#5941 Impact of neoadjuvant treatment on the presence of perineural invasion in rectal cancer: a national analysis.

Mohyeddine El Sayed[1], Sassine Youssef[2], Raymond N. Dubois[1]

[1]Hollings Cancer Center, The Medical University of South Carolina (MUSC), Charleston, SC,[2]Department of Biochemistry, The Medical University of South Carolina (MUSC), Charleston, SC

Background: Perineural invasion (PNI) is an independent prognostic factor associated with lower overall and disease-free survival in rectal cancer patients. Several studies have established nomograms predicting PNI presence using clinical data and radiomics. These nomograms will help guide treatment for patients with high risk for PNI. There is limited data on the impact of neoadjuvant therapy on the presence of PNI in pathological specimens. This study assesses whether neoadjuvant treatment reduces the odds of PNI at the time of surgical resection.
Methods: A retrospective analysis was conducted using the National Cancer Database, including patients aged ≥20 years diagnosed with rectal cancer from 2004 to 2020, with documented tumor stage and PNI status. Data collected encompassed demographics, tumor size and grade, TNM stage, and treatment sequences. Patients were categorized based on treatment sequence: surgical resection only (SRT), neoadjuvant treatment (NAT), adjuvant treatment (AT), and perioperative systemic therapy with neoadjuvant radiotherapy (PST/NART). Multivariable binary logistic regression analyzed the impact of neoadjuvant therapy on PNI presence, adjusting for significant covariates. Overall survival was assessed using multivariable Cox proportional hazards regression, adjusting for significant covariates.
Results: Among 38,537 patients, 25.3% received SRT, 38.7% NAT, 11.4% AT, and 24.6% PST/NART. In stage I, patients who received neoadjuvant treatment (NAT + PST/NART) were 50% less likely to have PNI compared to those who did not (SRT + AT) ($P < 0.001$). Stage II, III, and IV patients were 47%, 47%, and 40% less likely to have PNI with neoadjuvant treatment, respectively (all $P < 0.001$). In stage I, NAT patients had a 39% higher mortality risk compared to SRT patients ($P < 0.001$). In stages II and III, PST/NART patients had 38% and 34% lower mortality risks, respectively, compared to SRT patients ($P = 0.003$ and $P < 0.001$). In stage IV, AT patients had an 88% higher mortality risk compared to SRT patients ($P = 0.049$).
Conclusion: Neoadjuvant treatment significantly reduces the presence of perineural invasion across all stages of rectal cancer, potentially improving survival outcomes, particularly in stages II and III. However, the increased mortality risk observed in stage I patients receiving neoadjuvant therapy indicates that benefits may not extend to early-stage disease, underscoring the need for careful patient selection and further prospective studies.

#5942 Association of microsatellite instability status with pathologic complete response and tumor downstaging in locally advanced rectal cancer.

Mohyeddine El Sayed[1], Sassine Youssef[2], Raymond Dubois[1]

[1]Hollings Cancer Center, The Medical University of South Carolina (MUSC), Charleston, SC,[2]Department of Biochemistry, The Medical University of South Carolina (MUSC), Charleston, SC

Background: Two primary genomic instability pathways contribute to rectal carcinogenesis: microsatellite instability (MSI) and chromosomal instability, known as microsatellite stable (MSS). MSI rectal cancers generally have a better prognosis—attributed to enhanced immunogenicity, distinct molecular pathways, and reduced metastatic potential. This study assesses the impact of MSI status on pathologic complete response (pCR) and tumor downstaging after neoadjuvant treatment. We hypothesized that MSI rectal cancers are associated with higher odds of achieving pCR and tumor downstaging.

Methods: A retrospective analysis was performed using the National Cancer Database, including patients aged ≥20 years diagnosed with stage II-III rectal cancer between 2004 and 2020 with documented MSI status. All patients underwent surgical resection, chemotherapy, and radiotherapy. Collected data encompassed demographics, tumor size and grade, TN stage, lymphovascular invasion, perineural invasion, and immunotherapy. MSI status was categorized as MSS, MSI-low (MSI-L), and MSI-high (MSI-H). The primary outcome is pCR, defined as the absence of tumor in the pathological specimen (T0/x, N0/x). Tumor downstaging was assessed by comparing pathological T or N stage with clinical staging. Multivariable binary logistic regression analyzed the impact of MSI status on pCR and tumor downstaging, adjusting for significant covariates.

Results: Of the 5,124 patients included, 93.5% were MSS, 3.1% MSI-L, and 3.4% MSI-H. Immunotherapy was administered to 1.1% of MSS, 1.9% of MSI-L, and 3.5% of MSI-H patients. MSI tumors were less likely to achieve pCR compared to MSS tumors (OR = 0.62; $P = 0.023$). Specifically, MSI-L tumors had significantly lower odds of pCR (OR = 0.40; $P = 0.011$), whereas MSI-H tumors did not differ significantly from MSS tumors. For T downstaging, MSI tumors were less likely to have a reduced pathological T stage (OR = 0.72; $P = 0.009$). MSI-H tumors were associated with lower odds of T downstaging (OR = 0.69; $P = 0.027$), while MSI-L tumors showed no significant impact. Neither MSI-L nor MSI-H status significantly affected N downstaging.

Conclusion: Despite a better overall prognosis of MSI tumors, they are less likely to achieve pathologic complete response and T downstaging following neoadjuvant treatment. Additionally, MSI-L and MSI-H tumors exhibit distinct clinical outcomes in rectal cancer, indicating they should be considered separate entities in clinical management.

#5943 The impact of radiotherapy on prognosis in microsatellite stable rectal cancer: A national analysis.

Mohyeddine El Sayed[1], Sassine Youssef[2], Raymond N. DuBois[1]

[1]Hollings Cancer Center, The Medical University of South Carolina (MUSC), Charleston, SC,[2]Department of Biochemistry, The Medical University of South Carolina (MUSC), Charleston, SC

Background: Approximately 80-85% of rectal cancer cases are microsatellite stable (MSS), indicating a functional mismatch repair (MMR) system. Rectal cancer patients with microsatellite instability (MSI) exhibit better survival rates, mainly due to enhanced treatment responses linked to high tumor mutational burden (TMB). Radiotherapy (RT) induces DNA damage, increasing TMB and immune recognition. We hypothesize that RT improves prognosis in MSS rectal cancer patients.
Methods: A retrospective study was conducted using the National Cancer Database (NCDB), including patients aged ≥20 years diagnosed with MSS rectal cancer between 2004 and 2020 with documented tumor stages. All patients underwent surgical resection, chemotherapy, and immunotherapy. Collected data encompassed demographics, tumor grade, TNM stage, KRAS mutation status, lymphovascular invasion, and perineural invasion. RT was categorized into short-course RT (SC-RT; 25 Gy) and long-course RT (LC-RT; 45-54 Gy). The impact of RT on overall survival was assessed using multivariable Cox proportional hazards regression, adjusting for variables significant in univariate analysis.
Results: Of the 460 patients included, 70.9% received RT, while 29.1% did not. RT recipients demonstrated a 40% reduction in mortality risk compared to non-recipients ($P = 0.001$). Specifically, SC-RT and LC-RT were associated with 39% ($P = 0.042$) and 40% ($P = 0.002$) lower mortality risks, respectively. In stage II-III patients, LC-RT significantly reduced mortality risk (HR: 0.26, $P < 0.001$), whereas SC-RT showed no significant impact. In stage IV patients, neither SC-RT nor LC-RT significantly affected prognosis.
Conclusion: Radiotherapy is associated with improved prognosis in MSS rectal cancer patients, particularly with long-course RT in stages II-III. These findings advocate for clinical trials to further evaluate the role of RT in MSS rectal cancers.

#5944 Trend and treatment pattern of vulvar cancer in a single academic hospital in South Africa.

Adekunle Emmanuel Sajo[1], Edwin Mnisi[1], Cathy Visser[1], Sheynaz Bassa[2], Greta Dreyer[1]

[1]Obstetrics and Gynaecology, University of Pretoria, City of Tshwane, South Africa,[2]Radiation Oncology, University of Pretoria, City of Tshwane, South Africa

The incidence of vulvar cancer is increasing among younger women mainly to the coinfection of HIV and HPV infections which drive majority of cases in sub-Saharan Africa. We aimed to describe the trend and treatment patterns of vulvar cancer at the Steve Biko Academic Hospital, South Africa. This was a retrospective cross-sectional study between 1st January 2012 and 31st December 2022. Data were extracted from the participants' medical records on the demographics, medical history, histologic characteristic and treatment. We analyzed 317 vulvar cancer cases. The mean age was 45±12 yrs. Of the patients, 40% were younger than 40yrs. More than 77% (248) were living with HIV (WLHIV) with a mean CD4 count of 481.8 cell/µL. Of the WLHIV, 82% were virally suppressed. 64% of cases presented in advanced stage (stages III & IV). During the study period, the average age decreased from 56yrs to 40yrs in a linear fashion, p 0.012 while the number of cases rose exponentially. There was a steady decline of cervical cancer cases during the study period in contrast to the rising vulvar cancer. When the study period was halved, the mean age was significantly lower in the later half, 46yys vs 44yrs, p 0.001. Among the cases, the proportion of women with HIV increased steadily from 20% in 2012 to highest proportion of 98% in 2021, p 0.001. 70% of those who had surgery (152) had radical vulvectomy with nodal dissection. Of the total who had radiotherapy (114), only 47% had curative radiotherapy. The mean radiotherapy (RT)completion time was 48 days. 16% (51) of the total patient did not receive any treatment due to ill-health or failure to present for RT. Table 1 shows the comparison of our study with a previous study from the institution (Mnisi et al 2019). Vulvar cancer has transitioned to be a disease of the young. HIV is a major risk factor for vulvar cancer in our environment. Adequate surveillance of the genital area and screening of at risk group might help to stem the tide.

Comparison with previous study from the University of Pretoria

	Mnisi et al 2019	Current study
Study period	2001-2013	2012-2022
Institution	Data from 2 hospitals	single institutional data
Average age	43yrs	45yrs
Proportion of HIV	43.7%	78%
Disease stage	35.9% were advanced	64% were advanced
Proportion of HIV positive below 40yrs	29.6%	98%
Tumour size >4cm	88.8%	78%
Positive nodes	36.7%	35.8%
Total number of cases	134	317
Treatment	40% had surgery	48% had surgery

#5945 Cancer care in rural America: factors associated with acute care utilization following chemotherapy at a community cancer center.

McKenna Deaton[1], Crystal Hattum[1], Sam Gaster[1], Samantha Olson[2], Sheena Lewis[1], Katherine Rehfeld[1], Christina Early[1], Lacey Roberts[1], Maren Ernst[1], Cynthia Kannenberg[1], Mary Hughes[1], Julia Althoff[2], Jamie Arens[1], Tobias Meissner[1]

[1]Avera Cancer Institute, Sioux Falls, SD,[2]Avera Health, Sioux Falls, SD

Background Acute care use (ACU) events, including emergency department visits and hospitalizations following chemotherapy, are costly and often preventable with outpatient interventions. The Centers for Medicare & Medicaid Services track ACU within 30 days of outpatient chemotherapy through the OP-35 measure. While predictive models exist to identify at-risk patients, few have been validated on diverse populations. We aimed to quantify the differences between those who experience ACU and those who do not. Patients and Methods In a retrospective study of 5,575 patients receiving chemotherapy between October 2021 and May 2024, we assessed ACU within 180 days of any chemotherapy visit using institutional records and claims data. Of these, 3,230 patients (57.9%) experienced an ACU event, with a median of 75 days between chemotherapy and ACU. Among those with an ACU event, 2,491 patients (77.1%) experienced an event within 30 days of chemotherapy, 509 (15.8%) within 90 days, and 230 (7.1%) by 180 days. Results Demographics and comorbidities differed significantly between groups. Patients with ACU events were older (66 vs. 64; $p < .0001$), more likely to be former smokers (38% vs. 33%; $p < .0001$) or alcohol users (14% vs. 9%; $p < .0001$), less likely to live rurally (28% vs. 31%; $p = .003$), more likely to use Medicare (59% vs 53%; $p <.0001$), and more likely to be mobility impaired (38% vs 17%; $p <.0001$). These patients were also more likely to have multiple primary tumors (40% vs. 23%; $p < .0001$) and had higher weighted Charlson Comorbidity Index scores (4.52 vs. 3.19; $p < .0001$). There were notable differences between groups in terms of prior hospital utilization. Patients with ACU had a greater number of previous inpatient admissions (7 vs. 4; $p < .0001$) and spent more days hospitalized per admission (4.7 vs. 3.8 days; $p < .0001$). There was also variation in laboratory markers. Patients with ACU events exhibited lower pre-chemotherapy albumin levels (3.83 vs. 4.03 g/dL; $p < .0001$) and higher neutrophil-to-lymphocyte ratios (3.16 vs. 2.79; $p < .0001$), suggestive of greater inflammation. A LASSO logistic regression model was applied to predict ACU within 30-day and 180-day windows, achieving prediction accuracies of 69% and 72%, respectively (AUC: 0.76 and 0.79). Conclusions These findings show various factors are associated with increased risk of ACU, which is essential for determining which patients may benefit most from proactive outpatient support to reduce ACU rates, drive patient satisfaction, and lower costs. This work will be applied prospectively to triage patients at highest risk. Additionally, future work will focus on distinguishing preventable from non-preventable ACU events.

#5946 Five-year real-world survival outcomes of patients with advanced non-small cell lung cancer receiving first-line immunotherapy-based regimens.

David Waterhouse[1], Amanda Shawky[2], Aanal Desai[2], Keith A. Betts[3], Manasvi Sundar[3], Reginald Villacorta[2], David Stenehjem[4]

[1]OHC (Oncology Hematology Care) / Sarah Cannon Research Institute, Cincinatti, OH,[2]Bristol Myers Squibb, Lawrenceville, NJ,[3]Analysis Group, Los Angeles, CA,[4]Department of Pharmacy Practice and Pharmaceutical Sciences, University of Minnesota, Minneapolis, MN

Background: Five-year real-world outcomes of first-line (1L) immunotherapy (IO)-based regimens for advanced non-small cell lung cancer (aNSCLC) were assessed to describe how real-world outcomes correspond to those in clinical trials.

Methods: Adult patients (pts) with aNSCLC from Flatiron Health database receiving 1L IO monotherapy or single-agent IO + chemotherapy from Jan 1, 2016 to Jun 30, 2024 were identified. Pts were excluded if they had *EGFR/ALK* mutations or unknown histology type. Overall survival (OS) and real-world progression-free survival (rwPFS) of each 1L treatment were described using Kaplan-Meier analyses.

Results: A total of 17,070 pts with aNSCLC were included (6,039 pts receiving IO monotherapy; 11,031 pts receiving IO + chemotherapy). Among pts receiving IO monotherapy, the 1-, 2-, 3-, 4-, and 5-year OS rates were 52.7%, 36.4%, 27.3%, 21.6%, and 17.5% and the rwPFS rates were 29.5%, 18.0%, 13.2%, 10.0%, and 7.8% respectively. Among pts receiving IO + chemotherapy, the 1-, 2-, 3-, 4-, and 5-year OS rates were 51.0%, 32.9%, 24.0%, 19.4%, and 15.8% and the rwPFS rates were 27.6%, 15.6%, 10.6%, 8.3%, and 6.9%, respectively. Table 1 presents the 5-year OS and rwPFS rates stratified by histology type, tumor programmed death ligand 1 (PD-L1) expression level, and Eastern Cooperative Oncology Group (ECOG) performance status. Pts with lower PD-L1 expression level (<1%), worse ECOG performance status (≥2), and squamous cell carcinoma had worse survival outcomes, regardless of the type of 1L treatment.

Conclusions: Five-year real-world survival rates for pts with aNSCLC treated with 1L IO-based regimens were lower than those observed in pivotal trials, indicating an unmet need for the management of newly-diagnosed aNSCLC. New strategies are needed to treat aNSCLC. This gap is especially pronounced in pts with squamous histology or PD-L1 <1% emphasizing the need for new treatment strategies for these high-risk groups.

Table 1: 5-year OS and rwPFS rates

	1L IO monotherapy			1L IO+chemotherapy		
	PD-L1<1% N=426	PD-L1 1-49% N=1,040	PD-L1≥50%N=3,861	PD-L1<1% N=3,399	PD-L1 1-49% N=3,265	PD-L1≥50%N=1,939
OS (5-year rate, %)	14.2	11.2	20.0	11.2	15.0	25.2

#5947 Efficacy and safety of lorlatinib in first-line and later-line treatment for Chinese patients: a real-world study with retrospective and prospective bidirectional cohorts.

Jiayu Liu, Xin Zhang, Puyuan Xing, Junling Li

Cancer Institute & Hospital.Chinese Academy of Medical Sciences, Beijing, China

Background: Lung cancer is the leading cause of cancer-related deaths worldwide. Lorlatinib, a third-generation ALK inhibitor, is an important treatment for ALK-positive NSCLC. Hyperlipidemia is a common side effect, but its mechanism is not well understood. This study evaluates the efficacy and safety of lorlatinib in the Chinese population and explores the mechanisms of hyperlipidemia.
Method: This study included ALK-positive advanced NSCLC patients treated with lorlatinib between February 2020 and September 2024 at the Cancer Hospital of the Chinese Academy of Medical Sciences. Patients received lorlatinib either as first-line or later-line therapy. Data collected covered demographics, treatment efficacy (ORR, DCR), and survival outcomes using the Kaplan-Meier method. Safety analyses, focusing on hyperlipidemia, were performed with Fisher's exact test.
Result: This study included 63 ALK-positive advanced NSCLC patients, with 26 on first-line and 37 on later-line lorlatinib treatment. Most patients were female (55.6%), nonsmokers (66.7%), and had an ECOG score of 0-1 (98.4%). The median age was 57, and adenocarcinoma was the predominant type (87.3%). The median follow-up was 9.86 months. For first-line patients, the ORR was 85.7%, DCR was 100%, and the 12-month PFS rate was 94.4%, with median PFS not yet reached. For later-line patients, the ORR was 26.7%, DCR was 86.7%, and the 12-month PFS rate was 60.3%, with median PFS also not reached. Among 28 patients with baseline brain metastases (6 on first-line and 22 on later-line therapy), the intracranial ORR was 41.7%, DCR was 100%, and the median intracranial PFS was 30.59 months. The study found that all patients experienced hypercholesterolemia, with most also developing hypertriglyceridemia. Common side effects included peripheral edema, CNS effects, hypertension, weight gain, neuropathy, and joint pain. One patient discontinued lorlatinib due to grade III proteinuria. Patients without brain metastases had milder hypercholesterolemia, while severe hypercholesterolemia was more common in those with brain metastases (37.04% vs. 12.50%, P=0.03). Lipid metabolism testing in 12 patients (5 with brain metastases) showed no significant differences in enzyme levels between patients with and without brain metastases. However, patients on lipid-lowering therapy (n=9) had significantly improved LPL activity compared to untreated patients (n=3) (t=2.69, P=0.038), confirming the effectiveness of lipid-lowering therapy.
Conclusion: Lorlatinib shows strong efficacy for ALK-positive advanced NSCLC, with median PFS not yet reached in both first-line and later-line settings. Hyperlipidemia was common, especially in patients with brain metastases, and lipid-lowering therapy improved LPL activity. Further research into lipid metabolism mechanisms is underway.

#5948 Sequencing of antibody drug conjugates (ADCs) in metastatic breast cancer: A real-world analysis.

Dhairya Gor[1], Maria Jamil[2], Sunita Ghosh[2], Vrushali Dabak[1]

[1]Henry Ford Cancer Institute, Detroit, MI,[2]Henry Ford Hospital, Detroit, MI

Background- Hormone Receptor-Positive/HER2-low (HR+/HER2-low) and Triple Negative Breast Cancer (TNBC) represent distinct subtypes of breast cancer with varying treatment approaches and clinical outcomes. Trastuzumab Deruxtecan (T-Dxd) and Sacituzumab Govitecan (SG), the two ADCs, have emerged as promising therapeutic options for both subtypes. However, there is a lack of real-world data comparing the effectiveness of these agents in different treatment sequences. This retrospective study aims to compare the sequencing of T-Dxd and SG in HR+/ HER2-low and TNBC patients at Henry Ford Cancer Institute(HFCI), with a primary focus on median progression-free survival (mPFS).

Methods -The electronic medical records of patients at HFCI from January 2020 to August 2024 were searched to identify patients diagnosed with metastatic HR+/HER2-low and TNBC who had received both SG and T-Dxd. Patients with incomplete medical records were excluded. Based on the tumor type and sequencing of treatment, patients were divided into four groups: 1) HR+/HER2-low who received T-Dxd followed by SG, 2) HR+/HER2-low who received SG followed by T-Dxd, 3) TNBC who received SG followed by T-Dxd, and 4) TNBC who received T-Dxd followed by SG. The mPFS, median overall survival (mOS), overall response rate (ORR), and disease control rate (DCR) for each of these four groups were plotted using the Kaplan-Meier Method.

Results- A total of 33 patients were initially identified. Of these, 14 patients were HR+/HER2 low (median OS = 18 months, 95% CI 13.737 - 22.263), 14 were TNBC (median OS was 17 months, 95% CI 12.16 - 21.84), and 5 were excluded. Amongst Group 1 patients (n=12), mPFS after receiving T-Dxd was 7.09 months, mOS was 18.07 months, ORR was 33%, and DCR was 75%. On progression, they received SG with mPFS of 3.08 months, mOS of 5.61 months, and DCR of 40%. Amongst Group 2 patients (n=2), mPFS after receiving SG was 1.15 months, and mPFS after receiving sequential T-Dxd was 2.07 months. Amongst Group 3 patients (n=11), the mPFS after receiving SG was 5.06 months, mOS was 15.08 months, ORR was 22.2%, and DCR was 66.7%. Those who progressed and received T-Dxd had an mPFS of 2.16 months, an mOS of 6.3 months, and a DCR of 22.2%. Amongst Group 4 patients (n=3), mPFS after receiving T-Dxd was 7.95 months, mOS was 17.97 months, ORR was 33.3% and DCR was 100%. Those who progressed and received SG had mPFS of 3.08 months, mOS of 5.61 months, and DCR of 40%.

Conclusion- Our retrospective study presents real-world data on the effect of sequencing the ADCs. The overall benefit observed is lesser when a second ADC is used after the first ADC. Contrary to common practice, using T-Dxd followed by SG sequencing, regardless of receptor status, appears more effective in our patient population than the reverse. Further studies analyzing the sequencing of ADCs prospectively with larger cohort populations and identifying biomarkers to aid patient selection can be conducted.

#5950 Assessment of response and overall survival (OS) for various systemic therapies in *ERBB2*-altered advanced urothelial carcinoma (aUC).

J. B. Leary[1], **T. L. Enright**[1], D. Bakaloudi[1], R. Talukder[2], M. T. Schweizer[1], J. E. Hawley[1], B. Montgomery[1], E. Y. Yu[1], A. C. Hsieh[1], T. A. Yezefski[1], P. Grivas[1], A. Khaki[3], R. Raychaudhuri[1]; [1]University of Washington, Seattle, WA, [2]Baylor College of Medicine, Houston, TX, [3]Stanford University, Stanford, CA

Background: A subset of aUCs harbor *ERBB2* alterations. While anti-HER2 therapies in HER2-over-expressing aUC have been promising, relationships between *ERBB2* alterations and response to other systemic therapies are unclear. Based on available data, we hypothesized that *ERBB2*-altered aUC would respond less favorably to immune checkpoint inhibitor (ICI), enfortumab vedotin (EV), and sacituzumab govitecan (SG) than *ERBB2*-wildtype aUC.

Methods: This single-center retrospective study included patients (pts) diagnosed with aUC between 5/6/2016 and 9/23/2022 who underwent panel-based somatic tumor sequencing (120 tissue-based, 9 ctDNA) and received ICI, EV, or SG in first line (1L) or as salvage (2L+). Pts were grouped as *ERBB2*alt aUC, including tumors harboring *ERBB2* amplification (n=13) and/or *ERBB2* mutation (n=9), and *ERBB2*-wildtype(wt) aUC (n=107). Observed response rate (ORR) and OS measured from each therapy start were evaluated. Kaplan-Meier method was used to calculate OS curves. Log-rank and Fisher's exact tests were used to compare OS and ORR between groups, respectively.

Results: 129 pts were evaluable for *ERBB2* status; 22 (17%) were *ERBB2*alt. Baseline characteristics including age, sex, prior extirpative surgery rate, ECOG performance status, proportion of pts with liver metastases, and presence of *de novo* metastasis were similar between groups. One pt with *ERBB2*alt aUC received 1L EV; none received 1L SG. Results are shown in Table 1.

Conclusions: In pts receiving 2L+ ICI, significantly higher ORR and longer OS were noted in pts with *ERBB2*alt vs *ERBB2*wt aUC, contrary to our hypothesis; *ERBB2*alt was also associated with higher ORR to 2L+ EV. Limitations include retrospective design, limited sample size and power for subsets, lack of randomization, selection/confounding biases, and lack of HER2 protein IHC assessment. Results are hypothesis-generating and need external validation.

Table 1. ORR and OS analyses by group

		N	ORR %	OR (95%CI)	p	mOS, months(95%CI)	HR(95%CI)	p
1L ICI	*ERBB2alt*	10	40.0% (4/10)	1.50 (0.37 - 6.05)	0.714	30.0 (7.6 - NR)	0.64 (0.27 - 1.52)	0.3
	ERBB2wt	52	30.8% (16/52)			14.0 (8.5 - 29)		
2L+ ICI	*ERBB2alt*	7	57.1% (4/7)	7.40 (1.27 - 44.00)	0.034	29.2 (4.1 - NR)	0.34 (0.12 - 0.98)	0.046
	ERBB2wt	33	15.2% (5/33)			7.2 (4.1 - 19.8)		
2L+ EV	*ERBB2alt*	9	56.0% (5/9)	6.75 (1.33 - 34.27)	0.026	20.0 (6.9 - NR)	0.66 (0.26 - 1.66)	0.4
	ERBB2wt	32	15.6% (5/32)			11.0 (8.7 - 27.4)		
2L+ SG	*ERBB2alt*	5	40.0% (2/5)	4.44 (0.52 - 38.61)	0.210	38.0 (10.4 - NR)	0.33 (0.07 - 1.54)	0.2
	ERBB2wt	23	13.0% (3/23)			10.4 (6.7 - 25.1)		

#5951 Comparison of abdominal CT alone versus combined chest and abdominal CT on recurrence detection and mortality following gastrectomy for gastric cancer.

Chi Hoon Maeng[1], Yeonjin Kim[2], Hyun Ae Jung[3], Moon Ki Choi[4], Jung Yong Hong[3], Bo-Hyung Kim[5], Woojoo Lee[2]

[1]Hematology-Medical oncology, Kyung Hee University Hospital, Seoul, Korea, Republic of,[2]Public Health Science, Graduate School of Public Health, Seoul National University, Seoul, Korea, Republic of,[3]Hematology-Oncology, Samsung Medical Center, Seoul, Korea, Republic of,[4]Medical oncology, National Cancer Center, Ilsan, Korea, Republic of,[5]Clinical Pharmacology and Therapeutics, Kyung Hee University Hospital, Seoul, Korea, Republic of

Introduction
Recurrence patterns after gastrectomy for gastric cancer are diverse, with intraperitoneal recurrences being common and extraperitoneal also occurring. The optimal surveillance strategy remains unclear. This study examines the clinical significance of follow-up with abdominal CT (computed tomography) alone versus combined chest and abdominal CT.
Methods
We analyzed data on surgery and follow-up CT scans for patients who underwent curative gastrectomy for gastric cancer between 2014 and 2018. The data were sourced from the Cancer Public Library Database, a nationwide public registry established under the Korean Clinical Data Utilization for Research Excellence Project (K-CURE). This newly launched registry is dedicated to research, providing comprehensive clinical data, including information on cancer diagnosis, surgery, summary staging, medications, diagnostic tests, comorbidities, and mortality. Patients were categorized into two groups based on surveillance CT patterns: those followed with abdominal CT alone (Group AA) and those with combined chest and abdominal CT (Group CA). Recurrence detection and all-cause mortality were compared between the groups. Considering variations in CT usage patterns over time, a time-varying Cox model was applied for group comparisons. The analysis was adjusted for key clinical factors, including age, sex, summary stage, co-morbidities, and hospital location.
Results
Of the initial 69,090 patients, 50,813 were analyzed after excluding those with multiple primary cancers, missing, or unclear data. Among them, 44,488 were in Group AA and 6,325 in Group CA. Crude recurrence detection rate was higher in Group CA (13.17%, n=833) compared to Group AA (7.57%, n=3,368), and crude all-cause mortality was also higher in Group CA (21.47%, n=1,358) than Group AA (11.49%, n=5,110). Time-varying Cox regression analysis showed a significantly higher recurrence detection rate in Group CA (HR 1.21, 95% CI 1.12-1.30). Additionally, among patients with recurrence, Group CA was associated with a significantly lower mortality (HR 0.80, 95% CI 0.73-0.87) compared to Group AA. Subgroup analysis revealed higher recurrence detection rates in Group CA across all stages, with a significantly reduction in mortality among locally advanced-stage patients.
Conclusions
This study demonstrated that combined chest and abdominal CT surveillance, compared to abdominal CT alone, improves recurrence detection regardless of stage and contributes to reduced mortality, particularly among patients with recurrent cancer at locally advanced stages. Prospective studies are warranted to establish an evidence-based surveillance strategy following gastrectomy.

#5952 Modulating treatment outcomes of patients with solid tumors in immunotherapy trials: a drug interaction analysis from a phase I unit.

Camila Braganca Xavier, Clark Andersen, JoAnn T. Lim, Julian H. Slade, Stacie A. Bean, Lei Kang, Hung Le, Apostolia Tsimberidou, Aung Naing, David Hong, Ecaterina Dumbrava, Jordi Rodon, Paula Pohlmann, Sarina Piha-Paul, Stephane Champiat, Timothy A. Yap, Tin-Yun Tang, Funda Meric-Bernstam, Siqing Fu

The University of Texas MD Anderson Cancer Center, Houston, TX

The concurrent use of medications can either compromise or enhance treatment (Tx) outcomes in patients with solid tumors (pts) receiving immunotherapy compounds (IO) including monoclonal antibodies (Abs), fusion proteins (FP), immune modulators (IM), oncolytic viruses (OV) and vaccines (VAC). To assess the impact of concurrent medications on Tx outcomes, we conducted a retrospective analysis of pts enrolled in early IO clinical trials at the Department of Investigational Cancer Therapeutics (ICT) at MD Anderson Cancer Center between June 2014 and June 2024. A computerized data extraction tool was used to collect clinical data and identify the prescription of a predefined set of drugs within 30 days of the experimental IO infusion. Primary endpoints were median overall survival (mOS) and median progression-free survival (mPFS), defined as the time from first Tx cycle to death/last follow up or disease progression/death from any cause, respectively. Tumor responses were assessed according to RECIST; disease control rate (DCR) was defined as the proportion of pts achieving partial response (PR) or stable disease (SD) as the best response. Uni and multivariate analysis were performed to correlate variables and outcomes. A total of 827 pts were included (49.3% female, 50.7% male), with the median age of 58 years (range 20-85). The majority of pts (72.9%) were White/Caucasian. The most common tumor types were colorectal (24.5%), head/neck (10.5%) and pancreatic (9.4%), and 85.7% of pts had >2 metastatic sites. The most commonly used therapies were Abs and FP (64.7%) and IM (20.8%), followed by IM + Abs combination (9.2%), OV and VAC (5.3%). The median time from the first appointment to death was 9.26 mo (range 0.85-112). mOS was 6.14 mo (range 0.16-103) and mPFS 2.07 mo (range 0-37.8). Of 744 pts with evaluable response data, the DCR was 38.7%. For IM + Abs, SD and PR were 24% and 6% without antihistamines (AH) and 52% and 15.8% with AH (X2 8.48; p = 0.014). Univariate analyses identified higher body mass index (BMI) and cancer type (immune responsive *versus* immune insusceptible) associated with improved OS while low albumin level, presence of cancer pain, and use of steroids, proton pump inhibitors (PPI), antibiotics (ATB), anti-depressants, anti-emetics, anticoagulant and narcotics were related to worse OS ($p < 0.05$). Multivariate analysis adjusted for BMI, cancer type, albumin level and response to Tx revealed that AH were associated with improved OS (HR 0.752 [0.603,0.938], p = 0.012) while steroids (HR 1.413 [1.101,1.814], p = 0.007), PPI (HR 1.318 [1.02,1.703], p = 0.035) and ATB (HR 1.542 [1.222,1.947], $p < 0.001$) were related to worse OS. In conclusion, concurrent use of medications must be carefully evaluated as part of clinical trial protocols for experimental IO. Optimizing the management of drug prescriptions could improve patient outcomes and enhance the efficacy of experimental Tx.

#5954 Real-world (RW) second-line (2L) treatment (tx) patterns and clinical outcomes in patients (pts) with HER2-overexpressing biliary tract cancer (BTC).

Richard Kim[1], Xiaozhou Fan[2], Javier Sabater[3], Wayne Su[2], Kathleen Hurwitz[4], Kayla Hendrickson[4], Catherine Wiener[4], Phillip Garfin[5], Joan Zape[2], Mark A. Ozog[5], John Bridgewater[6], Juan W. Valle[7], **Farshid Dayyani**[8]

[1]Moffitt Cancer Center, Tampa, FL,[2]Jazz Pharmaceuticals, Philadelphia, PA,[3]Jazz Pharmaceuticals, Oxford, United Kingdom,[4]Target RWE, Durham, NC,[5]Jazz Pharmaceuticals, Palo Alto, CA,[6]UCL Cancer Institute, London, United Kingdom,[7]Cholangiocarcinoma Foundation, Herriman, UT,[8]University of California Irvine Chao Family Comprehensive Cancer Center, Orange, CA

Background: HER2 has emerged as a target for precision therapies in BTC. We describe the RW tx patterns and overall survival (OS) of pts with advanced HER2-overexpressing BTC treated in the 2L.

Methods: This retrospective observational study used the Flatiron Health Electronic Health Record-derived, deidentified database (01/2011 to 12/2023). Pts with HER2-overexpressing (IHC 3+) BTC who received 2L tx ≥6 months (mo) of potential follow-up time were included in the OS analysis. Follow-up began at initiation of 2L tx (index) to the earliest of last recorded activity, death, or end of data. Concordance between HER2 overexpression and amplification was assessed in all pts, regardless of HER2 status, with available testing results from IHC, (F)ISH, and NGS .

Results: Among 29,817 pts with BTC, 36 pts were included in the OS analysis; median age was 67 (range: 49-83) years. 47% of pts received 2L HER2-targeted therapy including pertuzumab + trastuzumab (HP; n=7), trastuzumab + chemotherapy (n=6), trastuzumab deruxtecan (n=2), HP + chemo (n=1), and HP + anti-PD-(L)1 (n=1). Non-HER2-targeted therapies included chemo only (n =14), chemo + anti-PD-(L)1 (n=3), and non-HER2 tyrosine kinase inhibitors ± bevacizumab (n=2). Diabetes and chronic pulmonary disease were more frequent in pts who received non-HER2-targeted therapy (Table). Median OS was 9.9 (95%CI 5.5-29.4) mo overall (HER2-targeted : 13.2 mo; non-HER2-targeted : 8.5 mo; and chemo only: 5.6 mo). Median OS was 8.7 mo in pts with ECOG 0 or 1 (n=21). Among the 80 pts in the concordance analysis, 79% and 90% of pts with HER2 overexpression had HER2 amplification as detected by NGS and (F)ISH, respectively.

Conclusions: The OS of pts with HER2 overexpression in the RW who received chemo only was consistent with previously reported OS for chemo only in 2L BTC regardless of HER2 status. In pts with HER2-overexpressing BTC, HER2-targeted therapy showed a numerical improvement in OS vs. chemo only.

#5955 A decade of discovery: Unveiling the prevalence, patient characteristics and histopathologic features of early-onset prostate cancer at a West African tertiary institution.
P. O. Commey;
Korle Bu Teaching Hospital, Accra, Ghana

BACKGROUND: Prostate cancer is commonly regarded as a disease that affects older men, with the average age of diagnosis being 66 years. A notable rise has been seen among men aged 55 years and below (early onset). This demographic shift, particularly pronounced in Sub-Saharan Africa highlights the urgent need for targeted research. The study aimed to determine the prevalence and describe the patient characteristics and histopathologic features associated with prostate cancer in focusing on a demographic that has been relatively underrepresented in prostate cancer research.
DESIGN: A retrospective descriptive study was conducted to evaluate histologically confirmed cases of prostate cancer in men aged 55 years and below at the National Radiotherapy, Oncology, and Nuclear Medicine Centre at the Korle Bu Teaching Hospital in Accra. We used secondary data from medical records over 10 years (2013 to 2022). Data were analyzed using STATA 14.
RESULTS: There were 81 cases of prostate cancer in men aged 55 years and below, comprising 4.5% of all prostate cancers diagnosed over 10 years. The average age at diagnosis was 52 years, ranging from 38 to 55 years. Of these, 98.8% were adenocarcinomas, and 1.2% represented a spindle cell sarcoma. Regarding the Gleason scores, most patients (53.1%) had a primary Gleason grade of 3, followed by 32.1% with a grade of 4. A smaller proportion had grades 5 or 2, and 3.7% of records did not report the primary Gleason grade. The most common secondary Gleason grade was also 3, found in 53.1% of cases, followed by grade 4 in 33.3%. Fewer patients had secondary grades of 5 or 2, and 2.5% of records lacked this information. Grade group 1 accounted for the most frequent pattern, observed in 41.8% of the cases, followed by grade group 4 in 16.5% of cases. The rest of the grade groups, including 2, 3, and 5, were present less frequently. Out of the 81 patients, the majority (48.15%) had evidence of perineural invasion, while 41.98% did not. A small percentage of records (9.88%) did not state whether perineural invasion was present. Interestingly, there was evidence of metastasis in 23.5% of the patients. The most frequently involved metastatic sites were the thoracolumbar vertebrae (14.9%), femur (12.8%), pelvis (12.8%), and liver (8.5%).
CONCLUSION: Given the distinct clinical features and the relatively high prevalence of metastasis in this age group, further research is needed to better understand the underlying biology of early-onset prostate cancer and to devise tailored diagnostic and therapeutic regimen for this unique cohort.

#5956 Glioblastoma in Appalachia: A retrospective analysis.

Umer Rizwan, Gary Monroe, **Sonikpreet Aulakh**

West Virginia Univ. School of Medicine, Morgantown, WV

Introduction: Glioblastoma (GBM) is a fatal malignancy of the brain. It has been observed that patients in rural areas with GBM have worse overall survival. Higher morbidity and mortality in these rural areas have been attributed to lack of optimal access to clinical care and lack of participation in clinical trials. However, the projected number of cases and mortality risk related to GBM do not reflect the reality of Appalachian region. In this retrospective study, we reviewed the survival data of patients with GBM in Appalachia.

Methods: 169 (of 761) patients with grade 4 *IDH* WT GBM from 1/16/2019 through 7/1/2024 were selected for this retrospective study. Patient data, including demographics, insurance status, comorbidities, tumor location, diagnosis date, treatment regimens, treatment start dates, progression dates, *MGMT* methylation status, genetic mutations, and date of mortality, were extracted from electronic medical records and stored in RedCap in a HIPAA compliant manner. De-identified data was exported, organized and processed using Microsoft Excel Version 2409. Progression-free survival (PFS) and overall survival (OS) were calculated using standard Excel functions. A Cox proportional hazards model was employed to estimate the hazard ratios and corresponding p-values.

Results: The median age of GBM diagnosis was 63.4 years. 91 patients were males and 78 were females. 164 patients were Non-Hispanic White. 96 patients with Medicaid, 53 had no insurance, and 11 had Medicare. The mean PFS was 22 months (mo) for the 1st line therapy (n=166), 12 mo for 2nd therapy (n=83), 10 mo for 3rd line therapy (n=28), and 16 mo for the targeted therapy (n=46). The mean OS was 22 mo for first-line therapy (n=61), 19 mo for first/second-line therapy (n=39), and 22 mo for 1st/2nd/targeted therapy (n=20). A significant association was found between RT-TMZ and increased mortality (95% CI 1.2-5.39, p=0.015) compared to RT-TMZ-surgery. In the 2nd line setting, no significant differences in PFS or OS were observed between bevacizumab+lomustine (n=7), bevacizumab+surgery (n=9), bevacizumab +temozolomide (n=8), and bevacizumab (n=41). In the 3rd line setting, a significant difference in PFS was observed between lomustine (95% CI 1.15-48.9, n=4) and bevacizumab (n=11), but not between bevacizumab and bevacizumab+lomustine (n=3). In the 2nd line targeted therapy setting, no significant differences in PFS or OS were observed between osimertinib (n=2), pembrolizumab (n=2), regorafenib (n=3), and abemaciclib (n=3). In the 3rd line targeted therapy setting, no significant differences in PFS or OS were observed between ipilimumab-nivolumab (n=3) and abemaciclib (n=2).

Conclusion: Our preliminary data suggests that mortality related to GBM in Appalachia follows the national trends. It is prudent to conduct rural-specific studies to understand the phenotypic, genotypic, and demographic characteristics.

#5957 A real-world study for cost-effectiveness analysis of nanoliposomal irinotecan in patients with pancreatic adenocarcinoma.

J. Chun[1], J. Lee[1], D. Jang[2], Y. Lee[3], J.-C. Lee[4], J.-H. Hwang[4], B.-G. Kim[1], S. Kim[1], G. Park[1], T. Kim[1], Y. Kim[1], S. Woo[1];
[1]National Cancer Center, Goyang-si, Korea, Republic of, [2]Seoul National University Boramae Medical Center, Seoul, Korea, Republic of, [3]Inje University Ilsan Paik Hospital, Goyang-si, Korea, Republic of, [4]Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of

Background: Systemic chemotherapy plays a crucial role in pancreatic adenocarcinoma (PAC), not only as palliative chemotherapy for unresectable PAC, but also as (neo-)adjuvant chemotherapy for (borderline) resectable PAC. Recently, nano-liposomal irinotecan plus 5-fluorouracil/leucovorin (nal-IRI/5-FU/LV) showed a survival benefit in the global phase 3 NAPOLI-1 trial. However, there is a paucity of studies that have evaluated the effectiveness and cost analysis of nal-IRI in the entire treatment course of PAC. Therefore, this study aimed to evaluate the effectiveness and cost of treatment according to exposure to nal-IRI in the management of PC using an electronic health record data.
Methods: We analyzed the effectiveness and cost according to the exposure of nal-IRI/5-FU/LV treatment during follow-up. Effectiveness was assessed by overall survival (OS) and direct medical costs including costs of imaging or laboratory tests, administration of chemotherapy, surgery, or radiotherapy, supportive care, management of adverse events during inpatient, outpatient, and emergency department were included in this study. Propensity score matching was used to adjust for potential differences in patient characteristics between nal-IRI group and non-liposomal irinotecan group. We defined the incremental cost-effectiveness ratio as the difference in mean total medical costs (per patient) divided by the difference in median OS between two groups.
Results: A total of 1,734 patients diagnosed with PAC were screened, and 705 patients who received at least one cycle of chemotherapy were included in the analysis. Median OS was significantly longer in the nal-IRI group compared to the non-liposomal irinotecan group (28.0 months vs. 18.3 months, P = 0.011). Patients in the nal-IRI group had more hospital visits and admissions during follow-up, the average total cost per patient was was higher in the nal-IRI group ($61,430 vs $39,129). The incremental cost-effectiveness ratio was $2,787 per month of median survival gained ($33,285 per life-year gained).
Conclusions: In this real-world retrospective study, patients treated with nal-IRI/5-FU/LV showed longer OS and the incremental cost-effectiveness ratio was acceptable given the poor prognosis of PAC.
Funding: This work was supported in part by Servier No. 2152460) and in part by the National Cancer Center, Korea (No. 2310280).

#5959 Outcomes of small HER2+ breast cancers including those with micro-metastatic lymph node involvement (SOLEMN HER2).

Uttamjot Kaur[1], Jacob M. Liberman[2], Ajay Dhakal[1]

[1]Department of Hematology and Oncology, University of Rochester Wilmot Cancer Institute, Rochester, NY,[2]University at Buffalo, Buffalo, NY

Background: HER2-positive breast cancer (HER2+BC) accounts for 15-20% of early-stage breast cancers and is treated based on tumor size and Stage. For locally advanced HER2+BC [Stage (AJCC 8th ed, Anatomic) II, III], patients typically receive 2-3 chemotherapy drugs plus two HER2-targeted monoclonal antibodies (HER2-MABs): trastuzumab (T) and pertuzumab (P) before surgery. Stage I cancers are treated differently. Stage IA tumors(≤2 cm, no lymph node involvement) usually receive one chemotherapy [paclitaxel (Tax)] plus T after surgery. However, it's unclear if chemotherapy is needed for a subset with very small tumors [T1a (≤5 mm), T1b (>5 - ≤10 mm)]. Stage IB cancers (≤2 cm tumor with micrometastases in axillary lymph node) may require more aggressive treatment. This study aims to describe various demographic, clinical, pathological characteristics, perioperative treatments, outcomes, including overall survival (OS) and invasive disease-free survival (IDFS) for patients with Stage IB (Cohort A) and very small (T1a/b) Stage IA (Cohort B) HER2+BC.
Methods: This is a single institution retrospective study conducted at URMC with IRB approval. It uses electronic medical records for data collection. Patients diagnosed with Stage IB or very small (T1a/b) Stage IA HER2+BC between January 2010 - June 2024 were included in the study. Patients who had received systemic therapy before surgery were excluded.
Results: Results from Cohort A are submitted in this abstract. Among seven patients included in the study, 43% had a pathological stage pT1a, 14% were pT1b and 43% were pT1c. Four patients received Tax+ T, one patient received Tax+T+P, one received two chemotherapies+T, and one received two chemotherapies+ T+P. There were no recurrence or death after a median follow-up of four years. Investigation into Stage IA cases (n= 91) is ongoing.
Conclusions: This small retrospective study suggests an excellent clinical outcome for Stage IB HER2+ breast cancer patients. A larger study is needed to validate this finding.

#5960 Outcomes of acute myeloid leukemia treated with a hypomethylating agent and venetoclax.

Markie Zimmer[1], Brigid Jacob[2], Mikayla Spica[1], Sunita Ghosh[3], Vrushali Dabak[1]

[1]Hematology/Oncology, Henry Ford Hospital, Detroit, MI,[2]Henry Ford Hospital, Detroit, MI,[3]Department of Public Health, Henry Ford Hospital, Detroit, MI

Introduction: VIALE-A confirmed the benefit of azacitidine (AZA) and venetoclax (VEN) compared to AZA alone in previously untreated patients with AML who were not eligible for intensive induction chemotherapy. Incorporation of this regimen into standard practice has varied across and within healthcare systems due to adjustments in regimen and supportive care use.
Methods: This was a retrospective, single institution analysis of adult patients greater than 18 years of age with AML, treatment related AML (t-AML) or MDS/AML treated with a hypomethylating agent (HMA) (azacitidine or decitabine) and VEN between January 2017 and January 2024. We sought to investigate overall survival (OS) and to explore the trends of regimen and prophylaxis dosing, the use of allogeneic stem cell transplant and outcomes of relapsed and refractory disease.
Results: Thirty patients received VEN and HMA between January 2017 and January 2024. The median age was 72 years. Ten patients were female and 20 were male. Twenty-four patients were Caucasian, 5 were African American and one patient's race was not recorded. Twenty-three patients were diagnosed with AML, 5 t-AML and 2 MDS/AML. Risk stratifying patients by ELN 2022 criteria, 5 (16.7%) were favorable, 6 (20%) were intermediate and 17 (56.7%) were adverse. Within the adverse risk group, 6 had mutated TP53. Patients completed a median of 3 cycles. The mean duration of VEN decreased throughout each cycle, from 21.60 days in cycle 1, to 15.38 in cycle 2, to 8.62 in cycle 3 and 8.10 in cycle 4. The median number of days between the starting of subsequent cycles generally increased (34.5 days from cycle 1 to cycle 2; 39 days from cycle 2 to cycle 3; 42 days from cycle 3 to cycle 4). Twenty-one patients received the treatment in the front-line setting, 7 as salvage therapy and 2 as salvage after allo-HSCT. Three patients proceeded to allo-HSCT a median of 179 days after initial diagnosis. Of all 30 patients, 9 (30%) were in remission, 20 (66.7%) had active disease and one patient's disease status was unknown at the time of data collection. Mean overall survival was 22.67 months (5.92-39.42, 95% CI, p=0.346). Caucasians had greater than 6 times OS than African Americans, (26.12 months, 10.42-41.82, 95% CI versus 4.44 months, 0-10.85, 95% CI, p=0.015). Frontline use of the regimen resulted in a numerically significant difference in OS compared to salvage use (22.67 versus 4.53 months, p=0.200).
Conclusions: In this retrospective analysis of VEN and HMA in patients with AML treated in an urban setting, we found that younger patients, Caucasians, favorable risk disease by ELN 2022 criteria and frontline use resulted in the highest OS. Overall, patients received decreasing number of days of VEN each cycle and had increasing number of days between cycles, suggesting significant treatment reduction and delays, however without compromise to overall survival.

#5961 MRI-based sternocleidomastoid muscle assessment as a predictive marker for sarcopenia and survival outcomes in nasopharyngeal carcinoma patients undergoing concurrent chemoradiotherapy.

Jeng-You Wu[1], Emily Chia-Yu Su[2]

[1]Graduate Institute of Biomedical Informatics, College of Medical Science and Technology, Taipei Medical University, Taipei, Taiwan,[2]Institute of Biomedical Informatics, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan

Purpose/Objective(s): Sarcopenia is strongly linked to poor survival outcomes and increased treatment-related toxicity in solid tumors. Both pre- and post-treatment muscle loss negatively impact prognosis, emphasizing the importance of muscle mass evaluation. This study investigates the sternocleidomastoid (SCM) muscle, an accessible target in head and neck examinations, as a predictive marker for survival outcomes in nasopharyngeal carcinoma (NPC). Using MRI-based assessment, this study aims to establish SCM's utility in prognosis prediction and improve patient management.

Materials/Methods: This multi-institutional study analyzed 976 NPC patients treated at three hospitals between 2002 and 2019. Among them, 504 newly diagnosed patients underwent concurrent chemoradiotherapy, and complete pre- and post-treatment MRI data were available for 286. SCM muscle analysis was conducted using post-contrast T1-weighted MRI at the third cervical vertebra (C3). Measurements included cross-sectional area (SCMA), long axis (SCML), and short axis (SCMS). Derived parameters included SCMAD (SCML + SCMS), SCMAA (SCML × SCMS), and SCMR (SCMS/SCML). Ratios of post/pre-treatment values were calculated to reflect muscle loss. Optimal cutoff points for sarcopenia-related parameters were determined, and predictors of overall survival (OS) were evaluated using Cox proportional hazards regression and Kaplan-Meier survival analysis to visualize OS differences among groups stratified by sarcopenia status.

Results: Among the 286 patients analyzed, 63% were male, and 51.2% were diagnosed between 40 and 60 years old. Advanced stages were common: 25.8% stage III and 40.7% stage IV. Over a median 4.7-year follow-up, 93 patients (31.8%) died. OS rates were 93.2% at one year and 68.9% at five years. Post/pre-treatment SCM parameters (SCMA, SCMS, SCMR) showed no statistically significant results. However, certain parameters approached significance: SCML (cutoff 0.75, $p = 0.1147$), SCMAD (cutoff 0.47, $p = 0.338$), and SCMAA (cutoff 0.26, $p = 0.328$), suggesting trends warranting further investigation.

Conclusion: BMI alone may inadequately reflect muscle loss, whereas SCM parameters measured via MRI offer a reliable method to assess sarcopenia and predict survival. Our findings indicate that SCM provides effective metrics for prognosis in NPC, but further studies with larger samples are needed to identify the most impactful predictive parameter and optimize its clinical utility.

#5962 A multicenter propensity score matched analysis of short and long term outcomes of octogenarian patients undergoing pancreaticoduodenectomy for extrahepatic cholangiocarcinoma.

Y. Choi, H.-S. Jo, D.-S. Kim, Y.-D. Yu;
Korea University, College of Medicine, Seoul, Korea, Republic of

Background: Elderly patients with cancer are at a crossroads to receive either invasive surgical resection or palliative treatment. Due to its invasive nature, surgeons are often reluctant to perform pancreaticoduodenectomy in patients with advanced age, especially octogenarian patients. However, due to enormous advancements in surgical technique and postoperative management, elderly patients with extrahepatic bile duct cancer should also be expected to receive survival benefits from pancreaticoduodenectomy. The aim of this study was to analyze the perioperative and oncological outcomes of pancreaticoduodenectomy for extrahepatic cholangiocarcinoma in octogenarian patients.

Method: A multicenter database (the Korea Tumor Registry System, KOTUS, 24 tertiary referral centered included) was used and patients over 70-years old who underwent pancreaticoduodenectomy for extrahepatic cholangiocarcinoma between 2000 and 2014 were included. They were divided into 2 groups: patients in their seventies (septuagenarians) and in their eighties (octogenarians). A comparative analysis between two groups was performed after the application of propensity score matching. Unadjusted Kaplan-Meier and marginal Cox regression analysis were performed.

Results: A total of 1327 patients were included in the study. After propensity score matching, 114 patients were comparable in each of the main groups. Also, the AJCC TNM (7th) stage (*P*=0.289) and R0 resection rate (*P*=0.061) revealed no significant difference. Postoperative complication rate (54% vs. 56%, *P*=0.329), postoperative mortality (2.7% vs. 1.0%, *P*=0.624), and 5Y-overall survival (58.5% vs. 58.3%, *P*=0.349) gave comparable results. On multivariate analysis, curative resection (HR=5.60, 95% CI=2.24-14.67, *P*<0.000) and lower N-stage (HR=2.19, 95% CI=1.34-3.59, *P*=0.002) were significantly associated with favorable overall survival, whereas age which was represented by the group variable (septuagenarians vs octogenarians) in this study, was not significantly associated (HR=1.01, 95% CI=0.623-1.638, P=0.968) with survival. Moreover, we found only the N-stage was significantly associated with disease-free survival (HR=2.35, 95% CI=1.463-3.776, P<0.000), but not age (HR=0.78, 95% CI=0.490-1.227, P=0.277).

Conclusion: There was no significant difference in postoperative complication and age was not a risk factor for poor overall or disease-free survival. Thus, pancreaticoduodenectomy may be safely performed in octogenarian patients with extrahepatic cholangiocarcinoma. Therefore, the octogenarians patient should not be deprived of the chance for curative resection for extrahepatic bile duct cancer solely because of age.

#5963 Pink to purple: Beyond traditional risk factors of female lung cancer.

Muhammad Rafiqul Islam, Mohammad Hasan Shahriar, Muhammad Ashique Haider Chowdhury, Siara Tasmin, Andrew Craver, Brisa Aschebrook-Kilfoy, Sreenivas Konda, Habibul Ahsan

Institute of Population and Precision health, University of Chicago, Chicago, IL

Background: The pink ribbon for breast cancer awareness is being overshadowed by purple, as lung cancer has become the leading cause of cancer deaths in women. While overall lung cancer rates are declining, younger women in high-income countries are being diagnosed more often than men, suggesting unique risk factors for women beyond smoking. The aim of this study was to identify the beyond-traditional risk factors for female lung cancer in a diverse population within the United States.
Methods: We conducted a nested age-matched case-control study within the All of Us Research cohort, analyzing 4,761 adult female participants (761 cases, 4,000 controls). Comprehensive phenotypic data, including demographic characteristics, reproductive history, and lifestyle behaviors, were extracted from electronic health records. Statistical analysis employed chi-square tests, multivariable logistic regression, and an Extended Gradient Boosting Classifier (XGBC) for risk prediction.
Results: Significant associations emerged between lung cancer risk and multiple factors. Age strongly predicts increased risk in females, with odds ratios rising from 5.14 (95% CI 3.22-8.19, $p<0.001$) in the 46-60-year group to 12.51 (95% CI 8.05-19.44, $p<0.001$) in the 61-95-year group. Smoking was a significant risk factor (adjusted OR: 2.54; 95% CI, 2.13-3.02; $p<0.001$), whereas Hispanic ethnicity (adjusted OR: 0.49; 95% CI, 0.32-0.73; $p<0.001$) compared to non-Hispanic white and high deprivation index (adjusted OR: 0.58; 95% CI, 0.47-0.71; $p<0.001$) had a protective role. Non-natural menopause consistently increased risk (adjusted OR: 1.36; 95% CI, 1.05-1.77; $p<0.01$). The XGBoost (XGBC) model achieved 84% accuracy in risk classification, identifying smoking, age, menopausal history, and deprivation index as primary predictive features compared to other machine learning models. The model revealed distinct risk patterns based on smoking status, age, and reproductive factors, with notable interactions between menopausal status among smokers.
Conclusions: This comprehensive analysis highlights the complex interplay between reproductive, sociodemographic, and lifestyle factors in female lung cancer risk. Our findings emphasize the need for personalized risk assessment strategies considering reproductive history alongside traditional risk factors. The successful implementation of machine learning approaches demonstrates the potential for developing more accurate risk prediction models for female lung cancer.

#5964 Real world efficacy and safety of anlotinib in solid tumors previously treated with immune checkpoint inhibitors.

Changzhen Shang, Xuan Luo, Jinyi Zhong, Yajin Chen

Department of Hepatobiliary Surgery, Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China

Backgrouds Immune checkpoint inhibitors (ICIs) resistance of solid tumors is common and subsequent treatment options offer limited clinical benefit. Anlotinib is a novel multitarget tyrosine kinase inhibitor (TKI) for tumor angiogenesis and proliferative signaling. Recent preclinical studies have suggested that anlotinib can reverse resistance to ICIs by modulating the immunosuppressive tumor microenvironment (TME). The current real-world study aimed to investigate the efficacy and safety of anlotinib for solid tumors in Chinese patients who have previously accepted ICIs alone or combined treatments.

Methods Data of patients diagnosed with solid tumors and previously accepted ICIs were collected retrospectively from six medical sites in China between Jan 2018 and May 2024. Patients were divided into two groups according to the subsequent treatments: anlotinib alone or combined therapy; other treatmental methods not including anti-angiogenic TKIs. Propensity score matching (PSM) based on age, gender, TNM staging, and lines of therapy was used. Progression-free survival (PFS) was estimated using the Kaplan-Meier method and compared using the log-rank test. Adverse Events were graded by CTCAE v4.03.

Results A total of 911 patients were enrolled, including 539 (59.2%) non-small cell lung cancer (NSCLC), 210 (23.1%) hepatocellular carcinoma, 65 (7.1%) esophageal cancer, 59 (6.5%) gastric cancer, 30 (3.3%) cervical cancer, and 8 (0.9%) endometrial cancer. The median age was 58.0 years (range 51.5-66.0), 74.6% were male, 63.6% were stage IV, and 63.9% had received only first-line treatment. In the total population, after 2:1 PSM, there were 431 and 216 patients in the anlotinib and other treatments group, respectively. The PFS was significantly longer in the anlotinib group than in other treatments group (median, 7.9 months vs 6.2 months; HR 0.79, 95% CI 0.62-1.00; P=0.039). The objective response rate (ORR) was 9.5% (41/431) with anlotinib and 11.6% (25/216) with other treatments. We further compared the outcomes of anlotinib combination therapy with other treatments, and results showed that after 2:1 PSM, the median PFS with anlotinib combination (n=404) was 7.9 months versus 6.1 months with other treatments (n=203) (HR 0.72, 95% CI 0.57-0.91; P=0.002). The ORR was 10.1% (41/404) with anlotinib combination and 11.8% (24/203) with other treatments. Of the 431 patients treated with anlotinib, the most common adverse events (≥5% of patients) were allergy (9.7%), gastrointestinal events (8.6%), bleeding (7.7%), and hand-foot syndrome (5.6%).

Conclusion Our study demonstrated the favorable anti-tumor activity and manageable toxicity of anlotinib treatment in solid tumors previously treated with ICIs, and anlotinib combination may provide more benefit. To our knowledge, this study represents the largest real-world clinical data of anlotinib therapy for solid tumors.

#5965 Brain tumor diagnostic interval and tumor size at detection: Impact on survival, recurrence, inpatient length of stay and neurological deficit.

J. M. Cameron[1], E. Gray[2], P. Brennan[3], M. Baker[1], P. Hall[3], A. Lishman[1], P. Karunaratne[3], G. Tramonti[3], M. Vallet[3];
[1]Dxcover Ltd., Glasgow, United Kingdom, [2]Independent Health Economics Consultant, Edinburgh, United Kingdom, [3]University of Edinburgh, Edinburgh, United Kingdom

Brain tumors commonly present in an emergency setting. However, the majority of brain tumor patients report one or more primary care visits in the preceding months. This suggests opportunities for earlier diagnosis. Early economic evaluation of a brain cancer liquid biopsy identified an evidence gap in quantifying the impact of earlier/later diagnosis on patient outcomes. The aim of this study is to estimate the association between two indicators of earlier/later diagnosis, tumor size and the length of diagnostic interval, and the patient outcomes of cancer-specific survival, overall survival, new or worsened neurological deficit, cancer recurrence and inpatient length of stay in 12 months following diagnosis.
A retrospective cohort study utilising a database of 1400 patients from Southeast Scotland, UK, diagnosed with brain tumors between 2010 and 2020. Diagnostic interval was defined as time from first presentation to radiological diagnosis. Tumor size was defined as the recorded maximum diameter at time of diagnosis. Hazard ratios for cancer-specific and overall mortality, per mm increase in tumor size or per day increase in diagnostic interval, were calculated. Odds ratios for new or worsened neurological deficit and for tumor recurrence were similarly calculated. Linear regression was used to estimate effects on total inpatient bed days. Regression was used for all outcomes to adjust estimates for possible confounding factors. Alternative diagnostic window definitions were explored in sensitivity analysis. Analysis was repeated stratified analysis by brain tumor subtype was used to explore generalisability across subtypes.
There were 1196 eligible patients that were included in the study. The mean tumor size was 40.6mm (SD: 17.5mm). Each 1mm increase in tumor size increases mortality risk by approximately 1%, increases the expected inpatient days by 0.15 days, and the risk of new or worsened neurological deficit by 2%. Diagnostic interval results (in preparation) will be presented at the meeting.
Based on previous estimates of brain tumor growth rates, a tumor with a 40mm diameter at diagnosis (mean diameter in this patient population) would be expected to be 28mm if diagnosed 1 month earlier. Applying the effect size estimates reported above would translate into clinically important differences in outcomes. This highlights the improvement in patient outcomes that could be expected if early intervention is made possible by new diagnostic tools.

#5967 Real-world outcomes of renal cell carcinoma and intracranial metastatic disease.

Madison Sherman[1], Karim Hafazalla[2], Arjun Sahgal[3], Georg Bjarnason[4], Sunit Das[5]

[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada,[2]Neurosurgery, Thomas Jefferson University, Philadelphia, PA,[3]Radiation Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[4]Medical Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[5]Neurosurgery, St. Michael's Hospital, Toronto, ON, Canada

Introduction: Intracranial metastatic disease (IMD) is a serious complication of renal cell carcinoma (RCC). However, large-scale data on its clinical characteristics, survival outcomes, and treatment strategies are limited, especially at the population level.
Objective: To examine the clinical features, survival outcomes, and treatment patterns of RCC patients with IMD in Ontario, Canada, and provide insights to optimize patient management.
Methods: This population-based retrospective cohort study included RCC patients diagnosed between 2010 and 2019 in Ontario. Demographics, treatments, and survival data were obtained from provincial healthcare records. Kaplan-Meier and Cox regression analyses assessed overall survival (OS). Propensity score matching (PSM) was used to compare survival outcomes between treatment groups.
Results: Among 13,353 RCC patients (mean age: 62 years), 4.6% developed IMD (71% metachronous, 29% synchronous), with a median time to IMD of 8.3 months [Interquartile Range: 1.3, 25.6]. Median OS was significantly shorter for patients with IMD (20.9 months) versus those without IMD (125.4 months; $p < 0.001$). Synchronous IMD (HR: 2.58) was linked to worse OS. Those without metastases at diagnosis had the longest OS (127.0 months), compared to patients with extracranial metastases alone (13.6 months; HR: 6.89) or synchronous IMD (4.8 months; HR: 14.71). Patients with stage 4 disease at diagnosis who developed metachronous IMD had better OS than those who never developed IMD (17.7 vs. 12.0 months). In patients with IMD, systemic therapy was associated with improved survival (HR: 0.47). Stereotactic radiosurgery (SRS) and/or neurosurgery was associated with improved survival, compared to whole-brain radiotherapy (WBRT) or no IMD-directed treatment (HR: 0.47). Propensity-matched analyses showed that receipt of SRS/neurosurgery was associated with improved OS, compared to WBRT or no IMD-directed treatment (25.9 vs. 13.1 months; HR: 0.55).
Conclusion: This study provides large-scale, population-based insights into the impact of IMD in RCC. Our findings show that SRS/neurosurgery is protective in all subgroups of RCC patients with IMD, informing clinical decision-making and offering valuable guidance for optimizing patient outcomes and resource allocation. Additionally, these findings highlight the need for routine brain imaging in RCC to enable early detection and improve management strategies.

#5968 Prognostic value of cachexia consensus criteria in pancreatic cancer.

April Bell[1], Noah Forrest[1], Steven Tran[1], Amber Willbanks[2], Vijeeth Guggilla[1], Akhil Chawla[1], Jodi Johnson[1], Ishan Roy[2], Theresa Walunas[1]

[1]Center for Health Information Partnerships, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Shirley Ryan AbilityLab, Chicago, IL

Background: Pancreatic ductal adenocarcinoma (PDAC) carries a poor prognosis due in part to cachexia diagnosed in up to 87% of patients. Cancer-associated cachexia is a muscle wasting syndrome unresponsive to nutritional support and associated with reduced treatment efficacy and higher patient mortality. Defining the relationship between cachexia and patient prognosis remains an unmet need, particularly in settings outside of clinical trials. Here, we applied weight-based markers of cachexia to real-world electronic health record (EHR) data to assess the prognostic ability of current consensus criteria toward PDAC patient survival.

Methods: We utilized EHR data from the Northwestern Medicine Enterprise Data Warehouse to design a PDAC-associated cachexia phenotype from weight-based markers of cachexia. To form our patient cohort, we identified patients by a PDAC diagnostic code billed by an oncology provider from records backdated to 2012. Of 1469 patients,1099 patients had sufficient weight data for cachexia classification at the time of diagnosis, defined by a pathology note indicating the presence of PDAC. We used the classification method from Fearon et al. 2011 to stratify patients by no cachexia, pre-cachexia and cachexia before constructing Kaplan-Meier curves. Our model, validated by manual adjudication of 300 patient charts, had an F1 score of 0.961.

Results: There was no significant difference in PDAC patient median overall survival (OS) comparing patients with no cachexia, pre-cachexia and cachexia, which was 19.04 months, 19.27 months and 16.96 months, respectively. However, there were differences in survival rate at one year, which were 60%, 67% and 59%, respectively (log-rank p=0.04). The pre-cachexia associated 1-year survival benefit was most pronounced in Stage IV patients. With pre-cachexia as the reference, the HRs for no cachexia and cachexia were 1.18 (0.97-1.44) and 1.23 (1.02-1.47), respectively. As compared to patients with no cachexia, those with pre-cachexia and cachexia experienced greater survival benefit with resection and chemotherapy.

Discussion: Cachexia status as defined by the Fearon criteria demonstrated a limited prognostic ability, as patient OS did not vary significantly with stratification. However, pre-cachexia was associated with a statistically significant improved 1-year survival and enhanced response to treatment. The unexpected pre-cachexia associated protective benefit suggests cachexia may serve as a double-edged sword in cancer, an observation deserving of further investigation. Overall, our results indicate that while cachexia status should be considered during PDAC management, better measures of cachexia are needed. Prognostication may be improved in future models by combining weight-based measures with factors that inform patient care, such as cachexia biomarkers and patient functionality.

#5969 Enhancing interobserver agreement in RENAL nephrometry scoring through the integration of center-based endophycity measurements.

Keenan Moore[1], Nicholas Heller[2], Clara Goebel[3], Jayant Siva[2], Jamee Schoephoerster[4], Griffin Struyk[5], Nitin Venkatesh[6], Beatriz Lopez Morato[7], Christopher Weight[2]

[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL,[2]Cleveland Clinic, Cleveland, OH,[3]University of Vermont Larner College of Medicine, Burlington, VT,[4]Oregon Health & Science University, Portland, OR,[5]HealthPartners Regions Hospital, Saint Paul, MN, Saint Paul, MN,[6]Oakland University William Beaumont School of Medicine, Auburn Hills, MI,[7]Autonomous University of Madrid, Madrid, Spain

INTRODUCTION: Since its introduction, the RENAL nephrometry score has proven to be an effective tool in medical decision-making and surgical planning for renal tumors and has been shown to be predictive of several important oncologic and operative outcomes. However, some studies have reported high interobserver variability, particularly within the endophycity or “E” portion of RENAL score. This variability can undermine the utility of the RENAL score in clinical management, as it may lead to inconsistent risk stratification and treatment recommendations. Here, we propose the use of center-based endophycity (CBE) scoring in place of the “E” score within RENAL as a means of facilitating interobserver agreement while maintaining utility.
METHODS: Medical records for patients who underwent radical or partial nephrectomy for suspected renal malignancy at a single institution over a 9-year span were retrospectively collected. Exclusion criteria included unavailable imaging, multifocal disease, and incomplete pathology data. Preoperative imaging was evaluated with six independent observers manually assigning RENAL scores to each case, and three observers assigning CBE scores. CBE scores were determined by approximating the center of the tumor and assessing whether it was interior or exterior to the corticomedullary boundary of the kidney. Exophytic and endophytic tumors were given a score of 1 and 2 respectively. These scores were then integrated in place of the “E” score of RENAL for analysis. Kappa coefficient was used to analyze interobserver agreement, and logistic regression was used for predicting outcomes.
RESULTS: A total of 288 cases met the inclusion criteria for this study. CBE scoring (kappa coefficient 0.77) had significantly higher interobserver agreement than RENAL “E” (kappa coefficient 0.17, $p < 0.0001$). Both traditional RENAL and RENAL with CBE were predictive of ISUP grade ($p < 0.0001$, $p < 0.0001$), tumor necrosis ($p < 0.0001$, $p < 0.0001$), and perioperative blood loss ($p = 0.001$, $p < 0.0001$). Traditional RENAL was predictive of malignancy ($p = 0.001$), while RENAL with CBE was not ($p = 0.058$). However, CBE independently predicted malignancy ($p = 0.039$), whereas RENAL “E” did not ($p = 0.365$).
CONCLUSIONS: These results suggest that the RENAL “E” score is prone to particularly low interobserver agreement. When integrated in place of RENAL “E”, CBE scoring represents a promising modification to the RENAL nephrometry score, offering a more reproducible method for assessing endophycity in renal tumors while preserving much of the predictive power of the original model. These findings have important implications for improving the accuracy and consistency of preoperative renal tumor assessments. Further studies are needed to elucidate currently insignificant yet promising predictive data points from this study and to confirm our findings in other cohorts.

#5970 Differences in survival outcomes based on timing and location of initial systemic therapy in patients with extensive stage small cell lung cancer.

Andrea Y. Lo[1], Zahra Hamedi[2], Taharah Islam[3], Erin Alesi[2], Jonathan Berkman[2]

[1]Internal Medicine, VCU Health System, Richmond, VA,[2]VCU Massey Comprehensive Cancer Center, Richmond, VA,[3]VCU School of Medicine, Richmond, VA

Background: Lung cancer is the leading cause of cancer deaths in the United States with small cell lung cancer comprising 20% of lung cancers and extensive stage small cell lung cancer (ES-SCLC) making up two thirds of these cases. ES-SCLC has a median progression free survival (PFS) of 5.2 months and overall survival (OS) of 13 months when treated with chemoimmunotherapy. Inpatient hospitalization for the patient's first cycle of therapy is often utilized. We aimed to identify whether location of treatment (inpatient vs outpatient) and timing of treatment have significant survival effects.

Methods: A retrospective chart review was done on ES-SCLC patients diagnosed and treated with standard of care systemic therapy between 2018-2023. Date of diagnosis, location of patient's first cycle (inpatient vs outpatient), treatment type and dates, progression dates, death dates, and hospice enrollment dates were obtained. Survival analysis was completed using Cox-regression and log-rank test. Fischer's exact test was used to compare differences in categorical data.

Results: 48 patients were identified—40 received their first cycle outpatient and 8 inpatient. Those who received their first cycle of therapy inpatient had worse OS compared to those who received it outpatient (median 126 days vs 408 days, p=0.002). None of the patients who were initially treated inpatient received immunotherapy (IO) with their first cycle. Proportion of patients who enrolled in hospice did not differ significantly between the inpatient and outpatient groups (80% vs 65%, p=0.70). Patients treated with IO within 6 weeks of diagnosis were found to have worse PFS compared to those treated after 6 weeks (median 178 days vs 236 days, p=0.034). OS did not differ significantly. Patients enrolled in hospice were more likely to have worse OS (HR: 2.2, p=0.05). Those with PFS <6 months did not show significantly different OS if they enrolled in hospice. Amongst patients who had PFS >6 months, hospice enrollment was associated with worse OS compared to those who did not enroll in hospice, (median 465 days vs 908 days, p=.006).

Conclusions: Patients who received their initial cycle of therapy inpatient had worse OS compared to those who began treatment outpatient. At our institution, IO is not administered inpatient. Further analyses show timing of IO did not significantly impact OS. However, those who received IO earlier did have worse PFS. These findings suggest that factors associated with inpatient treatment, such as more aggressive disease or significant medical comorbidities may contribute to the observed worse OS. Additionally, while hospice enrollment was associated with worse OS, the difference disappeared when analyzing patients with PFS <6 months, indicating that hospice enrollment itself may not directly impact survival in this subgroup.

CLINICAL RESEARCH: Targeted Therapies and Combinations 3
Poster Session

#5974 Novel combinational therapeutic strategy in angiosarcoma through PLK1 and mTOR co-inhibition.

Nimod D. Janson[1], Alejandra R. Alzate[2], Annaleigh Powell-Benton[1], Bozhi Liu[1], Ant Murphy[1], Jason A. Hanna[1]

[1]Department of Biological Sciences, Purdue University Institute for Cancer Research, West Lafayette, IN,[2]Purdue University Institute for Cancer Research, West Lafayette, IN

Angiosarcoma (AS) is a rare and highly aggressive vascular sarcoma characterized by a poor prognosis with a 5-year survival rate of only 20-30%. The underlying oncogenic drivers and potential therapeutic targets remain unidentified in most AS cases. Standard treatments, including chemotherapy, surgery, and radiotherapy, demonstrate limited efficacy and are frequently associated with relapse and metastatic progression. These challenges highlight an urgent need to identify novel therapeutic targets and develop effective strategies to improve outcomes for patients with angiosarcoma. We identified Polo-like kinase 1 (PLK1), an overexpressed mitotic kinase, as a potential therapeutic target in angiosarcoma (AS). PLK1, a key mitotic regulator, is a promising candidate for clinical intervention in AS. Through differential gene expression analysis in mouse and human AS models, combined with druggability assessments utilizing publicly available databases and AI-based tools, we have validated PLK1 as a promising therapeutic target for AS. Furthermore, our studies demonstrate the potential combinational synergy of PLK1 and mTOR inhibition using small molecule inhibitors. We have shown that genetic *Plk1* depletion by doxycycline-inducible shRNAs and pharmacological PLK1 inhibition using small molecule inhibitor BI 6727 in AS cells reduces cell proliferation colony forming ability *in vitro* and demonstrates significantly reduced tumor growth *in vivo*. Moreover, our data reveal that genetic depletion of *Plk1* delays tumor onset and significantly improves survival in genetically engineered angiosarcoma mouse models (GEMMs). Previously, we observed activation of the mTOR signaling pathway in AS GEMMs and demonstrated that AS cells are susceptible to mTOR inhibition. In the current study, we observed a synergistic combination of PLK1 inhibition by Volasertib and mTOR inhibition by Rapamycin in AS *in vitro* and *in vivo*. Our objective is to determine the mechanisms and pathways governing the development and progression of AS to generate novel precision-targeted therapies. Our findings conclude that PLK1 is a viable therapeutic target in AS, and the combined inhibition of PLK1 and mTOR represents a promising novel therapeutic strategy for this aggressive cancer.

#5975 Long-acting G-CSF empegfilgrastim with dose-dense chemotherapy for patients with stage II-III TNBC: Defendor Special trial, primary analysis.

Inna Ganshina[1], Elena Artamonova[1], Elena Lubennikova[1], Olga Gordeeva[2], Mariam Manukyan[1], Daria Filonenko[3], Lyudmila Zhukova[3], Irina Sorokina[3]

[1]FSBI "N.N. Blokhin National Medical Research Center for Oncology", MoH, Moscow, Russian Federation,[2]FSBI Federal Research And Clinical Center Of Physical-Chemical Medicine of FMBA named after Yu. M. Lopukhin, Moscow, Russian Federation,[3]A.S. Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation

Background: Dose-dense neoadjuvant chemotherapy (NAC) provides the best efficacy results, irrespective of aPD-1 combinatory agent use for the most aggressive subtype of breast cancer - triple negative (TNBC). Maintaining relative dose intensity (RDI)≥85% of NAC and RCB 0-1 achievement after NAC are significantly associated with improvement of patient's prolonged long-term efficiency outcomes. Neutropenia is one of the keys limiting adverse event (AE) reducing RDI. Long-acting G-CSF is an essential component for balanced RDI' maintenance. Here we present the results of efficacy and safety of original prolonged G-CSF empegfilgrastim for patients' (pts) cohort with TNBC under dose-dense therapy regimen from Defendor Special investigator-initiated trial.
Methods: High-risk stage II-III BC pts (n=60) received NAC: 4 dose-dense doxorubicin/cyclophosphamide (ddAC) with empegfilgrastim → 12 QW paclitaxel/carboplatin. RDI was primary endpoint and presented here for pts who completed the planned regimen. Analyses was performed for the 4ddAC part, paclitaxel/carboplatin part, and whole regimen. Secondary endpoints: pCR (ypT0/is, ypN0), RCB rate and safety are also presented here. NCT04905329.
Results: 60 pts were included and received at least 1 dose of NAC with empegfilgrastim at the time of data cut-off. Pts with initially negative prognosis are enriched in the population: 38 (63%) pts with IIIB/C stages, 36 (60%) pts with G3. 57 (95%) pts completed the planned course of sequential therapy, 3 (5%) pts had disease progression (local or distant) that precluded definitive surgery (initially resistant population). RDI≥85% of the whole NAC course was achieved in 54 (96%) pts. Median RDI for ddAC part was 100% and 94% - for paclitaxel/carboplatin part. pCR rate of operable stages was 50% and 43% - for locally advanced stages. 64% of pts in the whole population switched to the favorable prognosis group due to achieving the RCB level of 0-1. There were 58% of pts with initially stages IIIB/C and RCB 0-1 level was 60% in this group. Neutropenia as a reason for therapy discontinuation was in 1 pts for the whole NAC regimen. Main reasons for premature interruption were neuropathy or thrombocytopenia associated with paclitaxel/carboplatin use.
Conclusions: Empegfilgrastim allows for maintained RDI≥85% of sequential NAC therapy with dose-dense regimen part effectively and safely. Balanced neutrophil count could be able improve efficacy results and switched pts prognosis to favorable for majority of pts. In case of limited access to aPD-1 therapy, prolonged G-CSF (empegfilgrastim) becomes a full-fledged agent in a dose-dense regimen that can determine the outcome for patients with TNBC. Final analysis with long-term outcomes is awaited.

#5976 Importance of molecular diagnostic testing preliminary to personalized therapy in NSCLC patients.

Wiley Maxwell Turner, Raja Flores, Matthew Untalan, Stephanie Tuminello, Emanuela Taioli

Icahn School of Medicine at Mount Sinai, New York, NY

Background: Personalized medicine, including targeted and immunotherapy, has substantially changed the landscape of non-small cell lung cancer (NSCLC). About 30% of NSCLC tumors have targetable mutations, like EGFR, and about 28% of tumors will have a PD-L1 score or tumor mutation burden high enough to warrant immunotherapy; a molecular test prior to therapy assesses eligibility. However, the congruence between testing and treatment, and the effect of treatment without testing on outcomes have yet to be studied.

Methods: Surveillance, Epidemiology and End Results-Medicare linked data was queried for NSCLC patients diagnosed from 2013 (the first year that standard guidelines for molecular testing in lung cancer were available) to 2015 age > 66 years, stage > II with continuous Part A and B and no Part C coverage 1 year prior to 6 months post-diagnosis, and continuous part D coverage for 6 months after diagnosis. Patients treated with targeted therapy: EGFR, ALK1, KRAS, or BRAF; or immunotherapy: CTLA, PD1; were selected for. Patients with a claim for a molecular diagnostic test within 6 months after cancer diagnosis were defined as tested. Demographic and clinical characteristics of those receiving vs not receiving a molecular test were compared, and a multivariable Cox proportional hazards regression was used to assess the association of overall survival with receipt of molecular diagnostic testing, adjusting for sex, race, age, histology, and stage.

Results: There were 911 NSCLC patients treated with a personalized therapy, of which 513 (56.3%) had received prior molecular testing. Black patients were less likely than white patients to receive molecular testing (36.4% vs 59.9%; $p<0.001$). Molecular testing was significantly more frequent in patients with fewer comorbidities ($p<0.001$), adenocarcinoma ($p=0.004$), tumors in the lower lobe ($p=0.037$) or diagnosed at a later stage ($p=0.026$). Only 39.9% of patients receiving EGFR inhibitors were initially tested for an EGFR mutation. Overall, among NSCLC patients treated with personalized therapy, untested patients were at increased mortality risk compared to molecularly tested patients (median survival time 8.22 vs 12.79 months, $p=0.024$). After adjustment, untested patients had a significantly higher mortality risk compared to tested patients (HR_{adj} [hazard ratio]: 1.22; 95% CI [confidence interval]: 1.05-1.41).

Conclusions: Although based on claims data, significant incongruence between receipt molecular testing and personalized therapies exists, with only about half of treated patients having had an appropriate molecular diagnostic workup. This could explain, in part, the higher mortality among treated patients who did not undergo testing. Before expanding personalized therapies, studies should examine whether adequate testing is being coupled with these treatments, and outcomes in non-tested patients.

#5977 Identification and characterization of an allosteric and mutant-selective PI3Kα inhibitor.

Chengshan Niu*, #[1], Shengli Dong*, #[2], Shaoqing Chen*[2], Kaige Ji[1], Maolin Zheng[1], Mingtao Chen[1], Yuanjie Li[1], Meihua Li[2], Zhengfei Guo[2], Hongqiang Li[2], Yu Yu[2], Xinlong Yang[2], Chao Zhou[2], Apeng Liang[2], Yin Zhou[3], Wei Wu[2], Mingyu Jiang[3], Jun Li[3], Yusheng Wu[3]

[1]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, Henan, China,[2]TYK Medicines, Inc., Changxing, Zhejiang, China,[3]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China

Introduction: The PI3K-AKT-mTOR signaling pathway is pivotal in tumorigenesis. PIK3CA, a PI3K isoform, is one of the most frequently mutated genes, occurring in approximately 14% of cancers and in up to 40% of breast cancers. PIK3CA mutations are highly enriched at “hotspot” amino acid sites in the helical domain (E542K, E545K) and kinase domain (H1047R/L). PI3Kα mutations are often oncogenic drivers of other refractory cancers, including gastric cancer, colon cancer, uterine cancer, and head and neck squamous cell carcinoma. Orthosteric inhibitors of PI3Kα, such as alpelisib and inavolisib have been approved for the treatment of patients with advanced HR+/HER2− breast cancer. However, alpelisib and inavolisib lack mutant selectivity and inhibit WT PI3Kα, which plays a critical role in cellular glucose homeostasis, resulting in dose-limiting toxicity such as hyperglycemia and hyperinsulinemia. Selective targeting of mutant PI3Kα is anticipated to enhance antitumor efficacy and mitigate the toxicity associated with wild-type PI3Kα inhibition in normal tissues. Multiple allosteric and mutant-selective PI3Kα inhibitors have been successfully developed into clinical stage, including LOXO-783 (NCT05307705), RLY-2608 (NCT05216432) and STX-478 (NCT05768139). TY-2291 is an allosteric and mutant-selective PI3Kα inhibitor developed by TYK Medicines Inc.

Results: TY-2291 is a potent kinase inhibitor of mutant PI3Kα with high selectivity over WT PI3Kα. In *in vitro* antiproliferative test, TY-2291 showed better antiproliferative activity against multiple PI3Kα mutant cells than LOXO-783, STX-478, and RLY-2608. In the mouse HCC1954 CDX model, TY-2291 showed potent tumor-inhibitory activity and excellent tolerance. TY-2291 also demonstrated excellent DMPK properties and desirable drug-like properties. In the insulin tolerance test, TY-2291 had no effect on fasting plasma glucose levels after four days of treatment.

In conclusion, we have identified a potent allosteric and mutant-selective PI3Kα inhibitor. Our findings indicate that TY-2291 may significantly enhance the therapeutic index of PI3Kα-mutant cancers in the absence of PI3Kα WT-related toxicities.

#5978 Pharmacological blockade of AURKA and NOTCH3 oncogenic pathways to inhibit cancer cell plasticity in triple negative breast cancer.

Antonino Bonaventura D'Assoro[1], Matthew Goetz[1], Carol Lange[2], Roberto Leon-Ferre[1], Tufia Haddad[1], James Ingle[1], Annapaola Montagner[1], Andrew Takchi[1], Ellie Babadi[3], Lucio Miele[4], Urban Lendahl[5], Urban Lendahl[5]

[1]Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Masonic Cancer Center, Minneapolis, MN,[3]Emory, Atlanta, GA,[4]Louisiana State University Health Sciences Center New Orleans, New Orleans, LA,[5]Karolinska Institute, Stockholm, Sweden

Background: Despite recent advances in the treatment of triple negative breast cancer (TNBC) many patients are still suffering from early recurrence, therapy resistance, and organ metastasis 1 to 3 years post-chemotherapy. TNBC cells with stem cell-like properties are resistant to standard of care chemotherapy and are responsible for early tumor relapse and poor outcome. Up-regulation of PD-L1 expression in Cancer Stem Cells (CSCs) has been associated with immune evasion capacity and promotion of their stem-like properties. In this study we identify two druggable stemness target, Aurora-A Kinase (AURKA) and NOTCH3, with positive feedback on intra-tumoral PD-L1 expression and cancer cell plasticity.

Methods: MDA-MB 231, MDA-MB 231 LM and SUM149-PT TNBC cells were used both in 2D and 3D environment. Unique TNBC cells were established from metastatic PDX models. TNBC cells were treated with Alisertib (AURKA inhibitor, 50nM) or AV353 (NOTCH3 inhibitor, 200ng). Immunofluorescence and immunoblot were used to compare different biomarker expression. ALDH was measured using Aldefluor kit. Apoptotic cells were quantified in real-time using *IncuCyte S3*. *In vivo* studies; $1x10^6$ MDA MB 231/LM cells were injected into the mammary fat pad of NSG-female mice and treated with Alisertib or AV353. Control groups were treated with pacebo.

Results: Our study shows that AURKA and NOTCH3 pharmacological blockade reduced nuclear/undruggable PD-L1, that is not achieved clinically by using FDA-approved immune checkpoint inhibitors (ICIs). Significantly, following stemness-targeted therapy with alisertib or AV353, reduction of intra-tumoral PD-L1 resulted in inhibition of tumor growth, decreased levels of CD44 expression, increased CD8+ T-cell tumor infiltration, impairment in the enrichment of $ALDH^{high}$ CSCs and enhanced chemosensitivity. *In vivo* pharmacological blockade of AURKA and NOTCH3 signaling pathways induced inhibition of tumor growth, apoptosis, and impairment of organ metastases.

Conclusions: This study demonstrates that selective AURKA and NOTCH3 pharmacological blockade results in the inhibition of cancer cell plasticity that is linked to reduction of *undruggable* nuclear PD-L1 in TNBC cells. Our findings provide the strong preclinical rationale to develop novel clinical trials for patients with advanced TNBC that are refractory to chemotherapy and show limited response to FDA-approved ICIs.

#5979 Identification of DNA methylation based prognostic subtype and signature in epithelial ovarian cancer.

Wei Geng, Wei Liu, Lei Liu, Yuxin Chen, Dong Yang, Linqing Chai, Caiyun Huang, Lian Li

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Epithelial ovarian cancer (EOC) is a heterogeneous disease that exhibits different histological types, clinical characteristics, and molecular features. DNA methylation plays a crucial role in the development and progression of cancer and has been utilized for subtyping various tumors. This study focuses on classifying EOC based on DNA methylation and aims to characterize the disease through an integrated analysis of genomic, transcriptomic, and clinical data.
Methods: Genome-wide DNA methylation profiling was performed on 137 EOC tumor tissues using Infinium MehylationEPIC array. Prognosis-related differentially methylated positions (DMPs) were identified through multivariate Cox proportional hazards regression models, and non-negative matrix factorization (NMF) approach was used to classify different subtypes. A prognosis prediction model was constructed using LASSO regression and nomogram was constructed.
Results: Four methylation-based subtypes (MS1-MS4) were identified using 774 DMPs, showing significant differences in prognosis ($P = 2.413 \times 10^{-9}$).The MS1 group showed the best prognosis and the most favorable response to paclitaxel in combination with platinum-based chemotherapy. MS2 is characterized as an immune-excluded phenotype, while MS3 represents a metabolic subtype with a moderate prognosis as determined through differentially expressed genes and functional enrichment analysis. In contrast, MS4, recognized as a hypermethylated subtype, has the poorest prognosis and is marked by the highest methylation levels among the four subtypes. A four-DMP signature was developed to predict prognosis and methylation subtype, thereby enhancing clinical utility.
Conclusion: Together, this study identified a novel molecular subtype of EOC, elucidating the heterogeneity of EOC from an epigenetic perspective and providinga new strategy for personalized treatment options for EOC patients.
Key words: Epithelial ovarian cancer, Molecular subtypes, Chemotherapy, Immune therapy, DNA methylation, Prognosis

#5980 Leveraging large-scale PDO-based assays to optimize antibody-drug conjugate efficacy in digestive cancer.

Lelia Polit[1], Gizem Altay[1], Mia Cabantous[1], Anna-Rose Gryspeert[1], Jerome Cartry[2], Jacques RR. Mathieu[2], Sabrina Bedja[2], Alice Boileve[2], Michel Ducreux[2], Sophie Postel-Vinay[2], Fanny Jaulin[1], Gustave Ronteix[1]

[1]Orakl Oncology, Le Kremlin Bicetre, France,[2]Institut Gustave Roussy, Villejuif, France

Context:
Clinical trials are one of the major barriers in contemporary drug development. Functional assays based on patient-derived organoids (PDO) are a promising new tool for derisking clinical development of new therapies, but their use has been limited due to small cohort sizes and the absence of systematic validation studies. Using the largest cohort of matched PDOs, longitudinal clinical data, transcriptomic and WES data, we explore the use of large PDOs collections to characterize ADC efficacy and affinity with the targeted cells through systematic mapping of the relationship between target antigen abundance and payload efficacy.
Methods:
We have assembled a matched collection of PDOs and transcriptomic data from 135 colorectal (CRC) and pancreatic (PDAC) cancer patients, generated from primary tumour samples and metastatic biopsies. Patients ranged from 31 to 89 years old and had experienced an average of 2.6 lines of treatment prior to the PDO-generating tissue sampling. We used gene expression levels of well-known target antigens such as CEACAM5, HER2, and TROP2 as proxies for protein expression. This data is combined with PDO responses to microtubule and topoisomerase inhibitors, thereby enabling us to explore the relationship between target antigen abundance and payload efficacy. This allows us to generate data-driven hypothesis that were then validated *in vitro* on a pool of CRC and PDAC PDOs.
Results:
We identify patient subgroups by combining the RNA expression level and payload efficacy for ADCs against HER2 and CEACAM5. We systematically matched the RNA expression levels and histology for the corresponding proteins. Then we confirmed the response of the PDOs extracted from the tumors of these patients *in vitro*. We report that large-scale PDO-based assays can be a useful tool to anticipate clinical readouts. This work suggests that well-characterized PDO collections could also help redefine patient populations, increasing the likelihood of identifying those more likely to respond to a given ADC, and thus improving the success rates of clinical studies for new treatments in CRC and PDAC.

#5981 Over 200! The largest BaF3-EGFR engineering cell lines collection, a useful platform for novel drug discovery.

Yao Tang, Guoqian Wang, Tingduo Lv, Jingxiao Xu, Yao Peng, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

The epidermal growth factor receptor (EGFR) is a cell-surface receptor tyrosine kinase that belongs to the ERBB family, which includes HER1 (EGFR), HER2, HER3, and HER4. Each of these receptors has three key layers: an input layer, a signal-processing core, and an output layer. EGFR is activated primarily through ligand binding, with ligands such as EGF, TGF-alpha, HB-EGF, AR, EPR, BTC, and epigen. However, mutations or overexpression of EGFR can lead to ligand-independent activation. Once activated, EGFR triggers various downstream signaling pathways, such as PI3K-AKT, JAK-STAT, RAS-MEK/ERK, and PLC-gamma-PKC, which enhance cell proliferation, survival, and resistance to cell death.The overexpression or increased activity of EGFR is linked to several cancers, including non-small cell lung cancer (NSCLC), colon cancer, head and neck cancer (HNC), pancreatic cancer, breast cancer, and brain cancer. Recognizing EGFR as a driver gene has accelerated the development of targeted anticancer therapies, such as monoclonal anti-EGFR antibodies (cetuximab, panitumumab) and small molecule receptor tyrosine kinase inhibitors (TKIs). The first generation of EGFR TKIs, like gefitinib and erlotinib, specifically target mutations such as L858R and exon 19 deletions. To address resistance to these early inhibitors, second-generation EGFR TKIs (afatinib, dacomitinib) were developed. The EGFR T790M mutation is a major mechanism of resistance to both first and second-generation TKIs. Osimertinib, a third-generation TKI, was approved for use in EGFR-mutated NSCLC following the failure of first- and second-generation TKIs, although the EGFR C797S mutation limits its effectiveness. Fourth-generation EGFR TKIs, including BLU-945 and BBT-176, are under clinical evaluation but are not yet approved.We have created more than 200 Ba/F3-EGFR engineered cell lines, making this the largest in vitro and in vivo platform for drug discovery with the widest range of mutant cells. These cell lines include almost all clinically significant EGFR mutations, such as common mutations like L858R and exon 19 deletions, as well as rare mutations like L861Q, S768I, and combinations of mutations like L858R/T790M, Del19/T790M, and triple mutations. These Ba/F3-EGFR engineered cell lines are valuable tools for developing and assessing next-generation EGFR inhibitors and for studying newly acquired resistance mutations in EGFR.

#5982 Mechanisms underlying the anti-cancer activity of new, non-covalent thioredoxin reductase inhibitors.

Abigail Rullo[1], Brenna Flowers[1], Keacha Chang[1], Pavel Petukhov[2], Irida Kastrati[1]

[1]Loyola University Chicago, Maywood, IL,[2]University of Illinois, Chicago, IL

Triple negative breast cancer (TNBC) makes up only 15-20% of all breast cancer cases, yet it contributes to 50% of all breast cancer related mortalities. This highlights the urgent need to develop novel therapeutics for the treatment of TNBC. The thioredoxin (Trx) system is an important cellular antioxidant pathway that plays crucial roles in redox homeostasis and supports proliferation, apoptosis, and gene transcription; Thioredoxin reductases (TXNRDs) are the central enzymes in this pathway. Of note, TXNRDs are elevated in TNBC to help tumors cope with excessive redox stress resulting from deregulated metabolism and replicative stress, thus presenting a potential vulnerability. A series of breakthrough studies by our collaborators identified a novel regulatory and druggable “doorstop” pocket in this family of enzymes to which they have developed inhibitors for. These novel TXNRD(i)s show anti-cancer activity in a panel of TNBC lines, by inhibiting proliferation, inducing cell death, inhibiting clonogenic survival, mammosphere forming efficiency and invasion. Importantly, these TXNRD(i)s also inhibit tumor growth in a xenograft model of TNBC. Our goal is to understand the mechanisms underlying the pleiotropic anti-cancer activities elicited by these TXNRD inhibitors. We hypothesize our novel TXNRD(i)s work, in part, by increasing and shifting the balance of redox stress to block proliferation and induce cell death in TNBC cells. To understand major pathways implicated, we conducted transcriptomics (RNAsequencing) in TNBC cells treated with two lead TXNRD(i)s, 8VP101 and 9VP19. Bioinformatic analysis (GSEA) indicates multiple proliferation and mRNA related pathways predominantly enriched by 8VP101. This is consistent with induction of redox stress. To corroborate this finding, cells were treated with 8VP and ROS levels were determined by incubating cells with DCFDA, a ROS sensitive probe, and analyzed by flow cytometry. We find a significant induction in ROS levels comparable to auranofin, a non-specific covalent inhibitor of TXNRDs. Another predominant pathway emerging from GSEA was regulation of cell cycle. Cell cycle analysis in cells treated with 8VP also shows an accumulation in G1. Based on our data, we conclude that our novel TXNRD(i)s elicit anti-cancer activity by elevating intracellular ROS leading to cell cycle arrest and induction of apoptosis and necroptosis. Our findings have important implications for advancing new therapies for TNBC.

#5984 Overcoming osimertinib resistance in NSCLC with NXP900, a phase 1, highly selective and potent first-in-class total YES1/SRC inhibitor.

Neil O. Carragher[1], Enrique Poradosu[2], Asier Unciti-Broceta[1]

[1]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom,[2]Nuvectis Pharma inc., Fort Lee, NJ

Background: Mutant-selective epidermal growth factor receptor (EGFR) inhibitors such as osimertinib, demonstrate potent activity in the treatment of EGFR-mutant lung cancer, unfortunately, the development of resistance to such EGFR inhibitors is nearly universal. Recent phosphoproteomic analysis has identified Src family kinase (SFK) activity as an important mechanism of osimertinib resistance (Tozuka et al. JTO Clin Res Rep. 2024, 5(4):100668). NXP900 (eCF506) is a novel potent and highly selective SRC family kinase (SFK) inhibitor, (IC_{50} of 0.47 nM against YES1) which possesses a unique/first-in-class binding mode-of-action. NXP900 locks its target into its native “closed” conformation (type 1.5 inhibitor), thereby inhibiting both kinase activity and complex formation with protein partners (Temps et al. Cancer Res. 2021, 81, 5438-5450). In contrast, multi-kinase inhibitors, including dasatinib and bosutinib, block SRC in the active “open” conformation (type 1 inhibitors) promoting the association of SFK and signaling partners via allosteric facilitation (Higuchi et al. Cell Rep 2021, 34, 108876). NXP900 may therefore represent an optimal drug combination partner with osimertinib to overcome acquired resistance in EGFR mutant lung cancer.
Materials and Methods: Cell proliferation assay - Cells were diluted in the corresponding ATCC recommended medium and dispensed in a 384-well plate, depending on the cell line used, at a density of 100 - 6400 cells per well. To study drug combination effects, mixtures of osimertinib and NXP900 are used across three different fixed concentration ratios to calculate a combination index (CI) value to determine synergistic activity using the Oncolines SynergyFinder^{TM} platform. In vivo studies: Mice transplanted with osimertinib resistant cell lines were treated by oral gavage with single agents or combination after reaching a 100mm^3 threshold volume.
Results: NXP900 and osimertinib combination treatment demonstrates statistically significant and potent synergy in osimertinib resistant NSCLC cell lines in vitro. In vivo studies demonstrate significantly increased duration of anti-cancer response to the NXP900 and osimertinib combination treatment arm relative to corresponding monotherapy arms in an EGFR mutant lung cancer model.
Conclusions: Despite high response rates to osimertinib in EGFR mutant lung cancer patients acquired resistance almost universally arises. Here we demonstrate that NXP900 in combination with osimertinib demonstrates potent synergy and prolonged inhibition of tumor growth in in vitro and in vivo NSCLC models of acquired osimertinib resistance. Altogether, these data suggest that NXP900 may have therapeutic potential in EGFR mutant cancers with acquired resistance to osimertinib. A FIH, Phase1 dose escalation study for NXP900 is ongoing.

#5985 Low-grade serous ovarian cancer is effectively treated with a combination of trametinib and LIFR inhibitor therapeutics.

William C. Arnold[1], Durga Meenakshi Panneerdoss[1], Suryavathi Viswanadhapalli[1], Behnam Ebrahimi[1], Hareesh B. Nair[2], Ratna K. Vadlamudi[1], **Yasmin A. Lyons**[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Evestra.inc., San Antonio, TX

Background: Ovarian cancer (OCa) is the most lethal gynecologic malignancy in the United States, with low-grade serous ovarian carcinoma (LGSOC) constituting 10% of cases. LGSOC is characterized by slow progression, resistance to treatment, and mutations in BRAF (33%) and KRAS (35%). LGSOC is often diagnosed at an advanced stage with a 70% relapse rate. Thus, novel targeted therapies are needed. Trametinib, a kinase inhibitor, is used to treat KRAS-mutated cancers, but our studies show that it increases LIFR expression, forming an autocrine LIF/LIFR oncogenic signaling loop that reduces Trametinib effectiveness in LGSOC treatment. This study tests the hypothesis that targeting the LIF/LIFR axis can enhance trametinib's efficacy in treating LGSOC.
Methods: The combination effects of EC359 and Trametinib on LGSOC cells were evaluated using cell viability, colony formation, invasion, and apoptosis assays. Mechanistic studies were performed using Western blotting, RT-qPCR and RNA-seq. The *in vivo* efficacy of trametinib and LIFR inhibitor EC359 as a targeted combination therapy was tested using LGSOC cell-based xenografts. Immunohistochemistry was conducted on the xenograft tumor sections to assess the proliferative index through Ki67 antibody staining.
Results: Trametinib increased the expression of LIFR in LGSOC cells in a time-dependent manner, as confirmed by Western blotting analyses, but not in HGSOC cells. In multiple LGSOC cell models, the combination therapy of EC359 and trametinib exhibited superior efficacy in reducing cell viability, colony formation, as well as increasing apoptosis, when compared to monotherapies with either EC359 or trametinib. The biochemical analyses of these models demonstrated that trametinib treatment activated the LIFR signaling pathway, which included the activation of LIFR downstream effectors such as STAT3, mTOR, and AKT. However, this activation was significantly reduced when combined with EC359. In addition, the growth of LGSOC xenograft tumors was substantially suppressed by treatment with EC359 at a dose of 5mg/kg in cell-based xenograft models in comparison to the vehicle control. Furthermore, the tumor-suppressive effects of trametinib were further enhanced by EC359, which resulted in a further reduction in tumor growth. The proliferative marker Ki67 was significantly reduced in tumors treated with the combination therapy, as evidenced by immunohistochemical analysis, suggesting a potent anti-proliferative effect.
Conclusions: These results indicate that the EC359 + trametinib combination therapy may provide a promising therapeutic approach for the treatment of LGSOC by enhancing the efficacy of trametinib and targeting critical signaling pathways.

#5986 Lurbinectedin/Irinotecan as a new therapeutic combination for small cell lung cancer.

Miguel Ruiz Torres[1], Santiago Ponce[2], Juan Manuel Coya[2], Reyes Bernabe[3], Jon Zugazagoitia[2], Alvaro Ucero[4], Javier Baena[2], Luis Paz-Ares[2], Irene Ferrer[2]

[1]Spanish National Cancer Research Ctr. (CNIO), Madrid, Spain,[2]Hospital Universitario 12 de Octubre, Madrid, Spain,[3]Hospital Universitario Virgen del Rocio, Sevilla, Spain,[4]Universidad Complutense de Madrid (UCM), Madrid, Spain

Small Cell Lung Cancer (SCLC) is one of the most frequent and deadliest types of Cancer, with an overal survival (OS) of less than 14 months and a 2- year survival rate not exceeding 7%. Potentially targetable molecular alterations in kinase genes are uncommon in SCLC, and consequently, treatment has barely changed in the last fifty years. Irinotecan, a Topoisomerase II inhibitor, and Lurbinectedin, an inhibitor of transcription, are the two only recently approved chemotherapy agents employed as monotherapy in second line of treatment. Our group has led a Clinical Trial to test the efficacy of the combination of these two drugs in SCLC in patients previously treated with the standard of care. The Clinical trial shows a consistent reduction in tumor size and a significant improvement in the Progression-free survival (PFS) of patients. To determine the mechanisms behind this promising effect, we have conducted a series of experiments using our platform of Patient-Derived models (Patient Derived Xenografts (PDX), Circulating tumor Cell-Derived Xenografts (CDX) and PDX/CDX-derived organoids/spheroids). Treating our PDX/CDX models faithfully recapitulates the results observed in patients, with a clear increase in survival in mice treated with the combination. Short term treatment of PDX models, as well as 3D cultures of organoids (PDXDO) and spheroids (CDXDS) and 2D cultures of SCLC cell lines, helped us determine that the treatment causes elevated levels of DNA Damage, a blockade in DNA Replication, and finally apoptosis. The results from this study highlight the relevance of the combination of these two already approved drugs in the treatment of SCLC.

#5988 Microscopic colitis - rare events secondary to immune checkpoint inhibitors therapy.

Barbara Radecka[1], Michał Piątek[1], Jacek Pawełczak[2], Ewa Stobiecka[3], Krystian Kowalczyk[1], Patryk Zając[4]

[1]Department of Oncology, University of Opole; Tadeusz Koszarowski Cancer Center in Opole, Opole, Poland,[2]Department of Gastroentrology, Provincial Hospital in Opole, Opole, Poland,[3]Department of Patomorfology, Tadeusz Koszarowski Cancer Center in Opole, Opole, Poland,[4]Department of Clinical Biochemistry and Laboratory Diagnostics, University of Opole; Tadeusz Koszarowski Cancer Center in Opole, Opole, Poland

Introduction: Immune checkpoint inhibitors (ICIs) have become the standard of care for cancer treatment but are associated with immune-related adverse events (irAEs). The combination of Nivolumab and Relatlimab (N+R) was approved in March 2022 for the treatment of unresectable or metastatic melanoma. While colitis is a well-known toxicity of ICIs, microscopic colitis (MC) presenting as watery diarrhea with normal endoscopic mucosal appearance, has not yet been described in Summary of Product Characteristics of N and R.

Description: We present the case of a 54-year-old man undergoing treatment with N+R for recurrent *BRAF*^{V600E}mt cutaneous malignant melanoma with metastases to soft tissues and lymph nodes. Eight weeks after starting therapy, the patient developed grade 3 (per CTCAE v.5) watery diarrhea. Stool tests were negative for infectious agents, including Clostridium difficile. Abdominal imaging with computed tomography did not reveal any signs of colitis. However, due to elevated fecal calprotectin levels (12 times above normal) and N+R treatment, ir-colitis was diagnosed. Intravenous methylprednisolone at 1 mg/kg/day has been administered and led to a temporary reduction of symptoms to grade 1. However, within a week, watery diarrhea worsened again to grade 3 despite ongoing steroid therapy. Due to steroid refractory, another immunomodulator was administered, including two doses of infliximab, without improvement. The patient did not lose weight. Colonoscopy revealed normal-appearing mucosa in the entire colon and terminal ileum. Random biopsies were done throughout the colon and terminal ileum. Histopathological examination revealed inflammatory infiltrates and focal increases in intraepithelial lymphocytosis, confirmed by CD3+ immunohistochemistry across all samples. The treatment with next-generation steroid budesonide (9 mg orally once daily in the morning) was administered, resulting in symptom resolution within two days. Diarrhea did not recur over the following four months. The N+R was finished. The patient received three doses of N+R and achieved a complete response (CR) on imaging, which is ongoing.

Conclusion: Various types of colitis were found secondary to ICIs such as pseudomembranous, granulomatous, or collagenous with endoscopically visible changes in the mucosa. MC is suspected to result from increased immune activity in the gut mucosa. It can develop following ICIs therapy and presents with severe symptoms, often requiring hospitalization, steroids, and other immunomodulators. This case highlights that a normal mucosal appearance on colonoscopy does not exclude immune-mediated colitis. Next-generation steroids, such as budesonide, can be effective in managing MC during immunotherapy. Raising awareness of the uncommon irAEs is essential, as some rare events can lead to fatal outcomes. Radiological, endoscopic, and microscopic pictures will be presented on the poster.

#5989 Investigating the potential of EC359 in inducing ferroptosis for the treatment of type I and type II endometrial cancers.

Emily J. Aller[1], Xue Yang[1], Megharani R. Mahajan[1], Behnam Ebrahimi[1], Paulina Ramirez[1], Hareesh B. Nair[2], Edward Kost[1], Ratna K. Vadlamudi[1], Suryavathi Viswanadhapalli[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Evestra Inc., San Antonio, TX

Background: Over the past decade, the diagnostic and mortality rates of endometrial cancer, the most common malignancy of the female reproductive tract, have risen, highlighting the need for improvements in current therapeutic options. Recent studies suggest that targeting the cellular receptor LIFR with the small molecule inhibitor EC359 could be a potential treatment for endometrial cancers. EC359 has been shown to inhibit the viability and invasion of both Type I and Type II endometrial cancers. However, the underlying mechanisms by which EC359 induces cancer cell death remain unclear. Emerging evidence suggests that LIFR signaling may be linked to ferroptosis. The purpose of this study is to explore the potential of EC359 to induce ferroptosis as a therapeutic strategy for Type I and Type II endometrial cancers.
Methods: The effects of EC359 on multiple established and primary endometrial cancer cells were evaluated using colony formation, MTT based cell viability and apoptosis assays. Mechanistic investigations were performed with Western blot, RT-qPCR, transmission electron microscopy (TEM) evaluation, and Flow Cytometry analysis. Patient-derived xenograft (PDX) models were used for preclinical evaluation of EC359.
Results: EC359 was efficient in reducing cell viability and promoting programmed cell death in both Type I and Type II endometrial cancer cells. We have demonstrated that the ability of EC359 to reduce cell viability is markedly diminished when ferroptosis is inhibited by pharmacological agents like Ferrostatin 1. EC359 primarily induced ferroptosis by suppressing the glutathione antioxidant defense system, as demonstrated by mechanistic investigations using Western blot analysis. Accordingly, the viability of endometrial cancer cells is restored by the addition of extracellular cystine. Further, EC359 treatment resulted in the reduction of critical anti-ferroptosis proteins. Flow cytometry analyses confirmed that EC359 treatment resulted in an increase in lipid peroxidation and TEM investigations revealed the induction of mitochondrial death through ferroptosis. Additionally, EC359 substantially inhibited the progression of tumors in both Type I and II endometrial cancer PDX models.
Conclusion: In conclusion, our data indicate that EC359 is a potent inducer of ferroptosis in endometrial cancer cells and has the potential to be used as an additional tool in current endometrial cancer treatment regimens.

#5990 Pertuzumab enhances the antitumor activity of T-DXd in HER2-positive gastric cancer cells.

M. Kang, **K.-J. Kim**, J. Sung, M. Nam, S.-H. Hwang, E. Jung, K. Suh, J.-W. Kim, S. Kim, J. Kim, Y. Kim, J. Kim, K.-W. Lee;
Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of

Simultaneously targeting HER2 and HER3 pathways is a potentially effective strategy for treating patients with HER2-positive gastric cancer (GC). A recent significant advancement in targeted therapy for HER2-positive GC is the development of trastuzumab deruxtecan (T-DXd). However, the co-administration of HER3 blockade with T-DXd to HER2-positive GC has not yet been explored, making this a pioneering study. Our *in vitro* analysis showed that the cell growth inhibitory effect of T-DXd on HER2-positive GC cells resembled the antiproliferative effect pattern induced by trastuzumab, rather than that caused by DXd. T-DXd reduced the cell viability in a manner closely linked to HER2 expression on the cell membrane. We observed that T-DXd inhibited the phosphorylation of HER3 and, subsequently that of p-AKT S473. The addition of pertuzumab increased T-DXd-induced HER2 internalization and further enhanced its antitumor effect on HER2-positive GC cells, especially when the HER2-HER3 heterodimers are enriched in the cells. By translating our findings into a xenograft model, we showed that combining T-DXd and pertuzumab outperformed single-agent therapy, resulting in significant antitumor effects and apoptosis induction. Our study suggests additional clinical investigations of this new combination strategy using T-DXd and pertuzumab in patients with HER2 positive GC are warranted.

#5991 Novel triple-drug combination strategy for p53 mutant cancers leveraging their DNA damage response liabilities.

Mohammed M. Alruwaili[1], Aidan Mazierski[1], Erica Norris[1], Kyeong Beom Jo[1], Yanqi Guo[1], Priyanka Rajan[1], Henry Withers[2], Thomas Melendy[3], Christos Fountzilas[4], Andrei Bakin[1]

[1]Cancer Genomics and Computational Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Biostatistics & Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Microbiology and Immunology, University at Buffalo, Buffalo, NY,[4]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Genetic alterations in the tumor suppressor p53 gene (*TP53*) are found in most solid malignancies, including colorectal (CRC), breast (BC), and pancreatic (PANC) cancers. Mutant p53 contributes to cancer progression and metastasis. Current therapeutic options show low selectivity for p53-mutant cancers and frequently exhibit high toxicity. To address this unmet clinical need, we developed a two-drug therapeutic strategy that selectively targets p53-mutant cancers. This novel strategy combines a thymidine analogue TAS102, acting as an inducer of DNA damage, and PARP inhibitor (PARPi) that works as an amplifier of DNA damage. Our two-drug therapeutic strategy showed greater efficacy in p53 mutant cancer models (including patient-derived xenografts (PDXs)) than either drug alone. The two-drug regimen was well tolerated in animal preclinical PDX and cell-derived xenograft models. This two-drug strategy is now being tested in Phase I clinical trial for patients with advanced CRC (NCT04511039). Clinical data showed no major signs of toxicity and increased progression-free survival compared to TAS102 alone. Mechanistically, the incorporation of thymidine analogues into DNA provokes post-replicative repair, generating single-strand DNA break intermediates. Repair of these intermediates is assisted by PARP, while inhibition of PARP increases more lethal double-strand DNA breaks. Cells with p53 wild-type (p53WT) respond with G1 and G2 -checkpoint arrest and efficiently remove thymidine analogues. In contrast, p53 mutant cells, lacking the G1 checkpoint, accumulate in G2 with lethal DNA breaks. The current work investigated the mechanism of the DNA damage response (DDR) and the G2 checkpoint induction in response to the TAS102-PARPi regimen. Analysis of DDR signaling showed that the G2 checkpoint in response to TAS102-PARPi is mediated by ATR kinase that acts through CHK1 and WEE1 kinases. We next examined a drug combination using the two-drug TAS102-PARPi regimen and the G2 checkpoint kinase inhibitors together. The concurrent triple-drug regimen showed high toxicity to non-tumor cells and cancer cells. In contrast, a sequential drug regimen, the two-drug treatment followed by G2-checkpoint inhibitors demonstrated selective toxicity against p53 mutant cancer cells. This sequential triple-drug regimen was further examined in preclinical CRC model in mice. The triple-drug regimen showed substantially greater anti-tumor activity in p53 mutant CRC xenograft model without adverse side effects (based on mouse body weight and peripheral blood analysis). Based on these preclinical studies, we propose a novel triple-drug therapeutic strategy for p53 mutant cancers that has strong potential to improve cancer treatment and meaningfully impact the health of cancer patients.

#5992 In vitro efficacy of novel USP1 inhibitors as a single agent and in combination with SOC in ovarian, prostate, and breast cancer cells independent of BRCA mutational status.

Marina Curcic[1], Mohamed Eltokhy[1], Sanjay K. Srivastava[1], **Partha Pratim Sarma**[2], Prashant Kashinath Bhavar[3], Uday Kumar Surampudi[3]

[1]Texas Tech University Health Sciences Center, Abilene, TX,[2]VeGen Therapeutics, Hyderabad, India,[3]VRise Therapeutics, Cambridge, MA

Background: Ubiquitin-specific protease 1 (USP1) is a key regulator of DNA repair pathways and is implicated in the response to genotoxic stress. Targeting USP1 has emerged as a potential therapeutic strategy for cancer treatment. This study investigates the in vitro efficacy of a series of novel USP1 inhibitor both as a monotherapy and in combination with other treatment agents, in ovarian, prostate, and breast cancer cell lines.
Methods: In vitro efficacy of three different series of USP1i in ovarian (OVCAR-3), prostate (DU-145), and breast (SUM149) cancer cell lines were accessed using cell viability and colony formation assays. Combination included co-treatment with standard chemotherapy agents and determining synergy using composite score.
Results: Treatment with USP1i alone led to significant reductions in cell viability and colony formation irrespective of BRCA mutation status. Furthermore, in combination with USP1 inhibitors enhanced efficacy was seen, leading to a positive shift in IC50 in cell viability assay and a significant increase in apoptosis compared to either treatment alone.
Conclusion: Our results demonstrate the potent in vitro anti-cancer activity of series of USP1 inhibitors, both as single agent and in combination with chemotherapeutic agents in ovarian, prostate, and breast cancer cell lines, irrespective of BRCA mutational status. These findings suggest that USP1 inhibition could provide a promising therapeutic approach for a broad range of cancers, warranting further investigation in preclinical models and clinical trials.

#5993 Identification of predictive biomarkers of response to ADCs by HTS of highly molecularly characterized panels of patient-derived organoids (PDOs).

Yi-Hung Carol Tan, Brandon L. Mapes, Brian M. Larsen, Daniel Gorski, Jessica Barbeau, Shanzah Chaudhry, Megan Spector, Carrie A. Franzen, Richard A. Klinghoffer

Tempus AI, Inc., Chicago, IL

Background: Antibody-drug conjugates (ADCs) such as the HER2-targeting agent trastuzumab deruxtecan, the TROP-2 targeting agent sacituzumab govitecan, and the NECTIN4 targeting agent enfortumab vedotin-ejfv, have resulted in increased clinical response rates in previously difficult to treat solid tumor indications, but only a minority of patients exhibit such responses. Increased understanding of the molecular underpinnings of sensitivity and resistance to ADCs beyond membranous target expression is needed. To that end, we developed a platform for generating, deeply characterizing, and functionally screening extensive panels of patient-derived organoids. Here, to demonstrate feasibility, we report on a screening panel of 60 PDOs representing 10 solid tumor indications and focus on response to ADCs now widely used in the clinical setting: trastuzumab deruxtecan and sacituzumab govitecan.
Methods: PDOs were cultured in the presence of 8-dose dilutions of either trastuzumab deruxtecan or sacituzumab govitecan as monotherapies. Experiments were performed in 384 well plates with each dose in technical triplicate. Cells were plated and drugs were added after 24 hours. Cells were cultured for an additional 6 days with no media refreshes. The screen included staurosporine as a positive control and vehicle negative controls. On Day 7, CellTiter-Glo (CTG) was added to the plates to terminate the experiments and assess cell viability. To evaluate treatment activity, cell viability measurements were normalized to vehicle controls and dose-response curves were generated to estimate key efficacy metrics including IC50, EC50, and inverse area under the curve (iAUC).
Results: ADC specific responses were observed across the 60 models tested. As anticipated, response to ADC exposure was driven by target expression. This was most obvious in response to enfortumab vedotin-ejfv, and also observable to a lesser extent with sacituzumab govitecan and trastuzumab deruxtecan. To better understand other molecular indicators of response, differential gene expression analysis was performed. This revealed additional potential biomarkers of specific ADC response including *VIL1*, *MYO7B*, *HNF4A*, *EFS*, *EPS8L3*, and several of which interestingly regulate cell-cell junction proteins.
Conclusions: The results shown here demonstrate that screening pan indication panels of PDOs can reveal ADC specific differences in efficacy which are rooted in molecular factors that include, but are not limited to target expression. Further analysis is ongoing, including establishing the prevalence of non-ADC target biomarkers in real-world patient populations via the projection of our screen-derived data onto Tempus RWD.

#5994 Investigating druggability of myeloid and lymphoid lineage gene mutations in advanced phase CML by employing drug discovery tools: Implications in fatal blast crisis CML precision oncology.

Fatimah Alabdullah[1], Nawaf Alanazi[1], Abdulkareem AlGarni[1], Kanza Adeel[1], Yaqob Samir Taleb[1], Amer Mahmood[2], Sabreen Alanazi[1], Aamer Aleem[2], Zafar Iqbal[1]

[1]Ministry of National Guard Health Affairs (MNG-HA), Al Mubarraz, Saudi Arabia,[2]King Saud University, Riyadh, Saudi Arabia

Background: Chronic Myeloid Leukemia (CML) is a myeloproliferative stem cell malignancy. Chronic Phase CML (CP-CML) is treatable with overall survival equivalent to the general population. Nevertheless, a proportion of CP-CML progresses to the accelerated phase (AP-CML) and ultimately blast crisis (BC-CML), with the latter having an overall survival (OS) of 3-23 months, making it almost a fatal manifestation. Although BC-CML is a different clinical entity than acute leukemias, it resembles AML (as myeloid BC-CML) or ALL (lymphoid BC-CML). Therefore, this study was designed to find out druggable AML-/ALL-lineage gene mutations in BC-CML

Methods: The study included 141 CML patients. All response criteria were per European LeukemiaNet (ELN) guidelines 2020. Whole exome sequencing (WES) was carried out to find out druggable gene mutations and the druggability of the mutated genes was determined using the online artificial intelligence (AI) tool (https://www.pandrugs.org/#!/query/). SAS/STAT software version 9.4 was used for data analysis (SAS Institute Inc., Cary, NC, USA). For statistical computing, the R package was employed.

Results: Out of 141, 18 (12.8%) patients progressed to AP-CML while 12 (8.5%) to BC-CML. BC-CML patients had poorer response to TKIs and higher mortality rate (75%). WES showed 64 AML-/ALL-associated genes mutated in advanced phase CML patients. Overall WES coverage was about 110X. AP-CML had 1644 variants, whereas BC-CML had 2531 variants, with a 54% gain in mutations from AP-CML to BC-CML (P< 0.000001). Among AML-/ALL- related mutated genes were NPM1 (%1.98), DNMT3A (%1.86), PML (%1.82), AKT1 (%1.62), CBL (%1.30), JAK2 (%0.71), TET2 (%0.59), IDH1 (%0.32), and BCL2. We also found that some FDA-approved drugs for different hematological malignancies (e.g. VENETOCLAX, DECITABINE, AZACITIDINE, BORTEZOMIB, ZANUBRUTINIB, IVOSIDENIB, TAZEMETOSTAT, RUXOLITINIB, PACRITINIB, ARSENIC TRIOXIDE etc.) can effectively target multiple gene groups mutated in our advanced phase CML patients (Table 1-4, Figures 1-4).

Conclusions: NGS analysis of AP- & BC-CML found mutations in many AML-/ALL-lineage genes, which is much higher than previously reported. This shows a huge genetic similarity between BC-CML and AML/ALL. FDA-approved and various novel experimental drugs under clinical trials are available against some of the genes we reported. We conclude that our approach can help in finding drug-targetable gene mutations related to AML-/ALL-lineage & other hematological malignancies in almost every BC-CML patient and provides practical guidance for drug repurposing as well as a gateway for under-trial novel experimental drugs to individualize BC-CML patient treatment.

#5995 Leveraging GPCR overexpression for personalized nanomedicine: A novel approach in ovarian cancer therapy.

R. Khetan[1], P. Eldi[1], N. A. Lokman[2], C. Ricciardelli[2], M. K. Oehler[3], A. Blencowe[1], K. Pillman[1], S. Garg[1], H. Albrecht[1];
[1]University of South Australia, Adelaide, Australia, [2]University of Adelaide, Adelaide, Australia, [3]Royal Adelaide Hospital, Adelaide, Australia

Background and Aims: Genetic heterogeneity in ovarian cancer drives frequent aberrant expression of cell surface proteins including G-protein coupled receptors (GPCRs), which harbour untapped potential for active targeting with nanomedicines. Our goal was to systematically identify GPCRs with significant overexpression in ovarian cancer biopsies and assessing their suitability to develop personalized GPCR-targeted nanomedicines for precise drug delivery.
Methods: We ran a systematic analysis of public RNA-seq gene expression data, to reveal GPCRs with frequent overexpression in ovarian cancer tissues. To validate the relevance of initially identified receptors as targeting candidates, we confirmed their expression in six ovarian cancer cell lines and a selection of patient-derived samples (ascites derived tumour samples and solid tumours), using techniques such as RT-qPCR, flow cytometry, fluorescence imaging and immunofluorescence. This comprehensive analysis provided valuable insights into the prevalence and distribution of candidate receptors across different ovarian cancer probes. Furthermore, we utilized representative ovarian cancer cell lines as *in vitro* models to assess receptor-mediated cellular uptake and internalization processes, to further evaluate potential targets for nanoparticle delivery systems.
Results: Analysis of public RNA-Seq datasets revealed 13 overexpressed GPCRs in cancer tissues compared to healthy tissues. Among these, we focused specifically on the coagulation factor II thrombin receptor (F2R) to highlight its intriguing potential as a therapeutic target. The variable expression of F2R was confirmed in both ovarian cancer cell lines and patient-derived samples. Furthermore, peptide binding to the receptor was successfully demonstrated using flow cytometry and fluorescent imaging, suggesting a promising approach for targeted drug delivery.
Conclusions and Significance: Our findings underscore the importance of personalized targeting approaches in ovarian cancer therapy and highlight the potential of F2R as a promising therapeutic target. By integrating advanced molecular techniques with nanomedicine strategies, we strive to pave the way for more effective and tailored treatments for ovarian cancer patients.

#5996 New therapeutic approaches in NUT carcinoma: An unmet need.

M. Sanchez-Becerra[1], C. Escudero-Iriarte[2], L. Bigot[1], T. Tian[2], P. Aviles-Marin[3], M. Knetki-Wroblewska[4], S. Oreilly[5], M. Bover[6], J. Benitez-Montanez[7], P. Martin-Martorell[8], S. Italiano[1], B. Besse[1]; [1]Gustave Roussy, Villejuif, France, [2]Vall d'Hebron Institute of Oncology, Barcelona, Spain, [3]Pharmamar, Madrid, Spain, [4]The Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland, [5]The Christie NHS Foundation Trust, Manchester, United Kingdom, [6]Hospital Universitario 12 de Octubre, Madrid, Spain, [7]University Hospital Virgen de la Victoria, Malaga, Spain, [8]Hospital Clinico Universitario de Valencia, Valencia, Spain, [9]Instituto Valenciano de Oncologia, Valencia, Spain, [10]Iatriko Kentro Athinon), Athens, Greece, [11]Institut cancerologie Strasbourg Europe, Strasbourg, France, [12]Hopital Arnaud de Villeneuve-Centre Hospitalier, Montpellier, France, [13]Centre hospitalier universitaire de Nantes, Nantes, France, [14]CHU Clermont-Ferrand, Clermont-Ferrand, France, [15]Centro Oncologico Aliada, Lima, Peru, [16]Hopital Cochin, Paris, France

Background: NUT carcinoma (NC) is a rare, aggressive tumor with poor prognosis and no standard treatment. NC arises from *NUTM1* gene rearrangements, which drive epigenetic dysregulation and uncontrolled proliferation via enhanced RNA polymerase II (RNA-pol II) activity. An analysis of our registry (70 patient) revealed limited benefits from current systemic therapies. Among patients on first-line (26), progression-free survival was modest: immunotherapy (5.4months-mo-, 95%CI 3.6-7.1), chemo-immunotherapy(CTIO) (4.8mo, 95%CI 0.2-8.8), BET inhibitors (4.3mo, 95%CI 1-17.1), and chemotherapy (3.9mo, 95%CI 1.7-52.1). Given Lurbinectedin's (LUR) RNA-pol II-dependent mechanism and its regulation of BRD4, a critical partner of *NUTM1*, we investigated its potential therapeutic value in NC.

Methods: LUR efficacy was assessed in three settings. First, in vitro studies by 4 *BRD4:NUTM1* cell lines treated with escalating doses of LUR for 72 hours, and cell viability evaluated by MTT assays. Second, *in vivo,* with 2 patient-derived xenograft (PDX) models. Finally, under compassionate use, 3 patients with *BRD4:NUTM1*.

Results: NC cell lines demonstrated high sensitivity to LUR, with IC50: 22-122nM. Ongoing PDX model experiments are evaluating in vivo sensitivity. Clinically, a 54-year-old woman with metastatic thoracic NC pretreated with CTIO, showed rapid clinical and radiological response to second-line LUR, with a 3mo duration of response. A 20-year-old man with head and neck metastatic NC pretreated with VDC/IE, had clinical improvement (ECOG-PS, weight gain, and reduced morphine use) after a first cycle (imaging pending for response confirmation). The third patient, recently initiated second-line LUR.

Conclusion: Preliminary results suggest that LUR shows promising activity in NC, both in vitro and in early clinical cases. LUR offers a biologically informed therapeutic strategy in NC. These findings highlight the importance of leveraging tumor biology to guide treatment development for rare and aggressive cancers

#5997 Patient-derived cell line and organoid drug screening identifies synergistic PLK1 inhibitor in combination with senolytic ABT-263 for pancreatic cancer.

Madison Jenner[1], Brian Golitz[1], Yi Xu[2], Xianlu Peng[2], Mohammad Anwar Hossain[3], David Drewry[3], Shawn Gomez[4], Jen Jen Yeh[5]

[1]Department of Pharmacology, University of North Carolina, Chapel Hill, NC,[2]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC,[3]SGC-UNC, University of North Carolina, Chapel Hill, NC,[4]Joint Department of Biomedical Engineering, University of North Carolina at Chapel Hill and North Carolina State University, Chapel Hill, NC,[5]Department of Surgery, University of North Carolina, Chapel Hill, NC

BACKGROUND: Pancreatic cancer (PC) is the 4th deadliest cancer with a 5-year survival rate of only 13%. Chemotherapy remains the standard-of-care to treat PC, but recent retrospective analyses of the Know Your Tumor program found that matched, targeted therapy increases both progression-free survival and overall survival compared to the unmatched chemotherapy group. Therefore, there is a strong need to advance targeted therapy strategies to improve patient outcome in PC.
METHODS: To identify new targeted therapies in PC, we utilized a kinase inhibitor library, KCGS 1.0+, that is composed of clinical kinase inhibitors hitting known targets as well as tool compounds against understudied kinases. We screened KCGS 1.0+ against patient-derived xenograft cell line and organoid models representing both the basal-like and classical subtypes of PC. To assess compound sensitivity, we utilized high-content imaging to monitor cell morphology and CellTiterGlo to determine cell viability.
RESULTS: We found that overall, organoids were more sensitive than cell lines. 11% of KCGS 1.0+ had an IC_{50} of 1μM or less for organoids versus only 2% for cell lines. Several known PC targets sensitive to inhibition were recapitulated such as MAPK, PI3K, and CDK7/9 which provided validation for our screening strategy. A top ranked target was PLK1. Organoids were more sensitive to PLK1 inhibition compared to cell lines and cells of the basal-like subtype showed greater sensitivity compared to classical cells. PLK1 overexpression in a subset of basal-like lines was confirmed by western blot. Previous work has shown PLK1 inhibition induces cellular senescence which promotes therapeutic resistance. In our PC lines treated with PLK1 inhibitor and stained with DAPI, we observed enlarged and irregularly shaped nuclei which is a hallmark of senescence. We confirmed senescence by staining for β-galactosidase in PLK1 treated cells. Since senescent cells upregulate the BCL-2 family, we rationalized we could exploit this dependency and combine PLK1 inhibition with the senolytic BCL-2 inhibitor ABT-263. As expected, inhibition of PLK1 and BCL-2 in combination versus either inhibitor alone resulted in dramatic induction of apoptosis measured by Caspase 3/7 activation.
CONCLUSIONS: Our high-throughput screen of kinases inhibitors has identified PLK1 as a lethal target in PC. PLK1 inhibition induces cellular senescence, a putative escape mechanism. The combination of PLK1 inhibitor with the senolytic, ABT-263 results in greater cell death compared to either inhibitor alone. This combination strategy advances precision oncology and may have significant implications for patients with the more aggressive basal-like subtype in PC.

#5998 Patient-derived organoids and precision medicine: Insights from the PASS-01 clinical trial in PDAC.

Amber N. Habowski[1], Hardik Patel[1], Caitlin Tsang[1], Luce St. Surin[1], Dennis Plenker[1], Fatim M. Kouassi[1], Raditya Utama[1], James Rouse[1], Deepthi Budagavi[1], Grainne M. O'Kane[2], Stephanie Ramotar[2], Anna Dodd[2], Julie Wilson[2], Kenneth H. Yu[3], Faiyaz Notta[2], Robert C. Grant[2], Steven Gallinger[2], Eileen M. O'Reilly[3], Kimberly Perez[4], Andrew J. Aguirre[4], Brian M. Wolpin[4], Dan A. Laheru[5], Daniel A. King[6], Elizabeth M. Jaffee[5], Jennifer J. Knox[2], David A. Tuveson[1]

[1]Cancer Center, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[2]Princess Margaret Hospital, University Health Network, Toronto, ON, Canada,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Dana-Farber Cancer Institute, Boston, MA,[5]Johns Hopkins Medicine, Baltimore, MD,[6]Northwell Health Cancer Institute, New Hyde Park, NY

Pancreatic ductal adenocarcinoma (PDAC) is challenging as most patients are diagnosed at an advanced stage with limited treatment options. Tailoring therapies for individual patients is paramount due to the aggressive nature of the disease. Our work explores patient-derived organoids (PDOs) as *in vitro* tumor models to dissect molecular signatures and conduct pharmacotyping, aiming to enhance precision medicine. In the PASS-01 stage IV PDAC clinical trial, biopsies were collected for molecular correlatives, including establishment of PDOs. Tissue was collected from patients at six institutes across the United States and Canada, highlighting our ability to integrate PDOs into a robust, multi-institutional clinical framework. Most biopsies were collected from liver metastases, followed by primary pancreas tumors, peritoneal, omental, lymph node, lung, and brain metastases. KRAS mutation status determined by ddPCR was used to validate neoplastic cells in the organoid cultures and identify pseudonormal outgrowth. Established PDO lines were subjected to high throughput drug screening for 120+ compounds, comprising both standard-of-care and experimental agents. Subsequently, validated PDO lines were expanded, biobanked and harvested for RNA and DNA sequencing. During the trial, 186 biopsies from 183 enrolled patients were shipped to CSHL for PDO establishment. The overall malignant PDO establishment rate was 50% across biopsy sites and patients. Interestingly, PDOs could be generated more often from patients that rapidly progressed ($p<0.001$). Furthermore, by comparing the characteristics of primary biopsies to established PDO, PDOs were more frequently generated from Moffitt subtype classical (64% establishment) compared to basal (35%), and from those with a $KRAS^{minor}$ imbalance (67% establishment) compared with KRAS wild-type (36%), balanced (58%), and $KRAS^{major}$ imbalance (52%). The average time from tissue receipt to first drug screen data was 65 days, with six PDOs screened in under 30 days. This turnaround time enabled PDO therapeutic data to be presented at monthly molecular tumor boards. Consequently, these data were considered alongside other clinical trial correlates to aid in selection of second-line therapies when patients progressed. PDO pharmacoptyping identified sensitivity that correlated with patient outcomes, notably on gemcitabine/nab-paclitaxel. Patients with responder PDOs to the first-line regimen received had improved overall survival and progression-free survival. Additional transcriptomic and genomic analysis of patients and PDOs are ongoing, including identification of molecular markers of therapy response. Moving forward, we aim to continue incorporation of PDOs and tumor molecular profiling to aid in patient therapy selection. We anticipate this work to be crucial as targeted therapies, including KRAS inhibitors, become mainstream in PDAC care.

#5999 Therapeutic delivery of splice switching oligonucleotides to restore p53 function in liposarcoma.

Rafia Rahat[1], Akila S. Venkataramany[1], Matias Montes[2], Ravi Dhital[3], Kevin Cassady[1], Raphael E. Pollock[4], Dawn S. Chandler[1]

[1]The Ohio State University/ Nationwide Children's Hospital, Columbus, OH,[2]Stanford University, Stanford, CA,[3]Nationwide Children's Hospital, Columbus, OH,[4]The Ohio State University, Columbus, OH

Introduction: Dedifferentiated liposarcoma (DDLPS) is a soft tissue sarcoma characterized by genomic amplification of proto-oncogene MDM2 alongside wildtype P53. Disease progression and poor survival rates in DDLPS are driven by MDM2 overexpression, which negatively regulates the tumor suppressor p53. While small molecules such as Nutlin and its derivatives have been employed to inhibit MDM2-p53 interaction, their significant toxicity presents a major limitation. This clinical challenge highlights the pressing need for alternative approaches to reactivate P53 through less toxic mechanisms.

Alternatively spliced isoform of MDM2, MDM2-ALT1 inhibits full-length MDM2 (MDM2-FL) and stabilizes p53 expression. Additionally, MDM2-ALT1 can prevent the activity of MDMX, another negative regulator of p53, and the resulting p53 activation can sensitize tumor cells to p53-dependent chemotherapies. Thus, targeting MDM2 splicing to enhance MDM2-ALT1 production represents a promising non-toxic intervention strategy for DDLPS. Our laboratory has developed Splice Switching Oligonucleotides (SSOs) that can induce MDM2-ALT1 expression and subsequently reactivate p53 function. We hypothesize that *in vivo* delivery of SSOs to p53 wild-type tumor cells will induce MDM2-ALT1 expression and restore p53 activity to reverse the cancer phenotype.

Results: We have synthesized a 20-mer SSO targeting the SRSF2 binding site in MDM2 exon 11, which functions as a positive regulator of MDM2 splicing. These SSOs prevent SRSF2 binding and promote MDM2-ALT1 production. To enhance both *in vitro* and *in vivo* SSO delivery, we incorporated our SSO sequence in an AAV viral vector to be expressed as an anti-sense RNA and validated its ability to induce MDM2-ALT1 splicing *in vitro* using RT-PCR. The SSO sequence expressed by the AAV vector successfully induced MDM2-ALT1 expression. Next, we will measure the p53 activity and perform proliferation assay to validate that SSO expressed from the AAV viral vectors can reduce cellular proliferation through the activation of p53 tumor suppressive activity. Our goal is to facilitate target specific *in vivo* delivery of this SSO construct using AAV viruses or extracellular vesicles in Xenograft tumor models.

Conclusion: This research presents a novel therapeutic strategy by designing SSOs that reactivate p53 tumor suppressor function and developing methods for target-specific delivery. This innovative strategy could potentially revolutionize treatment for DDLPS and other cancers where p53 function is suppressed by MDM2 overexpression.

#6000 Vabametkib plus lazertinib shows promising antitumor activity in advanced NSCLC with MET amplification resistant to 3rd-gen EGFR-TKIs.

Nirmal Rajasekaran[1], Yeongmun Kim[1], Dawoon Jeong[1], Heesoo Ahn[1], Jeesun Kim[1], Yanghee Kim[1], Sangsuk Lee[1], Sunhye Im[1], Young Kee Shin[2], Jun Young Choi[1], Na Young Kim[1]

[1]ABION Inc., Seoul, Korea, Republic of,[2]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of

MET amplification (METamp) can emerge as a bypass mechanism of resistance to EGFR tyrosine kinase inhibitors (TKIs), occurring in up to 26% of patients with EGFR TKI-resistant EGFR-mutant non-small cell lung cancer (NSCLC). ABN401 (vabametkib), a highly specific MET inhibitor, is undergoing phase 2 trial (NCT04052971) and shows positive response in metastatic NSCLC patients harboring MET exon 14 skipping. Lazertinib, a 3rd Gen EGFR TKI, is effective against EGFR mutations, including common resistance mutations like T790M. To explore the potential of combination therapy of vabametkib and lazertinib in NSCLC patients, we evaluated the cytotoxic response of vabametkib in combination with various EGFR TKIs in NSCLC cell lines. To explore the feasibility of combination therapy in NSCLC patients, we assessed the drug-drug interaction (DDI) potential of vabametkib with various TKIs, focusing primarily on 3rd Gen EGFR TKI, according to *'In vitro drug interaction studies -Cytochrome P450 enzyme- and transporter-mediated drug interactions'* (Guidance for Industry, US FDA). Additionally, the anti-tumor efficacy of vabametkib plus 3rd Gen EGFRTKI was further validated in EGFR-mutant patient-derived xenograft (PDX) models. The combination of vabametkib and 3rd Gen EGFR TKIs demonstrated strong anti-tumor efficacy (96.6% TGI) in EGFR mutants and high MET-amplified PDX model. In contrast, vabametkib alone and 3rd Gen EGFR TKI alone did not show statistical significance. In drug interaction studies using the basic static model and physiologically-based pharmacokinetic (PBPK) modeling, vabametkib did not alter the PK of the co-administered TKIs. Especially ,the potential for DDI between vabametkib and lazertinib was found to be negligible. These findings support the safe and effective use of vabametkib in combination with lazertinib and other TKIs across a broad range of therapeutic applications. These findings support potential clinical benefits of combination therapy of vabametkib and 3rd Gen EGFR TKI in patients with MET-amplified/overexpressed, EGFRm advanced NSCLC with disease progression after 1st line 3rd Gen EGFR TKIs. Consequently, a clinical trial is underway to evaluate the efficacy and safety of combining vabametkib with lazertinib. The ABN401-003 trial, a phase-2 study comprising cohort-2, is an open-label, multicenter investigation aiming to assess the efficacy and safety in patients who have experienced progression on 1st line 3rd-Gen EGFR-TKIs. Cohort-2 consists of three parts: Part 1 (safety run-in), Part 2 (a randomized dose optimization), and Part 3 (a randomized clinical trial comparing the optimal dose of vabametkib in combination therapy with standard of care).

#6001 Unlocking therapeutic potential of rigosertib as a selective therapy for ovarian cancer.

S. Nath[1], S. Claridge[1], G. Lara Granados[2], M. Al Assaad[1], E. Park[2], J.-A. Cavallo[2], M. E. Ackon[2], L. De Boni[2], S. Baker[2], E. Reddy[2], S. V. Blank[2], O. Elemento[1], R. Brody[2], B. D. Hopkins[1]; [1]Weill Cornell Medicine, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Ovarian cancer has a devastating impact. In 2024 it is estimated that there will be 19,680 new ovarian cancer diagnoses and 12,740 fatalities in the United States. Despite advancements in treatment options, 80% of ovarian tumors recur or progress through treatments leading to a five year survival rate of just 50%. To address this unmet need, we employed a functional genomics approach to identify ovarian cancer specific drug sensitivities. Comparing the impact of each of the 117 drugs in our library across 32 cancer cell lines from 11 tumor lineages we identified Rigosertib, a small molecule RAS mimetic, as a selective agent for treatment of ovarian cancer. This ovarian cancer specific sensitivity to Rigosertib was validated in a panel of ovarian cancer cell lines and patient-derived organoids. This sensitivity fits with the observation that ovarian cancer exhibits a high frequency of alterations in both the PI3K and MAPK pathways, both of which can be negatively regulated through the disruption of RAS interactions. Concordantly, while the interplay between these pathways creates an inverse regulatory relationship by which inhibition of either pathway can lead to activation of the other, we observe that in all of the ovarian lines tested that treatment with Rigosertib leads to increases of MTOR signaling as indicated by phosphorylation of S6 both in vitro and in vivo. Subsequent combination drug screening revealed a cooperative effect between rigosertib and PI3K inhibitor (taselisib), suggesting that combining rigosertib with taselisib which restricts mTOR activation enhances therapeutic efficacy. This combination showed synergy across ovarian cancer cell lines, organoids, and xenograft models, with xenograft studies showing a significant reduction in tumor burden. These findings highlight the potential of rigosertib, especially when paired with PI3K inhibitors, to target the unique mutational landscape of ovarian cancer, offering a promising direction for more effective treatments.

#6002 Tyrosine kinase inhibitor (TKI) plus PD-1 blockade in TKI-responsive MSS/pMMR metastatic colorectal adenocarcinoma (mCRC): Results of a multicenter, phase II trial (TRAP).

J. Zhang[1], Q. Dong[1], Y. Wang[1], Y. Diao[1], X. Cui[2], L. Man[3], J. Zhang[4], Y. Zhang[5], T. Wu[6], T. Chen[7], Y. Dong[3], J. Zhang[8], Y. Huang[9], S. Wang[10];

Background: There is an unmet need in immunotherapy for patients (pts) with MSS/pMMR mCRC. PD-1 blockade combined with antiangiogenic therapy has synergistic effects and has shown clinical benefits in these pts in several studies. TRAP (NCT04483219) aims to explore the efficacy and safety of antiangiogenic TKIs combined with PD-1 blockade in TKI-responsive MSS/pMMR mCRC pts refractory to standard treatment.
Methods: Eligible pts were given 1 cycle of TKIs (fruquintinib 5mg or regorafenib 120mg, d1-21, q4w) and grouped by tumor response according to RECIST v1.1: arm A: reduction of target lesion to CR, PR or shrunken SD, or cavitation in metastatic lung lesions, or decrease in the density of liver metastatic target lesions ≥15%; arm B: enlarged SD; arm C: PD. Then arm B pts were given another cycle of TKIs and grouped again. Pts in arm A then received TKIs plus anti-PD-1 antibody (toripalimab 240mg, or sintilimab 200mg, i.v.gtt, q3w, until PD or up to 2 years), pts in arm B continued with TKIs until PD. The Simon 2-stage design tested the null 9-months (m) PFS rate of 27.1% vs. 55% (power = 0.90; α = 0.05). A total of >10 pts reaching ≥ 9-m PFS in 25 pts receiving TKI plus anti-PD-1 antibody is required to reject null hypothesis.
Results: As of Sep 16, 2024 (data cutoff), 58 eligible pts were enrolled. Median age, 60 (34-75); male, 56.9%; ECOG PS 1, 96.6%; KRAS mutation, 48.3%; median prior regimens, 2 (1-4); prior anti-VEGF, 73.7%; prior anti-EGFR, 28.1%. 25 pts entered arm A and 29 entered arm C. Baseline characteristics of arm A were generally consistent with the overall population. In arm A, ORR was 20.0% (95%CI, 6.8%-40.7%). Median PFS was 11.5m (95% CI, 7.31-18.9), 6-m, 9-m and 12-m PFS rates were 87.1% (95% CI, 74.4%-100%), 58.1% (95% CI, 40.4%-83.4%) and 42.6% (95% CI, 25.7%-70.6%), respectively. At median follow-up of 31.1m (95% CI, 29.0-NA), median OS was 24.7m (95% CI, 17.0-NA), 12-m, 24-m and 36-m OS rates were 82.4% (95% CI, 68.1%-99.7%), 53.3% (95% CI, 35.6%-79.6%) and 35.5% (95% CI, 19.2%-65.5%), respectively. Median PFS and median OS were numerically longer in fruquintinib versus regorafenib treated pts (13.21m [95%CI: 7.31-NA] vs 8.95m [95%CI: 6.82-NA], p=0.38; 29.0m [95%CI: 17.0-NA] vs 19.5m [95%CI: 16.9-NA], p=54) and in KRAS wild-type and KRAS mutant pts (13.21m [95%CI: 8.95-NA] vs 7.31m [95%CI: 4.85-NA], p=0.21; 26.6m [95%CI: 17.9-NA] vs 15.0m [95%CI: 14.2-NA], p=0.24). The most common treatment-related adverse events (TRAEs) (total; Grade ≥3) were hand-foot skin reaction (43.8%; 18.8%), hypothyroidism (37.5%; 6.3%), hypertension (31.2%; 25.0%) and proteinuria (31.2%; 6.3%). No treatment related death was observed.
Conclusions: TKIs combined with PD-1 blockade has shown encouraging efficacy with acceptable toxicities in MSS/pMMR mCRC pts responsive to TKI treatment. The regimen could be a preferred approach in pretreated MSS/pMMR mCRC.

CLINICAL RESEARCH: Therapeutic Antibodies, Including Engineered Antibodies 2
Poster Session

#6006 The discovery and development of a CD3 agonistic single domain antibody to accelerate the development of CD3 T cell engager multi-specific antibodies.

Yu Liang[1], Yingyu Li[2], Yi Zhou[2], Cheng Luo[2], Xin Wang[2], Yang Xin[2], Shishuai Shao[2], Tingting Yang[2], Mingzhu Shao[2], Jin Chen[2], Ziyu Chen[2], Sujuan Hong[2], Hai Huang[2], Cheng Chen[2], Hui Wang[2], Miaomiao Song[2], Yuanxin Zhang[2], Shuai Yang[3], Xiaojie Tu[3], Sujuan Wang[3], Li Chen[2]

CD3 T cell engager (TCE) bispecific antibodies (BsAbs) is a clinically well validated and dominant therapeutic modality of approved bispecific antibodies, contributing to 10 out of 14 marketed BsAb drugs. To develop a TCE BsAb with desired potency and safety profile, a CD3 agonist Ab with appropriate potency and ideal developability is critical. Currently, all approved TCE BsAbs are based on a CD3 agonist Ab in the format of conventional monoclonal antibodies containing both light chain and heavy chain, which may limit the flexibility in multi-specific antibody construction and development. In contrast, considering these limitations, single domain antibodies (sdAb, or VHH) are highly favored in the construction and development of bi- or multi-specific antibodies, mainly due to their smaller size, good stability and developability. Therefore, to ease the development of TCE multi-specific antibodies, we set forth to discover an agonist sdAb of CD3. We first identified a parental CD3 sdAb from an immunized camel phage display library. Through successful humanization and affinity maturation, we obtained a series of variants with a spectrum of binding affinity to CD3 and potency in activating T cells. These CD3 sdAb variants were then used to construct a series of bi- or multi-specific antibodies with ease and flexibility, no matter the TAA (tumor associated antigen) arm is a conventional monoclonal antibody (CD20, HER2, etc.), or sdAb (GPRC5D, etc.). The optimization process focused on fine-tuning the affinity, valency, and geometry of both the CD3 arm and TAA arm. This resulted in multi-specific antibodies with enhanced yield and developability, potent tumor cell killing capabilities, and with reduced cytokine release *in vitro* comparing to clinical benchmark antibodies. In preclinical in vivo studies, these TCE multi-specific antibodies showed favorable pharmacokinetics (PK) and safety profiles along with robust tumor growth inhibition. In summary, we have successfully discovered and developed a series of CD3 agonist sdAbs, showing a spectrum of affinity to CD3 and potency in T cell activation. These CD3 sdAbs have demonstrated a great potential in supporting and accelerating the development of diverse TCE multi-specific antibodies with enhanced ease and flexibility.

#6007 Neoadjuvant pepinemab enhances DC function associated with mature tertiary lymphoid structures and activity of immune checkpoint blockade in patients with metastatic melanoma.

Elizabeth E. Evans[1], Crystal Mallow[1], Terrence L. Fisher[1], Ayana Ruffin[2], Elaine Gersz[1], Maria Scrivens[1], Elizabeth Tuttle[1], Vuyani Matsenjwa[1], Ellen Giampoli[3], Manoj Chelvanambi[4], Brenda Melendez[4], Florentia Dimitrou[4], Alexander J. Lazar[4], Jennifer Wargo[4], Michael Lowe[2], Chrystal M. Paulos[2], Gregory B. Lesinski[2], Maurice Zauderer[1]

[1]Vaccinex, Inc., Rochester, NY,[2]Winship Cancer Institute at Emory University, Atlanta, GA,[3]University of Rochester, Rochester, NY,[4]University of Texas MD Anderson Cancer Center, Houston, TX

Neoadjuvant treatment with immune checkpoint blockade (ICB) improves clinical benefit relative to adjuvant therapy in multiple types of cancer. Window of opportunity studies employing neoadjuvant treatment permit integrated assessments of pathologic response along with assessments of treatment effects and mechanisms of resistance in the tumor microenvironment. Resistance mechanisms including immune exclusion and myeloid suppression have been shown to be regulated by semaphorin 4D (SEMA4D) in preclinical and clinical studies. A neoadjuvant window of opportunity study was designed to evaluate activity and efficacy of pepinemab, SEMA4D blocking antibody, combined with nivolumab (nivo) and/or ipilimumab (ipi) in patients with surgically resectable metastatic melanoma. Consenting patients with resectable stage III melanoma received neoadjuvant nivo alone, pepinemab/nivo, pepinemab/ipi, or pepinemab/nivo/ipi (NCT03769155). Patients underwent surgical resection following six weeks of immunotherapy. In separate studies conducted at University of Texas MD Anderson Cancer Center, patients received neoadjuvant treatment with nivo or nivo/ipi. Surgical tissue underwent high dimensional immune analysis using multiparametric flow cytometry, multiplex immunohistochemistry and Nanostring RNAseq and GeoMX imaging. Pepinemab in combination with nivo (either alone or with ipi) significantly increased tumor-infiltrating B cells and CD4+ T cells within surgical tissue, versus surgery or nivoalone. Compared to nivo alone, pepinemab plus nivo significantly influenced REACTOME pathways involved in degradation of extracellular matrix and signaling by Rho GTPases. Significant changes in DC activation markers including Flt3 ($p=0.03$) and cDC2 marker CD163 ($p=0.0071$), and the the Flt3/Wnt pathway correlated with pepinemab treatment and pathologic response. Multiplex IHC revealed tertiary lymphoid structures (TLS) within the tumor bed following treatment and were increased in patients who did not suffer tumor recurrence. TLS identified in biopsies of patients treated with pepinemab in combination with ICB were larger and more mature, containing high density of activated DCs and follicular DCs, follicular B cells, and Tfh cells expressing CXCR5, characteristic of germinal centers. Mature TLS were significantly increased in the triple combination compared to doublets or nivo alone. Increased density and maturity of TLS and increased T cell clonality correlated with pepinemab treatment and clinical benefit. All patients receiving triple combination therapy (8/8) were recurrence-free at 24 months with mature TLS in the resected tumors (6/6). Pepinemab represents a novel strategy to boost dendritic cell infiltration, activation, and organization of functional TLS to overcome limitations of ICB.

#6009 BGB-B2033, a novel 4-1BB/GPC3 bispecific antibody, exhibits potent in vitro and vivo antitumor activity in preclinical models.

Jie Li[1], Xi Yuan[2], Ruyue Ji[1], Chang Song[2], Yanwen Ma[2], Yuan Zhao[2], Yue Cao[2], Xinyi Liang[2], Yilu Zhang[2], Jingjuan Sun[1], Xiangli Ma[1], Lingmin Zheng[1], Beibei Jiang[2], Xiaomin Song[2], Yu Shen[1], Lai Wang[2]

4-1BB (CD137) is a key costimulatory immunoreceptor expressed on activated T-cells and natural killer cells, making it a promising therapeutic target in cancer. Glypican-3 (GPC3), a membrane-bound heparan sulfate proteoglycan, is overexpressed in approximately 70% to 80% of hepatocellular carcinomas, and extensively expressed in a variety of other solid tumors. GPC3 is recognized as an attractive drug target in precision cancer therapy as it is highly expressed in multiple tumors while minimally expressed in adult normal tissues. BGB-B2033 is a novel immunoglobulin G (IgG)-based bispecific antibody targeting 4-1BB and GPC3 and is under clinical development for the treatment of advanced or metastatic solid tumors in humans. BGB-B2033 binds to its target proteins with high specificity and affinity. Potent and GPC3-dependent functional activities were demonstrated using peripheral blood mononuclear cell (PBMC)-based immune cell activation and cytotoxicity assays. In humanized 4-1BB knock-in mice bearing human GPC3-expressing tumors, BGB-B2033 exhibited potent, dose-associated single-agent efficacy in Hepa1-6/hGPC3 orthotopic tumor model, as well as synergistic antitumor activity in combination with antiPD-1 antibody.
In conclusion, BGB-B2033 is a potent therapeutic agent with strong anti-tumor activity in both in vitro and in vivo studies. The phase 1 study of BGB-B2033, alone or in combination with Tislelizumab is ongoing (NCT06427941).

#6010 Evaluation of BsABN501: A novel T cell engager targeting CLDN3-positive solid tumors.

Saehyung Lee[1], **Sangin Lee**[1], Sunghyun Hong[1], Jaemun Kim[1], Jae Choi[1], Hobin Yang[2], Sungyoul Hong[3], Na Young Kim[1], Jun Young Choi[1], Young Kee Shin[4]

[1]ABION Inc., Seoul, Korea, Republic of,[2]College of Pharmacy, Kyungsung University, Busan, Korea, Republic of,[3]College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of,[4]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Claudin 3 (CLDN3) plays a critical role in tumor initiation, progression, and metastasis and is overexpressed in multiple solid tumors, including breast, ovarian, and small cell lung cancers. Previously, ABN501 was developed as a fully human monoclonal antibody targeting CLDN3, demonstrating strong anti-tumor activity and a favorable safety profile. In this study, we established the proof of concept for BsABN501, a CD3 T cell engager, utilizing the anti-CLDN3 sequence derived from the novel antibody ABN501. BsABN501 specifically binds to CLDN3 while concurrently targeting CD3 on T cells, thereby initiating T cell-mediated cytotoxicity (TDCC) against tumor cells. *In vitro* assays demonstrated that BsABN501 effectively activates peripheral blood mononuclear cells, resulting in potent TDCC against CLDN3-positive cancer cell lines. Notably, BsABN501 exhibited robust cytotoxic activity against CLDN3-expressing tumor cell lines compared to controls. Cytokine release assays further confirmed tumor-specific activation of T cells. Additionally, *in vivo* studies using xenograft mouse models bearing CLDN3-expressing tumors showed that BsABN501 induced significant tumor regression, highlighting its robust anti-tumor activity. In summary, BsABN501 represents a novel and promising therapeutic strategy for the treatment of CLDN3-positivie solid tumors by effectively recruiting and activating T cells to enhance TDCC. Moving forward, we aim to optimize the CD3 sequence and format of BsABN501 to further improve its anti-cancer efficacy and safety, paving the way for its development as a targeted immunotherapeutic for CLDN3-expressing malignancies.

#6011 Neoantigen peptide-loaded anti-CD40-spycatcher antibody as a novel cancer vaccine platform.

Xiaoying Cai[1], Dahee Jung[1], Seung-Oe Lim[2], Steve Seung-Young Lee[1]

[1]Pharmaceutical Sciences, University of Illinois at Chicago, Chicago, IL,[2]Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN

Precision cancer therapy opened up an attractive strategy by therapeutic vaccines targeting neoantigens. Neoantigens are immunogenic and HLA-bound epitopes capable of activating helper and cytotoxic T lymphocytes and not subject to immunological tolerance. However, personalized peptide-based cancer vaccines still have the limitations to formulate and deliver. For example, most vaccine technology was initially based on the use of adjuvants (e.g., alum), which only provides moderate therapeutic effects. To address these issues, we utilize the engineered anti-CD40 agonistic antibody expressing Spy-Catcher003 (αCD40-SC) as a novel antigen presenting cells (APCs)-targeted peptide vaccine delivery platform for effective cancer immunotherapy. Since targeting and activating the CD40 receptor on APCs via anti-CD40 agonistic antibody has been shown to elicit superior T cells priming and boost antigen-specific CD8+ T. Besides, the use of SpyCatcher003, which is a 113-residue protein with reactive Lys31, could trigger spontaneous and irreversible amidation reaction with SpyTag003. SpyTag003/SpyCatcher003 is a protein coupling approach, which can form an intermolecular isopeptide bond between Lys31 and Asp117. Moreover, the protein pair can react with a rate of 5.5×10^5 M^{-1} s^{-1}, which is helpful for potential therapeutic application.Therefore, we hypothesize the efficient and specific delivery, accomplished via SpyCatcher003-expressed anti-mouse CD40 agonistic antibody and SpyTag003-conjugated neoantigen peptide, will ensure the present of neoantigens to T cells and elicit robust and durable specific CD8+ T cell response. Our goal is to directly deliver neoantigen peptide-loaded αCD40-SC to APCs in draining lymph nodes (dLN) as a therapeutic vaccine.

#6012 PSMA x CD3 T-cell engagers show preclinical efficacy for the treatment of prostate cancer.

Peter Bergqvist, Alaa Amash, Kelly Bullock, Lauren Clifford, Patrick Farber, Jessica Fernandes Scortecci, Ingrid Knarston, Tallie Kuang, Ahn Lee, Amy Lee, Cindy-Lee Crichlow, Franco Li, Matt Mai, Stephanie K. Masterman, Janice Reimer, Eduardo Solano Salgado, Raffi Tonikian, Christopher Williamson, Allison Goodman, Lindsay DeVorkin

AbCellera, Vancouver, BC, Canada

Prostate-specific membrane antigen (PSMA) is a clinically validated target in metastatic castration-resistant prostate cancer (mCRPC) that is being prosecuted by a number of different modalities in the clinic. CD3 T-cell engagers (TCEs) targeting PSMA have shown promise in preclinical and early clinical studies, but generating a molecule with a therapeutic window that enables efficacious dosing in patients has been a barrier to development. Here, we present preclinical *in vitro* and *in vivo* data on novel PSMA x CD3 TCEs developed using our TCE platform.

To address the challenges of TCE development for mCRPC, we screened and identified hundreds of diverse PSMA- and CD3-binding antibodies with different affinities, epitopes, and biophysical properties using our proprietary antibody screening platform. From there, we engineered large panels of Orthomab^{TM} PSMA x CD3 bispecifics, varying TCE parameters that impact function. Detailed *in vitro* functional assessment and biophysical characterization assays were conducted to identify antibodies with promising functional and developability profiles.

IgG-like bispecifics comprised of PSMA- and CD3-binding arms with finely tuned affinity for each target were generated. PSMA binding epitopes were assessed using cryo-electron microscopy, and TCE function was measured using *in vitro* T cell co-culture assays. TCEs binding membrane-proximal epitopes drove optimal immune synapse formation, leading to potent killing of cells expressing high (C4-2) and low (22Rv1) levels of PSMA with EC_{50} values in the picomolar range. Molecules show target-dependent T-cell activation with no killing of a low PSMA-expressing cell line (DU-145) *in vitro*. Further, select molecules show robust $CD4^+$/$CD8^+$ T-cell activation and proliferation in the presence of target cells, as well as sustained killing of target cells over time in a repeat challenge assay. Finally, molecules evaluated *in vivo* in a humanized C4-2 xenograft mouse model demonstrated anti-tumor activity and a favorable IgG-like pharmacokinetic profile.

In summary, we engineered and assessed hundreds of PSMA x CD3 TCEs at high-throughput, conducted detailed *in vitro* functional and biophysical characterization, and identified molecules with promising preclinical *in vivo* efficacy that supports further evaluation and development towards the clinic.

#6014 A new generation of Tumor Microenvironment Activated Therapeutic (T-MATE) targeting solid tumors.

Xiaoya Ma, Yang Zhou, Xianzhi Jiang, Juy-Yi Chen, Rodrigo Rivera, Randall Bettman, Thanthar Aye, Ashley Navarro, Daniel Tong, Ricky Cheng, George Wu, **Aude Segaliny**, Yonglei Shang

Amberstone Biosciences Inc, Irvine, CA

T-cell engagers (TCEs) have emerged as potent immuno-therapies, demonstrating significant success in treating hematologic cancers and showing promising clinical benefits in solid tumors. However, their therapeutic potential is often limited by severe side effects, primarily due to cytokine release syndrome and on-target/off-tumor toxicities. To address these challenges, we leveraged Amberstone's Tumor-Microenvironment Activated ThErapeutic (T-MATE) technology to develop bispecific and multispecific TCE antibodies with strong potency in diseased tissues, specifically in the acidic tumor microenvironment, while exhibiting minimal activity in healthy tissue under normal physiological conditions. We have discovered and engineered a set of proprietary pH-dependent CD3 antibodies with varying affinities and binding kinetics. Due to the pH-induced conformational change, TCE T-MATEs offer a wide therapeutic index when paired with antibodies targeting several well-studied tumor associated antigens. Here, we demonstrate the potential of the T-MATE platform by targeting clinically validated tumor associated antigens that are widely expressed in healthy tissues, such as TROP2, FOLR1 and EGFR. All T-MATE TCEs were tested *in vitro* through various cell-based assays, including pH-dependent binding and T-cell-dependent cytotoxicity, and *in vivo* using xenograft models in humanized NSG mice, across several cancer indications (ovarian, endometrial, colon, gastric, pancreatic, breast, and non-small cell lung cancers). All TROP2, FOLR1 and EGFR-targeting TCEs showed robust pH-selectivity in target binding and exhibited potent T cell-dependent cytotoxicity (EC_{50} ~ 1-100 pM) against antigen-expressing tumor cells under acidic tumor conditions, while with minimal activity under physiological conditions. In preclinical xenografted tumor models, these TCE T-MATEs induced significant tumor regression. In Non-Human Primate pharmacology and toxicology studies, TCE T-MATEs exhibited exposure comparable to clinically validated TCEs, with negligible cytokine release and a favorable toxicity profile. These preclinical results confirm that the T-MATE platform offers a superior therapeutic margin, enabling the targeting of widely expressed tumor antigens that were previously considered intractable. Beyond oncology, the T-MATE platform holds promise for a broad range of indications, offering an optimal balance of safety and potency for patients with unmet medical needs. **Acknowledgements:** Ms. Lingrong Zhang for her vivarium support.

