histological scoring of human patient samples showed upregulation of DHCR7 in local and metastatic CRC tumors compared to normal colonic tissue. Surprisingly, DHCR7 expression was significantly higher in lymph node metastases than in the primary tumor. DHCR7 overexpression was also observed in tumor-bearing APC mice relative to tumor-free controls. Claudin-1 expression was found to be significantly downregulated in mice fed a high cholesterol diet compared to mice fed a low cholesterol or control diet. Finally, SW620 cells grown in cholesterol proliferated at a faster rate over 96 hours than control cells incubated in 0 µM cholesterol media, although a dose-dependent effect was not observed.

Conclusions: DHCR7 is systemically overexpressed in CRC primary tumors, and expression is even further elevated in metastatic disease. Therefore, *de novo* cholesterol synthesis is dysregulated in tumor cells, causing a profound disruption to cholesterol homeostasis which may potentiate EMT and metastasis. High cholesterol uptake also promotes a mesenchymal phenotype in tumor cells and stimulates proliferation. Our findings indicate that dysregulation of cholesterol homeostasis increases the tumorigenicity and metastatic potential of CRC cells and may be a target for therapy.

#5132 DNMT1-associated EMT promotes KRAS escape in pancreatic cancer.

Loan Duong, Xin Lu

Biological Sciences, University of Notre Dame, Notre Dame, IN

Pancreatic adenocarcinoma (PDAC) is presently the 3rd leading cause of cancer death in the United States and is further projected to overcome colorectal cancer to become the 2nd leading cause by 2030. The genetic landscape of PDAC is characterized by pervasive oncogenic mutations in KRAS, observed in over 90% of PDAC tumors. KRAS is considered essential for maintaining tumor progression and so targeting it has long been considered crucial to improving outcomes for PDAC patients. For preclinical studies of KRAS in our lab, we are using an inducible KRAS (iKRAS) model to model KRAS activation and inhibition. This model is based on iKRAS cell lines derived from transgenic tetO_LSL-KrasG12D; p53L/+; p48-Cre mice and upon doxycycline treatment, express oncogenic KrasG12D. Orthotopic implantation of iKRAS cells results in the formation of doxycycline-dependent pancreatic tumor growth in both immune-deficient and immunocompetent models. Withdrawal of doxycycline results in tumor regression. However, we have observed instances of tumor relapse despite the absence of doxycycline and established cell lines from these relapsed tumors. In vitro analyses confirm that these cells are independent of both doxycycline and KRAS, unlike the parental cell line. In vivo, upon reimplantation in the pancreas, they maintain the ability to grow independently of doxycycline. Transcriptome and reverse phase protein array analysis reveal an enrichment of markers associated with epithelial to mesenchymal (EMT) with western blot analyses further confirming increased expression of EMT markers, including Snail, Slug, and αSMA. The KRAS-independent cell line further demonstrated elevated DNMT1 expression, a previously described driver of EMT. Targeting DMNT demonstrated more pronounced effects on cell viability in the KRAS-independent cell line than the parental KRAS-dependent cell line. Deeper insight into the ability of these cells to escape KRAS addiction will enhance our understanding of resistance to KRAS inhibition and suggest further avenues for co-targeting.

#5133 End-stage breast cancer metastases manifest as two subtypes with distinct dissemination patterns, proliferation/EMT signatures, and immune microenvironments.

Isaac Bishara[1], Xuan Liu[2], Jason I. Griffiths[1], Patrick A. Cosgrove[1], Jasmine R. McQuerry[1], Jiayi Liu[2], Kena K. Ihle[1], Eliza R. Bacon[1], Feng Chi[1], Pierre Wallet[1], Vince Grolmusz[1], Diana Simons[1], Benjamin Copeland[1], Lance Pflieger[1], JinFeng Chen[1], Sumana Majumdar[1], Terron T. Crowder[1], Rena Emond[1], Rachel Factor[3], David D. L. Bowtell[4], Adam L. Cohen[5], Daniel D. Schmolze[1], Peter P. Lee[1], Lusine Tumyan[1], James R. Waisman[1], Andrea Bild[1], Aritro Nath[1], Jeffrey T. Chang[2]

[1]City of Hope National Medical Center, Duarte, CA,[2]University of Texas Health Science Center at Houston, Houston, TX,[3]University of Utah, Salt Lake City, UT,[4]Peter MacCallum Cancer Center, Melbourne, Australia,[5]Inova Schar Cancer Institute, Fairfax, VA

End stage breast cancer often presents with oligometastatic tumors and lacks effective treatment options. Previous studies leveraged post-mortem tissue procurement (also called rapid autopsy) programs to collect tumors shortly after death for profiling by bulk whole exome sequencing (WES). This has revealed substantial heterogeneity in the genomes of metastatic estrogen receptor-positive (ER+) and triple-negative breast cancers. In order to understand the heterogeneity of both the genotypes, transcriptional phenotypes, and evolution of these tumors, we collected multi-site metastatic tumors from two end-stage ER+ breast cancer patients enrolled in the LEGACY rapid post-mortem tissue procurement trial. Metastatic tumors were profiled using WES and single-nuclei RNA sequencing (snRNA-seq). We reconstructed high resolution phylogenies for each patient using the mutation called from the snRNA-seq reads to determine the subclonal architecture of cancer cells. Based on the mutation patterns, the gene expression profiles, and the subclonal architecture, we found that the tumors in each patient were divided into two distinct subtypes. A majority of the tumors were grouped into a subtype characterized by a high intra-tumor heterogeneity, with many cell lineages shared widely across metastasis, indicating extensive and undirected dissemination. The cancer cells of this subtype exhibited an EMT gene expression signature. In contrast, the second tumor subtype observed was rare and demonstrated little intra-tumor heterogeneity, a proliferative gene expression signature, and an interferon response signature present widely across cells in the microenvironment. Across all tumors, macrophages comprised the majority of the immune cells. Low diversity tumor macrophages exhibited strong activation of multiple interferon signaling pathways compared to high diversity tumor macrophages. Interestingly, these macrophages expressed a mixture of M1 and M2 polarization markers as STAT1, SOCS1, ISG15, ISG20, MX1, MX2, OAS1, OAS3 that did not correspond to classical M1 or M2 polarization states. This contrast demonstrates that multi-site metastatic tumors and their microenvironment adopt dichotomous states, which may contribute to the difficulties in treating progressive disease. It also underscores the need for a comprehensive and personalized late-stage therapeutic strategy to target the diversity of existing tumor phenotypes.

#5134 Cross-talk of EZH2/PRC2 and Gata5/Foxa2/miR-200 regulates EMT in lung cancer metastasis.

Cesar Seigi Fuziwara[1], Guilherme A. Gois[1], Pedro L. S. Oliveira[1], Joice M. Menezes[1], Bin Xue[2], Lin He[2], Edna T. Kimura[1]

[1]Cell and Developmental Biology, University of Sao Paulo, Sao Paulo, Brazil,[2]University of California Berkeley, Berkeley, CA

Introduction: Lung cancer is the most lethal type of cancer. Part of this lethality is due to late diagnosis when more than 60% of cases present distant metastases at bones, brain and liver, leading to an overall survival of less than 5%. Thus, investigating the biology of metastatic process is mandatory as a public health policy. One molecular mechanism involved in lung cancer progression is the repression of miR-200 family of miRNAs that regulate the epithelial-mesenchymal transition (EMT). Our previous study showed that miR-200 deletion accelerated the formation of lung adenocarcinoma and progression in KP transgenic mice model. Objective: Investigate the transcriptional regulation of miR-200 cluster and its impact in lung cancer metastasis.
Methods: For in silico analysis of promoter region, we used the FANTOM 5, genome browser and transcription factor (TF) prediction tools. We cloned several fragments of miR-200c/141 and miR-200b/miR-200a/miR-429 into the luciferase reporter plasmid pGL4-20, and transfected into a panel of murine lung cancer cell lines (metastatic: 889PF, 404M1 and KPT4-LM and non-metastatic: 368T1, 394T4 and KPT4). Gene expression analysis of TFs and miR-200s was performed for comparisons among lung cancer lines, including. For overexpression experiments, we cloned the coding sequence of TFs (Gata5 and Foxa2) into MSCV-puro plasmid and transfected into metastastic lines 889PF and 404M1. Modulation of Ezh2 was performed with CRISPR/Cas9 in 889PF cells.
Results: we defined the minimal promoter region of miR-200c/141 and miR-200b/miR-200a/miR-429 as the fragments -1246 to 0bp and -4363 to -4027bp from transcription start site, respectively. In silico search for TFs revealed a list of several TFs related to lung biology, such as Nkx2-1, Gata5 and Foxa2. Gene expression analysis showed that reduced levels of miR-200s expression in metastatic lines (889PF and 404M1) inversely correlated with TFs Gata5 and Foxa2 levels. The reactivation of Gata5 and Foxa2 in the metastatic lines reverted the mesenchymal phenotype to an epithelial phenotype while restored miR-200s expression and blocked EMT factors. Further investigation of Gata5 and Foxa2 genes promoter region revealed a common signature for polycomb gene Ezh2/PRC2. Overexpression of Ezh2 in non-metastatic cancer lines reduced TFs and miR-200 expression. Moreover, KPT4-LM, another metastatic line, showed activation of EMT and reduction of miR-200s and TFs, while Ezh2 and PRC2 components were upregulated. Ezh2 gene editing in 889PF induced epithelial phenotype in some clones.
Conclusion: mesenchymal phenotype is controlled by the loop between EZH2/PRC2 and TFs Gata5-Foxa2/miR-200s. Moreover, Gata5 and Foxa2 are pioneer TFs that can restore epithelial phenotype in lung cancer metastatic cell lines.

#5135 Effect of EZH2 inhibition in anaplastic thyroid cancer epithelial-mesenchymal transition revealed by transcriptome analysis.

Diego Claro de Mello, Kelly Cristina Saito, Marcella Maringolo Cristovao, Edna Teruko Kimura, Cesar Seigi Fuziwara

Institute of Biomedical Sciences, Departament of Cell and Devolpmental Biology, University of Sao Paulo, Sao Paulo, Brazil

Introduction: Anaplastic thyroid cancer (ATC) is a rare but highly aggressive endocrine malignancy characterized by rapid tumor growth, early metastasis (>40%), and resistance to standard therapies like radioiodine. The epithelial-mesenchymal transition (EMT) is a critical process driving ATC progression and metastasis, underscoring the urgency of identifying its molecular regulators. In that sense, EZH2, the catalytic subunit of the Polycomb Repressive Complex 2, promotes transcriptional silencing by deposition of trimethylation of histone H3 at lysine 27 (H3K27me3) at target genes. Previously, we demonstrated that CRISPR/Cas9-mediated EZH2 inhibition suppresses ATC cell dedifferentiation, growth, migration, and invasion by downregulating EMT markers. However, the mechanisms through which EZH2 regulates EMT in ATC are not fully understood.
Objective: To investigate the impact of EZH2 inhibition in the transcriptomic landscape of coding genes and miRNAs involved in EMT in ATC biology.
Methods: RNAseq analysis was performed on EZH2-inhibited SW1736-ClE cells to identify differentially expressed genes (DEGs), with sequencing conducted on an Illumina Nextseq 2000 (paired-end 2 × 100 bp), yielding up to 42 million reads for SW1736-CTR and SW1736-ClE. Functional enrichment and protein-protein interaction (PPI) analyses were carried out using Enrichr and STRING web tools, respectively. EZH2/H3K27me3 targets were predicted using the Cistrome Database. A miRNome analysis (Qiagen miScript Arrays) assessed the expression of 1,008 human miRNAs, and predicted miRNA targets were overlapped with DEGs for enrichment analysis. To explore the EZH2/Wnt/β-catenin/miR-200 axis in EMT regulation, Wnt signaling and miR-200 promoter activity were evaluated using β-catenin and miR-200 family overexpression models.
Results: RNAseq analysis identified 1,024 downregulated and 939 upregulated DEGs in SW1736-ClE. EZH2 inhibition suppressed EMT programs by downregulating canonical Wnt signaling genes, including *CTNNB1, FZD4*, and *ZEB1*, as shown by Enrichr and PPI analyses. Using Cistrome database, we observed that EZH2/H3K27me3 enrichment was observed at loci of negative Wnt signaling regulators (*WNT5A/7A, FZD2/7*), which were upregulated in SW1736-ClE cells. Suppressing canonical Wnt signaling reduced EMT-promoting factors and increased epithelial markers. miRNome analysis revealed significant upregulation of tumor suppressor miRNAs, notably the miR-200 family. The overexpression of the miR-200c or miR-200a alone in SW1736 cells did not independently inhibit Wnt signaling activity. Conversely, β-catenin overexpression impaired miR-200 promoter activity.
Conclusions: EZH2 is a key regulator of ATC oncogenesis, driving EMT through a mechanistic link between Wnt signaling and miR-200 family regulation, highlighting potential therapeutic targets in ATC.

#5136 Unraveling SMARCA1's role in cancer progression, drug resistance, and muscle differentiation through EMT-related signaling, TGF-β pathway, and key transcription factors SNAI1 and EGR1.

Ashwaq K. Aljabri[1], Yuliya Kriga[2], Juan Manuel Caravaca[2], Jyoti Shetty[2], Bao Tran[2], Matthew Geisler[3], Judith K. Davie[4], Marielle E. Yohe[1]

[1]Laboratory of Cell and Developmental Signaling Department, National Cancer Institute, National Institute of Health, Frederick, MD,[2]Sequencing Facility, Cancer Research Technology Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Department of Plant Biology, Southern Illinois University, Carbondale, IL,[4]Department of Biochemistry and Molecular Biology, Southern Illinois University School of Medicine, Carbondale, IL

SMARCA1, a member of the ISWI family of ATP-dependent chromatin remodelers, plays a crucial role in organizing DNA structure and regulating gene expression. The role of SMARCA1 in either normal skeletal muscle or rhabdomyosarcoma (RMS) development has not previously been explored. RMS, an aggressive soft tissue cancer, arises from cells resembling skeletal muscle precursor cells and exhibits invasive behavior. In this study, we conducted an integrated analysis of RNA-seq, ATAC-seq, and CUT&RUN data from RH30 cells, a PAX fusion-positive alveolar RMS line, with and without SMARCA1. This comprehensive data integration revealed that SMARCA1 knockout (KO) cells showed significant changes in gene expression and chromatin accessibility. Key genes such as TGFBR1, MYOG, and SMARCD3, critical for muscle differentiation, were highly active in normal RH30 cells but markedly reduced in SMARCA1 KO cells, underscoring SMARCA1's role in supporting genetic pathways essential for muscle growth, survival, and differentiation. Additionally, SMARCA1 influenced regulatory factors, including SNAI1, EGR1, PTEN, TBX2, and P53. Interestingly, SMARCA1 appears to interact with HDAC2, and combined inhibition of SMARCA1 and HDAC2 has shown promise in overcoming drug resistance in these models. Further cell survival assays revealed that SMARCA1 KO cells are particularly sensitive to the HDAC2 inhibitor Mocetinostat and the MEK inhibitor Trametinib, proposing that targeting SMARCA1 in combination with HDAC2 or MEK inhibition could be an effective therapeutic approach for RMS. Our integrated analysis also links SMARCA1 to regulatory genes and transcription factors such as SNAI1, EMC1, PPP2R5C, EGR1, EYA2, SMARCA4, MYCN, CDK4, and NFKB2, with SMARCA1 enriched on the DNA of these genes. These factors are essential for EMT, cell adhesion, and key cancer-related pathways, including MAPK, WNT, PI3K, and TGF-β. Additionally, SMARCA1 KO cells responded differently to both canonical and non-canonical TGF-β pathway inhibitors, including SB505124 (TGFBR1 inhibitor), the PI3K-mTOR inhibitor Dactolisib, and Withaferin A (NF-κB inhibitor). Notably, these TGF-β pathway inhibitors effectively overcame resistance in ARMS cells with SMARCA1 expression, exposing specific vulnerabilities in these otherwise resistant cells. Together, our findings suggest that targeting both canonical and non-canonical TGF-β pathways, alongside SMARCA1, presents promising therapeutic strategies for overcoming drug resistance and potentially limiting RMS progression.

#5137 Epithelial-to-mesenchymal transition coordinates REEP2 to drive pro-metastatic membrane trafficking program in lung cancer.

Kevin Fulp, Oluwafunminiyi Obaleye, Guan-Yu Xiao

University of Kentucky, Lexington, KY

Membrane trafficking governs the transport of molecules to both intracellular and extracellular locations, thereby maintaining cell homeostasis. During cancer progression, alterations in membrane trafficking are frequently observed. Nevertheless, no effective drugs target membrane trafficking currently and the many mechanisms underlying the dysregulation of membrane trafficking in cancer progression remain a significant unresolved question. Our recent research discovered that the epithelial-to-mesenchymal transition (EMT) employs a membrane trafficking program to coordinate cancer cell invasion and immunosuppression in the tumor microenvironment (TME) in lung adenocarcinoma (LUAD). Importantly, blocking the EMT-driven membrane trafficking program re-sensitizes LUAD to immune checkpoint inhibition, suggesting significant therapeutic potential for this pathway. To dissect the pro-metastatic membrane trafficking program, we initiated a CRISPRi *in vivo* screen to assess more than 2,000 trafficking-related genes in syngeneic mouse LUAD models for their requirements for tumorigenesis. Our preliminary studies identified REEP2 as a novel regulator of the EMT-dependent membrane trafficking program, which is linked to poor prognosis and an immunosuppressive TME in LUAD patients. Our findings here show that the EMT-activating transcription factor ZEB1 upregulates REEP2 by relieving its silencing mediated by miR-193a, thereby facilitating endoplasmic reticulum (ER) polarization to the Golgi apparatus. The REEP2-driven ER polarization promotes pro-metastatic secretory trafficking. Blockade of REEP2 suppresses LUAD cell proliferation, migration, invasion *in vitro*, and tumor metastasis in the syngeneic LUAD mouse tumor model. Our findings elucidate the molecular mechanisms underlying LUAD metastasis and support the development of REEP2 inhibitors to prevent EMT-driven cancer metastasis.

#5138 NRAS overexpression influences EMT in claudin-low triple negative breast cancer.

Jackson Marlon Rodney Thomas[1], Stephanie Dance-Barnes[2]

[1]DePaul University, Chicago, IL,[2]College of Science and Health, DePaul University, Chicago, IL

This study investigates Nras-mediated Ras-Mapk in epithelial-mesenchymal transition and the therapeutic potential of RAS-MAPK inhibitors in Claudin-low(CL) triple-negative breast cancer (TNBC). The K14TRT line represents a potential model for CL and metastatic TNBC research due to its genomic similarities to human CL, TNBC. Research at the Perou Lab indicated that the K14TRT cell line exhibited great expression of the NRAS gene, which may influence the EMT characteristics of the cell line. NRAS influences EMT by altering the expression of signaling proteins involving stem-cell characteristics, cell-to-cell attachment, and cell growth regulators. Subsequent knockout of NRAS via siRNA transfection and use of the MEK inhibitor Trametinib were used to observe changes in transcriptome expression. These changes in the transcriptome will then be analyzed to identify future vulnerabilities in the K14TRT cell line using significance analysis of microarray (SAM) in R-Studio. TNBC lacks targeted treatments that other subtypes of breast cancer have, leading to significant disparities in the 5-year survival rate of breast cancer (78.0% for TNBC vs. 91.2% AVG). In addition, triple-negative breast cancer disproportionately affects young Black American and pre-menopausal women. This study highlights the potential influence of NRAS-mediated RAS-MAPK on EMT in Claudin-low, TNBC. Highlighting the RAS-MAPK pathway for its potential use as a primary target in CL, TNBC.

#5139 PP2A-B56a as a critical regulator of cellular plasticity and epithelial-to-mesenchymal transition.

Brittany N. Heil[1], Claire M. Pfeffer[1], Garima Baral[1], Mei B. Bahler[1], Anna K. Darling[1], Sydney J. Clifford[2], Brittany L. Allen-Petersen[1]

[1]Purdue University, West Lafayette, IN,[2]Brandeis University, Waltham, MA

Metastasis is the major cause of death in cancer patients including lung cancer, the leading cause of cancer-related deaths in the United States. Fifty percent of patients have metastatic disease at the time of diagnosis, plummeting the 5-year survival rate from 26% to just 9%, demonstrating a critical gap in our understanding of the contributing cell signaling pathways. Epithelial-to-Mesenchymal Transition (EMT) is an important initiating step in metastasis, allowing cells to become more migratory and invasive to establish secondary tumors in distant locations. Previous studies have identified transcriptional reprogramming as the main driver of EMT. While transcription factors are important in this cell state switch, there are many factors that contribute to EMT outside of transcriptional regulation, such as post-translational modifications (PTMs). PTMs, such as phosphorylation, play a large role in cell signaling that can impact cellular identity and plasticity, yet these modifications are largely understudied, particularly in the context of EMT. The serine/threonine phosphatase, Protein Phosphatase 2A (PP2A), is a vital phosphatase, accounting for 50% of serine/threonine phosphatase activity in the cell. PP2A is a heterotrimeric complex consisting of a scaffolding subunit (A), a catalytic subunit (C), and regulatory subunit (B) which determines substrate specificity. Though PP2A has previously been shown to play a role in cell state regulation and EMT, the contribution of the individual B subunits is unknown. PP2A-B56α has previously been implicated in tumor suppression and the regulation of cellular plasticity. Through the use of 2D immunofluorescence, western blot analysis, and 3D invasion assays, our *in vitro* studies show that loss of PP2A-B56α leads to a significant alteration in cell identity, demonstrated by a reduction in epithelial markers (E-cadherin) and an increase in mesenchymal markers (Vimentin). These shifts in cell markers also correlate with enhanced migratory and invasive capabilities *in vitro* and are recapitulated *in vivo* via tail vein invasion assay. Collectively, these findings highlight PP2A-B56α as a key regulator of cellular plasticity and EMT in lung cancer.

#5140 Phenotypic plasticity and cellular decision-making: role of SLIT2 in epithelial-to-mesenchymal transition.

Sravani Ramisetty[1], Ayalur Raghu Subbalakshmi[1], Madhu krishna B[1], Atish Mohanty[1], Aditya Agarwal[2], Mathias C Emery[3], Andrew Mc Carthy[3], Dana Do[1], Mari Ida[4], Tamara Mirzapoiazova[1], Siddhika Pareek[1], Deric L Wheeler[4], Sharad S Singhal[1], Prakash Kulkarni[1], Ravi Salgia[1]

[1]Medical Oncology, City of Hope National Medical Center, Duarte, CA,[2]Indian Institute of technology, Varanasi, India,[3]European Molecular Biology Laboratory (EMBL), Grenoble, France,[4]Human Oncology, University of Wisconsin-Madison, Wisconsin, WI

Background: Epithelial-to-mesenchymal transition (EMT), a key driver of cancer progression, is influenced by cell-specific factors. SLIT2, a ligand for ROBO1, regulates tumor growth and migration through a non-canonical ROBO1/EPHA2 pathway in lung and head and neck cancers. Modeling of the SLIT2-EPHA2 EMT circuit revealed SLIT2 stabilizes the epithelial phenotype, while EPHA2 coupling diminishes this suppression, inducing a tri-stable system with epithelial, hybrid, and mesenchymal states. In vitro, recombinant SLIT2 increased E-cadherin and decreased SNAIL in NSCLC and HNSCC cells. SLIT2 knockdown elevated mesenchymal markers, and recombinant SLIT2 suppressed migration in zebrafish xenografts, highlighting its anti-metastatic potential. These findings demonstrate SLIT2's critical role in EMT regulation and its therapeutic promise for controlling metastasis.

Introduction: Phenotypic plasticity, including epithelial-to-mesenchymal transition (EMT), drives cancer progression and resistance. SLIT2, signaling through ROBO1, has dual roles in cancer. In lung and head and neck cancers, SLIT2 inhibits tumor growth via a non-canonical ROBO1/EPHA2 pathway, though its role in EMT remains unclear. This study models SLIT2's effect on EMT and confirms its potential to inhibit hybrid/mesenchymal transitions, offering therapeutic promise.

Methods: SLIT2's role in EMT was assessed in lung and head and neck cancers. A mathematical EMT model incorporating SLIT2 analyzed epithelial, hybrid, and mesenchymal states. Recombinant SLIT2 was tested on NSCLC and HNSCC cells, with EMT markers analyzed. SLIT2 knockdown was used to assess mesenchymal markers. Zebrafish xenografts quantified migration post-SLIT2 treatment.

Results: SLIT2 expression was inversely correlated with EMT scores in LUSC and HNSCC. Epithelial subtypes had higher SLIT2 levels, while mesenchymal subtypes had lower levels. SLIT2 suppressed SNAIL expression, maintaining epithelial characteristics and reducing mesenchymal markers. Recombinant SLIT2 treatment decreased cell proliferation, migration, and spheroid growth. Zebrafish xenografts showed reduced tumor growth and metastasis. Patient tumor analysis indicated that high SLIT2 expression correlated with better survival.

Conclusion: SLIT2 inhibits EMT in lung cancer cells, suppressing mesenchymal markers and maintaining the epithelial phenotype, thus limiting metastasis. Future studies will validate the therapeutic potential of the SLIT2 D2 fragment as an anti-metastatic treatment.

#5141 ADAR1 maintains cancer stem cell proliferation in a mouse model of TNBC-derived breast cancer brain metastases.

Teresa Sposito[1], Emma Klacking[2], Jessica Pham[2], Roman Sasik[2], Inge van der Werf[2], Najla Kfoury-Beaumont[3], Alexander Khalessi[3], Thomas Whisenant[2], Catriona Jamieson[2]

[1]University of California San Diego - UCSD, La Jolla, CA,[2]Medicine, University of California San Diego - UCSD, La Jolla, CA,[3]Neurological Surgery, University of California San Diego - UCSD, La Jolla, CA

Background: Essential for preventing autoinflammation, adenosine deaminase acting on double-stranded RNA (ADAR1) is also a recognized driver of epi-transcriptomic remodeling and tumor immune silencing. High levels of ADAR1 have been associated with a worse prognosis and reduced survival in patients with high-grade breast cancer (BC), especially in the $HER2^+$ and triple-negative BC (TNBC) subgroup, which are the most likely to develop brain metastasis (BrM), arising in up to 30% of TNBC and $HER2^+$ cases. Nevertheless, the role of ADAR1 in the metastatic context is only partially understood.
We have hypothesized that ADAR1 activation and upregulation of the p150 isoform play a pivotal role in promoting BC-BrM invasion by maintaining BC stem cell metastatic niches. We focused on the brain, one of the most aggressive and less studied metastatic sites.
Methods: We developed a BC-BrM model based on intracerebroventricular implants of MDA-MD-231 TNBC and primary BC-BrM patient cells in $Rag2^{-/-}\gamma c^{-/-}$ mice. Before implantation, tumor cells were transduced with a nanoluc-GFP reporter for tracing ADAR1 enzymatic activity in the brain niche, or shRNA vectors for ADAR1 down regulation studies.
Results: Upon establishment of BrM, scRNA sequencing and qRT-PCR revealed that ADAR1 p150 was upregulated, alongside WNT/β-Catenin pathway activation, a switch in the CD47 isoforms, and extra cellular matrix remodeling. Preliminary results from FFPE imaging of patient samples further suggested a correlation between ADAR1 and WNT/β-Catenin activation, showing that high levels of ADAR1 are associated with nuclear translocation of β-Catenin.
Additionally, sc-RNA sequencing of ADAR1 knocked-down TNBC-derived BrM compared to scrambled controls, identified a cluster with increased protein stress and arrest of growth-related processes, predominantly represented by the ADAR1 KD cells. These findings suggest that ADAR1 is essential for maintaining cancer cell proliferation in the brain.
Future Directions: We are now further validating the role of ADAR1 and its molecular interactors in maintaining the metastatic brain niche through scRNA-sequencing of BC-BrM patient samples collected from UCSD hospitals. Overall, this study provides new insights into the molecular role of ADAR1 deaminase activity in establishing and maintaining metastatic niches.

#5142 Role of UCA1 in Warburg effect during anoikis resistance in colorectal carcinoma.

Ricardo Pequeno Bracho, Salique H. Shaham, Yamile Abuchard Anaya, Sophia Leslie, Kyle Doxtater, Bilal B. Hafeez, Tamer Oraby, Subhash C. Chauhan, Manish K. Tripathi

Medicine and Oncology ISU, University of Texas Rio Grande Valley, McAllen, TX

Colorectal carcinoma (CRC) remains the second leading cause of cancer-related deaths in the United States. The survival rate for CRC patients drops precipitously from 90% for localized disease to only 14% upon metastasis. Approximately, 40-50% of CRC cases progress to metastasis, a multifaceted process requiring the acquisition of anoikis resistance as one of the critical steps. This anoikis or anchorage-independent resistance enables cancer cells to survive detachment from the extracellular matrix, migrate through vascular and lymphatic systems, and establish secondary tumor sites. A deeper understanding of the molecular mechanisms underlying anoikis resistance, particularly in the context glucose metabolism, is crucial for advancing therapeutic strategies in CRC metastasis. Cancer cells frequently exhibit the Warburg Effect, a metabolic adaptation characterized by preferential glycolysis over oxidative phosphorylation, even under normoxic conditions. This metabolic reprogramming supports proliferation and may promote survival under anchorage-independent conditions. Our preliminary data suggests that the long non-coding RNA (lncRNA) urothelial carcinoma-associated 1 (UCA1), which is overexpressed in CRC and correlates with poor prognosis, may play a pivotal role in metastasis and glucose metabolism. Utilizing isogenic a CRC cell line model SW480 (primary tumor-derived) and SW620 (metastasis-derived), we have developed stable UCA1-overexpressing (SW480+UCA1) and UCA1-knockdown (SW620+shUCA1) experimental models. In vitro characterization of the cell lines via phenotypic assays showing invasion, migration, and cell proliferation by xcelligence and colony formation to be enhanced through UCA1 overexpression and reduced by its knockdown. Furthermore, our data indicates that UCA1 overexpression enhances glucose uptake, lactate production, and anchorage-independent survival, suggesting its involvement in promoting anoikis resistance through metabolic reprogramming. Moreover, these cell lines will be subjected to anchorage-independent growth conditions to assess alterations in cell cycle, pro-survival, and stemness-related markers. Furthermore, glucose metabolism will be evaluated using Seahorse XFp metabolic analysis parameters.

#5143 Using a multipronged approach to characterize C-terminal domain polybasic motif STK11 variants.

Gopika Nandagopal, Peyton Jenkins, Olivia Morton, Shannon Prior, David Seward, Paula Deming

University of Vermont, Burlington, VT

KRAS-driven lung adenocarcinomas (LUADs) with concurrent STK11 loss of function (LoF) mutations are associated with aggressive tumors with increased risk of metastasis and lower overall and progression free survival. In LUAD, STK11 LoF impacts many aspects of coordinated cell motility and promotes alterations characteristic of metastasis. STK11 is a serine-threonine kinase that is comprised of an N-terminal, kinase, and C-terminal domain (CTD). With the goal of developing a method to identify pathogenic STK11 mutations, we previously evaluated functional impact of variants identified from the University of Vermont Medical Center on STK11 kinase activity using in-vitro kinase assays, and luciferase reporter assays. Here, we saw that CTD variants retained kinase activity and the ability to form the STK11 heterotrimeric complex. Although the CTD has no catalytic activity, it is thought to be integral for STK11 localization to the plasma membrane and cytoskeleton, where it negatively regulates the activity of focal adhesion kinase (FAK). Recent work by others has shown that a region of the CTD, the polybasic motif (PBM), (aa403-426) is key for localization of STK11 to the plasma membrane. Therefore, we reasoned that STK11 variants in the CTD would demonstrate altered subcellular localization and cytoplasmic functions. Indeed, we show in cell lines through immunofluorescent microscopy that expression of a truncated construct encoding STK11 with a CTD deletion results in full nuclear sequestration. Additionally, point mutants in 4 of the polybasic motif residues (R409W, K416E, A417S and K423E) retain kinase activity, but lead to partial nuclear sequestration despite their ability to bind heterotrimeric complex partners STRAD-α and MO25. This suggests a novel mode of dysregulated localization, independent of the known mechanism of STK11 export into the cytoplasm through binding of STRAD-α. This phenotype is exacerbated in a double mutant of STK11 PBM sites K416E and K423E. As FAK activity is known to be negatively regulated by STK11 in the cytoplasm, we used a KRAS-driven LUAD cell model system with (STK11-WT) and without STK11 (ΔSTK11) to monitor pY397 levels via SDS-Page and western blot analysis. This is a known FAK autophosphorylation site and was used as a proxy for active FAK. Under glutamine starved conditions known to activate STK11, the STK11 WT cells demonstrate a decrease in pY397-FAK levels. However, the levels of pY397-FAK in ΔSTK11 cells were significantly elevated. To determine if this elevated pY397-FAK phenotype is recapitulated in PBM mutants, we are generating a stable K416E_K423E double mutant cell line which will allow us to ascertain the ability of this mutant to regulate FAK activity. Ongoing experiments examine the migratory and invasive ability of the WT-expressing vs. PBM mutants. Additionally, we are utilizing the TurboID system to identify PBM-dependent STK11 interacting proteins.

#5144 Prevalence and clinical significance of CBP deficiency and disturbed CBP expression in human cancer.

Viktoria Chirico[1], Seyma Buyucek[1], Katharina Moller[1], Florian Lutz[1], Florian Viehweger[1], Martina Kluth[1], Claudia Hube-Magg[1], Elena Bady[1], Lisa Hornsteiner[1], Christian Bernreuther[1], Guido Sauter[1], Andreas H Marx[2], Till Krech[1], Stefan Steurer[1], Christoph Fraune[1], Sarah Minner[1], Natalia Gorbokon[1], Maximilian Lennartz[1], Eike Burandt[1], Anne Menz[1], Soren Weidemann[1], Waldemar WIlczak[1], Morton Freytag[1], Viktor Reiswich[1], Ronald Simon[1], Simon Kind[1], Ria Schlichter[1], **Nina Schraps**[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Academic Hospital Fuerth, Fuerth, Germany

CBP (CREB-binding protein) is a ubiquitously expressed multidomain protein with histone acetyltransferase and transcriptional co-activator activity. As a major histone modifier, it is involved in the regulation of thousands of genes. CBP has a complex role in cancer where both loss-of-function and overexpression can occur. To better comprehend the role of CBP expression in cancer, a tissue microarray containing 14,966 samples from 134 different tumor entities and 608 samples of 76 different normal tissue types was analyzed. In normal tissues, a strong nuclear CBP staining was ubiquitously seen except few cell types. Among 12,255 evaluable tumors, CBP staining was completely absent (CBP deficiency) in 226 (1.84%) while 232 (1.89%) showed only a faint to moderate staining of a minority of cancer cells (substantial reduction, SR), 384 (3.13%) a 1+, 3,079 (25.12%) a 2+, and 8,334 (68.00%) a 3+ CBP positivity. CBP deficiency or SR was particularly common in pancreatic acinar cell carcinoma (23,5%), endometrioid endometrial carcinoma (22,8%), hepatocellular carcinoma (19.0%), urothelial carcinoma of the renal pelvis (17,4%), medullary carcinoma of the breast (14.3%), serous carcinoma of the endometrium (12.5%), neuroendocrine carcinoma of the pancreas (11.1%), and chromophobe renal cell carcinoma (10.7%). Less than 10% CBP deficient or SR cases were seen in 57 additional tumor categories. Among tumors with detectable CBP expression, low CBP expression levels were linked to advanced pT stage ($p<0.0001$), high UICC stage ($p=0.0005$), poor ISUP ($p=0.0001$), Thoenes ($p=0.0001$) and Fuhrman ($p<0.0001$) grades in clear cell renal cell carcinoma (ccRCC). In papillary RCC (pRCC), low CBP was associated with high UICC grade ($p=0.0409$) and distant metastasis ($p=0.0022$). Low CBP was furthermore associated with advanced pT stage ($p=0.0003$) in colorectal carcinoma and reduced overall survival ($p=0.0236$) in muscle-invasive urothelial carcinoma. High CBP expression was statistically related to nodal metastasis in pancreatic ductal adenocarcinoma (p=0,0201). CBP expression was not unequivocally related to clinico-pathological parameters in breast, ovarian, endometrial and gastric cancer. It is concluded, that CBP deficiency - as a rare event - occurs in many different tumor types and that a reduced or absent CBP expression is linked to aggressive cancer in multiple tumor entities.

#5145 E-selectin binding is enriched within B-cell acute lymphoblastic leukemia compared to healthy lymphoid precursors.

Chase M. Weizer[1], Rachel A. Kraan[2], Evan Ales[2], Stella L. Jaeckle[1], Julia H. Keating[3], Marlise R. Luskin[1], Robert Sackstein[2], Mark A. Murakami[1]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Florida International University Herbert Wertheim College of Medicine, Miami, FL,[3]Data Science, Dana-Farber Cancer Institute, Boston, MA

Background: Adhesion molecules within the bone marrow vascular niche govern the self-renewal, differentiation, and proliferation of hematopoietic progenitors. Among these, E-selectin, a lectin expressed by endothelial cells which binds to the tetrasaccharide known as sialyl Lewis X (sLeX), promotes dormancy, self-renewal, and chemoresistance in native hematopoietic stem cells (HSCs). However, leukemic blasts hijack these signals, fueling their proliferation. While therapeutic disruption of E-selectin binding to its ligands has demonstrated clinical activity in acute myeloid leukemia, its role in B-cell acute lymphoblastic leukemia (B-ALL) remains underexplored. Identifying E-selectin ligands and associated downstream molecular effectors in B-ALL holds potential to reveal targetable mediators of leukemia-initiating capacity, drug tolerance, and persistence.

Methods: Fresh peripheral blood and bone marrow from appropriately consented healthy donors (n=9) and clinically annotated patients (n=11) with BCR::ABL1 B-ALL identically treated on a clinical trial (NCT03595917) were profiled for sLeX expression and E-selectin binding by flow cytometry using HECA-452 monoclonal antibody and E-selectin-Ig chimera (E-Ig) respectively, along with glycoproteomic analyses. Expression of canonical E-selectin ligands (HCELL/CD44, CLA/PSGL-1, CD43E/CD43) and B cell developmental markers (CD45, CD34, CD10, CD19, CD20, CD22) were also assessed.

Results: SLeX expression and E-selectin binding varied between native antigen-independent B cell developmental stages ($p < 0.05$). Malignant CD19+ B cells from the bone marrow of treatment-naïve B-ALL patients exhibited increased sLeX expression ($p < 0.05$) and a nominal increase in E-selectin binding compared to counterparts from healthy donors. E-Ig-reactive CD19+ B-ALL cells display higher CD43 expression and lower CD44 and PSGL-1 expression than E-Ig-reactive CD19+ healthy donor B cells ($p < 0.05$). Treatment-naïve leukemic progenitors displayed greater sLeX expression and E-selectin binding than patient-matched non-malignant populations ($p < 0.05$). Leukemic progenitors isolated from serial bone marrow specimens exhibited a nominal increase in sLeX expression and E-selectin binding at progression versus baseline.

Conclusions: Within the lymphoid lineage, E-selectin binding is developmentally determined and enriched in malignant compared to native cells. Interrogation of downstream effectors and functional phenotypes is ongoing.

#5146 E-cadherin expression as a prognostic biomarker in colorectal cancer.

Anika Bhandare[1], Anjana Saxena[2], Mintoo Patel[1]

[1]South Florida State College, Avon Park, FL,[2]Brooklyn College and the Graduate Center, City University of New York, New York, NY

Colorectal cancer (CRC) represents the third most common cancer in the United States, with increasing incidence among younger populations despite remaining predominantly prevalent in individuals over 65 years of age. E-cadherin, a critical cell-cell adhesion molecule, plays a significant role in the development and progression of colorectal cancer by regulating intricate cellular mechanisms including polarity, differentiation, proliferation, and migration through complex cytoskeletal network associations. Loss of E-cadherin expression fundamentally disrupts intercellular adhesion, triggering enhanced cellular motility and facilitating the epithelial-to-mesenchymal transition (EMT)—a critical transformative process that enables metastatic potential. This molecular mechanism represents a crucial turning point in cancer progression, where cellular architectural integrity becomes compromised. This study investigated E-cadherin expression across different stages of colorectal cancer using immunohistochemical analysis of de-identified formalin-fixed paraffin-embedded biopsy tissue samples categorized as precancerous, cancerous, and normal noncancerous groups. Complementing the primary immunohistochemical analysis, a rigorous systematic meta-analysis was conducted through an extensive PubMed literature search to validate and contextualize the findings. Immunohistochemical staining revealed a robust E-cadherin expression in the mucosal epithelial cells of the normal tissues, whereas cancerous tissue samples exhibited reduced E-cadherin levels that correlated directly with advanced cancer staging. Low E-cadherin levels correlate significantly with adverse clinicopathological features and potentially more aggressive disease progression. The comprehensive meta-analysis substantiated these immunohistochemical observations, reinforcing the potential diagnostic and prognostic significance of E-cadherin as a sophisticated molecular biomarker. This study underscores the potential of E-cadherin as a supplementary biomarker in routine histopathological examinations. By providing more nuanced molecular insights into cancer stage and progression, E-cadherin analysis could facilitate further personalized, targeted clinical treatment strategies for colorectal cancer patients.

#5147 Prognostic role of MTAP expression is reversed by the ERG status in prostate cancer treated by radical prostatectomy.

Natalia Gorbokon[1], Seyma Buyucek[1], Henning Plage[2], Neele Heckmann[1], Ronald Simon[1], Maximilian Lennartz[1], Martina Kluth[1], Elena Bady[1], Lisa Hornsteiner[1], Claudia Hube-Magg[1], Sarah Minner[1], Eike Burandt[1], Till S Clauditz[1], Waldemar Wilczak[1], Guido Sauter[1], David Dum[1], Andrea Hinsch[1], Hans Heinzer[1], Alexander Haese[1], Thorsten Schlomm[2], Andreas Lubke[1], Markus Graefen[1], Stefan Steurer[1], Christian Bernreuther[1], Luca Roma[3], Lukas Bubendorf[3], Sarah Weinberger[2]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Charite - Universitatsmedizin Berlin, Berlin, Germany,[3]University Hospital Basel, Basel, Switzerland

Loss of S-methyl-5′-thioadenosine phosphorylase (MTAP) expression offers an important therapeutic option through synthetic lethality with inhibitors targeting related pathways, and has been linked to resistance to immune checkpoint inhibitors in several tumor types. To better understand the prevalence and clinical relevance of MTAP expression in prostate cancer, a tissue microarray with 17,747 prostate cancer samples and a molecular and clinical database was analyzed for MTAP expression by immunohistochemistry. Normal prostate glands showed a weak to moderate, predominantly cytoplasmic MTAP positivity of epithelial and stromal cells. In 13,189 interpretable cancers, a complete loss of MTAP staining as compared to adjacent non-neoplastic cells was seen in 33 (0.3%) tumors, while MTAP staining was considered 1+ in 14.8%, 2+ in 42.2%, and 3+ in 42.7% of tumors. Fluorescence in situ hybridization analysis of 9 MTAP negative cancers confirmed homozygous *MTAP* deletion in all of these tumors. MTAP staining was significantly stronger in cancers harboring the *TMPRSS2:ERG* fusion than in *TMPRSS2:ERG* fusion negative tumors ($p<0.0001$). A comparison with clinico-pathological features revealed inverse correlations depending on the ERG fusion status: In ERG negative carcinomas, high (3+) MTAP expression was linked to advanced pT stage, high classical and quantitative Gleason grade, and early PSA recurrence in uni- and multivariate analysis ($p<0.0001$ each). In ERG positive cancers, MTAP expression decreased with advanced pT stage ($p<0.0001$), classical ($p=0.0004$) and quantitative Gleason grade ($p=0.0005$), and low (1+) MTAP expression was significantly linked to early PSA recurrence ($p=0.0012$). Comparison with 11 previously analyzed chromosomal deletions identified ERG-status-dependent positive or negative associations between MTAP expression and deletions of *PTEN* and 12p13 ($p\leq0.0274$) suggesting possible functional interactions with PTEN and one or several 12p genes. Taken together, the results of our study demonstrate that MTAP deficiency is exceedingly rare in prostate cancer, while high MTAP expression is a strong and independent marker for poor prognosis in ERG negative cancers.

#5148 Plakophilin 3 and ovarian cancer progression: Functional transition from early expression to advanced-state regulation through RB and STAT3 pathways.

Ha-Yeon Shin, JueYoung Kim, Jae-Hoon Kim

Department of Obstetrics and Gynecology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Ovarian cancer (OC) is a heterogeneous disease with a high mortality rate and poor prognosis, primarily due to late-stage diagnosis. The identification of reliable biomarkers is crucial for improving patient outcomes. Plakophilin 3 (PKP3) is often overexpressed in cancers, yet its role in OC remains poorly understood.
Methods: We performed immunohistochemistry with tissue microarray, including normal (n=39), benign (n=66), borderline (n=44), and ovarian cancer (n=187), and analyzed clinical and survival rates according to the expression of PKP3. Either lacking or overexpressing PKP3 in immortalized normal cell and OC cell lines, we measured cell proliferation, cell cycle, and migration. Molecule change associated them checked western blot and qRT-PCR. Additionally, cellular localization of PKP3 in cancer cells was confirmed via cell fraction and immunofluorescence.
Results: The expression levels of PKP3 in OC are higher than in normal and benign tissues; notably, PKP3 shows the highest expression in stage I compared to other stages. Analysis of overall and disease-free survival revealed that patients with high PKP3 expression had a better prognosis than those with low PKP3 expression. Overexpression of PKP3 in immortalized normal cell lines led to increased cell growth. The depletion of PKP3 in OC cells triggered G1 cell cycle arrest. This was achieved through the attenuation of retinoblastoma (RB) protein phosphorylation and suppression of E2F1 target gene expression, ultimately resulting in reduced cell growth. Although PKP3 depletion decreased OC cell growth, it paradoxically increased cell migration. This increase in migration was mediated by the activation of STAT3. Regulation of RB and STAT3 activation by PKP3 was confirmed to occur in the nucleus. We found that alteration of PKP3 expression in normal and OC ultimately regulates the progression of OC.
Conclusion: PKP3 promotes the initiation of OC by driving cell growth, and in advanced stages, its reduced expression is associated with increased epithelial-mesenchymal transition (EMT), leading to a worse prognosis. This study suggests that PKP3 could serve as a biomarker for early diagnosis and that targeting the PKP3-STAT3 axis may offer new therapeutic opportunities for OC.

#5149 Sialyation of desmosomal protein DSG2: A potential regulator of colorectal cancer cell junctions.

Teresa Chiyanne Beamon[1], Collin Ainslie[2], Regina Irwin[1], Jeremie M. P. Lever[1], Alexa L. Mattheyses[2], Karin M. Hardiman[1]

[1]Surgery, University Of Alabama At Birmingham, Birmingham, AL,[2]University Of Alabama At Birmingham, Birmingham, AL

Introduction: Colorectal cancer (CRC) remains one of the most common and deadly cancers in the US. Despite advances in treatment, once CRC is metastatic (spread from the original tumor site to other parts of the body), the 5-year survival rate is 20%. Metastasis requires a complex series of events, including the release of tumor cells from the origin site. Tumor cells adhere to each other via adhesive cell-cell junctions, one family of these is called desmosomes. A key desmosomal protein is Desmoglein-2 (DSG2), which is a cell surface protein. DSG2 function could influence cancer cell detachment and migration, essential steps in metastasis, which has not been fully studied. Upregulation of ST6GAL1, a sialyltransferase that adds sialic acid to proteins in the Golgi, is a hallmark of progression of certain types of cancer. High levels of ST6Gal1 have been linked to worse cancer outcomes. We hypothesized, that increased sialylation of the desmosome protein DSG2 by ST6GAL1 in CRC enhances its surface localization, possibly altering its function.
Methods: Human SW620 CRC ST6GAL1 control (CV) and ST6GAL1 knockdown (KD) cells were cultured and utilized to evaluate the presence of DSG2 through three methods: SNA- lectin pull-down assay (SNA recognizes α2,6-sialylation caused by ST6GAL1), immunofluorescence (IF), and western blotting (WB). The pull-down samples were evaluated for presence of sialylated DSG2 by WB and further analyzed and quantified using densitometry. For IF staining, cells were fixed, permeabilized, and stained with a DSG2 antibody and DAPI to assess differences in location and presence between KD and CV cells. Quantitative image analysis was performed, utilizing 5 high powered fields per experimental group. Further, to assess the relationship between cell density and DSG2 expression, cells were plated at increasing densities and analyzed by both WB and IF techniques.
Results: SNA pull-down assay and WB analysis revealed that DSG2 is α2,6 sialylated by ST6GAL1. ST6GAL1 CV cells had 2.31 times more sialylated DSG2 than ST6GAL1 KD cells. This was corroborated by DSG2 IF staining. We observed an average surface DSG2 to DAPI ratio in KD cells of 0.09 (SEM ± 0.01) and CV cells' ratio of 0.20 (SEM ± 0.03) (p=. 0.0353, n=3) such that CV cells had 2.7 times more DSG2.
Conclusions: Based on these findings, we hypothesize conclude that ST6GAL1 sialylates DSG2 and that this appears to alter its increased sialylation of the desmosome protein, DSG2, in CRC by ST6GAL1 may enhance DSG2's surface localization which likely alters its function. Further study is needed to investigate how this may alter CRC progression and metastasis.

TUMOR BIOLOGY: Mouse Models of Cancer and Mechanisms
Poster Session

#5153 Synergistic efficacy of PARP and DNMT inhibition in ATM and CHEK2 CRISP-engineered in vitro and in vivo models.

Fateme Karimi Dermani, Sibapriya Chaudhuri, Luika Timmerman, Scott Thomas, Pamela Munster

UCSF - University of California San Francisco, San Francisco, CA

Introduction: More than a decade of work has demonstrated the benefit of using poly (ADP-ribose) polymerase inhibitors (PARPi) in patients with BRCA1 and BRCA2 mutant tumors, based on their compromised ability to repair DNA damage by homologous recombination (HRD). While the benefits of PARPi monotherapy can be limited, our laboratory is working to identify co-therapeutics to improve therapeutic efficacy. Homologous recombination requires the function of many other proteins besides BRCA1 and BRCA2, and PARP sensitivity of tumors with these mutations has not been well explored. Of particular interest are tumors with mutations in the ATM and CHK2 proteins. Here in preclinical studies, we explore the sensitivity of these mutants to PARP directed therapeutics, and to our current therapeutic combination with a DNA methyltransferase inhibitor (DNMT1; decitabine) that we now have in Phase 1 clinical trials. We hypothesize that tumors with pathogenic ATM and CHK2 mutations may also show PARP inhibitor sensitivity, which might also be potentiated in combination with decitabine.
Methods: To test this hypothesis, we generated inducible RNA knockdown variants of the HR proficient triple negative breast cancer cell line MDA-MB-231, targeting *ATM* and *Chek2* transcripts under doxycycline control via dCAS9 technology. Responses to the PARP inhibitor talazoparib, with and without decitabine were assessed with and without doxycycline induction. We evaluated colony formation, cell death, cell cycle fraction alterations, DNA damage and measured PARP1-DNMT1 adduct formation using proximity ligation assays.
Results: Preliminary findings show that the combination of talazoparib and decitabine resulted in greater synergistic efficacy at lower doses than talazoparib alone. In the ATM dCas9, and CHEK2 dCas9 cell lines, the combined treatment led to substantial DNA damage, prolonged trapping of PARP1-DNMT1 complexes on DNA, and significant induction of cell death. Accordingly, potent growth inhibition was also seen in xenografts models with clinically relevant *ATM* and *CHEK2* mutations.
Conclusion: These results support further investigation into the combined use of PARP and DNMT inhibitors in tumors with these mutations. The synergistic effects observed in the MDA-MB231-derived models suggest that this combination could provide a more effective treatment option for HRD cancers, particularly in overcoming resistance to PARPi monotherapy.

#5154 Modeling luminal urothelial carcinoma in the bladder and the upper tract.

D. Xu, K. Wieczorek, L. Wang, Y. Zhang, J. Wang, B. Xu, D. W. Goodrich, A. A. Hussein, K. Guru, Q. Li;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Introduction: Pan-urothelial carcinoma (panUCC) involves synchronous or metachronous urothelial carcinoma of the bladder (UCB) and upper tract urothelial carcinoma (UTUC). We sought to model panUCC using a triple knockout (*TKO: Trp53; Rb1; Pten*) genetically engineered mouse model (GEMM).

Methods: Using a urothelium-specific *Uroplakin 2-Cre* ^{ERT2} (*Upk2-Cre*^{ERT2}), we generated novel *TKO* mice (*Upk2-Cre* ^{ERT2}; *Trp53*$^{f/f}$; *Rb1*$^{f/f}$; *Pten*$^{f/f}$). The mice were monitored for hematuria, urine retention, tumor formation, and survival. PCR primers were designed to amplify the genes after recombination. Tumor histology and metastasis were examined by hematoxylin and eosin (HE) and immunohistochemistry (IHC). The subtype of tumors was classified using luminal (Upk3, CK8, GATA-3) and basal markers (CK5, p63), and a neuroendocrine marker (synaptophysin, Syp).

Results: *Upk2-Cre*^{ERT2}; *TKO* mice (n = 34, 18 males and 16 females) developed non-muscle invasive urothelial carcinoma tumors located in the bladder and/or the renal pelvis/ureter with a median survival of 294 days. PCR results validated *Trp53/Rb1/Pten* mutations in UC tumors. Mice with UCB or mixed UCB/UTUC tumors exhibited a longer survival compared to mice with UTUC only [median survival 393 days (n = 7) VS 278 days (n = 27), P = 0.006]. No obvious evidence of distant metastases was detected. IHC of both UCB and UTUC tumors demonstrated luminal UC tumors with strong expression of luminal markers (Upk3, CK8, GATA-3) and no expression of basal and neuroendocrine markers (CK5, p63, and Syp).

Conclusion: We developed a novel *TKO* GEMM that faithfully recapitulates human panUCC. This GEMM provides a useful tool for investigating the molecular and therapeutic differences between UCB and UTUC tumors.

Funding: This research work was supported in part by NIH Grants, K08CA252161(Li, Q), P30CA016056 (NCI Cancer Center Core Support Grant), and the Roswell Park Alliance Foundation.

#5155 A novel lipid nanoparticle for delivering sgRNA and mRNA to develop lung cancer model mice.

Bingxin Liu[1], Yutaka Maeda[2]

[1]Materials Science and Engineering Program, University of Cincinnati, Cincinnati, OH,[2]Pulmonary Biology, Cincinnati Children's Hospital, Cincinnati, OH

Background: Genetically engineered mouse models (GEMMs) that develop autochthonous lung tumors are suitable to study lung tumor initiation and the tumor microenvironment involved in immune cells. However, GEMMs require lengthy mouse breeding with multiple crossing of genetic lines to develop mice carrying multiple alleles of specific genes. A more convenient approach to develop these GEMMs will facilitate lung cancer research.

Methods: We have recently developed a novel lipid nanoparticle PEG-PBAE/4A3-SC8/DOPE/Cholesterol/DOTAP (hereafter, LNP) that can deliver mRNA into lung epithelial cells in mice by intratracheal (IT) injection (Liu et al., bioRxiv 2024; https://doi.org/10.1101/2024.08.22.608643). Using this LNP, we delivered different sgRNAs and/or Cre mRNA into *Cas9* mice that constitutively express Cas9 (or *Kras*$^{LSL\text{-}G12D/+}$*;Cas9* mice) by IT injection and sought to develop lung cancer model mice.

Results: The LNP delivery of sgRNAs targeting *Eml4* (sgEml4) and *Alk* (sgAlk) into *Cas9* mice produced autochthonous lung tumors induced by the driver oncogene EML4-ALK two months after IT injection. The LNP delivery of Cre mRNA along with sgRNA targeting the lung lineage transcription factor *Nkx2-1* (sgNkx2-1) into *Kras*$^{LSL\text{-}G12D/+}$*; Cas9* mice produced autochthonous invasive mucinous adenocarcinomas of the lung (IMA) that carry *Kras*^{G12D} with loss of NKX2-1 and *de novo* expression of the gastrointestinal transcription factor HNF4A while the LNP delivery of only Cre mRNA into *Kras*$^{LSL\text{-}G12D/+}$*; Cas9* mice produced autochthonous non-mucinous adenoma/adenocarcinoma two months after IT injection.

Conclusion: Delivery of our novel LNPs encapsulating sgRNAs and/or Cre mRNA into *Cas9* or *Kras*$^{LSL\text{-}G12D/+}$*;Cas9* mice by IT injection successfully resulted in producing autochthonous lung tumors driven by EML4-ALK or KRAS^{G12D} similar to traditional GEMMs. This approach using our LNPs will allow for agile development of lung cancer mouse models for investigating novel lung cancer therapeutics.

#5156 Combining the RCAS/tv-a retrovirus and CRISPR/Cas9 gene editing systems to generate primary mouse models of midline glioma.

Sophie R. Wu[1], Julianne Sharpe[2], Joshua Tolliver[1], Abigail J. Groth[1], Reid Chen[1], Maria E. Guerra Garcia[3], Vennesa Valentine[4], Nerissa T. Williams[1], Sheeba Jacob[1], Zachary J. Reitman[1]

[1]Radiation Oncology, Duke University, Durham, NC,[2]Biology, University of Kentucky, Lexington, KY,[3]Biomedical Engineering, Washington University, St. Louis, MO,[4]Pharmacology & Cancer Biology, Duke University, Durham, NC

Diffuse midline gliomas (DMGs) are fatal pediatric brain tumors that commonly arise in the brainstem and other midline brain structures, with a median overall survival of less than two years. Genetically engineered mouse models (GEMMs) are key to studying tumorigenesis and tumor-immune interactions, which may inform the development of urgently-needed treatment approaches. However, current midline glioma GEMM approaches are limited in their ability to model multiple gene perturbations and to target specific cell lineages in the brain. Here, we establish a platform that combines the RCAS/tv-a avian retrovirus system with CRISPR/Cas9 gene editing to drive midline glioma formation in mice. To express endonuclease Cas9 and the avian retrovirus receptor TVA in mouse neural stem cells, we generated mice of genotype Nestin-TVA; Nestin-Cre; LoxP-STOP-LoxP-Cas9-EGFP (NNC). RCAS retrovirus plasmids were cloned containing guide RNAs (gRNAs) targeting various DMG-relevant genes for perturbation, including *Trp53, Cdkn2a, Atm, Pten,* and a non-targeting control (Cntl). Two types of plasmids were generated for each gene target, one with a platelet-derived growth factor beta ligand (PDGFB) oncogene driver and another with a blue fluorescent protein (BFP) marker.To confirm if the combined system could generate high grade midline gliomas in mice, the *Trp53* tumor suppressor that is frequently disrupted in midline gliomas was targeted for CRISPR/Cas9 based disruption. We observed high grade tumors with moderate latency (median time to tumor formation of 12.57 weeks). Immunohistochemistry (IHC) and next-generation sequencing (NGS) confirmed tumor features that model human DMG, expression of Cas9 and PDGFB, and CRISPR-mediated loss of p53. Next, we disrupted multiple tumor suppressor genes (*Trp53, Atm, Cdkn2a, Pten)* in a mini-pooled *in vivo* experiment, generating midline gliomas with decreased tumor latency (median time to tumor formation 3.6 weeks, $P < 0.0001$, log-rank test compared to a single-plex gRNA). Quantification of gRNA barcodes and CRISPR editing events using NGS revealed that all tumors contained cells with disruption of all target genes, suggesting a multiclonal origin for the tumors and stronger selection for *Trp53* disruption compared to other genes. This mouse modeling approach may streamline future GEMM DMG research by enabling complex experiments in which new genes of interest can be rapidly perturbed by CRISPR/Cas9. Sophisticated experiments such as pooled *in vivo* genetic experiments may allow for screens to identify genetic determinants of tumorigenesis or treatment response.

#5157 The novel CD34 huNSG-FLT3-IL15 mouse strain, which expresses human IL15 and FLT3 ligand, enhances the development T, myeloid, dendritic, and natural killer cells.

Peter Deng, Pali Kaur, Shuang Hu, Brian S. Soper, Voot Yin

The Jackson Laboratory, Sacramento, CA

Cell humanized mouse models that reconstitute the human immune system are valuable in the field of immuno-oncology (IO) and IO drug development. Importantly, the development of cell humanized mouse models that recapitulate a comprehensive immune system is critical for the study of the interplay between T, myeloid, dendritic, and natural killer cells in the context of cancer. In the present study, we have developed a novel NOD-scid IL2rγ^{null} (NSG) mouse variant (NSG-FLT3-IL15) that transgenically expresses both human IL-15 and human FLT3 ligand to enhance maturation of functional innate immune cells including human CD56+ CD16+ NK cells, CD33+ myeloid cells, CD141+ and CD1c+ conventional DC subsets, CD123+ pDCs, and CD14+ monocytes alongside adaptive immune cells such as CD4+ regulatory T cells and CD4+ and CD8+ effector T cells over a 28-week period.
NSG-FLT3-IL15 mice, along with control strains NSG, NSG-IL15, and NSG-FLT3, were engrafted with human umbilical cord blood-derived CD34^{+} hematopoietic stem cells from three different donors, and blood samples were collected until week 28 post-transplantation. Flow cytometry revealed that hCD45^{+} cell engraftment and T cell subpopulations (CD3+, CD4+, and CD8+) in NSG-FLT3-IL15 mice were comparable to parental control strains. Strikingly, NSG-FLT3-IL15 mice exhibited enhanced CD56$^{+/dim}$ CD16+ NK cells compared to the control strains. Furthermore, levels of myeloid sub-lineage cells such as monocytes, macrophages (M1), granulocytes, dendritic cells, and neutrophils, were higher than in NSG or NSG-IL15 strains but comparable to NSG-FLT3 strain mice. Current growth kinetic studies with human patient derived tumors will assess human immune cell infiltration across NSG variants. In vivo efficacy studies are underway to demonstrate therapy induced tumor killing by the enhanced innate human immune cells developed in NSG-FLT3-IL15 mice.
Overall, these results demonstrate that the NSG-IL15-FLT3 model supports enhanced development of functional human innate immune cells and serves as a novel comprehensive immune model for studying human IO.

#5158 Establishing novel patient-derived xenograft models for peritoneal metastasis in a racially diverse population.

Vashti Bandy[1], Adam Khader[1], Praveen Bhoopathi[1], Vignesh Vudatha[1], Arunima Punjala[1], Jose Trevino[1], Bhaumik Patel[1], Leopoldo Fernandez[1], Savannah Gregg[2]

[1]Virginia Commonwealth University, Richmond, VA,[2]Central Virginia VA Health Care System, Richmond, VA

Colorectal cancer (CRC) is highly treatable when localized, but survival drops sharply with metastasis, especially to the peritoneum (PM). CRC PM is particularly resistant to chemotherapy, emphasizing the need for models that replicate disease biology for use in drug discovery. Our study establishes reproducible CRC PM patient-derived xenografts (PDX) from a racially diverse patient population.

Patients with CRC PM were recruited for a tissue collection study at a single academic tertiary care center. Tumor samples were collected under sterile conditions and prepared for subcutaneous propagation into NOD.Cg-Prkdcscid/J (NSG) mice. Next, tumor was harvested and reimplanted intraperitoneally into new NSG models. Peritoneal metastasis was induced via 1) Intraperitoneal injection of a single cell suspension or 2) Intraperitoneal tumor implantation via laparotomy. Post-necropsy, peritoneal carcinomatous index (PCI) was calculated and pictures were taken using a cross-polarization technique to allow for PCI scoring by an independent investigator. Collected tumor was processed for histological analysis.

We developed four successful intraperitoneal PDX models using CRC PM derived from a 62-year-old non-Hispanic Black female with KRAS G12V mutation and a 60-year-old non-Hispanic White female with KRAS wildtype. Both tumors had microsatellite stability (MSS). All four PDX were representative of the human clinical condition as diffuse peritoneal metastases were found in each. The laparotomy group exhibited a higher tumor burden and PCI compared to the tumor injection group. In histological comparison of PDX to patient tissue, we observed that tumor gland formation and architecture were maintained.

Early findings show that CRC PM PDX models can be successfully established from a racially diverse patient population. Intraperitoneal tumor implantation into NSG mice via laparotomy resulted in a higher PCI compared to tumor injection, though the latter may be more reproducible. Cross-polarization imaging optimized tumor visualization and allowed PCI scoring by an independent investigator. These models mimic gross and histologic characteristics of the original patient tumor. Future directions include extensive multi-omic profiling to further characterize each PDX. We aim to expand our PDX library to better represent CRC PM heterogeneity with a focus towards drug development.

#5159 From subcutaneous to orthotopic: Bridging the gap to human disease in lung cancer research.

Daniel Orive, Benat Picabea, Maeva Houry, Ane Alava, Covadonga Rodriguez-Suarez, Alfonso Calvo, Luis M. Montuenga, Karmele Valencia

Center for Applied Medical Research (CIMA), Pamplona, Spain

Subcutaneous (SC) models are commonly used in preclinical lung cancer research. However, differences in outcomes of mouse-tested therapies suggest that SC models fail to accurately mimic the complexity of the tumor microenvironment, limiting their reliability for evaluating therapeutic responses, tumor-immune interactions, and metastasis. To overcome these limitations, we developed and analyzed novel orthotopic lung cancer (LuO) models using syngeneic and xenograft approaches with human and murine lung cancer cell lines. Tumors were implanted into the left lung via thoracotomy, forming a single nodule per lung. Depending on the cell line, the model generates metastasis and allows for organotropism studies, closely resembling key traits of human lung cancer.

Our study compares molecular and functional properties of SC and LuO models. Tumor microarrays (TMAs) were generated from 20 human and mouse lung cancer cell lines implanted either subcutaneously or orthotopically in mice. SC tumor cores were subcategorized into central and peripheral regions, while LuO cores were classified by parenchymal or pleural location when pleural seeding occurred. Two fluorescence-based multiplex (VECTRA®) panels characterized the tumor microenvironment (TME), profiling lymphoid and myeloid immune populations. Cancer hallmark-related proteins were also analyzed. Compared to SC tumors, LuO models showed significantly higher vascularization (CD31 area, $p<0.0001$), reduced hypoxia (HIF1-α, $p<0.0001$), and lower senescence marker expression (p16 and p21 H-scores, $p<0.0001$). Immune profiling revealed increased $CD4^+$ T-cell infiltration ($p=0.0128$) and elevated $CD4^+PD1^+$ populations ($p=0.0372$), indicating enhanced T-cell exhaustion in LuO tumors. LuO tumors also exhibited significantly higher PD-L1 expression ($p=0.0002$), more M2 macrophages ($p<0.0001$), and an increase in MDSCs ($p<0.0001$), suggesting a reliance on immune suppression mediated by M2 macrophages and MDSCs rather than the PD-1/PD-L1 pathway. Proliferative, apoptotic, and metabolic activity were also compared between LuO and SC tumors.

Although SC models are widely used for lung cancer research and therapy, our results show biological differences depending on the transplant location. Molecular features and TME profiles of SC tumors differ substantially from the clinically relevant LuO context. Our findings suggest that LuO models are more suitable for translational lung cancer studies. Therefore, beyond generating TMAs, we developed additional tools from our LuO models to support research into tumor biology and the TME. These resources are available to the scientific community for deeper understanding of lung cancer pathophysiology. In summary, LuO models improve the recapitulation value of mouse-transplanted models for human disease, offering a more robust platform for preclinical research and therapeutic development.

#5161 Preclinical evaluation of CD3/DLL3 bispecific antibody in syngeneic and humanized mouse models for solid tumor treatment.

Ravneet Chhabra, Chong Li, Shuangshi Liu, Qiang Liu, Liu Yang, Hui Xu

Biocytogen, Waltham, MA

In solid tumors, the number of T cells is limited, and immunosuppressive cells in the tumor microenvironment, such as cancer-associated fibroblasts (CAFs), myeloid-derived suppressor cells (MDSCs), and regulatory T cells (Tregs), can inhibit T cell activity. Additionally, T cells in solid tumors often exist in a state of exhaustion, reducing the effectiveness of treatments.

Delta-like 3 (DLL3) is abnormally highly expressed in various tumor cell lines and primary tumor tissues, particularly showing a significant increase in neuroendocrine tumors (NETs) and small cell lung cancer (SCLC). In SCLC, the expression of DLL3 is closely associated with poor prognosis in patients.

Tarlatamab is the first approved bispecific T cell engager (BiTE) therapy for the treatment of solid tumors and is the bispecific antibody (BsAb) that targets DLL3. This BiTE works by directing T cells to the vicinity of small cell lung cancer cells and activating them to eliminate tumor cells. While the powerful therapeutic effects of Tarlatamab are being highlighted, there is also a consideration for more effective assessment of bispecific antibodies. Appropriate preclinical evaluation models can provide critical data support for subsequent clinical trials of CD3/DLL3 bispecific antibodies, aiding in the understanding of their potential and mechanisms in therapy.

Biocytogen successfully developed a cell line B-hDLL3 B16-F10 that expresses human DLL3. B-hDLL3 B16-F10 cell line can bind to CD3/DLL3 BsAb Tarlatamab analog (in house) and is capable of forming tumors in C57BL/6 mice and B-hCD3E/hCD28 mice after injected. When B-hDLL3 B16-F10 cells are subcutaneously implanted in B-hCD3EDG mice, the Tarlatamab analog (in house) significantly inhibits tumor growth. In PBMC-reconstituted B-NDG mice implanted with human tumor cell line SHP-77, Tarlatamab analog (in house) almost completely suppresses tumor growth. These results indicate that both preclinical animal models can be used to evaluate the in vivo efficacy of the CD3/DLL3 BsAb treatment.

#5162 Decreases in blood pressure in a patient-derived xenograft model of pancreatic ductal adenocarcinoma.

Amelia R. Malicki[1], Leslie M. Ogilvie[1], Alexa N. King[1], Patrick Sanosa[1], Jana Michaud[1], Bridget Coyle-Asbil[1], Praveen Bhoopathi[2], Vignesh Vudatha[3], Jose G. Trevino[3], Keith R. Brunt[4], Jeremy A. Simpson[1]

[1]Human Health and Nutritional Sciences, University of Guelph, Guelph, ON, Canada,[2]Human and Molecular Genetics, Virginia Commonwealth University, Richmond, VA,[3]Department of Surgery, Virginia Commonwealth University, Richmond, VA,[4]Department of Pharmacology, Dalhousie University, Halifax, NS, Canada

Introduction: Chemotherapy and radiation treatment cause cardiac injury and dysfunction. It remains unclear how cancer affects cardiac structure and function in therapy-naïve mice. Emerging data shows that epithelial ovarian cancer affects hemodynamics by causing cardiac atrophy, intrinsic cardiac dysfunction and arterial hypotension in mice. As pancreatic cancer is associated with heart disease risk, we wanted to explore if impaired hemodynamics occurs in other types of cancer. Methods: We utilized a patient-derived xenograft (PDX) model of pancreatic ductal adenocarcinoma (PDAC), established by implanting fresh tumor fragments from a human PDAC patient into NSG mice. Cardiovascular hemodynamic parameters were analyzed at 28-weeks post-tumor implantation, which coincided with an advanced stage of tumor development. Results: Invasive hemodynamic assessments showed a decrease in systolic and diastolic blood pressure. Conclusion: Independent of chemotherapy, pancreatic cancer causes arterial hypotension, impairing perfusion and overall recovery. Monitoring cardiovascular health is crucial to prevent further deterioration, optimize outcomes, and improve the quality of life for pancreatic cancer patients throughout their journey.

#5163 Characterization of endometrial cancer xenograft humanized mouse models.

Sung Wan Kang[1], Ji-Young Lee[1], Min-Seo Lee[1], Ok-Ju Kang[1], Yong-Man Kim[1], Chong Jai Kim[2], Shin-Wha Lee[1]

[1]Obstetrics and Gynecology, Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of,[2]Pathology, Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of

Background: Recently, immunotherapy with immune checkpoint inhibitors (ICIs) has shown promising efficacy in endometrial cancer (EC), particularly in patients with mismatch repair deficiency (dMMR). Preclinical models of EC are essential for evaluating the efficacy of immuno-oncology (IO) drugs and investigating strategies to enhance the antitumor responses to immunotherapy. Humanized (Hu) mouse models can contribute to a better understanding of the underlying mechanisms associated with the improved efficacy of ICIs in treating patients with EC.
Methods: We established EC xenograft Hu-mouse models by subcutaneously transplanting dMMR HEC-1A and Ishikawa human EC cells into $CD34^+$ Hu-mice. Tumor growth was monitored by periodic measurements with a caliper. The immunophenotypical characterization of EC xenografts in Hu-mice was performed using immunohistochemical staining and flow cytometry analysis.
Results: Tumor development and growth were observed in both EC cell lines within $CD34^+$ Hu-mice. In the Hec-1A xenograft Hu-mouse model, tumor growth was significantly inhibited compared to the immunodeficient mouse model. Flow cytometry analysis of tumors, spleen, and blood from Hu-mice injected with HEC-1A cells revealed a high frequency of human immune cells, exhibiting various subtypes, including $CD4^+$/$CD8^+$ T cells, NK cells, NKT cells, B cells, and myeloid cells. In contrast, no significant difference in tumor growth was observed for Ishikawa xenografts between Hu- and the immunodeficient mouse model. While the spleen and blood of Hu-mice harboring Ishikawa tumors exhibited a high frequency of human immune cells similar to the HEC-1A model, the xenografts demonstrated an immune-desert phenotype, characterized by a low frequency of tumor-infiltrating immune cells. Notably, both HEC-1A and Ishikawa EC xenografts in Hu-mice exhibited a significantly higher proportion of PD-1/$PD\text{-}L1^+$ T and B cells compared to those found in the spleen and blood.
Conclusion: Two models of EC xenograft were successfully established in Hu-mice, demonstrating contrasting tumor immune phenotypes. These models might serve as valuable tools for evaluating the efficacy of immunotherapy in EC.

#5164 Deleterious germline *DDX41* variants drive solid tumors in conjunction with second cancer risk alleles and a pro-inflammatory environment.

Sophia C. Korotev, Joshua Y. Strauss, Salina Dominguez, Ashwin Koppayi, Hina Usman, Kehan Ren, Honghao Bi, Peng Ji, Lucy Godley

Hematology and Oncology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL

The presence of solid tumors in those with deleterious germline *DDX41* variants in addition to the expected myeloid malignancies suggests that these alleles could contribute to solid tumor development. To test if *DDX41* cancer risk alleles contribute directly to solid tumor development, we analyzed somatic mutations in solid tumors from people with these variants. We did not detect any somatic *DDX41* mutations (n=18) in contrast to myeloid malignancies in which somatic *DDX41* mutations are common. Moreover, we observed that among families with hematopoietic malignancies and solid tumors, 30% had second germline deleterious variants in other cancer-associated genes. Together, these data suggest that *DDX41* may contribute to solid tumor development indirectly. Since DDX41 regulates innate immunity, we hypothesized that *DDX41* cancer risk alleles could contribute to solid tumor development via inflammation. We measured inflammatory cytokine levels in conditioned media from lymphoblastoid cell lines with deleterious germline *DDX41* variants ($DDX41^{var/+}$) and found elevated levels of some cytokines in $DDX41^{var/+}$ versus controls. Western blots confirmed elevated NF-kB p65 subunit levels and increased nuclear NF-kB localization (p=0.008), suggesting that the DDX41-related inflammatory milieu may be partially characterized by dysregulated NF-kB-driven cytokine expression. To investigate the possibility that *DDX41* variants drive an inflammatory milieu, we performed flow cytometry on peripheral blood of germline $Ddx41^{+/-}$ versus WT mice. We found a 20% increase in T-cells (p=0.0069) in the context of Ddx41-deficiency, suggesting that Ddx41-deficiency contributes to inflammation in this mouse model. To test our hypothesis that DDX41 is a modifier of solid tumor pathogenesis, we have bred $Ddx41^{+/-}$ mice to $Apc^{Min/+}$ mice, which develop intestinal adenomas and are a model of human colon cancer. At three months of age, our preliminary data suggest there are more adenomas in Ddx41-deficient versus WT mice. We are now testing whether Ddx41-deficiency in the hematopoietic compartment drives the elevated adenoma levels, allowing us to delineate the role of immune cells in solid tumor development in the context of Ddx41-deficiency. Overall, our findings suggest germline deleterious *DDX41* variants contribute indirectly to solid tumor development in the context of other germline cancer risk disorders, possibly through elevated inflammation.

#5165 Development of a syngeneic mouse model to study small cell lung cancer (SCLC).

Aarushi Garg[1], Diego A. Velarde[2], Mario A. Pulido[2], Daniel J. Mullen[2], Chunli Yan[2], Matthew A. Gladstone[2], Ite A. Offringa[2]

[1]Biochemistry and Molecular Medicine, USC - University of Southern California, Los Angeles, CA,[2]Department of Surgery, USC - University of Southern California, Los Angeles, CA

Small cell lung cancer (SCLC) is an aggressive neuroendocrine carcinoma with limited treatment options and a 5-year survival rate of 8% (American Cancer Society, 2023). Preclinical models are essential for studying SCLC, yet traditional models either lack immune system relevance (when using nude mice with human SCLC samples) or have lengthy tumor development times (when using genetically-engineered models). The genetically-engineered mouse model originally developed in the Berns lab is the homozygously floxed *Tp53*fl/fl;*Rb1*fl/fl mouse. SCLC is induced through instillation of adenovirus carrying Cre recombinase into the lungs. It requires 6-8 months for proper SCLC development, limiting the model's utility for rapid therapeutic testing. This model has been combined with additional genetic hits to accelerate cancer development, but this narrows the diversity of developed SCLC tumors. Here, we aim to create a fast, immune-competent SCLC mouse model using cell lines derived in-house from three *Tp53*fl/fl;*Rb1*fl/fl SCLC-induced mice. Two types of cell lines were derived from each of three SCLC mouse lungs: cell lines that grow in suspension (S) or adhere (A) to the dish (477A, 477S, 494A, 494S, 625A, 625S, where the number indicates the mouse and A/S indicates attached/suspension growth, respectively). The different growth types mirror that seen in human SCLC cell lines, which can grow suspended in spheres ("classic" SCLC cell lines) or in loose aggregates that attach to plates ("variant" SCLC cell lines). We performed RNA sequencing to gain insight into the molecular characteristics of the six cell lines. Suspension cell lines express neuroendocrine-related genes and the adherent cell lines express epithelial to mesenchymal transition (EMT)-related genes. We tested different injection modes of the mSCLC cell lines (subcutaneous *vs.* tail vein) and different numbers of injected cells to optimize tumor formation. 477S and 625S cell lines induced subcutaneous tumors in several weeks. 477, 494, 625 (S) cell lines generated liver metastases in mice when injected via the tail vein. Adherent cell lines did not efficiently form tumors, though they did exhibit deletion of *Tp53* and *Rb1*. We are lentivirally-transducing the cell lines with a luciferase construct to allow *in vivo* imaging of tumor growth and metastasis. We will use the newly developed mSCLC cell lines to test the effects of immunotherapy following cisplatin-etoposide (CE) chemotherapy. We will focus particularly on the immune response to ELAVL4, which in human patients is associated with improved survival. The mSCLC cell line model will provide a new tool to accelerate the evaluation of novel therapeutic strategies and provide a robust platform for studying SCLC progression in mice. Funding: This work was supported by a Wright Foundation Transformative Cancer GrantAward and the Norris Comprehensive Cancer Center core grant, award number P30CA014089 from the NIH/NCI.

#5166 Increasing translatability of syngeneic mouse models of cancer through the application of human-validated, clinically relevant gene expression-based measurements of the tumor immune microenvironment.

Zachary D. Wallen[1], Kyle C. Strickland[1], **Sheri Barnes**[2], Sarabjot Pabla[1], Simon Brooks[1], Taylor J. Jensen[1], Brian Caveney[3], Marcia Eisenberg[3], Eric A. Severson[1], Scott C. Wise[2], Shakti Ramkissoon[1]

[1]Oncology, Labcorp, Durham, NC,[2]Pre-Clinical Oncology, Labcorp, Ann Arbor, MI,[3]Labcorp, Burlington, NC

Background: Syngeneic mouse models serve as invaluable tools in preclinical research. Implanting cancer cells into immunocompetent mice allows immunotherapy responses to be assessed in a physiologically relevant setting. To further improve the translatability of syngeneic models, we (1) characterized the immune landscape of different syngeneic models using human-validated immune gene expression (iGEX)-based measurements of the tumor immune microenvironment and (2) investigated the feasibility and utility of using these measurements to differentiate variable responses to treatment in mice.

Methods: Our study analyzed tumor fragments from 15 models covering 10 cancers. Tumor fragments were taken from treatment naïve tumors of representative mice from each model and subjected to whole-transcriptome RNA-seq. Non-implanted cell lines from each model were also subjected to RNA-seq for comparison to tumor fragments. Data for immune-related genes were extracted and normalized to gene expression ranks for analysis. Previously validated iGEX signatures for monitoring the tumor immune microenvironment were calculated including tumor immunogenicity (TIGS), cellular proliferation (CP), and cancer testis antigen burden (CTAB) signatures. RNA-seq and tumor growth data from 1,839 mice treated with 1 of 8 treatments were paired to observe iGEX-based tumor growth differences among treatment conditions.

Results: Tumor fragments and cell lines had distinct iGEX profiles with tumor fragments being highly enriched for genes involved in immune activity. Measures of iGEX in mouse tumor fragments recapitulated values in human patient tumors, providing confidence in the translatability of our results. Various associations were detected between iGEX signatures and response to treatment, most notably TIGS and CP. When testing mouse orthologs of 64 clinically relevant immune genes, almost all were associated with variable responses to therapy in at least one treatment condition. Robust positive associations were seen for *Gm5751* (ortholog of *SSX1/2* genes in humans), where high-expressing models had slower tumor growth overall and better responses to TNF receptor-based agonists (anti-CD137, -GITR, -OX40) and anti-CTLA4.

Conclusions: We characterized the immune landscape of different syngeneic models using human-validated iGEX-based measurements. We detected variable responses to treatment in mice treated with various immunotherapies and radiation based on the high or low expression of these measurements. Our work shows that human-validated iGEX-based measurements can be implemented in syngeneic models, which enhances the translatability of syngeneic models in pre-clinical research and reiterates their important role in informing therapeutic strategies.

#5167 Development of advanced preclinical models for an in-depth characterization of cardiac angiosarcoma.

Rosalba Minelli, Luigi Perelli, Benjamin J. Bivona, Sanjana Srinivasan, Desiree Catania, Bianca E. Amador, Frederick S. Robinson, Johnathon L. Rose, Christopher J. Terranova, Parth P. Shah, Alejandro Hernandez Martinez, Charles E. Deckard, Courtney Le, Kuo-Shun Hsu, Michael Peoples, Aparna Subramaniam, Hannah C. Beird, Ningping Feng, Joseph R. Daniele, Christopher Vellano, Joseph Marszalek, Vinod Ravi, Alexander J. Lazar, Andrew Futreal, Timothy P. Heffernan, Giannicola Genovese, Virginia Giuliani

UT MD Anderson Cancer Ctr., Houston, TX

Cardiac angiosarcoma (CAS) is a rare and highly aggressive tumor that originates from the endothelial cells lining the heart's blood vessels, with the right atrium being the most common site of occurrence. There are no effective treatments, and the five-year survival rate is under 10%. The absence of reliable preclinical models has also slowed progress in understanding its biology. To address this gap, we have developed a somatic mosaic genetically engineered mouse model (smGEMM) that faithfully recapitulates angiosarcoma features, including lung dissemination. Using an endothelial-specific CRE recombinase and CRISPR/Cas9, we engineered endothelial cells to express tdTomato and spCas9, enabling tissue-specific fluorescence and targeted mutation of CAS drivers. Primary endothelial cells from the cardiac tissue of our smGEMM were isolated and transduced with specific AAV particles *in vitro* and then transplanted orthotopically via ultrasound-guided injection. Primary and metastatic tumors were extensively characterized and closely mimic the features observed in CAS patients. Additionally, cell lines derived from both primary and metastatic tumors were established and comprehensively analyzed. Whole genome and RNA-seq were performed in all CAS samples and integrated with available patient data. Copy number profiling revealed whole genome duplication and loss of heterozygosity (LOH), further highlighting the complex genetic landscape of our CAS models in tumor tissues and cell lines. The comparison between our CAS samples and patient data displayed a similar mutation profile, highlighting the relevance of our model in replicating key genetic features of human cardiac angiosarcoma. To identify novel context-specific dependencies we conducted *in vitro* genome-wide CRISPR-Cas9 screens which revealed both common and unique hits across preclinical models. Several key pathways were identified and validated using different pharmacological tools. The results revealed critical therapeutic dependencies, not only when targeted with single agents but, more significantly, when these targets were evaluated in combination. This underscores the potential for developing novel, more effective therapeutic strategies for treating this rare and aggressive disease.

#5168 Mouse models accelerating cancer research at The Jackson Laboratory.

Jason Beckwith, Jen Merriam, Darcy Pomerleau, Crystal Davis, Jennifer Kelmenson, Hiroaki Onda

The Jackson Laboratory, Bar Harbor, ME

The Jackson Laboratory (JAX) provides genetically defined mutant and transgenic mice to support the scientific research community. Available are mouse models for specific cancers, xenograft recipients, immunodeficient platforms for PDX studies and multi-purpose tool strains having CRISPR utility, conditional/inducible expression (Cre-lox, FLP-frt, Tet-On/-Off), optogenetic function and calcium-sensing technologies. This poster will highlight newly developed models designed for cancer research. The portfolio of strains useful for transplantation and humanized mouse research continues to expand and complement the NSG (NOD scid IL2rγc-/-) model as premier tools for engraftment with a wide range of malignant or non-malignant human or mouse tissues. Novel fluorescent strains include Gene Editing Reporters for visualizing homology-directed repair (HDR) and non-homologous end joining (NHEJ) repair events, as well as several CRISPR Editing, Bxb1 Integrase Editing, Base Editor, Prime Editor and DNA repair pathway tools. Furthermore, new strains enable researchers to achieve extensive barcode diversity within targeted cell populations. Models utilizing the auxin-inducible degron system allow degradation of tagged proteins following administration of 5-Ph-IAA. In addition to cryopreserving each strain, JAX employs a genetic quality control program that confirms mutation identity and genetic background, and screens for unwanted alleles (such as stray GFP, Cre, neo, etc.). Cancer researchers can query the collection of innovative mouse models using the JAX Mouse Search site (mice.jax.org). This resource includes models created by many generous donating institutions. Researchers are encouraged to donate their mouse lines via a very short Strain Submission form (jax.org/donate-a-mouse). Please also visit the JAX Oncology webpage for cancer research related strains and resources (jax.org/jax-mice-and-services/solutions-by-therapeutic-area/oncology). JAX is supported by the NIH, The Howard Hughes Medical Institute and other private charitable foundations.

#5169 Validation of genetically defined Oncopig hepatocellular carcinoma cell lines for *in vitro* evaluation of targeted therapeutic efficacy.

Mahmoud Khalafalla[1], Navin Viswakarma[1], Lobna Elkhadragy[2], Theresa K. Kelly[3], Mark Eccleston[3], Lawrence B. Schook[1], Ron C. Gaba[2], Kyle M. Schachtschneider[1]

[1]Sus Clinicals, Inc., Chicago, IL,[2]Radiology, University of Illinois at Chicago, Chicago, IL,[3]Volition Rx, San Diego, CA

Hepatocellular carcinoma (HCC) is the second leading cause of cancer related death worldwide with a 5-year survival rate of 18%. Development of novel targeted therapeutics to advance HCC precision medicine approaches is challenging due to a lack of malleable large animal HCC models that replicate human genetics, anatomy, metabolism, and physiology. We previously demonstrated our ability to develop HCC cell lines and tumors that recapitulate clinically relevant characteristics of human HCC utilizing the Oncopig cancer model (capable of forming tumors through induced $KRAS^{G12D}$ and $TP53^{R167H}$ expression). Here, we demonstrate our ability to develop Oncopig HCC cell lines with differential therapeutic susceptibilities through introduction of clinically relevant HCC driver mutations ($PTEN^{KO}$, $AXIN1^{KO}$, or $ARID1^{KO}$) via CRISPR-Cas9 gene editing. Specifically, we demonstrate that $PTEN^{KO}$ increases susceptibility to PI3K inhibitors currently in clinical trials for treatment of *PTEN* null HCC and other cancer types. Therapeutic susceptibility of the established Oncopig WT, $PTEN^{KO}$, $AXIN1^{KO}$, and $ARID1^{KO}$ HCC cell lines was assessed for PI3K inhibitors (GSK2636771, BAY 80-6946, and BKM120). Consistent with human studies, Oncopig $PTEN^{KO}$ HCC cell lines displayed significantly increased sensitivity to GSK2636771 and BAY 80-6946, but not BKM120, compared to WT and PI3K inhibitor non-responsive $AXIN1^{KO}$ and $ARID1A^{KO}$ cells (see Table). In addition, Oncopig $PTEN^{KO}$ HCC cells possessed significantly increased proliferation and migration rates compared to WT Oncopig HCC cells (1.6 and 2.8 fold, respectively; $p < 0.01$). These results validate the utility of the Oncopig HCC model for preclinical evaluation of novel targeted therapeutics *in vitro*. Future work demonstrating consistent results *in vivo* will enable the genetically defined Oncopig HCC model to be an ideal animal system to test precision medicine therapeutics prior to entry into the clinic.

Therapeutic Susceptibility (Log IC50 (μM))

PI3K Inhibitor	Oncopig WT HCC	Oncopig $AXIN1^{KO}$ HCC	Oncopig $ARID1^{KO}$ HCC	Oncopig $PTEN^{KO}$ HCC	Human *PTEN* Null Cells
GSK2636771	1.46	1.17	0.66	0.07	Responsive
BAY80-6946	11.5	5.6	4.5	2.38	Responsive
BKM120	2.05	0.95	NA	2.3	Non-Responsive

#5170 A xenograft mouse model of virus-positive Merkel cell carcinoma directly links germ cell theory to somatic cancer.

Sara Contente, Sarah Rahman, **Wendy Yang**

USUHS - Uniformed Services University of the Health Sciences, Bethesda, MD

While mutation theory has dominated the somatic cancer arena for decades, germ cell theory has been the necessary alternative for germ cell tumors (GCTs) with their unique (epi)genomic profiles. However, all cancers are unified by a set of hallmarks and the paradigm division between somatic versus GCTs has been challenged by accumulating paradoxes. Merkel cell polyomavirus (McPyv) positive Merkel cell carcinoma (MCC), a very rare and highly malignant skin cancer, is one such striking paradox contradicting the cancer mutation theory. MCC is a small cell neuroendocrine carcinoma (SCNC) with 80% containing McPyv, a tiny ubiquitous DNA virus of normal skin flora. In common with GCTs, virus-positive (VP)-MCC exhibits striking genomic stability in dichotomy to its virus-negative counterparts and other SCNCs. Intriguingly, the SCNC phenotype is also the pan-cancer convergent end state of tumor progression/dedifferentiation, implicating closeness to somatic cancer stem cells. It is thus rational to hypothesize VP-MCC being an extra-gonadal GCT with oncovirus driven malignant somatic transformation (MST) in an adult cutaneous niche. GCT research has supported human primordial germ cells (hPGCs) being the cell of origin for GCTs. hPGCs are considered unipotent that cannot form teratomas in adult mice but are readily converted in vitro to pluripotent human embryonic germ cells (hEGCs) that can form teratomas in adult mice, like pluripotent human ESCs (hESCs) or human iPSCs (hiPSCs) which may rarely spontaneously differentiate to hPGCs in vitro. To validate our hypothesis, we performed a mouse study by injecting hPGC-like cells (hPGCLCs) with or without McPyv transfection to NSG mouse flank skin, as well as McPyv transfected hiPSCs and hEGC-like cells (hEGCLCs). We then monitored tumor formation and growth over 4 months. All tumors were analyzed for histology and gene/protein expression by H&E, immunohistochemistry, flow cytometry and/or RT-qPCR. 2 out of 3 mice injected by McPyv transfected hPGCLCs exhibited MST to typical MCC-like tumors from a background of teratoma. All mice injected with McPyv transfected hiPSCs or hEGCLCs formed teratomas as expected, but only tumors derived from very high number hiPSC injections showed MST to atypical MCC-like tumors. Our findings thus demonstrated McPyv transfection enabled MST to MCC-like tumors from hPGCLCs and high dose hESCs. Per literature search, this is the first MST model to directly link germ cell theory to somatic cancer, with its simplicity to enable easy tractability of molecular events.

#5172 Advanced models of breast cancer brain metastasis and imaging protocols for preclinical efficacy studies.

Sigrid Cold[1], Maria Z. Alfsen[2], Mark U. Juul[2], Camilla Malec[2], Camilla Christensen[3], Michael J. Wick[4], Lene Jessen[2], Trine B. Engel[2], Lotte K. Kristensen[2], Andreas Kjaer[1], **Carsten H. Nielsen**[2]

[1]Cluster for Molecular Imaging; Department of Biomedical Sciences, Copenhagen University Hospital - Rigshospitalet; University of Copenhagen; and Minerva Imaging ApS, Copenhagen, Denmark,[2]Minerva Imaging ApS, Oelstykke, Denmark,[3]Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital - Rigshospitalet; Minerva Imaging ApS, Copenhagen, Denmark,[4]XenoStart, San Antonio, TX

Introduction: Approximately 30% of breast cancer (BC) patients eventually develop metastases in distant organs and especially breast cancer brain metastases (BCBM) are associated with poor prognosis and high mortality. Translatable animal models mimicking and predicting clinical disease and outcomes are urgently needed to increase the success of novel anti-cancer therapies. In this study, we generated advanced orthotopic BCBM models established by three different inoculation methods. Furthermore, we optimized imaging protocols to monitor tumor growth, BBB permeability and efficacy in preclinical studies.

Methods: BCBM was established by stereotactic inoculation of human BC cells lines (BT474 and MDA-MB-231.Luc2) and cells isolated from patient derived xenografts (PDX) (ST1339, ST3338, ST941, ST340, ST1616B and ST1360B). To mimic metastatic spread, BCBM was also established by intracardial (ICar) and intracarotid (ICt) inoculation (BT474 and MDA-MB-231.Luc2). Metastatic spread and tumor growth were monitored using T2-weigthed MRI and bioluminescence imaging while BBB permeability was evaluated *in vivo* by Gd-contrasted MRI. Transport of HER2 targeting trastuzumab across the BBB was confirmed by PET/MRI, resulting in a subsequent study evaluating efficacy of Trastuzumab emtansine (T-DM1) (ST1339 and ST3338). IHC and light sheet microscopy (LSM) were performed to validate *in vivo* findings of tumor characteristics including metastatic spread and BBB permeability.

Results: BCBM were successfully established by stereotactic inoculation with high tumor take rates (>80%) and consistent tumor location and number (n=1 per animal). The BCBM presented with varying brain infiltration profiles and BBB permeability. ^{64}Cu-trastuzumab uptake in animals bearing ST1339 tumors (HER2 3+) confirmed delivery across the BBB. Animals treated with T-DM1 experienced tumor growth delay with ST1339 having the greatest response. ICar inoculation gave rise to metastatic spread, but <25% of animals inoculated developed BCBM prompting the need for a more targeted delivery of BC cells to the brain. ICt inoculation resulted exclusively in the formation of BCBM with a take rate of >65%. MRI imaging revealed 1-7 metastases per animal with intrasubject and intersubject variation in BBB permeability. *Ex vivo* analysis validated the *in vivo* imaging of metastases and showed multiple metastases of varying sizes and BBB permeability.

Conclusion: We've successfully developed multiple complex orthotopic models for BCBM mimicking different aspects of BCBM. ICar and ICt models especially resemble the pathophysiology of BCBM to a large extent with extravasation and micro seeding in the brain. Together with the developed imaging protocols allowing longitudinal evaluation of compound delivery, tumor growth and BBB permeability this serves as a great platform for preclinical studies with novel anti-cancer agents.

#5173 Heterozygous *Ppp2r1a* mutations with concurrent loss of Tp53 drive invasive high-grade uterine cancer.

Caitlin M. O'Connor[1], Kelsey Barrie[1], Kaitlin Zawacki[1], Ingrid L. Bergin[2], Gabrielle Hodges Onishi[1], Analisa DiFeo[3], Kathleen Cho[3], Thom Saunders[1], Goutham Narla[1]

[1]Internal Medicine: Genetic Medicine, University of Michigan, Ann Arbor, MI,[2]In Vivo Animal Core Facility, University of Michigan, Ann Arbor, MI,[3]Pathology, University of Michigan, Ann Arbor, MI

Uterine cancer is the only cancer type for which survival has fallen in the past four decades. This year in the United States, over 13,000 women will die from this disease, surpassing ovarian cancer for the first time: making uterine cancer the deadliest gynecological cancer. Mortality from uterine cancer is primarily due to the aggressive, non-endometrioid subtypes of the disease which include uterine serous carcinomas and uterine carcinosarcomas (high-grade subtypes). Molecularly, high-grade uterine tumors harbor few mutations, however, almost every high-grade uterine tumor harbors a *Tp53* mutation, and 30-40% of tumors also harbor a heterozygous *PPP2R1A* mutation, most commonly - P179R, S256F, or R183W. PPP2R1A encodes for the Aα scaffolding subunit of the heterotrimeric protein phosphatase 2A (PP2A). Previous literature from our group and others has shown that these mutations occur very early in uterine cancer development and that these mutations modulate PP2A function in a manner that impairs the formation of tumor-suppressive PP2A holoenzymes. However, a lack of models, particularly transgenic mouse models, of high-grade uterine cancers has limited our understanding of the disease as well as the preclinical testing of targeted therapeutics to the underlying drivers of disease development and progression. Knockout of p53 in mouse uterine epithelium has been shown to result in the formation of uterine tumors (uterine serous and carcinosarcomas) at 16-20 months of age. Our group has generated novel conditional Ppp2r1a-P179R and R183W knock-in mice. Because these mutations exclusively co-occur with Tp53 alterations, we crossed these mice to the $Tp53^{fl/fl}$ and Ksp1.3-Cre mouse to generate uterine epithelium-specific knockout of Tp53 and knock-in of either Aα-P179R or R183W PP2A mutant alleles. Our preliminary data demonstrate that these mice develop advanced high-grade uterine cancers as early as 6 months, compared to 16 months with Tp53 KO alone, showing that *PPP2R1A* mutations significantly accelerate uterine tumor formation. Pathological analysis of these tumors has shown that they are high-grade and resemble high-grade uterine tumors in humans. Combined, our data definitively show that *PPP2R1A* mutations are drivers of high-grade uterine cancers for the first time and provide a novel mouse model of high-grade uterine cancer that can be used to develop a better understanding of this deadly cancer.

#5174 Exploring extinction therapy for advanced cutaneous squamous cell carcinoma using UV-induced mouse models.

Karol M. Prieto-Sarmiento[1], Stanislav Avdieiev[1], Omar Chavez Chiang[1], Sofia Cordero[1], Irmak Aksit[1], Derek Weimer[2], Christopher J. Whelan[1], Joel S. Brown[1], Kenneth Y. Tsai[1]

[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]Nova Southeastern University, Davie, FL

Advanced cutaneous squamous cell carcinoma (cuSCC) remains a major therapeutic challenge, with an estimated 50.000 cases annually in the United States. While anti-PD1 immunotherapy—the only FDA-approved therapy—yields response rates of approximately 50%, responses to chemotherapy and radiotherapy are typically transient, and no comprehensive strategy for immunotherapy-refractory disease exists. We developed a novel K14-CreERT2 Confetti mouse model to investigate cuSCC progression, from UV-induced mutagenesis to invasive tumors. This model enables lineage tracing of keratinocytes and their progeny through fluorescent labeling, allowing precise monitoring of tumor evolution. Using this platform, we conducted a preclinical study across multiple tumor development stages to compare continuous therapy with extinction therapy—a novel first-strike-second-strike approach hypothesized to exploit vulnerabilities in fragmented cancer populations. Fifty-four mice were exposed to UV radiation on one side of their backs to induce mutagenesis, mimicking human cuSCC progression. The animals were divided into early-stage (tumors ~3mm) and late-stage (tumors ~6mm) cohorts based on tumor size at enrollment. Mice were assigned to either continuous or extinction therapy regimens, receiving combinations of anti-PD1 immunotherapy and the MEK inhibitor trametinib. Continuous therapy involved initial treatment with either immunotherapy or targeted therapy until the tumor grew 20% larger than its enrollment size. Then, the therapy switched to the alternate modality and continued until the endpoint (tumors >10mm). Extinction therapy began with either targeted therapy or immunotherapy, with treatments alternating under specific conditions: when tumors failed to respond after two weeks or when a different tumor exceeded the initial tumor's enrollment size. This adaptive strategy aimed to enhance efficacy by targeting dynamic tumor vulnerabilities. UV-irradiated versus non-irradiated skin was monitored through confocal microscopy for eight months post-irradiation to evaluate resistance evolution and underlying cellular and clonal changes. As observed previously, tumors only developed on UV-irradiated skin, with significant variability in tumor numbers (3-25 per animal). Tumor burden was assessed twice weekly to evaluate therapy efficacy. Preliminary results suggest that extinction therapy significantly reduced tumor burden and delayed resistance compared to continuous treatment, particularly in advanced disease stages. We provide valuable insights into therapeutic strategies for cuSCC management with our approximation of treatment regimen combinations and their efficacy across distinct tumor progression stages.

#5175 Investigating the cooperative effects of the *BRAF* oncogene and inflammation in *BRAF*-mutant CRC development.

Caleb Green[1], Catherine Andreadi[1], Emma Parrott[1], Hong Cai[1], Karen Brown[1], Abdolrahman Shams-Nateri[2], Alessandro Rufini[3]

[1]University of Leicester, Leicester, United Kingdom,[2]Biodiscovery Institute, University of Nottingham, Nottingham, United Kingdom,[3]Universita degli Studi di Milano, Milan, Italy

Colorectal cancer (CRC) currently represents the third most commonly diagnosed cancer worldwide, with its tumorigenesis associated with multiple risk factors, including the presence of inflammation. However, the pro-tumorigenic mechanisms of inflammation remain ill-defined, with poor understanding of the roles of individual inflammatory pathways. Mutations in the *BRAF* oncogene drive a CRC subtype with serrated histology, typically co-occurring with high levels of microsatellite instability. Unpublished gene set enrichment analysis revealed increased inflammatory signaling in human serrated colonic lesions from publicly available human transcriptomic data. Paradoxically, in-house RNA-sequencing analysis from mice harboring an inducible oncogenic mutation in *Braf* showed repression of inflammatory pathways in intestinal tissue. In addition, *in vivo*, *Braf* mutant mice exhibit long latency and low frequency of tumor formation, which may be due to repressed inflammatory signaling following $Braf^{V600E}$ induction. Our work aims to further investigate the impact of the *Braf* oncogene on specific inflammatory pathways through analysis of phosphorylated (p)STAT1 and (p)STAT3 expression, biomarkers for IFN-γ and IL6/JAK/STAT pathways respectively. This will be assessed by western blot using an *in vitro* mouse intestinal organoid (MIO) model, and through multiplex immunofluorescence (mIF) on *in vivo* murine intestinal tissue slides. To elucidate whether *Braf* mutations employ cell autonomous mechanisms to alter inflammatory signaling, inducible *Braf* mutant intestinal crypts were isolated and grown *in vitro* to form MIOs before treatment with IFN-γ. Western blotting of MIO lysates revealed unchanged phosphorylation status of STAT1 and STAT3 irrespective of Braf mutational status in our experimental conditions. Additionally, mIF revealed the expression and localization of phosphorylated STAT1/STAT3 in intestinal tissue were comparable in wildtype control and $Braf^{V600E}$ mice, 3 days and 6 weeks after induction of the mutant oncogene (n=9). However, in mice expressing $Braf^{V600E}$ for 6 months, there was significantly restrained signaling for both pSTAT1 ($p<0.05$) and pSTAT3 ($p<0.05$) in the mutant compared to the wildtype control animals (n=4). Overall, our data indicate temporal control of inflammatory signaling by the $Braf^{V600E}$ oncogene *in vivo*. With short term Braf induction leaving IFN-γ and IL-6 signaling unperturbed, assessed through pSTAT1/3, whereas mice with prolonged *Braf* expression showed modulation of both IFN-γ and IL6/JAK/STAT pathways. Further investigation is required into the repression of inflammation induced by the *Braf* oncogene, and whether subsequent restoration of inflammatory signaling would lead to increased potency in tumor formation. Knowledge of these mechanisms could prove crucial in understanding the development of human BRAF-mutant CRCs.

#5176 NaJa cells - the first syngeneic cell line model to study BRAF^{V600E}-driven colorectal cancer.

Jasmin Traichel[1], Ariane Lehmann[2], Nadine Wohlfeil[3], Ricarda Griffin[3], Maria Walz[3], Reinhild Feuerstein[4], Celia Asdih[3], Rebecca Kesselring[4], Melanie Boerries[2], Tilman Brummer[3]

[1]Institute for Molecular Medicine and Cell Research, University of Freiburg, German Consortium for Translational Cancer Research DKTK, Freiburg, Germany,[2]Institute of Medical Bioinformatics and Systems Medicine (IBSM), Medical Center University of Freiburg, Freiburg, Germany,[3]Institute for Molecular Medicine and Cell Research, University of Freiburg, Freiburg, Germany,[4]Department of General and Visceral Surgery, University of Freiburg, Freiburg, Germany

Background: Due to the lack of suitable syngeneic murine models to study malignant BRAF^{V600E}-driven colorectal cancers (CRC), the aim of this study was to establish new murine models that recapitulate this aggressive CRC subtype both *in vitro* and *in vivo* in an immunocompetent syngeneic context.

Methods: A murine colonic organoid model with VillinCreER^{T2}-inducible BRAF^{V600E}, TRP53^{R172H} and APC$^{\Delta}$ mutations (designated BPAC) was generated. Orthotopic transplantations with BPAC organoids resulted in tumor growth and spontaneous metastasis into the peritoneal cavity of immunocompetent syngeneic C57/Bl6 recipient mice. Through subsequent peritoneal lavages, three new murine cell lines (NaJa-D, NaJa-F and NaJa-G) originating from the same mutational background were established. These cell lines were thoroughly characterized by RNA- and whole exome sequencing. Furthermore, their response to kinase inhibitors was tested and validated by colony formation assays and Western blotting. To test their invasive potential *in vivo*, the NaJa cells were injected via the portal vein into immunocompetent syngeneic mice and the tumor microenvironment was subsequently analyzed by immunohistochemistry (IHC).

Results: The three established NaJa cell lines all expressed the aforementioned driver mutations and microsatellite stability was confirmed through whole exome sequencing. They differed greatly in their morphology despite the common genetic background, with NaJa-D displaying an epithelial morphology, NaJa-G adopting a mesenchymal phenotype and NaJa-F presenting an intermediate phenotype. Furthermore, they exhibited differential responses to treatment with clinically relevant kinase inhibitors, resulting in differentially altered signaling pathways and overall survival. Upon re-transplantation via the portal vein into immunocompetent syngeneic mice, all three NaJa cell lines induced fast and aggressive tumor growth in the liver while retaining their distinct morphological characteristics, and promoted metastasis, particularly to the peritoneal cavity and surrounding tissues. The tumor microenvironment was analyzed in terms of immune cell composition and distribution, revealing notable differences between the cell lines. These findings establish the NaJa cell-induced tumor model as a valuable tool for exploring the combinatory use of targeted therapies with immune checkpoint inhibition in future studies.

Conclusion: Given the general lack of murine cell lines to model BRAF^{V600E}-driven CRC, the NaJa cells provide a unique and valuable tool to research cancer heterogeneity, test clinically relevant kinase inhibitors and research the immune cell environment and immune escape of BRAF^{V600E}-driven metastatic CRC.

#5177 Modeling 6q deletion and MYD88^{L265P}-driven B-cell lymphomas in mice reveals early lymphomagenesis mechanisms and identifies the putative cell of origin.

Filip Garbicz[1], Johany Penailillo[1], Senthilkumar Muthiah[2], Fernanda Cuevas[1], Tuyet Nguyen[1], Elisa Mandato[3], Eleonora Calabretta[3], Tomasz Sewastianik[1], Elena Ivanova[4], Aisha Saldanha[4], Moataz Noureddine[4], Rafael Irizarry[2], Margaret A. Shipp[3], Zachary Hunter[5], Steven P. Treon[5], Ruben D. Carrasco[1]

[1]Department of Pathology, Dana-Farber Cancer Institute, Boston, MA,[2]Department of Data Science, Dana-Farber Cancer Institute, Boston, MA,[3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Belfer Center for Applied Cancer Science, Dana-Farber Cancer Institute, Boston, MA,[5]Bing Center for Waldenstrom's Macroglobulinemia, Dana-Farber Cancer Institute, Boston, MA

Chromosomal aberrations often represent early events in cancer development and might play a critical role in establishing malignant clones. Large chromosomal deletions typically involve the loss of multiple cooperating tumor suppressor genes, which makes it challenging to study their contribution to cancer pathogenesis. Recent genomic studies have identified the MYD88^{L265P} mutation and chromosome 6q deletion as frequent alterations in Waldenstrom's macroglobulinemia (WM)/lymphoplasmacytic lymphoma (LPL). These genetic abnormalities are considered to be key drivers of oncogenic NF-κB signaling and are also observed in diffuse large B-cell lymphoma (DLBCL). Previous studies, including our own, have demonstrated that neither human MYD88^{L265P} nor murine Myd88^{L252P} mutations alone are sufficient to induce neoplastic transformation in mouse models. Chr6q deletion, containing multiple genes involved in B cell biology, might constitute a critical "second hit" necessary for sustaining MYD88^{L265P}-induced signaling. This study aimed to elucidate the roles of MYD88^{L265P} and Chr6q (syntenic to murine Chr10q) deletion in B-cell lymphoma pathogenesis. We generated the following genetically engineered mouse models: *Myd88$^{L252P/+}$;Cd19$^{Cre/+}$*, *10q$^{+/-}$;Cd19$^{Cre/+}$* and *Myd88$^{L252P/+}$;10q$^{+/-}$;Cd19$^{Cre/+}$*. We have observed spontaneous development of low- and high-grade B cell lymphomas in aged cohorts of *10q$^{+/-}$;Cd19$^{Cre/+}$* and *Myd88$^{L252P/+}$;10q$^{+/-}$;Cd19$^{Cre/+}$* mice. Pathological analysis showed an expansion of lymphoplasmacytic B220^{-} SOX5+ PAX5+ IgM+ B cells, which infiltrated the bone marrow, spleen and lymph nodes. To investigate the progression of B-cell changes during premalignant and malignant stages, we performed scRNA-seq on murine lymphoid organ samples. There was an early clonal expansion of B1 and memory B cells, potentially representing lymphoma precursor cells. Later on, these populations were replaced by larger cells frequently positive for Ki67, IRF4, and IgM, suggesting a transition from a low-grade WM-like disease to a high-grade DLBCL. Both early- and late-stage lymphomas exhibited elevated expression of therapeutic targets, including *Bcl2*, *Ms4a1*, *Btk* and *Hck*, offering potential avenues for intervention and therapy response studies. Additionally, profound alterations were observed in the T-cell compartment, with an increased frequency of PD1^{+} LAG3^{+} TIM3^{+} cells, suggesting immunotherapy targets that merit further validation. The mouse models provide valuable platforms for investigating the mechanistic roles of these genetic alterations and testing therapeutic strategies. In the future, we plan to validate the models as preclinical tools for studying MYD88 and Chr6q deletion-driven lymphomagenesis. This project was supported by the Robert A. Kyle Career Development Award from the IWMF and NIH grant R01CA273123.

#5178 Ascites conditioning reduces latency in vivo for progression of ID8 TP53 KO murine ovarian cancer model.

Taylor Barnhisel, Zari Dehdashti, Stephen Kron

Ludwig Center for Metastasis Research and Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL

High-grade serous ovarian carcinoma (HGSOC), an aggressive subtype of epithelial ovarian cancer (EOC) characterized by peritoneal metastasis at diagnosis and poor prognosis, is almost universally associated with p53 mutations. Mouse models of EOC and particularly HGSOC remain unsatisfactory for therapy development. Underscoring its low-grade behavior, intraperitoneal injection of the C57BL/6-derived EOC cell line ID8 from tissue culture is followed by a 9-to-10-week latency before onset of peritoneal carcinomatosis, associated with development of ascites and abdominal distention. Toward overcoming limitations of ID8 cells as a mouse model for HGSOC, Walton et al. (2018) performed CRISPR/Cas9-mediated knockout and isolated the F3 Trp53-/- cell line. While the latency period was reduced upon Trp53 deletion, 5-to-6-weeks may pass before ascites can be observed after injection of plastic-grown F3 cells. Prior studies have ascribed the delay to a dearth of cancer stem cells and/or a low propensity for colonizing the omentum. Indeed, ID8 cells isolated after 11 or 12 weeks from ascites fluid were found to be enriched for stem cells and to display immediate omental colonization and ascites onset. We confirmed that transplanting even small volumes of F3 ascites fluid into naive mice led to rapid carcinomatosis and ascites. Strikingly, passaging F3 ascites cells in tissue culture did not restore latency. These observations suggested that ascites-derived Trp53-/- ID8 cells might provide superior HGSOC models. To form an ascites-conditioned F3 cell line, CF3, plastic-grown F3 cells were injected into a C57BL/6 mouse, allowed to progress to carcinomatosis and ascites, and the ascites cells isolated and passaged four to six times. Within 14 days after being injected with CF3 cells, mice display ascites. Examining the viscera reveals visible tumors studding the abdominal mesentery and omentum. At this timepoint, mice injected with F3 display no visible signs of engraftment. CF3-injected mice reach a humane endpoint within approximately 30 days, compared to about 54 days for F3. Underlining the primary effect of ascites conditioning as reduced latency, CF3 and F3 mice display similar ascites volume, size, and distribution of metastases at their endpoints. Despite the rapid onset of carcinomatosis, CF3 cells maintain similar sensitivity to carboplatin in vivo. We suggest that ascites-conditioned cells provide a rapid and robust preclinical HGSOC model that may streamline experimental timelines and facilitate evaluation of immune and other therapies. Supported by Roswell Park-University of Chicago Ovarian Cancer SPORE P50 CA159981 and the University of Chicago Medicine Comprehensive Cancer Center.

#5179 Investigating the tumor suppressive role of RanBP9 in mice deficient in p53.

Brianna Gonga-Cave[1], Gabriel Onea[1], Xu Wang[2], Sean Cregan[3], Patti Kaiser[4], Caroline Schild-Poulter[1]

[1]Biochemistry, Western University, London, ON, Canada,[2]Robarts Research Institute, Western University, London, ON, Canada,[3]Physiology and Pharmacology, Western University, London, ON, Canada,[4]Pathology and Laboratory Medicine, Western University, London, ON, Canada

RAN binding protein 9 (RanBP9) is a scaffolding protein that is essential for the formation a multi-subunit E3 ubiquitin ligase termed the C-terminal to Lis-1 homology (CTLH) complex. Multiple groups have identified the CTLH complex in regulating a broad range of biological processes including cell cycle, cell proliferation, and metabolism. Various studies have demonstrated that RanBP9 functions as a tumor suppressor, but none have shown whether the loss of RanBP9 can initiate spontaneous tumor formation. Here, we investigated the tumor suppressive role of RanBP9 in C57BL/6 mice. Bulk RNA sequencing (RNA-seq) analysis of 1-month-old *RanBP9*$^{-/-}$ mice liver identified an upregulation of several oncogenic signaling genes. Although *RanBP9*$^{-/-}$ mice displayed a shortened lifespan, these mice did not develop spontaneous tumors suggesting that additional genetic perturbations are required for tumor development. Next, we conducted an observational study in mice with *RanBP9*$^{+/-}$*: Trp53*$^{+/-}$ (*R9; p53*$^{+/-}$) and *RanBP9*$^{-/-}$*: Trp53*$^{-/-}$ (*R9; p53*$^{-/-}$) genotypes. These mice were monitored over 17 months for the development of spontaneous tumors. The primary endpoint was defined as the development of a visible mass (>1.5 cm) or symptoms of cancer. *R9; p53*$^{+/-}$ mice (n=23) developed sarcomas at an earlier time compared to control *p53*$^{+/-}$ mice (n=18; $p<0.05$). *R9; p53*$^{+/-}$ mice displayed altered tumor spectrum with increased frequency in soft tissue sarcoma (STS) development. H&E analysis of tumor biopsies revealed increased mitotic activity of sarcomas derived from *R9; p53*$^{+/-}$ mice compared to control *p53*$^{+/-}$ mice. We observed no significant difference in tumor incidence and altered tumor spectrum in *R9; p53*$^{-/-}$ mice compared to control *p53*$^{-/-}$ mice. Analysis of TCGA sarcoma database revealed a correlation between low gene expression of CTLH complex genes and reduced survival in sarcoma patients. Our data indicates that loss of RanBP9 alone is insufficient to initiate tumor development. However, the heterozygous loss of RanBP9 and p53 promotes increased STS development. Ongoing efforts are to further characterize *R9; p53*$^{+/-}$ tumors and identify the mechanism to understand how the loss of CTLH activity contributes to sarcoma development in the absence of p53. Our findings may support the development of anti-cancer therapeutics that activates RanBP9-CTLH complex activity.

#5180 CXCR7 mediates an immune-suppressive tumor microenvironment and promotes prostate cancer progression.

Hongshun Shi[1], Ziqi Zhang[2], Lourdes Brea[3], Zhuoyuan Lin[3], Viriya Keo[3], Sambhavi Senthil[1], BaoHan Thi Vo[1], Galina Gritsina[3], Xiaojun Kong[1], Jonathan Zhao[4], Haydn Thomas Kissick[1], Xiuwei Zhang[2], Jindan Yu[1]

[1]Department of Urology, School of Medicine, Emory University, Atlanta, GA,[2]School of Computational Science and Engineering, College of Medicine, Georgia Institute of Technology, Atlanta, GA,[3]Division of Hematology/Oncology, Department of Medicine, Northwestern University, Chicago, IL,[4]Department of Human Genetics, School of Medicine, Emory University, Atlanta, GA

Background: Genetic inactivation of Pten and/or TP53 are common in human cancers including advanced prostate cancer (PCa). We previously reported CXCR7 up-regulation in castration resistant prostate cancer (CRPC), following androgen-receptor-targeted therapies. However, how CXCR7 regulates PCa and the tumor immune microenvironment (TIME) is poorly understood.
Methods: We generated PbCre:Pten/TP53/Cxcr7 (TKO) mice, which were compared to the PbCre:Pten/TP53 (DKO) mice. We performed histology analyses of the mice aged from 12 to 24 weeks and utilized scRNA-seq to analyze prostate samples collected from transgenic mice of 12- and 18-week age. Multiplexed error-robust fluorescence in situ hybridization (MERFISH) platform was used to further confirm our results and demonstrate a spatial relationship. In addition, Cy-Tek and FACS analysis were employed to explore the tumor microenvironment focusing on immune cells. We then analyzed publicly available human PCa datasets to explore the correlation of CXCR7 with immune cell subsets using CIBERSORT.
Results: Prostate-specific deletion of Cxcr7 in the Pten/TP53-DKO mice resulted in significant delay in prostate tumor progression. We found differential enriched lymphoid cluster and decreased Spink1+ luminal and Tff3+ luminal clusters after Cxcr7 knockout. Cxcr7 deletion was associated with profound TIME remodeling characterized by increased CD8+ T cells and reduced Gr-1+CD11b+ myeloid-derived suppressor cells (MDSC). In addition, Cxcr7 knockout facilitated the invasion of CD4+ and CD8+ T cells into the tumors, while these immune cells were mainly located in the stroma of the prostates of the DKO mice. TKO mouse also exhibited enhanced cell-cell interactions with PCa, compared to the DKO mouse, characterized by a decrease of IL6 signaling and an increase of IFN-II and MHC-I signaling. Critically, examination of human PCa datasets confirmed that high levels of CXCR7 were indeed correlated with lower CD8+ T cell infiltration in the tumors.
Conclusion: Cxcr7 deletion delayed prostate cancer progression caused by Pten/TP53 loss. Combining scRNA-seq with a spatial framework of gene expression analyses of transgenic mouse models, we demonstrated a critical role of CXCR7 in remodeling the tumor microenvironment. Our result indicates CXCR7 as a promising therapeutic target for Pten/TP53-deficient prostate cancer.

#5181 SPTBN1$^{D1089Y/+}$ aggravates liver carcinogenesis via activating SIRT6 and TGF-beta signaling.

Kazufumi Ohshiro, Xiyan Xiang, Xiaochun Yang, Krishanu Bhowmick, Lopa Mishra

The Feinstein Institute for Medical Research, Manhasset, NY

Background: Obese-driven liver cancer (HCC) is alarmingly rising in the US. Yet, key signaling mechanisms underlying this obesity-driven HCC remain unclear. SIRT6 is a NAD^+-dependent deacetylase that limits the activity of the lipogenic transcription factors SREBP1/2 and TGF-β signaling. Reduced SIRT6 is associated with human fatty liver and HCC. We found that TGF-β/SMAD3 signaling pathway and SREBP1/2 are modulated by βII-spectrin (encoded by *SPTBN1*), and a mutation in human HCC, D1089Y abrogates SMAD3 binding (*Gastro 2018; 154:195-210*). In stressed hepatocytes, βII-spectrin promotes lipogenesis through interactions between Caspase-3-cleaved forms of both SREBP1 and βII-spectrin *(Sci TM 2021;13:624)*. Liver-specific knockout of βII-spectrin blocks fatty liver and HCC. Here, we examined the extent of SPTBN1-D1089Y regulation of SIRT6 expression through SMAD3, and the combined roles of SIRT6 and SPTBN1 in human HCC.

Methods: We generated a SPTBN1-D1089Y mutant mouse and examined SIRT6 expression in liver tissues and MEFs. Four-month-old Sptbn1$^{D1089Y/+}$ mutant and WT male mice were injected with DEN/CCI4 and fed on WD.TGF-β/SMAD3 pathway activity was analyzed by Western blotting and RNA-seq. SIRT6 expression was examined in mouse MASLD/MASH. Structure-based molecular docking simulations using structural coordinates of human SIRT6 and SPTBN1 from the AlphaFold database.

Results: SIRT6 expression is significantly decreased in liver macrophages from mice with MASLD/MASH. Sptbn1$^{D1089Y/+}$ mice receiving DEN/CCI4 plus WD displayed significantly more tumor nodules with severe liver injury, steatosis, and inflammation. TGF-β/SMAD3 pathway activity is suppressed in SPTBN1-D1089Y mutant MEFs with decreased phosphor-SMAD3 levels. SIRT6 levels are decreased in Huh7 cells overexpressing SPTBN1-D1089Y and the D1089Y-mutant mouse liver tissues. Structural modeling predicts that SIRT6 binding sites of SPTBN1 (R429-S439) are close to the region mediating SREBP1/SPTBN1 interaction. In HepG2 cells, overexpression of SIRT6 deacetylates βII-spectrin; SMAD3 and βII-spectrin were found to interact with SIRT6 upon TGF-β treatment by co-immunoprecipitation; SIRT6 knockdown increased nSREBP1, SCD1, and βII-spectrin. SPTBN1-WT overexpression increased slightly HCC cell viability, whereas SPTBN1-D1089Y mutant increased approximately more than two times of the WT viability. Exogenous SPTBN1-WT increased the expression of transcriptional repressor CTCF and SIRT6, and SPTBN1-D1089Y mutant decreased both expressions.

Conclusions: Our study indicates a SMAD3 dependent as well as a SMAD3 independent role of SPTBN1 in regulating SIRT6. Sptbn1-D1089Y heterozygous loss aggravates liver carcinogenesis. Sptbn1-D1089Y together with SIRT6 deficiency may increase the susceptibility to MASH/HCC.

#5182 Transcriptomic analysis of mouse models of lung adenocarcinoma with different metastatic phenotypes.

Naomi Mitchell-Hutchinson[1], Paige Ramkissoon[2], Julie Wells[1], Rick Maser[1], Tim Stodola[1], Brian Hoffman[1], Anne Marchini[1], Elaine Bechtel[1], Rosalinda Doty[1], Carol Bult[1]

[1]The Jackson Laboratory, Bar Harbor, ME,[2]Cincinnati Children's Hospital, Cincinnati, OH

Introduction: Lung cancer is the leading cause of cancer deaths worldwide with most deaths attributed to metastatic disease. Existing mouse models of lung adenocarcinoma (LUAD) rarely become metastatic, limiting their usefulness for basic and pre-clinical research aimed at identifying mechanisms of metastatic disease. We have developed two novel mouse models of LUAD, KPDT-1 and KPDT-2, that feature cell type-specific inducible oncogenic $Kras^{G12D}$, loss of *Trp53* function, and deleted/truncated *Dicer1*. The survival times, rate of tumor progression, and metastatic phenotypes of these models depend on the cell types that harbor the genetic alterations. We performed transcriptomics (mRNA and microRNA) to investigate the molecular and cellular drivers underlying the observed differences in the models.

Methods and Results: KPDT-1 and KPDT-2 models were generated by adding mutations in *Dicer1*, an RNAse III enzyme within the microRNA (miRNA) biosynthesis pathway, to a mouse model of *Kras*-driven LUAD. For KPDT-1, tumorigenesis was induced by conditional expression of an oncogenic $Kras^{G12D}$ allele, deletion of both alleles of *Trp53* and deletion of one allele of *Dicer1* in club cells and the expression of a truncated *Dicer1* allele in alveolar type II (ATII) cells. In KPDT-2 animals, the cell types were reversed. We observed decreased survival, accelerated tumor progression, and enhanced lymph node metastasis only in KPDT-1 animals. Induction of tumorigenesis in ATII cells and truncation of *Dicer1* in club cells (KPDT-2) did not accelerate tumor progression. Differential expression analysis using DESeq2 revealed 206 differentially expressed genes and 45 differentially expressed microRNAs between the two models. Term enrichment analyses showed that genes upregulated in KPDT-1 animals are associated with microtubule movement and organization. The upregulated genes of KPDT-2 animals are enriched in functions related to metabolism. Six microRNAs were upregulated in the KPDT-1 model. These miRNAs were reported previously as being differentially expressed in other cancers, and 4 of them (miR-92a-3p, miR-542-5p, miR-449a-5p, and miR-296-5p) have been linked previously to metastasis.

Conclusions: Through cell type-specific truncation/deletion of *Dicer1*, we have generated a new mouse model that rapidly develops *Kras/Trp53*-driven LUAD and metastatic disease. Our findings suggest that tumorigenesis and metastasis are influenced by miRNA-mediated communication between different cell types. Further investigation into the pathways involved in these models will give more insight into miRNA-mediated tumorigenesis and the underlying mechanisms of metastasis. We will continue to develop these models to support investigation of molecular mechanisms underlying metastasis.

TUMOR BIOLOGY: Organoids
Poster Session

#5187 Characterization and prediction of drug responses in NF1 patient-derived tumor organoids through multiplex phenotypic profiling.

Alberto Mendoza-Valderrey[1], Huyen T. L. Nguyen[1], Jenna Tomkinson[2], Cameron Mattson[2], Michael J. Lippincott[2], Summer Swearingen[1], Sara Gosline[3], Gregory P. Way[2], Alice Soragni[1]

[1]Department of Orthopaedic Surgery, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA,[2]Department of Biomedical Informatics, University of Colorado School of Medicine, Aurora, CO,[3]Earth and Biological Sciences Directorate, Pacific Northwest National Laboratory, Richland, WA

Neurofibromatosis Type I (NF1) is a tumor-predisposing genetic disorder driven by pathogenic variants in the *NF1* gene. The development of neurofibromas, including cutaneous neurofibromas (cNFs) and plexiform neurofibromas (pNFs), constitutes a major challenge of NF1 management. Although cNFs do not carry a risk of malignant transformation, they are associated with significant comorbidities. Furthermore, benign pNFs have a risk of evolving into malignant peripheral nerve sheath tumors (MPNSTs), a rare type of soft tissue sarcoma, in ≈15% of patients. Current therapies for NF1 are limited. To date, there are no systemic treatment options for cNF lesions other than desiccation or surgical removal. For pNF management, selumetininb (a MEK1/2 inhibitor) is the only approved treatment for pediatric patients with inoperable, symptomatic lesions. However, treatment is not curative and requires continuous administration, with toxicity concerns. Lastly, MPNSTs are resistant to most systemic therapies, with surgery being the only available approach for treating localized lesions. NF1-associated tumors present a complex microenvironment that comprise different cell types including Schwann cells, fibroblasts, and mast cells. The identification of effective non-surgical treatments has been severely limited by the rarity of these tumors, their pronounced cellular heterogeneity, and the lack of patient-derived models that accurately replicate these complex characteristics. We have developed patient-derived organoids of both neurofibromas (*Nguyen et al, Cell Reports Methods 2024*) and MPNSTs (*Al Shihabi et al, Cell Stem Cell* 2024) that maintain cellular and molecular features of parental tumors, as novel tractable models for drug discovery studies. Here, we develop a modified, 3D-compatible Cell Painting assay (*Bray et al, Nature Protocols 2016*) to stain cellular structures and provide unbiased phenotypic readouts of NF1 patient-derived tumor organoids. We combined Cell Painting with our high throughput mini-ring organoid screening platform (*Phan et al, Communications Biology 2019; Al Shihabi et al, Science Advances 2022*) to rapidly screen FDA-approved drugs. We are developing a deep-learning based microscopy analysis framework to extract phenotypic features, which we will integrate with omic-based readouts to prioritize candidate therapeutic agents and establish phenotypic biomarkers that predict clinical outcomes, enabling precision medicine approaches for NF1 patients.

#5188 Recapitulating the initiation, progression and functional heterogeneity of Barrett's esophagus using a comprehensive patient-derived organoid model platform.

Lizhe (John) Zhuang, Daniel H. Jacobson, Emily L. Black, Ginny Devonshire, Ahmad Miremadi, Massimiliano Di Pietro, Rebecca C. Fitzgerald

Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom

Barrett's esophagus (BE) is a common condition that increases the risk of esophageal adenocarcinoma (EAC). It originates from gastric cells at the gastroesophageal junction (GEJ) and can progress stepwise from BE to dysplasia and eventually to EAC. However, most BE cases do not progress, suggesting involvement of the tissue microenvironment and other extrinsic factors. BE is a mosaic tissue consisting of diverse clonal units of gastric and/or intestinal phenotypes, but the association between this heterogeneity and progression risk remains unclear. Further investigation is challenging due to a lack of human-based models. Here, we established a comprehensive organoid platform covering the full disease spectrum to study clonal and phenotypic heterogeneity, extrinsic factors, and other cellular components. Methods: We derived organoid cultures from endoscopic biopsies and organ donor tissues and developed a microscopic method to generate single-clonal organoids (sc-organoids) lines, serving as functional proxies of single clones in the original tissue. We comprehensively characterized the molecular features of all organoids and their parental tissues. We also established two models: an aggregated model that co-cultures esophageal fibroblasts with gastric/BE organoids under various pathological conditions; and a labeling-tracking model where BE/EAC organoids were genetically modified with fluorescent nuclear tags for live imaging and tracking. A mathematical model was developed to quantify organoid growth and morphological kinetics. Results: We established 48 organoid lines: 13 non-dysplastic BE, 7 dysplasia, 2 early EAC, and 26 gastric covering the full disease spectrum, recapitulating key molecular hallmarks of stepwise initiation, development, and progression. Transcriptomic analysis indicated that gastric cells at the GEJ are predisposed to BE development due to higher oncogenic stress. We developed 31 sc-organoids from 2 non-dysplastic BE cases and 1 dysplasia case, which captured phenotypic diversity and clonal heterogeneity with some displaying advanced-stage genomic features. The aggregated co-culture model revealed that BE cells promote polarization of fibroblasts into cancer-associated fibroblast-like phenotypes when exposed to refluxate, further enhancing BE's expansion. The labelling-tracking model showed increased BE organoid size and number when co-cultured with EAC, suggesting that cell competition and/or secreted factors alter the balance between precancerous lesions and established tumor. Conclusion: The organoid models provide a valuable platform to study mechanisms underlying precancerous initiation, progression, and neoplastic susceptibility in normal tissues, potentially informing risk stratification and new therapeutic strategies.

#5189 Exploring the clinical utility of HER2-targeted antibody-drug conjugate in urothelial carcinoma using patient-derived models.

Xinran Tang[1], Ziyu Chen[1], Jasmine Thomas[1], Karan Nagar[1], John Christin[2], Sizhi Gao[1], Jiaqian Luo[1], Elisa de Stanchina[1], Jonathan A. Coleman[1], Michael M. Shen[2], Hikmat Al-Ahmadie[1], Gopa Iyer[1], Kwanghee Kim[1], David B. Solit[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Columbia University Irving Medical Center, New York, NY

Introduction. The FDA granted accelerated approval for trastuzumab deruxtecan (T-DXd), a HER2-targeted antibody-drug conjugate (ADC), for the treatment of patients with advanced solid tumors with HER2 3+. However, the role of HER2 in bladder cancer pathogenesis and its utility as a therapeutic target for this disease remains unclear. Here, we characterized a growing biobank of patient-derived organoid (PDO) and xenograft (PDX) models for HER2-targeted kinase inhibitor and ADC sensitivity, with the goal of guiding future therapeutic strategies for patients with bladder cancer.

Methods. We generated and characterized the mutational status and HER2 expression levels of 19 urothelial cancer PDOs and 34 PDXs. A subset of these models was further characterized using a multiplatform approach, including single-cell DNA and RNA seq. We leveraged these models to study the biologic determinants of PDX sensitivity to neratinib and T-DXd. We also studied sensitivity to T-DXd, as well as to its cytotoxic payloads (exatecan) *in vitro* using paired PDO models. To understand the real-world clinical outcomes of T-DXd in metastatic urothelial carcinoma, we analyzed 28 patients treated with T-DXd at Memorial Sloan Kettering to evaluate the therapeutic outcomes and to identify potential biomarkers of sensitivity to HER2-targeted therapies.

Results. Single-cell RNA and DNA seq analysis of 4 PDOs demonstrated high interpatient and intratumoral heterogeneity of HER2 expression and *ERBB2* copy number. Our bladder cancer PDX models also demonstrated greater sensitivity to T-DXd than neratinib, consistent with clinical data in bladder cancer patients. Sensitivity to exatecan, as measured by inhibition of cell proliferation and induction of apoptosis, was more predictive of T-DXd sensitivity than HER2 expression level. 3 patients remained on the treatment for more than 1 year, all of whom had an IHC score of HER2 3+ and *ERBB2* amplification, suggesting HER2 3+ and *ERBB2* amplification are predictive of but not required for clinical benefit with T-DXd.

Conclusion. Multi-omic single-cell analysis demonstrated significant interpatient and intratumor heterogeneity of HER2 expression and *ERBB2* copy number gain. Sensitivity to the T-DXd payload was more predictive of PDX response than HER2 expression levels, with significant tumor regression observed with T-DXd in models with low HER2 expression. Our data suggest that clinical trials of HER2-targeted ADCs should not be restricted to patients with HER2 overexpression and that novel biomarkers will be needed to identify those urothelial cancer patients most likely to benefit from FDA-approved and investigational ADCs. Real-world data from metastatic urothelial carcinoma patients treated with T-DXd suggested that HER2 3+ and *ERBB2* amplification are associated with exceptional response to T-DXd treatment.

#5190 Leveraging the International Space Station to study glioblastoma-immune interactions in microgravity-grown organoids.

Alice Burchett[1], Maksym Zarodniuk[1], Fionn Lay[1], Ina Satpathy[1], Wenjun Zhao[2], Karyme Hernandez Torrens[3], Haley Marco[1], Maria Mendez[1], Julian Najera[1], Shelby Giza[4], Jason Rexroat[4], Paul Kuehl[4], Twyman Clements[4], Meenal Datta[1]

[1]University of Notre Dame, Notre Dame, IN,[2]Smith College, Northampton, MA,[3]University of Puerto Rico Mayaguez, Mayaguez, PR,[4]Space Tango, Lexington, KY

Glioblastoma (GBM) is the most aggressive primary brain cancer with current treatments achieving an average overall survival of less than 2 years. This is due in part to the highly immunosuppressive tumor microenvironment (TME), a characteristic of many solid tumors that thwarts immunotherapy. However, the complex interactions between cancer cells and immune cells are difficult to recapitulate in culture models. Microgravity offers key advantages for cancer organoid development, including the ability to generate more robust, larger, complex, uniform, and reproducible spheroids that recapitulate cell-cell interactions more accurately than ground-based 3-D models, which are subject to gravitational forces leading to spheroid settling, disassociation, and heterogeneity. We sent individual small-scale, static experiments contained within Space Tango's High Sample Capacity CubeLab to the International Space Station (ISS) in March 2024 aboard the SpX-30 commercial resupply mission. We first developed tumor-myeloid organoids to recreate the 3D spatial interactions in the TME. These combine human GBM cells with monocytes and macrophages and can be treated to polarize the macrophages into pro-inflammatory (M1-like) or anti-inflammatory (M2-like) phenotypes. Spheroids of uniform size and tunable cell content were generated using the hanging drop method. We then optimized spheroid size and media conditions to support long-term spheroid growth in the absence of gas or media exchange to be compatible with the carrier system. We observed intact spheroids with viable cells beyond two months in sealed vials. Over time, the organoids reside in an acidic and hypoxic environment, with live cells at the organoid edges and a necrotic central core. This recapitulates the microenvironment of GBM and other tumors, which is known to be acidic, hypoxic, and necrotic. The launched experiment contained spheroids with GBM cells alone, GBM cells + macrophages, GBM cells + monocytes, and GBM + macrophages with M1-like or M2-like polarizing agents. These were maintained in microgravity aboard the ISS for 40 days and were processed within 24 hours of their return to Earth. We collected RNA for bulk sequencing, media for secreted proteomics, and fixed intact spheroids for spatial sequencing, spatial proteomics, and histology. While analysis is ongoing to determine the impact of microgravity on GBM-immune interactions, this experiment has already laid the groundwork for future flights by revealing successful organoid culture conditions for future experiments. We anticipate that these microgravity immune-tumoroids will provide valuable insight into the role of macrophages in GBM biology that would not be possible to obtain in Earth’s gravity. Upcoming microgravity experiments will include more complex organoids from patient-derived glioma cells and the potential for drug screening.

#5191 Modeling the metastatic tumor microenvironment: A co-culture platform for cancer and vascular organoids in drug screening.

M. Lee, Y. Yoon, Y. Lee, J. Rheey;
Gradiant Bioconvergence, Seoul, Korea, Republic of

Patient-derived organoids (PDOs) have emerged as a promising tool for drug screening, as they can closely mimic the genetic profile and heterogeneity of real tumor tissues. Despite these advantages, PDOs cultured in isolation fall short in replicating the complex *in vivo* tumor environment, particularly the critical interactions with the vascular network. Research that neglects these tumor-vascular interactions provides only partial insights into drug responses and the metastatic potential of cancer cells. To address these limitations, we developed a co-culture system of cancer and vascular organoids to better simulate the authentic tumor microenvironment (TME). After four days of vascularized tumor organoid (vTO) culture, RFP-positive lung cancer organoids (LCO) were centrally positioned, encircled by blood vessels, creating an interconnected structure between the LCO and blood vessel organoids (BVO). As the culture period progressed, the LCO began to spread along the vascular network, and by day 10, RFP-positive LCO cells were observed in the peripheral BVO regions. To investigate strategies for limiting metastasis, we targeted the TGF-β pathway, known to play a key role in metastatic progression, within this novel metastatic platform. On day 5, we administered the TGF-β/Smad inhibitor A83-01. Image-based analysis revealed a reduction in LCO dissemination, while quantitative PCR analysis showed a dose-dependent decrease in the expression of genes associated with epithelial-to-mesenchymal transition (EMT) following A83-01 treatment. Additionally, to assess anti-cancer drug responses, we treated the vTO with the AXL inhibitor Bemcentinib. Image analysis indicated that the vTO exhibited higher drug resistance compared to LCO alone, and qPCR analysis confirmed a reduction in metastasis-associated gene expression. Taken together, this innovative co-culture platform, which incorporates metastatic cancer organoids, offers a structurally advanced model that more closely resembles the *in vivo* TME than previous drug screening methods. Therefore, this platform serves as a powerful new tool for studying metastatic cancer and provides a novel approach to evaluating metastasis-inhibiting drugs, new therapeutics targeting metastatic tumors, and combination therapies.

#5192 Next-generation NSCLC drug development powered by PDCs and PDOs: Mimicking real responses.

Sewon Park[1], Min Hak Lee[2], Ju-hyeon Lee[2], Mi Ran Yun[1], Min Hee Hong[3], Sun Min Lim[3], Jii Bum Lee[3], Byoung Chul Cho[3]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]JEUK Institute for Cancer Research, JEUK Co., Ltd., Seoul, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Seoul, Korea, Republic of

Purpose : Patient-derived cells (PDCs) and organoids (PDOs) derived from pleural effusion or ascites closely mimic the biological characteristics of individual patients. In cancer research, PDCs and PDOs serve as powerful tools for replicating tumor-specific mutations, overcoming the limitations of traditional cell lines, which fail to capture the heterogeneity and complexity of human tumors. Due to their ability to predict preclinical drug efficacy more accurately, PDCs and PDOs are increasingly utilized in therapy development. This study aims to demonstrate the potential of PDCs and PDOs as effective platforms for screening novel therapeutic strategies for non-small cell lung cancer (NSCLC).

Experimental design : Malignant effusions were samples were tested for malignancy, processed, observed by light microscopy, and cultured. The establishment of a PDC was considered complete when it was free of normal cells, maintained known patient tumor mutation, and recapitulated patient's response. Also, mutations that cell harbors are confirmed by Sanger sequencing, Whole exome sequencing, or RNA-sequencing.

Results : Total of 54 PDCs and 171 PDOs were established from NSCLC patients, including models harboring various EGFR, KRAS and BRAF mutations and EML4-ALK or ROS1-CD74 fusions. Particularly the 8 models of PDC and 7 models of PDO harbor mutations which are well known for resistance mechanisms to EGFR-TKIs (T790M, C797S/C797G, MET amplification). Also, some models of PDCs were harboring uncommon EGFR mutations(EGFR G719S, L861Q, S768I etc.).For example, YUO-139 and YU-1092 are patient derived models that harbors uncommon EGFR mutation G719S and L861Q respectively. The models response to afatinib sensitively. IC_{50} of YUO-139 and YU-1092 to afatinib were 2.1 nM and 23.8 nM respectively. These models were evaluated for novel strategies for targeting uncommon EGFR mutations. Another example is YUO-143, which harbors EGFR mutations E19del/T790M/C797S and was derived from a patient resistant to gefitinib and mavelertinib. YUO-143 was used in the development of the 4th gen TKI, BLU-945, and showed an IC_{50} of 43 nM.

Conclusions : Patient-derived models could serve as a crucial tool in developing novel therapeutic strategies and next-generation drugs for NSCLC.

#5193 Optimization of tumoroid size and payload delivery methods for the engineering of patient-derived tumoroid models.

Isha Dey[1], Xiaoyu Jenny Yang[2], Jacob Delgadillo[2], Garrett Wong[2], **Colin D. Paul**[3], Chris Yankaskas[3], Brittany Balhouse[3], Shyanne Salen[3], Sylvia Beam[3], Amber Bullock[3], Anthony Chatman[3], Pradip Shahi Thakuri[3], Kanika Singh[1], Jason Sharp[2], Matt Dallas[3], David Kuninger[3]

[1]Thermo Fisher Scientific, Bangalore, India,[2]Thermo Fisher Scientific, Carlsbad, CA,[3]Thermo Fisher Scientific, Frederick, MD

Tumoroids, also known as cancer organoids, are three-dimensional (3D) in vitro cell cultures established from primary tissue samples. These next-generation cancer cell models largely recapitulate the spatial organization, gene expression, and mutational profiles of patient tumors. It may be beneficial to engineer tumoroids to generate reporter lines, model specific mutations involved with tumor progression, or modulate gene expression to help understand the mechanism of action of therapeutics. Here, we explore methods for genetic engineering of tumoroids established and cultured in Gibco™ OncoPro™ Tumoroid Culture Medium to facilitate these studies. We first examined the impact of tumoroid size on transfection efficiency via electroporation with the Neon™ NxT Electroporation System. Colorectal tumoroids were transfected with enhanced green fluorescent protein (eGFP) immediately after dissociation or after 4 or 7 days in culture in OncoPro medium, at which point tumoroid size had reached approximately 400 µm in diameter. Nearly 80% of dissociated tumoroids were successfully transfected, while efficiency dropped to 35-40% when using intact 4- or 7-day old tumoroids. Therefore, dissociated tumoroids were used for further experiments. We then compared lipofection, electroporation, and lentivirus-based transduction in a difficult-to-transfect model, focusing on reporter line generation. While lipofection is easy-to-use and cost effective, delivery of enhanced green fluorescent protein (eGFP) by lipofection led to transfection efficiencies of only 15%. Electroporation of eGFP was more efficient, transfecting 30% of tumoroid cells for the tumoroid line used. Given the importance of preserving the cellular heterogeneity found in patient samples and recapitulated in tumoroid models, these lower delivery efficiencies indicate that lipofection- and electroporation-based methods are not ideal for the generation of stably engineered tumoroid models. In contrast, lentiviral transduction at high MOI was the most efficient method for eGFP overexpression, initially transducing 67% of cells and enabling stable pool reporter line generation with nearly identical mutational profile and gene expression compared to the parental population. In follow up experiments, transduction also enabled generation of eGFP-expressing breast and endometrial reporter tumoroid lines. Overall, our results indicate that electroporation may be more suited for transient transfection across a wide range of payloads, and siRNA, gRNA, and Cas9 protein were able to be delivered by electroporation in follow up experiments. Lentivirus-based transduction is more suitable for generation of stable tumoroid pools. The insights gained from this study can be applied to tumoroids derived from various tissues, potentially accelerating advancements in cancer research and personalized medicine.

#5194 Establishment and characterization of tumoroids from patient derived xenograft tissue for in vitro applications.

Jannik Scherer[1], Kanstantsin Lashuk[1], Julia Thiel[2], Meng Dong[2], **Julia B. Schueler**[1]

[1]Charles River Laboratories, Inc., Freiburg, Germany,[2]Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology and University of Tubingen, Stuttgart, Germany

Lung cancer remained the most frequently diagnosed cancer in 2022 and the leading cause of cancer-related deaths worldwide. Oncology drug development attrition is highest compared with other therapeutic areas, and success rates in clinical development range from 3.4-5%. Tumoroids as sophisticated three-dimensional *in vitro* cultures serve as an advanced near-physiological model but lung cancer tumoroid development remains challenging. The treatment strategy for lung cancer patients is currently determined based on histology, stage, and biomarker status, thus we aimed to establish a panel of complex *in vitro* tumoroids covering a broad range of different subtypes of the disease. Two methods of primary cell isolations, five different media formulations and two types of culture methods were assessed to find optimal conditions for tumoroids. Tumoroids were kept in culture for up to 10 passages including freeze-thaw tests. Characterization involved determination of morphology by brightfield microscopy, histology (H&E staining), biomarker expression using multiplex IHC staining and QuantiGene for murine stroma content assessment. Multiple commercial systems that allow uniform organoid formation using microwell technologies were compared. The models in question were mostly of lung adenocarcinoma origin, either “hot” or “cold” in terms of immune cell infiltration status. Tumoroid growth was dependent on the niche growth factor formulation. The highest success rates were achieved with a custom medium formulation (7/8 models). Feasibility of biobanking the organoids either as single cell suspension or whole organoids was confirmed. Different media formulations led to distinct phenotypes and retention of biomarkers in each model. Tumoroids showed signs of cellular plasticity by epithelial to mesenchymal transition characterized by simultaneous expression of EPCAM and aSMA in a subpopulation of cells. The process of de-differentiation during the culture phase has been explored in detail. After model establishment, the models will be tested in a viability assay with several SoC small molecules and in an immune cell co-culture with activated PBMCs and checkpoint inhibitors, to fully establish a platform for drug-screening and evaluation of immunotherapies. This study showcases a complete workflow in tumoroid establishment, highlighting the importance of adequate quality control and validation. Substantial variations of histological characteristics and biomarker expression depending on the culture condition, show the lineage-specific differences and the heterogeneity of the tumoroid. Organoid equivalence to the parental tissue is rarely addressed and this work highlights the impact of standardized culture conditions and thorough characterization of tumoroids to unfold their full potential as drug development platform.

#5195 Development of paired PDX-PDXO preclinical models for HER2-targeting ADC efficacy evaluation.

Jinxi Wang, Jun Zhou, Limei Shang, Qingzhi Liu, Binchen Mao, Yi Sun, Peng Han, Lin Zhang, Likun Zhang, Xiaolong Tu, Wubin Qian, Peng Wang, Leilei Chen, Marten Hornsveld, Marrit Putker, Ludovic Bourre, Jingjing Wang

Crown Bioscience, Inc., San Diego, CA

Introduction: Tumor organoids replicate cancer lesions and capture tumor heterogeneity *in vitro*, and are invaluable for cancer drug development. Combining Patient-Derived Xenograft (PDX) models with corresponding Patient-Derived Xenograft Organoid (PDXO) models offers a comprehensive approach, enabling high-throughput, scalable *in vitro* data collection and providing insights into tumor behavior and drug responses *in vivo*. HER2 amplification is frequent in cancers like breast and gastric cancer, and HER2-targeted ADCs have shown exceptional efficacy. To support preclinical and mechanistic investigations that develop next-generation HER2-targeted ADCs and therapies, we established a preclinical panel of paired PDX-PDXO models with varying HER2 expression levels.

Methods: Gastric (GA) and breast cancer (BR) PDXOs were generated from PDX tissue and authenticated by SNP assay. Morphology, histopathology, and genomic profiling were performed and compared with its corresponding PDX. *ERBB2* expression and HER2 levels in PDX-PDXOs were detected by RNA sequencing and IHC. *In vivo* efficacy of 10 mpk DS8201 was studied in the PDXs, and *in vitro* IC50 was assessed in the PDXOs using CellTiterGlo (CTG) and High Content Imaging (HCI), allowing differentiation between cytostatic and cytotoxic responses. Correlation analysis of DS8201 response were performed based on the efficacy data from PDXOs and PDXs.

Results: 34 GA and 24 BR PDXOs were developed from PDX tumors originally established from patients' biopsies. Hematoxylin-eosin (H&E) staining showed distinct features within PDXOs, similar to the corresponding PDXs. High correlation (>95%) in mutation and gene expression demonstrated that PDXOs largely preserve the genomic and transcriptomic features of the originating tumors. *In vivo* and *in vitro* efficacy studies of DS8201 were performed in 14 pairs of GA and BR PDX-PDXOs, among which 12 pairs display consistent HER2 IHC scores between PDX and PDXO. Overall, 6 out of 7 DS8201-sensitive PDXOs were also sensitive in PDXs and showed tumor regression, indicating high positive predictive value (PPV: 0.857) of PDXOs. The average TGI of PDXs classified for the corresponding PDXO as sensitive is much higher than TGI of PDXs classified for the corresponding PDXO as non-sensitive (97% vs. 69%, p=0.13). Besides, DS82001 sensitivity was observed in both HER+ and HER2- models, which might relate to the bystander effect of the payload and heterogeneity of PDX.

Conclusion: The paired PDX-PDXO models were successfully established and provided a novel preclinical platform for investigating mechanisms of action (MOA) and resistance in patient-relevant models matched in both *in vitro* and *in vivo* stages for developing next-generation HER2-targeting therapies.

#5196 Large scale in vitro expansion of primary tumors from metastasis cancer patients with different mutations for preclinical drug screening.

Dylan Bryda[1], Megan Groves[2], Anthony Tolcher[3], Alex Armento[1], **Seyoum Ayehunie**[1]

[1]MatTek Corporation, Ashland, MA,[2]Next Oncology, San Antonio, TX,[3]NextOncology, San Antonio, TX

The use of patient derived primary tumors (PDPT) is becoming a powerful vitro tool in candidate cancer drug screening for safety and efficacy. Compared to 2D cell lines, the PDPTs can 1) better recapitulate human tumor microenvironment, 2) predict drug responses in humans, 3) be used in high throughput drug screening platforms to test dose responses and drug-drug interactions, and 4) ultimately, be used in precision medicine. However, adoption of PDPTs has been hindered by challenges related to in vitro tumor cell growth and expansion without inducing phenotypic changes. Here, we present a novel system of in vitro PDPT expansion method and biobanking of tumoroids that can be used in high throughput drug screening for metastasis disease. We have combined a specialized matrix coated plates with that of microwell technology to scale-up in vitro tumor cell growth and expansion. In this study we introduced two assay systems for screening of drugs/compounds: a) expanded colorectal cancer (CRC) tumoroids as a stand-alone test system and b) reconstructed complex 3D tumor containing tissues with matrix, fibroblasts, endothelial cells, and immune cells that mimics the tumor microenvironment (TME). To examine the utility of both testing platforms, single tumoroids or tumoroids embedded in 3D tissues were exposed to different doses of 5 chemotherapeutic drugs Cisplatin, Doxorubicin, Oxaliplatin, Fluorouracil, and Cetuximab. Treatment was initiated on day 10 of the culture period. Thereafter, tumoroids were dosed with drugs every other day for 11 days. After each treatment cycle, tumoroids or tumoroid containing tissues were fixed for H&E and live/dead cell staining. The results showed that: 1) large scale expansion of PDPT is achievable, 2) PDPT can be cultured with multiple cell types to simulate the TME, 3) histological evaluation of the tumor models showed a glandular-like tumoroid structure, 4) immunohistochemical staining revealed epithelial origin of the CRC (CK20+), and 5) live-dead cell staining of tumoroids showed differential drug responses in a dose and time dependent manner. Additionally, a by-standard cell death effect was noted for some of the drugs. In summary, large-scale in vitro tumoroid expansion is critical to scale up metastasis cancer drug screening. The developed assay systems are more physiological, cost effective, less time-consuming, better predictive of drug responses in humans, can lead to precision medicine, and reduce animal use for experiments.

#5197 Establishing patient-derived xenograft organoids (PDXOs) from renal cell carcinoma for drug screening and identification of treatment-induced vulnerabilities.

Stefano Piatto Clerici[1], Adriano O. Beserra[1], Stephania M. Bezerra[2], Luciana M. Leite[3], Stenio C. Zequi[4], Tiago G. Santos[1], Vilma R. Martins[5]

[1]International Research Center, A.C. Camargo Cancer Center - Brazil, Sao Paulo, Brazil,[2]Department of Anatomic Pathology, A.C. Camargo Cancer Center - Brazil, Sao Paulo, Brazil,[3]Department of Medical Oncology, A.C. Camargo Cancer Center - Brazil, Sao Paulo, Brazil,[4]Reference Center of Urology, A.C. Camargo Cancer Center - Brazil, Sao Paulo, Brazil,[5]Aljava Biotech, A.C. Camargo Cancer Center - Brazil, Sao Paulo, Brazil

Clear Cell Renal Cell Carcinoma (ccRCC) is the most prevalent urinary kidney malignancy, presenting significant challenges in disease control, particularly for patients with locally advanced or metastatic disease. The urgent need for more effective therapies remains unmet. Patient-derived models, including 3D patient-derived organoids (PDOs) and *in vivo* patient-derived xenografts (PDXs), faithfully recapitulate tumor histological morphology, genetic landscape, and therapeutic responses. The ACCamargo Cancer Center PDX Biobank includes several ccRCC cases and comprehensive patient clinical data supporting the generation of PDX organoids (PDXOs) for high-throughput drug screening and The present work aims to a) establish and validate ccRCC PDXO as predictive models for standard-of-care treatments and b) investigate drug vulnerabilities and synthetic lethality approaches in BAP1-mutated tumors. Twelve PDX samples (fresh and cryopreserved) were enzymatically digested, resuspended, seeded in growth factor-reduced Geltrex®, and cultured in a kidney organoid medium. PDXOs were assessed using histology and immunohistochemistry. Cell viability assays evaluated six PDXOs' responses to Sunitinib (one of the stand-of-care drugs in RCC). Results were correlated with patients' clinical outcomes for three cases of PDXOs with BAP1 mutations ($BAP1^{MUT}$) and wild-type BAP1 ($BAP1^{WT}$) were treated with Olaparib (Poly(ADP-ribose) polymerase (PARP) inhibitor) and Vorinostat (Histone deacetylase (HDAC) inhibitor). The success of PDXOs' growth and expansion efficiency, at approximately 60%, proves our research's reliability. Histology and immunohistochemistry c confirmed that five PDXOs and PDX matched the characteristics of the corresponding patient tumors. PDXOs treated with Sunitinib exhibited varied responses. In three out of the five cases, the sensitivity of PDXOs to Sunitinib aligned with the clinical outcomes of the respective patients. Preliminary data indicated that $BAP1^{MUT}$ PDXOs were more sensitive to Olaparib and Vorinostat treatments than $BAP1^{WT}$ PDXOs. The study demonstrated the predictive power of PDXOs in correlating therapeutic responses to Sunitinib with clinical outcomes. BAP1 mutations in PDXOs also revealed drug vulnerabilities, highlighting increased sensitivity to Olarapib and Vorinostat. These findings underscore the value of PDXOs as robust tools for predicting patient responses to therapy and exploring target treatments for ccRCC.

#5198 Semi-automated, scaffold-free organoid workflow for the T cell screening assay using AI.

Zhisong Tong[1], Angeline Lim[1], Oksana Sirenko[1], Jia-Yang Chen[2], Hao-Wei Han[2], Ying C. Chang[2]

[1]Molecular Devices, LLC (Moldev), San Jose, CA,[2]AcroCyte Therapeutics Inc., New Taipei, Taiwan

Among the therapies for treating cancer, immunotherapy—especially chimeric antigen receptor (CAR) T-cell therapy—is increasingly popular. CAR T cells are genetically altered T cells that when injecting back into patients, they help arm the immune system to target and destroy cancer cells. Though it has achieved much success with immunotherapy in treating blood cancers, it remains challenging in targeting solid tumors due to the intrinsic solid tumor microenvironment (TME) which suppresses the tumor-killing ability of T cells. Thus, TME plays an important role in the treatment of solid tumors and finding an approach of mimicking TME in vitro is essential for Car-T cell screening. Studies show that the 3-dimensional (3D) patient-derived organoids (PDO) model more of the physical and chemical cues present within the TME that are lacking in traditional 2D cell line cultures. They also show similar responses to drugs as original tumors, suggesting the value of using PDOs to improve therapeutic outcomes. Despite the benefits associated with the use of PDOs, there are significant barriers that hinder the widespread adoption of PDOs in drug discovery, i.e., the costly and highly labor-intensive processes associated with their growth and maintenance. To address the challenges associated with the use of PDOs in large-scale applications, a semi-automated bioreactor was developed for the large-scale expansion of assay-ready organoids. Further, to free the burden of using Matrigel for organoid culture in the assay, we developed a Matrigel-free organoid workflow to quantify the efficacy of the cells in solid tumors, automatically seeding and culturing PDOs in a novel nano film coated cell culture plate enabling spontaneous scaffold-free 3D organoid formation using a fully integrated cell culture system. Using bioreactor-expanded patient-derived colorectal cancer organoids (CRCs), activated human peripheral blood mononuclear cells (PBMCs) were added to CRCs in a 96-well plate and monitored every 1 hour for 3 days. To quantify the morphological changes induced by T cells, we first segment each organoid with the transmitted light (TL) channel using a deep-learning model and extracted morphological features from each organoid. The resulting features were then classified using a trained Random Forest model that differentiates the morphologically modified organoids from the intact organoids. Using this approach, we found that—compared to control wells—the percentage of modified organoids in stimulated PBMC-treated wells increases more rapidly, suggesting a potential live T cell efficacy assessment approach with or without labeling. The results demonstrate the utility of the scaffold-free organoids with this analysis approach in large-scale T cell screening.

#5199 Enhancing precision medicine in advanced lung, gastric and rectal cancer: Exploring the reliability of Patient-derived organoids.

Hye Ryeong Jun[1], Shin Young Chang[1], Hyoyoung Kim[2], Hyunki Kim[3], Minkyu Jung[4], Hye Ryun Kim[4], Tae Il Kim[5], Jung Eun Kim[1]

[1]Department of precision medicine, PODO Therapeutics, Seongnam, Korea, Republic of,[2]Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Pathology, Yonsei University Health System, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Division of Gastroenterology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: A significant challenge in cancer treatment is the development of effective therapies, particularly for patients with recurrent and advanced-stage cancers. Major barriers to successful treatment include the identification of druggable targets and the exploration of novel drug modalities. Investigating strategies for effective combination regimen with standard therapies or immuno-oncology (IO) agents is crucial for optimizing treatment sequences. Traditional clinical trials are resource-intensive and time-consuming; in contrast, patient-derived organoids facilitate the efficient testing of tailored combination therapies specifically for recurrent and metastatic patients.
Method: We employed organoid cultures derived from patients with advanced lung, gastric and rectal cancer to assess their responses to a range of anticancer drugs, including standard agents, IO therapies, and radiotherapy. Drug responses and radiosensitivity data were correlated with matched clinical data, and metrics such as predictive accuracy, sensitivity, and specificity were calculated. The organoids were validated as reliable models reflecting clinical cancer behaviors, ensuring their relevance for evaluating treatment responses.
Results: We investigated drug and radiation responses, molecular marker expression, and dynamic caspase imaging of patient-derived organoids, validating these findings in conjunction with clinical data. Our analysis revealed a significant correlation between organoid based in vitro responses and clinical observations, suggesting potential pathways for personalized treatment strategies in advanced cancer settings. The distinct in vitro response patterns observed in organoids align with clinical experiences, underscoring the importance of optimizing treatment sequences and evaluating novel drug modalities alongside immunotherapy.
Conclusion: This research highlights the efficacy of patient-derived organoids (PDOs) in evaluating treatment responses, thereby contributing to the advancement of precision oncology for patients with advanced lung, gastric and rectal cancer. The findings underscore the importance of using PDOs as reliable preclinical models to tailor therapeutic strategies based on individual patient profiles. Future studies should focus on leveraging organoid models to optimize combinations of targeted therapies, radiotherapy and immuno-oncology agents, ultimately aiming to enhance clinical outcomes and personalize treatment approaches for advanced stage cancers.

#5200 Patient-derived esophageal squamous cell carcinoma organoids and analysis of MDR1 expression levels in clinical specimens for promoting personalized medicine.

Yasushige Takeda[1], Kazuhiro Noma[1], Hajime Kashima[1], Akito Shimizu[1], Tasuku Matsumoto[1], Seitarou Nishimura[2], Tatsuya Takahashi[1], Hijiri Matsumoto[1], Kento Kawasaki[3], Tomoyoshi Kunitomo[1], Naoaki Maeda[1], Satoru Kikuchi[1], Shunsuke Tanabe[1], Toshiaki Oohara[1], Hiroshi Tazawa[1], Hiroshi Nakagawa[3], Toshiyoshi Fujiwara[1]

[1]Gastroenterological surgery, Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan,[2]Surgery, Fukuyama City Hospital, Fukuyama, Japan,[3]Herbert Irving Comprehensive Cancer Research Center, Columbia University Irving Medical Center, New York, NY

Background
Esophageal cancer is the 7th leading cause of cancer-related mortality as of 2022, with esophageal squamous cell carcinoma (ESCC) comprising 90% of cases in Japan. The Japanese Clinical Oncology Group (JCOG) reported that preoperative DCF therapy (Docetaxel + Cisplatin + 5-Fluorouracil) improves prognosis over CF therapy (Cisplatin + 5-Fluorouracil). However, some patients exhibit resistance to DCF therapy, leading to recurrence or metastasis post-surgery. Tumor heterogeneity contributes to these outcomes. MDR1, a multidrug resistance protein, shows variable expression levels, and cancer tissues are composed of tumor cells alongside diverse microenvironmental components. To address this, accurate models are essential. Recently, three-dimensional patient-derived organoids (3D-PDOs) have gained attention as cost-effective platforms replicating cancer heterogeneity.
Method
3D-PDOs were derived from pre-treatment ESCC biopsy specimens. Their histological morphology was compared with clinical specimens, and responses to Docetaxel, Cisplatin, and 5-Fluorouracil were assessed. Additionally, 78 ESCC cases treated with preoperative DCF therapy followed by surgery (2012-2018) were analyzed. Immunohistochemistry (IHC) was performed on biopsy specimens to evaluate MDR1 expression and its association with prognosis.
Results
3D-PDOs formed three-dimensional epithelial aggregates. ESCC PDOs exhibited irregular edges compared to the spherical, well-defined shapes of normal PDOs. IHC revealed protein expression variability in 3D-PDOs, reflecting clinical specimen heterogeneity. Expression trends in PDOs matched those in clinical samples, demonstrating their histological accuracy. In one case, a therapeutic experiment with Docetaxel, Cisplatin, and 5-Fluorouracil showed significant efficacy for Docetaxel and Cisplatin but resistance to 5-Fluorouracil. MDR1 analysis in biopsy specimens indicated MDR1-positive cases had significantly shorter recurrence-free survival than MDR1-negative cases, though no significant difference was observed in 5-year overall survival. MDR1 IHC on 3D-PDOs used in treatment experiments confirmed MDR1 expression, consistent with observed 5-FU resistance and suggesting a high recurrence risk in this case.
Conclusion
3D-PDOs are valuable for analyzing histological features and therapeutic resistance in heterogeneous ESCC cases. MDR1 analysis demonstrated potential utility in predicting postoperative recurrence risk, supporting its role in personalized treatment strategies.

#5201 Modeling human mammary epithelial lineages using patient-derived organoid cultures.

David A. Rowbotham, Samantha Rothwell, Sharon A. Louis, Allen C. Eaves, John Stingl

Research and Development, STEMCELL Technologies Inc., Vancouver, BC, Canada

Organoids have emerged as a powerful model for studying normal and tumor cell biology; however, the application of organoid technology for culturing human breast epithelial cells has been challenging due to the difficulty in maintaining estrogen receptor (ER)-expressing cells in culture. To address this problem, we have developed MammoCult™ Organoid Kit (Human), a modular serum- and phenol red-free cell culture kit that promotes the growth of multilineage organoids, as well as organoids composed solely of ER+ and ER- luminal or basal cells. Primary human breast cells from reduction mammoplasty tissues from both pre- and postmenopausal donors were dissociated and seeded in 3D extracellular matrix domes, as either single cells or tissue fragments. Organoids were typically dissociated and passaged every 10 - 20 days. Cultures were analyzed by flow cytometry and immunocytochemistry for the expression of the pan epithelial marker EpCAM, the luminal markers Keratin 8 (K8), KIT, ER, MUC1, progesterone receptor (PR), and the basal markers CD49f, smooth muscle actin (SMA), and K14. Organoid cultures initiated from single cell suspensions generated distinct organoid morphologies reflective of their cell of origin. Luminal cells generated small hollow cystic organoids composed predominantly of cells that expressed K8, MUC1, and variable levels of expression of ER, PR, and KIT (n = 6 - 12). Notably, ER expression was maintained in luminal organoids for a minimum of 5 passages when split at a 1:3 to 1:5 split ratio (n = 3). Basal cells seeded in Corning® Matrigel® supplemented with collagen I (2 mg/mL) formed terminal ductal lobular unit (TDLU)-like branching structures that were composed solely of K14+SMA+ basal cells and could be passaged for a minimum of 2 passages when co-seeded with human mammary fibroblasts (n = 3). Multilineage organoids composed of both luminal and basal cells could be generated when cell aggregates or tissue fragments were initially seeded (n = 5). These results demonstrate that the MammoCult™ Organoid Kit (Human) offers a robust, in vitro model system for studying human mammary gland biology.

#5202 Clinical, molecular, and functional characterization of a diverse collection of patient-derived colorectal cancer organoids from the Human Cancer Models Initiative.

Matthew Graziano, Stephen Friend, James Clinton, Changsuk Moon, **Carolina Lucchesi**

Microphysiological System Department, ATCC, Manassas, VA

Background: In the United States, colorectal cancer (CRC) is the third most common cause of cancer-related mortality and is second in mortality rate. There is a need for clinically representative, in vitro CRC models that reflect the genomic and phenotypic diversity of disease seen in patient populations. The Human Cancer Models Initiative (HCMI) is a collaboration between the National Cancer Institute, Cancer Research UK, Wellcome Sanger Institute, Hubrecht Organoid Technology, and ATCC that has generated hundreds of novel patient-derived cancer models that are supported with clinical and molecular annotation. These models were manufactured, characterized, and validated at ATCC and are available for academic and commercial use to support cancer research and drug discovery.
Methods: CRC organoids available in the ATCC collection of HCMI organoid models (n=70 unique models, n=67 unique donors) were subjected to whole-exome sequencing. Models were derived from primary tissues including colon, rectosigmoid junction, and rectum across 10 different anatomical sites. Data were compared to publicly available clinical and genotyping results from the tumor of origin and large cancer datasets such as The Cancer Genome Atlas (TCGA). A subset of models was tested for sensitivity to a bespoke panel of compounds (n=24) that included drugs in clinical use, chemotherapeutics, and experimental compounds with a variety of mechanisms of action and molecular targets. Models were tested with a 12-point, half log dilution dose curve and drug sensitivity was calculated as the half-maximal inhibitory concentration (IC50). Post-treatment cultures were stained with live- and dead-cell fluorescent dyes and a luminescent ATP viability assay to assess response.
Results: CRC organoids from the HCMI were predominantly derived from primary tumors (83%) with an adenocarcinoma histological type (94%). Models had mutations in disease-relevant driver genes including APC, TP53, KRAS, PIK3CA, BRAF, ARID1A, GNAS, and SMAD4 at frequencies similar to the TCGA COAD cohort. Drug sensitivity testing revealed donor to donor variability in response to targeting compounds, which supplemented with WES data may suggest variant specific sensitivity to compounds of interest.
Conclusion: Patient-derived CRC organoids from the HCMI recapitulate genotypes seen in patient populations and respond to therapeutic treatment in vitro.

#5203 Patient derived organoids capture heterogeneity and uncover therapeutic opportunities in esophageal adenocarcinoma.

Dylan Peter McClurg[1], Kayli Bolton[1], Christopher M. Jones[1], Daniel Jacobson[1], Ahmad Miremadi[2], Ginny Devonshire[3], Xiaodun Li[1], Sriganesh Jammula[1], Adrienn Blasko[1], Rebecca C. Fitzgerald[1]

[1]Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom,[2]Department of Histopathology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,[3]Cancer Research UK Cambridge Institute, Cambridge, United Kingdom

Introduction: Esophageal adenocarcinoma (EAC) is a hard-to-treat cancer that contributes to considerable morbidity and mortality. A major treatment challenge is the inherent disease heterogeneity. We sought to recapitulate this *in vitro* using a comprehensive organoid platform to allow correlation with genomic driver events, including extrachromosomal circular DNA (ecDNA), and response to systemic therapies and radiation.

Methods: A total of 48 patient-derived organoids (PDOs) and their matched parental tissue were characterized using clinical annotations, whole-genome sequencing (WGS), and RNA sequencing. Additional phenotypic characterization was undertaken via immunohistochemistry (IHC) for key protein markers. Ten EAC organoids with distinct genomic driver events were selected for in-depth analysis, including evaluation of ecDNA events using IHC, Fluorescence in situ hybridization (FISH), and AmpliconArchitect tool, as well as characterization of sensitivity to chemotherapeutics and radiation. PDO cultures were treated with five anticancer compounds as single agents based on genomic drivers and GI_{50} values were calculated. Radiation sensitivity was assessed by exposure to a single fraction of 0-8Gy x-ray irradiation and subsequent evaluation of organoid forming efficiency (OFE) using an IncuCyte.

Results: The organoid platform successfully captured the heterogeneity of EAC, replicating key histological and molecular features observed in matched patient samples. WGS analysis demonstrated that EAC organoids reflect the heterogeneous genomic landscape of their primary tumor including point mutations, copy number alterations, structural variations, mutational signatures, and driver alterations. FISH analysis and AmpliconArchitect confirmed the presence of ecDNA events leading to focal amplification of up to 41 copy numbers of functionally relevant genes with corresponding RNA expression. HER2 amplified organoids were confirmed through IHC and FISH analysis. In addition, IHC staining for CDK6 demonstrated biomarker potential of ecDNA events. Therapeutic sensitivities were observed to CDK4/6 (GI_{50} < 10 μM) CDK2 (GI_{50} < 0.03 μM), HER2 (GI_{50} 1-10 μM), MEK (GI_{50} 0.3 - 10 μM) and mTOR (GI_{50} 0.3-10 μM) inhibitors. The most sensitive of responses were seen in the CDK2 inhibitor, with most organoids responding (n = 6). Putative ecDNA events were found to confer sensitivity to predicted targeted compounds and, in some cases, showed a greater response than nuclear amplification of the same oncogenic driver. Significant variation in OFE was seen in response to x-ray irradiation, highlighting novel molecular determinants of radiation response.

Conclusion: Our organoid platform captures the molecular and phenotypic heterogeneity of EAC and provides a platform in which to identify novel molecular determinants of therapeutic response.

#5204 Morphology-guided classification of oral cancer using patient-derived organoids and its therapeutic implications.

Mi Rim Lee[1], sumin Kang[2], Jonghyun Lee[3], Sun-Young Kong[4], Yu-Sun Lee[1], Hye Won Shon[1], Gyeongmin Kang[2], Jiyoung Lee[1], Suk Min Youn[5], Da Woon Kwack[5], Joo Yong Park[5], Soung Min Kim[6], Wonyoung Choi[7], Jong-Ho Lee[5], Dongkwan Shin[3], Ik-Jae Kwon[6], Sung-Woen Choi[5], Yun-Hee Kim[1]

[1]Molecular Imaging Branch, Division of Convergence Technology, National Cancer Center - Korea, Goyang-si, Korea, Republic of,[2]Department of Cancer Biomedical Science, National Cancer Center Graduate School of Cancer Science and Policy, Goyang-si, Korea, Republic of,[3]Bioinformatics Branch, Division of Cancer Data Science, National Cancer Center - Korea, Goyang-si, Korea, Republic of,[4]Department of Laboratory Medicine, National Cancer Center - Korea, Goyang-si, Korea, Republic of,[5]Oral Oncology Clinic, National Cancer Center - Korea, Goyang-si, Korea, Republic of,[6]Department of Oral and Maxillofacial Surgery, Seoul National University Dental Hospital, Seoul, Korea, Republic of,[7]Center for Clinical Trials, National Cancer Center - Korea, Goyang-si, Korea, Republic of

Oral cancer is an aggressive malignancy with a survival rate below 50% and a high rate of locoregional recurrence in advanced stages. The treatment method for patients with oral cancer is highly dependent on surgery and radiation, because there is still no therapeutic target due to the low mutation rate and the absence of molecular subtypes due to high tumor heterogeneity. Patient-derived organoid (PDO) is a good model that can overcome the limitations in translational study of oral cancer, as they reflect the characteristics of patient tissues at a high level and serve as a valuable preclinical model.In this study, we classified oral cancer into three subtypes based on patient-derived organoid (PDO) morphology and proposed new treatment strategies based on subtype-specific mutations and -transcriptional characteristics. First, we classified OSCC organoids into three distinct morphologies from successfully established 77 cancer and 81 normal oral cancer PDO libraries: normal-like, dense, and graph-like. Morphological subtypes were consistent with genomic mutations and transcriptome characteristics. Morphological subtypes were correlated not only with genomic mutations and transcriptomic characteristics, but especially with clinical recurrence prognosis. Patients with normal-like had a low mutation burden and a good prognosis, whereas patients with dense or grape-like had many mutations and a poor prognosis for recurrence. As a result of evaluating 14 drugs by organoid subtype in a high-throughput drug evaluation system using a 384-well plate, normal-like or grape-like organoids showed a good response to single drug treatment. We observed that dense organoids, which exhibited resistant responses to single drugs, showed an increased synergistic effect when co-treated with the first-line standard chemotherapy drug, cisplatin, and the ATR inhibitor (bay1895344), compared to other subtypes.

#5205 ECM-free patient-derived organoids preserve diverse prostate cancer lineages and uncover in vitro-enriched cell types.

Robin Dolgos[1], Romuald Parmentier[1], Jing Wang[1], Raphaelle Servant[1], Arnoud J. Templeton[2], Tobias Zellweger[3], Alastair Lamb[4], Kirsten Mertz[5], Svetozar Subotic[6], Tatjana Vlajnic[7], Helge Seifert[8], Ashkan Mortezavi[8], Cyrill A. Rentsch[8], Lukas Bubendorf[7], Clementine Le Magnen[1]

[1]Institute of Pathology, Department of Urology, Department of Biomedicine, University Hospital Basel, University of Basel, Basel, Switzerland,[2]Division of Medical Oncology, Faculty of Medicine, St. Claraspital, University of Basel, Basel, Switzerland,[3]Department of Urology, St. Claraspital, Basel, Switzerland,[4]Nuffield Department of Surgical Sciences, Department of Urology, University of Oxford, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom,[5]Institute of Pathology, Kanton Baselland Liestal Hospital, Liestal, Switzerland,[6]Clinic for Urology, Kanton Baselland Liestal Hospital, Liestal, Switzerland,[7]Institute of Pathology, University Hospital Basel, University of Basel, Basel, Switzerland,[8]Department of Urology, University Hospital Basel, Basel, Switzerland

Background: Patient-derived organoids (PDOs) offer new opportunities to model various cancers. However, their application in prostate cancer (PCa) has been hampered by poor success rates and overgrowth of cell types which are not representative of the patient samples. Here, we aimed at modulating culture conditions and investigating *in vitro*-associated cellular heterogeneity to identify refined PCa PDO culture conditions.

Methods: A cohort of 164 diverse samples was obtained from 162 PCa patients undergoing radical prostatectomy, prostatic biopsies, transurethral resection of the prostate or the bladder or metastasis biopsy/resection. Out of this cohort, PDOs were established in various extracellular matrices (ECM: Matrigel, Collagen I, Collagen IV, Laminin-I, or no ECM) and medium compositions. PDOs were characterized using IF, IHC, and FISH. Single-cell RNA sequencing (scRNA-seq) was performed on 11 tumor and organoid samples, followed by unsupervised clustering, trajectory inferring, cell type annotation, and CNV analysis. Published spatial and bulk transcriptomic data were re-analyzed to validate specific markers. A prostate PDO scRNA-seq atlas was generated by integrating three published PDO datasets (Huang 2023, Song 2022, McCray 2019) together with our newly-generated data.

Results: Out of 5 ECM conditions, an ECM-free culture system increased the take-rate of PDOs with luminal-like ($CK5^-$, $CK8^+$, AR^+) and PCa features ($AMACR^+$, $PTEN^-$), while standard Matrigel-based culture conditions yielded basal-like benign organoids ($CK5^+$, AR^-, $AMACR^-$). Cellular composition of organoids generated in ECM-free conditions differed significantly from those generated in Matrigel, with minimal overlap observed in their transcriptomic profiles. ECM-free PDOs comprised cell populations associated with known PCa signatures, exhibited transcriptomic resemblance with their respective parental tumors, and maintained patient-specific epithelial populations. Furthermore, we defined organoid cell type signatures and identified markers discriminating between several types of benign cells (basal, hillock, club, transitioning) *versus* tumor cell populations *ex vivo* and *in situ*. Finally, our integrative single-cell atlas highlighted that Matrigel-based organoids derived from primary PCa are essentially composed of benign epithelial cells, irrespective of the dataset or the malignant nature of the tissue of origin. In contrast, ECM-free conditions preserved heterogenous tumor-like cell populations with higher inferred copy-number variations and were enriched in intermediate club-like cell populations.

Conclusions: ECM-free PCa PDOs exhibit improved fidelity and *in vitro*-enriched cell populations, while aberrant benign lineage programs are associated with Matrigel culture. Our work contributes to significantly enhancing the potential of PDOs in PCa research.

#5206 ADC efficacy and safety evaluation based on organoid models.

Yuhui Wang, Junwen Zhang, Jiawen Xu, Lin Feng, Junjie Zhu, Pengwei Pan, Fang He

Pharmaron Beijing Co., Ltd., Beijing, China

Introduction: Antibody-drug conjugates (ADCs) are effective cancer therapies that selectively deliver cytotoxic payloads to tumors. For the discovery of new ADCs, *in vitro* efficacy testing with organoids is crucial, as they replicate the 3D structure of tumors, providing a more accurate model for assessing the complex mechanism of action of ADCs. In this poster, we present an organoid-based ADC testing platform suitable for high-throughput screening. We demonstrate its application through a case study targeting human epidermal growth factor receptor 2 (HER2) to predict ADC efficacy and safety.

Method: We established multiple PDX-derived organoid (PDXO) models from different cancer types with low, medium or high expression levels of HER2, which we verified by RNA-seq and immunohistochemistry. Responses to four groups of HER2-targeted ADC drugs were evaluated in these models by assessing cell viability, including Trastuzumab deruxtecan, Trastuzumab duocarmazine, Trastuzumab emtansine, Trastuzumab MMAE, and their corresponding payloads (with or without linker). Furthermore, we conducted additional safety studies to assess the intestinal toxicity of these drugs using human intestinal organoids (HIO) derived from normal intestinal tissues.

Results: The HER2 expression levels in the *in vitro* cultured PDXO models were almost consistent at both RNA and protein levels, and they accurately reflected the expression status of the original tissues. The ADC screening revealed a differential sensitivity of organoids based on HER2 expression levels, with high HER2 expression correlating with increased sensitivity to ADC treatment, while low expression indicated resistance. Interestingly, normal organoid models were insensitive to ADC treatment, suggesting a potential for minimal side effects. However, the payloads alone demonstrated strong, unbiased cytotoxic activity against all models. In addition, the cytotoxic efficacy of payloads connected to linkers was significantly reduced, likely because the linkers hindered the payloads from entering the cells.

Summary: Our organoid-based ADC screening platform offers a rapid and reliable method for early high-throughput screening, pharmacology, and efficacy research that help bridge the gap between in vitro and in vivo studies. The translational results enhance the development process of ADCs through more accurate assessments of their potential effectiveness and safety.

#5207 Organoid-based drug screening identifies CDK9 as a target for stratified treatment of high-grade serous ovarian cancer.

Wojciech Senkowski[1], David Fontaneda-Arenas[1], Yilin Li[2], Kari A. Lavikka[2], Aura Crispino[1], Jakub Červinka[1], Francesca Gorini[1], Kyriaki Driva[1], Laura Gall-Mas[1], Lidia Moyano-Galceran[1], Jaana Oikkonen[2], Yan-Jun Chen[1], Karolin Vo?grone[1], Elin Pietras[1], Jutta Huvila[3], Kaisa Huhtinen[2], Johanna Hynninen[4], Sampsa Hautaniemi[2], Krister Wennerberg[1]

[1]University of Copenhagen, Copenhagen, Denmark,[2]University of Helsinki, Helsinki, Finland,[3]University of Turku, Turku, Finland,[4]Turku University Hospital, Turku, Finland

High-grade serous ovarian cancer (HGSC) is the most common and lethal ovarian cancer type. Despite favorable response to first-line therapy, most HGSC patients eventually relapse. HGSC presents few recurrent mutations that could be used as therapeutic biomarkers and hence, the progress with genomic-based precision HGSC treatment has been limited. We therefore took a functional precision medicine approach and asked whether we could identify patient-specific vulnerabilities of refractory HGSC using patient-derived organoids. We have previously established a collection of HGSC organoids[1], which is currently being expanded to a publicly accessible biobank of >100 stable and expandable cultures (OvaCure Collection, ovacurecollection.com). We also demonstrated that organoid drug responses correlate with clinical treatment outcomes[1].

Herein, in organoids from several HGSC patients, we performed a large-scale drug-response profiling of a library of 370 compounds. Of these, we found that inhibitors of CDK9 (CDK9i), but not other CDKs, demonstrated pronounced activity in subset of patients. CDK9i have not yet been thoroughly assessed for the treatment of HGSC, and only *MYC* overexpression has been considered as a sensitivity biomarker[2]. To explore the CDK9i responses in HGSC, we profiled 18 organoid cultures against selective CDK9i (AZD4573, VIP-152, NVP-2 and KB-0742). We observed a range of CDK9i-sensitivities in the patient cohort, from resistant cultures to exceptional responders. As all organoids have been previously characterized with whole genome- and RNA sequencing, we assessed genetic and transcriptomic differences between models to identify potential biomarkers of CDK9i sensitivity. *MYC* expression, biomarker of sensitivity in previous CDK9i clinical trials, did not correlate with CDK9i sensitivity in organoids (Pearson r = 0.244, p=0.346), suggesting its poor predictive value. However, we identified a set of genes, expression of which closely correlated with sensitivity (36 genes with Pearson r>0.7) or resistance (84 genes with Pearson r<-0.7) to CDK9i. For instance, expression of phosphodiesterase 3B (*PDE3B*) was correlated with CDK9i resistance (Pearson r = -0.744, p<0.001), while expression of *ERBB3* was correlated with increased CDK9i sensitivity (Pearson r = 0.841, p<0.0001). Taken together, we demonstrate the application of an HGSC organoid biobank for identifying patient-specific targets, exceptional responder groups and potential CDK9i sensitivity biomarkers in HGSC. Results of this project could serve as a basis for designing a molecularly stratified CDK9 inhibitor-focused clinical trial in refractory HGSC patients.

#5208 The use of human small intestinal organoids as a preclinical screening tool to assess gastrointestinal toxicity induced by CDK inhibition.

Frida Ponthan, Thomas Kedward, Valentina Ubertini, Gary Beale, Cath Booth

Epistem Ltd., Manchester, United Kingdom

Dysregulated cell division is one of the most important hallmarks of cancer. Cyclindependent kinases (CDKs), involved in cell cycle regulation, have been identified to be overexpressed in many cancers. The development of CDK inhibitors has emerged as a promising and novel approach for cancer treatment in both solid and hematological malignancies. However, first generation pan-CDKIs, which initially showed reliable results *in vitro* and in Phase I trials, lacked selectivity. Many were discontinued due to adverse effects, including Gastrointestinal (GI) toxicity, and reduced efficacy *in vivo*. The development of specific CDKIs, which can provide optimum therapeutic outcomes with good efficacy and reduced off-target effects are therefore needed.

In this study, we have used a human small intestinal organoid model (adapted from Sato *et al*. 2009), as a screening tool to predict GI toxicity and subsequent mucosal regeneration. The culture conditions have been designed to mimic the stem cell niche and allow cell differentiation and proliferation to occur. All intestinal lineages were present in the organoids and resembled the frequency of linage observed *in vivo*.

The effect of several clinically available CDKIs, such as Dinaciclib, Palbociclib and Abemaciclib, some of them known to induce GI toxicity were assessed. Treatment was applied on Day 3 after plating of fragments, when the organoid structures had formed. On Day 5, the number of dead, viable unbranched and branched organoids were counted and IC50 values were calculated. Furthermore, morphometric analysis of acquired images were performed. To compare the toxicity profiles on a molecular level, organoids were harvested for RNA-seq.

The second generation pan-CDK inhibitor Dinaciclib was the most toxic. Whereas Palbociclib was the least toxic compound within the human organoid assay, reflecting clinical data that shows the lowest incidence of severe diarrhea.

We conclude that organoids are a predictive preclinical model that can be used to identify potential on-target, off-tissue GI toxicities induced by novel therapeutics such as CDKIs. Toxicity and mechanism of action (MOA) can all be addressed *in vitro* to potentially reduce *in vivo* experimentation.

#5209 Sequential orthogonal assays for longitudinal and endpoint characterization of three-dimensional cell and tissue culture models.

Olivier De Wever, Eva Blondeel

Ghent University Hospital, Gent, Belgium

Spheroids are near-spherical reaggregated multicellular three-dimensional (3D) structures generated from cells or cell cultures from healthy as well as pathological tissue. Basic and translational spheroid application across academia and industry led to the development of multiple set-ups and analysis methods which mostly lack the modularity to maximally phenotype spheroids. This protocol presents the self-assembly of single-cell suspensions into spheroids by the liquid overlay method followed by a modular framework for a multifaceted phenotyping of spheroids. Cell seeding, supernatant handling, and compound administration are elaborated by both manual and automated procedures. The phenotyping modules contain a suite of orthogonal assays to analyze spheroids longitudinally and/or at an endpoint. Longitudinal analyses include morphometry with/out spheroid or cell state specific information, and supernatant evaluation (nutrient consumption and metabolite/cytokine production). Spheroids can also be used as starting point to monitor single and collective cell migration and invasion. At an endpoint, spheroids are lysed, fixed, or dissociated into single cells. Endpoint analyses allow to investigate molecular content, single-cell composition and state, and architecture with spatial cell and subcellular specific information. Each module addresses time requirements and quality control indicators to support reproducibility. The presented complementary techniques can be readily adopted by researchers experienced in cell culture and basic molecular biology. We anticipate that this modular protocol will advance the application of 3D biology by providing scalable and complementary methods.

TUMOR BIOLOGY: Shaping Tumor Stromal Interactions in Cancer
Poster Session

#5213 Understanding how IDVCs (IDO1-dependent vascularizing cells) respond to and shape the inflammatory milieu to promote neovascularization.

S.-C. Shen[1], J. B. DuHadaway[2], E. Sutanto-Ward[2], G. C. Prendergast[2], A. J. Muller[2];
[1]Drexel University College of Medicine, Philadelphia, PA, [2]Lankenau Institute for Medical Research, Wynnewood, PA

Inflammation and angiogenesis are considered fundamental processes within the TME to the extent that they have been designated “hallmarks of cancer”. In studying tumor development in the lungs, we discovered that the tryptophan catabolizing enzyme IDO1 interconnects these two processes by realigning local inflammation to promote neovascularization. Specifically, the inflammatory cytokine IFNγ elicits neovascular regression, however, it is also a primary inducer of IDO1, which acts in a negative feedback capacity to counter the anti-neovascular activity of IFNγ through the GCN2/ISR dependent induction of an opposing inflammatory cytokine IL6. At the heart of these studies has been the identification of a unique, IDO1-expressing myeloid cell population designated IDVCs (IDO1-dependent vascularizing cells) based on their functional capacity to support neovascularization in an IDO1 dependent manner. A powerful tool used in these studies to analyze the biological activity of isolated IDVCs is the Matrigel plug assay in which FACS sorted cells are incorporated into a subcutaneously implanted Matrigel plug, which is subsequently evaluated by confocal microscopy for blood vessel density.
An actionable breakthrough in addressing the fundamental question of how the inflammatory cytokines IFNγ and IL6 respectively promote and mitigate neovascular regression has emerged from subsequent studies that have identified the NOS2 enzyme, previously implicated in facilitating the IFNγ mediated anti-tumor response, as playing a downstream effector role in driving neovascular regression. Based on aggregate evidence obtained from analyzing 4T1 metastatic tumors and Matrigel plugs, we have constructed a basic conceptual framework for how inflammatory neovascularization is orchestrated by IDVCs. The likely source of IFNγ appears to be NK cells, though how they are recruited and activated by IDVCs remains to be determined. In response, the IFNγ inducible chemokine CXCL10, also apparently produced by IDVCs and signaling through its receptor CXCR3, serves a bridging role leading to the induction of NOS2. However, through induction of IDO1 in IDVCs, IFNγ also drives IL6 trans-signaling, which counteracts the CXCL10/NOS2 neovascular regression pathway. Underlying all this, the initial process of establishing the neovasculature, which is also orchestrated by IDVCs but independently of IDO1, appears to involve vasculogenesis (vessels formed by recruited endothelial progenitor cells, EPCs) as it requires signaling by CXCL12, a key chemokine for EPC attraction. As we continue to interrogate how inflammatory neovascularization, autonomously nucleated by IDVCs, unfolds, we anticipate these ongoing investigations will continue to yield even deeper insights into the regulatory crosstalk between these complex biological processes involved in cancer and other diseases.

#5214 Nuclear APC maintains colon homeostasis and mitigates inflammation.

A. James, K. Neufeld;
University of Kansas, Lawrence, KS

Adenomatous polyposis coli (APC) is critical for maintaining intestinal homeostasis. Although widely recognized for its cytoplasmic tumor suppressor functions, the roles of APC in other subcellular compartments and inflammation are less defined. To investigate nuclear APC functions, we developed a mouse model with compromised nuclear Apc import ($Apc^{mNLS/mNLS}$ mice). $Apc^{mNLS/mNLS}$ mice displayed lower levels of mucin-2 (*MUC2*) RNA, the primary component of the intestinal mucus barrier, and had significantly thinner colonic mucus layers. These mice were more susceptible to experimentally induced colitis than their wild-type littermates. Importantly, male $Apc^{mNLS/mNLS}$ mice exhibited significantly increased weight loss and higher colitis scores compared to female mice. Therefore, we hypothesize that nuclear APC promotes gut barrier integrity by upregulating *MUC2* expression. In cultured human colon cells, APC positively regulates *MUC2* RNA levels and inhibits NF-κB signaling. Overall, this study provides evidence that nuclear APC upregulates colonic *MUC2* expression, increases the mucus barrier, and inhibits colonic inflammation. Furthermore, our results reveal notable sex-specific differences in colitis susceptibility.

#5215 IL-17RA expression by NSCLC is vital for restraining homeostatic tumor cell proliferation and baseline cytokine production.

Dongpu Li, Jun Wang

Microbiology and Immunology, Dalhousie University, Halifax, NS, Canada

Background: Lung cancer is the leading cause of cancer-related death worldwide. The Cancer Genome Atlas shows over 30% of non-small cell lung cancer (NSCLC) samples carrying genetic alterations in the *IL17RA* gene, and deletion of *IL17RA* is linked to poor overall survival rates. IL17RA is a transmembrane protein with multiple intracellular signaling motifs. The SEFIR domain is required for IL17-induced signaling, which is negatively regulated by A20 (TNFAIP3) via a self-feedback loop. The objective of our study is to examine the impact of IL17RA-deletion in NSCLC and the underlying molecular mechanisms.
Methods: Two complementary approaches were used in our study. IL17RA knockdown subclones were created in murine lung cancer cell lines (LLC and CMT167) via shRNA. Human NCIH23 cells carry homozygous deletion of *IL17RA* gene, whereas human A549 cells possess normal copy number of *IL17RA*gene. We expressed IL17RA in both human cell lines via a lentiviral vector. The effects of IL17RA expression on the tumor cell proliferation and the production of soluble mediators were compared in paired cell lines, with and without IL17RA expression. Domain-specific IL17RA mutants were constructed in NCIH23 cells to dissect their functional contributions. Western blots and human phosphorylation pathway profiling arrays were used to study how signaling pathways were affected by IL17RA-deletion.
Results: The knockdown of IL17RA significantly augmented the proliferation of cancer cells in LLC and CMT167 cells. Conversely, the expression of full-length IL17RA in both NCIH23 and A549 cells diminished proliferation rates. Furthermore, IL17RA knockdown increased the production of multiple proinflammatory cytokines, chemokines, and growth factors, whereas IL17RA expression in NCIH23 markedly inhibited their production. We showed that the SEFIR domain was not required for the effects of IL17RA expression on restraining tumor cell proliferation, while it is known to be vital for IL17A-induced cytokine production. The reduced expression of IL17RA was consistently associated with diminished A20 expression in all tested cell lines. Finally, we demonstrate that IL17RA-deletion caused a marked increase of Glycogen synthase kinase 3 beta (GSK3β) Serine-9 phosphorylation, an inactivated form of GSK3β, in NCIH23 cells.
Conclusion: Collectively, our data clearly demonstrate that IL17RA expression is critically required for restraining homeostatic tumor cell proliferation and baseline cytokine production via a previously undefined IL17RA-A20-GSK3β axis.

#5216 RPS19-C5AR1 axis in tumor-associated macrophages drives glioblastoma progression: Insights from single-cell transcriptomics.

Chan-Chuan Liu[1], Gangga Anuraga[2], Cheng-Lin Wu[3], Jian-Ying Chuang[4], Chih-Yang Wang[5], Pin-Yuan Chen[6], Kwang-Yu Chang[1]

[1]National Institute of Cancer Research, National Health Research Institutes (NHRI), Tainan, Taiwan,[2]PhD Program for Cancer Molecular Biology and Drug Discovery, Taipei Medical University, Taipei, Taiwan,[3]Department of Pathology, National Cheng Kung University Hospital, National Cheng-Kung University, Tainan, Taiwan,[4]Research Center for Neuroscience, International Master Program in Medical Neuroscience, Taipei Medical University, Taipei, Taiwan,[5]PhD Program for Cancer Molecular Biology and Drug Discovery, Taipei Medical University, Tainan, Taiwan,[6]Department of Neurosurgery, School of Medicine, Chang Gung Memorial Hospital, Chang Gung University, Taoyuan, Taiwan

Glioblastoma (GBM) is a prevalent and lethal disease with limited treatment options. Tumor-associated macrophages (TAMs), which comprise up to 30% of the GBM mass, play a pivotal role in shaping the TME by supporting tumor growth and establishing an immunosuppressive and inflammatory environment. To investigate how tumor cells affect TAMs during TME evolution, we analyzed single-cell transcriptomics (SCT) datasets from GBM patient-derived tumor mass (Core) and peri-tumoral adjacent tissues (Margin), alongside murine datasets from healthy and GL261-bearing brains. This comparison aimed to clarify the immunological landscapes of GBM and identify specific interactions between tumor cells and TAMs. Margin SCT data revealed increased cellular heterogeneity compared to the Core, with immune cells, tumor cells, and brain stromal cells contributing 57%, 3%, and 40% of the total cell population, respectively. UCell analysis of GBM subtype signatures demonstrated a strong association between TAMs in the Margin and mesenchymal signatures, which are linked to poor prognosis. Further reclustering of TAMs in Margin and the comparison with murine SCT datasets showed that these cells were predominantly derived from peripheral monocytes and macrophages, with M1-like TAMs representing the majority. Pseudotime trajectory analysis revealed that M1-like TAMs serve as precursors to protumoral M2 TAMs. Cell-cell communication mediated by ligand-receptor interactions among tumor cells, TAMs, T cells, and NK cells identified a critical interaction between tumor-derived ribosomal protein S19 (RPS19) and C5AR1 on TAMs. C5AR1 was highly expressed in M1-like TAMs across patient and murine datasets, while RPS19 was ubiquitously expressed by all cell types. *In vitro* models confirmed that M1 macrophages and microglia exhibited higher C5AR1 expression than their M2 counterparts. Analysis of public datasets (The Cancer Genome Atlas-GBM and Chinese Glioma Genome Atlas) showed elevated C5AR1 expression in GBM tissues, particularly in recurrent tumors, and a strong correlation between high C5AR1 expression and poor patient survival. Additionally, tumor-derived RPS19 was released extracellularly under growth stress or therapeutic interventions, promoting an inflammatory TME through M1 TAM polarization and driving GBM progression. These findings suggest that targeting the RPS19-C5AR1 axis, in combination with current therapies, may represent a promising strategy to improve GBM outcomes.

#5217 Interaction of cancer associated fibroblasts and apoptotic cancer cells reduces macrophage survival and promotes reprograming of tumor associated macrophages.

Jihee Lee Kang, Kyungwon Yang, Kiyoon Kim

Ewha Womans University, Seoul, Korea, Republic of

Recent studies highlight the critical role of cancer-associated fibroblasts (CAFs)- tumor-associated macrophages (TAMs) interactions in tumorigenesis. In prior work, we demonstrated that the interaction between CAFs and apoptotic cancer cells can inhibit tumor growth and metastasis. However, the molecular mechanisms underlying the crosstalk between CAFs reprogrammed by apoptotic cancer cells and TAMs are incompletely understood. In this study, we show, using immunohistochemistry in primary tumors, that intratumoral injection of conditioned medium (CM) from lung CAFs exposed to apoptotic cancer cells reduces the density of tumor-associated macrophages (TAMs) and the proportion of M2 TAMs. Additionally, this treatment shifts M2 TAMs toward an M1-like phenotype within the tumor microenvironment (TME). Furthermore, CM from apoptotic cancer cell-exposed CAFs promotes STAT1 phosphorylation in M2 TAMs. Depletion of WISP-1 from the CM reversed these effects, emphasizing its pivotal role. These findings suggest that CM from apoptotic cancer cell-exposed CAFs may provide a promising therapeutic strategy for targeting TAMs in the TME.

#5218 RGS4+aSMA+CAF subsets promote tumor immune escape by regulating the formation of immune-exhaustive mesenchymal networks.

Huiping Chen, Wenfeng Zeng

Sun Yat-sen University, Guangzhou, China

Solid tumors consist of tumor cells and the tumor microenvironment (TME), a dynamic system comprising various immune cells, mesenchymal cells, cytokines, microvesicles, extracellular matrix, and vascular lymphatic networks. The recruitment of lymphocytes into tumors is essential for effective anti-tumor immunity and successful immunotherapy. The tumor stroma serves as the initial site for effector immune cell infiltration, and the mesenchymal network directly influences immune cell function. Cancer-associated fibroblasts (CAFs) are the largest proportion of TME intrinsic stromal cells, with significant heterogeneity and multiple origins, and perform different biological functions. CAFs can not only induce PD-L1 expression in tumor cells, but also promote PD-L1 expression in TME immune cells through the release of cytokines and vesicles, thereby facilitating tumor immune escape. In this study, we found that in some breast cancer patients, PD-L1 in tumor stroma was abundantly expressed and associated with immunosuppression and poor prognosis, and the distribution of tumor stromal PD-L1 was also closely related to the activation status of CAFs. Furthermore, we performed high-throughput RNA sequencing on PD-L1^{low} and PD-L1^{high} stroma cells, respectively. We found a CAF subset in high PD-L1 expression group, which was characterized by immune exhaustion and hyperactivation. Notably, Regulator of G protein signaling 4 (RGS4) pathways were significantly upregulated in this subset. Furthermore, we confirmed that RGS4 induces fibroblasts to adopt a PD-L1 immunodepleting phenotype and establishes an immune-exhaustive mesenchymal network that modulates anti-tumor immunity. In addition, we validated in humanized murine models that targeting RGS4 significantly enhances the efficacy of immunotherapy in animal models. The spatial heterogeneity of PD-L1 expression in TME is a primary factor contributing to the limited efficacy of PD-L1/PD-1 antibody therapies. Currently, numerous studies aim to enhance the immune response by inhibiting or degrading PD-L1. A comprehensive understanding of the molecular mechanisms governing PD-L1's spatial distribution could fundamentally enhance its clinical application. This study explored the mechanism governing the spatial distribution difference of PD-L1, and provided more possibilities for the development of targeted intervention in CAFs.

#5219 Taxanes induce interleukin 6 cytokine in women's cancer and stromal cells in vitro.

Samantha S. Yee, Jacky Gomez-Villa, Sonia L. Hernandez

University of Chicago, Chicago, IL

Background: Taxane microtubule stabilizers, including paclitaxel (PTX), docetaxel (DTX) and nab-paclitaxel (Nab-PTX), are standard of care in the treatment of women's cancer alone or in combination with other therapies. The effects of specific taxanes on cancer cells have been well studied such as disruption of cell division and inhibition of cellular trafficking, inducing cancer cell death; however, their effect on the tumor microenvironment is less understood. Cytokines released by cancer cells into the tumor microenvironment such as interleukin 6 (IL-6) can contribute to therapeutic resistance. Specifically, IL-6 binds to the IL-6 receptor (IL-6R) consisting of alpha and beta subunits, and activates the JAK/STAT signaling pathway, promoting chemoresistance. Taxane effects on tumor microenvironment, specifically tumor vasculature, have been less studied. We hypothesized that PTX, DTX, and Nab-PTX, including pericytes, and human dermal lymphatic endothelial cells (HDLECs), result in IL-6 secretion unique to each taxane, promoting chemoresistance.
Methods: Primary human pericytes and HDLECs, 5 human women's cancer cell lines, and 2 human breast epithelial cell lines were grown in vitro. The CCK-8 cell viability/cytotoxicity assay determined IC_{50} potency for the taxanes in primary human cells and cancer cells. Quantitative-PCR and cytokine arrays were used to evaluate IL-6 transcript levels and protein secretion, and flow cytometry to determine the abundance of IL-6 receptors at the cell surface.
Results: DTX had the lowest IC_{50} values with a range of 0.3 - 2.1 nM, followed by PTX with 1.0 - 4.0 nM, and Nab-PTX with 2.9 - 64.5 nM after 72h treatment across 5 different cancer cell lines. DTX and PTX increased IL-6 transcript levels more than 2-fold following 24h treatment, $p<0.05$), whereas Nab-PTX showed a slight increase ($p > 0.05$). MDA-MB-231 cells had the highest basal IL-6 transcript levels compared to cancer and stromal cells. All cells tested expressed both IL-6R subunits at varying levels, suggesting taxane chemoresistance via IL-6R activation is possible in cancer cells and tumor associated cells. Primary human pericytes or HDLECs did not reach 50% survival following 24h treatment of 10 nM taxanes. DTX increased pericyte IL-6 transcript levels by two-fold following 24h treatment, $p<0.05$. Preliminary cytokine array data revealed IL-6 was increased in 10 nM DTX-treated pericytes following 24h treatment compared to DMSO (2-fold change).
Summary: We show that DTX is the most potent taxane following 72h treatment. DTX also induces IL-6 production in both women's cancer cell lines and stromal cells, potentially contributing to chemoresistance and cancer progression. All cells express varying levels of IL-6R subunits, suggesting that combining DTX treatment with IL-6 inhibitors may prevent DTX resistance in women's cancer patients.

#5220 Regulating tumor-associated macrophage polarization via inhibition of hedgehog signaling for treating colorectal cancer liver metastasis.

Bu Gyeom Kim[1], Bo Ram Kim[1], Dae Yeong Kim[1], Hyemi Yun[2], Okhyeon Kim[2], Yoon Namgung[1], Jun Woo Bong[3], Sanghee Kang[3], Sun Il Lee[3], Sang Cheul Oh[1]

[1]Department of Oncology, Korea University Guro Hospital, Seoul, Korea, Republic of,[2]Biomedical Sciences, Korea University College of Medicine, Seoul, Korea, Republic of,[3]Surgery, Korea University Guro Hospital, Seoul, Korea, Republic of

Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related mortality worldwide. The liver is the most frequent site of metastasis in patients with CRC. Approximately 15-25% of patients with CRC have synchronous liver metastasis (LM). Despite the development of surgical techniques and targeted therapy, the prognosis of colorectal cancer liver metastasis (CRLM) remains poor. The tumor microenvironment (TME) is composed of cancerous and non-cancerous cells, including fibroblasts, endothelial cells and immune cells, as well as non-cellular components. As a major component of immune cells in the TME, tumor-associated-macrophages (TAMs) account for up to 50% of cells in the tumor mass and are generally relevant to worse prognosis in cancer patients. TAMs are an important component of the immunosuppressive TME, but the precise mechanisms of the interactions between TAMs and tumor cells are still not completely understood. The hedgehog (Hh) signaling pathway is aberrantly activated in multiple types of human cancer. Hh signaling pathway plays an important role in tumorigenesis, including promoting tumor invasion, metastasis, and multi-drug resistance. However, it remains to be elucidated how Hh ligands ac on stromal cells within the TME to promote tumor growth and what cell types are involved in this process. In this study, we established an irinotecan-resistant colorectal cancer cell lines to represent liver metastatic colorectal cancer. We then found that irinotecan-resistant colorectal cancer cells significantly increased SHH secretion using quantitative reverse transcription PCR (qRT-PCR) and an ELISA assay. Subsequently, we used a THP-1 and bone marrow-derived monocytes (BMDMs) to determine whether Hh signaling and metastatic colorectal cancer cells affect the polarization and activity of macrophages. We found that tumor cells-derived SHH induced M2 polarization of TAMs under tumor cells-derived conditioned medium and co-culture systems using Western blot and Flow cytometry analysis. Moreover, phagocytosis ability of macrophages was decreased with irinotecan-resistant colorectal cancer cells compared with irinotecan-parent colorectal cancer cells under co-culture systems. To further investigate whether inhibition of Hh signaling affects macrophage polarization, we treated with Vismodegib, a Hh signaling inhibitor. M2 macrophage polarization increased by SHH was reduced by Hh signaling inhibitor treatment. Furthermore, TISIDB revealed that SHH was strongly negatively correlated with macrophage abundance and CD80, CD86 in COAD patients In conclusion, our study identified a novel mechanism for macrophage polarization through Shh signaling pathway and provided insights into developing macrophage-targeted therapeutic strategies for CRLM patients.

#5221 Immune-organoid cocultures to investigate the role of herpesvirus serology in oncolytic viral therapy for glioblastoma.

Ethan Chen[1], Alexander L. Ling[1], Michael C. Prabhu[2], Connor C. Bossi[3], Keith L. Ligon[4], E Antonio Chiocca[1]

[1]Neurosurgery, Brigham and Women's Hospital, Boston, MA,[2]West Virginia University School of Medicine, Morgantown, WV,[3]UMass Chan Medical School, Worcester, MA,[4]Pathology, Dana-Farber Cancer Institute, Boston, MA

Background: Complex relationships between treatment and intratumoral immunity are challenging to study in glioblastoma patients owing to the dynamic nature of these relationships and the difficulty in obtaining serial tissues from brain tumors. The importance of these processes necessitates the development of robust model systems that enable researchers to study immune dynamics in controlled and clinically relevant ways. To this end, we have generated a panel of patient derived organoids from glioblastoma patients with paired PBMCs and known clinical features. We are leveraging these models to more deeply study our recently published finding that patients with pre-existing seropositivity to herpesvirus 1 (HSV1) survive significantly longer than seronegative patients when treated with an engineered oncolytic HSV1 agent.

Methods: Resected tumor tissues were freshly obtained and cultured to establish glioblastoma organoids alongside paired PBMC and plasma samples. To assess differential immune activation between HSV1 seropositive and seronegative models, PBMCs were expanded for all antigen-experienced immune cells using IL-21, IL-15, and IL-7 and cocultured with their paired organoid in the presence or absence of oncolytic HSV1 infection. Cocultures were observed for spatial dynamics and viral infectivity under time lapse microscopy over 72 hours, followed by flow cytometric analysis at endpoint.

Results: Viable organoid cultures were successfully generated for 8 patients over a 7 month period, with paired PBMCs/plasma being available for 5 of these patients, of which two were HSV1 seropositive. Optimization experiments confirmed that expanded T cells and organoids could be cocultured for 72 hours, enabling interrogation of tumor-immune interaction dynamics. Initial results from our cocultures revealed serology-dependent T cell activation in the context of HSV1 infection, with effector CD4 T cells increasing with virus infection in seropositive but not seronegative coculture models.

Conclusion: Our results demonstrate that we can rapidly generate glioblastoma organoids with a high success rate. By coculturing these models with paired patient PBMCs, we were able to study dynamic tumor-virus-immune interactions with a high degree of spatiotemporal resolution. We believe this approach holds significant promise for enabling novel insights into the dynamic impact of immunotherapy on the tumor-immune microenvironment-potentially providing critical insights into why these therapies often show limited efficacy in glioblastoma and how they can be improved.

#5222 Establishment of a patient-derived organoid-PBMC co-culture model to investigate immune responses and immunotherapy sensitivity in advanced gastric cancer.

Han Byeol Mun[1], Woo Sun Kwon[2], Tae Soo Kim[2], Sun Young Rha[3]

[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University Health System., Seoul, Korea, Republic of

Advanced gastric cancer (AGC) exhibits significant molecular heterogeneity with aggressive behavior and treatment resistance. Immunotherapy (IO), such as PD-1 or PD-L1 inhibitors, has emerged as an important treatment for AGC, but only a small subset of patients responds to these therapies. Therefore, it would be of great benefit to understand mechanisms of anti-tumor immune response in AGC patients. This study aims to establish a co-culture model of patient-derived GC organoids and PBMCs that can recapitulate tumor-immune interactions PBMCs were isolated from healthy donors, pooled equally, and cryopreserved. They were activated with anti-CD3/CD28 Dynabeads at ratios of 1:1 (Bead : Cell) for 48 hours and stained with 1 μM CellTrace Far Red. Organoids with a diameter of ≥50 μm were harvested, filtered through a 50 μm strainer, and seeded (50 per well) into 96-well plates at ratios of 1:1 to 200:1 (PBMCs : Organoids). Pembrolizumab was treated in mono-culture and co-culture assays at a ratio of 50:1 for 48 and 72 hours, and sensitivity was measured with CCK-8. PBMC recruitment was analyzed using the Operetta CLS system and Harmony 4.9 software. Supernatants were collected post-co-culture and analyzed for cytokines (IL-2, IL-4, IL-6, IL-10, TNF, IFN-γ, and IL-17A) using BD Cytometric Bead Array, with values below the detection limit excluded from the analysis. In co-culture conditions, the organoids exhibited variable responses depending on the ratio in the co-culture conditions. YCC-GO10-1 showed 63.1% viability with a 5-fold increase in PBMC recruitment, while YCC-GO63 showed 14.8% viability with a 1.6-fold increase. This indicates that increased PBMC recruitment is not necessarily associated with organoid death. In the co-culture supernatant of YCC-GO10-1, higher levels of inflammatory cytokines were observed compared to YCC-GO63, including IL-6, a cytokine that promotes tumor progression, as well as IFN-γ, TNF and IL-2. Pembrolizumab had no impact on the viability of organoids or PBMCs under monoculture conditions. However, under co-culture conditions, it exhibited variable effects on organoid viability, reducing the viability of YCC-GO63, while YCC-GO10-1 remained resistant to the treatment. Even under identical immune environments, organoids displayed heterogeneous responses, resulting in distinct immune reaction patterns and cytokine secretion profiles. The established organoid-immune cell co-culture model demonstrates the potential to investigate tumor-immune interactions and study the mechanisms underlying sensitivity to IO, antibody-drug-conjugates, and other anticancer agents *in vitro*.

#5223 Deciphering cellular heterogeneity and therapeutic responses in NSCLC through scRNA-seq analysis.

Hwajin Choi[1], Kyoung-Ho Pyo[2], Sun Min Lim[2], Byoung Chul Cho[2], Seunghee Hong[1]

[1]Yonsei University, Seoul, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of

Programmed cell death protein and its ligand (PD-1 / PD-L1) blockades have been approved for the treatment of metastatic non-small cell lung cancer (NSCLC). PD-L1 binds to PD-1 and functions as a co-inhibitory factor. It is well known that in cancer, PD-L1 is highly expressed hence cancer cells can evade the host immunity in the tumor microenvironment (TME). Although PD-1 / PD-L1 blockades have been clinically utilized, the biological factors determining treatment outcome remain convoluted. An in-depth investigation of cellular heterogeneity including both cell subtypes and states (defined by cellular biomolecular programming) will provide foundational evidence for clinicians and researchers to improve PD-1 / PD-L1 immunotherapeutic practice. The recent decade has shown an explosive growth of single-cell RNA sequencing (scRNA-seq) to study biomedical phenomena. In contrast to bulk RNA-seq, scRNA-seq enables researchers to properly decipher and analyze the complex cellular heterogeneity. Our scRNA-seq data spans 674,609 cells populating early, late, metastatic stage lung cancer and the normal lung tissues from 100 subjects. Especially, part of our metastatic samples harbor classification based on the existence of immune checkpoint blockade (ICB) treatment and therapeutic efficacy of the treatment. Our scRNA-seq analysis results thoroughly provide an intensive comprehension of dysregulation in T cells. This single-cell analysis potentially reveals pathways targeted by immunotherapy and discovers possible therapeutic targets which could be combined with the current immunotherapy for the synergistic effects.

#5224 Systemic microenvironment determines the disease outcome in murine models of breast cancer.

Fulya Koksalar Alkan[1], Ahmet Burak Caglayan[1], Hilmi Kaan Alkan[1], Cordarryl Jones[1], Adriana Langer Gramer[2], Roni Bollag[2], Eric Sebzda[1], Kristen S. Purrington[1], Max Wicha[3], Huidong Shi[2], Hasan Korkaya[1]

[1]Wayne State University, Detroit, MI,[2]Augusta University, Augusta, GA,[3]University of Michigan, Ann Arbor, MI

The systemic immune microenvironment plays a critical role in determining disease outcomes in breast cancer, yet its molecular and functional characteristics remain largely unknown. Using single-cell RNA sequencing (scRNAseq), CyTOF, and functional assays, we investigated immune dynamics in metastatic (4T1) and non-invasive (EMT6) murine models of triple negative breast cancer (TNBC). While primary tumors in both models exhibited similar infiltration by macrophages and myeloid-derived suppressor cells (MDSCs), profoundly distinct immune profiles in target tissues of metastatic mice. In the metastatic 4T1 model, metastatic tissues showed an expansion of neutrophil progenitors and immature neutrophils ($CD11b^{+}CD33^{+}Ly6G^{+}CD115^{-}Ly6C^{low}$) at the expense of natural killer (NK) cells, T cells, and B cells. These immature neutrophils mediated systemic immune suppression, contributing to the establishment of pre-metastatic niches where they regulate cancer stem cell (CSC) proliferation. Recombinant S100A8/A9 (calprotectin) proteins induced a similar expansion of these immunosuppressive neutrophils in EMT6 models, driving metastasis and immune evasion. In contrast, S100A9 knockout mice showed reduced metastatic burden and enhanced anti-tumor immune responses. Depletion of $Ly6G^{+}$ immature neutrophils using anti-Ly6G antibody significantly restored systemic anti-tumor immunity and eliminated metastasis, while having no effect on primary tumor growth. Conversely, depletion of $CD115^{+}$ macrophages selectively inhibited EMT6 tumor growth without altering systemic immune profiles. Our findings highlight the critical influence of systemic immune dynamics in shaping metastatic progression and therapeutic resistance. The identification of neutrophil progenitors and inflammatory S100A8/A9 proteins as key mediators of immune suppression offers novel insights into the interplay between systemic immunity and tumor biology. Targeting these components may provide a promising approach to mitigating metastasis and improving therapeutic outcomes in aggressive breast cancer subtypes.