#6015 Unveiling RYK: A breakthrough tumor-associated antigen in lymphoma treatment.

Vallone[1], Victor Navarro-Tableros[2], Elisabetta Bolli[3], Samir Mouhissine[4], Riccardo Moia[4], Candida Vitale[5], Marta Coscia[5], Gianluca Gaidano[4], Brian J. Lannutti[6], Katti A. Jessen[6], Tiziana Vaisitti[1], Silvia Deaglio[1]

[1]Department of Medical Sciences, University of Turin, Turin, Italy,[2]2i3T, Societa Per La Gestione Dell'incubatore Di Imprese e Per Il Trasferimento Tecnologico, University of Turin, Turin, Italy,[3]Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy,[4]Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy,[5]Department of Molecular Biotechnology and Health Sciences and AOU Citta della Salute e della Scienza, University of Turin, Turin, Italy, [6]Solve Theraputics, Inc, San Diego, CA

This work explores expression and therapeutic potential of RYK, a ROR-family receptor tyrosine kinase (RTK) member, in chronic lymphocytic leukemia (CLL) and Richter syndrome (RS). RYK belongs to a family of conserved proteins acting as alternative receptors/co-receptors of Wnt ligands. While the best-known member of the family, ROR1, has been targeted with various therapeutic modalities, little is known for RYK. RNA-sequencing data shows that RYK is expressed in CLL, RS, diffuse large B-cell lymphoma, and Burkitt's lymphoma primary cells and malignant B cell lines of different developmental stages, as also confirmed both at mRNA and protein levels. Like ROR1, RYK expression was restricted to cancer cells, with undetectable levels in B, T, or NK cells, obtained from healthy donors. Given this pattern of expression, an antibody drug conjugate (ADC) against RYK, SLV-404, was generated, consisting of a chimeric antibody targeting the extracellular portion of the receptor, a cleavable linker, and a cytotoxic agent, Dxd, an inhibitor of the topoisomerase I (TOP1) with a target drug-to-antibody ratio (DAR) of eight. Expression data showed that TOP1 is mainly expressed in cancer cells and tumor cells are uniquely sensitive to its inhibition.We then investigated in vitro apoptotic responses following SLV-404 treatment. After 72/96 hours of exposure, a marked apoptotic induction was observed by conventional flow cytometry assays (Annexin V/PI staining) and at the biochemical level by Western blot analysis of PARP1/Caspase 3 cleavage, XIAP reduction, and histone H2A.X phosphorylation. SLV-404 effects were then evaluated in vivo exploiting four established RS patient-derived xenograft models (RS-PDX) and a cell line-derived xenograft model, U-RT1. RS cells were initially injected subcutaneously and left to engraft. Mice were then randomly assigned to two different groups: vehicle (phosphate-buffered saline) and SLV-404 (10 mg/kg), all treated by intravenous administration (iv), once a week for 3 weeks in total. SLV-404 significantly extended animal lifespan of 61 days (P<.04), 36 days (P<.02), 68 days (P<.02), 97 days (P<.01) and 47 days (P<.01), respectively for RS1316, RS9737, IP867/17, RS1050 and U-RT1.We then moved to a systemic model of RS, with leukemic cells injected iv and left to engraft 14 days before administering treatment once a week for 3 weeks in total. Disease spread was then evaluated by flow cytometry analysis of target organs, using tumor-specific human markers. Preliminary data confirm that treatment with SLV-404 resulted in dramatic decreases in RS cells to almost undetectable levels in all compartments, reaching statistical significance in spleen and bone marrow (P<.0001).Together, these results suggest that RYK is a novel tumor-associated antigen, making it a suitable ADC target. Moreover, we demonstrate the therapeutic potential of a novel RYK-based ADC for the treatment of RS.

#6016 AP402, a bispecific antibody targets p95HER2 and CD137, shows a potent antitumor activity in p95HER2-expressing cancers.

Po-Lin Huang, Hsin-Ta Hsieh, Hung-Tsai Kan, Ching-Hsuan Hsu, Kuan-Ming Huang, Hsin-Yu Chen, Jhong-Jhe You

AP Biosciences, Inc, Taipei, Taiwan

Introduction: p95HER2 is the extracellular domain-truncated form of HER2 receptor while preserves the intracellular tyrosine kinase activity to support tumor growth. p95HER2 was found in 30 to 40% HER2-positive breast cancer patients and associated with a more aggressive phenotype and worse prognosis. Due to the lack of extracellular domain, p95HER2 has been recognized as the potential mechanism of trastuzumab-resistance. The unmet need for trastuzumab-resistant patients and exclusive expression in cancerous tissues make p95HER2 as an ideal therapeutic target. Here, AP402 was designed to coordinate two dominant effector cells, natural killer and T cells, against p95HER2-positive cancers.

Experimental procedures: AP402 bispecific antibody was generated by conjugating CD137 single-chain variable fragment (scFv) to the heavy chain C-terminal of p95HER2 antibody (human IgG1). The affinity and specificity of p95HER2 antibodies were checked by biolayer interferometry (BLI) and flow cytometry, respectively. ADCC and ADCP activities of AP402 were determined by NK cells and monocyte-derived macrophages, respectively. AP402-mediated activation of T cells were studied by coculturing T cells with p95HER2-transgenic cells. Antitumor activity of AP402 was studied using humanized mice inoculated with p95HER2-transgenic cancer cells and p95HER2-positive breast cancer patient-derived xenograft (PDX). Safety of AP402 was determined by the 4-week toxicity study in monkeys.

Results: 1. AP402 showed the superior affinity (K_D 0.34 nM) to p95HER2 with the minimal crossreactivity to HER2 (K_D 38.4 nM). 2. AP402 elicited ADCC robustly in p95HER2-NCI-H292 (EC_{50} 0.006 nM) and p95HER2-MDA-MB-231 cells (EC_{50} 0.043 nM), while in SKBR3 cells to a minimal level, but not in the wildtype and CD137-HEK293 cells at all. 3. ADCP was induced by AP402 in macrophages cocultured with p95HER2-NCI-H292 cells. 4. Compared to the mono or combinational treatment of parental monoclonal antibodies, AP402 boosted the most vigorous T cell activation, which intensity corresponded to the expression levels of p95HER2 on cancer cells. 5. AP402 showed the potent antitumor activity in p95HER2-MDA-MB-231 (TGI 92.3%) and p95HER2-NCI-H292 (TGI 73.6%) tumor-bearing mice dosed with 0.4 mg/kg, BIW. Antitumor activity was also shown in mice inoculated with p95HER2-positve breast cancer PDXs (TGI 59%). 6. In monkey Tox study, the exposure of AP402 was approximately dose proportional in doses 25-100 mg/kg with $t_{1/2}$ ~108 hrs. NOAEL: 100 mg/kg.

Conclusions: Nonclinical studies demonstrated that AP402 is efficacious in triggering the effector functions of NK and T cells in vitro and blocking the growth of p95HER2-positive breast and lung tumors in vivo. AP402 was well tolerated in repeat doses up to 100 mg/kg in monkeys.

#6017 L19-mTNF as a novel synergistic combination partner to enhance the efficacy of CD3-based bispecific antibodies in colorectal cancer.

Gudrun Thorhallsdottir, Ramon Benz, Emanuele Puca, Mattia Matasci, Dario Neri, Abdullah Elsayed

Philochem AG, Zurich, Switzerland

T-cell-engaging bispecific antibodies (TCBs) are an expanding modality in immunotherapy, designed to redirect T-cell cytotoxicity toward tumor cells by cross-linking them with tumor-associated antigens[1]. While TCBs have shown significant efficacy in hematological malignancies, their success in solid tumors remains limited[2]. This is likely due to multiple factors, including the low number of T cells in the tumor microenvironment and the presence of immunosuppressive conditions that hinder T-cell activity[3, 4]. In this study, we evaluated the potential of three clinical-stage antibody-cytokine fusion proteins as combination partners to enhance the efficacy of a CEA-targeting CD3-based TCB in a challenging solid tumor model. Using the murine colorectal cancer cell line MC38-CEA, we combined the TCB with L19-mTNF, L19-mIL12, and L19-mIL2. Among these, L19-mTNF demonstrated remarkable synergistic anti-tumor activity, achieving complete tumor regression in treated mice, a significant improvement compared to the limited activity of either agent alone.Our findings suggest that mTNF enhances TCB activity by transforming "cold" tumors into "hot" ones. L19-mTNF appears to increase vascular permeability within the tumor microenvironment, improving T-cell and TCB infiltration and amplifying the immune response.These results highlight the novel potential of L19-mTNF as a powerful combination partner for CD3-based TCBs, offering a promising strategy to overcome the challenges of solid tumor immunotherapy. This preclinical work provides a strong rationale for future clinical translation, underscoring the importance of integrating cytokine-based therapies to maximize TCB efficacy in solid malignancies.

#6019 AI-guided development of CAR-T drugs.

C. Cheng[1], Y. Ge[2], E. Xie[1], H. Wang[1], **X. He**[1], H. Zhu[2];
[1]Oricell Therapeutics Co.,Ltd., Shanghai, China, [2]Shanghai Key Laboratory of Maternal Fetal Medicine, Shanghai Institute of Maternal-Fetal Medicine and Gynecologic Oncology, Shanghai First Maternity and Infant Hospital, School of Medicine, Tongji University, Shanghai, China

Background: Chimeric Antigen Receptor T-Cell (CAR-T) therapy is an innovative cancer treatment that involves genetically engineering a patient's T-cells to recognize and attack cancer cells.Artificial Intelligence (AI) is playing an increasingly important role in drug development, accelerating drug discovery, optimizing treatment protocols, and enhancing efficacy.Building on the in-depth research of Nobel laureates Demis Hassabis and John Jumper in structural prediction, AI technology has been combined with antibody library techniques. Under the guidance of AI, antibodies targeting the second epitope of FOLR1 were successfully identified from hundreds of candidates.
Methods: In this study, we performed phage display panning for FOLR1, a tumor target, followed by monoclonal identification and sequencing. This resulted in a large number of antibodies targeting the same epitope. Due to the structural characteristics of FOLR1, most antibodies bind to its folate binding site. To obtain antibodies targeting different epitopes and enhance therapeutic efficacy, we combined AI-guided selection with antibody library screening. We conducted NGS sequencing of the antibody library and utilized AI for extensive modeling analysis.
Results: Through next-generation sequencing (NGS) of the antibody library, we obtained a large number of sequences distinct from those obtained through monoclonal sequencing. We modeled and docked these antibodies to predict their targeted epitopes. After analyzing over 300 antibodies with the highest binding potential, we identified one antibody that targets a different epitope. This antibody demonstrated significant binding efficacy and does not compete with our previously identified candidate antibodies.
Conclusions: By integrating AI technology with our antibody library, we successfully identified a second epitope-targeting antibody against FOLR1. This antibody exhibits properties comparable to those obtained through wet lab experiments. As AI technology continues to advance, its role in antibody development will become increasingly significant, transitioning from AI-assisted drug development to AI-guided drug development. Finally, we extend our heartfelt gratitude to Demis Hassabis and John Jumper for their contributions to AI research. Without their foundational work, it would have been very difficult for us to achieve these results.

#6020 Quantitative measurement of Fc-mediated ADCC & ADCP activity of therapeutic antibodies using a robust, universal cell-based assay platform.

Alpana Prasad, Surekha Bonasu, Gaurav Agrawal, Jane E. Lamerdin

Eurofins DiscoverX, Fremont, CA

The clinical success of a broad range of biologics has driven the development of diverse immunomodulatory agents with unique mechanisms of action (MOA) targeting novel antigens. Regulatory guidelines now require evaluation of antibody effector functions, such as antibody-dependent cell-mediated cytotoxicity (ADCC), particularly for lot-release assays that measure immune cell-mediated killing directly rather than surrogate endpoints. Additionally, antibody-dependent cellular phagocytosis (ADCP) has become a key MOA, especially for IND-enabling studies involving antibodies with modified Fc regions. To address these needs, Eurofins DiscoverX® developed the KILR® cytotoxicity assay platform that accurately measures the killing of antigen-expressing target cells in co-culture with immune effector cells. This dye-free, radioactivity-free platform leverages the validated Enzyme Fragment Complementation (EFC) technology and supports various immune-mediated killing mechanisms, including ADCC, CDC, ADCP, and T-cell redirection. Here, we showcase the KILR platform's versatility across multiple antigens (e.g., HER2, CD20, CD19) and effector cell types. Combined with engineered KILR CD16 Effector Cells, the KILR platform provides robust, reproducible assay performance necessary for testing in the quality-controlled environment for commercial lot release. This platform also quantifies ADCP cost-effectively, simplifying traditional FACS or imaging-based workflows. To ensure assay reproducibility, many KILR target cell models are now available in an assay-ready format, with phase-appropriate qualification data supporting their suitability for potency and screening applications.

#6021 Development of JLF025, an anti-mesothelin T cell engager optimized for efficacy and safety.

Xiaodong Xiao[1], Zhidi Pan[2], Junjun Liu[3], Yali Yue[3], Fengzhi Li[4], Shusheng Wang[1], Haiqiu Huang[1], Kaiyong Yang[1], Zhangyi Song[1], Zhenyu Wang[4], Hua Jiang[1], Yueqing Xie[1], Jianwei Zhu[1]

[1]Jecho Laboratories, Frederick, MD,[2]Jecho Institute, Shanghai, China,[3]SJTU, Shanghai, China,[4]Jecho Biopharmaceuticals, Tianjin, China

Mesothelin (MSLN) is a GPI-anchored glycoprotein that is overexpressed in several solid tumors including mesothelioma, pancreatic cancer, ovarian cancer, non-small cell lung cancer, biliary cancer, and triple negative breast cancer with limited expression in normal tissues. This expression profile makes MSLN an attractive target for cancer immunotherapy. m912 antibody that has demonstrated positive effect in CAR T format in clinics is derived from a fully human Fab library. It has a 100% germline sequence, but its binding affinity is relatively poor (KD around 60 nM). To expand applications of the m912 to include the T-cell engager format, we used phage display to improve m912 affinity, and further, developed a bivalent T-cell engaging bispecific format by fusing the humanized OKT3 scFv to the C-terminus of the light chain. When the final lead with a KD of 1.4 nM was incorporated into this format, the resulting bispecific antibody JLF025 showed high potency in T-cell activation and T-cell dependent cytotoxicity in vitro. Interestingly, the cytotoxicity induced by MSLN-490 was not affected by soluble MSLN at a level found in cancer patient sera. Using a co-grafting mouse model in which a mixture of MSLN-positive NCI-N87 cancer cells and human PBMCs was co-injected with JLF025, we demonstrated that JLF025 exhibited a remarkable tumor suppressing activity. The potent tumor suppressing activity was also observed in a xenograft model in which PBMCs were not co-grafted with tumor cells but delivered from the periphery. In addition, combination of MSLN-490 with Atezolizumab or a chemotherapy drug paclitaxel produced a synergistic effect on tumor inhibition and more T cells were found infiltrated into tumors in the combo groups. In hMSLN and hCD3 double knock-in mouse, JLF025 demonstrated acceptable safety profiles. Thus, combination of JLF025 with immune checkpoint inhibitors and chemotherapy drugs represents a promising cancer treatment strategy and could be considered for future clinical trials.

#6022 YH006: a next-generation CTLA-4×OX40 Treg antagonist, demonstrates superior tumor-infiltrating Treg-depletion efficacy and favorable manufacturability.

Sarah Chan, Baihong Liu, Bahetiyaer Huwatibieke, Jing Zhang, Yang Chen, Minjuan Meng, Wenchao Zheng, Lei Zhang, Yi Yang, **Jeremy Lee**

Biocytogen, Waltham, MA

Immune checkpoint inhibitors have revolutionized the treatment of early and advanced cancer. Especially combination of anti-cytotoxic T lymphocyte associated antigen 4 (CTLA-4) antibody and anti-programmed death-1 (PD-1) antibody, has shown remarkable efficacy against various cancers and approved for 7 indications by the US FDA. However, there are still limitations with regard to response rates and dose-dependent immune related adverse events (irAEs) caused by CTLA-4 antibody for fully achieve the optimal therapeutic effect for the combination strategy. YH006 is a monovalent bsAb with effector enhanced Fc domain, generated from Biocytogen RenLite^{TM} common light chain mice, designed to deplete tumor-infiltrating Treg cells with better specificity, based on tumor-infiltrating Treg cells consistently exhibit higher expression levels of both CTLA-4 and OX40 compared to T cells in the periphery across multiple cancer types. YH006 potent to selectively depletion of tumor-infiltrating Tregs and increase the intra-tumoral CD8/Treg ratio, outperform the first and other next generation of anti-CTLA-4 agents in vivo efficacy at low dose. Notably, the antitumor activity of PD-1 mAb was significantly enhanced when combined with YH006 in syngeneic MC38 models at high tumor burden. Ongoing CMC process development has a titer of over 6 g/L at the 20 L scale, and the overall purification yield of >80%. YH006 also has consistent quality from research cell bank to passage 90, suggesting excellent developability.

#6023 Intrabody-mediated TLR2 and TLR9 blockade as new strategy to inhibit inflammation-driven pancreatic cancer growth.

Martin Gasser[1], Thomas Boeldicke[2], Ana Maria Waaga-Gasser[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Helmholtz Centre for Infection Research, Braunschweig, Germany

Pancreatic cancer (pancreatic ductal adenocarcinoma, PDAC) remains a deadly cancer worldwide with a need for new therapeutic approaches. A dysregulation in the equilibrium between pro- and anti-inflammatory responses with a predominant immunosuppressive inflammatory reaction in advanced stage tumors seem to contribute to tumor growth and metastasis. The current therapies do not include strategies against pro-tumorigenic inflammation in cancer patients. We have shown that the upregulated cell surface expression of Toll-like Receptor (TLR) 2 and of TLR9 inside PDAC cells maintain chronic inflammatory responses, support chemotherapeutic resistance, and mediate tumor progression in human pancreatic cancer. We further demonstrated intracellular TLR2 and TLR9 targeting using specific intrabodies, which resulted in downregulated inflammatory signaling. In this study, we tested, for the first time, an intrabody-mediated TLR blockade in human TLR2- and TLR9-expressing pancreatic cancer cells for its effects on inflammatory signaling-mediated tumor growth. Newly designed anti-TLR2- and anti-TLR9-specific intrabodies inhibited PDAC growth. Co-expression analysis of the intrabodies and corresponding human TLRs showed efficient retention and accumulation of both intrabodies within the endoplasmic reticulum (ER), while co-immunoprecipitation studies indicated both intrabodies interacting with their cognate TLR antigen within the pancreatic cancer cells. Cancer cells with attenuated proliferation expressing accumulated TLR2 and TRL9 intrabodies demonstrated reduced STAT3 phosphorylation signaling, while apoptotic markers Caspases 3 and 8 were upregulated. To conclude, our results demonstrate the TLR2 and TLR9-specific intrabody-mediated signaling pathway inhibition of autoregulatory inflammation inside cancer cells and their proliferation, resulting in the suppression of pancreatic tumor cell growth. These findings underscore the potential of specific intrabody-mediated TLR inhibition in the ER relevant for tumor growth inhibition and open up a new therapeutic intervention strategy for the treatment of pancreatic cancer.

#6024 A novel chemical conjugated anti-CTLA-4 antibody with tumor microenvironment activation.

Cheng Liu, Yuan Liu, Chengli Ding, Ying He

Affinity Biopharmaceutical Co., Ltd., Shanghai, China

Anti-CTLA-4 antibody is considered the “forefront” of immune checkpoint inhibitors as it plays a critical role in preventing CTLA-4 mediated inhibitory signals that downregulate T-cell immune responses, and functioning early at the initial phase of naive T-cell activation. However, CTLA-4 is not a tumor associated antigen and it’s expressed in a variety of normal tissues such as lymph nodes, tonsil and lung, therefore anti-CTLA-4 antibody can trigger severe on-target, off-tumor toxicities and immune-related adverse events (irAEs), substantially restricting its clinical applications and potential. IMD-303 is a novel Tumor MicroEnvironment Activated Antibody (TMEAbody) engineered through chemical conjugation of a legumain-activated chemical linker together with a 20kDa masking group at the variable region. The activating protease, legumain (AEP), is a tumor-specific, acid endopeptidase with tumor site over-expression and a strict specificity for one particular amino acid (Asn), making it a first-in-class, highly specific and pan-solid tumor target in novel drug design. Through screening of TME-activated linkers, glycosylation and masking structures, IMD-303 TMEAbody is inert in circulation as its binding to T cells is blocked in normal tissues, ensuring minimal immunogenicity and systemic toxicities; when entering the Tumor MicroEnvironment (TME), IMD-303 becomes rapidly activated and unmasked by legumain, effectively stimulating CD8+ T-cell proliferation and depleting Treg cells by antibody-dependent cellular cytotoxicity (ADCC). Preclinical pharmacological studies showed that the unmasked IMD-303 exhibited strong binding to CTLA-4, efficiently blocking its interaction with CD80/CD86 in the TME, and high affinity to CD16a, CD32a, and CD64 Fc receptors, enhancing ADCC/ADCP effector functions of Treg depletion locally within the TME. And IMD-303 with masking has greatly improved the safety profile due to the fact that it reduced binding to CTLA-4, CD16a, CD32b (FcγRIIb), and C1q far more than that of CD32a and CD64 in circulation. In animal models, IMD-303 demonstrated strong anti-tumor activities as single agent in multiple syngeneic murine tumor models, and it displayed significant synergistic effects when combined with IMD101 (a TMEA-Cytokine releasing IL-2) in EMT6 tumor model, in which IMD-303 can eliminate the number of Treg cells in tumors that are slightly up-regulated by IMD101. Preclinical toxicology studies showed that the favorable safety profile of IMD-303 allows for continued treatment with repeated dosing, and it’s well-tolerated with a weekly repeated regimen of 200mg/kg in cynomolgus monkeys. All these findings indicate that IMD-303, with its preferential activation within tumors, exhibits superior efficacy and safety performances and has the potential to successfully transform the cold tumor microenvironment which lacks T-cell infiltration and immune responses.

#6025 ABBV-514: an afucosylated CCR8 specific antibody that targets and eliminates key immunosuppressive tumor regulatory T cells.

Amanda Schmidt Paustian[1], Linlin Guo[2], Weiguo Feng[3], Ryan Duggan[1], Mitra Bhattacharyya[1], Andrew McCluskey[4], Kelsey Gallant[4], Christopher Negron[4], Michael McDevitt[2], Cyril Ramathal[1], Diana Chen[2], Maulik Patel[1], Heath Smith[1], Keith Hamel[1], Julie Wilsbacher[1]

[1]AbbVie Inc., North Chicago, IL,[2]AbbVie Inc., South San Francisco, CA,[3]Daiichi Sankyo Inc., Basking Ridge, NJ,[4]AbbVie Inc., Worcester, MA

Regulatory T cells (Tregs) have long been appreciated as a key suppressive cell type that limits anti-tumor immunity, yet it has been challenging to find an effective approach to target this important cell population. CCR8 has recently emerged as a promising target due to its enhanced expression on tumor Tregs compared to other Treg and T effector cell populations. A greater abundance of CCR8+ Tregs is also correlated with poor clinical outcomes in several solid tumor indications. Here we report the discovery and comprehensive preclinical characterization of ABBV-514, a human CCR8 specific afucosylated hIgG1 antibody and a functionally similar mouse CCR8 specific mIgG2a surrogate antibody. Both ABBV-514 and the mouse surrogate specifically bind to and robustly deplete CCR8 expressing cells via ADCC without inhibiting CCL1-stimulated signaling. The mouse surrogate selectively depletes CCR8+ intratumoral Tregs and has strong monotherapy activity in a variety of in vivo syngeneic tumor models including models that are insensitive to anti-PD-1 treatment. We have used scRNAseq and TCRseq studies to provide novel insights into the mechanisms behind the anti-tumor immune response mediated by the CCR8 mouse surrogate ± anti-PD-1 combination therapy. The transcriptional and phenotypic profiles of intratumoral CD8+ T cells are greatly altered upon CCR8+ tumor Treg depletion compared to anti-PD-1. Tumor Treg depletion upon anti-CCR8 treatment leads to enrichment of a distinct effector memory-like CD8+ T cell population with dramatically enhanced Granzyme K expression and reduced expression of exhaustion associated transcripts including TOX and Lag-3. This population is further augmented with anti-CCR8/anti-PD-1 combination therapy. Similarly, ABBV-514 binds human or cyno CCR8 expressing cells and mediates ADCC of CCR8+ Tregs in vitro. ABBV-514 is currently being evaluated in a Phase I clinical trial, both as a monotherapy and in combination with budigalimab, a PD-1-blocking antibody (NCT05005403). Together, these data highlight ABBV-514 as a therapeutic approach to enhance anti-tumor immunity. WF was an employee of AbbVie at the time of the study. All other authors are current employees of AbbVie. The design, study conduct, and financial support for this research were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication.

#6026 HX016-9, a novel PD1xVEGF BsAb, as a new candidate treatment of solid tumors.

H. Ke[1], T. Yang[1], F. Peng[1], J. Li[1], C. Chen[1], L. Zhang[1], S. Xiong[2], F. Zhang[1], **H. Q. Li**[1];
[1]Hanx Bio, Hangzhou, China, [2]Crown Bioscience, Hangzhou, China

With the clinical confirmation of the superior efficacy of AK112, a first-in-class (FIC) PD1xVEGF bispecific antibody (BsAb), in the treatment of NSLCL cancers, over the PD1 monoclonal antibody (mAb), as shown in a head-to-head phase III trial, we set out to engineer a novel and potentially best-in-class (BIC) PD1xVEGF BsAb using a unique PD1 (HX008, an approved PD1-mAb) and a novel VEGF (HX006, a mAb with more favor activity over Avastin) mAb sequences. HX016-9 has 2+2 IgG1 symmetric structure which was constructed by grafting the PD1 binding domain of HX008 onto the N-terminus of HX006. HX016-9 binds PD1 recombinant protein with EC_{50} of 0.13nM (vs. 0.1nM by HX008) and to VEGF recombinant protein with EC_{50} of 0.097nM (vs. 0.042 by HX006) in ELISA assay. It also binds similarly to the $PD1^+$ cell line as HX008 with slightly reduced affinity. A reporter bioassay for PD1 function demonstrated that HX016-9 has EC_{50} of 3.2nM (vs. 1.0nM for HX008), while a reporter- bioassay for the VEGF function demonstrated that HX016-9 has EC_{50} of 12.6nM (vs. 11.4nM for HX006), confirming HX016-9 designed function *in vitro*. Interestingly, HX016-9 demonstrated enhanced reporter activity (up to 5x) in the presence of VEGF than those without, while in contrast, no enhancement for HX008 in the presence of VEGF, similarly as reported for the FIC molecule previously. This enhancement could possibly be interpreted by the formation of the VEGF-HX016-9 complex, thus it facilitating efficient cis-binding to these PD1+ cells and higher avidity binding. This further implicates the enhanced PD1 blocking by HX-016-9 in these cells when VEGF presents. In the huPD1-C57/B6-based HuGEMM mouse, HX016 was shown to have stronger anti-tumor activity over the HX008 and HX006 in huPD-L1/huVEGF-MC38 CRC syngeneic CRC tumor, which can be attributed to both PD1- and VEGF-targeting. In a xenograft A549 NSCLC tumor in immunocompromised mice, HX016-9 also caused anti-tumor activity that can be attributed to anti-VEGF function. These activities are comparable or superior to those of the FIC molecule, warranting the HX016-9 candidacy to move into IND-enabling evaluation and further clinical development.

#6027 Translational medicine studies of BRY812, an anti-LIV-1 antibody drug conjugate for cancer therapeutics.

Qinqin Zhuang[1], Qianqian Tao[1], Xiaobei Zhao[2], Jie Zhu[2], Lei Nie[1], Gang Chen[2], Haibin Wang[1]

[1]Bioray Pharmaceutical Ltd., Hangzhou, China,[2]Bioray Pharmaceutical Co., San Diego, CA

LIV-1, also known as SLC39A6 or ZIP6, belongs to the zinc transporter family and was initially identified as an estrogen-inducible gene in breast cancer. Immunohistochemical (IHC) analysis have revealed escalated LIV-1 expression in estrogen receptor-positive (ER+), hormone-treated tumors (both primary and metastatic sites) as well as ER-/PR-/Her2- (triple-negative) breast cancers. Notably, healthy human tissues exhibit limited LIV-1 expression, primarily in hormone regulated organs (prostate, uterus, and breast). The escalated expression of LIV-1 in breast and prostate cancer, as well as melanoma and other tumors, positions LIV-1 as an excellent target for ADC therapeutics.

BRY812 is a monomethyl auristatin E (MMAE)-conjugated humanized IgG1 ADC against LIV-1. With Bioray's irreversible conjugation method CysLink™, BRY812 enables superior *in vivo* stability and eliminates off-target payload migration. Recent translational medicine studies have shown that BRY812 exhibits favorable efficacy in *in vitro* models of Breast cancer and Endometrial cancer. Additionally, BRY812 has demonstrated synergistic efficacy when combined with PD-1/L1 antibodies in a series of *in vitro* and *in vivo* models. Finally, BRY812 has shown improved efficacy in DS-8201 resistant cell line compared to the parental cell line. These results showed that BRY812, either as a monotherapy or in combination with other drugs, has a significant potential for application in various solid tumor indications, as well as in patients who are resistant to existing therapies.

IMMUNOLOGY: Adaptive Immunity in Tumors / Oncogenic Pathway-Mediated Regulation of Inflammation and Tumor Immunity
Poster Session

#6031 CD4+CD103+ tissue-resident memory T cells correlate with unfavorable prognosis in patients with head and neck cancer.

H. Takahashi[1], S. Ida[2], H. Tada[2], K. Chikamatsu[2];
[1]Ai Komagata Clinic, Aiyukai Medical Corporation, Maebashi, Japan, [2]Gunma University Graduate School of Medicine, Maebashi, Japan

T cell memory is an important mechanism for long-term protection against diverse pathogens such as cancers. Tissue-resident memory T cell (T_{RM}) is a subset of memory T cells that stably resides in tissues and controls local immune homeostasis. In the present study, we investigated the immunological profile and clinical significance of T_{RM} in patients with head and neck squamous cell carcinoma (HNSCC). We analyzed RNA-sequencing data and clinical data obtained from The Cancer Genome Atlas (TCGA) database. In total, 520 cases, including 97 human papillomavirus (HPV)-positive HNSCCs and 423 HPV-negative HNSCCs, were analyzed. T_{RM}-enriched tumors were identified based on the expression of both *CD4/CD8A* and *ITGAE (CD103).* T_{RM}-enriched tumors tended to correlate with HPV-positive status and early T factor. Gene Set Enrichment Analysis revealed the enrichment of pathways relating to cytotoxic immune response in T_{RM}-enriched tumors. Moreover, the expressions of immunostimulatory and immune checkpoint-related genes were elevated in T_{RM}-enriched tumors. Notably, the enrichment of CD4+T_{RM}s in tumors was an independent prognostic factor for shorter progression-free survivals (PFS). We also analyzed peripheral blood mononuclear cells obtained from 77 patients with HNSCC. The increased CD8+CD103+T_{RM}s correlated with HPV-positive status and primary lesion of oropharynx. The proportion of CD4+CD103+T_{RM}s negatively correlated with that of CD4+ naïve T cells, while that of CD8+CD103+T_{RM}s negatively correlated with that of effector T cells. The proportion of CD4+CD103+T_{RM}s positively correlated with Ki-67 expression in CD4+ T cells. Moreover, the elevated CD4+CD103+T_{RM}s was an independent prognostic factor for shorter PFS. In conclusion, we highlighted the clinical and immunological significance of CD103+T_{RM}s in both tumor tissues and peripheral blood of patients with HNSCC. Further characterization of T_{RM}s could lead to the development of novel biomarkers for patients with HNSCC.

#6032 Intratumoral Tregs restrain the immune response against primary and metastatic cancer.

A. Bockman, M. Moreno Ayala, B. Gittins, C. Zhang, S. Benyon, M. DuPage;
UC Berkeley, Berkeley, CA

Advancements in cancer immunotherapies have significantly improved patient outcomes in hematologic malignancies but are dramatically limited by the suppressive function of Regulatory T cells (T_{regs}) in solid cancers. Antibody-based therapeutics, such as anti-CTLA-4 and anti-CCR8, are being tested to selectively deplete intratumoral T_{regs}, with promising preclinical efficacy. However, these therapies have multiple effects that may do more than just deplete intratumoral T_{regs}, such as activate Fc receptors, bind to other types of immune cells, or bind to cells outside of the tumor microenvironment. While T_{regs} highly infiltrate most tumor types, it is unclear whether they function to suppress cancer immunity only in tumor tissue itself or at peripheral sites. To test whether T_{regs} function directly within the tumor microenvironment to suppress antitumor immune responses, we developed a model in which intratumoral (IT) delivery of low-dose diphtheria toxin (DT) in $Foxp3^{DTR}$ mice is used to only deplete IT T_{regs}. We show that mice that receive IT DT have reduced T_{regs} frequencies only in the tumor and do not succumb to lymphoproliferative disease, as observed with systemic T_{reg} depletion. Critically, tumor T_{reg} ablation via IT DT produced more effective and durable tumor control than systemic T_{reg} ablation. Mechanistically, we show that robust tumor control is achieved through enhanced function of effector $CD4^+$ and $CD8^+$ T cells and requires MHC II^+ $CD11b^+$ Batf3- type 2 conventional dendritic cells. Through the use of disseminated tumor models, we find that disrupting T_{reg} suppression within a primary tumor unleashes antitumor immunity against metastatic lesions that are not directly treated. Interestingly, this multifocal tumor control is dependent upon the cooperation between $CD4^+$ and $CD8^+$ T cells and requires matched primary and metastatic tumors. Through in vivo cellular trafficking experiments and blockade of T cell egress from lymphoid tissues we show a high frequency of T_{regs} circulate between local and metastatic tumors to mediate systemic immune effects. Upon disruption of tumor-T_{reg} circulation between lesions, we demonstrate enhanced effector function and decreased disease burden at both tumor sites. These findings identify a tumor-resident T_{reg} niche that limits $CD4^+$-cDC2 mediated antitumor immune responses. Importantly, our results uncover a novel T_{reg} suppressive mechanism that promotes systemic cancer progression.

#6034 Development of a pan-HLA-A02 restricted AFP targeting TCR for both TCR-T and TCR-bispecific therapy.

Junjun Chu, Jiajia Du, Tingfeng Liang, Shifan Wu, Yaolong Chen, Chunguang Yang, Qingjia Yan, Lulu Zhang, **Yanyan Han**

HRYZ Biotech Co., Ltd., Guangzhou, China

Background: Alpha-fetoprotein (AFP) is a well-established tumor-associated antigen, particularly in hepatocellular carcinoma (HCC). Although the AFP specific TCR-T cell therapy has shown promising clinical efficacy in HCC, the HLA restriction limits the patient population. We previously identified a T-cell receptor (TCR) sequence specific to an HLA-A*02:03-restricted $AFP_{158-166}$ antigen epitope. To broaden its therapeutic potential, we mutated the sequence of CDR regions of this TCR to recognize multiple major HLA-A*02 subtypes.
Method: We developed a novel human T-cell-based functional display platform to optimize the original AFP-specific TCR sequence. This platform facilitated the identification of TCR variants with broadened HLA-A*02 subtype recognition. The optimized TCR was engineered into TCR-T cells which were subsequently tested for their ability to recognize and lyse tumor cells both in vitro and in vivo models. Comprehensive safety evaluations were conducted to assess off-target effects. Additionally, the platform was also able to enhance the affinity of TCRs to picomolar level, leading to the development of a TCR bispecific protein.
Results: The original TCR could only recognize and kill AFP158-166 antigen presented by HLA-A*02:03. In contrast, the optimized TCR transduced T cells demonstrated the ability to recognize the same epitope presented by pan-HLA-A*02 molecules, including A*02:01, A*02:03, A*02:06, and A*02:07, significantly broadening their applicability. The pan-HLA-A*02 restricted TCR transduced T cells exhibited superior anti-tumor activity, as evidenced by stronger cytokines production and tumor cell lysis ability in vitro and the capability to completely eradicate tumors in vivo murine models. Toxicology studies revealed no off-target recognition of non-specific HLA or other antigens, indicating a favorable safety profile. Moreover, the high-affinity TCRs (-11M) were linked with an anti-CD3 scFv fragment to form a TCR bispecific protein, which demonstrated substantial anti-tumor efficacy in preclinical models.
Conclusion: To this end, the sequence-optimized AFP-specific TCR-T cells demonstrated robust therapeutic efficacy and a favorable safety profile, expanding potential treatment options for over 60% of patients with pan-HLA-A*02. Moreover, the successful development of a TCR bispecific antibody highlights its promise as an innovative off-the-shelf therapeutic solution, offering improved clinical accessibility and versatility to address the needs of a broader patient population.

#6035 The role of EBV+ nasopharyngeal carcinoma in shaping double-negative B cells to form a pro-metastatic niche.

M. K. Chung[1], N. Kam[2], Y. Zhang[1], Z. Hou[1], K. Islam[1], Y. Zhang[3], G. Lanqi[1], X.-Y. Guan[1], W. Dai[1];
[1]Li Ka Shing Faculty of Medicine, The University of Hong Kong, Pok Fu Lam, Hong Kong, Hong Kong, [2]Laboratory of Synthetic Chemistry and Chemical Biology Limited, Hong Kong, Hong Kong, [3]State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Introduction: B cells can play an anti-tumor role in the tumor microenvironment (TME) by secreting antibodies and activating other immune cells. In our previous study, IgD-CD27- double-negative (DN) B cells were associated with worse prognoses in nasopharyngeal carcinoma (NPC), a malignancy often associated with Epstein-Barr virus (EBV) infection, implying a potential role in NPC disease progression.
Methods: To characterize DN B cells and identify features associated with NPC clinical outcomes, we analyzed single-cell RNA-sequencing data (scRNA-seq) from NPC tumors, blood samples, and normal nasopharynx tissues (n = 49, 15, and 7), as well as bulk RNA-sequencing (RNA-seq) data from two cohorts of NPC patients with clinical data (n = 77 and 100) respectively. Multiplex Immunohistochemical (mIHC) staining of tumor slides from 40 NPC patients was analyzed for the spatial identification of tumor-infiltrating B cells. To understand the *in vitro* interactions between NPC cancer cells and B cells, tonsil-derived IgD+CD27- naïve B cells were cocultured with EBV-positive (EBV+) or negative (EBV-) NPC43 cells, followed by Flow Cytometry and scRNA-seq for quantifying DN B cells and investigating their interactions with cancer cells.
Results: Trajectory analysis identified DN B cells and Plasma B cells as potential terminal B cell development states in NPC, with both populations enriched in tumors. DN B cells could be classified into two major subpopulations in NPC: DN Branch 1 and DN Branch 2, with the former potentially being influenced by EBV infection and the latter being under stress. RNA-seq data revealed that B-cell-related biological pathways were downregulated in metastatic NPC, while mIHC staining showed that most DN B cells were in NPC tumor nests and were enriched in metastatic NPC. Flow cytometry on our co-culture experiments detected increased DN B cell content in EBV+ NPC43 co-culture (40.0%) compared to EBV- NPC43 (25.9%), supporting our hypothesis that EBV+ NPC malignant cells may be involved in promoting DN B cell development in NPC. Detailed cell-cell interaction analysis indicated that the EGFR-TGFB1, LTBR-LTB, and MIF-TNFRSF14 are potential key interactions between EBV+ NPC cells and naïve B cells, likely contributing to DN B cell development and tumour growth.
Conclusions: DN B cells in NPC may be in a stable development state, with their correlation with distant metastasis suggesting their involvement in B cell dysregulation involved in poor NPC prognosis. Taken together, our results suggest EBV+ NPC cells may receive pro-tumor signals from naïve B cells and promote the development of DN B cells to form a pro-metastatic niche. Future studies are needed for detailed validations of these findings.
Acknowledgments: This study is funded by Theme-based Research Scheme (TBRS) (T12-703/22-R), Health and Medical Research Fund (HMRF) (08192296) from Hong Kong (SAR), P.R. China.

#6036 Mining tumor B cell repertoires for the identification of novel antibody target pairs.

Matthieu Delince, Carlo Zimarino, Julia Steiger, Pattraporn Satitsuksanoa, Justina Rutkauskaite, Eveline Keller, Leandra Zehnder, Lorenza Ferretti, Simone Schmitt, Christoph Esslinger

Memo Therapeutics AG, Schlieren, Switzerland

Tumor-infiltrating B cells and especially B cells organized in tertiary lymphoid structures (TLS) correlate with better prognosis in lung, ovarian and colon cancer patients. TLS are ectopic lymphoid organs which may present B cell follicles of germinal center. B cells in the TLS were found to express typical markers of late-stage maturation, somatic hypermutation and class switch recombination of immunoglobulin genes, indicating a cancer-driven clonal expansion. In some cases, research showed that secreted immunoglobulins of the repertoire were having a direct tumor killing activity. To decipher and then harness the potential of these tumor-trained antibodies, we analyze recombinant cognate repertoires of tumor infiltrating B cells from lung, ovarian and colon cancer surgical resections. We leverage the capabilities of our cutting-edge single-cell microfluidic platform, to extract and clone the comprehensive B cell antibody arsenal from up to a million tumor-derived B cells. The cancer derived antibodies are then expressed as recombinant full-length human IgG maintaining the heavy and light chain pairing of the original B cells. The antibody repertoire obtained as a recombinantly expressed mixture or as individual monoclonals is then screened in a panel of assays designed to identify antibodies with a function of interest. For instance, identification of antibodies showing specific binding to cancer cells. Once identified, the monoclonal antibody is then used to deconvolute novel tumor associated antigens. An initial assessment of the tumor derived antibody repertoire revealed that a typical sample of approximately one cubic centimeter of tumor tissue yielded thousands of antibody-clonotypes. The sequences pattern bore signs of affinity maturation and clonal expansion which may indicate an antigen-driven evolutionary pressure exercised by the tumor and tumor surroundings. Screening the tumor derived antibody repertoire for binding to cancer cell lines, we identified several monoclonal antibodies specifically binding to cancer cells. In vitro, these antibodies show anti-tumor activity with several mechanisms of actions: direct growth inhibition or via effector functions (antibody-dependent cell-mediated cytotoxicity). Some antibodies are strongly internalized and meditate killing when coupled to a toxic payload. The tumor antigens of the antibodies are currently being evaluated as potential therapeutic targets. These promising results may lead us to discover novel tumor pathways and contribute to our further understanding of B cell biology in cancer.

#6037 Circulating CD8 T-cell responses to neoantigens predict responsiveness to PD-(L)1 axis blockade in non-small cell lung cancer.

Celia Ramade[1], Noemie Thebault[1], Clara-Maria Scarlata[1], Francoise Lauzeral-Vizcaino[1], Caroline Fournier[1], Victor Sarradin[1], Anna Salvioni[1], Marie Michelas[1], Daniel Oreper[2], Suchit Jhunjhunwala[2], William Thrift[2], Adric Quade Broadwell[2], Nicolas Lounsbury[2], Kai Liu[2], Meng Xiao He[2], Martine Darwish[2], Catherine Ross[2], Hang Xu[2], Milena Hornburg[2], Amy Heidersbach[2], Fanny Bouquet[3], Catia Fonseca[3], Laetitia Tudeau[3], Nicolas Congy-Jolivet[4], Carlos Gomez-Roca[1], Thomas Filleron[4], Lelia Delamarre[2], Julien Mazieres[4], Jean-Pierre Delord[4], Maha Ayyoub[1]

Tumor-specific T cells play a central role in tumor control, yet the attainment of their full tumor rejection potential is hindered by regulatory mechanisms, including expression of inhibitory immune checkpoints. Although immunotherapy by immune checkpoint blockade (ICB) has transformed cancer care, only a proportion of patients experience clinical benefit. Ancillary studies to clinical trials evaluating ICB have revealed an association between high tumor mutational burden (TMB) and treatment efficacy, suggesting that unleashing T cells targeting neoepitopes encoded by somatic mutations could underlie ICB-mediated tumor control or regression. Nevertheless, TMB or tumor neoantigenic burden (TNB) are not consistently related to clinical response, potentially because most studies have addressed the influence of TMB and TNB by *in silico* prediction without systematic analysis of actual neoantigen-specific T cells. We hypothesized that the presence of actual neoantigen-specific T-cell responses would predict response to ICB, rather than the mere presence of a high TMB or TNB. Using whole exome and transcriptome sequencing in a cohort of 29 non-small cell lung cancer patients receiving anti-PD-1/PD-L1, we assessed expressed non-synonymous exonic mutations in each patient's tumor and predicted the encoded neoepitopes restricted by each patient's HLA-I and -II alleles. In our cohort, HLA-I TNB was better correlated to clinical response and progression free survival (PFS) than TMB and HLA-II TNB. We developed a workflow allowing for the assessment of circulating CD8 T-cell responses to more than 400 prioritized neoepitopes, and to 50 long peptides harboring each several predicted CD4 neoepitopes containing the same mutated amino acid. We showed, in 28 patients from whom PBMCs were available, that circulating CD8 T-cell responses to predicted neoantigens were of higher magnitude and breadth in clinical responder compared to non-responder patients. The presence of a CD8 T-cell response to neoantigens was associated with better PFS. No correlation was observed between expressed TMB or TNB (HLA-I or -II) and the magnitude of CD8 or CD4 T-cell responses. Longitudinal ex vivo enumeration of neoantigen-specific CD8 T-cells using HLA/peptide tetramers showed that they had a memory phenotype and that they experienced significant proliferation under therapy. Our results ascertain the contribution of neoantigen-specific CD8 T-cells in therapeutic tumor rejection. They also provide an opportunity, through the analysis of tumor molecular signatures, to unveil the mechanisms supporting or restraining the priming of spontaneous T-cell responses targetable by ICB. This research was a collaborative effort by sites within the imCORE network, made possible through support from F.Hoffmann-La Roche.

#6038 An optimized off-the-shelf whole tumor cell vaccine activates T cells that recognize a diverse antigen repertoire with potential to provide meaningful clinical benefit to patients with NSCLC.

Bernadette Ferraro[1], Justin J. Arndt[1], Grace Tan[2], Nicholas S. LeFlohic[1], Jian Yan[1], Mark L. Bagarazzi[1], Natalia Savelyeva[2], Christian H. H. Ottensmeier[2]

One critical challenge of effective cancer therapies is addressing intertumoral and intratumoral heterogeneity of immunologically visible antigens. Antigenic diversity is a particular challenge for therapies that rely on the induction of a broad repertoire of cytotoxic T cells (CTLs) to eliminate malignant cells. Therapeutic interventions, such as αPD1, can partially mitigate this challenge by rescuing CTLs constrained by immune inhibitory mechanisms, such as intratumoral upregulation of the PDL1/PDL2 pathway.

Cancer vaccines are rapidly advancing as a mechanism to expand the repertoire of effector T cells thereby broadening immune recognition and elimination of tumor cells. Here we provide preclinical evidence that a carefully designed, off-the-shelf vaccine, derived from six immortalized tumor cell lines (NGEN-143) provides the necessary requirements for translation into clinical benefit. Vaccine immunogenicity was enhanced by limiting expression of proteins that suppress immune responses (B7H3, TGFβ1, TGFβ2) and by expression of key cytokines that facilitate activation of dendritic cells (CD40L, GMCSF, IL12).

In human in vitro assays, NGEN-143 significantly increased the breadth and magnitude of T cells activated against tumor associated antigens (TAAs) and shared neoantigens (TSAs) across a wide range of HLA types. IFNγ producing T cells measured by ELISpot (SFU/1e^6 PBMCs) were increased to 10 TAAs (42,972 ± 4,105) and 22 TSAs (2,493 ± 484) compared to unmodified controls (TAAs, 2,889 ± 993; TSAs, 200 ± 71). IFNγ responses were not preferentially directed against a subset of TAAs, TSAs or epitopes. NGEN-143 significantly increased activated T cells with anti-tumor effector function. NGEN-143 preferentially expanded CD8$^+$ polyfunctional (IFNγ$^{+/-}$TNFα$^{+/-}$GzmB$^+$) T cells with effector (CCR7$^-$CD45RO$^+$) and central memory (CCR7$^+$CD45RO$^+$) phenotypes, skewed CD4$^+$ T cells towards T_h1 (Tbet$^+$IFNγ$^+$) over T_h2 (GATA4$^+$IL4$^+$) cells, and increased CD8$^+$ T cell expression of PD1 demonstrating TCR engagement. Cytolytic function of NGEN-143 activated CD8$^+$ T cells was confirmed by caspase-3 mediated killing of tumor cell targets.

Consistent with in vitro data, murine vaccines with immunogenicity enhancing modifications homologous to NGEN-143 significantly improved survival outcome in immunologically 'cold' (B16F10) and 'warm' (CT26) syngeneic tumor models. In both models, vaccine significantly increased tumor infiltration of CD4$^+$ and CD8$^+$ T cells, inhibited tumor growth, and prolonged survival. In the CT26 model, vaccine monotherapy completely inhibited tumor growth (n=7/10) and mice were protected from rechallenge (n=7). Combination with αPD1 synergistically increased vaccine survival benefit.

Our data demonstrate NGEN-143 has all the features to underpin clinical use in patients with NSCLC.

#6039 Triads of dendritic cells, CD4$^+$ T cells, and CD8$^+$ T cells are found within PDA tumors and are associated with intrinsic anti-tumor immune responses.

Sheela R. Damle[1], Jason A. Carter[2], Jose M. B. Pineda[2], Kristin E. Goodsell[2], Lindsay K. Dickerson[2], Shreeram Akilesh[2], Ian N. Crispe[2], Venu G. Pillarisetty[1]

[1]University of Washington/Fred Hutch Cancer Center, Seattle, WA,[2]University of Washington, Seattle, WA

Cytotoxic T cells (CTLs) are the main effectors of anti-tumor immunity, and their activation is dependent on carefully coordinated interactions between antigen presenting cells (APCs) and CD4$^+$ T cells (Th). In a pivotal model, synchronized interaction between a dendritic cell (DC), Th, and CTL were posited as requisite for effective CTL responses. Recent studies have resurrected this hypothesis in the context of anti-tumor immunity and demonstrated the function of 3 cell type clusters in immune checkpoint blockade (ICB) response in murine tumors and human cancer. We hypothesized intratumoral 3-cell type clusters are present in an “immune excluded tumor”, pancreatic adenocarcinoma (PDA), outside the context of immunotherapy. Analysis of single cell RNAseq and PDA tumors identified DC:Th:CTL clusters, defined as DC, Th, and CTL within 20µm radius, occurring with ~15% of DCs. Analysis of multiplex proteomics data from fibrolamellar carcinoma, a rare stromal dominant liver tumor with poor immune infiltration, revealed the presence of DC:Th:CTL clusters. We sought to confirm our findings in a larger dataset using multiplex immunohistochemistry (mIHC) on a tissue microarray (TMA) of >500 patients with untreated resected PDA. Using automatic image analysis software, we identified cell types based on surface marker expression, specifically tumor cells, CTL, Th, macrophages, and non-macrophage APCs. 3-cell type clusters were found in 90% of tumor samples, occurred with ~10% of APCs, located >50µm from tumor cells, and correlated strongly with APC:Th dyads. Weak correlation was found between 3-cell type clusters and isolated cell types, suggesting cluster formation is unlikely to be related to abundance of infiltrating immune cells. DC:Th:CTL clusters were also readily seen in scST of untreated non-small cell lung cancer (NSCLC) and colorectal cancer (CRC). Analysis of PDA, NSCLC, and CRC scST datasets revealed that CTLs within triads were more likely to have an effector-like phenotype. Th within triads were enriched in CXCL13$^+$-like Th phenotype, which previously has been associated with immune triads. Using associated clinical data in the PDA TMA, we found that patients with the highest tertile of APC:Th:CTL clusters had improved overall survival compared to patients with the lowest tertile (HR=0.70, p=0.005). Similar findings were found for patients with the top tertile of APC:Th dyads (HR=0.63, p=6.x10^{-4}), but not APC:CTL or CTL:Th dyads (HR=0.76 and 0.77 and p=0.16 and 0.07, respectively). Overall, our findings demonstrate 3-cell type clusters are readily found in an “immune excluded” tumor like PDA without immunotherapy and are associated with improved patient outcomes. These data are strong evidence for the role of 3-cell type clusters in endogenous anti-tumor immune responses and point toward future opportunities for immunotherapeutic intervention.

#6040 Exploring the impact of analytical factors on B-cell receptor profiling with high-throughput sequencing technologies.

Xiashiyao Zhang[1], Rittika Mallik[2], Miguel Pacheco[2], Shaveta Goyal[3], Mark Izraelson[4], Li Song[5], Henk-Jan van den Ham[6], **Jun Wan**[7], Wenming Xiao[2], BCR-SEQC consortium

[1]Luddy School of Informatics, Computing, and Engineering, Indiana University at Indianapolis, Indianapolis, IN,[2]Center for Drug Evaluation and Research, U.S Food and Drug Administration, Silver Spring, MD,[3]Takara Bio USA, Inc, San Jose, CA,[4]MiLaboratories Inc, San Francisco, CA,[5]Department of Biomedical Data Science, Dartmouth College, Hanover, NH,[6]ENPICOM B.V., 's-Hertogenbosch, Netherlands,[7]Indiana University School of Medicine, Indianapolis, IN

This abstract reflects the views of the authors and should not be construed to represent FDA's views or policies.
High-throughput sequencing of B-cell receptor (BCR) gene rearrangements, along with downstream analysis, provides researchers with the tools to define the B-cell clonal landscape and identify biomarkers for minimal residual disease (MRD). Despite significant advancements in the field over the past decade, comprehensive comparisons on different analytical methods, sequencing technologies, and bioinformatics tools remain largely unexplored.
To bridge this gap, the FDA-led B-cell Receptor Sequencing Quality Control (BCR-SEQC) consortium developed protocols for generating reference materials derived from nine well-characterized B-cell lines and peripheral blood mononuclear cells (PBMCs) from healthy donors. This study aimed to evaluate the impact of key analytical factors—including input material quality and quantity, sequencing depth, sequencing technologies, and bioinformatics workflows—on BCR sequencing (BCR-seq) performance.
The study employed multiple commercial BCR-seq products to prepare libraries with varying input amounts (25ng, 100ng, and 500ng) of reference materials. These libraries were sequenced using three different platforms: Illumina NextSeq 2000, ElementBio Aviti, and MGI DNBSEQ. Subsequently, four bioinformatics workflows (MiXCR, Immcantation, TRUST4, and IGX-Profile) were applied to assemble BCR sequences and determine clonotypes.
This research provided the first comprehensive analysis of how variables in wet-lab and computational workflows influence sequencing-based BCR profiling, specifically in terms of linearity, accuracy, and sensitivity. Additionally, the study developed quality control (QC) metrics to ensure the robustness of assays and analytical workflows.
Ultimately, this work highlights current capabilities and limitations in BCR-seq technology, identifies critical technical challenges, and establishes actionable best practices for reconstructing BCR repertoires from high-throughput sequencing data.

#6041 Targeting the NuRD component, CHD4, impairs Foxp3+ Treg cell production and function and promotes anti-tumor immunity.

Wayne W. Hancock[1], Yan Xiong[2], Liqing Wang[3], Martina Minisini[4], Fanhua Kong[2], Eros di Giorgio[4], Tatiana Akimova[1], Ivan Babic[5], Elmar Nurmemmedov[5]

Chromatin remodeling enzymes, which reposition nucleosomes throughout the genome to regulate transcription and other processes, include 4 families: chromodomain helicase DNA-binding (CHD), switch/sucrose non-fermentable (SWI/SNF), imitation switch (ISWI), and inositol requiring 80 (INO80). CHD4, a ubiquitous and abundant chromatin remodeling enzyme essential for normal development across a range of tissues, and that is overexpressed in various cancers, is a core member of the nucleosome remodeling and deacetylase (NuRD) complex. Though originally described as a transcriptional repressor, the NuRD complex is now regarded as able to 'fine-tune' gene expression, acting as both an activator and a repressor of transcription. CHD4 is important to the development of lymphocytes but has not been studied in the context of Foxp3+ T-regulatory (Treg) cells. Our work involved genetic deletion of Foxp3 in Treg cells and use of a pharmacologic inhibitor of CHD4 (CHD4i) in studies with WT mice. In basic studies, Foxp3 co-immunoprecipitated with CHD4 and deletion of CHD4 led to decreased Foxp3+ Treg production in the thymus. In the periphery, CHD4-/- Tregs showed decreased Foxp3 expression and suppressive function *in vitro* and *in vivo*, with resultant severe autoimmunity and death by 3 weeks of life. These events were associated with an absence of CNS2 demethylation in the Foxp3 locus and hierarchical clustering map for differentially expressed genes included cytokines and chemokines, leukocyte antigens, transcription factors and genes associated with apoptosis, as well as enrichment of genes associated with regulation of the cell cycle and DNA damage and repair. Thereafter, a DEL screen involving cell target engagement led to discovery of a compound CH41, binding to the CHD4 chromodomain. CH41 impaired Treg suppressive function in vitro and when used in syngeneic tumor models led to inhibition of tumor growth in lung and liver carcinoma models but was ineffective in immunodeficient mice. Efficacy was associated with increased CD4 (IL-2) and CD8 (IFN-g) infiltration and effector cytokine production. Importantly, neither WT tumor bearing mice nor their immunodeficient partners developed evidence of autoimmunity under CHD4i therapy, consistent with our previous data that tumor-associated Tregs have distinctive properties rendering them especially susceptible to immunotherapy versus their peripheral counterparts. We conclude that CHD4 targeting has interesting immunologic effects that include preferentially inhibiting Treg vs. conventional T cell responses, leading to significantly increased anti-tumor immunity.

#6042 Baseline serum level of IgG targeting annexin A2 is predictive of response to immunotherapy in patients with advanced NSCLC.

Matthieu Roulleaux Dugage[1], Francois-Xavier Danlos[1], Melodie Bonvalet[2], Tyler Hulett[3], Sabine Messayke[4], Anne-Laure Voisin[4], Marie Naigeon[5], Jean Jouniaux[5], Aleksei Tikhonov[2], Chifaou Mohamed-Djalim[2], Severine Mouraud[2], Delphine Bredel[2], Scott Paschke[3], Mihaela Aldea[1], Pernelle Lavaud[6], David Planchard[6], Benjamin Besse[6], Nathalie Chaput[5], Aurelien Marabelle[2]

[1]Drug Development Department, Gustave Roussy, Villejuif, France,[2]Immunotherapy Translational Research Lab, Gustave Roussy, Villejuif, France,[3]CDI Laboratories, Baltimore, MD,[4]Pharmacovigilance Unit, Gustave Roussy, Villejuif, France,[5]Laboratory of Immunomonitoring in Oncology, Gustave Roussy, Villejuif, France,[6]Medical Oncology Department, Gustave Roussy, Villejuif, France

Introduction: Despite the success of immune checkpoint blockers (ICBs), predicting which patients will respond to treatment remains a significant challenge, particularly in those with advanced NSCLC. Some circulating antibodies may serve as indicators of a pre-existing antitumor adaptive immune response. This study investigated the potential of baseline serum antibodies as predictors of response and survival in patients with advanced NSCLC undergoing ICB, chemotherapy, or ICB + chemotherapy.
Materials and Methods: Baseline serum samples were collected from 256 patients with advanced NSCLC in two independent cohorts : the PREMIS cohort (NCT03984318, n=195 patients treated with either ICB alone (n=129) or combined chemo-immunotherapy (n=66)) and the MSN cohort (NCT02105168 - n=61 patients receiving first-line chemotherapy). Fluorescence intensities of IgG and IgM binding to individual human proteins were measured using the HuProt arrays containing over 20,000 human proteins. Survival analyses, including Kaplan-Meier, Log-Rank test and Cox regression models, were conducted to determine the predictive value of identified antibodies. Response was defined by RECIST 1.1.
Results: Few protein specific antibody levels were significantly different between responders and non-responders, including five that were significantly higher: ANXA2-IgG, METTL21B-IgG, SPHKAP-IgG, Lupus La-IgG, EDN1-IgG, and EFHC1-IgM. Four isoforms of the ANXA2 protein consistently exhibited elevated IgG antibody levels in responders, with a strong inter-isoform correlation ($R>0.95$, $p<0.0001$). These antibodies were correlated with baseline global IgG levels and antinuclear antibodies (ANA) status but not with tumor histology (squamous or non-squamous) or other clinical characteristics (including PD-L1 staining). ICB-treated patients with higher anti-ANXA2 IgG levels (n=23) had progression-free survival (PFS, Logrank p=0.02) and overall survival (OS, Logrank p=0.008) as compared to intermediate (n=86) and low (n=20) patients in ICB-treated patients. This effect was also suggested in the chemo-immunotherapy group (although not significant) but was absent in patients treated with chemotherapy without ICB. After adjusting for global IgG levels, anti-ANXA2 IgG levels independently predicted PFS and OS in ICB-treated patients.
Conclusion: Pre-existing humoral immunity against ANXA2 predicts response and survival in advanced NSCLC treated with ICB. Annexin A2 (ANXA2) has been implicated in immunosuppression, epithelial-to-mesenchymal transition (EMT), and poorer survival outcomes in cancer patients. Baseline anti-ANXA2 IgG levels could therefore be used as biomarkers to predict benefits of ICB and allow for patient stratification. Also, ANXA2 could become a novel target for NSCLC immunotherapy.

#6043 Role of Rab11 family interacting proteins in immune recognition of breast cancer.

Oly Khowash, Paras Sahani, Christopher Kywe, Kathleen Conway, Khushi Tekale, Jessica Contreras, Erin Howe

Rosalind Franklin Univ. of Med. & Science, North Chicago, IL

Breast cancer is the second leading cause of death for American women, with the majority of morbidity attributable to metastatic disease. Breast cancer brain metastases (BCBM) account for 30% of breast cancer mortality and treatment options remain limited. While immunotherapy holds great promise, objective response rates for metastatic disease are poor. To improve these outcomes, we must understand the context-specific mechanisms used by cancer cells to suppress and evade the immune system. Successful T cell interaction with cancer cells requires proper surface localization of proteins such as MHC complexes and co-activators, all of which are localized within the cell via endosomal protein trafficking. Immunotherapy also relies on CTLA-4 or PD-1/PD-L1 on the cell surface to remove inhibition of T cells and improve the anti-tumor response. How molecular trafficking controls localization of activating and inhibitory proteins to the surface in order to facilitate cancer-immune cell interaction is a key knowledge gap. We previously showed that Rab11b-mediated endosomal trafficking is required for BCBM. Here we investigate how trafficking-mediated control of the cell surface dictates immune recognition and response. Using a targeted CRISPR screen, we found that Rab11 family interacting proteins Rab11fip2 and Rab11fip3 are required for highly immunogenic ovalbumin (OVA) expressing breast cancer cells to be recognized by OT-I CD8+ T cells. Flow cytometry analysis revealed that the decrease in recognition is not due to surface localization of PD-L1 or the MHC/SIINFEKL complex (SIINFEKL is the OVA peptide presented for OT-I recognition). Knockout of Rab11fip2 or 3 did not change cell proliferation or tumor burden in immunocompromised animals, but led to significantly increased tumor growth in immunocompetent animals. This suggests that non-targeting control cells are partially restrained by the immune system, and knockout of either Rab11fip causes loss of immune recognition to allow faster tumor growth. Immunohistochemical analysis revealed a significant decrease of tumor infiltrating T cells in Rab11fip knockout tumors. Cytotoxic CD8+ T cells exhibited the most extreme decrease in infiltration, with CD4+ helper T cells decreasing in only the Rab11fip3 knockout condition. These results indicate that Rab11 may play a role in immune cell recruitment in addition to recognition and activation. We are currently focused on characterizing Rab11 control of the T cell-cancer cell interaction in human breast cancer cell lines. Dissecting the role of Rab11 in tumor cell antigen presentation, immune cell recruitment, T cell cytotoxicity and activation will help determine if inhibition of Rab11-mediated recycling can be used to increase the efficacy of immunotherapy for patients with BCBM.

#6044 T cell-mediated clearance of BCRABL^{+} leukemia cells in transgenic mice model of chronic myeloid leukemia.

Chang Liu, Fang Hui, Xuexiu Fang, Stephanie Mori, John Kenneth Cowell, Tianxiang Hu

Georgia Cancer Center, Augusta, GA

The *BCR-ABL1* fusion gene, which is present in ~95% of chronic myeloid leukemia (CML) patients, encodes a unique amino acid sequence that is exclusively expressed in leukemic cells. Tyrosine kinase inhibitors (TKIs) therapy targeting BCR-ABL1 are widely used as the first-line treatment for CML and has markedly improved the outcome of patients. However, there are still challenges in CML patient management, including the poor prognosis of patients with advanced-phase CML, the adverse effects associated with lifelong dependence on TKIs, and high relapse rates observed after TKI discontinuation. Restored anti-tumor immunity by immune effector cells, especially the NK cells, has been shown to be associated with deep molecular response and treatment-free remission in CML patients. However, there is a lack of direct evidence whether these cytotoxic T lymphocytes (CTLs) can really eradicate the BCR-ABL1^{+} leukemic cells and provide a cure for this disease. Primary murine CML was induced by the withdrawal of tetracycline (TET) from the drinking water of the *SCL:tTA*/*BCR-ABL1* transgenic mice, which served as the donor of BCR-ABL1^{+} leukemia cells for serial transplantation. We performed several engraftment experiments on mice from different strains and subjected them to different treatments. The CML progression in mice engraftment model was measured by white blood cell counts (WBC) and flow cytometry analysis of peripheral blood (PB). Our findings demonstrated that non-irradiated immunocompetent C57BL/6 mice did not develop CML after transplantation of primary leukemia cells, whereas irradiated recipient mice exhibited a typical phenotype of CML, as indicated by a significant increase in the percentage of neutrophil-like CML cells and WBC. Besides, the engraftment of BCRABL1^{+} leukemia cells to immunodeficient NSG mice led to rapid CML progression, indicating a critical role of the immune system in CML control. To test the direct involvement of CTLs, antibody-mediated CD8^{+} T cells depletion was performed, which restored CML progression in C57BL/6 mice. Furthermore, in vitro tumor killing assay revealed that CD8^{+} T cells from transplanted, CML-free mice exhibited enhanced cytotoxic activity against BCR-ABL1^{+} CML cells compared to neutrophil counterparts derived from naïve mice. Consistently, when T cells from tumor-challenged but CML-free mice were transferred together with CML cells into NSG mice, the recipient NSG mice got protected from CML development. Based on these findings, we concluded that CTLs play a key anti-tumor role in the prevention of CML in the mouse CML model. Further investigating these specific cytotoxic T cells and cloning their TCR sequences could provide an experimental basis for the design of TCR-T therapy targeting BCR-ABL1 neo-antigen for the cure of CML.

#6045 MHC II+ VEGFA+ neutrophils induce expansion of regulatory T cells and confer colorectal cancer peritoneal metastasis.

S. Deng, S. Liu, **J. Zheng**;
Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Peritoneal metastasis is a fatal mode of cancer metastasis that is accompanied by extensive stromal fibrosis and poor prognosis. Increasing evidence suggests that tumor associated neutrophils (TANs) constitute a major component of tumor-infiltrating cells in many types of cancer and contribute to tumor immunity; however, how TANs are connected to adaptive immunity and clinical relevance in peritoneal metastasis remains unclear. Here, we generated and integrated single-cell RNA and spatial transcriptomes in primary tumor, adjacent normal tissues and metastases from 7 cancer types that tend to develop peritoneal metastasis (235 samples from 124 patients). Neutrophils exhibited distinct states in different tissue types. Specially, a terminally differentiated MHC II $^{+}$ VEGFA^{+} neutrophil population with antigen presenting and oncogenic phenotype termed TAN-2 portended peritoneal metastasis and could further induce mesothelium to mesenchymal transition. These fibrotic mesothelial cells exhibit higher CXCL12 levels and recruited more TAN-2 cells via CXCR4. Notably, the antigen-presenting TAN-2 could invoke expansion of regulatory T cells in an antigen-specific manner and was associated with worse survival. Importantly, in vivo TAN-2 depletion or in combination with immune checkpoint inhibitors effectively attenuates peritoneal metastasis. Taken together, we elucidate how MHC II^{+} VEGFA^{+} TANs contribute to peritoneal metastasis, provide novel insights on innate and adaptive immunity, and demonstrate new strategies to enhance cancer immunotherapy effects.

#6046 Combination of RAS(ON) mutant-selective and multi-selective inhibitors sensitizes immune-refractory, RAS-driven preclinical models to immunotherapy.

M. Moreno Ayala, C. Blaj, M. Menard, A. Salmon, J. Lee, S. Ganesh, A. Pham, V. Morton, M. Sandoval, J. A. Smith, E. Quintana;
Revolution Medicines, Redwood City, CA

Oncogenic RAS promotes carcinogenesis by sustaining cell proliferation and orchestrating immune escape. We and others have shown that RAS inhibition combined with immune checkpoint blockade (ICB) prolongs durability of response in immunogenic, RAS-driven preclinical models. Clinical data have shown that most patients treated with KRAS G12C(OFF) inhibitors develop resistance through reactivation of the RAS pathway. We have previously demonstrated that the combination of a RAS(ON) G12C-selective inhibitor with a RAS(ON) multi-selective inhibitor can overcome mechanisms of intrinsic and acquired resistance in an immune-refractory preclinical NSCLC model. Here we evaluated if the RAS(ON) doublet combination of RMC-6291 or RMC-9805, a RAS(ON) G12C-selective inhibitor and a RAS(ON) G12D-selective inhibitor, respectively, with the RAS(ON) multi-selective inhibitor RMC-6236 can sensitize traditionally hard to treat, immune-refractory preclinical models to anti-PD-1. In a KRAS G12C NSCLC syngeneic model, RMC-6291, RMC-6236, and the RAS(ON) doublet induced rapid, transient tumor regressions, but some tumors progressed on treatment. This model is refractory to anti-PD-1 monotherapy and the combination of RMC-6291 or RMC-6236 with anti-PD-1 did not achieve significant combination benefit. RMC-6291 and RMC-6236 as single agents and the RAS(ON) doublet induced a similar favorable modulation of the TME, increasing tumor infiltrating lymphocytes and decreasing myeloid cells. Only the RAS(ON) doublet upregulated MHC class I expression, increasing the possibility of recognition of the tumor by T cells. Notably, the RAS(ON) doublet sensitized this model to anti-PD-1, with the triple combination achieving 100% CRs. In a GEMM-derived, KRAS G12D pancreatic model, the combination of RMC-9805 with RMC-6236 achieved RAS pathway inhibition as evidenced by deeper p-ERK suppression, and significantly increased the depth and durability of the antitumor response compared to either single agent alone. Tumors treated with RMC-9805 plus RMC-6236 showed a more profound transformation of the TME, characterized by a decrease in immunosuppressive myeloid cells, an increase in T cell infiltration, and a significant upregulation of the antigen presentation machinery. Combination of the RAS(ON) doublet with anti-PD-1 induced 90% CRs in this immune-refractory model. Collectively, these preclinical findings suggest that the RAS(ON) doublet combination of RAS(ON) mutant-selective and multi-selective inhibitors can reverse the immune-evasion mechanisms governed by oncogenic RAS and sensitize immune-refractory tumors to ICB to induce durable CRs. These preclinical data support the clinical evaluation of the RAS(ON) doublets in combination with ICB in patients with RAS driven cancers.

#6047 YTHDF proteins modulate gastric cancer immunity by regulating the IFN-γ response through the m6A-dependent degradation of IRF1.

Dongjun Jang, Sung-Yup Cho

Seoul National University College of Medicine, Seoul, Korea, Republic of

N^6-methyladenosine (m6A) RNA methylation is one of the most abundant post-transcriptional modifications in eukaryotic messenger RNAs and plays crucial roles in carcinogenesis and immune responses. YTHDF proteins including YTHDF1, 2, and 3 are ‘reader’ proteins of m6A methylated RNAs and have individual role. A recent report suggests that YTHDFs act redundantly to promote RNA decay. In this study, we found that YTHDF1 was overexpressed in gastric cancer (GC) tissues and correlating with the suppression of cancer immunity, particularly the responsiveness to interferon-gamma (IFN-γ). Overexpression of YTHDF1 reduced the responsiveness to IFN-γ in GC cells, while knockdown studies showed that YTHDF2 and YTHDF3 redundantly affect IFN-γ responsiveness alongside YTHDF1. Analysis of RNA immunoprecipitation (RIP)-sequencing data revealed that IRF1 mRNA, key regulator of IFN-γ signaling, is a direct target of YTHDFs and is degraded in an m6A-dependent manner. Likewise, downregulation of METTL3, which is a major component of m6A methyltransferase complex, using small interfering RNA or catalytic inhibitor increase IRF1 levels and IFN-γ responsiveness. Furthermore, depletion of Ythdf1 reduced tumor growth and increased immune cell infiltration into the tumor, dependent on IFN-γ signaling in mouse syngeneic tumor models. Collectively, our study suggests that YTHDFs modulate cancer immunity by influencing IFN-γ signaling through IRF1 regulation.

#6048 Genome-wide CRISPR screening identifies tyrosylprotein sulfotransferase-2 as a target for augmenting anti-PD1 efficacy.

Yumi Oh[1], Sung-Yup Cho[2], Sujeong Kim[3], Yunjae Kim[3], Hyun Kim[3], Hansoo Park([3], Yongsoo Jang[4], Soobin Park[4], Yong-Chul Kim[5]

[1]Medical Research Center, Genomic Medicine Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Department of Biomedical Science and Engineering, Gwangju Institute of Science and Technology (GIST), Gwangju, Korea, Republic of,[4]School of Life Sciences, Gwangju Institute of Science & Technology, Gwangju, Korea, Republic of,[5]R&D Center, PeLeMed, Co. Ltd., Gwangju, Korea, Republic of

Immune checkpoint therapy (ICT) offers durable responses in select cancer patients, yet resistance remains a significant challenge, prompting the exploration of underlying molecular mechanisms. We propose tyrosylprotein sulfotransferase-2 (TPST2), known for its role in protein tyrosine O-sulfation, as a suppressor of cancer immunity. Through *in vivo* genome-wide CRISPR screening, TPST2 loss-of-function emerged as a potential enhancer of anti-PD1 treatment efficacy. TPST2 suppressed interferon-γ (IFNγ) signaling by sulfating IFNγ receptor 1 at Y397 residue, while its downregulation boosted IFNγ-mediated signaling and antigen presentation. Depletion of TPST2 in cancer cells augmented anti-PD1 antibody efficacy in syngeneic mouse tumor models by enhancing tumor-infiltrating lymphocytes. RNA sequencing data revealed TPST2's inverse correlation with antigen presentation, and increased TPST2 expression is associated with poor prognosis and altered cancer immunity across cancer types. In an effort to develop novel cancer immunotherapies targeting TPST2, we have discovered LDD-5557, a lead compound with potent enzyme inhibitory activity through library screening and structure-based hit to lead optimization process. The lead compound showed an excellent in-vivo PK profile including high oral bioavailability and immunotherapeutic efficacies of significant upregulations of CD8 positive T-cells and antigen processing related genes in a dose-dependent manner by co-treatment with anti-PD1 in a MC38 syngeneic mouse model. These findings underscore TPST2's novel role in cancer immunity and advocate for its consideration as a therapeutic target in ICT-based treatments.

#6049 Fibroblast growth factor receptor modulates IFN-γ response in breast cancer.

Marvis Monteiro[1], Mitchell G. Ayers[1], Michael K. Wendt[2]

[1]Borch Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN,[2]Department of Internal Medicine, University of Iowa, Iowa City, IA

FGFR is amplified in 20% of metastatic breast cancer cells (MBCs) where it promotes growth, sustains mesenchymal plasticity, and mediates drug resistance. Systemic inhibition of FGFR kinase activity increases the numbers of $CD4^+$ and $CD8^+$ T-cells and decreases abundance of myeloid-derived suppressor cells (MDSCs) in the tumor microenvironment. These data indicate an immunosuppressive role of FGFR signaling pathway in MBCs. However, a mechanism by which blockade of FGFR kinase activity affects T-cell presence in the tumor is not well understood. T-cells decrease tumor progression by releasing cytokines such as interferon gamma (IFN-γ). IFN-γ binds to its cognate receptor to activate the JAK-STAT1 signaling pathway, promoting immune recognition of cancer cells. Herein, we investigate the signaling cross talk between FGFR-IFN-γ and the resultant pathophysiological effects on cancer cells. We observe that FGFR signaling reduces STAT1 phosphorylation in breast cancer cells. Conversely, inhibiting FGFR kinase activity in murine mammary carcinoma cells leads to increased STAT1 phosphorylation, increased expression of downstream interferon response genes including the T-cell chemoattractants CXCL9 and CXCL10, and increased cell surface expression of major histocompatibility complex I (MHC-I). A key mediator of the FGFR signaling cascade is SH2 containing protein tyrosine phosphatase (SHP-2). Pharmacological inhibition of SHP-2 causes a decrease in *in-vivo* metastatic burden and an increase in T-cell presence in the tumor. Similar to targeted inhibition of FGFR, blockade of SHP-2 activity also increases STAT1 phosphorylation and expression of IFN-γ response genes. We propose a mechanism in which FGFR mediated activation of SHP-2 dephosphorylates tyrosine 701 of STAT1 thereby tempering anti-tumorigenic effects of IFN-γ. Our findings suggest that increased immunogenicity caused by FGFR pathway inhibition can be leveraged to make tumor cells more susceptible to immune attack and can be used in conjunction with immunotherapy for treatment of MBCs.

#6051 Opposing function of USP5 in MRE11 endonuclease activity to evade anti-tumor immunity.

Chuan-Chun Lee[1], Wan-Rong Wu[1], Liang-Chih Liu[1], Ting-Yi Liao[2], You-Zhe Lin[1], Fang-Ying Lin[1], Yi-Chun Shen[2], Feng-Chi Chung[1], Yuan-Liang Wang[1], Chih-Hao Lu[3], Wei-Chung Cheng[1], Wei-Chao Chang[2], Yi-Chuan Li[1], Chih-Tung Lin[1], Chung-Yu Chen[1], Sheng-Wen Chen[1], Hsin-An Shih[4], Steven Lin[4], I-Wen Chou[1], Chen-Yuan Lin[2], Chang-Feng Chiu[2], **Shao-Chun Wang**[1]

[1]China Medical University, Taichung City, Taiwan,[2]China Medical University Hospital, Taichung City, Taiwan,[3]National Yang Ming Chiao Tung University, Hsinchu, Taiwan,[4]Academia Sinica, Taipei, Taiwan

Proliferating cancer cells frequently encounter replication stress, which is known to generate abnormal cytosolic DNA and trigger anti-tumor immune responses. Thus, the ability to evade immune surveillance is critical for the development and progression of malignant tumors for which the mechanisms are not fully understood. The MRE11 nuclease, essential for maintaining DNA integrity during cell proliferation, plays important roles in processing stalled replication forks during replication stress. This process produces single-stranded DNA (ssDNA) intermediates which activate the cGAS-STING cascade when released into the cytoplasm to trigger anti-tumor immunity. In this study, we demonstrate that in cancer cells experiencing endogenous replication stress induced by the loss of phosphorylation at tyrosine 211 of the proliferative protein PCNA (pY211-PCNA), MRE11 is modified by site-specific polyubiquitinations. The modifications activate the endonuclease activity of MRE11, favoring cytosolic ssDNA production and subsequent immune response, which sensitizes cells to killing by natural killer (NK) cells. In contrast, in cells expressing pY211-PCNA, the ubiquitin-specific protease USP5 is recruited to replication forks, where it deubiquitinates MRE11, selectively reducing its endonuclease activity, suppressing cytosolic ssDNA generation, and blunting the immune response. Elevated USP5 levels correlate with tumor metastasis and poor prognosis in breast cancer patients. Downregulation of USP5 results in enhanced NK cell infiltration and tumor suppression in immune-competent mouse xenograft models, but not in immune-deficient models. Inhibition of USP5 renders patient-derived tumor organoids susceptible to NK cell-mediated killing. Unbiased screening and biochemical verification identified two FDA-approved drugs as potent USP5 inhibitors. Treatment with these agents phenocopies USP5 downregulation by enhancing cytosolic ssDNA production, increasing sensitivity to NK-mediated killing, and tumor suppression in syngeneic mouse models. Furthermore, these treatments sensitize patient-derived tumor organoids (PDTOs) to cytotoxic killing by NK cells and patient-autologous primary peripheral blood mononuclear cells (PBMCs). This mechanistic insight advances our understanding of tumor progression and the programming of immune responses, potentially leading to novel therapeutic strategies that harness anti-tumor immunity.

#6053 Down-regulation of interferon gamma response and other immune-related pathways in *PIK3CA* mutant colorectal cancer.

Alec B. Cornelio, Alexa E. Schmitz, Xingqi Shen, Shirsa Udgata, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin - Madison, Madison, WI

Background:The *PIK3CA* gene, encoding the p110α protein, is commonly mutated across different cancer types, including colorectal cancer (CRC). As 18% of CRCs have a *PIK3CA* mutation, a more comprehensive understanding of its influence on immune processes is needed. Here we sought to isolate and characterize the RNA expression signature of *PIK3CA* mutant CRC at both the tumor and patient-derived cancer organoid (PDCO) level.

Methods:Patient/Originator Specimen (tumor) and Organoid Culture (PDCO) RNA sequencing data of CRC patients with and without *PIK3CA* mutations were sampled from the National Cancer Institute's Patient-Derived Models Repository (NCI PDMR) Database. After filtering out patients with coexisting *BRAF*, *KRAS*, and *NRAS* mutations, patients were separated into two groups: wild-type (WT) and *PIK3CA* mutant (PK). The PDCO dataset contained 15 patients (nine WT vs six PK), and the tumor dataset contained eight patients (four WT vs four PK). Gene Set Enrichment Analysis (GSEA) was performed on the differential expression results comparing these two groups. A cutoff of |log10 false discovery rate (FDR)| ≥ 1.3 was used to determine significance for pathways. Data analysis was performed in R with the following packages: DESeq2, tximport, tximportData, dplyr, readr, magrittr, and ggplot.

Results:In the PDCO data set, two immune pathways were significantly up-regulated in WT compared to PK: interferon alpha (IFNα, FDR q-value < 0.001) and interferon gamma (IFN-γ, 0.018). In the tumor data set, more immune pathways were significantly down-regulated in PK compared to WT. PK had a down-regulation in pathways involved in T cell activation and function like IL6 JAK STAT3 signaling (q = 0.009) and IL2 STAT5 signaling (q = 0.003). Interestingly, in the tumor data set, PK had multiple inflammatory pathways down-regulated compared to WT: TNFA signaling via NFKB, allograft rejection, inflammatory response, complement (all q < 0.001), IFN-γ response (q = 0.004). IFN-γ response was investigated further due to it being significantly down-regulated in PK in both PDCO and tumor data sets. Significant enrichment was seen in common genes for both groups as follows: *PDE4B* (organoid log2FC = -1.24 and tumor log2FC = -3.97), *IRF5* (-1.11 and -3.05), *BTG1* (-0.753 and -2.72), *TNFAIP2* (-0.5 and -2.69), and *CD40* (-0.405 and -2.09). *IRF5* has been implicated in M1 macrophage polarization, *CD40* in CD8 T cell activation, *PDE4B* and *TNFAIP2* in inflammation, and *BTG1* in B cell regulation. Downregulation of these genes hints at PK possibly inhibiting important immune cell markers and the possible mechanisms through which PK is acting.

Conclusions: These analyses indicate mutated *PIK3CA* may play a role in suppressing the immune response in CRC, which can be seen even in PDCOs. Further investigation is needed to determine the mechanisms by which *PIK3CA* is suppressing the IFN-γ response and other immune-related pathways.

#6056 Aging accelerates breast tumorigenesis though cancer immunosuppression.

Shanshan Yin[1], Kay Yeung[2], Jing Yang[2], Peter D. Adams[1]

[1]Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA,[2]University of California, San Diego, San Diego, CA

Age is a major risk factor for breast cancer. However, the mechanisms by which age affects breast cancer initiation and progression is not fully understood. Unfortunately, there is a paucity of mouse with which to study the role of aging in cancer, especially the impact of aging on the epithelial tumor cells-of-origin. To address this for breast cancer, we established a mouse model in which breast cancer was induced de novo in young and old wildtype mice through intraductal injection of a lentivirus carrying the breast cancer oncogene HER2/neu. Consistent with human data, breast tumors in the old mice grew more rapidly than in young mice. Old mice exhibited more aggressive, invasive and higher grade breast tumor lesions. GeoMx whole-transcriptome spatial transcriptomics revealed that old tumor cells upregulated genes associated with invasion, epithelial-to-mesenchymal transition, cell migration, blood vessel development, and extracellular matrix formation, while downregulating genes related to immune response, interferon gamma response, and antigen presentation. Specifically, several chemokines were downregulated in old tumor cells, with Cxcl9 and Cxcl10 (hereafter Cxcl9/10) being the most prominent, an observation confirmed by RNAscope and immunostaining. Expression of Cxcl9/10 is known to attract Cd8+ and Cd4+ T cells through binding to the T cell Cxcr3 receptor, thereby facilitating anti-tumor T cell infiltration into tumors. We observed fewer tumor infiltrating Cd4+ and Cd8+ T cells in old tumors. Simultaneous depletion of Cd4 and Cd8 T cells significantly accelerated tumor growth in young mice but not in old mice. Blocking Cxcr3 in young mice accelerated tumor growth and reduced T cell infiltration, while enhancing Cxcl9/10 expression slowed down the tumor growth in old mice. These results suggest that age-associated downregulation of Cxcl9/10 in tumor cells is responsible for an impaired anti-tumor immune response in aged tissue. Furthermore, scATACseq revealed that Cxcl9/10 gene regions were less accessible in old tumor tissues. Taken together, these results suggest that age-associated downregulation of Cxcl9/10 in tumor cells is responsible for an impaired anti-tumor immune response in aged tissue, with epigenetic rewiring playing a critical role in this process.

IMMUNOLOGY: Antibodies 3: Multi-Target Checkpoint Inhibitors and Immune Activators
Poster Session

#6060 A symmetrical hexavalent trispecific antibody, HH160, targeting PD-1, CTLA-4 and VEGF-A for enhanced anti-cancer effects.

Chunmei Liu, Jianhe Chen, Fang Yang, Fangfang Ren, Jing Shao, Juan Liu, **Bin Ye**, Jianhua Sui

Huahui Health, Ltd., Beijing, China

Background: Antiangiogenic agents, such as the anti-vascular endothelial growth factor A (VEGF-A) antibody Bevacizumab, are among the first targeted therapies in cancer treatment. Immune checkpoint inhibitors (ICIs), including anti-PD-1/L1 and anti-CTLA-4 antibodies, have revolutionized cancer therapy. Combinations of anti-VEGF agents and ICIs have demonstrated enhanced efficacy in treating various types of cancers, including liver cancer, non-small cell lung cancer, and cervical cancer, indicating synergistic anti-tumor mechanisms. Here, we report a novel symmetrical hexavalent trispecific antibody, HH160, which targets PD-1, CTLA-4, and VEGF-A, aiming to enhance therapeutic effects, increase dosing convenience, achieve tumor-specific drug distribution, and reduce treatment-related side effects.
Methods: HH160 was constructed by fusing anti-PD-1 and anti-CTLA-4 nanobodies to the N- and C-termini of the heavy chain of an anti-VEGF-A human IgG1 antibody with a silent Fc, forming a symmetrical hexavalent trispecific antibody. Binding affinity was assessed using Surface Plasmon Resonance, and the EC_{50} and IC_{50} were determined using ELISA and FACS. Immune-related cellular functions were evaluated using luciferase-based reporter assays and Mixed Lymphocyte Reaction (MLR) assays. CTLA-4 mediated cellular internalization was evaluated in Jurkat-PD-1/CTLA-4 cells, and pharmacokinetics (PK) in mice were also assessed. The anti-tumor efficacy of HH160, including anti-tumor immune functions and anti-angiogenesis were assessed respectively in syngeneic hPD-1/hCTLA-4 humanized C57BL/6 mouse tumor models and immunodeficient mice bearing VEGF-A-expressing cells.
Results: HH160 exhibited strong binding to the three targets—PD-1, CTLA-4 and VEGF-A— and effectively blocked their ligand interactions. HH160 showed strong stimulation of IL-2 and IFN-γ secretion in MLR assays, indicating enhanced anti-tumor immune activity and the potential to overcome resistance to single-targeting agents. HH160 was efficiently internalized in Jurkat-PD-1/CTLA-4 cells via receptor-mediated internalization, suggesting its potential to reduce the VEGF-A levels in the tumor microenvironment. HH160 also exhibited a favorable PK profile in BALB/c mice. Significant immune-mediated and anti-angiogenesis-mediated anti-tumor effects were observed in hPD-1/hCTLA-4 humanized mouse tumor models and immunodeficient mice bearing VEGF-A-expressing cells.
Conclusions: Our study demonstrates that HH160 is a promising trispecific antibody for simultaneously targeting PD-1, CTLA4 and VEGF-A. It has the potential to harness the synergistic anti-tumor mechanisms, overcome resistance to monotherapy, and simplify the dosing regimen, supporting further development and clinical investigation.

#6061 Dual PD-L1 blockade and VEGF-A neutralization with the bispecific antibody BNT327/PM8002 shows potent antitumor activity in preclinical models.

Xiaoniu Miao[1], Yifeng Xu[2], Shaogang Peng[2], Weifeng Huang[2], Junying Chen[1], **Maren Kohne**[3], Andrea Imle[3], Alexander Muik[3], Ozlem Tureci[3], Ugur Sahin[3], Andy Tsun[1], Yi Luo[1]

[1]Biotheus Inc., Zhuhai, China,[2]Biotheus (Suzhou) Co., Ltd., Suzhou, China,[3]BioNTech SE, Mainz, Germany

The combined blockade of the PD-1/PD-L1 checkpoint and VEGF-A driven angiogenesis has been shown to reduce immune suppression in the tumor microenvironment, to enhance antitumor immune responses, and exhibit improved antitumor activity compared to each individual treatment. BNT327 (also known as PM8002) is an investigational bispecific antibody (bsAb) composed of a bivalent Fc-silenced anti-VEGF-A IgG1 antibody fused at its C-terminus to two humanized anti-PD-L1 single-domain VHH antibodies. By simultaneously targeting PD-L1 and VEGF-A, BNT327 is designed to combine the two complementary functions of amplifying pre-existing immune responses and anti-angiogenesis. Here, we report preclinical studies characterizing the functional activity of BNT327 *in vitro* and antitumor activity *in vivo*. BNT327 bound with high affinity (*i.e.*, nanomolar or subnanomolar K_D) to recombinant human PD-L1 and VEGF-A, as shown by biolayer interferometry. In cell-based bioluminescent reporter assays, BNT327 inhibited PD-L1/PD-1 signaling and VEGF-A/VEGFR2 signaling with subnanomolar EC_{50} values. In mixed lymphocyte reaction assays using human PBMCs and allogeneic monocyte-derived dendritic cells, BNT327 and the parental anti-PD-L1 VHH dose-dependently increased IL-2 and IFN-γ secretion. Furthermore, BNT327 dose-dependently enhanced $CD8^+$ T-cell mediated tumor-cell killing in an antigen-specific cytotoxicity assay *in vitro*, with the effects being comparable to those of PD-L1 blockade by atezolizumab. *In vivo*, a BNT327 surrogate bsAb targeting human PD-L1 and mouse VEGF-A exhibited dose-dependent antitumor activity in human PD-L1 knock-in mice bearing syngeneic human PD-L1-expressing CT26 tumors. Tumor growth inhibition was superior to individual treatments with PD-L1 blockade (parental anti-PD-L1 or atezolizumab) or with anti-VEGF-A. Furthermore, BNT327 showed antitumor activity in several xenograft models, including A375 melanoma cells, NCI-H1975 lung carcinoma cells, LoVo colon carcinoma cells, and MDA-MB-231 breast carcinoma cells. Antitumor activity was dose-dependent where tested, and superior to single PD-1 (pembrolizumab) or PD-L1 (atezolizumab) checkpoint inhibitor treatment. In conclusion, BNT327 inhibits PD-1/PD-L1 signaling and VEGF-A/VEGFR2 signaling *in vitro* and shows potent antitumor activity *in vivo* both in syngeneic and xenograft models. The safety and efficacy of BNT327 as a monotherapy or in combination is being investigated in multiple clinical trials in patients with solid tumors, including Phase II and Phase III trials investigating the combination with chemotherapeutic agents in triple-negative breast cancer and lung cancer.

#6062 A novel bi-specific antibody targeting CD39 and PD-L1 for enhanced cancer immunotherapy.

Ze Yang*[1], Xiaopei Li*[2], Zhongliang Li*[3], Yongfa Chen*[4], Huajing Wang[2], Xu He[1], Hongwei Sun[3], Xiaowen Lin[3], Ligong Lu[1], Xiaowen He#[2], Meixiao Zhan#[1], Ke He#[5], Wei Zhao#[1]

[1]Interventional Medical Treatment Department, Guangzhou First Pepople's Hospital, the Second Affiliated Hospital, School of Medicine, South China University of Technology, Guangzhou, China,[2]R&D Department, OriCell Therapeutics Co. Ltd., Shanghai, China,[3]Guangdong Provincial Key Laboratory of Tumor Interventional Diagnosis and Treatment, Zhuhai People's Hospital (Zhuhai Clinical Medical College of Jinan University), Zhuhai, China,[4]The Affiliated Dongguan Songshan Lake Central Hospital, Guangdong Medical University, Dongguan, China,[5]Minimally Invasive Tumor Therapies Center, The Affiliated Guangdong Second Provincial General Hospital of Jinan University, Guangzhou, China

While immune checkpoint inhibitors have revolutionized cancer treatment, there remains a significant unmet need for more potent strategies to bolster anti-tumor immunity. This study introduces OriA631-B, a pioneering bi-specific antibody designed to simultaneously engage CD39 and PD-L1. By disrupting both the metabolic checkpoint CD39 and the immune checkpoint PD-L1, OriA631-B aims to amplify therapeutic efficacy.Leveraging advanced antibody engineering, OriA631-B was meticulously crafted to exhibit optimal binding affinity and specificity for its intended targets. In vitro studies revealed that
OriA631-B, rooted in a clinically validated PD-L1 antibody, effectively suppressed CD39-mediated adenosine generation, thereby invigorating effector T cell function and proliferation. In vivo investigations utilizing syngeneic tumor models demonstrated that OriA631-B treatment significantly curtailed tumor growth compared to monotherapy or combination therapies. Safety assessments indicated a favorable toxicity profile, with no substantial adverse events observed.Collectively, these findings highlight the promising potential of OriA631-B as a novel immunotherapeutic agent in cancer treatment. By concurrently targeting CD39-mediated immune suppression and PD-L1-mediated T cell exhaustion, this bi-specific antibody may circumvent resistance mechanisms and enhance T cell engagement with tumor cells, ultimately improving patient outcomes. Further clinical evaluation is warranted to fully assess the therapeutic potential of this innovative bi-specific antibody in cancer immunotherapy.

#6063 ROSE12, a novel anti-CTLA-4 Switch antibody™ with FcγR affinity-enhanced Fc, evokes tumor-selective anti-tumor immune activation by extracellular ATP without systemic immune activation.

Hiroki Hayashi[1], Kanako Tatsumi[1], Hitoshi Katada[1], Yutaka Matsuda[1], Toshiaki Tsunenari[1], Masaki Honda[2], Takayuki Nemoto[2], Shun Shimizu[1], Momoko Miura-Okuda[1], Yuri Ikuta[1], Ami Ito[1], Chika Ogami[3], Chie Kato[2], Masaki Kamimura[1], Tatsuya Kibayashi[1], Chiyomi Kubo[2], Shunichiro Komatsu[2], Yasunori Komori[2], Junko Shinozuka[2], Hiroaki Susumu[1], Honoka Tanno[2], Yasushi Tomii[1], Kenji Nakagawa[1], Hiroaki Nagano[1], Masahiko Nanami[2], Yukari Nishito[1], Nozomi Fujisawa[2], Tomochika Matsushita[2], Saki Michisaka[1], Moe Yoshimoto[1], Hiroaki Wakatsuki[3], Tetsuya Wakabayashi[1], Naoko Wada[1], Otoya Ueda[1], Hiroko Konishi[1], Kenji Kashima[1], Hiroshi Tanaka[1], Mika Endo[1], Takehisa Kitazawa[1], Shimon Sakaguchi[4], Mika Kamata-Sakurai[1], Tomoyuki Igawa[1]

[1]Research Div., Chugai Pharmaceutical Co., Ltd., Kanagawa, Japan,[2]Translational Research Div, Chugai Pharmaceutical Co., Ltd., Kanagawa, Japan,[3]Translational Research Div, Chugai Pharmaceutical Co., Ltd., Tokyo, Japan,[4]Laboratory of Experimental Immunology, Immunology Frontier Research Center, Osaka University, Osaka, Japan

Background: Tregs are considered potential target in cancer immunotherapy, as tumor-infiltrating Tregs express higher levels of CTLA-4. A promising way to evoke effective anti-tumor immunity is to use FcγR affinity-enhanced anti-CTLA-4 antibody to deplete Tregs via ADCC activity. Although anti-CTLA-4 antibodies with non-fucosylated Fc (NF) are being clinically developed, the number of NKs and macrophages that can be activated is limited, resulting in limited efficacy. Therefore, stronger FcγR affinity-enhanced Fc is needed to show efficacy across all tumors. Moreover, systemic Treg depletion can potentially cause autoimmune side effects. Aiming to enhance anti-tumor activity and avoid systemic Treg depletion, we generated ROSE12, a novel FcγR affinity-enhanced anti-CTLA-4 Switch™ antibody. ROSE12 uses our proprietary antibody engineering technology, Switch-Ig™, allowing it to bind to CTLA-4 only in the presence of extracellular ATP, which is well known to be elevated in tumor tissue but tightly regulated in non-tumor tissue. ROSE12 is also utilized ART-Fc® technology that strongly enhances FcγR affinity. Due to this novel engineering, ROSE12 is expected to selectively deplete Tregs in tumor tissue without affecting non-tumor tissues.

Methods: We evaluated ROSE12's in vitro FcγR-affinity, ATP-dependent binding affinity to human CTLA-4, ADCC activity, and selective CTLA-4$^+$ Treg depletion. We assessed in vivo anti-tumor efficacy in human CTLA-4 knock-in (hCTLA-4KI) mice treated with mROSE12, which has the same variable region as ROSE12 with FcγR affinity-enhanced mouse surrogate Fc. We also evaluated mROSE12 and FcγR affinity-enhanced ipilimumab (Ipi-ART)'s intratumoral Treg depletion and T cell activation in non-tumor tissues using flow cytometry.

Results: ROSE12 showed ATP-dependent binding to CTLA-4 and stronger FcγRIIIa-affinity than ipilimumab-NF. Consistent with the binding profile, ROSE12 showed stronger ATP-dependent selective CTLA-4$^+$ Treg depletion among CTLA-4$^+$ T cells than ipilimumab-NF. mROSE12 demonstrated anti-tumor efficacy in a MC38 and PD-L1 therapy-resistant Hepa1-6 bearing mouse model. Moreover, Ipi-ART, but not mROSE12, induced systemic T-cell activation in normal tissue. Consistent with its anti-tumor efficacy, mROSE12 also depleted intratumoral Tregs. Furthermore, ROSE12 was well tolerated in cynomolgus monkeys in a repeated-dose toxicity study.

Conclusion: ROSE12 is a novel FcγR affinity-enhanced anti-CTLA-4 Switch antibody™ with potent anti-tumor efficacy and a wide therapeutic window due to tumor-selective activity. These results strongly support the clinical testing of ROSE12 in the treatment of solid tumors. Currently, ROSE12 is undergoing a phase 1 clinical study (NCT05907980).

#6064 Multiomics preclinical characterization of SAR445877, an anti-PD-1 antibody-IL-15 mutein fusion protein with robust anti-tumor efficacy as monotherapy.

Julien Tessier[1], Joon Sang Lee[1], Ingeborg M. Langohr[2], Caroline Morel[2], Xiangming Li[3], Seth Garren[1], Virna Cortez-Retamozo[3], Dinesh Bangari[2], Donald Jackson[1], Donald Shaffer[3], Angela Hadjipanayis[1]

[1]Precision Medicine & Computational Biology, Sanofi, Cambridge, MA,[2]Translational In vivo Models, Sanofi, Cambridge, MA,[3]Oncology Research, Sanofi, Cambridge, MA

Mechanism of action studies are imperative for translating oncology therapeutics into the clinic informing testable hypotheses and potential combination partners. One class of oncology therapeutics, immune-stimulatory cytokines can augment the antitumor efficacy of checkpoint blockade, but further translational work is required to understand beneficial treatment effects versus unwanted immunotoxicities. SAR445877 (SAR'877, formerly KD050), is a novel antibody-cytokine fusion protein consisting of an Fc silenced human anti-PD-1 IgG1 fused to a mutated interleukin-15 (IL-15)/IL-15 receptor alpha sushi domain fusion, which can cis-activate effector T cells by biasing IL-15 stimulation to T cells expressing PD-1. Here we used immunohistochemistry (IHC), flow cytometry and spatial transcriptomics to characterize SAR'877 treatment effects on residual tumors in a B16-OVA mouse model. Mice were treated with isotype control, anti-mPD-1 (anti-murine PD-1), mntSAR'877 (mIgG2a-mutmIL15) or mSAR'877 (murine surrogate anti-mPD-1-mutmIL15). The mSAR'877 treated animals showed regression of tumors, decreased necrosis and increased tumor immune cell infiltration compared to isotype control, mntSAR'877, and anti-mPD-1. IHC performed on residual tumors treated with mSAR'877 displayed a further decrease of PD-L1+ cells compared to anti-mPD-1 or mntSAR'877. Spatial transcriptomic profiling using the GeoMx DSP instrument revealed significant infiltration of innate immune cells (NK, monocytes, and neutrophils) and adaptive immune cells (CD8 T and CTL cells) into the tumor leading-edge compartment when compared to anti-mPD-1. CD8 T cell and NK cell increases were orthogonally validated by IHC and flow cytometry. Pathway analyses showed these changes were also associated with an upregulation of cytotoxic pathways when compared to controls. Together, these data elucidated the mechanism of anti-PD-1/IL15 showing contributions of NK and CD8 T cells associated with anti-tumor activity observed in mice. These findings suggest that mSAR'877 shows superior efficacy to single agent PD-1 or untargeted IL-15 in mouse tumor models.

#6065 Preclinical evaluation of LM-168: A next-generation anti-CTLA4 antibody with promising efficacy and reduced toxicity.

Lei Shi, Yun Zhang, Tianen Yao, Xia Qin, Da Fei, Yuan Li, **Runsheng Li**

LaNova Medicines Limited, Shanghai, China

Background: Anti-CTLA-4 antibodies have demonstrated encouraging clinical outcomes across various tumor types, but systemic immune activation leads to severe immune-related adverse events. Thus, there is a medical need for novel CTLA-4 targeting therapies with improved benefit-risk profile. ANP (ATP/ADP/AMP) levels are highly elevated to micromolar levels in the tumor microenvironment (TME), whereas physiological ANP levels in healthy tissues remain in the nanomolar range. LM-168 is engineered to selectively bind CTLA-4 at high ANP level in TME, with weakly binding in healthy tissues, thereby reducing “on target off tumor” toxicity.
Methods: The target binding activity, specificity, and cross-species reactivity of LM-168 were evaluated by flow cytometry. The blocking efficacy of LM-168 against human CTLA-4 was determined by ELISA. *In vivo* efficacy was evaluated using three syngeneic models: monotherapy in MC38 and CT26 models, and combination therapy with anti-PD-1 in MCA205 model. The toxicity of LM-168 was evaluated in 4-week repeated-dose toxicity studies in SD rats and rhesus monkeys.
Results: LM-168 exhibited potent ANP-dependent binding affinity to huCTLA4-CHOK1 cells, with an EC_{50} of 1.56 nM in presence of high levels of ANP. In ANP-dependent binding assays, LM-168 exhibited a favorable specificity margin, achieving a 9.5-fold binding selectivity window. In addition, LM-168 demonstrated strong affinity for CTLA-4 in non-human primate and rodent models. In MC38 syngeneic model with hCTLA4 knock-in mice, LM-168 at 10 mg/kg significantly inhibited tumor growth with a tumor growth inhibition (TGI) of 102.6%. Tumor infiltrating lymphocytes were analyzed after treatment with either LM-168 or ipilimumab. Intratumoral Treg cells were significantly reduced, while CD8+ T cells were increased. Peripheral Treg cell proliferation was lower in LM-168 treated mice compared to those treated with ipilimumab. In CT26 syngeneic model, LM-168 showed comparable anti-tumor efficacy to ipilimumab, achieving a TGI of 67.2% at a dose of 3 mg/kg. The combination of LM-168 with an anti-mPD-1 antibody provided a synergistic anti-tumor effect, achieving 98.4% TGI in the MC205 syngeneic model. 4-week repeated-dose toxicity studies indicated that LM-168 was well tolerated in both SD rats and rhesus monkeys, and 248 mg/kg was considered the highest non-severely toxic dose.
Conclusion: By targeting CTLA-4 conditionally, LM-168 is designed to address the potency and tolerability challenges associated with current anti-CTLA-4 antibodies, and thus has the potential to be a next generation CTLA-4 target therapy with promising clinical efficacy and reduced toxicity. LM-168 is also expected act synergistically with anti-PD-1/PD-L1 therapy. The preclinical data support clinical development of LM-168. It is currently in the FDA IND stage with a first-in-human trial expected in Q1 2025.

#6066 Preclinical evaluation of toxicity reduction for ROSE12, a novel ATP-dependent anti-CTLA-4 Switch antibody™ with FcγR affinity-enhanced Fc.

Moe Yoshimoto[1], Hiroki Hayashi[1], Kanako Tatsumi[1], Hitoshi Katada[1], Toshiaki Tsunenari[1], Hiroaki Susumu[1], Kenji Nakagawa[1], Hiroaki Nagano[1], Saki Michisaka[1], Chie Kato[2], Junko Shinozuka[2], Hiroshi Tanaka[1], Takehisa Kitazawa[1], Mika Kamata-Sakurai[1], Tomoyuki Igawa[1]

[1]Chugai Pharmaceutical, Co., Ltd., Research Div., Yokohama, Kanagawa, Japan,[2]Chugai Pharmaceutical, Co., Ltd., Translational Research Div., Yokohama, Kanagawa, Japan

Introduction: Cytotoxic T-lymphocyte associated protein 4 (CTLA-4) is highly expressed on tumor-infiltrating regulatory T cells (Tregs), which are known to suppress immune activation. To enhance anti-tumor efficacy via antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP) activity, numerous Treg depletion antibodies with FcγR affinity-enhanced Fc are currently being developed. However, FcγR affinity-enhanced anti-CTLA-4 antibody may cause autoimmune toxicity due to systemic Treg depletion. In fact, it was reported that anti-CTLA-4 antibody with non-fucosylated Fc, a common FcγR affinity-enhancing Fc, causes autoimmune adverse events, such as colitis. Aiming to enhance anti-tumor activity without inducing systemic Treg depletion, we generated ROSE12, a novel anti-CTLA-4 Switch antibody™ with FcγR affinity-enhanced Fc. ROSE12 applies our proprietary antibody engineering technology, called Switch-Ig™, allowing it to bind to CTLA-4 only in the presence of high extracellular ATP. ROSE12 also utilizes a technology called ART-Fc® to strongly enhance FcγR affinity. Our results here show that ROSE12 avoids toxicity due to its ATP dependency.
Methods: We evaluated CTLA-4 binding affinity and ADCC activity of ROSE12 at varying ATP concentrations in vitro. To evaluate the efficacy and toxicity of ROSE12 in syngeneic mouse models, we established a mouse ROSE12 surrogate Switch antibody™ (mSW-ART) and a conventional mouse anti-CTLA-4 antibody (mCTLA-4-ART), which binds to CTLA-4 in an ATP-independent manner and has the same Fc as mSW-ART. We assessed the anti-tumor efficacy of mSW-ART by measuring the tumor volume in several tumor-bearing syngeneic mouse models. To investigate colonic toxicity, we evaluated diarrhea, colon weight, and colon length in a FM3A-bearing C3H mouse model. The frequency of Tregs in colon lamina propria was also measured using flow cytometry.
Results: ROSE12 both bound to CTLA-4 and exhibited ADCC activity in an ATP dependent manner. In vivo studies revealed that mSW-ART exhibited anti-tumor efficacy against several types of cancers. In the FM3A-bearing C3H mouse model, it was demonstrated that mSW-ART did not cause symptoms of colitis, while mCTLA4-ART did. Further, colonic Treg depletion was not induced by mSW-ART, in contrast to mCTLA4-ART. These results showed that mSW-ART avoids the colitis induced by anti-CTLA-4 Treg depletion antibodies which lack tumor selectivity.
Conclusions: Our study suggests that ROSE12, which has ATP dependency, may mitigate colonic toxicity by avoiding the depletion of Tregs in colon lamina propria. Thus, ROSE12 may show a wide therapeutic window. A phase I clinical trial for patients with solid tumors is ongoing (NCT05907980).

#6067 Preclinical evaluation of XB628: A novel PD-L1 x NKG2A bispecific antibody.

Bee-Cheng Sim[1], Bonnie Hammer[2], Dileep Pulukkunat[2], Jing Chen[1], Annika Lee[2], Mark Bercher[2], Hanying Li[1], Jeffrey Higaki[1], Anna Ritter[2], Seema Kantak[1]

[1]Exelixis Inc., Alameda, CA,[2]Invenra, Madison, WI

Background: Programmed death ligand-1 (PD-L1) is highly expressed by tumor cells and upon binding to PD-1 on T cells, inhibits T cells from killing tumor cells. NKG2A is expressed by NK cells and a subset of CD8+ T cells; upon binding to HLA-E on tumor cells, NKG2A inhibits NK cell-mediated cytotoxicity against tumor cells. Thus, engagement of the PD-L1 and NKG2A immune checkpoint pathways allows tumor cells to evade both adaptive and innate immune surveillance. A phase 2 clinical trial showed a significant clinical benefit with an anti-PD-L1 and anti-NKG2A antibody combination versus an anti-PD-L1 antibody alone,1 suggesting that dual inhibition of the PD-L1/PD-1 and NKG2A/HLA-E axes are complementary strategies. XB628 is a bispecific antibody with two distinct targeted monovalent binding domains, one each for PD-L1 and NKG2A, and is generated using the B-Body® platform. It is designed to kill tumor cells by acting as a dual checkpoint inhibitor targeting PD-L1 on tumor cells and NKG2A on NK cells, and by recruiting NK cells to tumor cells. Preclinical characterization of XB628 is reported here.
Methods: Binding of XB628 to PD-L1 and NKG2A was assessed using cell lines expressing PD-L1 and NKG2A. PD-L1/PD-1 reporter and HLA-E tetramer competition assays were used to assess XB628-induced release of PD-L1/PD-1- and NKG2A/HLA-E-mediated signaling blockade, respectively. Co-localization of tumor and NK cells with XB628 was assessed by flow cytometry using cell lines expressing PD-L1 and NKG2A. T-cell activation was evaluated by measuring interferon-gamma and granzyme B secretion. The ability of XB628 to promote NK-cell mediated tumor cell killing was assessed at varying ratios of tumor and NK cells. In vivo efficacy of XB628 was assessed using a genetically engineered mouse model.
Results: XB628 bound to PD-L1+ cell lines with high affinity and released PD-L1/PD-1 inhibition in a dose-dependent manner; it also bound to NKG2A+ cell lines and released NKG2A/HLA-E inhibition. XB628 induced a high degree of colocalization of PD-L1+ tumor cells and NK cells; an intrinsic property of XB628 not observed with an anti-PD-L1 and anti-NKG2A monoclonal antibody combination. XB628-induced activation of CD8+ T cells. XB628 promotion of NK cell-mediated tumor cell cytotoxicity was greater than anti-PD-1 or anti-NKG2A antibodies alone or in combination. XB628 promoted tumor cell death even when tumor cells significantly outnumbered NK cells. In a genetically engineered mouse model, XB628 demonstrated a significant dose-dependent reduction in tumor volume.
Conclusions: XB628 is a first-in-class, bispecific antibody that simultaneously inhibits both adaptive and innate immune checkpoints by engaging PD-L1 and NKG2A, while also recruiting NK cells to tumor cells. XB628 is highly efficacious in tumor cell killing in vitro and in vivo, supporting further clinical development.

#6068 CT111, a novel trispecific PD-1 x CTLA-4 x VEGF single-domain antibody, synergistically targets exhausted T cells and promotes cooperative antitumor effects.

John Lee[1], Huiyuan Tang[1], Jia Yu[2], Weihong Wang[1], Leo Ng[1], Jing Yu[2], Yong Wang[1], Toya N. Baral[1], Jiaguo Li[2], Xinhao Wang[1], Qijun Qian[2], Wenfeng Xu[1]

[1]Chantibody Therapeutics, Inc., Menlo Park, CA,[2]Shanghai Cell Therapy Group Co., Ltd, Shanghai, China

Background: Dual PD-1 and CTLA-4 targeting immunotherapy shows enhanced therapeutic efficacy and is approved across multiple advanced solid tumor indications. In recent clinical trials, combined treatment of anti-PD-(L)1 with anti-VEGF have also been shown to improve clinical outcomes and overcome treatment resistance to either drugs alone. Bispecific antibodies targeting PD-(L)1/CTLA-4 and PD-(L)1/VEGF synergistically potentiates antitumor activity in preclinical models, and more recently, demonstrated enhanced clinical efficacy and tolerability. We developed a de novo, multi-targeting PD-1 x CTLA-4 x VEGF single domain trispecific antibody with enhanced synergistic anti-tumor activity by combining the effects of dual immune checkpoint and VEGF blockade.

Methods: Novel function-blocking anti-PD-1, anti-CTLA-4 and anti-VEGF single-domain antibodies generated from protein-immunized camelids were screened, optimized, and humanized using the VHHMAb® AI-powered platform. Multiple VHH leads were combinatorially screened in different Fc-backbone formats for optimal engagement of all three targets. Binding affinity and specificity were evaluated by protein-based ELISA, cell-based FACS and Octet BLI, and ligand blocking activities were measured by competitive ELISA, cell-based FACS and reporter assays. Multitarget interactions and avidity were measured by competitive ELISA, Octet BLI, and cell-based FACS. Bioactivity of PD-1 and CTLA-4 blockade on primary immune cells was evaluated in CMV-recall and SEB assays for cytokine release, and anti-VEGF bioactivity was determined in a HUVEC proliferation assay. Anti-tumor activity of CT111 was assessed in multiple hPBMC-engrafted humanized xenograft tumor models.

Results: All three de novo VHH antibodies used as building blocks for CT111 were selected based on strong functional activities that were superior to clinical benchmarks in cell-based assays. CT111 exhibited strong binding and optimal ligand blocking activity to human PD-1, CTLA-4 and VEGF alone and simultaneously in different assay formats. In CMV-recall and SEB stimulation assays, CT111 mediated potent IFN-γ and IL-2 secretion compared to clinical mono-targeting Ab combinations and bispecific benchmarks across multiple donors, and CT111 effectively blocked VEGF-mediated signaling and attenuated HUVEC proliferation. CT111 showed significant antitumor activity compared to clinical benchmarks, including AK112 and AK104, in PBMC humanized tumor models.

Conclusion: CT111 is a novel, potential first-in-class single-domain trispecific antibody that can simultaneously target PD-1 and CTLA-4 immune checkpoints on exhausted T cells, while also targeting VEGF-mediated tumor angiogenesis to overcome immune suppression synergistically within solid tumors.

#6069 A bispecific S100A4/TFR antibody to reprogram the GBM tumor microenvironment and target GBM stem cells.

T. Wong[1], J.-S. Leu[1], X. Fan[2], F. Leonard[1], M. Faisal[1], R. Kang[1], Y. Ali[1], N. Abdelfattah[1], N. Zhang[2], K. Yun[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]University of Texas Health Science Center, Houston, TX

GBM (glioblastoma) is the most common and aggressive primary brain tumor in adults. Despite advances in immunotherapy, current treatment modalities have only provided a modest benefit to GBM patients. We propose that enhancing the efficacy of immunotherapy for GBM requires approaches that increase T cell infiltration and reprogram the myeloid cells to a more pro-inflammatory state. We previously reported that S100A4 is a critical regulator of immune suppressive myeloid and T cell phenotypes and also a major regulator of glioma stem cells in GBM. Our preliminary data show that targeting S100A4 in either glioma cells or stromal cells is sufficient to reprogram the tumor immune landscape and extend survival of glioma bearing mice, indicating that S100A4 is a promising therapeutic target. We recently developed a S100A4 blocking monoclonal antibody; however, this antibody does not cross the blood brain barrier (BBB) efficiently to confer significant therapeutic benefit in glioma bearing mice. To overcome this challenge, we generated a bispecific S100A4-TfR antibody (BsA) that allows robust BBB penetration and accumulation in the brain. We assessed efficacy of BsA treatment in a highly aggressive and therapy-resistant, syngeneic mouse model of GBM (SVP). Using ELISA, confocal immunofluorescent microscopy, flow cytometry, and bulk RNA sequencing, we report that BsA treatment accumulates in the gliomas and reprograms the tumor immune microenvironment to increase T cell infiltration and pro-inflammatory activation. Furthermore, BsA treatment in combination with αPD1 checkpoint blockade significantly extends survival in the *SVP* mouse glioma model. Combination treated tumors exhibit extensive CD8 T cell infiltration and increased tumor reactive CD4 and CD8 T cells compared to controls. In addition, the BsA is taken up intracellularly within GBM cells and depletes S100A4 and nuclear SOX2 protein. In vitro treatment of GBM stem cell cultures with the BsA reduced self-renewal, as measured by the secondary sphere formation assay. These results indicate that the BsA is a promising agent to reprogram the GBM immune landscape and target GBM cell stemness through inhibition of both extracellular and intracellular S100A4 protein. We are currently performing in vivo efficacy studies in additional murine glioma models, and deeper mechanistic studies using single cell RNA sequencing and functional assays.

#6070 A novel epitope specific TIM-3 antibody significantly enhanced anti-tumor activities with bispecific format, not with combination strategy.

Xin Dong[1], Bu Tining[1], Bishnu Nayak[2], Jinyu Dong[1], Meiguang Xiong[1], Binbin Wang[1], Dong Wang[1], Haojie Wang[1], Yu Zhang[1]

[1]NeoLogics Bioscience Co. Ltd., Suzhou, Jiangsu, China,[2]NeoLogics Bioscience Co. Ltd., San Diego, CA

Introduction: T-cell immunoglobulin and mucin domain containing-3 (TIM-3) is expressed on T cells, NK cells and some myeloid cells, like macrophage and dendritic cells. Moreover, TIM-3 plays as a negative regulatory receptor and increased expression upon resistance to checkpoint inhibitor therapy. Particularly, recent studies strongly suggest that TIM-3 on myeloid cells, like dendritic cells, play a critical role for anti-tumor activity. Therefore, the dual blockade of PD-1 and TIM-3 holds hopes for enhanced clinical benefits.
Results: we have designed a bispecific anti-PD-1/TIM-3 antibody to optimize the immune response and anti-tumor activities by utilizing a novel epitope-specific anti-human TIM-3 antibody which displays enhancing NK cell activity and improving antigen processing ability of antigen presenting cells (APC), like DCs. This PD-1/TIM-3 bispecific antibody has demonstrated high affinity binding to human TIM-3 and PD-1 in the low nanomolar range. Moreover, it simultaneously binds to TIM-3 and PD-1 receptors through a trans manner, suggesting its potent capacity to enhance the interaction between T-cells and dendritic cells (DCs). In both MLR (mixed lymphocyte reaction) and T cell stimulation assays, the PD-1/TIM-3 exhibits synergistic activity compared to combination of PD-1 mAb and TIM-3 monoclonal antibodies or mAb alone. In addition, we have demonstrated superior anti- tumor activities in PBMC humanized xenograft mouse model as well as syngeneic human PD-(L)1 and human TIM-3 knock-in mice.
Conclusion: A bispecific humanized PD-1/TIM-3 antibody binds to both human PD-1 and TIM-3 strongly and effectively blocks the interaction with its ligand. This bispecific antibody enhances immune responses and anti-tumor activities *in vitro* and *in vivo* as measured by MLR assay, various animal models, etc., supporting the synergistic effects by targeting both acquired and innate immunity with this bispecific antibody.

#6071 PD-1xTGFβR2 bispecific Biclonics® antibody INCA33890 augments human T-cell effector functions in vitro and ex vivo.

Jun Guan[1], Aidan Gilmartin[1], Kenji Kimura[2], Estela Noguera-Ortega[2], Ashwini Kulkarni[1], Pat Feldman[1], Michelle Kinder[1], Cynthia Timmers[1], Alejandro Amador Arjona[1], Patrick Mayes[1], Steven M. Albelda[2], Evgeniy Erulasnov[3], Liang-Chuan Wang[1]

[1]Incyte Corporation, Wilmington, DE,[2]Department of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Department of Surgery, University of Pennsylvania, Philadelphia, PA

Anti-programmed cell death (PD)-1 and anti PD-ligand1 antibodies have produced durable clinical responses in a wide variety of solid and hematologic malignancies; however, their clinical benefits are often limited to a subset of patients. One of the immune resistance mechanisms that limits the activity of PD-1 axis pathway blockers involves activation of the transforming growth factor beta (TGFβ) pathway within the tumor microenvironment (TME). To overcome this immune suppression, a PD-1 and TGFβ receptor 2 (TGFβR2) dual targeting bispecific Biclonics® antibody, INCA33890, was developed. INCA33890 inhibits TGFβR2 preferentially on PD-1-positive cells (Wang L-C, et al. AACR 2023. Abs 2936). In this study, various in vitro and ex vivo cell-based systems were used to evaluate changes in T-cell effector function induced by INCA33890 compared with the anti-PD-1 antibodies, nivolumab or pembrolizumab. We observed that INCA33890 induced higher interferon gamma (IFNγ) levels than nivolumab with and without exogenous TGFβ in an exhausted T-cell mixed lymphocyte reaction (MLR) assay. Additionally, INCA33890 was superior to nivolumab in enhancing T-cell proliferation in the presence of TGFβ. RNAseq analysis of samples from the exhausted MLR assay revealed that, compared with nivolumab, expression of cytotoxic genes (*GZMB*, *GNLY*), proinflammatory cytokines (IFNG), and T-cell activation markers (CD25, 4-1BB) were elevated following INCA33890 treatment in the presence of TGFβ. We next co-cultured T-cell receptor-engineered T cells with non-small cell lung cancer tumor digests to examine the impact of the TME on antigen-specific T-cell responses. INCA33890 increased the percentage of IFNγ-producing T cells compared with pembrolizumab over 72 hours. In summary, our data suggest that co-inhibition of both PD-1 and TGFβR2 by INCA33890 may provide greater therapeutic benefits than an anti-PD-1 antibody alone.

#6072 Engineering and preclinical development of an anti-TROP2/PD-L1 bispecific antibody drug conjugate (ADC) for enhanced anti-tumor efficacy.

Chuan Chen, Liang Tian, Chenpeng Su, Dandan Liu, Jiyuan Tian, Yujuan Li, Bing Yang, Yongxin Shan, Xiaoqian Chen, Jian Peng, Zhenping Zhu

Helixon US Inc., New York, NY

Human trophoblast cell surface antigen 2 (TROP2) and programmed death ligand 1 (PD-L1) are often overexpressed in a variety of human cancers. Both anti-PD-L1 antibodies and TROP2-based antibody drug conjugates (ADCs) have shown significant clinical benefit, and a number of these agents, including atezolizumab and durvalumab (both anti-PD-L1 antibodies) and sacituzumab govitecan (an anti-TROP2-SN38 ADC), have been approved by the US FDA for certain cancer indications. The efficacy of these agents is, however, often limited by the unwanted on-target/off-tumor toxicities and the emergence of resistance of tumor cells. In this study, we engineered a humanized bispecific antibody (bsAb) simultaneously targeting both TROP2 and PD-L1 and produced several drug conjugates utilizing various linkers and cytotoxic payloads. The bsAb ADC binds efficiently to tumor cells that express either or co-express both TROP2 and PD-L1, trigger rapid ADC internalization, and induce potent tumor killing activity. Further, the bsAb ADC also effectively blocks PD1/PD-L1 interaction, and in parallel, induce PD-L1 internalization and down-regulation on tumor cell surface, resulting in significantly enhanced T cell activation for tumor cell killing. In multiple xenografted tumor models, the bsAb ADC demonstrated greater tumor inhibitory activity than their respective monospecific parent antibody ADCs. Taken together, our findings support further development of this bsAb ADC for the treatment of multiple TROP2- and/or PD-L1-expressing cancers, and of those patients who are refractory and/or resistant to TROP2 or PD-L1 single target-based therapies.

#6073 IDP-002 is a PD-1xCD6 bispecific antibody that enables complete PD-1 receptor occupancy and enhances cytotoxic over regulatory T cell responses.

Marc Gavin, Tsadik Habtetsion, Christie Mortales, Hayley Ma, Aniruddh Saxena, Mikaela Rusnak, Jing Song, Ben Setter, Robert Gene, Heath Klock, Carina Xu, Ertan Eryilmaz, Pamela Holland, Scott Lesley

InduPro, Seattle, WA

High response rates observed with PD-1/L1 antagonists have advanced immunotherapy to the forefront of treatment options for multiple cancer types; however, a substantial proportion of partial and non-responders warrants development of novel and more effective approaches. Poor responses to current PD-1/L1 antagonists may result from incomplete receptor occupancy, partial reversal of T cell exhaustion, and proliferative responses in PD-1$^+$ FOXP3$^+$ immunosuppressive regulatory T cells (Tregs) which will suppress anti-tumor effector T cell responses.

Importantly, the recently demonstrated superiority of the PD-1xVEGF bispecific antibody (bsAb) ivonescimab over pembrolizumab in PD-L1$^+$ advanced NSCLC suggests greater PD-1 receptor occupancy (achieved through high-avidity PD-1 binding of ivonescimab/VEGF multivalent complexes) leads to significantly deeper clinical responses.

Enhanced PD-1 receptor occupancy may also be achieved with *cis*-acting bsAbs that target PD-1 and an abundant T cell surface protein, enabling more efficient PD-1 blockade compared to that achieved with conventional mAbs. Furthermore, candidate co-targets can be evaluated not only by expression level, but also for co-stimulatory capacity and differential cell subset expression. For example, low co-target expression on Tregs or co-target signaling that attenuates Treg fitness would skew PD-1 antagonist activity towards effector T cells and reduce therapy-induced Treg responses.

Here, we present IDP-002, a PD-1xCD6 bsAb that facilitates complete PD-1 receptor occupancy and promotes greater proliferative and cytotoxic responses *in vitro* and in tumor-bearing humanized mice compared to current PD-1 antagonist mAbs. Tregs, which express lower levels of CD6, proliferate less efficiently than effector CD4 and CD8 T cells in response to IDP-002. Enhanced effector T cell responses observed with IDP-002 derive from a combination of complete PD-1 blockade and the engagement of unique signaling pathways downstream of CD6. IDP-002 has the potential to become a leading therapeutic option for the next generation of PD-1 antagonists.

#6074 INCA33890, a bispecific antibody targeting PD-1 and TGFβR2, shows enhanced immune responses in models of ovarian cancer.

V. Pandey[1], K. M. Foos[2], I. Pargiolas[2], M. Poussin[2], A. Kulkarni[1], L.-C. Wang[1], P. Mayes[1], D. J. Powell Jr[2];
[1]Incyte Corporation, Wilmington, DE, [2]Center for Cellular Immunotherapies, University of Pennsylvania, Philadelphia, PA

Although immune checkpoint inhibitors (ICIs) targeting pathways involving programmed cell death 1 (PD-1) and its ligand (PD-L1) are promising for some diseases, they have shown modest responses in ovarian cancer patients. Multiple studies have shown that ICI resistance is associated with the prevalence of transforming growth factor (TGF)-β signaling in the tumor microenvironment (TME). In patients with ovarian cancer, TGF-β expression is associated with immunosuppressive features in the TME and poor prognosis. PD-1 and TGF-β inhibitory pathways play independent yet complementary roles in immunosuppression, providing rationale for simultaneous targeting of both pathways. However, agnostic inhibition of the TGF-β pathway has historically led to detrimental side effects. Therefore, we developed a bispecific Biclonics® antibody that conditionally blocks the TGF-β pathway through TGFβR2, only on immunosuppressed T cells that coexpress PD-1. In this study, we tested the efficacy of the dual PD-1- and TGFβR2-binding Biclonics® antibody, INCA33890, in models of ovarian cancer. We used patient ascites (N=6) as a model of ovarian TME. INCA33890 treatment resulted in significantly higher levels of secreted interferon (IFN)-γ compared with control antibodies targeting only PD-1 (pembrolizumab) or TGFβR2 (TGF-1). A significant increase in T-cell activation markers, such as CD137, CD25, and CD69, was also observed in some samples treated with INCA33890 compared with controls. Next, we tested INCA33890 in an autologous coculture of tumor-infiltrating lymphocytes expanded from an enzymatically digested-patient tumor and enriched tumor cells from the same patient. In these cocultures, IFN-γ levels were significantly higher with INCA33890 treatment compared with pembrolizumab; levels were similar compared with TGF-1. For an in vivo assessment, we used double huPD1/huTGFβR2 knock-in mice implanted with ovalbumin (ova) and luciferase-expressing murine ovarian cancer ID8 cells. Mice treated with INCA33890 showed a significant reduction in tumor burden and improved survival compared with controls. A significant increase in tumor-associated ova-specific CD8+ T cells was observed with INCA33890 treatment compared with controls. Phenotypic analysis of CD8+ T cells revealed a skew toward an effector memory subset ($CD44^{high}$; $CD62L^{low}$ expression) with INCA33890 treatment. Thus, INCA33890 showed favorable results in a humanized ovarian cancer model and demonstrated a tumor antigen-specific T-cell response resulting in reduced tumor burden. Altogether, we show that INCA33890 presents a promising immunotherapy option for patients with advanced ovarian cancer by targeting 2 prominent immunosuppressive pathways, leading to a coordinated immune response. Clinical assessment of INCA33890 for various advanced malignancies, including ovarian cancer, is ongoing (NCT05836324).

#6075 The combination of an EpCAMx4-1BB bispecific antibody with PD-1 blockade exhibits antitumor activity in a murine tumor model unresponsive to each individual antibody.

A. Imle[1], S. Fellermeier-Kopf[1], A. Ioan-Facsinay[2], L. Wiedmann[1], M. Kohne[1], A. Toker[1], A. M. Diks[2], T. Ahmadi[3], A. Muik[1], K. Kemper[2], O. Tureci[1], E. Breij[2], U. Sahin[1];
[1]BioNTech SE, Mainz, Germany, [2]Genmab B.V., Utrecht, Netherlands, [3]Genmab Inc., Plainsboro, NJ

Activation of the costimulatory receptor 4-1BB and blockade of the PD1/PD-L1 axis can augment immune responses through distinct mechanisms. DuoBody®-EpCAMx4-1BB (BNT314/GEN1059) is an investigational Fc-silenced bispecific antibody (bsAb) designed to boost antitumor immune responses via EpCAM-dependent 4-1BB agonist activity. We previously showed that combining DuoBody-EpCAMx4-1BB with PD-(L)1 blockade potentiated T-cell effector functions *in vitro* compared to single treatments[1]. Furthermore, combining an EpCAMx4-1BB bsAb with PD-1 blockade exhibited potent antitumor activity *in vivo* in the immunogenic MC38 tumor model. Here we further investigated this combination in *ex vivo* tumor-infiltrating lymphocyte (TIL) assays using resected human colorectal cancer (CRC) specimens and *in vivo* using the less immunogenic B16F10 tumor model. DuoBody-EpCAMx4-1BB promoted $CD8^+$ T-cell and NK-cell expansion in human TIL assays, whereas pembrolizumab alone had minimal effect. Combined treatment with both antibodies further enhanced $CD8^+$ T-cell expansion in three of six specimens tested. The combination of an Fc-silenced bsAb targeting human EpCAM and mouse 4-1BB (hEpCAMxm4-1BB) with anti-mouse PD-1 showed robust antitumor activity in mice bearing human EpCAM-expressing B16F10 tumors. This was evidenced by significantly delayed tumor outgrowth and prolonged survival compared to both single treatments and a nonbinding control antibody, whereas hEpCAMxm4-1BB or anti-PD-1 as single treatments showed no antitumor activity compared to the control. Furthermore, combination treatment led to complete tumor regression in 2 of 11 mice. Flow cytometry analysis of the peripheral blood of tumor-bearing mice showed that hEpCAMxm4-1BB treatment enhanced $CD8^+$ T-cell and NK-cell activation and proliferation, and frequencies of $CD8^+$ T cells with an effector phenotype. The pharmacodynamic effects on $CD8^+$ T cells were further potentiated by the combination with anti-PD-1, whereas anti-PD-1 alone had no effect. NK-cell activation and proliferation was modestly further enhanced by combination treatment, compared to hEpCAMxm4-1BB alone. In addition, the combination significantly enhanced $CD4^+$ T-cell activation and proliferation, compared to each single treatment. In conclusion, combining Fc-silenced hEpCAMxm4-1BB bsAb with PD-1 blockade exhibited antitumor activity *in vivo* in a model unresponsive to each single treatment, suggesting synergistic effects of the combination. The immunomodulatory activity of EpCAMx4-1BB bsAb in mice and in human CRC TIL cultures was further potentiated in combination with PD-1 blockade. These data provide preclinical rationale for the clinical evaluation of DuoBody-EpCAMx4-1BB in combination with PD-1/PD-L1 checkpoint blockade.

[1] Fellermeier-Kopf et al, *J Immunother Cancer* 2024; 12(S2): A833.

#6076 Non-clinical pharmacology of HX044, a novel FIC CTLA4xCD47 bi-specific antibody.

H. Ke[1], T. Yang[1], F. Peng[1], J. Li[1], C. Chen[1], L. Xiong[2], R. Sun[3], L. Zhang[1], F. Zhang[1], **H. Q. Li**[1];
[1]Hanx Bio, Hangzhou, China, [2]Crown Bioscience, Taicang, China, [3]SMOC, Shanghai, China

A bispecific CTLA4-antibody/SIRPα-fusion protein, HX044, was created based on the hypothesis that it would increase antitumor immunity/activities via efficient cis-binding to co-overexpressed CTLA4 and CD47 on regulatory T cells (T_{reg}) within tumor microenvironment while decrease toxicity via lowered affinity to each individual target in peripheral. HX044, as designed as 1+1 asymmetric IgG1 composed of half anti-CTLA4 mAb plus the extracellular CD47 binding domain of SIRPα, binds to human CTLA4 recombinant protein with a EC_{50} at 1.5 nM or human CD47 recombinant protein with a EC_{50} at 8.12 nM, which are 30 times weaker than the bi-valent CTLA4 mAb or 160 times weaker than the SIRPα-Fc fusion protein, respectively. In addition, HX044 exhibited reduced blocking activities on the binding of CTLA-4 to CD80 or CD47 to SIRPα, respectively, with an IC_{50} at 135.8 nM for CTLA4 or 6316 nM for CD47. While HX044 also binds to the respective single-positive cells with reduced binding as compared to the parental single-targeting molecules, HX044 has significantly enhanced binding to the $CTLA4^{hi}/CD47^{hi}$-double positive cells, suggesting an increased avidity via efficient cis-binding. HX044 showed little binding to the CD47-single-positive RBC and minimized binding to platelets, suggesting its potential minimal hematotoxicity usually associated with other CD47-targeting therapeutics. On the other hand, the minimized blocking function of HX044 showed ina CTLA4-ligand blockade function assay may also potentially contribute to its lower risks of inducing immune-related adverse effect (irAE) usually associated with CTLA4 targeting. HX044 mediates strong ADCC toward double target-expressing cells, which is highly dependent on the CTLA4 expression levels. It has comparable FcRn binding as Ipilimumab (Ipi). In the hCTLA4 x hCD47 x hSIRPα HuGEMM mouse model, HX044 was shown to have strong anti-tumor activity to huCD47-MC38 colorectal tumor (classic “hot” tumor) at significant low dose (<0.2mg/kg) and huCD47-B16F10 melanoma tumor (traditionally “cold” tumor) (6.6mg/kg) accompanied by the reduction of TIL-T_{reg}. Notably, the anti-tumor efficacy of HX044 is significantly superior to Ipilimumab or $SIRP_{\alpha}$-Fc fusion protein at equivalent molar doses, respectively., In the weekly repeated dosing study in cynomolgus monkeys, HX044 at 1 mg/kg or 6 mg/kg showed no significant drug-related or non-recoverable toxicity findings, while one animal died due to infusion reactions and one animal was euthanized moribund due to electrolyte imbalance and malnutrition caused by prolonged loose stool in the 40mg/kg group. The Highest Non-Severe Toxic Dose (HNSTD) was determined to be 6 mg/kg. A single-dose intravenous infusion of HX044 PK study showed dose-dependent exposure with half-life around 220 hours at low dose, going down with dose increase. Overall, preclinical data of HX044 support its further clinical testing in cancer patients.

#6077 PLT012, a humanized CD36-blocking antibody, is effective for unleashing anti-tumor immunity and against liver metastasis.

Yi-Ru Yu[1], Sheue-Fen Tzeng[2], Zheng Meng[3], Jaeoh Park[4], Lana Kandalaft[5], Yun-Han Lin[1], Chin-Hsien Tsai[2], Ping-Chih Ho[4]

[1]Pilatus Biosciences, Epalinges, Switzerland,[2]Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan,[3]Society of Toxicology, Reston, VA,[4]Department of Oncology, University of Lausanne, Epalinges, Switzerland,[5]Department of Oncology, University of Lausanne, CHUV, Epalinges, Switzerland

Tumor cells employ various mechanisms to evade immune surveillance, including metabolic modulation of the tumor microenvironment (TME). Lipid metabolic stress in the TME leads to upregulation of CD36 in tumor-infiltrating immune cells, impairing anti-tumor immunity by enhancing the survival and suppressive activity of regulatory T cells (Tregs) and promoting ferroptosis and exhaustion in CD8+ T cells. Here, we developed PLT012, a humanized anti-CD36 IgG4 antibody targeting the lipid-binding domain of CD36, with a remarkable safety profile and favorable pharmacokinetics demonstrated in cynomolgus monkey models. Moreover, PLT012 significantly reduces tumor growth and reprograms the immune landscape, enhancing CD8+ T cell effector functions while reducing Treg-mediated suppression. In both immunotherapy-sensitive and resistant hepatocellular carcinoma (HCC) models, PLT012 alone or in combination with PD-L1 blockade induces robust anti-tumor immunity. Importantly, in a syngeneic liver metastasis model, PLT012 decreases immunosuppressive populations, enhances effector T cell responses, and reduces ICI resistance. Notably, *ex vivo* studies with human HCC samples further confirm PLT012's capacity to remodel the immune microenvironment. Taken together, these findings position PLT012 as a first-in-class immunotherapy targeting CD36, addressing critical challenges in HCC and liver metastasis treatment.

#6078 GFS202A, a novel GDF15×IL-6 bispecific antibody for the treatment of cachexia.

Xiangyu He, Jingyang Zhang, Yumei Li, Hongcan Ren, Siyuan Le, Fusheng Zhou, Jiong Lan, Qiang Lu

Genfleet Therapeutics, Shanghai, China

Cancer cachexia is a complicated syndrome characterized by loss of body mass, anorexia and progressive functional impairment. It is associated with intolerance and poor response to therapy, reduced life quality and unfavourable prognosis. Currently, pharmacologic intervention is limited without any FDA approved drugs. GDF15 and IL-6 derived from tumor and immune cells are major drivers of cachexia. GDF15 acts on receptor GFRAL and co-receptor RET which are expressed on neurons localized in area postrema (AP) and nucleus of the solitary tract (NTS) of the hindbrain, subsequently triggers downstream signal. IL-6 initiates trans- and classic- signals upon binding to soluble and membrane IL-6Rα respectively. These pathways together regulate adipose catabolism, muscle proteolysis, and impact appetite through neuronal circuit. GFS202A is a humanized tetravalent GDF15×IL-6 bispecific antibody, the Fc region is engineered to reduce Fc-mediated immune effect. It had high affinity to human GDF15 (K_D 0.05 nM) and IL-6 (K_D 0.313 nM), cross-reacted with cynomolgus monkey counterparts. GFS202A bound to antigens with high specificity, without binding to TGFβ family members GDF-8, BMP-3 and TGFβ1 or other IL-6 family members. GFS202A blocked interaction between GDF15 and GFRAL (IC_{50} 2.653 nM), neutralized GDF15-induced GFRAL/RET signal activation in 293T-luc reporter cells (IC_{50} 0.242 nM). GFS202A can inhibit both trans- and classic IL-6 signal in IL-6-induced BaF3-gp130 and BaF3-IL-6Rα/gp130 cells (IC_{50} 1.967 nM and 2.734 nM). In vivo efficacy was evaluated in tumor-induced cachexia mice. In human fibrosarcoma HT-1080 induced cachectic model, weekly IV administration of GFS202A effectively reversed body weight loss, 1, 4, 12 mg/kg GFS202A resulted in 5.61%, 11.61% and 24.71% tumor-free body weight gain when compared to isotype control. In ovarian cancer TOV21G cachectic model, weekly treatment of 1, 4, 12 mg/kg GFS202A increased tumor-free body weight by 4.55%, 20.62% and 37.35% respectively compared to isotype control. Adipose and muscle tissue weights in GFS202A groups also increased dose-dependently. Noticeably, GFS202A effectively reversed CRP elevation, indicating the function of bispecific antibody in relieving inflammation. In cynomolgus monkey PK study, single dose of GFS202A exhibited linear PK profile, Cmax and AUC increased in proportion with dose at the range of 1~25 mg/kg. GFS202A was well tolerated in cynomolgus monkey toxicity study, with a weekly dose regimen (qw ×5) the NOAEL was 300 mg/kg. Taking together, these preclinical findings show the potential of GFS202A as an innovative treatment for cachexia, with a projected clinical trial initiation in the first half of 2025.

#6079 Two is better than one: First in class anti-TIGIT IL-15 fusion antibody for enhanced tumor killing.

Tejal Bhatt[1], **Joyce Kim**[1], Wondae Kang[2], Rachel Etherington[1], Seulki Cheon[2], Sabrina Nielsen[1], Christian Willberg[1], Hongseok Jo[2], Yu-Hoi Kang[2]

[1]Research and Development, Medimab Biotherapeutics Ltd, Abingdon, United Kingdom,[2]Research and Development, MEDIMABBIO INC., Seongnam City, Korea, Republic of

Introduction: Immune checkpoint inhibitor therapies have revolutionised cancer treatment however, a portion of patients across malignancies become resistant or refractory to existing treatment. We have a first in class anti-TIGIT-IL-15 fusion antibody (MFA011) for treatment of solid tumors. Modes of action including superior tumor cell killing and increased immune effector function was observed in vitro. Significant inhibition of tumor growth and minimum toxicity was observed in 3 different hTIGIT knock-in mouse models. MFA011 has consistently outperformed competitor drugs when assessing pharmacokinetic activity providing a novel therapeutic option for cancer.

Methods: Mechanism of action for TIGIT was measured using a CD155-TIGIT blocking luciferase bioassay platform (Promega). We assessed specificity of IL-15 binding by ELISA and IL-15R signalling by measuring pSTAT5 phospho-staining. Immunotoxicity was assessed by cytokine release assay and off-target effects of IL-15 was measured by flow cytometry. In vitro efficacy was assessed in human PBMC from healthy donors using cytotoxicity assays (IncuCyte, Sartorius), ELISA, and flow cytometry-based assays, including intracellular cytokine staining and immune cell proliferation. In vivo efficacy of MFA011 was assessed using CT26 and Renca bearing BALB/c-hTIGIT knock-in mouse models with i.v. dosing of MFA011. In addition, anti-tumor effects were also observed in Hepa1-6 bearing C57BL/6 hTIGIT knock-in mouse model.

Results and discussion: MFA011 robustly bound and blocked CD155-TIGIT interactions and showed sustained signalling in comparison to unbound IL-15 cytokine alone. NK and CD8+ T cells showed increased proinflammatory cytokine production (IL-2 and IFNγ) and proliferation which led to improved anti-tumor killing observed in cancer derived cell lines. Conversely, regulatory T cells were depleted by antibody-dependent cellular cytotoxicity. Minimal immunotoxicity was observed and IL-15 bound specifically to cells that had been stimulated with MFA011. Reduction in tumor growth and stable biosafety profiles was observed in all mouse models after administration of MFA011.

Conclusion: Dual targeting of TIGIT and IL-15 signalling through MFA011 effectively enhances anti-tumor immune responses while limiting the off-target effects of IL-15 signalling. Our combined in vitro and in vivo data provides strong evidence to pursue MFA011 to IND filing and to commence phase I clinical trials.

#6080 Preferential tumor uptake and retention of EGL-001, an anti-CTLA4 -IL2 mutein fusion antibody achieving selective tumor Treg depletion.

Fiorella Kotsias[1], Alvaro Lladser[2], Marine Dubois[1], Caroline Janot-Sardet[1], Erica Russo[1], Anupama Karnam[1], Yann Courbebaisse[1], Mercedes Tkach[1], Reno Winter[1], Monica Gostissa[1], Pejvack Motlagh[1], Bernard Vanhove[1]

[1]Egle Therapeutics, Suresnes, France,[2]Centro Cientifico y Tecnologico de Excelencia Ciencia & Vida, Fundacion Ciencia & Vida, Santiago, Chile

Background: Regulatory T cells (Tregs) play a pivotal role in the immunosuppressive tumor microenvironment (TME), contributing significantly to resistance against immune checkpoint inhibitors. Targeting Tregs could reinvigorate anti-tumor immune responses. Tumor-associated Tregs express CTLA-4 and CD25 at levels markedly higher than their peripheral counterparts. EGL-001 consists of an anti-CTLA-4 antibody fused to an IL-2 mutein with antagonistic properties. It blocks CD80/86 interaction with CTLA-4 and inhibits IL-2-induced STAT-5 signaling in Tregs. Importantly, EGL-001 induces CTLA-4-dependent CD25 internalization and degradation in early endosomes. Deprived of IL-2 signaling, CD25-negative Tregs undergo apoptosis. Further studies were performed to investigate EGL-001 biodistribution.
Methods: The ability of EGL-001 to selectively localize in the TME, downregulate CD25 on tumor-associated Tregs in a CTLA-4-dependent manner, deplete Tregs, and restore effector T cell (Teff) activity was investigated through in vitro studies by flow cytometry and radiolabeling.
Results: After administering therapeutic doses in the MC38 colorectal carcinoma model, EGL-001 binds to tumor-associated Tregs but not Tregs in the periphery. It was not binding to other T cell types in the TME. Radiolabeling with 125-Iodine enabled the study of distribution in the tumor and other organs. Following the infusion of subtherapeutic doses of 125-I-EGL-001, EGL-001 was largely cleared from all organs by Day 7, whereas tumor retention remained visible up to Day 10. Additionally, Indium labeling of EGL-001 was conducted to longitudinally and quantitatively investigate tumor uptake. 111-In-EGL-001 localized to MC38 tumor sites within 1 hour and accumulated until day 2 when it represented 5% of the infused material. EGL-001 persisted in the TME for several days while being rapidly cleared from peripheral tissues. An assessment of intratumoral distribution revealed that EGL-001 did not diffuse uniformly throughout the tumor tissue but instead concentrated in defined zones, likely corresponding to mononuclear cell infiltrates.
Conclusions: Preclinical studies have demonstrated that EGL-001 exhibits potent anti-tumor activity by depleting Tregs and reactivating anti-tumor immunity. The current data indicates that EGL-001 preferentially acts within the TME, a phenomenon attributed to the strong overexpression of CTLA-4 and CD25 by tumor-associated Tregs compared to other Treg populations. This unique tumor selectivity sets EGL-001 apart from other Treg-targeting agents, presenting a promising strategy to overcome resistance to immune checkpoint blockade. EGL-001 is currently assessed in a First-In-Human clinical trial (NCT NCT06622486).

#6081 Bispecific antibody drug conjugates (bsADCs) targeting DLL3 and B7-H3 demonstrated potent anti-tumor activity in preclinical models of small cell lung cancer (SCLC).

Frank An, Kaiqing Zhang, Liu Yang, Peiran Li, Yu Qi, Jushi Gai, Luheng Du, Gao An, Chengzhang Shang, Yanan Guo, Yi Yang

Biocytogen, Waltham, MA

Lung cancer is the most common type of cancers and the leading cause of cancer-related mortality worldwide, with 2.5 million new cases and 1.8 million deaths in 2022. Small-cell lung cancer (SCLC) accounts for ~15% of all lung tumors, representing the most aggressive high-grade neuroendocrine carcinoma with a five-year survival rate of less than 4%. The majority of patients are diagnosed with extensive stage SCLC (ES-SCLC) with brain metastases in ~80% of cases, yielding a grim 5-year survival rate of under 2%. Many patients experience relapse following front-line therapies, and current second-line treatment options remain limited. Delta-like ligand 3 (DLL3) is highly expressed in SCLC, neuroendocrine tumors, and glioblastoma with minimally or no expression in normal tissues, making it an attractive target for SCLC. B7-H3, an immunoregulatory protein, is overexpressed in several tumor types, including SCLC. Both DLL3 and B7-H3 are validated targets for SCLC. Tarlatamab, a T cell engager targeting DLL3, was recently approved for SCLC. ADCs targeting DLL3 have shown robust anti-tumor activities in clinical trials. Similarly, anti-B7-H3 ADCs have also shown promising clinical potential.

We constructed a series of bispecific ADC (bsADC) that target both DLL3 and B7-H3 (DLL3xB7H3) simultaneously for SCLC and other tumors expressing these markers. We hypothesized that dual targeting could enhance selectivity and potency, address tumor heterogeneity in tumoral DLL3 and B7-H3 expression levels and allow a broader patient population for treatment. The bispecific antibody (bsAb) moieties of the bsADCs were designed in a1+1 format and were conjugated to a novel TOPO1 inhibitor payload with potent bystander effect (DAR 8) and a highly hydrophilic, enzyme-cleavable linker. In vitro, the bsAbs showed superior internalization in double positive cell lines than the parental monovalent arms and outperformed the naked antibodies of DS-7300 and rovalpituzumab (Rova). In vivo studies using a SCLC CDX model, the bsADCs demonstrated robust anti-tumor efficacy that was superior to DS-7300 ADC when conjugated to BLD-1102. The specificity of DLL3 targeting was validated in DLL3 negative CDX and PDX models in vivo. The bsAbs for our lead bsADCs exhibited excellent stability under stress conditions, suggesting their suitability for CMC development. In summary, our DLL3xB7H3 bsADCs showed promising and superior in vitro and in vivo preclinical activities with first-in-class potential for SCLC treatment.

#6082 Enhanced NK cell reactivity with Fc-optimized B7-H3 antibody for colorectal and non-small cell lung cancer.

Sylwia Anna Stefanczyk, Xenija Kaiser, Samuel J. Holzmayer, Ilona Hagelstein, Latifa Zekri, Susanne Jung, Melanie Marklin

Clinical Collaboration Unit Translational Immunology, German Cancer Consortium (DKTK), University Hospital Tubingen, Tubingen, Germany

Colorectal cancer (CRC) and non-small cell lung cancer (NSCLC) are among the deadliest cancers worldwide, especially in advanced stages with limited treatment options. While immune checkpoint inhibitors (ICIs) targeting PD-1/PD-L1 have shown significant potential, their efficacy is limited to a small subset of CRC patients with microsatellite instability-high (MSI-H) tumors, and their use in NSCLC is often limited by severe side effects, further restricting their applicability. This underscores the urgent need for alternative immunotherapeutic approaches employing novel targets to expand clinical benefit.

Here, we present a novel strategy exploiting natural killer (NK) cell mediated antibody-dependent cellular cytotoxicity (ADCC) using a monoclonal antibody (mAb) targeting B7-H3 (CD276). B7-H3, a B7 family immune checkpoint protein, is overexpressed in several tumor types, including CRC and NSCLC, but minimally expressed in normal tissues, making it an ideal target for cancer immunotherapy. Our engineered B7-H3 mAb, 8H8, was modified by introducing amino acid substitutions (S239D/I332E) in the Fc region to create the Fc-optimized variant 8H8-SDIE. This variant shows increased affinity for CD16 on NK cells, thereby enhancing ADCC potential.

Preclinical characterization demonstrated robust B7-H3 expression and specific binding of 8H8-SDIE to CRC (n=5) and NSCLC (n=3) cell lines, with saturation at approximately 1 µg/mL. Co-culture of allogeneic peripheral blood mononuclear cells (PBMCs) with B7-H3-positive CRC and NSCLC cells confirmed that 8H8-SDIE significantly activated NK cells, as evidenced by increased expression of CD69 and CD25. Upregulation of CD107a further indicated NK cell degranulation.

Additional analyses showed that 8H8-SDIE treatment promoted the secretion of IFNγ, TNF, and effector molecules such as granzyme A, granzyme B, granulysin, and perforin, thereby enhancing NK cell-mediated cytotoxicity. In short-term, mid-term and long-term cytotoxicity assays, 8H8-SDIE induced potent target cell-restricted lysis of CRC and NSCLC cell lines, while the iso-SDIE control showed no effect.

In conclusion, 8H8-SDIE is a potent immunotherapeutic candidate that effectively induces NK cell anti-cancer reactivity and represents a promising treatment option for CRC and NSCLC.

#6083 A fully human agonistic antibody against a unique epitope on TREM1 demonstrates immune stimulatory activities both in vitro and in vivo.

L. Yang, D. Liu, Z. Zhang, Y. Jiang, Q. Liu, **Q. Shi**;
Singlomics (Beijing DanXu) Biopharmaceuticals Co., Ltd., Beijing, China

Triggering receptor expressed on myeloid cells-1 (TREM1) is a proinflammatory receptor that amplifies immune responses. TREM1 is expressed on neutrophils, subsets of monocytes and tissue macrophages, and suppressive myeloid populations in the tumor microenvironment (TME), including tumor-associated neutrophils, monocytes, and tumor-associated macrophages. Stimulation by TREM1-mediated inflammatory signaling may promote an immunostimulatory TME and inhibit tumor growth. We developed DX002, a fully human agonistic anti-TREM1 monoclonal antibody. DX002 binds to a unique epitope and has low internalization property. Deep mutational scanning (DMS) of the human TREM1 antigen was applied to map DX002 binding epitope and result showed that DX002 was a ligand-competitive agonist that mimic the function of ligand PGLYRP1 protein. In vitro, Plate-bound DX002 up-regulates the expression of costimulatory molecules on monocytes and induces the production of proinflammatory cytokines. Moreover, soluble DX002 also induces the production of proinflammatory cytokines in PBMCs. In vivo, DX002 exhibits significant tumor growth inhibition activity in MC38 syngeneic model in human TREM1 transgenic mice. Taken together, the TREM1 agonistic antibody DX002 is shown to be active both in vitro and in vivo.

#6084 YH32364 (ABL104), a bispecific antibody against EGFR and 4-1BB, demonstrates potent anti-tumor efficacy through tumor-directed 4-1BB agonism.

Jae-Won Lee[1], Yangsoon Lee[2], Eunjung Lee[1], Hanna Hong[1], Byeong-Yun Ahn[1], Jangbeen Kyung[1], Young Bong Park[1], Junhwan Kim[1], Kyeongsu Park[2], Wonjun Son[2], Jaehyun Eom[2], Hanbyul Lee[2], Kyeongnang Moon[2], Yelim Park[2], Jonghwa Won[2], Se-Woong Oh[1], Yeul Hong Kim[1]

[1]Yuhan Co, Ltd., Seoul, Korea, Republic of,[2]ABL Bio Inc, Gyeonggi-do, Korea, Republic of

The epidermal growth factor receptor (EGFR) regulates cellular proliferation, differentiation, and survival, making it a critical target in cancer therapy. While EGFR-targeted therapies show efficacy in EGFR-overexpressing cancers, their use is limited by the frequent onset of drug resistance, necessitating novel approaches. Combining EGFR inhibitors with immunotherapy, such as targeting the costimulatory receptor 4-1BB (CD137) on activated T and NK cells, holds potential to improve anti-tumor responses. Recent advances in bispecific antibodies (bsAbs) allow for dual targeting strategies. Specifically, bsAbs containing T cell engagers improve immune responses by guiding T cells directly to tumor cells, thus enhancing immune targeting. Additionally, bsAbs that engage both 4-1BB and tumor-associated antigens (TAAs) amplify T cell activation within the tumor microenvironment, increasing the precision and efficacy of immune responses.A novel therapeutic agent, YH32364, was designed to address EGFR-related drug resistance through a dual mechanism: tumor-directed 4-1BB agonism combined with EGFR signal blockade. This approach aims to enhance tumor-localized 4-1BB activation while reducing the risk of excessive 4-1BB stimulation. Its binding affinity and activity were determined using surface plasmon resonance (SPR), a cell-based 4-1BB bioassay and immune mediated tumor killing assays using human peripheral blood mononuclear cells (hPBMCs). *In vivo* anti-tumor efficacy and antitumor immune response of YH32364 were assessed in mice models. 4-Week repeated dose monkey GLP toxicity study was also conducted. SPR analysis revealed high-affinity binding of YH32364 to both human EGFR and 4-1BB. YH32364 demonstrated strong 4-1BB activation and anti-tumor effects in EGFR-expressing cancer cell lines, as shown by IFN-γ secretion and subsequent tumor cell lysis. *In vivo* studies confirmed dose-dependent tumor regression by YH32364 and the induction of adaptive immunity in h4-1BB KI mouse models. Additionally, YH32364 recruited immune cells into EGFR-positive tumors, leading to modulation of the tumor microenvironment. As anticipated, no signs of hepatotoxicity were observed in a 4-week toxicity study in monkeys with no severe adverse findings on mortality, body weight, hematology, clinical chemistry, and other parameters. etc.Collectively, non-clinical studies demonstrate that YH32364 exhibits EGFR-dependent antitumor activity and induces long-term immunologic memory without hepatotoxicity. These findings suggest that YH32364 offers distinct advantages over conventional EGFR-targeted therapies by leveraging 4-1BB-mediated immunotherapy.

#6085 Engineered anti-CD40 agonist antibody as a novel cancer neoantigen vaccine carrier.

Dahee Jung[1], Xiaoying Cai[1], Wonkyung Oh[2], Seung-Oe Lim[2], Steve Lee[1]

[1]Department of Pharmaceutical Sciences, University of Illinois at Chicago, Chicago, IL,[2]Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN

Somatic mutations in cancer cells lead to the expression of neoantigens that can be targeted by personalized vaccines utilizing patient's own host immune system to fight against cancer. However, current personalized cancer vaccines have shown poor clinical outcomes due to the lack of effective delivery methods. To address the issues, our study aims to develop a novel vaccine platform that targets dendritic cells (DCs) and delivers neoantigen peptides more effectively by an anti-CD40 agonistic antibody expressing monovalent streptavidins (αCD40-mSAs). The agonistic anti-CD40 antibody will target and activate DCs, and the mSA compartment will allow the easy and fast loading of two biotinylated payloads (e.g. peptides and RNAs) on each vaccine carrier. CHO cell-based recombinant protein production method was used to biosynthesize αCD40 and αCD40-mSAs. Cloning vectors were reconstructed using mouse IgG2a, incorporating peptide sequences from the anti-mouse CD40 agonist antibody (clone FGK45) and monovalent streptavidin. For the biophysical properties of produced αCD40-mSAs, Surface Plasmon Resonance (SPR) for mouse CD40 and fluorescence polarization for biotin binding of mSAs have been used. Biotin- ovalbumin (OVA) peptide loaded αCD40-mSAs were subcutaneously injected into the footpad of the mice, and the collected lymph nodes were imaged with confocal microscopy and checked subtype of immune cells using flow cytometry. Antigen-specific T-cell responses were evaluated seven days post-injection by collecting lymph nodes and spleen. We successfully produced αCD40-mSAs, confirmed by increased molecular weight on the light chain expressing monovalent streptavidin. Binding assays demonstrated high-affinity interactions with mouse CD40 and effective biotin binding by the mSA moiety. In vivo targeting studies using fluorescently labeled OVA peptides revealed that αCD40-mSAs significantly enhanced peptide uptake in lymph nodes, particularly by cDC1 cells and macrophages. There was a notable increase in antigen-specific T cells, with an increase of OVA-specific $CD8^+$ T cells and increased production of cytokines IL-2 and IFN-γ upon restimulation when OVA peptides were loaded onto αCD40-mSAs. In conclusion, αCD40-mSAs represent an effective delivery platform for personalized cancer vaccines by targeting DCs and improving neoantigen peptide uptake, offering a promising strategy to boost vaccine efficacy in cancer immunotherapy.

#6086 Preclinical safety evaluation of VP1186, a CD47xEpCAM bispecific antibody.

Xiaocheng Chen[1], Xinhua Wang[1], Oi Kwan Wong[1], Leonard Post[1], Laurie Tatalick[2]

[1]Virtuoso Therapeutics, San Mateo, CA,[2]Laurie Tatalick Consulting, PLLC, Redmond, WA

The CD47/SIRPα axis is a critical checkpoint in the innate immune system, and CD47 is recognized as a prominent target for cancer treatment. While the clinical potential of CD47 blockade is evident, significant safety concerns have emerged. One major challenge is that CD47 is also expressed on healthy cells such as red blood cells (RBCs) and platelets. As a result, the first generation of therapies often caused serious side effects, including anemia and thrombocytopenia, which limited their therapeutic utility. EpCAM is a well-established tumor marker that is highly expressed in many epithelial cancers, such as colorectal, gastric, ovarian and lung cancers. We previously introduced VP1186 (also known as VBI-003), a novel CD47xEpCAM bispecific antibody that cross-reacts with both human and cynomolgus monkey antigens with comparable affinities. VP1186 selectively targets cancer cells with high EpCAM expression while sparing healthy cells. This tumor selectivity allows VP1186 to retain its Fc region with full effector function, acting as a potent "eat me" signal to the immune system. Consequently, VP1186 effectively activates macrophages and natural killer (NK) cells within the tumor microenvironment, enhancing the immune system's ability to eliminate cancer cells (*Journal for ImmunoTherapy of Cancer* 2021;9:doi: 10.1136/jitc-2021-SITC2021.274*),* (*Cancer Res* 2023;83(7_Supplement):1870). To further evaluate the safety profile of VP1186, we conducted a GLP-compliant repeat-dose toxicity study in cynomolgus monkeys. The bispecific antibody was administered intravenously at three dose levels as a 30-minute infusion once weekly for five consecutive weeks (Days 1, 8, 15, 22, and 29). The study also assessed the reversibility, progression, or delayed onset of any observed effects following 1-week and 4-week post-dosing periods. All animals were older than 3 years, with body weights ranging from 2.3 to 3.6 kg at the start of dosing. The results showed no clinically significant changes in clinical pathology endpoints, including hematology, clinical chemistry and coagulation, in VP1186-treated animals at doses up to 60 mg/kg/dose. Notably, RBC and platelet counts remained within the normal range across all dose levels, and hemoglobin concentrations stayed above the transfusion threshold throughout the study. No significant changes were observed in pancreatic enzymes, including lipase and amylase. Minimal effects on T cells were observed based on immunophenotyping (IPT) results. Transient but fully reversible changes in B cell and NK cell counts were noted. Pharmacokinetic (PK) analysis confirmed good drug exposure. These findings, combined with the potent anti-tumor activity of VP1186, support its further clinical evaluation as a potential treatment for CD47- and EpCAM-expressing cancers, particularly small cell lung cancer, gastric cancer, ovarian cancer and colorectal cancer.

#6087 A novel Ly6G6D/4-1BB bispecific antibody targeting DNA mismatch repair proficient colorectal cancers shows potent antitumor activities.