#5225 Engineered signaling reporter immune cell lines for monitoring immune activation and multidirectional interactions among cancer cells, immune cells, and tumor microenvironmental cells.

Hyeyoun Chang, Alicia Walker, John Foulke, Luping Chen, **Fang Tian**, Zhizhan Gu

ATCC, Gaithersburg, MD

While immunotherapies targeting T cells have achieved remarkable success, a significant subset of patients remain unresponsive or experience relapse, often attributed to the immunosuppressive nature of the tumor microenvironment. Emerging evidence suggests that other immune cell types, such as B cells and myeloid cells, play crucial roles in modulating the efficacy of cancer immunotherapies. However, there remains a clear lack of widely accessible immunological models capable of accurately representing the intricate multidirectional interactions among cancer cells, adaptive and innate immune cells, and other tumor microenvironmental cells. To address this gap, we engineered signaling reporter cell lines of T cell, B cell, or myeloid origin to express luciferase reporter protein in response to the activation of nuclear factor of activated T cells (NFAT) or nuclear factor kappa B (NF-κB) signaling pathway. The cell lines also endogenously express high level of T cell checkpoints (PD-1, TIGIT, and/or GITR) or myeloid checkpoints (SIRPα, Siglec-10, LILRB1, and/or B7-1) for additional application in immune checkpoint research. To validate luciferase expression, NFAT luciferase reporter T cell lines were stimulated with phorbol 12-myristate 13-acetate (PMA) and ionomycin, while NF-κB luciferase reporter myeloid cell lines were activated with tumor necrosis factor alpha (TNF-α) or conditioned media from T cells. A B cell-derived NF-κB reporter cell line (BDCM-NFκB-Luc2) with high basal luciferase activity was treated with an NF-κB signaling inhibitor. These reporter cells were subsequently evaluated in various co-culture conditions with primary immune cells, cancer cells, and/or other tumor microenvironmental cells to study immune cell crosstalk. Luciferase assays were performed for convenient quantification of luminescence intensity under all conditions. The results demonstrated that stimulations leading to NFAT or NF-κB signaling activation yielded dose-dependent increase in luciferase expression. In contrast, inhibition of the signaling led to dose-dependent decrease in luciferase expression. Furthermore, co-culture of reporter cell lines with various other immune and cancer cells significantly enhanced luminescence signals, with increases of up to 200-fold. In summary, these newly developed luciferase reporter immune cell lines provide a robust ex vivo model for evaluating cancer immunotherapies. These cell lines enable sensitive and reproducible monitoring of complex interactions among cancer cells, innate and adaptive immune cells, and other tumor microenvironmental cells, offering a valuable standard for the assessment of combinatorial immune responses in the tumor microenvironment.

#5226 CD47-Sirpαblockade enhances antitumor activity against mouse liver cancer by boosting cDC2 functions.

Guan-Sian Low[1], Cheng-Zhe Jian[2], Yi-Chiao Tseng[1], Da-Liang Ou[2], Chiun Hsu[3], Chien-Kuo Lee[1]

[1]Graduate Institute of Immunology, National Taiwan University College of Medicine, Taipei, Taiwan,[2]Graduate Institute of Oncology, National Taiwan University College of Medicine, Taipei, Taiwan,[3]Department of Medical Oncology, National Taiwan University Cancer Center, Taipei, Taiwan

The CD47-SIRPα axis functions as an immune checkpoint, transmitting a “don’t eat me” signal to prevent macrophage-mediated phagocytosis of tumor cells. While CD47 is expressed on most immune cells and is highly induced in tumor cells, SIRPα is expressed on phagocytes, including macrophages and type II conventional dendritic cells (cDC2s). Blocking the binding between CD47 and SIRPα is shown to promote antitumor immunity. However, the mechanism of how CD47-Sirpα blockade regulates DC functions is still unclear. Here we demonstrated that anti-CD47 and/or anti-Sirpα antibodies increased the phagocytic activity and antigen presentation of MutuDC2, a cDC2 cell line, against Hepa1-6, a mouse hepatocellular carcinoma cell line expressing LCMV-GP protein. Moreover, CD47 blockade also enhanced BM-derived cDC2 functions in boosting the proliferation and cytotoxic activity of P14 CD8 T cells in vitro. More importantly, anti-CD47 antibodies reduced tumor growth in vivo and cDC2s and IFNγ+ functional CD8 T cells were enriched in the tumor microenvironment compared to isotype control. In conclusion, CD47-Sirpα blockade boosts cDC2 functions, including phagocytic activity, antigen presentation, and cross-presentation ability, eliciting a better antitumor activity in antigen-specific CD8 T cells and emphasizes the therapeutic benefits of immune checkpoint blockade through cDC2.

#5227 Extrachromosomal MYC-paralogs amplification shapes suppressive tumor microenvironment in small cell lung cancer.

Jingwei Zhang[1], Yueqi Jin[2], Ence Yang[2], Xiao Li[1]

[1]Peking University People's Hospital, Beijing, China,[2]School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China

Introduction: Although immunotherapy has demonstrated promise in small cell lung cancer (SCLC), certain patients encounter limited benefits, highlighting the need for identifying immunosuppressive biomarkers. Extrachromosomal circular DNA (ecDNA) promotes amplification of MYC-paralogs, which drive cross-resistance in SCLC. Here, we aim to investigate whether ecDNA-mediated MYC-paralogs amplification (ecMYC+) represents immunosuppressive features in SCLC.

Methods: Bulk RNA sequencing (RNA-seq) data were retrieved from public database and paraffin-embedded samples (n = 40). The copy number of MYC-paralogs was investigated using real-time polymerase chain reaction. RNA-seq, flow cytometry and metaphase fluorescence in situ hybridization (FISH) were performed in SCLC cell lines. The overexpression and amplification of MYC-paralogs in SCLC clinical samples (n = 42) were identified using immunohistochemistry (IHC) and FISH. The spatial distribution of tumor immune microenvironment (TIME) was characterized by multiplex immunofluorescence and imaging mass cytometry (IMC).

Results: The mean copy number of ecDNAs was higher in SCLC than in the other cell lines (15.3 vs 8.4, $p = 4.0\times10^{-3}$), and the frequency of ecMYC+ cell lines was higher in SCLC than that in the other lineages (SCLC 22/47 vs others 15/282, $p = 3.9\times10^{-12}$). In ecMYC+ SCLC, multiple immune-related pathways were down-regulated, while nucleotide metabolism processes were up-regulated. Inhibition of nucleotide metabolism by hydroxyurea and gemcitabine resulted in the reduction of ecDNA, along with the activation of antigen presenting pathways. Immunohistochemical analysis revealed that overexpression of MYC-paralogs was observed in 19 out of 42 resected SCLC samples. FISH identified 8 samples as MYC-paralogs copy number gain or amplification, and 3 samples exhibited a scattered signals distribution resembling ecDNA amplification. Through the resolution of 103,341 cells from 24 pathological regions, we observed higher expression of MKI67, VEGFA, FAP and FOXP3 and reduced T cell infiltration in ecMYC+ samples. Moreover, ecMYC+ samples exhibited elevated cellular neighborhoods dominated by Ki67+ tumors, with reduced spatial interaction with immune cells.

Conclusions: Extrachromosomal amplification of MYC-paralogs shapes suppressive tumor microenvironment, identifying potential subgroup of immunotherapy resistant patients.

#5229 From the patient to the culture plate and beyond: Challenges and opportunities in cancer-associated fibroblast research.

F. De Vuyst, S. Ernst, S. Vermeulen, Z. Xia, S. Dedeyne, O. De Wever;
Ghent University, Ghent, Belgium

Cancer-associated fibroblasts (CAFs) are a key component of the microenvironment of various solid tumor types. Due to their critical role in tumor progression and therapy resistance, a surge in CAF-related publications is observed exploring the functionality, heterogeneity and potential as therapeutic targets. To facilitate community wide data consolidation and sharing, we initiated a crowdsourcing data-repository together with both national and international collaborators. With this initiative we mapped 85 general and CAF-specific experimental, biological and functional parameters from more than 1000 CAF-related publications from the past decade. This unique set of data indicates a general heterogeneity and underreporting of crucial experimental parameters, related to isolation procedures, culture conditions and CAF characterization. Using single-cell RNAseq we were able to show a phenotypic shift in the CAF population going from the *in vivo* situation to an *in vitro* culture. Additionally, we empirically investigated the impact of *in vitro* aging and hTERT immortalization on the stability of this obtained *in vitro* CAF phenotype. At the molecular level, single cell RNAseq, bulk proteomics, flow cytometry and Luminex cytokine assay revealed a specific gene/protein and pathway rewiring upon passaging of primary CAF cultures, while immortalization resulted in a loss of heterogeneity in the culture but with gain of phenotype stability. Functional assays evaluating collective migration and type I collagen invasion confirmed the increased phenotypic stability in hTERT immortalized CAF cultures. In conclusion, CAF literature mining combined with empirical evaluation will further support interpretable, reproducible and transparent experimental reporting in the CAF research field.

#5230 Co-culture with glioblastoma stem-like cells induces neuron death.

Komal Nalinkant Rawal, Charlotte Degorre, Philip J. Tofilon

Radiation Oncology Branch, National Cancer Institute, National Institutes Of Health (NIH), Bethesda, MD

The vast majority of GBMs recur by 2 years after standard of care treatment, which includes radiotherapy. As a model for investigating the biology of recurrent GBMs, we used brain tumor xenografts initiated from human glioblastoma stem-like cells (GSCs). In this system brain tumors were irradiated (10Gy) on Day 35 after implantation into right striatum of nude mice and allowed to regrow for an additional 21 days. In untreated mice tumor cells are shown to invade throughout the right hemisphere with a high degree of cell-cell contact with mouse neurons as determined by immunohistochemical staining for NeuN, a marker for neuronal soma. In mice irradiated with 10Gy, tumors that regrow are less invasive with a loss of neurons. These data suggest that GBM cells may have a detrimental effect on neuronal survival. Of note, while recent literature suggests neurons contribute to GBM growth, seizures are a frequent occurrence in GBM patients, which may reflect neuronal toxicity. As an in vitro model for investigating the mechanisms mediating the loss of neurons in the recurrent GBM xenografts, neurons differentiated from iPSC derived Neural Progenitor cells (NPC) were directly cocultured with GFP-positive GSCs in stem cell growth medium. After the initiation of coculture the number of neurons and GSCs were determined from 24-96h. As compared to GSCs cultured alone, there was no difference in the number of GSCs in cocultures out to 96h. However, as compared to neurons cultured alone, there was a significant reduction in the number of neurons in cocultures beginning at 48h with further decreases out to 96h. These data suggest that GSCs induce neuron toxicity. As an initial step towards defining the mechanism through which GSCs induce neuronal death, cell culture supernatants from neurons, GSCs and cocultures were subjected to cytokine profiling after 48h. As compared to cell-free media, neuron culture media predominantly contained Osteopontin, TIMP-1 and TIMP-2, which have been implicated in neuron differentiation and functional development, while GSC culture media contained FGF-4, FGF-7 and TGFβ-3, which have been associated with GBM growth. However, in media isolated from cocultures MCPs, Angiogenin and IL-8 were uniquely detected suggesting an interaction between GSCs and neurons resulted in the production of these cytokines. IL-8, the most abundant cytokine detected in the coculture media, has previously been associated with neuron toxicity. These data suggest that interactions between GSCs and neurons alter cytokine levels, which then leads to neuron death. This effect may account for the loss of neurons observed in the GBM xenografts that regrow after irradiation.

#5231 Follistatin shapes the tumor microenvironment in head and neck squamous cell carcinoma through COL1A1-CD44-mediated tumor-stroma crosstalk.

Jennifer Sosa, Satrajit Sinha

Biochemistry, University at Buffalo, State University of New York, Buffalo, NY

Head and Neck Squamous Cell Carcinoma (HNSCC) is a common malignancy with limited therapeutic options. The initiation and progression of HNSCC is closely tied to epithelial cell fate decisions influenced by the tumor microenvironment (TME). The Transforming Growth Factor-β (TGF-β) Superfamily of ligands are pleiotropic growth factors and key mediators of cell-cell communication within the TME. Although TGF-β has been extensively studied for its critical role in cancer progression, therapeutic strategies targeting TGF-β have been largely unsuccessful. Such efforts have often overlooked the potential contribution of myriad factors that influence TGF-β signaling such as follistatin (FST), a secreted glycoprotein and potent inhibitor of TGF-β. FST is frequently upregulated in solid tumors where it is associated with dismal survival outcomes and reduced therapeutic responses. However, the molecular mechanisms by which FST counterbalances TGF-β and potentially other signaling pathways to modulate the TME is not well understood. This underscores the critical need for a more nuanced and molecular understanding of the FST driven networks to develop more effective therapeutic approaches. Here we examined the tumor cell intrinsic and extrinsic roles of FST within the TME of HNSCC by leveraging single cell RNA-seq and spatial transcriptomics datasets from HNSCC patients and analyzing transcriptional changes following depletion of FST in human HNSCC cell lines. We find that while fibroblasts and epithelial cells both express FST, tumor epithelial cells are the primary source of heightened FST levels in HNSCC. Notably, we discover that FST expression is intrinsically linked to a transcriptional program promoting a basal stem-like state in cancer epithelial cells, suggesting a role for FST in tumor plasticity. Consistently, tumor cells that express FST exhibit increased signaling and molecular attributes of the epithelial-to-mesenchymal transition (EMT) program and reduced differentiation. Since cancer stem cells are enriched at the tumor leading edge, where they leverage EMT processes for dissemination, we investigated the spatial distribution of FST-enriched tumor cells and their interactions with the surrounding extracellular milieu. Our analyses show that FST is enriched within the tumor leading edge invasive niche, and further, that tumor-stroma crosstalk via COL1A1-CD44 interactions is spatially localized within FST-rich domains. Finally, we find CD44 positively correlates with FST expression in patient tumors and cancer cells at the transcriptional and protein level. Collectively, our findings define the functional role of FST within the HNSCC TME and supports a model in which FST counterbalances TGF-β signaling and facilitates distinct epithelial-stroma interactions at the dynamic leading edge to enhance tumor aggression.

#5232 Tumor-adipose microenvironment drives progression in advanced oral squamous cell carcinoma.

Gyeongmin Kang[1], Mi Rim Lee[2], Sumin Kang[1], Yu-Sun Lee[2], Hye Won Shon[2], Jiyoung Lee[2], Sung Weon Choi[2], Sun Il Choi[2], Yun-Hee Kim[2]

[1]Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of,[2]Research Institute and Hospital, National Cancer Center, Goyang, Korea, Republic of

Advanced oral squamous cell carcinoma (OSCC) is an aggressive cancer with a recurrence rate of 40-60%, and lymph node metastasis (LNM) occurs in 50% of cases, serving as a critical prognostic factor. Recent evidence suggests that fatty acid oxidation (FAO) enhances cancer cell survival, invasiveness, and therapeutic resistance. OSCC's histological proximity to dense adipose tissue provides a unique opportunity for cancer cells to acquire energy from the adipose environment, underscoring the importance of elucidating the tumor-adipose interactions in OSCC progression and metastasis. In this study, we investigated the impact of the tumor-adipose microenvironment on OSCC progression, focusing on interactions between adipocytes and cancer cells. Human adipose-derived stem cells (ADSCs) were differentiated into adipocytes and co-cultured with the OSCC cell line YD10B for three weeks to induce cancer-associated adipocytes (CAAs). Co-cultured adipocytes exhibited fibroblast-like phenotypic changes, reduced expression of adipogenic differentiation markers, and increased free fatty acid release. Inflammatory cytokines (e.g., IL-6) and tumor-promoting proteins (e.g., IGFBP-2) were upregulated. YD10B cells exposed to co-cultured adipocytes showed enhanced proliferation, invasion, and epithelial-mesenchymal transition (EMT) signaling. Adipocytes and cancer cells both showed increased expression of matrix metalloproteinases (MMP-2 and MMP-9), indicating mutual reinforcement of tumor aggressiveness. Collectively, these findings indicate that adipocytes, through their interaction with OSCC cells, undergo changes to acquire a CAA-like phenotype , which support tumor progression by providing fatty acids as an energy source and promoting aggressive phenotypes, including proliferation, invasion, and LNM. Targeting tumor-adipocyte interactions could offer novel therapeutic strategies to mitigate OSCC progression and improve outcomes.

#5233 Increased galectin-3 in tumor-stromal cells enhances gemcitabine resistance in pancreatic cancer via suppressing oxidated phosphorylation.

Jia Tong[1], Guo An[2], Jingtao Liu[2], Chunxiang Ye[3], Huachiong Ma[3], **Wei Zhao**[2]

[1]Shandong Provincial Hospital Affiliated to Shandong First Medical University, Shandong, China,[2]Key laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China,[3]Beijing Chaoyang Hospital, Capital Medical University, Beijing, China

Pancreatic cancer accounts for nearly about 3% of all cancer cases, which represents a relatively common malignant tumor with rising incidence and mortality rates. Our previous studies have proved that Gal-3 could increase the malignancy of tumor cells and activate collagen and fibrin crosslinking in the stroma. Besides, Gal-3 promoted stromal cells releasing a large number of inflammatory cytokines, such as IL-6 and IL-8, which accelerated tumor progression through the tumor microenvironment deterioration. Additionally, we found the modified citrus pectin (MCP), a natural inhibitor of Gal-3, could inhibit tumor growth in the mouse xenograft model of pancreatic cancer. It is providing a new idea for tumor treatment using dietary interventions. However, there are still few reports on the role of Gal-3 in chemotherapy resistance in pancreatic cancer, so in-depth exploration of this area is urgently needed. This study aims to further elaborate on whether inhibition of Gal-3 expression in tumor cells or stromal cells can be combined with gemcitabine to effectively prevent pancreatic cancer progression. We evaluated Gal-3 levels in various types of pancreatic cancer samples and subsequently established stable-transfected pancreatic cancer cell lines. Based on our previous findings, gemcitabine sensitivity in different cell lines was determined to assess the relationship between Gal-3 expression and drug resistance. The results have indicated that inhibition of Gal-3 expression may reduce the dose-dependence of pancreatic tumors on gemcitabine chemotherapy, thereby enhancing treatment efficacy. Furthermore, we explored the effects of Gal-3 on the mitochondrial oxidative phosphorylation and reactive oxygen species (ROS) levels, during the substrate end of the respiratory chain in the mitochondrial membrane in PAAD cells, and its associated pathways in gemcitabine chemotherapy. It has been demonstrated that fibroblast-induced drug-resistant tumors exhibit a significant reduction through the CCL2-CCR2 axis. This reduction occurs in a multifactorial manner, involving calcium-dependent PPIA-BSG (CD147) pathway and dephosphorylation of NFAT1 intracellular mechanisms. The consequence of such a phenomenon is that it thereby enables these cells to effectively counter the DNA damage caused by gemcitabine. Our research provides significant insights for future dietary interventions and the development of novel agents, opening new avenues for improving patient prognosis.

#5234 A novel strategy to inhibit colorectal cancer liver metastasis by targeting plasminogen activator inhibitor-1 in liver stromal cells.

Tomokazu Ohishi[1], Yukinari Kato[2], Mika K. Kaneko[2], Shun-ichi Ohba[1], Akiko Harakawa[1], Hiroyuki Inoue[1], Junjiro Yoshida[3], Daisuke Tatsuda[3], Tomoko Nakanishi[4], Masanori Hatakeyama[5], Manabu Kawada[3]

[1]Numazu branch, Institute of Microbial Chemistry (BIKAKEN), Numazu, Japan,[2]Department of Antibody Drug Development, Tohoku University Graduate School of Medicine, Sendai, Japan,[3]Laboratory of Oncology, Institute of Microbial Chemistry (BIKAKEN), Shinagawa, Japan,[4]Center of Biomedical Research Resources, Juntendo University, School of Medicine, Bunkyo, Japan,[5]Laboratory of Microbial Carcinogenesis, Institute of Microbial Chemistry (BIKAKEN), Shinagawa, Japan

Liver metastasis significantly contributes to mortality in colorectal cancer (CRC) patients, highlighting the urgent need for more effective therapeutic strategies. CRC liver metastasis develops within a complex tumor microenvironment that promotes cancer cell colonization and growth. The liver's supportive role is well described in Paget's "seed and soil" hypothesis. It illustrates how metastatic cancer cells (the "seeds") spread and proliferate in a compatible microenvironment (the "soil"), which includes liver stromal cells. These stromal cells release various factors that aid tumor progression, making it crucial to understand these molecular interactions.This study aims to elucidate the contribution of liver stromal cell-derived factors in CRC metastasis and identify potential therapeutic targets. Using both in vivo and in vitro coculture systems, we found that plasminogen activator inhibitor-1 (PAI-1), a protein produced by liver stromal cells, significantly promotes CRC cell proliferation. Mechanistically, PAI-1 enhances CRC cell survival and proliferation by activating the Akt signaling pathway, which regulates key cellular processes. In xenograft models, therapeutically inhibiting PAI-1 markedly reduced liver metastasis. Furthermore, experiments using PAI-1 knockout mice showed a substantial decrease in metastatic burden, underscoring PAI-1's pivotal role in CRC progression.These results establish PAI-1 as a promising therapeutic target. Its inhibition could potentially reduce CRC liver metastasis and improve patient outcomes. Given the complex nature of tumor-stromal interactions, our findings provide critical insights into targeting liver stromal proteins for effective CRC metastatic treatment.

#5235 Cancer associated fibroblasts-derived SULF1 facilitated carcinogenesis and metastasis of esophageal squamous cell carcinoma.

Hongyu Zhou, Beilei Liu, Licheng Tan, Baifeng Zhang, Yingchen lyu, Xin-Yuan Guan

The University of Hong Kong, Hong Kong, China

Cancer-associated fibroblasts (CAFs) play a significant role in creating a supportive environment for tumor growth and progression. Esophageal squamous cell carcinoma (ESCC) ranks as the seventh leading cause of cancer-related deaths globally, characterized by poor clinical outcomes and limited treatment options. CAFs-based therapeutic strategies might benefit ESCC patients. In this study, we utilized single-cell RNA sequencing (scRNA-seq) data from four integrated ESCC cohorts to identify a unique protein, SULF1, secreted by CAFs. Primary human CAFs were isolated from six clinical samples of ESCC and various functional assays, such as transwell migration/invasion and co-culture/co-injection experiments, were conducted to assess the oncogenic or pro-metastatic effects of SULF1-secreting CAFs. Neutralizing antibodies against SULF1 was proposedly used for treatment. Here, we revealed that CAFs exhibited the highest expression levels of SULF1 compared to other cell types based on scRNA-seq data. Immunohistochemistry and immunofluorescence staining confirmed the unique expression of SULF1 in CAFs, particularly in αSMA-rich CAFs within ESCC patient samples. Furthermore, extracellular secretion of SULF1 was elevated in primary human CAFs compared to tumor cells and normal fibroblasts. Co-culture or co-injection of SULF1-knockdown CAFs mixed with tumor cells significantly inhibited tumor growth and metastasis both in vivo and in vitro. Mechanistically, RNA-seq data suggested that CAF-derived SULF1 might activate the TGF-beta and PI3K-AKT signaling pathways, thereby mediating the aggressive behavior of tumor cells. Notably, blocking SULF1-secreted CAFs resulted in suppression of ESCC tumor growth and progression in vivo. Collectively, CAF-secreted SULF1 emerged as a critical mediator in educating the ESCC tumor microenvironment and promoting tumor aggressiveness. Targeting SULF1-expressing CAFs could be viewed as a potential therapeutic strategy for ESCC treatment.

#5237 Optimizing multiple myeloma treatment approaches by elucidating tumor-stroma interactions in the bone marrow microenvironment.

Panteha Behboodi[1], Angelica Castano[2], Iriana Colorado[2], Mauricio Rigo[2], Martha Salas[2], Mariam Tariq[2], Woo Lee[1], Benjamin Tycko[2], Rena Feinman[2]

[1]Stevens Institute of Technology, Hoboken, NJ,[2]Hackensack Meridian Health Center for Discovery and Innovation, Nutley, NJ

Multiple Myeloma (MM) is a plasma cell malignancy arising in the bone marrow. Despite advancements in therapies, this disease becomes refractory such that relapse and death is inevitable. Immune evasion and drug resistance are partly due to MM-osteoblast cell interactions in the bone marrow microenvironment (BME). We conducted complementary in-vitro and in-vivo studies, each providing insights that converge to a treatment-relevant hypothesis. Several human MM cell lines (MM.1S, U266, NCI-H929, L363) were co-cultured with osteoblasts for two days to assess proliferation in response to two proteasome inhibitors, bortezomib, and carfilzomib. Osteoblasts, represented by the hFOB fetal osteoblast-derived cell line, markedly enhanced MM cell growth and conferred significant chemoresistance determined by a luciferase-based viability assay. We then performed RNA sequencing of FACS-sorted MM.1S and hFOB cells following 1 day of coculture. We found a significant upregulation of Type I Interferon (IFN) signaling pathway target genes (e.g. IRF7, ISG15, $p<0.001$) in co-cultured MM.1S cells compared to MM.1S cells alone. Two pro-inflammatory chemokines, CXCL1 and CXCL8, were markedly increased in hFOB co-cultured cells compared to hFOB monocultures. A 9-fold increase of CXCL1 ($p<0.0001$) and CXCL8 ($p<0.0001$) was validated by qPCR and both chemokines were elevated in co-culture supernatants in a cytokine array. Parallel studies in vivo, using the 5TGM1 MM immunocompetent mouse model, revealed that low-dose decitabine (DAC), a DNA hypomethylating agent known to induce a Type I IFN response significantly reduced MM burden ($p<0.0001$) and prolonged survival by 9 days ($p<0.001$), compared to MM-bearing mice treated with PBS vehicle. From these two lines of work, we hypothesize that low-level IFN signaling, mediated by MM cell cross-talk with osteoblasts, is supportive of MM cell proliferation and survival, while hyper-induction of the IFN pathway by DAC may contribute to the therapeutic efficacy of this epigenetic-modifying agent, both alone and in combination with immunotherapies, such as immune checkpoint inhibitors. This postulated biphasic response to Type I IFN signaling in MM cells is consistent with prior reports from other experimental systems. Our findings highlight the utility of epigenetic therapy in MM and suggest that hyper-induction of IFN signaling in MM cells, which already have low-level activation of this pathway from their interactions with osteoblasts, should be further investigated as a therapeutic mechanism.

TUMOR BIOLOGY: The Immune Microenvironment in Cancer
Poster Session

#5242 YTHDF2 is a radiotherapy checkpoint in dendritic cells.

Dapeng Chen, Hua Liang, Ralph Weichselbaum

Department of Radiation and Cellular Oncology, University of Chicago, Chicago, IL

Dendritic cells (DCs) play a central role for initiating anti-tumor immunity of T cells in radiotherapy (RT), yet its generalized success to cancer RT has been hampered by insufficient antigen presentation and induction of suppressive regulators from tumor microenvironment. Here, we reveal that ionized radiation (IR) induces the expression of m^6A reader YTHDF2 in DCs with clinical significance, and the depletion of Ythdf2 in DCs augments the anti-tumor effect of RT. We observed that following IR, SPI-1 promotes the transcription of YTHDF2 in DCs. The IR-induced YTHDF2 in DCs directly targets and degrades m^6A-binded *Mfng*, *Aph-1b*, and *Aph-1c,* which are essential for notch activation. YTHDF2 blockades in DCs activates notch signaling to promote the expression of MHC-I family gene *Gm8909*, thus enhancing cross-priming of $CD8^+$ T cells to afford amplified anti-tumor effect of RT. Pharmacological inhibition of YTHDF2 in DC vaccines contributes to RT efficacy in both local tumor control and distant metastasis suppression. Our findings identify IR-induced YTHDF2 as an immunosuppressor in DCs, reveal the mechanism for regulating anti-tumor immunity, and open a new path for the development of m^6A-mRNA targeting therapies

#5243 Peripheral Foxp3^{high} regulatory T cells develop into tumor-associated counterparts by proinflammatory cytokines and act as prognostic biomarker in patients with hepatoma.

Wei-Ting Ku[1], Chien-Hao Huang[2], Jayashri Mahalingam[2], Cheng-Heng Wu[2], Tsung-Han Wu[3], Jian-He Fan[2], Chung-Wei Su[2], Po-Ting Lin[2], Chien-Wei Peng[2], Wei Teng[2], Wen-Juei Jeng[2], Wen-Juei Jeng[2], Wei-Ting Chen[2], Chen-Chun Lin[4], Shi-Ming Lin[2], I-Shyan Sheen[2], Yung-Chang Lin[5], Chun-Yen Lin[6]

[1]Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan, Taiwan,[2]Division of Gastroenterology and Hepatology, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan,[3]Department of General Surgery,, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan,[4]Division of Gastroenterology and Hepatology, New Taipei Municipal TuCheng Hospital (Built and Operated by Chang Gung Medical Foundation), New Taipei City, Taiwan,[5]Department of Hematology-Oncology, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan,[6]College of Medicine, Chang Gung University, Taoyuan, Taiwan

CD4$^+$ regulatory T cells (Tregs) play a critical role in the progression of hepatocellular carcinoma (HCC). However, indiscriminate depletion of Tregs risks triggering autoimmunity. While previous research highlights the phenotypic and functional heterogeneity of Treg subpopulations, a unified classification system remains elusive. This study aims to characterize Treg subtypes in HCC patients using single-cell CITE-seq and validate their clinical relevance and prognostic potential. CITE-seq profiling of 51,067 CD4$^+$ T cells from eight HCC patients identified distinct Treg populations in tumor, non-tumor, and peripheral blood samples. Validation studies conducted on 96 HCC patients and 53 healthy donors using flow cytometry, functional assays, and clinical data revealed a peripheral Foxp3^{high} Treg subset that preferentially migrates to tumor sites. Upon infiltration, these Tregs undergo terminal differentiation, exhibiting heightened activation, immunosuppressive functions, and increased expression of LAYN and TRM-associated genes. Proinflammatory cytokines within the tumor microenvironment further amplify Foxp3 expression and the suppressive capacities of these cells. Mechanistic analysis implicated the CCL5/CCR5 signaling axis as essential for the recruitment of Foxp3^{high} Tregs from peripheral blood to the tumor microenvironment. Peripheral Foxp3^{high} Tregs strongly correlated with their tumor-infiltrating counterparts, suggesting their potential as a non-invasive biomarker. A threshold of peripheral Foxp3^{high} Tregs/CD4$^+$ T cells > 3.5% was found to predict overall survival and early recurrence, achieving AUROCs exceeding 0.75. In conclusion, peripheral Foxp3^{high} Tregs transition into tumor-associated counterparts via the CCR5-CCL5 axis and proinflammatory cytokines, contributing to immunosuppression in HCC. Their abundance in peripheral blood correlates with tumor infiltration and clinical outcomes, underscoring their utility as a prognostic biomarker for HCC.

#5244 Functional γδ T cells in humanized mice.

Florent Creusat, Siham Hedir, Alexis Gonon, Amelie Marguier, Yacine Cherifi, Fabiane Sonego, Gaelle Martin, **Kader Thiam**

genOway, Lyon, France

Development of immunotherapies has been a major landmark in the field of oncology, leading to numerous effective treatments. From the first use of an immunomodulatory agent in clinical studies to modern immunotherapies, these were mainly focused on modulating adaptive immune response. However, only a fraction of patients can respond to these treatments, and the complexity of the tumor microenvironment requires other players to be targeted. γδ T cells are unconventional T cells, as they recognize antigens mostly in a MHC-unrestricted fashion. They show a high diversity of effector functions, from cytotoxicity to mediators' production and wound healing. Their preactivated state allows a quick immune response, and their role in tumor development, both in beneficious or deleterious manner, was demonstrated in numerous types of cancer. Current therapeutic approaches involving γδ T cell include adoptive cell transfer, *in vivo* stimulation and combined therapies. While preliminary results are promising, investigation of such therapies in preclinical models is challenging, because γδ T cells are not developed at satisfactory levels in most of the humanized mouse models. Here we describe the presence and functionality of γδ T cell in BRGSF (Balb/C $Rag2^{-/-}$, $IL2R\gamma^{-/-}$, SIRPαNOD and $Flt3^{-/-}$), a highly immunodeficient mouse featuring reduced murine myeloid cells. BRGSF mice reconstituted with human cord blood $CD34^+$ cells (BRGSF-HIS) develop functional lymphoid and myeloid compartments. This engraftment is stable for over a year (Labarthe *et al.*, 2019) and mice do not develop GvHD. At steady-state, BRGSF-HIS mice show a diverse population of γδ T cells in their blood and peripheral organs, expressing Vδ1, Vδ2 or Vδ3 chains, although their ratio is different in blood from BRGSF-HIS mice and human PBMC. These cells can be expanded using zoledronate with human IL-2, allowing *ex vivo* or *in vivo* assays for γδ T cells targeting compounds. This specific activation, as well as the activation with a Vδ1-targeting agent, leads to an increase in γδ T cells activation state (expression of CD25, CD69, CD137) and their effector function (cytokine production or CD107a-associated degranulation). Similarly, an "Expander" targeting Vγ9 significantly increased Vγ9 expressing cells frequencies, and serum levels of perforin and INF-γ in treated mice. Interestingly, γδ T cells were recruited into the tumor microenvironment of the triple negative breast cancer line MDA-MB-231 and the colorectal adenocarcinoma cell lines HT29 and SW480, suggesting that therapies designed to expand and activate γδ T cells could be assessed in BRGSF-HIS tumor bearing mice. Therefore, the development of functional γδ T cells in BRGSF-HIS mice brings a new perspective on the assessment of therapies targeting this cell population in humanized mouse models.

#5246 Chromosomal instability promotes colorectal cancer progression through manipulation of gamma delta T cells.

Paulino Tallon de Lara[1], Aviad Ben-Shmuel[1], Wen-Hao Hsu[2], Chaohao Li[1], Kyle Labella[3], Chi Wut Wong[1], Yonghong Liu[1], Shan Jiang[1], Xiaoying Shang[1], Scott Kopetz[1], Ronald DePinho[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Stanford University, Stanford, CA,[3]Genentech, South San Francisco, CA

Colorectal cancer (CRC) can be divided into 2 genetically different subtypes: Microsatellite instable CRC (MSI-CRC; ~15% of CRC), and microsatellite stable (MSS-CRC; ~85%). While MSI-CRC develops point mutations that increase neoantigen burden and enhanced response to immunotherapy, MSS-CRC develops chromosomal instability (CIN) and resistance to immunotherapy. Current mouse models do not recapitulate the key genetic defect of MSS-CRC: CIN. This limits our understanding of CIN's role in regulating tumor immunity in CRC, and therefore our capacity to generate new immunotherapies for MSS-CRC.

To address this gap, we developed the first genetically engineered mouse model of MSS-CRC with human-like CIN. To recapitulate human CIN caused by telomere erosion, we incorporated the conditional null *Apc* and *Trp53*, and inducible Lox-Stop-Lox (LSL) mouse telomerase reverse transcriptase (*mTert*) alleles, referred to as iTAP. Due to LSL-*mTert*, mice lack *mTert* expression and therefore telomerase activity, which leads to telomere erosion upon successive generational intercrosses, evolving from G0 mice (LSL-*mTert*+/-) that have no CIN (CIN- iTAP) to G3 mice after 3 breeding generations with the mTert+/+ allele that develop CIN (CIN+ iTAP). Colonoscopy-guided submucosal administration of 4-OHT activates Villin-driven Cre-ER in colonocytes leading to *Apc* and *Trp53* deletion and deletion of the stop cassette of LSL-*mTert* causing activation of telomerase in cancer cells. Oncogenesis in cells with telomere erosion leads to CIN.

Consistent with worse OS in human MSS CIN^{high}, CIN+ iTAP tumors were more aggressive than CIN- iTAP. Single-cell RNA sequencing (scRNA-seq) confirmed that CIN+ iTAP tumors developed more copy number variations. Subclustering of the infiltrating immune populations revealed that γδ T cells expanded and changed their phenotype in CIN+ iTAP tumors, which was confirmed by flow cytometry. Treatment with a blocking antibody towards γδ TCR in mice with established tumors lead to increased survival in CIN+ iTAP mice but not in CIN- iTAP mice. ScRNA-seq of primary tumors of patients with MSS-CRC revealed that γδ T cells also exhibit phenotypic changes upon different levels of CIN in human MSS CRC.

#5247 Comprehensive characterization of pseudocapsules in clear cell renal cell carcinoma reveals unique invasion mechanisms: A multi-omics investigation.

Xiyi Wei[1], Yitong Pan[2], Weiyu Kong[1], Da Zhong[1], Zijie Yu[1], Yang Wang[1], Longjun Ma[3], Zhou Yang[1], Yize Li[4], Chenxi Tian[2], Bing Yao[3], Ninghong Song[1], Chao Qin[1]

[1]Department of Urology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China,[2]Key Laboratory of Genomic and Precision Medicine, Beijing Institute of Genomics, Chinese Academy of Sciences (CAS), Beijing, China,[3]Department of Medical Genetics, School of Basic Medical Sciences, Nanjing Medical University, Nanjing, China,[4]Division of Oncology, Department of Medicine, School of Medicine, Washington University in St. Louis, St. Louis, MO

Clear cell renal cell carcinoma (ccRCC) represents the most common subtype of renal cell carcinoma, accounting for approximately 70% of cases. Notably, the majority of ccRCC tumors are surrounded by a prominent pseudocapsule tissue, highlighting its potential diagnostic, prognostic, and therapeutic relevance. To comprehensively understand the implications of pseudocapsules in ccRCC, we constructed an extensive multi-omics atlas. The cohort included single-cell RNA sequencing, spatial transcriptomics, proteomics, and extracellular matrix (ECM) proteomics, derived from 36 ccRCC cases. These analyses were further augmented with functional assays and animal studies, enabling a multi-dimensional exploration of pseudocapsule biology. Our cohort analysis demonstrated that pseudocapsules are predominantly composed of fibroblasts and a rich diversity of immune cells, a finding corroborated through immunofluorescence (IF) and immunohistochemistry (IHC). The tissue was also characterized by a substantial accumulation of extracellular matrix components. Importantly, pseudocapsule invasion revealed significant alterations in the tumor microenvironment (TME). During tumor invasion, CD8+ T cells and dendritic cells (DCs) within the pseudocapsule exhibited increased activation, accompanied by pronounced exhaustion. Concurrently, tumor-associated fibroblasts underwent functional reprogramming, transitioning from a myofibroblast-like state (myoCAF) to an inflammatory CAF phenotype (iCAF). These iCAFs primarily interacted with T cells and promoted their exhaustion, which was critical to ccRCC progression. Additionally, our investigation identified a loss of chromosome 14q during tumor cell invasion. Notably, the FOS gene on chromosome 14 was significantly downregulated and identified as a key gene. Clinical data from large patient cohorts revealed that low FOS expression was associated with advanced tumor stage, higher histological grade, and poorer overall survival. Functional assays demonstrated that FOS overexpression reduced the invasive potential of ccRCC cell lines in vitro, whereas FOS knockdown enhanced lung metastasis in vivo. Transcriptomic analysis further indicated that FOS is involved in regulating extracellular matrix dynamics and immune-related pathways. These findings provide novel insights into the role of pseudocapsules in ccRCC and highlight critical molecular mechanisms underlying tumor progression. By uncovering key invasion biomarkers and therapeutic targets, this study lays the groundwork for precision medicine approaches in ccRCC management.

#5248 Identification of a chromatin-remodeling peptide in diffuse midline glioma by immunopeptidomics.

Niloofar Khairkhah[1], Ali Namvar[1], Arun Everest-Dass[2], Seeta Nyayapathy[3], Richard Jones[4], Julie M. Rumble[3], Christopher E. Whitehead[5], Judith S. Sebolt-Leopold[5], Stefanie Galban[6]

[1]Department of Radiology, University of Michigan Medical School, Ann Arbor, MI,[2]Institute for Glycomics, Griffith University, Gold Coast Campus, Gold Coast, Queensland 4222, Australia,[3]Immunology Services, Cayman Chemical, Ann Arbor, MI,[4]MS Bioworks, Ann Arbor, MI,[5]Department of Radiology (UMMS), University of Michigan Medical School and MEKanistic Therapeutics, Inc., Ann Arbor, MI,[6]Departments of Radiology and Surgery, Center for Molecular Imaging, Rogel Cancer Center, University of Michigan Medical School, Ann Arbor, MI

The identification of peptides presented by major histocompatibility complex class I (MHC-I) molecules on cancer cells is crucial for developing targeted immunotherapies, particularly for malignancies like pediatric diffuse midline gliomas (DMG), where therapeutic options remain limited. In this study, we applied advanced immunopeptidomics and mass spectrometry techniques to characterize the immunopeptidome of DMG H3K27M-altered. To identify DMG specific peptides, we included comparative studies to the immunepeptidome of adult glioblastoma (GBM). We identified a total of 454 peptides in DMG and U87 (glioblastoma) xenografts pertaining to 229 genes. Among these, 42 peptides were uniquely expressed in DMGs and 11 were shared with U87 xenografts, highlighting distinct antigen presentation profiles between these tumors. Notably, the peptide RSRKESYSVVYYKVLKQVHPD, which stems from the Histone H2B type 1-M (H2B1M) gene, is presented by the MHC-I molecule HLA-B*57:01, and is associated with chromatin remodeling, was enriched in DMG cells compared to GBM, revealing a potential immunotherapeutic target specific to DMG. To explore whether targeted therapies alter the identified immunopeptidome, we utilized MTX-241F, a previously described experimental compound that inhibits key proliferative pathways (EGFR/PI3K) in DMG and GBM. Comparative analysis of MTX-241F-treated DMGs and U87 xenografts revealed both overlapping and unique regulatory patterns of peptides, underscoring the tumor-specific effects of MTX-241F. MTX-241F selectively upregulated peptides in DMG stemming from the NCOA4, VATF and THOC2 genes that are linked to MHC-I presentation. In summary, our findings provide the first evidence of dynamic treatment dependent modulation of antigen presentation in DMGs and offer new insights into the tumor immunopeptidome. The distinct peptide profiles of DMG and U87 and their different responses to MTX-241F suggest potential therapeutic avenues for precision immunotherapy targeting DMG. In addition, the identification of a shared immunopeptidome presents an opportunity to develop a therapeutic for both pediatric and adult glioma.

#5249 *In vitro* co-culture CRISPR screen identifies SMG1 to potentiate T cell-mediated cytotoxicity in hepatocellular carcinoma.

Ka Hei Lam[1], Tin Lok Wong[1], Kai Yu Ng[1], Vincent Tano[2], Jia Jian Loh[1], Ianto B. Huang[1], Guang Sheng Ling[1], Terence KW Lee[3], Lei Lei Chen[2], **Stephanie KY Ma**[1]

[1]School of Biomedical Sciences, The University of Hong Kong, Hong Kong, Hong Kong,[2]Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore,[3]Department of Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

The overall response rate to immune checkpoint blockade (ICB) in hepatocellular carcinoma (HCC) patients remains suboptimal, highlighting the need for immediate efforts to identify resistance factors and develop synergistic strategies to enhance the antitumor activity of ICB. Cytotoxic T lymphocytes (CTLs) are the central effectors of anti-tumor immune response. Understanding the relationship between tumor intrinsic kinases and CTL-mediated cytotoxicity could reveal novel mechanisms in promoting immunotherapy efficacy. Here, we conducted a kinome knockout (KO) CRISPR screen in an *in vitro* tumor-T cell co-culture system to identify kinases in HCC cells that contribute to immune escape from cytotoxic T cell killing. Within the top depleted candidates, Tumor Immune Dysfunction and Exclusion (TIDE) analysis of The Cancer Genome Atlas (TCGA) HCC dataset revealed that higher suppressor of morphogenesis in genitalia 1 (SMG1) expression in patients predicted ICB resistance. Further bioinformatics analysis showed that SMG1 expression is inversely associated with CTL signature, and patients with low SMG1 expression and high CTL signature have more favorable survival outcomes. *In vitro* proliferation assay and orthotopic transplantation of murine HCC cells in mice demonstrated that SMG1 depletion elicited immune-dependent tumor suppressive effect. Using single-cell RNA sequencing (scRNA-seq), we observed an increased proportion of effector CD8+ T cells in SMG1-depleted tumors, which exhibited enhanced activation of T cell receptor (TCR) signaling pathway along pseudotime, indicating an enhanced T cell-mediated immune response in tumors following SMG1 inhibition. Additionally, we showed that SMG1 loss promoted transcription of major histocompatibility complex class I expression (MHC-I) genes and enhanced antigen presentation on the surface of tumor cells. On the other hand, further investigation of the transcriptome profile following SMG1 knockout indicated dysregulation of alternative splicing (AS) in HCC cells. We also demonstrated that nonsense-mediated mRNA decay (NMD) inhibition can enhance T cell-mediated cytotoxic response, and NMD signature is inversely associated with CD8+ T cells signature in HCC. This suggested the potential of inhibiting SMG1 to promote antigen presentation, as well as disrupt AS and NMD coupled events to drive the generation of splicing-derived neoantigens, thereby augmenting anti-tumor immunity.

#5250 Re-activating suppressed tumor-infiltrating lymphocytes from melanoma brain metastases.

Mark W. D. Sweep[1], Imke van Wandeloo[1], Mark A. J. Gorris[2], Guido van Mierlo[2], Benno Kusters[3], Kiek Verrijp[2], Alfred C. Koetsveld[4], Mark ter Laan[4], I. Jolanda M. de Vries[2], Carla M. L. van Herpen[5], Kalijn F. Bol[5]

[1]Medical Oncology & Medical BioSciences, Radboudumc, Nijmegen, Netherlands,[2]Medical BioSciences, Radboudumc, Nijmegen, Netherlands,[3]Pathology, Radboudumc, Nijmegen, Netherlands,[4]Neurosurgery, Radboudumc, Nijmegen, Netherlands,[5]Medical Oncology, Radboudumc, Nijmegen, Netherlands

Brain metastases (BrMs) occur in up to half of patients with metastatic melanoma and are a major cause of death. The response of BrMs to immunotherapy can be different from extracerebral metastases (ECMs). Hence, in this study the immune microenvironment of BrMs is compared with that of ECMs. Bulk RNA sequencing was performed on a retrospective cohort of 38 melanoma samples from 14 patients, consisting of 15 matched BrMs and 23 ECMs. This cohort was expanded to perform multiplex immunohistochemistry on a total of 107 matched BrM and ECM samples from 44 patients. Fresh BrM material was prospectively obtained from a total of 12 patients with melanoma BrM, who underwent surgical resection of their BrM. From this material, tumor-infiltrating lymphocytes (TILs) and corresponding tumor cells were cultured. These cells were characterized by flow cytometry. TIL cultures were expanded and tested for reactivity against autologous tumor cell lines using flow cytometry and ELISA. In a patient-matched comparison, gene set enrichment analysis showed that brain-specific pathways are enriched in BrMs, whereas immune activation pathways, especially pathways related to TILs, are suppressed in BrMs compared to ECMs. However, the computationally inferred abundance of TILs did not differ between BrMs and ECMs, but rather showed an increase of anti-inflammatory M2 macrophages in BrMs. This indicates that TILs are equally present in BrMs and ECMs, but that they are less activated in BrMs. Interestingly, M2 macrophages seemed reduced in patients who received prior treatment with BRAF/MEK inhibitors. When taken out of their native environment*, ex vivo* cultures of BrM-derived TILs and tumor cells are successful in 7/10 (70%) and 7/12 (58%) patients, respectively. In 3/6 (50%) patients with matched TIL and tumor cell cultures, tumor reactivity was indicated, without external stimulation, by production of TNFα, IFNγ, perforin, and expression of CD107a and CD137. Our data suggest that TILs are suppressed in melanoma BrMs as opposed to ECMs, possibly due to increased presence of anti-inflammatory M2 macrophages. Nevertheless, these TILs can efficiently be expanded *ex vivo* and show tumor reactive potential, providing opportunities for TIL-based and other immunotherapeutic treatments in BrM. Combined with macrophage targeting, TILs could synergize to provide effective targeting of the tumor.

#5251 Anergic response of NK cells mediated by killer cell lectin-like receptor C1 and tumoral HLA-E interaction in pleural metastasis of lung adenocarcinoma.

Ying-Ming Tsai[1], Kuan-Li Wu[2], Ya-Ling Hsu[3]

[1]Pulmonary and Critical Care Medicine, Gangshan Hospital, Kaohsiung Medical University, Kaohsiung City, Taiwan,[2]Pulmonary and Critical Care Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung City, Taiwan,[3]Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan

The presence of effusion is negatively correlated with prognosis in lung cancer. Despite the advent of novel therapies, clinical outcomes remain unsatisfactory. Pleural metastasis and malignant pleural effusion (MPE) result from tumor-host interactions involving mechanisms such as pleural inflammation, angiogenesis, and vascular hyperpermeability. Natural killer (NK) cells are potent immune effectors capable of responding to cancer. However, several aspects of NK cell biology remain under investigation. Understanding their role will aid in identifying effective therapeutic targets. Effusion samples from patients with congestive heart failure (designated as HP) and lung cancer pleural metastasis (LCP) were collected. Cells were harvested to delineate the functional phenotype of NK cells using single-cell RNA sequencing (scRNA-seq). Additionally, changes in NK cells were validated using immunohistochemistry and cell marker identification. The results revealed six subsets of NK cells: $CD16^+/CD56^-$ NK cells, $CD16^-/CD56^+/XCL2^+$ NK cells, $CD16^-/CD56^+/RUNX2^+$ NK cells, $CD16^+/CD56^+/BCL11B^+$ NK cells, $CD16^+/CD56^+/CCL3^+$ NK cells, and $CD16^-/CD56^-$ NK cells. Most NK cell subclusters dominated in the LCP group, except for $CD16^+/CD56^-$ NK cells, which were prevalent in the HP group. These NK cell subsets exhibited different expression patterns of inhibitory receptors (KLRC1 and KLRD1) and activating receptors (HCST and KLRK1). Notably, $CD16^-/CD56^+/RUNX2^+$ NK cells were present exclusively in MPE and absent in effusions from HP. Compared to other NK cell subsets, $CD16^-/CD56^+/RUNX2^+$ NK cells exhibited lower expression of activating receptors and higher expression of inhibitory receptors, particularly KLRC1, suggesting an immunosuppressive phenotype. Cell-cell interaction analysis using CellChat indicated that HLA-E in pleural tumors interacted with $RUNX2^+/CD16^-/CD56^+$ NK cells, resulting in decreased NK cytotoxicity. This interaction was further validated through higher expression of HLA-E in pleural tumor cells by immunohistochemistry and the presence of $CD16^-/CD56^+/RUNX2^+$ NK cells in malignant effusions of lung cancer by a flow cytometry. These findings imply that the presence of the inhibitory ligand HLA-E from tumor cells supports the formation of pleural metastasis by evading NK cell-mediated cytotoxicity. Further investigation into these cell groups may aid in the prevention and treatment of MPE in lung cancer.

#5252 2D and 3D spatial characterisation of tertiary lymphoid structures in head and neck cancer patients receiving immune checkpoint blockade therapy.

Meg L. Donovan[1], Habib Sadeghirad[2], Naomi Berrell[1], James Monkman[2], Vahid Yaghoubi Naei[3], Chin Wee Tan[4], Joseph Yunis[2], Zoe West[5], Majid E. Warkiani[3], Rahul Ladwa[6], Brett G. M. Hughes[7], Jessica Da Gama Duarte[8], Arutha Kulasinghe[2]

[1]Queensland Spatial Biology Centre, Wesley Research Institute, Brisbane, Australia,[2]Frazer Institute, Faculty of Medicine, The University of Queensland, Brisbane, Australia,[3]School of Biomedical Engineering, University of Technology Sydney, Sydney, Australia,[4]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,[5]UQ Centre for Clinical Research, Faculty of Medicine, The University of Queensland, Brisbane, Australia,[6]The Princess Alexandra Hospital, Brisbane, Australia,[7]The Royal Brisbane and Women's Hospital, Brisbane, Australia,[8]Olivia Newton-John Cancer Research Institute, and School of Cancer Medicine, La Trobe University, Melbourne, Australia

Tertiary lymphoid structures (TLS) play an important role in the tumor microenvironment (TME) of Head and Neck Cancer (HNC) and have been linked to improved response to immunotherapy. Moreover, HNC patients with human papillomavirus (HPV)+ tumors have better survival compared to those with HPV- tumors, although both groups have better clinical outcomes when the tumors are TLS-rich. How TLS composition, characteristics, and signatures differ between response to treatment in relation to HPV status is still unclear. To investigate this, whole-tissue samples from 55 HNC patients were collected across two separate sites in Brisbane, Australia (The Princess Alexandra Hospital and The Royal Brisbane and Women's Hospital) prior to immune checkpoint therapy (ICI). Using a multi-pathway panel, covering the 'hallmarks of cancer' and 'TLS-associated proteins,' we profiled 53 spatially resolved biomarkers using both a PhenoCycler-Fusion panel and 7-plex PSP panel (Akoya Biosciences). Using spatial proteomics, the TLS were assessed for their composition, activity, maturity, and distance metrics from the tumor. Using spatial transcriptomics, we profiled 96 TLS using whole transcriptome profiling (Bruker Spatial Biology). In addition, in patient samples abundant with TLS, we profiled 50 serial sections to obtain and profile the volumetric 3D data. Our study identified various degrees of TLS maturity, proteomic, and transcriptomic profiles associated with TLS localisation within the TME and proximity to the tumor. In addition, we identified TLS signatures associated with clinical endpoints such as response and resistance to ICI therapy. Taken together, this research highlights the multifaceted role of TLS in modulating the immunogenic landscape of HNC, influencing immunotherapy efficacy, and potentially serving as a biomarker for patient stratification and therapeutic strategies.

#5253 Immune landscape analysis of solid tumors *via* spatially guided cell isolation for enhanced immunotherapeutic development.

Elie Abi Khalil[1], Yi-Chien Wu[1], Jingtian Zheng[1], Joshua Plank[2], Alexander Lippert[2], Steve Lee[1]

[1]University of Illinois at Chicago, Chicago, IL,[2]Southern Methodist University, Dallas, TX

The tumor-immune microenvironment (TIME) in solid tumors is a complex ecosystem consisting of diverse interactions between cellular populations. Deeper investigation into the TIME reveals a prominent role of immune cells in regulating tumor progression- a novel phenomenon that has encouraged the evaluation of the crosstalk between cell types. The development of spatial omic technologies has thus enabled the exploration of these nuances at previously inaccessible resolutions, but the currently available platforms come at the cost of introducing bias, excluding molecular information, and incompatibility with single cell technologies. Here, we leverage a photoactivatable (PA) dye Janelia-Fluor-646 in combination with a digital light processing (DLP) microscope to address these issues by developing a platform that enables the spatially guided isolation of cell populations from a region of interest (ROI) for downstream multiomic and single cell analyses. As proof of concept, we show that ROIs identified via immunofluorescence could successfully be barcoded in mouse spleen and tumor sections using the dye and distinguished from the background by fluorescence activated cell sorting (FACS). We also demonstrate the ability to extract high quality DNA, RNA, and protein- as well as maintain high cell viability post-sorting. We have also developed a pipeline for the analysis of the sequenced RNA to identify differential patterns of gene expression present in immune cells from spatially distinct regions. Moving forward, we hope to establish this as a platform for immune landscape analysis within the TIME to uncover unique targets that could be explored within the context of tumor-immune interactions as well as immunotherapeutic development. Our findings will also help us generate the first single-cell atlas of niche-specific immune cells.

#5254 Multi-plexed spatial interaction analysis of the tumor microenvironment in head and neck cancers.

Vahid Yaghoubi Naei[1], Sara Bodbin[2], Habib Sadeghirad[1], Rafael Tubelleza[1], James Monkman[1], Agata Wicher[2], Subham Basu[2], **Arutha Kulasinghe**[1]

[1]University of Queensland, Brisbane, Australia,[2]Navinci Diagnostics AB, Uppsala, Sweden

Head and neck cancers are the 7th most common cancer type globally accounting for over 900,000 cases annually. With increasing numbers of systemic and targeted therapies, including immune checkpoint inhibitors (ICI), it has become increasingly important to understand the complex tumour microenvironment (TME) milieu dictating clinical responses to therapy. In this study, we profiled 40 whole slide, head and neck cancer tissues from patients prior to ICI therapy and profiled the TME for spatial interactions using the NaveniPlex in situ proximity ligation assay (isPLA, Navinci). Using the Leica BOND RX, formalin-fixed, paraffin-embedded (FFPE) tissue sections were prepared by baking, deparaffinization, and epitope unmasking. Staining was then carried out using the NaveniPlex isPLA technology on the Leica BOND RX instrument. To assess interactions between PD1/PD-L1, CD8/MHCI, and CD3+ T cells, three pairs of Navenibodies were employed simultaneously. Briefly, the NaveniPlex isPLA protocol involves tissue blocking, followed by incubation with primary Navenibodies, ligation, and rolling circle amplification (RCA). Each Navenibody pair generates a distinct RCA product. The RCA products for PD1/PD-L1, CD8/MHCI, and CD3+ T cells were visualized using oligonucleotides conjugated to Atto647N, Atto550, and AlexaFluor488, respectively.Our spatial interaction analysis for PD1/PDL1, CD8/MHCI and CD3+ T-cells showed distinct TME interactions associated with responders and non-responders to ICI therapy. Interactions mapped with cellular phenotypes revealed the cellular neighbourhoods and communities at which these interactions may be useful prognostically. Taken together, this study provides a methodological framework to profile pre-ICI treatment tissues to identify spatial interactions associated with clinical endpoints.

#5255 Systemic immunosuppression in pancreatic cancer.

Damian Matysniak, Chunbo He, Pankaj Kumar Singh, Kamiya Mehla

Oncology Science Department, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Natural killer (NK) cells play a critical role in cancer immunosurveillance and are considered a potent immunotherapeutic tool for many cancers, including pancreatic ductal adenocarcinomas (PDACs). Increased number of ongoing clinical trials investigating CAR-T/NK cell therapies in PDAC patients (NCT04390399, NCT02839954, NCT03634501, NCT03941457, NCT03323944, NCT05275062) driving the need for research understanding of how systemic immune perturbations regulate the effector function of adoptively transferred immune cells is important for development of these therapies. The immunosuppressive tumor microenvironment contributes to shaping antitumor immunity and can dramatically diminish the efficacy of immunotherapies. However, the effects of PDAC tumor burden on systemic NK cells remain poorly understood. Emerging evidence suggests that cancer can induce systemic immune perturbations, including an increase in immunosuppressive myeloid populations in lymphoid organs. Understanding the interplay between these systemic factors and local anti-tumor immunity is crucial for developing effective immunotherapies against PDAC.
Methods: To investigate the systemic effects of PDAC on the NKs, we orthotopically implanted immunocompetent C57BL/6 mice with syngeneic pancreatic tumor cell lines derived from *LSL-KrasLSL.G12D/+; LSL-p53R172H/+; Pdx1-Cre* (KPC mice) PDAC mouse model. Next, we evaluated the functional, transcriptional, and metabolic profiles of endogenous and adoptively transferred syngeneic NK cells.
Results: Our study showed remarkable impairment in the effector function of endogenous and adoptively transferred NKs obtained from tumor-bearing mice compared to the healthy mice. Endogenous and adoptively transferred NK cells displayed attenuated cytotoxic killing capabilities against pancreatic tumor cells in the *ex vivo* assay. Besides, our metabolomics data demon stared an altered metabolism in the NK cells from the pancreatic tumor mice compared to healthy control cohort. Depleting myeloid cells rescued the proportion and cytotoxic function of systemic NK cells in pancreatic tumor-bearing mice. Also, myeloid cells alter the metabolism of NK cells, which underlie the attenuated cytotoxic function of these cells in pancreatic cancer.
Conclusion: Our study proves the critical role of the systemic immunosuppressive in impairing the function of endogenous and adoptively transferred NK cells in pancreatic cancer. We demonstrate that inhibiting myeloid cells enhances the anti-tumor function of NK cells. Our findings also show the importance of considering the systemic immune microenvironment in cancer patients when utilizing CAR T/NK-based therapies.

#5256 Tertiary Lymphoid Structures as Predictors of Immune Checkpoint Inhibitor Efficacy in NSCLC and the Development of an Ex Vivo Model for Precision Medicine.

Jean-Philippe Guegan[1], Imane NAFIA[1], Florent PEYRAUD[2], Lucile VANHERSECKE[3], Christophe Rey[1], Lucie Lefevre[1], Assia CHAIBI[1], **Alban Bessede**[1], Antoine ITALIANO[1]

[1]Explicyte Immuno-Oncology, Bordeaux, France,[2]Department of Medicine, Institut Bergonie, Bordeaux, France,[3]Department of Pathology, Institut Bergonie, Bordeaux, France

Background: Tertiary lymphoid structures (TLS) emerge as essential players in modulating anti-tumor immune responses and shaping the outcomes of immune checkpoint inhibitor (ICI) therapies. Here we explored, on the one hand, the impact of TLS maturity on clinical outcomes in non-small cell lung cancer (NSCLC), and introduce, on the other hand, a novel ex vivo tool model to investigate TLS-mediated immune synapses and test potential therapeutic strategies.
Methods: In this study, 509 NSCLC patients from the BIP cohort (NCT02534649) - treated with ICI-based regimens - were retrospectively analyzed and assessed by multiplex IHC (Ventana Discovery, Roche) and digital pathology (PhenoImager HT, Akoya). TLS status and maturity were evaluated histologically in pre-treatment FFPE samples, with mature TLS (mTLS) defined by the presence of CD23+ follicular dendritic cells. Correlations with overall survival (OS), progression-free survival (PFS), and response rates were analyzed. Interestingly, an ex vivo model was developed using T follicular helper (Tfh) and memory B cells isolated from human tonsils. Tfh cells (CD4+/CXCR5+/PD1high/ICOShigh) and memory B cells (CD19+/CD27+) were co-cultured in the presence of staphylococcal enterotoxin B (SEB). Effects of ICIs (e.g., anti-PD1, anti-TIGIT, anti-CTLA4), anti-CD40, and kynurenine (IDO metabolite) were evaluated on IgG produced levels - quantified by ELISA - as a surrogate of synapse function.
Results: TLS were detected in 49.5% of cases, of which 28.7% were classified as mTLS. mTLS were significantly associated with improved OS and PFS, independent of PD-L1 expression and molecular status. Long-term survivors (≥24 months) had a higher frequency of mTLS (41.3% vs. 22.9%; $p < 0.001$). Response rates to ICIs were notably higher in mTLS-positive patients than in mTLS-negative patients (56.8% vs. 33.6%; $p < 0.001$). On the other hand, the ex vivo model demonstrated robust IgG production in Tfh-B cell co-cultures, modulated positively by ICIs (Nivolumab, Atezolizumab, Tiragolumab, Ipilimumab) and negatively by anti-CD40 and kynurenine.
Conclusions: This study highlights the critical role of TLS maturity in predicting response to ICIs and improving survival outcomes in NSCLC. The ex vivo Tfh-B cell model provides a novel platform to evaluate therapies targeting TLS function. Combining TLS stratification via histology with Tfh-B cell synapse-enhancing agents represents a promising approach in precision medicine.

#5257 Functional profiling of γδ T cell subsets in malignant pleural effusion and their prognostic value in advanced lung cancer.

Tsai-Tsen Shih[1], Yi-Chieh Wu[2], Hsing-Chen Tsai[3]

[1]Yanping High School, Taipei, Taiwan,[2]Institute of Toxicology, National Taiwan University, Taipei, Taiwan,[3]Department of Internal Medicine, National Taiwan University Hospital, Institute of Toxicology, National Taiwan University, Taipei, Taiwan

The tumor immune microenvironment reflects a patient's immune reserve and offers valuable insights for clinical decision-making. It has the potential to stratify late-stage cancer patients, identifying those likely to benefit from aggressive therapies and those better suited for palliative care. However, obtaining detailed immune profiling from tumor tissues often requires invasive biopsies and poses additional risks. Malignant pleural effusion (MPE), a common complication in advanced lung cancer, provides a minimally invasive alternative for evaluating microenvironmental immune dynamics via thoracentesis. In this study, we analyzed the immune cell composition of malignant pleural effusions (MPE) from 73 patients with late-stage lung adenocarcinoma using high-dimensional spectral flow cytometry and a comprehensive panel of immunophenotypic and functional markers. Our analysis focused on cytotoxic immune cell populations, including NK cells, NKT cells, CD8+ T cells, and γδ T cells. Notably, γδ T cells constituted approximately 1.4% of viable cells, with the Vδ1 and Vδ2 subpopulations representing 32.3% and 46.6% of the γδ T cell compartment, respectively. Higher γδ T cell abundance was associated with shorter overall survival, while no correlation was observed for other immune cell populations. Further analysis revealed that a higher Vδ2/Vδ1 ratio correlated with poorer clinical outcomes. Conversely, elevated expression of the activating receptor DNAM-1 (CD226) on Vδ1 cells was observed in long-term survivors (>2 years) compared to short-term survivors (<6 months), independent of mutation type or treatment modality. These findings were validated using the TCGA lung cancer datasets, confirming a strong link between high DNAM-1 expression and extended survival. In conclusion, γδ T cell subpopulations in MPE, particularly the Vδ1 and Vδ2 subsets, are promising biomarkers for immune fitness and prognosis in advanced lung adenocarcinoma. These results highlight the potential of γδ T cells to identify late-stage patients likely to benefit from aggressive therapies and emphasize the need for larger-scale studies to confirm these findings.

#5258 The immunomodulatory effects of daratumumab-based therapy on functional high-risk relapse/refractory multiple myeloma (fHRMM) patients enrolled in the MyDRUG trial.

Chaitanya R. Acharya[1], Darwin D'souza[2], Reyka Jayasinghe[3], Mark Hamilton[1], Zhihong Zhihong[2], Seunghee Kim-Schulze[2], Hearn J. Cho[1], Shaji Kumar[4], George Mulligan[1]

[1]Multiple Myeloma Research Foundation, Norwalk, CT,[2]Human Immune Monitoring Center, Icahn School of Medicine at Mount Sinai, New York, NY,[3]Washington University in St. Louis, St. Louis, MO,[4]Department of Internal Medicine, Mayo Clinic, Rochester, MN

Background: The goal of this study is to evaluate the immunomodulatory effects of daratumumab-(anti-CD38)-based therapy on fHRMM patients enrolled in the MMRF sponsored MyDRUG umbrella clinical trial (NCT03732703) over the duration of therapy and to correlate immune changes with patient response.
Methods: fHRMM who had received 1-3 prior therapies (exposed to at least one proteasome inhibitor and an IMiD) were given a combination of daratumumab (D), ixazomib (I), pomalidomide (P) and dexamethasone (d) (D-IPd) quadruplet therapy. Bone marrow (BM) aspirates were then collected from patients prior to therapy (BL), after 2 cycles (EOC2), after 4 cycles (EOC4) of the quadruplet therapy and at the end of treatment or disease progression (EOT). Immune and tumor fractions were enriched by CD138 selection. Here, CD138- bone marrow mononuclear cells were isolated and transcriptionally profiled by scRNAseq and scTCRseq.
Results: Single-cell RNA and TCR profiles were generated from ~90,000 cells across 41 samples from 16 subjects. scRNAseq identified CD3+ T cells, NK cells, classical and non-classical monocytes and B cells. CD8+ T cells were further resolved into their subsets including precursor (T_{PEX}) and terminally exhausted T cells (T_{EX}) within the bone marrow microenvironment. Within the CD8+ T cell compartment, an expansion of the effector memory (T_{EM}) cell population was observed following 2-cycles of therapy (EOC2). However, this T_{EM} expansion was not sustained at timepoint EOC4. Towards the end of therapy, enrichment of precursors to exhausted and terminal dysfunctional effector memory cells (T_{EMRA}) was observed. Subjects with partial (PR), very good partial (VGPR) and complete (CR) best overall responses showed an initial increase in T_{EM} cells followed by a slow expansion of T_{EX} and T_{EMRA} cells over time. Longitudinal tracking of T cell clonality showed preferential progressive expansion of T_{EMRA} cells after the therapy. We mapped hyperexpanded (more than 16 copies) clonotypes, presumed to be tumor-reactive, to various CD8+ T cell subsets. These hyperexpanded clonotypes mapped to the T_{EMRA}, T_{EX} and T_{EM} CD8+ T cells. Analysis of TCR repertoires clonality and diversity also demonstrated a reduced richness and increased clonality of CD8+ TCRs in responders.
Conclusions: Paired single cell RNA and TCR sequencing of BM T cells from RRMM patients receiving D-IPd quadruplet therapy revealed a selective expansion of clonotypic CD8+ T cells with a clonal replacement of BM exhausted clonotypes by dysfunctional circulating CD8+ T cells in responders over time.

#5259 Unraveling the impact of smoking behavior on the immune landscape of prostate cancer.

Amod Sharma[1], Mohammad Aslam Khan[2], Muhammad Tahir[3], Ajay P. Singh[1], Seema Singh[1]

[1]Department of Cell and Molecular Biology and Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS,[2]Department of Pharmacy and Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN,[3]Department of Pathology, University of South Alabama, Mobile, AL

Smoking is a significant modifiable risk factor for prostate cancer (PCa) diagnosis, recurrence, and mortality. Immune cells play crucial role in cancer-associated inflammation, having a significant impact on tumor fate from early neoplastic transformation to metastatic spread and influencing treatment outcomes. We hypothesize that, in addition to causing carcinogenic mutations, tobacco smoke alters the tumor microenvironment to promote tumor progression. In this study, we examined the effect of smoking behavior on the immune landscape of prostate tumors by performing multiplex gene expression analysis of various immune cell types using the nanoString nCounter® PanCancer immune profiling panel. A total of 24 prostate tumor tissues (Gleason's score: 7-8) were analyzed, including 12 from never smokers, 7 from current smokers, and 5 former smokers. Unsupervised hierarchical clustering based on the immune scores from different immune cell types grouped PCa samples into two major clusters, representing low and high immune cell infiltration. A higher proportion of current smokers were grouped in the high immune infiltration cluster, whereas never smokers and former smokers predominantly fell into low immune infiltration cluster. In direct comparisons, significantly higher infiltration of tumor-associated macrophages (TAM) ($p=0.037$) and regulatory T cells (Tregs) ($p=0.046$) was observed in current smokers compared to never smokers, with a trend for lower mast cell infiltration ($p=0.055$). Additionally, a significant positive correlation ($r=0.42$; $p=0.036$) was observed between TAM with Tregs infiltration in all samples, with a stronger correlation ($r=0.88$; $p=0.008$) in current smokers. A total of 89 differentially expressed genes (DEGs) at a 1.5-fold change cutoff were identified between current and never smokers, with 77 genes being upregulated and 12 downregulated in current smokers. Interestingly, only 17 DEGs were identified between never smokers and former smokers. Pathway analysis of the DEGs in current smokers revealed activation of 'primary immunodeficiency' and 'PD-L1 expression and PD-1 checkpoint' pathways, while the 'antigen processing and presentation' and 'NF-kappa B signaling' pathways were repressed. Collectively, these findings suggest that current smokers have a relatively compromised tumor immune microenvironment compared to never and former smokers with PCa, potentially facilitating rapid tumor growth and aggressive progression. These findings also have implications for developing novel immune-based therapeutic interventions for PCa patients based on their smoking behavior.

#5261 The significance of CD200R1 on NK cells in the endometrial cancer tumor microenvironment.

Youssef Youssef[1], Caprice D. Eisele[1], Joel Cesar[1], Noah Koenigs[2], Micheal Ruesch[1], Courtney J. Riedinger[1], Paulina J. Haight[1], Ankur Sheel[1], Bethany L. Mundy-Bosse[1], Bradley L. Blaser[1], Casey M. Cosgrove[1], Aharon G. Freud[1]

[1]The Ohio State University Wexner Medical Ctr., Columbus, OH,[2]Biomedical Sciences Graduate Program, The Ohio State University Wexner Medical Ctr., Columbus, OH

Endometrial cancer (EC) is the most common gynecologic cancer in the USA and is expected to surpass ovarian cancer in mortality. Advanced-stage EC has poor outcomes with high relapses (>35%) and low chemotherapy response (50%). Immune checkpoint blockade (ICB) therapies are often ineffective in EC, indicating a need for better understanding the tumor microenvironment (TME). In many cancers, cytotoxic NK cell (cNK) function is suppressed in the TME through dysregulated differentiation toward an immune-suppressive tissue-resident (trNK) state. Single cell RNA-sequencing (scRNA-seq) data on treatment naïve primary EC samples (n=6, unpublished; n=11; Regner MJ et al), revealed trNK populations expressing the inhibitory glycoprotein CD200 receptor 1 (CD200R1). CD200R1+ trNK cells correlated with high expression of CD200 (the corresponding ligand on EC). CD200 is known to promote NK cell-mediated immunotolerance in physiological settings such as pregnancy to prevent abortion and ectopic endometrial implantation (endometriosis). In cancers, CD200 mediates inhibition of CD200R1+NK cells and promotes an immunosuppressive TME through TGF-β. Given that TGF-β is known to drive cNK-to-trNK polarization, we investigated their patterns in the scRNA-seq data revealing correlation between CD200 expression and TGF-β. Immunohistochemical staining of EC tissue showed trNK cells were enriched within tumor glands compared to stroma (6 vs. 2 cells per 400× high-power field; n=6, p=0.046), suggesting an enrichment of non-cNK cells within EC glands. *Hypothesis: CD200+ ECs promote a TME conducive to dysfunctional trNK phenotypes with impaired differentiation into effector cNK cells, enabling immune evasion and reduced ICB efficacy.* To address this, we performed flow cytometry on EC primary samples (n=17) and confirmed CD200R1 expression on trNK compared to benign endometrium (n=8) (32% vs 5% respectively; p=0.006). CD200R1 expression on trNK correlated with low/undetectable levels of NK cell cytotoxic/maturity markers (granzymes, perforin, CD94, KIRs, CD16, and EOMES). Functionally, co-culturing CD200R1+ NK precursor cells with stromal feeder cells overexpressing CD200 impaired NK cell maturation (increased innate lymphoid cells and decreased cNK). Further, co-culturing immature NK cells with human stromal cells in the presence of TGF-β promoted a trNK phenotype with elevated CD200R1 expression. This trNK polarization was prevented by adding anti-TGF-β. Altogether, our findings suggest that a CD200/CD200R1 axis modulates NK cell differentiation and function within the EC TME, potentially downstream of TGF-β signaling. Ongoing studies seek to determine whether blocking this axis enhances ICB efficacy, and potentially support clinical trials using Samalizumab (humanized monoclonal anti-CD200 antibody).

#5262 A zinc transporter drives pancreatic cancer cachexia via the crosstalk between tumor cells and immune microenvironment.

Zhijun Zhou[1], Mingyang Liu[1], Yu Ren[1], Jingxuan Yang[1], Xiuhui Shi[1], Yang Cai[1], Alex X. Arreola[1], Wenyi Luo[2], Kar-Ming Fung[1], Chao Xu[1], Ryan D. Nipp[1], Michael S. Bronze[1], Lei Zheng[3], Yi-Ping Li[4], Courtney W. Houchen[1], Yuqing Zhang[1], Min Li[1]

[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Yale School of Medicine, New Haven, CT,[3]Johns Hopkins University School of Medicine, Baltimore, MD,[4]The University of Texas Health Science Center at Houston, Houston, TX

Background: Cachexia is a systemic disease manifested with muscle atrophy and appetite loss, especially in patients with pancreatic cancer. Emerging evidence showed that cachexia is an inflammation-associated disease. But the role of tumor immune microenvironment in cachexia remains elusive. ZIP4, a zinc transporter, plays a critical role in promoting pancreatic cancer cachexia. We aimed to study how ZIP4 promotes cancer cachexia via interacting with immune microenvironment.
Methods: We evaluated the association between cachexia and several major immune cell types in the tumor tissue of patients with cancer. Genetically engineered mouse models and clodronate treatment were used to establish the mouse models with macrophage depletion. Flow cytometry, western blotting, chromatin immunoprecipitation assay and luciferase assay were used to study the underlying mechanism.
Results: We found that macrophage infiltration level in tumor tissue is associated with the prevalence and severity of cancer cachexia.

Depletion of macrophage using *Ccr2* knockout mice (*Ccr2*$^{-/-}$ mice) or clodronate treatment ameliorated cancer cachexia. Cytokine array identified TWEAK (also known as TNFSF12) as a key player in cancer cachexia. The basal level of TWEAK is low in macrophages and tumor cells. However, TWEAK level drastically increased in tumor cells when cocultured with macrophages. Mechanistically, macrophage-derived CCL5 upregulates TWEAK expression in cancer cells through p65 signaling axis. On the other end, ZIP4 induced CCL2 secretion from cancer cells through ZXDC, a zinc dependent transcription factor, leading to the recruitment and activation of macrophages. Overexpression of TWEAK restored the cachexia phenotype of cancer cells with low cachexia potential. Blocking ZIP4-TWEAK signaling axis restored appetite and muscle mass in pancreatic cancer mouse models.
Conclusion: This study identified an uncharacterized role of tumor immune microenvironment in promoting cancer cachexia through increasing TWEAK secretion from tumor cells. Specifically, ZIP4 increased CCL2 secreting from tumor cells, which recruits and activates macrophages. The activated macrophages secreted CCL5, upregulating TWEAK expression in cancer cells through TRAF6/NF-κB axis, thus forming a feedforward loop to promote cancer cachexia.

#5263 The spatial landscape of tumor-infiltrating lymphocytes in stage III colorectal cancers by single-cell spatial analysis.

HoJoon Lee[1], Andrew Su[1], Minh Tran[2], Richard Delacruz[3], Anuja Sathe[1], Xiangqi Bai[1], Ignacio Wichmann[1], Lance Pflieger[3], Bryce Moulton[3], Tyler Barker[3], Derrick Haslem[3], David Jones[3], Lincoln Nadauld[3], Quan Nguyen[2], Hanlee P. Ji[1], Terence Rhodes[3]

[1]Stanford University, Stanford, CA,[2]University of Queensland, Brisbane, Australia,[3]Intermountain Healthcare, Saint George, UT

Colorectal cancer (CRC) is a leading cause of cancer-related deaths. An important contributor to CRC development, maintenance and metastasis is the tumor microenvironment (TME). This cellular milieu contains neighboring tumor epithelial cells, normal epithelium, fibroblasts, endothelial cells, immune cells and many others. The characterization of the TME is critical for understanding tumor biology as well as determining specific features with clinical implications. Representing a subset of the TME, the tumor immune microenvironment (TIME) has specific cellular characteristics that are important predictors for the response to treatments such as immunotherapy. However, the accurate interpretation of complex spatial cell patterns poses significant challenges. To address these issues, we developed a novel computational framework that systematically analyzes spatial data. We conducted a spatial analysis using imaging mass cytometry applied to stage III colorectal adenocarcinomas. This study used multiplexed markers to distinguish individual cells and their spatial organization from 52 colorectal cancers. We determined the landscape features of cellular spatial features in the CRC tumor microenvironment. This spatial single-cell analysis identified 10 unique cell phenotypes in the tumor microenvironment that included stromal and immune cells with a subset which had a proliferative phenotype. These special features included spatial neighborhood interactions between single cells as well as different tissue niches, especially the tumor infiltrating lymphocyte regions. We applied a robust statistical analysis to identify significant correlations of cell features with phenotypes such as microsatellite instability or recurrence. We determined that microsatellite stable (MSS) colorectal cancers had an increased risk of recurrence if they had the following features: 1) a low level of stromal tumor-infiltrating lymphocytes, and 2) low interactions between CD4+ T cells and stromal cells. Our computational framework precisely defined two types of tumor-infiltrating lymphocytes (TILs) based on their spatial properties in the local tumor microenvironment: 1) intra-tumoral TILs within cancer CNs and 2) sTILs within stromal CNs. These spatial characterizations of TILs provide deeper insights into their role, beyond simple lymphocyte abundance. Moreover, our results point to the utility of spatial single-cell interaction analysis in defining novel features of the tumor immune microenvironments and providing useful clinical cell-related spatial biomarkers.

#5265 Single cell and spatial analysis unravels the immunosuppressive tumor microenvironment, HPV-associated features, and potential immunotherapy response in vulvar squamous cell carcinoma.

Athena Golfinos-Owens, Taja Lozar, Evie Carchman, Paul F. Lambert, Megan Fitzpatrick, Huy Q. Dinh

University of Wisconsin-Madison, Madison, WI

Vulvar squamous cell carcinoma (VSCC) is a rare gynecological cancer with a projection of a 35% increase in the next 20 years in North America. HPV is a known risk factor in VSCC, but HPV+ and HPV- subtypes of VSCC have previously been reported to be biologically but not clinically distinct. In addition, VSCC could be categorized by HPV and TP53 status with different prognoses. However, the VSCC tumor microenvironment (TME) and its contributions to patient clinical outcomes are not well understood. Here, we use single-cell and spatial omics to interrogate VSCC TME transcriptional and cellular heterogeneity as a foundation for understanding the tumor, stromal, and immune cell compartments of HPV+ and HPV-VSCC. Our integrated bioinformatics analysis of 8 scRNA-seq samples (5 HPV+ and 3 HPV-) from vulvar cancer patients identified diverse stromal and immune compartments with immunosuppressive features (high presence of Tregs, pro-tumoral macrophages and myofibroblasts) presenting “immunologically cold” tumor phenotypes. In addition, we identified HPV+ epithelial cells and analyzed HPV-associated cell-cell interactions. Furthermore, we used scRNA-Seq gene signature to deconvolute a bulk 800-gene dataset from an independent patient cohort of 48 samples with different HPV subtypes, including integrated and beta-HPV, to identify TME features associated with different HPV risk subtypes. Bioinformatics deconvolution results showed a new way to subtype VSCC, including a subset of “immunologically hot tumors” (increased CD8 T cells and dendritic cells) with high expression of known and emerging immunotherapy response markers (PD-L1 high, CXCL9 high). Lastly, we integrate scRNA-Seq with patient-matched spatial transcriptomics to identify cellular neighborhood and Ligand-Receptor interactions that may be associated with HPV, subtypes, and clinical outcomes. This study reports a comprehensive single-cell and spatial VSCC TME atlas, highlighting the immunosuppressive features of the TME, differences between HPV+ and HPV- samples, and identification of a subset of patients with “immunologically hot” tumors that may respond favorably to immunotherapy. These findings provide a foundation and resource to further study VSCC TME in both HPV+ and HPV- subtypes. Future studies include validating and studying potential biomarkers of clinical outcomes and immunotherapeutic targets of VSCC treatment.

#5267 Unveiling associations between Duffy-null status and circulating chemokines among a diverse breast cancer patient cohort.

Stevens M. Patino[1], Kenya Bynes[1], Jason White[1], Danielle S. Doucette[1], Emma Guyonnet[2], Julie Sahler[3], Brian Stonaker[2], Avery August[3], Lisa Newman[2], Rachel Martini[1], Melissa Davis[1]

[1]Institute of Translational Genomic Medicine, Morehouse School of Medicine, Atlanta, GA,[2]Weill Cornell Medicine, New York, NY,[3]Cornell University, Ithaca, NY

Breast cancer (BC), the most diagnosed cancer and the leading cause of cancer-related mortality among women worldwide, includes triple-negative breast cancer (TNBC), its most aggressive subtype, which is disproportionately prevalent among individuals of West African ancestry. Our previous studies have demonstrated a correlation between West African ancestry-specific expression of the Duffy Antigen Receptor for Chemokines (DARC) and TNBC incidence. DARC regulates CC and CXC chemokines, maintaining homeostatic chemokine levels. However, the Duffy-null polymorphism (rs2814778), fixed in individuals of West African descent as an evolutionary defense against Plasmodium vivax malaria, results in the absence of DARC on erythrocytes. We aim to understand how this absence may influence chemokine regulation and contribute to ancestry-specific differences in the tumor microenvironment. We hypothesize that individuals with the Duffy-null genotype exhibit higher circulating chemokine levels than those with the DARC allele among BC cases.

Since 2006, the International Center for the Study of Breast Cancer Subtypes (ICSBCS) has recruited patients from sites across the United States and Africa, collecting blood and tumor tissue samples. We utilized the Luminex multiplex assay to analyze plasma from the ICSBCS cohort, quantifying 50 biomarkers using the bead-based ELISA platform. Plate/batch effect normalization was done with MDimnNormn, and statistical tests were performed using JMP Pro 16. Genotyping for the Duffy-null allele (C) was conducted using TaqmanTM GTXpressTM Master Mix and specific probes on an Applied Biosystems 7500 Fast Real-Time PCR system.

Our cohort included Duffy-null (CC, n = 183), Duffy-null carriers (CT, n = 40), and non-Duffy-null (TT, n = 294) individuals. Univariate analysis of chemokine levels revealed significant associations between Duffy-null status and the following biomarkers: MCP-1/CCL2 ($p = 0.0116$), Gro- b/CXCL2 ($p = 0.0137$), MIP1a/CCL3 ($p = 0.0316$), GCP2/CXCL6 ($p = 0.0423$), I-TAC/CXCL11 ($p = 0.0008$), BCA- 1/CXCL13 ($p = 0.0252$), MIP3b/CCL19 ($p = 0.0023$), 6Ckine/CCL21 ($p = 0.0066$), and MPIF1/CCL23 ($p < 0.0001$).

These findings highlight significant associations between Duffy-null status and circulating chemokine levels, introducing novel BC biomarkers that characterize the relationship between Duffy-null status, BC, and West African ancestry. Moreover, these findings have important prognostic and therapeutic implications, particularly for addressing ancestry-specific factors in BC. Understanding these associations advances precision medicine efforts to address BC disparities affecting individuals of West African ancestry globally. Multivariate analyses to control for co-variates are ongoing to support these findings further.

#5268 Impede cancer brain metastasis by enhancing innate immunity with CCL2 targeting.

Yimin Duan, Lin Zhang, Yutao Qi, Xiangliang Yuan, Dihua Yu

UT MD Anderson Cancer Center, Houston, TX

Among the more than 300,000 newly diagnosed breast cancer patients every year, 5~20% of them will develop symptomatic brain metastasis (BrM) with a lower than 20% of 1-year survival rate. Our group previously reported that brain tumor microenvironment (TME)-mediated *PTEN* downregulation in BrM tumor cells leads to increased secretion of the CCL2 chemokine, which enhances the infiltration of $CCR2^+$ bone marrow derived myeloid cells to promote brain metastasis outgrowth. Here, we further assessed whether targeting CCL2 can effectively inhibit BrM progression. Indeed, targeting CCL2 through either knocking-down CCL2 or with Ccl2-blocking antibody exhibited significant inhibition of BrM growth. Mass cytometry analysis of the brain TME demonstrated dramatically decreased immune suppressive myeloid populations in the CCL2-targeted group, which is consistent with our previous findings. Remarkably, natural killer (NK) and $CD8^+$ T cells were dramatically increased in the TME of CCL2-knockdown BrMs. To test the contribution of the increased NK cells and/or $CD8^+$ T cells on BrM inhibition by CCL2-targeting, we specifically depleted NK cells or $CD8^+$ T cells with anti-NK1.1 or anti-CD8 antibody. Our data showed that depleting NK cells, but not $CD8^+$ T cells, blocked BrM inhibition effect of CCL2-targeting, indicating that the increased infiltration of NK cells significantly contributed to the BrM inhibition under CCL2 knockdown. These findings led us to postulate that CCL2 inhibits NK cell infiltration into BrM TME to facilitate BrM growth. Our in vitro NK cell migration assay with high- versus low-CCL2 tumor cells showed that high CCL2 level inhibited NK cell migration. In summary, our data indicate the potential of CCL2 targeting for controlling breast cancer BrM progression and highlight the pivotal role of NK cell-mediated innate immunity in combating BrM.

#5269 CXCL10 promotes melanoma angiogenesis and tumor growth.

J.-H. Lee;
Dong-A University, Busan, Korea, Republic of

Upregulation of CXC motif chemokine 10 (CXCL10) in melanoma patients has been found to be associated with melanoma progression. However, the role of endogenous CXCL10 from the host in melanoma tumor growth remains unclear. In the present study, we found that host-derived endogenous CXCL10 production was dramatically augmented during subcutaneous B16F10 melanoma tumor growth and that host ablation of CXCL10 in Cxcl10-/- mice showed a decrease in both angiogenesis and tumor growth of B16F10 melanoma in vivo. Several signaling pathways involved in production of pro-angiogenic factors and tumor growth were activated by CXCL10 in B16F10 melanoma cells. CXCL10 increased expression of pro-angiogenic factors, such as vascular endothelial growth factor (VEGF), platelet-derived growth factor subunit-B (PDGF-B), fibroblast growth factor 2 (FGF2), hepatocyte growth factor (HGF), and angiopoietin 2 (Angpt2), in B16F10 melanoma cells, resulting in enhanced tube formation and proliferation of human umbilical vein endothelial cells in vitro. In addition, CXCL10 directly enhanced B16F10 melanoma tumor growth in an in vitro three-dimensional cell culture system. Together, our findings reveal that amplified host-derived endogenous CXCL10 is critical for B16F10 melanoma angiogenesis and tumor growth. Therefore, CXCL10 might represent a therapeutic target for melanoma.

#5270 Novel dual-stain IHC assay enables discovery with enhanced clarity.

Scott Anderson[1], Stephen Pyper[1], **Jack Heath**[2], Julio Poveda[3]

[1]Leica Biosystems, Newcastle Upon Tyne, United Kingdom,[2]Leica Biosystems, Vista, CA,[3]University of Miami Miller School of Medicine, Miami, FL

Background: Immunohistochemistry (IHC) analysis has become a powerful and integral component in the diagnostic workup of tumors. It has been essential in biomarker discovery, with a growing demand for high-output methods that maximize data from limited tissue samples. Chromoplex II, an advanced technique that enables the simultaneous detection of dual stains on a single slide, permits the selection of primary antibodies to be stained in either color, aiding tissue differentiation while minimizing the interference often seen with endogenous pigments or slide debris. The duplex approach also reduces slide usage compared to single-stains and individual slides.
Methods: Using the BOND-III Automated IHC and in-situ hybridization (ISH) stainer from Leica Biosystems, Chromoplex II was evaluated in three dual-marker applications. At least five cases with known tumors of distinct tumor histology/classification were utilized to examine differences between the distinct cellular histology (i.e., adenocarcinoma and squamous carcinoma) as well as classical Hodgkin lymphoma (cHL) versus nodular lymphocyte predominant Hodgkin lymphoma (NLP). Another commonly encountered scenario is the difficulty in separating lung adenocarcinoma and bystander macrophages, so these tissues were tested as well. Stained slides were scanned using the Aperio GT 450 scanner from Leica Biosystems and evaluated by a clinical pathologist for specificity and comparability to single staining. The marker combinations and tissues tested were the following:•CD20/CD30: Lymph node•CK5/Napsin A: Lung •CD163/PD-L1: Lung
Results: In all three marker combinations, the Chromoplex II kit produced distinct red and green stains, providing a clear visualization of target markers. Importantly, it minimized background interference, significantly enhancing clarity in challenging tissue sections. The slides exhibited comparable signal and reproducibility compared to single marker staining, and many examples were noted in which the dual stain provided vital context about the nature of the relationship between the two markers studied.
Conclusions: Chromoplex II represents a promising tool for high-throughput biomarker studies in research, offering benefits in both clarity of staining and operational efficiency by reducing slide volume. Furthermore, additional studies and/or combinations are necessary to explore expanded marker combinations for broader cancer biomarker research applications.

TUMOR BIOLOGY: Tumor Microenvironment and Metastasis
Poster Session

#5273 Changes in the tumor immune microenvironment during disease progression in gynecological carcinosarcoma: Exploratory analysis from the randomized ROCSAN GINECO trial.

Sonia Canjura-Rodriguez[1], Cassandra Assaf[2], Victor Heurtier[3], Annalisa Pesavento[4], Justine Berthet[2], Audrey Bellesoeur[3], Coriolan Lebreton[5], Sheik Emambux[6], Dominique Berton[7], Magali Provansal[8], Guillaume Bataillon[9], Lucas Michon[1], Jessie Auclair[1], Alexandra Laine[1], Valery Attignon[1], Christophe Caux[2], Anthony Ferrari[1], Ivan Bieche[3], Bertrand Dubois[2], Isabelle Ray-Coquard[1], **Pierre Saintigny**[1]

[1]Centre Leon Berard, Lyon, France,[2]Centre de Recherche en Cancerologie de Lyon, Lyon, France,[3]Institut Curie, Paris, France,[4]Universite de Bourgogne Franche-Comte, Besancon, France,[5]Institut Bergonie, Bordeaux, France,[6]CHU de Poitiers - Hopital de La Miletrie, Poitiers, France,[7]ICO - Centre Rene Gauducheau, Saint-Herblin, France,[8]Institut Paoli Calmettes, Marseille, France,[9]IUCT - Oncopole Toulouse, Toulouse, France

Background: Gynecologic carcinosarcomas (CS) are highly aggressive/rare tumors. Most patients relapse after first-line therapies and responses to systemic therapy remain low. ROCSAN (NCT03651206) is a multicentric randomized phase II evaluating dostarlimab (anti-PD1) in combination with niraparib (PARPi) compared to standard of care in the treatment of metastatic/recurrent (R/M) CS. Objective: Mandatory tumor tissue archival from naïve initial disease (ND) & baseline biopsies at relapse (R/M) were used to decipher the biological changes of CS in R/M disease vs. ND.
Methodology: bulk transcriptomic profiling was performed on paired samples from 60/63 included patients. Differential expression, gene ontology (GO), and immune cell deconvolution were performed. Our previously reported HOT signature was computed (GSVA) (PMID36038492). Additionally, a 7-color multiplex immunofluorescence (mIF) analysis of 52 paired samples (CD20, Ki67, CD3, CD8, FoxP3, panCK, DAPI) was done to evaluate total T cells, CD8 and CD4 Teff, Treg, and B cells cell densities and tertiary lymphoid structures (TLS).
Results: Differential expression analysis adjusted for FIGO stage, primary site and number of previous systemic therapies identified 1,502 and 584 genes up and down regulated respectively in R/M disease vs. ND. Among 13 immune checkpoints (ICP) and 22 of their ligands (ICPL), 8 ICP (TIGIT, HAVCR2, CTLA4, VSIR, CD40LG, TNFRSF9, CD27, ICOS) and 4 ICPL (PD-L1, PDCD1LG2, CD80, CD86), were upregulated in R/M disease vs. ND. Top GO enriched pathways in R/M vs. ND included immune activating pathways, regulation of lymphocyte activation and positive regulation of cytokine production. Among 50 biological hallmarks (GSEA), R/M showed a significant enrichment in inflammatory response, TNFA signaling via NFKB, and IFNG response vs. ND. Deconvolution analysis found an increase in NK cells (P=0.024), Macrophage/Monocyte (P=0.001) and Neutrophils (P=0.023) in R/M disease vs. ND. The HOT signature score was found to be increased in R/M disease vs. ND (P=0.01). The proportion of HOT CS (score>0) was 33/60 (55%) and 23/60 (38%) in R/M and ND respectively. Among the 37/60 (62%) COLD CS (score<0) in ND, 18/37 (49%) became HOT in R/M. Among the 23/60 (38%) HOT CS at ND, 8/23 (35%) became COLD at R/M. mIF analysis showed that total T cells (P=0.037), CD8 Teff (P=0.039), CD4 Teff (P=0.034), and CD4 Treg (P=0.003) increased in R/M disease vs. ND. Intriguingly, TLS density decreased in R/M disease vs. ND (P=0.035).
Conclusion: When compared with ND, R/M CS host a greatest immunologically active microenvironment, as suggested by the changes observed in the HOT score and HOT/COLD phenotype, implying potentially more activity for immune therapy in relapse than for localized initial therapy. Whether this could be used to select patients for immunotherapy should be investigated.

#5275 A dynamic equilibrium of innate immune deaminases and deregulation in hematopoietic malignancies.

Jane Marie Isquith[1], Inge Van der Werf[1], Jessica Pham[1], Thomas Whisenant[2], Ludmil Alexandrov[3], Catriona Jamieson[1]

[1]Sanford Stem Cell Institute, UC San Diego, San Diego, CA,[2]Center for Computational Biology and Bioinformatics, UC San Diego, San Diego, CA,[3]Department of Bioengineering, Department of Cell and Molecular Medicine, UC San Diego, San Diego, CA

Inflammatory cytokine responsive apolipoprotein B mRNA-editing enzyme, catalytic polypeptide (APOBEC3) cytosine deaminases have been shown to be deregulated during cancer evolution, presenting as gene expression changes and inclusion of distinct C-to-T mutation patterns. However, the exact mechanisms by which APOBEC3 enzymes promote cancer initiation and progression remain to be investigated, especially in hematopoietic malignancies. Building on our advanced sequencing data of healthy, pre-leukemic, and myeloproliferative neoplasm patient samples, we seek to uncover normal and malignant patterns of APOBEC3C overexpression in hematopoietic cells. Overexpression of lentiviral APOBEC3C in normal cord blood, healthy bone marrow, and myeloproliferative neoplasm (MPN) patient hematopoietic stem/progenitor cells (HSPCs) allows us to study the effects of deaminase dysregulation in the hematopoietic niche. These overexpression studies show novel differential gene expression changes, repetitive element alterations, RNA hyper-editing sites, and DNA mutation signatures induced by APOBEC3 mutagenesis. In addition to APOBEC3, we are exploring the upregulation of adenosine deaminase acting on RNA1 (ADAR1), as we have previously shown that these two innate immune deaminases are synchronously upregulated in the high-risk myelofibrosis (MF) stem cell population compared to normal aged bone marrow. We have discovered a co-regulatory relationship dependent on a delicate equilibrium between APOBEC3C and ADAR1, indicating a correlative association between the dysregulation of these essential deaminases and the initiation and progression of hematopoietic malignancies as indicated by survival statistics and gene expression changes. We will use this comprehensive study of innate immune deaminase deregulation to uncover predictive biomarkers and hallmarks of malignant transformation.

#5276 Comprehensive spatial mapping uncovers immune ecotypes linked to tumor heterogeneity in HCC lung metastasis.

J. Zhu[1], G. Cai[1], B. Guo[1], X. Chen[1], H. Zhang[1], H. Zhu[2], W. Zhang[1];

[1]Huazhong University of Science and Technology, Wuhan, China, [2]the First Affiliated Hospital of Soochow University, Suzhou, China

Tumor immune microenvironment (TME) heterogeneity, shaped by diverse immune and stromal cells, significantly influences tumor metastasis, yet the specific immune ecotypes involved and their relationship to intra-tumor heterogeneity remain unclear. In this study, we present a comprehensive spatial and cellular multi-omics analysis of 44 primary and 54 lung metastatic lesions from 34 HCC patients. By integrating public single-cell RNA sequencing data from 187,290 tumor cells across 146 HCC cases, we define HCC cellular states and uncover their organization in high-dimensional spatial expression profiles from paired HCC primary and metastatic lung lesions. Our integrated analysis, incorporating data with three independent cohorts, uncovers three pro-metastatic modules—Cell cycle(G2/M), Cellular Stress and Hypoxia —that contribute to early HCC lung metastasis. Notably, the first two modules are specific to lung metastasis, while the latter one is common across all extrahepatic organs. We show how tumor cells with distinct modules interact with various immune cell types, facilitating metastasis through different mechanisms. Additionally, these tumor cells form multi-layered structures of varying sizes, with specific state pairs preferentially clustering across multiple scales, all within a 55 μm limit. In vivo studies further reveal that interactions between G2/M-high tumor cells and Angio-macrophages and T3-neutrophils accelerate lung dissemination. Treatment with the G2/M inhibitor paclitaxel effectively disrupts this process, reducing metastasis. These findings provide critical insights into how tumor cell heterogeneity reshapes the TME to drive metastasis, underscoring the importance of spatially informed features for personalized cancer therapies. Our work emphasizes the potential of tailored strategies to prevent and manage metastasis based on tumor-immune interactions.

#5279 Utilizing intravascular MHC-I antibody labeling to investigate regulation of tumor cell extravasation by ACKR1.

Rishi Patel, Samuel Tanner Roach, Serena Thomas, Braulio Aguilar, Hsun Wang, L.A. Naiche, Jan Kitajewski

Department of Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL

Background: Endothelial Ackr1 is a major regulator of immune cell extravasation. Tumor cells can co-opt mechanisms of leukocyte extravasation to exit the vasculature at distant metastatic sites. Detection of intravascular vs. extravasated tumor cells in the lung has previously relied on time-consuming confocal imaging with 3-D reconstruction. We optimized an intravascular labeling procedure to easily and quantitatively detect tumor cell extravasation via flow cytometry, and used it to investigate the effect of endothelial Ackr1 expression on tumor cell extravasation into the lung metastatic niche.
Methods: To investigate the effect of endothelial Ackr1 on tumor cell extravasation, we employed an experimental metastasis model. Metastatic breast cancer cells (E0771.LMB) expressing mCherry were intravenously injected into Control or endothelial-specific Ackr1 knock out (Ackr1 ECKO) mice and allowed to circulate and extravasate into lung tissue over 24 hours. 3 minutes before sacrificing the mice, we intravenously injected a fluorescently labeled anti-MHC I antibody to label tumor cells remaining within the vascular compartment. Harvested lungs were dissociated, and tumor (mCherry+) cells were classified as intravascular or extravascular depending on the presence of the MHC I antibody signal. To confirm that inflammation from the tumor did not create extravascular antibody leakage, we treated wildtype mice intratracheally with either PBS (control) or 300 ng of TNF-α. After 24 hours, we administered 15 µg of anti-Type IV Collagen (Col4) antibody, which does not bind within the vascular lumen but will bind endothelial basement membrane if extravasated. Antibody leakage was evaluated via Col4 staining in lung tissue and in the liver, which served as a positive control due to its fenestrated endothelial barrier.
Results: We were successfully able classify intravascular versus extravascular tumor cells in the lung metastatic niche via flow cytometry using intravascular MHC I antibody labeling. We detected no leakage of antibody from the vascular compartment of the lung in naïve or inflamed settings. Despite the well-characterized role of Ackr1 in extravasation of other cell types, we observed that endothelial Ackr1 expression does not affect the ability of tumor cells to extravasate into lung tissue after 24 hours in circulation in an experimentally induced metastasis model.
Conclusions/Future Directions: Our results highlight an efficient intravascular antibody labeling technique to assess tumor cell extravasation at distant metastatic sites. While endothelial Ackr1 did not impact tumor cell extravasation in the lung metastatic niche, we are using this labeling technique to evaluate the impact of endothelial Ackr1 expression on neutrophil extravasation into the lung pre-metastatic niche.

#5280 A strategic framework for modeling abnormal quiescence that drives cancer evolution, and for preclinical development of therapies to prevent recurrence and metastasis in high-risk patients.

Balraj Singh, Anthony Lucci

Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX

Our goal is to develop a cell culture model of cancer cells that persist under all challenges including therapies, mostly in quiescence, and evolve further to cause recurrence. The rationale for the choice of model as cell culture is that it is ideal of evaluating therapeutic strategies that may inhibit highly abnormal but adaptable cells. Body imposes a variety of bottlenecks ranging from different components of immunity to metabolic challenges to enforce quiescence and influence cancer evolution. As it is not possible to replicate all such bottlenecks in cell culture, our approach is to apply as severe a bottleneck as possible, thus eliminating all proliferative (non-adaptable) cells, leaving behind rare cells surviving in deep quiescence. We hypothesize that if the quiescent cell state being modeled can survive a severe bottleneck, it can also survive other bottlenecks of similar or lower severity. We have arrived at a prolonged lack of glutamine in cell culture medium as a bottleneck for selecting evolutionarily fit rare cells after trying several alternatives, including a lack of glucose, a partial lack of oxygen (hypoxia), or a lack of serum on surface that is unsuitable for cell attachment. While investigating glutamine dependence in aggressive triple-negative breast cancer cell lines, we serendipitously discovered that some rare cells could survive in deep quiescence not only this but variety of other metabolic and therapeutic challenges. Since glutamine and its metabolites are important in protein synthesis, nucleic acid synthesis, epigenome and epitranscriptome regulation, and in maintaining redox status, its sudden disappearance creates a catastrophe killing 99.99% cells; only rare cells survive in deep quiescence and evolve further to proliferate (an important feature of cancer recurrence/metastases). The adaptable cells selected in this manner have many desirable functional and molecular features that are relevant in resistant cancers with an elevated risk of recurrence. We will discuss our observations with rare cells (0.01% in population) surviving in quiescence for several weeks in aggressive breast cancer and melanoma cell lines and their functional characteristics. Our results obtained with adaptable cells from SUM149 TNBC cell line suggest that they are stem-like quiescent cells. Our gene expression analyses and phenotypic changes during quiescence suggest that like a model proposed for stem cell quiescence, cancer stem cells are not dormant; instead, they represent states of poised potential and active restraint as cells “idle” in anticipation of activation, proliferation, and differentiation. We will also discuss how we choose and evaluate therapies that would likely inhibit quiescent and slow-growing cancer cells. This framework may significantly improve anti-cancer drug discovery.

#5281 Analysis of tumor cell and neutrophil distribution relative to ACKR1 expressing venules during breast cancer metastasis.

Serena Thomas, S. Tanner Roach, Rishi Patel, Lauren Raasch, L. A. Naiche, Jan K. Kitajewski

University of Illinois at Chicago, Chicago, IL

Background: Metastasis is the leading cause of breast cancer-related mortality. However, the success of metastatic colonization is not solely determined by tumor cells' ability to disseminate; it is also influenced by the establishment of premetastatic niches within distant organs. Neutrophils promote lung metastasis by priming the premetastatic niche to make it a more hospitable environment for disseminating tumor cells. Atypical Chemokine Receptor 1 (ACKR1) is expressed on endothelial cells and is critical for neutrophil migration in inflammatory conditions, but its role has not previously been characterized in pre-metastatic niche formation.
Methods: To study the role of endothelial ACKR1 in tumor cell and neutrophil extravasation, we analyzed the distribution of disseminating tumor cells and neutrophils relative to ACKR1-positive versus ACKR1-negative vessels in the lungs of orthotopic mammary tumor-bearing mice. To analyze disseminating tumor cells and extravasated neutrophils, we performed immunofluorescent staining of lung vasculature from immunocompetent mice implanted with E0771.LMB mammary tumor cells 28 days post-tumor injection. Lung samples were stained with ACKR1, CD31, and either Pan-CK (to label tumor cells) or Ly6G (to label neutrophils). We developed a semi-automated workflow to analyze the distance between disseminated tumor cells, neutrophils, and the closest venule within the lung. Images were blinded and target cells (tumor cells and neutrophils), ACKR1-positive venules, and ACKR1-negative venules were manually annotated in QuPath. A custom script was developed to outline venules and calculate the minimum distance between each target cell and the nearest vessel wall within 150 microns of a venule. These results were binned to categorize target cells based on their proximity within 50, 100, or 150 microns of an ACKR1-positive or -negative venule.
Results: Our analysis revealed a significant increase in the average number of tumor cells within 50 microns of ACKR1-positive venules compared to ACKR1-negative venules. Similarly, neutrophil analysis showed a significant increase of neutrophils within 50 microns of ACKR1-positive venules. In lung tissue more than 50 microns from a venule, no differences in the number of tumor cells or neutrophils were detected.
Conclusion/Future Directions: These findings demonstrate that both disseminated tumor cells and neutrophils preferentially localize near ACKR1-positive lung venules during breast cancer metastasis, suggesting that both cell types extravasate preferentially through ACKR1-expressing venules. Ongoing studies aim to define the role of ACKR1 in regulating neutrophil and tumor cell extravasation, phenotype, and survival in the premetastatic niche.

#5282 New insights into the roles of transcriptional regulation and differentiation state in rhabdomyosarcoma cell migration.

Andrea Largent, Yadong Wang, Abraham Hengyucius, Eleanor Chen

University of Washington, Seattle, WA

The differentiation state of a tumor cell has been known to impact the cell's pro-tumor and pro-metastatic abilities; for example, in epithelial tumors like lung cancer, epithelial-mesenchymal transitions (EMT) involve a conversion from a differentiated phenotype to a stem-like state, allowing for increased tumor cell motility and successful metastasis. In rhabdomyosarcoma (RMS), a pediatric soft tissue sarcoma, tumors are heterogeneous for cells at different stages of myogenesis or muscle cell differentiation, but it is not fully clear whether certain myogenic cell types have a propensity towards metastatic migration than others. In both development and RMS, master regulatory factors (MRFs) are essential for transcriptional regulation of genes involved in myogenesis. One of these MRFs is myogenin, a transcription factor expressed during mid-differentiation that leads to a more committed myocyte state. Myogenin-positive RMS cells in a zebrafish model have been shown to exhibit many metastasis-promoting abilities, such as increased migratory velocity compared to stem-like RMS cells, the ability to enter the bloodstream, and the capacity to seed tumor-free areas surrounding the tumor. This indicates that metastasis in RMS may rely heavily on transcriptional regulation and likely involves cells of a myocyte-like state. Knowing this, our lab carried out a human cell line knockdown (KD) scratch assay screen of multiple epigenetic factors to investigate if any may also be involved in RMS cell movement. From this screen, BRD1, a bromodomain-containing transcriptional regulator, emerged as a driver of RMS cell migration, and subsequent quantitative PCR (qPCR) analysis of BRD1 KD cells additionally indicated a significant role in MRF and stem cell marker expression. Immunofluorescent staining of untreated RMS cells 24 hours post-scratch revealed that migratory cells exhibit increased BRD1 and myogenin expression as well as decreased MyoD expression (an earlier MRF), suggesting that migratory RMS cells are at a later differentiation state. These results and future experiments would significantly impact the field, as the metastatic functions of BRD1 and myogenin were previously unknown and understudied, respectively.

#5283 Decoding and disrupting the coupled cellular plasticity and myeloid cell instigation in metastatic prostate cancer.

Tianhe Huang[1], Yaoyin Li[1], Jun Wan[2], Liang Cheng[3], **Xin Lu**[1]

[1]Biological Sciences, University of Notre Dame, Notre Dame, IN,[2]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[3]Department of Pathology and Laboratory Medicine, Brown University Warren Alpert Medical School, Providence, RI

Prostate cancer (PCa) metastasis significantly worsens patient prognosis, particularly when it spreads to the lungs. Understanding the mechanisms underlying PCa metastasis is crucial for developing effective therapies. Here, we developed a genetically engineered mouse model by activating MAPK pathway in the PB-Cre Pten p53 Smad4 mice, creating a model that mimics the aberrant cell signaling associated with human metastatic PCa and exhibits strong metastatic phenotype. We observed dynamic changes in epithelial-to-mesenchymal transition (EMT) and mesenchymal-to-epithelial transition (MET) during metastasis: circulating tumor cells (CTCs) displayed mesenchymal characteristics, while lung metastases regained epithelial features.

Transcriptomic profiling of primary tumors, CTCs, and lung metastases revealed that lung metastatic cells (LM) upregulated pro-inflammatory cytokines, notably IL-1α. This cytokine profile correlated with increased recruitment and activation of neutrophils in the premetastatic lung niche, as confirmed by single-cell RNA sequencing and flow cytometry. Functional experiments demonstrated that depleting neutrophils using anti-Ly6G antibodies or inhibiting their recruitment and activation via a CXCR1/2 antagonist (currently in clinical trials) significantly reduced lung metastasis and extended survival in mice. Similarly, IL-1 receptor knockout mice showed decreased neutrophil infiltration and fewer metastatic nodules, indicating the pivotal role of IL-1 signaling in neutrophil-mediated metastasis.

Mechanistically, we identified the transcription factor KLF4 as the master regulator of both the EMT-to-MET plasticity and IL-1α expression in metastatic cells. Chromatin immunoprecipitation confirmed KLF4 binding to the IL-1α promoter, leading to the upregulation of neutrophil-recruiting cytokines. Knockdown of KLF4 in LM cells reduced IL-1α levels and metastasis, while overexpression enhanced them. Co-culture of tumor cells with neutrophils increased KLF4 expression and cytokine production, suggesting a feedback loop promoting metastasis.

Clinical data analysis showed that high levels of KLF4 and IL-1α correlate with increased neutrophil infiltration and poorer disease-free survival in PCa patients. Our findings identify the crucial role of the KLF4/IL-1α axis and neutrophil recruitment in PCa lung metastasis. Targeting neutrophil activation or the KLF4/IL-1α signaling pathway may offer new therapeutic strategies for preventing or treating metastatic prostate cancer.

#5284 Reduced occludin expression is related to unfavorable tumor phenotype and poor prognosis in many different tumor types: a tissue microarray study on 16,870 tumors.

Seyma Buyucek[1], Florian Viehweger[1], Viktor Reiswich[1], Natalia Gorbokon[1], Viktoria Chirico[1], Christian Bernreuther[1], Florian Lutz[1], Simon Kind[1], Ria Schlichter[1], Soren Weidemann[1], Till S Clauditz[1], Andrea Hinsch[1], Ahmed Abdulwahab Bawahab[2], Frank Jacobsen[1], Andreas M Luebke[1], David Dum[1], Elena Bady[1], **Lisa Hornsteiner**[1], Claudia Hube-Magg[1], Martina Kluth[1], Katharina Moller[1], Anne Menz[1], Andreas M Marx[3], Till Krech[1], Patrick Lebok[1], Christoph Fraune[1], Guido Sauter[1], Ronald Simon[1], Eike Burandt[1], Sarah Minner[1], Stefan Steurer[1], Maximilian Lennartz[1], Morton Freytag[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]University of Jeddah, Jeddah, Saudi Arabia,[3]Academic Hospital Fuerth, Fuerth, Germany

Occludin is a key component of tight junctions. Reduced occludin expression has been linked to cancer progression. To study the role of occludin in cancer, a tissue microarray containing 16,870 samples from 148 different tumor types and 608 samples of 76 different normal tissue types was analyzed by immunohistochemistry. Occludin immunostaining was observed in 10,746 (76.6%) of 14,017 analyzable tumors, including 18.9% with weak, 16.2% with moderate, and 41.6% with strong staining intensity. Occludin positivity was found in 134 of 148 tumor categories and was most frequent in adenocarcinomas (37.5-100%) and neuroendocrine neoplasms (67.9-100%), less common in squamous cell carcinomas (23.8-93%) and in malignant mesotheliomas (up to 48.1%) and rare in Non-Hodgkin's lymphomas (1-2%) and most mesenchymal tumors. Reduced occludin staining was associated with advanced pT stage ($p<0.0001$), L1 status ($p=0.0384$), and absence of microsatellite instability ($p<0.0001$) in colorectal adenocarcinoma, advanced pT stage in pancreatic adenocarcinoma ($p=0.005$), high ISUP grade ($p<0.0001$), advanced pT stage ($p<0.0001$), high UICC stage ($p<0.0001$), distant metastasis ($p=0.0422$), and shortened overall ($p=0.0045$) or recurrence-free survival ($p=0.0116$) in clear cell renal cell carcinoma (RCC), high pT stage ($p<0.0001$) and UICC stage ($p=0.0228$), distant metastasis ($p=0.0338$), and shortened recurrence-free survival ($p=0.006$) in papillary RCC, and advanced pT stage ($p=0.0133$) in serous high-grade ovarian cancer. Occludin staining was unrelated to parameters of tumor aggressiveness in breast, gastric, endometrial, and thyroidal cancer. Our data demonstrate significant levels of occludin expression in many different tumor entities and identify reduced occludin expression as a potentially useful prognostic feature in several tumor entities.

#5285 Activation of endothelial ACKR1 in the pre-metastatic niche regulates neutrophil recruitment and tumor metastasis in breast cancer.

Samuel Tanner Roach, Serena Thomas, Rishi Patel, Hsun Wang, Braulio Aguilar, Chinwe Ewenighi-Amankwah, Lauren Raasch, William Muller, L.A. Naiche, Jan Kitajewski

University of Illinois at Chicago, Chicago, IL

Background: Extravasation of neutrophils into the pre-metastatic niche promotes metastatic breast cancer cell survival. ACKR1 is a non-signaling cytokine receptor expressed on endothelial and erythroid cells and acts as a critical regulator of neutrophil extravasation in multiple inflammatory contexts. Our work has shown that endothelial ACKR1 is upregulated in the lung pre-metastatic niche during primary breast tumor progression. Therefore, we tested the requirement for lung endothelial ACKR1 expression in neutrophil recruitment to the pre-metastatic niche and for breast cancer metastasis to the lung.
Methods: We investigated the role of endothelial ACKR1 in the lung pre-metastatic niche using a novel endothelial-specific ACKR1 knockout mouse model (ACKR1 ECKO). Pre-metastatic niche formation was induced in control and ACKR1 ECKO mice via daily intraperitoneal injections of tumor-conditioned media. Immunohistochemistry and flow cytometry were employed to analyze the percentage of neutrophils in the pre-metastatic niche and quantify neutrophil extravasation into the lung parenchyma. Intravenous tumor cell injections were performed following pre-metastatic niche formation to assess the impact of endothelial ACKR1 on tumor cell extravasation and colonization in the lung. Lung tissues were collected at 24 hours and 2 weeks post-tumor cell injection, and tumor cell extravasation and overall metastatic burden were analyzed using flow cytometry and whole-mount immunofluorescent imaging. The effect of endothelial ACKR1 expression on neutrophil adhesion and transendothelial migration under tumor inflammatory conditions was tested using monolayer transmigration assays *in vitro*.
Results: We found that endothelial ACKR1 expression was activated in the lungs of mice bearing mammary tumors or injected with tumor-conditioned media. After pre-metastatic niche induction, the lung parenchyma of ACKR1 ECKO mice had significantly fewer neutrophils than control mice, with no reduction in circulating neutrophils. Tumor cell extravasation and seeding of the lung 24 hours after tail vein injection were unaffected by endothelial ACKR1. However, at the 2-week timepoint, we found that ACKR1 ECKO mice had significantly decreased lung metastatic nodules compared to controls. Finally, we observed that tumor-conditioned media can induce high ACKR1-expressing HUVEC cells *in vitro* and promote neutrophil adhesion and transendothelial migration.
Conclusion: Our study shows that secreted factors from the primary tumor upregulate endothelial ACKR1 in the lung pre-metastatic niche and facilitate neutrophil recruitment, ultimately promoting lung metastasis. We are now investigating which steps of neutrophil extravasation are regulated by endothelial ACKR1 and identifying the chemokines that allow ACKR1 to regulate this process during metastasis.

#5286 The acquisition of CD11a via trogocytosis by gastric cancer cells after contact with T cells increases adhesion to endothelial cells.

Hideyo Miyato, Eri Suizu, Rei Takahashi, Misaki Matsumiya, Hirofumi Sonoda, Hideyuki Ozawa, Hironori Yamaguchi, Naohiro Sata, Joji Kitayama

Jichi Medical University, Shimotsuke, Japan

It has been revealed that plasma membrane and membrane molecules are frequently transferred upon cell-to-cell contact, which is named as trogocytosis, and that this phenomenon between immune cells plays an important role in the immune responses. However, the physiological roles of trogocytosis between cancer cells and immune cells are poorly understood. In this study, we hypothesized that the transfer of membrane molecules from immune cells to cancer cells arrows cancer cells to acquire the functions involved in extravasation, which results in increased metastatic ability. Gastric cancer cell line, OCUM-1 was co-cultured with T cells whose plasma membrane was stained with PKH26. Flowcytometric analysis revealed that OCUM-1 became positive for PKH26 at 3 hours and the positive rate increased over time. The acquisition of PKH26 was dependent on cell-to-cell contact and suggested to be attributed to trogocytosis. Among various immunological synapse molecules of T cells, OCUM-1 came to express CD45, CD3, CD4 and CD11a after 8 hours of coculture (positive rate, CD45: 64.0%, CD3: 36.0%, CD4: 11.3%, CD11a: 16.8%). We focused on CD11a, which belongs to β2 integrins and aids immune cells to adhere endothelial cells and extravasate. After co-culture OCUM-1 with T cells on which CD11a was fluorescently labelled with anti-CD11a antibody, CD11a was transferred from T cells to OCUM-1. The expression level of CD11a on OCUM-1 was accelerated after co-culture with activated T cells (positive rate, with T cells: 12.6% vs with activated T cells: 65.9%) and the adhesion rate on endothelial cells increased in a CD11a dependent manner (adhesion rate, monoculture: 2.0±0.64%, co-culture: 6.3±2.0%, co-culture (pre-treat with CD11a antibody): 2.3±1.4%, n=10, monoculture vs co-culture: $p<0.0001$, co-culture vs pre-treat: $p<0.0001$).These results suggest that after escape from attack of T cells, cancer cells could acquire CD11a from T cells and increase the adhesive property on endothelial cells of target organs, which might result in promotion of intravenous metastasis.

#5287 Decoding tumor-immune interactions in colorectal cancer liver metastases: Insights from single-cell analysis.

Ji Hye Choi[1], Yeong Hak Bang[2], Kyung Yeon Han[2], Woong-Yang Park[2]

[1]Sungkyunkwan University, Seoul, Korea, Republic of,[2]Samsung Genome Institute, Samsung Medical Center, Seoul, Korea, Republic of

Background: Liver is the most common site of colorectal cancer (CRC) metastasis. As liver microenvironment differs significantly from the colon microenvironment surrounding the tumor, we hypothesized that both cancer cells and liver microenvironment undergo changes that promote tumor growth and suppress the immune response. Here, we aimed to identify distinct cancer cell clusters in the liver and evaluate the upregulated interactions between immune cells in the liver.
Method: We conducted single-cell RNA sequencing of primary and liver metastasis (CRLM) samples, along with paired normal samples from colon and liver, respectively. We conducted non-negative matrix factorization to define multiple epithelial cell clusters and evaluate proportional enrichment and interactions between immune cells.
Results: To investigate colorectal epithelial cells and identify those contributing to liver metastasis, we analyzed a total of 273,711 cells derived from 78 CRC samples (primary tumor from localized CRC, N = 44; primary tumor from CRLM, N = 21; metastatic tumor from CRLM, N = 13), and 33 normal samples (25 from the colon and 8 from the liver). Excluding five epithelial cell clusters that clustered with normal tissues, we defined 14 tumor-associated epithelial cell clusters. Three dominant clusters in primary colorectal cancers (EPI_PC) showed upregulation of hypoxia, stress, and MHC pathways. On the other hand, two dominant clusters in CRLM (EPI_LM) exhibited enriched hyperkeratosis and cell junction pathways, and these cells were found to be in a later stage of differentiation in trajectory analysis. Furthermore, these clusters exhibited an increase in the activation of angiogenesis and epithelial-mesenchymal transition (EMT) pathways, from localized CRC (without metastasis) to primary tumor from CRLM, and metastatic tumor from CRLM. To examine differences in interactions between epithelial cells and the tumor microenvironment in the colon and liver, we performed cell-to-cell interaction analysis focusing on CRLM and matched primary CRC samples. The analysis revealed upregulation of semaphorin 6, semaphorin 7, CD137, and TRAIL pathways between these epithelial cells and C1QC+ macrophage and CD8+ effector T cells. Notably, immune checkpoint signaling, including TIGIT and PVR pathways, was upregulated between epithelial cells and CD8+ exhausted T cells in the CRLM. Spatial transcriptomics showed distinct showed distinct distributions of EPI_PC and EPI_LM, presenting specific immune-cell interactions in some CRLM samples.
Conclusions: Our study highlights that the CRLM-associated clusters were featured in a later stage of differentiation and high expression of angiogenesis and EMT pathways. Considering the upregulated pathway between EPI_LM and immune cells, treatment strategies targeting these interactions may be helpful for CRC patients with liver metastasis.

#5288 Identification of cancer cells with metastatic potential in nasopharyngeal carcinoma through spatial multi-omics analysis.

Songran Liu[1], Zhaozheng Hou[1], Kazi Anisha Islam[1], Yingpei Zhang[1], Larry Ka-Yue Chow[1], Ying Wang[2], Ping Feng[3], Michael King Yung Chung[1], Kiu-Wai Cheng[1], Dittman Lai-Shun Chung[1], Yunfei Xia[2], Wei Dai[1]

[1]Clinical Oncology, University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, China,[2]Radiation Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China,[3]Department of Experimental Research, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Metastasis is the leading cause of nasopharyngeal carcinoma (NPC) mortality. The understanding of the process of metastasis is inadequate.
Objectives: To identify the high-metastatic-potent (HMP) cluster in NPC using a set of key genes based on spatial multi-omics analysis.
Method: 238 NPC samples, 110 from Hong Kong (HK) and 128 from Guangzhou (GZ), were classified into the metastatic (MET) group if the patient developed a remote metastasis within 5 years after the diagnosis of NPC, and into the non-metastasis (nonMET) group vice versa. Two HK samples (MET vs. nonMET: 1 vs. 1) were profiled by single-cell spatial transcriptome sequencing (scST) to explore the HMP cluster and its signature genes. Twenty-eight GZ samples were utilized for spatial transcriptome (GZ_ST: 14 vs. 11) and spatial proteome (GZ_SP: 17 vs. 11) profiling to streamline the signature genes into a final gene list. Validation at the transcriptome level and protein level was accomplished by bulk RNA sequencing (HK: 39 vs. 38; GZ: 41 vs. 59) and spatial proteome sequencing (HK_SP: 19 vs. 12), respectively. Independent validation was performed by multiplex immunohistochemical staining (mIHC).
Results: Ten epithelial clusters from tumor cells were defined by cell segmentation and deconvolution in scST. Three clusters exhibited significant enrichment in the MET samples generating 69 signature genes for HMP. Gene set enrichment analysis (GSEA) in GZ_ST indicated a substantial activation of HMP signature in the MET group (two-sided $p = 0.044$). Thirty-three leading-edge genes in HMP signature were selected to evaluate the expression levels in scST, GZ_ST, and GZ_SP. Nineteen genes were included in the final gene list as their expressions were higher than average, upregulated in the MET group, and specific to HMP clusters. GSEA analysis in bulk RNA sequencing showed that the 19 HMP genes were activated in the MET group (one-sided $p = 0.032$). The lactate dehydrogenase A (LDHA)/enhancer of zeste homolog 2 (EZH2)/insulin-like growth factor 1 receptor (IGF1R) regulatory axis may play a key role in tumor metastasis by affecting tumor invasion. Pearson correlation analysis in bulk RNA sequencing displayed a positive correlation between HMP cluster and several lytic EBV genes transcribed from the BART regions ($r > 0.4$, $p < 0.05$), suggesting the potential role of EBV lytic reactivation in promoting metastasis.
Conclusions: The high-metastatic-potent cluster was identified through this spatial multi-omics study. The selected biomarkers well define this cluster and enlighten the underlying metastatic mechanisms and its relevance of EBV lytic reactivation.
Acknowledgement: This work was supported by General Research Fund (17102619) and Theme-based Research Scheme (T12-703/22-R; T123-70323-N) from Research Grant Council, and Technology Program of Guangdong Province in China (2021A0505110010).

#5289 Mechanisms of metastasis revealed through single-cell spatial transcriptome analysis in patients with liver metastatic colorectal cancer.

Jongwon Lee[1], Yeseul Kim[2], Hyo Seon Ryu[3], Jongmin Sim[2], Chungyeul Kim[2], Hyun Woo Kwon[4], Hyun Je Kim[5], Jong Min Park[6], Ah-Reum Lim[6], Jung Sun Kim[6], Hwa Jung Sung[6], Xingyi Guo[7], Jungmin Choi[1], **Jungyoon Choi**[6]

[1]Department of Biomedical Sciences, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Department of Pathology, Korea University College of Medicine, Seoul, Korea, Republic of,[3]Division of Colon and Rectal Surgery, Department of Surgery, Korea University College of Medicine, Seoul, Korea, Republic of,[4]Department of Nuclear Medicine, Korea University College of Medicine, Seoul, Korea, Republic of,[5]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[6]Division of Oncology/Hematology, Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea, Republic of,[7]Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Vanderbilt University School of Medicine, Nashville, TN

Background: The efficacy of treating colorectal cancer (CRC) liver metastases is hindered by significant tumor heterogeneity, both within and between tumors. This diversity stems from varied cell populations and complex interactions in the tumor microenvironment, necessitating a deeper understanding of spatial organization and cellular communication patterns.
Methods: We examined 23 formalin-fixed paraffin-embedded tissue samples from 11 patients, comprising primary lesions and matched liver metastasis (6 with synchronous and 5 with metachronous metastases) using NanoString 6K CosMx Spatial Molecular Imaging (SMI). Pathologists selected optimal fields of view at tumor invasive fronts. Image processing, cell segmentation, and feature extraction utilized an in-house CosMx SMI pipeline with the Cellpose algorithm. Following quality control, the remaining cells underwent unsupervised clustering with differential gene expression analysis and cell-to-cell interaction analyses performed using the Seurat R package.
Results: Analysis of 105,624 high-quality cells revealed 23 distinct clusters, categorized as ten epithelial tumors, three cancer-associated fibroblast (CAF), two endothelial cells, five immune cells (T cell, Monocyte, Macrophage, SPP1+ Macrophage, and Plasma cell), alveolar cells, hepatocytes, and low complexity cell populations. We identified significant differences in gene expression between colon and liver CAFs, with liver CAFs displaying upregulation of 92 genes associated with epithelial-mesenchymal transition (EMT). Enhanced communication between CAFs, T cells, and macrophages was observed in liver metastases, with specific ligand-receptor pairs (SPP1-ITGA4/ITGB1, LGALS9-P4HB, LGALS9-CD44, CXCL12-CXCR4) enriched in the metastatic microenvironment.
Conclusion: Our findings demonstrate distinct spatial heterogeneity and intercellular communication networks in CRC liver metastases. The identification of liver-specific CAF gene expression profiles and unique ligand-receptor interactions provides new insights into metastatic mechanisms and potential therapeutic targets.

#5290 Spatial multi-omics defines a shared glioblastoma infiltrative signature at the resection margin.

Balagopal Pai[1], Susana Ramos[1], Wan Sze Cheng[1], Tanvi Joshi[1], Gabrielle Price[1], Jessica Tome-Garcia[1], Kristin Beaumont[1], Robert Sebra[1], Raymund Yong[1], Elena Zaslavsky[1], **Nadejda M. Tsankova**[2]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]Pathology and Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY

Glioblastoma (GBM) remains an untreatable disease. Understanding of GBM's infiltrative biology at the resection margin is limited, despite causing disease recurrence and progression. To address this, we generated a high-throughput single-nucleus (sn)RNA-seq and snATAC-seq multi-omic dataset from six tumors with distinct genomic drivers and combined it with spatial transcriptomics to characterize the unique molecular phenotype of GBM near the margin. By contrasting GBM-specific biology in matching "Core" vs. "Margin" dissections, we define unique, shared "GBM infiltration" and chromatin accessibility signatures near the margin. We prioritize *EGFR* as a top differentially expressed and accessible "Margin" marker across GBM subtypes, show its dynamic expression along a core-to-margin infiltration trajectory, and validate its role in migration through CRISPR/Cas9 deletion in two patient-derived models. ChIP-seq studies further corroborate preferential TEAD1 binding at EGFR's accessible regulatory elements. This validated multi-omic dataset enables further studies into tumor and microenvironment biology in the context of residual GBM disease.

#5294 Prevalence of KDM6A deficiency in human cancer: a tissue microarray study on 14,814 cancers from 153 different tumor types.

Florian Viehweger[1], Paul Wirth[1], Natalia Gorbokon[1], **Maximilian Lennartz**[1], Viktor Reiswich[1], Till Krech[2], Claudia Hube-Magg[1], Elena Bady[1], Lisa Hornsteiner[1], Guido Sauter[1], Ronald Simon[1], Stefan Steurer[1], Martina Kluth[1], Andreas H Marx[3], Andrea Hinsch[1], Andreas M Luebke[1], Anne Menz[1], Clara von Bargen[1], Frank Jacobsen[1], Piero Caneve[1], Ria Schlichter[1], Sebastian Dwertmann Rico[1], Simon Kind[1], Soren Weidemann[1], Maria Christina Tsourlakis[1], Waldemar Wilczak[1], Till S Clauditz[1], Christian Bernreuther[1], Sarah Minner[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Clinical Center Osnabrueck, Osnabrueck, Germany,[3]Academic Hospital Fuerth, Fuerth, Germany

KDM6A (lysine demethylase 6A) is an epigenetic regulator and part of the COMPASS-like complex. Truncating KDM6A mutations commonly occur in cancer and may result in a dependency on EZH2, a potential therapeutic target. Because only one copy of X chromosome genes is normally active in human cells, truncating KDM6A mutations result in a complete expression loss which can be seen by immunohistochemistry. To assess the prevalence of KDM6A expression loss and its role in cancer, a tissue microarray containing 14,814 samples from 153 different tumor entities was analyzed. In normal tissues, KDM6A staining was ubiquitously seen in nuclei. At least one case with a complete KDM6A expression loss was observed in 58 of 153 tumor categories. KDM6A deficiency predominated in urothelial carcinomas (17.3-42.0%). Tumor entities with a KDM6A deficiency rate of 4-10% included adenocarcinomas of the gallbladder (9.3%), the stomach (up to 8.3%), the pancreas (7.7%), and the prostate (5.9%), endometrioid and serous endometrial carcinoma (up to 7.8%), squamous cell carcinomas (up to 7.5%), papillary renal cell carcinoma (5.1%), hepatocellular carcinoma (4.4%), and malignant melanoma (4.2%), and serous high-grade carcinoma of the ovary (4.1%). Reduced KDM6A expression was associated with advanced pT stage ($p=0.0233$), high grade ($p=0.0002$), distant metastasis ($p=0.0152$), and absence of ER ($p<0.0001$) and PR ($p=0.0045$) expression as well as HER2 amplification ($p=0.0005$) in breast cancer, nodal metastasis in squamous cell carcinomas ($p=0.0498$), advanced pT stage ($p=0.0002$), nodal metastasis ($p=0.0112$), and microsatellite instability (MSI; $p=0.0147$) in colorectal adenocarcinoma, and with MSI ($p=0.0033$) in gastric adenocarcinoma. Among gender agnostic cancers, KDM6A deficiency was markedly more common in tumors from males (4.3%) than from females (1.9%; $p<0.0001$). KDM6A sequencing of 78 bladder cancers revealed truncating mutations in 48.7% and non-truncating mutations in 5.1% of tumors. Truncating but not non-truncating KDM6A mutations were significantly associated with KDM6A expression loss ($p<0.0001$). All 15 (100%) male patients and 17 of 23 (73.9%) female patients with a truncating KDM6A mutation had a complete KDM6 expression loss. It is concluded that KDM6A deficiency predominates in urothelial neoplasms although it occurs in many different tumor entities, and that both reduced and absent KDM6A correlates with increased aggressiveness. Whether KDM6A deficient cancers are susceptible to EZH2 inhibitors in vivo remains to be seen.

#5296 Hepatocellular carcinoma resistance and recurrence to anti-PD-1 therapy is associated with tumor heterogeneity and plasticity driven by MYC.

S. Zhang, L. Danilova, J. T. Mitchell, I. Kwon, A. S. Popel, M. Yarchoan, E. M. Jaffee, E. J. Fertig, L. T. Kagohara;
Johns Hopkins University School of Medicine, Baltimore, MD

Hepatocellular carcinoma (HCC) is the most prevalent type of liver cancer and a major cause of cancer-related deaths worldwide. HCC is characterized by low survival rates and a high incidence of recurrence. Systemic therapy responses are observed in only a small proportion of HCC patients. Our spatial transcriptomics (ST) analysis of HCC tumors from patients treated with anti-PD-1 and cabozantinib (a multi-tyrosine kinase inhibitor) suggested that immunotherapy resistance is driven by cancer cell heterogeneity, tumor microenvironment (TME) dynamics, and cancer cell plasticity. These mechanisms were detected in an HCC sample collected from a responder who later experienced recurrence. To understand the genomic drivers of resistance and recurrence in HCC, we performed new bioinformatic analyses to investigate the molecular mechanisms associated with HCC plasticity that result in anti-PD-1 resistance. Across our ST samples, we observed up-regulation of oncogenic and immune evasion mechanisms following anti-PD-1 treatment. Interestingly, these signaling pathways share a common upstream modulation by MYC. Gene set enrichment analysis identified a significant upregulation of the MYC pathway in immune-poor cancer regions. Spatially weighted correlation analysis revealed that MYC upregulation is colocalized with cancer cell-intrinsic pathways, such as proliferation, metabolism, and cell plasticity, and is spatially exclusive with immune-related pathways, including antigen presentation and interferon-gamma response. Moreover, intercellular interaction analysis showed that MYC-upregulated cancer cells engage in crosstalk with cancer-associated fibroblasts (CAFs) via PDGF-PDGFR signaling, which is associated with the epithelial-mesenchymal transition (EMT) process, a hallmark of cell plasticity. Our findings were validated in additional anti-PD-1-treated HCC single-cell and ST public datasets, confirming that therapy-reinvigorated lymphocytes neutralize only MYC-downregulated HCC cells, leaving MYC-high HCC cells to survive. These residual HCC cells potentially become the source of tumor recurrence. Our findings highlight MYC as a key regulator of therapeutic resistance and immune suppression in HCC, potentially serving as a target for future interventions to delay anti-PD-1 treatment relapse and improve patient outcomes.

#5297 Immune profiling of CRC identifies a potential signature associated with immunosuppression.

Dongyu Han, Yong Qin

The University of Texas at El Paso, El Paso, TX

Colorectal Cancer (CRC) shows limited response to immunotherapies due to 85% of cases involving proficient mismatch repair. The immune profile of CRC remains poorly understood, making it critical to investigate immune infiltration patterns in the tumor microenvironment (TME) of CRC to improve therapeutic outcomes. Adenosine accumulates at high levels in the TME, suppressing immune responses via the A2A receptor (A2AR) on immune cells, a crucial pathway in immune suppression. This study aims to characterize the immune profile of CRC and identify the immune signature associated with adenosine-mediated immunosuppression. Multiplex immunofluorescence staining was performed on 170 CRC samples from 85 patients on 12 immune markers, including CD4+ and CD8+ for T cells, CD56+ NK cells, CD68+ macrophages, CD11b+ dendritic cells, FOXP3 for Treg cells, Glut-1 (hypoxia), Ki67, IDO and PD-1 (immune checkpoints), and CD73 and A2AR of the adenosine pathway. These markers provided a comprehensive assessment of immune suppression mechanisms. Our findings showed CRC tumors with specific immune infiltrates, including high levels of CD4+ and CD8+ T cells, CD11b+ dendritic cells, and CD68+ macrophages, alongside elevated Glut-1 and A2AR expression, marking A2AR's role in the adenosine-mediated suppression in CRC. Conversely, low levels of infiltrates were observed for CD56+, CD73+, FOXP3+, IDO+, Ki67+, and PD-1+ cells. Subdividing patients into A2AR-high and A2AR-low groups revealed that A2AR-high tumors exhibited significantly higher CD68+ macrophage infiltration, suggesting A2AR may mediate adenosine effects primarily through macrophages. Notably, A2AR was predominantly expressed on CD8+ T cells in CRC tumors, suggesting that infiltrating CD8+ cells are suppressed by adenosine signaling. Markedly, high A2AR expression was observed despite significant CD73 deficiency in CRC tumors. On average, only 0.09% CD73+ cells. with 39% of tumor cores showing no CD73 expression. Moreover, 40% of CD73-deficient tumors retained high A2AR expression, indicating the presence of alternative adenosine-producing pathways independent of CD73. Significant differences in immune infiltrates were also noted between CRC subtypes. Colon adenocarcinomas (n=50) exhibited higher A2AR+ infiltrates and lower CD4+ T cell infiltration compared to rectal adenocarcinomas (n=35), suggesting stronger adenosine-mediated immunosuppression in colon adenocarcinomas. These findings provide valuable insights into the role of adenosine-driven immunosuppression in CRC and highlight potential therapeutic targets to counter immune suppression. The observed CD73 deficiency suggests the need to explore alternative adenosine-producing pathways in CRC. Continued investigation into CRC immune signatures will aid in identifying new biomarkers and developing improved immunotherapy strategies for CRC patients.

#5298 Impact of targeted therapy on the tumor immune microenvironment in *EGFR*-mutated NSCLC.

Daisuke Shibahara[1], Satoshi Nakamura[1], Yasuyuki kishikawa[1], Keita Nakatomi[2], Noriaki Nakagaki[3], Kohei Otsubo[1], Yoshimasa Shiraishi[1], Yasuto Yoneshima[1], Eiji Iwama[1], Kentaro Tanaka[4], Isamu Okamoto[1]

[1]Kyushu University, Fukuoka, Japan,[2]Fukuoka Higashi Medical Center, Fukuoka, Japan,[3]Fukuoka Red Cross Hospital, Fukuoka, Japan,[4]Kagoshima University, Kagoshima, Japan

Background: In *EGFR*-mutated lung cancer, osimertinib, a third-generation EGFR tyrosine kinase inhibitor, has demonstrated durable efficacy in many cases. However, early resistance arises in some patients during treatment. The tumor immune microenvironment is believed to play a pivotal role in shaping treatment outcomes, though the detailed molecular mechanisms are not fully understood.
Methods: This study analyzed four cases with paired tissue samples collected both before and after osimertinib treatment. Using Visium-HD, we performed analyses comparing the pre-treatment samples between the early resistance and long-term efficacy groups, as well as paired samples collected before and after treatment. We converted the Visium-HD spot data into single-cell data using StarDist, a deep learning-based method for nuclei/cell detection and segmentation. Furthermore, by adding the calculated coordinate data derived from StarDist to the single-cell data, we performed spatial transcriptome analysis using single-cell coordinates instead of spot coordinates. This enabled spatial transcriptomic analysis at the single-cell level while preserving the actual spatial relationships between cells.
Results: In the post-treatment samples from early resistance cases, the proportion of macrophages, particularly SPP1-positive macrophages, was increased compared to that in long-term efficacy cases. In the comparison of pre-treatment samples between early resistance and long-term efficacy cases, the former exhibited a high degree of intermixing among diverse cell populations (e.g., lymphocytes, macrophages, and fibroblasts), whereas the latter showed minimal intermingling between tumor cells and other cell types. Furthermore, in early resistance cases, the expression levels of CXCR4 and CD74 were higher compared to long-term efficacy cases. Analysis of cell-cell interactions suggested potential effects of tumor cells on tertiary lymphoid structures.
Conclusions: *EGFR*-mutated lung cancer is typically characterized by reduced immune cell infiltration, often referred to as “cold tumor.” However, early resistance cases exhibited increased immune cell infiltration and the presence of tertiary lymphoid structures, indicating a “hot tumor” phenotype. This finding suggests that *EGFR*-mutated lung cancer cases prone to early resistance might possess a tumor immune microenvironment resembling that of *EGFR* wild-type tumors.

#5299 *BZW2*: a novel therapeutic target for liver metastasis in lung cancer.

Kuan-Li Wu[1], Ying-Ming Tsai[2], Ya-Ling Hsu[3]

[1]Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan,[2]School of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan,[3]Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

Introduction: Liver metastasis (LM) occurs in approximately 13% of patients with lung cancer at the time of diagnosis and is associated with poor prognosis. Currently, there are no effective preventive or therapeutic strategies specifically targeting LM. Investigating the LM microenvironment can not only elucidate the mechanisms underlying its development but also provide opportunities to identify novel therapeutic targets.
Methods: An LM-prone mouse model was established by repeatedly injecting and harvesting Lewis Lung Carcinoma (LLC) cells from LM lesions. The spatial transcriptomics (Visium, 10X Genomics) was applied to explore the microenvironment and intratumoral heterogeneity of LM. Validation was conducted using single-cell RNA sequencing and spatial proteomics (PhenoCycler System, Akoya Bioscience) on human and murine LM samples, respectively. Bioinformatics analyses, including Gene Set Enrichment Analysis (GSEA), were applied to infer gene function and associated behaviors. Gene set variation analysis (GSVA) was performed to evaluate lung cancer patient survival in relation to the expression of the *BZW2*-associated gene set. Functional validation of *BZW2* was conducted *in vitro* by assessing cell migration using transwell and wound healing assays, and by examining epithelial-to-mesenchymal transition (EMT) markers via immunoblotting.
Results: *Bzw2* is the significantly upregulated differential expressed gene in LM, particularly at the invasive front, based on the murine spatial transcriptomic data. The finding was further validated in murine LM samples using spatial proteomics as well. In human single-cell RNA sequencing data, *BZW2* exhibited high expression in LM subclusters characterized by aggressive phenotypes, including enhanced proliferation, hypoxia, mesenchymal traits, invasiveness, and cancer stemness. GSVA analysis demonstrated that elevated expression of the *BZW2*-associated gene set was associated with poorer patient survival and enrichment of EMT-related pathways using the TCGA LUAD dataset. Furthermore, *in vitro* functional assays showed that *BZW2* inhibition suppressed cell migration and reduced the expression of EMT markers, as confirmed by immunoblotting.
Conclusion: By integrating findings from spatial transcriptomics, proteomics, and single-cell RNA sequencing, this study elucidates the role of *BZW2* in promoting the aggressiveness of LM in lung cancer through its influence on cell migration and metastasis. These results suggest that *BZW2* could serve as a promising therapeutic target worthy of further advanced research for LM in lung cancer.

#5300 Spatially resolved integrated omics profiling for ADC targets in urothelial carcinoma.

Pranauti Panshikar[1], Eleanor O?Roberts[1], David Krantz[2], Tony Ullman[1], Carolina Oses Sepulveda[1], Fernanda Svedman[3], Paivi Ostling[4], Anders Ullen[3], Charlotte Stadler[1]

[1]Dept of Protein Science, KTH- Scilifelab, Stockholm, Sweden,[2]Department of Oncology and Pathology, Karolinska Institute, Stockholm, Sweden,[3]Department of Oncology & Pathology, Department of Pelvic Cancer, Genitourinary Oncology and Urology, Karolinska Institute, Stockholm, Sweden,[4]Department of Oncology and Pathology, Karolinska Institute- Scilifelab, Stockholm, Sweden

Background: Urothelial Carcinoma (UC) is the tenth most common cancer worldwide, accounting for more than 200 000 deaths annually (Ferlay, 2020, Sung, 2021). Despite advances over the past decade, particularly with the introduction of immunotherapy (ICI) in various disease settings alongside conventional platinum-based chemotherapy, the prognosis for metastatic UC (mUC) remains poor.
Antibody drug-conjugates (ADC) have emerged as a novel treatment option for mUC, offering selective and targeted delivery of cytotoxic agents to cancer cells. ADCs targeting tumor-associated surface proteins including Nectin-4, trophoblastic cell surface antigen 2 (Trop-2) and tyrosine kinase receptor ERBB-2 (HER2), have demonstrated promising efficacy and are all approved for mUC (Wong, 2021, Goodson, 2023). However, the response rate to these ADCs in mUC is limited 25-40% and with a growing portfolio of accessible ADCs, identifying predictive biomarkers to optimize treatment selection remains an unmet medical need.
The use of multiplexed immunofluorescence (mIF) offers deeper insights into tissue microenvironment and can potentially be used to better stratify patients for the various ADC targets in cancer. Recently, an integrated assay combining the sequential IF for protein detection with RNAscope was developed for Lunaphore's COMET platform. This allows for simultaneous detection of several RNA targets and their corresponding proteins to be analyzed within the same cells. While the ADC target proteins have been shown to be highly expressed in many UC patients, there are limited studies characterizing the spatial expression of these protein targets, especially in combination with their corresponding transcripts.
Methods: The integrated assay of the COMET platform offers a fully automated workflow that includes iterative cycles of staining, imaging and elution facilitating the simultaneous detection of RNA and proteins at single cell resolution. We used custom designed RNAscope probes (ACDBio), a SPYRE antibody panel (Lunaphore) and additional antibodies to detect the ADC-targets Nectin-4, Trop-2 and HER-2, and to spatially map the tumor microenvironment of human FFPE bladder cancer tissues from a cohort of mUC patients.
Results & Discussion: We have optimized the assay for bladder cancer tissues on the COMET platform to detect multiple ADC targets at transcript and protein levels. We aim to employ the integrated multi-omics setup to explore the expression of the ADC targets in sections from a retrospective cohort of mUC patients treated by monotherapy with Enfortumab Vedotin (EV) in the third line. We have already observed differences across patients with regard to Nectin-4, Trop-2 and HER-2 protein expression and aim to better characterize the spatial distribution and expression of these tumor-associated antigens with the inclusion of target transcripts and the association to treatment benefit from EV.

#5301 Visium HD 3' enables unbiased whole transcriptome spatial profiling of tumor microenvironment in fresh frozen cancer tissues at single cell-scale resolution.

Debashish Chitnis, Marco Serra, Josh Gu, Anushka Gupta, Nancy Conejo, Aarushi Kalaimani, Govinda Kamath, Zixue Ma, Monica Nagendran, Joey Arthur, Julia Cowen, Anuj Patel, David Sukovich, Augusto M. Tentori

RnD, 10X Genomics, Pleasanton, CA

Spatial transcriptomic technologies demonstrate the ability to comprehensively investigate the complexity of the tumor microenvironment, providing crucial insights into the interplay of different cellular and acellular components that orchestrate the tumor progression, angiogenesis, immune evasion, and metastasis. Here, we introduce Visium HD 3', a novel assay for unbiased spatial gene expression profiling of fresh frozen tissue sections mounted on a standard glass slide. The Visium HD slide's array has a gapless design that enables integration of unsupervised gene expression clustering data with high-resolution H&E images from the same tissue section, allowing precise profiling of finer anatomical features with high tissue coverage at single cell-scale resolution. Furthermore, this novel reverse transcription-based assay generates cDNA products compatible with both short reads and long reads sequencing, extending its utility beyond gene expression analysis to enable immune profiling and the discovery of isoforms and novel transcripts on a spatial level unlocking deeper insights into cancer diversity.

Our research focused on deciphering the spatial heterogeneity of gene expression patterns within the tumor microenvironment, shedding light on the interactions between cancer cells, stromal cells, and vasculature. Visium HD 3' was performed on fresh frozen human breast, pancreatic, liver, and lung cancer tissues. Spatial profiles of clinically-relevant cancer biomarkers such as AR, MUC1, CDH1, and ERBB2 were able to highlight tumor-prone regions in the tissues. Expression of known prognostic angiogenic markers such as VEGF, FGFR, PDGF was inline with the tumor region, indicating tumor growth and metastasis. Additionally, targeting stromal markers such as POSTN, LUM, MMP1, ACTA2, and SFRP4 revealed a distinct boundary between the tumor and stromal layer. The high resolution of this technology further enabled profiling of macrophage and T cell infiltration in cells surrounding the tumor by identification of immune markers like CD4, CD68, CD3E, PTPRC and CCL5.

Our study highlights the importance of exploring the spatial organization of the entire transcriptome in cancer tissues and demonstrates that Visium HD 3' platform is a powerful tool for unraveling the complexities of the tumor microenvironment. These findings lay the groundwork for the development of innovative therapeutic strategies and precision medicine approaches, ultimately contributing to improve outcomes for cancer patients.

#5302 Mapping the tumor microenvironment at single-cell resolution with Stereo-seq v1.3.

Jiajun Zhang[1], Xing Liu[1], Zexian Zeng[2], Rui Zhang[2], Tibby Tianbi Duan[1], Jing Guo[1], Liang Wu[3], Sha Liao[1], Ao Chen[1], **Weijia Su**[4]

[1]STOmics Tech Co., Ltd., Shenzhen, China,[2]Center for Quantitative Biology, Academy for Advanced Interdisciplinary Studies, Peking University, Peiking, China,[3]BGI Research, Shenzhen, China,[4]Complete Genomics, San Jose, CA

Tumor cell heterogeneity and the tumor microenvironment are fundamental questions that heavily influence the process of cancer development, disease progression, and the response to treatments. Knowledge of cancer biology facilitates understanding of pharmacological effects and mechanism of action to improve clinical outcomes. Spatial transcriptomics technology, particularly Stereo-seq, makes the groundbreaking advancement in cancer research with its outstanding performance with high capture efficiency and single cell resolution. It allows scientists to visualize and analyze the complexity of tumors at an unprecedented level of detail. In this study, we mapped tumor heterogeneity and microenvironment of fresh frozen section from colorectal cancer tissue (CRC) at a single-cell resolution with Stereo-seq v1.3 kit. We identified10 cell populations using cell2location, including B cells, fibroblasts, CD4+ T cells, CD8+ T cells, dendritic cells, endothelial cells, epithelial cells, macrophages, mast cells and NK cells. In situ mapping and portion analysis of cell identification revealed a B-cell dominated area which was confirmed by H&E staining of adjacent section. To comprehensively understand the immune activities, we quantified the interactions among different cell types (by StereoSite framework), revealing biologically meaningful intercellular communications mediated by GZMA-PARD3 and CCR10- CCL28 between B cells and epithelial cells. Further pathway enrichment analysis indicated cooperated molecular activities and underlying functions in CRC, which showed interaction activities significantly associated with EGF or BMP signaling pathways. Patteren recognition method identified how functional units assocatied with pathways. Take EGF pathway as an example, results revealed CD4+ T cells and macrophages may coordinated to impact EGF pathway by communication activities. Analysis in this study showed that spatial transcriptomic data at single-cell resolution is vital for exploring intercellular communications, molecular activities, and functional units by providing spatial context. Stereo-seq possess the ability to efficiently gathering evidence of mode of action and resistance mechanims by deeply mapping the spatial profiling in TME. It paves the ways for drug development by removing uncertainties and reducing time and cost. Implementation of Stereo-seq workflow could not only offer impetus to solve unmet needs in area of oncological research, but also bring new findings from lab to patients faster.

#5303 Temporal dynamics of transcriptional and spatial landscape in tumor microenvironment of esophageal squamous cell carcinoma during chemotherapy treatment.

H. Yamashita[1], C. Mashima[1], M. Narahara[2], R. Kamata[1], K. Watanabe[2], R. Nakamura[2], S. Muramatsu[2], A. Tezuka[2], E. Otsuka[2], C. Wada[2], Y. Ishimoto[2], D. Kotani[3], T. Kojima[3], N. Wada[2], H. Sumi[2], T. Yano[3], **G. Takayama**[4], A. Ohashi[1];

[1]National Cancer Center, Chiba, Japan, [2]Daiichi Sankyo Co. Ltd., Tokyo, Japan, [3]National Cancer Center Hospital East, Chiba, Japan, [4]Daiichi Sankyo Inc., Basking Ridge, NJ

Although esophageal squamous cell carcinoma (ESCC) is a highly aggressive malignancy, there is little knowledge about its tumor heterogeneity affecting treatment response. To decipher transcriptomic heterogeneity of tumor microenvironment (TME) from a therapeutic perspective, we conducted CITE-seq and immunostaining by Hyperion in ESCC with or without chemotherapeutic stimuli.
Tumor biopsies of ESCC were sequentially collected by endoscopy from 3 patients during chemotherapy treatments. CITE-seq samples were processed with Chromium Next GEM Single Cell 5′ Reagent Kit v2 (10 x Genomics) and TotalSeq Universal Cocktails (BioLegend) as per the manufacturer's recommendations, respectively. Cell-to-cell interaction analyses in CITE-seq and neighborhood analyses in Hyperion were performed.
Clinical responses of 3 patients for ESCC tumor biopsies were PD, SD, and PR, respectively. Cell annotation analyses in TME components revealed that populations of myeloid cells exhibited an overall decrease during the treatment across three patients, while the decrease in myeloid cell populations was more pronounced in the PR patient. The cluster analyses in epithelial cells exhibited 6 unique subclusters, which were transcriptionally characterized in proliferation, EMT, inflammation, and metabolic pathways. In spatial analyses, the epithelial cells in the PD patient adhered tightly to each other, while the epithelial cells in the SD or PR patient clustered relatively mixed with immune and stromal cells. In SD or PR patients, furthermore, varieties of T cell populations were more accumulated in response to the chemotherapy treatments compared to the PD patient. Neighborhood analysis and cell-cell interaction analysis together identified cell type pairs that showed consistent changes in physical and molecular perspectives. In PD patient, dendritic cell (DC)-macrophage pair was enriched in the proximity of each other, and also increased molecular interactions after chemotherapy. In contrast, activated T-Treg pair was depleted and decreased molecular interactions. Interestingly not just activated T-Treg interaction decreased, but proliferating T cells were also depleted from the tumor.
We conducted integrative analyses with cutting-edge technologies to determine temporal dynamics of TME landscape in ESCC during chemotherapy treatment. Our observations may indicate that chemotherapy increased DC-macrophage interaction to suppress antigen presentation by DC, which suppressed T cell activation and proliferation. The mechanism might contribute to the chemotherapy resistance. These findings will shed light on the molecular insights to deeply understand complexity of the TME networks for chemotherapy resistance in ECSS.

#5304 Profiling the tumor- immune landscape with a same-section multiomics assay.

Anushka Dikshit[1], Cansaran Saygili Demir[2], Rose Delvillar[1], Emerald Doolittle[1], Alice Comberlato[1], Arec Manoukian[2], Maria-Giuseppina Procopio[2], Pino Bordignon[2], Saska Brajkovic[3], Maithreyan Srinivasan[1]

[1]Bio-Techne Corporation, Newark, CA,[2]Bio-Techne Corporation, Tolochenaz, Switzerland,[3]Bio-Techne Corporation, Tolochenez, Switzerland

Checkpoint therapies and engineered immune cell therapies are increasingly becoming the mainstay when it comes to cancer treatments. Continued and improved success of these therapies relies on our deep understanding of the checkpoint marker and immune cell biology, cell-cell interaction in the tumor microenvironment (TME), and immune cell activation. Spatially visualizing the expression of soluble factors such as cytokines and chemokines along with immune cell markers can provide information about the immune cell composition and enable a comprehensive understanding of mechanisms underlying immune cell recruitment, infiltration and exclusion. To address this, we have developed a fully automated spatial multiomics protocol on the COMET™ platform that enables RNA detection using the RNAscope™ HiPlex Pro assay combined with protein detection using sequential immunofluorescence (seqIF™, (Rivest et al, 2023)) to integrate same-section sequential detection of up to 12 RNAs followed by up to 24 proteins. This workflow allows the detection of any RNA and protein target of interest by utilizing existing RNAscope probes or generating a custom design for any RNA target and use standard, non-conjugated primary antibodies for protein detection. We used Lunaphore's HORIZON™ software to analyze this multiomics dataset. Here, we have demonstrated the precise spatial profiling of FFPE solid tumors through the detection of key cytokines indicative of activated T cells and macrophages by using cytokine RNA probes targeting *IFNG*, *IL-1B*, *TNFA*, *TGFB1, IL-4, IL-6, IL-8, IL-10* among others in combination with cell marker antibodies detecting CD3,CD8,CD4, FOXP3 and CD68.In addition, we were also able to visualize T cell recruiting chemokines and receptors such as *CXCL10, CXCL9, CXCL13, CXCL12* and *CXCR3*, and spatially map tumor-infiltrating T cells within tissue context and with subcellular resolution. To that end, we successfully demonstrated same-slide RNA-protein detection for profiling the TME. Using single-cell spatial multiomics we were able to identify unique phenotypes within the tumors that might directly correlate to immunosuppressive or immunostimulatory microenvironments. Detailed mapping of the cellular components of the TME has the potential to better predict therapeutic response for checkpoint and immune-based therapies.

#5305 Tumor cell lineages and immune remodeling of *RHOA*^{Y42C}-driven diffuse gastric cancer.

Kyung Pil Ko[1], Jinho Jang[1], Gengyi Zou[1], Yuanjian Huang[2], Jie Zhang[1], Jae-Il Park[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Nanjing Medical University, Nanjing, China

Diffuse gastric adenocarcinoma (DGAC) is a highly aggressive cancer characterized by poor prognosis and distinct molecular subtypes. Among these, *CDH1* inactivation and *RHOA* mutations, particularly *RHOA*^{Y42C}, define separate oncogenic pathways with distinct biological and clinical implications. To elucidate the functional consequences of *RHOA*^{Y42C} mutation, we established genetically engineered murine gastric organoid models carrying genetic mutations frequently observed in human DGAC. Organoids harboring *RhoA*^{Y42C} in combination with *Kras*^{G12D} and *Trp53* loss (RKP: *RHOA*^{Y42C}, *Kras*^{G12D}, *Trp53*$^{-/-}$) and Cdh1 loss (EKP: *Cdh1*$^{-/-}$, *Kras*^{G12D}, *Trp53*$^{-/-}$) exhibited hyperproliferative and multilayered epithelial architectures, indicative of neoplastic cell growth. Transplantation of RKP organoids into immunocompetent mice displayed features of mucinous DGAC, marked by abundant mucin production and signet-ring cell morphology. By contrast, EKP resulted in tumor architectures with invasive features consistent with non-mucinous DGAC.O ur multiomic approaches combining single-cell RNA-sequencing and spatial transcriptomics (Xenium In Situ) revealed divergent tumor cell lineages and transcriptional programs between EKP and RKP models. EKP tumors displayed enrichment of Runx1-dependent epithelial lineages, whereas RKP tumors exhibited Aqp5-driven lineages with high transcriptional plasticity and robust activation of the Hippo signaling pathway. RKP tumors featured prominent MUC1/4+ mucinous cell populations, whose differentiation was mediated by YAP1, the Hippo pathway effector. Pharmacologic inhibition of Hippo signaling effectively abrogated these mucinous cell lineages, highlighting potential therapeutic vulnerabilities in *Rhoa*^{Y42C}-driven tumors. Additionally, immune profiling revealed significant differences in the tumor microenvironments (TMEs) of EKP and RKP tumors. RKP tumors exhibited an immune-suppressive microenvironment characterized by peripheral enrichment of exhausted T cells expressing markers such as *Pdcd1* and *Ctla4*. Consistently, cell-to-cell interaction analyses revealed enhanced interactions mediated by PDCD1 and CTLA4. Further analyses revealed that differentially secreted cytokines in EKP and RKP induced immune-suppressive genes expression in T cells of RKP tumor, suggesting that *Rhoa*^{Y42C} mutation not only drives tumor-intrinsic changes but also remodels the immune landscape to favor immune evasion. By contrast, the TME of EKP tumors exhibited lower immune suppression, with a reduced presence of T cell exhaustion markers. Together, these findings identified the genotype-specific nature of tumor cell differentiation programs, transcriptional plasticity, and immune microenvironmental remodeling in DGAC. This study highlights Hippo signaling and immune checkpoint pathways as promising therapeutic targets in *RHOA*^{Y42C}-driven mucinous DGAC.

#5306 Dissecting the formation mechanisms of tertiary lymphoid structures and their impact on prognosis and immunotherapy.

Ben Liu, Wenbo Zhu, Mengyue Qiu, Yanxin Yao, **Kexin Chen**

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: The mortality from gastric cancer is high due to its frequently advanced stage at diagnosis. The standard treatment is mainly surgical, including a comprehensive treatment model of chemotherapy, radiotherapy, targeted therapy and immunotherapy. However, the existing classification of gastric cancer cannot fully guide the precise treatment. TLSs, sometimes also referred to as tertiary lymphoid organs or ectopic lymphoid structures, are organized aggregates of immune cells that arise postnatally in nonlymphoid tissues. The presence of TLSs in tumor environment often indicates a better prognosis.

Method: Identifying the expression of TLSs and its maturation status on pathological sections of gastric cancer surgical specimens via HE staining, immunohistochemistry staining and multi-color fluorescence staining. Surgical tumor specimens were collected and analyzed using single-cell RNA sequencing and spatial single-cell transcriptomics sequencing. To identify TLSs artificially by establishing the artificial intelligence machine learning models of TLSs. To explore the mechanism of TLSs formation in the tumor environment in vivo by humanized PDOX mice and in vitro by co-culture systems of gastric organoids and immune cells.

Results: HE staining, immunohistochemistry staining and multi-color fluorescence staining of tumor sections identified the expression and mature status of TLSs. Single-cell sequencing and spatial single-cell transcriptomics sequencing found the specific markers to identify the TLSs and analyzed the cell composition and cell communication in the tumor environment. Artificial intelligence machine learning models of TLSs identified the presence of TLSs and its maturation status. Furthermore, in vitro co-culture systems of organoids and immune cells and humanized PDOX mice found that organoids of patients with high TLSs score increased apoptosis of tumor cells while using PD-1 antibody and CTLA-4 antibody.

Conclusions: The high expression of mature TLSs indicates a better survival. We establish the artificial intelligence machine learning models of TLSs to identify the presence of TLSs and its mature status. We establish the TLS score to predict the TLS expression and prognosis of patients. Patients with high TLSs score have a better survival and are more sensitive to PD-1 antibody and CTLA-4 antibody.

#5307 New developments in spatial transcriptomics unlock insights into the tumor microenvironment.

Manisha Ray, Justin He, Bin Wang, Bing Yang, Sudhir Tattikota, Timothy Wiggin, Hao Wang, Jichuan Zhang, Lizi Maziashvili, Alexander Genshaft, Peter Reinhold, Brittany Auclair, Robert Mathis, Shawn Wang, Jiang He, George Emanuel

Vizgen, Cambridge, MA

The emergence of tools enabling researchers to perform high-plex spatial transcriptomics with single-cell resolution has revolutionized our understanding of tumor development. However, tissue samples with degraded RNA or extensive crosslinking present challenges for gene expression measurements. For decades, cancer tissue samples have been collected and preserved using formalin-fixation and embedding in paraffin (FFPE), which is not optimal for preserving RNA integrity. This has limited the depth of insights researchers can obtain from archival samples.

The Multiplexed Error-Robust Fluorescence In Situ Hybridization (MERFISH) technology facilitates direct RNA profiling in situ with high sensitivity and resolution. The high accuracy and high plexity are enabled by tiling probes along the length of a transcript, which is particularly challenging in samples with fragmented RNA, such as in FFPE. The MERFISH 2.0 chemistry and sample preparation workflow was developed specifically to improve transcript detection efficiency in measurement of up to 1000 genes in low quality tissues. These improvements can be applied to tissues of up to $3cm^2$ using the MERSCOPE® Ultra™ Platform. Here we applied the improved capabilities of MERFISH 2.0 to profile human breast cancer and human lung cancer tumors over a range of sample qualities.

Breast and lung tumor samples, both whole sections and tissue microarrays (TMA), were run on the MERSCOPE Ultra Platform using a panel of 815 immuno-oncology genes with both MERFISH 1.0 and MERFISH 2.0. The resulting data was used for spatial and single-cell analyses. We show that in all tissues, particularly in lower quality tissues, MERFISH 2.0 increases the counts and subsequent quality of data analysis, such as increased detection of cell types and increased neighborhood associations. Inter- and intra-tumor immune profiling showed improved detection of low-expressing markers, enabling deeper study of the tumor microenvironment.

Spatially resolved transcriptomic profiling of low-quality samples at single-cell level offers significant opportunities for understanding how cancers develop in situ. These improvements will enable new genomic inquiries into how tumors develop and modulate their environment, which in turn will open up new areas of therapeutic research.

#5308 RePROBE: A simple and customizable multiplex immunohistochemistry technique.

Takashi Semba, Atsuko Yonemura, Huaitao Wang, Yilin Tong, Masaya Yamazaki, Takatsugu Ishimoto

Division of Carcinogenesis, The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Multiplex immunostaining techniques have been actively developed and have recently become more prevalent in cancer research. However, most of these techniques require specialized instruments and customized primary antibodies. Here, we established a simple and versatile workflow for multiplex immunohistochemistry (IHC) named RePROBE (Repetitive Primary antibody Replacement and Overlaying images from a Broad range of fluorescence imaging Equipment) that can be readily adopted in many laboratories, providing deeper insight into tumor organization and spatial molecular biology in the tumor microenvironment (TME).
Methods: Formalin-fixed paraffin-embedded (FFPE) sections of various tissue types, such as resected tumors of cancer patients, patient-derived xenografts, and syngeneic mouse tumors,, were subjected to the RePROBE workflow. Commercially available primary and secondary antibodies were used for fluorescence immunostaining with routine indirect IHC methods. Images were acquired by multiple imaging platforms, including fluorescence microscopes, confocal microscopes, and whole slide image scanners. Antibody complexes were removed by heat-based stripping after imaging, and the slides were subjected to the next cycle. All image processing and analysis were performed by open-source software.
Results: We confirmed that the RePROBE workflow worked across different types of tissue sections and imaging modalities and achieved up to 36-plex on human gastric cancer samples and more than 20-plex on syngeneic mouse tumors. The multiplex IHC images derived from the RePROBE workflow were able to be analyzed in downstream pipelines, such as QuPath, Cellpose, and MCMICRO. Heat-based stripping successfully removed most antibodies with some exceptions. Although some loss of cells was observed (less than 7%) after cycle 1, significant cell loss was not observed after cycle 2 up to cycle 10 in most of the samples. We also found that the cell loss was dependent on tissue type and samples.
Conclusions: The RePROBE workflow enabled up to 36-plex whole-slide single-cell resolution imaging and spatial phenotyping analysis, revealing the cell population and spatial organization of tumor cells, CAFs, and immune cells in TME.

#5309 Single-cell-based analysis of tumor microenvironment heterogeneity in human MASLD/MASH-associated HCC: Classifications by inter-cellular network variations.

Naoko Ohtani[1], Yoshiki Nonaka[1], Kanae Echizen[1], Yi Cheng[1], Takahiro Kodama[2]

[1]Pathophysiology, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan,[2]Gastroenterology and Hepatology, Graduated School of Medicine, Osaka University, Osaka, Japan

Immune checkpoint inhibitor (ICI) therapy has demonstrated limited efficacy in MASLD/MASH-associated hepatocellular carcinoma (HCC), suggesting distinct anti-tumor immune responses within the tumor microenvironment (TME) of this cancer type compared to other cancers. Understanding the mechanisms driving MASLD/MASH-HCC progression and identifying novel therapeutic targets are therefore critical. While ICI therapy alone may not be sufficient, combining it with drugs targeting key cancer progression pathways may hold promising enhancement of anti-tumor efficacy in this context. In this study, we sought to elucidate the tumor-promoting pathways in MASLD/MASH-associated HCC by characterizing the comprehensive transcriptomic landscape of cancer cells and stromal cells within the tumor microenvironment (TME). We conducted single-cell RNA sequencing on the samples from 31 HCC patients and 8 healthy donors. Using this data, we classified the samples based on the cellular composition of the TME and performed interactome analysis with CellChat version 2. This analysis stratified the samples into five distinct groups: Group 1, TME with stem cell-like cancer cells and immune cell infiltration; Group 2, TME with Wnt signaling-activated cancer cells regardless of immune cell infiltration; Group 3, TME containing cancer cells not classified in the categories mentioned above with immune cell infiltration; Group 4, TME containing cancer cells not classified in the categories mentioned above without immune cell infiltration; and Group 5, TME with normal hepatocytes, as observed in healthy donor livers. Detailed analysis highlights several notable features of the tumor stroma. For example, “senescent” cancer-associated fibroblasts (CAFs) exhibiting a senescence-associated secretory phenotype (SASP) are frequently observed in the TMEs of Groups 1-3. Interactome analysis revealed a VEGFA-VEGFR2 interaction between endothelial cells and various other cell types, consistent with the hypervascularity characteristic of HCCs and supporting the clinical efficacy of VEGF inhibitors. Furthermore, group-specific interactome analysis uncovered distinct novel interactions, indicating molecular network variations among TME groups. We will present spatial distributions of each cell type in TME and TME-dependent inter-cellular interactions. We discuss their potential as biomarkers and therapeutic targets for MASLD/MASH-HCC treatment.

#5310 Spatially resolved cell profiling of testicular diffuse large B-cell lymphoma unveils recurrent cellular neighborhoods associated with survival.

S.-K. Leivonen[1], M. Autio[1], M. Pollari[2], M.-L. Karjalainen-Lindsberg[3], T. Pellinen[4], S. Leppa[1];

[1]University of Helsinki and Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland, [2]Tampere University Hospital, Tampere, Finland, [3]Helsinki University Hospital, Helsinki, Finland, [4]Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland

Introduction: Testicular diffuse large B-cell lymphoma (T-DLCBL) is a rare and aggressive lymphoid cancer, accounting for 1% of all lymphomas. In recent years, the impact of the tumor microenvironment (TME) on DLBCL pathogenesis and survival has been recognized. We have previously shown that in T-DLBCL, the T cell-inflamed TME is associated with favorable survival. In this study, we aimed to dissect the T-DLBCL TME in more detail and characterize its spatial architecture at the single-cell resolution.

Methods: We used a tissue microarray (TMA) containing formalin-fixed paraffin-embedded diagnostic T-DLBCL samples from 79 patients. TMA was stained with a 12-plex antibody panel to characterize B cells, T cells, macrophages, and immune checkpoint molecules. Image processing and quality control were performed by combining Ilastik and CellProfiler softwares, and nuclei segmented by a pretrained deep learning segmentation model nucleAIzer. Single cell features from the images were extracted using histoCAT, and cell phenotyping and cell neighborhood analyses were performed utilizing Python package SCIMAP.

Results: We identified over 900,000 single cells, which were classified into 16 distinct phenotypes, including various subpopulations of B cells, T cells, and macrophages. In line with our previous findings, higher T cell proportions were associated with better outcomes. In addition, a subgroup of PD1+ B cells (13% of the whole cell population) was associated with worse outcomes independent of the treatment or international prognostic index (IPI). Neighborhood analysis revealed 10 recurrent cellular neighborhoods (RCNs) with differential cellular compositions, including B cell, macrophage, T cell, or immune checkpoint-rich RCNs. The most abundant was an RCN rich in B cells and macrophages (25% of all cells), followed by an immune-depleted RCN (17% of all cells) and an RCN rich in PD1+ B cells (16% of all cells). Interestingly, a subset of T-DLBCLs was characterized by a very high PD1+ B cell-rich RCN content (>50% of the total cellularity), which translated to poor survival independent of the treatment or IPI. In contrast, a T cell-rich RCN was associated with better outcomes. Finally, when we calculated the minimum average distance between the RCNs, we noticed that a shorter distance between the immune-depleted RCN and an RCN rich in T cells and non-immune cells was associated with better survival.

Conclusions: In summary, the study provides detailed insights into the spatial architecture of the T-DLBCL TME, highlighting the significance of specific cell populations and their neighborhoods in predicting patient outcomes.

#5311 Characterization of ADC and TCE targets in patient tumors using high-parameter spatial proteomics.

M. A. Conner, F. Xie, L. Zhou, E. McKinley, J. Tarrant, T. Sato, Y.-F. Chang, D. Poore, S. McKearnan, K. Hance, J. Waight;
GSK, Philadelphia, PA

Target heterogeneity and intensity of expression in patient tumors are two of many critical factors in understanding the clinical potential of antibody drug conjugates (ADCs) and T cell engagers (TCEs) in oncology.1,2 Despite extensive clinical usage, conventional immunohistochemistry (IHC) is often restricted to a handful of markers per section, limiting its capacity to identify complex patterns of antigen expression in patient samples. In contrast, high-parameter, spatially resolved, proteomic analysis has the potential to not only provide widespread characterization of tumor-associated antigens (TAAs) but also to reveal impactful cell-cell and protein-protein neighborhoods for bispecific pairings and/or novel biomarkers.

Here, we utilized imaging mass cytometry (IMC) complemented by multiplex immunofluorescence (mIF) to spatially evaluate the expression of greater than 30 protein markers simultaneously in 35 tumor specimens from 7 indications. Using whole slide imaging and a bespoke analysis pipeline, coupled with statistical modeling, we profiled multiple TAAs, including HER2, TROP2, B7-H3, and B7-H4 for expression in tumor and adjacent non-tumor tissues.3 Notably, whole-slide mIF was used in tandem with IMC on the same tissue section to enable both region of interest (ROI) selection and image co-registration. With this approach, we observed a high level of concordance between the two modalities for markers of interest such as B7-H3 and B7-H4, helping to further validate our findings. Stromal and immune markers such as SMA (cancer-associated fibroblasts [CAFs,]) CD3/CD8/FoxP3 (T cells,) and CD206 (macrophages) were also included to help characterize the tumor microenvironment and cellular distribution of each TAA. The panel was also incorporated with markers of sensitivity to common ADC payloads, such as SLFN11 and TOP1. In addition to differences in target prevalence and level of expression, we describe the spatial relationship between various TAAs across tumors including such parameters as the average distance between cytotoxic T cells and a given TAA+ cell.

Altogether, these results provide a framework to apply dual-modality imaging of mIF and IMC on the same tumor samples for comprehensive characterization of TCE and ADC targets. In the future, the total number of markers which can be characterized by both mIF and IMC are expected to increase, allowing for an even deeper characterization of tumor biology which may inform bispecific pairings and more precise treatment strategies for ADCs and TCEs.

#5312 Murine syngeneic tumor model characterization by ultrahigh-plexed immunofluorescence imaging.

Jaimee Wong, Ngan Doan, Andrew Woolley, Anandi Sawant, Shilpa Keerthivasan, Sunitha Bachawal, Jennifer Sahni, Nicholas Wilson, Amanda Mikels Vigdal, Xiaoyun Liao

Bristol Myers Squibb Company, Redwood City, CA

Murine syngeneic tumor models are widely used tools to demonstrate efficacy and the mechanism of novel anticancer immunotherapies. Each model is likely to have a unique tumor microenvironment (TME) with immune cells, fibroblasts, endothelial cells and extracellular matrix that may reflect a variety of TME profiles in humans. Baseline characterization of tumor TME features of each model paired with therapy-based mechanistic studies can confirm pharmacodynamic (PD) biomarker hypotheses and inform combination strategies. However, a comprehensive dataset of TME compositions and spatial information is unavailable. PhenoCycler is an ultrahigh-plexed spatial biology imaging platform that can detect up to 100 markers on formalin fixed paraffin embedded (FFPE) sections at a single cell resolution using cyclic detection of DNA-conjugated antibodies. Very few publications have used Phenocycler technology to image murine FFPE tissues. In this study, we constructed a FFPE tissue microarray (TMA) block that includes 12 commonly used preclinical murine models of breast, colon, lung, pancreatic ductal, renal and bladder carcinomas with duplicate cores, and built a 29-marker panel to characterize the complexity of the TME of these models. Our data showed distinct TMEs in the different models and cell-cell interactions that differed depending on the tumor type examined. For instance, Py2T and Pan02 are cancer associated fibroblast (CAF) and macrophage enriched tumors whereas MC-38 tumors have low levels of CAF and T cell infiltration. Based on these analyses, the EMT6 tumor model, an immunocompetent triple negative mammary carcinoma with adequate extracellular matrix, was selected for an in vivo pharmacology study for a novel anti-stroma immunotherapy. Evaluation of whole tissue tumor samples from the study revealed significant increases in CD8+ T cell infiltration and a reduction of COL1A1 expression in treated tumors compared to vehicle group tumors consistent with antitumor efficacy. Our study demonstrated that ultrahigh-plexed immunofluorescence imaging is a powerful technology that can efficiently assist in vivo model selection and support biomarker discovery, especially in combination with a TMA section that can include multiple tumor models.

#5313 Spatial transcriptomics reveals clone-specific features of primary and metastatic tumors in triple-negative breast cancer.

Yu-Ting Kang, Tzu-Hung Hsiao

Taichung Veterans General Hospital, Taichung, Taiwan

Breast cancer has become the most commonly diagnosed malignancy, with metastasis remaining the leading cause of mortality, particularly in triple-negative breast cancer (TNBC). In this study, we applied spatial transcriptomics with an 8 μm resolution to analyze the primary tumor and lung metastasis, occurring six months post-recurrence, of a TNBC patient, encompassing a total of 1,033,074 bins. Through this analysis, six tumor clusters (T0-T5) with distinct gene expression profiles were identified. Among these, T0 and T3 were the predominant clusters observed in the metastatic tumor. T0 was primarily distributed in the tumor core, while T3 localized at the tumor boundary. Both clusters exhibited high expression of *VIM*, a marker associated with epithelial-mesenchymal transition (EMT). Differentially expressed gene (DEG) analysis revealed that T3 displayed elevated levels of genes associated with extracellular matrix (ECM) remodeling pathways. Trajectory analysis indicated that T3 represented the most advanced differentiation stage as a subclone. Our findings provide insights into the dynamic spatial heterogeneity and metastatic progression of primary and metastatic TNBC tumor subtypes.

#5314 Prostate club-like cells resist treatment and carry prognostic value in lung and pancreatic adenocarcinoma.

Antti Kiviaho[1], Sini K. Eerola[1], Heini M. L. Kallio[1], Miina Hoikka[1], Aliisa M. Tiihonen[1], Iida Salonen[1], Alexander Giesen[2], Ebrahim Afyounian[1], Sini Hakkola[1], Charles T. A. [1]Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland,[2]Department of Urology, University Hospitals Leuven, Leuven, Belgium,[3]University College London Cancer Institute, London, United Kingdom,[4]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom,[5]Department of Cellular and Molecular Medicine, Laboratory of Molecular Endocrinology, Leuven, Belgium

Introduction: The prostate cancer tumor microenvironment (TME) contains various cell type identities. We recently described club-like epithelial cells as a constitutive part of the TME present in tissue regions with increased myeloid-derived suppressor cell infiltration. The origin, exact function, and identity of club-like cells remain unresolved.
Methods: Here we used bulk, single-cell, and spatial transcriptomics to characterize club-like cells and their relation towards androgen deprivation therapy. We additionally analyzed multiplex immunofluorescence data for interactions between club-like cells and myeloid-derived suppressor cells. Furthermore, we investigated club-like expression in lung and pancreatic tumors.
Results: In the spatial transcriptomics data, club-like enriched regions comprise a mixture of club, hillock, and senescent epithelial cells. Prostate cancer tumors from men treated with androgen deprivation therapy display elevated expression of hillock and senescence, but not the club signature. A high club signature score is associated with improved overall survival in TCGA lung adenocarcinoma (LUAD, HR = 0.59, $p = 5.1x10^{-4}$), while a high hillock gene signature score indicates worse overall survival in both LUAD (HR = 1.80, $p = 9.3x10^{-5}$) and pancreatic ductal adenocarcinoma (PDAC, HR = 1.94, $p = 1.4x10^{-3}$). In PDAC, club-like expression is associated with IL-1β^{+} myeloid cell interaction. We define IL-1β^{+} myeloid cells in the prostate single-cell data and demonstrate co-localization with club cells in the spatial transcriptomics data. Finally, we show that epithelial cells from castration-resistant prostate cancer samples have an elevated hillock signature compared to normal prostate and treatment-naïve prostate cancer, suggesting hillock expansion or phenotypic plasticity during disease progression.
Conclusion: Our results indicate that the canonical club phenotype arises in response to inflammatory signaling, while closely related hillock cells survive androgen deprivation in prostate cancer and indicate poor overall survival in LUAD and PDAC tumors.

#5315 Mapping tumor infiltrating lymphocytes in whole prostatectomy specimens to visualize and quantify the immune microenvironment of prostate cancer.

Yuwei Zhang[1], Rajarsi Gupta[1], Joel Saltz[1], Tahsin Kurc[1], Jakub Kaczmarzyk[1], Erich Bremer[1], Veronica Wallaengen[2], Amanda Galvez[2], Abigail Bartley[2], Leonard Salcedo[2], Alan Pollack[2], Sanoj Punnen[2], Oleksandr Kryvenko[2], Radka Stoyanova[2], Sandra M. Gaston[2]

[1]Stony Brook University, Stony Brook, NY,[2]University of Miami Miller School of Medicine, Miami, FL

Background: Prostate cancer (PCa) frequently presents as multifocal lesions with histologic and molecular heterogeneity. A comprehensive understanding of tumor immune responses within the context of the complex PCa microenvironment remains elusive. Through the use of Digital Pathology and innovative Pathomics image analysis tools, tumor infiltrating lymphocytes (TILs) can be mapped, visualized, and quantified in whole slide images (WSIs) of H&E stained PCa slides. We have developed a novel workflow to map and quantify TILs by Gleason histologic grade (Gleason-TIL maps) in whole radical prostatectomy specimens.
Approach: WSIs from 211 H&E tissue sections from eight whole radical prostatectomy specimens containing Gleason histologic patterns 3 and 4 were used in the development of the PCa Pathomics workflow. Pathomics tools generated PCa Tumor-TIL and Gleason-TIL maps for each corresponding H&E WSI for all eight prostatectomy specimens. To support tissue sampling for correlative biomarker studies and genomic testing in PCa clinical trials, each Tumor-TIL and Gleason-TIL map was partitioned to quantify total PCa content, Gleason grade (3 vs 4/5) content, and intratumoral and peritumoral TILs per 0.5 x 0.5 cm area tile of tissue in the WSI.
Results: Both Tumor-TIL and Gleason-TIL maps reveal complex and heterogeneous tumor immune interactions across multifocal lesions within each radical prostatectomy specimen. Our novel workflow added the ability to quantify PCa, Gleason grade, and TILs to specific 0.5 x 0.5 cm tissue tiles to quantify TILs relative to Gleason grade that varies within and across each case of multifocal PCa. Quantification of the TIL tile maps showed that in 6 of the 8 prostatectomies the “hot spot” tile with the most intratumoral TILs had more TILs in the Gleason 4/5 patches than in the adjacent Gleason 3 patches.
Conclusions and Future Studies: This novel workflow was developed to generate Tumor-TIL and Gleason-TIL maps for every PCa H&E WSI to serve as powerful visual tools for real world laboratory tissue sampling for downstream genomics, immunohistochemistry, and other correlative studies for PCa clinical trials. Adding a 0.5 x 0.5 cm tile partitioning function increases the efficiency of identifying and quantitatively mapping TILs in the complex and heterogeneous PCa microenvironment. The preliminary association of TILs with higher grade Gleason 4/5 PCa appears provocative as potential actionable information as an immune biomarker in PCa.

#5316 Multi-platform spatial profiling reveals intra-tumor heterogeneity in intrinsic subtypes and immune markers in breast tumors from Kenyan patients.

Mustapha Abubakar[1], Shahin Sayed[2], Hela Koka[1], Scott Lawrence[1], Karun Mutreja[1], Xing Hua[1], Viviane Oluoch[2], Veronica Ngundo[2], Zaitun Ajuoga[2], Difei Wang[1], Chad Highfill[1], Petra Lenz[1], Maria Brown[1], Aaron M. Rozeboom[1], Kristine Jones[1], Amy Hutchinson[1], Belynda Hicks[1], Paul S. Albert[1], Francis Makokha[3], Stefan Ambs[4], Jonine Figueroa[1], Jianxin Shi[1], **Xiaohong Rose Yang**[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Aga Khan University Hospital, Nairobi, Kenya,[3]Mount Kenya University, Thika, Kenya,[4]Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Breast cancer is a highly heterogeneous disease at the clinical, population, and molecular levels. Using key molecular markers, breast cancer can be classified into at least four major intrinsic subtypes: luminal A, luminal B, HER2-enriched, and basal-like or triple-negative. These subtypes are associated with distinct risk factors, clinical behaviors, treatment responses, and outcomes. Recent research highlights the importance of the breast tumor microenvironment (TME) in shaping tumor evolution and cancer progression. Both tumor and TME cells within an individual patient often exhibit substantial intratumoral heterogeneity (ITH), the extent of which may impact accurate tumor classification and treatment response, but has not been well characterized especially in women of African Ancestry. The goal of this study was to comprehensively investigate ITH of intrinsic subtypes and immune TME markers in breast cancer patients from an East African population. Specifically, we employed the Nanostring GeoMx^{TM} platform to quantify 44 key breast cancer intrinsic and immune subtyping markers in spatially defined regions of breast tumors from 31 Kenyan breast cancer patients. We found that all 31 tumors exhibited some degree of ITH, with a third of them showing substantial ITH. Cell composition (epithelial vs. stromal), spatial location of TME immune cells (tumor-leading edge, proximity to tumor or stroma), and intrinsic subtype (specifically, basal-like vs. luminal A) all contributed significantly to ITH of these markers. When comparing results to those obtained from an *in-situ* multiplex staining platform InSituPlex (ultivue) and bulk Nanostring nCounter RNA expression, all generated from the same set of cases, we found that intrinsic or immune subtyping by bulk approaches, which is heavily influenced by the predominant subtypes within a tumor, may lead to inaccurate classification when substantial ITH exists. Similarly, sampling-based approaches like tissue microarrays (TMAs) or region-of-interest (ROI)-based assays are also likely to be subjective to inaccurate and inconsistent measurements of immune markers due to sampling bias. In low-resource settings, *in-situ* assays combined with multi-region scoring may offer a more accurate yet practical alternative to bulk or single-cell assays, which are often costly and technically challenging.

#5317 Multimodal spatial analysis of colon cancer tissue reveals emergence of an immunosuppressive tumor maintenance mechanism.

Gaurav Joshi[1], Nicholas Sciascia[1], Michael Yang[1], Brian Falkenstein[2], Raymond Yan[2], Shannon Quinn[2], Brenna Fearey[1], Junya Yoshioka[1], Arif Burak Tosun[2], S. Chakra Chennubhotla[2], Filippo Pullara[2], Fumiki Yanagawa[1]

[1]Nikon Instruments, Inc., Lexington, MA,[2]PredxBio Inc, Pittsburgh, PA

Background: Colorectal cancer is the second most fatal cancer worldwide, accounting for 9% of all reported cancer deaths, and is the number one cause of death among people under the age of 50. Rapid technical advances in the field of spatial biology are allowing us to gain new insight into colorectal cancer biology and patient heterogeneity, which can help to guide the development of immunotherapies. Using a combination of modalities such as sequential multiplex immunofluorescence (mIF) and spatial transcriptomics (STx) on a colon cancer sample we determined the spatial distribution, phenotype, function, and a cytokine and chemokine profile within the colon cancer tissue.

Experimental Procedure: 5 um FFPE sections were prepared from a colon cancer sample exhibiting moderate to poorly differentiated adenocarcinoma of T3, N0 staging. mIF was performed using Lunaphore COMET with a 20-antibody panel, followed by H&E staining and imaging. An adjacent section was used for STx with the 10x Genomics Visium CytAssist platform. Data was analyzed with Lunaphore Horizon®, 10x Genomics Loupe Browser software and PredxBio SpaceIQ™ unbiased cell typing, microdomain discovery and network biology platform that co-analyzes mIF and STx datasets.

Results: The tumor showed an aberrant growth pattern and a highly proliferated crypt region. Three distinct microdomains in the tumor tissue were discovered: one with high levels of PD-L1+ cells, a second with high levels of NK cells and a third with low levels of infiltrating cells in the lumen and crypt. There was significant presence of VISTA+ and IDO1+ cells throughout the lumen. These cells interacted with CD4+ and CD8+ cells which were found to be present in both lumen and crypt regions. PD-L1 was prominent in the cells found in both lumen and crypt. Finally, NK cells were abundant throughout the lumen and in regions adjacent to the crypt.

Conclusions: Using multimodal spatial imaging and spatial co-analysis of mIF and STx data, we were able to elucidate relationships between different cell types in a complex tumor tissue and assign context to their activities. Despite high levels of NK cells, indicative of a possible active anti-tumor immune response, the tumor has developed an immune evasion mechanism due to the presence of cells expressing high levels of the anti-tumor immune response markers such as PD-L1, IDO1, and VISTA. Based on these results, therapies targeting more than one immune checkpoint protein may yield improved response due to an abundance of the existing NK cells. The transcriptomic profiling reveals a complex relationship between various cytokines secreted by different cell populations which alter the landscape of the tumor microenvironment, facilitating the emergence of an immunosuppressive phenotype.

#5318 Identifying immune cell phenotypes and their function by using high throughput spatial multiomics.

Debia Wakhloo[1], Julia Yu[1], Sonali Deshpande[1], Donald Allen[2], Anne Hellebust[2], Anushka Dikshit[1]

[1]Bio-Techne Corporation, Newark, CA,[2]Indica Labs, Albuquerque, NM

Advances in our understanding of the tumor microenvironment (TME) will help inform the development of next generation immunotherapies and engineered immune-cell therapies. Spatially characterizing immune cells with cell marker protein and activation marker RNAs is crucial to determine therapeutic efficacy and potential therapeutic toxicity. To address this, we have developed a high throughput RNAscope™ assay on the BOND RX to spatially visualize RNA and protein markers on the same slide. We utilized the new RNAscope™ Multiomic LS assay that can detect up to 6 RNA and protein targets on the same slide. The TSA-based amplification strategy offers signal boost for both RNA and protein targets. To optimize protein detection, the workflow is completely protease-free there by preserving antigen integrity and tissue morphology. The assay can be customized to include any target RNA and proteins of interest. Here, we demonstrate the use of our pre-conjugated antibody panel which includes CD8, CD4, FoxP3 and PanCK to visualize tumor infiltrating lymphocytes (TILs). We also utilized unconjugated primary antibodies for CD68 and CD163 to detect tumor macrophages in multiple tumor tissues. Using the HALO® image analysis software from Indica Labs, we performed RNA and protein quantification as well as cell phenotyping and spatial analysis. Infiltrating Cytotoxic T cell lymphocytes were detected using CD8, *GZMB* and *IFNG* co-expression. Regulatory T cells were detected using CD4, FOXP3 co-expression. PanCK was used as a tumor marker to delineate tumor from stroma. Similarly, tumor associated macrophages were detected using CD163, CD68 , *IL10* and *IL-1B* expression. We were also able to identify distinct M1 and M2 macrophage populations in the tumor samples. The protease-free RNAscope Multiomic LS assay was successfully able to interrogate different subpopulation of immune cells with high fidelity RNA and protein signal while maintaining tissue morphology. The higher plex capability provides detection of more markers simultaneously, in turn enabling immune phenotype profiling while maintaining the sensitivity and specificity. Finally, the assay affords a very high throughput on the BOND Rx allowing large-scale pre-clinical and patient sample analysis.

#5319 Simultaneous spatial epigenomic and transcriptomic analysis of human breast cancer reveals regulatory patterns governing tumor and microenvironment architecture at the cellular level .

Katelyn Noronha, Molly Wetzel, Gumaro Rojas, Jennifer Garbarino, James McGann, Jose Perez, Machele Riccio, Danijela Pavic, Jaden Joaquin, Joshua Barnett, Jeffrey Sabina, Colin Ng

AtlasXomics, New Haven, CT

Recent advances in spatial transcriptomics and spatial proteomics have enabled increasingly complex questions on the nature of gene regulation and expression in cellular subtypes in tumor tissue and the tumor microenvironment. However, most spatial omics techniques do not profile the epigenomic landscape responsible for downstream gene expression. Furthermore, current spatial technologies have yet to profile the epigenome and transcriptome simultaneously, and thus it remains a challenge to correlate multi-omics data across sections of extremely heterogenous tumor tissue. Co-profiling of spatial epigenomics and transcriptomics using principles of Deterministic Barcoding in Tissue for spatial omics sequencing (DBiT-seq) has been demonstrated on normal brain tissue. Joint spatial profiling of chromatin states and whole transcriptome in tissue allows for parallel characterization of gene regulation programs across all cell types, while preserving the tissue architecture for greater understanding of the cellular environment. Here we present the first application of spatial ATAC-seq and spatial transcriptomics on the same tissue section to characterize the tumor microenvironment of an infiltrating ductal carcinoma, the most common type of breast cancer, and adjacent normal tissue. Distinct spatial clusters representing different cell subtypes were identified via both spatial chromatin accessibility and spatial transcriptomics. Spatial ATAC-seq profiling of accessible regulatory elements correlated well with RNA expression. Spatial patterns of transcription factor motif accessibility also correlated well with the observed transcriptional program of tumor tissue. When compared to adjacent normal tissue, spatial co-profiling of chromatin accessibility and the transcriptome revealed that the epigenetic landscape is significantly altered in the tumor. Future work will focus on development of co-profiling of histone modifications and the transcriptome to enable the study of another layer of the epigenomic landscape, especially as targeting epigenetic modifiers such as HDACis in breast cancer is being tested in clinical trials with other standard of care therapeutics. Overall, we present a solution to profile multiple layers of gene regulation and expression with spatial context, which can be applied to most tumor types for better understanding of tumorigenesis and the consequences of new targeted therapies.

#5320 Integrative spatial omics reveals distinct tumor-promoting multicellular niches and immunosuppressive mechanisms in African American and European American patients with TNBC.

Qian Zhu[1], Akhila Balasubramanian[1], Jaya Ruth Asirvatham[2], Badrajee Piyarathna[1], Jaspreet Kaur[3], Nada Mohamed[2], Ling Wu[1], Megha Chatterjee[1], Stacy Wang[1], Niloufar Pourfarrokh[2], Uttam Rasaily[1], Yitian Xu[4], Junjun Zheng[4], Deborah Jebakumar[2], Arundathi Rao[2], Shu-hsia Chen[4], Yi Li[1], Eric Chang[1], Xiaoxian Li[5], Ritu Aneja[6], Xiang H.-F. Zhang[1], Arun Sreekumar[1]

[1]Baylor College of Medicine, Houston, TX,[2]Baylor Scott and White Hospital, Temple, TX,[3]The University of Alabama at Birmingham, Birmingham, AL,[4]Houston Methodist Research Institute, Houston, TX,[5]Emory University, Atlanta, GA,[6]Georgia State University, Atlanta, GA

Racial disparities in triple-negative breast cancer (TNBC) outcomes have been reported. However, the biological mechanisms underlying these disparities remain unclear. We integrated imaging mass cytometry and spatial transcriptomics, to characterize the tumor microenvironment (TME) of African American (AA) and European American (EA) patients with TNBC. The TME in AA patients was characterized by interactions between endothelial cells, macrophages, and mesenchymal-like cells, which were associated with poor patient survival. In contrast, the EA TNBC-associated niche is enriched in T-cells and neutrophils suggestive of an exhaustion and suppression of otherwise active T cell responses. Ligand-receptor and pathway analyses of race-associated niches found AA TNBC to be “immune cold” and hence immunotherapy resistant tumors, and EA TNBC as ‘inflamed’ tumors that evolved a distinctive immunosuppressive mechanism. Our study revealed the presence of racially distinct tumor-promoting and immunosuppressive microenvironments in AA and EA patients with TNBC, which may explain the poor clinical outcomes.

Statement of Significance We have uncovered distinct tumor-promoting and immunosuppressive microenvironments that may contribute to the observed disparities in patient outcomes. Our findings lay the groundwork for developing race-specific therapeutic interventions, potentially improving outcomes for patients with TNBC. Given that chemotherapy and anti-PD1 therapy are currently available treatments for TNBC, our finding of race-specific spatial multicellular niche-associated cell-cell interactions suggest that these treatments may have racially distinct response profiles among TNBC patients. Hence, our novel insights on molecular and cellular interactions in TNBC stratified by race has the potential to inform personalized treatment strategies.

#5322 Spatial profiling of the tumor microenvironment in colorectal cancer: Insights into immune, tumor, and stromal interactions using high-dimensional protein analysis.

Enrique Velazquez Villarreal[1], Ei-Wen Yang[2], Fernando C. Diaz[3], Maria Ninova[4]

[1]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Poliagent, San Francisco, CA,[3]Lineberger Comprehensive Cancer Center, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Department of Biochemistry, University of California Riverside, Riverside, CA

Introduction: Colorectal cancer (CRC) is the second leading cause of cancer-related deaths globally, claiming over 900,000 lives annually. In the US, CRC disproportionately affects certain populations, with higher prevalence among racial and ethnic minorities. The tumor microenvironment (TME) plays a pivotal role in CRC progression, therapeutic response, and overall patient outcomes. However, the spatially intricate interactions within the TME that distinguish effective from ineffective tumor control remain poorly understood. Addressing these gaps is essential for enhancing our understanding of spatial heterogeneity and advancing immunotherapy development.
Methodology: To investigate these dynamics, we employed a multi-modal approach using re-engineered co-detection by indexing (CODEX) on publicly available data (Schürch et al., 2020) from 35 late-stage CRC patients. Our systematic workflow classified cells, analyzed protein expression, and spatially represented the data. Cells were grouped into three main classes—stroma, tumor, and immune—based on structural characteristics and functional roles. Protein expression analysis was conducted by integrating data for individual surface protein expression, enabling direct comparisons between the stroma, tumor, and immune classes. Through this framework, 56 protein markers were profiled to identify conserved cellular neighborhoods (CNs) that characterize the spatial and functional organization within the CRC TME.
Results: Protein expression analysis revealed distinct patterns across the stroma, tumor, and immune classes for the biomarkers profiled. These markers exhibited differential expression profiles across the three classes, highlighting their unique roles within the TME. For instance, immune markers such as CD3, CD8, CD68, and PD-1 showed significant variation between the tumor and immune classes, underscoring their spatial organization and functional importance within the TME. Similarly, functional markers such as MMP9 and Ki-67 demonstrated distinct expression dynamics, reflecting their roles in tumor progression and immune responses. Auxiliary markers, including cytokeratins, highlighted structural differences unique to the stroma class. These results provided a comprehensive understanding of the spatial and functional interplay between immune, tumor, and stromal components in the CRC TME.
Conclusion: This study provides a deeper understanding of protein expression within the CRC TME, enhancing the classification and spatial characterization of TME. These results provide key insights into spatial heterogeneity within the TME through distinct protein expression profiles. These findings provide valuable guidance for future research in drug discovery, with the potential to significantly advance the field of precision oncology.

#5323 Spatial heterogeneity of tumor and stromal cells in desmoplastic small round cell tumors.

Jiaqian Fan, Adewale A. Adebayo, Diana Shamsutdinova, Davis Ingram, Clement Agyemang, Roberto Cardenas-Zuniga, Alexander Lazar, Danh Truong, Joseph Ludwig

UT MD Anderson Cancer Center, Houston, TX

Desmoplastic small round cell tumor (DSRCT) is a rare, aggressive sarcoma subtype that harbors a pathognomonic EWSR1::WT1 fusion protein (FP). DSRCT is usually incurable and FP-targeted agents are nonexistent. The five-year survival rate is below 20%. Tumor nests are classically surrounded by desmoplastic stroma in DSRCT, yet the interactions between the tumor cells and the stromal cells are poorly understood. Given this context, our study aims to understand the spatial heterogeneity within DSRCT and the tumor-stroma interactions. We utilized a 20-panel marker to study the cellular constituents of the tumor microenvironment (TME) in DSRCT and to characterize its multilineage expression, including epithelial and neural (NE) signatures. The markers included: DSRCT (ST6GALNAC, pan-Cytokeratin), Fibroblasts (Collagen, α-smooth muscle actin), Endothelial Cells (CD31, α-smooth muscle actin), T-cells (CD45, CD4, CD8), Macrophages (CD45, CD68, CD163, CD11c), and AR/NE markers (androgen receptor, neural-specific enolase, synaptophysin). Marker expression was explored in a nine-patient cohort using 9 x 9 mm² tissue sections imaged by the Lunaphore COMET system. A deep learning model, Visiopharm, extracted high-quality regions and segmented cells based on nuclear staining. Spatial data were transformed into matrix format for analysis in Python, where UMAP and Leiden clustering identified distinct clusters consisting of tumoral cells, fibroblasts, and endothelial cells. Our analysis revealed two distinct fibroblast clusters—one with high α-SMA expression and the other with high collagen expression. These two clusters exhibited distinct spatial distributions and proportions across patient samples, indicating heterogeneity in stromal composition within the DSRCT microenvironment. Our previous study identified three DSRCT subtypes: AR+/NE-, AR-/NE+, and Hybrid AR+/NE+. The current spatial analysis suggests that AR+/NE- tumor nests are consistently surrounded by α-SMA-high fibroblasts, hinting at subtype-specific stromal interactions. Preliminary findings from co-culture experiments of DSRCT cells with human mesenteric fibroblasts suggest that fibroblasts enhance the proliferative capacity of DSRCT cells. These findings provide novel insights into the stromal heterogeneity of the DSRCT microenvironment and its association with tumor subtypes. Our future work will focus on quantifying spatial relationships and patterns, which includes how tumor nest characteristics are associated with fibroblast cell type or DSRCT subtype. Proximity and neighborhood analysis in python and Visiopharm analysis will be applied. Ultimately, our results might reveal novel drug targets that stop oncogenic tumor-stroma signaling.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: CDK Inhibitors
Poster Session

#5327 CDK2 inhibition produces persistent polyploid cancer cells with a survival advantage.

Liliya Tyutyunyk-Massey[1], Zibo Chen[1], Xiuxia Liu[1], Masanori Kawakami[1], Adam Harned[2], Yeap Ng[3], Brian Luke[4], Sameul C. Okpechi[1], Blessing Ogunlade[1], Yair Alfaro[1], Roberto Weigert[3], Kedar Narayan[2], **Xi Liu**[1], Ethan Dmitrovsky[1]

[1]Molecular Pharmacology Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Center for Molecular Microscopy, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Laboratory of Cellular and Molecular Biology, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Advanced Biomedical Computational Science, Frederick National Laboratory for Cancer Research, Frederick, MD

Aneuploidy, a hallmark of cancer, drives chromosomal instability and antineoplastic drug resistance. Common in hematologic and solid tumors, centrosome amplification leads to supernumerary centrosomes, causing chromosomal missegregation in dividing cancer cells. This imbalance produces progeny with abnormal chromosome counts, leading to cell death, resistance to antineoplastics, and clinically-aggressive tumors. This study examined the effects of CDK2 inhibition on aneuploid lung cancer cells and tumors. It revealed that CDK2 antagonism triggers anaphase catastrophe through centrosome clustering disruption and multipolar mitosis. Unexpectedly, this also leads to the formation of a persistent population of polyploid, apoptosis-resistant cells. Using independent CDK2 inhibitors and shRNAs, we observed that some cancer cells underwent multipolar division and subsequent cell death. Others exhibited cytokinesis failure, resulting in multinucleated, and polyploid cancer cells that continued to survive and proliferate despite continuous CDK2 inhibition. Through time-lapse imaging with transfected FUCCI cell cycle probes and RNA-seq analysis of polyploid versus diploid populations, we identified upregulated CDK1-related pathways and kinesin (KIF) family members in the polyploid cellular population. This likely contributes to the persistent polyploid population, despite CDK2 antagonism. These findings were independently validated *in vivo* using intravital microscopy and patient-derived xenograft (PDX) lung cancer models. Intriguingly, polyploid and multinucleated cancer cells were found to proliferate post-CDK2 inhibitor treatments. In marked contrast, a polyploid population was not found in CDK2 inhibited primary human alveolar epithelial cells, indicating that this is a pathway that is preferentially activated in aneuploid cancer cells. Analysis of gene expression in TCGA lung cancer datasets linked CDK1 and KIF family overexpression to an unfavorable patient survival, implicating this persistent polyploid population as contributing to poor survival outcomes in lung cancer. These findings are relevant to the clinical development of CDK2 inhibitors. They indicate that despite the pro-apoptotic effects of CDK2 antagonism in aneuploid lung cancer cells, a population of drug-resistant, polyploid cells persists. We propose that a combinatorial therapy targeting CDK2 alongside polo-like kinase 4 (PLK4), CDK1 or kinesin family members would further disrupt centrosome clustering, eliminate polyploid cancer cells, and enhance tumor cell apoptosis and antineoplastic effects. This dual approach would enhance the anti-tumor efficacy of CDK2 inhibition, potentially overcoming resistance mechanisms. This provides a promising strategy to eradicate persistent lung cancer cells following CDK2 inhibition.

#5328 p16 confers sensitivity to CDK2 inhibitors in CCNE1-amplified ovarian cancers.

Chance Sine[1], Lotte Watts[1], Brianna Fernandez[1], Jianxin Wang[2], Erik S. Knudsen[2], Agnieszka K. Witkiewicz[2], Sabrina L. Spencer[1]

[1]University of Colorado Boulder, Boulder, CO,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Blocking the cell cycle is a promising avenue for cancer therapy, with Cyclin-Dependent Kinase 2 (CDK2) emerging as a key target. However, in multiple cell types, CDK4/6 activity compensates for CDK2 inhibition and sustains the proliferative program, enabling CDK2 reactivation. Thus, we hypothesized that sensitivity to CDK2 inhibition is linked to the absence of this CDK4/6-mediated compensatory mechanism. Here we show that Cyclin E1-driven ovarian cancers often co-express the tumor suppressor p16, which inhibits CDK4/6. We show that ovarian cancer cells expressing p16 exhibit heightened sensitivity to CDK2 inhibitors and that depletion of p16 renders them significantly more resistant. Multiplexed immunofluorescence of 225 ovarian patient tumors reveals that at least 18% of tumors express high Cyclin E1 and high p16, a group that we expect to be particularly sensitive to CDK2 inhibition. Thus, p16 may be a useful biomarker for identifying the patients most likely to benefit from CDK2 inhibitors.

#5329 Development of a novel selective CDK4 inhibitor for HR+/HER2- breast cancer.

Mei Hua Li*,#,[1], Apeng Liang*,#,[1], Kai Wang[1], Yi Long[1], Rui Wu[1], Hui Xu[1], Jian Zhu [1], Guangbin Liu[1], Ling Fang[1], Xi Wang[1], Chenjie Pan[1], Yiming Cai[1], Xiang Zhang [1], Shengli Dong[1], Yu Yu[1], Xinlong Yang[1], Chao Zhou[1], Wei Wu [1], Chengshan Niu[2], Mingyu Jiang[3], Shaoqing Chen[1], Jun Li*.1,2,[3], Yusheng Wu1,2, [3]

[1]TYK Medicines, Inc., Huzhou, Zhenjiang, China,[2]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, China,[3]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China

Introduction: FDA approved CDK4/6 inhibition medicines has demonstrated significant clinical benefits in patients with HR+/HER2- breast cancer. However, the dual CDK4/6 inhibitors also present severe on-target toxicity leading to severe adverse effects (SAE) in the clinic, such as neutropenia. Clinical studies with palbociclib reported grade 3-4 neutropenia events in 60-66% of patients receiving the treatment. To dissect the cause of the clinical toxicity of CDK4/6, it has been found that CDK6, not CDK4, is directly involved in the differentiation of myeloid cell in which CDK6 expression is up-regulated. Thus, we sought to develop a mono-CDK targeting agent, a CDK4 inhibitor, to grant similar pharmacological potency against HR+/HER2- breast cancer while diminishing or even abolishing CDK6 on-target toxicity to improve the efficacy, and more importantly, the safety of the hallmark cell cycle therapies. To this end, we at TYK Medicines have developed lead CDK4 inhibitor candidates (TY-2072) with high selectivity and potency.

Results: TY-2072 demonstrates high selectivity against CDK4, and more than 17-fold selectivity against CDK6 compared to palbociclib, proving that TY-2072 is a CDK4 inhibitor rather than a CDK4/6 dual inhibitor. Western blot assays showed a dose-dependent reduction in phosphorylated RB (Ser780) in breast cancer cell lines after 48 hours TY-2072 treatment. The anti-proliferation effects of CDK4 inhibitors were assessed with MCF7 (breast cancer, CDK4 sensitive), JEKO-1 (mantle cell lymphoma), and MOLM13 (acute myeloid leukemia, CDK6 sensitive) through a CTG cell viability assay after 5-day incubation. Palbociclib shows a strong inhibitory effect on MCF7/T47D cells due to dual CDK4 and CDK6 kinase activity. TY-2072 strongly inhibited JEKO-1, but had no inhibitory effect on CDK6 high-expression MOLM13. In MCF7-xenograft mouse model, TY-2072 showed significant suppression of tumor growth in a dose-dependent manner at 20 and 40 mg/kg BID, TY-2072 exhibited synergetic effects with Fulvestrant on anti-tumor growth inhibition with good tolerance, evidenced by the maintenance of body weight of the animals throughout the study. We conducted preliminary *in vitro* combination studies with lead CDK4 compounds, and the combination of a selective CDK4 inhibitor with a CDK2 inhibitor or a PI3K inhibitor demonstrated a significant synergistic inhibitory effect on MCF7 cells and MCF7 Palbociclib-resistant cells. Positive results were also observed when TY-2072 was combined with AMG510/MRTX849 in the NSCLC H2122 (KRAS G12C) cells.

In summary, the optimization of the lead compounds is continuing with goal to identify a PCC compound in the near future for IND-enabling studies.

#5330 Antitumor activity of potent and selective CDK2 inhibitors as monotherapy and in combination with chemotherapy in models of small cell lung cancer.

Nealia House, Liang Yuan, Christophe Lemetre, Maxine Chen, Philip Ramsden, Scott Ribich, Lakshmi Muthuswamy, Kerrie Faia

Blueprint Medicines Corporation, Cambridge, MA

Background: A molecular hallmark of small cell lung cancer (SCLC) is the high frequency of inactivating mutations in the retinoblastoma 1 (Rb1) gene, leading to loss of functional Rb expression and dysregulated G1-S phase progression. Analysis of publicly available DepMap data shows that Rb-mutant SCLC cell lines exhibit a genetic dependency on cyclin-dependent kinase 2 (CDK2), suggesting aberrant CDK2 activity may be essential in regulating cell cycle progression in the absence of CDK4/6-Rb signaling. BLU-222 is an investigational, potent, highly selective, orally bioavailable CDK2 inhibitor currently in Phase I/II clinical trials (NCT05252416). Here, we report on the activity of BLU-222 and BLU-956, a next-generation CDK2 inhibitor, in pre-clinical models of SCLC. Using *in vitro* cell line screening, we identified specific biomarkers predictive of response to BLU-222 and BLU-956.

Methods: The *in vitro* antiproliferative effect of BLU-222 and BLU-956 alone or in combination with cisplatin was assessed by CyQuant in a panel of SCLC cell lines. *In vivo* antitumor activity of BLU-222 or BLU-956 as single agents or in combination with cisplatin was measured in biomarker positive cell line-derived xenograft (CDX) models.

Results: Both BLU-222 and BLU-956 demonstrated strong anti-proliferative activity in Rb-null SCLC cell lines. Biomarker analysis identified high levels of *SKP2* expression as a predictive biomarker for CDK2 inhibitor sensitivity. Further, co-expression of high *SKP2*, high *CDKN2A*, and high *CCNE1* expression was associated with the strongest responses to BLU-222 or BLU-956 in Rb-null cell lines. BLU-222 and BLU-956 were well tolerated as single agents and in combination with cisplatin in immunodeficient mice. CDK2 inhibitor monotherapy achieved tumor stasis in pre-clinical SCLC CDX models, including NCI-H526. Responses were enhanced in combination with cisplatin, superior to cisplatin monotherapy, and led to tumor regression.

Conclusions: CDK2 inhibition represents a novel therapeutic approach in SCLC, an aggressive cancer with high unmet medical need. In pre-clinical models of SCLC, BLU-222 and BLU-956 demonstrated substantial anti-tumor activity as single agents, with enhanced effects in combination with cisplatin. These findings provide rationale for exploring targeting CDK2 in combination with cisplatin in SCLC and suggest that specific biomarkers could be useful to predict response.

#5331 Orthosteric CDK2 kinase inhibitors have a distinctive profile when compared to genetic perturbation of CDK2 in CCNE1-amplified and non-amplified tumor cell lines.

Joanne M. Munck[1], Susan J. Tudhope[2], Kleopatra Papa[2], Alex Howard[1], Sam Hogan[2], Suzanne Kyle[2], Jessica Watt[2], Luke Gaughan[3], Maria Ahn[1], Stephen R. Wedge[2], John F. Lyons[1]

[1]Astex Pharmaceuticals, Cambridge, United Kingdom,[2]Cancer Research Horizons Therapeutic Innovation, Newcastle University, Newcastle, United Kingdom,[3]Translational and Clinical Research Institute, Newcastle University, Newcastle, United Kingdom

Aim: There has been renewed interest in pursuing cyclin-dependent kinase 2 (CDK2) as a therapeutic target for cancer treatment, given its essential role in driving the survival of *CCNE1*-amplified tumors and mediating resistance to CDK4/6 inhibitor treatment in estrogen receptor positive breast cancer. This has resulted in the identification of a next generation of orthosteric inhibitors which have increased selectivity for CDK2 kinase versus other CDK-family members. This study aimed to contrast genetic and chemical perturbation of CDK2 in human tumor cell lines with and without *CCNE1*-amplification. Methods: Cellular responses were assessed using assays for proliferation (CyQUANT), clonogenicity, cell cycle (flow cytometry), and western blotting. NanoBRET tracer displacement assays were used to examine orthosteric kinase inhibition in cells. Genetic perturbation of CDK2 used siRNA and CRISPR-Cas9 editing with sgRNA. Four CDK2 inhibitors currently undergoing clinical trials were profiled. Results: CDK2-targeting siRNA conferred a >75% decrease in the clonogenicity of *CCNE1*-amplified OVCAR-3, Kuramochi and FUOV1 cells, thus confirming dependence of the cells on CDK2. The non-*CCNE1* amplified cells TYK-nu and PEA2 were not sensitive to CDK2-siRNA. The orthosteric CDK2 inhibitors inhibited cellular CDK2 with IC_{50} values in the range of 1-20 nM. As expected, the compounds inhibited the proliferation of *CCNE1*-amplified cell lines but they also demonstrated activity against non-*CCNE1* amplified TYK-nu cells (one example had GI_{50} values of 89 ± 8 nM in OVCAR-3 cells, and GI_{50} values of 122 ± 13 nM in TYK-nu cells, respectively). Consistent with the role of CDK2 in controlling the G1 checkpoint, we observed G1 arrest in the *CCNE1*-amplified cell line OVCAR-3 following CDK2 CRISPR knock-out. As expected, CDK2 gene deletion did not significantly impact the cell cycle in the TYK-nu non-*CCNE1* amplified cell line. In contrast, an orthosteric CDK2 inhibitor induced a G2 arrest in the TYK-nu cell line at doses 2 - 5-fold greater than the compound GI_{50}. Evidence of cyclin E1 accumulation was observed in both *CCNE1*-amplified and non-amplified cells following orthosteric CDK2 kinase inhibitor treatment (48 - 72 hours). It was also observed following generation of an F80G CDK2 mutant TYK-nu cell line and treatment with the bulky purine analog 3MB-PP1. In contrast, gene-silencing, or gene-editing of CDK2, had no effect on cyclin E1 levels. Conclusion: We demonstrate that the profiled orthosteric CDK2 inhibitors do not reproduce genetic perturbation of CDK2 in *CCNE1*-amplified and non-amplified cell lines. We propose the need for more selective CDK2 inhibitors and those that inhibit CDK2 in a manner that more closely reflects the genetic perturbation of CDK2.