Zhiheng Ren, Xiang Li, Shushan Lin, Kuo Zhang, Zhaofeng Li, Xiao Lin, Kaifeng Li, Ju Peng, Mi Zheng, Wen Yang, LiJia Li, Xiaoping Li, **Stewart Leung**

HEC Pharma Co., Ltd, DongGuan, China

HEC921 is a novel bispecific agonistic antibody targeting Lymphocyte Antigen 6 Family Member G6D (Ly6G6D) and the immune agonistic receptor 4-1BB for the treatment of colorectal cancers. Ly6G6D is a tumor associated antigen highly expressed in DNA mismatch repair proficient (pMMR) colorectal cancers frequently resistant to immune check-point therapies. Activating monoclonal antibodies against 4-1BB have shown clinical efficacy but was limited by systemic toxicity. The design of HEC921 enables Ly6G6D-dependent agonism of 4-1BB in the presence of Ly6G6D positive tumor cells, enabling tumor specific T cell activation while minimizing systemic immune toxicity. A high affinity antibody against Ly6G6D and a nanobody against 4-1BB were identified for the construction of HEC921 containing an ADCC-silenced Fc. HEC921 shows potent co-binding to both Ly6G6D and 4-1BB targets and is cross reactive to the cynomolgus orthologues. In an assay using 4-1BB high expression 293 cells with NFκB-luciferase reporter, HEC921 mediated 4-1BB activation in the presence of Ly6G6D positive cells but not Ly6G6D negative cells. HEC921 promoted the production of cytokines IFN-γ, IL-2, and IL-4 in co-cultures of human T cells and Ly6G6D positive tumor cell lines. HEC921 demonstrated effective tumor growth inhibition in xenograft models of Ly6G6D positive tumor lines. Initial drug feasibility and toxicity studies results of HEC921 were favorable. Overall result demonstrated that HEC921 is a promising candidate for Ly6G6D positive cancer immunotherapy.

#6088 The bispecific antibody KA-5377, targeting CD19 and 4-1BB, specifically enhances T cell activity against lymphoma.

Guojin Wu, Jiabei Liang, Hao Peng, Feng Hao, Jinying Ning

Kyinno Biotechnology Co., Ltd, Beijing, China

KA-5377 is a novel bispecific antibody (BsAb) developed to target CD19 and human 4-1BB, addressing the challenge of dose-limiting toxicity associated with traditional 4-1BB agonist cancer immunotherapy. CD19, which is highly expressed in lymphoma, serves as an ideal target for this therapy. By restricting 4-1BB activation to the tumor microenvironment, KA-5377 aims to mitigate systemic toxicity. The 4-1BB nanobody used in KA-5377 was developed through our nanobody antibody discovery platform. KA-5377 is designed in an IgG1 format with a LALA mutation in the Fc region to eliminate ADCC (antibody-dependent cellular cytotoxicity) and ADCP (antibody-dependent cellular phagocytosis) activity, ensuring that the antibody's activity is focused on stimulating 4-1BB in T cells. The bispecific antibody contains two 4-1BB nanobodies at the C-terminal that engage 4-1BB signaling upon binding, and two Fabs at the N-terminal that bind to CD19 expressed on tumor cells. KA-5377 demonstrates high avidity for lymphoma tumor cells expressing CD19, while binding to 4-1BB expressed on 293T cells with significantly lower avidity. Notably, 4-1BB signaling is strongly activated only when the antibody binds to CD19 on tumor cells, with much weaker activation observed when CD19 binding is absent. The difference in EC50 (effective concentration for 50% activation) between the CD19-bound and non-bound states is approximately 100-fold, compared to only a 2-fold difference observed with the benchmark bispecific antibody Englumafusp Alfa.When combined with a low concentration of CD3 antibody to stimulate T cell activation, KA-5377 significantly enhances T cell activation and proliferation in co-culture assays using primary T cells isolated from human PBMCs. In PBMC-humanized immunodeficient mouse tumor models, KA-5377 improves the cytotoxic activity of bispecific antibodies targeting CD20 and CD3 against WSU-DLCL2 tumors, which highly express CD19. Additionally, KA-5377 exhibits a normal half-life in the blood of Balb/c mice and demonstrates good developability. Toxicity studies are currently ongoing. In conclusion, KA-5377, developed using our nanobody antibody discovery platform, represents a promising preclinical candidate for the treatment of Relapsed/Refractory B-cell lymphoma.

#6089 The bispecific antibody KA-3458, targeting CD38 and CD28, specifically enhances T cell activation within the tumor microenvironment.

Guojin Wu, Jiabei Liang, Zhengcheng Guo, Hao Peng, Feng Hao, Jinying Ning

Kyinno Biotechnology Co., Ltd, Beijing, China

KA-3458 is a bispecific antibody (BsAb) designed to target CD38 and human CD28, aiming to enhance T cell activation within the tumor microenvironment, particularly in blood cancers like multiple myeloma and lymphoma, where CD38 is highly expressed. While bispecific antibodies targeting tumor antigens and activating T cell receptor signaling have shown clinical promise, the addition of CD28 co-stimulatory signals may further boost T cell responses against tumors. KA-3458, engineered in an IgG4 format with an identical light chain, was created using our common light chain bispecific antibody discovery platform and knob-into-hole technology. The antibody's two Fabs show high affinity for CD38 and relatively lower affinity for CD28. In in vitro combination assays, KA-3458 significantly enhances T cell activation and cytotoxic activity of CD3 T cell engagers targeting CD20 or GPRC5D, which are critical for the treatment of lymphoma or multiple myeloma, respectively. Cytokine release assays performed with human PBMCs co-cultured with lymphoma cells revealed that KA-3458 enhances the release of INF-γ but not IL-6, in the presence of a CD20 T cell engager, suggesting a favorable safety profile. In PBMC-humanized immunodeficient mouse models, KA-3458 further improves the cytotoxicity of CD3 T cell engagers against CD20 or GPRC5D, targeting tumors in lymphoma or multiple myeloma models, respectively, which strongly express CD38. Additionally, KA-3458 has a normal half-life in Balb/c mice and demonstrates excellent developability. Toxicity studies are currently underway. In conclusion, KA-3458, developed using our common light chain bispecific antibody discovery platform, shows great potential as a preclinical candidate for the treatment of relapsed/refractory B-cell lymphoma and multiple myeloma.

IMMUNOLOGY: CAR Therapies: Emerging Approaches and Combinations
Poster Session

#6093 A novel dual chemokine receptor-expressing CD19 CAR-iPSC-derived NK cells (TB-219) to enhance cancer homing and therapeutic efficacy.

Jin-Jae Sung, Sung-Jin Park, Ji-Hee Kwon, Seung-Ki Baek, **Youngwook Ki**, Do-Won Hwang, Shin-Il Kim, Sung-Chang Lee

Therabest CO., Ltd, Seoul, Korea, Republic of

Introduction: Induced pluripotent stem cell-derived natural killer (iPSC-NK) cell therapies, characterized by exceptional homogeneity and scalable production with a single gene engineering step, are emerging as promising alternatives for the treatment of hematologic malignancies. While NK cells offer a superior safety profile compared to T cells, their limited ability to migrate to the bone marrow (BM) and lymph nodes (LN) significantly hampers therapeutic efficacy and contributes to cancer relapse. To overcome these challenges, we developed an off-the-shelf novel CD19-CAR-dEiNK (TB-219) cell therapy engineered to express dual chemokine receptors to enhance BM and LN homing, incorporating improved persistence and immune evasion capabilities.
Methods: TB-219 was modified to express a CD19 CAR for targeted cytotoxicity, CXCR4 and CCR7 for improved homing to bone marrow and lymphoid tissues, and IL-15RF for autonomous survival support. β2M was knocked out to evade host immune recognition, to avoid host T cell attack. Genetic modifications were achieved via homology-directed repair, followed by iPSC differentiation and bioreactor-based expansion. *In vitro* assays measured cytotoxicity against CD19-positive tumor cells, homing, and persistence, while *in vivo* studies in mouse models assessed tumor control and survival outcomes.
Results: TB-219 exhibited an 80% increase in cytotoxicity against CD19-positive cancer cells compared to unmodified NK cells at an effector-to-target (E:T) ratio of 2:1. Migration efficiency was enhanced by 200% and 400% through the expression of CXCR4 and CCR7 in transwell cell culture system, respectively. Additionally, β2M knockout effectively minimized recognition and elimination by host T cells, thereby improving persistence. Following a single i.v. administration of TB-219, no bioluminescent signals indicative of luciferase-expressing B cell leukemia cancer were detected through day 31, demonstrating complete control of cancer without evidence of relapse in the murine model. By day 39 post-administration, all subjects (Single and multiple injection) in the TB-219 treatment group demonstrated 100% survival, whereas complete mortality was observed in the tumor control group.
Conclusion: The advanced engineering of TB-219 incorporates significant improvements in persistence, cancer homing, and immune evasion, positioning it as a highly promising therapeutic candidate for CD19-positive hematological malignancies. The observed improvements in cytotoxicity, targeting, and survival in preclinical models suggest TB-219 may provide a durable and efficacious treatment option. These findings warrant further clinical investigation, positioning TB-219 as a potent and accessible NK cell therapy for patients with limited therapeutic options.

#6094 Enhanced GPC3-chimeric antigen receptor T cells with secreted bi-specific CD39-PD-L1 antibody for improved liver cancer therapy.

Zhongliang Li*[1], Bing Liu*[1], Huajing Wang*[2], Ke He*[3], Xiaopei Li[2], Dingjie Liu[4], Ligong Lu[1], Xu He#[1], Xiaowen He#[2], **Ze Yang#**[5], Meixiao Zhan#[1]

[1]Interventional Medical Treatment Department, Guangzhou First Pepople's Hospital，the Second Affiliated Hospital, School of Medicine, South China University of Technology, Guangzhou, China,[2]R&D Department, OriCell Therapeutics Co. Ltd., Shanghai, China,[3]Minimally Invasive Tumor Therapies Center, The Affiliated Guangdong Second Provincial General Hospital of Jinan University, Guangzhou, China,[4]Guangdong Provincial Key Laboratory of Tumor Interventional Diagnosis and Treatment, Zhuhai People's Hospital (Zhuhai Clinical Medical College of Jinan University), Zhuhai, China,[5]The Affiliated Dongguan Songshan Lake Central Hospital, Guangdong Medical University, Dongguan, China

Glypican-3 (GPC3)-targeted chimeric antigen receptor (CAR) T cell therapy shows promise for treating liver cancer. However, the immunosuppressive tumor microenvironment (TME), characterized by elevated levels of adenosine and PD-L1 expression, significantly hinders CAR T cell efficacy. We previously demonstrated that a bi-specific antibody, OriA631-B, which targets CD39—an enzyme crucial for converting extracellular ATP into adenosine—and PD-L1, yields significant antitumor effects. Our findings indicate that GPC3 CAR T cells upregulate CD39 upon activation by liver cancer cells, which also express PD-L1.To enhance antitumor efficacy, we engineered GPC3 CAR T cells to secrete a fragment of OriA631-B that targets both CD39 and PD-L1 (termed GPC3 CAR-T-CD39-VHH-PD-L1-ScFv). In a mouse model of liver cancer, GPC3 CAR-T-CD39-VHH-PD-L1-ScFv exhibited superior antitumor activity compared to GPC3 CAR T cells alone. Specifically, while GPC3 CAR T cells inhibited tumor growth, the GPC3 CAR-T-CD39-VHH-PD-L1-ScFv nearly eliminated tumors by day 20, whereas tumors in the GPC3 CAR T group measured around 200 mm^3.This enhanced efficacy is attributed to the localized delivery of the bi-specific antibody fragment, which effectively inhibits adenosine signaling and PD-L1-mediated immune checkpoint blockade.
Our findings suggest that GPC3 CAR-T-CD39-VHH-PD-L1-ScFv represents a novel therapeutic strategy for liver cancer, offering improved efficacy and potentially reduced side effects associated with systemic antibody administration.

#6095 T-Pure^{TM}: A bispecific antibody cocktail for T cell isolation from human blood, enabling simple and affordable point-of-care CAR-T manufacturing.

Ying Xiong[1], Yanping Xie[1], Ann Wang[1], Victor Bass[1], Matt Addington-hall[1], Oxana Slessareva[1], Yang Liu[1], Tony Luo[1], Ibeawuchi Oparaocha[1], Kathy Schonely[2], Kara Anlauf[1], Megan Forrest[1], Jacqueline Schaeffer[2], Shashi Koduru[2], Andrew Worden[2], Mike Kadan[2], Boro Dropulic[1], Zhongyu Zhu[1]

[1]Caring Cross, Inc., Gaithersburg, MD,[2]Vector BioMed, Gaithersburg, MD

Adoptive immunotherapy with engineered T cells, especially chimeric antigen receptor (CAR) T cells, has revolutionized the treatment of leukemia, lymphoma, and multiple myeloma. However, the high production costs of CAR-T therapy severely limit patient access. To address this challenge, we developed T-pure^{TM}, a proprietary bispecific antibody cocktail for isolating T cells from human blood through negative selection. The Bi-specific antibody cocktail selectively links red blood cells (RBCs) to key marker antigens on non-target cells, such as B cell, NK cell, Monocytes, and granulocytes, allowing easy and cost-effective separation using Ficoll density gradient centrifugation. By isolating T cells without engaging their surface receptors, this approach avoids inadvertent activation of isolated T cells, while also preserving cell types like γδ T cells, which show promise for their anti-tumor potential. Additionally, the depletion process efficiently removes CD19-positive cancer cells and can be tailored to eliminate T cell subpopulations like T regulatory (T-reg) cells that could compromise CAR-T efficacy in clinical application. This versatile antibody cocktail can also be adapted to isolate other cell types, such as NK cells, B cells, and monocytes for various biomedical applications. Designed for cost-effective clinical manufacturing, our GMP grade T-pure reagents are commercially available to academic and industry partners for preclinical and clinical applications. This work highlights the ongoing innovation in CAR-T manufacturing and the potential for optimizing cell selection protocols to enhance efficacy and lower the cost of cell therapies.

#6096 Acquired CAR-T therapy resistance in a pre-clinical model of pediatric rhabdomyosarcoma minimal residual disease.

A. M. Lulu, D. A. Cobb, N. Park, L. Liu, D. W. Lee;
University of Virginia, Charlottesville, VA

Introduction: Current treatments for relapsed/refractory or metastatic rhabdomyosarcoma (RMS) are ineffective. Integrin αvβ3 plays a role in progression, metastasis and neovascularization in several cancers. HER2 is expressed on a majority of RMS and contributes to progression and metastasis in other cancers. Our lab previously demonstrated the efficacy of HER2 and αvβ3 CAR Ts in controlling or eliminating pediatric brain tumors. CAR T therapies for solid tumors face numerous obstacles with limited clinical success. While bispecific CAR Ts can overcome heterogeneous antigen expression and antigen modulation, CAR T suppression and tumor evasion is multifactorial. Success requires understanding the mechanisms driving clinical failure. Here we developed a minimal residual disease (MRD) model of CAR T resistant RMS to evaluate the mechanisms driving acquired resistance after profound initial tumor control.
Methods: Control of intramuscular RMS tumors (RH30) by αvβ3 or HER2 CAR Ts was assessed in NSG mice, with CD19 CAR T controls. After 7 weeks, CAR T infiltration, antigen expression and residual disease characteristics were determined by flow cytometry and immunohistochemistry (IHC). In a pilot experiment, mice were treated with a second CAR T dose or rechallenged with a second tumor in the opposite leg. Tumor burden was evaluated by bioluminescence imaging and caliper measurements; MRD and CAR T infiltration were determined by IHC.
Results: Both αvβ3 and HER2 CAR Ts nearly eliminate RMS tumors. However, despite robust initial control and CAR T persistence in both treatment groups, MRD remains. αvβ3 expression minimally decreases following αvβ3 CAR T treatment, although expression is 10-fold higher than the parental cell line. Both αvβ3 and HER2 CAR Ts control tumors in a delayed treatment model, despite HER2 down-regulation with tumor progression. By the time of MRD, 60% of tumor-infiltrating αvβ3 CAR Ts have upregulated multiple exhaustion markers (TIM3, LAG3, PD-1 and TIGIT), in contrast to only 10% of circulating αvβ3 CAR Ts and 10% of tumor-infiltrating CD19 CAR Ts. After αvβ3 or HER2 CAR T treatment, surviving tumor cells upregulate cognate exhaustion ligands (HLA-DR, Galectin3, Galectin9 and PD-L1), consistent with the development of a suppressive tumor environment. Despite this, αvβ3 and HER2 CAR Ts, likely from circulation, control a secondary tumor without delay. Neither the original CAR Ts nor a second dose of CAR Ts eliminate MRD at the primary tumor site.
Conclusions: We developed a pre-clinical model of CAR T resistant MRD in which to evaluate specific mechanisms of acquired tumor resistance and CAR T dysfunction in RMS. Different mechanisms, distinct from antigen modulation, arise based on the CAR treatment. Continued investigations into these mechanisms will ultimately enable superior CAR T cell design that is resistant to tumor-mediated inhibition.

#6097 FcRγ and TLR4 based CARs in DCs modulate antitumor T cell priming.

Shelby Namen, Alex Kim, Gaurav Pandey, Carl DeSelm

Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Immunotherapies have advanced the field of cancer therapy for hematologic malignancies but have not had similar success in solid tumors. Due to their abundance in solid tumors and ability to phagocytose, we developed a chimeric antigen receptor (CAR) macrophage (M) that reduced tumor burden in syngeneic mice. However, in syngeneic mice lacking conventional type 1 dendritic cells (cDC1) the effect was lost suggesting that a mechanism of CAR-M function is through antigen transfer to cDC1s, which then prime an antitumor T cell response.

Purpose: To directly induce antitumor T cell responses, we tested different antitumor CAR constructs in cDC1s (DCs). Toll-like receptors (TLRs) and Fc receptors (FcRs) are major types of receptors in phagocytes, with different downstream signaling; we focused on understanding the impact of TLR4 and FcRγ signaling CARs on DC function. We compared the impact of each CAR on the DC's ability to phagocytose tumor cells, cross-present or degrade the captured antigen, induce costimulatory molecule expression, and cross-prime tumor-specific T cells.

Methods: Mouse bone marrow derived DCs were electroporated with mRNA encoding for anti-B7H3 (B7) TLR4, FcRγ, or truncated (t) CAR. The CAR DCs were cultured with AF488-ovalbumen (ova) loaded MCA-induced sarcoma tumor that expressed human B7 (B7+) or was B7 negative (B7-) to assess uptake of tumor antigen. To determine the impacts on cross-priming, the CAR DCs were cultured with B7+ and B7- ova loaded MHCI negative tumor cells and naïve CD8 OTI T cells.

Results: The FcRγ CAR improved target-specific tumor antigen uptake by >10x compared to CAR(t), while the TLR4 CAR improved tumor uptake by 1.6x. Although the TLR4 CAR DCs did not take up as much antigen, it cross presented the antigen more effectively, as it had 4x more surface expression of MHCI:SIINFEKL compared to the FcRγ CAR. The TLR4 CAR induced slower degradation of antigen compared to the FcRγ CAR. The TLR4 CAR also induced higher levels of CD70, CCR7, and CD86 expression compared to the FcRγ CAR. Both the TLR4 and the FcRγ CAR DCs induced greater proliferation of OTI T cells relative to CAR(t) DCs. The proliferated OTI T cells from the TLR4 condition had a 2.8x increase in tumor killing of ova-loaded, B7- tumor cells, indicating that the quality of the T cell response may differ if the T cells are cross-primed by a DC experiencing TLR4 versus FcRγ signaling at the time of tumor antigen capture.

Conclusion: This data suggests that engineered DCs with either FcRγ or TLR4 CAR led to increased tumor uptake and cross presentation compared to a truncated CAR; however, the two CARs lead to different downstream signaling pathways that impact the amount of antigen cross-presented, activation marker expression, and the quality of the antitumor T cell response. These findings suggest *de novo* antitumor T cell responses can be enhanced and shaped by DCs engineered with CARs having different signaling domains.

#6099 STEAP1 targeting CAR-T cells equipped with collagen-binding IL-12 for advanced prostate cancer.

Koichi Sasaki[1], Vipul Bhatia[2], John K. Lee[2], Jun Ishihara[1]

[1]Department of Bioengineering, Imperial College London, London, United Kingdom,[2]Department of Medicine, UCLA, Los Angeles, CA

Metastatic castration-resistant prostate cancer (mCRPC) is a largely incurable, immunologically cold solid tumor. Six-transmembrane epithelial antigen of the prostate 1 (STEAP1) is a promising target specifically expressed in >85% of mCRPC patients. Chimeric antigen receptor (CAR)-T cells transformed the clinical landscape of blood cancers. However, CAR-T therapy is still not very effective against solid cancers including prostate cancer, in part due to immunosuppressive tumor microenvironment (TME) and antigen heterogeneity. Interleukin-12 (IL-12) is a promising cytokine to address these issues through activation and recruitment of immune cells to the tumor. IL-12 can induce epitope spreading to fight antigen heterogeneity. Previously, armored CAR-T cells that express wild-type (wt) IL-12 were developed, but there is still room for improvement in tuning potency and safety. Adoptive transfer of autologous IL-12-expressing T cells showed objective responses in melanoma patients; however, the trial was limited by toxicity. The result suggests that IL-12 secreted from CAR-T cells are locally produced but still toxic due to the cytokine's diffusion into systemic circulation. Here, we report STEAP1-targeting CAR-T cells that conditionally express collagen-binding domain fused IL-12 (CBD-IL-12) upon recognizing STEAP1 protein. We show that CBD fusion to IL-12 significantly increased the concentration of IL-12 in mouse prostate tumors and suppressed its systemic spread following secretion from the CAR-T cells. This resulted in equivalently high intra-tumoral levels of interferon-gamma (IFN-γ), C-X-C motif chemokine ligand 9 (CXCL9) and granulocyte-macrophage colony-stimulating factor (GM-CSF) without increase of serum alanine aminotransferase (ALT) and T cell infiltration into non-target organs compared to wt IL-12. Flow cytometric analysis showed increase of T cells, NK cells and cross-presenting dendritic cells and decrease of monocytic myeloid-derived suppressor cells (M-MDSCs) in the tumor following CBD-IL-12 expressing STEAP1 CAR-T cell therapy. CBD-IL-12 expressing CAR-T cells combined with anti-PD-1 and anti-CTLA-4 antibodies eradicated an established mouse prostate cancer model without preconditioning and generated anti-tumor immune memory. CBD fusion to potent yet toxic immunotherapies may make a breakthrough in the development of CAR-T therapy that can safely overcome solid tumors.

#6100 Point-of-care manufacturing of FOLR1-directed CAR T cells for the treatment of ovarian cancer.

Christoph Herbel[1], Manuel Martinez-Osuna[1], Larissa Steiner[1], Maria Bethke[1], Leon Osinski[1], Katrin Krischer[1], Janina Brauner[1], Cathrin Bleilevens[1], Jens Kopatz[1], Katja Petry[2], Dominik Eckardt[1]

[1]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany,[2]Miltenyi Biomedicine GmbH, Bergisch Gladbach, Germany

Treatment options for ovarian cancer patients are limited, highlighting a significant unmet need for targeted, durable, and effective therapies. In recent years, adoptive cell transfer therapies have made tremendous progress in the past years. Genetically engineered T cells expressing a chimeric antigen receptor (CAR) are promising drugs that can be directed towards a defined target and have shown efficient, as well as persisting, anti-tumor responses in different indications. Recently, we have reported the preclinical evaluation of a novel FOLR1-targeting CAR directed against ovarian cancer and potentially other FOLR1-expressing tumors. Despite advancements in T cell therapy, producing a functional and robust cell product in the necessary quantities remains challenging. Currently available processes for the preparation of CAR T are laborious and include numerous manual handling steps, which increase the risk of errors and may impose safety risks. This underscores the need for reliable and automated manufacturing processes to ensure high-quality cellular products for immunotherapy. This study aimed to develop an automated, closed, and good manufacturing practice (GMP)-compliant process for FOLR1-specific CAR T cells. Using the CliniMACS Prodigy® Platform, we established a streamlined process in a closed system that meets stringent regulatory requirements while reducing hands-on time. We optimized culture conditions to reduce the process time to 7 days. Starting from a cryopreserved leukapheresis we achieved a clinically relevant yield of FOLR1-specific CAR-engineered T cells. The cellular product mainly consisted of highly viable CAR-expressing T cells with an early memory phenotype. FOLR1-specific CAR T cells manufactured with the optimized process showed specific killing of ovarian cancer cells *in vitro* and in an ovarian cancer xenograft model *in vivo*. Moreover, the automated CliniMACS Prodigy Platform enables point-of-care (POC) manufacturing. In conclusion, we developed a robust, rapid, and efficient process for manufacturing anti-FOLR1 CAR T cells. This platform is well-suited for automated and decentralized POC manufacturing and can be adapted for the production of other CAR T cell therapies.

#6102 BAFF ligand CAR-T cells for hairy cell leukemia variant treatment.

Claire Elizabeth Fritz[1], Derek P. Wong[1], Akshaya Radhakrishnan[2], Philip Rock[3], Richard Burack[3], Reshmi Parameswaran[2]

[1]Pathology, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Medicine, Case Western Reserve University School of Medicine, Cleveland, OH,[3]Department of Pathology and Laboratory Medicine, University of Rochester Medical Center, Rochester, NY

Hairy cell leukemia variant (HCL-v) is a rare B-cell malignancy that is biologically distinct from the classical form (HCL-c) and presents unique treatment challenges. The characteristic genetic or molecular markers of classical HCL include CD11c, CD25, CD103, CD123, the $BRAF^{V600E}$ point mutation, and tartrate resistant acid phosphatase (TRAP) expression. However, HCLv cells have a low immunologic score and don't carry the $BRAF^{V600E}$ mutation or express TRAP. Treatment with the purine nucleoside analogs (PNAs) is effective in a majority of HCLc patients, who can look forward to a normal lifespan. However, HCLv patients are resistant to this treatment, which likely contributes to the significantly shorter prognosis of 6-9 years, in addition to the relative lack of druggable targets. To address poor clinical outcomes for HCL-v patients, we aimed to test a novel cellular therapy for HCL-v. We recently developed a third generation BAFF-ligand chimeric antigen receptor (CAR-T) cell product. B-cell activating factor (BAFF) is a critical factor that promotes B-cell maturation and survival. BAFF binds to three receptors, including BAFF-Receptor (BAFF-R), transmembrane activator and CAML interactor (TACI), and B-cell maturation antigen (BCMA). Because of the pro-survival signaling that BAFF enhances upon binding to its receptors, B-cell cancers tend to exploit this signaling, and serum BAFF levels are often elevated. In a panel of HCLv cell lines and patient-derived splenocytes, we found that HCLv cells have high expression levels of all three receptors. In co-culture assays with fluorescently labeled HCLv patient samples and cell lines, CAR-T cells express significantly elevated markers of degranulation (CD107a) and activation (CD69) and secrete elevated levels of pro-inflammatory cytokines and lytic enzymes relative to control T-cells. BAFF CAR-T cells also display significantly increased cancer cell killing relative to control T-cells. This enhanced cancer cell killing was also observed in an autologous model, where CAR-T cells were generated from a de-identified HCLv patient and co-cultured with the patients' own cancer cells. Similar findings were seen in multiple novel in vivo HCL xenograft models, in which BAFF CAR-T cell treatment (intratumor or intravenous) resulted in decreased tumor burden without significant toxicities.While we have seen success in our in vivo models, we also aim to generate a novel patient-derived xenograft model of HCLv to more accurately model the disease, both for more CAR-T cell translational studies and for more basic investigations into HCLv mechanisms. An additional future direction is to explore whether our BAFF CAR-T cells, which bind three receptors can mitigate antigen escape, the process by which tumor cells downregulate a target to avoid killing. To do so, we will perform single and double receptor knockouts of BAFF-R, TACI, and BCMA and assess if cell killing is intact with in vitro co-culture assays.

#6103 BCMA CAR engineering arms T cells with superior functions post *ex vivo* stimulation by MUC1 peptide-loaded autologous PBMCs.

Kun Yun[1], R. Leo Sakemura[1], Ismail Can[1], Omar Gutierrez Ruiz[1], Ekene J. Ogbodo[1], Truc N. Huynh[1], Claudia Manriquez Roman[1], Olivia Sirpilla[1], Carli M. Stewart[1], Jennifer M. Feigin[1], Grace E. DeFranco[1], Sophia Y. Goldberg[1], Dominic A. Skeele[1], Mariam Stein[1], Dara Missan[2], Latha Pathangey[2], Long Mai[1], Hong Xia[1], Brooke Kimball[1], Lionel A. Kankeu Fonkoua[1], Mehrdad Hefazi[1], Michael W. Ruff[1], Elizabeth L. Siegler[1], Leif Bergsagel[2], Michael Gustafson[2], Sandra Gendler[2], Saad S. Kenderian[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Phoenix, AZ

Chimeric antigen receptor T (CART) cell therapy has shown clinical successes in B cell hematological malignancies. Two B cell maturation antigen (BCMA)-directed CART cell therapies treating multiple myeloma (MM) were approved by FDA but most patients relapse within 1-2 years. *Ex vivo*-expanded antigen specific T cells as cancer treatment rely on TCR-mediated killing of tumors. We hypothesized that arming *ex vivo* enriched tumor-specific T cells with CARs targeting a different antigen improves T cell functions. First, we expanded mucin 1 (MUC1)-activated T cells from patients with MM through *ex vivo* stimulation by MUC1 peptides-loaded autologous PBMCs for 19 days. Then, we engineered MUC1-activated T cells with 4-1BB-co-stimulated BCMA CAR to generate MUC1 TCR^+BCMA CAR^+ T cells. Baseline T cells without MUC1 stimulation were engineered with BCMA CAR as control. Baseline T cells, MUC1 T cells, baseline BCMA CART cells, or MUC1 BCMA CART cells were cocultured with luc^+ RPMI-8226, a $MUC1^+BCMA^+$ MM cell line, for 3 days. MUC1 BCMA CART cells showed stronger tumor killing than BCMA CART or MUC1 T cells in all 3 patients ($p<0.0001$). MUC1 BCMA CART showed improved proliferation than BCMA CART or MUC1 T cells ($p=0.0765$, $p<0.0001$, respectively) after a 5-day stimulation by RPMI-8226. To exclude possibility of metabolic alterations by 19-day PBMC incubation leading to better T cell functions in MUC1 BCMA CART, baseline and MUC1-stimulated T cells from 3 healthy donors were processed for the same assays. Day-19 BCMA CART cells showed inferior tumor killing compared to baseline BCMA CART in all 3 donors ($p<0.0001$). Lower T cell proliferation was also observed in day-19 BCMA CART ($p=0.0838$). Our data indicate that improved T cell functions in MUC1 BCMA CART were unlikely due to metabolic changes and required stimulation by tumor antigens prior to CAR engineering likely through MUC1 TCR. Additionally, MUC1 T cells, BCMA CART, or MUC1 BCMA CART cells from tested patients were stimulated by RPMI-8226 for bulk RNA sequencing. Both BCMA CART and MUC1 T cells had distinct transcriptomic features from MUC1 BCMA CART cells. Differential gene expression analysis showed upregulation of T cell function-associated genes (*RYR2*, *ITGA1*, *GNLY*, *GZMA*, etc.) in MUC1 BCMA CART vs BCMA CART. Enrichment of T cell function-associated pathways was also observed in MUC1 BCMA CART. Analysis between MUC1 T cell and MUC1 BCMA CART showed upregulation of T cell function-associated genes (*CSF2*, *CRTAM*, *IFNG*, *GZMB*, etc.) and enrichment of immune response pathways in MUC1 BCMA CART. Our findings suggest that equipping *ex vivo*-enriched tumor-specific T cells with CARs targeting a different antigen improves T cell functions *in vitro*. Importantly, this provides a rationale for a therapeutic regimen where patients receive *ex vivo*-enriched tumor-induced T cells followed by CAR engineering. Persistence of the engineered T cells is being investigated

#6104 Comparative evaluation of CAR-expressing T-, NK-, NKT-cells and macrophages in an immunocompetent mouse glioma model.

Payal B. Watchmaker[1], Ryusuke Hatae[1], Akane Yamamichi[1], Keith Kyewalabye[1], Kaori Okada[1], Su Phyu[1], Yitzhar Goretsky[1], Jeffrey Haegelin[1], Psalm Pineo Cavanaugh[1], Marco Gallus[1], Lan Phung[1], Tiffany Chen[1], Hayou Long[1], Pavlina Chuntova[1], David H. [1]Neurological Surgery, UCSF, San Francisco, CA,[2]Department of Molecular and Cell Biology, UC Berkeley, Berkeley, CA,[3]Neuro-Oncology Branch, National Cancer Institute, Bethesda, MD

While chimeric antigen receptor (CAR) T-cells are promising, there is a rapidly growing interest in developing other CAR-expressing immune cells. However, to date, no reported studies evaluated these cells side-by-side in immune-competent glioma models. We developed a novel transgenic mouse strain with all hematopoietic cells expressing EGFRvIII-targeting CAR, allowing for rigorous evaluations of CAR-NK, CAR-NKT, and CAR-macrophages compared to CAR-T-cells in a syngeneic mouse SB28-EGFRVIII glioma model. CAR-NK and CAR-NKT-cells demonstrated anti-tumor effects comparable to CAR-T-cells in vitro. A single intratumoral administration of CAR-T and CAR-NKT-cells in combination mediated superior therapeutic efficacy compared to CAR-T-cells or CAR-NKT-cells alone. A single intravenous infusion of CAR-NK-cells following lymphodepletion failed to mediate significant anti-glioma effects associated with inferior persistence to CAR-T cells. Additionally, intratumoral injection of CAR-NK-cells did not confer therapeutic benefit. Contrary to previous reports using human macrophages, CAR-macrophages did not demonstrate enhanced antigen-presentation activity against glioma cells compared to non-CAR macrophages. Intratumorally administered CAR-macrophages failed to demonstrate local persistence or anti-tumor effects in vivo. These data provide a valuable basis as to which CAR-expressing immune cells can mediate effective anti-glioma response in an immuno-competent glioma environment. Our data also suggest that a combination of CAR-T and CAR-NKT-cells may represent a promising therapeutic strategy.

#6105 iPSC-derived HER2 CAR-iNKT cells enhance the activity of immune cells against cancer cells.

Koichiro Shioya[1], Tomio Matsumura[1], Akane Urakami[1], Tomokuni Shigeura[1], Aki Naito[1], Yu-Ching Lin[1], Mio Shiraishi[1], Yuji Mishima[1], Haruhiko Koseki[2], Shinichiro Motohashi[3], Lilin Zhang[1]

[1]BrightPath Biotherapeutics Co., Ltd., Tokyo, Japan,[2]Center for Integrative Medical Sciences, Riken, Yokohama, Japan,[3]Department of Medical Immunology, Graduate School of Medicine, Chiba University, Chiba, Japan

Invariant natural killer T (iNKT) cells directly kill tumor cells through TCR and NKG2D, and also exert anti-tumor activity indirectly by promoting dendritic cell (DC) maturation, activating CD8+T cells and repolarizing macrophages. iNKT cells do not trigger graft versus host disease, making them an attractive cell type for an “off-the-shelf” cell therapy platform. We are developing iPSC-derived iNKT (ipsNKT) cell therapy to overcome manufacturing challenges due to the low abundance of iNKT cells in blood. It is not clear whether ipsNKT cells, especially when the cells are gene edited, still preserve multifunctional properties of native iNKT cells. In this study, we evaluated these intrinsic direct and indirect anti-tumor functions of iNKT cells using HER2-targeting CAR-ipsNKT cells. HER2-CAR-ipsNKT cells were differentiated from HER2 CAR-edited iPS cell line under a feeder cell-free condition and exerted potent cytotoxicity when cultured with HER2 positive HCC1954-CMVpp65 cells. HER2-CAR-ipsNKT cells released cytokines including IL-4, TNF-α and IFN-γ upon CAR-stimulation by HER2 antigen. After co-culturing monocyte derived immature DCs with HER2-CAR-ipsNKT cells, the expression of DC maturation markers like CD80, CD83, CD86 and HLA-DR were markedly upregulated, suggesting that HER2-CAR-ipsNKT cells promote DC maturation. When monocytes were cultured in conditioned medium from HER2-CAR-ipsNKT cells, polarization of M1 macrophages was observed by detecting expression of the M1 macrophages markers using flowcytometry. Intriguingly, conditioned medium of HER2-CAR-T cells did not show the same result. To evaluate whether HER2-CAR-ipsNKT cells can promote cytotoxic T lymphocyte (CTL) activity *in vivo*, HCC1954-CMVpp65 cells were inoculated subcutaneously into NOG-hIL15Tg mice. After the tumor volumes reached 100~200 mm^3, 1×10^5 PBMCs were injected intratumorally, followed by intravenous doses of HER2-CAR-ipsNKT cells. Initially, all animals showed comparable tumor growth, however, the tumor xenografts in the HER2-CAR-ipsNKT cell treatment group started to regress after 3 to 4 weeks of treatment, suggesting an indirect anti-tumor contribution of HER2-CAR-ipsNKT cell by activating-tumor specific CTLs. This speculation is supported by the observation that the CD8+T cells and CMVpp65 tetramer+ cells were increased in both spleen and tumor of the treatment group. This study demonstrated that HER2-CAR-ipsNKT cells promote DC maturation and M1 macrophage polarization, likely due to cytokine release from HER2-CAR-ipsNKT cells as a result of CAR-stimulation, and also activate tumor antigen-specific CD8+T cells, thereby enhancing anti-tumor effect *in vivo*. These results suggest that administration of iPSC-derived CAR-iNKT cells to a patient can improve tumor microenvironment and activate the host endogenous tumor-specific CTLs, potentially achieving a durable therapeutic response.

#6106 A regulated, cell-intrinsic cytokine engineering strategy to enhance the in vitro and in vivo persistence of iPSC-derived CAR-T cell therapies.

Siddarth Chandrasekaran[1], Justin Yoo[1], Michael H. Cadell[1], Laura Prochazka[2], Elisa Martinez[2], Jen F. Lai[1], Muluken S. Belew[2], Amanda AuYeung[2], Chris Saxby[1], Omar Subedar[2], Zahra Sahaf[2], Dylan Lee[2], Sommer Apelu[1], Libin Abraham[1], Chloe Hurling[2], Vaisakh Rajan[2], Shruti Sharma[2], Charlie Liu[2], Richard Carpenedo[3], Shri Joshi[2], Elizabeth Csaszar[2], Emily Titus[2], Chris Bond[1]

Large-scale clinical production of induced pluripotent stem cell (iPSC)-derived CAR-T cells represents a remarkable opportunity in allogeneic cell therapies. Despite the growing advantages offered by iPSCs such as multiplex gene editing and unlimited starting material, most iPSC derived CAR-T cells demonstrate limited clinical proliferation and persistence. This has been partially attributed to existing iPSC differentiation protocols that yield only cytotoxic CD8 T-cells, whereas conventional autologous and donor-derived CAR-T therapies contain a mixture of CD8 and supportive CD4 T-cells. It has been established that cytokine signaling via the JAK/STAT pathway plays an important role in promoting CAR-T cell function. Herein we describe novel engineered receptors that can induce JAK/STAT signaling in iPSC derived CD8 T-cells. We show that iPSC derived CD8 T-cells have a unique JAK/STAT signaling requirement for long-term cytotoxicity and proliferation in our in vitro assays. We show that our engineered receptors can induce JAK/STAT signaling in the absence of exogenous cytokines in culture media. When fully differentiated CD8 T-cells are transduced with engineered cytokine receptors, they show long-term persistence in the absence of exogenous cytokines in vitro. We observed that premature activation of JAK/STAT signaling pathways can skew cells toward a myeloid or innate lymphoid cell lineage. To circumvent this, we designed iPSC clones with an engineered cytokine receptor integrated into a specific locus under the control of context-specific regulatory sequences. These designs exhibited a stringent off-state during differentiation and CAR-dependent transcriptional responsiveness when exposed to target antigen. This data reveals that a regulated strategy can control cytokine receptor expression during differentiation, to preserve phenotype and improve efficacy of differentiated cells. Further, constitutive activation of JAK/STAT signaling may drive adverse side-effects, and we demonstrate that our regulated designs show complete lack of activity in the absence of antigen stimulation. Finally, we evaluated iPSC derived CD8 T-cells harboring the regulated cytokine engineering strategy in vivo. Engineered iPSC derived CD8 T-cells showed tumor growth inhibition and persistence in the absence of exogenous cytokines in a disease relevant lymphoma Raji model. Engineering of appropriate cytokine support and strategies to regulate expression during differentiation is an important first step to enhance the persistence of iPSC derived CD8 T-cells. A major advantage of using iPSC derived CD8 T-cells is their potential for drug re-administration without toxic lymphodepletion and exogenous cytokine support. We believe that cell-intrinsic cytokine support is critical to develop durable and safe allogeneic T-cell therapies for patients.

#6107 Tailoring mRNA expression in T-cell therapy: advancing CAR-T functional optimization.

Gilad Gibor[1], Shai Kilim[1], Neve Tzvi[1], Ortal Harush[1], Orit Itzhaki[1], Ronnie Shapira[1], Elad Jacoby[2], Gal Cafri[3], Yochai Wolf[1]

[1]Immuno-oncology, Sheba Medical Center, Ella Institute, Ramat-Gan, Israel,[2]Center for Pediatric Cell Therapy, Sheba Medical Center, Ramat-Gan, Israel,[3]Immunotherapy and Genetic Engineering, Sheba Medical Center, Ramat-Gan, Israel

Background: T cell engineering is an emerging field in immune-oncology, and new T cell-specific modalities are required, such as gene insertion via mRNA. Cells display diverse functions and identities, requiring tailored approaches for efficient mRNA delivery. Most mRNA constructs contain standard α-globin UTRs, lacking the specificity needed for optimal T cell mRNA expression.
Methods: In our study, we developed modRNA constructs by replacing the standard hemoglobin 5'-UTR with sequences derived from genes highly expressed in normal or exhausted T cells, aiming to enhance mRNA stability and protein expression. mRNA constructs containing reporter genes were electroporated into PBMC-derived T cells, with expression levels measured by flow cytometry.
Results: Interestingly, we observed significant differences, with notable variability in expression arising from the replacement and directly linked to the specific gene substituted. Certain UTRs, such as Interferon gamma (IFNG), showed superior and sustained GFP expression, while others, such as TNF, exhibited reduced activity. Based on these observations, we expressed diverse CAR constructs in T cells, revealing distinct protein turnover and tonic signaling profiles. Specific constructs exhibited rapid decay, while others displayed more stable expression. These turnover patterns suggested significant differences in CAR expression levels across constructs and their impact on tonic signaling, reinforcing earlier findings on the influence of 5'-UTRs in CAR-T expression. Particularly notable were constructs that exhibited significantly lower activity and reduced expression of key activation and well-established hallmark markers of exhaustion. Cytokine secretion assays further confirmed diminished tonic signaling, especially in non-target co-cultures.
Conclusions: These results underscore the critical role of T cell-specific UTRs in fine-tuning CAR-T cell activity and reducing off-target effects.

#6109 Dual targeting of cancer and stromal cells, by combining a FAP-CAR and a PRAME TCR, enhances T cell infiltration and efficient eradication of a wide range of hard-to-treat solid tumors.

Paul Najm, Kathrin Skibbe, Mikhail Steklov, Panagiota A. Sotiropoulou, **Marleen M. Van Loenen**

T-knife Therapeutics Inc., San Francisco, CA

Background: The immunosuppressive tumor microenvironment (TME) is a significant barrier to improving the clinical efficacy of T cell receptor (TCR) T cell therapies in solid tumors. The TME largely consists of stromal cells such as cancer associated fibroblasts (CAF) that support tumor growth and hamper immune responses by forming a physical barrier preventing T cell infiltration and exerting immunosuppressive activity. A common cell surface antigen of CAFs with limited expression in healthy tissue is fibroblast activating protein (FAP). Dual targeting T cells expressing an anti-FAP CAR together with a PRAME-specific TCR and CD8 co-receptor (CoR) were generated using non-viral gene editing. This construct enables depletion of CAFs and disruption of the tumor's supportive stroma and immune barriers, thereby enhancing TCR-T cell infiltration and tumor eradication.

Methods: Ten scFvs against FAP were engineered into 2nd gen 4-1BB CARs and retrovirally transduced into PMBCs. FAP-CAR T cells were selected based on CAR expression using flow cytometry and cytotoxicity against FAP positive target cells. T cells were non virally gene edited with selected FAP-CARs in combination with a HLA-A*02 restricted PRAME-specific TCR and a CD8 CoR. Functionality was tested under repeated antigen stimulation in 2D and 3D in vitro cancer models expressing physiological levels of FAP and PRAME.

Results: Ten anti-FAP CARs bearing different scFvs were screened based on T cell surface expression and functional activity against FAP overexpressing BT-549 cancer cells. An in vitro multi-cellular model was developed consisting of GFP-labelled cancer cells expressing physiological levels of PRAME and immortalized RFP positive fibroblasts expressing physiological levels of FAP. T cells co-expressing a PRAME TCR, CD8 CoR and 4 selected FAP-CARs were generated and tested for cytotoxicity upon repeated stimulation. Two candidates enabled multiple rounds of killing. Then, a multicomponent 3D spheroid model of non-small cell lung cancer (NSCLC) was developed combining cancer cells, monocytes, CAFs and extracellular matrix, mimicking the dual action of TME, raising a physical barrier against T cell infiltration and mediating immune suppression. Constructs containing an anti-FAP-CAR demonstrated a superior infiltration, cytotoxicity and cytokine secretion profile compared to TCR-T cells without CAR armoring.

Conclusion: Dual targeting T cells incorporating both a FAP-CAR and a PRAME TCR demonstrated successful infiltration and effective eradication of both cancer cells and stromal cells within our proprietary, multicomponent 3D spheroid model mimicking the harsh NSCLC TME. This approach holds promise to tackle a major challenge in solid tumor therapy, increasing T cell infiltration and eliciting potent, durable anti-tumor responses.

#6110 Improving CAR T cell potency against low-density targets in rhabdomyosarcoma.

Caroline Piccand[1], Andrea Timpanaro[2], Dila Handan Kaymaz[3], Jochen Karl Rossler[3], Michele Bernasconi[3]

[1]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland,[2]Ben Towne Center for Childhood Cancer Research, Seattle Children's Research Institute, Seattle, WA,[3]Department for BioMedical Research (DBMR), University of Bern, Bern, Switzerland

Engineering of L1CAM-directed CAR T cells aims to demonstrate high efficacy and better persistence in rhabdomyosarcoma (RMS) models. RMS is the most common pediatric soft tissue sarcoma, and the low overall survival rates for metastatic RMS emphasize the urgent need for improved therapies. Chimeric Antigen Receptor (CAR) Ts have shown remarkable efficacy against hematological malignancies; however, their application in solid tumors remains challenging, mainly due to the absence of ideal targets and to the immunosuppressive nature of the tumor microenvironment (TME). To optimize antitumor activity against RMS and increase CAR T cell persistence *in vivo*, we investigated novel CAR constructs targeting newly identified RMS surface proteins. Through comprehensive RMS surfaceome profiling and validation in patient-derived tumor microarrays (TMAs), we identified L1CAM as attractive target. To evaluate the efficacy of L1CAM-directed CAR T cells against RMS, we generated a panel of anti-L1CAM.CE7 CARs expressing either a long (IgG4CH2CH3, 229aa) or a short (CD28, 35aa) hinge moieties, each paired with either a CD28- or 4-1BB-derived costimulatory domain (CSD).48h co-incubation experiments revealed that anti-L1CAM CAR T cells with long hinge and CD28 CSD showed superior efficacy, killing up to 60% of RMS cells at an Effector-to-Target (E:T) ratio of 1:1 and releasing double amount of IFN-γ compared to other constructs. To corroborate these findings *in vivo*, the selected anti-L1CAM.IgG4CH2CH3.28.3ζ CAR Ts were tested against the orthotopic RMS model Rh30, expressing low copy numbers of L1CAM (~10'000). Despite limited efficacy following the initial CAR T dose, we observed tumor eradication in 2/5 mice and survival benefit in the remaining cohort after administration of a second dose on day 12. Furthermore, by bioluminescence of CAR T cells, we observed long-term persistence of CAR T cells in murine lymph nodes and the abdominal region for up to 50 days post-injection. To enhance therapeutic outcomes and achieve complete remission in 5/5 mice, we modified the anti-L1CAM.IgG4CH2CH3.28.3ζ construct to co-express an additional CD3ζ-mock CAR targeting CD276 - highly expressed on RMS - designed to boost the activation of anti-L1CAM CAR Ts (termed "IF-BETTER" CAR). In vitro screening identified 4-1BB as the optimal CSD for the CD276-associated CAR, which conferred enhanced activity to the L1CAM.IgG4CH2CH3.28.3ζ construct against RD and Rh30 cells, reaching up to ~80% at the E:T ratio of 1:2. Furthermore, the selected IF-BETTER anti-L1CAM CAR Ts improved potency against the challenging Rh4 cells, which express very low copies of L1CAM (~2'000). The selected IF-BETTER CAR Ts are currently tested in preclinical studies. These findings highlight the potential of the IF-BETTER anti-L1CAM CAR T cells as a promising therapeutic strategy for L1CAM^{dim} tumors like RMS.

#6111 Reprogramming ROR1 CAR-T cells with SNIPR logic gating promote safety, while keeping anti-tumor efficacy in a tumor-bearing animal model.

Linyan Deng[1], Yuhua Wan[2], Jingyu Li[1], Jian Hua[2], Di Zhu[3], **Hua Zhang**[1]

[1]SPH Biotherapeutics (HK) Limited, Hong Kong, Hong Kong,[2]SPH Biotherapeutics (Shanghai) Limited, Shanghai, China,[3]Department of Pharmacology, Fudan University, Shanghai, China

CAR-T cell therapies have shown promise in the treatment of cancers. However, off-target toxicities often occur due to heterogeneous and low-abundance target expression by normal tissues. ROR1 is a good tumor target being expressed by many tumor tissues and cells. But normal tissues also express a lower level of ROR1, which sometimes led to patient fatalities in clinical trials with ROR1 CAR-T. Here we developed and demonstrated a two-antigen recognition platform using SNIPR logic gating to control the cytotoxicity of ROR1 CAR-T cells, limiting them to the tumor site *in vivo,* and thus mitigating the risk of attacking normal vital tissues.

Methods: Using SNIPR (synthetic intramembrane proteolysis receptors) (Zhu, et al. *Cell*, 185(8):1431-1443.e16, 2022), we engineered T cells with an inducible ROR1 VHH CAR expression that was controlled by an external sensor protein PD1. We then applied the PD1/SNIPR-based ROR1 CAR-T cells to a tumor-bearing animal model, which could recognize PDL1, commonly expressed in many tumor cells, and then turned on the CAR-mediated killings to those cells.

Results: PD1-specific reporter induction of the SNIPR-based ROR1 CAR-T cells was confirmed *in vitro* using flow, IL2 production, and Incucyte's real-time killing assays when co-culturing separately with PDL1-overexpressing MDA MB231 cells (ROR1+) as a positive control, and other ROR1+ tumor cell lines expressing variable levels of PDL1 at an E:T ratio of 1:1. In the native MDA MB231 and PD1-overexpressing MDA MB231 xenografted animal models, after we infused the CAR-T cells at $4x10^6$ cells/mouse via the tail vein, we found that non-gated ROR1 CAR-T group showing a quicker tumor shrinkage starting D11 at a mean tumor size of $70mm^3$ when treating the native tumor. However, in the gated group treating the same native tumor we observed a delayed and steady decline of the tumor volume starting D15 (the mean $120mm^3$). Its shrinkage continued down to a mean tumor volume of $48mm^3$ D29, almost close to the size (the mean $49mm^3$) of the non-gated ROR1 CAR-T group D29, whereas the gated group treating the PD1-overexpressing MDA MB231 revealed a quick tumor shrinkage D15 (the mean $100mm^3$), leveled the tumor curve D22 (the mean $50mm^3$), and began to show the signs of GHVD on D25.

Conclusion: We successfully demonstrated the therapeutic potential of our two-antigen recognition platform using SNIPR logic gating in an xenografted animal model. This platform enables us to reconfigure and develop safer and more effective CAR products suitable for clinical translation.

#6112 Supercharging anti-tumor immunity in hepatocellular carcinoma with PH102: A CAR T-cell-based platform.

V. T. Pham[1], S. Fu[1], V. Sanchez[1], Y.-G. Liu[2], K. Liu[1], A. Bernal[2], L. Sun[1], G. Huang[1];
[1]MD Anderson Mays Cancer Center at UT Health San Antonio, San Antonio, TX, [2]UT Health San Antonio, San Antonio, TX

Hepatocellular carcinoma (HCC) is the 5th leading cause of cancer death in the US among males (7th among females) and remains a major cause of cancer-related death worldwide with especially high prevalence in South Texas (12 per 100,000). HCC is caused by HBV/HCV infections, metabolic dysfunction, and alcoholic steatohepatitis. The majority of HCC patients present clinically with advanced disease and are treated with *ineffective* systemic therapies including chemotherapy and/or immune checkpoint inhibitors. There's a pressing need for an innovative, curative immunotherapy for advanced, unresectable HCC for whom liver transplantation is not possible. The tumor immune microenvironment (TiME) of HCC is a complex milieu of tumor, stromal, and immune cells that interact to modulate tumor growth. We designed a first-in-class precision immunotherapy approach based on established chimeric antigen receptor (CAR) T-cell technology that packages three different targeting approaches into a comprehensive cell-based platform to rebuild the anti-tumor TiME. PH102 is a CAR T-cell-based therapy targeting GPC3 (tumor antigen highly expressed in HCC but not healthy hepatocytes or normal tissues) while co-expressing factors A and B, immune signaling molecules that supercharge anti-tumor immune cells. We have shown exceptional preclinical safety and efficacy of PH102 in multiple solid tumor animal models including a tumor implantation model and a hydrodynamic tail vein injection (HTVI) murine model of *in situ* HCC. PH102 has been demonstrated to significantly improve probability of survival in mice carrying advanced HCC tumors, eliciting powerful elimination of advanced tumors via immune killing of cancer cells. Immunomodulatory factors A and B synergize to induce increased infiltration, expansion, and activation of cytotoxic T-cells, tissue resident memory T-cells, conventional NK cells, liver resident NK cells, and dendritic cells within the TiME. Altogether, PH102's triple-hit approach induces a potent and durable anti-tumor, immune-triad-mediated killing program alongside creating long-term immune memory that persists long after CAR T-cell exhaustion. PH102 is warranted to be translated into a phase I/II HCC trial following final preclinical safety and efficacy validation.

#6113 Cytotoxic and antitumoral effect of an anti-CD44v6 CAR-T against gastric cancer.

gonzalo gonzalez[1], Moonsoo Jin[1], Yanping Yang[1], Elizabeth Ortiz[2], Yogindra Vedvyas[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]Instituto Nacional de Cancerologia, Mexico City, Mexico

Background: Gastric cancer ranks among the top 5 cancer types in terms of both incidence and mortality, with a 5-year overall survival rate of only 29%. CD44 variant 6 (CD44v6) is an isoform of CD44 and is identified in 70% of gastric cancer cases. CD44v6 is considered a marker of poor prognosis, and its expression varies among different types of gastric cancer. CD44v6 has a role in apoptosis resistance, metastasis, and tumor progression, and is shown to be enriched in recurrent tumors. CD44v6 expression in normal tissue is very low and is restricted to certain cell types. Therefore, CD44v6 is a promising target for targeted therapies against gastric cancer. In this study, we aim to develop a chimeric antigen receptor (CAR) T cell therapy targeting CD44v6 and evaluate its functionality, cytotoxic activity and antitumoral effect. The scFv was derived from the monoclonal antibody (mAb) known as bivatuzumab (BIWA-4), a humanized mAb that has been used in clinical studies as radiotherapy and as antibody drug conjugates.
Methods: Plasmid containing the CAR sequence with the BIWA-4 scFv was synthesized, and Jurkat T cell line and primary human T cells were transduced with lentivirus containing the CAR sequence. Jurkat cell line was used to measure binding to recombinant protein and assess CD69 expression after antigen exposure. Primary T cells transduced with CAR were co-cultured at different E:T ratios with gastric cancer cell lines (AGS, SNU 638, and MKN45) with different levels of expression of CD44v6. Target cell killing was measured by flow cytometry, bioluminescence, and fluorescence microscopy. T cell exhaustion and exhaustion phenotype were evaluated prior killing assays. For *in vivo* experiments, NSG mice will be engrafted with gastric cancer cell lines and tumor progression will be evaluated by IVIS.
Results: While high affinity variants of bivatuzumab have been used to construct CAR (BIWA-8), ours is the first study that used medium affinity variant known as BIWA-4. Jurkat cells transduced with the car construct demonstrated specific binding to the recombinant monomeric CD44v6, which triggered surface expression of early T cell activation marker CD69. With varying concentrations of monomeric CD44v6, the affinity of CAR to CD44v6 was determined to be ~100 nM K_D. Transduction efficiency of primary T cells remained stable, reaching ~60% after 10 days of expansion. Most CAR T cells exhibited effector memory phenotype, with low levels of PD1. CD44v6 CAR T killing in vitro was correlated with the E: T ratio and the level of antigen expression, demonstrating specificity of CAR and avoiding off-target effects with CD44v6 negative cells.
Conclusion: We have successfully developed CAR T cells possessing medium affinity against CD44v6 and confirmed CAR-specific killing of CD44v6 positive gastric cancer cells.

#6114 Engineering novel synNotch CAR T cells to precisely and effectively target medulloblastoma.

Maggie Colton Cove[1], Senthilnath Lakshmanachetty[1], Milos Simic[1], Robert Zhu[1], Chanelle Shepherd[1], Lia Cardarelli[2], Sachdev Sidhu[2], Olga Troyanskaya[3], Wendell Lim[1], Hideho Okada[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]University of Toronto, Toronto, ON, Canada,[3]Princeton University, Princeton, NJ

Background: While clinical trials involving chimeric antigen receptor (CAR) T cells have shown promise for treating pediatric brain tumors, factors such as antigen heterogeneity, on-target, off-tumor toxicity and an immunosuppressive microenvironment limit the efficacy of these treatments. To overcome these challenges, we adopted synthetic notch receptor system and developed innovative synNotch-CAR T cell circuits. In this system, the first antigen which is expressed exclusively on the brain, primes the T cells to locally induce the expression of a CAR to completely kill the tumor cells. Here, we investigated the anti-tumor efficacy of synNotch CAR T cells in patient-derived models of Group 3 medulloblastoma, the deadliest subtype of medulloblastoma.
Methods: We utilized a synNotch receptor specific to brevican, a proteoglycan expressed solely in the central nervous system, for brain-specific priming. Human CD3+ cells were stimulated with CD3/CD28 beads for 24 hours and lentivirally transduced to express the synNotch receptor (α-BCAN) and a α-B7H3/IL13Ra2 CAR payload. α-BCAN synNotch-α-B7H3/IL13Ra2 CAR (B-SYNC) T cells were co-cultured with mCherry+ D425 and D283 tumor cells for 4 days and real-time cell growth monitoring was performed using incucyte live imaging. Brevican-priming was accomplished either through brevican-expressing K562 cells or tissue culture plates coated with recombinant human brevican. Tumor cell growth was measured by mCherry fluorescent signal.
Results: B-SYNC T cells completely killed the medulloblastoma cell line, D283, only when primed by K562 cells expressing BCAN. No killing was observed in the absence of priming cells. These cells also maintained killing of a more proliferative medulloblastoma cell line, D425, over an extended period than the constitutive -α-B7H3/IL13Ra2 CAR T cells. Furthermore, when cultured in brevican-coated plates, B-SYNC T cells killed D425 cells at a 17% faster rate than the constitutive -α-B7H3/IL13Ra2 CAR T cells.
Conclusions: B-SYNC T cells show superior cell-killing to constitutive -α-B7H3/IL13Ra2 CAR T cells in in vitro models of Group 3 medulloblastoma. We are currently validating this finding in vivo using patient-derived xenografts. Future studies are aimed at elucidating the mechanisms by which synNotch CAR T cells outperform constitutive CAR T cells. Furthermore, we will investigate the anti-tumor efficacy of synNotch CAR T cells in the more resistant hypoxic medulloblastoma tumor microenvironment.

#6115 MZB1 TCR-like CAR T cell therapy, a new weapon in the war against multiple myeloma and waldenström macroglobulinemia.

Elena Maroto-Martin[1], Marina He[1], Yingjie Zhao[2], Jessica Encinas[1], Sara M. Kolhatkar[1], Roberto Garcia-Vicente[3], Mubin Tarannum[4], Zachary R. Hunter[5], Rizwan Romee[4], Mehmet K. Samur[6], Mariateresa Fulciniti[1], Jianzhu Chen[7], Nikhil C. Munshi[8]

Multiple myeloma (MM) is a plasma cell neoplasm accounting for 10% of all hematological tumors. CAR-T cell therapies have demonstrated unprecedented response rates, resulting in the FDA approval of two BCMA CAR-T products. Despite good initial responses, relapses are common and caused by tumor antigen loss and/or CAR T cell exhaustion. One way to overcome tumor antigen loss is to target a different cancer antigen. However, a limited number of cancer-specific proteins are expressed on the cell surface, where they are accessible to immunotherapies. Normal cells ubiquitously express MHC Class I molecules, which present fragments of cellular proteins to the immune system. Here, we have developed a new generation of CAR T cells able to recognize intracellular antigens presented by an MHC molecule on the cell surface. To identify antigens for a TCR-like CAR T therapy, we combined transcriptomic and proteomic data from MM cell lines, MM patients, and healthy tissues. We found that the intracellular protein MZB1, which is involved in the maturation and function of plasma cells, is highly expressed in MM cells as well as a small subset of B cells including Waldenström Macroglobulinemia (WM) and B-cell lymphoma cells. By computational prediction, we identified putative MZB1 peptides that can be presented in the context of HLA-A*02:01, the most frequent HLA allele worldwide. We used a human scFv antibody yeast surface display library to select monoclonal antibody clones specific to the MZB1:HLA-A*02 complex. By performing binding affinity analysis by flow cytometry in a large panel of MM and WM cell lines with differential expression of MZB1 and/or HLA-A2, we selected two clones with higher binding affinity to the HLA-A2/MZB1 positive cells that were further utilized for CAR design. CAR constructs containing the MZB1-A2 scFv, a 41BB co-stimulatory domain and CD3z signaling domain were generated. MZB1 CAR T cells showed significant cytotoxicity against MZB1$^+$ HLA-A2$^+$ MM and WM cells compared to untransduced T cells, but not against HLA-A2 and/or MZB1 negative cells. Additionally, MZB1 CAR T cells showed higher expression of activation markers and significant increased release of IFNy and Granzyme A/B when co-cultured with MZB1$^+$ HLA-A2$^+$ cells, suggesting enhanced antitumor immune responses. To validate the translational potential of MZB1 CAR T cells we confirmed their tumor-killing activity *ex vivo* across primary MM cells from ND and relapsed MM patients. Importantly, *in vivo* administration of 1x10^7 CAR T cells reduced myeloma burden in a human MM disseminated murine model. In conclusion, we have generated TCR-like CAR T cells that show potent and specific *in vitro*, *ex vivo* and *in vivo* antitumor efficacy against MZB1/HLA-A*02:01 complex on the surface of MM and WM cells. This study provides the logic and framework for similar therapies to be developed against other intracellular targets in MM and other cancers.

#6116 Generation of multi-specific CAR T cells using a novel single-marker selection platform to target medulloblastoma heterogeneity.

Diren Usta, Yushen Feng, Yiyun Chen, Louai Labanieh, Nikoo Jafari, Peng Xu, Sabine Heitzeneder, Elena Sotillo, Crystal Mackall

Stanford Cancer Institute, Stanford, CA

High-risk Group 3 and Group 4 and recurrent medulloblastoma patients have a dismal prognosis, and emerging targeted therapies have not yielded promising results. While CAR T cell therapy has achieved unprecedented success in treating hematologic malignancies, translating this approach to solid tumors has been challenging due to tumor heterogeneity and the immunosuppressive microenvironment. To overcome these obstacles and address the urgent need for new treatments, we aimed to develop an enhanced multi-specific CAR T cell product targeting the antigens GPC2, GD2, and B7H3, which are described to be highly expressed across cancers, notably in tumors of neuroectodermal origin. We first conducted a comprehensive analysis of bulk and single-cell RNA sequencing data to validate the expression of GPC2, GD2, and B7H3 on medulloblastoma samples. Protein expression of these targets was confirmed on medulloblastoma cell lines and PDX models, and confirmation on patient samples using flow cytometry-based Quantibrite analysis is currently ongoing. Based on these findings, we generated tri-specific CAR T cells using the STASH select platform - a method for enriching cells containing multiple genetic modifications via a single selection marker - and performed phenotypic and functional assays in vitro and in vivo. Our initial results show that the selected tri-specific CAR T cells effectively control pooled populations of tumor cells expressing each of the antigens individually or in combination. However, we observed that the phenotype and function are dominated by the CAR with the highest level of tonic signaling, which decreased the overall efficacy of the tri-specific CAR T cells. By implementing downregulation of MED12, we found that the tri-specific CAR T cells demonstrated increased proliferation upon stimulation and enhanced cytotoxic efficacy in repeated stimulation assays, indicating exhaustion resistance. Further T cell engineering, including overexpression of cJUN and in vivo evaluations of antitumor activity in different mouse models are ongoing. In conclusion, our tri-specific CAR T cell product targeting GPC2, GD2, and B7H3 represents a promising novel therapeutic approach to overcoming T cell-intrinsic (exhaustion) and extrinsic (antigen heterogeneity) limitations in treating high-risk medulloblastoma. Ongoing studies aim to further assess their effectiveness and potential for broader clinical application.

#6117 Development of preclinical models for the evaluation of conventional and *in vivo* CAR-T therapies.

Hongyan Sun[1], Xiaoliu Yang[1], Shiying Guo[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Conventional CAR-T manufacturing involves *ex vivo* expansion and engineering of T cells either from patients (autologous) or healthy donors (allogenic), which is time- and cost-consuming. The recent advancement of *in vivo* gene editing using lentiviral vectors allows CAR-T generation *in vivo*, which is time- and cost-effective compared to the conventional approaches. To evaluate their *in vivo* anti-tumor efficacy and toxicity, genetically engineered mouse models which express the human-specific target represent a viable choice for preclinical testing. While immunodeficient mouse models are crucial for preclinical evaluation, their utility is often compromised by the development of graft-versus-host disease (GvHD). To overcome this limitation, GemPharmatech has developed a novel NCG-MHC-dKO mouse model, which combined severe immunodeficiency with MHC class I and II molecules knockout to minimize GvHD occurrence and extend treatment window.

We assessed the efficacy of an *in vivo* CAR-T vector using this newly developed model. NCG-MHC-dKO mice bearing luciferase-tagged Nalm6 tumors received intraperitoneal injection of 2×10^7 PBMCs, followed by administration of a single dose of the lentiviral vector encoding an anti-CD19 CAR transgene. Successful *in vivo* gene editing was confirmed by flow cytometry analysis using antibodies specific for CAR in reconstituted human T cells. Tumor burden was monitored longitudinally using an *In Vivo* bioluminescence Imaging System (IVIS®), quantified as total bioluminescent flux. The i*n vivo* CAR-T vector treatment demonstrated robust growth inhibition of Nalm6-Luc tumor in huPBMC-NCG-MHC-dKO mice, with minimal GvHD occurrence throughout the course of the study, while mock-treated groups did not show any obvious tumor growth inhibition, confirming the specificity of the CAR-T vector.

These findings established the NCG-MHC-dKO mouse model with PBMC engraftment as a suitable platform for preclinical evaluation of both conventional and *in vivo* CAR-T therapeutic strategies.

#6118 Engineering p95HER2 CAR T cells for the treatment of HER2-positive tumors.

Ariadna Grinyo-Escuer[1], Marta Bort-Brusca[2], Pablo Ovejero[2], Julia Fernandez Torrente[2], Judit Gago[2], Marta Escorihuela[1], Macarena Roman[1], Joaquin Arribas[2]

[1]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain,[2]Hospital del Mar Research Institute, Barcelona, Spain

Background: Clinical implementation of Chimeric Antigen Receptor (CAR) T cells in solid tumors has been more challenging than for hematological malignancies due in part to "on-target, off-tumor" toxicities. The tyrosine-kinase receptor HER2 is a potent oncogene amplified in almost 3% of all cancers. While most HER2-positive tumors diagnosed at early stages have already effective and available treatment, refractory and metastatic tumors still pose an unmet medical need. p95HER2, a truncated version of the HER2, is expressed in 30-40% of HER2-amplified tumors and, unlike HER2, its expression is restricted to tumor cells. Recent research in the CAR T field has explored novel logic gated CAR T cell designs using alternative signaling domains to CD3z and dual antigen targeting strategies to mitigate toxicity. Here we show the use of LINK CAR T cells to selectively target p95HER2 and HER2-positive tumors while sparing normal tissues expressing basal levels of HER2.

Methods: We generated LINK CARs: a CAR incorporating LAT signaling domain and another with SLP-76 domain, targeting p95HER2 and HER2. Then, transduced both CAR constructs into T cells from healthy donors. In vitro cytotoxicity was assessed through co-cultures with cell lines derived from gastric, breast, ovarian, and lung tumors expressing endogenous p95HER2 and HER2. Safety was evaluated by co-culturing the CAR Ts with cell lines from healthy tissues expressing basal HER2 levels. In vivo efficacy was investigated using immunodeficient mice implanted with cell-derived xenografts.

Results: We show the specific activation of these CAR T cells in the presence of both HER2 and p95HER2-expressing tumor cells. No cytotoxicity was observed in cells with only basal HER2 levels. Safety testing across a panel of healthy cell lines with varying HER2 expression confirmed the CAR T cells' specificity. In vivo studies demonstrated the p95HER2 LINK CAR's ability to eradicate tumors from cell lines expressing HER2 and p95HER2, while preserving MCF7 tumors representing tissues with basal HER2 expression. Patient-derived xenograft(PDX) models are currently being tested to evaluate the translational potential of this novel therapeutic.

Conclusions: Our preliminary results show the feasibility of LINK CAR T cells as a targeted therapeutic approach for HER2-positive tumors, leveraging p95HER2 specificity. Experimentation in PDX models and expansion into different tumor types will further validate this findings.

#6119 Efficient generation of active CAR-T cells from healthy donors and lymphoma patients.

Andrew J. Sawyer, Viktor Lemgart, William Kuhlman, Aaron Griset, Mir Ali, Jennifer Richards, Angela Hadjipanayis, Emiko Desvaux, Seth Garren, Chris Hoefler, Haley Nguyen, Laura Strauss, Jing Jiao, Brandon Quido, Laura Powers, Allison Caron, Eyoung Shin, Virna Cortez-Retamozo, Austin Boesch, Dharini Shah, Tiffany Le, Rasika Kunden, Samantha Stewart, Fazila Nasimi, Sampa Maiti, Olga Lihoradova, Christian Mueller, Christopher Borges, Carla Lawendowski, Ulrik Nielsen, Valeria Fantin, Daryl Drummond, Donald Shaffer

Sanofi, Cambridge, MA

CAR T-cells have set a new standard of clinical activity in patients with hematologic malignancies but there are several barriers to broader patient access. Currently, the genetic modification of patients' T cells to produce CAR-T cell therapies is carried out ex vivo before infusing the cells back into the patient, using methods that are complex and hinder widespread use. Here we share a targeted lipid nanoparticle (LNP) encapsulating mRNA to reprogram circulating human T-cells *in vivo*, designed to overcome the significant limitations of current CAR T therapy. The LNP consists of a proprietary ionizable lipid formulation, developed for efficient transfection of T cells and improved tolerability, containing an mRNA encoding a second-generation CD22 CAR. Transfection of human primary T cells was only observed with the addition of a NANOBODY® VHH targeting CD8 to the surface of the LNP. CAR expression was measured for multiple days in up to 80% of CD8+ T cells, with minimal loss of viability and no nonspecific activation. In a whole-blood assay, CAR expression was limited to CD8+ cells (T cells and NK cells), with no CAR expression observed in CD4+ T cells, B cells, or granulocytes. LNP transfected T cells are capable of antigen specific killing. In a serial transfection and rechallenge experiment, cultured T cells were able to maintain cytotoxicity against repeat challenges of Nalm 6 cells but only with additional LNP treatments. The repeated transfected and cellular challenge did not induce exhaustion or disfunction. The in vivo CAR LNP system also efficiently transfected T cells from lymphoma patient PBMCs. Overall levels of in vitro transfection were generally increased in lymphoma patients and the resulting CAR expressing cells were active. CAR expression was greatest in central memory and effector memory T cell phenotypes and decreased in naïve T cells. High-dimensional Spectral Flow profiling identified increased populations of Tem cells in both DLBCL and follicular lymphoma patients, potentially explaining the increased levels of CAR expression. In both healthy donors and lymphoma patient samples, treatment with CAR LNPs significantly reduced B cells, showing the activity of the transfected cells. The capabilities of the LNP system have also been demonstrated in a PBMC humanized mouse model. LNP dosing resulted in expression of CAR in over 80% of circulating human CD8 T cells 6 hours after a single dose. CAR expression was also observed after 4 serial doses, with no substantial loss of CAR expression. Expression of a CAR eliminated any remaining B cells from the PBMC population without severe systemic toxicities. Taken together, we have demonstrated that this targeted LNP system is capable of specific, re-dosable expression of an active CAR that is tolerable for multiple transfections. These are the necessary capabilities to fundamentally alter patient access to CAR-T therapies.

#6120 Combination of a novel allogeneic anti-cMet CAR-NK cell product with therapeutic antibodies in treating solid tumors.

C. Wang[1], T. Liu[1], Q. Wang[1], Y. Gong[1], F. Gao[1], F. Zhou[2], **Z. Cao**[1];
[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China, [2]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Both mesenchymal-epithelial transition factor (C-Met) and epidermal growth factor (EGFR) have been acknowledged as significant pan-tumor therapeutic targets. EGFR- and cMet-targeted autologous chimeric antigen receptor (CAR) T therapies have been tested in clinicals. However, the potential toxicity significantly limited their therapeutic outcomes. Compared to T cells, natural killer (NK) cells have a lower risk of inflammatory toxicity and graft-versus-host disease. CAR-NK therapies also can be produced as an off-the shelf product. To prevent antigen escape, we developed cMet targeted NK cells therapy in combination with EGFR targeted therapeutic antibody in treating solid tumors. Our preclinical results demonstrated cMet CAR-NK single treatment or combined with therapeutic antibodies showed better anti-tumor efficacy compared to EGFR/cMet dual-target CAR-NK cells. We verified EGFR and cMet expression in multiple tumor cell lines (HCT116-colon, NUGC4-gastric, and A549/NCI-1975-NSCLC), which were further engineered to express luciferase. EGFR targeted, cMet targeted, and cMet/EGFR dual-targeted CAR structures were designed and transduced with retroviral vectors into expanded NK cells. Flow cytometry was used to compare the transfection rates and phenotyping among different CAR structures. CAR-NK cell functionality was tested using *in vitro* cytotoxicity assays. *In vivo* study was performed in subcutaneously inoculated xenografts with intravenous delivery of cryopreserved CAR-NK cells. Flow cytometry analysis revealed efficient transduction in single targeted CARs and dual-targeted tandem CAR (~80%), but low transduction level in dual-targeted parallel CAR (~40%). All CAR constructs indicated *in vitro* specific cytotoxicity using luciferase- and RTCA-based assays. However, compared to dual-targeted CARs, EGFR and cMet single CARs demonstrated significant better tumor regression and NK cell persistence in peripheral blood in an NCI-H1975 s.c. xenograft mouse model. We demonstrated that combination of cMet CAR-NK with EGFR- or EGFR/cMet-targeted therapeutic antibodies resulted in both potent ADCC and CAR activity, whereas EGFR CAR-NK combo showed compromised *in vitro* tumor killing capacity. Furthermore, cMet CAR-NK solo or combo treatment showed excellent tumor control and survival prolong in different tumor cell line derived xenograft mouse models. These studies have a pivotal role in the evaluation of cMet CAR-NK cell combination therapies against solid tumors and reveal their therapeutic potential. Allogeneic cMet CAR-NK cell therapy and combo may provide safe and effective treatments for pan-tumor patients who have limited therapeutic options.

#6121 A novel allogeneic anti-DLL3 CAR-NK cell therapy in treating small cell lung cancer.

C. Wang[1], T. Liu[1], Q. Wang[1], Y. Gong[1], L. Chen[1], F. Gao[1], F. Zhou[2], **Z. Cao**[1];
[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China, [2]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Small cell lung cancer (SCLC) is an aggressively lethal malignancy with a high unmet medical need. Overexpression of Delta-like ligand 3 (DLL3) has been identified as a poor prognostic factor. Adoptive immunotherapy based on chimeric antigen receptor (CAR) T cells has been developed, however with significant adverse events. To address the critical need for an improved therapeutic intervention, we leveraged the ability of DLL3 targeted peripheral blood derived natural killer (PBNK) allogeneic cells therapy in treating SCLC. We describe preclinical *in vitro* and *in vivo* results demonstrating the antitumor efficacy of an off-the-shelf, cryopreserved DLL3 CAR-NK candidate. In addition, we make comprehensive comparison of PB units from different donors to establish criteria of starting materials selection for clinical and commercial supply of CAR-NK cells. PBNK cells were isolated from healthy donors with FcγRIIIA-158 (V/V, V/F) and propagated using feeder cells and cytokine cocktails. Various *in vitro* assays, including flow cytometry phenotyping, freeze-thaw viability/recovery, short-term and serial killing, cytokine releasing against tumor cells, were used for comprehensive function evaluation of PB units. DLL3 targeted CAR-NK cells were engineered by transducing donor-preselected NK cells with a retroviral vector encoding a DLL3 membrane-proximal epitope targeted scFv, a NK-optimized CAR backbone and a secreted IL15 armor. Activity of CAR-NK cells against target-expression SCLC cells was assessed *in vitro* and *in vivo*. PB Donors were selected with excellent NK expansion capacity and freeze/thaw recovery rate, stronger innate cytotoxicity and higher degranulation and intracellular IFN-γ buildup upon co-culturing with different tumor cells. The anti-DLL3 CAR was successfully transduced across all batches of CAR-NK cells derived from selected donors. NK-featured CAR backbone significantly enhanced expansion of NK cells and induced more activated NK phenotype compared to conventional CAR backbone. DLL3 CAR-NK cells was cytotoxic against DLL3$^+$ tumor cells (SHP-77 and NCI-H2171 cells), and DLL3 CAR-NK cells combined with anti-PD-L1 antibodies could further enhance NK cells proliferation in response to tumor cells and could control multiple rounds of tumor cells re-challenge *in vitro*. Using a cell line derived xenograft mouse model, we showed that a single dose of cryopreserved DLL3 CAR-NK cells delayed tumor growth and prolonged mice survival. Synergistic *in vivo* antitumor efficacy and enhanced NK cell expansion in peripheral blood were observed when using CAR-NK combined with anti-PD-L1. Collectively, these results demonstrated the favorable manufacturability, potency, and safety of a DLL3 CAR-NK cells product and its potential as a novel allogeneic treatment option for patients with SCLC.

#6122 Off-the-shelf BCMA/GPRC5D dual targeted CAR-NK cell therapy combined with Daratumumab in treating multiple myeloma.

C. Wang[1], T. Liu[1], Q. Wang[1], Y. Gong[1], F. Gao[1], F. Zhou[2], **Z. Cao**[1];
[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China, [2]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

B cell maturation antigen (BCMA), and Orphan G protein-coupled receptor, class C group 5-member D (GPRC5D) targeted chimeric antigen receptor (CAR) T cell therapies have been successful as treatment options for refractory/relapse multiple myeloma (RRMM) patients. BCMA/GPRC5D dual-targeting CAR-T to address antigen loss is also being explored. However, CAR-T cell manufacturing and potential toxicities have prevented broad patient access. Natural killer (NK) cells have demonstrated an allogeneic cell therapy modality showing promising antitumor efficacy while exhibiting a more favorable safety profile in clinical testing. We have previously shown the successful engineering of IL15 armored BCMA/GPRC5D dual targeted CAR-NK cell therapy for treating MM (AACR 2023; clinical candidate SNC112). To target MM in a broader and more comprehensive manner, SNC112 were tested in combination with Daratumumab (DARA). To improve antibody-dependent cellular cytotoxicity (ADCC) response, high-affinity variants of CD16 (158V/V polymorphism) peripheral blood donors were selected for manufacturing. To avoid self-inflicted NK-cell-mediated fratricide, the stimulation and expansion protocols were optimized to limit CD38 expression on NK cells without inducing gene editing into scaled manufacturing process. *In vitro* short-term and serial killing assays were performed against MM cell lines to verify CAR functions and evaluate ADCC responses between different manufacturing protocols. The NK purity and surface markers expression were characterized by flow cytometry. The combinational antitumor efficacy was assessed *in vivo* in multiple xenograft models using NPG mice. SNC112 induced near 100% *in vitro* specific cytotoxicity using luciferase-label MM cell lines while non-transduced NK showed no cytotoxicity. SNC112 displayed dual-targeted repetitive tumor-killing potential with a RTCA based serial killing assay using CHOK1-BCMA and/or CHOK1-GPRC5D cells. SNC112 manufactured with optimized protocols showed significantly decrease of CD 38 expression (10% vs 80%), improved freeze/thaw recovery, prolonged *in vivo* persistence, and enhanced ADCC responses. In a CD38-low expression animal model, a sub-optimal dose of SNC112 combined with DARA displayed synergistic increase in tumor targeting through various tumor associated antigens, whereas SNC112 solo and DARA solo resulted in no significant antitumor activity. In a CD38-high expression animal model, both of SNC112+DARA and Non-transduced NK+DARA combos were able to achieve complete clearance of tumor cells. However, only SNC112+DARA could achieve sustained tumor control against re-challenge tumor cells. Studies presented demonstrate the potential of SNC112+DARA combo as a highly effective multi-antigen targeting and a cost-effective off-the-shelf cell therapy in treating MM.

IMMUNOLOGY: Innate Immunity to Tumors

#6126 Natural killer activation drives immunotherapy efficacy in triple-negative breast cancer patients: Novel insights for therapeutic intervention.

G. Manzotti[1], E. Salviato[1], V. Manicardi[1], A. Redavid[1], E. Gasparini[1], M. Ragazzi[1], F. Torricelli[1], E. Vitale[1], G. Talarico[2], F. Bertolini[2], C. Pinto[1], A. Ciarrocchi[1], **F. Reggiani**[1];
[1]AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy, [2]European Institute of Oncology (IEO), Milan, Italy

Immunotherapy in combination with neoadjuvant chemotherapy is rapidly changing the therapeutic perspective for Triple-Negative Breast Cancer (TNBC) patients, as demonstrated by the KEYNOTE522 trial. Enhancing a proficient immune response to improve neoadjuvant therapy (NAT) efficacy is an urgent clinical need. We have previously shown by applying a morphology-guided digital spatial transcriptome profiling, that Natural Killer (NK) cell infiltration in diagnostic biopsies of TNBC patients was associated with increased chemotherapy success. In this work, we aim to characterize the specific NK landscape associated with NAT response in TNBC. We prospectively enrolled 35 patients with a new diagnosis of TNBC in our Institute and underwent the KEYNOTE522 neoadjuvant schedule. We collected peripheral blood at diagnosis (T0) and after NAT completion before surgery (T1). On peripheral blood mononuclear cells (PBMCs), we performed single-cell RNA sequencing (scRNA-seq) and flow cytometry analysis to profile circulating NKs and compare patients showing either pathological complete or partial response to the KEYNOTE522 schedule. We did not observe a significant difference in NK number or sub-clustering before therapy (T0) when comparing responders to partial responders. However, after the NAT conclusion (T1), NKs from partial responders displayed a prevalent immune tolerant profile, characterized by the down-regulation of NK cytotoxicity-related genes. Besides, $CD16^{-}CD56^{bright}$ NKs were significantly increased in partial responders, whereas $CD16^{+}CD56^{dim}$ NKs were enhanced in complete responders, confirming a divergent activation profile among circulating NKs that was detectable only after NAT. Altogether, our results pointed out the relevance of NK activation in supporting a proficient NAT response in TNBC patients. Still, the molecular mechanisms governing NK cytotoxicity toward TNBC are largely unknown, restraining their clinical exploitation. To fill this gap, we investigated the specific transcriptional landscape associated with NK effector functions in TNBC patients. We applied a predictive bioinformatic approach to reconstruct the hierarchical organization of the regulatory transcription network associated with NK activation in TNBC, identifying a list of top-scoring Transcription Factors (TFs). Among these, we found SMAD3, VEZF1, MAZ, and RXRA as putative novel master regulators of NK cytotoxicity in anti-TNBC response. We developed a CRISPRi-based system to knock down these TFs and confirm the impact of this transcriptional reprogramming on NK effector functions. Collectively, our data unveil a driving role of NKs in triggering NAT efficacy in TNBC patients and that transcriptional reprogramming can be exploited to potentiate NK-based adoptive cell therapies and further enhance immunotherapy efficacy in TNBC patients.

#6127 Genomic instability regulates STING mediated anti-tumor immunity through distinctive cytosolic DNA structures.

S. Mosley, N. Lapa, C. Mowat, K. Baker;
University of Alberta, Edmonton, AB, Canada

Background. Cancer genomes are characterized by instability, with significant levels of DNA damage and mutation due to DNA repair defects. In colorectal cancer (CRC), defects in mismatch repair define the microsatellite instable (MSI) subtype, with stronger immunogenicity and better prognosis than the more common chromosomally instable (CIN) subtype. The mechanisms behind these differences are unknown, but their understanding could identify strategies to improve CIN CRC prognosis. The STING pathway detects foreign DNA in the cytosol, leading to induction of innate and adaptive immune responses. In cancer cells, STING also recognizes self cytosolic DNA (cyDNA) in the form of micronuclei or diffuse fragments generated by endogenous or treatment induced DNA damage. Our lab previously identified this pathway as a key player in the increased cytotoxic T cell infiltration characteristic of MSI CRCs. As MSI CRCs do not contain more cyDNA than CIN, we hypothesize that specific sequence or structural patterns exist within cyDNA from different CRC subtypes that lead to differential STING activation and thereby induction of overall anti-tumor immunity.

Methodology. We first aimed to examine whether cyDNA produced in MSI vs CIN CRC cells differentially induce STING and thereby anti-tumor immunity. CyDNA isolated from MC38 CRC cells with mutations in *Mlh1* (modeling MSI) or *Kras* (CIN) were used to stimulate dendritic cells (DCs), key mediators of anti-tumor immunity. We found equal concentrations of MSI cyDNA more strongly activates STING, and thereby cytotoxic T cells, than CIN cyDNA. CyDNA from MSI CRC patient organoids showed similar results. Next, we aimed to characterize specific changes in cyDNA composition in MSI vs CIN CRC cells and examine how these alterations affect STING signalling. Sequencing identified patterns prevalent in highly stimulatory cyDNAs, including microsatellites. Stimulation with oligos and cyDNA enriched for microsatellites indicate enhanced STING and cytotoxic T cell activation through improved cGAS binding. Likewise, adoptive transfer of DCs activated by microsatellite rich DNAs induced stronger DC and T cell activation in orthotopic CIN tumors. Preliminary data suggests secondary DNA structures may influence this process. Finally, we aim to evaluate the contribution of micronuclei on STING activation in MSI vs CIN CRCs. DC stimulations with micronuclei isolated from MSI and CIN cells indicate MSI micronuclei also lead to enhanced STING activation over CIN micronuclei. We will evaluate micronuclei composition to identify underlying mechanisms.

Significance. CRC is the second most deadly cancer worldwide, and immune recognition is crucial to treatment efficacy. This project will further our understanding of immune differences between MSI and CIN CRCs that may be used to develop therapeutic strategies, such as STING agonists, to improve CIN patient prognosis.

#6128 Targeting DHX9 helicase with the novel small-molecule inhibitor ATX968 induces replication stress and innate immunity in small cell lung cancer.

Takahiko Murayama[1], Jun Nakayama[2], Xueying Ma[1], Siddharth Balachandran[1], Matthew H. Daniels[3], Jennifer Castro[3], Israel Canadas[1]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Osaka International Cancer Institute, Osaka, Japan,[3]Accent Therapeutics, Inc, Lexington, MA

Small cell lung cancer (SCLC) is the most lethal type of lung cancer. The uniqueness of this tumor lies in its initial exquisite response to chemotherapy, due to its high level of genomic instability. However, most patients experience relapse within 6 to 12 months. Although the addition of immune checkpoint blockade (ICB) therapy to standard chemotherapy has been approved by the FDA, only a small fraction of SCLC patients responds to immunotherapy because of an immunologically “cold” tumor microenvironment. Recently, using genetic depletion methods, we have demonstrated that targeting DExD/H-box helicase 9 (DHX9) in SCLC cells triggers tumor-intrinsic innate immunity, enhancing immunotherapy response and suggesting an effective and unexplored strategy to convert immunologically “cold” SCLCs into “hot”. DHX9 is a multi-functional RNA helicase capable of unwinding both RNA and DNA duplexes and more complex nucleic acid structures and has been considered an undruggable nuclear protein. Here, using SCLC models we characterized ATX968, an orally bioavailable DHX9 tool inhibitor developed by Accent Therapeutics. *In vitro* treatment with ATX968 induced an aberrant accumulation of R-loops (DNA/RNA hybrids), resulting in replication stress and an increase in DNA damage-derived cytoplasmic DNA in SCLC cells. In addition, ATX968 treatment led to an accumulation of cytoplasmic double-stranded RNA (dsRNA), which mainly derived from repetitive element sequences. Both cytoplasmic nucleic acids contributed to the induction of an innate immune response in SCLC cells. Notably, oral treatment with ATX968 monotherapy resulted in robust and durable tumor regression in SCLC mouse xenograft models, which was tolerable over a 28-day treatment period. Together, these findings suggest that DHX9 is a crucial repressor of tumor-intrinsic innate immunity and replication stress, and inhibitors of DHX9 represent a promising new therapeutic strategy for SCLC treatment and potentially other “cold” tumors characterized by replication stress and genomic instability.

#6129 Cancer cell attenuate tumor-associated macrophage TLR9 pathway through lipid-TFEB-PLD3 axis to induce immune suppression environment in ESCC.

Licheng Tan, Beilei Liu, Hongyu Zhou, Shuang Zhang, Bowen Yao, Jiayi Huang, Xinyuan Guan

University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, China

Introduction: Esophageal squamous cell carcinoma (ESCC) is one of the most threaten malignancies in China. Immunotherapy targeting PD-1/PD-L1 and CTLA-4 has achieved progress, while there remains about 30% patients that did not response. Tumor-associated macrophages (TAMs) are an important component of tumor microenvironment (TME), which may contribute to immunosuppression, tumor progression, and metastasis. Thus, targeting to TAMs in ESCC is with potential translational value. Phospholipase D3 (PLD3) is an exonuclease to degrade single strand DNA/RNA in lysosome to attenuate toll-like receptor 9 signaling (TLR9) in myeloid cells. Mice with PLD3 homozygous deletion sufferd from severe autoimmune disease. However, the role of PLD3 in TME has not been reported. Considering the innate immune inhibition effect of PLD3, we decide to explore its function in TAMs.
Material: We collected normal tissue, tumor, and metastatic lymph node samples from ESCC patients for single-cell RNA sequencing. After quality control, we got a total of 85263 cells and clustered cells by Seurat package. Then we integrated our cohort with 3 other ESCC single-cell sequencing cohorts and focused on macrophages. clusterProfiler package were used to do pathway enrichment analysis. JASPR were used for transcription factor prediction. THP-1 cells were cultured in complete RPMI1640 medium. Mouse bone marrow-derived macrophages (BMDM) were isolated and cultured as mentioned in references. KYSE-30, 180, 410, and 520 cell lines were cultured in complete RPMI1640 medium. mEC25 and mEC35 cell lines were cultured in complete DMEM medium.
Result: After integration and clustering, we found PLD3 was specifically expressed in macrophages among all cell types. After sub-clustering, only a small part of macrophages showed high expression of PLD3, which was defined as PLD3-high macrophages. PLD3-high macrophages presented an enrichment in tumors and metastatic lymph nodes, and pathway analysis revealed an inhibition of innate immune response and upregulation of cholesterol metabolism and lysosome pathway in these macrophages. Immunofluorescence staining verified these macrophages in ESCC patient samples. In vitro results showed that oxidized low-density lipoprotein and tumor cell conditioned medium could increase PLD3 expression both in THP-1 macrophages and BMDM, and attenuated TLR9 downstream cytokines expression. Cholesterol assay found ESCC tumor cells can secret considerable amount of cholesterol to extracellular environment. Since TFEB is the key transcription factor in macrophage lysosome biogenesis, we found TFEB may bind to the promoter region of *PLD3* to start its transcription.
Conclusion: Tumor cells can secret cholesterol to trigger TFEB/PLD3 signaling and suppress TLR9 activation in TAMs to achieve an innate immune inhibition effect in TME.

#6131 Temozolomide induces innate immune responses via the production of double-stranded RNAs in glioblastoma cells.

Natsuki Koide, Tatsunori Nishimura, Miho Suzuki, Keiko Shinjo, Yutaka Kondo

Nagoya University, Nagoya, Japan

Immunotherapy using immune checkpoint inhibitors (ICIs) has revolutionized cancer treatment by enhancing T cell-mediated anti-tumor immunity. However, its efficacy in glioblastoma (GBM) remains limited, as demonstrated by unsuccessful clinical trials. The primary challenge is the low abundance of tumor-infiltrating lymphocytes (TILs) within the GBM tumor microenvironment (TME), which fosters an "immune-cold" or "immune-suppressive" state, rendering the tumor resistant to immunotherapy. The first-line treatment for GBM is temozolomide (TMZ), and several studies have examined whether TMZ improves patient outcomes when combined with ICIs. However, one such trial, Ipi-Glio, did not demonstrate improved outcomes with the addition of ipilimumab to TMZ. In contrast, the MAYA study in metastatic colon cancer patients showed clinical benefits when patients were treated with TMZ followed by low-dose ICIs. As a result, it remains unclear whether TMZ has synergistic effects with ICIs in GBM treatment. To address this question, we consider the following: Does TMZ increase the abundance of TILs within the GBM TME? The recruitment and activation of TILs depend on pro-inflammatory cytokines, including type I interferons (IFN-I), which bridge innate and acquired immunity. Thus, we further investigate: Does TMZ stimulate IFN-I production to enhance TIL infiltration?When the U251 GBM cell line was treated with TMZ, the cells expressed IFNB1, a type of IFN-I, as well as interferon-stimulated genes (ISGs). We also aimed to clarify the pathway through which IFN-I is induced. Several pathways are known to activate IFN-I, so we knocked down the expression of key intermediates in these pathways and treated the cells with TMZ. As a result, the upregulation of IFNB1 and ISGs induced by TMZ was diminished when RIG-I was knocked down. RIG-I is a pattern recognition receptor that detects double-stranded RNA (dsRNA). This finding suggests that the IFN-I induction observed in TMZ-treated GBM cells is linked to the presence of dsRNA within the tumor cells. In this presentation, we will discuss the origins of the dsRNAs and whether TMZ-induced IFN-I is sufficiently strong to transform the "immune-cold" or "immune-suppressive" GBM TME into an "immune-hot" state.

#6132 The Fes kinase plays an innate immune checkpoint role to suppress CD8+ T cell mediated anti-tumor immunity.

Brian J. Laight, Danielle Harper, Natasha Dmytryk, Connie S. Zhang, Changnian Shi, Sameh Basta, Madhuri Koti, Peter A. Greer

Sinclair Cancer Research Institute, Kingston, ON, Canada

Introduction: Immunotherapy is a powerful pillar of cancer therapy that still faces barriers due to cancer-mediated immunosuppression. Immunogenic cell death recruits and activates antigen-presenting cells (APCs) through engagement of pattern recognition receptors (PRRs), leading to pro-inflammatory Signal 3 cytokine production required for full activation of adaptive immune cells, including cytotoxic T lymphocytes (CTLs). The Fes tyrosine kinase suppresses innate immune responses in APCs by inhibiting PRR signaling and regulating cytokine trafficking. In non-cancer contexts, Fes may guard against consequences of overactive innate immunity, such as endotoxic shock or autoimmunity. However, this inhibitory effect on APCs may serve as a checkpoint to suppress successful anti-cancer immunotherapy by obstructing efficient priming of cancer specific CTLs. We hypothesize that Fes inhibition in APCs will improve Signal 3 cytokine signaling, resulting in greater adaptive immunity and tumor control.

Methodology: Using bone marrow derived macrophages (BMDMs) from wildtype (WT) or Fes knockout (*fes*$^{-/-}$) mice, we assessed LPS-induced PRR signalling by immunoblot analysis, production of key Signal 3 cytokines by multiplex ELISA, and the level of cell-associated cytokines by flow cytometry. The ability of BMDMs to prime CTLs was assessed in antigen cross-presentation co-cultures with OT-1 T cells. Using E0771 and B16F10 syngeneic orthotopic mouse engraftment models, we compared the efficacy of doxorubicin and anti-PD-1 to control tumor growth and prolong survival in WT and *fes*$^{-/-}$ mice. Tumors and spleen immune profiles were analyzed by flow cytometry. WT or *fes*$^{-/-}$ BMDMs were adoptively transferred into E0771 and B16F10 tumours to directly assess their relative ability to control tumour growth.

Results: *fes*$^{-/-}$ BMDMs displayed improved PRR signaling, increased IFNβ, IL-12, and TNFα secretion, and greater levels of internal and cell-surface IL-12 following LPS stimulation. In antigen cross-presentation assays, LPS stimulated *fes*$^{-/-}$ BMDMs had improved CTL priming. Tumor control and survival were greater in *fes*$^{-/-}$ mice in both the E0771 and B16F10 engraftment models. Doxorubicin and the combination of doxorubicin and anti-PD-1 were more effective in *fes*$^{-/-}$. This was especially striking in the B16F10 model, which is known to be resistant to PD-1 therapy. Immune profiling of tumors showed increased CTL and NK cell activation and PD-1 positivity, and a shift from predominately M2- to M1-polarized tumor associated macrophages in *fes*$^{-/-}$ mice. Intratumorally injected M1-polarized *fes*$^{-/-}$ BMDMs were better able to control tumor growth in both E0771 and B16F10 models.

Conclusion: Fes acts as an innate immune checkpoint whose inhibition may enhance anti-cancer immunotherapy. We believe this effect is due to an increase in inflammatory signalling, and improved signal 3 cytokine signalling in *fes*$^{-/-}$ APCs.

#6133 Investigating the role of CXCR2 in NK cells in head and neck cancer.

Lindsey M. Bachmann[1], Donatien Kamdem Toukam[2], Maria Lehn[2], Sam Nusbaum[2], Katelyn Jansen[3], Vinita Takiar[4], Dalia El-Gamal[2], Trisha Wise-Draper[2]

[1]University of Cincinnati College of Medicine, Cincinnati, OH,[2]Hematology and Oncology, University of Cincinnati, Cincinnati, OH,[3]University of Cincinnati, Cincinnati, OH,[4]Radiation Oncology, University of Cincinnati, Cincinnati, OH

Head and neck cancer (HNC) is the sixth most common cancer globally, with 90% of HNC comprised of head and neck squamous cell carcinoma (HNSCC). Despite improvements in anticancer therapies, long-term survival rates for patients with advanced-stage HNSCC have remained stagnant for 30 years. Although the field of immunotherapy has primarily focused on the adaptive immune response, accumulating evidence suggests that natural killer (NK) cells are also important. Activation of the C-X-C chemokine receptor 2 (CXCR2) signaling axis has been implicated as a negative prognostic factor in many cancers, including HNSCC. Inhibition of CXCR2 results in reduction of tumor growth and increased infiltration of NK and T cells at least partially through suppressing myeloid derived suppressor cell (MDSC) recruitment. Our laboratory has recently demonstrated that the CXCL1/CXCR2 axis inhibits antitumor functions, including a direct attenuation of NK cellular cytotoxicity *ex vivo*, thereby promoting immune resistance and tumor growth. Here we investigate the effects of pharmacologic or genetic inhibition of CXCR2 *in vivo* using established murine oral cavity tumor models. Wild type C57BL/6 mice were injected into the buccal region with 1.5×10^6 mouse oral cavity (MOC-1) cells. Once tumors reached 50-150mm^3, mice were treated by IP injection 3 times per week for 3 weeks with either vehicle, 10mg/kg of CXCR2 inhibitor (SB225002), 1µg/kg of CXCL1, or the combination. Mice that were treated with the CXCR2 inhibitor (CXCR2i) had decreased tumor growth, increased immune cell infiltration (NK and T cells), and increased anti-tumor cytokines such as IFN-γ and IL-1β in the serum. Interestingly, the antitumor effects of the CXCR2i were abrogated by the addition of CXCL1. Furthermore, to determine if NK and/or T cells contributed to CXCR2i-mediated tumor control, C57BL/6 mice were injected into the flanks with MOC-1 tumors as detailed above and treated with either vehicle or CXCR2i in the presence or absence of antibodies to deplete NK and/or CD8+ T cells. Again, the observed decrease in tumor growth was abrogated in mice depleted of NK cells, CD8+ T cells, or both NK and CD8+ T cells suggesting that both cytotoxic cell types are important for inhibiting tumor growth upon CXCR2 blockade. Visualization of immune cell infiltration within tumor sites via multiplex immunofluorescence staining is ongoing. Next, we explored genetic inhibition of CXCR2 *in vivo*. Interestingly, MOC-1 cells injected into the flanks of C57BL/6 mice in which *Cxcr2* was globally knocked out had a paradoxical effect of enhanced tumor growth, suggesting that *CXCR2* may be important during development for immune cell function. Studies are ongoing to examine how NK cell-specific *CXCR2* knockout influences HNSCC tumor progression using an NK cell conditional *Cxcr2* knockout murine model. These preliminary results suggest that the CXCL1/CXCR2 axis is in fact important for HNSCC tumor control.

#6134 Identifying the mechanism of acquired resistance against cancer immunotherapy targeting innate immunity.

Hitomi Nishinakamura[1], Sayoko Shinya[2], Takuma Irie[1], Shugo Sakihama[3], Takeo Naito[1], Keisuke Watanabe[1], Daisuke Sugiyama[4], Motohiro Tamiya[5], Tatsuya Yoshida[6], Tetsunari Hase[7], Takao Yoshida[8], Kennosuke Karube[9], Yuka Maeda[1], Shohei Koyama[1], Hiroyoshi Nishikawa[1]

[1]National Cancer Center Research Institute, Tokyo, Japan,[2]Discovery and Research, Ono Pharmaceutical Co., Ltd., Osaka, Japan,[3]Laboratory of Hemato-Immunology, Graduate School of Health Sciences, University of the Ryukyus, Nishihara, Japan,[4]Department of Immunology, Nagoya University Graduate School of Medicine, Nagoya, Japan,[5]Respiratory Medicine, Osaka International Cancer Institute, Osaka, Japan,[6]Department of Thoracic Oncology, National Cancer Center, Tokyo, Japan,[7]Department of Respiratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan,[8]Research Canter of Oncology, Ono Pharmaceutical Co., Ltd., Osaka, Japan,[9]Department of Pathology and Laboratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan

Immune checkpoint blockade (ICB) efficiently reactivates effector T cells and induces antitumor efficacy. However, more than half of patients, particularly patients with the immunologically cold tumor microenvironment (TME), failed to experience clinical benefits, even in combination with other drugs. To augment the antitumor efficacy by ICB therapy, various attempts to modify the immunologically cold TME are under investigation. The activation of innate immune cells, particularly antigen-presenting cells (APCs), through pattern recognition receptors, such as Toll-like receptors (TLRs), is essential for the subsequent activation of acquired immunity, including $CD8^+$ T cells. However, several approaches employing ICB and reagents that can activate innate immunity have not shown antitumor efficacy in clinical trials, suggesting the existence of a resistance mechanism(s) against the combination treatment. Here we examine the potential of the combination treatment of OK-432 (Picibanil: a penicillin-inactivated and lyophilized preparation of a low-virulence strain of *Streptococcus pyogenes*), an agonist for multiple TLRs, including TLR2, TLR4, and/or TLR9, with PD-1 blockade against tumors with immunologically cold TME. Although OK-432 treatment effectively stimulated APCs in vitro, many innate immune suppressive cells, such as polymorphonuclear-myeloid-derived suppressor cells (PMN-MDSCs), were co-activated and accumulated in the TME upon OK-432 treatment in a CXCL1-CXCR2-dependent manner (acquired resistance). Accordingly, CXCR2 neutralizing antibody or anti-Ly6G antibody reduced the recruitment of PMN-MDSCs to the TME, consequently the triple combination with CXCR2 neutralizing antibody/anti-Ly6G antibody, OK-432, and PD-1 blockade exhibited a far stronger anti-tumor effect. On the other hand, anti-Ly6G antibody combined with PD-1 blockade sometimes inhibited tumor growth in certain tumor models inherently harboring the TME with abundant PMN-MDSCs (adaptive resistance). To further address the difference, tumor-infiltrating immune cells were comprehensively examined in 10 cancer cell lines; a PMN-MDSC-to-CD8 ratio and an infiltrating $CD45^+$ cells count became biomarkers for the necessity of the triple combination treatment. Thus, we argue that stimulators of innate immunity, such as TLR agonists including OK-432, are a double-edged sword. A stimulator of innate immunity may become an effective cancer immunotherapy by controlling the acquired resistance mechanism, namely, the activation of innate immune suppressive cells in the TME.

#6135 Characterization of monocytic-myeloid populations in the tumor microenvironment using patient-derived organoid xenograft models and macrophage-depleting therapies in esophageal squamous cell carcinoma.

Bryan Chee-chad Lung[1], Alvin Ka-kiu Leung[1], Ian Yu-hong Wong[2], Dora Lai-wan Kwong[1], Anthony Wing-ip Lo[3], Simon Law[2], Wei Dai[1], Maria Li Lung[1], **Valen Z. Yu**[1]

[1]Department of Clinical Oncology, School of Clinical Medicine, LKS Faculty of Medicine, Hong Kong, Hong Kong,[2]Department of Surgery, School of Clinical Medicine, LKS Faculty of Medicine, Hong Kong, Hong Kong,[3]Division of Anatomical Pathology, Queen Mary Hospital, Hong Kong, Hong Kong

Background: Esophageal squamous cell carcinoma (ESCC) is the predominant and highly lethal form of esophageal cancer in Asia. Monocytic-myeloid cells, including monocytes, myeloid-derived suppressor cells (MDSCs), and macrophages, are key components of the tumor microenvironment (TME) and represent promising targets for cancer immunotherapy. Tumor-associated macrophages (TAMs), which likely derive from both resident tissue macrophages and recruited monocyte-derived macrophages, play critical roles in the TME, although the precise origins of TAM subsets remain unclear. Utilizing our latest ESCC patient-derived organoid xenograft (PDOX) model, coupled with single-cell transcriptomic profiling, we aimed to elucidate the distinct subsets of monocytic-myeloid cells within the TME.
Results: We used two distinct monocyte/macrophage-depleting agents to selectively target resident and recruited macrophages in our ESCC PDOX model. Through single-cell profiling of xenografts from treated mice, we analyzed the characteristics and origins of monocytic-myeloid cell subsets in the TME and identified novel biomarkers associated with newly differentiated resident and recruited macrophage populations that contribute to TAMs. Specifically, we found that C1qa is a key marker of fully differentiated mature macrophages in ESCC. Additionally, we identified a bone marrow-derived monocytic-myeloid subset that was negative for C1qa and Cd68, resembling immature macrophages or partially differentiated monocytes. These cells were similar to the conventionally described S100a9-positive MDSCs but displayed distinct biomarker profiles. Using gene set analyses based on the single-cell enrichment index, we characterized the functional features of individual subsets and found that prolonged residence of macrophages within the TME led to polarization towards a pro-tumor M2-like TAM phenotype. Furthermore, we identified a distinct population of resident tissue macrophages expressing LYVE1, which exhibited pronounced angiogenic capabilities and characteristics typical of the M2-like phenotype. Based on molecular and signaling analyses, we speculated on the developmental trajectories and interactions between individual subsets. These findings were further validated in human ESCC samples.
Conclusions: Our findings provide new insights into the roles and origins of diverse monocytic-myeloid populations in the TME, their unique biomarker profiles, and the refined definition of recruited MDSCs, offering potential therapeutic targets for ESCC immunotherapy.
Acknowledgement: We thank the RGC (TRS T12-701/17-R to MLL and SL) and FHB (HMRF 06171566 to VZY) of HKSAR for funding support. We thank DSMZ for providing the KYSE cell lines and HKUMed-CPOS for imaging facilities.

#6136 Efficacy of LPS, flagellin, IFN-g, and sCD40L treated bone marrow-derived macrophages in murine mammary carcinoma.

Robert A. Kurt, Joshua Finn, Melissa Lass, Ernesto Oviedo-Bermudez

Biology, Lafayette College, Easton, PA

Previously we reported that treating bone marrow-derived macrophages (BMDM) with poly(I:C), IFN-γ, and sCD40L generated BMDM with more consistent anti-tumor activity than BMDM generated with the agonists alone. These BMDM also showed significant anti-tumor activity against the EMT6 and 168 murine mammary carcinoma models. However, the BMDM showed no activity against the 4T1 murine mammary carcinoma model. Here we asked whether BMDM generated with IFN-γ and sCD40L in combination with other TLR agonists would have greater anti-tumor activity than the poly(I:C) generated BMDM. For this purpose we generated BMDM and then activated them with IFN-γ, sCD40L, and either LPS, flagellin or R848. BMDM generated with a combination of four agonists (IFN-γ, sCD40L, LPS and flagellin) were also evaluated. Based on *in vitro* analysis these treatments led to a significant increase in nitrite and IL-12 production, and the levels of nitrite and IL-12 were significantly greater than the levels produced by the poly(I:C) generated BMDM. All treatments also led to a significant increase in expression of *il-1b*, *il-6*, *tnf-a*, *il-18*, *ccl5*, *cxcl9*, *cxcl10* and *cxcl11*. Moreover, the LPS, flagellin and R848 generated BMDM often expressed a significantly higher level of cytokines than the poly(I:C) generated BMDM. All treatments led to a significant increase in MHC Class II or CD80 expression, but only BMDM generated with IFN-γ, sCD40L, LPS, flagellin and BMDM generated with IFN-γ, sCD40L and LPS showed a significant increase in both MHC Class II and CD80 expression. Furthermore, BMDM generated by these same treatments showed significant anti-tumor activity against all three murine mammary carcinoma models; EMT6, 168, and 4T1. Depletion studies revealed that the BMDM exerted anti-tumor activity against the 4T1 and EMT6 tumors by recruiting CD8+ T cells and NK cells suggesting that expression of *ccl5*, *cxcl9*, *cxcl10*, and *cxcl11* may be critical for the *in vivo* anti-tumor activity of these BMDM.

#6137 Inhibition of FXR signaling in tumor-associated myeloid cells protects against melanoma progression.

Shiun Chang, Darwin C. Chang, Rachel V. Jimenez, Rosa A. Sierra-Mondragon, Julio A. Vazquez Martinez, Paulo C. Rodriguez

H. Lee Moffitt Cancer Center, Tampa, FL

Our study delves into the complex interplay between the tumor microenvironment and immune cell regulation, with a particular focus on myeloid-derived suppressor cells (MDSCs). A key discovery of our research is the accumulation of bile acids (BAs) within the tumor microenvironment and tumor-infiltrating myeloid cells. BAs significantly enhance the suppressive function of MDSCs and M2 macrophages via activation of Farnesoid X Receptor (FXR).Using melanoma as our primary model. We demonstrate that modulation of MDSCs' suppressive function can be achieved through the targeting FXR using specific agents like GW4064 and z-Guggulsterone (z-GS). Myeloid-specific elimination of FXR via Lysozyme M Cre led to a significant delay in tumor progression. This was accompanied by the reduction of PMN-MDSC and an increased infiltration of CD45 positive immune cells and a surge in the presence of anti-tumor specific T cells. Administration of FXR inhibitor, z-GS, through oral gavage also reduced tumor size in vivo. Additionally, targeting FXR by z-GS or myeloid specific genetic ablation enhances adoptive T cells transfer therapy efficacy. MDSCs with impaired FXR signaling result in reduced mitochondria activity and downregulation of Arg1. Furthermore, an enhanced antigen presentation function is observed in MDSCs and dendritic cells treated with z-GS. Our research presents a compelling case for targeting FXR signaling in myeloid cells as a novel therapeutic strategy and open new pathways for enhancing anti-tumoral immunity.

#6138 Generation of humanized C1Q mice for antibody-mediated CDC therapy research.

Mari Kuraguchi, James Jin, Ruili Lv, Zan Zhang, Jinyi Ma, Jiangfeng Yuan, Xuan Yu, Zhi Zhang, Jiansu Zhang, Xiaofei Zhou

Biocytogen, Waltham, MA

The complement system is an essential part of innate immunity, consisting of more than 30 proteins. A critical element in the pathway is C1q (Complement 1 q), an important recognition molecule in the classical pathway of the complement system that can initiate the classical pathway and plays a major role in bridging innate and adaptive immunity. C1q is also vital in monoclonal antibody (mAb) therapy, as it attaches to the Fc region of antibodies, initiating complement-dependent cytotoxicity (CDC).
Here, we generated a humanized C1Q model (B-hC1Q mice), by replacing the murine C1qa, C1qb, and C1qc genes that encode the full-length protein with the corresponding human C1QA, C1QB, and C1QC coding regions. We confirmed the exclusive expression of human C1Q in the serum of the humanized model at levels comparable to those of wild-type murine C1Q. We also performed classical pathway complement activity analysis on B-hC1Q mice, and the results showed that humanized C1Q performed the proper complement function in mice.
To evaluate the CDC effector of monoclonal antibodies in eliminating cancer cells, we conducted tumor efficacy experiments using B-hCD38-luc E.G7-OVA cells, engineered to express human CD38, injected via the tail vein into B-hC1Q mice. Treatment with Daratumumab analog effectively abolished tumor growth in humanized C1Q mice. Together, the B-hC1Q mice provide *in vivo* platforms to evaluate complement system-related disease and CDC effector functions in tumor therapy.

#6139 Changes in macrophage phenotype and function with aging affects tumor growth and tumor microenvironment in murine cancer models.

Manasa Suresh[1], Marie Durr[1], Xintang Li[1], Bryan Weselman[1], Francisco Tapia Belmonte[2], Nithya Gajendran[1], David Quiceno-Torres[1], Sonia Sebaoui[1], Adhithi Rajesh[3], Matias Hepp[4], Alexis Salas-Burgos[2], Satish Noonepalle[1], Alejandro Villagra[1]

[1]Department of Oncology, Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC,[2]Pharmacology Department, Concepcion University, Concepcion, Chile,[3]Georgetown University, Washington, DC,[4]Universidad Catolica de la Santisima Concepcion, Concepcion, Chile

Introduction: Tumor-associated macrophages (TAMs) constitute a significant population of immune cells in the tumor microenvironment (TME), mainly exhibiting an anti-inflammatory M2-like phenotype. They secrete angiogenic growth factors that support tumor growth with an immunosuppressive TME and contribute to developing resistance against immunotherapies. Therefore, there is an increasing effort to switch TAMs from protumoral M2-like to antitumoral and pro-inflammatory M1-like phenotype. Aging is a critical risk factor, with global cancer incidences increasing from 45 to 75 years of age and declining thereafter. The reason behind this decline beyond 75 years of age is unknown but needs further investigation. With the underrepresentation of aged population in preclinical and clinical studies, the role of aging in cancer development and the TME are understudied. Considering the multidimensional role of macrophages in the TME, this study determines the effects of age-associated changes in macrophage function and phenotype on tumor development.
Objective: To study the changes in macrophage biology with aging and understand the implications of aging macrophages on the TME in murine cancer models.
Methods: Wildtype mice of ages 6-8 WKS, 3-6 MO, 10-12 MO, and 20-24 MO were implanted with tumor cells (SM1 melanoma, 4T1 breast cancer) to study tumor growth kinetics. Immune cell profiling of TME, including TAMs, was performed using flow cytometry, single-cell RNAseq, and secretome analysis. Bone marrow-derived macrophages isolated from tumor-bearing and healthy mice of the above four age groups were polarized to M1 and M2 phenotypes to study age- and cancer-associated changes in macrophage function, phenotype, and metabolic signature. The changes in macrophage cytokine and chemokine secretion levels with aging were determined by multiplex ELISA assays.
Results: Tumor growth in older mice was significantly slower than in younger mice. A distinct change in immune cell populations within the TME and reduced secretion profile of TAMs with aging was observed from single-cell analyses. Additionally, the single-cell secretome analysis reflected an inefficient monocyte-to-macrophage transition in tumors of older mice. The defect in macrophage polarization to M1- and M2-like phenotypes with aging complemented with the sub-optimal function (phagocytosis, antigen presentation, and migration) and metabolic signatures of aged macrophages.
Conclusions: The phenotypic, functional, and metabolic changes in macrophages with aging significantly affect tumor growth in murine cancer models. Our study further emphasizes the important role of macrophages in the TME and the need for better representation of aged populations in preclinical and clinical studies.

#6140 Therapeutic benefits of innate immunity stimuli in hepatocellular carcinoma.

Longyue Lily Cao, Jonathan Kagan

Boston Children's Hospital, Boston, MA

Beyond personal hygiene, the most impactful public health innovation in human history has been the development of vaccines to protect against lethal infections. Cancer vaccines have long-been envisioned, with minimal clinical success. Hepatocellular carcinoma (HCC) is the most common liver tumor and one of the leading causes of cancer-related mortality worldwide. Unfortunately, most HCC patients fail to respond to widely used T-cell based immunotherapies, likely due to the relatively immunotolerant nature of the disease. Thus, there is an urgent need to develop more effective therapies against HCC. Dendritic cells (DCs) are an attractive immunotherapeutic target given their unique ability to induce anti-tumor T cell responses. Various key DC activities are needed for this function, including migration to draining lymph nodes, tumor antigen presentation, co-stimulation, and production of inflammatory cytokines like interleukin (IL)-1β. Conventional DC stimuli, such as the Toll-Like Receptor ligand lipopolysaccharide (LPS), activate only a subset of these activities. For instance, production of IL-1ß, a cytokine important for memory T cell function, requires a second signal that activates the NLRP3 inflammasome. Commonly used adjuvants that activate NLRP3 inflammasomes and induce IL-1ß release also trigger cell death, undermining the ability for DCs to engage in the other activities required for T cell stimulation. Our lab discovered that the oxidized phospholipid PGPC (1-palmitoyl-2-glutaryl-sn-glycero-3-phosphocholine) can augment IL-1ß release and migration of DCs while maintaining viability, generating a “hyperactive” DC (hDC) state that engender superior T cell responses compared to conventionally activated DCs. To study the anti-tumor benefits of hDCs, we adopted a genetically engineered mouse model of HCC that highly recapitulates human disease. We show that subcutaneous immunizations with hDCs suppress tumor growth and lethality, and that this protective phenotype is NLRP3-dependent. We also show that hDCs are uniquely able to traffic from the subcutaneous immunization site into the liver. Tumors isolated from hDC-immunized mice have an enrichment of antigen-specific CD8+ T cells with more robust IFNγ-production. Furthermore, hDC treatment resulted in a smaller proportion of antigen-specific CD8+ T cells expressing markers of dysfunction, such as PD-1. Remarkably, at 120 days post-tumor induction, there were more antigen-specific tissue resident memory T cells in the livers of mice previously treated with hDCs, and more of these T cells retained the capacity for antigen-specific IFNγ production. Our project demonstrates how novel concepts in innate immunity can be leveraged to engender more potent and durable anti-tumor T cell responses, and to generate vaccines against HCC that can overcome common limitations of conventional immunotherapies.

#6142 Functional reprogramming of neutrophils in the tumor microenvironment.

Filippo Veglia, Alessio Ugolini, Alessandra De Leo

The Wistar Institute, Philadelphia, PA

Despite functional heterogeneity, high frequency of intratumoral neutrophils predicts poor clinical outcome in cancer, including brain tumors. The tumor microenvironment reprograms neutrophils into immunosuppressive subsets that hinder anti-cancer immunity, thereby contributing to tumor growth and poor response to immunotherapy. However, the mechanisms underlying the regulatory reprogramming of neutrophils remain elusive. Here, we report that neutrophils suppress T cell function in mouse and human brain tumor tissues, contrasting with their non-immunosuppressive phenotype in the periphery. The immunosuppressive ability of brain-tumor infiltrating neutrophils was restricted to a subset of highly glycolytic neutrophils expressing the transferrin receptor CD71, which acquired immunosuppressive properties in response to hypoxia. Mechanistically, hypoxia boosted glucose metabolism in $CD71^+$ neutrophils, which was accompanied by high avidity for glucose and production of lactate. Intracellular lactate caused lactylation of histone lysine residues that directly regulated the expression of arginase 1 (ARG1), required for T cell suppression. Pharmacological inhibition of glycolysis, lactate production or the histone lactylation writer CBP/P300, impaired histone lactylation and the expression of ARG1 and, accordingly, reduced the immunosuppressive activity of $CD71^+$ neutrophils. Targeting histone lactylation with the anti-epileptic drug isosafrole blocked the immunosuppressive ability of $CD71^+$ neutrophils, delayed tumor progression and sensitized brain tumors to immunotherapy. Furthermore, a distinctive gene signature characterizing immunosuppressive and glycolytic $CD71^+$ neutrophils correlated with adverse clinical outcomes across diverse human malignancies. Thus, our study identifies hypoxia-driven histone lactylation as a critical determinant of the functional reprogramming of neutrophils within tumors, providing a potential therapeutic strategy to counteract neutrophil-induced immunosuppression.

#6143 Harnessing antiviral innate immunity regulated by *BRCA1 p*seudogene RNA in preclinical cancer models.

Yoo-Jane Han, Jing Zhang, Sulin Wu, Galina Khramtsova, Daniel Peiffer, Olufunmilayo I. Olopade

University of Chicago, Chicago, IL

Background: Antiviral innate immune responses hold intrinsic anticancer benefits by promoting antitumor immunity and thereby increasing the efficacy of chemotherapy and immunotherapy. They mediate essential antitumor responses through several mechanisms, including stimulation of cytokine production and activation of cytotoxic immune cells. Both cancer cells and virus-infected cells threaten the host by expressing damage-associated molecular patterns and by evading control mechanisms of host immune surveillance. Interestingly, current evidence suggests that not only exogenous non-self-RNA but also host-derived pseudogene RNAs regulate antiviral innate immunity.

Methods: Expression of the *BRCA1* pseudogene (*BRCA1P1*)-long noncoding RNA (lncRNA) was measured in 28 different cell lines using qRT-PCR and inhibited using CRISR-Cas9 genome editing tools or antisense oligonucleotides (ASOs). In patient samples, *BRCA1P1*-lncRNA was detected by BaseScope RNA-*In Situ* Hybridization. For phagocytosis assays, pHrodo™ red-positive cells were determined in cancer cells co-cultured with macrophage cells. Patient-derived organoids (PDOs) were established from primary and metastatic breast tumors and transfected with *BRCA1P1*-specific ASOs using electroporation. *In vivo*, mice were humanized with human PBMC and engrafted with breast cancer cells +/- *BRCA1P1*-knockout. Immune infiltration into tumors was measured by flow cytometry and immunohistochemistry.

Results: We discovered the regulation of viral mimicry and antiviral immunity by transcripts of *BRCA1P1*, which serve as immunoregulatory RNAs in pan-cancer cells and preclinical models of human cancers. *BRCA1P1* is expressed in 13 types of human (solid and blood) cancers, with elevated expression in cancer cells compared to normal cells. Depletion of *BRCA1P1* induced antiviral gene expression, stimulated apoptosis, and increased sensitivity to doxorubicin in various cancer cells, with no apoptotic effect on non-malignant cells. Subsequently, the increase in antiviral responses triggered macrophage-induced phagocytosis of *BRCA1P1*-depleted cancer cells. Mechanistically, *BRCA1P1* regulated NF-κB-driven antiviral gene expression in the nuclei of cancer cells. In PDOs of breast tumors, *BRCA1P1* depletion significantly inhibited growth of primary and metastatic tumor PDOs. Lastly, in a humanized mouse model of breast cancer, loss of *BRCA1P1* stimulated cytokine expression and immune cell infiltration into tumors, and reduced tumor growth.

Conclusion: This study identifies an important role for *BRCA1P1* in regulating innate immune defense mechanisms and antitumor responses in pan-cancers and preclinical models of human tumors. This mechanism of antitumor viral immunity regulated by a host-derived pseudogene RNA may guide the development of novel therapies to boost antitumor immune responses in various human cancers.

#6144 Peritoneal and omental macrophages provide anti-tumor immunity in an ovarian cancer model.

Joseph R. Dominguez[1], Jiseon Kim[1], Seung Hyeon Kim[1], Yeonwoo Choi[1], Soroush Tahmasebi[1], Brahm H. Segal[2], Burkhard Ludewig[3], Ki-Wook Kim[1]

[1]Department of Pharmacology and Regenerative Medicine, University of Illinois College of Med. at Chicago, Chicago, IL,[2]Department of Internal Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Institute of Immunobiology, St. Gallen, Switzerland

The omentum is a visceral adipose tissue that contains fat-associated lymphoid clusters (FALC) to aid in peritoneal immunity. These clusters consist of large aggregates of B cells, T cells, dendritic cells, macrophages, and innate lymphoid cells that participate in the clearance of pathogens. Tissue-resident macrophages (TRM) are immune cells found in every tissue and their function is influenced by the local tissue microenvironment. TRM can be defined by their origins, consisting of subsets maintained either by embryonic precursors or by bone-marrow progenitors. A recent study found embryonically derived TRM express at least one marker amongst Tim4, LYVE1, FOLR2 while bone marrow derived macrophages maintain CCR2 expression. Previous publications have shown the existence of $LYVE1^+$ macrophages surrounding each cluster, here we study an unexamined subset of FALC-associated macrophages that are imbedded within the lymphoid structures. Using confocal imaging, flow cytometry analysis with reporter/ conditional knock-out mice, we have characterized this TRM subset as CX_3CR1^+ $LYVE1^{lo/-}$ $Tim4^-$ and CCR2 dependent. Through Wt1-driven csf1 deletion, we depleted peritoneal and omental-resident (ORM) and found increased ID8 tumor cells in comparison to littermate controls. Lastly, promotion of CX_3CR1^+ ORM and reduction of $LYVE1^+$ $Tim4^-$ ORM led to reduced tumor growth in the omentum in early-stage tumor challenge.

#6145 Serological responses to phosphorylated adducts in pancreatic ductal adenocarcinoma.

Talita Aguiar[1], Shunya Mashiko[1], Kesava Asam[2], Poulomi Roy[1], Shikun Wang[3], Katharina Frank[1], Max Dietzel[1], Luca G. Z. Schahadat[1], Mattea Ausmeier[1], Andrea Hertel[1], Zhe Ran S Susan Duan[1], Bradley Aouizerat[4], Jeanine M. Genkinger[1], Helen Remotti[1], Emmanuel Zorn[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Dental Translational Research Center, New York University, New York, NY,[3]Department of Biostatistics, Columbia University Irving Medical Center, New York, NY,[4]New York University, New York, NY

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is characterized by late-stage diagnosis and poor survival rates. Identifying biomarkers that can aid in early detection and disease characterization is critical. This study leverages a novel ELISA platform to explore IgG reactivity to chemical adducts in the plasma of PDAC patients compared to healthy donors (HD).
Materials and Methods: Plasma samples from 39 PDAC patients and 40 age- and sex-matched HD were analyzed for IgG reactivity to 93 adducts, including phosphorylated amino acids, advanced glycation end products, and coenzymes. Reactivity to phosphoryl-Thr, -Ser, and -Tyr were further validated and characterized using IgG1-4-specific secondary antibodies. Paired tumor and non-tumoral tissues from a subset of cases underwent immunofluorescence and phosphoproteomic analyses to identify phosphorylation changes.
Results: Serum IgG reactivity to phosphorylated threonine, serine, and tyrosine was significantly higher in patients with pancreatic ductal adenocarcinoma (PDAC) than in healthy donors (HD). A Boruta-based random forest classifier identified these phosphorylated adducts as the most significant target adducts discriminating between the two groups. High-titer IgG responses to these phosphorylated adducts—predominantly IgG1 and IgG3—were observed for PDAC patients. Moreover, patients with metastatic disease exhibited greater IgG reactivity to phosphorylated adducts than those without metastasis. Immunofluorescence analysis demonstrated the accumulation of phosphorylated adducts in PDAC cells, suggesting that their abundance in the tumor triggered the specific antibody response. Additionally, phosphoproteomics revealed dysregulated phosphorylation pathways in PDAC, with 124 proteins showing significantly higher phosphorylation levels in tumor tissue compared to non-tumoral tissue. Gene ontology analysis linked these proteins to processes involving chromatin organization, transcription regulation, and histone acetylation. Essential molecular functions of these aberrantly expressed proteins included chromatin and RNA binding, evoking altered gene expression.
Conclusion: Serum IgG responses to phosphoryl adducts represent a robust biomarker for PDAC detection and may reflect disease progression. These findings highlight the potential of anti-adduct IgG profiles as tools for early cancer detection and therapeutic monitoring.

IMMUNOLOGY: Interplay between Immune System and Radio-, Chemo- and Targeted Therapies 2

#6150 Intramammary gland activation of invariant natural killer T cells with anti-tumor CD4Th1 cells prevents the development of invasive mammary carcinoma.

Camille C. Baumrucker[1], Ganesan Ramamoorthi[1], William Dominguez-Viqueira[2], Brian J. Czerniecki[1]

[1]Clinical Science & Immunology Program, Moffitt Cancer Center, Tampa, FL,[2]Small Animal Imaging Laboratory Core, Moffitt Cancer Center, Tampa, FL

Breast cancer (BC) remains one of the most prevalent cancers in the world thus prompting efforts in risk reduction and prevention. Current strategies for prevention are limited to hormone therapy or prophylactic surgery, which are not without complication. Patients with preinvasive malignant lesions of the breast, including ductal carcinoma in situ (DCIS), if left untreated or after surgical resection, have a higher risk of developing invasive BC (IBC). In addition, clinical studies have shown that a subset of DCIS patients who did not progress to invasive disease died from recurrence or distant metastasis. These findings highlight the need for an effective prevention strategy to halt IBC progression and recurrence. Recently, we reported the critical role of anti-tumor CD4Th1 cells in preventing early BC progression. Other studies have shown that enhancement of invariant natural killer T (iNKT) cells plays a role in preventing mammary carcinoma. However, loss of CD1d expression on mammary epithelial cells can suppress iNKT cells, leading to mammary carcinoma and progression of invasive disease. We tested the efficacy of combined activation of iNKT and CD4Th1 cells with intratumoral delivery of type 1 polarized dendritic cells targeting tumor antigen (HER2-DC1) and α-galactosylceramide (α-GalCer-DC1) in BALB-HER2/neu transgenic mice bearing spontaneous invasive mammary lesions. The intratumoral activation of iNKT-CD4Th1 cells with systemic anti-HER2 antibody therapy resulted in eradication of invasive mammary lesions with improved survival of BALB-neuT mice. We then investigated the efficacy of iNKT-CD4Th1 cells in a BALB-neuT mice preventive model. The combined activation of iNKT-CD4Th1 cells in one mammary gland (mammary gland 5) with systemic delivery of anti-HER2 antibody in BALB-neuT mice before the onset of a preinvasive malignant mammary lesion induced a strong anti-tumor response. Complete prevention of mammary carcinoma was observed in all ten mammary glands (up to 27 weeks of mice age) with improved survival. We further demonstrated that activation of iNKT-CD4Th1 cells in all ten mammary glands of BALB-neuT mice in a preventive model displayed a superior anti-tumor immunity and prolonged tumor prevention with survival benefits. The immune profiling revealed an increased infiltration of iNKT, CD4T, CD4T effector memory, CD4T central memory, CD4T effector, NK, and B cells in the mammary glands of BALB-neuT mice. Importantly, iNKT-CD4Th1 combined activation strategy also decreased the level of myeloid derived suppressor cells and tumor associated macrophages in the mammary glands of BALB-neuT mice. Collectively, these results suggest that iNKT-CD4Th1 cell mediated anti-tumor immunity is an effective strategy for BC prevention.

#6151 The investigation of a new combinatorial immunotherapy strategy to treat platinum-resistant penile cancer.

Yaoyin Li[1], Jad Chahoud[2], Xin Lu[1]

[1]Department of Biological Sciences, Boler-Parseghian Center for Rare and Neglected Diseases, Harper Cancer Research Institute, South Bend, IN, [2]Department of Genitourinary Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Penile cancer is a rare malignancy, with penile squamous cell carcinoma (PSCC) accounting for 95% of cases. Human papillomavirus (HPV) infection plays a key role in the carcinogenesis of HPV-positive PSCC. In addition to surgical treatment, multimodal therapies combining neoadjuvant cisplatin-based chemotherapy regimen is required for advanced and metastatic PSCC. However, disease-specific survival analysis showed disappointing results after systemic treatments. To identify an alternative treatment with more favorable outcomes, we investigated the effectiveness of a new combinatorial immunotherapy strategy for refractory PSCC. Here, we identify a therapeutic role of combining poly (ADP-ribose) polymerase inhibitors (PARPi) with anti-PD1 antibody treatment in the SAP (*PB-Cre4+ Smad4L/L ApcL/L PtenL/L*) model of PSCC, which was the first genetically engineered mouse (GEM) model of penile cancer in our previous report (Nat Commun. 2020; PMID 32358507). Mechanistically, PARPi-induced PARP1 trapping and dsDNA micronuclei activated cGAS-STING signaling pathway in both murine derived SA (*PB-Cre4+Smad4L/LApcL/L*) and SAP (*PB-Cre4+ Smad4L/L ApcL/L PtenL/L*) cell lines. HPV overexpression greatly downregulated the expression of type I interferons (IFNα and IFNβ) and pro-inflammatory chemokines (CCL5, CXCL9, CXL10 and CXCL11), while increasing the proliferation and motility of human PSCC cell lines. Furthermore, Niraparib, an FDA approved PARP inhibitor, reversed the effect of HPV overexpression on tumor growth by upregulating the expression of IFN-α/β and PD-L1 in vivo. Overall, this study revealed that the combination therapy of Niraparib and anti-PD1 inhibits the progression of PSCC via reprogramming tumor microenvironment, offering promising strategy for the treatment of refractory PSCC.

#6152 The inhibition of USP18 enhanced cancer immunogenicity in triple-negative breast cancer.

Chartinun Chutoe, Valerie G. Brunton, Alexander Von Kriegsheim

Institute of Genetics and Cancer, The University of Edinburgh, Edinburgh, United Kingdom

Triple-negative breast cancer (TNBC) is one of the most aggressive cancer, which exhibits highly metastasis and shows poorly response to many treatments. Immune checkpoint blockage (ICB) treatment induces anti-tumor effect by innate immune activation for tumor clearance. Nevertheless, ICB was shown to be effective in “hot” tumor microenvironment representing highly immune infiltration. Turning “cold” tumor into “hot” tumor may enhance ICB treatment in TNBC. Type I interferon (IFN) response regulates inflammation and immune modulation. However, IFN-response is abated by USP18, suggesting that inhibiting USP18 could enhance IFN signaling and tumor immunogenicity. To study USP18 inhibition, we employed CRISPR-Cas9 to engineered mutated-USP18 in TNBC cell lines. Mass spectrometry-based proteomic study of mutated-USP18 revealed the induction of IFN-response, cytokine response, MHC-I antigen presentation, while reduced cell proliferation- and cell motility- related pathways under IFN-modulation in TNBC cells. These proteome alterations further caused enhanced-cytotoxic effect of NK cells by inducing apoptotic-mediated cancer cell death in co-culture system. *In vivo* tumors with mutated USP18 also showed increased immune activation, suggesting that this loss of USP18 functions could enhance the immune response within the tumor microenvironment. This may lead to the enhancement of ICB treatment for TNBC. Our finding demonstrated that the inhibition of USP18 potentially enhanced IFN-response mediating hot tumor microenvironment by promoting cancer immunogenicity in TNBC. This inhibition of USP18 approach may hold promise for boosting the effectiveness of ICB therapies in TNBC.

#6153 Overcoming immunosuppression in pancreatic cancer: Efficacy of polyamine blockade and anti-PD-1 combinational therapy.

Joseph A. Goode[1], Diana Gaete-Alvarez[1], Otto Phanstiel[2], Deborah Altomare[1]

[1]Burnett School of Biomedical Sciences, University of Central Florida, Orlando, FL,[2]Department of Medical Education, University of Central Florida, Orlando, FL

Pancreatic ductal adenocarcinoma (PDAC) is an extremely aggressive cancer, with an only a 13% 5-year survival rate. This low survival rate is due to its dense microenvironment, late-stage diagnosis, and limited treatment options. Polyamines, small molecules essential for cell growth, play a critical role here because their dysregulation is linked to PDAC's tumor growth, invasion, and metastasis. Additionally, the tumor microenvironment becomes increasingly “cold,” or resistant to immune responses. This resistance is driven by the recruitment of immunosuppressive populations and immune evasion mechanisms, such as the programmed death-1 (PD-1) pathway, which conceals PDAC from immune detection. This study aims to explore the interaction between polyamines, the PDAC immune microenvironment, and evaluate the effectiveness of combining Polyamine Blockade Therapy (PBT) with anti-PD-1 inhibitors as a novel immunotherapy strategy. Using an orthotopic mouse model of PDAC with syngeneic GFP-Luc2 cells, we assessed the impact of PBT, consisting of Difluoromethylornithine (DFMO) and the polyamine transport inhibitor (PTI) Trimer 44NMe (Trimer PTI), in conjunction with anti-PD-1 therapy. Tumor growth was monitored by bioluminescence in vivo and shifts in immune populations were assessed using flow cytometry. The combination of simultaneous PBT and anti-PD-1 treatment resulted in a significant reduction in tumor mass, decreased levels of immunosuppressive cells, and an increase in anti-tumor immune populations. The combination of Polyamine Blockade Therapy with anti-PD-1 inhibition shows promise as an effective immunotherapy for PDAC, potentially improving patient outcomes by disrupting the polyamine-mediated immunosuppressive network while enhancing anti-tumor immunity.

#6154 Diffusing alpha-emitters radiation therapy in combination with anti-CTLA-4, as well as combination with both ATR inhibitor, and anti-CTLA-4 achieves long-lasting tumor regression in murine pancreatic cancer.

M. Reis[1], P. Marinello[2], A. Rubinstein[2], M. Wasley[2], W. Brito[2], R. Sega[3], V. Bachar[3], G. Sawakuchi[2];
[1]Rice University & MD Anderson Cancer Center, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX, [3]Alpha Tau Medical Ltd, Jerusalem, Israel

Pancreatic cancers (PC) are characterized by their aggressiveness, radioresistance, and immunologically "cold" nature, making them the third leading cause of cancer deaths in the US. Specifically, conventional radiotherapy approaches are limited by collateral damage to adjacent organs. Given the lack of effective treatments, this study investigates a novel therapy combining α-particle radiation through Diffusing Alpha-emitters Radiation Therapy (Alpha DaRT), an intratumoral source that releases alpha emitting atoms into the tumor microenvironment, with ATR inhibition (ATRi) to sensitize immunologically cold PC to anti-CTLA-4 (aCTLA-4). While conventional low linear energy transfer (LET) radiation (0.2 keV/μm) has lower capacity to induce double-strand breaks (DSBs), higher LET α-particles (70-200 keV/μm) generate more complex DSBs and micronuclei, activating an immune response through the cGAS-STING pathway. By combining Alpha DaRT with ATRi, we aim to impair radiation-induced DSB repair and checkpoint arrest, forcing mitotic progression despite unrepaired DNA damage, overstimulating this pathway. We hypothesize that the triple treatment (Alpha DaRT+ATRi+aCTLA-4) sensitizes immunologically cold tumors to aCTLA-4, delaying tumor growth, inducing tumor regression, and extending survival. Mice were implanted with 5×10^5 KPC cells subcutaneously in the left leg. After 7 days of tumor inoculation (day 0), Alpha DaRT sources were implanted. ATRi (or DMSO) was administered via oral gavage on days 0, 1, 2, 7, 8, and 9, at 75 mg/kg. Anti-CTLA-4 (or IgG) was delivered intraperitoneally on days 3, 6, 9, and 12. Tumor volumes were measured three times/week and mice were randomized into eight experimental groups, ranging from triple control to triple treatment. Tumor development was assessed according to tumor volume fold change, relative to Alpha DaRT insertion day. Both Alpha DaRT +ATRi or Alpha DaRT+aCTLA4 significantly reduced tumor development vs. monotherapies. Remarkably, more than 40% achieved complete tumor regression in the Alpha DaRT+DMSO+aCTLA-4 or Alpha DaRT+ATRi+aCTLA-4. Mice in which tumors regressed were re-challenged on day 130 with 5×10^5 KPC cells. Both the double treatment (Alpha DART + aCTLA4) or the triple treatment exhibited significantly smaller tumor development relative to naïve mice. These novel results suggest that the dual combination Alpha DaRT and aCTLA4 or the triple combination Alpha DaRT, ATRi, and aCTLA-4 may be a strategy to induce a robust and long-lasting immune activation in immunologically cold PC.

#6155 The combination of cisplatin and temozolomide triggers immune surveillance through antigen-dependent and independent mechanisms.

Pietro Paolo Vitiello[1], Rosaria Chila[2], Vito Amodio[2], Paolo Battuello[1], Vittorio Battaglieri[2], Sharon Scardellato[2], Gaia Grasso[1], Federica Pisati[3], Claudio Tripodo[2], Achille Anselmo[4], Francesca Clemente[4], Federica Di Nicolantonio[1], Giovanni Crisafulli[2], Benoit Rousseau[5], Luis A. Diaz[5], Giovanni Germano[6], Alberto Bardelli[1]

[1]University of Turin, Torino, Italy,[2]IFOM ETS - The AIRC Institute of Molecular Oncology, Milano, Italy,[3]Cogentech SRL, Milano, Italy,[4]IRCCS San Raffaele Hospital, Milano, Italy,[5]Memorial Sloan Kettering Cancer Center, New York City, NY,[6]University of Milan "La Statale", Milano, Italy

The combination of chemotherapy and immune checkpoint inhibitors (ICIs) has shown dramatic activity in a variety of malignancies. However, the addition of ICIs to standard of care (SOC) chemotherapy is not clinically effective in mismatch repair proficient (MMRp) colorectal cancer (CRC). We have previously reported that priming treatment with temozolomide (TMZ) induces hypermutability and immunotherapy clinical benefit in the molecular subset of CRCs characterized by inactivation of O6-methylguanine methyltransferase (MGMT). We reasoned that the combination of TMZ with cisplatin (CDDP), another active alkylating agent, might similarly increase mutational burden and induce cancer immunogenicity in the larger group of MMRp / MGMT wild-type tumors, which account for more than 80% of CRC cases. We investigated the impact of cytotoxic agents on the immunogenomic features of CRC, focusing on TMZ, CDDP, and their combination, in comparison to the SOC treatments (5-fluorouracil, irinotecan and oxaliplatin). Whole exome sequencing (WES) and RNA sequencing were performed to identify mutational signatures and for neoantigen prediction. We assessed treatment-induced antigenicity and immunoediting by injecting CRC cells that had been treated *in vitro* with chemotherapy into syngeneic immunodeficient and -competent mice. In parallel, we evaluated the activity of chemotherapy and immunotherapy performed *in vivo* in order to capture the effect of chemotherapy in the tumor immune microenvironment. Immune infiltration was assessed using a dedicated flow cytometry panel. We found that combinatorial treatment with CDDP and TMZ induces clonal and subclonal hypermutability resulting in an increase in predicted neoantigens. This combination specifically alters the immune fitness of the tumors and ultimately leads to immunoediting of chemotherapy-induced neoantigens and CD8+ T cell-mediated tumor rejection. Treatment-induced hypermutation and immune surveillance were also confirmed in an immune-refractory breast cancer model. Complete rejection of CDDP- and TMZ-treated tumors is associated with persistent immune surveillance that extends to the untreated counterpart. The same effect is not observed when cells are primed with the clinically approved combination of 5-flourouracil, oxaliplatin and irinotecan (FOLFOXIRI). *In vivo* chemotherapy potentiates immune effectors, allowing for durable responses and complete rejections when anti-PD1 is combined with CDDP and TMZ. These results suggest that rational combinations of alkylating agents can promote immune surveillance by enhancing immunologically relevant hypermutability and antigenicity and by remodeling the immune microenvironment. This can be exploited to promote cancer immunogenicity in otherwise immune-refractory CRC.

#6156 Engineering a PD-1 dependent 4-1BB agonist for combination immunotherapy.

Alana Kramer[1], Damien Ruiz[1], Jonathan Marable[1], Payal Agarwal[1], Deepa Bedi[2], Maninder Sandey[1]

[1]Pathobiology, Auburn University College of Veterinary Medicine, Auburn, AL,[2]Tuskegee University, Tuskegee, AL

First-generation 4-1BB (CD137) monoclonal antibody (mAb)-based agonists demonstrated significant potential in early preclinical and clinical studies by eliciting robust anti-tumor responses. However, their clinical development was hampered by dose-limiting hepatotoxicity, attributed to the systemic activation of 4-1BB receptors on monocytes, which in turn recruited CD8+ T cells to attack hepatocytes. To address this challenge, next-generation therapies have focused on decoupling the hepatotoxic effects of 4-1BB activation from its anti-tumor activity. These strategies utilize bispecific molecules to precisely target and activate 4-1BB receptors within the tumor microenvironment (TME). By binding to tumor-associated antigens, these molecules localize to TME, facilitating the hyperclustering and trimerization required for 4-1BB activation. This approach enhances tumor-specific immune responses while minimizing systemic activation and off-target effects. In this study, we introduce, to the best of our knowledge, the first PD-1-targeted 4-1BB agonist that leverages the PD-1 receptor on exhausted T cells to facilitate 4-1BB hyperclustering and activation. Three distinct murine-specific bispecific constructs were developed *in silico*, each employing an anti-PD-1 nanobody for crosslinking and trimerization of the 4-1BB receptor. Construct 1 was designed to function as a weak agonist in the absence of PD-1, transforming into a strong agonist in its presence. In contrast, constructs 2 and 3 are entirely dependent on PD-1 for hyperclustering and subsequent 4-1BB activation. The constructs were expressed and purified using Expi293F-based stable cell lines. Flow cytometry confirmed their ability to bind specifically to the cognate 4-1BB and PD-1 receptors. A 4-1BB luciferase bioassay was employed to demonstrate the PD-1 dependency of Constructs 2 and 3. As expected, constructs 2 and 3 exhibited no 4-1BB activation in the absence of PD1-expressing cells but transformed into potent agonists in their presence. Construct 1 activated the 4-1BB receptor regardless of PD-1, with its activity being markedly enhanced in its presence. Additionally, constructs 2 and 3 were shown to effectively block the PD-1/PD-L1 interaction. Preliminary preclinical evaluations confirmed that all three constructs function as designed. Following the completion of *in vitro* studies, we are currently conducting *in vivo* analyses using mouse xenograft models to evaluate the therapeutic efficacy, toxicity, and biodistribution of these constructs.

#6157 PAR2 inhibitors reduce resistance to immunotherapy against cancer.

Thibaut Brugat[1], Maleck Kadiri[2], Samya Aouad[2], David Allard[2], Camille Fuselier[2], Emma Skora[2], Antoine Mousson[1], Aurelie Janvier[1], Luc Baron[1], Christel Franchet[1], Anne-Laure Blayo[1], Stephan Schann[1], John Stagg[2]

[1]Domain Therapeutics, Illkirch, France,[2]Centre de recherche de l'universite de Montreal et Institut du Cancer de Montreal, Montreal, QC, Canada

A pan-cancer meta-analysis showed that Protease-activated receptor 2 (PAR2) is one of the genes most significantly associated with resistance to immune checkpoint blockade (ICB) and T cells dysfunction in cancer patients. PAR2 is also upregulated and associated with poor prognosis in several cancer types which makes it a promising therapeutic target in the fight against cancer. However, the potential of PAR2 inhibitors and their mechanism of action in immuno-oncology has not been determined yet. The efficacy of PAR2 knock out and a biased negative allosteric modulator (NAM) of PAR2, RD35-11, in monotherapy or in combination with an anti-PD1 was assessed in the MC38 model. Strikingly, the combination therapy significantly increased the number of complete responses compared with mice treated with immunotherapy alone. As MC38 cells do not express PAR2, this result indicated that RD35-11 promote tumor regression by changing the tumor microenvironment. To investigate this hypothesis, the effect of PAR2 inhibition alone or in combination with an anti-PD1 on tumor-infiltrating immune cells was assessed in vivo by flow cytometry, cytokine measurement, bulk and single cell RNA sequencing. Results obtained showed that a PAR2 NAM reduced the level of immune-regulatory cells (M2 macrophages) and cytokines (e.g. IL10) while promoting antigen presenting cells and pathways. Ex-vivo experiments further demonstrated that PAR2 inhibition reduces IL10 secretion by macrophages while enhancing antigen cross-presentation by dendritic cells. Taken together, our data clearly demonstrate that PAR2 NAM can alleviate resistance to immune checkpoint blockade by reducing macrophage-induced immunosuppression and promoting antigen presentation. Domain Therapeutics has identified a novel PAR2 biased NAM, DT-9045, orally available and with clear competitive advantages. IND-enabling studies are currently ongoing to bring this new hope for cancer patients to the clinic.

#6158 STING-MAVS interaction as novel immune mechanism of DNA-PK-inhibitor in SCLC.

Caterina De Rosa[1], Luisa Amato[1], Concetta Tuccillo[1], Francesca Iommelli[2], Viviana De Rosa[2], Virginia Tirino[3], Federica Papaccio[4], Kavya Ramkumar[5], Qi Wang[6], Jing Wang[6], Alberto Servetto[7], Floriana Morgillo[8], Lauren Averett Byers[9], Fortunato Ciardiello[1], Carminia Maria Della Corte[1]

[1]Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Napoli, Italy,[2]Institute of Biostructures and Bioimaging, National Research Council, Naples, Italy,[3]Department of Experimental Medicine, University of Campania "Luigi Vanvitelli", Napoli, Italy,[4]Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana", University of Salerno, Baronissi, Italy,[5]Department of Thoracic Head and Neck Medical Oncology, University of Texas, MD Anderson Cancer Center, Houston, TX,[6]Department of Bioinformatics and Computational Biology, University of Texas MD Anderson Cancer Center, Houston, TX,[7]Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy,[8]Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy,[9]Department of Thoracic Head and Neck Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX

Small cell lung cancer (SCLC) is a highly aggressive malignancy characterized by significant replication stress and DNA damage. Recently an "inflamed" subset of SCLC has been identified, showing high expression of genes associated with Stimulator of Interferon Genes (STING)-induced T-cell attracting chemokines, such as CCL5 and CXCL10. The addition of DNA damage repair inhibitors (DDRis) to immunotherapy has been shown to enhance immune responses through STING-dependent activation pathways.This study focuses on the role of DNA-PK inhibition (DNA-PKi), a key regulator of DDR, in the activation of multiple cytosolic DNA/RNA sensors (STING, cGAS, MAVS, IFI16) to elucidate the molecular mechanisms linking DNA damage to immune responses.Treatment-naïve SCLC patients (n=10) and patients undergoing chemotherapy treatment (n=10) were enrolled. Blood samples were collected at baseline and after chemo-immunotherapy to analyze the expression of cGAS, STING, MAVS, and IFI16. Comprehensive transcriptomic analysis, real-time PCR and protein analysis were performed. STING, MAVS and cGAS knockdown and subcellular localisation analysis were also reported.SCLC tumor tissues (n=81) with higher STING-related chemokines (CCL5/CXCL10) exhibited increased expression of genes involved in MAVS pathway (IFITH1, DDX60), suggesting a simultaneous activation of STING and MAVS. DNA-PKi enhanced STING and MAVS more effectively than other DDRis in SCLC patients-derived PBMCs post-cisplatin compared to naïve patients, indicating its unique role in promoting immune responses. No significant changes in cGAS expression were observed in immune cells from SCLC patients, suggesting that the upregulation of STING mediated by DNA-PK inhibition is independent of cGAS, as knockdown of cGAS did not influence the upregulation of STING and p-IRF3 following DNA-PKi treatment. DNA-PKi treatment resulted in novel mitochondrial co-localization and physical interaction between STING and MAVS in PBMCs, leading to improved functional activation via nuclear translocation of p-IRF3.In conclusion, the study posits that DNA-PK inhibition facilitates a non-canonical interaction between STING and MAVS, thereby enhancing the innate immune response against SCLC.

#6159 Transcriptional regulation of DNA damage response and associated inflammatory signaling by CDK7 in prostate cancer.

Chandan Kanta Das[1], Hesham Mohei[2], Brijesh Kumar Verma[1], Muzaffer Kassab[1], Phillip Wulfridge[3], Sharan Venkatesh[1], Mohammed Alhusayan[1], Reyaz ur Rasool[1], Kavitha Sarma[3], Roger A. Greenberg[1], Eric J. Brown[1], Malay Haldar[2], Irfan A. Asangani[1]

[1]Department of Cancer Biology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]Department of Pathology and Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Gene expression and Regulation program, The Wistar Institute, Philadelphia, PA

Metastatic prostate cancer (PCa) is incurable and the second leading cause of cancer death among men in the Western world. Although patients initially respond to androgen deprivation therapy (ADT), most eventually develop castration-resistant prostate cancer (CRPC) and metastasize to bone. Second-generation AR signaling inhibitors, such as abiraterone acetate and enzalutamide, have been shown to provide a median survival benefit of 6 to 24 months for metastatic CRPC patients. Therefore, more effective therapies are needed, including novel and innovative therapeutic combination approaches. PARP inhibitors are used primarily in treating patients with DNA damage response (DDR) pathway (e.g. BRCA1/2) mutated cancers because these mutations cause a deficit in homology-directed DNA repair (HDR) that confers sensitivity to these agents. Though BRCA1/2 mutations are relatively rare, genomic defects in other DNA repair genes account for approximately 20% of advanced CRPC. Therefore, PARP inhibitor was recently FDA-approved for metastatic PCa carrying these mutations. However, the rest of the 80% HR-proficient CRPC patients do not benefit from PARPi. Apart from that, prostate tumors are immunologically cold tumors and only 5% of PCa patients respond to immune checkpoint blockers. Using next generation genomics approaches, we have found that inhibiting transcriptional kinase CDK7 in PCa cells creates a BRCA-deficient state (BRCAness) that sensitizes these HR-proficient tumor cells to PARP inhibitors *in vitro* and *in vivo*. Mechanistically, knockdown or inhibition of CDK7 led to transcriptional downregulation of DDR genes through loss of Mediator activity along with accumulation of R-loops resulting in the induction of DNA damage, micronuclei formation with consequent activation of cGAS-STING mediated inflammatory signaling, and synergy with anti-PD1 therapy in a syngeneic PCa model *in vivo* without toxicity. These findings suggest that CDK7 inhibition synergizes with PARP inhibitors and immune checkpoint blockers, offering a promising therapeutic strategy for both HR-proficient and HR-deficient metastatic PCa. This approach has the potential to overcome current limitations of immune checkpoint inhibitors and provides new avenues for targeted combination therapies in advanced PCa treatment.

#6160 Design and preclinical evaluation of a first-in-class covalent reversible inhibitor of IRAK4 with immunomodulatory properties and selective anti-lymphoma effect.

Gema Gorjon de Pablo[1], Nuria Profitos-Peleja[1], Miek Jacobs[1], Aitor Gonzalez-Herrero[2], Jeronimo Parra[3], Elisabetta Mereu[2], Paula Cifuentes[4], Melissa Orphali[4], Jordi Teixido[4], Manel Esteller[3], Jose I. Borrell[4], Roger Estrada-Tejedor[4], Gael Roue[1]

[1]Lymphoma Translational, Josep Carreras Leukaemia Research Institute, Badalona (Barcelona), Spain,[2]Cellular Systems Genomics, Josep Carreras Leukaemia Research Institute, Badalona (Barcelona), Spain,[3]Cancer Epigenetics, Josep Carreras Leukaemia Research Institute, Badalona (Barcelona), Spain,[4]Pharmaceutical Chemistry Group, IQS School of Engineering, Barcelona, Spain

Oncogenic activating mutations in the myeloid differentiation primary response gene 88 (*MyD88*) and the consequent activation of the Toll-like receptor pathway are hallmarks of the activated B-cell-like (ABC) subtype of diffuse large B-cell lymphoma (DLBCL). This cascade includes phosphorylation of interleukin-1 receptor-associated kinase 4 (IRAK4), triggering downstream NF-κB activation and driving tumor survival, proliferation, and chemotherapeutic resistance. Although several IRAK4 small-molecule inhibitors (IRAK4-i) are undergoing clinical evaluation for various cancers, most are non-covalent inhibitors with limited activity and specificity.To address this, we employed computer-aided drug design to create a library of reversible covalent IRAK4-i based on a pyrido[2,3-*d*]pyrimidine scaffold with lysine-targeting warheads. From this library, the ten most promising candidates were synthesized using organometallic reactions and microwave-assisted techniques. Subsequent multikinase screening identified four potential IRAK4-specific inhibitors, with GGP314 emerging as the most potent. GGP314 exhibited IC_{50} values of 6.6-7.3 μM at 24 hours and 1.8-2.8 μM at 72 hours in MyD88mut ABC-DLBCL cell lines, while showing minimal activity against non-ABC-DLBCL cells and normal peripheral blood mononuclear cells (PBMCs). Mechanistically, GGP314 reduced IRAK4 phosphorylation and impaired NF-κB signaling, as evidenced by the downregulation of several target genes. The compound demonstrated antitumor activity in 3D spheroid cultures of ABC-DLBCL cells, achieving a 50-60% reduction in Ki67 levels. However, the cytostatic effect was partially attenuated in the presence of follicular dendritic or mesenchymal stromal cells, though not with M2-polarized macrophages. Single-cell RNA sequencing (scRNA-seq) analysis of 3D spheroids revealed that GGP314 preferentially targets tumor-associated macrophages, shifting the tumor microenvironment towards a pro-inflammatory state via upregulation of interferon-gamma response pathways. Finally, GGP314 efficacy was validated in vivo in an immunocompetent chicken embryo chorioallantoic membrane (CAM) model of MYD88-mutant ABC-DLBCL. Twice-weekly dosing resulted in up to 55% tumor growth inhibition in a dose-dependent manner without systemic toxicity. In conclusion, we report here the development and preclinical validation of GGP314, a first-in-class reversible covalent IRAK4 inhibitor. GGP314 exhibits significant antitumor activity, high specificity, and the ability to modulate both tumor-intrinsic and microenvironment-dependent signals, supporting its potential as a therapeutic candidate for ABC-DLBCL.

#6161 Exploring BRG399, a novel microtubule-binding agent, as an inducer of immunogenic cell death in cancer therapy.

Kaila M. Bennett, Jacob P. Matson, Sylwia Stopka, Juan J. Aristizabal-Henao, Archna Ravi, Andressa L. Mota, Dinesh Chimmanamada, Vivek K. Vishnudas, Stephane Gesta, Maria-D Nastke

BPGbio, Framingham, MA

Cancer therapy is transforming from traditional chemotherapeutic agents (CTAs) to innovative immunotherapies. Despite this shift, chemotherapy remains clinically stable, as CTAs are thought to convert the tumor microenvironment (TME) from immunosuppressive to immune-active by inducing immunogenic cell death (ICD) in tumor cells which leads to stimulation of immune cells. This ICD induction is thought to be crucial for enhancing the efficacy of immunotherapies. Thus, using CTAs as ICD agents—alone or in combination with immunotherapies—may offer significant anti-cancer benefits and new treatment avenues. This study investigates the potential of BRG399, a novel microtubule-binding agent, as an immunogenic cell death (ICD) inducer utilizing preclinical *in vitro* and *in vivo* models. Treatment of cancer cell lines with BRG399 showed a dose-dependent increase in surface calreticulin and secreted HSP70, measured by flow cytometry and enzyme-linked immunosorbent assay (ELISA), respectively. The enhancement of both ICD markers was comparable to that observed with established ICD agents. To explore the potential of BRG399 to exert influence on immune-regulated anti-tumor effects, *in vivo* studies in immune-competent syngeneic models were conducted with measurable endpoints of tumor growth inhibition and TME composition by flow cytometry and TIMS TOF spatial omics. BRG399 displayed anti-tumor activity while largely preserving tumor-associated immune cells and notably modifying the immune cell landscape within the tumor. Our findings suggest that BRG399 acts as an ICD agent, effectively modulating both tumor and immune cells within the TME and highlighting its potential for future combination therapies with immunotherapeutics. Further *in vivo* studies are currently being conducted to comprehensively elucidate the immune-mediated effects of BRG399 aiming to clarify its role in enhancing anti-tumor responses ultimately contributing to the development of more effective cancer therapies.

#6162 RRM1 inhibition enhances anti-tumor immunity by ubiquitination degradation DNMT1 through PI3K/AKT pathway.

Nan Jiang, Jianya Zhou

Zhejiang University, Hangzhou, China

Patients with driver-gene-negative non-small cell lung cancer still need to rely on chemotherapy combined with immunotherapy. Some studies have suggested that chemotherapy drugs can promote the innate immune system, but the mechanism of that is still unclear. Ribonucleotide reductase large subunit (RRM1) is the main target of the commonly used chemotherapy drug gemcitabine, which exerts anti-tumor effects by inhibiting DNA replication and repair. We constructed human A549, Calu-1 cell lines and mouse KP ($KRAS^{G12D}/P53^{KO}$) cell lines with stable knockdown of RRM1 and found that knockdown of RRM1 can significantly inhibit the growth of tumor cells *in vivo* and *in vitro*. RNA-sequencing was used to detect the changes in the transcriptome after RRM1 knockdown. Through GO analysis and KEGG analysis, we found that the DNA damage caused by RRM1 inhibition can cause the non-classical NF-κB signaling pathway to be upregulated, thereby causing an inflammatory response dominated by IL-6. However, at the same time, we found that the RNA recognition innate immune response pathway, which mainly recognizes dsRNA, was also activated. Therefore, we speculate that RRM1 inhibition affects the epigenetic changes of tumor cells. We found that the expression level of DNMT1 protein was downregulated after RRM1 knockdown, and its mRNA level remained unchanged, indicating that post-transcriptional modification of DNMT1 protein occurred. The reduction in DNMT1 protein expression reduced the overall DNA methylation level of the cell, thereby causing the activation of the type I interferon innate immune response pathway dominated by RIG-I/MAVS/TBK1/IRF3. Further mechanistic studies found that RRM1 inhibition mainly reduces the phosphorylation level of AKT protein by inhibiting the intracellular PI3K-AKT signaling pathway, thereby reducing the phosphorylation level of DNMT1 protein, and ultimately promoting the ubiquitination degradation pathway of DNMT1 protein. Therefore, by combining RRM1 inhibitors with DNMT1 inhibitors, the epigenetic drug decitabine (DAC) can further inhibit the expression of DNMT1, thereby promoting the type I interferon innate immune response pathway caused by chemotherapy drugs rather than the inflammatory response dominated by IL6, and exerting a synergistic anti-tumor effect on tumor growth *in vivo*. In summary, our research shows that inhibiting RRM1 can promote DNMT1 ubiquitination degradation through the PI3K/AKT signaling pathway, thereby activating the RNA recognition-induced type I interferon innate immune response pathway to exert anti-tumor effects. Combining with the epigenetic drug DAC can enhance the effect of this pathway, thereby better combining with immunotherapy to exert better anti-tumor effects. This provides a new idea for the treatment of chemotherapy combined with immunotherapy.

#6163 PARP inhibition induces the expression of interferon-response genes in both BRCAm and BRCAwt high grade serous ovarian cancer cells.

Daniel Falcon[1], Alyson Yeckes[1], Ania Klas[1], Andrea Corbet[1], Chelsea Goff[1], Sandra Orsulic[2], Rita Serda[1], Phyllis Gimotty[3], Sarah Adams[1]

[1]University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]University of California, Los Angeles, Los Angeles, CA,[3]University of Pennsylvania, Philadelphia, PA

Background: Therapeutic synergy of PARP inhibition (PARPi) and CTLA4 immune checkpoint inhibition (ICI) in BRCA1 mutated (BRCAm) ovarian cancer (OC) models was dependent on increased interferon gamma (IFNg) production in the tumor microenvironment (TME). Expression of interferon-response genes in tumor samples is also linked with CTLA4 ICI efficacy in melanoma. In an assessment of interferon-response gene expression in tumor samples from women with BRCAm ovarian cancer enrolled in a phase I/II clinical trial of PARPi and CTLA4 ICI, *IFIT1B* was significantly associated with both treatment benefit (AUC=0.842), and progression-free survival (PFS) (n=30, p=0.029). In this cohort, *IFIT1B* expression was also strongly correlated with other IFIT gene family members, and positively correlated with *CXCL10* expression among subjects with clinical benefit from treatment. In an analysis of TCGA data, *IFIT1B* expression was also significantly associated with PFS among BRCAm patients (n=16, p=0.0306), but not in the larger ovarian cancer cohort (n=299, p=0.1953). IFIT gene family expression is induced by type I and type II interferons, as well as cytosolic nucleic acid sensing. *CXCL10* expression is associated with anti-tumor immunity and is prognostic in ovarian cancer.
Objective: To examine the association between these candidate biomarkers and treatment outcomes, we exposed murine OC cells to PARPi, IFNg, or the combination in vitro, and compared gene expression by qPCR and production of CXCL10 and IFN beta by ELISA.
Results: Treatment with PARPi significantly increased expression of IFIT family members (*Ifit1, Ifit2, Ifit3*) compared with untreated cells, and additionally increased expression in combination with IFNg compared with IFNg exposure alone. PARPi-induced IFIT gene expression was independent of BRCA status and was observed in both PARPi-sensitive and -resistant BRCA1m models. PARPi also significantly increased expression of *CXCL10* by qPCR, and PARPi in combination with IFNg increased levels of secreted CXCL10 by BRCA1m cells compared with IFNg alone. Although expression of *IFNb* was similar across all treatment conditions, high IFN beta secretion was observed in BRCA1m cells treated with PAPRi in combination with IFNg.
Conclusions: These results indicate that PARPi can modulate tumor cell-intrinsic responses to IFNg independent of BRCAm status, including changes in secreted chemokines and cytokines associated with T cell recruitment and immune activation in the tumor microenvironment. With evidence that both IFN signaling and CXCL10 in the TME can impact treatment efficacy and disease outcomes, these data may inform the design of novel combinatorial regimens for ovarian cancer.