#5332 Targeting CDK2 in estrogen receptor-positive/RB-deficient breast cancer.

Chang-Ching A. Lin[1], Pamela Luna[1], Khushi Ahuja[1], Dan Ye[1], Yisheng V. Fang[1], Alec Trub[2], John Bisi[2], Jay Strum[2], Patrick Roberts[2], Jeon Lee[1], Ariella B. Hanker[1], Carlos L. Arteaga[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]Incyclix Bio, Durham, NC

The estrogen receptor-positive (ER+) subtype continues to be the leading cause of breast cancer-related mortality worldwide. Although CDK4/6 inhibitors (CDK4/6i) have extended survival of patients with ER+ breast cancer, resistance to these therapies is inevitable. *RB1* loss-of-function alterations are a well-established mechanism of resistance to CDK4/6i, occurring in approximately 10% of ER+ breast cancer patients who progress on CDK4/6i. With the broad use of CDK4/6i as the standard treatment, the population of patients with ER+/RB-deficient breast cancer is expected to rise, highlighting an urgent need for effective targeted therapies and therapeutic strategies for this drug-resistant subtype. Using a genome-wide CRISPR screen in ER+ *RB1* knockout (RBKO) T47D breast cancer cells, we identified CDK2 as an essential gene. Additionally, analysis of the DepMap dataset further confirmed *CDK2* as a top essential gene in cancer cells with low *RB1* mRNA expression, suggesting an RB-independent role for CDK2 and its potential as a therapeutic target in cancers with RB deficiency. Supporting this hypothesis, siRNA-mediated silencing of *CDK2* (siCDK2) in MCF7 RBKO cells and in lung (H596 and H1155), prostate (Du-145), and triple-negative breast (MDA-MB-468) cancer cells harboring somatic *RB1* mutations or deletions led to the accumulation of cells in the G1 phase and a reduction of cells in the S phase, indicating an overall delay in cell cycle progression. Similarly, treatment of MCF7 RBKO cells with a CDK2-specific small molecule inhibitor, INX-315, also resulted in suppression of G1-to-S cell cycle progression. In line with the cell cycle analysis, gene set enrichment analysis (GSEA) of RNA-seq data revealed a significant downregulation of the E2F Hallmark gene signature ($q<0.0001$) in MCF7 RBKO cells transfected with siCDK2 vs. control siRNA. Notably, the therapeutic combination of INX-315 and fulvestrant (a selective ERα degrader) synergistically suppressed the growth of MCF7 RBKO xenografts and ER+/*RB1*-deleted patient-derived xenografts in mice. Treatment with this combination reduced Ki67 levels more potently than each monotherapy or vehicle. These findings collectively identify CDK2 as a promising therapeutic target for ER+/RB-deficient breast cancer and support clinical testing of CDK2- and ERα-tagerted combination therapies in this refractory population.

#5333 CDK4/6 inhibitors in patients with bone-only metastatic breast cancer, the role of immune microenvironment.

Mahta Mardani[1], Suleyman Noordeen[1], Katherine Clifton[1], Cynthia Ma[1], Jingyu Xiang[1], Jingqin Luo[1], Takayuki Kobayashi[1], Jing Xi[2], Nusayba Bagegni[1], Foluso Ademuyiwa[1], Rama Suresh[1], Ashley Frith[1], Andrew A. Davis[1], Ron Bose[1], Lindsay Peterson[1], Shana Thomas[1], Yu Tao[1], Kaylee O'Donnell[1], Netra Navadkar[1], Kristin Kwakwa[1], Will Mattock[1], Thomas Walsh[1], Yalin Xu[1], Deborah J. Veis[1], Xinming Su[1], Katherine Weilbaecher[1]

[1]Washington University School of Medicine in St. Louis, Saint louis, MO,[2]Rocky Mountain Cancer Centers, Littleton, CO

Background: CDK4/6 inhibitors (CDK4/6i) have revolutionized HR+ metastatic breast cancer treatment. Trials like PALOMA, MONALEESA, and MONARCH showed improved progression-free survival (PFS) with endocrine therapy (ET), establishing it as first-line treatment. Bone metastases are common in HR+ breast cancer, with 40% of patients having bone-only disease (BoD), which has a distinct course and better prognosis. However, CDK4/6i trials showed less significant PFS benefits in BoD subgroups. This study explores BoD survival outcomes and CDK4/6i efficacy.

Methods: Patients with HR+, $HER2^-$ metastatic breast cancer from a retrospective study at Washington University School of Medicine were included. All the patients received CDK4/6i in the first- or second-line settings from June 2014 to March 2020. Outcomes were collected through June 2023. The Kaplan-Meier with log-rank test and multivariable Cox model were used for survival analysis. We used murine triple negative 4T1 and ER+ luminal B PyMT Bo1 breast tumor cell line-derived models in immunocompetent mice.

Results: We included 167 female patients (131 first, 36 second line) treated with palbociclib plus ET for at least two months. Median age was 62 years (28-87), and 70 (41%) were in the BoD group. Median PFS was significantly shorter in the BoD group compared to the BV (Visceral +/- Bone) group (16.8 vs. 25 months, p=0.04). Multivariate analysis, adjusted for age and race, showed BoD had an HR of 1.65 (95% CI: 1.05-2.68) for PFS.The results of preclinical models showed that single-agent ribociclib decreased the primary mammary gland tumor burden. This effect was abolished when CD8+ T-cells were depleted. However, in the bone colonization model, ribociclib had a nonsignificant effect on bone tumor burden despite decreases in tumoral Ki-67. Arg1+ immune suppressive macrophages were significantly decreased in primary tumors but not in bone tumors after ribociclib administration, suggesting a relative treatment resistance and immune suppression in the bone tumors. Next, we analyzed baseline bone biopsies from 44 patients, categorized as responders (PFS >1 year) or non-responders (PFS <6 months). Ki67 expression was not different between groups but was decreased in 4 patients with paired pre-and post-treatment biopsies. Using Hyperion imaging mass cytometry, we profiled a patient's bone tumor before and after Palbociclib; we found increased PD-L1, CD8+ T-cells, and CD206+ myeloid cells post-treatment. Immune profiling for all 44 patients is ongoing, with future efforts to understand different immune cell populations' role in CDK4/6i response and identify targets to enhance their effects in bone metastases.

Conclusion: Our retrospective study and preclinical data suggest CDK4/6i may be less effective in the bone microenvironment, underscoring the need for research into the role of the bone tumor immune microenvironment in treatment response.

#5334 Proliferative signaling through the ras-erk pathway can be inhibited by the overexpression of dual-specific phosphatase genes in collaboration with other negative regulators of cell cycle progression in the acute myeloid cell line HL-60.

Michael Roberts, Amelia Harper, Kishan Mangru, Katy Meta, Sophia Kovatsis, Jeffrey Forrester, Grace Crossland, Cuong Nguyen, Sher Bahadur

Dickinson College, Carlisle, PA

Reversing or reprogramming malignant cells toward their normal gene expression patterns, without repairing their oncogenic mutations, can be accomplished in culture as demonstrated by the treatment of certain acute myeloid leukemia (AML) cell lines with phorbol esters, which through the activation of PKC results in cell cycle arrest, myeloid differentiation, and ultimately programmed cell death. Gene therapy continues to show promise in the development of new and effective cancer treatments. At its inception, replacing deficient tumor suppressor gene functions was an attractive goal and with the development of gene editing strategies, the repair of activated oncogenes is possible. Here we report the delivery and overexpression of negative regulators of oncogenic RAS signaling, through transfection, that provide tumor suppressor functions in the NRAS-driven cell line, HL-60, that inhibit their proliferative competency. Genes belonging to the dual-specific phosphatase family (DUSPs), including DUSP1, 5 and 6, along with RAS-ERK pathway inhibitors RASA1 and SPRY2, when transfected and overexpressed in HL-60 cells, affects decreases in phospho-ERK and Ki67 levels resulting in reduced proliferation. In combination with the overexpression of genes encoding the cyclin-CDK inhibitors, CDKN1A and CDKN2B, these anti-proliferative alterations are enhanced. While efficient strategies wait for the delivery of lacking tumor suppressor functions to cancer cells through targeted gene therapies, we propose candidate genes for reversing the proliferation program of RAS-driven AML cells.

#5335 A comparative study of CDK2 inhibitors.

Lotte P. Watts[1], Lisa Nguyen[2], Marissa Baker[2], John Chionis[2], Ryan Vong[2], Advait Nagle[2], Stephen Dann[2], Sabrina L. Spencer[1]

[1]University of Colorado Boulder, Boulder, CO,[2]Genesis Therapeutics, San Diego, CA

CDK2 is a key Cyclin-Dependent Kinase that is responsible for driving cells through the cell cycle. CDK2 is both hyper-activated in a variety of cancers and is a mechanism of resistance to CDK4/6 inhibitors, making it an attractive therapeutic target. Using PF3600 and PF4091 (tagtociclib), we previously showed that upon CDK2 inhibition, cells exhibit a rapid drop in substrate phosphorylation that rebounds within several hours ('drop-rebound'). We further showed that CDK4/6 activity compensates for inhibition of CDK2 and sustains the proliferative program by maintaining Rb hyper-phosphorylation and E2F transcription, allowing many cell types to continue cycling in drug. With the advent of numerous new CDK2 inhibitors in development and in clinical trials, we sought to compare five CDK2 inhibitors side-by-side. We first show that all five CDK2 inhibitors elicit the drop-rebound in CDK2 activity. Thus, the drop-rebound response to CDK2 inhibition is not drug-specific, but instead reflects how the cell cycle is wired for robustness. Second, we find that GTAI-664 is ten times more potent than other CDK2 inhibitors. This potency advantage paired with improved selectivity may result in greater target coverage at attainable plasma concentrations in preclinical models. In agreement, several xenograft tumor models appear to respond with better tumor growth inhibition when treated with GTAI-664 relative to PF4091. Finally, we test the combinability of CDK2 inhibitors with CDK4/6 inhibitors *in vitro* and *in vivo.* We hypothesize that durable cell-cycle arrest requires forcing Rb kinase activity below a specific threshold where the Rb-E2F positive feedback loop is broken. Our results are timely given the increasing interest in CDK2 inhibitors across a variety of cancer types.

#5336 A RAS(ON) multi-selective inhibitor combination therapy triggers long-term tumor control through senescence-associated tumor-immune equilibrium in preclinical models of PDAC.

Caroline Broderick[1], Riccardo Mezzadra[1], Exequiel Sisso[1], Almudena Chaves-Perez[1], Ho Yu-Ji[1], Andrea Schietinger[1], Mallika Singh[2], Scott W. Lowe[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Revolution Medicines, Redwood City, CA

Pharmacological inhibition of oncogenic RAS represents an attractive strategy to target pancreatic ductal adenocarcinoma (PDAC), an almost ubiquitously RAS-driven disease. However, initial responses to targeted monotherapy inhibition of active RAS can be followed by relapses, potentially driven by the persistence of drug-tolerant tumor cells. To target these ‘persister’ cells, we investigated strategies to increase their immune visibility in mouse models of PDAC. We show that combining a RAS(ON) multi-selective inhibitor with the CDK4/6 inhibitor palbociclib drives persister cells into a senescent-like state, which coincides with improved tumor control and substantial remodeling of the tumor microenvironment. Combining RAS(ON) and CDK4/6 inhibition with a CD40 agonist results in durable regressions and CD4 T cell-dependent tumor-immune equilibrium. Our studies reveal a combinatorial approach that circumvents resistance to RAS(ON) inhibitor monotherapy in preclinical models and demonstrate a mechanism by which therapy-induced senescence can be reinforced by the immune system, resulting in durable tumor control.

#5337 Homogeneous bioluminescent immunoassay for hKi-67 provides a simple and robust screening tool for antiproliferative agents.

Dan F. Lazar, Kevin R. Kupcho, Andrew L. Niles, James J. Cali

Promega, Madison, WI

We present a robust, homogeneous, and luminescent microplate-based immunoassay utilizing Lumit® technology for fast and quantitative detection of human Ki-67, a marker of cell proliferation. This assay enables efficient screening of antiproliferative agents, demonstrating exceptional performance in assessing antiproliferative activity across multiple mechanisms of action.

We evaluated the Lumit® hKi-67 immunoassay in HCT116 colorectal cancer cells treated with increasing concentrations of four agents known to inhibit proliferation via different mechanisms: palbociclib (CDK4/6 inhibitor), samuraciclib (CDK7 inhibitor), nutlin-3A (MDM2/p53 interaction inhibitor), and thymidine (dNTP pool perturbation). With all four test agents, the Lumit® hKi-67 immunoassay detected a marked, dose-dependent 63-82% reduction in Ki-67 after only 24 hours, and an even greater 79-98% reduction at 48 hours, demonstrating a fast and reliable measure of antiproliferative effects. A same-well multiplex with a cell-impermeant fluorogenic DNA dye demonstrated no cell death provoked by these compounds at the doses and times tested.

In contrast to the large decrease in the proliferation marker Ki-67 elicited within 24 h of treatment by these antiproliferative agents, the response windows achieved with assays of viable cell number were significantly smaller at the early time point. Only 25-40% less viable-cell DNA was observed after 24 h compound treatment vs. untreated controls, with 48 h required to produce response windows of 57-89%. Similar observations were obtained with two other viability assays, one detecting ATP levels and the other live-cell protease activity. However, ATP levels were reduced more than expected by 24 h treatment with thymidine, likely due to perturbation of metabolic activity. Equally concerning, at 48 h, the live-cell protease assay and, especially, detection of ATP levels dramatically underreported the decrease in viable cell number (relative to time-matched untreated controls) in response to palbociclib and nutlin-3A. This latter effect is likely due to the substantial increase in cell size induced by palbociclib and nutlin-3A even as they inhibit cell proliferation. The strong antiproliferative effects induced by palbociclib and nutlin-3A and detected with the hKi-67 immunoassay, however, were further validated by two additional assays: Ki-67 immunofluorescence and BrdU ELISA. Notably, the Lumit® assay provides faster, more robust data compared to these more labor-intensive alternatives.

This study highlights the Lumit® hKi-67 immunoassay as an attractive, high-throughput alternative for screening antiproliferative agents, offering a simpler, faster, and more consistent approach than traditional methods. It is poised to be an invaluable tool in drug discovery and preclinical screening.

#5338 TY-1781, a potent and highly selective CDK2 inhibitor, demonstrates superior anti-tumor activity in CCNE1 high-expression solid tumor models.

Chengshan Niu*,#,[1], Meihua Li*,#,[2], Shaoqing Chen*,[3], Maolin Zheng[1], Mingtao Chen[1], Hui Xu[2], Kaige Ji [1], Yuanjie Li[1], Rui Wu[2], Shengli Dong[2], Yu Yu[2], Xinlong Yang[2], Chao Zhou[2], Apeng Liang[2], Wei Wu[2], Mingyu Jiang[2], Jun Li*,1,2,[3], Yusheng Wu1,2,[3]

[1]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, China,[2]TYK Medicines, Inc. (Changxing), Changxing, China,[3]TYK Medicines, Inc. (Shanghai), Shanghai, China

Background: The common prescription of Palbociclib and other approved CDK4/6 inhibitors in clinic have greatly benefitted breast cancer patients worldwide. The cell cycle regulation therapy however has been found that the long-term use of the CDK4/6 inhibition agents eventually causes primary or acquired resistance to the therapy, and patients eventually relapse from the treatment. Approximately 20% of patients treated with CDK4/6 inhibitors show initial treatment failure. Based on the finding that abnormal activation of CDK2/Cyclin E1 due to CCNE1 gene amplification is determined the key resistant mechanism to CDK4/6 inhibition. Amplification of CCNE gene is prevalent in multiple tumor types, particularly in high-grade ovarian, uterine, and gastric cancers. CDK2 activity is important for survival of CCNE aberrant cancer cells and is also associated with potential resistance to targeted therapies, such as CDK4/6 dual inhibitors. Therefore, CDK2 is a promising therapeutic target in cancer. However, due to the structural homology and functional conservation of CDK family members, as well as the toxic effects associated with the inhibition of other CDKs, the development of selective CDK2 inhibitor is challenging. Here, we present preclinical data of TY-1781, a novel CDK2 inhibitor for the treatment of CCNE1 high-expression tumors.

Results: TY-1781 demonstrates excellent CDK2 kinase inhibitory activity (IC_{50} 0.7 nM), and high selectivity against CDK1, CDK4, CDK6, CDK7, and CDK9 in a panel screening of CDK kinases. *In vitro* cell proliferation data shows that tumor cell lines bearing CCNE1 amplification, are highly sensitive to the TY-1781 treatment. TY-1781 inhibits cellular Rb phosphorylation in Cyclin E1 amplified OVCAR3 cells in a potent yet selective manner, but not in Cyclin E1 wild type TOV21G cells; TY-1781 blocks the G1/S transition in CCNE1 overexpression OVCAR3 cells; and the tumor inhibitory activity of TY-1781 is further underscored when combined with a CDK4/6 inhibitor (Palbociclib), as demonstrated in a cell colony formation assay with ER+/Her2- breast cancer cells. Consistent with the *in vitro* results, TY-1781 demonstrated a potent inhibitory effect in immune-defect mouse models of CCNE1-amplified cancer cells. When combined with a chemotherapy agent (gemcitabine) or PARP inhibitor, TY-1781 robustly suppressed tumor growth in the examined ovarian cancer models.

Conclusion: Taken together, we identified a highly selective and potent CDK2 inhibitor through medicinal chemistry screening and rounds of refining. The data suggest that TY-1781 may be eligible for further clinical development for Cyclin E1 high-expression patients who relapse from previous standard of care treatments.

#5339 Single cell analysis enables tracking the evolution of resistance to CDK4/6 inhibitors in ER+ breast cancer.

Yuki Matsunaga[1], Emma Aleksandrovic[2], Hima M. Patel[1], Dhivya R. Sudhan[1], Khushi Ahuja[3], Dan Ye[1], Chang-Ching A. Lin[1], Lei Guo[4], Cynthia X. Ma[5], Jeon Lee[3], Siyuan Zhang[2], Carlos L. Arteaga[1], Ariella B. Hanker[1]

[1]Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX,[2]Department of Pathology, UT Southwestern Medical Center, Dallas, TX,[3]Lyda Hill Department of Bioinformatics, UT Southwestern Medical Center, Dallas, TX,[4]Peter O'Donnell Jr. School of Public Health, UT Southwestern Medical Center, Dallas, TX,[5]Washington University School of Medicine in St. Louis, St. Louis, MO

The combination of CDK4/6 inhibitors (CDK4/6i) with endocrine therapy prolongs survival of patients with ER+/HER2- metastatic breast cancer. Nearly all patients with advanced disease treated with this combination eventually progress, highlighting a need for therapeutic interventions that prevent the emergence of drug resistance. Drug tolerant persister (DTP) cells represent a reservoir of surviving cells from which drug-resistant clones eventually emerge. We hypothesized that targeting breast cancer cells in a DTP state that emerge under selective pressure from CDK4/6i would prevent the emergence of drug resistance. First, we aimed to delineate genomic and epigenomic features of DTPs under continuous CDK4/6i + antiestrogen therapy. We treated MCF7 and T47D ER+ breast cancer cells with palbociclib + estrogen deprivation long-term (4 weeks). Cells that survived long-term treatment exhibited characteristics of DTPs, such as reversible sensitivity to CDK4/6i + estrogen deprivation, reversible cell cycle arrest, and reversible transcriptional programs associated with the DTP state. To translate these findings to patients, we examined gene expression data from residual tumors after neoadjuvant treatment with palbociclib and the aromatase inhibitor anastrozole in the NeoPalAna trial and found that these tumors showed a similar enrichment of gene signatures associated with DTPs compared to tumors before treatment. To elucidate with DTPs give rise to drug resistant clones, we barcoded MCF7 and T47D cells with a lineage and RNA recovery (LARRY) barcode library with ~315,000 diverse barcodes, such that we can track them during long-term treatment. Barcoded cells were treated with palbociclib plus estrogen deprivation for 0 h, 72 h, and 4 weeks and then subjected to single-cell RNA-seq; 101 and 15 clones that were initially arrested in G0/G1 eventually expanded at 4 weeks, while 376 and 27 clones were eliminated during treatment of MCF7 and T47D cells, respectively. Comparing the expanding clones with the exhausted clones, we identified 50 marker genes for DTP cells in each cell line. We are currently using a CRISPR-Cas9 targeted knockout screen to identify which of these genes are causal to DTP survival. We will then compare results from these single cell approaches with RNA microarray analysis from residual tumors after neoadjuvant treatment in the NeoPalAna trial. In summary, a small subset of ER+ breast cancer cells survive long-term treatment with CDK4/6i plus estrogen deprivation and exhibit reversible transcriptomic features of DTPs. Single-cell RNA-seq analysis in barcoded breast cancer cells revealed genes significantly upregulated in expanding clones that show features of the DTP state. We proposed therapeutic targeting of these genes may reduce survival of drug-tolerant cells and prevent the emergence of drug resistance.

#5340 Simultaneous targeting of CDK4/6 and BETs is independent of RB status in osteosarcoma.

Rada Malko[1], Pankita H. Pandya[2], Harlan E. Shannon[3], Erika A. Dobrota[3], Barbara J. Bailey[3], Niknam Riyahi[3], Keiko E. Kreklau[3], Ryli E. Justice[3], Melissa A. Trowbridge[4], Kathryn L. Coy[4], Anthony L. Sinn[4], Khadijeh Bijangi-Vishehsaraei[2], M. R. Saadatzadeh[3], Micheal J. Ferguson[2], Kyle W. Jackson[2], Brian D. Weiss[2], Karen E. Pollok[3]

[1]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Pediatrics, Hematology/Oncology, Indiana University School of Medicine, Indianapolis, IN,[3]Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[4]Preclinical Modeling and Therapeutics Core, IU Melvin and Bren Simon Comprehensive Cancer Center, Indiana University School of Medicine, Indianapolis, IN

Osteosarcoma (OS) is the most prevalent primary bone cancer in children and adolescents, characterized by genetic instability and aggressive progression leading to poor survival. Despite the use of multimodal therapies, survival rates have stagnated around 60% highlighting a critical need for the identification of effective drug targets to improve outcomes. Sequencing efforts reveal cell-cycle dysregulation which may be targeted via CDK4/6 inhibitors (CDK4/6i) such as palbociclib and abemaciclib. While Retinoblastoma proficiency (RB+) has been used as a biomarker of response to CDK4/6i clinically, over 70% of OS patients exhibit RB deficiency (RB-). Therefore, it is imperative to understand to what degree RB- affects response to CDK4/6i in OS. Based on in vitro screening data, we hypothesize a combination of CDK4/6i with bromodomain and extraterminal domain inhibitors (BETi) will potentiate the CDK4/6i anti-tumorigenic effects in both RB+ and RB- OS. A hallmark of OS is high levels of genomic instability and BETi may further induce DNA damage to kill DNA repair-deficient cells. In-vitro combination studies identified dose ratios of CDK4/6i and bivalent BETi (AZD5153) that induce synergistic growth inhibition in a panel of monoallelic and biallelic RB OS cell lines. CRISPR-mediated RB-knockout (KO) clones were developed in human (143B, MG63.3) and murine (K7M2) metastatic OS cell lines. In comparison to wildtype (WT) clones, KO clones were 2-10-fold more resistant to palbociclib and at most 2-fold more resistant to abemaciclib; with differences attributed to broader selectivity profile of abemaciclib. However, dual CDK4/6i and BETi therapy resulted in synergistic growth inhibition in both WT and KO clones. To track emergence of therapeutic resistance, a longitudinal growth assay indicated that dual therapy induced cytotoxicity over time with greater effects observed in KO clones, presumably due to increased genome instability. CDK4/6i therapy with abemaciclib, but not palbociclib, increased C-PARP expression by 2-fold in WT cells and 50-fold in KO cells. Annexin V flow cytometry corroborated these findings, showing apoptosis in 25% of WT cells and 75% of KO cells. Limiting dilution assays revealed that dual CDK4/6i and BETi therapy reduced clonogenic cell frequency, with a more pronounced effect in KO clones. Additionally, RB monoallelic OS PDX models TT2 (pretreated) and PDX96 (naïve), were treated for 6 weeks with CDK4/6i (palbociclib, 40mg/kg, BETi (AZD5153,1 mg/kg), or their combination and significantly reduced tumor growth compared to single agents in both models ($p<0.05$) and was well tolerated. A trend for increased probability of survival was observed in PDX96. Future studies will extend dosing duration and focus on metastatic and RB- variant models. These findings provide rationale for further study of novel therapeutic options which may expand the clinical utility of CDK4/6i regardless of RB status.

#5341 Duration of CDK4/6 inhibitor (CDKi) treatment in metastatic HR+ HER2- breast cancer (mHRBC) is associated with changes in AKT pathway protein expression.

Brie Chun[1], Allison Creason[1], Shaun M. Goodyear[1], Laura Heiser[2], Zahi Mitri[3]

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Biomedical Engineering, Oregon Health & Science University, Portland, OR,[3]BC Cancer Agency, Vancouver, BC, Canada

Background: First-line CDKi and endocrine therapy has improved survival for patients with mHRBC. Upon CDKi progression, the optimal treatment strategy for mHRBC without a targetable mutation in *PIK3CA, AKT, PTEN* or *ESR1* is unclear. The CAPItello-291 trial showed that targeting the PIK3CA pathway after CDKi improved progression-free survival, including mHRBC without identifiable genomic alterations in *PIK3CA, AKT* or *PTEN*. Protein expression analysis may identify whether signaling pathways such as PIK3CA/AKT are upregulated after CDKi and proffer rational targets even without genomic alterations. We used digital spatial profiling (DSP) to perform protein expression analysis of oncogenic pathways on mHRBC samples collected from patients before and after CDKi treatment.
Methods: Patients with mHRBC treated with a CDKi between 2015 and 2022 with available archival tissue were included in this study. Samples were obtained <2.5 years prior to CDKi start and <1 year after CDKi discontinuation. The sample cohort included 6 paired biopsies, which enable direct assessment of CDKi changes. A single FFPE slide per sample was stained with an 82-protein cocktail of antibodies conjugated to UV-photocleavable DNA barcodes and analyzed using the NanoString GeoMx platform. For each sample, three 660-micron regions of interest (ROI) were selected to maximize tumor cell content and avoid necrosis or sectioning artifacts. Protein expression data was normalized by geometric mean, ROI expression was averaged per patient, and means comparisons were made between groups. This study was approved by the OHSU Institutional Review Board
Results: Thirty-five samples from 29 patients were analyzed (23 pre-CDKi, 12 post-CDKi). AKT and INPP4B expression was greater post-CDKi in patients treated for >6 months compared to those treated for ≤6 months (AKT, >6 months: 2254, ≤6 months: 1194, p = 0.032; INPP4B, >6 months: 1135, ≤6 months: 390, p=0.032). BCL-2 expression was greater and Ki-67 expression was lower post-CDKi in patients treated for >6 months compared to those treated ≤ 6 months (BCL-2, >6 months: 1547, ≤6 months: 563, p=0.016; Ki-67, >6 months: 421, ≤ 6 months 1807, p=0.016).
Conclusion: Patients treated with CDKi for longer durations had increased expression of PIK3CA/AKT pathway proteins; suggesting that the pathway could become upregulated during CDKi treatment. Higher BCL-2 expression is associated with reduced apoptosis, and lower Ki-67 expression is associated with slower proliferation rates. Whether these observations are a result of CDKi treatment or are related to indolent tumor behavior merits further study. Future studies will evaluate RNA sequencing and multiplex immunohistochemistry of immune microenvironment on samples from the same cohort to more deeply characterize the effects of CDKi on mHRBC tumors.

#5342 Inhibition of glutaminase elicits senolysis in therapy-induced senescent melanoma cells.

Justin Kim[1], Bryce Brunetti[1], Ayanesh Kumar[1], Ankit Mangla[2], Kord Honda[3], **Akihiro Yoshida**[1]

[1]Dermatology, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Hematology and Oncology, University Hospitals Cleveland Medical Center, Cleveland, OH,[3]Dermatology, University Hospitals Cleveland Medical Center, Cleveland, OH

The cyclin D1-Cyclin-Dependent Kinases 4 and 6 (CDK4/6) complex is crucial for the development of melanoma. We previously demonstrated that targeting CDK4/6 using small molecule inhibitors (CDK4/6i) suppresses $Braf^{V600E}$ melanoma growth *in vitro* and *in vivo* through induction of cellular senescence. However, clinical trials investigating CDK4/6i in melanoma have not yielded successful outcomes, underscoring the necessity to enhance the therapeutic efficacy of CDK4/6i. Accumulated research has shown that while senescence initially suppresses cell proliferation, a prolonged state of senescence eventually leads to tumor relapse by altering the tumor microenvironment, suggesting that removal of those senescent cells (in a process referred to as senolysis) is of clinical necessity to facilitate clinical response. We demonstrate that glutaminase 1 (GLS1) expression is specifically upregulated in CDK4/6i-induced senescent $Braf^{V600E}$ melanoma cells. Upregulated GLS1 expression renders $Braf^{V600E}$ melanoma senescent cells vulnerable to GLS1 inhibitor (GLS1i). Furthermore, we demonstrate that this senolytic approach targeting upregulated GLS1 expression is applicable even though those cells developed resistance to the $Braf^{V600E}$ inhibitor vemurafenib, a frequently encountered substantial clinical challenge to treating patients. Thus, this novel senolytic approach may revolutionize current CDK4/6i mediated melanoma treatment if melanoma cells undergo senescence prior to developing resistance to CDK4/6i. Given that we demonstrate that a low dose of vemurafenib induced senescence, which renders $Braf^{V600E}$ melanoma cells susceptible to GLS1i and recent accumulated research shows many cancer cells undergo senescence in response to chemotherapy, radiation, and immunotherapy, this senolytic therapy approach may prove applicable to a wide range of cancer types once senescence and GLS1 expression are induced.

#5343 Proximity labeling reveals role of 14-3-3 protein in CDK4/6 inhibitors resistance for hormone positive breast cancer.

Wei-Ting Chung[1], Yi-Ru Tseng[1], Tsan-Jan Chen[2], Wenching Wang[2], Muh-Hwa Yang[1], Chun-Yu Liu[3], Yi-Fang Tsai[4], Chi-Cheng Huang[4], Ling-Ming Tseng[4], Ta-Chung Chao[4], **Jiun-I Lai**[1]

[1]National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]National Tsing Hua University, Taipei, Taiwan,[3]taipei veterans general hospital, Taipei, Taiwan,[4]Taipei Veterans General Hospital, Taipei, Taiwan

CDK4/6 inhibitors are currently standard of care for advanced hormone positive (HR+) breast cancer, and CDK6 overexpression induces resistance against CDK4/6 inhibitors. We incidentally discovered that overexpression of a CDK6 ^{D224Y} mutant mitigated this resistance. Mechanistic studies revealed that CDK6 overexpression resulted in suppressed apoptosis and increased G1/S progression after treatment with CDK4/6 inhibitors; these features were abolished when CDK6 ^{D224Y} was overexpressed. APEX2- based proximity labeling proteomics revealed CDK6 overexpression, but not CDK6 ^{D224Y}, induced proximity of the 14-3-3 protein YWHAB. Co-immunoprecipitation experiments confirmed YWHAB bound overexpressed wild type CDK6 but not CDK6 ^{D224Y}, and YWHAB knockdown decreased CDK6 protein in a proteosomal dependent manner, suggesting that YWHAB served as a chaperone role for CDK6 stablization. Knockdown of YWHAB reversed the resistance conferred by CDK6 amplification. Molecular modeling studies predicted that the aspartate-to-tyrosine mutation of CDK6 ^{D224Y} would result in destabilizing binding between CDK6 and YWHAB. Xenograft studies confirmed that CDK6 ^{D224Y} overexpression reversed the resistance conferred by CDK6 overexpression *in vivo*. Analysis of independent clinical cohorts revealed an association of 14-3-3 proteins with survival in HR (+) breast cancer. Both 14-3-3 beta (YWHAB) and zeta (YWHAZ) were associated with activation of G1/S pathway genes, suggesting a role for 14-3-3 proteins in CDK4/6 inhibitors treatment outcome. In a clinical cohort, high YWHAZ expression was associated with worse outcome to CDK4/6 inhibitors treatment. Transcriptomic studies revealed that high YWHAB/YWHAZ expression was associated with upregulated G1/S pathway signature, confirming a role of 14-3-3 proteins in CDK4/6-cyclinD-Rb-E2F axis. In summary, by studying CDK6 ^{D224Y}, we uncovered a role for the 14-3-3 protein YWHAB in CDK4/6 inhibitor resistance.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genomic Profiling of Tumors 1
Poster Session

#5347 Transcriptome analysis for Merkel cell carcinoma patients testing positive (+) and negative (-) for polyomavirus.

M. Perez Salva[1], N. Munoz[1], F. Srividya[1], M. Pirhoushiaran[1], D. Wang[1], M. Delgado Velez[2], J. A. Lasalde Dominicci[2], P. P. Aung[1], L. Y. Ballester[1];
[1]MD Anderson Cancer Center, University of Texas, Houston, TX, [2]University of Puerto Rico, School of Medicine, San Juan, PR

Merkel cell carcinoma is a rare, aggressive primary cutaneous malignancy with neuroendocrine differentiation. Approximately 3,000 new cases are diagnosed annually in the United States, with incidence rates rising partly due to advancements in diagnostic methods. The exact cause of MCC is unknown, but several potential etiologies have been proposed, including exposure to ultraviolet radiation (UVR) and integration of Merkel cell polyomavirus (MCPyV). MCPyV has been detected in up to 80% of MCC tumors in the United States, and its presence is associated with a better prognosis, with a five-year overall survival (OS) rate of approximately 50%. This study aims to investigate the transcriptomic and methylomic profiles of skin samples from 27 patients with MCC, comparing those positive and negative for MCPyV. The objective involves identifying potential genetic biomarkers that could be targeted for therapeutic intervention for both MCPyV (+) and MCPyV (-) patients.

#5348 Gene alterations in breast tumors reveal significant association with patient and tumor characteristics.

M. Al Dalali[1], B. Al Amri[1], N. Al Zeheimi[1], R. Al Busaidi[1], M. Islam[1], M. Al Riyami[1], A. Al Jarrah[1], Y. Tamimi[1], C. Crozier[2], J. Bartlett[3], J. Bayani[2], S. A. Adham[1];

[1]Sultan Qaboos University, Muscat, Oman, [2]Ontario Institute for Cancer Research, Toronto, ON, Canada, [3]University of Edinburgh, Edinburgh, United Kingdom

Background: Profiling breast tumor gene alterations gives insight into the nature of the disease and will eventually lead to better diagnosis and personalized treatments. Ethnicity plays a role in the behavior of breast cancer etiology. In this study, we aimed to verify gene mutations in the context of single nucleotide variation (SNV) and copy number variations (CNV) in a patient group from The Sultanate of Oman. We correlated the gene alterations with age and tumor characteristics simply because breast cancer in this population happens at an earlier age with an aggressive nature compared with Western women.

Materials and Methods: The DNA extracted from formalin-fixed paraffin-embedded FFPE tissues was analyzed using the Oncomine Comprehensive Assay Plus targeted cancer genes panel using a next-generation sequencing platform. The data was analyzed using the Oncomine informatics software, and statistical analysis was further employed to analyze the significant gene alterations with the patient and tumor characteristics.

Results and discussion: 40 Patients' tumors were collected and classified based on patient age and tumor-specific parameters, including tumor size, grade, lymph node status, hormone receptor status, and molecular subtypes. Remarkably, SNVs in NTRK1 (*p=0.003*) and *PIK3CA* (*p=0.008*) were more associated with the tumors of older patients. SNVs in *TP53* (*p=0.007*) and *CBFB* (*p=0.037*) exhibited significance with the molecular subtype of patients. Additionally, copy number amplifications in *FGF 3,4* and *19* were significant based on the tumor molecular subtype (P ≤0.05). *TSC1* with SNV was exclusively mutated significantly in smaller tumor sizes (*p=0.023*). Besides, the CNVs (gain) in *NBN* (*p=0.010*) and *RECQL4* (*p=0.028*) were also found in smaller tumors. Regarding tumor grade, five genes showed more CNV-gain in higher-grade tumors: *BRIP1* (*p=0.015*), *RPS6KB1*(*p=0.019*), *SOX9* (p=*0.015*), *CHEK2* (*p=0.013*), and *NOTCH1* (*p=0.045*). *CDK12* copy number gain led to a significant decrease in the overall survival of the studied patients (*p=0.048).* Conclusion: Like the international distribution of BC mutations, *TP53* and *PIK3CA* are still the most mutated in the studied cohort. The analysis indicated a few unique gene mutations in this study, such as *NTRK1* and its mutations in older breast cancer patients. Further analysis of the transcriptome data will confirm the highlighted gene activity and correlation with the characteristics of the disease.

#5349 Ferroptosis as a determinant of prognosis and response to immunotherapy in liver cancer.

Sowon Park[1], Hyewon Park[2], Yun Seong Jeong[3], Bo Hwa Sohn[3], Sun Young Yim[4], Sung Hwan Lee[5], Ju-Seog Lee[3]

[1]Bioengineering, Rice University, Houston, TX,[2]Elkins High School, Missouri City, TX,[3]UT MD Anderson Cancer Center, Pearland, TX,[4]Korea University, Seoul, Korea, Republic of,[5]CHA Bundang Medical Center, Seongnam, Korea, Republic of

Background & aims: Ferroptosis, a regulated cell death mechanism driven by iron-dependent lipid peroxidation, is important for survival of cancer cells due to the increased vulnerability of fast-growing cancer cells to oxidative stress. However, its impact on clinical outcomes and treatment responses is not well understood. Our goal is to explore ferroptosis' contribution to liver cancer, focusing on its association with clinical outcomes, specifically incidence rates in high-risk cirrhotic patients, overall survival, and responsiveness to immunotherapy in HCC patients.

Methods: Utilizing gene expression signature reflecting ferroptosis from liver cancer cells, we integrated gene expression profiles from patients with cirrhosis and liver cancer and from liver cancer cells under ferroptosis. To categorize patients, we developed a genomic predictor and applied it to gene expression data from a cirrhosis cohort (n=216) and large liver cancer cohorts (n=1390). Comprehensive statistical and informatics analyses were conducted to evaluate clinical significance, including overall survival and responses to standard treatments such as sorafenib and immunotherapy with atezolizumab and bevacizumab.

Results: In the cirrhosis cohort, the low ferroptosis baseline in cirrhotic liver was significantly associated with higher liver cancer development. Among liver cancer cohorts, patients with the low ferroptosis baseline exhibited characteristics such as poor survival, increased hepatic stem cell features, and increased genomic instability. Notably, when liver cancer patients undergoing systemic treatment with sorafenib or the combination of atezolizumab (anti-PD-L1) and bevacizumab (anti-VEGF) were stratified using our genomic predictor, those with high ferroptosis baseline derived significant benefits from the combination of atezolizumab and bevacizumab treatment. Conversely, such benefit of treatment was not visible in patients treated with sorafenib. This suggests that ferroptosis activity may influence liver cancer response to immune checkpoint inhibitor therapy. Gene network analysis of the ferroptosis signature using ingenuity pathway analysis revealed that statin signatures are strongly correlated with high sensitivity to the combination treatment with of atezolizumab and bevacizumab, indicating that statins may be used for sensitizing liver cancer to the combination treatment.

Conclusions: This study identifies clinically distinct subtypes of liver cancer associated with baseline ferroptosis, biomarkers associated with these subtypes, and potential mechanisms underlying ferroptosis-mediated sensitization of liver cancer cells to the combination of immunotherapy. This work emphasizes the potential of ferroptosis-targeted approaches in optimizing liver cancer treatment.

#5350 Establishment and validation of a prognostic signature based on thirteen hub genes in colorectal cancer.

H. Zhang#[1], Y. Lang#[1], Z. Tang#[2], J. Lin[3], L. Yang[4], J. Kang[5], C. Yang*[6], Q. Lin*[1], Q. Li*[7], F. Ye*[1], W. Tang*[1];
[1]Department of Medical Oncology, The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, The School of Clinical Medicine of Fujian, Medical University, Xiamen, China, [2]Department of Pharmacy, Zhongshan Hospital (Xiamen), Fudan University, Xiamen, China, [3]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [4]Department of Medical Oncology, Weifang People's Hospital, Weifang Medical University, Weifang, China, [5]Department of Medical Oncology, Zhangzhou Municipal Hospital, Zhangzhou Municipal Hospital Affiliated of Fujian Medical University, Zhangzhou, China, [6]Department of Surgical Oncology, Fujian Provincial Hospital, Fuzhou, China, [7]Department of Hematology, The First Affiliated Hospital of Xiamen University and Institute of Hematology, School of Medicine, Xiamen, China

Background: The survival rate for late-stage colorectal cancer (CRC) is extremely low (4%-12%). The prognosis assessment for CRC pose numerous challenges. Recently, the role of the immune microenvironment in CRC progression has increasingly garnered attention, with immune cell infiltration and molecular expression closely related to patient prognosis. Therefore, this study aims to deeply analyze the molecular mechanisms underlying CRC and identify novel immune-related biomarkers for prognosis evaluation.
Methods: High-throughput sequencing technology was utilized to compare and analyze the differential gene expression between CRC tumor tissues and normal tissues, as well as between patients with long and short survival durations. Univariate Cox analysis and Least Absolute Shrinkage and Selection Operator (Lasso) regression analysis were combined to screen hub genes closely related to CRC prognosis. A prognostic signature based on these hub genes was constructed to predict the prognosis of CRC patients. RNA sequencing (RNA-Seq) data from five paired CRC patients were collected to validate the expression patterns of the hub genes in CRC samples and their relationship with the immune microenvironment.
Results: We successfully identified 13 hub genes (HOXC6, IGF2BP3, SGCG, HTR2C, ADCY5, SHC2, SUCLG2, PDHB, TSLP, CCR9, TNFRSF19, TGFB2, and LEP) that compose the prognostic signature. In the Cancer Genome Atlas (TCGA) dataset, this signature accurately classified patients into high- and low-risk groups with high precision ($p < 0.001$). Similar results were obtained in the Gene Expression Omnibus (GEO) dataset ($p < 0.001$ and $p = 0.036$). The study also found that when patients were stratified into high-risk and low-risk groups using the prognostic signature, there were significant differences in the immune environment between the two groups, including the infiltration degree of immune cells ($p < 0.001$) and the expression levels of immune molecules($p < 0.01$). Additionally, when validated using RNA-Seq data from five paired CRC patients, the expression patterns of these hub genes in the five CRC samples were consistent with those observed in the TCGA analysis, further confirming the important roles of the 13 hub genes in CRC patients and their association with the immune microenvironment.
Conclusion: In summary, this research has developed a novel signature that can predict both the survival outcomes and the immune infiltration status of CRC patients. The clinical application of this signature has the potential to enhance survival rates and individualize therapy approaches for CRC based on their risk score.#These authors contributed equally: Hui Zhang, Yu Lang, Zhaoqi Tang.*Correspondence to:Dr. Weiwei Tang, weiweitang008@xmu.edu.cn;Dr. Feng Ye, yefengdoctor@xmu.edu.cn;Dr. Qiyuan Li, qiyuan.li@xmu.edu.cn;Dr. Qin Lin, linqin05@163.com;Dr. Changshun Yang, 282483331@qq.com

#5351 The landscape of somatic mutations and copy-number alterations in the Indian Cohort of Prostate Cancer Patients.

T. Biswas[1], P. Vats[2], V. Bhatia[3], A. Singhai[4], A. Srivastava[5], A. Chauhan[5], M. Ahmad[6], P. Tripathi[7], S. Mehrotra[7], A. Tewari[7], N. Husain[5], A. Goel[4], N. Palanisamy[8], B. Ateeq[1];

[1]Indian Institute of Technology Kanpur (IIT Kanpur), Kanpur, India, [2]University of Michigan, Ann Arbor, MI, [3]University of California Los Angeles Jonsson Comprehensive Cancer Center, Los Angeles, CA, [4]King George's Medical University, Lucknow, India, [5]Dr. Ram Manohar Lohia Institute Of Medical Sciences, Lucknow, India, [6]Jawaharlal Nehru Medical College, Aligarh Muslim University, Aligarh, India, [7]Regency Hospital, Kanpur, India, [8]Vattikuti Urology Institute, Detroit, MI

In India, prostate cancer (PCa) has the third highest incidence rate among males and is often diagnosed at the advanced stage. PCa is known to be molecularly heterogeneous, and an in-depth characterization of its subtypes by geographical ethnicities may aid in the understanding of its etiology and disparities. Hence, we perform molecular characterization of PCa patients from India. Integrative genomics studies categorized PCa into molecular subtypes based on genetic aberrations (e.g., somatic mutations, INDEL, etc.). Although genetic factors are known to impact PCa pathobiology, genomic profiling of Indian PCa patients and its clinical utility remain largely unexplored. Thus, in a prospective study, we performed whole exome sequencing (WES) of treatment-naive primary PCa (N=90) and benign prostatic hyperplasia specimens (N=14) along with matched blood. Our findings reveal distinct genetic alterations unique to the Indian cohort, wherein an elevated somatic tumor mutational burden and an increased percentage of clinically actionable alterations were noted. About 80% of the somatic variants (called using Mutect2) were found to be missense mutations with a high recurrence of C>T transitions, a signature of age-related human malignancies. Several novel pathogenic alterations affecting critical domains of the cancer-associated genes (e.g., *APC, BRCA2, PI3KCA,* etc.) were found, which have not been reported in the dbSNP or COSMIC databases. Systematic comparison of our findings with primary PCa data available at The Cancer Genome Atlas Prostate Adenocarcinoma (TCGA-PRAD) revealed distinct genomic alterations in Indian PCa patients: specifically, 35% of the patients showed presumed actionable lesions in the RTK-Ras pathway genes, while 10% had mutations in the PI3K pathway genes, and 21% of all the specimens harbored putative inactivating mutations of genes involved in the homologous recombination repair pathway. We also found major differences in the mutational frequency of some driver genes, such as *ATRX*, *PIK3C2G*, *TAL1*, etc., compared to the TCGA-PRAD cohort. Furthermore, GISTIC2 analysis revealed significant arm-level amplification at 8q (*MYC*, *GLI4*), 7q (*GNB2*, *PDIA4*), and 16p (*TELO2*, *TSC2*) regions and deletion at 8p (*NKX3.1*, *MSR1*), 9p (*CDKN2A*, *CDKN2B*), and 13q (*RB1*, *BRCA2*) regions. We also identified recurrent focal amplifications at 9q, 14q, and 11q, and deletions at 16q, 10q, and 5q loci. Further, integrating WES data with transcriptome data would be helpful in categorizing PCa patients based on gene fusion status and prioritizing functionally impactful and actionable variants. Collectively, our findings reveal molecular heterogeneity among PCa patients from India, leading to the identification of clinically relevant candidates that need to be further validated and would help in strategizing therapies and clinical management of this disease.

#5354 Single-cell sequencing resolves prevalence of PD-L1/2-expressing tumor-associated endothelial cells in human solid tumors.

C. Yan[1], F. T. H. Wu[1], J. Laskin[2], C. Ho[2], M. A. Marra[1];

[1]University of British Columbia, Vancouver, BC, Canada, [2]BC Cancer Vancouver Centre & University of British Columbia, Vancouver, BC, Canada

BACKGROUND: The PD-1 ligands (PD-L1 and PD-L2) are immune checkpoint proteins that can be expressed by stromal cells including endothelial cells (ECs) within the tumor microenvironment (TME). Pe-clinical studies have implicated endothelial PD-L1 as a contributory therapeutic target of immune checkpoint inhibitor drugs especially when combined with anti-angiogenic drugs. However, the clinical prevalence and implications of endothelial PD-L1/2 expression in human solid tumors remain unexplored.
HYPOTHESES: Endothelial PD-L1/2 expression occur at low frequencies in the TME overall, but may be upregulated in specialized EC phenotypes, e.g.,tumor-associated high-endothelial venules (TU-HEVs) or tip-like ECs of angiogenic sprouting blood vessels.
OBJECTIVES: (1) To explore the utility of single-cell profiling as a means to survey the levels of PD-L1 and PD-L2 transcription in ECs from clinical solid tumor specimens. (2) To identify potential EC subtypes in the TME that may be enriched for PD-L1/2 expression.
METHODS: We performed single-cell RNA-seq (scRNA-seq) and single-cell ATAC-seq (scATAC-seq) on a pan-cancer cohort of 33 clinical core biopsies from 25 patients using the 10X Chromium Multiome kit. After performing quality control and normalization using Seurat (v4.3.0), there was a median of 4367 cells per sample (IQR: 2548-6025).
RESULTS: Two orthogonal cell type classification methods - SingleR (v2.0.0) using the Human Primary Cell Atlas [PMID 24053356], and Seurat's reference mapping function using the annotations from Bassez et al., 2021 [PMID 33958794] - identified 3,829 ECs from 31 samples (median 102, IQR 43-141) with 99.7% concordance. The overall prevalence of ECs expressing PD-L1 or PD-L2 was low (1.4% and 2.6%, respectively). ECs were then classified into subtypes (arterial, venous, lymphatic, tip-like, TU-HEVs) by first clustering cells based on RNA expression using Seurat, and then assessing the expression of marker genes in each cluster against a published reference dataset Hua et al., 2022 [PMID: 36423635]. After subtyping, PD-L1 was enriched in lymphatic ECs (3.5%), and PD-L2 was enriched in lymphatic ECs (4.1%) and TU-HEVs (5.6%).
CONCLUSIONS: This study suggests that endothelial PD-L1/2 expression can be found in clinical core biopsies of human solid tumors, and that the role of endothelial PD-L1/2 within the TME warrants further investigation especially in the context of combined anti-PD-1/PD-L1 plus anti-angiogenic therapy. Ongoing work aims to confirm these results at the protein level using spatial imaging in larger cohorts of specific cancer types.

#5355 Whole genome landscape of small cell lung carcinoma and large cell neuroendocrine carcinoma of the lung.

Hisashi Hashimoto[1], Yosuke Tanaka[1], Jun Takahashi[1], Toshihide Ueno[1], Shinya Kojima[1], Kouya Shiraishi[2], Takashi Kohno[2], Yuichi Shiraishi[3], Yasushi Yatabe[4], Takeshi Kaneko[5], Hiroyuki Mano[1]

[1]Division of Cellular Signaling, National Cancer Center Research Institute, Tokyo, Japan,[2]Division of Genome Biology, National Cancer Center Research Institute, Tokyo, Japan,[3]Division of Genome Analysis Platform Development, National Cancer Center Research Institute, Tokyo, Japan,[4]Department of Diagnostic Pathology, National Cancer Center Hospital, Tokyo, Japan,[5]Department of Pulmonology, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Small cell lung carcinoma (SCLC) and large cell neuroendocrine carcinoma (LCNEC) are the most deadly forms of lung cancer. The advent of numerous molecular targeted therapeutics, including immune checkpoint inhibitors, has improved outcomes in non-small cell lung cancer. However, the prognosis for SCLC and LCNEC has shown slight improvement, and the development of novel therapeutics is craved. In addition, because SCLC frequently presents at advanced stages and resected samples are scarce, large-scale genomic analysis has rarely been performed. In particular, while molecular biological classification based on neuroendocrine markers has been proposed so far for SCLC, no classification has been fully established for LCNEC. To refine the classification and to identify vulnerabilities of SCLC and LCNEC, we performed comprehensive multi-omic analyses on 154 samples (107 SCLC and 47 LCNEC) using whole-genome sequencing with both short-read and long-read sequencers, RNA sequencing, and spatial transcriptomics. Integrated transcriptome clustering of SCLC and LCNEC allowed us to classify our cases into three clusters. Each cluster was characterized by distinct molecular features, with distinct profiles of expression patterns, mutations, structural variations, and copy number alterations. We also identified novel driver mutations and recurrent structural variations that were not previously reported. Importantly, we have successfully identified several gene mutations and structural abnormalities which may be functionally significant. *Gene X*, which we detected as a novel driver gene, is presumed to function as a tumor suppressor gene, and increased TMB was observed in cases with *Gene X* mutations, regardless of MSI status. In addition, *Splicing Factor Y*, identified as a novel recurrent structural variation, is a gene that functions as a splicing regulator, and these structural variations affect alternative splicing of genes related to cell morphology, suggesting that they may affect the phenotype of these cancers. Analysis of structural variation using long-read sequencing identified structural variations that could not be detected by short-read sequencing. In addition, spatial transcriptomics elucidated the differences in the tumor microenvironment between SCLC and LCNEC or among the molecular biological classifications. The findings of novel technology-based analyses suggest a new therapeutic strategy for SCLC and LCNEC.

#5357 Mutational landscape and tyrosine kinase inhibitor sensitivity in *EGFR* L833 and H835 mutated non-small cell lung cancer.

Nong Yang[1], Long Huang[2], Dou Ren[1], Fanxu Zeng[1], Chengchuan Jiang[1], Weiwei Zhang[1], Weifeng He[1], Wei Yin[1], Peng Huang[2], Hanlin Chen[3], Xiaoying Wu[3], Jiaohui Pang[3], **Haimeng Tang**[1], Xue Wu[3], Qiuxiang Ou[3]

[1]The Second People's Hospital of Hunan Province (Brain Hospital of Hunan Province), Changsha, China,[2]The Second Affiliated Hospital of Nanchang University, Nanchang, China,[3]Nanjing Geneseeq Technology Inc., Nanjing, China

Background: *EGFR* L833 and H835 mutations account for 0.5% of *EGFR*-mutated non-small cell lung cancer (NSCLC) cases and are not classified as sensitive mutations to EGFR tyrosine kinase inhibitors (TKIs) according to NCCN guidelines, while chemotherapy remains the standard of care for patients with these mutations. Previous case reports have shown favorable EGFR-TKIs efficacy in patients with EGFR L833 and H835 mutations, this has yet to be validated in larger cohorts.

Methods: DNA sequencing data from 240 NSCLC patients with *EGFR* L833 and H835 mutations were analyzed, including 57 with documented EGFR-TKI treatment records. Additionally, an external cohort of 346 NSCLC patients with *EGFR* L858R mutations and wild-type *EGFR* L833 and H835 was evaluated for comparative analyses of molecular landscapes. Kaplan-Meier survival curves were generated, and the log-rank test was employed to compare survival times between subtypes.

Results: In the study cohort, 98.3% (235/239) of patients with *EGFR* L833 mutations and 100% (82/82) with *EGFR* H835 mutations had concurrent *EGFR* mutations. Interestingly, 97.5% (78/80) of patients with *EGFR* H835L mutations had concurrent L833V mutations, while the most frequent co-mutations of *EGFR* L833V being L858R (44.1%, 93/211) and H835L (37.0%, 78/211). Compared to *EGFR* L858R patients in the external cohort, those with *EGFR* L833V+H835L and L833V+L858R mutations had lower frequencies of *LRP1B*, *RB1*, *TP53* mutations, as well as *CD4K* amplifications and mutations in the RTK-RAS and cell cycle signaling pathways. Tumor mutational burden (TMB), chromosomal stability, whole-genome duplication rates, and age-related and APOBEC-associated mutational signatures were also lower in patients with *EGFR* L833V+H835L and L833V+L858R mutations compared to those with *EGFR* L858R, with significant differences in TMB ($P = 0.110$ and $P = 0.001$), chromosomal instability ($P = 0.036$ and $P = 0.042$), whole-genome duplication rates ($P = 0.008$ and $P = 0.028$), age-related signatures ($P = 0.006$ and $P = 0.027$), and APOBEC-associated signatures (both $P < 0.001$). Notably, EGFR-TKI efficacy data revealed that patients with EGFR L833 and H835 mutations can benefit from EGFR-TKI treatment, with a median progression-free survival (PFS) of 16.4 months. PFS was comparable across mutation subtypes (L833V+H835L vs. L833V+L858R vs. others, $P = 0.096$) and across different generations of EGFR-TKIs received ($P = 0.533$).

Conclusion: This study demonstrates that patients with *EGFR* L833 and H835 mutations can benefit from EGFR-TKIs, with comparable median PFS to those with classical EGFR L858R mutations in previous literatures. Additionally, patients with L833 and H835 mutations displayed distinct molecular features compared to L858R, characterized by lower TP53 mutation frequencies, lower TMB values, and lower chromosomal instability.

#5358 A comparison of tumor microenvironment immune profiles using CIBERSORTx in breast cancer patients from Kenya and Hong Kong.

Li Feng[1], Shahin Sayed[2], Hela Koka[1], Viviane Oluoch[2], Veronica Ngundo[2], Alfred M. Githuka[2], Zaitun Ajuoga[2], Kristine Jones[3], Belynda Hicks[3], Amy Hutchinson[3], Maria Brown[3], Petra Lenz[3], Aaron M. Rozeboom[3], Difei Wang[3], Francis Makokha[4], Stefan Ambs[5], Jonine Figueroa[1], Xiaohong R. Yang[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Aga Khan University Hospital, Nairobi, Kenya,[3]Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Research and Innovation, Mount Kenya University, Thika, Kenya,[5]Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Tumor-infiltrating immune cells in the tumor microenvironment (TME) are critical for breast cancer (BC) progression and treatment outcomes, with notable variations observed across populations. Unique BC risk factors, such as germline genetics, mammographic density, infectious exposures, and lifestyle factors, may shape distinctive immune profiles and lead to distinct tumor characteristics and clinical outcomes in different populations. Comparing immune cell compositions across populations can improve our understanding of BC racial disparity and guide personalized treatment strategies.
Aims: This study aims to characterize and compare immune composition in the BC TME between East Africa (Kenya) and East Asia (Hong Kong) when accounting for age, intrinsic subtype, and analytical methods.
Methods: We collected formalin-fixed paraffin-embedded (FFPE) tumor blocks from BC patients in Kenya and Hong Kong, processed them for nucleic acid extraction and analyzed them using NanoString nCounter from a custom-designed code set including 50 PAM50 genes and 547 CIBERSORT panel genes. Samples were selected to match age and estrogen receptor (ER) status distributions. After removing duplicates and QC-failed samples, 467 samples from Kenya (mean age=50.57, ER+: 71.18%) and 118 samples from Hong Kong (mean age=54.94, ER+: 72.03%) were included in the subsequent analyses. CIBERSORTx was used to estimate relative fractions of 22 immune cell types. PAM50 subtype was defined as Luminal A, Luminal B, HER2-enriched, Basal-like, or Normal-like using the nearest centroid method. Multiple linear regression models were performed to identify the differences in immune cell proportions by ethnicity, adjusting for age, PAM50 subtype, and tumor grade.
Results: After filtering cells with mean fractions <5%, this analysis was focused on T follicular helper, CD8+, resting CD4+, activated NK, resting mast, and macrophage subsets (M0, M1, M2). Compared to Hong Kong, Kenyan samples exhibited higher relative fractions of CD8+ T cells ($p < 0.01$), activated NK cells ($p < 0.001$), and macrophages M2 ($p < 0.05$) but lower fractions of resting CD4+ T cells ($p < 0.05$) and macrophages M0 ($p < 0.01$). Similar results were observed with absolute abundance analyses.
Conclusion: This study reveals distinct immune profiles between Kenyan and Hong Kong BC TMEs. Kenyan samples exhibit a relatively “hot” immune TME with both pro-inflammatory and immunosuppressive components, while Hong Kong samples show a more quiescent or relatively “cold” immune environment. These population-specific differences highlight the potential need for tailored immunotherapy strategies considering unique immune characteristics shaped by genetic and environmental factors. Future analyses will explore associations with clinical outcomes and risk factors to elucidate mechanisms driving these racial disparities.

#5359 Multi-omics characterization of copy number variation in high-grade serous ovarian cancer.

Yuxin Jin[1], Jing Qian[2], Michelle G. Webb[1], David W. Craig[1], Lynda Roman[2], John D. Carpten[1], Rania Bassiouni[1]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]University of Southern California, Los Angeles, CA

Ovarian cancer is one of the most lethal gynecologic malignancies, primarily due to its late-stage diagnosis and intrinsic tumor heterogeneity. Histologically, epithelial ovarian cancer (EOC) accounts for approximately 70% of cases and exhibits distinct molecular and clinical characteristics. High-grade serous ovarian cancer (HGSOC), the most aggressive form of EOC, stands out for its widespread genomic instability and poor prognosis. Copy number variations (CNVs) play a critical role in tumor heterogeneity, treatment resistance, and disease progression. While CNVs have been extensively studied using bulk sequencing approaches, their spatial heterogeneity within tumors remains underexplored. To investigate this, we integrated spatial transcriptomics (10x Genomics Visium Spatial) with whole-exome sequencing (WES) in 24 fresh-frozen HGSOC samples. This dual approach enabled us to validate CNV patterns inferred from spatial data while leveraging WES for a genome-wide view of CNVs. First, spatial transcriptomics data were processed using the Space Ranger pipeline (10x Genomics) to generate spatially resolved gene expression matrices. Tumor purity scores were estimated using the R package ESTIMATE, and were then used to inform CNV inference with the tool InferCNV. This analysis revealed varied CNVs across spatial domains, indicating intratumoral heterogeneity and the existence of subclones with distinct CNV profiles and spatial niches. We further resolved loss of heterozygosity (LOH) in these samples using the R package tLOH. Clonal LOH of chr 17p, encompassing the TP53 locus, was detected in several samples. Pseudotime and spatial trajectory analysis confirmed that chr17 LOH is an early event in the trajectory of CNV development. To validate the CNV and LOH patterns inferred from spatial transcriptomics, we performed WES on paired tumor and normal tissues from the same cohort. WES data were first aligned to the human reference genome GRCh38 using BWA, followed by CNV profiling with GATK CNV. Recurrent CNV patterns, including gains on chromosomes 1q, 3q, 6p, 8q, and 20q, and losses on chromosomes 4, 5q, 6q, 9p, 13q, 14q, and 17, were observed, consistent with previous reports. A comparison between spatially inferred CNV clusters and GATK CNV results showed strong concordance, further validating the robustness of spatial CNV inference. Interestingly, germline BRCA-mutated samples exhibited a higher frequency of CNVs than BRCA wild-type samples, suggesting a link between BRCA status and genomic instability. By placing CNVs in tissue context, our findings highlight the genetic and spatial heterogeneity of HGSOC, and enhance our understanding of the driving role of CNVs in tumor evolution and growth. This abstract was developed with the assistance of generative AI to revise and clarify the text.

#5360 Comprehensive analysis of breast cancer genomic alterations across diverse populations using a large real-world database.

Vasily N. Aushev[1], Samuel Riviero-Hinojosa[1], Carly B. Scalise[1], Rich Green[1], J. Bryce Ortiz[1], Alyssa Antonopoulos[1], Adam C. ElNaggar[1], Angel Rodriguez[1], Minetta C. Liu[1], Alexey Aleshin[1], Laura Chambers[2], Marla D. Lipsyc-Sharf[3]

[1]Natera, Inc., Austin, TX,[2]Wexner Medical Center and James Cancer Hospital, The Ohio State University, Columbus, OH,[3]Division of Hematology/Oncology, UCLA David Geffen School of Medicine, Los Angeles, CA

Background: Breast cancer is genetically and phenotypically heterogeneous, with tumor-specific alterations influencing clinical outcomes. This variability underscores the importance of accounting for factors such as genetic ancestry in genomic studies to better understand tumor biology and improve patient care. However, most genomic studies have focused on individuals of European ancestry, leaving gaps in knowledge about other ancestries. Here, we analyzed genomic data from over 55,000 breast cancer patients in Natera's proprietary Real-World Database to assess the mutational landscape stratified by genetic ancestry.
Methods: Whole-exome sequencing (WES) data of tumor samples from patients with breast cancer were analyzed. WES was performed on tumor tissue for designing Signatera™ molecular residual disease testing, ordered from June 2019 - November 2024. After exclusions, 33,058 patients were included in the analysis. Mutect2 and VarScan2 callers were used for variant calling. Only non-synonymous mutations were included in prevalence analysis. Genetic ancestry was determined using the EthSeq algorithm with four groups: Africa (AFR), East Asia (EAS), Europe (EUR), and South Asia (SAS).
Results: The distribution of stage at diagnosis was: 26.6%, 26.7%, 19.4%, and 14.8% for Stage I, II, III, and IV, respectively; 12.5% of patients had unknown stage. Ancestry distribution was 81.7% EUR, 11.7% AFR, 4.9% EAS, and 1.8% SAS. *TP53* and *PIK3CA* were the most frequently mutated genes, with prevalence rates of 34.8% and 27.2%, respectively. *PIK3CA* variants were the most prevalent, with frequencies of *H1047R* (10.4%), *E545K* (5.2%), and *E542K* (3.0%). Estrogen receptor-negative (ER-) cases exhibited a lower prevalence of *PIK3CA H1047R* mutations and a higher prevalence of *TP53* mutations compared to ER+ cases. For genetic ancestry, individuals of AFR ancestry showed higher mutation rates in *GATA3* (11.2% vs. 9.9%, $p < 0.001$) and *TP53* (48.2% vs. 34.3%, $p < 0.001$) compared to individuals of EUR ancestry. In contrast, EUR individuals exhibited higher mutation rates in *PIK3CA* (29.4% vs. 23.4%, $p < 0.001$), *MAP3K1* (7.4% vs. 5.6%, $p < 0.001$), and *AKT1* (3.2% vs. 2.5%, $p < 0.001$) compared to the AFR group. *PIK3CA* variants *E542K* (3.3% vs. 2.2%, $p = 0.04$) and *E545K* (5.9% vs. 3.2%, $p < 0.001$) were higher in EUR compared to AFR, whereas the *TP53 R213* variant was enriched in AFR individuals when compared to EUR (2.1% vs. 0.9%, $p < 0.001$).
Conclusions: Our analysis reveals differences in breast cancer genomic landscapes across ancestral groups. The variation in somatic alterations between AFR and EUR ancestries suggests potential differences in tumor biology and therapeutic opportunities that may be targeted to improve racial/ethnic disparities in clinical outcomes. Equitable representation in genomic profiling is essential to understand breast cancer and ensure precision oncology benefits all populations.

#5361 Clinical implications of The Cancer Genome Atlas molecular classification system in esophagogastric cancer.

Henry Walch, Raktim Borpatragohain, Justin Jee, Walid Chatila, Christopher Fong, Steven B. Maron, Geoffrey Ku, David H. Ilson, Yelena Y. Janjigian, Abraham J. Wu, Pari Shah, Daniel G. Coit, Manjit S. Bains, Valerie W. Rusch, Bernard Park, Matthew Bott, Katherine Gray, David R. Jones, Michael F. Berger, Nikolaus Schultz, Vivian E. Strong, Daniela Molena, Smita Sihag

Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: The Cancer Genome Atlas (TCGA) project defined four distinct molecular subtypes of esophagogastric adenocarcinoma (EGAC): microsatellite instable (MSI), Epstein-Barr virus associated (EBV), genomically stable (GS), and chromosomally instable (CIN). However, an association between molecular subtype and clinical outcome has not been clearly demonstrated. Given few actionable biomarkers, we investigated the clinical relevance of the TCGA classification system.
Experimental Design: We identified all patients with EGAC whose tumors underwent prospective next-generation sequencing using the MSK-IMPACT assay from 2014 to 2023. We classified all tumors in accordance with TCGA methodology and correlated molecular subtype with high-quality clinicopathologic data.
Results: Among 1,438 included patients, 941 had CIN, 344 had GS, 103 had MSI, and 50 had EBV tumors. CIN was associated with White race, male sex, more-advanced stage, a high frequency of TP53 mutations, cell-cycle and RTK-RAS copy number alterations, and high metastatic potential. GS was associated with a higher proportion of Asians and females, Lauren's diffuse and signet ring histologies, heterogeneous driver alterations, and poor responses to systemic and radiation therapies. MSI and EBV tumors, by contrast, had lower metastatic potential and significantly better survival than CIN and GS tumors, although MSI tumors were associated with the worst rate of response to chemotherapy. Accounting for clinical stage and tumor grade, molecular classification was independently associated with overall cancer-specific survival ($p<0.001$) on Cox multivariable analysis. Furthermore, genomic signatures, patient demographics, pathologic responses to neoadjuvant therapy, patterns of recurrence, and metastatic organotropism differed significantly by molecular subtype. Although most distal esophageal and gastroesophageal junction tumors were CIN, up to 25% of these included GS, MSI, or EBV subtypes in contrast to the TCGA. Random-forest machine learning demonstrated that molecular subtype is more influential in predicting response to treatment than tumor location.
Conclusions: Molecular classification is independently prognostic and may warrant inclusion in future staging and treatment guidelines. Routine molecular profiling is clinically feasible and may play a role in the management of patients to help guide appropriate treatment selection and clinical trial enrollment in place of tumor location.

#5362 Molecular profiling of SW-682, a pan-TEAD inhibitor, as monotherapy and in combination with other treatments across tumor types.

Somdutta Saha, Veronica Jove, Amelia Schirmer, Lorne Celentano, Alma Chanelo, Connor Smith, Sarah Ahn, Jim Smothers, Wenlin Shao, Tai-An Lin, Paula Miliani de Marval, Lei Chen, Robert Dubose

SpringWorks Therapeutics, Inc., Stamford, CT

Hyperactivation of YAP/TAZ signaling (Hippo pathway) can drive oncogenesis across multiple cancer types by binding to the transcription factor TEAD and driving expression of target genes involved in cell proliferation and tumor progression. SW-682, an investigational pan-TEAD small molecule inhibitor, blocks TEAD-dependent transcription by binding to the palmitoylation pocket of all TEAD paralogs. We have previously demonstrated monotherapy efficacy of SW-682 in in vivo models of mesothelioma and head and neck squamous cell carcinoma (HNSCC) harboring Hippo pathway genomic alterations. We have also reported significant benefit of SW-682 in combination with KRAS G12C inhibitor, sotorasib, in KRAS G12C non-small cell lung cancer (NSCLC) models. Here, we sought to characterize the molecular signature of HNSCC, mesothelioma, and NSCLC tumors after TEAD inhibition either with SW-682 alone or in combination with KRAS G12C inhibitors.

To identify downstream targets of TEAD inhibition and compare them with other known Hippo pathway signatures, we performed RNA-seq analysis of tumors following SW-682 monotherapy in mesothelioma and HNSCC CDX (cell-line-derived xenograft) models. We identified TEAD-dependent transcriptional changes for each model that included significant overlap with published YAP/TAZ gene signatures. Additionally, we compared our data with publicly available preclinical RNA-seq data generated with other TEAD inhibitors. To account for experimental variability across datasets, the analysis was divided longitudinally into early (<6 hour) and late (>24 hour) timepoints for each disease model. This meta-analysis confirmed genes identified from RNA-seq and revealed complexities in identifying a universal TEAD-dependent gene signature.

Since hyperactivated YAP/TAZ signaling is also known to be a common resistance mechanism to targeted therapies, we assessed the relationship between dysregulated Hippo signaling and responses to SW-682 and sotorasib combination in a panel of KRAS G12C NSCLC xenograft models. We observed combination benefits more frequently in xenograft models with elevated tumor intrinsic YAP/TAZ activity. However, Hippo pathway gene alterations alone were not sufficient to predict sensitivity to combination of SW-682 and sotorasib. Therefore, we sought to characterize molecular signatures that correlated with combination benefits by analyzing baseline DNA mutation status and RNA expression levels in each model.

In conclusion, these results help elucidate SW-682 molecular signatures across different tumor types and can support combination strategies for SW-682 in clinical investigation. Supported by SpringWorks Therapeutics, Inc.

#5364 Multi-omic analyses reveal epigenetic and transcriptomic reprogramming behind ibrutinib-venetoclax resistance development in mantle cell lymphoma.

Kevin Qiu[1], Jing Gao[1], Qing Yin[1], Allen Hu[1], Zhenjia Wang[1], Loryn Blackburn[1], Bijal Shah[2], Jeffrey W. Craig[1], Craig Portell[1], Michael E. Williams[1], Chongzhi Zang[1], Jianguo Tao[1]

[1]University of Virginia Comprehensive Cancer Center, Charlottesville, VA,[2]Moffitt Cancer Center, Tampa, VA

Mantle cell lymphoma (MCL) is a rare and aggressive form of B-cell lymphoma that is characterized by aberrations in B-cell receptor signaling and BCL-2-mediated apoptotic pathways. MCLs treated with inhibitors of either have shown remarkable response rates but ultimately develop drug resistance, with patients suffering from rapid disease progression and experiencing poor clinical outcomes. Preclinical and clinical studies into the Bruton's tyrosine kinase inhibitor ibrutinib and the BCL-2 inhibitor ABT-199 (venetoclax) revealed that they were synergistic when combined against MCL and showed significant clinical efficacy, respectively. However, through an unclear mechanism, many cases of MCL similarly developed resistance to combination therapy. To elucidate the mechanisms by which MCL develops drug resistance, we induced resistance to BTKi-venetoclax in 2 patient-derived MCL cell lines, Mino and Rec1, and characterized transcriptional and epigenetic changes using bulk and single-cell RNA and ATAC-seq datasets. We conducted differential expression and accessibility analysis between BTKi-venetoclax-sensitive and resistant samples and identified significantly enriched pathways to find molecular processes that differentiate the two. We show that resistant MCL displays changes at the chromatin and RNA level associated with BCL-2 inhibition, including downregulation of E2F and E2F targets such as cyclin D1. However, we observe that both MCL lines that developed resistance to BTKi-venetoclax upregulate BCL-XL to evade BCL-2 inhibition-mediated apoptosis, likely through activation of the alternative JAK/STAT, interferon, NFKB, and Myc pathways, which are also significantly upregulated. These drastic transcriptomic changes provide an explanation of how resistant MCLs bypass both BCL-2 and BCR-signaling inhibition, leading to survival and neoplastic expansion. Additionally, we identify upregulated genes on both a transcriptional and epigenetic level that encode surface proteins that may inform future targeted therapies. These findings provide mechanistic insights into the transcriptomic reprogramming undertaken by mantle cell lymphoma when developing resistance to BTKi-venetoclax and identify potential vulnerabilities conferred by dual-therapy resistance. They suggest that future therapies optimized against MCL require a combination of immunotherapy and targeted therapies designed to counteract transcriptome reprogramming seen during drug resistance.

#5365 Comparison of whole genome sequencing and target capture sequencing in lung cancer.

Koki Fujii[1], Masahiro Sekiguchi[2], Hiroaki Ikushima[1], Kousuke Watanabe[3], Aya Shinozaki-Ushiku[4], Shuichi Tsutsumi[5], Kenji Tatsuno[5], Kuniko Sunami[6], Masaaki Sato[7], Tetsuo Ushiku[8], Katsutoshi Oda[4], Hiroyuki Aburatani[5], Motohiro Kato[2], Hidenori Kage[1]

[1]Department of Respiratory Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[2]Department of Pediatrics, The University of Tokyo Hospital, Tokyo, Japan,[3]Next-Generation Precision Medicine Development Laboratory, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan,[4]Department of Clinical Genomics, The University of Tokyo Hospital, Tokyo, Japan,[5]Genome Science Division, Research Center for Advanced Science and Technology, the University of Tokyo, Tokyo, Japan,[6]Division of Genome Biology, National Cancer Center Research Institute, Tokyo, Japan,[7]Department of Thoracic Surgery, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[8]Department of Pathology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Introduction: Comprehensive genomic profiling (CGP) tests using target capture sequencing are commonly employed clinically to detect gene alterations and to recommend treatment. Whole-genome sequencing (WGS) is capable of detecting all mutations and structural variants of the genome and may offer advantages over CGP. On the other hand, WGS covers the entire genome with a low depth of coverage, which may limit its sensitivity. This study evaluates the concordance of variants detected by WGS and Todai OncoPanel (TOP), a CGP test targeting 737 DNA and 455 RNA cancer-related genes.

Methods: We analyzed 32 consecutive lung cancer specimens collected through surgical resection, including two samples from the same patient, which underwent both WGS and TOP. Fresh frozen samples were used for WGS, while formalin-fixed paraffin-embedded samples were used for TOP. Variants annotated as "likely pathogenic/likely oncogenic" or higher in significance in databases such as ClinVar and COSMIC were compared between the two methods. The t-test and the Wilcoxon rank-sum test were used for comparison.

Results: The clinical characteristics of the cohort were as follows: the median age of 74 years (range: 37-85); 21 males (66%); 10 never-smokers (31%); 20 adenocarcinomas (63%); 10 squamous cell carcinomas (31%). The most frequent variants identified were *TP53* (22 cases, 69%), and *EGFR* (12 cases, 34%). Out of 134 single nucleotide variants (SNVs), short deletions, and insertions detected in at least one test, 65 variants (49%) were detected by both methods, 64 (48%) were exclusive to TOP, and 5 (4%) were exclusive to WGS. The median number of variants detected per sample between these two tests was significantly different (TOP: 3.5 (IQR: 2-6) vs WGS: 2 (IQR:1-3), $p < 0.001$). Twenty-three samples had variants that were only detected by TOP, and 9 samples did not have any. Comparing the variant allele frequency (VAF) of variants detected by TOP, those detected only by TOP had a significantly lower VAF compared with variants detected by both methods (median, 14% (IQR: 10-22%) vs. 22% (IQR: 17-40%)) ($p < 0.001$). There were no significant differences between the two groups in terms of DNA yield (mean 7.0 µg vs. 6.1 µg, $p = 0.37$), DNA Integrity Number (DIN, median 9.2 vs. 9.3, $p = 0.35$), TOP sequencing depth (mean 1095× vs. 1058×, $p = 0.44$), or WGS depth (median 120× vs. 120×, $p = 0.93$).

Conclusion: Significant differences were observed in the variants detected by target capture sequencing and WGS. However, the specimens analyzed using these two methods were obtained from different tumor sections. Therefore, the discrepancies in test results between the two assays may be due to intratumoral heterogeneity, different sample preparation methods, or low VAF. We will further investigate the causes underlying these findings and make a presentation.

#5366 DRAGEN pipeline validation for somatic variant detection in diagnostics using TSO500 panel.

Mehrdad Rakaee[1], Per Niklas Waaler[2], Falah Jabar[3], Krinio Giannikou[4], Elio Adib[4], Sigve Andersen[2], Erna-Elise Paulsen[2], Thomas K.Kilvaer[2], Elisabeth Jarhelle[3], Kristin Aberg[3], Espen Mikal Robertsen[3], Ane Yde Schmidt[5], Christina Westmose Yde[5], Christian Baudet[5], Aslaug Helland[1], Mette Pohl[5], Lill-Tove R. Busund[3], David J. Kwiatkowski[4], Tom Donnem[2]

[1]Oslo University Hospital, OSLO, Norway,[2]UiT The Arctic University of Norway, Tromso, Norway,[3]University Hospital of North Norway, Tromso, Norway,[4]Brigham and Women's Hospital, Boston, MA,[5]Copenhagen University Hospital, Copenhagen, Denmark

Background: The DRAGEN pipeline has recently been released for the analysis of whole genome and exome sequencing data (PMID:39455800). However, its performance in detecting clinically relevant alterations for routine diagnostic practice remains unknown.
Methods: This study includes 108 lung cancer patients consecutively collected from the TNM-I trial (NCT03299478). Tumor-only sequencing of FFPE DNA was performed using the TruSight Oncology 500 (TSO500) panel. Alignment and variant calling were conducted with DRAGEN (TSO500 v2.5.2) and Mutect2-GATK (v2.2), with subsequent annotation and classification using PCGR (v2.1.2) and OncoKB (v3.4.1).
Results: In the DRAGEN pipeline output, 4328 exonic and nonsynonymous variants with a variant allele fraction (VAF) >0.01 and a minimum supporting read count of 5 (normalized by depth) were analyzed. Among these, 214 variants met actionability tiers 1-3 (AMP/ASCO/CAP) and oncogenicity score >3 based on ClinGen/CGC/VICC Oncogenicity Guidelines, with the highest calls observed for *TP53* (44%, n=48) and *KRAS* (34%, n=37). DRAGEN and Mutect2 showed 100% concordance in detecting level 1 variants (OncoKB classifications), distributed as follows: *KRAS* (16 variants), *EGFR* (2 variants), and *BRAF* (1 variant). The median VAF difference between the two pipelines was 0.017, indicating strong alignment in allele frequency for high-confidence variants. Additionally, 174 variants (84%) showed a VAF difference within ±3.0%, suggesting minor VAF calculation variability in a subset of cases. Across all matched variants, DRAGEN reported consistently lower read depth values than Mutect2, with a median depth of 275 for DRAGEN versus 375 for Mutect2. DRAGEN also demonstrated a lower standard deviation in read depth (188 vs. 320 for Mutect2), indicating tighter depth distribution. This depth discrepancy was particularly pronounced in variants with a >3% VAF difference, suggesting that depth differences may contribute to VAF variability between the pipelines. No level-2 OncoKB classifications were detected by either pipeline.
Conclusion: These findings demonstrate DRAGEN concordance with GATK for detecting clinically significant Tier 1 variants, supporting its reliability in routine diagnostics despite read depth inconsistencies. Future studies should further explore DRAGEN performance in detecting copy number variants and fusion calls.

#5367 Distinct molecular characteristics and treatment implications of *TP53* gain-of-function mutations in non-small cell lung cancer.

Hanlin Chen, **Haimeng Tang**, Xue Wu, Qiuxiang Ou

Nanjing Geneseeq Technology Inc., Nanjing, China

Background: TP53 gain-of-function (GOF) effects lead to cellular responses beyond the capabilities of wild-type TP53 and are known to promote cancer progression and tumor growth. Clinical studies linked *TP53* GOF mutations to poorer outcomes in high-methylated metastatic colorectal cancer and advanced pancreatic ductal adenocarcinoma, while their impact on lung cancer remains unclear.
Methods: A total of 486 patients diagnosed with non-small cell lung cancer (NSCLC) with baseline DNA sequencing data were enrolled. Clinical and sequencing data from external two NSCLC cohorts treated with immunotherapy, one treated with ROS1 tyrosine kinase inhibitors, and one with histological data were analyzed to assess relationships between *TP53* GOF mutations and immunotherapy efficacy, TKI efficacy, and histological transformation. The *TP53* GOF mutations are defined by the “The TP53 Database” (https://tp53.cancer.gov/).
Results: Among all patients, 98 are with *TP53* GOF mutations (20.2%), 189 with *TP53* other mutations (38.9%), and 199 with *TP53* wild-type (40.9%). Compared to *TP53* non-GOF mutations, patients with TP53 GOF mutations show higher mutation rates in *PIK3CA* (P = 0.010), *STK11* (P = 0.026), and *CTNNB1* (P = 0.020) but lower in *NTRK1* (P = 0.018); increased *VEGFA* (P = 0.010) but decreased *DLL3* (P = 0.036) and *HRAS* (P = 0.036) amplification rates; and more frequent PI3K (P = 0.026) and WNT (P = 0.040) pathway alterations. Patients with *TP53* GOF mutations have significantly higher tumor mutation burdens (TMB) than those with other *TP53* statuses (P < 0.001). Moreover, *TP53*-mutated patients, both with GOF and other mutations, show significantly higher expression of immune checkpoints, including *CD274*, *PDCD1*, *PDCD1LG2*, *CTLA4*, and *LAG3*, compared to *TP53* wild-type patients. GOF-mutated patients also have higher M1 macrophage and CD8+ T cell infiltration, alongside elevated B cell receptor signaling, whereas patients with other *TP53* mutations display greater expression of inflammatory pathways. Notably, the ratio of *TP53* GOF mutations in *TP53*-mutated patients decreases with higher histological grades (lepidic vs. acinar/papillary vs. solid/micropapillary: 40.0% vs. 31.7% vs. 30.8%). For treatment efficacy, *TP53* GOF mutations are associated to improved outcomes with immunotherapy (mPFS: 5.37 months in GOF mutations vs. 3.03 in wild-type vs. 4.27 in non-GOF mutations) but poorer prognosis with ROS1-TKIs (mPFS: 10.65 months in GOF mutations vs. 19.60 in wild-type vs. 4.95 in non-GOF mutations).
Conclusions: This study demonstrates that *TP53* GOF mutations are associated with poorer TKI efficacy but improved immunotherapy outcomes in NSCLC. Patients with *TP53* GOF mutations also exhibit elevated immune activities and distinct molecular profiles, marked by higher TMB, *VEGFA* amplification rates, and mutation rates in *PIK3CA* and the PI3K pathway.

#5368 The differences in molecular profiles and survival outcomes between early and late-onset glioblastoma.

Hanlin Chen, Jiaohui Pang, **Haimeng Tang**, Xue Wu, Qiuxiang Ou

Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Age influences glioblastoma's molecular characteristics, with the 2021 WHO classification distinguishing pediatric and adult gliomas due to differing molecular profiles and prognoses, as pediatric glioblastomas show unique genetic alterations compared to adults and have a lower rate of malignant transformation. Although the molecular differences and prognosis between pediatric-type and adult-type glioblastoma are well-studied, the impact of age on adult glioblastoma patients remains underexplored.
Methods: Targeted DNA sequencing data from baseline tissue samples of 139 glioblastoma patients were analyzed. Additionally, clinical and sequencing data from 258 glioblastoma patients in the TCGA cohort were utilized for RNA expression and prognosis analyses. Kaplan-Meier survival curves were generated for the TCGA cohort, and the log-rank test was employed to compare survival times between subtypes.
Results: Among all patients in the study cohort, 11 patients were classified as early-onset glioblastoma (age ≤ 40), and 128 patients were with late-onset glioblastoma (age > 40). The results show that *TERT* mutations (P = 0.006), *MGMT* methylation (P = 0.043), and chromosome 7 gain and 10 loss (P = 0.012) are significantly enriched in late-onset glioblastoma patients, whereas *KIT* amplifications (P = 0.043) are more prevalent in early-onset patients. Beyond these genetic distinctions, patients with late-onset glioblastoma (P = 0.030) and positive *MGMT* methylation status (P = 0.050) exhibit higher tumor mutation burdens. The expression levels of chemokine (P = 0.002), IL-17 (P = 0.002), JAK-STAT (P = 0.011), NF-kappa B (P = 0.002), PI3K-Akt (P = 0.027), and TNF signaling pathways (P = 0.002) are elevated in late-onset patients, whereas early-onset patients show higher $CD4^+$ (P = 0.029) and $CD8^+$ (P = 0.077) T cell infiltrations. Notably, both early- and late-onset glioblastoma patients exhibited comparable actionable mutation profiles, except for a higher incidence of *BRAF* mutations in the early-onset group (P = 0.031). Survival analysis further revealed that late-onset (mPFS: 13.0 months in late-onset vs. 30.0 months in early-onset; P < 0.001) and elevated TMB (mPFS: 13.6 months in TMB-high vs. 15.3 months in TMB-low, stratified by the median value; P = 0.043) were associated with a poorer prognosis in patients with glioblastoma.
Conclusions: In summary, late-onset patients have a poorer prognosis, characterized by adverse biomarkers such as TERT promoter mutations and chromosome 7 gain and 10 loss, but are more likely to benefit from temozolomide chemotherapy, while early-onset patients, with a higher frequency of BRAF mutations, may have a higher chance respond to BRAF inhibitors.

#5369 Characterizing the molecular and clinical implications of *NRG1* fusions in NSCLC through integrated RNA and DNA sequencing analyses.

Minyi Zhu, Yang Xu, **Haimeng Tang**, Xue Wu, Qiuxiang Ou

Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Background: *NRG1* fusions are oncogenic drivers in NSCLC, with therapeutic implications underscored by FDA's designation of Zenocutuzumab for *NRG1* fusion-positive cases. Despite this, the molecular characteristics and clinical impacts of distinct *NRG1* fusion types remain poorly understood.

Methods: We retrospectively enrolled 435 NSCLC patients, comprising 78 with *NRG1* fusions and 357 wild-type (WT), from June 2016 to December 2023. We assessed mutational landscapes, tumor mutation burden (TMB), chromosomal instability scores (CIS), and gene expression using broad-panel targeted DNA and RNA sequencing analyses. Survival analyses were conducted in patients from our cohort (N=47) and online TCGA database (N=526).

Results: Among the *NRG1* fusion-positive patients, 65.8% harbored recurrent fusion partners like *CD74-NRG1* and *SLC3A2-NRG1*, with *CD74-NRG1* appearing most frequently (48.1%). These recurrent fusions were associated with significantly fewer *EGFR* and *KRAS* mutations and lower TMB and CIS compared to WT ($P < 0.01$). Additionally, 26 patients had unique singleton fusion partners, with 23 novel fusions identified, including *CEBPD-NRG1* and *BMP1-NRG1,* although validation through tools such as RNA sequencing is warranted in the future. Interestingly, this group showed significant enrichment of mutations in genes like *KRAS*, *MSH2*, *MSH6*, *FANCI*, and *MDM2*, impacting key oncogenic and DNA-repair pathways including Fanconi anemia, mismatch repair, PI3K-AKT, and MAPK pathways ($P < 0.01$). Additionally, the RNA profiling showed upregulation of *DNAJB1* ($P < 0.01$) and *LMNA* ($P = 0.02$) in the singleton group versus WT, linked to poorer overall survival (OS) in the TCGA cohort (HR: 1.52 for both). No significant differences in progression-free survival (PFS) were observed between uncommon and WT groups following the first-line anti-EGFR tyrosine kinase inhibitor (TKI) therapy.

Conclusion: This study revealed the diversity of *NRG1* fusions in NSCLC, identifying novel fusion partners and distinct molecular and clinical features across novel *NRG1+* groups, especially the enriched DNA repair/oncogenic signaling pathways and uniquely upregulated transcription profile. Our study highlights the need of subtyping different *NRG+* tumors to better understand their tumorigenesis and facilitates more personalized and targeted treatment of *NRG1+* NSCLC patients.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolic Reprogramming
Poster Session

#5373 ALDOA reprograms stemness and mitochondrial function in lung cancer by facilitating lactylation of m^6A regulators.

Han-Hsi Kuo, You-Yu Lin, Zhao-Jing He, **Yu-Chan Chang**

National Yang Ming Chiao Tung University, Taipei, Taiwan

Lactic acid-derived lactylation has recently emerged as a novel post-translational modification (PTM). This modification has been shown to regulate the N6-methyladenosine (m^6A) modification mechanism, thereby influencing RNA function. In lung cancer progression, dysfunctional aldolase (ALDOA) forms a positive feedback loop with HIF-1α, promoting lactate accumulation in the tumor and its microenvironment. We observe increased lactate production, hypoxia, acidification of the tumor microenvironment and increased lactylation levels of m^6A regulators. In particular, METTL16, a key m^6A transcription factor, was found to be modified by lactate. We also developed a methylated m^6A RNA immunoprecipitation (MeRIP) platform and identified ATPIF1, an inhibitor of mitochondrial F_0F_1-ATP synthase, as a direct target of lactylation. In our overexpression model, ATPIF1 was degraded following m^6A modification, which activated ATP biosynthesis. In a METTL16 knockout model, ATPIF1 expression was restored, leading to impaired ATP production and mitochondrial membrane potential. In addition, cancer spheroid formation and associated markers were reduced. Our *in vivo* model mirrored these findings, showing lactate-induced acidification and up-regulation of molecules involved in cancer stemness and mitochondrial function within the tumor region. Using multiplex staining, we detected reduced ATPIF1 expression alongside ALDOA overexpression, increased mitochondrial membrane potential and increased expression of OXPHOS-related molecules. In conclusion, we propose that ALDOA accelerates glycolysis in lung cancer progression and increases the global lactylation status of m^6A regulators. These findings highlight lactylation as a critical aspect of metabolic reprogramming in cancer.

#5374 Metabolic reprogramming regulates tyrosine receptor kinase c-Met in prostate cancer.

Songyeon Ahn, Tagari Samanta, Junhyoung Park, Benny A. Kaipparettu

Baylor College of Medicine, Houston, TX

Mitochondrial metabolic reprogramming is known to regulate oncopathways. To understand mitochondria-regulated oncopathways in prostate cancer (PC), we used a transmitochondrial cybrid system. Under a benign prostate cell line PNT1a, cybrids were generated after cytoplasmic fusion from PNT1a (PNT1/PNT1) and PC cell line PC3 (PC3/PNT1). PC3/PNT1 cybrids showed increased tumor stemness, metastasis, and mitochondrial activity with enhanced OXPHOS and fatty acid oxidation (FAO) compared to PNT1/PNT1 cybrids. RNASeq analysis of cybrids identified increased mRNA expression of Mesenchymal Epithelial Transition receptor (c-Met) in cybrids with cancer mitochondria. c-Met is a receptor tyrosine kinase (RTK) and an essential receptor that regulates multiple cellular signaling and homeostasis in mammalian cells. c-Met is often over-expressed in several types of cancers and is thus considered a potential therapeutic target. c-Met activation is known to increase glucose metabolism by upregulating the expression of glycolysis-related genes such as GLUT-1, HK-2, PFK-1, LDH-1, and SIRT1 in tumor cells. However, how tumor metabolism affects c-Met expression is unclear. Etomoxir (FAO inhibitor) and Atovaquone (OXPHOS inhibitor) suppressed c-Met protein expression through the mTOR-P70S6K pathway in PC cells. Rapamycin (mTOR inhibitor) reduced c-Met expression in PC3 and DU145 PC cells. Preliminary analysis suggests that the mitochondrial inhibitors and capmatinib, an FDA-approved c-Met inhibitor, have a combinatorial effect. Collectively, this study suggests that mitochondrial metabolic reprogramming to FAO in PC upregulates c-Met activity.

#5375 Sex-specific differences in response to exogenous asparagine supplementation during colorectal tumor growth is dependent on aromatase activity.

Oladimeji Aladelokun[1], Katherine Benitez[1], Yuying Wang[2], Abhishek Jain[1], Domenica Berardi[1], Georgio Maroun[2], Xinyi Shen[1], Jatin Roper[3], Joanna Gibson[2], Kaelyn Sumigray[2], Sajid A. Khan[2], Caroline H. Johnson[1]

[1]Yale University, New Haven, CT,[2]Yale School of Medicine, New Haven, CT,[3]Duke University School of Medicine, Durham, NC

Studies have shown that sex-related differences in asparagine metabolism are associated with gastrointestinal diseases prognosis. However, the effects of exogenous asparagine on the incidence and phenotype of colorectal cancer (CRC) in both men and women remain unclear. This study describes the relationship between exogenous asparagine supplementation and estradiol secretion which is critical for understanding mechanisms of sex-dependent signaling events. We show that asparagine supplementation causes pronounced sex-dependent alteration in cancer metabolomics using in vivo and in vitro approaches. We intraperitoneally administered asparagine to tumor-bearing immunodeficient male and female Rag2/Il2RG (R2G2) mice, at doses of 1 mg/kg and 10 mg/kg body weight. Asparagine supplementation causes a significant increase in cellular asparagine levels in the tumor-bearing male and female R2G2 mice but increases serum estradiol levels and suppresses tumor growth in females R2G2 mice only. Additionally, we combined transcriptome, metabolome and immunochemical analyses and found that asparagine treatment induces intra-tumoral metabolic changes in colorectal cancer cells based on biological sex. We established that in females only, exogenous asparagine exerts a negative feed-back effect on de novo asparagine synthesis and activates a sub-population of macrophages that secretes estradiol via a Cytochrome P450 Family 19 (CYP19)-dependent mechanism, resulting in improved tumor-specific survival. Conversely, in the male mice, asparagine treatment augments tumor growth by decreasing the number of tumor-associated macrophages and reduces CYP19-mediated estradiol secretion leading to worsened tumor-specific survival. Overall, our results revealed a novel role for exogenous asparagine supply during cancer progression and underscores the importance of understanding mechanisms that control asparagine biosynthesis, especially for patients with CRC.

#5376 Unraveling the metabolic Achilles' heel of pancreatic ductal adenocarcinoma: targeting ref-1 and beyond.

Silpa Gampala[1], Jacqueline Peil[2], Sanya Hayati[1], Sonia Kiran[1], Caleb Cheng[3], Elizabeth A. Potchanant[1], Costas Lyssiotis[4], Chi Zhang[5], Sha Cao[5], Mark R. Kelley[1], Melissa L. Fishel[1]

[1]Department of Pediatrics, Indiana University Simon Comprehensive Cancer Center, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Pediatrics and Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[3]Michigan Center for Translational Pathology, Cellular and Molecular Biology Program, University of Michigan, Ann Arbor, MI,[4]Rogel Cancer Center, Departments of Molecular and Integrative Physiology, Internal Medicine, University of Michigan, Ann Arbor, MI,[5]Biomedical Engineering, Oregon Health & Science University, Portland, OR

Background & Objective: Treating pancreatic ductal adenocarcinoma (PDAC) remains exceptionally difficult, with scant advancements in clinical management over the last thirty years. Aptly dubbed the "graveyard of chemotherapy," PDAC poses formidable clinical challenges. Even the most effective first-line chemotherapy regimens merely extend median survival for patients with metastatic disease beyond 12 months. Due to its poorly vascularized and fibrotic environment, tumor cells encounter hypoxia and nutrient scarcity and hence adapt metabolically by engaging processes like autophagy and macropinocytosis. Key genes such as HIF1A, KRAS, and MYC help PDAC reshape tumor metabolism favoring glycolysis thereby, promoting metastasis and therapy resistance. Targeting these cancer-specific metabolic genes offers a promising approach to overcoming PDAC's inherent and acquired chemoresistance. Redox effector factor-1 (Ref-1) activates various transcription factors through its redox activity, including HIF-1α, contributing significantly to metabolic reprogramming and altered gene expression in PDAC. We recently published Ref-1's redox function as crucial for mitochondrial metabolic regulation, and that inhibition of Ref-1 suppresses the TCA cycle, Oxidative phosphorylation (OXPHOS), and tumor growth and metastasis in PDAC models. As further proof of Ref-1's role in regulating OXPHOS, PDAC cells are more sensitive to Ref-1 inhibitors in galactose-containing media than glucose. *Therefore, we hypothesize that Ref-1 inhibitor efficacy can be increased by identifying additional tumor-specific metabolic targets that induce synthetic lethality when combined with Ref-1 inhibition.*

Methods: Two approaches were used to identify Ref-1 synergistic metabolic targets: global metabolomics profiling (Pa03C) and a metabolism-centered CRISPR/Cas9 KO library screening (MiaPaCa2) after treatment with APX2014, a potent Ref-1 redox inhibitor.

Results & Conclusion: The CRISPR screen identified several interesting synthetic lethal genes for combination with Ref-1 redox inhibition, including PRDX1, G6PD, and SEPHS2. Further, integration of the global metabolomics profile with our published scRNA seq data shows significant changes in both substrates and enzyme gene expression of multiple metabolic pathways, with a predicted decrease in TCA cycle and nucleotide biosynthesis, and increased glutaminolysis following Ref-1 inhibition. Ongoing studies include the prediction of combinatorial lethality enabled by co-suppression of Ref-1 and other metabolic targets and validation using our *in vitro* and *in vivo* model of PDAC PDX tumor lines co-cultured with matched cancer-associated fibroblasts.

#5377 FGF1 regulates breast cancer growth and metabolic reprogramming through ETV4.

B. Sankofi, S. Johnson Murguia, W. L. Berry, E. A. Wellberg;
University of Oklahoma Health Sciences Center, Oklahoma City, OK

Breast cancer is the most frequently diagnosed cancer in women worldwide. Obesity increases resistance to breast cancer therapies and patient mortality, particularly for estrogen receptor-positive (ER+) tumors that represent 70% of all cases. Adult weight gain in women with obesity, characterized by adipose tissue expansion, is an independent prognostic factor for breast cancer. In a preclinical model, we found that weight gain promoted ER+ tumor growth after endocrine therapy through adipose-derived fibroblast growth factor 1 (FGF1). To determine the underlying mechanisms, we used cultured ER+ breast cancer cells (MCF7, tamoxifen-resistant MCF7 cells, and UCD12 cells) treated with FGF1, combined with gene expression profiling and metabolic analysis. ETS variant 4 (ETV4), which regulates ER activity and cancer cell glycolysis, was the top gene induced by FGF1 in multiple ER+ lines. ETV4 was shown by others to regulate breast cancer metabolism and stemness, contributing to disease progression. We hypothesized that ETV4 mediates the FGF1-dependent effects on breast cancer glycolytic reprogramming in obesity-associated breast tumors. ETV4 was upregulated in human PDX tumors grown in obese versus lean mice. In invasive human breast cancer specimens, high versus low ETV4 expression predicted a shorter recurrence-free survival for patients with ER+ tumors. ETV4 knockdown in cultured endocrine-resistant breast cancer cells prevented the proliferation and induction of glycolytic genes with FGF1 treatment. Conversely, overexpression of ETV4 was sufficient to increase glycolytic gene expression and enzyme activity, as well as cell proliferation. Taken together, our data suggest a mechanism by which FGF1 supports breast cancer endocrine therapy resistance in the context of obesity through ETV4 induction and glycolytic metabolic reprogramming. Understanding this process may aid in designing effective treatments, especially for patients resistant to current ER-targeted therapies. Furthermore, ETV4 may be a biomarker to identify breast tumors with excess FGF signaling and patients at high risk for progression.

#5378 GLUD1 protects NSCLC from glucose starvation through a novel enzyme-independent function.

Ryan Clay, Lingtao Jin

Molecular Medicine, The University of Texas Health Science Center At San Antonio, San Antonio, TX

Lung cancer is the leading cause of cancer-related deaths among both men and women in the United States with non-small cell lung cancer (NSCLC) accounting for 85% of all lung cancers. However, regardless of genetic background, nearly all NSCLC are dependent on upregulation of glutamine metabolism for survival, and consequently, the nonessential amino acid glutamine becomes conditionally essential to many tumors. Tumor cells generate the bulk of their ATP by upregulating glycolysis and discarding of the majority of glycolytic carbon as lactate, known as the Warburg effect. This lost carbon is replaced by glutamine-dependent anaplerosis of the mitochondrial tricarboxylic acid (TCA) cycle, which maintains a pool of biosynthetic intermediates that contribute to cell growth. Glutaminolysis is also crucial for the regulation of cell proliferation, survival, and chemoresistance by supporting NADPH and GSH synthesis, regulating of redox metabolism, preventing apoptosis, activating of autophagy, as well as influencing oncogenic signalings such as mTOR, Ras, NRF2 and Hippo pathway. Glutamate dehydrogenase 1 (GLUD1) is an enzyme in the glutaminolysis pathway that catalyzes the reversible conversion of glutamate to alpha-ketoglutarate (aKG). GLUD1 acts as an energy sensor and undergoes a high degree of allosteric and post-translational regulation. GLUD1 also seems to play a direct role in the regulation of multiple cell signaling pathways including mTORC1 activation, signals through glutathione peroxidase 1 (GPX1) to regulate redox homeostasis, directly activates p38 MAPK signaling, and activates CamKK2-AMPKa1 signaling to prevent anoikis and promote metastasis. Our data shows knockout of GLUD1 sensitizes cancer cells to nutrient starvation, but expression of enzymatically dead GLUD1 mutants R443S or R463A still protect cancer cells from glucose starvation-induced cell death. We observe a rapid drop in ATP coupled with the loss of AMPK activation in GLUD1 KO cells under glucose starvation. Cell death can be rescued with the direct AMPK activator A769662 or exacerbated by the AMPK inhibitor Dorsomorphin. Inhibition of cysteine import with xCT-inhibiting compounds Erastin and Sulfasalazine, knockdown of xCT, or cysteine/glucose double starvation also rescues cell death. Novel post-translational modifications to GLUD1 were identified by mass spec including acetylation, methylation, and a previously unknown phosphorylation site. In addition, BioID protein proximity labeling identified several new potential interactors for GLUD1 including kinases and glycolysis proteins. We propose the GLUD1 protein possesses a previously undiscovered function that activates AMPK signaling, thereby inhibiting cysteine import and protecting against cell death under glucose starvation.

#5380 Chemotherapy induces a pro-metastatic secretome through cellular senescence.

Aidan Robert Cole, Katherine M. Aird

Department of Pharmacology and Chemical Biology, University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA

High grade serous ovarian cancer (HGSOC) is the most lethal gynecological malignancy, with 70-80% of patients having metastatic disease recurrence within 12 months of treatment with first line therapies. A potential factor in HGSOC metastasis and recurrence is chemotherapy induction of cellular senescence, a stable cell cycle arrest which includes a unique secretome (termed the senescence-associated secretory phenotype - SASP) comprised of cytokines, chemokines, small molecules, and differential usage of nutrients. Prior work found that senescent cells can promote tumor progression and metastasis; however, the direct contribution of the SASP to metastatic recurrence has not been deeply explored. Interestingly, we found that the SASP is sufficient to drive increased HGSOC metastatic tumor nodules *in vivo*. Mechanistically, we found that naïve cancer cells cultured in conditioned media from senescent cells expressed lower levels of multiple extracellular matrix and adhesion related proteins, including fibronectin and integrins. Indeed, the decrease in adhesion factors corresponds to lower cell adhesion and increased cell detachment in 3D conditions. Unexpectedly, experiments depleting SASP proteins suggest a metabolic component of the SASP contributes to the increased metastasis through loss of adhesion factors. We also found that the SASP induced an increase in basal and maximal oxygen consumption, further exhibiting altered metabolism. Using a metabolic CRISPR knockout screen to identify genes required for decreased adhesion after exposure to the SASP, we identified several genes in the electron transport chain, including *NDUFA5*, a subunit of complex I. Consistently, HGSOC patients with low *NDUFA5* expression have upregulated adhesion gene signatures, and *NDUFA5* knockdown or pharmacological inhibition of complex I both increase cell adhesion. *NDUFA5* is also required for SASP induced increase in basal and maximal respiration. Interestingly, use of scavengers to inhibit ROS did not rescue the adhesion phenotype in *NDUFA5* knockout cells, but supplementation with an NAD+ precursor did, implicating *NDUFA5*'s role as an NADH dehydrogenase in its effect on cell adhesion independent of redox status. Together, our data demonstrate that the chemotherapy-induced SASP has a paracrine effect on mitochondrial metabolism in tumor cells, which in turn decreases cell adhesion. We hypothesize this decrease in adhesion will lead to an increase in tumor metastasis, which contributes to recurrence. Future studies will identify the metabolic composition of SASP that leads to paracrine metabolic reprogramming, the mechanism behind *NDUFA5* and respiration's regulation of adhesion through NAD+ regeneration, and its role in SASP-induced dissemination *in vivo*.

#5381 Tumor nutrient stress regulates cancer-associated fibroblast heterogeneity.

Marta Storl-Desmond[1], Kevin Munoz Forti[1], Michał Nizio[1], Alexander Muir[2], Simon Schworer[1]

[1]Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, IL,[2]Ben May Department of Cancer Research, University of Chicago, Chicago, IL

Pancreatic ductal adenocarcinoma (PDAC) is a lethal cancer type with a 5-year survival rate of only 13%. PDAC is unique in that up to 90% of the tumor bulk is comprised of a dense desmoplastic stroma. Enriched within PDAC's extensive stroma are cancer-associated fibroblasts (CAFs). CAFs orchestrate tumor progression through the secretion of signaling molecules that impact cancer and immune cell function, and extracellular matrix proteins that remodel the surrounding stroma. CAFs are functionally and transcriptionally heterogeneous, with three distinct subtype classifications: myofibroblastic (myCAF), inflammatory (iCAF), and antigen-presenting (apCAF). In PDAC, an increased iCAF to myCAF ratio has been associated with worse clinical outcomes; however, efforts to selectively target CAF populations have been met with the challenge of CAF plasticity. A better understanding of the mechanisms underlying CAF state decisions is required before pro-tumor CAFs can be targeted. A key feature of PDAC is impaired perfusion, which leads to regions of hypoxia and altered nutrient availability; however, the significance of this unique metabolic environment to CAF state remains unknown. It has been reported that nutrient stress within the tumor microenvironment directly impacts cancer cell state leading to targetable metabolic adaptions, but how these same stresses affect the CAFs that share this microenvironment have been overlooked. To investigate how the altered nutrient availability of PDAC impacts CAFs, we acclimated pancreatic stellate cells (PSCs), a precursor CAF, to culture in tumor nutrient-relevant media. Characterization of these cells by high-dimensional flow cytometry and RNA-sequencing has revealed that the nutrient environment is sufficient to alter CAF state. CAFs in conditions of tumor nutrient stress are enriched for inflammatory signatures, along with higher expression and secretion of several potent cytokines and chemokines. Changes in CAF state induced by tumor nutrient stress are reversible, highlighting nutrient availability as a dynamic regulator of CAF plasticity. This work demonstrates the importance of the tumor nutrient environment to CAF state decisions. It further suggests that incorporating metabolic features of the PDAC TME increases the fidelity of existing model systems, which may allow uncovering novel regulators of CAF heterogeneity.

#5382 Comprehensive characterization of renal cell carcinomas identifies metabolic reprogramming of the tumor microenvironment associated with disease progression.

Kirsteen H. Maclean[1], Lakshmi Chandramohan[2], Qingyan Au[1], Harry Nunns[1], Jiong Fei[1], Erinn Parnell[1], Anna Juncker-Jensen[1]

[1]NeoGenomics, Aliso Viejo, CA,[2]NeoGenomics, Houston, TX

Background: Renal cell carcinoma (RCC) is one of the most frequent urological cancers with the most common histological subtype being clear cell renal cell carcinoma (ccRCC), an immunologically and histologically diverse tumor which is associated with a poor clinical outcome as up to 40% of ccRCC patients develop metastases. While significant progress has been made in the development of immunotherapy for ccRCC, there are still many unanswered questions about the mechanisms of immune evasion and resistance, and the development of predictive biomarkers for optimal treatment strategies for individual patients. Recently, it has become clear that cellular metabolism may play a significant role in the immune response to ccRCC tumors, affecting both the ability of T-cells to function and the overall composition of the tumor microenvironment (TME). This remodeled TME leads to changes in nutrients and metabolites that can promote an immunosuppressive environment and prevent lymphocyte activation and recruitment, eventually promoting T-cell exhaustion.
Methods: We performed transcriptomic and spatial profiling of 16 ccRCC patient samples across all clinical TNM stages (Stages I-IV) to define the changes in metabolic processes and infiltrating immune cells with advancing disease. Specifically, we included the spatial MultiOmyx™ IF multiplexing assay (NeoGenomics Laboratories, Inc.) using the new MO2.0 workflow with enhanced whole slide capability coupled to the NanoString nCounter® Metabolic Pathways Panel to investigate metabolic reprogramming, cellular stress, and the relationship to the composition of the TME in advancing disease progression in ccRCC.
Results and Conclusions: We identified significant changes associated with the TME, especially immunosuppressive immune cells in advanced disease, coupled to the identification of several metabolism-related genes that correlated with immune infiltrates in ccRCC. Identifying and understanding these metabolic alterations within the different staging of RCC will help in designing new targeted therapies and improving diagnostic tools to better care for patients with this disease.

#5383 Metabolic profiling of compressed stromal cells in the breast peritumor.

Julian Najera, Hao Chen, Scott Howard, Meenal Datta

University of Notre Dame, Notre Dame, IN

Breast cancer represents a significant public health concern for women across the globe. Although the breast peritumor is increasingly recognized for its active role in modulating breast tumor growth and progression, its biophysical relationship with the tumor is poorly understood. Of particular interest is the effect of compressive forces imparted onto the peritumor by the growing mammary tumor. In this study, we found that compression metabolically reprograms stromal cells—namely, fibroblasts and adipocytes—found in the breast peritumor *in vitro*. Using fluorescence lifetime imaging microscopy, we discovered that fibroblasts and differentiated adipocytes under compression adopt a more glycolytic state whereas compressed pre-adipocytes appear to favor oxidative phosphorylation. We were able to confirm this metabolic shift in fibroblasts using bulk RNA sequencing, with pathway analysis showing that compressed fibroblasts significantly downregulate oxidative phosphorylation and strongly enrich glycolysis. Moreover, by measuring glucose uptake, we found that compression moderately increases glucose uptake in fibroblasts. Furthermore, through single cell transcriptomic analysis of breast cancer patients, we discovered that, in relation to those found in normal (compression (-)) tissue, fibroblasts and mature adipocytes in the peritumor (compression (+)) tend to favor glycolysis. It remains to be determined, however, to what degree this metabolic reprogramming is a direct consequence of external tumor compression.

#5384 Targeting PIKfyve-driven lipid homeostasis as a metabolic vulnerability in pancreatic cancer.

Caleb Cheng[1], Jasmine Wisniewski[1], Sydney Peters[1], Ruya Pakkan[1], Jennifer P. Morton[2], Pietro Morlacchi[3], Yuanyuan Qiao[1], Costas A. Lyssiotis[1], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]CRUK Scotland Institute, Glasgow, United Kingdom,[3]Agilent Technologies, Inc., Lexington, MA

Pancreatic ductal adenocarcinoma (PDAC) subsists in a nutrient-deregulated microenvironment, making it particularly susceptible to treatments that interfere with cancer metabolism. For example, PDAC utilizes and is dependent on high levels of autophagy and other lysosomal processes. Although targeting these pathways has shown potential in preclinical studies, progress has been hampered by the challenge of identifying and characterizing favorable targets for drug development. Here, we characterize PIKfyve, a lipid kinase integral to lysosomal functioning, as a novel and targetable vulnerability in PDAC. Employing a genetically engineered mouse model, we established the essential role of PIKfyve in PDAC progression. Further, through comprehensive metabolic analyses, we found that PIKfyve inhibition obligated PDAC to upregulate *de novo* lipid synthesis. PIKfyve inhibition triggered a distinct lipogenic gene expression and metabolic program, creating a dependency on *de novo* lipid metabolism pathways, by upregulating genes such as *FASN* and *ACACA*. In PDAC, the KRAS-MAPK signaling pathway is a primary driver of *de novo* lipid synthesis, specifically enhancing *FASN* and *ACACA* levels. Accordingly, the simultaneous targeting of PIKfyve and KRAS-MAPK resulted in the elimination of tumor burden in numerous preclinical human and mouse models, including endogenous genetically engineered models. Taken together, these studies suggest that disrupting lipid metabolism through PIKfyve inhibition induces synthetic lethality in conjunction with KRAS-MAPK-directed therapies for PDAC.

#5385 Concurrent inhibition of the serine/threonine protein kinase AURKB and the fatty acid oxidation enzyme CPT1A demonstrates synthetic lethality in preclinical glioblastoma models.

Qiuqiang Gao[1], Chang Shu[1], Jeongyeon Mun[1], Zhe Zhu[1], Hasan O. Akman[2], Mike-Andrew Westhoff[3], Georg Karpel-Massler[4], Markus D. Siegelin[1]

[1]Department of Pathology and Cell Biology, Columbia University Medical Center, New York, NY,[2]Department of Neurological Surgery, Columbia University Medical Center, New York, NY,[3]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany,[4]Department of Neurosurgery, Ulm University Medical Center, Ulm, Germany

Glioblastoma IDH-wild type, an aggressive and treatment-resistant brain cancer, urgently requires novel and more effective therapeutic approaches to enhance patient outcomes. Analysis of public genomic databases has revealed that the serine/threonine protein kinase Aurora kinase B may represent a promising therapeutic target for GBM. This study provided compelling evidence that AURKB is significantly upregulated in GBM tumors, and elevated AURKB levels are associated with poorer survival in GBM patients. Remarkably, the selective AURKB inhibitor barasertib was found to potently suppress the growth of established GBM cell lines, patient-derived xenograft models, and neurosphere cultures at low, nanomolar concentrations. Similarly, genetic depletion of AURKB substantially impaired the growth of patient-derived xenograft lines. Notably, in an orthotopic PDX GBM xenograft model, the loss of AURKB function was found to extend animal survival. Mechanistically, the study revealed that AURKB depletion or inhibition significantly impacts mitochondrial energy metabolism in GBM cells. Paradoxically, the loss of AURKB led to increased cellular respiration and oxidative phosphorylation, facilitated by enhanced fatty acid oxidation. Consistently, the absence of AURKB sensitized GBM cells to the cytotoxic effects of CPT1A inhibition, i.e., fatty acid oxidation inhibition. Furthermore, the BH3-mimetic ABT263 was found to reduce the growth of GBM lines in the context of AURKB loss of function, likely due to the heightened dependence on mitochondrial metabolism. These findings uncover a previously unappreciated role for AURKB in regulating GBM metabolism and provide a strong rationale for further developing AURKB-targeted therapies, potentially in combination with metabolic inhibitors and BH3-mimetics, to improve clinical outcomes for patients with GBM.

#5386 Metabolic regulation of PARP inhibitor response in ovarian cancer cells.

Subin Myong[1], Hardik Shah[2], Benedikt Nagele[1], Anh Q. Nguyen[3], **Sridevi Challa**[3]

[1]The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL,[2]Metabolomics Platform, The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL,[3]Obstetrics and Gynecology, The University of Chicago, Chicago, IL

Ovarian cancer (OvCa) is the most lethal gynecologic cancer due to high mortality from therapeutic resistance. Recently, PARP inhibitors (PARPi) have shown efficacy in treating OvCa, and patients with DNA repair pathway defects are now on PARPi maintenance. However, heterogeneous responses and resistance to therapy limit the clinical efficacy of PARPi treatment.

Catalytic activation of the PARP1 enzyme consumes NAD^+, a metabolite coenzyme for redox reactions and a key regulator of energy metabolism. PARP inhibitors can change the metabolic state of cells by inhibiting PARP1 activation and altering cellular NAD^+ levels, but the role of metabolic dysregulation in PARPi resistance remains unclear. Here, we show that PARPi-resistant ovarian cancer cells have elevated NAD^+ biosynthesis through the NAD^+ salvage pathway.

Gene expression analysis using RNA sequencing and metabolomic analysis using metabolic profiling have identified key pathways downstream of NAD^+ biosynthesis that contribute to PARPi resistance. We also demonstrated that the metabolic changes caused by high NAD^+ biosynthesis in PARPi-resistant cells cause cell cycle arrest at the G0/G1 phase and increase cellular quiescence and cell motility. Inhibition of the NAD^+ salvage pathway and reduction of NAD^+ levels within PARPi-resistant cells reverse cellular quiescence and cell migration, ultimately increasing the PARPi response in these cells.

In summary, our results demonstrate that elevated NAD^+ biosynthesis in ovarian cancer cells causes PARP inhibitor resistance by altering the metabolic state of these cells. Furthermore, inhibition of the NAD^+ salvage pathway enhances the efficacy of PARP inhibitor-mediated control of ovarian cancer growth.

Supported by grants from the NCI SPORE and CRF to S.C.

#5387 Modeling physiological lipid availability of tumors to improve in vitro studies of cancer cell lipid metabolism.

Mete E. Ozgurses[1], Vipin S. Rawat[1], Kelly O. Conger[1], Huiping Zhao[1], Patrick B. Jonker[2], Alexander Muir[2], Jonathan L. Coloff[1]

[1]University of Illinois College of Med. at Chicago, Chicago, IL,[2]Ben May Department for Cancer Research, University of Chicago, Chicago, IL

Lipids are highly crucial in cellular physiology and pathology. They are the main structural components of cellular membranes and play critical roles in metabolism, signaling, and other core processes. Many studies of lipid metabolism, both in cancer and other fields, rely on the results of *in vitro* tissue culture experiments. Generally, *in vitro* culture systems use media containing non-physiological levels of nutrients, including high levels of critical nutrients like glucose and glutamine. Recently, several groups have generated culture media with physiological levels of polar metabolites, which can correct some tissue culture-related artifacts. However, these new-generation media still use traditional serum and still represent severe lipid starvation conditions. In lipid-deprived environments, cells respond by activating the sterol regulatory element binding protein (SREBP) pathway, a transcriptional regulator of global lipid metabolic gene expression. Our SREBP transcription factor signature scores comparing human tumor samples to established cancer cell lines growing in TM showed dramatic activation of SREBP in cell lines relative to tumors, supporting traditional tissue culture being a highly lipid-starved environment. We hypothesized that these lipid-starved conditions impact cancer cell behavior in vitro and that developing a more physiological lipid medium will maintain more accurate cell metabolic characteristics. To study this, we have generated two new physiological lipid media - one that mimics lipid levels found in human plasma (HSLM) and one that mimics the lipid levels found in the tumor microenvironment (TILM). The lipidomic analysis confirmed that HSLM closely resembles the lipidome of human serum, while TILM more accurately aligns with the lipid profile of tumor interstitial fluid (TIF). We found that cell lines were unable to survive when cultured in HSLM. However, cancer cell lines adapted to TILM, reduced de novo lipogenesis and proliferation rate and had a similar fatty acid profile to in vivo mouse tumors compared to TM. In the future, we would like to comprehensively study how cells change their metabolism, signaling, and lipid profile to see whether cells cultured in TILM better represent primary tumor metabolism.

#5388 Metastasis suppressor RKIP modulates mitochondrial metabolism in triple-negative breast cancer.

Joana Pinheiro[1], Dongbo Yang[1], Madeline Henn[1], Long Chi Nguyen[1], Olga Martinho[2], Brandon Faubert[1], Marsha Rich Rosner[1]

[1]University of Chicago, Chicago, IL,[2]ICVS/3B's-PT Government Associate Laboratory, University of Minho, Braga, Portugal

Triple-negative breast cancer (TNBC) remains the most aggressive subtype of breast cancer, with a high propensity for metastasis. Tumor cell heterogeneity has been closely linked to metastatic progression, therapy resistance, and disease recurrence in solid tumors, including TNBC. Within tumors, metabolic heterogeneity emerges as cancer cells adapt to diverse environmental pressures, further driving tumor aggressiveness. However, the role of metastasis suppressors, such as Raf Kinase Inhibitory Protein (RKIP), in regulating metabolic heterogeneity is not yet fully understood. Analysis of RNA sequencing data from breast cancer patients revealed a strong correlation between RKIP expression and oxidative phosphorylation (OXPHOS) genes. Together with this, by performing gene set enrichment analysis of bulk RNA sequencing of mouse xenografts we observed an enrichment of hallmark of OXPHOS in RKIP-overexpressing tumors compared to controls. Consistent with these findings, RKIP was shown to modulate oxygen consumption rates in vitro. Using stable isotope tracing with [U-^{13}C] glucose in vivo, we observed higher glucose contribution to citrate labeling in RKIP-overexpressing tumors compared to controls. Through single-cell RNA sequencing, we demonstrate that RKIP reduces overall transcriptional heterogeneity, particularly by decreasing the variability of genes involved in mitochondrial respiration. Importantly, treatment with the OXPHOS inhibitor metformin selectively inhibited the growth of RKIP-overexpressing tumors, while control tumors were unaffected. This study suggests that RKIP or drugs that mimic its action have the potential to promote OXPHOS in tumor cells, presenting an opportunity to suppress tumor growth by subsequent therapeutic targeting of mitochondrial respiration in TNBC.

#5389 Adaptive OXPHOS and antioxidant defense in glucose-deprivation-resistant colon cancer cells.

Elimelech Nesher, Subha Ranjan Das, Bar Levi, Igor Koman

Ariel University, Ari'el, Israel

Cancer cells are generally characterized by exhibiting the Warburg effect, favoring glycolysis over oxidative phosphorylation (OXPHOS) to produce ATP. This leads to an increase in glucose uptake and lactate production, fueling rapid proliferation by providing energy and intermediates for biosynthesis. In parallel, slow angiogenesis resulting in a blood supply insufficient for the tumor's rapid growth leads to glucose starvation in solid tumors. To mimic glucose starvation *in vitro*, we used a model of glucose deprivation in HCT116 cells. A Seahorse study demonstrated that HCT116 cells endured an adaptive state of dormancy during glucose deprivation, shifting their metabolic pathway from glycolysis to OXPHOS. Interestingly, a small percentage of survived cells after dormancy completely resumed their proliferative abilities without glucose supply. We showed that these glucose-deprivation-resistant (GDR) cells have significant activation in the tricarboxylic acid (TCA) cycle, as well as increased levels of antioxidants and their precursors, such as GSSG, GSH, glutamine, glutamate, proline, betaine, citrulline, and arginine. These findings suggest that GDR cells could scavenge reactive oxygen species (ROS) generated during accelerated OXPHOS. Furthermore, the GDR cells demonstrated additional resistance to oxidative stress, induced by hydrogen peroxide. Increased OXPHOS in dormant cells, associated with elevated ROS production, led to significant DNA damage. In turn, enhancing DNA repair mechanisms and boosting antioxidant activity in GDR cells were accompanied with one-carbon metabolism, supporting rapid proliferation by supplying nucleotides for DNA repair and synthesis. We believe that cancer cells which, under glucose starvation, can completely switch their metabolism from glycolysis to OXPHOS are able to survive and regain their proliferative capacity by boosting their antioxidant defenses and improving their DNA repair mechanisms. This phenomenon supports the thesis that targeting cancer cells' metabolic flexibility and antioxidant capacity is an effective anticancer therapeutic strategy.

#5390 Metabolic reprogramming and glutamine addiction in squamous cell carcinoma driven by mutant cyclin D1.

Shuyuan Zhang, Polly Phillips-Mason, J. Alan Diehl

Biochemistry, Case Western Reserve University, Cleveland, OH

Cyclin D1 overexpression contributes to abnormal cell proliferation and tumor development in multiple cancer types. Cyclin D1 overexpression occurs at the highest frequency in head and neck squamous cell carcinoma (HNSCC). Biological events that trigger cyclin D1 overexpression include CCND1 amplification, mutations that impair cyclin D1 degradation, and inactivation of the SCF E3 ubiquitin ligase, Fbxo4 which controls cyclin D1 degradation. We focused on a mutant, cyclin $D1^{T286A}$, which blocks the nuclear export of cyclin D1 and its subsequent degradation by the 26S proteasome. Cyclin D^{T286A} expression can drive a variety of cancer types murine models including endometrial and mammary carcinoma as well as B-cell lymphoma. However, the molecular mechanisms whereby cyclin D^{T286A} drives cancer progression remain to be fully identified. Here, we demonstrate that cyclin $D1^{T286A}$ drives metabolic reprogramming in squamous cancer cells resulting in glutamine addiction via activation of CDK4/6. Notably, cyclin $D1^{T286A}$ triggers downregulation of IDH3 contributing to cell glutamine dependency to enforce oxidative carboxylation benefiting both generation of biosynthetic intermediates and ATP. A decrease of NAD^+/NADH ratio induced by decreased IDH3 results in cellular ATP imbalance and compromised mitochondria which promote cell death under glutamine restriction. Finally, we demonstrate that cyclin $D1^{T286A}$ cooperates with mutant p53 to promote head and neck squamous tumor development in a genetically engineered mouse model. In conclusion, we have uncovered the novel mechanism whereby that cyclin $D1^{T286A}$ drives metabolic reprogramming and HNSCC and our results highlight the potential for targeting glutamine metabolism in cyclin D1-positive HNSCCs.

#5391 The hexosamine biosynthetic pathway promotes metastatic potential upon glutamine deprivation in STK11 null KRAS-driven lung adenocarcinoma.

Shannon Prior, Logan Sands, Sean Lenahan, Cole Royer, Melissa Scheiber, David Seward, Paula Deming

University of Vermont, Burlington, VT

Lung cancer is the leading cause of cancer-related deaths worldwide, with ~15,000 annual US cases presenting with an aggressive lung adenocarcinoma (LUAD) driven by co-mutations in KRAS and STK11 (KS). Loss of STK11 function in KRAS-driven LUAD dysregulates many cellular processes, including metabolism. Specifically, KS cells become “glutamine addicted” and enhance glutaminolysis to drive proliferation. Recent work from our group revealed pro-oncogenic signaling in KS upon glutamine deprivation. We hypothesize that glutamine scarcity promotes metastatic potential in KS via metabolic rewiring. To test this, we employed a cell culture model of KRAS-driven LUAD with and without STK11 (ΔSTK11). At baseline, ΔSTK11 cells demonstrate a hypermetabolic phenotype associated with enhanced glutamine utilization as assessed by Seahorse mitochondrial stress tests. Unexpectedly, deprivation of glutamine led to the detachment of live ΔSTK11 cells, measured by trypan blue exclusion and annexinV/PI staining, that maintained the ability to re-adhere and proliferate in nutrient replete media. Furthermore, ΔSTK11 cells upregulated anti-apoptotic and EMT marker expression in the absence of glutamine. Invasive capacity was assessed using a spheroid model, and while parental spheroids were unaffected by glutamine deprivation, ΔSTK11 spheroids displayed enhanced ameboid-like single cell invasion. To determine the mechanism(s) underlying this metastatic phenotype, we employed heavy nitrogen labeling, which revealed an upregulation of the hexosamine biosynthetic pathway (HBP) upon glutamine deprivation in ΔSTK11 cells. The HBP is an offshoot of glycolysis that serves as a central hub to regulate many cancer fitness pathways via the production of UDP-GlcNAc - a sugar moiety used for generation of glycosylation intermediates or O-GlcNAcylation. Far western blot analysis validated that ΔSTK11 cells have increased O-GlcNAcylation upon decreased glutamine availability. Treatment with FR054, an inhibitor of the intermediate HBP enzyme, PGM3, decreased metastatic potential of ΔSTK11 cells as measured by anchorage independent survival and 3D-spheroid invasion. These results suggest ΔSTK11 cells utilize the HBP as a protective shunt in response to glutamine deprivation, undermining the potential benefit of glutaminase inhibitors (i.e. “glutamine starvation”) as a therapeutic intervention in KS LUAD patients. Future work aims to further elucidate the role of the HBP in promoting metastasis and to determine the mechanism(s) by which ΔSTK11 cells regulate the HBP. Overall, our data reveal novel insight into the molecular mechanisms altered downstream of STK11 loss linking glutamine metabolism with metastatic potential in KRAS-driven LUAD.

#5392 Breast cancer cells that preferentially metastasize to lung are more adaptable to varying glucose levels compared to those that metastasize to the liver.

Marjorie Anne A. Layosa[1], Mike Wendt[2], Stephen Hursting[3], Dorothy Teegarden[1]

[1]Department of Nutrition Science, College of Health and Human Sciences, and the Institute for Cancer, Purdue University, West Lafayette, IN,[2]Department of Internal Medicine, and Holden Comprehensive Cancer Center, University of Iowa, Iowa, IA,[3]Department of Nutrition, Nutrition Research Institute, and Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Metastasis is the primary cause of breast cancer-related deaths. We investigated the metabolic adaptations of glucose, a major energy substrate, in breast cancer cells that metastasize to lung versus liver to determine the metabolic adaptations that may support site-specific metastasis. Utilizing a breast cancer model that preferentially metastasizes to the lung (metM-Wnt^{Lung} cells; MLg) or liver (metM-Wnt^{Liver} cells; MLr), we measured ^{14}C-glucose uptake, $^{13}C_6$-glucose flux into metabolic pathways, and viability under varying glucose concentrations. Results show that in 5 mM glucose (normal), MLg is more glycolytic with greater flux of $^{13}C_6$-glucose-derived carbons into the glycolytic intermediates pyruvate and lactate in comparison to MLr. In contrast, MLr showed higher levels of $^{13}C_6$-glucose-derived carbons in the tricarboxylic acid cycle metabolites including oxaloacetate and malate indicative of higher oxidative phosphorylation and higher pyruvate carboxylase (PC) activity. Interestingly, high glucose (25 mM) exposure reduced viability of MLr by 39%, suggesting MLg's adaptability to varying glucose levels. Although glucose uptake similarly increased in all cell lines under high glucose, flux results showed greater oxidative phosphorylation and increased PC activity in MLg, while MLr shifted to a more glycolytic phenotype. These results were consistent with improved oxidative stress protection in high glucose in MLg, but not MLr. Further, MLg deprived of glucose were more viable (9%) compared to MLr, suggesting a potential alternate use of other substrates to overcome glucose deprivation. Inhibiting the rate-limiting enzyme for gluconeogenesis, phosphoenolpyruvate carboxykinase, reduced viability of MLg by 9% compared to MLr. Further, inhibiting the catabolism of glutamine, a gluconeogenic substrate, reduced viability of MLg by 13% compared to MLr, suggesting that MLg utilizes the contribution of glutamine and gluconeogenesis in conditions of low glucose. Overall, breast cancer cells with preferential metastasis to lung are more adaptable to varying glucose concentrations than breast cancer cells with preferential metastasis to liver by shifting metabolism from glycolysis to oxidative phosphorylation under high glucose conditions and utilizing glutamine and gluconeogenesis under low glucose conditions.

#5393 Cancer cells surviving chemotherapy reprogram glucose and glutamine metabolism to combat oxidative stress.

Melvin Li, Luke V. Loftus, Sarah R. Amend, Kenneth J. Pienta

Johns Hopkins University School of Medicine, Baltimore, MD

Therapy resistance is the leading cause of cancer-related deaths across all tumor types. Our group has discovered a novel resistance mechanism where cancer cells enter a reversible non-proliferative state in response to chemotherapy. These cells exhibit a 40-fold increase in cell size and an increase in DNA content when compared to their proliferative counterparts. Cells surviving in this state eventually produce progeny that can repopulate the tumor, modeling cancer recurrence. This resistant phenotype has been reported in cell culture, pre-clinical mouse models, and in human patients. The surviving cells exhibited increased levels of reactive oxygen species (ROS) when compared to the untreated parental controls. It is well known that ROS is produced during oxidative metabolism, and cancer cells utilize a variety of mechanisms to neutralize oxidative radicals. Metabolic reprogramming is one of the main responses to oxidative stress, where cancer cells can better obtain resources from the extracellular environment and repurpose them to replenish their antioxidant defense systems. We hypothesize that cancer cells surviving in this non-proliferative state in response to cisplatin treatment alter their metabolism of major carbon sources to fuel antioxidant-generating pathways. Cells surviving chemotherapy exhibited an increase in glucose and glutamine consumption, but a decrease in lactate excretion and an increase in glutamate excretion when compared to the untreated parental population. We performed parallel labeling experiments with a variety of ^{13}C glucose and glutamine tracers to investigate how these carbon sources are broken down. We observed that surviving cells utilize glucose to fuel the pentose phosphate pathway (PPP), which is one of the major pathways to generate NADPH for ROS detoxification, rather than breaking it down through glycolysis. In addition, surviving cells exhibited decreased glutamine metabolism into the TCA cycle when compared to the parental cells. Thus, we hypothesize that cells surviving chemotherapy are consuming glutamine to generate glutamate for excretion. Single cell RNA sequencing data demonstrated that surviving cells exhibit an enrichment in NRF2 target genes such as SLC7A11, which encodes for a cystine-glutamate antiporter (system Xc) that exchanges glutamate for cystine, a major component in glutathione biosynthesis to combat oxidative stress. We are further characterizing these changes with mathematical modeling-based ^{13}C-metabolic flux analysis. Additionally, we are currently testing if cells surviving chemotherapy are susceptible to PPP and system Xc inhibitors. Our goal is to identify mechanisms of how cells in this resistant state reprogram their metabolism to survive therapeutic stress. Leveraging these key findings will provide insight for better treatment of therapy-resistant cancers and improve patient outcomes.

#5394 Transcriptional reprogramming, metabolic rewiring and tumor immune microenvironment (TIME) reconfiguration: investigating the molecular underpinnings of GRAMD2^{+}AT1 cell-derived murine LUAD.

Angel P. Hunt[1], Aaron Neely[2], Andrea Lanz[3], MauriAnna Richardson[1], Benecia Jackson[1], Zea Borok[4], Crystal N. Marconett[2]

[1]Integrative Translational Sciences, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Beckman Research Institute of The City of Hope, Duarte, CA,[3]Translational Genomics, University of Southern California, Los Angeles, CA,[4]Medicine, University of California, San Diego, La Jolla, CA

Arising from the distal alveolar epithelium, lung adenocarcinoma (LUAD) is the most common histological subtype of non-small cell lung cancer (NSCLC), accounting for approximately 40% of lung cancer cases. The distal lung houses a variety of cell populations in addition to alveolar epithelial type 1 (AT1) and type 2 (AT2) cells. The large, squamous-appearing AT1 cells facilitate gas exchange across the air blood barrier, while their smaller, cuboidal AT2 cell counterparts synthesize and secrete pulmonary surfactants to prevent alveolar collapse. It was previously believed that AT1 cells were terminally differentiated and devoid of tumorigenic properties, while AT2 cells that are capable of both self-renewal and differentiation to AT1 cells were designated as the primary cell of origin of LUAD. Our laboratory previously demonstrated that GRAMD2^{+} AT1 cells could serve as a cell of origin for KRAS-mediated murine LUAD (Yang M. *et al.*, 2023). In the current study, we investigated the functional roles of AT1 cells in EGFR-mediated LUAD tumorigenesis. We performed a longitudinal analysis spanning approximately 15 weeks where H&E-stained mouse lung tissues underwent a double blinded pathology review. We then employed spatial transcriptomic analysis to examine tumor cell composition, and the molecular underpinnings involved in cell of origin specific LUAD tumorigenesis at 5-, 10-, and 15-weeks post-activation of oncogenic transformation. Our findings illustrate that AT1 cell-derived LUAD undergoes significant transcriptional reprogramming, metabolic rewiring, and tumor immune microenvironment (TIME) reconfiguration over time. Our analysis revealed that Gramd2+ AT1 cell-derived tumors at 5 weeks exhibited a bioenergetic reliance upon mitochondrial OXPHOS, while AT1 cell derived LUAD tumors at 15 weeks exhibited metabolic flexibility as they underwent a glycolytic switch. As this metabolic rewiring and transcriptional reprogramming occurred, TIME reconfiguration also took place. At 5 weeks, tumors exhibited a robust anti-tumor immune response and infiltration, which declined by 15 weeks post tamoxifen administration. Furthermore, at 5 weeks there was significant extracellular matrix (ECM) remodeling and stromal promotion of angiogenesis (e.g. Vegfa, and Tgfb). This transcriptional reprogramming and metabolic rewiring may facilitate the observed progressive murine LUAD malignancy that occurs overtime. These findings provide key insights into the interchange between AT1 cell derived LUAD tumors and their TIME revealing potential metabolic vulnerabilities and targetable transcriptional events.

#5395 CDK12 regulates cellular metabolism to promote therapy resistance in glioblastoma.

Jeong-Yeon Mun[1], Chang Shu[1], Qiuqiang Gao[1], Hasan O. Akman[2], Mike-Andrew Westhoff[3], Georg Karpel-Massler[4], Markus D. Siegelin[1]

[1]Department of Pathology and Cell Biology, Columbia University Irving Medical Center, New York, NY,[2]Department of Neurology, Columbia University Irving Medical Center, New York, NY,[3]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany,[4]Department of Neurosurgery, Ulm University Medical Center, Ulm, Germany

Glioblastoma IDH-wildtype, the most common primary brain cancer in adults, has an exceedingly poor prognosis of only one to two years despite standard treatment involving surgery, temozolomide, and radiation. We evaluated patient-derived xenograft GBM cultures to determine their sensitivity to disrupting the function of CDK12, which was achieved through genetic manipulation, shRNA, or the novel inhibitor SR-4835. GBM metabolism was assessed using extracellular flux analysis and LC/MS-based carbon tracing. The in vivo efficacy was evaluated in orthotopic GBM mouse models. Comprehensive screening approaches identified CDK12 as essential for GBM growth. Consistently, inhibiting CDK12 function led to reduced growth in GBM PDX lines in vitro, but not in human astrocytes. Notably, SR-4835 inhibited GBM growth at low nanomolar concentrations and synergistically enhanced the potency of temozolomide. In vivo, SR-4835 activated cell death machinery related to intrinsic apoptosis. Metabolic analyses demonstrated that the loss of CDK12 function substantially impaired cellular respiration, coupled with the suppression of key metabolic transcriptional regulators, PGC1A and PPARD. This resulted in energy depletion and apoptotic cell death, partially mediated by the pro-apoptotic protein Noxa. The inactivation of CDK12 significantly extended the overall survival time without any harmful side effects in orthotopic mouse models of GBM. In some subjects, it also led to the complete elimination of brain tumors. When used together with temozolomide, blocking CDK12 eradicated brain tumors in all animals studied, indicating that CDK12 is a highly promising treatment target for GBM and providing a solid foundation for future clinical trials involving patients with this devastating disease.

#5396 NDUFA4L2 inhibits oxidative phosphorylation to drive primary tumor escape.

Emily Nicole Arner[1], Erin Q. Jennings[1], Daniel Crooks[2], Christopher J. Ricketts[2], Matthew A. Cottam[1], Kimryn Rathmell[2], Jeffrey C. Rathmell[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]National Cancer Institute, Bethesda, MD

Metastasis causes most cancer deaths and cancer cells require metabolic adaptation to spread to new tissues. However, the metabolic requirements of epithelial to mesenchymal transition (EMT) for primary tumor escape are uncertain. Analyses of Renal Cell Carcinoma (RCC) tumors found mesenchymal cancer cells had elevated expression of the mitochondrial electron transport inhibitor NDUFA4L2 and were glycolytic. NDUFA4L2 suppressed oxidative phosphorylation and was essential for EMT and spontaneous metastasis in RCC models. Mechanistically, NDUFA4L2 caused a build-up of TCA cycle intermediates and modified chromatin accessibility of EMT-related loci. This appeared due to altered mitochondrial oxidative phosphorylation, as increased electron transport complex 1 inhibited EMT and Fumarate Hydratase deficiency drove metastasis. Impaired oxidative phosphorylation thus drives EMT, which is essential for primary tumor escape and metastasis.

#5397 Role of pyruvate carboxylase in cancer-associated fibroblasts under tumor nutrient stress.

Michał Nizio[1], Marta Storl-Desmond[1], Kevin Munoz Forti[1], Julien Guillard[1], Shan Cao[1], Kristof Turan[1], Alexander Muir[2], Simon Schworer[1]

[1]Section of Hematology and Oncology, Department of Medicine, The University of Chicago, Chicago, IL,[2]Ben May Department of Cancer Research, The University of Chicago, Chicago, IL

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and hard-to-treat cancer types. PDAC is characterized by desmoplastic stroma enriched with extracellular matrix (ECM), immune cells and cancer-associated fibroblasts (CAFs). CAFs modulate PDAC progression by producing ECM and signaling molecules that influence cancer and immune cell function. Previous efforts to target CAFs' role in PDAC were unsuccessful but have instead revealed substantial heterogeneity within the CAF population. Two main subtypes of CAFs are tumor-restraining myofibroblastic CAFs (myCAFs) and tumor-promoting inflammatory CAFs (iCAFs). To effectively target CAFs in PDAC, there is a need to find CAF-state-specific vulnerabilities and mechanisms regulating CAF state. We discovered that myCAFs are excluded from hypoxic and nutrient-stressed regions of PDAC, and iCAFs are selectively enriched in those regions. Pyruvate carboxylase (PC) is an enzyme that allows cells to utilize pyruvate as an anaplerotic substrate. Our previous work showed that PC is important for CAFs under nutrient-stressed conditions. Here, we hypothesize that PC is required to promote the iCAF state and support their growth in the nutrient-stressed environments they occupy. To address this hypothesis, we acclimated pancreatic stellate cells (PSCs), CAF precursors in PDAC, to physiological media resembling the concentration of nutrients in human plasma (HPLM - human plasma-like medium) or PDAC (TIFM - tumor interstitial fluid medium). We used CRISPR/Cas9 to delete PC, allowing us to investigate the role of PC in PSCs under physiological conditions. We observed that PC expression is higher in cells cultured in TIFM than in HPLM or conventional RPMI. We confirmed higher PC activity in TIFM compared to HPLM or RPMI cultured cells using stable isotope tracing. These findings indicate that PC expression and activity are regulated by the nutrient conditions present in PDAC and suggest that PC might be selectively important in CAFs under tumor nutrient stress. A better understanding of PC's role in CAFs residing in nutrient-stressed niches in PDAC may lead to the discovery of a novel way of targeting tumor-promoting iCAFs.

#5398 Inhibition of PHGDH suppresses mTOR signaling and metabolic reprogramming in TSC2-deficient lymphangioleiomyomatosis cells.

E. K. Abor, E. Y. Zhang, J. J. Yu;
University of Cincinnati, Cincinnati, OH

Lymphangioleiomyomatosis (LAM) is a rare, progressive neoplastic disease primarily affecting women, characterized by TSC1/2 mutations' driven mTORC1 hyperactivation and the proliferation of abnormal smooth muscle-like cells within the lungs and lymphatics. Despite rapalogs ability to stabilize lung function and limit LAM tumorigenesis, they are cytostatic and tumors regrow post treatment cessation. As such, with mTORC1 being nutrient sensitive, it is of note that understanding and targeting metabolic vulnerabilities in the disease could induce LAM tumor cell death and limit associated lesions. Emerging evidence suggests that serine and the serine biosynthesis enzyme, PHGDH (phosphoglycerate dehydrogenase), may support mTOR-driven anabolic processes in LAM. This study investigated the effects of PHGDH inhibition on mTOR signaling, cell survival, mitochondrial function, and metabolic reprogramming in TSC2-deficient LAM cells. PHGDH expression was evaluated in human LAM lung tissue and nodules using immunohistochemical staining. In HPLM media, TSC2-deficient LAM (621-101) and their control TSC2-add back (621-103) cells were treated with a selective PHGDH inhibitor. mTOR, S6, and their phosphorylated levels were measured via Western blot, and autophagic flux was monitored by immunofluorescence staining targeting LC3-II expression. Mitochondrial membrane potential and biogenesis were assessed using TMRE staining and Western blot targeting PGC-1a and TFAM. Additionally, the effect of PHGDH on LAM cell growth and in metabolic reprogramming in LAM cells was analyzed respectively using CCK-8 and by examining the expression of key Warburg effect and anabolic synthesis markers such as G6PD and PKM2. PHGDH was highly expressed in LAM lung tissues and nodules, implicating its role in LAM progression. PHGDH inhibition in TSC2-deficient LAM cells significantly reduced mTOR, ATF4 and S6 ribosomal protein phosphorylation, suppressed mitochondrial membrane potential, and decreased mitochondrial biogenesis by inhibiting PGC-1a and TFAM protein levels. Furthermore, PHGDH inhibition induced RB1 phosphorylation with a reduction in E2F1 alongside total RB1 protein expression inhibition while, with rapamycin, upregulated autophagy, as indicated by increased LC3-II expression in autophagic flux quantification. This study, thus, discovers a significant LAM cell growth and Warburg effect inhibition by a downregulated G6PD and PKM2 protein expression post PHGDH inhibition. These results suggest that PHGDH supports mTOR-driven metabolic reprogramming in LAM. Targeting PHGDH significantly reduces mTOR signaling, mitochondrial function, and impairs glycolysis and PKM2 mediated Warburg effect in LAM cells. PHGDH inhibition may offer a novel therapeutic strategy to enhance mTORC1 inhibitors' efficacy and overcome resistance in LAM management.

#5399 Placental gene PEG10 promotes onco-fetal metabolic reprogramming in hepatocellular carcinoma.

Dong Yin, Xinyi Yao, Jingyuan Zhang, Yin Zhang, Jianyou Liao, Kaishun Hu, Jiehua He, Daning Lu

Sun Yat-sen University, Guangzhou, China

Tumorigenesis is a complex biological process, accompanied by cellular dedifferentiation and metabolic reprogramming, which similarities to the metabolic characteristics of embryonic development stages. In our research, we focused particularly on the RNA-binding protein PEG10, which is highly expressed in the placenta and found to be similarly overexpressed in liver cancer cells, playing a key role in the process of aerobic glycolysis in tumor cells. This discovery suggests that there may be a phenomenon of fetal-like metabolic reprogramming in hepatocellular carcinoma (HCC), which is of significant importance for understanding the pathogenesis of HCC and for seeking new therapeutic strategies. In hepatocellular carcinoma (HCC) cells, we found that PEG10 enhances the stability of mRNA for key glycolytic genes hexokinase2 (HK2) and Glucose transporter 1 (GLUT1) by inhibiting the STAU1-mediated RNA degradation pathway, thereby promoting aerobic glycolysis in tumor cells. This process not only promotes the proliferation of tumor cells but also reduces the sensitivity of tumor cells to sorafenib. Furthermore, we observed in clinical samples that high expression of PEG10 is closely associated with poor prognosis in HCC patients, further confirming the important role of PEG10 in the development of HCC. Our research also found that retinoic acid can effectively inhibit aerobic glycolysis in tumor cells by suppressing the transcriptional expression of PEG10, thereby inhibiting the growth of tumor cells. In animal models, mice with liver-specific PEG10 gene knockout showed significant resistance to oncogene-induced liver cancer occurrence and development, providing strong evidence for PEG10 as a therapeutic target. These findings not only reveal the biological link between PEG10 and onco-fetal metabolic reprogramming at the molecular level but also indicate from a clinical perspective that PEG10 may be a potential biomarker and therapeutic target for HCC. The high expression of PEG10 is associated with poor prognosis in HCC patients, and the inhibitory effect of retinoic acid on PEG10 expression provides a new strategy for the treatment of HCC. These results provide new ideas for the future diagnosis and treatment of HCC, especially in the development of targeted therapeutic drugs against PEG10, which has important application prospects. Our research has laid a solid foundation for a deeper understanding of the metabolic reprogramming mechanisms of HCC and the development of new therapeutic methods.

#5400 SEPHS2 loss reprograms glucose metabolism to activate the pentose phosphate pathway by stabilizing PCK1 through NAD(+).

Y. Zhang, Q. Zhang, W. Zhang, W. Ding, B. Zhang, S. Xia;
Southern University of Science and Technology (SUSTech Shenzhen), Shenzhen, China

Selenium is an essential trace mineral that plays a crucial role in metabolism, primarily through its incorporation into selenoproteins. However, whether and how selenium modulates glucose metabolism in cancer cells remains unclear. This study focuses on SEPHS2, a key enzyme in synthesizing selenoproteins, which converts hydrogen selenide into selenophosphate. We found that *SEPHS2* knockout inhibits both glycolysis and oxidative phosphorylation (OXPHOS), as indicated by an seahorse assay. Interestingly, *SEPHS2* loss redirects more glucose to the pentose phosphate pathway. Mechanistically, *SEPHS2* knockout elevates NAD+ levels, which are essential for SIRT2/3 enzymatic activity. The increase in the activity of SIRT2/3 leads to deacetylation of PCK1, a posttranslational modification required to prevent PCK1's ubiquitination and subsequent degradation. Thus, *SEPHS2* knockout stabilizes PCK1 by reducing its ubiquitination. Since PCK1 is a key regulator of gluconeogenesis, *SEPHS2* knockout promotes gluconeogenesis while reducing cellular glucose uptake, suppressing glycolysis, down-regulating oxidative phosphorylation and enhancing the pentose phosphate pathway. Collectively, our findings define the selenium-metabolizing enzyme SEPHS2 as a key regulator of glucose metabolism, guiding cancer cells in choosing between glycolysis and the pentose phosphate pathway. This study offers valuable insight into the essential role of selenium metabolism in maintaining glucose homeostasis.

#5401 Revealing the influence of reprogrammed PI3K and glucose metabolism on the progression of hormone-refractory and metastatic prostate cancer.

Prathiksha Prabhakaraalva, Nabila Zaman, Sarah Ann King, Goutam Chakraborty

Icahn School of Medicine at Mount Sinai, New York, NY

Background: Prostate cancer, despite advancements in early detection and therapies, remains an incurable disease when it transform to metastatic and castration-resistant. A significant knowledge gap exists in understanding the mechanistic insights that drives hormone-refractory progression and metastasis. The PI3-Kinase pathway, altered in over >50 % of metastatic prostate cancer cases, plays a pivotal role in oncogenesis and therapy resistant. Although PTEN deletions are well-characterized, the specific contributions of other PI3K pathway components, particularly PIK3R1 mutations, remain underexplored. Our previous study reported that PIK3R1 mutations are highly enriched in metastatic castration-resistant prostate cancer (mCRPC) and are associated with increased glucose uptake detected by FDG-PET scans. Therefore, these mutations are crucial for further investigation.
Method: We generated 22 patients derived naturally occurring prostate cancer specific PIK3R1 mutations by site directed mutagenesis and verified their expression by western blotting. Using CRISPR and shRNA we have also established double PIK3R1-PTEN null prostate cancer cells. Prostasphere experiments was performed to analyzed the impact of these double loss on prostate cell growth in vitro Isogenic pairs of these double-knockout prostate cancer cells were treated with increasing concentrations of insulin in the under serum starvation to study the impact of PIK3R1-PTEN loss on reprogramming of insulin-glucose metabolism and oncogenic signaling pathways associated with this reprogramming
Results: Our results reveal that PIK3R1 mutations exhibit distinct, mutation-specific effects on PI3K-AKT signaling, where some variants induce AKT phosphorylation and destabilize PTEN, while others inhibit AKT and stabilize PTEN, underscoring diverse roles of specific PIK3r1 mutation within the PI3K pathway. Interestingly, PIK3R1-KO cells displayed heightened androgen receptor (AR) pathway activity and enhanced tumor sphere formation, suggesting increased tumorigenic potential. Furthermore elevated levels phosphorylated mTOR in PIK3R1 knockout clones indicate potential mechanisms of oncogenesis, which may further drive metastatic progression. Our primary data also demonstrated that insulin treatment in PIK3R1-PTEN null cells alters androgen receptor (AR) function, indicating a direct association between PIK3R1-PTEN-glucose metabolisms and AR-signaling that is crucial for prostate tumor growth.
Conclusion: Our findings emphasize the critical role of PIK3R1 in both AR and PI3K-AKT-mTOR signaling cascades, offering insights into the complex interplay of PIK3R1 mutations in therapy-resistant prostate cancer. This research underscores the need to explore mutation-specific PIK3R1 effects as we move toward more personalized therapies for lethal mCRPC.

#5402 Metabolic shift towards the *de novo* serine pathway in non-transformed breast cells drives epigenetic plasticity, oxidative DNA damage, and pro-tumorigenic cChanges associated with aging.

Mariana Bustamante Eduardo[1], Gannon Cottone[1], Curtis McCloskey[2], Flavio Palma[1], Shiyu Liu[3], Maria Paula Zappia[4], Abul B.M.M.K. Islam[4], Elizaveta Benevolenskaya[4], Maxim Frolov[4], Jason Locasale[3], Marcelo Bonini[1], Rama Khokha[2], Navdeep Chandel[1], Seema A. Khan[1], Susan E. Clare[1]

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]Duke University, Durham, NC,[4]University of Illinois at Chicago, Chicago, IL

Introduction: A lipid metabolism gene signature is enriched in breast tissue at risk for estrogen receptor negative (ERneg) breast cancer (BC). Fatty acid (FA) exposure alters histone methylation, gene expression and increases metabolic flux through serine, one-carbon, glycine (SOG) and methionine pathways. We hypothesize that FA exposure induces a metabolic shift towards the SOG, increasing S-adenosylmethionine (SAM), altering histone methylation, gene expression, and promoting ERneg BC.
Methods: Proteomics, metabolomics, Reactive Oxygen Species (ROS) measurement, comet assay and H3K4me3 CUT&RUN were performed in MCF-10A cells exposed to octanoic acid (OA). Single-cell RNA-seq (scRNAseq) was performed in breast tissue derived microstructures exposed to OA. Intracellular communication was analyzed using CellChat, and metabolic flux with Compass.
Results: OA increased SAM, glutathione (GSH) and 2-hydroxyglutarate (2-HG); blocking the serine pathway (SSP) prevented these increases. ScRNAseq revealed that OA increased expression of the SSP transcription factor ATF3 and genes PHGDH and PSAT1 in epithelial and stromal compartments. Metabolic flux analysis revealed a significant increase in flux through SSP in Basal BSL1, Luminal Progenitor LP3, and Hormone Sensing HS1 cells after OA exposure. Differential proteomics reveals PHGDH overexpression and downregulation of proteins involved in extracellular matrix (ECM)-receptor interaction and focal adhesion post-OA exposure, along with significant increase in mitochondrial and nuclear ROS ($p < 0.01$). OA exposure also induced DNA damage, likely due to elevated nuclear ROS. OA increased GSH metabolism and ROS detoxification in BSL1. CUT&RUN identified 661 peaks significantly enriched upon OA (FDR < 0.01) in regulatory regions of OA-induced genes involved in neural pathways and BC, including MDK, NGF, and NGFR. CellChat predicted a decrease in ECM-cell interactions, a reduction in cell-cell adhesions, and an increase of secreted signaling upon OA exposure. The strongest secreted signals in OA were AREG (linked to proliferation, growth, and invasiveness), GDF15 (involved in EMT, invasion, and aging), and MDK (linked to neurogenesis, and aging).
Conclusions: We demonstrate an FA-induced shift towards the SOG and methionine pathways that promotes epigenetic plasticity, regulates ROS, and supports the survival of cells with 'inappropriate' phenotypes. These accumulate DNA damage, leading to age-related changes in the mammary gland (elevated ROS, disrupted junctions, altered ECM interactions, and increased MDK/GDF15 expression), all supporting carcinogenesis. Our findings also provide a metabolic explanation for the elevation of PHGDH in 70% of ERneg BCs, despite gene amplification in only 6%, and point to preventive strategies targeting the SSP.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: S/G2/M phase

#5406 Evaluation of antitumor effects of plogosertib, PLK1 inhibitor in biliary tract cancer with BUBR1 as a potential biomarker.

Yoojin Jeong[1], Ah-Rong Nam[1], Kyoung-Seok Oh[1], Jae-Min Kim[1], Ju-Hee Bang[1], Sea Young Choo[1], Hyo Jung Kim[1], Jeesun Yoon[2], Tae-Yong Kim[2], Do-Youn Oh[2]

[1]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Polo-like kinase 1 (PLK1) has been emerging as a promising therapeutic target in solid tumors due to its central role in cell cycle regulation and cancer cell proliferation. In biliary tract cancer (BTC), cell cycle-related factors such as PLK1, CDKs, and Aurora kinase are frequently overexpressed or aberrantly activated, driving tumor progression. However, studies targeting these proteins in BTC remain limited. BUBR1, a critical mitotic checkpoint protein, is essential for maintaining chromosomal stability by ensuring proper chromosome alignment and segregation during cell division. This study evaluated the antitumor effects of a PLK1 inhibitor plogosertib in BTC and identified BUBR1 as a potential biomarker to predict treatment response.
Methods: Total 9 BTC cell lines (SNU-245, SNU-308, SNU-478, SNU-869, SNU-1196, HuCCT-1, TFK-1, SNU-2670, SNU-2773) were used. We used plogosertib (PLK1 inhibitor), ceralasertib (ATR inhibitor) and panobinostat (HDAC2/3 inhibitor). The anticancer effects of plogosertib, both alone and in combination with ceralasertib and panobinostat, were evaluated through MTT assay, Colony formation assay, Annexin-V assay, and Cell cycle analysis. The effect of plogosertib on mitotic arrest was assessed using phospho-histone H3 assay and Immunofluorescence.
Results: Plogosertib monotherapy showed higher anticancer effects in BUBR1-high BTC cells (SNU2773, SNU478) compared to BUBR1-low cells (SNU869, SNU245). Plogosertib promoted mitotic checkpoint complex (MCC) formation in prometaphase, arresting mitosis and ultimately leading BTC cells to undergo apoptosis. However, plogosertib also induced ATR activation, which may limit its efficacy by initiating DNA repair pathways. ATR inhibition by ceralasertib further enhanced the anticancer effects of plogosertib in BUBR1-high cells. In BUBR1-low cells, plogosertib reduced BUBR1 protein expression, possibly through ubiquitination-proteasome-mediated degradation, limiting MCC formation and its therapeutic effects. Among several candidates regulating ubiquitination processes, HDAC2/3 inhibition by panobinostat enhanced the responsiveness of BUBR1-low cells to plogosertib.
Conclusion: BTC cells with high BUBR1 expression are sensitive to the PLK1 inhibitor plogosertib, which shows synergistic effects when combined with an ATR inhibitor. In contrast, BTC cells with low BUBR1 expression which are relatively insensitive to plogosertib, HDAC2/3 inhibition increases the sensitivity to plogosertib. These findings suggest that targeting PLK1 could be an effective strategy for BTC treatment, especially with BUBR1 expression as a potential biomarker to inform optimal combination therapies.

#5407 Identifying synthetic lethality targets in DDX41-mutated MDS/AML.

Sohaumn Mondal, Shizuo Yang, Vincent Maranda, Frederick Vizeacoumar, Franco Vizeacoumar, Yuliang Wu

Department of Biochemistry, Microbiology and Immunology, University of Saskatchewan, Saskatoon, SK, Canada

DDX41 (DEAD-box helicase 41) is a member of the DEAD-box helicase family, critical for RNA metabolism and genome stability. Mutations in *DDX41* are strongly associated with myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML), particularly in patients carrying inherited mutations or somatic alterations. Among these, the R525H missense mutation in *DDX41* is found in over 70% of affected individuals, impairing helicase activity and contributing to disease pathology. Directly targeting mutant DDX41 (e.g., R525H) with inhibitors remains challenging due to the structural similarity of mutant and wild-type (WT) proteins, as well as the conserved helicase domains shared by the 37 DEAD-box helicases in humans. To overcome these challenges, we are leveraging synthetic lethality (SL) as an innovative therapeutic strategy. Bioinformatic analyses identified potential SL partners of *DDX41*, including *WRN* and *DDX23*. Functional validation experiments revealed that inhibiting WRN helicase selectively impairs the growth of *DDX41*-deficient cells. In *DDX41*-knockout HeLa cells, treatment with WRN inhibitors NSC 617145 and HRO761 significantly reduced cell growth compared to WT controls. Similarly, in *DDX41*-knockdown U2OS cells, WRN inhibitors markedly inhibited cell proliferation compared to WT cells. Future studies aim to elucidate the molecular mechanisms underlying SL interactions between *DDX41* and its partners, providing insights into the therapeutic potential of targeting these vulnerabilities. This work offers a promising avenue for developing novel treatments for MDS/AML patients harboring *DDX41* mutations, ultimately improving clinical outcomes.

#5408 Unraveling c-MYC role in DNA replication origin licensing through non-canonical pathways.

D. Fleifel[1], E. Elkoumy[1], A. Adavikolanu[1], S. Qayyum[2], J. Cook[1];
[1]UNC Chapel Hill, Chapel Hill, NC, [2]Duke University, Durham, NC

Origin licensing is essential for DNA replication, confined to the G1 phase of the cell cycle, where human cells must license thousands of origins to ensure complete genome duplication. Insufficient licensing, or "underlicensing", leads to genome instability and increased sensitivity to chemotherapeutic agents. Altered G1 duration and dysregulated origin licensing are characteristic features of many cancers, potentially contributing to their aberrant cell proliferation. However, how origin licensing rates are controlled in cells with varying G1 lengths is poorly understood. Our research reveals that while cyclin E1 overproduction shortens G1 and causes severe underlicensing, c-MYC overproduction also shortens G1 but uniquely accelerates licensing, preventing underlicensing. *We identified a separation of function c-MYC mutant that fails to induce rapid licensing despite upregulating mRNA levels of licensing factors akin to wild-type c-MYC, indicating the involvement of non-canonical pathways beyond traditional transcriptional mechanisms*. c-MYC influence on global chromatin structure through hyperacetylation is pivotal. Our data show that c-MYC's role in licensing acceleration depends on the recruitment of TRRAP—a transcription cofactor involved in chromatin modification—and the histone acetyltransferase GCN5. Notably, euchromatin is preferred for origin licensing in early G1. We hypothesize that heterochromatin may be rapidly licensed in c-MYC overproducing cells to compensate for potential underlicensing. We are currently profiling early versus late G1 cells overproducing c-MYC to determine the genomic locations of the licensed origins. Unraveling c-MYC downstream pathways regulating origin licensing could revolutionize therapeutic strategies by precisely controlling proliferation in MYC-driven cancers, increasing their sensitivity to DNA-damaging treatments, and paving the way for targeting non-canonical pathways in cancer therapy.

#5409 Asymmetric interdependency among the CDK8 module subunits.

Tzu-Hao Liu[1], Xiao Li[2], Fu-Ning Hsu[3], Mengmeng Liu[1], Rajitha-Udakara-Sampath Hemba-Waduge[1], Jun-Yuan Ji[1]

[1]Biochemistry and Molecular Biology, Tulane University School of Medicine, New Orleans, LA,[2]Lewis-Sigler Institute, Princeton University, Princeton, NJ,[3]Bionova Scientific Inc, Fremont, CA

The CDK8 kinase module (CKM) of the transcriptional cofactor Mediator complex plays a pivotal role in regulating RNA polymerase II-dependent transcription. Dysregulation of the CKM has been implicated in various diseases, as CDK8 overexpression promotes tumorigenesis in colorectal cancer and melanoma, CKM subunits are mutated or amplified in other types of cancers and cardiovascular diseases. Understanding the *in vivo* functions and regulatory mechanisms of the CKM and Mediator complexes is essential for uncovering their contributions to tumorigenesis. Previous studies showed that the loss of CKM subunits in *Drosophila* resulted in distinct phenotypes, particularly in the eyes and wings. In this study, we observed that loss of Med13 and Med12 caused more significant reductions in multiple biological functions compared to the effects observed with CDK8 and CycC. Depleting individual CKM subunits revealed that Med13 has the strongest influence on cell growth and cell proliferation, likely due to differences in the rate of nascent protein synthesis. This hierarchy is followed by Med12 and then the CDK8-CycC complex, suggesting a differential impact of these CKM subunits at the cellular level. Immunoblot analyses further revealed that the stability of CDK8 and Med12 depends on the presence of Med13 in *Drosophila*. These findings support the hypothesis that CKM subunits are asymmetrically interdependent. Furthermore, knockdown of CKM subunits via lentiviral transduction in human LnCaP cells confirmed this asymmetric interdependency in mammalian systems. Taken together, our results suggest the stability and asymmetrical dependence of CKM subunits play a critical role in regulating nascent protein synthesis, cellular growth, and proliferation, with Med13 serving a critical role within the CKM module.

#5410 CDK9 pharmacological inhibition has antitumor activity in marginal zone lymphoma models and can improve the effects of BTK, PI3K, and BCL2 inhibitors.

Alberto J. Arribas[1], Eleonora Cannas[1], Davide Rossi[1], Anastasios Stathis[2], Diane Heiser[1], Francesco Bertoni[1]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]Oncology Institute of Southern Switzerland, Ente Ospedaliero Cantonale, Bellinzona, Switzerland

Background: CDK9 inhibition rapidly down-regulates oncogenes, such as MYC, MCL1, PIM and PI3Ks. Indeed, CDK9 inhibitors, either as a single agent or in combination, can decrease proliferation and induce apoptosis in preclinical models of B cell lymphomas and show promising early signs of activity in B cell lymphoma patients (Diamond et al, CCR 2022; Frigault et al, Can Res Com 2023; Jiang et al, Biomark Res 2024). PRT2527 is a highly selective, ATP-competitive, CDK9 inhibitor with preclinical activity in diffuse large B cell lymphoma, mantle cell lymphoma, and chronic lymphocytic leukemia (Fultang et al, AACR 2024). PRT2527 has shown favorable tolerability, with manageable toxicity in a phase 1 study for solid tumor patients (Patel et al, ENA 2023), and it is now in phase 1 as a single agent and in combination with the BTK inhibitor zanubrutinib for hematological cancers patients (NCT05665530). Here, we studied PRT2527 in models derived from marginal zone lymphoma (MZL), including derivatives with acquired resistance to PI3K, BTK, and BCL2 inhibitors.
Methods: MZL cell lines (VL51, Karpas1718, SSK41, ESKOL, HC1, HAIRM) and their derivatives with secondary resistance to targeted agents obtained by long drug exposure (n.=3 from VL51, n.=1 from Karpas1718, n.=1 from SSK41; Arribas et al, Haematologica 2022, Mol Cancer Ther 2024, ENA 2019, ENA 2020, AACR 2024) were exposed to increasing concentrations of PRT2527 or DMSO (control) for 4 h and then washed out. Anti-proliferative activity was then assessed by MTT assay after 48 h.
Results: Despite the limited exposure time, CDK9 inhibitor PRT2527 exhibited antiproliferative activity in the nM range (average IC50 724nM; 95%CI, 467-981) across the MZL models. The anti-tumor activity was maintained in MZL cell lines with acquired resistance to PI3K, BTK, and BCL2 inhibitors. The combination of PRT2527 with the PI3K inhibitor idelalisib, with the BTK inhibitor ibrutinib, or triple combination with the PI3K inhibitor copanlisib and the BCL2 inhibitor venetoclax was beneficial in all parental cells, and the benefit was maintained, although reduced, in derivatives with acquired resistance to PI3K and BTK inhibitors. Only the VL51 model with resistance to copanlisib/venetoclax benefited from the addition of PRT2527 in the VL51 model, while no advantage was observed with the triple combination in the SSK41 derivative.
Conclusions: CDK9 inhibition with PRT2527 has in vitro antitumor activity in MZL models, which is maintained in models with acquired resistance to PI3K, BTK, or BCL2 inhibitors. CDK9 inhibition with PRT2527 can improve the sensitivity of MZL cells to BTK, PI3K, and BCL2 inhibitors.

#5411 The IL-23 receptor localizes intracellularly in AML and stem cells where it regulates mitotic spindle formation to maintain cell viability.

Nathan Duong[1], Dilshad H. Khan[1], Geethu E. Thomas[1], Yue Feng[1], Rose Hurren[1], Jong Bok Lee[2], Jonathan St-Germain[1], Lily Drimmer[1], Yongran Yan[1], Lan Xin Zhang[1], Dakai Ling[1], Mary L. Ma[1], Neil MacLean[1], Marcela Gronda[1], Vincent Rondeau[1], Brandon D. Brown[3], Laura Matellan[4], Courtney L. Jones[1], Hong Chang[2], Andrea Arruda[1], Stephanie Xie[1], Laurence Pelletier[4], Mark D. Minden[1], Li Zhang[2], Steven M. Kornblau[3], Brian Raught[1], Kevin Jacobs[5], Max G. Jacobs[5], Daniel Goede[5], Vito Spadavecchio[5], Aaron D. Schimmer[1]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Toronto General Hospital Research Institute, Toronto, ON, Canada,[3]MD Anderson Cancer Centre, Houston, TX,[4]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,[5]Interlinked Therapeutics, Portland, OR

IL-23 receptor (IL-23R) is canonically a T cell surface cytokine receptor known for its role in inflammatory diseases. In this study, we demonstrated that IL-23R localizes intracellularly in AML where it regulates mitotic spindle formation. Differential gene expressions were analyzed in AML samples compared to normal controls. Of the upregulated processes, the mitotic spindle ontology was most enriched. Analyzing all protein coding genes for their correlation to the mitotic spindle ontology surprisingly returned IL-23R as a top hit. We confirmed IL-23R expression in 7 of 7 tested AML cell lines and 15 of 20 primary AML patient samples. Protein expression was >2 fold higher in AML compared to normal hematopoietic (n=5) and CD34+ sorted cells (n=3).Canonical IL-23R cell surface expression was confirmed in T cells, but minimal amounts were detected on AML cells. Rather, in AML cells, primary AML samples, and AML stem cells, IL-23R was detected intracellularly as determined by 4 different modalities using 4 different epitope targeting antibodies. IL-23R's heterodimeric subunit, IL-12Rβ1, was also detected intracellularly in AML cells. We performed BioID mass spectrometry to identify novel interactors with IL-23R. Pathway analysis of interactors returned mitotic spindle formation as a top pathway. We confirmed interactions between IL-23R and mitotic spindle proteins (NuMA, TMEM201, TACC1, BAG6) via proximity ligation assays in bulk and leukemic stem cell (LSC) sorted AML cells. Furthermore, in bulk AML and LSC sorted fractions, we demonstrated that IL-23R colocalized with the mitotic spindle and centrosomes via confocal microscopy. IL-23R interacted with the mitotic spindle via its (S/T)x(I/L)P motif (amino acids 588-591). IL-12Rβ1 was also found at the mitotic spindle with exogenous IL-23 in culture promoting intracellular translocation of IL-23R. Depletion of IL-23R led to dysregulation of the mitotic spindle with spindle defects such as multipolarity and lagging chromosomes. Additionally, in IL-23R depleted mitotic AML cells, NuMA has decreased localization to mitotic spindle poles thus attenuating its ability to regulate mitotic spindle assembly. Knockdown of IL-23R reduced proliferation and clonogenic growth, reduced marrow engraftment, and increased differentiation of AML cells, thus demonstrating an effect on the leukemia initiating cells. In normal hematopoietic cells, however, knockdown of IL-23R did not impair engraftment. Consistent with this, constitutive homozygote IL-23R knockout mice had no difference in complete blood counts and stem cell number/function compared to wild type mice. In summary, intracellular IL-23R regulates mitotic spindle formation to maintain AML and stem cell growth and viability. We demonstrated a novel function and intracellular localization for IL-23R and its potential as a therapeutic target in AML.

#5412 Developing combination therapies for telomerase-overexpressing cancers.

V. Maranda, F. S. Vizeacoumar, Y. Zhang, L. Kyrylenko, A. Freywald, F. J. Vizeacoumar;
University of Saskatchewan, Saskatoon, SK, Canada

Cancer heterogeneity poses a significant medical challenge, necessitating therapies tailored not only to individual patients but also to the unique cancer clones that exist within diverse microenvironmental contexts. Despite this diversity, nearly all cancer cells share a reliance on telomeres to maintain genomic stability. The telomerase (hTERT) gene is hyperactive in many cancers and has been identified as a potential target for treatment. While this has led to the development of multiple telomerase-targeting approaches, disappointingly, none have been approved in clinical applications yet. To circumvent this concern, our team has applied a genetic approach called synthetic dosage lethality (SDL), to exploit hTERT overexpression to identify potential targets to treat cancer. SDL is a genetic concept, where a normally non-lethal gene inactivation kills cells only in the context of overexpression of another gene like hTERT. Our laboratories have used lentiviral-based pooled CRISPR/Cas9 and pooled shRNA-screening platforms to systematically query the genome and recently identified several SDL partners of hTERT. Through extensive validation using pooled *in vivo* CRISPR/Cas9 screens across multiple cell lines, tumor xenografts, and patient-derived organoids, we identified RMT1, an RNA 2'-O-methyltransferase, as a prominent SDL partner of hTERT. In collaboration with the AtomWise and Thoth Biosimulations companies, we have developed novel inhibitors for RMT1 that preferentially suppress hTERT-overexpressing cell lines growth and viability. We have also performed a large-scale screen of FDA-approved small molecule inhibitors with the goal of repurposing these drugs to target hTERT-overexpressing cancers. Subsequently, we plan to apply these therapies in combination to amplify the efficiency of treatment against cancers, yielding preclinical evidence to support the development of novel cancer therapies. Since hTERT activity is essential in all cancer cells, our findings introduce a transformative approach to overcoming cancer cell heterogeneity by targeting the SDL interactions of hTERT. This strategy also capitalizes on the ubiquitous overexpression of hTERT in all cancer types, enabling the selective eradication of hTERT-dependent malignancies.

#5413 Temporal regulation of c-Myc in endocycling cancer cells facilitates mitotic bypass in response to chemotherapy.

Michael Loycano, Kenneth J. Pienta, Sarah R. Amend

Johns Hopkins University School of Medicine, Baltimore, MD

Chemotherapy resistance remains a major challenge in clinical oncology. The mechanisms that regulate dynamic movement through adaptive cell states to survive through chemotherapeutic stress need to be understood to advance treatment options for patients and move towards curative therapies. In response to various stressors, cancer cells can reprogram their cell cycle, uncoupling DNA replication from mitotic division to acquire a large polyploid phenotype. This alternative cell cycle of repeated G and S phases is known as an endocycle, observed across the tree of life during both development and stress response. Cells exhibiting this phenotype exist in the transient endocycling cancer cell state. Endocycling cancer cells (ECCs) may serve as an actuator of chemotherapy resistance and disease recurrence. Understanding the mechanisms regulating the mitotic-to-endocycle switch and back are crucial to enhance treatments for patients with chemotherapy resistant cancer. A major driver of endocycling described in the literature is the transcription factor, c-Myc, due to its role in governing the G1/S transition. C-Myc is dysregulated in >70% of cancers, functioning as a critical cell cycle driver through transcriptional regulation of cyclins and CDKs, as well as essential metabolic programs necessary for cycle progression. Despite the published roles of Myc in both cancer and endocycling, we have shown through single cell RNA sequencing and western blotting that ECCs exhibit a low-Myc phenotype across multiple contexts. Myc protein levels can be rescued using the proteasome inhibitor, MG132, demonstrating that the low Myc status is driven by proteasomal degradation. To test if Myc degradation serves a mechanistic function, the small molecule inhibitor, MYCi975, was used to inhibit Myc activity at various points in the mitotic cell cycle. Our data shows that loss of Myc activity in cells beyond the restriction point induces mitotic bypass, generating a 4N G1 population. Notably, cells actively replicating their DNA in S phase show high sensitivity to Myc inhibition after skipping to G1, displaying cytotoxic effects not seen in other phases of the cell cycle. Similarly, when ECCs are challenged with the Myc inhibitor, the treatment promotes mitotic bypass and enriches for G0 and G1 populations, primed to enter the next S phase upon release from Myc inhibition. Together, these data suggest a temporal aspect of Myc regulation that has not been described in the literature. Myc activity beyond the restriction point appears to commit cells to mitotic entry, playing a functional role in coupling DNA replication to mitosis. This data supports our hypothesis that the low-Myc status of endocycling cells plays a mechanistic role in permitting mitotic bypass through premature loss of activity in G2. Preliminary data suggests that rescuing Myc activity will force mitotic entry producing mitotic progeny cells.

#5414 The RNA-binding protein HNRNPH1 regulates the expression of cell cycle-related genes to promote glioblastoma progression.

Genaro Villa[1], Paolo Alimonti[1], Joseph Toker[2], Raziye Piranlioglu[1], Andrew Chiocca[1], Alexa Lauinger[3], E. Antonio Chiocca[1], **Marco Mineo**[1]

[1]Brigham and Women's Hospital, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Carle Illinois College of Medicine, Urbana, IL

Heterogeneous nuclear ribonucleoprotein H1 (HNRNPH1) is a critical regulator of several aspects of RNA metabolism, including RNA stability and splicing. Alteration of the expression of RNA-binding proteins, such as HNRNPH1, has been shown to affect the RNA life cycle. This, in turn, results in the production of abnormal proteins that may promote the development of cancer. While aberrant expression of HNRNPH1 has been linked to several neuronal-related disorders, its role in the progression of glioblastoma (GBM), the most frequent and aggressive primary brain tumor, is still poorly understood. Given our previous findings that HNRNPH1 binds the RNA of several genes involved in cell-cycle regulation and cell proliferation, we hypothesized that HNRNPH1 regulates cell division and glioblastoma growth. Analyses of GBM patient data from The Cancer Genome Atlas database, combined with tissue microarray immunostaining and qPCR analyses of patient-derived tumors and patient-derived glioblastoma cells (PDGCs), revealed that *HNRNPH1* was upregulated in GBM compared to normal brain. Single-cell RNAseq data showed that *HNRNPH1* was more expressed in malignant cells than in other cells within the tumor microenvironment, and its expression was associated with specific cellular states. Knocking out *HNRNPH1* in both U87 cells and PDGCs using the CRISPR/Cas9 system caused the downregulation of several genes involved in cell division, such as *AURKB*, *ESPL1*, *PRC1*, and *UBE2S*. This was associated with an increased number of cells stuck in G2M, reduced cell proliferation, abnormal cell morphology, and an increase in polynucleated cells. Silencing *HNRNPH1 in vivo* suppressed the tumor growth of PDGC-originated intracranial xenografts and had significant survival benefits. Together, our results showed the critical importance of HNRNPH1 in cell cycle progression and tumor growth, with a potential impact on developing novel strategies to overcome the current limitations of GBM therapies.

#5416 Cyclin K deficiency suppresses tumor growth, activates systemic immunity, and confers vulnerability to chemotherapy in pancreatic cancer.

Y. Xiao, Y. Chen, J. Dong;
University of Nebraska Medical Center, Omaha, NE

Pancreatic cancer is a highly lethal disease worldwide, therefore, it is imperative to identify critical targets to inform alternative therapeutics in this disease. Cyclins and cyclin-dependent kinases (CDKs) are key drivers in the hallmarks of cancer, and important targets in clinical trials and cancer treatment. Proven as a druggable target in recent years, however, the function of Cyclin K in pancreatic cancer is still unknown. This study characterizes the role of Cyclin K in tumorigenesis, systemic immunity, and GemTaxol (gemcitabine and paclitaxel) sensitivity in pancreatic cancer, aiming to provide a pre-clinical basis for Cyclin K-targeted therapies in this disease. Data from TCGA and GTEx indicated that Cyclin K expression was high in pancreatic tumors, and elevated expression of Cyclin K was associated with shorter survival. Consistent with this finding, transgenic mouse models suggested Cyclin K expression was induced in KPC ($Kras^{G12D}$; $Trp53^{flox/flox}$; Pdx1-Cre) tumors, whereas homozygous deletion of Cyclin K in KPC mice ($Kras^{G12D}$; $Trp53^{flox/flox}$; Pdx1-Cre; $Ccnk^{flox/flox}$) offered survival benefit. Next, Cyclin K expression was depleted in pancreatic ductal adenocarcinoma (PDAC) cells to investigate the gene function. Inducible knockdown of Cyclin K restricted proliferation and G1-S transition of PDAC cells, while enhanced expression of Cyclin K promoted cell proliferation and cell cycle progression. Cell division cycle 20 (CDC20) was identified by a cell cycle array to mediate Cyclin K-induced cell proliferation. The loss of Cyclin K also hampered PDAC tumor growth in athymic nude mice. Interestingly, in immunocompetent mice, Cyclin K depletion not only attenuated tumor growth, but also led to some levels of complete tumor regression. Cyclin K deficiency-triggered systemic immunity was further examined by rechallenging the tumor-cleared mice with control murine cancer cells. As a result, the tumor clearance rate is 100% in these immunized mice. In addition, RNA-Seq identified immune response and inflammatory response to be the top 10 significantly altered gene ontology terms in Cyclin K-knockdown cells. Importantly, genetic depletion of Cyclin K synergized with GemTaxol to restrain PDAC tumor growth. Furthermore, the combination of GemTaxol and Cyclin K depletion, either by genetic or pharmaceutical methods, markedly induced apoptosis in cells. Finally, two PROTAC degraders (7f and YJ9069) were shown to exert significant anti-tumor growth effect in immunocompetent mice. Together, this work highlights that Cyclin K is a master regulator of tumor growth, immune response, and chemoresistance in PDAC, and a promising target for the treatment of pancreatic cancer.

#5418 Targeting PKMYT1 to preferentially kill tumor cells that have CCNE1 amplifications.

Samantha S. Hodge, Natalie Hill, Kayla Walzer, Ritu Kushwaha, Yihong Guan, Jeremy Fournier, Ester Fernandez-Salas

Arcus Biosciences, Inc., Hayward, CA

BACKGROUND: Cyclin E1 (CCNE1) amplification occurs in endometrial (40%), ovarian (20%), stomach (11%) and breast (3%) cancers and is associated with poor clinical outcomes. CCNE1 amplification deregulates the G1/S checkpoint and causes premature entry into S phase. Consequently, CCNE1 amplified cells depend on the G2/M checkpoint to ensure genomic stability before mitosis. PKMYT1, a member of the WEE1 family of enzymes, phosphorylates and inhibits CDK1 to regulate the G2/M checkpoint and prevent entry into mitosis. Here, we show that PKMYT1 inhibition in CCNE1-high cancer cells results in premature entry into mitosis, catastrophic DNA damage, and cell death. PKMYT1 inhibition also synergizes with chemotherapy to increase CCNE1-high cancer cell killing. Importantly, non-tumorigenic cells are not dependent upon PKMYT1 and do not exhibit DNA damage in response to PKMYT1 inhibition.

METHODS: An isogenic pair of CCNE1-low and CCNE1-high expressing cell lines was generated using lentiviral transduction. PKMYT1 was inhibited using Compound A, a tool small molecule PKMYT1 inhibitor. Inhibition of PKMYT1 was measured by CDK1 pT14 via western blot and HTRF. Cell cycle was monitored by flow cytometry using EdU and DNA content stains. DNA damage was measured by western blot and flow cytometry for yH2AX. Viability was measured with AlamarBlue and Caspase3/7. Bliss Synergy scores were calculated and used to assess synergy after combination treatments.

RESULTS: CCNE1 overexpression increases entry into S phase and dependence on the G2/M checkpoint (CDK1 pT14 and pY15 levels) without changing basal levels of DNA damage. While PKMYT1 inhibition decreases CDK1 pT14 in both CCNE1-low and CCNE1-high cells, only CCNE1-high cells exhibit decreased S phase and increased SubG1 (apoptotic) and G2/M phases. CCNE1-amplified breast and ovarian cancer cells display similar inhibition of CDK1 pT14, reduction of S phase, and increased DNA damage and cell death as a consequence of PKMYT1 inhibition. Combination treatment of PKMYT1 inhibition and chemotherapy synergistically reduced cell viability in CCNE1-amplified cancer cells. Non-tumorigenic cells are not dependent upon PKMYT1 and do not exhibit changes in the cell cycle or DNA damage after PKMYT1 inhibition. In contrast, WEE1 inhibition is detrimental to non-tumorigenic cells and induces cell cycle dysregulation and DNA damage.

CONCLUSIONS: The data presented here provide a rationale for targeting PKMYT1 in cancer cells that are dependent on the G2/M checkpoint to maintain genomic stability, such as CCNE1-amplified tumors. PKMYT1 inhibition selectively kills CCNE1-amplified cancer cells while sparing non-tumorigenic cells that have intact G1/S checkpoints. Our results highlight the importance of developing selective PKMYT1 inhibitors to avoid toxicities related to WEE1 inhibition.

#5419 Cyclin E1 overexpression as a predictive biomarker for PLK1 and WEE1 inhibitor efficacy in ovarian cancer.

Q. Xi[1], A. Kunita[1], M. Ogawa[1], M. Ka[1], S. Nagai[1], A. Matsunaga[2], K. Watanabe[1], T. Fukuda[1], K. Sone[1], K. Kawana[2], K. Katayama[3], H. Kage[1], K. Oda[1];

[1]The University of Tokyo, Tokyo, Japan, [2]Nihon University School of Medicine, Tokyo, Japan, [3]Nihon University, Chiba, Japan

Ovarian cancer remains a lethal malignancy with limited treatment options, particularly for platinum-resistant cases. Key molecular alterations in ovarian cancer include Cyclin E1 overexpression and *TP53* mutations, both of which disrupt cell cycle regulation and contribute to poor prognosis. Cyclin E1 overexpression drives unchecked G1/S progression, promoting treatment resistance. *TP53* mutations, common in high-grade serous carcinoma, impair checkpoints and increase genomic instability. These features underscore the urgency for cell cycle-targeted therapies. PLK1 and WEE1 inhibitors have shown promise by disrupting cell cycle control, but predictive biomarkers remain unclear.

Twelve ovarian cancer cell lines (5 high-grade serous [HGSOC], 5 clear cell [CCOC], and 2 endometrioid [EOC] ovarian carcinomas) were treated with the PLK1 inhibitor volasertib and the WEE1 inhibitor adavosertib to evaluate drug sensitivity, cell cycle effects, and apoptosis *in vitro*, as well as tumor growth *in vivo*. Cyclin E1 expression was elevated in 5 cell lines (2 HGSOC, 2 CCOC, and 1 EOC) and *TP53* was mutated in 6 cell lines (5 HGSOC and 1 EOC) out of 12 cell lines by qPCR and western blotting. Drug sensitivity assays revealed a strong correlation between Cyclin E1 expression levels and sensitivity to both volasertib and adavosertib. Cell lines with high Cyclin E1 expression showed significantly lower IC50 values compared to those with low/normal expression (volasertib: 0.022-0.089 μM vs. 0.311-28.1 μM, $p<0.05$; adavosertib: 0.071-0.346 μM vs. 0.368-90.4 μM, $p<0.01$). Cyclin E1 knockdown reduced sensitivity to both inhibitors ($p<0.001$), supporting its role as a predictive biomarker, whereas *TP53* status did not affect drug response. Flow cytometry showed distinct cell cycle effects of the inhibitors. Volasertib induced M-phase arrest and subsequent cell death, as indicated by a significant increase in the sub-G1 population in high Cyclin E1-expressing cells ($p<0.001$). Similarly, adavosertib dose-dependently increased sub-G1 cells and depleted G1-phase cells in high Cyclin E1-expressing cells ($p<0.001$). These effects were absent in low Cyclin E1-expressing cells. Both inhibitors elevated apoptosis markers and the DNA damage marker, γH2AX, in high Cyclin E1-expressing cells but not in low-expression cells. *In vivo*, volasertib and adavosertib significantly suppressed tumor growth in xenograft models derived from high Cyclin E1-expressing cells ($p<0.001$), with no significant effects observed in low-expression tumors. Both inhibitors induced cleaved PARP and γH2AX in high Cyclin E1-expressing tumors but not in low-expression models. Cyclin E1 overexpression, regardless of *TP53* status, may serve as a predictive biomarker for the efficacy of these inhibitors, thereby offering potential personalized treatment strategies for ovarian cancer.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Therapeutic Targets and Mitochondrial Function
Poster Session

#5423 A focused shRNA library screening identifies MRPL38 as an oncogenic regulator of lung cancer via regulation of mitochondrial homeostasis.

Jieun Seo, So Young Lee, Sangwon Byun, Kyung Chan Park

Personal Genomic Medicine Research Center, Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

To identify a novel gene that contributes to lung cancer progression, we performed RNA interference genetic screening combined with multi-omics analysis of never-smoker lung cancer cohort (GSE256091). As a result of the screening and MAGeCK analysis, mitochondrial ribosomal protein L38 (MRPL38) was identified as a positive regulator of lung cancer progression. Mitochondrial dysfunction and metabolic reprogramming are key features of lung cancer. Despite their significance, the precise underlying mechanisms of these processes and the role of MRPL38 in lung cancer progression have not been fully elucidated. A significant upregulation of MRPL38 was observed in lung cancer patient tissues, which was associated with advanced tumor stages and poor prognosis. Knockdown of MRPL38 significantly reduced cell viability and colony formation and increased apoptosis in human lung cancer cells. Moreover, MRPL38 has been found to be crucial for maintaining mitochondrial protein translation and homeostasis. Loss-of-function experiments targeting MRPL38 in various lung cancer cell lines resulted in alterations in oxidative phosphorylation (OXPHOS) complex proteins, oxygen consumption rate (OCR), and mitochondrial biogenesis. In MRPL38-deficient cells, the expression levels of proteins encoding subunits of the respiratory chain complexes were significantly reduced, and both basal and maximal mitochondrial respiration were decreased. Furthermore, the inhibition of MRPL38 was found to significantly reduce the mass and number of mitochondria associated with mitochondrial biogenesis. These results suggest that MRPL38, a novel regulator in lung cancer, may promote lung cancer progression by regulating mitochondrial homeostasis.

#5424 Exploring the potential role of PGC-1β in ovarian cancer malignancy.

Laura Formenti, Francesca Abramo, Giulia Dellavedova, Raffaella Giavazzi, **Carmen Ghilardi**

Oncology, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milano, Italy

Mitochondrial metabolism plays a role in tumor development and metastasis. PGC-1β is recognized as a key regulator of mitochondrial biogenesis and metabolic activity. We have recently demonstrated that PGC-1β is a biomarker of addiction to mitochondrial metabolism in ovarian cancer and determines sensitivity to OXPHOS inhibitors. Its role in cancer is largely unexplored, but some reports suggest that PGC-1β exerts pro-tumorigenic actions. We aim at unraveling the influence of PGC-1β on ovarian cancer malignancy and how it regulates ovarian cancer cell functions, besides its metabolic role. To this purpose, murine ovarian cancer cells were silenced for PGC-1β and their behavior characterized in vitro and in vivo. First, we confirmed that PGC-1β silencing caused an alteration of oxidative metabolism by Seahorse analysis, showing the reduction of oxygen consumption. Then, we found that PGC-1β depletion did not affect ovarian cancer cell proliferation in standard culture conditions, but decreased proliferation compared to control cells in starvation conditions. Moreover, PGC-1β silenced cells showed reduced invasive potential, evidenced by decreased migration and invasion, associated to diminished collagenase activity. When injected in immunocompetent mice, PGC-1β silenced cells exhibited delayed tumor growth compared to control cells. In PGC-1β silenced tumor bearing mice ascites formation, a key indicator of disease progression, was reduced compared to controls, along with decreased metastatic dissemination in the peritoneal cavity. Our data suggest that the PGC-1β depletion reduces not only cancer cell ability to survive and proliferate under nutrient limited conditions, but also their invasive potential, leading to a delay in ovarian cancer progression in vivo. Further studies are needed to elucidate the underlying molecular pathways regulated by PGC-1β. (Supported by “HEAL ITALIA” project PE_00000019 to F.A., CUP: B43D22000710006)

#5425 Human mitochondrial ClpXP protease degrades serine phosphorylated substrates.

Y. Feng[1], M. M. Goncalves[2], Y. Jitkova[1], A. F. A. Keszei[1], Y. Yan[1], C. Sarathy[1], J. St-Germain[1], T. M. G. Kenney[1], M. Tcheng[1], V. Trudel[3], R. S. Mancini[4], R. Upadhyay[4], R. ClpXP is an AAA+ protease located in mitochondria matrix. In human, ClpXP degrades damaged respiratory chain proteins and is essential for acute myeloid leukemia (AML) cell survival. This complex consists of the tetradecameric ClpP protease and regulatory particles ClpX. In bacteria, ClpXP targets substrates with a co-translationally added SsrA sequence. However, human lacks this tag and the degron for ClpXP remain unidentified. Notably, bacterial ClpXP homologues degrade substrates with phosphorylated arginine (pArg). We hypothesized that phosphorylated amino acids also facilitate substrate degradation by ClpXP in human mitochondria.

Here, we demonstrate that ClpXP selectively degraded phosphorylated α-casein and tau proteins over dephosphorylated forms. Replacing ClpX with ONC201 or *E. coli* ClpA abolished phosphorylation selectivity, indicating ClpX imparts substrate specificity for phosphorylation. Next, we screened a panel of phosphorylated amino acids and peptides for their effect on ClpXP-mediated degradation of α-casein. Phosphorylated serine (pSer) amino acids and peptides inhibited ClpXP protease activity, while phosphorylated tyrosine (pTyr) or pArg did not. Free serine and phosphate also had no effect. Differential scanning fluorimetry showed that pSer stabilized ClpX, consistent with pSer binding to ClpX. We then used hydrogen/deuterium exchange mass spectrometry (HDX-MS) to reveal the ClpX conformational changes upon pSer containing peptides (Ala-pSer-Ala) binding. HDX analysis indicated the ClpX RKL loop as a putative binding site. Mutating this loop in ClpX ($ClpX_{AAL}$) disrupted its interaction with pSer, resulting in loss of specificity for phosphorylated substrates. This suggests ClpXP selectively recruits phosphorylated protein for degradation through its RKL loop.

In AML cells, ClpP knockdown impaired the respiratory chain and increased reactive oxygen species. Through mass spectrometry analysis of ClpXP interactome and their phosphorylation status upon ClpP inhibition, we identified potential ClpXP endogenous substrates SDHA and NDUFA4, components of the OXPHOS complex. Knockdown of ClpX or ClpP increased levels of pSer-SDHA and pSer-NDUFA4 without changing total protein levels. Recombinant ClpXP degraded pSer-SDHA in a dose-dependent manner, with degradation blocked by pSer peptides. ClpXP did not degrade total SDHA, consistent with its preference for phosphorylated substrates. Further analysis showed elevated pSer-SDHA levels only in the insoluble mitochondrial protein fraction after ClpX knockdown, suggesting these might be damaged proteins. In conclusion, ClpXP degrades damaged mitochondrial proteins with serine phosphorylation, maintaining proper mitochondrial function.

#5426 Vesicle-mediated mitochondrial clearance presents an actionable metabolic vulnerability in triple-negative breast cancer.
M. Zuo;
UT MD Anderson Cancer Center, Sugar Land, TX

Selective autophagy of mitochondria is known to promote survival and progression of cancer cells in various malignancies including triple-negative breast cancer (TNBC). Here, we aimed to identify the essential metabolic adaptations that support mitochondrial quality control with the goal to uncover actionable metabolic vulnerabilities with therapeutic potential. Using an integrated approach of proteomics and untargeted and stable-isotope resolved metabolomics, coupled with functional experimental analyses, we define an alternative mechanism to mitophagy enabled by an onco-metabolic program of heightened extracellular sphingomyelin salvaging in TNBC that facilitates extracellular vesicle (EV)-mediated intracellular clearance of mitochondrial damage. Targeting of the cancer cell sphingolipid onco-metabolic pathway via repurposing of eliglustat, a selective small molecule inhibitor of glucosylceramide synthase (UGCG), resulted in ceramide-mediated compensatory mitophagy and subsequent cancer cell death *in vitro* and attenuated tumor growth and prolonged overall survival at clinically achievable doses in an orthotopic syngeneic mouse models of TNBC as well as in human xenograft models. Our study defines a mechanism of aberrant sphingolipid metabolism that underlies an actionable metabolic vulnerability for anti-cancer treatment.

#5427 Targeting mitochondrial protein translation in chemo-refractory triple negative breast cancer.

Mariah J. Berner, Steven W. Wall, Mokryun L. Baek, Audra Lane, Allison S. Greer, Karen Wang, Lacey Dobrolecki, Bing Zhang, Jonathan T. Lei, Michael T. Lewis, Gloria V. Echeverria

Baylor College of Medicine, Houston, TX

Nearly 45% of patients with triple negative breast cancer (TNBC) treated with neoadjuvant chemotherapy have residual tumors that are correlated with worse overall survival. Residual TNBC patient-derived xenograft (PDX) tumors were found to have heightened oxidative phosphorylation (oxphos) and enhanced dependency when pharmacologically targeting the electron transport chain (ETC; PMID 30996079). We have since established *in vitro* models recapitulating this biology and documented pro-mitochondrial effects of conventional chemotherapies in residual cells (PMID: 36813854). Proteomic profiling of pre-treatment TNBC patient biopsies and PDX tumors matched to their responses to carboplatin (CRB), docetaxel (DTX), or the combination revealed mitochondrial translation as a top up-regulated pathway significantly associated resistance (PMID 36001024, PMID 36619972, *Lei JT et al. manuscript in preparation*). Furthermore, on-treatment biopsies were collected from a subset of the TNBC patient samples, and mitochondrial translation pathways were significantly elevated. Leading-edge proteins included several core mitoribosome components and the accessory protein Oxidase (Cytochrome C) Assembly 1-Like (OXA1L). OXA1L plays two critical roles in the mitochondria: 1) it promotes translation termination for the 13 mtDNA-encoded ETC proteins, and 2) it aids in inner mitochondrial membrane insertion of both mtDNA- and nDNA-encoded ETC proteins. Therefore, we hypothesize that mitochondrial translation supported by OXA1L promotes oxphos dependence in residual TNBC cells surviving conventional chemotherapies. Transient siRNA-mediated knock-down (KD) of OXA1L in TNBC cell lines reduced ETC protein levels, reduced mitochondrial ‘respirasome’ supercomplex levels, and diminished oxphos. Notably, the CRB-induced elevation of oxphos characteristic of ‘residual’ cells was significantly diminished by OXA1L KD. Concomitantly, inducible shRNA OXA1L KD cells exhibited significantly enhanced CRB sensitivity relative to control cells. These results highlight the importance of OXA1L for mitochondrial respiratory chain production and functionality. Aiming to translate these findings, we are leveraging the mitochondrial bacterial ancestry to repurpose the FDA-approved antibiotic tigecycline as a chemo-sensitizing drug based on its mitoribosome inhibitory function (PMID 25625193). We demonstrate inhibition of mitochondrial respiratory chain production, respirasome formation, and oxphos with tigecycline. While we observe minimal toxicity to TNBC cells from tigecycline alone, we observe a profound enhancement of efficacy when combined with CRB or DTX both *in vitro* and in an orthotopic PDX model. In summary, our data provide evidence that disrupting mitochondrial translation may be a promising approach to target mitochondrial vulnerabilities in chemo-refractory TNBC cells.

#5428 Detachment from the extracellular matrix induces loss of the mitochondrial phosphatase PGAM5 in cancer cells.

Matthew Fink, Zachary Schafer

Biological Sciences, University of Notre Dame, Notre Dame, IN

Cancer cells often experience altered mitochondrial metabolism due to loss of integrin-mediated attachment to the extracellular matrix (ECM). Relatedly, work from our lab has revealed that ECM-detached cells undergo mitophagy, which subsequently results in the activation of cell death pathways. Cancer cells, however, can circumvent the induction of mitophagy during ECM-detachment to promote their viability, however, the mechanisms underlying mitophagy regulation during ECM-detachment remain poorly understood. The mitochondrial phosphatase PGAM5 is a part of a proteinaceous complex that initiates mitophagy during ECM-detachment, but its regulation in this context has not been extensively studied. Interestingly, we find that certain cancer cell lines have an innate ability to reduce the levels of PGAM5 protein when cultured under ECM-detached conditions. We find that this phenomenon is primarily due to alterations in PGAM5 transcription, rather than from alterations in protein stability. Given that ECM-detachment has been previously shown to impair proliferation, we analyzed PGAM5 expression in ECM-attached cells treated with CDK4/6 inhibitors. Our data suggest that expression of PGAM5 is indeed linked to proliferation, as arresting cells in G1 results in decreased PGAM5 expression. We also examined the consequences of reduced PGAM5 on mitochondrial dynamics. Previous research has discovered that PGAM5 dephosphorylates Drp1, a key regulator of mitochondrial fission. Indeed, we observe that decreased expression of PGAM5 (both during ECM-detachment and after treatment with CDK4/6 inhibitors) results in elevated phosphorylation of Drp1, suggesting an increase in mitochondrial fusion in detached and G1 arrested cells are likely. These data collectively support the conclusion that ECM-detachment causes changes in mitochondrial dynamics as a consequence of impaired proliferation and subsequent loss of PGAM5.

#5429 NRF2 activation sensitizes the Fe-S cluster synthesis pathway to iron restriction.

Maddison A. T. Olley, Nathan P. Ward

Metabolism & Physiology, Moffitt Cancer Center, Tampa, FL

Enhanced mitochondrial metabolism in human lung tumors relative to normal lung and lung tumorigenesis offers a potential therapeutic vulnerability in non-small cell lung cancer (NSCLC) due to the dependence on iron-sulfur (Fe-S) clusters. Recent data indicates that the incorporation of Fe-S clusters into recipient proteins is influenced by iron availability, with possible hierarchical loading when iron is limited. The labile iron pool which Fe-S clusters derive iron from is partly regulated by the transcription factor NRF2, which coordinates restriction of the labile iron pool through increased storage and efflux of free iron when activated. Given the aberrant activation of NRF2 in a significant proportion of NSCLC cases due to amplification or mutations in its negative regulator, KEAP1, we hypothesized that NRF2 regulation of intracellular iron availability may sensitize the Fe-S cluster synthesis pathway in NSCLC when iron is limiting.

To investigate this potential vulnerability, we stratified 14 NSCLC lines based on the activation status of NRF2 and evaluated the sensitivity of Fe-S cluster biology to iron chelation with deferoxamine (DFO). Seahorse analyses of mitochondrial function showed that the decline in mitochondrial respiratory function under iron starvation is exacerbated in NRF2-high cells compared to NRF2-low counterparts. Furthermore, ^{13}C-glucose tracing under DFO treatment revealed a significantly greater reduction in M+2 isotopologue enrichment of TCA cycle intermediates in NRF2-high cells relative to NRF2-low cells. In association with this enhanced mitochondrial metabolic dysfunction, we observe a more rapid loss of Fe-S protein activities such as aconitase and respiratory super complexes I-III and II-III in NRF2-high cells relative to NRF2-low cells following DFO treatment. Importantly, we find that NRF2 knockout protects against the loss of Fe-S protein function in response to iron restriction. Moreover, we find that the loss of mitochondrial iron in response to DFO treatment is dampened in NRF2 knockout cells, indicating that NRF2 coordinates mitochondrial iron availability in a manner relevant to Fe-S cluster biology. Overall, our data indicates that NRF2 activation augments the sensitivity of the Fe-S cluster synthesis pathway to iron restriction in NSCLC, presenting a vulnerability with potential therapeutic relevance.

#5430 Hematopoietic stem cells conditioned media alters the colorectal cancer cells metabolism by disrupting the mitochondrial bioenergetics in vitro.

Sumit Mallick, Sudheer P. Shenoy, Bipasha Bose

Stem Cells and Regenerative Medicine Centre, Yenepoya University, Mangaluru, India

Colorectal cancer (CRC) is a major public health issue, and mitochondrial dysfunction plays a pivotal role in its development. Mitochondria, the "powerhouses of the cell," are particularly important in cancer cells due to their high energy demands. The dynamic nature of mitochondria, including their ability to fuse and divide, is crucial for their role in signal transduction and metabolism. Enhanced mitochondrial fission, a process that divides mitochondria into smaller fragments, promotes the metabolic reprogramming of CRC cells. These reprogramming fuels cell proliferation, metastasis, and resistance to chemotherapy. However, excessive fission can also trigger apoptosis, leading to cell death. Our work shows that hematopoietic stem cells (HSCs) derived conditioned media (CM) altered metabolic activities by altering the mitochondrial oxidative phosphorylation through an excessive mitochondrial fission by upregulating the Drp-1 and downregulating the fusion protein Opa-1 and Mito-fusion proteins. Moreover, HSCs-CM dysregulated the electron transport chain complexes with high dysregulation of complex-III. Our integrated omics and mitochondria-targeted studies provided the dysregulation of the critical proteins involved in mitochondrial bioenergetics in CM treated CRCs. Our findings reveal the therapeutic nature of HSCs-conditioned media for colorectal cancer therapy.

#5431 The mitochondrial protease, YME1L regulates interferon signaling and is essential for AML growth and differentiation.

Yihe Zhang, Rose Hurren, Yongran Yan, Marcela Gronda, Dakai Ling, Karen Kai-Lin Fang, Andrea Arruda, Mark D. Minden, Aaron D. Schimmer

Princess Margaret Cancer Centre, Toronto, ON, Canada

Yeast Mitochondrial Escape 1-Like 1 (YME1L) is an ATP-dependent metalloprotease located in the inner mitochondrial membrane. Here, we examined the expression and function of this protease in AML. YME1L protein was expressed in 6/7 tested AML cell lines. In 17 of 23 primary AML samples, YME1L protein was > 2-fold higher than normal hematopoietic cells. High YME1L mRNA expression was associated with lower five-year survival rates in AML patients.To assess the dependency of AML cells on this protease, we knocked down YME1L with shRNA in OCI-AML2, NB4, TEX, and THP-1 AML cell lines. YME1L knockdown reduced AML cell proliferation in these tested lines. In addition, the depletion of YME1L reduced the clonogenic growth of leukemia cells, and decreased the engraftment of AML cells into the marrow of immune-deficient NS-GF mice. Thus, YME1L is essential for AML cells and leukemia-initiating cells. To understand the mechanisms of action of this protease and the downstream consequences of its depletion, we measured changes in gene expression after the knockdown of YME1L in OCI-AML2 cells. By RNA sequencing, knockdown of YME1L upregulated genes associated with defense response to viruses, response to type I interferon, and type I interferon signaling pathways, consistent with viral mimicry and induction of interferon (IFN) signaling. Using real-time PCR we confirmed the importance of YME1L in regulating these pathways. Knockdown of YME1L upregulated the expression of beta and gamma IFN, as well as downstream interferon-stimulated genes *ISG15*, *IFI44*, and *IFIT2*. Upregulation of IFN pathways and induction of viral mimicry, can promote the differentiation of AML cells. Therefore, we assessed the differentiation of leukemic cells after the knockdown of YME1L. Knockdown of YME1L induced the differentiation of OCI-AML2 cells as evidenced by upregulation of CD14 protein expression.In summary, YME1L is overexpressed in a subset of AML cells. This protease is essential for AML cells and controls differentiation by regulating IFN and viral mimicry pathways.

#5432 Restoring mitochondrial quantity and quality to reverse Warburg effect and drive tumor differentiation.

Haowen Jiang[1], Sarah Jane Tiche[1], Clifford JiaJun He[1], Junyan Liu[1], Fuyun Bian[1], Mohamed Jedoui[1], Balint Forgo[1], Md Tauhidul Islam[1], Meng Zhao[1], Pamela O. Cuthbertson[2], Florette K. Hazard[1], Lei Xing[1], Hiroyuki Shimada[1], Bill Chiu[1], Jiangbin Ye[1]

[1]Stanford University School of Medicine, Palo Alto, CA,[2]Agilent Technologies, Santa Clara, CA,[3]Olivia Consulting Service, Redwood City, CA

Reduced mitochondrial quality and quantity in tumors is associated with dedifferentiation and increased malignancy. However, it remains unclear how to restore mitochondrial quantity and quality in tumors, and whether mitochondrial restoration can drive tumor differentiation. Our study shows that restoring mitochondrial function using retinoic acid (RA) to boost mitochondrial biogenesis and a mitochondrial uncoupler to enhance respiration synergistically drives neuroblastoma differentiation and inhibits proliferation. U-^{13}C-glucose/glutamine isotope tracing revealed a metabolic shift from the pentose phosphate pathway to oxidative phosphorylation, accelerating the TCA cycle and switching substrate preference from glutamine to glucose. These effects were reversed by ETC inhibitors or in ρ0 cells lacking mtDNA, emphasizing the necessity of mitochondrial function for differentiation. Dietary RA and uncoupler treatment promoted tumor differentiation in an orthotopic neuroblastoma xenograft model, evidenced by neuropil production and Schwann cell recruitment. Single-cell RNA sequencing analysis of the orthotopic xenografts revealed that this strategy effectively eliminated the stem cell population, promoted differentiation, and increased mitochondrial gene signatures along the differentiation trajectory, which could potentially significantly improve patient outcomes. Collectively, our findings establish a mitochondria-centric therapeutic strategy for inducing tumor differentiation, suggesting that maintaining/driving differentiation in tumor requires not only ATP production but also continuous ATP consumption and sustained ETC activity.

#5435 OXPHOS as a driver of treatment resistance in NSCLC? From computational analysis to preclinical validation.

Katarina Benejova[1], McKenzie Kreamer[2], Nicholas Denko[2], **Martin Benej**[1]

[1]Department of Molecular Medicine and Therapeutics, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]Department of Radiation Oncology, The Ohio State University, Columbus, OH

Lung cancer is the leading cause of cancer deaths in the U.S. and worldwide. Up to 90% of all lung cancer cases are non-small cell lung cancer (NSCLC); a complex and highly aggressive disease typical for poor prognosis and high rates of treatment resistance. Clinical management of NSCLC varies according to the stage. High-dose stereotactic body radiation therapy (SBRT) is the standard of care for localized non-resectable NSCLC. In the last decade, first line NSCLC treatment has been substantially reinforced with the introduction of immunotherapy targeting immune checkpoints such as programmed cell death 1 (PD-1). However, despite initial good response, up to 75% of NSCLC patients may experience disease progression and the reasons for this heterogeneity are not fully understood. Several lines of evidence suggest that the highly hypoxic tumor microenvironment in NSCLC contributes to the high rates of treatment resistance. The basis of tumor hypoxia has traditionally been attributed to the oxygen supply deficit as malformed tumor vasculature fails to meet the high demand of the rapidly proliferating tumor mass. However, our preliminary analysis of NSCLC patient datasets in the Cancer Genome Atlas (TCGA) PanCancer dataset revealed a significant correlation between high-level expression of nuclear genes encoding mitochondrial subunits essential for oxidative phosphorylation (OXPHOS), and high-level expression of hypoxia-regulated genes (Buffa hypoxia score). Furthermore, we have observed a direct correlation between copy number amplification (CNA) of several OXPHOS genes and hypoxia levels in patient samples. Because mitochondrial function consumes up to 90% of available cellular oxygen, its activity may be indirectly regulating oxygen availability in the tumor microenvironment by rapidly consuming oxygen upon its delivery to the tumor. Moreover, we have identified that almost 70% of NSCLC patients harbor CNA of these essential OXPHOS genes. To provide mechanistic insight into these clinical observations, we have generated mouse syngeneic NSCLC cell lines with modified mRNA expression levels of OXPHOS genes (representing deletion, diploid and amplified number of copies) identified in our screen and observed a direct effect on the rates of mitochondrial oxygen consumption in vitro and hypoxia levels in vivo, leading to increased resistance to anti-cancer therapy in preclinical mouse model of NSCLC. Our study investigates the previously unknown role of OXPHOS gene copy number in driving mitochondrial oxygen demand and thus contributing to tumor hypoxia and treatment resistance in NSCLC.

#5436 MED8-orchestrated C24 sphingolipid metabolism promotes tumor progression through enhanced tumor cell membrane fluidity and mitochondrial oxidation.

Zhixian Chen, Xiaoxin Zhang, Judy Wai Ping Yam

Department of Pathology, The University of Hong Kong, Hong Kong, China

Mediator complex is a large protein complex containing up to 30 proteins that coactivates the RNA polymerase II (Pol II) enzyme to transcribe all protein-coding and most non-coding RNA genes. Recently, it has been reported that various subunits of the complex may possess distinct functions in cancer progression. After comparing the expression of all the subunits between normal and tumor tissue and analyzing their prognostic potential, we found that mediator complex 8 (MED8) was the most oncogenic gene that consistently predicted poor survival in liver hepatocellular carcinoma (LIHC), kidney renal clear cell carcinoma (KIRC), sarcoma (SARC), and uterine corpus endometrial carcinoma (UCEC) according to TCGA database. Next, we aimed to explore the common functions and mechanisms of MED8 involved in the development of the aforementioned tumor types. Pathway analysis revealed a strong association between MED8 and sphingolipid metabolism. To further study the role of MED8 in LIHC, KIRC, SARC, and UCEC, we established shMED8 stable clones using cell lines of each tumor type followed by metabolomics profiling. Notably, a significant correlation was observed between MED8 levels and a cluster of C24 lipids. ELOVL1, which specifically produced C24 acyl-coAs and linked to C24 sphingolipid synthesis, was confirmed to be positively regulated by MED8. Also, as one of the main groups of C24 sphingolipid, C24 ceramide was found to be reduced by the knockdown of MED8 indicated by the mitigatory phosphorylation of LYN, further underscoring the regulatory role of MED8 in sphingolipid metabolism. Although ceramide is known to initiate apoptosis and suppress tumor development, the metabolism of ceramide into other forms of sphingolipid including sphingomyelin (SM), sphingosine (Sph), and sphingosine-1-phosphate (S1P) has been reported to promote tumor progression. Specifically, C24-SM has been found to increase cell membrane fluidity, contributing to the distant metastasis of tumor cells. Furthermore, S1P has been reported to promote cytochrome c oxidase (COX IV) and mitochondrial respiration. In our studies, MED8 was validated to enhance tumor cell membrane fluidity, COX IV expression, and migratory ability, likely mediated by altered C24-SM and C24-S1P metabolism. Besides being converted into other metabolites, ceramide is involved in small extracellular vesicles (sEV) biogenesis via the complex TSG101-CERT (ceramide transport). Decreased formation of such complex and sEV secretion were observed in shMED8 tumor cells. In addition, MED8-enriched sEV endowed recipient cells with enhanced invasive ability by increasing their membrane fluidity and respiration.

#5437 N-myristoylation inhibitor zelenirstat reduces mitochondrial complex I activity, OXPHOS, glycolysis, and cancer stem cell growth in triple-negative breast cancer (TNBC) cells.

Rony Pain[1], Erwan Beauchamp[2], Morris A. Kostiuk[1], Claudia Y. Acevedo-Morantes[1], Luc G. Berthiaume[1]

[1]Cell Biology, University of Alberta, Edmonton, AB, Canada,[2]Pacylex Pharmaceuticals, Edmonton, AB, Canada

Two mammalian N-myristoyltransferases (NMT1 and NMT2) catalyze the addition of the fatty acid myristate to >200 different proteins and regulate cellular processes such as signal transduction, organelle trafficking, and metabolism. The pan-NMT inhibitor zelenirstat preferentially killed hematologic cancer cells while sparing normal cells, was safely administered, and showed early signs of efficacy in cancer patients during phase I clinical trials.

Normally-myristoylated proteins exposing their un-myristoylated N-terminal glycine resulting from zelenirstat treatment are susceptible for degradation by a glycine-specific N-degron. Using differential mass spectrometry proteomics of *NMT1*/*NMT2* CRISPR/Cas9 knockout (KO) HAP1 cells or HAP1 cells treated with zelenirstat compared to untreated WT HAP1 cells, we identified multiple NMT-specific substrates. Surprisingly, *NMT1* KO statistically reduced the protein levels of only a few signaling proteins, while preferentially reducing the levels of 36 mitochondrial respiratory proteins including the myristoylated complex I assembly factor NDUFAF4.

MISS-54, a gene signature that predicts the sensitivity of cancer or normal cells to zelenirstat, is significantly higher in TNBC than in other breast cancer subtypes or normal breast cells. Zelenirstat abrogated mitochondrial complex I assembly and activity as well as oxidative phosphorylation (OXPHOS) in MDA-MB-231 TNBC cells. The KO of *NDUFAF4* in these cells recapitulated all these results but also increased glucose utilization measured through extracellular acidification rates (ECAR). Zelenirstat significantly decreased respiration through complex I, overall oxygen consumption, ECAR, and the use of glucose as an alternate energy source. Zelenirstat treatment also resulted in pyruvate dehydrogenase inhibition, decreased AMPKβ levels, and decreased the NAD/NADH ratio. Thus, zelenirstat caused significant metabolic disruption that drastically impaired energy production in TNBC cells. We hypothesize that the inability of TNBC cells to switch to glucose utilization upon zelenirstat treatment is due to the loss of myristoylated AMPKβ.