#6164 Novel heparin nanoparticles targeting BDCA2 promote immune response.

Greg Kirkpatrick, Caitlin Lemke-Miltner, Rui He, Sue Blackwell, Aliasger Salem, George J. Weiner

University of Iowa, Iowa City, IA

Immune checkpoint inhibitors have revolutionized treatment of many types of cancer, but are not effective for all patients. One proposed mechanism of resistance is lack of local interferon production that results in an immunologically “cold” tumor. This barrier may be overcome by direct immune stimulation with TLR9 agonists. Early phase clinical studies in a variety of cancer types have demonstrated intratumoral injection of TLR9 agonists, as free drug or formulated into nanoparticles (NP), is safe and capable of inducing systemic tumor regression alone or in combination with immune checkpoint inhibitors.

Plasmacytoid dendritic cells (pDCs) are potent producers of type I interferon such as interferon alpha (IFNα). They are key immune system regulators and play a central role in the response to TLR9 agonists. BDCA2 is a cell surface receptor expressed uniquely on pDCs. Signaling through BDCA2 is thought to decrease the immune response initiated by pDCs, particularly in response to TLR agonists. Heparin is a BDCA2 ligand and has been shown to inhibit the TLR9 agonist-driven IFNα response. We developed a novel heparin-coated, polyamidoamine (PAMAM) NP containing a TLR9 agonist to investigate whether heparin-mediated targeting of these NP to pDCs via BDCA2 modulates the pDC response to TLR9. Control NP included those without surface heparin and those without TLR9 agonists. Fresh normal donor human peripheral blood mononuclear cells (PBMCs) were treated with NP for 20 hours. Supernatants were collected for IFNα ELISA to determine whether a functional PBMC response, mediated in large part by pDCs, was stimulated by the NP. Flow cytometric evaluation was used to assess whether NP induced a phenotypic change in pDCs.

Heparin-coated NP containing a TLR9 agonist was more effective than soluble TLR9 agonist at inducing IFNαproduction from PBMCs. Such NP also increased expression of PD-L1 on pDCs. Increased IFNα production and PD-L1 expression were most pronounced with TLR9-containing particles that had a high heparin coating amount. Of note, a low heparin coating amount resulted in reduced IFNα production and PD-L1 expression on pDCs.

The published literature suggests BDCA2 signaling inhibits pDC activation induced by TLR9 agonists. In contrast, here we show that TLR9-containing NP coated with high concentrations of the BDCA2 ligand heparin actually enhances activation of pDCs. Biologically, this suggests signaling via BDCA2 may vary based on the concentration of ligand or how it is presented. Therapeutically, heparin-coated NP containing TLR9 agonists may represent a promising novel approach for stimulating a local immune response, with potential relevance in both cancer immunotherapy and vaccination. Additional studies are ongoing to confirm NP activity is mediated by BDCA2 and to optimize NP composition. This includes assessment of various NP structural components, concentrations and types of BDCA2 ligands, and various TLR agonists.

#6165 Antiprogestin- mediated endocrine therapy activates immunotherapy- responsive programs in hormone receptor positive breast tumors.

Mariana Salatino, Joaquin Pedro Merlo, Tomas Dalotto-Moreno, Magali Berton, Ramiro Martin Perrotta, Andres Elia, Karina V. Marino, Claudia M. Lanari, Gabriel A. Rabinovich

Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina

The endocrine status of the patient is a critical factor that may modulate the immune response in breast cancer and, accordingly, should be considered during immunotherapy regimens. Given the immunosuppressive and tolerogenic activities of the sexual hormone progesterone and its roles in promoting breast cancer initiation, we aim to evaluate the effect of the antagonist of the classical progesterone receptor, Mifepristone (MIFE), as an endocrine therapy to alter the tumor microenvironment, and particularly to shape an immunogenic and immunotherapy-responsive profile. We evaluated the breast tumor immune landscape both in a mouse model of luminal tumors (C4HD) treated with a synthetic progestin MPA and with MIFE; and in human tumor samples derived from the MIPRA clinical trial (NCT02651844), where breast cancer patients harbouring HR+ tumors were treated with MFP for 14 days before surgery. Using RNA-seq, bioinformatics tools and flow cytometry, we interrogated the C4HD tumor immune infiltration profile after MPA and MIFE treatment, including several global gene expression signatures associated with T-cell exclusion and Immune Checkpoint Inhibitors (ICI) sensitivity and resistance. We observed that treatment with MFP in HR+ luminal breast tumors restrains the progestin-mediated tolerogenic infiltrate composed of Tregs, exhausted CD8+ T cells and TAM macrophages. Importantly, MIFE downregulates the suppressive pathway of IDO, CXCL5, VEGF and Galectin-9, which in turn contributes to the persistence of a population of CD8+ T cells that highly produce granzymes and express lower TIM-3 and PD-1, exhibiting a reinvigorating phenotype. On the contrary, MIFE treatment upregulated several immune-associated genes such as chemokines, granzymes, ICOS-L, EOMES, CD86, CD8 and PD-L1. More importantly, we showed that in both mouse models and human tumors, treatment with MIFE reverts transcriptional signatures associated with T cell exclusion and ICI resistance and significantly upregulates programs associated with immunogenic cell death and PD-1/PD-L1 treatment response. To summarize, our results demonstrate that endocrine therapy as MIFE can foster in HR+ tumors a complete remodelling of the immune landscape, promoting immune cell infiltration and immunogenicity. As a result of the neoadjuvant MIFE treatment, HR+ luminal tumors that traditionally were considered “cold” tumors are now heavily enriched with an immunogenic PD-L1-expressing infiltrate, thus opening a new window of treatment opportunity that may sensitize luminal breast tumors to ICI.

#6166 Identification of immunogenic cell death inducers from Komaroviquinone (KQN)-derived compounds.

Maiko Matsushita[1], Koki Kurita[2], Taisei Fujinami[1], Himari Yamada[2], Yusuke Yamamoto[3], Yutaka Suto[4]

[1]Keio University, Faculty of Pharmacy, Keio Univ., Tokyo, Japan,[2]Keio University, Faculty of Pharmacy, Tokyo, Japan,[3]Division of Cellular Signaling, National Cancer Center Research Institute, Tokyo, Japan,[4]Takasaki University of Health and Welfare, Gunma, Japan

Background: Immunogenic Cell Death (ICD) is a type of cell death accompanied by expression of calreticulin (CRT) and release of ATP and HMGB1, which is induced by photodynamic therapies (PDT), oncolytic viruses and several chemotherapeutic drugs. ICD could enhance the therapeutic effect of other immunotherapies through maturation of dendritic cells and activation of T cells. Multiple myeloma (MM) remains incurable despite of the development of novel therapies including several immunotherapies, such as CAR-T therapy. Therefore, we tried to detect novel drugs which can induce immunogenic cell death in MM cells using a library of Komaroviquinone(KQN) - derived compounds (GTN compounds). We also investigated the mechanism of the ICD induced in MM cells.

Methods: We screened 38 kinds of GTN compounds. MUM24 cell line was treated with each of GTN compounds and the cell surface expression of calreticulin (CRT) and release of ATP and HMGB1 were evaluated by FACS, ENLITEN ATP Assay System® and Western Blotting respectively. We also examined the effect of candidate drugs on differentiation of dendritic cells (DCs) by coculture of human monocyte-derived DCs with drug-treated MUM24 and detection of the expression of CD80, CD83 and HLA-DR by FACS. Production of ROS was also measured by CM-H_2DCFDA assay. Finally, RNA sequence analysis was conducted using total RNA extracted from 4 MM cell lines treated with GTN057.

Results: Five out of 38 GTN derivatives could induce ICD in MM cells. When DCs were co-cultured with drug-treated MUM24, increased expression of HLA-DR, CD80 and CD83 were observed with GTN025, 040,057. Cell surface expression of CRT was not abrogated by antioxidants, despite that those compounds facilitated ROS production. Furthermore, analysis of RNA sequences revealed that ER-stress-related genes were up-regulated by GTN057.

Conclusions: Our results suggest that some of GTN compounds effectively induce ICD in MM cells. Although further investigation using *in vivo* model is needed, those compounds might have synergistic effects when used in combination with other immunotherapies.

#6167 Defining the role of transcriptional coregulator MED15 in immune adaptation in cancer.

Sara Cristiano, Xuanjin Cheng, Stefan Taubert

Medical Genetics, University of British Columbia, Vancouver, BC, Canada

The immune system is widely recognized as an important regulator of cancer progression and metastasis, where immune cells can actively promote or inhibit tumor growth. Initially, immune cells act to eradicate cells with emerging cancerous properties, but cancer cells reprogram these immune cells to instead help promote growth of the cancer. Modulating the immune system is therefore an important approach in cancer therapy, however, the identification of new molecular targets is still needed. A potential target includes MED15, a subunit of the transcriptional coregulator complex Mediator, which interacts with transcription factors (TFs) bound to gene regulatory elements. MED15 upregulation occurs in several cancers and is associated with aggressive clinical presentation and shorter patient survival. The precise role that *MED15* plays in immune responses in cancer, however, is not known. To investigate this, *MED15*KO A549 lung adenocarcinoma cells were used to analyze the expression and secretion of various pro-inflammatory immune response genes. The *MED15*KO cells displayed downregulated expression of the immune genes *CXCL3*, *CXCL5*, and *PTGS2,* and the immune receptor *TLR4*, indicated by qPCR. Decreased expression of the pro-inflammatory modulator COX2 (the product of *PTGS2*) was also observed using immunoblot analysis and decreased secretion of CXCL chemokines and PGE2 (the proinflammatory mediator synthesized by COX2) was observed using ELISA and multiplex assays. The functional effects resulting from this lower expression/secretion of pro-inflammatory mediators were examined, specifically the migration of immune cells towards the cancer cells. A decrease in the migration of THP-1 differentiated macrophages was observed towards the *MED15*KO cells in comparison to WT A549 cells, using a transwell migration assay. To determine how MED15 regulates the expression/secretion of these pro-inflammatory genes a Cut&Run protocol was optimized. This will reveal if MED15 binds chromatin near TFs known to regulate these immune genes, identifying candidate TFs that may cooperate with MED15. In sum, this data suggests that *MED15* is required for the expression and secretion of these immune genes and their ligands, while highlighting an important role for *MED15* in pro-inflammatory immune responses in cancer.

#6168 CAF-mediated cancer immunotherapy resistance can be overcome via selective inhibition of NOX 2 and 4.

Jihyun Um, Heesu Kim, Hyeji Jang, Eun Sil Lee, Sung Hwan Moon, Soo Jin Lee

Aptabio Therapeutics Inc., Yongin, Korea, Republic of

Cancer-associated fibroblasts (CAFs) are a functionally heterogeneous population that constitutes tumor stroma. CAFs interact with cancer cells and immune cells by secreting various chemokines/cytokines, participating in extracellular matrix (ECM) remodeling and affecting the immune invasion in the tumor microenvironment (TME). Finally, CAFs promote tumor growth and induce resistance to chemotherapy or immunotherapy, making tumors more aggressive associated with poor prognosis in various types of solid tumors. The primary function of NADPH oxidases (NOXs) is to produce reactive oxygen species (ROS). NOX enzymes, which are clinically upregulated in CAFs, have been reported to be critical effectors of tumor fibrosis and immunosuppression of the TME. It suggests that modulation of CAF-mediated immunosuppression via NOX regulation could be a potential strategy for cancer immunotherapy. In this study, NOX2 and 4 are markedly increased in human pancreatic CAFs (pCAFs) compared to human pancreatic fibroblasts (PFs) and knockdown of NOX2 or 4 effectively decreased fibrosis-related markers and immune cytokines/chemokines in pCAFs, respectively. In order to confirm the importance of NOX in CAF functions, we utilized compound-19, a selective NOX inhibitor. Com-19 treatment significantly reduced the expression of fibrosis-related factors and immune cytokines/chemokines in pCAFs. In addition, com-19 inhibited monocyte infiltration and their differentiation into M2 macrophages in CAF-rich tumor-mimicking 3D spheroids *in vitro*. The *in vivo* efficacy was evaluated using a CAF-rich colorectal cancer mouse model. Com-19 inhibited tumor fibrosis and immune cytokines in CAF-rich tumors via NOX inhibition. Importantly, com-19 increased the intratumoral infiltration of CD8+ T cells, resulting in excellent synergistic tumor growth inhibition when co-administered with immune check inhibitors (ICIs) in the model which poorly responses to ICIs. Taken together, the results support that NOXs play a crucial role in CAF-mediated ICIs resistance in cancers and NOX inhibition can be a promising strategy to overcome the resistance. Com-19 effectively regulated the fibrotic and immune-suppressive properties of CAF-rich tumors via NOX inhibition. Therefore, com-19 can potentiate cancer immunotherapy by overcoming CAF-Mediated ICIs resistance. GLP safety/toxicity studies of com-19 have been completed and phase 1 clinical studies are scheduled in 1Q, 2025.

#6169 Immunogenic cell death mediates the anticancer efficacy of high dose vitamin C.

A. Cavaliere[1], M. Macagno[1], F. Maione[1], V. Amodio[2], M. Escobosa Olmo[3], R. Chila[2], S. Lamba[4], P. Vitiello[2], V. Pessei[5], D. Grases[3], E. Perez[3], A. Bartolini[5], N. Congiusta[1], G. Germano[2], A. Sartore-Bianchi[6], T. Troiani[7], M. Esteller[3], E. Porta[3], A. Bardelli[2], **F. Di Nicolantonio**[1];

[1]University of Turin, Candiolo, Italy, [2]IFOM ETS - The AIRC Institute of Molecular Oncology, Milan, Italy, [3]Josep Carreras Leukaemia Research Institute (IJC), Barcelona, Spain, [4]University of Turin, Turin, Italy, [5]Candiolo Cancer Institute, FPO - IRCCS, Candiolo, Italy, [6]Department of Hematology, Oncology and Molecular Medicine, Grande Ospedale Metropolitano Niguarda, Milan, Italy, [7]Department of Precision Medicine, Universita degli studi della Campania Luigi Vanvitelli, Naples, Italy

Background: We previously reported that high-dose Vitamin C (VitC) can synergize with immune checkpoint blockade in immunocompetent mice bearing colorectal, pancreatic and breast tumors. Here, we aim to unveil the molecular mechanisms underlying the above preclinical observations. We hypothesized that VitC could trigger immunogenic cell death (ICD), thereby stimulating an immune-mediated anticancer response.

Methods: Induction of ICD was assessed by the expression or emission of specific markers, including calreticulin, as well as by ex-vivo phagocytosis assays by co-culturing dendritic cells with breast or colon cancer cells treated with VitC. A calreticulin blocking antibody was administered in vivo in combination with VitC to functionally characterize the role of ICD induction in the anticancer effects of vitC. Ex-*vivo* spatial transcriptomic and immunofluorescence analyses were performed to characterize the impact of the treatment on tumor and immune cell populations.

Results: Pharmacological doses of VitC were able to induce oxidative stress as indicated by spatial transcriptomic data and confirmed by ex vivo 8-hydroxyguanine staining in tumor sections. VitC treatment induced ICD markers and among these calreticulin and HMGB1. Although the induction of these danger markers was seen in tumors grown both in immunocompromised and immunocompetent VitC treated mice, anticancer activity was evident only in the presence of an intact immune system. In vivo, a calreticulin blocking antibody effectively prevented its translocation and inhibited HMGB1 release in murine tumors. Notably, preventing calreticulin exposure abrogated the immune mediated anticancer effect of VitC. VitC enhanced the infiltration of natural killers, activated CD8+ T lymphocytes, while it decreased the number of Tregs. Calreticulin blockade impaired the modulation of the immune tumor microenvironment induced by VitC.

Conclusions: VitC treatment can mobilize calreticulin and HMGB1, which are among the established markers of immunogenic cell death. These results, alongside the observation that VitC exerts its maximal antitumor activity only in immunocompetent mice and its anticancer activity is abolished by anti-calreticulin blocking antibody demonstrated that VitC is an ICD inducer when given at pharmacological doses. These findings lend the preclinical rationale and inform the translational analyses planned within the ALFEO clinical trial (Clinical trial information: ECTR2022-502101-15-00), that is investigating pharmacological doses of vitC in combination with nivolumab and ipilimumab in mismatch repair proficient colon cancer patients. Funded by- Next Generation EU - PNRR M6C2 - PNRR-MAD-2022-12376593.

#6170 SPHK2 modulates the tumor-intrinsic response to STING agonism in triple-negative breast cancer cells.

Colette R. Worcester[1], Shane R. Stecklein[2]

[1]Cancer Biology, The University of Kansas Medical Center, Kansas City, KS,[2]Radiation Oncology, The University of Kansas Medical Center, Kansas City, KS

Triple-negative breast cancer (TNBC) accounts for 10-15% of breast cancers and has a poorer prognosis than other breast cancer subtypes. TNBCs with robust immune infiltrates are known to have improved responses to chemotherapy, immunotherapy, and radiotherapy. Stimulator of interferon genes (STING) promotes both innate and adaptive anti-tumor immune cell infiltration through type I interferon production, and we and others have shown that its activation is associated with therapeutic sensitivity in TNBC. Repression of STING expression or activity are commonly observed in various cancer types, and this has been shown to attenuate responses to treatment. TNBCs overexpress sphingosine kinase 2 (SPHK2), which produces the bioactive lipid spingosine-1-phosphate (S1P). SPHK2-mediated S1P biosynthesis has been shown to suppress inflammatory responses in lung injury models via inhibition of STING. In this study, we sought to determine if SPHK2 attenuated STING activity in TNBC cells. We analyzed publicly available RNA-seq data in The Cancer Genome Atlas and found that TNBC patients with higher *SPHK2* expression had significantly worse disease-free survival and overall survival. For *in vitro* studies, we stably overexpressed *SPHK2* in two commonly studied TNBC cell lines with mid-range SPHK2 and STING protein expression: MDA-MB-231 and BT-549. STING was stimulated with the synthetic agonist diABZI, the endogenous agonist 2'3'-cGAMP, or with ionizing radiation. Phosphorylated interferon regulatory factor 3, a downstream event of STING activation, was decreased in *SPHK2* overexpressing cells following diABZI stimulation. We measured type I interferon signaling by analyzing transcriptional activity of interferon-stimulated response elements (ISRE) using a luciferase reporter assay. *SPHK2* overexpressing MDA-MB-231 and BT-549 cells had decreased transcriptional activity of ISRE compared to controls at baseline and after both diABZI and 2'3'-cGAMP treatment, suggesting that SPHK2 suppresses STING-dependent type I interferon production in TNBC. To test a therapeutically relevant model, cells were also exposed to photon radiation. Compared to control cells, *SPHK2* overexpressing cells had decreased radiation induced ISRE activity. The FDA-approved SPHK2 inhibitor opaganib was able to augment diABZI-stimulated ISRE transcriptional activity in a dose-dependent manner. These data suggest that malignancy-associated SPHK2 overexpression may attenuate STING activation in TNBC, and that SPHK2 inhibition may be a therapeutically relevant and viable approach to augment anti-tumor immunity. The interactions between SPHK2 and the STING-interferon pathway warrants further study to develop potential therapeutic combinations to benefit patients with TNBC.

#6171 Flt3 ligand and CD40 agonist-based therapy in breast cancer promotes myeloid cell CXCL9 secretion and CD8 T cell recruitment but is not dependent on CXCL9 for efficacy.

Preteesh L. Mylabathula, Anas Alkhani, James Zhu, Skanda Hebbale, Riyasat Ali, Vivek Mathesh, Isaac Chan, Tao Wang, **Sangeetha M. Reddy**

UT Southwestern Medical Center, Dallas, TX

Background: Breast cancers have defects in antigen presentation, limiting T cell-mediated immunity. Flt3 ligand (Flt3L) is a growth factor that supports the differentiation of DC1 antigen-presenting dendritic cells (DCs), which are deficient in breast tumors, while CD40 agonist (CD40a) activates dendritic cells and also macrophages. We previously demonstrated that the combination of Flt3L, CD40a, and chemotherapy synergizes to improve outcomes in murine breast cancer models.
Methods: C57BL/6 mice (6-8 weeks old) were orthotopically injected with E0771, AT3, and 4T1 breast cancer cells in the mammary fat pad. Tumors were allowed to grow to ~50 mm^3 before mice were randomized into treatment groups. Mice received triplet therapy consisting of pegylated liposomal doxorubicin (PLD) administered via tail vein, followed by Flt3L intraperitoneally (IP) for 5 consecutive days, and CD40a IP one week later. Control groups included monotherapy and doublet therapy. Tumor growth and survival were monitored. Tumors and tumor draining lymph nodes were harvested from E0771 tumor bearing mice for single-cell RNA sequencing (scRNAseq) and spectral flow cytometry. To study if CXCL9 secretion and CD8 T cells mediate effects of therapy, CXCL9 chemokine and CD8 T-cells were systemically depleted with anti-CXCL9 and anti-CD8 antibodies administered IP every 4 and 2 days respectively during treatment.
Results: Triplet therapy led to improved tumor control compared to no treatment, monotherapy, and doublet controls ($p<0.0001$). Treatment led to significant increase in CD8 T cell recruiting chemokine CXCL9 expression from all intra-tumoral cDC populations including, cDC1, cDC2, and mregDCs ($p<0.01$). Additionally, there was a significant increase in an inflammatory macrophage population characterized by high CXCL9 expression. Increased tumor infiltration with CD8 T cells was observed with triplet therapy via both scRNAseq and flow cytometry ($p<0.01$), with an increase in stem-like and effector memory phenotype ($p<0.01$) and a decrease in exhaustion ($p<0.01$). While depletion of CD8 T cells significantly reduced treatment effect, efficacy was maintained in setting of CXCL9 depletion.
Conclusion: Our findings demonstrate that the combination of Flt3L, CD40 agonist, and chemotherapy significantly enhances tumor control in murine breast cancer models through increased recruitment of CD8 T cells which have more stem-like and effector memory phenotype. While significant increase in CXCL9 was observed, the efficacy of treatment was independent of CXCL9, suggesting importance of factors improving CD8 T cell quality and not just quantity. A clinical trial with this combination in metastatic triple negative breast cancer patients is open and recruiting (NCT05029999).

#6172 PI3K/Akt signaling pathway regulates CD155 expression involved in resistance to cancer immunotherapy.

Katsushige Kawase[1], Shusuke Kawashima[2], Tatsuya Nishi[3], Takashi Inozume[2], Takao Morinaga[1], Masahito Kawazu[1], Toyoyuki Hanazawa[4], Yosuke Togashi[3]

[1]Chiba Cancer Center Research Institute, Chiba-shi, Japan,[2]Department of Dermatology, Graduate School of Medicine, Chiba University, Chiba-shi, Japan,[3]Department of Tumor Microenvironment, Faculty of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama-shi, Japan,[4]Department of Otorhinolaryngology/Head & Neck Surgery, Graduate School of Medicine, Chiba University, Chiba-shi, Japan

Although anti-programmed death 1 (PD-1)/PD-1 ligand 1 monoclonal antibodies are effective against various cancers, resistance remains a significant issue in many patients. The immunosuppressive T cell immunoreceptor with Ig and ITIM domains (TIGIT)/CD155 axis has emerged as one of the crucial mechanisms contributing to this resistance. However, the complexities of CD155 expression remain incompletely understood. In this study, we conducted clustered regularly interspaced palindromic repeats (CRISPR) screening to identify key molecules involved in the regulation of CD155 expression and to investigate their roles in modulating CD155 within the tumor microenvironment (TME). CRISPR screening revealed that dual-specificity tyrosine-(Y)-phosphorylation regulated kinase 1A (DYRK1A) as one of the key regulators of CD155 expression via the PI3K/Akt signaling pathway. In mouse models, inhibition of *Dyrk1a* using CRISPR/CRISPR-associated protein 9 (Cas9) technology or treatment with harmine, a DYRK1A inhibitor reduced CD155 expression, resulting in overcoming the resistance to PD-1 blockade. Moreover, in human head and neck squamous cell carcinoma (HNSCC) cell lines, inhibition of the PI3K/Akt signaling pathway reduced CD155 expression, similar to mouse models. In addition, cetuximab-mediated epidermal growth factor receptor blockade reduced CD155 expression by targeting downstream PI3K/Akt signaling in certain HNSCC cell lines. Clinically, patients with HNSCC harboring high CD155 expression exhibited elevated levels of Akt phosphorylation, consistently indicating that the PI3K/Akt signaling pathway is involved in CD155 expression. Furthermore, high CD155 expression contributed to PD-1 blockade resistance especially in patients who had high $CD8^+$ T cell infiltration. These results emphasized the role of the PI3K/Akt signaling pathway in regulating CD155 expression, which may influence resistance to PD-1 blockade therapies in various cancers, particularly those characterized by an inflamed TME. This study suggests that the reduction of CD155 expression by inhibiting the PI3K/Akt signaling pathway could overcome resistance to PD-1 blockade therapies.

#6173 Preclinical studies of BB-1712: A B7H3-targeting eribulin-containing ADC with the potential to overcome resistance to DNA topoisomerase I inhibitor-containing ADCs.

Y. Wang, B. Xia, L. Cao, J. Yang, C. Feng, F. Jiang, C. Li, L. Gu, Y. Yang, J. Tian, J. Geng, Q. Zhang, Z. Wei, Y. Zhou;
Bliss Biopharmaceutical (Hangzhou) Co., Ltd., Hangzhou, China

B7-H3, a member of the B7 family of proteins, is overexpressed in various solid tumors, including small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC), while exhibiting minimal expression in healthy tissues. This unique expression profile positions B7-H3 as a promising target for antibody-drug conjugates (ADCs). Multiple B7H3-targeting ADCs are currently being tested in different stages of clinical trials and several of them have reported antitumor activities in heavily treated patients. In this study, we introduce BB-1712, a novel B7-H3-targeting ADC that incorporates eribulin as its cytotoxic payload, with the potential to treat patients not sensitive to ADCs containing DNA topoisomerase I inhibitors as payload toxin such as DS-7300a. BB-1712 was designed to leverage eribulin's distinct mechanism of action, which effectively inhibits tumor growth through multiple mode of actions including promotion of apoptosis, tumor microenvironment modulation, immunogenic cell death and bystander killing. We conducted extensive preclinical evaluations of BB-1712, focusing on its *in vitro* cytotoxicity and *in vivo* tumor inhibitory activities against a range of B7-H3-expressing cancer cell lines and xenograft models.Our results demonstrated that BB-1712 exhibited binding activity to B7-H3-positive cell lines similarly to that of Infinatamab, and displayed potent cytotoxic effects across multiple human cancer models, including non-small cell lung cancer, breast cancer, gastric cancer and small cell lung cancer cell lines. In xenograft studies, BB-1712 achieved significant tumor regression at well-tolerated doses without obvious toxicity. Notably, BB-1712 effectively overcame resistance to DS-7300a in both SCLC and NSCLC models previously treated with this agent. Pharmacokinetic and toxicology assessments in non-human primates revealed a favorable safety profile for BB-1712 at clinically relevant dosages and administration schedules.In summary, our findings suggest that BB-1712 has promising preclinical efficacy and safety profiles as well as the potential to circumvent resistance mechanisms associated with current therapies. These results support the advancement of BB-1712 into clinical trials for patients with B7-H3-expressing solid tumors.

#6174 Macrophage-based immunotherapy of platinum-resistant ovarian cancer.

Jan Brancewicz, Maciej Bialasek, Bartłomiej Taciak, Ilona Marszalek, Konrad Gabrusiewicz, Tomasz Rygiel, **Magdalena Krol**

Cellis AG, Zurich, Switzerland

Platinum-resistant ovarian cancer remains one of the greatest challenges in oncology, with limited treatment options and poor survival outcomes. To address this unmet need we develop MDC-735, a novel allogeneic, off-the-shelf macrophage-based therapy. MDC-735 leverages the breakthrough TRAIN (TRAnsfer of Iron-binding proteiN) mechanism, discovered by our team, to enable macrophages to deliver drug-loaded ferritin complexes directly to tumor cells. This approach bypasses drug resistance, penetrates hypoxic tumor regions, and overcomes challenges faced by conventional therapies. In preclinical studies, MDC-735 demonstrated remarkable efficacy in multiple solid tumor models, including platinum-resistant ovarian cancer, showing significant tumor shrinkage, long-term animal survival and immune activation. This unique therapy employs allogeneic macrophages loaded with a tubulin polymerization inhibitor, achieving targeted delivery while minimizing systemic toxicity. The ability of MDC-735 to alter the tumor microenvironment and induce immune resistance to recurrence highlights its potential as a game-changing therapy. This innovative therapy promises to transform the landscape of platinum-resistant ovarian cancer treatment, providing a scalable and effective solution for a disease with limited options.

#6175 Sting pathway activation potentiates the antitumor efficacy of doxorubicin in soft-tissue sarcoma.

Wonyoung Choi, Gi Yeon Lee, Sun-Young Kong

National Cancer Center - Korea, Goyang, Korea, Republic of

Background: Systemic treatment for soft-tissue sarcoma (STS) primarily relies on cytotoxic chemotherapy. Doxorubicin remains the key agent for systemic treatment in STS, as effective targeted treatment is unavailable and immune checkpoint inhibitors have shown limited efficacy. This study investigated whether activation of the STING pathway could enhance the antitumor effect of doxorubicin in STS.
Methods: STS cell lines were treated with doxorubicin to assess STING pathway activation, with Sting1 gene deletion used to validate its essential role. In a syngeneic mouse model of STS, the STING agonist ADU-S100 was administered intratumorally in combination with doxorubicin. Tumor-infiltrating $CD45^+$ immune cells were magnetically sorted for RNA sequencing to identify differentially expressed genes and enriched pathways linked to STING activation. These immune-related genes were analyzed for their association with survival in the TCGA-SARC patient cohort.
Results: Doxorubicin treatment in STS cell lines induced cytosolic DNA leakage, triggering STING pathway activation. Sting1 gene deletion in cells attenuated this doxorubicin-induced activation, but did not impact cell proliferation in vitro. In a syngeneic mouse model, doxorubicin suppressed tumor growth in vivo, an effect further enhanced by intratumoral co-administration of ADU-S100. RNA sequencing of $CD45^+$ tumor-infiltrating immune cells revealed upregulation immune response pathways linked with STING signaling. In the TCGA-SARC cohort, patients with higher expression of genes upregulated in STING-activated tumors exhibited improved survival, while those with lower expression showed poorer overall survival.
Conclusion: STING pathway activation by ADU-S100 enhances the antitumor efficacy of doxorubicin in STS, suggesting that combining doxorubicin with ADU-S100 may be a promising strategy for future clinical trials.

#6176 Selective HDAC6 inhibitor ITF3756 induces IL-2 production and CD4 and NK cells activation in MLR assay.

Gianluca Fossati, Chiara Ripamonti, Valeria Spadotto, Michela Bottani, Christian Steinkuhler

New Drug Incubator, Italfarmaco S.p.A., Cinisello Balsamo, Italy

Over the recent years, it has become increasingly clear that epigenetics plays a key role in regulating the anti-tumor immune response. Modification of the altered epigenetic status generated by tumors is a new and promising approach to induce an efficient antitumor immune response. Epigenetic drugs could represent a new avenue for cancer immunotherapy, particularly in combination with immune checkpoint inhibitors. Acetylation of proteins is one of the epigenetic modifications that has a recognized role in shaping the tumor microenvironment and the antitumor immune response. Among the histone deacetylase family, HDAC6 is a peculiar enzyme involved in tumor growth and in the modulation of the immune functions, that has recently taken hold. We have developed ITF3756, a selective HDAC6 inhibitor, currently in Phase I clinical trial, which exerts in vivo antitumor activity that is strictly dependent on a functional immune system. In vitro, it reduces the immunosuppressive function of myeloid cells and promotes their T cell stimulating activity. T cell development is also influenced by driving CD8 T cells towards a more central memory, less exhausted phenotype with an increased effector function upon tumor cells co-culture. These data derived from studies done with purified cells from human Peripheral Blood Mononuclear Cells (huPBMC). To shed light on the activity of ITF3756 in a more complex environment, Mixed Lymphocyte Reaction (MLR) was chosen as a model. MLR is largely used for investigating the activity of immunotherapy compounds including immune checkpoint inhibitors and can give insights on the possible in vivo mechanism of action of the investigated compounds. HuPBMC from different donors were cocultured in the presence or absence of ITF3756. Supernatants and cells were collected at different time-points and analyzed by ELISA and flow cytometry respectively. ITF3756 enhanced the production of IL-2 in the supernatants at 48 and 72h. Flow cytometry analysis showed that CD4 T cells and B cells, but not CD8 T cells, were the major populations where IL-2 was significantly increased in the presence of ITF3756. The increase of IL-2 production by ITF3756 at the earlier time points is correlated with a significant increase of CD4+CD25+ cells at day 6 and with a significant enhancement of the expression of the activator receptor NKG2D in Natural Killer cells (NK). Further analysis of CD4+CD25+ cells showed that ITF3756 activated CD4+CD25+CD127+ cells, but not the T regulatory cells (CD4+CD25+CD127-). Our data indicate that in a multicellular in vitro immune microenvironment, ITF3756 activates CD4 and NK cells and increases the production of IL-2. Given the importance of IL-2 in the tumor microenvironment, these new results, in addition to those previously collected on isolated myeloid and CD8 T cells, support the notion of the use of a HDAC6i such as ITF3756 for a promising immune checkpoint co-treatment therapy.

#6177 Deciphering the molecular determinants of testosterone paradox in prostate cancer.

Abhishek Shetty[1], Lillian Wilson[2], Deven Topiwala[2], Vaishnavi Anand[2], Zhen Wong[1], Yuhan Yang[2], Chandana Kruthiventi[2], Sai Harshitha Dakoor[2], Virginia Bencosme[2], Taylor Blanco[2], Boan Yang[2], Sayyada Kazim[2], Olutosin Owoyemi[2], Nathaniel Brennen[1], Eugene Shenderov[1], Michael Carducci[1], Samuel Denmeade[1], Sushant Kachhap[1]

[1]Oncology, Johns Hopkins Medicine, Baltimore, MD,[2]Johns Hopkins University, Baltimore, MD

Androgen deprivation therapy (ADT) is the mainstay of PC treatment for lethal, recurrent and metastatic prostate cancer (PCa). Although the initial response rate to ADT is high, the therapy invariably fails as cancer cells become resistant to therapy and progress into a castration-resistant stage called castration-resistant prostate cancer (CRPC). Based on a long-standing paradoxical observation that the growth of PCa could be inhibited by supraphysiologic testosterone (SupraT) treatment, we devised a therapy called the bipolar androgen therapy (BAT) to treat the CRPC. BAT involves a rapid cycling of testosterone between two polar extremes from supraphysiological to near castrate levels with each cycle lasting 28 days. Following the significant clinical efficacy of BAT in a subset of men with metastatic CRPC, we elucidated that SupraT can induce a non-apoptotic cell death called ferroptosis and activate innate immune genes in SupraT-sensitive PCa cells. The current study aims to identify molecular determinants of SupraT-induced cell death and immune activation. This study sheds light on the molecular mechanisms involved in the BAT therapeutic response. Understanding and characterizing the molecular determinants of PC response to BAT is crucial as it will help us stratify patients who would benefit from the therapy and also devise novel combination therapies with BAT including immunotherapeutics, for an enhanced clinical outcome.

#6178 Photochemical immune stimulation eradicates primary tumor and induces long-lasting anti-tumor immunity in a murine cutaneous melanoma model.

Layla Pires[1], Carla Calcada[2], Tracy McGaha[2], Gang Zheng[2], Brian Wilson[2]

[1]Biomedical Engineering, Texas A&M University, College Station, TX,[2]Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada

Background: Photodynamic therapy with light-activation of photosensitizers to induce cell death has been used in the treatment of various tumor types but has been ineffective to date in melanoma due to tumor pigmentation that limits the depth of light penetration. In previous studies in immunodeficient mice using a combination of tumor-cell and vascular targeting we demonstrated eradication of thin primary tumors. Here, we extend this to immunocompetent mice bearing full-thickness primary tumor, investigating both the primary and metastatic responses. Initial evidence of strong immune stimulation was also seen in multifunctional porphyrin-lipid nanoparticles (Porphysomes) as the photosensitizer.

Methods: S91 tumors were induced in the flank of DBA mice by intradermal injection of 10^6 cells in 40μL PBS. Tumor growth was monitored by ultrasound imaging. The main treatment protocol comprised a combination of the clinical photosensitizers: chlorin e6 (1 mg/kg) plus Visudyne (0.8 mg/kg) at 1 h and 15 min drug-light intervals using light fluences of 50 J/cm² at 670 and 690 nm, respectively. Immune biomarkers were measured in spleen, blood, tumor-draining lymph nodes and tumors at 3, 6, 12, 24, 72 h and 5 and 10 d post-treatment. The mice were monitored for 90 d to determine disease-free and overall survival. The functionality of the immune stimulation was demonstrated by tumor re-challenge, abscopal and adoptive immune transfer experiments. Initial studies were also performed using multifunctional porphyrin-lipid nanoparticles (Porphysomes, PS).

Results: The dual-agent protocol resulted in disease-free and overall survival rates >95% at 90 d post-treatment. A robust immune response was triggered, with recruitment and activation of both innate and adaptive immune systems. Upon re-challenge with 10^6 tumor cells at 45d post primary tumor treatment, mice previously treated with PCIS showed no systemic tumor development at 30 d, confirming induction of long-lasting anti-tumor immunity. Adoptive immune transfer was demonstrated by delayed growth of primary intradermal tumor in naïve mice co-injected with splenocytes from previously-treated mice. Abscopal response was seen in mice bearing bilateral tumors when only one tumor was treated. Survival was reduced (20% at 90 d) in $CD8^+$ T cell-depleted mice. PS-mediated treatment exhibited strong immune stimulation even at a fraction of the light dose (25 J/cm^2), as measured by adoptive immune transfer and immune biomarkers.

Conclusions: This study provides the first evidence that, using non-conventional treatment protocols, photodynamic tumor cell kill can eradicate primary pigmented melanoma far beyond the depth of light penetration and markedly impact systemic metastatic disease. PCIS could be used either stand-alone or an adjunctive treatment with surgery, chemotherapy and/or immunotherapy.

POPULATION SCIENCES: Breaking Barriers in Cancer Care: Addressing Disparities and Improving Outcomes
Poster Session

#6182 Receipt of survivorship care plans is associated with self-reported health status for Black female cancer survivors in Maryland.

Camryn Mae Cohen[1], Kassandra I. Alcaraz[2], Lensa S. Keno[1], Mu Jin[3], Avonne E. Connor[1]

[1]Epidemiology, Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[2]Oncology, Johns Hopkins School of Medicine, Baltimore, MD,[3]Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Survivorship care plans (SCPs) support the transition from specialized cancer treatment to primary care and have been promoted for improving cancer survivorship. We previously demonstrated that non-Hispanic Black (NHB) female cancer survivors in Maryland are more likely to receive SCPs than their non-Hispanic White (NHW) counterparts. Here, we assessed whether receipt of SCPs is associated with general health of female cancer survivors.

Methods: Using cross-sectional data from the 2011-2023 Maryland Behavioral Risk Factor Surveillance System (BRFSS) survey, we evaluated receipt of SCPs and general health for NHB and NHW female cancer survivors (N, weighted %). A survey-weighted multivariable logistic regression model was used to estimate odds ratios (ORs) with 95% confidence intervals (CIs) for the association between self-reported receipt of a SCP and general health (fair or poor health vs. excellent or very good health); stratified by race, adjusted for time since cancer diagnosis (1-5, 6-10, 11+ years), age (years), income (≤$50k vs. >$50k), education (less than college vs. at least some college or greater) and body mass index (underweight, normal weight, overweight, obese). Individuals on active treatment and <1 year out from their cancer diagnosis were excluded.

Results: Of the 2,854 female cancer survivors, 312 (14%) were NHB and 2,542 (86%) were NHW. Most women received an SCP (73%), with NHB women being more likely to receive a SCP than NHW women (80% vs. 72%). High income and high education individuals were more likely to receive SCPs (76% vs. 72% and 76% vs. 70%, respectively). While most women reported excellent or very good health (75%), NHB vs. NHW women were more likely to report fair or poor health (38% vs. 22%, respectively). NHB vs. NHW women were significantly [OR: 48.31; 95% CI: 5.35-436.02, p=0.001] more likely to report fair or poor general health. However, NHB women who received a SCP were significantly less likely [OR: 0.031; 95% CI:0.003-0.31; p=0.003] to report fair or poor health compared to NHB women who did not receive a SCP. There was no significant difference in health status for NHW women who did vs. did not receive a SCP [OR: 1.20; 95% CI: 0.62-2.36; p=0.587].

Conclusions: Our results indicate that receipt of SCPs post-treatment is important for current health status among NHB women and highlights a potential intervention for improving the general health of minoritized female cancer survivors.

#6183 Social determinants and survivorship care among Black women breast cancer survivors in Maryland.

L. S. Keno[1], **C. M. Cohen**[1], K. E. Dibble[2], K. Visvanathan[1], A. E. Connor[1];
[1]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD, [2]Dana-Farber Cancer Institute, Boston, MA

Purpose: Limited research has examined the impact of social determinants of health (SDOH) on survivorship care experiences exclusively among Black breast cancer (BC) survivors who face survival disparities due their high prevalence of obesity, comorbidities, and inequities in access and quality of care. Survivorship care experiences among Black BC survivors should be examined to identify potential interventions to improve health outcomes. The goal of this study is to test the feasibility of establishing a state-wide cohort study of Black BC survivors residing in Maryland to address this research gap.
Methods: This study will recruit 350 Black women BC survivors, aged ≥18 years, and diagnosed with stage I-III primary BC who have completed recommended adjuvant treatment including surgery, chemotherapy, and/or radiation. Recruitment approaches include targeted Facebook ads, outreach to previous study participants, and mailed recruitment letters from the Maryland Cancer Registry (MCR). Participants complete a 30-40-minute online survey, covering demographic and lifestyle factors, clinical and SDOH characteristics, and survivorship care questions. The study also pilots medical record abstractions with the MCR for cancer characteristics and the state designated health-information exchange, Chesapeake Regional Information System for Patients (CRISP), for follow-up care.
Results: Recruitment began in July 2024, and by September 2024, 61 self-reported Black participants with a prior diagnosis of BC have completed the survey. The average age at survey is 58.96 (standard deviation (SD)= 11.84)) years, with an average age at diagnosis of 46.42 (SD=13.35) years. 40% are married/living as married, 36.7% are college graduates, all have health insurance, and only 20% reported household incomes <$40,000/year. Almost half of the survivors self-reported being diagnosed with stage 1 BC (45.9%), followed by 31.1% stage 2, 18% stage 3, and 4.9% unknown stage. The most common self-reported comorbidities include hypertension (39.3%), diabetes (16.7%), and obesity (12.3%). Related to care, 83.3% have a family doctor, and 73.8% received a treatment summary. Additionally, 56.1% and 54.4% consented to medical record linkages with MCR and CRISP, respectively. Recruitment is ongoing.
Conclusion: This study will inform future interventions by identifying disparities in survivorship care experiences among Black BC survivors and evaluating the impact of this care on health outcomes.

#6184 A literature-based data scanning and prioritization study to guide future systematic literature reviews for WCRF International CUP Global Programme.

Georgios Markozannes, Ahmad Jayedi, Sofia Cividini, Sayada Zartasha Kazmi, Margarita Cariolou, Rita Vieira, Sonia Kiss, Katia Balducci, Dagfinn Aune, Marc Gunter, Amanda Cross, Doris Chan, **Konstantinos Tsilidis**

Epidemiology and Biostatistics, Imperial College London, London, United Kingdom

Background: In 2018, the World Cancer Research Fund (WCRF)/American Institute for Cancer Research published the Third Expert Report (TER) synthesizing the evidence on diet, adiposity, physical activity and risk of 19 cancers and 10 updated evidence-based cancer prevention recommendations. As part WCRF International's Global Cancer Update Programme, we aimed to develop a prioritization support tool to identify what systematic literature reviews (SLR) of the epidemiological evidence published after the TER would help strengthen the TER's conclusions and deepen our understanding on emerging topics.

Methods: We developed a literature scanning and prioritization strategy in six actions. From January 2019 (after TER publication) to February 2024, we searched PubMed for: 1) meta- and pooled analyses, 2) randomized controlled trials (RCTs) and protocols, 3) Mendelian randomization (MR) studies, and 4) prospective cohort studies (≥100,000 participants) on diet, adiposity, physical activity, sedentary behavior and cancer risk. In action 5, we utilized the fail-safe number and conditional power statistics to estimate the number of additional studies needed to change the existing TER meta-analytic findings. Finally, action 6 integrated data from actions 1-5, to construct an exposure-based prioritization ranking across all cancer sites. A prioritization score (PS) was derived by assessing the number of new studies, the concordance of association measures (direction and statistical significance) against the TER, and the volume of new associations not covered in the TER.

Results: We reviewed 366 meta-analyses, 121 pooled analyses, 19 RCTs, 368 MR studies and 359 cohort studies covering 151 exposures and 28 cancers, comparing them to 1371 TER meta-analyses. TER meta-analyses most likely to change from not statistically significant to significant when adding new studies included folate and colorectal cancer, waist circumference and lung cancer in never smokers, poultry and breast cancer, total fat and ovarian cancer, tea and ovarian cancer, and red meat and kidney cancer, but most associations observed in the TER are unlikely to change with additional similar research. The median PS score across exposures was 6 (range -11 to 163). Top ranked exposures with new literature evidence included anthropometric measurements (PS_{height} 40 to PS_{BMI} 163), physical activity (PS 100), sedentary behavior (PS 64), alcohol (PS 52), tea (PS 36), milk and dairy products (PS 29), micronutrients ($PS_{retinol}$ 27 to PS_{iron} 38), vitamins (PS_{B12} 22 to PS_{vitD} 91), soy (PS 24), isoflavones (PS 23), and soft drinks (PS 22). Across exposures, the top cancers were colorectal, breast, lung, liver, and endometrium.

Conclusions: The outputs from the prioritization support tool can help target SLRs that would most usefully contribute to evidence-based cancer prevention recommendations.

#6185 Integrating internships into the CaRE^2 Health Equity Center: A pathway for developing future health equity leaders.

Nazleen Del Rio[1], Brooke Hensel[1], Ileana Guzman[1], Eduardo Ibarra[2], Carolina Aristizabal[2], Rosa Barahona[2], Lourdes Baezconde-Garbanati[2], Mariana Stern[2], John Luque[3], Sandra Suther[3], Fern J. Webb[4]

[1]University of Florida, Orlando, FL,[2]University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Florida Agricultural and Mechanical University, Tallahassee, FL,[4]University of Florida, Jacksonville, FL

The CaRE^2 Health Equity Center's Community Outreach Core (COC) provides internships to prepare students for meaningful careers in cancer health disparities by bridging classroom learning with community work. These internships equipped students with skills in data analysis, community outreach, cancer health education, and cultural humility. Tailored internships provide a unique opportunity for students to gain hands-on experience in health equity research focused on eliminating cancer health disparities. As a full-time intern, one of my first activities was to create a work plan to include objectives, goals and anticipated deliverables of my internship. My orientation included completing ethics training and joining institutionally-approved research studies. I worked directly with community partners and received mentorship from leading scientists and researchers. I helped plan and implement health promotion programs, create materials and organize events designed to increase knowledge about cancer screening, treatment and prevention. I also contributed to outreach activities and analyzed program data which strengthened my skills and broader network in community health. My internship provided me with a comprehensive understanding of health disparities work, preparing me to make a lasting difference in the field. The internship aimed to yield lasting benefits by equipping aspiring health equity advocates with practical skills and opportunities to work directly with others committed to community impact. Interns are encouraged to share their innovative ideas and perspectives on CaRE^2's projects, further enhancing the effectiveness and relevance of its initiatives to meet community needs. Looking to the future, expanding CaRE^2's internship program to include students from all partner institutions Florida A&M University, the University of Florida, and the University of Southern California would further enhance the Center's capacity to conduct research studies and educational programs. Currently, Florida A&M University hosts two 12-week public health internships annually with COC. Overall, interns contribute skills that support COC's aims: increase the number of people informed and prepared to advocate for cancer research (aim 1), share information that increases awareness and knowledge about cancer prevention, screening and ongoing research (aim 2); and provides additional opportunities to disseminate cancer-related information. Internships like those offered by CaRE^2 empower students to engage in health equity. These experiences prepare interns to carry forward culturally sensitive approaches, strengthening CaRE^2's legacy and contributions to a more inclusive healthcare future. For others considering an internship, seek programs with diverse, hands-on opportunities that are designed to help you define your career path and make a meaningful difference.

#6187 Venous thromboembolism in metastatic and non-metastatic head and neck cancer.

Ted Akhiwu[1], May Gao[2], **Nosayaba Osazuwa-Peters**[2]

[1]Medstar Union Memorial Hospital, Baltimore, MD,[2]Duke University, Durham, NC

Background: Venous thromboembolism (VTE) is a comorbidity in many cancer patients, however, data in patients with head and neck cancer (HNC), as well as the burden in patients with metastatic HNC compared to non-metastatic HNC is limited. This study aimed to examine the prevalence, hospitalization outcomes, and correlations of VTE in patients with HNC.
Methods: We utilized retrospective data from the 2016-2020 National Inpatient Sample (NIS) to evaluate VTE in HNC patients. We included adults ≥ 18 years with a diagnosis of HNC using ICD-10 codes. The primary outcome was the odd of VTE among patients with metastatic (M-) vs non-metastatic (NM-) HNC. VTE was defined as deep vein thrombosis (DVT) or pulmonary embolism (PE) using ICD-10 diagnosis codes. Secondary outcomes were the odds of in-patient mortality and prolonged length of stay [LOS (≥ 21 days)] among HNC patients with VTE. We compared demographic, clinical, and hospital characteristics between metastatic and non-metastatic HNC patients using $\chi 2$ for categorical and t-tests for continuous variables. Multivariable logistic regression models were fit to assess the relationship between clinical, patient, and hospital characteristics and study outcomes.
Results: There were 351850 weighted hospitalizations with a diagnosis of HNC between 2016 and 2020 (23.20% M-HNC and 76.80% NM-HNC). Among HNC patients, 2.74% had VTE (3.26% M-HNC vs 2.59% in NM-HNC). The mean age of HNC patients was 64.11 years (± 11.66) [64.55 years (±11.70) NM-HNC vs 62.63 years (±11.40) M-HNC]. Among HNC patients, higher odds of VTE were associated with Black race (aOR: 1.25, 95% CI 1.08 - 1.43), having higher Charlson comorbidity (CCM) scores [aOR 1.34 (1.20 - 1.50)] and lower odds were associated with Asians/Pacific Islanders (PI) (vs White, aOR0.62 (0.44 - 0.84)] and those undergoing major surgery [(aOR 0.63 (0.54-0.74)]. Among NM-HNC, higher odds of VTE were associated with Black race [(vs white, aOR 1.23 (1.04 - 1.45)] and higher CCM [(aOR 1.19 (1.01 - 1.41)]. Among patients with M-HNC, higher odds of VTE were associated with Black race [(vs White aOR 1.30 (1.02 - 1.68)], and higher CCM [(aOR 1.34 (1.09 - 1.64)] and lower odds were noted in Asian/PI [(vs white aOR 0.44 (0.25 - 0.79)]. VTE was associated with increased odds of in-hospital mortality [aOR 2.26 (1.91-2.67)] and prolonged LOS [AOR 3.60 (3.13-4.15)] overall and in both M-HNC [AOR for mortality 2.06 (1.55-2.73) and LOS 3.36 (2.57 - 4.40] and NM-HNC [AOR for mortality 2.35 (1.91-2.89) and LOS 3.73 (3.16 - 4.41)].
Conclusion: VTE is more prevalent in M-HNC patients and is associated with adverse in-hospital outcomes including increased mortality and a prolonged LOS. Black race and higher comorbidity were positively associated with VTE, while Asian/PI race and head and neck surgery were negatively associated. Findings highlight the need for targeted interventions to prevent VTE in high-risk HNC patients and reduce adverse in-hospital outcomes.

#6188 Evaluating impact and progress in the iCCaRE consortium for Black men's approach to reducing prostate cancer disparities.

Ivey Breland, Ernest Kaninjing, Damian Francis

Georgia College & State University, Milledgeville, GA

The purpose of the Inclusive Cancer Care Research Equity for Black men (iCCaRE) Consortium is to address prostate cancer disparities impacting Black men through collaborative research, education, and advocacy. This study evaluates the progress of iCCaRE in achieving its core objectives across five pilot projects supported by multi-institutional partners. Specifically, iCCaRE aims to expand research infrastructure, develop culturally tailored interventions using artificial intelligence to address social determinants of health, explore modifiable social-biological factors affecting patient outcomes, and provide extensive research training for underrepresented minority scientists and advocates. Our methodology involved the creation and implementation of a comprehensive data collection tool via Qualtrics to assess activity outcomes across the Consortium. This tool enabled standardized reporting on publications, grants awarded, media reach, community impact, and additional metrics tied to scientific productivity and partnership engagement. Unpublished data collected this year indicate substantial progress, including an increase in collaborative research outputs, expanded access to prostate cancer care resources, and enhanced engagement with both clinical and community-based partners. These findings underscore the Consortium's effectiveness in fostering scientific collaboration, developing targeted interventions, and creating infrastructure to support sustainable improvements in prostate cancer outcomes for Black men. These accomplishments provide a strong foundation for iCCaRE's transition into Phase 2, with plans to deepen community engagement, expand research training, and enhance data-driven insights through advanced analytics.

#6189 Educational level as a determinant of breast cancer stage at diagnosis.

Xiaying Kuang

The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Presently, there is a gap in literature regarding specific demographic characteristics and the stage of breast cancer at diagnosis. Herein, we examined patients' educational levels to explore effective strategies for early breast cancer diagnosis.
Methods: Convenience sampling method was used to select invasive breast cancer patients treated at a tertiary hospital in Guangzhou between January 2018 and March 2023 to determine patients' breast cancer stage at diagnosis and individual characteristics. The associations were analyzed using Student's t-test and the chi-square test, and binary logistic regression analysis was conducted to assess the odds ratios (ORs) for the occurrence of late-stage breast cancer.
Results: The study encompassed a total of 3225 patients diagnosed with invasive breast cancer. Among them, 707 patients were identified with late-stage cancer (stage III-IV), comprising 21.9% of the total sample. Univariate analysis revealed a significant inverse correlation between patients' educational level and the stage of breast cancer at diagnosis, regardless of age stratification. The results of the chi-square test revealed a significant correlation between patients' educational level and their perception of illness ($P < 0.001$), with patients with higher levels of education being more likely to demonstrate a more comprehensive understanding of the disease. Upon controlling for other potential confounding variables, these findings were confirmed by binary logistic regression analysis, which demonstrated that individuals with lower education levels had a significantly increased likelihood of being diagnosed with late-stage breast cancer (adjusted OR = 1.409 for the middle school group and 1.518 for the illiterate and primary school group).
Conclusions: Patients with lower educational levels could be more likely to present with late-stage breast cancer at diagnosis. Therefore, it is imperative to prioritize popular science and early prevention strategies for breast cancer among less educated populations.

#6190 Descriptive analysis of selenium levels in a healthy Malawian subpopulation: Findings from a control study on esophageal squamous cell carcinoma (ESCC).

Emmanuel Uduh, Yukiko Yano, Yingxi Chen, Christian Abnet, Bongani Kaimila, Shiraz Khan

Division of Cancer Epidemiology and Genetics, NIH-NCI, Rockville, MD

Background: Esophageal squamous cell carcinoma (ESCC) is the third most common cancer in Malawi, with an estimated 1,871 new cases and 1,766 deaths in 2024 in Malawi. Although drinking alcohol and smoking tobacco are major causes of ESCC in some populations, the high rates in Malawi are unlikely to be due to these agents. Several East African countries have high incidence rates of ESCC and low soil selenium concentrations. Observational and intervention studies in East Asia have shown that low selenium concentrations are linked to an increased risk of ESCC.
Methods: We used control subjects from a previously reported hospital-based case-control study of ESCC conducted at two hospitals in Lilongwe, Malawi (2017-2020). The study collected questionnaire data and stored fractionated blood. ESCC cases were excluded due to reverse causation for nutritional biomarkers. Instrumental neutron activation analysis (INAA) was used to measure serum selenium concentrations. Using R, we generated descriptive statistics and tested for associations with demographic variables. We also compared this study population to other previously studied populations with high ESCC incidence rates.
Results: We successfully measured 247 control subjects from Malawi and found a median (IQR) serum selenium concentration of 77.3µg/L (65.9-89.5). 79 (31.9%) subjects were below the 72.2 subjects µg/L threshold of the median level of selenium We found no statistically significant associations between serum selenium concentrations and demographic characteristics including sex, education, marital status, and several risk factors for ESCC previously identified in the underlying case-control study. The serum selenium concentrations in these subjects were low and similar to previously studied regions where ESCC is common including both Bomet, Kenya and Linxian, China.
Conclusion: We found low median serum selenium levels in control subjects from a hospital-based case-control study of ESCC conducted in Malawi, a region known to have high rates of ESCC. The range was similar to other populations with high incidence of ESCC. Direct linkage to disease risk will require different study designs, but our findings suggest that selenium deficiency could be a factor in the high burden of ESCC in East Africa.

#6191 Associations of alcohol consumption with expression of CD44, CD24, and ALDH1A1 stem cell markers in incident benign breast biopsy samples.

Rulla M. Tamimi[1], Maisey Ratcliffe[2], Yu Jing J. Heng[3], Brian Sardella[3], Lusine Yaghjyan[4]

[1]Pathology, Cornell University, New York, NY,[2]University of Florida, Gainesville, FL,[3]Pathology, Beth Israel Deaconess Medical Center, Boston, MA,[4]Epidemiology, University of Florida, Gainesville, FL

Purpose: We investigated the associations of alcohol consumption with expressions of stem cell markers CD44, CD24, and ALDH1A1 in cases of incident benign breast disease.
Methods: This study included 721 cancer-free women with biopsy-confirmed benign breast disease (BBD) within the Nurses' Health Study II cohort. Histologically normal breast tissue cores were used to construct tissue microarrays (TMAs). Immunohistochemistry (IHC) was performed on TMA sections to analyze the expression of stem cell markers. For each core, the IHC expression was assessed using semi-automated software and reported as the % of positively stained cells for each of the markers out of the total cell count. All expression measures were log-transformed for analysis. Alcohol consumption was obtained from semi-quantitative food frequency questionnaires. Other covariate information was collected on the initial questionnaire and updated biennially thereafter. We examined associations for recent (at the time of biopsy) and cumulative average alcohol consumption (from all questionnaires before the biopsy), modeled as a continuous variable (drinks/day). Generalized linear regression was used to examine the associations of alcohol with each marker's expression (within stroma and epithelium), while adjusting for known breast cancer risk factors and BBD subtype.
Results: In this study of 721 cancer-free women, the average age at the time of biopsy was 44 (range 27-63), with the majority of participants being premenopausal at the time of biopsy (81.28%). Recent and cumulative average alcohol consumption were not associated with expression of CD44, CD24, or ALDH1A1 in stroma (recent: β per drink/day=0.08, 95% Confidence Interval [CI] -0.16,0.32; β=-0.03, 95% CI -0.11,0.05; β=0.01, 95% CI -0.26,0.29, respectively; cumulative average: β=-0.09, 95% CI -0.38,0.19; β=-0.01, 95% CI -0.10,0.08; β=-0.04, 95% CI -0.36,0.27, respectively) or epithelium (recent: β=0.08, 95% CI -0.04,0.21; β=0.02, 95% CI -0.01,0.06; β=$0.23x10^{-2}$, 95% CI -0.15,0.15, respectively; cumulative average: β=-0.06, 95% CI -0.08,0.20; β=0.04, 95% CI -0.01,0.08; β=-0.01, 95% CI -0.18,0.17, respectively).
Conclusion: Our findings suggest that alcohol use is not associated with the expression of CD44, CD24, and ALDH1A1 in histologically normal breast tissue from benign biopsies.

#6193 Population-level interventions to prevent alcohol-related cancers: A scoping review.

Priyanka Basu[1], Jovan Julien[2], Sangeeta Goswami[3], Anton L.V. Avancena[4]

[1]Texas A&M University School of Medicine, Round Rock, TX,[2]Georgia Institute of Technology, Atlanta, GA,[3]MD Anderson Cancer Institute, Houston, TX,[4]University of Texas, Dell Medical School, Austin, TX

Alcohol use and misuse are associated with at least eight types of alcohol-related cancers, namely cancers of the oral cavity, pharynx, larynx, esophagus (squamous cell carcinoma only), stomach, colon, liver (hepatocellular carcinoma only), and breast in females. Population-level interventions that reduce alcohol use may mitigate this cancer burden. This scoping review examines and synthesizes evidence on the effectiveness of these interventions on cancer-related outcomes.

We followed the PRISMA-ScR guidelines and searched MEDLINE and Web of Science for English-language articles (1987 onwards) using keywords and terms related to interventions, alcohol use, and cancer in titles and abstracts. Only original quantitative research articles evaluating population-level interventions' impact on cancer outcomes were included. Initial data extraction was conducted using Elicit, an AI-based research tool, which was reviewed by the research team for accuracy.

Out of 1,531 studies, 68 full-texts were assessed for eligibility, and 35 were included in the final qualitative synthesis. Most studies were focused on Europe (N=17), Asia and Oceania (N=11), and North America (N=4). Study designs included randomized controlled trials (N=6), observational studies (N=18), and simulation models (N=11). The most common cancer-related outcome was cancer incidence (N=19), followed by cancer mortality (N=11) and knowledge/awareness of alcohol as a carcinogen (N=10). Primary prevention studies (N=31) focused on reducing alcohol-related cancers through educational or media initiatives (N= 13), adherence to clinical guidelines (N=11), and alcohol pricing policies (N=6) like alcohol taxes and minimum unit pricing. Five studies addressed secondary prevention via educational and clinical interventions like screening, health assessment, and treatment of alcohol misuse. No tertiary prevention studies were identified.

This scoping review identified several gaps in our understanding of population-level interventions for alcohol-related cancers. Given the number of ever and current drinkers globally, additional studies are needed on secondary and tertiary prevention strategies. Few studies evaluated alcohol pricing policies despite the long-standing evidence supporting its effectiveness in reducing alcohol use. Meeting cancer prevention guidelines may reduce cancer incidence and mortality, and future research should focus on the most effective and cost-effective ways of translating recommendations into interventions in real-world contexts.

#6194 Unveiling cancer disparities: a task force report on multilevel drivers impacting equitable cancer care among Latinos in the US.

Amelie G. Ramirez[1], Edgar Munoz[1], Lorna Rodriguez-Rodriguez[2], Leon Bernal-Mizrachi[3], Patricia Chalela[1], Jose Lopez[4], Paulo S. Pinheiro[5], Barbara Segarra Vasquez, DHSc[6], Gregory A. Talavera[7], Luis G. Carvajal - Carmona[8], Adolfo Diaz Duque[1], Cliff Despres[1], Edward J. Trapido[9]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]City of Hope, Duarte, CA,[3]Emory University, Atlanta, GA,[4]University of Washington, Seattle, WA,[5]University of Miami, Coral Gables, FL,[6]University of Puerto Rico, San Juan, PR,[7]San Diego State University, San Diego, CA,[8]UC Davis - California, Davis, CA,[9]Louisiana State University, New Orleans, LA

Background: Cancer disparities among Latinos in the US are a critical public health issue, with this group experiencing inequitable outcomes across the cancer continuum, from screening to end-of-life care. Latinos have higher rates of certain cancers and poorer outcomes compared to other populations, driven by a complex interplay of environmental, genetic, cultural, behavioral, and systemic factors. While earlier research has highlighted some of these disparities, comprehensive analyses of the multilevel factors affecting cancer care among Latinos are still limited. This report aims to identify these factors to help guide the work of current and future researchers who can address Latino cancer outcomes.
Methods: The Task Force: Latino Researchers Against Cancer (TFLRAC) held structured meetings in 2023 to share expertise. Participants included specialists in oncology, public health, and behavioral sciences who examined environmental, genetic, cultural, behavioral, and systemic contributors to cancer care disparities among Latinos. The goal was to explore the causes and multilevel drivers of health impacting the Latino cancer experience.
Results: Findings show that cancer disparities among Latinos are influenced by multiple factors, including environmental exposures associated with higher pollution levels and occupational hazards, genetic variations affecting cancer risk and prognosis, and cultural and linguistic barriers affecting healthcare decisions. Behavioral factors, such as unhealthy dietary habits, and systemic issues, such as limited access to healthcare, inadequate insurance coverage, and lack of diversity in the healthcare workforce, further contribute to these disparities. Additionally, socioeconomic barriers and restrictive eligibility criteria contribute to the underrepresentation of Latinos in clinical trials, while cultural stigmas, limited support services, and language barriers pose challenges in cancer survivorship.
Conclusions: Reducing cancer disparities among Latinos requires a multifaceted approach, including targeted research on environmental and genetic factors, culturally sensitive interventions, and policy reforms to improve healthcare access and workforce diversity. Collaboration among academia, healthcare providers, Latino communities, government, and industry is essential to achieve equitable cancer care for Latinos.

#6195 Rural and urban disparities in distance to childhood cancer survivorship care.

Amanda S. Thomas[1], David Van Riper[2], Jesse Berman[3], Helen M. Parsons[4], Lucie Turcotte[5], Logan Spector[6], Jenny Poynter[6], Erin Marcotte[6]

[1]Epidemiology & Community Health, University of Minnesota, School of Public Health, Minneapolis, MN,[2]University of Minnesota, Institute for Social Research and Data Innovation, Minneapolis, MN,[3]Environmental Health Sciences, University of Minnesota, School of Public Health, Minneapolis, MN,[4]Health Policy & Management, University of Minnesota, School of Public Health, Minneapolis, MN,[5]Pediatrics, University of Minnesota Medical School, Minneapolis, MN,[6]Division of Pediatric Epidemiology and Clinical Research, University of Minnesota Medical School, Minneapolis, MN

Presently, 1 in 530 young adults (ages 20-39 years) in the US is a survivor of childhood cancer. These individuals are burdened with high risks for chronic disease, disability, secondary cancers, and a shortened lifespan. Because of these late health consequences, survivors are recommended to receive specialized healthcare according to survivorship care guidelines. Despite this, a significant proportion of survivors fail to receive survivorship-directed care, particularly among the adolescent and young adult (AYA) population, suggesting systematic barriers to care. The goal of this analysis was to assess one possible barrier by characterizing where AYA survivors live in the US and their distance to survivorship care centers.

The Children's Oncology Group (COG) Childhood Cancer Research Network (CCRN), a large registry of childhood cancer patients, includes information on cancer diagnosis, place of residence, and initial treatment institution for >50,000 childhood cancer patients treated in North America. In this analysis, CCRN data were linked to LexisNexis via probabilistic matching to derive residential history for each case and up to two parents or guardians and used to evaluate distance to survivorship care. Those with low confidence scores were excluded and the remaining true addresses were geocoded with a 94% good match rate. Distance to care was calculated from the most recent address to nearest COG survivorship center based on those publicly available in the 'COG Late Effects Directory of Services' online database.

Of individuals of AYA age at diagnosis (15-39 years), 3,396 had successfully geocoded case-specific addresses for survivorship at an average of 14.8 years post-diagnosis (survival time). The most common primary diagnoses were leukemias and lymphomas (54.8%) and mean diagnosis age was 16 years (IQR: 15-18). Nearly 60% were male with 15.8% of Hispanic origin and 74% identifying as White. The most populous states for this cohort (CA, TX, FL, NY) comprised about one-third of all survivors. Average straight-line distance to survivorship care among all AYA survivors was 18.2 miles (IQR: 7.9-45.8), with rural residents having to travel more than four times as far than urban to COG-specific centers. Those that had to travel farther for care were primarily in the low/middle socioeconomic classes (Kruskal-Wallis p-value <0.001) with no considerable differences existing based on sex. Among diagnoses, survivors initially treated for CNS tumors and renal cancer were furthest from survivorship care (average 20.5 and 23.3 miles to nearest COG location, respectively).

Treatment at greater distances can become a burden logistically and financially, potentially limiting access to care. As patients transition into survivorship care, distance to care could impact healthcare choices and long-term health outcomes, especially among those with higher-risk initial diagnoses or those from disadvantaged backgrounds.

#6196 Characteristics of individuals with early-onset multiple myeloma in South Carolina.

Amy F. Ballou[1], Tomotaka Ugai[2], Abbas Tavakoli[1], Karen Wickersham[1]

[1]University of South Carolina, Columbia, SC,[2]Harvard Medical School, Boston, MA

Background: The incidence of early-onset cancers, defined as cancer in adults under 50 years, are on the rise. Early-onset multiple myeloma (MM), which is the second most common hematologic cancer in the U.S., is one of early-onset cancer types with increasing incidence. This age/race disparity is believed to be linked to genetic factors and social determinants of health (SDOH), though the precise causes are still under investigation. Data on risk factors for early-onset MM are limited. The incidence rate of MM in South Carolina is higher than the U.S. average. A geospatial analysis study showed differences in average county-level age-adjusted incidence rates (ASR) across U.S. counties, with high ASR found primarily in the Southeast and two major high-high local clusters of the ASR in Georgia and South Carolina. To address this gap, we first examined the characteristics of patients with early-onset MM in South Carolina.
Purpose: To examine 1) the prevalence of patients with early-onset MM in South Carolina and 2) their characteristics and SDOH.
Methods: A retrospective review of electronic medical records (EMR) from 1/1/2020 to 8/30/2023 was conducted to identify patients with early-onset MM (N=23) at a community oncology clinic in South Carolina. Potential cases were identified by EMR reports based on age and diagnosis. EMR confirmed eligibility, and socio-demographics and cancer-related information was entered into a REDCap database. SAS (v.9.4) was used for descriptive statistics.
Results: The total number of MM cancer cases in all ages observed during the study period was 247. Among them, twenty-three cases were diagnosed before age 50 (prevalence: 10.7%). The average age at diagnosis was 44.5 (SD: ±5.29, range: 27-49). The average BMI was 33.87 (SD±9.81). MM stages based on the Revised International Staging System (R-ISS) were as follows: Stage I, N=6, stage II, N=7, stage III, N=4, and missing, N=6. Over half of the individuals with early-onset MM were male (52%). The ethnicity/race was Black (57%), White (39%), and Asian (4%). Other sociodemographic characteristics included unemployment status (35%), rurality (53%), and smoking history (43%). About 52% of early-onset MM patients had commercial insurance, 30% Medicare/Medicaid, 4% no insurance, 4% Department of Corrections, and 8% had veteran insurance. Notably, 43% of early-onset MM patients had high-risk cytogenetics (gain 1q21, gain 1q, del 1/p32/CDKN2C, IGH rearrangement, del 1p, del 17p, del 13q, del TP53, monosomy 13, Trisomy 1) and 18% received allogeneic stem cell transplant.
Discussion: We demonstrated that patients with early-onset MM in South Carolina often have characteristics such as race, unemployment, and high-risk cytogenetics. Future research should explore how genetic, environmental, lifestyle factors and SDOH influence the risk and prognosis of early-onset MM, particularly in areas with persistent poverty and historically disadvantaged communities.

#6197 Examining the impact of food cost and accessibility on nutrition insecurity and food choice among postmenopausal African American breast and endometrial cancer survivors.

Amirah Burton, Zakirah Abdul-Hameed, Mohamed Mubasher, Brian Rivers, Desiree Rivers

Morehouse School of Medicine, Atlanta, GA

Background/Significance- Scientific literature continues to demonstrate the beneficial impact of lifestyle modifications, such as diet, on overall health and in reducing recurrence of breast and endometrial cancers. However, more research is needed to identify and understand how certain structural and social barriers impede cancer survivors' ability to maintain a healthy diet. The purpose of this study is to examine 1) the prevalence of nutrition insecurity and 2) how food cost and accessibility influence food choices and nutrition security status among low-income postmenopausal African American breast and endometrial cancer survivors. This sub-study is part of a larger study funded by the ACS Research Scholar grant.
Methods- Sixteen postmenopausal (50+ years of age) African American women diagnosed with breast or endometrial cancer before 2020 completed cross-sectional surveys assessing nutrition security status and healthfulness choice (ability to meet dietary needs by having control over food options), food accessibility (Neighborhood Environment Walkability Scale), and food expenditures. Nutrition security and healthfulness choice assessment tools were from the Center for Nutrition and Health Impact. Descriptive statistics and univariate analyses were performed to determine nutrition security status, healthfulness choice, average walking distance to food retailers, and food expenditures.
Results- Forty-two percent of participants were nutrition insecure, while 5.3% scored low for household healthfulness choice. Most participants are in closer walking distance to fast food restaurants compared to a supermarket or fruit/vegetable market and purchase most of their food at a supermarket (75%), supercenter (25.8%), or small grocery store (6.3%). Sixty-two percent of participants rated the price of fresh fruits and vegetables as somewhat expensive, 12.5% not expensive, 18.8% very expensive, and 6.3% very inexpensive.
Conclusion- Although many participants experience nutrition insecurity, few participants feel constrained in their ability to meet their dietary healthfulness needs and control their food options. Despite living in closer proximity to fast food restaurants, participants spend more money on food at supermarkets or supercenters. Additional studies are needed to further explore the multi-level factors impacting nutritious food access, diet quality, and health status of African American breast and endometrial cancer survivors.

#6198 Framework for Pacific Island Cancer and Obesity Across the Lifespan: PICOLI, A multi-dataset analysis approach.

A. B. Yamanaka[1], M. B. Laguana[2], M. Chong[3], R. T. Leon Guerrero[2], R. Novotny[1], G. Badowski[2], L. R. Wilkens[3];
[1]University of Hawaii at Manoa, Honolulu, HI, [2]University of Guam, Mangilao, GU, [3]University of Hawaii Cancer Center, Honolulu, HI

Background: Pacific Islanders experience disproportionate rates of obesity and cancer, contributing to morbidity and mortality. Comprehensive analyses examining obesity and cancer across age groups are limited. Objective: We propose to develop a framework identify and harmonize existing datasets to assess lifestyle factors, obesity, and cancer across various age groups, with a focus on Pacific Islander populations.
Methods: We have identified several key datasets for this analysis, including the the Children's Healthy Living Program (CHL), Pacific Islands Cohort on Cardiometabolic Health (PICCAH), Breast Cancer Risk Project (BRISK), and Multiethnic Cohort Study (MEC). These datasets contain approximately 22,000 participants from 2-80 years old, which capture essential factors, such as body mass index, physical activity levels, dietary habits, sleep behavior, tobacco use, and cancer incidence.
Expected Outcomes: The framework will guide future research to provide insights between lifestyle factors, obesity, and cancer risk that evolve throughout life. Anticipated identification of consistent patterns across age groups and potential modifiable lifestyle factors associated with reduced cancer risk. We will contribute valuable knowledge about the long-term effects of lifestyle factors on obesity and cancer risk in Pacific populations. Inform public health strategies tailored to address significant health disparities in this population.
Conclusion: Developing this analytical framework aims to bridge current gaps in understanding the complex relationships between lifestyle factors, obesity, and cancer risk among Pacific Islanders, ultimately contributing to improved health outcomes. Future researchers can apply this framework to existing datasets, facilitating comprehensive analyses across age groups and potentially guiding targeted interventions.

Table 1. Key Datasets for Pacific Island Cancer and Obesity Across the Lifespan Study

Study Name	Children's Healthy Living Program (CHL)	Pacific Islands Cohort on Cardiometabolic Health (PICCAH)	Breast Cancer Risk Project (BRISK)	Multiethnic Cohort(MEC)
Participants, n	1,263	500 dyads	245	~20,000
Age, years	2 - 8y	4 - 10y & 21 - 50y (biological adult parents)	25 - 80y	45 - 79y
Study Design	Cross-sectional and Randomized Controlled Trial	Cohort	Case Control	Cohort
Location	CNMI, Guam, Hawaii	Guam	CNMI, Guam	Hawaii
Health Outcome	Obesity, Acanthosis nigricans	Obesity, Diabetes, Acanthosis nigricans	Breast Cancer, Diabetes	All Cancers, Diabetes
Measured Anthropometry	Height, weight, waist circumference	Height, weight, waist circumference	Height, weight, waist circumference	Height, weight, waist circumference
Lifestyle Measures	Diet, physical activity, sleep	Diet, physical activity, sleep, tobacco use	Diet, physical activity, tobacco use	Diet, physical activity, sleep, tobacco use

#6199 Interlab study supporting hereditary cancer testing in an NGS-focused landscape.

Dana Ruminski Lowe, Deepika Philkana, Krystyna Nahlik, Melissa Berenger, Andrew Anfora, Yves Konigshofer, Catherine Huang, Russell Garlick, Bharathi Anekella

LGC Clinical Diagnostics, Gaithersburg, MD

Up to 10% of all cancers may be caused by inherited genetic changes. Consequently, the increasing prevalence of cancer is driving the growth of the hereditary cancer testing as it is important to implement surveillance and risk-reduction strategies, detect cancer at an early, more treatable stage, and provide tailored treatment and therapies. Panels are often designed to cover hundreds of genes and performing validation and assessing performance requires samples with common mutations in each of those genes. Biosynethic reference materials can address these challenges. Here we describe the development and multisite evaluation of Seraseq® Inherited Cancer DNA Mix v2, which contains genes recommended for testing by the American College of Medical Genetics, the National Comprehensive Cancer Network, and the American Society of Clinical Oncology. Genomic DNA from the GM24385 cell line was blended with 61 biosynthetic DNA variants in 55 different genes including 21 deletions, 16 duplications, 3 insertions, 5 INDELs, 15 SNVs and 1 Inversion. Variant allele frequency (VAF) was targeted to 50% and verified using the Bio-Rad QX-200 Droplet Digital PCR (ddPCR) System. The mix was analyzed with the Axen Hereditary Cancer Panel v2 (Macrogen), the ViennaLab Hereditary Cancer Assay (ViennaLab) on the MiSeq System (Illumina), the Twist Library Preparation and AVITI 2x150 Sequencing Kit Cloudbreak Low Output on the Element Biosciences AVITI (Halo Precision Diagnostics), the GALEAS Hereditary Plus v2 Panel (Nonacus) on the NextSeq 2000 System (Illumina), and the Celemics Library Preparation Kit and Celemics Target Enrichment Kit and the NextSeq 500/550 Kits v2.5 (Illumina) on the NextSeq 500 System (Illumina).All biosynthetic variants were detected within 40-60% by ddPCR. Most NGS assays were not able to detect all variants as many that were included are difficult to detect. Identification of these complex variants required modifications to alignment, variant calling, and annotation settings. For example, RAD51D c.694_715delins is detected as two separate c.694C>T and c.715C>T variants (e.g. at ViennaLab), unless the variant caller is set to merge. At Nonacus, the Boland inversion and BRCA2 and STK11 large deletions were detected by a combination of short-range and long-range paired-end mapping and split-read analysis. An Alu-specific module using repeat masking allowed successful calling of the BRCA2 AluY insertion; both increased detection accuracy from 85.5% to 95.1%.
The performance of the Seraseq Inherited Cancer DNA Mix v2 across NGS assays, supported by robust digital PCR data, demonstrated that these materials have broad compatibility and will allow for assessment of the ability of variant callers to detect complex variants.

#6200 Context-specific strategies for enhancing HPV vaccination: insights from the US and territories in the post-COVID-19 era.

Erika Escabi-Wojna, Mariola Acosta-Rullan, Natalie Alamo-Rodriguez, Grace Velez-Crespo, Vivian Colon-Lopez

Department of Cancer Control and Population Sciences, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Introduction: Over 42 million people in the United States (US) are affected by Human Papillomavirus (HPV), which causes over 90% of cervical cancer cases. Despite there being an FDA-approved HPV vaccine for cancer prevention, vaccination completion rates significantly vary by state, ranging from 38.5% to 85.2% among adolescents, leaving many vulnerable to this infection and contributing to cancer health disparities.
Objective: This qualitative study aimed to identify effective HPV vaccination strategies and context-specific factors, including the impact of the COVID-19 pandemic, that influence policy adoption and vaccination uptake across the US and its territories, that will offer insights into effective methods for addressing this public health challenge.
Methods: To date, we have purposely sampled key informants, including immunization program managers, health department personnel, and others, from the following states and territories: (1) Puerto Rico, (2) Virginia, (3) D.C., (4) New York, (5) Rhode Island, and (6) California. Inclusion criteria required participants to have expertise in an area related to health or public policy focused on vaccination, at least three years of experience, and knowledge of HPV vaccination policies or strategies. Eligible key informants (n=9) participated in virtual, audio-recorded semi-structured interviews via Microsoft Teams, lasting 45 to 90 minutes. Preliminary analyses were conducted using Dedoose.
Results: Several effective strategies were identified for promoting HPV vaccination, including provider education, the implementation of school vaccination policies, and the use of cancer prevention messaging. Barriers included the spread of vaccine misinformation by anti-vaccine groups, which hindered organizational efforts and complicated the implementation of HPV vaccination strategies. Collaboration with health departments, schools, and immunization programs, emerged as a key facilitator in overcoming these challenges and promoting HPV vaccination uptake. Participants noted that the introduction of the COVID-19 vaccine negatively influenced parents' perceptions of vaccinations, increasing resistance and opposition to HPV vaccination efforts.
Conclusions: Our preliminary results suggest that educating healthcare providers, implementing school vaccination policies, and shifting HPV messaging to focus on cancer prevention are effective strategies for improving vaccination rates. Collaboration between health departments and educational institutions is also crucial. Our analysis highlights the need to address vaccine misinformation and improve perceptions, especially post-COVID-19 vaccine rollout. Future efforts will include expanding participant recruitment to include other states, conducting interviews, and applying thematic analysis to our data.
Funding: NCI grant R01CA232743.

#6201 The factors influencing quality of life among patients with hepatobiliary and pancreatic cancers.

Sieun Lee[1], Sunhee Hwang[2], Junglyun Kim[1]

[1]Chungnam National University, College of Nursing, Jung-gu, Daejeon, Korea, Republic of,[2]nursing, Chungnam National University Hospital, Jung-gu, Daejeon, Korea, Republic of

Background: Hepatobiliary and pancreatic cancers are aggressive malignancies with poor survival rates, largely due to challenges in early diagnosis and limited curative treatment options. These cancers significantly impact patients' quality of life (QOL), which is strongly associated with treatment outcomes and overall survival. Despite its importance, comprehensive research on QOL in these patients remains limited, highlighting the need to identify factors influencing QOL to improve care and outcomes. The purpose of this study is to identify the factors influencing the QOL among patients with hepatobiliary and pancreatic cancers. To describe comprehensive factors associated with QOL, we applied the biopsychosocial model (Engel, 1977) in the study. The study examined comprehensive clinical data, which included individuals' characteristics, symptom assessment, and medical information.
Methods: The patients with hepatobiliary or pancreatic cancers were recruited from a university hospital between September 2022 and November 2023. Along with collecting medical and treatment information, pain, depression, anxiety, and QOL were assessed using the Numeric Rating Scale, Hospital Anxiety and Depression Scale, and Functional Assessment Cancer Therapy-General, respectively. Multiple regression analysis was performed to identify factors influencing the QOL using SPSS 26.0.
Results: Among the 204 participants, the mean age was 66.7 (±8.52) years old;141(69.1%) were males; 107(52.5%) were diagnosed with liver cancer. Depression, anxiety, pain, and serum albumin significantly influenced the QOL, explaining 68.1% of the variance. Patients who were employed or had no metastasis reported significantly higher QOL. Patients who had higher albumin, lower pain, depression, and anxiety reported higher QOL. These findings emphasize the need for psychosocial support, pain management, and nutritional care to improve the QOL in patients with hepatobiliary and pancreatic cancers.
Conclusions: To improve the QOL of patients with hepatobiliary and pancreatic cancers, we suggest providing appropriate psychosocial support, pain control, and nutritional management during the cancer treatment.

#6202 Liquid biopsy multi-omic TempO-Seq platform for efficacy, safety, diagnosis, and subtyping using fingerstick blood.

Bruce Seligmann, Megan Opichka, Monica Hernandez, Zhoutao Chen, Joanne Yeakley, Joel McComb, Gregory Sahagian, Salvatore Camiolo

BioSpyder Technologies, Inc., Carlsbad, CA

Background and Purpose: While liquid biopsy assays are well described for plasma obtained from venipuncture, we used blood from a fingerstick, spotted onto filter paper, to profile gene expression of the whole transcriptome with the TempO-Seq® DBS assay and established a classifier for Alzheimer's Disease (AD) [Seligmann et. al., J. Alz. Dis. 101(2024) 813-822] achieving 98% accuracy classifying patients. Fingerstick samples can be self-collected, making this method a potentially transformative diagnostic tool. We describe expanding this fingerstick liquid biopsy assay to measure DNA variants and protein biomarkers, increasing its diagnostic potential and ability to monitor therapeutic response.
Methods: Blood was spotted onto 903 Proteinsaver cards and dried. Areas from each spot were then punched out into wells to measure the whole transcriptome (mRNA), alternatively spliced isoforms, the whole miRNome (miRNA), select DNA variants, and, after elution, select protein biomarkers providing a multi-omic profile of each sample. Commercial TempO-Seq assays were used, with additional attenuators added to reduce signal from highly expressed genes in blood. TempO-Seq DBS results were benchmarked against standard assays.
Results: Genotyped DNA was spotted and analyzed to derive calling algorithms for AD pathogenic and polygenic risk DNA variants, including APOE4. Assays for Tau and β-amyloid were established. Then patient samples were tested, and clinical diagnosis of AD and plasma biomarker results were correlated to the liquid biopsy protein, mRNA, miRNA, mRNA isoforms, and DNA variant profiles derived from TempO-Seq DBS data. The results demonstrated that the criteria for a definitive diagnosis of Alzheimer's Disease, suitability for immunotherapy, and prognosis via polygenic risk could all be assessed from the same fingerstick blood sample. To demonstrate its applicability monitoring drug response, samples were profiled from a subject administering weekly injections of the GLP-1 agonist (a therapeutic target for Type 2 diabetes and AD) peptide Zepbound. These results will be presented.
Conclusions: The results demonstrate the utility of the TempO-Seq DBS multi-omic liquid biopsy assay of gene expression, DNA variants, and protein biomarkers from a fingerstick. We demonstrate the potential to diagnose disease using AD as an exemplar case, and to monitor drug response. Since fingerstick samples can be self-collected, or collected in any doctor's office or clinic without a lab visit or phlebotomist, this test has the ability to address health disparities and may have the utility to; a) enable early at home diagnosis; b) provide home monitoring of therapy; c) facilitate recruitment of subjects for trials; d) serve as a companion diagnostic; and e) potentially provide a novel approach for early diagnosis of cancer and monitoring of recurrence through a convenient at-home test.

POPULATION SCIENCES: Health Disparities and Systemic Inequities: Lifestyle, Metabolism, and Disparities in Cancer Risk and Outcomes
Poster Session

#6206 The role of lifestyle factors in the disparities of colorectal cancer incidence: Findings from the Multiethnic Cohort Study.

Joel Sanchez Mendez[1], Jonanne Talebloo[2], Adelynn Paik[1], Sihao Han[1], Iona Cheng[3], Anna H. Wu[1], Ugonna Ihenacho[1], Lynne R. Wilkens[4], Loic Le Marchand[4], David V. Conti[1], Christopher A. Haiman[1], Brian Z. Huang[1], Mariana C. Stern[1]

[1]Department of Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA,[2]University of California Berkeley, Berkeley, CA,[3]Department of Epidemiology & Biostatistics, Unversity of California San Francisco, San Francisco, CA,[4]University of Hawai'i Cancer Center, University of Hawai'i, Mānoa, HI

Introduction: Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer death in the United States (US). In 2018, the World Cancer Research Fund/American Institute for Cancer Research (WCRF/AICR) published a score that allows the combined evaluation of adherence to their 2018 cancer prevention recommendations on diet, nutrition, and physical activity. We investigated associations between this score, and incidence of invasive colorectal adenocarcinoma across different racial and ethnic populations in the Multiethnic Cohort Study (MEC).
Methods: We leveraged data collected on 204,278 Non-Hispanic Black/African American (NHB), Japanese American, Hispanic/Latine (H/L), Native Hawaiian, and Non-Hispanic White (NHW) from the MEC. The WCRF/AICR score (range 0-7) was computed at both baseline (1993-1996) and the third follow-up questionnaire (2003-2008), with higher values representing healthier lifestyle behaviors. Covariate-adjusted Cox-proportional hazards models were used to estimate the association between the WCFR/AICR score and the colorectal cancer diagnosis. Dummy variables for a 1 SD decrease or increase between the baseline and follow-up WCFR/AICR score were generated to assess trends over time in relation to CRC incidence.
Results: A total of 5,993 events were reported, with 5,726 events 1 year or later after the collection of the baseline questionnaire and 1,276 a year or later after the follow-up questionnaire. Participants (55% female) had a mean age at cohort entry of 59.86 years (SD = 8.84), with a median follow-up time of 24 years (IQR = 15.31-25.74). The mean value of the WCRF/AICR score at baseline was 3.60 (SD = 0.89), with a significant decrease on the follow-up questionnaire (mean 3.53; SD = 0.85; paired t-test p-value <0.001). Unhealthier patterns of body mass index, fruit and vegetable, fiber, red meat and processed meat intake were reported at follow-up. We found improvements in the patterns of physical activity, sugar-sweetened drinks, and alcohol consumption. A one unit increase in the baseline WCRF/AICR score was associated with a ~10% decrease in the risk of developing CRC (HR = 0.89; 95%CI = 0.86-0.92). When stratified by race and ethnicity, Hawaiian participants showed the greatest reduction in CRC risk (HR = 0.82; 95% CI = 0.72-0.94), followed by NHW (HR = 0.84; 95% CI = 0.78-0.90), US-born H/L (HR = 0.88; 95% CI = 0.80-0.97) and Japanese (HR = 0.90; 95% CI = 0.85-0.95) (p-heterogeneity <0.001). We saw no association was observed in NHB or non-US-born H/L. There was no evidence of differential CRC risk associated with a 1 SD change (increase or decrease) in the WCRF/AICR score between the two time points.
Conclusions: Higher WCRF/AICR score values were associated with a reduced CRC risk. Moreover, the risk differs by race and ethnicity. Finally, lifestyle changes at later stages in life may not change the risk of developing CRC.

#6207 Trends in breast cancer incidence-based mortality among US women aged 20-49 by molecular subtypes and race.

Yueshiu Lyu, Suleepon Uttamapinan, **Adetunji T. Toriola**

Surgery, Washington University School of Medicine in St. Louis, Saint Louis, MO

Background: Breast cancer incidence is rising in women aged 20-49 years, yet data on trends in mortality for this age group are limited. Mortality varies by several factors, underscoring the need for comprehensive analyses. We, therefore, investigated trends in breast cancer incidence-based mortality (IBM) by race and molecular subtypes.
Methods: We performed a population-based study of women aged 20-49 years diagnosed with breast cancer between 2010 and 2020 using SEER 17-registry data. We applied IBM method to evaluate mortality trends by molecular subtype and race/ethnicity. We used Joinpoint regression models to identify changes in IBM trends, using annual percent changes (APC). Additionally, we evaluated breast cancer survival rates by race/ethnicity.
Results: We analyzed data on 11,661 breast cancer deaths among women aged 20-49 years. Overall, IBM declined from 9.70/100,000 in 2010 to 1.47/100,000 in 2020. The declines occurred in all subtypes and racial/ethnic groups, with some differences in the points of inflexion. IBM for luminal A decreased consistently from 2010, with more marked decline from 2017 (APC, -32.88; 95%CI, -55.17 to -21.30). TNBC followed a similar pattern, with marked decline in 2018 (APC, -32.82; 95%CI, -41.47 to -17.79). Non-Hispanic Black (NHB) women had the highest IBM in 2010 (16.56/100,000) and 2020 (3.41/100,000) compared with Non-Hispanic White (NHW) women (9.18/100,000 in 2010 and 1.16/100,000 in 2020). Declines in IBM in NHB women become pronounced from 2016 (APC, -24.15; 95% CI -34.36 to -17.92), narrowing the gap with other racial groups. Significant declines in IBM for non-Hispanic Asian/Pacific Islander (API) women started earlier from 2013, compared to 2017 for NHW, non-Hispanic American Indian/Alaska Native, and Hispanic women. Survival analyses showed that NHB women had the worst survival outcomes, while NHW and non-Hispanic API had the best.
Conclusion: IBM among US women aged 20-49 years with breast cancer declined significantly from 2010 to 2020, with variations by molecular subtype and race/ethnicity. The rapid decline in IBM after 2016-2018 likely reflects advancements in breast cancer management, particularly in novel treatments. Although NHB women still have the highest IBM, the differences have narrowed in recent years. Efforts should continue to focus on further enhancing access to early screening for high-risk women and effective treatment to fully mitigate racial disparities in mortality.

#6208 Impact of primary site in hepatobiliary and pancreatic lymphomas on overall survival: analysis of SEER database.

JOSEPH SPEAR[1], Carmen Lessani[1], Olivia Davis[2], Silas Day[1], Noha Soror[1], Taha Mahdi Salih Al-Juhaishi[1]

[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]University of Michigan, Ann Arbor, MI

Introduction: Primary hepatobiliary and pancreatic lymphomas (PHBPL) are a rare and aggressive subset of lymphomas, comprising <0.5% of pancreatic cancers and 1% of extranodal lymphomas; due to limited data on their clinicopathological features and treatment, we used the SEER database to compare overall survival (OS) of PHBPL with those of primary nodal disease.

Methods: We used the SEER database to extract demographic and disease data on patients diagnosed with lymphoma from 2010-15. Primary site was classified into three categories: primary hepatic lymphoma (including biliary tract, gallbladder, liver), primary pancreatic lymphoma (including ampulla of Vater), and primary nodal lymphoma (lymph nodes and spleen). Ann Arbor stages I-II were grouped as early-stage disease, while III-IV were grouped as late-stage. Patient cases were also divided into three distinct groups based on the histologic subtype: aggressive NHL (DLBCL, Burkitt lymphoma, MCL, T-cell lymphoma), indolent NHL (FL, marginal zone lymphoma), and Hodgkin's lymphoma. Summary statistics were used to analyze demographic and disease data. Our outcome of interest was OS defined as time in months from diagnosis to death from any cause. Cox-proportional hazards models and Kaplan-Meier method were used to perform univariate analysis. Multivariate analysis was also performed to control for age, Ann Arbor stage, race, and income. Primary nodal lymphoma was the comparison group for both. Statistical significance was defined using a 95% confidence interval and a p-value < 0.05.

Results: A total of 55,115 cases were included. The most common primary disease site was primary nodal lymphoma (54,454 cases, 98.8%) followed by primary hepatic lymphoma (435 cases, 0.79%) and primary pancreatic lymphoma (226 cases, 0.41%). The median age at diagnosis was 63 years old with majority of patients identifying as male and Caucasian (56.26% and 70.4% respectively). Late-stage lymphoma represented 62.69% of the cohort while early-stage lymphoma represented 37.31%. Primary hepatic lymphoma was associated with worse OS when compared to nodal lymphoma (HR = 2.077, $p < 0.0001$). This finding remained statistically significant even after controlling for age, race, income, and stage (HR = 1.836, $p < 0.0001$). Primary pancreatic lymphoma was also associated with worse OS (HR = 1.226, $p = 0.0349$). This association persisted on multivariate analysis though statistical significance was not met (HR= 1.1182, P = 0.0841).

Conclusions: Hepatic and pancreatic lymphomas have respectively significantly and slightly worse OS than their nodal counterparts. This association persisted on multivariate analysis, though multivariate findings for primary pancreatic lymphoma did not meet statistical significance. These results warrant validation in future prospective studies, including those using risk-adapted approaches to guide therapeutic decisions.

#6209 Different types of diabetes and pancreatic ductal adenocarcinoma risk: A Mendelian randomization and pathway/gene-set analysis.

T. Zhang[1], X. Hua[1], C. Mohindroo[2], X. Wang[1], P. Consortium[1], B. M. Wolpin[3], H. A. Risch[4], L. T. Amundadottir[1], A. P. Klein[5], K. Yu[1], H. Zhang[1], R. Z. Stolzenberg-Solomon[1];
[1]National Cancer Institute, Rockville, MD, [2]National Cancer Institute, Bethesda, MD, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Yale School of Public Health, New Haven, CT, [5]Johns Hopkins School of Medicine, Baltimore, MD

Objective: The associations between different types of diabetes, characterized by distinct pathophysiology and genetic architecture, and pancreatic ductal adenocarcinoma (PDAC) risk are not fully understood. We investigated associations of genetic susceptibility to type 2 diabetes (T2D), its eight mechanistic clusters and type 1 diabetes (T1D) using Mendelian randomization (MR) and maturity-onset diabetes of the young (MODY) pathway/gene-set analysis with PDAC risk.
Method: Using summary-level genome-wide association statistics for T2D (242,283 cases, 1,569,734 controls), T1D (18,942 cases, 501,638 controls), and PDAC (10,244 cases and 360,535 controls) in individuals of European ancestry, we conducted two-sample MR to examine associations of genetic susceptibility to T2D and T1D with PDAC risk, using single nucleotide polymorphisms (SNP) significantly associated with T2D, eight mechanistic TD2 clusters (i.e., β-cell dysfunction with a positive or negative association with proinsulin, residual glycaemic, body fat, metabolic syndrome, obesity, lipodystrophy, and liver and lipid metabolism), and T1D identified from published genome-wide association studies ($P<5\times10^{-8}$) as instrumental variables. We also assessed associations of genetic susceptibility to PDAC risk with T2D and T1D using reverse MR. We used MR-RAPS method as the primary analysis approach complemented with sensitivity analyses using MR-IVW, weighted-median, MR-Egger, MR-PRESSO and MR-PIVW. We applied the Summary-based Adaptive Rank Truncated Product (sARTP) method to evaluate the associations for PDAC and the MODY gene set, which consists of 26 genes identified from the Kyoto Encyclopedia of Genes and Genomes (KEGG) database.
Results: Genetic susceptibility to T2D (MR-RAPS: OR=1.10; 95% CI 1.05-1.14), particularly the obesity (OR=1.28; 95% CI 1.15-1.42) and lipodystrophy (OR=1.25; 95% CI 1.04-1.50) clusters, was associated with PDAC risk. T1D showed no association with PDAC risk (OR=1.01; 95% CI 0.99-1.02). Reverse MR found no evidence that genetic susceptibility to PDAC risk was associated with T2D or T1D (P>0.05). Sensitivity analyses using other MR methods supported these findings, with no evidence of pleiotropic effects (MR-Egger intercept P>0.05). The MODY gene-set was significantly associated with PDAC risk ($P=2.5\times10^{-6}$), with *HNF1A*, *HNF1B, FOXA3, HNF4A*, and *HNF4G* as the top five contributing genes.
Conclusion: Our findings support a role of T2D, particularly the obesity and lipodystrophy clusters, in PDAC risk. Additionally, the genomic susceptibility regions of MODY were significantly associated with PDAC.

#6210 The predictive performance of risk prediction models in determining lung cancer incidence in Western and Asian countries: A systematic review and meta-analysis.

Yah Ru Juang, Lina Ang, **Wei Jie Seow**

Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore

Introduction: Numerous prediction models have been developed to identify high-risk individuals for lung cancer screening, aimed at improving early detection and survival rates. However, there has been no comprehensive review and meta-analysis of model performance across different sociocultural contexts. Therefore, this review aims to systematically examine the performance of lung cancer risk prediction models in Western and Asian populations.

Methods: PubMed and EMBASE were searched from inception to January 2023. Studies published in English and proposed a validated model on human populations with well-defined predictive performances were included. Two reviewers independently screened titles and abstracts and the Prediction Model Risk of Bias Assessment Tool (PROBAST) was used to appraise study quality. A random-effects meta-analysis was performed and a 95% confidence interval (CI) for model performance was provided. Between-study heterogeneity was adjusted for using the Hartung-Knapp-Sidik-Honkman test.

Results: Fifty-four studies were included, with 42 from Western and 12 from Asian countries. Most Western studies were designed for ever-smokers (19/42; 45.2%) and the general population (17/42; 40.5%), and only two Asian studies developed models exclusively for never-smokers. Across both Western and Asian prediction models, the three most consistently included risk factors are age, sex, and family cancer history. In 45.2% (19/42) of Western and 50.0% (6/12) of Asian studies, models incorporated both traditional risk factors and biomarkers; 14.8% (8/54) directly compared their biomarker-based models with those incorporating only traditional risk factors, demonstrating better discrimination. Machine-learning algorithms were applied in eight Western models and two Asian models. External validation of $PLCO_{M2012}$ (AUC=0.748; 95% CI: 0.719-0.777) outperformed prediction models such as Bach (AUC=0.710; 95% CI: 0.674-0.745) and Spitz models (AUC=0.698; 95% CI: 0.640-0.755).

Conclusion: Despite showing promising results, the majority of Asian risk models in our study lack external validation. Our review also reveals a significant gap in prediction models for never-smokers. Future research should externally validate existing Asian models or incorporate relevant Asian risk factors in widely-used Western models ($PLCO_{M2012}$) to account for their unique risk profiles and lung cancer progression patterns.

#6211 Personalized risk models based on lung cancer screening history: post hoc analysis of the National Lung Screening Trial (NLST).

Sofia Haddan, Matthew Schabath, Asim Waqas, Ghulam Rasool

Moffitt Cancer Center, Tampa, FL

Introduction: Our group previously revealed (PMID27509046) that lung cancer (LC) screening history is an independent prognostic factor whereby incidentally-detected lung cancer cancers with one or more preceding negative screens is associated with poorer survival outcomes compared to those preceded by only positive screens. As a follow-up study, we sought to develop personalized risk models that considered screening history for incidence cancers, interval LCs, and prevalence LCs.
Methods: Using data from the CT-arm of the NLST, we conducted our independent case-control analyses to develop parsimonious risk models. Controls (n=26,038) were those never diagnosed with LC through the end of follow-up. The four LC case groups were 270 prevalence LCs (diagnosed at baseline screen), 44 interval LCs (diagnosed following a negative screen at any time point prior to the next screening), 206 screen-detected LCs (SDLCs) that had a baseline positive screen, and 164 SDLCs that had a baseline negative screen. For each case-control analysis, univariable analyses identified statistically significant covariates from 47 variables including demographics, smoking history, alcohol use, medical history, family history of LC, and occupational exposures. Then, for each analysis, statistically significant covariates were included into a stepwise backwards selection approach to identify a model with the most informative covariates.
Results: Age was the only covariate found in all four models; pack-years smoked, BMI, and smoking status were found in three of models. For prevalence LCs, the model (AUC=0.711) included age, pack-years smoked, BMI, smoking status, smoking onset age, personal history of cancer, family history of LC, frequency of alcohol consumption, and milling occupation. For interval LCs, the model (AUC=0.734) included age, smoking status, smoking onset age, cigar smoking, marital status, and asbestos occupation. For baseline positive SDLCs, the model (AUC=0.685) included age, pack-years smoked, BMI, emphysema, chemicals/plastics exposure, and milling occupation. For baseline negative SDLCs, the model (AUC=0.701) included age, pack-years smoked, BMI, smoking status, emphysema, sarcoidosis, and sandblasting occupation.
Conclusions: We deployed a rigorous model building approach to identify unique personalized risk models that considered screening history and timing of LC diagnosis. Besides smoking and age, which are inclusion criteria for screening, these models identified other important risk factors including occupational exposures, medical history, alcohol use, personal history of cancer, and family history of LC. These models could be used to provide personalized risk assessment and screening management in screening. Including additional biomarkers (e.g., radiomics, circulating, etc.) could improve the statistical performance of the models.

#6213 T-cell receptor excision circles (TRECs) at birth and risk of childhood cancers.

Jun Tao[1], Paul S. Albert[1], Nellie Gottlieb[2], Eric A. Engels[1]

[1]National Cancer Institute, Rockville, MD,[2]California Cancer Reporting and Epidemiologic Surveillance, Sacramento, CA

Introduction: Acquired immunosuppression is associated with higher risk for infection-related cancers. However, cancer risk among children born with primary immunodeficiency is unknown. Circulating T-cell receptor excision circles (TRECs) are a marker of thymus production of T-cells, which is used to identify severe combined immunodeficiency (SCID) at very low levels during newborn screening. It is unknown whether TREC levels at birth are associated with cancer risk in children.
Methods: The California (CA) and Texas (TX) cancer registries identified cancers in children aged 0-5 years born during 2013-2018. Controls were matched to cases by birth year and sex. TREC levels, measured at birth by the state SCID screening programs were linked to cases and controls. Conditional logistic regression was used to assess the association between tertiles (T) of TREC levels and cancer risk.
Results: We included 1,450 cancer cases and 7,250 controls from TX and 2,564 cases and 12,820 controls from CA. Only 13 newborns in CA and 15 in TX had extremely low TREC level at birth. T2 levels of TREC was inversely associated with cancer risk compared to the lowest (T1), for several cancers (Table 1). However, only acute myeloid leukemia showed an inverse association for T2 and T3 in CA (odds ratio [OR] 95%CI: T2, 0.38, 0.22-0.66; T3, 0.47, 0.27-0.82), but this was not replicated in TX. Both T2 and T3 were associated with increased risk of acute lymphoblastic leukemia in TX (T2, 1.45, 1.05-1.99; T3, 1.49, 1.06-2.08) but not in CA.
Conclusion: SCID is rare among children with cancer. We did not see consistent associations between TREC levels and cancer risk, either across tertile levels or between CA and TX. This indicates that differences in immune function do not contribute to the etiology of the childhood cancers examined. Alternatively, TREC assays are designed to detect children with the abnormally low TREC levels, and higher TREC levels may not reflect immune function.

Table 1. Association between TREC level and childhood cancer risk

	OR (95%CI)	
	Texas	**California**
T1	Ref	Ref
Acute lymphoblastic leukemia

#6214 Vitamin metabolites in neonatal dried blood spots and risk of retinoblastoma in California.

C. Deng[1], K. C. Paul[2], D. I. Walker[3], D. P. Jones[4], B. R. Ritz[1], J. E. Heck[5];
[1]UCLA Fielding School of Public Health, Los Angeles, CA, [2]David Geffen School of Medicine, Los Angeles, CA, [3]Rollins School of Public Health, Emory University, Atlanta, GA, [4]Division of Pulmonary, Allergy, and Critical Care Medicine, School of Medicine, Emory University, Atlanta, GA, [5]College of Health and Public Service, University of North Texas, Denton, TX

Background: Vitamin intake may influence carcinogenesis through various pathways. In particular, vitamin B6 metabolites have been implicated in cancer development due to their involvement in processes such as oxidative stress and inflammation. However, conclusions remain inconsistent, and epidemiological studies are limited, particularly for retinoblastoma. In this exploratory study, we examined associations between vitamin metabolites in neonatal dried blood spots and retinoblastoma risk in California.
Methods: This study included 497 retinoblastoma cases born between 1983 to 2011 and 893 controls matched by birth year in California. Vitamin feature intensities were measured in neonatal blood spots from the California newborn Genetic Disease Screening Program. Logistic regression was used to evaluate associations between quartiles of vitamin levels and retinoblastoma risk, adjusting for sex, birth year, maternal age, maternal race and ethnicity, maternal place of birth, and socioeconomic status. We also stratified the analyses by retinoblastoma subtypes (i.e., unilateral, bilateral), sex and maternal birthplace (U.S. vs. Mexico).
Results: For vitamin B6 metabolites, the highest quartile of pyridoxamine was associated with a 32% increase in retinoblastoma risk (95% confidence interval (CI): 0.97-1.80), while the highest quartile of 4-pyridoxic acid was associated with a 32% reduction (95% CI: 0.56-1.07), compared to the lowest quartile. Additionally, the highest quartiles of NAD+ were associated with a reduced risk (adjusted odds ratio (aOR): 0.78; 95% CI: 0.57-1.06 and aOR: 0.76; 95% CI: 0.55-1.05). No overall association with retinoblastoma risk was observed for pantothenic acid (vitamin B5), vitamin A, vitamin D2, or methylcobalamin (vitamin B12). After stratification, we did not observe clear dose-response relationships, although some estimates suggested an increased risk. For example, the 3rd quartile of pantothenic acid was associated with an increased risk among female (aOR: 0.65, 95% CI: 0.40-1.04) and children with Mexican-born mothers (aOR: 0.56, 95% CI: 0.30-1.05). The 2nd quartile of methylcobalamin was associated with a 56% increase in retinoblastoma risk among males (95% CI: 1.01-2.44).
Conclusion: Several vitamin metabolites showed a differential abundance in neonatal blood spots of children who later did or did not develop retinoblastoma in California. These results suggest that further research into the role of maternal vitamin intake during pregnancy may hold promise for pediatric cancer prevention.

#6215 Metabolic risk is an important determinant of adipocyte hypertrophy beyond age, BMI and breast density in patients with ductal carcinoma *in situ*.

Charlotta V. Mulder, Mathilde Almekinders, Renaud Tissier, Lennart Mulder, Petra Kristel, **Esther Lips**, Marjanka Schmidt, Jelle Wesseling

Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Ductal carcinoma in situ (DCIS) is a non-obligate precursor to invasive breast cancer, but distinguishing patients with harmless from potentially hazardous DCIS remains a challenge. Consequently, a cornerstone of DCIS research is finding prognostic biomarkers. One such recent biomarker is adipocyte hypertrophy, which has been shown to be prognostic of ipsilateral invasive breast cancer (iIBC) in post-menopausal women with primary DCIS. However, little is known about the correlation between adipocyte size, clinical factors and mammographic density.
Methods: Archival hematoxylin and eosin- stained breast biopsy and excision specimens were retrieved from 669 women diagnosed with primary DCIS between 2000 and 2020 treated at the Netherlands Cancer Institute. These slides were digitized whereafter a machine-learning algorithm using HALO®, was applied to retrieve adipocyte size. Radiology reports were obtained to extract mammographic BI-RADS density. Age at diagnosis, body mass index (BMI), menopausal status and information on comorbidities were extracted from electronic patient records. Associations between adipocyte size and clinical factors and mammographic density were investigated using univariable and multivariable linear regression models. Using a clinically relevant cutoff point for adipocyte size, multivariable logistic regression was performed.
Results: The median age at primary DCIS diagnosis was 55 years (interquartile range (IQR): 49.0 -63.0) and most DCIS lesions were grade 3 (40.9%). The median BMI was 24.1 (IQR: 21.9 - 27.1). The majority of women were post-menopausal (47.8%) and had dense breasts (53.8%). Significant positive correlations were found between adipocyte size and age, BMI and all metabolic comorbidities with the exception of smoking. Strong negative correlations were found between adipocyte size and mammographic density categories C and D. In univariable linear models with age and BMI, metabolic risk was able to further differentiate between patients with and without adipocyte hypertrophy beyond age and BMI. This was confirmed using multivariable logistic regression comparing models adjusted and unadjusted for metabolic risk.
Conclusion: BMI is the strongest predictor of adipocyte hypertrophy in DCIS patients, however metabolic risk further differentiates between patients with and without adipocyte hypertrophy. Future work should be done on collecting long term follow-up and ascertaining subsequent breast cancer in these patients. If successful, BMI and metabolic risk can potentially be incorporated into risk prediction models for subsequent invasive breast cancer.

#6217 Methylation-derived inflammation phenotypes and anal cancer risk among men with HIV.

Shuai Xu[1], Bryan E. Shepherd[2], Tebeb Gebretsadik[2], Anna Junkins[3], Jirong Long[3], Qiuyin Cai[3], Staci L. Sudenga[3]

[1]Epidemiology, Vanderbilt University, Nashville, TN,[2]Biostatistics, Vanderbilt University, Nashville, TN,[3]Epidemiology, Vanderbilt University Medical Center, Nashville, TN

Introduction: Inflammation is a hallmark of cancer. DNA methylation (DNAm) derived immune cell type proportions and circulating inflammation-related protein markers are precise measures of inflammatory phenotypes. We investigated the associations of DNAm-derived inflammation-related phenotypes with risks of anal cancer and precancer (high-grade squamous intraepithelial lesions, HSIL) among men with HIV.

Method: We matched 22 anal cancer cases to 37 controls with normal anal epithelium and 54 HSIL to 90 controls using propensity score methods. DNAm data were profiled by MethylationEPIC v2.0 array on the pre-diagnostic blood biospecimens and processed by R *minfi* and *ChAMP* packages. Immune cell composition, including 4 myeloid (neutrophils, eosinophils, basophils and monocytes) and 8 lymphoid cell sub-lineages (B lymphocytes naïve (Bnv), B lymphocytes memory [Bmem], T helper lymphocytes naïve [CD4nv], T helper lymphocytes memory [CD4mem], T regulatory cells [Treg], T cytotoxic lymphocytes naïve [CD8nv], T cytotoxic lymphocytes memory [CD8mem], and natural killer lymphocytes) were estimated among normalized DNA methylation β values using a reference-based deconvolution algorithm. Proportions of these 12 major immune cell types were estimated to be 100%. Ratios of CD4nv/CD4mem, CD8nv/CD8mem, Bnv/Bmem, CD8/Treg, and neutrophil/lymphocyte were computed. Additionally, 47 DNAm-predicted circulating inflammation-related protein levels were calculated using well-established prediction models. Conditional logistic regression models were built to estimate odds ratios (OR) and 95% confidence intervals (CI) on per standard deviation increase in inflammation phenotypes adjusting for cell type heterogeneities.

Results: Higher CD4nv/CD4mem (OR=2.70, 95%CI:1.09-6.70) and lower CD8/Treg (OR=0.56, 95%CI:0.31-0.99) was positively associated with anal cancer risk at nominal $P < 0.05$. Higher Bnv/Bmem (OR=1.47, 95%CI:1.02-2.12) was linked to increased HSIL risk at nominal $P < 0.05$. Elevated levels of DNAm-derived circulating protein MMP9 (OR=1.86, 95%CI: 1.20-2.88), C5 (OR=1.78, 95%CI: 1.23-2.57), B2M (OR=1.75, 95%CI:1.16-2.65), CRP (OR=2.39, 95%CI:1.32-4.33), MMP12 (OR=1.66, 95%CI:1.15-2.41), CCL11(OR=1.66, 95%CI:1.15-2.38) , TNFRSF1B (OR=1.85, 95%CI:1.20-2.87), HGF (OR=2.10, 95%CI:1.32-3.35), TGFA (OR=2.38, 95%CI:1.31-4.35), VEGFA (OR=1.82, 95%CI:1.21-2.72), CCL17 (OR=1.93, 95%CI:1.26-2.95); and decreased levels of ADAMTS13 (OR=0.47, 95%CI:0.28-0.78) were associated with increased risk of anal cancer and HSIL (combined analysis) compared to controls at false discovery rate (FDR) <5%. No significant associations were observed when comparing cancers with controls or comparing HSIL with controls, separately at FDR<5%.

Discussion: Our findings suggest that inflammation plays a role in anal carcinogenesis. Future research is warranted to validate our results.

#6218 Impact of body composition on tumor proteomics and survival outcomes in clear cell renal cell carcinoma.

Cuthbert M. Mahenge, Rand T. Akasheh, Xuan Nguyen, Ting-Yuan D. Cheng

Cancer Control and Prevention, The Ohio State University, Columbus, OH

Background: The prognosis of clear cell renal cell carcinoma (ccRCC) is affected by a complex interaction of tumor characteristics and patient factors. This study investigates the association between body composition components with survival and tumor proteomics in patients with ccRCC.
Methods: We identified 178 patients from the TCGA-Kidney Renal Clear Cell Carcinoma project with CT images and tumor proteomic data (233 proteins). CT images corresponding to the 3rd lumbar vertebrae were assessed using Slice-O-Matic software for adipose and skeletal muscle tissue areas. The Contal and O'Quigley's method was used to obtain the cutoffs for categorizing patients into high or low groups of adiposity and muscle based on survival. Patients were further classified into four body composition types: (1) High Muscle/Low Adiposity, (2) High Muscle/High Adiposity, (3) Low Muscle/Low Adiposity, and (4) Low Muscle/High Adiposity. Linear regression was used to assess the associations for protein expression. Cox's hazard models were used for survival analysis. All models were adjusted for age, stage, gender, race, and ethnicity.
Results: There was no significant difference in survival based on muscle quantity alone. However, patients with low adiposity had worse survival than those with high adiposity (hazard ratio [HR] = 2.7; 95% CI= 1.2, 5.8). For body composition types, compared to the high muscle/high adiposity group, which had the best survival, the low muscle/low adiposity group had a significantly worse survival (HR = 3.5; 95% CI = 1.5, 8.2). Different muscle/adiposity combinations exhibited distinct protein expression patterns (all false-discovery-rate p-value ≥0.2). Low muscle/low adiposity exhibited a pattern of increased cell survival and proliferation with decreased tumor suppression, while low muscle/high adiposity exhibited increased cell motility and migration. Body composition also significantly affected survival based on expression levels of PREX1 and JAK2. Low muscle/high adiposity (vs. high muscle/high adiposity) was associated with increased mortality among patients with high PREX1 expression (HR =6.72; 95% CI = 1.88, 24.03) but not among those with low PREX1 expression (HR=1.07; 95% = 0.28, 3.99); p-value for interaction = 0.048). Also, the body composition type was associated with increased mortality among patients with high JAK2 expression (HR= 7.50; 95% CI = 1.37, 41.07) but not among those with low JAK2 expression (HR = 1.09; 95% CI= 0.35-3.39; p-value for interaction = 0.065).
Conclusion: Body composition in patients with ccRCC is associated with overall survival and with several tumor protein expressions. The mortality risk can vary based on tumor protein markers. These findings warrant further validation as they highlight the potential utilization of body composition as a prognostic biomarker and therapeutic target.

#6219 Population-based analysis of rurality and its impact on survival in gastric adenocarcinoma.

N. M. Hwang[1], M. Dixon[2];
[1]Rush Univ. - Rush Medical College, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

Background: Despite growing efforts to understand the impact of rurality on cancer survival outcomes, significant gaps remain on how it influences prognosis within specific cancer types. In this study, we examine how residential location (rural vs urban) affects survival outcomes for patients diagnosed with gastric adenocarcinoma.
Methods: Using the Surveillance, Epidemiology, and End Results (SEER) database, we identified 56,371 patients with gastric adenocarcinoma between 2007 and 2020, who were 18 years or older at diagnosis and had complete data for all analyzed variables. Demographics of patients living in rural vs urban areas were compared using Wilcoxon rank sum or chi-squared testing for categorical or continuous variables, respectively. The impact of area of residence on cancer-specific survival (CSS) was assessed through Kaplan-Meier and Cox proportional hazards analysis. A multivariable Weibull regression survival model was used to control for potential confounding covariates.
Results: Most patients lived in urban areas (88.9% vs 11.1%). There were no significant differences in age and stage at diagnosis between rural and urban populations. Rural patients tended to be male ($p < 0.001$) and non-Hispanic White ($p < 0.001$) with lower median household income ($p < 0.001$). Patients residing in rural areas had significantly worse CSS [hazard ratio (HR) = 1.158; 95% CI: 1.122-1.195; $p < 0.0001$]. When stratified by race, the prognostic impact of rurality was absent in Non-Hispanic Black patients ($p = 0.62$). When adjusting for age, sex, race, stage, and income, rurality remained an independent predictor of survival [HR = 1.064; 95% CI: 1.026-1.103; $p = 0.0007$].
Conclusion: Rurality is associated with worse prognosis in patients with gastric adenocarcinoma. Further research is needed to understand the mechanisms of how area of residence contributes to outcome disparities to identify targeted interventions.

Table 1: Weibull multivariable regression model estimates of hazard ratios

Variables	**Hazard Ratio**	**95% CI**	***P-value***
Age	1.02	1.019-1.021	< 0.0001
Sex

#6220 Disparities in cancer incidence among African American and non-Hispanic white participants in the Agricultural Health Study and North Carolina residents.

Somayina C. Ezennia[1], Christine G. Parks[2], Laura E. Beane Freeman[1], Anne Taylor[3], Gabriella Andreotti[1], Stella Koutros[1], Dale P. Sanders[2], Jonathan N. Hofmann[1]

[1]NIH-NCI, Rockville, MD,[2]NIH-NIEHS, Durham, NC,[3]Information Management Services, Inc, Rockville, MD

Disparities in cancer incidence between African American (AA) and non-Hispanic white (NHW) populations in the U.S. are well documented. However, no studies have examined cancer incidence disparities in farming populations. Given unique occupational hazards (e.g., pesticides, zoonotic diseases, diesel exhaust), we hypothesized that racial disparities in cancer incidence may be more pronounced among AA farmers than in the general population.

We investigated cancer incidence among North Carolina (NC) participants in Agricultural Health Study (AHS), a prospective cohort of pesticide applicators and their spouses enrolled between 1993-1997. This investigation included 28,579 participants (1,511 AA, 27,068 NHW), identifying 6,511 cancer cases (432 AA, 6,079 NHW) through 2021. We calculated standardized incidence ratios (SIRs), standardized incidence rate estimates (SREs) and 95% confidence intervals (CI) for overall and site-specific cancers in the AHS relative to the general population in NC.Overall, the SIR was higher for AA in the AHS (SIR = 1.19, CI 1.08 - 1.31) than for AA in NC (SIR = 1.05, CI 1.04 - 1.05), with notably high SIRs for certain sites like prostate cancer, multiple myeloma, and colorectal cancer (Table 1). For prostate cancer and multiple myeloma, we observed the lowest incidence among NHW in the general population and the highest in AA in the AHS cohort. Our findings of greater disparities in cancer incidence among AA in the AHS compared with AA in the general population may be related to differences in certain agricultural exposures or economic and social barriers faced by AA farmers; we plan to further investigate these factors in future efforts. These findings and ongoing efforts are needed to help promote the health and well-being of AA farmers.

#6221 Gastric atrophy is associated with increased risk of esophageal squamous cell carcinoma in Lilongwe, Malawi.

Kadiatou Traore[1], Yingxi Chen[1], Yukiko Yano[1], Paul S. Albert[1], Sung Duk Kim[1], Sanford M. Dawsey[1], Shiraz Khan[2], Christian C. Abnet[1]

[1]National Cancer Institute, Rockville, MD,[2]UNC Project-Malawi, Lilongwe, Malawi

Background: Esophageal cancer (EC) is the 7th leading cause of cancer worldwide, with nearly 500,000 annual deaths. Esophageal squamous cell carcinoma (ESCC), the most prevalent subtype, has high incidence in East Asia, South and East Africa. Malawi has the highest EC incidence rate, almost exclusively ESCC, with risk factors including tobacco use, hot beverages, fuel source, moldy grain consumption, geophagia, poor oral health, and possibly HIV. *H. pylori's* role in ESCC is unclear, with adverse, null, and protective effects across different populations. Gastric atrophy, a potential result of *H. pylori* infection, may increase ESCC risk by promoting gastrointestinal bacterial overgrowth that exposes esophageal mucosa to carcinogens (e.g. nitrosamines). HIV, common in Malawi, may interfere with *H. pylori* antibody tests. Limited data, especially from African populations, leaves a gap in understanding the roles of *H. pylori* and gastric atrophy in ESCC.

Methods: We enrolled 300 ESCC cases and 300 controls, matched by age, sex and region, at two Lilongwe, Malawi hospitals (2017-2020) and collected demographic, health, and behavioral data. We measured *H. pylori* antibodies and gastric atrophy (pepsinogen I (PGI), pepsinogen II (PGII)) via serology. Atrophy was defined as PGI:II <3 or PGI <30µg/L per kit specifications. We adjusted logistic regression models for design variables, known and potential confounders.

Results: *H. pylori* seropositivity was 68% in cases, 80% in controls and significantly associated with lower ESCC risk (aOR 0.54; 95% CI 0.32-0.92). High HIV positivity in cases (21%) may obscure the association due to assay interference. Having a PGI <30µg/L was significantly associated with higher ESCC risk (aOR 4.92; 95% CI 2.04-11.87) while having a PGI:II <3 was marginally associated (aOR 2.14; 95% CI 0.97-4.70).

Conclusion: Serologic gastric atrophy was associated with strongly increased ESCC risk. *H. pylori's* protective effect may be due to measurement interference.

TABLE: Associations between *H. pylori*, Pepsinogen Ratio, Pepsinogen I and ESCC risk

			Base Model[a]		Adjusted Model[b]	
	Cases, n (%)	**Controls, n (%)**	**OR (95% CI)[c]**	**Pvalue**	**aOR (95% CI)[c]**	**Pvalue**
H. pylori Status						
Negative	96 (32%)	61 (20%)	Reference	-	Reference	-
Positive	204 (68%)	239 (80%)	0.53 (0.35-0.81)	0.003	0.54 (0.32-0.92)	0.024
PGI:II ≤ 3						
Negative	260 (87%)	277 (92%)	Reference	-	Reference	-
Positive	40 (13%)	23 (8%)	1.92 (1.02-3.61)	0.043	2.14 (0.97-4.70)	0.059
PGI <30µg/L						
Negative	253 (84%)	285 (95%)	Reference	-	Reference	-
Positive	47 (16%)	15 (5%)	3.79 (1.79- 8.00)	0.001	4.92 (2.04-11.87)	<0.001

#6222 Racial and socioeconomic influences on survival outcomes in small cell lung cancer: Analysis of concomitant radiation, immunotherapy, and demographic variables.

Helen Gandler[1], Pranay Adavelly[1], Parth Anil Desai[2]

[1]Medicine, Lewis Katz School of Medicine, Philadelphia, PA,[2]Fox Chase Cancer Center, Philadelphia, PA

Background: Small cell lung cancer (SCLC) is the most aggressive form of lung cancer, marked by rapid progression, frequent metastases, and poor survival rates. Real-world data from contemporary cohorts is vital to validate current treatments and develop novel hypotheses. SCLC staging typically depends on whether the disease can be encompassed within a definitive radiation field.
Methods: A retrospective cohort study of 381 SCLC patients treated at a single center from January 1, 2014, to December 30, 2022, was conducted. Data included stage at diagnosis, race/ethnicity, treatment modalities (chemotherapy, radiation, and immunotherapy), and survival outcomes. Socioeconomic factors such as insurance status and lifestyle variables (e.g., alcohol and tobacco use) were analyzed. TNM staging was stratified into Early Limited Stage (E-LS, stages I-IIA), Advanced Limited Stage (A-LS, stages IIB-IIIC), and Extensive Stage (ES, stage IV).
Results: Among the 381 patients, 54% were women, 51% were European American (EA), and 29% were African American (AA), the largest minority subgroup. Most (60%) presented with ES disease, while 20% had E-LS and 20% A-LS. Over 96% of patients had a history of smoking. AA patients were more likely to be insured through government programs (Medicare/Medicaid, 87% vs. 72% for EA, p=0.005) but had similar stage distributions. Notably, AA ancestry did not correlate with poorer survival compared to EA patients, unlike trends observed in other cancers. Radiation therapy combined with chemotherapy significantly improved survival in A-LS patients (median overall survival [OS]: 27.42 months vs. 7.5 months without radiation, p=0.0001). In E-LS patients, radiation showed a non-significant trend toward improved survival (median OS: 33.76 months vs. 23.77 months, p=0.09). In ES disease, where radiation was used palliatively or for oligometastatic control, there was no survival benefit (median OS: 6.93 months with radiation vs. 7.33 months without radiation, p=0.90). Immunotherapy significantly extended survival in ES-SCLC patients compared to those not receiving immunotherapy (p=0.03).
Conclusion: This analysis highlights racial and socioeconomic factors in SCLC outcomes, showing AA patients, despite higher reliance on government insurance, had survival outcomes comparable to EA patients—unlike other cancers where disparities persist. Radiation therapy demonstrated the greatest survival benefit in A-LS patients, while its impact in other stages was limited.

#6224 Lifestyle patterns and mortality in a population-based cohort of Black breast cancer survivors.

Bo Qin[1], Shromona Sarkar[1], Tengteng Wang[1], Nur Zeinomar[1], Marley M. Perlstein[1], Coral O. Omene[2], Karen S. Pawlish[3], Kitaw Demissie[4], Christine B. Ambrosone[5], Chi-Chen Hong[5], Elisa V. Bandera[1]

[1]Section of Cancer Epidemiology and Health Outcomes, Rutgers Cancer Institute, New Brunswick, NJ,[2]Clinical Investigations and Precision Therapeutics Program, Rutgers Cancer Institute, New Brunswick, NJ,[3]New Jersey Department of Health, New Jersey State Cancer Registry, Trenton, NJ,[4]Department of Epidemiology and Biostatistics, SUNY Downstate Health Sciences University School of Public Health, Brooklyn, NY,[5]Department of Cancer Prevention and Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: African American/Black women have a nearly 40% higher breast cancer (BC) mortality rate compared to White women, reflecting a significant health disparity. Although lifestyle modifications may improve BC survival, robust, population-specific estimates quantifying the association between pre-diagnosis lifestyle patterns and mortality among Black women with BC are lacking. This study leverages data from a population-based cohort of Black BC survivors in New Jersey to examine the relationship between pre-diagnosis lifestyle patterns and mortality outcomes in this high-risk group.

Methods: Lifestyle pattern scores for approximately one year before diagnosis were computed based on adherence to the World Cancer Research Fund/American Institute for Cancer Research recommendations, which align with the American Cancer Society guidelines. These scores were calculated using lifestyle factors measured or self-reported during baseline home interviews, including adiposity (BMI and waist circumference), physical activity, and dietary quality (consumption of fruits and vegetables, fiber, ultra-processed foods, red and processed meat, sugar-sweetened beverages, and alcohol). Scores ranged from 0 to 7, with higher scores indicating greater adherence to guidelines. Associations between lifestyle pattern scores and mortality outcomes (all-cause and BC-specific) were analyzed using Cox proportional hazards models and competing risk models to estimate hazard ratios (HR) and 95% confidence intervals (95% CI).

Results: Among 1,710 women (mean age: 54.1 [SD: 10.7]), 391 deaths occurred over a median follow-up of 8.6 years, including 205 BC-related deaths. The average lifestyle score was 2.9 (SD: 1.1). In multivariate models adjusted for age, education, household income, health insurance, marital status, and smoking status, women with the highest scores (5-7) had a 39% lower risk of all-cause mortality (HR = 0.61, 95% CI: 0.39-0.95) and a 31% lower risk of BC-specific mortality (HR = 0.69, 95% CI: 0.37-1.29) compared to those with the lowest scores (0-2), though the latter CI includes the null. Women with the highest lifestyle pattern scores (5-7) also had significantly lower risks of all-cause mortality by 53% over 5 years and 45% over 10 years, respectively. Findings were consistent across subgroups defined by age at diagnosis, tumor subtype, and stage.

Conclusion: High adherence to cancer-related lifestyle guidelines was associated with lower mortality rates among Black BC survivors compared to those with low adherence. These findings suggest that adherence to lifestyle guidelines encompassing multiple lifestyle factors may improve survival outcomes among Black women following a BC diagnosis.

#6225 Association of UV radiation exposure with risk of malignant melanoma and melanoma in situ in the NIH-AARP Diet and Health Study.

Samer Wahood[1], Yufei Li[2], Matthew Kaczynski[1], John Monroe[3], Fatima N. Mirza[4], Linda M. Liao[5], Rashmi Sinha[5], Martin A. Weinstock[4], Abrar A. Qureshi[4], Eunyoung Cho[4]

[1]The Warren Alpert Medical School of Brown University, Providence, RI,[2]Department of Health Law, Policy and Management, Boston University of Public Health, Boston, MA,[3]Norton College of Medicine, Upstate Medical University, Syracuse, NY,[4]Department of Dermatology, The Warren Alpert Medical School of Brown University, Providence, RI,[5]Division of Cancer Epidemiology and Genetics, Department of Health and Human Services, National Cancer Institute, National Institutes of Health, Bethesda, MD

While ultraviolet radiation (UVR) exposure is a risk factor for skin cancer, there is little evidence from prospective studies exploring the association with both malignant melanoma (MM) and melanoma in situ (MIS).1,2 Within the NIH-AARP Diet and Health Study involving 491,367 participants ages 50-71 when the study began in 1995, we investigated the relationship between July erythemal UVR levels and the incidence of MM and MIS prospectively. July erythemal UVR is the average noon-time ground-level erythemal dose measured in July.3 UVR levels were linked to participants' residences at baseline and categorized into quartiles. Participants were predominantly non-Hispanic white with a median age of 62 years. After adjusting for demographic and lifestyle factors, we utilized multivariable-adjusted Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). Over 6,611,941 person-years, with a median follow-up time of 15.5 years, 5,034 MM and 3,284 MIS cases were documented. We found a significant trend between higher erythemal UVR levels and increased risk of both MM and MIS. The highest quartile of UVR exposure (>236 J/m^2), compared with the lowest quartile (≤180 J/m^2), was significantly associated with a greater risk of MM; the HR was 1.32 (95% CI:1.22-1.44) for MM and 1.37 (95% CI:1.25-1.51) for MIS (P-trend <0.001 for both). The study underscores the need for heightened awareness and preventative measures for MM and MIS, especially in regions with higher UVR levels. Further research is needed to explore this association across different body sites.

#6226 Chinese visceral adiposity index outperforms other obesity indexes in association with increased overall cancer incidence: Findings from prospective MJ cohort study.

M. Wang[1], C. P. Wen[2], D. T. Chu[3], H. Tu[1], W. Li[1], X. Wu[1];
[1]Zhejiang University, Hangzhou, China, [2]National Health Research Institutes, Taiwan, China, [3]MJ Health Management Center, Taiwan, China

Background: Chinese Visceral Adiposity Index (CVAI) is an integrated index to measure visceral adiposity tissue (VAT). This study is to assess the relationship between VAT indices such as CVAI, Visceral Adiposity Index (VAI), Lipid Accumulation Product (LAP) waist circumference (WC) and waist-hip ratio (WHR) with overall and specific cancer incidence in Chinese.
Methods:332,297 individuals from the MJ cohort were tracked from 1996 to 2007. We utilized multivariable Cox proportional hazards models to examine the connections of five baseline visceral obesity indices and cancer incidence.
Results:A robust dose-response correlation between CVAI and the risk of overall cancer incidence was observed. The HRs were 1.45 (95% CI: 1.2-1.76) and 2.03 (95% CI: 1.52-2.72) for males and females when comparing Quintile 5 to the reference. The HRs for WC were 1.27 (95% CI: 1.08-1.49) among males and 1.19 (95% CI: 1.01-1.40) among females, and WHR showed significance in males (HR:1.28; 95% CI: 1.13-1.45), LAP showed significance in females (HR: 1.25; 95% CI: 1.04-1.5). VAI was not related to overall cancer incidence.
Conclusion: The results support CVAI's practicality as a superior clinical marker for predicting cancer incidence in the Chinese population compared to traditional central obesity indices.

#6227 Contemporary incidence of gastroesophageal junction and gastric cancers in the United States, 2016-2021.

Jessie T. Yan[1], Alexander Wu[1], Hongyu Wu[1], Margarita Kouzova[2], Steven P. Stratton[1]

[1]Roche Diagnostics, Santa Clara, CA,[2]Roche Diagnostics, Tucson, AZ

Background: Limited data are available on the contemporary incidence of gastroesophageal junction cancer (GEJC) and gastric (GC). This study aimed to examine the incidence rates and trends of GEJC and GC overall and by gender and race/ethnicity.
Methods: In this cross-sectional study, we used 2016-2021 data from the U.S. Epidemiology, and End Results (SEER) 22 registries. Per the primary International Classification of Diseases for Oncology, 3rd Edition (ICD-O-3) used by SEER, GEJC cases were identified by “C16.0 Cardia” under GC “C16 Stomach”. Age-adjusted incidence rates were calculated using the SEER*Stat software, and annual percentage change (APC) in incidence was analyzed using the Joinpoint regression program.
Results: During 2016-2021, 17,959 GEJC and 65,899 GC cases were identified. For both cancer types, the age-adjusted incidence rate was higher in men than in women (4.42 vs. 1.16 per 100,000/year for GEJC; 12.83 vs. 7.58 per 100,000/year for GC). By race and ethnicity, for GEJC, non-Hispanic white people had the highest rates of new cancer diagnoses (3.05 per 100,000/year) while non-Hispanic black people had the lowest (1.79 per 100,000/year). For GC, non-Hispanic black people had the highest rates of new cancer diagnoses (13.81 per 100,000/year) while non-Hispanic white people had the lowest (7.61 per 100,000/year). By race/ethnicity and gender, the highest incidence rate of GEJC was found among non-Hispanic white men (5.17 per 100,000 person /year). The highest incidence rate of GC was found among the non-Hispanic black men (18.29 per 100,000/year). From 2016 to 2021, there were no significant changes in both GEJC and GC incidence rates overall and by gender, and race/ethnicity. However, when limiting the analysis to more recent years between 2018 and 2021, there was a falling trend in GEJC but a rising trend in GC incidence overall (APC of -4.08% for GEJC and 3.00% for GC) and by gender (APC of -3.67% for GEJC male and -5.69% for GEJC female; 1.61% for GC male and 4.75 % for GC female). The incidence of GEJC among non-hispanic white men and GC among non-Hispanic black men remained stable.
Conclusion: This population-based study highlights the gender and racial/ethnic differences in GEJC and GC incidence in the United States. Ongoing efforts in increasing awareness, prevention, diagnostic, and treatment strategies for these cancers are needed, particularly for sub-populations with the highest incidence. Future studies should investigate the underlying reasons for the increasing trend in gastric cancer.

#6228 Spatial regression analysis for colorectal cancer mortality rates in Puerto Rico: 2012-2016 and 2017-2021.

Brenda C. Torres-Velasquez[1], **Liliana M. Castro-Jimenez**[1], Carlos R. Torres-Cintron[2], Elba V. Caraballo[3]

[1]Division of Shared Resources & Scientific Operations, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Puerto Rico Central Cancer Registry, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[3]Division of Cancer Clinical & Translational Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Objective: Despite efforts to improve screening and early detection, colorectal cancer (CRC) remains a leading cause of cancer-related deaths in Puerto Rico. This study aimed to analyze the spatial distribution of CRC mortality rates (MR) in Puerto Rico during two time periods—2012-2016 (before Hurricane Maria) and 2017-2021 (after Hurricane Maria, earthquakes, and the onset of the COVID-19 pandemic) to identify factors contributing to the observed mortality rates.

Methods: Age-adjusted CRC MR for 2012-2016 and 2017-2021 were obtained from the Puerto Rico Central Cancer Registry (PRCCR). Sociodemographic data were sourced from the American Community Survey using the *tidycensus* R package. The study included 34 treatment centers across Puerto Rico and employed Spatial Cross-Regressive Models (SLX) to examine the influence of factors such as distance to treatment centers, median income, transportation access, and age distribution on CRC MR. Statistical analyses were conducted using R version 4.4.1 (R Foundation for Statistical Computing) and R-Studio (Posit Software, PBC).

Results: In simple models, distance to treatment centers significantly impacted CRC mortality in both periods but with reduced influence in 2017-2021 (2012-2016: coefficient = -0.5, $p < 0.01$; lag coefficient = -37.6, $p < 0.01$ vs. 2017-2021: coefficient = -0.37, $p < 0.05$; lag coefficient = -28.9, $p < 0.05$). In multivariate models, additional sociodemographic factors were significant in 2012-2016, including: Proportion of workers without vehicles (coefficient = 3.22×10^{2}, $p < 0.01$; lag coefficient = 2.55×10^{4}, $p < 0.01$), Median income (coefficient = 7.03×10^{-3}, $p < 0.01$; lag coefficient = 5.24×10^{-1}, $p < 0.01$), and Proportion of inhabitants aged 18 or younger (coefficient = 5.6×10^{2}, $p < 0.01$; lag coefficient = 3.95×10^{4}, $p < 0.01$). However, in 2017-2021, these variables were no longer significant, suggesting the impact of systemic disruptions from disasters and the pandemic.

Conclusions: The findings indicate that CRC mortality in Puerto Rico is driven more by sociodemographic factors such as income and transportation access than by geographic proximity to treatment centers. The reduced significance of these factors in 2017-2021 emphasizes the need for further studies to understand the compounded effects of natural disasters and the COVID-19 pandemic. Addressing disparities in transportation, income, and healthcare accessibility is essential to reducing CRC mortality in Puerto Rico.

#6230 Meta-analysis with a total of 4,978,125 cancer patients reveals depression as a major mortality risk factor.

Janos Tibor Fekete[1], Zoltan Ungvari[2], Monika Fekete[1], **Balazs Gyorffy**[1]

[1]Semmelweis University, Budapest, Hungary,[2]University of Oklahoma, Oklahoma, OK

Background: Depression is a prevalent comorbidity in cancer patients, potentially affecting their quality of life, treatment adherence, and biological processes such as immune function and inflammation. Evidence suggests that depression may contribute to poorer outcomes. The objective of our study was to identify studies examining the association between depression and the risk of cancer-specific mortality as well as all-cause mortality in cancer patients.
Methods: A comprehensive search of online databases was conducted for studies published up to October 1, 2024. Only cohort studies that assessed clinical depression using established diagnostic criteria and reported risk estimates for mortality (such as relative risk, hazard ratio, or odds ratio) were included. A random-effects model was used for statistical analysis, and heterogeneity was assessed using Cochran's Q and the I^2 statistic. The analysis was further refined by conducting cancer-type specific analyses for the most common cancers, including lung, breast, colorectal, and prostate cancers. Statistical analysis was performed using www.metaanalysisonline.com web platform.
Results: After screening of 9,306 studies, we included 65 studies with a total of 4,978,125 patients. In these studies, depression was associated with increased cancer mortality in each of the major cancer types. In colorectal cancer, the hazard ratio (HR) was 1.83, 95% CI: 1.47-2.28, indicating an 83% higher risk, while breast cancer showed a 23% higher risk (95%CI: 1.13-1.34). Lung cancer patients had a 59% higher risk (95%CI: 1.36-1.86), and prostate cancer patients faced a 74% higher risk (95%CI: 1.36-2.23). In mixed cancer types, depression was linked to a 38% higher mortality risk (95%CI: 1.20-1.60). Z-score analysis proved sufficient case number to draw a definitive conclusion in each of the sub-cohorts.
Conclusions: Our results suggest that the presence of depression is significantly associated with 23%-83% increase of cancer-specific mortality across various cancer types, including colorectal, breast, lung, and prostate cancers.

#6231 Associations of serum concentrations of α- and γ-tocopherols with cancer mortality.

Yoo-Min Koh[1], Jae Jeong Yang[1], Young-Rock Hong[2], Shama Karanth[1], Dejana Braithwaite[1], Hyung-Suk Yoon[1]

[1]University of Florida, Gainesville, FL,[2]Emory University, Atlanta, GA

Background: While tocopherols' antioxidant and anti-inflammatory properties suggest their potential anti-cancer effects, little is known about the association between circulating tocopherols and mortality outcomes, particularly among cancer survivors. This study aimed to evaluate whether serum concentrations of α- and γ-tocopherols were associated with the risk of death from all causes, cancer, and cardiovascular disease (CVD).
Methods: We incorporated 16,696 US adults aged ≥20 (1,466 cancer survivors and 15,230 cancer-free individuals) from the National Health and Nutrition Examination Survey, 1999-2006. Serum α- and γ-tocopherols were quantified by high-performance liquid chromatography and categorized into quartiles. Mortality and cause of death were ascertained by linkage to National Death Index records through December 31, 2019 (median follow-up of 16.1 years). Cox proportional hazards regression was used to estimate hazard ratios (HRs) and 95% CIs for all-cause, cancer, and CVD mortality after adjustment for comprehensive covariates, including serum cholesterol levels, sociodemographics, lifestyle (e.g., diet, physical activity), and comorbidities. Restricted cubic splines were used to evaluate the potential non-linearity of the associations.
Results: Cancer survivors in the highest quartile of serum α-tocopherol demonstrated a 50% lower risk of cancer mortality compared to those in the lowest quartile (HR=0.50, 95% CI:0.32-0.80, *p*-trend=0.009). Similar protective associations were observed in cancer-free individuals, with those in the highest quartile of serum α-tocopherol showing a 31% reduction in cancer mortality risk (HR=0.69, 95% CI: 0.46-1.02, *p*-trend=0.05). The association between α-tocopherol and cancer mortality was non-linear ($p<0.001$), exhibiting the strongest protective effects at concentrations ranging from 35 μmol/L to 50 μmol/L. All-cause mortality risk was also lower among those with higher α-tocopherol in cancer survivors (HR=0.75, 95% CI: 0.54-1.03, *p*-trend=0.02) and cancer-free individuals (HR=0.86, 95% CI: 0.74-1.00, *p*-trend=0.03). No significant associations were found for γ-tocopherols.
Conclusions: In this nationally representative sample of US adults, higher circulating concentrations of α-tocopherol were associated with a reduced risk of cancer mortality among both cancer survivors and cancer-free individuals. Our findings indicate the potential health benefits of circulating α-tocopherol in reducing preventable deaths and provide population-based evidence for the role of α-tocopherol in cancer survivorship care.

#6232 Pancreatic cancer epidemiology and impacts in patients admitted with sepsis: Insights from a nationwide inpatient sample.

Abdu Mohammed[1], Adamsegd I. Gebremedhen[2], Mamdouh Souleymane[2], Ibrahim Shanti[2], Jennifer Wiese[2], Stephen Roy[2], Toni O. Pacioles[3]

[1]Internal Medicine, Trinity Health System, Steubenville, OH,[2]Internal Medicine, Marshall University Joan C. Edwards School of Medicine, Huntington, WV,[3]Hematology and Oncology, Marshall University Joan C. Edwards School of Medicine, Huntington, WV

Background: Sepsis is a critical public health issue, contributing to high rates of hospitalization and mortality worldwide. While existing studies primarily focus on sepsis in patients with blood cancers or stem cell transplants, limited research addresses the impact of solid tumors, such as pancreatic cancer, on sepsis outcomes. This study examines the epidemiology and outcomes of sepsis in patients with pancreatic cancer, filling a crucial gap in the literature.
Methods: Data from the National Inpatient Sample (NIS) spanning January 2019 to December 2021 was analyzed. Patients with a primary diagnosis of sepsis or severe sepsis were categorized based on the presence of pancreatic cancer. Key comparisons included demographic data, coexisting conditions, and clinical outcomes, with all-cause mortality as the primary endpoint. Secondary outcomes assessed complications, treatments, hospital length of stay, and costs. Statistical analyses employed multivariate regression models, with significance defined as $p < 0.05$.
Results: The analysis included 7,032,966 adult sepsis admissions from January 1, 2019, to December 31, 2021, with 43,779 (0.62%) also having pancreatic cancer. Patients with pancreatic cancer were older (average age 68.5 vs. 64.5 years, $p < 0.001$), predominantly male (56.9% vs. 43.1%, $p < 0.001$), and more frequently had a Charlson Comorbidity Index of 3 or higher (89.9% vs. 44.5%, $p < 0.001$). These patients exhibited a significantly higher risk of all-cause mortality, with an adjusted odds ratio (aOR) of 1.24, (95% CI 1.16 - 1.31). They also had increased odds of venous thromboembolism (aOR 2.65, 95% CI 2.27 - 3.10), gastrointestinal hemorrhage (aOR of 1.105, 95% CI 1.002 - 1.220) and disseminated intravascular coagulation (aOR of 1.19, 95% CI 1.01 - 1.40). However, renal replacement therapy, mechanical ventilation and vasopressors were used less frequently in pancreatic cancer patients (aOR 0.50, 95% CI 0.43-0.59), (aOR 0.78, 95% CI 0.70 - 0.87) and (aOR 0.51, 95% CI 0.46 - 0.56), respectively. Pancreatic cancer in sepsis patients was also associated with shorter hospital stays (6.66 days vs. 7.65 days) with an adjusted incidence rate ratio (aIRR) of 0.69, (95% CI 0.68 - 0.71) and lower hospitalization costs ($86,649 vs. $98,342, aIRR of 0.68, 95% CI 0.66 - 0.70).
Conclusions: Sepsis patients with concurrent pancreatic cancer experienced significantly higher risks of mortality and other adverse outcomes, yet received less aggressive treatment, had shorter hospital stays, and incurred lower hospitalization costs. These findings may reflect a shift toward avoiding aggressive end-of-life care, as advocated by professional societies and governmental organizations. The results underscore the need for customized management strategies to minimize the impact of pancreatic cancer on outcomes for sepsis patients.

#6233 Human cytomegalovirus, tumor characteristics and patient survival in head and neck squamous cell carcinoma.

Heather H. Nelson[1], DeVon Hunter-Schlichting[1], Rondi Butler[2], Karl Kelsey[2]

[1]Masonic Cancer Center, Minneapolis, MN,[2]Brown Unversity, Providence, RI

Human cytomegalovirus (CMV) is a beta-herpes virus that may play a role in head and neck squamous cell carcinoma (HNSCC). CMV is a highly prevalent latent infection among older US adults, and viral reactivation occurs in response to immune suppression and inflammation. Previously, in a study of 184 HNSCC we reported that elevated CMV IgG titers were associated with worse patient survival. Here, we have expanded our evaluation of CMV IgG and patient survival in 983 cases from the CoHANDS study. CMV positive patients had significantly worse HNSCC survival ($p<0.003$); this association remained after controlling for age, sex and stage (HR=1.30, 95% CI 1.02- 1.74). The association between CMV and outcome was independent of the known association between human papilloma virus infection (HPV) and patient survival. Next, we used nCounter gene expression data to evaluate immune infiltration and inflammation in 34 tumors from HNSCC patients with and without active CMV infection; active infection was defined as having DNAemia, the presence of cell-free CMV DNA in serum. Tumors from patients with active CMV infection were more likely to contain CMV transcript ($p<0.06$) and have increased T-cell infiltration ($p<0.05$), however there were no other differences in the immune infiltrate. The Tumor Inflammation Signature (TIS), a gene expression indicator that correlates with response to immune checkpoint inhibitors, was significantly higher in CMV positive patients ($p=0.007$). CMV positive patients were 12 times more likely to have an elevated TIS score (adjusted OR 12.4, 95% CI 1.2 - 124.2). In summary, HNSCC patients who are CMV IgG positive have poor survival and tumors from patients with active CMV infection have both increased T-cell infiltration and elevated tumor inflammation. These findings may have potential implications for immune therapy in HNSCC.

#6234 Association of cultural racism with breast cancer mortality among adults in the United States, 2018-2020.

A. Gupta[1], O. L. Osazuwa-Peters[2], N. Krieger[3], T. Brown[4], T. F. Akinyemiju[2];
[1]Stanford University School of Medicine, Stanford, CA, [2]Duke University School of Medicine, Durham, NC, [3]Harvard T.H. Chan School of Public Health, Boston, MA, [4]Duke University, Durham, NC

Background: Breast cancer is the most common cause of cancer among women in the United States, with persistent disparities in mortality by race and ethnicity. Given the extent to which systemic racism is inextricably part of the social environment, we evaluated the relationship between cultural racism, a poorly examined but prevalent component of systemic racism, and breast cancer mortality overall and by molecular subtype.
Methods: We utilized a novel state-level multi-dimensional latent measure, the cultural racism factor (CRF), incorporating seven indicators (public symbols of the confederacy, online racial animus, racial resentment, anti-immigrant sentiments, lack of White public support for Medicaid expansion, lack of community-oriented policing prevalence, and aggregate implicit bias of White residents; ≤2017 US national data). We applied the CRF in continuous and dichotomized forms (highest vs. lowest two tertiles). Using cancer data from the Surveillance, Epidemiology, and End Results (SEER) Program (2018-2020), we evaluated the associations of CRF with breast cancer mortality via Cox proportional hazards models with clustering by state and adjusting for sociodemographic and clinical characteristics. We examined whether these associations varied by cancer subtype - Luminal A, Luminal B, HER-2 enriched and triple negative (TNBC).
Results: Among the 225,991 patients included in this analysis, 62% were Non-Hispanic (NH)-White, 12% were NH-Black, and 16% were Hispanic. Kaplan-Meier curves by CRF category showed higher survival probabilities among patients living in states within the lowest CRF tertile compared to the highest two tertiles (log-rank $p<0.0001$). For patients with survival times of 10 month or less, those in the highest CRF tertile had 15% higher risk of death relative to patients in the lowest two tertiles after sequentially adjusting for sociodemographic variables (HR: 1.15; 95% CI: 1.01-1.30), and clinical characteristics (HR: 1.15; 95% CI: 1.03-1.27). Additionally, each unit increase in the CRF score was associated with 7% increased hazard of death after adjusting for covariates (HR: 1.07; 95% CI: 1.02-1.11). However, no significant associations were observed among those with longer survival times. In race and ethnicity-stratified models for survival times of 10 months or less, NH-Black (HR: 1.21; 95% CI: 1.10-1.34) and Hispanic (HR: 1.60; 95% CI: 1.13-2.26) patients living in states in the highest CRF tertile had a higher risk of death than their counterparts living in lower CRF states. No significant associations were observed in subtype-stratified models.
Conclusions: Our findings highlight that state-level CRF increases the risk of breast cancer mortality among patients with shorter survival periods, potentially linked to delayed diagnosis, other aspects of inadequate health care, or more aggressive disease.

#6235 Cancer risk behaviors and adverse childhood experiences among cancer survivors.

Oluwole Adeyemi Babatunde[1], Melanie Jefferson[2], Swann Adams[3], Chanita Hughes Halbert[4], Nosayaba Osazuwa Peters[5], Frank Clark[1], Jessica Obeysekare[1], Anusuiya Nagar[1], Eric Adjei Boakye[6]

[1]Prisma Health, GREER, SC,[2]Medical University of South Carolina, Charleston, SC,[3]University of South Carolina, Columbia, SC,[4]University of Southern California, Los Angeles, SC,[5]Duke University School of Medicine, Durham, NC,[6]Henry Ford Health System, Detroit, MI

Introduction: Adults who have experienced Adverse Childhood Experiences (ACEs) are at a higher risk of engaging in health-risk behaviors. While previous studies have examined the connection between ACEs and health-risk behaviors in the general population, there is a scarcity of research specifically addressing cancer survivors. This study investigates the association between three individual ACEs—mental illness in family members, physical abuse, and sexual abuse—and cancer-related risk behaviors (binge drinking and smoking) among cancer survivors.

Methods: Using cross-sectional data from the 2020 Behavioral Risk Factor Surveillance System, we analyzed a sample of 7,896 cancer survivors aged 18 and older. The exposure variables included three ACEs: having a family member with a mental illness, experiencing physical abuse, and experiencing sexual abuse before the age of 18 dichotomized as yes/no. The outcome measures were cancer risk behaviors: smoking status (categorized as current, former, or never smoker) and binge alcohol use (yes or no). Binge drinking was defined as consuming five or more drinks on one occasion for males and four or more drinks for females in past seven days or/and past 30 days of the survey. Weighted multivariable logistic regression models were used to evaluate the association between ACEs and binge drinking, while multinomial logistic regression models assessed the relationship between ACEs and smoking status, adjusting for sociodemographic factors.

Results: In this sample of cancer survivors, 15.5%, 23.6%, and 6.3% reported experiencing the three ACEs: mental illness in family members, physical abuse, and sexual abuse, respectively. Regarding smoking history, 50.9% were never smokers, 34.3% were former smokers, and 15.0% were current smokers, while 7.8% reported binge alcohol use. Adjusted models revealed that cancer survivors with a history of mental illness in family members had significantly higher odds of being current smokers (aOR: 2.15, 95% CI: 1.41-3.26) or former smokers (aOR: 1.70, 95% CI: 1.27-2.29). Similarly, those who experienced physical abuse had increased odds of being current smokers (aOR: 2.29, 95% CI: 1.64-3.20) or former smokers (aOR: 1.53, 95% CI: 1.22-1.91). Survivors who reported sexual abuse had higher odds of being current smokers (aOR: 3.61, 95% CI: 2.18-5.99) or former smokers (aOR: 1.96, 95% CI: 1.15-3.32). However, the adjusted models showed no statistically significant association between the three ACEs and binge alcohol use among cancer survivors.

Conclusion: Among cancer survivors, ACEs are independent predictors of former and current smoking status in adulthood, a well-established risk factor for cancer. As such, individuals with a history of ACEs may constitute a critical target group for preventive interventions designed to mitigate this risk and promote healthier behaviors.

#6237 Eco-evolutionary guided pathomics analysis to predict DCIS upstaging.

Mehdi Damaghi, Yujie Xiao

Stony Brook University, Renaissance School of Medicine, Stony Brook, NY

Cancers evolve in a dynamic ecosystem. Thus, characterizing cancer's ecological dynamics is crucial to understanding cancer evolution and can lead to discovering novel biomarkers to predict disease progression. Ductal carcinoma in situ (DCIS) is an early-stage breast cancer characterized by abnormal epithelial cell growth confined within the milk ducts. In this study, we show that ecological habitat analysis of hypoxia and acidosis biomarkers can significantly improve prediction of DCIS upstaging. First, we developed a novel eco-evolutionary designed approach to define habitats in the tumor intra-ductal microenvironment based on oxygen diffusion distance. Then, we identify cancer cells with metabolic phenotypes attributed to their habitat conditions, such as the expression of CA9 indicating hypoxia responding phenotype, and LAMP2b indicating the acid adaptation. Traditionally these markers have shown limited predictive capabilities for DCIS upstaging, if any. However, when analyzed from an ecological perspective, their power to differentiate between pure DCIS and upstaged DCIS increased significantly. Second, using eco-evolutionary guided computational and digital pathology techniques, we discovered distinct niches with spatial patterns of these biomarkers and used the distribution of such niches to predict patient upstaging. With a 5-fold validation on the biopsy cohort, we trained a random forest classifier to achieve the area under curve (AUC) of 0.74. Our results affirm the importance of using eco-evolutionary-designed approaches in biomarkers discovery.

#6238 Interactions between ploidy and resource availability shape clonal interference in glioblastoma.

Zuzanna Nowicka[1], Frederika Rentzeperis[2], Vural Tagal[3], Konstantin Maksin[4], Parag Katira[5], **Noemi Andor**[3]

[1]Department of Biostatistics and Translational Medicine, Medical University of Łodź, Łodź, Poland,[2]Icahn School of Medicine at Mount Sinai, New York City, NY,[3]H. Lee Moffitt Cancer Center, Wesley Chapel, FL,[4]Medical Department (WSHIU), The University of Commerce and Services, Poznan, Poland,[5]Department of Mechanical Engineering and the Computational Sciences Research Center, San Diego State University, San Diego, CA

Whole-genome doubling (WGD) transforms a diploid cell into a tetraploid state, making it prone to genomic instability, aneuploidy, and malignancy. Tumors with evidence of past WGD events range from less than 10% in Non-Hodgkin's Lymphoma to almost 60% in germ cell cancer. WGD confers advantages, including resistance to stressors, making it a powerful macroevolutionary force. *Why, then, isn't WGD a precursor for most cancers?* In Glioblastoma **(**GBM**)**, *~86% of tumors lack evidence of WGD in their evolutionary history*. We integrated a multi-modal dataset of 11 histopathology whole slide images (WSIs), 68 medical images, and whole-genome sequencing data (WGS) from six patient-matched primary and recurrent GBM. Three atlases were derived from FDG PET/MRI (glucose uptake), quantitative BOLD imaging (oxygenation), and magnetic resonance elastography (stiffness), capturing variability across brain regions and patient age. Using HATCHet, which infers clone-specific karyotypes from WGS, we quantified GBM clonal composition and its changes between surgeries. Chromosome 7 amplification and chromosome 10 loss were detected in at least one clone in all tumors. **Genetic intra-tumor heterogeneity (coexistence of ≥2 clones) was found in 4/6 patients**, with moderate to strong clonal changes between surgeries in all four. This data informed parameters governing how cells of variable (poly)aneuploidy respond to oxygen and glucose by dying (α_d, s_r), switching to glycolysis (O_th), or migrating (v_max). Two parameters significantly differed among patients: oxygen-dependent death constant α_d (ANOVA p = 1.7E-5) and oxygen level prompting a metabolic shift to glycolysis O_th (ANOVA p = 1.9E-4). **Higher-ploidy GBMs showed elevated** O_th **values, and higher-ploidy clones within tumors had consistently higher** O_th **than coexisting lower-ploidy clones**. Between surgeries, simulated tumors with distinct karyotype compositions progressed at different rates. Whether higher ploidy predicted fast recurrence was however a function of the tumor anatomic location, in line with the hypothesis that environments with limited resources are likely to exert selective pressure against WGD. Compared to intra-brain differences in resource supply, the differences observed between organs can be larger, providing an opportunity to further test this hypothesis. Indeed, the **average ploidy** of 20 different cancer types was **positively correlated with the oxygen** levels recorded in their respective organ of origin (Spearman r = 0.65, P = 0.002) **and negatively correlated to the glucose** uptake rates in the organ of origin (Spearman r = -0.70, P = 0.026). Overall, our findings suggest that metabolic substrate availability in the tissue micro-environment influences cell fate decisions based on karyotype, shaping GBM initiation and recurrence.

#6239 Modeling and simulation of CRS events in low-risk populations with a rapid ramp-up SUD regimen of epcoritamab.

Matthew Putnins[1], Eric Song[1], Merzu Belete[1], Sri Sridhar[1], Han Si[1], Behnam Noorani[2], Mohamed-Eslam Mohamed[2], Manish Gupta[1], Mariana Sacchi[1], Steven Xu[1], Tommy Li[1]

[1]Genmab, Princeton, NJ,[2]AbbVie, North Chicago, IL

Background: Epcoritamab is the only subcutaneous CD3xCD20 bispecific antibody approved for the treatment of adults with different types of relapsed or refractory (R/R) large B-cell lymphoma (LBCL) and R/R follicular lymphoma after ≥2 prior lines of systemic therapy. Cytokine release syndrome (CRS) is a known adverse event with T-cell engagers. A 2-step step-up dosing (SUD) in cycle 1 with CRS prophylaxis consisting of dexamethasone and fluids, involving a priming dose (0.16 mg on day 1) and an intermediate dose (0.8 mg on day 8) before the target dose (48 mg on day 15), has been identified as the optimal SUD for epcoritamab to reduce CRS risk in patients with diffuse LBCL (DLBCL). However, due to the aggressive disease and fast progression, patients with R/R DLBCL with a low risk of developing CRS may benefit from a shorter SUD regimen, allowing for quicker administration of the target dose without significantly increased CRS event rates following treatment.

Methods: We performed model-based simulations for patients with R/R LBCL at lower risk of developing CRS (eg, patients who received prior CAR T therapy) utilizing a previously validated repeated time-to-event model which captures the time course and frequency of grade (G) ≥2 CRS under various SUD regimens. Specifically, we explored regimens that would shorten the 14-day period between the initial priming dose and the target full dose. For each simulated regimen, the predicted event rate of G≥2 CRS was assessed to determine the impact of the modified SUD.

Results: The model was able to accurately predict CRS event risk: approximately 11% of GCT3013-01 DLBCL optimization cohort patients (9/81) had a G≥2 CRS event, with CRS prophylaxis consisting of dexamethasone and adequate hydration, and our model predicted a CRS event rate of ~11%. Patients with prior CAR T therapy are predicted to have even lower CRS risk: ~4% risk of a G≥2 CRS event under the current 2-step SUD regimen, and ~5% risk of a G≥2 CRS event under a rapid ramp-up 1-week SUD (eg, priming on day 1, intermediate on day 4, and target dose on day 8). Despite the small increased risk of a CRS event with the rapid ramp-up SUD, the risk of an event is still lower than the observed G≥2 CRS event rate in the overall GCT3013-01 optimization cohort (ie, ~11%).

Conclusions: Shortening the SUD to 1 week in patients at low risk for CRS (eg, patients with prior CAR T) resulted in a similar G≥2 CRS rate compared with the current SUD regimen, as predicted by the model. Based on these simulations, a 1-week rapid ramp-up SUD may be beneficial in selected patients to deliver the target full dose of epcoritamab in a shorter time without undue risk. Further confirmation of this finding in clinical studies may be warranted.

#6241 Predicting treatment outcomes from adaptive therapy: a new mathematical biomarker.

Kit Gallagher[1], Maximilian A. Strobl[2], Philip K. Maini[3], Alexander R. Anderson[1]

[1]Integrated Mathematical Oncology, Moffitt Cancer Center, Tampa, FL,[2]Theory Division, Cleveland Clinic, Cleveland, OH,[3]Institute of Mathematics, University of Oxford, Oxford, United Kingdom

Standard-of-care cancer therapy regimens are characterized by continual treatment at the maximum tolerated dose, however, this approach often fails on metastatic cancers due to the emergence of drug resistance. An evolution-based treatment paradigm known as 'Adaptive Therapy' has been proposed to counter this, dynamically adjusting treatment to control, rather than minimize, the tumor burden, thus suppressing the growth of treatment-resistant cell populations and hence delaying patient relapse. Promising clinical results in prostate cancer indicate the potential of adaptive treatment protocols, but demonstrate broad heterogeneity in patient response. This naturally leads to the question: why does this heterogeneity occur, and is a 'one-size-fits-all' protocol best for patients across this spectrum of responses?

Using a Lotka-Volterra representation of drug-sensitive and -resistant tumor populations' dynamics, we obtain a predictive expression for the expected benefit from Adaptive Therapy and show that this is effective at identifying the best responders in a clinical dataset. Incorporating techniques from Optimal Control theory, we further derive an analytic expression for the optimal treatment strategy, based on individual patient tumor dynamics. In contrast to prior approaches, this strategy also accounts for clinical limitations such as fixed time intervals between clinical appointments, to produce clinically realistic treatment strategies. We show that this strategy varies significantly between patients, and present a framework to generate individual treatment schedules from a patient's initial treatment data. Finally, we develop metrics to predict which patients have the greatest sensitivity to unplanned schedule changes, such as delayed appointments, allowing clinicians to identify high-risk patients that need to be monitored more closely and potentially more frequently. Overall, the proposed strategies offer personalized treatment schedules that consistently outperform clinical standard-of-care protocols.

#6242 Adaptive therapy in advanced basal cell carcinoma driven by imaging and mathematical modeling.

Jill Gallaher, Masud M A, Zeynep Eroglu, Alexander R. A. Anderson

Moffitt Cancer Center, Tampa, FL

Basal cell carcinoma (BCC) accounts for 80% of skin cancers and in most cases is very treatable. However, due to either neglect or aggressive growth, roughly 1-10% of BCCs are considered advanced and infiltrated into surrounding tissue such that it is challenging to clear without causing morbidity. These advanced cancers are treated with a systemic therapy inhibiting the Hedgehog signaling pathway, such as vismodegib, which is mutated in 85% of BCCs. Whilst Hedgehog inhibitors have a median progression-free survival (PFS) of approximately 1 year, they come with significant toxicity that often disrupts standard treatment scheduling, and even for those that can tolerate it, there is the possibility of treatment resistance. Here we show interim results from an ongoing clinical trial (NCT05651828) where we design an adaptive therapy strategy for BCC to increase PFS by controlling growth whilst reducing toxicity and the risk of treatment resistance. We use measurements and photographic images of skin lesions over time integrated with a mathematical model to adapt treatment scheduling (either on or off) in a dynamic patient-specific manner. We develop a burden metric based on the color and texture of a lesion to define its current state. We also define a system of ordinary differential equations comprising sensitive and resistant cells along with compartments to capture the drug's unique pharmacodynamics to make predictions for future treatments. We fit the model to each patient's lesion dynamics and predict when to start and stop therapy, iteratively driving treatment decisions in our ongoing clinical trial. We find considerable heterogeneity amongst patients due to the number, size, and morphology of lesions and amongst lesions within a single patient. Drug response and clearance rate of the drug may differ between patients and lesions, so pharmacokinetics and pharmacodynamics parameters need to be carefully calibrated to make good response predictions. Importantly, we define a new strategy for treatment of multiple lesions that are responding differently to treatment within the same patient. We can predict BCC patient growth and response dynamics by fitting a mathematical model to a novel tumor burden metric based on size, color, and texture.

#6243 Mathematical modeling of cell-free DNA fragmentation to map chromatin landscapes in health and cancer.

Brian Sun Liu[1], Mengran Zhang[2], Takeshi Sugio[3], Mohammad Shahrokh Esfahani[2]

[1]Institute for Computational & Mathematical Engineering, Stanford University, Stanford, CA,[2]Department of Radiation Oncology, Stanford School of Medicine, Stanford, CA,[3]Divisions of Oncology and Hematology, Stanford University, Stanford, CA

Background: Cell-free DNA (cfDNA) fragments are shed into bodily fluids as a result of apoptosis and necrosis. Profiling plasma cfDNA has emerged as a powerful tool in cancer diagnostics and research, through circulating tumor DNA (ctDNA) fragments that enable genotyping of many tumors, and epigenetic analysis of cfDNA, including fragmentomics. Fragmentomics encompasses the analysis of fragment lengths, end motifs, and central dyads, which reflect epigenetic patterns, to identify the cell of origin for each fragment.
We previously showed that fragment size diversity is strongly correlated with gene expression (Esfahani et al, NBT 2022). We hypothesize that parameters inferred from a mathematical model for the fragmentation process can enhance gene expression inference from cfDNA.
Methods: We followed the mechanistic model previously proposed (Esfahani et al, NBT 2022), and modified it with additional steps. For each transcription start site (TSS), we input the mean and variance of the linker DNA length, fraction of nucleosomes sites occupied, cut frequency, and DNA degradation factor among other factors. Then, in accordance with the given parameters, we generate a sequence of nucleosome units, a sample of nucleosome sites occupied, and a sequence of fragments, and degrade them.
For chromatin landscaping of plasma cfDNA, we used four cfDNA samples profiled by deep whole genome sequencing (~250X). For each of 500 TSSs, we fitted our model to the fragment size distribution from data by minimizing the Jensen-Shannon (JS) divergence between the generated fragment size distribution and the fragment size distribution from the sample. Finally, we performed regression analysis on the fitted parameters to infer gene expression.
Results: We analyzed cfDNA fragmentation spectra at TSSs genome-wide in relation to transcriptome-wide gene expression levels. The regression shows that gene expression has a negative correlation ($P<0.001$) between fraction of nucleosome sites occupied, a positive correlation ($P=0.002$) with the degradation factor, and a negative correlation ($P=0.009$) with the mean linker length.
Conclusions: We show that cfDNA fragmentation can be modeled as a multi-step stochastic process. Through surveying TSSs, we showed significant correlation between certain model parameters and gene expression. Our findings that gene expression is negatively correlated with model parameters for fraction of nucleosome sites occupied and mean linker length is consistent with previous literature suggesting that higher fraction of nucleosome sites occupied and longer linker length lead to suppressed gene expression (Valouev et al, Nature 2011). We envision this model-based approach will enhance gene expression inference that can ultimately improve cancer detection and tissue of origin classification.

#6244 Comparative diversity analysis of microbial composition across tissue and fecal samples in multi-cohort, multi-study cancer analyses.

Tiffany Zhang[1], Kylie Chan[1], Caitlin Guccione[1], Bertalan Takacs[2], Antonio Gonzalez[1], Gail Ackermann[1], Kathleen Curtius[1], Rob Knight[1]

[1]University of California, San Diego (UCSD), San Diego, CA,[2]University of Szeged, Szeged, Hungary

The microbial ecosystems in tumors, surrounding tissues, and the gut (which influences processes throughout the body) offer new opportunities for oncology diagnostics and treatment, but inconsistencies in metadata quality and parameters across abundant public data hinder generalizable conclusions. To address these issues, we analyzed alpha and beta diversity metrics across multiple studies, focusing on how variables like collection site or cancer type influence microbiome profiles.

We compiled a list of over 180 publicly available studies from the European Nucleotide Archive that sequenced human stool and/or tissue. Studies without publications or sufficient metadata were removed, and remaining studies were narrowed to those using 16S rRNA gene amplicon sequencing, leaving 38 studies with 10,796 samples. Using Qiita, an open-source multi-omics platform, samples were split into fecal and tissue. All fecal samples were analyzed as their own category and came from patients with various cancer types (FEC). Each tissue sample was placed into at least one of the following categories: all cancer tissue samples (CAN), tissue from patients with both healthy adjacent biopsies and cancerous biopsies (ADJ), and tissue from healthy donors and matched cancer patients (HEA). Some samples fell into multiple categories, but each category was analyzed independently. After default QC and rarefying, we used QIIME2, a microbiome bioinformatics platform, to apply diversity metrics.

We explored microbial differences across cancer types using Bray Curtis (BC) and Jaccard diversity metrics for tissue (CAN) and fecal (FEC) categories. In the CAN category, PERMANOVA results for both beta diversity metrics showed a statistically significant difference across the six cancer types ($p < 0.00001$). The same result was replicated in the FEC category. In the CAN category, Kruskal-Wallis results for Shannon diversity (SH) showed a significant difference across cancer tumor types ($p = 1.5e-28$). The same result was observed in the FEC category ($p = 4.6e-48$), indicating that cancer type may be related to microbial diversity differences in both contexts. In the ADJ category, significant differences were observed between adjacent and cancerous tissue for both BC ($p < 0.00001$) and SH ($p = 0.017$). In the HEA category, significant differences were found between matched healthy donors and cancer patients for both BC ($p < 0.00001$) and SH ($p = 0.00004$), highlighting variations driven by tissue context and disease state. Finally, our findings reveal substantial and statistically significant variability using both BC and SH diversity when comparing across the unique study ID in both CAN (BC $p<0.00001$, SH $p=3.9e-38$) and FEC (BC $p<0.00001$, SH $p=4.1e-48$) categories. This underscores the need for standardized guidelines in microbiota sample collection and processing to enhance comparability in future analyses.

#6245 Predicting and optimizing the response of breast cancer patients to neoadjuvant therapy using a multiscale computational model.

Mahesh Nandyala[1], Chengyue Wu[2], **Casey E. Stowers**[1], Reshmi Patel[1], Clinton Yam[2], Jingfei Ma[2], David Fuentes[2], Gaiane M. Rauch[2], Thomas E. Yankeelov[1]

[1]The University of Texas At Austin, Austin, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX

The high risk for metastasis, poor prognosis, and low overall survival rates in triple-negative breast cancer (TNBC) underline the crucial need for more accurate prediction and optimization of the therapeutic response. The goal of this work is to combine patient-specific imaging with a multi-scale mathematical model to predict and optimize the treatment response of TNBC on an individual basis. This study employed a cohort of 50 TNBC patients from the ARTEMIS trial (NCT02276443) who received standard-of-care neoadjuvant chemotherapy that consisted of four cycles of Adriamycin/cyclophosphamide (A/C) and 12 cycles of paclitaxel. We established a cell-scale model that describes drug transport via vascular delivery, tissue distribution, and cellular uptake and coupled it to a tissue-scale model of tumor size and cellularity to predict treatment response. Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) data were used to inform patient-specific pharmacokinetic parameters to estimate drug concentration in tissue, and *in-vitro* drug uptake data were used to model cellular drug concentration. The tissue-scale model incorporates cell movement, proliferation, and treatment-induced death and was calibrated using DCE-MRI and diffusion-weighted MRI data from pre- and post-two cycles of A/C treatment. Once calibrated on a patient, the model ran forward in time to predict tumor status at the end of A/C. Over the cohort, the concordance correlation coefficient between the predicted and measured changes in total tumor cellularity and volume were 0.96 and 0.91, respectively.We also evaluated hypothetically alternative treatment protocols for each patient by varying the total dose from 180-300 mg/m^2 and the number of cycles from four to eight within a 56-day A/C treatment period. For the standard-of-care total dose of 240 mg/m^2, eight cycles of A/C treatment resulted in a median (range) of 10% (7.12%-14.99%) reduction in total tumor cell count compared to the standard-of-care four cycles. Further, increasing the total dose improved the patients' response. Within the cohort, a median (range) of 36.83% (29.33%-47.41%) reduction of total tumor cellularity was observed for the 300 mg/m^2 total dose over eight treatment cycles.To the best of our knowledge, this is the first multi-scale model calibrated with patient data to generate a testable prediction of treatment response. The methods in this study accurately captured the spatio-temporal dynamics of drug distribution and the response of TNBC to neoadjuvant A/C. Our ongoing work focuses on using this approach to assess the effects of increasing or decreasing the intensity of the treatment on non-responding and responding patients, respectively. Integrating MRI data with pharmacokinetic and mechanistic models has the potential to accurately predict treatment response in TNBC and bring tangible benefits to the patients.

#6246 Graph-based integration of multi-modal data uncovers cell-type specific vulnerabilities and advances toward a multi-scale digital twin.

Ying Zhu, Li Zhao, David Maxwell, Michael Darkoh, Bissan Al-Lazikani

1Department of Genomic Medicine, 2Institute for Data Science in Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: While recurrent cancer drivers have facilitated drug discovery, strong driver signals are elusive in rare and heterogeneous cancers. Importantly, therapeutically actionable molecular vulnerabilities often extend beyond conventional cancer drivers. We previously developed a graph-based AI approach that identified key molecular vulnerabilities across 19 solid tumor types leveraging bulk sequencing data, outperforming standard methods in target hypothesis generation by three fold (https://doi.org/10.1101/2024.06.04.597409). However, a critical factor in cancer progression and therapeutic resistance lies in the interplay between tumor cells with their microenvironment, surrounding tissue and beyond. There is a real need for a generalizable multiscale communication model that captures molecular and cellular interactions within cells, between cells, and across cellular niches and organs. Such a model could pave the way for constructing a comprehensive multiscale digital twin, offering a transformative framework for understanding cancer dynamics and identifying novel therapeutic cancer targets.
Methods: Graph-based computational models provide a powerful framework for analyzing complex biological systems, making them especially effective for any nodal communication, where a node can represent an individual molecule, a cell, a group of cells or an organ. We introduce a probabilistic graph-based approach that integrates data across multiple modalities and scales—from bulk to single-cell resolution—through network fusion to identify cell-specific vulnerabilities. This method, FN-MVP (Fusion Net-Molecular Vulnerability Picker), is, to our knowledge, the first molecular resolution multiscale model able to model intracellular molecular networks together with cell-cell, cell-niche communication. It unifies data from both single cell and bulk data to provide a comprehensive view of these combined modalities.
Results: By leveraging the cooperativity of weak signals within cancer molecular networks, FN-MVP amplifies true molecular vulnerabilities with greater accuracy (significantly higher than bulk MVP, p = 1.3e-3), as validated by genetic perturbation data. Applying FN-MVP to lung cancer patients revealed cell subtype-specific vulnerabilities and identified critical ligands and receptors that drive TME dynamics in a context-specific manner.
Conclusions: These findings underscore the power of this approach in uncovering actionable molecular interactions. FN-MVP represents a foundational step toward building a generalizable multiscale communication model, capable of integrating molecular, cellular, and tissue-level interactions. This progress lays the groundwork for developing a multiscale digital twin, a transformative tool for understanding cancer and advancing therapeutic strategies.

#6247 Artificial intelligence predicts 2021 WHO glioma subtypes from whole slide images.

Shubham Innani[1], W. Robert Bell[1], MacLean Nasrallah[2], Bhakti Baheti[1], Spyridon Bakas[1]

[1]Indiana University, Indianapolis, IN,[2]University of Pennsylvania, Philadelphia, PA

Diagnosis of diffuse glioma according to the WHO 2021 classification criteria mandate the integration of histologic features with molecular profiling. However, molecular profiling is expensive, time-demanding, and when not available leads to the 'not-otherwise-specified' status. We seek interpretable AI-based classification of glioma, as oligodendroglioma, astrocytoma, or glioblastoma, from H&E-stained slides alone. We identified 2,114 multi-institutional whole slide images (WSIs), from two independent retrospective glioma collections, following reclassification according to the WHO 2021 criteria: a) TCGA-GBM/TCGA-LGG (n_{WSI}=1,320, $n_{patients}$=654) & b) EBRAINS ($n_{WSI}=n_{patients}$=794). TCGA data are used for model development, whereas EBRAINS as hold-out data. Each WSI undergoes comprehensive curation to account for any artifacts, such as tissue foldings, glass reflections, and pen markings. We then conduct a quantitative performance evaluation across: i) eight pathology-specific AI foundation models (FM) and an ImageNet-trained AI model that facilitate robust feature extraction, and ii) nine multiple-instance learning (MIL) approaches that are used to aggregate features into slide-level representations, to differentiate across the three glioma classes. Finally, we take into account magnification level combinations of the WSIs (2.5x, 5x, 10x, 20x), in an attempt to mimic the approach that expert neuropathologists follow to histologically assess tissue slides. Our approach yields AUC_{TCGA}=0.979 over a 10-fold cross-validation schema, and generalizable performance on the independent validation ($AUC_{EBRAINS}$=0.963), for the best performing FM and MIL in the multi-magnification setting. Our key findings indicate: i) domain-specific FMs outperform the ImageNet model, ii) MILs yield larger performance contributions when used with ImageNet models than with FMs, iii) Fusion of multiple magnifications adds value on both development and validation datasets. Interpretability analysis through attention heatmaps highlights distinct identifiable morphology features for each glioma class. Oligodendroglioma show uniform, round nuclei with perinuclear halos, microcystic and gemistocytic cells. Astrocytomas contain cells resembling astrocytes with irregular, elongated shaped nuclei and fibrillary cytoplasmic processes. Glioblastomas display highly heterogeneous cellular composition, pleomorphic astrocyte cells, microvascular proliferation, multinucleated giant cells, and pseudo palisading necrotic regions. Determination of glioma classes directly from routine clinically acquired H&E slides can obviate the need for molecular profiling, expedite conclusive diagnosis and hence clinical decision-making, even in underserved regions. Interpretability analysis towards distilled human-identifiable features can contribute in disease understanding.

#6248 Leveraging knowledge graphs and AI to uncover premalignant disease mechanisms for early detection and prevention of lung cancer.

C. Riquelme-Vano, S. Shikhare, M. O'Donoghue, J. Cohen-Setton, M. Carmona, A. Reynolds, K. Bulusu, K. Nurzynska;
AstraZeneca in Cambridge, Cambridge, United Kingdom

Background: Early detection and treatment of lung cancer markedly improve patient outcomes, with a 5-year survival rate of 68-92% for stage I diagnoses compared to 0-10% for stage IV. Targeting early-stage cancer is pivotal in addressing tumour heterogeneity and therapeutic resistance, critical factors for effective treatment development. This study leverages knowledge graphs and AI to identify novel premalignant disease mechanisms at the early lung cancer stage, serving as potential biomarkers and therapeutic intervention opportunities for prevention of advanced disease.
Methods: In this study, we built the Early Cancer Knowledge Graph (ECKG), an integrative framework that connects multi-omics data from both external and AstraZeneca's internal resources, employing advanced machine learning algorithms to uncover novel disease insights and therapeutic opportunities. Our methodology involves mapping the ontological landscape of early-stage lung cancer through AstraZeneca's internal Biological Insights Knowledge Graph (BIKG) and integrating comprehensive multi-omics datasets. Utilising scalable KG build and clustering algorithms, we cluster ECKG into communities based on disease mechanism similarity and rank genes based on their significance in the disease network.
Results: This approach identified multiple potential novel disease mechanisms, including >20 potential targets highlighting intervention opportunities. These targets underwent pathway enrichment analysis, Gene Set Variation Analysis (GSVA), and correlation to hallmarks of cancer at the single-cell level, enhancing our understanding of their biological significance. Key pathways enriched in early lung cancer cells include MAPK/ERK signaling (KRAS, EGFR) and mTOR signaling (mTOR, AKT1/2). Notably, genes influencing immune cell states within the tumour microenvironment (TME), such as IL-1 signaling, immune checkpoints, and immunosuppressant genes like TGFB1, were highly enriched, among others. These findings underscore the importance of the TME in early lung cancer progression. Most of these targets were supported by evidence in an extensive literature review of early lung cancer patient data.
Conclusion: Future research should focus on experimentally validating these targets, identifying potential intervention strategies, and recommending therapeutic approaches, especially leveraging AstraZeneca's early oncology assets. Furthermore, our ECKG framework could be a generalisable blueprint that is capable of expanding to other critical indications of unmet need, e.g., pancreatic and childhood cancers. Ultimately, the goal is to provide a comprehensive, unbiased assessment of the early disease landscape, facilitating strategic decision-making and shifting the focus from cancer cure to prevention.

#6249 Probabilistic causal network models from real-world prostate cancer data identify potential synergistic combinations with CBP/P300 inhibitors.

Veronica Calvo[1], Bonnie Dougherty[1], Ananya Dutta[2], Duo Xu[1], Qi Pan[1], Andrew Armstrong[3], Jens Renstrup[1], Jason Somarelli[2], Eric Schadt[1]

[1]Pathos AI, Chicago, IL,[2]Department of Medicine, Duke University, Durham, NC,[3]Duke University, Durham, NC

The current standard of care for metastatic castration resistant prostate cancer (mCRPC) includes androgen-receptor signaling inhibitors (ARSIs), chemotherapy, PARP inhibitors (PARPi), or PSMA-radioligand therapies. Although these novel therapies have yielded substantial benefits for patients, many fail to respond or quickly develop resistance. Previous work identified key regulatory programs driving AR-altered, ARSI-resistant, late-stage prostate cancer, and further identified and validated that treatment with the CBP/p300 inhibitor pocenbrodib inhibits cancer cell growth both in vitro and in vivo. Here, we focus on identifying targeted therapies where combination with pocenbrodib could improve clinical response in late-stage prostate cancer. Previous analyses identified that treatment of prostate cancer cell lines with pocenbrodib downregulates a group of genes, termed a subnetwork, capturing G2M, E2F, and DNA repair mechanisms, suggesting that combination with a therapy that induces DNA damage or inhibits DNA repair could be additive or synergistic. Cell cycle profiling following treatment of cell lines with pocenbrodib confirmed induction of G2M cell cycle arrest. Next, we systematically ranked current targeted therapies based on publicly available RNA-seq signatures and signatures derived from RWD (e.g. BRCA2 alterations) to identify therapies that target our subnetwork of genes enriched for G2M, E2F, and DNA repair mechanisms. Given that both PSMA-radioligand therapies and PARP inhibitors induce DNA damage or inhibit DNA repair, we hypothesize that these drugs in combination with pocenbrodib would lead to additive or synergistic effects by enhancing the PARPi and PSMA-radioligand efficacy via their known mechanisms of action.

To validate these hypotheses, we treated a panel of 5 genetically-diverse prostate cancer PDX-derived organoids with pocenbrodib, the PARPi olaparib, and in combination. The combination of pocenbrodib with olaparib led to additive or synergistic effects in 3 out of the 5 organoids, consistent with those showing some level of response to olaparib as a single agent. To evaluate the potential for combination benefit with PSMA-radioligand therapy, an in vivo efficacy study was performed using the PSMA+ 22Rv1 prostate cancer xenograft model. Addition of a low dose of pocenbrodib to a single dose of Lu177-PSMA617 (60 MBq) led to better tumor growth inhibition control than either single agent on its own. Mechanistic analyses from RNAseq are ongoing. Together, our integrated omics and experimental analyses support the hypothesis that combination of pocenbrodib with DNA damage-inducing or -inhibiting targeted therapies may provide further therapeutic benefit to prostate cancer patients than single agent therapies alone.

#6250 Clinical significance of co localization index in rectal cancer: a deep learning approach to cell interaction analysis.

Kimihiro Yamashita[1], Tomoki Abe[2], Toru Nagasaka[3], Masayuki Ando[2], Takao Tsuneki[2], Yukari Adachi[2], Takaaki Tachibana[2], Hiroki Kagiyama[2], Tomoaki Aoki[2], Yasufumi Koterazawa[2], Ryuichiro Sawada[2], Hitoshi Harada[2], Yasunori Otowa[2], Naoki Urakawa[2], Hironobu Goto[2], Hiroshi Hasegawa[2], Shingo Kanaji[2], Takeru Matsuda[2], Ryohei Sasaki[4], Yoshihiro Kakeji[2]

[1]Department of Biophysics, Kobe University Graduate School of Health Sciences, Kobe City, Japan,[2]Department of Surgery, Kobe University Graduate School of Medical Science, Kobe City, Japan,[3]Association of Medical Artificial Intelligence Curation, Nagoya City, Japan,[4]Department of Radiation Oncology, Kobe University Graduate School of Medical Science, Kobe City, Japan

Background: Tumor tissue is not just a cluster of cancer cells, but an organized ecosystem in which various cells, extracellular matrices, and various types of liquid factors interact with each other. There are high technical barriers to processing this complex ecosystem in large quantities and quantitatively. Therefore, we have established a histological analysis method using deep-learning-based imaging cytometry (DL-IC) (Abe T, Yamashita K, et al. Anticancer Res. 43:3755 2023). Identification of the constituent cells of tumor tissue and spatial understanding of the tumor immune microenvironment using DL-IC are important for predicting cancer prognosis and treatment efficacy. In this study, we propose a co-localization index (CLI) as a new indicator for analyzing the tumor immune microenvironment using AI.
Purpose: We investigated the impact of the co-localization of cytotoxic lymphocytes and cancer cells on the prognosis of rectal cancer after surgery.
Subjects and Methods: Forty rectal cancer surgical specimens were analyzed using the DL-IC system Cu-Cyto. A bit pattern kernel filtering algorithm was implemented to prevent duplicate cell counting, and its performance on immunohistochemistry (IHC) specimens was evaluated. The accuracy was compared between analyses with and without the algorithm. Cell-cell interactions were quantified using CLI, and the usefulness of CLI as a prognostic indicator was evaluated, particularly focusing on interactions between cancer cells and CD8+ T cells. Additionally, a comprehensive analysis of CLI was conducted using combinations of multiple cell types.
Results: In the training process, where the data size of the training data was scaled, the F1 scores for adenocarcinoma cells, lymphocytes, and CD8+ T cells were 0.589, 0.889, and 0.911, respectively, at a cell number of 1013. The introduction of a bit pattern kernel filtering algorithm improved the accuracy of the determination of each cell type. The 5-year disease-free survival rate was significantly prolonged in the high CLI group between cancer cells and CD8+ T cells (P=0.041), and multivariate analysis also showed that it was an independent prognostic factor. On the other hand, there was no significant difference in the 5-year overall survival rate (P=0.41). Furthermore, it was found that the CLI of the three-way interaction between cancer cells, macrophages, and CD8+ T cells was also an independent prognostic factor.
Conclusion: Cu-Cyto has achieved highly accurate cell determination by introducing a bit pattern kernel filtering algorithm. CLI has shown correlation with patient prognosis as an objective and reproducible quantitative evaluation method for cell-cell interactions. In the future, it will be necessary to elucidate the oncological and biological significance of the combinations of each cell type.

#6254 Detection of anti-CMV TCR CDR3s correlates with increased survival for soft tissue sarcoma and stomach adenocarcinoma.

Utsav Kapoor[1], Michael T. Aboujaoude[1], Konrad Cios[1], Andrea Chobrutskiy[2], Boris I. Chobrutskiy[2], George Blanck[3]

[1]Molecular Medicine, USF Health Morsani College of Medicine, Tampa, FL,[2]Pediatrics, Oregon Health and Science University, Tampa, OR,[3]Molecular Medicine and Immunology, USF Health Morsani College of Medicine and Moffitt Cancer Center, Tampa, FL

Introduction: While the role of anti-cytomegalovirus (CMV) T-cell responses in the cancer setting is becoming increasingly recognized, the association between CMV and survival outcomes has not been subject to study through more recent immunogenomic approaches. This study aimed to investigate the association between anti-CMV T-cell receptor (TCR) sequences and improved survival outcomes in two types of cancers where the role of CMV remains currently underexplored, stomach adenocarcinoma (STAD) and soft tissue sarcoma (SARC). The significance of this study is that, to our knowledge, it is the first to identify a potential prognostic role of CMV in both STAD and SARC and highlights the potential for future development of anti-CMV T-cell therapies.
Methods: We extracted TCR recombination reads from whole exome sequencing (WXS) and RNA sequencing (RNASeq) files of STAD and SARC samples from the Cancer Genome Atlas (TCGA) and matched the corresponding TCR complementarity determining region-3 (CDR3) AA sequences represented by these reads to known anti-CMV CDR3 sequences.
Results: Results indicated that, in STAD cases, the recovery of both TRA and TRB recombination reads from WXS files, from either normal blood or tumor samples, which corresponded to AA sequences matching anti-CMV CDR3s, correlated with improved disease-free survival (DFS) (logrank p=0.025) and improved overall (p=0.026), progression-free (p=0.015), and disease specific (p=0.026) survival on an STP comparison (i.e., a comparison at 45 months). Within the SARC WXS dataset, these were associated with better overall survival (OS) (logrank p=0.021) and disease-specific survival (DSS) (logrank p=0.008). However, TCR CDR3s represented by recombination reads recovered from RNAseq files and matching anti-CMV TCR CDR3 AA sequences correlated with lower DFS probabilities (i.e., STAD STP comparison at 45 months, p=0.035, SARC STP comparison at 65 months, p=0.032).
Conclusion: This study reveals a novel association between anti-CMV TCR sequences and survival probability in STAD and SARC. This suggests that TCR CDR3s may be possible indicator of prognosis for STAD and SARC and supports further research into anti-CMV CDR3s as a tool for the development of immunotherapy for these cancers. Additionally, the contrasting results between WXS and RNASeq-derived sequences warrant further investigation into the timing and nature of anti-CMV immune responses in cancer progression. One explanation for these results include the possibility that exposure to CMV prior to onset or progression of cancer may lead to better survival probability, while a potentially active T-cell response to CMV during cancer onset or progression could represent an ongoing comorbidity.

#6255 Patient response to immune checkpoint inhibitors (ICI) informs neoantigen prioritization: Applications to personalized cancer vaccines (PCVs) and ICI response prediction.

R. Burns, S. L. Bristow, J. B. Ortiz, M. Malhotra, J. Hundal, A. M. Rosenfeld, H. A. Costa, A. Aleshin, M. Rabinowitz;
Natera, Austin, TX

Accurate identification of neoantigens that can stimulate a cytotoxic immune response is essential in designing PCVs. Here, we describe the design and performance of a neoantigen prioritization model for PCV design and ICI response prediction.The machine learning (ML)-based neoantigen prioritization model was implemented using tumor and matched normal whole exome sequencing data and clinical information to identify candidate neoantigens. Neoantigens were grouped across combinations of three characteristics: MHC-I binding IC50, T-cell immunogenicity predictions, and inferred gene expression. For each neoantigen combination, ICI response, as measured by progression-free survival (PFS), was compared using Cox proportional hazards tests. Statistically significant hazard ratios were used as a prioritization metric for each neoantigen combination. Model performance for neoantigen prioritization was evaluated using three publicly available datasets (TESLA N=8, NCI N=97, HiTIDE N=10) with known immunogenic, true-positive (TP) neoantigens. The percent of TP neoantigens prioritized within the top 100, 50, and 20 per patient was computed. Furthermore, a real-world clinical cohort (N=543; training 80%, test 20%) and an additional 66 patients with solid tumors from the Bespoke IO clinical study were utilized to validate our model for ICI response prediction as compared to TMB.In this cohort, hazard ratios of candidate neoantigens correlated with higher inferred gene expression and inversely correlated with IC50 and T-cell activation rank. In a separate analysis, we demonstrated that TCGA-based inferred gene expression, in the absence of patient-matched RNAseq, was sufficient to identify immunogenic neoantigens. Across all three test sets, the known TPneoantigens were consistently prioritized in the top 100 (NCI 89.7%, TESLA 91.4%, HiTIDE 96.4%) and top 50 (NCI 77.2%, TESLA 80.0%, HiTIDE 78.6%). Approximately half of TP neoantigens were prioritized in the top 20 (NCI 54.5%, TESLA 54.3%, HiTIDE 46.4%). These results outperformed other methods that have used TESLA data. The classification of patients into non-responders and responders was significantly better by our model for ICI response prediction [melanoma (HR: 13.69, p=0.0005), NSCLC (HR: 5.79, p=0.036) and MSI-H CRC (HR: 23.1, p=0.0001)] compared to TMB [melanoma (HR: 2.56, p=0.07), NSCLC (HR: 1.04, p=0.96) and MSI-H CRC (HR: 3.31, p=0.09)]. Similar trends were observed in the blinded validation cohort [(model: HR=3.16, p=0.006) vs. TMB (HR=1.47, p=0.33)].Our ML-based neoantigen prioritization model is the first to our knowledge to be informed by in vivo ICI response that effectively identifies and prioritizes immunogenic neoantigens for PCV design and ICI response prediction.

#6256 Dissecting tumor-intrinsic programs and immune dynamics driving response to immunotherapy in metastatic melanoma through non-negative matrix factorization decomposition.

Priyanka Solanky[1], Giuseppe Tarantino[1], Yiwen He[2], Xinyu Cui[2], Kathleen Pfaff[3], Aaron R. Thorner[4], Tyler J. Aprati[4], Boyang Zhang[5], Timothy Blosser[6], Jiajia Chen[4], Junko Tsuji[4], Elliot Boblitt[6], Allison Frangieh[3], Hannah Mae Faulkner[3], Marta M. Holovatska[3], Aleigha R. [1]Harvard Medical School, DFCI, Broad Institute, Boston, MA,[2]Immunology, DFCI/Harvard Medical School, Boston, MA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]DFCI, Broad Institute, Boston, MA,[5]Stanford University, Stanford, CA,[6]Broad Institute of MIT and Harvard, Cambridge, MA,[7]Massachusetts General Hospital, Boston, MA,[8]Brigham and Women's Hospital, Boston, MA,[9]MIT, Cambridge, MA,[10]Chemistry, Harvard University, Cambridge, MA,[11]DFCI/Broad Institute, Boston, MA

Background: Understanding the biological mechanisms underlying differential responses to immunotherapy is critical for advancing treatment strategies in metastatic melanoma. We analyzed single-nucleus RNA sequencing data from 66 melanoma samples, including 18 with matched spatial transcriptomics data via MERFISH, across metastatic sites such as lymph nodes, colon, skin, lung, brain, and liver. Our study aimed to identify tumor-intrinsic transcriptional programs and their association with durable clinical benefit.
Methods: We employed non-negative matrix factorization to delineate distinct tumor programs within tumor cells. To assess the robustness and biological relevance of these programs, we conducted hallmark pathway analyses and utilized spatial transcriptomics to examine their associations with biopsy sites, response, and immune infiltration. Comparisons with published datasets were performed to characterize and ensure the stability and applicability of these programs.
Results: We identified five distinct tumor programs with differential enrichment between responders and non-responders. Tumor programs enriched in responders demonstrated strong associations with interferon alpha-beta signaling and antigen presentation pathways. This program was also enriched across diverse lymphocyte populations. Via MERFISH analysis, we classified patients into three categories based on the spatial distribution of immune cells relative to tumor borders: immune-enriched, immune-excluded, and immune-desert. Notably, the program enriched in responders was prevalent in the immune-excluded samples, suggesting that robust signaling pathways can drive therapeutic responses even in the absence of high immune infiltration. In contrast, a mesenchymal-like tumor program was predominant in non-responders, characterized by elevated epithelial-mesenchymal transition activity and diverse tumor-associated macrophage infiltration. This program was particularly enriched in colon metastases.
Conclusion: Our findings underscore the importance of interferon signaling in driving therapy response and the role of mesenchymal-like programs in resistance. The unique association of immune-excluded but therapy-responsive samples with interferon-related pathways raises intriguing questions about tumor-immune dynamics. By integrating single-cell and spatial transcriptomics, this study provides insights into tumor heterogeneity and the tumor microenvironment, offering avenues for targeted therapeutic interventions. Future research will focus on spatial interactions, the characterization of immune subpopulations within tumor programs, and the dynamics of cell-cell communication between tumor and immune cells, aiming to refine and advance personalized treatment strategies.

#6257 Spatial and multi-omic profiling of metastatic colorectal cancer reveals key cellular ecosystems and drivers of heterogeneity.

Chien-Wei Peng[1], Michael Iglesia[1], Adrienne Visani[2], Xiang Li[1], Xiangwei Fang[1], Reyka G. Jayasinghe[1], Jingxian Liu[1], John Herndon[2], Jacqueline Mudd[1], Andrew Houston[1], Preet Lal[1], Siqi Chen[1], Ambrose Plante[1], Andre Targino da Costa[1], Kapur B. Dhami[1], Jennifer Ponce[3], Robert Fulton[3], Michael Heinz[3], Milan Chheda[4], Feng Chen[5], Ryan C. Fields[2], Li Ding[1]

[1]Department of Medicine, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Department of Surgery, Washington University School of Medicine in St. Louis, St. Louis, MO,[3]McDonnell Genome Institute, Washington University School of Medicine in St. Louis, St. Louis, MO,[4]Department of Neurology, Washington University School of Medicine in St. Louis, St. Louis, MO,[5]Department of Nephrology, Washington University School of Medicine in St. Louis, St. Louis, MO

Colorectal cancer (CRC) metastasis is highly aggressive and associated with poor outcomes. Recent studies have highlighted greater heterogeneity in gene expression within metastatic tumor cells compared to primary tumor cells. However, the underlying factors driving these differences remain poorly understood. We hypothesize that both genetic alterations and the tumor microenvironment play key roles in shaping this heterogeneity. To investigate these aspects, we established a cohort through the Human Tumor Atlas Network composed of 26 primary CRC samples and 41 metastatic CRC samples from multiple organs. We conducted whole exome sequencing (WES), single-nucleus ATAC/RNA-seq (snATAC/RNA-seq), and spatial transcriptomics (Xenium) assays to comprehensively analyze genetic alterations, gene expression patterns, and their spatial relations. Our findings revealed a higher proportion of TP53 and KRAS mutations in metastatic samples compared to primary tumor samples. Analysis of snRNA-seq data identified distinct tumor cell populations characterized by gene signatures from 12 published gene expression modules. Primary tumor cells were predominantly enriched for tumor intestinal stem cell-like and intestinal modules, while metastatic tumor cells showed higher representation of injury repair, epithelial-mesenchymal transition (EMT), osteoblast-like, and neuroendocrine modules. Notably, a microsatellite instability-high (MSI-high) metastatic sample exhibited relatively higher signatures of absorptive intestinal and squamous cancer modules than other microsatellite-stable samples, suggesting a unique gene expression profile in MSI-high CRC metastasis. To spatially study these cancer modules, we defined spatial tumor microregions as regions of tumor cells separated by stromal tissues. Using the Xenium assay, we mapped the gene modules within these microregions and observed significant enrichment of EMT and injury repair modules at the peripheral tumor microregions in metastatic samples. Conversely, the hypoxia module was more prominently enriched at the core of tumor microregions in metastatic samples compared to primary tumors. These findings suggest a strong association between tumor cell location within the microenvironment and their gene expression profiles, shedding light on the spatial dynamics of tumor heterogeneity in CRC metastasis. In summary, our results suggest that the heterogeneity of gene expression in metastatic CRC is driven by genetic alterations and strongly influenced by the tumor microenvironment.

#6258 Inter- and intra-tumoral heterogeneity of TNBC determined by spatial gene transcriptomics.

Fengyuan Huang[1], Deepa Bedi[1], Clayton Yates[2]

[1]Center for Biomedical research, Tuskegee University, Tuskegee, AL,[2]School of Medicine, Johns Hopkins University, Baltimore, MD

Triple-negative breast cancer (TNBC), one of the most aggressive subtypes of breast cancer, is associated with poor prognosis and limited treatment options, particularly when diagnosed at later stages. The extensive inter- and intra-tumoral heterogeneity observed in TNBC further complicates its clinical management. Understanding the molecular difference within this TNBC is crucial for elucidating its biological characteristics and clinical behaviors, as well as for developing personalized therapeutic approaches. In this study, we employ digital spatial profiling (DSP) technology to quantitatively analyze transcript and protein abundance across spatially distinct regions of TNBC, including primary tumor cores, surrounding stroma regions, and metastatic sites. The analysis reveal marked spatial heterogeneity in gene expression profiles, cellular composition, and the immune microenvironment across these regions. Additionally, we identify distinct TNBC subtypes based on unique gene expression patterns. In primary tumor, Basal-like 1 (BL1) emerged as one of the predominant subtypes and was associated with an increased present of memory B cells. We also identified a subgroup resembling unclassified (UNS) subtypes, characterized by low macrophage levels. Moreover, tumor tissues exhibited multiple TNBC subtypes within a single tumor site. This intricate subtyping within the tumor mass underscores the challenges associated with developing effective treatment for TNBC. Our findings demonstrate the power of DSP technology in elucidating the spatial dynamics of TNBC at the molecular level. The identified molecular signatures and subtypes hold potential for improving diagnostic accuracy, enabling targeted drug development, and guiding personalized treatment approaches. Ultimately, this work underscores the utility of spatial transcriptomics for addressing the challenges posed by TNBC heterogeneity and advancing precision medicine for this aggressive cancer subtype.

#6259 Spatial transcriptomics-driven in silico modeling of therapeutic effects of antibody-drug conjugates and their association with treatment response in lung adenocarcinoma.

Sungwoo Bae, Minki Choi, Hongyoon Choi, Dongjoo Lee, Kwon Joong Na, Daeseung Lee

Portrai, Inc., Seoul, Korea, Republic of

Background: Antibody-drug conjugates (ADCs) are targeted therapies that deliver cytotoxic payloads to cells expressing specific antigens. Despite their increasing use in clinical trials for advanced non-small cell lung cancer (NSCLC), many patients experience suboptimal outcomes. While ADC efficacy depends on factors such as antibodies, linkers and payloads, the impact of the tumor microenvironment (TME) remains unclear. This study uses spatial transcriptomics (ST) to investigate the spatial dynamics influencing ADC efficacy within the TME of NSCLC.

Methods: Visium ST datasets from 36 lung adenocarcinoma (LUAD) tissues were analyzed to identify factors influencing ADC efficacy. Key indices included Target Specificity Score (TSS), which reflects the ratio of target expression in malignant versus normal epithelial cells; Target-Linker Match Score (TLM), which measures overlap between target regions and linker enzyme activity; Therapeutic Index (TI), calculated as TSS × TLM; and Intratumoral Target Expression (ITE), which quantifies average target expression. To evaluate the bystander effect, Moran's I index assessed spatial clustering patterns of target expression, and Minimum Target-High Distance (MTHD) assessed the average of the minimum distance from low to high target expression regions. Fifteen ADCs were selected from NSCLC clinical trial data, including targets, linkers, and overall response rates (ORRs). Correlations between spatial indices and ORRs were analyzed to validate the utility of the indices.

Results: Of the 36 tissues analyzed, 3 were excluded due to insufficient or excessive tumor regions. Among the six indices evaluated, only MTHD showed a strong negative correlation with the reported ORRs (Spearman's R: -0.715, $p = 0.003$). This suggests that shorter distances between low and high target expression regions are associated with improved ADC efficacy, highlighting the critical role of spatial homogeneity in the bystander effect. To further evaluate the potential of the indices in identifying ADCs with poor therapeutic efficacy, we compared the indices between ADCs with ORR values below the 10th percentile (ORR Low) and those above (ORR High); only the TSS showed a significant difference ($p < 0.05$). ROC analysis identified a TSS cut-off value of 4.744, yielding an AUC of 0.962 for discriminating between ORR Low and High groups.

Conclusion: Spatial indices derived from spatial transcriptomics, particularly those reflecting target specificity and bystander effect, were found to significantly influence treatment response and predict ADC failure, respectively. This in silico modeling approach offers a promising screening method to identify ADCs with the highest potential for therapeutic efficacy.

#6260 Characterization of the tumor microenvironment's histologic landscape through histology-based deep learning spatial transcriptomic cell-type deconvolution of colon tumors.

Minh-Khang Le[1], Gokul Srinivasan[1], Fred Kolling[2], Keluo Yao[1], Alos Diallo[2], Zarif Azher[1], Louis J. Vaickus[3], Xiaoying Liu[3], Joshua Levy[1]

[1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]Dartmouth College Geisel School of Medicine, Hanover, NH,[3]Dartmouth Health, Lebanon, NH

The tumor microenvironment (TME) is an essential component of cancer biology. TME-derived measures such as tumor-infiltrating lymphocytes proportions (TILs) and tumor-stroma ratio (TSR) are used to evaluate TME composition. We leveraged spatial transcriptomics (ST) data from colon tumors to deconvolve cell-type populations and developed a deep learning (DL) algorithm to infer local ST-derived TIL and TSR estimates reflecting TME heterogeneity from held-out H&E whole slide images (WSIs). A total of 44 colon tumors surgical sections were profiled using matched H&E WSI and Visium ST, with 10 patients profiled for single-cell RNASeq. A pathologist annotated tumor microarchitecture within each slide. A total of 284,770 512x512 pixel^2 image patches were extracted and paired with corresponding Visium ST spots. Using SCANVI, cell type labels from the Human colon cancer atlas (c295) were lifted over to our in-house scRNASeq data. Cells were mapped spatially to estimate spot-level cell-type proportions using Cell2Location (C2L). Cell-type mapping was validated through human-in-the-loop (HITL) testing, where 512-pixel image crops around 400 randomly selected spots were annotated at each pixel. Spot-level TIL/TSR measures were estimated using cell-type proportions from the C2L-transformed ST data and proportion of pixels within each patch assigned to lymphocytes and tumor. Next, Virchow, a state-of-the-art deep learning pathology foundation model, was used to extract spot-level histological features- a Random Forest model was trained on spot-level features to infer cell-type proportions. Spot-level performance for cell-type mapping (evaluated through HITL) and cell-type proportion inference from histology was measured using the area under the curve (AUC) on a held-out test set of 9 patients. HITL tests demonstrated high agreement between H/ST-TIL (AUC=0.71; 95% CI: [0.60-0.82]) and H/ST-TSR (AUC=0.86; 95% CI: [0.81-0.92]). DL spot-level cell-type deconvolution within tumor-only slide regions achieved a macro-averaged AUC of 0.812 (Tumor: 0.85, Mesenchymal: 0.91, Lymphocytes: 0.79, Monocytes: 0.76, Mast: 0.79, Plasma: 0.78). Previous work inferred spatial expression patterns across broader regions, reporting cell-type AUCs of Tumor: 0.93, Mesenchymal: 0.82, Lymphocytes: 0.76, Monocytes: 0.74, and Mast: 0.91. Our results show that DL can infer ST-labeled cell types from H&E WSI, capturing TME features beyond tissue architecture. HITL testing demonstrated strong concordance between derived spot-level ST-TSR/TIL metrics with their histology-based counterparts (H-TSR/TIL), with utility for pathologist validation of spatially mapped cell-type data. This study highlights future potential of DL to capture spatial distribution of TME measures as prognostic biomarkers through ST inference from histology.

#6262 Changes in the spatial architecture of the tumor microenvironment associated with treatment resistance in muscle invasive bladder cancer.

Nikolay Alabi[1], Nicolas Zheng[2], Joshua Scurll[2], Jussi Nikkola[2], Alberti Contreras-Sanz[2], Morgan Roberts[2], Ali Bashashati[1], Peter Black[2]

[1]University of British Columbia, Vancouver, BC, Canada,[2]Vancouver Prostate Centre, Vancouver, BC, Canada

Approximately one-third of bladder cancer (BC) patients are diagnosed with muscle-invasive bladder cancer (MIBC). Despite recent successes in clinical trials with neo-adjuvant therapies such as checkpoint inhibitors and chemotherapy, clinical implementation is hindered by a lack of biomarkers to guide therapy decisions, as not all patients respond to certain treatments. While the prognostic value of immune biomarkers in BC has been studied in the tumor microenvironment (TME), previous studies only evaluate single therapies, lack comparison to untreated groups, and fail to examine post-treatment residual tissue, limiting cross-therapy comparisons. Most studies have also relied solely on immune cell densities, ignoring spatial immune interactions critical for anti-tumor responses. Measuring spatial relationships (SRs) between immune cells in the TME provides a mathematical description of proximity and adjacency, which is more biologically relevant. Associations between SRs, prognosis, and treatment response have been reported across cancer types. For MIBC, analyzing SRs may improve tumor immunology insights and reveal treatment-response biomarkers. We analyzed four MIBC cohorts using multiplex immunofluorescence (mIF, three panels with six markers): 49 pre-NAC, 90 pre-CPI (pembrolizumab), 41 pre-NAC and CPI (nivolumab), and 70 untreated, plus corresponding residual tissue (N=26, 13, 20, and 35). A univariate logistic regression model identified spatial immune features associated with treatment resistance, examining metrics like first nearest neighbor (1NN) distances (e.g., median, Weibull distribution shape/scale) and frequency of cellular triads (interaction patterns). Model coefficients were exponentiated into interpretable odds ratios (ORs) for resistance associations. Multiple immune features were linked to NAC resistance. For example, pre-treatment, a higher Weibull shape parameter for CD4+ T cells and Tregs was associated with resistance to NAC (OR = 0.22, 95% CI [0.05, 0.67], p = 0.02). Similarly, increased pre-treatment abundance of triads involving B cells, CD4+ T cells, and Tregs was associated with NAC resistance (OR = 0.77, 95% CI [0.55, 0.94], p = 0.04). Importantly, these associations were NAC-specific, as no negative prognostic associations were observed in untreated patients (Weibull shape: OR = 2.22, 95% CI [0.71, 8.2], p = 0.19; triads: OR = 0.99, 95% CI [0.97, 1.01], p = 0.33). These findings highlight the potential of spatial immune metrics to refine biomarker identification and improve personalized treatment strategies in MIBC.

#6263 Multi-transcriptomic analysis reveals tumor microenvironment differences associated with anti-EGFR therapy responsiveness between left- and right-sided colorectal cancer.

Atsuki Taniguchi, Shunsuke Kagawa, Shohei Nogi, Nobuhiko Kanaya, Yoshihiko Kakiuchi, Satoru Kikuchi, Shinji Kuroda, Hiroshi Tazawa, Toshiyoshi Fujiwara

Okayama University Hospital, Okayama, Japan

Background: Regarding the sidedness of colorectal cancer, right-sided colorectal cancer (RCRC) and left-sided colorectal cancer (LCRC) originate from the midgut and hindgut, respectively. It is known that in stages III and IV, RCRC has a poorer prognosis compared to LCRC. Furthermore, the prognosis of colorectal liver metastasis (CRLM) also varies depending on the primary tumor's sidedness. Although differences such as MSI-H status, BRAF mutations, and histological types have been noted between right- and left-sided colorectal cancers, clinical observations have recognized that differences in treatment efficacy exist even when these factors are excluded. This study aimed to compare left- and right-sided colorectal cancers based on their responsiveness to anti-EGFR therapy and to elucidate differences in cancer cells and the tumor microenvironment (TME).
Methods: We collected microsatellite stable (MSS) and BRAF mutation-negative cases from six scRNA-seq cohorts, integrating data from 28 right-sided and 57 left-sided cases. Specifically, on the left side, only KRAS wild-type cases that respond to anti-EGFR inhibitors were included. Cancer cells were extracted from the integrated data, and differences in the therapeutic effects of anti-EGFR drugs were analyzed. Subsequently, focusing on cancer-associated fibroblasts (CAFs) that strongly interact with cancer cells, we analyzed differences in cell-cell communication within the TME.
Results
After extracting cancer cells and performing pseudobulk analysis and PCA, significant differences were observed between cancer cells of left-sided and right-sided colorectal cancers. Furthermore, evaluation of copy number variations (CNVs) using inferCNV revealed that left-sided colorectal cancers exhibit higher chromosomal instability (CIN). In analyses related to responsiveness to anti-EGFR therapy, it was confirmed that the expression of EREG (epiregulin), one of the EGFR ligands, was significantly higher in left-sided colorectal cancers. Additionally, focusing on cell-cell communication within the TME mediated by EREG, we found that only cancer cells of left-sided colorectal cancer interact with fibroblasts—especially inflammatory CAFs (iCAFs)—through the EGF pathway.
Conclusion: This study identifies key differences in tumor cell characteristics and the TME between RCRC and LCRC. The higher responsiveness of LCRC to anti-EGFR therapy may be attributed to intrinsic features such as elevated EREG expression and CIN, as well as enhanced interactions with fibroblasts via the EGF pathway. These findings provide insights into the mechanisms underlying the differential efficacy of anti-EGFR therapy based on tumor sidedness.

#6265 Cross-tissue atlas of human disease identifies tumor-specific components in tumor microenvironment.

S. Kim, S. Cheong, S. Lee, Y. Kim, J.-E. Park;
Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Human diseases affect various cell types within the local niche, but the multicellular responses of human diseases have not been collectively assessed across organs. Here, we categorize multicellular responses of human diseases based on a remapped human cell atlas, incorporating 12 million single-cell transcriptome profiles acquired from an automated data collection pipeline. Additional curation expands the collection up to 46 million cells, covering 160 disease conditions across 49 distinct organ identities. From the re-aligned atlas of single-cell transcriptome data, we constructed a hierarchical cell classification framework comprising 32 major cell types and 165 cell subtype annotations. Systematic profiling of disease and organ association patterns of cellular subtype reveals archetypes of human diseases repeatedly found across organs, including a multicellular phenotype highly specific to the tumor microenvironment. The universal cell atlas could serve as a reference for unbiased deconvolution of spatial transcriptome datasets, revealing spatial distribution patterns associated with immunotherapy responses. Collectively, our study provides foundational resources for cross-tissue cell type annotation, presents a comprehensive multicellular overview of disease-associated responses across human tissues, and highlights multicellular responses in tumor microenvironments.

#6266 Spatial profiling of prognostic differences in the tumor microenvironment between primary and metastatic ovarian cancer using multiplexed protein imaging.

Raymond M. Moore[1], Brenna C. Novotny[1], Chathu L. Atherton[2], Matthew S. Block[3], Bryan M. McCauley[1], Stacey J. Winham[1], Ellen L. Goode[1], Ray Guo[4], Yajue Huang[5], Svetomir N. Markovic[6], Chen Wang[1]

[1]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[2]Department of Oncology, Mayo Clinic, Rochester, MN,[3]Departments of Oncology and Immunology, Mayo Clinic, Rochester, MN,[4]Department of Laboratory Medicine and Pathology, Mayo Clinic, Jacksonville, FL,[5]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[6]5. Departments of Oncology, Immunology, and Internal Medicine, Mayo Clinic, Rochester, MN

Background: The tumor microenvironment (TME) plays a pivotal role in ovarian cancer (OC) progression and prognosis, while also contributing to biological differences between primary and metastatic tumors. This study examines OC TMEs to uncover associations with clinical prognosis and tumor biology by analyzing paired primary and metastatic tumors from the same patients.
Methods: This study focused on 57 stage-IIIC/IV OC patients treated at the Mayo Clinic, all of whom underwent surgical debulking and adjuvant therapies. All patients provided informed consent, and the study received IRB approval. A tissue microarray (TMA) was specifically designed and constructed, containing paired primary and metastatic tissue cores from the same patients. 147 tissue cores from the constructed TMA were profiled using a 35-antibody panel, with 17 antibodies for cell phenotyping and 18 for functional state characterization. Profiling was performed using Cell DIVE, a multiplexed imaging solution at the single-cell level developed by Leica Microsystems. After cell segmentations and classifications, detailed spatial niche and regional analyses were performed at the single-cell level. Immune cell populations, as well as their TME distributions, were characterized to conduct prognostic associations and contrast primary and metastasis differences.
Results: A total of 1,292,988 total cells (after excluding low-density signals and ambiguous classifications) were analyzed, with a median of 8,033 cells per core. Using spatial neighborhood analysis, 12 distinct spatial niches were identified with specific cell types and/or unique functional states. Among these, a macrophage- and fibroblast-enriched niche at the tumor-stroma interface was associated with improved overall survival (p=0.008). Another rare Treg-enriched niche, along with other immune cells, demonstrated protective effects, particularly in patients with residual macroscopic tumors after debulking surgery (p=0.05), while no significant effects were observed in those without visible residual disease (p=0.8). When comparing primary and metastatic tumors, metastatic lesions exhibited significantly increased tumor mass (p=2e-4) and a notable reduction in helper T cells (p=0.04) in tumor areas, as well as significantly increased fibroblast cells in tumor-stroma interfacing regions (p=0.002), reflecting distinct immunosuppressive and tumor-promoting shifts.
Conclusion: This study reveals spatial and cellular differences in primary and metastatic OC TMEs, distribution differences linked to prognosis and surgical outcomes. These findings emphasize the potential of spatially resolved TME profiling to refine adjuvant and neoadjuvant therapeutic strategies.

#6267 Training a machine learning model to predict T cell cytokine secretion function using a novel single-cell flow cytometry method that measures kinetic phenotypes.

Sheldon J.J. Kwok[1], Yulia Shulga[1], Emane Rose Assita[1], Sarah Forward[1], Trevor Brown[1], Pratip Chattopadhyay[2]

[1]LASE Innovation Inc., Waltham, MA,[2]Talon Biomarkers, Whippany, NJ

Advances in high-dimensional single-cell analysis have transformed our understanding of cellular heterogeneity and its role in complex pathologies. Most datasets are acquired through single-cell RNA sequencing, which provides expression of thousands of genes on each cell at a given timepoint. The typical workflow involves identifying potential new cell types via clustering, generation of hypotheses, and followed by post-hoc experiments to test these hypotheses. Technical bottlenecks include the sparse and noisy nature of sequencing data, and the inability to link observations directly to function due to the destructive nature of sequencing.

Supervised machine learning (ML) is an increasingly useful approach to generate powerful predictive models of complex processes. This approach requires both high quality and high quantity of training data. An ideal method to acquire this data would be able to follow individual cells over time while measuring changes in phenotype and function. Here, we describe a novel single-cell method using non-destructive optical barcodes that enables acquisition of dynamic high-dimensional data at scale. We apply this method to generate unprecedented predictive models of single-cell function using a human T-cell activation model.

Our barcoding approach relies on laser particles (Kwok et al., Nat. Biomed. Eng. 2024) to track individual cells over time. T-cells are barcoded, activated, and measured repeatedly over time using a flow cytometer to capture kinetic changes in expression of protein biomarkers (“kinetic phenotyping”). We link these kinetic phenotypes to cytokine secretion function through a stimulation step and cytokine secretion assay. The single-cell phenotype-to-function datasets are then used to train ML models to predict cytokine secretion prior to stimulation.

We observed increased expression of CD25, PD-1 and CD69 in T cells post-activation from 2h to 48h, as expected. However, distinct kinetic patterns were observed. For example, while CD25 increased largely monotonically, there was significant transient expression of PD-1. These observations were consistent across multiple donors. We employed supervised ML (Random Forrest) to train a classification model to predict cytokine secretion from single-cell kinetic phenotypes. The model was validated using 5-fold cross-validation and achieved ROC-AUC values of 0.74 to 0.89 for predicting TNFa, IFNg and IL2 secretion. For each cytokine, we identified the most predictive biomarkers (and timepoint). Finally, we used our classification model to describe T-cell heterogeneity by probability of cytokine secretion and validated our method using conventional analyses. Our approach is expected to be of great utility for predicting single-cell function in complex systems, from immunotherapy development to cancer pathogenesis.

#6268 JANUS: A unified deep learning framework for predicting peptide binding to MHC I and II alleles.

Alan Perez-Rathke[1], Justin Balko[1], Jens Meiler[2]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Vanderbilt University, Nashville, TN

The accurate prediction of peptide binding to major histocompatibility complex (MHC) molecules is crucial for advancing cancer immunotherapy, particularly in the design of personalized cancer vaccines and in identifying antigens which may be predictive of immunotherapy-related adverse events. Existing computational models for prediction of peptide binding are generally restricted to a single MHC class. We hypothesize that a unified model capable of predicting peptide binding to both MHC I or MHC II alleles can lead to a synergistic improvement in model performance and thereby facilitate advances in cancer neoantigen discovery. Challenges to this approach include finding a universal encoding for both MHC I and MHC II candidate peptide binders as well as addressing data imbalances arising from training with disparate datasets. Using publicly available datasets including from the Immune Epitope Database (IEDB), we developed a novel deep learning framework JANUS (Joint Allele-specific Neural prediction of MHC I/II-binding Universal Sequences) that leverages biological sequence embeddings from a protein large language model and adapts our loss function to resolve data imbalance issues. The model utilizes a feed-forward multi-layer perceptron with dropout layers for regularization. Ultimately, this model explores whether a unified approach demonstrates competitive performance compared to current single class models, particularly regarding increased predictive accuracy for rare or infrequent alleles, or in scenarios with sparse data.

#6269 Advanced single-cell RNA-seq reveals complex interactions between circulating tumor cells and immune subtypes in prostate cancer.

Han Hong Huynh[1], Tzu-Hao Chang[2], Shauh-Der Yeh[3], Chia-Ling Hsieh[4], Shian-Ying Sung[4]

[1]International Master Program for Translational Science, College of Medical Science and Technology, Taipei Medical University, Taipei, Taiwan,[2]Graduate Institute of Biomedical Informatics, College of Medical Science and Technology, Taipei Medical University, Taipei, Taiwan,[3]Taipei Cancer Center, Taipei Medical University Hospital, Taipei, Taiwan,[4]International Master and Ph.D. Program for Translational Science, College of Medical Science and Technology, Taipei Medical University, Taipei, Taiwan

Background: Prostate cancer is marked by extensive cellular diversity within its tumor microenvironment (TME), significantly impacting disease progression and responses to treatment. The study aims to dissect this heterogeneity at the single-cell level, identify distinct subpopulations within key cell types such as circulating tumor cells (CTCs) and T lymphocytes, and uncover potential therapeutic targets.
Methods: We analyzed single-cell RNA-seq data from 16 prostate cancer samples, which included over 170,000 cells. Initially, we performed data integration and normalization using Reciprocal Principal Component Analysis (R-PCA) to mitigate batch effects and enhance data quality. For dimensionality reduction, both PCA and UMAP (Uniform Manifold Approximation and Projection) were applied, allowing us to visualize and identify patterns in the high-dimensional dataset. Clustering of cells was conducted using the k-means algorithm to categorize cells into distinct clusters based on their gene expression profiles. Finally, cell type classification within these clusters was achieved using Support Vector Machines (SVMs), enabling the precise identification of cellular identities and states based on their molecular signatures.
Results: Our comprehensive analysis unveiled a remarkable diversity among the circulating tumor cells (CTCs) within the Taiwanese prostate cancer tumor microenvironment. Specifically, we identified four distinct CTC clusters, each infused with different cellular components that suggest unique roles in tumor dynamics. CTC1 is comprised purely of epithelial cells, presenting a classical phenotype of circulating tumor cells, which underscores the conventional understanding of CTCs in cancer dissemination. Meanwhile, CTC2 is characterized by an infusion with N1 neutrophils, highlighting its potential role in promoting inflammatory responses that could affect tumor growth and patient prognosis. In contrast, CTC3 includes an infusion with N2 neutrophils, indicating a possible contribution to enhanced tumor progression and metastatic potential, thereby suggesting a target for therapeutic intervention to curb tumor spread. Lastly, CTC4 is infused with plasmacytoid dendritic cells, which are known for their role in immune suppression, thereby aiding the tumor in evading immune surveillance.
Conclusion: This study underscores the utility of single-cell technologies in uncovering the complex cellular interactions within prostate cancer. By detailing the unique profiles of CTC subclusters and their associations with specific immune cells, our research provides novel insights into the tumor microenvironment and identifies new targets for immunotherapy. Future research will focus on validating these markers and integrating broader genomic data to refine treatment approaches and enhance patient outcomes.

#6270 AI-derived tumor-infiltrating lymphocytes predicts risk of invasive breast cancer recurrence in ductal carcinoma in situ (DCIS).

Sara Ranjbar[1], Xiaoxi Pan[1], Karina Pinao[1], Caner Ercan[1], Roberto Salgado[2], Hugo M. Horlings[3], Allison Hall[4], Lorraine M. King[5], Carlo Maley[6], E Shelly Hwang[5], Yinyin Yuan[1], Simon Castillo[1], Pingjun Chen[1]

[1]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Pathology, ZAS Hospitals, Antwerp, Belgium,[3]Department of Pathology,, The Netherlands Cancer Institute, Amsterdam, Netherlands,[4]Department of Pathology and Laboratory Medicine, The University of British Columbia, Vancouver, BC, Canada,[5]Duke University School of Medicine, Durham, NC,[6]Center for Evolution and Medicine, Biodesign Institute and School of Life Sciences, Arizona State University, Tempe, AZ

Background: The abundance of tumor-infiltrating lymphocytes (TILs) has demonstrated prognostic value in breast cancer recurrence. However, manual TIL assessment is both time-consuming and prone to inter-observer variability. This study aimed to evaluate the performance of two AI-based TIL scoring pipelines, emphasizing the added value of incorporating tissue-based context insights for automated TILs scoring.

Methods: We compared two in-house AI-based TILs scoring pipelines using the Translational Breast Cancer Research Consortium DCIS cohort. The first pipeline employs single-cell classification to identify epithelial, lymphocyte, stromal, and other cell types, followed by spatial analysis of immune populations relative to epithelial cells through clustering (AI-TILs-cluster). The second pipeline builds on this foundation by integrating a tumor microenvironment segmentation model as context guidance to compute the proportion of lymphoid cells within the epithelium and stromal compartments (AI-TILs-seg). In a cohort of 45 retrospectively collected hematoxylin and eosin (HE)-stained whole-slide tissue sections from 38 patients with available pathologists manual TILs, we evaluated the correlation of both scores and the median manual TIL score across the pathologists. Additionally, we assessed the prognostic value of the AI-derived TILs in 232 patients (530 HE slides) with up to 228 follow-up months (median: 78 months) by examining the association of per-patient AI-TILs with time to invasive breast cancer recurrence. This analysis was conducted using a multivariate Cox Proportional Hazards model that included patient age, tumor grade, DCIS lesion size, and estrogen receptors (ER) and progesterone receptors (PR) status.

Results: AI-TILs-cluster was not significantly correlated with median pathologist TILs, AI-TILs-seg, however, demonstrated a moderate correlation (Spearman's rho = 0.43, p = 0.003). This finding was expected as the automatic scores were not designed to replicate the manual TILs. AI-TILs-seg was associated with an increased risk of invasive breast cancer (Hazard Ratio = 1.067, 95% Confidence Interval: 1.017-1.119, p= 0.008) independent of other variables. In comparison, the multivariate analysis including AI-TILs-cluster did not show significance in predicting the risk of invasive breast cancer.

Conclusion: These findings suggest that incorporating contextual tumor microenvironment segmentation can enhance AI-derived TIL scoring, leading to better alignment with pathologist assessments and improved clinical relevance. Future work will focus on validating this scoring approach in larger cohorts and improving correlation with pathologist TILs.

#6271 Interactions between CD8⁺ T cells and tumor cells decode tumor heterogeneity and provide treatment recommendations for colorectal cancer.

Hongyu Huang[1], Zize Zhao[1], Fan Huang[1], Luoxinyi Yang[1], Shichu He[1], Boya Mu[1], Xiaoyue Liu[1], Ruixi Li[1], Yaqi Guan[1], Jiahao Li[1], Chen Gu[1], Jing Xu[2], Na Li[1]

[1]Nankai University School of Medicine, Tianjin, China,[2]Department of Colorectal Surgery, Tianjin Union Medical Centre, Tianjin, China

Introduction: Individual heterogeneity in colorectal cancer (CRC) remains a major challenge in therapy optimization, despite diagnostic and treatment advances. CD8⁺ T cells, pivotal players in anti-tumor immunity, display diverse functional subtypes shaped by interactions within the tumor microenvironment (TME). However, the specific role of CD8⁺ T cells in mediating heterogeneity through interacting with CRC cells, as well as their influence on the immune response of CRC, remains poorly understood. Here, we employ multi-transcriptomic analyses to discover the factors underlying patient heterogeneity based on interactions between various CD8⁺ T cell subtypes and CRC cells and develop effective, personalized therapeutic strategies.

Methods & Results: Data analysis of CRC patients was conducted by harmonizing information from reputable public databases. Single-cell analysis was used to investigate the functionality and evolutionary trajectories of various CD8⁺ T cell subgroups. Cellular interactions and spatial omics analyses were employed to examine the receptor-ligand pairs between CD8⁺ T cell subtypes and CRC cells. Based on TCGA-CRC data, patients were classified into three prognostically distinct clusters through consensus clustering of the receptor-ligand pairs. Among them, cluster 2 (C2) was the most crucial one with poorest prognosis. TME patterns were predicted with multiple algorithms, and immunotherapy responses were evaluated using the TIDE and EaSleR analysis. Notably, C2 was significantly associated with exhausted CD8⁺ T cells and Tregs, with the lowest response to immunotherapy. High-activity transcription factors for each cluster were predicted using the univariate linear model, while hub genes were identified via WGCNA. Furthermore, functional insights into each cluster were derived from GO and KEGG enrichment analyses. We found that C2 exhibited up-regulated SMADs and SP1, signifying high immunosuppressive potential. Prognostic risk models were built utilizing multivariate Cox regression and LASSO analysis, identifying a predictive model for C2 including GPT, GPX3, etc., with robustness validated. Finally, using the oncoPredict algorithm, we predicted chemotherapy drug sensitivity and discovered that C2 showed a superior response to dasatinib and AZ960, while exhibiting resistance to ulixertinib.

Conclusions: This study provides critical insights into the complex interactions between CD8⁺ T cells and CRC cells, highlighting their pivotal role in tumor heterogeneity. Leveraging these findings, we developed a novel classification system for CRC patients that captured TME heterogeneity and stratified patients into distinct groups. This system lays a foundation for personalized therapeutic strategies based on tumor-immune dynamics, offering significant potential to improve prognosis for CRC patients.

#6273 AI-based serum proteomics models predict survival outcomes in NSCLC patients undergoing immunotherapy.

Junho Song[1], Leeseul Kim[2], Donghoon Shin[3], Jongwoo Kim[1], Taegyu Um[1], Allen Cho[4], Jaeyoung Bae[1], **Liam IL-YOUNG Chung**[1], Jeeyeon Lee[5], Young Kwang Chae[1]

[1]Northwestern University, Chicago, IL,[2]University of Chicago, Chicago, IL,[3]Metrowest Medical Center, Framingham, MA,[4]Weiss Memorial Hospital, Chicago, IL,[5]Kyungpook National University, Daegu, Korea, Republic of

Background: Clinical responses to immune checkpoint inhibitors (ICIs) are highly variable. Pre-treatment serum proteomic biomarkers offer a promising tool to predict response outcomes by capturing the biological mechanisms underlying response variability.
Methods: This retrospective cohort study analyzed pre-treatment serum samples from 158 consecutive locally advanced or metastatic (palliative intent treatment) NSCLC patients treated with ICI monotherapy or ICI-chemotherapy combination. Deep proteomic profiling via mass spectrometry identified protein interaction patterns, and three machine learning models—XGBoost, logistic regression, and multilayer perceptron (MLP)—were evaluated using 5-fold cross-validation. The primary outcomes were progression-free survival (PFS) and overall survival (OS) at multiple time points (3, 6, 9, 12, 36, and 60 months), with performance assessed using the area under the receiver operating characteristic curve (AUC).
Results: The study group had a median age of 70.8 years, with 51.9% female and 67.7% with adenocarcinoma. Smoking history showed 15.8% never smoked, 69.6% were former smokers, and 13.9% were current smokers. Performance status (PS) was 0 in 19.0%, 1 in 54.4%, 2 in 19.6%, and 3 in 5.7%. The median tumor mutational burden (TMB) was 5.3 mut/Mb, with PD-L1 <1% in 31.6%, >1% in 55.7%. Treatment regimens included mono-ICI (38.0%), dual ICI (13.9), and ICI + chemotherapy (48.1%). Median OS was 19.5 months, PFS was 6.6 months. Proteomic-based models showed varying performance across outcomes and time points. For PFS, XGBoost achieved the highest performance at 90 days (AUC=0.67), maintaining moderate prediction at 270 days (AUC=0.65) and 1 year (AUC=0.65). For OS, performance improved over time, with the best results at 1 year (AUC=0.61). Using 4,000 highly variable proteomic mass spectrometry features, risk stratification at 1 year OS showed significant differences between groups (log-rank p=0.05) in PFS, with median PFS of 187 and 283 days for high- and low-risk groups, respectively (HR=1.38, 95% CI: 0.95-2.02, log-rank p=0.09).
Conclusion: Serum proteomics-based AI model can predict PFS and OS in NSCLC patients treated with ICIs, achieving AUCs up to 0.67 for PFS and 0.61 for OS. Larger studies are needed to validate our findings.

#6274 Establishment of a quantitative systems pharmacology platform for syngeneic tumor mouse models: Application in immuno-oncology drug development.

T. Nakayama, A. Kikuchi, K. Toshimoto, H. Sayama, T. Nakazawa, M. Oishi;
Astellas Pharma Inc., Ibaraki, Japan

[Introduction] Quantitative Systems Pharmacology (QSP) modeling is a promising technique for model-informed drug discovery and development, and various QSP models for immuno-oncology (IO) have been published. Syngeneic tumor mice are often used for in vivo pharmacology study, and many kinds of IO QSP models have been reported to understand in vivo data and make prediction. However, published QSP models have varying structures across tumor types that makes it difficult to analyze data across different syngeneic tumor models. In addition, there are few QSP models calibrated by actual data of tumor infiltrating lymphocyte (TIL) dynamics. In this study, we present platform IO QSP modeling for syngeneic tumor mice (MC38, B16F10, CT26, 4T1 and LLC1) with a unified structure based on observed data of TIL dynamics and antitumor efficacy of anti-programmed cell death-1 (anti-PD-1) treatment.
[Methods] (Mouse study for TIL dynamics) Five mouse tumors were inoculated into C57BL/6 (MC38, B16F10, LLC1) or BALB/c (CT26, 4T1). Tumors were sampled at three time points (mean tumor volume was about 50 mm^3, 300-700 mm^3 and 500-2000 mm^3) and immune cells in the tumors were analyzed by flow cytometry. (IO QSP platform development) The structure of IO QSP platform was based on a published QSP model for CT26-bearing mice [1] and modified with reference to a comprehensive IO QSP model for breast cancer in human [2] to improve physiological interpretability of model components. The TIL dynamics data and published anti-mouse PD-1 (anti-mPD-1) antibody efficacy data for syngeneic tumor mice [3] were used for model calibration. The platform model was validated by confirming predictability of combination therapy of anti-mPD-1 antibody with a multiple kinase inhibitor (lenvatinib) for syngeneic tumor mice.
[Results] The IO QSP platform model contains 12 tumor-specific parameters for each tumor type of syngeneic mice and successfully captured the observed TIL dynamics and antitumor effect of anti-mPD-1 antibody treatment. Mechanism of action of lenvatinib was incorporated into the IO QSP platform and calibrated with published data. The final model was successfully validated by comparing simulation and observation of combination therapy of anti-mPD-1 antibody with lenvatinib.
[Conclusions] The IO QSP platform was established for several types of syngeneic tumor mice, which captured TIL dynamics and antitumor efficacy of anti-mPD-1 antibody. This platform model enables us to test a hypothesis by incorporating candidate compounds, to support study design with a translational biomarker and to investigate combination strategies, thus having the potential to facilitate new drug development. #6275 Leveraging the tumor microenvironment (TME) atlas to identify the best PDX-model for pre-clinical testing of TME targeting agents.

Mara Gilardi, Gilad Silberberg, Kurtis Cruz, Stefano Cairo, Marianna Zipeto, Michael Ritchie

Champions Oncology, Inc., Hackensack, NJ

Tumor-infiltrating immune cells play a critical role in tumor progression, metastasis, and resistance to anti-cancer therapies. This is particularly evident in the context of tumor evasion from immune surveillance, which is driven by tumor microenvironment (TME) modulation, ultimately impairing therapeutic efficacy. Consequently, accurately predicting the composition of immune populations within the TME holds great promise for uncovering the complex interplay between immune cells and tumors, as well as for the selection of the optimal pre-clinical model to test new TME-targeted therapeutics. The relevance of experimental settings in preclinical immunotherapy studies is often undermined by the lack of comprehensive TME characterization in the cancer models selected for pre-clinical testing. To address this gap, Champions Oncology generated the TME Atlas. Champions Oncology's preclinical program is built on Patient-Derived Xenograft (PDX), a highly accurate and clinically relevant platform for preclinical research. The PDX bank encloses 1500 models, characterized with transcriptomic, proteomic, and patient treatment history data to guide the model's selection mimicking the future clinical patient cohorts. On top of this, the TME Atlas will provide an additional layer of characterization to refine the model selection based on TME composition, including immune cells and fibroblasts. The TME Atlas derived from the transcriptomic data from Champions Oncology PDX bank and enabled the prediction of TME composition patterns in each specific model. To profile the TME, we applied different computational methods to Champions Oncology's proprietary datasets. The computational tool xCell was identified as the optimal strategy to perform cell-type enrichment analysis for 64 immune and stromal cell types. The implementation of xCell enabled comprehensive profiling of immune infiltration across the entire PDX bank. This detailed characterization of the TME unlocks the selection of optimal models and experimental settings to test TME-engaging drugs. Histological analyses further validated the computational findings enclosed in the TME Atlas. To validate the computational data, we engrafted selected PDX models in humanized mice and assessed TME composition in tumors through Immunohistochemistry (IHC). IHC analyses validated the profile predicted within Champions Oncology TME Atlas. This immune atlas enables the selection of the most suitable PDX models, and humanized hosts to optimize preclinical studies targeting immune and stromal components of the TME. This approach ensures clinically translatable results, that will advance the development of innovative TME targeting strategies.

#6276 Comparative analysis and integration of image-based and high-resolution sequence-based spatial transcriptomics platforms for tumor microenvironment analysis.

Dongjoo Lee, Yeonjae Jung, Jae Eun Lee, Myunghyun Lim, Daeseung Lee, Kwon Joong Na, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background: Advances in spatial transcriptomics (ST) enable precise gene expression analysis within the tumor microenvironment (TME). VisiumHD and Xenium Prime 5K are cutting-edge platforms offering unique strengths in spatial resolution, sensitivity, and multiplexity. This study evaluates their performance metrics in heterogeneous tumor tissues from the same slide, focusing on technical performance, spatial resolution, and cell type identification. Additionally, post-Xenium VisiumHD datasets were generated and integrated to harness the complementary strengths of both platforms. We aimed to investigate a head-to-head comparison in spatially registered ST to provide guidance for researchers in selecting the appropriate platform for specific cancer research objectives.
Methods: ST data were analyzed from tumor samples processed with Xenium Prime 5K followed by VisiumHD. Evaluations included transcript capture efficiency, gene detection sensitivity, and signal-to-noise ratios. Spatial resolution was assessed using cell- and transcript-level metrics, gene expression correlations, and spatial mapping accuracy. Cell type identification focused on assignment accuracy and rare population detection. Custom workflows integrated post-Xenium VisiumHD datasets, combining platform strengths for detailed TME analysis.
Results: Gene expression correlations were highly consistent across platforms. VisiumHD provided superior transcriptome-wide coverage (~18,085 genes), making it ideal for exploratory studies, while Xenium offered 2-3x greater per-gene sensitivity for detecting low-abundance transcripts. Xenium Prime 5K excelled in spatial resolution, with precise cell-level annotations, whereas VisiumHD mapped broader spatial patterns via deconvolution. Integration of Xenium cell segmentation with VisiumHD enabled single-cell transcript analysis with comprehensive gene expression data. This approach improved rare cell population detection and overcame limitations of individual platforms.
Conclusions: VisiumHD is ideal for transcriptome-wide exploratory studies, while Xenium Prime 5K excels in high-resolution, focused cellular analyses. Cross-platform integration bridges gaps between resolution and coverage, enabling robust analysis of complex TMEs. This study provides critical guidance for platform selection and highlights the potential of integrated approaches to advance cancer research through spatial transcriptomics.

#6277 A time-series mouse model identifies an early post-treatment effective liquid biomarker of ICB response in human head and neck cancer.

B. Wang[1], R. Saddawi-konefka[2], L. M. Clubb[3], S. Tang[4], D. Wu[5], S. Mukherjee[1], S. Sahni[1], S. R. Dhruba[1], K. Wang[5], J. Gutkind[3], E. Ruppin[1];
[1]NIH-NCI, Bethesda, MD, [2]UC San Diego School of Medicine, San Diego, CA, [3]UC San Diego, La Jolla, CA, [4]Stanford University, San Jose, CA, [5]University of Illinois Urbana-Champaign, Urbana, IL

Background & Approach: Immune checkpoint blockade (ICB) therapy has shown promise for head and neck squamous cell carcinoma (HNSCC); however, response rates remain limited, with only a subset of patients exhibiting significant clinical benefits. Identifying non-invasive liquid biomarkers to predict ICB response is crucial for optimizing patient selection and treatment strategies. In this study, we generate and analyze time-series RNA and T-cell receptor (TCR) sequencing data from blood in a murine HNSCC model treated with anti-PD-1 therapy to identify potential liquid biomarkers predictive of ICB response
Results: Our analysis reveals significant differences in the clonal expansion and temporal dynamics of effector T cells (Teff) and B cells between responders and non-responders, indicating distinct immune profiles associated with therapeutic outcomes. Notably, these immunological changes are most prominent at early post-treatment timepoints, suggesting that this period is optimal for assessing ICB efficacy and for the potential
identification of predictive biomarkers. Importantly, the Teff and B cell transcriptomic gene signatures identified at these early post-treatment timepoints predict ICB treatment responses in HNSCC patient cohorts without the need for additional training, underscoring their potential clinical utility. Further time-series ligand-receptor interaction analyses uncover potential immune cell communication pathways that may mediate ICB outcomes, offering insights into mechanisms underlying ICB resistance.
Conclusions: Our findings highlight the importance of early post-treatment timepoints for assessing ICB response and suggest blood-based Teff and B cell signatures as effective biomarkers for predicting ICB treatment outcomes in HNSCC patients. This study provides a potential framework for translating findings from murine models to human clinical practice, facilitating the development of personalized immunotherapeutic strategies.

#6278 Reprogramming of the tumor microenvironment via lipid-associated macrophage subtypes after neoadjuvant osimertinib treatment in *EGFR*-mutantnon-small cell lung cancer.

Su-Jin Choi, Jii Bum Lee, Hyo Sup Shim, Byung Jo Park, Chang Young Lee, Min Hee Hong, Byoung Chul Cho, Sun Min Lim

Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Despite treatment with adjuvant osimertinib, some patients experience relapse. NORA is a trial designed to identify persistent drug resistance (DTP) to neoadjuvant osimertinib in resectable non-small cell lung cancer (NSCLC) with *EGFR* mutations (NCT04816838). We aimed to identify tumor-surrounding cellular characteristics that change the tumor microenvironment (TME) after neoadjuvant osimertinib for surgically resected *EGFR*-mutant NSCLC.
Methods: Neoadjuvant osimertinib was given daily for two 28-day cycles followed by surgical resection and adjuvant osimertinib for 3 years. We performed single-cell RNA sequencing (scRNA-seq) on samples from 25 patients with *EGFR* mutations (Exon 19 deletion, N=10; L858R, N=15) before (N=18) and after (N=24) osimertinib treatment. The analysis was based on the Scanpy package in python, and the interaction was performed with Liana. We divided the pathological response according to major pathological response (MPR, N=6) and non-MPR (N=19).
Results: After 8 major clustering from total cells, 60 subclusters were divided. Among them, myeloid cells were classified into 14 clusters. We found 3 macrophage subclusters (MAC1-SELENOP, MAC3-SPP1, and MAC7-PLXDC2) that were significantly increased after treatment with neoadjuvant osimertinib. Macrophage polarization status using the signature scoring method showed that the M2 phenotype was the strongest in the MAC1-SELENOP subcluster, while the M0 signature was high in MAC3-SPP1, and the M1 signature was high in MAC7-PLXDC2. These three macrophage subclusters showed enrichment in lipid metabolism compared to those of pre-neoadjuvant samples. In addition, the MAC1-SELENOP subcluster was significantly increased in non-MPR patients compared to MPR patients. This finding is paramount since MAC1-SELENOP may play a role in modifying the TME through various interactions with epithelial cells with DTP signature.
Conclusion: Among several subclusters, three macrophage clusters enriched in the post-osimertinib samples were associated with lipid metabolism. In particular, the MAC1-SELENOP cluster with a tumor-associated macrophages (TAMs) phenotype had multiple interactions with tumors. This may lead to reprogramming of cancer cells to survive in TMEs. These finding may be applied to identifying DTPs and discovering potential therapeutic applications.

#6280 Exploring the dynamics of plasma proteins and their effect on outcomes in patients with bladder and lung cancer.

Randi Istrup Juul[1], Asbjorn Kjar[1], Nanna Kristjansdottir[1], Iver Nordentoft[2], Lars Dyrskjot[1], Nicolai J. Birkbak[1]

[1]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,[2]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark

The immune system's state and composition affects the outcome for patients with cancer. Here we investigated the dynamics of immune-related proteins in relation to treatment or recurrence in muscle-invasive bladder cancer (MIBC) and non-small cell lung cancer (NSCLC).
Using the Olink Proteomics Explore 1536 panel, we measured the level of 1536 proteins across multiple time points (2-6) for 25 patients with MIBC. Additionally, we obtained public data from the TRACERx cohort, where 151 patients with NSCLC had been profiled using the Olink Explore 3072 panel, measuring 3072 proteins at two time points. We investigated the association of the protein levels with immune-related parameters (T cell receptor diversity and relative T cell fraction) and patient outcome using mixed effects models. Significant proteins were further investigated in pathway enrichment analyses using both the Hallmark and Reactome pathways, and selected proteins were investigated individually. Cox Proportional Hazard Ratio was used to evaluate the proteins' association with survival.
We found 70 proteins that were significantly associated with metastatic disease in MIBC with enrichment of proteins in immune-related pathways. Seven proteins were associated with T cell receptor diversity and 19 were associated with the T cell fraction, which were enriched in proliferation pathways. In NSCLC we found 66 proteins that were associated with the T cell receptor diversity, and these were enriched among immune regulation pathways and pathways related to NOTCH signaling and cell-cell communication. Only six proteins were associated with the T cell fraction in the patients with NSCLC, and these were enriched in immune-related pathways. In the NSCLC cohort, we found 400 proteins that were negatively associated with overall survival and 86 proteins that were associated with improved overall survival. Among the 400 proteins, we observed an enrichment of proteins related to the innate immune system.
In conclusion, we find proteins that are associated with outcome or immune-related measures in both cohorts, and combined these proteins are enriched across pathways associated with the immune system, proliferation, or cell-cell communication, all pathways that have a role in cancer development.

#6282 Age-related shifts in the immune system revealed from single-cell RNA-seq using non-negative matrix factorization.

Ragnhild Laursen[1], David Martin-Pestana[2], Nicolai J. Birkbak[1]

[1]Clinical Medicine, Aarhus University, Arhus, Denmark,[2]Bioinformatics Research Centre, Aarhus University, Arhus, Denmark

Unraveling the molecular mechanisms driving aging and identifying potential therapeutic targets for age-related diseases are essential to increase healthspan. The aging immune system undergoes significant alterations, contributing to immune dysfunction and increased susceptibility to diseases. Identifying gene programs associated with immune aging is key to understanding these changes and developing strategies to counteract their effects.
In this study, we leverage non-negative matrix factorization (NMF), an interpretable and powerful dimensionality reduction technique, to identify gene expression programs in the immune system that shift with age. We analyze single-cell RNA sequencing (scRNA-seq) data from the large OneK1K cohort, which includes 981 participants aged 19 to 97 years and encompasses 1.27 million peripheral blood mononuclear cells.
We reveal two distinct age-related transitions in the immune system composition and function occurring with an average peak around 39.3 and 71.8 years of age. These transitions are characterized by the activation or suppression of particular gene programs, reflecting changes in immune cell types, their interactions, and signaling pathways.
Our findings provide a clearer understanding of the molecular underpinnings of immune aging by uncovering gene programs associated with it. These potential biomarkers of immune aging could enhance therapeutic strategies aimed at rejuvenating immune function in aging populations.

#6283 Performance evaluation of tumor microenvironment deconvolution and gene prediction methods in lung cancer.

F. Tang, D. Lee, L. Ji, J. Wu;
Novartis Biomedical Research, Cambridge, MA

The tumor microenvironment (TME) is complex and plays a key role in cancer development, progression and metastasis. Two layers of information are critical for understanding tumor compositions (1) the proportion of each cell type (2) the level of gene expression in each cell type.
Many single-cell profile-assisted algorithms have been developed to infer cell type proportions from bulk RNA-seq data, including CIBERSORTx, MuSic and Scaden, and there are several benchmark studies published to compare the methods. However, most of the deconvolution methods do not support prediction of gene expression in a heterogenous population of tumor cells, and there's no published study systemically comparing the gene expression prediction performance of the methods.
To overcome the limitations, we simulate large-scale of pseudobulk data using scRNA-seq profiling from lung tumors, representing various levels of tumor purities and cell lineages, to compare the cell fraction and gene expression prediction performance of recently published TME deconvolution methods. Our results indicate BayesPrism is the best at predicting gene expression in each of the cell types, and differential gene expression between two groups across cell types, especially in tumor epithelial cells, with higher balanced accuracy and correlation with ground truth. The inclusion of normal epithelial cells in the reference could increase additional risks for tumor deconvolution.
Altogether we evaluate both cell type proportion and gene expression prediction performance of recently published methods and offer a guideline for future benchmarking work. Currently we're working on the downstream application of inferring cellular composition and gene expression in large cohorts of bulk RNA-seq data, allowing for more insights into tumor-intrinsic expression and tumor-microenvironment interactions.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: New Software Tools and Machine Learning Methods
Poster Session

#6287 Bulk transcriptomic analysis with InMoose, the Integrated Multi-Omic Open-Source Environment in Python.

Maximilien Colange, Guillaume Appe, Lea Meunier, Solene Weill, Akpeli Nordor, Abdelkader Behdenna

Epigene Labs, Paris, France

We introduce InMoose, an open-source Python environment for omic data analysis. Due to its wide adoption, Python has grown as a de facto standard in fields increasingly important for bioinformatic pipelines, such as data science, machine learning, or AI. As a general-purpose language, Python is also recognized for its versatility and scalability. InMoose aims at bringing state-of-the-art tools, historically written in R, to the Python ecosystem. Our intent is to provide a drop-in replacement for R tools, so our approach focuses on the faithfulness to the original tools outcomes.
The first development phase has focused on bulk transcriptomic data, with current capabilities encompassing data simulation, batch effect correction, and differential analysis and meta-analysis. InMoose offers a Python implementation of several state-of-the-art tools originally written in R:• ComBat and ComBat-Seq (batch effect correction)• edgeR, DESeq2, limma (differential gene expression analysis)• splatter (RNA-Seq data simulation)
To our knowledge, InMoose is the sole Python implementation of ComBat-Seq, edgeR and limma. InMoose also offers original features:• a quality control report for cohorts built through the batch effect correction features;• a differential gene expression meta-analysis module.
We present the range of capabilities of InMoose, illustrating them with an example workflow. We also compare InMoose with the R original implementations and alternative Python implementations when available. Our experiments show that the results of InMoose are very similar, if not identical, to those of the original R tools. This positions InMoose as a key tool to bridge R and Python ecosystem and to ensure reproducibility and comparability between R-based and Python-based bioinformatics pipelines.
We put the emphasis on making InMoose easy-to-use and open source to reach as many bioinformaticians as possible. Since the first version of InMoose has been made public, multiple users shared their experience with us, and even contributed code enhancements, which led us to update our software and plan to release more bioinformatics tools on Python in the future.
Python has grown as the language of choice for machine learning and AI, and streamlining ML and AI-powered pipelines for biomolecular data has become an essential step to unlock the full potential of biomolecular analysis. Single-cell omic data is well connected to AI/ML tools through scanpy and the scverse ecosystem, but no similar initiative exists for bulk transcriptomic data. Omicverse aggregates existing Python tools into a single-entrypoint, but has not endeavored to port R capacities to the Python world. InMoose addresses this gap, which hinders the smooth integration of bulk transcriptomic data with ML and AI tools.

#6288 Precise characterization of complex repeats in cancer genomes.

Khi Pin Chua[1], Egor Dolzhenko[1], Zev N. Kronenberg[1], Seiya Imoto[2], Seiichi Mori[3], Michael A. Eberle[1]

[1]PacBio, Menlo Park, CA,[2]Institute of Medical Sciences, University of Tokyo, Tokyo, Japan,[3]Genome Center, Japan Foundation for Cancer Research, Tokyo, Japan

The characterization of somatic variation, especially in complex genomic regions, is crucial for understanding the molecular drivers of cancer progression. Accurate PacBio long-read sequencing (HiFi) enables detection of all variant classes, from simple SNVs and INDELs up to complex structural variation, tandem repeats, and changes in epigenetic signatures. Complex and repetitive regions, while fully sequenced by HiFi reads, remain bioinformatically challenging, requiring tailored solutions. Here, we describe new tools to genotype understudied repetitive regions in cancer genomes, a task that has historically posed significant challenges to short-read sequencing.Our software tool, TRGT, resolves the sequence and methylation patterns of complex repetitive regions at a single-nucleotide resolution. A recent algorithmic improvement (vclust module) enables us to type expanded hyper-polymorphic regions, termed variation clusters. Variation clusters usually result in many incorrect variant calls in computational pipelines. By analyzing a variation cluster as a single region, rather than many small variants, we can accurately measure genetic variation. To demonstrate the importance of variation clusters in cancer, we comprehensively resolved repeat regions in five cell lines and 50 clinical tumor samples (with matched healthy tissue). We identified 5,500 new variation clusters across the tumors and an average of 46,220 (out of 4 million, 1%) loci that are contracted or expanded in a tumor compared to its matched normal tissue. We find 3% of these loci can be located within genes found in the Compendium of Cancer Genes, suggesting potentially oncogenic significance. In addition, using TRGT, we were able to detect microsatellite instability (MSI) in a tumor with a compound heterozygous coding mutation in MSH2. Lastly, we further analyzed haplotypes in selected variation clusters to detect and resolve sequences in somatic mosaicism. By incorporating this new class of variants—complex repeats—into our analysis, we significantly enhanced the capability of HiFi reads to detect a comprehensive spectrum of genomic variations. The inclusion of complex repeat genotyping with PacBio HiFi reads will enable a more detailed understanding of cancer genetics and open new avenues for research and clinical applications.

#6289 SCplot: an interactive platform for single-cell RNA-seq analysis in colorectal cancer.

William Kothalawala, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

Background: Single-cell RNA sequencing (scRNA-seq) is a powerful tool for detailed characterization of the processes driving cancer and the interactions between different cell types in neoplastic tissues. However, the large volume of resulting data and the complexity of downstream analytic software and statistical approaches can make it challenging for researchers and clinicians without bioinformatics expertise to extract meaningful insights. To address this need, we developed SCplot, an integrated database and interactive online analysis platform for single-cell colorectal cancer (CRC) RNA-seq data.
Methods: SCplot allows users without prior programming experience to explore an integrated single-cell dataset. We compiled eight publicly available raw scRNA-seq CRC datasets from GEO, performed quality control and normalization, combined the datasets, and annotated the cell types. The complete database includes among others 102,195 cancer cells, 19,942 vascular endothelial cells, 25,027 cancer associated fibroblasts, and 7,438 smooth muscle cells. The platform available at www.scplot.com enables downstream analysis features, including differential gene expression, volcano plots, expression heatmaps, and gene-gene correlation analyses across various cell types.
Results: To demonstrate SCplot's utility, we investigated correlations of VEGFA between cancer cells and vascular endothelial cells, cancer-associated fibroblasts, and smooth muscle cells. Notably, the transcription factor JUND was among the top five positively correlated genes to VEGFA in cancer cells in each of these cell types (Pearson's correlation coefficient: 0.27-0.37, $p<0.001$). Other strongly positively correlated genes included those involved in cell signaling (*TCF4*, *CALCRL*, *GNAS*) and angiogenesis (*MCAM*, *COL4A1*, *SOX18*). Conversely, negatively correlated genes were associated with immunoregulation (*B2G*, *FKBP2*), iron metabolism (*FTL*, *FTH1*), apoptosis (*SOD1*), and cell differentiation (*PPDPF*).
Conclusions: These findings provide new insights into VEGF-driven interactions in CRC, revealing potential therapeutic targets to modulate the tumor microenvironment and disrupt angiogenesis. The SCplot platform can be mined to uncover, visualize, and validate cellular interactions in CRC.

#6290 sc2DAT: workflow for targeting tumor subpopulations of single cells.

Giacomo B. Marino, Nasheath Ahmed, Daniel J. B. Clarke, Avi Ma'ayan

Pharmacological Science, Icahn School of Medicine at Mount Sinai, New York, NY

Single-cell RNA sequencing (scRNA-seq) provides enhanced insights into the cellular composition of human tissues. In cancer, normal proportions of single cells are aberrantly dysregulated, and thus targeting subpopulations of cells within a tumor might be more effective than targeting all cells of a tumor. Here we present Single Cells to Drugs And Targets (sc2DAT), a unique workflow for the analysis of bulk and single cell RNA-seq datasets collected from tumors of the Clinical Proteomic Tumor Analysis Consortium (CPTAC). sc2DAT can take in as input single cell or bulk RNA profiles from one or two conditions. When processing scRNA-seq samples, sc2DAT first clusters the single cell vectors of expression to identify cell type subpopulations. It then bulkifies the vectors of expression in each cluster of single cells. For bulk RNA-seq, sc2DAT applies deconvolution with BayesPrism to infer cell-type-specific expression profiles for each identified subpopulation within a tumor. The sc2DAT platform currently has over 20 precomputed single-cell reference datasets derived from human and mouse studies. The expression vectors in each cluster of single cells are analyzed to discover genes that give rise to cell-surface proteins that are highly expressed in the tumor's subpopulation, but lowly expressed across all human healthy cell types and tissues. These identified cell-surface proteins can become immunotherapy targets for selectively elimination of subpopulation of single cells within a tumor. In addition, sc2DAT integrates the LINCS L1000 perturbational gene expression dataset to predict drugs and preclinical compounds that could induce a healthy phenotype in subpopulations of single cells within a tumor. Once datasets are uploaded to sc2DAT, the results are presented in a comprehensive report with an abstract, introduction, methods, results, conclusions, and references sections. The reports have many figures and tables, and it can be exported and shared in several formats including a PDF file. We applied sc2DAT to several CPTAC3 and CPTAC4 datasets to identify cell-type-specific subpopulation targets and reverser compounds, uncovering many potential personalized therapeutic strategies for immunotherapy and small-molecule interventions. sc2DAT is available from: https://sc2dat.maayanlab.cloud.

#6291 CellPyAbility: an integrated toolkit for high-throughput cell viability assays and automated analysis.

James L. Elia[1], Sam L. Friedman[2], Ranjit S. Bindra[2]

[1]Pathology, Yale University, New Haven, CT,[2]Therapeutic Radiology, Yale University, New Haven, CT

Assessing cell viability and proliferation in response to chemical gradients is fundamental to cancer biology research. We provide a cell viability “toolkit” that includes detailed protocols for high-throughput cell viability assays in response to a single agent or two agents in combination at varying concentrations with several advantages over other methods. Additionally, we developed automated software (CellPyAbility) that seamlessly integrates with the provided protocols, outputting detailed tabular and graphical analyses of experiments from bulk raw images. This combined approach significantly lowers the barriers to implementing cell viability assays by simplifying experimental setup and accelerating data analysis.

Our lab often uses short-term, nuclei-based growth delay assays (GDAs) to assess the selectivity of drugs against specific genetic alterations found in tumors. A GDA is conducted using a single 96-well plate with the innermost 60 wells containing two cell lines, a vehicle control, and a log-based gradient of nine concentrations in technical triplicate. Nuclei counting provides several advantages over other common methods. Compared to the commonly used methylthiazol tetrazolium (MTT; reduction-based) or CellTiter-Glo (ATP-based) assays, GDAs provide single-cell resolution of survival; are insensitive to metabolic variability within a cell or between cell lines; are compatible with redox-altering drugs; require simpler methodology; and could be used on live cells using non-toxic nuclear dyes like Hoechst. A disadvantage of the GDA is the computational and temporal cost of the required image analysis. We present CellPyAbility, which rapidly generates dose-response metrics and publication-ready graphics from a folder of unedited, whole-well GDA images in approximately one minute on commodity hardware.

Similarly, a researcher may want to assess how two drugs act in combination with one another across a wide range of concentrations. Our lab uses modified GDAs with simultaneous vertical and horizontal drug gradients, referred to as synergy assays. Synergy assays use three 96-well plates to assess 59 unique drug concentration combinations and a vehicle control in technical triplicate. CellPyAbility includes a synergy analysis module which generates dose-response metrics for each condition and a 3D surface map of cell viability and Bliss independence, a mathematical model for synergy in cellular systems, in approximately three minutes on commodity hardware. By making these tools open-access, we aim to empower cancer researchers with a streamlined, user-friendly platform for the rapid assessment of single- and dual-agent therapies in cell line models.

#6292 Highly sensitive detection of circulating-tumor DNA in plasma using whole genome sequencing.

Sven Bilke, Alex Buerkle, Christine Eng, Theo Heyns, Yuka Suzuki, Yunjiao Zhu, Yuan Ding, Jacob Gibson, Artem Movsesyan, Heather Talia, Pete Taylor, Jacquelyn Truong, Jeff Tsai, Li Liu, Khai Luong

Illumina, Inc., San Diego, CA

Sensitive detection of circulating-tumor DNA (ctDNA) in plasma is increasingly utilized as a biomarker of minimal residual disease (MRD) in assessing oncology therapy response, relapse detection, and as a surrogate endpoint in clinical trials for solid tumors. Both tumor-naïve and informed MRD strategies have been described in literature, some of which are available commercially. Tumor-naïve MRD assays detect tumor-specific biomarkers in cfDNA without the patient's tumor. Although tumor-naïve approach is beneficial in non-resectable tumor cases, tumor-informed assays are generally more sensitive. In a tumor-informed approach, the tumor-specific variants (SNV, indels, MNV, CNV, SV, methylation, etc.) are determined from a patient's tumor and matched-normal, which are subsequently monitored in the patient's cell-free DNA (cfDNA) using a patient-specific bespoke panel, a fixed panel, or whole genome sequencing (WGS). Amongst the tumor-informed approaches, tracking tumor mutations in cfDNA with patient-specific bespoke probes has become a popular approach due to its potential for high analytical accuracy and low sequencing cost. However, bespoke approaches require high DNA input for high accuracy, longer turnaround times, and operational complexity when running a patient-specific assay. Fixed, small panels have the potential to improve operational efficiency and reduce turnaround time. But creating a panel with high sensitivity across multiple tumor types can be a challenge due to tumor type specific mutational rates and patterns. We have developed a simple tumor-informed multi-cancer WGS method that can detect ctDNA down to 10 ppm with low DNA input requirements. WGS of a patient's tumor and matched-normal yields a patient and tumor-specific set of somatic variants for MRD detection. These variants can then be monitored in the plasma using low-pass WGS. Because the WGS data inherently contains the genomic signatures of the tumor, additional biomarkers beyond SNVs that may be more salient of certain cancer types may be additionally assessed without the need to redesign the assay. We demonstrate that this technique can work across a range of tumor mutational burden (TMB) and various tumor types, achieving detection in the range of 10-100ppm.

#6293 Developing and deploying the UCSC Xena gene set enrichment analysis appyter.

Cally Lin[1], Jingchun Zhu[2], Mary Goldman[2]

[1]Stanford University, Stanford, CA,[2]UC Santa Cruz Genomics Institute, Santa Cruz, CA

UCSC Xena (https://xena.ucsc.edu/) is a popular web-based visual integration and exploration tool for multiomic data and associated clinical and phenotypic annotations. Xena users want to be able to run Gene Set Enrichment Analysis (GSEA) to compare gene expression between their two dynamically created sample subgroups and determine which gene programs are upregulated or downregulated. However, the traditional GSEA implementation was not performant enough to support Xena's interactive web-based data visualizations. To overcome this challenge, blitzGSEA, a more performant implementation of GSEA developed in 2022 by the Ma'ayan Lab at Mount Sinai, was integrated to be available within the Xena browser using the Appyter framework, a tool also developed by the Ma'ayan lab. Appyter allows users to use Jupyter Notebooks to run bioinformatic methods without having to interact with the code directly and also allows developers to dynamically code inputs, such as the subgroups created by a user. The framework handles users running analyses concurrently and will cache results if two users run the same analysis, such as part of a workshop. Before development, blitzGSEA was rigorously compared to traditional GSEA to confirm that it provided similar, biologically consistent results with efficient memory usage and runtime. The blitzGSEA Appyter was implemented alongside the addition of a Plotly Dash page to provide users with interactive plots and tables of the analysis results. The blitzGSEA Appyter was then deployed on the production Xena Browser using Docker and an AWS EC2 instance. The blitzGSEA Appyter is now publicly available to Xena users for any sample subgroups they create and averages 500 analyses per month around the world.

#6294 Motif-independent Identification of functional transcription factors from single-cell multiomics data.

Hongpan Zhang[1], Jingyi Wang[1], Zhenjia Wang[2], Chongzhi Zang[2]

[1]Department of Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA,[2]Department of Genome Sciences, University of Virginia, Charlottesville, VA

Transcription factors (TF) are proteins that control when and how genes are turned on or off in a cell by binding to specific DNA sequences. The activation of one TF may induce gene expression cascade of other TFs or genes, suggesting the critical role of TFs in cell differentiation and cancer development. Techniques such as ChIP-seq, CUT&RUN and CUT&Tag are widely used to examine TFs' genomic binding activity, but only one or a few TFs can be examined at once, making them low-efficient considering that hundreds of TFs can be typically expressed in a cell. Recently emerging single-cell genomic technologies provide an alternative approach, using computational tools to predict functional TFs from single-cell transcriptomics or chromatin accessibility assays. However, most existing computational methods share similar limitations, including the use of static TF binding motifs and the inability of considering distal enhancer regulation. We developed BARTsc, a precise and time-efficient TF prediction tool for clustered single-cell genomics data and it overcomes aforementioned pitfalls. BARTsc leverages differential features between cell clusters and does model-based predictions of cis-regulatory profiles based on given feature sets. Association scores were then calculated between the predicted cis-regulatory profiles and a collection of TF binding profiles derived from published ChIP-seq datasets. BARTsc implemented a set of handy downstream analysis modules that reveal the TFs that lead to signature gene expression in each cell type, the relative TF activity across cell types and the key regulators for each cell type. By benchmarking against other methods in predicting key regulators, we showed that BARTsc exhibits superior performances in various contexts. A promising impact of this work is that BARTsc can facilitate more precise identification of key regulators driving cancer development and can lead to discovery of new therapeutic targets.

#6296 Unlocking scalable and efficient multiomic analysis of 5- and 6-base genomes.

Sabri Jamal[1], Michael J. Wilson[2], Jean Teyssandier[1], Gary Frewin[1], Mark S. Hill[1], William Stark[1], Nicola Wong[1], Robert Blanshard[1], Andrada Tomoni[1], Tom Charlesworth[1], Nicholas J. Harding[1], Paidi Creed[1]

[1]biomodal, Cambridge, United Kingdom,[2]Princeton University, Princeton, NJ

We present a computational toolkit to analyze 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC) Cytosine modifications at scale and describe its performance on a liquid biopsy dataset.

Methylation data has diverse applications in cancer, including early-stage diagnosis through liquid biopsy, classification to guide treatment pathways, and prognosis. However, analyzing methylation data poses significant challenges. Many existing tools are difficult to use and struggle to scale as sample sizes grow. This lack of scalability makes standard tasks, such as identifying differentially methylated regions (DMRs) or summarizing methylation fractions across genomic regions, time- and memory-intensive, often requiring large-scale compute resources. A recently introduced technology, duet multiomics solution evoC, enables the reading of 6-base information from DNA, further increasing the scale and complexity of data that can be extracted from a single sequencing experiment. With this expanded multiomic dataset, the lack of scalability is compounded, hindering interactive data analysis that provides rapid and detailed insight. To address this, we present a fast and scalable array-based python package (modality) for the analysis of 6-base genomes (A, T, G, C, 5-mC and 5-hmC), using multi-core out-of-memory processing to enable extremely efficient computation, even for datasets that are too large to fit into memory.

Our approach enables local analysis of large datasets, scaling to thousands of samples. Unlike existing tools that exceed typical laptop memory with ~10 samples, the modality package efficiently generates hundreds of thousands of features for classification, processing a colorectal cancer liquid biopsy dataset of over 100 samples in minutes on a standard laptop. Furthermore, it runs a complex DMR model (logistic regression with covariates) genome-wide in under an hour, a task infeasible with current tools.

modality combines efficient computation with tools for exploratory (e.g., plotting, methylation summaries) and downstream analyses (e.g., DMR identification, PCA). Designed for efficiency and ease of use, it enables users to rapidly transition from raw data to actionable insights and publication-ready results. As multiomic data become the standard in cancer research, our data structure supports the integration of additional data types, allowing us to handle combined genomic and epigenomic data from solutions like duet evoC. This will enable streamlined and efficient multiomic analysis to uncover deeper biological insights.

#6297 Mapping cellular interactions from spatially resolved transcriptomics data.

J. Zhu[1], Y. Wang[2], W. Chang[1], A. Malewska[1], F. Napolitano[1], J. C. Gahan[1], N. Unni[1], M. Zhao[1], R. Yuan[1], F. Wu[1], L. Yue[1], L. Guo[1], Z. Zhao[3], D. Chen[3], R. Hannan[1], S. Zhang[1], G. Xiao[1], P. Mu[4], A. B. Hanker[1], D. Strand[1], C. L. Arteaga[1], N. Desai[1], X. Wang[5], Y. Xie[1], T. Wang[1];

[1]UT Southwestern Medical Center, Dallas, TX, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Notre Dame, Notre Dame, IN, [4]Yale School of Medicine, New Haven, CT, [5]University of Texas at Arlington, Arlington, TX

Cell-cell communication (CCC) is essential to how life forms and functions. However, accurate, high-throughput mapping of how expression of all genes in one cell affects expression of all genes in another cell is made possible only recently through the introduction of spatially resolved transcriptomics (SRT) technologies, especially those that achieve single-cell resolution. Nevertheless, substantial challenges remain to analyze such highly complex data properly. Here, we introduce a multiple-instance learning framework, Spacia, to detect CCCs from data generated by SRTs, by uniquely exploiting their spatial modality. We highlight Spacia's power to overcome fundamental limitations of popular analytical tools for inference of CCCs, including losing single-cell resolution, limited to ligand-receptor relationships and prior interaction databases, high false positive rates and, most importantly, the lack of consideration of the multiple-sender-to-one-receiver paradigm. We evaluated the fitness of Spacia for three commercialized single-cell resolution SRT technologies: MERSCOPE/Vizgen, CosMx/NanoString and Xenium/10x. Overall, Spacia represents a notable step in advancing quantitative theories of cellular communications.

#6298 The first fully automated, integrated workflow between a small animal imaging tool and animal study management software improves the accuracy, reproducibility, and efficiency of small animal imaging studies.

Sean R. Gallagher[1], Meng Yang[2], Eric Ibsen[3], Antonio Boccia[3], Madalin Florescu[4], Qi Wang[5], Neil Chang[1]

[1]Analytik Jena US LLC, Claremont, CA,[2]R&D, InvivoxBio, San Diego, CA,[3]R&D, studylog, Pacifica, CA,[4]R&D Programming, Cardinal Cognition SRL, Claremont, CA,[5]R&D, Analytik Jena US LLC, Claremont, CA

Preclinical imaging systems and electronic data capture (EDC) technologies are transforming biomedical research and drug discovery by offering powerful, time-saving tools for oncology study data acquisition, analysis, and management. Advanced imaging modalities, such as bioluminescence, fluorescence, CT, MRI, and PET imaging, allow researchers to non-invasively visualize and quantify biological processes in small animal models. These systems support longitudinal studies of disease progression, therapeutic efficacy, and molecular mechanisms, aiding novel drug development while minimizing animal usage through precise data collection. Companies like Analytik-Jena provide high-resolution small animal imaging solutions that help researchers gain deeper insights into biological phenomena. Complementing these innovations, EDC systems like Studylog Animal Study Software streamline preclinical workflows by automating data collection, validation, and analyses. Together, preclinical imaging and EDC technologies drive innovation in biomedical science by enabling robust and efficient data capture. However, before this writing, no integration between preclinical imaging and EDC technologies existed, forcing researchers to rely on a heavily manual process of imaging data association with study animals to generate statistical and graphical results This manual process is fraught with a variety of error types and is extremely time-consuming. Furthermore, access to results and original animal images in the context of the study is absent altogether. This paper reports on the first automated integration of preclinical imaging and animal study workflow software available. Having tools that enable seamless tracking of the animals used for the collective small animal imaging study processes, such as substrates administered, incubation time points, anesthesia records, image collection, animal identification association, -including region of interest (ROI) determination, and tracking—is crucial to improving the accuracy, reproducibility, and efficiency of these studies. Equally important is the accurate transfer of this data into a database, ensuring the integrity and long-term accessibility of study data and results. The novel integration feature enables seamless communication between Studylog and VisionWorks by exchanging data in a standardized format via local methods or internet-based APIs. This allows scientists to initiate workflows in Studylog, process imaging and analysis in VisionWorks imaging software, and then send results back to Studylog with a single click, supporting both local and remote collaboration.

#6300 Global fit normalization for circulating microRNA measured by quantitative PCR.

K. Song, C. Wang, J. W. Kardos, N. Sarkar, Y. Liu, O. Yoon;
Gilead Sciences, Inc., Foster City, CA

MicroRNAs (miRNAs) are small RNA molecules that regulate gene expression at the post-transcriptional level and play a key role in cancer biology affecting cancer cells' proliferation, metastasis, and drug resistance. Cancer cells can release miRNAs into the bloodstream and can potentially be non-invasive markers for cancer diagnosis and prognosis. However, variations in quantitative PCR (qPCR) preparation have limited their clinical utility, and normalization of circulating miRNA qPCR data remains challenging due to low amount of circulating RNA and the lack of universal housekeeping miRNAs. To address these limitations, we have developed Global Fit (GF) normalization, a novel approach that accounts for technical variations from RNA input by fitting a sigmoidal curve to the reverse cumulative distribution of miRNA cycle threshold (Ct) values and subsequently adjusting sample bias through distribution unification. Additionally, we introduce an extended normalization method that employs linear regression (LR) to further correct residual sample bias. The performance of the GF was compared against the commonly used normalization method, Global Mean (GM) using simulated data based on a murine plasma dataset and three public human cancer plasma datasets. In the murine dataset, we demonstrated that sample input bias is reflected by the horizontal shift of the cumulative distribution of Ct values, and GF normalization yielded more aligned distributions compared to GM. Simulation showed that GF outperformed GM by reducing post-normalization variability across scenarios considering different dropout rates and panel sizes. Across multiple simulations of differentially expressed miRNAs, GF showed higher statistical power compared to GM (median 51.9% vs 20.4%), while maintaining similar type I error rates. LR further improved the detection power beyond GF alone. Across three human cancer miRNA datasets, GF consistently demonstrated better correction of circulating miRNA distribution compared to GM. In ANOVA analyses, GF normalization consistently accounted for higher data variability than GM normalization. GF also outperformed other normalizers in stability score (ranked No. 1) as measured by NormFinder. Consequently, GF allowed better detection of biologically meaningful circulating miRNAs in colon and liver cancers, such as miR-210, miR-532-3p and miR-195. These findings support the use of GF normalization in circulating miRNA data analysis to enable more robust biomarker identification for cancer diagnosis and prognosis in clinical settings.

#6301 ARLVPI: A novel machine-learning-informed platform for assessing somatic variant classification and pathogenicity.

Arlen Larry Gyden[1], Nicole Ambroise[2], Tarsus Lam[2], Zehra Ordulu[2], Petr Starostik[2], Kimberly Newsom[2], Mohammed Gbadamosi[1]

[1]College of Pharmacy, Pharmacotherapy and Translational Research, University of Florida, Gainesville, FL,[2]Pathology, Immunology and Laboratory Medicine, UF Health, Gainesville, FL

Cancer comprises several heterogeneous multifaceted diseases characterized by dysfunctional cellular differentiation and excessive proliferation. With its prevalence expected to rise, particularly among middle-aged adults, the burden on pathologists to identify and characterize pathogenic variants increases. Current clinical practices rely on molecular profiling, pathologist interpretation, and supplemental information from disease databases to classify these variants. In this context, variants of unknown significance (VUS) pose a significant clinical challenge due to their uncertain biological and clinical effects that make them inhibitive towards diagnoses and treatment decisions. Representing 40% of Next-Generation Sequencing (NGS) signals, VUS indicates a significant unmet clinical need demanding urgent solutions. To meet this unmet clinical challenge, we utilized 20,756 variants from 415 cancer patient samples to develop the Advanced Risk Locating Variant Pathogenicity Index (ArlVPI). ArlVPI employs a mechanistic model based on information from a random forest classifier and dimensional reduction analyses to identify and flag VUS variants likely to require further investigation from pathologists. In downstream analysis, ArlVPI exhibited a strong correlation with variant pathogenicity and correctly categorized variants as benign or pathogenic with <1% error. With respect to VUS, ArlVPI flagged 16% as requiring potential follow-up, corroborating metrics observed in literature. Furthermore, ArlVPI demonstrated >93% concordance with clinical pathologists in the identification of VUS which were reclassified as pathogenic in an array of solid tumor, hematologic, and myeloproliferative malignancies. Our study illustrates how ArlVPI can be integrated into existing NGS analysis pipelines to support molecular professionals, offering an efficient resource that enhances variant classification and supports targeted cancer treatment strategies. Future work focuses on developing a streamlined application that interfaces with existing clinical diagnostic systems.

#6302 A CellProfiler pipeline for RNAscope analyzing multiple markers across adjacent tissue sections spatially.

Meng-Shin Shiao[1], Natini Jinawath[1], Katherine Copeland[1], Ariestya Indah Permata Sari[2]

[1]Mahidol University, Bangkok, Thailand,[2]Swadaya Gunung Jati University, Cirebon, Indonesia

Understanding the spatial distribution of cancer cells and how they interact with other cell types in the tumor microenvironment (TME) is crucial to elucidate the mechanisms of cancer development and progression. The identification of cell types in the TME relies on the distinct expression profiles of different cell types. Compared to sequencing-based spatial transcriptomics analysis, multiplex nucleic acid *in-situ* hybridization (ISH) at a single-molecule level is more focused and cost-effective. Based on ISH technology, RNAscope developed novel approaches to detect multiple gene expression profiles on tissue sections at a single-molecule level. It is highly sensitive and specific and can simultaneously quantify gene expression at sub-cellular levels. Although the technology has been applied to study spatial gene expression in various cancer types, few have applied it to elucidate the association between different markers in different cell compartments within the TME.This protocol describes an image analysis pipeline for multiplex fluorescent signals detected by RNAscope technology. It was developed based on a previous CellProfiler pipeline, facilitating spatial expression analyses across different cell compartments through a flexible, user-friendly interface for non-computational biologists. We describe specific steps to analyze the expression and spatial arrangement of four endogenous housekeeping genes as quality controls (QCs): *POLR2A*, *PPIB*, *HPRT1*, and *UBC*. We further apply these pipelines to analyze target genes in breast cancer samples, comparing those with and without skin metastasis. The analyses were demonstrated in one sample each using formalin-fixed paraffin-embedded tissue (FFPET) and fresh-frozen tissue (FFT) sections with the ISH steps followed the manufacturer's protocol.

#6303 DrBioRight: an AI-driven chatbot for cancer data analysis.

Han Liang, Jun Li, Wei Liu

UT MD Anderson Cancer Center, Houston, TX

We present DrBioRight, a cutting-edge chatbot designed to streamline omics data analysis by employing large language models (LLMs). Modern omics technologies generate extensive cancer omics datasets, but conventional software often requires significant technical expertise. DrBioRight addresses this challenge by enabling researchers to interact with the platform in a conversational manner, simplifying complex analytical workflows. DrBioRight's chatbot-driven interface allows users to search datasets, perform data analysis, access insights, and generate visualizations by posing natural language questions or commands. This intuitive approach eliminates the need for programming knowledge, making omics research more accessible. Key features include LLM-powered conversational capabilities, real-time task prediction and guidance, collaborative functionalities for research teams, and integration of new tools and datasets via community contributions. By transforming the interaction model from technical to conversational, DrBioRight serves as an intelligent research assistant that democratizes omics data analysis, enhances collaboration, and accelerates scientific discoveries in cancer research.

#6304 RUO LymphoTrack Enterprise Software v3.0.1 - A comprehensive suite to standardize analyses of IG and TCR sequencing data.

T. Nguyen, J. Witsotsky, J. D'Angelo, J. Velazquez-Muriel, A. Arias, J. Jablanovic, J. Miller;
Invivoscribe, Inc., San Diego, CA

This study introduces the LymphoTrack Enterprise Software v3.0.1 (LTE), a high-throughput Research Use Only (RUO) software suite for analyzing all RUO LymphoTrack Assays offered by Invivoscribe on a single platform. LTE provides a comprehensive solution for the analysis of immunoglobulin and T-cell receptor nucleotide sequences. LTE is specifically designed to meet the needs of higher volume laboratories seeking compatibility with a broader range of sequencers and increased automation flexibility. Unlike the desktop RUO LymphoTrack Software - MiSeq for clonality and MRD analyses, which caters to smaller-scale users, LTE offers an advanced enterprise architecture featuring containerization, a REST API for seamless integration, and scalable infrastructure to handle large datasets efficiently. These enhancements make LTE an ideal choice for labs focused on high-throughput analysis and integration into automated workflows. Notably, LTE significantly reduced MiSeq processing time to 2.2 ± 0.34 minutes (n=3 runs, 24 samples each) vs. 30.3 ± 1.50 minutes in RUO LymphoTrack v2.4.6—an ~92.8% reduction. LTE also includes compatibility with more assay and sequencing platforms, supporting Illumina NextSeq1000 and Complete Genomics DNBSEQ-G99, with planned support for NovaSeq6000 in future releases to further increase compatibility. For example, it recognizes DNBSEQ-G99 FASTQ files, performs adapter trimming, and proceeds to clonality analysis, with total analysis times of 20.1 ± 0.56 minutes for a NextSeq550 run (n = 3 runs, 12-25 samples each run), 8.98 ± 2.23 minutes for a NextSeq1000 run (n = 4 runs, 96 samples), and 70.3 ± 6.35 minutes (n = 3 runs, 24 samples each run) for a DNBSEQ-G99 run (including 65.7 ± 7.06 minutes for adapter trimming step). Key advancements in this release include enhanced CDR3 region identification, a critical feature for immunogenomics, enabling rapid and precise immune repertoire and clonality analyses. Testing over 220,000 unique sequences, the RUO LymphoTrack Enterprise v3.0.1 algorithm achieved a CDR3 identification rate of 98.6%, a substantial improvement from the 58.4% rate observed with the previous version. The software also supports multiple immunogenetic databases, including IgBlast, IMGT/V-QUEST, and IMGT/GENE-DB, allowing for customized antibody and T-cell receptor profiling. By offering faster processing, broader platform compatibility, and enhanced analytical capabilities, RUO LymphoTrack Enterprise v3.0.1 provides a robust, all-in-one solution for researchers seeking to streamline immunogenomic workflows. This upgraded version establishes a new standard in cancer genomics, with potential to significantly advance biomarker discovery, immune response characterization, and cancer subtype differentiation.

#6305 hGRN-ChEAR: human transcription factor regulatory network with a knowledge graph interactive user interface.

Anna I. Byrd, John Erol Evangelista, Alexander Lachmann, Ho-Young Chung, Sherry L. Jenkins, Avi Ma'ayan

Pharmacological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY

Gene expression is controlled by transcription factors that selectively bind to DNA to regulate mRNA expression of all human genes. In cancer, gene expression regulation is misconfigured to accelerate uncontrolled cell proliferation. Transcription factors control the expression of other transcription factors, forming a complex gene regulatory network (GRN) with switches, feedback loops, and other regulatory motifs. Many experimental methods and computational tools have been developed to reconstruct GRNs in-silico. Here we present a novel approach to reconstruct the human GRN. By submitting thousands of gene sets from the RummaGEO resource for transcription factor enrichment analysis with ChEA3, we are able to distill a signed and directed edges that connect all human transcription factors to construct a novel human GRN. The GRN has 130,793 signed and directed edges between 703 source and 1,543 target nodes. The network is made accessible via an interactive web-based application called the Human Gene Regulatory Network based on ChEA3 and RummaGEO (hGRN-ChEAR). hGRN-ChEAR enables users to query the GRN by searching for single or pairs of transcription factors, as well as by submitting their gene sets to perform transcription factor enrichment analysis. To demonstrate the utility of hGRN-ChEAR, we systematically identified transcription factor subnetworks that regulate differentially expressed genes in tumors from ten cancer types, and 69 subtypes, profiled by the Clinical Proteomic Tumor Analysis Consortium (CPTAC). hGRN-ChEAR is freely available from: https://hgrn-chear.maayanlab.cloud/.

#6306 Topological arrangement of samples based on high dimensional feature similarities: the NetFlow framework.

Rena Elkin, Jung H. Oh, Joseph O. Deasy

Memorial Sloan Kettering Cancer Center, New York, NY

At the core of exploratory data analysis is the development of effective informatics tools to represent and visualize how samples are organized in a dataset. Cancer heterogeneity between and within cancer types poses challenges for many clustering and dimensional reduction approaches as biological data often vary continuously rather than form distinct clusters. It is therefore essential to develop a visualization tool that can expose the underlying clusters as well as the broader relational structure of the samples in the data. We introduce NetFlow, an open-source software tool designed to address this need. NetFlow serves as a comprehensive and interactive investigative platform to aid researchers in visualizing and analyzing complex biological data to support the generation and evaluation of hypotheses.

NetFlow arranges samples in an undirected graph based on similarities of the underlying high dimensional feature set. It takes biological feature data and provides a visually informative relational topology where each node represents a sample. To incorporate ordering and clustering behavior, the relational topology is derived from the underlying metric structure and constructed by combining the pseudo-ordering of the samples, generated via lineage tracing techniques, with nearest-neighbor information. In addition to classic metrics, NetFlow uses Optimal Mass Transport which offers a network-level and robust metric to compare high dimensional sample profiles with respect to a feature network. NetFlow supports the computation of kernel transformations and diffusion distances to account for local and multi-scale geometry which influence aspects of the similarity structure that will be reflected in the extracted organizational representation.

NetFlow is designed in a modular fashion to facilitate easy integration with diverse computational pipelines. The modules support data input/output, similarity structure derivation, visualization, and down-stream analyses. A key feature of NetFlow is its interactive visualization dashboard for exploring the resulting relational topology and its associations with biological or clinical features. The dashboard offers multiple capabilities for customizing the visualization and enhancing interpretability. For instance, the user can select features of interest to color-code the nodes (i.e., samples) and edges (relationships), and can select samples of interest to identify statistically significant characteristic features. These functionalities empower users to gain deeper insights into the underlying data structure and its potential biological or clinical implications.

NetFlow results in an abstract sample-space network rather than a 2D spatial arrangement. Its topological nature enables interpretable, uncluttered visualizations of relations within and between clusters for identifying novel inter-sample similarities.

#6307 ELViS : An R package for estimating copy number levels of viral genomic segments at base-resolution.

J.-Y. Lee[1], H. Choi[1], J. R. Holt[1], X. Zhao[1], K. A. Hoadley[2], D. N. Hayes[1];

[1]University of Tennessee Health Science Center, Memphis, TN, [2]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC

Tumor virus is one of the major causes of human cancers, accounting for about 10-20% of their global incidence. Viral oncogenes in the tumor viruses promote tumorigenesis by deregulating host cancer genes. For instance, E6 and E7 proteins of human papillomavirus 16 (HPV16) induce the degradation of the protein products of tumor suppressor genes (TSGs) including p53 and pRb, to promote head and neck squamous cell carcinoma (HNSCC). Therefore, it is imperative to understand how differences in the dosage of viral genes affect cancer biology. However, how the relative and absolute abundance of each viral gene affects tumorigenesis and tumor biology has remained elusive, due to the difficulties in the analysis. Unlike human genomes that exist in two copies per cell, viral genome copies can take dynamic ranges, making copy number analyses challenging. Thus, we developed an R package ELViS that analyzes viral copy number change events from targeted DNA sequencing of whole viral genomes. In the first step, it takes aligned reads in the BAM file to generate base-resolution read depth and finds baseline regions based on the shape of the data. Next, to overcome the uneven base-resolution depths of targeted sequencing data and find copy number events, our framework performs joint segmentation in two-dimensional data space using both normalized read depths and Z-scores. In the simulation dataset, ELViS could detect deletions as small as 50bp and duplications as small as 500bp with F1 score &gt 0.75 at 50X coverage depths. ELViS provides base-resolution copy number change calls, along with publication-ready read depth line plots and cohort-level heatmap visualization of multiple data tracks with integrative clustering results.

#6308 Dory: a computational method for differential chromatin tracing analysis.

Zhaoxia Ma[1], Miao Liu[2], Mengwei Hu[2], Shengyuan Wang[1], Siyuan Wang[2], Chongzhi Zang[1]

[1]University of Virginia, Charlottesville, VA,[2]Yale University, New Haven, CT

The spatial organization of the genome plays a vital role in maintaining the cell type-specific chromatin structures and regulating gene expression. The three-dimensional (3D) genome structures can be measured by sequencing-based techniques such as Hi-C on the ensemble level or by imaging-based techniques such as chromatin tracing on the single-molecule level. Chromatin tracing is a multiplexed DNA fluorescence in situ hybridization (FISH) technique that can directly trace the 3D positions of genomic loci along individual chromosomes in single cells. By designing the primary probes targeting specific genomic regions and dye-labeled secondary probes to indicate their positions, chromatin tracing can construct the 3D trace of chromatin at high resolution using microscopy. However, few computational tools have been developed for differential analysis of chromatin tracing data. Major challenges include the high variability of chromatin traces and missing values in the 3D coordinates of some loci. Here, we present Dory, a statistical method for identifying differential patterns from two groups of chromatin traces without imputation of missing data. Dory measures the spatial distance between each pair of regions in each chromatin trace and employs multi-level statistical tests to quantify the distance difference between the two groups of chromatin traces. The output of Dory includes the differential score for each region pair comparing chromatin traces between two biological conditions. We applied Dory to chromatin tracing data from six cell types in mouse fetal liver and from a mouse lung cancer progression model. We found that the changes in chromatin structure are associated with A-B compartment alterations and promoter-enhancer interaction alterations that cause differential gene expression. Dory is a user-friendly computational tool that can be applied to multiple types of imaging-based 3D genome data analysis for studying genome functions and gene regulation.

#6309 CliPP-on-Web: a dynamic platform for clonal structure identification through penalizing pairwise differences in cancers.

Aaron Wu, Quang Tran, Matthew D. Montierth, Yujie Jiang, Jessica C. Lai, Shuangxi Ji, Wenyi Wang

Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX

Background: Intra-tumor heterogeneity plays a crucial role in tumor evolution and response to therapy, highlighting the need to understand mutation clonality and subclonal architecture to drive advancements in precision cancer treatments. However, existing tools for subclonal reconstruction are typically too slow for large cohort analyses, and lack an accessible web-based interface for widespread use.
Methods: We developed CliPP-on-Web, an interactive platform built with R Shiny, to streamline subclonal analysis for researchers and clinicians. Its back-end algorithm is based on model-based clustering with regularized maximum likelihood estimation, derived from the core methodology of CliPP. This algorithm models variant allele counts using a binomial distribution, incorporating tumor purity, copy number alterations (CNAs), and cancer cell fractions (CCFs) of somatic mutations. By penalizing pairwise differences in CCFs, it effectively clusters mutations without requiring predefined subclone numbers. Optimization is achieved through the Alternating Direction Method of Multipliers (ADMM), ensuring high computational efficiency.
Results: CliPP-on-Web simplifies subclonal analysis by enabling users to process up to 10 samples simultaneously with user-uploaded. Interactive visualization tools, such as Variant Allele Frequency (VAF) and Cellular Prevalence (CP) plots, offer features like zooming, hover details, and adjustable smoothing for enhanced clarity. Pre-loaded integrated datasets from TCGA and PCAWG enable comparative studies, while the Driver Mutation module highlights key cancer mutations with searchable and downloadable results. Capable of processing 100 samples in just30 minutes — far outpacing the ~3 hours per sample required by tools like PhyloWGS — CliPP-on-Web provides efficient and comprehensive subclonal analysis, advancing cancer genomics research.
Conclusions: CliPP-on-Web offers a powerful, accessible platform for analyzing mutation clonality and subclonal architecture across diverse tumor types, facilitating both large-scale studies and individual sample exploration.

#6310 Bridging spatial proteomics and classical histopathology: advanced spatial analysis through H&E-enhanced multiplexed immunoprofiling.

Michael Downing, Ruben Cardenes, Douglas Wood, Gourab Chatterjee, Lorenz Rognoni

Ultivue, Inc., Cambridge, MA

Background: Multiplex immunofluorescence (mIF) is increasingly adopted in translational research due to its ability to provide rich spatial and molecular information. Nevertheless, H&E staining remains the gold standard for clinical diagnosis, revealing essential histological context and morphological features not visible in mIF images. While H&E is routinely performed on serial sections in analytical mIF workflows, biological variability between sections limits its utility. Co-registration of H&E and mIF images from the same slide enables precise colocalization of cells across channels, combining the histological detail of H&E with the spatial insights of mIF to enhance both biological assessment and image analysis.
Overview: This study explored the integration of same-section H&E staining and imaging into mIF workflows using formalin-fixed paraffin-embedded (FFPE) tissue samples from mixed cancer indications. After mIF staining and imaging with InSituPlex™ technology, same-section H&E images were co-registered with the mIF images before incorporation into a standard image analysis pipeline. Co-registration and analysis were performed through the STARVUE™ image data science pipeline, using UltiStacker.AI™ and UltiAnalyzer.AI™. The integration was evaluated across several key applications. --Pathology Assessment: H&E image data was overlaid onto the mIF channels, allowing for the histological context to be directly referenced when identifying the tumor and excluding non-target tissues from the analysis. --mIF-Enhanced H&E: Marker expression from mIF channels was overlaid onto the H&E images, allowing biomarker profiles to be visualized in the histological context. This colocalization enriched the understanding of immune activity beyond what H&E alone can provide. --Tissue Detection: mIF-based tissue detection often struggles with non-stained elements. Co-registered H&E images addressed this limitation by offering additional features for refined tissue-background separation, improving accuracy in measurements such as cell density. --Tumor Segmentation: Cytokeratin (CK) is commonly used to identify tumor epithelia in both brightfield and mIF assays. Tumors lacking CK expression or using non-CK assays pose challenges for segmentation. By leveraging co-registered H&E images, a deep learning model trained on H&E data successfully segmented tumor compartments, enabling accurate mIF-based cell analysis where CK-based methods failed.
Conclusions: The results of this study highlight the enhanced utility of the gold standard H&E stain through integration of co-registered same-section H&E images into mIF workflows. This approach not only enriches tissue analysis but also lays the groundwork for developing novel methods that further broaden the applications of H&E in spatial biology.

#6311 Enabling scalable, precise, and fast spatial biology studies with Orion and OMERO Plus.

Erin Diel[1], Edward Lo[2]

[1]Glencoe Software, Inc., Seattle, WA,[2]RareCyte, Inc., Seattle, WA

The field of spatial biology requires the simultaneous evaluation of 10s to 100s of biomarkers across entire tissue sections, as these complex measurements yield key insights into the organization and state of cells in tissues, and thus are critical for discovery and clinical applications. However, producing such data at speeds consistent with translational applications and enabling responsive visualization of this multidimensional data remain a challenge. We present the integration of fast data acquisition with performant data management and visualization for employing these spatial biology workflows at scale.

RareCyte's Orion is a next generation imaging instrument powering a new paradigm in spatial biology. Utilizing a novel, single round staining technique, Orion spatial biology allows for up to 20 channels (18 marker + 2 autofluorescence channels), same section H&E, and flexible panel design, all within the context of whole-specimen tissue imaging. The combined power of the Orion instrument and workflow enables ultra-fast imaging at a low run cost and preserves the integrity of the tissue sample, providing scale to translational and clinical studies.

Glencoe Software's OMERO Plus is a powerful enterprise image data management platform which enables remote viewing, sharing and analysis of large-scale biological image datasets, including metadata ranging from simple annotations to complex, quantitative descriptions of cells within images. Furthermore, OMERO Plus' open API allows for flexible customization and integration with other tools and pipelines. Additionally, OMERO Plus ensures data integrity and reproducibility by tracking experimental conditions and data provenance.

The seamless integration of Orion and OMERO Plus enables efficient workflows connecting data acquisition to analysis and visualization. Here, we introduce a new visual data mining interface called Pageant, which supports the exploration and classification of millions of cells based on hundreds of features. Using image data from Orion systems, diverse cell types can be classified based on intensity features from 18 markers of interest, in addition to cell morphometric features. Cell-cell interactions can then be studied using the spatial location and distribution of classified cell types. We performed an iterative classification workflow, first by finding marker-positive cell populations, then by creating boolean combinations of these markers into biologically-meaningful cell types, all within a web browser. We report speed improvements in using OMERO Plus and Pageant for remote interactions with analytical data, in some cases greater than 10x. Pageant transforms the scientist's ability to make conclusions from analytical data without code at scale.

#6312 AI-Driven Identification of Drug-Tolerant Persister Cells in Lung Cancer.

Balaji Selvaraj[1], Abinaya Vairam[2], Pablo Andres Moreno Cortez[3], Ramya Tanikanti[2], Anca M. Farcas[4], Yi Wei[5], Martin L. Miller[3], Viia E. Valge-archer[6], Ultan McDermott[4]

[1]R&D IT, AstraZeneca AB, Molndal, Sweden,[2]R&D IT, AstraZeneca India Pvt Ltd, Chennai, India,[3]Oncology Data Science, AstraZeneca plc, Cambridge, United Kingdom,[4]Oncology Bioscience, AstraZeneca plc, Cambridge, United Kingdom,[5]R&D IT, AstraZeneca plc, Cambridge, United Kingdom,[6]External R&D and Strategic Alliances, AstraZeneca plc, Cambridge, United Kingdom

Drug-tolerant persister cells (DTPs) are cancer cells that evade the effects of therapies through a reversible, non-genetic mechanism, leading to therapeutic resistance and cancer recurrence. Single cell RNA sequencing data is a promising modality to study the mechanism behind DTPs' survival. The first step of such studies is to classify persister vs. non-persister cells. Today, bioinformaticians identify persister cells manually from RNA sequencing data; this is a tedious and time consuming task.

This paper introduces the first end-to-end, fully automatic pipeline for DTPs classification using an adapted Transformer-based scGPT model. Our contributions are as follows:

(1) Persister cells are transient and reversible in nature. In our training data, even if a cell is labeled as a persister cell, it is better to inform the model that this cell has certain probability of being a persister cell and some probability of being a non-persister cell. The default one-hot cross-entropy loss of the scGPT model assumes label certainty and will lead to overfitting. To overcome this, we fine-tuned a pre-trained scGPT model using a label smoothing cross-entropy loss that encourages the model to give probabilities to both classes.

(2) Single cell data is sparse; many genes are not expressed. Non-expressed genes bring noise to the model. We leveraged statistical analysis to understand significant genes across cell lines, resulting in a threshold that our pipeline uses to only keep highly variable genes as inputs to the model.

(3) When assigning data points to different cross validation folds, the original scGPT pipeline stratifies them by only constraining on cell types. This will result in imbalanced distribution of data points from different batches in different folds, preventing the model from generalizing to unseen batches. We stratified data using both cell type and batch, mitigating the batch effect.

We evaluated our pipeline on a proprietary data processed through the Persist-seq baseline scRNA-seq pipeline, with 41071 data points, coming from four non-small cell lung cancer cell lines. We performed 4-fold cross validation with each fold using data from 3 cell lines for training and data from the fourth cell line for testing. Averaging over testing folds, our model achieved 90% accuracy, with a 0.89 F1 score. Our finding suggests that transformer-based deep learning pipelines are effective alternatives to traditional manual approaches for persister cell classification. Future research will focus on developing a multi-step approach, where the initial step is to classify cancer cells vs non-cancer cells, followed by persister cell classification.

#6313 Context-aware pathway enrichment clustering and interpretation using large language models.

Yibing Guo[1], Yanhao Tan[2], Li-Ju Wang[2], Chien-Hung Shih[2], Yu-Chiao Chiu[2]

[1]Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA,[2]UPMC Hillman Cancer Center, Pittsburgh, PA

Pathway enrichment analysis is pivotal for elucidating key oncogenic processes from high-throughput cancer profiling. However, the inherent redundancy and interdependence in biological pathway annotations complicate the meaningful interpretation of enrichment results. This challenge necessitates the effective clustering of enriched pathways. Traditional clustering methods predominantly rely on structural matrices, such as gene overlap within hierarchical pathway graphs. However, these methods do not account for the biological context of the experiment, potentially overlooking critical, context-specific insights tied to cancer types, stages, and other key factors. To address these limitations, we present a context-aware approach for clustering and interpretating pathway enrichment results using emerging large language models (LLMs). Our method involves: 1) generating contextually enriched pathway summaries based on original definitions, using LLMs with prompt engineering techniques; 2) embedding these summaries into high-dimensional quantitative representations, to capture pathway-level contextual semantics; and 3) clustering pathways into biologically coherent themes by computing pairwise similarities between embeddings. We applied this approach to a case study involving 144 up-regulated Reactome pathways from pediatric acute myeloid leukemia (AML) samples compared with normal controls in the TARGET dataset. A widely used overlap-based method, EnrichmentMap, yielded clusters with uneven sizes and fragmented groupings. For instance, the largest cluster contained 79 pathways spanning diverse processes, while immune-related pathways formed several separate clusters. In contrast, our LLM-based approach produced more cohesive and interpretable results, with 11 clusters ranging from 5 to 25 pathways. These clusters successfully delineated distinct biological processes, such as platelet activation and coagulation, and chromatin remodeling. Notably, our approach demonstrated the value of contextualizing pathways. For example, the “pentose phosphate pathway” was grouped with iron metabolism and autophagy pathways, emphasizing its role in providing NADPH for iron metabolism, which is relevant to AML. This insight was missed by EnrichmentMap, as this pathway was left unclustered. Additionally, “nuclear events stimulated by *ALK* signaling in cancer” was grouped with oncogenic signaling, reflecting the role of *ALK* in nuclear processes that drive survival, transformation, and apoptosis escape. Overall, this pilot study underscores the potential of LLM-generated contextual pathway summaries and embeddings to produce biologically coherent pathway clusters that highlight their collective roles. Our approach represents a novel strategy for enhancing the interpretability of pathway analysis results, particularly in complex disease contexts such as cancer.

#6314 Development of g-rate based random forest machine learning model to predict overall survival for patients with metastatic prostate cancer.

Mohamed Azzam[1], Harshraj Leuva[1], Mengxi Zhou[2], Benjamin A. Teply[1], Raymond C. Bergan[1], Susan Elaine Bates[2], Shibiao Wan[1], Antonio Tito Fojo[2], **Jieqiong Wang**[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]Columbia University Medical Center, New York, NY

Metastatic prostate cancer (mPC) is among the most common causes of cancer-related death affecting men worldwide. Currently, predictive biomarkers and models are available to estimate a patient's prognosis, but we lack reliable treatment assessment measures once a patient starts on a treatment. We have developed the ***g***-rate method to measure treatment efficacy, which estimates tumor growth (***g***) and decay (***d***) rates using prostate-specific antigen (PSA) values while the patient is on treatment and have shown that ***g***-rate has a robust inverse correlation with overall survival(OS) in patients with mPC. We have now developed a machine learning model based on g-rate and other clinical measures to predict the survival probability over time for individuals who are receiving treatment for mPC. We included variables of patient demographics, Charlson Comorbidity Index (CCI), mPC history (Gleason score, hormone sensitivity, line of treatment, PSA at diagnosis), variables available at the first visit of the start of treatment such as first PSA and first CBC at start of treatment, and g-rate derived from serial PSA values while on treatment. A random forest machine learning (ML) algorithm was employed to construct the survival prediction model. Harrel's concordance index (C-index), Uno's C-index, and time-dependent area under the receiver operating characteristic (ROC) curve were used for performance evaluation. Permutation importance was applied to assess variable contributions. Our experiment uses 18,018 treatment records of 11,849 unique US veteran patients to train the model. Besides the training data, 4,501 treatment records of 2,963 unique patients are used for model evaluation. The model achieved a remarkably high Harrel's C-index of 0.76 and Uno's C-index of 0.747, with 23.68% of treatment records censored. The time-dependent ROC curve averaged 0.83, demonstrating robust predictive capability. The permutation importance analysis identified ***g***-rate as the most influential variable, followed by the first PSA and first Hgb at the start of treatment. Our g-rate based ML model highlights that it is possible to estimate treatment efficacy early via reliable survival probability prediction while on a treatment for mPC. Once validated, it can be used for both research and clinical purposes to make timely treatment escalation or de-escalation decisions.

#6315 Rapid automatic segmentation of murine lung volumes from micro-CT images using deep learning to reduce analysis burden.

Adam M. Aji[1], Thomas M. Kierski[1], Juan D. Rojas[1], Ryan C. Gessner[1], Yair Reisner[2], Irit Milman-Krentsis[2], John Hazle[3], Kiersten L. Maldonado[3], Charles Kingsley[3], Richard R. Bouchard[3], Tomasz J. Czernuszewicz[1]

[1]Revvity, Durham, NC,[2]Department of Stem Cell Transplantation and Cellular Therapy, MD Anderson Cancer Center, Houston, TX,[3]Department of Imaging Physics, MD Anderson Cancer Center, Houston, TX

Micro-computed tomography (micro-CT) has emerged as a powerful tool for non-invasive small animal imaging, particularly in lung cancer and fibrosis research. This high-resolution imaging modality allows researchers to visualize and quantify lung structures and pathologies with unprecedented detail, enabling sophisticated longitudinal studies. However, the analysis of these complex 3D datasets presents a significant challenge. Manual segmentation of lung tissues from micro-CT images is time-consuming and prone to inter-observer variability, often becoming a bottleneck in study workflows. This analysis burden can impact study design, potentially limiting sample sizes or the frequency of imaging timepoints. As a result, there is a growing need for efficient, automated lung segmentation solutions that can accelerate analysis, improve reproducibility, and ultimately enhance the throughput and statistical power of preclinical lung studies. We address these challenges by training a new fully automatic deep learning model for whole lung segmentation. The goal of this work is to create a single model that generalizes well to data representing various manufacturers, disease states, and fields-of-view. In this pilot study, we collected 321 scans using a SkyScan 1276 (Bruker, Kontich, Belgium) and a Quantum GX2 (Revvity, Waltham, MA, USA). The lungs were segmented from each image by an expert reader. Data were shuffled and divided into groups for training, validation, and testing using a 70%-20%-10% split. Models were trained with different sets of hyperparameters and evaluated on the validation set. The model with the best validation Dice coefficient was selected for analyzing the test set. A linear regression analysis between the predicted and the ground truth test volumes resulted in a R^2 value of 0.96, indicating strong correlation between the output of the model and the human annotator. The average time for the model to compute a single label is roughly 2 seconds, compared to an average of 15 minutes per volume for the expert reader, representing a significant improvement in processing time. Furthermore, the model is fully automatic, reducing the need for user input which might generate user fatigue. Taken together, these results suggest that this deep learning approach may be an effective aid for increasing throughput and reliability for micro-CT workflows in preclinical studies.

#6316 Predictive performance comparison of foundational and CNN models for single-cell immune profiling.

Colwyn Jia Kang Lai[1], Wei Kit Tan[2], Marcia Zhang[3], Timothy Wang[4], Felicia Wee[5], Ai Lin Wang[6], Solomonraj Wilson[4], Tomotaka Ugai[7], Joe Sheng Yeong Poh[5], Jonathan A. Nowak[8], Shuji Ogino[9], Juha P. Vayrynen[10], **Mai Chan Lau**[4]

[1]School of Biological Sciences, Nanyang Technological University, Singapore, Singapore,[2]Bioinformatics Institute, Agency for Science, Technology And Research, Singapore, Singapore,[3]Faculty of Science, National University of Singapore, Singapore, Singapore,[4]Singapore Immunology Network, Agency for Science, Technology And Research, Singapore, Singapore,[5]Institute of Molecular and Cell Biology, Agency for Science, Technology and Research, Singapore, Singapore,[6]National Taiwan University, Taipei, Taiwan,[7]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[8]Department of Medical Oncology, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA,[9]Program in MPE Molecular Pathological Epidemiology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[10]Translational Medicine Research Unit, Medical Research Center Oulu, Oulu University Hospital, and University of Oulu, Oulu, Finland

Introduction

Characterizing the immune contexture is key to understanding the tumor microenvironment, developing biomarkers, and guiding therapeutic strategies. In our previous work on colorectal cancer (CRC), we used a pathologist-guided approach to annotate/count eosinophils and lymphocytes. Their abundance and spatial relationships with tumor cells revealed prognostic significance. While clinically valuable, identifying this demands significant pathologist effort. Advancements in AI, particularly foundational models trained on millions of histology images, have driven significant progress in digital pathology and hold promise to address this gap. However, their application to single-cell tasks remains underexplored. This study investigates the potential of foundation model and compares it with conventional convolutional neural network (CNN) using previously annotated eosinophils and lymphocytes in CRC histology images.

Methods

We used 578 CRC cases in The Cancer Genome Atlas with H&E-stained whole-slide images (WSIs) containing 8,836,393 cells, including 896,322 lymphocytes and eosinophils. For evaluation, 109 WSIs were held out as a test set, with 5 WSIs per density quartile selected from our previous study. The foundational model UNI (11.2M parameters) was fine-tuned and a ResNet18 (303M parameters) model was trained. Performance was evaluated using F1-score and AUROC, with Spearman's correlation accessing WSI-level cell density correlations.

Results

For eosinophil, ResNet18 achieved an F1-score of 0.841, AUROC of 0.986, and Spearman's correlation of 0.679, compared to UNI's 0.847, 0.990, and 0.697, respectively. For lymphocytes, ResNet18 scored 0.697, 0.932, and 0.686, while UNI achieved 0.719, 0.941, and 0.662. ResNet18 performed comparably to UNI despite simpler architecture, at both cell and patient levels. Predicted cell densities generally aligned with the annotated quartiles from previous work, particularly in the 1st and 4th quartiles. Moderate density correlations (0.66-0.69) were observed, but a pathologist's review of misclassified cells revealed imperfections in the semi-supervised cell annotations.

Conclusion

The H&E-based AI model for predicting immune cells offers a scalable alternative to manual annotation, enabling automated quantification of existing immune biomarkers like tumor-infiltrating lymphocytes and tumor-associated tissue eosinophilia. Adaptable to other tumor types, it also opens opportunities to discover novel spatial immune biomarkers by leveraging large H&E cohorts and integrating protein-stained immune cell data with histopathological knowledge. Future work will focus on enhancing performance through weakly supervised approaches using carefully selected training cells, and multi-cell type modeling to better capture the morphological characteristics of diverse cell types in a single model.

PREVENTION / EARLY DETECTION / INTERCEPTION: Development of Chemopreventive Agents and Preclinical Models
Poster Session

#6320 Benfotiamine and fursultiamine prevent glioblastoma cells growth, invasion and migration.
B. Keane, S. Senthil, **K. V. Ramana**;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Glioblastoma is the most common malignant and aggressive brain tumor in adults. Recent advances in surgical techniques and adjuvant therapies have modestly improved the overall survival rate. Thus, there is a need for novel therapeutic approaches and preventive strategies to control glioblastoma. Lipophilic derivatives of vitamin B1 have been used for many health conditions due to their substantial antioxidant and anti-inflammatory properties. However, their chemopreventive effects in glioblastoma are not known. This study investigated the chemopreventive potential of benfotiamine and fursultiamine using glioblastoma cells. Human glioblastoma (U-87) cell lines grown in Eagle's Minimum Essential Media (EMEM) were treated with various concentrations of benfotiamine and fursultiamine. Cell viability was determined by MTT assay in a time- and dose-dependent manner. Apoptotic cell death was determined by Annexin-V staining and live-dead cell assay kits. The expression of various pro-apoptotic and anti-apoptotic factors and other inflammatory factors, including Bad, Bax, Bcl-2, cIAP-1, cIAP-2, and procaspase 3, was determined using a human apoptosis antibody array. Our results suggest that benfotiamine and fursultiamine prevent the growth of U-87 cells in a dose- and time-dependent manner. Further, they prevented the invasion and migration of glioblastoma cells. They also elevated the caspase-3 activation and reduced the mitochondrial reactive oxygen species. These compounds also regulate the expression of various pro- and anti-apoptotic factors. These findings suggest vitamin B1 derivatives could prevent glioblastoma tumor growth by upregulating the caspase-3-mediated apoptotic signaling pathways. Next, we plan to inject glioblastoma cells into the athymic nude mice xenograft model and examine the growth of glioblastoma cells in the absence and presence of vitamin B1 derivatives.

#6321 Vialinin-A, an antioxidant isolated from edible mushroom *thelephora vialis*, inhibits colorectal cancer growth.

D. Lahori, D. Thornton, **K. V. Ramana**;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the United States. While CRC screening typically begins at age 45-50, its incidence is rising in younger populations, highlighting the need for diversified treatment options. Genetic predisposition, oxidative stress, and inflammation are recognized as major contributors to the pathogenesis of this disease. Current treatments, such as chemotherapy and surgical resection, often lead to unwanted side effects and risks, including potential cardiotoxicity from chemotherapeutics like anthracyclines. Vialinin-A, a compound isolated from the edible Chinese mushroom *Thelephora Vialis*, has demonstrated antioxidant and anti-inflammatory properties. However, its anti-carcinogenic mechanisms are not well known. Human colon cancer cells such as SW480 and CaCO-2 were treated with varying concentrations of Vialinin-A for 24 and 48 h. Cell viability was determined by MTT assay. Apoptosis was evaluated through the activation of caspase-3 and the use of a human apoptosis array to analyze the expression of key apoptotic markers. Additionally, a multiplex array was used to identify oncogenic, inflammatory, and apoptotic markers in treated cells. Next, we plan to use nude mice xenografts to examine the chemopreventive role of Vialinin-A in vivo. So far, our results indicate that Vialinin-A inhibits CRC cell growth in a dose-dependent manner and suppresses the generation of reactive oxygen species (ROS). Vialinin-A activates caspase-3 in growth factor-treated cancer cells. Furthermore, Vialinin-A modulates the expression of various apoptotic and inflammatory markers in CRC cells, supporting its potential role in anti-carcinogenic pathways. Ongoing experiments aim to further elucidate the molecular mechanisms through which Vialinin-A inhibits CRC growth.

#6322 Lipid-soluble vitamin B1 derivatives prevent pancreatic cancer growth and migration.

Nathan Kobus, Nancy Kaushal, **Kota V. Ramana**

Noorda College of Osteopathic Medicine,, Provo, UT

Pancreatic adenocarcinoma is a lethal type of cancer often diagnosed in the end stages, commonly leading to metastasis. Surgical resection and chemotherapy are not well curative, leading patients to seek alternative therapies via clinical trials. Lipid-soluble derivatives of thiamine, Benfotiamine (Ben), and Fursultiamine (FS) exhibit antioxidative and anti-inflammatory properties. However, their chemo-preventive efficacy is not well known. Therefore, we examined their chemo-preventive potential in pancreatic cancer cells. Human Pancreatic adenocarcinoma (MIA PaCa-2) and metastatic pancreatic adenocarcinoma (BxPC-3) cell lines were incubated for 24 h with varying concentrations (0-100 uM) of Ben and FS. Cell viability was determined by MTT assay. Our results indicate that both Ben and FS prevented the growth of MIA-PaCa2 and BxPC-3 cells in a time- and dose-dependent manner. Ben and FS treatments also increased the expression of caspase-3 and prevented the invasion and trans-well migration of pancreatic cancer cells. Further, human apoptosis array analysis indicates that Ben regulated the expression of various pro-apoptotic factors such as BAD and Bax and anti-apoptotic factors such as Bcl-xL and Bcl-2 in MIA PaCA-2 cells. In addition, human oncology array analysis indicates that Ben regulated the expression of various carcinogenic proteins such as amphiregulin, cathepsin D, HIF-1alpha, osteopontin, p27, and Kallikrein. Next, we planned to examine the in-vivo chemo-preventive efficacy of Ben using nude mice xenografts. So far, our data suggests that treatment with vitamin B1 derivatives is effective against pancreatic cancer cell growth in culture.

#6323 Cancer chemopreventive effects and mechanisms of *Citrus depressa* leaf extracts.

Z.-Y. Su, H.-Y. Chiang;
Chung Yuan Christian University, Taoyuan City, Taiwan

Many diseases such as cancer are closely linked to excessive intracellular oxidative stress and chronic inflammatory responses. Studies have demonstrated that dietary interventions can mitigate or prevent the progression of certain chronic diseases, which reinforces the significance of the 'prevention is better than cure' concept. This study evaluated the antioxidant capacity and chemopreventive mechanisms of *Citrus depressa* leaf (CDL) extracts in mouse JB6 P+ skin cells in inhibiting carcinogenesis induced by the tumor promoter 12-*O*-tetradecanoylphorbol-13-acetate (TPA). The preparation of various solvent extracts from CDL revealed a richness in flavonoids, which are key bioactive compounds commonly found in citrus fruits. CDL-WE (water extract) and CDL-95EE (95% ethanolic extract) (5-40 μg/mL) both effectively prevented the anchorage-independent growth of JB6 P+ cells with minimal cytotoxicity, but CDL-95EE was found to have superior effects. In addition, CDL-95EE promoted the expression of UGT1A and HO-1 enzymes at the protein level, enhanced the expression of Nrf2 pathway-related genes in mRNA, and decreased TPA-related ROS levels. The protein expression of DNA methyltransferases (DNMTs) and histone deacetylases (HDACs) was also reduced by CDL-95EE, which indicates that it is involved in epigenetic regulation. These findings demonstrate the chemopreventive capacity of CDL and endorse their use in creating agricultural byproducts from this resource.

#6324 Intercepting bladder cancer progression using androgen receptor inhibitor, apalutamide, in a carcinogen BBN-induced rat bladder tumor model.

Venkateshwar Madka[1], Gopal Pathuri[1], Surya Pratap Singh[1], Anil Singh[1], Anh Bao[1], Nicole Stratton[1], Shizuko Sei[2], John L. Clifford[2], Chinthalapally V. Rao[1]

[1]Center for Cancer Prevention and Drug Development, Department of Medicine, OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]Division of Cancer Prevention, National Cancer Institute, Rockville, MD

Bladder cancer (BC) is the 2nd most commonly diagnosed genitourinary cancer. While the majority of cancers are diagnosed and treated at the non-muscle invasive stage; high recurrence rate, treatment resistance, and tumor progression cause significant mortality. Epidemiologic and preclinical data have long demonstrated clear differences in incidence and progression of BC between genders, suggesting strong association with hormonal pathways with development and progression in these tumors. Based on these studies, androgen receptor (AR) signaling pathway emerged as a critical player and a promising target for BC interception. Thus, in the current study, BC preventive efficacy of the nonsteroidal AR antagonist, apalutamide, was evaluated in a N-butyl-N-(4-hydroxyl)-nitrosamine (BBN)-rat BC model. At 7 weeks of age, fisher rats were randomized by weight into 4 groups (30 rats/group/gender: 24 BBN + 6 Vehicle). Starting at 8 weeks of age, rats were administered BBN by oral gavage (150mg/dose; twice weekly for 8 weeks) to induce BC. A week after BBN treatment, rats in each group received apalutamide by oral gavage (5 days/wk) at increasing doses, 0, 7.5, 15, or 30mg/kg BW, until termination. Male and female bladder tumors were assessed at 40 & 50 weeks of age, respectively. Body and organ weights, blood profile, liver and kidney enzyme function analysis suggested non-significant differences, indicating safety of the tested doses. BBN treatment induced bladder tumors in both genders, resulting in significantly larger bladders (~0.75±0.25g) compared to vehicle group (0.12±0.08g) with the incidence of large tumors (≥200mg) in 87% and 75% of male and female rats, respectively. Importantly, apalutamide treatment led to a significant reduction of bladder weights suggesting tumor growth inhibition in treated rats compared to control. Bladder weights were reduced by 60%-65% in males ($p<0.05$) and by 54%-63% in females ($p<0.05$) when compared to the untreated group. Moreover, the incidence of large bladder tumors was also significantly decreased with apalutamide treatment by 30%-47% in males ($p<0.05$-$p<0.01$) and by 32%-50% in females ($p<0.05$) in a dose dependent manner. Histopathological analysis of the tumor demonstrated a significant decrease in papillomas (40%-60% less vs control; $p<0.01$-$p<0.0001$), NMIBC (48%-76% less vs control; $p<0.001$-$p<0.0001$) and MIBC (>77% less vs control; $p<0.001$-$p<0.0001$) at all three doses tested. Biomarker analysis showed reduction in the proliferation markers Ki67 and cyclin D1 in apalutamide treated rats tumors. In conclusion, our study demonstrated that an AR antagonist, apalutamide, can intercept bladder tumor growth and progression in a preclinical rat model and warrants further investigation in clinical trials.

[1]Medicine, University of Chicago, Chicago, IL,[2]Obstetrics & Gynecology, University of Chicago, Chicago, IL,[3]Chemistry, University of Chicago, Chicago, IL,[4]Internal Medicine, Rush University Medical Center, Chicago, IL,[5]Department of Radiology and Imaging Sciences, Emory University School of Medicine, Atlanta, GA,[6]Pritzker School of Molecular Engineering, University of Chicago, Chicago, IL,[7]University of Texas Southwestern Medical Center, Dallas, TX,[8]Beckman Research Institute, City of Hope, Duarte, CA

The evolution of diet has played an essential role in shaping human physiology and pathology, including the development of the immune system and responses to environmental stimuli. However, the specific mechanisms underlying the regulatory significance of dietary components in modulating anti-tumor immunity remain largely unknown. Here, we applied a co-culture screen approach using a blood nutrient compound library to identify zeaxanthin, a dietary carotenoid pigment found in many fruits and vegetables that is important for eye health, as an immunomodulator that enhances cytotoxicity of CD8⁺ T cells against tumor cells. Oral zeaxanthin, but not lutein, a zeaxanthin structural isomer, enhances anti-tumor immunity *in vivo*. Integrated multi-omics mechanistic studies reveal that zeaxanthin directly promotes T-cell receptor (TCR) stimulation on CD8⁺ T cell surface, leading to improved intracellular TCR signaling for effector T cell function. Hence, zeaxanthin treatment augments effectiveness of immune checkpoint inhibitor *in vivo* and human TCR-engineered CD8⁺ T cells to induce cell death against co-cultured tumor cells. Our findings uncover a previously unknown immunoregulatory function of zeaxanthin, which has translational potential as a dietary element in bolstering immunotherapy.

#6326 A comparative study of C3H and C57Bl/6 murine models of radiation-induced fibrosis.

Pierre-Antoine Bissey, Justin Williams, Wei Shi, Madison Hossack, Ken W. Yip, Fei-Fei Liu

Research, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Introduction: Approximately 50% of cancer patients are treated with radiation therapy; ~60% of whom will experience significant radiation-induced fibrosis (RF) caused by excessive collagen accumulation. RF reduces tissue function and flexibility, increasing surgical complications during disease recurrence. Accurate and reproducible *in vivo* models are required to elucidate the mechanisms of this condition and to facilitate the development of effective therapeutic strategies. Although there have been comprehensive studies related to model development for other forms of fibrosis, the characterization and comparison of murine RF models remains limited in the literature. This work aims to assess and contrast C3H and C57Bl/6 mice as models for RF.
Methods: RF was assessed in two mouse strains, C3H and C57BL/6. Mice were irradiated using the Precision SmART+ irradiator. C3H mice received 40 Gy, while C57BL/6 mice received 10 Gy, 15 Gy, or 20 Gy. Following irradiation, the tibiofemoral joint angle was measured using X-ray images acquired weekly. At 4-, 8-, 12-, and 16-weeks post-irradiation, skin samples were collected, and collagen deposition was analyzed. Collagen was measured using: a) picrosirius red staining and polarized light microscopy; b) pro-collagen ELISA; and c) the hydroxyproline assay.
Results: The pattern of RF development was unique to each mouse strain. In C3H mice, three phases were observed: an acute response with increased limb stiffness, a recovery phase with reduced stiffness, and a fibrotic phase correlating with collagen accumulation, evidenced by histology and biochemical analyses. At 16 weeks post-irradiation, collagen deposition was observed to increase by 1.48- ($p<0.05$), 1.62- ($p<0.05$), and 1.32-fold *via* picrosirius, ELISA, and hydroxyproline assays, respectively. In C57BL/6 mice, 20 Gy induced RF without a recovery phase, 10 Gy did not induce fibrosis, while 15 Gy induced RF in 50% of cases, revealing unexpected variability despite genetic uniformity. At 16 weeks post-20 Gy irradiation, collagen deposition was observed to increase by 4.2- ($p<0.01$), 1.55-, and 2.69-fold ($p<0.05$) *via* picrosirius, ELISA, and hydroxyproline assays, respectively. Skin thickness following irradiation increased by 1.66-fold ($p<0.05$) in C3H mice, and by 2.35-fold ($p<0.01$) in C57BL/6 mice, compared to non-irradiated controls.
Conclusions: Measuring the tibiofemoral joint angle using weekly X-ray is non-invasive approach in assessing murine RF. The data reveal mouse strain-specific differences in RF. C3H mice may more accurately recapitulate the development of RF in humans. However, due to many more gain- and loss-of-function genetic models, C57BL/6 mice remain essential for investigating RF.