Cancer stem cells (CSCs) have metabolic plasticity and can use either OXPHOS or glycolysis. Since zelenirstat reduced both pathways, we hypothesized that zelenirstat could also reduce the growth of CSCs in vitro. Both zelenirstat and *NDUFAF4* KO individually reduced mammosphere formation and produced dose-dependant additive effects on CSC growth when combined.

Overall, our results indicate that N-myristoylation is required for optimal energy production, cancer cell respiration, and CSC growth. In addition to inhibiting cell growth signaling, our data indicate that zelenirstat reduces OXPHOS and glycolysis, which may reduce CSC survival and prevent metastasis.

#5438 Exploring glioblastoma pharmacotherapy with an anti-epileptic drug: Multi-omic insights and tumor xenograft studies.

Anjali Yadav, Shraddha P. Bhutkar, Vikas V. Dukhande

St. John's University, Queens, NY

Glioblastoma multiforme (GBM) remains one of the most aggressive brain tumors, with a 5-year survival rate of only 6%. GBM resistance to standard-of-care therapies underscores the need for novel treatment approaches. Metabolic reprogramming is a promising hallmark of cancer, indicating a therapeutic avenue. Lactate dehydrogenase (LDH) is upregulated in GBM and adversely affects the survival of GBM patients. In this study, we investigated the repurposing potential of a putative LDH inhibitor Stiripentol (STP), an FDA-approved anti-epileptic drug, to inhibit GBM progression. Using various *in vitro* biological assays and 3D spheroid assays, STP treatment demonstrated a reduction in GBM cell viability and growth. However, the precise mechanism of STP's anticancer activity remains unclear. We aimed to elucidate STP's molecular mechanism and metabolic alterations underlying its anticancer activity in GBM. Additionally, we studied the efficacy of STP through *in vivo* tumor xenograft model. We adopted a multi-omics approach consisting of transcriptomics and metabolomics coupled with bioinformatic analyses. Our results from transcriptomics showed significant alterations in genes such as ALDH1A3, SERPINB2, AOX1, FGF1, TRIM22 and others involved in several biological processes such as oxidoreductase activity, extracellular membrane binding and response to DNA damage. Our metabolomic analysis demonstrated highly dysregulated metabolite enrichment in the Warburg effect, pentose phosphate pathway, glycolytic pathway, and homocysteine degradation upon STP treatment. Our metabolic and transcriptomic analysis bridges the mechanistic gap into the oxidoreductive stress and DNA damage response upon STP treatment. Our tumor xenograft studies showed significant efficacy of STP with decreased tumor volume and tumor weight. Our future studies will further elucidate the mechanistic basis of STP effects in GBM. Taken together, our findings suggest that STP has potential as a novel therapeutic lead for GBM that merits further validation and optimization to enhance its efficacy.

This research was supported by an award from the National Institute of General Medical Sciences of the National Institutes of Health under Award Number R16GM145557 and by funds from the College of Pharmacy and Health Sciences, St. John’s University, NY

#5439 Sphingolipid modulating compounds BXQ-350 and desipramine display synergy in reducing viability across multiple cancer cell types in vitro.

Tariq Arshad, Tim Stephens, Nikhil Wilkins, Robin Furnish, Mike Gazda

Bexion Pharmaceuticals, Inc, Covington, KY

Background: A cancer cell's ability to dictate sphingolipid metabolism is necessary for its survival. Two sphingolipids play a key role in cancer cell survival: Ceramide and Sphingosine-1-Phosphate (S1P), and the relationship between these two is known as the Ceramide-S1P rheostat. High levels of S1P, which favors cancer cell survival, proliferation, chemotherapeutic resistance and immune suppression, have been associated with poorer clinical outcomes; while higher levels of Ceramide, which is associated with cell death signaling and immune activation, lead to more favorable outcomes. Pushing this ratio in favor of Ceramide can weaken cancer cells making them more susceptible to a variety of therapeutic treatments. BXQ-350 is a novel anti-cancer and anti-neuropathy drug consisting of the lysosomal activator protein Saposin C (SapC) and the anionic phospholipid Dioleoyl Phosphatidylserine (DOPS). Together they are an allosteric activator of glucocerebrosidase (GCase) which is responsible for converting glucosylceramides into Ceramide (and glucose). Desipramine is a tricyclic antidepressant that blocks the reuptake of norepinephrine and serotonin. It binds to the inner leaflet of the lysosomal membrane changing the polarity and preventing certain enzymatic activities. Of note, it prevents acid-Ceramidase (ACMase) from converting Ceramide into Sphingosine, the precursor to S1P.
Method: Cells were treated, in vitro, with BXQ-350 and Desipramine for 72hrs. Viability was measuring using the MTT kit from Roche (#11465007001). Synergy was calculated utilizing the online website Synergy Finder (https://synergyfinder.org/). The aim of synergy calculations is to quantitate the change between an assumed no interaction reference model and the observed response when drugs are used in combination. The Zero Interaction Potency (ZIP) model (Yadav, et al., 2015) assumes the single drugs have no effect on the other's potency curve.
Results: Although BXQ-350 and Desipramine concentrations varied between specific cell lines, synergy was observed in colorectal, glioblastoma multiforme and pancreatic cancer cell lines.
Conclusion: Disrupting a cancer cell's sphingolipid metabolism, specifically the Ceramide-S1P rheostat, is a viable strategy for clinical therapeutics. The synergy BXQ-350 and Desipramine combinations show across cancer cell types, with varying oncogenic profiles, suggests that targeting sphingolipid metabolism is an agnostic approach to treating cancer, not related to any specific mutation or cell type. The possibility exists for sphingolipid modulating drugs to be combined with specific chemotherapeutics to increase their efficacy.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody-Based Cancer Therapeutics 3
Poster Session

#5443 IPH4502, a differentiated Nectin-4 exatecan antibody-drug conjugate.

Romain Remark, Cecile Bonnafous, Laura Chiossone, Caroline Soulas, Cyril Perrier, Sivan Bokobza, Rachel Courtois, Julie Lopez, Gregory Fenaux, Olivier Benac, Barbara Carrette, Robin Letay-Drouet, Raja Bonifay, Marion Gaudin, Severine Augier, Lea Simon, Agnes Represa, Ariane Morel, Eric Vivier, Yannis Morel, Nicola Beltraminelli, Carine Paturel

Innate Pharma, Marseille, France

Background: Nectin-4 is a cell-adhesion molecule expressed in many solid tumors. Enfortumab vedotin (EV, PADCEV®), an antibody-drug conjugate (ADC) targeting Nectin-4 with a monomethyl auristatin E (MMAE) payload, is approved for the treatment of urothelial cancer (UC), which exhibits the highest Nectin-4 expression among all solid tumor types. To address the unmet medical need of UC patients who discontinue EV due to toxicity, lack of efficacy, or ineligibility for this approved therapy, and to expand Nectin-4 targeting in tumor indications with lower Nectin-4 expression beyond UC, we have developed IPH4502, a differentiated anti-Nectin-4 ADC conjugated to exatecan with a cleavable hydrophilic linker, and a drug-to-antibody ratio of 8.
Methods: Nectin-4 immunohistochemistry (IHC) was performed on formalin-fixed, paraffin-embedded tissue-microarrays. Internalization was evaluated *in vitro*, and bystander effect was evaluated *in vivo*. *In vivo* studies were also conducted to evaluate anti-tumor activity using syngeneic mouse models, cell line-derived xenografts, and patient-derived xenografts (PDXs) from various indications.
Results: IHC revealed that Nectin-4 is overexpressed in tumor tissues from several cancer types including but not limited to UC, esophageal cancer, triple-negative breast cancer (TNBC), non-small cell lung cancer (NSCLC), and prostate cancer. IPH4502 demonstrates strong bystander killing effect *in vivo,* and high internalization efficiency *in vitro* in comparison to other Nectin-4 ADCs. These attributes contribute to enhanced anti-tumor activity in comparison to EV, across a spectrum of Nectin-4 expression levels, ranging from low to high expression, in PDX models. Moreover, IPH4502 shows efficacy in an *in vivo* model with primary resistance to MMAE due to MDR1 transporter expression and demonstrates anti-tumor activity in a PDX model of UC that acquired resistance to EV. Finally, IPH4502 shows activity in PDX models from indications beyond UC.
Conclusion: The strong internalization and bystander effect of IPH4502 enable an efficient anti-tumor activity in Nectin-4 positive tumor models independent of Nectin-4 expression levels. In addition, IPH4502 shows efficacy in models resistant to EV, indicating that IPH4502 has potential for UC patients relapsing or refractory to EV treatment, as well as for cancer patients treated with MMAE-based ADCs. Finally, IPH4502 shows anti-tumor activity in various preclinical cancer models, including PDX models from different indications, supporting its development beyond UC.

#5444 ImmuMab® mice enable efficient development of antibody therapeutics by unparalleled diversity across multiple formats.

Yuan Li, Wenbao Wu, Yu Wei, Yingjun Zhao, Yu Zhang, Jiwei Zhang

Shanghai Immunocan Biotech Co. Ltd, Shanghai, China

This study highlights the latest advancements of ImmuMab® gene-edited mouse platform, engineered with human immunoglobulin germlines to facilitate efficient antibody therapeutic development across diverse formats, including canonical, heavy-chain-only (HCO), common-light-chain (CLC), or combinations thereof. Utilizing massive-fragment across species *in situ* replacement technology, these mice underwent Mb-scale humanization of immunoglobulin gene fragments in single-step operations, circumventing the cumulative cellular damage associated with traditional transgenic approaches.

These new mice all deliver distinguished immune dynamic profiles featuring rapid initial immune responses and compelling titer plateaus. Since their introductions, the ImmuMab® mouse suite (HK, HKL, HL, HCO, CLC) has consistently delivered highly diversified repertoires across 35+ antibody discovery programs, with no failures due to suboptimal immune responses.

Designed for canonical antibody generation, the ImmuMab HK, HKL and HL mice (the latter two newly introduced), feature up to over 3.2 Mb human Immunoglobulin variable region genes. The ImmuMab HK mice in different project had deliver stable median titers ranging from 72.9k to 656.1k by the third dose, with some maximum titers approaching 1968.3k. Their immune responses exhibit robust resilience against challenging targets, including seven-transmembrane receptors and antigens with over 99% human-mouse homology. Notably, in one hybridoma screening against hROR1, the primary clone positivity rate (OD_{450} > 0.5) exceeded 33%. Selected monoclonal antibodies demonstrating affinities ranging from 0.001 to 1 nM (by BLI) and internalization rates of 20%-90% (Temperature-dependent). Some antibodies further demonstrated superior cytotoxic efficacy (MMAE-conjugated) compared to benchmark antibody-drug conjugates (ADC).

Additionally, one discovery program with ImmuMab Light® (CLC) mice by rapid immunization (1-week intervals) yielded seven candidate antibodies with picomolar EC_{50} values ($EC_{50} < 5 \times 10^{-10}$ M, ELISA) within a single screening cycle. Furthermore, the ImmuMab Heavy® (HCO) mouse enabled rapid heavy-chain-only immune response, reaching titers of 218.7k~656.1k within four weeks and identifying nanomolar heavy-chain-only antibodies with low single-digit nanomolar EC_{50} values for both human and cynomolgus monkey antigens.

The ImmuMab® mouse platform enables efficient development of antibody therapeutics across multiple formats. Its robust immune responses and high repertoire diversity make it a powerful tool for generating high-quality candidates, even against challenging targets.

Keywords: *diversity, fully human antibody, common-light-chain antibody, heavy-chain-only antibody, ImmuMab*

#5445 Discovery and optimization of IDP-001, a bispecific ADC targeting EGFR and CDCP1.

Anna de Regt, Clare Malone, Payam Farahani, Ben Setter, Robert W. Gene, Carol F. Farr, Zachary Caldwell, Brian Woodruff, Gyuna Kim, Hengyu Xu, Heath Klock, Rob Oslund, Niyi Fedyi, Michael Hornsby, Pamela Holland, Scott Lesley

InduPro Therapeutics, Seattle, WA

EGFR is a clinically-validated target that is overexpressed and activated in many human cancers and associated with poor prognosis. However, ADCs targeting EGFR exhibit toxicity due to expression on healthy tissue (1), and EGFR can show heterogeneous tumor expression (2). To engineer a next-generation bispecific EGFR ADC, we utilized InduPro's proprietary MInt^{TM} platform to identify proteins inherently proximal to EGFR on tumor cells. Among multiple proteins in proximity to EGFR, CDCP1 was identified as a TAPA (tumor associated proximity antigen) of interest. Like EGFR, CDCP1 is over-expressed in multiple cancers and plays key roles in oncogenic signaling and malignant transformation (3). Moreover, EGFR signaling induces upregulation and cell surface localization of CDCP1 as well as inhibition of its palmitoylation-dependent degradation (4).

Here we report the development of IDP-001, a novel bispecific ADC targeting EGFR and CDCP1. To identify antibodies that display selective activity only on cells that express both EGFR and CDCP1, we generated antibodies to both targets and then combined them to form over 250 hIgG1-based 1+1 bispecific antibodies with diverse epitopes and affinities. This bispecific library was screened on internalization and cytotoxicity assays, yielding a lead candidate that bound domain III of EGFR with a kappa Fab and bound the membrane-distal domain of CDCP1 with an alpaca-derived VHH. We performed further sequence optimization to affinity tune and humanize this antibody, engineer its Fc, and conjugate it with a DAR of 2 via engineered cysteines to a vcMMAE drug linker to yield our final development candidate, IDP-001. IDP-001 incorporates several design principles that distinguish it from other EGFR ADCs, including possible higher tumor exposure and penetration because of its smaller size. Due to its format and conjugation strategy, IDP-001 exhibits excellent biophysical properties and is highly developable. IDP-001 has potent in vitro cytotoxic activity against cancer cell lines with varying target expression levels. IDP-001 is a first-in-class bispecific ADC with the potential for a wider therapeutic window and best-in-class efficacy.

#5446 Development of a novel TCR based bispecific platform for cancer therapy.

Danqing Wu, Li Hu, Lini Huang, Beilei Shi, Lijun Wang, Xuan Wu, Shiyong Gong, Chengbin Wu

Shanghai EpimAb Biotherapeutics Co., Ltd., Shanghai, China

TCR-T therapies emerged as a new generation of therapeutics targeting solid tumors with high specificity but are not “off-the-shelf”. TCR based T-cell engagers follow the same concept, however it remains challenging to generate such molecules containing TCRs, which usually requires extensive engineering and optimization to achieve good solubility and functionality. To solve this problem, we developed a “plug-n-play” technology, namely TCR-Fab in tandem (T-FIT) fusion protein, for generating off-the-shelf TCR based therapeutics. The design of T-FIT was optimized by comparing recombinant production yield and purity in various formats with different spacers, binding valencies and TCR-Fab geometries. The selected T-FIT format showed IgG like production properties across different TCRs and Fabs. Based on the T-FIT format and our proprietary CD3 antibody, we generated 3 TCR based T-cell engagers, targeting NY-ESO-1, MAGE-A3 and Survivin respectively, and validated the T-FIT platform in preclinical functional assays. All three T-FIT molecules demonstrated potent redirected T-cell lysis activity against target positive cells in vitro. The MAGE-A3 and Survivin targeting T-FIT molecules also showed complete tumor inhibition in xenografted models.

#5447 Development and preclinical evaluation of JK06, a biparatopic ADC against 5T4.

Jonathan McNally, Binyam Bezabeh, Jijun Dong, Samuel Murphy

Salubris Biotherapeutics, Gaithersburg, MD

Trophoblast glycoprotein, also known as 5T4, is an oncofetal antigen that is upregulated on a variety of solid tumors including breast, lung, and genitourinary cancers. 5T4 expression levels correlate with stage of cancer progression and are associated with poor clinical outcomes. Herein, we describe the pre-clinical design and validation of JK06, a humanized, quadrivalent, biparatopic antibody-drug conjugate (ADC) that targets 5T4, allowing for efficient and selective delivery of a cytotoxic payload, monomethyl auristatin E (MMAE), to tumor cells. JK06 is engineered from 2 monoclonal antibodies (mAbs) that bind to distinct epitopes of 5T4. The first mAb clone was converted to a single-chain fragment variable (ScFv) format and fused to the C-terminal Fc end of a second mAb. This yields a hybrid molecule with four 5T4 binding sites, targeting two distinct epitopes of the 5T4 antigen. This design increases 5T4 avidity, an important feature given the generally low expression of 5T4 on tumor cells and enhances internalization of the drug. JK06 binds to recombinant 5T4 protein with low picomolar affinity measured by surface plasmon resonance, an approximately 10-fold increase in comparison to the two parental mAbs. JK06 induces internalization into 5T4 expressing tumor cells more rapidly and to a greater extent *in vitro,* than the parental mAbs. The tubulin inhibitor MMAE was conjugated to the Fc backbone of JK06 in a site-specific manner with a cleavable linker at a drug:antibody ratio (DAR) of two. *In vivo* CDX studies utilizing the MDA-MB-461 breast cancer and H1975 lung cancer cell lines in nude mice demonstrated that JK06 induces robust control of tumor growth *in vivo.* A repeat-dose GLP toxicology study, with a once every 3-week (Q3W) dosing schedule, demonstrated that JK06 was well tolerated, and without any observed adverse effects at the tested doses. Toxicokinetic evaluation showed a half-life which projects sustained exposure in humans with a Q3W dosing regimen. JK06 is currently being evaluated in an open-label, dose-escalation and expansion Phase I study to assess the safety, pharmacokinetics, and preliminary efficacy in a basket of solid tumors known to express 5T4.

#5448 Single domain antibodies, EGFR and cancer: a small solution to a big problem.

Adam T. Nelczyk[1], Kimberly J. Anderson[1], Nicholas Wu[2]

[1]Helixon US Inc, Champaign, IL,[2]Department of Biochemistry, University of Illinois at Urbana-Champaign, Urbana, IL

The primary purpose of our work is to identify high-affinity, efficacious single-domain antibodies (sdAbs, also known as nanobodies) targeting significant molecular drivers of cancer. The epidermal growth factor receptor (EGFR) family play a prolific role in the development and progression of numerous cancers. The clinical importance of these receptors is exemplified by the fact that 14 small molecule tyrosine kinase inhibitors as well as several monoclonal antibodies (mAbs) have received approval for therapeutic intervention. While these medications have undoubtedly had significant, positive impacts on patient outcomes, loss of efficacy due to mutagenic changes is a persistent issue. Unlike mAbs, sdAbs bind to a substantially smaller epitope, reducing the chances of mutation-induced loss of activity. Additionally, the distinct structure of sdAbs imparts them with highly desirable drug characteristics, such as exceptional tissue penetration, solubility, stability, and binding affinity. Considering these favorable traits, it is no surprise that the pharmaceutical industry is now allocating significant resources towards the development of sdAb-based drugs, with over a dozen in clinical trials, and 2 FDA approvals since 2019. While several anti-EGFR sdAbs have been described, at the time of this abstract submission, we were only aware of one sdAb-based drug targeting an EGFR family member under clinical investigation (I-GMIB-Anti-HER2-VHH1, Precirix). To address this currently unmet need, we first generated a novel sdAb library from 24 naïve crias (immature alpacas). Utilizing an iterative process of magnetic bead panning, mammalian cell display in a high EGFR-expressing cell line, and flow cytometric sorting, we were able to identify several candidates of interest via sequence analysis. Individual evaluation in our reporter cells showed that our candidates were capable of suppressing EGFR signaling, as determined by our fluorometric reporter. Following this validation, we assessed the impact of sdAb-mediated signaling regulation on classical cancer hallmarks. Data from *in vitro* migration and proliferation assays demonstrated that sdAb-antagonism caused significant inhibition of both hallmark properties. These findings were further supported by differential gene expression data, which highlighted significant changes in the expression of well-established regulators of these processes. Taken together, these data demonstrate our sdAb development pipeline can accurately identify multiple candidates capable of inhibiting crucial cancer hallmarks via EGFR antagonism. Ultimately, our goal is to utilize our process across a spectrum of cancers in order to provide patients with a new generation of high-efficacy, low-side effect therapeutics that more precisely and effectively target the primary molecular driver of their malignancy.

#5449 Preclinical development of SCR-A003, a novel topoisomerase I inhibitor-based antibody-drug conjugate (ADC) targeting LIV-1 for solid cancer.

Yayuan Fu, Changyan Chen, Xiaohua Yan, Zhiyong Yu, Zhuangzhi Zhao, Jingli Liao, Zhenyun Tian, Renhong Tang

Simcere Zaiming Pharmaceutical Co, Ltd., State Key Laboratory of Neurology and Oncology Drug Development. Simcere Pharmaceutical Group, Shanghai, China

Background: LIV-1, also known as SLC39A6 or ZIP6, a multi- transmembrane protein with putative zinc transporter and metalloproteinase activity. LIV-1 is expressed in a number of cancers with the highest prevalence in breast, prostate, ovary and melanoma, but a limited presence in vital organs. Currently, the clinical-stage ADC drug targeting LIV-1, Ladiratuzumab vedotin (SGN-LIV1A), is undergoing Phase 2 trials and has demonstrated clinical benefits, thus further underscoring LIV-1 as a promising target for advanced solid tumors. Given the broad spectrum of tumor indications addressable by targeting LIV-1, we utilized Simcere Zaiming' proprietary ADC technology to generate a novel ADC targeted to LIV-1 named SCR-A003.
Method: SCR-A003 is comprised of a LIV-1-targeted monoclonal antibody linked to a novel cytotoxic topoisomerase I inhibitor by a protease-cleavable linker. Pharmacokinetic study was conducted in mice in which SCR-A003 administered IV infusion. In vivo efficacy studies were conducted in immunodeficient mice with human tumor cell-lines including NCI-H838 and OVCAR3.The anti-tumor efficacy of SCR-A003 was evaluated in comparison to SGN-LIV1A analogue.
Result: SCR-A003 had highly specific binding affinity with human and could cross-bind to cyno LIV-1. Moreover, SCR-A003 exhibited excellent internalization and cell killing ability on multiple tumor cells in-vitro assay. SCR-A003, demonstrated specific, dose-dependent in vivo antitumor activity toward LIV-1-positive tumor xenografts representing lung, ovary and breast cancers. Compared to SGN-LIV1A analogue, SCR-A003 exhibited more robust tumor inhibition capacity at lower doses in OVCAR3 and NCI-H838 xenograft models. Additionally, SCR-A003 also showed prolonged serum half-life and higher drug exposure than SGN-LIV1A analogue in pharmacokinetic study.
Conclusions: SCR-A003, exhibited a favorable preclinical profile, with potent in vivo activity toward LIV-1-expressing tumor xenografts representing a range of cancer indications. These data support clinical development of SCR-A003 for the treatment of LIV-1-expressing solid cancers.

#5450 JSKN022, a first in class multi-specific ADC targeting PD-L1 and ITGB6/8 with an innovative DNA topoisomerase I inhibitor demonstrates encouraging efficacy in preclinical models.

Ting Xu, Ling Wang, Yongli Dong, Chuankun Shan

Jiangsu Alphamab Biopharmaceuticals Co.,Ltd., Suzhou, China

Background: Monoclonal antibodies targeting PD-1/PD-L1 have significantly transformed cancer therapy. However, the majority of patients still cannot get benefit from this treatment or may develop resistance afterwards. The increased expression of PD-L1 in tumors makes it an attractive target for ADC development leading to the most advanced program in registration trials. We developed a multi-specific ADC targeting another set of antigens, ITGB6/8. Integrins are cell surface receptors that usually mediate cell to cell adhesion. Integrin β6/8(ITGB6/8), which can only form a heterodimer with the αv integrin subunit, is highly expressed in various tumors. Utilizing our proprietary site-specific glycan conjugation, we generated JSKN022, an innovative PD-L1/ITGB6/8 targeting ADC, which structurally composed of a sdAb (single domain antibody) Fc fusion protein targeting PD-L1 and ITGB6/8, a cleavable linker and a novel DNA topoisomerase I inhibitor (T01, Alphatecan). In this study, the pharmacological activity of JSKN022 was evaluated using preclinical in vitro and in vivo models.
Methods: Based on Envafolimab, we designed a novel sdAb-Fc fusion protein which targeting both PD-L1 and ITGB6/8. Then T01 was homogeneously and stably conjugated to glycan located on Fc. The conjugated product (DAR4) was thoroughly characterized by LC-MS. The binding specificity of JSKN022 and its internalization rate were assessed. Pattern of payload released were analyzed using LC-HRMS. Serum stability was tested across various species. In vitro cell growth inhibition and in vivo antitumor efficacy of JSKN022 were examined using a range of cancer cell lines and CDX models with parental antibody ADC as control.
Results: JSKN022 demonstrated specific binding to the αvβ6/8 protein, without cross-reactivity with other members of integrin family. JSKN022 exhibited a consistent DAR4. Bridging ELISA indicated that JSKN022 can simultaneously bind to both PD-L1 and ITGB6/8. Flow cytometry binding assays revealed that JSKN022 possessed a superior binding capacity compared to both parental antibodies. Correspondingly, the naked antibody of JSKN022 showed an increased internalization rate relative to parental antibodies in HCC4006 and BxPC-3 tumor cells. JSKN022 effectively inhibits the proliferation of antigen-positive cancer cells and exhibited enhanced tumor suppression compared to the single-target ADCs. Furthermore, benefiting from glycan conjugation, JSKN022 demonstrated excellent stability in serum from rats, mice, monkeys, and humans, with minimal T01 release.
Conclusion: This preclinical study suggests JSKN022, as a first in class multi-specific PD-L1/ITGB6/8 ADC, might potentially bring in novelty in the therapeutic approach for cancers that are refractory or resistant to PD-1/PD-L1 inhibitors.

#5451 JSKN021, an innovative site-specific dual-payload bispecific antibody drug conjugate targeting EGFR and HER3 exhibits potent preclinical activities.

Ting Xu, Fan Li, Zhilong Lai, Rupeng Qu

Jiangsu Alphamab Biopharmaceuticals Co., Ltd., Suzhou, China

Background: EGFR and HER3, both belong to the EGFR family, are widely overexpressed in human malignancies, rendering them promising targets for cancer treatment. Cancer is a heterogeneous disease. Inter- and intratumor heterogeneity is believed to be a major factor contributing to recurrence, metastasis and resistance to current socs. To address these therapeutic challenges, we generated JSKN021, a dual payload ADC targeting EGFR/HER3. Both payloads, a novel DNA topoisomerase I inhibitor (T01, Alphatecan) and MMAE, are conjugated to glycan on Fc via cleavable linkers. The conjugation processes were carried out via combination of glycan transferase and click reaction. The streamlined process generated site specific and homogeneous conjugation with DAR4(T01)and DAR2 (MMAE).In this study, the pharmacological activity of JSKN021 was evaluated using relevant in vitro cell killing assays and in vivo models.
Methods: A novel Topo 1 inhibitor T01 and MMAE were stably conjugated to an EGFR/HER3 mAb using a glycan based site-specific manner. The conjugated products were characterized by LC-MS. Binding specificity of JSKN021 was confirmed by ELISA. In addition, release of payload were evaluated by LC-HRMS. At last, in vitro cell growth inhibitory and in vivo antitumor activities of JSKN021 were evaluated using different cancer cell lines and CDX models in comparison to single payload ADCs.
Results: After conjugation, LC-MS results showed that JSKN021 had a homogeneous DAR4 for T01 payload and DAR2 for MMAE. JSKN021 was demonstrated to bind EGFR and HER3 simultaneously. In addition, both T01 and MMAE were detected in cell culture supernatant and suspension of HCC827. Yet, no other metabolites were found detectable. JSKN021 demonstrated excellent stability in rats, mice, monkeys, and human serum, with minimal payload release. The stability was derived from the advantage of glycan based conjugation. JSKN021 inhibited the growth of cancer cells with either Her3 or EGFR or both expression, such as HCC827, MDA-MB-468, A431 and NCI-H1975. Furthermore, JSKN021 showed stronger tumor inhibition efficacy than mono payload ADCs in multiple CDX models.
Conclusion: The preclinical studies suggest JSKN021, as a dual-payload EGFR/HER3 bispecific ADC, might be a promising novel antitumor therapeutic agent.

#5452 Novel tryptophan-based antibody-drug conjugate (ADC) targeting EGFR-positive lung cancer demonstrates robust antitumor efficacy by triggering immunogenic cell death.

Hiroyuki Inoue[1], Kounosuke Oisaki[2], Hiroshi Tagawa[3], Akira Nakao[1], Noriyuki Ebi[1], Takeshi Mori[3], Masaki Fujita[1]

[1]Department of Respiratory Medicine, Faculty of Medicine, Fukuoka University, Fukuoka, Japan,[2]Catalysis Chemistry Research Center, National Institute of Advanced Industrial Science and Technology (AIST), Ibaraki, Japan,[3]Department of Applied Chemistry, Faculty of Engineering, Kyushu University, Fukuoka, Japan

Background and Aim: Antibody-drug conjugates (ADCs), which combine a cytotoxic small molecule drug with an antibody to enable targeted delivery at tumor sites, are emerging as next-generation therapeutic options for non-small cell lung cancer with HER2 mutations. However, clinical development of ADCs for solid tumors has been hindered by hematologic toxicity, such as thrombocytopenia, caused by FcγRIIa-mediated uptake into megakaryocytes (antibody-dependent cellular cytotoxicity: ADCC), as well as the prolonged time and high cost required for linker optimization at cysteine (Cys) or lysine (Lys) residues on antibodies. This study aimed to develop a novel ADC targeting the human EGFR surface antigen, which is expressed in a broad range of lung cancers, through collaborative research in pharmaceutical engineering.
Method: We synthesized novel ADCs using our proprietary ABNO linker, which offers high stability through tryptophan (Trp) modification on anti-EGFR IgG4 antibodies. This approach allows for more homogeneous and stable ADC production at a lower development cost compared to conventional linkers. We assessed whether the synthesized ADCs eliminated ADCC activity in co-culture with NK cells and examined their ability to induce immunogenic cell death by evaluating calreticulin exposure on the surface of dying cancer cells.
Results: We successfully synthesized a novel ADC (Anti-hEGFR(IgG4)-ABNO-DM-1: E4-AD) by conjugating the cytotoxic drug DM-1 to an anti-human EGFR-IgG4 antibody using the ABNO linker. In CKK8 assays, E4-AD demonstrated potent, concentration-dependent cytotoxic activity against EGFR-positive human lung cancer cell lines, with IC_{50} values ranging from 2 to 20 nM, while showing no cytotoxicity in EGFR-negative lung cancer cells. Furthermore, E4-AD effectively abolished NK cell-mediated ADCC in vitro and significantly increased calreticulin exposure on cell surface and HMGB-1 release from dying lung cancer cells, indicating the induction of immunogenic cell death.
Conclusion: These findings suggest that the newly developed E4-AD, with its innovative tryptophan-based linker technology, holds promise as a safer and more effective ADC for treating EGFR-positive lung cancers.

#5453 E-M ADC, a promising EGFR-MUC1 bispecific antibody drug conjugate, with superior anti-tumor effect in a wide range of tumors.

Ziheng Liu, Le Sun, Bing Hu, Lingfeng You, Xinyu Gao, Jin Shao, Shimeng Liu, Beibei Fu, Ying Li, Manting Zhang, Dandan Xiong, Yan Liu, Guangbao Qiu, Ziwei Ren, Zhendong Xue, Yuchang Mao, Huaixin Dang, **Ting Zhang**, Xin Ye, Shuyu Cai, Jun Feng, Min Hu, Feng He

Shanghai Hengrui Pharmaceutical CO., LTD., Shanghai, China

Mucin 1 (MUC1) is a transmembrane glycoprotein with abundant glycosylation. In normal tissues, MUC1 is present at the apical surface of epithelial cells, while epidermal growth factor receptor (EGFR) is present at the basal surface of epithelial cells. Tumor cells lose apical-basal polarity, leading to even distribution of EGFR and MUC1 on cell surface, a phenomenon that allows EGFR and MUC1 to be spatially close together. And EGFR and MUC1 are highly co-expressed in a variety of tumors, e.g., non-small cell lung cancer (NSCLC), esophageal squamous cell carcinoma (ESCC) and breast cancer (BC), among others. Accordingly, bispecific ADCs targeting EGFR and MUC1 preferentially target dual-expressed tumor cells, reducing the binding to normal tissues, meanwhile conjugating with TOPi, which can improve the efficacy. And the EGFR-MUC1 bispecific ADCs have a wider range of indications and patient populations. E-M-TOPi, a EGFR and MUC1 bispecific ADC, consists of a EGFR-MUC1 bispecific antibody (E-M), a cleavable linker and a topoisomerase I inhibitor. TOPi exhibited potent cytotoxicity with good membrane permeability. The binding affinities of E-M to EGFR and MUC1 were optimized to enhance tumor cell selectivity, increase endocytosis, and improve pharmacokinetics (PK). Considering the wide expression of EGFR in normal tissue, the binding affinity of E-M to EGFR was reduced to be weaker than that to MUC1, thereby enhancing the selectivity for EGFR-MUC1 co-expressing tumors while minimizing the toxicity to normal tissues. E-M-TOPi demonstrated significantly stronger EGFR/MUC1 dependent growth inhibition in various tumor cell lines. In HCC827 and HPAC (different EGFR-MUC1 co-expression levels) xenograft mouse models, E-M-TOPi inhibited tumor growth in a dose-dependent manner. Tumor regression was observed at 6 mg/kg of E-M-TOPi and sustained till day 30 in HCC827 model and day 28 in HPAC model. In addition, E-M-TOPi showed good human plasma stability and favorable cyno PK profile. Less than 0.5% of payload was released into human plasma after a 21-day incubation. Half-life of E-M-TOPi was more than 4 days in cyno monkey. In summary, by fine-tuning the EGFR-MUC1 bispecific antibody affinity and incorporating a superior bystander effect, E-M-TOPi holds the potential to be a best-in-class therapeutic candidate.

#5454 DB-1325, a BCMA-targeting antibody-drug conjugate with a Duality Unique Payload, exhibits promising efficacy and safety in preclinical multiple myeloma treatment.

Shengchao Lin, Bing Li, Yu Zhang, Jun Yao, Rong Shi, Yang Qiu, **Haiqing Hua**

Duality Biologics, Shanghai, China

Introduction: B cell maturation antigen (BCMA) overexpression has been found on the surface of the malignant plasma cells in the bone marrow of multiple myeloma (MM) patients. In recent years, innovative medicines targeting BCMA such as antibody-drug conjugates (ADC), T-cell engager and CAR-T have made great progress in the treatment of MM patients. Among them, belantamab mafodotin has been approved by FDA. However, a significant fraction of patients does not respond, or respond for a short period of time, to belantamab mafodotin. Thus, there remains unmet medical needs for BCMA-targeting ADC with novel mode of actions. DB-1325 is a novel BCMA-targeting ADC comprised of belantamab and PDUP5, a Duality Unique Payload (DUP) inhibiting mRNA translation, conjugated through a cleavable linker.

Methods: A proprietary inhibitor of mRNA translation PDUP5 was discovery through a campaign of medicinal chemical design and screening. A cleavable linker was designed to be attached to PDUP5, resulting in LPDUP5. Belantamab was conjugated with LPDUP5 to yield DB-1325. The therapeutic profile of DB-1325, including in vitro and in vivo efficacy, and its safety profile was assessed in preclinical models.

Results: PDUP5 exhibited sub-nanomolar to nanomolar potency in *in vitro* cell killing test on various MM cell lines. DB-1325 (belantamab-LPDUP5) showed robust in vitro anti-proliferation activity in multiple BCMA-expressing cell models (e.g. NCI-H929, KMS-11, MM1S, MOLP8) with activity similar to belantamab mafodotin. In addition, we observed robust efficacy of DB-1325 in several in vivo xenograft models following a single dose treatment. In NCI-H929 CDX model, treatment with DB1325 demonstrated anti-tumor activity superior to belantamab mafodotin when given at an equivalent dose. Furthermore, DB-1325 was well-tolerated at a preliminary toxicology assessment using monkeys, with favorable toxicokinetic profile.

Conclusions: DB-1325 is a novel and promising therapy for MM and currently in preclinical development as a first-in-class ADC with mRNA translation inhibitions as its major mode of action.

#5455 TAVO605, a novel CD318 (CDCP1) ADC, for the treatment of solid cancers that are non-responding or resistant to Enhertu treatment.

Guangmao Mu[1], Fulai Zhou[1], Honglei Bi[1], Zhengxia Zha[1], Sheng Huang[1], Ying Jin[1], Mingcan Yu[2], Chao Han[2], Mark Chiu[2], **Di Zhang**[2]

[1]Tavotek Biotherapeutics, Suzhou, China,[2]Tavotek Biotherapeutics, Lower Gwynedd, PA

Background: CD318, also known as Cub Domain Containing Protein 1 (CDCP1), is a single span transmembrane receptor containing three Cub domains with low level expression in healthy epithelial tissues. The CD318 expression is significantly upregulated in response to RAS transformation in several major types of solid tumors, including breast, lung, pancreatic, colorectal, bladder and prostate cancers. CD318 is an important mediator of aberrant cancer-associated cascades critical for survival, growth, metastasis, and treatment resistance of tumor. The elevated expression of CD318 is associated with poor prognosis and overall survival of cancer patients.

Methods and Results: We discovered several anti-CD318 antibodies with high binding affinities and prepared ADC conjugates with MMAE/MMAF. The CD318-ADC showed potent cytotoxicity to multiple cancer cell lines in *in vitro* cytotoxicity assays. The cytotoxicity activities correlated with the cell surface receptor densities and the binding affinities of CD318 antibodies. In multiple CDX and PDX solid tumor xenograft models involving pancreatic, colon, triple negative breast and non-small cell lung cancer, CD318-MMAE (DAR=4) showed potent tumor growth inhibition activities with efficacies comparable to or better than Enhertu (DS-8201). By employing an anti-CD318 antibody with cross-reactivity to murine CD318, we confirmed that the CD318-ADC with high drug dosing level was tolerable in a mouse toxicity study.

Conclusions: By targeting a novel tumor associated antigen CD318 (CDCP1) with high expression in multiple major solid tumors, our lead CD318-ADC molecule (TAVO605) showed potent cytotoxicity to multiple tumor cell lines as well as in CDX and PDX solid tumor xenograft models. CD318-ADC was tolerable and will be further evaluated in preclinical monkey toxicity studies. Our data supported the further development of TAVO605 as a potent therapy for solid tumors non-responding or resistant to current available treatments, e.g., by Enhertu, especially in tumors with low or no HER2 expression such as triple negative breast cancers. This antibody can also be used in other modalities to control solid tumors.

#5456 Development of human antibodies targeting a novel cancer-associated fibroblast protein identified from spatial transcriptomics.

Jin Yeong Choi[1], Shengjun Li[2], MinKyu Kim[1], Yeonjae Jung[1], Jae Eun Lee[1], Daeseung Lee[1], Hongyoon Choi[1], Hyung-Jun Im[1]

[1]Portrai, Inc., Seoul, Republic of Korea, Seoul, Korea, Republic of,[2]Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Background Cancer-associated fibroblasts (CAFs) are key components of the tumor microenvironment and play a critical role in tumor progression and therapy resistance. Recent advances in spatial transcriptomics (ST) enable precise analysis of gene expression within the spatial context of tissues, offering new avenues for target discovery. Using spatial and single-cell transcriptomic data, we identified a novel target protein, POR-CAF-001, predominantly expressed in CAFs within solid tumor tissues and minimally in normal tissues, making it a promising candidate for therapeutic intervention. **Method** Spatial and single-cell transcriptomics data from human tumor samples were analyzed using our proprietary target discovery program to identify CAF-specific targets. Two human IgG antibodies (POR-CAF-001-01 and POR-CAF-001-02) against the POR-CAF-001 were generated through phage display, ELISA screening and recombinant production in mammalian cells. Surface plasmon resonance (SPR) was employed to validate a binding affinity of antibodies against POR-CAF-001 protein. Also, flow cytometry and immunocytochemistry (ICC) were performed to evaluate the binding specificity of the antibodies. Antibody internalization was assessed via an imaging-based internalization assay using pH-sensitive fluorophore-labeled antibodies, and their internalization was monitored over time. POR-CAF-001-positive, -negative and knockout cell lines were used to confirm binding specificity and internalization. **Results** Differential expression and spatial specificity analyses identified POR-CAF-001 with high expression in various types of tumor tissues with minimal expression in normal tissues. SPR analysis demonstrated binding affinities (KD) of 1.15 nM and 4.1 nM for POR-CAF-001-01 and POR-CAF-001-02, respectively. Flow cytometry and ICC analyses confirmed robust binding of both antibodies to POR-CAF-001-positive cells, with negligible binding in POR-CAF-001-negative and the target knockout cells. Both antibodies showed substantial internalization in POR-CAF-001-positive cells during the internalization assay, while minimal internalization was observed in the negative cell line. **Conclusion** Through our target discovery program with ST data, we identified POR-CAF-001 as a novel CAF-specific target protein and developed two human IgG antibodies against it. These antibodies demonstrated high specificity and successful internalization in target-positive cells. These findings provide a solid foundation for further preclinical development, including antibody-drug conjugates (ADCs), radiopharmaceutical therapy (RPT) or other therapeutic modalities targeting POR-CAF-001. Our study underscores the potential of ST in identifying novel targets and advancing cancer therapy.

#5457 Dual-antigen bridging ELISAs to validate bispecific molecules with CD3-directed T cell engager function.

Connie Zhang, Katarzyna Zientara-Rytter, Moji Samoudi, Sean Green, Kimberly Skuster, Charlene Chang, Mohammad Awad, **Veronique Baron**, Michelle Kinbara, Jonathan Mikolosko, Pavel Shashkin

BPS Bioscience, Inc., San Diego, CA

Bispecific antibodies (bsAbs), designed to recognize two distinct antigens or epitopes, represent a promising class of next-generation biological therapeutics. These macromolecules, capable of engaging multiple targets, have gained significant interest over the past decade for their potential to harness the immune system against specific targets. With additive or synergistic mechanisms of action, bsAbs and other engineered dual-targeting molecules often exhibit greater potency than monoclonal antibodies (mAbs) or combination therapies. By simultaneously bridging two targets, bsAbs provide additional clinical benefits, such as enhanced target cell killing. Therefore, assessing their ability to bind both targets concurrently is essential for advancing their therapeutic potential. CD3-bispecific antibodies (CD3-bsAbs) have emerged as a promising approach in cancer immunotherapy, particularly for hematological cancers. These bsAbs activate T cells by binding both a tumor-associated antigen (TAA) on tumor cells and CD3 on T cells, leading to tumor cell destruction. Recent advancements in bsAb biology and technologies have enabled the development of diverse CD3-bsAb formats, ranging from small fragments with dual variable domains to larger structures incorporating additional domains linked to conventional immunoglobulins. Here, we present dual-target bridging ELISAs for bispecific molecules designed to engage T cells via CD3 binding. These assays are simple, cost-effective, and require no elaborate equipment, making them accessible to most laboratories. By leveraging the bridging capability of bispecific molecules, the method uses an immobilized capture recombinant antigen 1 and a CD3-containing detection reagent (antigen 2) to assess both binding events simultaneously, regardless of molecule format, isotype, or species of origin. Our assays feature low background, high signal-to-noise ratios, and compatibility with purified proteins, human serum, or cell culture supernatants, making them ideal for evaluating bsAb bridging abilities in drug discovery and high-throughput screenings (HTS). Additionally, the all-in-one HRP-conjugated CD3 complex simplifies the protocol by reducing steps what makes these assays less time consuming and more cost effective when compared to surface plasmon resonance (SPR) or cell-based bioassays.

#5459 Accelerating the development of biologics: PRISM high throughput screening enables rapid preclinical characterization of antibodies, ADCs and payloads.

Jillian N. Eskra, Alvin Kalathungal, Aydin Golabi, Bailey Porter, Antonella Masciotti, Nashielli Diaz-Gallegos, Anup Jonchhe, Maha Naim, Lia Petronio, Maggie LeMaitre, Jacob Asiedu, Ashish Bino George, Mustafa Kocak, Melissa M. Ronan, Matthew G. Rees, Jennifer A. Roth

Broad Institute of MIT and Harvard, Cambridge, MA

Biologic agents, such as monoclonal antibodies and antibody-drug conjugates (ADCs), have emerged as a highly promising class of the cancer therapeutics due to their ability to target specific tumor antigens with high specificity, be engineered for selective delivery of cytotoxic payloads, and work through diverse mechanisms of action. While these complex characteristics render biologics highly effective in vivo, they pose difficulty for systematically evaluating these agents in vitro. Here, we describe a multiplexed screening approach to overcome these challenges using the PRISM assay, where antibodies and ADCs are screened across 900+ cancer cell lines. We first investigated a panel of HER2-targeting ADCs conjugated to several different linkers and payloads. We assessed target selectivity and observed a clear association between cell line sensitivity and HER2 expression, with the strongest effects on viability observed in a subset of cell lines overexpressing HER2. We further compared profiles across different ADC targets and payloads to investigate predictive biomarkers of payload sensitivity and characterize bystander killing capabilities. Finally, we developed an antibody internalization reporter (AIR) assay to enable screening of unconjugated monoclonal antibodies. We optimized the AIR methodology using a secondary Fab-drug conjugate which can be used to load drug payload onto any IgG antibody to target and kill cells that are recognized by the primary antibody. To validate this approach, we screened trastuzumab in combination with a secondary Fab conjugated to MMAF via a non-cleavable linker. Comparative profiling with trastuzumab directly conjugated to the same payload revealed similar cytotoxic potency and target selectivity. These results demonstrate how the PRISM AIR method can enable screening of antibody candidates for ADC development to evaluate antigen-specific binding, internalization and cell killing potential. Overall, our study highlights the capabilities of the PRISM assay for investigating antibodies and ADCs.

#5460 C6P, a claudin 6 (CLDN6) directed ADC containing pyrolobenzodiazepine (PBD) for the treatment of advanced solid tumors.

Xiaolan Yu, Shuting Wang, Lingfeng You, Zhibin Xu, Zhendong Xue, Yuchang Mao, Shuyu Cai, Jun Feng, **Ting Zhang**, Xin Ye, Min Hu, Feng He

Shanghai Hengrui Pharmaceutical CO., LTD., Shanghai, China

Claudin 6 (CLDN6), a member of the claudin family of tight junction proteins, is highly expressed in multiple solid tumors such as ovarian and endometrial cancers with limited expression in normal tissues. Here we developed an anti-CLDN6 ADC C6P comprising a Fc-silenced anti-CLDN6 monoclonal antibody, a cleavable linker and a modified PBD (compound A). C6P selectively bound to CLDN6 without cross-reactivity to other claudin family members such as CLDN 3/4/5/8/9. Additionally, it also bound to I143V-mutated CLDN6, a major single nucleotide polymorphism (SNP) in human population. The antibody demonstrated strong binding affinity to several ovarian cancer cell lines with different CLDN6 expression levels and showed good endocytosis. Compound A was an optimized mono-imine PBD dimer with less cytotoxicity than conventional bis-imine PBD dimers. High systemic clearance of this payload was also designed to minimize toxicities. To achieve homogeneous ADC, a glycan mediated site-specific conjugation was used to generate C6P. C6P showed CLDN6-dependent growth inhibition against various cell lines, without effect on CLDN6 negative cells. In PA-1 and OVCAR3 xenograft mouse models, C6P showed a dose-dependent anti-tumor effect and led to robust and sustained tumor regression. C6P demonstrated good stability and safety profiles, likely due to site-specific conjugation and the higher systemic clearance of compound A. Less than 1% payload release was observed in human plasma after a 21-days incubation. C6P was well-tolerated at a single dose of 0.5 mg/kg in cynomolgus monkeys and did not show hematology-related toxicity. The intact ADC/total antibody AUC ratio was above 95%, and the payload was undetectable in the plasma of cynomolgus monkeys after injection with C6P. Overall, the highly specific CLDN6-targeting antibody, the optimized PBD payload, site-specific conjugation and well-controlled DAR value collectively contributed to the potent anti-tumor efficacy, and good safety profile of C6P, supporting its future clinical research.

#5461 BG-C477, a novel topoisomerase 1 inhibitor-based ADC, exhibits antitumor activity in carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5)-expressing preclinical models.

Daochuan He, Yiren Xiao, Zhuo Li, Jie Li, Hongyu Chen, Weijie Li, Huang Yan, Kunji Liu, Yang Lyu, Qingsong Hu, Mengjia Wang, Lai Xu, Zhitao Wan, Xiaomin Song, Yu Shen, Lai Wang

BeiGene Ltd., Shanghai, China

CEACAM5 (CEA) is a cell surface glycoprotein highly expressed in many cancers, including colorectal cancer (CRC), gastric cancer (GC), lung and pancreatic cancers. BG-C477 is a novel ADC that is composed of a CEACAM5-specific antibody conjugated to Top1i payloads (drug-to-antibody ratio = 8) via a cleavable linker. It remains stable in human plasma and mice blood circulation. BG-C477 showed specific binding to CEA-expressing MKN45 cells and stronger internalization activity compared to anti-CEA DM4 ADC. BG-C477 exhibited robust and CEA-dependent cytotoxicity in cell lines with different CEA expression levels. A potent bystander effect of BG-C477 was observed in co-culture killing assay with mixed CEA-positive MKN45 and -negative HCT116 cells, indicating the potential to treat tumors with heterogeneous CEA expression. In the animal studies, BG-C477 demonstrated potent and dose-associated single-agent efficacy in multiple CEA-expressing cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Moreover, BG-C477 exhibited superior antitumor efficacy in GC and CRC PDX models that anti-CEA DM4 ADC was ineffective.
In summary, BG-C477 is a promising CEA targeting ADC with great anti-tumor activity across multiple types of tumors. The first in human study to evaluate the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity of BG-C477 is ongoing (NCT06596473).

#5462 AMB303: A novel topo I payload ADC showing efficacy in NSCLC and TNBC, with potential for immune checkpoint combination therapy.

Do-Hyun Nam[1], Yuna Park[2], Byeongkwi Min[2], Wonsik Jung[2], Yunsu Park[2], Hye-Mi Kim[2], Min-A Park[2], Nam-Gu Her[2]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Aimed Bio Inc., Seoul, Korea, Republic of

Background: AMB303 is an ADC targeting ROR1 (Receptor Tyrosine Kinase-Like Orphan Receptor 1), a tumor-specific protein highly overexpressed in tumors. ROR1 is crucial for cancer cell differentiation, proliferation, migration, and metastasis, which drive recurrence and therapy resistance. These tumor-specific functions make ROR1 a highly attractive candidate for ADC development, offering the potential for more precise and effective cancer treatments. To optimize the therapeutic potential of AMB303, a novel topoisomerase I (Topo I) inhibitor payload has been incorporated, designed to overcome the limitations of existing Topo I inhibitors in clinical use. This novel payload aims to enhance the efficacy of AMB303, addressing drug resistance and minimizing the risk of tumor recurrence, offering a more effective approach to cancer treatment.
Method: The novel antibody and drug-linker components of AMB303 were optimally characterized and integrated. The binding affinity and cellular internalization of the AMB303 were assessed in cells with high ROR1 expression. In vivo efficacy was evaluated using a non-small cell lung cancer (NSCLC) patient-derived xenograft (PDX) model, while triple negative breast cancer, colorectal, and ovarian cell-derived xenograft (CDX) models were used to investigate the correlation between in vivo efficacy and target expression levels. Additionally, the combination of AMB303 with mouse PD-1/PD-L1 inhibitors was tested to evaluate antitumor activity in syngeneic mouse models.
Results: AMB303 has demonstrated excellent antitumor efficacy in in vitro and in vivo studies. By combining the new Topo I with an antibody showed target-specific binding affinity and rapid internalization, it also showed stronger cytotoxic effect compared to the clinically validated TopoI. Additionally, AMB303 demonstrated robust antitumor effect in NSCLC PDX and CDX models, including breast and colon cancer. In comparative studies with a benchmark ADC in clinical trials, AMB303 exhibited superior in vivo efficacy in a lung PDX model. In syngeneic mouse models, AMB303 demonstrated potential for enhanced efficacy when combined with PD-1/PD-L1 inhibitors.
Conclusion: AMB303, an ADC conjugated with a novel Topo I inhibitor, is a potent therapeutic designed to target both primary tumor cells and recurrence or relapsed cancer tissues. When combined with immune checkpoint inhibitors, AMB303 demonstrated enhanced therapeutic efficacy, presenting a promising strategy to overcome immune resistance and improve treatment outcomes in cancer therapy.

#5463 AMB304: A next generation ADC with topo I inhibitor, demonstrating robust preclinical efficacy against target overexpression tumors and high tolerability in non-human primate (NHP).

Do-Hyun Nam[1], Yeong-Woo Kim[2], Byeongkwi Min[2], Wonsik Jung[2], Eunsuk Choi[2], Jungsu Shin[2], Nam-Gu Her[2]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Aimed Bio Inc., Seoul, Korea, Republic of

Background: AMB304 is an antibody-drug conjugate (ADC) combining a human IgG1 monoclonal antibody and a high efficacious topoisomerase I inhibitor (Topo I) payload with site-specific conjugation. The target of AMB304 is a cell surface expressed glycoprotein, elevated in a range of tumors, and is associated with cancer survival, growth, metastasis, drug resistance and poor prognosis. This target is highly expressed in various epithelial cancers, including triple negative breast cancer and non-small cell lung cancer. Additionally, advanced malignancies with limited treatment options also demonstrate high target expression, suggesting that AMB304 may provide potential clinical benefits. Furthermore, elevated expression of the target is associated with resistance to anti-tumor drugs, such as EGFR TKIs (e.g., Gefitinib) and trastuzumab, via signaling. In this study, we investigated the cancer-specific therapeutic potential of AMB304, focusing on its preclinical characterization, including anti-cancer efficacy and safety profile.
Methods: Various types of tumor cell lines were treated with AMB304 using tumor spheroid model. For in vivo efficacy study, cancer cell lines or patients derived cells were inoculated subcutaneously in mice xenograft models. Target expression intensity in each tumor model was identified through immunohistochemistry (IHC). The toxicity profiles of AMB304 were analyzed, and its pharmacokinetics were evaluated in cynomolgus monkeys.
Results: AMB304 exhibited robust potency against target-expressing cancer cell lines, as evidenced by cell viability assay and compelling efficacy in various xenograft models, with IHC confirming its tumor regression depends on target expression. It exhibited target-specific binding, efficient internalization, and a strong bystander killing effect. In cynomolgus monkeys, AMB304 was well- tolerated with no significant adverse events at tolerable doses. Its stable linker chemistry minimized payload release, and it showed favorable pharmacokinetics, supporting its clinical potential.
Conclusion: This study demonstrates that AMB304 is potent ADC with significant anticancer efficacy and an excellent safety profile. Moreover, its superior stability in plasma enhances its potential for clinical treatment. Therefore, AMB304 could be developed as a targeted therapy for advanced solid tumors with high target expression.

#5464 A novel T-cell-engager targeting BCMA and GPRC5D with balanced killing efficacy to overcome potential resistance mechanisms in multiple myeloma treatment.

Xiaochuan Ma, Hanxiao Ying, Chunhong Yu, Ting Qiu, Shu Wang, Pu Pu, Zhibin Xu, Zhendong Xue, Shuyu Cai, Jun Feng, **Yi Mao**, Min Hu, Feng He

Shanghai Hengrui Pharmaceutical CO., LTD., Shanghai, China

B-cell maturation antigen (BCMA) and G protein-coupled receptor class C group 5 member D (GPRC5D) are critical surface markers expressed on multiple myeloma (MM) cells. BCMA-targeting T cell engagers (TCEs) and CAR-T therapies have achieved significant success in late-line MM treatment. However, antigen loss or downregulation, as well as point mutations, can result in relapse and resistance. Presence of soluble BCMA in circulation due to protein shedding also jeopardized the efficacy of BCMA-targeted therapies. GPRC5D exhibits both overlapping and independent expression profiles with BCMA, making it a compelling complementary target. Dual-targeting strategies leveraging these two antigens thus offer a promising approach to overcome resistance, improve therapeutic durability, and enhance clinical outcomes. Here, we developed a novel tri-specific TCE targeting BCMA, GPRC5D, and CD3 to optimize T cell-mediated cytotoxicity in MM. This molecule exhibited potent and selective tumor cell lysis in T cell-directed killing assays. Notably, it demonstrated balanced killing activity in cells expressing either BCMA or GPRD5D, reducing dependency on a single target antigen. Moreover, the molecule maintained its efficacy and potency in the presence of high levels of soluble BCMA (sBCMA) and overcame resistance associated with BCMA point mutations observed in patients treated with current approved TCEs. The molecule displayed potent anti-tumor efficacy in vivo in RPMI8226 cell-derived-xenograft models with hPBMC reconstitution. In addition, the molecule was well tolerated in cynomolgus monkeys with favorable pharmacokinetics and deep B cell depletion. In summary, this dual-target TCE offers a promising therapeutic option for addressing resistance of current approved TCEs, and further improving clinical outcomes in MM patients.

#5465 A novel CD3 VHH—based multi-specific T cell engager platform and multiple leads for gastric cancer and auto-immune disease.

Toya N. Baral[1], Jia Yu[2], Weihong Wang[1], Huiyuan Tang[1], John Lee[1], Leo Ng[1], Jing Yu[2], Peng Bo[2], Yong Wang[1], Jiaguo Li[2], Xinhao Wang[1], Qijun Qian[2], **Wenfeng Xu**[1]

[1]Chantibody Therapeutics Inc., Menlo Park, CA,[2]Shanghai Cell Therapy Group Co., Ltd, Shanghai, China

T cell engagers (TCEs) have recent approvals and great potential in the treatment of various diseases such as cancer and auto-immune diseases. The challenge of TCE in solid tumor is the therapeutic window due to limited tumor specific targets, and the CD3 arm requires fine tuning for specific targets and indications. The anti-CD3 used in current TCEs are monoclonal based and are limited in diversity of epitope and potency, which narrows the full potential of TCEs. VHHs being single domain, are ideal for bi- and multi-specific molecule design and engineering. We have identified anti-CD3 VHHs with diverse portfolio using in house llama, alpaca, and camel immunization with cells, protein and mRNA. We utilized VHHMAb® platform to capture full repertoire of the binders. The humanized anti-CD3 VHHs are diverse in epitope, affinity, T cells activation and in T cell dependent cytotoxicity. We have identified NHP cross binding anti-CD3 with great value for pre-clinical evaluation of TCE. We utilized in house developed AI-powered lead design for optimal TCE structure for best synapse between T cell and target cells. AI powered method was also used to design the TCEs for better developability attributes such as expression, solubility, aggregation. The TCEs, we have generated are with all single domain VHHs (anti-CD3 and TAA targeting) and are first of such kind. Colorectal cancer (CRC) has huge unmet clinical need as current treatments have limited clinical efficacy. We have identified targets which are differentially and restrictively expressed in the CRC in comparison to healthy tissues. Beside the tumor specific expression, the specific epitope on target have impact on effective T cell mediated killing of TCE. The membrane proximal domains are desired for TCE. With the VHHMAb® platform we have identified sets of VHHs which target different domains of two novel CRC targets. These VHHs are cross species (hu, NHP and mouse) binders that provide seamless path of pre-clinical to clinical development. With the binders of diverse epitopes on tumor antigen and various affinity and potency anti-CD3 VHH, we have generated TCEs that are functionally the best possible. Therapeutic efficacy, durability and safety are unmet medical needs in auto-immune diseases. For single target therapeutics, relapse due to antigen escape is one of the major problems. We have identified VHHs with NHP cross binding for multiple B cell targets of auto-immune diseases. Due to the single domain and modular nature of VHHs, we have generated TCEs with multi-targeting for better efficacy, durability and potentially overcome the relapse. Conclusion: We have generated diverse humanized anti-CD3 VHHs, different epitope and domain binding VHHs for target antigens. Due to modular nature of VHHs, we have generated multiple potentially FIC and or BIC TCE lead molecules which are composed of all VVHs arms, for CRC and auto-immune diseases.

#5466 7MW4911, a novel cadherin 17-targeting ADC, demonstrates potent efficacy in preclinical models of gastrointestinal cancers.

Rui Wang[1], Peng Fang[2], Wei Zhou[1], Cuicui Guo[1], Xiaoding Tan[2], Hai Wu[1], **Xun Gui**[1]

[1]Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China,[2]Jiangsu Mabwell Health Pharmaceutical R&D Co., Ltd., Taizhou, China

Background: Cadherin 17 (CDH17), a member of the 7D-cadherin superfamily, is critically involved in intercellular adhesion, tissue integrity, and intestinal peptide transport. It is predominantly expressed on the basolateral membrane of intestinal and pancreatic ductal epithelial cells, with minimal expression in non-gastrointestinal (GI) tissues. Overexpression of CDH17 is strongly associated with tumor progression and metastasis in colorectal, gastric, and pancreatic cancers, making it an attractive target for therapeutic intervention. Here, we report the development of 7MW4911, a novel ADC designed to selectively target CDH17-positive tumors while sparing normal tissues.
Methods: CDH17 expression as a therapeutic target was validated using comprehensive omics analyses. An anti-CDH17 specific mAb Mab0727 was generated using Mabwell's integrated novel antibody discovery system. The ADC 7MW4911 was constructed by conjugating Mab0727 to the proprietary payload MF-6 via a cleavable linker, achieving a drug-to-antibody ratio (DAR) of 4 using site-specific inter-chain disulfide bond conjugation technology. Binding affinity, internalization, and cytotoxicity of 7MW4911 were evaluated in CDH17-positive GI cancer cell lines. Efficacy was further assessed in cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Pharmacokinetics and safety were studied in cynomolgus monkeys.
Results: Immunohistochemistry (IHC) analysis confirmed CDH17 as a highly specific target, with expression observed in 100% (110/110) of colorectal, 77% (110/142) of gastric, and 55% (58/105) of pancreatic cancer samples. 7MW4911 demonstrated strong binding, efficient internalization, and potent cytotoxicity in CDH17-positive cell lines. *In vivo*, 7MW4911 showed substantial tumor growth inhibition (TGI), with TGI ranging from 29-97% in nine colorectal CDX models, 56-95% in three gastric models, and 81% in one pancreatic model. In PDX models, TGI ranged from 71-99% across nine colorectal and one gastric model. Importantly, 7MW4911 outperformed MMAE-based ADCs in multidrug-resistant CDX and PDX models. Pharmacokinetic studies in cynomolgus monkeys demonstrated a favorable safety profile, with a maximum tolerated dose exceeding 20 mg/kg and minimal off-target toxicity.
Conclusions 7MW4911 demonstrated exceptional preclinical efficacy, including robust activity against multidrug-resistant cancers, along with a strong safety profile. These findings highlight its potential as a transformative therapeutic candidate for CDH17-positive GI cancers, addressing significant unmet needs in oncology.

#5467 Therapeutic potential of antibody-drug conjugate with PARP1 selective inhibitor as a payload: A promising therapeutic approach for potent antitumor efficacy with reduced toxicity.

Jina Koo, Jeong Eun Kim, Hyeon Woong Park, Won Sik Lee, Myongjae Lee

Idience, Seoul, Korea, Republic of

Poly (ADP-ribose) polymerase inhibitors (PARPi) have been extensively studied as anticancer agents that selectively induce cancer cell death by disabling complementary DNA repair pathways. Despite PARPi's initial effectiveness, tumors often develop drug resistance, limiting the long-term effectiveness of these drugs. Combining PARPi with chemotherapeutics or other DNA damage response inhibitors have been explored to enhance the efficacy and overcome resistance. However, these combinations had significantly more side effects, highlighting the need for innovative therapeutic approaches that preserve anti-tumor efficacy while minimizing side effects. Incorporating PARPi as a payload within an antibody-drug conjugate (ADC) may offer a promising strategy for targeted delivery to tumor cells, to overcome drug resistance and to reduce systemic toxicity. To establish proof-of-concept, a TROP2 antibody was conjugated with a PARP1 selective inhibitor using a cleavable linker. *In vitro* cytotoxicity assays were conducted in MDA-MB-436, MDA-MB-468, and HCC1937 cell lines to compare the effects with the naked mAb, ADC, and free payload. An *in vivo* efficacy study was conducted using the MDA-MB-436 subcutaneous xenograft model in NOD-SCID mice. The PARPi payload was confirmed to be PARP1 selective via surface plasmon resonance and trapping assays. *In vitro*, ADC demonstrated potent cytotoxicity in MDA-MB-436 cells, which are known to be PARPi-sensitive with low levels of TROP2 expression, with an IC50 value of approximately 1 nM, whereas the naked mAb showed no cytotoxicity. In contrast, MDA-MB-468 and HCC1937 cells (with high levels of TROP2 expression and homologous recombination proficiency) showed cytotoxicity, only with free payload at high concentrations. *In vivo*, ADC and the free payload induced tumor regression and sustained antitumor effects, whereas the naked TROP2 mAb showed no efficacy. Hematological analysis reveals that the ADC-treated groups showed improved side effects compared to the free payload group. This study highlights the potential of a PARP1 selective inhibitor as an ADC payload, utilizing ADC as a drug delivery system, to achieve substantial antitumor activity with reduced side effects *in vitro* and *in vivo*. These findings emphasize the enhanced safety of PARP1i-based ADC compared to standalone PARP1 inhibitor, enabling novel strategies such as combination therapies or dual-payload ADC apporaches to effectively overcome drug resistance.

#5468 A novel kinase degrader antibody conjugate for the treatment of mCRPC.

Joost C. M. Uitdehaag, Jos de Man, Freek van Cauter, Sander P. W. van Gemert, Yvonne G.T. H. van Mil, Milan J. Hoffmann, Daphne Montizaan, Winfried R. Mulder, Michelle Muller, Martine B. W. Prinsen, Jan Gerard Sterrenburg, Diep Vu, Joeri J. P. de Wit, Erik Ensing, Rogier C. Buijsman

Crossfire Oncology B.V., Oss, Netherlands

Antibody Drug Conjugates (ADCs) represent an efficacious therapeutic modality. However, the classical payloads currently employed are limited in diversity, targeting mostly DNA, topoisomerases or tubulin and are sensitive to developing resistance. The high off-tumor toxicity observed with these payloads furthermore leads to a narrow therapeutic window. To overcome these challenges there is an urgent need for novel payloads that have a different mechanism of action and a more benign free-payload toxicity profile.

Kinases play an essential role in the development and growth of many different cancers and thus form a target class of particular interest for novel payloads. To date, over 80 kinase inhibitors have been developed as therapeutic agents. The vast majority, however, lacks the potency required for an ADC payload. One of the main reasons for this is their inability to abrogate the scaffolding function of kinases, which is known to contribute to their oncogenic signaling. For this reason, heterobifunctional kinase degraders have gained interest. These are small molecules that mediate the degradation of a kinase-of-interest by the proteasome. Their catalytic functionality endows them with high potency. An ADC with a degrader-based payload is generally referred to as a Degrader Antibody Conjugate (DAC).

We selected a cell cycle kinase that is known to be a tumor driver in many types of cancer. Knocking down this kinase using CRISPR technology is cytotoxic to many cancer cell lines representing major tumor indications (DepMap database). Using libraries of kinase ligands, spacers and E3 ligase ligands we identified degraders that rapidly and deeply degrade the kinase target and have potent antiproliferative activity in cancer cell lines, including those resistant to classical payloads. Degrader payloads were further selected for high microsomal lability, predicting rapid liver clearance, contributing to a more benign free payload toxicity profile. Mechanistic studies show that our lead degrader has a unique mode of action that results in complete cell cycle disruption, leading to DNA damage and potent immunogenic cell death.

Our lead degrader was coupled to various maleimide-based hydrophilic linkers and conjugated to clinically validated antibodies to generate DACs. The high hydrophilicity of the linker-degrader combination allows for the generation of DACs up to DAR8 while retaining good monomericity and stability.

Active DACs for various indications were generated, showing the wide applicability of our cell cycle kinase degrader-based payload. Our lead DAC for the treatment of metastatic castrate resistant prostate cancer (mCRPC) shows sub-nanomolar cytotoxic activity, potent target degradation, and effective bystander kill. The lead DAC was tested in a therapeutic *in vivo* xenograft model for prostate cancer and is currently progressing towards clinical development for mCRPC.

#5469 Preclinical safety and efficacy of SOT109, an antibody-drug conjugate targeting cadherin 17 (CDH17) for the treatment of colorectal and other gastrointestinal tract tumors.

Nataliia Kalynovska[1], Diana Hudecz[1], Matous Hrdinka[1], Ilona Prochazkova[1], Eliska Kohelova[1], Lenka Palova Jelinkova[1], Filip Jaburek[1], Tomas Zimmermann[1], Lukas Fojtik[1], Irena Adkins[1], Sarka Stehlikova[1], **Amy Jensen-Smith**[2], Radek Spisek[1], Martin Steegmaier[1]

[1]SOTIO Biotech, a.s., Prague, Czech Republic,[2]SOTIO Biotech, Inc., Boston, MA

Background: Colorectal cancer is the third most prevalent type of cancer, with an incidence of nearly 2 million new cases annually, and ranks as the second leading cause of cancer mortality worldwide. CDH17 is a single-pass transmembrane glycoprotein involved in calcium-dependent cell-cell adhesion and epithelial homeostasis regulation. In normal physiology, CDH17 is predominantly localized on the lateral surfaces of intestinal and pancreatic ductal epithelial cells. However, it is frequently overexpressed and aberrantly localized in gastrointestinal tumors including colorectal, gastric, pancreatic and gastroesophageal carcinomas. We have developed SOT109, a proprietary CDH17 targeting exatecan-based antibody-drug conjugate (ADC) and evaluated its preclinical safety and efficacy.
Results: Immunohistochemical staining of patient tumor and healthy tissue microarrays confirmed CDH17 expression in normal tissues including the colon, stomach and small intestine, with pronounced expression in colorectal, gastric, and gastroesophageal junction tumors, consistent with previously published literature. SOT109 candidates were generated from a fully human CDH17 monoclonal antibody conjugated via a hydrophobic linker to exatecan, a cytotoxic topoisomerase I inhibitor payload. Candidates were selected by rigorous screening for optimal binding epitopes and affinity, together with binding, internalization, and cytotoxicity *in vitro*. SOT109 candidates demonstrated specific binding to CDH17 and selective internalization and killing of target-positive cancer cells. Lead candidates underwent evaluation in several preclinical *in vivo* mouse tumor models, including cell-derived and patient-derived xenografts. Treatment with SOT109 resulted in profound and sustained tumor regressions. The doses tested in these studies were well tolerated in mice, with no dose-limiting toxicities observed. Subsequent studies in non-human primates revealed a favorable pharmacokinetic and safety profile.
Summary: SOT109 targets the overexpressed tumor antigen CDH17 and exhibits potent anti-tumor efficacy coupled with a clean safety profile in preclinical models of colorectal carcinoma. These data suggest that SOT109 holds significant potential as a therapeutic candidate for patients with gastrointestinal malignancies and supports the further clinical development of SOT109.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Discovery Assay Technologies
Poster Session

#5473 Development of a novel fluorescent ELISpot assay using the Celigo^{TM}Image Cytometer.

Wen-Chieh Liao[1], Julia Abdalla[1], **Carolina Franco Nitta**[2], Mackenzie Pierce[2], Bo Lin[2], Jessie Ni[1]

[1]BioLegend, San Diego, CA,[2]Revvity, Lawrence, MA

ELISpot and its variant, fluorescent ELISpot (FluoroSpot), are commonly used methodologies that monitor and detect cytokine and/or antibody secretion from peripheral blood mononuclear cells (PBMCs). Conventional ELISpot and FluoroSpot assays utilize PVDF-membrane plates, which require labor-intensive washing steps that may introduce variability in performance and results. Here, we have developed a novel FluoroSpot assay using polystyrene-, clear-bottom microplates with simplified automated washing steps to minimize operator variability and error. In this work, we assessed multiple critical cellular immune-related activities, including IL-6, IFN-g, and TNF-a secretion in PBMCs using this novel FluoroSpot methodology in comparison to the conventional ELISpot assay. To detect cytokine secretion of IL-6, IFN-g, and TNF-a, the Celigo™ Image Cytometer (Revvity Health Sciences, Inc., Lawrence, MA) was incorporated to capture whole-well images of fluorescently labeled detection antibodies. Results for both methodologies were comparable to one another, validating the use of polystyrene plates on Celigo™ as opposed to PVDF-membrane plates. In addition to FluoroSpot detection, the Celigo™ was used as a quality control check to provide a comprehensive analysis of live cell distribution prior to performing the FluoroSpot assay. Live cell imaging results were used to correlate downstream cytokine-releasing cell spot formation results. Combinational use of the novel FluoroSpot polystyrene plate with the Celigo™ reduced operator variability and errors, while streamlining a multiparametric analysis to identify the number of fluorescent spots, spot morphology (size), and whole-well mean fluorescence intensity values. This methodology may prove useful for researchers interested in monitoring and detecting cytokine and/or antibody-releasing PBMCs.

#5474 QUANTROseq, a transcriptomic based drug discovery platform using time-resolved gene expression profiling: identification of inhibitors and degraders of transcription factors and cell signaling regulators.

Arianna Sabo, QUANTRO Therapeutic Team

QUANTRO Therapeutics GmbH, Vienna, Austria

Transcription factors (TFs) and related signaling pathways have long been considered among the most challenging targets in drug discovery. To address these limitations, QUANTRO Therapeutics has developed QUANTROseq, a pioneering transcriptomic discovery platform designed to match transcriptional dynamic profiles or “fingerprints” triggered by small-molecule drug candidates with those derived from controlled, acute degradation of specific targets. This innovative approach enables the identification of novel inhibitors, modulators, and degraders with unprecedented precision and sensitivity, targeting even previously undruggable proteins. Analysis of our data demonstrated that time-resolved transcriptional profiling not only allows identification of drug candidates in HTS screening, it also reveals the mode of action of these drugs with unprecedented precision and sensitivity, provided that these act on targets that have a direct effect on transcriptional regulation, such as transcription factors (TFs) and signaling pathways (e.g. c-MYC, YAP/TEAD or KRAS). This approach allows for the clear discrimination between molecules that directly act on a specific transcription factors or directly associated regulatory co-factors, and drugs that only indirectly affect its function. The transcriptional fingerprinting approach is employed by QUANTRO at various stages of the drug discovery process: 1. Benchmarking the real mode of action of existing drugs; 2. Interrogating the efficiency, selectivity, and potency of drug candidates during Hit-validation and Hit-to-Lead optimization activities, overcoming the limitation of standard biochemical/biophysical assays in their capacity to inform regarding compounds selectivity; 3. Identifying new mode of action drug candidates that specifically interfere with disease-causing transcriptional programs in cancer, through the proprietary QUANTROseq screening platform. During last year, QUANTROseq screening technology has been employed by QUANTRO in multiple large HTS screening campaigns, which yielded high quality hits against several key oncogenic transcription factors. Screening results will be presented at the conference.

#5475 Leveraging LC-MS workflows to characterize a novel WRN covalent inhibitor.

Kurt Baltier[1], Anthony Tubbs[2], Doug McLaughlin[2], Giulia Bottoni[2], Allison Drew[2], Brian Erickson[1], **Craig Braun**[1]

[1]IQ Proteomics LLC, Framingham, MA,[2]MOMA Therapeutics, Cambridge, MA

Werner protein (WRN) is a helicase with functions critical to DNA repair pathways, and as such is an active target for the development of cancer therapeutics. Notably, WRN has been demonstrated as a synthetic lethality target in DNA mismatch repair deficient (dMMR)/microsatellite instable (MSI-H) tumors owing to its role in the DNA damage response. Accordingly, the development of small-molecule WRN inhibitors is an active and attractive area of cancer research and has the potential to be a powerful new therapeutic modality in several cancers including colorectal, gastric, and endometrial. Here, we report the application of targeted and discovery LC-MS workflows towards the characterization of M6021, a small molecule covalent inhibitor of WRN. A custom targeted LC-MS assay has been developed and optimized for detection and quantification of covalent compound engagement to WRN in preclinical models, including several cancer cell lines and mouse xenograft models. This assay enables reproducible, precise and accurate quantitative characterization of near-complete WRN engagement in clinically relevant biological matrices, despite low endogenous WRN expression and treatment-induced reduction in WRN levels. Plate-based sample preparation and analysis enables high-throughput evaluation of multiple experimental parameters (dose, treatment time, matrix, etc) across meaningful cohorts of replicates. Further, we employed a discovery LC-MS based covalent inhibitor selectivity assay to demonstrate that M6021 is highly selective for WRN, proteome-wide. Using this assay, we demonstrate that the novel WRN inhibitor M6021 is a potent and selective covalent inhibitor of WRN helicase, suitable for use as a high-quality chemical probe for understanding WRN biology in dMMR/MSI-H tumors.

#5476 In vitro real-time evaluation of bystander effects of antibody-drug conjugates.

Xiaoyu Zhang[1], Yun-fei Pu[2], Tian Wang[2], Grace Yang[2], Peifang Ye[2], Nancy Li[1]

[1]Agilent Technologies, Inc., La Jolla, CA,[2]Agilent Technologies, Inc., Hangzhou, China

Antibody-drug conjugates (ADCs) represent a pivotal advancement in biotherapy, leveraging targeted internalization to treat tumors effectively. A critical phenomenon associated with ADCs is the bystander effect, where cytotoxic drugs released from lysed cancer cells diffuse into neighboring tumor cells, enhancing therapeutic efficacy—particularly in tumors with heterogeneous antigen expression. Despite its significance, methods for detecting and evaluating the bystander effect of ADCs remain under development. In this study, we present a robust approach to monitor and analyze the bystander effect of ADCs in real-time using live-cell imaging and impedance measurements with the Agilent xCELLigence RTCA eSight system. Two innovative assays—the in vitro co-culture assay and the conditioned medium transfer assay—were established for this purpose. The cytotoxic effects of DS8201, an ADC with bystander activity, and T-DM1, an ADC without bystander activity, were assessed in these assays. In the co-culture assay, HER2-positive SKBR3 cells and HER2-negative MCF7 cells were co-seeded in a biosensor plate (E-Plate VIEW 96) the day before testing. The results revealed that DS8201 treatment led to the death of HER2-negative MCF7 cells in the presence of SKBR3 cells, indicative of a bystander effect. In contrast, T-DM1 did not affect MCF7 viability under similar conditions. Both DS8201 and T-DM1, however, induced cytotoxicity in HER2-positive SKBR3 cells. In the conditioned medium transfer assay, medium from SKBR3 cells treated with DS8201 significantly reduced MCF7 cell viability, demonstrating a bystander effect. Conversely, conditioned medium from T-DM1-treated SKBR3 cells did not impact MCF7 viability. Notably, neither DS8201 nor T-DM1 exhibited direct cytotoxic effects on MCF7 cells in isolation. In conclusion, we describe two robust methodologies for detecting and evaluating the bystander effect of ADCs using the RTCA eSight system. These approaches provide valuable tools for optimizing the efficacy, safety, and pharmacokinetics of therapeutic ADCs during biopharmaceutical development.

#5477 Cell avidity - the next-gen cell binding to understand the mechanism of action through cell-cell and cell-protein interaction.

Zhou Zhong, **Keith Bailey**, Justin Moser, Bella Perez, Brian Kierce, Michael Savage

LUMICKS, Boston, MA

Traditional assays such as affinity measurements, cytokine secretion, and cytotoxicity provide informative insights but are insufficient for comprehensively characterizing and selecting the most effective cell therapy candidates. The complexity of cell-cell interactions that drive functional outcomes remains inadequately understood. Cell avidity, defined as the aggregate strength of interactions between effector and target cells, serves as a novel pivotal metric for uncovering the mechanism of action behind therapeutic candidates. The z-Movi Cell Avidity Analyzer, part of our versatile Cell Avidity platform, leverages the integration of fluorescence microscopy with precise acoustic force application to measure cell binding under physiologically relevant conditions. This approach allows for a detailed analysis of binding profiles, encompassing cell surface receptors and ligands, cell phenotype, cell status, and more to elucidate potency, safety, sensitivity, and binding kinetics essential for robust therapeutic evaluation. Our platform is designed to support the characterization and screening of a wide array of therapeutic modalities, including molecular binders like antibodies and small molecules, as well as cell-based therapies. By providing extensive insights into the mechanism of action and functional performance, Cell Avidity enables the development of next-generation therapeutics with enhanced safety and efficacy profiles.

#5478 From 2D to 3D: Advancing preclinical platforms in cancer models.

Hussein Chehade, Amber Rowse, David Draper, Anita J. Zaitouna, Daniel Saims, Sheri Barnes, Heidi Nielsen, Scott Wise

Labcorp Drug Development Inc., Ann Arbor, MI

Solid tumors account for about 90% of all adult human cancers. These tumors have a heterogeneous cellular composition that includes cancer cells, stromal cells, immune cells, and more. Developing effective treatments relies on experimental models that can recapitulate the original tumor and effectively predict clinical outcomes. Two-dimensional (2D) cell cultures have been extensively used as tools to predict promising outcomes before proceeding to more expensive animal studies. However, results from 2D models often fail to replicate *in vivo* conditions, necessitating the development of 3D multi-cellular spheroids that better mimic the physiology, architecture, and native microenvironment of parental tumors. In this study, we highlight the differences in drug response between 2D and 3D cancer cell line cultures and how 3D cultures better simulate the response observed in vivo.Human (MDA-MB-231) and mouse (EMT6 & 4T1) cancer cell lines were cultured in 2D as monolayers or in 3D utilizing a species- and histotype-specific extracellular matrices (ECM). Cultures were treated with increasing doses of small molecule drugs (Cisplatin, Paclitaxel, or Gemcitabine) and cell viability was quantified using CellTiter-Glo™ luminescent cell viability assay and/or Celltox™ Green viability dye along with serial imaging quantification. Half-maximal inhibitory concentration (IC_{50}) curves were plotted and quantified using GraphPad Prism™ software.Microscopic imaging revealed morphological differences between 2D and 3D cultures. Unlike 2D cultures, 3D cultures formed either compact or loose spheroids, allowing for cell-cell and cell-matrix interactions that mimic tumor morphology. MDA-MB-231 and EMT6 breast cancer cells showed higher cytotoxicity to Cisplatin in 2D cultures compared to 3D cultures (IC_{50} of 3.5 µM for 2D and 13.47 µM for 3D; IC_{50} of 21.28 µM for 2D and 42.36 µM for 3D respectively). This corresponds to *in vivo* MDA-MB-231 and EMT6 tumors, which show slight tumor growth inhibition post Cisplatin treatment. However, 4T1 cancer cells showed similar Cisplatin cytotoxicity in both 2D and 3D cultures (IC_{50} of 4.21 µM and 5.73 µM respectively), which also aligns with *in vivo* response, where Cisplatin resulted in significant reduction in tumor volume. These *in vitro* results were further confirmed by viability analysis using serial imaging.These findings underscore the efficacy and predictability of this 3D platform in drug development. Not only does this platform help in decreasing the use of laboratory animals, but it also allows to reproduce key aspects of the tumor physiology and architecture. Consequently, 3D cultures have the potential to better predict treatment response and help identify drug resistance mechanisms.

#5479 Development of novel luminescent assays for sensitive and specific quantitation of double-stranded RNA in mRNA vaccines.

Rich Moravec, **Jun Wang**, Jim Hartnett, Mei Cong, Jamison Grailer

Promega, Fitchburg, WI

Personalized mRNA vaccines, designed with patient-specific tumor mutations, are now advancing in clinical trials and showing promising results. Additionally, the delivery of therapeutic proteins (e.g., antibodies) encoded by mRNA is under active development. The large-scale production of mRNA is through the process of in vitro transcription (IVT). A significant byproduct and contaminant of IVT is double-stranded RNA (dsRNA), which is highly immunogenic. dsRNA can trigger inflammation, induce cell death, and inhibit protein translation. Therefore, accurate quantification of dsRNA is essential to ensure the safety and efficacy of mRNA therapeutics. However, current technologies, such as dot blot and ELISA, lack the sensitivity and quantitation needed for robust dsRNA detection. In this work, we describe the development of novel luminescent assays for the sensitive and specific quantitation of dsRNA in IVT products. First, we applied NanoBiT® split luciferase technology to detect dsRNA in mRNA drug substance. In this assay, dsRNA-binding domains are fused to the SmBiT and LgBiT components of NanoBiT®. In the presence of dsRNA, these domains dimerize, reconstituting a functional NanoBiT® luciferase enzyme that generates light proportional to the dsRNA concentration. The assay detects dsRNA longer than 30 base pairs and is agnostic to sequence and size. It exhibits high specificity, with no cross-reactivity to single-stranded RNA or DNA, and a limit of quantitation below 10 pg/ml. As a complementary approach, we developed a cell-based bioassay to detect encapsulated dsRNA within LNPs. Upon endocytosis, LNP-encapsulated dsRNA is recognized by Toll-like receptor 3 (TLR3). This activation is captured via a TLR3-specific promoter driving luciferase expression, offering a physiologically relevant readout of dsRNA bioactivity. Both assays are streamlined in an “add-mix-read” format, requiring no wash steps or media transfers, and deliver robust, sensitive, and reproducible performance. Together, these tools enable precise detection of dsRNA contaminants in IVT products, ensuring the quality and safety of mRNA therapeutics.

#5480 Live cell real-time quantification of drug-target engagement for rapid drug discovery.

Ivan Babic[1], Nikolas Bryan[1], Claire Cunningham[2], Avery Sampson[2], Daniel Starczynowski[2], Elmar Nurmemmedov[1]

[1]CellarisBio, San Diego, CA,[2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Drug discovery for challenging drug targets necessitates the proteomic complexities of the cellular milieu for proper folding and function. Therefore, the conventional biophysical methods are not sufficient due to the artificial acellular environment they impose on the target. Cell target engagement is a powerful paradigm in drug discovery, as measures transitions in the thermodynamic state of target protein during engagement with drug molecules. The currently available luminescence-based cell target engagement methods are limited to measurement of end-point signal, poor utility across multiple challenging target families and insufficient resolution and integration for kinetic and mechanistic readouts. We have developed a highly sensitive and versatile fluorescence-based cell target engagement strategy designed for challenging drug targets. The technology enables interrogation of drug targets without interfering with folding, localization and function - all within the physiological milieu of the cell. Importantly, this new method allows for quantitation and monitoring of cell target engagement in real time using live cells. The system seamlessly integrates with readily available real-time systems such as QuantStudio, thus making it highly sensitive and scalable. We share data on challenging drug targets such as Myc, MAPK1, UBE2N and KRAS, and we demonstrate utility of this new methodology for future drug discovery.

#5481 A 3D bioprinted vascularized human tumor-on-a-Chip model for simultaneous evaluation of immunotherapeutic efficacy and safety.

Juliana Navarro-Yepes, Queeny Dasgupta, Purboja Purkayastha, Clara Erice, Carly Truong, Kim Phan, YongDuk Han, Michael Doerfert, Cassio Mello, Kevin Janson, Alma Antonio, Tracy Lin, Ameya Narkar, Sammy Datwani, SoonSeng Ng, Taci Pereira

Systemic Bio, Houston, TX

Immuno-oncology has revolutionized cancer treatment by harnessing the immune system to target tumors. However, developing effective therapies is challenging due to the complexity of the tumor microenvironment (TME), which influences therapy response, and toxicity risks like vascular injury and off-tumor effects. Traditional preclinical models fail to replicate human-specific immune responses and TME complexities, such as immune cell trafficking and tumor immune evasion. Additionally, current safety assessments for immunotherapies are inadequate in predicting systemic risks. These limitations highlight the need for more accurate, human-relevant tumor models. To address these challenges, we developed a 3D vascularized tumor-on-a-chip platform that incorporates key TME features for enhanced clinical relevance. Using 3D bioprinting, we integrated vascular structures with our human vascularized integrated organ system (h-VIOS™), enabling dynamic perfusion and simulating immune cell flow. The vasculature, endothelialized with primary human endothelial cells, forms a functional barrier expressing junctional markers and adhesion molecules, supporting immune cell interactions during T cell trafficking and tumor infiltration, while facilitating immunotherapy safety evaluation. Our model also integrates patient-derived tumor organoids that replicate key tumor characteristics, including heterogeneity and genetic diversity, and simulates TME interactions through co-culture with endothelial and immune cells. In a colorectal cancer model, we demonstrated chemokine-driven T cell infiltration from the endothelialized vasculature into the tumor, confirmed by confocal imaging and flow cytometry. We also modeled T cell responses to immune checkpoint inhibition with pembrolizumab, showing increased tumor killing, evidenced by elevated markers such as IFN-γ, Granzyme B, and cleaved-caspase 3. These results validate anti-PD-1 therapy in our model, highlighting its ability to capture T cell reactivation and tumor killing. In a TROP-2-expressing lung cancer model, we recapitulated the efficacy of the TROP-2 antibody-drug conjugate Sacituzumab govitecan, shown by increased cleaved-caspase 3 and reduced tumoroid viability. We also observed drug-induced vascular injury (DIVI) and off-tumor toxicity, evidenced by upregulation of inflammatory markers (ICAM-1, PECAM, P-selectin, IL-6, TNF-α) in endothelial cells. In conclusion, our 3D vascularized tumor-on-a-chip model outperforms traditional models by accurately replicating the TME and enabling the simultaneous assessment of drug-induced toxicities. This customizable platform facilitates mechanism-of-action studies and holds significant potential for personalized medicine, offering a powerful tool for advancing immuno-oncology research and improving therapeutic outcomes.

#5482 In vitro assays for prediction of ADC hematological toxicities: contribution of antibody, linker, and payload.

Yongzhao Huang[1], **Emer Clarke**[1], Graham A. E. Garnett[2], Manuel Lasalle[2], Jodi Wong[2], Ambroise Wu[2], Araba P. Sagoe-Wagner[2], Elena Barbosa[2], Catalina Suarez[2], Stuart D. Barnscher[2], Jamie R. Rich[2], Raffaele Colombo[2]

[1]Discovery Life Sciences, Seattle, WA,[2]ADC Therapeutic Development, Zymeworks Inc., Vancouver, BC, Canada

Antibody-drug conjugates (ADCs) are one of the fastest-growing therapeutic modalities, with 11 FDA-approved ADCs and more than 250 different ADCs in clinical development. Despite their success, significant hurdles remain. Notably, translating preclinical findings to the clinic remains challenging. Hematological toxicities are commonly associated with many ADCs and may arise from the direct killing of hematopoietic cells by the ADC itself or indirectly from payload released elsewhere in the body. Therefore, development of in vitro assays capable of predicting clinical findings could help improve ADC development and guide the selection of optimal linkers and payloads. Different ADCs were generated by conjugating targeted and non-targeted antibodies to a common microtubule inhibitor, while varying the protease-cleavable linkers. Clinically approved ADCs spanning different payload classes were used as benchmarks. ADC cytotoxicity was evaluated in both antigen-positive and antigen-negative cancer cell lines in vitro. Lysosomal cleavage of different linkers was evaluated in-vitro. ADC linker stability was also evaluated via a neutrophil differentiation assay, using expanded and differentiated CD34+ hematopoietic stem cells, which were treated with various ADCs before assessing CD66b neutrophil maturation. Finally, in vitro off-target toxicity was evaluated using a colony forming cell (CFC) assay to assess cytotoxicity of ADCs and their payloads on erythroid, myeloid, and megakaryocyte progenitors differentiated from hematopoietic stem cells.

In vitro cytotoxicity assays revealed variable potency among the ADCs tested. Some linkers (e.g., VK, FK) resulted in potent ADC cytotoxicity irrespective of the targeting antibody, while others (e.g., VA, VCit, GGFG, K) had target-dependent cytotoxicity in vitro. We identified linkers with different payload release rates in lysosomes, where GGFG and K showed the slowest rates. In vitro off-target and linker stability assays highlight how ADCs may induce toxicity in different healthy cell subsets depending on the ADC components (antibody, linker, and payload). In addition, by comparing results for ADCs and payloads, it is also possible to estimate if these toxicities are likely driven by the conjugated drug, the payload, or both. These results underlined how off-target toxicity and neutrophil differentiation assay may be useful during preclinical development to identify potential off-target effects and to improve the translation of ADC from preclinical to clinical settings.

#5483 High-throughput transcriptomics dose response profiling: identification of functional molecular signatures reflecting efficacy and safety of mTOR inhibitors.

Bruce Seligmann[1], Megan Opichka[1], Monica Hernandez[1], Zhoutao Chen[1], Joanne M. Yeakley[1], Salvatore Camiolo[2]

[1]BioSpyder Technologies, Inc., Carlsbad, CA,[2]BioClavis, Ltd., Glasgow, United Kingdom

Background and Purpose: Recent publications demonstrate the utility of the TempO-Seq® high-throughput transcriptomics (HTTr) assay in generating *in vitro* dose response data for 1751 compounds in MCF-1 cells [Harrill et al, Tox Sci 2024, 202(1): 103-122] and 1201 compounds in U-2OS cells [Bundy et al, Tox & Applied Pharmacol 491 (2024) 117073]. These studies identified biological pathway altering concentrations (BPACs) for functional molecular signature patterns by evaluating 11,037 functional gene signatures for each compound and dose. We applied this same approach to identify novel differences in the modulation of molecular/functional signatures by mTOR rapalogs and ATP-competitive inhibitors.

Methods: To cover a broad range of functional molecular signatures we profiled the selected compounds, at 8 concentrations each, in MCF-7, U-2OS, and HepaRG cells using the commercial TempO-Seq whole transcriptome v2.1 assay. We identified differentially expressed genes between treated and untreated cells using DESeq2, calculated BPACs as previously described [Harrill et. al. Tox Sci 2021, 18(1): 68-89], then identified which of the 11,037 functional molecular signatures were modulated (as published by Harrill and Bundy).

Results: Signature patterns with different BPACs were identified for each compound. Each cell line generated a set of compound modulated molecular signatures that overlapped with one or both of the other cell lines, as well as unique molecular signatures to that cell line. From these data, we identified a set of functional molecular signatures associated with the class of mTOR inhibitors. We also identified molecular signatures that differentiated the rapalogs, which bind to FKBP12 and the mTORC1 complex to inhibit its kinase activity, from the ATP-competitive inhibitors, which inhibit the kinase activity of both mTORC1 and mTORC2. Finally, we identified compound-specific molecular signatures. These data will be presented.

Conclusions: The results demonstrate the utility of HTTr dose response compound profiling in differentiating compound activity using a database of 11,037 functionally annotated molecular signatures. The TempO-Seq assay effectively distinguished these activities for each compound and provided data that reflected potential efficacy and safety. Each cell line contributed unique modulated signatures that were absent in others, offering a more complete view of the activity of each compound. These findings demonstrate the value to therapeutic target focused drug discovery programs of the TempO-Seq HTTr assay in generating functional mechanistic dose response data, and underscore the potential of HTTr TempO-Seq assays to differentiate chemical series not only based on compound structure, but also on functional dose response activity that may impact both efficacy and safety.

#5484 Expanding the role of western blot imaging for oncology research: novel applications for in-cell western assays and single cell analysis using the ChemiDoc Go imaging system.

Michael Kirmiz[1], Deanna Woo[2], Nikolas Chmiel[1], Kenneth Oh[2], **Angelica P. Olcott**[2]

[1]R&D, Bio-Rad Laboratories, Hercules, CA,[2]Bio-Rad Laboratories, Hercules, CA

Western blotting is widely used to detect cellular proteins and nucleic acids in cell lysates; however, its application for analyzing intact cells remains largely unexplored. Here, we evaluate compatibility of Bio-Rad's ChemiDocTM Go Imaging System with chemiluminescence and multi-channel fluorescence detection for in-cell western immunofluorescence assays performed on 96-well plates and microscopy slides. Emphasis was placed on use of the StarBright Blue 700-conjugated secondary antibody due to its strong, stable fluorescence, wide dynamic range, and compatibility with multiplexed assays. In 96-well assays, HEK293 cells were stained with anti-mortalin primary antibodies, followed by StarBright Blue 700-conjugated secondary antibodies. These exhibited a three-fold signal increase compared to control samples lacking the primary antibody. This scalable and high-throughput platform offers a valuable tool for cancer research, particularly for evaluating protein expression in cancer cell lines, facilitating drug discovery, and assessing therapeutic efficacy across diverse cancer models. On microscope slides, HEK293 cells were stained with anti-mortalin primary and StarBright Blue 700 secondary antibodies further demonstrating the imager's strong compatibility with immunofluorescence on fixed, intact single cells. This capability enables simultaneous detection of multiple biomarkers in cancer-related pathways, supporting target validation and pathway analysis in cancer biology. Additionally, the imager was used to validate T cell staining with CD3-labeled fluorescent antibodies prior to multiplexed flow cytometry. This step simplifies the confirmation of T cell staining before performing more complex flow cytometry assays, with direct applications in immuno-oncology. These include monitoring immune cell activation and characterizing tumor-infiltrating lymphocytes (TILs), both critical for developing immune-based cancer therapies. Potential oncology research applications of these novel techniques may include:

- Quantification of protein expression changes following drug treatments or genetic modifications
- Evaluation of protein-protein interactions relevant to cancer signaling pathways
- High-throughput screening of compound libraries
- Provide insights into the analysis of protein localization within entire cells, aiding in biomarker identification and therapeutic targeting efforts.

Together, these findings highlight novel applications of western blot imaging technology as a fast, scalable, and sensitive platform for multiplexed protein analysis, supporting cancer research and therapeutic development.

#5485 A new 30-color spectral flow cytometry panel for T cell characterization.

David Draper, Brogan Yarzabek, Stacey Roys, Anita J. Zaitouna, Philip Lapinski, Amber Rowse, Scott Wise

Labcorp, Ann Arbor, MI

Spectral flow cytometers have facilitated the development of antibody panels with 30 colors or more to provide deep insights into the immune response. With a focus on T cell therapies, Labcorp has developed the 30-color immunophenotyping panel using the Cytek Aurora™ Spectral Flow Cytometer. The panel backbone includes 1 viability dye and 10 lineage markers to profile T cell, NK, and B cell subsets. 19 additional functional markers enable the characterization of activation, exhaustion, cytotoxicity, and proliferation in each subset, plus memory T cell subset delineation. Antibody-fluorophore combinations in a novel 30-color spectral flow cytometry panel were carefully considered and the resulting panel was developed utilizing primary PBMCs cultured with IL-2 and anti-CD3/CD28 to activate T cell subsets. Modulation of the expression levels for each functional marker was validated via comparisons made to unstimulated PBMCs. The most notable changes observed were in the expression of CCR7, CD25, ICOS, and Granzyme B which were expressed at levels between 60-95% of CD8+ T cells. Checkpoints including PD-1, LAG-3, TIM-3, and TIGIT were also upregulated, albeit to a lesser extent (<50% of CD8+ T cells). For memory phenotypes, analysis of CD45RA, CD45RO, CCR7, CD95, CD62L, and CD103 were combined to delineate Tn, Teff, Tte, Tcm, Tem, and Trm subsets. To provide an additional unbiased and wholistic analysis, t-SNE was conducted to deliver a comprehensive interpretation T cell functionality in the context of various exhausted phenotypic profiles. Finally, Nanostring® analysis using the nCounter® CAR-T Characterization panel was performed to further validate the modulation of gene sets underlying the TCR-driven PBMC activation. As expected, the transcriptomic analysis mirrored the flow cytometry immunophenotyping data with regard to activation and immunosuppressive gene modulation downstream of the TCR signaling. Taken together, a lymphoid panel was developed that measured multiple phenotypic and activity markers in T cells. Importantly, our data demonstrate how spectral flow cytometry can be applied to assess T cell therapies in preclinical tumor-bearing mouse models or clinical trials.

#5486 Bioluminescent assays for antibody-drug conjugate development: internalization and Fc-mediated functions.

Julia K. Gilden[1], Christopher Eggers[1], Yitong Li[1], Rod Flemming[1], Nicholas Hess[2], **Gopal B. Krishnan**[2], Frank Fan[1], Brock Binkowski[1], Marjeta Uhr[1], Mei Cong[1]

[1]R&D, Promega, Madison, WI,[2]Promega, Madison, WI

Antibody-drug conjugates (ADCs) combine targeted delivery with potent cytotoxic payloads, utilizing multiple mechanisms of action (MoA). These include direct cytotoxicity following internalization of the ADC by antigen-expressing cells, killing of bystander cells through cleaved payloads, antigen function blockade, and immune-mediated cytotoxicity (e.g. Antibody-Dependent Cellular Cytotoxicity and Antibody-Dependent Cellular Phagocytosis) driven by the antibody Fc region. Comprehensive characterization and potency testing of ADCs require assays that capture each MoA. To address this need, we developed bioluminescent tools to streamline ADC evaluation, focusing on antibody internalization, Fc-mediated effector functions, and bystander killing. Studying bystander killing is particularly important in immunotherapy strategies for cancer, as it allows ADCs to target heterogenous tumors where not all cells express the antigen. The internalization assay employs luciferase-labeled Fab fragments with a quenching mechanism to measure intracellular antibody localization. The assay was validated using HER2-expressing SKOV3 cells with anti-HER2 monoclonal antibodies as model systems. It shows strong time- and antigen-dependent luminescence, achieving over 100-fold signal increases compared to controls, enabling quantitative ADC screening. Additional assays include Fc receptor (FcR) binding assays and cell-based reporter bioassays for ADCC and ADCP activities. The HiBiT technology is a luminescent tagging system that enables precise and sensitive detection of protein interactions and cellular events, making it a powerful tool for evaluating Target Cell Killing (TCK) by effectors and cytotoxic payloads carried by antibodies. To assess payload efficacy, a HiBiT-enabled bystander killing assay was developed, distinguishing ADCs with varying payload properties. Taken together, the internalization assay, bystander killing assay, and Fc effector bioassays, all based on bioluminescent platforms, offer a comprehensive and high-throughput solution for evaluating ADC functionality. With exceptional sensitivity, broad dynamic range, and efficient workflows, these tools enable precise optimization of therapeutic efficacy, delivering significant value for preclinical ADC development.

#5487 IndEx-2: An *in vitro* model to evaluate the impact of target antigen density on antibody and immune therapeutics.

G. Meehan, A. Patakas, H. Findlay, V. Senthivel, T. London;
RoukenBio, Motherwell, United Kingdom

The density of cell-surface receptors targeted by therapeutic agents profoundlyinfluences their safety, efficacy, and pharmacokinetics. Low receptor expression on healthy cells can result in on-target, off-tumor toxicities, while tumor heterogeneity in receptor density may allow low-expressing clones to evade treatment. Traditional *invitro* evaluation relies on panels of cancer cell lines with varying receptor levels, anapproach that is both logistically challenging and experimentally inconsistent. This limitation is particularly pronounced for therapeutics targeting two receptors.To address this, we developed IndEx-2, an *in vitro* cell line platform that employs chemical proximity promoters to achieve a high dynamic range of tuneable and independent expression of up to two target antigens within a single, uniform cell line background. We have demonstrated precise control of antigen density for several receptors ranging from a few hundred up to a million receptors, including a cell line thatallows independent control of two target antigens (CD19 and CD22). We report herethree examples of the utility of the system. In the first, we have compared CLN978, a novel CD19- TCE developed for B-cell malignancies and autoimmune diseases, with Blinatumomab and demonstrated that the former retained its activity in terms of cytotoxicity and cytokine production at much lower levels of CD19 expression and estimate the threshold for each molecule in a cohort of 10 healthy donors. In the second, we assessed the ability of two HER2-targeting CAR-T cells, employing high and low antigen binders, and estimate the number of receptors that resulted in half maximal response (R50) for cytotoxicity and IFNγ production, demonstrating the utility of the system as an “on-target, off-tumor” hazard assessment screening tool. Lastly, using our CD19/CD22 dual-antigen cell line, we compared tandem (“OR”) CD19/CD22-CD3zCD28 and dual (“AND”) CD19-CD3z and CD22-CD28 CAR constructs targetingboth antigens. The tandem CAR exhibited enhanced cytotoxicity when either or both antigens were expressed, whereas the dual CAR required co-expression of both antigens for optimal T-cell activation. These results underscore IndEx-2's robustcapability to evaluate the influence of antigen density on therapeutic safety andefficacy, providing a powerful tool for the development of antibody-based and immune-targeting cancer therapies.

#5488 Identifying novel Ewing sarcoma therapeutics using a high-throughput chromatin accessibility assay.

Darian Williams[1], Andrew McFadden[2], Austin Hepperla[2], Min Shen[1], Tino Sanchez[1], Gordon Stott[3], Mark Henderson[1], Ian Davis[4], Samantha Pattenden[2]

[1]Early Translation Branch, National Center for Advancing Translational Sciences, Rockville, MD,[2]School of Medicine, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD,[4]Department of Pediatrics, School of Medicine, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Chromatin dysregulation has been implicated in the development of a wide range of diseases, including cancer, as well as therapeutic resistance. Genetic alterations in chromatin regulatory factors and aberrant activity of transcriptional regulators alter chromatin states and drive tumor growth in cancer. One example of a cancer that is driven by alterations in chromatin landscape is Ewing sarcoma, a highly aggressive pediatric cancer of bones and soft tissues. Ewing sarcoma is driven by an oncoprotein generated by the translocation of the EWSR1 and FLI1 genes, resulting in the fusion oncoprotein (EWSR1::FLI1), which activates noncanonical enhancers and alters the expression of critical genes associated with the disease. EWSR1::FL1 is challenging, if not impossible, to target directly with small molecules, and viable therapeutic targets for Ewing sarcoma have been slow to emerge. To broaden the search for druggable targets we developed a target agnostic screening approach that exploits oncoprotein-specific chromatin accessibility states as a relevant and direct functional readout for identifying novel therapeutics. We developed and optimized a 384-well, high throughput (HT) version of the Assay for Transpose-Accessible Chromatin assay (HT-ATAC-seq) that was applied to 500 EWSR1::FLI1-regulated chromatin regions. Using Ewing sarcoma-derived A673 cells, we conducted a pilot screen of 12,000 small-molecule compounds comprising approved drugs, investigational agents, and bioactive compounds. The screen identified 285 compounds that partially reversed Ewing sarcoma chromatin abnormalities. The set of active compounds included Panobinostat, which is currently in preclinical development for Ewing sarcoma. This pilot screen supports the HT-ATAC-seq assay as a robust approach to identify novel compounds that reverse the chromatin alterations associated with Ewing sarcoma. This approach and assay can be adapted to investigate other cancers or pathologies associated with chromatin state alterations.

#5489 Quantitative intracellular immunoassay for monitoring poly (ADP-ribose) in cancer cells treated with PARP inhibitors.

Hans Layman[1], Dusit Natrakul[2], Maya Kim[2], Lars Duerig[2], Sripriya Ranganathan[2], Belinda Jackson[2], Lalitha Srinivasan[2], Enrique Sanchez-Lemus[2], Chin-Chi Chen[2], Caitlin Hansen[2], Jacob N. Wohlstadter[2]

[1]Meso Scale Diagnostics, LLC, Pacifica, CA,[2]Meso Scale Diagnostics, LLC, Rockville, MD

Poly (ADP-ribose) polymerase (PARP) enzymes play a crucial role in cellular DNA repair mechanisms by catalyzing the addition of poly (ADP-ribose) (PAR) chains to target proteins in response to DNA damage. The overactivity of PARP has been implicated in various pathological conditions, including cancer, where PARP inhibitors (PARPi) have emerged as an important therapeutic strategy. Monitoring PAR levels within different cellular environments is essential for understanding PARP activity and optimizing PARP inhibitor efficacy. This study outlines the characterization and development of a sensitive electrochemiluminescence immunoassay designed to quantitatively measure PAR in multiple cancer cell lines treated with PARP inhibitors.

The PAR assay was developed on the MSD MULTI-ARRAY platform. Multiple anti-PAR antibodies were tested in all possible capture/detection combinations using a wide range of PAR polymer concentrations. An optimal pair was selected based on response linearity and high sensitivity. Cancer cell lines were subjected to treatment with hydrogen peroxide (MCF-7) or cultured under hypoxia (Cos7, HeLa) over 24 hours, followed by whole cell lysate collection for sample detection using the PAR immunoassay to demonstrate assay utility (e.g., linearity, sample detectability, matrix tolerance). To demonstrate the functional application of the PAR immunoassay, three human cancer cell lines were cultured under standard conditions in 96-well plates and treated with varying concentrations (0.1-100 µM) of three PARP inhibitors over time periods ranging from 1 to 24 hours. Cell lysates were harvested, protein was quantified, and lysates were added to the PAR immunoassay to determine PAR concentration. IC_{50} curves were generated to evaluate each PARPi's potency.

Following optimization, the PAR immunoassay demonstrated good sensitivity with an LLOD of 3.34 pM in an assay diluent containing protease and phosphatase inhibitors. Using cell lysates from MCF-7, Cos7, or HeLa cells, assay linearity was demonstrated between 0.156-10 µg protein/well, resulting in a linear concentration range of 7 to 2,630 pM. Upon treatment with PARPi, a time and dose-dependent modulation of PAR levels was observed across all cell lines and inhibitors. Specifically, significant changes in IC_{50} values were found across cell lines and PARP inhibitors tested, indicating the assay's sensitivity for differentiating inhibitory effects of PARP compounds.

This study demonstrates the utility of a novel immunoassay for accurately quantifying PAR in various cancer cell lines subjected to PARP inhibition. This assay offers a robust tool for evaluating PARP inhibitor efficacy and can serve as a valuable asset for researchers in drug development and cellular biology to explore PARP-related cellular responses in different disease contexts.

#5490 Biochemical tools to characterize specific Werner syndrome helicase inhibitors and accelerate drug discovery.

Thibault Annaval[1], Jeremy Lhomedet[1], Amelie Moreau[1], Chantal Rein[1], Alastair King[2], Sophie Raynal[1], **Vanessa Jahnke**[1]

[1]Eurofins Discovery France, Celle-Levescault, France,[2]Eurofins Discovery USA, St-Charles, MO

WRN has various roles in the maintenance of genome stability and is commonly found upregulated in cancers. Therefore, new WRN inhibitors have emerged for selective cancer therapy. Eurofins Discovery researchers have developed assays to accelerate helicase drug discovery focusing on WRN. Relaying on three different biochemical assays: Binding, ATPase and unwinding, these tools can be used to screen, validate, and characterize inhibitors mode of action (MOA). Using clinical-stage WRN helicase inhibitor HRO761 and VVD214, we present a complete MOA study demonstrating that the assays generated by Eurofins Discovery teams are well suited for WRN drug discovery project. The full length protein was used in the three biochemical assays. First protein stability was tested to qualify the protein used in all assays. ATPase activity was performed using DNA double strand substrate with ADP Hunter Plus assay kit (Eurofins DiscoverX). Unwinding activity was performed using the same substrate labelled in 5' end by the fluorophore TAMRA and at the 3' end by the quencher BHQ2. Compounds IC_{50} were validated in the two assays. MOAs were characterized by testing the reversibility of the interaction, substrate competition and ATP cooperativity. Binding analysis was assessed using UHPLC/MS/MS. Methods were first determined and then K_d, B_{max}, k_{on}, k_{off} were analyzed. Stability assay demonstrated that our enzyme is stable with cycle of freezing/thawing. IC_{50}s for ATPase activity correlate well with available publication on the HRO761 and VVD214 with 220 nM and 3.5µM respectively. The panel of selectivity testing, developed by the Eurofins Discovery team, showed high selectivity of the two compounds for WRN. ATPase activity assay pharmacologies of the two compounds were validated in unwinding activity assay . IC_{50}s were 29nM and 6.4µM respectively. Reversibility testing showed that HRO761, is a reversible inhibitor and that VVD214 is an irreversible inhibitor. WRN mass spectrometry binding assay was successfully developed using HRO761, as reference compound. The binding assay using ATP as nonspecific ligand demonstrates a decrease in HRO761 binding to its site suggesting a competition or a negative cooperativity. Enzymatic assay showed that HR0761 is a mixed ATP allosteric inhibitor. Further experiment demonstrates that ATP prevent HR0761 binding when it binds first to the helicase. In this project, we have performed a complete characterization of two different compounds MOA. We were capable of validating HRO761 as an allosteric inhibitor with ATP negative cooperativity and VVD2014 as covalent inhibitor. This demonstration provides strong evidence that the developed assays are well suited for helicase drug candidate discovery, development and characterization. These will help providing innovative solution to fight against cancer an especially the one involving WRN over expression.

#5491 High throughput bioluminescent homogenous assay to monitor N6-methyladenoisne (m6A).

Said A. Goueli[1], Dareen Mikheil[2], Kevin Hsiao[1], WeiWei An[1], Matt Larsen[1]

[1]Promega, Madison, WI,[2]Research and Development, Promega, Madison, WI

N6-methyladenosine (m6A) is a modified nucleoside derived from adenosine, distinguished by the presence of a methyl group at the N6 position. This structural modification enables m6A to play unique roles in cellular signaling, gene expression regulation, and metabolic processes, positioning it as a crucial player in cellular function and disease pathology. Its involvement ushered the beginning of the field of in epitranscriptomics, particularly N6-methyladenosine (m6A)-related pathways, which modulate mRNA stability, translation, and splicing have lent tremendous significance to this form of RNA modification. There are about 7000 mRNAs with m6A modifications and they are highly conserved. Non-coding RNA is mainly regulated by m6A methyltransferase and demethylase, which plays an important biological role in the occurrence and development of tumors. Recent studies suggest that m6A and its derivatives could serve as potential biomarkers for disease diagnosis and as therapeutic targets. Recognizing how important the early detection of m6A is, we have developed an assay that monitors the concentration of m6A so it can be used for screening of m6A-RNA from patients with cancer such as liver cancer. The assay relies on new concept of novel nanoluciferase (nanoluc) complementation where a small peptide (SmBiT) linked to m6A through a linker (m6A tracer) can be recognized by an anti m6A antibody that is linked to a nanoluc complementary fragment (LgBiT) resulting in a bioluminescence upon the addition of nanoluc substrate. The presence of m6A-RNA that is generated in the reaction with RNA substrate, S-adenosylmethionine (SAM) and METTL 3/14 complex can be detected with this assay. Using MTTL3/14 complex we show that SAM is an excellent substrate for this enzyme with a Km of 240nM. The assay does not recognize Adenosine, AMP, ADP, or ATP in the reaction. We will show data in support of this technology to monitor the presence of m6A in methylated RNA. The assay is homogenous, HTS formatted and can be completed in less than one hour. Thus, this assay provides valuable contributions for investigating modulators of the MTTL3/14 complex or FTO demethylating enzymes and facilitates the search for novel therapeutics.

#5492 Application of Optim.AI™ platform for predictive evaluation of immunotherapy combinations in breast cancer.

Sharon Pei Yi Chan, Jhin Jieh Lim, Masturah Mohamed Abdul Rashid, **Edward Kai-Hua Chow**

KYAN Technologies Pte Ltd, Singapore, Singapore

PURPOSE: Successful pre-clinical evaluation of immunotherapy within ex vivo settings require complex systems to accurately represent tumor heterogeneity and the surrounding tumor microenvironment (TME). With expanding immunotherapy combinations being investigated in clinical trials, particularly for breast cancer (BC), there is a growing need for reliable methodologies for functional immune-oncology drug testing in a patient- and subtype-specific manner. We have developed Optim.AI™, a hybrid experimental-analytics platform designed to predict and rank actionable treatment options, with successful application in clinical settings to guide cytotoxic and targeted therapies. However, its potential for evaluating immunotherapy responses remains underexplored. In this study, we present an integrated platform that combines short-term 3D tumor-immune cell co-culture with high content imaging and Optim.AI™ to evaluate immunotherapy-focused drug sets in HER2-positive and triple-negative BC subtypes.

METHODS: BC cells were pre-labeled with cell tracker and seeded in a 384-well format for 3-4 days to allow spheroid formation, and co-cultured with PBMCs. Optim.AI™ combinatorial drug testing was then applied to the co-culture system with up to 12 FDA-approved chemotherapies, targeted agents, monoclonal antibodies, and antibody-drug conjugates. Utilizing real-time fluorescent apoptosis signal as the phenotypic readout, high-content analysis of tumor-specific cell death was evaluated at specific timepoints and used for Optim.AI™ analytics and predictive ranking of combinatorial immunotherapy sensitivities.

RESULTS: Quantitative, real-time, image-based analysis allowed for phenotypic measurement of complex tumor-immune cell interactions within the 3D co-culture system, including immune cell migration, infiltration into spheroids, and subsequent tumor-specific killing. Co-culturing BC spheroids with PBMCs at an optimized effector-to-target ratio induced significant antibody-dependent cellular cytotoxicity, with measurable responses observed within 72 hours post-treatment. Through Optim.AI™, we observed distinct sensitivities towards the different antibody-based therapies, in HER2-positive and triple-negative BC spheroids. These findings underscore the potential of Optim.AI™ to effectively evaluate and rank immunotherapy-based treatment combinations in a physiologically relevant, 3D TME model.

CONCLUSIONS: We present an integrated platform combining high-content screening of a 3D tumor-immune cell co-culture system with Optim.AI™ and demonstrated both visualization and quantification of tumor-specific responses in the context of the TME. Future applications to ex vivo patient samples hold promise for personalized treatment regimens and identifying more effective immunotherapy combinations for BC and other solid malignancies.

#5493 3D bone marrow niche: Scalable and physiologically relevant *ex vivo* drug screening platform for acute myeloid leukemia and multiple myeloma.

Talita Stessuk, Dorrith Verstegen, Sophia Ajala, Hanna Vermeer, Jolie Flach, Marrit Putker, Nataliia Beztsinna, Ludovic Bourre

Crown Bioscience Netherlands B.V., Leiden, Netherlands

Introduction: Preclinical screening of drugs targeting hematological cancers, like Acute Myeloid Leukemia (AML) or Multiple Myeloma (MM), is challenging due to limited *ex vivo* growth and short viability of cells from bone marrow and blood cancers. Consequently, most of the preclinical studies rely on short-term suspension cultures of cell lines and/or primary cells, which undergo spontaneous apoptosis and do not predict the *in vivo* response. Physiologically relevant *in vitro* screening of cells from hematological malignancies requires the recapitulation of the human bone marrow niche (BMN) to provide cell-cell interactions and paracrine factors that are critical for the *ex vivo* proliferation of malignant hematopoietic cells. In our 3D BMN platform, homogeneous and reproducible 3D endothelial-mesenchymal networks that resemble pre-vascularization are used to integrate primary cells isolated from malignant bone marrow disorders and assess Standard of Care (SoC) drug responses
Methods: Bone marrow and whole blood from newly diagnosed and relapsed-refractory (RR) patients with AML and MM were processed to isolate, respectively, CD34+ myeloid blasts and CD138+ myeloma cells. Heterologous mesenchymal stromal cells (MSC) and endothelial cells were embedded in a protein-rich hydrogel in a 384-well format until network formation was microscopically observed. Cryopreserved primary cancer cells were integrated into the 3D BMN and exposed to SoC drug panels for 6-7 days. Quantitative assessment of the SoC drug effects was performed using our proprietary automated high content imaging (HCI) analysis platform. Immunofluorescence (IF) staining and flow cytometry were used for in-depth characterization of BMN-malignant cell co-cultures.
Results: 3D BMN networks were homogeneously distributed throughout the hydrogel and supported the integration of AML and MM cells. Colony-like clusters of cancer cells were observed within the BMN networks, suggesting outgrowth of the cells, which was validated by Ki67 staining. IF staining was also used to characterize and observe the maturation of the BMN over time (CD31, fibronectin). FACS analysis confirmed MSCs immunophenotype and revealed the proportion of myeloid blasts and myeloma cells in the bone marrow of each donor. Dose-dependent responses to Cytarabine and Daunorubicin were observed in primary AML and MM cells integrated in 3D BMN.
Conclusion: The complex bone marrow microenvironment is critical for the maintenance, proliferation, and drug responses of malignant cells from bone marrow disorders. Here, we present a robust and reproducible 3D BMN platform that supports medium-throughput HCI drug screening in primary patient cells from different hematologic malignancies. In addition, our HCI analysis offers the possibility to study off-target effects to the MSCs and endothelial cells within the niche.

#5494 Pursuit of novel first-in-class medicines with a suite of AI-enabled platform technologies.

Jenny Rudnick, Chase Neumann, Kelly Biette, Aurora Blucher, Matias Casas-Selves, Yoon-Chi Han, Gabriela Andrejeva, Rebecca Sarto Basso, Sarah Jo DeVore, Mark Parnell, Christina Egbert, Michaela Hatch, Guillaume Barbe, Carl Brooks, Weston Judd, Vamshi Manda, Zhijuan Cao, Ashraf Saeed, Robin McDougall, Doo-Hyun Kwon, Elizabeth Bruckheimer, Hayley Donnella, Paul Rearden, Joseph Carpenter, Najat Khan, Aimee Iberg, Brandon Probst

Recursion Pharmaceuticals, Salt Lake City, UT

At Recursion, we are on a mission to radically improve patient lives by revolutionizing drug discovery through technological innovation and multi-modal insight generation. Here we describe three preclinical pipeline platform methods that can be assembled in a modular fashion to identify and achieve key stage gate milestones in hit-to-lead and lead-optimization while simultaneously reducing timelines, cutting costs and increasing scale. We show examples from our preclinical pipeline demonstrating the utility of these methods to drive target agnostic discovery of novel first-in-class small molecule oncology therapeutics.(1) Early MoA prediction and derisking: Utilizing our powerful phenomics platform, we can identify starting novel chemical matter predicted to impact disease-relevant biology. However, within most disease-relevant areas of biology, there are strategic or toxicity-based rationales to avoid certain MoAs. By using a combination of phenomics and structural insights, we have built a powerful MoA prediction tool that provides an early view into compound mechanistic insights at the initial hit stage. Hit compounds can then be tested in biochemical assays informed by the predictive model to validate desirable MoAs and/or de-risk undesirable MoAs and therefore advance only those with a desirable path forward. (2) Translational model selection: The pursuit of first-in-class approaches combined with target agnostic discovery presents a challenge to early discovery teams seeking to select best-fit translational models, as the information and predictive value provided by literature is limited. Here we show an example of how we can leverage a combination of public large-data insights, Tempus patient data, DepMap dependency scores, and phenomic relationships to select preclinical translational models that are well suited for testing our hypotheses. Such selection strategies can be automated, enabling rapid execution and decision making in the hit-to-lead stage of discovery. (3) Multimodal SAR: We leverage both phenomics and transcriptomics to drive structure-activity relationship (SAR) optimization in a target agnostic fashion. We integrate these two data layers to select novel chemical entities (NCEs) that drive our biology of interest in both orthogonal assay modalities, enabling us to select compounds with the best in vivo potential. We show an example of how to drive lead optimization SAR by comparing the phenomic and transcriptomic signature of NCEs to those of an efficacious hit compound that potentiates immunotherapy response in vivo, resulting in a polypharmacologic profile that eradicates tumors in 100% of treated animals. Because our approach does not require target-based bespoke cellular or biochemical based potency assays, SAR is highly scalable and is currently being utilized in other programs with a diversity of MoAs.

#5495 Screens to identify TCR-specific epitopes using engineered antigen-presenting cells.

Debbie Deng, Tianbing Liu, Kitt Paraiso, Paul Diehl, **Alex Chenchik**

Cellecta, Inc., Mountain View, CA

Despite the key role of T-cell receptors (TCRs) in adaptive immune responses, experimental validation of interactions between activated TCRs and cognate antigens remains a holy grail in developing novel molecular and cell-based therapeutics. To facilitate efficient screening of TCR-antigen interactions, we engineered both reporter Jurkat-NFAT-GFP cells to express candidate-activated TCRs, and antigen-presenting K562-HLA cells (APC) expressing a library of predicted peptide epitopes. To detect antigen-activation of Jurkat cells interacting with cognate epitopes, the K562 cells were engineered to express a single-chain variable fragment (scFv) which could bind IL2 released by the activated Jurkat-TCR cells. Jurkat-TCR reporter cells co-cultured with K562-APC cells induce expression of the HLA cognate epitope, which enables them to be labeled with PE anti-IL2 antibody and purified by FACS. The cognate epitope is characterized using NGS. To validate this TCR-epitope library screening system, we constructed and expressed a library of ~100 cancer-associated epitopes in K562-HLA_A02:01 cells. The K562-HLA-epitope library was then co-cultured with the Jurkat reporter cells expressing MART1 TCR, NY-ESO-1 TCR or, as a control, CMV TCR. After staining with the IL2 antibody and FACS selection, stained APC cells detected specific epitopes with high specificity for cancer-associated and control TCRs.

#5496 Target density matters: Binding kinetics of antibody-based therapeutics are highly influenced by target expression levels.

Eric Cruickshank[1], Nichole Cerutti[1], Hannah Findlay[1], Timothy London[1], Vivien Hafner[2], Andreas Kratzert[2]

[1]RoukenBio, Motherwell, United Kingdom,[2]Bruker Biosensors (Dynamic Biosensors GmbH), Munich, Germany

Understanding antibody-based therapeutic behaviour under varying target expression levels iscrucial for effective tissue and cell-specific targeting. Traditional *in vitro* evaluations often relyon cancer cell line panels with differing receptor levels, which can be logistically challengingand yield inconsistent results. Standard techniques like SPR are poorly suited for analyzingmolecule binding to eukaryotic cells, as detection depth (~200 nm) covers only ~2% of a typical10-20 µm cell and unstable immobilization limits SPR to cell attachment studies. Similarlimitations apply to BLI and QCM. Other cell-based binding technologies have not gainedwidespread adoption due to challenges in automation, sensitivity, and throughput. Measuringhow binding is influenced by differential target expression is critical for tumor-targetingtherapeutics, as antigen density impacts safety through on-target, off-tumor toxicities andaffects efficacy by enabling tumor escape at low target expression levels.The purpose of this study was to investigate how target antigen density influences the bindingkinetics of therapeutic molecules under physiologically relevant conditions, addressinglimitations inherent to traditional kinetic assays. To achieve this, we utilized the novel IndEx-2system, which employs CHO-K1 cells engineered for tuneable expression of one or two targetantigens via chemically induced proximity-mediated induction. This was paired with single-cellInteraction Cytometry (scIC), a unique biosensor-based technology that measures real-timebinding directly on captured cells. By combining these two systems, we examined the bindingkinetics of trastuzumab to HER2 expressed at varying levels, serving as a model for tumourheterogeneity. HER2 expression was quantified using flow cytometry, while scIC was used toperform kinetic measurements on the same cells. The analysis revealed that higher HER2expression levels prolonged trastuzumab residence time due to avidity effects. Notably,differences in affinity (Kd) across HER2 densities were driven by variations in the dissociationrate (k*off*), rather than the association rate (k*on*), underscoring the critical influence of targetdensity on binding kinetics.This study demonstrates how target density can affect therapeutic binding kinetics, offeringcritical insights into drug efficacy and duration of action. By integrating scIC with the IndEx-2platform, we provide a robust framework for assessing kinetic behaviour of targetedtherapeutics in a cellular context, including bispecific binders and receptor internalisationstudies. These results pave the way for safer, more effective therapeutics, selected in morecomplex, and more relevant, biological systems.

#5497 Sacituzumab govitecan screening in a large organoid panel reveals the importance of functional assays for predicting ADC tumor response.

Marten Hornsveld[1], Jinxi Wang[2], Jun Zhou[2], Xiaolong Tu[2], Peter van Schaik[1], Mariusz Madej[1], Hester Bange[1], Jessie J.J. Wang[2], Ludovic Bourre[3], Marrit Putker[1]

[1]Crown Bioscience Netherlands B.V., Leiden, Netherlands,[2]Crown Bioscience Taicang, Taicang, China,[3]Crown Bioscience Inc, San Diego, CA

Introduction: Antibody-drug conjugates (ADCs) represent an innovative approach in targeted cancer therapy, combining antibodies' specificity with therapeutic modalities such as cytotoxic or targeted chemical compounds. This study presents an ADC testing platform, leveraging patient-derived organoids (PDO) and advanced 3D high-content imaging.
Methods: The efficacy of FDA-approved ADC Sacituzumab Govitecan/SN38 (SG), was evaluated in the CellTiter-Glo (CTG)-based OrganoidXplore panel, a 3D in vitro screening panel of 50 organoid models across 7 indications. The panel was characterized by NGS (WES, RNAseq) but selected without bias for TROP2/TACSTD2 expression. The OrganoidXplore screen was followed up with validating SG and payload responses using CTG and high-content imaging (HCI). ADC target engagement was assessed via immunofluorescence (IF) and ADC responses were validated in a selection of in vivo PDX models.
Results: SG demonstrated a broad differential response (<0.01nM<IC50<50nM) in the OrganoidXplore panel, with 18 models showing strong responses (IC50<0.01nM). Response rates did not correlate with mRNA expression TROP2/TACSTD2. IF staining of the original PDX tumor tissues and organoids confirmed the correspondence between TROP2/TACSTD2 mRNA and protein expression levels, reaffirming that SG sensitivity did not directly correlate with gene and protein expression. Additional studies were performed with SG and SN38 in selected resistant and sensitive organoid models by HCI analysis. Similarly to the CTG assay, TROP2/TACSTD2 protein expression did not correlate with increased SG efficacy, showing that PDO sensitivity was not primarily driven by absolute target levels but rather through the mode of action of ADC uptake and payload sensitivity. Preliminary in vivo ADC efficacy results supported the in vitro findings.
Conclusion: The OrganoidXplore screening platform provides insights into ADC efficacy, and responses and target engagement were validated with HCI. Combined, this demonstrates a lack of correlation between target expression (mRNA and protein) and drug efficacy, and the importance of functional testing for efficacy across a diverse patient population. The unique application of the 3D HCI platform for additional characterization, including ADC binding and uptake assays, will be an essential step to gain insight into the mode of action requirements for ADCs to be effective. These findings highlight the application of functional screening in organoid to better understand the complexity of ADC efficacy and identify responder/non-responder patient profiles to guide on resistance mechanism, in vivo modeling, and biomarker identification for patient stratification.

#5498 Microenvironmental control eliminates edge effect from 96-well plate-based in vitro assays.

Shannon Darou, Graham Jackson, Yan He, Alicia Henn

BioSpherix, LLC, Parish, NY

The most widespread format for *in vitro* drug discovery is the 96-well-plate, but edge effect causes inconsistent results in edge wells due to variations in plate environment. Researchers often avoid using the outermost edge wells, reducing plate capacity by 37 percent, requiring more plates, and increasing assay costs and time. Using the entire plate could save an estimated USD 119M in research costs annually and reduce waste. Finding methods to counteract edge effect is crucial for efficiency, sustainability, and reproducibility of in vitro drug discovery. Previous studies showed that constant thermal control of plating conditions reduces variability in cell distribution in edge wells. Here, we ask the question: can evaporation be eliminated as a difference between edge wells and the other wells of a plate? We plated water in traditional 96-well plates or plates with a water-filled moat around the edges. The plates were covered with either traditional plastic lids that allow gas exchange at the plate edges or an adhesive film that allowed gas exchange across the whole plate. Triplicate plates were incubated for 3 days at 95% relative humidity (RH) in the Xvivo System, a closed system which controls temperature, humidity, and gas levels for cell incubation and handling spaces. Crystal violet dye was added to each well and 0.1ml transferred from each well to a fresh plate. Absorption was read on a plate reader to assess dilution of the dye by the volume of water remaining in each well after incubation (triplicate plates each experiment, n=3 separate experiments). The wells were grouped as four concentric rings, with edge wells as Ring 1, and the center 8 wells as Ring 4. One-way ANOVA with Brown-Forsythe test was used for comparisons. Even at 95 percent RH, traditional plates/lids had edge wells volumes slightly lower than the central rings of wells. There was more overall evaporation from traditional plates covered with film than from the other plate/cover combinations, but there was no difference between the variance in edge wells and other wells. With a moat plate and regular lid, there was no difference between concentric rings on the plate, and there was less overall loss of water across the whole plate. Studies with A549 human lung carcinoma cells also confirmed that the edge effect can be eliminated when temperature and humidity are controlled at all times in a closed cell handling system. We concluded that the proper control of the plate microenvironment in a fully controlled cell handling and incubation environment can allow usage of edge wells for *in vitro* drug discovery, improving efficiency, sustainability, and reproducibility.

#5499 A comparison of spheroid formation using AcroCyte's 3-dimensional R^{3}CE spheroid culture platform *versus* traditional 3D culture methods.

Zichun Wang[1], Di Zhan[1], Qikuan Chen[1], Chao-Jie Yang[2], Jia-Yang Chen[2], Ying C Chang[2], Yinfei Yin[1]

[1]Shanghai ChemPartner Co., Ltd., Shanghai, China,[2]AcroCyte Therapeutics Inc., New Taipei City, Taiwan

Three-dimensional (3D) spheroid culture systems have gained attention due to their evident advantages in mimicking the *in vivo* tumor microenvironment, making them highly valuable for drug testing and cancer research, as the behavior of 3D-cultured cells is more reflective of *in vivo* cellular responses. However, traditional spheroid methods, including ultra-low attachment plates, Matrigel, and soft agar, have limitations, especially for certain cell lines that fail to form stable spheroids. Here, we introduce a novel 3D spheroid culture method using the AcroCyte R^{3}CE plate, and compare it to the generation of spheroids using traditional 3D culture methods. R^{3}CE is a revolutionary scaffold-free single-cell proliferation 3D cell culture platform that can quickly and reliably culture spheroids from a variety of samples including cell lines, circulating tumor cells and biopsies. This technology is highly efficient and can help researchers gain insight into cancer research, clinical treatments, and drug discovery. 20 cell lines with historically poor spheroid formation in standard methods were subjected to the novel AcroCyte R^{3}CE plate culture system which enabled robust and consistent spheroid formation. RNA sequencing (RNA-seq) was performed to compare gene expression profiles between 3D spheroids cultured using the R^{3}CE plate and traditional 2D monolayer cultures. Our analysis identified distinct biomarker expression profiles associated with spheroid cultures, including cancer stem cell-related proteins and key signaling pathways relevant to cell differentiation and tumor biology. The unique biomarker expression profiles of the cancer spheroid cells were validated at the protein level by way of immunofluorescence or western blot. This innovative approach utilizing the R^{3}CE 3D cell culture platform, not only improves spheroid formation across difficult-to-culture cell lines, but also preserves critical biomarker expression profiles and pathways linked to tumorigenesis. These findings highlight the potential of the R^{3}CE 3D culture system to establish a reliable and versatile spheroid panel for high-throughput drug screening, providing a more physiologically relevant model to evaluate drug efficacy and mechanistic insights.

#5500 A customizable, end-to-end platform for the screening and characterization of ADCs.

Zichun Wang, Qiong Wang, Shuyue Wang, Guilan Wang, Qikuan Chen, Wei Xue, Yinfei Yin

Shanghai ChemPartner Co., Ltd., Shanghai, China

Chemotherapy and radiotherapy have been considered the first line of antitumor therapies for patients with advanced or metastatic cancer, however these therapies demonstrate numerous drawbacks and acquired resistance is still inevitable in most cases. In order to address these challenges, scientists have discovered a novel class of cancer-targeted drugs referred to as antibody-drug conjugates (ADCs). ADCs are an emerging class of therapies that conjugate monoclonal antibodies with cytotoxic payloads through a chemical linker, allowing precise delivery of drugs to cancer cells. Trastuzumab deruxtecan (T-DXd) is an ADC composed of a humanized IgG antibody that specifically targets HER2, a tetrapeptide-based cleavable linker and a topoisomerase I inhibitor payload. T-DXd is the second HER2-targeting ADC approved by the FDA after trastuzumab emtansine (T-DM1); approved for HER2-positive unresectable or metastatic breast cancer in the second line and as an adjuvant therapy for residual disease in breast cancer patients with early stage disease. Both ADCs have demonstrated promising clinical efficacy in the treatment of HER2-positive solid cancers, which has sparked great interest in the development of the next generation of ADCs. Emerging evidence indicates that the efficacy of a given ADC depends on a number of key factors including the fine tuning between the combination of the antibody, linker and payload components, how the ADC is processed and it's interaction with the cancer cells. Here we present robust and reproducible data from our comprehensive modular *in vitro* and *in vivo* screening platform, that has been developed to facilitate efficient and streamlined approaches for ADC screening and characterization, and have been validated using T-DXd and T-DM1 as proof-of-concept agents. Our platform offers assays that can evaluate ADC binding, internalization, anti-proliferative activity, ADC effects on cell cycle, apoptosis, and bystander effects. Immunological assays, such as antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent cellular phagocytosis (ADCP) can be employed to assess the induction of Fc effector functions. Additionally, we have validated a number of *in vivo* models including co-inoculation and intracranial xenograft models. Our data demonstrates that both ADCs exhibit strong binding and internalization, with T-DXd showing a pronounced bystander effect due to its payload release via a cleavable linker. Both agents effectively induced ADCC and ADCP, with minimal complement-dependent cytotoxicity observed. The T-DXd bystander effect was also confirmed used an *in vivo* co-inoculation xenograft model and efficacy of both T-DXd and T-DM1 against a human intracranial xenograft model was confirmed. This platform provides a comprehensive and customizable tool for ADC preclinical assessment, supporting the optimization of ADC therapeutic efficacy and safety.

#5501 An integrated end-to-end platform facilitating the evaluation of next generation KRAS inhibitors.

Di Zhan, Lingling Huang, Lei Zhang, Ting Ma, Yuzhou Xu, Yinfei Yin, Zichun Wang

Shanghai ChemPartner Co., Ltd., Shanghai, China

Kirsten rat sarcoma viral oncogene homologue (KRAS) is the most frequently mutated oncogene, and has attracted substantial attention in the preclinical arena. Over the last 40 years, KRAS has been deemed a challenging therapeutic target and has even been described as “undruggable” due to the intrinsic characteristics of KRAS proteins. This has resulted in an urgent and unmet clinical need to target KRAS mutations in KRAS-driven cancer. Recent advances have uncovered a new allosteric site of KRAS (G12C) that facilitates the development of novel covalent allosteric inhibitors targeting this shallow pocket on the surface of KRAS, thereby raising the hope of effectively drugging KRAS. Encouraging clinical trial results have been reported for two KRAS G12C inhibitors, AMG510 (sotorasib) and MRTX849 (adagrasib), with AMG510 being approved by the FDA for clinical use in 2021. Despite the clinical benefits of KRAS G12C inhibitors such as AMG510 and MRTX849, there are still problems that need to be overcome including optimization of clinical efficacy and overcoming drug resistance. Recent clinical research has identified diverse genomic and histological features underlying the resistance of KRAS G12C mutant cancer patients. These resistance mechanisms include co-occurring mutations such as KEAP1, SMARCA4 and CDKN2A, and the acquisition of genetic mutations such as H95D, H96D and R68S in the switch-II pockets. Other non-genetic mechanisms such as reactivation of RAF-MEK-ERK pathway and cell state transition have also been identified. To enable discovery of the new generation of KRAS inhibitors, we have developed a comprehensive KRAS assay platform, which includes biochemical and cell based *in vitro* assays, and *in vivo* efficacy evaluation in KRAS mutant xenograft models. In addition, to allow researchers to have a better understanding of the biological basis of drug resistance, we have established and validated a panel of lung and pancreatic cell models that are resistant to AMG510 and MRTX849 through CRISPR-Cas9 editing and drug-induced approaches. Our continuously evolving assay platform facilitates the discovery and development of new generation KRAS inhibitors and combinational strategies.

#5502 An integrated oligonucleotide synthesis and cellular *in vitro* assay platform to support oligonucleotide-based drug discovery and development.

Di Zhan, Shuyue Wang, Qiuya Huang, Zichun Wang, Wei Xue, Yinfei Yin, Xingquan Ma

Shanghai ChemPartner Co., Ltd., Shanghai, China

Oligonucleotide-based therapeutics, such as small interfering RNAs (siRNAs), represent a transformative approach for gene-specific modulation in various diseases due to their capacity to regulate gene expression and protein function, with reduced toxicity compared to conventional treatments. Our oligonucleotide synthesis platform offers a comprehensive range of specialized monomers, diversified oligonucleotides, and customized solutions for oligonucleotide conjugation. To support research into oligonucleotide drugs, we have established a comprehensive *in vitro* assay platform that includes a series of critical evaluations such as oligonucleotide screening by transfection and RT-qPCR or western blot, oligonucleotide binding and uptake, sub-cellular localization, off-target assessment, and functional efficacy testing. For proof of concept, we employed inclisiran, one of the clinically approved siRNA therapeutics targeting PCSK9, to demonstrate our platform's capabilities. RT-qPCR-based oligo screening assays confirmed the highly effective silencing of PCSK9, with inclisiran achieving >90% reduction in target mRNA, with the IC50 concentration in the single picomolar level. High levels of cellular binding, uptake and subsequent successful co-localization with endosome and lysosome within target cells were observed by means of flow cytometry or high-content imaging. The cellular binding and uptake assay verified that inclisiran maintains high affinity and selective binding of GalNAc, mediating delivery to cellular targets, while the subcellular co-localization studies demonstrated inclisiran effectively trafficking to intracellular compartments, which is essential for its gene-silencing function. Off-target assessments were conducted using a transcriptome-wide approach, which showed minimal off-target effects and confirmed specificity. Functional assessments, which included cellular LDL uptake, further validated the efficacy of inclisiran in modulating PCSK9 expression. In conclusion, we provide an integrated one-stop platform for oligonucleotide-based drug discovery and development, aiming to expedite the early-stage discovery process. Our *in vitro* platform allows for a thorough evaluation of oligonucleotide drugs, covering critical functional and efficacy aspects that are essential for preclinical development. Our data with inclisiran as a model therapeutic confirm the platform's efficiency and robustness in supporting the discovery and optimization of oligonucleotide therapeutics, providing a valuable resource for advancing gene-silencing therapies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance in Molecular Targeted Therapies 3
Poster Session

#5506 Inactivation of mTOR is a strategy for tumor resistance to ribosome biogenesis inhibition.

Wenjun Fan[1], Lijing Yang[2], Hester Liu[1], Steffie Pitts[1], Niladri Sinha[3], Rajeshkumar N.V.[1], Hariharan Easwaran[2], Rachel Green[3], Marikki Laiho[1]

[1]Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Oncology and The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Molecular Biology and Genetics, Johns Hopkins University School of Medicine, Baltimore, MD

Increased ribosome biogenesis supports the need for high translation capacity and is a hallmark of cancer. Targeting this process presents a promising strategy for cancer therapy. We have developed first-in-class inhibitors of RNA polymerase I (Pol I) transcription that block the first and rate-limiting step of ribosome biogenesis, rRNA synthesis. We find that Pol I inhibition by BMH-21 leads to a significant decrease in active ribosomes. We found a broad, but heterogenous efficacy in 18 cancer cell lineages. To identify genes that drive potential resistance to Pol I inhibition, we performed genome-wide CRISPR-Cas9 screens in human colorectal carcinoma cells. These positive selection screens identified high-confidence hits leading to drug resistance and included all key positive regulators of the mTORC1 complex. These findings are striking and counterintuitive given that mTOR is a major driver of ribosome biogenesis and cellular translational programs. The findings were validated using chemical inhibition of mTOR by Torin-1, a catalytic mTOR inhibitor and genetic knockout of an activator of mTOR signaling. Consistently, compromised mTOR activity led to resistance to BMH-21. However, loss of mTOR activity did not abrogate Pol I transcription inhibition by BMH-21. To assess the impact on protein translation, we used polysome profiling and found that BMH-21 treatment caused a severe defect in ribosome biogenesis. Surprisingly, mTOR inactivation partially rescued the translation repressed by Pol I inhibition, suggesting that this rescue could be pivotal for cell survival. To profile translational events, we performed Ribo-seq and RNA-seq in the BMH-21 sensitive and resistant cells. These multi-omics results revealed that mTOR inactivation decreased polysome-based translation on 5'TOP mRNAs encoding ribosomal proteins, suggesting that mTOR inactivation reduces ribosome occupation on ribosomal mRNAs. We propose that mTOR inactivation switches off polysome translation to rearrange active ribosomes for translation of survival-essential mRNAs. We further quantified newly synthesized proteins by AHA-labeling combined with TMT-mass spectrometry. These data show that distinct proteins continue to be translated when both Pol I transcription and mTOR activity are blocked. Next, we will examine preferentially translated proteins in resistant cells, and explore combination therapies to circumvent the drug resistance. In summary, we uncover a new non-genetic model of cancer drug resistance termed as translational fitness that enables cells to survive severe translational repression. These findings reveal an unexpected complication by mTOR inhibitory strategies and have implications for exploring effective drug combinations in cancer therapy.

#5507 Mechanisms of resistance to RAS-GTP inhibition in pancreatic cancer.

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Revolution Medicines, Redwood City, CA,[3]Department of Radiation Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Massachusetts Institute of Technology, Cambridge, MA,[5]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[6]Massachusetts General Hospital, Boston, MA,[7]Department of Cancer Biology, Dana-Farber Cancer Institute, Boston, MA

Targeting oncogenic RAS signaling has the potential to be effective for many RAS-addicted cancers, including pancreatic ductal adenocarcinoma (PDAC). RMC-7977 is a RAS(ON) multi-selective tri-complex inhibitor exhibiting broad-spectrum preclinical activity against both wild-type and oncogenic RAS variants and has shown encouraging anti-tumor activity in preclinical models of PDAC. A related compound, RMC-6236, is under clinical investigation for both RAS-mutant solid tumors and metastatic PDAC. Tumor progression due to acquired resistance is frequently observed for targeted agents, but potential mechanisms of resistance specific to RAS(ON) multi-selective inhibitors have not been characterized. Here, we investigate both on-target and off-target mechanisms of resistance to RMC-7977 in pre-clinical models of PDAC. Using deep mutational scanning and structure-function analysis, we define the landscape of secondary KRAS mutations that confer resistance to RMC-7977. Leveraging insights from ctDNA analysis of patients, we validated putative genetic mechanisms of resistance in PDAC cell line and xenograft models, finding that PI3K pathway activation can drive proliferation under RAS blockade. Furthermore, we performed a multi-omic characterization of human PDAC cell lines and organoids, as well as murine PDAC tumors, to identify factors contributing to RAS independence. Epithelial-to-mesenchymal transition emerged as highly associated with both innate and acquired resistance. To further understand the adaptive signaling that promotes survival in mesenchymal, resistant PDAC cells, we applied phosphoproteomics followed by kinase motif enrichment analysis in resistant cells after RAS inhibition. We determined multiple kinases involved in ECM and cytoskeletal signaling that are activated upon MAPK suppression uniquely in mesenchymal PDAC cells. Targeting these kinases in combination with RMC-7977 reverted resistance in models of innate and acquired resistance, suggesting a potential approach to investigate preventing or overcoming resistance in patients. Collectively, our pre-clinical data suggest that resistance to RAS inhibition with RMC-7977 may arise via multiple mechanisms, among them secondary RAS mutations, PI3K pathway-activating mutations, or cell-state changes that drive adaptive signaling through ECM-signaling pathways.

#5508 Direct inhibition of RAS reveals the features of oncogenic signaling in RAS-mutant cancers.

[1]Cancer Genetics and Epigenetics Program, Johns Hopkins Medicine, Baltimore, MD,[2]Molecular Pharmacology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Cancer Biology and Genetics, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[5]Antitumour Assessment Core Facility, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Department of Oncology, Molecular Biotechnology Center, Torino, Italy,[7]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

RAS genes are frequently mutated in cancer, often at hotspots altering codons 12, 13, and 61. The role of mutant RAS in driving overactivation of ERK signaling in cancer has long been elucidated, but its involvement in the oncogenic activation of PI3K is still controversial, and different studies have reported conflicting findings regarding the requirement of RAS for physiological and oncogenic PI3K signaling. One of the reasons for this lack of understanding has been the inability to directly target RAS, which has historically been circumvented through genomic perturbation and murine models. However, these approaches are limited because it is not possible to distinguish between the direct effects of RAS on PI3K and compensatory events that occur as an adaptation to the oncogene. With the discovery of RAS inhibitors, we can now directly interrogate the biological effects of RAS isoforms and hotspot mutations in cancer cells with improved time resolution. Here, we use RMC-7977, a first-in-class RAS·GTP inhibitor (RAS^{MULTI}(ON)), to characterize the features and therapeutic vulnerabilities of mutant RAS signaling in various human cancers. Through a detailed biochemical analysis of the signaling response to RAS inhibition, we reveal that RAS-mediated oncogenic signaling is largely independent of the mutant RAS isoform, rather depending on the mutant codon. Specifically, RAS^{Q61X} is exquisitely sensitive to MAPK pathway inhibition, confers near-complete independence of upstream regulation, and is impaired in its signaling to PI3K/Akt/mTOR. Conversely, RAS^{G12X} enables oncogenic signaling to both MAPK and PI3K/Akt/mTOR by amplifying upstream input from receptor tyrosine kinases (RTKs). Simultaneous RAS and RTK inhibition selectively impairs the growth of RAS^{G12X}-mutant tumors, irrespective of RAS isoform and tumor type, and we investigate the molecular mechanisms behind this synergistic effect. Additionally, we have generated a genetically modified mouse model (GEMM) harboring liver tumors induced by RAS^{G12D} or RAS^{Q61R}. In cell lines derived from these respective models, RAS^{G12D} but not RAS^{Q61R} activates PI3K upon growth-factor stimulation. These findings provide mechanistic insights into how mutant RAS interacts with upstream and downstream partners to maximize oncogenic signaling. Furthermore, our results shed light on the selective pressure driving the emergence of RAS^{Q61X} mutations as a mechanism of resistance against RTK inhibition in colorectal cancer: we show that colorectal cancer cells that acquire RAS^{Q61X} mutations to overcome EGFR inhibition become more independent of upstream signaling than those that acquire RAS^{G12X} and this may explain the predominance of this mutation in colorectal cancer patients who acquire resistance to EGFR inhibitors.

#5509 Mechanisms regulating resistance to KRAS inhibitor driven by DNp63/YAP regulation of tissue stiffness and metabolic alterations in lung adenocarcinoma.

Santanu Adhikary[1], Marco Napoli[1], Suehelay Acevedo[1], Christina L. Carr[1], Jaden R. Baldwin[1], Nicole Hackel[1], Hitendra S. Solanki[2], Yaakov E. Stern[2], Laxmi Swetha Karanam[3], Duy T. Nguyen[3], Eric B. Haura[2], Elsa R. Flores[1]

[1]Molecular Oncology, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Thoracic Oncology, H. Lee Moffitt Cancer Center, Tampa, FL,[3]Bioengineering, H. Lee Moffitt Cancer Center, Tampa, FL

Targeted therapies to the KRAS oncogene have shown significant success in treatment of lung adenocarcinoma (LuAD). Challenges emerge when tumors acquire resistance to these targeted KRAS inhibitors (KRASi). Recent studies have reported several mechanistic pathways associated with the development of resistance which includes nuclear localization of YAP. TP53 mutations are the predominant genetic changes responsible for inducing resistance to targeted therapies and chemotherapy drugs. Mutations in *TP53* lead to the inhibition of the tumor and metastasis suppressor TAp63 and the activation of the oncogenic isoform ΔNp63. We have previously shown that loss of ΔNp63 in KRAS driven LuAD results in fewer tumors indicating an oncogenic role for ΔNp63 in LuAD. Here, we demonstrate that cells and tumors resistant to KRAS G12C inhibitors ($KRASi^R$) exhibit increased expression of ΔNp63 while the sensitive cells express lower levels of ΔNp63. The $KRASi^R$ cells showed increased total and nuclear localization of YAP/TAZ along with increased expression of ΔNp63 in the nucleus. $KRASi^R$ resistant cells also had increased proliferation, mitochondrial membrane potential and mitochondrial fusion, promoting oxidative phosphorylation in $KRASi^R$ LUAD cells. We further found that ΔNp63 is crucial for driving resistance to KRAS G12C inhibitor *in vivo* using genetically engineered mouse models and patient derived xenografts. Therefore, ΔNp63 is an ideal target to overcome acquired resistance to KRAS inhibitors. Additionally, using atomic force microscopy (AFM), we found that $KRASi^R$ cells are stiffer, and that tissue stiffness regulated by YAP/ΔNp63 can also result in KRASi resistance. ChIP-seq analysis for ΔNp63 and YAP bound targets are revealing the molecular basis of the mechanisms driving resistance to KRAS G12C inhibitors.

#5510 Targeting BET, Hippo-YAP and RAS-MAPK signaling interplay in lung cancer and therapy resistance.

Nilanjana Chatterjee[1], Victor Olivas[1], Wei Wu[1], Tracy Tang[2], Ben Powell[3], Trever Bivona[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Vivace Therapeutics, San Mateo, CA,[3]Kinnate Biopharma, San Francisco, CA

Identifying alternate survival pathways or compensatory mechanisms that limit the response to targeted therapy is critical to discover effective combinatorial strategies for lung cancer treatment and prevention of drug resistance.Using a combinatorial drug screen in a panel of non-small cell lung cancer (NSCLC) cell lines, we identified a functional interplay between RAS-MAPK pathway oncoproteins and BET chromatin regulators in non-small cell lung cancer (NSCLC). We found that combination of BET and RAS-MAPK inhibitors caused pronounced cell death and potent tumor regression/ stasis in several KRAS or BRAF mutant models of NSCLC with potent apoptosis induction, pro-apoptotic BIM upregulation, and pro-survival MYC and BIRC5 (Survivin) downregulation. However, NSCLC cells and tumors with co-occurring alterations in the tumor suppressor STK11 were found to be partially sensitive/ resistant to the BET and RAS-MAPK inhibitors combination. By modeling STK11 deficiency in NSCLC cells and tumors, we further found that STK11 loss creates an unprecedented dependence on YAP/TEAD TFs in lung cancer. STK11 silencing in NSCLC cells resulted in the nuclear translocation of the Hippo pathway effector, YAP and activation of YAP targets, conferred resistance to RAS-MAPK inhibitors and their combination with BET inhibitors and restored cell viability. Furthermore, phenocopying STK11 loss, constitutively active 5SAYAP mitigated the deleterious effects of BET and RAS-MAPK co-inhibition in STK11-proficient NSCLC cells with concomitant upregulation of YAP targets, such as, MYC and BIRC5. Conversely, YAP/TEAD suppression re-sensitized STK11-deficient NSCLC cells and tumors to BET and RAS-MAPK inhibitors combination and induced apoptosis, pronounced loss in cell viability, and tumor regression.This study uncovered a functional interplay between BET chromatin regulators, YAP/TEAD TFs and RAS-MAPK oncoproteins that drives therapy resistance in lung cancer, specifically upon loss of key tumor suppressors, such as, STK11 and suggests rational combinatorial strategies with BET, TEAD and RAS-MAPK inhibitors.

#5511 KRAS inhibition targets and depends on pro-oncogenic HuR in PDAC.

Hen Halamish[1], Yiefe Guo[1], Jennifer M. Finan[1], Vlad Grigoriev[2], Oleh Taratula[2], Alexander Smith[3], Rosalie C. Sears[3], Jonathan Brody[1]

[1]Surgery, Oregon Health and Science university, Portland, OR,[2]OSU/OHSU College of Pharmacy, Portland, OR,[3]Oregon Health and Science university, Portland, OR

The Kirsten rat sarcoma viral oncogene homolog (KRAS) mutation is found in more than 90% of pancreatic ductal adenocarcinomas (PDACs) making it an attractive therapeutic target. However, even with the recent promise of new KRAS inhibitor drugs, the overall enthusiasm is dampened due to reports of drug resistance. Our recent work has shed light on the critical role of Human Antigen R (HuR), an RNA-binding protein, in its role in KRAS signaling and inhibition. Using *KRAS* mutant patient derived models and cell lines derived from genetically engineered mouse models, we surprisingly found that transient siRNA silencing or CRISPR gene deletion of HuR, *ELAVL1* (HuR-KO) led to resistance of 2.5- fold to more than 1000-fold to KRAS inhibitors compared to control cells. Moreover, other relevant therapies for PDAC such as gemcitabine and Oxaliplatin showed no significant difference between our models. Validating this using an *in vivo* orthotopic model, MRTX1133 induced profound tumor regression solely in the wild-type group compared to the HuR-KO cohort. The wild-type treated tumors exhibited a 3.8-fold reduction in weight, contrasting with a mere 1.1-fold change observed in the HuR-KO treated group, as compared to the vehicle-treated group ($p < 0.0001$). Using a lipid nanoparticle loaded strategy to deliver HuR mRNA to HuR-KO cells *in vitro* and *in vivo* rescued the Kras inhibitor resistance phenotype and made the cells sensitive to a Kras inhibitor. A significant increase in tumor-infiltrating T cells was observed in both wild type and HuR ko treated groups ($p < 0.001$), however only treated wild-type group had a significant difference in activated (Tbet) $CD4^+$ and $CD8^+$ cells. Moreover, a significant decrease was observed in DCs and an increase in macrophages between vehicle wild-type group to all the other groups, which suggest that the resistance mechanism cannot be completely attributed to the immune microenvironment. Mechanistically, we applied phospho-proteomic, proteomic and RNAseq analysis on our PDAC models treated and untreated with Kras inhibitors which revealed a possible compensation mechanism that occurs with overexpression of IGF family members genes. Furthermore, a potential connection between HuR and MYC has emerged from our data, as MYC is an established HuR target and driver of Kras inhibitor resistance. More mechanistic studies determining the molecular interaction between HuR and KRAS and KRAS related mRNAs are underway. combined with ongoing studies, we highlight a significant breakthrough in the understanding of PDAC cells addiction to Kras signaling in the context of the pro-oncogenic HuR molecule, revealing that the absence of HuR confers resistance to KRAS inhibitor drugs. Understanding the interplay between KRAS and HuR could offer a novel strategy to disrupt the oncogenic KRAS signaling cascade and overcome the potential inherent and acquired resistance mechanisms of KRAS-mutant PDACs to promising, KRAS-targeted therapies.

#5512 Combining RAS(ON) G12C-selective and RAS(ON) multi-selective inhibitors overcomes sotorasib resistance driven by *KRAS^{G12C}* amplification or *NRAS^{G13R}* mutation.

H. S. Solanki[1], D. Imbody[1], B. Desai[1], D. Miroshnychenko[1], B. Sarcar[1], A. Majumder[1], Y. Zhang[1], U. Rix[1], A. Marusyk[1], M. Singh[2], I. Aronchik[2], E. B. Haura[1];

[1]Moffitt Cancer Center, Tampa, FL, [2]Revolution Medicines, Redwood City, CA

Amplification of the *KRAS^{G12C}* mutant allele and acquisition of NRAS mutations have been reported as resistance mechanisms in tumors progressing on sotorasib and adagrasib. We also identified these alterations in resistance models generated in vitro and in vivo utilizing H358 cells. We evaluated the activity of the RAS(ON) multi-selective noncovalent tri-complex inhibitor RMC-7977, both alone and in combination with the RAS(ON) G12C-selective covalent inhibitor RMC-4998. We generated five sotorasib-resistant cell lines from relapsed tumors of sotorasib-treated H358 xenografts (MR1-MR5) and two vehicle-treated tumors (MV1 and MV2). We created an additional isogenic cell line model, H358-MX1, by treating H358 cells with sotorasib and a SHP2 inhibitor, RMC-4550. Whole exome sequencing (WES) and digital polymerase chain reaction (dPCR) were performed to study mutant allelic fractions. Taqman copy number analysis and fluorescence in situ hybridization (FISH) were performed to assess copy number alterations. The anti-proliferative activity of RMC-7977 alone and in combination with RMC-4998 was evaluated. We identified increased allelic frequency of *KRAS^{G12C}* in MR2 and acquisition of a secondary *NRAS^{G13R}* mutation in H358-MX1 models. Copy number analysis revealed nearly 20 *KRAS* copies in MR2 compared to parental controls. *KRAS* amplification in MR2 was confirmed by dPCR and FISH. RAF-RBD pull down assays confirmed elevated KRAS-GTP and pan-RAS-GTP levels in MR2 cells. A small molecule screen using a customized library revealed that sotorasib had synergistic anti-proliferative activity in vitro with agents targeting the MAPK pathway. We hypothesized that simultaneous suppression of SHP2 and KRAS^{G12C} could elicit more pronounced inhibition of MAPK signaling and tumor growth. Dual inhibition of KRAS^{G12C} and SHP2 provided effective tumor control in vivo for 2 weeks before tumors started to regrow. Treatment with either RMC-4998, RMC-7977, or the combination of RMC-4998 + RMC-4550 did not sustain long-term tumor growth inhibition in this model. However, the RMC-4998 + RMC-7977 combination drove sustained, significant regressions compared to single-agent treatments or other combination regimens. In H358-MX1 model, siRNA-based knockdown of NRAS in combination with sotorasib reduced ERK phosphorylation and inhibited cell proliferation more effectively than NRAS knockdown or KRAS^{G12C} inhibition alone. In H358-MX1 mouse xenografts, RMC-7977 + RMC-4998 significantly inhibited tumor growth compared to single-agent treatments or other combination regimens. These preclinical data suggest that combination of RAS(ON) mutant-selective and RAS(ON) multi-selective inhibitors overcome resistance to KRAS^{G12C} (OFF) inhibitors driven by *KRAS^{G12C}* amplification and secondary *NRAS^{G13R}* mutation in *KRAS^{G12C}* mutated lung cancer models.

#5513 Discovery of SC2073, a potent and mutant selective EGFR degrader that overcomes 3rd generation EGFR inhibitors resistance in NSCLC.

Jihoon Choi[1], **Jun Gyu Kim**[1], Ok Young Lee[1], Young Jun Park[1], Young Min Jeong[1], Chung Sil Lee[1], Sun Ho Choi[1], Hye Yeon Lee[1], Yu Jin Lee[1], Punna Reddy Ullapu[1], Dae Young Lee[1], Hye Sun Lee[1], Jong Ryoul Choi[2], Daseul Yoon[2], Yanghun Tae[2], Ji-Young An[2], Hyo Ju Lee[2], Bong Tae Kim[2], Mi-Kyung Kim[1]

[1]Research Headquarter, Dong-A ST, Yongin-si, Korea, Republic of,[2]New Drug R&D institute, HK inno.N Corp., Seoul, Korea, Republic of

Epidermal growth factor receptor (EGFR) mutations, including the L858R activating mutation in exon 21, are major drivers of non-small cell lung cancer (NSCLC) and are targeted by EGFR tyrosine kinase inhibitors (TKIs). However, despite significant initial clinical benefits, resistance to EGFR TKIs frequently develops due to secondary mutations such as T790M and C797S, which reduce the therapeutic efficacy of second- and third-generation inhibitors. Consequently, extensive efforts have been made to develop new small molecule inhibitors to overcome this resistance, including novel approaches such as proteolysis targeting chimera (PROTAC) technology. We identified a promising heterobifunctional degrader, SC2073, designed to target a unique allosteric binding site on mutant EGFR while sparing wild-type EGFR. SC2073 effectively induced the degradation of EGFR proteins harboring single, dual, or triple mutations through the ubiquitin-proteasome system. It exhibited potent anti-proliferative activity against Ba/F3 cells with common EGFR resistance mutations, including L858R, L858R/T790M, L858R/C797S, and L858R/T790M/C797S as well as NCI-H1975 (L858R/T790M) cells without affecting the expression levels of GSPT1 and SALL4, which are substrates of the E3 ligase protein (CRBN). Notably, SC2073 showed no effect on the proliferation of Ba/F3 and A549 cells expressing wild-type EGFR, thereby minimizing potential toxic side effects associated with wild-type EGFR inhibition. SC2073 demonstrated a favorable pharmacokinetic profile, rapidly degrading mutant EGFR in tumors within 6 hours of oral administration and maintaining efficacy for 24 hours. Further investigations confirmed that oral administration of SC2073 resulted in a dose-dependent, robust anti-tumor activity in allograft and xenograft models resistant to EGFR TKIs by promoting the degradation of mutant EGFR. In this study, we present SC2073, an orally bioavailable, highly potent, and mutant-selective degrader with the potential to provide more durable, safer, and improved therapeutic responses. SC2073 effectively inhibited the proliferation of Ba/F3 cell expressing EGFR mutants while sparing WT EGFR cells and it demonstrated robust anti-tumor activity in EGFR mutation-driven *in vivo* tumor models. Our data suggests that SC2073 could be a promising treatment option for NSCLC patients harboring various EGFR mutations, including L858R, T790M, and C797S, which are associated with acquired resistance to EGFR inhibitors.

#5515 ELVN-001, a highly selective ATP-competitive ABL1 tyrosine kinase inhibitor for the treatment of chronic myeloid leukemia alone or in combination with asciminib.

Stefan David Gross[1], Christopher A. Eide[2], Michael R. Burkard[1], Anna Reister Schultz[2], Yiheng Zhang[3], Joseph E. Aslan[4], Owen J. McCarty[3], Monette A. Aujay[1], Samuel Kintz[1], Brian J. Druker[2], Joseph P. Lyssikatos[1]

[1]EnLiven Therapeutics, Boulder, CO,[2]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[3]Department of Biomedical Engineering, Oregon Health & Science University, Portland, OR,[4]Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR

ELVN-001 is a potent, highly selective ABL1 Tyrosine Kinase Inhibitor (TKI) currently being evaluated in a Phase 1a/b clinical trial in patients with BCR-ABL1-driven chronic myelogenous leukemia (CML). Due to its unique binding mode, ELVN-001 retains activity against many of the TKI-associated ABL1 resistance mutations including T315I as well as most of the emergent resistance mutations associated with the allosteric inhibitors like asciminib. While the active-site TKI ponatinib is active against T315I, its poor kinome selectivity limits its clinical utility. In contrast, ELVN-001 is highly kinome-selective thereby avoiding off-target kinases, including KDR, c-KIT, FLT3, PDGFR and SRC, which underlie many of the adverse events associated with the approved active-site TKIs; notably myelosuppression, edema, pleural effusions, hypertension, and certain cardiovascular events. Accordingly, ELVN-001 has demonstrated early signs of efficacy with good tolerability in heavily pre-treated patients with CML. Asciminib represents an important alternative for patients who have become intolerant of active site TKIs or whose disease is relapsed or refractory to treatment. As asciminib inhibits ABL1 by engaging its myristoyl pocket, it is highly kinome-selective and thus demonstrates an improved clinical safety profile. Because asciminib binds outside the kinase domain, it is not sensitive to most mutations conferring resistance to active site TKIs including T315I although a 5-fold higher dose is required to effectively treat this mutation. ABL1 mutations conferring clinical resistance to asciminib (and likely other STAMP inhibitors) have been reported which largely reside within the non-catalytic myristoyl pocket. Importantly, ELVN-001 retains potency against a panel of clinically relevant asciminib resistance mutants in a Ba/F3 cell background. As ELVN-001 and asciminib target distinct non-overlapping regions in ABL1, we evaluated the potential advantage of combining these agents. The mechanistic and functional effects of these drugs both alone and in combination were assessed in cell models of CML including a model of T315I resistance. Results showed that while each compound exerted differentiated effects on the known BCR-ABL1 effector pathways, both exhibited potent antiproliferative and pro-apoptotic activity, especially in combination. Therefore, the combination of ELVN-001 and asciminib was evaluated in a mouse tumor xenograft model of CML. Results demonstrated that combining ELVN-001 and asciminib was not only well tolerated but elicited profound anti-tumor activity. Finally, ENU mutagenesis screens were conducted in a Ba/F3 BCR-ABL1 line with ELVN-001 and asciminib, alone and in combination. Results of these studies and their impact on the clinical utility of this combination will be discussed.

#5516 Deciphering mechanism of resistance to anti EGFR treatment regimen in a NSCLC PDX model.

Philipp Meyer[1], Ruzica Bago[2], Balasz Pograny[2], Kanstantsin Lashuk[1], Diarmuid Kenny[2], Blake Rushing[3], Eva Oswald[1], **Julia B. Schueler**[1]

[1]Charles River Laboratories, Inc., Freiburg, Germany,[2]Charles River Laboratories, Inc., Chesterford Research Park, United Kingdom,[3]Nutrition Research Institute, University of North Carolina at Chapel Hill, Kannapolis, NC

Acquired resistance prevents patients from long term benefits of targeted therapies in many different cancer types. Overactivation of EGFR in malignant cells is a prominent example for acquired resistance since anti-EGFR treatment in NSCLC patients often starts showing loss of activity after a certain period. We have developed three NSCLC PDX lines carrying an acquired resistance towards Gefitinib, a highly selective EGFR inhibitor. All three sublines depict a specific mutational and gene expression pattern. These PDX models were now further characterized by assessment of in vivo sensitivity versus Cetuximab, a chimeric anti-EGFR antibody. The characterization included assessment of tumor growth over time, proteomic and metabolomic analysis at different time points: 24h after treatment, in remission and at regrowth. The parental PDX line and clones 1-3 displayed distinct sensitivity patterns against Cetuximab. The parental PDX was highly sensitive showing no regrowth for >100 days post treatment. Clone2 went into full remission, with only six out of 30 tumors demonstrating regrowth by day 70 post treatment. Clone1 was completely resistant, whereas clone3 showed partial remission and regrowth of 28/30 tumors beginning 21 days after treatment. These sensitivity patterns do correlate with the molecular profile of the different lines, as Clone1 and Clone3 exhibit a downregulation of pTEN in combination with an upregulation of HER2 thereby bypassing survival signals via other RTKs than EGFR. The complete resistance of Clone1 is most likely driven by the NRAS mutation. The proteomics analysis (LC-MS) retrieved a range of 7700 - 8200 proteins per sample. The replicates (n= 4-5 per setting) displayed a Pearson's correlation coefficient >0.95 indicating high data quality across the dataset. A PCA supported that finding with replicates grouping together. In the PCA the original PDX separated from the acquired resistant clones regardless of the treatment and time point. Within those groups samples taken when tumors were in remission separated from the other time points. A deeper analysis comparing individual groups with each other (t-test: limma package, RStudio) revealed an upregulation of proteins that are involved in EMT (TLE1), bad prognosis (UBE2D2 and MAST4), or resistance (SORL1) in the Gefitinib-resistant clone1 under treatment with Cetuximab. The upregulation of TPK1 which was observed as well might give a hint towards new treatment options as the protein is related to sensitivity towards PARP inhibitors. The full analysis of the LC-MS data will elucidate the mechanism behind those resistance mechanism and will help to identify new targets as well as favorable combination regimen for pre-treated NSCLC patients. The currently ongoing metabolomics studies will help to build a more complete picture of the cellular regulations leading to the different outcomes observed in the current study.

#5517 Overcoming sotorasib acquired resistance in KRAS^{G12C} mutant NSCLC by TUSC2 gene therapy.

Ismail M. Meraz[1], Mourad Majidi[1], Renduo Song[1], Shuhong Wu[1], Lihui Gao[1], Feng Meng[1], Chenghui Ren[1], Yi Xu[1], Qi Wang[2], Yuanxin Xi[2], Jing Wang[3], Sung Yun Jung[4], Elizabeth Shpall[5], Jack A. Roth[1]

[1]Thoracic and Cardiovascular Surgery, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Bioinformatics and Computational biology, UT MD Anderson Cancer Center, Houston, TX,[4]Biochemistry, Baylor College of Medicine, Houston, TX,[5]Stem Cell Transplantation, UT MD Anderson Cancer Center, Houston, TX

Acquired resistance (AR) to sotorasib, an FDA-approved KRAS inhibitor, poses a significant challenge in treating KRAS^{G12C} mutant NSCLC. Despite initial responses, patients invariably develop resistance, necessitating alternative therapeutic strategies. The mechanisms of AR include the emergence of additional mutations in KRAS gene, reactivation of KRAS pathway, or activation of alternative signaling pathways. TUSC2, a potent tumor suppressor gene with immunogenic properties, exhibits multifunctional activity by a) inhibiting signaling pathways, including MAPK and mTOR, b) arresting the growth and proliferation, c) inducing tumor cell death, and d) activating immune responses. This study shows that TUSC2 gene therapy effectively overcomes the AR in KRAS^{G12C} mutant NSCLC. AR patient-derived xenografts (PDX), cell line-derived xenografts (CDX), PDX-derived organoids (PDXO), and cell lines were generated. Both AR cell lines and PDXOs showed >100-fold resistance over sensitive counterparts. The resistant cell lines also showed resistance to adagrasib, another KRAS^{G12C} inhibitor. Whole Exome Sequencing (WES) was performed for AR PDXs, CDX, and cell lines and all retained the KRAS^{G12C} mutation with no additional KRAS mutations. Mass spectrometry (MS) on TC303AR and TC314AR PDXs showed significant sets of differentially regulated proteins in AR vs parental. A significant upregulation of MTORC1 signaling in AR PDXs was found. Proteins involved in the PI3K-AKT-mTOR pathway were significantly upregulated in AR PDX and cells. TUSC2 transfection reduced considerably colony formation and increased the annexin V-positive apoptotic cells in both H23AR and H358AR cells. Re-expression of TUSC2 into AR PDXOs significantly decreased the viability of organoids compared with the empty vector. The H23AR tumors, which exhibited no significant sensitivity to sotorasib, showed robust antitumor effects of quaratusugene ozeplasmid, a lipoplex gene therapy containing the TUSC2 gene in both H23AR and TC314AR PDXs. However, a synergistic antitumor effect was observed when TC314AR PDXs were treated with the combination of TUSC2 and sotorasib. To evaluate the antitumor immune responses, immune-competent humanized-NSG mice are generated by transplanting fresh human cord blood-derived CD34+ stem cells into sub-lethally irradiated NSG mice to reconstitute a human immune system. The robust antitumor effect of TUSC2 was observed in both PDX and xenograft humanized mice. When sotorasib was combined with TUSC2, synergistic antitumor activity was found. This antitumor effect was correlated with significant infiltration of human CD8 T, NK, DC, and M1 MQ, and downregulation of MDSCs and exhausted T cells. TUSC2 therapy, alone or in combination with sotorasib, induced apoptosis, inhibited colony formation, and showed significant antitumor efficacy in KRAS^{G12C} AR tumors

#5518 Targeting FAK by Ifebemtinib synergizes with Pan RAS inhibitors in treating RAS mutant cancers.

B. Zhang, R. Pang, J. Gao, J. Cheng, P. Zhang, N. Qin, L. Liu, Z. Wang;
Inxmed, Shanghai, China

Pan-RAS inhibitors have been developed for the treatment of RAS-mutant cancers. Despite the challenges in achieving clinical benefits, targeting Pan-RAS represents a novel strategy for treating these previously considered untargetable malignancies. Previous studies have demonstrated that targeting FAK enhances the therapeutic efficacy of KRAS G12C inhibition in clinical settings, as hyperactivated FAK signaling is a major mechanism of acquired resistance following KRAS G12C inhibition. In the present study, we observed that Pan-RAS inhibitors can induce acquired hyperactivity of FAK, potentially rendering cancer cells resistant to Pan-RAS inhibition. Co-administration of a clinical-stage FAK inhibitor, Ifebemtinib (also known as Ifebe, IN10018), with RMC6236, a Pan-RAS inhibitor, exhibited synergistic cytotoxic effects in multiple RAS-mutant cancer cell lines. Furthermore, we evaluated the dual regimen in KRAS-mutant and NRAS-mutant animal models, where the combination therapy demonstrated superior tumor growth inhibition compared to monotherapy. Our previous findings indicated that FAK inhibition in conjunction with KRAS G12C/G12D inhibition enhances the anti-cancer effects of PD-1 blockade. Here, we confirmed that the combination of Ifebe and RMC6236 also augments the anti-tumor efficacy of PD-1 antibody therapy, suggesting that this treatment enhancement is independent of the specific RAS mutation type. In summary, our study reveals that the combination of FAK inhibitor Ifebe with Pan-RAS inhibitor exhibits synergistic anti-cancer effects and further improves the outcomes of PD-1 blockade therapy. These preclinical results support the need for further clinical investigation.

#5520 NXP900, a phase 1, first-in-class YES1/SRC inhibitor demonstrates potent single agent activity and synergy with ALK inhibitors in ALK resistant NSCLC models.

Neil O. Carragher[1], Enrique Poradosu[2], Asier Unciti-Broceta[1]

[1]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom,[2]Nuvectis Pharma Inc., Fort Lee, NJ

Background: NXP900 (eCF506) is a novel potent and selective SRC family kinase (SFK) inhibitor, (IC_{50} of 0.47 nM against YES1) which possesses a unique/first-in-class binding mode-of-action. NXP900 locks its target into its native “closed” conformation, thereby inhibiting both kinase activity and scaffolding function with protein signaling partners (Temps et al. Cancer Res. 2021, 81, 5438-5450). In contrast, multi-kinase inhibitors, including dasatinib and bosutinib, lock SRC in the active “open” conformation (type 1 inhibitors) promoting the association of SFK and signaling partners via allosteric facilitation (Higuchi et al. Cell Rep 2021, 34, 108876). Anaplastic lymphoma kinase (ALK) inhibitors are clinically effective for the treatment of non-small cell lung cancer (NSCLC) patients whose tumors harbor ALK fusion genes. However, the development of resistance to ALK inhibitors in patients is nearly universal. Activation of SFK signaling has previously been shown to mediate acquired resistance to ALK inhibition in NSCLC lines (Yoshida et al. Int J Oncol. 2017, 51,1533-1540, Sato et al., JCO Precis. Oncol., 2022) indicating a potential for NXP900 to overcome an important bypass resistance mechanism and offer therapeutic potential in cancers with acquired resistance to ALK inhibitors.
Materials and Methods: Cell lines: Resistant cell lines to ALK inhibitors were generated from NCI-H2228 (EML4-ALKv3) and NCI-H3122 (EML4-ALKv1). Cell proliferation assays: Cells were diluted in the corresponding ATCC recommended medium and dispensed in a 384-well plate, depending on the cell line used, at a density of 100 - 6400 cells per well. For each cell line the optimal cell density is used and cells were treated with ALK inhibitors lorlatinib and/or NXP900 for 120 h and underwent ATPlite viability assay. Drug combination effects in vitro were studied using synergy scoring methods applied across multiple fixed dose-ratio mixtures.
Results: NXP900 single agent potently inhibited cell proliferation of ALK resistant cell lines, with a median GI50=30nM. At the same concentration range, NXP900 potently inhibited the activating SRC autophosphorylation, and demonstrated synergy in combination with lorlatinib in lorlatinib-resistant cell lines derived from NCI-H2228 (EML4-ALKv3) and NCI-H3122 (EML4-ALKv1) cells.
Conclusions: Despite high response rates to lorlatinib and long duration of response, acquired resistance almost universally arises. Here we demonstrate that NXP900 can potently inhibit cell proliferation of ALK resistant cell lines as a single agent and is synergistic with lorlatinib in NSCLC models harboring different variants of the ALK gene fusion. Altogether, these data suggest that NXP900 may have therapeutic potential in cancers with acquired resistance to ALK inhibitors. A FIH, Phase1 dose escalation study for NXP900 is ongoing.

#5521 Integrative analysis of acquired drug resistance to KRAS(G12D) inhibitors.

Ines Pulido Endrino[1], Laura Gunder[1], Malek Massad[1], Julian Carretero[2], Takeshi Shimamura[1]

[1]University of Illinois at Chicago, Chicago, IL,[2]Universitat de Valencia, Valencia, Spain

KRAS is the most frequently mutated oncogene in cancer and, until recently, targeted therapies against mutant KRAS haven't been successful. However, new breakthroughs in pharmacological design have led to the FDA-approval of two KRAS G12C inhibitors and one inhibitor specific to target the KRAS glycine to aspartic acid in codon 12 (G12D) mutation has shown strong responses *in vitro* and has entered phase I in clinical trials, MRTX1133. KRAS(G12D) is the most common KRAS mutation, being found in 37% of pancreatic ductal adenocarcinomas (PDACs), as well as in 12.5% of colorectal cancer and 4.9% of lung adenocarcinoma (LUAD) patients. MRTX1133, a selective non-covalent inhibitor of the KRAS(G12D) mutation, has demonstrated promising preclinical efficacy and has entered phase 1 clinical trials; however, the acquired drug resistance is expected to emerge. We have generated an acquired resistant model to KRASG12D inhibitors by drug escalation of MRTX1133. Our results show that although the IC50 for parental AsPC-1 cells is 0.2nM, drug resistant AsPC-1M-R cells can grow normally at 10 µM. Expression of KRAS, NRAS but more significantly HRAS are increased in the drug-resistant phenotype, likely to bypass inhibition of KRAS(G12D). Oncogenic KRAS(G12D) signaling isn't essential in AsPC-1M-R cells as determined by a persistent RAS-GTP activity after MRTX1133 treatment due to the emergence of a secondary mutation in KRAS. In fact, tumor proliferation and survival in the resistant phenotype is sustained by increased receptor tyrosine kinase (RTK) phosphorylation. Evaluation of RTK activity demonstrated that resistant tumor cells activated several RTK such as the ErbB and Eph families and MET, predominantly. Dual inhibition with SHP2, SOS or ErbB in combination with MRTX113 didn't exhibit a synergistic effect. Novel therapeutic approaches such as RAS(ON) inhibitors like RMC-6236 or specific KRAS(G12D) PROTAC degraders can significantly inhibit cell proliferation *in vitro* not only in MRTX1133 acquired resistance but also in adagrasib resistance models. To determine the underlying mechanisms of acquired drug resistance to MRTX1133, RNAseq analysis was performed. Complex transcriptomic reorganization shows the upregulation of CD24 -a potential cancer stem cell related gene- and the epithelial to mesenchymal signature highlight the difficulty to target drug resistant cells. These findings emphasize the necessity to design combinatorial treatments to prevent and delay the acquisition of drug resistance in KRAS-driven cancers.

#5522 Cell state modulates the KRAS^{G12C} proximal proteome.

Anurima Majumder, Liznair Bridenstine, Denis Imbody, Kiah Bowers, Dalia Ercan, Bin Fang, Eric Haura

Moffitt Cancer Center, Tampa, FL

Background: KRAS mutations occur in ~25% of lung adenocarcinomas (LUAD), with KRAS^{G12C} being the most common. There has been limited clinical success with KRAS inhibitors due intrinsic/acquired resistance. EMT is a known mechanism by which cancer cells become resistant to targeted therapy. Here, we aim to map protein interactors of KRAS^{G12C} in lung cancer cells using proximity-dependent biotin labeling (BioID) to gain insights into key regulators/effectors of oncogenic signaling and therapy resistance.

Methods: Dox-inducible fusion of KRAS^{G12C} with the BirA biotin ligase was expressed in H358 LUAD cells. To determine alterations in KRAS^{G12C} interactome induced by EMT, BioID/mass spectrometry was performed on BirA-KRAS^{G12C} expressing cells, with or without chronic TGF-β treatment (to induce EMT). Transduced H358 cells treated either with Biotin or Dox alone were used as controls for the BioID experiment.

Results: BioID analysis identified 144 proteins as potential proximal interactors for KRAS^{G12C}, which include known effectors of RAS signaling, such as NF1, RAF1, RASA1, MTOR, as well as novel ones, such as KEAP1, ASAP1, CRIP2, CRK, GULP1, AFDN. Pathway analysis suggests that these proximal proteins are involved in regulation of actin cytoskeleton, RAP1, PI3K-Akt, focal adhesion, and Ras signaling pathways. Our data also shows that TGF-β induced EMT reduces KRAS^{G12C}'s interaction with several of these known effectors, such as MTOR, RICTOR, and RAF1, while gaining new interactors, such as SPRED2, NOTCH2, DEPC1B and F11R. We also observe a reduction in RAS activity, RAS-RAF proximity and pERK/pRSK in TGF-β induced cells compared to parental cells.

Conclusions: We show that BioID system can identify KRAS^{G12C} interactome proteins in a cell line model of LUAD. Our data suggests that upon undergoing TGF-β induced EMT, the KRAS^{G12C} interactome in these cells alter and now couple less with RAS/MTOR signaling effectors. We also observe similar change in sotorasib-resistant H358 cells showing EMT features, where KRASi no longer suppresses ERK signaling. These studies can understand variations in KRAS^{G12C} interactome under epithelial vs mesenchymal state and potentially identify new therapeutic vulnerabilities for cells that have undergone EMT.

#5523 Inhibition of FASN postpones development of resistance to PLX8394 in colorectal cancer.

Mariah E. Geisen, Josiane Weber Tessmann, Courtney O. Kelson, Ellen Beswick, Daheng He, Chi Wang, Abu Saleh Mosa Faisal, Jill M. Kolesar, Yekaterina Zaytseva

University of Kentucky, Lexington, KY

Background: Mutations in proto-oncogene B-Raf (BRAF) occur in about 10% of colorectal cancer (CRC) patients and $BRAF^{V600E}$ is the most common type. This subset of CRC is associated with a reduced response to chemotherapy and poor prognosis compared to BRAF wild-type CRC. While the FDA-approved encorafenib plus cetuximab therapy for BRAF-mutant CRC provides a significant benefit, only 22% of patients respond to this therapeutic approach and resistance ultimately develops in the majority of patients. Therefore, development of new efficacious strategies based on further characterization of resistance mechanisms is needed to improve outcomes for $BRAF^{V600E}$ CRC. We found that development of resistance to PLX8394, a second-generation BRAF inhibitor, is associated with an increase in cellular proliferation, invasion, and lipid metabolism. We identified fatty acid synthase (FASN), a key enzyme in lipid synthesis, as a major lipogenic enzyme overexpressed in PLX8394-resistant cells. Therefore, the goal of this study is to test if inhibition of FASN will enhance the efficacy of PLX8394 in BRAF-mutant CRC.
Methods: HT29, PT130, and PT24249pt, parental and PLX8394-resistant, CRC cells were utilized. The effect of PLX8394 alone and in combination with FASN inhibitors (TVB3664 and C75) was tested using cell viability and colony formation assays. The synergy score was determine using a BLISS synergy model (SynergyFinder 3.0). The development of resistance to PLX8394 in the presence or absence of TVB3664 was evaluated using IC50 analysis, flow cytometry, and western blot.
Results: We found that PLX8394-resistant cells exhibit an increase in FASN expression, oxidative phosphorylation, and triglyceride storage. Combination of PLX8394 and FASN inhibitors led to a significant decrease in cell viability and colony formation as compared to each drug alone. Consistently, we found a significant synergy between PLX8394 and C75 using the BLISS synergy model. FASN-knockdown cells exhibited higher sensitivity to PLX8394 as compared to control cells supporting the role of FASN in resistance to PLX8394. Importantly, an addition of TVB3664 to PLX8394 treatment postpones the development of resistance to PLX8394. Analysis of cell cycle by flow cytometry confirmed a suppression of cell cycle progression via a decrease in a number of cells entering the S phase when cells are treated with combination of PLX8394 and TVB3664. Consistently, we observed a decrease in expression of proteins associated with the cell cycle such as cyclin D, pRB, and E2F expression in this group.
Conclusion: Collectively, these data show that combination of PLX8394 with FASN-targeted therapy at treatment initiation reduces $BRAF^{V600E}$ CRC cell proliferation via inhibition of their cell cycle progression. These findings suggest that targeting FASN could enhance the efficacy and delay the development of resistance to PLX8394 in BRAF-mutant CRC.

#5524 Developing KRAS^{G12C} inhibitor-resistant tumor models for efficacy evaluation of next-generation anticancer therapies.

Jian Feng, Dan Zhang, Aaron Hua, Chenpan Nie, Jessie(Jingjing) Wang, Ludovic Bourre, **Jun Zhou**, Peng Wang

Crown Bioscience, Inc., San Diego, CA

Background: For decades, KRAS was considered undruggable due to the lack of suitable binding sites. However, advancements in bioengineering and chemistry have enabled the approval of targeted therapies. Success was first seen with allele-specific targeting of KRAS^{G12C} in non-small cell lung cancer (NSCLC), leading to the approval of sotorasib (AMG510, Lumakras^{TM}). Despite its clinical benefits, resistance emerged in some patients due to secondary KRAS mutations, which necessitates next-generation or combination therapy development. In this study, we outline the development of KRAS^{G12C} inhibitor-resistant models overcome this hurdle.
Methods: Secondary KRAS mutations (Y96D/C/S, H95D/Q/R, R68S, Q61H, A59T/S, and Q99L) were introduced by CRISPR/Cas9 in MIA PaCa-2 with a homozygous KRAS^{G12C} mutation. Knock-in of point mutation was validated by Sanger sequencing. Cell viability was assessed by CellTiter-Glo (CTG) with AMG510 and MRTX849 (Adagrasib, Krazati^{TM}). RAS-MAPK pathway activity was evaluated by western blot. Xenograft models of MIA PaCa-2 cells with Y96D/C, H95D/Q/R, R68S, Q61H and A59T were established. Additionally, *in vitro* chronic dosing of AMG510 generated AMG510-resistant MIA PaCa-2 and NCI-H358 cell lines were validated by CellTiter-Glo and western blot. RNA-seq identified potential resistance mechanisms. Xenograft models were also established.
Results: A successful homozygous point mutation knock-in was confirmed by Sanger sequencing. Cells expressing double-mutant alleles KRAS G12C Y96D/C/S, A59T/S and R68S showed resistance to both AMG510 and MRTX849, while KRAS G12C H95D/Q/R was more resistant to MRTX849, and KRAS G12C Q61H, Q99L didn't show significant resistance. Persistent phosphorylated ERK (pERK) and pRSK levels indicated sustained RAS-MAPK activity in cells expressing KRAS G12C Y96D, H95D, A59T/S, and R68S, even at high KRAS inhibitor concentrations. Furthermore, a KRAS G12C Y96D/C, A59T, Q61H, R68S and H95D/Q/R double mutant cell-derived xenograft was established in vivo. Additionally, MIA PaCa-2 AMG510-resistant and NCI-H358 AMG510-resistant cells showed resistance to AMG510 and MRTX849 in cell viability assays. RNA-seq data identified c-MET amplification in AMG510-resistant MIA PaCa-2 cell, while FGFR1/3/4 amplification was found in AMG510-resistant NCI-H358 cells.
Conclusion: CRISPR/Cas9-engineered KRAS secondary mutations cell lines displayed differentially resistant profile to KRAS^{G12C} inhibitors, and drug-induced resistant cell models developed *in vitro* displayed KRAS-independent mechanisms of resistance. These novel cell models offer a valuable preclinical platform to evaluate therapeutic strategies to overcome resistance to KRAS-targeted therapies.

#5525 YTHDF3 and RAS-ERK1/2 pathway generate a negative feedback loop to maintain phosphorylation cascade and contribute to EGFR-TKI resistance.

Jaeik Oh[1], Sung-Yup Cho[2]

[1]Department of Translational Medicine, Seoul National University, College of Medicine, Seoul, Korea, Republic of,[2]Department of Biochemistry and Molecular Biology, Seoul National University, College of Medicine, Seoul, Korea, Republic of

About half of East Asian patients with lung adenocarcinoma harbor EGFR mutations, which lead to dramatic initial response to EGFR tyrosine kinase inhibitors (EGFR TKI); however, the resistance to these therapies is ultimately inevitable. Several previous studies on EGFR TKI that typically utilized genomic, epigenomic and transcriptomic data of resistant tumors from patients attributed their resistance to bypass signal activation or downstream target mutations, however, mostly failed to overcome resistance by targeting such signals. The gap between RNA and protein expression, which obscures changes in actual phosphorylation cascade, is one plausible explanation for the previous failures of multi-layer omics studies and genome-wide screening. Given that posttranslational modification contributes to this gap, N6-Methyladenosine, which is dynamically regulated and present in the mRNAs of various genes in the RAS pathway, has emerged as an intriguing target for studying its role in EGFR TKI resistance. Here, we demonstrated that the phosphorylation cascade of EGFR-RAS-ERK1/2 and YTHDF3 regulate each other and are composed of a negative feedback loop between two independent systems. We identified blocking the EGFR signal decreased the protein stability of YTHDF3 while negative regulation of YTHDF3 intensified EGFR-RAS-ERK1/2 signaling. Our findings reveal that YTHDF3 plays a critical role in modulating EGFR TKI resistance, suggesting its potential as a therapeutic target to overcome resistance in lung cancer treatment.

#5526 Inhibition of MEK and AKT synergistically induces melanoma stem cell apoptosis and blocks NRAS-mutant xenograft growth.

Nusrat Islam[1], Ryyan Alobaidi[1], Toni M. Olkey[1], Yogameenakshi Haribabu[1], Mathew Shamo[1], Peter Sykora[2], Cynthia M. Simbulan-Rosenthal[1], Dean S. Rosenthal[1]

[1]Biochemistry and Molecular & Cellular Biology, Georgetown Univ. School of Medicine, Washington, DC,[2]Amelia Technologies, LLC, Washington, DC

Melanoma-initiating cells (MIC) are involved in tumorigenesis, drug resistance and metastasis, and are characterized by upregulated stem cell markers, including CD133. Our previous studies showed that CD133 siRNA increases apoptosis in response to the MEK inhibitor trametinib. The current study employs CRISPR-Cas9 CD133-KO or Dox-induced expression of CD133 to investigate the anti-apoptotic mechanism of CD133 in patient-derived BAKP melanoma cells, harboring an $NRAS^{Q61K}$ driver mutation. CD133-KO cells downregulated pro-survival markers p-AKT and p-BAD, and upregulated pro-apoptotic BAX. On the flip side, Dox-induced CD133 increased expression of p-AKT and p-BAD, and decreased activation of BAX and caspase-3. Hence, an alternate survival pathway may be activated in MICs, wherein CD133 induces AKT phosphorylation and activation, which phosphorylates and inactivates BAD, decreasing BAX activation, and reducing caspases-3 activity and caspase-mediated PARP cleavage, ultimately resulting in apoptosis inhibition and chemoresistance in melanoma. However, trametinib in combination with the pan-AKT inhibitor, capivasertib, can synergistically reduce cell survival even in trametinib-resistant CD133-expressing MICs *in vitro*, as determined by XTT, annexin-FITC, and colony forming assays. Similarly, *in vivo* mouse xenograft studies using Dox-inducible BAKP cells revealed increased rates of tumor growth after induction of CD133 expression in trametinib-treated +Dox mice, an effect that was most effectively suppressed by the combination treatment. Therefore, targeting nodes of the AKT and MAPK survival pathways with trametinib and capivasertib underscores the potential for combination therapies for difficult-to-treat NRAS-mutant melanoma stem cells, paving the path towards improved treatment strategies for patients with high-risk melanoma.

#5527 Optimization of CRISPR-Cas9 library screens in pancreatic cancer organoid models targeting KRAS^{G12D}.

Md Shahadat Hossan[1], Lauryn Flannagan[1], Molly A. Nellen[1], Austin Stram[1], Ethan S. Lin[1], Michela Cadarso[1], C. Dustin Rubinstein[2], Sean M. Ronnekleiv-Kelly[3], Jeremy D. Kratz[1]

[1]Department of Medicine, University of Wisconsin-Madison, Madison, WI,[2]University of Wisconsin-Madison, Madison, WI,[3]Department of Surgery, University of Wisconsin-Madison, Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) has a critical need in systemic therapeutic development, with hallmark activation of the mitogen-activated protein kinase pathway. Novel mutant-specific KRAS inhibitors have been developed, however no method to date can predict patient-specific resistance mechanisms. Here, we optimize a CRISPR-Cas9 lentivirus screen in 3D patient-derived cancer organoids (PCOs) to study resistance mechanisms and guide combination therapy using the KRAS^{G12D} inhibitor MRTX1133.

Methods: PDAC PCOs were derived from surgical specimens. Puromycin (puro) dose-response curves were established using cell viability assays. PCOs were transfected with a lentiviral-based 'druggable genome' CRISPR-Cas9 library of 2,292 unique targets (Millipore-Sigma) overnight (18h) in a liquid phase with the addition of polybrene (5ug/mL). Puro selection was compared for efficiency at 6 days and 12 days. Western blotting was used to confirm Cas9 expression. Multiplicity of infection (MOI) optimization was performed by digital droplet PCR (ddPCR) on selected cells to measure lentiviral genome copy number efficiency. MOI was compared across traditional cell viability assays using CellTiterGlo (CTG, 50% v/v) and cell counting methods.

Results: Molecular profiling of the PDAC PCO line confirmed KRAS^{G12D} mutant by DNA sequencing (SureSelect Cancer, Agilent). Puro dose was selected at 2 μM to exceed the IC_{90} of 1.95 ± 0.1 μM. Western blots confirmed Cas9 presence in selected cells. The KRAS^{G12D} inhibitor MRTX1133 revealed an IC_{50} of 11.16 ± 0.36 nM. The 1:5 cell-to-lentivirus ratio after 6 days of puro selection was selected based on copy number analysis by ddPCR (0.93 ± 0.01). The control, 1:2, and 1:10 ratios after 6 days of selection exhibited copy numbers of 0 ± 0, 0.53 ± 0.13, and 1.52 ± 0.38, respectively. Selection for 12 days yielded higher copy numbers (1.13 ± 0.38 at 1:2, 1.19 ± 0.11 at 1:5, and 1.72 ± 0.43 at 1:5) compared to the 6 day puro selection. Increased selection time also revealed reduced viability compared to the 6 day selection. The 1:5 ratio showing 16.8% ($p<0.0001$) and 22.65% ($p<0.0001$) viability, respectively. Post-selection, the viability of puro-selected, non-transfected cells was 0%, confirming selection efficiency.

Conclusions: Here, we demonstrate the optimization of CRISPR-Cas9 screening with 3D PDAC PCOs using ddPCR to validate the efficiency of transfection. Importantly, the degree of puro selection and lentivirus transfection did confer multiplicity in viral transfections. The ongoing work is aimed at understanding the time course dynamics of gene editing between early (14 day) and late (28 day) resistance to KRAS^{G12D} inhibition using the Model-based Analysis of the Genome-wide CRISPR/Cas9 Knockout (MAGeCK) method. This work extends the efficiency of novel gene editing technologies for screening applications in organoid models of pancreatic cancer.

#5529 Development and characterization of BRAF/MEK inhibitor resistant anaplastic thyroid carcinoma patient-derived xenograft and cell line models.

Ahmad Abubaker[1], Meredith Miller[2], Ying Henderson[1], Brooke Meyers[2], Ningping Feng[2], Stephen Wang[2], Jessica Molkentine[2], Andy Zuniga[2], Virginia Giuliani[2], Stephen Y. Lai[3], Christopher Terranova[2], Anastasios Maniakas[1]

[1]Department of Head and Neck Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Translational Research to AdvanCe Therapeutics and Innovation in ONcology (TRACTION), The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Head and Neck Surgery, Radiation Oncoloy, Molecular and Celluler Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Anaplastic Thyroid Carcinoma (ATC) is one of the deadliest malignancies with 5-month median overall survival (OS). Treatment of BRAFV600E-mutated (BRAFm) ATC with BRAF/MEK inhibitors (BRAF/MEKi) revolutionized disease management and improved median OS to 16 months for this subgroup. However, like other BRAFm cancers, tumors develop resistance within a few months, and patients are often inoperable, making tumor specimen retrieval difficult for studying resistance development. The utilization of patient-derived xenograft (PDX) models and cell lines (CDX) is therefore an integral part of disease mechanism understanding and therapeutics development. To date, there is no BRAF/MEKi resistant ATC model available in the scientific community.
Aim: Report the development and characterization of a BRAF/MEKi resistant ATC cell-line and PDX models.
Methods: Our group previously established and characterized BRAFm ATC PDX models. MDA-ATC1 is BRAFV600E, TP53, TERT, PI3K-mutated. These were implanted in 5-8-week-old nu/nu nude mice and treated with dabrafenib+trametinib (D/T) 15mg/kg+0.5mg/kg, at half or full dose, followed by dose doubling of D once resistance was observed. For CDX modelling, MDA-T220 (BRAFV600E, TP53, TERT, and PI3K mutated, from patient previously treated with D/T) was implanted into 6-12-week-old NSG mice and treated with two D+T concentrations (low: 15mg/kg + 0.25mg/kg and high: 30mg/kg + 0.5mg/kg) once tumors reached ~200mm3. Successful establishment of resistant PDX & CDX models was determined when tumors continued to grow beyond 1000mm3 despite maximum dose escalation, and if growing following cryopreservation for the PDX models.
Results/Discussion: At first passage, resistance to BRAF/MEKi was detected in MDA-ATC1 at week 12 for half and 18 for full dose. On second & third passage, tumors continued to show resistance, even following dose escalation. Resistance in the CDX was observed during the initial treatment period and tumor growth continued under consistent low and high D/T dosing concentrations. The first passage tumors grew rapidly under both dosing concentrations and were subsequently used in the second passage for dose escalation and resistance maintenance studies until tumors reached >1000mm3. At each passage and at study completion, tumors from PDX and CDX models were harvested and evaluated with short tandem repeats, immunohistochemistry for BRAF-status, and standard H&E staining.
Conclusion: To our knowledge, these are the first BRAF/MEKi resistant ATC models described and characterized. We expect these models to play an integral role in drug development and evaluation for this difficult-to-treat population with no adequate therapeutic option to date.

#5530 Combination of BRAF and ACLY inhibition synergistically reduces melanoma cell viability.

Anastasiia Vaska, Michael Ferretti, Daniel A. Ho, Rachel E. Harmon, Robert F. Green, Aaron B. Steiner, **Nancy A. Krucher**

Biology, Pace University, Pleasantville, NY

Fifty percent of Melanoma cases harbor the activating BRAF V600E mutation which prompted the development of BRAF inhibitors Vemurafenib, Dabrafenib and Encorafenib, used clinically in combination with MEK inhibitors Trametinib, Cobimetinib and Binimetinib. Together, these agents serve to inhibit the MAPK pathway, but the PI3K/AKT pathway is often upregulated in response to MAPK pathway inhibition which can lead to clinically important treatment resistance. AKT functions in numerous cellular processes including survival, growth, proliferation, invasion and metabolism. With respect to metabolism, AKT activates lipogenesis by direct phosphorylation and activation of the enzyme ATP-Citrate Lyase (ACLY). ACLY expression and activity are elevated in melanoma and are associated with a poor prognosis. A new inhibitor of ACLY, NDI-091143, was recently identified based on the structure of ACLY and was used in this study. A panel of BRAF mutant melanoma cell lines was used to investigate whether combining the ACLY inhibitor NDI-091143 with the BRAF inhibitor Vemurafenib would enhance the latter's pro-apoptotic effects. Using concentrations of each drug that inhibited cell viability individually by 25%, we found that the combination exhibited synergistic reduction of cell viability in all melanoma lines tested, and similar results were obtained using melanoma cells grown in 3D culture. Normal human keratinocytes treated with the same concentrations of Vemurafenib and NDI-091143 did not exhibit reduced viability. In melanoma cell lines, the combination of BRAF and ACLY inhibition activated the ER stress pathway including phosphorylation of eIF, increased CHOP and ATF4 expression, and induced caspase-mediated apoptosis. In addition, the combination of these agents elicited an increase in reactive oxygen species (ROS) as well as activation of the Jun N-terminal kinase (JNK) pathway, both of which stimulate apoptosis. *In vivo* assessment of this combination treatment in a zebrafish model of melanoma is underway.

#5531 A 3D CRISPR screening identified RET-TKI resistance through MIG6 loss in RET rearranged NSCLC.

X. Wei, K. Uchibori, M. Nishio, R. Katayama;
Japanese Foundation for Cancer Research, Koto City, Japan

RET-fusion positive non-small cell lung cancer (NSCLC) accounts for 1-2% of total population of NSCLC. RET selective tyrosine kinase inhibitors (TKIs) have demonstrated remarkable efficacy, and 2 RET-TKIs have been approved for the treatment of RET-rearranged NSCLC. However, the emergence of acquired resistance which remains unclear largely. To better simulate in vivo tumor conditions, we employed a 3D culture system using LC2/ad (CCDC6-RET) and LCC190 (CCDC6-RET, originally established from RET-TKI naïve patient's pleural effusion) cell lines. RET-TKIs showed significant increased efficacy in this 3D system compared to standard 2D cultures with increased apoptosis pathway and reduced ERBB-mediated MAPK and PI3K/Akt/mTOR signaling pathways.Further, we conducted a genome-wide CRISPR/Cas9 screening in the 3D condition in LCC190, which identified multiple candidate genes including *ERRFI1* (MIG6) contributor to drug-tolerant persister (DTP) cell survival during RET-TKI treatment. Knockout of MIG6, a negative regulator of EGFR signaling, induced significant EGFR activation in the presence of extreme low ligand concentrations (1 ng/mL), leading to resistance through the activation of MAPK and PI3K/Akt/mTOR pathways. These findings highlight the critical role of regulation of MIG6 on EGFR in bypassing RET inhibition. Notably, combining RET-TKIs with EGFR inhibitors (afatinib or cetuximab) markedly reduced the survival of DTP cells *in vivo* and *in vitro* suggesting a potential combination strategy to overcome such resistance. Conversely, overexpression of MIG6 restored sensitivity to RET-TKIs under conditions of low EGFR ligands with reduced level of phosphorylation of EGFR. In conclusion, this study identifies MIG6 as a critical mediator of RET-TKI resistance in NSCLC and highlights the utility of 3D culture systems in uncovering key resistance mechanisms in RET-fusion positive NSCLC. Targeting EGFR in combination with RET-TKIs presents a promising therapeutic strategy to overcome drug-tolerant persistence and improve treatment outcomes in RET-rearranged NSCLC. Besides MIG6, we have also found several candidate genes related to DTP cell survival or RET-TKI resistance from the genome-wide Crispr screening. Further studies are needed to clarify the mechanisms of resistance induced by loss of these candidate genes to comprehensively understand the mechanisms how DTP cells survive against TKI treatment and how such resistance could be overcome by novel treatment methods.

#5532 Combinational targeted therapy effects on EphA2 and KRAS G12C inhibitor against KRAS G12C mutated non-small cell lung cancer cells.

H. Kawachi, T. Yamada, Y. Katayama, T. Koichi;
Kyoto Prefectural University of Medicine, Kyoto, Japan

Background: KRAS is the most frequent oncogene in non-small cell lung cancer (NSCLC), and some KRAS G12C inhibitors have been clinically developed for treatment of KRAS G12C-mutated NSCLC patients. However, these KRAS G12C inhibitors have shown limited efficacy, and developing novel treatment strategy is warranted to improve clinical prognosis in this clinical population. EphA2, a receptor tyrosine kinase overexpressed in various cancers including NSCLC, plays a critical role in tumorigenesis and cancer progression, with high expression levels associated with poor prognosis. Recent studies indicate that targeting EphA2 can effectively inhibit tumor growth and induce apoptosis in KRAS-mutated NSCLC, underscoring its potential as a promising therapeutic target.
Methods: In this preclinical study, we investigated the combined effect and underlying mechanisms of KRAS G12C inhibitors and EphA2 inhibition using multiple human KRAS G12C-mutated lung cancer cell lines.
Results: The combined inhibition of KRAS G12C and EphA2 resulted in enhanced suppression of cell proliferation via increasing cell apoptosis in a subset of these KRAS G12C-mutant lung cancer cells. The KRAS G12C and EphA2 inhibitor combination also suppressed cell migration, compared with the effects in each monotherapy. Cell line-derived xenograft model indicated that the combination of KRAS G12C inhibitor plus EphA2 inhibitor enhanced anti-tumor effects compared with KRAS G12C inhibitor monotherapy. Further examination of apoptosis-related proteins revealed that the combination treatment reduced Mcl-1 expression. Additionally, combining KRAS G12C with an Mcl-1 inhibition led to further increases in cell death and enhanced suppression of cell proliferation.
Conclusions: The combination of KRAS G12C inhibitors and EPhA2 inhibition is expected as the promising strategy for those tumors.

#5533 Drug tolerance mechanisms in patient-derived xenograft models with *epidermal growth factor receptor* mutated tumors treated with tyrosine kinase inhibitors.

Arundhathi Arivajiagane, Quan Li, Nhu-An Pham, Ming Li, Katrina Hueniken, Takamasa Koga, Nikolina Radulovich, Ming-Sound Tsao

UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Background and Purpose: Epidermal growth factor receptor (EGFR) mutations on exon 18-21 are oncogenic drivers in 10-60% of patients with lung adenocarcinoma. First and second-generation EGFR tyrosine kinase inhibitors (TKIs) have high efficacy but resistance quickly develops, with 60-70% caused by the emergence of T790M secondary mutation. Osimertinib (osi) is effective against common *EGFR* mutations as well as T790M, yet most patients eventually also develop resistance. Understanding post-osi resistance mechanisms is a priority research goal. Our goal is to establish large cohort of patient-derived xenograft (PDX) and/or organoid models with *EGFR* mutations from patients who have progressed on osimertinib and use them to characterize the mechanisms of drug tolerance and resistance.
Methods: We have established six PDX models from tumor biopsies and one organoid-derived xenograft (ODX) from a pleural effusion. To assess models response to osi, donor xenograft tumor fragments were implanted into replicate NOD SCID mice and once tumors reached an average tumor volume of 400 mm^3, they were randomized into vehicle and osi treatment groups. Osi was dosed at 25mg/kg daily oral gavage for 30 days. Excised tumors were profiled by bulk RNAseq in two models PHLC4547 and 4672.
Result: Models were established from tumors of three patients who have progressed on geftinib and osi treatment (PHLC4683^{Ex19delE746_A750del}, PHLC4697$^{L858R/L833V}$, PHLC4547^{L858R}). Additionally, one progressed on gefitinib PHLC4223^{L858R} and one on afatinib and gefitinib PHLC4192 ^{Ex19delE746_A750del}. One progressive on osi PHLC4672$^{L858R/G719}$ and another patient who progressed on afatinib and osi treatment is PHLC4754$^{L858R/T790M/C797S}$. PHLC4672 PDX demonstrated drug tolerance and stable tumor size to osi treatment, all other models showed resistance to osi. However, PHLC4547, 4223, 4683 and 4754 showed initial transient tolerance to osi and resistance quickly followed. PHLC4192 and PHLC4697 were completely osi-resistant. Transcriptomic profiling of osi-resistant PHLC4547 revealed no changes in gene expression profile during all three serial passages of osi-treated tumors. However, PHLC4672 with osi-tolerance revealed downregulation of Hallmark gene set enrichment in pathways of G2M checkpoint, E2F targets, mitotic spindle, glycolysis and estrogen response. The EGFR-TKI responses in patients and PDX models showed high concordance among the resistant models.
Conclusion: The altered pathways in tolerance model appears to be unique to an osi-stable response compared to an osi-resistance response. PDX models from post-TKI patients may be useful to study the drug resistant mechanism.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance in Molecular Targeted Therapies 4
Poster Session

#5539 Single-cell and spatial approaches of identifying targets in endocrine therapy-resistant breast cancer.

Svetlana E. Semina[1], Rosemary Huggins J. Huggins[2], Debra Tonetti[3], Kent Hoskins[4], Geoffrey L. Greene[5], Jonna Frasor[1], Jonathan Coloff[1]

[1]College of Medicine, University of Illinois, Chicago, IL,[2]UChicago Comprehensive Cancer Center, University of Chicago, Chicago, IL,[3]College of Pharmacy, University of Illinois, Chicago, IL,[4]Division of Hematology and Oncology, University of Illinois, Chicago, IL,[5]Ben May Department for Cancer Research, University of Chicago, Chicago, IL

Even though most women with estrogen receptor (ER) positive breast tumors can benefit from endocrine therapy (ET), up to 40% of these patients will experience relapse. The percentage of tumor cells expressing ER varies from 1 to 100%, and some studies suggest that higher expression of ER positively correlates with ET efficiency and reduced rate of tumor relapse. We have previously identified a cell population with active NFκB and integrated stress response pathways that is able to survive selective pressure of ET and contribute to the tumor relapse. However, we and others routinely use models that are highly enriched for ER-expressing cells to study the effect of ET. Much less is known about ET efficiency for breast cancers with a low to moderate number of ER-expressing cells, which tend to be more aggressive. Here, we decided to use patient-derived xenograft organoids (PDxOs) and a single-cell-based approach in order to study how breast cancer models with low to moderate levels of ER expression respond to ET. In addition to the already established PDxOs (HCI003 and HCI017), we developed another two models (UIC013 and UIC020), in which 22%, 30%, 12%, and 7% of cells express ERα, respectively. Using single-cell RNA sequencing (scRNAseq), we established that each PDxO has a model-specific transcriptional profile that is reflected in differentially activated pathways and in the expression of clinically relevant markers associated with more aggressive phenotypes. More specifically, we found that HCI003 and UIC020 are enriched for gene signatures associated with ET resistance and breast cancer stem cells, whereas UIC013 is enriched for invasive/EMT signatures. To understand whether PDxOs are sensitive to ET, we treated each model with fulvestrant and 4-hydroxytamoxifen. We found that some of the cell populations are lost with ET, suggesting that they are responsive to ET, while others showed no change or even enrichment with ET, suggesting that they are resistant to ET. To identify alternative therapeutic options for the ET-resistant cell population, we used DREEP analysis (DRug Estimation from single-cell Expression Profile), a bioinformatic tool that predicts drug response to 450 compounds for scRNAseq dataset. Multiple compounds were predicted to be effective in combination with ET, including vandetanib, an inhibitor of VEGFR2, which is now in a clinical study as an additional treatment to fulvestrant for metastatic breast cancer. We also found several novel therapeutic compounds that can be used to eradicate ET-resistant cell populations. Taken together, these findings indicate that stratifying breast cancer cell populations based on response to ET, rather than ER expression or activity, can lead to the identification of new cell populations, as well as therapeutic strategies to target these populations, thereby improving outcomes for women with breast tumors.

#5540 Deconstructing the lethality of recurrence in ovarian cancer through multi-modal spatiotemporal analysis.

James M. Whipman[1], Francis Jacob[2], Viola Heinzelmann[2], Bernd Bodenmiller[1]

[1]ETH Zurich, Zurich, Switzerland,[2]University Hospital Basel, Basel, Switzerland

Epithelial ovarian cancer (EOC) represents the world's most lethal gynecological malignancy and is commonly associated with chemo-resistance and recurrence. Strikingly, up to 70% of EOC patients will relapse where subsequent care becomes palliative. Owing to a lack of model systems and a scarcity of matched treatment-naïve and recurrent clinical samples, few studies have addressed the complex relationship between first-onset EOC and its respective relapse. Identification of *in situ* tumor phenotypes that resisted initial chemotherapy treatment and initiate recurrent tumors, will allow us to understand which cellular features lead to relapse. This will allow us to better predict tumor recurrence and to ultimately suggest novel therapies. Here we analyze primary and recurrent tumor pairs using highly multiplexed imaging technologies. Through integration of spatial transcriptomics and imaging mass cytometry (IMC), we identify and classify resistance phenotypes in over 320 EOC patients, identifying phenotypes that persist in recurrent tumors. We leverage these technologies to assign novel proteo-transcriptomic resistance modules that allow us to independently observe these phenotypes across multiple single-cell modalities. To uncover phenotype-specific drug sensitivities, we utilized scRNA-seq data to predict *in silico* drug-response and validated these findings through large-scale image-based *ex vivo* drug screening. These screens revealed significant multi-drug resistance (MDR) properties of persistent phenotypes, but unveiled sensitivity to alternate FDA-approved drug classes. Together, our work represents the first-of-its-kind high-dimensional map of resistant and recurrent EOC, offering tangible therapeutic solutions for the treatment and prevention of recurrence.

#5541 Dissecting chemotherapy resistance development in triple negative breast cancer through single cell multiome and lineage tracing.

Chufan Zhang, Chu Pan, Meghan Mcguire, Jennifer Cruickshank, Dave Cescon, Mathieu Lupien

UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Triple negative breast cancer (TNBC) is a breast cancer subtype that manifests fast disease progression and very poor overall survival. Despite initial response to standard of care, development of therapy resistance remains the major challenge in TNBC clinical management. Delineating the mechanisms underlying resistance development has been impeded by the still unknown cell population of origin and lack of longitudinal molecular profiling. To investigate this question, we applied a CRISPR based lineage tracing system into TNBC cell lines. Longitudinal samples from an Antibody Drug Conjugate (ADC), Sacituzumab Govitican sensitive to resistance were collected in vitro via stepwise drug dose escalation and in vivo via xnenograft serial transplantation. We leveraged cellular barcoding with single cell multiome from 10X genomics to simultaneously capture clonal identity, accessible chromatin and gene expression and hence, directly linked lineage with functional cell states. Preliminary results suggest that TNBC cells adopted distinct cell states shortly after drug exposure with characteristics including upregulation of epithelial-to-mesenchymal transition (EMT) genes, stemness markers and downregulation of immune related pathways. Clonal level analysis revealed only a subset of clones survived initial treatment and are enriched in specific “primed” cell states. Next, we will construct single cell lineage trees and quantify clonal dynamics and cell state transition rates. We will identify and validate regulators of cellular plasticity and explore if potential drug combinations will prevent emergence of resistance cell state. Overall, this study will build a comprehensive map of the phenotypic trajectory towards chemotherapy resistance and pinpoints biomarkers of therapy response in triple negative breast cancer.

#5542 A novel approach for establishing clinically relevant models of chemoresistance.

Jared R. Fischbach, Geoffrey A. Wood, Courtney R. Schott

Department of Pathobiology, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada

This study provides a novel methodology for generating *in vitro* chemoresistance models that maximize clinical relevance, aimed at improving the translatability of downstream experimental insights to clinical contexts. Our approach prioritizes an accurate translation of clinical chemotherapy treatment regimens to *in vitro* applications. We present our methodology in this study using canine osteosarcoma (OS), but our approach is designed to broadly apply to other cancer types.

Chemoresistance poses a significant challenge to improving cancer treatment outcomes, as the underlying mechanisms driving it are not well understood. One approach to studying these mechanisms is generating *in vitro* chemoresistance models. However, there has yet to be a consensus on the optimal method for developing clinically relevant chemoresistance models. Many existing guidelines either produce levels of chemoresistance that are not clinically achievable or offer incomplete strategies for producing clinically relevant models.

To establish a clinically relevant model of chemoresistance, we treated canine OS cell lines with carboplatin under conditions designed to precisely mimic the standard-of-care (SOC) treatment regimen used in clinical practice. To translate this clinical regimen to our *in vitro* application, we utilized numerous pharmacokinetic parameters derived from serum concentration curves for carboplatin in dogs treated in accordance with the SOC regimen, including area under the curve (AUC), peak serum concentration (Cmax), time to peak serum concentration (Tmax), and time from treatment initiation to when the serum concentration falls below detectable levels. Utilizing these pharmacokinetic parameters, a biphasic treatment protocol was developed to provide a SOC-equivalent treatment regimen for *in vitro* application. Before commencing model generation, the baseline chemosensitivity of each parental canine OS cell line was determined in triplicate via its respective half-maximal inhibitory concentration (IC50) of carboplatin. These parental cell lines were then split into two identical plates each, with one plate from each cell line treated periodically with our SOC-equivalent regimen, administered every twenty-one days for six cycles, in accordance with the SOC regimen. Untreated cell lines were passaged alongside their treated counterparts as model controls.

Twenty-one days after the final treatment, the IC50s of all treated cell lines and their respective controls will be re-assessed in triplicate to quantify the fold change in chemoresistance induced by our SOC-equivalent regimen. We anticipate that treated cell lines will exhibit appreciable increases in chemoresistance, highlighting the potential of our methodology to establish clinically relevant *in vitro* models of chemoresistance that support future investigations into the underlying mechanisms of chemoresistance.

#5543 High resolution lineage tracing for the study of cancer drug persistence.

Binyanim Zhitomirsky, Jideofor Ezike, Brian P. Danysh, Gad Getz

Broad Institute of MIT and Harvard, Cambridge, MA

Drug-tolerant persister cells (DTPs) are a subpopulation of cancer cells that survive initial anticancer drug treatment despite lacking genetic resistance-driving alterations. DTPs have been shown to serve as an intermediate stage in the evolution of acquired drug resistance, facilitating the adaptation and survival of cancer cells under sustained therapeutic pressure. Recent studies have shed light on the biological characteristics of DTPs during and following drug treatment, describing the various adaptations that cells undergo while transforming into a DTP state. However, little is known about the biology of persistence potential — the cellular and molecular characteristics that prime certain drug-naïve cells to survive initial drug exposure. The main challenge in studying the persistence potential of drug-naïve cells lies in the need to treat cells to determine whether they will persist. To address this issue, we demonstrated the hereditary nature of persistence potential and adopted a high-resolution lineage tracing technology, to develop an assay for the study of persistence potential. This method, utilizing CRISPR-targeted evolving barcodes to reconstruct a lineage tree from a single-cell-derived clone, allows for the placement of persister cells along drug-naïve cells on the lineage tree. Utilizing this technology to study persistence to EGFR inhibitors in EGFR-positive non-small-cell lung cancer cells, we identified events on the lineage tree that alter the persistence potential of specific clades and derived the persistence potential of drug-naïve cells. Combining single-cell RNAseq data with cell persistence potential, we developed a computational pipeline to study the molecular mechanisms that govern the probability of drug-naïve cells to persist through drug treatment. We demonstrated that upregulation of genes related to oxidative phosphorylation correlates with a significant increase in persistence potential. These results agree with previous studies that demonstrate that cells in the DTP state are less dependent on glycolysis and rely more on oxidative phosphorylation for energy production and suggests that drug-naïve cells with elevated persistence potential are primed towards a high oxidative phosphorylation state. Intriguingly, we also described a module of translation-related genes that are negatively correlated with persistence potential, in agreement with recent results that show that persister cells undergo reversible remodeling of mRNA translation. This work introduces a novel approach and computational framework to study persistence potential and allows for the identification of potential drivers of persistence. A better understanding of the unique cellular and molecular traits that drive persistence potential is crucial for the study of drug persistence and development of targeted therapies preventing persistence and enhancing the likelihood of curative treatment.

#5544 Identification, isolation and molecular characterization of drug-resistant sub-populations of pancreatic cancer cells.

Subhendu Roy Choudhury[1], Shixiong Wang[1], Yevhen Akimov[2], Katarina Willoch[1], Biswajyoti Sahu[3], Alfonso Urbanucci[4], Thomas Fleischer[1], Tero Aittokallio[1]

[1]Department of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway,[2]Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,[3]Centre for Molecular Medicine Norway (NCMM), Faculty of Medicine, University of Oslo, Oslo, Norway,[4]Department of Tumor Biology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway

Pancreatic ductal adenocarcinoma (PDAC) has a poor prognosis, since most PDAC tumors develop resistance to the standard of care (SoC) treatments like chemotherapy, radiation, and targeted therapies. All tumors consist of multiple, genetically related subpopulations of cancer cells that evolve in parallel and display heterogeneity at genomic, epigenetic, or phenotypic levels. As cancer develops, some subpopulations of cancer cells may show faster growth, increased metastatic potential, and resistance toward SoC treatment. A key challenge in PDAC management is understanding chemoresistance driven by cancer subpopulation dynamics. This would broaden our understanding of tumor adaptation to treatments and guide targeting resistant subpopulations to improve therapeutic outcomes. In this study, we identified PDAC cell subpopulations resistant to chemotherapy using our DNA barcoding system B-GLI (barcode-guide lineage isolation). The B-GLI system leverages a highly complex DNA barcode library and CRISPR activation (CRISPRa) to trace and isolate sub-lineages within heterogeneous cell populations by their DNA barcodes. PDAC cell lines PANC-1 and Mia-PaCa-2 were barcoded with the B-GLI barcode library, which consist of two optimized guide RNA binding sites in each barcode. After DNA barcoding, we performed treatments with two SoC chemotherapeutics, gemcitabine + paclitaxel and FOLFIRINOX, to induce a selection pressure in the PDAC cell lines, and then identified the resistant subpopulations through differentially represented barcodes and sequencing. Furthermore, we designed barcode-specific single guide RNAs (sgRNAs) targeting the resistant subpopulations and activated the expression of the puromycin resistance gene by CRISPRa. This allowed us to enrich and isolate chemoresistant subpopulations by puromycin treatment. After having isolated the resistant PDAC subpopulations, we performed ATAC-seq and RNA-seq for molecular characterization of the resistant and parental cell populations, along with phenotypic drug screening with 384 compounds to identify novel treatment vulnerabilities. The compound testing confirmed that the resistant cells were less sensitive to the two SoC treatments, as well as identified selective sensitivity to specific compounds. ATAC-seq and RNA-seq data will allow us to decode whether and how chromatin structure and transcriptomic changes are associated with the treatment resistance, and the confirmation screen of the drug sensitivities will identify potential compounds for future pre-clinical and clinical testing in PDAC models and patients with resistant disease. In summary, this study will identify targeted treatment alternatives, accompanied by molecular biomarkers for chemotherapy resistant PDAC.

#5545 Dynamic Precision™: a scalable tech-bio platform to identify immune-mediated resistance through dynamic monitoring.

Ronan O'Hagan, **Lynda Chin**

Apricity Health, Houston, TX

Background: Understanding immune-mediated resistance requires recognizing the immune system as a complex adaptive system and studying its dynamic responses to drugs in diverse patient populations. Current approaches are hindered by (1) reliance on static, pre-treatment tumor analyses or preclinical models, and (2) sampling bias, as 80% of cancer patients are treated in community settings without enrollment in translational research. We hypothesized that combining dynamic analysis of immune response on treatment with broader patient representation would reveal previously unrecognized resistance mechanisms.

Methods: We developed a tech-bio platform to overcome these limitations. First, applying complex system insights, we pioneered Dynamic Precision™, a AI/ML-based approach to identify emerging resistance targets and blood-based biomarkers from longitudinal patient data. Second, we developed ApricityCare, a HIPAA-compliant virtual care service, to engage diverse populations outside academic institutions in research under the SMART (Serial Molecular and Clinical Annotation of Responses to Therapies) protocol. SMART is IRB-approved for serial liquid biopsy collection, incorporating ApricityCare to enable research-grade data collection. ApricityCare offers 24/7 symptom monitoring and virtual management by nurses augmented with a clinical intelligence co-pilot, ensuring standardized side effect management, documentation, and automated data capture. Coupled with mobile phlebotomy, SMART reduces participation burdens for providers and patients.

Results: We analyzed longitudinal clinical and serial plasma proteomic data from melanoma patients on standard-of-care ICI therapy. Dynamic Precision™ identified early on-treatment signatures predictive of treatment failure and uncovered dynamically regulated immune proteins as potential therapeutic targets. Triangulation with clinical insights revealed druggable immune regulators with validated resistance mechanisms to T-cell checkpoint inhibitors. In parallel, ApricityCare demonstrated its ability to provide proactive symptom monitoring and side effect management while capturing high-quality clinical data without increasing workload for in-clinic care team. Leveraging mobile phlebotomy, SMART has been piloted successfully in multiple states.

Conclusions: We demonstrate here a dynamic approach to identifying immune-mediated resistance mechanisms, with a blood-based biomarker strategy for longitudinal monitoring to detect the molecular signals of resistance months before clinical progression of disease. With ApricityCare-enabled SMART protocol, we have also a scalable platform to bridge the representation gaps, generating more inclusive datasets to elucidate a more diverse range of drug resistance mechanisms. Proof-of-concept data will be presented.

#5546 Sorting to enrich for chemotherapeutic-resistant glioma cells based on unique membrane properties.

V. P. Dang, A. Y. L. Jiang, J. N. Hanamoto, N. S. Lav, C. R. Douglas, D. A. Bota, L. A. Flanagan;
University of California, Irvine, Irvine, CA

The purpose of this study was to leverage dielectrophoresis (DEP) as a novel method for sorting glioma cells based on their innate cell electrophysiological properties. Glioblastoma, astrocytoma, and oligodendroglioma comprise a class of aggressive and deadly brain tumors, termed as diffuse gliomas, with 20,000 cases diagnosed annually in the US. The current standard chemotherapy treatment, temozolomide (TMZ), is insufficient as the 5-year survival rate of glioblastoma patients has remained at roughly 8%. One major contributing factor to treatment inefficacy is the presence of TMZ-resistant cells within tumors that lead to chemoresistance and tumor recurrence. Thus, there is an unmet need to further understand the molecular properties of TMZ-resistant cells which could enable more effective means of targeting them and improve patient outcomes. Here we utilized microfluidic sorting devices and applied DEP, a phenomenon by which non-uniform electric fields induce differential movement of cells, as a novel label-free technique to sort glioma cells based on their membrane electrophysiological properties. With this technique, we successfully sorted cells from glioblastoma and oligodendroglioma established cell lines, which yielded fractions that differed in membrane capacitance, the membrane's ability to store charge. Interestingly, the DEP-sorted cell fractions also exhibited significant differences in TMZ resistance, indicating that DEP can be used robustly to enrich for TMZ-resistant cells across different gliomas. Further, differences in TMZ resistance were coupled with membrane capacitance differences. Since we previously identified links between membrane capacitance and cell-surface glycosylation, we utilized lectin analysis to assess the glycan expression of DEP-sorted oligodendroglioma cells and found inverse correlation between TMZ resistance and mannose glycan expression. Collectively, our study concluded the novel finding that (a) TMZ-resistant glioma cells can be enriched by DEP, and (b) TMZ resistance is correlated with membrane capacitance and cell surface glycosylation. These results could enable downstream molecular characterization of TMZ-resistant cells to uncover less explored mechanisms of TMZ resistance and the development of more effective treatment strategies for gliomas that specifically target membrane properties such as glycosylation.

#5547 High resolution target identification by unbiased forward genetics.

Moritz Horn[1], Georg Michlits[1], Andreia Rocha[1], Christoph Stelzer[1], Josef M. Penninger[2]

[1]JLP Health GmbH, Wien, Austria,[2]Helmholtz Centre for Infection Research, Braunschweig, Germany

Forward genetic screens have revolutionized the field of target discovery, target deconvolution, and target validation, particularly in the oncology field. However, most approaches are limited to the interrogation of non-essential factors and identify gene networks rather than direct target structures. Therefore, the identification of druggable target structures and understanding an active molecules target space remains a challenge in drug discovery and development. To address this, we established a chemical mutagenesis approach in relevant cell types that allows entirely unbiased identification of small molecule targets at amino acid resolution, literally mapping compound-target interaction surfaces. Chemical mutagenesis randomly introduces single nucleotide variants into the entire genome resulting in cell populations which carry substitutions in statistically more than 90% of all amino acids. Challenging such mutagenized cell populations with a drug candidate of interest, followed by next generation sequencing and analysis, reveals direct drug target interactions, drug resistance mechanism, and potential off-targets or concealed efficacies. The alteration of single amino acids thereby allows interrogation of non-essential as well as most essential factors and increases screening resolution to the amino acid level. Several case studies will be shown.

#5548 Single-cell transcriptome analysis reveals the role of myofibroblastic cancer-associated fibroblasts in chemotherapy resistance in pancreatic cancer.

Jiahao Guo[1], Samuele Cancellieri[1], Liangru Fei[1], Tero Aittokallio[2], **Biswajyoti Sahu**[3]

[1]NCMM, University of Oslo, Oslo, Norway,[2]FIMM and Oslo University Hospital, Oslo, Norway,[3]NCMM, University of Oslo and University of Helsinki, Helsinki, Finland

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal cancer types often diagnosed late due to lack of specific biomarkers and its high capacity to metastasize early. In PDAC, tumor microenvironment (TME) is particularly complex, representing up to 80% of the tumor mass. Thus, better understanding of the cellular states and their controlling transcriptional networks within both malignant and stromal cells is pertinent to improve the survival of PDAC patients. The goal of this project is to elucidate the dynamic non-genetic regulatory mechanisms that contribute to PDAC progression and development of chemoresistance. We have performed in-silico analysis of single-cell RNA-sequencing data from >200,000 cells derived from pancreatic cancer patients with and without neoadjuvant treatment. Based on their gene expression profiles, we identified 12 distinct cell types including three major fibroblast subtypes: regular cancer-associated fibroblasts (CAF), inflammatory CAFs (iCAF), and myofibroblastic CAFs (myCAF). We found that tumors from patients with poor treatment response as well as from untreated patients exhibited a higher proportion of myCAFs compared to treatment-responsive patients. Using specific markers derived from each fibroblast subtype, we applied these signatures to the PAAD cohort from TCGA and found a significant association between the myCAF signature and worse prognosis as well as advanced TNM staging. Functional analyses further demonstrated elevated levels of Wnt/β-Catenin and Notch signaling pathways in the untreated and poor-response groups. Second, we utilized state-of-the-art machine learning methods to model robust relations between transcription factors (TF) and gene regulatory networks from treatment-naïve and neoadjuvant-treated PDAC patients. Our analysis revealed both well-known and new TFs related to pancreatic cell identity and PDAC progression. In-silico perturbation of these TFs was performed to study their effect on gene expression and cell state dynamics. The predictions reported a strong activity from both well-known and newly predicted TFs regarding the cell state transitions and their regulatory role. Currently, we are further characterizing the identified cell states and associated transcriptional programs, and the findings will be presented in the meeting.

#5549 Identification of genes associated with drug persistence/resistance using CRISPR screening and scRNA-seq of ALK rearranged lung cancer.

Ryohei Katayama[1], Takahiro Utsumi[1], Nobuyuki Kondo[1], Ken Uchibori[2], Makoto Nishio[1]

[1]Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan

ALK-rearrangement is found in 3-5% of non-small cell lung cancer (NSCLC), and currently five ALK tyrosine kinase inhibitors (TKIs) have been approved, and several TKIs are in development. These ALK TKIs have contributed to a significant improvement in patient prognosis, such that the median survival of patients with advanced ALK-positive lung cancer has exceeded 5 years. However, it has been a problem that cancers eventually relapse due to drug resistance. To date, many investigators have reported the mechanism of ALK-TKI resistance; secondary mutation(s) in the ALK kinase domain that disrupt ALK-TKI binding, or the activation of bypass signaling pathways that promote cell proliferation even under ALK fusion protein-mediated signaling that is suppressed by ALK-TKIs. However, in a significant number of cases, the mechanism of resistance is still unknown. Therefore, in this study, we first performed a genome-wide CRISPR screen using two ALK-positive NSCLC cell lines derived from patients with ALK-rearranged cancer prior to ALK-TKI treatment. Cas9 and genome-wide sgRNA-introduced cells were cultured with alectinib or lorlatinib for 9 days, and sgRNAs in surviving drug-tolerant cells were analyzed by NGS. Several candidate genes were identified, such as MED12, PTEN, NF2 or MIG6, and confirmed whether knockout of these genes induced drug tolerance/resistance in the ALK-TKI-naive cells. For example, loss of MIG6, an EGFR-binding negative regulator protein, activates EGFR at very low concentrations of EGF (less than 1 ng/mL, which is similar to the healthy human plasma concentration) and induces marked resistance to ALK inhibitors. In contrast, NF2 knockout itself induces drug resistance rather than drug persistence, and we found that brigatinib may be able to overcome the resistance induced by NF2 loss, because brigatinib inhibited ALK as well as several other kinases at single digit nM. As recently published in the NF2 loss Schwannomatosis, NF2 loss induce multiple kinase activation not only mTOR pathway and MAPK pathways, and brigatinib was shown to be an effective treatment option for NF2 loss Schwannomatosis. In addition, from the analysis of alectinib-resistant pleural effusion-derived cells, we found AXL overexpression but not Gas6, a ligand of Axl, in the resistant tumor. Therefore, we performed an in vivo experiment by inoculating Axl-overexpressing ALK-positive cancer cells and analyzed the tumor tissue with or without alectinib treatment. Single-cell RNA sequencing revealed that MMP11-positive cancer-associated fibroblasts (CAFs) and a subset of tumor-associated macrophages (TAMs) were the major sources of Gas6 in the tumor microenvironment. This study uncovered some of the unidentified resistance mechanisms and potential therapeutic strategies to overcome the resistance.

#5550 Understanding therapy resistance in T-cell acute lymphoblastic leukemia.

A. Nasimian, K. Shah, **J. U. Kazi**;
Lunds Universitet, Lund, Sweden

The deregulation of BCL2 family proteins is a key contributor to the development of T-cell acute lymphoblastic leukemia (T-ALL). Pharmacological inhibition of these proteins, particularly through the BCL2-specific inhibitor venetoclax, has emerged as a promising therapeutic approach. However, the clinical efficacy of venetoclax is often compromised due to primary and acquired resistance mechanisms that remain incompletely understood. We employed a deep tabular learning algorithm to develop a drug sensitivity prediction model using T-ALL patient samples. Our findings revealed distinct expression profiles between drug-sensitive and drug-resistant samples. Specifically, in the context of venetoclax sensitivity and resistance phenotypes, we observed associations with several key proteins regulating the cell cycle, cytokine signaling, and mitochondrial apoptosis. Our data suggest a key link between lipid metabolism and beta-catenin signaling, which may cooperate with transcription factors regulating the transcriptional activation of key apoptosis regulatory genes. Together, our results underscore the complexity of therapy resistance and highlight the therapeutic potential of targeting multiple pathways for growth inhibition. Future research should focus on clinical trials exploring this combinatorial approach to overcome resistance and improve patient outcomes in T-ALL.

#5551 From persistence to resistance: insights into the mechanisms of drug tolerance in cancer therapy using patient-derived organoids.

Yasmine Abouleila, Timo Voskuilen, Mayke Doorn, Roel Verkerk, Joris Maas, Carla Verissimo, **Sylvia F. Boj**

HUB Organoids B.V., Utrecht, Netherlands

Resistance to cancer treatment remains a significant obstacle in curing cancer patients. Despite recent advancements in novel cancer drugs, patients often experience treatment resistance even after initially responding to therapy, leading to tumor relapse. To understand how resistance develops against standard cancer therapies, it is essential to study the gradual changes leading to full resistance. Recent research shows that cancer cells can evade the effects of chemotherapy and targeted therapies by entering a reversible, slow-growing phase called the drug-tolerant persister (DTP) state. In this DTP state, cancer cells survive drug treatment long enough to begin accumulating mutations and eventually develop additional mechanisms of irreversible resistance. Patient-derived organoid (PDO) models, also known as HUB Organoids®, are directly derived from patient tissues, making them more physiologically relevant than traditional cell lines. This study highlights the value of PDO models in studying drug persistence and resistance, as they are more likely to reflect in-vivo conditions. Here, we demonstrate the successful development of colorectal cancer (CRC) PDO models that can persist and resist standard therapies. These models were characterized using whole exome sequencing and bulk RNA sequencing to assess their persistent or resistant state and to identify potential pathways and new drug targets involved in resistance. In conclusion, developing persistent and resistant PDO models is essential for understanding the mechanisms behind drug resistance. This research contributes to developing patient-relevant preclinical models to develop more effective and personalized cancer treatments and expands our overall understanding of how resistance develops in cancer patients.

#5553 Acquisition of adaptive and reversible drug-tolerance state to cabozantinib in renal cell carcinoma cell lines.

Angela Zaccagnino, Hiresh Ayoubian, Kerstin Junker

Saarland Univ. Faculty of Medicine, Homburg, Germany

Drug-tolerant (DT) state has been recognized as a transient, adaptive process whereby tumour cells endure therapy with tyrosine kinase inhibitors (TKIs) through non-genetic/epigenetic mechanisms, which might be responsible for driving tumour relapse and therapy resistance. Considering that resistance to the targeted systemic therapies remains challenging in metastatic renal cell carcinoma (mRCC), here we elucidated the DT-state as response to the TKI cabozantinib (CBZ) targeting c-MET/Axl/VEGFR in RCC cell lines.After chronic exposure to CBZ (IC50) for 4 months, the 786-O/DTC, Caki-2/DTC and KTCTL-26/DTC cells were profiled for cell survival (WST-1), proliferation (BrdU), migration/invasion, apoptosis (caspase 3/7) and compared to untreated wild-type (wt) cells. Molecular analyses were carried out via immunoblotting and miRNA expression assays (hs-miRNA microarray and RT-qPCR).The DTC-cell lines were successfully induced. The DT-cell lines maintained viability after long-term therapy with a slow growing state. To investigate the mechanisms that drive DT-state, we compared the DTC and WT cells under CBZ. The DTC-cell lines showed higher proliferation ($p<0.001$), along with lower caspase 3/7 activity in KTCTL-26/DTC and Caki-2/DTC ($p<0.001$). CBZ impaired migration and invasion, except in KTCTL26/DTC, which displayed higher invasion ($p<0.001$). Phospho-TK c-MET was inhibited in DT-cells but not Axl. Yet, c-MET was partially restored in KTCTL-26/DTC. The downstream ERK was unchanged in Caki-2/DTC and KTCTL-26/DTC or boosted in 786-O/DTC. BCL-2 was enhanced in Caki-2/DTC or unaffected in the other two DTC- cell lines hinting at an ability to bypass cell death. The DTC-state was reversible, as the cells recovered cell growth after CBZ-withdrawal implying a dynamic regulation. Among 4 miRNAs, namely hs-miR-551b-3p, hs-miR-34a-5p, hs-miR-424-5p and hs-miR-9-3p that were commonly dysregulated in DTC-cell lines, the hs-miR-424-5p and hs-miR-9-3p (regulation of cell cycle, MAPK signalling and apoptosis) were consensually upregulated in DTC-cells by 2.5-fold change ($p=0.001$), but their expression was reversed after treatment discontinuation. Remarkably, their regulation matched the changes in We established CBZ-DT cell lines and characterised the related spectrum of molecular changes, while considering tumour heterogeneity crucial to drug-adaptation. We identified previously unrecognised miRNAs associated with DT to emphasise the dynamic epigenetic changes that are critical in the initiation of DT-state.

#5554 Intrinsic resistance mechanism of squamous cell lung carcinomas to the multiangiokinase receptor inhibitor Nintedanib through CXCL-1 upregulation in tumor associated fibroblasts.

Natalia Isabel Diaz Valdivia[1], Paula Duch[1], Alejandro Bernardo[1], Marselina Arshakyan[1], Noemi Reguart[2], Derek Radisky[3], Oriol Casanovas[4], Jordi Alcaraz[1]

[1]Unit of Biophysics and Bioengineering, Department of Biomedicine, Universitat de Barcelona, Barcelona, Spain,[2]Thoracic Oncology Unit, Hospital Clinic, Barcelona, Spain,[3]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[4]Tumor Angiogenesis Group, ProCURE, Catalan Institute of Oncology, Oncobell, IDIBELL, Barcelona, Spain

Background: Lung adenocarcinoma (ADC) and squamous cell carcinoma (SCC) are the most common lung cancer subtypes. SCC is traditionally resistant to anti-angiogenic therapies, though the mechanisms remain unclear. Nintedanib, a multi-angiokinase receptor inhibitor, is approved for treating ADC in combination with docetaxel, based on selective efficacy in the LUME-1 trial. It is also FDA-approved for idiopathic pulmonary fibrosis due to its antifibrotic properties. Both ADC and SCC feature fibrotic stroma rich in activated tumor-associated fibroblasts (TAFs). Our prior work showed Nintedanib has stronger antifibrotic effects on ADC-TAFs than SCC-TAFs. However, its impact on TAF-driven angiogenesis and the role of TAFs in SCC resistance to multi-angiokinase inhibitors remain unexplored.
Methods: The pro-angiogenic activity of TAFs secretome from ADC and SCC patients was assessed. TAFs were stimulated with TGF-β1 to mimic their activated phenotype, then treated with Nintedanib. Conditioned media from treated TAFs was used to assess endothelial cell migration and vascular network formation. Pro-angiogenic factor secretion was analyzed using antibody arrays, and functional roles of selected proteins were validated in vitro and in vivo using genetic approaches.
Results: Nintedanib inhibited the pro-angiogenic effects of ADC-TAF secretome but paradoxically enhanced angiogenesis in SCC-TAFs, increasing endothelial cell migration in vitro and in vivo. Notably, Nintedanib selectively upregulated CXCL-1 secretion in SCC-TAFs. Silencing CXCL-1 using siRNA in SCC-TAFs abrogated the Nintedanib-induced angiogenesis. Similar findings with other multi-angiokinase inhibitors suggest aberrant CXCL-1 production in SCC-TAFs may drive universal resistance to these therapies.
Conclusion: SCC-TAFs are resistant to the anti-angiogenic effects of Nintedanib, which paradoxically promotes angiogenesis via CXCL-1 upregulation. This study provides the first mechanistic insight into SCC resistance to anti-angiogenic therapies and underscores the critical role of TAFs in modulating therapeutic responses. Targeting CXCL-1 or TAF-mediated pathways may inform alternative anti-angiogenic strategies in SCC, potentially in combination with immune checkpoint inhibitors.

#5555 Potential pathways underlying sorafenib resistance in hepatocellular carcinoma.

Yamile Abuchard Anaya[1], Ana Ayala Pazzi[2], Dennis Kwabiah[1], Veerababu Nagati[1], Ricardo Pequeno Bracho[1], Manish K. Tripathi[1]

[1]Medicine and Oncology ISU, University of Texas Rio Grande Valley, McAllen, TX,[2]Biomedical engineering, UT Southwestern Medical Center, Dallas, TX

Background: Hepatocellular carcinoma (HCC), the most prevalent form of liver cancer, is heavily influenced by socioeconomic and health disparities. In the Rio Grande Valley (RGV), risk factors such as Hepatitis B and C, diabetes, and non-alcoholic fatty liver disease (NAFLD) contribute significantly to HCC prevalence. McAllen, TX, ranks as the most obese city in the United States, compounding the HCC burden in this underserved area. Limited access to screening and early detection often results in late-stage diagnoses and poor outcomes. A deeper understanding of the molecular mechanisms driving HCC, particularly drug resistance, is crucial for improving early detection and treatment strategies. Our lab investigates the role of Y-Box Binding Protein 1 (YBX1) in HCC progression and resistance to sorafenib, the first-line tyrosine kinase inhibitor (TKI) for advanced HCC. YBX1, part of the Cold Shock Domain (CSD) protein superfamily, is a 324-amino acid protein involved in mRNA translation regulation via interactions with microRNAs and non-coding RNAs. While sorafenib shows initial efficacy, resistance frequently develops, and its mechanisms remain poorly understood.
Methods: HCC cell lines were cultured following ATCC guidelines. Lentiviral overexpression plasmids for YBX1, incorporating GFP and a puromycin selection marker, were obtained from Abmgood. YBX1 expression was validated using Western blot and RT-PCR. Functional assays, including invasion, migration, proliferation, colony formation, and Xcelligence impedance analysis, were conducted to assess phenotypic changes. A phosphoproteome array identified kinase pathways influenced by YBX1, while specific kinase activators and inhibitors clarified YBX1-regulated signaling pathways linked to sorafenib resistance.
Results: Analysis of The Cancer Genome Atlas (TCGA) confirmed that YBX1 expression is significantly elevated in HCC tumors compared to normal tissues and correlates with disease progression, metastasis, and poor survival. In vitro studies demonstrated that YBX1 overexpression (OE) enhanced invasion, migration, proliferation, and colony formation, while knockdown (KD) reduced these behaviors. Xcelligence assays further revealed accelerated proliferation in YBX1-OE cells and diminished growth in KD cells. Phosphoproteome analysis identified several kinases modulated by YBX1, and pathway analysis is ongoing to determine their roles in sorafenib resistance.
Conclusion and Future Directions: We established GFP-expressing SK-Hep1 cell lines with stable YBX1 overexpression and knockdown, confirming YBX1's role in driving oncogenic phenotypes in HCC. Ongoing proteomic studies aim to identify YBX1-associated proteins and pathways, with a focus on kinase modulation. These insights will enhance our understanding of sorafenib resistance mechanisms and inform the development of targeted therapies to overcome resistance in HCC.

#5556 Development of osimertinib resistant mouse models for preclinical evaluation of third-generation EFGR-TKI therapies.

Hongyan Sun[1], Yinuo Wang[1], Shiying Guo[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Osimertinib was developed as a third-generation EGFR tyrosine kinase inhibitor. Numerous clinical trials have demonstrated that EGFR-TKI targeted drug therapy for non-small cell lung cancer can prolong the survival of patients. However, its efficacy is impacted by acquired EGFR C797 mutations (including EGFR triple mutations Del19/T790M/C797S and L858R/T790M/C797S). To better understand the drug resistance mechanism towards Osimertinib, we have developed both *in vitro* and *in vivo* models associated with Osimertinib resistance for the evaluation of novel therapeutics that overcome Osimertinib resistance.

The human lung adenocarcinoma H1975 is a cell line with double mutations in the EGFR gene (L858R/T790M). To create a model which mimics patients in clinic who received Osimertinib treatment and developed drug resistance thereafter, the C797S mutation was introduced using advanced gene editing technology for site-directed mutagenesis, resulting in the EGFR triple-mutant cell line (H1975 with EGFR L858R/T790M/C797S).

To explore other Osimertinib resistance mechanisms than the C797 mutation, we induced cell lines *in vitro* with multiple rounds of increasing concentrations of Osimertinib. Following the induction of Osimertinib, the IC50 of different cell lines treated by Osimertinib was assessed, confirming increased resistance to Osimertinib. *In vivo* tumorigenicity and efficacy studies with Osimertinib were performed to screen and validate our Osimertinib-resistant models. Currently, we have obtained the EGFR triple mutant H1975 and PC-14 cell lines that exhibit resistance to Osimertinib for *in vitro* and *in vivo* study, which serve as vital tools for studying drug resistance mechanisms and developing innovative treatment strategies.

#5557 Deciphering the interplay of β-catenin/YAP signaling and alveolar lineage plasticity during targeted therapy in non-small cell lung cancer.

Yu-Ting Chou, Wei Wu, D. Lucas Kerr, Victor Olivas, Macey Slota, Trever G. Bivona

UCSF - University of California San Francisco, San Francisco, CA

Molecularly targeted therapies have significantly improved clinical outcomes by directly addressing oncogenic driver mutations in genes such as EGFR. However, despite their initial success, long-term patient survival remains limited due to the emergence of drug tolerance and resistance. This study investigates the molecular mechanisms underlying drug tolerance in response to targeted therapies in non-small cell lung cancer (NSCLC). Using single-cell RNA sequencing of oncogene-driven human NSCLCs at the residual disease (RD) state during active targeted therapy, we observed an enrichment of an alveolar type I/II (AT1/2) mixed lineage program in surviving cancer cells, resembling an alveolar cell-like state. This transition is characterized by increased expression of WNT3A/4 ligands, FZD2 receptors, β-catenin signaling, and AT1/2 signatures in RD cells. Consistent with these clinical observations, preclinical models of drug-tolerant persister (DTP) cells exhibited elevated AT1/2-like transcriptional signatures and target gene expression associated with β-catenin and YAP signaling. Further analysis revealed the formation of a stable nuclear protein complex between β-catenin and YAP in DTP cells, which appears to play a critical role in sustaining drug tolerance. Disrupting the expression and stability of the β-catenin/YAP complex, either through knockdown of these genes or by using Tankyrase inhibitors (e.g. XAV-939 or IWR1) to regulate the β-catenin destruction complex, re-sensitized DTP cells to the EGFR inhibitor Osimertinib. In xenograft mouse models, the combination of Osimertinib with a Tankyrase inhibitor significantly improved tumor growth inhibition compared to Osimertinib alone. This therapeutic strategy also led to a notable reduction in AT1/2 gene signatures, a decrease in nuclear β-catenin and YAP protein expression, reduced stability of these proteins, and suppression of their interaction, further supporting its potential in overcoming drug tolerance. Additionally, we identified specific domains within both β-catenin and YAP proteins that are essential for their interaction. This interdependence underscores the critical roles of β-catenin and YAP in maintaining DTP cell survival and driving alveolar cell-like lineage plasticity. Our findings shed light on the interplay between β-catenin/YAP signaling and alveolar cell-like lineage signatures in residual cancer states. By targeting this axis, we propose a novel therapeutic approach to overcome drug tolerance and improve clinical outcomes for patients with NSCLC undergoing targeted therapy.

#5558 Stress-induced sympathetic stimulation inhibits sorafenib-induced ferroptosis in renal cell carcinoma.

Masaki Ushijima[1], Sei Naito[2], Hiromi Ito[2], Osamu Ichiyanagi[3], Takafumi Narisawa[2], Norihiko Tsuchiya[2]

[1]Urology, Yamagata Prefectural Shinjo Hospital, Shinjo, Japan,[2]Urology, Yamagata University Faculty of Medicine, Yamagata, Japan,[3]Urology, Yamagata Prefectural Kahoku Hospital, Kahoku, Japan

Background and Objective: Cancer patients are often in a chronic state of stress. There have been several reports on the relationship between stress and cancer progression, as well as the development of drug resistance. Our purpose is to investigate the effect of stress-induced sympathetic stimulation on drug resistance, especially on sorafenib, which has been reported to induce ferroptosis, in renal cell carcinoma (RCC).
Methods: First, we investigated the expression of β1- (ADRB1) and β2-adrenergic receptor (ADRB2) in surgical specimens by immunohistochemistry and in RCC cell lines by RT-qPCR. Isoproterenol (ISO), a non-specific β-adrenergic receptor agonist, was added into RCC cell lines ACHN and A498 before the addition of clinically-used-drugs (sorafenib, cabozantinib, lenvatinib, and rapamycin), and cell viability was analyzed by MTS assay. BALB/c nude mice were subcutaneously implanted with ACHN on the right side and ADRB2 knockdown ACHN on the left side of the mice. The mice were divided into the following groups: saline, sorafenib, stress+saline, stress+sorafenib. To explore the mechanisms of sorafenib-induced suppression of cell viability, we examined the effects of sorafenib by adding the ferroptosis inhibitors and inducers.
Result: All examined surgical RCC specimens and RCC cell lines were expressed ADRB1 and ADRB2. Drug resistance due to ISO was observed in sorafenib treatment in ACHN but not in A498. siADRB1 became resistant to sorafenib due to ISO, whereas siADRB2 was not affected. In mouse models, sorafenib inhibited tumor growth in the mock ACHN of control-reared mice. Within the vehicle-treated group, no significant differences in tumor volume due to stress exposure were observed. However, in the sorafenib-treated group, the stress-exposed group showed a greater increase in tumor volume compared to the control-reared group. In the shADRB2 ACHN, no differences in tumor volume changes were observed between the control-reared and stress-exposed groups under sorafenib treatment; both groups showed a suppression of tumor volume increase by sorafenib. In brief, ADRB2-mediated stress stimulation induced sorafenib resistance. Ferrostatin-1, a ferroptosis inhibitor, was able to significantly inhibit the effect of sorafenib in ACHN, but not in A498. The ferroptosis inducers Erastin and RSL3 decreased cell viability in both ACHN and A498 cells, and this induction of ferroptosis was suppressed in the presence of ISO. ISO significantly reduced reactive oxygen species increased by Erastin in ACHN and A-498.
Conclusion: Stress-induced sympathetic stimulation inhibits sorafenib-induced ferroptosis in RCC.

#5559 Receptor tyrosine kinase-like orphan receptor 1 (ROR1) in BTKi-treated mantle cell lymphoma.

A. Sircar[1], S. Parsa[2], L. B. Prickett[1], V. Munugalavadla[2], C. Rhee[1], R. Tourdot[1], A. Nelson[1], M. Ophir[1], W. Zhong[3], M. Sung[1], D. Auclair[1], C. D. Palmer[1];

[1]AstraZeneca US, Waltham, MA, [2]AstraZeneca US, South San Francisco, CA, [3]AstraZeneca US, New York City, NY

Mantle cell lymphoma (MCL) is a rare, aggressive B-cell non-Hodgkin lymphoma with a poor patient overall survival rate. While Bruton tyrosine kinase inhibitors (BTKis) have shown benefit in relapsed/refractory MCL (Wang M, *et al*., 2018; Song Y, *et al*.,2020; Wang ML *et al*., 2013) a portion of patients eventually progress. Here, we explored which biomarkers might be associated with resistance to acalabrutinib, a second generation BTKi, by analyzing samples from MCL patients who were on treatment or progressed on acalabrutinib from the ACE-LY-004 study (NCT02213926), as well as using a pre-clinical MCL cell line model. Receptor tyrosine kinase-like orphan receptor 1 (ROR1) is an important oncofetal protein and a target of clinical relevance in MCL. It was previously attributed to a bypass resistance mechanism to first generation BTKi ibrutinib (Zhang *et al*., 2019). We hence analyzed ROR1 expression levels using available exploratory biomarker flow cytometry data from ACE-LY-004, which revealed that MCL patients who progressed or pre-progressed on acalabrutinib showed a higher percentage of circulating CD5+ROR1+ tumor cells (78.3%; n=7 and 63.6%; n=4 respectively) than patients who continued responding to treatment (23.8%; n=6). Interestingly, although progression was associated with higher frequency of CD5+ROR1+ tumor cells, the per-cell surface ROR1 expression on these cells from patients who pre-progressed/ progressed on acalabrutinib treatment (longitudinal analysis; n=6) was lower. While acute 5-day BTKi treatment in the Jeko-1 MCL cell line led to transiently higher surface expression of ROR1, chronic 4-month exposure of sensitive cells led to ROR1 surface downregulation in acalabrutinib or reversible BTKi acquired resistant (R) Jeko-1 MCL cells. Total ROR1 expression (western blot), was increased in Jeko-1R versus sensitive, suggesting that BTKi chronically treated MCL cells may upregulate intracellular ROR1 and/or partially internalize surface ROR1. To assess potential therapeutic implications of decreased surface expression of ROR1 in MCL post BTKi treatment, we assessed activity of a ROR1-targeted ADC (Zilovertamab vedotin; Wang *et al*., 2021) in BTKi-R cells. In line with downregulated surface ROR1 levels, the response to ZV was lower in BTKi-R compared to sensitive cells. However, Wnt5a (ROR1 ligand) expression was increased in these Jeko-1R cells, indicating a potential increase in ligand-dependent ROR1 activity. These preliminary results highlight the possible association between ROR1 expression on MCL tumor cells and BTKi response. To further dissect the interplay between ROR1 and second generation/reversible BTKi treatment in MCL, studies utilizing a multi-omics integration approach, BTKi-R MCL cell lines, and *ex vivo* propagated MCL patient cell models are ongoing.

#5560 Exploring the role of Wnt, NFκb, and PI3 kinase pathways in oxaliplatin-resistant triple-negative breast carcinoma cell line.

Asif Ahmad[1], Sheerien Rajput[2], Areeb Ahmed[2], Kulsoom Ghias[1], **Azhar Hussain Rajabali**[3]

[1]Biological and Biomedical Sciences, Aga Khan University Hospital, Karachi, Pakistan,[2]Centre for Regenerative Medicine and Stem Cell Research, Aga Khan University Hospital, Karachi, Pakistan,[3]Aga Khan University Hospital, Karachi, Pakistan

Breast cancer (BCa) is one of the major causes of mortality and morbidity in women globally. Triple negative breast cancer (TNBC) is known for its aggressive nature and is associated with high recurrence and metastasis with poor overall survival; 50% of the patients relapse in the first three years. Development of metastasis and drug resistance impacts survival in TNBC patients. The reasons for drug resistance and metastasis are complex and involve dysregulation of different cell signaling pathways, such as Wnt/β-catenin, NFκB and PI3K/AKT. Clinical studies have shown a favorable response to combination therapy using oxaliplatin in the treatment of metastatic breast cancer. This study explored the role of Wnt/β-catenin, NFκB and PI3K/AKT survival pathways in oxaliplatin-resistant TNBC cell line *in vitro*. Oxaliplatin-resistant clones were developed in the TNBC cell line MDA-MB-231 through sequential treatment with increasing doses of oxaliplatin. Differential gene expressions between chemoresistant clones and parental cells revealed the dysregulation of resistance-related genes, such as at 4μM treatment CD44 ($p< 0.001$), COX-2 ($p < 0.001$), ABCG2, BCL-2 ($p < 0.05$) and BAX ($p < 0.01$), alongside a shift towards a mesenchymal phenotype in resistant clones. Signaling pathways were altered, such as the upregulation of β-catenin in the Wnt/β-catenin pathway, Rel-A and NFκB1 in the NFκB pathway, and differential expression of AKT1, PIK3CA and mTOR1 in the PI3K/Akt pathway. Additionally, resistant clones displayed G2/M cell cycle arrest. The findings of the study enhance the understanding of drug resistance mechanisms in triple-negative breast cancer (TNBC) and identify possible targets for therapy.

#5561 Ankyrin repeat domain 1 confers resistance to tepotinib in MET-altered cancers.

Ryunosuke Fujii[1], Tomoaki Higashihara[1], Ken Suzawa[2], Kousei Ishimura[1], Kazuya Hisamatsu[1], Ryota Fujiwara[1], Atsushi Matsuoka[1], Ryo Yoshichika[1], Naohiro Hayashi[1], Yuma Fukumoto[1], Kazuhiro Okada[1], Fumiaki Mukohara[1], Mao Yoshikawa[1], Kazuhiko Shien[2], Shinichi Toyooka[1]

[1]Thoracic, Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Dentistry and Phamaceutical Sciences, Okayama, Japan,[2]Thoracic, Breast and Endocrinological Surgery, Okayama University Hospital, Okayama, Japan

Purpose: The mesenchymal epithelial transition factor receptor (MET) is a promising therapeutic target in various cancers, including non-small cell lung cancer (NSCLC). In NSCLC, activation of the MET pathway occurs through diverse mechanisms, influencing cancer cell survival, growth, and invasiveness. These tumors exhibit oncogene addiction to MET and show remarkable responses to MET-Tyrosine Kinase Inhibitors (TKIs). However, the long-term effectiveness of MET-TKIs is usually limited due to acquired drug resistance. The mechanisms underlying primary and acquired resistance to MET-TKIs in NSCLC remain poorly understood. In this study, we investigated the mechanisms to tepotinib in *MET*-amplified and *MET* exon 14 skipping cancer cell lines.

Experimental Design: Two *MET*-amplified lung cancer cell lines, EBC-1 and H1993, and one *MET* exon 14 skipping gastric cancer cell line, Hs746T, were used to establish models of acquired resistance to MET-TKI tepotinib. Resistance mechanisms were explored through functional analyses, comprehensive gene expression analysis using RNA sequencing, and the alterations hypothesized to confer resistance were validated.

Results: Multiple mechanisms contributing to tepotinib resistance were identified. In EBC1 and Hs746T derived resistant cells, *Ankyrin Repeat Domain 1* (*ANKRD1*) was highly expressed, and suppression of *ANKRD1* using shRNA impaired resistance to tepotinib. Additionally, activation of the MAPK pathway was observed in EBC1 derived resistant cells, and inhibition of this pathway with MEK inhibitors had a synergistic effect with tepotinib. All 3 resistant cell lines used in this study showed epithelial-mesenchymal transition (EMT), which may further contribute to the resistance.

Conclusions: In this study, we revealed the different mechanisms of acquired resistance to MET-TKI tepotinib with potential therapeutic application.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Identification of Molecular Targets 2
Poster Session

#5565 Dysfunction in ATP-binding cassette 1 (ABCA1): a driver of intracellular cholesterol accumulation and potential therapeutic vulnerability of bowel cancers.

Daniel J. Gironda, Calvin J. Wagner, Ashok K. Pullikuth, Lance D. Miller

Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC

Background: Cholesterol is an integral sterol lipid that influences the homeostatic maintenance of cellular structure, hormone synthesis, and metabolic regulation within the cell. Accumulation of intracellular cholesterol has shown to drive the progression of multiple human cancers. Here we report that mutation or transcriptional repression of the cholesterol exporter, ABCA1, is a common phenomenon conserved in bowel cancers with novel mechanistic and therapeutic implications.
Methods: Whole-exome sequence analysis was conducted on 24 appendiceal cancers (AC) from consented patients. ABCA1 coding mutations and expression levels were analyzed in tumors from The Cancer Genome Atlas (TCGA) and Broad DepMap databases. One AC cell line (Naxorini) was created in house and four commercial CRC cell lines were used in ABCA1 functional studies. Combination treatment of 22-(R)-hydroxycholesterol (OHC) and 9-cis-retinoic acid (CRA) was used to induce ABCA1. ABCA1 knockdown (KD), measures of cellular viability, cell death, apoptosis, and free cholesterol were quantified.
Results: Protein coding mutations in the ABCA1 gene were identified in 7/24 (29%) AC specimens. Mutational analysis of other gastrointestinal cancers shows that ABCA1 is preferentially mutated in mucinous CRCs and mucinous stomach adenocarcinomas compared to their non-mucinous counterparts (X^2 p-value <0.001 and 0.047). ABCA1 mRNA expression levels were significantly lower in CRC and gastric tumors as compared to 28 different tumor types (ANOVA $p<0.001$), and significantly lower in bowel cancer cell lines as compared to 34 different cancer lineages (ANOVA $p<0.001$). 10uM OHC+CRA treatment robustly induced ABCA1 protein expression in ABCA1 wildtype (WT) cell lines (Naxorini, MDST8, COLO201), but not in ABCA1 mutant lines (HCT15, SNU81), significantly induced cell death in ABCA1 WT cell lines (all, $p<0.001$), and decreased free cholesterol accumulation (MDST8, $p=0.010$; Naxorini, $p=0.007$). Importantly, KD of ABCA1 rescued the viability of OHC+CRA treated cells (MDST8, $p<0.001$) demonstrating that OHC+CRA cytotoxicity is dependent on the induction of ABCA1. Furthermore, the KD of ABCA1 in untreated MDST8 cells significantly enhanced cell viability ($p=0.004$) consistent with a growth advantage owing to reduced activity of ABCA1. Analysis of ABCA1-dependent, OHC+CRA induced cell death found alterations in protein levels of Bad, Bcl-2 and HtrA2/Omi (all, $p<0.05$), associating ABCA1 induction with mitochondrial apoptosis.
Conclusions: Dysregulation of cellular cholesterol due to dysfunctional ABCA1, whether by somatic mutation or transcriptional downregulation, may represent an oncogenic addiction conserved in bowel cancers. These findings warrant further investigation into the therapeutic potential of ABCA1 and cholesterol targeting strategies for bowel cancers.

#5566 Comprehensive protein and genomic analysis demonstrate IGF2BP2 promotes cell proliferation via NF-kB signaling pathway in endometrial cancer..

Hiroki Kurahashi, Yuko Watanabe, Kosuke Hiramatsu, Tatsuo Masuda, Mamoru Kakuda, Satoshi Nakagawa, Tadashi Iwamiya, Shinya Matsuzaki, Yutaka Ueda

Obstetrics and Gynecology, Osaka University, Suita, Japan

Introduction: Endometrial cancer (EC) is the most common gynecological cancer. While multidisciplinary therapy including surgery and chemotherapy improves the prognosis, that of refractory cases remains poor. In this study, we aimed to investigate the new treatment target and predictive marker for treatment of refractory EC using comprehensive protein analysis and TCGA genomic data.
Materials and Methods: We performed iTRAQ-based comprehensive protein analysis using EC tissue samples before treatment, and compared protein expression data of refractory and responsive cases. To evaluate the function of Insulin-like growth factor 2 mRNA-binding protein 2 (IGF2BP2) which is highly expressed in refractory EC, we generated IGF2BP2 knockdown (KD) EC cells using siRNA and shRNA and evaluated cell proliferation after IGF2BP2 KD in vitro and in vivo. Moreover, we investigated signaling pathway regulated by IGF2BP2 using protein dataset. Finally, we measured IGF2BP2 cfDNA in the case of EC before and after treatment.
Results: iTRAQ-based comprehensive protein analysis identified 2,299 proteins, and IGF2BP2 had the highest expression in refractory EC. High expression of IGF2BP2 in refractory EC was validated by immunohistochemistry. TCGA data analysis revealed the significant correlation between elevated IGF2BP2 mRNA levels and poor prognosis of EC ($p < 0.01$). Furthermore, we demonstrated that IGF2BP2 KD in EC cell lines significantly suppressed cell proliferation in vitro and tumor growth in vivo ($p < 0.01$, respectively). Moreover, analysis of protein datasets (Cell. 2020) of EC showed that high expression of IGF2BP2 was associated with activation of NF-kB pathway, and IGF2BP2 KD inactivated NF-kB in vitro. Finally, we demonstrated that IGF2BP2 cfDNA was decreased after complete surgery for EC.
Conclusion: IGF2BP2 is highly expressed in refractory EC and contributes to cell proliferation via NF-kB pathway and poor prognosis.

#5567 Targeted immunotherapies in multiple myeloma: focus on flow cytometry markers and therapeutic implications .

Haoting Hsu, Elena Bruni, Claudia Carenza, Karolina Pilipow, Paolo Schiavini, Christine Baer, Gilad Silberberg, BanuPriya Sridharan, Mara Gilardi, Stefano Cairo, Brandon Walling

Champions Oncology, Inc., Hackensack, NJ

Multiple myeloma (MM) is a hematologic malignancy characterized by the clonal proliferation of malignant plasma cells. Despite advancements, MM remains one of the most prevalent hematological malignancies with over 30,000 new cases annually. However, the emergence of immunotherapy through the targeting of specific cell surface proteins has transformed the treatment landscape for MM and highlights the need for the identification and evaluation of unique immunotherapy targets, particularly in relapsed or refractory cases. Drugs to CD38 (Daratumumab & Isatuximab) and SLAMF7 (Elotuzumab) have demonstrated the potency of these therapies, particularly when utilized in combinations. Flow cytometry plays a vital role in diagnosing MM and in evaluating minimal residual disease (MRD), however, it also functions as an excellent method through which to interrogate the expression of unique markers and subpopulations. Here we have utilized Champion Oncology's cryopreserved primary MM patient samples derived from bone marrow aspirates to generate a platform for the interrogation of novel biomarkers utilizing flow cytometry, sequencing, and ex vivo analysis. We have performed cellular deconvolution on these models to sort and interrogate populations based on numerous factors including tumor type, treatment history, and diagnosis. This provides rapid mechanisms to identify populations of interest for unique signatures. These identified targets may then be utilized via flow cytometry to characterize models with an adaptable "drop-in" panel which facilitates the addition of multiple novel targets for rapid screening. These data can be further stratified utilizing the canonical MM markers to evaluate the expression within subpopulations and how these subpopulations evolve throughout treatment. Finally, those models that have been identified can be utilized in ex vivo assays. Using six unique MM models stratified into refractory, naive, and relapsed, we evaluated the ex vivo response to current standard of care (SOC) treatments allowing for drug sensitivity screening and the evaluation of novel target responses. Collectively, these data demonstrate a robust method for rapid identification and evaluation of unique MM targets.

#5568 The estrogen sulfotransferase drives pancreatic ductal adenocarcinoma.

Syamprasad NP, Shijia S. Feng, Donovan Whitfield, Wen Xie

Centre for Pharmacogenetics, University of Pittsburgh School of Pharmacy, Pittsburgh, PA

Background: pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal cancers, with only a 12% five-year survival rate. The complex nature of PDAC limits treatment options, highlighting the need to identify novel therapeutic targets. Males are more likely to develop PDAC than females, so we performed an initial screening of estrogen-metabolizing enzymes associated with PDAC development. Interestingly, Estrogen sulfotransferase (SULT1E1 or EST) was found to be the most over-expressed in pancreatic ductal adenocarcinoma (PDAC) compared to normal tissues, and it is associated with a poor prognosis for patients. A primary function of EST is sulfonating and deactivating estrogens. Hence, we aimed to investigate the role of EST in PDAC development and progression.
Methods: Human PDAC transcriptome and proteome data were accessed from TCGA and CPTAC databases respectively. The expression pattern of EST in human PDAC tissues and genetically engineered PDAC mice model, KC (K-rasLSL.G12D/+; Pdx-1-Cre) and KPC (K-rasLSL.G12D/+; Trp53R172H/+; Pdx-1-Cre) tissues was determined using IHC and immunofluorescence. MIA PaCa-2 ($KRAS^{MT}$ $TP53^{MT}$ $CDKN2A^{HD}$ $SMAD4^{WT}$) and CFPAC-1($KRAS^{MT}$ $TP53^{MT}$ $CDKN2A^{PM}$ $SMAD4^{HD}$) cells were used to investigate the role of EST in both *in vitro* and *in vivo* models.
Results: In the TCGA pan-cancer atlas, we identified that EST is over-expressed only in PDAC compared to other cancer types. Analysis of single-cell RNA sequencing data, Immunohistochemistry, and immunofluorescence studies revealed that EST is overexpressed in PDAC-specific ductal cells in human tissue, as well as in tissues from KC and KPC mice, compared to normal tissues. Overexpression of EST in MIA PaCa-2 and CFPAC-1 cells increased proliferation, migration, wound healing, and sphere formation, along with significantly less stem cell frequency. Moreover, we observed increased Ki-67 positive nuclei, elevated nuclear Cyclin D1 levels, and the upregulation of cyclin D1 target gene signatures in EST overexpressed cells. Additionally, the overexpression of EST was linked to increased tumor growth *in vivo* in both male and female xenograft models, highlighting EST's significant role in the progression of PDAC. Enzyme activity dead mutant EST overexpression revealed that the pro-PDAC effect of EST depends on its enzymatic activity but is independent of estrogen.
Conclusion: We have uncovered a novel function of EST in the development of PDAC, and it may represent a potential target for treating PDAC.

#5569 FBXW7 functional loss enhances IGF2BP1 levels, implicating oncogenic m^{6}A RNA modification dynamics in colon cancer.

Soo-Jin Lee, Sung-Yup Cho

Department of Biomedical Sciences, Seoul National University, College of Medicine, Seoul, Korea, Republic of

FBXW7 is an E3 ubiquitin ligase and known as a tumor suppressor gene. Considering the high mutation frequency of FBXW7 observed in colon cancer mutation profiling, it is important to identify the interactive partners of FBXW7 for developing effective colon cancer treatments. Many reports have demonstrated diverse changes in cancer development and progression under FBXW7 mutant conditions at transcriptomic and proteomics levels. However, it is unclear how post-transcriptional modifications, especially RNA modifications, are affected under FBXW7 mutant conditions. To find the candidate targets of FBXW7 in protein level, we performed LC-MS analysis under conditions of FBXW7 functional loss. We analyzed gene ontology biological pathway (GOBP) enrichment analysis with up-regulated genes and found gene terms associated with RNA metabolism (such as mRNA metabolic process, positive regulation of 3'-UTR-mediated mRNA stabilization and mRNA transport). As the RNA metabolism is influenced by various types of RNA modifications, we focused on N^6-methyladenosine (m^{6}A) RNA methylation, a prevalent and significant post-transcriptional modification that plays a crucial role in regulating various RNA functions in eukaryotic messenger RNAs. To validate the LC-MS analysis, we profiled m^{6}A regulators (writer, eraser and reader groups) in protein and mRNA level in FBXW7 knock-out and transient knock-down cells. The protein level of IGF2BP1, which belongs to m^{6}A reader proteins, was up-regulated in both FBXW7 knock-out and knock-down conditions, but not in mRNA level. Additionally, the expression of IGF2BP1 increased compared to normal tissue, and expression of IGF2BP1 was associated with decreased survival rates, suggesting that IGF2BP1 plays an oncogenic role, as indicated by the TCGA colon cancer database. Our study suggests that IGF2BP1 is a crucial target in FBXW7 mutant colon cancer.

#5570 Characterizing a CRISPR/Cas9-mediated deletion in the extracellular domain of HER4 in a model of cutaneous melanoma.

Marta Valenti[1], Shubhangi Kandwal[2], Yonglun Luo[3], Georg F. Bischof[4], Darren Fayne[5], John Crown[6], **Denis M. Collins**[1]

[1]Cancer Biotherapeutics Research Group, School of Biotechnology, Dublin City University, Dublin, Ireland,[2]Molecular Design Group, School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland,[3]Department of Biomedicine, Aarhus University, Aarhus, Denmark,[4]Puma Biotechnology, Inc., Los Angeles, CA,[5]Molecular Design Group, School of Chemical Sciences, Dublin City University, Dublin, Ireland,[6]Dept of Medical Oncology, St. Vincent's University Hospital, Dublin, Ireland

Introduction: HER4, a tyrosine kinase receptor belonging to the Human Epidermal Growth Factor/HER/ErbB-family, has a complex biology (four isoforms (JMa-CYT1/2 and JMb-CYT1/2) and tissue specific oncogenic or tumor suppressor roles). Cutaneous melanoma (CM) showed the highest HER4 genomic alteration frequency (17.34%) across 33 cancer types (cBioPortal). To investigate the potential role of HER4 in CM, the SKMEL24 CM cell line was CRISPR/Cas9-edited to contain HER4 with a 30bp deletion (DEL) in the extracellular domain. The HER4 30bp DEL was modelled *in silico* and the SKMEL24 HER4 30bp DEL cell line assessed for HER-family protein expression levels, HER4 isoform RNA levels, and HER4 receptor activation upon neuregulin-1 (NRG-1) stimulation. Moreover, cellular morphology, cellular proliferation and response to the Tyrosine Kinase Inhibitor (TKI) neratinib was assessed.

Material and Methods: All studies compared the wild-type (WT) and the CRISPR/Cas9-edited HER4 30bp DEL SKMEL24 cell line. For *in silico* HER4 3D crystal structure modelling, input files for GROMACS 2020.7 molecular dynamics simulations were generated using CHARMM-GUI. The CHARMM36m force field was used for parameterization of protein chains. The GROMACS in-built tools were used to calculate heavy atom Root Mean Square Deviation (RMSD). HER-family protein levels (EGFR, HER2, HER3, HER4) and their phosphorylated forms (pEGFR Y1173, pHER2 Y1221, pHER3 Y1197, pHER4 Y984/Y1284) were investigated via Western blot. RNA was extracted from cells 24h after seeding using TRIzol, with qRT-PCR used to examine HER4 isoform expression. NRG-1 stimulation was performed in complete growth medium with HER4 receptor activation determined by Western blot. Cellular morphology and proliferation were monitored using the IncuCyte Live Cell Analysis Instrument (Sartorius). Acid phosphatase proliferation assays were used to assess the anti-proliferative effects of neratinib.

Results: *In silico* modelling of the HER4 30bp DEL showed reduced HER4 receptor stability compared to WT (RMSD = 6.465 Å and 6.631 Å, respectively). No changes in expression or activation of EGFR, HER2, or HER3 were detected in the SKMEL24 HER4 30bp DEL cell line. Full-length (180kDa) HER4 expression was decreased and cleaved HER4 expression (80kDa) and activation (pHER4 Y984) were increased in the HER4 30bp DEL cell line. NRG-1 treatment did not activate HER4 but activated EGFR, HER2 and HER3 in the HER4 30bp DEL cell line. The HER4 30bp DEL cell line also displayed a more stellate phenotype, reduced proliferation over 3 days in culture, and an increased sensitivity to neratinib (IC_{50} = 0.17 ± 0.04 µM) compared to the WT (IC_{50} = 0.26 ± 0.04 µM).

Conclusion: These findings suggest HER4 may play a role in cellular morphology, proliferation and response to treatment. Further studies are needed to clarify the specific role of HER4 in CM.

#5571 Identifying and targeting novel kinase regulators for cancer metastasis.

Wenliang Li

University of Texas Health Science Center At Houston, Houston, TX

Background: Metastasis is responsible for >90% of cancer death. However, metastasis is still poorly understood and the current approaches to prevent or treat human metastatic cancers are largely unsuccessful.
Methods and Results: Through RNAi and cDNA functional screening, genomics analysis, and functional validations, we have identified several critical but previously unknown/understudied kinase regulators for metastasis. As an example, shRNA screening revealed that GPCR-kinase 3 (GRK3) is essential preferentially for highly metastatic cancer cells as compared to lowly metastatic cancer cells. GRK3 is significantly overexpressed in metastatic prostate tumors from patients, especially in the aggressive variant of prostate cancers, so called treatment-related neuroendocrine prostate cancer (NEPC). We further found that GRK3 is a key missing link between two prominent phenotypes of NEPC, i.e. angiogenesis and neuroendocrine feature. Mechanistically, GRK3 phosphorylates histone deacetylase 2 (HDAC2) at S394 and enhances HDAC2's epigenetic activity. Through compound library screening, we have identified several compounds that block the kinase activity of GRK3 much more potently than that of GRK2, the closest-related kinase to GRK3. Of note, our GRK3 inhibitors could significantly inhibit NEPC cell growth in culture and in mouse xenografts. Another group of potential metastasis regulators we identified are new EMT-regulating kinases from our kinome cDNA screening for epithelial-mesenchymal transition (EMT). For example, mixed lineage kinase ZAK positively regulates EMT phenotypes and migration of cancer cells in culture, as well as metastasis in mice. ZAK overexpression correlates with poor prognosis in cancer patients. We are carrying out in silicon docking analysis and chemical genomics to identify potent and specific inhibitors for ZAK as research tools and drug candidates for metastatic cancers.
Conclusions: Our robust and unbiased functional screening has identified several novel kinase regulators and potential drug targets for cancer metastasis. For example, GRK3 has emerged as a critical kinase for metastatic prostate cancer cells and a key regulator of aggressive neuroendocrine prostate cancer phenotypes, while ZAK has been identified as a potent new regulator of epithelial-to-mesenchymal transition (EMT).

#5572 The transcription factor hepatic leukemia factor (HLF): a potential therapeutic target in triple negative breast cancer.

Ibrahim Bouakka, Marine Sirerol, Aymeric Silvin, Alicia Tran-Dien, Anna Rocca, Fabrice Andre

INSERM U981 (Gustave Roussy), Paris, France

Pivotal role of immune response in the evolution of triple negative breast cancer has been largely reported in the last decade. Our previous study highlighted the role of HLF gene as part of a four gene signature and was found to be negatively correlated with tumoral immune cells infiltration. We investigated more precisely its implication in the immune response and TNBC tumor development. Bioinformatics analysis of publicly available TNBC patient datasets revealed that in mesenchymal tumor subtypes expressing low levels of HLF upregulation of genes associated with neutrophil attraction and activation pathways was observed in comparison with those expressing high HLF levels. The implication of neutrophils in cancer is contentious as they can function either as active anti tumoral partners or as pro tumoral agents promoting immunosuppression and tumor growth. This ambiguity stems from their high plasticity which enables them to switch roles during tumor progression influenced by signals from tumoral microenvironment in particular those from surrounding tumor cells. In this study we employed CRISPR Cas9 technology to inactivate the HLF gene in TNBC cell lines enabling us to elucidate the downstream effects on the chemokine and protease inhibitor landscape that governs neutrophil infiltration and function within the microenvironment of TNBCs especially in mesenchymal subtypes. In vivo experiments using immunodeficient mouse models revealed that HLF downregulation in TNBC mesenchymal subtypes correlates with increased neutrophil infiltration into the tumor leading to inhibit tumor growth. Altogether our results suggest that a reduction of HLF expression can lead in the early steps of tumor development to the awakening of the anti tumoral function of neutrophils to enforce the necessary immunological tone to tumor elimination. Thus HLF emerges as a potential therapeutic target in order to favor infiltration and function of anti tumoral neutrophils to restore an efficient immune response in the aggressive mesenchymal TNBC subtype.

#5573 Validation of Aspyre Clinical Test for Lung at low input levels: Simplified genomic profiling for NSCLC with minimal tissue requirements.

Christina Xyrafaki[1], Katherine Knudsen[1], Magdalena Stolarek-Januszkiewicz[2], Rebecca Palmer[2], Sam Abujudeh[2], Ryan Evans[1], Eleanor Gray[2], Amanda Green[1], Robert Osborne[2], Barnaby Balmforth[2], Wendy Levin[1], Shari Brown[1]

[1]Biofidelity Inc, Morrisville, NC,[2]Biofidelity Ltd, Cambridge, United Kingdom

Although many assays exist for detecting actionable variants in NSCLC, few of them are suitable for use in low quantity or quality specimens, which significantly contribute to biomarker testing failures. Aspyre Clinical Test for Lung (Tissue) is a robust simplified genomic profiling panel that tests for 114 biomarkers in NSCLC across 11 genes (*ALK*, *BRAF*, *EGFR*, *ERBB2*, *KRAS*, *MET*, *RET*, *ROS1*, *NTRK1/2/3*) and was able to rescue 96% of samples that failed NGS-based testing. Aspyre Clinical Test for Lung (Tissue) was initially validated for 20ng DNA and 6ng RNA input from FFPE lung tissue samples, though it was predicted to have robust performance at even lower inputs. In this study we tested the impact of using low input levels down to 5 ng DNA and 1.5 ng RNA on the sensitivity (LoD95), specificity, analytical accuracy and analytical precision of Aspyre Clinical Test for Lung (Tissue). The study included FFPE lung tissue samples from patients with NSCLC (> 10% tumor content), variant-negative FFPE tissue from tonsil tissue, and contrived samples with controlled variant allele fractions of mutant oligonucleotides in an FFPE-based background.The LoD95 for eleven different single nucleotide variants or insertions/deletions from the Aspyre Clinical Test for Lung panel were established at ≤ 3% VAF, and one SNV at 7.5% VAF. The sensitivity for seven gene fusions, which are detected by Aspyre through RNA, was ≤ 100 copies, and for *MET* exon 14 skipping at ≤ 200 copies. The specificity was 100% with no false positive results for any healthy tonsil tissue samples (30 samples in 60 replicates). The analytical accuracy study found no discordant variant calls between Aspyre and 1) 19 contrived samples at 2x LoD95 or 2) 29 NSCLC patient samples compared to both an orthogonal target-enrichment NGS and Aspyre at higher inputs. Results were replicable and precise across operators, reagent lots, runs, and real-time PCR instruments.This low-input study demonstrates the opportunity to deploy Aspyre Clinical Test for Lung (Tissue) for slide samples with few cells, as well as small biopsy specimens, ensuring reliable genomic profiling even in limited or challenging samples. Combined with a high success rate and a proven 2-day turnaround time, this expands access to precision medicine for NSCLC patients.

#5574 Exploring the therapeutic potential of USP14 in cervical cancer: mechanisms of oncogenesis and metabolic regulation.

Ravi Chauhan[1], Lakshay Malhotra[2], Ashna Gupta[1], Gunjan Dagar[1], Harshul Kapoor[1], Sandeep R. Mathur[3], Ethayathulla Abdul Samath[4], Mayank Singh[1]

[1]Department of Medical Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[2]Department of Biochemistry, Sri Venkateswara College, University of Delhi, New Delhi, India,[3]Department of Pathology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[4]Department of Biophysics, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Cervical cancer is the most common cancer among women worldwide, predominantly caused by human papillomavirus (HPV) subtypes, particularly HPV 16 and 18. Although it is largely preventable through vaccination and early detection, cervical cancer remains a significant health issue, particularly in low- and middle-income countries, mainly due to acquired chemoresistance. This study explores the therapeutic potential of deubiquitinating enzymes (DUBs), with a focus on ubiquitin-specific proteases (USPs), in combating oncogenesis in cervical cancer. Using the TCGA database, we assessed the prognostic relevance of USP14, revealing that elevated levels of this enzyme correlate with poorer overall and disease-free survival among cervical cancer patients. In-silico analysis of publicly available gene expression datasets also indicates a significant upregulation of USP14 in cervical cancer tumor tissues compared to their paired normal tissues. USP14 expression was analyzed at both the RNA and protein levels across various cervical cancer cell lines, followed by assays for proliferation, metastasis, and invasion to assess the impact of USP14 depletion. Elevated USP14 expression was observed in the cervical cancer cell lines, and inhibiting USP14 resulted in significant reductions in cell proliferation, metastasis, and invasion. A novel USP14 inhibitor, IU-1, produced similar results. Proteomic analysis indicated that the lactate transporter MCT-4, a crucial metabolic regulator, was dysregulated following USP14 alteration. Immunoprecipitation studies confirmed stable interactions between USP14 and MCT-4. Cycloheximide and Deubiquitination assays further demonstrated that USP14 modulates MCT-4 stability via deubiquitination at specific sites. Additionally, docking studies and molecular dynamics simulations illustrated the interaction between USP14 and MCT-4. Furthermore, the lactate shuttle was evaluated following USP14 inhibition, demonstrating the effect of MCT-4 inhibition on lactate production in cervical cancer cells. Immunohistochemical analysis of retrospective tissue samples assessed the expression of USP14 and MCT-4 and their correlation with patient prognosis. Collectively, our findings highlight the vital role of USP14 in the oncogenic and metabolic processes of cervical cancer, suggesting their potential as therapeutic targets. This research enhances the understanding of the molecular mechanisms driving cervical cancer progression and underscores the need for targeted therapeutic strategies.

#5575 Identification of Novel *RBBP6* transcripts: modulation by *Drimia calcarata* plant extracts.

Zukile Mbita, Kagiso Laka

University of Limpopo, Polokwane, South Africa

Cancer, an assortment of maladies that are epitomized by deregulated cell proliferation, remains a thorn throughout the world. The soaring cancer cases can be attributed to deregulation of cancer-related genes and lack of effective therapeutics. Thus, this work was aimed at understanding the anticancer mechanisms associated with *Drimia calcarata* (*D. calcarata*) plant extracts, targeting cancer-related genes; particularly, *Retinoblastoma binding protein 6* (*RBBP6*) gene. *D. calcarata* phytochemicals were extracted using both water and methanol, and characterized using Liquid Chromatography Mass Spectrometry (LC-MS). The resultant extracts were used to treat various lung cancer cell lines; namely, H1437, H1573 and A549 cells. The inhibitory effects and half maximal inhibitory concentration (IC_{50}) values of *D. calcarata* extracts were established using the (3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide (MTT) and Muse® Count and Viability assays. Using the IC_{50} values, induction of cellular apoptosis was evaluated using both fluorescence microscopy, and the Muse® Cell Analyzer, while gene expression analysis was done using Polymerase Chain Reaction (PCR). The *D. calcarata* extracts, water and methanol, were found to contain a number of compounds with anticancer activities, which include Psoralene ($C_{11}H_6O_3$), Limonin-17-beta-D-glucoside ($C_{32}H_{42}O_{14}$), Oleuropein ($C_{25}H_{31}O_{13}$), Isorhamnetin derivative ($C_{16}H_{12}O_7$), and various uncharacterized compounds. The anticancer cancer activities were demonstrated to involve apoptosis induction, which was measured by both fluorescence microscopy and flow cytometry. Additionally, and most importantly, PCR showed that the *D. calcarata* extracts modulated the expression of novel *RBBP6* splice variants. Intriguingly, the *D. calcarata* plant extracts differentially regulated the expression of novel *RBBP6* transcripts in different lung cancer cells. *D. calcarata* extracts down-regulated *RBBP6* transcripts 1 and 2; however, subjecting the A549 cells to stress, *D. calcarata* extracts and curcumin, resulted in the expression of a novel transcript that has not been identified previous. In H1437 and H1573 cells, this novel transcript is down-regulated by the *D. calcarata* plant extracts. In H1437, the *RBBP6* transcripts 1 and 2 were up-regulated by the *D. calcarata* plant extracts. This suggests that *RBBP6* gene can be targeted for development of novel biomarkers, and *D. calcarata* extracts should be further explored for novel therapeutic targets.

#5576 Identification of inter-organ targets to mitigate cachexia while enhancing tumor suppression by anti-PD-L1.

Se-Young Park[1], Jiwoo Kim[1], Kyuwon Son[2], Haeseung Lee[2], Na-Young Song[1]

[1]Yonsei University College of Dentistry, Seoul, Korea, Republic of,[2]Pusan National University, Busan, Korea, Republic of

Immune checkpoint inhibitors (ICIs), such as anti-PD-L1, have revolutionized cancer therapy but are frequently associated with immune-related adverse events (irAEs). Here, we show a significant correlation between ICI treatment and weight loss in cancer patients. Similarly, anti-PD-L1 therapy exacerbates muscle wasting in a cancer cachexia (CAC) mouse model, despite its anti-tumor effects, suggesting that muscle atrophy may represent a potential irAE. Single-cell RNA sequencing reveals that cytotoxic T-like cells accumulate in the skeletal muscle of CAC mice, directly contributing to muscle wasting. While their depletion prevents cachexia, it compromises the anti-tumor efficacy of anti-PD-L1. To address this discrepancy, we identify cathepsin L (CTSL) as an inter-organ target capable of inhibiting both cancer and cachexia, particularly muscle wasting driven by cytotoxic T cells, through unbiased integrative transcriptome analysis. Notably, CTSL inhibition not only reduces muscle wasting but also enhances the anti-tumor efficacy of anti-PD-L1. These findings highlight CTSL as a promising therapeutic target for cancer cachexia, offering a novel strategy to prevent muscle-specific irAEs while enhancing the benefits of ICIs.

#5578 Role of differentiation driver gene HOXD4 in anaplastic thyroid cancer.

Kaci Kopec[1], Nicole R. DeSouza[1], David Garber[2], Steven A. Hemmerdinger[2], Augustine Moscatello[1], Humayun K. Islam[1], Jan Geliebter[1], Raj K. Tiwari[1]

[1]New York Medical College, Valhalla, NY,[2]Westchester Medical Center, Valhalla, NY

Anaplastic thyroid cancer (ATC) is a rare and extremely aggressive subset of thyroid cancer, noted for its refractory nature and poor prognosis. Conventional cancer treatments are ineffective in treating ATC while targeted therapies are of limited use due to a lack of targetable genetic lesions in this cancer type thus rendering a five-year survival rate of 4%. The low mutational burden of ATC prompted analysis of differential gene expression patterns using NCBI Gene Expression Omnibus publicly available transcriptomic datasets (GSE33630, GSE85457). Bioinformatic analysis of ATC compared to normal thyroid cancer tissue was carried out using GEO2R software. Strikingly, differentiation driver gene Homeobox D4 (HOXD4) was significantly upregulated in ATC patient tissue samples by 3-fold and 12-fold respectively. Kaplan-Meier analysis indicates a significant decrease in survival in patients with high HOXD4 levels (HR: 3.08, logrank: 0.019). Unlike most cancers, ATC lacks differentiation therefore losing its thyroid-like morphology and function. Thus, the marked upregulation of differentiation gene HOXD4 warranted further exploration in vitro. HOXD4 expression was upregulated in ATC cell line T238 by 23-fold compared to immortalized “normal” thyroid epithelial cell line Nthy-ori-3-1. CRISPRi knockdown of HOXD4 in T238 and SW1736, another ATC cell line, was needed for functional analysis rendering HOXD4 knockdown cell lines T238-HOX and SW1736-HOX as well as non-specific oligonucleotides control cell line. Cell proliferation was reduced in T238-HOX by 36%, 29%, 28%, and 38% and SW1736-HOX by 51%, 56%, 59%, and 52% at 24, 48, 72, and 96 hours respectively. Migratory capacity measured via scratch wound assay was significantly reduced in T238-HOX by 31% and 13% and SW1736-HOX at 45% and 22% at 16 and 22 hours respectively. Migration through Boyden chambers decreased by 72% in T238-HOX and 62% in SW1736-HOX and invasion was reduced by 40% and 51% respectively. We are currently evaluating the impact of HOXD4 knockdown on viability, clonogenicity, and senescence. The data reveal the novelty of HOXD4 as a putative carcinogenic driver of ATC and its function as both a diagnostic and prognostic biomarker, with the potential to be used as a therapeutic target. We are currently investigating various differentiating agents and their efficacy in a possible clinical application with or without other therapeutic agents.

#5579 Identification of MTA1 as a new molecular marker in urothelial carcinoma.

G. Campanelli, N. Waxner, N. Parkhomovsky, R. Vanderstichel, C. Yang, A. S. Levenson;
Long Island University, Brookville, NY

Metastasis-associated protein 1 (MTA1), a master transcriptional co-regulator and chromatin modifier, is strongly associated with many types of clinically aggressive cancers. Loss of MTA1 reduces aggressiveness and metastatic potential in cancer cells. A publicly available human dataset predicts that MTA1 might work as a prognostic marker, however, the exact role of MTA1 in the pathobiology of bladder cancer is unknown. We sought to evaluate the expression of MTA1 and associated epithelial-to-mesenchymal (EMT) events using canine urothelial carcinoma (UC) clinical samples as well as cell lines. We found that MTA1 and cyclooxygenase 2 (COX2) are overexpressed in canine UC samples compared to normal bladder samples, whereas E-cadherin (E-cad) levels are higher in normal bladder. The results of samples demonstrated that MTA1 expression correlated with aggressive clinicopathological features such as high tumor-grade, muscular/vascular invasion, and metastasis. The MTA1 expression differed in tumors depending on their localization, with the highest being in the urethra adjoining the prostate. Unexpectedly, higher E-cad levels were detected in metastatic tumor cells compared to primary tumor cells. Further, we analyzed MTA1 and EMT-associated markers in four invasive canine UC cell lines. Using two cell lines, AxA and SH, and their corresponding MTA1 knockdown (shMTA1) clones, we validated the direct link between MTA1 and these markers on mRNA and protein levels. Overall, these findings suggest that MTA1 may represent a key upstream effector tightly associated with COX2 and EMT-mediated events in canine UC. Accordingly, MTA1 may be considered a feasible interceptive and therapeutic target for canine UC treatment.

#5580 Determining the effects of serine-arginine protein kinases inhibition on splicing factors and long non-coding ribonucleic acids regulation in cervical cancer cells.

Lydia Mphahlele, Zodwa Dlamini, **Rahaba Makgotso Marima**

University of Pretoria, Pretoria, South Africa

Cervical cancer (CCa) remains a significant global health challenge, with high morbidity and mortality rates, particularly in developing countries. The pathogenesis of CCa is largely driven by persistent infection with high-risk strains of *Human Papillomavirus* (HPV). Serine-arginine protein kinases are a family of cell cycle-regulated kinases that phosphorylate the serine/arginine (SR) domain-containing proteins in the nuclear patches to intervene with pre-mRNA splicing, signals splicing controls in response to extracellular stimuli and contributes to tumorigenesis. It has been reported in recent studies that the dysregulation of splicing factors and lncRNAs affects the progression of CCa. The involvement of SRPKs with lncRNAs regulation remains unelucidated in CCa. This study aimed to investigate the association of lncRNAs and SRPKs inhibition by SRPIN340 in CCa cells SiHa and C33A. Alamar blue cell viability assay, 84 lncRNA gene panel, bioinformatics analysis and RT-qPCR were used to achieve the aim of the study. SRPIN340 showed no cytotoxicity to CCa. Differential lncRNA gene expression, favoring CCa progressing was observed and these results were verified by increased expressions of MALAT1 and TUG1. The association between splicing factors and lncRNAs is complex, as influence of these 2 parities may be bi-directional. Understating this relationship may unlock diagnostic, prognostic and therapeutic targets in CCa.

#5581 Melatonin and 17β-estradiol treatment modulating TIMP's family gene expression profile in IDCC.

Kelly P. Ferreira, Bruna C. Almeida, **Katia C. Carvalho**

University of Sao Paulo, Faculty of Medicine, Sao Paulo, Brazil

Introduction: *Tissue Inhibitor of Metalloproteinases (TIMPs)* are genes that encodes four (TIMP1-4) proteins that act as endogenous protease inhibitors. They regulate directly the matrix metalloproteinases (MMPs) known to be associated with growth and invasiveness of sundry cancer types, including breast cancer cells. Several evidences have shown that melatonin can present both anti-proliferative and invasiveness role in cancer, while estrogen seems to have the opposite function. Thus, our goal was to evaluate the expression of TIMPs' family compounds in invasive ductal carcinoma cells (IDCC) of breast cancer after treatment with 17β-estradiol (malignancy inducer), melatonin (malignancy inhibitor), isolated and associated with each other.
Methods: IDCC [T47D (ER+/PR+), MCF7 (ER+), and MDA-MB231 (triple-negative)] were cultured as recommended by ATCC. All three cell lines were plated ($5X10^5$ in 6 wells plate) and treated with 17β-estradiol (E2 - 100 nM), Metatonin (Mel - 3000 μM) or both (Mel + E2). After treatment the RNA was extracted using *mirVana miRNA Isolation Kit* (Ambion, CA, USA) and then, purity and concentration of total RNA were accessed. The Reverse transcription synthesis was performed using High-Capacity cDNA Reverse Transcription Kit and RT-PCR was accessed for *TIMP 1 - 4* using TaqMan assay system. The *beta2-microglobulin (B2M)* was established as a housekeeping gene and the relative quantification was determined by 2-DDCT method.
Results: All members of the TIMPs' family were expressed in IDCC tested with significant differences in their expression when compared to control cells. Mel treatment led to *TIMP1, -3* and *-4* mRNA upregulation, while E2 upregulated *TIMP1* but downregulated *TIMP2* in T47D cells. Otherwise, *TIMP1* and *-3* were downregulated and *-2* and *-4* were upregulated in MCF7 cells treated with Mel, while an increase of *TIMP1, -2* and *-4* were observed for E2. In comparison with control group, E2 treatment of MDA-MB231 cells led to upregulation of *TIMPs -1, -3* and *-4*, and Mel upregulated all, except *TIMP4* that was downregulated.
Conclusion: Melatonin and 17β-estradiol treatments seems to modulate negative or positively the gene expression profile of all the assessed members of TIMPs' family in IDCC cells.

#5582 Interrogating the K-ras/p53 transcriptional readout for synthetic lethality applications.

Samuel L. Schach, Farah Mazahreh, A. Mazin Safar

University of Arkansas for Medical Sciences, Little Rock, AR

Some Oncogenes (Onc) are physiologically indispensable or have proven difficult to inhibit (Myc and Ras, respectively). Onc addiction, reflecting the need for specific stress adaptations (SA) to accommodate constant onc signaling, provide a novel approach to disrupt the SA producing synthetic lethality (SL). Broad's dep map CRISPR screens (CS) suggest SA is NOT monogenic. Combinatorial consideration is unavoidable and can only be fruitful if aided by biologic insights. Genetically engineered mouse models confirmed that p53 is sufficient to facilitate full oncogenic abilities of Ras. p53 transcriptional (Tr) network is a mere 110 genes and includes many repressed targets (T) but some that retain Tr activity despite the p53 DNA binding domain mutations (mu). Retained genes (g) are being considered here as putative therapeutic Ts. Identifying indispensable g in Ras onc SA is needed for CRISPR multiplexed screen. We focused on pancreatic adenocarcinoma (PA) due to high prevalence of Ras/p53 and the poor available treatment options. We hypothesize that specific set of p53 retained Tr Ts provide the SA and this may be phenocopied in few wild type (WT) p53 PA. This would guide CS for therapeutic applications. Methods: We probed TCGA and the Broad public databases for expression of the canonical p53 Tr T in Ras & p53 double mutant PA. We reasoned that MDM2 represents the most rational internal control for reduced Tr in basal, unstimulated conditions; all g with higher Tr are scored as retained; the remaining as lost Tr. WT PA were analyzed to identify phenocopy providing additional strength to the hit. The table summarizes the findings at the different levels of scrutiny. Conclusion: Our work represents a rational biologic approach to select a rational set of SL g in the Ras/p53 interdependence circuitry. Such Ts need to be examined by CS to validate their cellular importance. Pathway analysis and considering the possible double negative inhibition of repressed Ts are additional approaches to this analysis.

#5583 Small molecule mediated restoration of PAX3 inhibits malignant features in neuroblastoma cells.

Abinayaselvi Murugan[1], Sowndharyalatha Balasubramanian[1], Narenkumar Muralidharan[1], Ann Mary Alappat Sanjive[1], Prabhuraj Andiperumal Raj[2], **Mathivanan Jothi**[1]

[1]Human Genetics, National Institute of Mental Health and Neurosciences (NIMHANS), Bengaluru, India,[2]Neurosurgery, National Institute of Mental Health and Neurosciences (NIMHANS), Bengaluru, India

Neuroblastoma is the most common extracranial childhood tumor diagnosed in the first year of life. A complete molecular understanding of neuroblastoma is necessary to identify novel therapeutic targets for their management, particularly for high-risk groups. Many transcription factors play an essential role during development, and their expression is restricted to specific cells/tissues after development is completed. *PAX3* belongs to the paired box family of transcription factors involved in various cellular processes like cellular proliferation, migration, lineage specificity, and differentiation. Reexpression of *PAX3* is reported in various childhood tumors, including neuroblastoma; however, its role in tumor development is contradicting. Here, we investigated the contribution of *PAX3* in neuroblastoma in a panel of neuroblastoma cell lines and identified a PAX3-targeted small molecule activator that can alter tumorigenic phenotypes. Specifically, we have analyzed the *PAX3* mRNA, protein, subcellular localization, and its isoform expression in various neuroblastoma cell lines and correlated the results with their tumorigenic potential. Our results showed that most of the PAX3 expressed in these cells are PAX3a/b isoforms that lack PAX3's transactivation domain. Further, we have observed the depletion of *PAX3a/b* isoforms could not alter the malignant properties of neuroblastoma cells. Interestingly, the ectopic *PAX3* expression in the absence of *PAX3a/b* isoform in these cells inhibited malignant phenotypes including growth, colony formation and migration potentials. Furthermore, we have identified potential small molecule *PAX3* activators from our previous small molecule screening. *PAX3* activators effectively inhibited in vitro malignant properties of neuroblastoma cell lines. Our results revealed that tumor inhibitory properties of transcriptionally active *PAX3* and its reactivation using small molecules have great potential in inhibiting neuroblastoma development.

#5584 The critical role of CLIC1 in mediating metformin's antitumoral effects on glioblastoma.

Guido Rey[1], Francesca Cianci[1], Ivan Verduci[1], Sara Torabi[1], Alessandro Fantin[1], Federica Barbieri[2], Tullio Florio[2], Michele Mazzanti[1]

[1]University of Milan, Milano, Italy,[2]University of Genova, Genova, Italy

Glioblastoma (GBM) is the most common and lethal brain tumor and there is a general agreement that GBM stem cells (GSCs) are primarily responsible for its high invasiveness and recurrence. It has been demonstrated that several membrane proteins are upregulated in GSCs and support tumor relapse. However, most of these membrane resident proteins are also involved in essential physiological processes, limiting their use as selective anticancer targets. The ideal target will be a membrane protein only present on the tumor surface. CLIC1 is a metamorphic protein that can transition between cytoplasmic and transmembrane forms (tmCLIC1), with the latter associated with chloride conductance. tmCLIC1 is enriched in the plasma membrane of GSCs, while it is largely absent in healthy cells. Previous experiments demonstrated that impairment of tmCLIC1 downregulated tumor growth and invasion. Thus, this protein could represent a promising antitumoral target. It has been demonstrated that tmCLIC1 is sensitive to metformin, a widely used antidiabetic drug. Previous data showed contradictory results about the use of metformin against solid tumor growth. We have recently demonstrated that in human primary GSCs, tmCLIC1 is the principal target of metformin. There are two main problems to adopt metformin as a chemotherapic molecules on glioblastoma patients: the high drug concentration needed to be effective and the time at which tumor cells are exposed to the drug. The final aim of the present study is to improve metformin-CLIC1 interaction, trying to lower metformin effective concentration. The first step is to uncover the molecular mechanism of metformin binding to tmCLIC1. Our results show how mutating a specific single arginine of tmCLIC1 (R29) leads to the loss of metformin's antitumoral properties. Nonetheless, since arginine and metformin carry the same charge, we tried to investigate more deeply this interaction through a molecular docking simulation. We found that this residue coordinates different negatively charged amino acids, that might create the correct environment in which metformin could bind the protein. The electrophysiological test confirmed that mutating only one of these negatively charged residues partially impairs the effect of metformin on the tmCLIC1 current. Finally, we demonstrated that CLIC1 is essential in metformin antitumoral mechanism against GBM also in zebrafish embryos and in murine model. The project's long-term goal is to develop a personalized medicine against GBM based on the use of metformin.

#5585 DNA methylation and transcription factors regulate overexpression of PVT1 in prostate cancer.

Chinedum C. Udekwu, Colin Finnegan, Murtaza Barkarar, Oluwabusola Ajagbe, Rachel E. Bonacci, Olorunseun O. Ogunwobi

Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI

Population-level genomic analysis of the PVT1 gene, in the 1000 Genomes Project, revealed genetic differentiation between African and non-African populations at PVT1 exons 4A and 4B. Also, PVT1 exons 4A and 4B showed increased expression in prostate cancer (PCa) tissues relative to normal prostate tissues and benign prostatic hyperplasia tissues in men of African ancestry (moAA). We demonstrated that overexpression of PVT1 exons 4A, 4B and 9 caused increased migration and proliferation of prostate epithelial cells. Further, overexpression of PVT1 exon 9 transformed non-tumorigenic prostate epithelial cells into tumorigenic cells that form tumors with neuroendocrine phenotype when implanted in mice. Gene expression is modulated by DNA methylation (DMT), so we investigated the role of DMT as a mechanism of regulating PVT1 expression. Using qPCR analysis, we tested this hypothesis by treating five prostate epithelial cell lines (RWPE-1, WPE1-NA22, DU145, PC-3 and MDA-PCa-2b) with 5-azacytidine (a global DMT inhibitor) and found significantly (p-value <0.05) increased expression of PVT1 exons 1A, 4A, 4B and 9 in the PCa cell lines when compared to RWPE-1 and no treatment. We further identified 13 distinct promoter regions on the PVT1 gene annotated on Ensembl database and compared the strength of the PVT1 exon 9 - associated promoter with the canonical promoter using a luciferase reporter assay. We found that the canonical promoter was stronger in driving the expression of luciferase when compared to the PVT1 exon 9 - associated promoter and the ubiquitin C promoter, a well-established weak promoter. Further, EM-seq of human prostate tissues from men of African ancestry confirmed differential methylation peaks in tumor versus adjacent normal tissues within the PVT1 canonical and PVT1 exon 9 - associated promoter. Additionally, we investigated the role of MYC-PVT1 co-amplification regulation and PVT1 associated extra chromosomal DNAs (ecDNAs) using fluorescence in-situ hybridization. We found that MYC had no regulatory function on the expression of PVT1 exon 9 and there were no PVT1 associated ecDNAs in all the prostate epithelial cell lines used in this study. Lastly, we used bioinformatics to probe the PVT1 canonical and exon 9 - associated promoters for transcription factors. We found NKX2.5 and CDX1 to have the highest binding scores and significantly overexpressed in aggressive PCa. We will further characterize their function in the transcriptional regulation of PVT1. In conclusion, DMT regulates PVT1 exon 9 overexpression; the canonical PVT1 promoter is stronger than the PVT1 exon 9 - associated promoter, PCa in moAA is characterized by hypomethylation at PVT1, and NKX2.5 and CDX1 are putative transcriptional regulators of PVT1 expression in PCa. Understanding of these epigenetic regulatory mechanisms of PVT1 overexpression in PCa in moAA may lead to uncovering novel therapeutic targets in aggressive PCa.

#5586 *In vitro* investigation of the proliferative and metastatic role of CD13 in cancer.

April J. Baral, Gabriel C. Nwokolo, Sarah Mcgowan, Steven D. Shnyder, Robert A. Falconer

Institute of Cancer Therapeutics, University of Bradford, Bradford, United Kingdom

CD13 (Aminopeptidase N,APN) is a glycosylated ectopeptidase with diverse physiological functions including proliferation, differentiation, migration and angiogenesis[1]. CD13 is a marker for neoangiogenesis that is detected in tumor neovasculature, but not in the normal vasculature, contributing with tumor growth, invasion, and metastasis. *In vitro* studies have revealed association between CD13 various cancer types including human glioblastoma[2] and prostate[3] cancers. Thus, CD13 is an appealing target for the delivery of drugs in CD13-expressing tumors which can reduce tumor growth and progression. An example is the aminopeptidase inhibitor, Ubenimex (Bestatin), which has been approved in Japan as an adjuvant to chemotherapy for acute non-lymphocytic leukemia. However, the overlapping substrate specificity of the aminopeptidase family of proteins leads to the challenge of developing a specific CD13 inhibitor. Prostate cancer (PC) and neuroblastoma (NB) are both highly malignant tumors that can spread into the bone marrow, liver, lymph nodes and bones. The effect of CD13 inhibition by Ubenimex in PC cells has previously been investigated with results showing decrease of cell growth *in vitro and in vivo*, however, this was only shown in two PC cell lines, LNCaP and PC-3[3]. Hence, we are expanding this study into additional PC cell lines. Meanwhile, 70% of NB patients demonstrate a metastatic profile and there is currently no evidence yet of a link between NB to CD13. Given that CD13 is a regulator of tumor invasion, investigating the significance of CD13 in PC and NB can deepen our understating in its role in cell proliferation, migration, and metastasis. CD13 protein expression in PC and NB tumor xenografts and cell lines were investigated using western blot analysis, with differential expression identified between the cell lines. The importance of CD13 protein expression status will be reported; cell lines were treated with CD13 inhibitors including bestatin and actinonin, with evaluation of cell proliferation and migration using functional assays (MTT and scratch assays respectively). These data provide evidence towards the importance of CD13 in PC and NB, which will facilitate the development of a novel targeted therapy for CD13-expressing tumors that reduces the toxicity of traditional chemotherapy.

#5588 Efficacy of TGR-5 inhibition in cholangiocarcinoma using the novel small molecule inhibitor SBI-364.

Enis Ozmert, **Jennifer L. Tomlinson**, Danielle M. Carlson, Rory L. Smoot

Mayo Clinic Hospital-Rochester, Rochester, MN

Background: Cholangiocarcinoma (CCA) is a malignancy of the biliary epithelium with increasing incidence and poor survival. Despite the advances in targeted therapies, treatment success has been hindered by primary or acquired resistance. New therapeutic strategies are necessary to improve outcomes in this patient population. This study investigates the anti-tumor efficacy of TGR-5 inhibition in CCA using a novel small molecular inhibitor, SBI-364.
Methods: Cell viability was assessed using a CellTiter-Glo assay in four unique CCA cell lines treated with SBI-364 at concentrations ranging from 1 nM to 100 µM for 48 hours. Viability was expressed as a percentage relative to untreated controls. Cell migration was assessed using a scratch wound healing assay at 0, 12, and 24 hours following SBI-364 treatment. Migration was reported as the percentage of wound closure relative to the initial scratch width. Apoptosis was assessed using the Caspase-Glo® 3/7 Assay (Promega) after 12 hours of treatment with SBI-364. Caspase activity was normalized to untreated controls and expressed as relative luminescence units.
Results: SBI-364 reduced cell viability in a dose-dependent manner across all CCA cell lines with IC50 values ranging from 4.1-15.8 µM. Higher concentrations of SBI-364 induced increased cytotoxicity. In the scratch assay, untreated CCA cells achieved 100 % wound closure within 24 hours. Treatment with SBI-364 at 10 µM significantly inhibited cellular migration, with reduced wound closure compared to controls ($p < 0.05$). Apoptosis analysis revealed a significant increase in caspase-3/7 activity in three CCA cell lines following treatment with 10 µM SBI-364 for 12 hours ($p < 0.01$).
Conclusion: TGR-5 inhibition using novel small molecule inhibitor SBI-364 demonstrates potent anti-tumor effects in CCA by reducing viability, inhibiting migration, and promoting apoptosis. These findings support further investigation of SBI-364 as a promising therapeutic strategy in CCA.

#5591 Development of a BCR-ABL degrader overcoming resistance by BCR-ABL1 kinase domain mutations in chronic myeloid leukemia.

Ye Seul Lim, Na-rae Jeong, Sun-Mi Yoo, Han Wool Kim, So Hyuk Kim, Hyun-Hwi Kim, Yongdae Kwon, Heejung Moon, Hohyun Lee, Jungmin Ahn, **Jihye Lee**, Je Ho Ryu, Song Hee Lee

Ubix Therapeutics, Seoul, Korea, Republic of

Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell disorder characterized by the presence of the BCR::ABL1 fusion gene. Tyrosine kinase inhibitors (TKIs) have revolutionized the treatment of CML, yielding remarkable responses in patients. However, resistance mutations within the BCR-ABL1 kinase domain can arise, leading to treatment failure and disease progression. In this study, we report the identification of potent, orally efficacious BCR-ABL1 PROTACs. UBX-362 exhibits strong degradation activity against BCR-ABL1 proteins in CML cell lines. Consistently, it effectively suppresses cell viability in these cell lines, with low nanomolar IC50 values. Additionally, we evaluated the effects of single and combination therapies with TKIs (Asciminib or Ponatinib) using cell proliferation assays in K562 and Ba/F3 BCR-ABL1 mutant cell lines. Co-treatment of UBX-362 with Asciminib or Ponatinib resulted in a synergistic anti-proliferative effect in K562 cells. Notably, the combination of UBX-362 and Asciminib showed synergistic growth-inhibitory effects in Ba/F3 cell lines harboring BCR-ABL1 mutations. Oral administration of UBX-362 significantly reduced BCR-ABL1 protein levels in tumor tissue and robustly inhibited tumor growth in a CML CDX mouse model. These preclinical findings suggest the potential for the clinical development of a BCR-ABL1 degrader. Furthermore, UBX-362 demonstrates the ability to overcome resistance in CML patients with BCR-ABL1 mutations and shows promise as a candidate for combination therapy with other BCR-ABL1 inhibitors, providing new therapeutic possibilities for CML patients.

#5592 Modeling response prediction to a novel GCN2 kinase activator (NXP800) in patient-derived xenograft cholangiocarcinoma models using a multi-omics approach.

Danielle Marie Carlson[1], Hendrien Kuipers[1], Amro Abdelrahman[1], Erik Jessen[1], Joshua Roldan Kalill[2], Jennifer Tomlinson[1], Jack Sample[1], Akhilesh Pandey[1], Mark Truty[1], Rory Smoot[1]

[1]Mayo Clinic Hospital-Rochester, Rochester, MN,[2]Puerto Rico School of Medicine, San Juan, Puerto Rico

Introduction: Cholangiocarcinoma (CCA) is an aggressive biliary malignancy with poor survival outcomes and multiple mechanisms of resistance to targeted therapies. We previously validated NXP800, a novel GCN2 small-molecule activator, as an effective anti-cancer drug in six CCA cell lines. *In vitro* testing identified upregulation of phosphorylated eIF2a, as well as upregulation of ATF4, in CCA cells treated with of NXP800 compared to vehicle, suggesting that treated cells led to stimulation of stress-induced genes and subsequently, apoptosis. Furthermore, patient derived xenografts (PDX) models treated with NXP800 were found to have decreased tumor size, particularly in models containing *ARID1A, FGFR1*, and *ATM* mutations. Here, we aimed to predict response to NXP800 using sensitivity and resistance signatures from our profiled PDX models.

Methods: GCN2 activation in multiple previously profiled PDX models was evaluated. Whole Exome Sequencing (WES) was done on multiple PDX models to characterize the mutational signature and activity in CCA. Two additional CCA xenografts were expanded into the flank of NOD/SCID mice. Tumor bearing mice were treated with NXP800 (35 mg/kg) or vehicle via oral gavage for 28 days once tumors averaged 120 mm^3. Tumor volume and animal weight were collected twice weekly. Median Efficacy Index (MEI) scores were generated as drug response rates based on tumor growth. Predicted sensitivity and resistance kinase signatures to predict drug response were produced using multi-omics.

Results: Treatment with NXP800 was associated with a statistically significant decrease in tumor size in two additional PDX models, which included *ARID1A* and *BRAF* mutants. Preliminary multi-omics on the PDX models revealed that sensitivity mechanisms were upregulated most in EGFR signaling, while resistance signatures were focused around CSNK2A1 signaling.

Conclusion: Multi-omics analysis revealed a sensitivity mechanism structured around EGFR signaling, providing insights into which patients should be selected for treatment with NXP800. A Phase 1b clinical trial investigating the effects of NXP800 use in patients with advanced CCA is open and currently accepting patients.

#5593 The multi-kinase inhibitor tinengotinib as a novel therapy for advanced prostate cancer.

Brandon Hernandez[1], Jason Somarelli[1], Andrew Armstrong[1], Anaya Dutta[1], Bilal Ashraf[1], Xiaoyan Qiang[2], Yichang Zeng[2], Peng Peng[2], Jean Fan[2]

[1]Medicine, Duke University, Durham, NC,[2]TransThera Sciences, Nanjing, China

Purpose: Metastatic castration-resistant prostate cancer (mCRPC) is responsible for nearly 30,000 deaths each year in the US. While androgen receptor pathway inhibitors (ARPIs) significantly prolong the lives of men with mCRPC, the evolution of resistance to these agents is nearly universal. Among the mechanisms of resistance to ARPIs, studies have pinpointed activation of JAK/STAT and fibroblast growth factor receptor (FGFR) signaling as key mediators of ARPI resistance by mediating lineage plasticity and loss of AR dependence. To target these multiple resistance mechanisms, we interrogated the potential of tinengotinib, a spectrum-selective multi-kinase inhibitor for the treatment of ARPI-resistant mCRPC that targets Aurora Kinase A/B, JAK1/2, FGFRs and VEGFRs. Our study aims to characterize efficacy and resistance mechanisms of tinengotnib in prostate cancer cell lines and to develop novel combinatorial treatment strategies for mCRPC.

Methods: Baseline expression of Aurora A/B, STAT3, JAK1/2, VEGFR1/2/3, FGFR1/2/3, and CS1FR in a panel of prostate cancer cell lines (LNCaP, LNCaP95, LNCaP XER, 22RV1, PC3, and LASCPC-01) was assessed by qPCR and western blots. Single-agent and combination dose-response curves were performed with tinengotinib and standard-of-care agents using IncuCyte imaging and CellTiter Glo. Small molecule inhibition was used to assess the role of tinengotinib targets in driving cancer cell survival and growth.

Results: Tinengotinib potently inhibited growth of all cell lines, including enzalutamide-sensitive and -resistant AR signaling-dependent models (LNCaP, LNCaP95, LNCaP-XER), double negative models (PC-3) and neuroendocrine-like (LASPC-01) lineages, with IC50s ranging from low nanomolar to ~1 μM. Tinengotinib demonstrated additive effects with enzalutamide. Consistent expression of Aurora A and B, JAK2, and FGFR3 was observed across all cell lines while VEGFRs and FGFR1, 2, and 4 showed more variation in expression across lines. Interrogation of potential drivers will be presented.

Conclusion: Preclinical evaluation of tinengotinib shows efficacy across a range of prostate cancer phenotypes and combined effectively with standard agents. Gene expression across this panel of cell lines pinpoints Aurora A and B, JAK2, and FGFR3 as potential mechanisms of action for tinengotinib in prostate cancer. Future studies are aimed at understanding its mechanisms of action and determining its potential as a combination therapy for mCRPC.

#5594 Targeting ribosomal S6 kinase for the treatment of pediatric acute leukemia.

Kailen Mark, Jenny Youm, Ana San Jose Gonzalez, Kathleen M. Sakamoto

Stanford University School of Medicine, Stanford, CA

Pediatric acute leukemia accounts for about one third of all childhood cancers. Although the overall survival has improved to 60-70% for pediatric acute myeloid leukemia (AML) and up to 90% for pediatric acute lymphoblastic leukemia (ALL), standard treatments involve intensive chemotherapy and are associated with significant morbidity and mortality. There are few therapies available for relapsed/refractory pediatric acute leukemia. More targeted, less toxic therapies are needed to improve the outcomes for these patients. Ribosomal S6 kinase (RSK) is a serine-threonine kinase activated downstream of the Ras/MAPK signaling pathway and regulates cell proliferation, protein synthesis, and cell survival. RSK activates the transcription factor CREB, which has been found to mediate the proliferation and survival of myeloid cells. RSK is overexpressed and hyperactivated in pediatric AML and associated with a worse prognosis. Here, we evaluated two novel RSK inhibitors for treatment of pediatric AML and ALL. PMD-026 is a specific RSK inhibitor currently in a Phase II clinical trial for adults with metastatic breast cancer. We treated AML cells with a range of doses of PMD-026 and measured the viable cell number after 72 hours. The IC50 of PMD-026 was 298-560nM in Molm13, MV4;11, and Kasumi-1 cells and 1.02-2.24uM in two pediatric AML patient samples. Daunomycin, a standard chemotherapy agent used to treat AML, had synergistic effects when combined with PMD-026 in MV4;11 cells. To evaluate the effects of PMD-026 on normal hematopoietic stem and progenitor cells, we cultured healthy bone marrow mononuclear cells (10^4) with PMD-026 in methylcellulose containing SCF, GM-CSF, IL-3, IL-6, and EPO. Colony formation was not affected up to 10uM for a 17- to 30-fold therapeutic window. The multikinase inhibitor TAS0612 targets RSK, AKT, and S6K and is in Phase I clinical trials for adult solid tumors. In AML cell lines, the IC50 of TAS0612 was between 181-677nM. TAS0612 did not affect normal hematopoietic colony formation up to 1uM. Furthermore, when testing TAS0612 on ALL cell lines, we found that both B-ALL (REH, Nalm-6) and T-ALL cell lines (Loucy, Jurkat) were highly sensitive to TAS0612 with IC50 values of 56-190nM. Healthy T cell proliferation was not affected by TAS0612 up to 5.41uM for a 28- to 97-fold therapeutic window. Further studies are warranted to investigate the roles of RSK and other targets of TAS0612 in ALL. RSK inhibition is a promising approach for the treatment of pediatric acute leukemia. PMD-026 suppresses the proliferation of AML cells and synergizes with chemotherapy. TAS0612 reduces the growth of AML cells and is also effective at targeting B- and T-ALL cells. Both compounds have minimal toxicity to healthy hematopoietic cells. Therefore, PMD-026 and TAS0612 are strong candidates for translation into future clinical trials for AML and ALL.

#5595 Multiomic profiling identified biomarkers of response to selective Src family kinase inhibition in preclinical models of cholangiocarcinoma.

Hendrien Kuipers[1], Danielle M. Carlson[1], Jack W. Sample[1], Erik Jessen[1], Dong-Gi Mun[1], Aushinie M. Abeynayake[1], Jennifer L. Tomlinson[1], Amro M. Abdelrahman[1], Nathan W. Werneburg[1], Binbin Li[1], Mitesh J. Borad[2], Mark J. Truty[1], Sumera I. Ilyas[1], Gregory J. Gores[1], Rory L. Smoot[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Phoenix, AZ

Introduction: Src Family Kinases (SFKs) have a crucial role in tumor proliferation, survival, and metastasis. NXP900 is a highly selective SFK inhibitor a novel mechanism of action that locks SFKs in a closed, inhibited conformation, preventing interaction with substrate proteins, unlike other SFK inhibitors like dasatinib. A phase 1 study of NXP900 in patients with advanced solid tumors was recently initiated. Our preclinical studies showed therapeutic efficacy of NXP900 in cholangiocarcinoma (CCA) through decreased YAP, RAF-MAP and PI3K-AKT signaling. Here, we examined mechanisms of sensitivity and resistance to SFK inhibition.

Methods: Secondary resistance was explored by generating a NXP900-resistant human cell line (HuCCT1-R) via prolonged exposure to NXP900, followed by multiomic profiling. Primary resistance was studied in vivo using nine heterogeneous patient-derived xenograft (PDX) tumors implanted in the flanks of NOD/SCID mice. Tumor-bearing mice were treated with vehicle or 40 mg/kg NXP900 daily for up to 4 weeks. To identify factors associated with response, a multiomic approach was used, integrating RNA-Seq, global proteomics, and phosphoproteomics. A hierarchical-all-against-all algorithm (HallA) assessed associations between multiomic features and drug response in tumor growth. Kinase enrichment analysis (KEA3) identified features linked to sensitivity or resistance.

Results: HuCCT1-R cells showed increased pTyr abundancy of TNK2, a protein known to increase PIP3 levels leading to AKT activation, and of DYRK3 and LAMTOR1, both of which can sustain AKT phosphorylation via mTORC, indicating acquired resistance through bypassing inhibited PI3K-AKT signaling to rescue AKT. NXP900 reduced tumor growth rates in 5 of 9 PDX models. Kinases associated with sensitivity in the PDX models included SFKs (SRC, LYN, and FYN), and AKT, PTK2, PRKCZ, EGFR, SYK, and GSK3B, suggesting involvement of the PI3K-AKT pathway in responsiveness to NXP900. Based on tumor inhibition responses in the tested models, we estimated NXP900 response for our additional PDX models, predicting 39% (11/28) of patient tumors may respond.

Conclusion: This study identified molecular markers linked to response to SFK inhibition, which could be utilized for patient selection for NXP900 treatment. Further studies are validating these findings and exploring combination therapies to address resistance mechanisms.

#5596 Novel multikinase CLK inhibitor BH-30236 targets hematological malignancies through alternative splicing regulation.

Nancy Ling[1], Gregory Sims[1], Ping Jiang[1], Wei Deng[1], Dayong Zhai[1], Danan Li[1], Zhenping Wang[1], Yue Hu[1], Joshua Choi[1], Eric Wang[2], Armin Graber[1], Jean Cui[1]

[1]BlossomHill Therapeutics, Inc., San Diego, CA,[2]The Jackson Laboratory for Genomic Medicine, Farmington, CT

RNA splicing dysregulation plays a critical role in tumorigenesis, cancer progression, and therapeutic resistance. Components of the spliceosome machinery are frequently mutated in myeloid malignancies, affecting 40-85% of patients with Myelodysplastic Syndrome (MDS), and 10–25% of Acute Myeloid Leukemia (AML) cases. Recurrent aberrant alternative splicing (AS) patterns have also been detected in AML patients even in the absence of somatic spliceosome gene mutations. Furthermore, genetic screens have shown that the loss of splicing factors sensitizes AML to BCL2 inhibitor venetoclax. As such, splicing modulators are now acknowledged as a promising therapeutic target for hematologic malignancies. CDC2-like kinases (CLKs) play a pivotal role in regulating mRNA splicing *via* the phosphorylation of serine/arginine-rich splicing factor (SRSF) proteins which facilitate pre-mRNA splice site recognition. Consequently, inhibiting CLKs may offer a viable strategy for targeting cancers dependent on aberrant splicing. BH-30236 is a novel, orally bioavailable, ATP-competitive, macrocyclic inhibitor of CLKs, proviral integration for the Moloney murine leukemia virus 3 kinase (PIM3), FMS-like tyrosine kinase 3 (FLT3), and dual-specificity tyrosine-regulated kinase (DYRK) 1/2. BH-30236 potently suppressed SRSF phosphorylation and demonstrated *in vitro* efficacy at nanomolar range across immortalized and patient-derived AML cells, including cells insensitive to venetoclax. To evaluate how BH-30236 impacts mRNA expression and alternative splicing, RNA sequencing was performed on 6 patient-derived AML cells before and after BH-30236 treatment. BH-30236 modulated AS in genes associated with DNA damage response, mRNA splicing, and chromosome remodeling. Gene ontology enrichment analysis of genes downregulated by BH-30236 included terms related to mitochondrial translation, respiratory chain complex assembly, and regulation of cytochrome c release. Specifically, BH-30236 decreased the expression of anti-apoptotic BCL2 family genes MCL1 and BCL2A1, whose expression correlates with venetoclax resistance. Consistent with this, BH-30236 enhanced the potency of venetoclax in AML cell lines, including those with TP53 mutations. The combination of BH-30236 and venetoclax also synergistically suppressed tumor growth or induced deep tumor regression in venetoclax-resistant AML cell-derived xenograft models (Kasumi-1, MOLM-13). These observations support further evaluation of BH-30236 in combination with venetoclax for hematologic malignancies. A Phase 1 study to evaluate the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary anti-leukemic activity of BH-30236 in adults with relapsed/refractory AML and higher-risk MDS is currently ongoing (NCT06501196).

#5597 Efficacy of novel urokinase plasminogen activator receptor-associated protein targeted antibody-drug conjugates in patient-derived xenografts of soft tissue sarcoma.

Chao-Chi Wang[1], Agnieszka Wozniak[1], Luna De Sutter[1], Lore De Cock[1], Karo Wyns[1], Ulla Vanleeuw[1], Sander Van Putten[2], Carmel Lynch[2], Patrick Schoffski[3]

[1]KU Leuven, Leuven, Belgium,[2]Adcendo ApS, Frederiksberg, Denmark,[3]University Hospitals Leuven, Leuven, Belgium

Objective: Soft tissue sarcoma is a heterogeneous group of rare malignant tumors with a high unmet medical need. We evaluated the efficacy of two novel antibody-drug conjugates (ADC), ADCE-017 and ADCE-202, each consisting of three components: (1) an antibody targeting urokinase plasminogen activator receptor-associated protein (uPARAP), a collagen receptor highly expressed on mesenchymal tumor cells, (2) a linker, (3) and deruxtecan, a topoisomerase I inhibitor payload. The efficacy of ADCE-017 and ADCE-202 was assessed in 4 in vivo experiments using three different patient-derived xenograft (PDX) models with high uPARAP expression.

Methods: A total of 164 NMRI nu/nu mice were transplanted with PDX models of dedifferentiated liposarcoma (models UZLX-STS5, -STS200) or myxofibrosarcoma (-STS45). Mice were randomized for the following treatments: (1) vehicle control, (2) doxorubicin, (3) targeted antibody ("naked" antibody without payload), (4) ADC-isotype control (deruxtecan linked to a non-specific antibody), (5) uPARAP-targeted ADC. Treatments were given as tail vein injection on days 1, 8 and 15. Tumor volume, bodyweight and general well-being of animals were monitored until day 100 or until reaching the humane endpoint. Statistical analysis was performed with Wilcoxon test and Mann-Whitney U-test, with $p < 0.05$ defined as statistically significant.

Results: Treatment with ADCE-017 and ADCE-202 resulted in significant tumor growth delay in two experiments with STS200, compared to vehicle control and doxorubicin, and tumor volume shrinkage compared to baseline (day 1). Similar results were obtained with STS45, however, in this experiment the ADC-isotype control showed superior tumor volume shrinkage compared to ADCE-017. In STS5, tumor growth delay was observed with ADCE-017 as compared to the vehicle control and ADC-isotype control, with effects being similar to doxorubicin. Based on bodyweight assessment and necropsy of the mice, no severe toxicity was observed.

Conclusion: In general, the novel uPARAP-targeted ADCs ADCE-017 and ADCE-202 showed superior anti-tumor effect in all three soft tissue sarcoma models as compared to vehicle control without any treatment-related side effects. These results warrant further preclinical studies in other types of sarcoma and a clinical evaluation of the ADCs as a potential new treatment option for soft tissue sarcoma.

#5598 First-in-class casein kinase 1 alpha inhibitors for overcoming treatment related resistance in AML and pancreatic cancer.

Pavlina Janovska[1], Tomasz Radaszkiewicz[1], Martin Čulen[2], Ingrid Pristicova[1], Hana Plesingerova[1], Petra Prochazkova[1], Michal Smida[3], Daniel Busa[2], Adriana Ladungova[3], Lukas Maier[4], Stěpan Havel[4], Kamil Paruch[4], Jiři Mayer[2], Alexander Scheer[5], Vitězslav Bryja[1]

[1]Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic,[2]3 Department of Internal Medicine, Hematology and Oncology, Faculty of Medicine, Masaryk University, Brno, Czech Republic,[3]Central European Institute of Technology, Masaryk University, Brno, Czech Republic,[4]Department of Chemistry, Faculty of Science, Masaryk University, Brno, Czech Republic,[5]CasInvent Pharma, Brno, Czech Republic

Background: Inhibition of Casein kinase 1 alpha (CK1α) represents a new attractive concept for the therapy of acute myeloid leukemia (AML). Despite this, currently available small-molecule CK1α inhibitors lack sufficient activity and selectivity to fully exploit the therapeutic potential of CK1α inhibition. We have developed a series of potent and highly selective CK1 kinase inhibitors, including the most effective CK1α inhibitors to date. They inhibit all CK1α/δ/ε isoforms, blocking both CK1δ, ε- and CK1α-dependent processes, which leads to higher efficacy and good tolerability. Targeting of CK1 kinases in resistant cancers is a novel concept - several preclinical studies showed the potential of CK1δ/ε targeting to overcome/avoid resistance - e.g. to potentiate Gemcitabine efficacy in pancreatic cancer, or Enzalutamide in prostate cancer. The precise role of CK1α inhibition is still under evaluation; nevertheless, knockout experiments have revealed that CK1α is essential for survival of most cancer cells and could bring benefit when targeted alone or together with CK1δ/ε.

Material and Methods: Cellular target engagement assays, *in vitro* kinase assays, ADME profiling, testing of *in vitro* sensitivity to CK1 inhibition and standard-of-care treatments in cell cultures (cell lines, primary AML samples), *in vivo* efficacy and tolerability studies in mice.

Results: First-in-class CK1 inhibitors were developed and evaluated for their potential in preclinical and clinical settings. These inhibitors exhibited sub-nanomolar activity against CK1α, translating into superior on-target activity in cells compared to the previously reported BTX-A51 compound. High efficacy and safety were observed in both in vitro and in vivo AML models, including Venetoclax-resistant AML, underscoring the significant potential of selective CK1α inhibition. A set of biomarkers predicting sensitivity to CK1α inhibitors, including resistance to Venetoclax (a standard-of-care BCL-2 inhibitor), was identified. Additionally, a Gemcitabine-resistant pancreatic cancer model confirmed the efficacy of combining CK1 inhibition with Gemcitabine, resulting in improved outcomes in resistant in vivo models. Proof-of-concept studies are also underway for melanoma and prostate cancer.

Conclusions: Our findings highlight the therapeutic potential of selective CK1α inhibition for treating Venetoclax-resistant AML. Furthermore, the data suggest that dual targeting of CK1α/δ/ε may help overcome resistance in specific cancers, such as Gemcitabine-resistant pancreatic cancer and melanoma.

This project is co-financed with state support from the Technology Agency of the Czech Republic within the TN Program for the Support of Applied Research, Experimental Development, and Innovation of the National Competence Center (2018 - 2028); project TN02000109

#5599 NXP900, a novel YES1/SRC kinase inhibitor currently in clinical development, blocks YAP1 signaling in NSCLC cell lines.

Boback Kaghazchi[1], Inigo Lanzagorta Calvillo[1], Ben King[1], Enrique Poradosu[2], Neil O Carragher[1], Asier Unciti-Broceta[1]

[1]University of Edinburgh, Edinburgh, United Kingdom,[2]Nuvectis Pharma Inc., New Jersey, United Kingdom

Background: Most kinase inhibitors exert their anticancer effects by targeting the ATP binding site, either binding and locking an active or inactive kinase conformation, with targeting inactive conformation typically leading to a superior selectivity profile[1]. NXP900 (eCF506), a highly-potent SRC family kinase (SFK) inhibitor has previously demonstrated high SFK selectivity and the capability to lock the native “closed” conformation (type 1.5), resulting in inhibition of both enzymatic and scaffolding activities[2] (IC_{50} of 0.47 nM against YES1). Conversely, multi-kinase inhibitors dasatinib and bosutinib target the “open” conformation (type 1), thus promoting SFK association with signalling partners[3]. The aim of this study was to examine the signaling pathways targeted by NXP900, including the Hippo pathway, and unravel potential synergy mechanism of NXP900 with existing targeted therapies against NSCLC. **Materials and methods:** Cell confluence and viability were determined by automated image analysis of confluence and Presto Blue assay, respectively. NSCLC cells were treated with NXP900 for 24 hours prior to fixation and subsequent immunostaining with anti-YAP, anti-YES1, phalloidin and Hoechst. Images were analysed using ImageJ software. mRNA abundance of SRC, YES1, YAP1, NF2/MERLIN, Cyclin D were quantified utilising TaqMan RT-PCR. **Results:** NXP900 inhibited cancer cell proliferation of NSCLC cell lines. NXP900 showed dose-dependent decreases in YAP1 and YES1 nuclear localization across all cell lines and prevented SRC phosphorylation. **Conclusions:** NXP900 prevents YAP1 nuclear localization and cell cycle progression in a panel of NSCLC cell lines, decreasing expression of total YAP1 and YES1. Our data suggests that NXP900, currently in a Phase1 dose escalation study, is an attractive and translatable combination partner that could synergize with existing targeted therapies against NSCLC when the Hippo pathway is dysregulated. **1** C. #5600 BTK T474I with enhanced kinase activity confers growth advantage over BTK-L528W with kinase deficiency in B malignant cells.

Wenjing Zhang[1], Xinxin Zhu[1], Qiming Zhou[1], Jiayun Song[1], Yang Li[2], Bo Li[2], Ming Jiang[2], Xiaoliang Cheng[2], Teiko Sumiyoshi[3], Yangbo Yue[1], Wei Jin[2], Zhirong Shen[2]

[1]BeiGene (Shanghai) Biotechnology Co., Ltd., Shanghai, China,[2]BeiGene (Beijing) Co., Ltd., Beijing, China,[3]BeiGene Co., Ltd., San Mateo,CA, CA

Background: Covalent BTKi have transformed the therapeutic landscape for chronic lymphocytic leukemia (CLL). However, acquired mutations in BTK, often occurring at C481, lead to drug resistance and disease progression. While non-covalent BTKi has demonstrated promising efficacy in CLL patients with BTK C481X mediated resistance, non-C481 mutations within BTK kinase domain confer ineffectiveness to cBTKi and ncBTKi as well. Those BTK mutations most commonly involve BTK T474I and L528W. To compare their role in promoting B malignant cell growth, we developed clonal competition models by co-culturing isogenic B malignant cells harboring BTK T474I and L528W and monitor the clonal dynamics in long term culture.
Methods: The T474I and L528W were introduced to BTK allele of B malignant cell line TMD8. BTK downstream signaling in BTK wildtype or mutant cells with or without anti-IgM stimulation was assessed by western blot. In vitro and in vivo pooled clone models containing both TMD8 wildtype and mutant cells were employed to investigate the clonal competition. The dynamics of individual clones were monitored by measuring the changes of BTK variant allele frequency (VAF) via amplicon sequencing.
Results: Hyperactivation of phosphorylated BTK Y223 in TMD8 BTK T474I cell and very limited BTK Y223 phosphorylation in TMD8 BTK L528W upon IgM stimulation was observed. Enhanced B-cell receptor (BCR) downstream signaling indicative of pPLCγ2, pERK and pAKT were noted in BTK T474I cells compared to those expressing BTK L528W. Those findings suggest that BTK T474I encodes a kinase exhibiting enhanced activity while BTK L528W results in a catalytically inactive form. Clone competition was evaluated using co-culture experiments containing TMD8 BTK T474I, BTK L528W and WT cells in medium with various FBS concentration. T474I clones were significantly expanded while L528W clones were declined in 4 weeks culture period. The outgrowth advantage of BTK T474I was particularly pronounced when cultured in medium with low FBS concentration, which simulated a relatively harsh condition for cell growth. Similar results were observed when those clonal pools were grown as xenografts. An increase in T474I VAF and a decrease in L528W VAF were noted during tumor growth in subcutaneous models incorporating TMD8 wildtype and mutant cells.
Conclusion: Our in vitro and in vivo clonal competition assays provided novel insights into the impact of BTK T474I and L528W on growth fitness. These findings suggested that BTK T474I, characterized by enhanced kinase activity, confers a growth advantage over the kinase deficient form BTK L528W.

#5601 ID11916, a novel androgen receptor antagonist with cGMP-dependent protein kinase activation for next-generation therapeutics in AR positive tumors.

Jeong Eun Kim[1], Ji-Yun Lee[2], Jaebeom Cho[2], Won Sik Lee[1], Myongjae Lee[1]

[1]Idience, Seoul, Korea, Republic of,[2]College of Pharmacy, Chung-Ang University, Seoul, Korea, Republic of

Androgen receptor (AR) signaling plays a crucial role in hormone-dependent cancers. In prostate cancer, AR signaling-targeted therapies, including second-generation AR antagonists such as enzalutamide, are initially effective for castration-resistant prostate cancer, but often develop resistance. AR is expressed in 60-80% of breast cancers and known to contribute to tumor aggressiveness. However, the clinical efficacy of AR-targeted therapies in breast cancer remains limited. Therefore, numerous AR targeted therapies are under development to improve efficacy and overcome resistance. However, given that AR resistance results from the complex interplay of both AR-dependent and AR-independent mechanisms, a strategy targeting both pathways is required. We developed ID11916, a novel orally available AR antagonist that modulates AR-dependent and AR-independent pathways by activating cGMP-dependent protein kinase (PKG). ID11916 effectively blocks androgen binding to AR, nuclear translocation, and androgen-dependent transcriptional activity of AR, while increasing intracellular cGMP levels and activating PKG via phosphodiesterase 5 inhibition. ID11916 demonstrated potent anti-cancer effect in prostate cancer cell lines VCaP and 22Rv1, where enzalutamide showed limited efficacy. In VCaP, where bicalutamide exhibited an agonistic effect, ID11916 showed approximately 60-fold greater anti-proliferative activity (IC_{50}: 2.77 μM) than enzalutamide (IC_{50}: 163 μM). ID11916 demonstrated greater potency in colony formation assays than enzalutamide in AR-positive breast cancer cell lines SK-BR-3 (ID11916 IC_{50}: 0.653 μM vs Enzalutamide IC_{50}: > 30.0 μM) and MDA-MB-231 (ID11916 IC_{50}: 1.96 μM vs Enzalutamide IC_{50}: 18.1 μM). ID11916 also showed superior tumor growth inhibition in xenograft models. In the MDA-MB-453 xenograft model, daily oral administration of ID11916 at 30 mg/kg inhibited tumor growth by 74.7%, compared to 53.0% inhibition with clinically relevant dose of enzalutamide. In a repeated-dose pharmacokinetic study in the MDA-MB-453 xenograft model, oral administration of 30 mg/kg ID11916 showed a 7-fold lower C_{max} and an 8-fold lower AUC compared to enzalutamide. These findings indicate that the enhanced potency of ID11916 compared to enzalutamide is consistently demonstrated *in vivo*. In conclusion, our preclinical data introduce ID11916, a novel compound with a potential of overcoming resistance through both AR-dependent and AR-independent mechanisms by combining AR and PKG modulation. These findings support its potential as a next-generation AR-targeted therapy, offering an alternative to currently available AR targeting approaches.

#5602 Galactokinase 1 is a novel metabolic target against bladder cancer.

Surya P. Singh, Chinthalapally V. Rao, Venkateshwar Madka

Department of Medicine, Center for Cancer Prevention and Drug Development, Stephenson Cancer Center, Hem-Onc, University of Oklahoma HSC, Oklahoma City, OK

Urinary bladder cancer (BCa) is the second most prevalent cancer of the genitourinary tract. Although BCa affects both genders, it is more predominant among men. Most of the tumors are non-invasive at diagnosis, however, high rates of recurrence, heterogeneity, and treatment resistance lead to significant mortality. Therefore, it is necessary to identify and understand the role of novel metabolic targets and explore their therapeutic potential against BCa. Rapidly proliferating cancer cells have high nutritional demand which necessitates metabolic reprogramming and reliance on the alternative nutrients in the tumor microenvironment. Based on the human BCa transcriptome data analysis (TCGA data), we identified that the Galactokinase-1 (GALK1) gene is significantly overexpressed ($p<0.0001$) in human bladder tumors compared to normal tissue, and its expression also correlates with disease stage and poor prognosis. GALK1 is a member of the Leloir pathway that facilitates the initial step of galactose breakdown. Interestingly, we observed abundant expression of GALK1 in various human and rodent BCa cell lines as well as rodent bladder tumor tissues. Hence, we hypothesized that GALK1 may contribute to BCa survival by contributing to the cancer cell proliferation and could serve as a novel target for the management of this malignancy. To understand this, we abrogated GALK1 gene expression in MB49 cells using siRNA and found a significant decrease in cell proliferation with increased apoptosis. Further treatment of various human bladder cancer cells, in vitro with a small-molecule GALK1 inhibitor (Cpd36), resulted in reduced proliferation (IC_{50} = 29.09 - 43.67μM), migration and invasion potential. A similar growth inhibitory effect was also observed in BCa spheroids and tumoroids. Cell cycle analysis indicated that Cpd36 induced significant G1 arrest ($p<0.0001$) in BCa cells and pronounced G2/M arrest ($p<0.0001$). GALK1 inhibition increased mitochondrial ROS production while lowering the mitochondrial membrane potential and triggered apoptosis in BCa cells. GALK1 inhibition induced cell growth arrest was associated with decrease in protein levels of GALK1, PCNA, and Cyclins. Additionally, the induction of apoptosis was associated with increase in cleaved caspase-3 and cleaved poly (ADP-ribose) polymerase (PARP). Further, we investigated the effect of GALK1 abrogation on chemotherapeutic drugs sensitivity. Invitro drug combination data suggested that targeting GALK1 sensitized the BCa cells to cisplatin or gemcitabine as evident from significant reduction in the IC50 of these chemotherapeutic drugs. Based on these findings, GALK1 plays a tumor promoting role in BCa and its inhibition may be a promising therapeutic target for its prevention and treatment.

#5603 A precision polypharmacology approach to co-target EGFR and PI3 kinase: the power of structure-based drug design to generate therapeutic agents with versatility in multiple combination settings.

Elizabeth K. Ziemke[1], Christy L. Frankowski-McGregor[1], Madeline Walker[1], Christopher E. Whitehead[2], **Judith S. Sebolt-Leopold**[3]

[1]Radiology, University of Michigan, Ann Arbor, MI,[2]MEKanistic Therapeutics, Inc., Ann Arbor, MI,[3]University of Michigan, Ann Arbor, MI

Adaptive resistance mechanisms significantly curtail the long term effectiveness of molecular targeted agents directed against a single protein. MTX-531 was computationally designed to selectively target two critical oncogenic drivers, EGFR and PI3 kinase. We recently reported unique structural and pharmacological features of this lead molecule, including strong monotherapy activity against squamous head and neck cancers (HNSCC), which are prone to adaptive resistance when either oncogenic protein is targeted alone (Whitehead et al, Nature Cancer 2024). Based on the central role of the PI3K pathway in driving resistance to a broad spectrum of targeted agents and modalities, we report here pilot studies carried out with MTX-531 to elucidate its potential in combination with other targeted agents, radiation, and immunotherapy. In vivo studies were carried out in KRAS G12D mutant tumor-bearing mice showing that treatment with MTX-531 led to striking enhancement of KRAS inhibitor (MRTX-1133) activity against a broad spectrum of gastrointestinal cancers (pancreatic, colorectal, gastric) as evidenced by a high incidence of durable tumor regressions. In a separate line of investigation, nanomolar potency of MTX-531 against DNA-PK, a PI3K-like family member involved in DNA damage repair, led us to explore the radiosensitizing potential of this molecule in models of HNSCC and triple negative breast cancer. Combination of MTX-531 and daily low dose (2Gy) radiation resulted in prolongation of survival with a high incidence of durable complete regressions in HNSCC. Furthermore, based on the pan-PI3K inhibitory profile of MTX-531, we hypothesized that this molecule would exert immunomodulatory effects to improve therapeutic outcome in the immunotherapy setting. Studies carried out in syngeneic mouse models of pancreatic cancer (KPC) and HNSCC (MOC1) showed that the combination of MTX-531 with anti-PD-1 antibody led to improved survival and increased incidence of objective responses compared to the single agent arms. Collectively, these studies demonstrate the versatility of MTX-531 to serve as the backbone of combination regimens across diverse modalities encompassing treatment with targeted therapies, radiation, or immune checkpoint inhibitors. Based on its promising preclinical profile, MTX-531 represents a first-in-class approach to precision polypharmacology that demonstrates the power of rational structure-based drug design to target multiple resistance drivers in a single molecule.

#5604 Antitumor activity of YH42946, a potent tyrosine kinase inhibitor, in NSCLC harboring EGFR exon 20 insertion mutations.

M. Yu[1], J. Lee[1], K. Lee[2], M. Hong[1], S. Lim[1], B. Cho[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of

Introduction: Epidermal growth factor receptor (EGFR) mutations are the most common in non-small cell lung cancer (NSCLC) patients, with around 30% carrying these mutations, of which approximately 4-10% are EGFR exon 20 insertion (ex20ins) mutations. The most common EGFR ex20ins mutations in NSCLC are ASV and SVD variants in the kinase domain. Currently, treatment options for this subset of patients are limited. YH42946 is an orally available tyrosine kinase inhibitor (TKI) targeting EGFR ex20ins mutations, and the potential to be a best-in-class drug candidate to address this unmet clinical need.

Method: Competitive binding affinity was measured using the KINOMEscan screening platform. The inhibitory activity of YH42946 was evaluated through a cell viability assay in Ba/F3 cell lines expressing EGFR ASV, SVD, GY, and HH mutations. A549 cells were used to assess the cellular activity of EGFR wild-type (WT). To further confirm the mechanism of action, western blot analysis was performed on patient-derived cells (PDCs), including YU-1163 (S768_D770dup, SVD) and DFCI-127 (P772_H773insPNP).

Results: Kinome profiling against a panel of various kinases revealed that 100 nM of YH42946 bound strongly to EGFR mutants. In a cell viability assay, YH42946 strongly inhibited cellular activity in Ba/F3 cell lines engineered to express the EGFR mutants ASV, SVD, GY (IC_{50} < 10 nM), and HH (IC_{50} < 30 nM). It demonstrated superior activity compared to Mobocertinib (IC_{50} < 30 nM for ASV and IC_{50} < 30 nM for SVD), Furmonertinib (IC_{50} < 100 nM for ASV and IC_{50} < 100 nM for SVD), and Zipalertinib (IC_{50} < 100 nM for ASV and IC_{50} < 100 nM for SVD), and was comparable to Poziotinib (IC_{50} < 10 nM for ASV and IC_{50} < 10 nM for SVD). In normal cell lines, YH42946 did not inhibit the activity of normal cell lines, largely sparing EGFR WT activity (IC_{50} > 1000 nM). In protein expression analysis, YH42946 effectively inhibited the signaling pathways of p-EGFR, p-AKT, p-ERK1/2, and p-S6 in YU-1163 and DFCI-127 PDC cell lines at a low dose level.

Conclusion: YH42946 is a potent small-molecule inhibitor that selectively targets EGFR ex20ins while sparing EGFR WT in preclinical models, offering potential therapeutic benefits for NSCLC patients with EGFR ex20ins mutations. Additionally, YH42946 has demonstrated effective inhibition of the EGFR pathway. Given these robust activities against EGFR ex20ins, YH42946 is anticipated to provide a significant therapeutic option for NSCLC patients harboring EGFR ex20ins mutations.

#5605 Development of a novel protein phosphatase 2A (PP2A) activator, PPA27, as a potential therapeutic for melanoma.

Hannah Johnson[1], Amandeep Singh[1], Asif Raza[1], Satya Narayan[2], **Arun K. Sharma**[1]

[1]Penn State College of Medicine, Hershey, PA,[2]3Department of Anatomy and Cell Biology, University of Florida, Gainesville, FL

Protein phosphatase 2A (PP2A) is a vital serine/threonine phosphatase acting as a tumor suppressor, often inactivated in melanoma and other cancers. This study builds upon our initial findings on the PP2A activators PPA24 and PPA27, focusing on extended *in vitro* and *in vivo* evaluations to assess PPA27's therapeutic potential against melanoma. In our previous work, both compounds demonstrated selective cytotoxicity in melanoma cell lines. Here, we further characterize PPA27's efficacy across five melanoma cell lines (SK-MEL-2, SK-MEL-28, A375, Mel1241, and 451Lu), showing IC_{50} values ranging from 3.45-8.94 μM, with consistent effectiveness regardless of BRAFV600E mutation status. Mechanistic analyses revealed that PPA27 induced apoptosis in a dose-dependent manner as confirmed by increased caspase-3/7 activation and PARP cleavage. Notably, PPA27 treatment significantly downregulated phosphorylated ERK1/2, particularly in BRAFV600E-positive A375 cells, suggesting differential modulation of MAPK pathways in mutant and wild-type contexts. To validate these findings *in vivo*, the efficacy of PPA27 was assessed in xenograft melanoma mouse models. The compound significantly reduced tumor growth compared to control without any apparent systemic toxicity. Additionally, pharmacokinetic and ADMET analyses indicate that PPA27 possesses excellent bioavailability, stability, and metabolic properties, supporting its potential for clinical translation. Furthermore, combinatorial studies suggest that PPA27 enhances the efficacy of existing BRAF inhibitors, potentially addressing drug resistance issues in melanoma therapy. These findings highlight PPA27's robust therapeutic potential and provide new insights into its mechanism of action. In conclusion, our expanded investigation establishes PPA27 as a promising candidate for melanoma treatment, warranting further preclinical studies before consideration for clinical trials targeting both BRAF-mutant and wild-type melanoma subtypes.

#5606 The novel brain-penetrant paradox breaker BRAF inhibitor RG6344 manifests exceptional activity in BRAF mutant colorectal cancers.

F. Renner[1], J. Eckmann[1], C. Handl[1], N. Kratochwil[1], J. Wichmann[1], G. Schnetzler[1], N. Keshelava[2], H. G. Palmer[3], J. Martinez-Quintanilla[3], I. Chicote[3], J. Verges[3], P. Pettazzoni[1];
[1]F. Hoffmann-La Roche Ltd., Basel, Switzerland, [2]F. Hoffmann-La Roche Ltd., Zurich, Switzerland, [3]Val d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Despite the approval of the combination Encorafenib/Cetuximab in metastatic colorectal cancers (CRC) harboring BRAF V600E mutations, the therapeutic benefits offered by this regimen remains limited and short lived.
We developed a next generation brain permeable, paradox breaker BRAFi (RG6344, previously identified as Compound Ia in Wichmann et al., Clin Cancer Res 2022) currently undergoing clinical testing (ISRCTN13713551). Here we present its preclinical activity for BRAF mutated CRC.
RG6344 proves paradox breaking properties by not triggering MAPK over-activation in BRAF WT contexts at all levels. For in vivo testing regimens covering IC_{80} (60 mg/kg) and IC_{95} (140 mg/kg) p-ERK inhibition were used.
RG6344 was highly tolerated in all studies as a single agent and in all combination regimens tested clearly highlighting that the lack of paradoxical MAPK activation allows superior target inhibition in vivo. In BRAFi naïve xenograft models (LS411N, HT29) RG6344 as monotherapy outperformed Encorafenib/Cetuximab at all doses tested indicating higher activity of this agent even at doses targeting only IC80 p-ERK inhibition, the same BRAF inhibition levels reached by Encorafenib in CRC approved clinical regimens. RG6344 activity was further strengthened in combination with cetuximab and demonstrated long-lasting responses in PDX models derived from patients that progressed to Encorafenib/Cetuximab therapy supporting the use of RG6344 even in BRAFi experienced patients.
Additional combination studies of RG6344 with FOLFOX in BRAFi naive models resulted in tumor regression and dramatic superiority compared to the same combination with Encorafenib.
These data collectively provide strong preclinical translational evidence for the potentially transformative activity of RG6344 in BRAF mutated CRC.

#5607 Discovery and preclinical evaluation of a potent, orally bioavailable, highly selective, small molecule PTPN2/1 inhibitor.

A. Pushechnikov[1], V. Parchinsky[2], A. Riakhovskii[2], S. Mochalov[2], R. Karapetian[1], A. Burd[3], N. Savchuk[1], I. Dukes[3], R. Abagyan[4];
[1]Expert Systems, Inc., San Diego, CA, [2]ChemDiv, Inc., San Diego, CA, [3]Eilean Therapeutics LLC, Philadelphia, PA, [4]MolSoft LLC, San Diego, CA

Protein tyrosine phosphatase non-receptor type 2 (PTPN2) is ubiquitously expressed, primarily in hematopoietic and placental cells. Critical negative regulator of the JAK-STAT pathway, PTPN2 functions to directly regulate signaling through cytokine receptors, including IFNγ. Thus, enhancing IFNγ sensing and signaling through the inhibition of PTPN2 is a potential therapeutic strategy to improve the efficacy of cancer immunotherapy regimens. Historically, phosphatases are difficult drug targets; due to an intrinsic physicochemical profile of phosphatase inhibitors, finding bioavailable molecules is a great challenge. ZE00-0388 demonstrates sub-nanomolar PTPN2/N1 inhibitory activity and outstanding over 1000-fold selectivity against all other phosphatases. ZE00-0388 demonstrated complete tumor remission in combination with the anti-mPD-1 recombinant mAb therapy in the murine colon adenocarcinoma MC38 in vivo model. ZE00-0388 demonstrates good safety and tolerability; its ADME properties confirm that ZE00-0388 is suitable for further development for combination therapies.

#5608 Design and discovery of BH-30643: A novel, reversible, mutant-selective macrocyclic EGFR inhibitor invulnerable to common resistance mutations.

J. Jean Cui, Eugene Rui, Evan Rogers, Dayong Zhai, Ping Jiang, Zhenping Wang, Yue Hu, Nancy Ling, Danan Li, Joshua Choi, Anindya Sarkar, Levan Darjania, Zhengwei Peng, Wei Deng

BlossomHill Therapeutics, Inc., San Diego, CA

Outcomes on tyrosine kinase inhibitor (TKI) treatment in *EGFR*-mutant NSCLC fall short of the durable benefit observed with next-generation targeted therapies in *ALK* and *ROS1*-driven NSCLC. We reviewed the chemical structures of 30+ existing EGFR TKIs in pursuit of a novel chemical scaffold that could offer a more durable treatment response. First-generation (1G) (e.g. gefitinib) and second-generation (2G) (e.g. afatinib) EGFR TKIs share an anilinoquinazoline scaffold which is vulnerable to T790M gatekeeper resistance. Third-generation (3G) (e.g. osimertinib) EGFR TKIs employ a less potent pyrimidine scaffold and obtain good potency including T790M through introduction of an irreversible binding at C797. However, the dependence of 3G EGFR TKIs on irreversible binding renders these agents vulnerable to C797S resistance. The established EGFR TKI scaffolds additionally have more limited potency against a growing family of non-classic EGFR mutations (atypical and ex20ins). To increase the breadth and durability of EGFR TKIs in *EGFR* mutant NSCLC, we have designed a novel reversible macrocyclic scaffold that fully leverages the characteristics of EGFR active conformation and introduces novel and precise interactions with mutant EGFRs *via* a three-dimensional macrocyclic structure. Our efforts led to the discovery of BH-30643, a potent, orally bioavailable, reversible, ATP-competitive macrocyclic inhibitor selective for mutant EGFRs. BH-30643 demonstrates potent anti-cell proliferation activity against classical mutations (IC_{50}: ex19del 0.73 nM and L858R 0.18 nM), with >250-fold selectivity over wildtype (WT) EGFR (IC_{50}: 191.5 nM). It additionally exhibits ~50-fold selectivity compared to WT HER2 (IC_{50}: 42.2 nM), in contrast to the 2G and 3G EGFR TKIs with limited selectivity over WT HER2, which may contribute to diarrhea as a side effect. The potency of BH-30643 is maintained in the presence of T790M (IC_{50}: ex19del/T790M 0.43 nM and L858R/T790M 0.69 nM), C797S (IC_{50}: ex19del/C797S 0.05 nM and L858R/C797S 0.10 nM) or both (IC_{50}: ex19del/T790M/C797S 0.43 nM and L858R/T790M/C797S 0.54 nM). Potency is additionally evident across a breadth of EGFR mutations including atypical mutations (IC_{50}: 0.05-8.84 nM), and ex20ins mutations (IC_{50}: 1.74-64.68 nM). BH-30643 also showed potent activity against mutant HER2s (IC_{50}: 3.25-18.8 nM), especially in the presence of T780M or C805S resistance mutation. Moreover, BH-30643 showed great selectivity in screens against 372 WT human kinases and 87 safety-related targets. The unique profile of BH-30643 offers a promising strategy to target a range of classical and non-classical *EGFR* activating mutations without vulnerability to common on-target resistance mutations. Such an "OMNI-EGFR^{TM}" inhibitor may represent a new generation of EGFR TKIs with potential to overcome some of the limitations of earlier agents.

#5609 A novel PTPN1/2 inhibitor with high oral bioavailability enhances the antitumoral response.

Angelique Pabois, Alessandra Lopes, Clement Bonnel, Joao Marchante, Theodore J. Sanders, Michael Deligny, Alexis Goffaux, Wilfried Cathou, Aurore Smets, Ines Amendoeira Cabral, Marie-Claire Letellier, Berenice Lossignol, Geraldine Genard, Aura Condila, Celine Dotreppe, Margreet Brouwer, Annelise Hermant, Catherine Hoofd, Reece Marillier, Yvonne McGrath, Steven Van der Plas, **Silvia Pandolfi**

iTeos Therapeutics, Charleroi, Belgium

PTPN1/2 phosphatases are major negative regulators of the antitumor immune response. Inhibiting or depleting PTPN1/2 sensitizes cancer and immune cells to interferon gamma (IFNγ), reshapes the tumor microenvironment and triggers a coordinated antitumor immune response involving myeloid cells, NK, T cells, and cancer cells. Although protein phosphatases were long considered undruggable due to their highly polar catalytic pocket, several small molecule inhibitors of PTPN1/2 have recently been discovered. Most of these inhibitors mimic the phosphate of the natural substrate by the 1,2,5-thiadiazolidin-3-one 1,1-dioxide (TDZ) moiety. Although incorporating a TDZ ensures potency while overcoming the instability of the phosphate group, the resulting inhibitors are very polar. As a consequence, most of the TDZ-containing inhibitors suffer from low oral bioavailability. Nevertheless, 2 small molecules have entered clinical trials. We have discovered a small molecule inhibitor of PTPN1/2 with high specificity and human potency comparable to known PTPN1/2 inhibitors. This novel small molecule displays high exposure in preclinical species, due to its high oral bioavailability. To assess the human and mouse cellular potency of our compound, we measured pSTAT1 in cancer cells upon IFNγ treatment and we observed large discrepancies between human and mouse potency for most PTPN1/2 inhibitors. Whereas previously described PTPN1/2 inhibitors show much higher potency in mouse compared to human cells, our novel compound displays higher potency in human compared to mouse cells. Upon in vivo dosing, our PTPN1/2 inhibitor showed efficacy in a syngeneic model, resulting in tumor growth inhibition, target engagement and pharmacodynamic readout. To further determine efficacy in human cells, we tested our compound on human cancer and immune cells, as well as on Patient Derived Tumor Fragments (PDTFs), an innovative ex vivo technique proven to be highly predictive of patient clinical responsiveness to immunotherapy. In this system, drugs are directly applied to slices of fresh human tumors and treatment-induced changes (e.g. cytokines levels) are measured. In both *in vitro* assays and PDTFs, our PTPN1/2 inhibitor showed signs consistent with a robust anti-tumor response in line with the expected mechanism of action, creating confidence that the molecules will engage the immune system in human patients. Overall, this is the first report of a specific PTPN1/2 inhibitor with competitive human potency and high bioavailability, making it an ideal candidate for clinical development.

#5610 BAY 2927088: a novel treatment option for patients with NSCLC with *HER2* mutations.

Franziska Siegel[1], Kristyna Kotynkova[2], Gizem Karsli-Uzunbas[2], Thibaud Jourdan[1], Melanie Berthold[1], Stephan Siegel[1], Daniel Korr[3], Markus Berger[1], Haruna Tomono[2], Sawyer Andersen[2], Daniel Denney[2], Jeremie Mortier[1], Andrew Cherniack[2], Matthew Meyerson[4], Heidi Greulich[2]

[1]Bayer AG, Berlin, Germany,[2]Broad Institute of MIT and Harvard, Cambridge, MA,[3]Nuvisan ICB GmbH, Berlin, Germany,[4]Dana-Farber Cancer Institute, Boston, MA

Lung cancer is the most prevalent tumor type worldwide, and despite advancements in providing patients with improved therapies, the 5-year overall survival rate is still only 5.8%. About 2-4% of patients with non-small cell lung cancer (NSCLC) carry either a *HER2* exon20 insertion or a *HER2* point mutation, which are potent oncogenic drivers.

The antibody-drug conjugate fam-trastuzumab deruxtecan-nxki was the first targeted treatment option to be approved for patients with *HER2*-mutant NSCLC. However, there is still a significant unmet need for more effective and better tolerated therapies with the potential to improve response rates and response durability.

Here we present preclinical data for BAY 2927088, a highly potent and selective tyrosine kinase inhibitor targeting *HER2*. BAY 2927088 shows potent *in vitro* antiproliferative activity in tumor cell lines carrying *HER2* mutations, and strongly blocks *HER2* phosphorylation, thereby inhibiting *HER2*-mediated downstream MAPK signaling. We also confirmed the strong anti-tumor activity of BAY 2927088 in *in vivo* models with *HER2* exon20 insertions.

To further explore the therapeutic potential of BAY 2927088, we evaluated combination treatment with current standard-of-care therapies in NSCLC *in vitro* and *in vivo*. In addition, we profiled BAY 2927088 vs. other *HER2* tyrosine kinase inhibitors by pooled screening of 866 barcoded human cancer cell lines to identify additional oncogenic dependencies and patient populations that might benefit from treatment with BAY 2927088. We found that BAY 2927088 was also active in a subset of *HER2*-amplified breast and gastroesophageal cancer cell lines.

Single-agent BAY 2927088 is currently being evaluated in clinical trials in patients with NSCLC with *HER2* mutations. Preliminary results demonstrate efficacy and safety in pretreated patients (NCT05099172, NCT06452277).

#5611 Preclinical evaluation of SNH-110: A potent, selective, next-generation RET inhibitor overcoming adaptive drug resistances.

Shaomei Zeng[1], Jing Wang[1], Zanyang Yu[1], Xuezhen Wei[1], Xueyu Li[1], Can Yong[1], Zhiqiang Jia[1], Shuchun Zhao[1], Min Li[1], Liyang Wang[1], Nan Li[1], Zhiqiang Li[1], Yuanqing Tang[2], **Jun Tang**[2]

[1]ScinnoHub Pharmaceutical Co., Ltd., Chengdu, China,[2]Chengdu Brilliant Pharmaceutical Co., Ltd., Chengdu, China

Background: Inhibiting RET kinase is a fundamental therapeutic approach for malignancies related to RET alterations. Despite the remarkable efficacy of pralsetinib and selpercatinib in treating various cancers, resistances due to newly surfacing on-target mutations pose a challenge. The emergence of adaptive mutations at the solvent-front, such as G810C/S/R, coupled with the occurrence of concurrent mutations at both the gatekeeper and solvent front regions, render these medications ineffective. Furthermore, off-target VEGFR2 inhibition can lead to the onset or exacerbation of hypertension, frequently necessitating dose adjustments or termination, consequently hindering cancer treatment outcomes. In response to this urgent challenge, we identified SNH-110, a potent next-generation RET inhibitor.

Methods: The selectivity and activity of SNH-110 were assessed via *in vitro* kinase assays, and its potency was evaluated using modified Ba/F3 cell lines. The *in-vivo* efficacy of SNH-110 was further validated in a variety of RET-driven tumor models.

Results: In a comprehensive analysis of 378 kinases, SNH-110 demonstrated a level of selectivity on par with selpercatinib, but without the concerning interactions with JAKs and VEGFR2. In cellular proliferation tests, SNH-110 exhibited robust inhibition of a range of Ba/F3 cell lines expressing various RET mutations. The IC_{50} values indicated a significant enhancement over selpercatinib, particularly in activities related to G810 mutations. Notably, SNH-110 displayed almost 100-fold selectivity against VEGFR2 in a cellular assay, a non-RET target associated with hypertension. At the anticipated effective concentration, SNH-110 showed no inhibitory effects on JAKs, suggesting a reduced risk of lung infection side effects compared to pralsetinib. SNH-110 demonstrated impressive anti-tumor efficacy across various RET-based models. Administered in doses from 0.1 to 3 mg/kg, SNH-110 significantly reduced tumor growth in various murine models, with inhibition rates between 85-146%. In the Ba/F3 KIF5B-RET G810R model, a 3 mg/kg dose of SNH-110 resulted in an exceptional 99% tumor growth inhibition. It's worth highlighting that SNH-110's effectiveness in controlling tumor proliferation increased with the dose across these models.

Conclusions: SNH-110 stands out as a powerful contender in the field of next-generation RET inhibitors. It showcases impressive efficiency in both *in vitro* and *in vivo* studies, working against a broad array of RET mutations. Importantly, it effectively combats resistance prompted by solvent front mutations, while retaining selectivity over JAKs and VEGFR2. Its remarkable potency allows for a daily dosage as low as single-digit milligrams to be effective in humans, as indicated by animal efficacy models. A submission of an IND application to the FDA and NMPA is planned for 2025.

#5612 Taletrectinib, a next generation selective ROS1 inhibitor, inhibits growth of ROS1 wild-type and ROS1-G2032R xenografts.

H. K. Patel, L. Heller, K. Bowman, Z. Hu, Y. Zhang, I. M. Grossi, M. Pan, G. Hattersley;
Nuvation Bio Inc., New York, NY

The ROS1 gene is altered in approximately 2% of non-small cell lung cancer (NSCLC) patients. ROS1 fusions demonstrate ligand independent activity driving cell growth and survival. While several inhibitors for ROS1 have been FDA approved, including crizotinib, entrectinib and, more recently, repotrectinib, each present unique challenges. Resistance mechanisms such as secondary kinase-domain mutations including ROS1-G2032R can limit the efficacy of crizotinib and entrectinib, while repotrectinib can cause central nervous system (CNS) adverse reactions including dizziness, ataxia and cognitive impairment that have been attributed to inhibition of the tropomyosin receptor kinase B, TRKB. Therefore, a need remains for more tolerable and effective treatment options for ROS1 positive cancers.Taletrectinib is an oral, potent, selective and CNS-active next-generation ROS1 inhibitor specifically designed for the treatment of patients with ROS1-positive NSCLC**.** Herein, we describe taletrectinib and its activity in multiple in vitro and in vivo ROS1 fusion tumor models. Additionally, the antitumor activity of taletrectinib in comparison to other ROS1 inhibitors is examined. Taletrectinib exhibits selectivity for ROS1 over other kinases, including TRKB. Taletrectinib exhibits in vivo activity in models harboring ROS1 wild-type (ROS1-CD74, ROS1-SLC34A2) and ROS1-G2032R resistance mutation fusions (ROS1 G2032R-CD74, ROS1 G2032R-SLC34A2). Moreover, taletrectinib prolonged survival (>70 days) of mice implanted intracranially with a ROS1 fusion xenograft model. Our nonclinical data illustrates that taletrectinib has a profile which exhibits efficacy in ROS1 wild-type-, and mutant-driven cancers while maintaining selectivity against TRKB, resulting in an overall favorable profile. Taletrectinib is being evaluated in patients with locally advanced or metastatic ROS1-positive NSCLC in two Phase 2 single-arm pivotal studies: TRUST-I (NCT04395677) in China, and TRUST-II (NCT04919811), a global study. Based on the integrated analysis of the TRUST-I and TRUST-II clinical studies, an NDA has been submitted for taletrectinib to the U.S. FDA for the treatment of patients with locally advanced or metastatic ROS1-positive NSCLC.

#5613 TQB3002: A potent fourth-generation small molecule EGFR-TKI.

Xun Chen, Lihua He, Xin Tian, Fei Liu, Hongjiang Xu, Ling Yang, Wei Zhao, Xiquan Zhang

Chia Tai Tianqing Pharmaceutical Group Co., Ltd., Nanjing, China

Purpose: EGFR-TKIs have become important targeted therapies for patients with EGFR mutation-positive advanced NSCLC. However, EGFR-TKI resistance, particularly the C797S mutation resulted from the use of third-generation EGFR-TKI therapy, presents clear clinical and scientific concern. Therefore, novel EGFR-TKIs that can effectively inhibit triple mutations are urgently needed. Our clinical candidate, TQB3002, can effectively inhibit EGFR single/double/triple mutations.

Method: The HTRF method was used to test the kinase inhibition activities of TQB3002 against $EGFR^{WT}$, $EGFR^{d746\text{-}750}$, $EGFR^{L858R}$, $EGFR^{d746\text{-}750/T790M}$, $EGFR^{L858R/T790M}$, $EGFR^{d746\text{-}750/T790M/C797S}$ and $EGFR^{L858R/T790M/C797S}$. The anti-proliferative activities of TQB3002 were measured in cell lines including PC-9 ($EGFR^{d746\text{-}750}$), NCI-H3255 ($EGFR^{L858R}$), NCI-H1975($EGFR^{L858R/T790M}$), 32D ($EGFR^{d746\text{-}750/T790M/C797S}$, $EGFR^{L858R/T790M/C797S}$), ect. The anti-tumor activities of TQB3002 were studied in animal models, including five CDX models of PC9($EGFR^{d746\text{-}750}$), 32D($EGFR^{d746\text{-}750/T790M}$), NCI-H1975($EGFR^{L858R/T790M}$) and triple mutations PC9($EGFR^{d746\text{-}750/T790M/C797S}$) and 32D ($EGFR^{L858R/T790M/C797S}$), as well as in two Osimertinib-resistant PDX models.

Results: TQB3002 potently inhibited the kinase activities of EGFR single and double mutations, with IC_{50} of 0.01 - 0.12 nM, which was 4 - 12 times better than that of Osimertinib. It had extremely potent inhibitory activities against the C797S mutant kinases which were resistant to Osimertinib, with IC_{50} of 0.01 - 0.093 nM. In EGFR triple mutant cell lines, TQB3002 had strong inhibitory activities with IC_{50} of 0.05 - 0.42 nM. In EGFR single/double mutant cell lines, it also showed superior or equivalent inhibitory activities compared with Osimertinib. In animal models of EGFR single/double/triple mutations, TQB3002 dose-dependently inhibited tumor growth with good animal tolerance. In the EGFR triple-mutation PDX model, TQB3002 could achieve tumor regression at a lower dose (15 mg/kg) compared with other fourth-generation EGFR-TKIs under development.

Conclusion: With a clearly differentiated chemical structure, TQB3002 has shown strong activities both in-vitro and in-vivo against EGFR single/double/triple mutants, and is much more effective against the C797S mutation resistant to third-generation EGFR-TKIs. In addition, TQB3002 has good druggability and supports clinical oral QD dosing. It has good selectivity in EGFR single/double/triple mutant cells (36.5-fold selectivity over WT), and low risk of DDI and in-vitro cardiotoxicity are also observed in preclinical studies. In the GLP toxicological studies, the toxicity of TQB3002 is comparable to marketed third-generation EGFR-TKIs, with no significant toxicity concerns. IND of TQB3002 has been approved in China and the US, and phase I clinical trial has started in China (NCT06662760).

#5614 Advancing treatment for brain tumors and metastases with brain permeable SHP2 inhibitor I-1000233.

Francesca Puca, Alina Ciammaichella, Danilo Fabbrini, Martina Nibbio, Antonino Cucinotta, Giulio Auciello, Francesco Scalabri, Christian Montalbetti, Alessia Petrocchi, Alessandro Carugo, Carlo Toniatti

IRBM S.p.A., Pomezia, Italy

Background: SHP2, a non-receptor protein tyrosine phosphatase encoded by *PTPN11*, plays a pivotal role as a downstream effector of receptor tyrosine kinases (RTKs) in the MAPK signaling cascade. We report the discovery of I-1000233, a potent and selective SHP2 allosteric inhibitor that is orally bioavailable and penetrates the blood-brain barrier (BBB). This compound holds great potential for treating primary brain tumors and brain metastases associated with dysregulated RTK/RAS/ERK signaling pathways.
Experimental Procedures: Through iterative optimization of the physicochemical and pharmacological properties of a lead compound series, we identified I-1000233 as a SHP2 inhibitor with excellent drug-like characteristics. Preclinical studies included *in vitro* assays to assess potency, *in vivo* pharmacokinetics to confirm BBB penetration, and proof-of-concept studies in orthotopic xenograft models of glioblastoma and brain metastases. Combination studies were conducted using other brain-penetrant agents targeting the MAPK pathway. Additionally, patient-derived glioblastoma stem cell (GSC) models were collected to refine a responder identification (ID) strategy for potential application in personalized medicine.
Results: I-1000233 demonstrated potent *in vitro* inhibition of SHP2 activity (IC50 = 2 nM) with prolonged target residence time. *In vivo*, the compound exhibited strong anti-tumor activity in orthotopic glioblastoma and brain metastasis models, both as a monotherapy and in combination with other brain-permeable inhibitors, underscoring its versatility and potential for combination treatment regimens. Moreover, I-1000233 showed efficacy not only in targeting tumor cells bearing EGFR/RAS/MAPK mutations but also in modulating the tumor microenvironment (TME), enhancing the overall anti-tumor response. Further studies using patient-derived GSC models were conducted to identify biomarkers predictive of response, facilitating the development of precision medicine approaches for SHP2-targeted therapies.
Conclusions: I-1000233 is a potent, selective, and orally available SHP2 inhibitor with demonstrated efficacy in preclinical models of primary brain tumors and metastases. Its ability to penetrate the BBB, modulate the tumor microenvironment, and provide combinatory potential with other agents highlights its promise as a therapeutic candidate for treating SHP2-responsive brain cancers.

#5615 ALRN-0192519 is a potent and selective EGFR L858R mutation inhibitor that demonstrates anti-cancer activity in preclinical cancer models as monotherapy or in combination with osimertinib.

Jiaqi Liang[1], Yezhen Zhang[1], Lisha Xie[1], Jihong Chen[1], Xipan Liu[1], Wenheng Liang[1], Tingru Zhou[1], Xiaobin Zhang[2], Tao Ji[2], David Pirovich[2], Xiang Zhai[2], Yipin Lu[2], Ming Yu[2], John Campbell[2], Fang Li[2], Yaoyu Chen[2], **Lina Gu**[2]

[1]Allorion Therapeutics, Guangzhou, China,[2]Allorion Therapeutics, Natick, MA

Epidermal growth factor receptor (EGFR) therapy with small-molecule tyrosine kinase inhibitors (TKIs) is initially effective in patients with EGFR-mutant lung cancer, but resistance to the treatment typically emerges over time. EGFR allosteric inhibitors bind to a distinct site on the EGFR protein, separate from the ATP-binding site targeted by existing EGFR TKIs, offering a potential strategy to overcome resistance associated with EGFR mutations. Here we report the development and preclinical characterization of ALRN-0192519, a novel, orally bioavailable small molecule mutant-selective allosteric EGFR inhibitor. In an enzymatic assay, ALRN-0192519 potently inhibits the activity of EGFR carrying L858R mutation with 50% inhibitory concentration (IC50) in the sub-nanomolar range. A very low hit rate is observed when ALRN-0192519 is assessed in kinome profiling, further revealing the selectivity of this compound. ALRN-0192519 exhibits single-digit nanomolar potency against the proliferation of BaF3 cells carrying different EGFR mutations and is more than 400× fold selective against BaF3 EGFR WT cells. In addition, X-ray crystal structure analysis revealed ALRN-0192519 as an EGFR allosteric binder. ALRN-0192519 led to tumor regression in multiple EGFR dependent CDX and PDX tumor models with daily oral dosing, while showing no effects on tumor growth in the EGFR WT xenograft tumor model at comparable dosing levels. When combined with osimertinib, ALRN-0192519 delayed the tumor regrowth much longer than osimertinib alone, demonstrating the potential advantage of combination therapy. Taken together, these results support that ALRN-0192519 is a promising EGFR allosteric inhibitor for treating lung cancer patients with the EGFR L858R mutation as either monotherapy or in combination with osimertinib.

#5616 Crystal structure of drug-resistant ROS1 G2032R in complex with zidesamtinib, a clinical-stage ROS1 inhibitor with best-in-class potential.

Joseph M. Magrino, Anupong Tangpeerachaikul, Henry Pelish, Scot Mente

Nuvalent, Cambridge, MA

Introduction. *ROS1* fusions are recurrent oncogenic drivers in non-small cell lung cancer (NSCLC). Tyrosine kinase inhibitors (TKIs) crizotinib, entrectinib, and repotrectinib are FDA-approved for treatment of *ROS1*-positive NSCLC. Approximately 40% of patients progressing on crizotinib harbor the ROS1 G2032R resistance mutation, which is thought to sterically clash with and reduce the activity of many ROS1 TKIs. To address this and other medical needs, zidesamtinib was designed to 1) maintain activity for ROS1 and ROS1 resistant mutants, including G2032R; 2) be brain-penetrant, given the high incidence of brain metastases in ROS1-positive NSCLC; and 3) avoid TRK-family kinases, including TRKB, whose inhibition is associated with neurological toxicity. Here, we disclose the first known crystal structure of ROS1 G2032R, solved in complex with zidesamtinib. Analysis of this structure, combined with computational simulations, provides a molecular explanation for zidesamtinib's high affinity and selectivity for this drug-resistant ROS1 mutant.

Methods. ROS1 G2032R was expressed in Sf9/Sf21 cells, purified via standard nickel chromatography, and crystallized in the presence of zidesamtinib via sitting-drop diffusion methods. Using our and other crystal structures, free-energy perturbation (FEP) calculations were conducted with the Schrodinger-Maestro software to predict affinity changes caused by the ROS1 G2032R mutation for various ROS1 TKIs.

Results. We solved a 2.2 Å crystal structure of ROS1 G2032R in complex with zidesamtinib. The aminopyridine moiety of zidesamtinib forms key hinge interactions with the E2027 - M2029 backbone. There is no apparent steric clash between zidesamtinib and R2032—a feature thought to underlie affinity loss for many prior ROS1 TKIs. FEP calculations predicted affinity changes caused by the G-R mutation for various ROS1 TKIs that correlate well with biochemical inhibition data, with zidesamtinib showing the smallest experimental potency shift between ROS1 and ROS1 G2032R. Our modeling also suggests a steric clash between zidesamtinib and TRKA Y591, providing a rationale for selectivity for ROS1 over TRK-family kinases.

Conclusion. Analysis of our ROS1 G2032R crystal structure and FEP modeling provide a structural explanation for how ROS1 G2032R impairs the binding of many ROS1 TKIs while maintaining high sensitivity to zidesamtinib. The data presented here, together with previously disclosed preclinical and clinical data, support our design of zidesamtinib as a differentiated ROS1 TKI with best-in-class potential for the treatment of ROS1-positive NSCLC.

#5617 Development of an initial triple combination therapy targeting EGFR, AXL, and FGFR for EGFR-mutated non-small cell lung cancer.

Ryota Nakamura[1], Tadaaki Yamada[2], Tomoko Yasuhiro[3], Ryohei Kozaki[3], Koichi Takayama[2]

[1]Japanese Red Cross Kyoto Daini Hospital, Kyoto, Japan,[2]Kyoto Prefectural University of Medicine, Kyoto, Japan,[3]Ono Pharmaceutical Co., Ltd., Osaka, Japan

Background: Based on our prior preclinical research, a clinical trial is currently underway to assess the safety and efficacy of combining the third-generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) osimertinib with the AXL inhibitor ONO-7475 in treatment-naive patients with advanced EGFR-mutated non-small cell lung cancer (NSCLC) in Japan (jRCT2051210045). However, even with this combined treatment, the development of acquired resistance is expected in clinical settings. Therefore, we aimed to establish a multidrug combination therapy from the first-line setting to eliminate such resistance.
Methods: We investigated adaptive resistance mechanisms to the combination of osimertinib and ONO-7475 and developed a novel therapeutic strategy to overcome them using in vitro and in vivo experiments.
Results: In an siRNA screening assay, knockdown of fibroblast growth factor receptor 1 (FGFR1) significantly inhibited cell viability in the presence of osimertinib plus ONO-7475. The combination of osimertinib and ONO-7475 activated FGFR1 through the upregulation of FGF2 via the c-Myc pathway. In cell-based assays, triple combination therapy with the pan-FGFR inhibitor BGJ398, along with osimertinib and ONO-7475, significantly enhanced cell apoptosis by increasing the proapoptotic factor Bim and inhibited cell viability compared to the combination of osimertinib and ONO-7475 alone. In cell line-derived xenograft (CDX) models, the combination of osimertinib, ONO-7475, and BGJ398 substantially suppressed tumor regrowth. No apparent adverse effects were observed during this treatment.
Conclusions: Our findings demonstrate that the FGF2-FGFR1 signaling pathway contributes to adaptive resistance to the combination of osimertinib and ONO-7475 in EGFR-mutated NSCLC with high AXL expression. The triple combination therapy of osimertinib, ONO-7475, and BGJ398 showed safety and prevented tumor regrowth in CDX models, suggesting that this regimen has the potential to improve outcomes for patients with EGFR-mutated NSCLC.

#5619 An oral BTK degrader TGRX-3911 overcomes resistance conferred by kinase-proficient and kinase-impaired mutations.

Yanxia Shi, Linxin Li, Fengli He, Li Hu, Xiangyu Hong, Tingting Yan, Shuzhen Jiang, Yingying Zuo, Haoran Tang, Yuanpeng Shen, Huanyin Li, Yixin Ai, **Yihan Wang**

Shenzhen TargetRx, Inc., Shenzhen, China

As a key component of the B-cell receptor (BCR) signaling complex, Bruton's tyrosine kinase (BTK) plays an essential role in B-cell malignancies via both kinase and non-kinase functions. This was revealed by early genetic studies and the emerging kinase-impaired mutations, which activate BCR signaling via intricate protein-protein interactions, conferring resistance to a range of covalent or non-covalent BTK inhibitors (BTKi). Therefore, a new targeting strategy is urgently needed for patients who acquired kinase-impaired mutations of BTK. Targeted protein degradation is a potential and powerful means to modulate the non-catalytic functions. TGRX-3911 is a heterobifunctional molecule that promotes ubiquitination and proteasomal degradation of BTK. In a diffuse large B cell lymphoma (DLBCL) cell line TMD8 featuring chronic active BCR signaling, TGRX-3911 induced rapid (4h) and potent degradation of wildtype (WT) and knock-in mutant BTK proteins including the kinase-proficient C481S and T474I, the kinase-impaired L528W and V416L, and even the compound mutants C481S/T474I, C481S/L528W and T474I/L528W, with DC_{50} < 1 nM and near 100% D_{max}. Functionally, in Ramos cells expressing WT or knock-in C481S, T474I, V416L or L528W mutant BTK, TGRX-3911 diminished anti-IgM induced phosphorylation of BTK (excluding V416L and L528W) and PLCγ2, and strongly blocked Ca^{2+} flux. TGRX-3911 also reduced surface CD86 expression in TMD8 cells, as well as in C481S, T474I, V416L and T474I/C481S mutant cells. These results confirm that degradation of BTK induced by TGRX-3911 abolishes the BCR signaling pathway. TGRX-3911 potently inhibited proliferation of TMD8 parental cells and those harboring knock-in BTK mutations that are resistant to currently approved ibrutinib, zanubrutinib and/or pirtobrutinib, including C481S, T474I, L528W, V416L, A428D, T474I/C481S, T474I/L528W and C481S/L528W (IC50 from 0.4 to 9.9 nM). Remarkably, TGRX-3911 potently inhibited the A428D mutant which is still resistant to current BTK degraders, NX-5948, BGB-16673 and ABBV-101. It also demonstrated higher potency against the T474I/L528W compound mutant. *In vivo*, oral dosing of TGRX-3911 led to tumor shrinkage in a mantle cell lymphoma (MCL) REC-1 xenograft model expressing BTK-C481S, and the effect was superior to pirtobrutinib. No sign of toxicity was observed. In summary, TGRX-3911 has potent and robust degradation activity and effectively suppresses the BCR signaling pathway. It has potent anti-proliferation activity against kinase-proficient, -impaired and even compound mutants of BTK, and has *in vivo* anti-tumor activity. By eliminating both the catalytic and scaffold functions of BTK, TGRX-3911 has the potential to overcome clinical resistance which can hardly be achieved by conventional BTKi. The potential clinical application of TGRX-3911 for patients with B-cell malignancies is worth exploring.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 3
Poster Session

#5623 Identification of CGT4255 an EGFR sparing, pan-mutant HER2 clinical development candidate with potential best-in-class brain penetration.

Mark J. Chicarelli, Tanna Bettendorf, Abiezer Blandon, Karyn Bouhana, Richard K. Brizendine, LouAnn Cable, Michelle Crow, Brad Fell, John Fischer, Jennifer Fulton, Anna Guarnieri, Leyla Haygood, Maddie Hillman, Ravi Jalluri, Vijay Kumar, Cori A. Cogent Biosciences, Boulder, CO

HER2 alterations such as amplification, overexpression, insertions, and point mutations, are established oncogenic drivers in many solid tumors. Activating HER2 mutations are found in 2-4% of advanced lung cancers and have emerged as mechanisms of acquired resistance to targeted therapies. Patients with HER2 mutant lung tumors develop more brain metastasis during treatment than patients with any other oncogenic drivers in lung cancer. Addressing brain metastasis in this group of patients remains a clinical challenge with limited therapeutic options. Approved HER2 tyrosine kinase inhibitors have inferior potency against key mutations and lack sufficient brain penetration to be an impactful treatment option for patients with brain metastasis. Herein, we describe advanced preclinical profiling of an EGFR-sparing, HER2 inhibitor clinical development candidate CGT4255 with potential best-in-class brain penetrance and potent activity across prevalent point mutations and exon 20 YVMA insertions. CGT4255 demonstrates robust efficacy in intracranial tumor growth inhibition studies and shows an additive effect on intracranial tumor shrinkage when combined with a HER2 ADC. Pre-clinical studies with the CGT4255 and T-DXd combination demonstrate enhancement of ADC internalization, thus highlighting a biological rationale for combination therapy.

#5624 The antiviral, Daclatasvir, disrupts ASCL1-EZH2 signaling and impairs survival of neuroendocrine prostate cancer cells.

Rohith Guddeti, Jitender Monga, Craig Rogers, Dhananjay Chitale, Shirish Gadgeel, Jagadananda Ghosh

Henry Ford Health System, Detroit, MI

Management of neuroendocrine prostate cancer (NEPC) is extremely difficult not only because available therapeutic regimens cannot effectively kill NEPC cells but also due to the aggressive, highly metastatic nature of NEPC cells to invade distant organs. Development of effective therapeutic agents for NEPC is urgently needed but is suffering from lack of proper understanding about critical and selective molecular targets. Recent molecular analyses revealed that the pseudokinase, Tribbles 2 (TRIB2), is consistently overexpressed both in the treatment emergent as well as *de novo* NEPC cells and tumors and plays a critical role in the survival and maintenance of neuroendocrine characteristics in NEPC cells. Daclatasvir (DCV), an FDA-approved antiviral agent, was found to directly bind and destabilize TRIB2 protein and prime it for degradation via activation of proteasomes. However, the extent to which DCV impacts the viability and lineage characteristics in NEPC cells remain unclear. We report here that DCV inhibits the growth and survival of NEPC cells by inducing caspase-mediated apoptosis. Mechanistically, DCV disrupts the TRIB2 downstream signal transduction cascade which involves the proneuronal transcription factor, Achaete-scute homolog 1 (ASCL1) and the epigenetic regulator, Enhancer of zeste homolog 2 (EZH2). Interestingly, inhibition of the ASCL1-EZH2 signaling axis by DCV showed an increase in the protein level of the androgen receptor (AR). Moreover, we found that DCV at lower, sub-lethal doses synergize with AR inhibitors, such as enzalutamide, to enhance NEPC cell death, suggesting improved efficacy of these two classes of anticancer agents in combination. Since DCV is well-tolerated in humans, and is approved for treatment of viral hepatitis, our findings position DCV as a promising therapeutic agent for NEPC, a highly aggressive, drug-resistant subtype of prostate cancer with extremely limited therapeutic options.

#5625 EphB4 agonist B4-007 was effectively against high-grade serous ovarian cancer (HGSC) as a single agent in cell-based and patient-derived xenograft models.

Qiu-Xu Teng, Chiyi Xiong, Ping Pan, Thanh Chung Vu, Yunfei Wen, **Chun Li**

UT MD Anderson Cancer Center, Houston, TX

Introduction: This study aimed to assess the therapeutic potential and molecular mechanisms of B4-007, an agonist peptide with high binding affinity (Kd = 7.0 nM) to EphB4, a receptor tyrosine kinase implicated in cancer progression and angiogenesis, in preclinical models of high-grade serous ovarian cancer (HGSC).
Methods: EphB4-agonistic activity of B4-007 or its analogues was confirmed by determining tyrosine-phosphorylation levels of EphB4 (p-EphB4) treated with a gradient of B4-007 (500 nM-10 μM) and incubation times (up to 60 minutes). Two orthotopic HGSC models, including a platinum-resistant patient-derived xenograft (PDX2428) model carried by female NOG mice and a human tumor xenograft OVCAR8-ip2-luc carried by female nude mice were used. On 2 weeks after tumor inoculation, B4-007 was injected intraperitoneally (IP) at a dose of 13 mg/kg, 3 times a week for 6 weeks. After 18 doses, all mice were euthanized, and tumor weight and number of tumor nodules in the peritoneal cavity were recorded. For the OVCAR-ip2-luc mouse model, B4-007 was injected via IP at doses of 13 or 52 mg/kg/injection, three times a week for a total of ten doses. Tumor growth was monitored weekly using bioluminescence imaging.
Results: *In vitro*, B4-007 or its analogues induced EphB4 phosphorylation, with maximal phosphorylation observed at 60 minutes at 1.0 μM. Notably, higher concentrations (10 μM) did not yield further increase in p-EphB4 level. *In vivo*, B4-007 demonstrated significant antitumor efficacy in both HGSC models as a single agent. In the PDX2428-NOG model, tumor burden in the B4-007-treated mice was significantly decreased than those in the control mice ($p<0.05$). In the OVCAR8-ip2-luc model, bioluminescence imaging showed that B4-007 at both doses (13 mg/kg and 52 mg/kg) was effective in suppress tumor growth. However, treatment at the higher dose did not provide additional benefit. B4-007 was well tolerated as reflected by stable mouse body weight across each group. These findings underscore the importance of optimizing dosing schedules and suggest that future studies should prioritize lower concentrations (e.g., <13 mg/kg/injection) to determine the minimal effective dose.
Conclusion: B4-007 demonstrated significant anti-tumor efficacy as a single agent without apparent toxicity in orthotopic HGSC models. Our finding has implications for further developing a novel EphB4-targeted therapy to maximize antitumor efficacy and minimize toxicity.

#5626 Exploring a new therapeutic strategy through hyperactivation of the unfolded protein response pathway in bone cancer treatment.

Yoongyeong Lee[1], Michael Mulligan[1], Brooke Bouwens[1], Jenny Drnevich[1], Keith Bailey[2], Michael Spinella[1], David Shapiro[1], Paul Hergenrother[1], Timothy Fan[1]

[1]University of Illinois at Urbana-Champaign, Champaign, IL,[2]Alnylam Pharmaceuticals, Cambridge, MA

Bone cancer is the third leading cause of cancer-related deaths among children and teenagers. Malignant subtypes such as osteosarcoma (OS), Ewing sarcoma (ES), and chondrosarcoma (CS) originate from distinct cell types within the bone. These malignant bone sarcomas pose significant treatment challenges, particularly in cases of relapse or metastasis due to chemoresistance. Therefore, there is a clinical need for newer, effective therapies for recurrent or relapsed disease. This study explores the therapeutic potential of ErSO, a small molecule previously shown to selectively kill estrogen receptor alpha (ERα)-positive breast cancer cells by hyperactivating the unfolded protein response (UPR) and TRPM4. We evaluated anti-cancer activity of ErSO across multiple bone cancer subtypes. Our findings categorized human bone cancer cell lines, including patient-derived xenograft (PDX) cell lines, into ErSO-sensitive and ErSO-insensitive groups. Surprisingly, unlike in breast cancer cells, ErSO sensitivity in bone cancer cells did not correlate with ERα expression. However, ErSO treatment consistently activated ATF6 and PERK in the UPR pathway in ErSO-sensitive OS cell lines. Furthermore, ErSO-induced cytotoxicity was specifically linked to ATF6 activation. Importantly, we discovered that TRPM4 expression on the membrane was a critical determinant of ErSO-induced cell death. Additionally, ErSO-resistant clones derived from ErSO-sensitive OS cell lines consistently showed a reduction in ErSO-induced ATF6 activation and, in some cases, decreased TRPM4 expression. In mouse models of experimental lung metastasis using ErSO-sensitive human OS cells, a single ErSO injection dramatically reduced tumor burden in the lungs. In models with tumor burdens ranging from low to high, ErSO treatment significantly extended survival. In conclusion, ErSO demonstrated potent anti-cancer activity against certain bone cancers via ATF6 activation, acting independently of ERα expression. These effects were particularly dependent on the expression of TRPM4 on the membrane. Our findings highlight the potential anti-cancer activity of ErSO as a therapeutic agent for bone cancer, including advanced cases with lung metastases. Ongoing studies aim to further evaluate the effectiveness of ErSO in models of spontaneous lung metastasis and chemoresistant OS to support its potential for treating late-stage patients.

#5627 Characterization of the Rac inhibitor CPV-337 in metastatic breast cancer.

Jessica Colon Gonzalez[1], Nilmary Grafals Ruiz[1], Anamaris Torres Sanchez[1], Stephanie Dorta Estremera[2], Cornelis Vlaar[3], Suranganie Dharmawardhane[4]

[1]Department of Biochemistry, University of Puerto Rico School of Medicine, San Juan, PR,[2]Department of Microbiology, University of Puerto Rico School of Medicine and Comprehensive Cancer Center, San Juan, PR,[3]Department of Pharmaceutical Sciences, University of Puerto Rico School of Pharmacy, San Juan, PR,[4]Department of Biochemistry, University of Puerto Rico School of Medicine and Comprehensive Cancer Center, San Juan, PR

Rac and Cdc42 are homologous Rho GTPases that act as anticancer and antimetastatic targets regulating cancer progression and metastasis-associated cell functions such as cell survival, cell polarity, proliferation, migration, and invasion. Our lead compound MBQ-167, a dual Rac/Cdc42 inhibitor (IC_{50} of ~100nM; GI_{50} of 130nM), is currently in Phase I clinical trials for advanced triple-negative breast cancer (NCT06075810). By screening a panel of MBQ-167 derivatives to identify molecules with a range of inhibitory mechanisms that address distinct cancer types, we identified CPV-337, with an IC_{50} of ~50nM for inhibiting Rac activation, via pulldown assays to capture the GTP bound Rac, and a GI_{50} of ~55nM for inhibiting the viability of metastatic breast cancer cells, as measured by MTT assays. However, CPV-337 does not affect the viability of human mammary epithelial cells (HMECs), demonstrating non-toxic effects in primary epithelial cells. Additionally, wound healing assays show that CPV-337 reduces breast cancer cell migration by ~50% at 50nM. These data show that CPV-337 is ~2.5X more effective than MBQ-167. We then compared the efficacy of CPV-337 and MBQ-167 in nude mice with orthotopic tumors established from green fluorescent protein-tagged metastatic HER2-positive breast cancer cells. Results demonstrate that CPV-337 administered at 5mg/kg Body Weight (BW) parallels MBQ-167 treatments of 10mg/kg Body Weight (BW) at 5X a week for 2 months. Compared to the vehicle, both CPV-337 and MBQ-167 reduced tumor growth by ~90-95%, from quantification of the integrated density of fluorescent tumors for 62 days. Lung metastases were inhibited by ~50% in CPV-337 treated mice, and both compounds inhibited liver and kidney metastases by ~95%. At necropsy, blood was collected, and whole blood was analyzed by flow cytometry for the phosphorylated form of the Rac and Cdc42 downstream effector p21-activated kinase (p-PAK), using a fluorescent anti-p-PAK^{T423}antibody, as a measure of Rac activation inhibition. CPV-337 inhibited PAK activation significantly by 37.4%, compared to vehicle. Interestingly, a significant increase in M1 anti-tumorigenic macrophages was observed in splenocytes of mice treated with CPV-337, implicating CPV-337 in the anticancer immune response. Further evaluation of CPV-337's inhibitory mechanism, toxicity, bioavailability, and Rac/Cdc42 regulated processes in the tumor microenvironment are warranted to translate this promising anticancer compound to the clinic.

#5629 TEQ103, a novel therapeutic for the treatment of estrogen receptor alpha positive (ERα+) breast cancer.

Marie-Christine Bissery[1], Eef Hoeben[2], Elisabeth Bertrand[3], Sylvie Maubant[3], Maeva Albanese[3], Olivier Duchamp[3], Isabelle St-Jean[4], Mads K. Dalsgaard[1]

[1]Oncoteq AG, Cham, Switzerland,[2]eScienceQPS, Tongerlo, Belgium,[3]Oncodesign Services, Dijon, France,[4]Universite de Montreal, Montreal, QC, Canada

Background: Breast cancer is the most prevalent female cancer. Approximately 75% of them are ERα+ and are treated with ERα targeting agents. However, a good portion will ultimately relapse. TEQ103 (Sera2, ErSO-TFPy) is a first-in-class small molecule acting through the anticipatory unfolded protein response (aUPR) following dysregulation of calcium homeostasis in ERα+ tumor cells. The goal of this work is to further evaluate the efficacy, the influence of schedules of administration and the pharmacokinetics (PK) of TEQ103.

Methods: TEQ103 was evaluated IV in advanced stage human breast adenocarcinoma MCF-7 implanted in athymic female mice. Mice with approximately 500mm^3 tumors were randomized and 2 schedules evaluated, daily x 10, (0, 1, 2, 4, 15 & 30mg/kg/injection), and intermittent on day1 & 10, (1, 5, 20, 75 & 150mg/kg/injection), 9 mice/group. Tumors were measured with a caliper and efficacy endpoints included tumor growth delay (TGD), complete regressions (CR), and Tumor Free Survivors (TFS). PK evaluation was performed post one IV administrations at 5, 20 & 75mg/kg (6 mice/ dose) over 8 hours in plasma, at 4 and 8h post injection in tumors, and at a late 10 day sampling in both matrices. Plasma and tumor concentrations were measured using LC-MS/MS SCIEX QTRAP 6500+ and PK parameters in plasma were determined using noncompartmental methods (Kinetica Software v5.1).

Results: TEQ 103 was found highly active in MCF-7 tumor bearing mice with a large therapeutic index. With the daily schedule, the lowest active dose was 2mg/kg/injection (i.e., 20mg/kg total dose (TD)) with 2/9 TFS and 44 days TGD for the 7 relapsing mice. With the intermittent schedule, the lowest active dose was 5mg/kg/injection (10mg/kg TD) with 4/9 TFS and 56 days TGD for the 5 relapsing mice. At total dosages equal and above 40mg/kg TD, both schedules lead to 100% TFS (CRs lasted 121 days post tumor induction). This indicates that TEQ103 is schedule independent. Overall TEQ103 was well tolerated and did not induce body weight loss in the dose ranges studied. PK profiles in plasma showed biphasic kinetics of TEQ103 in MCF-7 bearing mice. The C_{max} and $AUC_{0\text{-}8h}$ increase was approximately dose-proportional over the dose range studied. The 4h concentrations in plasma and tumor at 5, 20 and 75 mg/kg were 7.25, 16.7 and 178 ng/mL and 582, 1796 and 5709 ng/g, respectively. There was a very good tumor retention with levels of TEQ 103 detectable 10 days post treatment with 75mg/kg dose.

Conclusion: These results demonstrate the significant durable antitumor effect of TEQ103 driven by the total dose administered regardless of schedule of administration, the wide therapeutic index and the concentration in the tumor tissue at levels markedly above the nM IC50 reached in vitro. These studies form the basis for PKPD Tumor Growth Inhibition modeling that will be used for projection of an efficacious starting dose in a subsequent breast cancer patients' phase 1 clinical trial.

#5630 Ecubectedin as a promising therapeutic agent against gastric cancer through WNT/β-Catenin modulation.

Alejandro Losada, Marta Martinez Diez, Eugenio Bustos-Moran, Ismael Fernandez-Miranda, Maria Jose Guillen, Pablo M. Aviles, **Marcelo Lima Ribeiro**, Carmen Cuevas

Pharma Mar, S.A., Madrid, Spain

Gastric cancer continues to be a major global health challenge due to its high mortality rate, with over half of patients showing significant dysregulation of the WNT/β-catenin pathway. Ecubectedin, a novel transcriptional inhibitor, has shown potent antiproliferative effects across several solid tumors. The aim of this study was to characterize the molecular effects of ecubectedin in gastric cancer, both in vitro and in vivo, focusing on transcriptomic analysis of key regulatory pathways. Ecubectedin´s antineoplastic activity was evaluated through MTT assays in a representative panel of 15 gastric cancer cell lines. Eight cell lines were chosen to assess the effects of ecubectedin on the transcriptome following a 6-hour exposure to 50 nM. Ecubectedin´s in vivo antitumor effects were evaluated in HGC-27 xenograft mouse models. Ecubectedin demonstrated potent antitumor activity in vitro, with GI_{50} values in the low nanomolar range (from 0.3 to 8 nM). Ecubectedin exerts a potent effect as a transcription inhibitor, leading to significant repression of 2,775 genes. Gene set enrichment analysis revealed that Ecubectedin disrupted key signaling pathways, especially WNT/β-catenin. At the protein level, Ecubectedin (50 nM) modulated the WNT/β-catenin pathway and inhibited TCF/β-catenin-mediated transcription. In vivo, a single i.v. dose of Ecubectedin (0.6 mg/kg) inhibited tumor growth by 61% after 7 days in both RNA-seq and in vivo protein data (from tumors in ecubectedin-treated mice) support that ecubectedin represses WNT/β-catenin signaling. In conclusion, ecubectedin shows strong antitumor activity against gastric cancer, modulating the often-dysregulated WNT/β-catenin pathway, highlighting its potential as a promising therapeutic for further clinical exploration.

#5631 ZSTK3744, a novel AhR agonist, demonstrates antitumor efficacy in TNBC cell lines *in vitro* and *in vivo*.

Kayoko Kawai-Asami[1], Takahiro Ohashi[2], Sayuri Terada[2], Kotomi Akatsuka[2], Yuko Nagata[1], Shinsuke Hiramoto[2], Tsubasa Nagasaki[3], Eika Higashi[3], Ryuichiro Ohshita[3], Keiko Fukushima[2]

[1]Pharmacology, Department of Drug Discovery, R&D Center, Zenyaku Kogyo Co., Ltd., Tokyo, Japan,[2]Biosciences, Department of Drug Discovery, R&D Center, Zenyaku Kogyo Co., Ltd., Tokyo, Japan,[3]Organic Synthesis, Department of Drug Discovery, R&D Center, Zenyaku Kogyo Co., Ltd., Tokyo, Japan

Background: Breast cancer is the most commonly diagnosed cancer among women worldwide. Triple-negative breast cancer (TNBC) is the most aggressive form of breast cancer and has limited treatment options. TNBC lacks key molecular targets, making it challenging to treat with conventional therapies and limiting the availability of effective treatment options. Herein, we report a novel small molecule, ZSTK3744, which exhibits potent inhibitory effects on the proliferation of TNBC-derived cell lines both *in vitro* and *in vivo*.
Method: We found a compound, ZSTK3744, that exhibits potent antitumor effects against the TNBC-derived cell line MDA-MB-468. We employed DNA microarray analysis and CRISPR-Cas9 technology to determine the molecular targets of ZSTK3744. Mechanistic studies were performed to evaluate ROS generation, DNA damage, and intracellular signaling pathways in ZSTK3744-treated cells. *In vivo*, ZSTK3744 was administered at a dose of 2.5 mg/kg every four days (days 0, 4, and 8) via tail vein injection in an MDA-MB-468 xenograft model. Tumor size and body wight were measured until day 28. In addition, safety was evaluated in dogs with weekly dose escalation to assess tolerability.
Results: ZSTK3744 exhibited potent antitumor activity (GI_{50}: 0.69 nM) against MDA-MB-468 cells. Target analysis identified ZSTK3744 as an aryl hydrocarbon receptor (AhR) agonist and demonstrated that AhR is essential for its growth-inhibitory effects. ZSTK3744 induced ROS generation, DNA damage, and apoptosis in MDA-MB-468 cells in a dose-dependent manner. *In vivo*, ZSTK3744 demonstrated significant anti-tumor activity, reducing tumor size from baseline and maintaining this reduction throughout the 3-week post-administration observation period. Importantly, ZSTK3744 treatment did not adversely affect the body weight of treated mice. In contrast to aminoflavone, a previously developed AhR agonist associated with severe lung toxicity, ZSTK3744 showed no evidence of lung toxicity in dog studies.
Conclusion: ZSTK3744 demonstrated potent antitumor effects on TNBC-derived cells *in vitro* and *in vivo*, as well as having a favorable safety profile. These results suggest that ZSTK3744 is suitable for development as a novel therapeutic agent for TNBC. Ongoing studies are needed to identify biomarkers that predict response to ZSTK3744.

#5632 HDM2006, A novel and potent HPK1 PROTAC, enhances immune cell activation and induces robust tumor growth inhibition.

Liubin Guo, Zhimin Zhang, Xi Yang, Rongyao Zhu, Zhiping Zhang, Sirui Liu, Hao Pan, Zhao Dong, Chunhua Jiang, **Dongzhou Liu**

Global Drug R&D Center, Huadong Medicine, Hang Zhou, China

Background: HPK1 (Hematopoietic Progenitor Kinase 1) is a member of the MAP4K family, which is a group of kinases that catalyze the phosphorylation of serine or threonine residues in proteins. HPK1 is mainly expressed in hematopoietic and immune cells. Loss of HPK1 kinase function increases cytokine secretion, enhances T cell signaling, viral clearance, and tumor growth inhibition. Therefore, HPK1 is considered as a promising target for tumor immunotherapy. Currently, there are several small molecule inhibitors targeting HPK1 in clinical trials, which only inhibit the kinase activity of HPK1, and cannot completely block its downstream signal transduction, and have low selectivity and poor safety. Therefore, we developed a proteolysis targeting chimera (PROTAC) drug, HDM2006, that specifically targets HPK1 while inhibiting HPK1 kinase activity and deleting its skeletal function, and has better efficacy and safety than small molecule inhibitors. The robust monotherapy and combined with anti-mPD-1 efficacy of HDM2006 makes it a IO drug and also a new option for patients with advanced tumors.
Methods: TR-FRET assay were utilized to assess the target binding activity and ternary complex formation activity. Western blot was utilized to investigate the degradation activity of HDM2006 in human T lymphoma Jurkat cells. The effect of HDM2006 on the secretion of IL-2 and IFN-γ by human Pan-T cells was detected by ELISA. *In vivo* anti-tumor efficacy of HDM2006 monotherapy and combined with anti-mPD-1 was evaluated in murine colorectal cancer MC38 cell allograft models. Oral-bioavailability and repeat-dose GLP toxicity studies were profiled in rats and cynomolgus monkeys.
Results: HDM2006 bound to human HPK1 and E3 ubiquitin ligase CRBN, and formed a ternary complex. Meanwhile, HDM2006 targeted and degraded HPK1 in Jurkat cells, with a DC_{50} of 20.68 nM and a D_{max} of 96.36% (24 h). HDM2006 did not degrade other CRBN substrates, avoiding IMiDs off-target effect. HDM2006 can stimulate hPBMCs to secrete IL-2 and IFN-γ, the maximum activation fold can be more than 9.3-41.6 folds. Furthermore, immune activation upon HPK1 degradation was observed even in immune-suppressed environments (PGE2, adenosine, and T cell exhaustion). *In vivo*, HDM2006 showed efficacy in mouse colorectal cancer model in mono and in combination with anti-mPD-1, and TGI was similar to the small-molecule inhibitor at very low dose. In addition, the results of GLP toxicity studies in rats and cynomolgus monkeys indicated that HDM2006 has a large safety margin, and the NOAEL dose exposure was approximately 435.9-fold and 21.4-fold of the optimal effective dose exposure.
Conclusions: HDM2006 is a novel, potent, highly selective and orally active PROTAC targeting HPK1. Preclinical studies have confirmed that HDM2006 has excellent profile for druggability, safety, and efficacy. HDM2006 has entered the clinical Phase 1 trial.

#5633 Rewiring cancer drivers to induce apoptosis in chronic lymphocytic leukemia.

Weiguo Han[1], Aisharya Bhattacharya[1], Basel Karim[2], Wenzhi Ji[2], Roman C. Sarott[2], Meredith Nix[2], Sai Gourisankar[2], Andrey Krokhotin[3], Sutapa Sinha[1], Zhiquan Wang[1], Tait D. Shanafelt[4], Sameer A. Parikh[1], Nathanael S. Gray[2], Gerald R. Crabtree[3], Neil E. Kay[1]

[1]Hematology, Mayo Clinic, Rochester, MN,[2]Chemical and Systems Biology, Stanford University, Stanford, CA,[3]Pathology, Stanford University, Stanford, CA,[4]School of Medicine, Stanford University, Stanford, CA

Chronic lymphocytic leukemia (CLL) is one of the most common types of leukemia among adults in the US. Despite significant improvement of current novel agent treatments, CLL remains incurable with many eventually experiencing disease relapse. Therefore, it remains of high interest to expand therapeutic options. Transcriptional chemical inducers of proximity (TCIPs) are a new class of anticancer drugs designed and developed by Stanford teams. These agents recruit cancer drivers or transcription factors to activate proapoptotic genes' expression and kill cancer cells. Current TCIPs are produced by covalently linking small molecules that bind B-cell lymphoma 6 (BCL6) to those that bind to transcriptional activators, such as bromodomain-containing protein 4 (BRD4) (BRD4-BCL6, TCIP1) or cyclin-dependent kinases 9 (CDK9) (CDK9-BCL6, TCIP2). In collaboration with the Stanford teams, we have initiated TCIPs cytotoxicity assessment in primary leukemic cells from untreated CLL patients and found heterogeneous but evident drug responsiveness with a panel of TCIPs. Our current work has shown that TCIP2 demonstrated remarkable killing ability of CLL B cells with IC50 of 9nM in 72-hours (h), while the IC50 of TCIP1 was 560nM. TCIPs showed time and dose-dependent drug-associated killing in primary CLL B cells over a 24-72h interval using a flow cytometry-based apoptosis assay. After 24, 48, and 72h exposure of CLL B cells to TCIPs, the IC50 was 1054, 820 and 555nM for TCIP1, and 9, 8, and 9nM for TCIP2, respectively. TCIP2 is designed and produced by covalently linking BI-3812 (BCL6 inhibitor) as a BCL6 binder and SNS-032 (CDK9 inhibitor) as a CDK9 binder with a rigid linker. Comparing TCIP2 to its negative controls (TCIP compounds with only one active binder, either BCL6 or CDK9), TCIP2 exhibited significant cytotoxicity in primary CLL B cells. TCIP2 also showed a significant increase in potency, compared to SNS-032 and BI-3812 alone at 72h. Normal human peripheral blood mononuclear cells (PBMCs) were 6-fold less sensitive to TCIP2 compared to CLL PBMCs with high percentage of CLL B cells. Immunoblotting data showed induction of BCL6 protein level after 20nM TCIP1 treatment in CLL B cells. In samples from relapsed/refractory (RR) CLL patients, TCIPs maintained good cytotoxicity with IC50 of 1805nM for TCIP1 and 84nM for TCIP2 in 24h using a cell viability assay. Our study indicates that TCIPs targeting BCL6 and BRD4/CDK9 have a strong capacity to induce high levels of cell death in primary CLL B cells. This notable killing effect may be due to its unique gain-of-function drug mechanism where BCL6 is induced. This is the first study of TCIPs ability to target CLL B cells from both untreated and RR patients. Further studies to more fully evaluate the preclinical activity of TCIPs and investigate the molecular mechanism(s) for TCIP mediated killing of leukemic B cells will help to define the potential role of TCIPs as a novel therapeutic approach in CLL.

#5634 Macrocycle drug conjugate NOVO-111 induces ribosome biogenesis stress and is efficacious in colorectal cancer xenografts.

Jonathan Arambula[1], Garrett Kimble[2], Calvin Chau[3], Michael Buszczak[2], Jonathan Sessler[3], Krystle Karoscik[1], Zahid Siddik[4], Adam Sedgwick[5]

[1]InnovoTEX Inc, Austin, TX,[2]University of Texas Southwestern Medical Center, Dallas, TX,[3]University of Texas at Austin, Austin, TX,[4]MD Anderson Cancer Center, Houston, TX,[5]Chemistry, Kings College London, London, United Kingdom

Purpose: NOVO-111 is a novel macrocycle drug conjugate (MDC) comprised of an expanded porphyrin conjugated to a lipophilic Pt(IV) analogue of oxaliplatin. NOVO-111 has been shown to overcome both multifactorial and transport-defective mechanisms of platinum resistance. While platinum agents often induce DNA damage repair pathways, it has recently been demonstrated that certain agents such as oxaliplatin induce ribosomal biogenesis stress (RBS) as its primary anticancer mechanism. To further assess the clinical translational potential of NOVO-111, ribosome functional assays and efficacy studies involving human colorectal cancer (CRC) models were evaluated.
Procedures: HCT116 cells with both copies of RPL28 SNAP-tagged at the endogenous locus were assessed for RBS. HCT116+L28SNAP tagged cells were cultured and SNAP-tagged RPL28 was labeled with benzylguanine. Cells were then incubated with 2.5uM NOVO-111 at variable time points then incubated with benzylguanine Oregon Green, fixed with 4%PFA, labeled with Hoechst and mounted in anti-fade Vectashield media. For a given cell (N=43 cells), the number of Oregon Green spots observed in the nucleus was recorded and analyzed. Athymic Nude-Foxn1nu female mice (8 mice/group), with subcutaneously implanted (flank) patient derived xenografts (PDX) using CTG-0401 and CTG-0066 received maximum tolerated doses of oxaliplatin (6 mg/kg) and NOVO-111 (70 mg/kg) i.v. on days 1, 5, 9, and 13. The body weights and tumor volumes were monitored. Mice that had reached maximum tumor burden were euthanized.
Results: The data indicate NOVO-111 induces RBS in HCT116+L28 SNAP cells. The number of puncta and mean intensity of RiboSNAP signal in the puncta increase with NOVO-111 treatment while puncta size is reduced. NOVO-111 and control oxaliplatin were further evaluated in nude mice bearing CRC PDX tumors. Minimal to no body weight loss was observed for either treatment group. The treatments resulted in tumor growth inhibitions (TGI) of 94% and 62% for NOVO-111 and oxaliplatin for CTG-0066, respectively. Survival >80 days revealed a significant increase in survival for the NOVO-111 treatment group. Treatment of CTG-0401 bearing mice resulted in TGIs of 59% and 18% for NOVO-111 and oxaliplatin, respectively. Survival >80 days revealed that a mere 25% of the oxaliplatin treatment group survived, compared to a survival of 88% for the NOVO-111 treatment group.
Conclusions: Results indicate that NOVO-111 is capable of inducing RBS as a potential anticancer mechanism in human CRC cells. In addition, NOVO-111 was found to induce a statistically significant tumor growth delay and increase survival in CRC PDX models compared to oxaliplatin. These data demonstrate that NOVO-111, as an MDC, has a distinct advantage over the current standard of care for CRC.

#5635 In vivo assessment of a potent TEAD inhibitor in a panel of malignant mesothelioma PDX model.

Loreley Calvet[1], Odette Dos-Santos[1], Emmanuel Spanakis[2], Anne Caron[3], Laurence Noblet[1], Isabelle Sanchez[1], Yvette Ruffin[1], Laurent Dassencourt[1], Philipe Prigent[1], David Machnik[4], Olivier Venier[5], Laurent Debussche[6], Iris Valtingojer[1], Valeria Fantin[7], **Sukhvinder Sidhu**[1]

[1]Oncology, Sanofi, Virtry-sur-seine, France,[2]Precision Oncology Data Science, Sanofi, Virtry-sur-seine, France,[3]Molecular & Digital Histopathology, Sanofi, Virtry-sur-seine, France,[4]Small Molecules Medicinal Chemistry, Sanofi, Virtry-sur-seine, France,[5]Syngene, Bangalore, India,[6]Dlog Consulting, Paris, France,[7]Oncology, Sanofi, Cambridge, MA

There has been a growing interest in understanding the involvement of the HIPPO tumor suppressor pathway and its downstream effector, Yes1-associated transcriptional regulator (YAP1), in the context of cancer. The YAP1-TEAD complex plays a pivotal role in controlling transcription, influencing cell proliferation, survival, adaptability, and cell migration. Abnormal activation of YAP1 has been documented in various cancer types, including Malignant Mesothelioma (MM). To assess the proportion of MM cases in which YAP1/TEAD-dependent transcription contributes to tumor initiation and progression and to evaluate the pharmacodynamic effects of a new TEAD inhibitor (Compound A), we previously established a gene expression signature associated with YAP1 activity. This signature was employed to monitor the level of YAP1 inhibition in three Cell Line Derived Xenografts (CDX) and eight Patient Derived Xenografts (PDX) of malignant mesothelioma, and it was used to further assess the effectiveness of compound A in vivo. Here we present, for the first time, the potent in vivo antitumor properties of the novel TEAD inhibitor, compound A, in all of these models and we confirm the reliability of the YAP1-transcription signature as a biomarker for patient selection and for assessing the pharmacodynamic effects of YAP1-TEAD inhibition.

#5636 SKY-1214, a small molecule splicing modulator of members of the Fanconi anemia pathway, exerts anti-cancer activity both as single agent and in combination in multiple myeloma and non-Hodgkin's lymphoma.

Simone Rauch[1], Stefan Reber[1], Montserrat Perez-Salvia[1], Marco Pregnolato[1], Botao Liu[2], Loren Berry[2], Olesia Buiakova[2], Hasane Ratni[1], Brian Gudenas[2], Carlo Cusulin[1], Lauren Shanahan[1], Davide Isaia[1], Corinna Spohr[1], Anna Groener[1], Joseph Duffy[2], **Steven Taylor**[2], Veronica Costa[1], Sergey Paushkin[2]

[1]Skyhawk Therapeutics, Basel, Switzerland,[2]Skyhawk Therapeutics, Waltham, MA

The growing multiple myeloma (MM) and non-Hodgkin's lymphoma (NHL) patient population which becomes refractory to available treatments requires new, effective and convenient therapies with novel mechanisms of action. SKY-1214 is a small molecule that modulates splicing of FANCL and FANCI pre-mRNA, causing exon skipping and introduction of premature termination codons leading to the downregulation of FANCL and FANCI mRNAs and proteins. FANCL and FANCI are critical components of the Fanconi anemia DNA damage repair pathway, which contributes to maintenance of genomic integrity. SKY-1214 shows anti-cancer activity as single agent in multiple MM and NHL cell lines, including models of high-risk MM and NHL. In vivo, SKY-1214 treatment results in tumor growth inhibition and regression in MM and NHL cell line-derived xenograft (CDX) models. The combination of SKY-1214 with small molecule agents used for the treatment of MM and NHL, including vincristine, dexamethasone and selinexor, results in improved inhibition of cell growth and viability in multiple cell lines. In vivo, the combinations result in improved tumor growth inhibition and regression and increased durability of effect upon treatment cessation in CDX models. Here, we describe the results of in vitro combination studies of SKY-1214 with antibody-drug conjugates (ADC) and monoclonal antibodies. Cell growth and viability were assessed using cell viability assays (CellTiter-Glo2.0 or FACS-based assays) in tumor cells monoculture or in co-culture with T cells or NK cells to evaluate the combination with monoclonal antibodies. Combination of SKY-1214 with the BCMA-targeting ADC belantamab mafodotin shows additive and synergistic effect in specific concentration ranges resulting in enhanced cell killing in a panel of MM cell lines. Combination of SKY-1214 with bispecific antibodies, including αCD3-αBCMA, in co-culture with T cells shows additive effect. Additive effect is observed also for the combination of SKY-1214 with monoclonal antibodies in co-culture with NK cells. SKY-1214 treatment shows single agent anti-cancer activity in vitro and in vivo in MM and NHL models and combines well with small molecule agents, ADCs and monoclonal antibodies used for the treatment of these disorders. These data, together with the favorable oral bioavailability and pharmacologic characteristics of SKY-1214 with a distinctive mechanism of action, warrants future development in the clinic.

#5637 A novel KIF18A inhibitor for targeting chromosomal instability in cancer.

Lana Kulyk, Shawn Wright, Jill Hallin, Michael Maestre, Joseph Dennis, Iriny Botrous, Anders S. Christensen, Jan Pencik, Craig Gutierrez, Afsheen Banisadr, Jeeyoung Park, Abby Adams, Chang Zhao, Kelly Chen, Stephen Munoz, Shane Yost, Marcelo Lacerda, Angus Voice, Mary L. Anderson, Bo Liu, Matt Welborn, Chao Zhang, Jeff Hager, Fred Manby, Tom Miller, Hui Zhang, Laurent Gomez, Peter Olson, Zhongdong Huang, Chunmei Zhao

Iambic Therapeutics, Inc., San Diego, CA

Anti-mitotic drugs are frequently used to treat cancer and many work by targeting microtubules and disrupting the mitotic phase of the cell cycle. However, dose-limiting toxicity associated with inhibition of cell division in normal cells limits the clinical benefit of this drug class. The spindle assembly checkpoint (SAC) has emerged as a vulnerability for cancer cells with chromosomal instability due to their increased dependence on proper chromosome alignment. KIF18A is a kinesin family motor protein that promotes chromosome alignment by dampening chromosome oscillation. Targeting KIF18A provides an opportunity for cancer-specific dysregulation of the SAC and therefore a significantly improved therapeutic window. Here we describe a novel series of potent KIF18A inhibitors (IC50 < 30 nM) in both KIF18A ATPase biochemical and OVCAR-3 cell growth inhibition assays. These KIF18A inhibitors demonstrated >300-fold selectivity against other kinesins that are essential for various cellular functions. The high selectivity of these inhibitors is reflected in the lack of in vitro toxicity in normal dividing cells and bone marrow hematopoietic progenitor cells. Furthermore, the anti-proliferative activity is highly correlated with biochemical activity, with increased levels of the mitotic phase biomarker pHH3, and with increased arrest of cells in the mitotic phase. Utilizing the predictive power of Iambic's AI-driven platform, compounds in this series were optimized to exhibit a favorable ADME profile, low risk of drug-drug interaction liabilities and good bioavailability across multiple rodent and non-rodent preclinical species. The lead molecule IAM-K1 in this series is negative in the mini Ames genotoxicity test and has favorable predicted human pharmacokinetics and metabolism. IAM-K1 displays >10 uM direct IC50 inhibition against the major human cytochrome P450 enzymes, including 2C9, 2C19 and 3A4, reducing the risk to alter the metabolism of co-administered drugs. IAM-K1 has robust anti-proliferation activity in a number of cell lines, representing different cancer indications, and is approximately 2-3 fold more potent than a reference compound AMG650. Furthermore, IAM-K1 achieves similar PD and TGI efficacy as AMG650 in vivo at much lower systemic exposure. Repeat oral dosing of IAM-K1 led to durable tumor regression in the OVCAR-3 xenograft mouse model without impacting body weight. The anti-tumor activity is correlated with an increase in pHH3 in xenograft tumors, consistent with the on-target mechanism of mitotic arrest. Together with a predictive biomarker approach, targeting KIF18A with IAM-K1 and other compounds in this series is expected to provide a novel anti-cancer treatment to patients with a wide therapeutic window.

#5638 Preclinical and clinical studies of PEP07, a novel brain penetrating Chk1 inhibitor, on solid tumor treatments.

Chieh-Fang Cheng[1], Hui-Ling Chen[1], Feng_Yu Lee[1], Cheng-Hao Liu[1], Chien-Feng Li[2], Hong-Ren Wang[1]

[1]Pharmaengine Inc., Taipei, Taiwan,[2]Chi Mei Medical Center, Tainan, Taiwan

PEP07 is a potent and selective brain penetrating oral Chk1 inhibitor. Chk1 is involved in the DNA damage response and cell cycle regulation and helps maintain the integrity of the genome during cell division, especially in response to DNA damage or replication stress.
PEP07 showed strong activity in repressing cancer cell growth in vitro and in vivo in different solid cancer models. Over 100 cell lines showed IC50<0.5μM toward PEP07 in vitro, and PEP07 achieved over 90% tumor growth inhibition (TGI) in multiple in vivo models either by monotherapy or combined with standard of care (SoC) treatments. With the property of blood-brain barrier (BBB) penetration, PEP07 was able to inhibit brain cancer in orthotopic models when combined with SoC treatments. In addition, in vitro cell proliferation and transcriptome data were used to train artificial neuron network (ANN) models to identify cancer cells that are sensitive to PEP07. Patient-derived tumor cells (PDCs) were used to validate the prediction of sensitive cells by ANN models.
PEP07 is currently being evaluated in clinical studies for both hematologic and solid cancers. PEP07-102 (NCT05983523), a Phase 1, open-label, multi-center PK/PD and dose-escalation study employs an accelerated titration design combined with a traditional 3+3 approach assessing PEP07 as monotherapy in patients with advanced or metastatic solid tumors.

#5639 A potent aminosteroid (RM-581) that inhibits orally in mice the tumor growth in an orthotopic xenograft pancreatic cancer model.

Donald Poirier[1], Qi Chen[2], Rene Maltais[1], Jenny Roy[1], Forkan Ahamed[2], Shannon Arnold[2]

[1]CHU de Quebec Research Center-Universite Laval, Quebec, QC, Canada,[2]University of Kansas Medical Center, Kansas City, KS

Pancreatic cancer has a very poor prognosis, with a 5-year survival rate of only 10%, making it imperative to develop effective small molecules as new drugs. The aim of this study was to validate the in vitro and in vivo efficacy of a promising endoplasmic reticulum-stress aggravator, the synthetic aminosteroid RM-581, that induces apoptosis, as a potential treatment for pancreatic cancer. When tested on a panel of human (PANC-1, MIACaPa2, L3.6, CAPAN-1, BxPC3) and murine (Pan02) pancreatic cancer cells, RM-581 strongly reduced their proliferation (IC50 = 0.83, 0.45, 2.10, 0.78, 5.75 and 1.77 µM, respectively), which justified its evaluation in a PANC-1-Luc cell-derived orthotopic xenograft model in nu/nu mice. After 5 weeks of oral treatment with RM-581 by gavage (po) daily, in vivo fluorescence imaging (IVIS) imaging showed inhibited tumor growth of 11, 54 and 76% at 10, 40 and 80 mg/kg, respectively, compared to the untreated control group. Compared with a cholesterol biosynthesis inhibitor pravastatin (4 mg/kg/subcutaneous (sc)), the effect of RM-581 was similar at 40 mg/kg/po and greater at 80 mg/kg/po. Inhibitions obtained with RM-581 and pravastatin were also confirmed by tumor weight measurement at necropsy. A comparison with antineoplastic drug docetaxel (4 mg/kg/intraperitoneal/2 x weekly) was however not possible, since several toxicities were found after 2 weeks of treatment, forcing euthanasia of the mice. From histological evaluation (hematoxylin and eosin staining), no differences were found in the liver, kidney and spleen in all groups, which is consistent with the clinical observation of no signs of toxicities and no differences in body weight for RM-581 treatments. In summary, RM-581 is therefore a promising candidate for a possible oral treatment of pancreatic cancer.

#5640 The KRAS^{G12D}inhibitor MRTX1133 demonstrates significant antitumor activity and enhances nanoparticle-paclitaxel chemotherapy outcomes in pancreatic cancer.

Mitchel Ramos, Nicola Grimaldi, Sazzad Hassan, Urs von Holzen, Niranjan Awasthi

Indiana University School of Medicine, South Bend, IN

Objective: Pancreatic ductal adenocarcinoma (PDAC) remains a highly lethal malignancy with an extremely grim prognosis. The combination of nab-paclitaxel and gemcitabine (NPT-GEM) represents the standard treatment for advanced and metastatic PDAC, yielding a median survival of approximately 8.5 months. Genetic studies have identified *KRAS, TP53, p16/CDKN2A*, and *SMAD4* as the most commonly mutated genes in PDAC, with *KRAS* mutations occurring in over 90% of cases, and playing a central role in tumorigenesis. The *KRAS*-mutation subtypes most common in PDAC are G12D (~49%), G12V (~30%), and G12R (~12%). Recent advances in direct KRAS inhibitors provide new opportunities for improving PDAC therapy. MRTX1133, a novel KRAS inhibitor, specifically targets the *KRAS^{G12D}* mutation in both active and inactive states, selectively inhibiting *KRAS^{G12D}*-mutant tumor cells while sparing wild-type KRAS, highlighting its significant therapeutic potential for PDAC.