#6327 Prevention of glioblastoma cell growth by Vialinin A.

Chandu Goli, Roxana Nojoumi, Kota V. Ramana

Noorda College of Osteopathic Medicine, LLC, Provo, UT

Glioblastoma is regarded as the most aggressive and common type of primary malignant brain tumor in adults that is characterized by rapid growth of glial cells. It is mainly resistant to therapy and exhibits a universally poor prognosis. Therefore, there is a vital need to explore other alternatives to complement current standard treatment modalities. Recent studies have revealed that Vialinin A, a small antioxidant molecule isolated from the Chinese edible mushroom, has potential antioxidant and anti-inflammatory properties. However, its chemopreventive role is not clear. We now examined the chemopreventive efficacy of this compound in glioblastoma growth and invasion. The different capabilities of Vialinin A and downstream effects, such as cell viability, invasion, migration, and apoptosis induction, were explored in various experiments using human U-87 Glioblastoma cell lines obtained from ATCC. Our results indicate that Vialinin A prevents the growth of glioblastoma cells in a time- and dose-dependent manner. Vialinin A also prevented the invasion and trans-well migration of glioblastoma cells. Further, it also regulated the expression of various pro-apoptotic and anti-apoptotic factors and other inflammatory factors, including Bad, Bax, Bcl-2, cIAP-1, cIAP-2, and procaspase 3. These results suggest that Vialinin A promotes the cancer cell apoptotic pathways to prevent glioblastoma cell growth. Further, we plan to examine how Vialinin A prevents glioblastoma growth in nude mice xenografts.

#6328 Metformin induces cell cycle arrest and inhibits proliferation in *KRAS*-mutated colorectal cancer.

Devanshi Patel, Michelle Pham, Parthiv Medidi, **Holli Ann Loomans-Kropp**

The Ohio State University, Columbus, OH

Purpose: Our objective was to evaluate the potential of metformin for colorectal cancer (CRC) prevention.

Methods: HT-29 (*KRAS* wild-type) and SW837 (*KRAS* G12D mutated) CRC cells were used for *in vitro* analyses. Cells were treated with 10mM (HT-29) or 2mM (SW837) metformin for up to 96 hours. Proliferation was assessed by raw cell counts, CellTiter 96 Aqueous Proliferation Assay, and 0.5% crystal violet staining. Propidium iodide staining was used to evaluate cell cycle and analyzed on a BD FACS Aria III. Experimental results were analyzed using Student's *t*-test or Mann-Whitney U and expressed as the mean +/- standard deviation. Statistical analysis of *in vitro* experiments was performed in Prism 10.0 (GraphPad) and significance was set at $p<0.05$. Sequencing was completed using an Illumina NovaSeq X Plus (Novogene). Differential expression analysis was performed using DESeq2RPackage and enrichment analysis using clusterProfiler and GSEA for Go, KEGG, Reactome, DO, and DisGeNET. Statistical significance was set at an adjusted $p<0.05$.

Results: We found that metformin treatment of CRC cells *in vitro* significantly reduced proliferation and cellular growth after 48 and 96 hours in SW837, but not HT-29 cells. Cell cycle analysis showed that SW837 metformin treatment increased the percent of cells in G1, suggesting G1 cell cycle arrest. Sequencing analysis of SW837 cells identified 2738 and 2492 genes significantly up- and downregulated with metformin treatment, respectively. The top significantly differentially regulated genes were *ATF3*, *SNAI2*, *UPP1*, *GDF15*, and *SLC20A1*. Gene ontology analysis of metformin-treated SW837 cells showed differentially regulated genes involved in chromosome segregation, DNA replication, and cell cycle checkpoint, supporting our findings. Independent validation of top hits and key genes in pathways of interest, including *CDC42, BRIP1, EME1*, and *POLE2*, is ongoing.

Conclusions: Treatment of *KRAS*-mutated CRC cells with metformin significantly reduced cell proliferation and induced cell cycle arrest. Sequencing analysis showed significant regulation of cell cycle and proliferation-associated pathways, supporting our observed phenotype and providing insight into previously unidentified pathways regulated by metformin. The results from this study may have implications for the future use of metformin for CRC prevention.

#6329 Edible Chinese mushroom-derived antioxidant, vialinin A, prevents breast cancer cell growth.

Malak Rafik, Afnan Khan, Kota V. Ramana

Noorda College of Osteopathic Medicine, LLC, Provo, UT

Breast cancer ranks as the second most prevalent cancer worldwide, impacting millions annually, and stands as the leading cancer affecting women. Neoplasia occurs when free radicals, antioxidants, and reactive oxygen species increase in the cell, which can alter protein function and cause mutations and genomic instability. Current breast cancer treatments typically include chemotherapy and radiation. However, different breast cancer cell types have different antioxidative capacities, which allow them to resist these treatments, thereby reducing the efficacy of these expensive treatments. Several vitamins, antioxidants, and anti-inflammatory compounds have been tested for their effectiveness in preventing breast cancer. However, the role of vialinin A, an antioxidant and ubiquitin-specific peptidase inhibitor derived from edible Chinese mushrooms, is unknown. Therefore, in this study, we examined the chemopreventive effect of vialinin A in preventing breast cancer cell growth and migration. Human breast cancer cells (MCF-7) were treated with vialinin A in a time- and dose-dependent manner. Cell viability assay indicates that vialinin A prevents the growth of breast cancer cells in a dose-dependent manner. Further, vialinin also prevented the EGF-induced invasion of MCF-7 cells in a scratch assay. Vialinin A also prevented the EGF-induced trans-well migration of breast cancer cells. Vialinin A also regulated the growth factor-induced expression of various pro- and anti-apoptotic factors in breast cancer cells. Vialinin A also increased the activation of caspase-3 and cleavage of PARP in growth factor-treated breast cancer cells. Next, we plan to examine the chemopreventive efficacy of vialinin A in a nude mouse xenograft model. In conclusion, our results indicate that vialinin A could prevent breast cancer cell growth and invasion, suggesting its potential development as a chemopreventive drug.

#6330 Unveiling the anticancer potential of *Rheum webbianum* in colorectal cancer defense through modulation of key wnt/β-catenin and TGF-β signaling pathways: An in-vitro and in-vivo investigation.

Umer Majeed Khaja[1], Reena Singh[1], Showkat Ahmad Ganie[2]

[1]Bioengineering and Biosciences, Lovely Professional University, Jalandhar, Punjab, India,[2]Department of Clinical Biochemistry, University of Kashmir, Srinagar, Jammu and Kashmir, India

Purpose of the Study: Colorectal cancer (CRC) remains a significant health concern worldwide. Lifestyle and environmental factors are primary contributors to CRC, emphasizing the need for effective preventive strategies. *Rheum webbianum* (RW), a plant with a rich ethnopharmacological background, has demonstrated promising chemopreventive potential. In our previously published study on the ameliorative potential of *Rheum webbianum* extracts in DMH-induced colorectal cancer (U.M. Khaja et al., 2024), the ethanolic extract of RW demonstrated the highest ameliorating potential in both *in-vitro* and *in-vivo* experiments. Building on these findings, this study aims to further investigate the anticancer effects of RW ethanolic extracts through additional *in-vitro* and *in-vivo* assays, focusing on their impact on critical molecular pathways involved in CRC progression.

Materials and Methods: The study evaluated the anticancer potential of RW ethanolic extracts using the HT-29 human colon cancer cell line and a 1,2-dimethylhydrazine (DMH)-induced rat CRC model. In vitro assays assessed the effects of RW on cancer cell viability and migration, using cytotoxicity and scratch wound migration assays. Western blot analysis was conducted to explore the extract's influence on key signaling pathways, including Wnt/β-catenin and TGF-β, both of which are critical drivers of CRC progression and metastasis.

Results: *In-vitro*: The ethanolic extract of *Rheum webbianum* (RW) significantly inhibited the viability of HT-29 cells in a dose- and time-dependent manner, with up to 80% inhibition observed at a concentration of 200 µg/mL. Scratch wound migration assays demonstrated a substantial reduction in cancer cell migration, with progressively stronger inhibitory effects seen at higher RW concentrations. *In-vivo*: In the DMH-induced rat CRC model, molecular analysis revealed that RW extracts suppressed β-catenin expression, indicating inhibition of the Wnt/β-catenin signaling pathway, a hallmark of CRC progression. Furthermore, the extracts downregulated TGF-β1 expression, implicating their role in reducing pro-metastatic signaling. These findings highlight the extract's ability to target critical pathways involved in tumor growth and metastasis.

Conclusion: This study provides compelling evidence of the anticancer potential of RW ethanolic extracts. The results highlight their ability to inhibit cell viability, suppress migration, reduce metastatic behavior, and modulate key signaling pathways associated with CRC progression. These findings emphasize the potential of RW as a natural, plant-based chemopreventive agent and pave the way for future research to isolate active bioactive compounds and explore their applications in cancer prevention and integrative treatment strategies.

#6331 Prevention of lung cancer growth by an edible mushroom-derived p-terphenyl antioxidant, Vialinin-A.

N. Ratna, A. Namit, K. A. Ramana;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Lung cancer remains the leading cause of cancer-related deaths in the United States, surpassing the combined fatalities from colon, breast, and prostate cancer. In 2024, approximately 234,580 individuals were diagnosed with lung cancer, with projections indicating an increase in 2025. A history of smoking, both first and secondhand, the use of other combustible tobacco products, and hereditary risk factors have been strongly associated with lung cancer. Environmental exposures to radon, asbestos, arsenic, air pollution, and other occupational exposures exacerbate the likelihood of developing the disease. Novel treatment approaches are required to improve outcomes in lung cancer prognosis. Vialinin-A, a ubiquitin-specific peptidase inhibitor derived from Chinese edible mushrooms, T. terrestris and T. vialis, has potent antioxidant and anti-inflammatory properties. However, its potential anti-carcinogenic effects remain unexplored. Therefore, we hypothesize that Vialinin-A, with its potent anti-oxidative and anti-inflammatory effects, could prevent lung cancer growth. Human Non-Small Cell Lung Cancer (NSCLC) cell lines (A549) were used to investigate the potential chemopreventive role of Vialinin-A on lung cancer. An MTT assay was conducted to evaluate EGF-induced cell viability without or with Vialinin-A. The expression of pro-, anti-inflammatory, and apoptotic proteins was then assessed via multiplex antibody arrays. Mitochondrial reactive oxygen species (ROS) and a scratch array were then used to calculate cell migration. Cell death was observed using a live and death assay. Our results suggest that Vialinin-A could prevent EGF-induced lung cancer growth in a dose- and time-dependent manner. The expression of apoptotic proteins such as Catalase, Cleaved Caspase-3, cIAP-1, Claspin, SMAC/Diablo, and Clusterin was significantly upregulated in A549 cells treated with EGF+Vialinin-A. EGF-induced cell migration and invasion were prevented with Vialinin-A treatment. Vialinin-A also decreased the EGF-induced ROS and elevated caspase-3 levels. Thus, our data suggests that by increasing the caspase-3-mediated apoptotic pathway, Vialinin-A could prevent lung cancer growth and migration. Next, we will examine how Vialinin-A prevents lung cancer growth using nude mice xenograft models.

#6332 Targeting PARP for the prevention of BRCA1-deficient triple-negative breast cancers.

Amanda Lanier[1], John Clifford[2], Jamal Hill[1], Darian Coleman[1], Cassandra Moyer[1], Alejandro Contreras[1], Mark Albertella[3], Anna Staniszewska[3], Andrew Reynolds[3], Shizuko Sei[2], Powel Brown[1], Abhijit Mazumdar[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]National Cancer Institute, Rockville, MD,[3]AstraZeneca, Cambridge, United Kingdom

Background: Triple-negative breast cancer (TNBC) tumors frequently harbor *BRCA1* gene mutations especially in women with a family history of breast cancer. It has been shown that *BRCA1*-deficient cells are highly sensitive to Poly ADP ribose polymerase (PARP) inhibitors as PARP inhibition and trapping leads to synthetic lethality due to increased genomic instability. PARP inhibitors are therefore effective treatments for breast cancers with *BRCA1* or *BRCA2* mutations and may have potential utility for cancer prevention and risk reduction strategies, in particular for women with germline *BRCA1* or *BRCA2* pathogenic variants. For this study, we hypothesized that PARP inhibitors will prevent the development of TNBCs in a mouse model of mammary tumorigenesis with *BRCA1* deficiency.

Methods: Two studies were conducted in immune competent models: (1) a dose and schedule finding study using syngeneic *BRCA1*-deficient graft model, and (2) a long-term study to determine whether a PARP inhibitor can prevent *de novo* tumor formation. In the dose-finding study, mammary tumor fragments from MMTV-Cre$^{+/+}$/BRCA1$^{co/co}$/p53$^{+/-}$ mice were transplanted into the mammary fat pads of MMTV-Cre$^{+/+}$/BRCA1$^{co/co}$/p53$^{+/+}$ mice. When these mice developed palpable tumors, they were treated by oral gavage with talazoparib or AZD5305. In the second series of experiments designed to determine the preventative efficacy of the PARP inhibitors, mice were treated with PARP inhibitors from 4 months of age until tumors reached 1,500 mm^3. Mice were observed daily for tumor formation and toxicity. Tumor incidence and time to tumor formation were visualized using Kaplan Meier curves and analyzed using the log-rank test.

Results: All three doses and schedules of talazoparib and AZD5305 significantly suppressed the growth of MMTV-Cre/BRCA1$^{co/co}$/p53$^{+/-}$ tumors in the syngraft model. Our current results from the long-term study show that (a) treatment with AZD5305 (at 0.5mg/kg; 5X/week for one week followed by 3 weeks off) significantly (p=0.0001) delays mammary tumor formation in MMTV-Cre/BRCA1$^{co/co}$/p53$^{+/-}$ mice with median survival increasing from 213 days to 383 days, and (b) daily treatment of AZD5305 (5 days treatment, followed by 2 days off) at a lower dose (0.125mg/kg) also significantly delays mammary tumor formation in MMTV-Cre/BRCA1$^{co/co}$/p53$^{+/-}$ mice with median survival increasing from 266 days to 320 days (p=0.004). Long term treatment with AZD5305 at these doses was not associated with any observable toxicity in this study.

Conclusions: Both talazoparib and AZD5305 greatly suppress the growth of syngrafted *BRCA1*-deficient tumors in mice. AZD5305 also delayed the development of TNBC mammary tumors in MMTV-Cre/BRCA1$^{co/co}$/p53$^{+/-}$ mice. Based on these results, in the future, PARP inhibitors may be effective drugs to reduce the risk of *BRCA1*-deficient breast cancer. (Supported by NCI-PREVENT to PB & AM)

#6333 Interactions between endocrine-targeting therapies and short-chain fatty acids in reducing ER+ breast cancer.

Alana Arnone, Adam S. Wilson, Valerie S. Payne, Katherine Ansley

Wake Forest Baptist Comprehensive Cancer Ctr., Winston-Salem, NC

Emerging evidence highlights the gut microbiome as a key player in estrogen receptor-positive (ER+) breast cancer development and recurrence, with breast cancer patients often exhibiting altered gut microbial profiles. Although oral endocrine-targeting therapies have proven effective in treating and preventing ER+ breast cancer recurrence, the risk of therapeutic resistance and tumor recurrence remains decades post-diagnosis. Whether these endocrine targeting therapies interact to shift the gut microbiome and whether modifying diet-microbe-metabolite interactions could enhance the efficacy of these therapies remains largely unexplored. Preliminary data indicate that supplementing with bacterial-derived metabolites, particularly short-chain fatty acids (SCFAs), may impact ER+ breast cancer by influencing tumor initiation, progression, and response to treatment. In both chemical-carcinogen-induced and spontaneous genetic MMTV-PyMT murine models of mammary tumorigenesis, exogenous SCFA supplementation increased tumor-free survival and reduced tumor multiplicity in the context of a high-fat diet. Additionally, in a 4T1.2ER+ syngeneic murine breast cancer model, exogenous administration of SCFA butyrate alone reduced tumorigenesis by modulating apoptosis (cleaved caspase 3) and immune infiltrate (F4/80 macrophages and infiltrating CD8+ T-cells). Further, exogenous administration of all three SCFA (butyrate, acetate, propionate) in mice on high-fat, low-fiber diet significantly reduced tumor growth and enhanced tamoxifen anti-tumor efficacy. SCFA interventions modulated tumor proliferation (Ki67), tumor apoptosis, and enhanced anti-tumor immunity (infiltrating CD8+ T-cells). Plasma butyrate levels were negatively correlated with breast cancer patient BMI, suggesting obesity interactions regulate gut microbial metabolite generation. To explore direct drug-microbe interactions we used an *ex vivo* colonic bioreactor and human donor fecal samples, we show that the aromatase inhibitor (AI) letrozole increased the proportional abundance of several SCFA-producing microbes. Moreover, metagenomic sequencing of DNA isolated from fecal samples obtained from postmenopausal breast cancer patients before and 3 months after AI treatment (NCT05030038) further revealed shifts in gut microbial populations, including increases in the proportional abundance of SCFA-producing species. These changes were associated with decreased circulating inflammatory cytokines. These findings suggest that SCFAs may suppress breast carcinogenesis, promote endocrine-targeting therapy responsiveness, and AI may directly modify SCFA-producing microbiota in breast cancer patients. SCFA may represent a promising adjunctive strategy to improve the outcomes of endocrine-targeting therapies for ER+ breast cancer patients.

#6335 Structure-activity relationship (SAR) studies identify region B capsaicin analogs with growth-inhibitory activity in human small cell lung carcinoma.

Amanda B. Sugrue[1], Kushal J. Modi[1], Reagan S. Light[1], Rama S. Gadepalli[2], John M. Rimoldi[2], Stephen D. Richbart[1], Justin C. Merritt[1], Piyali Dasgupta[1]

[1]Biomedical Sciences, Marshall University School of Medicine, Huntington, WV,[2]Biomolecular Sciences, University of Mississippi, University, MS

Purpose of the Study: The long-term research objective of our laboratory is to identify natural phytochemicals that could have potential applications for the treatment of human small-cell lung cancers (SCLC). Specifically, published data from our laboratory shows that capsaicin (the hot and spicy component of chili peppers) potently abrogates the growth and progression of human SCLC *in vitro* and *in vivo*. Conventionally, capsaicin is recognized as a powerful pain-relieving agent which is present in many over-the-counter creams and lotions. However, the clinical applications of capsaicin as a viable pain-relieving agent (and an anti-cancer drug) are hindered by its adverse side effects, such as gastric irritation, stomach cramps, and burning sensation. Such drawbacks of capsaicin may be circumvented by the rational design of non-pungent capsaicin analogs with comparable/greater bioactivity than capsaicin. The structure of capsaicin may be divided into three regions: Region A (the aromatic ring), Region B (the amide group), and Region C (the hydrophobic side chain). As a first step, we synthesized a panel of compounds with variations in Region C of capsaicin.
Experimental Procedures: The growth-suppressive activity of these Region C capsaicin analogs was evaluated using an MTT-based screening assay. The results of the MTT assay were confirmed by measuring the pro-apoptotic activity of these compounds. Based on our findings, our hit compounds were “ARVANIL” and “DOHEVANIL”. Using these two compounds as the template, we then sought to design analogs that would have different chemical groups in Region B of the molecule. The growth-suppressive activity of these Region B analogs was measured using an MTT-based screening assay in human SCLC cells. The results obtained from the MTT experiments were verified by soft agar assays and experiments in patient-derived organoids.
Results: SAR studies led to the identification of a panel of synthetic Region B capsaicin analogs with varying growth-inhibitory activity in human SCLC cells. The pro-apoptotic activity of these compounds correlates well with their ability to inhibit the viability of human SCLCs.
Conclusions: The Region B capsaicin analogs may have applications in the therapy of human SCLC. Our future studies will examine the anti-cancer activity of selected Region B capsaicin analogs in vivo.
Support or Funding Information Funding for our study was supported by a NIH R15-AREA Grant (2R15CA161491-03) and a Center for Natural Products pilot grant from the WV-INBRE Grant Program (P20GM103434, PI: Gary Rankin). Furthermore, this study was supported in part by an Institutional Development Award (IDeA) Grant number P20GM104932 from the National Institute of General Medical Sciences (NIGMS) and the Research Core B of COBRE, a component of the National Institutes of Health (NIH).

#6336 Preclinical efficacy of TRAIL inducing ONC201 against carcinogen (NNK)-induced lung adenocarcinoma in A/J mouse model.

Karthikkumar Venkatachalam[1], Venkateshwar Madka[1], Gopal Pathuri[1], Anil Singh[1], Anh Bao[1], Nicole Stratton[1], Shizuko Sei[2], Vignesh Gunasekharan[2], **Chinthalapally V. Rao**[1]

[1]Center for Cancer Prevention and Drug Development, Department of Medicine, OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]Division of Cancer Prevention, National Cancer Institute, Rockville, MD

Lung cancer is the 2nd most commonly diagnosed cancer in both genders in the US. Most lung tumors are diagnosed at late stages and distant metastasis drastically reduces 5-year survival to <10%. Hence, intercepting lung tumor progression would aid in reducing tumor burden and cancer mortality. Preclinical and TCGA data demonstrated that the TNF Related Apoptosis Inducing Ligand (TRAIL/TNFSF10) is incrementally downregulated with lung tumor progression. Hence we evaluated ONC201 (Dordaviprone), a orally active TRAIL-inducing small molecule for its cancer preventive efficacy in the tobacco carcinogen Nicotine-derived Nitrosamine Ketone (NNK) driven A/J mouse lung cancer model. Prior to the efficacy studies, five different oral doses of ONC201 (0-200mg/kg BW) were tested in A/J mice (n=6/gender/group) for optimal dose range selection. For efficacy evaluation, A/J mice (6 weeks age; n=20/sex/group) were randomized into vehicle control and intervention groups; and lung tumors were induced by a single i.p. injection of NNK (2.07mg/mouse). Six-weeks after NNK injection, mice were given 0, 25, 50, or 100mg/kg BW ONC201 (in PBS) by oral gavage twice weekly for 28 weeks. Mice were then euthanized and lungs were evaluated for tumor incidence and multiplicity. All of the NNK-injected control mice developed lung tumors (100% incidence); but significant difference ($p<0.001$) was observed in tumor multiplicity between genders (17±2.18 in females (Mean±SEM) Vs 7.7±0.89 in males). ONC201 treatment led to significant decrease in tumor multiplicity at all 3 tested doses in both genders (25-43% less tumors; $p<0.05$-$p<0.001$). Lung tumors were classified as adenomas (AD), and adenocarcinomas (AdCa) based on histological criteria. Control mice developed 2.25±0.19 AD, and 5.45±0.69 AdCa in male; 3.89±0.57 AD, and 11±1.24 AdCa in female mice. While ONC201 treatment reduced the adenomas moderately, AdCa was significantly inhibited at all 3 doses in both genders in a dose dependent manner. In the female mice, AdCa multiplicity was reduced by 27% ($p<0.05$), 53% ($p<0.001$), and 70% ($p<0.0001$) in 25 mg/kg, 50 mg/kg, and 100 mg/kg BW ONC201 respectively. Similarly, AdCa was inhibited by 55% ($p<0.001$), 67% ($p<0.0001$), and 84% ($p<0.0001$) in male mice at the 3 dose levels as compared to controls. No toxicities were observed in all doses tested in both genders. Biomarker analysis of the lung tumors using IHC and Western blotting analysis suggested an induction of TRAIL signaling pathway markers, increased apoptosis, and a decrease in proliferation markers (PCNA, Cyclin D1, EGFR, Ki67). In conclusion, our data indicate a strong preventive efficacy of ONC201 in a preclinical model of lung cancer and warrant further development towards clinical applications for lung cancer prevention in high-risk cohorts. (*Project funded 100% with Federal funds from NCI, NIH, DHHS, under Contract 75N91019D00020_75N91022F00003*)

#6337 A novel PMS2 mutant Lynch syndrome mouse model for cancer prevention studies.

Kajal Biswas[1], Yurong Song[2], Vaishnavi Peddibhotla[3], Brandon Somerville[2], Mary Albaugh[3], Dillon Dierman[3], Rameesha Mustafa[3], Altaf Mohammed[1], Shyam K. Sharan[3], Robert H. Shoemaker[1]

[1]Chemopreventive Agent Development Research Group, Division of Cancer Prevention, National Cancer Institute, Rockville, MD,[2]Vaccine, Immunity and Cancer Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Mouse Cancer Genetics Program, Center for Cancer Research, National Cancer Institute, Frederick, MD

Mono-allelic germline pathogenic variants (GPVs) in MMR genes (*MLH1, MSH2, PMS2*, and *MSH6)* predispose individuals to hereditary non-polyposis colorectal cancer (HNPCC), better known now as Lynch syndrome (LS). Bi-allelic GPVs in MMR genes lead to a severe phenotype, constitutional MMR deficiency (CMMRD), that is characterized by early onset of leukemia/lymphoma, colorectal/gastrointestinal tumors, brain tumors, and sarcomas. MMR deficient mouse models have provided many mechanistic and translational insights. *Pms2*-null (*Pms2*$^{ko/ko}$) mice were found to be viable but showed an increase in microsatellite instability and developed lymphomas and sarcomas. One of the most frequently occurring human mutations in *PMS2* is a founder mutation NM_000535.5:c.2002A>G (p.I668V), observed in the Canadian Inuit population (1 in 16 Inuits are carriers). This mutation acts as a de novo splice site that creates a 5 bp deletion resulting in a truncated protein (p.I668*). A mouse model with an equivalent germline mutation (*Pms2c.1993A>G*) results in a splicing defect like that observed in humans and exhibits a significant increase in microsatellite instability and intestinal adenomas on an *Apc* mutant (*Apc*^{tm1Rak}) background. We are now further characterizing this model for intestinal tumor initiation and progression using time course experiments and comparing tumor development by histopathological examination with the *Pms2*$^{ko/ko}$ model. Moreover, we are also examining this model to identify neoantigens, that may lead to development of a new vaccine for *PMS2* mutation carriers.This mouse model can be a valuable tool to test the efficacy of new strategies for cancer prevention in PMS2 mutation carriers. We have developed a luciferase based splicing reporter assay in HEK293 cells that can be used to screen splicing modulators to suppress aberrant splicing of this splice site mutation. The efficacy of these modulators to suppress aberrant splicing in the small intestine of mice can be further tested using this mouse model.

#6338 CRISPR/Cas9 *in vitro* modelling of a VUS mutation found in Peruvian patients diagnosed with hereditary breast cancer.

S. R. Paredes-Moscosso, C. Villegas-Llerena, B. E. Quispe-Bravo, J. Buleje, M. L. Guevara-Fujita, R. Fujita;
Universidad de San Martin de Porres, Lima, Peru

Breast cancer is the most common neoplasm in women worldwide. In Latin America, rapid economic growth has driven epidemiological and demographic transitions that have increased the breast cancer burden. In Peru, breast cancer is the leading malignancy among women, with approximately 10% of cases linked to hereditary factors, primarily mutations in the *BRCA1* and *BRCA2* tumor suppressor genes. Many genetic variants are classified as Variants of Uncertain Significance (VUS), as their biological and clinical impacts remain unknown. In a previous work, our group identified six novel VUS in Peruvian families with hereditary cancer, including the c.5074+28T>A variant found in seven families. The overriding aim of the present study was to model the c.5074+28T>A VUS in a healthy breast tissue cell line (SVCT) using CRISPR/Cas9 technology. Gene editing was performed using ribonucleoprotein complexes (RNPs), whereby 03 different guide RNAs were tested. RNPs were transfected into SVCT cells by electroporation. Transfection and VUS insertion were verified via flow cytometry, T7EI assay, and Sanger sequencing. Single-cell clones were expanded, cryopreserved, and analyzed by PCR and enzymatic digestion (RFLP). Positive clones were further analyzed by Sanger sequencing, where 01 clone carrying the VUS c.5074+28T>A was identified (SVCT-VUS, clone C59). RT-PCR analyses showed no difference between unmodified SVCT cells (ctrl) and clone C59 at the mRNA sequence level. *BRCA1* gene expression was then assessed by qPCR (Taqman assay), where *BRCA1* downregulation was observed on SVCT-VUS compared to unmodified SVCTs. Although RNA from patients carrying the c.5074+28T>A variant was not available for analysis, SVCT-VUS cells showed a comparable *BRCA1* gene expression to MDA-MB-231 breast cancer cell line, which possess a reportedly reduced *BRCA1* mRNA and protein expression levels. Functional studies are still needed to confirm whether c.5074+28T>A affects *BRCA1* expression at a protein level. These findings demonstrate a proof-of-concept for a CRISPR/Cas9 cell-modeling platform to study VUS in Peruvian patients with breast cancer and other diseases.

#6339 Reprogramming SREBP1-dependent metabolism and inflammation in high-risk breast with licochalcone A for the prevention of breast cancer.

Atieh Hajirahimkhan[1], Elizabeth T. Bartom[2], xingyu Guo[3], Kyli Berkley[3], Ruohui Chen[2], Wonhwa Cho[3], Michael Avram[1], Susan E. Clare[1], Seema A. Khan[1]

[1]Surgery, Northwestern University - Chicago, Chicago, IL,[2]Northwestern University - Chicago, Chicago, IL,[3]University of Illinois Chicago, Chicago, IL

Breast cancer (BC) risk-reducing drugs have minimal impact due to their adverse effects and low acceptance. Novel non-endocrine agents with reduced toxicity and efficacy beyond HR+ BC are needed. We recently showed that in high-risk women's breast treated with licochalcone A (LicA) *ex vivo*, changes in metabolism flux led to reduced proliferation, NF-kB-dependent inflammation, and SREBP1-dependent lipogenesis. Additionally, LicA suppressed the proliferation of pre-malignant and malignant breast cell lines (HR+ and HR-) and their xenografts in mice. Now we present confirmatory evidence that LicA prevents BC by reducing SREBP1-dependent metabolism and inflammation. We also show the promising pharmacokinetic (PK) profiles of our novel oral formulations. We performed NanoString metabolism panel assay in MDA-MB-231 (HR-) and MCF-7 (HR+) cells treated with LicA (10 μM, 24 h) and analyzed data by ROSALIND. We also conducted Proteome Integral Solubility Alteration (PISA) proteomics and Enrichr analysis to confirm transcriptomic data and the main targets of LicA. We validated the findings with western blots. In addition, we evaluated spatiotemporal changes in cholesterol concentrations in the inner leaflet of the plasma membrane. Five proprietary novel formulations of LicA were developed and administered orally and intravenously to female BALB/c mice and Sprague-Dawley rats followed by LC-MS/MS analysis of the plasma and mammary tissue, and PK modeling using SAAM II. We observed significant (adj $P < 0.05$) upregulation of anti-inflammatory signals (up to 9-fold) such as HMOX1, and downregulation (up to 6-fold) of NF-kB-dependent inflammatory pathways such as prostaglandin E2 synthesis at the level of genes and proteins. We also observed significant downregulation of SREBP1-dependent lipogenesis signals such as ACAT2, FASN, SCD, and proliferation markers such as MKI67. Proteomics results further revealed a reduction in neddylation responsible for stabilizing SREBP1, and a metabolic shift from lipogenesis to the degradation of fatty acids and branched amino acids, and an enhanced TCA cycle. Western blots revealed significant suppression of SREBP1 (4-fold), and the reduced phosphorylation of PI3K (5-fold) and AKT (6-fold, at Ser 473). These results were confirmed by cholesterol depletion in the inner leaflet of the plasma membrane in HR- (8-fold) and HR+ (4-fold) cells. These results demonstrate that LicA reduces cell proliferation by suppressing SREBP1-dependent lipogenesis and inflammation. Our novel oral formulation of LicA, L13 showed promising PK ($C_{max} \approx 6$ μM, $T_{1/2} = 26$ h) suitable for BC prevention efficacy. Our data suggests that reprogramming SREBP1-dependent metabolism and inflammation by LicA prevents BC regardless of HR status. We will test L13 in immunocompetent models of BC to further establish its preventive efficacy.

#6340 Pancreatic cancer specific *Bmal1*-floxed mice reduced malignant potentials and prolonged survival.

Jinsuk Kim[1], Yukino Oshima[1], Ichie Kajiwara[1], Tomoaki Itaya[1], Tomoya Kuramochi[1], kaori saito[2], Taira Wada[3], Takahiro J. Nakamura[4], Shigeki Shimba[3], Hideaki Ijichi[5], Makoto Sano[1], Takahiro Suzuki[1]

[1]Department of Anesthesiology, School of Medicine, Nihon University, Tokyo, Japan,[2]Department of psychiatry, School of Medicine, Nihon University, Tokyo, Japan,[3]School of Pharmacy, Nihon University, Chiba, Japan,[4]Laboratory of Animal Physiology, School of Agriculture, Meiji University, Kanagawa, Japan,[5]Department of Gastroenterology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan

Introduction: Dysregulation of clock genes has been reported in pancreatic ductal adenocarcinoma (PDAC), but the effects of the dysregulation on circadian rhythm, PDAC carcinogenesis, progression and prognosis remain unclear. To investigate the effects of dysfunctional *Bmal1*, a major clock gene, we compared *KPPC* (*LSL-Kras*$^{G12D/+}$*; Trp53*$^{flox/flox}$*; Pdx-1*$^{cre/+}$) and *KPPBC* (*LSL-Kras*$^{G12D/+}$*; Trp53*$^{flox/flox}$*; Bmal1*$^{flox/flox}$*; Pdx-1*$^{cre/+}$) transgenic mice with PDAC.

Methods: Six-week-old *KPPC* and *KPPBC* mice were housed in wheel cages, and the circadian rhythms were measured until the humane endpoint. Tumor status and plasma cytokine levels were determined using histopathological analysis and cytokine array, respectively.

Results: *KPPBC* mice retained wheel activity at the terminal stage and prolonged the survival rate compared to *KPPC* mice. The pancreatic tumor volume of *KPPBC* mice was smaller than that of *KPPC* mice. The proliferative Ki67 index and invasive frequency of PDAC in *KPPBC* mice were lower than in *KPPC* mice. Local MPO$^+$ tumor-associated neutrophils (TANs) and arginase-1$^+$ M2-like tumor-associated macrophages (TAMs) mice decreased in *KPPBC* mice compared to *KPPC* mice, whereas iNOS$^+$ M1-like TAMs and CD8$^+$lymphocytes increased in *KPPBC* mice compared to *KPPC* mice. Indeed, gastrocnemius muscle atrophy with cachexia was observed in both mice groups at the terminal stage, but average area of the gastrocnemiusmuscle in *KPPBC* mice was larger than in *KPPC* mice. Plasma levels of IGF-I and IGF-II in *KPPBC* mice were higher than in *KPPC* mice. The proliferation of PDAC cell lines with *Bmal1*-deficient was slower than that of PDAC cell lines with wild type of *Bmal1* in vitro.

Conclusions: These results suggest that inhibition of the proliferative potential of *Bmal1*-floxed PDAC could result from the direct effect of *Bmal1* deficiency and alteration of tumor microenvironment. Meanwhile, the delay of gastrocnemius muscle atrophy in *KPPBC* mice may be due to an increase in cytokines such as IGF-I and IGF-II.

#6341 Inhibition of 15-PGDH prevents tumor development in the AOM/DSS model.

Mariana Franco Fragoso[1], Filip Goshevski[1], Stephen P. Fink[1], Won Jin Ho[2], Sanford D. Markowitz[1]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Johns Hopkins University School of Medicine, Baltimore, MD

Patients with ulcerative colitis (UC) face a cumulative risk of developing colitis-associated cancer (CAC) that is significantly higher than that of the general population. This increased risk is directly associated with the inflammatory process that occurs throughout the disease, creating the appropriate environment for the development of neoplastic lesions and impacting treatment decisions for these patients. Therefore, developing a drug capable of both mitigating the inflammatory response associated with ulcerative colitis and preventing tumor development would be an ideal therapeutic approach for UC patients. Using the murine dextran sulfate sodium (DSS) model of acute colitis, the Markowitz lab has previously demonstrated that inhibition of 15-PGDH, the primary enzyme responsible for PGE2 degradation, can markedly enhance tissue repair capacity in the colon as well as multiple additional organs (Science, 2015. PMID: 26068857). We demonstrated that treatment with (+)-SW033291 (‘291), a small molecule 15-PGDH inhibitor, increased the levels of tissue PGE2, near completely reversed colitis mucosal damage and promoted mucosal regeneration by sustaining colonocyte proliferation. We now aim to evaluate the safety of this 15-PGDH inhibitor in the context of CAC by testing ‘291 efficacy in the azoxymethane (AOM)/DSS model. Colon carcinogenesis was induced by a single dose of AOM (10 mg/kg) on day 1 of the experiment followed by 7 days of DSS treatment in drinking water (from days 8 to 15). Animals were treated with daily injections of ‘291 (10 mg/kg, twice daily, i.p.) or it is vehicle for 15 days (from days 8 to 22) and were monitored for signs of disease. Euthanasia occurred on day 47 of the experiment. At the time of sacrifice, colons were isolated and analyzed for the presence of macroscopic lesions and then fixed for histopathology and IHC staining (analyses that are in progress). Macroscopic evaluation of the colons demonstrated that inhibiting 15-PGDH reduced tumor number and tumor burden in the ‘291-treated mice when compared to vehicle controls by 50 and 60%, respectively. Additionally, treatment with ‘291 prevented body weight loss ($p=0.02$) during the disease course. This data indicates that ‘291 can not only reverse epithelial damage after DSS-induced colitis, but also be an effective strategy in preventing the development of colitis-associated dysplastic lesions in the AOM/DSS model. This data reinforces the rationale for developing a 15-PGDH inhibitor therapeutic to be used for patients with UC with the ultimate goal of mitigating colitis symptoms and preventing neoplastic lesion formation.

#6342 Ensuring diverse *in vitro* lung cancer models: development of alveolar epithelial cell lines from individuals of African ancestry.

Bianca Dal Bo[1], Sofia A. Lugo[1], David M. Lee[1], Kweku Ofosu-Asante[2], Kyle R. Phillips[3], Benjamin J. Ryder[3], Yong Huang[3], Nazarius S. Lamango[2], Ite A. Offringa[1]

[1]University of Southern California Keck School of Medicine, Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Florida Agricultural and Mechanical University, Tallahassee, FL,[3]Department of Mechanical and Aerospace Engineering, University of Florida, Gainesville, FL

Lung cancer disproportionately affects Black/African American (B/AA) individuals, particularly men, who experience 12% higher incidence and 15% higher death rates than White/European (W/E) men. Lung adenocarcinoma (LUAD) originates in the alveolar epithelium and is the most common histological subtype of lung cancer for all racial groups. Immortalized human alveolar epithelial cells (ihAEC) are key tools to study the etiology and development of LUAD, as well as effects from environmental exposures. We recently established three ihAEC lines from remnant lung tissue of deceased unidentified W/E individuals using lentiviral transduction of simian virus 40 large-tumor antigen (SV40 LgT) and human telomerase reverse transcriptase (*TERT*) genes. SV40 LgT is an oncogene that promotes constant proliferation, while *TERT* prevents telomere shortening. Lentiviral vectors randomly integrate into the host genome, causing potential unwanted side effects. In addition, integrated transgenes may become silenced in the long-term. Furthermore, viral vectors that deliver oncogenes are a considerable biosafety concern that warrants avoidance whenever possible. Here, we describe an alternative gene-delivery approach that avoids the use of lentiviral vectors, and we use this new strategy to generate ihAEC lines of diverse ancestry. We have constructed a plasmid carrying SV40 LgT, an internal ribosome entry site, and *TERT*, as well as a puromycin resistance gene. The SV40 LgT sequence has been engineered with flanking loxP sites to allow its excision by Cre recombinase, if desired. To direct genomic integration by CRISPR/Cas9, the transgene is surrounded by homology arms that target integration into the adeno-associated virus integration site 1 (AAVS1), a safe harbor region that prevents inserted genes from being silenced. We will electroporate this plasmid into AECs isolated from remnant non-tumor lung tissue that was collected with full consent from lung cancer patients of diverse ancestry, including B/AA men. Development of new ihAEC lines will provide valuable tools for studying responses to environmental exposures, carcinogen detoxification processes, oncogenic transformation, and for testing novel therapies in models distinct from W/E genotypes. This work is an important step towards minimizing lung cancer health disparities caused by the absence of diverse model systems. Supported by grants U54CA233396, U54CA233444, and U54CA233465 from the National Institutes of Health (NIH)/National Cancer Institute (NCI), and the Norris Comprehensive Cancer Center core grant, award number P30CA014089 from the NIH/NCI.

#6344 Effects of psychological stress early in NNK-induced lung carcinogenesis in young female mice.

Dana H. Bovbjerg[1], Laura P. Stabile[1], Beatriz Kanterewicz[1], Jessica Manculich[1], Jessie R. Nedrow[1], Patrick Tarwater[2], Lora H. Rigatti[1], Frank J. Jenkins[1]

[1]UPMC Hillman Cancer Center, Pittsburgh, PA,[2]Texas A&M University, College Station, TX

Tobacco smoke contains many known carcinogens, chief among which is nicotine-derived nitrosamine ketone (NNK). However, even among individuals with high exposure levels, only a minority develop lung cancer. Prior research highlights additional exogenous (e.g., air pollution) and endogenous (e.g., estrogen exposure) factors that may increase risk. Currently lacking in the literature is consideration of possible effects of psychological stress. To experimentally test stress effects, we utilized a well-established mouse lung adenocarcinoma model with NNK exposure of young female mice, along with a mouse stress protocol. We previously reported that repeated exposure to stress before, during and after 4 weeks of exposure to NNK (IP; 2x/week; 3 mg/injection) increased both overall lesion size and the total number of lung lesions compared to controls when assessed 19 weeks post completion of NNK exposure. The present study used the same protocol to test stress effects earlier in the process of NNK carcinogenesis. FVB/N female mice (4-6 wk) bought from a commercial supplier were acclimated for two weeks before study initiation. The repeated stress protocol was then begun (Week-0) for the Stress group (n=40) and continued throughout the study, while the Control group (n=40) remained in their home cages. The stress protocol included social disruption via changes in cage mates at the time of routine cage cleaning (2x/week) and 90-minute restraint stress prior to a cage mate change (1x/week). NNK treatment began on week-1 (IP; 2x/week; 3 mg/injection) and continued for 4 weeks. At 8 and 15 weeks after the end of NNK exposure, 20 mice in each study group were euthanized. Lungs were formalin inflated. Surface lung lesions were counted under a dissecting microscope and lesion sizes were objectively measured (blind) using Motic Images software. Lungs from mice euthanized at 15 weeks were then imbedded in paraffin and serially sectioned (4 μm) to allow H&E confirmation of lesion numbers and sizes by a veterinary pathologist and to provide slides for ongoing immunohistochemical characterization. Statistical analysis (ANOVA) revealed significant main effects of study group, with lungs from stressed mice having larger overall lesion sizes (p=.007), and total number of lesions (p=.012), compared to controls. As expected, those two outcomes were also significantly increased in the lungs from mice euthanized at 15- vs. 8-weeks (no interaction with group). Providing independent corroboration of the Motic imaging results, data from the histological evaluation of lesion sizes and numbers were significantly correlated (p's <.001). Conclusion: We replicated and extended our initial study demonstrating effects of repeated stress in an NNK model of lung cancer in young female mice to earlier phases of NNK-induced lung carcinogenesis.

#6345 Establishing a preclinical cell model to assess the impact of metabolic status on the efficacy of preventive therapies: insights for the COLO-PREVENT trial.

Eve Jarman, Catherine Andreadi, Karen Brown

University of Leicester, Leicester, United Kingdom

Despite numerous advances in colorectal cancer (CRC) treatment, it continues to impose a significant global burden. The COLO-PREVENT polyp prevention trial platform seeks to address this by investigating interventions in 'elevated-risk' cohorts identified through the NHS Bowel Cancer Screening Program (BCSP) by repurposing the drugs aspirin and metformin, as well as the dietary compound resveratrol. The seAFOod polyp prevention trial, which recruited a similar population through BCSP, reported that 82% of participants were classified as overweight or obese (BMI ≥ 25) (Hull, 2018, Lancet). This suggests that COLO-PREVENT participants may also exhibit metabolic dysregulation, potentially modulating the efficacy of preventive interventions. Obesity and type 2 diabetes, both linked to metabolic dysregulation, are well-established risk factors for CRC, supported by both preclinical and epidemiological studies. This study aims to develop an *in-vitro* model of metabolic dysregulation associated with high-fat diet consumption. A non-tumorigenic cell line derived from a colonic tubular adenoma (Williams, 1990, Cancer Res.) was used to explore interactions with therapies under investigation in COLO-PREVENT. Preventive activity will be assessed using MTT assays for cell viability, measurement of free fatty acid levels, analysis of reactive oxygen species (ROS), and confocal microscopy to visualize morphological changes and fatty acid droplet localization in response to treatment. Initial results indicate that clinically achievable concentrations of COLO-PREVENT therapies increase cytotoxicity when cells were cultured under normal conditions. The effect was observed after 72 h of incubation with both single agents and low-dose combinations. Among single agents, only 1 µM aspirin significantly reduced cell viability ($p \leq 0.05$). Low-dose combinations further enhanced cytotoxicity, with 0.5 µM aspirin and 0.005 µM resveratrol increasing cytotoxicity to 37%, while 0.625 µM metformin with 0.0005 µM resveratrol increased cytotoxicity to 65% compared to vehicle control. When exposed to the lipids palmitic acid (PA) and oleic acid (OA) to mimic high fat intake, cells showed enhanced cytotoxicity with PA, while OA exposure had a weak proliferative effect. High concentrations of PA (1 and 5 mM) significantly reduced cell viability, causing 73% and 89% cytotoxicity, respectively, compared to control ($p < 0.001$). In contrast, OA exhibited weak proliferative activity across most tested concentrations. These preliminary findings suggest that metabolic dysregulation may influence the growth of colorectal adenomas and modulate the efficacy of preventive therapies. Further studies are warranted to investigate mechanisms underlying potential interactions and how this might influence precision prevention within the COLO-PREVENT framework.

#6346 The chromatin remodeler SMARCA5 selectively shapes nuclear receptor signaling in African American prostate cancer.

Shahid Hussain[1], Debasis Nayak[1], Sajad A. Wani[2], Isra Elhussin[3], Michael R. Freeman[1], Christopher C. Coss[4], Solomon O. Rotimi[5], Adam R. Murphy[6], Clayton Yates[3], Moray J. Campbell[1]

[1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]University of Cincinnati, Cincinnati, OH,[3]Johns Hopkins School of Medicine, Baltimore, MD,[4]The Ohio State University, Columbus, OH,[5]Covenant University, Ota, Nigeria,[6]Northwestern University, Chicago, IL

SMARCA5 is found in distinct chromatin remodeling complexes where it regulates ATP hydrolysis to control nucleosome positioning required for gene expression and DNA repair. Previously, we established the chromatin remodeling enzyme SMARCA5 is significantly down-regulated in African American (AA) compared to European Americans (EA) prostate cancer (PCa). We have now explored how SMARCA5 distorts the epigenome and impacts transcription, as well as cell phenotypes. Firstly, we revealed that the H3K27ac cistrome had significantly different distributions between AA (RC43N) and EA (HPr1AR) normal cells, and AA (RC43T) and EA (LNCaP) PCa cells. Motif enrichment in H3K27ac revealed significant differences with Helix-Loop-Helix motifs enriched in RC43N compared to HPr1AR; and STAT motifs enriched in RC43T compared to LNCaP. Similarly, nuclear receptor (NR) motifs were distinct with vitamin D receptor (VDR) and orphan receptors (e.g., RORG) enriched in RC43T compared to LNCaP. Next we up-regulated SMARCA5's using dCas9-VP64-activator in the same cells and tested the impact on gene expression with RNA-Seq following treatment with the VDR ligand ($1,25(OH)_2D_3$, 100nM). SMARCA5 regulated ~1200 genes in both RC43T and RC77T, and only ~200 genes in LNCaP. The SMARCA5-dependent genes in AA PCa cells models were significantly enriched for luminal-differentiation genes. Likewise, in the AA compared to EA PCa models, GSEA analyses revealed enrichment for inflammation responses, and distinct NR signaling, such as progesterone signaling. Likewise LISA analyses revealed enrichment in the SMARCA5-dependent genes in AA PCa for progesterone signaling. Finally, we also identified a subset of miRNA related to differentiation that were uniquely regulated in AA PCa models by $1,25(OH)_2D_3$ and a significant number were also SMARCA5-dependent. Ongoing studies are addressing the effect of SMARCA5 on chromatin accessibility using ATAC-Seq. Overall, these studies support the concept the epigenome is shaped by genomic ancestry. The epigenomic-regulator SMARCA5 is significantly downregulated in AA PCa and impacts NRs, including VDR signaling. These findings suggest that African ancestry shapes SMARCA5 functions, NR signaling, and tumor outcomes.

#6347 Epithelial stem cells in tumorigenesis of the lung: lessons from a murine model of lung adenocarcinoma.

Bridget K. Greuel[1], Thomas Danhorn[2], Caroline Hauer[1], Meredith Tennis[1], Alison Bauer[3], Daniel T. Merrick[4], Debashis Ghosh[5], Robert L. Keith[6], York E. Miller[6], Moumita Ghosh[1]

[1]Pulmonary Sciences and Critical Care Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Pharmacology, University of Colorado Cancer Center, University of Colorado Anschutz Medical Campus, Aurora, CO,[3]Environmental and Occupational Health, Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO,[4]Pathology, School of Medicine, University of Colorado, Aurora, CO,[5]Biostatistics and Bioinformatics, Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO,[6]Rocky Mountain Veteran Affairs Medical Center, Aurora, CO

Introduction: Lung cancer is the leading cause of cancer-related deaths, with a poor five-year survival rate. The period of premalignancy is marked by structural and functional alterations in the epithelium that eventually progress to cancer. Epithelial stem/progenitor cells are essential for the maintenance and repair of the airway epithelium. Prior research from our group demonstrated a reduction in the function of normal progenitors in human lung premalignancy. However, studying progressive changes in the epithelium as it advances from normal to premalignant is challenging in humans. This led us to conduct a time-course study of urethane-induced lung adenocarcinoma (ADC) in mice to better understand the role of normal tissue stem cells in tumorigenesis.

Methods: Tumorigenesis was induced in A/J mice (12 mice/group) by a single intraperitoneal injection urethane (1mg/gm), and control mice were injected with saline. Lung tissues were harvested at 2-, 4-, 10-, 16-, and 22-week post-injection; the left lobe was used for histological analysis, and the rest of the lung tissue was digested proteolytically to generate single-cell suspensions. Stem cell function was determined by organoid-forming assay, and molecular analysis of organoids was performed to identify genetic changes in stem cell populations.

Results & Conclusions: Histological analysis revealed that the premalignant changes induced by urethane closely resembled the lesions observed in human lung ADC, including adenomatous hyperplasia, nodular hyperplasia, and adenoma. Immunofluorescence staining (IF) with cell type-specific markers to track the progression of these changes identified hyperplasia of club cells ($CCSP^+$) at 2 weeks, followed by proliferation of type II (SPC^+) cells, the formation of adenomas by 10 weeks, and the development of adenocarcinoma at 22 weeks. Quantification of organoids at all time points showed fewer organoids in urethane-treated mice compared to saline at 2 weeks, but the reverse was true at subsequent time points when greater numbers of organoids were made by the urethane-treated mice (*$p<0.01$ for both directions*). IF staining of organoids identified both airway and alveolar organoids, and there was no difference in their proportions between saline and urethane-treated mice. Interestingly, a small number of bronchoalveolar organoids containing both club and type II cells were detected exclusively in the saline-treated mice that were absent in the urethane group. Significantly, whole exome sequencing of organoids identified several oncogenic mutations in organoids from urethane-treated mice but did not detect mutation in Kras, the known driver for urethane-induced ADC. Thus, our results pointed to an early response of stem cells following urethane exposure, with notable shifts in their behavior during premalignant progression to cancer.

#6348 Cholecystokinin receptor blockade modulates in vitro fibrosis gene expression.

Martha Gay, Hong Cao, Jill P. Smith

Medicine, Georgetown University, Washington, DC

Introduction: Cholecystokinin (CCK) receptors, G-protein coupled receptors, play crucial roles in gastrointestinal physiology, but their overexpression in cancer and fibrosis is implicated in disease progression and therapeutic resistance. Recent evidence suggests that activation of CCK receptors in hepatic stellate cells (HSCs) induces fibrosis-associated gene expression, contributing to liver pathology in conditions like metabolic dysfunction-associated steatohepatitis (MASH) and hepatocellular carcinoma (HCC). We have shown that a diet high in saturated fat induces the expression of hepatic CCK- B receptors in a murine model of nonalcoholic steatohepatitis. The CCK receptor antagonist, proglumide, reversed inflammation, fibrosis, and steatosis prevented the development of HCC in the murine Metabolic dysfunction-associated steatohepatitis (MASH) model.
Hypothesis: The blockade of CCK-B receptor signaling using proglumide will reduce the activation of fibrosis-related genes and prevent the progression of liver injury and carcinogenesis in both murine and human in vitro models.
Methods/ murine cells: Using C57BL/6 mice we will follow the standard protocol for isolation of murine HSC. Stellate cells will be isolated and cultured then stimulated with CCK *in vitro* (1-100nM). Another group of stellate cells will be treated with CCK and proglumide to determine if proglumide can prevent activation in fibrosis genes. Stellate cellular protein will be also extracted and subjected to Western analysis for fibrosis/collagen associated proteins. Macrophages release cytokines/chemokines that activate stellate cells. For our co-culture experiments we will culture murine RAW264.7 macrophages with the mouse HSC to activate fibrosis genes and proteins by cytokine /chemokine activation of stellate cells.
Methods/ human cells: We will use the immortalized LX-2 human HSC line to evaluate the activation of the fibrosis genes with addition of CCK to the growth media and examine if proglumide prevents the activation of the LX-2 cells and perform independently CCK-B or CCK-A receptor CRISPR to determine if CCK-induced fibrosis activation is mediated by the CCK-B or CCK-A receptor. Clonal CRISPR CCK-receptor KO stellate cells will also be activated by co- culture and /or with spent media from our human U937 macrophages.Anticipated outcomes: When stellate cells are grown on plastic *in vitro*, they become activated. We know the cytokines / chemokines released from macrophages will stimulate stellate cells, but the stimulation and collagen synthesis may not be as pronounced if the stellate cells were not already in an activated state. Ongoing data collection.
Conclusion: This investigation aims to clarify the molecular mechanisms by which CCK receptor signaling drives hepatic fibrosis and explore the therapeutic potential of proglumide in reversing fibrosis-related gene expression in liver disease.

#6349 Degradation of Aurora Kinase A, Alters Immune Checkpoint Expressions in Prostate Cancer.

S. Shukla[1], A. Venkatesh[1], J.-P. Kanumuambidi[1], R. D. Rodriguez Rosales[1], M. Al-Toubat[1], S. Sparks[1], A. Yamaguchi[1], S. Pogash[2], S. Fletcher[2], K. Balaji[1];
[1]University of Florida, Jacksonville, FL, [2]University of Maryland, Baltimore, MD

Pre-metastatic niche of tumor microenvironment supports tumor progression and regulates cancer cell survival. Aurora kinase A is a key molecule implicated in establishing this niche by promoting tumor cell migration, invasion, and survival within the secondary organ, thus contributing to metastasis. The Cancer Genome Atlas program data suggested increased expression of Aurora Kinase A (AURKA), Ninein (NIN) and Aurora Kinase A Ninein Interacting Protein (AUNIP) in prostate cancer as compared to normal prostate tissue. We are exploring how these interactions might influence immune cell infiltration, both in immune-responsive and immune-suppressive cells. Regulation of immune checkpoint proteins like PD-L1 and LAG3 is crucial for immune evasion by cancer cells. This study investigates the effects of a novel AURKA degrader compound, SP-02-067, on the downstream signaling cascade that regulates immune checkpoints PD-L1 and LAG3. We analyzed expression data of 702 prostate cancer patients using the Tumor Immune Microenvironment Estimation Resource and involved various immune responsive (CD8+; dendritic cells; natural killer) and immune suppressive (T-reg; myeloid derived suppressor cells; neutrophils) cells. Gene expression analysis showed significant correlation between NIN and PD-L1 ($R = 0.12$, $p = 0.01$), NIN and LAG3 ($R = -0.22$, $p < 0.001$). Combined immune responsive and combined immune suppressive cells were significantly associated with AURKA ($R = 0.03$, $p = 0.24$), NIN ($R = 0.1$, $p = 0.1$) and AUNIP ($R = 0.13$, $p = 0.21$) expression. Next, we treated prostate cancer C4-2 cells with varying concentrations of the novel SP-02-067 compound in a time-dependent manner, which led to degradation of AURKA and altered expressions of PD-L1 and LAG-3. Using an siRNA gene silencing approach for AURKA and AUNIP in C4-2 cells showed increased expression of PD-L1 and decreased LAG3 expression. The data suggests that increased expression of PD-L1 may be associated with an increase in tumor infiltrating cells, which could improve the efficacy of subsequent immunotherapy. Spearman correlation showed a positive correlation with infiltrating immune-responsive CD8+ T cells, dendritic cells, and NK cells. Similarly, immune suppressive regulatory T-cells and neutrophils were positively correlated with LAG3. Based on these findings, we suggest that SP-02-067, a novel degrader of AURKA, could be developed as a promising agent for prostate cancer and inspire innovative approaches to overcome drug resistance in prostate tumor-targeted therapy.

#6354 ATTUNE: optimizing the treatment journey for lung cancer patients by predicting EGFR mutation from routinely stained histology images.

Talha Qaiser[1], **Harish RaviPrakash**[2], Jose Domingo Salazar[3], Marco Rosati[4], Alma Andoni[5], Guillem Portella[6], Adriana Hepner[7]

[1]Computational Pharmacology and Safety Sciences, AstraZeneca UK, Cambridge, United Kingdom,[2]Oncology Data Science, AstraZeneca US, Waltham, MA,[3]Oncology Data Science, AstraZeneca US, Cambridge, United Kingdom,[4]Cancer Biomarker Discovery, AstraZeneca, Munich, Germany,[5]Cancer Biomarker Development, AstraZeneca US, Gaithersburg, MD,[6]Precision Medicine and Biosamples, AstraZeneca UK, Cambridge, United Kingdom,[7]Clinical Development, AstraZeneca US, Gaithersburg, MD

Background: Identifying targetable mutations through tissue-based molecular testing is part of the standard of care management of patients with NSCLC. Nevertheless, globally up to 50% of lung cancer patients are currently not being tested. Liquid biopsy can provide valuable material for molecular diagnosis; however, low sensitivity, especially in early-disease stages, may prevent its broader applicability in the clinic. Predicting EGFR status from digitalized hematoxylin and eosin (H&E) images using machine learning (ML) could be key to addressing such unmet needs.
Methods: We propose an automated deep learning algorithm that retrospectively analyzes H&E images for EGFR status in a pivotal clinical trial (ADAURA), in early stage resectable EGFRm NSCLC and in a publicly available data from TCGA; totaling more than 1,000 patients. The proposed algorithm includes automated tumor segmentation (trained using all TCGA data) and prediction of EGFR mutation from tumor regions with weakly supervised learning (trained using 80% of ADAURA). The segmentation was validated on ADAURA and the proposed EGFR mutation prediction task was validated on held-out 20% of ADAURA and all of TCGA data.
Results: We outperformed existing published solutions by a margin of 10% in terms of the AUC metric. The model achieved the AUROC of 0.81 ± 0.04 and 0.75 ± 0.01 on over 100 phase III clinical trial patients and over 500 patients in TCGA, respectively. The model can be calibrated to achieve either > 90% sensitivity or specificity, depending on the clinical use case.
Conclusion: The proposed approach does not require any regions marked by pathologists to predict EGFR status and our results reinforce using H&E digital pathology slides with ML to predict molecular status, thereby optimizing the treatment journey for millions of lung cancer patients.

#6439 ROME, a novel membrane protein in vertebrates, is a key modulator of embryonal development and cancer metastasis.

Anna Molotkova, Emre Deniz, Matthew Swift, Eric Glasgow, Jeffrey Toretsky, Aykut Uren

Georgetown University Medical Center, Washington, DC

Despite many advances in cancer treatment, metastasis remains the major cause of mortality: over 90% of cancer-related deaths are due to metastasis. We chose Ewing sarcoma (ES) as a model to study cancer metastasis since less than 25% of ES patients with metastatic disease live beyond five years and there are no effective therapies available to specifically target metastatic disease. Through an *in vivo* genome-wide CRISPR/Cas9 transcriptional activation screen using human ES cells as xenografts, we identified the human *INAFM2* gene as a strong driver of metastasis and therefore named the vertebrate gene and its protein product, ROME (Regulator of Metastasis). Up until now, *INAFM2* has not been studied in-depth and INAFM2 protein expression profile or function is not known. We characterized aspects of ROME expression and function in vertebrate development, physiology, and pathology. Blocking ROME expression in zebrafish embryos resulted in severe developmental defects and early mortality. Single cell RNA sequencing of zebrafish embryos with rome knockdown and RNA sequencing of cancer cell lines with ROME modulation revealed that ROME negatively regulates calcium and canonical Wnt pathways. We also discovered that ROME directly interacts with CAV1, FLOT1, and Vimentin proteins. ROME overexpression increased metastasis of ES xenografts in zebrafish and immunodeficient mice while ROME knockout in ES xenografts reduced metastasis. Human tumor RNA sequencing data revealed a negative correlation between ROME expression and patient survival. In summary, we discovered a previously unstudied human glycoprotein located on the plasma membrane that can regulate cell motility and invasion, is essential for normal development in vertebrates, and increases the metastatic phenotype of human tumor cells.

#6440 Spatial transcriptomics of Ewing sarcoma: evolution of tumor associated extracellular matrix from localized to metastasis-associated primary Ewing sarcomas.

Christopher Kuo[1], Krinio Giannikou[1], Nuoya Wang[2], Mikako Warren[1], Andrew Goodspeed[3], Masanori Hayashi[4], Micha S. B. Raredon[5], James F. Amatruda[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Yale School of Medicine, New Haven, CT,[3]University of Colorado, Anschutz Medical Campus, Denver, CO,[4]Children's Hospital Colorado, Denver, CO,[5]Anesthesiology, Yale School of Medicine, New Haven, CT

Objective: To date, the response rate of immunotherapy in Ewing sarcoma (EwS) has been poor. The tumor immune microenvironment (TME) has a vital role in cancer survival and progression with implications in drug resistance and immune escape. However, there is a lack of understanding of the TME of EwS. Although recent single-cell RNA sequencing of EwS and immune cells have revealed a heterogenous transcriptional landscape with distinct subsets of immune cell populations in EwS, little is known about the spatial organization and spatial microenvironmental niches of the TME of EwS.
Methods: We performed Spatial Transcriptomics (ST) on 16 primary pre-treatment biopsied EwS tumors (10 with localized EwS (L-EwS); 6 with metastatic EwS (M-EwS)).
Results: Integrated analysis revealed inter- and intra-tumoral heterogeneity. We inferred the stromal regions of tumors transcriptionally and noted that tumors from L-EwS had significantly more stromal signature than M-EwS (p-value <2.2e-16). Gene set enrichment analysis using Hallmark gene sets revealed that L-EwS tumors were enriched in epithelial mesenchymal transition (EMT) and inflammatory signatures (adjusted p-value <0.05) and M-EwS tumors were enriched in proliferative signatures (adjusted p-value <0.05). We identified a set of 46 unique genes enriched in L-EwS that overlapped with genes in EMT hallmark pathways and were predominantly extracellular matrix related (ECM-r) genes such as *COL3A1, ITGB1, MMP2, ACTA2, TNC, TGFB1*. These ECM-r genes spatially overlapped with the stromal regions of individual tumors. Furthermore, gene composite analysis demonstrated spatial colocalization of macrophages and cancer-associated fibroblasts (CAFs) within the ECM-r regions of the tumors. Spatially informed cell type deconvolution revealed EwS tumor regions that correlated well with histology. Moreover, majority of macrophages/monocytes in L-EwS tumors colocalized with CAFs. Deconvolution analysis also uncovered previously unreported B cell infiltrates and CD8 T cell infiltrative tumors. Spatial cellular microenvironment analysis revealed immune microenvironmental signaling throughout all tumors and unique ECM microenvironmental signaling predominantly in L-EwS compared to M-EwS (p-value <0.05) (TGF-B, cell adhesion and ECM remodeling signals).
Conclusion: L-EwS tumors are enriched in ECM and ECM-related microenvironmental signals compared to M-EwS. Spatial cellular microenvironmental signals reveal that components of the ECM may serve as anchors for tumors to eventually metastasize, nutrients for EwS to proliferate, and most importantly as a communication network with host immune cells. Further studies will be performed on a novel immunocompetent zebrafish genetic EwS model to identify conserved mechanisms of host-tumor interactions and further dissect the role of ECM in EwS.

#6444 PP2A activation targets PAI-1/CCL2 to suppress therapy-induced senescence in neuroblastoma.

Nazia Nazam[1], Maryam Ghufran[2], Morgan L. Brown[2], Sorina Shirley[1], Jerry E. Stewart[2], Michael Ohlmeyer[3], Taylor Schanel[4], Elizabeth A. Beierle[2]

[1]Pediatric Surgery, University of Alabama at Birmingham, Birmingham, AL,[2]University of Alabama at Birmingham, Birmingham, AL,[3]Atux Iskay LLC, Plainsboro, NJ,[4]Department of Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL

Background: Neuroblastoma (NBL) is the most common extracranial childhood solid tumor, and it is responsible for 15% of pediatric cancer deaths. Refractory and relapsed disease are exceedingly difficult to treat and the survival for these children is less than 50%. One hypothesis to explain this poor therapeutic response and tendency for disease recurrence is therapy-induced senescence (TIS) which is a temporary state of growth arrest following treatment. Protein phosphatase 2A (PP2A), a known tumor suppressor, is downregulated in NBL. Preliminary studies indicate that PP2A reactivation reduces TIS in NBL, therefore, we investigated the effects of a novel PP2A activator as a senotherapeutic in NBL.
Methods: We employed the human NBL cell line, SK-N-AS. Topotecan, a common NBL chemotherapeutic, known and confirmed to induce senescence, and ATUX-1215, a novel small molecule PP2A activator were utilized. NBL cells were treated with topotecan and ATUX-1215 alone, as well as in combination. TIS was detected by senescence associated SA-β-galactosidase (SA-β-gal) assay. Colony forming assay detected cell proliferation while immunoblotting identified senescence associated proteins including γ-H2AX, plasminogen activator inhibitor-1 (PAI-1) and C-C motif chemokine ligand 2 (CCL2). R2 Genomics Analysis and Visualization Platform was used for mRNA expression data from human neuroblastoma samples to evaluate the association of *PAI-1* and *CCL2* gene expression with relapse free survival.
Results: PP2A activator reduced SA-β-gal staining and protein expression of γ-H2AX, two markers of senescence, that were induced by topotecan treatment. Further, activation of PP2A in combination with topotecan significantly reduced colony forming potential in NBL cells. Immunoblotting demonstrated the reduction of two mediators and markers of senescence-associated secretory phenotype, PAI-1 and CCL2 with PP2A activation. Clinically, neuroblastoma patients with low PAI-1 as well as CCL2 expression have significantly higher ($p=0.054$, $p=3.74e-03$, respectively) relapse free survival.
Conclusions: PP2A activator, ATUX-1215, holds potential as novel senotherapeutic adjunct by targeting PAI-1 and CCL2. Further investigations into the mechanisms responsible for these findings will be required with goals to advance this therapy to the clinical arena to prevent disease relapse.

#6445 Atypical teratoid rhabdoid tumor development mirrors developmental programs.

F. Yao[1], D. Popovski[1], A. Bondoc[1], J. Rutka[1], T. Pugh[2], A. Huang[1];
[1]SickKids, Toronto, ON, Canada, [2]Princess Margaret Cancer Centre, Toronto, ON, Canada

Atypical Teratoid Rhabdoid Tumors (ATRTs) are pediatric malignancies that arise primarily in young children under the age of 3. While ATRTs are known to segregate into three epigenetically defined subgroups, termed SHH, TYR, and MYC, little is known about the cellular contexts of how these deadly tumors arise and gain tumorigenic properties. We hypothesized that this early onset of disease reflects tumorigenic events in utero. Indeed, previous research has demonstrated maintenance of embryogenesis programs in other pediatric brain tumors.
To characterize the cellular contexts that give rise to ATRTs, we curated 12 single cell and single nuclei RNAseq datasets of human and mouse embryogenesis and developed an atlas and well as a pipeline to match tumors to their most similar embryogenic landmark and timepoint, based on the published cell type identification tool SingleR. We applied this pipeline to two ATRTs single cell datasets generated on the 10X genomics platform: one from primary human samples (N = 33), and one from a tamoxifen inducible ATRT mouse model (N = 8).
To validate the accuracy of our pipeline, we first examined the signatures from our ATRT mouse model. Our pipeline accurately predicted cell types and timepoint within the induction window of E6.5-8.5, suggesting that indeed tumors transcriptionally resemble their cellular contexts.
Results on both human and mouse ATRTs reveals that ATRTs resemble two distinct developmental trajectories: one resembling a gradient of neuronal differentiation from neuroepithelial (NES, SOX2, OTX2) to radial glial cell (TTYH1, ASCL1, FAPB7) types, and a second trajectory characterized by distinctly mesenchymal signatures (COL1A2, PDGFRB). Single cell GSEA showed enrichment of pathways involved in radial glial and mesenchymal signalling, such as WNT, SHH, and PDGFRB signalling. Findings were validated through marker gene immunohistochemistry and spatial transcriptomics.
Taken together, our results demonstrate that ATRTs transcriptionally resemble the developmental contexts of which they arise from. By identifying cellular origins of tumorigenesis, we can exploit this novel information to discover potential therapeutic avenues.

#6446 *Yap1* and CD276/B7-H3: key players in Sex-biased SHH medulloblastoma immune evasion.

Nourhan Abdelfattah[1], Sivaraman Natarajan[2], Han Nhat Tran[1], Thomas Wong[1], Jose Maldonado[1], Rachael McMinimy[3], Hannah Borland[4], Shu-hsia Chen[1], Fernando Camargo[5], James Olson[6], Joshy George[7], Kyuson Yun[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]The Jackson Laboratory for Mammalian Genomics, Bar Harbor, ME,[3]Molecular and Cell Biology, University of California, Berkeley, Berkeley, ME,[4]Borland, College Station, TX,[5]Department of Stem Cell and regenerative medicine, Harvard, Boston, MA,[6]Fred-Hutch, University of Washington School of Medicine, Seattle, WA,[7]The Jackson Laboratory for Genomic Medicine, Farmington, CT

The molecular mechanisms driving sex disparities in cancer prevalence, progression, and treatment outcomes represent a crucial yet understudied area with significant implications for cancer therapy. Medulloblastoma (MB), exhibits a pronounced sex bias in incidence and survival rates, with males experiencing higher incidence and poorer prognoses compared to females. This study focused on the role of *Yap1* in Sonic Hedgehog medulloblastomas (SHH MBs), which revealed an unanticipated sex-biased role of Yap1 in MB immune evasion. Hippo/Yap pathway is one of the top 10 most dysregulated pathways in human cancer. Our in vivo studies uncovered that *Yap1* deletion in a spontaneous SHH MB model significantly extended survival, providing genetic evidence that *Yap1* is a critical oncogene in MB formation. Notably, *Yap1* deletion/inhibition benefitted males, but not females, revealing its sex-biased function for the first time. Integrated multi-omics analyses showed *Yap1* is essential for maintaining MB stem/progenitor cells by activating stemness genes (*Sox2*) and repressing differentiation genes (*Neurod1*, *Zic1/2*) in both sexes. However, *Yap1* plays a more pivotal role in immune evasion in males, particularly by regulating the immune checkpoint molecule; *Cd276*/B7-H3. In males, either CD276 blockade or *Yap1* deletion reverses T cell suppression. In contrast, in females, CD276 blockade or *Yap1* deletion is not sufficient to overcome T cell suppression, and it requires both interventions to activate T cells. Furthermore, our newly discovered transcriptional target gene signatures of YAP1 predict survival in male but not female patients across multiple human cancers, indicating a highly conserved mechanism across species and cancer types. This study highlights sex-specific differences in tumor:immune interactions downstream of YAP1/CD276. In addition, it reveals a novel sex-biased role of YAP1 transcriptional programs, providing molecular entry points for future research on sex differences in immune response. These results underscore the importance of considering sex as a major variable in mechanistic and therapeutic studies involving *Yap1* and CD276, with broader implications for targeted cancer therapies.

#6447 Preclinical efficacy of GCN2 inhibition by KAS-1155 in targeting the integrated stress response in rhabdomyosarcoma.

Da Yeon Kang[1], Hae Won Lee[1], Jong Woo Yoon[2], Jung-Nyoung Heo[2], Youngki Choi[3], Seung Min Hahn[1], Won Ki Ahn[1], **Jung Woo Han**[1]

[1]Department of Pediatrics, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Korea Reserch Institute of Chemical Technology, Daejon, Korea, Republic of,[3]Aston Research Institute, Seoul, Korea, Republic of

The integrated stress response (ISR) is an crucial adaptive mechanism that enables the cells to survive microenvironment stress, such as nutrient deficiency. General control non-derepressible 2 (GCN2) and its relevant pathway is essential and pivotal for ISR activation, in which the cells undergo amino acid deficiency. GCN2 phosphorylates Eukaryotic Translation Initiation Factor α (eIF2α) and enhances Activating Transcription Factor 4 (ATF4) expression to regulate the genes involved in physiological responses including cellular adaptation and survival. The roles of GCN2 in cancer survival have been studied and suggested as a target of cancer treatment. Rhabdomyosarcoma is one of the most common cancer types in childhood and adolescence, however, there was little progress in the treatment development over the past two decades. This study evaluated the efficacy KAS-1155, a novel GCN2 inhibitor in two representative rhabdomyosarcoma cell lines. Two rhabdomyosarcoma cell lines (RD, RH-30) were treated with KAS-1155 which is a GCN2 inhibitor produced and provided by Korea Research Institute of Chemical Technology (KRICT). RD was cultured in DMEM, transferred to glutamine-free media for 8 hours, and treated with KAS-1155. The RH30 was initially grown in RPMI media, and the cell line was sub-cultured twice in the glutamine-free media to establish a resistant cell population. This glutamine-starvation-resistant RH30 cell line was treated with KAS-1155 in the same conditions as RD. Cellular viability was assessed using Cell Counting Kit-8(CCK-8) assays. GCN2 pathway activation, including phosphorylated GCN2 (p-GCN2), eIF2α, and ATF4 expression, was analyzed by western blotting. In the glutamin-free media, p-GCN2 was detected after 8 hours in RD cells and, persisted up to 40 hours. In RH30, the p-GCN2 was detectable at 8 hours, and peaked at 40 hours ,and then maintained elevated until 72 hours. Following the 14 hours and 49 hours of glutamine-free media exposure for RD and RH30 respectively, p-GCN2, p-eIF2α and ATF were suppressed successfully with the treatment of KAS-1155 at the concentration of 0.1μM and 1μM for each cell line. Viability assays demonstrated IC50 values of 1.06 μM for RD cells and 1.87 μM for RH30 cells, indicating moderate growth suppression by KAS-1155. GCN2 pathway activation represented the adaptive response in rhabdomyosarcoma cell lines under glutamine-free, amino acid starvation condition. The KAS-1155 inhibited RD and RH30 proliferation suppression at moderate concentrations. This suggests the GCN2 inhibitor may have a role in the treatment of rhabdomyosarcoma, especially in the resistant cell types. Further preclinical investigation is needed to clarify its therapeutic potential and proper use of the GCN2 inhibitor in the rhabdomyosarcoma cell lines.

#6448 Determinants of chemotherapeutic resistance in fusion-positive rhabdomyosarcoma.

T. E. Shaw, F. Shah, J. Toretsky, A. Uren;
Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Rhabdomyosarcoma (RMS) is the most common pediatric soft tissue sarcoma, and is classified as fusion-positive (FP) or fusion-negative (FN) based on the presence of the PAX3::FOXO1 or PAX7::FOXO1 fusions. These chimeric proteins are formed by reciprocal chromosomal translocations and consist of an N-terminal portion of the PAX3 or PAX7 transcription factor fused to a C-terminal portion of the FOXO1 transcription factor. FP status is associated with worse event free survival for patients with RMS. Regardless of fusion status, most RMS patients receive a chemotherapy regimen consisting of some combination of vincristine, actinomycin D, and cyclophosphamide (VAC). Unfortunately, tumors may acquire resistance to these drugs over time, leading to relapse. Our work aimed to uncover genes that drive VAC resistance in FP-RMS using a two-pronged approach. To assess how FP-RMS cells gradually acquire resistance, we cultured FP-RMS cell lines (RH30, RH41, CW9019, U48484, U66788) in sublethal concentrations of vincristine, actinomycin D, or 4-hydroperoxy cyclophosphamide (4-HC, the active metabolite of cyclophosphamide) for multiple passages. We periodically assessed the IC_{50} of cells growing in drugs and increased drug doses as cells developed resistance. We generated four cell lines with a ~5- to ~20-fold increase in IC_{50}. Using RNAseq, we identified differentially expressed genes between the parental and resistant cell lines that may act as drivers of chemotherapeutic resistance. To assess de novo resistance in FP-RMS, we used CRISPR inactivation and activation library screening. We generated FP-RMS cell lines (RH30, RH41, CW9019) stably expressing Cas9 or dCas9-VPR, an endonuclease-dead version of Cas9 fused to three transcriptional activators. We then transduced these cells with a CRISPR inactivation sgRNA library (18,885 gene targets) or a CRISPR activation sgRNA library (19,113 gene targets). Transduced cells were cultured in vincristine, actinomycin D, or 4-HC, and surviving cells were expanded and sequenced to determine which genes provided drug resistance when activated or deleted. We hope that the findings of these experiments will contribute to novel therapeutic targets for patients with VAC-resistant RMS tumors.

#6449 Unique site-specific phosphorylation of PML co-ordinates disease aggravation of neuroblastoma.

Sreenidhi Mohanvelu[1], Poorvi Subramanian[1], Madhi Oli Ramamurthy[1], Sheeja Aravindan[2], Natarajan Aravindan[1]

[1]Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK

Neuroblastoma a fatal infant malignancy accounts for 15% of pediatric cancer deaths. The standard treatment for children with neuroblastoma is intensive and include induction, consolidation, maintenance, and salvage therapy. Despite the largely evolving molecular targets for maintenance therapy, retinoic acid (RA) remains the most promiscuous therapy. Restoration of promyelocytic leukemia protein nuclear body (PML-NB) is a crucial cofactor for RA mediated signal transduction, potentially improving the treatment response and outcomes. Phosphorylation at PAS-NA is one of the (if not the only one) crucial phosphorylation site of PML that direct PML degradation through ubiquitin pathway thereby modulating abundance and stability of PML-NB. Herein we investigated the vital association between phosphorylation of PML at PAS-NA and the clinical outcomes of neuroblastoma patients (n=124). To study the spatio-temporal expression of PML and pPML (PAS-NA) at specific tumor sites determined by pathologists, we custom archived the tumors in triplicate in a tissue microarray and effectuated a chromogenic IHC using our custom synthesized antibodies. The analytical endeavor was accomplished by using the modified Multiplex IHC 3.4.9 module integrated into Indica Lab's HALO platform. We observed a strong and definitive inverse correlation of PML to pPML (PAS-NA) expression in the tumor tissues. Negative correlation of pPML (PAS-NA) with patient survival (overall-, relapse-free, progression-free survival) indicating phosphorylation of PAS-NA as a key regulatory mechanism mediating the stability of PML-NBs and impacting the survival outcomes. While PML exhibits an inverse association to disease progression, we observed a proportional increase in pPML (PAS-NA) to the advanced disease stages in neuroblastoma. Furthermore, increased phosphorylation of PML at PAS-NA in patients presenting with metastatic disease or relapse state also emphasizes the critical role of its site-specific phosphorylation in regulating disease aggravation, dissemination and recurrence in neuroblastoma which is mediated by perpetuating PML-NB stability. Together, these results unveil a prominent molecular mechanism that mediates the evolution of neuroblastoma. Critically, these outcomes would have major implications on developing novel molecular targeted therapy and would pave way for achieving desirable clinical outcomes for children affected with this disease. Funding: This work was partially or in full, funded by Department of Defense CA-210339; OCAST-HR19-04; NIH-P20GM103639 to Dr. Aravindan. The work was also supported by NCI Support Grant [P30CA225520], NIGMS [P30GM154635] and a grant from the Oklahoma Tobacco Settlement Endowment Trust [R23-03] to OU Health Stephenson Cancer Center.

#6450 High-throughput screening identified Brefeldin A as a compound that reduces STAT3-dependent survival in acute leukemia and neuroblastoma cells.

Mitsuteru Hiwatari, Masakazu MImaki

Pediatrics, Teikyo University School of Medicine, Tokyo, Japan

Leukemic stem cells exhibit several dysregulated pathways, with the Janus kinase (JAK) and signal transducer and activator of transcription (STAT) pathway being among the most prominent. Additionally, phosphorylated STAT3 is observed following prolonged activation of the anaplastic lymphoma kinase (ALK) ligand-binding site, although the level of phospho-STAT3 induced by ligand-independent activation of ALK is exponentially higher. In ALK-positive tumors, ALK-STAT3 activation promotes tumor cell outgrowth and directly prevents apoptosis. The role of ALK in various ALK-expressing solid tumors, along with the therapeutic use of ALK inhibitors in treating these cancers, has been reviewed in several recent studies. Amplified or mutated ALK is found in approximately 14% of neuroblastomas (NB), one of the most common and aggressive childhood malignancies.In this study, we conducted a high-throughput chemical screen in twenty NB-derived cell lines to identify compounds that could inhibit the oncogenic activity of ALK in NB, using a curated library of around 450 compounds. Brefeldin A (BFA), an inhibitor of protein transport from the endoplasmic reticulum (ER) to the Golgi apparatus, was identified as a promising candidate. Given the increasing evidence linking abnormal expression and activation of STAT3 with leukemia development, suggesting its potential role in leukemia pathogenesis, we next assessed the cytotoxicity and antitumor effect of BFA against 12 T-ALL and 6 AML cell lines.The antitumor effect of BFA, assessed using an MTT assay, revealed potent cytotoxicity across a broad spectrum of hematopoietic malignancies, with particularly strong efficacy observed in 10 T-ALL and 5 AML cell lines. Specifically, T-ALL and AML cell lines were significantly inhibited by BFA, with IC50 values as follows: ICH-TALL-UK, 168.1 nM; MOLT-4, 23.2 nM; Jurkat, 66.6 nM; MOLT14, 97.3 nM; and ICH-TALL-SM, 54.9 nM.In NB cell lines harboring mutated ALK, BFA exhibited notable cytotoxicity. Furthermore, BFA was found to reduce the phosphorylation of ALK in NIH3T3 cells stably expressing mutated ALK. Among the key molecules phosphorylated downstream of ALK, which are critical for the survival of anaplastic large cell lymphoma (ALCL) cells, BFA inhibited the phosphorylation of STAT3, AKT, and ERK.These results suggest that BFA can effectively target the STAT3 signaling pathway, presenting a potential therapeutic approach for leukemia treatment. Moreover, the effects of BFA on ALK-mutated NB cell lines are accompanied by a reduction in the phosphorylation of both ALK and its downstream effector, STAT3. Investigating the antitumor effects of BFA in vivo will be an important next step in the development of future therapeutic strategies.

#6451 Tocilizumab in fibrolamellar carcinoma.

Paul M. Kent[1], Jennifer Hamm[2], Tom Stockwell[3], Jordan Tasse[4]

[1]Pediatric Oncology, FibroFighters Foundation, River Forest, IL,[2]Pediatric Oncology, East Tennessee Children's Hospital, Knoxville, TN,[3]FibroFighters Foundation, Temecula, CA,[4]Interventional Radiology, Rush University Medical Center, Chicago, IL

Background: Fibrolamellar Carcinoma (FLC) is a rare liver cancer of young people. Interleukin-6 (IL-6), is overexpressed in many cancers, including FLC, drives inflammation, angiogenesis, and activation of the JAK-STAT signaling pathway associated with progression, a worse prognosis, and inhibition of T-cell tumor attack. Check-point inhibitor (CPI) drugs induce T-cell tumor attack, but also induce immune-related adverse effects (irAEs), often with elevated IL-6 and eosinophilia. Tocilizumab (TOC), an IL-6 receptor blocker, approved for inflammatory diseases and steroid-refractory CPI irAEs, has been shown in the lab to both mitigate CPI toxicity and promote tumor immunity, while avoiding the toxicity, immune suppression, and tumor promoting effects of steroids, and allowing patients to restart CPIs. We prospectively collected data over 18 months on all FLC TOC patients seen and report on those with irAEs. This is the first report of TOC use in FLC.

Methods: With IRB approval and consent (NCT03793088), data was collected prospectively on all FLC TOC subjects from Apr. 1, 2023 to Dec. 1, 2024.

Results: Overall, 83% of 24 FLC patients with irAEs responded to TOC (13F, median age 24, 50% recent CPI, 92% AE grade 3-4, 1/3 with concurrent steroids). The most common irAEs were ascites, hepatitis, pneumonitis and colitis, with a median serum IL-6 of 163 [<5 pg/ml], median tumor IL-6 overexpression at the 96Th percentile, and median 9% eosinophilia [<2%]. The median tumor volume and circulating tumor DNA response was -20% and -78%, respectively. Proximal follow-up scans showed CR/PR/SD/PD rates of 5%/40%/40%/15%. Most (74%) resumed CPI after TOC treatment and 41% continued TOC as maintenance [Table 1]. Best tumor responses corresponded with CR for irAE, higher IL-6, CPI continuation, and no steroids. No side effects were attributed to TOC (total 174 doses).

Conclusions: TOC used for inflammatory conditions in FLC showed reliable responses, with many patients restarting CPI, and a majority with tumor burden reduction, suggesting a double benefit.

Fibrolamellar Carcinoma Treated with Tocilizumab

#6452 Role of obesity in regulation of acute myeloid leukemia progression.

Jieyun Jiang, Samantha R. Melendez, Vivek M. Rangnekar

Radiation Medicine, Markey Cancer Center, University of Kentucky College of Medicine, Lexington, KY

Acute myeloid leukemia (AML) accounts for 15-20 percent of childhood leukemia. Although improved treatment options have increased the overall survival for AML, approximately 30% of the cases tend to relapse. The management of AML patients is an ongoing challenge due to the relapse rates and treatment related mortality. Obesity is a leading cause of preventable death in the United States. Clinical outcome is linked to the degree of genetic heterogeneity of AML and higher body mass index (BMI) at diagnosis. As these underlying factors are associated with poor survival for AML, we are addressing the role and mechanism of obesity-associated factors in progression of AML in mouse models. Since obesity during pregnancy and childhood obesity may be associated with increased risk of developing AML, we tested the growth of the mouse AML cell line C1498 (ATCC.org) in the progeny of obesity-prone C57BL/6J *db/db* and *ob/ob* mice or normal (wild-type) C57BL/6J mice. Our data indicated that both *ob/ob* mice that lack leptin and *db/db* mice that lack the leptin receptor were prone to increased AML growth and showed significant increase in CD33-positive cells compared to wild-type C57BL/6J mice. Kaplan-Meier analysis of survival curves showed statistically significant differences between obese mice and wild type control C57BL/6J mice. Since obesity may change the immune phenotype and thereby affect AML growth, we performed blood cell immunophenotyping in C57BL/6J, *db/db* and *ob/ob* mice before C1498 engraft. We found that the T-cell numbers were significantly lower in the blood of *db/db* and *ob/ob* mice compared to the wild type control C57BL/6J mice. In contrast, myeloid-linage cell numbers were high in the blood of *db/db* and *ob/ob* mice than wild type C57BL/6J mice. The same pattern of immunophenotyping was found in post-AML blood as in pre-AML blood. Pearson Correlation analysis showed that survival of the mice positively correlated with the T-cell population and negatively correlated with myeloid population in blood. As diet-induced obesity (DIO) is the most common cause of obesity in humans, we used C57BL/6J mice that were fed with normal chow diet or high-fat diet (Research Diets, Inc., Catalog # D12492) and tested them for AML growth. Our data showed that obesity associated with high-fat diet also promoted AML growth with decreased survival when compared to normal chow-fed C57BL/6J mice. Taken together, our studies performed in mice with genetically driven obesity or high-fat diet induced obesity indicate that obesity promotes the growth of AML cells and is associated with decreased survival in mice. Our results suggest that T-cell and myeloid cell populations that are modulated by obesity may play an important role in AML progression.

#6453 Dual-omic characterization of the immune landscape of pediatric solid tumors revealed putative epigenetic mechanisms of immune evasion.

Stephanie Bianco[1], Anas Belaktib[1], Virgile Raufaste Cazavieille[1], Charles Joly-Beauparlant[1], Mona Patoughi[1], Lara Herrmann[1], Emeric Texeraud[1], Sylvie Langlois[2], Thomas Sontag[2], Alex Richard-St-Hilaire[2], Vincent-Philippe Lavallee[2], Thai Hoa Tran[2], Sonia Cellot[2], Daniel Sinnett[2], Arnaud Droit[1], **Raoul Santiago**[1]

[1]CHU Laval Research Ctr., Quebec, QC, Canada,[2]CHU Sainte-Justine Research Ctr., Montreal, QC, Canada

Background: There is a general lack of efficacy of immune checkpoint blockades (ICBs) in pediatric solid tumors. Methylation reprogramming is a major player in tumor immune microenvironment (TiME) modeling and ICB resistance. Its role in pediatric-specific TiME has yet to be explored.
Hypothesis: Dual-omic classification, combining DNA-methylation and RNA-sequencing, can identify tumors with epigenetically altered TiME, potentially responsible for ICB resistance.
Objective: Identify and characterize pediatric solid tumors with epigenetically altered immune phenotypes.
Methods: We studied bulk tumor gene expression and DNA-methylation profiles from 184 pediatric extracranial solid tumors. To individualize immune phenotypes, we used similarity network fusion (SNFtool) for dual-omic clustering of immune genes. Clusters were compared for differential expression and differential methylation using volcano3D. We studied the relationship of enhancer methylation to gene expression (ELMER package) to reconstruct regulatory networks (genes and pathways). Transcription factor and cofactor binding motifs were identified to characterize the regulatory element landscape specific to each phenotype. Adjusted p-values <0.01 were deemed significant.
Results: A total of 184 samples were included. SNF clustering identified 3 phenotypes regrouping 52 (28%), 83 (45%), 49 (27%) samples in clusters (cl) 1, 2 and 3, respectively. Cl1 exhibited low expression of immune genes (“cold” phenotype), cl2 overexpressed immune genes (“hot” phenotype), and cl3 featured global hypermethylation (epigenetically “altered” phenotype). Both hot and altered phenotypes overexpressed immune checkpoints (*CD274*, *PDCD1*), T-cell activator chemokines (*CXCL9*, *CXCL10*) and pro-inflammatory pathways, central to ICB sensitivity. However, only hot tumors overexpressed genes and pathways essential for antigen (Ag)-presenting machinery and immune recognition.
The methylation regulatory network indicated that the derepression of genes and pathways related to Ag-presenting machinery (mainly MHC-II and regulators) was specific to hot tumors. In contrast, gene silencing in the altered phenotype relied on hypermethylation/downregulation of the CIITA cofactor domain, the master control of MHC-II genes, interferon-regulated factors (IRFs), and immune-specific master regulators (*SPI1* and *BATF2*). These factors are crucial for anti-tumor immunity and ICB sensitivity.
Conclusion: We demonstrated that DNA-methylation participates in reshaping the TiME of pediatric solid tumors. A subset of tumors with epigenetically altered immune phenotype is characterized by an inflamed immune environment but altered antigen presentation by methylation reprogramming. Future studies should investigate methylation modulators to reverse these mechanisms and enable ICB sensitivity.

#6454 Extracellular matrix topography drives adrenergic to mesenchymal transition in neuroblastoma.

Antonios Chronopolous, Chandra Vemula, Vic Zamloot, Ivan Chavez, Rebekah Kennedy, Shahab Asgharzadeh, **JinSeok Park**

Children's Hospital Los Angeles, Los Angeles, CA

Neuroblastoma (NB), the most common extracranial solid tumor in children, exhibits intra-tumoral heterogeneity with two interconvertible identities: adrenergic (ADRN) and mesenchymal (MES). MES cells display phenotypes associated with metastasis and resistance to therapies compared to ADRN. Thus, the reprogramming of ADRN to MES may contribute to poor NB outcomes, and the process requires further elucidation to improve NB clinical outcomes. The extracellular matrix (ECM), a critical component of the tumor microenvironment (TME), provides structural support and delivers mechanical signals that modulate oncogenic regulation. We demonstrate that high-risk NB contains more topographically aligned ECM fibers than low-risk NB. By using nano-fabricated biomaterials that mimic ECM alignment, we reveal that ECM topography drives the transition from ADRN to MES. This transition involves transcriptional and epigenetic changes, accompanied by the enhanced phenotypic features of MES cells. We also reveal that the Rho-associated kinase and YAP signaling pathways, stimulated by the ECM topography, mediate ECM-driven reprogramming. In summary, ECM-driven transition of NB cells toward MES offers new insights into TME-targeted therapeutic strategies to suppress MES cells and improve NB outcomes.

#6455 Development of a H3K27M inducible and reversible model of diffuse midline glioma (DMG) to characterize tumor microenvironment and epigenetic memory.

Niloofar Khairkhah[1], Sienna L. Galban[2], Megan Faunce[1], Rodrigo T. Cartaxo[1], Carl Koschmann[3], Yue Zhao[4], Stefanie Galban[5]

[1]Department of Radiology, University of Michigan Medical School, Ann Arbor, MI,[2]Davidson School of Chemical Engineering, Purdue University, West Lafayette, IN,[3]Department of Pediatric Neuro-Oncology, University of Michigan Medical School, Ann Arbor, MI,[4]Gilbert S. Omenn Department of Computational Medicine and Bioinformatics, University of Michigan Medical School, Ann Arbor, MI,[5]Departments of Radiology and Surgery, Center for Molecular Imaging, Rogel Cancer Center, University of Michigan Medical School, Ann Arbor, MI

Diffuse Midline Gliomas (DMGs) with a lysine to methionine mutation in Histone 3 are lethal pediatric brain tumors. Despite ongoing efforts to develop new therapies, it remains unclear whether targeting this oncohistone or downstream epigenetic pathway activation are sufficient to halt and eradicate tumors. Here, we introduce a H3K27M inducible and reversible mouse model for DMG that allows precise control of oncohistone expression. This model enables us to study the effects of H3K27M activation, inactivation and re-activation on tumor growth and recurrence and additionally, characterize changes in the microenvironmental and epigenetic memory. We employed the in utero electroporation-based (IUE) delivery method to express the PiggyBac-based expression vectors mutant PDGFRA and dominant-negative TP53 and the newly designed tetracycline inducible H3K27M, along with the transposon. Upon tetracycline induced H3K27M activation, DMG tumors were detected and dissected to generate a new DMG cell line (PPiK27M), which can also be used for intracranial implantations in immunocompetent mice. In addition, we used two patient-derived DMG cell models wherein H3K27M was CRISPR edited (H3K27M-KO) to reintroduce the inducible and reversible H3K27M construct to provide an orthotopic model closely recapitulating human disease. We validated inducibility and reversibility of H3K27M by intracellular flow cytometry and western blotting in the murine and human cell models. We detected characteristic morphological changes and repression of astrocytic markers upon H3K27M re-expression in KO cells. In conclusion, our results indicate that the new inducible and reversible H3K27M IUE model and cells faithfully recapitulate DMG characteristics. We are currently performing single-cell RNA sequencing (scRNA-seq) of tumors to track cellular and molecular alterations in the surrounding tumor immune microenvironment. Additionally, we are characterizing the epigenome to understand whether transcriptional changes persist after inactivation of the oncohistone. Our study provides new tools to mechanistically decipher the role of the oncohistone, and potentially, identify new therapeutic targets for DMG.

#6456 Investigating neuronal signatures in treated fusion positive rhabdomyosarcoma.

Sophie Q. Burke, Roketa Henry, Angelica Oliveras Alsina, Avanthika Balu, Elisabet Olsen, Anand Patel

Oncology, St. Jude Children's Research Hospital, Memphis, TN

Rhabdomyosarcoma (RMS) is the most common pediatric soft-tissue sarcoma with features of skeletal muscle and can be split into two subtypes: fusion positive and fusion negative. Fusion positive-rhabdomyosarcoma (FP-RMS) have a higher likelihood of resurgence over three years after treatment, and patients with recurrent disease experience dismal outcomes with a survival rate under 20%. While long-term treatment responses for this subtype have remained elusive, recent studies have been able to identify the presence of a neuronal cell state in FP-RMS, which has not been observed in FP-RMS cell lines. Furthermore, it is unknown if FP-RMS cell lines can recapitulate this neuronal state. We predicted chemotherapy exposure to be a driving stimulus for lineage transition of FP-RMS cells and examined the neuronal gene expression of chemotherapy-treated FP-RMS cell lines using quantitative PCR (qPCR) and TaqMan Array Cards. We find that treated FP-RMS cell lines induce a dose-dependent increase of expression in neuronal cell markers, and a dose-dependent decrease of expression in muscle cell markers, which suggests the induction of a new cell state in FP-RMS cell lines. For future direction, we will utilize RNA-seq and single cell multi-omics to examine molecular determinates of this linage plasticity. These findings collectively will support future studies by serving as an in vitro model for the study of lineage plasticity in childhood cancer.

TUMOR BIOLOGY: Multi-omics and the Predictive Power of the Tumor Microenvironment
Poster Session

#6461 The spatial cellular landscape of Gleason pattern 3 and 4 prostate tumors.

C. Ak[1], Z. Sayar[1], G. Thibault[1], M. Kuykendall[1], G. Thomas[1], V. Stavrinides[2], Y. Chang[1], **E. S. Eksi**[1];
[1]OHSU Knight Cancer Institute, Portland, OR, [2]University College London, London, United Kingdom

The cellular heterogeneity of prostate cancer cells has been well-established, yet the spatial diversity of stromal cells in the tumor microenvironment remains largely unexplored. In this study, we utilized cyclic immunofluorescence imaging of whole-tissue sections to map spatial relationships between cancer cells and various immune and non-immune stromal populations in primary Gleason pattern 3 and 4 tumors. Our analysis identified over 20 androgen receptor (AR)-positive stromal cell types, many of which have minimal data on their response to AR inhibitors. Notably, we identified distinct AR+ mast cell populations exhibiting unique spatial associations with M2 macrophages and regulatory T cells. Using spatial statistical tools and recurrent cellular neighborhood analysis, we identified disease-specific microenvironments predominantly driven by AR+ stromal cells and uncovered inflammatory gene networks active within AR+ stromal regions. Future work will expand this analysis to spatiotemporal profiling of intermediate-risk patients, aiming to improve tumor stratification for more precise clinical decision-making.

#6463 Interrogating the tumor microenvironment of nasopharyngeal carcinoma by single-cell spatial transcriptomics.

Chee Yit Lim[1], Yi Ren[1], Wei Keat Teo[1], Chor Hiang Siow[1], Kwok Seng Loh[1], Raymond KY Tsang[1], Bingcheng Wu[2], Joshua K. Tay[1]

[1]Otolaryngology - Head & Neck Surgery, National University of Singapore, Singapore, Singapore,[2]Pathology, National University Hospital, Singapore, Singapore

Introduction: Nasopharyngeal carcinoma (NPC) is an Epstein-Barr virus (EBV) associated malignancy characterized by a dense lymphocyte infiltrate and a complex tumor microenvironment (TME). This heterogenous ecosystem influences tumor progression, immune evasion and the variable treatment outcomes observed in NPC patients. Conventional approaches such as bulk RNA sequencing lack the resolution to capture the complex heterogeneity of the TME. Spatial transcriptomics allows us to uncover the heterogeneity and cellular interactions at a single-cell resolution, providing insights into the tumor biology of NPC.

Methods: Recent formalin-fixed, paraffin-embedded (FFPE) NPC tissue samples were selected for analysis with the NanoString CosMx Spatial Molecular Imaging platform. Quality control, dimension reduction and unsupervised clustering at a resolution of 0.6 using the Louvain/Leiden algorithm were performed using Seurat package (v5.1.0). Cluster level annotation was performed using the singleR package using the human primary cell atlas reference. Cell type identities were validated by comparing cluster specific marker genes with canonical markers of known cell types.

Results: Six NPC tissue biopsies were fully interrogated comprising 254 ROIs. Post-filtering, 162,290 cells were examined. A total of 7 clusters were identified, broadly comprising immune, stromal and epithelial cells. Tumor composition was heterogenous (B cell 4.68-50.4%, T cell 0.74-8.78%, endothelial cells 0.91-3.66%, epithelial cells 28.5-66.8%, fibroblasts 1.16%-23.9%, macrophages 6.43%-29.1%, pro B cell CD34+ 0.01-7.1%) despite similar clinical stages III-IV.

Conclusion: We describe the single-cell spatial landscape of nasopharyngeal carcinoma, providing insights into the heterogeneity of the TME. We will evaluate epithelial - immune cell interactions, differential biological processes at the cellular level and compare them with deep gene expression profiles from our larger laser-capture microdissection mRNA-Seq cohort of patients to glean further insights.

#6464 Spatial mapping of the tumor microenvironment for combination therapy design.

A. Bose[1], S. Keezer[2], E. Q. Alonzo[2], S. Struble[1], J. Fisher[2], M. Norton[2], R. A. Heil-Chapdelaine[1], N. F. Diaz Granados[1], V. Agrawal[1];
[1]Leica Microsystems, Inc., Waltham, MA, [2]Cell Signaling Technology, Danvers, MA

Cancer immunotherapy is a promising treatment for many forms of cancer, however only a small subset of patients benefit, and relapse/recurrence frequently occurs due to various resistance mechanisms. To overcome this challenge combinatorial therapeutic strategies are needed targeting multiple steps of the cancer-immunity cycle to achieve long-term efficacy in a large population of cancer patients. It is now known that DNA damage activates the innate immune response and improves immune checkpoint blockade (ICB) efficacy. Combination immunotherapy can target several immunosuppressive elements in the tumor microenvironment and activate multiple steps of the cancer-immunity cycle. For developing an effective combination treatment strategy, including ICB with various other therapeutic modalities, we need to first understand the diverse expression pattern of various factors within tumor immune microenvironment. Multiplex immunofluorescence (mIF) is an important tool for profiling protein expression patterns in tumor tissues. This can provide a framework to understand the sensitivity to a particular combination of therapies and identify potential predictive biomarkers. Here we show spatial proteomics profiling of a diverse range of biomarkers in human colon adenocarcinoma tissue. Our findings demonstrate that spatial proteomics can be tailored to precision oncology using artificial intelligence to predict a patient's response to combination treatment strategies. The Cell DIVE Multiplex Imaging Solution in combination with AI-based image processing software, AIVIA delivers a comprehensive solution for exploring immune landscape of tumor tissue. The broad portfolio of robust IHC- validated antibodies from Cell Signaling Technology (CST) enables the detection of key proteins in the tumor microenvironment (TME). Here, we demonstrate multiplexed Cell DIVE imaging using a novel CST panel to probe human colon adenocarcinoma. The availability of cell type specific biomarkers, combined with the ability to interrogate using multiplexed tissue imaging, provides unprecedented and novel insights and spatial resolution of diverse cell populations in the TME.

#6465 Triple co-culture spheroid models of lung and ovarian carcinoma for the in vitro testing of anti-tumor agents.

Shrey Shah[1], Yongwoon Kim[2], Rock Pulak[2], Gerard G. M. D'Souza[1]

[1]Department of Pharmaceutical Sciences, MCPHS University, Boston, MA,[2]Union Biometrica, Holliston, MA

Tumor spheroids have emerged as superior *in vitro* models for studying solid tumors compared to monolayer cultures due to their ability to replicate key aspects of the tumor microenvironment (TME), including cell-cell interactions, extracellular matrix deposition, and nutrient and oxygen gradients. However, spheroids composed solely of tumor cells, i.e. monoculture spheroids, still lack the non-tumor cell components that contribute to additional *in vivo* TME complexity. This study focuses on developing triple co-culture spheroid models that integrate tumor cells, tissue-specific fibroblasts, and endothelial cells to better replicate the structural and functional features of the TME. Using an optimized liquid overlay technique, triple co-culture spheroids were successfully generated with drug-resistant lung and ovarian tumor cells. These spheroids demonstrated key tumor-like characteristics, such as extracellular matrix production and distinct spatial localization of cell types. Specifically, fibroblasts concentrated at the spheroid core during growth, while endothelial cells localized to the core only in the presence of fibroblasts. When treated with a liposomal formulation previously identified as selectively toxic to drug-resistant tumor cells in monolayer cultures, the triple co-culture spheroids exhibited reduced sensitivity to the treatment in a manner dependent on their composition. These results highlight the potential of triple co-culture spheroids as advanced in vitro models for investigating tumor biology and optimizing therapeutic strategies prior to *in vivo* evaluation.

#6466 Discovery Proteome and Whole Transcriptome Atlas analysis of skin cancer reveals biomarkers associated with immunotherapy response and resistance.

Arutha Kulasinghe[1], Christine Kang[2], Hiromi Sato[2], Brian Filanoski[2], Lori Hamanishi[2], Ashley Heck[2], Margaret Hoang[2], Alyssa Rosenbloom[2], Michael Rhodes[2], Joseph M. Beechem[2]

[1]University of Queensland, Woolloongabba, Australia,[2]Bruker Spatial Biology, Seattle, WA

Cutaneous squamous cell carcinoma (cSCC) is the second most common skin cancer and represents a major global health burden. Approximately 50% of cSCC patients develop primary resistance and 20% will develop secondary resistance to immune checkpoint inhibitors (ICI). There are limited biomarkers that reflect the tumor dynamics predictive of response to ICI therapy and we need to develop a better understanding of the cSCC tumor microenvironment (TME). Enabling simultaneous analyses of proteins and RNAs at ultra-high plex in spatial context, the GeoMx Digital Spatial Profiler (DSP) offers an advanced same slide multiomics workflow and is uniquely positioned to help unravel cellular dynamics throughout the cSCC TME. In this study, we spatially profiled over 1000 proteins (GeoMx Human Discovery Proteome Atlas (DPA)) and over 18,000 transcripts (GeoMx Whole Transcriptome Atlas) using the DSP on formalin fixed paraffin embedded sections of pre-treatment cutaneous skin cancers prior to immunotherapy. Pathology-informed, tumour and stromal regions were sampled across whole tissues to generate histologically relevant assessments of the skin tissues. Covering areas such as immuno-oncology, oncology, immunology, epigenetics, metabolism, cell death, and signaling pathway regulation, the DPA panel supported the discovery of biomarkers and potential therapeutic targets. Our study identified unique tumour and stromal signatures and biomarkers associated with both resistance and sensitivity to immunotherapy at both protein and RNA resolutions. Moreover, coverage across the protein hallmarks of cancer provided deeper insights into the tumour microenvironment dictating clinical responses to therapy. Our study provides an integrated pipeline for discovery based spatial proteomic and transcriptomic assessments of skin cancers.

#6467 Specificity and sensitivity assessment of Xenium in situ platform in multiple human carcinomas for clinical studies.

Jinghao Tian, Tong Lu, Elim Cheung, Lutong Zhang, **Vidyodhaya Sundaram**, Rikita Gakhar

BioChain Institute, Inc., Newark, CA

Spatial transcriptomics is advancing at a rapid pace since being named the Nature ‘Method of the Year’ in 2020. The 10x Genomics Visium and Xenium platform and assays are now providing sub cellular resolution and mapping transcripts to the tissue morphology to study complex biology from whole transcriptomics to precisely targeted gene panels. These assays are of great significance to clinical research in precision medicine and biomarker discovery. However, third party validations on reproducibility, orthogonal concordance, specificity and sensitivity raise questions that are critical to their use. At BioChain Institute Inc. (BioChain), we are running a series of tests on Xenium V1 as well as Visium Cytassist V2 chemistry, using multiple human carcinoma FFPE tissues to address the specificity and sensitivity questions in regard to these platforms. FFPE tissues from BioChain’s repository were screened for quality assessment by our pathologist and molecular scientists for tumor content above 30% as well as the RNA quality. Four carcinoma tissues from Breast, Colon, Lung, and Kidney with high DV200 scores were selected. An array was constructed with these tissues to fit the Xenium slide’s imageable area. Two serial sections were used for the Xenium V1 run per 10x Genomics’ protocol. The Off-the-shelf Human Multi-Tissue and Cancer Panel was used for targeting 377 genes. After the Xenium run completion, these slides were used for H&E staining and imaging as well as Visium V2 assay. The H&E images were annotated by the pathologist and integrated with Xenium images using Xenium Explorer.The data was sub-sampled for the different regions per pathologist’s annotations of stroma, tumor and immune cell regions. Data from these regions were compared between the serial sections from Xenium run as well as the Visium run for specificity and sensitivity. Sensitivity of Xenium data versus the visium data was also compared for these specific regions.We have previously demonstrated reproducibility of Xenium data between serial sections prepared by different operators as well as concordance of the two assays run on the same section. With this study we are zooming into specificity and sensitivity via pathologist annotations of the morphology and the gene expression data across multiple carcinomas. For example, in the breast cancer sample cluster 10 (Figure 1) in the Xenium data corresponded to the immune region as annotated by the pathologist. This cluster was noted to have high expression of immune cell infiltration marker genes such as CD3E, CD8A, CD2, CCL5, PTPRC, etc. Our findings show the sensitivity and specificity of Xenium and Visium assays to delve further into the heterogeneity of tumor microenvironment and patient stratification for precision medicine and biomarker discovery studies.

#6468 Dissecting the immune landscape in EBV+ classical Hodgkin lymphoma following IL-23 inhibition using single-cell hyperplex immunofluorescence analysis: A case report.

Janusz Franco-Barraza[1], Bhaumik Shah[2], Mariia Dmitrieva[1], Joanna Kowal[3], Erica Geneletti[3], Mariusz Wasik[2], Reza Nejati[2], Edna Cukierman[1]

[1]Cancer Signaling and Microenvironment Program, Fox Chase Cancer Center, Philadelphia, PA,[2]Department of Pathology, Fox Chase Cancer Center, Philadelphia, PA,[3]Lunaphore Technologies, Tolochenaz, Switzerland

Background: The immune tumor microenvironment (TME) in Epstein-Barr Virus (EBV)+ classic Hodgkin lymphoma (cHL) displays a T helper (Th) 1 profile typical of effective antitumor response with increased infiltration of CD8+ T-cells. cHL cases showing evidence of interleukin (IL)-23 /IL-17 axis activation are usually EBV-. The TME of EBV+ cHL developed after IL-23 repressive therapy has not been reported. We report the TME characteristics of EBV+ cHL in a psoriasis patient on IL-23 inhibition therapy.
Case Presentation: A 40-year-old male with chronic plaque psoriasis underwent Guselkumab (IL-23 inhibitor) treatment for four months before developing bulky cervical lymphadenopathy. Excisional biopsy revealed Hodgkin and Reed-Sternberg (HRS) cells, predominantly in the interfollicular area, with weak to moderate expression of B-cell markers (PAX-5, CD20, CD79a) along with MUM1, CD30 and CD200. Importantly, HRS cells were strongly positive for EBER by in situ hybridization, showing a latency pattern IIa (LMP-1+, EBNA-2-) with a viral load of 75 IU/ml. A diagnosis of EBV+ cHL, possibly iatrogenic/related to IL23 inhibitor therapy was proposed.
Hypothesis: IL-23/IL-17 axis promoted the reprogramming of the TME, fostering the emergence of EBV-driven HRS cells.
Methods: Excised lymph node sections were analyzed using an automated sequential immunofluorescence (seqIF™) protocol (Lunaphore COMET™), tailored for the TME of cHL. This enabled the spatial mapping of 9 markers (CD20, T-bet, CD4, CD163, CCR4, CCR6, HLA-DR, Ki67, CTLA4). Utilizing the HORIZON™ image analysis software, which integrates single-cell segmentation and rule-based classification algorithms, we identified 8 distinct cell populations, including HRS cells, B cell subsets, Th1, Th2, Th17, Tregs, and macrophage subsets. Additionally, this unbiased approach allowed for the precise measurement of immune exhaustion and proliferation markers expression.
Findings: The seqIF™ analysis revealed an immunosuppressive TME showing predominance of Th2 cells (CCR4+, CCR6-), numerous CTLA-4+ immunosuppressive CD4+ T cells, a very low Th1/Th2 ratio and a significant reduction of Th17 cells. Our study suggests reprogramming of Th17 to Th2 response following IL-23 inhibitory therapy, promoting the development of EBV+ cHL. This contrasts with the Th1 profile reported for the TME of EBV+ cHL.
Conclusions: This single case study highlights the utility of spatial proteomics mapping immune interactions in the TME of EBV+ cHL. A larger study of EBV+ and EBV- cHL cases is planned to further characterize these TMEs, including fibroblastic populations, and identify potential immuno-oncology targets. These findings could guide personalized treatments and identify EBV+ cases unsuitable for IL-23 inhibitors to mitigate cHL risk.

#6469 Defining architectural tissue features and cell composition of IDH-mutant gliomas.

Elisabet Rodriguez Tomas[1], Lina Leiss[1], Rasul Tabiev[1], Fredrik Nysjo[2], Anna Klemm[2], Carolina Wahlby[2], Thomas Olsson Bontell[3], Anna Denes[4], Asgeir S. Jakola[4], Anja Smits[4], Arne Ostman[1]

[1]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden,[2]Department of Information Technology; Vi3; Image Analysis, Uppsala University, Uppsala, Sweden,[3]Department of Physiology, Institute of Neuroscience and Physiology, University of Gothenburg, Gothenburg, Sweden,[4]Department of Clinical Neuroscience, University of Gothenburg, Gothenburg, Sweden

This study tests the hypothesis that quantitative profiling of cell type composition and tissue architecture in isocitrate dehydrogenase (IDH)-mutant gliomas can provide valuable insights into tumor aggressiveness, treatment response, and survival. Towards this goal, we have established a novel method to analyze cell composition and tissue architectural features in IDH mutant gliomas based on multiplex immunohistochemistry staining and automated image analysis.Two independent clinically well-annotated TMAs, derived from approximately 200 patients with IDH1-mutant tumors, are being analyzed. A multiplex fluorescence antibody panel was designed to include markers for astrocytes ($GFAP^+$/$IDH1\text{-}R132H^-$), glioma cells ($IDH1\text{-}R132H^+$), oligodendrocytes ($IDH1\text{-}R132H^-/SOX10^+$), leukocytes ($CD45^+$), tumor-associated microglia and macrophages (TAMMs) ($IBA1^+$), endothelial cells ($CD34^+$) and perivascular cells ($PDGFR\beta^+$). QuPath software was employed for image analysis. Statistical analyses were performed using Python.For cell classification we firstly created single-core “ground truth data” from 20 cores by manual/visual training of core-specific cell classifiers. Second, we created a “multiple-core-trained” classifier by training on 10 of the ground truth cores and testing on the remaining 10 cores. Comparison between ground truth data and “multiple-core-trained” data indicated overall cell classification accuracy of 0.8.A pilot-study of 20 tumors demonstrated that the most abundant cell types were glioma cells, while leukocytes and perivascular cells were the least abundant. The abundance of glioma and perivascular cells showed good consistency between cores from the same patient (corr = 0.8 for both). In contrast, the abundance of oligodendrocytes and leukocyte cells was less consistent (corr = 0.4 and 0.3, respectively).Analyses of spatial pairing of cell types demonstrated strongest positive spatial enrichment between endothelial cells and pericytes and between endothelial cells and TAMMs. In contrast, glioma cells and endothelial cells showed negative spatial enrichment. Notably, inside-case concordance for these “pair-metrics” was high (0.8-0.9).Analyses aiming to identify co-regulated “pair-metrics” revealed strong positive correlations between the three pair-metrics TAMMs/perivascular cells, TAMMs/endothelial cells and endothelial cells/perivascular cells indicating inter-case variability of multi-cellular vascular niches."Cell abundance metrics" and "cell pair metrics" are currently being explored for their associations with clinical characteristics and their potential to enhance prognostic value relative to 1p19q status and WHO grades.

#6470 Spatial analysis of the tumor microenvironment in diffuse large B-cell lymphoma reveals clinically relevant recurrent cellular neighborhoods.

M. Autio[1], S.-K. Leivonen[1], L. Meriranta[1], M.-L. Karjalainen-Lindsberg[2], T. Pellinen[3], S. Leppa[1];
[1]University of Helsinki and Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland, [2]Helsinki University Hospital, Helsinki, Finland, [3]Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland

Introduction: The tumor microenvironment (TME) of diffuse large B-cell lymphoma (DLBCL) has been recently dissected and different TME-based subtypes of DLBCL proposed (Kotlov et al. Cancer Discov. 2021, Steen et al. Cancer Cell. 2021). Previous studies have, however, not systematically explored the spatial organization of the DLBCL TME and its association with biological and clinical factors.
Materials and Methods: We performed multiplex immunofluorescence using a 12-plex antibody panel on diagnostic tumor samples from 99 patients with DLBCL. We characterized B cells, T cells, tumor-associated macrophages (TAMs), and immune checkpoint molecules. We processed images using Ilastik and CellProfiler softwares, and segmented nuclei with a pretrained deep-learning model. We phenotyped the cells using the Phenograph algorithm combined with manual thresholding. We identified recurrent cellular neighborhoods (RCNs) and performed cell-cell interaction analyses using the scimap package (Python 3.9). We correlated the findings with biological and clinical characteristics and survival.
Results: We analyzed over 1.2 x 10^6 single cells with a median of 12 354 cells per patient. We identified 17 cell phenotypes, including various subgroups of B cells, T cells, and TAMs. Of the cell types, B cells were the most abundant (mean 55%), followed by CD4+ helper and CD8+ cytotoxic T cells (means 14% and 10%), and M2-like TAMs (mean 8%) with great heterogeneity between the samples. We identified 10 different RCNs with distinct cellular compositions across DLBCLs. The most common RCN was an immune-poor RCN (30% of the cells), followed by an RCN with high B cell content and a moderate immune cell infiltrate (22% of the cells). We also identified different T cell and TAM-rich RCNs. The RCNs subdivided DLBCLs into immune-poor areas and areas with diverse immune cell infiltrates. Notably, HLA-ABC positive lymphomas consisted of larger proportions of CD4+ T cell-rich RCNs ($p < 0.05$). Defined by the shortest average distance, immune-poor RCNs were located close to the RCNs that had high B cell content combined with moderate immune cell infiltrates but far from the T cell-rich RCNs. However, when CD8+ T cell-rich and immune-poor RCNs were close to each other, the outcome was favorable (progression-free survival (PFS); $p < 0.05$), whereas the proximity of PD-L1+ B cell-rich and CD8+ T cell-rich RCNs was associated with poor survival (PFS; $p < 0.05$). Finally, we correlated RCN proportions with lymphoma microenvironment (LME) and genetic subtypes. Immune-poor RCNs were common in the depleted LME subtype, whereas PD-L1+ M2-like TAM-rich RCNs were more common in the inflamed LME. In contrast, PD-L1+ M2-like TAM-rich RCNs were rare in EZB-type DLBCLs.
Conclusions: Our data show that DLBCL TME is organized into RCNs that are associated with distinct molecular and subtypic features and patient outcomes.

#6471 Spatial multiomics reveals T-cell activation and exhaustion states in the tumor microenvironment.

Steve Zhou, Yifan Wang, **Debia Wakhloo**, Anushka Dikshit, Li-Chong Wang, Maithreyan Srinivasan

Bio-Techne Corporation, Newark, CA

Spatial Multiomics allows for context-based study of the tumor microenvironment (TME). TME consists of diverse cells that collectively influence tumor progression, therapeutic response, and immune activation. CD8 T-cells, essential for antitumor immunity, often become exhausted in the TME. Recent studies show that PD1+ TCF1+ stem-like CD8 T-cells retain differentiation potential and can be rejuvenated through cytokine signaling and immune checkpoint modulation. This detailed spatial profiling of RNA and protein expression in the TME is crucial to understanding immune cell function, activation, and differentiation. Here we introduce a protease-free workflow for RNAscope™ Multiplex Fluorescent v2 assay combining RNA *in-situ* hybridization (ISH) and protein immunofluorescence to study cell marker proteins (CD8, PD1) with RNA targets (*TNFA, TCF7, IFNG*) in a tumor microarray (TMA). The Manual Multiplex Protease-Free workflow enables simultaneous RNA and protein visualization without enzymatic disruption, preserving antigen integrity and tissue morphology. Using this Multiomics assay we can study CD8 T-cell differentiation and activation. Co-detection of *TNFA*, *TCF7*, and *IFNG* transcripts with CD8 and PD1 proteins provides insights into specific T cell phenotypes and their activation/exhaustion status. Data reveal robust co-expression patterns of these targets, particularly in the tumor-cell neighboring stromal and immune cells in breast, cervical and stomach cancers, reflecting immune activation and exhaustion across distinct TME niches. This methodology lays a foundation for refining immunotherapeutic strategies targeting PD1+ TCF7+ CD8 T-cells, enhancing effector functions, and advancing precision oncology interventions.

#6472 Integrative multi-omic analysis of the multiple myeloma bone marrow reveals alterations of the immune microenvironment in treatment naïve patients.

Siobhan B. Cashman[1], Aruna Ayer[2], Teresa Swift[1]

[1]Advanced Technology Group, BD Biosciences, Limerick, Ireland,[2]Advanced Technology Group, BD Biosciences, Milpitas, CA

Multiple myeloma (MM) is defined by the uncontrolled clonal proliferation of plasma cells in the bone marrow (BM). It is one of the most frequent hematological cancers, representing 10% of hematological malignancies in the US. Although recent advancements in therapies have led to improved outcomes, MM remains incurable. Disease development and progression are impacted by alterations in the local immune microenvironment, and dysfunction in both the innate and adaptive immune responses are characteristic of the MM BM microenvironment. With the increasing use of immunotherapeutic strategies to treat MM, there is a growing need to understand the existing immune landscape in these patients. We sought to gain a greater understanding of the immune cell diversity in MM by sampling BM from healthy and newly diagnosed cohorts. A combination of traditional flow cytometry, spectral flow cytometry, and single-cell RNA sequencing (scRNA-seq) with the addition of CITE-seq, enabled the high-resolution analysis of surface protein and targeted immune response-related transcriptomic changes within individual cells. In this study, we found a high degree of inter-patient heterogeneity within the aberrant plasma cell population. We report an expanded population of $CD57^+$ effector memory expressing CD45-RA (T_{EMRA}) cytotoxic T cells, and an overall reduction in T cell effector responses. Our scRNA-seq approach demonstrated a strong correlation of CITE-seq signal with key cell identifying markers. Investigation of the suppressive cell subsets found that overall, these cell frequencies were maintained across health and disease. However, we found altered T_{REG} phenotypes with an increased frequency of a highly suppressive T_{REG} subset in MM patients. In summary, our study provided insight into the significant differences observed in the frequency and functionality of the principal immune populations of the BM microenvironment. By combining flow cytometry with scRNA-seq and CITE-seq, the changes in the immune landscape in the BM of treatment naïve MM patients can be mapped more comprehensively, allowing correlation of surface marker expression with gene expression profiles. #6473 Determining the spatial composition of immune infiltrate in HER2+ breast cancerHER2+ breast cancer.

Jessica Linak, David Page, Jason Schlumbohm, Fred Robinson, **Sasha Elizabeth Stanton**

Medical Oncology, Earle A. Chiles Research Institute, Portland, OR

Background: Immunotherapy has improved outcomes in triple negative breast cancer but there is less response in the other subtypes. Tumor infiltrating lymphocytes (TIL) infiltrated tumors respond better to immune therapy in other tumor types. We wanted to be able to identify tumor infiltrated verses sequestered tumors and then identify the immune populations of infiltrated/sequestered tumors using spatial localization of immune and breast cancer receptors. To do this we optimized digital spatial profiling using 2 methods (Nanostring GeoMx and 10X Genomics Xenium), immune protein expression using Lunaphore COMET, and hemoxylin & eosin (H&E) TIL evaluation on a single slide. Our goal was to identify an immune infiltrate biomarker that could predict patients that would respond to neoadjuvant immune therapy in HER2+ breast cancer.
Methods: We evaluated 6 HER2+ breast cancer biopsies. Formalin fixed paraffin embedded (FFPE) 10 µM slides from untreated core biopsies were evaluated by the Xenium breast, GeoMx Cancer Transcriptome Atlas, and Comet Lunaphore 21 immune target panels. 4 of the 6 tumors were ER neg PR neg HER2 pos, one was ER neg PR pos HER2 pos, and one was ER pos PR neg HER2 pos. For GeoMX, each ROI was ≥ 250 nuclei and ≥ 400 µM diameter to ensure a sequencing depth of 30X and allow segmentation.
Results: We sequentially stained and evaluated the entire specimen on a single FFPE slide using Xenium, Lunaphore, and H&E. The immune infiltrate for HER2 breast cancer was predominantly sequestered in stroma. In GeoMX, the highest expression in CK positive cells was ERBB2 (p=9.6X10-12), proliferation markers (CCND1 p=1.2X10^{-8}), and cytokeratins (KRT7 p=-1.3X10^{-10}) while in the stroma the highest expression was immune markers (CD163 p=6.1X10^{-12} and CD4 p=6.6X10^{-12}). This was similarly seen in Xenium evaluation where the immune infiltration was predominantly CD163^{+}CD68^{+} macrophages and FOXP3^{+}CD4^{+} T cells in the stroma and ERBB2 and cytokeratins in the tumor. Lunaphore protein evaluation confirmed the findings on the same slide. Even with fewer targets in Xenium, similar results were seen between GeoMx and Xenium but the whole slide was able to be evaluated with Xenium.
Conclusion: Sequential evaluation of Xenium, Lunaphore, and H&E is feasible and allows spatial identification of the TIL populations in HER2+ breast cancer. Consistent with previous studies, most immune infiltrate is localized in the stroma along the immune front and is predominantly CD4^{+} regulatory T cells and CD163^{+} macrophages.

#6474 Comprehensive immunophenotypic profiling in anti-PD-1-responsive and -resistant mouse models reveals perforin-expressing CD4+ T cells as key effectors of cytolytic activity.

Hiroyuki Inoue[1], Takayuki Hamasaki[2], Kazuhiko Inoue[2], Akira Nakao[1], Noriyuki Ebi[1], Hirofumi Minomo[2], Ichiro Nagata[2], Naoto Horai[2], Masaki Fujita[1]

[1]Department of Respiratory Medicine, Faculty of Medicine, Fukuoka University, Fukuoka, Japan,[2]Drug Safety Research Laboratories,, Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan

Immune checkpoint inhibitors targeting the PD-1/PD-L1 axis have dramatically advanced cancer therapy, but resistance mechanisms remain a significant hurdle. This study explores immune changes in syngeneic mouse models sensitive (MC-38) or resistant (LLC1) to anti-PD-1 monoclonal antibody (mAb) treatment. Multicolor flow cytometry was employed to assess immune cell profiles in the tumor microenvironment (TME) and tumor-draining lymph nodes (TdLNs). In the MC-38 model, anti-PD-1 mAb therapy significantly altered immune landscapes, including enhanced dendritic cell (DC) and macrophage populations and decreased myeloid-derived suppressor cells (MDSCs). Upregulated antigen presentation molecules (MHC I/II) and functional markers (CD80, CD86, CCR7, PD-L1) were observed in tumor-associated DCs and macrophages. Notably, there was an increase in tumor-infiltrating CD4+ T cells, CD8+ T cells, including central memory (TCM) and effector memory (TEM) subsets, regulatory T cells (Tregs), natural killer (NK) cells, and natural killer T (NKT) cells. A key finding was the enhanced cytotoxic potential across various lymphocyte subsets, with perforin identified as a pivotal marker among 3 different cytolytic markers, correlating with therapeutic efficacy. Tumor volume inversely correlated with levels of perforin-expressing CD4+ T cells and NKT cells, highlighting their critical roles in antitumor responses. Conversely, the LLC1 model displayed limited immune alterations following anti-PD-1 mAb treatment, emphasizing distinct resistance mechanisms. This study delineates the dynamic immunophenotypic changes induced by anti-PD-1 therapy and identifies perforin, particularly in CD4+ T cells and NKT cells, as a promising biomarker for treatment response. Furthermore, these findings suggest potential combinatorial strategies targeting DC/MDSC ratios and perforin pathways to overcome resistance in refractory tumors.

#6475 Characterizing peri-tumoral tertiary lymphoid structures in non-muscle invasive bladder cancer using a spatial whole transcriptomics approach.

Kartik Sachdeva[1], Priyanka Yolmo[1], Abdulhameed Abdulhamed[1], Sadaf Rahimi[1], David M. Berman[1], Roger Li[2]

[1]Queen's University, Kingston, ON, Canada,[2]Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Intravesical Bacillus Calmette-Guérin (BCG) immunotherapy is the gold standard for high-risk NMIBC, however over half of patients experience early recurrence or disease progression, highlighting the need for reliable predictive biomarkers. Our previous research identified that B cell dominant peri-tumoral tertiary lymphoid structures (TLSs) evolve during chronic carcinogenesis in a subset of patients who experience early recurrence or progression. TLSs generally correlate with favorable outcomes following treatment with immune checkpoint inhibitors, chemotherapy or oncolytic viruses. In contrast, their abundance in peri-tumoral regions in BCG-naïve NMIBC tumors associates with poor prognosis. This highlights the importance of their in-depth characterization and further exploring their biomarker potential in NMIBC.
Methods: Peri-tumoral TLSs and tumor epithelial regions were profiled using the NanoString GeoMx Digital Spatial Profiler based whole transcriptome analysis. Multiplex Immunofluorescence was performed to infer spatial profiles of B, T and myeloid cell functional states as well as immune checkpoint proteins.
Results: Spatial whole transcriptome analysis displayed increased expression of genes associated with antigen presentation, complement activation, B cell recruiting chemokines, and immunoglobulins in the TLSs regions. Tumor epithelial regions located adjacent to TLSs showed elevated expression of genes reflective of a luminal subtype. Increased PD-1+ cells in the peri-tumoral regions and enrichment of luminal subtype genes in the epithelial compartment indicated cancer cell intrinsic aggressive features associated with immune exclusion.
Conclusion: The novel findings from this study will help establish peri-tumoral TLSs as biomarkers for predicting BCG therapy response, enabling early identification of patients who may benefit from alternative immunomodulatory treatments like oncolytic viruses, gemcitabine-docetaxel chemotherapy, or immune checkpoint inhibitors.

#6476 Multimodal single cell analysis of cholangiocarcinoma subtypes reveals distinct immune microenvironments.

H. E. Stumpf[1], J. Yang[2], H. Dong[2], R. L. Smoot[1], S. I. Ilyas[1];
[1]Mayo Clinic College of Medicine and Science, Rochester, MN, [2]Mayo Clinic, Rochester, MN

Cholangiocarcinoma (CCA), an aggressive cancer of the bile ducts, is classified into intrahepatic (iCCA), perihilar (pCCA), and distal (dCCA) anatomic subtypes. Each subtype has a distinct epidemiology and pathogenesis. The tumor immune microenvironment (TIME) of each subtype is poorly understood. CCAs are poorly immunogenic tumors and systemic therapy has had subpar efficacy in CCA subtypes. Thus, we hypothesized that each anatomic subtype has a distinct TIME. To address this hypothesis, we completed single cell sequencing of tumor, liver, and bile duct from patients with either iCCA or pCCA/dCCA. 182,054 cells from paired liver (n=16), tumor (n=16) (9 iCCA, 7 pCCA/dCCA), and normal bile duct (n=9) samples were obtained from treatment-naïve patients undergoing resection from June 2020 to August 2023. The tissues were homogenized and flow sorted for immune ($CD45^+$) populations immediately following resection. The cells then underwent single cell RNA sequencing (scRNA-seq) and cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq) with antibodies for 157 proteins. Multiple immunocompetent, syngeneic/orthotopic murine models of iCCA with distinct genetic drivers were used to assess immunotherapeutics (PMID: 38458319). Immune cells of interest were isolated by flow sorting and functionally validated via suppression assays and multiparameter flow cytometry. Additionally, a novel pCCA murine model was established by injection of an $Pik3ca^{H1047R}/p27^{Kip1}$-derived extrahepatic biliary cancer cell line into the porta/hilar tissue plane. Compared to non-involved liver, the bile duct immune microenvironment composition closely resembled that of the tumor. Multimodal analysis demonstrated both human and murine iCCA tumors have a significant upregulation of regulatory T cells (Treg) expressing T cell immunoreceptor with Ig and ITIM domain (TIGIT) compared to controls. Suppression assay with intratumoral $TIGIT^+$ Treg from mouse compared with $TIGIT^-$ Treg indicate $TIGIT^+$ Treg are more potent in inhibiting proliferation of $CD8^+$ T cells. Moreover, TIGIT blockade using a monoclonal antibody resulted in a significant reduction in tumor burden in multiple iCCA murine models, including SB1, a model resistant to anti-PD-(L)1 monotherapy. Meanwhile, human pCCA tumors had a significant increase in IgA^+ plasma cells compared to iCCA tumors. An innovative genetically and anatomically relevant pCCA murine model was developed to interrogate this unique plasma cell population. In summary, these data suggest that iCCA and pCCA have distinct immune microenvironments which likely impacts the differences in response to ICB between the subtypes observed in phase III clinical trials. Additionally, the uninvolved, tumor-adjacent bile duct immune microenvironment resembles that of the tumor, suggesting a pre-malignant niche that facilitates tumor development.

#6477 Tumor microenvironmental alterations and novel biomarkers in metastatic ovarian cancer identified with spatial transcriptomics.

S. Ouedraogo, J. Yu, N. Li, X. Zhan;
Shandong Key Laboratory of Precision Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Ovarian cancer (OC) is one of the most common causes of cancer in women in the developed world and causes many cancer-related deaths every year. Patients are frequently discovered at advanced stages of the disease, and metastasis can be detected in 30% of patients at the time of diagnosis, with an additional 30%-40% developing metastases few years later. Current therapy methods for ovarian cancer metastasis are typically ineffectual, and mortality rates for individuals with ovarian cancer metastases are consequently high. As a result, OC remains one of the most serious clinical disorders and a life-threatening risk to women. Investigations into the tumor microenvironment (TME) and biomarkers associated with ovarian cancer metastasis may give critical benefits in understanding the underlying molecular pathways and identifying new targets for clinical diagnosis and treatment.
Methods: We investigated the TME between metastatic platinum sensitive recurrent ovarian cancer (PSROC) tissues and primary OC tissues using sc-RNAseq, spatial transcriptomics with 10x Visium spatial capture technology. The data were analyzed using R, DAVID and Cytoscape software to identify potential biomarkers.
Results: By analyzing the spatial transcriptomic data of PSROC metastases and primary lesions, we identified significant changes in multiple energy metabolism signaling pathways and significantly different tumor-associated macrophage groups. Notably, the metastatic tissue showed fewer B cells, T cells, and macrophages differentiation and infiltration. On the other hand, the metastatic tissue showed more monocyte and DC cell proportion when compared to primary tissue. The spatial location of each cell type in the different tissues was investigated, showing great disparity in the cell arrangement within each tissue type. The average log2FC of the differentially expressed genes (DEG) between the two tissue types was determined, thus providing us with cell and type-specific gene sets. The cutoff values were set to avg_Log2FC >= |0.58| and p_val_adj (FDR) < 0.05. We obtained 1226 DEG ups and 1011 DEG downs. The DEGs were used for KEGG pathways analysis which gave 40 significantly enriched pathways, with notably oxidative phosphorylation, p53 signaling pathway, cell cycle and HIF-1 signaling pathways. By combining KEGG pathway data with PPI and hub-gene analysis we identified potential genes that may play significant role in ovarian cancer metastasis, energy reprogramming and immune escape; TOP2A, CCNB1, CDK1, CCNA2, AURKB, TP53, CD4, EGFR, JUN, HIF1A, FN1 and CTNNB1. These genes will be further investigated through in vitro and in vivo experiments.
Conclusions: Those results provide a new theoretical basis for the diagnosis and treatment of PSROC, which will undoubtedly help in the prevention, molecular diagnosis and development of more precise therapeutic approaches.

#6478 Relapse prediction of stage III MSS colon cancer by certain cell subtype distribution characteristics in tumor and tumor invasive margin.

Hanqing Hu[1], Hongzhe Sun[2], Xia Liu[2], Shuo Han[2], Lin Zhu[2], Miao Wang[2], Zhifu Zhang[2], Na Li[3], **Guiyu Wang**[1]

[1]Department of Colorectal Surgery, the Second Affiliated Hospital of Harbin Medical University, Haerbin, China,[2]Beijing PhenoVision Bio Co., ltd, Beijing, China,[3]Hangzhou PhenoVision Bio Co., ltd, Hangzhou, China

Colorectal cancer (CRC) is a frequent gastrointestinal malignancy with high rates of morbidity and mortality. Previous studies have shown a significant correlation (p<0.001) between immune score and recurrence time, overall survival, and disease-free survival in subgroups of microsatellite stability (MSS) patients with stage II colon cancer. Current study reviewed 17 stage III MSS CRC patient archived FFPE samples including 11 relapse and 6 no-relapse, to investigate their immune cell features and the correlation to relapse after chemotherapy. IHC control, multiplex immunofluorescence (mIF) panel control and the followed mIF staining were conducted using PN 6-Plex Detection Kit (PhenoVision Bio Co., ltd) targeted CD68, CD3, CD20, panCK, PD-L1 and PD-1. The 17 staining slides were scanned, tumor areas were lined out by pathologist based on H&E staining from the serial section of each sample. Non-tumor region, tumor invasive margin (IM) , which was defined as 360μm within and outside of tumor boundary *i.e.* total 720μm, tumor islands and stromal areas were analyzed using PhenoVision mIF AI analysis system trained from Oncotopix Discovery system (Visiopharm). Statistical analysis exhibited significant correlation of MSS mIF results to relapse rate based on binary logistic regression (p<0.05). Positive cell percentage and positive cell densities were both analyzed in 17 samples. When focused in tumor region, there were significant variated PD-1 negative/CD20 positive cells in tumor stromal region between relapse and non-relapse group (6.64% in non-relapse *vs.* 2.58%in relapse, p=0.026). Significant differences were observed in PD-L1/CD3 co-positive cell subtype (p=0.01) between relapse and non-relapse groups. Further focus on tumor and IM region, we observed significant more PD-1 negative/CD20 positive cell subtype in IM region compared to tumor area in relapse groups (0.68% tumor *vs.* 2.21% IM, p=0.0483). Similar trend of less in tumor and more in IM region with CD3 positive and PD-1 negative/CD3 positive cell subtypes was observed in non-relapse group, with p=0.05. Current study indicated that tumor microenvironment carried significant amount variations of cell subtypes between relapse and non-relapse groups. Although there were certain amount of PD-1 negative/CD20 positive cell subtype in relapse group, most located in IM region. The cell distribution feature may be utilized for prognosis prediction of MSS stage III CRCs after chemotherapy to guide patients' health monitoring plans after treatment. Moreover, therapies improve PD-1 negative/CD20 positive and such immune cell subtypes infiltrated into tumor region may improve patient prognosis which need more studies in the field.

#6479 High expression of the exhaustion markers PD-1 and PD-L1 in non-muscle invasive bladder cancer is associated with poor outcome following Bacillus Calmette-Guérin immunotherapy.

T. G. Andreasen, T. Strandgaard, L. Raaby, J. Jensen, L. Dyrskjot;
Aarhus University Hospital, Aarhus N, Denmark

Introduction: The recommended treatment for high-risk non-muscle invasive bladder cancer (NMIBC) includes intravesical instillations of Bacillus Calmette-Guérin (BCG). Despite completing BCG therapy, up to 40 % of patients experience disease recurrence within five years. T cell exhaustion has been associated with poor outcome following treatment with BCG. In this study, we investigated whether T cell exhaustion, characterized by protein expression of PD-1 and PD-L1 in paired samples obtained before and after BCG treatment could provide further insight into BCG response and help predict outcome in patients with NMIBC.
Methods: We included 105 patients with NMIBC, with transurethral resection of bladder tumor (TURBT) samples obtained prior to BCG (n=122) and after in cases with disease recurrence (n=44). Tissue sections from tissue microarrays (TMAs) were stained using immunohistochemistry to analyze the protein expression of the exhaustion markers PD-1 (clone EP239) and PD-L1 (clone 22C3). Data was analyzed using digital pathology software. Cells were scored as positive when detection of a nucleus was combined with a positive PD-1 or PD-L1 stain in both tumor or stromal area (defined by presence of positive pan-CK stain or not, respectively). In total, 167 samples were considered suitable for further analysis (cell count > 200 in tumor and stromal areas). Stratification of samples into high or low expression was based on a median split of the positive cell fraction.
Results: When investigating the fraction of PD-1 and PD-L1 positive cells in the tumors, we observed that PD-1 expression significantly increased with tumor stage in pre- ($p=0.002$) and post-BCG ($p=0.006$) tumor samples. PD-1 expression was also increased in high-grade tumors compared to low-grade tumors in pre-BCG samples ($p = 0.001$). Furthermore, we observed a significant association between tumors of higher stage and high PD-L1 expression in the pre-BCG samples ($p = 0.007$). Patients with low expression of PD-1 and PD-L1 in the pre-BCG tumor samples had a superior high-grade recurrence-free survival (HG-RFS) compared to patients with high PD-1 ($p=0.002$) and PD-L1 ($p=0.021$) expression. In addition, low expression of PD-L1 in pre-BCG tumors was correlated with a better progression-free survival compared to the patients with high PD-L1 expression ($p = 0.013$). When creating a combined score with PD-1 high and PD-L1 high samples, we saw that these patients demonstrated a worse HG-RFS compared to patients with either mixed or low scores ($p = 0.005$).
Conclusion: Protein expression of the exhaustion markers PD-1 and PD-L1 in pre-BCG tumor samples were correlated to higher stage and grade as well as worse HGFRS, indicating that T cell exhaustion plays an important role in resistance to BCG treatment and may be used to guide treatment.

#6480 Single-nucleus RNA sequencing reveals the immunological microenvironment of HPV+ and HPV- penile squamous cell carcinoma.

Andres E. Hernandez-Gonzalez[1], Maria Sanchez-Vazquez[2], Yakshi Ortiz-Maldonado[2], Carlos Rivera-Lopez[3], Brandon Torres-Rivera[4], Hector L. Franco[2], Josue Perez-Santiago[2], Maria Marcos-Martinez[4], Antonio Puras-Baez[3], Magaly Martinez-Ferrer[2]

[1]Department of Pharmaceutical Sciences, University of Puerto Rico - School of Pharmacy, San Juan, Puerto Rico,[2]Division of Cancer Clinical & Translational Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[3]Department of Surgery, Urology Section, University of Puerto Rico - School of Medicine, San Juan, Puerto Rico,[4]Department of Pathology and Laboratory Medicine, University of Puerto Rico - School of Medicine, San Juan, Puerto Rico

Penile squamous cell carcinoma (PSCC) has high morbidity and mortality rates in developing countries. Puerto Rico has the fifth-highest incidence of PSCC globally. HPV-associated PSCC accounts for 20-63% of cases, depending on the geographical area. The tumor microenvironment (TME) plays a crucial role in modulating disease progression. In this study, we seek to characterize the immunological TME in HPV+ and HPV- PSCC using single-nucleus RNA sequencing. We sequenced (Illumina HiSeq, CA, USA) approximately 3,000 nuclei from thirteen fresh PSCC tumor samples (8 HPV- and 5 HPV+) using the 10X Chromium System (10X Genomics, CA, USA). Quality control and filter of raw data was performed using Seurat and UMAP dimension reduction technique was used to cluster the nuclei. Cell types were predicted based on nuclei gene expression using two reference datasets from the Curated Cancer Cell Atlas: Ji 2020 (Skin Squamous Cell Carcinoma) and Kurten 2021 (Head and Neck Squamous Cell Carcinoma). Enrichment and functional analysis of genes that were significantly different between HPV+ and HPV- within each cell type were performed using Metascape. There were 19 distinct cell clusters identified among all samples. Six immune cell clusters were identified: T cells, macrophages, myeloid cells, B cells, dendritic cells, plasma cells. The relative abundance of each cell type was not significantly different between HPV+ and HPV- PSCC. In this study we focused on the T cell, macrophage, and myeloid cell clusters, which are immunologically relevant in cancer. These cell clusters contain differentially expressed genes that belong to pathways associated with protein synthesis (PS), extracellular matrix modulation (ECMM), blood vessel development (BVD), cytokine signaling (CS), and cell motility (CM). In all three immune cell clusters, PS pathway genes such as RPL7, RPL18A, RPL21 were overexpressed in the HPV + tumors. ECMM pathway genes (MMPs, COL1A1), BVD pathway genes (VEGFA), and CM pathway genes (CXCL1, CXCL8) were found to be overexpressed in HPV + tumors. For T cells and macrophages, CS pathways genes such as IL1A and CXCL8 were overexpressed in HPV + tumors. However, myeloid cells overexpressed different genes from the CS pathways in both HPV + (IL18, CCL3) and HPV - (CDKN1A, IFNAR2) tumors. In our analysis of the cancer cell clusters, the top differentially expressed genes among HPV+ tumors were: IL1A, IL24, ATP13A3, CCN1, AREG. Meanwhile the top differentially expressed genes among cancer cells of HPV - tumors were: ATP10B, FXYD3, CSRP2, CYP2C18, and KCTD1. Understanding how HPV infection affects the TME through changes in the molecular pathway interactions is critical for the identification of novel biomarkers and therapeutic targets that could improve treatment outcomes for penile cancer.

#6481 Multiplexed single-cell pharmacotranscriptomics and spatial tumor biology reveals targetable reciprocal cancer-stromal interactions in prostate cancer.

Astrid Murumagi[1], Frida Rantanen[2], Alice Dini[2], Mariliina Arjama[1], Katja Valimaki[1], Elina Multamaki[2], Tuomas Mirtti[3], Antti Rannikko[4], Teijo Pellinen[1], Daniela Ungureanu[2], Olli Kallioniemi[1]

[1]Institute for Molecular Medicine Finland (FIMM), Helsinki Institute of Life Science (HiLIFE), University of Helsinki, Helsinki, Finland,[2]Disease Networks Unit, Faculty of Biochemistry and Molecular Medicine, University of Oulu, Oulu, Finland,[3]HUS Diagnostic Center, Department of Pathology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,[4]Department of Urology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland

Prostate cancer (PCa) remains a leading cause of cancer-related deaths, with castration-resistant metastatic disease posing significant therapeutic challenges. The tumor microenvironment, particularly cancer-associated fibroblasts (CAFs), plays a crucial role in cancer development and in its progression to an aggressive and lethal stage. Previously, we identified a specific CAF subtype expressing fibroblast activation protein and platelet-derived growth factor receptor beta (FAP$^+$/PDGFRβ$^+$) as a strong predictor of poor patient prognosis, associated with PTEN loss and PI3K/pAKT activation in adjacent tumor cells. This study aimed to functionally characterize and pharmacologically inhibit this lethal cancer-stroma interaction phenotype. We first developed a 3D co-culture system using patient-derived primary CAFs and human PCa cells that recapitulates the lethal tumor microenvironment phenotype ex vivo and in vitro, providing robust models for functional studies. Utilizing 96-plex single-cell RNA sequencing with antibody barcoding of live cells, we analyzed the transcriptomic landscape of primary CAFs and assessed the impact of mono- and co-culture conditions on both cell types. Each patient-derived CAF model possessed a unique transcriptional profile, indicating patient-specific CAF characteristics. In 3D co-culture with PCa cells, CAFs exhibited upregulation of FAP and degradome genes, suggesting cancer-induced reprogramming of CAFs to remodel the extracellular matrix and support malignant progression. Concurrently, co-cultured CAFs induced pAKT upregulation in PCa cells, implicating stromal cells in promoting cancer cell proliferation. Hence, we functionally confirmed reciprocal cancer-stroma interactions in co-cultured models, mirroring changes seen in human tumor tissues of aggressive prostate cancers. To investigate potential therapeutic interventions, we applied a 96-plex single-cell pharmacotranscriptomic platform to evaluate drug responses using a library of 30 cancer drugs and key pathway inhibitors. Our findings indicate that dual inhibition of PI3K-AKT signaling in cancer cells and stromal signaling in CAFs could pave the way for combinatorial therapies targeting the reciprocal interactions between PCa cells and CAFs. This approach highlights the opportunity to develop precision cancer medicine strategies aimed at disrupting critical cell interactions within the tumor microenvironment in a tailored fashion.

#6482 Phenoplex™ spatial analysis of whole-slide colon adenocarcinoma imaged with Orion™ 13-plex one-round staining and imaging.

Regan Baird[1], Fabian Schneider[1], Edward Lo[2], Tad George[2], Joshua Nordberg[2]

[1]Visiopharm, Horsholm, Denmark,[2]RareCyte Inc, Seattle, WA

Background: The ability to stain and image tissue at high-plex over an entire slide in a single round enables insights into tissue architecture and the molecular mechanisms of immune and disease processes at unprecedented throughput. Here we investigate a whole slide tissue section of high-grade colon adenocarcinoma, a hot tumor that contains prominent clusters of PD-L1 expression scattered throughout, using single-step high-plex staining and imaging at single-cell resolution followed by the analysis of single-cell phenotypes, tissue segmentation and spatial proximity and nearest neighbor analysis.

Methods: A standard pathology slide was stained in one round with a 13-plex immune-oncology panel then a 21.7 x 18.5 mm area imaged in one round with the Orion™ spatial biology platform (RareCyte). The panel consisted of Hoechst/nucleus, autofluorescence, Ki-67, CD3e, CD4, CD163, CD8a, PD-L1, PD-1, FOXP3, CD68, CD20, Pan-CK, and Vimentin. Analysis was performed on the resulting OME.TIFF file with Phenoplex™ (Visiopharm) using the following pipeline: tissue segmentation into epithelial, necrotic and stromal regions of interest; cell segmentation using the Visiopharm Blueprint APP for DAPI nuclear detection; and phenotyping and spatial biodistribution analysis using the Guided Highplex Workflow.

Results: Data revealed intricate architecture and cellular transitions as tumor cells express varying levels of PAN-CK, with a subset proliferating, and PD-L1 clusters within the lamina propria. Leukocyte clusters are seen interacting with PD-L1+ macrophages and, at higher zoom level, the proximity can be measured of infiltrating T and B cells near the tumor cells. A variety of spatial distance-metric analyses were performed. As an example, neighbor analysis within the stromal ROI showed that PD-L1+ macrophages had a different neighborhood of immune cells within their vicinity compared to PD-L1- macrophages.

Conclusions: These data highlight the importance of sufficient plex, resolution and whole slide context to derive reliable spatial biomarkers of potential prognostic value. The ability to generate such rich data in just hours across a whole section with multiplexed biomarker quantitation makes this approach suited to multi-patient clinical studies. Deep-learning based image analysis enables deeper insights into the TME of cancer samples and enables researchers to robustly and accurately quantify and classify tissue samples to understand biology of disease.

#6483 Powerful end-to-end spatial analyses using precise spatial proteomics.

Charles E. Jackson[1], Matthew H. Ingalls[1], Kayla E. Cashion[1], J Spencer Schwarz[1], Adam Northcutt[1], Arne Christians[2], Oliver Braubach[1]

[1]Bruker Spatial Biology, Saint Louis, MO,[2]Bruker Spatial Biology, Hannover, Germany

Spatial biology supports our understanding of the progression and treatment of cancer by distilling complex cellular interactions into actionable spatial signatures. The most actionable targets to study with spatial methods are protein biomarkers, but non-destructive, high-plex spatial proteomics has been challenging to achieve due to technical limitations posted by available technologies. With the recent advent of enhanced photobleaching in cyclic immunofluorescence (EpicIF™) technology, multiplex immunofluorescence (mIF) can now be achieved more easily and inexpensively. EpicIF technology quickly and safely removes signal from even the brightest organic fluorophores, enabling the use of standard fluorescent antibodies in high-plex spatial proteomic protocols. We leveraged EpicIF technology to design modular mIF assay panels targeting key tumor immune microenvironment (TiME) biomarkers, tissue structural features, and markers enabling accurate cell segmentation. These assay panels were validated for performance (including sensitivity, specificity, and reproducibility) across a range of carcinoma tissues using the CellScape™ Precise Spatial Proteomics platform. Our validated panels enabled robust segmentation of immune, tumor and stromal cell types, ultimately permitting robust and comprehensive end-to-end spatial analysis of the TiME. We identified complex spatial neighborhoods composed of cellular interactions between immune infiltrates containing B-cells and T-cells, with mosaic expression of developmental and activation status markers in the TiME. Together, the use of these modular mIF panels, coined Next-Generation VistaPlex™ Assays, provided a fast foundation for accurate spatial analyses. The pairing of EpicIF technology with ready-to-use mIF assay panels provides the first simple, achievable access to spatial proteomics, including those without previous expertise in spatial biology.

#6484 Single-cell transcriptomic analysis of hepatocellular carcinoma: elucidating intratumoral heterogeneity and immune microenvironment crosstalk.

Qingyang Zhang, Yu-Man Tsui, Vanilla Xin Zhang, Daniel Wai-Hung Ho, Irene Oi-Lin Ng

The University of Hong Kong, Hong Kong, Hong Kong

Background: Hepatocellular carcinoma (HCC), the third leading cause of cancer deaths worldwide, exhibits significant cellular and molecular heterogeneity. The advent of single-cell transcriptomic methodologies has significantly disclosed its intra-tumoral cellular diversity to an unprecedented level. Interactions between cells within the tumor microenvironment (TME) are crucial for cancer progression and affect how tumors respond to current therapies.
Objective: This study aimed to utilize single-cell data to address two main objectives: (1) to dissect the heterogeneous nature of HCC tumors by identifying tumor subclones and their molecular features, key transcription factors, and implicated pathways; and (2) to explore the intricate communication between tumor cells and immune cells, with a focus on the pathways that significantly influence tumor growth and metastasis.
Methods: The tissue samples of HCC were obtained from nine patients undergoing surgery immediately from the operation theater after resection, with informed consent. Dissociated tumor single cells were subjected to scRNA-seq by 10X Genomics platform.
Results: Our analysis identified seven distinct tumor subclones, validating the presence of high tumor heterogeneity. Among these, one subclone, designated as SC6, exhibited particularly distinctive molecular characteristics. Further investigation revealed that NFE2L3 exhibited the highest activity score during the TFs analysis, indicating its significant regulatory role in SC6 cluster, and was intricately associated with pathways involved in extracellular matrix organization and immune regulation. Through cellular communication analysis, we discovered that tumor-associated macrophages (TAMs) and dendritic cells (DCs) exhibited the highest communication intensity with SC6 cluster when acting as the source of ligands. Further investigation revealed critical ligand-receptor pairs, including some integrin family genes functioning as receptors. This interaction suggests that these integrins may engage with ligands secreted by TAMs or DCs within the TME, potentially promoting tumor cell proliferation and migration.
Conclusions: Through comprehensive analysis of scRNA-seq data, we elucidated the intricate heterogeneity within HCC, identifying distinct characteristics of various tumor subclones. Our investigation revealed key transcription factors that predominate in specific subclones. Additionally, we uncovered robust intercellular communication between tumor cells and myeloid cells.

#6485 Prognostic impact of immune cells in vulvar carcinomas.

Zhihao Huang[1], **Elena Bady**[1], Maximilian Lennartz[1], Lisa Hornsteiner[1], Jan Hendrik Muller[1], Monika Kaszubowski[1], Ronald Simon[1], Guido Sauter[1], Sven Mahner[2], Niclas Blessin[1], Nikolaus de Gregorio[3], Rudiger Klapdor[4], Matthias Kalder[5], Elena I Braicu[5], Sophie Furst[2], Maximilian Klar[6], Hans-Georg Strau?[7], Katharina Prieske[1], Linn Wolber[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]LMU Munich, Munich, Germany,[3]Klinikum am Gesundbrunnen, SLK-Kliniken Heilbronn GmbH, Heilbronn, Germany,[4]Hannover Medical School, Hannover, Germany,[5]Charite-University Hospital, Berlin, Germany,[6]University of Freiburg, Freiburg, Germany,[7]University Hospital Martin-Luther-Universitat Halle-Wittenberg, Halle, Germany

Quantification of tumor infiltrating lymphocytes (TILs) and immune checkpoints in the cancer microenvironment has become of increasing interested in immuno-oncology. Vulvar cancer is emerging as a promising target for immune checkpoint blockade therapy. However, only little is known about the presence of TILs and the expression of immune checkpoint molecules in the tumor microenvironment and its predictive value in vulvar cancer. To better comprehend the role of immune cell expression and composition in vulvar cancer, a tissue microarray containing 479 vulvar cancer samples with clinic-pathological data was analyzed by multiplex fluorescence immunohistochemistry including 21 marker proteins to determine the composition of the immune cell infiltrate. Benjamini-Hochberg correction for multiple testing was applied. A total of 479 (85,4%) of the 561 cancers had interpretable results for all 21 markers. The identified immune cell types included cytotoxic-, T-helper- and regulatory T-cells, M1/M2 macrophages, dendritic cells, B-cells, TIM-3, PD-1 and CTLA-4 on immune cells and PD-L1 on immune and tumor cells. Comparison with clinical data revealed significant associations between prolonged progression-free survival and low expression of PD-1 (p=0.008) and TIM3 (p=0.039) on CD8+ T-cells, as well as low PD-L1 expression on M1 macrophages (p=0.046), dendritic cells (p=0.028), and tumor cells (p=0.013). Comparison with the human papilloma virus (HPV) status of the cancers showed a link between high numbers of tumor infiltrating B-cells and a favorable overall survival in HPV+ vulvar carcinomas (p=0.0464, AUC:0.67), but not in the HPV-negative subgroup. The quantification of immune cells alone did not reveal any significant correlation between the overall extent of inflammation and the histopathological parameters of the aggressive disease or the patient outcome. These data suggest that the impact of the immune reaction on the prognosis of vulvar carcinoma patients may be less dramatic than seen for other tumors. However, major differences of the role of anti-tumor immunogenicity between HPV positive and negative cancers, as well as a particular prognostic role of the quantity of B-lymphocytes and the expression of multiple checkpoint proteins is highlighted.

#6486 Prognostic impact of the immune environment in non-small cell lung cancer.

Lisa Hornsteiner[1], Natalia Gorbokon[1], Jonas B Raedler[2], Claudia Hube-Magg[1], Monika Kaszubowski[1], Nina Schraps[1], Katharina Moller[1], Florian Viehweger[1], Florian Lutz[1], Till S Clauditz[1], Christoph Fraune[1], Eike Burandt[1], Ronald Simon[1], Guido Sauter[1], Martin Reck[3], Klaus Raabe[3], Maximilian Lennartz[1], Stefan Steurer[1], **Elena Bady**[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Harvard University, Boston, MA,[3]German Center for Lung Research, Grosshansdorf, Germany

Lung cancer is the most frequent tumor related reason for death worldwide. It is hoped that a better understanding of the immune environment can foster the development of new immune checkpoint therapies to improve patient management and survival. To study the composition and prognostic impact of the immune infiltrate in non-small cell lung cancer, a tissue microarray containing 798 lung cancer patients, including 441 lung adenocarcinomas, 219 squamous cell carcinomas, was analyzed by multiplex fluorescence immunohistochemistry. A set of 14 antibodies was used to detect cytotoxic-, T-helper- and regulatory T-cells, B-cells, M2 macrophages, and dendritic cells (CD3, CD4, CD8, FOXP3, CD20, CD11c, CD163) expression of immune checkpoint molecules (TIGIT, PD-1, CTLA-4, TIM-3, PD-L1), and immune cell proliferation (Ki67) as well as panCK as an epithelial cell marker for tumor detection. Comparison with clinical data revealed significant associations between a high fraction of intratumoral $CD3^+$ T-cells (p=0.0182), cytotoxic T-cells (p=0.0192) and dendritic cells (p=0.0080) and favorable prognosis, and between a low fraction of intratumoral $CD3^+$T-cells (p=0.0007) and advanced tumor stage. A high Ki-67 labelling index was linked to poor prognosis (p=0.0002) and nodal positivity in all 798 lung cancer patients (p<0.0001), as well as in the subsets of 441 lung adenocarcinomas (p=0.0002) and 219 lung squamous cell carcinomas (p=0.0015). No prognostic relevance was found for the expression of the immune checkpoint molecules TIGIT, PD-L1, TIM-3, CTLA-4 and PD-1 on the immune cells in our series of cancers. In conclusion, a high T-cell infiltrate is linked to beneficial tumor characteristics in non-small cell lung cancers.

TUMOR BIOLOGY: Other Organisms and in Vivo/in Vitro Models
Poster Session

#6490 Patient-derived organotypic tumor spheroids (PDOTS) optimize donor selection in allogenic cell therapy development.

Chunxiao Cui[1], Raluca Dumitru[2], Danielle Hagee[1], Anthony Attardo[1], Kirti Khardenavis[1], Wassim Basheer[2], Sabrina D. Munnik[3], David C. Lopez[3], Gemma Moiset[3], Ketki Bhise[1], Sinal Patel[1], Alyssa Martin[1], **Michael Perricone**[1], Aaron Goldman[4]

[1]Xsphera Biosciences, Inc., Boston, MA,[2]Cell Solutions, Charles River Laboratories, Inc., Northridge, CA,[3]Discovery, Charles River Laboratories, Inc., Leiden, Netherlands,[4]Engineering in Medicine Division, Mass General Brigham, Boston, MA

Introduction: Donor-to-donor variability significantly impacts the process development of cell therapies for cancer. Characterizing the donor-specific functional variances enables donor selection for successful cell therapy development. Ex vivo human models provide unique opportunities to evaluate the functionality of cell therapies in the patient's native tumor microenvironment (TME). Here, using the Xsphera human tumor system, we assessed the specificity, migration, anti-tumor efficacy, and immune modulation of CAR-T cells from different donors to identify the optimal donor characteristics.
Methods: HER2-targeting CAR-T cells were generated from the peripheral blood mononuclear cells (PBMCs) of two healthy donors (CAR-D1 and CAR-D2). HER2+ (ZR-75-30) and HER2- (MDA-MB-468) cell lines were used to generate tumor spheroids. Fresh tumor samples collected from patients with ovarian cancer were partially dissociated into spheroids (PDOTS) ranging from 40-100 µm. Tumor spheroids and PDOTS were loaded into microfluidic devices containing extracellular matrix (ECM) and exposed to CAR-D1 and/or CAR-D2. CAR-T cell migration, proliferation and anti-cancer efficacy were measured and quantified using image-based analysis. RNA transcription was analyzed via NanoString to study tumor response and immune modulation.
Results: Both CAR-D1 and CAR-D2 showed time-dependent tropism through the ECM towards HER2+ tumor spheroids, but not HER2- tumor spheroids. Increased cytotoxicity was observed in HER2+ tumor spheroids with both CAR-T cells, with CAR-D2 showing greater cytotoxicity. CAR-D1 also induced off-target tumor killing in HER2- spheroids, which was not observed in CAR-D2. Nanostring analysis revealed higher cytotoxic signals in CAR-D1, whereas CAR-D2 showed higher antitumor cytokine signaling in HER2+ tumor spheroids and lower anti-tumor activity in HER2- tumor spheroids. In PDOTS derived from ovarian patient tumors (N=3), CAR-D2's cytotoxic effect appeared to be correlated with tumor cells' HER2 expression levels. In high HER2 PDOTS, CAR-D2 led to downregulation of tumor-related genes (ERBB2/HIF1A/EPCAM/EGFR), upregulation of CAR-T activation associated genes (IFNg/GZMB/PRF1/CXCL9/CXCL10/IL1A), and increased CD8 T cell abundances (CD8A/CD8B). In summary, CAR-D2 showed higher target specificity, slower ECM migration, faster spheroids uptake, greater anti-tumor efficacy, and lower off-target cytotoxicity than CAR-D1. Its efficacy in PDOTS appeared to be HER2 expression dependent.
Conclusion: The use of Xsphera's platform to study cell therapies provides a valuable tool for uncovering donor-to-donor variability by differentiating the variability in performance of CAR-T cells derived from different donors. This unique approach will support optimal donor selection and accelerate cell therapy development.

#6491 Advancing precision oncology: Integrating AVI-PDX and patient-derived organoid technologies for enhanced preclinical modeling in immuno-oncology.