Methods: *In vitro* proliferation assays were performed on PDAC epithelial cells harboring *KRAS^{G12D}*-mutations, *KRAS^{G12C}*-mutations, or KRAS^{wt} using the colorimetric WST-1 method. Protein expression levels were assessed via Immunoblot analysis. Tumor growth studies were conducted using 4-6-week-old female NOD/SCID mice with AsPC-1 subcutaneous xenografts.

Results:*In vitro* assays demonstrated dose-dependent inhibition of proliferation in *KRAS^{G12D}*-mutant PDAC cell lines (AsPC-1, HPAF-II, SW-1990) treated with MRTX1133 and NPT-GEM. A synergistic effect was observed with the combination therapy. MRTX1133 alone had minimal effects on *KRAS^{G12C}*-mutant Mia PaCa-2 cells and *KRAS^{wt}* BxPC-3 cells. Immunoblot analysis of KRAS^{G12D}-mutant cells (AsPC-1 and HPAF-II) revealed that MRTX1133 treatment reduced phosphorylation of ERK, AKT, S6, MEK, RAF, while increasing apoptosis marker proteins cleaved-PARP-1 and cleaved-caspase-3. In vivo tumor growth inhibition studies exhibited significant delays in tumor growth with MRTX1133 and NPT-GEM, with their combination showing synergistic effects. Compared to the control (average net tumor growth: 327 mm^3), NPT-GEM reduced growth to 129 mm^3, MRTX1133 reduced it to 56 mm^3 and the combination resulted in tumor regression (-4 mm^3). Tumor weight findings corroborated these results. Importantly, no body weight changes were observed in treated mice, indicating no discernable toxicity associated with MRTX1133, NPT-GEM, or their combination.

Conclusion: These findings highlight the significant therapeutic potential of MRTX1133, particularly in combination with standard chemotherapy, for the clinical management of *KRAS^{G12D}*-mutant PDAC patients.

#5641 Role of ceramide synthase 2 in drug-induced ER-stress, Ca2+ release and apoptosis in triple-negative breast cancer cells.

Hissah Alatawi[1], Haritha Nair[1], Garrette Timothy[2], Vulpe Christopher[3], Sharma Arun[4], Narayan Satya[1]

[1]Anatomy and Cell Biology, University of Florida, Gainesville, FL,[2]2Department of Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL,[3]Department of Physiological Sciences, University of Florida, Gainesville, FL,[4]4Department of Pharmacology, Penn State Cancer Institute, Hersey, PA

Breast cancer can be classified in five subgroups: Luminal A (ER+/PR+/HER2-), Luminal B (ER+/PR-/HER2- or ER+/PR+/HER2+), ER-/PR-/HER2+, and ER-/PR-/HER2- (triple-negative). Significant progress has been made in the treatment of hormone-responsive and HER2-overexpressing breast cancer; however, the treatment for TNBC is underdeveloped due to lack of appropriate targeting. Further, all subtypes of breast cancer quickly become resistant to the current available therapy. Hence, there is an urgent need to develop a therapeutic strategy that targets a common molecular pathway, irrespective of their biological markers. Recent studies recognized lipid metabolism as one of the important cancer hallmarks. Among many lipids, ceramides play a crucial role in cell signaling, apoptosis, and the regulation of cell growth and differentiation. Very long-chain fatty acid (VLCFA)-ceramides (C20-C26), which are synthesized by ceramide synthase 2 (CerS2), suppress cancer cell invasion and metastasis. The decreased expression of CerS2 is known as a poor prognostic factor for BC patients. The reduction in CerS-2 expression may be due to genetic mutations, epigenetic modifications, or changes in the cellular microenvironment. Thus, the increased level or the activity of CerS2 can be a better prognostic factor for BC patients. In this effort, we have synthesized a novel biisoquinoline-derivative, DH20931 (US Patent ID: US9914733B2) that causes death of breast cancer cells, including TNBC cells. The spatial molecular modeling and enzymatic assays show that DH20931 interacts with and stimulates ceramide synthase 2 (CerS2) activity, reduces the growth of hormone-responsive, HER2-overexpressing, and TNBC cells. DH20931 treatment increases the level of VLCFA-ceramides, induces lipotoxic endoplasmic reticulum (ER) stress, and ATF4/CHOP/PUMA pathway of apoptosis. Here, we show an additional apoptotic pathway that is linked with DH20931-mediated ER-stress. DH20931 induced ER-stress causes the release of Ca2+ from ER to mitochondria, leading to the release of cytochrome c, that in turn leads to significant increase of apoptosis in TNBC cells. We provide evidence that CerS2 plays an important role in the release of Ca2+ from ER to mitochondria where it forms an active IP3R1 channel complex and reduces the distance between ER and mitochondria. Based on Swiss-ADME analysis and laboratory experiments, DH20931 possess all the properties of a druggable molecule and obeys the Lipinski-rule-of-five. Thus, DH20931 can be developed as a novel therapeutic agent that can induce apoptosis by ATF4/CHOP/PUMA axis and Ca2+-dependent pathways, which are independent to ER, PR and HER2 status. The use of this therapy can potentially reduce the morbidity and mortality of women of all races and ethnic groups with BC of hormone-responsive, HER2-expressing, and TNBC.

#5642 Datopotomab deruxtecan (Dato-DXd), a TROP2 directed antibody-drug conjugate, demonstrates remarkable antitumor activity in uterine serous carcinoma.

Michelle Greenman, Cem Demirkiran, Stefania Bellone, Tobias Hartwich, Blair McNamara, Victoria Ettorre, Niccolo G. Santin, Namrata Sethi, Luca Palmieri, Yang Yang-Hartwich, Katyayani Papatla, Elena Ratner, **Alessandro D. Santin**

Yale University, New Haven, CT

Objective: Uterine serous carcinoma is a rare biologically aggressive type of endometrial cancer associated with a high rate of mortality. Datopotamab deruxtecan (Dato-DXd) is a novel ADC composed of the humanized anti-TROP2 IgG1 monoclonal antibody, a cleavable tetrapeptide linker, and a topoisomerase I inhibitor payload. TROP2 expression is detected in up to 95% of uterine serous carcinoma (USC) cases, making it an excellent target for therapy. We evaluated the preclinical activity of Dato-DXd *in vitro* against primary USC cell lines with various TROP2 expression and *in vivo* in TROP2 overexpressing cell-line derived xenografts in mice.

Methods: Primary USC cell lines were established from chemotherapy-naïve patients at time of surgery and analyzed by flow cytometry for TROP2 expression. USC cell lines with varying TROP2 expression levels were treated with scalar concentrations of Dato-DXd or a non-targeting ADC isotype control (CTL ADC). Flow cytometry-based assays were used to evaluate viability. RepresentativeTROP2 expressing USC were co-cultured with a TROP2 non-expressing USC cell line to evaluate bystander effect. Four-hour chromium release assays were used to evaluate Dato-DXd ability to induce antibody dependent cell cytotoxicity (ADCC) in vitro. Finally, mice xenograft models were established from a selected TROP2 3+ cell line (ie, USC-ARK2) to evaluate the *in vivo* activity of Dato-DXd vs treatment with vehicle, datopotomab (unconjugated antibody), or control (CTL) ADC with an endpoint of overall survival.

Results: *In vitro*, TROP2 overexpressing cell lines demonstrated remarkable sensitivity to Dato-DXd compared to CTL ADC. When high TROP2 USC cells were admixed with TROP2 low-expression cells, significant bystander cytotoxicity was observed ($p=0.03$). Mechanistically, double stranded DNA breakage was demonstrated by increased phosphorylation of the histone H2AX in TROP2 positive cell lines after DATO-DXd exposure vs CTL ADC. In the TROP2 selected cell lines, both Dato-DXd and datopotomab were effective in inducing significant ADCC when challenged with heterologous peripheral blood lymphocytes ($p= \leq 0.05$). *In vivo,* Dato-DXd demonstrated a significant survival advantage in mice xenografted with ARK2 compared to the other treatment groups ($p<0.0001$). By day 10, ARK-2 xenografted mice treated with Dato-DXd had significantly decreased growth when compared to the other three treatments which experienced continued linear growth. The median survival for Dato-DXd was not reached as all mice were still alive at the conclusion of the study on day 60 ($p<0.0001$).

Conclusions: Dato-DXd demonstrates remarkable preclinical activity both *in vitro* as well as *in vivo* against biologically aggressive USC primary cell lines and xenografts. Clinical trials are warranted.

#5643 Aryl hydrocarbon receptor agonist ZSTK3744 overcomes chemotherapy resistance in TNBC.

Takahiro Ohashi[1], Kayoko Kawai-Asami[2], Sayuri Terada[1], Kotomi Akatsuka[1], Yuko Nagata[2], Shinsuke Hiramoto[1], Tsubasa Nagasaki[3], Eika Higashi[3], Ryuichiro Ohshita[3], Keiko Fukushima[1]

[1]Biosciences, Department of Drug Discovery, R&D Center, Zenyaku Kogyo Co., Ltd., Tokyo, Japan,[2]Pharmacology, Department of Drug Discovery, R&D Center, Zenyaku Kogyo Co., Ltd., Tokyo, Japan,[3]Organic Synthesis, Department of Drug Discovery, R&D Center, Zenyaku Kogyo Co., Ltd., Tokyo, Japan

Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer with a poor prognosis compared with other subtypes. Due to the lack of therapeutic targets, such as hormone receptors and human epidermal growth factor receptor 2, systemic chemotherapy remains the primary treatment option for TNBC. However, chemotherapy has limited benefits and some patients acquire resistance, further complicating treatment. New therapeutic approaches are urgently needed to overcome chemotherapy resistance in TNBC. ZSTK3744 is an aryl hydrocarbon receptor agonist developed as a novel therapeutic candidate for TNBC. ZSTK3744 has shown inhibitory effects on the proliferation of various cancer cell lines, including TNBC cell lines, *in vitro*. Moreover, it suppressed tumor growth in TNBC xenograft models. In this study, we evaluated the effects of ZSTK3744 on chemotherapy-resistant TNBC cells. Chemotherapy-resistant MDA-MB-468 cells, derived from TNBC, were developed through long-term exposure to adriamycin or paclitaxel. Compared to wild-type cells, the anti-tumor effects of adriamycin, paclitaxel, and eribulin were weakened in these resistant cells; however, ZSTK3744 maintained its efficacy. Transcriptome analysis was conducted to elucidate the mechanism of chemotherapy resistance, revealing alterations in several resistance-associated genes. In particular, upregulation of the ATP-binding cassette transporter 1 gene (ABCB1) was commonly observed in these cells. The anti-tumor effects of adriamycin, paclitaxel, and eribulin were reduced in cells with high ABCB1 expression, whereas those of ZSTK3744 were unaffected. Moreover, ZSTK3744 significantly inhibited tumor growth in xenograft models implanted with adriamycin-resistant MDA-MB-468 cells, showing a higher potency than eribulin. ZSTK3744 is a promising agent for overcoming chemotherapy-resistance in TNBC.

#5644 Identification of alexidine as a novel small molecule inhibitor of TAZ-TEAD interaction in breast cancer cell migration.

A. Ge[1], Y. Hao[1], K. Klupt[1], Z. Jia[1], Y. Du[2], H. Fu[2], X. Yang[1];
[1]Queen's University, Kingston, ON, Canada, [2]Emory University, Atlanta, GA

Breast cancer (BC) is the most commonly diagnosed malignancy in women, with a risk of distant metastases after a primary tumor has developed. Despite concerns about the aggressive pathology of metastatic BC (MBC), current medical interventions inadequately address the clinical needs of MBC patients, resulting in worse outcomes compared to other BC cases. This highlights the critical requirement for more effective therapies for MBC patients. The Hippo pathway is often dysregulated during tumorigenesis, and one of the Hippo signaling transducers, Transcriptional co-activator with PDZ-binding motif (TAZ), is involved in multiple stages of BC development. Since TAZ mostly interacts with TEAD to facilitates its function, targeting TAZ-TEAD interaction may be a treatment approach for MBC patients. To identify small molecules that inhibit TAZ-TEAD interaction, we established a highly sensitive NanoLuc and TR-FRET applicable biosensor for quantifying protein-protein interaction of TAZ and TEAD. Using this biosensor, we performed an ultra-high throughput screen (uHTS) and identified alexidine as a novel TAZ-TEAD binding inhibitor capable of suppressing TAZ-induced migration and invasion in BC cells. In conclusion, we describe a robust method for screening inhibitors of TAZ-TEAD interaction, contributing to the development of effective cancer treatments.

#5645 Targeting transcription-replication conflict for selective chemotherapy in glioblastoma.

L. Gu, R. J. Hickey, L. H. Malkas;
City of Hope National Medical Center, Duarte, CA

The current standard of care for glioblastoma (GBM) is surgical intervention followed by a combination of temozolomide (TMZ) and radiation therapy. Only 5% GBM patients survive more than five years despite aggressive therapeutic treatment. A significant hurdle to develop target-based therapies for GBM is the complexity and diversity of the disease. Genomic and epigenetic profiling has found a broad range mutational and transcriptional events across this histologically diverse disease. A hallmark of GBM is genomic instability, which is a key factor in its progression and complexity. The fast growing and aggressive GBM cells demand rapid DNA replication and hypertranscription, leading to enhanced transcription-replication conflicts (TRCs). A major source of genomic instability, TCR causes lethal double stranded DNA breaks (DSBs) if not resolved properly. We hypothesize that enhanced TRC is a weak link and a promising target for treating GBM.

Proliferating cell nuclear antigen (PCNA) is a key component of DNA replication machinery and plays an essential role in the DNA replication and repair. Through a rational drug design, we identified a small molecule PCNA inhibitor, AOH1996, which selectively kills cancer cells. Mechanistically, AOH1996 enhances the interaction between PCNA and the largest subunit of RNA polymerase II, RPB1, and dissociates PCNA from actively transcribed chromatin regions. By interfering with TRC resolution as evidenced by induction of R-loop levels in cancer cells, AOH1996 induces DSBs in a transcription-dependent manner. Orally administrable and metabolically stable, AOH1996 can freely pass the blood brain barrier and enter brain tumors. Here, we report that it selectively kills GBM cells as a monotherapy or in combination with TMZ but causes no discernable side effects. Importantly, AOH1996 targets a cancer specific region of PCNA that is a highly conserved through evolution and influences the activity of broad cellular processes that are essential to the growth and survival of cancer cells. GBM cancer cells are, therefore, less likely to develop resistance to AOH1996 through mutagenesis in PCNA. If combined with the existing chemotherapeutic regime and inhibitors of DNA repair pathways, AOH1996 may provide a new and unique therapeutic avenue for exploiting this cancer-selective vulnerability to deliver a durable response in GBM.

#5646 A novel *in vivo* self-assembled peptide-drug conjugate targeting HER2 with potent anti-tumor efficacy overcoming resistance of HER2 ADCs.

Gantian Lyu, Min Han, Yuzhen Qian, Yingbin Zhang, Lin Fu, Hao Wang

Isap (Beijing) Biotechnology Co., Ltd., Beijing, China

Background: Several HER2-targeting antibody-drug conjugates (ADCs) have demonstrated significant clinical effectiveness on HER2-expressing cancer. However, these ADCs still face challenge of disease progression in most patients due to diverse resistance mechanisms. Herein, we report preclinical studies of iSAP-0913, a novel *in vivo* self-assembled peptide-drug conjugate (PDC) targeting HER2. iSAP-0913 demonstrates significant antitumor activity in both *in vitro* and *in vivo* models, overcoming the resistance of HER2 ADCs with Topo I inhibitor payload.

Method: The strategy of *in vivo* self-assembly was leveraged to construct iSAP-0913 with a HER2 targeting peptide possessing binding epitopes located in domain II of HER2, a tubulin inhibitor MMAE, and a self-assembling peptide linker. A series of *in vitro* assays were conducted to evaluate biological functions and anti-tumor activities. The *in vivo* anti-tumor efficacy was assessed in a DS8201-induced NCI-N87 resistance model. Preliminary safety of iSAP-0913 was evaluated by repeated dose toxicity (DRF) study in cynomolgus monkeys.

Results: iSAP-0913 binds HER2 receptor to form nano-assemblies on tumor cells, contributed by the design of self-assembling peptide sequence in linker. As a result, *in vivo* self-assembled PDC monomers accumulate in tumor lesions through assembly induced retention (AIR) effect. In NCI-N87 cells, the payload delivery efficiency of iSAP-0913 was 2-3 times higher than that of HER2 ADCs. Desorption Electrospray Ionization imaging results demonstrated that iSAP-0913 exhibits significantly enhanced tumor tissue penetration compared to HER2 ADCs (DS8201, RC-48) in NCI-N87 xenograft tumor models. iSAP-0913 induced tumor-growth suppression, even regression in *in vivo* models with 1-3 mg/kg dosage. iSAP-0913 also showed more effective tumor suppression with TGI% of 73.4% in xenograft models established with DS8201 induced resistant cells, whereas DS8201 exerted negligible anti-tumor activity (TGI%<19.6%). Tissue distribution studies in NCI-N87 tumor-bearing mice revealed that both iSAP-0913 and MMAE are rapidly cleared from plasma. However, MMAE exhibited an elimination half-life of up to 57 hours in the tumor lesion, which may be attributed to the AIR effect. Preliminary repeat-dose toxicological assessment of iSAP-0913 in pharmacologically relevant species cynomolgus monkey demonstrated that iSAP-0913 is well tolerated with no signs of lung toxicity. TK data showed that free MMAE in plasma is 1/100th of iSAP-0913, without MMAE accumulation during dosage.

Conclusion: Comprehensive preclinical data have supported iSAP-0913 as a promising PDC candidate for HER2-low expression and/or patients insensitive to other HER2-targeting ADCs, particularly as a sequential treatment following resistance to HER2 ADCs. iSAP-0913 is now undergoing preclinical development.

#5647 Targeting HAUS7/gamma-tubulin interaction with HTIP1 suppresses tumorigenesis in esophageal squamous cell carcinoma.

Z. CAI, Y. I. WONG, Y. S. LAW;
The University of Hong Kong, Hong Kong, Hong Kong

Background: Unlimited cell division resulting from cell cycle deregulation is a cancer hallmark. We hypothesized targeting deregulated cell cycle molecule with prognostic significance could be viable to counteract tumorigenesis. Our on-going effort showed HAUS7 was such a molecule highly relevant to esophageal squamous cell carcinoma (ESCC). This research targeted HAUS7/gamma-tubulin interaction using a novel peptide HTIP1, which was strategically designed based on our new understanding on the therapeutic mechanism associated with HAUS7 suppression (attached figure).
Methods: Clinical relevance of HAUS7 upregulation was studied in local and public ESCC cohorts. Physiological microtubule-regulating and tumorigenic functions of HAUS7 relative to other HAUS members were examined in vitro and/or in vivo. A multidisciplinary approach, which included using RNA-seq, mass spectrometry, electron microscopy, in silico predictions, bioinformatics analysis, biochemical methods, cellular assays, immunoassays and animal models, was employed to decode the mechanism underlying HAUS7 suppression. HTIP1 was designed by structure modelling and docking simulation. Its properties, cancer selectivity, anti-tumor efficacy, off-target effect and mechanism of action were comprehensively evaluated. Patient-derived tumor xenograft models were used to provide preclinical evidence.
Results: Among HAUSs, HAUS7 was most essential for regulating microtubule dynamics in ESCC. Its overexpression was correlated with aggressive tumor phenotypes and poor prognosis. Mechanistically, HAUS7 suppression released its binding partner g-tubulin. The free g-tubulin upon phosphorylation seized LMAN1 and together both of them relocalized to the nucleus. Given the protein-transporting function of LMAN1 at endoplasmic reticulum (ER), its removal from the innate location triggered ER stress and apoptosis. Capable to perturb HAUS7/gamma-tubulin interaction, HTIP1 treatment manifested similar anti-tumor effects like HAUS7 suppression, while demonstrating high tumor specificity, negligible off-target effects and more potent than relevant compounds.
Conclusions: We first discovered a unique physiological function and pathological relevance of HAUS7 among other HAUSs in ESCC. A new therapeutic mechanism was dissected under HAUS7 suppression. To target cancer with HAUS7 dependency, a novel peptide HTIP1 was designed to interrupt HAUS7/gamma-tubulin interaction. This invention paved a new strategy to counter tumorigenesis. By translating the scientific evidence to support further R&D of HTIP1, our ultimate goal is to produce a brand new drug.

#5648 Effects of olverembatinib (HQP1351) in combination with BCL-2 inhibitor lisaftoclax (APG-2575) in T-cell acute lymphoblastic leukemia (T-ALL).

Bo Peng[1], Yan Xiong[1], Zhiyan Liang[2], Ping Min[1], Huidan Yu[1], Bingxing Wu[1], Guoqing Zhai[1], Zhou Yu[1], Dajun Yang[1], Yifan Zhai[1]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: T-ALL is a high-risk hematologic cancer arising from malignant transformation of T-cell progenitors, affecting approximately 15% of newly diagnosed pediatric and 25% of adult ALL cases. Survival in children, young adults, and patients with relapsed or refractory disease is poor with limited treatment options. Some T-ALL subtypes depend on pre-TCR/Src signaling and antiapoptotic BCL-2 family proteins for growth and survival. Olverembatinib, a novel multikinase inhibitor, targets oncogenic Src-family kinases (Lck, Fyn, and YES1) essential for T-cell differentiation, survival, and activation. Lisaftoclax is a novel BCL-2 inhibitor under investigation in late-stage clinical trials for multiple hematologic malignancies. Here, we examined the antitumor effects of olverembatinib combined with lisaftoclax in human T-ALL cell lines and explored potential mechanisms of action.

Methods: Cellular proliferation was measured using CellTiter-Glo® assays and apoptosis by flow cytometry. Western blotting was used to elucidate potential mechanisms of action. *In vivo* activity was evaluated using a subcutaneous MOLT4 cell-derived xenograft mouse model.

Results: Olverembatinib in combination with lisaftoclax exhibited strong synergistic antiproliferative effects in T-ALL cell lines MOLT4 and Jurkat, with combination indices of 0.2 and 0.1, respectively; apoptosis analyses revealed that the combination significantly increased the percentage of apoptotic cells compared to either agent alone ($p < 0.0001$). Olverembatinib 10 mg/kg or lisaftoclax 100 mg/kg alone resulted in no or limited tumor inhibition in MOLT4 xenograft model, with treatment-to-control (T/C) values of 113% and 89%, respectively. However, when co-administered, the combination enhanced tumor growth inhibition (T/C, 60%), achieving a synergy index of 1.67. Mechanistically, olverembatinib inhibited Lck activity, and when combined with lisaftoclax, synergistically reduced activity of downstream transcription factor NF-kB p65, leading to downregulation of the key antiapoptotic protein BCL-xL, which is typically upregulated in BCL-2 inhibitor-resistant T-ALL. In addition, the combination downregulated phosphorylation of AKT and GSK3b kinases, resulting in significant degradation of antiapoptotic protein MCL-1 and c-myc, an essential pro-survival oncogene in T-ALL. Increased cleavage of PARP and caspase-3 (markers of apoptosis) was also observed.

Conclusions: Olverembatinib in combination with lisaftoclax demonstrated synergistic antitumor effects in T-ALL, providing a scientific rationale for further clinical evaluation of this novel combination therapy in patients with T-ALL.

#5649 Potentiation of AKR1C3- and P53-dependent AST-3424 activity via PUMA-mediated degradation of Rad51.

J. Duan[1], T. Qi[1], Y. Wang[1], X. Liu[1], Z. Lu[1], J. Yu[1], X. Cai[1], A. Li[1], D. Jung[1], C. Xun[2], Y. Xie[1], F. Meng[1], S. Qin[3];
[1]Ascentawits Pharmaceuticals, LTD, Shenzhen, China, [2]The First Affiliated Hospital of China Pharmaceutical University, Nanjing Tianyinshan Hospital, Hepatobiliary and Pancreatic Tumor Department., Nanjing, China, [3]GI Cancer Center, Nanjing Tianyinshan Hospital affiliated to China Pharmaceutical University, Nanjing, China

AST-3424 is a novel, highly tumor-selective prodrug activated by tumor-specific AKR1C3 to release AST 2660, a toxic bis-alkylating moiety that induces DNA alkylation and cross-linking. Currently undergoing evaluation in various clinical trials for solid and hematologic malignancies, AST-3424 has demonstrated promising efficacy in a Phase II study as a later-line monotherapy for advanced hepatocarcinoma, particularly in patients who have progressed after immunotherapy. Subgroup analysis suggests enhanced clinical benefit in patients with wild-type P53. This study elucidates the mechanism underlying AST-3424's enhanced therapeutic effect in cancer cells expressing high levels of AKR1C3 and wild-type P53. Co-treatment with AST-3424 and the P53 activator nutlin-3 significantly potentiated AST-3424's pharmacological activities, including *in vitro* cytotoxicity, reduced colony formation, apoptosis induction, DNA damage (γH2AX), and G2/M phase cell cycle arrest. Targeted deletion of P53 in P53 wild type cells markedly attenuated AST-3424 activities without affecting its AKR1C3 dependence, highlighting P53's pivotal role in cancer cell sensitivity to AST-3424. Given RAD51's crucial role in homologous recombination repair and genomic stability maintenance, we investigated its involvement in P53-dependent AST-3424 activity. Our findings reveal that AST-3424 activates the P53 signaling pathway while concurrently reducing RAD51 expression exclusively in P53 wild type cells. This P53-dependent reduction of RAD51 is mediated by upregulation of PUMA, which promotes RAD51 ubiquitination and diminishes its half-life. Importantly, the effects of AST-3424 on P53 signaling, RAD51, and PUMA were entirely dependent on AKR1C3, as evidenced by complete reversal of these effects upon treatment with the AKR1C3-specific inhibitor AST-3021. The AKR1C3 dependence confers tumor specificity to AST-3424's regulation of P53, RAD51, and PUMA, as AKR1C3 is highly expressed only in tumor cells. In conclusion, this study demonstrates that AST-3424's pharmacological activity is enhanced in cancer cells with high AKR1C3 expression and wild-type P53. We elucidate the mechanism of tumor-specific enhancement associated with P53-dependent RAD51 degradation, leading to decreased homology-directed DNA repair and synthetic lethality. These insights have significant implications for optimizing AST-3424's antitumor efficacy and potentially improving survival rates in patients with functional P53.

#5650 Small molecule CB001 downregulates cFLIP, potentiates the effects of androgen receptor inhibitors in prostate cancer models, and enhances NK cell activity.

Claire Lin[1], Connor Purcell[2], Shengliang Zhang[2], Vida Tajiknia[2], Wafik S. El-Deiry[2], Benedito A. Carneiro[3]

[1]The Warren Alpert Medical School of Brown University, Providence, RI,[2]Department of Pathology and Laboratory Medicine, Brown University, Providence, RI,[3]Hematology-Oncology Division, Brown University Health, Providence, RI

Background: Androgen deprivation therapy (ADT) and androgen receptor inhibitors (ARi) represent a cornerstone treatment for prostate cancer (PCa). However, resistance often leads to castration-resistant prostate cancer (CRPC). Dysregulation of the extrinsic apoptosis pathway contributes to therapeutic resistance in PCa. Overexpression of FADD-like IL-1β-converting enzyme-inhibitory protein (cFLIP), an endogenous caspase-8 inhibitor, promotes PCa progression and ADT resistance. Targeting cFLIP may represent a novel therapeutic strategy for PCa. This study investigated the potential of CB001, a cFLIP inhibitor, to enhance the effect of ARi and overcome resistance in PCa models.

Methods: We investigated the prevalence of cFLIP molecular alterations in PCa and its impact on patient survival using The Cancer Genome Atlas (TCGA) dataset. We investigated cytotoxic effects of CB001 [0-10μM] in ARi-sensitive (LNCaP) and -resistant (22rv1, DU145, PC3) PCa cell lines. Combination indexing for dual treatment with CB001 [0-5μM] ± ARi (enzalutamide [0-150μM] or darolutamide [0-150μM]) was performed on SynergyFinder. cFLIP, cleaved caspase 8, and cPARP expression were investigated after treatment with CB001 (10μM) ± ARi (10-100μM) at 24 hours by western blot (WB). PCa cells were co-cultured 1:1 with natural killer cells (NKc) in the presence of CB001 (10μM), and tumor cell killing was quantified using the MetaXpress cytoplasmic/nuclear staining software.

Results: Amplifications and deletions of the gene encoding cFLIP were identified in up to 2.7% and 1.34% of PCa tumors in TCGA, respectively. Solid tumors with cFLIP alterations had inferior overall survival compared to wild-type tumors. Single-agent CB001 cytotoxicity displayed a spectrum of sensitivity across different PCa cell lines, with DU145 (3.1μM) and neuroendocrine-phenotype PC3 (11.1μM) requiring higher IC50s than LNCaP (1.1μM) and 22rv1 (0.7μM). CB001 treatment decreased cFLIP expression and increased PARP and caspase 8 cleavage by WB consistent with extrinsic apoptosis pathway activation. CB001 plus ARi was synergistic; combination of CB001 with ARi induced apoptosis in ARi-resistant cell lines 22rv1, DU145, and PC3, reversing apoptosis resistance to single-agent ARi. CB001 also increased immune-mediated NKc killing of 22rv1 ($p=7.3e^{-4}$), DU145 ($p=2.41e^{-4}$), and PC3 ($p=9.83e^{-4}$) cells in co-culture experiments.

Conclusion: CB001 demonstrates potent cytotoxicity and synergizes with ARi in PCa cell lines to overcome resistance to apoptosis with single-agent ARi. In addition to direct tumor cytotoxicity, CB001 enhances NK cell-mediated killing of PCa cell lines. Targeting cFLIP may represent a novel therapeutic strategy for PCa.

#5651 Discovery of AS03157 as a highly potent and orally active antagonist of inhibitor of apoptosis proteins (IAPs).

Yan Xiong[1], Zhou Yu[1], Jiantao Hu[1], Jianyong Chen[1], Xiao Han[1], Zhiyan Liang[2], Yifan Zhai[1], Dajun Yang[1]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: Overexpression of antiapoptotic proteins, such as cellular inhibitor of apoptosis proteins 1 (cIAP1) and 2 (cIAP2) and X-linked IAP (XIAP), occurs in various hematologic and solid cancers and is associated with drug resistance and poor prognosis. Several small molecules are being investigated clinically as monotherapy or in combination therapy in solid tumors. AS03157, a novel and structurally distinct IAP antagonist, was identified with enhanced specificity towards cIAP1 and XIAP, and its pharmacological profiles were characterized *in vitro* and *in vivo.*

Methods: Homogeneous time-resolved fluorescence assays were used to measure the binding of the compound to its target. Detroit 562 cell line was used to test the target degradation. MDA-MB-231 and EVSA-T breast cancer cell lines were used for antiproliferation assay. In vivo efficacy was evaluated in MDA-MB-231-derived xenograft model.

Results: AS03157 strongly bound to cIAP1-BIR3 and XIAP-BIR3 at half-maximal inhibitory concentration (IC_{50}) values of 4.3 nM and 13.7 nM, respectively. AS03157 inhibited cIAP1 with a half-maximal degradation concentration (DC_{50}) of 1.38 nM after treatment for 2 hours in a Detroit 562 pharyngeal carcinoma cell line *in vitro*. AS03157 demonstrated potent growth inhibitory activities in MDA-MB-231 and EVSA-T breast cancer cell lines, with IC_{50} values of 20 nM and 2 nM, respectively. In addition, AS03157 exhibited high aqueous solubility, metabolic stability, as well as high oral bioavailability in both rodent and non-rodent species. Of interest, AS03157 10 and 20 mg/kg administered orally daily demonstrated dose-dependent antitumor activity in an MDA-MB-231-X1 human breast cancer xenograft model, with T/C values of 69.81% and 26.67% on Day 22, respectively.

Conclusions: AS03157 showed promising *in vitro* and *in vivo* activity in preclinical cancer models, and these data provide a rationale for further clinical studies.

#5652 Olverembatinib (HQP1351) in combination with lisaftoclax (APG-2575) overcomes venetoclax resistance in preclinical models of acute myeloid leukemia (AML).

Yan Xiong[1], Zhiyan Liang[2], Ping Min[1], Bingxing Wu[1], Huidan Yu[1], Guoqin Zhai[1], Zhou Yu[1], Dajun Yang[1], Yifan Zhai[1]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: Combining BCL-2 inhibitor venetoclax with hypomethylating agents is the standard of care for older patients with AML or those ineligible for intensive chemotherapy. However, resistance to venetoclax is a major clinical challenge, necessitating alternative therapeutic options. Olverembatinib targets kinases associated with leukemogenesis and venetoclax resistance, including FLT3, KIT, PDGFR, Src family kinases, PI3K, and FGFR. Here, we evaluated the effects of olverembatinib combined with investigational BCL-2 inhibitor lisaftoclax in venetoclax-resistant AML models.

Methods: Primary venetoclax-resistant AML cell line OCI-AML-3 and venetoclax-induced resistant (VEN-RES) *FLT3-ITD* mutant AML cell lines MOLM-13 and MV-4-11 were used for *in vitro* experiments. Cellular proliferation was assessed using CellTiter-Glo® assays, and apoptosis was measured by flow cytometry. Western blotting was used to explore mechanisms of action. Both subcutaneous and systemic models using MOLM-13-VEN-RES models were used to evaluate antitumor effects *in vivo*.

Results: Olverembatinib combined with lisaftoclax synergistically inhibited proliferation in all three VEN-RES AML cell lines vs. either drug alone. Flow cytometry confirmed this, revealing limited apoptotic effects with single agents but a significant increase in apoptosis when combined ($p < 0.0001$). *In vivo*, in a subcutaneous MOLM-13-VEN-RES model, lisaftoclax (100 mg/kg) administered daily for 14 days exerted no antitumor activity, with a treatment-to-control (T/C) value of 96.54%; olverembatinib (10 mg/kg) alone yielded a T/C value of 12.31%. When coadministered, the combination enhanced antitumor activity (T/C value, 5.05%), with a synergistic index of 2.36. This synergy was recapitulated in a systemic MOLM13-VEN-RES model. Mechanistically, western blot analysis showed that the combination synergistically downregulated FLT3 and its phosphorylation, along with downstream proteins such as AKT, STAT, and ERK and antiapoptotic proteins MCL-1 and BCL-xL; notably, significant upregulated phosphorylated FLT3, AKT, MCL-1, and others have been reported to be associated with mechanisms of venetoclax resistance. The combination also promoted upregulation of proapoptotic proteins BAX, BAK, BID, PUMA, and Noxa, resulting in increased cleavage of caspase-3 and PARP-1.

Conclusions: In summary, olverembatinib in combination with lisaftoclax successfully overcame venetoclax resistance in preclinical AML models by downregulating key signaling pathways shown to mediate such resistance. Overall, these findings suggest a potential new therapeutic strategy for venetoclax-resistant AML.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Methods in Small Molecule and Biologics Drug Discovery
Poster Session

#5656 Next-level efficiency: StraightFrom Spleen Isolation Kits - standardizing isolation of untouched B cells with minimal hands-on time.

Sebastian Flade, Amelie Borczewski, Stefano Vergani, Gregor Winkels, Anna Baranska, **Anne Richter**

Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany

The study of mouse B cells is essential for advancing our understanding of the immune system, developing new vaccines, and driving progress in immunotherapy through the discovery of new targets. Mouse B cells are abundant in the spleen, one of the major lymphoid organs, making splenic isolation a critical step in B cell research. General workflow to isolate these cells relies on manual mechanical disruption of the mouse spleen and subsequent magnetic purification. However, this combination of methods is time-consuming and operator dependent, with important implication for reproducibility and major impact on downstream application. To address this gap, we at Miltenyi have developed the StraightFromSpleen kit, an all-in-one solution for isolation of highly pure murine B cells from mouse spleen. Briefly, we used the GentleMACS dissociator to disrupt the spleen while labeling unwanted cells with an antibody cocktail. We then performed automated magnetic labeling of cells and isolation of untouched B cells and Pan B cells using the autoMACS NEO Separator. After separation, we measured purity, viability and yield and compared these results with those obtained using a standard isolation kit. Finally, we tested the functionality of the isolated B cells and Pan B cells by culturing then with LPS or in presence of anti-CD40 antibody and IL-4, to promote proliferation, IgG class-switch and differentiation to antibody secreting cells. We demonstrated that the newly developed StraigthFrom Spleen kits allow for isolation of highly viable and pure B cells. Isolated B cells efficiently proliferated in vitro, differentiate to CD138+ antibody secreting cells and were able to class-switch. In conclusion, we have developed a simple, fast, and reliable cell isolation method that significantly accelerates the isolation of functional B cells. This represents an attractive alternative to the laborious multi-step protocols commonly used in academic and industrial laboratories and has the potential to set a new standard for the B cell field.

#5657 Carbon monoxide-releasing molecules as top-notch candidates for prostate cancer therapy.

Gaston Pascual[1], Pablo Sanchis[2], Agustina Sabater[2], Rocio Seniuk[1], Javier Cotignola[1], Elba Vazquez[1], Ayelen Toro[1], Roberta Foresti[3], Roberto Motterlini[3], Geraldine Gueron[1]

[1]IQUIBICEN (UBA-CONICET), Buenos Aires, Argentina,[2]Department of Genitourinary Medical Oncology, IQUIBICEN (UBA-CONICET), Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), The University of Texas MD Anderson Cancer Center, Houston, TX,[3]University Paris-Est Creteil, INSERM, IMRB, Creteil, Paris, France

Carbon monoxide (CO) is an endogenous gasotransmitter with proven anti-inflammatory, anti-apoptotic, and antiproliferative effects. CO-releasing molecules (CO-RMs) have been developed to deliver controlled doses of CO, differing in their CO-release kinetics and chemical structure, showing promise as therapeutic agents in various diseases, including cancer. The main goal of our study is to identify the effectiveness of CO-RMs as a therapeutic strategy to counteract prostatic carcinogenesis. This study aimed to assess the effects of three water-soluble CO-RMs—CORM-3, CORM-401, and CORM-A1—on key hallmarks of prostate cancer (PCa). Using the PCa cell line PC3 we evaluated cell viability across a range of CO-RM concentrations (25-150 µM; 6 h) to identify doses that do not compromise cell viability for further analyses. Confocal microscopy with the DCFH-DA probe revealed that CO-RM treatments significantly reduced reactive oxygen species (ROS) levels ($p<0.001$). Furthermore, CO-RMs enhanced cell adhesion ($p<0.001$) and inhibited cell migration ($p<0.01$). Moreover, mitochondrial integrity, mitochondrial mass and mitochondrial DNA copy numbers were significantly altered ($p<0.0001$), as shown by MitoGreen, TMRE staining and RT-qPCR. Metabolically, PC3 cells treated with CO-RMs exhibited significant reductions in ATP content ($p<0.05$), LDH activity ($p<0.01$) and lactate amounts ($p<0.01$). At the molecular level, CO-RMs repressed markers of oxidative stress (*NFkB*, *SOD-2*), metabolism (*PKM2*, *PDHB*, *ACO2*), proliferation (*Ki67*) ($p<0.01$) and angiogenesis (*VEGF*) ($p<0.05$), as assessed by RT-qPCR. Additionally, analyzing stem-like characteristics, we observed that CO-RMs reduced spheroid size in a hanging drop assay ($p<0.0001$), as well as colony formation in a clonogenic assay ($p<0.01$). As PCa predominantly metastasizes to bone, we further analyzed the potential of CO-RMs to modulate the communication between tumor and bone cells using indirect co-cultures of PC3 cells with osteoblasts precursor cells (MC3T3). CO-RMs decreased osteoblastic marker levels in bone cells (*COL1A1*, *SPP1*, *RUNX2*) ($p<0.01$) and increased *OPG* expression in PCa cells ($p<0.01$) demonstrating that this molecule impaired the crosstalk between both cell types, probably affecting the osteotropism of PC3 cells. This study demonstrates that CO-RMs has a strong effect on modulating key biological processes in PCa cells, highlighting its potential as a therapeutic agent for PCa.

#5658 Overcoming resistance in mCRPC: drug discovery using PDX models and high-throughput drug screening.

Irene Marin-Goni[1], Huanyao Gao[1], Joachim L. Petit[2], Shreya Indulkar[1], Adam M. Kase[3], Cassandra N. Moore[4], Krishna R. Kalari[5], Michael T. Barrett[2], Richard Weinshilboum[1], Winston Tan[3], John A. Copland[6], Liewei Wang[1]

[1]Molecular Pharmacology and Experimental Therapeutics Department, Mayo Clinic, Rochester, MN,[2]Division of Hematology-Oncology, Mayo Clinic, Scottsdale, AZ,[3]Division of Hematology-Oncology, Mayo Clinic, Jacksonville, FL,[4]Division of Hematology-Oncology, Mayo Clinic, Phoenix, AZ,[5]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[6]Cancer Biology Department, Mayo Clinic, Jacksonville, FL

Background: Second generation androgen receptor signaling inhibitors (ARSIs), such as abiraterone, have demonstrated improved survival in metastatic castration-resistant prostate cancer (mCRPC) patients, however, acquired resistance to these agents often arises. Novel and alternative therapies are needed to combat the ARSI resistant tumor. In the last two decades patient-derived xenograft (PDX) and PDX organoids have become pivotal models in anticancer drug development and biomarker discovery due to their ability to faithfully recapitulate the complex and heterogeneous tumor biology.
Methods: We analyzed RNAseq data from mCRPC patients and corresponding PDX models (PROMOTE study, NCT #01953640) and employed L1000 Chem Perturbation down/up signatures database to find candidate drugs to overcome abiraterone resistance by reverse signature search. We then performed proliferation assay using 49 compounds in three PROMOTE-PDX organoid models (2 abiraterone-resistant and 1 abiraterone-sensitive) using our semi high-throughput drug screening platform.
Results: Overall, we identified a total of 32 compounds with IC50<10μM in at least one of the models, among which, 5 agents are active in all three models and 5 in at least two of the models. (Table 1). Within active compounds we find selective kinase inhibitors (BRAF, JAK2, AKT, FLT3) and histone deacetylase inhibitors (belinostat and pracinostat). Particularly interesting are two drugs that are only active in the abiraterone resistant setting but not the sensitive PDX.
Conclusions: In summary, we leveraged RNAseq data from mCRPC patients and PDX models and performed a high-throughput drug screen in PDX-derived organoid models to identify potential drugs that could overcome abiraterone-resistance in lethal advanced prostate cancer. These data highlight potential drug combinations or subsequent therapeutic strategies for these patients.

Summary of drug screening in PDX-derived organoids

	Abiraterone Sensitive	Abiraterone Resistant-1	Abiraterone Resistant-2
Active (IC50<10μM)	21	16	13
Intermediate (IC50:10-25μM)	3	2	1
Inactive (IC50>25μM)	25	14	35
Number of total drugs tested	49	32	49

#5659 High-throughput screening reveals novel synergistic drug combinations for metastatic castration-resistant prostate cancer.

Jessica D. Kindrick[1], Benjamin C. Brim[1], Kinjal Bhadresha[1], Xiaohu Zhang[2], Keith T. Schmidt[1], Michele Ceribelli[2], Douglas K. Price[1], Cindy Chau[1], Craig J. Thomas[2], William D. Figg[1]

[1]Genitourinary Malignancies Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Division of Preclinical Innovation, National Center for Advancing Translational Sciences, National Institutes of Health, Rockville, MD

Metastatic castration-resistant prostate cancer (mCRPC) remains a significant clinical challenge, with patients often developing resistance to androgen receptor (AR)-axis-targeted therapies such as Abiraterone and Enzalutamide. A key resistance mechanism involves the AR splice variant AR-V7, which drives tumor progression and poor prognosis. To address the need for novel, effective treatment strategies, we conducted unbiased high-throughput screening (HTS) to discover highly synergistic drug combinations that improve therapeutic efficacy, overcome resistance mechanisms, and minimize toxicity. Leveraging a robotic automation platform, we quantitatively screened 2,480 mechanistically annotated compounds from an oncology-focused library, targeting over 800 biological pathways, across 8 prostate cancer cell lines representing various stages of disease progression. Single-agent cytotoxicity was evaluated using an area under the 11-point dose-response curve (AUC) metric, identifying therapeutically vulnerable targets in mCRPC, including tubulin, MCL-1, CDK9, BRD4, and PI3K/AKT. This led to the selection of 42 compounds for pairwise study of all possible 861 dual-drug combinations in two AR-V7-expressing mCRPC cell lines, LNCaP-95 and VCaP-CR. Utilizing the Excess Highest Single Agent (HSA) model to quantify synergy/antagonism, this large-scale analysis revealed highly synergistic combinations, particularly between MCL-1 and BcL-xL inhibitors. These results guided the development of a novel triple combination therapy to simultaneously target CDK9-regulated productive RNA polymerase II phosphorylation (Enitociclib), BRD4-mediated epigenetic remodeling (Pelabresib), and pro-survival BcL-xL (Navitoclax). Notably, the triple combination demonstrated robust synergy at low doses, inducing apoptosis as early as 4 hours post-treatment through rapid Caspase 3/7 cleavage. Further mechanistic investigation through RNA-sequencing revealed significant downregulation of key oncogenes, including MYC and AR-V7, alongside disruption of downstream transcriptional pathways. Importantly, the triple combination was validated in patient-derived mCRPC organoid models LuCaP167 and LuCaP136, confirming its translational potential. These findings provide a strong rationale for clinical development of multi-drug targeted combination regimens to overcome AR-V7-driven resistance and deliver durable responses with reduced toxicity for mCRPC patients with limited treatment options. Our approach also highlights the power of HTS to unbiasedly innovate synergistic therapies while uncovering critical biological mechanisms underlying cancer drug resistance.

#5660 Optimizing and integrating high-throughput cell-based assays to enable SAR studies of metarrestin to target cancer metastasis.

Asia S. Almarales[1], Yi-Han Lin[1], Harrison Daly[1], Samarjit Patnaik[1], Abhijeet Kapoor[1], Jing Ran[1], Soumita De[2], Udo Rudloff[2], Juan Marugan[1], Mark Henderson[1]

[1]Early Translation Branch, Division of Preclinical Innovation, National Center for Advancing Translational Sciences, Rockville, MD,[2]Rare Tumor Initiative, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD

The perinucleolar compartment (PNC), a marker of genome organization / a membrane-less organelle (condensate) adjacent but structurally distinct from the nucleolus, associates with metastatic behavior in cancer cells and has been used as biomarker in high-throughput screening assays to identify small molecules that target metastasis. We discovered metarrestin, an investigational agent that disassembles the PNC in multiple cancer cell lines as a novel treatment for cancer metastasis. Metarrestin is currently in phase I clinical trials. Metarrestin treatment effects phase-separation, rapidly disrupts nucleolar function and inhibits ribosomal RNA synthesis. Pre-clinical structure activity relationship (SAR) studies, to further improve metarrestin's pharmacological properties, are ongoing. These require robust cell-based assays to evaluate PNC disassembly, rRNA synthesis and growth phenotypes. Our prior studies relied heavily on the Incucyte live-cell imaging system to characterize the cytostatic effect of metarrestin derivatives by tracking the growth of treated cells over days. However, this experimental setup requires long machine times and is limited by the capacity of a single Incucyte to accommodate six 384-well format plates. To address these throughput limitations, we optimized an orthogonal viability assay using Cell Titer Glo which measures luminescence and detects ATP in metarrestin treated cells. Using 1536-well plates, we examined the assay performance using cell numbers ranging from 125-1,000/well, and incubation time between 48-96 hr, in two cell lines PANC1, a pancreatic cancer cell line and PC3M, a prostate cancer cell line. Unlike the measurement of cytotoxic effect, which is typically performed at higher cell densities and shorter incubation times, the cytostatic effect was best captured after 96 hr incubation with cells seeded at 250/well in a 1536-well plate. For detection of rRNA inhibition and PNC disassembly in cells, we utilized a rRNA selective fluorescent probe (Probe 1) and a GFP-based reporter of the PNC, respectively, followed by confocal microscopy using an Opera Phenix. Using this suite of cell-based assays, we evaluated the compound of ~160 metarrestin derivatives and performed comparative analyses of compound activities in measurements of PNC disassembly, rRNA synthesis inhibition, and cytostatic growth effect in PANC1 and PC3M cells.

#5661 A 45-color panel for comprehensive immunophenotyping of human leukocyte.

Xiaoyu Zhang[1], Ming Lei[2], Peifang Ye[2], Xiaohuan Wang[2], Yan Lu[2], Garret Guenther[1], Nancy Li[1]

[1]Agilent Technologies, Inc., La Jolla, CA,[2]Agilent Technologies, Inc., Hangzhou, China

Multicolor flow cytometry has advanced significantly with instruments capturing more lasers and detectors. Spectral flow cytometry, which records full emission spectra rather than peak emissions, allows fluorochromes with distinct spectral fingerprints to expand panels beyond the 40+ color limit of traditional methods. Agilent's NovoCyte Opteon spectral flow cytometer, with its five-laser configuration (349nm, 405nm, 488nm, 561nm, 637nm) and 70 fluorescence detection channels, exemplifies this advancement. Using the OMIP-069 panel as a foundation, we expanded it to detect more biomarkers by adding dyes that either fill spectral gaps or possess unique spectral fingerprints despite similar emission maxima. The original OMIP-069 panel allowed characterization of PBMC subsets (e.g., CD4+, CD8+ T cells, B cells, NK cells, monocytes) and included activation/differentiation markers. Our modified 45-color panel introduced five biomarkers: CD31, CD45RO, CD69, CD33, and LAG-3. CD31 and CD45RO identify recent thymic emigrants (RTEs) among CD4+ T cells, CD69 tracks early activated T cells, LAG-3 assesses exhausted T cells alongside PD-1, and CD33 excludes residual monocytes. The results demonstrate that despite incorporating highly overlapping fluorochromes, immune subsets were accurately resolved, preserving dimensionality reduction and clustering outcomes. This highlights the NovoCyte Opteon's excellent performance, enabling high-dimensional panel design and robust biomarker resolution.

#5662 Deep-mining the antibody repertoires of transgenic mouse models with high-throughput single cell BCR and whole transcriptome sequencing.

Ajay Sapre, Alec Salvino, Guillermo Gallareta-Olivares, Efi Papalexi, Jose Jacob, Ashwath Kumar, Charles Roco, Alexander Rosenberg

Parse Biosciences, Inc., Seattle, WA

Transgenic mouse models are excellent tools to model human antibody response against antigens or disease of choice, given their ability to undergo diversification, in vivo affinity maturation, clonal selection and clonal expansion in their natural immune environment. Current antibody discovery methods lack the scale required to fully screen the antibody repertoire of transgenic mouse models to uncover maximum desirable antibody hits per discovery campaign. Here, we demonstrate our novel combinatorial barcoding approach to enable high-throughput single cell BCR and whole transcriptome profiling of transgenic mouse samples with unprecedented sensitivity, scalability, and flexibility.
As a proof of concept, we profiled over 1 million cells from multiple transgenic mice that were either naive or immunized with antigens of interest to obtain hundreds of thousands of paired BCR clonotypes. Using the whole transcriptome data, we detected all B cell subpopulations including plasma cells at single cell resolution. We then used the paired heavy and light chain BCR data to detect productive chains in the majority of B cells revealing both unique and expanded clonotypes. In the expanded clonotype pool we found specific patterns of VDJ utilization and amino acid motifs compared to the naive pool. This method paves the way for high throughput screening of antibody repertoires from transgenic mice to allow for deep mining of repertoires for antibody discovery and therapeutic outcomes.

#5663 High-content screening platform for comprehensive profiling in drug discovery.

Maciej B. Olszewski, Natalia Gostynska, Klaudia Lesniak, Alicja Martyniak, **Magdalena Kieltyka**

Selvita S.A., Cracow, Poland

A robust, multi-modal high-content screening (HCS) platform enables fast and quantitative assessment of cellular phenotypes over a variety of research applications. Our integrated system combines innovative imaging technologies, automated analysis, and cell profiling capabilities to drive drug discovery and biological research programs. Selvita HCS platform features multiparametric cellular phenotyping: simultaneous measurement of morphological, functional, and molecular cellular properties. The data is acquired by automated fluorescence microscopy: high-resolution imaging with multiplexed fluorescent markers. The images are then analyzed, as needed, by standard or machine learning-assisted image analysis. Advanced algorithms are used to accurately extract cellular features. This enables building various kinetic and endpoint assays: cell viability, apoptosis, proliferation, and subcellular localization studies, to name a few. The platform allows multiple application domains, including therapeutic target validation, mechanism of action studies, pharmacological screening and toxicity assessment. Validated across a variety of models under different experimental conditions, our HCS platform generates high-throughput data with high inter-assay consistency. The customizable protocols facilitate adaptable research support across programs in oncology, neuroscience, immunology, and metabolic disease. Examples of successful cases include: tissue analysis with automated identification of areas of interest and subsequent high-resolution rescanning, combined FISH / immunofluorescence studies in target validation, 100+ K compound screening campaign based on reporter cell line and protein-protein interaction study in DNA repair complex assembly, using proximity ligation assay. Future development will focus on expanding the machine learning capabilities, multiplexing potential, and integration of advanced computational biology tools to aid in the improvement of predictive cellular modeling.

#5664 Identifying novel vulnerabilities in clear cell sarcoma through functional and genomic screening.

Laura Leuenberger[1], Larissa Isenegger[1], Yanjiang Chen[2], Miles Burri[1], Sarah Kollar[2], Lara Planas-Paz[2], Peter Karl Bode[3], Agnieszka Wozniak[4], Sebastian Bauer[5], Patrick Schoffski[6], Chantal Pauli[2], Christian Britschgi[7]

[1]Department of Medical Oncology and Hematology, University Hospital Zurich, Zurich, Switzerland,[2]Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland,[3]Department of Pathology, Cantonal Hospital Winterthur, Winterthur, Switzerland,[4]Laboratory of Experimental Oncology, Department of Oncology, KU Leuven, Leuven, Belgium,[5]Department of Medical Oncology and Sarcoma Center, West German Cancer Center, University Hospital Essen, Essen, Germany,[6]Department of General Medical Oncology, University Hospitals Leuven, Leuven, Belgium,[7]Cantonal Hospital Winterthur, Winterthur, Switzerland

Introduction: Clear Cell Sarcoma (CCSA) is a rare soft tissue sarcoma characterized by specific gene fusions *EWSR1::ATF1* or *EWSR1::CREB1*, leading to the expression of an oncogenic fusion protein. Metastasized CCSA is resistant to conventional chemotherapy, targeted therapy or immunotherapy. This study aims to uncover new therapeutic strategies for CCSA by utilizing a whole-genome CRISPR/Cas9 knock-out screen combined with functional drug screening.
Methods: We performed a genome-wide knock-out screen in the CCSA cell line model KAS using the pooled Brunello sgRNA library (Addgene # 73178, ~4 guides/gene, 19'114 genes). In parallel, three CCSA patient samples and multiple CCSA cell lines (SU-CCS-1, DTC-1, KAS) were treated with a library of 84 solid tumor pan-cancer drugs, and a custom drug library tailored to the hits of the CRISPR screen (70 compounds). Genes identified as critical vulnerabilities in CCSA were validated through single-gene knockouts, and promising therapeutic targets were further mechanistically interrogated and evaluated in a CCSA xenograft model.
Results: Results revealed 1'552 significantly depleted genes (log fold change <-1 and FDR < 0.01) after 21 days, with enriched pathways in proteasome activity, mismatch repair, DNA replication, and, mTORC1 signaling, revealing critical vulnerabilities. Notable highly ranked depleted genes include the transcription factor and CCSA marker *SOX10*, as well as *MDM2, MCL1, CHEK1, HSPA5, PSMA5* and mTOR. Through integration of genetic knock-out and pharmacological inhibition data identified in our dual screening, we were able to identify several overlapping vulnerabilities. Initial validation of the therapeutic potential of PI3K/mTOR inhibition in CCSA cell models *in vitro* revealed an induction of apoptosis upon treatment. We then corroborated those findings in a CCSA xenograft mouse model *in vivo*. Treatment with the two combined PI3K/mTOR inhibitors omipalisib and copanlisib both resulted in significantly improved survival ($P = 0.027$ and $P = 0.036$, respectively) of tumor bearing mice, and reduced tumor growth, each compared to vehicle treatment.
Conclusion: These findings offer new insights into actionable vulnerabilities in CCSA, with PI3K/mTOR inhibitors showing potential for therapeutic development. Future studies will investigate synergistic combinations to further optimize treatment efficacy and validate further vulnerabilities identified by our dual screening approach.

#5665 Targeted cell killing: a versatile platform for cell therapy and cytotoxicity assays in diverse cell lines.

Nicholas J. Hess, Brock Binkowski, Julia Gilden, Gopal Krishnan, Mei Cong, Marjeta Urh

Promega Corporation, Fitchburg, WI, USA, WI

The HiBiT Target Cell Killing Assay (HiBiT TCK Assay) is a streamlined, sensitive method for selectively quantifying target cell lysis in coculture experiments with effector cells. HiBiT is an 11AA peptide that binds with high affinity to LgBiT, forming a bright, luminescent enzyme. For HiBiT TCK, target cells are engineered to express a HiBiT-tagged protein, and release of this protein by dead/dying cells leads to complementation with the cell impermeable LgBiT. This gain-of-signal approach enables precise measurements of target cell killing induced by various effectors, including CAR-T cells and cell killing mediated by bispecific antibodies. Here we demonstrate the use of HiBiT TCK with ADCC, ADCP, TDCC and CAR-T applications. Furthermore, we present data of mRNA transfection to transiently express HiBiT in a variety of target cells, allowing for the rapid and uniform labeling of both dividing and non-dividing cells. This approach extends the HiBiT TCK products beyond use of stable cell lines alone and allows users to screen a variety of cell lines.

#5666 Akos: A novel CAF-targeted therapy to reprogramming the tumor microenvironment to reverse metastatic traits in all solid tumors.

Javier Cerda-Infante[1], Benjamin Prieto[2], Valentina I. Cerda[2], Muriel Nunez[2]

[1]Pontificia Universidad Catolica de Chile, Santiago, Chile,[2]Environ, Santiago, Chile

Introduction: Metastasis is responsible for approximately 90% of cancer-related deaths, yet current therapies fail to effectively address this critical challenge. The tumor microenvironment (TME), particularly carcinoma-associated fibroblasts (CAFs), plays a pivotal role in metastatic progression by driving extracellular matrix (ECM) remodeling, epithelial-to-mesenchymal transition (EMT), and immune evasion. Within metastatic CAFs (mCAFs), we identified a key protein that regulates these processes and developed Akos, a small molecule that selectively inhibits this protein, reprogramming the TME to disrupt the metastatic cascade. This study evaluates the preclinical efficacy, specificity, and safety of Akos across multiple solid tumor models.
Materials and Methods: Primary stromal cell cultures were obtained from needle biopsies of primary tumors from patients with advanced/metastatic cancer (mCAFs), non-metastatic cancer (CAFs), and non-cancerous patients (BAFs). Protein expression was validated through gene profiling, immunohistochemistry, and western blot. In vitro assays were conducted to assess Akos' ability to inhibit mCAF-mediated tumor cell invasion, proliferation, and EMT marker expression. In vivo xenograft models of prostate, breast, colorectal, and pancreatic cancers were utilized to evaluate Akos' effects on tumor growth, weight, and metastatic spread. A spontaneous metastasis assay, replicating the full metastatic cascade, was employed to evaluate its anti-metastatic potential. Toxicology and pharmacokinetic studies were conducted to assess systemic safety and drug stability.
Results: Akos demonstrated significant in vitro efficacy, inhibiting mCAF-driven tumor cell invasion and proliferation while reducing EMT marker expression. In in vivo xenograft models, Akos reduced tumor volume by 50-fold and tumor weight by 30-fold compared to untreated controls. In the spontaneous metastasis assay, Akos completely blocked 100% of metastatic foci across all tested models. Toxicology studies confirmed Akos' safety profile, with no significant off-target effects observed, while pharmacokinetics showed stable systemic exposure.
Discussion: These findings position Akos as a promising therapeutic candidate for targeting the TME to address the unmet need in metastatic cancer treatment. By inhibiting a key protein in mCAFs, Akos effectively disrupts the processes driving metastatic progression, offering a novel approach to halting the spread of cancer. The observed efficacy across multiple tumor types, combined with its favorable safety profile, supports further clinical investigation of Akos as a first-in-class therapeutic for metastatic solid tumors. These results underscore the potential of targeting the TME to improve patient outcomes and advance the standard of care in oncology.

#5667 Epidemiology of tissue factor expression in soft tissue sarcoma.

Francesca La Greca[1], Agnieszka Wozniak[1], Chao-Chi Wang[1], Daniel Gorgels[1], Flavia Paternostro[1], Luna De Sutter[1], Lore De Cock[1], Kimberly Verbeeck[1], Ulla Vanleeuw[1], Raf Sciot[2], Patrick Schoffski[3]

[1]Laboratory of experimental oncology, KU Leuven, Leuven, Belgium,[2]Department of Pathology, Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium,[3]Department of General Medical Oncology, Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium

Objective: Soft tissue sarcoma (STS) is a heterogeneous group of rare, malignant mesenchymal tumors, comprising over 70 subtypes. Doxorubicin-based chemotherapy, the standard treatment for the majority of advanced or metastatic STS, has limited efficacy, with low response rates and poor disease control. Identifying new molecular targets is crucial for developing more effective treatments and overcoming resistance, considering the high unmet medical need in this indication. Tissue factor (TF) is a transmembrane protein essential for hemostasis and thrombosis. High levels of TF have been observed in cancers, particularly adenocarcinomas, where it promotes tumor growth, invasion, metastasis and angiogenesis. TF expression in tumors and in tumor-associated endothelial cells is currently considered a putative therapeutic target. Consequently, a TF-targeted antibody-drug conjugate (tisotumab vedotin) has been approved by the Food and Drug Administration for the treatment of cervical cancer.As its expression in STS remains unexplored, we aimed to assess the expression of TF in tissue microarrays (TMA) constructed from archival tumor material from patients and patient-derived xenograft (PDX) models.
Methods: Immunohistochemical staining was performed on TMA. Over 550 patient samples with 2-3 cores per tumor were analyzed, covering the 11 most common STS subtypes, such as leiomyosarcoma (LMS), liposarcoma (LPS), angiosarcoma (AS) and myxofibrosarcoma (MFS).In addition, TMA from 31 PDX models from our XenoSarc platform, covering 14 STS subtypes, were included with at least 2 cores per model, with multiple passages of the xenografts to account for potential intra-tumor variability of TF expression during passaging.TMA were evaluated using the scoring: 0 (no expression), 1 (<25% positive cells), 2 (25-50%), and 3 (>50%); scores of 2 or 3 were considered as high expression.
Results: Analysis of a multi-sarcoma clinical TMA revealed a limited number of cases with high expression of the target in only a few samples from AS, LPS, LMS and MFS, subtypes that were selected for further analysis using subtype-specific TMAs from these entities. High expression was found in 22.5% of MFS (27 out of 120 donors), 8.0% of AS (6 out of 79 cases), 4.7% of LMS (6 out of 128 patients), 3.2% of LPS (2 out of 62 patients). Detailed correlations with relevant clinical data are currently ongoing and results will be disclosed at the meeting.In the PDX, high TF expression was observed in 9 out of 31 models in at least one passage. Three out of 4 MFS models showed TF high expression in at least one passage and two high-grade sarcoma models maintained high expression across multiple passages (≥3).
Conclusion: TF expression in STS is generally limited, with MFS showing the highest number of positivity in clinical samples and xenograft models. Nevertheless, the observed frequency appears insufficient to support TF as suggestive therapeutic target across other subtypes of sarcomas.

#5668 Preclinical efficacy of tumor treating fields (TTFields) for small cell lung carcinoma (SCLC).

Rotem Engelman, Lina Somri-Gannam, Talya Borkum, Roni Blatt, Daria Gerasimova, Shay Cahal, Catherine Tempel Brami, Mai Shai, Eyal Dor-On, Itai Tzchori, Adi Haber, Moshe Giladi, Yoram Palti

Novocure Ltd, Haifa, Israel

Purpose: Small cell lung cancer (SCLC) is a highly aggressive malignant neoplasm, accounting for 10-15% of lung cancer cases, characterized by rapid growth, and early metastasis. The standard of care is combination chemotherapy with cisplatin or carboplatin plus etoposide, administered together with immunotherapy and concurrent chest radiotherapy. The current preclinical study aimed to investigate the efficacy of TTFields for treatment of SCLC and examine the effect of TTFields together with the standard-of-care chemotherapies.
Methods: DMS-53 and H196 SCLC cells were treated with TTFields (1 V/cm RMS, 150 kHz, 72 h for DMS-53 cells; 1.62 V/cm RMS, 150 kHz, 120 h for H196 cells), alone or with the addition of different concentrations of cisplatin or etoposide. Efficacy was measured by analyzing cell count, colony formation, and apoptosis induction. The overall effect was calculated by multiplying cell count with colony formation. TTFields efficacy was further evaluated in vivo, in mice orthotopically inoculated with murine KP3 SCLC cells. 7 days after inoculation, TTFields or sham-heat were continuous applied for 9 days. Tumor volume was examined by magnetic resonance imaging (MRI) at treatment end.
Results: TTFields reduced cell count, induced apoptosis, and provided an increased overall effect relative to control in both cell lines. Application of cisplatin or etoposide alongside TTFields showed a synergistic interaction in H196 cells, which was higher for the latter chemotherapy. In DMS-53 cells, the concomitant treatment of TTFields with either chemotherapy showed an additive interaction in cytotoxicity and a synergistic overall effect, which matched the relatively high levels of apoptosis in this cell line. Furthermore, TTFields significantly reduced tumor growth relative to control in the mouse model.
Conclusions: Our results demonstrate efficacy for TTFields for the treatment of SCLC in preclinical models, and a potential advantage for TTFields concomitant with the standard-of-care chemotherapies for this malignancy. Future studies will test the effect of TTFields concomitant with both chemotherapies, in vitro and in vivo; and together with immunotherapy and chemotherapy.

#5669 Performance characterization of the Cellometer Ascend automated cell counter following ISO cell counting standards.

Carolina Franco Nitta, **Yongyang Huang**, Daniel Browe, Allen Lin, Sopaul Hem, Leo L. Y. Chan, Bo Lin, Dmitry Kuksin

Revvity Health Sciences, Inc., Lawrence, MA

In modern therapeutics, cell counting and viability are extremely common, yet vital measurements in research, process development, and manufacturing for novel discoveries and development. Many challenges are associated with these frequent readouts, specifically due to the absence of reference materials, cell sample heterogeneity, stability of living cells, complexity of cell sample preparation, and differences in chemical staining methods. The International Organization for Standardization (ISO) has published two documents to help support cell counting procedures: ISO 20391 - 1:2018 Biotechnology - Cell Counting - Part I: General Guidance on Cell Counting Methods; and ISO 20391 - 2:2019 Biotechnology - Cell Counting - Part II: Experimental Design and Statistical Analysis to Quantify Counting Method Performance. The Cellometer Ascend, Revvity's next generation automated cell counter, has been designed to provide reliable and consistent cell counting and viability measurements as an all-in-one standalone instrument with a user-friendly streamlined workflow allowing for cell counting at a larger concentration range. In this work, we characterized the cell counting performance of the Cellometer Ascend, following ISO cell counting standards. Linearity tests using Jurkat cells showed that Cellometer Ascend reliably covered a concentration range from 2.6×10^4 cells/mL to 4×10^7 cells/mL, with a precision below 10%. A truncated version of the ISO cell counting Part II protocol was developed internally to evaluate the performance and compare quality metrics for four distinct cell counting methods. These methods were compared simultaneously to minimize the variation from cell sample stability and results revealed comparable mean cell counts, precision, coefficient of determination (R^2), and proportionality indices (PI). We further conducted multiple cell counting comparisons using the Bland-Altman comparative analysis, and showed that the Cellometer Ascend was in line with the other three instruments with a less than 6% difference observed in all cases. In addition, we investigated instrument-to-instrument consistency using two different concentrations of fluorescent beads on five Cellometer Ascend instruments. Results from the 5×10^6 beads/mL and 2.5×10^5 beads/mL concentrations showed coefficient of variation (CV) of 0.8% and 2.2%, respectively. In conclusion, the Cellometer Ascend can be used to provide high-quality cell counts and viability readouts according to ISO Cell Counting standards, is comparable to other cell counting methodologies, and could therefore be the benchtop solution for multiple cell counting needs.

#5670 Using molecular docking to develop a novel peptide targeting tumor-associated macrophages based on RXRB recognition.

Nianwu Wang, Hong-Bo Pang

Department of Pharmaceutics, College of Pharmacy, University of Minnesota, Minneapolis, MN

Tumor-associated macrophages (TAMs) play a critical role in tumor progression, and thus have attracted great attention for therapeutic development. However, macrophage-modulating strategies suffer from drawbacks that they may interfere with normal immunity. Therefore, it is desirable to target and modulate macrophages in tumor-specific manner. We previously identified one such peptide, termed CRV, which selectively homes to a variety of solid tumors and bind TAMs within upon systemic administration. This TAM-targeting ability was then attributed to CRV receptor, retinoid X receptor beta (RXRB). While CRV demonstrated desirable properties in tumor homing and TAM recognition *in vivo*, the actual affinity to RXRB was very weak. We hypothesize that peptide variants with a higher affinity to RXRB may exhibit a more specific targeting of TAMs. To test this hypothesis, we employed molecular docking to optimize the CRV sequence. Seven rounds of optimization were carried out to replace one residue of CRV peptide in each round with nineteen other amino acids, and the binding energy was calculated as the selection criterion. This study identified a novel peptide, termed CRH, with an improved predicted binding affinity compared to CRV (-12.2 kcal/mol vs. -8.9 kcal/mol). In vitro assays verified that CRH possesses a higher affinity to RXRB than CRV. Ongoing studies include surface plasmon resonance (SPR) binding analysis and *in vivo* homing evaluations. Overall, we showcase here the identification of a novel peptide to target TAMs, which may enable a more precise drug delivery and TAM modulation.

#5671 Development of HTS enzymatic assays for VPS4A and related ATPases.

Anibal Ramos Martinez, Camdon Yemm, **Ha Pham**, Robert Lowery

BellBrook Labs, Madison, WI

VSP4A and VSP4B (Vacuolar Sorting Protein) are members of the meiotic clade ATPases, which function as oligomers and use ATP hydrolysis to drive protein translocation through their central pore. VPS4B is frequently deleted in several cancers, and VPS4A has been shown to be synthetic lethal with VPS4B in cells and animals, causing cell death accompanied by induction of inflammatory cytokines and anti-tumor responses. To accelerate development of selective VPS4A inhibitors while avoiding off target effects with related ATPases, we are assembling a panel of high throughput biochemical assays using the Transcreener ADP^2 assay for homogenous detection of ATPase activity with a far-red fluorescence polarization (FP) readout. Here we describe development of assays for VPS4A, VPS4B, as well as Spastin, Katanin and Fidgetin, related meiotic clade ATPases that play important roles in microtubule metabolism. Using purified recombinant enzymes, we established reaction conditions, determined kinetic parameters, and optimized the assays for initial velocity detection of ATPase activity with a Z' value greater than 0.7, ensuring a sufficient signal window for inhibitor screening and dose response assays. We validated the VPS4A assay for HTS by screening a collection of bioactives (Tocris 2.0) and confirming two hits in dose response mode: BVT948, a PTP inhibitor, and polygodial, an antifungal that has been shown to inhibit a mitochondrial ATPase, both inhibited VPS4A and VPS4B with low micromolar potency. We then profiled BVT948 and polygodial for inhibition of Spastin, Katanin and Fidgetin: both molecules showed modest selectivity (2-5-fold) vs. Katanin and Fidgetin but had similar or greater potency for inhibition of Spastin. These assays will aid efforts to exploit the VPS4A/4B synthetic lethality therapeutically, including screening and SAR-driven hit-to-lead to minimize off-target effects with related ATPases.

#5672 Detecting tissue susceptibility to celecoxib treatment using a whole-body imaging approach.

Steven Johnson[1], Justin Jeffery[2], Jungwha Lee[1], Ming Zhao[1]

[1]Northwestern University, Chicago, IL,[2]University of Wisconsin Madison, Madison, WI

Purpose: The goal of this study was to evaluate an in vivo imaging technique, which detects phospholipid membrane reorganization, as a molecular marker for tissue response induced by celecoxib as a canonical black box drug which is also being repurposed for anticancer treatment.
Methods: 99mTc-duramycin was used as a phosphatidylethanolamine (PE)-binding imaging agent and was injected intravenously at 1 hour prior to imaging at designated time points. Sprague Dawley rats (male, 8-10 weeks) were treated with a single dose of 200 mg/kg or 1000 mg/kg celecoxib via oral gavage. A pilot study was conducted in duplicates with planar imaging on days 1, 3, 5 and 7 to determine the approximate window of signal changes, then whole-body single photon emission computed tomography (SPECT) was acquired for nontreated control, 200 mg/kg and 1000 mg/kg celecoxib-treated groups (n=12 per group). Blood and tissues from 4 animals in each group were collected for complete blood and serum panels and histopathology. The radioactivity uptake in tissues and organs were determined and statistically compared to the control group using unpaired t test.
Results: The imaging data detected no significant changes with low dose (200 mg/kg) celecoxib treatment, but in a number of tissues/organs in high dose (1000 mg/kg) treatment, including the adipose tissue, blood, brain, upper right quadrant of the abdomen, heart, kidney, skeletal muscle, stomach, and testes. Histopathology analysis is ongoing to validate the imaging findings. Data from complete serum panel detected significantly elevated total protein, albumin and sodium.
Conclusion: The study demonstrated the assessment of tissue susceptibility as a result of celecoxib treatment, which were consistent with known adverse effects of the drug. The current approach will be useful for detecting potential off-target side effects of anticancer treatments and drug candidates.

#5673 Identification of potential therapeutic targets by in vivo CRISPR screening on xenograft models.

Ce Zhong, Lu Bai, Tongtong Wang, Yiying Shao, Lingyun Zhang, Lu Zhang, **Jingqi Huang**

Pharmaron, Inc., Beijing, China

Introduction: CRISPR screens have been successfully used to identify targetable genes for anti-cancer research and drug development. Typically, CRISPR screens are conducted *in vitro* on cell lines, which do not fully capture the influence of the in vivo physiological environment. It is well known that any genetic editing might trigger the adjustment of gene balance to compensate for the modifications in the target cells and tissues. To address the complexity of cellular interactions and the immunological response, in vivo CRISPR screening on a xenograft model is a compelling approach to unravel biological processes where cells are targeted within their natural physiological conditions.
Methods: We have conducted a CRISPR screening approach using the human non-small cell lung cancer cell line A549 by knocking out tumor suppressor genes using a library of 3,188 single guide RNAs (sgRNA). Subsequently, in vivo testing was carried out with the genetically edited A549 cells with or without treatment with the kinase inhibitor Trametinib. At the study endpoint, tumor samples were isolated and analyzed. Amplicon sequencing was used to capture residual sgRNA. MAGeCK was used to calculate the gene enrichment score.
Results: After CRISPR editing, 37 sgRNA corresponding to 20 genes were captured in the edited A549 cell line. In the vehicle-treated A549 xenograft tumors, 45 sgRNA corresponding to 27 genes were captured, of which 17 genes were overlapping with engineered A549 cell culture, 8 upregulated and 9 downregulated. In comparison, in the A549 xenograft tumors of the Trametinib treated group, 38 sgRNA corresponding to 23 genes were discovered, with 15 overlapping genes, 9 upregulated and 6 downregulated. The change in expression levels was abundant. Of the 3,188 sgRNA, the majority of sgRNAs were filtered out in the A549 cell line, under in vivo evolution and the influence of Trametinib treatment. We believe that the pathways related to this small set of identified genes may reveal potential new targets for anti-cancer research and drug development.
Conclusion: The in vivo CRISPR approach offers a valuable and translational tool for discovering novel targets in cancer research, providing insights for new anti-cancer therapies.

#5674 StarBright^{TM} Dyes for flow cytometry, western blotting, microscopy and Genesis System with CelSelect Slides.

Michael Blundell[1], Leon Huang[2], Sharon Sanderson[1]

[1]Bio-Rad Laboratories, Kidlington, United Kingdom,[2]Bio-Rad Laboratories, Hercules, CA

There are many antibody-based applications in the researcher's toolbox that rely on both high-quality antibodies and bright stable fluorescent dyes. Antibodies are usually validated for specific applications and may only work on fresh samples and not work if a sample is fixed. The same application specificity can also be observed with fluorescent dyes. Some dyes are easily bleached, may not be stable after fixation and have spectral profiles that make it impossible to multiplex in some applications. To be able to use multiple applications, researchers may need to purchase three or four versions of an antibody or use sub-optimal choices to keep costs manageable. Here we present data on StarBright Dyes, a range of 33 fluorescent dyes, in a multitude of antibody-based applications. They are bright, have low cross laser excitation, can be fixed in PFA and alcohol-based buffers and work in all protocols without specific buffers, especially when multiplexing. StarBright Dyes have been developed to give researchers high quality data whilst providing flexibility and choice regardless of the application. They work in flow cytometry, allowing very high plex panels to be developed with manageable spillover and spreading, require no special buffer and even allow storage of premixed panels. In western blot their brightness, short exposure time and low background makes them ideal for detection of a single target, or in multiplexing. Their brightness allows easy identification and enumeration in cell enrichment systems such as the Genesis System^{TM}. Finally in microscopy, both wide field and confocal, their photostability, range of emission, and brightness, not only gives more choice, but as they can be used as primaries without the need for secondary amplification can speed up staining protocols and allow panel expansion without species cross reactivity. Here we demonstrate how you can reduce the number of fluorophores and antibodies required for each application and simplify your protocols by including StarBright Dye conjugated antibodies in your experiments.

#5675 ThiOBI® platform, a novel hydrophilic linker for irreversible cysteine-selective biomolecular conjugation, demonstrated potent and durable antitumor activities in various animal models.

Yu-Chao Huang, Ting-Wei Liu, Chi-Huan Lu, Ren-Yu Hsu, Nan-Hsuan Wang, Ya-Chi Chen, **Ming-Tain Lai**, Teng-Yi Huang

OBI Pharma, Inc, Taipei, Taiwan

The ThiOBI® platform represents a cutting-edge approach for the development of next-generation cysteine (Cys)-based drug conjugates including a wide range of cysteine-containing biomolecules, such as nanobodies, antibody fragments, and peptides. This platform leverages a novel hydrophilic stable linker that efficiently delivers the drug to the site of action to enhance therapeutic potential. In addition, an irreversible thiol conjugation enables Cys-selective biomolecular modification providing meticulous control of the drug conjugation process.
Maleimide is a chemical group commonly used in the design of linkers for bio-conjugation, particularly in antibody-drug conjugates (ADCs), where it plays a key role in attaching a cytotoxic payload to the antibody through a linker. Seven FDA approved ADCs used Cys-maleimide chemistry. However, a major limitation of the traditional cysteine-maleimide conjugated ADCs is their instability due to retro-Michael deconjugation, which can lead to premature payload release in circulation. The ThiOBI® platform addresses this challenge by employing a stable hydrophilic linker to prevent such reaction ensuring drug delivery in a more controllable manner. This innovation profoundly improves stability and physicochemical properties of the conjugated biomolecules, minimizes off-target effects, and enhances the overall therapeutic index.
In preclinical studies, ThiOBI®-based ADCs demonstrated potent and durable antitumor activities across a variety of animal models. Notably, the platform possesses substantial flexibility that is capable of incorporating a range of payloads and biomolecular formats, including antibody fragments, nanobodies, and peptides, all of which show enhanced therapeutic activity. This versatility allows for targeting a broader spectrum of cancers and diseases that are not easily addressed by conventional antibody-based ADCs.
The promising preclinical results highlight the versatility and therapeutic promise of the ThiOBI® platform, positioning it as a powerful tool for the development of next-generation drug conjugates. The successful demonstration of potent and durable antitumor activities in animals provides a strong foundation for future clinical development of the biomolecules derived from ThiOBI®.

#5676 TFC Quick ‘n’ Clean, a next-gen platform for high-throughput production of true four-chain bispecific antibodies.

Julia Su[1], Gaozhan Zhang[2], Xiayan Li[2], Dawei Zhang[2], Mengjie Lu[2], Zhumei Feng[2], Jiansheng Wu[2], **Doris Wei**[1]

[1]WuXi Biologics, Cranbury, NJ,[2]WuXi Biologics, Shanghai, China

Introduction: Bispecific antibodies (BsAbs) are a promising class of biologics with substantial therapeutic potential. However, the production of bsAbs, particularly four-chain bsAbs containing two distinct LCs, presents significant challenges. Issues such as LC mispairing, fragmentation, and aggregation complicate purification processes and impact overall yield, purity and throughput. To address these challenges, WuXi Biologics has developed the True Four Chain (TFC) Quick ‘n’ Clean platform. By leveraging the WuXiBody™ backbone, this platform eliminates LC mispairing and enables high-throughput, high-purity production of four-chain bsAbs. This innovative approach accelerates the identification of optimal four-chain bsAb pairings during early-stage drug discovery.

Methods: All experiments were conducted at WuXi Biologics’ Protein Sciences Department. Briefly, the codons of DNA sequence were optimized, and the plasmids were constructed into WuXi Biologics’ proprietary plasmid vector. Transient transfection was performed in CHO cells, with the culture medium harvested after 7 days. The harvested culture medium was clarified and subsequently processed using an AKTA Pure system with a tandem purification strategy using Nickel, anti-DYKDDDDK, and SEC columns. Final products were analyzed using SDS-PAGE, SEC-HPLC, Intact Mass, and LAL assays.

Results: Using the TFC Quick ‘n’ Clean platform, we successfully produced 15 four-chain bsAbs in 20 mL CHO cell cultures within 3-4 weeks. The platform achieved an average monomer purity of 98.23%, an average yield of 3.34 mg, and an average endotoxin level of 0.06 EU/mg. Intact Mass analysis confirmed the absence of impurities such as homodimers and LC mispairing, with heterodimer purity exceeding 99%.

Conclusion: The TFC Quick ‘n’ Clean platform overcomes key challenges associated with four-chain bsAb production by harnessing the WuXiBody™ backbone, high-titer CHO expression systems and advanced tandem purification strategies. This platform provides high-throughput, high-purity production of four-chain bsAbs, enabling the rapid, cost-effective identification of optimal parings to accelerate early-stage drug discovery and development.

#5677 Targeting G protein-coupled receptors in cancer pharmacotherapy: a comprehensive screening platform establishment and application in drug discovery.

Xiaoyan Wang, Dandan Hu, Ziwei Zhang, **Tj (Tiejun) Bing**

ICE Bioscience, Inc., Beijing, China

G protein-coupled receptors (GPCRs) constitute the largest family of membrane protein family in the human genome with over 800 members. They play an important role in various physiological and physiological processes and, such as proliferation, differentiation, neurotransmission, development and apoptosis. Several studies demonstrated that GPCRs play significant roles in the development of cancer, with their involvement in the initiation, growth, and spread of tumors being well-established. Several drugs targeting different GPCRs have been approved for the treatment of cancers, including CXCR4 (C-X-C chemokine receptor type 4) antagonism has been demonstrated to interfere with the communication between tumors and their surrounding stroma, enhance the susceptibility of cancer cells to chemotherapy, and reduce tumor growth and metastatic burden, GnRH (gonadotropin-releasing hormone) antagonists, which are used to treat hormone-dependent tumors like prostate cancer and breast cancer. Despite the increasing recognition of GPCRs' critical functions in cancer pathogenesis, it is noteworthy that only a small number of GPCR targets have been successfully leveraged for the development of anti-cancer treatments. Consequently, comprehensive compound screening platform is particularly important for highlighting the potential of pharmacologically modulating these GPCRs for the development of novel anti-cancer therapeutics.
This research established stable cell lines expressing GPCRs and constructed multiple assay modes for GPCR drug discovery and screening, including in vitro HTRF cAMP assay, calcium flux assay and β-arretin2 NanoBiT assay, which can be used for agonist, antagonist and inverse agonist validation. Meanwhile, several CDX modes are constructed for promisingly conducting in-vivo experiments and biomarker detection. Thus, our GPCR platform can provide comprehensive screening cascade for compound evaluation, support multiple approaches to facilitate anti-cancer drug discovery.

#5678 LC-HRMS based kinetic characterization platform for irreversible covalent inhibitor screening.

Cai Fu, Tong Wu, Li Li, **Tj (Tiejun) Bing**

ICE Bioscience, Inc., Beijing, China

Covalent inhibitors are recognized as indispensable parts in drug discovery and therapeutic researches. The irreversibility of covalent conjugation makes Liquid Chromatography-High Resolution Mass Spectrometry (LC-HRMS) a suitable tool for covalent inhibitor screening. LC-HRMS allows label-free, direct detection of the native protein and the covalent adduct in the sample, providing relative quantification of target engagement. Several methods have been developed for covalent screening using intact protein MS or peptide mapping, including binding site mapping, covalent binding rate determination and Kinact/Ki value measurement.
In this study, the final protein concentration was 1.5 μM and the serial concentrations of positive control AMG510 were from 0.49 μM to 4.00 μM, and the total incubation time was 100 seconds. The intensity of the native protein and covalent adducts were collected on a QE Plus coupled with a C4 column.
A relatively high binding rate was observed by intact mass analysis. And a sequence coverage of GDP-KRASG12C was above 75% using peptide mapping, the specific binding site was confirmed by MS2 data. Kinact/Ki value were fitted using more than six concentrations and five timepoints. This method was used for covalent inhibitors screening, binding site characterization and Kinact/Ki measurement.

#5679 A novel approach for antibody affinity maturation using AI-driven mutation prediction.

Yiran Li, Hao Peng, Hui Zhao, Xiaoyi Han, Panpan Zhang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Background: Therapeutic antibodies, characterized by their exceptional specificity and efficacy, have been a cornerstone of biotherapeutics development since their discovery. However, achieving high-affinity functional antibodies remains a significant challenge. Traditional affinity maturation methods, such as saturation mutagenesis combined with phage display screening, require extensive library construction and screening, which are time-consuming, costly, and present a high barrier to implementation. Here, we introduce a novel affinity screening approach leveraging AI-based deep learning networks to predict potential mutation sites that enhance affinity. Coupled with high-throughput expression systems, this approach effectively reduces screening scale and rapidly generates higher-affinity antibodies.
Methods: We developed and trained a novel AI model based on deep learning networks to facilitate antibody affinity optimization. The model simulates antigen-antibody docking and predicts affinity improvements by mutating the parent antibody's CDRs, identifying hotspot residues. We constructed the hotspot mutations and high-throughput expression in 96-well deep plates. The expressed antibody in supernatants were captured by protein A, and screened using sandwich ELISA. Mutations showing at least a 1.2-fold increase in OD450 are selected in preliminarily screening for AI to design combination mutations.
Results: For IgG antibodies, computational simulations reduced the initial single-point mutation library size by an order of magnitude, from 10^3 to 10^2 mutations, significantly decreasing library construction and screening costs. This approach enabled the completion of the initial screening within three weeks, with 10% of positive mutations exhibiting an OD450 increase of at least 1.2-fold. For VHH antibodies, optimization resulted in blocking activity increase up to a twofold reduction in IC50 and an 18.89-fold increase in affinity as measured by SPR. Similarly, IgG antibodies exhibited a 6.01-fold improvement in affinity (SPR).
Conclusions: We developed an AI model to simulate antigen-antibody binding and identify mutations for affinity enhancement. These predicted mutations were subsequently validated through experimental screening, confirming improved affinity. This approach enables the rapid and cost-effective generation of high-affinity antibodies.

#5680 MPSA-AB5000: a high-throughput membrane proteins screening array for therapeutic biologics specificity profiling.

Liping Wang, Yuanyuan Sun, Guoqian Wang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Antibody drug development is lengthy and complex, often hindered by various challenges in clinical advancement. Reports indicate that off-target binding of antibodies may be a significant issue, with approximately 25% of preclinical candidates potentially experiencing these off-target problems. With the rise of new modalities such as CD3 bispecific antibodies, ADCs, and CAR-T therapies, preliminary off-target screening of antibodies has become increasingly important. Despite the use of techniques like immunohistochemistry, ELISA, and flow cytometry (FACS) for off-target testing of antibodies, these methods still exhibit limitations in sensitivity, specificity, and throughput. To address the need for antibody target deconvolution and receptor identification, we developed a novel membrane protein screening array (MPSA) AB5000. MPSA-AB5000 is a high-throughput, cell-based platform for identifying antibody targets and off-targets, enhancing antibody specificity screening and reducing development risks. The MPSA-AB5000 covers diverse human membrane proteins, expressed in live cells to preserve native conformations. C-terminal epitope-tagged clones allow for expression confirmation and cellular localization. To provide the highest level of sensitivity, MPSA-AB5000 uses luciferase reporter cell line detection. The wash-free strategy reduces false negatives, and signal amplification makes remarkable discrimination. Compared to similar technologies, we possess significant advantages in the following aspects: a. High sensitivity and sigh throughput: our technology platform offers not only high sensitivity, capable of detecting subtle interactions but also supports high-throughput screening, allowing for the evaluation of a large number of samples in a short timeframe. b. Avoidance of false negative signals: by eliminating washing steps, our method reduces the risk of false negative signals, ensuring reliable detection of non-specific binding. c. Comprehensive validation approaches: we employ various validation methods such as FACS and ELISA to eliminate false positive signals, enhancing the accuracy and credibility of our results. All the advantages ensure that MPSA-AB5000 is more rapid, simple, and highly sensitive than traditional assays.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Oncogenes, Tumor Suppressor Genes, and Gene Products as Targets for Therapy 2
Poster Session

#5684 PARP inhibitors boost antitumor effects of ADAR1 inhibition regardless of BRCA1 status.

Sophie O'Keefe, Dhillon Parikshak, Marcus Meade, Qiwei Wang

University of Virginia, Charlottesville, VA

Triple-negative breast cancer (TNBC), characterized by the absence of estrogen and progesterone receptors and HER2, is the most aggressive form of breast cancer. Despite recent advances in treatment, patients with advanced TNBC continue to face the worst prognostic outcomes among all breast cancer subtypes. In this project, we aim to develop new and more effective therapies for advanced TNBC. Poly (ADP-ribose) polymerase (PARP) inhibitors (PARPis), a class of drugs that target the DNA damage repair response, are the first and only targeted therapy approved for patients with advanced or metastatic TNBC. PARPis are best known for inducing synthetic lethality in tumors deficient in homologous recombination (HR) repair proteins like BRCA1/2. Thus, their approval is limited to BRCA1/2-deficient breast cancer. We and others recently demonstrated that PARPis can also trigger anti-tumor immunity by activating the STING-type I interferon signaling axis (PMID: 30540933, 35641483). However, it remains unclear whether the immunomodulatory role of PARPis can be exploited to expand their use in TNBC. In this study, we found that PARP inhibition increased interferon-stimulated gene (ISG) expression in both BRCA1-deficient and BRCA1-proficient breast cancer cells. This finding is significant because previous studies suggest that cancers with elevated ISG expression are highly reliant on the RNA editing enzyme adenosine deaminase 1 (ADAR1) for survival, making them susceptible to ADAR1 inhibition (ADAR1i). To investigate this further, we utilized tumor cell lines derived from genetically engineered mouse models (GEMMs) of TNBC and employed siRNA, shRNA, and small molecule inhibitors against ADAR1. Notably, we demonstrated that combining PARPi with ADAR1i synergistically killed TNBC cells, regardless of their BRCA status. Taken together, our results highlight the potential of combing PARPis with ADAR1i for treating TNBC, including BRCA-proficient tumors.

#5685 Targeting the NR2F6-NACC1-NOTCH3 axis: a promising therapeutic strategy to combat tumor progression and resistance in endometrial cancer.

Xiaoqi Sun[1], Xiaofang Guo[1], Tram Le[1], Vaagn Andikyan[2], Thomas J. Rutherford[2], Eduardo Sotomayor[2], Matthew L. Anderson[2], **Adrian Kohut**[2]

[1]University of South Florida, Tampa, FL,[2]University of South Florida/Tampa General Cancer Institute, Tampa, FL

Background: Uterine corpus endometrial carcinoma (UCEC) is the most common gynecologic malignancy, with poor prognoses in advanced, high-grade, or treatment-resistant cases. The transcription factor NR2F6 (nuclear receptor subfamily 2 group F member 6) has emerged as a key regulator of immune evasion, tumor progression, and therapy resistance, suppressing T-cell activation by regulating PD-L1 (programmed death-ligand 1) expression. Nucleus accumbens-associated protein 1 (NAC1), encoded by the NACC1 gene, is a transcriptional repressor critical for tumor growth, metastasis, and drug resistance. NOTCH3 (Notch homolog 3), a downstream regulator, contributes to therapy resistance and tumor aggressiveness. This study investigates the significant therapeutic potential of targeting this axis.

Methods: Gene expression data from 529 UCEC patients were obtained from The Cancer Genome Atlas (TCGA), and survival analyses were performed using R Studio. Microsatellite instability (MSI) cell line HEC1A and microsatellite stable (MSS) cell line KLE were obtained from ATCC. Knockdowns of NR2F6 and NACC1 were performed using small interfering RNA (siRNA). Semi-quantitative real-time PCR (RT-qPCR) and Western blot were used to measure NR2F6, NACC1, NOTCH3, and PD-L1 expression. Cell proliferation was evaluated using Promega assays. NIC3, a small-molecule inhibitor that prevents NAC1 homodimerization and induces proteasomal degradation, was applied to validate findings from siRNA experiments. Statistical significance was determined using paired Student's t-tests.

Results: High expression of NR2F6 and NACC1 was associated with poor survival in UCEC patients (NR2F6: $p = 0.0017$; NACC1: $p = 0.019$). Correlation analyses showed a strong relationship between NR2F6 and NACC1 (Pearson $r = 0.54$, $p < 0.0001$) and a moderate relationship between NACC1 and NOTCH3 ($r = 0.45$, $p < 0.0001$). RT-qPCR and Western blot analyses revealed that NR2F6 knockdown significantly reduced NACC1, NOTCH3, and PD-L1 expression. NACC1 knockdown similarly decreased NOTCH3 and PD-L1 expression, confirming its regulatory role in the axis. Notably, siRNA-mediated knockdowns and NIC3 treatment significantly reduced cellular proliferation across all treated cell lines (HEC1A, KLE, and Colo 684). NIC3 similarly demonstrated the ability to degrade NAC1 protein and reduce downstream NOTCH3 and PD-L1 expression.

Conclusions: This study highlights the therapeutic potential of targeting the NR2F6-NACC1-NOTCH3 axis in UCEC. Validation at both mRNA and protein levels, combined with the observed reduction in cellular proliferation, underscores the promise of this axis as a critical target in high-grade or treatment-resistant tumors. The small-molecule inhibitor NIC3 offers a novel strategy to disrupt NAC1-mediated signaling, and potentially target UCEC.

#5686 Revealing the unique malignant mechanism of gastric-type adenocarcinoma of the cervix.

Hiroaki Yamada[1], Akira Yokoi[2], Kazuhiro Suzuki[2], Kosuke Yoshida[2], Eri Inami[2], Masami Kitagawa[2], Naotake Tsuda[1], Hiroaki Kajiyama[2]

[1]Obstetrics and Gynecology, Kurume University Hospital, Kurume, Japan,[2]Obstetrics and Gynecology, Nagoya University Graduate School of Medicine, Nagoya, Japan

Objective: Gastric-type adenocarcinoma of the cervix (GAS) is an HPV-independent malignancy that accounts for 20-25 % of cervical adenocarcinomas. Compared to usual-type endocervical adenocarcinoma (UEA), GAS is resistant to chemotherapy and radiotherapy, and has a poor prognosis. However, its molecular biological mechanisms remain unclear. This study aimed to identify specific RNA profiles associated with GAS pathophysiology to discover diagnostic and therapeutic targets.
Methods: We examined 15 tumor samples from patients who underwent primary hysterectomy (7 GAS, 8 UEA). From FFPE specimens, only the tumor region was obtained, and miRNA-seq and mRNA-seq were performed. RNA was also extracted from the GAS-derived KGAS cell line, UEA-derived HCA-1 cell line, and normal cervical epithelial HCK1T cell line for miRNA-seq. Extracellular vesicles (EVs) from each cell line were collected, and miRNA-seq was performed by using EV-RNA. Detail functional analyses were performed using cell lines.
Results: miRNA sequencing of FFPE samples, cell lines, and EVs derived from GAS and UEA identified 48 miRNAs highly expressed in GAS tissue, 37 in GAS cell lines, and 41 in GAS-EVs. Further target exploration revealed one miRNA specifically highly expressed in GAS. Additionally, mRNA sequencing analysis of tumor tissue samples with 10 cases (5 GAS, 5 UEA) identified a total of 14,541 genes, and clustering analysis showed that GAS and UEA had clearly distinct expression profiles. Differential expression analysis identified 449 upregulated genes in GAS and 577 downregulated genes in UEA, meeting the criteria of FC ≥ 1 and p-value < 0.05. Among these, the top 30 genes with the highest FC values and basemean ≥ 50 were selected. IPA and GSEA analyses significantly detected cancer-related pathways, including RTK-RAS-PI3K, PDGF signaling, and cell cycle-related pathways. The top 10 significant genes were validated by qRT-PCR, and protein expression was confirmed by immunohistochemistry. Functional validation in cell lines showed that GAS exhibited significantly higher cisplatin resistance ($p < 0.05$) than other cell lines, and suppression of newly identified specific target gene in GAS cells resulted in increasing sensitivity of cisplatin.
Conclusion: This study revealed detailed miRNA and mRNA profiles of GAS and UEA, identifying GAS-specific miRNA and gene expression. Identified genes were confirmed as not only useful as disease markers but also functional targets. These findings contribute to understanding the unique malignant mechanisms of GAS and highlight promising targets for future therapeutic strategies.

#5687 Immune-associated genes as potential therapeutic targets in small cell lung cancer.

Akihiko Miyanaga, Yang Yunchu, Kuniko Matsuda, Takehiro Tozuka, Aya Fukuizumi, Kakeru Hisakane, Naomi Onda, Susumu Takeuchi, Koichiro Kamio, Kazuo Kasahara, Masahiro Seike

Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan

Background: Recently, immune checkpoint inhibitors (ICIs) have been increasingly applied in the treatment of small cell lung cancer (SCLC). While their development has enhanced treatment options for SCLC, the effectiveness of immunotherapy remains limited due to the low expression of Programmed Cell Death Ligand 1 (PD-L1) and the emergence of immunotherapy resistance. As a result, there is a pressing need for new biomarkers to guide SCLC treatment.

Methods: We obtained four microarray datasets from GEO (Gene Expression Omnibus) database and screened differentially expressed genes (DEGs). After the establishment of protein-protein interaction network through Cytoscape, key hub genes were selected via a volcano plot. To validate these results, we used an independent dataset as a test cohort. We also analyzed differences in immune cell infiltration between normal and SCLC samples. Lastly, we identified a marker gene associated with immune cell infiltration and validated its role in SCLC through in vitro experiments.

Results: We screened GEO gene expression database for DEGs, which are immune-related genes, in SCLC. A PPI network analysis revealed seven overexpressed hub genes (*AURKB, BIRC5, TOP2A, TYMS, PCNA, UBE2C, AURKA*) in the SCLC cohort, which were significantly more expressed than in normal cells. Correlation analysis between immune cells and the seven hub genes showed that BIRC5 expression was inversely correlated with monocytes. In SCLC cell lines such as SBC5 and SBC3, downregulation of BIRC5 using siRNA induced apoptosis and inhibited cell activity, tumor invasiveness and proliferative potential. Furthermore, treatment with a BIRC5 inhibitor (YM155) reduced SCLC cell viability and increased apoptosis. Co-culture experiments with SBC3 and monocytes (e.g., THP1) led to decreased BIRC5 expression in SBC3 cells.

Conclusion: We identified *AURKB, BIRC5, TOP2A, TYMS, PCNA, UBE2C*, and *AURKA* genes as potential immune-related therapeutic targets for SCLC. In particular, high BIRC5 expression promotes SCLC progression and may influence the immune microenvironment of the tumor by affecting monocytes.

#5688 DSTYK dependent regulation of autophagy protects against TNF alpha induced apoptosis in lung cancer.

Andrea Pasquier[1], Cristina Viu-Idocin[1], Andrea Arricibita[1], Mirari Echepare[1], Benat Picabea[1], Ane Alava[1], Joaquin Fernandez-Irigoyen[2], Enrique Santamaria[2], Eva Molina[1], Antonio Pineda-Lucena[1], Luis Montuenga[1], **Karmele Valencia**[1]

[1]Center for Applied Medical Research (CIMA), Pamplona, Spain,[2]Public University of Navarra, Pamplona, Spain

The emergence of immunotherapy has significantly advanced the treatment of non-small cell lung cancer (NSCLC), yet acquired resistance remains a critical challenge. Understanding the molecular mechanisms behind tumor cell sensitivity to T-cell killing is essential to overcome resistance and improve treatment outcomes. Previous studies have indicated the roles of T cell-derived tumor necrosis factor-α (TNFα) and nuclear factor κB (NF-κB) signaling in tumor cell killing, with autophagy inhibiting TNF-α-induced apoptosis.Previous research in our lab has identified DSTYK, a dual serine/threonine and tyrosine kinase amplified in NSCLC, as a key regulator of mTOR. DSTYK plays a critical role in preventing TNF-α-mediated $CD8^+$ T cell killing and impairs the response to immunotherapy in non-small cell lung cancer by inhibiting autophagy. However, the specific mechanism by which autophagy constrains TNF-α-dependent apoptosis remains unclear.In this study, we demonstrate that inhibition of DSTYK disrupts ULK1 phosphorylation, leading to RIPK1 autophosphorylation and promoting proapoptotic signaling through TNFR1 complex II. Furthermore, we demonstrated that ULK1 inhibition replicates the effects of DSTYK inhibition, reducing tumorigenic properties and sensitizing cells to apoptosis and necroptosis. *In vivo* experiments in syngeneic and xenograft mouse models corroborated these findings, showing significant tumor size reduction upon ULK1 inhibition. In conclusion, our study identifies DSTYK as a key regulator of the TNFR1 pathway via ULK1 phosphorylation, suggesting that targeting ULK1 could be a viable therapeutic strategy for sensitizing DSTYK-amplified NSCLC tumors to cell death.

#5689 Proliferating cell nuclear antigen as a new therapeutic target in multiple myeloma.

Jeffrey Zonder[1], Bin Bao[1], Amro Aboukameel[1], Sahar Bannoura[1], Husain Y. Khan[1], Hafiz Uddin[1], Mohamad B. Hamami[1], Ali Rehman[1], Ramzi Mohammad[1], Long Gu[2], Linda Malkas[2], Asfar Azmi[1]

[1]Oncology, Wayne State University School of Medicine, Detroit, MI,[2]City of Hope National Medical Center, City of Hope, CA

Background: Multiple myeloma (MM), a plasma cell cancer, is the second most common hematologic malignancy. Despite advances in treatment (proteasome inhibitors, cereblon-targeting immunomodulatory drugs, and anti-CD38 and anti-BCMA immunotherapies) MM remains incurable. Proliferating cell nuclear antigen (PCNA) is an essential protein which is involved in chromatin remodeling, cell cycle progression, and DNA repair and replication, plays a key role in regulation of cell growth and proliferation. A post-translationally modified isoform of PCNA plays a critical role in the pathogenesis of a wide variety of malignant diseases including MM. Increased expression of PCNA has been shown to be associated with an aggressive MM phenotype, making it an attractive therapeutic target.
Methods: We tested the anti-tumor activity of the novel small molecule PCNA inhibitor AOH-1996 (alone and in combination with either bortezomib or venetoclax) against MM cell lines (MM1.S, SKMM2, RPMI-8226). We assessed the cytotoxic anti-MM effects of varying doses AOH-1996 using standard viability assays and also 3D spheroid degradation assays. Changes in gene expression relevant to cell growth, cell-cycle progression, apoptosis, methylation status, and cytokine production following AOH-1996 exposure were analyzed using RT-PCR and Western blotting, as appropriate. We also evaluated the impact of AOH-1996 exposure on miRNA levels. The anti-MM effect of AOH-1996 monotherapy and combinations versus the same cell lines was then further evaluated in xenograft animal model.
Results: AOH-1996 demonstrated dose-dependent reduction of cell growth (2D) and CSC-like sphere formation (3D) of MM1.S, SKMM2, and RPMI-8226 MM cell lines. Either short (2 days) or long (7 days) incubation with AOH-1996 significantly down-regulated the gene expression of selected anti-apoptotic markers (PCNA, CDK4/6, BCL2), cancer stem cell markers (EZH2, vimentin), and inflammatory and pro-survival cytokines (IL-6, VEGF, MIP-1alpha). AOH-1996 treatment down-regulated miR-21, miR-142, and miR-222 levels along with the reduced cytokine production of VEGF. There was a synergic effect on cell growth and CSC-like sphere formation when either bortezomib or venetoclax was added to AOH-1996. AOH-1996 significantly inhibited MM.1S cell line-derived xenograft tumor growth. Additional xenograft studies using other MM cell lines, as well as AOH-1996/bortezomib and AOH-1996/venetoclax combinations are ongoing.
Conclusions: These findings clearly suggest that PCNA is a potential therapeutic target in MM. We have demonstrated for the first time that the PCNA inhibitor AOH-1996 shows potent anti-myeloma activity through its effects on several key tumor-associated genes and miRNAs. AOH-1996 is currently being evaluated in a Phase I trial.

#5690 Targeting MET activation in CDH1 deficient diffuse gastric cancer with peritoneal metastases.

Hannah Sofield[1], Hyun-Kyung Ko[2], Dipti Athavale[3], Yan-ting Yann Zhan[3], Xiaodan Yao[3], Luke Chen[1], Young K. Hong[1], Francis Spitz[1], Generosa Grana[2], Madeline Torres[1], Shumei Song[2]

[1]Department of Surgery, Cooper University Hospital, Camden, NJ,[2]MD Anderson at Cooper University Healthcare, Camden, NJ,[3]Coriell Institute for Medical Research, Camden, NJ

Background: Peritoneal metastasis (PM) is common in advanced gastric cancer (GC). PM has a poor prognosis with a short average survival of 2 to 9 months. Currently, the only treatment option for these patients is palliative chemotherapy, which has poor efficacy. Improving patient survival requires a better treatment approach. Germline mutations in CDH1 (E-cadherin) tumor suppressor gene are associated with hereditary diffuse gastric cancer (HDGC) syndrome, a very aggressive form of GC and lobular breast cancer. Our prior studies on GC PM patient samples have demonstrated increased incidence of CDH1 deficiency (mutations/deletions; 26%) compared to primary tumor samples (9%). Further molecular integrated analysis has shown that CDH1 mutant tumors are correlated with increased expression of MET oncogene, suggesting that targeting MET could be beneficial in the treatment of the subset of PM patients with CDH1 deficiency (somatic or germline). This study seeks to target MET activation in CDH1 deficient diffuse GC cells.
Methods: Three diffuse GC cell lines derived from human PM samples were used: SNU-16 (CDH1 wild-type), GA0518 (CDH1 deletion), and MKN45 (CDH1 mutant). We examined MET and phosphorylated MET (p-MET) expression in all cell lines using qPCR, immuno-blotting and immuno-fluorescence. We then evaluated the *in vitro* effects of two commercially available MET inhibitors, Cabozantinib and Crizotinib. Drug effects on cell viability, colony formation, migration, and downstream MET signaling pathways were assessed.
Results: MET and p-MET expression, and downstream MET signaling were significantly enhanced in CDH1 mutant diffuse GC cell lines compared with the wild-type. Cell viability results demonstrated that CDH1 mutant cell lines were highly sensitive to MET inhibitors. IC50 values showed higher susceptibility for both drugs in CDH1 mutant cell lines, MKN45 (0.01nM and 0.2nM for Crizontinib and Cabozantinib, respectively) and GA0518 (648nM and 824nM) compared to wild-type, SNU16 (1.9uM and 3.2uM). Downstream pathways, PI3K and MAPK, were suppressed at concentrations between 10-50nM. Cell migration and colony formation were inhibited between 10nM-500nM.
Conclusions: CDH1 deficient (mutant/deletion) GC cell lines have increased MET expression and activation (p-MET) compared to wild-type cells. We showed that CDH1 mutant cell lines with high MET activation were susceptible to MET inhibitors. Furthermore, at low concentrations, targeting activated MET led to complete loss of p-MET expression, suppression of its downstream signaling, and impaired cell growth, migration, and colony formation. Thus, blockade of MET signaling could be clinically useful for the treatment of CDH1 deficient diffuse GC PM patients, while CDH1 mutations could serve as a biomarker. Future *in vivo* PDX and syngeneic mouse models are under investigation to validate these results.

#5691 Preclinical evaluation of RMC-7977, a multi-selective RAS(ON) inhibitor, as a therapeutic strategy for KRAS-mutant cholangiocarcinoma.

Rodrigo Entrialgo-Cadierno[1], Iker Feliu[1], Ines Lopez[1], Yaiza Senent[1], Shruthi Narayanan[1], Nicole Nasholm[2], Ruben Pio[1], **Jingjing Jiang**[2], Silvestre Vicent[1]

[1]Center for Applied Medical Research (CIMA), Pamplona, Spain,[2]Revolution Medicines, Redwood City, CA

Background: Cholangiocarcinoma (CCA), comprises approx. 3% of all gastrointestinal tumors, and is characterized by highly dismal prognosis. Therapies predominantly rely on chemotherapy, and treatment advancements have been stagnant over the past decades, underscoring the critical need for innovative therapies. Mutant KRAS is among the most prevalent oncogenes in CCA, highlighting a potential role for KRAS inhibitors as therapeutic avenues. Here, we present preclinical data on RMC-7977, a RAS (ON) inhibitor as a potential therapeutic strategy for CCA with KRAS mutations.

Materials and Methods: Human and murine KRAS mutated cell lines were utilized to determine the effect of RMC-7977 both in vitro and in vivo. H69 immortalized cholangiocytes were virally infected with KRAS mutant isoforms (4B, G12, G13, Q61). RNA-seq and Western blot was conducted to analyze the molecular changes and potential resistance mechanisms. The tumor immune microenvironment was assessed via multiplex flow cytometry. Combinatorial pharmacological treatments were conducted in vitro and in vivo to study resistance mechanisms overcome. Both human and murine cell lines resistant to the RAS(ON) inhibitor were generated. Subsequently RNA seq and WES were performed to identify possible transcriptomic changes and acquired mutations in resistant cells.

Results: RMC-7977 elicited antiproliferative effects in mouse and human CCA cell lines with different KRAS mutations (G12D/G12V/G13C) and H69 expressing various KRAS mutations in vitro. In vivo experiments with human xenografts or mouse allografts revealed heterogeneous antitumor responses ranging from tumor regressions to growth delay. In vitro mouse cell line/CD8+ co-culture experiments, showed RMC-7977 capacity to increase CD8 cytotoxicity. Tumor immune phenotyping of immunocompetent mice showed a notable increase in NK, CD8, and CD4 infiltration, and a reduction of PMN-MDSCs, indicative of a less immunosuppressive microenvironment. RNA-seq and Western blot analysis revealed increased activity of the SHP2, FGFR, and JAK/STAT pathways. Further in vitro testing confirmed the synergistic effects when we combined RMC-7977 plus SHP2 (in parental and resistant models) but also combinatorial benefit in xenograft models in vivo. Addition of the standard of care (Gem/Cis/PD1) to the RAS(ON) inhibitor resulted in significant tumor regression and enhanced anti-tumor activity compared to single treatments. Identification of potential resistant mechanisms related to transcriptomic changes, acquired mutations and CNV in resistant models is currently ongoing.

Conclusion: In summary, our preclinical findings support the clinical testing of a RAS(ON) multi-selective inhibitor, either alone or in combination with other in-pathway or out-of-pathway partners, as a potential therapeutic strategy for CCA treatment.

#5692 Distinct effectors of FSTL1 promote melanoma growth and angiogenesis and FSTL1 blockade mitigates resistance to BRAF and MEK inhibitors.

Umar Patel, **Jiaying Ng**, Chiu Wang Chau, Alex To, Ryohichi Sugimura, Martin Cheung

University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Melanoma is a highly lethal form of skin cancer due to its propensity for metastasis through angiogenesis, which confers melanoma initiating cells with resistance to BRAF and MEK inhibitors. However, current drugs for targeting angiogenesis have shown limited efficacy, highlighting the need to develop new anti-angiogenic therapies to effectively combat this devasting malignancy. Here, we found that Follistatin-like 1 (FSTL1) expression is significantly increased in metastatic melanoma, and correlates with higher microvessel density, and poor prognosis. FSTL1 is both required and sufficient for the growth, metastasis, and angiogenesis of melanoma. FSTL1 functions downstream of SOX10-DLC1-FOXK1 to mediate its oncogenic activity, which can be inhibited by FSTL1 neutralizing antibody (FSTL1 nAb). Mechanistically, intracellular FSTL1 promotes G1/S transition in proliferative melanoma cells by activating an AKT/Lamin B2 axis. Secreted FSTL1 activates endothelial expression of TMSB4X to induce nuclear NF-kB-dependent regulation of angiogenesis. Furthermore, FSTL1 expression is selectively upregulated in melanoma-initiating cells that are resistant to BRAF and MEK inhibitors, driving stemness through interactions with the tumor microvasculature. Treatment with FSTL1 nAb depletes melanoma-initiating cells and slows down drug resistance development, suggesting that FSTL1 nAb may be a promising adjunct therapy to BRAF and MEK inhibitors for melanoma treatment.

#5693 Diagnostic and predictive biomarkers for canine prostatic carcinoma: translational therapeutic insights.

Alexandre Matheus Baesso Cavalca[1], Marxa Leao Figueiredo[1], Maricy Apparicio Ferreira[2], Carlos Eduardo Fonseca Alves[3]

[1]Basic Medical Sciences, Purdue University, West Lafayette, IN,[2]Departamento de Reproducao Animal, Universidade Estadual Paulista, Botucatu, Brazil,[3]Universidade Paulista, Bauru, Brazil

The prostate is an organ prone to diseases typical of human aging, with benign and malignant prostatic disorders being among the most common diseases that affect men. There are a wide variety of treatment options for diagnosing prostate cancer in humans, depending on the risk category the disease falls into. The dog is the only mammal, besides man, that spontaneously develops canine prostatic hyperplasia (PH), prostatic atrophy and prostatic carcinoma (PCa), which are associated with age and androgenic hormones. However, unlike PCa in humans, PCa in dogs is not androgen dependent, therefore androgen deprivation therapy is not effective, and animals develop castration-resistant prostatic carcinoma (CRPC). Many treatment modalities usually for human PCa cannot be applied in CRPC. And regarding dogs, unfortunately, there is still no effective therapy for the treatment of these tumors. Available pharmacological treatments are scarce, based primarily on the prescription of anti-inflammatory drugs, with a low degree of survival. Therefore, we intend to carry out new translational studies on human and canine PCa samples, aiming to identify predictive markers and potential common therapeutic targets, to subsequently elucidate the antitumor effect of existing drugs, aiming to develop targeted therapies. The study included 20 animals, with 4 in the control group and 16 in the neoplasia group, under CEUA approval. Samples underwent proteomic analysis, RT-qPCR, RNA sequencing (RNAseq), and Next-Generation Sequencing (NGS) to evaluate gene expression patterns, tumor microenvironment interactions, and immune cell infiltrate estimates. Cross-validation with independent data from canine and human prostate carcinoma databases was performed. Biological triplicates were analyzed, and differential protein and gene expression were assessed using Student's t-test ($p < 0.05$, expression change > 1.5x). A total of 44 proteins, including significantly elevated levels of Vimentin and Peptidase S1, were identified in the neoplasia group. Additionally, 1,412 differentially expressed genes were enriched in prostate cancer-related pathways, with 536,200 SNPs identified across 291 genes in the canine exome. Thirteen genes co-expressed in RNAseq and NGS analyses emerged as potential direct therapy targets. Increased secretion of Vimentin and Peptidase S1 in the neoplasia group highlighted their potential as tumor biomarkers. These findings reveal a significant overlap in tumor progression and biomarker expression between canine and human PCa, offering promising avenues for translational studies to develop effective diagnostic tools and targeted therapies for both species.

#5694 Targeting NAD(P)H: Quinone oxidoreductase 1 (NQO1) for colorectal cancer diagnosis and therapy.

Chaithanya Ganji[1], Santosh Behera[2], Lakkakula V. K.S. Bhaskar[3], Mehmet Akce[4], Bassel F. El-Rayes[4]

[1]Biomedicine, University of Alabama at Birmingham, Birmingham, AL,[2]Biotechnology, National Institute of Pharmaceutical Education and Research-Ahmedabad (NIPER-A), Gandhinagar, India,[3]Zoology, Guru Ghasidas Vishwavidyalaya, Bilaspur, India,[4]Hematology and Oncology, University of Alabama at Birmingham, Birmingham, AL

Background/Objective: Colorectal cancer (CRC) is the third most common cancer in the United States and is associated with poor outcomes. NAD(P)H: Quinone Oxidoreductase 1 (NQO1), an enzyme, shown to contribute to chemoprotection for CRC. This meta-analysis aims to examine the association between NQO1 C609T polymorphisms and CRC risk. Furthermore, the study explores the binding capacity and efficacy of BBI 608 against NQO1 in CRC through molecular docking. The inhibitor will then be tested *in vitro*.

Methods: PubMed, Web of Science, and Google Scholar were used in bibliographic searches. For the NQO1 C609T analysis, 18 studies were used. Data was gathered and subsequently calculated using the pooled odds ratio (OR) (95% confidence interval, CI). Molecular docking, Western Blot, and QRT-PCR were used to determine the molecular function of BBI 608 and NQO1.

Results: The relation between NQO1 polymorphism and CRC risk (TT + CT vs. CC: OR=1.19, 95% CI =1.06-1.34, p<0.001) was significant. Furthermore, stratified investigation based on ethnicity indicated a significant association between NQO1 polymorphism and CRC risk (TT + CT vs. CC: OR=1.17, 95% CI =1.08-1.27, p<0.001). This study indicates that the C609T polymorphism of NQO1 is linked with CRC risk in Asians and Caucasians. Computational approaches were applied to observe the molecular properties of BBI 608 (NQO1 inhibitor) and analyze the exact mechanism of NQO1 on CRC. This investigation provides a detailed understanding of the interaction between NQO1 and BBI 608 and its implication in CRC therapy. *In vitro* studies were performed to support this computational analysis. BBI 608 creates higher cytotoxicity in a dose-dependent manner in CRC cell lines. BBI 608 treatment significantly (p<0.001) reduced the NQO1 expression at protein and RNA levels in both CRC (HCT 116 and RKO) cell lines.

Conclusion: Based on meta-analysis and a computational approach, NQO1 is a viable biomarker and a possible molecular target in CRC. *In vitro*, results showed that inhibiting NQO1 by BBI 608 decreased cell proliferation in both CRC cell lines. Knockout, overexpression, or site-directed mutagenesis is essential for a better understanding of BBI 608-targeted NQO1 and its amino acids.

#5695 Examining the tumor suppressor function of FBXW7 in endometrial cancer.

Sophia E. Agrusa, Swornalata Pukhrambam, Areebah Qazi, Madelyn Maurer, Sneha Aradhya, Jessica Back, Mike R. Wilson

Wayne State University School of Medicine, Detroit, MI

Endometrial cancer (EC) is the sixth most commonly occurring cancer in women, with incidence rates steadily increasing in recent years. The American Cancer Society estimates 67,880 new cases and 13,250 deaths in 2024. A racial disparity is observed in EC as Black patients often have higher grade disease, worse outcome and the more serve subtype of EC, uterine serous carcinoma (USC). The National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) program estimates that per 100,000 cases of EC, Non-Hispanic Black (NHB) patients have a death rate of 9.5 while Non-Hispanic White (NHW) patients have a death rate of 4.7. Disparity is most evident in metastatic USC, since NHW patients have a 5-year survival of 20% while NHB patients only have 5-year survival of 10%. In metastatic disease, FBXW7 mutation rates are higher in NHB patients compared to NHW patients. Using the TCGA database, we found FBXW7 is a tumor suppressor that is frequently mutated in endometrial cancer and has a higher mutation rate in USC compared to endometroid carcinoma. FBXW7 functions as a tumor suppressor through its ubiquitinase activity, in which it targets many oncoproteins for degradation including c-Myc, Notch1, Cyclin E, and mTOR. Previously our lab worked to purify FBXW7 via immunoprecipitation and found that FBXW7 may interact with MLH1, a DNA mismatch repair enzyme. To characterize potential-protein interactions between FBXW7 and MLH1, we transfected endometroid carcinoma cells with FBXW7 or MLH1 plasmids to elevate expression of these proteins and found that overexpression of FBXW7 results in a decrease in MLH1 expression. This may indicate MLH1 is a substrate for FBXW7 and is regulated via FBXW7 mediated ubiquitination. We then generated a FBXW7 knockout model in 12Z cells using a CRISPRCas9 system. With our successful FBXW7 knockout clone, we examined alterations of protein expression via Western Blot analysis. We see an increased expression of mTOR following knockdown of FBXW7, as this is a canonical substrate of FBXW7 ubiquitination. To investigate potential effects on invasion, we examined EMT markers Vimentin and E-Cadherin, where we see a decreased expression of Vimentin but unaltered expression of E-Cadherin following FBXW7 knockout. Due to the mutational frequency of FBXW7 in NHB metastatic UCS, we also examined changes in HER2 expression. Herceptin, which targets HER2, was previously clinically used as a therapy for UCS and had variable success in patients. Here we see a decrease of HER2 following FBXW7 knockout. Using the CRISPR-mediated knockout cells, ongoing studies will investigate cell growth rates and invasion FBXW7 mutant 12Z.

#5696 Hanmi's p53 mRNA and abraxane synergistically promote tumor control in PTX-prefered cancer through p53 stabilization.

Jooyun Byun, Jongmin Hong, Seungheon Baek, Gunwoo Lee, Hocheol Shin, Miyoung Lee, Seung-Hyun Shin, Yong Ho Heo, Daejin Kim, In Young Choi

Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

TP53 is the most frequently mutated tumor suppressor gene in human cancers and plays a critical role as a master regulator of apoptosis and cell cycle. Approximately 50% of human cancers harbor TP53 mutations, which are associated with accelerated tumor progression and resistance to anti-cancer therapies leading to unfavorable prognosis. As the way to restore the loss of function caused by p53 mutations, mRNA-based therapy is expected to yield novel therapeutic outcomes that remain unattainable with current approaches. This study endeavored to characterize the types of p53 mutations that exhibit heightened sensitivity to lipid nanoparticle (LNP)-encapsulated mRNA expressing wild-type p53. The anti-cancer potential of Hanmi p53 mRNA was demonstrated in a large number of cancers with p53 mutations, sparing to normal cells. Notably, p53 null/nonsense mutations were more sensitive to the Hanmi p53 mRNA compared to missense mutations or p53 WT cancer demonstrating a positive biomarker. High-throughput screening was performed to investigate the combination of Hanmi p53 mRNA with standard-of-cares, assessing the synergistic growth inhibition in cancer cells including lung, pancreatic, and breast, which exhibit high frequencies of p53 mutations. Taxanes such as paclitaxel, abraxane or docetaxel exhibited the best combinational synergy with Hanmi p53 mRNA in various p53-mutated cancer cell lines. Specifically, combination of Hanmi p53 mRNA and abraxane led to a dramatic increase in acetylated as well as phosphorylated p53 levels compared to Hanmi p53 mRNA alone. These results suggest that abraxane stabilizes wild-type p53 through acetylation, sustaining its expression and enhancing transcriptional activity in p53-mutated cancer. Restoration of p53 function highly elevated p21 expression, inducing G1 phase cell cycle arrest. Importantly, the combination of Hanmi p53 mRNA and abraxane synergistically amplified apoptotic activity, as evidenced by a marked increase in PARP cleavage. In vivo efficacy assessments of IV administration for LNP-encapsulated Hanmi p53 mRNA in combination with abraxane were conducted in PTX-preferred indication such as lung and ovarian cancer xenograft models. Tumor regression in mice treated with Hanmi p53 mRNA and abraxane was remarkably enhanced, with complete responses observed in 4 out of 5 mice, demonstrating the synergistic efficacy of the combination therapy. NGS-based gene set enrichment analysis conducted on NCI-H1373 xenograft tumors treated with p53-mRNA plus abraxane exhibited up-regulation of apoptotic gene sets compared to vehicle, consistent with our in vitro results. These results highlight Hanmi p53 mRNA exhibits strong synergy with taxanes, providing robust anti-cancer effects in indications requiring such therapeutic approaches.

#5697 Targeting CBL and CBLB ubiquitin ligases to exhaust cancer stem cells in metastatic breast cancer.

Bhopal C. Mohapatra[1], Aaqib M. Bhat[1], Mohsin Raza[1], Haitao Luan[2], Santosh Shrestha[2], Sowmya Kolluru[3], Matthew D. Storck[2], Lusheng Li[1], Fu-Shan Kuo[4], Silvana Leit[4], Fang Qiu[5], Subodh M. Lele[6], David Ciccone[4], Christine Loh[4], Shibiao Wan[1], Vimla Band[1], Hamid Band[2]

[1]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Eppley Institute and Fred & Pamela Buffett Cancer Center, University of Nebraska Medical Center, Omaha, NE,[3]Creighton University, Omaha, NE,[4]Nimbus Therapeutics, Boston, MA,[5]Department of Biostatistics, University of Nebraska Medical Center, Omaha, NE,[6]Department of Pathology, Microbiology and Immunology, University of Nebraska Medical Center, Omaha, NE

Introduction: Recurrence, therapy resistance and metastasis remain major challenges in cancer therapy, accounting for nearly all deaths from cancer. The inability of current therapies to eliminate cancer stem cells (CSCs) is widely believed to underlie these challenges. Targeting molecular pathways that help maintain the CSCs could open new avenues to devise durable cancer therapies. The CBL-family E3 ubiquitin ligases (CBL, CBL-B and CBL-C) attenuate tyrosine kinase signaling through ubiquitin-dependent degradation of tyrosine kinase-coupled receptors and signaling components. Gene deletion studies have shown that CBL-B, the predominant family member expressed in mature immune cells, mediates tumor-induced “immune editing” to generate a pro-tumor immune microenvironment. This mechanism has provided one line of evidence to develop chemical CBL-B inhibitors as cancer immune modulators, and candidate inhibitors exhibit anti-tumor activity in mouse implant models, supporting the general idea that CBL-family E3s are potential therapeutic targets. Using mouse genetic models, we have established that CBL and CBL-B are redundantly required for the maintenance of adult stem cell compartments, and that this role is dependent on the core function of CBL/CBL-B as negative regulators of the AKT-mTOR axis downstream of tyrosine kinase signaling. As normal organ stem cell programs are frequently co-opted by CSCs; we used a 3-pronged approach to ask if CBL/CBL-B are required to maintain CSC function.

Methods/Results: 1. Based on higher CBL/CBL-B expression in TNBC cell lines, and TCGA data that CBL/CBL-B mRNA expression positively correlates with shorter patient survival, we engineered Dox-inducible shRNAs in TNBC cell lines and showed that CBL/CBL-B KD impaired cell migration and invasion, reduced the population with CSC markers and impaired orthotopic xenograft tumorigenesis and metastatic seeding. 2. We generated a unique mouse model in which the C3(1)-TAg transgene drives mammary tumors known to resemble human triple-negative breast cancer (TNBC) and floxed-*Cbl and Cblb* genes can be inducibly deleted using tamoxifen (via *CreERT*^{2}). Tumors of these mice established as tumor-derived organoids (TDOs) exhibited significant impairment of growth and CSC signature gene expression upon *Cbl/Cblb* KO. 3. Since the developed “CBL-B” inhibitors target a mechanism shared between CBL/CBL-B, we used two active compounds (NTX-801, NTX-944) and one inactive compound (NTX-616) developed by Nimbus Therapeutics. The active inhibitors mimicked the genetic *Cbl/Cblb* KO to inhibit the mouse mammary TDOs growth, while the inactive analog was without effect.

Conclusions: Our results establish a tumor-intrinsic requirement of CBL/CBL-B to maintain breast cancer CSCs and add a critical second rationale for the use of chemical inhibitors of CBL/CBL-B as targeted therapeutics to counter BC recurrence and metastasis.

#5698 Opposing roles of HOXC6 isoforms in promoting head and neck squamous cell carcinoma.

Ishita Gupta[1], Subhendu Roy Choudhury[2], Anirudh Saxena[1], Madeleine Ndahayo[1], Vera Mukhina[1], Andrey Loginov[1], Nadya Vorobyeva[3], Daria A. Gaykalova[1]

[1]Department of Otorhinolaryngology, Institute of Genome Sciences, University of Maryland Baltimore, Baltimore, MD,[2]Department of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway,[3]Russian Academy of Sciences, Institute of Gene Biology, Moscow, Russian Federation

HOXC6, a member of the homeobox (HOX) family is a homeoprotein transcription factor regulating embryonic development, differentiation, and pathways like TGF-β/smad, PI3K/Akt, and Wnt. Although aberration in HOXC6 promotes onset and progression of several cancers, our previous study indicated an oncogenic role of HOXC6 in head and neck squamous cell carcinoma (HNSCC). Despite its role in HNSCC progression, the specific role of HOXC6 in HNSCC lies nascent. Emerging evidence suggests that alternative splicing events of HOXC6 generate distinct isoforms with diverse biological functions. While the HOXC6 transcript variant 1 encodes the primary isoform, variant 2 differs in the 5' UTR coding region and produces a shorter N-terminal isoform. In this study, we performed in-silico analysis alongside in vitro functional studies to delineate the roles of the primary and short isoforms in HNSCC progression. In-silico analysis revealed isoform-specific expression patterns across HNSCC and correlated with clinical outcomes. Our in vitro data demonstrated that the primary isoform enhances cell proliferation and migration by activating oncogenic pathways, while the shorter isoform counteracts these effects by inhibiting cell proliferation and suppressing metastatic potential. These findings highlight the impact of alternative splicing in modulating HNSCC function and reveal the opposing roles of its isoforms in HNSCC progression. This study underscores the importance of targeting isoform-specific mechanisms for developing biomarkers and therapeutic strategies in HNSCC.

#5699 Development of Elephant *TP53* loaded lipidoid nanoparticles for the treatment of non-small cell lung cancer and colon cancer.

Bhoomi Dholariya[1], Akanksha Patel[1], Joshua Schiffman[2], Aaron Rogers[2], Lisa Abegglen[2], Ketan Patel[1]

[1]St. John's University, Queens, NY,[2]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Worldwide, lung cancer and colon cancer are the most frequently diagnosed cancers with high mortality. Targeted therapy, including small molecule inhibitors and monoclonal antibodies of various oncogenic proteins, has improved survival, but the development of resistance remains a significant issue. TP53 is a critical tumor suppressor gene and loss of function occurs in over 50% of all human cancers. In lung and colon cancer, the evolutionary conserved codons of the tumor suppressor gene TP53 are frequently mutated. Among the range of mammalian species, elephants develop less cancer than predicted based on their size and lifespan. The search for potential mechanism of cancer defense in elephants revealed that elephants possess 19 retrogene copies of TP53 in addition to ancestral TP53. Elephant cells exposed to DNA damage undergo significantly more apoptosis than human cells, and increased apoptosis is associated with increased TP53 activity. Specifically, elephant TP53 (EP53) induced mitochondrial mediated apoptosis in human cancer cells. The objective of the current research work was to 1) To investigate the anticancer activity of ancestral elephant TP53 in various non-small cell lung cancer and colon cancer cell lines and 2) develop and optimize elephant TP53 loaded lipidoid nanoparticles. Ancestral elephant TP53 (EP53) showed significant anticancer activity at doses 500 ng-125 ng in A549, H460, HT29 and HCT116 ($p<0.05$). The combination of EP53 with p53 activators and DNA damaging agents is under investigation. Amongst various transfecting reagents screened, Fugene® showed maximal transfecting efficiency for EP53 with minimal reagent toxicity. Apoptotic assay confirmed the anticancer activity of EP53. Building on the promising activity of EP53 in human lung and colon cancer cells; we further investigated formulation strategies to deliver EP53 into tumor effectively. Being a large, anionic, hydrophilic structure, a plasmid/gene poses tremendous challenges in *in vivo* delivery. Non-viral gene delivery by cationic ionizable lipidoid was developed for in vivo delivery of EP53. Lipidoid nanoparticles prepared using DSPC, cholesterol, DOPE, DMG-PEG-2000, DOTAP and C12-200 showed particle size of 73.98 nm with +49 mV zeta potential. High transfection (EP53 with EGFP) with complete binding of the gene (agarose gel electrophoresis) to the lipoid was observed at a 1:10 ratio of gene:lipidoid. Further, *in vitro* assays and tumor marker analysis are currently ongoing.

#5700 Simultaneous expression of MUC13 and N-Myc contributes to diethylnitrosamine-induced hepatocellular carcinoma in rats.

Mohammed Sikander[1], **Shabnam Malik**[1], Swatantra K. Jain[2], Deepshikha P. Katare[3], Murali M. Yallapu[1], Subhash C. Chauhan[1]

[1]University of Texas Rio Grande Valley, McAllen, TX,[2]Hamdard University, New Delhi, India,[3]Amity University, Noida, India

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, with its development intricately linked to environmental factors such as chemical carcinogens and viral infections. Recent studies have highlighted a connection between obesity and non-alcoholic fatty liver disease with modern diets high in fats and processed meats. Despite this, the specific mechanisms by which dietary factors contribute to hepatocarcinogenesis remain inadequately understood. Our study demonstrates that diethylnitrosamine (DEN), a N-nitroso compound found in food additives and tobacco smoke upregulates N-Myc. N-Myc is a member of the Myc family of proto-oncogenes, essential for regulating gene expression, growth, apoptosis, energy metabolism, and differentiation. Additionally, we investigated the relationship between MUC13 and N-Myc, potential oncogenes, in human HCC tumors, proposing a potential link further facilitated by the suppression of miR-145, which contributes to hepatocarcinogenesis.
Methodology: We utilized a chemically induced rat model with DEN; 200 mg/kg bw and 2-acetylaminofluorene (2-AAF; 150 mg/kg bw) to investigate N-Myc and MUC13 expression. Serum levels of AST, ALT, and ALP were measured using Span Diagnostics kits. We assessed N-Myc expression in tumor tissue through immunohistochemical staining and measured miR-145 levels via in situ hybridization. Additionally, we analyzed patient-derived tissue samples to evaluate N-Myc and MUC13 protein expression, supplemented by bioinformatics analyses from various public databases.
Results: Liver sections from the DEN+2-AAF-treated group displayed hepatocyte vacuolization in the centrilobular area, accompanied by variations in nuclear size and significant nuclear atypia in adenomas. Serum levels of AST, ALT, and ALP correlated with liver cancer progression, and DEN treatment notably upregulated MUC13 and N-Myc in liver tissues. In normal tissues, MUC13 and N-Myc showed minimal staining, whereas levels were significantly higher in DEN+2-AAF-induced HCC, suggesting that MUC13 and N-Myc expression is crucial for hepatocyte malignant transformation. A strong correlation between MUC13 and N-Myc expression was observed in human HCC tumors. Additionally, miR-145, a repressor of MUC13, was significantly downregulated in tumor tissues compared to normal controls. Molecular modeling revealed that DEN forms a stable complex with N-Myc through multiple interactions.
Conclusion: This study highlights the pivotal role of MUC13 and N-Myc in the progression of diethylnitrosamine induced HCC.

#5701 MUC13 expression renders radio-resistance in human colorectal cancer cells through NRF2 signaling pathway.

Shabnam Malik, Mohammed Sikander, Daniel Zubieta, Kyle Doxtater, Manish K. Tripathi, Sheema Khan, Murali M. Yallapu, Everardo Cobos, Subhash Chauhan

University of Texas Rio Grande Valley, McAllen, TX

Background: Colorectal cancer (CRC) ranks as the third most commonly diagnosed cancer worldwide and poses a significant public health challenge due to its high incidence and mortality rates. A critical challenge in the management of CRC is the development of radio resistance, which compromises the efficacy of radiotherapy. Identifying novel molecular mechanisms that contribute to radio-resistance in CRC are imperative. Recently, we and others have reported that MUC13 as a pivotal factor in CRC progression and metastasis; however, its role in chemoresistance has not yet thoroughly elucidated. In this study, we have investigated the influence of MUC13 expression on radio-resistance in CRC cells.
Methodology: To evaluate the influence of MUC13 on the radio-resistance of CRC cells, we generated genetically modified cell lines exhibiting either MUC13 overexpression (MUC13-OE) or knockdown (MUC13-KO). These cell lines were subjected to X-ray irradiation (0-6 Gray) to assess the effects of MUC13 modulation on critical cellular functions and tumorigenic features (proliferation, migration, and invasion). Furthermore, we quantified the expression levels of NRF2 and its nuclear localization post-irradiation to delineate the interplay between MUC13 and NRF2 signaling pathways. IHC analysis of patient-derived tissue samples was conducted to ascertain the expression profiles of MUC13 and NRF2 proteins, complemented by bioinformatics analysis utilizing various public databases to investigate the correlation between these two molecules.
Results: Our findings reveal that the ectopic expression of MUC13 (MUC13-OE) in CRC cells caused a higher level resistance to radiotherapy (X-ray)-induced apoptosis as compared to MUC13 knockdown (MUC13-KO) cells. Additionally, MUC13-OE cells exhibited significantly enhanced migratory and invasive capabilities as compared to MUC13 KO cells after radiation treatments. This effect was correlated with the upregulation of NRF2 expression and its enhanced nuclear localization. Interestingly, a robust correlation between the expression levels of MUC13 and NRF2 was observed in human CRC tumors. This observation was supported by bioinformatics analyses. Moreover, we noted modulation of additional oxidative stress regulators, including HO-1, Keap1, and NQO1, which are critical mediators of cellular responses to oxidative stress. Collectively, these results implicate MUC13 as an important modulator of NRF2 signaling pathway.
Conclusion: In this study, we for the first time delineate the influence of MUC13 on CRC radio-resistance. We have also established a relationship between MUC13 and NRF2 expression/subcellular localization, that might contribute to MUC13 mediated radio-resistance in CRC patients. Thus, strategic repression of MUC13 by small molecule inhibitors/siRNAs might improve the therapeutic outcome of radiotherapy in CRC patients.

#5702 Knockdown of COP1 disrupts lipid metabolism and reduces migration ability in hepatocellular carcinoma cells.

Hun-Mo Ryoo[1], Eun-Hye Jeon[2], Keon Uk Park[3], Ilseon Hwang[4], Yun-Han Lee[5]

[1]Internal Medicine, Daegu Catholic University, Daegu, Korea, Republic of,[2]Keimyung University Dongsan Hospital, Daegu, Korea, Republic of,[3]Internal Medicine, Keimyung University Dongsan Hospital, Daegu, Korea, Republic of,[4]Pathology, Keimyung University Dongsan Hospital, Daegu, Korea, Republic of,[5]Molecular Medicine, Keimyung University Dongsan Hospital, Daegu, Korea, Republic of

Hepatocellular carcinoma (HCC) is one of the cancers with the highest mortality rates worldwide, being the sixth most commonly diagnosed cancer globally and the third leading cause of cancer-related deaths. COP1 gene, an E3-ubiquitin ligase, is generally overexpressed in human HCC and that plays an important role in the degradation of p53 tumor suppressor via ubiquitination. We have previously defined the COP1 gene as a therapeutic target in HCC. A recent study demonstrated that COP1 induces nonalcoholic fatty liver disease (NAFLD) in normal hepatocytes and that reducing COP1 expression in the liver significantly improves high-fat diet-induced hepatic steatosis. Thus in this study, we investigated if the function of COP1 was associated with HCC metabolism as well. siRNA-mediated inhibition of COP1 expression suppressed long-term colony formation in both Huh7 and HepG2 HCC cell lines. RNA sequencing of COP1-silenced HCC cells revealed the same directional regulation of 24 (10 down- and 14 up-regulated) genes. Notably, AKR1D1 gene, which negatively regulates bile acid biosynthesis and lipid metabolism, was up-regulated and that TMEM65 gene, which promotes migration and invasion of cancer cells, was down-regulated. Correlation analysis using publicly available databases further supported an inverse relationship between COP1 and AKR1D1 expression in HCC. Subsequent studies showed that COP1 knockdown inhibits synthesis of cellular lipids through the downregulation of GLUT4, DGAT2, FASN, and ChREBPα genes that are functionally involved in glucose transport or fatty acid synthesis. Furthermore, silencing of COP1 significantly reduced the abilities of migration and sphere formation in HCC parental cell population. Collectively, our findings indicate that the function of COP1 is associated with HCC lipid metabolism and migration.

#5703 NDRG1 enhances cisplatin-induced apoptosis by upregulating BMF in ovarian cancer cells.

Yajing Yang[1], Ananya Banerjee[1], Linzhou Wang[1], Na Li[1], Patrick Stevens[2], Elsa Wani[1], Jessica Miao[1], Aidan Li[1], Xiaoli Zhang[1], Qi-En Wang[1]

[1]Radiation Oncology, The Ohio State University, Columbus, OH,[2]The Ohio State University, Columbus, OH

Epithelial ovarian cancer (EOC) is the most lethal malignancy of the female reproductive system, with a five-year survival rate of just 32% for patients diagnosed at distant stages, which accounts for over 48% of cases. Although most EOC patients initially achieve a complete response with surgery and chemotherapy, the majority experience relapse, and recurrent tumors often develop resistance to the original drug regimen. Tumor relapse and acquired chemotherapy resistance are primary contributors to the high mortality associated with EOC. Ovarian cancer is a highly heterogeneous disease, exhibiting extensive variability at the molecular, cellular, and clinical levels. This heterogeneity significantly impacts therapeutic responses, particularly to platinum-based chemotherapies such as cisplatin, leading to variable treatment outcomes among patients. To gain deeper insights into the heterogeneity of ovarian cancer cells in response to cisplatin treatment, single-cell RNA sequencing (scRNA-seq) was conducted on spheroid-cultured ovarian cancer cells exposed to cisplatin. Following a two-week treatment period and a subsequent two-week recovery phase, several distinct clusters of cisplatin-surviving ovarian cancer cells were identified, exhibiting enhanced growth advantages. Analysis of the gene expression profiles of the cell clusters revealed that N-myc downstream regulated 1 (NDRG1) is highly expressed in clusters eliminated by cisplatin, whereas its expression is significantly lower in clusters that survive cisplatin treatment. Further investigation demonstrated that NDRG1 plays a critical role in promoting cisplatin-induced apoptosis. RNA sequencing of NDRG1-knockdown cells identified Bcl2 Modifying Factor (BMF) as a downstream target positively regulated by NDRG1. Given that BMF can bind to Bcl2 protein and functions as an apoptotic activator, these findings suggest that ovarian cancer cells with high NDRG1 expression are more susceptible to cisplatin-induced apoptosis due to NDRG1-mediated upregulation of BMF.

#5705 CHI3L1 overexpression predicts poor prognosis and drives aggressiveness in papillary thyroid cancer.

Pratheesh Kumar Poyil, Abdul K. Siraj, Sandeep Kumar Parvathareddy, Khadija Alobaisi, Rafia Begum, Fouad Al-Dayel, Khawla S. Al-Kuraya

King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, Riyadh, Saudi Arabia

Chitinase-3-like protein 1 (CHI3L1) is a secreted glycoprotein that is pivotal in regulating inflammation, macrophage polarization, apoptosis, and the process of carcinogenesis. While its expression is markedly increased in various cancer types, its specific role in papillary thyroid cancer (PTC) has not been fully elucidated. In our study, we assessed the expression of CHI3L1 protein in a large cohort of PTC patient samples and investigated its functional significance and underlying mechanisms in PTC cell lines. CHI3L1 over-expression was noted in 38.9% (638/1613) of PTC cases and was significantly associated with aggressive clinicopathological characteristics such as extrathyroidal extension ($p < 0.0001$), advanced T stage ($p < 0.0001$), lymph node metastasis ($p < 0.0001$), distant metastasis ($p = 0.0003$), stage IV tumors ($p = 0.0007$) and tumor recurrence ($p < 0.0001$). Interestingly, a significant association was also noted between CHI3L1 over-expression and phosphor-AKT ($P = 0.0007$) as well as PD-L1 ($P < 0.0001$). In addition, CHI3L1 was associated with shorter recurrence-free survival ($p = 0.0004$). Our *in vitro* studies revealed that inhibition of CHI3L1 reduced cell proliferation and triggered apoptosis in PTC cell lines. Notably, the downregulation of PLK1 impaired the self-renewal capacity of spheroids derived from PTC cells, indicating its role in maintaining cancer stem-like properties. Furthermore, CHI3L1 knockdown resulted in decreased expression of phosphorylated AKT and PD-L1, while its overexpression led to an upregulation of both. These findings underscore the role of CHI3L1 in PTC prognosis and promoting its progression. This study also identifies CHI3L1 as a promising therapeutic target, offering a novel strategy for managing aggressive and treatment-resistant forms of PTC.

#5706 A patient-derived organoid screening platform as a powerful tool to study efficacy of KRAS inhibitors.

Merel Derksen, Mariana Silva, Gerben ten Hag, Nilofar Ehsani, Yasmine Abouleila, Vineeta Adegbenro, Annemarie Buijs, Mayke Doorn, Nikki van Dorp, Javier Frias Aldeguer, Foteini Gkogkou, Yara Hendriksen, Ricardo Korporaal, Ka Wai La, Joris Maas, Francisco Morales-Rodrigues, Daniele Mori, Sumeyra Mucuk, Cesar Oyarce, Nima Salehi, Anna Schepers, Marvin Statia, Roel Verkerk, Timo Voskuilen, Rene Overmeer, Farzin Pourfarzad, **Sylvia F. Boj**

HUB Organoids B.V., Utrecht, Netherlands

Kirsten rat sarcoma (*KRAS*) gene is a proto-oncogene frequently mutated in various cancer types. Upon activation by growth factors such as Epidermal Growth Factor (EGF), KRAS initiates signaling pathways promoting cell proliferation and survival. Activation KRAS mutations are most common in colorectal cancer (CRC), Pancreatic Ductal Adeno Carcinoma (PDAC) and Non-Small Cell Lung Cancer (NSCLC) and are associated with worse disease outcomes. Though KRAS is an interesting target for cancer treatment, the development of specific KRAS inhibitors has, for many years, been challenging due to its small and smooth binding pocket, making KRAS a challenging “druggable” protein. Recently, advances have been made in this area, with the development and approval for clinical use of the KRASG12C inhibitors (Sotorasib and Adagrasib). These developments can pave the way for the design of novel compounds targeting KRAS G12C and other KRAS mutations, which can be accelerated when developed in patient-relevant preclinical models. Patient-derived organoids (PDOs) or HUB Organoids® are generated from the adult stem cells of normal and malignant tissues of epithelial organs, including the colon, pancreas, and lung. HUB Organoids recapitulate tissue physiology, molecular heterogeneity, and morphological and functional characteristics, including mimicking patient response. Organoids are suitable for high-throughput screening and serve as a platform for testing drug efficacy and safety. In this study, we showcase the suitability of our PDO-based platform for screening the efficacy of several KRAS inhibitors in 4 weeks. Eight KRAS inhibitors in different clinical research stages were tested in a panel of over 20 PDOs (including CRC, PDAC and NSCLC) harboring different KRAS mutations (G12C, G12D, Q61R, G13C, G12V and G12S) and using an ATP-based cell viability readout. As expected, various responses were identified among the 20 PDOs. In addition, the results show specific responses of G12C and G12D mutants to KRASG12C and KRASG12D-selective inhibitors, respectively. KRASG12CPDO resistance to KRASG12C inhibitors was alleviated by combinatorial treatment with an EGFR inhibitor, which aligns with the KRASi resistance mechanism driven by EGF signaling. In conclusion, our PDO platform effectively captures the efficacy and specificity of KRAS inhibitors in models with different KRAS mutations. The HUB PDO platform is valuable for studying combinatorial treatments to overcome KRAS inhibitor resistance, highlighting the potential of PDOs in developing novel KRAS inhibitors.

#5707 Augmentation of statin-induced ATF4 stress response enhances the cancer cell-killing effect of statin.

T. Nguyen, G.-B. Tran, J. Ding, H.-f. Ding;
O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL

Statins are a class of drugs widely used to reduce cholesterol levels and have been rediscovered as promising anti-cancer drugs. Statins inhibit HMG-CoA reductase (HMGCR), a rate-limiting enzyme in cholesterol synthesis. We found that statin treatment of neuroblastoma cells triggered stress responses characterized by upregulation of the master stress regulator ATF4. The primary function of ATF4 is to initiate a gene expression program to mitigate stress and promote cell survival. However, ATF4 can also induce cell death under severe or prolonged stress conditions. Our study revealed that combinations of simvastatin with compounds that amplify ATF4 stress signaling synergistically inhibited the growth and survival of neuroblastoma cells. These compounds include the endoplasmic reticulum (ER) stress sensor ATF6 activator, AA147, and the two ATF4 activators, Sal003 and Nelfinavir. The combination of simvastatin with AA147, Sal003 or Nelfinavir significantly increased ER stress marker, XBP1s, and strongly stimulated ATF4-ATF3-CHOP signaling, leading to apoptosis as evidenced by cleavage of caspase 3 and PARP. Moreover, knocking down ATF4 was able to inhibit apoptosis and partially protect neuroblastoma cells from the effects of these drug combinations. These results suggest a strategy to enhance the anti-tumor effect of statins by amplifying ATF4 stress signaling to trigger apoptosis.

#5708 Investigating the role of SMYD3 in medulloblastoma progression and treatment response: Implications for targeted therapy.

Swapna Asuthkar[1], Erick Benjamin Saldes[2], katherine Shishido[2], Ilango Balakrishnan[3], Sujatha Venkataraman[3]

[1]University of Illinois College of Medicine (Peoria), Peoria, IL,[2]Departments of Cancer Biology and Pharmacology,, University of Illinois College of Medicine (Peoria), Peoria, IL,[3]Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO

Medulloblastoma (MB), the most prevalent malignant brain tumor in children, presents significant treatment challenges, particularly in the aggressive Group 3 subtype, which is associated with poor prognosis. Current therapeutic strategies, including surgery, chemotherapy, and radiotherapy, often result in severe side effects and inadequate long-term outcomes. This study investigates the role of SMYD3, a histone methyltransferase known for its overexpression in various cancers, in mediating radioresistance in MB. We analyzed SMYD3 expression levels in MB cell lines and patient samples, revealing a notable overexpression in Group 3 MB, which correlated with diminished patient survival rates. Notably, ionizing radiation exposure resulted in a dose-dependent increase in SMYD3 expression, suggesting a potential adaptive response to treatment. Inhibition of SMYD3 using the small molecule BCI-121 significantly reduced cell viability and enhanced radiosensitivity in vitro. Preliminary in vivo studies utilizing a BALB/c nude mouse orthotopic MB model demonstrated promising outcomes, indicating that targeting SMYD3 may improve therapeutic efficacy. Our findings underscore the critical role of SMYD3 in promoting radioresistance in MB and suggest that SMYD3 inhibition could be a viable strategy to enhance the effectiveness of radiotherapy, particularly in aggressive MB subtypes. Further investigations are warranted to elucidate the underlying mechanisms and to explore the potential for combination therapies aimed at improving treatment outcomes in MB.

#5709 Furin drives colorectal cancer progression and chemoresistance through the TGF-β/ERK signaling pathway.

Abdul K. Siraj, Pratheesh Kumar Poyil, Sandeep Kumar Parvathareddy, Saravanan Thangavel, Fouad Al-Dayel, Khawla S. Al-Kuraya

King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Furin, a key member of the pro-protein convertase (PC) family, is unfavorably involved in the proteolytic activation of various precursor proteins. While aberrant expression of furin has been extensively documented in multiple malignancies, its functional significance and mechanistic role in colorectal cancer remain inadequately characterized. We analyzed furin expression in a comprehensive cohort of Middle Eastern colorectal cancer (CRC) patient samples and investigated its functional role and underlying mechanisms using in vitro studies with CRC cell lines. Furin over-expression was noted in 46.9% (530/1131) of CRC cases. A significant association was noted between Furin over-expression and older age at diagnosis of CRC (>50 years; $p = 0.0156$), but no significant association was noted with other clinico-pathological characteristics. However, Furin over-expression was found to be associated with phosphor-ERK1/2 ($p < 0.0001$) and TGFβ ($p < 0.0001$). For *in vitro* analysis, we selected three chemosensitive CRC cell lines—HCT116, DLD1, and LOVO—and generated chemoresistant cells by treating them to prolonged low-dose 5-fluorouracil (5-FU). Our results revealed that 5-FU-resistant CRC cell lines exhibited elevated furin expression, accompanied by increased levels of TGF-β protein and phosphorylated ERK1/2 (pERK1/2). Notably, furin knockdown restored chemosensitivity, highlighting its critical role in drug resistance. Furthermore, we demonstrated that TGF-β treatment upregulated furin and pERK1/2 expression, while forced furin overexpression similarly induced TGF-β and pERK1/2 expression. Collectively, these findings suggest that furin plays a pivotal role in CRC progression and chemoresistance by activating the TGF-β/ERK signaling pathway.

#5710 Anticancer effects of 2,3-*bis*(bromomethyl)-quinoxaline 1,4-dioxide on uterine cancer.

Kaitlyn Mayo, Kennedy Szabo, **Calli A. Davison-Versagli**

Saint Mary's College, Notre Dame, IN

Uterine cancer will claim an estimated 17,610 lives in the United States in the year 2024. Lack of funding and focus have resulted in little advancement in treatment options for uterine cancer patients. Consequently, uterine cancer incidence and mortality have consistently increased since the 1990's in the United States. Thus, further investigation and development of uterine cancer therapies is needed. The Peroxiredoxins (I-VI) family of enzymes is responsible for eliminating reactive oxygen species throughout the cell and has been studied in multiple organisms and diseases, including cancer. The compound 2,3-*bis*(bromomethyl)-quinoxaline 1,4-dioxide (Conoidin A) is a Peroxiredoxin II inhibitor that has been studied in the parasite, *Toxoplasma gondii*. It inhibits the enzymatic activity of Peroxiredoxin II when studied *in vitro* by covalently binding to cysteine. Recent reports identify Peroxiredoxin II as a potential therapeutic target for cancer therapies and indicate that Peroxiredoxin II down-regulation promotes cancer cell death. Thus, the purpose of these studies was to evaluate Conoidin A as a potential therapeutic for uterine cancer. Here, we report that concentrations of 100 µM, 75 µM, and 50 µM of Conoidin A decreased growth of the uterine cancer cell line, HEC-1-A, after 24 hours as measured using crystal violet assays. Conoidin A concentrations of 100 µM, 75 µM, and 50 µM compromised anchorage-independent growth of HEC-1-A cells in soft agar assays. Furthermore, p53 up-regulation (p53+) correlates with poor prognosis in uterine cancer patients. To determine if Conoidin A is capable of decreasing growth of p53+ tumors, increasing Conoidin A concentrations were tested on the p53+ cell line, C-33a, using crystal violet assays. Preliminary studies found Conoidin A abolishes C-33a growth at concentrations of 100 µM, 75 µM, and 50 µM after 24 hours of treatment. These data identify Conoidin A as a potential therapeutic for uterine cancer, including p53+ tumors. Furthermore, these studies establish Peroxiredoxin II as a novel therapeutic target for this disease.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: PARP Inhibitors
Poster Session

#5714 EP102: pharmacological inhibition of METTL3 in tumor growth inhibition and comparative efficacy in combination with anti-PD1 or PARP inhibitors.

Graeme L. Fraser, Catherine Sorlet, Nicolas Parmentier, Killian Oukoloff, Guillaume Dutheuil

EPICS Therapeutics, Gosselies, Belgium

METTL3 is the RNA methyltransferase predominantly responsible for the addition of N-6-methyladenosine (m6A), the most abundant epigenetic modification to mRNA. The prevalence of m6A and the activity and expression of METTL3 have been linked to the appearance and progression of numerous hematological and solid tumor cancers. EPICS has previously presented tumor growth inhibition with its small molecule inhibitors of METTL3 ("M3i") in various models including in SKOV3 (ovarian) in NSG mice. The aim of the current study is to evaluate whether the efficacy of M3i combines favorably with anti-PD1 inhibitors in comparison to PARP inhibitors. M3i compound potency was evaluated *in vitro* by measuring the anti-proliferative effects in cell viability assays following a 72h treatment of A20 (B-cell lymphoma, IC_{50} = 310 nM), SKOV3 (ovarian, IC_{50} = 9 nM) and MDA-MB-231 (TNBC, IC_{50} = 24 nM) cells. Compound M3i-A (30 mg/kg, IP, QD) effectively elicited tumor growth inhibition ("TGI") in SKOV3 (orthotopic implant, NSG mice) but not in A20 (syngeneic mice) either as a standalone therapy nor in combination with anti-PD1. In CD34+ humanized mice, compound M3i-B (20 mg/kg, PO, QD) elicited TGI >60% in the SKOV3 model (SC implant) and >40% TGI in the MDA-MB-231 model (orthotopic implant), but in the latter model with no additional benefit in combination with anti-PD1. SKOV3 is an HR-proficient tumor known to be less sensitive to PARP inhibitors; in a final study, M3i-B effectively prolonged survival in the SKOV3 model in NSG mice (orthotopic implant) and further demonstrated heightened efficacy when tested in combination with Olaparib (50 mg/kg, PO, QD) in data complemented by the resolution of various downstream biomarkers. The current results extend the application of METTL3 inhibitors as a single-agent in the treatment of selected tumors and further suggest that METTL3 inhibitors may be ideally combined with cancer therapies targeting DNA damage response mechanisms, such as PARP inhibitors, as a refined strategy for treatment of solid tumors.

#5715 Enhancing PARP inhibitor efficacy with CDK12/7/9 degradation in prostate cancer.

Fu Gui[1], Baishan Jiang[2], Jie Jiang[2], Marian Kalocsay[3], Anne Fassl[4], Steven P. Balk[5], Adam S. Kibel[1], Li Jia[1]

[1]Department of Urology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Department of Cancer Biology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[3]Department of Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Department of Urology, University Hospital Frankfurt, Goethe University Frankfurt, Frankfurt am Main, Germany,[5]Department of Medicine and Cancer Center, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Current treatments for advanced prostate cancer (PCa) mainly target the androgen receptor (AR) signaling pathway. However, the development of castration-resistant prostate cancer (CRPC) and resistance to AR signaling inhibitors remains a significant clinical challenge.In recent years, the FDA has approved four PARP inhibitors (PARPis) - olaparib, rucaparib, talazoparib, and niraparib - either as monotherapy or in combination with AR signaling inhibitors for CRPC patients carrying deleterious germline or somatic BRCA1/2 mutations or other homologous recombination repair (HRR) gene mutations. CDK12, a kinase associated with the phosphorylation of the carboxy-terminal domain of RNA polymerase II, is crucial for the transcriptional processivity of long mRNA transcripts, including key HRR genes such as BRCA1 and BRCA2. CDK12 alterations, primarily biallelic truncating mutations, have been identified in 5-7% of PCa cases. In this study, we demonstrate that acute CDK12 loss results in BRCA1/2 downregulation and sensitizes CRPC cells to PARP inhibition. However, this sensitization is absent in CRPC adapted to chronic CDK12 loss, where BRCA1/2 expression is restored. Furthermore, degradation of CDK12/7/9 enhances the synthetic lethality of PARP inhibition through acute induction of a "BRCAness" state and AR signaling suppression in PCa. We developed BSJ-5-63, a CDK12/7/9 proteolysis-targeting chimera (PROTAC) degrader, which effectively degrades CDK12 to induce an acute "BRCAness" state, sensitizing cancer cells to PARP inhibitors regardless of their HRR status. In addition, BSJ-5-63 degrades CDK7/9, attenuating AR signaling and further promoting the synthetic lethality of PARP inhibition.Acute CDK12/7/9 degradation by BSJ-5-63 exhibits potent anti-tumor effects in both in vitro and in vivo CRPC models. This study introduces BSJ-5-63 as a promising therapeutic agent that targets both DNA repair and AR signaling pathways, offering potential benefits for a broad patient population.

#5716 XPO1 inhibition synergizes with PARP inhibitor in metastatic castration resistant prostate cancer via the regulation of DNA damage response.

Md. Hafiz Uddin[1], Aaban A. Azmi[1], Laiba M. Monir[1], Amro Aboukameel[1], Husain Y. Khan[1], Sahar F. Bannoura[1], Frank Cackowski[1], Yusra Shao[1], Vinod Shidham[2], Sunil Jaiman[2], Rafic Beydoun[2], Gregory Dyson[1], Seongho Kim[1], Yang Shi[1], Vy Ong[1], Julie Boerner[1], Ramzi M. Mohammad[1], Elisabeth I. Heath[1]

[1]Department of Oncology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[2]Department of Pathology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI

Background: Dysregulated nuclear protein transport, commonly observed in cancer, results in the mislocalization-mediated inactivation of many proteins. We showed that overexpression of exportin 1 (XPO1) is linked to higher grade and Gleason score in metastatic castration-resistant prostate cancer (mCRPC). Using network topology computational approaches, XPO1 and PARP1 were identified as synthetic lethal partners and we have demonstrated synergy between XPO1 and PARP inhibitors in mCRPC cell lines. This study evaluates the combination's efficacy in cell line-derived (CDX) and patient-derived xenograft (PDX) models, investigating the mechanisms of synergy.
Methods: For the CDx and PDx models, 22rv1 cells and CTG-3581 tissue (Champions Oncology) were grown subcutaneously in ICR-SCID and CEIA/NOG male mice, respectively. XPO1 inhibitor was dosed orally at 10-15 mg/kg twice a week and PARP inhibitor was dosed orally at 50 mg/kg daily. For *in vitro* mechanistic study, 22rv1 cells were subjected to RNAseq, proteomic analysis, and Digital Spatial Profiling (DSP; 10x Genomics Visium platform) after treatment. Data analysis was performed using iPathwayGuide (advaitabio.com) and cLoupe browser.
Results: The XPO1-PARP inhibitors combination showed enhanced anti-cancer efficacy in both CDx and PDx models, with no significant weight loss or organ toxicity such as liver, spleen, and kidney. Survival benefits were evident in the combination group. Immunohistochemistry revealed apoptotic cell death, shown by cleaved caspase 3 and terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining. Mechanistic studies with 22rv1 cells showed downregulation of DNA replication genes (e.g., MCM6 and CDC6) and reduced enrichment scores for DNA replication pathways in gene set enrichment analysis. The proteomic analysis highlighted decreased levels of DNA replication modulators HMGB2 and DNAJC9. Besides the suppression of various DNA damage response genes (e.g. BRCA2 and RAD51), XPO1 inhibition also reduced the PARylation of mCRPC cells. DSP analysis of 22rv1 CDx tissue revealed a reduction of unbiased cellular clusters and increased differentially expressed genes in the combination treatment. The DNA replication pathway was among the top 5 pathways modulated by XPO1i treatment in DSP analysis.
Conclusions: Taken together, this study revealed the therapeutic potential of XPO1-PARP inhibitors combination via targeting of the DNA damage response pathway in mCRPC.

#5717 Nesuparib, a dual inhibitor of PARP and tankyrase, is efficacious in preclinical gastric cancer models by regulation of HIPPO and Wnt pathway.

Banyoon Cheon, Jung Young Shin, Dae-In PARK, Jun Kim, John Kim, Hyunju Cha

Onconic Therapeutics, Seoul, Korea, Republic of

Gastric cancer is the fifth most common cancer and it still needs to identify novel actionable targets to bring clinical benefits. Here we explored the efficacy of nesuparib, a dual inhibitor for poly-ADP-ribosyl transferase 1/2 (PARP 1/2) and tankyrase 1/2 (TNKS 1/2) in vitro and in vivo models using BRCA wild type gastric cell lines. In addition to PARP 1/2 inhibition, nesuparib selectively inhibits TNKS 1 and 2 enzymatic activities; TNKS is a member of PARP family, and poly-ribosylates target proteins that are involved in Wnt/β-catenin and Hippo signaling pathways. The poly-ribosylated proteins are subsequently ubiquitinated by E3 ligases and undergo proteasomal degradation. The inhibition of TNKS is known to attenuate cancer promoting signaling like Wnt and Hippo signaling. To evaluate the impact of nesuparib on cell growth, half maximal inhibitory concentration (IC_{50}) of nesuparib, Olaparib, and XAV939 in clonogenicity was compared in BRCA wild type gastric cancer cells. Nesuparib is at least 28-fold more potent than Olaparib and 13-fold more potent than XAV939 among cell lines. To examine how nesuparib modulates Wnt/β-catenin and Hippo signaling through TNKS inhibition, we assessed changes in canonical Wnt/β-catenin and Hippo signaling-related molecules at protein levels. Nesuparib stabilized AXIN, reducing nonphospho β-catenin, c-myc, and cyclin D1. In addition, nesuparib stabilized AMOT proteins and increased phospho-YAP reflecting inhibition of the oncogenic YAP pathway. Given the findings that nesuparib treatment regulates Wnt and Hippo signaling in KATO III and NCI-N87 cells (BRCA wild type), we tested its efficacy as a single or with a combination of irinotecan in these cell line xenograft mouse models. Nesuparib showed superior potency than Olaparib alone in both xenograft models. The combination of nesuparib with irinotecan enhanced the anti-tumor activity compared with nesuparib single treatment. In addition, the combination of nesuparib with irinotecan showed stronger tumor growth suppression than the combination of Olaparib with irinotecan.In summary, these results suggest that nesuparib may exert anti-tumor efficacy in specific types of cancers with pro-cancerous signaling of the Wnt or Hippo pathway by the regulation of TNKS. This warrants a proof-of-concept of anti-tumor effect of nesuparib in gastric cancers and its potentials for clinical benefits.

#5718 Molecular determinants of platinum resistance in ovarian cancer: Linking PARP1, DNMT1, γ-GCS expression, and LINE1 hypermethylation.

L. Devi, A. Kumar, L. Kumar;
All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Background: Ovarian cancer is a leading cause of gynecological cancer-related mortality worldwide. Alarmingly, 80% of patients are diagnosed at an advanced stage (FIGO stage III-IV), where the prognosis is poor. The current standard of care for advanced epithelial ovarian cancer (EOC) includes cytoreductive surgery followed by taxane and platinum-based chemotherapy. Despite initial responses, resistance to platinum remains a significant cause of treatment failure and relapse in EOC. This study aims to investigate the molecular underpinnings of platinum resistance by examining the expression and enzymatic activity of PARP1 and γ-GCS and their correlation with DNA methylation patterns in ovarian cancer. Based on existing evidence, we hypothesize that inhibition of PARP1 or γ-GCS may enhance cisplatin (CDDP) sensitivity, offering new therapeutic opportunities. Understanding these mechanisms could pave the way for innovative strategies to overcome chemotherapy resistance in ovarian cancer.
Material and Methods: Peripheral Blood (PB) and Ascitic Fluid (AS) samples were collected from 20 EOC patients. The cohort was divided into two groups: Group A (n=10) included treatment-naive baseline patients, and Group B (n=10) comprised relapsed patients. Additionally, healthy control samples (n=10) were collected for comparison. The study involved:

1. Gene Expression Analysis: Differential expression levels of PARP1, DNMT1, and γ-GCS were evaluated using qPCR.
2. Enzymatic Activity Measurement: Glutathione (GSH) activity was quantified using ELISA.
3. Global DNA Methylation Assessment: LINE1 methylation levels were measured via pyrosequencing to examine epigenetic changes.

The resulting data were correlated with clinico-pathological parameters, including age, stage, CA markers, and hematological indices. Statistical analysis was conducted using GraphPad Prism 6, and a p-value < 0.05 was considered statistically significant.
Results: High γ-GCS expression increases glutathione levels in newly diagnosed ovarian cancer patients, potentially driving platinum resistance. Consistent LINE1 hypermethylation across patients, influenced by various factors, highlights its potential as both a biomarker and a therapeutic target, paving the way for strategies to overcome chemotherapy resistance.
Keywords: Ovarian Cancer, cisplatin, PARP-1, γ -GCS and DNMT1, Glutathione, LINE1.
Abbreviations: Epithelial Ovarian Cancer (EOC), cisplatin (CDDP), Glutathione (GSH), Gamma Glutamyl Cysteine Synthetase (γ-GCS), Poly (ADP ribosyl) polymerase-1 (PARP1), Enzyme-linked immunosorbent assay (ELISA), Quantitative Polymerase Chain Reaction (qPCR), DNA methylation LINE1, Peripheral Blood (PB), Ascitic Fluid (AS).

#5719 Identification of EIK1004 (IMP1707), a CNS-penetrant, potent, and selective PARP1 inhibitor poised for testing in patients with HRD mutant tumors.

Melissa Dumble[1], Ye Edward Tian[2], Ali Tabatabaei[1], Brenda Smith[1], Viola J. Chen[1], Ning Ma[2], Xiaozhu Wang[2], Yuxiao Zhao[2], Ruiyu Zhou[2], Yangzhen Jiang[2], Mu Chen[2], Sui Xiong Cai[2]

[1]Eikon Therapeutics, Inc., New York, NY,[2]IMPACT Therapeutics, Inc., Shanghai, China

INTRODUCTION: Nonselective poly(ADP-ribose) polymerase (PARP) inhibitors have proven to be effective in patients whose tumors harbor mutations in DNA repair proteins, although their efficacy is hampered by dose reductions and suspensions due to on-target toxicity resulting from PARP2-related hematologic suppression. Currently available PARP inhibitors have limited brain penetrance, limiting their utility for central nervous system (CNS) tumors or brain metastases. PARP1 inhibition alone can result in an antitumor effect similar to pan-PARP inhibition; therefore, development of PARP1-selective inhibitors with broad selectivity over PARP2 and brain penetrance is desirable. EIK1004 (previously IMP1707) is a potent, CNS-penetrant, PARP1-selective molecule with robust pharmaceutical properties.

METHODS: Inhibitory activity of EIK1004 was measured using recombinant PARP1 and PARP2 proteins in an in vitro PARylation assay and separately in an in vitro PARP trapping assay. Antiproliferative potential was measured in cell-based 7-day growth assays utilizing MDA-MB-436 (triple negative breast cancer, *BRCA1* mutant), DLD1 (colorectal, *BRCA2* knockout [KO]), and parental cell lines. In vivo antitumor effects were assessed in MDA-MB-436 and DLD1 KO subcutaneous xenograft models grown in NOD/SCID and nude mice, respectively. Brain penetrance and CNS antitumor activity were evaluated using an MDA-MB-436-luc intracranial xenograft model, and target engagement was measured in tumors using Western blot analysis to assess total PAR levels.

RESULTS: EIK1004 potently and selectively inhibits PARP1 enzyme (IC_{50} < 1 nM) with > 800-fold selectivity over PARP2, and potently traps PARP1 on DNA (IC_{50} < 1 nM). As a result of PARP1 inhibition and trapping, EIK1004 inhibits the growth of homologous recombination deficient (HRD) cell lines with potencies of < 5 nM, while having no effect on the growth of cells with intact DNA repair mechanisms. The antitumor activity of EIK1004 was tested in mouse xenograft models. In MDA-MB-436 and DLD1 *BRCA2* KO xenograft models, oral EIK1004 administered once daily at doses ≤ 1 mg/kg led to significant, dose-dependent tumor regression in these 2 models, respectively. In the MDA-MB-436-luc intracranial xenograft model, EIK1004 was shown to result in robust tumor regression at doses ≤ 1 mg/kg daily. In this model, total PAR levels in the tumor were shown to be significantly reduced (~90%) at all dose levels tested.

CONCLUSION: EIK1004 potently and selectively inhibits and traps PARP1, with downstream activity in cells and mouse models. EIK1004 exhibits robust pharmacokinetic properties including brain penetration, high bioavailability across preclinical species, and a safety profile that supports further development. EIK1004 is currently being evaluated in a Phase 1 clinical trial in solid tumors with or without brain metastasis.

#5720 Novel selective FEN1 nuclease inhibitor shows synergy with PARP-targeting drugs.

Jason Munguia[1], Sanjay Agarwalla[1], Dave Martin[1], Junhua Fan[1], Dave Lonergan[1], Celeste Giansanti[2], David Cortez[2], David Puerta[1], Zachary Zimmerman[1], **Konstantin Taganov**[1]

[1]Blacksmith Medicines, Inc., San Diego, CA,[2]Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN

Tumors with homologous recombination defects (HRD) due to mutations in BRCA1/2 genes or other genes associated with HR repair are typically sensitive to poly(ADP-ribose) Polymerase 1/2 inhibitors (PARPi), platinum-based drugs or other agents that target DNA repair pathways. Despite initial responsiveness to PARPi, many patients eventually experience disease progression. To that end, novel drug combination strategies involving PARPi plus other DNA replication and repair inhibitors have the potential to achieve more durable responses.

Flap endonuclease 1 (FEN1) is a structure-specific metallonuclease that has been shown to be overexpressed in a variety of tumor types and has been reported to have many synthetic lethality partners, including PARP and BRCA2, making it an attractive target for the development of novel anticancer therapeutics. Utilizing an innovative library of metal-binding pharmacophores (MBPs) and a fragment-based drug discovery approach we identified a novel FEN1-selective chemical scaffold represented by BSM-1516 (IC_{50} of 7 nM and 460 nM in biochemical assays for FEN1 and EXO1, respectively; FEN1 cellular thermal shift target engagement assay EC_{50} of 24 nM).

Examination of proteins on replication forks by iPOND-SILAC-MS in the presence of BSM-1516 revealed rapid enrichment of Okazaki fragment maturation (OFM) proteins FEN1/PCNA/LIG1, PARP1/2 enzymes, poly(ADP-ribose) binders (e.g. CHD1L) and alternative OFM pathway repair proteins XRCC1 and LIG3.

Combination of BSM-1516 with inhibitors of PARP1/2 was strongly synergistic in vitro, enhanced their antiproliferative effect up to 100-fold (an effect not observed in normal fibroblasts) and led to robust activation of ssDNA break repair markers: phospho-Chk1(Ser345), phospho-RPA2(Ser33) and chromatin-bound RPA2.

In vivo PK studies showed that BSM-1516 had oral bioavailability of 40% and $T_{1/2}$ of 2.9 hours in mice. Safety of BSM-1516 was assessed in vitro in lineage-specific differentiation of human hematopoietic CD34+ progenitor cells and in vivo in mice at a daily dose of 120 mg/kg PO and 90 mg/kg IP for 7 days and revealed no signs of hematological toxicity. These collective data support further in vivo testing in PD and efficacy studies either as a single agent or in combination with PARPi.

#5723 XL309 is a potent, selective, and orally bioavailable USP1 inhibitor active as monotherapy and in combination with PARP inhibitors or irinotecan.

Alex Charruyer-Reinwald[1], Aditya Kumar[1], Jimmy Lai[1], Scott Simonovich[1], Christopher Kochansky[1], Amy DeMicco[1], Tina Huynh[1], Avinash Kumar[2], Amit A. Dhudashiya[2], Kishore Narayanan[2], Kiran Aithal[2], Shailesh V. Jadhav[2], Anthony Flores[1], Richard Mansfield[1], Randy Wu[1], Jae H. Chang[1], Andrew Simmons[1], Paige Mahaney[1], Lisa D. Belmont[1]

[1]Exelixis, Alameda, CA,[2]Aurigene Oncology, Karnataka, India

Background: Ubiquitin-specific protease 1 (USP1) catalyzes selective removal of ubiquitin from its substrate proteins. During translesion synthesis (TLS), USP1 cleaves ubiquitin from proliferating cell nuclear antigen (PCNA), facilitating exchange of TLS polymerases for polymerase delta. Inhibition of USP1 prevents the repair of DNA lesions by TLS, resulting in single-stranded DNA gaps which are synthetically lethal with *BRCA1/2* mutations. Poly (ADP-ribose) polymerase (PARP) inhibitors have shown clinical benefit in *BRCA*-mutated cancers, but some patients do not respond, and many responders develop resistance to treatment. USP1 inhibition could potentially benefit patients by synergizing with PARP inhibition or bypassing resistance mechanisms. We report preclinical data for XL309, a potent and selective orally bioavailable small molecule inhibitor of USP1.
Methods: XL309 selectivity was assessed using a DUBprofiler-Cell™ assay. Viability was measured using CellTiter-Glo® in MDA-MB-436 cells. Ubiquitinated PCNA (Ub-PCNA) and PCNA levels after XL309 treatment of cell lines were quantified using global ubiquitination levels and total proteomic analysis (PTMScan and TMT). The antitumor activity of XL309 alone or in combination with saruparib, olaparib, or irinotecan was evaluated in the *BRCA1* mutant MDA-MB-436 cell-derived xenograft (CDX) model or in *BRCA1/2* mutant patient-derived xenograft (PDX) models. Drug-like properties were assessed, and pharmacokinetic (PK) parameters were determined following administration of XL309 in rat, mouse, and dog.
Results: XL309 is a potent inhibitor of USP1 in biochemical and viability assays. XL309 showed selectivity for USP1 versus other ubiquitin-specific proteases, increased Ub-PCNA levels while decreasing PCNA in the global ubiquitination profiling, and exhibited dose-dependent antitumor activity and induction of Ub-PCNA in a CDX model. XL309 exhibited single-agent activity in *BRCA1/2* mutant PDX models. XL309 also elicited durable tumor regression in combination with saruparib and irinotecan in a CDX model, and with olaparib in a PDX model. XL309 showed favorable drug-like properties including high permeability in Caco-2 cells. Low clearance and high bioavailability were observed for XL309 in rat, mouse and dog. Preliminary predictions of human PK parameters estimate a low clearance and long half-life for XL309 in humans.
Conclusions: XL309 is potentially a best-in-class USP1 inhibitor. PK assessments in conjunction with preclinical antitumor activity suggest that once daily oral administration of XL309 may achieve clinical activity alone or in combination with PARP inhibitors. XL309 is currently under investigation in a phase 1 first-in-human trial as monotherapy and in combination with olaparib in patients with advanced solid tumors (NCT05932862).

#5724 Dual inhibition of PARP and STAT3 as a novel therapeutic approach for triple-negative breast cancer cells.

Changyou Shi, Li Pan, Satomi Amano, Jiayuh Lin

University of Maryland, Baltimore, Baltimore, MD

Triple-negative breast cancer (TNBC) is a highly aggressive and metastatic subtype of breast cancer with limited therapeutic options, contributing significantly to patient mortality. This highlights an urgent need for novel treatment strategies. Olaparib, an FDA-approved poly ADP-ribose polymerase (PARP) inhibitor, is effective in human epidermal growth factor receptor (HER2) negative breast cancer, especially in BRCA-mutated subtypes. However, BRCA-mutant TNBC could eventually develop resistance to PARP inhibitors. We recently found that Olaparib treatment induces elevated IL-6 levels in TNBC cells, which may generate resistance to PARP inhibitors and reduce their effectiveness. Furthermore, knockdown of STAT3, a main downstream effector of IL-6 signaling, enhanced TNBC sensitivity to Olaparib. This study explored the combination of Olaparib and a novel orally bioavailable small-molecule STAT3 inhibitor, LLL12B, in human and murine TNBC cell lines. Both Olaparib and LLL12B independently reduced cell viability, migration, and invasion, but their combination demonstrated significantly greater efficacy than either treatment alone. These results support that dual inhibition of PARP and STAT3 is a novel targeted therapeutic strategy for TNBC.

#5725 The potent and selective PARP1 inhibitor and trapper SNV1521 exhibits combination activity with targeted and chemotherapeutics.

Mingming Gao, Qipeng Fan, Zhentian Li, Jun Pan, Renxu Chang, Liangxing Wu, Wenqing Yao, Phillip CC Liu

Synnovation Therapeutics, Inc., Wilmington, DE

SNV1521 is clinical stage PARP1 inhibitor and trapper with excellent potency and selectivity against other MARP and PARP proteins. Although several first generation non-PARP1 selective inhibitors have been approved primarily as monotherapy for BRCA-associated tumors, they have not fully realized the potential of PARP inhibition as a mechanism for potentiation of chemo-, DNA damage response, and radiation therapy because of overlapping toxicities including hematologic suppression. SNV1521 shows exquisite selectivity for PARP1 over PARP2 and other related proteins in biochemical assays compared with both first-generation PARPi and saruparib. In colony formation assays using normal donor HSPCs, SNV1521 exhibited significantly less suppression of the proliferation of both myeloid and erythroid lineages compared with these inhibitors. When comparing with the target efficacious concentration using a BRCA2-deficient cell line versus the NOEL for suppression of heme progenitors, SNV1521 showed an expanded margin versus either olaparib or saruparib. These data support the potential of SNV1521 to combine more effectively with approved and experimental oncology drugs. In cell-based combination experiments, SNV1521 strongly synergized with topoisomerase-1 inhibitors as well ADCs utilizing topo-1 based warheads. Importantly, the combination benefit extended to cell lines that were not intrinsically sensitive to PARP inhibitors suggesting activity in cell models beyond those with functional defects in homologous recombination. In a PDX model of breast cancer, the combination of topotecan with SNV1521 showed deeper tumor regression than either agent alone. Moreover, this activity showed durable anti-tumor activity after cessation of dosing. In summary, these data support the continued clinical development of SNV1521 as monotherapy and also in combination with drugs that are mechanistically synergistic but cannot be effectively combined with less selective PARP1 inhibitors because of overlapping toxicities.

#5726 QLS1103, A highly potent and selective PARP7 inhibitor treating advanced solid tumors.

Yuxing Zhang[1], Xiaoxia Yan[1], Yiming Xu[1], Difei Dong[1], Huijie Guo[1], Junguo Hao[1], Xinrui Shao[1], Ling Li[1], Guanxin Huang[1], Dong Yang[1], Guqin Shi[1], Yanling Xu[2], Daqing Sun[1], Weimei Sun[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center Ltd., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

PARP7, a member of the ADP-ribose polymerase family, is an enzyme that modifies proteins by attaching mono ADP-ribose to substrates. This post-translational modification is crucial for a variety of cellular functions, including the regulation of innate immune responses, the control of autophagy, and the facilitation of apoptosis. In some tumor cells, PARP7 may facilitate immune surveillance evasion by inhibiting type I interferon signaling pathways. Additionally, PARP7 has been reported to promote tumor growth in a cell-autonomous manner. Due to its multifaceted functions, PARP7 is an important target for cancer research and therapeutic intervention. QLS1103 is a proprietary, highly potent and selective PARP7 inhibitor. Study findings showed that treatment with QLS1103 may restore Type I IFN responses in tumor cells and trigger anti-tumor immunity in CT26 and EO771 syngeneic models. Analysis of tumor-infiltrating lymphocytes (TILs) revealed that QLS1103 not only increases the percentage of TILs but also enhances the activity of cytotoxic T cells. Furthermore, the combination of QLS1103 with an anti-PD-1 antibody showed a significant survival benefit over monotherapy in the CT26 model, with a complete regression (CR) rate rising to 75% in the combination group, compared to 25% in the monotherapy group. QLS1103 was also evaluated in a lung cancer xenograft model (NCI-H1373) to confirm the cell-autonomous effects of PARP7 inhibition. It was observed that QLS1103 could dose-dependently inhibit tumor growth and even induce tumor regression. QLS1103 has exhibited a favorable safety profile with excellent safety margins in preclinical studies and is currently under investigation in a phase I clinical trial. In conclusion, QLS1103 emerges as a promising candidate for the treatment of advanced solid tumors, either as a monotherapy or in combination with immune checkpoint inhibitors, warranting further investigation in clinical settings to fully realize its therapeutic potential.

CHEMISTRY: Drug Design, Synthesis, and Disposition

#5730 Discovery of a novel antibody-drug conjugate linker-payload with a distinct killing mechanism via prolonged unfolded protein response activation.

Rui Liu, Yushi Chi, Yongqiang Shan, Chenqiang Jia, Yingying Zhang, Xiayan Zhang, Wentao Zhang, Xuemei Tian, Yifan Zhang, Fan Yang, Dongmei Han, Simon Hsu, Jiamin Su, Jijun Yuan, Wan-Jen Yang, Xiaoling Yuan, Zhiyu Ma, Chen Hu

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: A specific class of compounds featuring a 3-(4-hydroxyphenyl) indoline-2 scaffold demonstrated potent antitumor activity against cancer cells with elevated TRPM4 expression or estrogen receptor positivity through the sustained activation of unfolded protein response. This mechanism is distinct from existing toxins. Generally, these compounds exhibit low toxicity to most healthy tissues, with gastrointestinal toxicity being the primary adverse effect. Notable examples of this class include ErSO and laxative oxyphenisatin acetate. This study aimed to optimize this scaffold for use as antibody-drug conjugate (ADC) payloads. By selecting antigens with low gastrointestinal expression, this strategy could potentially overcome ADC resistance or synergize with existing ADCs, leading to durable patient responses and improved survival outcomes.
Methods: The cytotoxicity of lead toxin, HLX91-048, and its related ADCs were evaluated in immortalized cell lines and treatment-resistant patient-derived organoids (PDOs) using the CellTiter-Glo® Assay. To create the HER2-targeting ADC, HLX91-048 was linked to a HER2 antibody via a cleavable GGFG linker, resulting in drug-to-antibody ratio (DAR) of 4 or 8 as needed. Flow cytometry was employed to analyze the binding and internalization of the ADCs. Bystander killing assays were performed on the $HER2^-$ MCF-7 cells using conditioned media from $HER2^+$ BT474 cell cultures. *In vivo* efficacy was tested in the BT474 breast cancer model and the DS-8201-resistant NCI-N87R gastric cancer model. The tolerability of HLX91-048 and the ADC was compared in parallel to DXd and DS-8201 in rats.
Results: HLX91-048 demonstrates >10-fold increase in cytotoxicity compared to ErSO, exhibiting sub-nanomolar to nanomolar IC_{50} values across various tumor cell types. When compared to DS-8201 analog the HLX91-048-based ADC showed enhanced cytotoxicity in multiple cell lines, stronger bystander killing, and greater stability in human and monkey plasma. As expected, the HLX91-048-based ADC significantly activates the UPR. The DAR4 HER2 ADC derived from HLX91-048 exhibited dose-dependent antitumor efficacy in both BT474 and NCI-N87 models, leading to substantial tumor regression at higher doses (10-12 mpk). Notably, 5 out of 8 PDOs from patients resistant to various standard treatments remained sensitive to the HLX91-048-based ADC, while showing reduced sensitivity to DS-8201. Lastly, in a pre-toxicology evaluation in rats, both the DS-8201 analog and the HLX91-048-based ADC were well-tolerated at a dose of 60 mpk once weekly for three weeks.
Conclusion: We reported a first-in-class ADC linker-payload featuring a highly differentiated killing mechanism that demonstrated exceptional efficacy and safety in preclinical evaluations. Preliminary toxicology studies in non-human primates have been scheduled.

#5731 BGB-C354, a novel B7H3 ADC with high DAR stability and strong bystander effect, demonstrates robust antitumor activity in preclinical models.

Xiao Ding[1], Charng-Sheng Tsai[2], Mei-Hsuan Tsai[2], Maggie Tang[1], Liu Xue[1], Chi Guan[1], Meiling Tan[2], Yiren Xiao[2], Yuanyuan Xie[1], Kunpeng Lyu[2], Xiaotong Chen[1], **Wenhao Li**[1], Qi Liu[1], Yun Chen[2], Jie Pan[2], Wenjin Yao[1], Yang Lyu[2], Kaiying Jia[1], Chang Song[1], Weiwei Song[1], Ce Wang[1], Fan Wang[1], Zhitao Wan[2], Mingming Guo[1], Beibei Jiang[1], Xiaomin Song[1], Wei Jin[1], Qiansheng Ren[1], Yu Shen[2], Zhirong Shen[1]

B7H3 is a type I transmembrane protein belonging to the B7 immunoregulatory family. B7H3 is overexpressed on a wide range of solid tumors such as lung cancers, gastrointestinal cancers and gynecological cancers, but its expression is absent or low in normal tissues, making it an attractive target for anticancer therapies. BGB-C354 is a B7-H3-targeting antibody-drug conjugate (ADC) composed of a humanized anti-B7-H3 monoclonal antibody conjugated via a cleavable linker to a novel TOP1i payload, and the drug to antibody ratio (DAR) is approximately 8. Utilizing a stable ring-open conjugator, BGB-C354 demonstrated improved ADC stability and sustained high DAR in vivo, which may enable more efficient payload delivery to B7H3-expressing tumors. In nonclinical pharmacological studies, BGB-C354 exhibited strong target binding activity, high target-dependent internalization, and potent cytotoxicity toward B7H3-expressing tumor cells. In addition, BGB-C354 demonstrated strong bystander killing effect in the presence of B7H3-expressing cell lines to potentially overcome the tumor heterogeneity. Notably, robust anti-tumor activity was observed in a panel of cell-derived xenograft (CDX) models with varying levels of B7-H3 expression, as well as in patient-derived xenograft (PDX) models. Consistent with its mechanism of action, DNA damage and apoptosis biomarker changes were induced by BGB-C354 in a dose-dependent manner after single dosing in preclinical models. Recently, a phase I study of BGB-C354 has been initiated to investigate its potential safety and preliminary efficacy in patients with B7H3-expressing advanced solid tumors (NCT06422520).

#5732 DXC020, a novel anti-CD54 antibody conjugate with a functional linker, exhibits potent anti-tumor efficacy.

Xingyan Jiang, Tianyu Zhou, Junxiang Jia, Huihui Guo, Yuanyuan Huang, Hangbo Ye, Lingli Zhang, Jun Zheng, Lu Bai, Wenjun Li, Binbin Chen, Qingliang Yang, Robert Zhao

Hangzhou DAC Biotechnology Inc. Ltd, Hangzhou City, China

Intercellular adhesion molecule-1 (ICAM-1, CD54) is a transmembrane glycoprotein of the immunoglobulin superfamily and involved in intercellular adhesion during inflammatory injury, viral infection, and tumorigenesis. The overexpression of CD54 is associated with the aggressiveness of liver cancer, non-small cell lung cancer, triple-negative breast cancer, melanoma, oral squamous cell carcinoma, and pancreatic cancer. Moreover, CD54's role in immune cell adhesion implies that targeting this molecule could potentially enhance the immune response against cancer cells. The identification of CD54 as a candidate gene in prostate tumors exposed to chronic cisplatin administration highlights its potential as a therapeutic target in cancer, including liver cancer. These properties make CD54 a promising target for the development of antibody-drug conjugates (ADCs) and other targeted therapies in hepatocellular carcinoma (HCC) and other malignancies. Through preliminary screening, several monoclonal mouse-derived antibodies with a strong affinity for CD54 were identified. To prevent the human body from developing a human anti-mouse antibody response (HAMA), these antibodies were subjected to a process of mutation and back-mutation to humanization. This meticulous engineering resulted in humanized antibodies with affinities comparable to their murine counterparts, with a dissociation constant (KD) in the pM range. Endocytosis experiments demonstrated that these humanized antibodies effectively internalized within tumor cells, a crucial property for the efficacy of antibody-based therapies. These antibodies were then conjugated with both tubulysin based and CPT-payloads to create series of ADCs. In vitro cytotoxicity assays revealed that many of the ADCs exhibit potent cytotoxicity against a range of cancer cell lines, including non-small cell lung cancer, prostate cancer, breast cancer, liver cancer, and bile duct cancer. In vivo studies using cell-derived xenograft (CDX) models demonstrated that a single, low-dose administration of a CD54-ADC candidate, DXC020, can significantly inhibit tumor growth and even induce tumor regression in cases such as non-small cell lung cancer. These promising results indicated that CD54-ADCs could become a viable candidate for targeted therapy against tumors expressing CD54, offering a new frontier in the treatment of various cancers, in particular for hepatocellular or hepatobiliary carcinoma, which still remains a global health challenge. The successful humanization of the antibodies, their effective internalization in tumor cells, and the robust cytotoxicity of the resulting DXC020 both in vitro and in vivo models, position the CD54-ADC as a promising candidate in further clinical study.

#5733 Design and synthesis of the novel camptothecin analog MF-6 for application into site-specific antibody-drug conjugate.

Xiaowei Cen, Hui Xu, Huikai Zhu, Hua Deng, Zhenzhen Wang, Junwei Xu, Xueying Li, Zhiheng Wu, Yiyan Zhang, Yuhang Chen, Xiaolin Chen, Li Chen, Wei Zhou, Hai Wu

Mabwell (Shanghai) Bioscience Co., Ltd. , Shanghai, China

Introduction: Antibody-drug conjugates (ADCs) have emerged as a revolutionary breakthrough in cancer treatment by precisely targeting tumor cells with high-potency payloads attached to specific antibodies. However, the efficacy and safety of ADCs largely depend on the design and optimization of their payloads. This study leverages the advanced Mtoxin^{Tm} platform to develop a novel ADC payload, MF6, aiming to enhance the antitumor activity of ADCs through precise drug design.

Methods: Supported by the Mtoxin^{Tm} platform, we first modified camptothecin-based compounds by preparing a series of camptothecin analogs with different substituents at the core position. Through in vitro efficacy testing, we screened out a series of compounds with significant antitumor activity and further optimized their attached dipeptide linkers. Subsequently, we conjugated the optimized drug-linker conjugates with anti-Trop2 and anti-B7H3 monoclonal antibodies to form novel ADCs. To comprehensively evaluate the potential of these ADCs, we conducted multiple experiments in vitro and in vivo, including pharmacodynamics, pharmacokinetics, safety, and antitumor activity studies.

Results: The experimental results showed that MF6, as a free molecule, exhibited good drug-killing activity and maintained significant efficacy in multidrug-resistant models resistant to DXd. ADCs constructed using the clinically validated site-specific conjugation technology IDDC™ and our novel payload MF6 demonstrated good uniformity and stability, and exhibited significant antitumor efficacy in multiple CDX models. Additionally, these ADCs showed good bystander killing activity, meaning they could kill nearby tumor cells, thereby further enhancing their antitumor effect. We also found that ADCs synthesized with MF6 had excellent serum and plasma stability and pharmacokinetic properties, providing strong support for their future clinical application.

Conclusions: This study successfully developed a novel ADC payload MF6 based on the Mtoxin^{Tm} platform and initially validated its antitumor activity and safety in multiple *in vitro* and *in vivo* models. These results provide a solid experimental foundation for the further development of MF6-based ADCs for the treatment of various cancers. In the future, we will continue to explore the potential of MF6 and anticipate that MF6-based ADCs will undergo further clinical validation and application, bringing more precise, effective, and safe treatment options to cancer patients.

#5734 Advancing ADC discovery with a highly versatile linker-camptothecin library.

Meijun Xiong, Qingsong Wu, Yanchun Li, Chong Liu, Yajun Sun, Zengyan Mu, Xinju Gao, Yanwen Feng, Haibo He, Paul H. Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Camptothecin derivatives have gained prominence as payloads in investigational antibody-drug conjugates (ADCs), exemplified by the clinical success of Trodelvy and Enhertu. The precise design of these linker-camptothecins has been instrumental in achieving optimal safety and efficacy for specific therapeutic indications. Growing evidence suggests that a single linker-payload design cannot accommodate the diverse requirements of various therapeutic targets. For instance, while the linker-payload of Enhertu (GGFG-DXd) has shown exceptional efficacy in HER2-targeted therapies, its performance is less promising in TROP2- and HER3-targeted indications. This highlights the critical need for linker-camptothecin systems with greater diversity in drug release mechanisms, kinetics, and payload potency to address varying therapeutic needs. To address the limitations of existing linker-camptothecin designs, including issues with stability, release efficiency, and specificity, we have developed a comprehensive library of linker-camptothecins with enhanced molecular diversity. Our design strategy incorporates a range of stimuli-responsive release mechanisms, such as cathepsin-, legumain-, and glucuronidase-mediated cleavage, as well as pH-sensitive linkers. Multiple camptothecin derivatives, including SN38, Exatecan, and TopoIx, were selected based on their distinct pharmacological properties—such as antitumor efficacy, lipophilicity, and half-life—and were conjugated to various linkers, creating a versatile library with broad applicability. This molecular diversity facilitates optimized release profiles and payload activities, tailored to specific therapeutic scenarios. Leveraging this library, we constructed a series of highly refined ADCs targeting different antigens and evaluated them systematically in both in vitro and in vivo preclinical models. These studies revealed that the ADCs incorporating the novel linker-camptothecin designs demonstrated significantly enhanced therapeutic efficacy and improved safety profiles compared to conventional linker-payload systems. In summary, we have established a novel linker-camptothecin library with diverse release behaviors optimized for specific therapeutic contexts. This approach facilitates the discovery and development of potent ADC candidates with superior efficacy and safety profiles, providing a robust platform for precision drug development targeting diverse indications.

#5735 Design of a peptide-targeted radiotherapy for treatment of bone cancers.

Losha D. Jung[1], Philip S. Low[2]

[1]MCMP, Purdue University, West Lafayette, IN,[2]Purdue University, West Lafayette, IN

According to the American Cancer Society, ~400,000 new cases of malignant bone metastases are diagnosed each year in the United States, with prostate and breast cancers accounting for the largest fractions. Unfortunately, progression of these metastases can lead to bone fractures, spinal cord compressions, hypercalcemia, and severe pain, resulting in a decrement in quality and duration of life. Given the limited effectiveness of existing clinical interventions in alleviating these symptoms, there is a critical need for therapies capable of selectively eradicating bone metastases without harming healthy tissues. To address this problem, we have developed a novel bone cancer-targeted radiotherapy comprised of an acidic oligopeptide that homes specifically to exposed hydroxyapatites (i.e. the mineral component of bone that becomes exposed in bone metastases) linked to a universal chelating agent (e.g. DOTA) that can bind to various cytotoxic radionuclides such as ^{177}Lu, ^{225}Ac, or ^{90}Y. Tail vein administration of the ^{177}Lu-labeled form of the above conjugate into nu/nu mice bearing intratibial C4-2 human prostate cancer revealed pronounced accumulation and retention of the conjugates in the tumor-induced bone lesions, with associated radioactivity decreasing modestly from 38% to 23% injected dose per gram (ID/g) from 4 hours to 240 hours. As the uptake in healthy tissues, aside from the kidneys, was minimal, and renal accumulation declined significantly from 2.8% to 0.13% ID/g over the same 240-hour period, it was concluded that bone metastases could be effectively irradiated without inducing measurable toxicity to healthy tissues. Subsequent therapeutic efficacy studies validated this prediction, demonstrating that serum PSA levels, a biomarker of C4-2 tumor growth, were significantly reduced in mice treated with the targeted radiotherapy, whereas untreated mice experienced disease progression necessitating euthanasia. Comparison of microCT scans between treated and untreated cohorts revealed a substantial reduction in bone lesions in the treated groups. Additionally, pathological examinations showed no detectable harm to kidney, blood, and bone marrow. These findings conclusively suggest that our bone cancer-targeted radiotherapy has the potential to improve survival and quality of life in this challenging patient population while minimizing toxicity.

#5736 Design of CYP1-activated 2,4-diaryl-substituted pyridine analogues with significant anti-proliferative effects in breast cancer cells *in vitro*.

Federico Brucoli, Ketan Ruparelia

De Montfort University, Leicester, United Kingdom

Cytochromes P450-1A1 and 1B1 (CYP1A1 and CYP1B1) are over-expressed in several human malignancies and represent an excellent target for enzyme prodrug therapy of cancer. The extrahepatic CYP1A1 isoform is constitutively expressed in a number of human breast cancers. CYP1B1 has been consistently detected in both pre-malignant tissue and metastatic cancer and its expression is associated with hormone-dependent tumours (e.g., breast and ovary). We have developed lead-prodrugs that selectively targeted CYP1 family enzymes. Here, we report the extensive chemistry work, which included the synthesis of more than 150 analogues, cytotoxicity screening results and CYP1 metabolisation data that led to the identification of a series of 2,4-diaryl-substituted pyridine lead-compounds. In our *in vitro* breast cancer model, the CYP1-activated pro-drugs were highly active against triple negative breast cancer MDA-MB-468 cells (IC_{50}=0.08μM), which constitutively express CYP1B1. The pro-drugs also had significant antiproliferative activity against MCF7 cells, which were induced to express CYP1A1 upon treatment with aryl hydrocarbon agonist 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). The hit-compounds exhibited no toxicity in "normal" human breast MCF10A cells (IC_{50}>100μM), which have no basal CYP1 expression. Cytotoxicity assays conducted in the presence of known CYP1 inhibitor α-naphthoflavone resulted in a 300-fold increase in the pro-drugs IC_{50} values from 0.01 to 3μM in MDA-MB-468 cells. Dose-response studies using the NCI 60 human tumour cells panel showed that selected prodrugs were 4-fold more selective towards breast cancer cells (GI_{50}=41nM) compared to the other cell lines tested. *In vitro* metabolism of selected lead-compounds was assessed by separate incubation with human CYP1A1, CYP1A2, CYP1B1 and CYP3A4 enzymes using HPLC methods. Both CYP1A1 and A2 were the most efficient catalysts of the pro-drugs metabolism, followed by CYP1B1. The prodrugs were not metabolised by CYP3A4. Tandem mass spectrometry (MS/MS) fragmentation and HPLC co-elution analysis allowed for the identification of the structure of the main metabolite of a benzodioxole-containing lead-compound that was produced by CYP1A1, CYP1A2 and CYP1B1 isozymes. The CYP1-generated metabolite was synthesised and cytotoxicity screening revealed that the compound exhibited antiproliferative activity with an IC_{50} <0.07μM against all the cell lines used in this study (e.g., MDA-MB-468, MCF10A and MCF7) irrespective of their levels of CYP1 expression. Further investigations on the metabolite mode of action are underway. In summary, we have identified cancer pro-drug chemotherapeutic agents that exhibit significant anti-proliferative activity in a CYP1-enzyme expressing breast cancer *in vitro* model and are suitable candidates for pre-clinical development.

#5737 Preclinical study of a novel long-acting receptor-biased rhIL-2 drug with sustained activation of cytotoxic T cells.

Peipei Cao, Biaxue Zhao, Jun Wang, Chenyang Jiang, Yu Zhuang, Bruce Y. Ma

Zonhon Biopharma Institute, Inc., Changzhou, China

Purpose: Human Interlukin-2 (hIL-2) targets at malignant tumors, such as renal cell carcinoma and melanoma, and has been on the market for many years. Due to its adverse effects, hIL-2 is limited in clinical use. However, with in-depth studies on the mechanism of action of IL-2 related drugs, IL-2 has been found to have a high potential for use in immunotherapy of oncology, setting off the upsurge of developing improved innovative IL-2 related drugs at home and abroad. The joint application of these drugs and PD-1 in clinical trials for malignant tumors displays a better efficacy and huge market potential. A lot of drug companies have developed IL-2 related drugs and now they are conducting phase I and II clinical trials for metastatic solid tumors and other indications. All of these IL-2 related drugs are designed and developed by half-life extension methods such as molecular mutagenesis and PEGylation, while problems are also existed, for example, a weak-effect and severe side effects. Consequently, according to QbD drug design concept, we have combined molecular mutagenesis with PEGylation to design new molecules and screen out feasible drugs through in vitro and in vivo evaluation experiments, and devoted to developing a novel long-acting IL-2 drug of sustained activation of T cells, offering an alternative choice for current tumor immunotherapy.
Method: Facing the defects of these products under development, we carried out molecule design and completed molecular screening of drug candidates through in vitro and in vivo evaluation experiments and pharmacological studies. After that, non-clinical studies were carried out and the comparison with analogous drugs in development was implemented in aspects of efficacy, safety and pharmacy.
Result: ZHB114 was screened out as a drug candidate with a better efficacy and fewer side effects. According to the pharmacological studies, ZHB114 was capable of releasing drug activity in a controlled and sustained manner within a safe therapeutic window, thereby enhancing its safety profile. In a number of animal models bearing tumors, ZHB114 has been demonstrated to possess a significantly higher potency than analogous drugs under development. In some models, ZHB114 can elicit complete tumor growth inhibition. The repeated dosing toxicity studies conducted on rats and cynomolgus monkeys have shown that ZHB114 has a wide security window and minimal adverse effects at efficacious doses. It is noteworthy that ZHB114 has been approved by CDE in China, and now it is in the process of preparing for the approval of FDA.
Conclusion: Compared with other analogous drugs in development, ZHB114 is more potent and is expected to become a novel long-acting IL-2 agent for tumor immunotherapy, with fewer side effects.

#5738 Napabucasin analogues with increased bioavailability and efficacy in fibrolamellar hepatocellular carcinoma.

Shalini Rawat, Jared Alderman, Priscilla Baeza, Lianna Hartshorn, Celeste Villasenor, Jakim Brazil, Barbara Lyons

Chemistry and Biochemistry, New Mexico State Univ. - Las Cruces, Las Cruces, NM

Fibrolamellar Hepatocellular carcinoma (FLC) is a very rare liver cancer which occurs in young adults and children under the age of 40. This cancer is lethal and was first recognized in 1980. The term “fibrolamellar” refers to the fibrous bands that are visible when examining tumor tissue under a microscope. In FLC, a deletion of 400,000 base pairs occurs in a chromosome 19 copy, leading to the formation of a fusion protein comprising heat shock protein DNAJB1 and the catalytic subunit of Protein Kinase A (DNAJB1-PRKACA). Patients show no symptoms in the early stage of the disease. The reported survival rate over the past five years is below 50%. Surgery remains the sole partially effective treatment for FLC, with no currently approved systemic therapies available. The primary model compound of this project is Napabucasin. It is also known as BBI608 is a naphthoquinone natural product isolated from the plants *Newbouldia laevis*, *Ekmanianthe longiflora*, and *Handroanthus impetiginosus*. It has shown wide spectrum anti-cancer activities and is now in trials for cancer treatment. The Napabucasin was found to be a top hit in drug screening showing potency against all FLC patient derived xenografts (PDX) models. Napabucasin is known to work in multiple signaling pathways and have been shown cytotoxic against both PDX and direct-from-patient FLC tumor cells. We anticipate that the organic synthesis and development of optimized Napabucasin analogues, along with the evaluation of their cytotoxicity and proliferation effectiveness compared to the parent compound, Napabucasin, will result in compounds with improved bioavailability and efficacy, particularly in FLC model cell lines (FLX1 and Huh7-Chimera).

#5739 Small molecule modulation of autoinhibition to inhibit DNA binding of ERG and FLI1 - therapeutic for Ewing sarcoma, prostate cancer, and ALL.

John H. Bushweller[1], Kiran Srimath Tirumala[1], Ashish Kabra[1], Adam Boulton[1], Karla Rubio[2], Michael Bond[3], Anglea Su[3], Miguel Rivera[2], Kim Stegmaier[3]

[1]University of Virginia, Charlottesville, VA,[2]Massachusetts General Hospital, Boston, MA,[3]Dana Farber Cancer Institute, Boston, MA

Targeting transcription factor-DNA interactions presents substantial challenges due to the convex and highly positively charged surface on the DNA binding domains that mediate DNA binding. Such a surface is far from ideal for development of drug-like molecules, making this a challenge. Furthermore, as many transcription factors are members of families with highly conserved DNA binding domains, there are also concerns with respect to what level of specificity could be achieved with an inhibitor targeting the DNA binding domain in a family of transcription factors. The 28 member Ets family of transcription factors has numerous members implicated in various cancers. EWS::FLI1 and EWS::ERG fusions are drivers in Ewing sarcoma, ERG overexpression via the TMPRSS2::ERG fusion is a driver in half of prostate cancer, and ERG has been identified as a marker for poor prognosis in AML patients. Based on this, small molecule inhibitors of DNA binding of ERG and FLI1 could have utility for these cancers.To overcome the challenges mentioned above, we chose to target the autoinhibition of ERG and FLI1 to generate inhibitors of their binding to DNA. Numerous transcription factors modulate their activity via autoinhibition and this has been characterized for many of the members of the Ets family including our own work on ERG. By so doing, we hypothesized we could achieve selectivity within the Ets family due to the differing sequences and mechanisms mediating autoinhibition among the different family members.We screened using fragment libraries for compounds inhibiting DNA binding of an autoinhibited ERG construct but were not active against the uninhibited DNA binding domain. Optimization of these gave a fragment with excellent selectivity but limited potency. We subsequently screened for a molecule that could covalently add to ERG and linked a derivative of this to the autoinhibition fragment. Biochemical assays of effects on DNA binding show low μM IC_{50} values and a shift in the K_d of DNA binding of ~2.5-fold for both ERG and FLI1. Importantly, characterization of effects on 7 other Ets family members representing 7 other subfamilies shows the inhibitors are not active against other Ets family members, demonstrating we have achieved a high level of selectivity within the family.We have shown that the ERG/FLI1 inhibitors inhibit the proliferation of Ewing sarcoma cell lines at low μM concentrations and preferentially inhibit Ewing sarcoma cell lines versus other sarcoma cell lines. As EWS::FLI1 is known to bind at enhancers, we evaluated effects on H3K27ac levels at enhancer elements. We observe no global reduction in H3K27ac levels at enhancers but H3K27ac levels at EWS::FLI1 bound enhancers are reduced. In addition, we observe a reduction in the occupancy of RNA Pol II at EWS::FLI regulated genes with inhibitor treatment. Both these results are consistent with an on-target mechanism of action.

#5740 Disruption of the acetylcholine signaling pathway inhibits angiogenesis and tumor growth in human lung adenocarcinoma.

Piyali Dasgupta[1], Eric W. Bow[2], Krista L. Denning[3], Rama S. Gadepalli[2], John M. Rimoldi[2], Yi Charlie Chen[4], Sarah L. Miles[1]

[1]Biomedical Sciences, Marshall University School of Medicine, Huntington, WV,[2]Department of Biomolecular Sciences, University of Mississippi, University, MS,[3]Department of Pathology, Marshall University School of Medicine, Huntington, WV,[4]Department of Biology and Environmental Science, Bluefield State University, Bluefield, WV

Purpose of the study: Lung adenocarcinoma (LUAD) accounts for about 60% of all lung cancers and shows a strong etiological correlation with smoking. Nicotine, the addictive component of tobacco smoke is known to accelerate the growth of human lung tumors by stimulating tumor angiogenesis. The pro-angiogenic effects of nicotine are mediated by nicotinic acetylcholine receptors (nAChRs). The endogenous ligand for nicotine is the neurotransmitter acetylcholine (ACh). The primary aim of this study was to determine if disruption of ACh production (via inhibition of the enzyme choline acetyltransferase; ChAT) could inhibit angiogenesis and suppress the growth of human LUADs. We used a small molecule inhibitor of ChAT namely BW813U for our studies.
Experimental procedures. Primary human microvascular endothelial cells from the lung (HMEC-L) were used for all the experiments. These cells were used between passage 3-7. The anti-angiogenic activity of BW813U was measured in cell culture models by using the “MATRIGEL ASSAY”. The results obtained from the “MATRIGEL ASSAY” were confirmed using chicken chorioallantoic membrane (CAM) angiogenesis experiments. Finally, the anti-tumor activity of BW813U was measured in vivo by using xenograft model systems in SCID mice. Our studies also investigated the signaling pathways underlying the anti-angiogenic activity of BW813U, using chemical inhibitors and siRNA methodology.
Results: BW813U robustly suppressed angiogenesis in Matrigel assays and CAM model systems. The administration of BW813U potently decreased the growth rate of H838 tumors xenotransplanted in SCID mice. Immunohistochemical staining experiments revealed that the anti-tumor activity of BW813U was correlated with decrease of CD31 angiogenic biomarker in H838 tumor sections. The anti-angiogenic activity of BW813U was mediated by the alpha7-nAChR pathway and involved the nitric oxide pathway. Taken together, our studies show that ChAT may be a valuable drug target for the therapy of LUAD.
Conclusions: ChAT antagonists like BW813U decrease the growth of LUAD by suppressing tumor angiogenesis.
Support or Funding Information: Funding for our study was supported by a NIH R15-AREA Grant (2R15CA161491-03) and a Center for Natural Products pilot grant from the WV-INBRE Grant Program (P20GM103434, PI:Gary Rankin). Furthermore, this study was supported in part by an Institutional Development Award (IDeA) Grant number P20GM104932 from the National Institute of General Medical Sciences (NIGMS) and the Research Core B of COBRE, a component of the National Institutes of Health (NIH).

#5741 6-((1,4-naphthoquinone-2-yl)methyl)thio-glucose conjugates, a novel targeted approach for advanced prostate cancer.

Sergey Dyshlovoy[1], Tobias Busenbender[1], Dmitry Pelageev[2], Jessica Hauschild[1], Moritz Kaune[1], Lukas Bockelmann[1], Christoph Krisp[1], Mohamed Elsesy[1], Alexandra Zielinski[1], Thomas Mair[1], Simone Venz[3], Malte Kriegs[1], Konstantin Hoffer[1], Yuri Sabutski[2], Ksenia Borisova[2], Nadja Strewinsky[1], Svetlana Kovach[2], Ekaterina Khmelevskaya[2], Klaus Pantel[1], Hartmut Schluter[1], Victor Anufriev[2], Derya Tilki[1], Markus Graefen[1], Wael Mansour[1], Carsten Bokemeyer[1], Gunhild von Amsberg[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Vladivostok, Russian Federation,[3]University of Greifswald, Greifswald, Germany

The Warburg effect is a shift from oxidative phosphorylation to anaerobic glycolysis, accompanied by an enormous increase in glucose uptake into cancer cells. We have utilized this effect to design a new group of targeted 1,4-naphthoquinone-glucose derivatives conjugated with a novel thiomethylene linker, which were cytotoxic to prostate cancer cells. Compound PeS-9 revealed the highest efficacy and selectivity, which was conditioned by a GLUT-1-mediated uptake. PeS-9 induced androgen receptor degradation followed by downregulation of its signaling. In addition, it increased reactive oxygen species production and induced DNA double-strand breaks. Combinational therapy with PARP-inhibitor olaparib resulted in synergistic effects in homologous recombination-deficient cells. The underlying mode of PeS-9 cytotoxic action involved mitochondria targeting, leading to a loss of mitochondrial membrane potential, release of cytochrome C and AIF, activation of caspases-3 and -9, PARP cleavage, and apoptotic cell death. This process was stipulated by down-regulation of several antiapoptotic factors and induction of endoplasmic reticulum stress. Moreover, drug-induced activation of signaling pathway mediated by kinases p38, JNK1/2, and ERK1/2 was identified as an important factor of the cytotoxic activity. The anticancer activity of PeS-9 could be confirmed *ex vivo* using patients-derived tumoroids as well as *in vivo* resulting in decreased tumor growth and dissemination of prostate cancer cells to the lungs. No serious side effects were observed in animal models. This unique combination of anticancer properties makes PeS-9 an attractive candidate for targeted monotherapy against GLUT-1-overexpressing tumors and as a potential combination partner, especially with PARP inhibitors.

#5742 Synthesis of substituted benzimidazole tetrahydropyridines as anti-breast cancer agents.

Kinfe Ken Redda[1], Madhavi Gangapuram[1], Absera W. Haile[1], Suresh Eyunni[2]

[1]College of Pharmacy and Pharm Sciences, Florida A&M University, Tallahassee, FL,[2]Chemistry, College of Science and Technology, Florida A&M University, Tallahassee, FL

Breast cancer is the most common type of cancer worldwide. In 2023, the World Health Organization (WHO) reported that 2.3 million women were diagnosed with breast cancer, leading to 670,000 deaths. Furthermore, the incidence rates of breast cancer have been rising at 3% each year. Overexpression of COX-2 in breast cancer tissues is associated with poor prognosis, including higher tumor grade, increased metastatic potential, and resistance to therapy. Selective COX-2 inhibitors have demonstrated potential in reducing tumor growth in preclinical and some clinical studies. These inhibitors may also enhance the effectiveness of chemotherapy and radiotherapy. The benzimidazole nucleus is a valuable subunit for the development of pharmaceuticals and biologically relevant molecules. Tetrahydropyridine (THP)analogs are compounds with diverse biological activities, including analgesics, anti-inflammatory agents, and chemotherapeutic agents. Our previous research findings indicated that the THP derivatives exhibited COX-2 inhibition and demonstrated anti-inflammatory effects in rat paw edema assays. The pharmacological activities of THP derivatives depend on the nature of the substituents in the THP ring system. The incorporation of a benzimidazole moiety may enhance the biological activity of these THP derivatives. Thus, the design and synthesis of novel series of benzimidazole-THP derivatives with potential anticancer and anti-inflammatory activities were initiated. In the current investigation, we synthesized numerous analogs maintaining the *N*-(5-(1*H*-benzo[*d*]imidazol-2-yl)-3,6-dihydropyridin-1(2*H*)-yl)benzamide/benzene sulfonamide having modifications on the phenyl ring. We expect that these structural modifications would affect the compounds electron density, lipophilicity and the compounds steric configurations. The starting material 2-(pyridin-3-yl)-1H-benzo[d]imidazole was obtained by the reaction of nicotinic acid, 1,2-phenyldiamine and polyphosphoric acid by stirring in an oil bath at 180° C for 2 h. N-Amination of substituted 2-(pyridin-3-yl)-1H-benzo[d]imidazole by an aminating agent O-(mesitylsulfonyl)hydroxylamine (MSH), followed by ylide formation and further reduction yielded the desired substituted N-(5-(1H-benzo[d]imidazol-2-yl)-3,6-dihydropyridin-1(2H)-yl)benzamide derivatives. Final compounds were analyzed via NMR spectroscopy, IR and elemental analysis. The analogs were evaluated for through docking studies. Two products showed significant anti-inflammatory and anti-breast cancer activities.

#5745 Selective anticancer activity and mechanistic insights of novel compounds identified through NCI-60 cancer cell line screening.