Clelia Costechareyre[1], **Romain Teinturier**[1], Jurgen Loskutov[2], Mayrone Mongellaz[1], Madeleine Nadolny[2], Marjorie Lacourrege[1], Loraine Jarrosson[1], Celine Delloye-Bourgeois[1], Lena Wedeken[2], Valerie Castellani[1]

[1]Oncofactory, Lyon, France,[2]Cellphenomics, Berlin, Germany

The AVI-PDX platform enables the creation of miniature, patient-specific tumor models within living organisms, specifically avian embryos. We have developed next-generation, humanized models that incorporate immune cells, expanding the utility of AVI-PDX for investigating immune cell-based therapies and checkpoint inhibitors, both as monotherapies and in combination with standard treatments. Recently, patient-derived organoids have become valuable models for oncology research, offering diverse molecularly characterized resources. However, traditional organoids often lack key components of the stroma and immune microenvironment, limiting their application for studying immune-modulating therapies. To overcome these challenges, we combined AVI-PDX with patient-derived organoid technologies to create an avian patient-derived organoid model, termed AVI-PDO. Here, we describe the generation of a colorectal cancer (CRC) AVI-PDO model.Colorectal tumor organoids from a patient sample were cultured, dissociated, and micro-implanted into avian embryos at established sites within the AVI-PDX model. We conducted a time-course analysis, harvesting embryos 3 to 6 days post-implantation and visualizing them using light-sheet microscopy. Notably, we observed that initially dispersed tumor cells aggregated and reformed 3D organoid-like structures within the embryo. To further characterize these structures, we performed immunolabeling on tissue cryosections, revealing tumor cells organized into spherical formations with central lumens, expressing polarity markers. Additionally, a significant number of Ki67-positive cells were present, indicating active proliferation within these structures. This study demonstrates that our combined AVI-PDX and organoid approach allows the re-creation of organoid-like structures within avian embryo tissues, providing a novel humanized model. This model paves the way for studying immune-based therapies within a whole organism context, offering a comprehensive system that includes systemic signaling and the tissue microenvironment.

#6492 Development of transparent compound zebrafish tumor microenvironment (TME) model system.

Surendra Rajpurohit[1], **Arishia Mishra**[1], Rohan Pasi[1], Shubhra Rajpurohit[2], Sai Nasanally[1], Sreeja Sappati[1], Keyana Williams[1], Timothy Pham[1], Ethan Clegg[1], Kirk Kimmerling[3], Vishal Arora[2], Balakrishna Lokeshwar[1]

[1]Georgia Cancer Center, Medical College of Georgia, Augusta University, Augusta, GA,[2]Cardiology, Medical College of Georgia, Augusta University, Augusta, GA,[3]FiteBac Technology, Marietta, GA

Transgenic (Tg) zebrafish are paramount for studying the phenotypes resulting from overexpression of selected genes globally, or in a tissue-targeted fashion and growing numbers of tissue-specific promoters are becoming available to allow very precise targeting of transgene expression. In our proposed zebrafish glioblastoma experimental therapeutic model system, the first specific aim to develop the homozygous transparent compound transgenic strains from individual transparent transgenic progenies for glioblastoma tumor microenvironment (TME). Development and generation of transparent compound transgenic line *Casper; Tg(mpeg1:mcherry*; *islet1:GFP*) to study CNS resident macrophage, microglial activity and glial cell Interaction. Development and generation of transparent compound transgenic line Casper; Tg(mpeg1:mcherry; myl7:RFP; secA5:YFP) to study microglia, cardiac function, and cell death marker Annexin-5.Development and generation of transparent compound transgenic line *Casper; Tg(mpeg1:mcherry*; *islet1:GFP;* myl7:RFP; secA5:YFP) to study microglia, glial cell, cardiac function and cell death marker Annexin-5. Development and generation of transparent compound transgenic line *Casper; Tg(mpeg1:mcherry;NF-kB:GFP)* to study microglia, NFkB Inflammatory activity. Development and generation of transparent compound transgenic line Casper;Tg(mpeg1:mcherry; myl7:RFP; secA5:YFP; NF-kB:GFP) to study microglia, cardiac function and cell death marker Annexin-5 and NF-kB Inflammatory activity. Development and generation of transparent compound transgenic line *Casper; Tg(mpeg1:mcherry; vgfr:EGFP) and Casper; Tg(mpeg1:mcherry; kdrl:EGFP)* to study microglia and blood vessels and angiogenesis. Development and generation of compound transgenic line *Casper; Tg(mpeg1:mcherry;fli:GFP*) to study microglia, blood vessels, and vasculature. Development and generation of compound transgenic line *Casper:Tg(mpx:GFP);Tg(fms:gal4); Tg(UAS:nfsB.mCherry)* to study neutrophils, macrophages inflammatory process. Development and generation of compound transgenic line: *Casper:Tg(VEGFR2:AcGFP x CREST3-tag RFP-2A-NTR)* to study Crest trigeminal nerve and VGFR blood vessel interaction. By developing a transparent compound transgenic zebrafish model, this specific aim will lead us to explore the glioblastoma tumor microenvironment related biological process alterations and screening of new drugs to improve the diagnosis and treatment of this deadly invasive brain tumor.

#6493 Comparison of NK-92MI cell line vs. primary NK cells derived from peripheral mononuclear blood cells.

Ina Rohleff, Kanstantsin Lashuk, **Julia B. Schueler**

Charles River Laboratories, Inc., Freiburg, Germany

Natural Killer (NK) cell-based therapies are a rapidly growing area in cancer treatment. Preclinical research uses both cell line derived NK cells, such as NK-92MI, and primary NK cells derived from peripheral blood mononuclear cells (PBMCs). Each of these NK cell sources offers distinct advantages and limitations. The NK-92MI cell line, an immortalized and IL-2-independent derivative of the parental NK-92 line, provides a standardized, robust, and easily expandable cell source, making it highly attractive for large-scale experiments. However, NK-92MI cells lack certain activating receptors present in primary NK cells, which may limit their targeting range and reduce their cytotoxic potential against specific cancer types. Conversely, primary NK cells isolated from PBMCs mirror more closely the heterogeneous and receptor-diverse populations present in the human immune system. Yet, primary NK cells also present challenges, including variability between donors, limited proliferation in culture, and complex handling and isolation processes. This study compared the cytotoxic efficacy of the NK-92MI cell line and primary NK cells against HER2+ cancer cells in combination with trastuzumab (anit-HER2 antibody). Using a live-cell imaging platform, we quantitatively assessed the killing dynamics of these NK cell types over time. HER2+ cancer cells (SK-OV3, SK-BR3, HCC1954, JIMT-1) were co-cultured with either NK-92MI cells or PBMC-derived NK cells, and their effect on tumor cell killing was monitored continuously in a 2D and 3D setup. In addition, the migration of different NK cell types through a trans-well membrane was measured to see their migration potential. Key parameters, including the rate of cancer cell death and NK migration activity, were analyzed to determine differences in killing efficiency and sustained potency. The results indicate differential cytotoxic behavior between PBMC-derived NK cells and NK92-MI. In monotherapy the NK92-MI cell line exhibited strong proliferation and increased cytotoxic activity compared to PBMC-derived NK cells, which demonstrated moderate tumor cell killing. However, the treatment with trastuzumab in the presence of the two different NK cell types displayed equally effective killing. Despite JIMT-1 which was resistant towards trastuzumab but displayed reduced growth over time when co-cultured with NK-92MI alone. The migratory capacity of the NK cells was mainly driven by the different CCL2 levels secreted by the four HER2+ cancer cell lines evaluated in the study. In summary, this study highlights the feasibility to use NK cell lines such as NK-92MI for screening and proof-of concept experiments, where the need for scalability and reproducibility is mandatory. However, the limited heterogeneity and lack of certain activating receptors of the NK cell line must be considered when interpreting these studies.

#6494 Genetically characterized canine tumoral cell lines are relevant models to test the efficacy of new targeted therapies: Example of anti-MDM2 targeted therapy.

Pierre Montagne[1], Ulrich Jarry[1], Caroline Confais[1], Edouard Cadieu[2], Aline Primot[1], Nicolai Hoffman[2], Armel Houel[2], Remy Le Guevel[3], Thomas Derrien[2], Catherine Andre[2], Jerome Abadie[4], Christophe Drieu La Rochelle[1], Benoit Hedan[2]

[1]Biotrial, Rennes, France,[2]Institut de genetique et developpement de Rennes UMR6290, CNRS, Rennes, France,[3]UAR Biosit-Oncotrial, Rennes, France,[4]LabOniris, Ecole Nationale Veterinaire de Nantes, Nantes, France

Genetic characterization of cell lines is essential for understanding and predicting sensitivity to anti-tumoral targeted therapies. This study develops a panel of genetically characterized tumoral cell lines to test novel and repositioned anti-tumor therapies, focusing on canine mucosal melanoma (MM) and histiocytic sarcoma (HS) models. We established a diverse panel of MM and HS canine cell lines, leveraging the strong genetic and clinical similarities between canine and human cancers. Using long-read sequencing (Nanopore) technology, we performed comprehensive genetic characterization, identifying single nucleotide variants, structural variations, and copy number alterations. RNA sequencing complemented our genomic analysis by assessing gene expression profiles and potential fusion transcripts. Our methodology involved several key steps:1. Cell line establishment from tumor samples2. Comprehensive genetic profiling3. In vitro drug sensitivity screening4. In vivo validation through mouse xenograft modelsAs a proof of concept, we evaluated Idasanutlin, an MDM2 inhibitor, across our developed cell lines. Our findings demonstrated a clear correlation between TP53 status and drug sensitivity: cell lines with wild-type TP53 were sensitive to the drug, while those with mutated TP53 showed resistance. This result underscores the potential of genetic profiling to guide treatment decisions. The unique value of our approach lies in its ability to:· Identify biomarkers of drug response· Elucidate resistance mechanisms · Discover treatment-responsive subgroups based on genetic profile in previously untreated cancer· Inform the potential of new or repositioned targeted therapiesCanine cancer models offer distinct advantages, including:· Higher incidence of rare cancers in specific breeds· Genetic predispositions from selective breeding· Closer genetic and clinical similarity to human cancersOur cell line panel provides a systematic approach to validate therapeutic strategies tailored to specific genetic contexts. By integrating genomic, transcriptomic, and drug sensitivity data, we create a powerful research tool for both veterinary and human oncology. The research demonstrates the potential of comparative oncology in advancing cancer treatment. Our genetically characterized cell lines offer a comprehensive platform for drug screening and biomarker discovery, ultimately aiming to improve patient care and survival rates for challenging cancers. This work represents a significant step towards more personalized and precise cancer therapies, bridging the gap between preclinical research and clinical application.

#6495 Development of a drug screening platform of glioblastoma utilizing microgel encapsulation.

Brittany A. Payan[1], Annika Carrillo Diaz de Leon[1], Tejasvi Anand[2], Gunnar B. Thompson[3], Brendan A. C. Harley[3]

[1]Bioengineering, University of Illinois at Urbana-Champaign, Urbana, IL,[2]Molecular and Cellular Biology, University of Illinois at Urbana-Champaign, Urbana, IL,[3]Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign, Urbana, IL

Background. We report a method to encapsulate glioblastoma (GBM) cells in maleimide-functionalized gelatin (GelMAL) microparticles for *in vitro* drug screening. GBM is the most common primary malignant brain tumor. Standard of care is surgical resection followed by treatment with the alkylating agent temozolomide (TMZ). GBM cells that evade surgery eventually become resistant to TMZ and lead to recurrence of tumors in patients. Hydrogels have been implemented as matrices for 3D culture that can recapitulate tumor biology and tumor microenvironment. However, bulk hydrogels require large numbers of cells per construct and possess inherent diffusional limits. With only four drugs currently FDA-approved for GBM treatment, there is a need for a platform capable of accelerating the identification of new therapies in a highly controlled and physiologically relevant environment. Hydrogel microparticles allow encapsulation of GBM cells in a tailorable 3D matrix, rapid diffusion to limit spatial hypoxia gradients, and ease of handling for high-throughput screens (HTS).
Methods. U87MG cells are encapsulated in GelMAL microparticles using a flow-focusing microfluidic device. Viability and proliferation of GBM cells is assessed via LIVE/DEAD cell imaging kit and double stranded DNA (dsDNA) quantification, respectively. We record a response from encapsulated cells after TMZ exposure (0-1000 μM) via cellular activity using alamarBlue.
Results. Cellular viability within microfluidic emulsion is limited by shear forces exhibited in the microfluidic device. Here, we report a method to encapsulate GBM cells in microgels and retain cellular viability. Increasing levels of dsDNA suggest maintenance of cellular health in microgels and indicate a proliferative population of encapsulated cells. Metabolic profile of encapsulated cells shows a decrease in cellular activity in response to increasing concentrations of TMZ, concurrent with 2D and bulk hydrogel culture. Ongoing experiments will assess cellular behavior post-movement by liquid handler of encapsulated cells to establish a drug screening platform amenable for HTS.
Conclusion. We have developed a method to reliably encapsulate GBM cells into GelMAL microgels while retaining viability. The recorded cellular activity of encapsulated cells in response to TMZ demonstrates the utilization of microgels as an *in vitro* drug screening platform. We will leverage this platform to examine drug response *in vitro* amenable for high-throughput screening to identify possible therapeutics for TMZ resistant tumors.

#6496 Humanized tridimensional model of osteosarcoma to test immunotherapeutic strategies.

Bobby Dow[1], Federica Banche-Niclot[1], Lorenzo Apolloni[2], Giada Bassi[2], Jason Yustein[3], Monica Montesi[2], Francesca Taraballi[1]

[1]Center for Musculoskeletal Regeneration, Houston Methodist Research Institute, Houston, TX,[2]Institute of Science, Technology, and Sustainability for Ceramics, National Research Council, Faenza, Italy,[3]Winship Cancer Institute and Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, GA

Osteosarcoma (OS) is the most common primary malignant bone cancer, affecting both young adults (ages 10-30) and older adults (over 60). Despite progress in cancer research, survival rates have remained largely unchanged for the past 40 years, particularly for patients with metastatic disease, where 5-year survival rate is about 20%. This lack of progress is partly due to inadequate preclinical models that replicate the complex tumor microenvironment, hindering the development of effective new treatments.

Traditional 2D cell culture models fail to replicate the intricate interactions between tumor cells, the extracellular matrix (ECM), and stromal cells, which are key factors in cancer behavior and therapy response. In contrast, three-dimensional (3D) models offer a more accurate representation of the tumor's architecture, improving predictions of drug efficacy and tumor progression. Moreover, one of the most critical factors influencing OS treatment outcomes is the presence of a subpopulation of cells known as cancer stem cells (CSCs). CSCs contribute to tumor recurrence and metastasis due to their self-renewal and differentiation ability. Furthermore, CSCs are resistant to conventional therapies, such as chemotherapy and radiotherapy. This, coupled with the fact that OS is considered a 'cold tumor,' makes it particularly challenging to treat with immunotherapy.

Our lab is dedicated to developing humanized 3D OS models that closely mimic the tumor microenvironment, integrating OS cells, immune components, and ECM elements such as collagen. These advanced models address the limitations of animal studies by offering a physiologically relevant platform to investigate CSC behavior, drug resistance mechanisms, and tumor-stroma interactions specific to OS. Utilizing patient-derived xenografts (PDX), we generated 3D tumor sarcospheres that recapitulate key features of OS, including high CSC enrichment and resistance to conventional therapies.

To characterize these 3D sarcospheres, we employed CellTiter Glo assays and Live/Dead staining to evaluate viability, flow cytometry for stemness markers (CD44, CD117, and CD133), and PCR analysis for CSC-associated genes (OCT4, Nanog, and SOX2). Our findings consistently demonstrate enhanced CSC populations and distinct tumorigenic features in 3D cultures compared to traditional 2D models.

Additionally, we incorporated immune components in the 3D model by co-culturing OS PDX cells with immune cells (THP-1), further refining the tumor microenvironment. This integrated approach facilitates a comprehensive understanding of tumor cell-immune cell interactions and provides a robust, scalable platform for testing immunotherapeutic strategies. Ultimately, these humanized 3D models aim to address a significant gap between preclinical studies and clinical applications, thus improving the development of novel and effective therapies for OS.

#6497 Modeling HCC molecular and histological features by CRISPR editing of primary hepatocytes.

Lobna Elkhadragy[1], Olayinka G. David[1], Caitlyn C. Castillo[1], Isadora Andre Rosa Lopes1[1], Hannah Liu[1], Luke R. Jordan[1], Luke N. Redlon[1], Grace Guzman[1], Jonathan P. Samuelson[2], Lawrence B. Schook[1], Amaia Lujambio[3], Kyle M. Schachtschneider[4], Ron C. Gaba[1]

[1]University of Illinois at Chicago, Chicago, IL,[2]University of Illinois at Urbana-Champaign, Champaign, IL,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Sus Clinicals, Chicago, IL

Background: Hepatocellular carcinoma (HCC) is an aggressive disease with poor response to current therapies, highlighting the need for more effective therapeutic strategies. Preclinical HCC models are necessary tools for assessment of novel therapies. Pigs offer a valuable disease model due to their similarities with humans and their large size which allows testing clinically relevant procedures. Here, we aimed to develop HCC cell and animal models by precise gene manipulation of primary porcine hepatocytes.
Materials and Methods: Hepatocytes were isolated from minipigs (n=4) and subjected to CRISPR knockout (KO) of tumor suppressor genes, with or without oncogene overexpression (OE). Gene alteration combinations included KO of *TP53*, *PTEN*, and/or *CDKN2A*, with or without c-myc overexpression. Gene alterations were validated by Sanger sequencing, PCR, and Western blotting. The developed cell lines were injected subcutaneously into severe combined immunodeficient (SCID) mice to confirm their tumorigenicity and assess histological features. Cells with *TP53*^{KO}; *PTEN*^{KO}; *CDKN2A*^{KO}; c-myc^{OE} (TPKM) were then autologously injected into pigs (n=2) by percutaneous ultrasound-guided liver parenchymal injection and tumor development was monitored by ultrasound and CT imaging. Tumors from mice and pigs were analyzed by histological and transcriptional analyses.
Results: The induced gene alterations in porcine hepatocytes resulted in the successful development and propagation of four distinct cell lines, all validated for the intended modifications. Injection of these cells into SCID mice resulted in tumor development confirming *in vivo* tumorigenicity. Histological analysis of mouse xenograft tumors identified epithelial neoplasms with multiphenotypic cells, displaying moderate to poor differentiation, and closely mimicking human liver cancer. In pigs, autologous injection of TPKM cells resulted in intrahepatic mass formation within 3 weeks. Histological analysis of the porcine masses revealed neoplastic cells with positive Arginase staining, negative CK19 staining, and intratumoral immune cell infiltration. Transcriptional analysis of the mouse and pig tumors showed activation of pathways associated with cancer cell proliferation and hepatic fibrosis.
Conclusion: This study successfully establishes genetically defined HCC models with histological and molecular features resembling human HCC by CRISPR editing of primary porcine hepatocytes. These innovative HCC cell models provide valuable tools for drug screening and mechanistic studies, and the porcine model is a promising tool that harbors defined tumor driver mutations and is suitable for locoregional therapy testing. Together, these novel HCC cell and animal models offer promising avenues for preclinical evaluation of innovative therapeutic strategies.

#6498 Development of a rat model to study *ESR1* mutations in estrogen receptor-positive breast cancer.

Lillian He[1], Wen Bu[2], Ruixin Xu[2], Yi Li[2]

[1]Rice University, Houston, TX,[2]Baylor College of Medicine, Houston, TX

Estrogen receptor α (ER)-positive breast cancers constitute approximately 70% of all breast cancers and are commonly treated with surgery and endocrine adjuvant therapies. While these treatments significantly reduce mortality, resistance to endocrine therapies often emerges, leading to metastatic disease. One notable mechanism of resistance is *ESR1* gene mutations, which usually alter the ligand-binding domain of ERα. To advance the understanding of *ESR1* mutation-driven tumorigenesis and metastasis, an immunocompetent animal model is essential. Existing models, such as patient-derived xenografts, lack an intact immune system. However, rat mammary tumors are predominantly ER-positive, offering a unique advantage over mouse models, which typically form ER-negative tumors. Despite this, no rat models harboring *ESR1* mutations currently exist. Here, we report the development of a novel ER-positive breast cancer model in rats carrying the *Esr1* D538G somatic mutation, created using a CRISPR-Cas9-mediated homology-directed repair (HDR) precision genome-editing approach. The *Esr1* D538G mutation is paired with a tumor-initiating Neurofibromin 1 (*Nf1*) loss-of-function mutation which was previously shown to establish ER-positive and estrogen-dependent rat mammary tumors. Detailed characterizations of this tumor model will be presented at the conference. This innovative platform provides an essential tool for investigating mechanisms of endocrine resistance in ER-positive breast cancer and for exploring novel therapeutic strategies to treat endocrine-resistant breast cancer.

#6499 Miniaturized 3D cancer models for measuring efficacy of cancer therapeutics.

Jamie Hodgson[1], Hannah Findlay[1], Timothy London[1], Agapitos Patakas[1], Michele Zagnoni[2], Karla Paterson[3], Ronan Mellin[3]

[1]RoukenBio, Motherwell, United Kingdom,[2]Electronic & Electrical Engineering, University of Strathclyde & ScreenIn3D Ltd, Glasgow, United Kingdom,[3]ScreenIn3D Ltd, Glasgow, United Kingdom

Whilst Chimeric Antigen Receptor T-cell (CAR-T) therapy has been proven beneficial in treatinghaematological malignancies and melanoma, their clinical success against the majority of solidtumour types has been limited thus far. The need for physiologically relevant 3D, complex *in vitro*models of cancer is steadily increasing due to the emergence of drugs targeting the immunesystem and the tumor microenvironment (TME). Current *in vivo* and *in vitro* models are notsufficiently representative of the human (TME) and can fail to accurately predict the clinicaloutcome of immunotherapies. Furthermore, an increasing interest in precision treatment of cancerpatients and the rise of anticancer therapies used in combination has highlighted the need forlarge-throughput 3D efficacy tests capable of maximizing data generation using very smallquantities of 3D tumour models, especially including those from clinical samples. To this aim,microfluidic and organ-on-a-chip technologies can facilitate mechanistic studies and, at the sametime, miniaturize investigation of therapy efficacy on relevant human tumor samples.This work aimed to develop novel, high-throughput and miniaturized efficacy assays todemonstrate CAR-T mediated cytotoxicity using the Her2 receptor, a common target over-expressed on many types of solid tumors. $Her2^+$ and $Her2^-$ expressing cancer cells were culturedin 3D within $UpScale^{3D}$ microfluidic platforms (ScreenIn3D Ltd). Hundreds of spheroids wereformed within 48 hours and, subsequently, CAR-Ts with low and high affinity for the target(RoukenBio) were co-cultured with the spheroids over 72-hour incubation at the desired E:T ratio.Viability staining and cell type specific markers were used as readouts. Results showed that CAR-T quickly targeted, disaggregated and specifically killed high $Her2^+$ expressing cells in 3D models.In contrast, CAR-T cells did not elicit statistically significant cytotoxicity in low/non-$Her2^+$expressing spheroids. Immunotherapy treatment was compared to cytotoxicity elicited bychemotherapy agent carboplatin.This versatile microfluidic platform offers high quality and multiplexed efficacy screening assays onspheroid co-cultures, organoids and primary tumour fragments. The platform is designed for self-generation of multiple drug concentration gradients, offering a unique system to miniaturize drugcombination studies using patient's tissue and, at the same time, creating cost-effective and fastimmune-oncology assays for extensive drug combination studies and precision medicine drugdiscovery.

#6500 Application of human inducible pluripotent stem cells (hiPSCs) with CRISPR/Cas9-mediated deletion of *CUX1* as a model for high-risk myeloid neoplasms.

Joseph Michael Cannova[1], Kaina A. Millan[2], Yuqing Xue[2], Aubrianna S. Ramsland[2], Zara Khosravi[3], Adesewa Ogunsusi[4], Matthew Jotte[5], Megan McNerney[6], Michael Drazer[1]

[1]The University of Chicago Medicine Comprehensive Cancer Center, Hyde Park, IL,[2]Biological Sciences Division, The University of Chicago, Hyde Park, IL,[3]Biological Sciences Division, The University of Chicago Medicine, Hyde Park, IL,[4]The University of Chicago, Hyde Park, IL,[5]Pritzker School of Medicine, The University of Chicago, Hyde Park, IL,[6]Pathology and Pediatric Hematology/Oncology, The University of Chicago, Hyde Park, IL

Acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) with cytogenetic abnormalities of chromosome 7 have dismal survival outcomes. Monosomy 7 or deletion of 7q (-7/del7q) are adverse-risk cytogenetic features found in up to 12% of MDS/AML patients and are further enriched in therapy-related MDS/AML. Despite significant scientific effort, no targeted therapy is available for patients with -7/del7q MDS/AML. Several genes are associated with -7/del7q leukemogenesis. Cut-like homeobox 1 (*CUX1*) is a gene encoding a context-dependent transcription factor required for several molecular pathways, including epigenetic signaling. *CUX1* is deleted in -7/del7q MDS/AML and somatically mutated in 2-4% of MDS/AML. *CUX1* mutations and *CUX1* deletions are associated with a poor prognosis, and are known to co-occur with adverse risk *TP53* mutations and a complex cytogenetic background. Thus, there is a need for novel human models of MDS/AML to isolate the effect of *CUX1* alterations. To address the need for high-fidelity models of MDS/AML with high-risk genetic changes, we transfected human inducible pluripotent stem cells (hiPSCs) with *CUX1* targeting gRNA and CRISPR/Cas9 ribonucleotide-protein (RNP) complexes to generate isogenic hiPSC lines bearing $CUX1^{+/-}$ and $CUX1^{-/-}$ genotypes alongside parent hiPSCs and sham transfection lines with a $CUX1^{+/+}$ background. These derivative cell lines underwent rigorous validation by karyotypic G-banding analysis, sequencing, immunoblotting, trilineage germ layer differentiation, and analysis of hiPSC transcriptional and immunophenotypic markers. We hypothesized that the loss of one or both alleles of *CUX1* would result in transcriptional changes similar to *CUX1* mutated and -7/del7q MDS/AML. This model can be further leveraged to identify potential treatment targets. We obtained bulk RNA sequencing of undifferentiated hiPSCs and hiPSC-derived hematopoietic stem and progenitor cells (i-HSPCs) of each genotype ($CUX1^{+/+}$, $CUX1^{+/-}$, and $CUX1^{-/-}$). We identified several differentially expressed genes and novel long non-coding RNAs in hiPSCs with Cas9-mediated *CUX1* deletions, including downregulation of distinct subsets of genes in $CUX1^{-/-}$ and $CUX1^{+/-}$ hiPSCs. Bulk RNA sequencing of $CUX1^{-/-}$ and $CUX1^{+/-}$ i-HSPCs identified an association between reduced expression of thioredoxin-interacting protein (*TXNIP*), a known regulator of autophagy. This study supports the use of hiPSC-based CRISPR/Cas9 gene editing as a novel platform to identify gene-specific alterations in genotypically and cytogenetically complex myeloid neoplasms.

#6501 The SRG RAT supports in vivo human cell xenotransplantation through enhanced tumor microenvironment interactions.

Caitlin M. O'Connnor, Diane Begemann, Kaitlin P. Zawacki, Kelsey Barrie, Fallon K. Noto, Grace Walton, Gabrielle H. Onishi, Jessica Durant, Taylor Branyan, Mike Schlosser, **Goutham Narla**

University of Michigan, Ann Arbor, MI

The use of immunodeficient mice for human tumor engraftment has proven to be an essential model of human cancer, with uses ranging from basic science to translational research. However, low engraftment rates, slow growth, and smaller tumor volumes can be limitations. Previously, we reported a highly immunodeficient rat strain developed by Hera BioLabs, with the functional deletion of both the Rag2 and Il2rg genes on the Sprague-Dawley background (**SRG RAT®**), which lacks B, T, and NK cells. We have shown that the SRG rat supports the growth of multiple PDX and CDX models, however, the mechanisms underlying the supportive growth are not fully understood. Additionally, direct comparison of tumor growth and the rates of engraftment between the SRG rat and NSG mice has remained limited. Here, we subcutaneously engrafted two CDX and five PDX models into SRG or NSG animals and tracked tumor growth. These models included prostate, lung, ovarian, and uterine cancer models. In all cases, the engraftment and tumor growth rates were better supported in the SRG rat compared to the NSG mouse. Interestingly, the SRG rat is not more immunocompromised than the NSG mouse, suggesting alternative mechanisms leading to the supportive growth in the SRG rat. To understand this, we explored potential differences in the tumor microenvironment (TME) between models grown in the two host animals. We analyzed tumors from the H660 CDX model of castrate-resistant prostate cancer grown in either SRG rats or NSG mice using markers of the TME via immunohistochemistry. This analysis showed differences in the vasculature and macrophages between the two host species. We complemented this analysis using Xenium in situ by 10X genomics to allow for single-cell spatial imaging of engrafted tumors. This analysis showed upregulation of the human CXCL2, LAMP3, and other genes in H660 tumors grown in the SRG rat vs the NSG mouse. Interestingly, high expression of these two genes has been linked to poor prognosis in cancer. Combined, our data demonstrate that the SRG rat supports the growth of multiple human cancer types and displays enhanced tumor microenvironment interactions compared to NSG mice.

#6502 Inhibition of VCP in an *in vivo* model of metastatic melanoma selected based on a predictive biomarker demonstrates tumor reduction.

Aofie Campbell, Dora Kallai, Boldizsar Elek, Csilla Hegedűs, Magdolna Djurec, Ivan Fekete, Peter Szikora, Csaba Szantai-Kis, Amrik Basran, Stephen Connolly, **Daniel Veres**

Turbine Simulated Cell Technologies Ltd., Budapest, Hungary

Valosin containing protein (VCP) is a member of the AAA-ATPase family. It is involved in multiple cellular processes, such as protein degradation, DNA damage response, protein quality control and clearance in the endoplasmic reticulum, all of which are important functions often dysregulated in cancer. VCP is a common essential gene and there have been reports of toxicity associated with its inhibition, therefore a predictive biomarker is needed to stratify patients who are selectively vulnerable. Turbine's Simulated Cell model highlighted VCP from an *in silico* target identification screen where a subgroup of melanoma was found to be most sensitive to VCP inhibition (VCPi). These findings were confirmed in a cell line panel covering 12 indications, consisting of 64 cell lines. Next, a simulated drug modifier screen was run using patient relevant avatars with prevalent alterations, which identified MITF as a predictive biomarker of VCPi sensitivity. An *in vitro* melanoma model of MITF dependency, SKMEL5, was used to test our hypothesis. Hypotheses derived from *in silico* predictions were validated using various forms of VCP loss including pharmacological inhibition using a phase 1 VCPi, CB5083, as a reference compound, siRNA and by conditional knockout. The sensitivity of VCPi in melanoma was confirmed *in vitro* and a correlation (R= -0.86) was found between the protein levels of MITF and IC50 values of VCPi. In the SKMEL5 cells, we observed a dose dependent reduction in levels of MITF following VCPi. Next, we sought to test the efficacy of VCPi in the SKMEL5 *in vivo* CDX model. Four weeks of CB5083 dosing using 50 mg/kg 4on/3off schedule was tolerated, resulted in 46% tumor growth inhibition, and this was accompanied by a downregulation of MITF and one of MITFs targets, DCT, in tumor samples post treatment. These studies support the therapeutic potential of VCP inhibitors in the MITF ^{High}/MITF ^{Amplification} subgroup of patients with metastatic melanoma with a poor prognosis and a decreased 5-year survival. Targeting a common essential gene such as VCP is associated with a narrow therapeutic index, however, we have demonstrated efficacy using a relatively low dose of 50 mg/kg . Taken together, we are proposing a patient stratification strategy based on the identification of a predictive biomarker from an *in silico* screen.

#6503 Preclinical insights into chemotherapy-induced alopecia: a focus on mouse and rat models.

Simonetta I. Gaumond, Isabella Kamholtz, Caroline A. Crowley, Claudia Kersting, **Joaquin J. Jimenez**

University of Miami Miller School of Medicine, Miami, FL

Chemotherapy-induced alopecia (CIA) is a prevalent and distressing side effect of cancer treatment, significantly affecting patients' quality of life and highlighting the critical need for preclinical models to investigate its mechanisms and develop effective interventions. Murine models, including both rat and mouse species, are indispensable in advancing our understanding of CIA. This review explores the use of murine models in CIA research, focusing on the most commonly used strains, chemotherapies, and administration methods. Rat models primarily utilized Fischer, Long-Evans, and Sprague-Dawley strains, treated with chemotherapeutic agents such as cyclophosphamide, cytarabine, doxorubicin, and etoposide. Most of these chemotherapies were injected intraperitoneally (IP), with occasional intravenous (IV) or subcutaneous (SQ) injections. Mouse models primarily involved C57/BL mice, with chemotherapy also administered predominantly via IP injection, along with a few IV and one SQ method. The primary agents responsible for inducing alopecia in these models included cyclophosphamide, doxorubicin, and, less frequently, 5-fluorouracil, cytosine arabinoside, etoposide, and paclitaxel. The assessment of alopecia progression relied on visual evaluation, photography, and histological analysis. While these models provide critical insights into CIA mechanisms, variability in outcomes underscore the need for standardized protocols to enhance reproducibility and translational relevance in preclinical CIA research.

#6504 Generation of stable reporter pools in established patient-derived tumoroid models.

Xiaoyu Yang[1], Jacob Delgadillo[1], Garrett Wong[1], Matthew Woods[1], Jakhan Nguyen[1], Colin Paul[2], Chris Yankaskas[2], Pradip Shahi Thakuri[2], Shyanne Salen[2], Sylvia Beam[2], Matt Dallas[2], David Kuninger[2], Jason Sharp[1]

[1]Thermo Fisher Scientific, Carlsbad, CA,[2]Thermo Fisher Scientific, Frederick, MD

Tumoroids are patient-derived cancer cells grown as 3D, self-organized multicellular structures. Recently, tumoroids have emerged as powerful and reliable platforms for preclinical cancer drug discovery due to their ability to retain key characteristics from the original tumor. However, traditional tumoroid culture relies on complex media formulations and labor-intensive culture workflows. To tackle this issue, we have developed the serum-free, conditioned medium-free Gibco™ OncoPro™ Tumoroid Culture Medium for derivation and expansion of tumoroids. Our previous data demonstrated that OncoPro medium enabled the transition of 18 out of 19 previously established tumoroid models of various cancer indications from the National Cancer Institute Patient-Derived Models Repository (NCI PDMR) and another commercial source and preserved their genetic and transcriptional characteristics. Here, we extend this work demonstrating the compatibility of OncoPro medium with many previously established tumoroid lines and present a stable reporter pool generation custom project for a leading pharmaceutical company using a client-provided colorectal tumoroid line. We first tested the ability for the tumoroids to adapt to OncoPro medium and a suspension culture protocol. Tumoroids displayed higher growth rate when cultured in OncoPro medium compared to client-provided media (CM) in both embedded and suspension culture. To enable scalability, suspension culture was selected for downstream reporter pool generation. Firefly luciferase (fLuc)- and green fluorescent protein (GFP)-expressing tumoroids were generated by lentivirus transduction followed by antibiotic selection in OncoPro medium and CM. 5 days after transduction, >90% of cells were GFP-positive, minimizing the selection bias from editing and preserving population heterogeneity. 6 weeks after selection began, GFP-expressing pools evaluated by flow cytometry showed >97% GFP positive cells, while fLuc-expressing pools showed a cell number-dependent increase of luciferase activity in both media systems. Notably, OncoPro medium displayed a considerable advantage for reporter pool expansion, saving >50% of media and hands-on time compared to CM. To test for genetic and transcriptional stability, stable pools were compared with parental cells grown in CM using targeted NGS and bulk RNA sequencing. High correlation coefficients ($r \geq 0.99$ for targeted NGS and ≥ 0.90 for RNA sequencing) were observed in pre- and post-edited pools, suggesting minimal genetic and gene expression drift over the engineering process. Taken together, these findings represent the ability of OncoPro medium to support cell engineering workflows on established tumoroids while preserving characteristics of the parental tumoroids. These tumoroid reporter pools serve as effective and clinically relevant models for evaluating cancer therapies in downstream applications.

#6505 Evaluation of the potential role of K21 pharmacogenomics and its application in the tumor microenvironment and experimental therapeutics by using zebrafish model.

Surendra Rajpurohit[1], Sai Nasanally[1], Pragya Rajpurohit[1], Arishya Mishra[1], Devan Manhiani[1], Rohan Pasi[1], Sharad Purohit[2], Nikhil Patel[3], Kirk Kimmerling[4], Bhupesh Prusty[5]

[1]Georgia Cancer Center, Medical College of Georgia, Augusta University, Augusta, GA,[2]Center for Biotechnology and Genomic Medicine, Medical College of Georgia, Augusta University, Augusta, GA,[3]Pathology, Medical College of Georgia, Augusta University, Augusta, GA,[4]Fitebac Technology, Marietta, GA,[5]INSTITUTE OF MICROBIOLOGY AND VIROLOGY, Riga Stradins University, Riga, Latvia

The zebrafish is an ideal vertebrate model system for glioblastoma experimental therapeutics. Our laboratory is a pioneer in glioblastoma related to zebrafish genomics. We study to identify signature genes through differential expression and pathway analysis and evaluate their potential role in tumor microenvironment (TME) related biological process alterations and screening of new drugs in glioblastoma therapeutics. K21 is an established antimicrobial drug known for its antimicrobial activity. We have examined the potential role of K21 pharmacogenomics in the study of tumor microenvironment and experimental therapeutics by using zebrafish. In this study, the experiments were designed to study the K21 drug impact on zebrafish genomic common pathway enrichment analysis and the comparison of Gene set enrichment analysis (GSEA) between control and K21 drug-treated larvae to define activated and suppress gene ratio. The novel finding reveals the Significant Activated group: regulated to DNA templated transcription, brain development, regulation of transcription by RNA-polymerase-II, monoatomic ion transport, nervous system development, neuron differentiation, monoatomic ion transmembrane transport, anterior/ posterior pattern specification, neuropeptide signaling pathway, chemical synaptic transmission. Significant Suppressed Group: intracellular signal transduction, lipid metabolic process, protein transport, steroid biosynthetic process, endoplasmic reticulum to Golgi vesicle-mediated transport, intermediate filament cytoskeletal, keratinocyte differentiation, and keratinization. Surprisingly, K21 shows significant over-expressed GSEA-like brain development, neuronal differentiation, neuropeptide pathways, regulation of transcription, nervous system development, and significant suppression of innate immune response, T-cell co-stimulation, apoptotic process, lipid metabolism, Neglog10. These significant activations and suppression will be helpful to establish a potential therapeutic application of the K21 drug candidate for glioblastoma tumor microenvironment (TME) and associated ramifications. The outcomes of this study will open a new window in glioblastoma translational research, which explores novel areas to improve the discovery of therapeutic targets and novel agents to improve patient outcomes in an area where current therapies are mostly suboptimal.

#6507 Using induced pluripotent stem cells to model tyrosine kinase inhibitor response heterogeneity in chronic myeloid leukemia.

John Joson Ng[1], Lin Ming Lee[2], Yi Yang Lim[1], Kian Leong Lee[1], Fengcong John Ouyang[1], Vaidehi Krishnan[1], Sin Tiong Ong[1]

[1]Duke-NUS Medical School, Singapore, Singapore,[2]National Cancer Centre Singapore, Singapore, Singapore

Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm caused by the fusion of *BCR* in chromosome 22 and *ABL1* in chromosome 9. The resulting BCR::ABL1 fusion protein transforms the hematopoietic stem cell into a leukemic stem cell (LSC), driving malignant proliferation. CML is managed using targeted cancer therapy with tyrosine kinase inhibitors (TKIs), notably imatinib, which binds to the ATP-binding pocket of BCR::ABL1, inhibiting its kinase activity. While most patients respond well to TKI treatment, about 40% of patients experience suboptimal responses and primary resistance, warranting an in-depth exploration of the underlying molecular causes. Here, we employ BCR::ABL1-expressing induced pluripotent stem cells (iPSCs) as a platform for modelling treatment response heterogeneity in CML, and development of novel therapeutic approaches that convert poor TKI-responders into optimal responders.

Our laboratory has previously shown that specific cellular and molecular features in diagnostic patient bone marrow (BM) predict future TKI sensitivity (Krishnan *et al.*, *Blood*, 2023). Optimal responders show an enrichment of erythroid progenitor populations, an LSC gene expression signature indicating increased BCR::ABL1 activity, as well as aberrant expression of a canonical erythroid transcriptional program (ETP) that is known to induce an erythroid lineage bias. Consistent with an LSC-intrinsic mechanism for TKI sensitivity, hematopoietic stem and progenitor cells (HSPCs) from optimal responders exhibited a profound erythroid progenitor bias in colony-forming assays, coupled with an exquisite TKI sensitivity when compared to those with primary resistance. HSPCs from poor responders exhibited a myeloid bias in colony-forming assays, with myeloid colonies being more TKI resistant as compared to erythroid counterparts. We hypothesize that higher *BCR::ABL1* activity in LSCs from optimal responders results in ETP-driven erythroid lineage skewing *in vivo*, generating a higher proportion of erythroid progenitors which are intrinsically TKI-sensitive. To test our hypothesis, we reprogrammed diagnostic CML bone marrow samples from 3 optimal responders and 3 poor responders into iPSCs and validate their pluripotency and that any mutations and chromosomal aberrations are conserved. Examination of the transcriptome reveals that key CML-related gene programs are conserved from the primary sample to their iPSC-derived counterparts, e.g., MYC gene programs in poor responder primary and iPSC-derived samples. We conclude that iPSCs will provide a useful platform for testing hypotheses accounting for response heterogeneity in CML, as well as uncovering novel therapeutic approaches.

#6508 The SRG RAT, an immunodeficient model for immortalized cell line and primary patient derived orthotopic glioblastoma xenograft tumors.

Diane Begemann[1], Elizabeth Fenton[2], Niveen Fulcher[2], Cynthia Dunn[1], Darrell Robertson[1], Cassandra Scutchfield[1], Tanner Keener[1], Cleusa De Oliveira[3], John Kelly[4], Ying Xia[2], John Ronald[4], R. Grace Walton[1], Shilpa Sampathi[1], Valeriya Steffey[1], Michael J. Schlosser[1], Susanne Schmid[5], Matthew O. Hebb[2], Fallon K. Noto[1]

[1]Hera BioLabs, Lexington, KY,[2]Department of Clinical Neurological Sciences, Western University, London, ON, Canada,[3]Department of Anatomy and Cell Biology, Western University, London, ON, Canada,[4]Robarts Research Institute, Western University, London, ON, Canada,[5]Program in Neuroscience, Western University, London, ON, Canada

Human cancer xenografts are vital for understanding tumor biology, growth kinetics, and therapeutic efficacy. Historically, immunodeficient mice have been the standard rodent species for cancer xenografts. However, an immunodeficient rat that supports a variety of human cancer cell types would provide a larger rodent for easier surgical manipulation, serial blood sampling, and combined efficacy, pharmacokinetics, and toxicology studies. Hera BioLabs created a Sprague Dawley *Rag2 -/-, Il2rg -/-* Rat (*SRG RAT®)* that provides a highly supportive environment for growing tumors of human origin. The SRG rat lacks B, T, and NK cells and is more immunodeficient than the Nude rat, suggesting it may be permissive to a wider variety of human cancer types. Here we demonstrate the utility of the SRG rat in supporting intracranial growth of cell- and patient-derived (CDX and PDX) human cancers that grow in the brain. We inoculated female SRG rats with human primary glioblastoma cell lines U87MG-luc and U118MG-luc to establish tumors in the striatum of the rat brain. Additionally, PDX models from both glioblastoma stem cells and adherent, differentiated glioblastoma cells from different human tumors in the brain were isolated, briefly cultured, and inoculated into the striatum of male and female SRG rats. Preliminary biomarker analyses including Ki67, p53, IDH1, and Map2 indicate clinically relevant gene expression. Through a multifaceted approach including in-life bioluminescent imaging, MRI data, and post-mortem histology, we demonstrate robust tumor growth in the brains of SRG rats when established from human glioblastoma CDX, glioblastoma stem cell PDX tumors and differentiated glioblastoma PDX tumors. These data confirm that the SRG rat is an excellent host for studying subtypes of glioblastoma with several clinically relevant markers. These data demonstrate that the SRG rat has a high utility for studies requiring intracranial orthotopic tumor implantation due to its larger size, permissiveness to human xenografts, and ability to support a higher tumor burden when compared to mice. As the most immunodeficient rat commercially available, the SRG RAT supports preclinical testing of brain cancer therapeutics in a larger rodent strain relative to commercially available mouse models.

#6510 The study of the potential role of K21 in cardiovascular genomics and its application cardio-oncology experimental therapeutics by using zebrafish model.

Surendra Rajpurohit[1], Sai Nasanally[1], Shubhra Rajpurohit[1], **Rohan Pasi**[1], Arishia Mishra[1], Devan Manhiani[1], Kailash Jain[2], Kuntal Jain[3], Vishal Arora[4]

[1]Georgia Cancer Center, Medical College of Georgia, Augusta University, Augusta, GA,[2]Cardiology, RNT Medical College, Udaipur, India,[3]OBG and Gynecology, RNT Medical College, Udaipur, India,[4]Cardiology Division, Medical College of Georgia, Augusta University, Augusta, GA

Cardio-oncology is an emerging field that studies cancer therapy-associated cardiotoxicities. Cardiotoxicity is the second leading cause of death among cancer survivors. Developing reliable and effective preclinical models for cardiotoxicity prediction and prevention is essential to improving the long-term cardiac health of cancer patients. Zebrafish is an established model, to study cancer therapeutics for potential cardiovascular toxicity. In this study, we are developing zebrafish pharmacogenomics and experimental therapeutics to address cardiovascular complications induced by cancer drugs and identification and evaluation of potential drug candidates that can mimic the cancer-induced cardio-vascular complexity and mortality of cardio-oncology patients to identify co-treatments that might alleviate the heart disease risk in cancer survivors. K21 is an established antimicrobial drug known for its antimicrobial activity. In this study, we have studied K21 drug impact on zebrafish genomic common pathway enrichment analysis and comparison of Gene set enrichment analysis (GSEA) between control and K21 drug-treated larvae to define activated and suppressed gene ratio. The novel finding reveals the Significant Activated group: regulated to DNA templated transcription, brain development, regulation of transcription by RNA-polymerase-II, monoatomic ion transport, nervous system development, neuron differentiation, monoatomic ion transmembrane transport, anterior/ posterior pattern specification, neuropeptide signaling pathway, chemical synaptic transmission. Significant Suppressed Group: intracellular signal transduction, lipid metabolic process, protein transport, steroid biosynthetic process, endoplasmic reticulum to Golgi vesicle-mediated transport, intermediate filament cytoskeletal, keratinocyte differentiation, and keratinization. In zebrafish, a significant over-expressed GSEA K21 drug has an increased number of genes associated with the development of heart and blood vessels. Some of the gene sets were also associated with heart development in the initial stages. The presence of genes that engage in cardiovascular events is an important indication of cardiotoxicity and vessel damage as a part of cancer treatment. K21 also shows significant over-expressed GSEA like significant suppression of innate immune response, T-cell co-stimulation, apoptotic process, and lipid metabolism. These significant activations and suppression will be helpful to establish a potential therapeutic application of K21 in glioblastoma TME and associated ramifications to serve as potential cardioprotective agents during cancer treatment.

#6511 Immunocompetent large animal model of mesenchymal glioblastoma achieved through somatic gene editing technology.

Nicholas Koes[1], Mandy Taisto[1], Barbara R. Tschida[1], Daniel F. Carlson[1], Maryam Aftabizadeh[2], H. Nayanga Thirimanne[3], Eric C. Holland[3], Massimo D'Apuzzo[2], Christine E. Brown[2], Adrienne L. Watson[4]

[1]Recombinetics, Inc., Eagan, MN,[2]City of Hope, Duarte, CA,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]Therillume, Inc, Eagan, MN

Glioblastoma multiforme (GBM) is the most common primary brain tumor. GBM tumors are invasive and highly proliferative, with less than 3% of patients surviving five years from initial diagnosis. Current standard of care treatment consists of surgical resection, radiation, and chemotherapy, and despite this aggressive treatment, nearly all patients succumb to disease recurrence. GBM tumors have heterogeneity, high mutation rates, infiltrating growth, and a complicated tumor-immune microenvironment making treatments difficult and complex. Additionally, therapies must cross the blood brain barrier, a significant problem preventing therapeutic efficacy. Novel drugs, promising therapeutic targets, and new targeting strategies frequently fail in late Phase 2 and Phase 3 clinical trials due to lack of efficacy. The therapies often show effectiveness in a subset of patients, but fail in the majority, leading to clinical trial failure. Because GBM clinical trials are not enrolled based on patient specific biomarkers or genetic subtypes, precision medicine approaches have faced an uphill battle for a patient population that is too small for multiple concurrent clinical trials and a disease with a severe lack of predictive preclinical models. GBM tumors fall into three subtypes, mesenchymal, classical and proneural, each with distinct genetic profiles. Variations in progression and survival and differences in therapeutic response suggest that each subtype should be treated with a regimen unique to that subtype. Roughly 30-50% of GBMs are characterized as mesenchymal, the most common and aggressive subtype. In this study, we demonstrate the development of a large animal (mini pig), immunocompetent model of mesenchymal GBM, using stereotactic delivery of gene editing reagents. 50% of injected animals rapidly develop reproducible tumors that genetically and immunologically resemble human tumors, making this an ideal preclinical model for therapeutic development and biomarker identification. Importantly, tumors can be detected within weeks of injection through a simple, cost-effective blood-based assay. Cell lines developed from these tumors show temozolomide sensitivity and provide an opportunity for high throughput drug screening prior to animal trials. Recombinetics is utilizing these animals to identify, develop, and validate novel drugs, prognostic and diagnostic biomarkers, therapeutic devices, and effective drug delivery strategies. In particular, Recombinetics has focused on identifying targeted therapies that previously failed in clinical trials, despite showing efficacy in a subset of patients, and validating the safety and efficacy of these therapies in animals that have a companion biomarker that predicts therapeutic efficacy, in hopes of developing new strategies for clinical trials that will enable biomarker-driven therapeutic development and success.

TUMOR BIOLOGY: Our Commensal Tumor Microenvironment and Its Role in Cancer

#6515 *Candida*-associated microbiome in pancreatic ductal adenocarcinoma.

Carlos H.F. Chan[1], Casandro J. Chan[1], Ashutosh K. Mangalam[2], Po Hien Ear[1]

[1]Department of Surgery, University of Iowa Health Care, Iowa City, IA,[2]Department of Pathology, University of Iowa Health Care, Iowa City, IA

Candida species are commonly found in bile collected during surgery in pancreatic ductal adenocarcinoma (PDAC) patients. We have previously shown that bile and tumor-associated *Candida albicans* are associated with higher pathological stage, worse pathological response to neoadjuvant chemotherapy, worse overall survival, and epithelial-mesenchymal transition gene signature. Here we investigated the association between *Candida* species and other commonly found bacterial species in the biliary system of PDAC patients with biliary stents. Patients undergoing pancreatectomy with available intraoperative bile cultures (aerobic, anaerobic and fungal) were identified in a prospective single-institution cohort. 16S rRNA and ITS sequencing was performed using available frozen banked bile samples from these patients. Relative abundance (RA) was determined as the ratio of an individual microbial count over the total microbial count in a given sample. Bile acid contents in these bile samples were determined using LC-MS methods. Of 135 patients with preoperative biliary stenting, the most commonly found bacteria were *Enterococcus* (56%), *Streptococcus* (47%), *Klebsiella* (47%), *Enterobacter* (26%), *Escherichia* (25%), *Prevotella* (22%), and *Clostridioides* (15%). *Candida* species were found in 36% of these patients. 76% of patients without preoperative biliary stenting had negative bacterial cultures. Using 16S rRNA and ITS sequencing data (N=27), the presence of *Candida* (RA > 0) was significantly associated with the presence of *Enterococcus* species (RA of 24.8% in *Candida*+ samples vs. 7.8% in *Candida*- samples, P=0.046). *Enterococcus* was also found to be associated with more unconjugated bile acids in the bile samples (unconjugated/conjugated bile acid ratios: cholic acid, 3.07 vs. 0.30, P=0.089; deoxycholic acid, 3.57 vs. 0.39, P=0.029; chenodeoxycholic acid, 2.54 vs. 0.35, P=0.045). Our data show *Candida* and *Enterococcus* species frequently co-exist in the biliary system of PDAC patients with biliary stents and that *Enterococcus* species may be responsible for bile acid deconjugation within the biliary system. Whether *Enterococcus* species and unconjugated bile acids promote the colonization and survival of *Candida* within the biliary system remains to be determined in future investigation.

#6516 Comparative microbiome analysis of tumor and normal colorectal tissue across diverse racial and ethnic groups.

S. D. Labrie[1], C. E. Thomas[1], N. Lorona[2], K. R. Curtis[1], H. Yin[1], T. W. Randolph[1], N. Ma[1], J. R. Huyghe[1], S. S. Thomas[1], L. Hsu[1], A. L. Koehne[1], S. Nayemi[1], O. J. Kahsai[1], J. C. Figueiredo[2], L. Li[3], D. G. Redwood[4], T. Thomas[4], C. I. Li[1], A. I. Phipps[1], U. Peters[1], M. Hullar[1];

[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]Cedars Sinai Medical Center, Los Angeles, CA, [3]Ochsner Clinic Foundation, New Orleans, LA, [4]Alaska Native Tribal Health Consortium, Anchorage, AK

Background: Disparities in colorectal cancer (CRC) incidence and outcomes are notable between racial and ethnic groups. While these differences may be associated with various factors, established risk factors do not fully explain observed disparities. Increasingly, evidence suggests that the microbiota associated with the tumor microenvironment may play a role in CRC initiation and/or progression. However, few studies have investigated the microbiome of CRC tumor tissue compared to the microbiome in paired normal tissue as a reference. This study explores the microbial landscape of tumor and normal colorectal tissues from diverse racial and ethnic patients with CRC to understand the microbiome's potential role in CRC disparities.
Methods: We conducted bacterial 16S rRNA gene sequencing of colorectal tumor and normal tissue from 283 individuals of varied racial and ethnic backgrounds (African American, Alaska Native, Hispanic, and Non-Hispanic White). We extracted genomic DNA from tumor and normal colon tissue. We used amplicon sequencing of the 16S rRNA gene to classify the relative abundance of different bacterial amplicon sequence variants (ASVs), genera, and phyla in colon tissue. 8 phyla and 48 genera were identified across all samples. We used linear mixed models to identify differences in alpha diversity (assessed as Shannon diversity) between tumor and normal tissue in all participants combined, as well as within each racial and ethnic group. Linear mixed models were also used to identify associations of specific genera with the tumor and normal tissues. All models were adjusted for sex, race, age, ethnicity, tumor stage, tumor site, and year of diagnosis.
Results: Our analysis identified significant differences in microbial composition and diversity between normal and tumor tissue. Alpha diversity of the microbiota was significantly lower in tumor tissue compared with normal tissues when all racial and ethnic participants were combined ($p < 0.001$). There were also significant differences in alpha diversity between normal and tumor tissue within different racial and ethnic populations ($p < 0.05$) as well as within tumor tissue between different racial and ethnic populations ($p < 0.05$). After accounting for multiple testing, several genera were found to have a lower relative abundance in tumor tissue compared to normal tissue ($p < 0.05$). These included Bacteroides, Parabacteroides, Ruminococcus, Faecalibacterium, and other genera.
Conclusion: This study enhances our understanding of the CRC-related microbiome. By detailing the diversity and abundance profiles of microbial communities in tumor microenvironments versus normal tissues, we identified differences in the distribution and composition of the microbiome in tumor versus normal tissue, as well as identified specific bacterial genera that were found to have a lower relative abundance in tumor tissues.

#6517 Extracellular vesicles derived from vaginal bacteria initiate the progression of early phase ovarian carcinoma at fallopian tubes.

A. Yokoi, E. Asano-Inami, K. Yoshida, Y. Nagao, M. Kitagawa, H. Kajiyama;
Nagoya Univ. Graduate School of Medicine, Nagoya, Japan

[Objective] Microbiota contributes to cancer hallmarks, but the relationship vaginal bacteria and ovarian cancer are entirely unclear. Extracellular vesicles (EVs), including exosomes, play a crucial role in cancer biology, and bacteria secrete EVs, named bacterial EVs (bEV). Recent understanding revealed that high-grade serous carcinoma (HGSC) has raised from fallopian tube epithelial cells (FT cells) but the detailed mechanism how FT cells acquired malignant potential is largely unknown. This study aimed to elucidate the mechanism of initiation of early-phase ovarian carcinoma at fallopian tubes via vaginal bEV.
[Methods] For selecting promising bacteria, vaginal bacterial 16s sequencing data were referred to, and the data from 181 patients with ovarian tumors were analyzed. bEVs were directly collected from patients' fallopian tubes using cellulose nanofiber-based EV sheets (Yokoi A et al. Nat Commun. 2023), and bEV-RNA was extracted. Selected bacteria were cultured with monitoring OD values, and bEVs were isolated using the optimal serial centrifugation method. bEV-RNA were analyzed by small RNA sequencing and validated by qRT-PCR. Functional analyses were performed in vitro and in vivo, and the effect of bEVs on FT cells was investigated.
[Results] Based on vaginal bacterial 16s rRNA sequencing, four indigenous common vaginal bacteria were selected. Those bacteria were successfully cultured and cryo-electron microscopy confirmed isolated bEV. Cell viability analysis showed that none of the bEVs affected the proliferation of FT cells. On the other hand, specific Lactobacillus species promoted cell motility ($p < 0.05$), especially in p53 gain-of-function (GOF) cells. Furthermore, treatment of bEV resulted the sloughed-off features of p53-GOF-FT cells on basement membrane components ($p < 0.05$). These phenotypes mimic the actual progression of FT cells implant to ovaries. In in vivo experiments, although vaginal treatment of bacterial bodies did not reach FT, bEVs were incorporated by FT cells, which were confirmed by confocal microscopy imaging. We collected bEVs on FT from 15 ovarian cancer patients using cellulose nanofiber-based EV sheets, and small RNA sequencing for bEV-RNA revealed that the profiles between HGSC and benign patients were different, and specific sequences of Lactobacillus species were detected. mRNA sequencing for FT cells treated with bEV from specific Lactobacillus species showed that gene expression was significantly altered, and IPA/GSEA analyses identified several cancer-related pathways. Target functional genes in FT cells were identified and validated by qRT-PCR.
[Conclusions] These results demonstrated the unknown early mechanism of ovarian cancer development by pathogenic bEV exposure, and the new target gene alternation was identified in FT cells as the new therapeutic target.

#6518 Sex-biased intratumoral microbiome impact cancer cell proliferation and treatment outcomes in gastrointestinal cancers.

Yuting Shan, Yingbo Huang, Adam Lee, Radwa Elmorsi, Tuyen Phan, R. Stephanie Huang

Experimental and Clinical Pharmocology, University of Minnesota, College of Pharmacy, Minneapolis, MN

Objectives: Sex differences in cancer treatment responses and disease prognosis are well-documented. Our study investigates the intratumoral microbiome, hypothesizing that its composition varies between sexes which contributes to the observed differences. Specifically, our study aims to identify sex-biased intratumoral microbiome and investigate their influence on host gene expression, survival rates, and responses to treatment.

Method: We analyzed intratumoral microbiome abundance in 5 gastrointestinal cancers to identify differentially abundant (DA) microbes between sexes. After initial identification, these microbes were validated using independent datasets. A total of six large-scale intratumoral microbiome datasets were included for discovery and validation. We then assessed differential gene expression and gene set enrichment that are associated with these DA microbes. Experimental examination were carried out for two DA microbiome, Epstein-Barr virus (EBV) and Capnocytophaga, to assess their impact on cancer cell proliferation and responses to standard-of-care (SOC) treatments.

Results: From more than one thousand microbes analyzed, we identified 22 DA microbiome, comprising 17 bacteria, 3 fungi, and 2 viruses, each validated with an independent dataset. EBV is one of the 22 reproducible DA microbiome found to be significantly male-enriched in gastric cancer (GC). Further analysis unveiled the association between intratumoral EBV infection and better overall survival in GC patients. To investigate whether the survival difference partially attributes to difference in response to treatments, we treated EBV positive and negative GC cell lines with 5 SOC chemotherapies. We observed that EBV infection sensitized 3 of 5 SOC treatments (paclitaxel, docetaxel, and 5-FU), while had no effects on the others (cisplatin, oxaliplatin). Moreover, pathway analysis revealed enrichment of inflammatory response, interferon response, and apoptosis pathways in EBV-infected GC. Capnocytophaga, a reproducible female-enriched microbiome in head and neck cancer (HNSC), was found to be significantly associated with improved survival. Further co-culturing experiments found that Capnocytophaga supernatant significantly inhibited HNSC cell proliferation *in vitro*.

Conclusion: Our research identified intratumoral microbiome with sex-specific abundance patterns in gastrointestinal cancers. The identified DA microbes are closely associated with differences in the host transcriptome, drug responses, and survival outcomes. This underscores the potential of the intratumoral microbiome as a significant factor in personalized cancer treatment and management.

#6519 Tumor sidedness of colorectal cancer shows differential abundance of tumor microbiota and plausible implications.

Kuo-Hsing Chen

National Taiwan University College of Medicine, Taipei, Taiwan

Background: The tumor microbiota in colorectal cancer (CRC) plays a significant role in carcinogenesis, progression and metabolic interaction. Studies have shown the microbiota composition may be different between left-sided and right-sided CRC (LCRC and RCRC).

Materials and methods: We conducted a multi-cohort study to investigate the role of tumor microbiota in CRC in Taiwan. Cohort 1 included 140 CRC pairs from the National Taiwan University Hospital biobank. Cohort 2 was a prospective study to recruit patients with newly diagnosed CRC and collect their surgical specimens and physical activity status. Cohort 3 included 30 colon polyps. The V3-V4 regions of the bacterial 16S ribosomal RNA gene were amplified, and the amplicons were sequenced using the MiSeq system. Left-sided (LCRC, descending colon to rectum) and right-sided (RCRC, cecum to splenic flexture of transverse colon) CRC were defined according to the location of primary tumor. An integrated analysis of clinicopathological characteristics and tumor microbiota was conducted. Co-occurrence networks was used to understand the relationships and interactions between different microbial species within a community.

Results: Among 140 CRC in cohort 1, 93 (66.4%) of them were left-sided. There were significantly more CIMP-high tumors in LCRC than in RCRC ($p = 0.0002$). The diversity of microbiota was not different between LCRC and RCRC. LefSe (Linear discriminant analysis Effect Size) analyses revealed many bacteria had significantly higher abundance in LCRC and RCRC (LDA score ≥ 2, $p < 0.05$). The top 3 microbiota were *Bacillaceae, Sphingomonadaceae, Propionibacteriacea* in LCRC and *Enterococcus, Enterococcaceae, Lachnospiraceae* in RCRC. Clinically, high abundance of *Flavobacterium* was significantly correlated to absence of high body mass index (BMI ≥ 27.5 kg/m^2) ($p = 0.0019$) and low abundance of *Lachnoclostridium* was significantly associated with late-stage (stage 3 and 4) ($p = 0.0363$) in right-sided CRC. Co-occurrence networks and pathway analysis showed *Flavobacterium* was negatively associated with multiple nutrients metabolism.

Conclusion: The microbiota composition between LCRC and RCRC was different. The clinical implications of *Flavobacterium* and *Lachnoclostridium* warrants further validation.

#6520 Intratumoral microbiome profiling using high-depth whole-genome sequencing highlighted *Cutibacterium acnes* in chemoresistance in ovarian cancer.

Tatiana V. Karpinets, Xiaogan Wu, Wayne W. Xy, Amma Asare, Sara Corvigno, Joseph Celestino, Ridge T. Rogers, Raymond N. Montoya, Mark S. Kim, Pamela T. Soliman, Shannon N. Westin, P. Andrew Futreal, Amir A. Jazaeri, Anil K. Sood, Jianhua Zhang, **Sanghoon Lee**

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: High-grade serous ovarian cancer (HGSC) is the most lethal gynecologic malignancy, with high recurrence rates and the development of chemoresistance significantly limiting patient survival. While the tumor microenvironment (TME), including extracellular matrix (ECM) remodeling and epithelial-mesenchymal transition (EMT), is known to contribute to chemoresistance, non-genetic factors remain poorly understood. Emerging evidence implicates the intratumoral microbiome in modulating the TME and influencing chemoresistance in several solid tumors, but how composition and diversity of the bacterial communities contribute to the efficacy of neoadjuvant chemotherapy (NACT) in HGSC is not known.
Methods: We analyzed multi-omics data from HGSC samples previously reported. Tumor-associated microbial communities were profiled using metagenomic analysis of whole-genome sequencing data and ECM- and EMT-associated gene expression profiles were evaluated through RNA sequencing. Samples included tumor tissues from 30 patients with complete gross resection (CGR) at primary surgery, neoadjuvant chemotherapy (NACT) excellent responders (NACT-ER), and poor responders (NACT-PR). Each group had 10 patients with a primary tumor site and two synchronous metastatic sites.
Results: Microbial profiling revealed that *Cutibacterium acnes* (CB) is the most common and abundant organism within HGSC intratumoral microbiome. It was more abundant in tumor and metastatic tissue from patients treated with NACT (P=0.001) versus those who had upfront CGR. Integration of RNA sequencing data demonstrated a strong correlation between CB abundance and EMT signature, which emerged as the most significantly enriched hallmark gene set according to the Gene Set Enrichment Analysis. Additionally, tumors enriched in CB exhibited transcriptional signatures associated with aggressive tumor behavior (e.g., enhanced activity of TNFA signaling, adipogenesis, and oxidative phosphorylation). Tumors with high CB abundance displayed a distinct ECM organization, decreased infiltration of T and B cells and increased abundance of fibroblasts, neutrophils, and endothelial cells, potentially indicative of an angiogenic phonotype.
Conclusions: The tumor-associated microbiome, particularly CB, may play a critical role in HGSC chemoresistance through EMT induction and ECM remodeling. This study highlights the potential of microbiome in shaping tumor phenotypes and identifies possible therapeutic targets.

#6521 Tumor colonization with *Candida albicans* increases tumor growth and decreases treatment response by influencing tumor hypoxia and immune activity.

Dennis Grencewicz[1], Alexander Loncar[1], Ruohan Wu[1], Rebecca Hoyd[1], Jinghai Wu[1], Yogita Mehra[1], Shiva Jahanbahkshi[1], Sylvain Ferrandon[1], Matthew Anderson[2], Martin Benej[1], Jiangjiang Zhu[1], Matthew Kalady[1], David Carbone[1], Nicholas Denko[1], ORIEN Microbiome Research Interest Group, Daniel Spakowicz[1]

[1]The Ohio State University College of Medicine, Columbus, OH,[2]The University of Wisconsin-Madison, Madison, WI

Microbes residing in either the gut or inside tumors have been shown to affect tumor growth and therapeutic response in cancer. Our preliminary data supported an association between the presence of *Candida* fungi within tumors and decreased therapy response and survival of rectal cancer patients. However, whether intratumoral *Candida* drive, support, or simply inhabit tumors with poor prognoses remains unclear. Here, we identify that *C. albicans* plays a causal role in modifying tumor physiology and response to treatment.

Immune competent C57BL/6 mice bearing MC38 colorectal or LLC lung cancer flank tumors were gavaged with *C. albicans* or PBS. MC38 mice were treated with 1 fraction of 7.5 Gy radiation and at size endpoint, tumors were stained for fungi and underwent bulk RNA-sequencing. LLC tumors underwent tumor electron paramagnetic resonance monitoring for intratumoral oxygen content, inorganic phosphate, and pH. MC38 cells were cultured in filtered *C. albicans* conditioned media. Metabolomics was performed on the conditioned media. RNA-sequencing from human tumors from the ORIEN database was analyzed for gene expression related to *C. albicans.*

C. albicans translocated to tumors following oral gavage. The presence of *C. albicans* reduced radiation efficacy in MC38 tumors and increased LLC tumor growth ($p<0.05$). LLC tumors from mice gavaged with *C. albicans* had lower pH and decreased oxygen tension. Transcriptional profiling indicated that colonization of these murine tumors and as well as human samples with *C. albicans* showed decreased CD8+ T cell activity and increased glycolytic metabolism. Mechanistic studies further showed that MC38 cells grown in the presence of *C. albicans* metabolites exhibited an increased oxygen consumption rate, and that this conditioned media supported increased mitochondrial beta-oxidation.

Here, we show through *in vitro* assays, murine models, and human samples that *C. albicans* can directly affect tumor growth and treatment resistance, potentially through generating an immune cold and more hypoxic and acidic environment. These data support experimentation to determine clinical relevance of depletion of *C. albicans* or related metabolites from tumors to improve clinical outcomes.

#6522 Sex differences in gut microbial composition during pelvic radiation therapy in experimental models of muscle-invasive bladder cancer.

Eva Michaud[1], Matthew Stendel[1], Jose Joao Mansure[1], Fabio Cury[2], Wassim Kassouf[3]

[1]McGill University Health Centre Research Institute, Montreal, QC, Canada,[2]Radiation Oncology, McGill University Health Centre, Montreal, QC, Canada,[3]Urology, McGill University Health Centre Research Institute, Montreal, QC, Canada

Background: Radical cystectomy is the standard of care for muscle-invasive bladder cancer (MIBC) but significantly impacts patients' quality of life. As not all patients are surgery-eligible, radiation therapy (RT) has emerged as a viable bladder-sparing approach. Yet, 25-30% of patients do not respond and will require salvage cystectomy. To add, while females are less at risk for bladder cancer, they tend to develop more aggressive disease phenotypes, and poorer response to surgery or RT. Determinants of radiation efficacy may reside outside the stole study of the tumor micro-environment (TME), as the gut microbiome, which is implicated in radiation-induced toxicity, may be influential in polarizing tumor responses to RT. Although RT effects on the microbiome have been previously studied, relationship between TME, local immune responses and gut microbes have yet to be described in MIBC.
Methods: C57Bl/6 male (n=20) and female (n=20) mice were treated with 6x6Gy of RT to the bladder or left untreated (n=10 per group) then monitored for 4 weeks without tumor induction. We then generated a N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN) bladder tumor model where 3x8Gy radiation was administered to the bladder tumor at week 16 of BBN exposure. After RT was administered, stool samples were collected from all mice for 4 weeks for 16S rRNA-sequencing. Sequence data was converted to metabolic pathways using PiCRUST2. Formalin-fixed tumor tissues were stained by immunohistochemistry for B cell, T cell, macrophages and neutrophil markers.
Results: RT-treated males associated with high abundance of *Akkermansia*, *Bifidobacterium* and *Faecalibaculum*, all promoters gut health and response to anti-cancer therapies in humans. In contrast, RT-treated females selectively clustered according to *Roseburia*, *Romboutsia* and *Bifidobacterium* abundance. Females appeared more resistant to RT-induced dysbiosis at baseline, a protection that is abrogated upon tumor induction. RT treatment following tumor induction led to increased *Clostridium* abundance in females but decreased abundance in males. To add, KEGG pathways analysis predicted increased proteasome and flavonoid synthesis activity in females receiving RT, suggesting higher rates of metabolic conversion in females compared to males. Lastly, tumor immune infiltrates varied in composition and quantity according to both sex and treatment, underlining the sex-specific impacts of RT on both the microbiome and TME.
Conclusion: Our results indicate pelvic RT does affect microbiome composition with significant dysbiosis in males compared to females. Differential composition in both sexes upon tumor induction suggest RT does not affect males and female microbiomes similarly, which may condition distinct tumor immune responses. This is the first study to link sex, microbiome and RT in experimental models of MIBC to our knowledge.

#6523 A multi-omics analysis correlating intratumoral microbial abundance with methylation patterns in hepatocellular carcinoma.

Tianyi Chen, Annie N. Do, Suravi Bajaj, Erin Jang, Rishi Yalamarty, Pranava Gande, Kevin Zhang, Ellie Sang, Wei Tse Li, Jessica Wang-Rodriguez, Weg M. Ongkeko

UC San Diego, San Diego, CA

Background: Liver Hepatocellular Carcinoma (LIHC) is estimated to be the fourth leading cause of cancer worldwide. LIHC is often aggressive, as most patients are diagnosed at advanced stages. Our study aims to understand the molecular mechanisms driving the development and progression of LIHC. The microbiome has been hypothesized to contribute to many diseases, including cancer. Although microbes reside primarily within the gut, they may translocate to the liver by the gut-liver axis. Such microbes may produce metabolites that can regulate epigenetics. DNA methylation influences tumor progression by silencing tumor suppressors and activating oncogenes. Using the theoretical framework of metabolite interactions, we explore the correlation between microbe abundance and methylation patterns to expand research on the pathogenesis of LIHC.
Methods: We analyzed sequencing data for 376 primary LIHC tumor samples and 85 solid tissue normal samples from The Cancer Genome Atlas (TCGA). Using the PathoScope 2.0 framework, we successfully extracted microbial read counts from 446 samples. Microbial contamination correction was performed by three methods: sequencing date, sequencing plate, and overall microbial abundance. Bacterial species identified as contaminants were excluded from downstream analysis. Differential abundance analysis was conducted to identify bacteria species with altered abundance between normal and tumor samples. We used the Kruskal-Wallis test with a Bonferroni-adjusted p-value threshold of 0.05. Methylation data was downloaded from TCGA and filtered by a panel of genes relevant to LIHC oncogenesis. Methylation score disparities between cancer and normal tissues were assessed by the Kruskal-Wallis test. We employed Spearman's rank correlation to identify associations between microbial counts and methylation scores.
Results: We identified 27 differentially expressed microbes and 533 differentially methylated sites in LIHC tissue (p-value < 0.05). Between these microbes and methylation sites, we found 58 statistically significant correlations between the microbial abundance and methylation scores (p-value < 0.05). Notably, species involved in these correlations include the pathogenic *E. coli* O26:H11 str. 11368 and *E. coli* UMN026 and the probiotic *Ligilactobacillus salivarius.* Additional findings indicate significant microbial and methylation correlations, with further analysis underway to integrate these findings with clinical variables including cancer stage and alcohol consumption history. Additionally, microbial metabolic pathways are profiled using the HUMAnN 3.0 pipeline to provide insights into the potential mechanisms by which the microbiome may influence methylation. Further research is needed to elucidate the specific pathways mediating epigenetic modifications induced by the bacterial microbiome.

#6524 In vivo selection of tumoral microbiota identified pro-metastatic anaerobes: A novel experimental platform allowing mechanistic studies leading to the discovery of bacteria-derived molecular therapeutic targets.

Adriana Zingone, Senthil Muthuswamy, **Norihiro Yamaguchi**

National Cancer Institute, Bethesda, MD

Introduction: Tumoral microbiota is a strong predictor of gastrointestinal cancer outcome. However, our efforts in identifying bacterial molecular drivers of cancer progression are hindered by 1. the lack of efficient anaerobic bacteria culturing system, 2. >90% of human gut microbiota are anaerobes. This predicament limits our capability to conduct mechanistic studies in tumor microbiota research. To fill this gap, we sought to establish a novel experimental system allowing the propagation of metastasis-associated tumoral microbiota by taking advantage of the curated culturable human gut microbiota library.
Methods: We established a gnotobiotic system following to a sequential oral gavage of the curated human gut microbiota library in germ-free C57BL/6 mice. Subsequently, the mice underwent intrapancreatic injections of syngeneic KPC pancreatic cancer cells. Liver metastatic foci, primary pancreatic cancer, and the duodenum with their associated bacteria were subject to 16s sequencing and direct culture-based propagation.
Results: To validate the feasibility of our experimental platform in identifying bacterial species despite the expected low biomass, we conducted proof-of-concept experiments by intraspenically injecting KPC cancer cell lines in wild-type C57BL/6 mice. Liver metastatic foci, primary pancreas tumors, and the duodenum were subject to 16s sequencing and direct culture. Bray-Curtis dissimilarity matrix-based PCoA plot revealed an apparent dissimilarity between samples from tumor-bearing mice and the corresponding samples from non-tumor-bearing mock-surgery mice in a sample-site agnostic manner, suggesting a systemic impact from the tumor-bearing state. In the tumor-bearing duodenum and liver samples, there was systemic depletion of the Bacteroidetes phylum. Conversely, there is the enrichment of the Firmicutes phylum. Within the Firmicutes phylum, Clostridia species were particularly enriched in the tumor-bearing duodenum and liver metastatic samples, suggesting a biological pressure in the hypoxic tumors and hypoxic liver microenvironment favoring obligate anaerobes such as Clostridia species.
Conclusion: Our pilot studies suggest the presence of tumor microenvironment-driven biological selection of bacteria. The observed symbiosis in metastasizing tumors between obligate anaerobes such as Clostridia and cancer cells in the hypoxic tumor microenvironment warrants further functional validation, which is uniquely feasible in our proposed system. In summary, we established a novel experimental platform allowing tumor microbiota mechanistic studies to determine bacteria-derived molecular drivers of cancer progression and metastasis.

#6526 Phylogenetic and metagenomic analysis of the human pancreatic cancer microbiome.

Gabrielle Morgan[1], Colby Hunter[2], Michael Hall[2], Narendra Banerjee[2], Erik Armstrong[2], Kanisha McNeil[2], Karington Perry[2], Santanu Bhattacharya[3], **Hirendra N. Banerjee**[4], Krishna K. Rachamala[5], Shamit Dutta[5], Naga M. Nakka[5]

[1]Computer Science, Elizabeth City State University, Elizabeth City, NC,[2]Natural Science, Elizabeth City State University, Elizabeth City, NC,[3]Biochemistry and Molecular Biology,Mayo Clinic College of Medicine and Sciences, Mayo Clinic, Jacksonville, FL,[4]Natural Science, Elizabeth City State University, University of North Carolina, Elizabeth City, NC,[5]Biochemistry and Molecular Biology, Mayo Clinic College of Medicine and Sciences, Jacksonville, FL

Pancreatic cancer ranks third in cancer related deaths in the USA, however, no reliable theragnostic biomarker exists for the disease. The community of bacteria within the body can become dysbiotic and promote cancer through inflammation and other means. The objectives of this study were to determine the identity and abundance of bacterial species in the gut of mice before and after development of pancreatic cancer. As there can be significant variation in the genomes of different strains of bacterial species, a metagenome analysis was also performed. We hypothesized that there would be significant variation in species and genes of the gastrointestinal tract of mice before and after xenografting with pancreatic cancer. A decrease in ecological diversity was also predicted. Fifteen female SCID mice were divided into three cages. To develop the SubQ pancreatic cancer model, 5 X 10^6 Panc1 cells were injected at the flank. Fecal materials were collected prior to tumor cell implantation and after tumor development. DNA was extracted from the fecal material. For phylogenetic analysis the seven variable regions of the 16S rRNA gene were amplified and sequenced. Metagenomic analysis was performed as well. Average tumor size in mice after 40 days was ~ 32 mm^3. Microbial diversity was decreased in two out of the three groups of mice. Principle component analysis showed major differences between all samples. There were at least 15 OTUs in each set of samples specific to pretumor mice and 15 OTUs specific to tumor bearing mice. One genus of bacteria, *Alistipes*, was specific to each set of tumor bearing mice. Taxa at significantly increased abundances in tumor bearing mice included Prevotellaceae and Porpyromonadaceae. Moreover, there were several gene functions that were enriched in tumor bearing mice. This study produced data that demonstrates that there is a link between health status and the gut microbiome. However, this is not a new idea. This study could serve as foundation to establish a gut microbiota profile of pancreatic cancer. Precision medicine is becoming more common due to the decreasing costs of DNA sequencing. The findings of our investigation strengthens the hypothesis that there is an interaction between gut microbiome and pancreatic cancer development and bacteria or bacterial genes could serve as theragnostic biomarker for pancreatic cancer.

Banerjee and Dr. Colby Hunter.

#6527 Ginseng polysaccharides circumvent acquired resistance to anti-pd1 immunotherapy in patients with non-small cell lung cancer.

J. Huang[1], Z. Wang[1], Y. Cao[2], W. Liang[3], **E. L. Leung**[1];

[1]University of Macau, Macau, Macao, [2]Kiang Wu Hospital, Macau, Macao, [3]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

In 2021, we demonstrated that ginseng polysaccharides (GPs) enhance the therapeutic efficacy of anti-programmed cell death 1 (PD-1) immunotherapy by modulating the gut microbiota. GPs may serve as a beneficial dietary supplement for non-small cell lung cancer (NSCLC) patients undergoing immunotherapy. We reported GPs increased the anti-tumor response to αPD-1 mAb by increasing the microbial metabolites valeric acid, and decreasing the ratio of Kyn/Trp, which contributed to the suppression of Treg and induction of T_{eff} cells. Besides, the microbial analysis of patients fecal samples indicated that the abundance of *Parabacteroides distasonis* and *Bacteroides vulgatus* was higher in responders to anti-PD-1 blockade than non-responders. In this study, we aim to further validate and extend these previous findings. Therefore, we designed the first World Health Organization-registered clinical trial of traditional Chinese medicine combined with immunotherapy (ChiCTR2100046431) to investigate whether oral administration of GPs can circumvent acquired resistance to anti-PD-1 immunotherapy in patients with advanced NSCLC. Eligible acquired drug-resistant patients continued the use of PD-1 inhibitors as per their initial immunotherapy regimen and initiated oral administration of GPs twice daily upon enrolling in the trial. Longitudinal stool and blood samples were systematically collected from participants. The gut microbiome was profiled through third-generation amplicon sequencing. Simultaneously, comprehensive analyses of blood samples were conducted, utilizing metabolomics and quantification of cytokines. Clinical trial results showed that five patients regained response to anti-PD-1 immunotherapy, with an objective response rate of 50%. Comprehensive analysis of the gut microbiome and blood samples revealed a significant increase in the relative abundance of *Parabacteroides distasonis* after treatment, along with a significant upregulation of tumor necrosis factor-α (TNF-α) and various metabolites levels in the blood. In this study, we report the first case series of patients with advanced NSCLC with acquired resistance to anti-PD-1 immunotherapy who were treated with oral administration of GPs, which resulted in overcoming acquired resistance and regaining a response to immune checkpoint inhibitors. These preliminary data provide valuable clinical clues for overcoming the acquired resistance to PD-1 immunotherapy.

#6528 The role of health behaviors in microbial dysbiosis and lung cancer inequities.

Murugesh Eswaran[1], Briana A. Brock[1], Hina Mir[1], Gabriela Oprea-Ilies[2], Eric Flenaugh[1], James W. Lillard[1], Brian M. Rivers[1], Rajesh Singh[1], Shailesh Singh[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]Emory University School of Medicine, Atlanta, GA

Lung cancer remains the leading cause of cancer-related morbidity and mortality worldwide. African Americans (AA) are disproportionally affected by the disease, and mortality is higher in AA compared to European Americans (EA). The mortality rate among AA is higher than EA even when diagnosed at an early stage, implying biological differences associated with health behaviors such as smoking and its impact on microbial dysbiosis. A higher mortality rate in AA diagnosed at an early stage compared to EA highlights the biological differences in AA are primarily due to health behaviors such as smoking and its impact on microbial dysbiosis, making AA predisposed to higher risk and mortality. Microbial dysbiosis in lung cancer was analyzed using GEO and All of Us data repositories. Our analysis provides compelling evidence of the interplay between microbial dysbiosis, health behaviors, and racial disparities in lung cancer outcomes. Our study shows that smoking exacerbates microbial imbalances, particularly with the prevalence of *Streptococcus* and its differential impact on AA and EA. Dysbiosis correlates strongly with lung cancer pathogenesis, particularly the abundance of *Streptococcus*, *Haemophilus*, *Neisseria*, and *Pseudomonas*. AA participants show higher susceptibility to *Streptococcus* invasion, with detectable levels in the blood at just 7 cigars daily compared to 23 cigars in EAs. Urine samples of AAs smoking only 17 cigars per day are positive for *streptococcus,* while for EAs the bacteria is detected only when they smoke 20 cigars daily. These findings underscore a biological predisposition that amplifies cancer risk for AAs at lower smoking intensities. The lower thresholds for *Streptococcus* detection among AA populations suggest a heightened biological vulnerability, emphasizing the need for tailored public health interventions and early screening programs in these communities. These results underscore the importance of integrating microbial profiling in personalized medicine approaches and addressing underlying health inequities to improve lung cancer outcomes across diverse populations.

#6530 A comprehensive genomic analysis elucidates the microbial landscape of cancer.

Anders B. Dohlman[1], Robin Mjelle[1], Henry Wood[2], Iris Lee[1], Kevin Jiang[1], Ethan Shurberg[1], Alaina Shumate[1], Blake Sanders[1], Guanxi Qiao[1], Jodi Hirshman[1], Andrew Cherniack[1], Phil Quirke[2], Matthew Meyerson[1]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Pathology and Data Analytics, University of Leeds, Leeds, United Kingdom

There is growing evidence that microorganisms are an important component of the tumor microenvironment. However, conflicting reports regarding the cancer microbiome have left the extent of microbial presence across cancer types unclear, highlighting the need for more accurate methods of profiling of tumor-associated microorganisms. Leveraging the new human genome T2T-CHM13, we developed a new host-subtraction and decontamination pipeline for accurately profiling tumor-associated microorganisms in tumor sequencing data and benchmarked it on simulated and real-world datasets. We used this pipeline to perform a pan-cancer analysis of new high-depth whole-genome tumor sequencing data from The Cancer Genome Atlas (n = 8,840) and the UK 100,000 Genomes Project (n = 15,223). Our analysis revealed that in both cohorts, most cancer types do not harbor a detectable microbiome. However, we identified polymicrobial communities in association with nearly all oral, esophageal, gastric, and colorectal cancers, each of which harbored cancer-type specific microbiomes. Within cancer types, microbial communities differed by anatomical site and tumor subtype. Notably, we observed increased bacterial colonization in microsatellite-instable (MSI) cancers of the upper and lower gastrointestinal tract, and a correlation between bacterial colonization and tumor mutational burden in a pattern that persisted after controlling for MSI status. This trend was driven by a specific community of pathogens including *Fusobacterium animalis,* and was linked to a tumor-specific immune signature using patient-matched RNA-sequencing. Finally, we demonstrate that complete microbial genomes can be assembled from bulk tumor sequencing data, allowing phylogenetic and functional analysis of tumor-resident microorganisms. Together, our analysis helps clarify the microbial landscape of cancer and highlights its potential clinical importance in gastrointestinal malignancies.

#6531 High resolution analysis of Fusobacterium infection in colorectal cancer.

Heiko Dussmann[1], Barry Maguire[2], Caoimbhe Burke[3], Arman Raman[3], John Burke[4], William M. Gallagher[3], Jochen H. M. Prehn[1]

[1]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[2]Physiology and Medical Physics, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[3]UCD School of Biomolecular and Biomedical Science, UCD Conway Institute, University College Dublin, Dublin, Ireland,[4]Department of Colorectal Surgery, Beaumont Hospital, Dublin, Ireland

Previous research provided evidence pointing towards an important role for bacterial infection with *Fusobacterium nucleatum* (*F. nucleatum*) and *F. animalis* (previuosly *F. nucleatum subsp. animalis*) in colorectal cancer (CRC) progression. Both are oral commensal Gram negative anaerobes with recent evidence suggesting *F. animalis* predominates in CRC (Zepeda-Rivera et al., 2024). We recently applied spatial transcriptomics to demonstrate local effects of *Fusobacterium* infection on cancer and immune cell gene expression in CRC (Duggan *et al*, Gut Microbes, 2024). While *Fusobacterium* infection was observed in specific patches in the tumors, the precise cell types infected with bacteria and the precise localization of bacteria in cells still requires further elucidation. Commercially available strains of *F. nucleatum* (ATCC 25586) and *F. animalis* (ATCC 51191) were purchased and separately co-cultured with MDA-MB-468 breast cancer cells. Immuno cytochemistry using a commercial Fusobacteria antibody (ANT0084) and a Fusobacteria antiserum (Prof Slade group), along with pancytokeratin and Hoechst staining was undertaken. High resolution confocal microscopy using an LSM 980 Airyscan 2 microscope (Carl Zeiss, Jena, Germany) was performed to create image stacks of optical sections. CRC tissue sections were subsequently prepared and stained by immunohistochemistry (IHC) for pancytokeratin, CD68, and Fusobacteria (Slade antisera). Imaging of the full tumor face was undertaken at a lower resolution using Cell DIVE (Leica Microsystems, Wetzlar, Germany) to select regions rich in Fusobacteria for further study. Selected regions were then imaged using high resolution confocal microscopy. Fusobacteria antisera stained both *F. nucleatum* and *F. animalis* while the commercially produced antibody stained only *F. nucleatum*. Both bacteria can populate the cell surroundings, cell surface, cytoplasm as well as nucleus. The typical morphology of both *F. nucleatum* and *F. animalis* is seen, allowing antibody validation. In CRC tissue intracellular bacteria are seen in both pancytokeratin positive tumor epithelial cells as well as in CD68 (Cluster of Differentiation 68) positive cells (tumor associated macrophages). Tumor associated macrophages (TAMs) have an important role in the tumor immmune microenvironment. In particular, studies have highlighted the importance of M1/M2 macrophage polarization on immune-evasion and prognosis. Our spatial transcriptomic study highlighted reduced M2 polarization as associated with increased Fusobacterial load. The intracellular location of Fusobacteria may suggest a mechanism for altered macrophage polarization. Recent studies suggest a role for the microbiome in modulating anti-cancer treatment responses, but the impact of the oral microbiome on head-and-neck squamous cell carcinoma (HNSCC) treatment outcomes remains largely unexplored, prompting our analysis of its potential influence following definitive (chemo)radiation. Saliva samples of two independent prospective trials including HNSCC patients undergoing definitive (chemo)radiation were analyzed in terms of the oral microbiome composition before treatment initiation using V3-4 16S rRNA sequencing. Significant findings of the saliva microbiome were validated using information on the intratumoral HNSCC microbiome from The Cancer Genome Atlas (TCGA) database. Immunohistochemistry analyses of tumor-infiltrating lymphocytes (TILs) were carried out to reveal potential differences in the tumor microenvironment depending on microbiome findings. A subset of patients received serial [18F]FMISO-PET imaging as part of a prospective study (n=11) and were analyzed regarding a potential link between their oral microbiome and tumoral hypoxia. A total of 92 HNSCC patients treated with definitive (chemo)radiation were analyzed. Median age was 61 years (IQR, 56-66), most patients were male (n=77, 84%), and oropharyngeal cancer was the most common carcinoma (n=53, 58%). Higher salivary levels of *Lachnoanaerobaculum* spp. was associated with longer locoregional recurrence-free (p=0.0115) and overall survival (p=0.0417), which remained significant in the multivariable regression analysis (p=0.049974 [locoregional recurrence-free survival], p=0.0187 [overall survival]). Validation using intratumoral data from the TCGA cohort demonstrated an association of higher intratumoral *Lachnoanaerobaculum* levels with improved overall survival (p=0.0380). Neither the overall prevalence (p>0.9999) nor the time until occurrence of acute higher-grade mucositis (p=0.8414) was influenced by *Lachnoanaerobaculum* abundance. Patients with higher salivary *Lachnoanaerobaculum* levels had more CD4-positive stromal *(*p=0.0269*)* and CD8-positive intraepithelial TILs (p=0.0123). There was an inverse correlation between higher baseline salivary *Lachnoanaerobaculum* levels and a prognostically favorable early resolution of intratumoral hypoxia during chemoradiation (r = -0.6514, p=0.0229). High *Lachnoanaerobaculum* levels in the oral microbiome are associated with better locoregional control, overall survival, and factors predicting improved chemoradiation response in HNSCC patients, such as higher CD8-positive TILs levels and early hypoxia resolution. While *Lachnoanaerobaculum* may serve as a prognostic marker for improved treatment outcomes, further research is required on the mechanistic role of *Lachnoanaerobaculum*.

#6533 Microbial metabolite ammonia disrupts CEACAM1 TGF-β signaling to drive colon cancer progression.

Krishanu Bhowmick[1], Puja Ghosh[1], Xiyan Xiang[1], Xiaochun Yang[1], Taj Mohammad[2], Bibhuti Mishra[3], Md. Imtaiyaz Hassan[2], Adrian R Krainer[4], Srinivasan Dasarathy[5], Keith A Crandall[6], Lopa Mishra[1]

[1]CTR For Translational Research, The Feinstein Institute for Medical Research, New York, NY,[2]Centre for Interdisciplinary Research in Basic Sciences, Jamia Millia Islamia, Jamia Nagar, New Delhi, India,[3]Department of Neurology, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell Health, New York, NY,[4]Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, NY,[5]5Division of Gastroenterology and Hepatology, Cleveland Clinic, Cleveland, Ohio, OH,[6]Computational Biology Institute and Department of Biostatistics and Bioinformatics, Milken Institute School of Public Health, Washington DC, Washington DC, WA

Background: Colorectal cancer (CRC) is rising alarmingly in younger populations, potentially arising from additional risk factors such as obesity, pro-inflammatory microbiomes and accumulation of toxic metabolites. However, how metabolites such as ammonia impact key signaling pathways to promote CRC remains unclear. Our study investigates a critical link between gut microbiome alterations, ammonia, and their toxic effects on the TGF-β signaling pathway, to drive CRC progression.
Methods: Through human TCGA-CRC data analyses, with animal model studies, molecular docking and signaling studies, we examine how gut microbiome alterations, particularly ammonia production, modulate key oncogenic pathways involving Smad3 adaptor, SPTBN1, CEACAM1, and TGF-β. Our work builds on two of our recent publications (*Cell Rep.*2024.43(9):114676 and *Sci Transl Med.2021.13(624): eabk2267*). Results We observe altered microbial populations in an obesity induced mouse model of cancer, where ammonia promotes caspase-3-mediated cleavage of the SMAD3 adaptor βII-spectrin (SPTBN1). Cleaved SPTBN1 fragments form adducts with ammonia that induce pro-inflammatory cytokine expression and disrupt TGF-β signaling. Extending on AlphaFold docking simulations, we identified that ammonia interacts with six polar residues at SPTBN1 (S553, Y556, S663, Y666, N986, and T1178) to form hydrogen bonds that disrupt downstream SMAD3 signaling, altering TGF-β signaling to a protumor genic phenotype. Blocking SPTBN1, through an SPTBN1-specific siRNA blocks ammonia toxicity and restores normal SMAD3/TGF-β signaling by reducing the abundance of SPTBN1-cleaved fragments in SW480 and HCT116 (CRC) cell lines. In addition, our research establishes crosstalk between TGF-β signaling and a microbial sensor, carcinoembryonic antigen-related cell adhesion molecule 1 (CEACAM1), which is significantly overexpressed in CRC patients. We identified CEACAM1-SPTBN1 interactions at specific residues (E517 and Y520) within the immunoreceptor tyrosine-based inhibitory motif (ITIM) of CEACAM1 cytoplasmic domain, identifying a potential axis that is harnessed by the altered microbiome.
Conclusions: Our study identifies mechanistic insights into how microbial metabolites such as ammonia target TGF-β, a major signaling pathway, to promote CRC. These findings underscore the therapeutic potential of targeting SPTBN1 to restore tumor-suppressive TGF-β signaling and improve outcomes for CRC patients.

#6534 Bacterial infection as a modulator of tumor growth in ovarian cancer.

Shinya Nakano, Ryosuke Sonobe, Miho Suzuki, Keiko Shinjo, Yutaka Kondo

Nagoya University, Nagoya, Japan

Ovarian cancer exhibits the lowest survival rate among gynecologic malignancies, emphasizing the critical need for more effective treatment strategies and a comprehensive understanding of its progression mechanisms. Recent studies have suggested that certain microorganisms may contribute to the development and progression of various cancers. Our previous research identified specific microbiota in the uterus and ovaries, which were considered to be sterile. This finding raises the possibility that microbiota within the female reproductive organs may influence the progression of gynecologic cancers. In this study, we investigated whether bacterial communities contribute to the proliferation of ovarian cancer. To confirm the presence of bacteria in ovarian cancer tissues, we performed DNA fluorescence in situ hybridization (DNA FISH) using 16S rRNA probes specific to bacteria on ovarian cancer specimens. Approximately 60% of the tissue samples were found to harbor specific bacteria, predominantly located in the stroma. To evaluate the impact of these bacteria on tumor growth, we developed an in vivo mouse model by introducing bacteria found in ovarian cancer tissues via intraperitoneal injection, followed by intraperitoneal transplantation of mouse ovarian cancer cells. Tumor growth was significantly enhanced in the bacteria-exposed group compared to the control group, indicating that bacterial infection promotes tumor progression. Bacterial infection in the stromal area may induce chronic inflammation conducive to tumor growth, modulate the immune microenvironment, reprogram fibroblasts, and promote angiogenesis. We aim to further discuss these multifaceted roles and their implications in tumor biology and potential therapeutic strategies.

#6535 Association of *Bacteroides fragilis* and enterotoxigenic *Bacteroides fragilis* with specific T-cell subsets in the colorectal carcinoma microenvironment.

Satoko Ugai[1], Yuxue Zhong[2], Yasutoshi Takashima[3], Kosuke Matsuda[2], Claire E. Thomas[4], Daniel D. Buchanan[5], Conghui Qu[4], Li Hsu[4], Steven Gallinger[6], Robert C. Grant[7], Marios Giannakis[3], Meredith Hullar[4], Jeroen R. Huyghe[4], Sushma S. Thomas[4], Ulrike Peters[4], Amanda I. Phipps[4], Jonathan A. Nowak[3], Tomotaka Ugai[2], Shuji Ogino[2]

[1]Harvard T.H. Chan School of Public Health, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Fred Hutch Cancer Center, Seattle, WA,[5]University of Melbourne, Parkville, Australia,[6]Lunenfeld Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,[7]Ontario Institute for Cancer Research, Toronto, ON, Canada

Objectives: Experimental studies indicate that *Bacteroides fragilis* (BF), including enterotoxigenic *Bacteroides fragilis* (ETBF), could contribute to colorectal tumorigenesis through immune-mediated inflammation. However, the interactive effect of BF, ETBF, and T cell infiltrates in colorectal tumors is still unclear. In particular, not all T cells are the same, and the implications of different T cell subsets are uncertain; therefore, it is crucial to identify specific T cell subsets associated with BF and ETBF. We hypothesized that infiltration of certain T cell subsets might differ by tumor BF and ETBF status in colorectal cancer tissue.

Methods: The abundance of BF and ETBF was measured by the quantitative polymerase chain reaction in 827 incident colorectal cancer cases that had occurred in the Health Professionals Follow-up Study and Nurses' Health Study. T cell density in intraepithelial and stromal regions was assessed by a customized 9-plex multispectral immunofluorescence assay (CD3, CD4, CD8, CD45RA, CD45RO, FOXP3, KRT, MKI67, and DAPI) with digital image analyses and pathologist-supervised machine learning algorithms. We analyzed the association of the abundance of BF and ETBF with T cell subset densities using logistic regression models adjusted for age at diagnosis, sex, primary tumor location (proximal, distal, rectal), MSI, CIMP status, and *BRAF* and *KRAS* mutation status. We also applied the multivariable-adjusted Cox proportional hazards model using the same covariates to estimate the hazard ratios (HRs) for colorectal cancer-specific mortality according to BF or ETBF status. Two-sided P values <0.005 were considered statistically significant as recommended by the expert statisticians.

Results: Among 827 cases with available tumor BF, ETBF, and T cell data, BF levels were negative, low, and high in 416 (51%), 205 (25%), and 206 (25%) cases, respectively. ETBF levels were negative, low, and high in 753 (91%), 36 (4%), and 38 (5%) cases, respectively. High abundance of BF was statistically significantly associated with a lower stromal $CD3^+CD4^+FOXP3^+$ regulatory T cell density [multivariable OR, 0.61; 95% confidence interval (CI), 0.45-0.84, for BF-high vs. -negative category; P trend = 0.0034]. ETBF was not significantly associated with the densities of any T cell subsets. Neither BF (HR of high vs. negative, 0.84; 95% CI, 0.59–1.26) nor ETBF (HR of high vs. negative, 0.65; 95% CI, 0.34–1.25) was associated with colorectal cancer-specific mortality.

Conclusions: We observed that a high abundance of BF was associated with lower stromal $CD3^+CD4^+FOXP3^+$ regulatory T cell density in the tumor microenvironment. Our findings support the interactive effect of BF on specific T cells, which could explain why colorectal tumors harbor highly variable BF abundances and T cell densities.

TUMOR BIOLOGY: The Soil Matters: Tumor Microenvironment Complexity and Targeting
Poster Session

#6539 Lung cancer microphysiological systems for modeling sex-specific effects of estradiol on treatment response and proangiogenic capacity.

Wills Kpeli, Conner Sweat, Mark J. Mondrinos

Biomedical Engineering, Tulane University, New Orleans, LA

Lung cancer (LC) is the leading cause of cancer deaths in the US, accounting for 20.4% of all cancer deaths. LC incidence and progression exhibits distinct sex differences. Despite higher rates of smoking-related LC in men, premenopausal women never-smokers experience higher age-matched incidence and worse outcomes, suggesting a role for estrogens in disease initiation and progression. Along these lines, combining anti-estrogenic therapy with platinum-based agents such as cisplatin has been shown to enhance cytotoxicity, thereby underscoring the influence of sex hormones on LC treatment responses. Regarding LC progression, estradiol (E2) is known to potentiate angiogenesis in various contexts. A lack of sex-specific cellular models has limited in vitro investigations of sex hormone modulation of LC treatment responses and progression. This study aims to define E2's sex-specific effects on LC growth characteristics and angiogenesis within cisplatin-treated LC tumor microenvironments.
Methods: A549 spheroids were seeded in collagen I + 5% Matrigel and cultured in hormone-depleted medium as a baseline. Proliferation and cytotoxicity post E2 + cisplatin treatment was assessed via Ki67 and caspase 3/7 staining and quantification. A membrane-free organ chip that patterns a vascularized margin tissue and an engineered tumor microenvironment (TME) was used to model LC angiogenesis. Morphometric analysis of lectin-stained vasculature was used to quantify sprouting induced by VEGF gradients or TME-secreted growth factors. Patient-derived LC organoids (LC-PDO) were maintained and expanded in Matrigel. For angiogenesis assays LC-PDO were combined with sex-matched cancer-associated fibroblasts in a collagen I, fibrin, and Matrigel to engineer LC TMEs.
Results: The baseline Ki67 index of 27 +/- 22% in A549 spheroids was decreased to 8 +/- 5% ($p=0.042$) by 25 μM cisplatin. The baseline caspase 3/7 index of 4 +/- 4% was increased to 49 +/- 9% ($p<0.01$) with cisplatin treatment. The addition of 0.1 nM E2 dampened the effect of 25 μM, as evidenced by a Ki67 index of 14 +/- 12% and a caspase 3/7 index of 16 +/- 5%. E2-rich medium significantly increased sprouting angiogenesis induced by externally applied VEGF gradients in female models. Studies using spheroids comprised of cisplatin-resistant A549 derivatives selected for in expansion culture simultaneously displayed features of EMT, pseudo-dormancy, and an increased proangiogenic capacity.
Conclusions: Our proof-of-concept studies with A549 cells demonstrate that E2 decreases cisplatin toxicity. Ongoing work will reveal sex-specific effects of E2 on cisplatin toxicity and sprouting angiogenesis in LC-PDO models. This research could potentially inform the development of sex-specific LC treatment strategies that account for hormonal status and integrate modulators of sex hormone signaling in combination therapies.

#6540 Lung adenocarcinoma cancer cells that metastasize to the brain bring their own soil.

Alejandro Bernardo Suarez[1], Gabriela Caballero[2], Iban Aldecoa Ansorregui[2], Natalia Isabel Diaz-Valdivia[1], Patricia Fernandez-Nogueira[1], Noemi Reguart[3], Jordi Alcaraz Casademunt[1]

[1]Unit of Biophysics and Bioengineering, Department of Biomedicine, Universitat de Barcelona, Barcelona, Spain,[2]Anatomical Pathology, Hospital Clinic Barcelona, Barcelona, Spain,[3]Thoracic Oncology Unit, Hospital Clinic Barcelona, Barcelona, Spain

Lung adenocarcinoma (LUAD) is the most common histologic subtype of non-small cell lung cancer (NSCLC). Unlike other prevalent NSCLC subtypes, LUAD is characterized by an early dissemination, most frequently to the brain, particularly in patients harboring EGFR mutations. Although the mechanisms underlying LUAD metastasis to the brain are poorly understood, tumor-associated fibroblasts (TAFs) are increasingly recognized as major drivers of tumor progression and have also been hypothesized to contribute to tumor dissemination and metastasis. However, current experimental evidence of TAFs in brain metastasis is very limited. To address this gap of knowledge, we aimed to analyze retrospectively common markers of immunosuppressive TAFs phenotypes in LUAD in patient biopsies from primary tumors and paired brain metastases (n=17). These markers included α-SMA, FAP and MYH11, and were analyzed by immunofluorescence. We confirmed the presence of TAFs that were positive for these markers in primary tumors, although α-SMA$^+$ TAFs were dominant, in line with previous observations. Notably, our preliminary analysis in brain metastases revealed numerous cells exhibiting an elongated nuclear morphology comparable to that found in fibroblasts in LUAD primary tumors; moreover, these cells were also positive for either α-SMA, FAP and MYH11 or a mixture of these markers. In further agreement with the primary tumor, α-SMA$^+$ TAFs were dominant, whereas FAP$^+$ TAFs were patient dependent and MYH11$^+$ TAFs accounted for a smaller TAF population. In contrast, these TAF-like cells were negative for standard markers of activated astrocytes and pericytes. Moreover, brain metastasis showed patterns of T-cell exclusion similar to those reported in primary tumors. Because the normal brain is devoid of fibroblasts, these preliminary observations strongly support the presence of bona fide TAFs in brain metastasis. Moreover, the striking similarities between major immunosuppressive TAFs populations in the primary tumors and brain metastases support that disseminated cancer cells from LUAD patients bring their own soil during brain metastasis. Future analysis should validate these observations to ultimately define major immunosuppressive TAFs populations in brain metastasis, which could be used to design more specific therapeutic approaches against these populations.

#6541 Spatial and longitudinal characterization of tumor microenvironment of peritoneal carcinomatosis: Nab-PIPAC phase IB trial.

Laura Grassi[1], Raphael Genolet[2], Valentine Du Bois[1], Manuela Undurraga[1], Thibaud Koessler[1], Jean-Christophe Tille[3], Antonella Diciola[4], Mariagrazia Di Marco[5], Noemie Lang[6], Nicolas Mach[6], remi Peanne[1], Eileen Zhao[1], Nawel Zouggari[1], Julie Terzic[1], Catherine Raimond[6], Patrick Petignat[6], Christian Toso[6], Stefan Monig[6], Martin Hubner[4], Frederic Ris[6], Alexandre Harari[4], **Intidhar Labidi-Galy**[1]

[1]University of Geneva, Geneve, Switzerland,[2]University of Lausanne, Lausanne, Switzerland,[3]Hopitaux Universitaires de Geneve, Geneve, Switzerland,[4]University Hospital of Lausanne, Lausanne, Switzerland,[5]Hopitaux Universitaires de Geneve, Geneve, Switzerland,[6]Hopitaux Universitaires de Geneve, Geneve, Switzerland

Peritoneal carcinomatosis is a major therapeutic challenge in gynecological and gastrointestinal malignancies, associated with poor quality of life and short survival. Little is known about the tumor microenvironment (TME) of peritoneal carcinomatosis resistant to chemotherapy. Using multiplexed immunohistochemistry (FoxP3, CD163, CD8, CD68, FAP and Cytokeratin) and sensitive T cell receptor (TCR) repertoire analysis, we investigated spatial and longitudinal changes of the TME of 54 biopsies collected from 18 patients with peritoneal carcinomatosis (six ovarian cancer, nine gastric cancer and three pancreatic cancer) treated in the Nab-PIPAC phase IB trial (repeated cisplatin and nab-paclitaxel by pressurized intraperitoneal aerosol chemotherapy [PIPAC]). Overall, tumors were cold with low T cell infiltration. There was high intra- and inter-patient heterogeneity of TCR repertoire and immune cell distribution, with different tumor patterns and TME compositions depending on the primary cancer. Ovarian and gastric cancers were enriched in CD163+ tumor-associated macrophages while pancreatic cancer was enriched in FAP+ cancer-associated fibroblasts and FoxP3+ regulatory T cells. TCR clonality was higher in ovarian cancer, as compared to oesogastric cancer, likely reflecting expansion of tumor reactive T cells. Focusing on ovarian cancer, hyperexpanded T cells were more abundant in the tumor core as compared to matched stroma. Our spatial and longitudinal study brings new insights into the TME of peritoneal carcinomatosis, with implications for the future design of precision medicine in this disease.

#6543 Progesterone signaling alters the metabolic profile and immune cell landscape of mammary gland tumors.

Eilidh I. Chowanec[1], Christy R. Hagan[1], Jason Gertz[2]

[1]University of Kansas Medical Center, Kansas City, KS,[2]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Estrogen and progesterone signaling together drive hormone-receptor positive breast cancer growth and progression. However, there have been limited studies on the independent role that progesterone and its receptor, the progesterone receptor (PR), play in the development of breast cancer. Using the SSM2 tumor cell line, that expresses both the estrogen receptor (ER) and PR, we treated cells with either progesterone or vehicle (EtOH) and performed RNA-seq. The results of these experiments showed that progesterone treatment changes the metabolism of SSM2 tumor cells *in vitro*, altering the amount of free cholesterol and fatty acids in conditioned media. Previous studies in the Hagan lab have shown that progesterone signaling promotes mammary tumor growth and changes the immune landscape of the mammary gland towards immunosuppression. Therefore, we performed a tumor study using orthotopic injection of SSM2 tumor cells. Mice were treated with progesterone or placebo at the time of SSM2 tumor cell implantation. The results of this study showed that progesterone increases SSM2 tumor growth. Additionally, to investigate immune cell changes, we performed scRNA-seq on the progesterone and placebo-treated tumors. ScRNA-seq showed that progesterone-treated tumors harbored less CD3+ T cells than placebo-treated tumors. Additionally, progesterone-treated tumors had a greater number of TREM2+ macrophages than the placebo-treated tumors. The findings of our scRNA-seq data corroborated our *in vitro* findings that progesterone treatment of SSM2 tumor cells changes their metabolic profile. Our findings demonstrate that progesterone signaling promotes an immune suppressed microenvironment in the mammary gland through an increase in TREM2+ macrophages and a decrease in CD3+ T cells. This evidence provides rationale to investigate the use of anti-progestins as a mechanism to overcome the immune-cold tumor microenvironment seen in progesterone receptor positive breast tumors.

#6544 Effects of lipid metabolism on therapy-resistant prostate cancer cell-derived extracellular vesicle function in the tumor microenvironment.

Carolina Restrepo Soto[1], Katherine Carrero Figueroa[2], Carlos Joel Diaz Osterman[2]

[1]Mathematics, UPR - Rio Piedras Campus, San Juan, Puerto Rico,[2]UPR - Comprehensive Cancer Center, San Juan, Puerto Rico

Background: The chemotherapeutic agent docetaxel is a gold standard treatment for advanced, metastatic prostate cancer. However, the development of docetaxel resistance is a challenge to the effective management of the disease. Fatty acid synthase (FASN) is a central enzyme involved in lipid biosynthesis, a process linked to a therapy resistant phenotypes an immunosuppressive microenvironment. We hypothesize that FASN-driven lipogenesis alters prostate cancer cell-derived extracellular vesicle function within the tumor microenvironment. In particular, we will test whether extracellular vesicles from highly lipogenic docetaxel-resistant prostate cancer cells promote alternative macrophage activation.
Methods: Using cell-based models of docetaxel resistance (including both androgen receptor [AR]-positive and AR-negative lines), we first tested whether exposure of U937-derived macrophages to prostate cancer cells influenced the frequency of M1(CD86) or M2 (CD163) marker expression by immunocytochemistry. Next, we isolated extracellular vesicles from chemosensitive and chemoresistant prostate cancer cells and performed Western blots to detect FASN. Ongoing studies are evaluating the role of extracellular vesicles from prostate cancer cells, compared to vesicle-free cultured medium, on macrophage polarization by immunocytochemistry and/or flow cytometry. To assess the clinical relevance and prognostic utility of FASN/macrophage polarization overlap, we performed multiplex immunohistochemistry using human prostate cancer tissue microarrays. FASN and M1 (CD86) and M2 (CD163) macrophage markers were detected and quantified using a Keyence fluorescent microscope.
Results: Our data indicate that FASN is detectable in extracellular vesicles from prostate cancer cells and that the co-expression of FASN with a high M1-to-M2 ratio of macrophage markers in human prostate tumors correlates with aggressive disease based on clinicopathological variables.
Conclusions: These findings suggest that FASN may play a significant role beyond the confines of prostate cancer cells, extending to the tumor immune system and possibly to other cell types in the tumor microenvironment. Further work is needed to define the mechanism and intracellular impact of tumoral FASN uptake by tumor-associated macrophages.
Acknowledgements: Funding was provided by the Puerto Rico Science, Research and Technology Trust through the Catalyzer Research Grant mechanism to C.J.D.O. during his tenure at the Ponce Research Institute, Ponce, Puerto Rico.

#6545 Targeting NOS2 and the tumor microenvironment in ovarian cancer: Switching the immune system from "cold" to "hot".

Gianmarco Melone[1], Ivonne Uzair[1], Mailin Li[1], Maria Chervo[1], Karina Ortega[1], Jenying Deng[1], Wei Qian[1], Jianying Zhou[1], Liliana Guzman[1], Kristina Zambo[1], Harika Nagandla[1], Hong Zhao[1], Christoforos Thomas[1], Fotis Nikolo[1], Keith Chan[1], Lewis Francis[2], Jenny Chang[1], Aireana Phillips[1], Xen Ping Hoi[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]Swansea University, Swansea, United Kingdom

Purpose of the study: The goal of this study is to understand how targeting inducible Nitric Oxide Synthase 2 (NOS2) may alter the ovarian cancer tumor microenvironment. NOS2 is part of many proinflammatory pathways and plays a key role in immune response regulation and cancer cell proliferation. By combining pan-NOS inhibitor L-NMMA with conventional Cisplatin administration, we want to convert the immune environment from “cold” or non-responsive to “hot” or responsive to chemotherapy. **Experimental procedures:** We established an *in vivo* late-stage syngeneic ovarian cancer model by intraperitoneal (IP) injection of ID8 cells in C57BL/6 mice. We administered Cisplatin (2 mg/kg, IP), L-NMMA (4 mg/Kg at day 1, 200 mg/Kg starting from day 2**,** IP), and Cisplatin + L-NMMA combination at the above-mentioned doses starting from week five (ascites formation phase). At the endpoint (11 weeks), ascites was analyzed through flow cytometry to describe the immune population in different treatment regimens. We also developed a NOS2 knockout (KO) human ovarian cancer cell line (OVCAR8) through CRISPR double nickase system. The NOS2 KO and the reduction of NOS2 downstream proteins like ZEB1 and Vimentin were validated through western blot. Sensitivity to Cisplatin for the OVCAR8 KO cell line was tested through RealTime-Glo™ MT Cell Viability Assay. A p-value of <0.05, as measured using the One-way Anova test, was considered significant. **Results:** In comparison to single agents, the combination treatment into ascites showed a significative increase of CD62L- CD44+ markers in $CD4^+$ T cells (35.67% in Cisplatin treatment vs. 59.72% in Combination treatment, $p < 0.05$), increased infiltration of T cells (30.74% in Cisplatin treatment vs. 43.57% in Combination treatment, $p < 0.05$), NK (0.3408% In Cisplatin treatment vs 3.270% in Combination treatment, $p < 0.05$) and NK/NKT cells (2.677% in Cisplatin treatment vs. 7.090% in Combination treatment, $p < 0.05$). A reduction of the ascites formation in the combination treatment group (6.83 cm vs. 6.619 cm abdomen diameter) was also observed. The development of an *in vitro* OVCAR8 NOS2 KO model showed that the depletion of NOS2 can reduce Vimentin and ZEB1 expression together with a reduced KO cell proliferation after treatment with Cisplatin, compared to OVCAR8 parental cell line (90.73% residual proliferation in parental cell line vs 38.17% residual proliferation in the KO clone after 72 h administration of 4 µM Cisplatin). **Conclusions:** Our results showed the potential of the combination therapy to increase the infiltration of NK and NK/NKT cells and T lymphocytes into ascites together with the increase of effector markers in $CD4^+$ T cells. The development of a second *in vivo* model based on the OVCAR8 NOS2 KO cell line will provide a better understanding of the role of NOS2 in the metastasis formation process and the impact of NOS2 on patients' survival.

#6546 Iron accumulation correlates with tumor progression in mouse models of prostate cancer.

Jennifer Rooks[1], Caleb Taylor[2], Asmaa El-Kenawi[1]

[1]Urology, Indiana University School of Medicine, Indianapolis, IN,[2]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Tumor-associated macrophages (TAMs) are well-known as anti-inflammatory immune cells that contribute to various facets of prostate cancer development. An emerging aspect of TAMs is their "iron-rich" phenotype. This accumulation of iron can contribute to cancer cell initiation and tumor progression. In the current study, we aim to explore the key role of TAMs in regulating iron balance within the prostate tumor microenvironment (TME). We induced prostate tumorigenesis in the NP mice using Tamoxifen. The NP mice (*Nkx3.1*$^{CreERT2/+}$ *; Pten*$^{flox/flox}$ *; Rosa26-CAG-LSL-EYFP/+* mice) develop prostate intraepithelial neoplasia and localized prostate adenocarcinoma by 12 months of age. We also utilized male TRAMP which spontaneously develops poorly differentiated prostate tumors reminiscent of the neuroendocrine subtype. We then stained prostate tissues using different immune cell markers and Perls"s method which stains "non-heme" iron to identify cells with high abundance of iron. Our results demonstrate that prostate tissues from two distinct transgenic prostate cancer models (adenocarcinoma and neuroendocrine), spanning different developmental stages (12 and 18 months) exhibited high level of non-heme iron in stromal regions compared with non-tumor bearing controls. The areas with high iron abundance exhibited high expression of F4/80 and the iron exporter Ferroportin-1, also known as solute carrier family 40 member 1 (SLC40A1). In summary, we found that the availability of non-heme iron correlates with the abundance of TAMs in prostate tumor microenvironment. Future studies will focus on understanding how TAMs are regulating iron availability in the dynamic tumor environment.

#6547 Ivospemin and doxorubicin cooperatively modulate polyamine metabolism and the tumor immune microenvironment to improve survival in a murine ovarian cancer model.

Cassandra E. Holbert[1], Ashley C. Nwafor[2], Jennifer K. Simpson[3], Tracy Murray Stewart[2], Robert A. Casero, Jr.[2]

[1]Department of Biology, Loyola University Maryland, Baltimore, MD,[2]Department of Oncology, Johns Hopkins School of Medicine, Baltimore, MD,[3]Panbela Therapeutics, Waconia, MN

Polyamines are polycationic alkylamines that are essential for the continual growth and proliferation of cancer cells. The pharmacological modulation of polyamine metabolism is a promising avenue in cancer therapeutics due to the dependency of numerous cancers on continually elevated polyamine levels. Ivospemin, a spermine analogue, has shown efficacy in slowing pancreatic and ovarian tumor progression *in vitro* and *in vivo* and has demonstrated encouraging results in pancreatic cancer clinical trials. We have previously shown that ivospemin exposure decreases polyamine content both *in vitro* and *in vivo* through downregulation of the polyamine biosynthetic enzyme ornithine decarboxylase (ODC) and induction of the polyamine catabolic enzyme spermidine/spermine N^1-acetyltransferase (SSAT). We have also shown that ivospemin increases the efficacy of gemcitabine and topotecan *in vivo* by delaying tumor onset and reducing overall tumor burden. Here we examine the potential of combining ivospemin with doxorubicin, a common chemotherapeutic used in platinum-resistant ovarian cancer. Ovarian adenocarcinoma lines cotreated with ivospemin and doxorubicin exhibit an additive decrease in survival that is associated with upregulation of SSAT and decreased polyamine levels. Using the syngeneic VDID8+ ovarian model, we evaluated the ability of ivospemin to improve response to doxorubicin. Compared to untreated animals, ivospemin and doxorubicin cotreatment increased median survival by more than 200%, delayed tumor onset, and decreased overall tumor burden. Notably, this benefit was lost in an immunocompromised NSG mouse model. Ascites fluid from immune-competent animals was processed for evaluation of polyamine content by HPLC and immunophenotyping by multiparameter flow cytometry. Combination treatment decreased overall polyamine content by 75% and N^1-acetylated spermidine accumulation was observed, consistent with an upregulation of SSAT activity. Compared to single agents, ascites from co-treated animals exhibited an increased presence of CD45+ cells associated with an increase in lymphocyte recruitment. Treatment did not influence peritoneal macrophage numbers, however M1-like macrophages were increased while M2-like macrophages were decreased, resulting in an overall reversal of the M2/M1 ratio in ascites fluid. Cytokine analysis was performed on supernatant from cultured ascites cells to evaluate immune cell activity. Recognizing the non-representative mutational status of the VDID8+ model as a limitation, we are currently evaluating the combination of ivospemin and doxorubicin in genetically defined murine models that better recapitulate human high-grade serous ovarian carcinomas.

#6548 Tumor microenvironment of previously irradiated recurrent head and neck squamous cell carcinoma in humans.

Tarralyn Y. Clark[1], Jeromy Dooyema[1], Nabil Saba[2], Shlomo Koyfman[3], Haydn Kissick[4], Nicole C. Schmitt[5], Christine Lee-Poturalski[6], Tim Chan[3], David Yu[1], Zachary S. Buchwald[1]

[1]Radiation Oncology, Emory University, Atlanta, GA,[2]Hematology and Medical Oncology, Emory University, Atlanta, GA,[3]Radiation Oncology, Cleveland Clinic, Cleveland, OH,[4]Urology, Emory University, Atlanta, GA,[5]Otolaryngology, Emory University, Atlanta, GA,[6]Center for Immunotherapy and Precision Immuno-Oncology, Cleveland Clinic, Cleveland, OH

With increasing annual incidence, head and neck squamous cell carcinoma (HNSCC) is the most common head and neck cancer histology. Approximately half of HNSCC patients will develop recurrent disease. It is, therefore, important to understand the mechanism(s) and factors that may affect patient outcomes including the tumor microenvironment (TME). Previous studies have shown that patients with more TCF1+ PD-1+ CD8+ cells in the tumor prior to anti-PD-1 have superior outcomes. It is unknown whether these cells are present in recurrent tumors following radiation and what prognostic role they serve when patients receive concurrent radiation and anti-PD-1 (nivolumab). In our prior work, we evaluated PBMCs from recurrent HNSCC patients receiving reirradiation and nivolumab and correlated findings with progression free survival (PFS). Results indicated a shorter PFS for patients with a 1.5-fold increase in peripheral blood PD1+Ki67+CD4+ T cells from baseline to week 2 or 4 of treatment, suggesting the further need to assess potential biomarkers in the tumor. Thus, in this study, we provide a phenotypic analysis of cells present in recurrent previously irradiated tumors at baseline and plan to correlate with patient outcomes. Retrospective analysis of patient TME prior to receiving reirradiation and nivolumab was assessed utilizing multiplex immunofluorescence (mIF). T cells within the TME of previously irradiated disease revealed that 48.64% of CD8+ cells were PD-1+ at the time of resection (N=20, range=8.050%-62.16%). Of the PD-1+ CD8+ T cells, a higher percentage of effector TCF1-PD1+CD8+ cells (median= 58.94%, N=20, range= 28.43%-85.90%) were present compared to stem-like TCF1+PD1+CD8+ cells (median= 41.06%, N=20, range= 14.10%-71.57%). Likewise, cell density per mm^2 for effector TCF1-PD1+CD8+ cells (median=46.01, N=20, range= 1.006-265.9) was higher compared to stem-like TCF1+PD1+CD8+ cells (median= 30.81, N=20, range=0.7669-142.7). In parallel, a prospective analysis of PBMCs of standard of care HNSCC patients with no prior history of treatment was assessed longitudinally during radiation by flow cytometry. We found the percentage of CD8+ T cells remained relatively stable throughout radiation treatment though the percentage of CD8 T_{EMRA} cells increased 1.2-fold from baseline to 3 months post treatment. Naïve CD8 T cells, in contrast, experienced a 2-fold decrease from baseline to 3 months post treatment after an initial increase during treatment. Activated CD8 T cells (CD38+ HLA-DR+) decreased gradually from baseline to week 3 of treatment before rebounding 3 months post treatment. These data suggest that previously irradiated tumors still possess the T cell population necessary to mount a robust anti-PD-1 and anti-tumor immune response. Additionally, H&N radiation has an impact on circulating T cell populations in the absence of immunotherapy.

#6549 Immune cell-derived lymphotoxin associated with survival of patients with endometrial cancer.

T. Lau[1], J. Wu[1], K. Chan[1], J. Kwong[2], H. Lee[1], C. Wang[1];
[1]The Chinese University of Hong Kong, Shatin, NT, Hong Kong, [2]Keele University, Keele, Staffordshire, United Kingdom

Background: Endometrial cancer (EC) is a prevalent gynecological malignancy, often associated with poor prognosis in advanced stages. The tumor microenvironment (TME) plays a critical role in modulating immune responses and disease progression. This study aimed to investigate the prognostic significance of lymphotoxin (LT) in EC patients.
Methods: Transcriptomic data from The Cancer Genome Atlas (TCGA) for EC were analyzed to access LT expression level, identified LT-associated gene signatures and evaluate the clinical outcomes. The cellular source of LT was determined by analyzing single-cell RNA sequencing (scRNA-seq) data from public databases. Additionally, these findings were validated in a cohort of 138 EC tissue samples from our center using quantitative PCR (qPCR) and multiplex immunofluorescence (mIF) staining.
Results: Analysis of TCGA data demonstrated that EC patients with high LT expression exhibited significantly improved overall survival (OS) and disease-free survival (DFS) compared to those with low LT expression. Gene signature analysis indicated that high LT expression correlates with increased immune cell infiltration, suggesting a robust anti-tumor immune response. scRNA-seq analysis suggested that LT is predominantly expressed in T cells and B cells in EC samples when compared to normal samples. Validation in our cohort of 138 EC tissues revealed that patients with high LT expression had better OS. EC patients with high LT expression showed high expression of immune cell-related gene signatures, including Territory lymphoid structure signature, Tfh cell signature, Th1 and B cell signature and HEV signature, by qPCR. mIF staining further confirmed that increased infiltration of T cells and B cells in the TME of patients with high LT expression.
Conclusion: Our findings indicate that immune cell-derived lymphotoxin serves as a potential prognostic biomarker in endometrial cancer, associated with enhanced immune cell infiltration and improved patient outcomes. These results highlight the importance of the immune microenvironment in tumor progression and support further exploration of lymphotoxin regulations in TME for identification of therapeutic target in EC.

#6550 Cancer-associated fibroblast-targeted near-infrared photoimmunotherapy induces tumor specific memory T cells from TDLNs.

Akito Shimizu[1], Kazuhiro Noma[1], Tatsuya Takahashi[1], Tasuku Matsumoto[1], Seitaro Nishimura[1], Yasushige Takeda[1], Hijiri Matsumoto[1], Tomoyoshi Kunitomo[1], Masashi Hashimoto[1], Hajime Kashima[1], Naoaki Maeda[1], Satoru Kikuchi[1], Shunsuke Tanabe[1], Toshiaki Ohara[1], Hiroshi Tazawa[1], Hisataka Kobayashi[2], Toshiyoshi Fujiwara[1]

[1]Department of Gastroenterological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Okayama, Japan, [2]Molecular Imaging Branch, Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD

<Introduction> Our laboratory previously showed that cancer-associated fibroblasts (CAFs) suppress antitumor immunity in the tumor microenvironment (TME) and that CAF-targeted near-infrared photoimmunotherapy (CAF-PIT) improves antitumor immunity in the TME and reduces tumor size by TME remodeling. Dendritic cells have been suggested to migrate from the TME to the tumor drainage lymph nodes (TDLNs) and promote the proliferation of tumor-specific memory T cells and their migration to the tumor. We hypothesized that CAFs inhibit this process.
<Methods> To evaluate the effect of memory T cells in the TME on prognosis, we evaluated memory T cells in the TME of clinical specimens of esophageal squamous cell carcinoma using immunohistochemistry with a CD45RO antibody. We also examined its correlation with area of CAF evaluated by α-SMA antibody in previous studies. We evaluated tumor-specific memory T cells and dendritic cells in the TME and ipsilateral inguinal lymph nodes (TDLNs) and contralateral inguinal lymph nodes(non-TDLNs) in flank subcutaneous tumor models of MC38, a mouse colon cancer tumor strain that is highly immunogenic and can be used to evaluate tumor-specific T cells using H-2Kb p15E tetramers. We created CAF-rich models co-inoculated with MEF and evaluated the effect of CAFs, CAF-PIT, and TDLNs using flow cytometry.
<Results> Among patients with esophageal squamous cell carcinoma, those with a high number of CD45RO-positive cells in the TME had a better prognosis. Furthermore, in cases with T2 or deeper, there was a negative correlation with area of CAF which suggested that CAF might inhibit the migration of memory T cells.Evaluation of tumor-specific T cells in a mouse model showed that TDLNs contain more tumor-specific T cells and dendritic cells than non-TDLNs. In addition, tumor-specific T cells were present mainly as effector and central memory T cells in the TME and TDLNs, respectively.In CAF-rich tumor mouse, tumor-specific effector memory T cells in the TME were significantly lower than in CAF-poor tumor mouse, and tumor-specific central memory T cells in the TDLNs were lower. When CAFs were removed by CAF-PIT, the number of tumor-specific effector memory T cells in the TME increased significantly. In addition, resecting TDLNs before FAP-PIT decreased the number of tumor-specific effector memory T cells in the TME and weakened the therapeutic effect.
<Conclusion> CAF-PIT induces tumor-specific memory T cells from TDLNs via TME remodeling.

#6551 Exploring oncolytic viral therapy to target osteosarcoma.

Sumbul Khan, Terri Higgins, Isabella Shimko Lofano, Payal Agarwal

Auburn Univ. College of Veterinary Med., Auburn, AL

Osteosarcoma (OS) is a mesenchymal neoplasm. OS makes up approximately 3% of all malignancies in children. The mortality rate has not changed in the last few decades; therefore, the development of advanced cancer therapies is essential. We hypothesize that next-generation conditionally replicative oncolytic virus with an armed anti-PD1 HcAb will lyse the OS cells and initiate the immune response against tumor cells in the tumor microenvironment.The purpose of the study is to evaluate the oncolytic activity and production/ secretion of anti-PD1 Hcab by conditionally replicative Canine adenovirus armed with anti-PD1 Hcab (CAV 2 AU M3). We have infected canine OS cell lines viz D17-GLP, CF11-GLL, MCKOS and D22-GLP with CAV2 AU M3 and measured its cytotoxicity by performing cell viability assay (Luciferase assay) and cytotoxicity assay (LDH assay). To assess whether the virus can stimulate an immune response or not, we performed an immunogenicity assay (ATP assay). To evaluate the secretion and expression of anti-PD1 HcAb we have performed western blot. Flow cytometry was done to confirm the functionality of anti-PD1 Hcab i.e binding of anti-PD1 HcAb to PD1 receptors and inhibition of PD1 and PDL1 interaction. We have found that CAV2 AU M3 is lytic in OS cell lines (D17-GLP, CF-11-GLL, and MCKOS) in both 2D (Monolayers) and 3D (Tumor spheroids) cell cultures and it also produced and secreted anti-PD1 HcAb, which binds to PD1 receptor efficiently and inhibited the interaction between PD1 and PDL1. We concluded that CAV2 AU M3 is a potent armed oncolytic virus that can lyse and kill OS cells and produce functional anti-PD1 HcAb.

#6552 Siglec1 expression on the tumor-associated macrophage in breast cancer.

Shinyoung Park[1], Chul Hwa Hong[2], Won-Ji Ryu[2], Jeong Dong Lee[3], Ja Seung Koo[4], Min Hwan Kim[5], Joo Hyuk Sohn[5], Hyung Seok Park[6]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Avison Biomedical Research Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea, Republic of,[4]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Department of Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of

Breast cancer is a common malignant tumor with four distinct subtypes, based on the presence of estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2 (HER2): luminal A, luminal B, HER2-enriched, and triple-negative. There is currently no effective immune checkpoint blockade (ICB) against breast cancer. The tumor microenvironment comprises not only cancer cells, but also fibroblast and tumor-infiltrating immune cells. Macrophages are the largest subset of tumor-infiltrating immune cells, called tumor-associated macrophages (TAMs). It has been reported that Siglec1 is a selective marker of TAM. Siglec1 is also known as CD169 Sialoadhesin, and is typically found on the surface of monocytes and macrophages. Macrophages can be divided into two groups: M1- and M2-like. Although Siglec1 does not belong to either of these, macrophages that express Siglec1 have been associated with immunosuppressive functions, which can facilitate tumor progression. Given the observed differences in Siglec1 mRNA expression among breast cancer subtypes, we postulated that Siglec1 protein expression would also vary between subtypes, resulting in different prognoses. We also evaluated the impact of ICB on Siglec1 expression in an immune co-culture system utilizing patient-derived organoids (PDOs). Formalin-fixed paraffin-embedded blocks were prepared from fresh frozen surgical tissues. Using them, hematoxylin and eosin staining and immunohistochemistry (IHC) were conducted, and the percentage of Siglec1+ cells was obtained from the slides. The relationship between Siglec1 expression and patient baseline characteristics, including age, hormone receptor status, HER2 status, Ki67 level, subtype, histologic grade, and TNM stage, was examined. To evaluate the impact of ICB on Siglec1 expression, PDOs were co-cultured with their own peripheral blood mononuclear cells (PBMCs) and cytokines in minimum medium. Following a 24-hour and 10- to 14-day incubation period, the immune cells were analyzed by flow cytometry. In clinicopathological analyses, no correlation was identified between Siglec1 expression and subtype, but Siglec1 expression was significantly associated with tumor stage. Furthermore, survival analysis revealed a correlation between Siglec1 expression and recurrence and/or mortality. In the co-culture system, Siglec1 was expressed in both M1- and M2-like subsets, and the ratio of Siglec1+ macrophages was decreased when PBMCs were cultured with PDOs. Administration of anti-PD-1 in the models has been observed to alter the proportion of Siglec1+ macrophages compared to the control. In conclusion, the results demonstrated that Siglec1 may be related to both subsets of macrophages and be associated with large tumors and prognosis. Anti-PD-1 treatment may influence the expression of Siglec1+ macrophages. Further investigation is required to ascertain the impact of ICB on Siglec1+ macrophages.

#6553 Ex vivo investigation of estrogen receptor-related macrophages polarization in breast cancer and its prognostic significance.

Daria Kalinska-Lysiak[1], Katarzyna Zielniok[2], Zak Kinsella[1], Radoslaw Zagozdzon[2], Darran O'Connor[1]

[1]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[2]Laboratory of Cellular and Genetic Therapies, Center for Preclinical Research, Medical University of Warsaw, Warsaw, Poland

Breast cancer (BC) is the second most frequent cause of cancer-related deaths. In clinical practice, ER, PR and HER2 assessment in histopathological samples divides BC into biological subtypes and guides treatment decisions. While these subtypes reveal key insights on prognosis they crucially also exhibit distinct immune environments, with ER-positive disease being considered 'immune-cold'. Recently, though immunotherapy has shown efficacy in treating ER-negative tumors, there is a lack of biomarkers that may select patients as good candidates for immunotherapy treatment in BC. In this study, we characterized the immune milieu across tumors of different ER-positivity, challenging the canonical breast cancer ER+/ER- dichotomy. A publicly available RNA-seq dataset (TCGA BRCA) with 481 breast cancer patients and complete information on ER percentage IHC status was analyzed in R Studio (v 4.4.0). We demonstrated that patients with ER IHC expression below 50% (ER-low: <10% and ER-intermediate: 10-49%) exhibit worse prognosis than those with ER-high (above 50%, p-value = 0.0082), throwing doubt onto the sufficiency of the contemporary therapy in ER+ disease for patients of lower ER expression. We have further investigated immune enrichment using the quantiseqr package, and observed gradual changes in immune fractions across three clusters of ER expression (<10%, 11-49%, >50%). While macrophages constitute the most numerous population in ER-high and ER-intermediate tumors, for ER-low patients' cell proportions are more balanced: the fraction of M2 macrophages, B-cells and CD4+ T-cells is reduced whereas macrophages M1, neutrophils, and T-reg increase. Differences between mean abundances in high vs low clusters remain statistically significant for all measured cells except for NK cells. We also noticed effects for M1- and M2-like macrophages by underlying ER expression: the higher the ER expression the more relative abundance of M2 cells, with moderate positive correlation across the tumors with increasing ER deciles (Spearman correlation r = 0.4, p-value < 0.0001). Conversely, M1-like cells decrease at once. Median relative abundance of macrophages M1 had prognostic value in the entire cohort of breast tumors (log-rank test p-value = 0.041), what mostly originated from tumors of high ER levels (n = 151 vs 193, p-value=0.0089), and did not achieve statistical relevance in any other subgroup. While recent in-vitro research postulated existing difference of macrophages' populations in cancers of distinct ER expression, and in environment of variable estrogen levels, this study demonstrates the fluctuation of ER-related M1- and M2-like macrophage proportions in clinical samples. We moreover provide evidence that M1-like macrophages have prognostic relevance in the ER-high subgroup. Further experiments detailing mechanisms of the observed phenomenon are underway.

#6554 Characterization of the tumor immune infiltrate in a colorectal syngeneic model dosed with anti PD1 in combination with radiotherapy or PARP inhibitor.

Theoni (Tania) Katopodi, Charlotte Bell, Pablo Binder, Lyndsey Hanson, Emily Wright, Amy Cantrell, Stewart Brown, Paul Farrington, **Tobias Bunday**, Nick Moore, Lorraine Mooney, Jane Kendrew

Sygnature Discovery, Alderley Edge, United Kingdom

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of many cancers, significantly improving survival outcomes. However, for some indications, phase I and II studies have not demonstrated substantial antitumor activity when ICIs are used as monotherapy. Combining ICIs with poly(ADP ribose) polymerase (PARP) inhibitors (PARPis) or radiotherapy are currently being explored in numerous clinical trials. Therefore, understanding the impact of these therapies on the tumor immune microenvironment (TIME) and the responses after combining radiotherapy, PARPis and ICIs in preclinical tumor models is crucial for guiding drug discovery research.
Methods and Experimental Procedures: The murine colorectal carcinoma cell line MC38 was subcutaneously implanted into C57BL/6 mice. The response of the MC38 cancer model to anti PD1, fractionated radiotherapy, and the PARPi Niraparib was assessed by measuring tumor growth with calipers three times per week. Mice receiving radiotherapy were administered targeted X rays using an Xstrahl CIX3 cabinet irradiator, with animals shielded by lead panels to expose only the tumor for localized treatment. Changes to the TIME following these treatments were evaluated using multi color flow cytometry, and plasma cytokines were assessed by Luminex xMAP technology. Data Treatment with anti PD1 resulted in a mixed response, with tumor regressions observed in a subset of treated animals. The combination of anti PD1 with fractionated radiotherapy significantly enhanced therapeutic efficacy, whereas combining anti PD1 with Niraparib did not yield additional benefits. Characterization of the tumor immune microenvironment (TIME) following these treatments revealed modulation of the intra-tumoral immune infiltrate. Notably, a significant decrease in tumor-associated macrophages and an increase in CD8 cytotoxic T cells were observed in tumors treated with the combination of anti PD1 and fractionated radiotherapy. These results were consistent with the increased efficacy observed in the combination group. However, combining Niraparib with anti PD1 did not show any advantages over the anti PD1 monotherapy which was also reflected by the changes seen when TIME was characterized.
Conclusion: In this study we have characterized and established effective dosing regimens for anti PD1, fractionated radiotherapy, and Niraparib, both as monotherapies and in combination. Additionally, we evaluated changes to the tumor immune microenvironment (TIME) in a syngeneic mouse cancer model. The differences in efficacy and TIME findings with the combinations evaluated demonstrate the value of these models for immuno-oncology (IO) drug discovery research.

#6555 A method for preparing tumor tissues for ex vivo culture that retains T cells within live tumor fragments while preserving tissue viability and T cell function.

Michael Korrer[1], Christina Scribano[1], Pichet Adstamongkonkul[1], Todd Bakken[1], Torey Browning[1], Christian Baltes[1], **Sean Caenepeel**[1], Nicholas Dana[1], Jackie Derrick[1], Thomas Dietz[1], Evan Flietner[1], Hilary Hernan[1], Christin Johnson[1], Payton McDonnell[1], Jacob Nesemeier[1], Josh Porter[1], Abhijeet Prasad[1], Jordyn Richardson[1], Sidney Schneider[1], Rebecca Tarlazzi[1], Noah Van Der Weide[1], Lindsey Vedder[1], Ming (Veronica) Wang[1], Hinco Gierman[1], Andreas Friedl[2], Laura Hrycyniak[1], T.S. Ramasubramanian[1]

[1]Elephas, Madison, WI,[2]University of Wisconsin, Madison, WI

Characterization of response to immunotherapy ex vivo requires preservation of the live tumor microenvironment (TME), including the sequestration of immune cells. Elephas has developed a methodology that incorporates proprietary cutting instruments designed to optimally fragment live tumor resections and core needle biopsies (CNBs), and a proprietary hydrogel that supports the viability of tumor fragments in ex vivo culture while sequestering T cells in their native TME. In this study, tumor specimens (human tumors and humanized PDX) were fragmented using one of two proprietary cutting instruments designed to cut tumor resections into 300 x 300 x 300µm fragments or CNBs into 300µm thick slices. Both tissue form factors were then encapsulated in a propriety hydrogel. Tissue viability was assessed via the Cell Counting Kit 8 (CCK8) assay and in some cases a lactate dehydrogenase assay. Conditioned media from culture plates harboring encapsulated fragments was collected for multiplex cytokine analysis. At the end of ex vivo experimentation tissue was paraffin embedded and formalin fixed for H&E staining and immunohistochemistry was performed to assess T cell retention. Elephas proprietary cutting instruments produced tumor fragments of consistent size and volume. These fragments retained histological characteristics of the original tumor resections from which they were derived and their encapsulation in a proprietary hydrogel improved T cell retention over 2 days of ex vivo culture. Preservation of the native TME was further demonstrated following αPD-1 treatment of tumor fragments with known CDx biomarker status where an enriched cytokine response profile was observed in biomarker positive samples. In CNBs processed on the Elephas platform, overall viability and T cell function were maintained following simulated overnight shipment at 4°C. To overcome challenges associated with the limited amount of tissue in CNBs (e.g. heterogeneity), we developed a treatment strategy where control and treatments were performed sequentially on the same tissue within a single well. Fold changes in the rate of cytokine secretion following sequential (1) control and (2) αPD-1 + STING agonist treatment exhibit improved CVs (%) relative to an inter-well treatment design (control and treatment wells). Additionally, live tumor biopsies were shown to exhibit comparable IFNγ response following treatment with αPD-1 + STING agonist at the experiment start vs. following 20 hrs of control treatment. The Elephas platform preserves overall cell viability and T cell function in the TME of CNBs ex vivo using proprietary cutting instruments and hydrogel encapsulation techniques. Using this preparation method, the Elephas platform optimally captures the heterogeneity in human tumors (resections and CNBs) while allowing for comparisons between treatment conditions.

#6556 Model characterization and tumor immune profile assessment of syngeneic Renca murine renal cell carcinoma in female BALB/c.

Justin Snider, Lauren Kucharczyk, Anita Zaitouna, Sheri Barnes, David Draper, Scott Wise

Laboratory Corporation of America, Ann Arbor, MI

Renal cell carcinoma (RCC) affects over 80,000 people in the U.S. annually, leading to ~15,000 deaths. Although immuno-oncology therapies can yield responses for some patients, complete remissions are rare. This limitation highlights the importance of new therapeutic approaches, necessitating effective animal models for preclinical testing. Syngeneic models, which allow for functional immune systems capable of influencing tumor growth and metastases, are valuable for studying immune responses and immunosuppressive factors. One such model is Renca, derived from a spontaneous renal cortical adenocarcinoma in a BALB/c mouse. Renca is relevant because it varies in immunogenicity and mirrors human RCC in many aspects. This model is a promising tool in immuno-oncology, enabling the testing of new treatments, alone and in combination with other therapies. To ensure reproducible growth, a well-established tumor was collected and processed. The resulting cells where then implanted subcutaneously at two inocula (1.0E+06 and 5.0E+05 cells), with and without dietgel, to observe known weight loss characteristics of the model. Renca demonstrated aggressive growth, with a median tumor volume doubling time of ~3 days, a median time to 2000 mm^3 of ~30 days, disease related mortality of 12.5-25% with dietgel and 37.5%-62.5% without dietgel and disease associated body weight change ranging from -5.1 to 0% with dietgel and -15.1 to -14.6% without dietgel. The baseline tumor immunophenotype in vehicle control treated animals was measured by flow cytometry and revealed myeloid-derived suppressor cells to be the dominant subset in the tumor. With G-MDSCs and M-MDSCs representing 31.5% and 16% of total CD45+ cells, respectively. In addition, tumors were poorly infiltrated with lymphocyte subsets as CD8+ T cells and NK cells each represented less than 0.25% of the CD45+ cell compartment. Furthermore, checkpoint inhibitors including PD-1, TIM-3, and LAG-3 were highly expressed on the T cells present (90.0%, 80.5%, and 74.7% positive respectively), suggesting an immunosuppressed state. Next, response to standard of care (SoC), checkpoint inhibitors, and radiation were evaluated. All treatments had limited impact on tumor regression, but focal beam radiation showed the most significant effect by extending the time to progression. Checkpoint inhibitors were minimal effective, while SoC treatment produced a moderate response. In summary, the Renca model has proven to be a reliable syngeneic tumor model for RCC research. Its immunosuppressive microenvironment is valuable for studying combination therapies that could potentially convert non-immunogenic tumors into more immunogenic tumors, enhancing treatment responsiveness. Future studies will focus on optimizing orthotopic implantation and sampling tumors at varying sizes, which has been shown to impact TIL populations.

#6557 Human 16p11.2 microdeletion suppresses malignant progression of colon cancer through dysregulation of the tumor microenvironment.

Jacob L. Billingsley, Joshua Haebe, Chris Bergin, Tanguy Fenouil, Baptiste Lacoste, Yannick Benoit

University of Ottawa, Ottawa, ON, Canada

Colorectal cancer (CRC) is the third most diagnosed malignancy in Canada, where nearly half of diagnoses occur at late stages. The tumor microenvironment (TME), including host mesenchymal, immune, and endothelial cells, is an important driver of colorectal tumor progression toward late-stage disease. Tumor cells can instruct the TME to support invasion and metastasis via angiogenesis, immunosuppression, and extracellular matrix (ECM) remodeling. Next-generation cancer therapeutics must account for the complexities of the TME. Thus, the discovery of vulnerabilities therein is of critical importance. Our group contributed to a study showing that the hemi-deletion of the 16p11.2 locus (16p11.2+/-), associated with the autism spectrum disorder, significantly impairs cortical vascularization. Given that several genes within 16p11.2 are critical to CRC development, we found that primary CRC tumors with high 16p11.2 locus activity correlated with shorter overall survival rates than low 16p11.2 activity tumors. Pan-cancer hazard ratio analysis showed this relationship with 16p11.2 gene expression is specific to CRC. To study the role of the 16p11.2 locus in CRC tumor progression, we introduced a monoallelic deletion of the 7F3 locus (homologous to human 16p11.2 and termed h16p11.2 for clarity) in the APCmin/AOM tumorigenesis model. CRC tumors developing in the h16p11.2-deficient animals showed a significantly reduced size. Similarly, syngeneic CRC tumor engraftment assays using MC38 cells (h16p11.2 wt) showed delayed tumor growth in h16p11.2-deficient recipients compared to wt controls. CRC tumors developing in an h16p11.2-deficient niche presented significant disruptions in critical elements of the TME. Specifically, 3D mapping of CD31-positive endothelial structures revealed a 50% reduction in blood vessel density for tumors engrafted into h16p11.2-deficient animals. Transcriptome profiling of tumor and tumor-adjacent tissues identified several aspects of the TME perturbed by the h16p11.2-deficient niche, such as extracellular matrix (ECM) composition and enhanced adaptive immune response in macrophages. Polarized light microscopy and immunohistochemistry confirmed ECM gene regulation by showing a reorganization of collagen fiber and SPARCL1 deposition inside CRC tumor mass. Moreover, macrophage infiltration is enhanced within CRC tumors grown in a h16p11.2-deficient TME, with enhanced M1 anti-tumor and reduced M2 pro-tumor polarization. Overall, our data support that a 16p11.2-deficient TME represents an inhospitable niche for CRC tumor growth and progression. Gaining a better understanding of the biological mechanisms associated with lower 16p11.2 locus activity in CRC will reveal novel treatment modalities targeting both tumor and TME tissues.

Background: Neuroblastoma (NB) represents the most frequent form of extracranial solid tumor of children, responsible for 15% of childhood cancer deaths. Recently, cell surface Nucleolin (NCL) was suggested as a target for NB therapy and its expression at RNA level was validated as an independent (adjusting for age, INSS stage, and *MYCN* status) prognostic marker for NB. Extracellular vesicles (EVs) may express different surface proteins derived from the parental cells. Liquid biopsy-derived EVs from NB patients might reveal a possible diagnostic/prognostic role of NCL at the protein level.

Methods: Here we evaluated the expression of small EVs (sEVs)-derived NCL in the peripheral bloods (PB) of low risk- (LR) and high risk- (HR) NB patients at onset and in relapse, and of aged-matched controls (CTRs). PB were firstly centrifuged at 400 g for 10 min at 4°C, then the supernatant was re-centrifuged at 1600 g for 10 min at 4°C to collect plasma. Isolation of EVs was performed from 500 µl of plasma through ultracentrifugation at 20.000 g to remove large EVs and secondly at 100.000 g to isolate sEVs. sEVs were characterized in term of size distribution by using Nano Traking Analysis (NTA). Twenty µg of sEVs-derived proteins were used in Western Blot analysis to evaluate the expression of the EVs markers as well as NCL.

Results: The isolated CD63- and CD9-expressing sEVs range in size between 81.6 and 138.7 nm. Interestingly, particles concentration results significantly higher in the PB derived from HR-NB, both at onset and at relapse, compared to that from both CTR and LR-NB patients. Furthermore, we have found a higher NCL protein expression on sEVs derived from the PB of all NB patients, compared to that derived from CTR. Noteworthy, NCL expression results significantly higher in the sEVs derived from HR-NB patients at onset, compared to that observed in LR-HR patients, suggesting a potential prognostic value of sEVs-derived NCL in clinic.

Conclusion: The extracellular vesicles-derived protein nucleolin in the peripheral blood of patients may represent a prognostic factor for neuroblastoma.

#6562 Bro1 proteins govern a multivesicular bodies fate switch to regulate exosome secretion, metastasis and tumor immune evasion.

N. Yeat[1], L.-H. Liu[1], Y.-H. Chang[1], C.-K. Lai[2], R.-H. Chen[1];

[1]Academia Sinica - Institute of Biological Chemistry (IBC), Taipei, Taiwan, [2]Academia Sinica - Institute of Atomic and Molecular Sciences (IAMS), Taipei, Taiwan

Exosomes play pleiotropic tumor-promoting functions and are secreted by fusion of multivesicular bodies (MVBs) with the plasma membrane. However, MVBs are also directed to lysosomes for degradation and the mechanism controlling different fates of MVBs remains elusive. Here, we show that the pro-tumor protein WDR4 enhances exosome secretion through degrading the ESCRT-associated Bro1-family protein PTPN23. Mechanistically, PTPN23 and its paralog ALIX compete for binding to syntenin, thereby directing MVBs towards degradation and secretion, respectively. ALIX, but not PTPN23, recruits actin capping proteins CAPZA1/CAPZB to prevent branched F-actin accumulation around MVBs, thus enabling MVBs trafficking to cell periphery for secretion. Functionally, WDR4/ALIX dependent exosomes preferentially load a set of pro-tumor proteins to potentiate metastasis and immune evasion. Our study highlights a previously unprecedented coupling between biogenesis mechanism and fate decision of MVBs and its importance in exosome cargo landscape, which have potential broad impacts on boosting exosome production and devising cancer therapeutic strategy.

#6563 Mechanisms of extracellular vesicle uptake in chemotherapy resistant and sensitive ovarian cancer: insights into tropism and resistance transfer.

Joana Sousa Esteves[1], Kadie Edwards[1], Jetzabel Garcia-Parra[1], Claire Donnelly[1], Francesca Taraballi[2], Deyarina Gonzalez[1]

[1]Reproductive Biology and Gynaecological Oncology Group, Swansea University Medical School, Swansea, United Kingdom,[2]Center for Musculoskeletal Regeneration, Houston Methodist Research Institute, Houston, TX

Background: Ovarian cancer is the most lethal gynecological malignancy, with approximately 19,000 new cases and 12,000 deaths projected in the US for 2024. Despite therapeutic advancements, including platinum-based chemotherapies, the 5-year survival rate remains at 50.8%, largely due to chemotherapy resistance. Extracellular vesicles (EVs), nanosized particles involved in intercellular communication, play critical roles in ovarian cancer progression by promoting tumor aggressiveness and chemoresistance. This study investigates the uptake mechanisms and potential tropism of EVs derived from chemotherapy-sensitive (SensC-EVs) and chemotherapy-resistant (ChemoRC-EVs) ovarian cancer (OC) cell lines. All EVs were tested for uptake in both cisplatin-sensitive and cisplatin-resistant cell lines to characterize their interactions comprehensively. EVs were isolated via size exclusion chromatography from serous (SKOV3 wild type [wt] and SKOV3 cisplatin-resistant [cis]) and endometrioid (A2780 wt and A2780 cis) OC cells. EV characterization was performed using nanoparticle tracking analysis, and EVs were fluorescently labeled with Vybrant DiD for uptake studies. Endocytosis inhibitors were employed to identify dominant uptake pathways.
Results: In the serous subtype, ChemoRC-EVs exhibited higher tropism towards SKOV3 cis cells, with significant uptake also observed in SKOV3 wt cells. In SKOV3 wt cells, uptake inhibition by dynasore, nystatin, and NAV2729 revealed the predominant involvement of clathrin-mediated, caveolin-mediated, and receptor-mediated pathways. In SKOV3 cis cells, dynasore and NAV2729 confirmed clathrin- and caveolin-mediated endocytosis as the primary uptake mechanisms, with minimal receptor-mediated involvement. Interestingly, SKOV3 wt cells internalized more ChemoRC-EVs than SensC-EVs, potentially contributing to chemoresistance. In the endometrioid subtype, A2780 wt cells demonstrated higher tropism for SensC-EVs compared to ChemoRC-EVs, while A2780 cis cells exhibited similar uptake levels for both types. Uptake inhibition with dynasore and nystatin highlighted clathrin- and caveolin-mediated mechanisms in A2780 wt cells, whereas nystatin indicated caveolin-mediated uptake as the predominant pathway in A2780 cis cells.
These findings suggest that EV uptake mechanisms, and their tropism, vary by OC subtype, resistance status, and EV source. Generally, sensitive cells internalized more ChemoRC-EVs, implicating a potential role in the transfer of resistance traits. Future work will engineer EVs to deliver anticancer agents into OC cells, leveraging their tropism and uptake pathways to overcome chemoresistance. This approach could transform EVs from mediators of resistance into therapeutic vehicles, offering innovative strategies to combat ovarian cancer and improve outcomes.

#6564 Conversion of fibroblasts into Cancer-associated-fibroblasts (CAF) by small extracellular vesicles from EGFR mutated adenocarcinoma: Implication of SDC1 in the establishment of the lung premetastatic niche.

A. Jouida, C. McCarthy, M. P. Keane;
UCD Conway Institute of Biomolecular & Biomedical Research, Dublin, Ireland

Evidence across several cancer types supports the existence of metastasis-supportive microenvironments, called the premetastatic niche (PMN) which form at sites of future metastasis, allowing the colonization and growth of disseminated tumour cells. Extracellular vesicles (EVs) contribute to the establishment of a favourable microenvironment by the development of those niches. EVs and their contents have emerged as a potential source of information on tumour detection and regulatory drivers of tumour progression and metastasis. Recently, we have demonstrated that EVs are mediators of EMT and tumour invasion. We reported that EVs derived from serum of patients with EGFR mutated non-small cell lung cancer (NSCLC) mediates the activation of the PI3K/AKT/mTOR pathway and induce an invasion in epithelial cells through the up-regulation of MMP-9 by promoting partial EMT. This study aims to investigate the impact of EVs on fibroblasts, another key component of the PMN. Using PCR, we observed increased expression of fibroblast activation protein (FAP), COL1a1, MMP-2, and fibronectin in human lung fibroblasts treated with EVs derived from the EGFR-mutated cell line HCC827. Functional assays revealed that these EV-treated fibroblasts exhibited enhanced invasive and migratory abilities, as shown through a modified Boyden chamber assay and a wound healing assay. We also showed that the knock-out of SDC-1 prevents the activation of fibroblast by sEVs. Additionally, in an indirect co-culture system, epithelial cells exposed to EVs were capable of activating and recruiting fibroblasts. Our results suggest that EVs derived from EGFR-mutated adenocarcinoma serum could be a potential contributor to the establishment of a favourable metastatic microenvironment through the remodelling of the stroma. This may provide insights into the mechanisms of lung cancer progression and metastasis. However, additional studies are required to precisely delineate these mechanisms.

#6565 *In-vitro* assessment of the effect of peri-pancreatic adipose tissue derived extracellular vesicles on the tumorigenicity of pancreatic cancer.

A. Arora, V. Sharma, R. Gupta, S. Bhattacharya, S. Pattanaik, A. Aggarwal;
Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: Pancreatic cancer (PC) is an aggressive malignancy marked by highinvasiveness, metastasis, and resistance to chemotherapy, presenting a significant global healthchallenge. Visceral obesity has been identified as key risk factors of PC. Significant progresshas been made in understanding the relation between visceral obesity and PC, particularly incontext of pro-inflammatory cytokines and adipokines secreted by surrounding adipose tissue.However, various aspects mediating this relationship remain unclear. Recent studiesilluminated the multifaceted role of extracellular vesicles (EVs) as key communicatorsregulating physiological and pathological processes. Despite their recognised significance, nostudy has yet unveiled the specific contribution of peri-pancreatic adipose tissue (PAT) derivedEVs in driving pancreatic tumorigenesis. The aim of this study is to assess the tumorigenicpotential of PAT-EVs in PC.
Methods: The peri-pancreatic adipose tissue was collected from patients undergoing pancreatictumor surgical resection followed by EVs isolation via differential ultracentrifugation andcharacterization using DLS, TEM, Western blot and flow cytometry following MISEV 2023guidelines. Subsequently, the tumorigenic effect of PAT-EVs were determined by treatingPANC-1 cells (pancreatic cancer cell line) with PAT-EVs. The effect on proliferative potentialwas assessed by Colony formation and BrdU assay, while migration potential by Scratch assay. Further, effect on stemness, ECM modulation, EMT and chemoresistance was assessed viaqRT-PCR and western-blot.
Results: The size (50-1000 nm), morphology (round and bilayer) and specific proteins (CD63,CD9, TSG101, Flotilin-1) observed through DLS, TEM, Western blot and flow cytometryrespectively confirmed the presence of EVs. Through *in-vitro* experiments, we observed asignificant increase in cell viability of PC cells with increasing EVs concentration (0, 10, 25,50, 100, 200 µg/mL). Further, we check the effect of 100 µg/mL and 200 µg/mL dose of EVson tumorigenicity of PANC-1 cells. The colony forming assay revealed that surviving fractionof PANC-1 cells increased by 34.5% and 69.13% at 100 µg/mL and 200 µg/mL doses of EVsrespectively. Additionally, the wound closure percentage increased by 62.3 % in 100 µg/mLEV treated PC cells and 74.9% in 200 µg/mL EV treated PC cells. The qRT-PCR analysisshowed an increase in fold change of markers related to stemness (Oct 4, Sox 2, Nanog); ECMmodulation (MMP 2, MMP 9); EMT (N-Cad, Vimentin); proliferation (p53, Ki67);angiogenesis (VEGF) and chemoresistance (ABCA7).
Conclusion: Our results indicate that peri-pancreatic adipose tissue enhances the tumorigenicpotential of PC cells via EVs. The evaluation of PAT-EVs cargo molecules can further elaboratethe molecular-mechanism behind the interactions between PAT and PC cells.

#6566 FTIR microscope imaging and neural network analysis reveal consistent spectral markers of cancer-associated fibroblasts in cells, plasma sEVs, and tissues.

Abhay Mishra[1], Akhilesh Mishra[2], Saroj Kumar[3]

[1]All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[2]Johns Hopkins University, Baltimore, MD,[3]Biophysics, All India Institute of Medical Sciences, New Delhi, India

Background: Cancer-associated fibroblasts (CAFs) are pivotal contributors to tumor progression, influencing tumor biology through interactions within the tumor microenvironment. Distinguishing CAFs from normal fibroblasts is essential for understanding their molecular mechanisms and identifying relevant biomarkers. This study utilized Fourier-transform infrared (FTIR) microscope imaging spectra and neural networks (NNs) to classify CAFs and normal fibroblasts and explored the consistency of identified spectral markers across blood plasma small extracellular vesicles (sEVs) and tissue samples.
Methods: FTIR spectra from CAFs and normal fibroblasts were preprocessed using normalization and baseline correction. A feed-forward NN model was developed, employing regularization techniques to reduce overfitting. Model performance was evaluated using 10-fold cross-validation, with metrics including accuracy, area under the curve (AUC), sensitivity, and specificity. NN-based sensitivity analysis identified key infrared (IR) spectral regions for classification. Comparative FTIR analysis of blood plasma sEVs and tissue samples was conducted to assess the reproducibility of identified spectral markers.
Results: The NN model demonstrated high classification performance, achieving 92% accuracy, an AUC of 0.89, and robust sensitivity and specificity metrics. Sensitivity analysis highlighted significant IR spectral regions, including
Amide I and Amide II (proteins): Indicative of changes in protein structure and extracellular matrix remodeling.
Lipid Regions: Reflecting altered lipid metabolism, critical for membrane dynamics and signaling in CAFs.
Nucleic Acid-Associated Regions: Suggesting transcriptional and epigenetic modifications linked to fibroblast activation.
Notably, similar spectral markers were observed in FTIR analysis of blood plasma sEVs and tissue samples, revealing a consistent pattern associated with CAFs. This suggests systemic changes in the tumor microenvironment that are detectable across different biological matrices.
Conclusion: This study highlights the potential of NN-based FTIR spectral analysis as a robust and versatile tool for identifying biomarkers of CAFs. The reproducibility of key spectral markers in blood plasma sEVs and tissue samples underscores the translational potential of this approach for cancer diagnostics and therapeutic targeting of the tumor microenvironment.

#6567 Metabolic reprogramming of pentose phosphate pathway mediated by small extracellular vesicles facilitates tumor metastasis and drug resistance in HCC.

Xiaoxin Zhang, Zhixian Chen, Jiaqi Lai, Judy Wai Ping Yam

The University of Hong Kong, Hong Kong, Hong Kong

Emerging evidence have proved that the interplay between tumor and its microenvironment facilitate tumor metastasis, including the hepatocellular carcinoma (HCC). Therefore, identifying novel target for HCC metastasis and is essential to improve the survival. In recent years, extracellular vesicles (EV) mediated metabolic regulation has been a growing interest in cancer metabolism. For instance, the ectosomal pyruvate kinase M2 isoform (PKM2) was found to facilitate glycolysis reprogramming in monocyte-to-macrophage differentiation and tumor microenvironment remodeling. Compared to directly receiving metabolite or substance from the EV, we proposed that the tumor cells are more likely to obtain proteomics alteration to exert long-term metabolic reprogramming. EVs were extracted from the metastatic and non-metastatic HCC cells. The DEPs were identified by LC-MS/MS. Meanwhile, the metabolomic screening will also be conducted to clarify the differences of metabolite which the HCC cells produced after the treatment of sEVs which derived from metastatic and non-metastatic HCC cell. The expression of G6PD was knockdown by shRNA. The plate cloning and transwell assays were conducted to evaluate the effect of G6PD on the metastasis. Besides, parallel validation of G6PD inhibitors was performed. The expression of gene was validated by real-time PCR. The MTT assay was conducted to test IC50 of sorafenib resistance HCC cells. Western blot was performed to measure expression of different proteins. Our study found that key enzyme involved in pentose phosphate pathway (PPP) was extremely enriched in metastatic HCC derived small extracellular vesicles (sEVs). Inhibition the enzymic activity of sEVs-derived G6PD significantly reduce the invasion and metastasis of HCC tumor cells. Besides, the sEV-G6PD was associated with activation of cancer-associated fibroblast. Moreover, sEV derived PPP enzymes enhanced sorafenib resistance. In conclusion, PPP enzymes derived from sEV in metastatic HCC cells promotes tumor metastasis and sorafenib resistance.