Rakaia S. Abdullah, Md Emran Hossain, Eneye David Ajayi, Mostafa M. A. Aref, Hamed I. Ali

Pharmaceutical Sciences, Texas A&M University, College Station, TX

Targeted cancer therapies aim to maximize efficacy while minimizing side effects. The NCI 60 Human Tumor Cell Line Screen provides a comprehensive platform for identifying compounds with selective anticancer potential across various subtypes. To identify and validate potent anticancer compounds from a 150 compound library, focusing on molecular selectivity, mechanistic insights, and preclinical efficacy. High-throughput screening was performed using the NCI60 platform, followed by cytotoxicity assays (IC_{50}), kinase selectivity profiling, and molecular modeling. Further evaluation utilized 3D spheroid and organoid models, in vivo testing in xenograft models, and mechanistic studies via Western blot to assess apoptosis and pathway modulation. Seventeen compounds (HA45, HA46, HA7, HA12, HA14, HA15, HA16, HA19, HA21, HA23, HA25, HA26, HA64, HA88, HA94, HA96) exhibited significant selectivity, with GI_{50} values in the nanomolar and micro range. Lead compounds HA45 and HA46 against CNS SNB 74 cell line demonstrated potent kinase inhibition profiles and induced apoptosis through disruption of critical signaling pathways. Molecular docking and dynamics simulations revealed stable interactions with target kinases, corroborating structure-activity relationships. Testing in 3D models confirmed their physiological relevance, and in vivo studies showed tumor growth inhibition with minimal toxicity. This study highlights the utility of integrated methodologies for advancing selective anticancer agents toward clinical application. The findings underscore the importance of combining computational, in vitro, and in vivo approaches in the development of novel cancer therapeutics.

#5746 Development of Pt-HDACi complexes to enhance potency and selectivity for advanced cancer therapy.

Rabeya Bosri, Jayden Stahl, Nghia Tran, Chao Feng, Liang Xue, Qinliang Zhao

Department of Chemistry, University of the Pacific, Stockton, CA

Combining standard chemotherapy drugs with low doses of histone deacetylase inhibitors (HDACis) has emerged as a promising approach to enhance cancer treatment efficacy. Incorporation of HDACi onto the platinum (Pt) core as a non-leaving group may improve the potency and selectivity of the Pt anticancer drugs and maintain the synergistic effect. In the newly synthesized inhibitors, the linker domain was modified by including heterocyclic rings or amine groups. One or two amine groups were installed onto the aromatic ring in the protein recognition domain to build monodentate or bidental coordination sites to incorporate Pt. Four HDACi derivatives (L19, L20, L21, L22) were successfully synthesized and fully characterized. Pt-HDACi complexes were obtained by reacting K_2PtCl_4 with bidentate L19 and L20, and $K[PtCl_3(2\text{-picoline})]$ with monodentate L21 and L22. Intermediates and final compounds were analyzed using mass spectrometry and NMR spectroscopy. The purity was confirmed by melting point measurement, analytical HPLC, and/or elemental analysis. Different bioassays, such as enzyme inhibition, cell viability studies with cell lines K562, HCT-116, and A549, and DNA binding assay, have been applied to evaluate their efficacy. All four derivatives and Pt-HDACi conjugates have shown promising enzyme inhibition and potent bioactivities. Particularly, L19 and L21 with a heterocyclic ring in the linker showed the highest potency, with IC50 values significantly lower than the FDA-approved Vorinostat and Panobinostat. Molecular docking studies further supported these findings by revealing stronger binding affinity towards the HDAC enzymes, demonstrating similar trend in inhibition and potency toward cancer treatment.

#5747 Assessment of neuro-pharmacokinetic behavior of BDTX-1535 in brain tumor patients by a validated LC-MS/MS method.

Vahuni Karapetyan, Tigran Margaryan, Nader Sanai, Artak Tovmasyan

Ivy Brain Tumor Center, Barrow Neurological Institute, Phoenix, AZ

BDTX-1535 is an orally available, highly potent, irreversible inhibitor of epidermal growth factor receptor (EGFR), targeting a range of EGFR mutations, including extracellular variants and amplifications commonly expressed in glioblastoma. To assess CNS penetration of BDTX-1535 in glioblastoma patients, a novel bioanalytical method was developed to measure total and unbound BDTX-1535 levels in human brain tumor tissue, plasma, whole blood and cerebrospinal fluid (CSF). The method was validated using plasma as a surrogate matrix over the concentration range of 0.2-500 nM on an LC-MS/MS system. The MS/MS detection was conducted in positive electrospray ionization mode, while chromatography was performed using a Kinetex™ F5 column (50 × 2.1 mm, 1.7 µm) with a total 3.8-minute gradient elution time. The maximum coefficient of variation for both intra- and inter-day precision was 16.3%, with accuracy ranging from 91.5% – 107.2% across all matrices. BDTX-1535 was stable in human whole blood, plasma and brain homogenate for at least 4 hours at room temperature (RT) and 105 days at -20°C, as well as in stock and working solutions for at least 9 hours (RT) and 52 days (4°C). Equilibrium dialysis experiments revealed the unbound fractions of 0.01 and 0.08 for BDTX-1535 in human brain and plasma, respectively. The validated method is currently employed to assess BDTX-1535 levels in human brain tumor tissue, CSF, blood and plasma in an ongoing trial on recurrent high-grade glioma patients (NCT06072586). Initial results of measured total and unbound drug levels in the gadolinium-enhancing and non-enhancing brain tumor regions indicate significant brain penetration ability of BDTX-1535 in high-grade glioma patients.

#5748 Metabolites of the orally potent anticancer agent and endoplasmic reticulum stress inducer RM-581.

Donald Poirier[1], Martin Jutras[2], Rene Maltais[1], Jenny Roy[1], Maude Fleury[1], Camille Gagne[1]

[1]CHU de Quebec Research Center-Universite Laval, Quebec, QC, Canada,[2]Universite de Montreal, Montreal, QC, Canada

The development of new and more effective chemotherapy agents is a biomedical research priority, especially for cancer, still one of the deadliest diseases. To progress towards clinical phase studies with RM-581, an aminosteroid derivative producing promising in vitro and in vivo results against several types of cancers, including some with a poor prognosis such as pancreatic, prostate and breast cancers, it was necessary to address its metabolic stability. Analysis by ultra high-pressure liquid chromatography (UPLC) quadrupole time-of-flight (QTof)-mass spectrometry (MS) showed the gradual disappearance of RM-581, making it possible to determine a half-life of 14 and 15 min in concentrated preparations of mouse and human liver microsomes, respectively, and the presence of 6 metabolites in varying proportions (M1 to M6). The MS/MS spectra of metabolites were investigated to assign sub-structures to fragment ions. These analyses made it possible to conclude that the amino acid proline in the side chain at position C2 of the steroid mestranol was the main site of metabolism and the following mass shift relative to the parent compound were observed for each metabolite relative to RM-581: M1 (+34), M2 (-2), M3 (+16), M4 (+18), M5 (+32) and M6 (+16). Suspecting the formation of RM-581 analogs whose pyrrolidine ring of proline has been opened, we synthesized an aminosteroid where the proline was replaced by a 2-amino-5-hydroxypentanoic acid. Starting from steroid estrone, 4 steps were needed to introduce a piperazine at position C2, an ethynyl at C17α and to methoxylate the OH at C3. The key Fmoc and TBS-diprotected amino acid was then added by a coupling reaction, the Fmoc protecting group removed before adding the quinaldic acid. A cleavage of the TBS protecting group then allowed to obtain the targeted RM-581 analog. After a full chemical characterization of this compound, these chromatographic and MS properties made it possible to formally identify the major metabolite M4 ($M+H^+$ = 665.3684; Rt = 9.11 min) as a primary alcohol derivative. This result also indirectly supports the proposed structures of the other metabolites M6 (aldehyde), M5 (carboxylic acid) and M1 (primary alcohol or oxygen on the quinoline ring). When determining the concentration inhibiting 50% of cell proliferation (IC50) on 8 human leukemia and pancreas cancer cell lines, M4 (IC50 = 17-454 µM) was found to be much less potent than RM-581 (IC50 = 0.78-7.55 µM). The loss of efficiency ranged from 16 to 111-fold, according to cell lines. Furthermore, only M4 was observed when RM-581 was administered by gavage to mice at a 30 mg/kg dose with the plasma analyzed 2 h post-administration. The glucuronidated form of M4 was also detected at 2 h, suggesting the RM-581 elimination pathway and the fact that it does not accumulate in the blood.

#5749 Determination of the mTOR inhibitor temsirolimus and its active metabolite sirolimus in human blood, plasma, cerebrospinal fluid, and brain tumor tissue using a validated LC-MS/MS assay.

Gerold S. Kaplan, Tigran Margaryan, Nader Sanai, **Artak Tovmasyan**

Ivy Brain Tumor Center, Barrow Neurological Institute, Phoenix, AZ

Temsirolimus is an FDA approved mTOR (mammalian target of rapamycin) inhibitor that is presently under investigation in multiple clinical trials for various cancers, including for recurrent high-grade glioma. Here, we report A robust, sensitive, and extremely rapid liquid chromatography tandem mass spectrometry (LC-MS/MS) method for the quantification of total concentrations of temsirolimus and its active metabolite sirolimus in human blood, plasma, brain tumor and cerebrospinal fluid (CSF) samples. The method was validated for the simultaneous determination of both analytes over a concentration range of 1-1000 nM within a total run time of 2.6 min. Simple one-step protein precipitation with methanol was employed to extract analytes from biomatrices. Chromatographic separation of analytes was achieved on Kinetex™ EVO C18 (50 × 2.1 mm, 1.7 µm) column using gradient elution with mobile phases of 5 mM ammonium formate and methanol at a flow rate of 0.5 mL/min and an injection volume of 5 µL. Detection was performed with a Sciex QTRAP 6500+ mass spectrometer, utilizing multiple reaction monitoring mode to register the precursor-to-product ion transitions under positive electrospray ionization. The maximum coefficient of variation for both intra- and inter-day precision was 12.3%, with accuracy ranging from 85.6% - 114.2% in all matrices. Combined temsirolimus and sirolimus samples were determined to be stable at room temperature (RT) in whole blood and brain homogenate for at least 4 hours and in plasma for at least 1 hour. At -80±15°C in a freezer, samples in plasma, brain homogenate, and whole blood were stable for at least 132 days. Stock and working solution stability was also evaluated to be stable for at least 4 hours (RT) and 113 days (-20°C nominal for stock solutions and 4°C for working solutions). The validated method is currently employed in a clinical trial evaluating the efficacy of super-selective intra-arterial infusion for the CNS delivery of temsirolimus in recurrent high-grade glioma patients (NCT05773326) to determine temsirolimus and sirolimus pharmacokinetics in blood, brain tumor, plasma, and CSF.

#5750 Discovery of GSK4418959 (IDE275): A novel, non-covalent, reversible Werner Helicase inhibitor and a new potential therapeutic for the treatment of MSI-H cancers.

Joshua P. Taygerly[1], **Michael P. DeMartino**[2], Brian T. Jones[1], Edward J. Brnardic[2], Joshua E. Cottom[2], Yang Lee[3], Diana M. Munoz[1], Claire Neilan[1], Sunjay Sethi[1], Robert A. Reid[2], Apirat Chaikuad[4], Lisa M. Shewchuk[2], Ethan McSpadden[1], Daniel L. Severance[1], Kira Campbell[2], Philip Landis[2], Jay P. Jain[1], Richard Zhang[1], Leng Nickels[2], Dennis K. Murphy[2], Hans C. Eberl[5], Muzaffar Alam[1], Melissa Fleury[1], Lara K. Leister[2], Tessa Lynch-Colameta[2], James P. Phelan[2], Michael D. VanHeyst[2], Amberly B. Sanford[2], Ann M. Rowley[2], Hongyi Yu[2], Anna Rutkowska-Klute[5], Thilo Werner[5], Stephan Gade[5], Damian Hruszkewycz[2], Tyler Higgins[2], Xin Linghu[1], Ian S. Young[1], An D. White[1], Benjamin Schwartz[3]

[1]Ideaya Biosciences, San Francisco, PA,[2]GSK, Upper Providence, PA,[3]GSK, Cambridge, MA,[4]GSK, Stevenage, United Kingdom,[5]GSK Cellzome GmbH, Heidelberg, Germany

Recent large-scale genome wide CRISPR screens identified Werner (WRN) Helicase as uniquely essential to cell survival specifically in the microsatellite instability-high (MSI-H) cancer setting. This synthetic lethal relationship elevated WRN as an attractive precision therapeutic target for the treatment of MSI-H cancers, irrespective of tumor type. High-throughput screening identified a hit characterized by low potency inhibition of ATPase function. This poster describes the systematic optimization of this hit resulting in the discovery of clinical candidate GSK4418959, a novel, potent and selective small molecule that binds to WRN in an allosteric pocket and inhibits ATPase and DNA unwinding functions in an ATP-competitive manner. GSK4418959 phenocopies the genetic silencing studies in cells and organoids and accordingly, elicits complete tumor regression in murine xenograft MSI-H models (CDX and PDX) following oral dosing. Importantly, no response is observed in analogous microsatellite stable (MSS) models, exemplifying the precision effect of the WRN inhibition mechanism. GSK4418959 will be investigated as a potential treatment for patients with MSI-H cancer, including those who have been treated with and failed at least one line of checkpoint immunotherapy for their advanced disease.

CHEMISTRY: Multi-omics for the Cancer Proteome

#5753 Multi-omic analysis links neighborhood disadvantage to elevated stress hormones and tumorigenic markers in ER+ breast cancer patient plasma and tumor samples.

Hannah Heath[1], Oana C. Danciu[2], Garth Rauscher[2], Natalie Pulliam[3], Elona Liko-Hazizi[3], Sarah Friedewald[3], Seema Khan[3], Julie Kim[3], William Gradishar[3], Jonna Frasor[2], Kent F. Hoskins[2], Zeynep Madak-Erdogan[1]

[1]University of Illinois at Urbana-Champaign, Champaign, IL,[2]University of Illinois at Chicago, Chicago, IL,[3]Northwestern University, Chicago, IL

Intro: Estrogen receptor positive (ER+) breast cancer (BC) patients living in disadvantaged neighborhoods experience worse survival compared with patients in advantaged neighborhoods. Chronic stress, indicated by elevated cortisol levels, may mediate this disparity by dysregulating inflammatory responses driving BC tumorigenesis. However, the role of cortisol in ER+ BC remains underexplored.
Objective: To explore associations between pre-treatment plasma cortisol, inflammatory proteins, tumoral gene expression changes, and neighborhood disadvantage in women with primary ER+ BC compared to cancer-free controls.
Methods: Pretreatment plasma samples were collected from women with primary ER+ BC (n=98) and cancer-free controls (n=144). Tumor samples were obtained from a subset of cases (n=77). Samples were from three Chicago hospitals serving disadvantaged or advantaged neighborhoods, as determined by Community Needs Assessment reports. Plasma samples were analyzed via a steroid hormone metabolomics assay and Olink Proteomic's inflammatory proteins panel. Gene expression in tumor samples was analyzed via the Breast Cancer 360 Nanostring panel. Mixed models, adjusted for age and BMI, compared: plasma samples from disadvantaged cases (n=48) vs. controls (n=114), advantaged cases (n=50) vs. controls (n=27), advantaged (n=27) vs. disadvantaged (n=117) controls, and advantaged (n=50) vs. disadvantaged (n=48) cases, and tumor samples from advantaged (n=44) vs. disadvantaged (n=33) cases.
Results: Thirteen steroid hormones, 85 plasma proteins, and 759 tumor tissue genes were detected. Among cases vs. controls, cortisol-related metabolites (cortisol/cortisone ratio, 11-deoxycortisol, 17a-OH-progesterone, androstenedione) were elevated in cases ($p<0.05$). The cortisol/cortisone ratio remained significantly elevated in disadvantaged cases vs. controls ($p<0.01$) but not advantaged cases vs. controls.
In disadvantaged individuals, 62 inflammatory proteins were elevated ($p<0.05$). Forty overlapped between controls-only and cases-only analyses, while 21 were unique to cases, including five weakly correlated with the cortisol/cortisone ratio ($p<0.05$). Seventy-six genes were upregulated in tumors from disadvantaged vs. advantaged cases, including those involved in cell cycle regulation, proliferation, and HIF-1 signaling. Motif analyses showed NFKB as a top motif ($p<0.01$), suggesting dysregulated cortisol signaling. Of the 45 downregulated genes, many were involved in anti-inflammatory pathways ($p<0.05$).
Conclusion: BC diagnosis in disadvantaged individuals is associated with elevated cortisol, potentially contributing to elevated circulating inflammatory proteins and intratumoral gene expression changes that promote tumor progression.

#5754 An LC-MS toolbox for identifying and guiding the development of cysteine-targeted small molecule covalent inhibitors.

Kurt Baltier, Alison Erickson, Craig R. Braun, Ryan Kunz, **Brian Erickson**

IQ Proteomics LLC, Framingham, MA

Covalent inhibitors are a powerful class of therapeutic agents, and have gained particular traction with oncogenic targets. FDA-approved covalent inhibitors have been introduced for treatment of a range of cancers, including mantle cell lymphoma (ibrutinib), non-small cell lung cancer (osimertinib, sotorasib, afatinib), and breast cancer (neratinib). Notably, the recent surge in preclinical covalent inhibitor pipelines across biotech and pharma highlights the methodological and technological advancements in covalent inhibitor research and development. Owing to the mechanism of action of this compound class, mass spectrometry is uniquely positioned as an ideal analysis tool for identification, optimization, and mechanistic characterization of covalent inhibitors across the entire developmental cycle of these therapeutics from library screening to clinical evaluation. IQ Proteomics leverages mass spectrometry to empower biotechnology and pharmaceutical companies as a contract research organization, and has developed a comprehensive, turn-key LC-MS based pipeline for supporting the preclinical development of covalent inhibitors. We present a case study exemplifying this LC-MS pipeline centered on the clinically approved KRAS inhibitor sotorasib. We first describe a high-throughput, proteome-wide cysteine ligandability assay ideally suited for initial identification of library hits and SAR evaluation of preliminary lead compounds, and demonstrate the complimentary utility of multiomics characterization (proteome expression profiling, PTM profiling, etc) to global cysteine profiling data. We further present an optimized targeted LC-MS (PRM) workflow for evaluating target-engagement both indirectly (disappearance of unmodified cysteine peptide) and directly (appearance of adduct peptide) for characterization of preclinical lead compounds over large numbers of in vitro and in vivo samples. We finally evaluate an isobaric multiplexed assay for rapid target engagement characterization of covalent inhibitors in complex matrices. Together, this suite of template assays represents a set of powerful tools for covalent inhibitor discovery, optimization, and therapeutic evaluation that empowers the oncology community as exciting covalent modalities continue to emerge with the potential to treat an increasing number of diseases.

#5755 Expansion of the known functional diversity of human T cells achieved due to the unprecedented resolution of intracellular proteins by mass cytometry (CyTOF).

Laura Polanco[1], Michael J. Cohen[2], Erika L. Smith-Mahoney[1], Ling Wang[2], David King[2], Madison Bailey[1], Christina Loh[2], Anna C. Belkina[1], Amedeo J. Cappione[2], Jennifer E. Snyder-Cappione[1]

[1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA,[2]Standard BioTools, Markham, ON, Canada

Measuring the functional signatures of immune cells comprehensively, spanning the inflammatory (Th1/Th17) and immunosuppressive (Th2/Treg) lineages, provides key insights into several facets of cancer research and therapy. Single-cell detection of cytokines from diverse functional lineages is required to determine mechanisms underlying success/failure of checkpoint blockade, define immunosuppressive activity of the tumor-resident cell subsets and identify immunological biomarkers that predict clinical outcomes. Powerful cytometric research tools, such as fluorescence cytometry, enable important intracellular measurements of functional potential, such as cytokines, phosphorylation events and transcription factors in single cells. However, expanding the number of targets detected per cell by these methods has limitations in commercial availability of compatible conjugates and the technology's resolving capacity for rare subsets, specifically due to spectral signal overlap and autofluorescence.
Many readouts, including cytokines of the Th2/Treg lineages (IL-5, IL-10 and IL-13), have also been notoriously difficult to reproducibly detect in human cells using fluorescence-based cytometry. We predicted that mass cytometry may overcome such limitations and enable better signal resolution for such applications. We evaluated three small (11-12-plex) panels using a full-spectrum flow cytometer and the CyTOF™ XT mass cytometer to address this. Each panel was comprised of surface and intracellular analytes (cytokines, phospho-epitopes or transcription factors) and designed to minimize potential impact of spectral overlap on the resolution of spectral flow data. PBMC were stimulated, split and stained with either fluorochrome- (Cytek Aurora) or metal-conjugated antibodies (CyTOF). Datasets were analyzed by PhenoGraph clustering and visualized with opt-SNE to determine cellular functional diversity.
Overall, data collected on the CyTOF XT system demonstrated superior resolution for many intracellular readouts, including cytokines IL-10 and IL-13, with stimulation-specific events only detected using CyTOF technology. Additionally, improved signal:noise (S/N) provided better resolution of phospho-activation events and transcription factor expression, particularly TOX and Tbet. Further, better S/N with CyTOF technology enabled more accurate population clustering using PhenoGraph, and more distinct functional signatures resulted from mass cytometry datasets compared with fluorescent counterparts. CyTOF XT mass cytometry platform clarifies understanding a sample's immune signatures in unsupervised analysis. Our findings indicate that the CyTOF XT platform could serve as a catalyst for seminal discoveries in immune profiling to drive therapeutic design and advanced disease monitoring in cancer.

#5756 Quantification of SHetA2 in patient-derived ovarian cancer spheroids to study drug uptake and resistance in a physiologically relevant model.

Annelise Huynh[1], Amit Singh[1], Zongkai Peng[1], Doris M. Benbrook[2], Anthony W. G. Burgett[2], Zhibo Yang[1]

[1]Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK,[2]Department of Obstetrics & Gynecology, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Ovarian cancer presents therapeutic challenges, particularly in advanced stages, where malignant ascites—a buildup of fluid in the abdominal cavity—complicates treatment. Within this ascitic environment, clusters of cancer cells, known as spheroids, form, proliferate, and implant upon various organs, contributing to the metastatic nature of ovarian cancer. As they limit drug penetration and have a hypoxic environment that fosters angiogenesis, spheroids exhibit significant chemoresistance, amplified by the inflammatory and tumor-promoting microenvironment (Peng). Therefore, to reveal the potential mechanisms of chemoresistance in ovarian cancer, directly targeting these spheroids is crucial to develop effective therapies that could help reduce the high mortality rate associated with ovarian cancer. ShetA2 (Sulfur Heteroarotinoid A2) is a novel, promising anticancer drug that exhibits unique potential by inducing apoptosis in cancer cells and disrupting mitochondrial pathways without harming healthy cells (Benbrook). Currently in phase 1 clinical trials, it is vital to understand its efficacy and optimize its therapeutic potential. However, conventional quantification methods for SHetA2 primarily rely on plasma analysis in animal models or human samples, providing only indirect measures and failing to replicate microenvironmental factors in the tumor's 3D structure that inhibit drug access to spheroids (Sharma et al.). Consequently, a direct approach to measure drug concentration in single spheroids is necessary to understand the pharmacodynamics and pharmacokinetics of anticancer drugs (Peng). To address this gap, we developed a highly sensitive nano-flow liquid chromatography-mass spectrometry (nanoLC-MS) method for quantification of SHetA2 in patient-derived spheroids treated ex vivo with cell free-ascites. First, spheroids are washed and lysed. Second, an isotopically labeled compound d4-SHetA2 with known concentration is added to the lysate as the internal standard. Third, a C18 ZipTip is used to clean and desalt the sample to remove competing ions that could reduce detection sensitivity. Lastly, the prepared samples are analyzed using flow ultra-high-performance liquid chromatography (UHPLC) coupled with a high-resolution Thermo Orbitrap mass spectrometer. This integrated approach will provide highly sensitive and accurate quantification of SHetA2 at low concentrations, offering insights into its distribution, penetration, and activity within single patient-derived spheroids. Furthermore, by enabling a more precise and clinically relevant analysis of SHetA2's efficacy in targeting spheroids, this approach will help establish robust criteria for dose selection and scheduling intervals in clinical applications.

#5757 Identification of breast cancer-associated changes to the Rab11 interactome.

Jessica Contreras, Joseph Kainov, Yaneli Betancourt, Oly Khowash, Charlie Yang, Erin N. Howe

Proteomics and Molecular Therapeutics, Rosalind Franklin Univ. of Med. & Science, North Chicago, IL

Breast cancer is the second leading cause of death for American women. Recent advances have improved patient outcomes, but metastatic disease continues to be devastating, and its mechanisms are not fully understood. We made the exciting discovery that Rab11b, a small GTPase that controls endosomal recycling, is required for breast cancer brain metastatic outgrowth, through control of the cell surface proteome. Rab11b interacts with numerous proteins, including GTPase activating proteins (GAPs), guanine exchange factors (GEFs) and motor proteins to facilitate cargo recycling and control the cell surface proteome. We found that Rab11-mediated recycling is dependent on the cellular context, and hypothesize that these changes are driven by dynamic, microenvironment-mediated changes to the Rab11 interactome. To elucidate these changes, we used a proximity labeling approach to identify the Rab11 interacting proteins (the interactome). We used the promiscuous biotin ligase, TurboID, for proteomic analysis of protein-protein interactions. TurboID confers the advantage of detecting highly dynamic changes characteristic of GTPases. To identify the full range of changes to the Rab11 interactome, we are using HEK-293 cells to identify the canonical interactome, immortalized normal breast epithelial cells and triple negative breast cancer cells to identify the breast-specific Rab11 interactome. We have successfully expressed wild-type, dominant negative and constitutively active Rab11a and Rab11b constructs, and shown that they co-localize with endogenous proteins and that biotinylation is indeed spatially restricted. Proteomics studies identified known Rab11 interacting proteins, confirming the reliability of our approach. Importantly, we also identified differences in the canonical and breast cancer-associated Rab11 interactomes, supporting our hypothesis that recycling is context dependent. Current work is focused on validating two such proteins found to be differentially interacting with Rab11 in the different cellular contexts, AnnexinA1 and AnnexinA2. The annexins are phospholipid binding proteins that have a range of functions dependent on cellular location including roles in inflammation and cell trafficking. They've been historically implicated in tumorigenesis, though their functions as tumor suppressors or promoters vary greatly depending on tumor type, subtype, and even stage. Future work will focus on further elucidating the interaction between AnnexinA1/A2 and Rab11 in distinct metastatic microenvironments.

#5758 Identification of MUC13 mediated molecular interactions in pancreatic cancer cells using immunoprecipitation combined with liquid chromatography mass spectrometry analysis.

Anupam Dhasmana, Swati Dhasmana, Rajasekhar Baru, Abigail Gomez, Sheema Khan, Murali M. Yallapu, Subhash Chauhan

Medicine and Oncology ISU, University of Texas Rio Grande Valley, McAllen, TX

Background: MUC13, a recently identified oncoprotein, exhibits aberrant overexpression in pancreatic ductal adenocarcinoma (PDAC) and plays a crucial role in cancer progression. However, the precise molecular interactions mediated by MUC13 that contribute to PDAC progression and metastasis remain incompletely understood. To address this gap, we employed a comprehensive molecular interaction study using an integrated approach combining immunoprecipitation and Liquid Chromatography-Mass Spectrometry (IP-LCMS). This unique study revealed a novel cohort of MUC13-interacting proteins, potentially driving its oncogenic functions in PDAC.
Methodology & Results: Five PDAC cell lines (CaPan2, HPAF-II, HPNE, Panc1, and MiaPaCa) were used for this analysis. Initial LCMS profiling showed high MUC13 expression in HPAFII, moderate levels in CaPan2, and minimal to undetectable expression in Panc1, MiaPaca, and HPNE (normal pancreatic cells). To validate these findings, ELISA, confocal microscopy, and immunoblotting complementary analyses were performed. immunoprecipitation (IP) was performed with MUC13-positive (MUC13+, HPAF-II) and MUC13-negative (MUC13~~-~~, Panc1) cells with our in-house generated unique MUC13 monoclonal antibodies and appropriate IgG control antibodies. The immunoprecipitated proteins were processed for LCMS analysis. This IP-LCMS analysis demonstrated a robust channel signal for MUC13 in positive controls, whereas negative controls yielded minimal or non-significant signals. After normalization across experimental conditions, a total of 54 unique MUC13-interacting proteins were identified. Functional enrichment analysis highlighted the involvement of MUC13 associated interactome with various oncogenesis mechanisms, including central carbon metabolism, PD1/PD-L1 expression and immune checkpoint pathways, adherent junctions, senescence, cell cycle, apoptosis, viral carcinogenesis, diabetic cardiomyopathy etc.
Conclusion: This study established a robust methodology (IP-LCMS) to identify MUC13 interactome, unveiling a cohort of molecular partners potentially mediating MUC13's oncogenic functions in PDAC cells. These findings provide critical insights into MUC13-mediate oncogenic pathways, underscoring its role in cancer progression and therapeutic resistance. This work paves the new way for novel therapeutic strategies targeting precise MUC13-mediated molecular interactions. Key Word: MUC13, Pancreatic Cancer, IP-LCMS, Interactome, Functional Enrichment

#5759 Unraveling the roles of mTORC2 signaling in promoting aggressive glioblastoma characteristics through multi-omics analysis.

Nuttiya Kalpongnukul[1], Rungnapa Bootsri[2], Gea A. Ecoy[2], Tankun Bunlue[2], Napatsakon Youngsanbhu[2], Chatchapon Chuenjit[2], Nuanwan Songcharoen[2], Trairak Pisitkun[1], **Naphat Chantaravisoot**[2]

[1]Research Affairs, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[2]Biochemistry, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

The mechanistic target of rapamycin complex 2 (mTORC2) is a pivotal component of the mTOR signaling pathway, regulating critical cellular processes such as growth, proliferation, differentiation, survival, motility, and metabolism. Notably, mTORC2 facilitates actin cytoskeleton reorganization, cell motility, survival, and DNA damage repair. Aberrations in mTORC2 signaling are strongly associated with aggressive features of cancers, including glioblastoma (GBM), driving metastasis, drug resistance, recurrence, and tumor progression. However, unlike mTORC1, the molecular mechanisms governing mTORC2 functions remain less understood. To address this gap, we employed a comprehensive multi-omics approach—integrating transcriptomics, proteomics, phosphoproteomics, and interactomics—to investigate mTORC2-driven mechanisms underlying GBM aggressiveness. By leveraging computational big data analyses, we aimed to uncover therapeutic targets, identify biomarkers, and explore chemotherapy resistance mechanisms. Our findings reveal that mTORC2 signaling is intricately linked to key GBM hallmarks, including enhanced invasion, metastasis, genome instability, deregulated metabolism, and phenotypic plasticity. Disrupting mTORC2 profoundly altered intracellular regulatory mechanisms controlling these traits. Importantly, our analyses identified key molecular players driving these processes. Furthermore, we demonstrated that ATP-competitive inhibitors of mTOR kinase significantly enhanced the efficacy of temozolomide in GBM spheroid models, offering a promising strategy to overcome chemoresistance. These findings highlight the potential of targeting mTORC2-mediated pathways to develop more effective therapeutic strategies for aggressive cancers.

#5760 Mass spectrometry-based proteomic investigation of patient-derived tumoroids employing fast, high-resolution accurate mass technologycatalyzes precision oncology and drug discovery.

Dominique B. Figueroa[1], Kevin Yen-Yu Yang[1], Colin Paul[2], Pradip Shahi Thakuri[2], Anthony Chatman[2], Brett Larsen[1], Julian Saba[1], Tonya Pekar Hart[1], Amirmansoor Hakimi[1]

[1]Thermo Fisher Scientific, San Jose, CA,[2]Thermo Fisher Scientific, Frederick, MD

The inherent heterogeneity of cancer has spurred significant technological advancements to enhance the detailed study required to characterize this complex disease, predominantly defined by uncontrolled changes. Efforts to address and treat this multi-faceted variability are demonstrated by use of patient-derived tumoroids, which model the conditions and complexities observed in patient tumors using an in vitro cell culture system. Despite the strong correlation between patient response and that observed in matched tumoroid models, tumoroid technology has suffered from a lack of standardization in both culture methods and characterization, hindering widespread clinical translation. This work seeks to present robust and standardized methods for the generation and characterization of tumoroid models. Specifically, our methods aim to reduce variability and labor across workflows and spur the adoption of next-generation tumoroid culture and mass spectrometry methods in discovery and development research. Colorectal, lung, breast, and endometrial tumoroids were derived from donor cancer samples in OncoPro™ Tumoroid Culture Medium, a serum-free, conditioned medium-free system with broad applicability across solid cancer indications. After tumoroid cell pellets were collected, samples were digested using the AccelerOme automated sample preparation platform . Peptides were then loaded onto an IonOpticks Aurora Frontier TS 60×75 column, and separated using Vanquish Neo UHPLC system. Data was acquired on anOrbitrap Astral mass spectrometer in narrow window data-independent acquisition (DIA) mode, and the resulting raw fileswere analyzed with Proteome Discoverer using the CHIMERYS™ intelligent search algorithm or Spectronaut with 1% FDR control at the peptide-spectrum match (PSM) and protein level. Proteins identified in the breast cancer model in our experiments were linked to MAPK, ALK, and ERBB2 signaling pathways, as well as protein and RNA metabolism. The next steps in our experiments involve validating the identified proteins in the breast cancer tumoroid model, and understanding the underlying mechanisms to assess the model's efficacy. Future directions will leverage the unique capabilities of mass spectrometry-based proteomics to investigate post-translational modifications, including phosphorylation and glycosylation, which are crucial in signaling and cancer. By integrating cancer tumoroid models, serum-free media, and the Orbitrap Astral mass spectrometer, we aim to streamline precision oncology and drug discovery by minimizing variability in these dynamic models.

#5761 Unbiased phosphoproteomic and metabolic profiling in WT and KRAS mutant colorectal cancer cells reveals molecular interplay between protein regulation and metabolic rewiring.

Ethan Stancliffe[1], Tom Cohen[1], Ashima Mehta[1], Cassandra Kempf[2], Adam Richardson[1], Monil Gandhi[1], Douglas V. Guzior[1], Kevin Cho[2], Gary J. Patti[2]

[1]Panome Bio, St. Louis, MO,[2]Washington University in St. Louis, St. Louis, MO

Introduction: KRAS mutations cause significant metabolic and protein dysregulation in cancer, leading to alterations in cellular signaling pathways, promoting uncontrolled cell growth and proliferation. The metabolic reprogramming of altered KRAS function includes increased glucose, amino acid, and lipid metabolism. The changes in the cellular proteome stem from modifications in protein expression and phosphorylation. Understanding the interplay between these metabolic and protein-level alterations is crucial for developing targeted therapeutic strategies against KRAS-driven cancers. Accordingly, we performed an integrated metabolomic and phosphoproteomic analysis of HCT116 cells with and without a KRAS mutation.
Experimental: HCT-116 cells containing wildtype (WT, n=5) and mutant KRAS (MUT, n=5) were profiled to assess metabolite, protein, and phosphoprotein levels between WT and MUT cells. Metabolomic profiling was completed with LC/MS to capture polar and lipid metabolites. Data was processed through an in-house untargeted metabolomic analysis pipeline. For phosphoteomic analysis, enriched phosphopeptides and flow-through peptides were analyzed with DIA LC/MS/MS. The resulting data was processed with DIA-NN and combined into aggregated protein and phosphosite profiles.
Results: The multi-omic analysis profiled 2,025 metabolites, 6,654 proteins, and 10,034 phosphosites. When considering each data type individually, all three analyte types seperated the WT and MUT cells through PCA analysis, underscoring the magnitude of dysregulation from KRAS mutation. When considering the metabolites, proteins, and phosphosites that reached statistical significance, 85 metabolites and 145 proteins were differentially abundant. Strikingly, 1,036 phosphosites were unique to either KRAS and WT samples, with ~800 of these being unique to KRAS samples. The results of a joint pathway analysis identified >70 pathways that reached significant enrichment ($p<0.05$) and had support at both the protein, metabolite, and phosphosite level. The most enriched pathway was RAS signaling. Other enriched pathways include selenocysteine synthesis, sialic acid metabolism, ROS detoxification, and respiration.
Conclusions: This study showed extensive differential phosphorylation in KRAS mutant cells, suggesting a widespread rewiring of signaling networks thatimpacts diverse cellular functions. The multi-omic approach taken enabled the identification of previously known and novel pathways affected by KRAS signaling, offering potential new targets for therapeutic intervention in KRAS-driven cancers.

#5762 RPPA kinomic profiling of a tumor eradication phenotype induced by SIAH inhibition, a major tumor vulnerability in the EGFR/HER2/RAS signaling pathway, in late-stage and metastatic human cancer cell lines.

Jonathan M. Baker[1], Andrew Howell[2], Daniel J. McWilliams[1], Ashleigh E. Hannah[1], Julia Wulfkuhle[3], Rosa Gallagher[3], Emanuel Petricoin III[3], Amy H. Tang[1]

[1]Department of Biomedical and Translational Sciences, Old Dominion University, Norfolk, VA,[2]Old Dominion University, Norfolk, VA,[3]Center for Applied Proteomics and Molecular Medicine, George Mason University, Manassas, VA

Introduction: Persistent activation of the EGFR/K-RAS pathway is a major driver of tumor malignancy. Therapies attempting to contravene intertwined RAS effector pathways have yet to achieve durable antitumor efficacy. Seven in absentia homologues ($SIAH_1$ and $SIAH_2$) are RING-domain E3 ubiquitin ligases that function as the most downstream signaling gatekeeper of the EGFR/K-RAS pathway. We showed that SIAH inhibition led to tumor eradication against late-stage human cancer cell lines in xenograft mouse models. We propose that SIAH is a major tumor vulnerability whose complete inhibition impedes EGFR/K-RAS pathway activation driving cancer progression. We aim to elucidate the molecular mechanisms underpinning the curative efficacy of our anti-SIAH strategy.

Methods: Reverse phase protein arrays (RPPA) and principal component analysis (PCA) were used to quantify the changes of 300 proteins/phospho-proteins that were significantly up- or down-regulated in response to SIAH blockade. Independent RPPA assays were performed in triplicate on doxycycline (DOX)-inducible MiaPaCa, MDA-MB-231, MDA-MB-468, HeLa, and A549 cell lines in which our SIAH inhibitor, $SIAH_2^{PD}$, expression was controlled by a Tet-ON/OFF system. Four experimental conditions were used: Tet-ON control cells without DOX (group A) and with DOX induction (group B), Tet-ON-$SIAH_2^{PD}$ cancer cells without DOX (no $SIAH_2^{PD}$ expression in group C) and with DOX induction ($SIAH_2^{PD}$ expression in group D). The ratios of D/C/B/A, D/C, D/B, C/A, and B/A were calculated in a pairwise comparison after normalization to GAPDH. Western immunoblotting (WB), immunofluorescence staining (IF), and flow cytometry of the Tet-ON/OFF cancer cells and protein extracts were analyzed at 3-, 5-, and 7-days (+/-) DOX induction in triplicate to validate the results. $SIAH_2^{PD}$-induced protein expression alterations were normalized to β-Actin or α-Tubulin, and the standardized data were quantified. Statistical analyses were performed by one-way ANOVA using GraphPad Prism software.

Results: We identified the altered expression of NFκB, Caspase-3, Caspase-7, and PARP in response to $SIAH_2$ blockade, with independent confirmation by RPPA, WB, and flow cytometry, supporting their roles as a mechanistic readout of SIAH inhibition in human cancer cells.

Conclusion: RPPA cancer pathway mapping provides molecular insights into cancer network rewiring in response to SIAH blockade. This study supports our innovative strategy to design anti-SIAH-based, anti-EGFR/K-RAS targeted therapies to control and eradicate late-stage and incurable human cancers in the future.

#5763 How cancer drugs work, and fail: proteome-wide cellular thermal shift assay (CETSA) to define cellular mechanism of action and resistance of clinical cancer drugs.

Par Nordlund[1], Sara Loof[1], Anderson Ramos[1], smaranda Bacanu[1], Marc Antoine Gerault[1], Ying Yu Liang[2], Wai Leong TAM[2], Nayana Prabhu[2]

[1]Karolinska Institutet, Stockholm, Sweden,[2]Agency for Science, Technology and Research, Singapore, Singapore

Resistance to cytotoxic cancer drugs is considered a key cause of cancer deaths worldwide. Although extensive understanding of cancer drug mechanisms of action (MoA) and resistance has been derived through focused research, our understanding of these process still remains fragmented.
The Cellular Thermal Shift Assay (CETSA) was originally developed in our lab for accessing drug target engagement in intact cells (Martinez Molina, 2013), and is now widely used for this application in academia and industry. However, CETSA can also detect modulations of cellular biochemistry (Dai, 2018), e.g. effects on downstream-of-target pathways, although this application of CETSA remains relatively unexplored. Using a comprehensive and highly sensitive mass-spectrometry implementation of CETSA, we have studied the cellular biochemistry induced by more than 50 clinical cancer drugs. By applying a systematic approach, including time dependent responses to dissect sequential pathway activation, we can confirm components of previously known MoAs for these drugs but also provide comprehensive new insights into their MoA (Ramos 2024). Moreover, parallel studies in sensitive and resistant cancer cell lines provide differential pathway activation in sensitive and resistant cells (Liang, 2021), giving new insights into how cancer cells acquire drug resistance at the biochemical level. Together our data illustrate that CETSA can yield valuable information on modulation of downstream-of-target biochemistry during cancer drug action, information that is not easily accessed with other omics methods. Proteins discovered in some specific pathways also constitute new candidate drug targets for attenuate resistance responses, as well as potential clinical biomarkers.

#5764 The emerging protective role of silymarin in stress associated hepatocellular carcinoma.

Mohammad S. Hussain[1], Yamile Abuchard Anaya[1], Ricardo Pequeno Bracho[1], Amayrani Sanchez[1], Sophia Leslie[1], Kyle Doxtater[1], Subhash C. Chauhan[1], Tamer Oraby[2], Elias George[3], Manish K. Tripathi[1]

[1]Medicine and Oncology ISU, University of Texas Rio Grande Valley, McAllen, TX,[2]School of Mathematical and Statistical Sciences, University of Texas Rio Grande Valley, Edinburg, TX,[3]Clinical Support Services, University of Texas Rio Grande Valley, Edinburg, TX

Background: Texas is projected to have the second-highest liver cancer-related deaths in the nation, with Hispanic populations experiencing the highest mortality rates. In the South Texas Rio Grande Valley (RGV), where ~90% of the population is Latino/Hispanic, socioeconomic disparities, poverty, obesity, diabetes, and low-income levels contribute to heightened stress prevalence. Stress accelerates cancer progression by impairing immune responses, inducing inflammation, and activating the hypothalamic-pituitary-adrenal (HPA) axis, releasing cortisol and leptin, key drivers of oncogenesis. Silymarin, a polyphenolic antioxidant from milk thistle seeds, is a known hepatoprotective agent with benefits in stress-related hypertension, atherosclerosis, and cardiotoxicity. However, its role in stress-induced HCC remains unexplored. This study investigates silymarin's effects on stress-induced proteins in HCC.
Methods: HCC cell lines were treated with cortisol and leptin to simulate acute and chronic stress conditions. Gene expression was analyzed via reverse transcription-polymerase chain reaction (RT-PCR), and overexpression models were established using lentiviral vectors. Proteins and pathways associated with stress were identified through liquid chromatography-mass spectrometry (LC-MS). Identified genes were validated via RT-PCR and western blot analysis in stress-treated and silymarin-treated cells.
Results: LC-MS analysis identified over 3000 proteins, with 6.3% categorized as stress-response proteins. Eleven key stress-associated proteins, including IPO7, SCFD1, TIPRL, SCL25, SERPINB6, TRMT2, and HSP90B1, were validated in leptin- and cortisol-treated SK-Hep1 cells and Malat1 overexpression cell lines. The Cancer Genome Atlas (TCGA) database analysis confirmed these findings in HCC patient cohorts. Notably, silymarin significantly reduced stress-response gene expression in treated SK-Hep1 cells while sparing untreated parental cells. Further pathway analyses and validation in knockdown models are ongoing to elucidate mechanisms underlying these effects.
Conclusion: Silymarin effectively downregulated cortisol- and leptin-induced stress-response proteins in SK-Hep1 cells, highlighting its therapeutic potential in stress-associated HCC. These findings underscore silymarin's role in targeting novel molecular pathways, offering promising strategies to address HCC disparities in underserved populations in the RGV. This research aims to improve outcomes and reduce mortality among high-risk groups, addressing a critical healthcare challenge in Texas.

#5765 Illuminating the kinase activity starmap in NSCLC via tyrosine phosphoproteomics.

N. Zheng[1], Y. Liu[1], J. Yuan[2], Y. Hu[3], Y. Wang[2], T. Zhang[4], A. Yu[1], H. Zhou[1], C. Zhou[1], J. Hou[1], Y. Xu[1], X. Xu[5], H. Ding[1], Y. Zhang[1], R. Zhong[2], M. Yang[2], C. Chang,[2], H. Yan[2], Y. Shang[2], W. Ren[2], S. Li[2], H. Zhong[1], Y. Xiao[1], Z. Zhang[5], M. Han[4], Y. Pang[2];

[1]DeepKinase, Chaoyang, Beijing, China, [2]Department of Bacteriology and Immunology, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China, [3]Department of Medical Oncology, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China, [4]Department of Thoracic Surgery, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China, [5]Jinan University, Guangzhou, China

In lung cancer treatment, understanding kinase activity, particularly tyrosine phosphorylation, is crucial but incomplete. We studied tyrosine phosphoproteomics in 74 patients with non-small-cell lung cancer (NSCLC) using SH2-Superbinder and data-independent acquisition mass spectrometry. We identified 1,048 tyrosine phosphosites, the highest number reported in lung cancer research. We constructed a tyrosine phosphorylation starmap, enabling a novel and intuitive analysis of tumors versus normal adjacent tissues, revealing kinases driving tumor progression and metastasis. Subsequently, patients were stratified by kinase activity for multiple precision medicine perspectives. “Cold” and “hot” tumors were divided based on immune kinase activity, while cancer driver kinase profiling revealed vulnerability to BRD4 inhibitors in wild-type lung cancer cells. EGFR-L858R mutations benefited from combining MEK and EGFR inhibitors. Two distinct kinase activity panels predicted patient survival across different mutation backgrounds. Our findings underscore the diverse kinase activities in NSCLC and highlight the need for personalized therapy based on these profiles.

#5767 Multiplex in situ proximity ligation assay for functional studies of proteins and their interactions in patient samples.

Hampus Elofsson, Desiree Eden, **Olof Hahne**, Linda Arngarden, Frida Tallqvist, Carl-Magnus Clausson, Axel Klaesson, Annica Onell, Sara Bodbin, Caroline Gallant, Agata Zieba Wicher

Navinci Diagnostics AB, Uppsala, Sweden

Detecting protein-protein interactions (PPIs) and their localization is essential for the understanding of protein function and enables deep-diving into processes such as signal transduction, synaptic signaling, regulation of gene expression in cancer, identification of diagnostic markers, patient stratification and more. *In situ* proximity ligation assay (isPLA) is a well-established tool for the study of PPIs in cell and tissue samples. It detects proteins located within 40 nm of each other via antibodies conjugated to oligonucleotides that generate amplified fluorescent or chromogenic signal. The method can be automated and/or combined with multiplexed immunofluorescence (mIF) staining of individual proteins to visualize tissue context e.g., the tumor microenvironment or the immune landscape. However, current isPLA technology has been limited to the detection of a single PPI at a time. We hereby present a new multiplexed mix-and-match approach to isPLA, which overcomes this limitation. We developed a 9-plex assay based on the Naveni® technological solution, suitable for the simultaneous detection of up to nine PPIs or single proteins (here collectively referred to as markers) of the user's choice. Every marker is detected by two directly conjugated primary antibodies (Navenibodies) that participate in the isPLA reaction provided the proximity criterion is fulfilled, leading to specific and strong signal. Additional cycles incorporating other technologies such as mIF or HCR-FISH are also compatible with the method. For isPLA markers, users can choose from a set list of possibilities, including various signal transduction networks such as the RAS/MAPK pathway, the PD1/PD-L1 and PD1/PD-L2 receptor-ligand interactions, various B- and T-cell markers, cell adhesion proteins and more. Thanks to this flexible approach, it was possible to create a tailored 9-plex study, investigating interactions involving and downstream of PD1, as well as activation of nodes in the RAS/MAPK pathway. ERK activation downstream of KRAS mutations has been shown to increase PD-L1 expression in several cancers (e.g., lung and colorectal cancer), which in turn helps tumor cells evade immune detection by binding to PD1 on T-cells, inhibiting T-cell activity and promoting immune tolerance to the tumor. Our data could help indicate which patients would be the best candidates for immune checkpoint or MAPK inhibition therapy. In summary, our multiplex isPLA approach is a sensitive and specific method that visualizes low and high abundant targets in tissues and adds value by uncovering protein interplay in complex signaling networks with implications in translational research.

#5768 Identifying signaling changes that give rise to drug resistance in acute myeloid leukemia through multiomic modeling across diverse model systems.

Juan Camilo Posso[1], Setareh Sharzehi[2], Marina A. Gritsenko[1], McKenna Finley[2], Chelsea M. Hutchinson-Bunch[1], Keith Beadle[2], Karl K. Weitz[1], Melissa Stewart[2], Samantha A. Obermiller[1], Belinda B. Garana[1], Anupriya Agarwal[2], Cristina Tognon[2], Jeffrey Tyner[2], Paul D. Piehowski[1], Elie Traer[2], **Sara J. C. Gosline**[1]

[1]Pacific Northwest National Laboratory, Seattle, WA,[2]Oregon Health and Sciences University, Portland, OR

Acute myeloid leukemia (AML) is a blood cancer that affects ~20,000 people annually, with an overall 5-year survival rate of ~30%. Leukemia cells originate in the bone marrow where normal cell differentiation goes awry, leading to the expansion of immature myeloid cells that retain partial differentiation, or cell state (monocytic, granulocytic, primitive, etc. [Van Galen et al, *Cell* 2019]). However, the mechanism by which cell state shifts cooperate with protein signaling changes to bring about secondary mutations is still unknown. In this work we generated AML cell lines resistant to venetoclax (BCL2 inhibitor), decitabine (hypomethylating agent) and gilteritinib (FLT3 inhibitor) as single agents and in combination and found changes in cell state, protein signaling, and mutational burden. To interrogate the mechanisms behind these changes, we treated four primary AML cells with these drugs (alone and in combination) and captured transcriptomic and proteomic measurements of persistent AML patient cells after 1 month of treatment to compare drug-induced shifts in cell state.

We collected single-cell transcriptomic and global proteomic measurements across two models of venetoclax, gilteritinib, and decitabine resistance: (1) MOLM14 cells treated for up to 6 months with each drug/drug combination, and (2) 4 *ex vivo* patient primary AML cells treated with monotherapy and drug combination for 1 month. In each model system, we measured shifts in cell populations using single cell-derived signatures of cell state based on the transcriptomic data, then calculated differential expression and pathway enrichment statistics of drug resistance models compared to their untreated control using the proteomic data.

In our model of short-term drug resistance, transcriptomic data indicated that leukemia cells acquired a more granulocytic phenotype upon treatment with gilteritinib, became more monocytic with venetoclax treatment, and remained unchanged with decitabine treatment. These shifts occurred with little change in protein abundance (<40 proteins differentially expressed) according to our proteomics measurements of the same samples. Venetoclax combined with decitabine also caused cells to become more monocytic, while combining venetoclax with gilteritinib caused a decrease in monocytic cells as well a noticeable shift (100-500 proteins) in protein expression. Long term drug exposure caused further changes in MOLM14 cells, with many drug-resistant cells becoming more monocytic and exhibiting dramatic changes to protein signaling with up to ~2000 proteins differentially expressed. We are now using these omics measurements to identify putative drug targets that prevent the development of drug resistance. In conclusion, we found that drug-induced protein changes can alter leukemia cell phenotypes that influence mutations and resistance in AML.

#5769 Silibinin profiles the immune microenvironment via mast cell regulation: Potential immunomodulation in cancer prevention and therapy.

N. Mishra, S. Paudel, C. Agarwal, R. Agarwal;
University of Colorado Anschutz Medical Campus, Aurora, CO

Immune cells are critical check points, not only for foreign pathogens, but also for proper growth and proliferation of bodies' own cells. They play crucial and complex roles in cancer, beginning at initiation of malignancy, proliferation of tumors, establishment of the cancer microenvironment, to metastasis and spread of malignant cells throughout the body. In our ongoing studies with silibinin (SB; flavonolignan obtained from milk thistle seeds), we showed that it is an effective preventive natural agent for several cancers including, basal cell carcinoma, prostrate cancer, colon cancer, and hepatocellular carcinoma. SB was also shown to regulate immune responses in several of these studies. Notably, SB treatment was found to significantly regulate mast cell (MC) infiltration and functioning in our completed and ongoing studies. However, since MCs are associated with the functions of other immune cells, it is also important to delve deeply into the downstream effects of SB treatment on other immune components regulated directly and/or indirectly by MCs. Thus, in the present study, in-depth mechanistic aspects of SB treatment on other cells of the tumor immunological microenvironment were determined, leveraging SB regulation of MCs. MCs were derived from bone marrow (BMMCs) of C57BL/6 mice in presence of IL-3 and SCF and confirmed using flow cytometry (dual staining: cKit/Fc€RI). Thereafter, BMMCs were exposed to 25-100 µM SB and two concentrations (25 µM; SB 25 and 100 µM; SB 100) were selected for further experiments. BMMCs treated with SB 25, SB 100, and vehicle control were subjected to proteomics (LCMS on Fusion Lumos mass spectrometer); 3575 proteins were identified using the annotated mouse proteome. Statistical analysis was performed using ANOVA followed by Fisher's posthoc analysis ($p<0.05$, FDR<0.01) and 166 proteins were found to have statistically significant differential expression amongst the three groups (n=4/group). These 166 proteins were selected for further pathway analysis using Ingenuity Pathway Analysis (IPA; Qiagen). Stringent IPA filter settings were used to select pathways specifically *"demonstrated experimentally"* in *"immune cells/cell lines"* for further analysis. Top canonical pathways associated with SB treatment of immune cell regulation via MCs were found to be eukaryotic RNA processing (processing of capped intro-containing pre-mRNA), ISG15 mediated immune responses (ISG15 antiviral mechanism), eukaryotic-translation elongation, and RHO GTPase pathway. Important nodes determined were TNF, CD-28, IL-2, IL-4, IL-15, NR4A1, IFNB, and RAC2, suggesting SB plays an important immunomodulatory role via regulation of MCs. Further studies are warranted to delineate these mechanisms in cancers as well as other injury mechanisms and SB' therapeutic potential (supported by R01 CA140368).

#5770 Single-cell Raman-based omics of the melanoma tumor-immune microenvironment for precision therapy.

Kai Chang[1], Mamatha Serasanambati[2], Baba Ogunlade[1], Ariel Stiber[1], Fareeha Safir[3], Hamish Carr Delgado[1], Amanda Kirane[2], Jennifer Dionne[1]

[1]Stanford University, Stanford, CA,[2]Stanford University School of Medicine, Stanford, CA,[3]Pumpkinseed Technologies, Inc., Palo Alto, CA

Immunotherapy and targeted therapy have altered the standard of care for cancer patients, improving survival rates and cancer control, even in intransigent metastasis. Yet, only 20-40% of patients respond to immunotherapy, and up to 50% experience severe adverse events, limiting therapy application. Notably, cellular heterogeneity and diversity in the makeup of the tumor immune microenvironment (TiME) present extraordinary challenges in finding predictive biomarkers correlating to therapeutic response. Existing profiling methods, even with highly resolved, cutting-edge transcriptomic and proteomic mapping methods remain costly, time-intensive, and do not faithfully capture structural or post-translational modifications actively impacting tumor behavior. Here, we present a high-fidelity, single-cell omics approach based on Raman spectroscopy and machine learning to provide rapid, cellular profiling that enables non-destructive therapeutic response characterization.

Using Raman, we first demonstrate single-cell differentiation and functional state phenotyping of various melanoma and immune cells found in the TiME. Our ML models yield a classification accuracy of >94% across all cell types and parent and derivative cancer lines. We then extend our characterization to track temporal changes across multicellular systems; by investigating cell growth in normal and apoptotic-inducing environments, we show how melanoma-immune cell interactions preserve certain spectral features while introducing new features via cell fusioning under selective pressures. By stimulating cells with small molecule therapeutics serving as growth and inhibiting factors, we demonstrate the potential to monitor melanoma cell plasticity and macrophage polarization changes. Finally, we illustrate the potency of Raman phenotyping by examining the collective drug response in clinically relevant patient melanoma samples and extract pertinent biomarkers associated with small molecule and immunotherapy treatment outcomes. In combination with neural networks, our approach correctly predicts therapy response with >75% accuracy for unseen melanoma patient samples, demonstrating Raman as a powerful rapid, label-free omics approach with groundbreaking potential to advance clinical biomarker efforts and impact the precision treatment decisions of cancer patients.

CLINICAL RESEARCH: Functional and Molecular Imaging and Radiomics
Poster Session

#5774 Enhancing urothelial carcinoma treatment with nectin-4-PET: A predictor of enfortumab vedotin efficacy.

Akhilesh Mishra, Ajay K. Sharma, Kuldeep Gupta, Burles A. Johnson, Jeannie Hoffman-Censits, David J. McConkey, Sridhar Nimmagadda

Johns Hopkins University, Baltimore, MD

Introduction: Enfortumab vedotin (EV), an antibody-drug conjugate targeting nectin-4, has shown significant promise in treating urothelial carcinoma (UC). However, optimizing its efficacy while minimizing treatment-related toxicities necessitates a deeper understanding of EV's target engagement at tumors and its correlation with therapeutic outcomes. To address this, we developed a peptide-based nectin-4 specific positron emission tomography (PET) radiotracer, [^{68}Ga]AJ647, to visualize and quantify EV-induced pharmacodynamics (target engagement) across different EV doses.

Methods: Six UC cell lines representing luminal (HT-1376, UC-14, RT-112) and basal (UC-9, SCaBER, T24) morphologies were used to evaluate in vitro and in vivo nectin-4 specificity of [^{68}Ga]AJ647. Effect of EV on [^{68}Ga]AJ647 uptake was evaluated using competitive binding studies. Target engagement was defined as the percentage reduction in [^{68}Ga]AJ647 tumor uptake, pre-therapy normalized, following EV therapy. In vivo EV target engagement was assessed via PET in HT-1376 xenografts at FDA-equivalent doses (6, 9, 15 mg/kg) on days 1, 3, and 6 post-treatment. Long-term responses to 6 and 15 mg/kg with Nectin-4-PET evaluated target engagement metrics' predictive value.

Results: In vitro assays revealed a strong correlation between [^{68}Ga]AJ647 uptake and nectin-4 expression (R^2=0.85). PET and biodistribution studies confirmed nectin-4-specific uptake across xenografts at 60 minutes post-injection. EV treatment reduced [^{68}Ga]AJ647 uptake in a dose-dependent manner, validating the tracer's ability to measure unoccupied nectin-4. At 24 hours post-treatment, unoccupied nectin-4 levels were similar between 15, 9, and 6 mg/kg groups at approximately 23%. By day 6, these levels diverged significantly, indicating reduced target engagement over time, particularly at lower doses. Further analyses revealed that tumor volume reductions exhibited dose-dependent trends but showed high variability. While pre- and post-treatment [^{68}Ga]AJ647 imaging measures (standard uptake values) were not strongly predictive of therapeutic outcomes, the normalized ΔSUV, reflecting EV-induced target engagement, demonstrated a stronger correlation (r=-0.7877). Mice with less than 25% target engagement showed significantly poorer therapeutic responses, regardless of injected dose. ROC analysis confirmed the predictive power of normalized ΔSUV, with an AUC of 0.87 and a 25% engagement threshold as a robust predictor of positive therapeutic outcomes.

Conclusion: [^{68}Ga]AJ647-PET provides a non-invasive quantitative approach to assessing nectin-4 expression and EV-induced pharmacodynamics. Normalized ΔSUV values, which integrate pre- and post-treatment data, serve as reliable predictors of therapeutic efficacy. These findings highlight the potential of nectin-4 PET to optimize personalized EV dosing.

#5775 Direct prediction of tumor cellular phenotypic composition from multi-parametric MRI in neuroblastoma murine models.

Konstantinos Zormpas-Petridis[1], Matthew Blackledge[2], Louis Chesler[2], Yinyin Yuan[3], Simon P. Robinson[2], **Yann Jamin**[2]

[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy,[2]Institute of Cancer Research, London, United Kingdom,[3]MD Anderson Cancer Center, Houston, TX

Introduction. The clinical prognosis for children with high-risk neuroblastoma, a cancer of the sympathetic nervous system, remains poor. Non-invasive imaging biomarkers of treatment response are essential for precision medicine. Here, we evaluated a supervised machine learning model trained on co-registered MRI-histology maps to predict density maps of key neuroblastoma cell populations (undifferentiated, differentiating, apoptotic) directly from multi-parametric mpMRI in murine models of neuroblastoma.

Methods. Tumour MRI parametric maps for spin-lattice relaxation time (T_1, sensitive to undifferentiated cells), transverse relaxation rate (R_2*, sensitive to red blood cells), and apparent diffusion coefficient (ADC, sensitive to cell density) were co-registered with digitized H&E slides (20x, 0.46µm resolution) from 11 Th-MYCN mice. Automated cell segmentation/classification into 6 categories allowed for the generation of density maps at MRI resolution.

Classical ML models were trained to simultaneously predict 5 histological labels using a supervised regression approach on 9095 MRI voxels (n=4 mice), each represented by 5 normalized input features: R_2*, T_1, and ADC, along with median values of the pixels' square neighbourhood (2px wide). Model performance was evaluated using 10-fold cross-validation and the negative mean-squared-error metric before application to remaining tumours.

Results/Discussion. The random forest classifier achieved the lowest mean-squared-error and smallest variation during the 10-fold cross-validation and was selected as the best model. Extra trees, XGBoost and light-gradient-boosting machines also performed well.

The similarity of the entire MRI-generated maps (for all 11 mice in the dataset) was compared to the histology maps using the mean squared error (MSE) and structural similarity index (SSIM) metrics. The model achieved an average MSE of 0.0037, 0.0089, 0.0016, 0.0014, and 0.0008 for cellular density, undifferentiated neuroblasts, apoptotic neuroblasts, differentiating neuroblasts and red blood cells density respectively. The SSIM indexes were 0.90, 0.88, 0.90, 0.88 and 0.92 for cellular density, undifferentiated neuroblasts', apoptotic neuroblasts', differentiating neuroblasts' and red blood cells density respectively.

Conclusion. This proof-of-concept study demonstrates that mpMRI can characterize neuroblastoma phenotypes and generate quantitative data previously accessible only through digital histology analysis, including cellular density maps. Validation in more diverse datasets could enable "non-invasive" or "virtual" biopsies, capturing entire tumour volume to enhance diagnostic precision, guide surgical planning, and refine response assessment.

#5776 Integrative analysis of regional MRI phenotypes in high-grade glioma: Dimensional reduction of multi-omics imaging and molecular profiles.

Matthew W. Kenaston[1], Matthew Flick[1], Kasthuri Kannan[2], Michele Ceccarelli[3], Nhan Tran[4], Leland S. Hu[5]

[1]Mayo Clinic Alix School of Medicine, Phoenix, AZ,[2]Departments of Translational Molecular Pathology and Neurosurgery, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Public Health Sciences Research, Miller School of Medicine, University of Miami, Miami, FL,[4]Cancer Biology, Department of Research, Mayo Clinic, Phoenix, AZ,[5]Comprehensive Cancer Center, Radiology, Mayo Clinic, Phoenix, AZ

Introduction: High-grade gliomas (HGG) are aggressive brain tumors with heterogeneous cell populations, including invasive regions driving disease progression and recurrence. Our previous work integrated molecular profiling with spatially matched advanced multiparametric MRI in a cohort of HGG patients with multi-regional sampling, uncovering distinct biological signatures linked to individual advanced MRI phenotypes. Yet, the relationships between MRI phenotypes—and how this potentially informs underlying biology—remains unexplored. Here, we leverage an unsupervised approach to dimensional reduction for a broad array of MRI features and compare regional transcriptomic signatures in a cohort of image-localized HGG samples.
Methods: From our existing data, we selected 20 HGG patients with 73 multi-regional tumor biopsies, each including 18 advanced MRI parameter calculations. With an iterative approach, data was projected using uniform manifold approximation (UMAP) at multiple resolutions and clustered, producing high-confidence stable clusters. We used random forest modeling to assess cluster associations with previously identified signatures. Cluster-specific transcriptomic profiles were detected by DESeq2 and subsequent gene-set enrichment analysis. We further evaluated Pearson correlations and statistical fit with MRI image parameters by performing pathway analysis on genes with significant correlations by image feature, across clusters.
Results: 8 clusters emerged from our analyses. Most advanced MRI features exhibited statistically significant differences across clusters, forming unique patterns of feature behavior. Notably, while these image-based clusters did not correlate well with metabolic profiles, contrast enhancement, or genomics, they did demonstrate distinct and HGG-relevant transcriptomic profiles, with shared and divergent signatures. Across clusters, we also identified several correlations between specific MRI parameters and gene pathway trends. These highlighted combined patterns of multiple MRI features, offering a spectrum of regional phenotypes imperceptible with single feature analysis. We generalize these results to an image-based decision matrix to detect biologic signatures for validation.
Conclusion: Our integrative analysis of MRI mapping stratifies imaged-based patterns to non-invasively assess molecular signatures within HGG. This approach will help elucidate MRI biomarkers that may predict glioma behavior and support future individualized treatment approaches.

#5777 A guidance platform for nanoparticle mediated photothermal therapy for solid tumors.

Ivan Kosik[1], Robert Weersink[2], Margarete Akens[3], Fumi Yokote[4], Sangeet Ghai[1], Gang Zheng[5], Brian Wilson[3]

[1]Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada,[2]Institute of Biomaterials and Biomedical Engineering, Radiation Oncology, University of Toronto, Toronto, ON, Canada,[3]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[4]Division of Thoracic Surgery, Toronto General Hospital, Toronto, ON, Canada,[5]Princess Margaret Cancer Center, University of Toronto, Toronto, ON, Canada

Introduction Nanoparticle-mediated Photothermal therapy (PTT) is an option for treating solid tumors with low cost and toxicity. Except for a limited set of cancers, PTT in general has not seen widespread clinical adoption, due in part to lack of effective treatment guidance technology. Recent clinical trials here and elsewhere investigating MRI-guided PTT have highlighted 3 critical requirements, including visualization of (1) tumor nanoparticle uptake, (2) temperature distribution during PTT and (3) treatment effect. These trials also highlighted shortcomings of MRI guidance, including high cost and limited access, complexity, speed and indirect functionality, so there is a need for novel direct, real-time PTT-guidance technology. Methods and Results We have designed and constructed a PTT-guidance platform based on hand-held multispectral photoacoustic (PA) tomography enabled by an in-house built frequency-optimized acoustic sensor array designed specifically to capture volumetric PA signals at depths of up to several cm. This is able to quantitatively image bulk-tissue endogenous and exogeneous contrast, including nanoparticle distribution in tumor (Requirement #1). In addition, this platform provides highly sensitive deep-tissue temperature mapping through the temperature dependence of the tissue Gruneisen parameter, matching or exceeding MRI-based thermometry but with direct, real-time precision in an ergonomic hand-held configuration (Requirement #2). Integration of a custom-built diffuse optical tomography (DOT) module into the PAI platform provides measures of the time-dependent tissue optical properties during PTT, particularly scattering that is known to increase 2 to 3-fold with coagulation above ~55°C. Thereby, it provides immediate feedback on the size and location of the photocoagulated lesion (Requirement #3). Results of in vivo and pre-clinical validation studies are presented, showing nanoparticle injection and distribution in tissues, PA thermal mapping and DOT-based proof-of-principle monitoring of PTT treatments in patients with localized prostate cancer. Conclusions These studies indicate that we can provide the three needed functionalities for PTT guidance and that, for the first time, this can be done on a spatial scale relevant to clinical translation. This work is supported by the Terry Fox Research Institute and the Canadian Cancer Society.

#5778 Intra-operative visualization of metastatic sentinel lymph nodes in early breast cancer: An approach to omission of axillary surgery.

Yuanyuan Zhu[1], Wei-Ling Chen[1], Zao Wu[1], Jun-hong Chen[1], Ting-wen Guo[1], **Guo-Jun Zhang**[2]

[1]Xiamen University, Fujian, China,[2]The Breast Center, Yunnan Cancer Hospital, The Third Affiliated Hospital of Kunming Medical Universi, Beijing University Cancer Hospital, Fujian, China

Purpose: Sentinel lymph node biopsy (SLNB) has become the established approach, and is the standard of care for staging clinically node-negative breast cancer. The pathological examination is the golden standard during this procedure. However, its sensitivity is less than 80%, and requires significant time, manpower, and material resources. Noteworthy, the fluorescent imaging in the second near-infrared region (NIR-II) window offers greater tissue penetration and contrast compared to conventional imaging, which is more suitable for detecting the metastatic status of SLN in real-time and dynamically *in vivo.* In this study, we developed a new technology that can quickly identify the metastatic status of SLN both *in vivo* and the resected SLN tissue during the operation.

Methods: 1. Characterization and biosafety of the probe ICG-POL6326 were performed. 2. The targeting efficacy of probe was confirmed through in vitro fluorescence co-localization experiments and *in vivo* fluorescence imaging in tumor-bearing and SLN metastatic mouse model. 3. SLN from mice with lymphatic metastasis were excised and incubated with ICG-POL6326 for subsequent imaging by a NIR-II system to evaluate the efficacy of ex vivo incubation and imaging methods. 4. Ten surgically removed SLN tissues from ten breast cancer patients undergoing resection were incubated with the probe immediately and imaged to identify the metastatic status of SLN. The accuracy of fluorescence imaging was confirmed by pathological diagnosis.

Results: 1. ICG-POL6326 was successfully synthesized with good stability, biocompatibility with high intensity of NIR-II fluorescent imaging. 2. ICG-POL6326 could specifically target 4T1-Luc and MDA-MB-231-Luc cell which with high CXCR4 expression compared with ICG-NHS. 3.ICG-POL6326 group exhibited a 3.15-fold higher maximum signal-to-background ratio (SBR) compared to the ICG-NHS group ($p < 0.0001$) in 4T1-Luc subcutaneous tumor models. 4. ICG-POL6326 was able to detected the metastatic status of SLN in 4T1-Luc SLN metastasis models. the SBR of metastasis SLN was 4.1-fold higher than normal SLN ($p < 0.001$). In addition, via co-incubation of ICG-POL6326, the metastatic SLN exhibited a higher MFI relative to normal SLN with a TNR more than 5 (tumor to normal ratio) ($p < 0.0001$). 5. This new technology yielded more than 90.31% specificity and 100% sensitivity in identifying the metastatic SLN.

Summary: ICG-POL6326 can dynamically evaluate the status of SLN in real-time, with a positive correlation between fluorescence signal and lymph node metastasis. By using ICG-POL6326 to incubate freshly isolated SLN during surgery, the probes can quickly accumulate in SLN invaded by breast cancer cells and identify the metastatic status of SLN. This technology is expected to be used for rapid intraoperative pathological detection and identification of metastatic SLN.

#5779 A comparison of CT/RNASeq and MRI/RNASeq-based radiogenomics for staging muscle-invasive bladder cancer: a pilot study.

Joshua Levy[1], Toru Sakatani[2], Kaoru Murakami[2], Takashi Kobayashi[2], Charles J. Rosser[1], **Hideki Furuya**[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Urology, Kyoto University, Kyoto, Japan

Introduction: Accurate staging of bladder cancer (BCa) assists in identifying optimal treatment (e.g., transurethral resection vs. radical cystectomy vs. bladder preservation). Current clinical tumor staging methods for BCa leverages axial computed tomography (CT) scans due to its speed and cost-effectiveness. Prior research has demonstrated staging uncertainty with CT, leading to under- or over-staging of patients. Improving staging accuracy is crucial for treatment decisions. Recent work has suggested that MRI can better emphasize contrast between abnormal structures and thereby improve stratification, while genomics signatures can identify molecular changes underpinning tumor spread (e.g., collagen remodeling). Thus, we hypothesize that magnetic resonance imaging (MRI)/RNASeq-based radiogenomics can more accurately stage BCa.

Method: A total of 31 matched CT scans, MRI and formalin-fixed paraffin-embedded (FFPE) tissues were collected and made available for analysis. CT and MR images were reviewed by at least two radiologists to generate a consensus BCa T-stage. Next, RNASeq gene expression was profiled from TURBT FFPE tissue using the nf-rnaseq workflow to generate count matrices from the reads. PyRadiomics was used to extract MR/CT features. A radiogenomic analysis was conducted to identify imaging signatures of advanced T-stage through integration of MR/CT imaging and RNASeq data, using Bayesian LASSO for feature selection followed by unpenalized regression modeling, adjusted for age and sex. The performance of image-only and radiogenomic signatures were compared between MR/CT through likelihood ratio testing (LRT).

Results: CT and MRI resulted in the same accuracy of staging pT2 or less. Interestingly, the accuracy of staging >pT2 is better in MR than CT scan, suggesting that MR resolution is superior to CT allowing more accurate staging. CT radiogenomic signatures (p=5.9e-4) stratified patients more effectively than the MR radiogenomics (p=2.9e-3) though changes appeared to be driven by genomic features more than imaging features. In reviewing hierarchical clustering of the radiogenomic features (Fig. 1), we found that MR imaging influenced clustering of the signature more than in CT data, speculating that the MR data delivers more useful information other than tumor stage (e.g. predicting survival and treatment response in addition to stage).

Conclusion: These early findings from the pilot study suggest promising results. The limited sample size restricts our ability to draw definitive conclusions or apply more sophisticated machine learning methods, such as the investigation of how genes may further stratify radiomic features by disease progression and vice versa.

#5780 Prognostic implications of prostatic gonadotropin releasing hormone receptor and androgen receptor expression in non-metastatic prostate adenocarcinoma.

Donghyun Kim

University of Iowa, Iowa City, IA

Background: Suppression of pituitary gonadotropin releasing hormone receptor (GnRHR) is the mainstay systemic therapy for prostate cancer. GnRHR is also expressed in the prostate and its correlation with direct anti-tumorigenic effects have been demonstrated. The inhibition of prostatic androgen receptor (AR) signaling is another potent therapeutic option. Despite their crucial role in prostate cancer proliferation, prognostic implications of prostatic *GNRHR* and *AR* expressions remain uncertain. To investigate the prognostic utility of *GNRHR* and *AR* expressions, a public prostate cancer transcriptomic profile and progression-free survival (PFS) data were reviewed.

Methods: The Cancer Genome Atlas (TCGA) Pan-Cancer project batch-corrected treatment-naïve primary tumor mRNA expression profiles (RNA Seq V2 RSEM) of 324 non-metastatic (M0) prostate adenocarcinoma cases and their associated clinical data were retrieved from the *cBioPortal*. Log-rank Kaplan-Meier was used for survival analysis. The “low” vs. “high” expression cutoffs for *GNRHR* and *AR* were defined as the cohort’s lower 30th and 25th percentiles, respectively.

Results: Prostatic *GNRHR* and *AR* mRNA expressions were heterogeneous, but apart from low *AR* expression in Gleason grade group (GGG) 1, levels were similar across age, anatomical T N stage or all other GGGs. For T2b-4 N0 disease, neither *GNRHR* nor *AR* expression alone was significantly associated with PFS. However, in a subgroup of patients with T2b-3a N0 disease with high *GNRHR*, those with concomitant low *AR* (n=21) were associated with superior 4-year PFS compared to high *AR* (n=119) with hazard ratio (HR) 0.28 (95% CI 0.080-0.976, p=0.046). The composition of GGG was similar between these groups. *GNRHR* or *AR* expression-dependent differential PFS was not observed in patients with T3b-4 N0 disease. For N1 disease, high *GNRHR* (n=38) was associated with superior 4-year PFS compared to low *GNRHR* (n=25) with HR 0.32 (95% CI 0.12-0.85, p=0.007), independent from *AR* expression levels.

Conclusions: High *GNRHR* and low *AR* expression were associated with superior PFS in an anatomical stage-dependent manner. The superior PFS of low *AR* was more pronounced for localized T2b-3a N0 disease, while high *GNRHR* was most pronounced in regional node-positive N1 disease. Prostatic *GNRHR* and *AR* mRNA expression levels may allow tailored strategies in utilizing GnRH agonist/antagonist and AR signaling inhibitors in treating non-metastatic castrate-sensitive disease. Further investigation is warranted.

#5781 Comparing prognostic association of manual vs. artificial intelligence derived quantifications from baseline computed tomography scans in MYSTIC, a global phase 3 trial for treatment of metastatic non-small cell lung cancer.

Harish RaviPrakash[1], Qin Li[2], Kedar Patwardhan[1], John Riskas[3], Shahid Haider[3], Oleksandra Samodorova[3], Jay Hennessy[3], Vignesh Sivan[3], Felix Baldauf-Lenschen[3], Omar Khan[4]

[1]Oncology Data Science, AstraZeneca US, Waltham, MA,[2]Cancer Biomarker Discovery, AstraZeneca US, Waltham, MA,[3]Altis Labs, Inc., Toronto, ON, Canada,[4]Department of Oncology, University of Calgary, Calgary, AB, Canada

Background: Sum of longest diameters (SLD) of target lesions per response evaluation criteria in solid tumors (RECIST) 1.1 is the standard measure of baseline (BL) disease burden, which plays an important prognostic role. Fully automated, artificial intelligence (AI) derived measures from BL computed tomography (CT) scans like imaging-based prognostication (IPRO) and lung volumetric tumor burden (VTB), generated by AI models trained on real-world imaging data, have shown promising association with overall survival (OS).
Methods: BL CT scans acquired in MYSTIC (NCT02453282) were combined across trial arms and retrospectively analyzed. Patients with consent were included in this study. We compared the prognostic association of manually derived SLD with AI derived IPRO and lung VTB using concordance index (c-index), Kaplan-Meier methods, time-dependent area under the curve (TD-AUC), and standardized hazard ratios (HRs) from Cox proportional hazards models.
Results: BL CT scans of 672 patients had available quantifications for comparative analysis. Median OS (mOS) was 12.2 months, 194 patients (29%) were female, 106 (16%) were non-smokers,193 (29%) had squamous cell carcinoma and 201 (30%) had PD-L1 > 50%. SLD, IPRO, and lung VTB, yielded c-indexes of 0.56 (95% CI: 0.54-0.59), 0.61 (0.59-0.64), and 0.57 (0.54-0.60), respectively. Results are shown in Table 1.
Conclusions: BL IPRO has greater association with OS than SLD, and VTB shows similar prognostic association as SLD. AI derived quantifications offer enhanced stratification and may provide an efficient way to analyze treatment effects.

Overall survival strength of association and stratification by variable

Variable	c-index (95%CI)	TD-AUC (12 months)	HR (95% CI)	mOS (months)	
				Above Median	Below Median
SLD	0.56 (0.54-0.59)	0.64	0.76 [0.64, 0.90]	14.6 [6.9, 27.8]	10.3 [4.1, 22.8]
IPRO	0.61 (0.59-0.64)	0.70	0.57 [0.48, 0.68]	16.1 [9.0, 28.4]	8.2 [3.5, 20.3]
Lung VTB	0.57 (0.54-0.60)	0.62	0.68 [0.57, 0.81]	15.5 [7.2, 28.1]	9.8 [4.0, 20.3]

#5782 Effect of tremelimumab in combination with durvalumab and chemotherapy in heterogeneous metastatic lesions: A volumetric analysis.

Q. Li[1], H. RaviPrakash[1], K. Patwardhan[1], J. MacKay[2], A. Shakur[2], Z. Wei[1], J. Parkin[2], M. Parker[2], S. V. Patel[2], R. Stewart[2];
[1]AstraZeneca, Waltham, MA, [2]AstraZeneca, Cambridge, United Kingdom

Background: Patients with metastatic non-small cell lung cancer (mNSCLC) in 1L therapy treated with a limited course of five cycles of the anti-CTLA-4 antibody *tremelimumab (T)* added to *durvalumab (D)* plus four cycles of platinum-based chemotherapy (CTx) experienced a reduction in the risk of death versus CTx alone, especially in non-squamous (NSq) patients. One potential mechanism of anti-CTLA-4 is the diversification of the T-cell response, which may help address tumor heterogeneity more effectively. RECIST based measurements may fail to capture this impact by mainly quantifying target lesions in 2D. Here we assess the ability of volumetric radiographic data to more comprehensively assess the impact of anti-CTLA-4 treatment on tumor growth.
Methods: We analyzed the Computed Tomography (CT) images from 369 NSq patients in the T+D+CTx and D+CTx arms of the Poseidon Phase III trial. Five experienced radiologists annotated and segmented up to 10 lesions in the baseline scans (start of the induction phase), including the RECIST-based target lesions as well as additional measurable non-target lesions (a maximum of 4 lesions per organ). These segmented lesions were tracked, and new lesions were annotated in the follow-up scans of 316 patients at week 12 (end of induction phase) and 276 patients at week 20 (maintenance phase). 3D volume of lesions as well as the RECIST 1.1 lesion diameters were noted and the percentage change in these metrics were observed and compared across the selected trial arms.
Results In comparing the T+D+CTx arm to the D+CTx arm, we observed a significantly larger median volumetric reduction at the end of the induction phase, at both lesion level (69.5% vs 53.4%, $p<0.001$) as well as patient level (65.0% vs 52.3%, $p < 0.001$). Analysis of the volumetric change in metastatic lesions in the liver and adrenal glands showed a similar trend of deeper response in patients given T+D+CTx as compared to D+CTx which was not observed with the 2D diametric change. This deeper response was noted in both the Programmed death-ligand1 (PD-L1, used as a randomization covariate) < 1% and >/=1-49% groups comparing T+D+CTx to D+CTx cohort. Analysis of change in tumor burden from week-12 to week-20 (after the end of CTx) showed that a larger proportion of T+D+CTx treated patients (60.7%) continued with tumor volumetric reduction compared to patients in D+CTx arm (44.6%).
Conclusions This volumetric analysis offers more accurate quantification of tumor size change than the 2D diametric approach. This analysis of the NSq patients suggests that tremelimumab in combination with durvalumab may result in a deeper and longer response in adult patients with Stage IV (metastatic) NSCLC compared to durvalumab-only.

#5783 CT radiomics-based machine learning models for diagnosing para-aortic lymph node metastases in colorectal cancer.

Yingqian Zhou[1], Ximin Pan[2], Qiongwei Tang[3], Zhaoliang Yu[1], Zerong Cai[1], Peiyi Xie[2], Yufeng Chen[1]

[1]Department of General Surgery (Colorectal Surgery) & Biomedical Innovation Center, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]Department of Radiology, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[3]Guangdong Provincial Key Laboratory of Colorectal and Pelvic Floor Diseases, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Para-aortic lymph node (PALN) metastasis is a rare but clinically challenging manifestation in colorectal cancer (CRC). Its management is complicated by the high risks associated with radical PALN dissection and the limited diagnostic accuracy of preoperative imaging. This study aims to develop CT radiomics-based machine learning models to predict PALN metastasis in CRC patients.

Methods: A retrospective analysis was conducted on 116 CRC patients who were enrolled between December 2012 and December 2019 and underwent PALN dissection and preoperative enhanced CT imaging within two weeks before surgery. CT images were semi-automatically segmented using 3D Slicer to delineate PALNs as regions of interest, from which a series of shape and texture radiomics features were extracted. Key features were selected using least absolute shrinkage and selection operator (LASSO) regression with cross-validation. Machine learning models, including logistic regression, support vector machine (SVM), extreme gradient boosting (XGBoost), and random forest, were constructed and cross-validated to assess the predictive value of these radiomics features for PALN metastasis.

Results: A total of 1,037 CT radiomics features were extracted from the regions of interest, with six features selected based on their recurrence in over 200 instances. All four machine learning models performed well, with the random forest model exhibiting the most balanced performance: an average accuracy of 0.836, average precision of 0.842, average recall of 0.978, average F1 score of 0.905, and average AUC of 0.809. Compared to traditional diagnostic criteria based on lymph node short-axis diameter, the random forest model significantly improved diagnostic performance, with a net reclassification improvement (NRI) of 0.789 (95% CI, 0.378-1.199, $P < 0.001$) and an integrated discrimination improvement (IDI) of 0.116 (95% CI, 0.024-0.208, $P = 0.014$).

Conclusion: CT radiomics-based machine learning models provide a robust, non-invasive tool for predicting PALN metastasis in CRC, offering superior diagnostic accuracy over traditional imaging metrics. Keywords: CT radiomics, Machine learning model, Para-aortic lymph node, Lymph node metastasis, Colorectal cancer, Prediction.

#5784 An image based assay platform for drug screening with a 3D bioprinted vascularized lung cancer model.

Fahimeh Shahabipour, Yuchi Yuchi Chen, Yen-Ting Tung, Marc Ferrer, Min Jae Song

NIH-NCATS (National Center for Advancing Translational Sciences), Maryland, MD

3D tissue models that mimic the physiology of human tissues and organs are being developed in multi-well plate format as predictive assays for drug screening. 3D bioprinting enables the fabrication of tissues with precision and reproducibility in a 96-well plate for medium throughput drug screening. We have established robust protocols for the 3D bioprinting vascularized lung tissue models using human primary pulmonary endothelial cells constitutively expressing green fluorescent protein (GFP), pericytes, and fibroblasts mixed with a fibrin-based hydrogel. We create a vascularized lung tissue model in a ring-shaped structure that facilitates image-based quantification of vasculogenesis and angiogenesis. This bioprinted vascularized lung tissue model was used as a tumor microenvironment to grow lung cancer cells. We incorporated three immortalized lung cancer cell lines, A549, H1975, and H460, constitutively expressing red fluorescent protein (RFP) into the 3D bioprinted vascularized lung tissues. Cancer cells were added as single cells embedded in the hydrogel (1K cancer cells/well) covering the bioprinted vasculature. Fluorescence microscopy was used to quantify the growth and morphology of the cancer cells by measuring total red fluorescence intensity surface roundness and compactness of red fluorescence objects, as well as angiogenesis from the green fluorescence intensity. After 21 days of culture, the three cancer cell lines showed distinct growth morphology and migration patterns. We characterized tumor localization according to the three regions of interest: angiogenesis outwards or inwards and tumor growth inside or outside the bioprinted vasculature area. A549 and H1975 showed a strong tendency to migrate towards the bioprinted vascularized structure, growing as low compact structures. The H460 cell line formed small compact spheroid structures and did not prefer the vasculature area. We also compared cancer cell growth and morphology with and without vascular components to assess any effects of the vasculature on tumor growth. We observed that this study helps demonstrate the usefulness of the bioprinted vascularized lung tissue cancer model as an assay platform for screening for anti-cancer drugs in an assay that includes the tumor microenvironment. ***Keywords:*** 3D bioprinted, 3D cancer-vascularized lung tissue model, drug Screening,

#5785 A novel technique for rapid intra-operative assessment of margins and sentinel lymph node metastasis status in human breast-conserving surgery.

Wei-ling Chen[1], Yuan-yuan Zhu[1], Zhao Wu[1], Jun-hong Chen[1], Ting-wen Guo[1], Li-xin Zhang[2], Guo-jun Zhang[3]

[1]Xiamen University, Xiamen, China,[2]Kunming Medical University, Kunming, China,[3]The Third Affiliated Hospital, Kunming Medical University, Kunming, China

Purpose: The swift and precise evaluation of margin and sentinel lymph node (SLN) metastasis status during breast-conserving surgery is imperative in minimizing the likelihood of requiring additional surgical procedures. Near-infrared optical molecular imaging technology has been extensively utilized in the realm of surgical navigation, representing a significant advancement in the field of surgical oncology. However, due to safety and other concerns, very few effective probes can be applied to clinical trials, hindering the clinical implementation of fluorescence imaging. In this study, a novel technology was developed to rapidly identify tumor areas *in vivo* and *ex vivo* during surgical procedures, and delineate tumor boundaries and SLN metastases to assist surgeons in intraoperative decision-making. **Methods:** For animal studies, an orthotopic breast cancer mouse model, a spontaneous breast cancer transgenic mouse model, and a SLN metastasis mouse model of breast cancer were established. The tumor tissues and SLNs of mouse models above were surgically removed and incubated with a probe of different concentrations for different incubation time, then imaged by a second near-infrared window fluorescence imaging system. For clinical samples, surgically removed breast tissues and SLNs from 13 breast cancer patients were incubated with the targeting probe immediately after intraoperative resection and imaged to identify the tumor area and distinguish the tumor boundary and metastatic SLNs. The accuracy of fluorescence imaging was validated through pathological examination. **Results:** The *ex vivo* animal imaging experiments showed a fluorescence enhancement of tumor tissue and metastatic SLNs. For clinical samples, our results showed that this new technology yielded more than 90 % sensitivity and specificity in identifying the tumor area in the resected breast tissue. The average fluorescence tumor-to-normal ratios were more than three in different incubation conditions. Furthermore, we also used this technique to image metastatic SLNs intra-operatively and showed that metastatic SLNs exhibited a nearly 3-fold increase in fluorescence signal compared to benign SLNs. Calculations on the results of the fluorescence signal in relation to the metastatic status of SLNs yielded values of more than 90 % for sensitivity and specificity. **Conclusions:** The utilization of fluorescently labeled ADC that specifically targets tumor surface proteins combined with intraoperative fluorescence imaging has effectively delineated boundaries in breast cancer specimens and facilitated the detection of metastatic SLNs. This approach has the potential to inform decisions regarding optimal resection strategies in oncology, particularly within the constraints of a limited surgical window.

#5786 Rapidly assess sentinel lymph node metastasis status in breast cancer by a near-infrared fluorescent probe targeting CK.

Purpose: At present, surgery is still a main treatment method for breast malignant tumors, but the problems of edema and tumor recurrence faced by patients after surgeries are still relatively common. The main reason for this is closely related to the resection of metastatic sentinel lymph node (SLN) during surgery. The method of identifying SLN by methylene blue (MB) and technetium 99m tracing is not clearly targeted and can't judge the metastatic status of SLNs. Therefore, there is an urgent need to develop tracers that specifically identify the metastatic status of SLN. Our team successfully synthesized ICG-CK, a fluorescent molecular probe targeting pan-CK. Through animal experiments, we found that the probe can identify the metastatic status of SLN *in vivo* and *ex vivo*.

Methods: 1. The penetration and characteristics of the ICG-CK were evaluated. 2. The ability of ICG-CK to recognize different breast cancer cell lines was verified by cell uptake experiments. 3. The ability of ICG-CK to identify the metastatic status of SLN was verified by *in vivo* imaging experiments. 4. The ability of ICG-CK to identify the metastatic status of *ex vivo* SLN was verified by co-incubation with *ex vivo* tissue.

Results: 1. The ICG-CK probe was successfully synthesized, with good stability, biocompatibility and strong NIR-II fluorescence emission ability. 2. ICG-CK could specifically target 4T1 cell which with high CK expression compared with ICG-IgG, and there was a statistically significant difference between the two, $p<0.0001$. 3. *In vivo* imaging experiments, the fluorescence imaging of tumor-bearing mice showed that ICG-CK was easily drained to SLN and targeted to identify metastatic 4T1 tumor cells, producing a strong fluorescent signal, and the SBR of metastatic SLN and normal SLN was 3.34, $p<0.05$. 4. By imaging isolated SLN from tumor-bearing mice, we found that after co-incubation with ICG-CK of isolated SLN, isolated SLN produced a strong fluorescent signal that was significantly different from normal SLN, $p<0.01$.

Summary: Our results show that ICG-CK has a strong ability to identify metastatic SLN compared with normal SLN in breast cancer, both *in vivo* and *ex vivo* imaging experiments, and it can produce a strong fluorescence signal in the near-infrared second region. Therefore, our study provides a basis for further exploration of the use of ICG-CK to assess the metastatic status of SLN in real-time intraoperatively.

#5787 Mutation prevalence in metastatic castration-sensitive prostate cancer based on metastasis timing and risk stratification.

Maria Ovejero-Sanchez[1], Ana Jambrina[1], Ignacio Gonzalez-Ginel[2], Daniel Tello[3], Manuel Balongo[1], Ana Gutierrez-Pecharroman[4], Pedro P Lopez-Casas[3], Alfredo Rodriguez-Antolin[2], Elena Castro[1], David Olmos[3]

[1]Translational Research in Cancer Genetics group, Instituto de Investigacion Hospital 12 de Octubre, Hospital Universitario 12 de Octubre, Madrid, Spain,[2]Urology Department, Hospital Universitario 12 de Octubre, Madrid, Spain,[3]Genomics and Therapeutics in Prostate Cancer, Instituto de Investigacion Hospital 12 de Octubre, Hospital Universitario 12 de Octubre, Madrid, Spain,[4]Department of Pathology, Hospital de Getafe, Madrid, Spain

Introduction and Objectives: Metastatic castration-sensitive prostate cancer (mCSPC) is a clinically heterogeneous disease in which genetic mutations and tumor burden influence patient outcomes. Mutations in some DNA repair genes (e.g. *BRCA1/2* and *ATM*) have been related to prostate cancer development and progression and may serve as therapeutic targets. The GENPRO12 study aims to evaluate the mutational profiles in non-mCSPC and mCSPC patients and to explore its clinical associations.
Material and Methods: This preliminary report includes 109 mCSPC patients, stratified by synchronous/metachronous disease. Each group was further classified into risk/volume (high/low) categories based on CHAARTED and LATITUDE criteria. Tumor samples were collected and analyzed using next-generation sequencing (NGS) ACHILLES test (Olmos et al. Ann Oncol 2024) to identify mutations in 40 genes, including *BRCA1/2, ATM*, and other prostate cancer-related genes. Clinicopathological data were extracted from medical records.
Results: Median age at diagnosis of mHSPC was 72 (range 47-92) with a median PSA 46.9 (0.3-3956). 90 patients had synchronous metastatic disease, 69 were CHAARTED high-volume, 76 were LATITUDE high-risk, and 25 had visceral metastases (17 in the lung only). All but 11 patients had at least 1 alteration in the genes analyzed. The most relevant altered genes are listed in the table. *BRCA2*, *PTEN*, *RB1* Loss of Function (LoF) and *MYC* gain were more frequent in de novo and/or high-volume cases.
Conclusions: Genetic alterations with prognostic and/or predictive value can be detected using prostate-specific NGS assays on archived diagnostic FFPE samples. Their prevalence may vary based on mCSPC clinical presentation, reflecting distinct disease biologies. Updated results, including outcomes and treatment responses, will be presented at the meeting.

Most relevant altered genes

Gene alteration	All patients (n=109)	De novo high-volume (n=61)	De novo low-volume (n=29)	Metachronic high-volume (n=8)	Metachronic low-volume (n=11)
ATM LoF	9 (8%)	3 (5%)	4 (14%)	0 (0%)	2 (25%)
BRCA1 LoF	3 (3%)	0 (0%)	2 (7%)	0 (0%)	1 (9%)
BRCA2 LoF	22 (20%)	13 (21%)	7 (24%)	2 (25%)	0 (0%)
CHEK2 LoF	6 (6%)	5 (8%)	1 (3%)	0 (0%)	0 (0%)
FANCA LoF	12 (11%)	9 (15%)	2 (7%)	0 (0%)	1 (9%)
MYC gain	7 (6%)	6 (10%)	0 (0%)	1 (13%)	0 (0%)
PALB2 LoF	2 (2%)	0 (0%)	1 (3%)	0 (0%)	1 (9%)
PTEN LoF	34 (31%)	21 (34%)	10 (34%)	1 (13%)	2 (18%)
RB1 LoF	29 (27%)	19 (31%)	5 (17%)	3 (38%)	2 (18%)
SPOP mut	13 (12%)	8 (13%)	4 (14%)	0 (0%)	1 (9%)
TP53 LoF	40 (37%)	26 (43%)	11 (38%)	0 (0%)	3 (27%)

#5788 Molecular profiling of NSCLC patients associates CT-based radiomic features with a tumor microenvironment favorable for immunotherapy.

Lauren K. Brady[1], Amogh Hiremath[2], Mohammed Qutaish[1], Kai Zhang[2], Kaustav Bera[3], Anant Madabhushi[2], Sri Sridhar[1], Nora Pencheva[4], Patricia Garrido-Castro[4], Maria Jure-Kunkel[1], Omar Jabado[1], Matthew Loya[1], Erin Henitz[1], Regina Aquino[1], Teng Jin Ong[1], Nathaniel Braman[2], Brandon W. Higgs[1]

[1]Genmab, Plainsboro, NJ,[2]Picture Health Inc, Cleveland, OH,[3]Case Western Reserve University, Cleveland, OH,[4]Genmab, Utrecht, Netherlands

Radiomics provides a powerful, noninvasive way to capture tumor heterogeneity and predict therapy response. However, its clinical utility is limited by feature interpretation. Here, we integrate radiomics with tumor transcriptomic profiles to enhance biological interpretation of CT-based features linked to an immune-responsive tumor microenvironment (TME), in non-small cell lung cancer (NSCLC) treated with acasunlimab, a DuoBody® PD-L1×4-1BB bispecific antibody, +/- pembrolizumab.

This study used contrast-enhanced CT images (n=62) and gene expression (HTG EdgeSeq) from tumor biopsies (n=25) of advanced NSCLC subjects in GCT1046-01 (NCT03917381) and GCT1046-04 (NCT05117242). Gene signatures (n=104) linked to cancer and immune pathways were analyzed. Radiomic features were extracted using Picture Health Px Platform, creating a 4-feature composite radiomics score optimized to assess clinical benefit (one quantitative vessel tortuosity (QVT) and three textural features (Laws, Gabor, and GLCM). Performance and treatment specificity were cross-validated and evaluated in 85 NSCLC patients treated with chemotherapy.

The radiomics score was not associated with baseline BMI, ECOG score, gender, age, or tumor size. Clustering radiomics features with mRNA signatures identified distinct biological pathways, such as immune regulation, angiogenesis and apoptosis. Specifically, QVT was negatively associated with immune regulation and antigen presentation, while positively correlated with hypoxia and tumor immune evasion. In contrast, GLCM correlated with B cell signaling, immune checkpoint activation and lymphocyte infiltration, indicating a TME suitable for immunotherapy. Laws showed positive correlation with antiviral defense and immune activation, and negative association with tumor immune evasion. Gabor was negatively correlated with cancer associated fibrosis and extracellular matrix remodeling.

These results show that integrating radiomics with tumoral mRNA data identified key characteristics of a TME conducive for immunotherapy, advancing the interpretability of AI-derived imaging features. The composite radiomics score was independent of traditional prognostic factors and reflected immunotherapy-specific mechanisms, highlighting its potential as a noninvasive tool for characterizing tumor biology and determining immunotherapy relevance in NSCLC patients.

CLINICAL RESEARCH: Immune Response to Therapies
Poster Session

#5792 Characterization of the tumor microenvironment in a relapsed refractory multiple myeloma patient undergoing daratumumab therapy.

Siobhan B. Cashman[1], Aruna Ayer[2], Teresa Swift[1]

[1]Advanced Technology Group, BD Biosciences, Limerick, Ireland,[2]Advanced Technology Group, BD Biosciences, Miloitas, CA

Multiple Myeloma (MM), a hematological malignancy, is characterized by the clonal proliferation of plasma cells in the bone marrow (BM), which serves as the tumor microenvironment. Despite recent advancements in MM treatment, many patients experience disease progression after multiple therapies. Daratumumab, a human IgG1 monoclonal antibody targeting CD38, has emerged as a breakthrough in the treatment of MM, including in cases of relapsed and refractory MM. However, MM remains incurable and therefore understanding the impact of daratumumab on immune microenvironment may enable the development of better-targeted therapies. This study represents a detailed case of a 45-year-old female with relapsed refractory MM undergoing daratumumab therapy. BM aspirates were collected from the patient before treatment initiation & 7-days post final infusion. To delineate the early cellular and molecular changes induced by daratumumab within the TME, we employed flow cytometry and single-cell whole transcriptome sequencing with CITE-seq. Flow cytometry was used to assess the changes in cell populations within the TME, particularly focusing on $CD8^+$ T cells and NK cells. Single-cell RNA sequencing enabled the high-resolution analysis of both transcriptomic and surface protein changes within individual cells. Post-infusion, we observed an increased percentage in $CD8^+$ T effector memory (T_{EM}) cell subsets accompanied by a corresponding decrease in effector memory expressing CD45-RA (T_{EMRA}). Single-cell sequencing identified heightened activity in the interferon and TNF pathways. Additionally, there was an increased percentage of granzyme B expressing $CD8^+$ T cells. Although we observed no significant change in the percentage of NK cells post-infusion, we did note an increased percentage of $CD56^{Bright}CD16^-$ NK and $CD3^+CD8^+CD56^+$ NK-T-like subsets as well as decreased $CD57^+$ terminally differentiated NK cells. We observed increased transcript expression of *CD160* (encoding the activating receptor CD160/NK1) in the post-daratumumab NK cell cluster. Further, we noted increased activity in the NFκB pathway in post-treatment NK cells. This case study underscores daratumumab's rapid impact on the immune cell landscape within the BM TME. By combining flow cytometry with single-cell whole transcriptome sequencing and CITE-seq this study provided a comprehensive view of the effect of therapy on the MM TME. Through CITE-seq, we identified the dynamic changes in the BM immune cell landscape and captured protein expression patterns specific to targeted cell populations. This approach allowed us to link surface marker expression with gene expression profiles, enabling a comprehensive analysis of the BM TME. For Research-Use Only. Not for use in diagnostic or therapeutic procedures. BD and the BD Logo are trademarks of Becton, Dickinson and Company. © 2024 BD. All rights reserved. NPM-5206

#5793 Measurement of basophil activation using a flow cytometry method for applications in clinical research and clinical trials.

J. J. Stewart, L. Brown;
Translational Drug Development (TD2), Bothell, WA

Background: Basophils are a type of white blood cell that play a role in the immune system, particularly in defending the body against allergens, pathogens, and parasites. Basophils also can contribute to the immune response directed against cancer cells by releasing histamine and other mediators that can enhance inflammation and recruit other immune cells to the tumor site. They express high-affinity immunoglobulin E (IgE) receptors, which are involved in recognizing and responding to antigens presented by cancer cells. Basophils may also play a role in modulating the tumor microenvironment, potentially influencing the effectiveness of immunotherapies and understanding the exact mechanisms make the study of basophil activation an exciting area for developing novel therapeutics.
Methods: Basophil cells can become activated when the antigen loaded IgE antibody recognizes and binds to the Fc receptor (FcεRI) on the basophil surface. Basophil activation also causes certain markers to be upregulated on the surface of the cell that can be measured by flow cytometry to determine basophil activity. The basophil activation test (BAT) was conducted with human whole blood samples using a commercially available basophil activation kit. Whole blood specimens from human donors were collected in EDTA blood collection tubes. Blood was stimulated with FCεR1 and fMLP and staining reagent for 25 - 30 minutes at 37°C. Cells were lysed, washed and acquired on the flow cytometer.
Results: CCR3 was used to identify the basophil population in human whole blood. CD63 and CD203c were then used to identify the unstimulated and stimulated state of the cells. Upon stimulation there was an increase in CD63 and CD203c expression on the surface of the basophils.
Conclusions: These results showed that the basophil activation can be measured using flow cytometry with the increased expression of CD63 and CD203c on stimulated basophils. This method could be used to help scientists in clinical research and clinical trials to monitor allergic diseases, predict responses to immunotherapy, and assess the effectiveness of treatments, including immunoncology drugs.

#5794 Tumor cell targeted granzyme B fusion constructs mediate immunogenic cell death (ICD) in addition to their direct cytotoxic effects.

Khalid A. Mohamedali[1], Brian Aguirre[2], Lawrence H. Cheung[1], SuYin Kok[2], David Casero[3], Madhuri Wadehra[2], Michael G. Rosenblum[1]

[1]Department of Translational Medical Sciences, Texas A&M Univ. Health Science Center, Houston, TX,[2]Department of Pathology and Laboratory Medicine, University of California Los Angeles, Los Angeles, CA,[3]Department of Medicine, Cedars Sinai Medical Center, Los Angeles, CA

Therapeutic agents targeting tumor cells have a cytotoxic effect that primarily results in an apoptotic insult through numerous mechanisms. Recently, immune activation mechanisms directed against tumor cells have been identified as a secondary effect of targeted therapy. In this mechanism, targeted tumor cells release ATP and various intracellular proteins into the intratumoral space including HSP70, HMGB1 and calreticulin. These damage-associated molecular patterns (DAMPs) then decorate nearby undamaged tumor cells where infiltrating host immune cells generate a secondary immune response to these decorated bystander cells. Epithelial membrane protein-2 (EMP2) is highly expressed in invasive breast cancer (BC), including triple negative breast cancer, and represents an attractive therapeutic target. We generated a fusion construct containing human granzyme B fused to an scFv antibody recognizing the EMP2 antigen, tethered through a fragment of an IgG heavy chain (Fc) domain and containing the dimerization domain. The 160 kDa dimeric protein was expressed by HEK-293E cells into conditioned media. The construct was assessed for GrB enzymatic activity, EMP2 binding affinity and cytotoxicity against various breast cancer cell lines. The purified GrB-Fc-KS49 demonstrated exceptional binding to an EMP2 peptide with a K_D of 1 x 10^{-12} M and GrB enzymatic activity was preserved compared to native GrB. The IC_{50} ranged from 40-83 nM against a panel of murine and human EMP2+ BC cell lines. Treatment of mice bearing well-established syngeneic EMT6 or 4T1 breast tumors on a twice weekly schedule (IP, 40 mg/kg total dose) showed a significant (50%) reduction in cell growth and in tumor cell turnover (Ki-67). Importantly, in the 4T1 model tumors, there was a 20-fold increase in CD45+ immune cells and a 60-fold increase in tumor-inhibitory M1 macrophages. We found similar results in the EMT6 tumor model with a significant decrease in tumor supportive M2 macrophages. Studies are ongoing to identify potential directly cytotoxic molecules released from cells intoxicated by GrB-based fusion constructs and to identify DAMP-related proteins which may mediate the secondary immunogenic bystander effect against tumor cells. These data support a proposed “dual mechanism” for GrB-based therapeutics which include a direct, antigen-mediated cytotoxic effect and a secondary, immune-mediated effect which can target both antigen-positive and antigen-negative tumors. Research conducted, in part, by the Clayton Foundation for Research and generously supported by the NCI R21 CA163971.

#5795 Dynamic proteomic biomarkers of survival outcomes with anti-PD-1 immunotherapy in head and neck squamous cell carcinoma.

Md Saiful Islam Sai[1], Kartik Sehgal[2], Ze Zhang[2], Rondi Butler[3], John Wiencke[4], Annette Molinaro[5], Juliana Miller[2], Hannah Stolrow[5], Keisuke Shirai[5], Lucas Salas[5], Devin Kosetler[1], Robert Haddad[2], **Brock C. Christensen**[5], Karl Kelsey[5]

[1]University of Kansas Medical Center, Kansas City, KS,[2]Dana Farber Cancer Institute, Boston, MA,[3]Brown University School of Public Health, Providence, RI,[4]University of California San Francisco, San Francisco, CA,[5]Dartmouth Geisel School of Medicine, Lebanon, NH

Background: Despite advances in anti-programmed death (PD)-1 based immunotherapy in recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC), challenges remain in identifying who will benefit from these therapies. Current tissue-based biomarkers have many limitations. Due to its accessibility and ease of longitudinal monitoring, there is growing interest in blood-based dynamic biomarkers for immunotherapy outcomes in R/M HNSCC.
Methods: In a prospective multicenter study of patients with R/M HNSCC (n=38) receiving anti-PD-1 based therapy, peripheral blood was collected pre-treatment and post-treatment (cycle 2 day 1). A total of 83 serum-derived cytokine biomarkers were evaluated with the Olink Target 96 Immuno-Oncology panel. Associations of pre-treatment, post-treatment, and the change in cytokine levels (post minus pre) were assessed with overall survival (OS) and progression-free survival (PFS). Unsupervised clustering analysis identified subgroups based on cytokine profiles. Further analyses were conducted using univariable and multivariable Cox proportional hazards and Cox Elastic Net machine learning models.
Results: Among the 83 cytokines, 49 (59%) exhibited a statistically significant within-patient increase from pre- to post-treatment. Further, several cytokines were significantly associated with OS and PFS and 10 associated with OS were shared in both pre- and post-treatment analyses. Generally, increased cytokine levels were associated with poorer outcomes. In analyses of cytokine level change (post minus pre), seven cytokines were significantly associated (FDR0.05) with OS (i.e., VEGFA, HGF, PGF, CCL19, CCL23, MCP3, TNFRSF12A) and three with PFS (i.e., NOS3, MMP12, and CCL23) after adjustment for potential confounders. An unsupervised clustering analysis of patients based on the change in the levels of all 83 cytokines uncovered two subgroups that differed significantly with respect to OS and PFS even after adjustment of potential confounders. A prognostic cytokine score was derived using machine learning analysis using elastic net regularization. Not only were cytokine scores significantly associated with platelet count and, in some cases, neutrophil count, they also provided additional prognostic value beyond established prognostic factors.
Conclusion: Dynamics of serum cytokines related to blood platelets during anti-PD-1-based therapy may serve as prognostic biomarkers in patients with R/M HNSCC.

#5797 Impact of baseline tumor size on response to anti-CD47 immunotherapy in an osteosarcoma mouse model.

R. Roudi, I. Vasylkiv, L. Pisani, T. Liang, R. Saab, H. Daldrup-Link;
Stanford University School of Medicine, Palo Alto, CA

Background and Purpose. Activation of tumor-associated macrophages (TAMs) by CD47 mAb therapy can be monitored with ferumoxytol-enhanced magnetic resonance imaging (MRI). The purpose of our study was to investigate if tumor size at baseline affects TAM response to CD47 mAb, as measured with ferumoxytol-MRI.
Methods. Thirty female NOD scid gamma (NSG) mice with small-sized (tumor volume = 30 mm3), medium-sized (tumor volume = 500 mm3), and large (tumor volume = 1200 mm3) 143B osteosarcoma xenografts were treated with human CD47 mAb (10 mg/kg, day 1, 3, and 5 for 1 week) or PBS (control group). All mice underwent MRI scans at baseline and at one week after CD47 mAb or sham treatment. Post-treatment scans were obtained before and after intravenous infusion of ferumoxytol nanoparticles (30 Fe mg/kg). We measured tumor T2* relaxation times as a quantitive measure of nanoparticle retention in TAM. The tumor ferumoxytol enhancement, calculated as: ΔT2* = 100 * (T2*precontrast - T2*postcontrast) / T2*precontrast, was compared between experimental groups using exact two-sided Wilcoxon rank-sum tests. Histology served as standard of reference.
Results. At baseline, tumors of CD47 mAb and PBS-treated mice demonstrated no significant difference in T2* relaxation time, regardless of tumor size (all $p>0.05$). After CD47 mAb therapy, tumors treated with CD47 mAb demonstrated significantly shorter T2* relaxation times compared to PBS-treated mice (all $p<0.001$). The tumor T2* enhancement was significantly higher in small tumors (ΔT2* = 41.3% +/- 2.182%) compared to large tumors (ΔT2* = 2.93% +/- 2.474%; $p=0.001$), indicating stronger nanoparticle phagocytosis in small sized tumors, apparently due to increased TAM activation. There was not statistically significance difference between T2* relaxation time of small and medium-sized tumors in all time points (all $p> 0.05$). Histopathological correlations confirmed a significantly higher number of CD80-positive TAMs in small sized tumors after CD47 mAb therapy (61.28% +/- 1.77%) compared to large sized tumors (3.38% +/- 0.81%, $p<0.001$).
Conclusion. Tumor size at baseline affects TAM response to CD47 mAb. Smaller osteosarcomas exhibit a more pronounced TAM response to CD47 mAb therapy compared to larger tumors.

#5798 Characterization of neoantigen peptides reveals key factors for sequence design to achieve immunogenicity.

Piriya Wongkongkathep, Worawan Bunrasmee, Jirattha Siriluksana, Korn Chotirosniramit, Pimpayao Sodsai, Nattiya Hirankarn, Trairak Pisitkun

Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Immunotherapy has become a powerful approach by utilizing immune systems to combat cancer. Therapeutic cancer neoantigen vaccines targeting tumor-specific antigen (TSA) have demonstrated promising results in several clinical trials, particularly in adjuvant settings. Neoantigens are tumor-specific antigens that are derived primarily from somatic mutations or non-canonical sequences, which can be presented on major histocompatibility complex (MHC) complexes to stimulate T cells. However, selecting mutations and designing neoantigen sequences to achieve high immunogenicity remains challenging. Compared with RNA-based vaccines, the peptides are more difficult to design due to solubility issues. We have analyzed immune response data from an enzyme-linked immunospot (ELISpot) assay collected from patients enrolled in Phase I clinical trial of neoantigen peptide vaccine at Faculty of Medicine, Chulalongkorn University, Thailand. A total of 12 patients with metastatic melanoma and renal cell carcinoma were treated with neoantigen synthetic long peptides, derived from 15-20 patient-specific somatic variants. The patients received neoantigen vaccine alone, intramuscularly administered in 5-7 injections, without combination with immune checkpoint inhibitors. A total of 239 peptides have been tested by ELISpot. We have characterized several contributing factors to immune response. Notably, we found no significant difference in immunogenicity based on peptide solubility, gene expression levels, variant allele frequency, or sites of injection. However, neoantigen peptides derived from indel mutations exhibited slightly stronger immune responses, than those from single nucleotide variants (SNVs) or frameshift variants. In conclusion, we identified some key factors that can assist in the design of neoantigen peptide sequence, and help prioritize neoantigen candidates for cancer treatments.

#5799 The immune and metabolic profile in the response to neoadjuvant treatment with immune checkpoint inhibitors in triple-negative breast cancer patients.

Lucia Serrano Garcia[1], Guillermo Quintas[2], Maria Portero Hernandez[1], David Collado Martinez[1], Maria Dolores Torregosa[3], Sara Marin[1], **Mario Mancino**[4], Jose Enrique O'Connor Blasco[5], Antonio Llombart-Cussac[1], Maria Leonor Fernandez-Murga[1]

[1]Hospital Arnau de Vilanova, Valencia (Spain), Valencia, Spain,[2]Health and Biomedicine Department, Leitat Technological Center, Barcelona, Spain,[3]Medical Oncology department Hospital Doctor Peset, Valencia, Spain,[4]Medica Scientia Innovation Research (MEDSIR), Jersey, NJ,[5]Universitat de Valencia, Valencia, Spain

Background: Immune checkpoint inhibitors (ICIs) are a promising option for early triple negative breast cancer (TNBC) treatment, although not all the patients get good responses. The objective of the present work is to research immune and metabolic profiles through non-invasive methods that allow us to differentiate responders (R) and non-responders (NR) patients prior to receive neoadjuvant chemotherapy (NAC) with ICIs.
Methods: 34 TNBC patients treated with NAC and ICIs were enrolled and blood samples were collected before treatment (baseline), after 3 weeks (3W) and at the end of treatment (Endpoint). Patients were classified as responders and non-responders based on whether they achieved histologically complete pathological response respectively after treatment. Cellular immune populations were characterized by flow cytometry. Metabolomic profile was determined by mass spectrometry.
Results: We observed a significant increase in the percentage of total lymphocytes ($p<0.001$), Natural Killer T (NKT) cells ($p=0.01$) and CD8 T cells ($p<0.001$) throughout treatment for the total set of patients. When classified into response (R) and No-response (NR), only the R group obtained a significant increase in NKT ($p<0.001$) and CD8 T cells ($p<0.001$) after therapy. NR group showed higher percentages of Myeloid Derived Suppressor Cells (MDSCs) at all time points. These changes were statistically significant for total MDSCs (3W; $p=0.03$ and endpoint; $p=0.01$) and granulocytic-MDSCs at baseline ($p=0.02$) and endpoint ($p=0.006$). NR patients also had a significant increase of platelet to lymphocyte ratio (PLR) after treatment ($p=0.017$). Metabolomic analysis revealed differences in Tryptophan, cytochrome p450, arginine and proline, nicotine and nicotinamide and Lysine degradation pathways at baseline point between responses ($p<0.05$). At 3W the changes appeared in Tryptophan, steroid hormone biosynthesis, amino sugar and nucleotide sugar, bile acid, purine and cytochrome p450 pathways ($p<0.05$).
Conclusion: Immunotherapy induced an activation of the immune system in patients with TNBC. This activation was more evident in patients in the R group, while in the NR groups had activated immunosuppression mechanisms such as MDSCs and PLR, which are associated with worse prognosis. Both groups of responses showed altered metabolites of different pathways that vary depending on the sample point. The changes observed between R and NR groups could allow establishing an immunosuppression mechanism in TNBC, as well as personalized patterns that predict the effectiveness of NAC with ICIs and help in clinical decision making. This investigation is still in the recruitment phase and metabolomic analysis of endpoint samples, hoping this tendency to continue.

#5802 Somatic variant predictors of cutaneous immune-related adverse events in cancer patients treated with immunotherapy.

Ninghui Hao[1], Jenny Lai[1], Crystal Chang[1], Ahmad Rajeh[1], Chuck Lin[1], Cameron Moseley[1], Arjun Mahajan[1], Matthew Tran[1], Coleen Valery[1], Christopher J. Thang[1], Guihong Wan[1], Alexander Gusev[2], Yevgeniy R. Semenov[1]

[1]Department of Dermatology, Massachusetts General Hospital, Boston, MA,[2]Department of Medicine, Dana Farber Cancer Institute, Boston, MA

Cutaneous immune-related adverse events (cirAEs) affect nearly one-third of patients treated with immune checkpoint inhibitors (ICIs). Identifying patients at high risk for cirAE can help guide monitoring and therapeutic management. Whether tumor somatic mutations are associated with the risk of cirAE development remains unknown. We analyzed tumor somatic single nucleotide variants (SNVs) from a discovery cohort of 733 patients with stage III/IV melanoma receiving ICIs at Dana Farber Cancer Institute and Massachusetts General Hospital. CirAE development was determined by chart review. SNVs were detected by OncoPanel v1-3. Nonsynonymous SNVs were used to calculate tumor mutational burden (TMB) and determine gene mutation status. Logistic regression models were used to test the association between gene mutation status and the binary outcome cirAE, while Cox regression models were used to examine the association between TMB or gene mutation status with time to cirAE development. Models were adjusted for demographic covariates (age at ICI, sex, self-reported race/ethnicity) and clinical covariates (melanoma subtype and ICI type). To validate significant associations identified in the discovery cohort, we used an independent cohort of 792 non-melanoma cancer patients treated with ICIs. Consistent with prior studies, TMB-high (>10 mutations/Mb) was significantly associated with improved overall survival (hazard ratio (HR) [95% CI] = 0.72 [0.53, 0.98]) in melanoma. However, TMB-high was not associated with cirAE development (HR = 0.92 [0.69, 1.22]). Binary logistic regression revealed that somatic mutations in PRKCI (OR = 2.76 [1.27, 6.33]), STAG2 (OR = 2.25 [1.09, 4.80]), and CXCR4 (OR = 2.56 [1.02, 6.80]) were associated with increased odds of cirAE. Furthermore, time-to-event Cox regression identified that somatic mutations in PRKCI, STAG2, and CXCR4 as well as five additional genes (MEN1, AKT3, FANCG, DAXX, H3F3B) were significantly associated with increased risk of cirAE development (nominal p-values<.05). Mutations in CXCR4 replicated in the validation cohort as significantly associated with time to cirAE (HR = 4.02 [1.22, 13.21]) adjusting for cancer type, ICI type, and demographics. Of the CXCR4 mutations identified in patients with cirAE, 5/15 (33%) localized to the C-terminus, were predicted deleterious by SIFT and PolyPhen2, and altered key residues known to be involved in CXCR4 degradation, suggesting a mechanistic link between CXCR4 gain-of-function mutations and increased risk of cirAE. We identified somatic mutations in several genes as significant predictors of cirAE development in melanoma. The association between mutations in CXCR4 and cirAE was replicated in a pan-cancer validation cohort, providing mechanistic insight into cirAE development across cancers.

#5803 Computational modeling of immune cell phenotypes enhances prediction of clinical anti-cancer drug response.

Gema Sanz, Reka Borocz, Bence Czako, Gerold Csendes, Csaba Gor, Gabor Kovacs, Laszlo Merő, Kristof Szalay, **Daniel Veres**, Bence Szalai

Turbine Simulated Cell Technologies Ltd., Budapest, Hungary

Preclinical cancer model systems, such as large-scale drug screens in cancer cell lines, are pivotal for identifying drug-sensitive indications and biomarkers of drug efficacy. However, these systems often lack the tumor microenvironment's complexity, including interactions with immune cells, which play a critical role in modulating drug response. Investigating drug-induced effects on immune cells is experimentally challenging due to the diversity of immune cell types and the complexity of co-culture systems. Computational models of immune cells can help to overcome these limitations and to guide further experiments. Leveraging public post-perturbation single-cell RNA sequencing datasets from various immune cells (including CD8 and CD4 T cells), we trained Turbine's Simulated Cell engine to predict transcription factor (TF) activity changes in 17 immune cell types post-drug treatment. We compared the predicted, drug induced TF activity changes to immune killing effects from public co-culture experiments. Predicted activity changes of CD8 T-cell activator TFs, such as FOSL and MYC, positively correlated with tumor-killing effects (Pearson r = 0.35 and 0.42, respectively). Conversely, inhibitor TFs such as NR4A1 and IRF4 exhibited inverse correlations (Pearson r = -0.27 and -0.47, respectively).To assess clinical relevance, we analyzed oncology clinical trial data from ACTT. We calculated mean overall response rates (ORRs) for indication - drug pairs and compared it to in vitro indication specific relative IC50 values of drugs. Using a linear model to predict ORRs from in vitro cancer cell line drug response data alone, we predicted ORRs with a Pearson correlation of 0.28. Integrating simulated drug induced TF activities of CD8 T-cells improved this correlation to 0.48, showing that combining tumor-intrinsic mechanisms with immune-mediated cell killing enhances the predictive performance of the model. Our findings suggest that augmenting traditional in vitro drug screening with simulated immune cell activity significantly enhances the clinical translatability of preclinical drug response models, paving the way for improved therapeutic strategies.

#5804 Pathologic responses to neoadjuvant immune checkpoint inhibitor (ICI) combinations in head and neck squamous cell carcinoma (HNSCC) associate with specific CD4$^+$ helper and regulatory T cell activation states and clonal plasticity.

M. Brand[1], A. Kulkarni[1], H. Li[2], P. Upadhyay[1], S. I. Chiosea[2], P. M. Santos[1], B. R. Isett[1], M. Joy[1], G. L. Sica[2], U. Duvvuri[3], S. Kim[1], M. Kubik[1], F. Tu[1], T. C. Bruno[2], D. A. A. Vignali[2], A. R. Cillo[2], R. Bao[1], D. P. Zandberg[1], J. Wang[1], L. Vujanovic[1], R. L. Ferris[4];

[1]University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]NYU Grossman School of Medicine, New York, NY, [4]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Background: The clinical benefits observed with anti-PD-1 therapy in the recurrent and metastatic setting have sparked greater interest in exploring immunotherapy at an earlier stage of the HNSCC treatment regimen. However, response rates in HNSCC patients are limited, and mechanisms of treatment failure remain poorly understood. In an ongoing neoadjuvant trial, we investigate the transcriptional and spatial dynamics of tumor-infiltrating CD4$^+$ T cells in HNSCC patients treated with neoadjuvant nivolumab (anti-PD-1, Nivo) ± ipilimumab (anti-CTLA-4, Ipi) or relatlimab (anti-LAG-3, Rela). Our goal is to elucidate mechanisms of tumor-infiltrating CD4$^+$ T cells associated with positive clinical response to ICI therapy.

Methods: Pre- and post-treatment tumor samples from HNSCC patients were processed for single-cell RNA-sequencing, T cell receptor (TCR) sequencing and spatial imaging, with sequencing successfully completed for 39 patients. Specific T cell transcripts defined cellular subpopulations, revealing distinct transcriptional and clonal dynamics. Multispectral imaging of tissue sections was performed to evaluate changes in T cell composition within the tumor microenvironment. Pathologic response was linked to observed cellular dynamics to treatment outcomes.

Results: Pathologic response rates were highest in the Nivo+Rela arm (11/15, 73%) versus Nivo+Ipi (7/11, 64%) or Nivo (5/12, 42%). While both combination ICI therapies increased total CD3$^+$ T cell frequencies within tumor and stromal compartments, only Nivo+Ipi led to a significant increase of conventional CD4$^+$ T helper (Tconv) and regulatory T cells (Treg) in both regions. Notably higher CD8$^+$/Treg and Tconv/Treg ratios positively correlated with tumor rejection in the Nivo+Rela arm. In contrast to Nivo+Ipi, Nivo+Rela therapy expanded clonal diversity exclusively within Tconv populations in major responders, with a majority of emerging clones showing effector characteristics. Moreover, Nivo+Rela altered the phenotype of activated Treg to a more naïve or memory-like phenotype in major responders, suggesting a distinct regulatory landscape with implications for long-term tumor control.

Conclusion: Neoadjuvant combination ICI therapies directly influence spatial CD4$^+$ T cell composition and TCR clonal dynamics and modulate the frequency and phenotype of Tconv and Treg cells in the tumor in treatment-specific patterns. These immunological shifts correlate with tumor rejection and improve clinical outcomes. Our findings suggest that a dual ICI approach may enhance response rates beyond those achieved with monotherapies. They also indicate a possible biologic basis in CD4$^+$ T cell activity for precision ICI treatment, supporting more personalized ICI strategies in the neoadjuvant setting.

#5805 Immunomodulatory effects of TG2 in the ovarian cancer tumor microenvironment.

Hao Huang, Ping Xie, Ujin Kim, Longzhen Song, Jianjun Wei, Daniela Matei, Bin Zhang

Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Background: Transglutaminase 2 (TG2), an enzyme highly expressed in ovarian cancer (OC) and secreted in malignant ascites, is a key driver of peritoneal metastasis. Previous research has focused on TG2 activity within cancer cells, while the role of TG2 in the tumor microenvironment remained unexplored.
Methods: To investigate the impact of host TG2 deficiency on antitumor immunity and tumor progression, we injected ID8 or BPPNM cells intraperitoneally (i.p.) into TG2–/– (TG2KO) and wild-type (WT) (TG2+/+) mice. Synergy with PD-1/PD-L1 immune checkpoint blockade was also investigated. Tumor immune infiltrates within the ascites microenvironment or tumors were determined by high-dimensional spectral flow cytometry (CyTEK) and multiplex IHC (mIHC). To validate the spatially correlated expression of TG2 in tumor and stromal regions with immune cell signaling programs, we conducted spatially indexed transcript profiling (GeoMx digital spatial profiling) of FFPE OC sections.
Results: Significantly reduced ascites volume, tumor size, and weight ($p<0.05$) were observed after ip inoculation of ID8 or BPPNM murine cells in TG2 KO vs. WT mice. Survival of TG2 KO mice bearing BPPNM isografts was longer ($p<0.0001$) compared to WT mice (64 vs. 46 days). Treatment with anti-PD-L1 antibody inhibited tumor growth in WT and TG2 KO mice, with reduction in ascites and tumor weight in TG2 KO vs control mice ($p=0.223$ and $p=0.053$, respectively). There was an overall tendency toward increased CD45+ immune cell density within the TG2-/- ascites microenvironment upon anti-PD-L1 treatment. Frequencies of NK and NKT among CD45+ tumor infiltrates in tumor-bearing TG2-/- mice were increased following anti-PD-L1 compared to the control mice. By contrast, the frequency of immunosuppressive TAMs and PMN-MDSCs was decreased. Although there was no difference in the frequency of B cells, dendritic cells (DC), CD4+ Treg, and CD8+ exhausted-like T cells (TEX) between control and TG2-/- mice, stem-like progenitor exhausted CD8+ T cells were more abundant in TG2-/- mice following anti-PD-L1 treatment. There was a trend to increased density of CD8+ T cells in TG2-/- mice after anti-PD-L1. Tumor-promoting PD-L1+CD11b+ myeloid cells were decreased in tumors from TG2-/- mice following anti-PD-L1 compared with control mice.Co-staining of TG2 and CD8 was used for spatial segmentation analysis in human tumors. TG2 expression in tumor cells and $CD8^+$ T cell infiltration were inversely correlated in stromal areas. An in-depth gene pathway enrichment analysis is underway.
Conclusion:The data support the potential of TG2 inhibition to mitigate OC immune evasion and sensitize tumors to immune checkpoint inhibitors.

#5806 Analyzing tumor treating fields (TTFields) therapy combined with checkpoint inhibitors in a GBM mouse model.

S. Lee[1], C. C. Perry[2], K. Cho[1], M. Lim[1], G. Li[1], R. T. Nitta[1];
[1]Stanford University School of Medicine, Palo Alto, CA, [2]Stanford University, Palo Alto, CA

Glioblastoma (GBM) is the most common malignant form of adult brain tumor, with a median survival of around 15 months. Despite multimodal treatments (tumor resection, radiotherapy, and chemotherapy) achieving an effective cure remains a significant challenge due to its highly aggressive nature. Immune checkpoint inhibitors have emerged as a promising strategy to combat GBM; however, limitations have hindered clinical success, largely due to the “cold” and immunosuppressive tumor microenvironment (TME). Previous studies have demonstrated that the TME can transform from “cold” to “hot” by upregulating tumor-specific antigens, thereby enhancing immune cell recognition. Tumor Treating Fields (TTFields) are a non-invasive treatment for solid tumors that employs specific frequency ranges (100-500 kHz) delivered through transducer arrays placed on the body. TTFields are currently being investigated for various tumor types and have received FDA approval and shown efficacy in GBM, pleural mesothelioma and metastatic NSCLC following platinum-based therapy. In our present study, we studied the effects of TTFields treatments on the immune response in GBM by using a syngeneic murine glioma model. Our initial in vitro studies demonstrated that TTFields enhanced the immune response in GBM by inducing immunogenic cell death, which led to the recruitment of immune cells through the release of damage-associated molecular patterns (DAMPs). Additionally, co-culture experiments with splenocytes and GBM cells treated with TTFields showed an increase in activated dendritic cells and macrophages, as well as early activated T cells (CD69/CD4+, CD69/CD8+). We verified these findings by demonstrating TTFields increased T-cell activity (IFNγ and perforin), and enhanced the motility and phagocytic activity in antigen presenting cells (Raw 264.7) and dendritic cells (JawsII). Since our in vitro findings indicated that TTFields enhanced the immune response, we studied the therapeutic potential of directly applying TTFields (200kHz) to a subcutaneous syngeneic GBM mouse model (GL261-luciferase) using the inovivo system. We observed a 2- to 4-fold decrease in tumor volume with mice that received TTFields treatment with the subcutaneous array compared to the control group (n = 8). In our subsequent studies, we anticipate that combining TTFields and the checkpoint inhibitor anti-PD-1 will result in greater tumor regression than TTFields monotherapy. Our findings suggest that concomitant treatment of TTFields with systemic anti PD-1 therapy has the potential to help transform GBM into a “hot” tumor, making it a more attractive target for immunotherapy.

#5807 Differential T cell response to anti-PD1 in breast cancer Sub-types is driven by activity of intra-tumoral immune cells.

Mouniss MM[1], Biswajit Das[1], Kowshik Jaganathan[1], Syamkumar V[1], Moumita Nath[1], Chandan Bhowal[1], Dharanidharan M[1], Saikrishna S[1], Abdul Haseeb[1], Pallavi R[1], Kubera Chandran[1], Rajashekar M[1], Oliyarasi M[1], Mehul Kapur[1], Jayaprakash C[2], Venkatesh T[2], Ganesh MS[3], Amritha Prabha[3], Prakash BV[4], Ravi Krishnappa[5], Upendra K[1], Ritu Malhotra[1], Govindaraj K[1], Pavithira .[1], Mohit Malhotra[1], Nandini Pal Basak[1], **Satish Sankaran**[1]

[1]Farcast Biosciences India Pvt. Ltd., Bangalore, India,[2]DBR & SK Super Speciality Hospital, Tirupati, India,[3]Vydehi Institute of Medical Sciences and Research Centre, Bangalore, India,[4]Sri Lakshmi Multi Speciality Hospital, Bangalore, India,[5]JSS Hospital, Mysuru, India

Immune checkpoint inhibition (ICI) holds great promise for triple-negative breast cancer (TNBC), while it shows limited response hormone receptor positive (ER/PR+) breast cancer (CaBr). We employed the Farcast CaBr TruTumor histoculture platform, that preserves the native tumor microenvironment (TME), to study the role of tumor resident immune cell types in determining T cell activation levels on ICI treatment, in the two CaBr sub-types. Freshly resected tumor tissue samples along with matched blood were collected from consented patients. Tumor explants were generated and distributed into arms and cultured for 72 h. Media was replenished every 24 h and the supernatant was stored. The response to stimulation with anti-CD3 (100 ng/mL) + Interleukin-2 (IL-2, 100 IU/mL) and treatment with Nivolumab (132 µg/mL) was evaluated using cytokine release and flow cytometry based immune profiling. CaBr (n=115) samples had lower immune component than head and neck squamous cell carcinoma (n=113) ($p<0.0001$) but similar to ovarian (n=21) and renal cell (n=52) cancer prior to treatment with ICI. Amongst the two sub-types, immune component in TNBC (n=43) was higher than ER/PR+ subtypes (n=46) ($p<0.05$). TNBC (n=10) showed a greater proportion of lymphocyte (58.46%) compared to myeloid (39.21%) compartment. This bias was not observed in ER/PR+ samples (n=12). Anti-CD3+IL2 stimulation showed similar response between the two CaBr sub-types. Upon treatment with Nivolumab, 2 out of 4 TNBC samples exhibited a response phenotype, with >1.6-fold increase in CD8+GzmB+ cells and interferon-gamma (IFN-γ) release. In contrast, only 1 out of 4 ER/PR+ CaBr samples showed a modest increase of 1.3 fold for CD8+GzmB+ cells with no detectable IFN-γ release. To understand the basis for the differential response in the two sub-types, we studied in detail, one ER/PR+ (H1) and two TNBC (T1 and T2) samples, displaying varying levels of response. T2 and H1 did not show a Nivolumab response phenotype, whereas T1 demonstrated a strong T-cell reinvigoration and tumor cytotoxicity. Interestingly, all three samples showed anti-CD3+IL2 stimulation driven T cell response. tSNE analysis of CTLs in the control arm showed two distinct sub-populations of exhausted CTLs (CD8+PD1+). Population1 (Pop1) was Granzyme B-positive, while population2 (Pop2) was not. Upon anti-CD3 stimulation, Pop1 showed further increase of activation whereas Pop2 did not, indicative of Pop2 being an irreversibly exhausted T cell population. T2 notably had lower Pop1 and Pop2 CTLs, along with highest proportion of monocytes across all three samples pointing towards an immunosuppressive TME. H1 mainly contained over-exhausted Pop2 and negligible Pop1 CTLs. Interplay between different TME immune sub-types, thus influence response to Nivolumab in CaBr. This is effectively captured by the TruTumor platform.

#5808 Differential clinical outcomes of immune vs non-immune based therapeutics in gastrointestinal malignancies: A retrospective, single center experience of early phase studies.

Tarik Demir[1], Nicole Altomare[2], Katrina Dobinda[3], Ruohui Chen[3], Carolyn Moloney[1], Pedro Hermida de Viveiros[1], Aparna Kalyan[1], Young Kwang Chae[1], Devalingam Mahalingam[1]

[1]Division of Hematology and Oncology Developmental Therapeutics Institute, Northwestern University, Chicago, IL,[2]Northwestern University, Chicago, IL,[3]Preventive Medicine; Feinberg School of Medicine, Northwestern University, Chicago, IL

Introduction: Evidence suggest that the immunosuppressive environment of liver parenchyma, leads to a specific resistance to immunotherapy (IO) in patients with liver metastasis (LM). This study seeks to evaluate the outcomes of patients (pts) with advanced gastrointestinal (GI) cancer who have undergone treatment with novel therapeutics (IO vs non-IO agents) within early-phase clinical trials. Further, we aim to identify oncogenic molecular signaling pathways and phenotypes that may indicate a poor response to IO in patients with LM.
Methods: This retrospective study focused on patients treated at Northwestern University from August 2014 to August 2023, who were enrolled in early-phase clinical trials and had CLIA certified next-generation sequencing available. Standard radiologic evaluations were per study, and efficacy based on progression-free survival (PFS) were defined as responders (PFS ≥ 3 months) vs non-responders (PFS < 3 months). Survival curves were calculated using the Kaplan-Meier method. For responder vs non-responder analyses, logistic regression assessed the impact of clinical variables on response, with significance defined as $p \leq 0.05$.
Results: 265 pts participated in this study with 11 pts participating in two studies during the course of their visits to the unit. The median age was 65 years (range 55-72), with 52% being male. Three tumor types were represented: colorectal (49%), pancreatic (43%), and gastroesophageal (8%) cancers. 218 (82%) pts had documented LM. 102(39%) patients were treated with IO based vs 157 (61%) in non-IO based therapeutics. When evaluating efficacy (n=276), the median PFS was 2.28 months, and 43% of patients had a PFS rate of ≥ 3 months. We found that pts with treated non-IO-based therapy were associated with higher PFS, median 3.48m (1.68-6.12m) vs 1.8m (1.4-3.48) for IO-based therapy ($p<0.0001$). In contrast to other studies, LM did not have prognostic significance for patients treated with IO ($p=0.49$). Among IO-based LM patients, KRAS (OR: 6.35, $p=0.028$) and TP53 (OR:4.23, $p=0.044$) pathway mutations were significantly associated with higher odds of non-response. No significant differences were found in the pathways involving APC, CDKN2A, ARID1A, PIK3CA, PTEN, SMAD4, NOTCH1, RB1, FBXW7, and FGF4.
Conclusion: In contrast to findings from earlier studies, our data did not establish a significant association between LM and survival outcomes in patients receiving IO. This discrepancy may result from the variety of IO regimens used in early-phase trials and the limited number of patients. Nonetheless, our findings contribute valuable insights into this complex area, offering important perspectives for future research and potential therapeutic strategies, particularly as IO treatments evolve and more extensive patient data becomes available.

#5809 Spatially resolved immunologic hallmarks of response to neoadjuvant immune checkpoint blockade in metastatic melanoma.

Zichao Liu[1], Xiaofei Song[2], Jodi Balasi[2], Wei-Shen Chen[3], Jiang He[4], Justin He[4], Jonathan Nguyen[2], Carlos Moran-Segura[2], Joseph Johnson[2], Chaomei Zhang[2], Jane Messina[2], Zena Sayegh[2], Nan Sun[2], Douglas Marchion[2], Sean Yoder[2], Vernon K. Sondak[2], Jeffrey H. Chuang[1], Pei-Ling Chen[2]

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[2]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[3]USF Medical Group, Tampa, FL,[4]Vizgen Inc., Cambridge, MA

Background: The groundbreaking SWOG S1801 and NADINA trials herald the use of neoadjuvant immune checkpoint blockade (NICB) as the standard of care for stage III-IV melanomas. The shift from radiographic to pathologic response scoring offers an unprecedented window of opportunity to interrogate 'on-treatment' biospecimens for the immune mechanisms of response and resistance at curative-intent surgeries. To date, single-cell/bulk RNA studies have demonstrated that TCF7+ stem-like CD8+ T cells and tertiary lymphoid structures (TLS) are positive predictors of ICB response. However, how these immune cells organize and communicate within the spatial context of the neoadjuvant tumor microenvironment remains poorly understood.
Methods: We assembled a retrospective cohort of 68 patients with stage 3 melanoma: 35 NICB (Ipilimumab-nivolumab, nivolumab-relatlimab, nivolumab) (14 complete response, 5 partial response, 14 non-response) and 33 treatment-naive (TxN). We dissected the spatial molecular architecture of all tumor beds (n= 68) and 10 uninvolved LNs (5 post-PD-1/5 TxN) using integrative multiplexed error-robust fluorescence in situ hybridization (MERFISH, 305 genes), Vectra multiplex IF and RNAscope multiomics in 38 whole slides and 3 TMAs (77 cores). We also performed single-cell-FFPE-seq using matched blocks (n=12) as an orthogonal benchmark for the MERFISH data.
Results: To analyze these high-dimensional datasets, we built a computational framework that includes 1) cell-typing with scFFPEseq validation, 2) novel spatial quantification methods to compute receptor-ligand (R-L) interactions that account for cell-cell distance and chemical signaling, 3) a graph-based clustering that quantifies germinal centers (GCs)/TLS, B-cell follicles and other spatial topography, and 4) MERFISH/ scRNA imputation via generative AI. Here, we showed that the quantity and size of spatially resolved GC/TLS and B-cell follicles surrounded by TCF7+ stem-like CD4+ and CD8 + T-cells, plasma cells, Tregs and myeloids are associated with positive response to neoadjuvant ICB. Our R-L analysis further revealed the critical importance of CXCR4-CXCL12 between TCF7+ T-cells and M2-myeloids and CCR7-CCL19/21 between TCF7+ T-cells in organizing the immune hubs in NICB response. Lastly, we incorporated scFFPEseq and MERFISH data into a unified latent embedding by environmental variational inference (ENVI) allowing us to impute melanoma phylogenetics, geographically accentuated hypoxic foci, and immune hubs within the spatial MERFISH images.
Conclusions: We leveraged cutting-edge spatial -omics technologies and novel computational methods to resolve the immunologic hallmarks of NICB response in metastatic melanoma. We believe our approach will usher in a new paradigm for the investigation of other cancer biospecimens in the new era of standard of care neoadjuvant immunotherapy.

#5810 Distinct mechanisms of CD28 and 4-1BB costimulation in glofitamab combination therapies for relapsed/refractory non-Hodgkin lymphoma (R/R NHL).

K. Korfi[1], Z. Jiang[2], S. Wilson[3], A. Christiansen[4], W. Leung[5], K. Lechner[6], N. Dimier[3], P. Knuckles[2], K. Reyskens[4], I. Lelios[2], A. Blank[1], A. Epp[6], S. Herter[1], J. Sam[1], P. Caimi[7], L. Falchi[8], R. Houot[9], F. Offner[10], H. Walter[11], H. Ghesquieres[12], G. Cartron[13], W. Townsend[14], G. Gritti[15], F. Bosch[16], M. Dickinson[17], C. Carlo-Stella[18], M. Hutchings[19], F. Morschhauser[20];
[1]Roche, Schlieren, Switzerland, [2]Roche, Basel, Switzerland, [3]Roche, Welwyn, United Kingdom, [4]A4P Consulting Ltd, Sandwich, United Kingdom, [5]Genentech, San Francisco, CA, [6]Roche, Penzberg, Germany, [7]Cleveland Clinic Taussig Cancer Institute, Cleveland, OH, [8]Memorial Sloan Kettering Cancer Center, New York, NY, [9]Centre Hospitalier Universitaire Rennes, Rennes, France, [10]Universitair Ziekenhuis Gent, Gent, Belgium, [11]University of Leicester and University Hospitals Leicester, Leicester, United Kingdom, [12]Hospices Civils de Lyon - Centre Hospitalier Lyon Sud, Lyon, France, [13]Centre Hospitalier Universitaire Montpellier, Montpellier, France, [14]University College London Hospitals NHS Foundation Trust, London, United Kingdom, [15]ASST Papa Giovanni XXIII, Bergamo, Italy, [16]University Hospital Vall d'Hebron, Barcelona, Spain, [17]Peter MacCallum Cancer Center and Royal Melbourne Hospital, Melbourne, Australia, [18]Humanitas University and IRCCS Humanitas Research Hospital, Milan, Italy, [19]Rigshospitalet and University of Copenhagen, Copenhangen, Denmark, [20]Univ. Lille, GRITA - Groupe de Recherche sur les formes Injectables et les Technologies Associees, Lille, France

Background: Two recent Phase I studies (NCT04077723, NCT05219513) investigated CD19-targeted 4-1BB or CD28 costimulatory bispecifics combined with glofitamab in patients with R/R NHL, showing added efficacy benefit but with distinct response dynamics (Hutchings et al; Dickinson et al, ASH 2024). While both costimulators are designed to enhance the anti-tumor effects of T-cell engagers, we present, for the first time, key differences in the mechanisms and response profiles of CD28 and 4-1BB costimulation in these combinations.
Methods: Exploratory biomarker analyses included 28 indolent and aggressive NHL patients treated with RO7443904 (CD19-CD28) and 99 with englumafusp alfa (CD19-4-1BBL) on Cycle 2 (C2) Day 8, after completion of glofitamab step-up dosing, followed by administration on the same day as glofitamab from C3 onwards (Q3W) for a fixed duration of 12 cycles. Peripheral immune profiling was done by flow cytometry, and gene expression and mutational profile of the tumors were characterized by mRNA- and targeted DNA-sequencing. On-treatment pharmacodynamic changes were compared to historical glofitamab data from NCT03075696 (n=140). The cross-trial comparisons were adjusted for differences in baseline characteristics and sample size.
Results: Compared to glofitamab monotherapy, both costimulators boosted and sustained peripheral T-cell activation and proliferation, with 4-1BB primarily expanding HLA-DR+ CD8 cells (1.5-fold), indicating prolonged activation, and CD28 boosting CD4/CD8 proliferation (2-fold). Additionally, 4-1BB further increased both effector and central memory CD8 cells (1.5-fold), while CD28 selectively expanded effector memory CD8 cells (1.5-fold) relative to glofitamab alone. Both costimulators limited PD1+ T-cell expansion in a dose-dependent manner, with 4-1BB mainly affecting Temra cells and CD28 targeting effector memory cells. Complete responses occurred independently of recurrent mutations (e.g. *TP53, CREBBP, B2M*) or cell-of-origin. However, tumor-infiltrating conventional dendritic cells (cDCs) were linked to response to 4-1BB and immunosuppressive macrophages were linked to lack of response to CD28, as determined by gene expression profiling of pre-treatment biopsies.
Conclusion: Our findings reveal distinct mechanisms of CD28 and 4-1BB costimulation with glofitamab, which may explain their different response dynamics. Specifically, 4-1BB promotes a sustained and prolonged immune response, while CD28 triggers rapid T-cell activation and proliferation. Moreover, 4-1BB appears to bypass macrophage suppression, and benefits from cDC-mediated antigen presentation and CD8 T-cell priming. These effects mirror those observed in second-generation CAR T-cell therapies and provide insight into how these off-the-shelf costimulators may be utilized based on tumor biology.

#5811 ABL103, a bispecific antibody targeting B7-H4 and 4-1BB, shows synergistic immune responses with combination of pembrolizumab in the immunosuppressive tumor microenvironment.

Chorong Yang, Eunhee Lee, Yangsoon Lee, Daehae Song, Byungje Sung, Jiseon Yoo, Kyungjin Park, Jonghwa Won

ABL Bio, Inc., Gyeonggi-do, Korea, Republic of

B7-H4 (B7x, VTCN1) is overexpressed in many types of cancers, including breast, ovarian, and endometrial cancers. B7-H4 expression is also observed in tumor associated macrophages and implicated as an immune checkpoint regulating T cell responses. 4-1BB (CD137/TNFRSF9) is an inducible co-stimulatory receptor and expressed in a wide variety of immune cell types, including activated T cells, natural killer (NK) cells, dendritic cells (DCs). Previously, we demonstrated that ABL103, B7-H4x4-1BB bispecific antibody, induced *in vitro* T cell activation only in the presence of B7-H4-expressing tumor cells through B7-H4-dependent 4-1BB clustering, resulting in strong *in vivo* antitumor effects. While ABL103 augmented T cell infiltration and the ratio of intra-tumoral $CD8^+$ T/Treg in tumor microenvironment (TME), no systemic immune response was observed. Mutually exclusive expression pattern of B7-H4 and PD-L1 raised the question on combination effect of ABL103 and PD(L)-1 inhibitors. While most ovarian and triple negative breast cancer patient tissues showed B7-H4 expression, only a few tissues showed PD-L1 expression. To understand how ABL103 modifies TME alone or in combination with immune checkpoint inhibitors, ABL103 was treated alone or in combination with pembrolizumab in two mouse models including MC38/hB7-H4 (immune hot tumors) and B16F10/hB7-H4 (immune cold tumors). In the advanced murine tumor model of MC38/hB7-H4, ABL103 strongly suppressed tumor progression alone or in combination with pembrolizumab. Marked increase of T cell infiltration was observed in the combination group compared to ABL103 alone or pembrolizumab alone. In the rapidly growing B16F10/hB7-H4 tumor model, pembrolizumab alone failed to suppress tumor progression and did not induce T cell infiltration. However, combination of pembrolizumab and ABL103 showed a marked increase of intra-tumoral $CD8^+$ T cells. Interestingly, pembrolizumab induced 4-1BB expression on CD8 T cells, whereas ABL103 induced PD-L1 expression in $CD11b^+$ cells when combined with pembrolizumab. The combination group also showed an increased proportion of MHC I/II double positive macrophages. These results support the interactive immune activation of ABL103 and pembrolizumab, which leads to synergistic activation of T cells and transition of cold TME to inflammatory TME. Overall, our study suggests that ABL103 could be a promising therapeutic antibody as monotherapy as well as combination strategy with pembrolizumab by reinvigorating immune responses in the immunosuppressive TME.

#5812 Single-cell dissection of checkpoint inhibitor hepatitis reveals insights into immune tolerance in the human liver.

Molly Fisher Thomas[1], Thomas Chan[2], Neal Smith[2], Marc Sherman[3], Swetha Ramesh[2], Alice Tirard[2], John McGuire[2], Mazen Nasrallah[4], Kasidet Manakongtreecheep[2], Jessica Tantivit[2], Leyre Zubiri[5], Dejan Juric[5], Ryan Sullivan[5], Nir Hacohen[6], Genevieve Boland[7], Georg Lauer[3], Kerry Reynolds[5], Alexandra-Chloe Villani[2]

[1]Division of Gastroenterology, Department of Medicine, Oregon Health & Science University, Portland, OR,[2]Center for Immunology and Inflammatory Diseases, Department of Medicine, Massachusetts General Hospital, Boston, MA,[3]Division of Gastroenterology, Department of Medicine, Massachusetts General Hospital, Boston, MA,[4]Division of Rheumatology, Department of Medicine, North Shore Physicians Group, Lynn, MA,[5]Division of Hematology-Oncology, Department of Medicine, Massachusetts General Hospital, Boston, MA,[6]Broad Institute of Harvard and MIT, Cambridge, MA,[7]Department of Surgery, Massachusetts General Hospital, Boston, MA

Background: Immune checkpoint inhibitors (ICIs) to treat cancer have revolutionized immuno-oncology. However, therapy is limited by frequent immune-related adverse events, including immune-mediated liver injury from checkpoint inhibitors (ILICI), which occurs in ~1-17% of patients on anti-PD-1 and/or CTLA-4 therapy. While ILICI is often mild, it can cause severe hepatic dysfunction, delay cancer therapy, and require immunosuppressive treatments that may compromise anti-tumor immune responses. ILICI shares clinical and histologic features with autoimmune hepatitis (AIH). Therefore, the study of ILICI and AIH is important for understanding how immune tolerance is lost across a spectrum of inflammatory liver diseases.
Methods: To characterize the cellular and molecular underpinnings of ILICI, we used single-cell and single-nuclei RNA sequencing with paired antigen receptor sequencing to characterize ~300,000 cells from paired liver and blood specimens from 23 patients (9 ILICI, 4 AIH, 3 controls on ICB, 7 controls not on ICB) and ~150,000 peripheral blood cells from an additional 28 control patients on ICB. ILICI was defined by a hepatocellular or cholestatic rise in liver function tests and centrilobular or panlobular inflammatory liver injury. Controls had drug-induced liver injury, hepatic steatosis, or venous outflow obstruction.
Results: Both AIH and ILICI patients showed marked expansion of clonally-related liver *CXCR6*^{Hi} *GZMK*^{Hi} tissue-resident memory CD8 T cells expressing *IFNG* and *GZMB* and multiple CD4 T cell populations including cytotoxic *GZMA*^{Hi} effectors, *CXCL13*^{Hi} effectors, and T regulatory cells. Compared to patients with AIH, those with ILICI showed a marked expansion of intravascular *CX3CR1*^{Hi} CD8 T cells and a relative depletion of tissue dendritic cells while only patients with AIH had expanded plasma B cells. Analysis of matched blood samples from the same patient cohort revealed how cellular and transcriptional signatures in the liver were mirrored in circulating immune cells. Further analysis revealed that patients with ILICI and AIH had a marked interferon stimulated gene signature in a subset of hepatocytes, increased cholangiocyte progenitors, and increased periportal liver endothelial cells, which suggests significant liver parenchymal remodeling. Lastly, we identified a *CXCL10*-expressing cholangiocyte population that was expanded in both AIH and ILICI and was most pronounced in an individual with checkpoint inhibitor-associated cholangitis.
Conclusions: In defining the cellular and transcriptional programs that are altered in ILICI and AIH, we have identified novel immune perturbations implicating PD-1 and CTLA-4 in liver immune tolerance. These discoveries offer promising avenues for the development of targeted diagnostics and therapeutics in the management of liver-related toxicities associated with immunotherapy.

#5813 Evolution of the tumor immune microenvironment (TIME) in hepatocellular carcinoma (HCC) with liver metastases treated with atezolizumab-bevacizumab (INTEGRATE).

Harry Myles Harvey[1], Stephanie Wong[2], Selina Melillo[2], Jehan Vakharia[2], Simone Stone[2], Azin Sayad[1], Ben Wang[2], Pamela Ohashi[2], Rachel Garonce-Hediger[3], Raymond Jang[1], Robert C. Grant[1], Eric X. Chen[1], Jennifer Knox[1], Adrian Sacher[2], Leo M. L. Chan[2]

[1]Department of medical oncology, UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Department of Immunology, University of Toronto, Toronto, ON, Canada,[3]F. Hoffmann LaRoche, Basel, Switzerland

Background: HCC is the most common form of primary liver cancer and the 3rd leading cause of cancer death globally. Combination of atezolizumab-bevacizumab (AB) demonstrated an impressive 19-month median survival in 1st line HCC (IMbrave-150) and a HR (0.66) that has not been surpassed by newer combinations and remains an important standard of care with an ORR of 32%. Despite advancements in the treatment of advanced HCC, ~30% of patients demonstrate no response to therapy. It is theorized that there is a dynamic interplay between the liver TIME and HCC. We performed an exploratory evaluation of the evolution of the TIME in HCC treated prospectively with AB

Methods: The study was carried out at Princess Margaret Cancer Centre between July 2021 and June 2024. Patients had a histologically confirmed diagnosis of inoperable HCC, Child's Pugh Class A and were receiving AB. Biopsies of tumor and normal liver were performed at pre-treatment and at the time of progression. Blood and stool samples were collected at pre-treatment, 3-4 weeks post initiation of therapy and the time of progression. Blood samples were analyzed for cfDNA, alpha-fetoprotein (AFP) and immune cell phenotyping using 30+ marker spectral flow cytometry panels and stool samples were analyzed for microbiome.

Results: The analysis included 8 treatment response evaluable patients with paired tumor samples, median age of 63 (46-77) years, 5 patients had hepatitis B/C as a risk factor for HCC, 2 non-alcoholic and 1 alcoholic liver disease. 3 patients had progressive disease at 1st interval CT, with 2 patients had ongoing response after >30 months. Patients with a baseline frequency of circulating cytotoxic CD8+ T_{EFF} cells (effector T cells) above the median value (3.78%) exhibited numerically improved PFS (P=0.0265) compared to those with lower frequencies (median PFS: 12.67 months vs. 2.4 months; HR 0.12, 95% CI: 0.01-1.08). T_{EFF} cells are terminally differentiated (TCF1-CD57+), but not exhausted ($PD1^{low}TIGIT^{low}$).

Conclusion: A greater knowledge of the TIME and how it changes with therapy is key to understand which patients are likely to respond to immune checkpoint inhibition. Our findings suggest that enrichment of preexisting, circulating cytotoxic CD8+ T_{EFF} cells may be important for mediating treatment responses to immune checkpoint inhibition in HCC patients. Deep immune profiling is being conducted on serial tumor biopsies using combined single-cell TCR sequencing, and transcriptomic and protein expression analysis (CITE-Seq) to characterize tissue-specific immune responses and identify potential virus-specific T cell clones. This analysis will be updated and has the potential to identify mechanistic biomarkers predictive of response or resistance to treatment.

#5814 Immune-related adverse effects in patients with autoimmune disorders treated with immune checkpoint inhibitors.

Aseel Saadeh[1], Pragosh Saini[2], Favour Nelson[1], Sumera Khan[3], Christian Adonizio[3], Ahmad Hanif[3]

[1]Internal Medicine, Geisinger Medical Center, Danville, PA,[2]Geisinger Commonwealth School of Medicine, Scranton, PA,[3]Hematology and Oncology, Geisinger Wyoming Valley Medical Center, Wilkes Barre, PA

Background: Immune checkpoint inhibitors (ICI) have tremendously improved outcomes for various cancers but can be associated with immune-related adverse effects (IrAE), which can affect multiple organ systems. For patients with pre-existing autoimmune diseases (AD), there is an added risk of exacerbating autoimmunity, either through a flare of prior IrAEs or the development of de novo IrAEs during ICI therapy. Clinical trials leading up to FDA approval of ICIs excluded patients with pre-existing AD, resulting in a lack of data on the specific risks faced by this patient population. Our study aims to assess whether patients with pre-existing AD are more likely to develop IrAEs when treated with ICIs, and if so, whether these IrAEs are more severe.

Methodology: We conducted a retrospective chart review of all patients diagnosed with AD and received ICIs for treatment of a solid tumor malignancy within the Geisinger Health System from January 1, 2017, to December 31, 2023. We analyzed the occurrence, subtype, and severity (grade) of IrAEs based on the Common Terminology Criteria for Adverse Events (CTCAE). Additionally, we assessed steroid use, treatment discontinuation, and hospitalization rates.

Results: A total of 250 patient charts were identified using the cancer registry, 105 of them were excluded due to the absence of a pre-existing AD. Of the 145 patients with a pre-existing AD, 59 (40.7%) developed an IrAE, and 21 (14.5%) developed a severe (grade 3/4) IrAE. Additionally, 44 (30.3%) patients required steroids for the treatment of IrAE, and 12 (8.3%) were hospitalized due to an IrAE. The most prevalent IrAEs were colitis, rash, hypothyroidism, transaminitis, and pneumonitis, which occurred in 52 (35%) cases; of these, 13 (8.9%) were severe (grade ¾).

Discussion: When comparing our results to those of previous studies, we found that the rates and severity of IrAEs were higher in patients with pre-existing AD compared to historical data on patients without AD. A meta-analysis by de Velasco et al. of 21 studies reported an IrAE incidence of 28% for all grades and 5% for grades 3 and 4. Similarly, Silverstein et al. analyzed 3,137 patients treated with ICIs and found that 3.8% were hospitalized due to IrAEs. These significant differences underscore the need for multidisciplinary collaboration and heightened monitoring for IrAEs in patients with AD.

#5815 Both CD4 and CD8 T cells mediate antitumor immunity to prevent development of neoantigen-expressing autochthonous sarcomas.

Sabelo Mndeni Lukhele[1], David G. Kirsch[1], Jonathon E. Himes[2]

[1]Princess Margaret Cancer Centre (UHN), Toronto, ON, Canada,[2]Department of Pharmacology and Cancer Biology, Duke University, Durham, NC

Sarcoma is a rare, aggressive and highly metastatic disease. The efficacy of current treatment approaches including surgery, chemotherapy and radiation is limited hence the recent focus in novel immunotherapy. However, immunotherapy research for sarcoma is impeded by our limited understanding of the antitumor immune responses, largely due to the lack of faithful mouse models expressing known sarcoma neoantigens. Here, we combined CRISPR/Cas9 and sleeping beauty transposase technology to develop an autochthonous orthotopic murine sarcoma model that allows the tumor to coevolve with the immune system and expresses MHCI (mLama4) and/or MHCII (mItgb1) sarcoma neoantigens. We show that expression of mLama4 and/or mItgb1 neoantigens prevented tumor development in a T-cell dependent manner. Indeed, tumors expressing both neoantigens only developed following depletion of both CD4 and CD8 T cells. Similarly, growth of mItgb1-expressing tumors was observed only in CD4 T cell deficient mice. Tumor-specific T cells were detected, using MHC-mLama4/mItgb1 tetramers, as early as ten days post tumor induction and persisted for more than three months. Both CD4 and CD8 tumor-specific T cells were activated, in cycle, and produced effector cytokines IFNγ and TNFα, suggesting that they both mediate antitumor immunity in part by direct killing of tumor cells. Thus, CD4 and CD8 T cells independently contribute to cancer immunosurveillance leading to clearance of neoantigen-expressing sarcomas.

#5816 TCR clonal tracking maps tumor-draining lymph nodes as reservoirs fueling neoadjuvant PD-1 blockade in resectable NSCLC.

Rachel L. Honigsberg[1], Tatiana Cruz[2], Geoffrey Markowitz[2], Liron Yoffe[2], Stephanie Tang[2], Marissa Micheal[2], Ozge Dicle[2], Olivier Elemento[2], Nasser Altorki[2], Jonathan Villena-Vargas[2]

[1]Cornell University, Ithaca, NY,[2]Weill Cornell Medicine, New York, NY

Introduction: PD-1 blockade with platinum chemotherapy (chemo/IO) has transformed treatment for resectable non-small cell lung cancer (NSCLC). However, gaps in understanding the adaptive T cell response impede progress, resulting in a lack of predictive biomarkers and mechanism-informed combination therapies. We hypothesize that novel T cell clones activated in the tumor draining lymph node (tdLN) in response to PD-1 blockade are critical drivers of therapeutic outcomes.
Methods: Tumor, tdLNs (stations 11-12), and peripheral blood (PB) were collected from 16 NSCLC patients (stage I-IIIB). Nine patients received neoadjuvant chemo/IO, while seven were treatment naïve. Samples underwent pathological evaluation and stratified by pathological response based on residual viable tumor. Clonal dynamics were assessed across tissues using single-cell TCR barcoding integrated with transcriptional profiling (scRNASeq) by using machine learning (ML) approaches.
Results: Paired scRNA/TCR sequencing of 670,000 T cells and 110,000 clones from 47 tissue samples revealed deep clonal dynamics across tumor, tdLN, and PB. Tumor matched and expanded ($n \geq 10$) shared TCRs between tumor and tdLN (TM clones) accounted for 5% of clones, 75% of which were found in the PB (3.7% of clonal population). Chemo/IO-treated patients exhibited an increase in expanded TM clonal diversity (69 vs. 47 clones/1000 expanded T cells, $p = 0.07$) and a higher proportion of TM T cells within expanded T cells across all three tissues (83% vs. 68%, $p < 0.05$). Notably, 12 of 111,000 unique TCRs were shared across at least two patients. Clonal fate mapping using TCR sequences and UMAP clustering revealed distinct phenotypic trajectories. TM tdLN-resident clones were enriched in stem-cell quiescence genes (SELL, TCF7, CCR7) and signatures ($p < 0.001$), relative to the cytotoxic and exhausted tumor-infiltrating T cells (TILs) ($p < 0.001$). Chemo/IO patients' tdLN and TILs exhibited T cell activation via AP-1 pathway ($p<0.05$), while untreated patients' TILs were exhaustion. Patients with pathologic response had a less differentiated TM TILs compared to non-responders. ML further identified a 280-gene activation signature indicative of tdLN-linked responses to PD-1 blockade ($p < 0.05$) led by CXCL13 and CXCR6, validated in a resectable murine model. Persisting TM clones circulating in PB 6 months post-resection retained effector-memory phenotypes (CXCR3, TCF7, CD44).
Conclusion: Our findings highlight the distinct role of tdLNs in contributing to treatment responses to PD-1/PD-L1 blockade. This alternative mechanism appears driven by tdLN-mediated T cell activation and tumor infiltration, rather than the reactivation of pre-existing TILs. These insights strongly support the development of pre-lymph node resection treatment strategies, and future approaches targeting lymph node-driven immunity in resectable NSCLC.

#5817 Single cell profiling of diffuse pleural mesothelioma reveals tumor cell plasticity and dynamic immune responses when exposed to platinum, pemetrexed and nivolumab.

Michael Offin, **Matthew Zatzman**, Yonit Lavin, Jennifer L. Sauter, Nataly Naser Al Deen, Nicholas Ceglia, William D. Travis, Rania G. Aly, Andreas Rimner, Annemarie Shepherd, Charles B. Simone, Mark G. Kris, Michelle S. Ginsberg, Andrew Chow, Alvaro Quintanal-Villalonga, Sohrab P. Shah, Charles M. Rudin, Valerie W. Rusch, Prasad S. Adusumilli, Marjorie G. Zauderer

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Diffuse pleural mesothelioma (DPM) is an aggressive malignancy where even patients with potentially resectable disease have poor outcomes. With an evolving understanding of the role of pleurectomy/decortication (P/D) in patients with resectable disease, the need to improve upfront therapies is more urgent. In this single institution prospective pilot study of nivolumab with platinum (cisplatin/carboplatin) and pemetrexed prior to P/D (2 cycles) for patients with resectable DPM (NCT04162015), we report clinical outcomes and multimodal profiling of tumor tissue and plasma samples using single cell RNA sequencing (scRNAseq), whole exome sequencing, and gross pathological assessment. In particular, we perform in-depth exploration of DPM transcriptional heterogeneity, including tumor cell intrinsic changes and microenvironment features associated with clinical responses to ICI.
Results: 22 patients received neoadjuvant chemo-immunotherapy and 19 underwent attempted P/D (2 progressed and 1 declined surgery) within 30 days of the planned resection date. In the 19 patients that went for P/D, the median OS from the start of neoadjuvant therapy was 34mos with a PFS of 14mos (median follow-up: 32mos). scRNAseq was performed on 20 resection specimens from 16 patients with available material, including three patients with matched pre/post resection specimens. We also analyzed single cell transcriptomes from five non-ICI treated DPM samples. We discover that malignant DPM cells exist on a phenotypic continuum between mesothelial-like and fibroblast-like states, defined based on transcriptional similarity to their normal counterparts. Notably, these ‘fibroblast-like’ DPM cells were present in multiple patients, including those pathologically defined as epithelioid, and were predicted to arise from the same ancestral clonal expansion based on single-cell derived copy number profiles. These cells were present in patients prior to receiving ICI, and in certain cases corresponded to samples with gross pathological features such as a spindle-like tumor cell morphology. Focusing on features defining ICI-responsive patients, we find significantly increased abundance of cytotoxic CD8 T cells, ISG^+ (interferon stimulated) T cells, $FOXO1^+CD4^+$ and $CXCL13^+CD4^+$ T cells in patients with PFS greater than 12 months.
Conclusions: Neoadjuvant platinum, pemetrexed, and nivolumab was reliably able to be given to patients with DPM without impacting their ability to undergo P/D. To our knowledge this is the largest cohort of DPM resection specimens analyzed by scRNA-seq and has revealed important insights into the transcriptional heterogeneity of DPM. This in depth characterization provides foundational insights needed to characterize DPM response to chemo-IO and support future biomarker development.

#5818 Incidence and management of steroid-refractory immune checkpoint inhibitor pneumonitis: a single-center retrospective analysis.

MacKenzie Adams[1], Charmi Trivedi[1], Sapana Gupta[1], Jacqueline Chu[1], Curtis Petruzzelli[1], Kanika Malani[2], Rebecca Steuer[3], William Park[4], Sathwik Madireddy[1], Sandeep Jain[3], Benedito Carneiro[3], Matthew J. Hadfield[3]

[1]Brown University Health, Providence, RI,[2]Warren Alpert Medical School of Brown University, Providence, RI,[3]Department of Hematology/Oncology, Brown University Health, Providence, RI,[4]Department of Gastroenterology, Brown University Health, Providence, RI

Introduction: Pneumonitis is a serious and potentially lethal complication of treatment with immune checkpoint inhibitors (ICI). In a rare subset of patients, front-line treatment with steroids is ineffective, necessitating a second-line steroid-sparing agent. We conducted a single-center, retrospective analysis of patients treated with ICIs to determine incidence and outcome patterns of patients who develop pneumonitis.

Methods: We conducted manual chart review on a cohort of 2,820 patients treated with ICIs at our institution from 2015 to 2024. Steroid-refractory pneumonitis was defined as no clinical improvement between 48 hours and up to 14 days after initiation of high-dose corticosteroids. Electronic medical records were then reviewed to identify the clinical features at presentation and overall outcomes.

Results: Of 2,820 patients, we identified 69 with ICI pneumonitis and 11.6% (8/69) with steroid-refractory ICI pneumonitis. The mean age was 69.5 years (range: 42-91) and 53.6% were female (37/69). Most patients had lung cancer (53.6%, 37/69) followed by both renal cancer and melanoma (both: 13%, 9/69), with the treatment goal being palliative for 79.7% (55/69). The mean number of ICI treatments before steroid-refractory ICI pneumonitis diagnosis was 5, compared to 12 for all patients with pneumonitis. Diffuse alveolar damage (DAD) was the most common radiologic pattern amongst steroid-refractory cases (5/8, 62.5%). After corticosteroid failure, patients were managed with: infliximab (n=1), mycophenolate (n=1), a combination of IVIG and infliximab (n=1), no second-line agent in lieu of a longer steroid course (n=1), or hospice alone (n=4); 3/8 (37.5%) required ICU-level of care, 7/8 (87.5%) required some form of oxygen supplementation (ranging from nasal cannula to noninvasive positive pressure ventilation). Ultimately, 6/8 (75%) patients died from steroid-refractory ICI pneumonitis. The patient that received infliximab alone recovered from his pneumonitis but ultimately died from cancer progression. The patient that elected a longer steroid course had recurrent pneumonitis after steroid taper but eventually recovered.

Conclusions: Steroid-refractory ICI pneumonitis is uncommon, only affecting 11.6% of ICI pneumonitis cases at our institution, however, it is responsible for significant mortality. As seen in other studies, steroid-refractory ICI pneumonitis occurred early in ICI treatment. After corticosteroid failure, only 3/8 patients were treated with a second immunosuppressant agent, indicating second-line immunosuppressants may be underutilized in this population. Little data has been generated on outcomes of patients treated with high-dose steroids without second-line therapy. There is a significant need for prospective, randomized trials to determine the best treatment strategies for this patient population.

#5819 Anti-cancer immune effects of PT-112 monotherapy across two disease indications.

Arun Rajan[1], **Tyler D. Ames**[2], Carolina Celades-Errando[1], Christina Y. Yim[2], Shannon Swift[1], Meredith J. McAdams[1], Laercio DaSilva[1], Wiem Lassoued[1], Hana Bagheri[1], Maria T. Congenie[2], Howard I. Scher[3], Alan H. Bryce[4], James L. Gulley[1], Jeffrey Schlom[1], Renee N. Donahue[1]

[1]National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Promontory Therapeutics Inc., New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]City of Hope Cancer Center, Phoenix, AZ

Background: PT-112 is a small molecule inhibitor of ribosome biogenesis under development for several cancer indications. Preclinical studies have demonstrated PT-112's ability to induce immunogenic cell death (ICD) and synergize with various anti-cancer agents, including immune checkpoint inhibitors (ICIs). PT-112 has shown durable benefit in patients with advanced cancers, with pre-clinical data supporting an immune-mediated mechanism of action. This report aims to further elucidate the immunological effects of PT-112 through comprehensive immune profiling of blood and tissue samples from ongoing Phase II trials in thymic epithelial tumors (TETs, NCT05104736) and metastatic castration-resistant prostate cancer (mCRPC, NCT02266745).

Methods: Patient samples from the TET trial were analyzed by flow cytometry for 158 subsets of peripheral blood mononuclear cells and serum cytokines and soluble factors. Paired tumor biopsies from a subset of patients were analyzed for changes in immune cell composition before and on treatment. Patient blood samples from the mCRPC trial were analyzed via TCR sequencing to identify novel and expanding T cell clones and to monitor changes in the T cell fraction.

Results: In the TET trial (14 patients), peripheral immunome changes reflective of immune activation included an increase in proliferative CD4+ T cells, activated and proliferative CD8+ T cells and NK cells, including NKp46+ NK cells, and PD-L1-expressing refined monocytes, and a decrease in naïve CD4+ T cells. Furthermore, increases in proinflammatory cytokines IFN-γ and TNF-α, along with decreases in immunosuppressive factors VEGF and TGF-β1 were observed (n = 7). Pooled results from tumor biopsies (n=3) showed an increase in immune cell density with increased expression of markers of immune activation (granzyme B and IFN-γ). In the mCRPC trial, 26/74 (35%) patients showed evidence of marked T cell clonal expansions, many of which were novel clones not detected at baseline. Across the population there was a statistically significant (Wilcoxon signed-rank test, $p < 0.0005$) median increase in the T cell fraction of 20%.

Conclusions: In line with prior non-clinical and clinical findings, data from these ongoing Phase II trials show that PT-112 induces robust signals of immune activation and ICD across the adaptive and innate immune systems and are indicative that PT-112's immune effects play a significant role in its anti-cancer mechanism.

#5820 Spatial and cellular immune landscapes of non-small cell lung cancer in association with response to neoadjuvant chemoimmunotherapy.

Zahraa Rahal[1], Tieling Zhou[1], Alejandra G Serrano[1], Jiping Feng[1], Alessandra Vaccaro[1], Ansam Sinjab[1], John T. Le[1], Xin Sun[1], Michael Wang[1], Wei Hu[1], Jianjun Zhang[1], Tullia Bruno[2], Hai T. Tran[1], Stephen G. Swisher[1], Cheuk Hong Leung[1], J. Jack Lee[1], Jing Wang[1], John Victor Heymach[1], Don Lynn Gibbons[1], Ignacio Ivan Wistuba[1], Annikka Weissferdt[1], Jared K. Burks[1], Luisa Maren Solis Soto[1], Humam Kadara[1], Tina Cascone[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]UPMC Hillman Cancer Center, Pittsburgh, PA

Neoadjuvant and perioperative immunotherapy with checkpoint inhibitors (ICIs) combined with chemotherapy (CT) has improved outcomes for patients with resectable non-small cell lung cancer (NSCLC). However, over half of treated patients experience non-response due to poorly understood mechanisms, underscoring the need to elucidate the factors mediating therapeutic efficacy.

Here, we aimed to dissect the tumor-associated immune landscape in lung tissues from patients with varying levels of residual viable tumor (%RVT) following neoadjuvant chemoimmunotherapy. We analyzed 28 lung tissue samples from 24 patients, including non-squamous (n=17) and squamous (n=7) NSCLCs, with pathological complete response (pCR, n=5), major pathological response (MPR, n=1), and no MPR (n=18). Multimodal spatial transcriptomics (ST) (Visium CytAssist, 10x Genomics) and single-cell RNA sequencing analysis of fixed cells (scFFPE-seq) from consecutive tissue sections was performed in association with therapeutic response and clinicopathological variables.

ST analysis revealed lymphoid aggregates (LAs) and tertiary lymphoid structure (TLS) signatures in both responders and non-responders. Notably, pCRs were enriched in squamous cases. B cells and plasma cells (PCs) were significantly more enriched in responders (pCR and MPR), with CXCL13-CXCR5 ligand-receptor interactions spatially overlapping with TLS signature expression, suggesting a functional interplay that may be crucial in mediating response to therapy. In responders, PCs appeared to differentiate from the LAs in space into the tumor bed, possibly alluding to active humoral anti-tumor immunity. A significant abundance of macrophages, including *CTSK+*, *C1Q*$^{+}$ and M2-like *SELENOP*$^{+}$ subsets, was observed in responders, particularly surroundings TLSs. *IL2RB*$^{+}$ natural killer (NK) cells were also more prevalent in cases with pCR and MPR. The abundance of immune populations was inversely correlated with %RVT; we observed incremental increase in immune proportions with decreasing %RVT. Conversely, non-responders exhibited higher levels of migratory dendritic cells (cDC3) and cDC2 subsets, CD4^{+} naïve T, regulatory T (Tregs), Th17 CD4^{+}, and *GZMK*$^{+}$ exhausted T, Th1, and *FCGR3A*+ NK cells, as well as higher levels of *KIT*$^{+}$ *AHR*$^{+}$ *KLRG1*$^{+}$ group 3 innate lymphoid cells (ILC3).

These findings reveal distinct immune cell compositions and states associated with response to neoadjuvant chemoimmunotherapy in NSCLC. Ongoing efforts aim to characterize lineage-restricted subpopulations and immunogenomic features underlying therapeutic response, which thus could inform biomarker discovery and streamline development of personalized therapeutic strategies to further improve patient outcomes.

#5821 Targeting adenosine receptor signaling enhances anti-PD-L1 therapy efficacy in MTAP-deficient urothelial cancer via reprogramming tumor-associated macrophages.

Ying Mei, Jianfeng Chen, Yuxue Zhang, Yu-Yi Chu, Omar Alhalabi, Jianjun Gao

UT MD Anderson Cancer Center, Houston, TX

Methylthioadenosine phosphorylase (MTAP) deficiency in urothelial cancer (UC) correlates with poor clinical outcomes and reduced response rates to immune checkpoint inhibitor (ICI) therapy. Understanding the mechanisms by which MTAP loss contributes to ICI resistance and identifying therapeutic strategies to enhance ICI efficacy in MTAP-deficient tumors is of critical importance. Using CRISPR-Cas9, we deleted MTAP in the MB49 murine UC cell line and established orthotopic bladder tumors with wild-type (WT) and MTAP knock-out MB49 cells. CyTOF analysis revealed that MTAP-deficient tumors showed a marked reduction in M1-like macrophages (~50%) and a substantial increase in M2-like macrophages (~3-fold). Mechanistically, MTAP-deficient tumors accumulated elevated levels of methylthioadenosine (MTA, >100-fold) in the tumor microenvironment (TME), which drove the polarization of tumor-associated macrophages (TAMs) towards a pro-tumorigenic M2-like phenotype via adenosine receptor (A2A/A2B) signaling. Notably, inhibition of A2A/A2B adenosine receptors significantly enhanced anti-PD-L1 therapy efficacy, achieving an overall tumor growth inhibition of 50% compared to anti-PD-L1 monotherapy. These findings suggest that targeting the adenosine pathway may provide a promising strategy to improve therapeutic outcomes in MTAP-deficient urothelial cancer.

#5825 SWA1211, a next generation HPK1 inhibitor exhibits superior anti tumor efficacy in preclinical studies.

Guanglong Sun, Yuyang Ge, Huting Wang, Desheng Kong, **Carrie Xiang**

Beijing Stonewise Technology Co., Ltd., Beijing, China

Immune oncology is an important breakthrough for cancer therapy represented by immune checkpoints inhibitors like PD-1/L1, CTLA4 antibody drugs. Although this type of drug has become the standard treatment for many kinds of cancers, a large proportion of patients fail to respond to them or become resistant eventually. Therefore, new mechanisms or targets remain urgent to further improve the therapeutic outcomes or overcome the resistance of immunotherapy.Hematopoietic progenitor kinase 1 (HPK1), also known as MAP4K1, belongs to the MAP4K family of protein serine/threonine kinases. HPK1 is a negative regulator of T-cell signaling and has been identified as a promising target to combat cancers by eliciting robust anti-tumor immunity. Many HPK1 inhibitors are under active clinical development.SWA1211 is a best-in-class (BIC) HPK1 inhibitor designed using Stonewise's proprietary 3D molecular generation model. To conquer the challenge of selective inhibition on HPK1, a steric group was designed to extend toward the small hydrophobic pocket formed by Leu23 and Val31 in HPK1, which does not exist in GLK due to the different residue, Ile22. This unique molecular structure design significantly improved potency and selectivity of our compounds, and excellent immune cell activation was achieved (biochemical assay IC_{50}=0.9nM @ATP 1mM; human T-cell activation EC_{50}=9nM). Selectivity study showed a unique kinases inhibition profile with no obvious off-kinase activity related risk.More importantly, when compared to other HPK1 inhibitors developed by leading developers, SWA1211 stimulates T cell activation efficiently in an ever-known broadest concentration range without any exhaustive effect (up to a concentration of 1000 folds of EC_{50}). This unique non-bell-shaped immune cell activation curve translates to unmatched efficacy as no other HPK1 inhibitors have shown in preclinical settings. Single agent of SWA1211 induces tumor shrinkage in Hepa1-6 and EMT6 mouse syngeneic tumor models. GLP toxicity studies indicated ideal therapeutic index was obtained. We believe SWA1211 to be a promising next generation immune therapy for cancer patients.We have completed all IND enabling studies for SWA1211 and the results demonstrated a favorable drug-like profile. We expect to receive the green light for a clinical trial from the FDA and NMPA by March 2025; the clinical trial will be initiated immediately afterward.

#5826 Development of multivalent antibody-based novel therapeutic cancer vaccine in glioblastoma multiforme (GBM) treatment.

Sunghyun Yoon[1], Sungmuk Kang[1], Yeji Byeon[1], Dongmin Chun[1], Hong Kyu Lee[2], Kyung-gi Hyun[1], Sunghyun Byun[1], Eunyoung Cho[1], Yongjun Kang[1], Chaerin Yoo[1], Hong Jai Lee[1], **Jiyeon Hong**[1], Chungmin Lee[1], Kyung-Chul Choi[2], Gyongsik Ha[1]

[1]IMBiologics Corp., Suwon, Korea, Republic of,[2]Chungbuk National University, Cheongju, Korea, Republic of

Glioblastoma multiforme (GBM) is the most prevalent high-grade malignant brain tumor and is associated with a very poor prognosis. Currently, there are no targeted therapies available for this cancer, and only general chemical drugs are being used. This is primarily due to the challenges posed by the blood-brain barrier (BBB) in drug delivery and the lack of sufficient research on its pathogenesis. Recently, a strong association between CMV (Cytomegalovirus) and GBM has been reported in various studies, and therapies targeting CMV are now undergoing clinical trials. Especially, dendritic cell (DC) cancer vaccines represent a promising therapeutic strategy for GBM, with CMV pp65 emerging as a particularly relevant target antigen. Recent clinical trials have provided evidence supporting the efficacy of select DC vaccines. Nevertheless, the production of DC vaccines remains a labor-intensive, costly, and time-consuming process, emphasizing the critical need for innovative approaches to overcome these limitations. In this study, we developed IMB-402, containing the Specific T-cell Activating Modulator (STAM) built on our engineered IgM-based multivalent antibody backbone platform, ePENDY (engineered PENtamer boDY). IMB-402 consists of ten CMV pp65-derived peptide-loaded-HLAs linked to ePENDY to stimulate priming signal of CD8+ T cell by TCR cluster. Also, we linked a CD40 agonistic scFv as a costimulatory signal molecule to the J chain of ePENDY, mimicking cognately licensed dendritic cells (DCs) to prevent T cells from entering an anergic state. We observed that IMB-402 can expand CMV pp65-specific CD8+ T cells and functionally activate these cells. Notably, we found that this effect occurs even in conditions where only CD8+ T cells are present, without any DCs. This highlights the potential of IMB-402 as an alternative to DC vaccines, offering a promising treatment option for immunosuppressive cancer patients whose DCs fail to respond appropriately. Moreover, the superior effects on expansion and activation of CMV pp65-specific CD8 T cells, compared to a competing drug currently in clinical trials, suggest that IMB-402 has the potential to become a successful treatment for GBM. Additionally, synergistic effect of IMB-402 with anti-PD1 observed using a humanized mouse model indicates that IMB-402 is expected to have robust anti-tumor activity in combination with immune checkpoint inhibitors. Overall, these findings suggest that IMB-402 could represent a new paradigm in cancer vaccine technology, highlighting its potential for development as a GBM treatment.

#5827 Hydroxychloroquine increases the tumor killing efficiency via elevating the membrane MHC-I protein levels of tumor cells.

Man Zhang, Chen Huang, Xingming Ma, Wenjia Zhuang, Huajun Jin

Shanghai Juncell Therapeutics Co., Ltd, Shanghai, China

Background: Hydroxychloroquine (HCQ) was firstly developed as an antimalarial drug, while recently it has been used to treat various types of cancer due to its molecular mechanism in inhibiting autophagy process, induction of apoptosis, and the inhibition of CXCL12/CXCR4 pathway in cancer cells. Previous studies found that autophagy promotes immune evasion of pancreatic cancer by degrading major histocompatibility complex class I (MHC-I), so we supposed HCQ treatment might restore or even elevate the MHC-I levels of tumor cells through inhibiting autophagy and then benefit tumor infiltrating lymphocytes (TILs) immunotherapy.
Methods: Malignant melanoma cell line A-375, non-small cell lung cancer (NSCLC) cell line NCI-H2122, ovarian cancer OVCAR-8 and glioblastoma U-87 MG were subjected to HCQ treatment for 48 hours and the protein levels of membrane MHC-I and programmed cell-death ligand 1 (PD-L1) were measured by flow cytometry. IFN-γ was set as a positive control for its well-known function in elevating MHC-I levels. Western blots were carried out to verify the autophagy inhibition. Real-time cell analysis (RTCA) was used to evaluate the in vitro cytotoxicity for transgenic hmTCRT cells specifically recognizing NY-ESO-1 epitope and targeting HCQ treated or non-treated NY-ESO-1 positive A-375 cells. Using the same concentrations as treating tumor cells, 15μM, 20μM HCQ treatment was carried out on TILs in rapid expansion phase to determine whether their proliferation would be affected.
Results: HCQ treatment can significantly elevate the protein levels of membrane MHC-I for tumor cell lines A-375, NCI-H2122, OVCAR-8 and U-87 MG (P value of t-test <0.01), and the elevation can sustain for 72 hours after removing HCQ from the culture system. After HCQ treatment, the surface PD-L1 levels of aforementioned four cell lines didn't change significantly compared to DPBS negative control group, contrarily PD-L1 levels of IFN-γ treatment groups increased significantly. Western blot results indicated that levels of LC3II and p62 increased significantly after HCQ treatment, suggesting that the autophagy process was inhibited. HCQ pre-treatment can significantly elevate the killing efficiency of hmTCRT cells targeting NY-ESO-1 positive A-375 cells. 15μM, 20μM HCQ treatment didn't affect TILs' proliferation, which were the same concentrations as treating tumor cells.
Conclusions: Our studies indicated that HCQ can significantly increase the tumor killing efficiency via elevating the membrane MHC-I protein levels of tumor cells while it doesn't affect TILs' propagation. In addition, its effect on surface PD-L1 is not significant, which is more advantageous than IFN-γ. These results can provide preclinical evidences for HCQ pretreatment before the adoptive cell therapy of TILs in our clinical trials (NCT06375187).

#5828 Development of NK humanized mice models for the in vivo evaluation of NK cell-based therapeutics.

Dong Wang[1], zhixiang zhang[1], zhongbao song[2], xiangnan qiang[1], qingyang gu[1]

[1]WuXi AppTec, Shanghai, China,[2]WuXi AppTec, nantong, China

With the recent advancements in anti-tumor immunotherapy, novel treatments have emerged and progressed rapidly. Several strategies are now being employed to enhance the efficacy of natural killer (NK) cells in tumor immunotherapy, including the use of monoclonal and multi-specific antibodies, as well as immune modulator molecules. Given these developments, there is an urgent need for the establishment of appropriate mouse models to effectively evaluate the therapeutic potential of these emerging immunotherapies.

In this study, we developed a humanized mouse model for the specific reconstitution of functional and durable human NK cells within a murine system. In this model, human NK cells were purified from peripheral blood mononuclear cells (PBMCs) using magnetic bead separation, expanded in vitro, and subsequently engrafted into human IL-15 transgenic NOG mice. We collected blood samples from these mice to monitor human NK cell kinetics and profile using flow cytometry. The therapeutic efficacy of an anti-CD20 antibody was then evaluated in NK-humanized model using the SU-DHL-2 subcutaneous xenograft tumor model. Results indicated that anti-CD20 treatment was ineffective in non-NK-humanized mice. In contrast, in NK-humanized mice, human NK cells significantly inhibited tumor growth via antibody-dependent cellular cytotoxicity (ADCC). Additionally, we assessed NK cell intratumoral infiltration and the expression of activation markers at the end of the in vivo efficacy study, providing further insights into the immune response in the tumor microenvironment.

In summary, we have developed a humanized mouse model capable of sustaining functional human NK cells for extended periods, ranging from weeks to months. This NK-humanized model provides a valuable preclinical platform for evaluating NK-modulating therapies and hold promise as a tool to accelerate the development of novel NK-based immunotherapeutics.

#5830 Combining DNA methylation inhibition and STING agonist in the treatment of metastatic triple-negative breast cancer.

Sofiane Berrazouane[1], Xiaoting You[1], Jack Su[1], Margarita Bartish[1], Rhea Dumitrescu[1], Marios Langke[1], Young Im[1], Benjamin Lebeau[2], Sonia del Rincon[1], Josie Ursini-Siegel[1], Michael Witcher[1]

[1]Oncology, McGill University, Montreal, QC, Canada,[2]Nanyang Technological University, Singapore, Singapore

Triple-negative breast cancer (TNBC) is an aggressive breast cancer associated with early metastatic events leading to a poor prognosis. According to the American Cancer Society, the 5-year relative survival rate is 91% in patients with localized TNBC but only 12% for those with metastatic TNBC. Thus, there is an urgent need to understand the mechanisms that drive TNBC metastasis to uncover more effective therapeutic approaches. In this regard, we first profiled the RNA-Seq and DNA methylation enrichment in 8 metastatic TNBC cell lines with bone, liver and lung organotropism and then compared them to 3 parental TNBC cell lines. The RNA-Seq data showed that the downregulation of IFN-type-1 pathways is associated with TNBC metastatic organotropism in the lung, liver and bone. Surprisingly, the DNA methylation profiling revealed that the IFN-type-1-related genes are under DNA methylation regulation. The inhibition of DNA methylation with decitabine increased the expression of IFNβ gene in metastatic TNBC cell lines. This supports that targeting DNA methylation and stimulating the IFN-type-1 pathway could represent a new vulnerability for metastatic-TNBC. In this regard, the use of STING agonist, a known stimulator of IFN-type-1, synergizes with decitabine in reducing the viability of 6 metastatic TNBC cell lines with lung, liver and bone organotropism. More importantly, the decitabine/STING therapy showed a potent effect in targeting TNBC metastatic lesions in vivo and improved survival. Altogether, this work suggests that the DNA methylation inhibition and the stimulation of the IFN-type-1 pathway represent a new approach to target the metastatic-TNBC.

#5831 ABN202 (αTROP2), a sacituzumab-interferon-beta mutein fusion protein: a novel approach beyond antibody-drug conjugate therapeutics in ADC-naïve and ADC-refractory cancers.

Hee Geon Park[1], Hyun Kyung Lee[1], Myeung Ryun Seo[2], Soo Jin Ryu[2], Sungyoul Hong[3], Chan Gyu Lee[4], Hae Min Jeong[4], Sae Hyung Lee[1], Na Young Kim[1], Young Kee Shin[2], Jun Young Choi[1]

[1]ABION Inc., Seoul, Korea, Republic of,[2]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of,[3]Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of,[4]Genopharm Inc., Seoul, Korea, Republic of

Trophoblast cell surface antigen 2 (TROP2) is a cell-surface glycoprotein overexpressed in various solid tumors, including triple-negative breast cancer (TNBC), hormone receptor-positive breast cancer (HR^+ BC), and non-small cell lung cancer (NSCLC). TROP2-targeting antibody-drug conjugates (ADCs) such as Sacituzumab-govitecan (SG) and Datopotamab deruxtecan (Dato-DXd) demonstrated promising clinical efficacy in patients with TROP2-positive cancers. However, TROP2-targeting ADCs exhibit a high incidence of adverse events, a short duration of response, and frequent recurrence. Therefore, there is an unmet medical need for treatments beyond ADC therapeutics, particularly for ADC-naïve and ADC-refractory patients.
ABN202 is an antibody-cytokine fusion protein platform that fuses a potent cytotoxic and immune-modulating cytokine, interferon-beta mutein (IFN-β mutein), with an antibody via flexible protein linker. In previous studies, ABN202 utilizing the TROP2-targeting antibody, Sacituzumab (ABN202, αTROP2), demonstrated potent anti-tumor efficacy by inhibiting cancer cell growth and activating anti-tumor immunity within the tumor microenvironment. In this study, we compared the *in vitro* and *in vivo* anti-cancer efficacy of ABN202 (αTROP2) with those of SG and Dato-DXd in ADC-resistant preclinical models, as well as in xenograft and human IFNAR knock-in (hIFNAR KI) mouse models. The preclinical toxicity profiles of SG, Dato-DXd, and ABN202 (αTROP2) were evaluated using human immune cells and hIFNAR KI mouse models.
In conclusion, ABN202 (αTROP2) demonstrated potent anti-cancer efficacy and a tolerable safety profile compared to SG and Dato-DXd. Our findings suggest that ABN202 (αTROP2) represents a novel therapeutic approach beyond ADCs for both ADC-naïve and ADC-refractory cancers.

#5833 Overcoming immune anergy by targeting tumor macrophages: Rearranging the tumor microenvironment.

Frederick O. Cope, Simon A. Blackburn

Physis International, Columbus, OH

There are remarkable advances in immunotherapy which have transformed solid tumor therapy outcomes for many patients. Immunotherapy rationales include checkpoint inhibitor monoclonal antibodies (CIMA) or chimeric antigen receptor T cell therapy that have become primary treatment options and provide remarkably durable treatment responses that are generally not achieved with standard systemic non-targeted chemotherapy. A hallmark of solid tumors is their ability to induce immune anergy where the target tumor is able to evade immune surveillance. Within the solid tumor micro-environment, a critical element of this anergy maintenance is the presence of tumor-associated macrophages (TAMs). Indeed, the localization of TAMs in the tumor micro-environment is effectively co-opted into contributing toward tumor growth. We have developed two new immune-modulating therapeutic drugs that specifically address the role of TAMs in anergic immune responses. These include the synthetic CD-206 ligand PHY-001, a macrophage phenotype-shifting agent designed to act through CD-206-expressing M2-like TAMs. Its application to solid tumor microenvironments is indicated to result in a shift of TAMs to an antitumor M1-like phenotype. Alternative to TAM phenotype shifting is the induction of apoptosis of TAMs. This too, is effectively achieved through the CD-206 receptor with modification of PHY-001, such that loading of PHY-001 with an elemental anion, results in mitochondrial disruption and TAM apoptosis (Modified PHY001 --> PHY-003). Both agents have been target-tested (CD206) in vivo in humans using an approved isotopically labeled version of the molecule core. Either approach to the modification of TAMs releases the immune micro-environment from the existing anergic lock, resulting in significantly improved adaptive and innate tumor immune responses including increased cancer cell phagocytosis by a] reprogrammed existing TAMs or b] neo-localization of invading immunologically functional macrophages. These two new agents provide a novel approach to solid tumor immunotherapy where they may be used singly or in conjunction with other immunomodulating drugs. Such agents are a rational expansion in available approaches to solid tumor therapy.

#5834 Discovery of a novel Trop2-targeting immune-stimulating antibody conjugate with efficacy in pancreatic cancer models.

M. R. Mullapudi, A. Zhang, S. J. McKay, T. A. Brooks, N. L. Tumey;
Binghamton University, Johnson City, NY

Background: Toll-like receptor (TLR) and Stimulator of interferon genes (STING) agonists are emerging as potent agents in cancer immunotherapy. However, systemic administration of these small molecules carries the risk of severe off-target toxicities, such as cytokine storm. A more targeted delivery approach could enhance specificity and reduce these toxic effects. Immune-stimulating antibody-drug conjugates (ISACs), which utilize TLR or STING agonists conjugated to antibodies via specific linkers, have gained attention for their improved targeting. Our team previously designed a potent TLR7 agonist, E104, and developed a successful E104-based HER2 targeting ISAC. This new study summarizes the identification of a novel Trop2-targeting ISAC with efficacy in pancreatic cancer models.
Methods: We synthesized a library of novel linkers and their corresponding E104 ISACs. These ISACs include both glycosylated and deglycosylated versions of sacituzumab, an anti-Trop2 monoclonal antibody, alongside a control Trop2_mcValCitPABC_E104 ISAC. The ISACs were then tested for NFκB/IRF-7 activation and IL-6 induction in co-culture models and for in vivo efficacy using mouse xenograft models.
Results: Both glycosylated and deglycosylated ISACs exhibited drug-to-antibody ratios (DAR) of 6-8. The next-generation ISACs showed significantly reduced aggregation (<1-2%) compared to the control Trop2_mcValCitPABC_E104 ISAC (30%) and were significantly less hydrophobic, thus imparting an improved PK profile. In co-culture studies using BXPC3/ CFPAC-1 and RAW-Dual mouse macrophage reporter cell lines, deglycosylated ISACs triggered more specific NFκB activation than their glycosylated counterparts. Similar results were observed for the coculture of BXPC3/ CFPAC-1 and Ramos Blue, a human B lymphocyte cell line. Further, co-culture of BxPC-3/CFPAC-1 with mouse splenocytes/bone marrow-derived dendritic cells (BMDCs) resulted in strong antigen-dependent IL-6 induction. In vivo testing of these ISACs in immunodeficient mice with CFPAC xenograft models revealed that one specific ISAC, has efficacy against this pancreatic tumor model. Furthermore, a DAR 4 version of this ISAC, showed complete tumor regression in C57BL/6J mice using a hTrop2-MC38 model.
Conclusion: Pancreatic cancer is aggressive and has a poor prognosis. It has limited treatment options and urgently needs more effective therapies. Toward this end, we have designed and evaluated a library of novel Trop2-targeting ISACs. These engineered ISACs exhibited reduced aggregation and improved pharmacokinetics. One of these achieved complete tumor regression in vivo in two different tumor models leading to the identification of an efficient ISAC for pancreatic cancer. These findings highlight the critical role of linker engineering in the development of more effective ISACs.

#5835 Good quality sixty-eight percent 5-year survival in patients with treatment refractory stage IV lung cancer following treatment with a single agent progesterone receptor antagonist.

Jerome H. Check[1], Diane Check[2], Carrie Wilson[2], Maddison Neulander[2]

[1]Cooper Medical School of Rowan University (CMSRU), Melrose Park, PA,[2]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ

Both the fetus and malignant tumors utilize membrane progesterone receptors (mPRs) to produce immunomodulatory proteins e.g., the progesterone induced blocking factor (PIBF) to escape immune surveillance. This study evaluated the efficacy of treating stage IV NSCLC or SCLC with single agent oral mifepristone 200-300mg/day. To be included, the cancer had to have progressed despite chemo or immunotherapy or the patient considered likely to die within 1 month. Six patients were evaluated, 4 with NSCLC, 2 with SCLC. Patients were not excluded for co-morbidities or if there were brain metastases. The patients completed a quality of life form every month for the first six months, then every third month, fourth, and six. 3 of 4 NSCLC patients had brain metastases and 2 had COPD with one considered end-stage COPD. 2 were positive for EGFR mutation, the other 2 had no markers to target. One of the two patients with SCLC had no prior therapy since her serum Na+ was 118 mmol/L and PO2 72 mmHg, with extremely rapid progressing SCLC. She was considered by her oncologist to be within two weeks of death with hospice recommended. All six patients showed marked palliative benefits even to the day they died. 3 of 4 with NSCLC lived 5+ years with one still alive. None showed any new metastases and many decreased in size. The 78-year-old woman with severe hyponatremia had a serum Na +of 145 mmol/L and serum PO2 of 100 mmhg one month after treatment and eventually went into full remission. She died at the age of 83 with myocardial infraction with no evidence of cancer. The 68-year-old woman with end stage COPD died after 1.5 years from COPD with her cancer stable from COPD. The 68-year-old male with COPD died at age 73 with pneumonia during the COVID pandemic. His cancer was relatively stable with just slight growth of his primary lung lesion. Both women with NSCLC EGFR + lived five years despite not starting mifepristone until 1 year after treatment with Osimertinib when the cancer was now rapidly progressing with the presence of multiple brain metastasis. One died, but her cancer was stable. We could not ascertain the cause of death. The 65-year-old male with SCLC was clinically doing well after 1 ½ years of mifepristone. However, because the lesions were still present (but smaller) his oncologist enrolled him in a clinical trial requiring him to stop the mifepristone. He died 3 months later. Though some studies find with the new therapies available some patients with stage IV NSCLC may have a 15% 5-year survival from first diagnosis. Though there were only 6 patients in this study, this excellent 5-year survival outcome in previously treated or terminal patients with NSCLC or SCLC strongly suggests the efficacy of single agent mifepristone for advanced lung cancer with no more treatment options available.

#5836 Suppression of TNFα and IFNγ signaling are key molecular events in KRAS^{G12C} mutant cancer cells to confer therapeutic resistance to Sotorasib and promote immune evasion.

M. L. Ibrahim, X. Yu, D. Foresman, Z. Hong, E. Haura, A. Beg;
H. Lee Moffitt Cancer Center, Tampa, FL

The groundbreaking development and FDA approval of the mutant and cancer selective KRAS^{G12C}is Sotorasib and Adagrasib to treat NSCLC and CRC patients have revolutionized the field of cancer biology. While these inhibitors demonstrated efficacy in patients with KRAS^{G12C} mutation, their response was limited and short lived due to rapid and frequent emergence of therapeutic resistance. Multiple genetic alterations in KRAS^{G12C} cancer cells (mainly in RTK and MAPK pathways) have been reported to contribute to their acquired resistance to Sotorasib. However, there is unmet need to fully understand how cancer cells manipulate the immune regulatory signals in the TME to acquire therapeutic resistance and evade antitumor immunity. To this end, we utilized single cell profiling technology to delineate the intricate transcriptomic landscape of tumor cells and tumor infiltrated immune cells in the tumor microenvironment of Sotorasib-resistant tumors. Our single cell RNA seq analysis demonstrated that Sotorasib generated hot TME dominated by effector/cytotoxic T cells and inflammatory macrophages in Sotorasib-responsive CT26^{G12C} colon tumors. Importantly, these Sotorasib-responsive tumors are enriched with immune active tumor populations with highly upregulated TNFα and IFNγ signals. Conversely, these immune-sensitive tumor clusters (with high TNFα and IFNγ signals) were strikingly contracted in Sotorasib-resistant tumors. Furthermore, Sotorasib-resistant tumors exhibited non-inflamed TME dominated by immune suppressive neutrophils and monocytes populations. Intriguingly, Sotorasib failed to suppress or delay tumor growth of resistant tumors even when combined with anti-PD1 immune checkpoint blockade, indicating that KRASi-resistant tumors are in nature less vulnerable to antitumor T cell immunity. In vitro, single-cell imaging flow cytometry revealed that Sotorasib-tolerant cancer cells displayed remarkable reduction in nuclear translocation of NFkB and STAT1 as compared to parental cells, highlighting the importance of TNFα and IFNγ signaling to maintain optimum immune modulatory response of KRAS^{G12C} mutant cancer cells to KRAS inhibition. Collectively, our findings uncovered cancer cell-intrinsic and extrinsic molecular mechanisms underlying clinical resistance to Sotorasib and provide a comprehensive profiling of tumor/immune microenvironment ecosystem in refractory tumors to lay the groundwork for developing promising treatment platforms to overcome this inevitable resistance and achieve optimum clinical outcome.

#5837 Lurbinectedin-induced transcriptional reprogramming: A pathway to sensitise SCLC to immunotherapy.

Joan Salvador Russo-Cabrera[1], Santiago Ponce-Aix[1], Patricia Cozar[1], Alicia Luengo[1], Belen Revuelta[1], Laura Garcia-Redondo[1], Alejandro Navarro[2], Reyes Bernabe[3], Maria Eugenia Olmedo[4], Jose Manuel Trigo[5], Jon Zugazagoitia[1], Luis Paz-Ares[1], Itziar Otano[1]

[1]H12O-CNIO Lung Cancer Clinical Research Unit, Health Research Institute Hospital 12 de Octubre (i+12)/Spanish National Cancer Research Center (CNIO), Madrid, Spain,[2]Medical Oncology Department, Hospital Universitario Vall d'Hebron, Barcelona, Spain,[3]Medical Oncology Department, Hospital Universitario Virgen del Rocio, Sevilla, Spain,[4]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain,[5]Medical Oncology Department, Hospital Universitario Virgen de la Victoria, Malaga, Spain

Background: For decades, platinum-based chemotherapy plus etoposide (ChT+E) has remained unchallenged at the first-line treatment for extensive-stage-SCLC (ES-SCLC), that is, until the introduction of immune-checkpoint blockade (ICB) anti-PD-L1. ChT+E susceptibility of SCLC relies in the high genomic instability observed in SCLC, further increased by ChT+E and surpassing DNA Damage Repair (DDR) capabilities. In the context of DNA damage and cell-intrinsic immunity, the addition of ICB improves the response of SCLC to ChT+E through tumour immunogenicity. Although initially responding to treatment, almost all patients relapse within the first 6 months, leading to limited options at second-line treatment, Lurbinectedin (LUR) among them. While LUR acts by degrading RNA polymerase II and, therefore, inhibiting transcription, it also causes DNA damage synergising with ICB. 2SMALL is a phase 1/2 study assessing the safety, tolerability and efficacy of LUR plus atezolizumab (ATZ) as second-line treatment for ES-SCLC.

Methods: 2SMALL Phase-I was a dose exploration trial combining increasing doses of LUR plus a fixed dose of ATZ every 3 weeks. Study endpoints included safety profile and LUR recommended dose, as well as, Objective Response Rate (ORR), Progression-Free Survival (PFS) and Overall Survival (OS). Pre-clinically, efficacy of LUR plus anti-PD-L1 mAb was evaluated *in vivo* in a syngeneic immunocompetent mice model for SCLC (*Rb1*$^{-/-}$*Trp53*$^{-/-}$), and *in vitro*/*ex vivo* in several SCLC cell lines and PDX-derived-spheroids.

Results: LUR+ATZ was well tolerated, without unexpected toxicities. ORR were observed in 16/24 patients, including: 3/24 Complete Responses; 13/24 Partial Responses; 5/24 Stable Disease; and 3/24 Progressive Disease. Median PFS was 4.7 months (3.37-7.4) and median OS 14.5 months (9.5-23.4). In pre-clinical in vivo experiments, LUR+anti-PD-L1 achieved tumour rejection in 16/28 mice and 13/16 mice did not show tumour growth when exposed to a rechallenge. At the tumour, LUR increases Antigen Processing and Presentation (APP), activates IFN type-I signalling and promotes immune infiltration when combined with anti-PD-L1, particularly CD8+ T lymphocytes, at Tumour Immune Microenvironment (TIME). Finally, anti-tumour effect was mainly mediated by CD8+ T-cells.

Conclusions: LUR+ATZ anti-tumour activity is remarkable both in patients and pre-clinical *in vivo* experiments. Our results show effective tumour-activating IFN type-I, which increases immunity against tumours and provides the rationale to combine LUR with ICBs.

#5838 Quantification of ERAP-1 inhibition-dependent HLA-I peptides using targeted mass spectrometry for TCR-based therapeutics target discovery.

Anamarija Pfeiffer[1], Lucy Yang[1], Maik Mueller[1], **Daniel Redfern**[1], Yuehan Feng[1], Kris Clark[2], James Bishop[2], Juanita Carrey[2], Sam Humphrey[2], Wayne Paes[2]

[1]Biognosys AG, Schlieren, Switzerland,[2]Greywolf Therapeutics, Oxford, United Kingdom

Human leukocyte antigens (HLA) play a central role in orchestrating immune responses by presenting antigenic peptides derived from both self and foreign proteins. The identification of neoantigens, unique to individual tumors due to somatic mutations, has become a focal point in immunopeptidomics studies. In particular, accurate quantification of immunogenic peptides to evaluate their potential as novel targets for TCR-based therapeutics has been of increasing interest in immuno-oncology and autoimmune diseases, where regulating the immune response is of growing therapeutic importance. Additionally, precise (neo)antigen quantification can guide the development of personalized vaccines and cell therapies, further highlighting the need for robust methods to evaluate peptide presentation in diverse disease contexts.

Current methodologies to measure presented antigens are hampered by low sensitivity. Here, we employed a targeted mass spectrometry technique FAIMS-PRM to overcome these challenges. This method allows for development of highly sensitive targeted assays for the quantification of immunopeptide(s) of interest from minimal sample inputs: 25 million cells or 15mg fresh frozen tissue. Coupled to the spike-in of chemically synthesized internal standards (SIS), FAIMS-PRM enabled the estimation of copy number per cell of immunopeptides, thus providing essential information to assess potential targets in both disease and healthy matrices.

To exemplify the analytical benefits of this workflow, we quantified neoantigens presented by HLA-I complexes in cancer cells upon treatment with a small molecule ERAP1 inhibitor. ERAP1 trims peptide precursors to optimal lengths for loading onto HLA-I molecules in the endoplasmic reticulum, thereby regulating the repertoire of peptides available for recognition by $CD8^+$ T cells. Inhibition of ERAP1 results in an entirely novel repertoire of peptides being presented for immune recognition, generating functional anti-tumor T-cell responses and a novel target space for TCR-based therapies. In this study, a panel of peptide assays containing 30 ERAP1 inhibition-dependent HLA Class I peptides was developed with SIS for each target. This includes peptides from industry-validated TCR targets and from novel targets selected from prior discovery studies. In the tested melanoma and ovarian cancer cell lines, this targeted assay could demonstrate a lower limit of quantification (LLOQ) reaching low single-digit range (1-3 copies) per cell.. Treatment of these cells with ERAP1 inhibitors resulted in a 2- to 10-fold increase in epitope copy number depending on cell type.

In conclusion, we established a robust pipeline for HLA class I peptide quantification which can be routinely applied to estimate copy number per cell in biological samples such as cancer cell lines or tissues for target discovery.

#5839 Mimicking the immunosuppressive tumor microenvironment: a complex primary immune cell tumor killing assay to support candidate vaccine or immunomodulator screening.

Oliver J. Brand, Elizabeth Lieverse, Henry Leonard, Elsenoor Klaver, Lauren Schewitz-Bowers, **Louise S. Brackenbury**

Charles River Laboratories, Bristol, United Kingdom

Recent advances in oncology vaccine strategies, from off-the-shelf to personalized approaches offer a promising new weapon in the cancer treatment arsenal. The ability of these vaccines to exploit host immunity by priming and expanding Tumor Associated Antigen (TAA)-specific T cells presents a tractable tool to eradicate cancer whilst limiting systemic toxicity. TAA-specific $CD8^+$ T cells possess a potent capacity for tumor cell killing, and it is widely accepted that patients with higher frequencies infiltrating the tumor exhibit improved clinical outcomes. However, the complex tumor microenvironment (TME), composed of various stromal and regulatory immune cells such as regulatory T cells (Tregs), cytokines and extracellular matrices is often immunosuppressive and can reduce immune surveillance and favor uncontrolled tumor growth. Building preclinical screening platforms that better reflect the complexity of the TME are therefore crucial to enable better interrogation of therapeutic efficacy. To address this, we have developed a primary human TAA-specific tumor killing platform utilizing a tri-culture of antigen specific $CD8^+$ T cells (TAA-CD8), expanded natural T regs (nTregs) and appropriately selected tumor cells. Mart-1 was chosen as the model TAA to generate proof-of-concept data. This platform overcomes the anticipated low precursor cell frequencies by expanding both antigen specific T cells and nTregs. Following expansion, tumor killing assays (TKA) were established with TAA-CD8 and HLA-matched tumor targets with either: (1) endogenous TAA expression, (2) over-expression of target antigen following lentivirus transduction or (3) target peptide loading of MHC class I with exogenous peptide. Tumor killing was assessed in these cultures in the presence or absence of nTreg by time-lapse imaging (IncuCyte S3, Sartorious), with readouts including both tumor growth and apoptosis. Robust killing following antigen-specific expansion of CD8+ T cells was demonstrated and addition of expanded nTreg to these cultures resulted in reduced tumor cytotoxicity. Therapeutics can be tested for their efficacy in overcoming nTreg-mediated immunosuppression. Complex primary immune cell cultures provide an opportunity to test both immunomodulators and vaccines in vitro, and to better predict responses in patients by mimicking the suppressive nature of the TME. Adoption of translationally relevant platforms early in hit-to-lead campaigns for candidate vaccines or immunomodulators can accelerate drugs to the clinic through early screening.

#5840 PF-08046037, a PD-L1 targeted TLR7 agonist ISAC, drives innate immune activation and anti-tumor efficacy in preclinical in vitro and in vivo models.

Giacomo Tampella, Catalina Sakai, Weiping Zeng, Eleanor Hendrickson, Sasha Lucas, Kung-Pern Wang, Aly Smith, **Ryan A. Heiser**

Pfizer, Inc., Bothell, WA

PF-08046037 (formerly known as SGN-PDL1iT) is an immune-stimulating antibody conjugate (ISAC) designed to induce an immune response against cancer cells by delivering a potent Toll-like receptor 7 (TLR7) agonist to tumor associated antigen-presenting cells (APCs) expressing PD-L1. The ISAC consists of an anti-PD-L1 antibody linked to an imidazoquinoline-based TLR7 agonist using a mannosidase-cleavable maleimidopropionyl-mannose linker (mp-mann). Upon binding to PD-L1 on APCs, PF-08046037 internalizes and releases the payload into TLR7-containing endosomes. To minimize off-target immune activation, PF-08046037 incorporates Fc mutations in the antibody to reduce FcγR binding, and the agonist payload is designed to have low membrane permeability. Through targeting PD-L1-expressing immunosuppressive macrophages and dendritic cells within the tumor and associated immune compartments, PF-08046037 aims to repolarize the suppressive tumor microenvironment, enhance antigen presentation, and establish robust anti-tumor immunity. Here, we present preclinical data demonstrating the potency, targeted delivery, and anti-tumor efficacy of PF-08046037 in both in vitro and in vivo models. In vitro, PF-08046037 induces potent and selective activation of TLR7 reporter cells and PD-L1-expressing human macrophages and dendritic cells. In syngeneic hPD-L-1 .CT26 and hPD-L-1 .MC38 tumor models using human PD-L1-expressing mice, PF-08046037 shows single-agent efficacy and provides anamnestic protection against tumor rechallenge. The in vivo pharmacodynamic effects of PF-08046037 align with its intended mechanism of action, including acute tumor inflammation, loss of CD206+ suppressive macrophages, upregulation of activation and costimulatory molecules on APCs in tumors and tumor-draining lymph nodes (tdLN), and increased activity of cytotoxic cells. Collectively, these data highlight the therapeutic potential of targeted TLR7 agonist delivery to PD-L1-expressing APCs in cancer and support the clinical investigation of PF-08046037 in advanced malignancies.

#5841 SARS-CoV-2 mRNA vaccines sensitize tumors to immune checkpoint blockade.

Adam Grippin[1], Christiano Marconi[2], Sage Copling[1], Priti Gupta[1], Elliana Young[1], Padmanee Sharma[1], Don Gibbons[1], Hai Tran[1], Yon Son Betty Kim[1], Jianjun Zhang[1], Jennifer Wargo[1], John V. Heymach[1], Hector Mendez-Gomez[3], Wen Jiang[1], Elias Sayour[2], Steven H. Lin[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Florida, Gainesville, FL,[3]University of Florida, Houston, TX

Background: We previously reported that personalized mRNA vaccines enhance responses to immune checkpoint inhibition (ICI) in part by stimulating IFN-α production. We hypothesized that mRNA vaccines encoding non-tumor antigens, including those targeting SARS-COV-2, would similarly augment responses to ICI.
Methods: We utilized institutional databases to extract clinical data for patients with Stage III/IV non-small cell lung cancer (NSCLC) (n=2406) and metastatic melanoma (n=757) with biopsy specimens between August 2019 and August 2023, as well as a separate “tissue agnostic” cohort with pathology reports quantifying “PD-L1” from August 2020 to November 2023 (n=5,524). We then generated a preclinical model of ICI-resistance with subcutaneous murine B16F0, and analyzed plasma from a cohort of healthy volunteers (n=5) at baseline and 6 hours, 24 hours, 1 week, and 2 weeks after SARS-COV-2 mRNA vaccination with NULISA-Seq and flow cytometry. Differences were assessed with Wilcoxon rank-sum tests, Cox proportional hazards regression, and Gehan-Breslow-Wilcoxon tests.
Results: Median overall survival (OS) was doubled for patients with Stage IV NSCLC who received a SARS-COV-2 mRNA vaccine within 100 days of initiation of ICI compared to patients diagnosed before the pandemic (555 days vs 1120 days, HR 0.5, 95% CI 0.4-0.7) and contemporary patients who did not receive a vaccine (646 days vs 1120 days, HR 0.6, 95% CI 0.4-0.9, p=0.007). OS was unchanged for vaccinated patients who did not receive ICI and those who received non-mRNA vaccines. In the melanoma cohort, SARS-COV-2 mRNA vaccination was associated with substantially improved OS (HR 0.42, 95% CI 0.24-0.74, p=0.003) and progression free survival (HR 0.64, 95% CI 0.44-0.92, p=0.022). In our preclinical model, SARS-COV-2 mRNA vaccines stimulated a surge in many inflammatory cytokines including IFN-α, leading to systemic innate immune activation, expansion, activation, and persistence of tumor-reactive T cells, and increased expression of PD-L1 on tumor cells. SARS-COV-2 mRNA vaccines significantly inhibited growth of B16F0 tumors only when combined with ICI. This effect required Type I IFN signaling but was not recapitulated with systemic IFN-α alone. We then recapitulated these results in human subjects, where SARS-COV-2 mRNA vaccinaties were associated with an 8-fold increase in IL-6 and at least 265-fold increase in IFN-α (p<0.001) in five healthy volunteers. Finally, SARS-COV-2 mRNA vaccination within 100 days of biopsy was associated with a 23% increase in mean tumor proportion score (TPS) of PD-L1 in patients with NSCLC (31% vs 26%, p=0.029) and a 55% increase in mean TPS (14% vs 8.9%, p=0.029) in the tissue agnostic cohort.
Conclusions: SARS-COV-2 mRNA vaccines are associated with a cytokine cascade that likely induces PD-L1 expression in tumors and augments responses to ICIs, leading to improved survival in patients with metastatic melanoma and NSCLC.

#5842 A novel formulated neoantigen DNA vaccine with promising anticancer efficacy in B16F10 mouse melanoma model.

Kempaiah Rayavara, Subeena Sood, Majed Matar, Jessica Kim, John Henderson, Jeff Sparks, Meredyth Kinsella, Olivia Signer, Joseph Rogers, Chelsey Bellmon, **Khursheed Anwer**

IMUNON, Huntsville, AL

Cancer vaccine approaches targeting neoantigens are gaining credence due to their specificity for tumors while sparing healthy tissues. Cancer vaccines based on DNA technology are attractive anti-cancer therapeutic tools due to their ability to elicit an effector T-cell-based immune responses. We report the development of a novel DNA-based cancer vaccine that relies on the delivery of a plasmid DNA vector encompassing immune epitopes of multiple neoantigens delivered with a novel synthetic DNA delivery system with the aim to elicit a broader immune response against cancer. The formulated vaccine was also investigated in combination with different adjuvants to maximize the anti-cancer responses. The vaccine vector encoding the immunogenic epitopes of multiple melanoma neoantigens and flanked by signal peptide at N-terminus and an MHC-targeted domain at the C-terminus end was formulated with a functionalized novel synthetic polymer with or without the adjuvants Poly I:C, diABZI, a STING agonist, or a mouse IL-12 plasmid. Mice were implanted subcutaneously with 0.5×10^6 B16F10 tumor cells on Day 0 and vaccinated intramuscularly with the DNA formulations on Day 2, 9, 16 and 23, and monitored for tumor growth and survival . For cellular responses, mice were injected intramuscularly with the DNA formulations on Day 0, 21, 42 and sacrificed 7 days later for cellular immune response by ELISPOT assay. Vaccination with formulated DNA alone yielded a significant inhibition (60%, $p<0.01$) of tumor growth and improved survival. Addition of Poly I:C, diABZI, or IL-12 plasmid further augmented the tumor inhibition to 90%($p<0.0001$), 94% ($p<0.0001$), and 88% ($p<0.0001$), respectively, and improved the survival outcome. All animals in the adjuvant groups also lived longer. The anti-tumor efficacy results are supported by the onset of robust T-cell responses in all treatment groups supporting the involvement of immune activation in the action of this novel DNA vaccine that does not require a virus or device and can be manufactured rapidly with a simple and cost-effective manufacturing process critical for the viability of cancer vaccines.

#5843 Selective small molecule inhibitor of STAT3 suppresses tumor growth and improves immune checkpoint inhibitor efficacy in *KRAS* mutant lung cancer.

Shanshan Deng[1], Kris Eckols[1], Moses Kasembeli[1], Katherine E. Larsen[1], Nastaran Karimi[1], Michael J. Clowers[1], Anthony Zhang[2], Leticia G. Hamana Zorilla[1], Luisa M. Solis Soto[1], Imran Alibhai[3], Sofia de Achaval[4], Ferdinandos Skoulidis[1], David J. Tweardy[1], Seyed Javad Moghaddam[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Rice University, Houston, TX,[3]Tvardi Therapeutics, Houston, TX,[4]Tvardi Therapeutics, Inc., Houston, TX

KRAS mutant (KM) lung cancer is the most common molecular subtype of lung adenocarcinoma (LUAD) and is strongly associated with cigarette smoking. KM-LUAD has a poor prognosis as it is resistant to most chemotherapy and targeted therapies. Also, despite recent breakthroughs in development of KRAS inhibitors (KRASi) and immune checkpoint inhibitors (ICIs), only a small sub-population of patients benefit from these therapies and resistance eventually develops. Thus, an urgent unmet medical need exists for alternative strategies that can complement KRASi and/or ICI to improve responses. KM-LUAD is closely associated with tumor-promoting inflammation, particularly the activation of the IL-6/STAT3 pathway. We previously showed in KM-LUAD patients that higher levels of STAT3 mRNA was associated with worse disease-free survival, and that targeting IL-6 in the $CCSP^{Cre}$/LSL-$Kras^{G12D}$ (CC-LR) mouse model of KM-LUAD reduced STAT3 activation and lung tumorigenesis. In this study, we targeted STAT3 directly with a safe and selective small molecule STAT3 inhibitor, TTI-101, that currently is in Phase II studies for treatment of hepatocellular carcinoma and idiopathic pulmonary fibrosis. Starting at 14 weeks of age, when tumors are established, four groups of CC-LR mice (n= 9-16 per group) received TTI-101 alone (100 mg/kg by oral gavage daily), anti-PD-1 mAb alone (10 mg/kg intraperitoneally thrice weekly), TTI-101 plus anti-PD-1 mAb, or no treatment for four weeks. TTI-101 alone reduced lung surface tumor number (LSTN) by 39.5% (22.4 ± 12.0 LSTN; mean ± SD) compared to the no-treatment group (37.0 ± 12.8 LSTN; p=0.02; Welch's ANOVA), while anti-PD-1 mAb alone failed to reduce LSTN (43.8 ± 17.0 LSTN; p=ns). Notably, the combination of anti-PD-1 with TTI-101 further decreased LSTN by 46.4% (12.0 ± 5.7 LSTN) compared to TTI-101 alone (22.4 ± 12.0 LSTN; p=0.04) and by 72.6% (12.0 ± 12.0 LSTN) compared to anti-PD-1 mAb alone (43.8± 17.0 LSTN; p=0.0002). Daily monitoring indicated no significant weight changes or toxicity from either TTI-101 or anti-PD-1 mAb treatment. Thus, STAT3 inhibition using TTI-101, either alone or in combination with anti-PD-1, is a promising new strategy for treating KM-LUAD.

Funding support: This project has been funded by an NIH/NCI R01 grant (1R01CA279452-01A1) awarded to SJM, DJT, and FS. AZ was partly supported by the Carl B. and Florence E. King Foundation Summer Program in Biomedical Sciences, MD Anderson Cancer Center.

#5844 Initial findings on the immunomodulatory effects of histotripsy combined with N-dihydrogalactochitosan in a comparative oncology model of canine osteosarcoma.

Ny Luong[1], Alayna Hay[1], Elliana Vickers[2], Samuel S. K. Lam[3], Wei R. Chen[4], Eli Vlaisavljevich[2], Joanne Tuohy[1]

[1]Virginia-Maryland College of Veterinary Medicine, Roanoke, VA,[2]Virginia Tech, Roanoke, VA,[3]Immunophotonics, Inc., St. Louis, MO,[4]University of Oklahoma, Norman, OK

Background: Osteosarcoma (OS) is the most common primary malignant bone tumor in children and adolescents, associated with poor prognosis, especially in cases with metastatic disease at diagnosis. Canine OS shares many biological and clinical similarities with human OS, making dogs valuable comparative models for OS research. Histotripsy is a non-thermal, non-invasive high-intensity focused ultrasound modality that mechanically disrupts tumor cells, triggering the release of neoantigens and damage-associated molecular patterns (DAMPs) to potentially promote an anti-tumor immune response. N-dihydrogalactochitosan (GC) is a novel immunostimulant shown to enhance systemic immune responses when delivered intratumorally after thermal ablation. However, the combination of GC with a non-thermal ablation modality such as histotripsy remains unexplored. This study evaluates the safety, feasibility, and immunomodulatory effects of combining histotripsy with GC in pet dogs with spontaneous OS.

Methods: Pet dogs with spontaneous OS were treated with a 700 kHz histotripsy system at a1000 Hz pulse repetition frequence and 500-750 pulses/point. Patients underwent 1-5 fractionated histotripsy treatments , ablating the majority of the tumor. After the final histotripsy treatment, GC (10 mg/mL) was injected intratumorally under ultrasound guidance, with the dose proportional to tumor size. Peripheral blood was collected at baseline and 2-, 4-, and 8-weeks post-histotrispy+GC treatment and peripheral blood mononuclear cells (PBMCs) were isolated and immune cell signatures were characterized, serum cytokines and chemokines profiles were evaluated using a Milliplex Canine Cytokine Panel. At the follow up timepoints lung metastases were monitored via thoracic radiographs.

Results: The combination of histotripsy and GC was tolerated, with swelling at the treatment site resolving within one week. At 2 weeks post-treatment, circulating monocytes (CD11b+CD14+) increased with upregulation of CD80 and CD62L expression compared to baseline level. Although the percentage of gated CD11b+CD14+CD80+ monocytes remained stable after two weeks, CD80 expression continued to increase, suggesting sustained monocyte activation. CD62L expression on CD4+ and CD8+ T cells decreased at 2 weeks but increased again by 4 weeks post treatment, potentially reflecting changes in T cell trafficking. Two of three patients remained free of lung metastases at 10 weeks post treatment. Cytokine and gene expression analyses are ongoing and will further inform systemic immune responses.

Conclusion: These preliminary findings suggest that histotripsy combined with GC may induce immune activation and holds promise as a therapeutic strategy for targeting primary tumors and metastases in OS.

#5846 A potent STING agonist induces endothelial PD-L1 and enhances antitumor efficacy of a novel PD-L1/PD-L2 antibody.

Ahmad Salameh, Manuela iezzi, Andrew Lewis, Christine Gagliardi, Laura Conti, Elisabetta Bolli, Chiara Cossu, Martina CECI, Paul Blezinger, Michael A. Curran, Federica Cavallo, James Barlow, Federica Pericle

RD, Immunogenesis, Inc., Houston, TX

Background: The activation of stimulator of interferon genes (STING) has emerged as a promising strategy to reprogram the tumor microenvironment (TME) and enhance antitumor immunity. We previously demonstrated that combining a potent STING agonist (8803, IMGS-203) with a novel dual-specific anti-PD-L1/PD-L2 monoclonal antibody (27907) produced curative responses in checkpoint-refractory tumor models. In this study, we investigated the mechanisms underlying these effects by analyzing the TME of tumors treated locally with 8803 and systemically with 27907 using immunohistochemistry and flow cytometry.
Objective: To evaluate the necrobiotic effects of the STING agonist 8803 combined with the cytotoxic anti-PD-L1/PD-L2 antibody 27907 across multiple tumor models by characterizing the TME and tumor vascularization.
Methods: The efficacy of 8803 was assessed in vivo in combination with 27907 in murine melanoma (B16F10 expressing mouse PD-L2) and mammary adenocarcinoma (TS/A) models. Mice with established tumors received intratumor injections of 8803 (10 ug/dose, twice) and systemic administration of 27907 (10 mg/kg, twice weekly for three weeks). Tumors were harvested 32 days post-challenge and analyzed via H&E staining, IHC, and FACS to evaluate necrobiosis, immune cell infiltration, and vascularization.
Results: The combination of 8803 with 27907 demonstrated robust antitumor activity in both melanoma and breast cancer models. IHC and FACS profiling revealed a significant increase in infiltrating myeloid cells alongside a notable reduction of the immunosuppressive M2 macrophage phenotype (CD206+). Intratumor 8803 markedly upregulated PD-L1 expression in endothelial cells, that were effectively disrupted by systemic 27907, as evidenced by increased caspace-3 and CD62p co-expression in endothelial cells within treated tumors. This endothelial disruption was absent in tumors treated with 8803 alone. Further, western blot and FACS analyses of human and murine endothelial cells co-cultured with 8803 confirmed upregulation of PD-L1 and PD-L2. Critically, PD-L1+/PD-L2+ endothelial cells were selectively eliminated by monocytic-enriched bone marrow-derived myeloid cells and PBMCs in the presence of 27907, suggesting a direct effect of the antibody on tumor vasculature.
Conclusion: Tumors treated with the combination of 8803 and 27907 exhibited extensive necrobiosis and endothelial damage, uniquely observed in the combination treatment group and correlating with curative outcomes. This enhanced antitumor response was associated with increased myeloid infiltration, a shift away from M2 macrophage phenotype, and an elevated effector T-cell population. These findings underscore the potent therapeutic synergy of 8803 with 27907 and support their further development for clinical applications.

#5848 Oxygen-releasing cryogel reinforce dendritic cell function and T-cell mediated tumor immunity in hypoxic microenvironments.

Khushbu Bhatt

Department of Pharmaceutical Sciences, Northeastern University, Boston, MA

Cancer immunotherapy faces significant barriers due to tumor heterogeneity and the hypoxic nature of the solid tumor microenvironment (TME). Hypoxia, defined by reduced oxygen (O_2) tension, induces immunosuppression, impairing dendritic cell (DC) and T-cell function, which are critical for robust anti-tumor immunity. Here, we report on the evaluation of a novel hyaluronic acid (HA)-based cryogel scaffold, termed O_2-cryogels, engineered to counteract hypoxia by releasing O_2 through encapsulated calcium peroxide (CaO_2) particles and catalase enzyme. Our results demonstrate that O_2-cryogels effectively alleviate hypoxia-induced suppression of murine and human DC function. Specifically, they rescue critical DC processes such as antigen uptake, migratory activity, and the expression of activation and co-stimulatory molecules essential for T-cell priming. Moreover, O_2-cryogels enhance the secretion of proinflammatory cytokines, mitigate hypoxia-induced phenotypic switching of mouse DCs to tolerogenic plasmacytoid DCs (pDCs), and suppress the upregulation of hypoxia-induced tolerance markers. These effects translate to restored allogenic T-cell proliferation and improved OT-I cell-mediated cytotoxicity against B16-OVA tumor cells under hypoxic conditions. This study highlights the ability of O_2-cryogels to locally modulate oxygen levels, reinvigorate DC function, and enhance T-cell-mediated tumor cell killing, addressing a critical bottleneck in cancer immunotherapy. By targeting hypoxia, O_2-cryogels offer a novel and promising approach to amplify the efficacy of immunotherapeutic strategies, paving the way for innovative treatments in hypoxia-driven solid tumors.

#5849 Re-Phen, a novel OXPHOS enhancer that reprograms T cell mitochondrial metabolism to potentiate anti-PD-1 immunotherapy.

Boping Jing[1], Qiuxu Teng[1], Guodong Zhang[1], Chiyi Xiong[1], Ping Pan[1], Qizhen Cao[1], Ningbo Zhang[2], Si Chen[2], Weiyi Peng[2], **Chun Li**[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Houston, Houston, TX

Introduction: Immune checkpoint inhibitors fail to control most PDAC tumors. Identifying novel ways to enhance immunotherapy in PDAC is highly desired. This study aimed to evaluate a new phenformin analogue, termed Re-Phen, that targeted intratumoral dysregulated metabolism pathways.

Methods: Re-Phen was encapsulated into a polymeric micellar to give MRP. ^{99m}Tc-Phen, a structurally matched radiotheranostic counterpart of Re-Phen was also synthesized and encapsulated into polymeric micelles (i.e. ^{99m}Tc-MRP) for SPECT/CT imaging and biodistribution study. The effects of Re-Phen on mitochondrial membrane potential, generation of reactive oxygen species (ROS), and ATP production were studies *in vitro* with both tumor cells and T cells. Antitumor efficacy of MRP in combination with anti-PD-1 was studied in both subcutaneous and orthotopic models murine Kras* PDAC cells. In addition, immune cells in Kras* tumor and spleen of MRP-treated mice were profiled at 5 days after initiation of treatments.

Results: SPECT/CT with ^{99m}Tc-MRP and biodistribution studies revealed that MRP had higher uptake in tumor and reduced uptakes in the liver and kidneys compared to un-encapsulated Re-Phen. *In vitro,* Re-Phen displayed similar activity as Phen in reducing mitochondrial membrane potential. However, unlike Phen, Re-Phen reduced ROS, increased ATP production by OXPHOS instead of by glycolysis without suppress T cell proliferation. In the orthotopic Kras* model, MRP administered at a dose of 12.5 mg/kg in combination with anti-PD-1 demonstrated superior anti-tumor efficacy, achieving a long-term survival rate of 55.6%. In comparison, mice treated with MRP at 25 mg/kg plus anti-PD-1, anti-PD-1 alone, MRP (12. 5 mg/kg) alone, and untreated control achieved long-term survival rate of 33.3%, 12.5%, 0%, and 0%, respectively. In a subcutaneous Kras* PDAC model, MRP plus anti-PD-1 showed strong abscopal effect as evidenced by suppression of tumor growth in the contralateral tumors that were not treated by a local intervention with irreversible electroporation (IRE). Moreover, MRP significantly increased survival rates when combined with IRE and anti-PD1 in the subcutaneous Kras* PDAC model. The triple combination achieved an 87.5% long-term survival rate, compared to 25% with IRE alone and 25% with anti-PD1 alone. In the subcutaneous pancreatic tumor models, the combination of MRP and anti-PD1 therapy elicited a stronger immune response compared to the untreated and anti-PD1-only groups. This included an increase in CD4+ T cells, CD8+ T cells, and dendritic cells (DCs) in both tumors and spleens, along with a reduction in neutrophils.

Conclusions: Re-Phen is a novel OXPHOS enhancer that induced a robust antitumor immune response, resulting in potentiation of antitumor immunotherapy. Further development of this class of drugs is warranted.

#5850 AXA-042, a systemically administered TLR2/6 agonist, demonstrates innate immune engagement and Th1 polarization in patients with advanced solid tumors.

B. Tran[1], S. Frentzas[2], C. Lemech[3], M. Millward[4], D. Day[2], J. Desai[1], A. Latifi[5], P. Wabnitz[5], P. Kearney[5], **A. V. Galkin**[5];
[1]Peter MacCallum Cancer Centre, Melbourne, Australia, [2]Monash Health, Clayton, Australia, [3]Scientia Clinical Research, Randwick, Australia, [4]Linear Clinical Research, Perth, Australia, [5]Axelia Oncology, Melbourne, Australia

Background: AXA-042 is a novel, systemically delivered synthetic toll-like receptor (TLR) 2/6 agonist in development for the treatment of advanced solid tumors. A first-in-human study evaluating the safety, tolerability, pharmacokinetics, and pharmacodynamics of AXA-042 as monotherapy and in combination with a checkpoint inhibitor in subjects with advanced solid tumors is currently ongoing (ACTRN12622000993796). Cytometry by time-of-flight (CyTOF) analysis was performed to characterize AXA-042 immune modulation signatures in patient whole blood samples.
Methods: AXA-042 was administered intravenously q21d. Informed consent was obtained and whole blood samples were collected pre-dose on C1D1, and 24h and 168h post-treatment (C1D2, C1D15) across three dose levels of AXA-042. Stabilized whole blood samples were immunophenotyped using a 43-marker CyTOF panel.
Results: In pre-dose samples, TLR2 was most frequently expressed on Monocytes (>80%), cDCs (47%) and in 20-30% of CD8, CD4 and γδ-T cell subsets. AXA-042 treatment led to the re-distribution of neutrophil, monocyte and cDC subset frequencies on C1D2, consistent with the expected acute inflammation response to a TLR2 agonist. Furthermore, AXA-042 increased the frequency of activated CD69+ cytolytic NK cells and γδ-T cells on C1D2. A general immune reset to baseline levels occurred for most populations on C1D15. Notably, a decrease in CTLA4+ Tregs and an increase in T-bet+ NK, γδ-T cells and TCF1+ CD8, CD4 T-cell subset frequencies, indicating a potential increase in Th1 polarization and preservation of effector function, was observed on C1D15 (Table 1).
Conclusions: The whole blood immunophenotyping analysis identified early pharmacodynamic markers of innate immune response engagement in response to AXA-042 and demonstrated sustained presence of Th1-polarized NK and T cell subsets with potential for enhanced cytotoxicity and effector function on C1D15.

#5851 The role of IL-9 on NK and T cell infiltration and immune response to promote tumorigenesis in HNSCC.

Samantha L. Nusbaum, Maria Lehn, Vinita Takiar, Dalia El-Gamal, Trisha Wise-Draper

University of Cincinnati, Cincinnati, OH

Head and neck squamous cell carcinomas (HNSCC) are the sixth most common cancer type worldwide and result in 400,000 deaths annually. Interleukin-9 (IL-9) is a pleiotropic cytokine largely produced by CD4+ Th9 cells. IL-9 is known to function in allergic inflammatory processes and is involved in both positive and negative regulation of immune responses. The role of IL-9 in cancer, however, differs depending on the cancer type and the tumor microenvironment, harboring both tumorigenic and anti-tumorigenic effects. The role of IL-9 in HNSCC specifically is poorly understood. We begin here to elucidate the possible functions of IL-9 on the immune system in the context of HNSCC.IL-9 plasma levels were determined by ELISA and cell proliferation was measured using a metabolic absorbance assay. Kaplan-Meier Plotter was used to determine if tumor IL-9 mRNA expression affects survival probability in HNSCC patients. Immune cell infiltration was determined by a novel infiltration assay designed by our laboratory. Briefly, we co-cultured Cal27 spheroids, a 3D model made with the HNSCC cell line Cal27, with peripheral blood mononuclear cells (PBMCs) isolated from HNSCC patients. The spheroids were then dissociated and the percentage of live infiltrating PBMCs was analyzed by flow cytometry. To assess the influence of IL-9 on immune cell killing, NK and CD8+ T cell cytotoxicity was measured by co-culturing CFDA-SE-labeled HNSCC cell lines with HNSCC patient-derived NK or T cells treated with recombinant IL-9 or a neutralizing antibody to IL-9 followed by flow cytometry analysis to determine the percentage of dead target cells.IL-9 plasma levels were found to be significantly increased in HNSCC patients as compared to healthy subjects. Additionally, high tumoral mRNA expression of IL-9 was associated with decreased survival in HNSCC cohorts. IL-9 did not affect tumor cell proliferation in vitro. However, higher concentrations of IL-9 significantly decreased immune cell infiltration into Cal27 spheroids, while a neutralizing antibody to IL-9 reversed these effects. Additionally, while studies are ongoing, IL-9 may decrease NK and CD8+ T cell cytotoxicity against HNSCC cell lines.Since IL-9 did not directly enhance or inhibit HNSCC cell proliferation in vitro, we extended our studies to explore IL-9's potential effects on the immune system. Importantly, IL-9 significantly decreased immune cell infiltration into HNSCC spheroids, suggesting that IL-9 inhibits tumor immune cell infiltration. IL-9 may also decrease immune cell cytotoxicity against HNSCC cells. Taken together, this data suggests that IL-9 negatively regulates the immune system in HNSCC, allowing for tumor growth. Future studies will focus on the effects of IL-9 on immune cell cytotoxicity and immune infiltration in vivo and will utilize single-cell transcriptional profiling to delineate the multifaceted role of IL-9 in the HNSCC immune microenvironment.

CLINICAL RESEARCH: Inflammation, Immunity, and Cancer

#5856 Secondary hemophagocytic lymphohistiocytosis: A systematic review of incidence and prognostic outcomes.

Maha Hameed[1], Gustavo Garcia[1], Kevin C. Zhen[1], Brooke A. Hartenstein[1], Laura D. J. Herrera[1], Utkarsh Acharya[2], Kai He[2], Karen Hamad[1], Wilhelmine Wiese-Rometsch[1]

[1]Florida State University, Tallahassee, FL,[2]The Ohio State University, Columbus, OH

Introduction: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening condition characterized by immune system dysregulation of natural killer cells, cytotoxic CD8+ T-cells, and macrophages, resulting in malignant inflammation and multi-organ failure. Secondary HLH, often triggered by malignancies, infections, and/or autoimmune disease, typically affects adults. This systematic review investigated the characteristics and prognostic factors associated with secondary HLH.
Methods: A systematic review was conducted in adherence to the PRISMA guidelines. A literature search was performed utilizing Medline, Embase, Scopus, Cochrane, and Clinicaltrials.gov databases without restricting to a starting date. Inclusion criteria encompassed retrospective or prospective, randomized, or non-randomized controlled studies published in English, focusing on adult patients over the age of 18 with secondary/acquired HLH. The primary outcomes of interest were overall survival (OS) and HLH-free/relapsed-free survival.
Results: The systematic review yielded 23 eligible studies, including 2833 patients with a median age of 48.3 years and 1482 (52%) males. Most studies originated from China (48%), followed by Korea (13%) and the USA (13%). Malignancies, particularly lymphomas, and infections, notably Epstein-Barr virus (EBV), were identified as the most common underlying causes of secondary HLH. Two studies involved ICU-related secondary HLH diagnoses, whereby sepsis-associated HLH with gram-negative bacteremia, particularly E. coli (30%), was most implicated. OS was a ubiquitously reported outcome, with only two studies (9%) including HLH-free survival/HLH-relapse-free survival. Most frequently reported statistically significant worse prognostic factors in terms of OS included older age in 8 (35%), low platelets <100 in 7 (30%), and malignancy-associated HLH in 7 (30%) studies. Two studies demonstrated worse prognosis in terms of HLH-free survival. Other poor OS prognostic factors included EBV-associated HLH in 6 (26%), low fibrinogen in 5 (22%), elevated AST in 5 (22%), elevated LDH >400 in 4 (17%), high bilirubin in 4 (17%), albumin <2.8 g/dL in 4 (17%), male sex in 3 (13%), ferritin >2000 in 3 (13%), low hemoglobin in 3 (13%), prolonged APTT in 3 (13%), prolonged PT in 3 (13%), elevated creatinine in 2 (9%), elevated sCD25 in 2 (9%) and elevated IL-10 in 2 (9%). Least frequently reported were prolonged INR, fever, low total T3, and elevated beta-2-microglobulin. One study demonstrated that germline HAVCR2 mutation had a better prognosis.
Conclusion: Older age, thrombocytopenia, and malignancy were the most common poor prognostic indicators for secondary HLH when indexed to outcomes of OS. This review also highlights a potential gap in the global understanding and documentation of secondary HLH, given the notable scarcity of studies from countries outside of China.

#5857 Targeting KDELR2 remodels the immune tumor microenvironment for enhanced anti-cancer response.

Shakti Prasad Pattanayak[1], Boaz Tirosh[2]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Department of Biochemistry, Case Western Reserve University School of Medicine, Cleveland, OH

Inflammation within the tumor microenvironment (TME) boosts anti-cancer immune responses by activating both innate and adaptive immunity. In situ inflammation enhances antigen presentation, immune cell infiltration and supports immune-cancer cycle. KDEL receptors (R1,R2 & R3) are critical for retaining KDEL proteins in the endoplasmic reticulum (ER). Their compromise can cause a concerted release of pro-immunogenic molecule, such as calreticulin. This can provoke conditions similar to immunogenic cell death (ICD) in the absence of chemotherapy. To address the role of KDEL receptors in immune-cancer interactions, we generated a mouse colon cancer model equipped with doxycycline (DOX)-induced silencing of the KDELRs. We found that in these cells KDEL-R2 isoform controls the intracellular retention of a large number of secretory proteins including calreticulin. Surprisingly, *in vivo* when cells with silenced KDEL-R2 were mixed with normal tumor cells in a 1:10 ratio and treated with DOX, tumors significantly regressed in mice. Analysis of the TME (via flow cytometry, IHC, and IF) revealed a massive infiltration of neutrophils and macrophages, most are polarized to M1. In vitro macrophage polarization studies confirmed that from the silencing of KDEL-R2 confers polarization. Using a novel biotin-labeled probe to detect extracellular PDIs, we confirmed the robust ICD intensity of KDEL proteins in the TME. In athymic Nu/Nu mice, KDEL-R2 silencing also induced tumor regression, underscoring the dominant role of innate immunity. Re-challenge experiments demonstrated T-cell priming and the establishment of immune memory, supported by T-cell and macrophage infiltration in the TME. Additionally, using tumor cells that present an antigenic MHC class I peptide, we demonstrate T cell priming in the absence of vaccination. This study reveals a significant advancement in cancer immunotherapy and potential for synergistic effect with other treatments such as CAR-T therapy and checkpoint inhibitors through immune memory and inflammation-driven immunity.

#5858 Prognostic and predictive role of T cell infiltration in stage III colon cancer (CC) treated with celecoxib: CALGB/SWOG 80702.

Yasutoshi Takashima[1], Chao Ma[1], Qian Shi[2], Andressa Dias Costa[1], Tyler Twombly[3], Juha P. Vayrynen[4], Melissa Zhao[3], Ardaman Shergill[5], Pankaj Kumar[6], Felix Couture[7], Philip Kuebler[8], Smitha Krishnamurthi[9], Benjamin Tan[10], Eileen M. O'Reilly[11], Anthony F. Shields[12], Shuji Ogino[3], Charles S. Fuchs[13], Jeffrey A. Meyerhardt[1], Jonathan A. Nowak[3]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Alliance Statistics and Data Management Center, Mayo Clinic, Rochester, MN,[3]Brigham and Women's Hospital, Boston, MA,[4]University of Oulu and Oulu University Hospital, Oulu, Finland,[5]The University of Chicago Medical Center, Chicago, IL,[6]Heartland Cancer Research NCORP, Illinois CancerCare PC, Peoria, IL,[7]Hotel-Dieu de Quebec, Quebec City, QC, Canada,[8]Columbus NCI Community Oncology Research Program, Columbus, OH,[9]Cleveland Clinic, Cleveland, OH,[10]Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO,[11]Memorial Sloan Kettering Cancer Center, Weill Cornell Medical Center, New York, NY,[12]Karmanos Cancer Institute, Wayne State University, Detroit, MI,[13]Genentech, South San Francisco, CA

Observational studies have demonstrated that aspirin and/or PTSG2 inhibitor (e.g., celecoxib) use, before or after colon cancer (CC) diagnosis, is associated with a lower risk of recurrence. However, a randomized trial of adjuvant celecoxib therapy in stage III CC did not show improved survival compared to placebo treatment. We therefore hypothesized that immune microenvironment features may identify patient subgroups with stronger survival benefits from anti-inflammatory celecoxib treatment. Drawing from an NCI-Intergroup trial (Cancer and Leukemia Group B [now Alliance for Clinical Trials in Oncology]/SWOG 80702) for patients with stage III resected CC that compared 3 versus 6 months of adjuvant fluorouracil, leucovorin, and oxaliplatin ± 3 years of celecoxib, we conducted tissue-based tumor microenvironment profiling on 1,098 resected tumors using a custom 9-plex, T-cell multiplex immunofluorescence assay coupled with digital image analysis and supervised machine learning. The Kaplan-Meier method was used to describe disease-free survival, based on T cell density, and log-rank testing was performed. Cox proportional hazards models were used to examine unadjusted and adjusted associations between T cell density and disease-free survival (DFS). Two-sided P values ≤0.05 were considered statistically significant. We found that higher $CD3^+$ T cell density was associated with longer DFS with an adjusted hazard ratio (HR) of 0.69 (95% confidence interval [CI] 0.52-0.91) for patients with densities in the highest tertile as compared the lowest tertile (P=0.01). T cell subset analysis showed that stromal regulatory T helper cells (HR 0.42 comparing highest to lowest tertile, CI 0.31-0.58, P<0.001) and stromal memory cytotoxic T cells (HR 0.55 comparing highest to lowest tertile, CI 0.42-0.74, P<0.001) were most strongly associated with longer DFS. Compared to the placebo group, adjuvant celecoxib use associated with improved DFS for patients with low but not high stromal $CD3^+$ T cell density (adjusted HRs of 0.45 [CI 0.31-0.65] for lowest tertile and 1.13 [CI 0.73-1.74] for highest tertile; $P_{interaction}$=0.01). This association was also seen when the analysis was restricted to microsatellite stable tumors (HR 0.50 [CI 0.32-0.80] for lowest density tertile and 1.50 [CI 0.87-2.59] for highest density tertile; $P_{interaction}$=0.01). T cell subset analysis showed that DFS benefit for celecoxib use most strongly associated with stromal memory helper T cell density (HR 0.38 [CI 0.26-0.56] for lowest density tertile and 1.26 [CI 0.80-1.97] for highest density tertile; $P_{interaction}$<0.001). Together, these results show that while higher T cell infiltration is associated with improved DFS, lower T cell infiltration is associated with improved DFS for patients treated with celecoxib. This unexpected finding may inform immunomodulatory treatment strategies for CC.

#5859 Circulating myeloid-derived suppressor cells (MDSC) are increased and correlated with immunosuppression, systemic inflammation and malnutrition in patients with anaplastic thyroid cancer.

M. Shibata, S. Suzuki, K. Kono, S. Takenoshita;
Fukushima Medical Univ., Fukushima, Japan

Anaplastic thyroid cancer (ATC) is one of the most aggressive neoplasm in humans. Myeloid-derived suppressor cells (MDSC) contribute to the negative regulation of immune responses in cancer and are reported to be further increased in patients who immune checkpoint inhibitor is not effective. In order to investigate the pathophysiology of thyroid cancer, peripheral blood mononuclear cells (PBMC) were obtained from 49 patients with thyroid cancer, 18 with non-cancerous thyroid diseases and 22 healthy volunteers. MDSC were detected by flow cytometry (CD14-CD11b+CD33+) and Tcell-mediated immune response is measured by stimulation index (SI) of PHA-stimulated proliferation of lymphocytes. CRP (C-reactive protein) levels were used as inflammatory and serum albumin levels were used as nutritional parameters. MDSC levels were significantly higher in thyroid cancer than in healthy volunteers and non-cancerous patients, and those of ATC was highest among patients with thyroid cancer. SI were significantly lower, and CRP levels were higher in ATC than other histological types of thyroid cancer. The patients with thyroid cancer were divided into 2 groups with the average level of MDSC (1.578 %PBMC) in patients with thyroid cancer. CRP levels were significantly higher, serum albumin levels were significantly lower in high MDSC group than in low MDSC group. These data indicate that MDSCs are increased in patients with ATC. Furthermore, these patients exhibited immunosuppression, enhanced chronic inflammation and nutritional impairment.

#5860 Stimulator of interferon genes protein (STING) expression in tumor cells is linked to favorable disease parameters and a high density of tumor infiltrating inflammatory cells in urinary bladder cancer.

Henning Plage[1], Jacob Schmidt[1], Sebastian Hofbauer[1], Kira Furlano[1], Sarah Weinberger[1], Bernhard Ralla[1], Annika Fendler[1], Nadine Biernath[1], Barbara Erber[1], Florian Ro?ner[1], Simon Schallenberg[1], Sefer Elezkurtaj[1], Maximilian Lennartz[2], Elena Bady[2], Lisa Hornsteiner[2], **Claudia Hube-Magg**[2], Margit Fisch[2], Michael Rink[2], Henrik Zecha[3], Thorsten Ecke[4], Stefan Koch[4], Nico Adamini[3], Ronald Simon[2], Guido Sauter[2], Tobias Klatte[5], David Horst[1], Martina Kluth[2], Stefan Steurer[2], Sarah Minner[2], Thorsten Schlomm[1]

[1]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany,[2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Albertinen Hospital, Hamburg, Germany,[4]Helios Hospital Bad Saarow, Bad Saarow, Germany,[5]Helios Hospital Bad Saarow, Bad Saarow, Germany

STING is a key element in the cGAS/STING cytosolic DNA sensing pathway which can stimulate immune response through type I interferon (IFN) production. Numerous STING agonists are currently evaluated for their suitability as anticancer drugs. Most previous studies focused on STING expression in inflammatory cells, but STING can also be expressed in cancer cells. To evaluate the potential clinical significance of STING expression in bladder cancer cells, STING was analyzed by immunohistochemistry in more than 2,500 urothelial bladder carcinomas in a tissue microarray format. STING staining in tumor cells occurred in 59.1% of urothelial carcinomas including 31.1% with weak, 11.6% with moderate, and 16.3% with strong staining. Detectable STING expression in tumor cells was associated with histo-pathological features of favorable disease course including absence of invasion ($p<0.0001$), low grade in pTa ($p<0.0001$) and in pT2-4 ($p=0.0018$) tumors, pN0 ($p=0.0036$), L0 (0.0084), and V0 (0.0006) status in pT2-4 cancers, but was not significantly associated with overall, recurrence-free and tumor specific survival. A comparison with previously collected immune cell parameters revealed significant associations between high STING expression in tumor cells and high numbers of tumor infiltrating lymphocytes including various T-cells populations (CD8: $p<0.0001$, CD4: $p=0.0462$, FOXP3: $p=0.0001$), macrophages (M1: $p=0.00003$, M2: $p<0.0001$), dendritic cells ($p<0.0001$), and PD-L1 expression on tumor cells ($p<0.0001$). It is concluded that high STING expression of tumor cells is strongly linked to a high density of tumor infiltrating inflammatory cells which is most likely causative for the significant associations with favorable disease parameters. Given the abundant presence of STING in immune cell rich urothelial cancers, STING agonists may exert significant effects in STING positive cancers.

#5861 Characterizing an immune synapse between plasmacytoid dendritic cells and cancer cells that drives cancer cytotoxicity.

Tobias Wang Bjerg[1], Ian Helstrup Nielsen[1], Sabina Sanchez Hernandez[1], Anders Laustsen[1], Isabella Barbutti[2], Shuli Svetitsky[2], James Lee[2], Rasmus Bak[1], Martin Jakobsen[1]

[1]Aarhus University, Aarhus, Denmark,[2]Francis Crick Institute, London, United Kingdom

Background: Plasmacytoid dendritic cells (pDCs), a unique type of innate immune cells, are known to play an important role in fighting viral infections, especially due to their capacity to sense DNA/RNA nucleic acids by TLR7/-9, and production of type-I interferons. The role of pDCs in driving immunological effects in cancer development and mounting antitumoral responses remains to be elucidated, though few studies describe opposing outcomes in patients based on tumor infiltrating pDCs. These observations come with little evidence explaining the immunosuppressive or tumorigenic state of pDCs.

Methods: To study fundamental anti-tumoral functions of pDCs we utilized a robust and validated *in vitro* stem-cell derived human pDC model. Importantly, this model permits genetic manipulation prior to pDC differentiation and enables large-scale co-culture studies with various cancer types. Using this model, we recently employed a CRISPR library screening approach to identify factors that aid the cytotoxic mechanisms of pDCs following co-culture with tumor cell lines.

Results: Initially, using co-culture assays consisting of hematological, lung, or breast cancer cell lines in combination with *in vitro* generated pDCs, we demonstrated a time-dependent cytotoxic effect using Incucyte live imaging. Importantly, cytotoxic effects were elevated when pDCs had been stimulated with TLR9 agonists. We demonstrated that a direct cell-to-cell interaction was essential for pDC cytotoxicity, and that promoting stronger cell-to-cell interaction, by genetically modifying pDCs to express scFv targeting a tumor antigen, increased the killing effects. CRISPR knock-out of Granzyme B in pDCs did not remove the cytotoxic capabilities of pDCs. We are currently conducting a genetic screen to identify universal factors vital for pDC interactions and cytotoxicity effects in cancer settings. This preliminary data will be presented at the AACR meeting.

Conclusion: Using *in vitro*-generated pDCs we explore an important anti-tumoral function of pDCs. If successful, our work can open for potential new therapeutics and prognostic possibilities in cancer treatment, harnessing the cytotoxic effects of pDCs.

#5862 Combining circular RNA and a silicon membrane-based cell engineering approach to create CAR-Ts with membrane bound IL-2 and IL-12.

Zhihui Song, Andrew Larocque, Sophia Hirsch, Eleni Rogers, Darby Kreienberg, Jacquelyn Hanson, Alec Barclay, Armon Sharei

Portal Biotechnologies, Inc., Watertown, MA

Engineered immune cell therapies have great potential to revolutionize the treatment of many pathologies such as cancer, autoimmunity and infectious diseases. However, limitations remain in some areas including long manufacturing times, inability to engineer critical cell functions, potential for cell exhaustion, and limited access to the disease site as in the case for solid tumors. Portal has developed a novel implementation of mechanoporation technology using a silicon membrane with pores which enables deformation of the cell and poration of the cell membrane, allowing for diffusion of any cargo, charged or uncharged, into the cell. Mechanoporation is a gentle intracellular delivery technique that preserves cell viability and function (DiTommaso, et al., PNAS 2018). It can shorten manufacturing time and enable the introduction of key therapy-enhancing factors via transient modifications shortly before administration. Portal has established methodology for cytoplasmic introduction of many diverse cargo including mRNA, circular RNA, siRNA, proteins, peptides, and CRISPR RNPs to primary immune cells, including both unstimulated and activated T cells, B cells, NK cells, monocytes and iPSCs. In this work, we demonstrated simultaneous expression of a functional CD19 CAR, membrane bound IL-2 and membrane bound IL-12 through delivery of three circRNAs into activated T cells. They are highly expressed for multiple days while maintaining high viability and ensuring robust in vitro killing. The expression of mbIL2 and mbIL12 not only promotes T cell proliferation but also upregulates CD62L and enhances the cytotoxic function of CAR T cells. At clinical scale, we have demonstrated delivery of RNA to over 1 billion T cells while achieving over 90% expression. Portal's technology and approach has the potential to further advance immune cell therapy developments, particularly in multiplexed engineering approaches involving simultaneous delivery of multiple cargos. Coupled with Portal's compatibility with diverse immune cell types and next generation cargos. We believe this simple approach to intracellular delivery can dramatically reduce manufacturing time and cost, easily integrate into existing clinical equipment and enable unique enhancements that underpin a new generation of therapeutics.

#5863 Mapping tumor metastasis and EMT-associated immune changes in HNSCC through spatial transcriptomic analysis.

Chih-Hung Chung, Muh-Hwa Yang

National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Head and neck squamous cell carcinoma (HNSCC) is a globally prevalent malignancy. Standard treatments typically include surgical resection, radiation therapy, and chemotherapy. However, for patients with recurrent or distantly metastatic tumors where surgery or radiation is no longer feasible, the primary treatment strategy shifts to combining targeted therapies with chemotherapy or immune checkpoint blockade (ICI) therapy. Despite these approaches, the overall prognosis remains poor. Therefore, identifying key changes in immune cell composition within the tumor microenvironment of malignant or metastatic tumors is crucial for improving the management and outcomes in HNSCC therapy.

The aim of this study is to analyze changes in the immune microenvironment composition across different HNSCC specimens. We utilized tools including the GeoMx Digital Spatial Profiler (DSP) for imaging-based digitized gene expression analysis. We identified region of interesting (ROI) from distinct tumor regions, such as the tumor invasive front, tumor core, and paired lymph node metastases. Through the Cancer Transcriptome Atlas (CTA) analysis, we identified two distinct epithelial-mesenchymal transition (EMT) gene signatures, which were highly expressed in particularly aggressive tumor tissues. Additionally, within the myeloid activation signature, we observed that immune cell composition in primary tumor site was predominantly neutrophil-activated, whereas in lymph node metastases, macrophages were the dominant immune cells. To further validate these observations, we applied other spatial transcriptomics tools, including 10x Visium and 10x Xenium, to analyze specimens from six HNSCC patients. Transcriptomic trajectory analysis and ligand-receptor pair analysis revealed significant changes in the immune microenvironment of malignant HNSCC tissues.

These results provide crucial insights into head and neck cancer treatment strategies tailored to different tumor microenvironment (TME) characteristics.

#5864 Preclinical investigation of anti-tumor efficacy of allogeneic natural killer cells combined with cetuximab for head and neck squamous cell carcinoma.

Chaeyeon Kim[1], Mina Han[1], Gamin Kim[2], Wonrak Son[1], Jeongah Kim[1], Minchan Gil[3], Yong-Hee Rhee[3], Nam Suk Sim[4], Chang Gon Kim[5], Hye Ryun Kim[5]

[1]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Oncology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]NKMAX Co., Ltd., Seoul, Korea, Republic of,[4]Department of Otorhinolaryngology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Head and neck squamous cell carcinoma (HNSCC) is a challenging malignancy with limited response rates to conventional therapies, including immune checkpoint inhibitors and cetuximab monotherapy. Despite recent advancements in immunotherapy, a significant unmet need remains owing to suboptimal efficacy. This study investigated the potential of a novel combination therapy using allogeneic natural killer (NK) cells and cetuximab, an anti-epidermal growth factor receptor monoclonal antibody, to enhance anti-tumor efficacy in HNSCC.
Method: Allogeneic NK cells from healthy donors were expanded and tested *in vitro,* and NOG (NOD/Shi-scid/IL-2Rγ null) xenograft mouse models were used to evaluate their efficacy and functionality. *In vitro* assays were employed to evaluate cytotoxicity against HNSCC cells (FaDu) in combination with cetuximab, focusing on the effects of antibody-dependent cellular cytotoxicity (ADCC). *In vivo* experiments assessed the efficacy of high-dose NK cell infusion with cetuximab in reducing tumor growth and improving survival in xenograft mouse models. NK cell infiltration and cytotoxicity were analyzed using flow cytometry and immunohistochemistry.
Results: An increased dose of NK cells was selected for subsequent studies owing to its superior ability to improve survival outcomes and inhibit tumor cell proliferation despite no marked differences growth between the NK-low and NK-high groups. During the selection process for allogeneic NK cells and their partner drugs, interleukin (IL)-2 was selected and tested in the xenograft mouse model. However, the lack of an improved anti-tumor response through the IL-2 combination in vivo prompted us to investigate other combination treatment partners. While IL-2 showed limitations in enhancing NK cell activity in vivo, Combination therapy encompassing allogeneic NK cells and cetuximab demonstrated significantly enhanced cytotoxicity against FaDu cells in vitro, which was attributed to ADCC. In vivo, the combination of allogeneic NK cells and cetuximab effectively managed HNSCC in NOG xenograft mouse model, showing significant reductions in tumor growth and improved survival rates. Additionally, Flow cytometry and immunohistochemistry revealed increased infiltration of NK cells within the tumors, confirming enhanced ADCC-mediated anti-tumor activity. These results highlight the potential of this combination therapy to enhance anti-tumor efficacy.
Conclusion: These findings underscore the potential of combining allogeneic NK cells with cetuximab to improve the therapeutic outcomes in HNSCC. The observed synergy between NK cells and cetuximab highlights a promising therapeutic approach for enhancing NK cell-mediated cytotoxicity through ADCC and, lays a foundation for future clinical trials aimed at addressing unmet needs in HNSCC treatment.

#5865 Novel allosteric STING agonists in combination with DNA methyltransferase inhibitors induce an interferon-driven apoptotic response in *TP53*-mutated acute myeloid leukemia.

Kaushlendra Tripathi[1], Lora Stojanovic[1], Monali BanerJee[2], Sandip Middya[2], Ritesh Srivastava[2], Arjun surya[2], Stephen B. Baylin[3], Michael Topper[3], Maria R. Baer[1], Fervez Rassool[1]

[1]University of Maryland, Baltimore, Baltimore, MD,[2]Curadev Pharma, Noida, India,[3]Johns Hopkins School of Medicine, Baltimore, MD

TP53-mutated acute myeloid leukemia (AML) has dismal outcomes; new therapies are needed, and immunotherapeutic approaches are being explored. STimulator of INterferon Genes (STING) is a key innate immune driver that activates interferon (IFN) and nuclear factor Kappa B (NFκB)/tumor necrosis factor-alpha (TNFα) signaling. We previously reported that phospho (activated)-STING expression is higher in *TP53*-mutated AML and that DNA methyltransferase inhibitors (DNMTis) demethylate epigenetically silenced endogenous retroviruses (ERVs), increasing cytosolic dsRNA and IFN signaling in a viral mimicry mechanism. Moreover DNMTis upregulate STING transcription. Thus STING agonists in combination with DNMTis could be an attractive therapy in *TP53*-mutated AML.

The next-generation allosteric STING agonists CPD 1 and 2 potently bind and activate all human STING variants. While CPD 1 has been extensively used for *in vitro* cellular studies, the more advanced analogue CPD 2 (CRD3874-SI) is currently in Phase I clinical trials in patients with solid cancers (MSKCC) and AML (UMGCCC). We perfomed MTS assays in *TP53*-mutated and -WT AML cell lines and primary cells (N=4) treated with CPD 1 and DNMTi decitabine (DAC) combination *in vitro.* Decreased viability was particularly noted in *TP53*-mutated cells, and the drug combination was synergistic, with combination index <1. To test the transcriptome-wide effects of CPD 1 and DAC, we performed ribosomal depleted RNA-seq on WT and *TP53* CRISPR KO MOLM-14 AML cells after treatment for 3 days. Differentially expressed genes (DEGs) were markedly increased in *TP53* CRISPR KO MOLM-14 treated with CPD 1 and CPD 1 + DAC. Moreover, increased repetitive element (RE) expression was largely restricted to *TP53*-KO cells treated with CPD 1 and CPD 1 + DAC. Pathway analyses for both CPD 1- and CPD 1 + DAC-treated *TP53*-KO cells showed conserved positive enrichment of gene sets associated with Type I/II IFN, TNFα, and apoptosis. Drug combination-specific augmented genes resided in critical interferon gene categories such as Th1 type chemokines (*CXCL10, CXCL11*), RNA detection (*DHX58, EIFAK2, IFIH1, OASL, PARP9, RIGI*), and IFN signaling-induced cell death (*IFI27, IFI44L, IFIT2, MX1, OAS1, OAS2, OAS3, and TNFSF10)*, thus potentially combining substrate, sensors, and effectors in a suicidal interferon-driven apoptosis response in TP53 KO cells. qPCR and apoptosis detection by Annexin V staining validated these findings in *TP53*-mutated vs -WT AML cell lines and patient samples. Treatment with the IFN inhibitor ruxolitinib or the pan-caspase inhibitor ZVAD rescued IFN-driven apoptosis. Finally CPD 1 in combination with DAC significantly reduced leukemia burden in humanized AML mouse models. These results support development of a clinical trial combining CRD3874-SI with DAC for patients with *TP53*-mutated AML.

#5866 Role of inflammatory cytokines and matrix metalloproteinases in colorectal cancer in a Hispanic population.

Elba V. Caraballo, Sheila Natalie Lopez Acevedo, **Camille Zenon-Melendez**, Josue Perez Santiago, Marcia R. Cruz-Correa

University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Colorectal cancer (CRC) is a leading cause of cancer-related deaths in Puerto Rico and the United States. Puerto Rican Hispanics (PRH) experience disproportionately higher CRC incidence and mortality rates compared to the general Hispanic population in the U.S. Biological processes, such as cytokine dysregulation and extracellular matrix remodeling, may contribute to these disparities. However, the molecular mechanisms driving CRC disease progression in PRH remain poorly understood. This study investigates the roles of inflammatory cytokines and matrix metalloproteinases (MMPs) in CRC disease progression.
Methods: We conducted a case-case study using tumor (n=15) and adjacent mucosa (n=15) tissue samples collected from early (n=7) and advanced-stage (n=8) CRC archived cases recruited through the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR). RNA-seq was performed and analyzed for differential gene expression and fold changes (FC) for key immune-related pathways, including MMPs, interleukin IL-17(IL17), associated cytokines, and chemokines. STRING database was used to identify protein-protein interaction networks and functional associations (≥5 gene connections).
Results: Transcriptomic analysis revealed stage-specific expression patterns. IL-13 was differentially expressed in early-stage tumors, while advanced-stage tumors were characterized by CXCL10 expression Both IL-17A and IL-8 were upregulated in early and advanced stages. Elevated expression levels of IL-17A (log2 FC: 2.72 vs 3.11) and IL-8 (log2 FC: 5.73 vs 3.44) were observed in tumor tissues compared to adjacent mucosa (adj. $p<0.05$). Advanced-stage tumors also showed increased expression of MMP13 and MMP3, indicating extracellular matrix remodeling and invasion. IL-17A-related pathways were consistently upregulated, suggesting their involvement in chronic inflammation, tumor growth, and immune escape.
Conclusions: Our results show that differential expression of IL-17A and IL-8 at early-stage CRC may contribute to immune dysregulation and a tumor-promoting microenvironment. In advanced stages, elevated MMP expression could promote extracellular matrix remodeling, metastasis, and immune evasion. These findings suggest that IL-17A, IL-8, and MMPs are potential therapeutic targets for addressing CRC disease progression and reducing health disparities among PRH.

#5867 Uncovering T-cell receptor clones and immunogenic targets in HER2DX-defined HER2-positive breast cancer.

Victor Albarran-Fernandez[1], Carlota Rubio-Perez[2], Patricia Galvan[3], Oleguer Castillo[3], Paula Blasco[3], Esther Sanfeliu[4], Anabel Martinez-Romero[3], Mercedes Marin[5], Patricia Villagrasa[5], Francisco Pardo[5], Laia Pare[5], Isabel Garcia-Fructuoso[1], Raquel Gomez[1], Elia Segui[1], Barbara Adamo[1], Benjamin Walbaum[1], Olga Martinez-Saez[1], Tomas Pascual[1], Maria Vidal[1], Montserrat Munoz[1], Sonia Guedan[6], Fara Braso[3], Laura Angelats[1], Aleix Prat[7]

[1]Medical Oncology Department, Translational Genomics and Targeted Therapeutics in Solid Tumors, Hospital Clinic, Barcelona, Spain,[2]Medical Oncology Department, Hospital Clinic, Barcelona, Spain,[3]Translational Genomics and Targeted Therapeutics in Solid Tumors (IDIBAPS), Hospital Clinic, Barcelona, Spain,[4]Anatomic Pathology, Translational Genomics and Targeted Therapeutics in Solid Tumors, Hospital Clinic, Barcelona, Spain,[5]Reveal Genomics, Barcelona, Spain,[6]Cellular Immunotherapies for Cancer, August Pi I Sunyer Biomedical Research Institute (IDIBAPS), Hospital Clinic, Barcelona, Spain,[7]Medical Oncology, Translational Genomics and Targeted Therapeutics in Solid Tumors, Reveal Genomics, Hospital Clinic, Barcelona, Spain

Purpose: To explore the role of the immune system in early-stage HER2+ breast cancer (HER2+ BC), focusing on how T-cell receptor (TCR) dynamics relate to the prognostic 14 B-cell gene/IgG immune signature (IGG) included in the clinically available HER2DX genomic test. This study aims to clarify how TCR diversity and targeting of tumor-associated antigens (TAA) contribute to patient outcomes and could inform potential therapeutic strategies.
Experimental design: TCR/BCR clones were identified by PCR amplification and deep sequencing (ImmunoSEQ) in 41 early-stage HER2+ BC samples. CDR3 sequences were cross-referenced with the VDJ database, excluding inconclusive matches (VDJdb score 0-1). Protein expression was analyzed by digital spatial profiling (GeoMx) in 23 samples. In 6 samples, TCR identification was performed through single-cell RNA sequencing (scRNAseq; Chromium). IGG expression in each sample was evaluated using the HER2DX assay and correlated with bulk RNA data from TCGA and MTBC datasets. Spearman's correlation and Wilcoxon tests were used for statistical analysis (R software).
Results: Of the 12,575 TCR clones with predicted targets, 759 (5.9%) showed reliable matches (score 2-3). 53 of them (7%) recognized TAA, primarily MART1 (18.9%), followed by gp100, ABCD3, MAGEA6, KRAS, NY-ESO1, p53, TERT, and others. Most non-human epitopes belonged to common viruses such as Influenza A (31.2%), EBV (30.7%), and CMV (20%). IGG expression was correlated with the number of TCR templates (Cor: 0.47, $p<0.01$), TCR entropy (Cor: 0.60, $p<0.001$), and shared TCR clonotypes between samples (Cor: 0.48, $p<0.01$). IGG was higher in samples with TCR clones against TAA (p50 75.6 vs. 61.1, $p=0.044$). A positive correlation was observed between the number of clones targeting human and viral epitopes (Cor: 0.44, $p=0.013$). The scRNAseq data confirmed that IGG-high samples exhibit greater TCR polyclonality and a higher fraction of cytotoxic CD8+ T cells ($p<0.05$), with upregulated perforin and granzyme A/B expression. IGG correlated with CD27 (Cor: 0.47, $p=0.025$) and CD3 (Cor: 0.52, $p=0.011$) protein levels, as well as the IFN-γ signature in TCGA (Cor: 0.56, $p<0.01$) and MTBC (Cor: 0.71, $p<0.01$) data. Fibronectin correlated with PD1 (Cor: 0.61, $p<0.01$) and CTLA4 (Cor: 0.81, $p<0.001$) levels, and inversely with IGG (Cor: -0.50, $p=0.017$), indicating that IGG-low tumors might have a denser stroma and a more exhausted, less active immune infiltrate.
Conclusions: Early-stage HER2+ BC with high IGG expression is characterized by a robust, polyclonal immune response, with TCR clones targeting both tumor and viral antigens. These findings suggest enhanced immune fitness and may explain IGG favorable prognostic value. The discovery of shared TCR clones across tumors may help identify immunogenic targets, providing new opportunities for developing immune-based treatments or engineered T-cell therapies.

#5868 Differential tumor immunity in limited-stage vs extensive-stage small cell lung cancer.

Jiyeon Kim[1], Jun-Gi Jeong[2], Sehhoon Park[3], Hyun Ae Jung[3], Jong-Mu Sun[3], Jin Seok Ahn[3], Myung-Ju Ahn[3], Se-Hoon Lee[3]

[1]Department of Health Sciences and Technology, SAIHST, Sungkyunkwan University, Samsung Medical Center, Seoul, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of,[3]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Introduction: Small cell lung cancer (SCLC) is an aggressive malignancy characterized by rapid progression and early metastasis. Immunotherapy has become the standard treatment for extensive-stage SCLC (ES-SCLC), but its role in limited-stage SCLC (LS-SCLC) remains under investigation in clinical trials. This study aims to explore the differences in tumor immune microenvironment (TIME) of LS-SCLC and ES-SCLC and to suggest how these differences may influence therapeutic strategies and patient outcomes.
Methods: Samples from 365 patients were collected with histologically confirmed SCLC who had available tissue samples. Whole transcriptome sequencing (WTS) was performed on all samples. The patients were categorized based on clinical staging at the time of biopsy. Using WTS data, immune cell composition was analyzed using CIBERSORTx deconvolution algorithm, and the signature was calculated as the mean of the Transcripts Per Million (TPM) values using curated genes. edgeR was used for differential gene expression and performed GSEA using KEGG pathway database. SCLC subtypes were assigned based on lineage-defining transcription factor (TF) markers (as described by S Park, et al., eBioMedicine, 2024). Statistical significance was evaluated when the P value was below 0.05.
Results: Of the 365 patients, 100 were classified as LS-SCLC, and 265 as ES-SCLC. The median age was 65.3 years for LS-SCLC and 67.8 years for ES-SCLC. The LS-SCLC included 6% never smokers, while the ES-SCLC cohort comprised 8.3% never smokers. Biopsy site distribution was as follows: in LS-SCLC, 28% of tissues were obtained from the lung, bronchus, or trachea, 72% from lymph nodes. Similarly in ES-SCLC, 23% of tissues were from the lung, 69% from lymph nodes, and 9% from other distant organs. Immune cell profiling identified stage-specific differences in the immune landscape. LS-SCLC exhibited significantly higher levels of B cells and activated dendritic cells (DCs), whereas ES-SCLC showed increased proportions of resting DCs and neutrophils. The angiogenesis signature was significantly elevated in ES-SCLC, reflecting distinct immune-modulating effects in TIME. Differential gene expression revealed enrichment of KEGG gene sets related to the peroxisome proliferator-activated receptor (PPAR) signaling and ERBB signaling in ES-SCLC. Subtype distribution based on WTS data showed a significant difference between stages, with the ASCL1 subtype (SCLC-A) more frequent in LS-SCLC and the POU2F3 subtype (SCLC-P) more common in ES-SCLC.
Conclusions: Our findings highlight significant differences in the TIME and molecular subtypes between LS-SCLC and ES-SCLC. These differences may inform the development of tailored therapeutic strategies, ultimately improving patient outcomes by addressing the unique immune and molecular characteristics of LS-SCLC and ES-SCLC.

#5869 Exploring chronic stress-induced hippocampal changes in murine ovarian cancer models and their relevance to depressive-like behaviors.

Luinet Lee Melendez-Rodriguez[1], Luis M. Rivera-Perez[1], Yadiel A. Rivera-Lopez[1], Melanie Ortiz-Leon[1], Jaydiel Casiano-Martinez[1], Alanis P. Torres-Rosado[1], Zuliann S. Galarza-Ruiz[2], Nemesis J. Torres-Rivera[3], Orlando I. Torres-Rodriguez[1], Guillermo N. Armaiz-Pena[1]

[1]Ponce Health Sciences University, Ponce, Puerto Rico,[2]Interamerican University of Puerto Rico, Ponce, Puerto Rico,[3]Pontifical Catholic University of Puerto Rico, Ponce, Puerto Rico

Patients with ovarian cancer (OC) often experience depression, which can negatively impact their quality of life and overall prognosis. Our research group has demonstrated that chronic stress (CS) induces systemic inflammation, contributing to disease progression. Other studies have also highlighted its role in the development of depressive symptoms. Microglia are key regulators of brain inflammation and serve as a primary source of brain-derived neurotrophic factor (BDNF), which is crucial for maintaining synaptic plasticity, neuronal survival, and reducing symptoms of depression. However, the influence of CS and OC on the development of depressive symptoms in OC patients remains poorly understood. This study aims to investigate whether CS and OC can induce changes in the hippocampus (HPC) that may lead to depressive-like behavior in mice with OC. We hypothesize that CS will increase microglial infiltration and inflammatory markers, while reducing BDNF levels and neuronal activity in the HPC of mice with OC. To test our hypothesis, we inoculated 8- to 12-week-old C57BL/6 mice with ID8^{luc} or IG10^{luc} OC cells and subjected them to daily restraint stress for four weeks. Upon sacrifice, we collected and processed their brains for immunofluorescence analysis of BDNF, IBA1, and c-Fos. Our data suggest that CS accelerated tumor growth and led to increased microglial infiltration, decreased BDNF levels, and reduced neuronal activity in the HPC. These findings align with the BDNF hypothesis, which posits that a loss of BDNF in the HPC is directly involved in the development of depression. This study lays the groundwork for further research on how OC and CS can modulate brain activity and behavior.

#5870 Blocking cadherin-11 activates pyroptosis-mediated antitumor immunity via the PD-L1/GSDMD/CCL3 axis in bladder cancer.

Thomas I-Sheng Hwang[1], **An-Chen Chang**[2]

[1]Department of Surgery, Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan,[2]School of Oral Hygiene, Taipei Medical University, Taipei, Taiwan

Introduction: Pyroptosis, a form of programmed cell death driven by proinflammatory signals, plays a dual role in inflammation and cancer progression. Cadherin-11 (CDH-11), a type II cadherin, is known to mediate cell-cell and cell-extracellular matrix adhesion. Emerging evidence suggests that CDH-11 contributes to tumor progression and metastasis, making it a potential therapeutic target. In this study, we investigate whether targeting CDH-11 can suppress bladder cancer (BC) cell invasiveness and activate pyroptosis-mediated antitumor immunity.
Materials & Methods: Transwell assays were conducted to evaluate cell migration and invasion abilities. Pyroptosis was measured using lactate dehydrogenase (LDH) assays, while calcein AM staining-based cytotoxicity assays were employed to measure natural killer (NK) cell-mediated cytotoxicity. Inflammatory cytokine levels in BC tissues were determined using a human antibody array. To investigate the role of CDH-11 in tumor progression, a subcutaneous tumor model and a popliteal lymph node model were established to evaluate tumor growth and lymphatic metastasis *in vivo*. Immunohistochemistry staining was utilized to assess CDH-11 protein expression in human BC tissues.
Results: Elevated CDH-11 expression was observed in BC patients compared to healthy individuals, with a positive correlation to advanced clinical stages, lymphatic metastasis, and poor overall survival. In vitro analyses demonstrated that blocking CDH-11 significantly reduced BC cell invasiveness. Notably, CDH-11 blockade induced bubble-like protrusions on the cell surface and increased LDH release, indicative of enhanced pyroptosis. Mechanistically, CDH-11 inhibition activated PD-L1-mediated GSDMD expression, with the GSDMD N-terminal domain forming membrane pores to initiate pyroptosis. Further analysis revealed that CDH-11-induced pyroptosis elevated the release of the proinflammatory cytokine CCL3 within the tumor microenvironment, thereby enhancing natural killer (NK) cell-mediated cytotoxicity against BC cells. In vivo, CDH-11 blockade effectively suppressed tumor growth, lymphatic metastasis, and lung metastasis, highlighting its therapeutic potential.
Conclusions: These findings reveal a novel role of CDH-11, demonstrating that its inhibition suppresses cell invasion and enhances pyroptosis-mediated antitumor immunity through CCL3 in BC. Targeting CDH-11 represents a promising therapeutic strategy for the management of BC.

#5871 Comparative analysis of single-cell immune cell transcriptional profiles in humans, mice, and dogs: insights from normal and tumor states.

Aaron L. Sarver[1], Caitlyn M. Callaghan[2], Marissa Macchietto[2], Lauren Burt[2], Meagan Wojtysiak[2], Courtney H. Labe[2], Taylor DePauw[2], Ashley Schulte[2], Kelly M. Makielski[2], Julia E. Medland[2], Jaime F. Modiano[2]

[1]Institute for Health Informatics Masonic Cancer Center, University of Minnesota, Minneapolis, MN,[2]University of Minnesota, Minneapolis, MN

The immune system plays a critical role in defending against pathogens and surveilling tumors. Understanding immune cell behavior in both health and disease is essential for advancing therapeutic strategies, particularly in oncology. However, there remains a gap in knowledge regarding how immune cell profiles differ across species and how these differences might impact cancer immunology. In this study, we conduct a comparative analysis of single-cell transcriptional profiles of immune cells from three mammalian species—humans, mice, and dogs—under both normal and tumor-bearing conditions. Using high-throughput single-cell RNA sequencing (scRNA-seq), we aim to identify both conserved and species-specific transcriptional signatures that define immune cell function in health and cancer, with the ultimate goal of enhancing translational research and therapeutic development. To generate a comprehensive dataset, we analyzed immune cell samples from both normal and tumor tissues across humans, mice, and dogs. These species were selected for their distinct immunological and clinical features: humans as the primary model for clinical oncology, mice as the standard laboratory model for cancer research, and dogs as a naturally occurring cancer model with genetic and environmental similarities to humans. Immune cells from canine samples were isolated and analyzed using scRNA-seq. Publicly available human, mouse and canine datasets were also incorporated into the analysis. Analyses of these datasets enabled high-resolution characterization of the immune landscape in each species. We developed a pipeline to systematically identify both commonalities and species-specific differences in immune cell transcriptional profiles. In tumor free samples, immune cell profiles were broadly similar across species, with T cells, B cells, macrophages, and dendritic cells as the dominant populations. However, we also observed notable species-specific variations in the transcriptional features of immune cells in normal and tumor tissue. This study provides a comprehensive cross-species analysis of immune cell transcriptional profiles in both normal and tumor states. Our findings highlight the importance of considering species-specific differences when translating preclinical results to human cancer research, emphasizing the value of utilizing multiple animal models, including canines, to enhance our understanding of cancer immunology. These insights are critical for the design of immunotherapies and the optimization of preclinical cancer models.

#5872 The gut microbiota from vasoactive intestinal peptide knock-out mice confers resistance to the growth of leukemia in wild-yype mice.

Kayla Robinson, Shayna Jankowski, Jian Ming Li

Emory Winship Cancer Institute, Atlanta, GA

Mice Resistance to Leukemia via Gut Microbiota Transfer Vasoactive Intestinal Peptide (VIP) regulates adaptive immunity through receptors expressed in T lymphocytes, VPAC1andVPAC2. VIP over production in leukemia suppresses immune function, facilitating cancer progression. VIP-knockout (VIP-KO) mice show a survival advantage against leukemia, likely due to gut microbiota-mediated immune response regulation. Cohousing enables gut microbiota transfer from VIP-KO to wild-type (WT) mice via coprophagy, potentially enhancing WT mice's resistance to leukemia. This study investigates whether cohousing WT and VIP-KO mice alters WT gut microbiota and confers resistance to leukemia challenge. Eighty mice, 42VIP-KO 38WT, were cohoused across 10cages for six weeks. Blood and stool samples were collected pre- and post-cohousing for immune and microbiome analyses. Mice were injected with syngeneic CD1498leukemiacells post-cohousing and monitored for survival. Gender differences in survival outcomes were also assessed. WT mice cohoused with VIP-KO mice demonstrated significant colonization by VIP-KO-derived gut microbiota, including Ruminococcus gnavus and Lactobacillus murinus, characterized by lower gut pH. Cohousing improved WT survival rates after leukemia challenge($p<0.009$), producing long-term survivors. *VIP-KO mice showed the highest presence of R. gnavus after cohousing ($p=0.017$)*Cohousing-induced microbiota transfer enhances leukemia resistance in WT mice through gut microbiota-mediated immune modulation. Survival improvements are independent of gender, underscoring the robustness of this therapeutic strategy. These findings highlight microbiota-targeted therapies, such as fecal microbiota transplantation, as promising approaches for leukemia treatment. Future studies will evaluate combined microbiota transfer and VIP antagonism therapies i.e. ANT308tooptimizeoutcomes.

Wild Type cohousing had a significance of $p<0.001$. Knockout cohousing had a significance of $p<0.009$. Wild type mice had the highest median survival time at 27days.

#5876 ctDNA as predictor for systemic therapy response in patients with colorectal cancer: A systematic review and meta-analysis.

Anja Holz, Bidisha Paul, Antonia Zapf, Klaus Pantel, **Simon A. Joosse**

University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: The response to systemic therapy against metastatic colorectal cancer (mCRC) is currently assessed by radiologic imaging. However, an increasing number of studies have shown that circulating tumor DNA (ctDNA) as liquid biopsy can be used as an alternative method to assess therapy efficacy. We conducted a systematic review with subsequent meta-analysis of primary studies to assess the predictive value of sequential liquid biopsies in patients with colorectal cancer treated with systemic therapy.
Methods: Randomized, non-randomized, as well as prospective observational studies, reporting on the change in ctDNA concentration in total cell-free DNA over the course of systemic therapy of patients treated for metastatic colorectal cancer to predict treatment response according to RECIST criteria were included.
Results: Forty-one studies involving 4546 evaluable patients with metastatic colorectal cancer were included in the meta-analysis. ctDNA increase during systemic therapy as compared to baseline was significantly associated with progression-free survival (HR: 2.47, 95%CI: 1.97-3.10) and overall survival (HR: 2.18, 95%CI: 1.66-2.86), which were reported in 31 and 22 studies, respectively.
Conclusion: Longitudinal plasma-based ctDNA liquid biopsy has prognostic value and may help to identify those patients that benefit of continuing therapy or therapy switch. Although further standardization and randomized controlled clinical trials are required, based on the available data, we recommend longitudinal ctDNA measurements to be included in clinical practice and inclusion in the RECIST criteria.
Protocol registration: The protocol for this review was registered on PROSPERO (CRD42023420012).

#5877 Feasibility of ctDNA detection with a low-volume blood collection device.

Brad Evans[1], Jordan Feeney[2], Derrick Renner[2], Alexey Aleshin[2], Matthew Rabinowitz[2], Steven Townson[1], **Himanshu Sethi**[2]

[1]Merck & Co., Inc., Rahway, NJ,[2]Natera, Austin, TX

Patient-centric technology for personalized healthcare can transform medical research and disease management by addressing logistical hurdles, and enabling flexible, ongoing patient monitoring with reduced blood volumes. The Tasso+ low blood volume collection device allows a shift from traditional in-clinic blood collection to patient-centric, home, blood collection for volumes up to 1 mL of capillary blood. To demonstrate the utility of low blood volume collection and subsequent molecular residual disease surveillance, we evaluated the capability of the Signatera™ RUO tissue-informed assay (Natera, Inc.) to detect single nucleotide variants (SNVs) using whole blood samples collected by a microsampling device that can collect up to 500 µL, the Tasso+, as compared to traditional venipuncture. We first tested the technical feasibility of the Signatera assay to detect SNVs using a commercial circulating tumor DNA (ctDNA) reference standard (Seraseq ctDNA mutation mix v2, 0.625-5ng) spiked into low blood volumes that are representative of those obtainable from routine Tasso+ collection. Next, we tested the clinical utility of low blood volume collection using commercially obtained traditional venipuncture and Tasso+ samples from 7 cancer patients (pt) with advanced relapsed/refractory solid tumors (bladder n=1, colorectal cancer n=3, lung n=1, melanoma n=2). Venipuncture plasma samples (4 mL, 1mL, 2✕ 500µL) and 1 in the Tasso+ device (250-500µL) were extracted per patient and assessed for ctDNA detection using the patient-informed 16-plex Signatera mPCR-NGS-based RUO ctDNA assay. The feasibility study demonstrated the ability to detect ctDNA at the single variant molecule level down to the lowest quantity of reference standard in the 250µL plasma sample. In the clinical setting, ctDNA was consistently detected among 6 of 7 pts (86%) at the 4 mL plasma volume and in 5 of 7 pts (71.4%) at all other volumes, including the 250µL volume of plasma from Tasso+ samples. The levels of ctDNA detected were generally consistent for most patients across all sample volumes, including that from the Tasso+ device. These results demonstrate that ctDNA can reliably be detected down to the single variant molecule level using the Signatera RUO assay on small plasma volumes collected with the novel Tasso+ microsampling technology. Additional evaluation using larger patient numbers would further validate this technique.

#5878 Landscape of tumor heterogeneity index and tumor mutational burden in non-small cell lung cancer.

Jongwoo Kim[1], Jong Yeob Kim[1], Leeseul Kim[2], Junho Song[1], **Liam Il-Young Chung**[1], Young Kwang Chae[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL,[2]University of Chicago, Chicago, IL

Background/Aims
Tumor heterogeneity and tumor mutational burden (TMB) are novel biomarkers associated with the response to immunotherapy in non-small cell lung cancer (NSCLC), but studies report conflicting results. We aim to describe the associations between these biomarkers.
Methods
From records of 77 NSCLC patients, tissue next-generation sequencing (NGS) data and circulating tumor DNA (ctDNA) NGS data, along with corresponding tissue TMB (tTMB) and blood TMB (bTMB) values, were obtained. PyClone was used to estimate tumor heterogeneity from tissue sequencing data. Tumors with ≥3 clusters were defined as having high tumor heterogeneity, and those with <3 clusters as having low heterogeneity. Mutant-allele tumor heterogeneity (MATH), another estimate of tumor heterogeneity, was calculated from tissue and blood NGS data.
Results
Out of the 77 NSCLC cases, 21 cases had high tumor heterogeneity, and 56 cases had low tumor heterogeneity according to PyClone. High tumor heterogeneity was statistically significantly associated with higher tTMB (p-value = 0.02) but was not significantly associated with bTMB. Tumor heterogeneity was not significantly associated with age, sex, smoking status, tumor histology, or metastasis. Tumor heterogeneity was not associated with either tissue MATH (p-value = 0.86) or blood MATH (p-value = 0.30), and there was no significant association between tissue MATH and blood MATH (p-value = 0.96). There was a statistically significant positive correlation between tTMB and bTMB ($r = 0.75$, $p < 0.001$). Neither tissue MATH nor blood MATH showed significant associations with tTMB or bTMB.
Conclusions
High tumor heterogeneity as defined by PyClone was associated with high tTMB but not bTMB. tTMB and bTMB were strongly positively correlated. There were no evident correlations between the estimates of tumor heterogeneity.

#5879 An optimized sample-to-result workflow for detection of tumor mutations and immune sequencing in liquid biopsies.

Anagha Kadam[1], Margaret R. Heider[1], Chen Song[1], Jian Sun[1], Ariel Erijman[1], Nicholas M. George[2]

[1]New England Biolabs, Ipswich, MA,[2]Streck LLC, La Vista, NE

Non-invasive liquid biopsies are helping advance various aspects of disease assessment including early detection, disease monitoring, and therapy selection, while also allowing for improved patient follow-up and economic efficiency over traditional tissue biopsies. Plasma cell-free DNA (cfDNA) applications have recently been adopted in prenatal screening, tumor mutation profiling and post-transplant monitoring. Additionally, combining cfDNA profiling with paired RNA analysis of peripheral blood mononuclear cells (PBMCs) can provide useful insights into biomarkers and immune phenotypes, and present a comprehensive multiomic profile from a single blood draw. Several technical and analytical challenges persist in the liquid biopsy field including immediate preservation of draw time levels of cfDNA, minimizing PBMC lysis during storage, low concentrations of cfDNA with even lower tumor fraction, as well as the need for a higher sensitivity in downstream applications to accurately interpret clinical signals. Here, we present an efficient blood-to-result workflow for tumor-specific mutation detection and immune profiling using contrived samples spiked with known mutation controls. Whole blood was collected in Streck Nucleic Acid BCT enabling preservation of draw time concentration of cell-free nucleic acids and prevention of immune cell lysis. Nucleic acid extraction was performed on the isolated PBMCs and plasma fraction using an optimized protocol for the Monarch Mag Viral DNA/RNA Extraction Kit which features a simplified, magnetic bead-based workflow. Isolated cfDNA was used to prepare sequencing libraries using an optimized library prep workflow to maximize conversion efficiency from cfDNA. Isolated PBMC RNA was utilized to prepare RNA-seq libraries and Immune-seq libraries using the NEBNext UltraExpress RNA Library Prep Kit and NEBNext Immune Sequencing Kit, respectively. Combining these sample storage, extraction, and library prep methods resulted in a high yield of cfDNA libraries with minimal contaminating genomic DNA, enabling improved sequencing data quality, high conversion efficiency, and high sensitivity for clinical research, including detecting spike-in mutations. Transcriptome and immune repertoire profiling from the preserved PBMC in the same blood sample provided complementary biomarker information to enable a comprehensive evaluation of the disease status of these samples.

#5880 Leveraging cell-free DNA methylation biomarkers for pancreatic cancer detection and minimal residual disease monitoring.

Ziqi Zhu, Giancarlo Bonora, Chao Dai, Kemin Zhou, Binggang Xiang, Shidong Jia, Pan Du

Predicine Inc., Hayward, CA

Introduction: Detecting pancreatic cancer from plasma cell-free DNA (cfDNA) is particularly challenging due to the low circulating tumor DNA (ctDNA) shedding associated with pancreatic tumors, especially in localized cases. Pancreatic cancer often exhibits differential methylation across hundreds or thousands of genes. We applied fragment-level DNA methylation analysis to tissue and plasma samples from a pancreatic ductal adenocarcinoma (PDAC) cohort to obtain differentially methylated fragment regions (DMFRs) alongside traditional differentially methylated regions (DMRs). Mutation-based tumor fractions using orthogonal assay were calculated for comparison. Additionally, we developed a PDAC DNA methylation subpanel using patient data based on DMFRs obtained from fragment-level analysis.

Methods: Pancreatic cancer samples from localized (n = 36) and metastatic (n = 117) stages were profiled by methylation-based PredicineEPIC™, PredicineALERT™, and mutation-based PredicineBEACON™ assays. Abnormally methylated fragments were identified using a background model based on healthy plasma donors. A PDAC panel was created using both tissue (n = 45) and plasma (n = 117) samples, as well as public datasets such as TCGA.

Results: Fragment-level analysis identified a comparable number of DMFRs in PDAC plasma and tissue samples, with strong overlap between the two. While DMFRs and DMRs were comparable in the tissue samples, significant fewer DMRs were identified in the plasma samples. This underscores the superior sensitivity of fragment-level analysis for detecting abnormal methylation in the liquid biopsy samples. Furthermore, key PDAC-related biomarkers were more distinctively identified using DMFR analysis. Genome-wide DNA methylation losses were also observed in many pancreatic samples, and combining these with location-specific methylation signals enhanced both the robustness and sensitivity of the assay. The incorporation of the PredicineALERT PDAC panel, informed by the methylation fragment-level analysis, improved concordance between methylation and mutation-based tumor fractions in both metastatic and localized PDAC plasma samples. Sensitivity for minimal residual disease (MRD) detection was also markedly improved using PredicineALERT panel compared to genome-wide methylation profiling using PredicineEPIC.

Conclusion: This study demonstrates the value of fragment-level cfDNA methylation analysis for detecting and monitoring PDAC using plasma samples. DMFR analysis demonstrated greater sensitivity than traditional DMR analysis. In addition, a PDAC panel designed through fragment-level analysis enhanced correlations between methylation abnormalities and mutation-based tumor fractions, offering a robust tool for early detection and disease monitoring in PDAC.

#5881 Transcriptomic profiling of extracellular vesicle subpopulations enables liquid biopsy-based brain tumor classification.

Margie Kinnersley, Claire Seibold, Tre Blohm, Riley Kemp, Sean Lodmell, Amanda Mast, Tia Seibold, Rachel Short Miller, Kelley Van Vaerenberghe, Katie Havranek

FYR Diagnostics, Missoula, MT

Liquid biopsies based on circulating tumor-derived cell-free DNA (ctDNA) have become an increasingly common tool for minimally invasive diagnostic testing. However, as ctDNA does not easily cross the blood-brain barrier, cell-free DNA tests for identifying and classifying brain tumors are of limited utility. Extracellular vesicles (EVs), which carry heterogeneous protein, nucleic acid, and metabolite cargos derived from various cell types including cancer cells, are an attractive alternative to ctDNA that can cross the blood-brain barrier. Because only a small fraction of circulating EVs are derived from diseased cells, current EV-based methods for cancer detection often suffer from low signal-to-noise ratios. To circumvent this issue, we have developed an extracellular vesicle subpopulation enrichment technology that specifically targets EVs derived from diseased cells. EV subpopulation transcriptomics interrogated using machine learning and gene network analyses can distinguish healthy patients, patients with benign tumors, and patients with glioma. Known tissue markers as well as novel features provide the basis for patient stratification. Coupled with a state-of-the-art multi-omics workflow, our novel EV enrichment platform allows us to capitalize upon the powerful diagnostic information contained within EV subpopulations to identify and characterize cancers from standard blood plasma samples.

#5882 A novel NGS-based assay in kit format for tumor-independent cancer monitoring, and evaluation of patient treatment response using cfDNA genomic alteration and methylation duo analysis.

Tali Azenkot[1], Grace Zhao[2], Heng Wang[2], Xiaomu Chen[2], Margherita Corioni[3], Michael Ruvolo[2], Teressa Celma[1], Jeff Pawelek[1], Aswati Aravind[2], Douglas Roberts[2], Yun Bao[2], Bram Herman[2], Annie Wu[4], William Mitchell[1], Kathryn Gold[1], Lyudmila Bazhenova[1], Shengrong Lin[2], Sandip Patel[1]

[1]UC San Diego Moores Cancer Center, La Jolla, CA,[2]Agilent Technologies Inc., Santa Clara, CA,[3]Agilent Technologies Inc., La Jolla, CA,[4]Rensselaer Polytechnic Institute, Troy, NY

Introduction: While circulating tumor DNA-based tests have shown promise in evaluating treatment response, predicting prognosis, and detecting measurable residual disease, tumor-informed personalized strategies have limitations. For example, the need for large tumor samples and the complexity and high cost of personalized testing can be barriers to clinical use. Commercially available genomic and methylation tumor-independent assays require large panels and sample splitting, further limiting their practicality. Both these assays require samples to be sent to centralized CLIA-certified labs. To address these challenges, we explored the Agilent Avida target enrichment technology in a small sample of patients with non-small cell lung cancer (NSCLC). This kit-based solution reduces sequencing costs, is compatible with automation systems like the Agilent Bravo NGS Workstation, and enables decentralized, faster molecular analysis.

Methods: We applied the Agilent Avida circulating cell-free DNA (cfDNA) genomic alteration and methylation combined analysis for tumor-independent cancer monitoring in patients with NSCLC. First, we demonstrated the differential hypermethylation cancer-specific signal in 4 different lung cancer tumors, with low background noise in normal lung tissues, non-cancerous pathological lung tissue, control peripheral blood mononuclear cells, and cfDNA. We then showed feasibility of this cfDNA technology in patients with stage I through III NSCLC. In 4 patients with stage III NSCLC, plasma samples were collected before and 1-3 months after initiating immunotherapy treatment to assess whether the assays correlated with known clinical and imaging markers of disease response.

Results: Using 1 mL of plasma from NSCLC patients, we detected cancer in 8 of 10 stage I patients and 10 of 11 stage II patients. Fifteen of 16 control samples were below the cutoff threshold. Among 4 patients with stage III NSCLC, we performed cfDNA Duo analysis, capturing both DNA mutations and methylation information from one input without sample splitting. The combined genomic and methylation analysis provided information on actionable mutations and tumor mutation burden for these patients. The overall methylation signal correlated with CT imaging-based tumor changes for most cases.

Conclusion: Our results demonstrate the feasibility of the Agilent-Avida DNA/methylation DUO kit for tumor-independent cancer monitoring in patients with NSCLC undergoing immunotherapy treatment.

#5883 Estimation of blood volume collected on plasma-separating dried blood spots using gravimetric and imaging analysis.

Elise C. Dietmann, Michelle D. Stephens, Olivia Krebs, Everlyne N. Nkadori, Pallavi Tiwari, Stephanie M. McGregor, Muhammed Murtaza

University of Wisconsin-Madison, Madison, WI

Background: Analysis of plasma-separating dried blood spots (psDBS) holds promise for circulating tumor DNA (ctDNA) measurement, enabling at-home sample collection, room temperature storage, and easy shipment. However, unlike collection in a blood tube, it is not feasible to directly measure blood volume collected from a fingerstick using psDBS. Here, we evaluate whether analysis of psDBS mass, color, and area can infer blood volume and enable downstream measurement of DNA concentration.
Methods: Whole blood from patients with head and neck, breast, gynecologic, genitourinary, and gastrointestinal malignancies was collected on psDBS devices by the University of Wisconsin-Madison Carbone Cancer Center BioBank. In addition, whole blood from healthy individuals was commercially obtained and between five and nine psDBS were prepared with volumes ranging from 50 to 250 µL. All samples underwent analysis for mass, area, and color. psDBS were imaged using a flatbed scanner. Total area of erythrocytes and mean grey value of center erythrocytes were measured using image segmentation. Using mass of the psDBS membrane, erythrocyte area, erythrocyte mean grey value, and sex as predictors, a linear regression model was developed to predict whole blood volume. Mean absolute percent error (MAPE) was used to assess model accuracy.
Results: One hundred ninety psDBS samples from 30 healthy individuals and 100 psDBS from 100 patients with cancer were analyzed. Using 132 samples from 20 healthy individuals (training set), a linear regression model was fit to the data, showing a very strong correlation between actual and predicted blood volume (MAPE = 7.6, Pearson r = 0.97). The model was then tested using 58 samples from 10 different healthy individuals (independent validation set), as well as psDBS from patients with cancer, and predicted blood volume collected on psDBS with high accuracy (MAPE = 6.8 and 9.3, respectively).
Conclusion: Our results suggest estimating blood volume from psDBS is feasible using gravimetric and imaging analysis. By establishing a linear regression model that incorporates weight, area, and color, we can infer blood volume collected on psDBS samples for healthy individuals and patients with cancer. Ongoing work will incorporate this approach to enable measurement of plasma DNA concentration in blood spots.

#5884 Cancer subtype classification by cfDNA fragmentomics analysis.

Lisha Zhu[1], Chao Dai[1], Shuang Gan[2], Shidong Jia[1], Pan Du[1]

[1]Predicine Inc., Hayward, CA,[2]Huidu Shanghai Medical Sciences, Ltd., Shanghai, China

Introduction: Nucleosome occupancy patterns at transcription factor binding sites (TFBS) exhibit differences between circulating tumor DNA (ctDNA) in cancer patients and normal plasma controls, as well as among different tumor subtypes. Therefore, cell-free DNA (cfDNA) fragmentomics can be employed for cancer subtyping analysis. The tumor fraction in cfDNA can affect the performance of nucleosome profiling, and a minimal tumor fraction is required to obtain high sensitivity of cancer subtyping. This study investigated the detection sensitivity - specifically, the minimal tumor fraction required - for different TFBS analyses.

Methods: We utilized the Griffin framework to classify tumor subtypes based on nucleosome profiling of cancer-specific TFBS from low-pass whole genome sequencing data of cfDNA. Androgen receptor (AR) and ASCL1 binding sites were used to distinguish between AR-dependent prostate cancer (ARPC) and neuroendocrine prostate cancer (NEPC). Estrogen receptor (ER+) ATAC-seq peaks were employed for subtyping of ER-positive breast cancer. For each tumor type, we selected three tumor samples with highest nucleosome profiling abnormality scores for simulation studies. Each cancer sample was down-sampled at various percentages and mixed with six down-sampled normal samples, with three replicates per normal sample using different random seeds, to obtain simulated cancer samples with a serious of predetermined tumor fractions.

Results: The specificity of nucleosome profiling at AR, ASCL1 and ER binding sites was high (> 95%) for all 87 normal samples. The limit of detection (LoD) for tumor fraction of AR binding sites ranged between 10% and 14%, with the average of 12% and standard deviation of 0.0098. Similarly, the LoD for ER binding sites was between 10% and 13%. The LoD of ASCL1 binding sites was higher, ranging from 20% to 25%. When genome-wide DNA methylation data were incorporated, both the specificity and sensitivity of nucleosome profiling increased. Interestingly, we observed methylation loss at AR and ER binding sites in prostate and breast cancer patients respectively.

Conclusion: Prostate and Breast Cancer cfDNA samples sequenced by low-pass whole-genome sequencing can be assigned to subtypes according to nucleosome profiling of AR, ASCL1 and ER binding sites. The minimum tumor fraction required for AR and ER is at least 10%, while for ASCL1 it is as high as 20%. Integrating DNA methylation data into nucleosome profiling analysis can enhance sensitivity and lower the limit of detection, which we are actively investigating.

#5885 Streck Urine Preserve provides cell-free DNA stabilization in whole urine for liquid biopsy.

J. Li, S. Mehta;
Streck LLC., La Vista, NE

Urinary cell-free DNA (ucfDNA) has gained recognition as a critical biomarker for liquid biopsy, as it provides comprehensive and invaluable insights for cancer researchers, especially for urological cancers such as bladder, kidney, and prostate cancers. While urine as a sample matrix offers appealing advantages over blood, including large sample volume and truly non-invasive and easy self-collection, ucfDNA is a challenging and unstable analyte, as it is vulnerable to DNase degradation and contamination from bacterial and genomic DNA. Here, we describe the use of Streck Urine Preserve to minimize pre-analytical variables before ucfDNA extraction and downstream analysis. To determine whether Streck Urine Preserve effectively stabilizes ucfDNA and limits DNA contamination, second void urine was collected from donors, treated with Streck Urine Preserve, and stored at 2 °C to 37 °C for up to 7 days. Following storage, ucfDNA was isolated from 4 or 8 mL urine using a modified automated extraction method with MAGicBead cfDNA Isolation Kit (Zymo Research) on a KingFisher Apex System. Target human ucfDNA concentrations were monitored by ddPCR or dPCR using a housekeeping gene (ACTB) as a surrogate marker. The total bacterial burden in the extracted ucfDNA sample was analyzed using qPCR targeting 16S rRNA. While unpreserved urine samples exhibit rapid ucfDNA degradation during ambient temperature storage, samples stored in Streck Urine Preserve (at a preservative-to-urine ratio range between 1:20 to 1:5) maintained the void-time human ucfDNA target concentration for up to 7 days regardless of temperature (2 °C to 37 °C). Further, a marked increase in bacterial cfDNA contamination was observed in the unpreserved urine sample, whereas samples treated with Streck Urine Preserve displayed minimal changes in Cq values of 16S rRNA in the extracted ucfDNA from void time to day 7. Taken together, these data indicate that Streck Urine Preserve protects ucfDNA targets in the sample from DNase degradation and genomic and bacterial DNA contamination during storage**.** Streck Urine Preserve ensures sample integrity and minimizes pre-analytical variables, providing cancer researchers and assay developers flexibility in sample handling and enhanced confidence in the validity of downstream ucfDNA analysis results. Streck Urine Preserve is for Research Use Only. Not for use in diagnostic procedures. Streck Urine Preserve should only be used for research or the development of new assays.

#5886 Cross-test performance verification of tissue-TMB and a cfDNA somatic variant Next Generation Sequencing (NGS) panel for detection of actionable mutations.

Leisa Jackson[1], Ashley King-Roads[2], Gary A. Pestano[2]

[1]Development, Biodesix, Inc., Louisville, CO,[2]Biodesix, Inc., Louisville, CO

Introduction: Comprehensive tumor profiling by NGS has become widespread in oncology. However, a relatively small number of the developed panels have gained regulatory approvals and/or authorization. Given the need for higher levels of compliance for panels used for clinical laboratory testing, we sought to extend the utility of panels intended for use in blood and tissue testing. In this study we verified the performance of a 52-gene liquid biopsy hotspot panel [evaluated for single nucleotide variants (SNVs) and insertions/deletions (Indels) as low as 0.5% allele frequency (AF) and copy number amplifications (CNAs) down to 1.4x] to be used with formalin-fixed paraffin embedded (FFPE) specimens. In the same study, we evaluated the performance of a well characterized tissue TMB/TML (tumor mutation burden) assay for concordance in somatic variant calling against the hotspot panel. The targeted TMB/TML assay covers 1.7 Mb of the genome (1.2 Mb exome) and detects variants at 5% AF. The performance of the latter panel was previously reported in the harmonization study conducted by the FOCR TMB consortia.

Methods: Twelve de-identified clinical FFPE specimens and a commercial (contrived) FFPE reference material were tested for SNVs and Indels using the validated 52-gene hotspot pan-cancer assay and the TMB/TML panel. Co-occurrence of SNVs/INDELs (n = 40) was observed between the two panels. The reference result for the clinical FFPE specimens was generated by the variant caller function in the TMB/TML bioinformatic workflow and included 14 SNVs. The pan-cancer panel was also used to test for 19 SNVs and 7 Indels present in the contrived FFPE reference specimen.

Results: TMB scores ranged from 1.7-104 Muts/Mb. A high level of inter chip concordance was observed between duplicate runs (R^2 = 0.997). Duplicate NGS libraries were generated from the reference contrived FFPE specimen, and both passed QC. Eleven of 12 clinical samples passed the pan-cancer informatics QC thresholds. Thirteen of 14 SNVs (93%) were detected in the clinical samples (AF range: 13-58%) and eighteen of 19 SNVs (95%) and 5 of 7 Indels (71%) were detected in both replicate tests of the FFPE reference material (AF range:1.9-13.9%). Although no reference was available, one ERBB2 CNA was also detected with the pan-cancer panel (at 10.45x). Since the starting material was DNA (and not RNA or cDNA), fusion variants could not be detected although they are covered by the hotspot panel.

Conclusions: These studies demonstrate extended utility for a previously validated liquid biopsy hotspot pan-cancer panel for the detection of SNVs/Indels and CNAs in FFPE. We simultaneously demonstrated the potential utility of a well characterized TMB panel for detection and reporting of actionable SNVs/Indels. Additional studies are on-going to further validate the TMB panel for actionable variant reporting.

#5887 *NALCN* promoter methylation as a biomarker for metastatic risk in a cohort of non-small cell lung cancer patients.

Eleni Thanou[1], Dora Londra[1], Ioanna Balgouranidou[2], Eleni Eftimiadou[1], Alexandra Delipetrou[1], Emilia Tsaroucha[3], Vasilis Georgoulias[4], Athanasios Kotsakis[5], Evi Lianidou[1], **Athina N. Markou**[1]

[1]Chemistry, University of Athens, Athens, Greece,[2]Department of Medical Oncology, University General Hospital of Alexandroupolis, Medical School, Democritus University of Thrace, Aleandroupolis, Greece,[3]8th Department of Pulmonary Diseases, "Sotiria" General Hospital, Athens, Greece,[4]First Department of Medical Oncology, Metropolitan General Hospital, Athens, Greece,[5]Department of Medical Oncology, University General Hospital of Larissa, Larissa, Greece

Liquid biopsy enables real-time monitoring of tumor development and response to therapy through the analysis of CTCs and ctDNA. NALCN is a sodium leak channel that is frequently involved in tumor evolution and immunity and acts as a tumor suppressor. Deletion of NALCN has been shown to increase cancer metastasis and the number of CTCs in peripheral blood. In this study, we investigated for the first time NALCN promoter methylation in (a) Aza-treated cell lines (A549, TE671, BT20, and MDA-MB-468), (b) paired NSCLC tissues (n = 22), and (c) plasma cell-free DNA (ctDNA) from patients with NSCLC (early stage n = 39, metastatic n = 39) and DNA from 10 healthy donors (HD) using a newly developed highly specific and sensitive real-time MSP method. Treatment with 5′-aza-dC induced the expression of NALCN only in the A549 cell line, suggesting that DNA methylation regulates its expression in certain cancers. The mRNA expression levels of NALCN were quantified in non-small cell lung cancer (NSCLC) and adjacent non-cancerous tissues, and it was found to be underexpressed in 54.5% of tumor tissues, with significantly higher expression in recurrence-free patients ($p = 0.009$) than in patients who relapsed. The NALCN methylation level was not statistically significantly correlated with the corresponding expression ($p = 0.439$), while Kaplan-Meier analysis showed an association between NALCN promoter hypermethylation and worse disease-free intervals (DFIs) ($p = 0.017$). Evaluation of NALCN methylation in ctDNA revealed that it was detected in 5.1% of early and 10.2% of advanced cases. Our results strongly suggest that epigenetic inactivation of NALCN may predict metastasis in NSCLC. Our results should be validated in further studies based on a larger patient cohort to investigate whether DNA methylation of the NALCN promoter could serve as a potential prognostic DNA methylation biomarker and predictor of metastasis in NSCLC.

#5888 Urinary ctDNA tumor fraction monitoring enhances non-invasive assessment of molecular response in bladder-preserving treatment of muscle-invasive bladder cancer.

Jiani Deng[1], Feng Wen[1], **Haoran Tang**[2], Cancan Jia[2], Yue Zhang[2], Peng Zhang[3], Yali Shen[1]

[1]Abdominal Oncology Ward, Division of Radiation Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China,[2]Huidu Shanghai Medical Sciences, Ltd., Shanghai, China,[3]Department of Urology, Institute of Urology, West China Hospital, Sichuan University, Chengdu, China

Introduction: While radical cystectomy (RC) following neoadjuvant therapy remains the standard of care for muscle-invasive bladder cancer (MIBC), bladder-preserving treatments offer a viable option for selected patients to improve quality of life. Rapid detection of therapeutic response is critical for clinical decision-making but remains challenging. Here, we introduce a non-invasive liquid biopsy assay based on next-generation sequencing (NGS) to monitor the molecular response in both urine and blood during neoadjuvant therapy in MIBC patients.
Methods: This ongoing trial has enrolled 20 patients treated with HER2 ADC neoadjuvant therapy, followed by radiotherapy and clinical evaluation to decide between RC or bladder preservation. In a completed pilot cohort of seven patients, both urine and blood samples were collected before and after HER2 ADC treatment to evaluate therapy response. The study utilized PredicineCARE, a targeted NGS assay, to analyze circulating tumor DNA (ctDNA) in urine and blood samples, aiming to detect genetic variations and evaluate tumor fractions in patients.
Results: In the pilot cohort of seven patients, the ctDNA assay detected a greater number of somatic mutations and exhibited higher detection positivity in urine samples compared to blood samples. Specifically, in urine samples, the assay identified 138 somatic mutations at baseline and 18 mutations at the end of therapy, achieving positivity in all seven patients at both time points. In contrast, in blood samples, it identified 11 mutations at baseline and 6 mutations at the end of therapy, with positivity in 5 out of 7 and 4 out of 7 patients, respectively. The overall tumor fractions detected in urine samples were significantly higher at baseline than at the end of therapy (median tumor fraction: baseline 10.6% vs. end of therapy 0.8%; p=0.043), a trend not observed in blood samples. Moreover, through paired comparisons of each patient's urine samples at the two time points, we observed a molecular response—defined as a tumor fraction decrease greater than 20%—in six of the seven patients, and molecular progression—defined as a tumor fraction increase greater than 20%—in one patient. These findings were consistent with the clinical evaluations conducted at baseline and at the end of therapy.
Conclusion: Our study demonstrates that urine-based ctDNA analysis using a non-invasive liquid biopsy assay provides a reliable method for monitoring molecular response during neoadjuvant therapy in patients with MIBC undergoing bladder-preserving treatments. These findings suggest that urine ctDNA analysis can serve as a valuable tool for rapid detection of therapeutic response, aiding clinical decision-making. Further validation in larger cohorts is warranted to establish its utility in routine clinical practice.

#5889 Combined cfDNA and cfRNA enhanced gene fusion detection and drug resistance mechanism insights in mCRPC through combined cfDNA and cfRNA assays profiling.

Haoran Tang, Feng Xie, Yue Zhang, Yutao Feng

Huidu Shanghai Medical Sciences, Ltd., Fengxian District, Shanghai, China

Background: Metastatic castration-resistant prostate cancer (mCRPC) is a complex disease characterized by distinct molecular features related to genomic instability and selective treatment pressures. Cell-free DNA and RNA (cfDNA and cfRNA) found in blood offer potential for disease diagnosis, monitoring, and interrogation of resistance mechanisms by detecting genomic alterations from tumors. Here, we introduce comprehensive cfDNA and cfRNA assays to profile the genomic landscape in mCRPC patients for the purposes of disease diagnosis and monitoring.
Methods: In this retrospective study, plasma samples were collected from 52 patients with mCRPC at treatment baseline. For some patients, additional plasma samples were obtained at both cycle 1 day 1 (C1D1) and cycle 3 day 1 (C3D1) during androgen receptor inhibition therapy. We employed PredicineCARE, a 152-gene cfDNA assay, and PredicineRNA, an 88-gene cfRNA assay, to detect genomic alterations at both DNA and RNA levels in these samples.
Results: The TMPRSS2-ERG fusion is a common genomic alteration in prostate cancer and serves as a potential diagnostic and prognostic indicator. In baseline samples from 52 patients, the cfDNA assay detected a TMPRSS2-ERG fusion positive rate of 25.0%, while the cfRNA assay detected a higher rate of 38.5%, although this difference did not reach statistical significance (McNemar's test, $p = 0.065$). Importantly, using a simultaneous testing strategy with both cfDNA and cfRNA increased the detection rate to 42.3%, which is comparable to the prevalence previously reported in tissue samples. Furthermore, by comparing the same androgen receptor (AR) mutations (W742C and T878A) detected by cfDNA and cfRNA assays at C1D1 and C3D1, this comprehensive analysis illustrates the potential biological mechanisms of acquired drug resistance.
Conclusion: This study demonstrates that combining cfDNA and cfRNA assays enhances gene fusion detection in mCRPC patients and provides insights into the mechanisms of acquired drug resistance. These findings support comprehensive liquid biopsy approaches for improved diagnosis, monitoring, and personalized treatment strategies in mCRPC.

#5890 Personalized detection of circulating cell-free tumor DNA in gynecologic cancer.

Andrea B. Moffitt[1], Jude Kendall[2], Joan Alexander[2], Asya Stepansky[2], Arisa Kapedani[3], Zihua Wang[2], Dan Levy[2], Kenny Ye[4], Abba M. Krieger[5], Marina Frimer[3], Gary L. Goldberg[3], Michael Wigler[2]

[1]Hematology and Medical Oncology, Emory University, Atlanta, GA,[2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[3]R.J. Zuckerberg Cancer Center, Northwell Health, Lake Success, NY,[4]Systems & Computational Biology, Albert Einstein College of Medicine, Bronx, NY,[5]Statistics and Data Science, University of Pennsylvania, Philadelphia, PA

Endometrial and ovarian cancers are among the most common gynecologic malignancies in the U.S., with 5-year overall survival rates of 81% and 50% respectively. Ovarian cancer often presents late due to asymptomatic early stages and nonspecific symptoms in advanced stages. Few markers exist for early detection, and they lack the sensitivity and specificity needed for high-risk screening.

Given the absence of informative protein blood biomarkers, cell-free DNA analysis has become a promising tool for early detection, treatment evaluation, and monitoring. However, previous studies of circulating tumor DNA (ctDNA) in gynecological cancers had limited sensitivity. We adapted MASQ (Multiplex Accurate Sensitive Quantitation), originally developed to measure residual cells in leukemia, to the measurement of ctDNA in solid cancers. MASQ detects patient-specific mutations simultaneously in up to 50 loci with exceptional sensitivity, below one part per million.

This study uses MASQ to measure tumor-specific variants in blood (cell-free DNA) from endometrial and ovarian cancer patients, aiming to determine the range of ctDNA signals at presentation and explore correlations with clinicopathological features and patient outcomes.

We analyzed samples from 46 gynecologic cancer patients (12 ovarian, 34 endometrial) treated at Northwell Health. Samples were collected in collaboration with gynecologic oncology research coordinators and the Northwell Health Biorepository. Peripheral blood was collected at diagnosis (n=46) and post-surgery (n=14), along with surgical tumor specimens. Whole genome sequencing of tumor and blood identified thousands of somatic tumor variants per patient.

For each patient, 30 representative variants were selected for MASQ sequencing. MASQ libraries were generated from cell-free DNA isolated from pre- and post-surgery plasma. Ultrasensitive variant counts across 30 loci were aggregated and analyzed for clinical correlations.

ctDNA signal was detected in 35 of 46 cases at presentation, with variant allele frequencies ranging from below 10^-4 to 10^-1. ctDNA signal was higher in ovarian cancer (13/13 detected) than endometrial cancer, and higher in aggressive Type II endometrial cancer (15/16) vs. Type I (5/13). ctDNA levels correlated with tumor size and copy number imbalance, but not with total cell-free DNA. Detection of ctDNA predicted worse overall survival (p=0.023) and was the strongest predictor of survival in multivariate analysis. Post-surgery follow-up in 10 of 14 patients showed significant ctDNA reduction following treatment, highlighting MASQ's sensitivity in tracking treatment response.

This study highlights the potential of sensitive ctDNA detection for early diagnosis and monitoring in gynecologic cancers. However, limited cell-free DNA abundance necessitates even more sensitive methods to enhance clinical utility.

#5892 Optimized enzymatic conversion method for improved methylation detection in low-input cfDNA samples.

Hong Xu[1], Quan Wang[1], Nan Zhang[1], Zhuoran Jiang[2], Lei Song[2], Ming Yang[2], Jing Zhao[2], Yue An[2], Congchong Wei[2], Yuting Liu[2], Feng Xu[2], Min Li[2], Jing Liu[2], Baoliang Zhu[2], Xiaohui Wu[2], Xueguang Sun[2]

[1]The First Hospital of Jilin University, Changchun, China,[2]Shanghai Weihe Medical Laboratory Co., Ltd, Shanghai, China

Background: Cell-free DNA (cfDNA) is widely utilized in liquid biopsy-based early cancer screening, where DNA methylation serves as a predominant detection marker via next-generation sequencing. Enzymatic Methyl-Seq (EM-Seq) preserve cfDNA integrity and significantly improved methylation marker detection. However, with its expanded application, several limitations have been identified, including insufficient protection of 5-methylcytosine (5mC) in samples below 10 ng, leading to diminished methylation signals and inconsistencies across different input amounts. Additionally, uneven CH conversion results in background noise akin to bisulfite methods. These issues are critical as clinical cfDNA samples of early-stage cancer often fall below the 10 ng threshold, indicating great room for improvement in enzymatic conversion.
Methods: To enhance the compatibility of enzymatic conversion methods with low-input cfDNA samples, we have made a series of improvements, including refining oxidation and deamination reaction systems. We evaluated these optimizations by testing on cfDNA from healthy donors and two cancer patients (colorectal cancer, CRC and gastric cancer, STAD).
Results: The optimized enzymatic conversion method significantly improved library quality, increasing average mapped ratios by 4.24% and 7.53% for healthy samples and for cancer samples, with library complexity rising from 38.04% to 75.52% consequently. The average CpG sites protection efficiency at 1 ng input is nearly equivalent to that at 30 ng input (98.11% vs. 99.27%), and shows a notable improvement over the original method (96.49% vs. 99.11%). The CH non-conversion rate decrease from 0.13% to 0.065%, significantly reducing the background noise. Consequently, more CpG sites are captured with equivalent sequencing depths. Samples with inputs ranging from 1 to 30 ng showed greater consistency in methylation beta values, with an average Pearson's correlation of 0.93, compared to 0.87 for the original method. Sensitivity analysis indicated that optimized method detected more methylation haplotypes in artificially pooled samples with varying cancer cell spike-in ratios: 589 vs. 379 at 0.05%, 935 vs. 502 at 0.1%, 3,326 vs. 1,236 at 0.5%, and 6,318 vs. 2,126 at 1%, enabling detection at lower cancer cell abundances. Using healthy samples as a reference, the optimized method consistently identified more differential haplotypes in CRC and STAD samples at 1, 5, and 30 ng cfDNA inputs, with the disparity between methods decreasing as input increased, confirming its advantages in low-input conditions.
Conclusion: Our optimized enzymatic conversion method provides superior library quality, increased complexity, reduced CH background and enhanced 5mC protection in low-input samples. These improvements enhance the sensitivity for detecting aberrant methylation signals in low-input cfDNA.

#5893 Feasibility of DNA analysis in peritoneal fluid from patients with peritoneal carcinomatosis.

Muhammad Talha Nawaz[1], Muhammad Talha Waheed[2], Kirsten Dennison[1], Bradon McDonald[1], Stephanie McGregor[3], Syed Nabeel Zafar[1], Mustafa Raoof[2], Muhammed Murtaza[1]

[1]Department of Surgery, University of Wisconsin-Madison, Madison, WI,[2]Department of Surgery, City of Hope National Medical Center, Duarte, CA,[3]Department of Pathology, University of Wisconsin-Madison, Madison, WI

Introduction: Gastrointestinal (GI) cancers often metastasize to the peritoneum. Current diagnostic tools for peritoneal carcinomatosis (PC) show limited accuracy. Reliable biomarkers to detect and monitor treatment response for PC are urgently needed. While circulating tumor DNA in plasma is a promising cancer biomarker, contribution of tumor DNA from PC into blood is minimal. We hypothesize that peritoneal fluid tumor DNA (ptDNA) may be useful for PC detection and response monitoring. Currently, there are no established laboratory methods for ptDNA analysis. In this study, we evaluate the feasibility of two DNA extraction methods using peritoneal fluid (PF) samples.

Methods: We evaluated the performance of two cell-free DNA extraction kits based on magnetic beads (MagMax) or silica columns (QIAamp) using commercially obtained PF from two individuals, at 1 mL and 4 mL starting volumes. Based on these results, we evaluated the optimal method further using PF samples from 24 patients with PC from GI cancers (biliary tract, appendiceal, and colorectal primary) undergoing surgery or paracentesis at City of Hope National Medical Center. PF samples were collected immediately before the start of the procedure. We extracted DNA using 4 mL inputs, eluted in 30 µL buffer and assessed using electrophoresis (TapeStation) and fluorometry (Qubit).

Results: In commercially obtained ascites samples, adequate DNA yield and quality was obtained using both kits. Compared to QIAamp, mean DNA concentration was slightly lower using MagMax (24.9 ng/mL [range 13.9 - 35.9] vs. 25.7 ng/mL [range: 16.1-35.3; p=0.91). Similarly, mean fragment length was also shorter using MagMax compared to QIAamp (287.5 bp [range 202-350] vs. 294.3 bp [range: 239-348; p=0.80). In contrast to our prior experience with plasma, peritoneal fluid DNA was observed at higher concentrations (3.7-fold higher) and longer fragment lengths. Based on these results and processing considerations, we selected MagMax kit to evaluate patient PF samples. We observed similar fragment lengths (mean: 281.5 bp, range: 136-369), with concentrations ranging from 0.80 ng/mL to 105 ng/mL in PF (mean: 20.6 ng/mL).

Conclusions: Our results demonstrate the feasibility of DNA analysis using PF samples in patients with PC Furthermore, the yield and quality of DNA extracted is adequate for downstream molecular analyses. We were able to detect differences in PF vs. plasma DNA and observe inter-patient variability in concentration and fragmentation. On-going work will evaluate detection and quantification of peritoneal tumor-specific DNA as a biomarker for PC detection and monitoring.

#5894 Detection of a novel GNA11 processed pseudogene from cfDNA and implications for liquid biopsy.

Jan Wignall, Wen Zhou

Oncology Development, BillionToOne, Inc., Menlo Park, CA

Processed pseudogenes are messenger RNAs that have been reverse transcribed and inserted into the genome. While the functional implications of these processed pseudogenes remain unknown, their presence can lead to variants being mistakenly detected and classified as copy number amplifications and deletions in comprehensive genomic profiling (CGP) assays for cancer treatment selection. False positive amplifications run the risk of patients being prescribed ineffective therapies.

Northstar Select is a liquid biopsy CGP assay which covers 84 genes. In this retrospective analysis of 1800 patients, amplification signals due to a pseudogene were observed in 4 patients on *SMAD4* and 7 patients on *GNA11* and confirmed via orthogonal methods. These samples showed abnormal exonic amplifications and intronic deletions in the *SMAD4* and *GNA11* genes. Splice site variants were present at low variant allele fraction (VAF) on either side of each exon. Notably, the copy number detected does not correlate with estimated tumor fractions or other ctDNA mutations detected in these samples.

Whole genome sequencing (WGS) of selected patients harboring the *SMAD4* amplifications revealed the presence of a poly-A tail and a breakpoint in *SCAI* on chromosome 9, consistent with a pseudogene previously described in the literature. WGS of *GNA11* amplification-positive samples revealed the presence of a novel processed pseudogene in chromosome 20 that has not been previously described, which may have further implications on cancer-driving mutations as *GNA11* is an oncogene. Northstar Select's copy number calling algorithm measures a copy number of 3 for *GNA11*, indicating an additional copy from the pseudogene. qPCR of extracted buffy coat gDNA across the suspected breakpoint in chromosome 20 confirms the insertion and its germline nature. The presence of the same breakpoint in multiple patients suggests this is an ancestral integration event. Similar to the previously described *SMAD4* pseudogene, false positive splice site variants are results of mismapping of reads. In conclusion, we have determined a framework to confirm pseudogene presence that is not tumor DNA derived. Bioinformatic analysis of CGP tests should carefully screen suspicious results for the possibility of as-yet undiscovered processed pseudogenes to avoid reporting such false positive amplifications and deletions.

#5895 Development and analytical validation of a highly sensitive tumor fraction estimation method using blood samples without matched normal controls.

Junmei Wang, Wanshu He, Lisha Zhu, Yong Huang, Xiaohong Wang, Shidong Jia, Pan Du

Predicine Inc., Hayward, CA

Background: Tumor fraction (TF) in cell-free DNA (cfDNA) is a quantitative indicator of circulating tumor DNA (ctDNA) and has become an important biomarker for disease monitoring and tracking therapeutic responses. We developed a longitudinal TF estimation method that does not require matched normal control samples and analytically validated its ability to accurately estimate TF when longitudinal blood samples are available.
Methods: Both reference materials and clinical blood samples were used in the analytical validation. We first determined the limit of detection (LoD) of TF for our PredicineCARE cfDNA assay at targeted sequencing depth of 20,000x using serially diluted reference materials with 12 gradient values from 0 to 4% TF. We further used a sequentially diluted clinical sample (with known TF) with healthy donor cfDNA to a gradient of expected TF values. We evaluated the variant calling and TF calculation algorithm by treating each dilution separately or treating the immediately nearby samples as longitudinal samples. We further evaluated our longitudinal-aware analysis method on 20 clinical subjects tested with PredicineCARE cfDNA assay with ≥2 time points to evaluate the improvement in TF estimation compared to individual estimation.
Results: With the titrated reference materials and manufacturer-labelled somatic variants, we achieved an LoD of 0.01% TF for 30ng cfDNA input and a sequencing depth at 20,000x using PredicineCARE cfDNA assay. When approaching the LoD, the number of reads for the somatic variants becomes more stochastic, which resulted in big variances in the calculated TF values. When independently estimating the TF without referring to matched normal or longitudinal samples, the LoD was 0.5% TF. When the longitudinal sample information was included, the LoD went down to 0.01% TF, contingent on the number of trackable variants. Our simulated results showed that when there are 4 or more tracking variants between longitudinal samples, the LoD can go down to 0.01% TF most of the time. We further applied this longitudinal sample aware dynamic TF estimation method to 20 clinical subjects tested with PredicineCARE cfDNA assay and with ≥2 time points, most showed improved TF estimation with ≥50% of the subjects having questionable somatic/germline calls if called separately.
Conclusions: We developed a dynamic TF estimation methodology that leverages longitudinal samples to improve somatic/germline variant calling and exclude CHIP mutations. Our results demonstrated that with longitudinal samples, the accuracy in TF estimation can approach the ideal situation where all somatic/germline status of the variants are known. Notably, longer interval between time points and a higher number of tracking somatic mutations (≥2) in longitudinal samples generally enhance the effectiveness of this dynamic estimation methodology.

#5896 Tissue naive comprehensive methylation profiling enhances the identification of ctDNA in lung cancer.

Yu Sun, Nafisa Bulsara, Qin Tang, Becky Wang, Neil Peterman, Varahenage Namali Perera, Brian Giacopelli, James Yu, Jason Close, Peter George, Andy Eang, Ashley Linares, Alex Robertson, Nicole Lambert, Yexun Wang

Foundation Medicine, Inc., San Diego, CA

Liquid biopsy of circulating tumor DNA (ctDNA) in plasma has shown to have great clinical value by offering real-time insights into disease progression and response to treatment. Mutation focused cell-free DNA (cfDNA) analysis is limited by low ctDNA levels and is restricted by mutation frequency. DNA methylation is a key epigenetic mechanism for regulating gene expression, gene silencing, and genomic imprinting. In the process of tumorigenesis, aberrant methylation patterns, such as CpG island hypermethylation in promoters of tumor suppressor genes play crucial roles. Tracking the methylation patterns in differential DNA methylation regions (DMRs) in cfDNA can be used to monitor biological changes such as tumor progression or treatment response. Here we developed a novel, multi-omics platform that leverages both genetic and epigenetic information from plasma cfDNA. This platform allows simultaneous extraction of genetic information (mutations, sequence variants) and epigenetic modifications (DNA methylation patterns) at the single-DNA-molecule level. To explore the methylation profiling potential of this platform, we conducted a study using a targeted high-depth sequencing approach on procured plasma cfDNA samples from individuals with lung cancer (n=34) and healthy controls (n=78). Along with the data generation, a robust bioinformatics pipeline was designed and implemented for the analysis, including raw sequence alignment, quality control (QC), methylation status assignment, and cancer associated methylation assessments. The platform demonstrated high sensitivity and specificity in detecting cancer-derived cfDNA in this independent sample set. Overall, approximately 29000 of the DMRs (representing >90% of the designed panel), exhibited aberrant methylation in patient samples. For each individual sample, an integrated methylation score was calculated to quantify the cancerous and non-cancerous cfDNA sources based on methylation profiles. This methylation score effectively stratified samples by both cancer presence and disease stage. The overall detection rate (sensitivity) for this sample set was 0.88 at a specificity of 0.91, with sensitivity of 0.66 in stage I (n=5) and 0.92 in stage II/III (n=29). Notably, this assay maintained high sensitivity for (4/6) samples with low ctDNA levels or minimal mutation burden, as evidenced by a circulating tumor fraction (cTF) below 1e-5, identified by variant allele frequency (VAF).In summary, this assay represents a powerful tool for sensitive and specific ctDNA detection.

#5897 Noninvasive tumor genetic profiling and disease surveillance in mantle cell lymphoma via plasma circulating tumor DNA.

Z. Ouyang[1], R. Zeng[1], S. Wang[2], X. Wu[2], Y. Li[1], Y. He[1], C. Wang[1], C. Xia[1], Q. Ou[2], W. Yang[2], **H. Tang**[3], L. Xiao[4], H. Zhou[1];
[1]The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Hunan Cancer Hospital, Changsha, China, [2]Nanjing Geneseeq Technology Inc., Nanjing, China, [3]Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Jiangsu, China, [4]School of Basic Medical Science, Central South University, Changsha, China

Background: Mantle cell lymphoma (MCL) is an aggressive subtype of B-cell non-Hodgkin's lymphoma. While plasma circulating tumor DNA (ctDNA) has demonstrated diagnostic and prognostic value in diffuse large B-cell lymphoma and Hodgkin lymphoma, its significance in MCL remains unclear.
Methods: This study analyzed paired treatment-naïve plasma and tissue samples from 34 MCL patients with response data after first-line chemotherapy, targeting 475 genes associated with hematopoietic and lymphoid neoplasms. We assessed the ability of plasma ctDNA to detect tumor-specific genetic alterations and explored its potential as a non-invasive biomarker for predicting treatment response and prognosis.
Results: The most frequently mutated genes in baseline tissues were *CCND1* (93.5%), *ATM* (48.4%), *KMT2D* (25.8%), and *TP53* (25.8%). Subgroup analysis showed that genetic alterations in *CDKN2A* (*P*=0.028), along with those in the B cell antigen receptor (BCR) and endosomal Toll-like receptor (TCR) signaling (*P*=0.004), as well as the PI3K pathway (*P*=0.008), were significantly enriched in the blastoid type of MCL. *ATM* mutations (*P*=0.041) were more prevalent in patients with low scores on the Mantle Cell Lymphoma International Prognostic Index (MIPI), while epigenetic chromatin remodeling pathway alterations (*P*=0.028) were more common in MIPI-high patients. Plasma ctDNA detected 66.3% (118/178) of tissue-based somatic variants, yielding an overall detection sensitivity of 73.3%. The highest sensitivity was observed for structural variants (96.6%), followed by mutations/indels (71.3%) and copy number variants (30.0%). At the patient level, 75% (21/28) of patients with paired tissue and plasma samples exhibited moderate to almost perfect agreement in detecting genomic variants in panel-targetable genes, achieving a kappa coefficient ≥ 0.6. Pretreatment ctDNA levels were highly specific for predicting treatment response (100%), although the sensitivity was suboptimal at 68.2%. Higher ctDNA levels were independently associated with shorter progression-free survival (PFS; *P*=0.002) and overall survival (OS; *P*=0.009). Additional genetic features associated with shorter PFS included mutations in *TP53* (*P*=0.002), *SMARCA4* (*P*=0.023), and *TRAF2* (*P*=0.023). Furthermore, mutations in *TP53* (*P*=0.006) and *TERT* (*P*=0.031) in baseline plasma ctDNA were predictive of reduced OS.
Conclusions: Plasma ctDNA serves as a noninvasive approach for detecting tumor-derived genetic aberrations associated with treatment response and survival outcomes in MCL. These findings underscore its clinical utility for diagnosis, recurrence prediction, and surveillance monitoring in MCL.

#5898 Investigation of EGFR mutations in lung cancer patients through liquid biopsy analysis.

Pin-fei Wei[1], Shang-Gin Wu[2]

[1]Department of Laboratory Medicine, National Taiwan University Hospital, Taipei City, Taiwan,[2]Department of Internal Medicine, National Taiwan University Cancer Center, Taipei City, Taiwan

Objective: Lung cancer is the leading cause of cancer-related mortality in Taiwan as of 2023. Early diagnosis and continuous monitoring are critical for improving patient prognosis. Studies indicate that approximately 50% of lung cancer patients in Asia have EGFR gene mutations. Among patients receiving first- and second-generation targeted therapies, over 50% develop resistance due to T790M gene mutations. The gold standard for lung cancer diagnosis involves pathological tissue examination, including cytological analysis, immunohistochemistry, and genetic testing. Recently, blood-based liquid biopsy for EGFR qPCR gene mutation analysis has emerged as a novel method due to its rapid turnaround time and reduced invasiveness. This study aims to compare EGFR gene qPCR mutation detection via liquid biopsy with tissue biopsy results and assess the clinical utility of liquid biopsy for EGFR qPCR testing.
Methods: From March 2018 to April 2020, we collected 416 peripheral blood samples via venipuncture for EGFR liquid biopsy using the Cobas EGFR Mutation Test v2. Simultaneously, corresponding tissue biopsy samples were obtained for EGFR genetic analysis using Sanger or MASS sequencing. We compared results from both testing methods and statistically evaluated sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and concordance rate.
Results: Among the 416 samples, 280 were from females and 136 from males, aged 32 to 92 years (average age 65). The EGFR mutation test results included: negative (221 cases), deletion in exon 19 (Del 19) (65 cases), L858R (65 cases), Del 19+T790M (34 cases), Del 19+L858R (21 cases), T790M (2 cases), and other mutations (8 cases). Of the 416 cases, 230 lacked available pathological tissue reports for comparison. In the 186 cases with pathology reports, we noted various timing discrepancies between liquid and tissue biopsies. Among 94 patients with both liquid biopsy and tissue biopsy results, the overall concordance rate was 77.7%. Using tissue biopsy as the gold standard, sensitivity, specificity, PPV, NPV, and concordance rates for detecting Del 19, L858R, and T790M mutations were as follows: Del 19 (0.83/1/1/0.86/0.92), L858R (0.67/1/1/0.87/0.89), T790M (0.38/0.93/0.64/0.81/0.79).
Conclusion: EGFR liquid biopsy qPCR can be effectively utilized at lung cancer diagnosis and for monitoring drug resistance during targeted therapy. Compared to tissue biopsy, liquid biopsy qPCR using peripheral blood is a less invasive procedure with improved efficacy and an overall concordance rate deemed clinically acceptable.

#5899 Comparative analysis of transcription factor activities derived from low-pass whole genome sequencing of cell-free DNA and from ATAC-sequencing of tumors.

Ryuji Tamaki[1], Koji Sagane[1], Shuyu Dan Li[2], Taisuke Hoshi[1]

[1]Eisai Co., Ltd., Tokyo, Japan,[2]Eisai Inc., Nutley, NJ

Background: cell-free DNA (cfDNA) in plasma primarily originates from hematopoietic cells in healthy individuals, but in cancer patients, it includes circulating tumor DNA from dead tumor cells. cfDNA mutation analysis is already used in clinical practice for biomarker research and treatment decisions. Recent studies have shown that cfDNA fragmentation patterns reflect tumor tissue chromatin status. Inferring transcription factor (TF) activity from cfDNA TF binding site (TFBS) coverage patterns offer a minimally invasive assay to understand cancer biology with limited sequencing depth. However, the accuracy of TF activity inference has only been examined for a few well-known TFs such as AR and ESR1. We conducted a comparative analysis of 377 TF activities between cfDNA whole genome sequence (WGS) and tumor Assay for Transposase-Accessible Chromatin using sequencing (ATAC-sequencing).
Methods: Two liver cancer cell lines, HepG2 with a gain-of-function CTNNB1 mutation and HuH7 with wild-type CTNNB1, were used to generate xenograft models. ATAC-sequencing/RNA-sequencing and WGS were performed on the tumors and pooled plasma-derived cfDNA from each model. TCF/LEF family TF activities, downstream targets of CTNNB1, were compared between models with different CTNNB1 mutation statuses in both tumor ATAC-sequencing and cfDNA WGS. For 377 TFs with at least 10,000 TFBS, the correlation of TF activities between tumor ATAC-sequencing and cfDNA WGS was examined in each model. Furthermore, tumor model-specific TFs were identified based on ATAC-sequencing, followed by comparison of cfDNA TFBS coverage of these TFs between the two models.
Results: In pilot analysis with TCF/LEF family TFs, both tumor ATAC- sequencing and cfDNA WGS from HepG2 xenograft model showed higher TCF7 and TCF7L2 activities compared to HuH7. In an expanded analysis of 377 TFs, we found a significant and strong correlation between tumor and cfDNA TF activities (Spearman's rank correlation coefficients for HepG2 and HuH7: -0.90 and -0.86, respectively). For tumor model-specific TFs, "HepG2-HIGH" and "HuH7-HIGH" which are composed of 29 and 18 TFs with the highest variance between models, cfDNA TFBS coverage of these two groups of TFs also showed significant differences between tumors ($p<0.05$).
Conclusion: Our results indicate that cfDNA can accurately estimate the activity of over 300 TFs in tumor. To assess the potential utility of cfDNA TFBS analysis in clinical samples, further studies are warranted.

#5900 Tumor-independent cfDNA methylation analysis for cancer monitoring during total neoadjuvant treatment in rectal cancer patients.

Kim Nguyen-Ta[1], Grace Zhao[2], Heng Wang[2], Teressa Celma[1], Lisa Kim[1], Jeff Pawelek[1], Bram Herman[3], Annie Wu[4], Yun Bao[2], Gregory Botta[1], Aaron Miller[1], Hitendra Patel[1], Shengrong Lin[2], Peter Vu[1]

[1]UC San Diego Moores Cancer Center, La Jolla, CA,[2]Agilent Technologies Inc., Santa Clara, CA,[3]Agilent Technologies Inc., Harwell, United Kingdom,[4]Rensselaer Polytechnic Institute, Troy, NY

Introduction: Total neoadjuvant therapy (TNT) is the standard curative-intent treatment for locally advanced rectal cancer (LARC), where patients receive all of their chemotherapy and radiation therapy before surgery. However, monitoring treatment response during TNT can be challenging since radiographic changes are often delayed. Methylation changes in colorectal cancer (CRC) and other cancers are relatively consistent and can be monitored in real time using cell-free DNA (cfDNA), making them a promising strategy for cancer detection and treatment monitoring. This study aims to determine if methylation changes in cfDNA can be used to monitor treatment response in LARC undergoing TNT.
Methods: Plasma of CRC patients stage I-IV and healthy controls were obtained to establish the methylation classifier. Patients with stage II or III rectal cancer undergoing TNT were recruited. Blood samples were collected at baseline and about 6 weeks after the start of treatment. Tumor and normal CRC genomic DNA were analyzed using the Agilent Avida Methyl 3400 DMR panel to generate a methylation index score. Cancer treatment response was assessed by the investigator based on computed tomography and/or magnetic resonance imaging.
Results: We confirmed low background methylation signals in cfDNA and peripheral blood mononuclear cells of healthy controls. Subsequently, we analyzed methylation signals from plasma of CRC patients with stage I (n=20), II (n=12), and IV (n=5) disease. The sensitivity of the assay was 60%, 75%, and 100% for stages I, II, and IV, respectively, while the specificity was 87.5%. Among LARC patients undergoing treatment with TNT, we observed a decrease in methylation index scores compared to baseline in all three patients who experienced a treatment response and an increase in all three patients who experienced disease progression. Notably, the methylation index scores did not correlate with carcinoembryonic antigen values.
Conclusions: Our preliminary results show the feasibility of monitoring rectal cancer treatment response during TNT using a tumor-independent cfDNA methylation analysis. Methylation analysis is a promising technology that may aid in quantifying treatment response to systemic therapy and/or radiation.

#5901 Circulating tumor DNA in non-viral head and neck squamous cell carcinoma: A systematic review and meta-analysis.

V. Helou[1], N.-H. Abdul-Rahman[2], S. Loo[2], S.-J. Gao[2], J. P. Zevallos[1], D. Zandberg[3], M. E. Spector[1], H. D. Skinner[1], R. L. Ferris[4], K. J. Contrera[1];
[1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]UPMC Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA, [4]University of North Carolina, Chapel Hill, NC

Purpose: Circulating tumor DNA (ctDNA) is a promising non-invasive biomarker offering insights into tumor biology, treatment response, and disease monitoring, particularly for less accessible tumors. Although ctDNA in viral-mediated head and neck squamous cell carcinoma (HNSCC) is widely studied, research into the role ctDNA for non-viral HNSCC is limited. This systematic review and meta-analysis consolidates evidence on ctDNA in non-viral HNSCC and examines its implications for diagnosis, prognosis, and management.
Experimental Design: A comprehensive literature search was conducted in September 2024 across Medline, PubMed, Embase, and the Cochrane Library. Following PRISMA guidelines, two reviewers independently screened titles, abstracts, and full texts. Clinical outcomes were extracted in duplicate into a standardized pilot-tested form. Pooled hazard ratios (HR) were calculated using a fixed-effect model.
Results: Out of 1915 screened studies, 47 studies involving 3,574 patients were included. The median publication year was 2022, with 64% of studies being prospective. The most common ctDNA assays were next-generation sequencing (n=28, 60%) and PCR-based techniques (n=21, 45%). Median assay sensitivity was 80% (range 38-100%), and specificity was 99% (range 60-100%), with twelve studies reporting specificity exceeding 91%. Pre-treatment ctDNA detection
rates ranged from 50% to 100%, with a median of 83%, while post-treatment rates ranged from 28% to 100%, with a median of 48%. ctDNA identified recurrence or progression in 80% of patients (range 40-100%) prior to clinical diagnosis, with five studies reporting 100% detection of recurrence or progression. The median lead time between ctDNA detection and clinically or radiologically confirmed disease progression was 4.6 months (range 1-27 months). On survival analyses, ctDNA detection, SEPT9 methylated ctDNA, and mutated ctDNA were associated with worse overall survival, with pooled HRs of 10.26 (95% CI: 3.58-29.40; *P < .0001*), 1.15 (95% CI: 1.08-1.23; *P < .0001*), and 1.96 (95% CI: 1.28-3.00; *P = 0.002*), respectively. ctDNA correlated with worse progression-free survival (HR 7.32, 95% CI: 4.17-12.86; *P* < .00001) and recurrence-free survival (HR 7.33, 95% CI: 2.75-19.58; *P < .0001*).
Conclusions: ctDNA shows promise for enhancing diagnostic accuracy, monitoring progression and recurrence in non-viral HNSCC. While additional research is necessary, our findings could inform the development of evidence-based clinical guidelines for the personalized management of non-viral HNSCC.

#5902 Quantification of the effect of early-stage cancer on cell-free DNA levels in plasma.

K. Mamis, I. Bozic;
University of Washington, Seattle, WA

Elevated cell-free DNA (cfDNA) levels are often observed in cancer patients. However, the exact effect of cancer on cfDNA concentration is not fully understood. In order to obtain insight into cfDNA dynamics in the presence of early-stage cancer, we analyze a rich, previously published dataset of cfDNA in healthy individuals and patients with stage I-III lung, breast, colorectal, pancreatic, ovarian, esophageal, stomach and liver cancer. We find that, despite the high variance of cfDNA levels among both healthy individuals and cancer patients, early-stage cancer exhibits a systemic effect resulting in a multiplicative, cancer-type specific increase in cfDNA concentration originating from healthy tissue. For each cancer type, we also observe similar multiplicative increases in the concentration of mutant DNA fragments detected in plasma that do not originate from tumor, providing additional validation that increased cfDNA levels in early-stage cancer originate from healthy tissue and not from the tumor. The magnitude of the multiplicative increase in cfDNA differs greatly between the cancer types considered, ranging from a ~1.3-fold increase in lung cancer, to a ~12-fold increase in patients with liver cancer. To determine the mechanism responsible for the increase in cfDNA levels, we employ an additional dataset that reports the cfDNA composition regarding its tissue of origin, in healthy individuals and patients with pancreatic and ovarian cancer. We find that elevated cfDNA levels in cancer patients do not originate from a proportional increase in cfDNA shedding, but from impaired clearance of cfDNA. The impaired cfDNA clearance could stem either from a direct decrease in cfDNA clearance rate in the presence of cancer, or can be due to a saturation effect in the cfDNA clearance mechanism, triggered by smaller increases in cfDNA shedding due to cancer. Our results contribute to the development of quantitative understanding of cfDNA dynamics in the presence of cancer.

#5903 Real world assessment of quality control metrics impacting performance of a commercially available liquid biopsy NGS panel.

Emma Longshore, Nylev Vargas, Colin Cochran, Amanda Weaver, Brittany D'Alessio, Leisa Jackson, Gary A. Pestano

Biodesix, Inc., Louisville, CO

Introduction: NGS panels allow rapid detection of rare variants through detection of targeted nucleic acid (NA) sequences. This technology is capable of sensitive and specific detection of many variants simultaneously in a single specimen. However, assay performance may be impacted by the quality and amount of input of the template. Liquid biopsy assays are then vulnerable to compromised NAs dependent on pre-analytic conditions and the tumor biology. This report reviewed real world data to determine the performance impact of nucleic acid quality and quantity on the detection of the four major variant classes in liquid specimens.

Materials and Methods: Varying input amounts of total nucleic acids (TNA) were examined to determine influence of quantity on passing pre-established Quality Control (QC) for a commercially available, targeted amplicon based NGS assay. Retrospective analysis of approximately 12 months of QC measurements was performed. Reaction input quality control data from 185 batches (2k+ specimens) was collected to analyze frequency of qBittorent failure. Input of TNA was measured by fluorescence, quality by qPCR, and pass/fail in the NGS pipeline by multiple QC metrics. A supervised, linear discriminant analysis (LDA) was conducted to identify significant combinations of primary features that best separate the classes of the five primary quality control metrics and their relation to a final PASS/FAIL QC call.

Results: QC metrics for raw sequencing reads were analyzed using a set of five primary metrics, including minimum mean read length (MRL ≥ 65bp = PASS) and Q-Score [Q = -10log 10 (e)]. Higher Q Scores indicate a smaller probability of error. Q-Score returned a strong negative coefficient correlation in the LDA, indicating as the independent variable, Q-Score, increases, prevalence of the dependent variable, “FAIL” call, decreases. Additionally, SNV/Indels, CNA, and fusion/exon skipping, were called Pass/Fail based on variant detection in the bioinformatics pipeline. The coefficients of linear discriminants identified that a final QC call is most positively influenced by quality control measures Mean Read Length (MRL; > 65) and Reaction Input (> 13ng).

Conclusions: We observed least impact of total nucleic acid input on QC calls for SNV, Indels and Fusions. Modest performance improvements for copy number amplifications (CNA) were observed at the higher input. Overall, there was not a significant impact to any primary or secondary QC metric comparatively in the low input quantity groups. Additional data are being reviewed to trend performance over time.

#5905 A non-invasive, methylation-based NGS assay for sensitive detection and monitoring of bladder cancer in urine.

Feng Xie, Hang Dong, Haoran Tang, Yue Zhang

Huidu Shanghai Medical Sciences, Ltd., Fengxian District, Shanghai, China

Background: Bladder cancer, the sixth most common cancer worldwide, has a high recurrence rate, necessitating frequent and reliable disease monitoring. Current methods, such as cystoscopy, are invasive and can hinder patient compliance. However, detecting therapy response and disease progression on a molecular level still remains challenging. Urinary tumor DNA (utDNA) analysis offers a promising, non-invasive, and highly sensitive diagnostic tool for bladder cancer diagnosis and monitoring. By detecting utDNA methylation profiles, this analysis could enable personalized treatment decisions and improve clinical outcomes.
Methods: We developed PredicineALERT, a methylation-based next-generation sequencing (NGS) assay designed for bladder cancer monitoring using urine. Methylation markers were identified through comparative analysis of profiles from bladder cancer patients and healthy donors. These markers were used to train a model capable of distinguishing bladder cancer from non-cancer samples. The assay's sensitivity and specificity were validated using serially diluted methylated DNA controls to determine its detection limit. To assess the performance of the PredicineALERT assay in detecting tumor fractions, serial urine samples were collected from muscle-invasive bladder cancer (MIBC) patients undergoing neoadjuvant therapies and analyzed using both PredicineALERT and a tumor-informed minimal residual disease (MRD) assay.
Results: A panel of methylation markers was identified from urine samples, enabling the model to accurately differentiate bladder cancer patients from healthy individuals. PredicineALERT demonstrated the ability to detect tumor signals at levels as low as 0.01%, underscoring its potential for minimal residual disease detection and early recurrence monitoring. Comparison with the tumor-informed MRD assay revealed excellent concordance in tumor fraction detection, further highlighting the assay's robustness and reliability.
Conclusion: PredicineALERT is a non-invasive and highly sensitive assay for bladder cancer monitoring. Its design facilitates early recurrence detection while enhancing patient compliance, presenting a promising advancement in bladder cancer management.

CLINICAL RESEARCH: Predictive Biomarkers 6 / Diagnostic Biomarkers 3
Poster Session

#5909 MRD as a predictive biomarker in patients with small cell lung cancer.

J. Chang[1], Q. Zhang[1], D. Dai[2], B. Chen[2], M. Zhang[2], Z. Cai[1], L. Guo[1], S. Huang[1], S. Lyu[1];
[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, China, [2]BGI Genomics, Shenzhen, China

Background: Despite the high response rate to initial treatment, the clinical outcomes of small cell lung cancer (SCLC) remain challenging. Tumor-informed minimal residual disease (MRD) assessments, leveraging circulating tumor DNA (ctDNA) detection, offer a promising approach for early detection and personalized treatment guidance in SCLC. However, their full potential is yet to be demonstrated.
Objective: This study aims to investigate the predictive value of a plasma-based personalized MRD monitoring assay in SCLC patients.
Methods: We conducted a prospective study, collected clinical data and performed high-throughput whole-exome sequencing (WES) on baseline tumor tissue from SCLC patients. Personalized panels were constructed based on WES data to dynamically monitor MRD through ctDNA extracted from plasma. To evaluate the correlation between MRD dynamics and treatment outcomes, peripheral blood samples were collected at baseline, every 6 weeks ±7 days during treatment, and at disease progression.
Results: Seven SCLC patients with consent were recruited for the study, including those with limited stage (n=2) and with extensive stage (n=5). One patient was diagnosed with combined SCLC. Five patients received platinum-based combination regimens, and the other two received monotherapy irinotecan and anlotinib hydrochloride, respectively. The median age was 60 years (range, 68 to 74 years), and all patients had a smoking history. The MRD positive rate at baseline was 100%. *TP53* and *RB1* genes were the most frequently mutated genes, at 100% and 85.7%, respectively. The MRD elevated up to 48 days prior to disease progression. Patients in the MRD increase group (n=5) experienced progressive disease (PD) finally and the other in the MRD decrease group (n=2) maintained stable disease (SD) or partial response (PR), with one achieving durable MRD clearance after three cycles of sequential chemoradiotherapy. At the end of follow-up, the PFS analysis between the MRD increase and decrease cohorts revealed a clear trend of separation, despite the lack of statistical significance (p=0.06, 95% CI: 1.09-42.81). Moreover, MRD dynamics were more pronounced than the traditional cancer markers, neuron-specific enolase (NSE) and progastrin-releasing peptide (ProGRP), highlighting its high sensitivity and clinical applicability. WES analysis revealed a diverse landscape of genetic alterations, with prevalent missense mutations in genes such as TTN, MUC2, and ZNF676, alongside coding-synonymous variations.
Conclusion: Our study indicates that MRD could predict clinical outcomes and surpass traditional biomarkers, presenting its potential as a biomarker for the management of SCLC patients. Personalized MRD monitoring may provide valuable insights into treatment response and disease progression in SCLC. Further validation with a larger sample size is ongoing.

#5910 Characterizing spatial expression patterns and prevalence of folate receptor alpha in relation to other existing and emerging ovarian cancer biomarkers.

Marian Themeles, Kevin Kolahi, Amita Mistry, Erik Huntzicker, Peter Ansell, Emily Deutschman

AbbVie Inc., Waltham, MA

The ovarian cancer treatment landscape has seen an emergence of biomarker-targeted therapies following accelerated approval of the folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC) mirvetuximab soravtansine-gynx (MIRV, Elahere) in November 2022 (with full US approval granted in March 2024). Many therapies in development are biomarker-directed ADCs with distinct cytotoxic payloads, which is the major effector component of the ADC. Data suggest mechanisms of resistance may be largely payload specific, meaning patients may only be able to receive a limited number of these therapies; thus making it paramount to identify the therapy from which each individual patient will derive maximal clinical benefit. Eligibility for MIRV is currently evaluated by FRα expression as assessed by the immunohistochemical VENTANA FOLR1 (FOLR1-2.1) RxDx Assay (FOLR1 CDx). FRα is expressed in roughly 95% of high-grade serous ovarian cancer, with around 36% prevalence observed at the cutoff for MIRV eligibility (PS2 ≥ 75%, or ≥75% of viable tumor cells with ≥2+ staining). The goal of this study was to characterize the spatial overlap of FRα expression and prevalence with biomarkers that are currently being or could be leveraged for targeted therapeutics in the ovarian space. FRα expression was evaluated in commercially procured, formalin-fixed, paraffin-embedded (FFPE) primary ovarian tumor specimens using the FOLR1 CDx. HER2, Muc16, Mesothelin, TROP2, CLDN6, B7-H4, CDH6, Tissue factor and Napi2B were also evaluated by immunohistochemistry from serial sections taken from the same FFPE blocks. Intensity staining for each biomarker was correlated to FRα intensity staining to identify overlapping eligible patient populations. In addition to intensity overlap, spatial expression patterns of each biomarker relative to FRα were also evaluated to understand sequencing and combinability options. These data shed light on biomarker co-expression in ovarian cancer to best match patients to the ideal targeted therapy and to best tailor optimal combination therapies in ovarian cancer patients.

#5911 The role of CD53+ subsets and the JAK/STAT3 pathway in regulating cancer stemness and immune escape in esophageal squamous cell carcinoma.

B. Liu[1], H. Zhou[2], L. Tan[2], B. Yao[2], S. Zhang[2], J. Huang[2], M. Yang[1], X. Guan[2];

[1]City University of Hong Kong, Hong Kong, China, [2]The University of Hong Kong, Hong Kong, China

T cell therapy has revolutionized treatment for hematologic malignancies but faces significant challenges in solid tumor applications, including esophageal squamous cell carcinoma (ESCC). In this study, we utilized a dynamic subcutaneous tumor growth model in mice to investigate how ESCC tumors modulate T cell activity through four distinct phases: initial enlargement, reduction, stabilization, and explosive growth. Single-cell sequencing revealed that CD53+ subsets were enriched in the reduction stage and showed their function in stemness regulation and immune escape. Functionally, CD53+ mouse ESCC cell lines showed a higher organoid formation ability when compared with CD53- cells. When co-cultured with T cells, CD53+ ESCC cell lines revealed their capability in regulating T cell exhaustion. Mechanically, GO enrichment analysis and western blotting demonstrated that CD53+ cells activated IL-6/JAK/STAT3 signaling pathways and upregulated their downstream genes such as C-myc and PD-L1. Furthermore, in vivo study showed that JAK inhibitor Ruxolitinib and STAT3 inhibitor C188-9 could efficiently reduce tumor growth and enhance T cell infiltration in CD53+ mouse ESCC cell lines, suggesting a role in tumor proliferation and T cell editing. This study aims to elucidate the biological function of CD53+ subset ESCC cells in tumor progression and verify their role in T cell regulation, offering new therapeutic targets for ESCC treatment.

#5913 Longitudinal blood-based immuno-monitoring reveals distinct immune profiles in colorectal cancer patients with divergent responses to first-line systemic therapy.

Jia Meng[1], **Yong Xiang Gwee**[2], Kai Soon Ng[1], Wei Peng Yong[2], Gloria Hui Jia Chan[2], Hon Lyn Tan[2], Joan Choo[2], Robert John Walsh[2], Jingshan Ho[2], Joe Yeong[1], Cheng Ean Chee[2]

[1]Institute of Molecular and Cell Biology (IMCB), A*STAR, Singapore, Singapore,[2]Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore, Singapore

Introduction: Peripheral blood mononuclear cells (PBMCs) are key mediators of immune surveillance and response against malignancies. Profiling PBMC subsets provides insights into immune dynamics in cancer progression and therapeutic response, reflecting systemic immune changes that may mirror the tumor microenvironment. This study aimed to identify differences in PBMC profiles between colorectal cancer (CRC) patients deriving clinical benefit from first-line systemic therapy and those with poor outcomes.

Methods: We recruited patients with locally advanced, unresectable or metastatic CRC initiating first-line systemic therapy. PBMCs were isolated from venous blood samples at two time points: baseline prior to treatment initiation (L1) and before cycle two of treatment (L2). Flow cytometry was used to assess dynamic changes in immune cell subsets for each patient at L1 and L2. Patients were grouped into Cohort A (clinical benefit: partial response or stable disease ≥6 months) and Cohort B (no clinical benefit: stable disease lasting less than 6 months or progressive disease). The GLIMMIX model was used to compare the differences in cell subset proportions between the two cohorts.

Results: Between November 2023 and April 2024, seven patients (median age 64 years, with 71.4% Chinese ethnicity and 57.1% male) were recruited, with four in Cohort A and three in Cohort B. Median progression-free survival was significantly longer in Cohort A (7.0 versus 1.0 months, p=0.029).

Immune profiling revealed distinct differences between cohorts. $CD4^+$ T cell subset patterns were suggestive of immune activity potentially associated with better outcomes in Cohort A compared to Cohort B patients; at L1, Cohort A showed increased $CD4^+$ effector memory T cells (p=0.03) while Cohort B displayed a higher proportion of naïve $CD4^+$ T cells (p=0.015). At L2, $CD4^+$ T cell activation, as indicated by Ki67 expression, trended higher in Cohort A (p=0.09), and was accompanied by a lower Treg population (p=0.022).

Additionally, patterns of B cell subsets of Cohort B at L2 were consistent with an exhausted immune environment which correlated with poorer prognosis, with Cohort B exhibiting elevated expression of CD38 (p=0.007) and PD-1 (p=0.05) compared to Cohort A. These immune profiles may reflect potential mechanisms underlying early progression and treatment resistance, and warrant further investigation as biomarkers for treatment response in CRC.

Conclusions: Dynamic PBMC profiles, particularly $CD4^+$ T cell and B cell subset patterns, show promise as predictive biomarkers for treatment response in advanced CRC. These preliminary findings warrant validation in larger cohorts and highlight the potential of immune profiling to identify patients at risk for early progression, guide therapeutic strategies and improve patient outcomes.

#5914 Development of immunohistochemistry detection kits for claudin family: CLDN6, CLDN9, and CLDN18.2.

Q. Wang, X. Wang, J. Tao, T. Xiao, X. Wang, M. Li, X. Lv, W. Zhao, J. Geng, Y. Liu, Z. Yu, **Y. Li**;
RemeGen Co., Ltd., Yantai, China

Background: Claudins are a family of integral membrane proteins that are critical for the formation of tight junctions in epithelial and endothelial cells. Aberrant expression of Claudin family members is implicated in the progression of various cancers, making them valuable biomarkers for tumor diagnosis, prognosis, and therapeutic targeting. such as CLDN-6, CLDN-9, and the splice variant CLDN-18.2. An antibody drug targeting CLDN18.2 was recently approved by the FDA for the treatment of advanced gastric cancer. Despite their clinical potential, routine assessment of these proteins in cancer diagnostics is limited because of the lack of highly specific detection tools. we developed novel immunohistochemistry (IHC) detection kits for CLDN-6, CLDN-9, and CLDN-18.2 to facilitate their use as diagnostic and therapeutic biomarkers.
Methods: We used AI-designed peptides from the CLDN-6, CLDN-9, and CLDN-18.2 proteins conjugated with keyhole limpet hemocyanin (KLH) as immunogens to immunize the BABL/c mice. The initial IHC antibody candidates were identified by ELISA and further optimized using various structurally facilitated AI approaches. The selected antibodies were evaluated by IHC in formalin-fixed paraffin-embedded (FFPE) CHOK1 cells expressing full-length CLDN6, 9, 18.2 or CLDN 3, 4, 18.1. These IHC antibodies were also subjected to ELISA, Western blotting, and tumor tissue microarray IHC staining to determine the features of IVD products. Furthermore, we conducted intra-day, inter-day, and inter-operator studies to assess the consistency of IHC staining under the conditions of our established system.
Results: The final IHC antibody clones obtained for CLDN6, CLDN9, and CLDN18.2 were #7, #10, and #9B3, respectively. ELISA tests showed that they all had good binding affinity. Tumor tissue microarray staining showed that these antibodies can specifically stain the target protein in paraffin samples from testicular, endometrial, gastric cancer, and other tumor tissues. The WB assay and IHC staining results confirmed their binding specificity. We established a preliminary reaction system for the IHC assay with final working concentrations of 0.25 μg/ml, 0.25 μg/ml, and 20 μg/ml for #7, #10, and #9B3, respectively. The three IHC assays showed good intra-day, inter-day, and inter-operator reproducibility under the current reaction system, demonstrating good robustness as IHC diagnostic products.
Conclusions: We successfully developed IHC antibodies against CLDN6, CLDN9, and CLDN18.2. These antibodies were incorporated into IHC diagnostic kits for clinical and research applications. The IHC kits are sensitive and robust for specific detection in FFPE tissues. They hold promise in enhancing cancer diagnosis, identifying patients for targeted therapies, and improving clinical stratification among patients with Claudin family disorders.

#5915 Real world clinical characteristics of claudin 18.2 expression in patients with pancreatic adenocarcinoma.

Allison Kerper[1], Robert H. Getzenberg[2], Rondell P. Graham[1]

[1]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[2]Astellas Pharma Inc, Northbrook, IL

Background: Pancreatic cancer is a frequently fatal disease that is often diagnosed at a late stage associated with a poor prognosis and an increasing impact on cancer related mortality. Despite advances, chemotherapy remains the mainstem of therapeutic interventions for this disease and most of the currently identified molecular alterations are not currently targetable. Therefore, novel biomarkers and strategies are necessary to impact patient outcomes. Claudin-18.2 (CLDN18.2) is a splice variant of the Claudin 18 family and is a component of tight junctions, which seal the paracellular spaces of epithelial and endothelial cells. CLDN18.2 is frequently retained in malignant gastric tissue and overexpressed in pancreatic and gastroesophageal adenocarcinomas. CLDN18.2 overexpression at the message and protein levels has been observed in pre-clinical studies involving pancreatic cancer cell lines and in tumors from pancreatic cancer patients. The goal of this study was to obtain a deeper understanding of CLDN18.2 positivity and CLDN18.2 expression and the associated clinical prevalence, prognostic implications, patient clinical characteristics and relationship with other biomarkers in pancreatic ductal adenocarcinoma (PDAC) patient samples.
Design: This was a single institution/reference laboratory based retrospective study including as many as 320 patients, in which CLDN18.2 positivity as defined by ≥ 75% of the tumor cells expressing moderate to strong membranous staining was examined. The goals were to evaluate CLDN18.2 in tumor samples by immunohistochemistry for prevalence in pancreatic adenocarcinoma patients. Claudin 18.2 expression was assessed by the Ventana (43-14A) Class I IVD that was purchased from Ventana/Roche Diagnostics. In addition to prevalence, CLDN18.2 was evaluated with respect to the clinicopathological features of patients, patient prognosis, adjusted for clinical covariables, response to treatments and relationship to patient demographics, tumor grade and disease status. Patient information has been obtained from electronic medical records and research database to establish clinical course (survival status, metastatic sites, etc.) along with patient demographics.
Conclusions: CLDN18.2 is a novel potentially actionable biomarker in patients with advanced and metastatic pancreatic adenocarcinoma. This study provides important clinical information regarding CLDN18.2 expression in these patients that is important to consider when evaluating biomarkers in these patients. Funding for the study was provided by Astellas Pharma Global Development, Inc.

#5916 Investigating the antiproliferative effects of green synthesized silver and gold unfunctionalized nanoparticles on cervical cancer cell lines.

Nrateng Tsotetsi, Lesetja Motadi, Mpho Choene

Biochemistry, University of Johannesburg, Johannesburg, South Africa

Background: Across the globe cervical cancer is the 4th most common cancers affecting women; however, the burden of CC is greater in Sub-Saharan Africa as it ranks 2nd common cancer and number one cause of deaths. Although cervical cancer can be successfully treated if diagnosed early, many women are diagnosed in advanced stages, rendering current treatments ineffective. Metal nanoparticles which are commonly used in optic imaging of tumours have shown potential as anti-tumour agents when either used alone or in combination with other chemotherapy drugs. Therefore, this study investigated the anti-proliferative potential of Cannabis Sativa synthesized Ag and Au NPs using Me-180 and HeLa human cell lines.

Methods: Metallic Ag and Au nanoparticles were synthesized biologically using Cannabis *sativa* plant. The cell viability was assessed following treatment with Au and Ag NP of 0-200µg/ml in some cases in combination with Hexaxim (DTaP-IPV-HB-Hib) vaccine using alamar blue assayall subsequent assays in combination with. Following treatment, ATP levels, pyruvate kinase activity, effector caspase 3/7 and mitochondrial toxicity were evaluated, to further investigate induction of apoptosis, annexin V staining, Hoechst staining, and deoxyribonucleic acid (DNA) fragmentation analysis by agarose gel electrophoresis were performed. Through siRNA, P53, MDM2 and RBBP6 genes were silenced, and the amplification of pro-apoptotic and cell cycle genes were assed using qPCR.

Results: The Me-180 IC_{50} values of 24.17 ug/m 28,35ug/ml and 37.31 ug/ml for AgNP, AuNP and C. Sativa respectively. The IC_{50} of HeLa were 35.43, 39.02 and 41.45 ug/ml for AgNP, AuNP and C. Sativa respectively. The increased mitochondrial toxicity was consistent with the decrease in ATP levels, pyruvate kinase activity and the decrease in effector caspase 3/7 in NPs treatments. With C. sativa caspase 3/7 activity and ATP levels slightly increased with decreased mitochondrial toxicity. Hoechst staining and DNA fragmentation analysis showed apoptotic bodies in Me-180. In all silenced C. sativa treatments, the expression of P53 remained unchanged with increase expressions of Bax and Bak-1 in Me-180 cell lines whereas in HeLa all were decreased.

Conclusion: Me-180 cell lines that expresses wild-type P53 was more sensitive to apoptosis induction by C. sativa. The increased Bax/Bax expression suggest intrinsic pathway of apoptosis supported by decreased ATP and mitochondrial activity.

#5917 A novel ROR1 antibody with high specificity and sensitivity for predictive biomarker detection in various tumor types.

Xin Zhang, Qianqian Lian, Qian Qian, Dan Lu, Yanling Liu, **Ying Tong**, Qingyang Gu

WuXi AppTec, Shanghai, China

ROR1, a receptor tyrosine kinase-like orphan receptor, is a key mediator of non-canonical Wnt signaling and plays a critical role in cancer progression. ROR1 is selectively and highly expressed in various solid tumors and hematological malignancies while absent in normal adult tissues, making it a promising target for cancer therapy.
Despite this potential, the lack of effective tools has hindered sensitive detection of ROR1 in patient tumor samples by IHC. To address this, we have developed a recombinant rabbit monoclonal antibody in-house, demonstrating superior sensitivity and specificity across multiple methodologies compared to existing antibodies. Additionally, we have established standardized interpretation criteria and performed an extensive epidemiological survey across ROR1-associated cancer types, reporting the following detection rates: 45% in pancreatic cancer (n=40), 39% in ovarian cancer (n=150), 48% in lung adenocarcinoma (n=140), 15% in endometrial cancer (n=97), 18% in triple-negative breast cancer (n=110), 23% in mesothelioma (n=47), and 10% in esophageal squamous carcinoma (n=70).
These results validate this antibody as a reliable tool for clinical biomarker detection, potentially advancing ROR1-targeted cancer treatment.

#5918 Vascular endothelial growth factor A (*VEGF-A*) gene expression profiling in Northern Thai gastric cancer patients and potential biomarker for anti-VEGF therapy selection.

Amonnat Sukhamwang[1], Hathairat Thananchai[2], Supachai Yodkeeree[1], Pornngarm Dejkriengkraikul[1], **Sirikan Limpakan (Yamada)**[3]

[1]Department of Biochemistry, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand,[2]Department of Microbiology, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand,[3]Division of Upper Gastrointestinal Surgery and Endoscopy, Surgery, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

Background: Vascular endothelial growth factor (Anti-VEGF) drugs are used to treat advanced-stage gastric cancer to inhibit angiogenesis, which is the process of new blood vessel formation that tumors need to grow. These drugs have improved progression-free survival and overall survival when combined with traditional chemotherapy as the second-line treatment. However, the effectiveness of these drugs can vary among patients. Some patients may have tumors that do not express high levels of *VEGF-A*, making the drugs less effective. Additionally, the high cost of these treatments can be a barrier for many patients. This study aims to profile *VEGF-A* gene expression in the Thai population and investigate the relationship between *VEGF-A* and *IL-8*, a poor prognostic marker for advanced-stage gastric cancer, before and after chemotherapy.

Methods: From 2006 to 2018, 149 patients with advanced-stage gastric cancer were collected from Maharaj Nakorn Chiang Mai Hospital in Thailand. These gastric mucosal biopsy tissues were investigated for *IL-8* and *VEGF-A* gene expression using the RT-qPCR technique with specific primer probes for particular genes.

Results: In pre-chemotherapy conditions, 71.15% of 52 cancer gastric mucosal biopsy tissues had higher levels of *IL-8* gene expression than the adjacent normal tissue. In contrast, only 31.51% of 73 cancer tissues had higher levels of *VEGF-A* gene expression than adjacent normal tissue, low expression in 10, 13.7% of patients, and 40, 54.79% of patients showed down-regulate or no expression of *VEGF-A* in cancer tissue in tumor and adjacent normal tissue in the pre-chemotherapy group. Furthermore, when investigating both *IL-8* and *VEGF-A* expression in the same tissues under pre-chemotherapy conditions, the results indicated that most samples had an independent correlation between *IL-8* and *VEGF-A* levels. Specifically, 27.66% of 47 cancer tissues exhibited higher *IL-8* but lower *VEGF-A* levels than adjacent normal tissues in the same patient controls. However, in the subgroup analysis, three of six, 50% of patients with post-chemotherapy conditions showed downregulation of the *IL-8* gene. While only two of nine, 22.22% of patients demonstrated downregulation from post-chemotherapy, and one of nine, 11.11% of patients demonstrated up-regulation post-chemotherapy. There were 6 out of 9, 66.67% patients had no up or down-regulation. Therefore, *VEGF-A* could be used as a specific biomarker for targeted therapy for advanced gastric cancer, as its expression level did not correlate with *IL-8* levels or prior chemotherapy treatment.

Conclusion: The authors found that 23 out of 73, 31.51% of patients had *VEGF-A* expression in pre-chemotherapy conditions. The authors recommend that *VEGF-A* gene expression levels should be tested in patients who intend to use anti-VEGF drugs.

#5919 Performance of the Oncuria-detect bladder cancer test for evaluating patients presenting with hematuria: results from a real-world clinical setting.

Ian Pagano[1], Zhen Zhang[2], Sergei Tikhonenkov[1], Florence Le Calvez-Kelm[3], Steve Goodison[4], Toru Sakatani[5], Kaoru Murakami[5], Takashi Kobayashi[5], Howard Kim[6], Riko Lee[6], Sunao Tanaka[6], Charles J. Rosser[6], **Hideki Furuya**[6]

[1]University of Hawaii Cancer Center, Honolulu, HI,[2]Johns Hopkins Medical Institutions, Baltimore, MD,[3]International Agency for Research on Cancer, Lyon, France,[4]Mayo Clinic, Jacksonville, FL,[5]Urology, Kyoto University, Kyoto, Japan,[6]Cedars-Sinai Medical Center, Los Angeles, CA

Background and Objective: Bladder cancer is the 9th most diagnosed cancer worldwide with high incidences reported in Europe and the United States. Here, we evaluated the real-world performance of a commercially available multiplex immunoassay Oncuria-Detect that detects bladder cancer by simultaneously measuring a panel of 10 biomarker proteins in naturally voided urine samples.
Methods: We tested prospectively collected urine samples from a real-world cohort of 1,002 patients presenting to five USA centers, one European center and one Japanese center with hematuria. Assay results were collated with patient clinical data and a cancer diagnosis was defined by biopsy and pathology. The prevalence of bladder cancer in the cohort was 15.9%.
Results: In a training set (n=684), the Oncuria-Detect assay correctly identified bladder cancer in 94/109 cases, representing a sensitivity of 91.8%, specificity of 71.6% (AUC 0.885; 95% CI 0.843 - 0.927) and with improved performance for high-grade bladder cancer and muscle-invasive bladder cancer (sensitivity 93.6% and 92.1%, respectively). In a test cohort of n =339 the AUC for detecting bladder cancer was 0.850 (95% CI 0.779-0.920).
Conclusions and Implications: The multiplex Oncuria-Detect assay identified bladder cancer with high sensitivity and NPV, for low-grade and high-grade tumors alike. Oncuria-Detect's high NPV could effectively rule out 66% of patients from requiring subsequent cystoscopy.

#5920 Nanomechanical signatures: a breakthrough in personalized diagnosis and treatment optimization for lung cancer.

Jordi Alcaraz[1], Elba Marin[1], Hector Sanz-Fraile[1], Marina Querol[2], Paula Gausa[3], Kate Neal[1], Marselina Arshakyan[1], Marc Rico-Pasto[1], Marc Boada[2], David Sanchez[4], Daniel Martinez[5], Reinier Oropesa Nunez[6], Gitika Srivastava[6], Ahmed Jizawi[6], Carolina Ortiz-Velez[6], Tobias Appenzeller[6], Sara Nizzero[7], Marko Loparic[6], Marija Plodinec[6], Noemi Reguart[2]

[1]Universitat de Barcelona, Barcelona, Spain,[2]Hospital Clinic Barcelona, Barcelona, Spain,[3]Thoracic Oncology Unit, Hospital Clinic Barcelona, Barcelona, Spain,[4]Thoracic Surgery, Hospital Clinic Barcelona, Barcelona, Spain,[5]Anatomophatology, Hospital Clinic Barcelona, Barcelona, Spain,[6]ARTIDIS AG, Basel, Switzerland,[7]ARTIDIS Inc, Houston, TX

Background: Non-small cell lung cancer (NSCLC) is the most common lung cancer subtype and the leading cause of cancer-related deaths worldwide. Advances in treatment have focused on personalized approaches that use targeted therapies and immunotherapies based on protein, DNA, or RNA biomarkers. Assessing molecular biomarkers typically takes 1-2 weeks with challenges such as tissue exhaustion and poor response prediction. Atomic Force Microscopy (AFM) allows for point-of care evaluation of nanomechanical signatures (NS) in hours, offering a fast and accurate method for diagnosis and treatment personalization.
Methods: We used the AFM-based Automated and Reliable Tissue Diagnostics (ARTIDIS) platform to evaluate the diagnostic and prognostic capabilities of NS. Fresh tumor and paired uninvolved pulmonary tissue samples were collected from 70 early-stage NSCLC patients who underwent curative surgical procedures at the Hospital Clinic of Barcelona. Measurements were blinded, and samples were preserved in formalin for further histopathological and molecular analyses.
Results: In this proof-of-concept study, ARTIDIS NS successfully distinguished malignant tumors from uninvolved pulmonary tissue with 88% sensitivity, 86% specificity, and 87% accuracy (n=52). The NS also accurately identified histological subtypes, including adenocarcinoma (ADC, 100% sensitivity) and squamous cell carcinoma (SCC, 83% specificity). ARTIDIS NS identified aggressive features predictive of early recurrence in non-involved samples (82% sensitivity, 72% specificity). Out of 70 patients, 17 had recurrences (median time: 7.7 months), leading to 12 deaths, 10 due to cancer. Remarkably, ARTIDIS NS accurately predicted tumor progression within 10 months post-surgery, achieving 100% sensitivity and 93% specificity in identifying patients at risk of recurrence after curative treatment.
Conclusions: The findings suggest that ARTIDIS NS is a rapid and reliable tool for predicting recurrence and assessing outcomes in NSCLC while preserving tissues for downstream assessment. The ARTIDIS platform not only demonstrated significant accuracy in differentiating malignant tissues, but also showed exceptional precision in predicting early recurrence and progression, effectively identifying high-risk patients. Furthermore, NS identified early recurrence indicators through nanomechanical changes in uninvolved samples, offering insights beyond traditional pathology. A 200-patient extension specifically in neoadjuvant treatment is planned to enhance NSCLC management and improve patient outcomes.

#5921 Correlation between MET amplification/overexpression status and response to MCLA-129 in advanced non-small-cell lung cancer (NSCLC): biomarker results from a phase 1 trial.

Jie Wang[1], Jia Zhong[1], Yu Yao[2], Di Wu[3], Xiujuan Qu[4], Guojun Zhang[5], Haibo Zhang[6], Yu Cao[7], Zhuang Yu[7], Kai Chen[8], Maoqiong Jiang[9], Zhihua Li[10], Jianlin Long[11], Xiubao Ren[12], Huijuan Wang[13], Zhehai Wang[14], Lin Wu[15], Bolin Chen[15], Aimin Zang[16], **Haie Chen**[17], Lin Ma[17], Kan Liu[17], Peiqi Li[17], Lieming Ding[17]

[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China,[3]Shenzhen People's Hospital, Shenzhen, China,[4]The First Hospital of China Medical University, Shenyang, China,[5]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China,[6]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China,[7]The Affiliated Hospital of Qingdao University, Qingdao, China,[8]The First Affiliated Hospital of Soochow University, Suzhou, China,[9]The Second People's Hospital of Yibin, Yibin, China,[10]Sun Yat-sen Memorial Hospital, Guangzhou, China,[11]Chongqing University Cancer Hospital, Chongqing, China,[12]Tianjin Medical University Cancer Institute & Hospital, Tianjin, China,[13]Henan Cancer Hospital, Zhengzhou, China,[14]Shandong Cancer Hospital, Jinan, China,[15]Hunan Cancer Hospital, Changsha, China,[16]Affiliated Hospital of Hebei University, Baoding, China,[17]Betta Pharmaceuticals Co Ltd, Hangzhou, China

Background: In this ongoing phase 1b study (NCT04930432) of the MET/EGFR bispecific antibody MCLA-129 in patients (pts) with advanced NSCLC, we aimed to gain a deeper insight into the relationship between MCLA-129 and efficacy in the MET amplification (METamp) or protein overexpression (OE) population.
Methods: Eligible pts (≥18 years; ECOG PS 0-1; confirmed metastatic or unresectable NSCLC; and positive EGFR or MET alterations) received MCLA-129 (1500 mg biweekly) intravenously. MET OE was defined as IHC 2+/3+ and METamp was defined based on the gene copy number (GCN). Using a wide range of GCN cut-offs, we aimed to explore its relationship with efficacy outcomes.Results: At data cut-off (March 31, 2024), in 24 NSCLC pts, 6 with MET IHC 2+/3+ and 18 with METamp were evaluable for efficacy. Four out 6 pts with MET IHC 2+/3+ (median No. of previous lines: 1 [0-1]) achieved confirmed PRs (ORR: 66.7% [95% CI 22.3-95.7]), and all these 4 pts harbored concurrent mutations (3 METex14 skipping and 1 EGFR exon20ins). The median DOR and PFS were not reached. Eight out of 18 pts with METamp achieved confirmed PRs (median No. of previous lines: 2 [1-7]) (ORR: 44.4% [95% CI 21.5-69.2]; DOR: NR [2.8-NR]; PFS: 4.8 months [2.7-9.6]). Of 7 pts with METamp (METamp was detected prior to systemic antitumor therapy), 4 pts achieved confirmed PRs, with an ORR of 57.1% (95% CI 18.4-90.1), and all these 4 pts harbored concurrent mutations (2 EGFR exon20ins, 1 METex14 skipping and 1 L861Q). Among 9 pts that progressed on 3rd-generation EGFR-TKIs, 3 pts achieved confirmed PRs. Pts with different cut-offs of MET showed a differentiated ORR (Table).
Conclusions: MCLA-129 showed clinically meaningful antitumor activity in advanced NSCLC with MET OE or METamp, particularly in pts with concurrent mutations. High GCN seemed to be associated with better efficacy in MET-amplified advanced NSCLC, suggesting its predictive properties.

GCN cut-off	N	ORR, % (95% CI)
≥3	15	46.7 (21.3-73.4)
≥4	10	60.0 (26.2-87.8)
≥5	7	71.4 (29.0-96.3)
≥6	6	66.7 (22.3-95.7)
≥7	2	100 (15.8-100)

#5922 B cell subtype is a predictive and pharmacodynamic biomarkers for combination therapy in stage III-IV melanoma: a simon phase II trial.

Teruyuki Mizutani, Amrutesh Puranik, Tomoaki Muramatsu, Joanna Handzlik, Ankita Mitra, Diana Kimono, Stanzin Idga, Eddy Yang, Ramin Herati, Michelle Krogsgaard, Mehnert Janice

Perlmutter Cancer Center, NYU Langone Health, NYC, NY

Background: Assessing biomarkers to predict immune-related adverse events (irAEs) is crucial for optimizing melanoma treatment with immune checkpoint inhibitors (ICIs). T and B lymphocytes are key mediators of autoimmunity and are implicated in the development of irAEs. Here we focus on analysis of specific B cell subsets, as predictive and pharmacodynamic biomarkers for irAEs in a phase II trial combining nivolumab (3 mg/kg), ipilimumab(1 mg/ml), and the IL-6 receptor inhibitor tocilizumab (4 mg/kg) in unresectable/advanced stage III/IV melanoma patients.
Methods: We analyzed cryopreserved PBMC from melanoma patients collected at baseline and week 7, and categorized by irAE severity. Patients were categorized as either experiencing severe irAEs (grade 3-4) (TOX) or no toxicity or grade 1-2 irAEs (NT). We used multi-parameter flow cytometry panel to analyze B cells. PBMCs analyzed by a 35-color antibody B cell panel by spectral flow cytometry. The data underwent quality control, and normalization and initial clustering. CD19+ B cells were concatenated and clustered by FlowJo software. Fifteen B cell clusters was obtained and phenotyped using Cluster Explorer. Statistical analyses were performed using multiple logistic regression and Mann-Whitney U test, with a significance level set at 0.05.
Results: Among the 70 patients administered treatment, we observed a best overall response rate of 57%. Grade 3-5 irAEs occurred in 22% of patients by week 24. We analyzed 58 quality-controlled baseline samples and 54 7-week samples. Fifteen distinct clusters were identified after clustering B cell populations using UMAP and re-clustering using PHATE. Two of these clusters showed significant differences in both multivariate logistic regression and Mann-Whitney U tests. TOX patients had significantly lower baseline naive B cell counts than NT patients ($p=0.016$), suggesting naïve B cells as a predictive marker for toxicity. A significant increase in late memory B cells at week 7 was a key pharmacodynamic marker ($p=0.003$).
Conclusion: Our findings suggest that naive B cells could serve as a toxicity biomarker in combination therapy with ipilimumab, nivolumab, and tocilizumab. Late memory B cells emerged as a promising pharmacodynamic biomarker. Immunological monitoring may help elucidate the mechanisms of irAEs and predict irAE occurrence.

#5923 Human dose-escalation study of CD8$^+$T-cell infiltration in solid malignancies with^{68}Ga-NODAGA-SNA006 by PET imaging.

Y. Wang[1], M. Zheng[1], J. Zhao[1], C. Wang[2], C. Wei[2], S. Zhao[1], Y. Bian[1], N. Dai[1], Y. Zheng[1], S. sang[1], L. Guo[1], C. Huang[1], H. Zhang[1], J. Jiang[1], C. Xu[1], Q. Zhao[1], J. Han[1], T. Xu[2], S. Qin[1], L. Miao[1];

[1]First Affiliated Hospital of Soochow University, Suzhou, China, [2]SmartNuclide Biotech, Suzhou, China

Purpose: A noninvasive method for evaluating the infiltration of CD8$^+$ T cells in tumors is urgently needed for monitoring the response to immunotherapy. This study (NCT05126927) investigated the performance of a ^{68}Ga-NODAGA-SNA006 by positron emission tomography (PET) imaging of CD8$^+$ T cells in patients with solid malignancies.

Methods: This human dose-escalation PET imaging study included nine patients (lung cancer, 7; gastric carcinoma, 1; esophageal carcinoma, 1). Approximately 150 MBq of ^{68}Ga-NODAGA-SNA006 with varying nanobody masses (100 μg, 300 μg, 500 μg, 800 μg) was administered, and PET/computed tomography (CT) scans were performed at 15-30 min, 60-90 min, and 120 min postinjection (*p.i.*). Data regarding biodistribution, pharmacokinetics and radiation dosimetry were evaluated. CD8$^+$ T-cell infiltration in biopsy samples was also measured by IHC staining for correlation analysis with tumor uptake of ^{68}Ga-NODAGA-SNA006 PET.

Results: ^{68}Ga-NODAGA-SNA006 was well tolerated by all nine subjects. The highest radioactive uptake was observed in the spleen, with SUVmax ranging from 60.77 ± 25.05, 66.78±5.64, 70.36±20.94, 56.17 ± 4.69 at 60 min for 100 μg, 300 μg, 500 μg, and 800 μg, respectively, followed by the kidneys and bladder. The SUVmax of kidneys are from 9.20 ± 1.85 to 18.54 ±2.36 for 100 μg to 800 μg. However, the uptake of ^{68}Ga-NODAGA-SNA006 in bladder varied dramatically, depending on the excretion status of patients. Liver uptake decreased with increasing dose of nanobody, maximal (SUVmax: 14.07 ± 2.88) with low nanobody masses (100 μg) and significantly reduced (SUVmax: 6.64 ± 1.30) with high nanobody masses (800 μg). Rapid clearance ($t_{1/2}$<30 min) of ^{68}Ga-NODAGA-SNA006 from whole blood and serum was observed. Furthermore, the uptake of ^{68}Ga-NODAGA-SNA006 in tumors (SUVmean) exhibited a linear relationship with the CD8$^+$ T-cell infiltration in biopsy samples (R^2=0.757, p=0.011), suggesting that the tumor uptake of ^{68}Ga-NODAGA-SNA006 may represent the degree of CD8$^+$ T-cell infiltration in the tumor.

Conclusion: The use of ^{68}Ga-NODAGA-SNA006 is safe, feasible, and well tolerated. ^{68}Ga-NONAGA-SNA006 PET imaging can accurately detect CD8$^+$ T cells with favorable pharmacokinetics, thus providing a feasible method for the noninvasive quantitative assessment of CD8$^+$ T-cell infiltration and monitoring of response to immunotherapy.

#5924 A Tumor-specific, methylation-based algorithm to identify *MTAP* gene deletions via tissue-free circulating tumor DNA.

Sean Gordon, Evan Warner, Geethika Yalamanchili, Jill Tsai, Scott Shell, Shile Zhang, Martina Lefterova, Justin Odegaard, Darya Chudova

Guardant Health, Palo Alto, CA

Background: Methylthioadenosine phosphorylase (MTAP) is a tumor suppressor involved in the methionine salvage cycle. The *MTAP* gene is adjacent to the tumor suppressor *CDKN2A* on the chromosomal locus, 9p21.3. In ~15% of all cancers, the locus 9p21.3 is deleted, and *MTAP* is co-deleted with homozygous loss of *CDKN2A* in >80% of cases. Clinical trials investigating PRMT5 and MAT2A inhibitors have demonstrated potential for inducing synthetic lethality in *MTAP*-deleted tumors. Thus, the characterization of *MTAP* deletion in solid tumors is necessary to identify eligible patients. However, robust detection of biallelic gene deletion in liquid biopsies requires high levels of tumor shedding. Here we show performance of a methylation-informed *MTAP* deletion classifier able to resolve copy loss down to 1% tumor fraction.

Methods: We performed genomic and epigenomic profiling across samples from three distinct pan-cancer cohorts with the Guardant Infinity platform: 1. Discovery cohort of 14,895 minimal-residual disease (MRD) plasma samples from patients after curative-intent treatment for early-stage tumors to identify tumor-specific methylation at the 9p21 locus 2. Discovery cohort of 23,143 plasma samples from late-stage tumors to identify which candidate biomarkers were informative as to *MTAP* status, and 3. Independent validation cohort of ~14,000 plasma samples from late-stage tumors to confirm the association of candidate biomarkers to *MTAP* status. Quantification of tumor-specific DNA was done using an analytically validated methylation-based methodology, and we obtained synchronous mutation, copy-number, and genome-wide methylation data from all samples.

Results: We identified 6 genes within 1MB of the *MTAP* locus (*CDKN2A, CDKN2A-DT, CDKN2B-AS1, DMRTA1*, *MIR31HG*, and *HACD4*) that demonstrated cancer-specific promoter hypermethylation in our MRD discovery cohort. In our late-stage cancer cohort, we observed that hypermethylation of all 6 candidate biomarkers was mutually exclusive with *MTAP* homozygous deletion relative to distal sites. A logistic regression model utilizing methylation of the *MTAP* proximal sites along with distal site hypermethylation was trained on a subcohort of 297 samples balanced for *MTAP* deletion status and tumor fraction. On the independent multicancer validation cohort, the AUC of the *MTAP* predictive model was 0.91. Incorporation of methylation signals increased *MTAP* homdel detection in liquid by 1.3-fold to several fold depending on sample tumor fraction.

Conclusion: We have developed a novel method for improving the sensitivity of *MTAP* biallelic deletion detection in liquid biopsies using tumor-specific methylation. These findings offer biological insight into the relationship between localized deletion and methylation patterns and provide a framework to improve deletion calling in other genes with critical roles in tumor biology.

#5925 Circulating cell-free methylated tumor DNA measurements correlate with plasma VAF-based tumor fraction estimates.

Lee Davis McDaniel, Joseph Schull, David Tsao

BillionToOne, Menlo Park, CA

Introduction: Cell-free DNA (cfDNA) consists of circulating tumor DNA (ctDNA) and DNA shed by non-tumor cells such as immune and endothelial cells. Tumor fraction (TF) is the proportion of ctDNA present in cfDNA. TF is often estimated by summary statistics on somatic variants such as the mean or maximum variant allele fraction (VAF). The Northstar Response (NSR) assay quantifies ctDNA by accurately and precisely counting methylated cfDNA molecules across over 500 loci uniquely methylated in tumor tissue but not in any non-cancerous cells. We hypothesize that the NSR quantification of plasma methylated DNA, via the Tumor Methylation Score (TMS), correlates with tumor fraction as estimated by VAF.

Methods: A pan-cancer cohort of 271 longitudinal blood samples across 74 patients was gathered and run on the Northstar Select (NSS), an 84-gene liquid biopsy panel for somatic variant detection, and NSR assays. Samples were required to have positive detection in both assays to ensure precise TF measurements (max(VAF)>0.01%, TMS>25 methylated molecules). Tumor fractions were estimated by removing germline variants and evaluating the max(VAF) and sum(VAF), with the latter measurement paralleling the summation of methylated molecules used by the TMS. Due to the high variability of tumor mutational burden (TMB) and tumor methylation levels between tumors, correlations between VAF and TMS were calculated on a per-patient basis for patients with at least 3 longitudinal samples.

Results: TMS ranged from 25 to 253k molecules with a mean of 16k; sum(VAF) ranged from 0.06 to 782 with a mean of 67; max(VAF) ranged from 0.06% to 100% with a mean of 34%. TMS correlated most strongly with sum(VAF) with mean(R^2)=0.77, median(R^2)=0.96, whereas for max(VAF), mean(R^2)=0.67, median(R^2)=0.91. A linear regression model between max(VAF) and TMS demonstrated a mean increase of 1.3k methylated molecules per unit percent increase in max(VAF).

Conclusions: Previous studies have demonstrated that VAF decreases are prognostic to targeted therapy response including immune checkpoint blockade and tyrosine kinase inhibitors. However, VAF-based tumor burden measurements are limited by the paucity of somatic variants. In contrast, aberrant DNA methylation is a well-known hallmark of cancer that is an abundant source of ctDNA. The strong, linear correlation between TMS and VAF shown here suggests that TMS is an effective measure of ctDNA burden and can similarly be used to monitor response to therapy. Furthermore, the large amount of methylated DNA in patient samples (mean=16k molecules) suggests that epigenetic approaches can be highly sensitive even at very low tumor fraction (<1%).

#5926 Determining classical-basal transcriptional subtypes of pancreatic ductal adenocarcinoma using circulating tumor DNA epigenomic profiling.

Karl Semaan[1], **Marc Eid**[1], Damien Vasseur[1], Gunsagar S. Gulati[1], Ji-Heui Seo[1], Alexander Jordan[1], Andressa Dias Costa[1], John Canniff[1], Leigh Culnane[1], Elizabeth Andrews[1], Emma C. Coleman[1], Noa Phillips[1], Brad Fortunato[1], Hunter Savignano[1], Rashad Nawfal[1], Razane El Hajj Chehade[1], Talal El Zarif[2], Ze Zhang[1], Paulo Cordeiro[1], Antoine Hollebecque[3], Antoine Italiano[3], Brandon M. [1]Dana-Farber Cancer Institute, Boston, MA,[2]Yale School of Medicine, New Haven, CT,[3]Gustave Roussy, Villejuif, France,[4]Brigham and Women's Hospital, Boston, MA,[5]Emory University, Atlanta, GA

Introduction: Classical (C) and basal (B) transcriptional subtypes are key prognostic biomarkers of pancreatic ductal adenocarcinoma (PDAC). The B subtype is associated with higher rates of metastases, chemoresistance and poor outcomes. Early data suggest that the B subtype may predict response to KRAS inhibition. Current subtyping methods rely on tissue biopsies, which may not capture subtype heterogeneity, and are difficult to implement clinically. Here, we report a novel non-invasive approach for PDAC subtyping based on profiling circulating tumor chromatin.

Methods: RNA-seq, chromatin immunoprecipitation and sequencing (ChIP-seq) for H3K27ac and H3K4me3, assay for transposase-accessible chromatin sequencing (ATAC-seq), and methylated DNA immunoprecipitation sequencing (MeDIP-seq) were performed on PDAC patient derived xenografts (PDX, n = 17). C and B subtypes were called using PURIST algorithm on RNA-seq. Differential features between C and B PDXs for each epigenetic mark were identified using DESeq2. H3K27ac and H3K4me3 ChIP-seq, MeDIP-seq and low pass whole genome sequencing (LPWGS) were then performed on plasma of patients with metastatic PDAC from two clinical cohorts where C and B subtypes were previously determined. Circulating tumor DNA (ctDNA) fraction was estimated from LPWGS data using ichorCNA. A C/B score was derived for each epigenetic feature in individual patients by calculating the ratio of aggregate signal at classical:basal regions. Finally, a plasma integrated epigenomic score (PIES) was developed by combining various epigenetic features and its ability to distinguish subtypes was assessed using the area under the receiver operating characteristic (AUROC) curve.

Results: Overall, 17 PDAC PDXs (C = 13, B = 4) were profiled with ChIP-seq (H3K27Ac, H3K4me3), ATAC-seq and MeDIP-seq. We identified 7,855 differential H3K27ac sites that were also differentially accessible by ATAC-seq, 1,603 differential H3K4me3 sites and 308 differentially methylated regions between the 2 subtypes. We then profiled 53 plasma samples from patients with metastatic PDAC who had previously undergone tissue-based RNA analysis (C = 33, B = 20). The median ctDNA fraction was comparable between the two subtypes (3.1 vs. 3.3%; p=0.4). The H3K27ac and H3K4me3 C/B scores were significantly higher in plasma from patients with classical PDAC ($p<0.001$) compared to basal PDAC. The methylation signature did not distinguish the two subtypes (p=0.2). PIES showed high discriminatory power between classical and basal samples, with an area under the curve (AUC) of 0.84 for all samples regardless of ctDNA fraction and an AUC of 0.88 for samples with >3% ctDNA.

Conclusion: We present a non-invasive approach for distinguishing classical versus basal PDAC based on circulating tumor epigenomic profiles, which could facilitate subtyping to guide clinical decision making.

#5927 Assessing the impact of improved pre-analytic tissue handling on immunohistochemistry and breast cancer subtypes in Ghana.

Patrick Akakpo[1], Sylvester Antwi[2], Kwabena Agbedinu[3], Emmanuel G. Imbeah[1], Foster Amponsah[4], Veneranda Nyarko[5], Harriet Larrious-Lartey[2], Samuel Mensah[6], Josephine Nsaful[5], Valerie Ofori Aboah[2], Moses Dokurugu[7], Michael Nortey[1], Mohammed Sheriff[7], Nelson Affram[8], Jessica Bensenhaver[2], Haythem Ali[2], Ghassan Allo[2], Eleanor Walker[2], Evelyn M. Jiagge[2]

[1]Cape Coast Teaching Hospital, Cape Coast, Ghana,[2]Henry Ford Health System, Detroit, MI,[3]Komfo Anokye Teaching Hospital, Kumasi, Ghana,[4]Eastern Regional Hospital, Koforidua, Ghana,[5]Korle Bu Teaching Hospital, Accra, Ghana,[6]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,[7]Tamale Teaching Hospital, Tamale, Ghana,[8]Ho Teaching Hospital, Ho, Ghana

Background: The prevalence of triple negative breast cancer (TNBC) in sub-Saharan Africa has been inconsistently reported, with some studies in Ghana citing rates as high as 80%. The discrepancies in TNBC prevalence have been partly attributed to poor tissue handling during the pre- analytic phase, and the lack of 10% neutral buffered formalin for proper fixation. With a higher proportion of TNBCs being reported, many women are not candidates for targeted therapy. This study evaluates the impact of improved pre-analytic tissue handling on the diagnostic outcome of 4000 breast biopsies in Ghana, focusing on molecular subtypes, including TNBC

Methods: A multi-center approach was employed by Precision Medicine for Aggressive Breast Cancer (PMABC) across Ghana to refine pre-analytic tissue handling. Interventions included: (1) training providers on core needle biopsy techniques and supplying them with biopsy needles, (2) providing and training centers on the preparation and use of 10% neutral buffered formalin and (3) conducting workshops and hands-on training on proper tissue handling. Histopathology and immunohistochemistry were performed on 4000 cases at a partner pathology center (Pathologists without Borders) using Ventana BenchMark GX and CAP reporting protocols

Results: Among the 4000 cases analyzed, the mean age was 52.77 +/- 13.45 years (range: 14-101 years), with male breast cancer accounting for 1.6% of cases. Molecular subtype analysis revealed the following prevalence: Luminal A (12.1%) Luminal B (40.7%), HER2-enriched (12.6%), TNBC (29.7%). About 4.9% of cases which were classified as Other, comprised of HER2 equivocal. A comparative analysis of age group and molecular subtype revealed Luminal A is more predominant in the age group 50-69 years, Luminal B, HER2-enriched and TNBC are most prevalent in age group 40-59 year. TNBC was most prevalent in patients younger than 40 years, particularly those under 30. A statistically significant association was observed between age and molecular subtype ($p<0.001$).

Conclusion: The prevalence of TNBC in Ghana was revised to 29.7% (excluding HER equivocal cases) following improved tissue handling practices, contrasting with earlier inflated estimates. TNBC remains the most common subtype in younger patients, underscoring the need for tailored diagnostic and treatment strategies. Notably, molecular subtype varied significantly with age, showing a strong association between age group and subtype ($p<0.001$). This study highlights the importance of ensuring quality pre-analytic practices to ensure correct molecular sub-typing for accurate treatment stratification of breast cancer patients in sub-Saharan Africa to improve outcome.

#5928 Baseline serum protein analysis of patients with interstitial lung disease/pneumonitis (ILD) in 3 trastuzumab deruxtecan (T-DXd) trials: DESTINY-Breast01, DESTINY-Breast04, and DESTINY-Lung01.

Z. Tsuchihashi[1], K. Contrepois[2], K. Kubota[1], J. Zhao[1], X. Wang[1], V. Kumar[1], N. F. Blasco[3], B. Jakubison[4], S. Terrillon[2], Y. Cheng[1], T. Kaji[5], M. Nakamura[5], C. A. Powell[6], E. F. Smit[7], S. Modi[8], P. Newham[9];

[1]Daiichi Sankyo, Inc, Basking Ridge, NJ, [2]AstraZeneca, South San Francisco, CA, [3]AstraZeneca, Barcelona, Spain, [4]AstraZeneca, Gaithersburg, MD, [5]Daiichi Sankyo, Tokyo, Japan, [6]Mount Sinai National Jewish Health Respiratory Institute, New York, NY, [7]Leiden University Medical Center, Leiden, Netherlands, [8]Memorial Sloan Kettering Cancer Center, New York, NY, [9]AstraZeneca, Cambridge, United Kingdom

Background: The mechanism of T-DXd-related ILD remains unknown. Understanding the pathophysiology of drug-induced ILD and identifying biomarkers for patients (pts) at higher risk of T-DXd-related ILD is crucial. Krebs von den Lungen-6 (KL-6) has been analyzed as a biomarker for ILD, but its relevance to T-DXd-related ILD is undetermined. This exploratory analysis aimed to identify candidate ILD risk biomarkers via proteomic analysis and evaluate KL-6 levels in serum samples from pts in 3 T-DXd studies.
Methods: Baseline serum samples were collected from 189 pts in 3 T-DXd clinical trials: DESTINY-Breast01 (DB-01; n = 56; NCT03248492), DESTINY-Breast04 (DB-04; n = 78; NCT03734029), and DESTINY-Lung01 (DL-01; n = 55; NCT03505710). Pts were divided into 3 groups: 94 non-ILD controls, matched 1:1 based on patient characteristics, and 95 pts who later developed ILD, further categorized by worst adjudicated grade (G): G1/2 ILD (n = 74) and G3-5 ILD (n = 21). Available baseline serum samples were analyzed using the SomaScan™ proteomics platform. Baseline and longitudinal serum KL-6 levels were measured by ELISA.
Results: From ~6000 analytes tested, elevated baseline serum interleukin 1 receptor-like 1 (ST2) levels were observed in pts with incident G3-5 ILD in all 3 studies. In DL-01, median levels of baseline ST2 relative fluorescence units (RFU; IQR [Q1-Q3]) in non-ILD pts were comparable to G1/2 ILD cases (n = 27, 3838 RFU [2873-4910] vs n = 20, 4374 RFU [3417-5122]), in contrast, the median baseline ST2 level in G3-5 ILD cases was elevated (n = 8, 8512 RFU [6824-23494]). Elevation of median baseline ST2 levels in G3-5 ILD cases was also observed in DB-01 (n = 6, 7707 RFU [6503-19035]) and DB-04 (n = 7, 5973 RFU [3972-14682]). In DB-01, the median baseline ST2 levels were 3816 RFU (n = 28, [2757-4712]) in non-ILD patients and 3529 RFU (n = 22, [2742-4695]) in G1/2 ILD cases. In DB-04, the median baseline ST2 levels were 4420 RFU (n = 39, [3051-6002]) in non-ILD patients and 4140 RFU (n = 32, [2714-5758]) in G1/2 ILD cases. Baseline KL-6 levels were elevated in G3-5 ILD cases in DB-01. This elevation was not observed in DB-04 or DL-01. Longitudinal sample analysis showed that KL-6 levels decreased with T-DXd treatment, mirroring the reduction in tumor burden observed after treatment.
Conclusions: Proteomics analysis revealed elevated baseline serum ST2 levels as a potential baseline marker for T-DXd-related G3-5 ILD in lung and breast cancer. Luminex™ analysis is ongoing to quantify ST2 levels. The utility of KL-6 as a biomarker for T-DXd-related ILD appears to be limited. KL-6 levels decreased after T-DXd treatment, likely due to tumor shrinkage and reduction of tumor-derived KL-6. Given the limited number of clinical studies included and few G3-5 ILD events, the suitability of these candidate biomarkers needs further investigation.

#5929 High performance miRNA and mRNA signatures that in combination with serum PSA levels predict prostate cancer patients with lymph-node invasion.

Matias A. Bustos[1], Kelly K. Chong[1], Yoko Koh[1], SooMin Kim[2], Eleanor Ziarnik[2], Romela I. Ramos[1], Gianna Jimenez[3], David L. Krasne[4], Warren A. Allen[4], Timothy G. Wilson[3], Dave S. B. Hoon[1]

[1]Dept. Translational Molecular Medicine, Providence Saint John's Health Center, Santa Monica, CA,[2]Dept. Genome Sequencing Center, Providence Saint John's Health Center, Santa Monica, CA,[3]Dept. Urology and Urologic Oncology, Providence Saint John's Health Center, Santa Monica, CA,[4]Dept. Surgical Pathology, Providence Saint John's Health Center, Santa Monica, CA

Background: Nomograms or comparable techniques can be used to determine patients with primary prostate cancer (PCa) which are more likely to have lymph node metastasis (LNM) and will benefit from extended pelvic lymph node dissection (ePLND). However, ~80% of PCa patients undergo unnecessary ePLND, and PCa patients suffer from post-surgical morbid complications. This study aimed to identify both whole transcriptomic mRNA and microRNA (miR) signatures in primary PCa tumors that are associated with the development of regional draining LNM.
Methods: Primary PCa obtained from 88 patients [pN0 (n = 44) and pN1 (n = 44)] were profiled using the same tissue section by two different probe-based captured direct Next-Generation Sequencing assays targeting 19,398 human mRNA transcripts and 2,083 human miRs, respectively. Bioinformatic analyses and publicly available TCGA-PRAD [pN0 (n = 382) and pN1 (n = 70)] and GSE220095 [pN0 (n = 138) and pN1 (n = 17)] databases were used for verification and validation.
Results: A four-mRNA signature (*CHRNA2*, *NPR3*, *VGLL3*, and *PAH*) was commonly found in primary tumor tissue samples from PCa patients who had LNM. The results were validated using the TCGA-PRAD and GSE220095 datasets. The four-mRNA signature identified PCa patients with pN1 status [HTP dataset (AUC = 0.83, p = 1.54e-08), the TCGA-PRAD (AUC = 0.708, p = 2.4e-07), and the GSE220095 datasets (AUC = 0.83, p = 8.7e-06)]. Adding serum PSA values, to the four-gene signatures increased the performance to identify pN1 [mRNA dataset (AUC=0.8487 p=2.18e-09), the TCGA-PRAD (AUC=0.7150, p=8.66e-08), and the GSE220095 datasets (AUC=0.8772, p=4.09e-07)]. Paired miR analyses showed that eight miRs were significantly upregulated in primary PCa that were pN1 ($p < 0.01$). The eight-miR signature significantly identified pN1 patients [miR dataset (AUC=0.8568, p=9.86e-10)], and the performance increased with serum PSA [miR dataset (AUC=0.8626, p=4.66e-10)]. When combining the miR/mRNA signatures (miR-663b, *CHRNA2*, and *PAH*) with serum PSA levels showed the best performance to distinguish pN1 from pN0 patients.
Conclusions: This study found miR/mRNA signatures in primary PCa tumors that in combination with serum PSA levels may complement nomograms for better detection of PCa patients that develop LNM and triage patients into better surgical decision-making.

#5930 The Pancreas Tissue Bank (PCRFTB): Global facilitation of pancreatic research.

Hemant M. Kocher[1], Brian Davidson[2], John Isherwood[3], Stuart Robinson[4], Zahir Soonawalla[5], Lulu Tanno[6], Satyajit Bhattacharya[7], Bilal al-Sarireh[8], Somaiah Aroori[9], Rhiannon Roberts[1], Christine S. Hughes[1], Ahmet Imrali[1], Amina Saad[1], Trupti S. Kolvekar[1], Maryam Abollahyan[1], Dayem A. Z. Ullah[1], Claude Chelala[1]

[1]Cancer Research UK Barts Centre, London, United Kingdom,[2]University College London, London, United Kingdom,[3]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom,[4]Newcastle Hospitals NHS Foundation Trust, Newcastle, United Kingdom,[5]Oxford University Hospitals, Oxford, United Kingdom,[6]University Hospital Southampton, Southampton, United Kingdom,[7]The London Clinic, London, United Kingdom,[8]Swansea Bay University Health Board, Swansea, United Kingdom,[9]University Hospitals Plymouth NHS Trust, Plymouth, United Kingdom

Pancreatic cancer is one of the most devastating diseases. Worldwide, the disease claims >300,000 lives per year with the worst 5-year survival of all common cancers (<7%), with little improvement over the last 50 years. Even though pre-clinical work has led to greater understanding of the patho-physiology of the disease, research into human disease is hampered by lack of availability of well-annotated human samples. With this in mind, Pancreatic Cancer Research Fund Tissue Bank (PCRFTB) was set up as world's first national pancreas tissue bank. PCRFTB facilitated pancreatic research globally by providing access to clinically well-annotated samples collected according to standardised protocols and reliably stored. Informed consent is obtained from patients with suspected benign, pre-malignant and malignant pancreatico-biliary diseases, together with healthy controls to provide contemporaneous controls for case-control studies using blood and its components, urine, saliva in addition to matched fresh frozen and FFPE tissue diseased and healthy tissues. Comprehensive clinical data with 300 data-points per visit include medical history, medications, clinical test results (radiological, blood, tissue, mutational), histological findings, treatment and outcomes which are clinically verified. Since 2015, across nine tertiary referral Centres across England and Wales, we have obtained consent from over 3,700 donors and collected over 110,000 tissue, fluid and cell samples. Patient derived organoids and cancer-associated fibroblasts (CAFs) derived from various primary pancreas tumours using standardised protocols and with certification. The process of consenting, collection, storage and distribution of data and samples are performed, quality controlled and quality assured using over 100 standardised operating procedures in a custom-built Quality Management System (QMS) with additional audits, dashboards and governance to achieve highest quality, robust and reliable research from these valuable human samples. We are in the process of achieving ISO 20387 certification in early 2025.A multidisciplinary PCRFTB Tissue Access Committee (PCRFTB TAC) undertakes in-confidence, rapid-access peer review of applications for access of samples and / or data based on quality of the science, priority, power and supporting preliminary data. Thus far 108 expressions of interest has led to provision of samples and/or data to 50 research projects from commercial and academic institutions globally. Research impact emanating from PCRFTB samples data is enhanced by mandating experimental data return from researchers through the custom-built pancreatic cancer bio-informatics portal Pancreatic Expression Database (PED). PED also allows researchers to access, mine and investigate datasets, preventing duplication of investigation efforts and conserving sample resources.

#5931 Unraveling the genetic complexity of Ph-like ALL: development of a cost-effective diagnostic qPCR panel.

Anita Chopra, Jay Singh, Mercilena Benjamin, Avanish Pandey, Jayanth Kumar Palanichamy, Sameer Bakhshi, Deepam Pushpam, Akash Kumar Jha, Pranay Tanwar

All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Background: Advancements in high-throughput sequencing have significantly expanded our understanding of B-cell Acute Lymphoblastic Leukemia (B-ALL). In particular, whole-transcriptome sequencing (WTS) has facilitated the discovery of the Ph-like ALL subtype. However, clinical integration of WTS remains challenging due to high costs and lack of standardized workflows. Ph-like ALL is marked by genetic heterogeneity, including diverse fusions and mutations, which complicates its diagnosis and limits targeted therapeutic options. This genetic complexity correlates with poor prognosis, emphasizing the need for accessible and effective diagnostic approaches.
Aim: To develop a cost-effective, qPCR-based diagnostic panel for its detection and classification in clinical settings.
Methods: A cohort of 394 newly diagnosed B-ALL cases were analyzed using RT-PCR and FISH for initial genetic screening. WTS was employed for comprehensive fusion detection, mutation analysis, and subtype classification. Kaplan-Meier survival analysis was used to evaluate patient outcomes, and a qPCR-based likelihood scoring model was developed based on differential gene expression (DEGs) to identify Ph-like ALL.
Results: Whole transcriptome sequencing revealed that 13.1% of the B-ALL cases have Ph-like phenotype, found in different age groups: 9.7% in pediatric patients (n=15), 20.5% in adolescents and young adults (AYA, n=8), and 50% in adults (n=3). Ph-like ALL cases predominantly exhibited fusions involving JAK-STAT pathway genes (n=10), ABL-class genes (n=9), or NTRK1 (n=1), in addition to a novel RUNX1::FGF13 fusion (n=2). Differentially expressed genes were tested for diagnostic potential, with 9 genes (*FZH2, PON2, CA6, OLFML2A, BAALC, PRKCZ, ZFPM2, TCFL5* and *ENPP2*) demonstrating significant ROC ($p<0.0001$ and sensitivity and specificity >80%) curves in a discovery cohort (n=79). This likelihood model also effectively distinguished Ph-like ALL in a validation cohort (n=150). Additionally, survival analysis revealed significantly worse event-free survival (EFS) and overall survival (OS) in Ph-like ALL patients compared to non-Ph-like patients (EFS: 0% vs. 43.3%, HR 3.40, p=0.006; OS: 0% vs. 45.4%, HR 3.57, p=0.005).
Conclusion: This study underscores the genetic diversity of Ph-like ALL. The poor prognosis of Ph-like ALL, marked by significantly reduced EFS and OS, highlights the need for targeted therapeutic approaches. The cost-effective qPCR-based diagnostic panel provides a promising tool for the early detection of Ph-like ALL, offering potential for improved patient outcomes through timely intervention.

#5932 Molecular determinants of 10-second diagnosis of brain cancer types with laser mass spectrometry.

Alexa Fiorante[1], Michael Woolman[2], David Munoz[3], Lan Anna Ye[4], Taira Kiyota[4], Sunit Das[3], Ahmed Aman[5], Howard Ginsberg[3], Gelareh Zadeh[4], **Arash Zarrine-Afsar**[4]

[1]Medical Biophysics, Univerity of Toronto, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada,[3]Unity Health Toronto, Toronto, ON, Canada,[4]University Health Network, Toronto, ON, Canada,[5]Ontario Institute for Cancer Research, Toronto, ON, Canada

Surveys of neurosurgical outcome data have suggested suitable extents (aggressiveness) of resection to improve survival for many brain cancer types. Here, personalization of the extent of resection relies on highly subjective intraoperative diagnoses wherein the depth of the diagnostic information depends on the level of experience of the pathologist.
Picosecond InfraRed Laser Mass Spectrometry (PIRL-MS) uses picosecond bursts of mid- infrared laser radiation to extract, in a non-thermal manner, tissue lipids (1) present in cellular membranes, giving cells and nuclei their unique shapes (utilized in morphometric pathology with staining & microscopy) and (2) altered in tumorigenesis due to cross-talk with cellular signalling in metabolism (potentially also revealing cancer molecular subtypes in 10 seconds as shown) for real-time profiling of molecular content unique to each tumour type.
In our laboratory, close to 1,300 frozen brain cancer specimens over 30 different classes of adult and pediatric cancers are being subjected PIRL-MS to build a comprehensive molecular signature library using various supervised and unsupervised dimensionality reduction and data analysis methods. The sensitivity and specificity of the integrated morphometric and molecular diagnosis for pediatric brain cancers with 10-second PIRL-MS was > 96%. This classification could use as little as only 18 tissue lipids whose identities were determined using chromatography and tandem mass spectrometry. Greater than 90% sensitivity and specificity have been obtained for adult brain cancer classifications with 10-second PIRL-MS analysis utilizing 40 lipids spanning fatty acids, phospholipids and ceramides.
PIRL-MS can provide non-subjective differentiation between various brain cancer types with as little as 10 seconds of sampling and analysis time.

#5933 Improved identification of lung neuroendocrine neoplasms using INSM1 (SP493) Rabbit Monoclonal Primary Antibody.

K. Dvorak, R. Sainz, A. Gomez;
Roche, Tucson, AZ

Introduction: About 20% of lung cancers are of neuroendocrine origin. In addition to evaluation of morphological features, these neoplasms can be identified by immunohistochemistry (IHC) using neuroendocrine markers such as synaptophysin, chromogranin A and neural cell adhesion molecule, CD56. Recent studies showed that INSM1 is increasingly used as a diagnostic marker for cancers of neuroendocrine origin, since it is highly sensitive and specific. The primary focus of this study was to assess the sensitivity and specificity of a newly developed assay that is using a new INSM1 (SP493) antibody in detecting neuroendocrine lung cancers and to compare this IHC assay with currently used neuroendocrine markers.
Method: Tissue microarrays containing 292 lung tumors were stained with INSM1 (SP493) antibody, INSM1 (MRQ-70) antibody, CONFIRM anti-Synaptophysin (SP11) antibody, anti-Chromogranin A (LK2H10) antibody, and CD56 (MRQ-42) antibody on a BenchMark ULTRA instrument using OptiView DAB IHC Detection Kit or ultraView Universal DAB Detection Kit and sensitivity and specificity was calculated for each biomarker.
Results: The sensitivity and specificity of this new assay with INSM1 (SP493) antibody were 92.5% and 95.8%, respectively. Similar results were obtained for the lung cancer cases stained with INSM1 (MRQ-70) antibody; the specificity was 90.6% and sensitivity was 95.9%. In contrast, anti-Synaptophysin (SP11) antibody and anti-Chromogranin A (LK2H10) antibody demonstrated considerably lower sensitivity when used to stain these lung cancer cases. The sensitivity was 79.7% and 75.8% for anti-Synaptophysin (SP11) antibody and anti-Chromogranin A (LK2H10) antibody, respectively. The specificity of anti-Chromogranin A (LK2H10) antibody was comparable with the specificity of the INSM1 (SP493) antibody (97.5%); while the specificity of anti-Synaptophysin (SP11) antibody was lower (90.8%). The performance of CD56 (MRQ-42) antibody was suboptimal with the sensitivity of 86.2% and the specificity of 84.9%.
Conclusions: Overall, our data showed that the new IHC assay with INSM1 (SP493) antibody is highly specific and sensitive in detecting neuroendocrine lung tumors.

#5934 Functional biomarkers for bladder cancer.

Tianyu Yang, Karina Aguilar, Joshua van der Eerden, Vinata Lokeshwar

Augusta University, Augusta, GA

Introduction and Objective: Urine tests could offer a less invasive method for identifying bladder cancer, including in patients with hematuria and history of bladder cancer. We previously discovered a first-in-class human Chondroitinase (Chase) that degrades chondroitin sulfate. This Chase is a splice variant of HYAL4 (V1) and promotes a malignant phenotype and chemoresistance in BC cells. The Chase test quantifies enzyme activity by measuring the degradation of chondroitin sulfate using an ELISA-like assay. We evaluated the efficacy of the Chase urine test in identifying bladder cancer.
Methods: Test and validation cohorts came from three centers. The validation cohorts were prospective cohorts and assays were conducted in a blinded fashion. The cohorts included patients with microscopic and gross hematuria, benign genitourinary (BGU) conditions, history (HX) of BC or other genitourinary cancers (prostate and renal cell carcinoma). BGU cases included patients with BPH, cystitis, urinary tract infection, renal insufficiency, hematuria, urethral stricture, urolithiasis, and UPJ obstruction. V1 levels were measured by q-PCR and Chase activity by the Chase urine test.
Results: Chase levels were significantly elevated in both low- and high-grade tumors, correlating strongly with BC across three cohorts ($P<0.0001$; OR: 4.4; 95% CI: 3.3-5.9). The Chase test demonstrated high sensitivity in detecting BC, regardless of grade. Similarly, HYAL-4 (V1) transcript levels were elevated in urine exfoliated cells ($P<0.0001$; OR: 1.5; CI: 1.3-1.7), with 83% sensitivity and specificity, increasing to 86% sensitivity at a lower threshold (79% specificity). In comparison, FDA-approved BTA and NMP22 tests showed <60% efficacy. In cohort 2, Chase achieved 84% accuracy in cases with atypical cytology, while cytology alone had 67% sensitivity and 96.6% specificity. Urinary Chase and HYAL-4 mRNA levels were 4-5 times higher in patients with BC during surveillance than in those without recurrence ($P<0.0001$).
Conclusion: In test and validation cohorts Chase and V1 tests showed high sensitivity to detect BC and to monitor its recurrence. The Chase urine test is a less invasive alternative that could potentially reduce the need for cystoscopies for hematuria work-up and BC surveillance.

#5935 Analytical validation of a robust, integrated multiomics tissue assay powered by the Guardant Infinity platform.

Introduction: Next-generation sequencing (NGS) of tumor tissue is an integral technique to identify actionable alterations and inform oncology treatment. While established, tissue NGS is limited by variability in quantity and quality of both samples and test platforms, which limits its effectiveness. A robust workflow with high sample success rate, providing comprehensive molecular profiling, and fast turn-around time can improve this technology and support patient care. Here, we report the analytical validation of Guardant360 Tissue, a comprehensive molecular profiling test comprising DNA and RNA analysis of 950 genes and epigenomic methylation profiling powered by Guardant Infinity technology.
Methods: The analytical and clinical performance for DNA and RNA profiling was assessed using clinical FFPE samples and reference material at 50-100 ng inputs for DNA (N=556) and 25-50 ng inputs for RNA (N=282). Samples from over 10 common cancer types were analyzed, with tumor fractions as low as 5%, using as little as 6 slides (30 µm) of FFPE tissue as input.
Results: Guardant360 Tissue demonstrated high sample success rates detecting somatic alterations in >98% of DNA and >91% of RNA samples, including challenging specimen types like fine needle aspirates and core needle biopsies. Panel-wide limits of detection (LoD) were 1.8% MAF for SNVs, 1.5% MAF for indels, 0.4% MAF for DNA fusions, 3.5 copies for CNAs, 37.9% TF for gene deletions, 3.3% TF for microsatellite instability-high (MSI-H), 1.8% for promoter methylation, and 15.1 copies for RNA fusions and splice isoforms. Clinical samples demonstrated 100% sensitivity for SNVs (N=4149), indels (N=646), and MSI-H (N=19), and ≥95% sensitivity for CNAs (N=121), DNA rearrangements (N=34) and RNA fusions/splice isoforms (N=59) against FISH, ddPCR or multiple DNA/RNA/methylation based NGS platforms. High clinical specificity was also established at 100% for all guideline approved biomarkers and ≥99.99996% across the entire panel. Guardant360 Tissue TMB score demonstrated a strong linear correlation (R=0.95, Spearman method) and 94.2% categorical concordance (cutoff of 10 mut/Mb) with an orthogonal NGS panel.
Conclusions: Guardant360 Tissue offers a high success rate with minimal input, delivering competitive performance in detecting a wide range of actionable alterations. With a low limit of detection and excellent specificity, this assay achieves comprehensive molecular profiling using as little as 30 µm of FFPE tissue. Its robust capabilities not only enable precise clinical insights but also support the acceleration of novel biomarker discovery through a multiomics approach.

#5936 Landscape of epigenomic tumor fraction in large pan-cancer cfDNA cohort.

Introduction: Cell-free DNA (cfDNA) tumor fraction (TF) quantification is an emerging biomarker with many promising applications, including the potential to complement tumor size measurements from imaging. Genomic approaches for TF estimation are limited by the presence of cancer driver alterations, detection sensitivity, and may be confounded by non-tumor derived variants. Therefore, we have previously developed a method using differentially methylated regions to robustly estimate TF (Chen et al AACR 2023). Here we leverage a rich dataset of >50,000 cfDNA samples from >20 cancer types to better understand the variability of epigenomic signals in cancer and non-cancer individuals and inform an update of this TF estimation algorithm.

Methods: We employed a data-driven approach to update the TF algorithm leveraging a large cohort of cfDNA samples with simultaneous genomic and epigenomic profiling. This extensive dataset allowed for robust modeling of non-tumor variability in epigenetic profiles, and better calibration of tumor signals across diverse primary tissue sources shedding signals into plasma. The method update includes a data-informed region selection targeting high pan-cancer signal to noise, as well as more robust accounting for rare sources of non-tumor methylation signals including technical variation and treatment associated tissue damage.

Results: We evaluated the performance of epigenomic TF estimates using 1203 samples with somatic maximum MAF, establishing 88% concordance within 0.2-5X range. Next, samples were computationally titrated into non-tumor background samples, demonstrating consistent concordance with genomic data at up to 10-fold dilutions and maintenance of precision well below the resolution of genomic profiling, largely driven by algorithmic improvements in this updated release. Case studies of discordant samples show the benefit of TF over genomic quantification, especially in scenarios with an ambiguous genomic driver, or low genomic precision. In analytical validation studies of experimental titrations over replicates, linearity and quantitative precision of TF was demonstrated down to an order of ~0.01%, compared to >0.4% for genomic TF.

Conclusions: Our liquid only TF has been analytically validated for use in clinical, research, and trial settings in patients with solid tumors. In addition to its use for absolute quantification, it is incorporated into downstream applications including therapy response monitoring and algorithms for labeling germline variants, clonal hematopoiesis, and wild-type variant calling. Finally, its application in a clinical cohort of over 50,000 samples has led to insights into the dynamics of cfDNA tumor shedding across pre- and on- treatment individuals improving accuracy of quantification and providing results for more patients.

#5937 Development of a protein and clinical multiparametric biomarker panel for assessing pancreatic adenocarcinoma risk.

Detection of pancreatic adenocarcinoma represents a major burden on the healthcare system due to its latent detection, generally in the metastatic stage. To this end, we developed a prospective biomarker clinical trial to clinically and molecularly characterize at risk and confirmed pancreatic adenocarcinoma patients. This multicenter (n=6) clinical trial (NCT 02781012) of PDAC, referred to as Project Survival, combined high-fidelity longitudinal phenotypic characterization and multi-omic profiling to identify biomarkers with diagnostic and therapeutic utility. The study included collecting plasma, serum, buffy coat, urine, saliva, and tumor tissue samples and followed 140 non-cancer patients and 280 PDAC subjects for up to 7 years. Plasma samples were analyzed to identify circulating biomarkers using comprehensive proteomics profiling by LC MS/MS analysis. We first identify proteins that demonstrated a significant change between non-cancer (e. g., relatives with no signs of cancer, pancreatitis patients) and cancer patients. Then, top analytes were examined for impact from confounders (age, gender, BMI, and diabetes) using multivariate regression analysis. Four proteins were selected that demonstrated a robust signal with minimal impact from confounders. Next, multivariate logistic models were fit to distinguish cancer patients from non-cancer patients along with stratification across cancer staging to determine the predictive performance of the four-protein panel. Finally, an additional panel was developed that incorporated clinical features along with the protein panel to further improve predictive performance. We identified a distinct panel of four proteins that produced an optimal predictive diagnostic performance. The protein panel demonstrated ROC AUC of 0.77 for distinguishing cancer (n=273) from non-cancer (n=140) patients (PPV 0.76, NPV 0.70, OR 7.2), followed by ROC AUC of 0.70, 0.75, and 0.85 for distinguishing early stage (n=65), locally advanced (n=117), or metastatic (n=91) patients from non-cancer patients, respectively. Further, adding the four clinical features (Age, History of Pancreatitis, Family History of Cancer, and Weight Loss at Study Entry) further improved the ROC AUCs to 0.85, 0.79, 0.86, and 0.90 respectively. This prospective biomarker-driven clinical trial identified a distinct four-panel biomarker for Pancreatic Ductal Adenocarcinoma. The four proteins individually demonstrated a robust ability to distinguish cancer patients while controlling for confounding factors. The four-protein diagnostic panel showed superior ability to identify cancer patients and showed high predictive performance based on staging predictions. The panel is currently being explored for commercial development.