#6568 Extracellular vesicles containing circular RNAs derived from cancer-associated fibroblasts enhance adhesion and tumor formation of gastric cancer cells in the peritoneal tissues.

Yulim Lee, Hoon Hur, In-Hye Ham

Ajou University, Yeongtong-gu, Suwon-si, Gyeonggi-do, Korea, Republic of

Purpose: The poor prognosis of gastric cancer (GC) patients is strongly associated with peritoneal recurrence. Clinically, a high level of cancer-associated fibroblast (CAF) accumulation correlates with an increased risk of peritoneal recurrence after gastric cancer resection. This observation suggested that CAFs may establish metastatic niches in peritoneal tissues, distant from the primary GC. Extracellular vesicles (EVs) have been identified as key transporter for stable communication between donor and recipient cells, even over long distances. Taken together, CAF-derived EV may play a crucial role in creating a metastatic precondition at the mesothelial cells lining the peritoneal tissue. Understanding the mechanisms underlying this process may provide new insight into therapeutic strategies for preventing peritoneal recurrence in GC patients.
Methods: We collected formalin-fixed paraffin-embedded (FFPE) primary GC tissues from the patients who developed peritoneal recurrence (PR group, n=5), and patients without recurrence during follow-up (Non-PR group, n=5). CAF accumulation was assessed using Mason's trichrome staining, and circular RNA (circRNA) arrays were performed on those tissues. The expression of candidate circRNAs in cell lysates and EVs from various GC cell lines and non-cancerous cells including CAFs using qRT-PCR. The effect of CAF-derived EVs on the adhesion between mesothelial cells and cancer cells was evaluated via adhesion assay. Furthermore, CAF culture media and cancer cells were injected into the mouse peritoneum to assess the number of tumor nodules formed.
Results: We observed that CAFs are more significantly accumulate in GC tissues of the PR group compared to the Non-PR group. Six circRNAs were identified as being more abundant in the PR group based on the circRNA array. Among those, that circTSSC2, circALG1, and circALG1L2 were more abundant in CAF cell lysate and CAF-derived EVs compared to GC cells, mesothelial cells, and other immune cells. The resistance to treatments with actinomycin D and RNAse R and the Sanger's sequencing confirmed the circular structure of those RNAs. CAF-derived EVs were shown to enhance adhesion between mesothelial cells and cancer cells in our experimental models. Additionally, CAF-conditioned media significantly increased the number of tumor nodules formed in the mouse peritoneum.
Conclusions: This study suggests that the EVs including specific circRNAs, secreted by CAFs accumulated in primary GC tissues, may contribute to the formation of a pre-metastatic niche in peritoneal tissues of GC patients. Those CAFs-derived EVs could serve as predictive markers for peritoneal recurrence after GC resection and as therapeutic targets to mitigate the risk of peritoneal metastatic recurrence.

#6569 Extracellular vesicle delivery of functional extrachromosomal DNA in FGFR2-amplified cancer of unknown primary.

I. Salamon[1], G. Gallerani[2], G. Storci[1], B. Fontana[2], S. Serravalle[1], F. Valle[3], M. Brucale[3], M. Pagano Mariano[2], A. Cavazzoni[4], R. Roncarati[3], S. Santi[3], M. Bonafe[2], **M. Ferracin**[2];
[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Bologna, Italy, [2]University of Bologna, Bologna, Italy, [3]National Research Council, Bologna, Italy, [4]University of Parma, Parma, Italy

The extracellular vesicle (EV) route is essential for cell-to-cell communication. Cancer cells release EVs in the extracellular space, where they can interact with cancer and non-cancer cells, activating specific signaling pathways, modulating tumor microenvironment remodeling and inducing gene expression alterations. We investigated the functional role of EVs released by cancer of unknown primary (CUP), a rare disease (1-3% of novel cancer diagnoses) that presents with metastasis of unknown or uncertain origin and no apparent primary tumor. We derived three CUP cell lines from patient's tumor cells, CUP#55A and S and CUP#96, both characterized by *FGFR2* gene amplification, either in the form of trisomy (CUP#55A), chromosomal homogeneously staining region (CUP#55S) or double minute chromosomes (CUP#96). It has been recently recognized that tumors use extrachromosomal circular DNA (eccDNA) as a way to increase oncogenic amplification, thus conferring resistance to therapy and contributing to a worse survival. We demonstrated that *FGFR2* amplification in CUP cell lines is associated with ecDNA generation and that this ecDNA is loaded as cargo inside EVs and exert a functional activity in nearby cells. The full-length *FGFR2* DNA was detectable inside both small and large vesicles isolated from cell culture medium and we confirmed the circular nature of a fraction of this *FGFR2* ecDNA using DNAse based strategies and visualizing DNA circles in cells and in EVs with atomic force microscopy. The protein surface profile of small and large EV populations revealed the presence of cancer related molecules that mirrored the cells of origin, including EpCAM and CD44, and variable degrees of FGFR2pos EVs. Cancer (NCI-N87) and non-cancer cell exposure (THP1 and HUVEC) to CUP EVs (by direct administration and co-culture) revealed an increase of *FGFR2* DNA copies at 24 hours and its functional transcription in *FGFR2* mRNA after 48 hours in all exposed cells. In addition to oncogenic delivery, CUP#96 EVs induced a polarization of THP1 cells towards M2 subtype, while CUP#55S EVs exerted a proliferative effect on HUVEC. In conclusion, we identified a model of oncogene amplification and EV-mediated delivery recurrent in cancer of unknown primary, whose DNA content was demonstrated to be functionally active in recipient cells and proportional with extrachromosomal DNA generation. This mechanism could contribute to the high metastatic potential of this cancer type. (The research leading to these results has received funding from AIRC under IG 2021 - ID. 25789 project - P.I. Ferracin Manuela)

#6570 Characterization of diverse extracellular nanoparticles and tumorigenic relevance in hepatocellular carcinoma.

Jiaqi Lai[1], Cherlie Lot Sum Yeung[1], Cui Le[1], Lavisha Korani[1], Tung Him Ng[1], Xiaoxin Zhang[1], Zhixian Chen[1], Ruiqi Ma[1], Chi Ming Che[2], Judy Wai Ping Yam[1]

[1]Department of Pathology, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong,[2]Department of Chemistry, Faculty of Science, The University of Hong Kong, Hong Kong, Hong Kong

Introduction: Tumor-derived extracellular nanoparticles termed exomeres (EM), distinct to small extracellular vesicles (sEV), act as critical mediators of the tumor microenvironment (TME) formation and are associated with tumor progression and therapy resistance in hepatocellular carcinoma (HCC).
Methods: sEV and EM were isolated from various normal and cancer cell lines using serial ultracentrifugation. The physical and biomedical characterization of EM versus sEV was conducted through transmission electron microscopy (TEM) and mass spectrometry (MS) analysis. Potential molecular EM markers were identified based on the distinct proteomic profiles between sEV and EM. The tumorigenic potentials of HCC-EM were evaluated using *in vitro* functional assays and *in vivo* mice models. Relevant oncogenic mechanisms were studied according to the differential cargo contents of HCC- and normal-EM, as well as differential gene expression of the recipient cells by RNA sequencing. The effects of EM on cell cycle progression and metabolic dysregulation were investigated by flow cytometry and analytical metabolomic/lipidomic approaches.
Results: The TEM and MS analysis demonstrated distinct morphological and protein differences between sEV and EM. GALNS and MAN2B1 were two proteins identified as potential EM markers, showing exclusive or significantly higher expression. Functionally, EM released from HCC cells, instead of normal hepatocytes, stimulated cell growth, motility and tumor development. The EM originated from human HCC cells exhibited increased WNT5A, LRP5, and LRP6 levels, activating the PI3K/AKT/mTOR pathway in recipient cells. In addition, EM derived from murine HCC cells were shown to accelerate cell cycle progression by shifting cells through the checkpoint into the G1 phase, and reconstitute the lipid pattern to be enriched with a very-long chained saturated fatty acid, which triggers the metabolic reprogramming.
Conclusions: Collectively, our findings underscore the unique characteristics of EM as a nanoparticle subpopulation that differs from sEV, and that EM derived from HCC can play a significant role in tumorigenesis and metastasis.

#6571 Natural killer cell-derived exosomes encapsulated with IL-12 as nanocarriers for cancer immunotherapy.

Monu Pandey, Vidit Gaur, Jayanta Bhattacharyya

Centre For Biomedical Engineering, Indian Institute of Technology Delhi (IIT Delhi), New Delhi, India

Cold tumors, owing to poor immune cell infiltration, immunosuppressive tumor microenvironment (TME) and low immunogenicity, are marked as a therapeutic challenge in cancer. Immunomodulatory cytokines showed encouraging outcomes in clinical settings by converting TME more immunoresponsive. Among the cytokines, IL-12 has drawn attention for its role in bridging innate and adaptive immunity, by inducing the proliferation and activation of NK and T cells. IL-12 enhances antigen-specific cell-mediated immunity by promoting Th1 immunity that in turn boosts IFN-γ production and inhibits angiogenesis. It also drives M2 to M1 macrophage polarization, enhances the infiltration of tumor-targeting immune cells, and depletes immunosuppressive cells. This action is critical in converting "cold" into "hot" tumors, making them more susceptible to immunotherapy. Additionally, IL-12 has a short plasma half-life and shows systemic toxicity which limits its use in clinical settings. We aim to deliver IL-12 encapsulating inside NK cell derived nanovesicle (NKnvs) which will bring many attributes- small size of NKnvs will facilitate better tumor accumulation, encapsulation will enhance the plasma half-life of IL-12, slow release of payload will-lower the dose-limiting systemic toxicity, NKnvs will carry cytotoxic proteins, miRNAs, and cytokines with tumor-killing and immunomodulatory properties. NKnvs was isolated by differential ultracentrifugation method, the purity of the isolated NKnvs was determined by Western blot. NTA, DLS and SEM was performed to determine the concentration, size and morphology of NKnvs. Next, IL-12 was encapsulated inside NKnvs by probe sonication method and the loading percentage was quantified by ELISA. To visualise the accumulation of NKnvs in different tissues and to determine the plasma half-life, NKnvs was labelled with DiI dye and purified by size exclusion chromatography. NKnvs showed the hydrodynamic radius and zeta potential of 189±20.61 nm and -10.5±10.1 mV respectively. SEM confirmed the spherical morphology of NKnvs. Loading percentage of IL-12 inside NKnvs was found 20.5±0.5 %. NKnvs induced activation and polarization of immune cells, enhancing tumor cell killing. Pharmacokinetic analysis indicated that NKnvs extended the half-life of the payload. The biodistribution study revealed that DiI labelled NKnvs showed enhanced tumor accumulation which also increased till 48 hrs. In conclusion, the developed nanoformulation offers a promising strategy to target the tumor microenvironment, improving therapeutic efficacy and reducing systemic toxicity. Further, the efficacy of immunovesicle (IL-12 NKnvs) can be explored *in-vivo* to determine the further therapeutic benefits associated with the developed nanoformulation.

#6572 High-frequency irreversible electroporation (H-FIRE) enhances extracellular vesicle release and promotes immune system interaction in cancer treatment.

David Ogburn[1], Irving Allen[2], Nikolaos Dervisis[3]

[1]Virginia Tech Carilion School of Medicine, Roanoke, VA,[2]VA-MD College of Veterinary Medicine, Blacksburg, VA,[3]Veterinary Clinical Science, Purdue University College of Veterinary Medicine, West Lafayette, IN

Background: High-Frequency Irreversible Electroporation (H-FIRE) is a non-thermal tissue ablation technique that induces cell death by destabilizing the cell membrane. This innovative approach has demonstrated significant potential in cancer treatment and has been associated with modulation of the tumor microenvironment in both in vivo and in vitro settings. Recent findings from our lab reveal that extracellular vesicles (EVs) released by cells lethally treated with H-FIRE exhibit a unique proteomic profile. These EVs may play a pivotal role in modulating the tumor microenvironment. Building on our preliminary experiments, we hypothesize that EVs released following H-FIRE-mediated tumor ablation actively engage with and influence the immune system.
Methods: Established carcinoma cell lines of breast (4T1) and exocrine pancreas (PanO2) were used. Cells will be treated with sham, sublethal H-FIRE (1500V), and lethal H-FIRE (3000V). The supernatant of the treated cells was collected and EVs were isolated by ultracentrifugation. EVs were then assessed quantitatively via Nanosight. Mouse monocytes (J774a) were then exposed to EVs and evaluated for extracellular vesicle uptake via confocal imaging and evaluation of mean fluorescence intensity.
Results: In quantitative analysis of the EVs from each treatment group, we found a significantly increased number of EVs present within the supernatant of lethally treated cells, in comparison to both the untreated and sublethal treatment groups (4T1 - sham 1.52e11/mL, sublethal 6.89e10/mL, lethal 3.25e11/mL, $p<.0001$ between all groups) (PanO2 - sham 2.18e11/mL, sublethal 1.1e11/mL, lethal 1.34e12/mL, $p<.0001$ when comparing lethal group to other groups). No significant difference in particle size was observed between the treatment groups. J774a macrophages were exposed to TDEVs from each of the treatment groups, and confocal imaging and evaluation of mean fluorescence intensity showed a qualitative and quantitative increase in macrophage uptake of TDEVs from both the lethal and sublethal groups relative to uptake of TDEVs from the sham group. Using TDEV from the 4T1 cell line, average mean intensity was increased in macrophages exposed to EVs from the lethal and sublethal groups relative to those from the sham group (lethal 2.50, sublethal 2.32, sham 2.04, $p<0.0001$ between sham and both treatment groups).
Conclusion: Our study demonstrates that lethal treatment of carcinoma cells with H-FIRE results in a significant increase in extracellular vesicle (EV) release. Furthermore, we provide evidence that EVs derived from H-FIRE-treated cells exhibit enhanced uptake by macrophages. These findings are in support our working hypothesis that H-FIRE exerts some of its effects in cancer immune system modulation through EV release.

#6573 Real-time precision analysis of exosome treatment in cancer immunodynamics using intravital microscopy.

Hyunseok Kim, Hyungjin Kwon, Jenny Junghyon Ohm, Junyoung Park, Sungwoon Yoon, Kubra Akyildiz, Hsuan-Ju Chen

Technical Application Solution, IVIM Technology, Daejeon, Korea, Republic of

Exosomes play a crucial role in cancer therapy, actively engaging in stimulating the tumor microenvironment and recruiting immune cells, as demonstrated by numerous studies. In exosome-based cancer therapy, precision diagnosis of immune mechanisms utilizes technologies such as X-ray, PET, CT, MRI, and bioluminescence analysis. However, further research is needed to fully understand the impact of exosomes on cancer development and suppression. Particularly, the potential functions of exosomes in cancer immunotherapy and drug delivery have garnered significant attention. Therefore, novel precision analysis methods are essential to further advance these well-established functions in cancer therapy. This is because exosomes play a vital role in critical steps of cancer cell therapy, such as efficient trafficking in cancer metabolism, navigation through the tumor microenvironment, entry into the vasculature, and resumption of inhibitory processes.To address these needs, we conducted a study utilizing exosomes in a brain cancer cell xenograft mouse model and analyzed cancer metabolism treated with exosomes using intravital microscopy (IVM), comparing it with a bioluminescence system. First, exosome fluorescence signals in the xenograft mouse model were screened using the IVIS system. Subsequently, intravital microscopy was performed on the same mouse model to track the trafficking of the exosome fluorescence signals.As a result, IVM demonstrated more detailed and precise expression of exosome fluorescence signals in the xenograft mouse model compared to the IVIS system, which also revealed macrophage activity in the same region. While the IVIS system displayed fluorescence signals as contour-like patterns, IVM provided significantly more detailed and meaningful signals, especially in terms of efficacy, based on the morphology of blood vessels observed in the in vivo mouse model. Furthermore, IVM revealed how interactions between exosomes and cancer cells manifest as phenotypic signals. This indicates that exosome activation is expressed not only at the site of cancer cell accumulation in the brain but also directly at the cancer cell site. Such detailed observations are achievable only with the IVM system, as the IVIS system is insufficient to monitor these intricacies in the xenograft model.These findings suggest that IVM systems are likely to align with the trends in new drug development and regulatory guidelines from institutions such as the FDA, EMA, and TGA. Additionally, the efficiency and functionality of exosomes are best expressed and validated through intravital microscopy, demonstrating its potential as an essential precision analysis method.

#6574 Plant-derived vesicles as potential therapy for neuroendocrine prostate cancer.

Sharanjot Saini, Amritha Sreekumar

Augusta University, Augusta, GA

Background: Neuroendocrine prostate cancer (NEPC) is a highly aggressive lethal variant of prostate cancer (PCa) with extremely poor survival times (<1 year). Clinical management of NEPC is currently challenging as there are limited treatment options for these patients. These patients are treated with platinum-based chemotherapy that is associated with toxicity and relapses. This emphasizes the need for newer, more effective therapeutic interventions against this challenging disease. The overall objective of this study was to develop an effective, non-toxic, cheap yet scalable extracellular vesicle (EV)/nanovesicle-based therapeutic intervention against NEPC.
Methods: We isolated intact nanovesicles from pomegranate juice, referred to as POM-EVs, using a combination of ultracentrifugation and filtration. Vesicles were characterized by Nanosight Tracking Analyses and Electron Microscopy. Further, we examined the therapeutic potential of POM-EVs in a panel of prostate cell lines in vitro. Prostate cancer cell lines were treated with POM-EVs for 7 days followed by assessment of cellular proliferation, apoptosis, RNA analyses and Western blot analyses. To understand the mechanistic basis of POM-EV induced alterations in NCI-H660 cells, we performed next generation RNA sequencing in control vs POM-EV treated NCI-H660 cells on Illumina HiSeq platform. To examine the effect of POM-EVs in NEPC, we established LuCaP 145.1 tumors in FOX-Chase SCID mice. Once established, animals were divided into two groups: Control and Test (n=5/group). Test mice were administered POM-EVs via tail vein twice a week. Controls included xenografts treated with PBS. Tumor volumes were measured regularly. Further, studies were conducted to assess active moieties of POM-EVs with therapeutic activity in NEPC.
Results: POM-EVs led to a significant reduction in viability of neuroendocrine cell lines, NCI-H660 and LASCPC-01 as assessed by MTT assay. We further performed apoptosis assay that showed that POM EV treatment led to a significant increase in apoptotic populations. POM-EV treated mice showed significant regression of LuCaP145.1 tumors. Sequencing studies identified that genes involved in ECM-receptor interaction, focal adhesion, proteoglycans in cancer and small cell lung cancer genes were significantly impacted by treatment with POM-EVs. Remarkably, POM-EVs led to significantly attenuated levels of key proneural/neuronal transcription factors.
Conclusions: Systemic administration of POM-EVs can be employed as a novel treatment modality in neuroendocrine prostate cancer.

#6575 Overexpression of fatty acidy synthase increases exosomes secretion in colorectal cancer.

Josiane Weber Tessmann, Yekaterina Zaytseva

Department of Toxicology and Cancer Biology, University of Kentucky, Lexignton, KY

More than 50% of colorectal cancer (CRC) patients develop metastases, with the liver being the most common site of metastasis. Fatty acid synthase (FASN), a key enzyme of de novo lipid synthesis, is overexpressed and strongly associated with metastasis and poor prognosis in CRC. FASN catalyzes the biosynthesis of palmitate, an essential component of structural lipids. Exosomes are composed of a lipid bilayer membrane and carry a wide range of bioactive molecules. Tumor-derived exosomes play a critical role in establishing a pre-metastatic niche (PMN) to support metastasis. Hepatic stellate cells (HSCs) can be activated by tumor signals and transformed to cancer-associated fibroblast, thus, contributing to PMN formation. However, the mechanisms by which exosomes promote HSCs activation and their subsequent contribution to PMN formation during CRC liver metastasis are not fully understood. Therefore, this study aims to investigate the contribution of FASN in exosomes formation, release, and HSCs activation in CRC. To delineate the role of FASN in exosomes formation, FASN-knockdown (FASN KD), FASN-overexpression (FASN OE), and pharmacological inhibition of FASN in CRC cells were utilized. Cells were cultured in media containing exosome-free FBS for 48h. Exosomes were isolated from cell culture media using ultracentrifugation. The concentration and size of exosomes were measured using nanoparticle tracking analysis. Exosomes markers were assessed using western blot. To investigate the functional impact of CRC-derived exosomes, HSCs LX-2 was used. The purity of isolated exosomes was confirmed by assessing the expression of CD9, Alix, TSG101, and syntenin. Secretion of exosomes by FASN-KD cells ($Exo^{FASN\text{-}KD}$) and by cells treated with FASN inhibitors was significantly reduced as compared to control cells. Moreover, FASN expression was decreased in $Exo^{FASN\text{-}KD}$. In contrast, secretion of exosomes by FASN-OE cells ($Exo^{FASN\text{-}OE}$) was significantly increased as compared to control cells. Consistently, we observed an increase in expression of FASN in $Exo^{FASN\text{-}OE}$. To test if FASN expression in CRC cells affects the ability of secreted exosomes to activate HSCs, LX-2 cells were incubated with exosomes from control and FASN-KD CRC cells. We found that the exposure to exosomes from control CRC cells leads to robust activation of LX-2 cells as determined by FAP and α-SMA expression; however, the level of LX-2 activation was significantly reduced when cells were exposed to $Exo^{FASN\text{-}KD}$. In summary, our data suggests that FASN promotes exosomes secretion in CRC. Importantly, the association between the level of FASN expression in CRC cells and activation of LX-2 cells by secreted exosomes suggests a potential role for FASN in PMN formation. Further studies are needed to elucidate the functional importance of FASN in PMN formation via exosomes secretion in CRC.

#6576 Exploring the role of circulating extracellular vesicles in chemotherapy resistance and cachexia in advanced pancreatic cancer.

Shatovisha Dey, Tammy Lo, Alpana Dholakia, Julianna Cuateco, Sabina Swierczek, Richard C. Frank

Nuvance Health, Danbury, CT

Advanced-stage pancreatic (ductal adenocarcinoma) cancer (APC) is an incurable malignancy with an average survival of less than a year. Although combination chemotherapy (FOLFIRINOX, gemcitabine/nab-paclitaxel, liposomal irinotecan-based) regimens offer improved survival compared with single agent gemcitabine, chemotherapy resistance (CR) and cancer cachexia (CC) are universal phenomena near the end of life. CC is an inflammatory process marked by anorexia and weight loss, muscle wasting (sarcopenia), fat depletion (adipopenia) and profound fatigue. CR leads to the uncontrolled growth of tumor cells that accelerates CC. Both processes are thought to be reflected in and in part mediated by circulating extracellular vesicles (EVs), which contain molecular cargo from their tissues of origin. Given the lack of tumor biopsies performed during the treatment course of APC, we analyzed circulating EVs from a patient-derived, serially collected blood biobank to identify proteins that could serve as potential biomarkers of and therapeutic targets for both CR and CC.

In this study, we isolated EVs from nine patients with double- and triple-chemotherapy refractory APC from our Pancreatic Cancer Biobank. Proteomic and phospho-proteomic analyses via mass spectrometry were conducted and differential protein expressions were compared across 3 timepoints: 1. Pre-treatment; 2. Remission; and 3. Chemotherapy resistance towards the end of life. These were also compared against healthy matched controls (n=5).

Our analysis identified 269 differential proteins, with 61 unique to late relapse and 66 unique to pre-treatment, indicating their associations with CR and CC. At late-relapse, 16 proteins were downregulated and 16 were upregulated ($log2FC>1$, $p<0.05$). Top downregulated proteins included RAPGEF1, PPP1CA, LUZP2, PIGG, and NAMPT, while the most upregulated proteins were WNT9B, GFAP, POLK, ADGRB3, and MYH8. Several of these proteins are associated with the Wnt signaling pathway, known to influence cachexia. Phosphoproteomic analysis identified 15 uniquely phosphorylated proteins at relapse, including BRD7 and UBR2, also implicated in Wnt signaling.

This is the first study to longitudinally track proteomic changes in circulating EVs from stage IV, chemotherapy-refractory PC patients, providing a unique perspective on CR and CC. Ongoing validation of these results in additional patient samples, coupled with in-vitro studies exploring the functional and mechanistic roles of these proteins in CR and CC offer the potential to disrupt pancreatic cancer progression and its devastating consequence of cancer cachexia.

#6577 ST6GAL1^{+} exosomes confer treatment resistance in rectal cancer.

J. M. P. Lever, R. Irwin, V. Somasundaram, M. Stiles, M. C. McLeod, K. Hardiman;
University of Alabama at Birmingham, Birmingham, AL

Rectal cancer (RC) is a highly morbid and fatal disease. Locally advanced RC is treated with neoadjuvant chemoradiation. Patients with a complete pathologic response have improved outcomes compared with those with incomplete response and may be able to avoid surgical resection. Among incomplete responders, we have found that there is increased tumor ST6GAL1 protein, which is a glycosyltransferase that adds alpha 2,6-sialic acid to N-glycans. Through knockdown (KD) studies, we have shown that ST6GAL1 causes chemoradiation treatment resistance in RC. Exosomes are small particles that can be transferred between cells. We hypothesized that these exosomes transfer functional ST6GAL1 thereby spreading treatment resistance and can be found in the plasma of a mouse model of RC. In order to test these hypotheses, we cultured colorectal cancer SW620 cells and isolated exosomes by ultracentrifugation from the media. Exosome yield and size were determined using a NanoSight particle analyzer and further characterized using transmission electron microscopy (TEM). Exosomes from ST6GAL1 CV cells were used to treat ST6GAL1 KD. Western blot, immunofluorescence (IF) microscopy, and flow cytometry for alpha 2,6-sialic acid by SNA lectin were utilized. Colony formation assay and cleaved caspase-3 IF staining were performed. Mice bearing a patient derived xenograft model of rectal cancer were treated with chemoradiation daily for 2 weeks (5 days on, 2 days off) and tumor and mouse plasma exosome samples were tested for ST6GAL1. We found that human colorectal cancer cells in culture produced exosomes containing ST6GAL1. These exosomes were 91.2 ± 6.8 nm in diameter and had an umbilicated appearance on TEM. When ST6GAL1 KD cells were treated with ST6GAL1^{+} exosomes, the protein was transferred to KD cells as measured by western blot. IF staining showed that transferred ST6GAL1 protein co-localized to the Golgi apparatus, where it is natively found. Additionally, exosome-treated cells became more resistant to chemoradiation-induced apoptosis and showed improved colony formation (CV 21.7 ± 4.6 colonies vs KD 12.7 ± 3.5 colonies, $p = 0.03$; KD plus exosomes 17.7 ± 3.0 colonies vs CV, $p = 0.38$). ST6GAL1 protein levels increased in tumors from a patient derived xenograft during treatment and peaked at 2 days. We further found that ST6GAL1 protein in exosomes isolated from the plasma of these mice peaked at the same time as in the tumor. In conclusion, rectal cancer exosomes carrying ST6GAL1 spread treatment resistance to previously sensitive cells and can be detected in the plasma of tumor bearing mice. Interfering in exosome-mediated sharing of ST6GAL1 is a promising and entirely novel potential therapeutic strategy for RC. These exosomes may also serve as a biomarker for identifying patients with treatment resistant rectal cancer.

#6578 Effects of the PAX3-FOXO1 fusion oncogene on secreted microvesicle-mediated priming of the pre-metastatic niche in rhabdomyosarcoma.

Yu-Lieh Lin, Monireh Asoudeh, Faiz Ahmad, Pratibha Mishra, Raya Saab

Department of Pediatrics, Stanford University School of Medicine, Stanford, CA

Fusion-positive rhabdomyosarcoma (FP-RMS) is an aggressive childhood soft tissue sarcoma, driven by the expression of a fusion oncoprotein PAX3-FOXO1. It presents with high metastatic potential, with 80% of tumors already metastatic at diagnosis, and a less than 20% cure rate with current available treatment. Paracrine and distant signaling, including via small secreted extracellular microvesicles including exosomes (sEVs), play a critical role in priming the pre-metastatic niche and enhancing tumor metastasis, but their role in FP-RMS, and specifically relating to fusion oncoprotein signaling, has not been studied. In this study, we aim to investigate the role of sEVs in mediating the effects of PAX3-FOXO1 signaling on the tumor microenvironment at the pre-metastatic niche, hypothesized to promote FP-RMS invasion and metastasis. We use the mouse myoblasts C2C12 model, with expression of the fusion oncogene *PAX3-FOXO1*. sEVs are extracted by serial ultracentrifugation and verified by size analysis and western blotting. We utilize *in vitro* cell culture studies as well as immunocompetent mouse models for tail vein injections to study effect of sEVs on the lung tumor microenvironment. We show that sEVs play a key role in enhancing cell migration and invasion of recipient stromal cells by comparing their effects on fibroblasts using treatment with 1) conditioned medium; 2) sEVs extracted from conditioned medium; and 3) an sEV-depleted fraction of the conditioned medium, all derived from PAX3-FOXO1-expressing cells versus controls. Furthermore, through RNA sequencing, we analyze the transcriptome of recipient fibroblasts treated with sEVs derived from PAX3-FOXO1-expressing cells versus those derived from cells expressing empty-vector control and identify signaling pathways differentially influenced by oncogene-modulated sEVs. *In vivo*, we found that sEVs were predominantly taken up by alveolar macrophages in the lung, in addition to other cells. Immunofluorescence staining further revealed that the populations of macrophages and cancer-associated fibroblasts were increased in the lungs of mice receiving sEVs derived from PAX3-FOXO1-expressing cells, as compared to those receiving sEVs from control cells. Ongoing work is focused on dissecting the proteomic and molecular signaling affected by PAX3-FOXO1-modulated sEVs on both fibroblast and immune cell compartments. In conclusion, this study reports that PAX3-FOXO alters the microenvironment of the distant pre-metastatic niche through sEV-mediated distant signaling. Ongoing investigations will provide deeper insights into the mechanisms underlying tumor metastasis in FP-RMS, potentially identifying novel therapeutic molecular targets to address current treatment gaps.

#6579 Elucidating glioblastoma-derived extracellular vesicle cargo using TurboID: Implications for tumor microenvironment adaptation.

M. Russo, E. Norton-Ramos, M. Ulloa Navas, A. Quinones-Hinojosa, H. Guerrero-Cazares;
Mayo Clinic Florida, Jacksonville, FL

Glioblastoma (GBM), the most aggressive primary brain tumor in adults, presents significant challenges due to its universal recurrence and limited survival rates, exacerbated when proximal to the lateral ventricles (LV). The subpopulation of brain tumor-initiating cells (BTICs) plays a pivotal role in tumor initiation and invasiveness, interacting with the microenvironment, particularly the cellular components in the subventricular zone (SVZ). Some mechanisms of intercellular communication present in the SVZ include paracrine, autocrine, direct cell contact, gap junctions, nanotubes, and more recently extracellular vesicles (EVs). EVs are membrane-bound particles released by cells that are central to intercellular communication. They have the ability to carry bioactive proteins, RNA, and other molecules that influence recipient cell behavior.This study investigates the role of EVs in GBM's communication with non-cancer cells. Our findings indicate that BTIC-derived EVs promote migration and proliferation ($*p < 0.02$, $***p < 0.001$) in neural progenitor cells (NPCs) *in vitro*, highlighting the EVs' role in altering the microenvironment. To identify the protein cargo contained in GBM-derived EVs, we utilized the innovative proximity-labeling system TurboID. We successfully induced TurboID expression in primary-cultured human BTICs from GBM patients, enabling the unbiased biotinylation of proteins in EVs. We isolated biotinylated proteins from BTIC lysates and BTIC-EVs, preserving the integrity of EVs, and conducted proteomic analysis via mass spectrometry. Our method marks the first implementation of TurboID for unbiased global labeling of EV protein cargo in primary GBM cells. This approach facilitates the investigation of EV-mediated communication and potential therapeutic targets, contributing to the understanding of GBM's complex interactions with the brain's microenvironment and the identification of biomarkers for improved diagnosis and treatment response.

#6580 Impact of copy number variations on EV-miRNA profiles in ovarian cancer.

Hajime Araki, Yokoi Akira, Kosuke Yoshida, Kazuhiro Suzuki, Hironori Suzuki, Masami Kitagawa, Eri Asano-Inami, Hiroaki Kajiyama

Nagoya Univ. Graduate School of Medicine, Nagoya, Japan

[Objective] Ovarian cancer has poor prognosis due to its late diagnosis and the development of drug resistance, particularly in advanced stages. High-grade serous ovarian carcinoma (HGSOC), the most common subtype, is characterized by extensive genomic alterations, including *TP53* mutations and copy number variations (CNVs). However, the functional impact of CNVs remains largely unclear. This study aimed to investigate how CNVs influence extracellular vesicle (EV)-associated microRNA (miRNA) profiles to identify potential diagnostic biomarkers and therapeutic targets.

[Methods] Clinical and genomic data from 489 ovarian cancer patients in The Cancer Genome Atlas (TCGA) dataset were initially reviewed. From these, *TP53*-mutant cases (n=247) were selected and classified into CNV-high (n=21) and CNV-low (n=62) groups. Additionally, 23 *TP53*-mutant ovarian cancer cell lines were divided into CNV-high (n=17) and CNV-low (n=6) groups. miRNA expression profiles were compared to identify CNV-associated miRNAs. Selected miRNAs were further analyzed through prognostic assessments, tumor validation, and functional assays. Finally, in vitro assays were performed to confirm miRNA expression levels and cisplatin resistance.

[Results] Compared to the CNV-low group, patients in the CNV-high group exhibited shorter OS within 30 months. In 23 cell lines, a comparative analysis of miRNA expression profiles revealed that 7 miRNAs were significantly upregulated, while 9 were downregulated in the CNV-high group ($p < 0.05$). Among the upregulated miRNAs, miR-203a showed the highest expression levels in CNV-high cell lines and was strongly correlated with poor prognosis. Tumor tissue analysis confirmed that miR-203a expression was significantly higher in ovarian cancer tissues compared to adjacent normal tissues ($p < 0.01$), and elevated miR-203a levels were also detected in the serum of ovarian cancer patients. Furthermore, EVs isolated from *TP53*-mutant CNV-high cell lines (CAOV3, OVCAR3, RMUGS) were found to secrete miR-203a in abundance. Functional assays demonstrated that overexpression of miR-203a in these cell lines led to increased resistance to cisplatin, as evidenced by a higher IC50, particularly in the CNV-high group. Knockdown of miR-203a in CNV-high cell lines resulted in enhanced sensitivity to cisplatin and reduced cell proliferation.

[Conclusion] Elevated miR-203a expression was linked to poor prognosis and chemoresistance in ovarian cancer patients with high CNV levels. Detection of miR-203a in EVs indicates its potential as a non-invasive biomarker for early diagnosis. Targeting CNV-associated miR-203a may provide new therapeutic strategies to overcome platinum resistance in HGSOC, offering insights into molecular mechanisms and potential treatment approaches.

#6581 Evaluating the impact of the tumor microenvironment on EV-mediated intercellular exchange of nanoparticles.

Yiqin Li, Hongbo Pang

University of Minnesota, College of Pharmacy, Minneapolis, MN

The limited delivery efficacy of nanoparticles (NPs) continues to impede their clinical translation for cancer therapy. Recent studies have demonstrated that active trans-endothelial pathways dominate NP delivery. While extensive research has focused on endocytosis and subcellular transport, there remains limited understanding of how NPs undergo exocytosis and subsequently re-enter neighboring cells—a process we termed intercellular exchange. Our previous studies established a collagen-based three-dimensional assay designed to specifically quantify the intercellular exchange of NPs and distinguish the contributions of various potential mechanisms. The findings revealed that a significant portion of NPs are transferred within extracellular vesicles (EVs). By modulating EV biogenesis, we successfully altered tumor accumulation and vascular penetration of various NPs in vivo. Here, we further enhance this assay by incorporating critical tumor microenvironment (TME) factors—such as acidity, hypoxia, and the dense extracellular matrix (ECM). This improved model provides a more physiologically relevant platform to evaluate the impact of TME-specific conditions on EV-mediated NP intercellular exchange. Our findings demonstrate that different TME factors exert varying effects on NP transfer efficiency, with ongoing studies evaluating their implications for in vivo delivery. These investigations not only shed light on the mechanisms by which NPs are transported within tumors but also enhance our understanding of the role of EVs in intercellular communication under highly stressed environments.

#6582 HD-PTP modulates anti-tumor immunity via extracellular vesicles in triple-negative breast cancer.

Chenxu Guo, Sheng Sun, Nayana Thimmiah, Ilze Smidt, Shufeng Zhou, Thomas J. Kania, Taisha Joseph, Mark N. Melkonyan, Siang B. Koh, Leif W. Ellisen

Cancer Center, Massachusetts General Hospital, Boston, MA

The tumor immune microenvironment (TIME) is a critical driver for the progression of triple-negative breast cancer (TNBC), directly impacting patient prognosis and treatment response. One emerging mechanism underlying immune evasion in TNBC involves extracellular vesicles (EVs), which act as carriers of immunosuppressive factors (ISFs) that shape the immune landscape. Here, we identify HD-PTP, an ESCRT-associated protein encoded by the *PTPN23* gene, as a key regulator of EV-mediated immune modulation. Clinically, we reveal that HD-PTP loss is frequently observed in TNBC and correlates with immune cold microenvironment, as shown by reduced tumor infiltration levels of lymphocytes, poor response to immune checkpoint inhibitors, and worse overall survival. Additionally, we observe that knockdown of HD-PTP promotes systemic tumor growth only in a syngeneic, immunocompetent TNBC mouse model, but not in the matched, immunodeficient nude mice. Through proteomic profiling of the EVs purified from HD-PTP proficient and deficient cells, we find that HD-PTP downregulation dramatically changes EV protein composition and identify PD-L1 as a major ISF cargo selectively incorporated into EVs upon loss of HD-PTP. Using a co-culture assay with antigen-presenting B cells and PD-1 overexpressing T cells, we show that EVs derived from HD-PTP knockdown TNBC cells significantly reduce IL-2 secretion and impair antigen-dependent T cell activation via EV-associated PD-L1. Mechanistically, HD-PTP inhibition redirects PD-L1 from the plasma membrane to the endosomes, which increases PD-L1 co-localization with the EV marker CD63 and upregulates its subsequent release into EVs. However, blocking EV biogenesis in HD-PTP deficient cells – either by genetic knockdown of Alix or syntenin, or by pharmacological inhibition with GW4869 – reduces EV release of PD-L1, confirming that HD-PTP plays an essential role in regulating EV-associated PD-L1. Perturbation of either PD-L1 expression or EV release by Rab27A in the HD-PTP knockdown tumors abolishes the accelerated growth observed in the immunocompetent mice. Furthermore, we demonstrate that HD-PTP knockdown tumors had significantly fewer infiltrating T cells and altered macrophage polarization, while such immune exclusion was partially reversed by PD-L1 or Rab27A disruption. Collectively, our results unveil a novel tumor suppressor pathway controlling specific ISF cargos in EVs, while HD-PTP loss leads to altered EV-mediated signaling that facilitates immune suppression, remodels TIME, and fosters tumor growth, which eventually leads to inferior patient outcomes.

#6583 Optimized production, biodistribution, and targeted delivery of T cell-derived extracellular vesicles for liver cancer therapy.

Aminah Jaffery[1], Andrea C. Cortes[1], Kiyoyuki Minamiguchi[1], Simone Anfossi[2], Rony Avritscher[1]

[1]Interventional Radiology, University of Texas MD Anderson Cancer Center, Houston, TX,[2]Translational Molecular Pathology, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Extracellular vesicles (EVs) have emerged as potent mediators of physiological and pathological processes. By transporting bioactive molecules such as proteins and RNAs, EVs play a pivotal role in maintaining tissue and organ homeostasis. This unique functionality positions EVs as highly promising therapeutic agents. Notably, their ability to penetrate solid tumors and deliver targeted treatments underscores their potential in oncology. However, the preclinical use of EVs requires the development of robust and scalable production methods. This study aimed to establish standardized protocols for efficient EV production while evaluating their tissue and organ targeting capabilities, with a focus on achieving precise and efficient delivery to the liver. Furthermore, the potential application of EVs in minimally invasive interventions, such as portal vein embolization, opens new avenues for therapeutic delivery to liver tissues.
Methods: EVs were isolated from T cells derived from Buffalo rat spleens and activated with concanavalin A. After 48 hours of culture, EVs were precipitated from the cell culture supernatant. The size and concentration of the isolated EVs were assessed using NanoSight technology. EVs were labeled with IVISense 750 dye and resuspended in either a saline solution or an oil-based contrast agent. These labeled EVs were administered to tumor-bearing rats via three routes: tail vein, portal vein, and intratumoral injections. Biodistribution of the EVs in liver tissue and other organs was analyzed using in vivo and ex vivo imaging. Results: Portal vein injection of saline-suspended EVs demonstrated superior liver targeting, achieving rapid and efficient accumulation in the liver. Intratumoral injection successfully delivered EVs to localized tumor regions, while tail vein injection, despite a slight delay, also enhanced liver biodistribution. Imaging results revealed a strong tropism of EVs for tumor tissues. Interestingly, systemic administration via the tail vein resulted in reduced kidney signals, suggesting urinary clearance of EVs within 72 hours.
Conclusions: This study established a reproducible, standardized protocol for activating spleen-derived T cells, enabling large-scale production of EVs suitable for in vivo applications. The findings highlight the potential of EVs as effective delivery vehicles for therapeutic cargo, particularly for liver-targeted and tumor-specific treatments. Moreover, EV application in minimally invasive interventions, such as portal vein embolization, could further enhance targeted delivery to liver tissues. By optimizing both production and delivery methods, this research lays a foundation for advancing EV-based strategies in cancer therapy, paving the way for future clinical applications.

#6584 Slamming the breaks on extracellular vesicles that cause breast cancer.

A. R. Khaled[1], C. Dang[1], L. Truong[1], S. Laxton[1], J. Velazquez[1], S. Kankipati[2], P. Gopalan[2], S. Litherland[1];
[1]University of Central Florida, Orlando, FL, [2]Orlando VA Healthcare System, Orlando, FL

Breast cancer (BC) recurrence and metastasis are significant causes of death, mainly due to the emergence of therapy-resistant cells. Secreted factors known as extracellular vesicles (EVs), especially small EVs (SEVs) or exosomes less than 100 nanometers in size, have been implicated in the plasticity associated with drug resistance, BC recurrence, and metastasis. EVs derived from BC cells can transform local or distal non-tumor cells, induce the epithelial-to-mesenchymal transition, and trigger uncontrolled proliferation, angiogenesis, and immune suppression of tumor cells. EVs also mediate resistance to hormone therapy and chemotherapy. Given these oncogenic activities, the production of EVs by BC cells presents an attractive target for inhibition. However, the complexity of EV biogenesis and uptake hampers the effectiveness of most pharmacological inhibitors that target single or specific EV synthetic pathways. Because protein synthesis and sorting are the initial steps in the biogenesis of EVs, we inferred that protein folding is a necessary part of EV synthesis. Previous studies revealed that the protein-folding complex, Chaperonin-Containing TCP-1 (CCT), is upregulated in cancer cells to mitigate the damage from misfolded proteins that accumulate due to increased somatic gene alterations and driver mutations. Using RNA sequencing and optimized methods of EV characterization by flow cytometry and nanoparticle tracking analysis (NTA), we determined that CCT has a role in the production of EVs by BC cells. Inhibition of CCT2, the second subunit of the CCT complex, in BC cells deregulated the gene expression of critical components involved in the early stages of EV biogenesis and decreased the release of CCT2-containing EVs. The exogenous expression of CCT2 in BC cells produced small EVs (SEVs) with increased and selective loading of CCT2 RNA and protein cargo. BC cell culture media, enriched for CCT2-containing SEVs using a 0.1 micromolar filter, increased CCT production and activity in recipient cells. Exogenously expressed CCT2 in BC cells also enriched gene expression associated with extracellular exosomes (GO:0070062). Hence, CCT may be essential for the biogenesis of SEVs with transformative properties and a promising therapeutic target for inhibiting cancer-causing EVs. These studies show that CCT directly regulates components of EV biogenesis in BC cells and advances CCT as an essential driver of BC progression through the production of oncogenic EVs.

#6585 Distinct small-EV proteomic landscape mediated by annexin A2 alters recipient cell signaling in triple negative breast cancer metastasis.

Rucha Trivedi, Jamboor K. Vishwanatha

Microbiology, Immunology and Genetics, University of North Texas Health Science Ctr., Fort Worth, TX

Cancer metastasis is promoted through interactions between tumor-derived extracellular vesicles (EVs) and recipient cells in distant organs. The lungs are frequently affected as secondary organs in metastatic triple-negative breast cancer (TNBC), occurring in approximately 20-30% of cases. A membrane-associated protein, Annexin A2 (AnxA2), is significantly upregulated in TNBC tissues and EVs, leading to poor outcomes in patients. It is among the most identified EV proteins and recruits microRNAs and proteins into the EVs. Previous reports from the lab have shown a direct correlation between AnxA2 levels in small-EVs (sEVs) and metastasis in the lungs and brain *in vivo*. This study aims to examine how AnxA2 contributes to the promotion of TNBC lung metastasis mediated by sEVs. MDA-MB-4175 (LM2) lung metastatic TNBC cells were used to downregulate AnxA2 protein, and the metastatic potential was assessed through invasion, migration, and proliferation assays. Downregulation of AnxA2 significantly reduced invasive, migratory, and proliferative potential, as well as decreased plasmin-generating abilities. An optimized differential ultracentrifugation and filtration method was used to isolate sEVs, which were characterized according to MISEV2023 guidelines. sEVs obtained from conditioned cell culture media ranged in size from 30-300 nm and exhibited a distinct double membrane under cryo-electron microscopy. Biological analysis revealed that the sEVs were positive for ESCRT and heat shock proteins, as well as CD9 and CD81 tetraspanins. Following characterization, the sEVs were subjected to quantitative proteomics to assess their protein cargo. Additionally, the uptake by recipient cells and downstream signaling alterations were analyzed. A unique sEV protein landscape was observed, which differentially affected biological processes such as tumor cell viability and proliferation, and the migration of fibroblasts and tumor cells. Altered uptake by recipient non-metastatic TNBC cells and lung fibroblasts was revealed, leading to changes in downstream functional processes. Decreasing AnxA2 expression in TNBC cells diminishes their ability to metastasize by modifying the sEV proteome, thereby influencing interactions with recipient cells at both local and distant sites. These findings uncover a novel role for AnxA2 in promoting TNBC metastasis through sEVs. [This research is supported by the NCI of NIH under Award Number R01CA220273 (JKV), awarded to Dr. Jamboor K. Vishwanatha and partially supported by Cancer Prevention and Research Institute of Texas grant (Award#: RP210046).]

#6586 Targeting cancer cell dynamin activity *in vitro* impacts exosome production and cell proliferation.

Alexander J. Willis, Indira Kondapally, Narjess Hajilou, Paul Grippo, Tolou Shokuhfar, Herbert H. Engelhard, Yolande Chen

University of Illinois at Chicago, Wilmette, IL

Introduction: These experiments aimed to determine the effects of dynamin (DNM) on the exosome production of cancer cells. Researchers can easily collect exosomes, which are circulating extracellular vesicles, from the blood and analyze biological processes from the tumors of origin. This is particularly advantageous in solid tumors with limited tissue available for study.
Methods: Pancreas cancer and glioblastoma cells were grown until confluent, then seeded at equal density with 75 uM dynasore (DNSR), 30 uM Bis-T-23, or control (DMSO) for 24, 48, 72, and 96 hours (h). At the specified time, media was gathered for exosome precipitation, and cells were counted with trypan blue exclusion for proliferation. Exosomes were precipitated by SBI exosome tc precipitation solution, protein yield was measured by nanodrop, and the # of CD63 exosomes was determined using SBI's CD63 ELISA kit. Additionally, the exosomes were fixed on silicon chips for SEM and imaged using the JEOLJEM-ARM200CF. All statistical analysis was done using a t-test: Paired Two Sample for Means.
Results: DNM inhibition had a more significant effect on cell proliferation and exosome precipitation than DNM oligomerization. AsPC cells treated with DNSR had a significant decrease in proliferation compared to DMSO at 72h (1.0×10^5 cells + 3.536×10^4 vs 7.125×10^5 cells + 7.181×10^4, respectively, p=0.005) and 96h (2.125×10^5 cells + 5.154×10^4 vs 6.625×10^5 cells + 7.181×10^4, respectively, p=0.025). U87 (1.5×10^5 cells + 3.536×10^4 vs 4.875×10^5 cells + 8.985×10^4, respectively, p=0.02) cells had decreased proliferation after 96h compared to DMSO. AsPC cells also had a significant increase in proliferation after 96h in response to Bis-T-23 compared to DMSO (1.125×10^6 cells + 1.561×10^5 vs 6.625×10^5 cells + 7.181×10^4, p=0.024). Exosome concentrations were measured in the supernatant and normalized to cell concentrations, AsPC had a significant difference in exosomes per cell in response to DNSR at 72h (25.8 ng/cell + 7.0 vs 2.6 ng/cell + 0.2, respectively, p=0.013) and 96h (10.3 ng/cell + 2.8 vs 2.6 ng/cell + 0.2, respectively, p=0.039), and to Bis-T-23 at 96h (1.7 ng/cell + 0.2 vs 3.1 ng/cell + 0.4, respectively, p=0.013). U87 (14.6 ng/cell + 5.8 vs 3.4 ng/cell + 0.5, respectively, p=0.002) had a significant change in exosomes precipitated per cell at 96h after dynamin inhibition.
Conclusions: Data show extracellular vesicles, specifically exosomes, have been implicated as data transfer units between cells. To be an exosome, a membrane vesicle needs to be 30-90 nm and of endocytic origin enriched with tetraspanin molecules. Here, we demonstrate the impact of targeting DNM activity on the cells' ability to proliferate and the quantity of exosomes produced over time. Exosomes have implications in both tumor suppression and proliferation. Our data shows that targeting DNM and exosomes could aid in the effectiveness of diagnosis or treatment of cancer.

#6587 Plasma-derived exosomes in the frontier of gene therapy development.

Gizem Kursunluoglu[1], Omer Aydin[2], Mukerrem Betul Yerer[3]

[1]Drug Application and Research Center (ERFARMA), Erciyes University, Kayseri, Turkey,[2]Department of Biomedical Engineering, Erciyes University, Kayseri, Turkey,[3]Drug Application and Research Center (ERFARMA) - Department of Pharmacology, Faculty of Pharmacy, Erciyes University, Kayseri, Turkey

Gene transfer refers to the process of incorporating foreign genetic material, such as DNA or RNA, into target cells or organisms. Gene transfer is a dynamic field with significant potential for advancing medicine, biotechnology, and scientific research. Ongoing research and technological developments aim to enhance the efficiency, safety, and precision of gene transfer techniques for various applications. In the transportation of genetic materials such as DNA, miRNA, mRNA, and siRNA, various challenges are encountered, and these challenges are being addressed through the approach of nanobiotechnology.

Exosomes are promising natural carriers for gene delivery systems. Due to their high biocompatibility, stability, and low immunogenicity, exosomes are preferred as cargo carriers. The lipid bilayer membrane of exosomes also provides protection against cargo degradation, making exosomes a desirable candidate for gene delivery. Despite the various strategies developed to facilitate the loading of the desired cargo, such as incubation, electroporation, sonication, extrusion, freeze-thaw cycles, and transfection, insufficient efficiency persists. Our main goal is to develop a highly efficient gene transfer method for exosomes isolated from healthy human blood plasma. In our study, the gene transfer capacities of exosomes isolated from human blood plasma were examined. First, an exosome isolation method from plasma was developed. The most efficient method for exosome isolation has been developed, and for this purpose, both the ultracentrifugation method without gradients and the sucrose gradient have been studied. Based on exosome characterizations with NTA and Western blot, it was determined that the best method was the 30% sucrose gradient. Then, the gene delivery capacity of exosomes as a cargo molecule was examined using FAM-labeled GAPDH-siRNA. In our study, the sonication and the extrusion methods were compared for the loading of genes into exosomes. When evaluating all parametric comparisons, the highest efficiency of gene loading capacity into exosomes was achieved using the sonication method. The gene loading efficiency of exosomes was also determined using FAM-labeled GAPDH-siRNA through fluorescence microscopy and flow cytometry. The cellular uptake of GAPDH-siRNA-loaded exosomes was evaluated based on time and concentration. Cellular uptake within 6-12-24 hours was evaluated. When all these results are evaluated, our study has developed a gene therapy agent to be used for gene therapy purposes, which will guide us in our future gene therapy studies against cancer. In this way, fundamental cases will be provided for more efficient and effective gene therapy through exosomes, which is one of today's most important and favored treatments. Research has been supported by the Erciyes University Scientific Research Projects (BAP) Grant No: TSAÜ-2024-13269.

#6588 Characterization of TGFb1-induced ApoEVs and their potential role in epithelial cell plasticity.

Daxime F. R. Genier, Sarai A. Gomez Perez, Alicia Viloria-Petit

Biomedical Sciences, University of Guelph, Guelph, ON, Canada

Extracellular vesicles (EVs) are membranous particles that carry cargo such as proteins, lipids, and nucleic acids that can be crucial for intercellular communication. Epithelial-mesenchymal transition (EMT) is implicated in tissue remodeling and has been documented in the mammary gland during involution. Transgenic models and clinical studies suggest that both post-lactational and age-related lobular involution may increase susceptibility for breast cancer development. Transforming growth factor-beta 1 (TGFβ1) induces apoptosis of epithelial cells during involution and is also a potent inducer of EMT. TGFβ-induced apoptosis generates a subpopulation of EVs called apoptotic cell-derived EVs (ApoEVs), a potential cell-cell communication avenue that may be crucial for tissue remodeling. Here, we optimized a protocol to generate, isolate, and analyze TGFβ-induced ApoEVs. This may reveal potential EV-mediated signaling in driving EMT, tissue remodeling and cancer susceptibility in the mammary gland.

The murine mammary gland epithelial cell line NMuMG was used, as they are known to both die and undergo EMT in response to TGFβ1 stimulation. NMuMG cells were cultured in DMEM with 10% FBS, 10 µg/mL insulin, and 1% antibiotics. Once 90% confluency was reached, growth media was replaced with starvation media consisting of DMEM, 5% EV-depleted FBS, and antibiotics. After 2.5 hours, one plate was treated with 5 ng/mL of TGFβ1 while the other received PBS. The conditioned media (CM) produced was centrifuged at 400g for 20 minutes to remove debris and then ultracentrifuged for 1 hour at 4ºC at a speed of 10,000g to generate a pellet of large EVs. This was followed by two PBS washes under the same ultracentrifugation conditions. Next, the CM was again ultracentrifuged at a speed of 100,000g to isolate smaller EVs. Both EV populations were resuspended in 10mM Hepes (pH 7.2) and characterized by western blot, dynamic light scattering (DLS), and transmission electron microscopy (TEM).

Western blots for markers of EVs and potential contaminants suggest successful EV isolation. Blotting for apoptotic markers presented results consistent with ApoEVs, which were enriched in the samples obtained by 10,000g ultracentrifugation. DLS analysis showed that EVs released by TGFβ-treated cells were larger and more abundant compared to those released by untreated cells; TEM analysis confirmed these results. Culturing NMuMG cells with either full CM or EV-depleted CM from either control or TGFβ1-treated cells showed morphological changes consistent with cell plasticity in response to EVs released by TGFβ1-treated cells.

Our findings suggest that EVs produced during TGFβ1-induced apoptosis of NMuMG cells contain cargo capable of modulating epithelial phenotype and may aid directly or indirectly in tissue remodeling. Additional biological studies on target cells are necessary to confirm our results.

#6589 Exosomal miR-155-5p from early myeloid-derived suppressor cells promotes breast cancer invasion and metastasis by regulating SIRT1.

Guidong Chen, Jinpu Yu

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Early myeloid-derived suppressor cells (eMDSCs) are a heterogeneous group of myeloid cells and have a critical role in the progression of breast cancer. Therefore, exploring the mechanism of communication between eMDSCs and tumor cells is particularly important. In this study, the results showed that eMDSCs co-incubation improved the migration and invasion ability of breast cancer cells by up-regulating the expression of microRNA(miR)-155-5p. Further, we found that eMDSCS-derived exosomes transfer miR-155-5p to breast cancer cells and down-regulate sirtuin 1(SIRT1) expression to promote breast cancer progression. To overcome this challenge, we developed a nanodelivery platform targeting the tumor microenvironment to co-deliver the oligonucleotide inhibitor of miR-155, which demonstrated significant inhibition of tumor growth, migration and invasion in vivo experiments. Overall, our findings suggest that the eMDSCS-derived exosome miR-155-5p promotes invasion and metastasis of breast cancer by targeting SIRT1 and the construction of a tumor microenvironment responsive nanodelivery platform targeting eMDSCs exosome-derived miR-155-5p provides a promising strategy for overcoming breast cancer progression.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genomic Profiling of Tumors 2
Poster Session

#6594 Constrained hypermutation and absence of TERT promoter mutations in Lynch syndrome-associated urothelial cancer.

Jussi Nikkola[1], **Lauri Ryyppo**[1], Juuso Vuorinen[1], Lauri Moilanen[2], Maarit Ahtiainen[2], Kirsi Pylvanainen[3], Hanna Selin[1], Tuomo Virtanen[1], Matti Nykter[1], Thea Veitonmaki[4], Jukka-Pekka Mecklin[3], Toni T. Seppala[1], Matti Annala[1]

[1]Tampere University, Tampere, Finland,[2]Hospital Nova of Central Finland, Jyvaskyla, Finland,[3]The Wellbeing Services County of Central Finland, Jyvaskyla, Finland,[4]Tampere University Hospital, Tampere, Finland

Lynch syndrome (LS) is a hereditary cancer syndrome characterized by a defective DNA mismatch repair (MMR) system and a high frequency of different cancers, including urothelial cancers (UC) of the upper urinary tract and bladder. We studied the somatic landscape of LS-associated UCs (LS-UC) by analysing 41 tumor samples and 3 urine DNA samples collected from 34 LS-UC patients. We demonstrate that mutations of the telomerase reverse transcriptase (*TERT*) promoter are present in 83% of sporadic UC and are scarcely present (5%) in LS-UC ($p < 0.00001$). As a substitute, all LS-UC patients possessed a 5-methylcytosine deamination (CG>TG) and microsatellite instability driven mutation landscape with highly frequent *ARID1A* (82%), *FGFR3* (80%), and *KMT2D* (78%) mutations. We suggest that the scarcity of *TERT* promoter mutations in LS-UC is due to an inability to create the required GABP binding motif (5'-GGAA) through CG>TG mutation or microsatellite instability. Our data indicates that LS-UC is a distinct disease entity characterized by unique genomic features.

#6595 Lineage markers and driver oncogenes coordinate through gene expression subtypes of lung adenocarcinoma.

Minjeong Kim[1], Wisut Lamlertthon[2], Heejoon Jo[1], Yan Cui[3], Hyo Young Choi[4], Matthew D. Wilkerson[5], Liza Makowski[1], D. Neil Hayes[6]

[1]Division of Hematology and Oncology, Department of Medicine, University of Tennessee Health Science Center, Memphis, TN,[2]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand,[3]Department of Genetics, Genomics, and Informatics, University of Tennessee Health Science Center, Memphis, TN,[4]Department of Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN,[5]Department of Anatomy, Physiology, and Genetics, Uniformed Services University, Bethesda, MD,[6]UTHSC Center for Cancer Research, University of Tennessee Health Science Center, Memphis, TN

Background: EGFR-directed therapy marked the beginning of personalized medicine in lung adenocarcinoma (LUAD), where a single gene could be effectively targeted by a specific class of drugs, leading to remarkable treatment responses. After additional targets have been identified, the search for other druggable mutations has slowed despite the need to improve clinical outcomes, underscoring the need for new approaches.

Hypothesis: We hypothesize that gene expression signatures will predict EGFR mutation status in patients and identify cases with similar signaling pathways but without canonical EGFR mutations. Deciphering the role of the EGFR signature in mutant (mt) and wild-type (WT) cases may provide potential therapeutic and classification strategies for understanding LUAD.

Experimental design: To define an EGFR mutation signature ("mSig") as a predictor of EGFR mutation status, we analyzed gene expression and clinical data from four lung adenocarcinoma cohorts. Microarray data from Memorial Sloan Kettering Cancer Center (MSKCC, n=192) served as the training set. For validation, we used combined microarray data from UNC (n=73) and TSP (n=41) as one dataset, and RNA-seq data from The Cancer Genome Atlas (TCGA, n=486) as another. Multiple model evaluation algorithms tested the performance of the predictor. Other key genetic mutations found in TCGA cohort were included in integrative analysis.

Results: Comparing EGFR-mt to EGFR WT tumors identified 1,020 differentially expressed genes in the training dataset as an EGFR mSig. Semi-supervised clustering visualized molecular profiles in both training and validation data. The EGFR mSig achieved an average negative predictive value (NPV) of 96.3% across datasets and was robust across multiple dataset combinations and six machine learning models (AUROC = 0.83-0.95). The EGFR mSig strongly correlated with LUAD subtypes (Bronchioid, Magnoid, Squamoid), particularly with Bronchioid [odds ratio (OR) = 9.2, $p < 0.001$]. EGFR mSig-positive EGFR-mt ("*EGFR-mt/mSig(+)*") tumors were primarily Bronchioid (OR = 4.5, $p < 0.001$). Almost 50% of mSig(+) Bronchioid tumors in fact lacked EGFR mutations, often showing EGFR amplifications or RAS mutations. Two lung lineage markers and driver mutations associated with LUAD subtypes and EGFR activation patterns. Interestingly, *EGFR-mt/mSig(-)* tumors were generally non-Bronchioid, suggesting alternative pathways (e.g., RAS, TP53). RAS/RAF/RTK-mt tumors (*EGFR WT* or *mSig(-)*) showed high dual specificity phosphatase 4 (*DUSP4*) expression, a known repressor of multiple key activated RAS genes. Therefore, *DUSP4* represents an attractive novel target in selected LUAD samples.

Conclusions: Our results define a novel EGFR mSig that identifies EGFR-mt-like tumors. Identifying patients with driver gene mutations lacking EGFR mutations suggests a new approach of identifying new druggable targets.

#6596 Tumor molecular landscape and therapy implications in young BRCA1/2 carriers with breast cancer.

Mwangala P. Akamandisa[1], Mingyi Xia[1], Wilson Cheah[2], Bradley Wubbenhorst[1], Kurt D'Andrea[1], Mengyao Fan[1], Jake Shilan[1], William J. Tapper[2], Ellen Copson[2], Ramsey I. Cutress[2], Diana M. Eccles[2], Susan M. Domchek[1], Katherine L. Nathanson[1]

[1]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[2]University of Southampton, Southampton, United Kingdom

Women with *BRCA1/2* pathogenic variants (PVs) have a high likelihood of developing young onset breast cancer (BC) compared to noncarriers. In women enrolled in the POSH prospective cohort study of young women diagnosed with BC under age 40 or under age 50 if known *BRCA1/2* positive, no difference in overall survival was observed in *BRCA1/2* carriers vs noncarriers. Treatment options for BC include PARP inhibitors (PARPi) for *BRCA1/2* driven tumors and CDK4/6 inhibitors (CDK4/6i) plus endocrine therapy for ER-positive, HER2-negative tumors. In BC from *BRCA1/2* carriers unselected for age, up to 10% *BRCA1* and 46% *BRCA2* carriers do not have loss of heterozygosity (LOH) at the germline variant locus, suggesting non-*BRCA1/2* tumorigenesis. It is not known what the tumor molecular landscape, including rates of LOH and homologous recombination deficiency (HRD), is in young *BRCA1/2* PV carriers with BC, and whether the tumor molecular features impact disease outcomes or predict therapy response. To elucidate the molecular landscape of breast tumors in young women with *BRCA1/2* PVs, we evaluated treatment naïve primary breast tumors from 136 (86 [63.2%] *BRCA1*; 50 [36.8%] *BRCA2*) PV carriers in the POSH study. 71 (52.2%) of the tumors were ER-positive. We performed whole exome sequencing and called single nucleotide variants, indels, copy number variants, and *BRCA1/2* allele specific LOH in the tumors, calculated HRD scores and tumor mutational burden (TMB), and evaluated single base substitution (SBS) signatures. We found high rates of LOH by gene: *BRCA1* (93%) and *BRCA2* (96%), and by ER-status: ER-negative (94.4%) and ER-positive (93.8%). Mean HRD scores were significantly higher in tumors with LOH compared to nonLOH tumors in both *BRCA1* (57.4 vs 22.6, p<0.0001) and *BRCA2* (43.7 vs 23.5, p=0.005) carriers as well as ER-negative (57.6 vs 22.8, p<0.0001) and ER-positive tumors (46.4 vs 22.8, p<0.001). LOH tumors had higher proportional contribution of HRD-associated SBS3 than nonLOH tumors (0.36 vs 0.22, p=0.048). *BRCA1* LOH tumors had higher median TMB than *BRCA2* LOH tumors (4.8 vs 2.5, p=0.034). Overall survival in women with nonLOH tumors was 100% throughout the follow-up period but was not significantly different from that of women with LOH tumors. Overall survival did not differ by tumor HRD status: analyses were limited by small numbers in the non-LOH and low HRD groups. We found statistically significant enrichment of *AURKA* (OR:4.2, 95%CI:1.3-16.6, p=0.015) and *MYC* (OR:2.4, 95%CI:1.0-5.7, p=0.043) amplification which are associated with resistance to CDK4/6i in ER-positive, HER2-negative tumors from POSH cohort PV carriers compared to noncarriers from the TCGA. Given the high levels of LOH and presence of CDK4/6i resistance associated alterations, our data suggest that PARPi may be preferable over CDK4/6i in young *BRCA1/2* carriers with ER-positive, HER2-negative BC when both therapies are being considered in the adjuvant setting.

#6597 Optimization of DNA and RNA extraction from tumor FFFPE samples and end-to-end automation and analytical validation of the TSO 500 HT v1 library preparation.

Nripesh Prasad, Supriya Singh, Rebecca Beatty, Rachel Rock, Melanie Robinson, Annamaria Szanto, Sara Hildebrand, Boris Umylny, Thomas Halsey

Discovery Life Sciences, Madison, AL

Formalin-fixed paraffin-embedded (FFPE) techniques are cost-effective, long-term preservation methods for clinical samples, enabling next-generation sequencing (NGS) for expanded discovery and diagnostic applications. DNA and RNA extraction and library preparation must be optimized to ensure efficient downstream NGS analysis. We first focused on optimizing the quality and quantity of DNA and RNA recovery from FFPE samples representing various oncology conditions, using the truXTRAC® FFPE Tissue Extraction Kits (Covaris) automated on the Kingfisher Flex instrument (Thermo). We then analyzed the extracted DNA and RNA from FFPE tumor samples, including colorectal, kidney, breast, lung, gastric, and endometrial cancer, along with control samples from Horizon Oncospan and Seraseq, for analytical validation of the TSO 500HT v1 assay. RNA inputs were tested at 20ng, 40ng, and 80ng, while DNA inputs were tested at 20ng, 40ng, and 100ng. The TSO 500HT assay targets 523 genes to assess all DNA and RNA variant types, including SNV, CNV, indels, fusions, MSI, and TMB. For library preparation, 72-sample batches were processed using manual and fully automated workflows, with the automation protocol executed on the Biomek i7 (Beckman Coulter). Sequencing was performed on the Illumina NovaSeq 6000 and NovaSeq X Plus, using a 2x100bp paired-end configuration to generate approximately 50 million DNA reads and 8-10 million RNA reads per library. This approach demonstrated an overall inter-run and intra-run variant detection accuracy of over 90%, indicating highly repeatable and reproducible results. Variability between runs, lots, and operators was ≥99%. Our analysis showed high assay performance, with ≥96% of samples passing Illumina's cut-off metrics, particularly with 40ng DNA and 80ng RNA inputs. The analytical sensitivity for the TSO 500HT assay was benchmarked with ≥95% sensitivity for SNVs, ≥85% for InDels, ≥90% for CNVs, ≥90% for MSI, and ≥90% for TMB. These results provide a high-throughput, automated solution for dual DNA and RNA extraction from FFPE samples, demonstrating a robust, reproducible, and highly accurate targeted sequencing method for variant detection in oncology patients.

#6598 MET gene polymorphisms and breast cancer: A study of Nigerian patients.

Emeka Eze Joshua Iweala[1], Doris N. Amuji[2]

[1]Covenant University, Ota, Nigeria,[2]Department of Biochemistry, Covenant University, Ota, Nigeria

Breast cancer (BC) remains a major cause of cancer-related mortality among women worldwide. Genetic polymorphisms, such as those in the Mesenchymal Epithelial Transition (MET) proto-oncogene, may influence susceptibility and tumor progression as seen in gastric, liver, and thyroid cancer in Japanese and Chinese populations. This study evaluated the association between three MET gene single nucleotide polymorphisms (SNPs) namely rs40239, rs1621, and rs41736 and breast cancer risk and tumor grade among Nigerian women. A case-control study was conducted with 150 participants, comprising 75 breast cancer patients and 75 healthy controls. DNA was extracted from blood samples and genotyped using the TaqMan SNP assay. Genotype and allele frequencies for the SNPs were compared between the groups, and associations with BC risk were evaluated using the chi-square test and odds ratios (ORs). In addition, ordinal regression analysis was performed to assess the relationship between SNP (rs1621) and tumor grade. Genotyping revealed distinct distributions of genotype in both groups. For rs40239, the AA genotype was more frequent in controls (60%) than in cases (17%), though the association with BC risk was not statistically significant (OR=4.706, 95% CI: 0.959-23.096, p=0.062). No significant associations were observed for rs1621 (OR=1.188, 95% CI: 0.516-2.733, p=0.426) or rs41736 (OR=0.954, 95% CI: 0.904-1.006, p=0.262). The mutant allele rs1621 was associated with reduced odds of being in a higher tumor grade (OR=0.475), suggesting a potential protective effect against aggressive tumors. However, this association was not statistically significant (p=0.090, 95% CI: -1.606-0.116). While rs1621 showed a non-significant trend towards a protective role against higher tumor grades, no statistically significant associations were observed between the examined SNPs (rs40239, rs1621, and rs41736) and breast cancer risk. Future research should focus on expanding sample sizes, including diverse African populations, and exploring the role of genetic variants in breast cancer predisposition and progression.

#6599 A comprehensive benchmark study of multiple library amplification solutions for NGS.

Giulia Corbet[1], Caitlyn Mendik[1], Lee French[2], Leo Karamanof[2], Meghan Oddy[2], Andrew Sutherland[2], Philip Benson[1], Josh Haimes[1], Ross Wadsworth[2], Travis Sanders[1], Craig Marshall[1], Kristina Giorda[1], Thomas Harrison[1], Eduard Casas[1], Brian Kudlow[1]

[1]Watchmaker Genomics, Inc., Boulder, CO,[2]Watchmaker Genomics, Inc., Cape Town, South Africa

The emerging field of precision oncology utilizes next-generation sequencing (NGS) to guide decisions based on individual genetic signatures. As demand for these applications grows, minimizing errors and biases introduced during library preparation and sequencing is critical. Advances in sequencing chemistries have improved base quality scores, shifting the focus to library preparation to improve data quality. PCR amplification is a key potential source of error during NGS library preparation; single-base substitutions, insertions, and deletions (indels) introduced by PCR in addition to PCR-induced biases in DNA length and GC content can distort data leading to decreased assay sensitivity and specificity. Improved library amplification, combined with recent innovations in sequencer technology, will increase the reliability of NGS assays and lead to better assay performance.

Herein, we benchmark several commercial PCR amplification systems, including two solutions from Watchmaker Genomics: Equinox, and a re-engineered library amplification mix in development. We employed a UMI-powered NGS assay to quantify GC-uniformity, chimeric reads, base incorporation fidelity, and indel rates in microsatellite sequences. Libraries were sequenced on multiple platforms to leverage the ultra-high base quality scores of recent sequencing chemistries, resulting in low-noise measurements of polymerase fidelity. We also interrogate UMI family depth uniformity, a powerful proxy for template sequence bias and an informative indicator for error-correction efficacy. Furthermore, we assess amplification size bias by comparing the ability to amplify long templates in the presence of short templates. Compatibility with both SPRI and streptavidin beads was assessed. Finally, we test the ability to generate high terminal library yield, which is important for hybridization capture workflows.

These results indicate that while some products may excel in one or two metrics, they dramatically underperform in others. Equinox, in particular the newly engineered variant, demonstrates robust performance across all relevant metrics, making it a leading solution for precise and unbiased library amplification.

#6600 Dissecting genomic features of BCG unresponsive non-muscle-invasive bladder cancer identifies drivers of sensitivity to intravesical gemcitabine/docetaxel.

Matias Vergara[1], Kendrick Yim[2], Kevin R. Melnick[3], Brendan Reardon[1], Timothy N. Clinton[2], Matthew Mossanen[2], Graeme S. Steele[2], Michelle S. Hirsch[4], Natalie M. Rizzo[4], Kent W. Mouw[5], Matthew F. Wszolek[6], Keyan Salari[6], Adam S. Feldman[6], Adam S. Kibel[2], Eliezer M. Van Allen[1], Mark A. Preston[2], Filipe LF. Carvalho[2]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Department of Urology, Brigham and Women's Hospital, Boston, MA,[3]Department of Urology, Brigham and Women's Hospital, Boston, MA,[4]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[5]Department of Radiation Oncology, Dana-Farber Cancer Institute, Boston, MA,[6]Department of Urology, Massachusetts General Hospital, Boston, MA

Introduction: Intravesical Gemcitabine/Docetaxel (GemDoce) is an effective therapy in patients with Bacillus Calmette-Guérin (BCG) unresponsive non-muscle-invasive bladder cancer (NMIBC) with 50% response at 2 years. However, the genomic landscape of BCG-unresponsive NMIBC and whether distinct mutations are associated with response and resistance to sequential intravesical GemDoce is unknown. Our goal is to define mutational features of BCG-unresponsive NMIBC and nominate genomic drivers of response and resistance to GemDoce.
Methods: We identified patients with BCG unresponsive NMIBC who subsequently received intravesical Gem/Doce. We performed whole-exome sequencing of BCG unresponsive bladder tumors (total tumors n=23; Tumor-normal pairs n=3; Tumor-only n=20) prior to GemDoce administration and classified patients in “responders” (recurrence free survival (RFS) > 18 mo) and “non-responders” (RFS < 18 mo). The Broad Institute’s CGA pipeline was used to account for mutation calls, ABSOLUTE was used to define copy number alterations (CNA) and PhylogicNDT was applied to model phylogenetic and evolutionary tumor trajectories.
Results: Median follow-up was 45 months. Median time to HG-recurrence and cystectomy were longer in the responder group (33 mo, 28 mo) in comparison to the non-responder group (3.5 mo, 8 mo). We identified alterations in known bladder cancer genes including *TP53* (10/20 tumors), *KDM6A* (9/20 tumors) and *FGFR3* (5/20 tumors) in both responders and non-responders. Most alterations in *TP53* and *KDM6A* were predicted loss-of-function mutations, consistent with the known tumor suppressor roles for these genes. Mutations in two genes that control cell division and chromosomal stability, *CREBBP* and *STAG2*, were exclusively present in responders to GemDoce. Both responders and non-responders harbor CNA in *CDKN2A* that characterize NMIBC. However, *FGFR3*, *E2F2* and *MDM2* amplifications were exclusively present in non-responders. Phylogenic analysis showed BRCA1 clonal mutations and subclonal BRCA2 mutations only in responders.
Conclusions: BCG unresponsive NMIBC harbor mutational features that biologically explain response to GemDoce. Mutations in *CREBBP* and *STAG2,* and clonal BRCA1 mutations may sensitize tumors to GemDoce resulting in long-term responses to intravesical chemotherapy. Future efforts should focus on determining the presence of *CREBBP* and *STAG2* using immunohistochemistry prior to GemDoce to improve intravesical treatment response in NMIBC.

#6602 Spatial transcriptomic profiling of the mouse distal colon during early carcinogenesis reveals transitional cell states that precede cancer.

Yujin Lee, James C. Fleet

Nutritional Sciences, The University of Texas At Austin, Austin, TX

Early onset colorectal cancer (EOCRC) is increasing yet the mechanism for the accelerated shift to a younger age is unknown. We hypothesize that sporadic gene mutations that are necessary for colon carcinogenesis but not sufficient to cause cancer, create a preneoplastic cell state for increased risk of transformation. To identify transitional cell phenotypes, we used Spatial Transcriptomics (ST) on distal colon samples from Car1-Cre (CAC) mice with Cre expression limited to ~6% of the distal colon/rectum epithelium, where EOCRC is more prevalent. CAC;ROSA$^{mT/mG}$ (CR) mice (where eGFP marks cells expressing Cre) were crossed to those with floxed oncogene alleles to generate mice with one (Apc$^{+/-}$, ACR) or two (Apc$^{+/-}$;Kras$^{G12D/wt}$, AKCR) non-transforming mutations. ACR mice had normal crypt morphology and low adenoma incidence (<5% of mice), while 4-week-old AKCR mice exhibited crypt elongation, and 8-10 wk-old AKCR developed 3-8 advanced adenomas/mouse. Distal colon Swiss rolls (n=9) and tumors (n=3) with phenotypes ranging from normal to malignant were collected and processed using the 10X Visium Spatial Gene Expression System. Sequencing data was processed, and sample data were pooled for analysis using Seurat. Spatial counts were normalized, dimensionality was reduced with PCA, then clustered and visualized as UMAP projections. Clusters were annotated to known cell types, and differential gene expression (DEG) analysis was followed by functional annotation using GO and Pathway terms. In normal tissue, clusters for the crypt base, middle, and top were identified. These spatially restricted clusters were replaced in early AKCR crypts and again in late AKCR crypts. The clusters from late AKCR crypts were distinct from those in ACR tumors, which were different from clusters in AKCR tumors. This indicates the existence of transition states from normal to “not normal, not cancer” to early adenoma to late adenoma. Normal epithelial clusters were enriched for genes controlling typical colonic functions, e.g. metabolism, and transmembrane transport pathways. AKCR crypt clusters lost these functions and gained others, e.g. immune and antimicrobial genes normally associated with Paneth cells (e.g., Defa22, Defa24, Defa30), gene markers associated with CRC tumors (e.g. Egfr, Hamp, Plet1, Wfdc18), genes for xenobiotic inactivation (Maoa, various Cyp, Gst, Ugt, and Sult genes). Compared to late AKCR crypts, AKCR tumor clusters lost even more colonic functions (e.g. downregulation of differentiation marker Krt20 and xenobiotic metabolism markers) and expressed genes related to mitosis, DNA replication, and DNA repair, highlighting a transition to uncontrolled proliferation and genomic instability. Our findings delineate key early molecular transitions in epithelial cells during colon carcinogenesis that may increase the risk of transformation.

#6603 Analytical validation of a new plasma-only bioinformatics classifier to identify variants from clonal hematopoiesis (CH) in cfDNA liquid biopsy assays.

Patrick C. Fiaux, Mingyang Cai, Pegah Safabakhsh, Jeffrey L. Werbin, Che-Yu Lee, Katie Quinn, Marisa Juntilla, Tingting Jiang, Reagan M. Barnett, Errin Lagow, Arielle Yablonovitch, Shile Zhang, Martina Lefterova, Darya Chudova

Guardant Health, San Francisco, CA

Introduction: Distinguishing between tumor derived variants and those from clonal hematopoiesis (CH, or CHIP) can impact clinical decisions. It is essential to develop tools that can accurately differentiate tumor vs CH in clinical tests with expanded gene panels. One method to confirm CH involves sequencing both the buffy coat and plasma samples. However, this approach is cost-prohibitive and has two key limitations: detection sensitivity of buffy coat sequencing for low allele fractions, and the possibility that variants originate from tissues other than the immune cells present in the buffy coat. To address this, we developed a plasma only CH classifier to detect CH variants with high specificity in the Guardant360 test for late-stage cancer patients.
Methods: First, limitations of the buffy coat sequencing were explored by sequencing over 60 healthy donor plasma and buffy coat samples. Second, data with more than 2000 variants observed in over 200 clinical samples across more than 15 cancer types (median age of 69) with paired buffy coats and plasma were utilized to train a boosted tree classifier. The final model was built using 14 features which included variant-level metrics derived from fragmentomics, methylation patterns, and variant allele frequencies, as well as metadata features aggregated from over 250,000 Guardant Health samples and public databases such as COSMIC and GnomAD. The classifier was trained to predict CH variants with high specificity to ensure that informative tumor-derived variants are accurately reported.
Results: In 62 healthy donors, we observed that 18% of variants detected in plasma at low allele frequency were not detected in buffy coat, highlighting the need for bioinformatic solutions to capture CH variants. Our bioinformatic approach was validated on an independent cohort of 173 Guardant360 late-stage, pan-cancer samples, each with paired buffy coat and plasma samples. In a set of clinically actionable genes, consisting of National Comprehensive Cancer Network (NCCN) recommended genes for biomarker testing and canonical CH-associated genes, the classifier successfully detected CH variants with a specificity of 98% and a positive predictive value (PPV) of 99%.
Conclusion: We present here a plasma only CH classifier developed for late-stage cancer patients run on Guardant360 powered by Infinity. The performance of the classifier to detect non-tumor variants in the Guardant360 test achieves a specificity exceeding 98% in clinically relevant genes, with a PPV of 99% in detecting CH variants.

#6604 Characterizing the tumor microenvironment using spatially barcoded archival FFPE tissue: converting single-nucleus RNA-seq into spatial transcriptomics.

Cedric R. Uytingco, Julie Wilhelmy, Bryant Ngo, Jonathan Sakkos, Wanxin Wang, Christina Chang, Christina Fan

Assay Development, Curio Bioscience, Inc., Palo Alto, CA

Identifying the contribution and the role of each individual cell in the spatial context of the tumor microenvironment (TME) is crucial in determining tumor progression, examining the extent of immune infiltration, and identifying potential therapeutic targets. While single-cell sequencing-based techniques help reveal cellular heterogeneity in a cell population, they do not provide spatial context. In turn, recently emerged spatial transcriptomics techniques are challenged by the difficulty in pinpointing the spatial measurement to single cells, requiring either complex cell segmentation or deconvolution algorithms in the data processing.

To address these limitations, we introduce Curio Trekker single-cell spatial mapping kit, a unique platform that turns a single-cell experiment into a spatial experiment, essentially providing a spatial measurement that has true single-cell resolution. It is based on the Slide-tags methodology (Russel et al, 2023) that spatially tags each nucleus within its native tissue environment. This approach utilizes existing single-nuclei sequencing infrastructure to generate high-resolution spatial transcriptomics data. Using archived FFPE samples, we demonstrate the effectiveness of Curio Trekker by aligning 25-30 µm tissue sections to spatially barcoded tiles. Spatial barcodes are cleaved and hybridized to cells and nuclei in the intact tissue, followed by tissue dissociation and nuclei isolation. The tagged nuclei are processed with established snRNA-seq workflows (e.g., 10x Chromium FLEX), producing gene expression and spatial libraries for the individual nuclei in the tissue section. This spatial tagging allows each nucleus to be bioinformatically mapped back to its original tissue location.

We applied this solution to breast cancer biospecimens from different patients using whole transcriptome probes (10x Genomics). The resulting data allowed for detailed characterization of the TME, confidently identifying epithelial-malignant, stromal, and immune cells from each biospecimen. This enabled marker-guided regional selection and differential gene expression analysis based on both cell type and spatial location. Overall, the Curio Trekker platform provides a streamlined, high-resolution solution for profiling cellular heterogeneity and interactions within tumors, seamlessly integrating with existing workflows to generate rapid insights into disease mechanisms and therapeutic development.

#6605 Spatially-resolved single-cell transcriptome landscape of response and resistance to CDK4/6 inhibitors in patients with hormone receptor-positive metastatic breast cancer.

[1]Cancer Program, Broad Institute, Cambridge, MA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA,[4]Gladstone Institutes, San Francisco, CA,[5]Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA,[6]Center for Immuno-Oncology, Dana-Farber Cancer Institute, Boston, MA,[7]Center for Cancer Genomics, Dana-Farber Cancer Institute, Boston, MA,[8]Institute for Medical Engineering and Science, Department of Chemistry, Massachusetts Institute of Technology, Cambridge, MA,[9]PreDICTA Biosciences, Cambridge, MA,[10]Spatial Technology Platform, Broad Institute, Cambridge, MA,[11]Genentech, Inc., San Francisco, CA

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) have significantly improved the treatment of hormone receptor (HR+) positive breast cancer. Clinical trials have demonstrated that addition of CDK4/6i to endocrine therapy (ET) improves both progression-free and overall survival in patients with HR+ metastatic breast cancer (MBC). Nevertheless, their impact remains limited by the eventual development of resistance. While a number of resistance mechanisms have been identified using both preclinical model systems and translational interrogation of patient specimens, these are not apparent in all cases. As part of the Human Tumor Atlas Network, we integrated genomic (whole-exome sequencing; n=47), single-nucleus transcriptomic (snRNA-seq; n=56), and spatial expression profiling (MERFISH and multiplex immunofluorescence; n=22 and n=17, respectively) from 58 clinically annotated MBC biopsy specimens collected before or after treatment with CDK4/6i plus ET to dissect the roles of tumor-intrinsic programs and the tumor microenvironment (TME) in CDK4/6i resistance.

Transcriptomic analysis of the tumor cell compartment with snRNA-seq not only extended prior findings including an association between expression of cell-cycle programs and CDK4/6i resistance, but importantly identified additional programs associated with response and resistance including ciliogenesis, immune evasion, and inflammation. Additionally, tumor-intrinsic gene programs related to epithelial-to-mesenchymal transition had a decreased activity in *ESR1* mutant biopsies, a mutational feature of CDK4/6i-resistant MBC associated with upregulated estrogen receptor pathway activity. In the TME, CD8+ T cells were depleted in the CDK4/6i-resistant biopsies, both before and after treatment. In contrast, the CDK4/6i-sensitive biopsies displayed pro-inflammatory features including an increased number of CXCL9+/CXCL10+ macrophages and clustering of CD8+ T cells in the vicinity of the malignant cells spatially. Notably, MERFISH also demonstrated an association between spatial architecture and CDK4/6i response, with the malignant cells in the CDK4/6i-resistant biopsies dispersed spatially compared to the sensitive biopsies. In summary, to the best of our knowledge, this study represents the largest spatially-resolved single-cell MBC cohort with curated CDK4/6i response status established to date. Our findings offer insights into potential biomarkers for CDK4/6i response based on tumor-intrinsic and tumor-microenvironment mechanisms, as well as therapeutic opportunities.

#6606 Genomic features of histological and molecular subtypes in Japanese ovarian cancer.

Osamu Gotoh, Norio Tanaka, Tomoko Kaneyasu, Seiichi Mori, Tetsuo Noda

Japanese Foundation for Cancer Research, Tokyo, Japan

Ovarian cancer is an intractable disease and comprises a number of histological subtypes that are associated with clinical characteristics such as therapeutic efficacy and likelihood of relapse. Since ovarian cancer exhibits heterogeneity even within a same histological subtype, it is critical to develop a complementary classification framework, in which clinicopathological and biological features are associated with each subtype. Previously, for endometrial cancer, a molecular subtyping scheme based on genomic features was developed by The Cancer Genome Atlas (TCGA) and the scheme has been currently integrated into the system of 2020 WHO classification of Female Genital Tract tumor. A similar classification scheme has been needed developed for ovarian cancer diagnosis for further clinical stratification. Whereas genomic features can be utilized for this purpose because of the tight relationship with clinical manifestations, previous large-scale genomic studies of ovarian cancer have been conducted mainly with high-grade serous (HGS) histology, a major histological subtype in Caucasian. The remaining histologies exemplified by clear cell carcinoma, which is uniquely prevalent in the East Asian population, have not been covered by these studies, and therefore genomic features that can be utilized for molecular subtyping have not been well characterized for non-HGS ovarian cancer. To link genomic features with histological subtypes and to obtain wealthy information for further potential genomic stratification, we conducted genome sequencing analyses of 1,412 Japanese ovarian cancers across 6 major histotypes (clear cell, high-grade serous, endometrioid, mucinous, carcinosarcoma and sex cord-stromal). Using copy number information derived from sequenced data, we identified a novel copy number subtype, which is uniquely associated with clinicopathological and genomic attributes. The results will be presented focusing on the genomic features including germline mutations, somatic driver events and mutational signatures, in association with histological and molecular subtypes.

#6607 Leveraging somatic mutations to distinguish tumor/normal cells in scRNA-seq datasets across different cancer types.

Cindy Kim[1], Eke Snoeren[1], Francesc Muyas[2], **Natasha Markuzon**[3]

[1]Imperial College, London, United Kingdom,[2]AstraZeneca Oncology, Barcelona, Spain,[3]AstraZeneca Oncology, Waltham, MA

Recent advancements in single-cell RNA sequencing (scRNA-seq) have significantly impacted clinical oncology. However, the accurate interpretation of scRNA-seq data remains challenging due to the limitations of current methodologies in distinguishing between different cell types within a tissue sample. Despite substantial efforts to construct comprehensive cell atlases, differentiating malignant from non-malignant cells is still a time-consuming process. Current approaches primarily rely on marker genes, gene expression signatures, and copy number alterations (CNAs), though these methods are not universally applicable to all cancer types. In our study, we explored the potential of leveraging somatic mutations to differentiate tumor and normal cells within scRNA-seq datasets from ovarian and colorectal cancer samples. We conducted a comparative analysis of the effectiveness of CNAs and single nucleotide variants (SNVs), as well as developed a supervised machine learning (ML) method leveraging their combination for improved prediction. The findings highlighted the importance of understanding the biological mechanisms underlying mutational processes for accurate tumor cell detection. Specifically, tumor cells in ovarian cancer samples exhibited a higher prevalence of CNAs, whereas colorectal cancer samples, particularly those with mismatch repair deficiency (MMRd), showed limited utility of CNAs for predicting tumor/normal cell status. In contrast, SNVs proved to be extremely valuable in identifying highly mutated tumor cells in colorectal cancer, with tumor mutational burden (TMB) serving as one of the highly effective predictors. In conclusion, our study utilizes a previously developed framework for detecting somatic mutations in scRNA-seq data for the robust and effective identification of tumor cells and their clusters in tissue samples. This framework is cancer-type agnostic and could help improve tumor cell detection in cancers with a high prevalence of CNAs.

#6608 Integrating HCMI models and tumors with CCLE and TCGA: Advancing cancer modeling and precision oncology.

The Human Cancer Models Initiative (HCMI) has developed 665 novel cancer models, including organoids and matched parental tumors, providing a significant addition to existing cancer model resources. To evaluate the transcriptional relatedness of HCMI models and tumors to the Cancer Cell Line Encyclopedia (CCLE) and The Cancer Genome Atlas (TCGA), we used the Celligner algorithm to align transcriptomic profiles across datasets, removing systematic biases while preserving intrinsic biological variability.

HCMI models and tumors both exhibited high transcriptional fidelity to TCGA tumors, clustering closely with their respective tumor types in the Celligner-aligned space. Pairwise Euclidean distances showed complementary strengths between HCMI and CCLE models. For example, HCMI models demonstrated significantly closer alignment to TCGA tumors in glioblastoma, breast cancer, and ovarian cancer, while CCLE models performed comparably or better in colorectal cancer. Notably, aligning HCMI tumors to TCGA confirmed their strong transcriptional relatedness, validating the fidelity of these models to their original tumor states. Combining HCMI and CCLE datasets further enhanced the total transcriptional representation across the diversity of TCGA tumors, underscoring the complementary roles of these resources.

The HCMI collection uniquely includes rare cancer types such as nephroblastoma, desmoid tumors, and ampulla of Vater carcinoma, which are absent in CCLE. Celligner analysis confirmed that these rare HCMI models faithfully retained transcriptional features of their corresponding TCGA tumors. This expands opportunities to study rare and clinically challenging cancers that have been underrepresented in preclinical models.

These findings demonstrate the value of integrating HCMI, CCLE, and TCGA datasets. Together, they form a complementary and robust compendium for studying tumor biology, enabling improved cancer modeling and advancing precision oncology.

#6610 Detection of homologous recombination deficiency in targeted long read sequenced tumors using mutational signatures.

Alvin Wei Tian Ng[1], Sheryl Li Lynn Wong[1], Siao Ting Chong[1], Jieru Ye[2], Joanne Ngeow[1]

[1]Lee Kong Chian School of Medicine, Nanyang Technological University Singapore, Singapore, Singapore,[2]National Cancer Centre, Singapore, Singapore

Background: Homologous recombination deficiency (HRD) affects cancer types including breast, ovarian, pancreas and prostate and patients with HR deficient tumors can respond to poly ADP-ribose polymerase (PARP) inhibitors and platinum-based therapies. HRD is associated to the loss of either germline or somatic, *BRCA1* or *BRCA2* and other associated variants. However, a large proportion of tumors do not have an identifiable variant in *BRCA1* or *BRCA2* and other related genes. Patterns of mutations—Mutational Signatures—of HRD can identify changes in DNA sequences due to defective DNA repair and genomic instability in HRD tumors. Current computational tools to detect HRD are based on whole genome sequencing (WGS) and an assessment of robustness of these approaches for clinical implementation are lacking.

Methods: We developed mSigDetect to identify HRD associated mutational signature (SBS3) in breast cancers, sequenced on Oxford Nanopore Technologies (ONT) targeted adaptive sampling technology. We built our mutational signatures classifier based on mutational profiles of 567 breast cancers from the International Cancer Genome Consortium (ICGC) and tested mSigDetect and the targeted panel on synthetic tumors (n=200) and two independent cohorts of breast cancer patients sequenced on Illumina short reads (n=224) and on ONT long reads (n = 38).Using the simulated synthetic tumours, we determined the sensitivity and specificity of our tool. We tested the performance of mSigDetect under different scenarios of tumour cellularity by down sampling and mixing HR deficient cell lines with paired normal lines in a range of 30-90% tumour cellularities. Last, we developed a computational workflow for ONT sequencing, to carry out real-time variant calling and mutational signature identification to reduce the turnaround time of the diagnostic test.

Results: With a target region of 5% of the human genome sequenced, mSigDetect could identify HR deficient tumors in both synthetic (sensitivity = 0.73, specificity = 1) and breast cancer patient tumors (sensitivity = 0.81, specificity = 0.99) compared to WGS. We designed mSigDetect to detect SBS3 in a tumor-only setting, without the need of a paired normal sample. Signature detection of SBS3 using mSigDetect greatly outperformed sequencing whole exome targeted regions. Based on cell line mixing simulations, we recommend sequencing at 45x for 30% tumor purity or higher, or 30X for 50% purity. ONT adaptive sampling identifies HR deficient tumors robustly in a clinical setting, based on targeted sequencing of a tumor-only sample.

#6611 Genome-wide cfDNA fragmentomics combined with machine learning enhance non-invasive prostate cancer detection.

Shuang Gan, Haoran Tang, Feng Xie, Yue Zhang, **Hang Dong**

Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

The liquid biopsy approach focusing on DNA molecules offers a promising non-invasive method for prostate cancer diagnosis. Next-generation sequencing (NGS) of targeted gene panels is widely used for detecting somatic mutations but is limited by confounding clonal hematopoietic variants and narrow genome coverage. We propose a solution that encompasses genome-wide DNA fragmentation features for tumor fragment evaluation. This study collected plasma samples from 209 patients with prostate cancer and 49 healthy individuals as controls. Cell-free DNA (cfDNA) was extracted and tested using PredicineSCORE™, a low-coverage whole-genome sequencing assay designed to identify tumor-specific features. Tumor content assessed by mutation-based detection assays served as the reference indicator. Fragmentomics characteristics—including regional coverage, fragment length, and end-motif features—were profiled as tumor markers. Copy number burden and tumor fragment content were refined using the expectation-maximization algorithm. An ensemble machine learning model was then developed to estimate tumor fractions. We found strong correlations between estimated tumor fraction and fragmentomics features. The absolute correlation coefficients for tumor fraction with the relative depth at LYL1 binding sites, the insert size ratio of short reads, and the CCCA end motif were higher than 0.9, 0.75, and 0.7, respectively. To validate these findings, a total of 500 simulated samples with tumor content ranging from 0.1% to 50% were generated by mimicking tumor and normal reads. The ensemble model outperformed single-method approaches, with the XGBoost algorithm achieving high predictive performance (Pearson correlation $r > 0.9$, $p < 0.01$) for predicting tumor fraction in cfDNA. The model demonstrated a limit of detection (LoD) at 2%, surpassing previously proposed models in sensitivity. This study highlights the potential of plasma cfDNA fragmentomics profiling as a highly precise and non-invasive method for quantifying and detecting prostate cancer. The findings support its utility in advancing liquid biopsy applications with improved sensitivity and accuracy.

#6612 Deep and scalable spatial transcriptomics for oncology research.

Joseph W. Foley[1], Wei K. Teo[2], Joshua K. Tay[2]

[1]Picopoint Genomics, Singapore, Singapore,[2]Otolaryngology - Head & Neck Surgery, National University of Singapore, Singapore, Singapore

The emerging field of spatial transcriptomics is revolutionizing histopathology by simultaneously quantifying numerous RNA transcripts *in situ* across a tissue section. However, current technologies provide a broad survey of the spatial environment at the expense of low-complexity genomic data. We present the Picoception RNA platform, which produces deep genomic data from spatially targeted regions of a tissue section. This platform combines laser-capture microdissection (LCM) with comprehensive mRNA-sequencing, which reads all polyadenylated transcripts including pathogens and model organisms. From a single <10 µm section of formalin-fixed paraffin-embedded (FFPE) tissue, Picoception RNA can profile an unlimited number of target regions smaller than 0.1 mm^2, typically reading 200,000-1,000,000 unique molecules each with a dynamic range of more than 100:1.

By isolating small areas of a tissue section, Picoception RNA allows deep molecular profiling of pure, distinct cellular regions such as tumor epithelial vs. normal or immune microenvironment. Combined with the depth of the gene-expression data, the cost-effectiveness of this technique enables statistically powerful analyses from large clinical cohorts. Furthermore, Picoception RNA's compatibility with archived FFPE samples unlocks genomic signals from patients with known clinical outcomes, allowing the process of biomarker and pathway discovery to begin immediately without prospectively recruiting new subjects.

We have applied this technique successfully in a wide range of applications, including oncology clinical trials for targeted therapy and immunotherapy, rare cancers, and cancers with limited biopsy material (including punch biopsies and core-needle biopsies), as well as rodent models. We have had consistent success profiling FFPE samples more than 20 years old.

Picoception RNA complements previous spatial transcriptomics techniques, filling the need for deep genomic analysis at microscopic resolution using large-scale cohorts of FFPE samples.

#6613 Triple-negative breast cancer evolution and therapy response: Breast TRACERx.

Ieva Usaite[1], Thomas B. K. Watkins[2], Olivia Lucas[1], Carlos Marinez-Ruiz[1], Francois Legrand[3], Constance Lamy[4], Marta Jimenez[3], Nusaibah Ibrahimi[5], Stephan Michiels[6], Simone Zaccaria[1], Thibault de la Motte Rouge[7], Anthony Goncalves[8], Jean-Yves Pierga[4], Monica Arnedos[3], Christophe Le Tourneau[4], Fabrice Andre[9], Mariam Jamal-Hanjani[1], Nnennaya Kanu[1], Charles Swanton[10]

[1]University College London (UCL) Cancer Institute, London, United Kingdom,[2]Cancer Research UK Lung Cancer Cenrtre of Excellence, University College London (UCL) Cancer Institute, London, United Kingdom,[3]Unicancer, Paris, France,[4]Institut Curie, Paris, France,[5]Office of Biostatistics and Epidemiology, Gustave Roussy, Villejuif, France,[6]Office of Biostatistics and Epidemiology, Gustave Roussy, Paris, France,[7]Medical oncology department, Centre Eugene Marquis, Rennes, France,[8]Medical oncology department, Institut Paoli Calmettes, Maeseille, France,[9]Institut de Cancerologie, Gustave Roussy, Villejuif, France,[10]Cancer Evolution and Genome Instability Laboratory, The Francis Crick Institute, London, United Kingdom

Introduction: Breast cancer is the most commonly diagnosed cancer and the main cause of cancer-related mortality in women worldwide. Despite advances in our knowledge of the underlying genetic alterations and improvements in treatment, 25-30% of patients with early breast cancers still relapse with distant metastatic disease. Presenting a clear unmet clinical need to improve our understanding of breast cancer evolution, and the drivers of genomic instability in primary breast cancers.
Methodology: We have analyzed multi-region sequencing data from 280 treatment-naïve primary breast cancer tumor regions sampled from 139 patients with triple-negative breast cancer (TNBC) prospectively enrolled into the Breast TRACERx and SCANDARE studies. Here we aim to decipher breast cancer evolution and address the primary study endpoints: determining the relationship between intratumor heterogeneity and clinical outcomes.
Results: In TNBC, 74% of tumors demonstrated a whole-genome doubling event (WGD), whereby 77% of these events were clonal, suggesting that whole-genome duplication is primarily an early event in TNBC evolution. Additionally, 27% of these events where subclonal, and 8% of cases harboured a clonal followed by a second subclonal WGD event. Defects in homologous recombination repair (HRD) occur early in TNBC evolution, which may be driven by the truncal selection of *BRCA1* mutations. Furthermore, HRD levels are significantly higher in BRCA-deficient TNBC tumours, here 17% of TNBC tumours demonstrated either a germline or tumour driver mutation in BRCA in addition to an LOH event in the wild-type allele. BRCA-wild-type tumours were significantly enriched for clonal WGD events, here suggesting increased chromosomal instability early in evolution within these tumours. BRCA-wild-type tumours demonstrated selection for mutation in tumour suppressor genes such as *RB1*, which were not selected for in BRCA-deficient tumours, suggest alternative routes to generating chromosomal instability (CIN) compared to HRD in BRCA-deficient tumours. Amplification of *CCND1* were observed across both BRCA -wild-type and -deficient tumors, however the timing of these events suggests additional CIN in BRCA-deficient tumors later during tumor evolution, with amplifications occurring subclonally, and clonal amplifications in BRCA-wild-type tumors. Parallel evolutionary events occur in 22% of TNBC tumors, demonstrating loss of genes such as *B2M* and LILR receptor family genes, which have been implicated in cancer immune evasion. TNBC tumors further demonstrated additional patterns of immune evasion through parallel gains of genes such as *CD274* and *PDCD1LG2*, suggesting selection for an immuno-suppressed phenotype.
Conclusions: These data demonstrate the evolutionary landscape of primary TNBC tumors and highlight the magnitude of events driving chromosomal instability in TNBC.

#6614 Small cell lung cancer (SCLC) at recurrence has a "colder" tumor microenvironment than primary SCLC according to gene expression profiling.

Farhad Kosari[1], Mohamed Ali[1], Sarah H. Johnson[1], Alex Adjei[2], Julian R. Molina[1], Aaron S. Mansfield[1], Anastasios Dimou[1], Kaushal Parikh[1], Mohamed Shanshal[1], Katherine E. Smith[1], Ailsa G. Luce[1], Anna J. Schwecke[1], Janet Lensing[1], Ying-Chun Lo[1], John C. Cheville[1], George Vasmatzis[1], **Konstantinos Leventakos**[1]

[1]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[2]Cleveland Clinic, Cleveland, OH

Recent studies have described the tumor microenvironment and the key transcription factors in untreated small cell lung cancer (SCLC), but less is known about the salient features in recurrent SCLC (rSCLC). This information could provide valuable insight about the effectiveness of second and later line therapies. In this study, we compared transcriptome profiles (by RNA-seq) of rSCLC against untreated primaries (pSCLC). rSCLC samples (n=23) were obtained from frozen biopsies in patients enrolled in our MC1923 (NCT04607954) phase 2 clinical trial whose disease progressed after chemoimmunotherapy. The pSCLC group (n=73) included publicly available data from fresh frozen primary tumors after surgical resections. Normalized expression data were used in immune deconvolution and gene set enrichment analysis (GSEA) in molecular signature database. Additional GSEA included gene sets describing ASCL1 (A), NEUROD1 (N), ASCL1 and NEUROD1 (AN), and POU2F3 (P) transcription factor activities which are used for subtyping of SCLC. Immune deconvolutions by multiple software algorithms suggested depletion of immune infiltrates in rSCLC compared with pSCLC including dendritic cells, B cells, $CD8^+$ T cells, and M1 macrophages. Furthermore, we found decreased chemotaxis and increased apoptosis of dendritic cells, reduced TNF signaling, and reduced lymphocyte co-stimulation in rSCLC by GSEA. Additionally, in comparisons with pSCLC, rSCLC tumors had significantly lower enrichment scores for POU2F3 activity, representing the SCLC-P subtype ($p < 0.007$). Importantly, the SCLC-P was recently reported to be more immune inflamed than the other A, N, and AN subtypes. Altogether, our analyses provide strong evidence that the tumor microenvironment of rSCLC is significantly more immunosuppressed and with reduced immune cell infiltrates compared to pSCLC. Developing therapeutic strategies aimed at "warming" the tumor microenvironment and enhancing anti-tumor immune activity in ongoing multimodal therapies of recurrent SCLC will likely provide significant benefits to patients.

#6615 Uncovering the landscape of cellular heterogeneity in low- and high-grade endometrial cancer using single cell profiling.

Sabina I. Swierczek*[1], Elizabeth A. R. Garfinkle*[2], Sophia A. Paxton[3], Katherine E. Miller[4], David Doo[5], Leslie Andriani[5], Shatovisha Dey[1], Steven Sieber[6], Alpana Dholakia[1], Syeda Rashid[1], Linus Chuang[5]

[1]Rudy L. Ruggles Biomedical Research Institute, Nuvance Health, Danbury, CT,[2]The Steve and Cindy Rasmussen Institute for Genomic Medicine, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH,[3]Biomedical Sciences Graduate Program, The Steve and Cindy Rasmussen Institute for Genomic Medicine, The Ohio State University College of Medicine, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH,[4]The Steve and Cindy Rasmussen Institute for Genomic Medicine, Department of Pediatrics, Abigail Wexner Research Institute at Nationwide Children's Hospital, The Ohio State University College of Medicine, Columbus, OH,[5]Department Obstetrics and Gynecology, Nuvance Health, Danbury, CT,[6]Department of Pathology, Nuvance Health, Danbury, CT

Introduction: Endometrial cancer (EC) is the most common gynecologic malignancy in women, with rising incidence and mortality. EC is classified into low-grade (I/II), less aggressive, and high-grade (III), associated with poor prognosis and aggressive behavior. Single-cell RNA sequencing (scRNA-seq) offers insights into the interplay between tumor cells and the tumor microenvironment (TME), improving diagnosis and treatment strategies. This study aims to identify unique cell subtypes and factors distinguishing low-grade from high-grade EC, uncovering therapeutic targets to address tumor progression.

Methods: Tumors from ten treatment-naïve EC patients (four low-grade endometrioid, six high-grade (three endometrioid, three serous), and two age-matched non-malignant endometrial samples were collected at surgery and frozen. Nuclei were isolated from the frozen samples and single-cell libraries prepared using the Chromium Next GEM Single Cell Kit v3.1 according to the manufacturer's recommendations. Data were analyzed using Seurat v5 in R v4.3.3.

Results: Multiple phenotypic subsets of EC cells, T cells, fibroblasts, macrophages, endothelial, and epithelial cells were identified. Six distinct EC cell subsets were present across tumors, showing significant intratumoral heterogeneity. The *MKI67+* EC subcluster predominated in high-grade endometrioid EC, while *CHRM2/3+* EC subclusters were exclusive to high-grade serous EC. Both low- and high-grade endometrioid EC exhibited a high proportion of *PROM1+* (CD133) cancer stem cells. Epithelial-to-mesenchymal transition (EMT) genes (*COL1A2, BNC2, HNF1A-AS1, ITMC2, ZNF492*) were upregulated in high-grade EC compared to low-grade, correlating with aggressive phenotypes and poorer prognoses. High-grade EC showed increased activated T cells (PTPN14+), suggesting immune evasion, interestingly, low-grade EC had the highest proportion of exhausted T cells (TIM3+, PD1+) typically associated with aggressive tumors. Consistent macrophage subtypes were observed across EC cells, indicating T-cell-mediated alterations in the TME between EC grades.

Conclusion: This study provides the first comprehensive comparison of tumor cell diversity and TME components in low- and high-grade EC (endometrioid and serous). These findings, alongside ongoing *in vitro* studies, aim to uncover viable, subtype-specific therapeutic targets. *Both authors contributed equally

#6616 LMNA-FOSB fusions are a recurrent event in meningiomas.

Mateo Gomez Hjerthen[1], Josiah Wong[2], Juan Wang[2], Harrshavasan Congivaram[2], Priscilla K. Brastianos[3], Akash J. Patel[4], Craig M. Horbinski[1], James P. Chandler[1], E. Zeynep Erson Omay[5], Jennifer Moliterno[5], Murat Gunel[6], Stephen T. Magill[1], David R. Raleigh[7], Feng Yue[2], Mark W. Youngblood[1]

[1]Department of Neurosurgery, Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Department of Biochemistry and Molecular Genetics, Northwestern University Feinberg School of Medicine, Chicago, IL,[3]Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA,[4]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX,[5]Department of Neurosurgery, Yale School of Medicine, New Haven, CT,[6]Department of Neurosurgery, Genetics and Neuroscience, Yale School of Medicine, New Haven, CT,[7]Department of Neurological Surgery, University of California San Francisco, San Francisco, CA

Meningiomas are common tumors of the central nervous system associated with a small number of mutually exclusive genetic events. We identify a cohort of seven meningiomas that harbor fusions between the genes *LMNA* and *FOSB*, with no other known meningioma mutations. Previous reports of *LMNA-FOSB* fusions in epithelioid hemangiomas suggest a broader oncogenic potential for this event across tumor types. Lamin A/C is a structural protein involved in chromatin organization expressed ubiquitously in nearly all differentiated cells, while FOSB is an AP-1 family transcription factor implicated in cell proliferation and differentiation. Targeted, whole-genome, and RNA-sequencing approaches revealed a near identical *LMNA-FOSB* fusion comprising exons 1-2 of *LMNA* (chr1) and exons 2-4 of *FOSB* (chr19). The fusion event therefore includes key phosphorylation sites in Lamin A/C such as Ser22 that interact with active enhancers, while preserving the DNA binding domain of FOSB. Expression of these genes was not significantly altered among fusion samples, suggesting neomorphic protein function as an underlying oncogenic mechanism. Transfection of the *LMNA-FOSB* constructs into CH157 and IOMM-LEE meningioma cell lines resulted in changes to chromatin architecture and gene expression, which were validated using Hi-C and ChIP-seq profiling of frozen tumor tissues harboring this event. Our findings suggest that *LMNA-FOSB* fusions represent a novel and recurrent meningioma genetic event, providing new insights into the molecular pathogenesis of these tumors and role of FOSB across cancer.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genomic Profiling of Tumors 3
Poster Session

#6620 Low interferon expression coupled with 9p21 loss in non-small cell lung cancer (NSCLC) patients associated with distinct somatic landscape, altered immune population, and poorer response to immune checkpoint inhibitor (ICI) therapies.

Natalie Vokes[1], Jessica L. Symons[2], Brooke Rhead[2], Pooja A. Shah[1], Santiago Trevino[1], Konstantinos Levantakos[3], Stamatina Fragkogianni[2], Calvin Chao[2], Jordi A. Rodon[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Tempus AI, Chicago, IL,[3]Mayo Clinic, Rochester, MN

Deletions in 9p21 are common across multiple cancer types including NSCLC. Notably, 9p21 deletions have been implicated in an immune-excluded tumor immune phenotype and worse outcomes following ICIs. Whether this effect is due to *CDKN2A* loss, collateral loss of *MTAP*, or loss of type I interferon genes (*IFNK, IFNA*) has not been fully adjudicated. The Tempus Database (Tempus AI, Inc., Chicago, IL) was queried for de-identified records of patients with NSCLC and DNA (Tempus xT) and RNA (Tempus xR) molecular profiling. *CDKN2A*/*MTAP* deleted samples were defined as those containing biallelic loss of *CDKN2A/B* and *MTAP*. As *IFNK* is not included in the DNA sequencing bait set, *IFNK* status was defined as low in any sample with expression ≤ the first quartile of *IFNK* expression from samples with intact *CDKN2A*/*B* and *MTAP*. Samples with tumor purity < 40% or mixed loss of *CDKN2A*/*B* and *MTAP* were excluded. Association analysis of *CDKN2A*/*MTAP*/*IFNK* status with other genomic events and clinical outcomes was performed. N=16,947 patients were included in the overall analysis, of whom n=1,991 had *CDKN2A/B*/*MTAP* deletion (11.7%, CM^{del}). Significantly more CM^{del} patients had low *IFNK* expression compared to *CDKN2A/B*/*MTAP* intact (CM^{wt}) patients (n=14,956); of CM^{del} (n=1300), 65.3% had high *IFNK* expression ($IFNK^{hi}$) and 34.7% had low *IFNK* expression ($IFNK^{lo}$). Among CM^{del} patients, $IFNK^{hi}$ samples were enriched in never smokers compared to $IFNK^{lo}$ patients (24% vs 18%, p=0.002). CM^{del} was enriched in samples with *EGFR* and *ALK* driver alterations, and depleted in samples with *KRAS* or *TP53* alterations. In both CM^{del} and CM^{wt} contexts, *KRAS*, *EGFR*, and *ALK* alterations associated with $IFNK^{hi}$ expression, whereas *TP53*, *NFE2L2*, *STK11*, *KEAP1*, *SMARCA4*, and *KMT2D* associated with $IFNK^{lo}$ expression. $IFNK^{hi}$ expression within CM^{del} patients was associated with an increase in the estimated proportion of immune cell subpopulations, including CD8 T cells and macrophages (M1 and M2), and a decrease in neutrophils and NK cells. In metastatic/unresectable stage III patients with recorded ICI-containing 1L therapies (n=1,795), patients with CM^{del} and $IFNK^{lo}$ trended toward higher rates of progressive disease (PD) (37%), whereas $CM^{del}/IFNK^{hi}$ had comparable rates of PD to $CM^{wtl}/IFNK^{hi}$ and $CM^{wtl}/IFNK^{lo}$ (28%, 27%, 30%, respectively). $CM^{del}/IFNK^{lo}$ patients treated with non-ICI/TKI therapies (mostly consisting of chemotherapy) had a non-significant trend toward increased rate of PD (63%). CM^{del} associates with driver alterations in *EGFR* and *ALK*, along with worse ICI and chemotherapy outcomes in the context of $IFNK^{lo}$ but not $IFNK^{hi}$ expression. Further work to disentangle the impact of immune infiltrate and the co-mutation landscape will help clarify the underlying associated biology.

#6623 Ultra-deep multi-omics sequencing to identify drivers of glioblastoma recurrence and evolution.

Alexander Bahcheli[1], Philip Zuzarte[1], Sunit Das[2], Jared Simpson[1], Juri Reimand[1]

[1]Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Univeristy of Toronto, Toronto, ON, Canada

Glioblastoma (GBM) is the most prevalent and deadliest form of brain tumor with a median patient survival of 15 months after diagnosis. However, the mechanisms of tumor recurrence and the molecular alterations contributing to therapy resistance remain poorly understood. To address this challenge, we performed ultra-deep whole transcriptome, whole genome, and nanopore long-read sequencing of matched primary and recurrent GBMs of 12 adult patients with matching germline controls (fresh-frozen blood) and patient treatment and clinical histories. We generated a multi-omics datasets of single nucleotide variants (SNVs), structural variants (SVs), copy number alterations, genome-wide DNA methylation patterns, and transcriptomics. Our long-read sequencing data provided nucleotide-level methylation data to analyze genome-wide methylation patterns and high-quality structural variants for profiling complex genomic rearrangements and identifying episomes. Major changes between primary and recurrent samples in SVs, such as selection for *EGFR* translocations in recurrent tumors, and nucleotide-level methylation patterns, such as increased methylation of the *FUBP1* and *IDH1* promoters in recurrent tumors, were only detectable using long-read sequencing strategies, emphasizing the value of long-read sequencing in evolutionary analyses. We identified distinct mutational processes responsible for primary and recurrent tumor mutations and driving evolution of a recurrent tumor with therapeutic resistance. We found evidence of multi-omics dysregulation of oncogenes including promoter silencing by methylation and SVs selecting for the EGFR-vIII variant. Extensive inter- and intra-tumor heterogeneity and evidence of clonal selection in recurrent tumors was detected from ultra-deep whole genome sequencing, including selection for *EGFR* SNVs and *PTEN* and *RB1* copy number deletions in recurrent tumors. We found an enrichment of SVs and epigenetic modifications in recurrent tumors, such as increased methylation of *CDK4* and *CDK6* promoters, and a depletion of classical tumor drivers, such as *EGFR* and *CDK4* amplifications. Our integrative pathway analysis of multi-omics data of differentially methylated and expressed genes between primary and recurrent GBMs prioritized several glioma pathways enriched in recurrent tumors associated with glioma processes such as gliogenesis and angiogenesis. Our cohort had comparable mutation rates and processes as the Glioma Longitudinal Analysis (*GLASS*) consortium of paired primary-recurrent GBMs. However, our unique dataset of paired primary and recurrent GBMs provides an unprecedented multi-omics, multi-layered view of the genetic, transcriptomic, and epigenetic processes of GBM evolution.

#6624 Comprehensive, multi-omic detection of somatic variants from the GIAB HG008 matched tumor-normal pair using highly accurate long- and short-read whole-genome sequencing.

Alexandra Sockell[1], Khi Pin Chua[1], Christopher Kingsley[1], Dan Nasko[1], Matthew Boitano[1], Young Kim[1], Melanie Wescott[1], Ian McLaughlin[1], Primo Baybayan[1], Jennifer McDaniel[2], Andrew Shaver[1], Justin M. Zook[2], Aaron Wenger[1]

[1]PacBio, Menlo Park, CA,[2]National Institute of Standards and Technology, Gaithersburg, MD

Disentangling the molecular drivers of cancer progression requires a precise understanding of the somatic alterations that take place at the DNA level during tumor development. These include not only small changes like SNVs and indels, but also structural variants, changes in repetitive elements, differential methylation, as well as the haplotype context in which these changes occur. Existing short-read sequencing methods using sequencing by synthesis (SBS) chemistry lack the read length to characterize large structural variants or to span longer repetitive regions as well as to phase variants into haplotypes, while simultaneously lacking the sequencing accuracy to distinguish very low frequency somatic variants from background sequencing error or to sequence through shorter repetitive elements like microsatellites. Long-read PacBio HiFi data addresses the first set of challenges by accurately sequencing long fragments up to 25 kb, while highly accurate short-read sequencing by binding (SBB) chemistry from PacBio addresses the latter by improving raw sequencing accuracy by orders of magnitude, including in homopolymer regions which make up most microsatellites in the human genome.

Here we apply these highly accurate long- and short-read sequencing technologies from PacBio to perform whole-genome sequencing of the newly described HG008 matched tumor-normal pair from the Genome in a Bottle (GIAB) consortium. This reference sample includes an adherent, epithelial-like pancreatic adenocarcinoma (PDAC) cell line as the tumor material, with the matched normal obtained from adjacent duodenal and pancreatic tissue. We perform whole-genome sequencing with both PacBio HiFi (35X normal, 80X tumor) and SBB (50X normal, 100X tumor), followed by alignment and tumor-normal variant calling for all variant types. These accurate long- and short-read sequencing technologies offer a more robust and comprehensive picture of somatic variation in this reference sample and contribute to developing this novel benchmark.

#6625 LinkPrep™ - a comprehensive assay for cancer genome characterization - enabling structural variant detection and discovery of enhancer hijacking.

Ericca Stamper, Jon Torchia, Daniel Hwang, Chu Yuan Wu, Ek Danwanichakul, Cory Padilla, J. Zachary Sanborn, Lisa Munding

Dovetail Genomics, Cantata Bio, LLC, Scotts Valley, CA

Cancer arises from genetic and/or epigenetic disruptions. Currently, no single technology can capture the full range of variation that drives tumorigenesis with high sensitivity. Furthermore, epigenetic changes resulting from somatic variation remain poorly understood. The LinkPrep™ technology, a multi-purpose NGS assay, generates unbiased linked-read libraries through DNA proximity ligation that enable the discovery of structural variants (SVs) while simultaneously capturing 3D chromosome conformation linked to the tumor's epigenetic state. Importantly, LinkPrep data provides uniform coverage, allowing for the detection of single nucleotide variants (SNVs), insertions/deletions (InDels), and copy number variants (CNVs) with similar performance to whole genome shotgun sequencing (WGS). Libraries are generated from a single-day workflow and are compatible with Illumina sequencers.

In a comparison study, a fresh-frozen, clinical ovarian serous adenocarcinoma sample was profiled with LinkPrep (30X), WGS (30X), and RNA-seq (100M reads). Additionally, the same sample stored in FFPE was profiled with Dovetail-FFPE (30X), a linked-read technology designed to extract long-range genomic interactions from FFPE tissue. LinkPrep & Dovetail-FFPE both identified three translocations (tlocs) at high SV-VAF (>30%) between chromosomes 1, 3, and 12. These tlocs were supported by strong evidence (LinkPrep: 589 - 3,282 read pairs, Dovetail-FFPE: 417 - 5,802 read pairs) and confirmed by copy number changes. The tlocs were further validated through PCR and Sanger sequencing. By comparison, RNA-Seq detected only one fusion consistent with tloc(1;12), and WGS identified two tlocs with low specificity (ranked 140 and 374 of 404 putative tlocs). Furthermore, LinkPrep detected a subclonal event present at SV-VAF of 4.5% at tloc (2;15). LinkPrep and WGS produced concordant variant calls that showed >95% overlap with the set of known variants. Similarly, copy number profiles between LinkPrep and WGS showed >98% similarity.

To profile the promoter-enhancer genomic interactions at high coverage (200X), LinkPrep libraries were paired with the Dovetail® Pan Promoter Enrichment Panel. This revealed SV-driven neo-interactions, with interaction strength independent of SV VAF, suggesting biological mechanisms such as enhancer hijacking are at play.

In summary, LinkPrep outperforms WGS and RNA-seq in SV discovery with superior sensitivity and specificity, while maintaining comparable performance to WGS in the detection of SNVs, InDels, and CNVs. Additionally, LinkPrep captures epigenetic information in the same library, providing insights into epigenetic changes and drivers. Taken together, LinkPrep is a powerful tool for comprehensive profiling of the cancer genome - capturing the whole range of genetic variants and the 3D genome in a single dataset.

#6626 Comprehensive, high sensitivity, high resolution, somatic variant detection in solid tumors with LinkPrep - an NGS assay.

Cory C. Padilla, Ericca Stamper, Jonathan Torchia, Daniel Hwang, Mark Wadolkowski, Ek Danwanichakul, J. Zachary Sanborn, Lisa Munding

Dovetail Genomics, Scotts Valley, CA

The characterization of somatic variants, including structural variants (SVs), copy number variations (CNVs), and single-nucleotide variants (SNVs), is essential for understanding tumor biology. Current methodologies for somatic variant profiling are fragmented across several assays and requires ample sample material. We present LinkPrep™ assay, a novel linked-read NGS assay utilizing DNA proximity ligation, optimized for high sensitivity and high-resolution whole genome somatic variant detection. LinkPrep data enables unified profiling of SVs, CNVs, and SNVs/InDels from the same dataset, providing a streamlined approach to comprehensive genomic analysis. We applied the LinkPrep assay to a benchmark cohort consisting of cell lines (ductal carcinoma, HCC1187; myelogenous leukemia, K562) and clinically relevant tumor samples (ovarian serous adenocarcinoma, metastatic ovarian carcinoma, and nasal osteosarcoma). LinkPrep achieved high concordance with whole-genome sequencing (WGS) for CNVs (correlations >89% across all samples) while also detecting SVs with superior mean read support and robust F1 scores (cell lines). Moreover, LinkPrep demonstrated excellent overlap with WGS for SNVs and InDels, exceeding 92% across all samples, and identified critical oncogenic candidates. Notably, LinkPrep uncovered additional high-confidence SVs (including low SV VAF down to 1%) in clinical samples that were missed by WGS, highlighting its enhanced sensitivity for somatic variant detection in low tumor fraction samples. Furthermore, we demonstrate the ability to use LinkPrep data to refine SV breakpoints down to base pair resolution.
The data underscore the utility of the LinkPrep assay in translational research, where precise and comprehensive variant detection is imperative. This study establishes the LinkPrep assay as a next-generation tool for the detection of somatic variants, offering a robust and scalable solution for cancer genomics.

#6627 Clonal architecture analysis of response to PARP inhibition in prostate cancer.

Matias Vergara[1], Alok K. Tewari[2], Jake R. Conway[3], Sabrina Y. Camp[2], Jihye Park[2], Brendan Reardon[2], Wassim Abida[4], David B. Solit[5], Nikolaus Schultz[6], Keyan Salari[7], Eliezer M. Van Allen[2]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]PathAI, Boston, MA,[4]Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Department of Urology, Massachusetts General Hospital, Boston, MA

Background: Prior studies have charted the clonal and subclonal evolutionary dynamics (“clonal architecture”) of prostate cancer (PC), although the relationship between PC clonal architecture and therapeutic response remains unclear. PARP inhibition (PARPi) is an approved genomic strategy for treating PCs deficient in homologous recombination (HRD) as determined by specific gene alterations. As clinical responses to PARPi are heterogeneous and not exclusively associated with specific gene mutations, and HRD can exhibit discrete mutational and copy number signatures, we hypothesized that deriving overall tumor and clone-specific mutational signatures in prostate tumors may reveal novel associations between clonal architecture and clinical response to PARPi.

Methods: We analyzed two independent cohorts of PC whole exome sequencing data that passed quality control metrics (Cohort 1: N=845 patients and 1 sample per patient, Cohort 2: N= 185 patients and 21 patients having multiple samples, enriched for patients with known deleterious BRCA2 alterations). For each tumor/normal paired sample, mutations and copy-number alterations were identified and used as input for phylogenetic reconstruction as well as single-nucleotide and copy-number mutational signatures. We examined the relationship between single gene germline or somatic alterations, tumor and clone-specific mutational signatures of HRD such as COSMIC mutational signature 3 (Sig3), and clinical response to PARP inhibition or immune checkpoint blockade. Here we report features of tumor and clone-specific Sig3 positivity (Sig3+) and association with clinical response in these two cohorts.

Results: In Cohort 1, evidence of HRD at the tumor level by Sig3+ was detected in 2% (11/560) of primary tumors and 23.6% (67/285) of metastatic tumors. 31 Cohort 1 patients had germline or somatic alterations in BRCA2. 51.2% (40/78) of Sig3+ tumors had detectable Sig3+ at the individual and clone-specific level, including 12 tumors with only clone-specific Sig3+. Of the 37 patients in cohort 1 treated with PARPi and Sig3+ information, patients with detectable Sig3+ had a lower hazard for progression with treatment at the tumor level (HR = 0.60, p = 0.31), individual clone level (HR = 0.45, p = 0.095), or either (HR = 0.59, p = 0.20) compared to patient tumors with no detectable Sig3+. In Cohort 2, 68.4% (63/92) of primary and 76.7% (89/116) of metastatic tumors were Sig3+. 30 primary and 59 metastatic samples in Cohort 2, the majority of patients in each category, harbored deleterious BRCA2 alterations. 90.1% (137/152) of Sig3+ tumors had detectable Sig3+ at the individual clone level, including 18 with only clone-specific Sig3+. Analysis of clinical outcomes in Cohort 2 is ongoing.

Conclusions: Clone-specific evidence of HRD using clonal architecture and mutational signature analysis is detectable and may identify additional PC patients who could benefit from PARPi.

#6628 Deep dive into the performance of structural variants reported by PGDx elio plasma focus Dx.

Amy Meltzer[1], Jesse Fox[1], Kenneth C. Valkenburg[1], Tonya Watkins[1], Sonomi Dillon[1], Pengfei Gu[1], Ana Perez-Lebron[1], Robert Summersgill[1], Annabelle Culi[1], Nesha Jackson[1], Stephen Higgins[1], Kristy Waszkiewicz[1], Nobel Girmay[1], James Occean[1], Cal Palumbo[1], David Holcomb[1], Kelly Gerding[1], David Riley[1], Sam Angiuoli[1], Aanavi Karandikar[2], Rami Zahr[2], Jennifer Dickey[3], Eric Severson[4], Shakti Ramkissoon[4], Brian Caveney[5]

[1]Research and Development, PGDx Labcorp, Baltimore, MD,[2]Labcorp Oncology, PGDx Labcorp, Baltimore, MD,[3]Regulatory & Quality, PGDx Labcorp, Baltimore, MD,[4]Labcorp Oncology, Labcorp, Durham, NC,[5]Chief Medical and Scientific Officer, Labcorp, Durham, NC

Introduction: Liquid biopsy NGS assays allow for detection of genes clinically relevant to oncology including structural variants such as amplifications and translocations. Due to their low concentration in plasma, structural variants can be difficult to detect with liquid biopsy. Translocations in particular present challenges due to their low prevalence in ctDNA as opposed to RNA. PGDx elio™ plasma focus Dx is an IVD tumor profiling assay which reports 33 genes including difficult to detect structural variants with high sensitivity, specificity, accuracy, and reproducibility. Here, the performance of structural variants is explored using data from analytical validation studies.
Methods: Samples were processed with PGDx elio plasma focus Dx, a NGS based tumor profiling assay capturing 33 clinically relevant genes using cfDNA obtained from plasma. For amplifications, 5 genes are reported (ERBB2, MET, CCND1, CD274, and FGFR2) and for translocations, 3 genes are reported (ALK, NTRK1, and RET). Libraries were sequenced with 150 bp paired end NGS and processed through the EPF software which performs demultiplexing, alignment, and variant calling utilizing DK for amplifications and PARE for translocations. Analytical validation studies were conducted at the gene level across key studies including accuracy, sensitivity, specificity, and reproducibility. For accuracy, results were compared to 5 orthogonal methods with a total of 931 clinical samples across 35 solid tumor types. Specificity was assessed with 68 healthy plasma samples. To assess sensitivity, all amplifications and translocations were established with a dilution series using cell line blends spiked into plasma and confirmed with clinical plasma blends diluted into normal plasma. Performance between clinical plasma and contrived samples was established with a contrived sample functional characterization study. Reproducibility was assessed with an interlaboratory reproducibility (ILR) study across 3 different sites with over 500 total replicates.
Results: The test demonstrated variant concordance of 93.1% PPA and 99.8% NPA for translocations and 90.1% PPA and 100% NPA for amplifications (excluding borderline calls, 1.2-1.8-fold). Analytical specificity was 100% for both amplifications and translocations. Analytical sensitivity (limit of detection, (LoD) 95%) was assessed for each structural variant on the panel and ranged from 0.41% - 0.49% FRF for translocations and 1.3 - 1.7-fold for amplifications. The ILR study resulted in 96.1% average percent agreement (APA) and 99.6% average negative agreement (ANA) for amplifications and 95.3% APA and 99.5% ANA for translocations.
Conclusions: These analytical validation results demonstrate PGDx elio plasma focus Dx detects structural variants with high accuracy, sensitivity, specificity, and reproducibility, supporting the use for precision oncology.

#6629 Spatial immunogenomic analysis of the transformation process in acquired cystic disease of the kidney.

Jun TAKAHASHI[1], Yosuke Tanaka[1], Yusuke Sato[2], Tetsuo Ushiku[3], Hiroyoshi Nishikawa[4], Haruki Kume[2], Hiroyuki Mano[1]

[1]Division of Cellular Signaling, National Cancer Center Research Institute, Tokyo, Japan,[2]Department of Urology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[3]Department of Pathology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[4]Division of Cancer Immunology, National Cancer Center Research Institute, Tokyo, Japan

Chronic kidney disease (CKD) is one of the leading causes of death, affecting more than 10 % of the general population worldwide. When CKD progresses to the advanced stage known as end-stage renal disease (ESRD), patients require kidney replacement therapy such as dialysis or kidney transplantation. The prevalence of dialysis patients in Japan is 2,535 per million population, which is much higher than those in Western countries, mainly due to the low number of kidney transplants in Japan. One of the critical complications of dialysis is the high incidence of kidney cancer, which is approximately 15 times higher than in the general population. More than 90 % of patients on dialysis for more than 10 years develop acquired cystic kidney disease (ACKD), which has been reported to be associated with the development of kidney cancer. However, the molecular mechanism underlying ACKD-associated RCC(ACD-RCC) has not been elucidated. We performed multi-omic analyses of ACKD especially from a spatial immunogenomic perspective. We collected the data of 26 single-cell transcriptomes and 26 spatial transcriptomes using 10x Genomics platform as well as 42 exome sequencing and 86 RNA sequencing for renal cysts and tumors from ACKD patients. Normal kidney tissues from non-dialysis patients were also analyzed. The mutational landscape of ACD-RCC and ESRD-clear cell renal cell carcinoma(ccRCC) was totally different from that of the sporadic ccRCC. Specifically, ccRCC in ACKD patients was characterized by a higher incidence of *TCEB1* mutations (35.3%). Analysis on the noncancerous tissues in ACKD revealed the unique transcriptomic features of renal cysts in ACKD with a characteristic of inflammatory signaling activation. Specifically, unique immune cell infiltration patterns of lymphocytes and macrophages in ACKD were identified, which are distinct from those in normal kidney tissue. Our integrative single cell and spatial analyses identified renal cyst cluster which is characterized by activation of proximal tubular genes, and our data support that renal cysts and subsequent dialysis-related tumors both originate from proximal tubular cells. Also, we estimated copy number variation in renal cysts and found shared copy number variation with tumors. Furthermore, we identified specific mutations concentrated in the cyst wall using laser capture microdissection, suggesting that a single cyst may have arisen from a single clone. Also, we analyzed intercellular communication and identified important pathways for nurturing cysts formation including signaling pathway. Collectively, our results will contribute to the suppression of cystic kidney and renal tumors, and pave the way for improving the prognosis of patients with ACKD.

#6630 Ancestry and lung adenocarcinoma: exploring ancestry-associated variations in tumor metabolism, mitochondrial dysfunction, and immune dynamics.

Yuxin Jin[1], Yonatan Amzaleg[1], Angel P. Hunt[1], Benecia Jackson[2], Dan Raz[3], Loretta Erhunmwunsee[3], John Carpten[1], **Aaron M. Neely**[1]

[1]Integrative Translational Sciences, Beckman Research Institute of The City of Hope, Los Angeles, CA,[2]Division of Health Equities, Beckman Research Institute of The City of Hope, Los Angeles, CA,[3]Division of Thoracic Surgery, Beckman Research Institute of The City of Hope, Los Angeles, CA

Lung adenocarcinoma (LUAD) is a highly heterogeneous cancer, characterized by diverse genetic mutations, metabolic reprogramming, and complex immune microenvironments. Patients of African ancestry (AFR) often experience distinct clinical outcomes in LUAD (Manojlovic Z, et al. 2017), potentially driven by unique genetic and metabolic adaptations within tumors (Telonis, Aristeidis G et al. 2024, Kap EJ, Seibold P, et al.,. 2016). Global and local ancestry analyses have shown that genetic ancestry can influence tumor behavior, including immune interactions and cellular energy metabolism (Manojlovic Z, et al., Telonis, Aristeidis G et al. 2024). However, there is limited understanding of how AFR ancestry impacts LUAD, particularly regarding tumor metabolism, mitochondrial dynamics, programmed cell death (PCD) pathways, and immune response. The immune microenvironment of LUAD tumors varies widely, and understanding how ancestry affects immune compartment composition and immune cell infiltration could offer insight into observed disparate phenotypic severity and differential responses to therapy. This study aims to uncover the ancestry-linked mutational landscape across tumor metabolism, mitochondrial dynamics, and immune recruitment in LUAD, hypothesizing that these differences may contribute to demonstrative disparities in differential LUAD malignancy severity and patient outcomes. We hypothesize that LUAD tumors in patients of AFR genetic similarity will exhibit unique mutations and transcriptional profiles in metabolic, mitochondrial, and immune-related genes, resulting in distinct metabolic programs, immune infiltration patterns, and differential activation of PCD pathways. These variations could influence tumor progression, immune evasion, and response to treatment in an ancestry-dependent manner. By combining spatial, single-cell, and genetic profiling techniques, this study aims to uncover the ancestry-associated interplay between tumor metabolism, mitochondrial dynamics, PCD, and immune compartment composition in LUAD. Insights from this work could inform ancestry-tailored therapeutic strategies and ultimately improve clinical outcomes for LUAD patients across diverse populations. Admixture analysis highlighted genetic diversity within our diverse LUAD patient cohort as Black patients illustrated predominant AFR genetic similarity with varying proportions of EUR, AMR and SAS similarity. Local ancestry analysis revealed admixture across different regions of the genome demonstrating variations in ancestral contributions within and between individuals of the same cohort and compared to counterparts in other populations. Additionally, we observed associations between high AFR genetic similarity and mutations in metabolic, immune and mitochondrial genes.

#6631 High-resolution characterization of FFPE-derived linked-read libraries for cancer genomics.

Alexander Fortuna, Jon Torchia, Mital Bhatka, Natalie Fredriksson, Daniel Hwang, Ek Danwanichakul, Cory Padilla, J. Zachary Sandborn, Lisa Munding

Cantata Bio, Scotts Valley, CA

Deciphering genomic architecture is crucial for identifying novel disease drivers and understanding cancer initiation and progression mechanisms. While short-read sequencing remains the primary tool in cancer genomics, it may miss important structural variants (SVs), especially large chromosomal alterations. A further challenge to cancer researchers is working with FFPE (formalin-fixed, paraffin-embedded) samples, the most common source of archived material, as this sample type is often at risk of nucleic acid fragmentation, DNA crosslinks, and deamination, further complicating variant discovery. We present a Dovetail-FFPE assay, an MNase-HiC-based method compatible with FFPE samples that generates linked-reads to enable improved sensitivity for SV detection. Here, we evaluate the performance of Dovetail-FFPE against a shotgun sequencing library in FFPE and FF (fresh frozen) using a clinical serous ovarian adenocarcinoma (HGSOC) sample. We generated WGS and Dovetail-FFPE libraries at 30x target coverage and utilized BWA for alignment, with Hi-C breakfinder (Dovetail-FFPE) and Manta (WGS) for SV calling. Both Dovetail-FFPE and WGS datasets were analyzed using DeepSomatic for SNV and intel detection, while CNVs were identified using Purple. Dovetail-FFPE analysis revealed four translocations (tlocs) with strong supporting evidence (1;12, 3;12, 3;4, 2;15). These tlocs, also identified in a MicroC-FF sample and validated by PCR and Sanger sequencing, corresponded with copy number changes and occurred at CNV boundaries. In contrast, WGS detected only two of these four tlocs with lower precision. Somatic mutations in coding regions showed high concordance between methods. The Dovetail-FFPE library successfully recalled all pathogenic variants from the truth set (defined as pathogenic/likely pathogenic significance by ClinVar in the FF WGS sample). Copy number analysis demonstrated strong concordance between Dovetail-FFPE and FF-WGS (89%), recalling a heterozygous deletion of chromosome 1p and gains of 1q and 12. Additionally, shotgun, Dovetail-FFPE, and MicroC-FF showed agreement in predicted purity, ploidy, and percentage of genome altered. Our findings demonstrate that Dovetail-FFPE libraries can effectively detect SVs identified in FF libraries and outperform shotgun libraries. Combined with its capability to identify SNVs, indels, and CNVs, linked-read sequencing proves to be a valuable tool for comprehensive genetic variation discovery.

#6633 Survival implications of *CDKN2A/2B* deletion, *MET* amplification and *PIK3R1* mutation in adult type diffuse glioma.

Yongjae Kim[1], Soyoung Park[1], Soo Jeong Nam[2], Kang-Seo Park[3], Ji Eun Park[4], Hye Hyeon Moon[4], Chang Ohk Sung[2], Sang Woo Song[5], Young-Hoon Kim[5], Chang-Ki Hong[5], Jeong Hoon Kim[5], Shinkyo Yoon[3], Ho-Su Lee[1]

[1]Department of Biochemistry and Molecular Biology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[3]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[4]Department of Radiology and Research Institute of Radiology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[5]Department of Neurological Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Diffuse gliomas, the most common primary brain tumors, present significant variations in morphology, location, genetic alterations, and treatment responses. However, the relationship between their molecular profiles and disease outcomes remains poorly understood. This study analyzed 470 primary diffuse glioma samples collected between 2017 and 2021 using the next-generation sequencing Oncopanel AMC, following the 2021 WHO criteria, to classify the tumors and analyze their clinical impact on overall survival. Statistical analyses included multivariable Cox regression, reporting hazard ratios (HR) with 95% confidence intervals (95% CI), and Kaplan-Meier survival analysis. The classification resulted in three subtypes: oligodendroglioma (n=68), diffuse astrocytoma (n=63), and glioblastoma (n=339). The median age of glioblastoma patients (64 years) was higher compared with oligodendroglioma (50 years) and diffuse astrocytoma (41 years). Gender and tumor mutational burden showed no significant association with subtypes. Oligodendroglioma was characterized by *IDH* mutations and 1p/19q co-deletion (100%), with frequent mutations in *NOTCH1* (27.9%), *FUBP1* (20.6%), and *ARID1A* (19.1%). Diffuse astrocytoma was marked by *IDH* mutations (100%) and high prevalence of mutations in *TP53* (92.1%) and *ATRX* (79.4%). Glioblastoma showed *CDKN2A/2B* loss (52.5%), *EGFR* amplification (30.4%), and *TP53* mutation (35.1%). The incidence of *MTAP* loss identified using specific version of the Oncopanel was observed to be 2.4% in oligodendroglioma, 14.3% in diffuse astrocytoma, and 45.4% in glioblastoma, with no significant association observed with survival. The median overall survival from the diagnosis were 30.7 months for oligodendroglioma, 27.8 months for diffuse astrocytoma, and 14.9 months for glioblastoma. In glioblastoma patients, a multivariable Cox regression analysis identified significant survival factors: older age≥60years (HR=1.35 [1.03-1.76], p=0.031), lack of MGMT promoter methylation (HR [95% CI]=1.53 [1.16-2.02], p=0.003), impaired performance status (HR [95% CI]=1.68 [1.30-2.16], $p=7.03\times10^{-5}$), bilateral disease (HR [95% CI]=1.71 [1.13-2.57], p=0.010), *PIK3R1* mutation (HR [95% CI]=1.52 [1.05-2.18], p=0.025), *CDKN2A/2B* deletion (HR [95% CI]=1.41 [1.09-1.83], p=0.010), and *MET* amplification (HR [95% CI]=2.33 [1.19-4.54], p=0.013). This study provides insights for improved understanding and potential targeted therapies based on genetic profiling of diffuse gliomas, particularly highlighting the prognostic significance of *CDKN2A/2B* deletion, *MET* amplification, and *PIK3R1* mutation in glioblastoma. These findings may guide future clinical trials drug repurposing, potentially leading to improved outcomes for patients with diffuse gliomas.

#6634 Enhanced detection of gene fusions in sarcoma using Genomic Proximity Mapping in FFPE tissue.

Yajuan J. Liu[1], He Fang[2], Maika Malig[3], Emily Reister[3], Mary Wood[3], Ivan Liachko[3], Stephen M. Eacker[3]

[1]The Permanente Medical Group Regional Genomics Laboratory, Kaiser Permanente, San Jose, CA,[2]University of Washington, Seattle, WA,[3]Phase Genomics, Inc., Seattle, WA

Sarcomas are soft-tissue tumors that pose significant diagnostic challenges for clinical laboratories. With more than 80 subtypes, accurate classification of sarcomas is crucial for providing valuable prognostic and therapeutic guidance. Gene fusions are a hallmark of many sarcoma subtypes, offering pathognomonic markers for diagnosis. Routine pathological diagnosis typically involves hematoxylin and eosin (H&E) staining and immunohistochemistry (IHC), with diagnostic samples most commonly preserved as formalin-fixed, paraffin-embedded (FFPE) specimens. However, FFPE preservation precludes conventional chromosome analysis and presents challenges for molecular tests such as those require high molecular weight DNA (i.e. long read sequencing and optical genome mapping). In addition, current methods, such as fluorescence in situ hybridization (FISH) and targeted RNA-seq panels, have limitations, including the restricted number of genes interrogated, dependence on known gene rearrangement breakpoints or chimera transcripts, and sensitivity to RNA quality, especially in FFPE samples. To address these limitations, we developed a new protocol for genome-wide detection of chromosomal abnormalities using Genomic Proximity Mapping (GPM) technology. GPM is a next-generation cytogenomic technique that employs proximity ligation and low-pass sequencing to identify structural variants and gene fusions across the entire genome. As a DNA-based, genome-wide assay, GPM overcomes the primary constraints of FISH and targeted gene panel by RNA-seq. To evaluate the performance of GPM, we applied it to 12 sarcoma samples that had previously underperformed or failed Anchored Multiplex PCR (AMP) analysis using the FusionPlex solid tumor gene panel. In all cases, GPM not only recapitulated the previous findings but also identified additional pathognomonic fusions in 33% of cases where targeted RNA-seq methods failed due to RNA quality issues or the limited scope of targeted analysis. Overall, GPM detected novel structural variants genome-wide and identified definitive gene fusions were in 8 sarcoma subtypes, achieving a sensitivity >0.9 and specificity of 1. In addition to detecting translocations, inversions, and insertions, GPM can identify novel gene fusions, deletions, duplications/amplifications, and copy-neutral loss of heterozygosity. GPM represents a novel, genome-wide approach to identifying both known and novel gene fusions, as well as other chromosomal abnormalities, in FFPE tissue. It enhances sarcoma classification where other methods fail, addressing the limitations of current cytogenetic and other NGS technologies.

#6635 Use of contrived multiplexed FFPE specimens to evaluate CGP from extraction to variant calling.

Dana Ruminski Lowe, Richard Howard, Edward S. Davis, Andrew Anfora, Yves Konigshofer, Catherine Huang, Russell Garlick, Bharathi Anekella

LGC Clinical Diagnostics, Gaithersburg, MD

Formalin fixed and paraffin embedded (FFPE) samples are a common, yet challenging type of patient sample in comprehensive genomic profiling (CGP). DNA extracted from FFPE is often highly cross-linked, degraded, and fragmented. Yield from patient samples can also be limited, thus optimization of extraction in regard to amount and quality of DNA is crucial to the success of downstream analysis. Contrived reference materials are a convenient sample source to evaluate all steps in a CGP workflow. First, they can be used to optimize and validate extraction as they are readily available and consistent in yield and composition. In addition, they are highly multiplexed, making validation of the analytical part of CGP more efficient and cost effective. Finally, complex, difficult to call variants can be easily included to critically analyze the bioinformatics as well. Here we describe the development and evaluation of Seraseq® FFPE Solid Tumor Reference Material.

GM24385 cells were engineered to carry 74 biosynthetic DNA variants across 62 genes including single nucleotide variants (SNVs), insertions and deletions (indels), structural variants (SVs), and mono- and dinucleotide biomarkers for microsatellite instability (MSI). Variant allele frequency (VAF) was verified using the Bio-Rad QX-200 Droplet Digital PCR (ddPCR) System. The cells were formalin fixed, embedded in paraffin blocks and sectioned at 10 micron thickness. Extraction was performed with various commercially available kits from QIAGEN, Promega, and AutoGen. Yields were analyzed using Qubit dsDNA HS and ddPCR. TapeStation Genomic DNA ScreenTape assay was used to assess fragment size and DNA integrity. The extracted DNA was analyzed with the Illumina TruSight™ Oncology 500 (TSO 500) and the ArcherDx VariantPlex (IDT) NGS assays as well as the Biocartis Idylla IDH1-2 Mutation Assay.

Yields were variable between extraction kits; interestingly, yields determined using Qubit did not always correlate with those measured by ddPCR indicating some kits result in more amplifiable DNA than others. Quality and average fragment size also varied between kits but did not affect downstream analysis. The Idylla platform showed positive detection for all IDH1 and IDH2 variants in the FFPE sections. The average VAF was 26.7% ± 5.7% and 36.3% ± 7.3% as measured by the TSO 500 and VariantPlex assays, respectively. Variants that were originally missed by variant callers could often be seen in raw data files upon further investigation.

This study indicates that use of a multiplexed FFPE reference material that provides a data rich readout of actionable variants can be valuable in the initial assessment, analytic validation, and performance monitoring of all parts of CGP workflows.

#6636 Multi-site evaluation of expanded solid tumor, pan-cancer reference material.

Dana Ruminski Lowe, Patricia Helsel, Praveena Kamineni, Edward S. Davis, Andrew Anfora, Yves Konigshofer, Catherine Huang, Russell Garlick, Bharathi Anekella

LGC Clinical Diagnostics, Gaithersburg, MD

Next generation sequencing (NGS) of biopsy-extracted material remains the gold standard for tumor profiling. Panels designed for this type of testing often target 500+ genes, creating a challenge for analytic validation in a clinical setting. Use of patient-like multiplexed commercial reference materials can be a more cost effective and reliable option versus relying on remnant samples with mutations of interest, especially with more stringent requirements from the FDA and other regulators in the early stages of implementation. Here we describe the development and multisite evaluation of expanded Seraseq® Tumor Mutation DNA Mix v3 reference materials, which contain an expanded variant list to meet the growing needs of NGS tumor profiling assay developers.

Genomic DNA from the GM24385 cell line was blended with 113 clinically relevant biosynthetic DNA variants including single nucleotide variants (SNVs), insertions and deletions (indels), structural variants (SVs), copy number variations (CNVs), and mono- and dinucleotide biomarkers for microsatellite instability (MSI). Three mixes were made: AF7% in which all variants were targeted at variant allele frequency (VAF) of 7% and CNVs at 6 additional copies, AF10% in which all variants were targeted at VAF of 10% and CNVs at 12 additional copies, and Tri-Level in which certain variants were targeted at 4%, 7%, or 10% and CNVs at 3, 6, or 12 additional copies. All VAFs and CNVs were measured using the Bio-Rad QX-200 Droplet Digital PCR (ddPCR) System. DNA quality was analyzed with the Agilent TapeStation Genomic DNA ScreenTape assay. The mixes were analyzed with the Illumina TruSight™ Oncology 500 (TSO 500) assay and additional assays.

All biosynthetic SNVs, indels, SVs, and CNVs were detected near target values and DIN (DNA integrity number) values were >7. The VAFs and CNVs observed in the TSO 500 data correlated well with those that were obtained by dPCR. Variants reported by all evaluation site assays showed good concordance of VAF values. Even when variant callers did not report an expected variant, raw data files were investigated and reads with evidence of those variants were discovered.

The performance of the Seraseq Mutation DNA Mix v3 materials across NGS assays, supported by robust digital PCR data, demonstrated that these materials will allow for assessment of more complex and tumor profiling tests using a single reference sample.

#6637 Whole exome analysis of oral squamous cell carcinoma in local patients at tertiary care hospitals in Peshawar, Pakistan.

Faisal Khan[1], Hina Zamir[1], Khudeja Salim[1], Madina Shirdel[1], Arsalan Riaz[1], Aqsa Hussain[1], Yusra Ilyas[1], Momal Agha[1], Zainab Jahan[1], Saba Saeed[1], Khadim Shah[2], Yasir Rehman[2], Fahim Uddin[2], Zahid Qayyum[2], Zubair Durrani[3], Muhammad Mushtaq Khattak[2], Johar Ali[4]

[1]Precision Medicine Lab, Peshawar, Pakistan,[2]Hayatabad Medical Complex, Peshawar, Pakistan,[3]Rehman Medical Institute, Peshawar, Pakistan,[4]Usman Institute of Technology, Karachi, Pakistan

The Precision Medicine Lab (PML) was established by the Federal Government in 2018 to pilot precision medicine in Pakistan using genomics in oral cancer. Oral squamous cell carcinoma (OSCC)—often called the "poor man's cancer"—constitutes 90% of all head and neck cancers and is the most common cancer in Pakistani males. Supported by a bio-repository of clinical samples and primary cell lines, PML employs a multi-omic approach to identify actionable biomarkers for diagnostic, prognostic, and therapeutic applications.

With ethical approvals from IRBs and informed consent, treatment-naive biopsy-confirmed OSCC patients were recruited from two tertiary care hospitals in Peshawar, Pakistan. The cohort predominantly included older individuals (37.84% aged 41-60 years), late-stage cases (78.46% in stage IV), and self-reported non-alcohol consumers (96.9%). Smokeless tobacco use was reported by 44.6%, while 30.8% reported both smoked and smokeless tobacco use. Tumors were mostly located in the buccal mucosa (29.2%), alveolar region (27.7%), or vestibular region (24.6%). Blood and tumor samples were collected for whole exome sequencing, transcriptomics, and metabolomics, along with saliva for oral microbiome analysis. Combined with clinical history and histopathology, this multi-omic dataset enables machine learning experiments.

For somatic mutation analysis, raw reads were aligned to the GRCh38.p14 genome, and variants were identified using GATK (v4.5). Mutational analyses with maftools (v2.18.0) in R (v4.3) referenced the COSMIC SBS Signature database (v3.2). Results revealed CASP8 (39%), TP53 (38%), FAT1 (29%), and NOTCH1 (29%) as frequently mutated genes. Pathways such as NOTCH (80.3%), RTK-RAS (64.3%), and Hippo (60.7%) were commonly affected. Deletions were observed in over 60% of samples in chromosomal regions 5q13.2, 6p21.32, 6p21.33, 11p15.5, 19q13.42, and 22q11.23, along with loss of heterozygosity at chromosome 17. The top three mutational signatures included those linked to DNA mismatch repair (SBS6).

This study is the first to report the mutational landscape of an OSCC cohort from Pakistan. Our findings highlight potential targets for further investigation and emphasize the utility of a multi-omic approach. With matched primary cell lines for each patient, experimental validation of identified biomarkers is underway to assess their diagnostic, prognostic, and therapeutic relevance. Our integrated dataset offers a resource for machine learning studies to identify novel mutational signatures and actionable biomarkers for OSCC in local populations.

#6638 Identifying cancer germline variants associated with patient prognosis and response by applying clinico-genomics data.

Si Wu[1], Margaret Tsui[2], Robert T. McLaughlin[1], Hiteshi Dehal[1], Conor M. O'Donoghue[1], Jifeng Qian[1], Kevin Zhao[1], Bridget Riley Gillis[3], Fedik Rahimov[3], Josue Samayoa[1], Xi Zhao[1], **Weilong Zhao**[1]

[1]Abbvie South San Francisco, South San Francisco, CA,[2]UC San Francisco, San Francisco, CA,[3]Genomics Research Center, Human Genetics, Abbvie, North Chicago, IL

Germline variants have been recognized as a key determinant in cancer susceptibilities, patient prognosis and treatment outcome. Previous studies have highlighted significant differences in pathogenic variant frequencies across different populations, underscoring the influence of ancestry-specific genetics on cancer risk, survival and drug response. Leveraging extensive real-world data from ConcertAI® electronic health records (EHR) linked with Caris Life Sciences genomic data, we analyzed germline variants in a diverse multi-cancer cohort of 2,776 tumors, including five indications: non-small cell lung cancer (NSCLC, 1,514), colorectal cancer (860), pancreatic (218), gastroesophageal (96), and breast (88) cancers. Notably, we observed a higher proportion of African Americans in breast cancer and more males with gastroesophageal and pancreatic cancers, mirroring US cancer incidence across racial and gender groups. Following germline variant calling by DNA-seq pipeline and annotation by snpeff and snpsift dbSNP, we filtered out low quality and suspected somatic mutations. Utilizing the ClinVar database and the CharGer tool, we identified pathogenic variants in cancer risk genes for each cancer type. When comparing the frequencies of pathogenic variants in ASCO-recommended high-risk genes between our pan-cancer cohort and TCGA, we found that the frequencies were generally comparable. Subsequently, we tested for the association of these pathogenic variants with patient overall survival. Statistically significant associations were detected between patient poor survival and pathogenic variants in *STK11* ($p = 0.005$, in lung NSCLC), *SMAD4* ($p = 0.013$, in colorectal cancer), and *CDKN2A* ($p = 0.034$, in pancreatic cancer), alongside novel associations with *PTH* ($p = 0.012$ and 0.024 in gastroesophageal and pancreatic cancers) and *HFE* ($p = 0.037$, in pancreatic cancer). Intriguingly, Asian patients exhibited a much higher frequency of *PTH* variants (allele frequency > 0.30 %) than other races, while *HFE* variants were more common in Hispanic/Latino populations, reported to cause hereditary hemochromatosis. Although no significant association with immunotherapy (IO) response was detected in the curated NSCLC IO response cohort, the potential links with additional IO markers (e.g., tumor mutational burden, immunologic constant of rejection score, Miracle score) warrant further exploration. Our study describes an innovative approach for investigating the relationships between germline variants and cancer patient prognosis and treatment responses using the EHR linked genomics data — an area often under-explored. Our approach integrates genetic profiling with comprehensive clinical data to characterize germline variants that may serve as predictive biomarkers, ultimately aiming to advance personalized medicine and improve patient outcomes.

#6639 Optimized selection of tumor-informed MRD panels enhances sensitivity of ctDNA detection.

Ashley Acevedo, Ravi Patel, Kyle Trettin, Nafei Xu, Genevieve Gould, Dale Muzzey

Myriad Genetics, Inc., Salt Lake City, UT

Circulating tumor DNA (ctDNA) is a highly sensitive and specific biomarker for molecular residual disease (MRD) and can be by identified by the presence of tumor-specific somatic variants. We have developed a second-generation hybrid-capture-based tumor-informed MRD assay to detect the presence and quantity of ctDNA in plasma-derived cell-free DNA (cfDNA). Our assay surveys the whole tumor genome to identify the superset of high-confidence somatic variant targets that can be used to distinguish ctDNA from non-tumor cfDNA. Each panel consists of up to 1000 targets that are selected based on target-specific and tumor-specific features that impact the representation of tumor variants or the effective molecular depth of a panel, such as somatic call confidence, zygosity, copy number, background error rate and expected molecular depth following capture and sequencing. cfDNA captured using a patient-matched panel undergoes targeted sequencing and that sequence data is fit to a statistical model that evaluates the presence and fraction of ctDNA in the sample. Here, we evaluated the performance of our target-ranking algorithm using contrived mixtures of matched tumor and normal cell lines, with tumor DNA concentrations ranging from 5 to 10,000 parts per million (ppm) and samples processed across multiple days, reagent lots, operators and instruments. Identical sets of contrived samples were analyzed using subsets of panel targets, including top-ranking and bottom-ranking target sets. We found the Limit of Detection with 95% sensitivity (LoD95) for top-ranking targets was 40% of the LoD95 for low-ranking targets, demonstrating the effectiveness of our ranking algorithm in stratifying high and low sensitivity targets. In conclusion, the constituents of tumor-informed MRD panels have a measurable impact on the sensitivity of ctDNA detection and, with optimization, can enhance the resolution of residual disease detection.

#6640 The characteristics of IgD subtype myeloma with distinctive genomic mutational signature and gene expression patterns.

Sheehyun Kim[1], Hyundong Yoon[2], Youngil Koh[1], Sung-Soo Yoon[1]

[1]Seoul National University Hospital, Seoul, Korea, Republic of,[2]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of

Background: Multiple myeloma (MM) is characterized by the neoplastic proliferation of a single clone of plasma cells that produce monoclonal immunoglobulins. Among its subtypes, immunoglobulin D multiple myeloma (IgD MM) is rare, accounting for less than 2% of all MM cases. IgD MM is often associated with rapid disease progression at diagnosis, an aggressive clinical course, and a poor prognosis compared with other MM subtypes.
Methods: Samples were collected from patients diagnosed with MM through bone marrow examination, and myeloma cells were isolated using the CD138-positive marker. Paired datasets (n=37), including whole genome sequencing (WGS) and bulk RNA sequencing (RNA-seq), were generated and analyzed. We utilized whole exome sequencing (WES) and RNA-seq data from the CD138-positive fraction of bone marrow mononuclear cell (BMMC) samples provided by the Multiple Myeloma Research Foundation (MMRF) CoMMpass study.
Results: The WGS data revealed an average of 8,872 single nucleotide variants (SNVs) and 934 insertions and deletions (Indels) of somatic mutations in 37 MM patients, respectively. Using these somatic mutations, we performed a mutational signature analysis to infer the cause of the malignancy and were able to identify different proportions of mutational signatures in each MM patient. Interestingly, among the single base substitution (SBS) 9 signature varied widely between patients, four patients with non-IgG and non-IgA heavy chain and lambda light chain myeloma had significantly high SBS9 signature. Notably, three IgD MM patients were included exclusively in the high SBS9 signature group and not in the low SBS9 signature group ($p = 0.001$). Analyzing RNA-seq data, we found that the high and low SBS9 signature groups had different gene expression patterns. In particular, differentially expressed genes (DEGs) analysis suggested features of IgD myeloma, including high expression of *IGHD,* in high SBS9 signature group. Pathway gene expression analysis showed higher expression of genes associated with the DNA repair system and somatic hypermutation in IgD MM patients. We performed the identical mutation signature analysis on WES data of 784 MM patients from the MMRF database. Of the 30 patients for whom sufficient somatic mutations could be obtained, there were three IgD MM candidates with a high SBS9 signature, whereas there were no IgD MM candidates in the low SBS9 signature group. Similarly, three high SBS9 patients with suspected IgD MM showed characteristic gene expression patterns and upregulation of the DNA repair system.
Conclusions: We found that IgD MM has distinctive features, including high SBS9 mutation signatures and upregulation of genes related to the DNA repair system and somatic hyper-mutation. Further research into IgD MM may reveal the detailed characteristics and underlying mechanisms of IgD MM and lead to tailored treatments.

#6641 Inclusion of INDEL somatic variants in MRD panels improves confidence in ctDNA residual disease detection.

Ravi Patel, Elise Buser, Nafei Xu, Matthew LaBella, Kyle Trettin, Long Tian, Ashley Acevedo, Christopher Battey, Genevieve Gould, Dale Muzzey

Myriad Genetics, Inc., Salt Lake City, UT

Molecular residual disease (MRD) tests detect residual tumor in a patient by identifying the presence of circulating tumor DNA (ctDNA) in cell free DNA (cfDNA). We have developed a highly sensitive MRD test that utilizes panels of hybridization probes targeting somatic variants specific to each patient's tumor. Our tumor-informed MRD assay utilizes whole genome sequencing (WGS) of tumor and normal tissue followed by a somatic calling pipeline to identify tumor variants and generate a panel targeting these variants. The sensitivity of bespoke MRD tests, like ours, is a function of each patient's panel content. A major challenge of ctDNA detection at low tumor concentrations is differentiation of true tumor variants from technical errors. The variants that are most informative for detection of low tumor fraction residual disease are those that are the least likely to occur due to PCR errors or other artifacts during sample preparation. Here we assessed the technical error rates of single nucleotide variants (SNVs) and insertions and deletions (INDELs). In our experiments, many INDELs were less likely to occur due to PCR errors compared to many SNVs, though the error rates of individual variants depended on their genomic context. Several features impacted the error rate of individual INDEL variants in cfDNA including the number of bases inserted or deleted in the INDEL variant and the proximity of the INDEL variant to homopolymer regions. The lower error rate from many INDEL variants resulted in more signal to noise when detecting the presence of the tumor variant. We identified INDEL somatic variants using an ensemble of somatic callers with 99.8% confirmation rate. INDELs were typically less prevalent than SNVs but we observed that INDELs made up as much as 26.4% of a 1000 variant panel. To assess the impact of INDELs on our ability to detect residual tumor, we ran our MRD assay on patients with residual disease. Our detection pipeline was run using a 1000 probe panels that included both INDELs and SNVs or just SNVs alone. INDELs improved the sensitivity of our assay; we observed 60-90%lower error rates for INDELs with more than a single base inserted or deleted compared to SNVs in cfDNA. In conclusion, the likelihood of detecting low abundance ctDNA is higher for panels with INDELs included than for panels without INDELs. Overall, our assay achieved high sensitivity at low tumor concentrations by prioritizing the inclusion of low error rate variants including INDELs in bespoke patient panels.

#6642 Inter-alpha-trypsin inhibitor heavy chain (ITIH) genes: expressional profile in colorectal cancer and potential targeting by using a ribosome inactivating protein.

Aiman Shahzad[1], **Asim Pervaiz**[1], Afraz Numan[2], Sana Iqbal[1], Martin R. Berger[3]

[1]Human Genetics and Molecular Biology, Univ. of Health Sciences, Lahore, Pakistan,[2]Institute of Allied Health Sciences, Univ. of Health Sciences, Lahore, Pakistan,[3]Immunodiagnostic, Bensheim, Germany

Introduction: Expression deregulation of Inter-α-Trypsin Inhibitor Heavy (ITIH) genes at circulatory and tissue levels has been reported in various cancers. These altered levels are linked with worse pathogenesis and low treatment response. ITIH genes are being considered as novel prognostic/ therapeutic targets. Knowledge about ITIH expression profile in primary/metastatic cancers and regulation control via synthetic/natural anticancer compounds deemed crucial. Present study was designed to uncover these facets in colorectal cancer.
Materials & Methods: Total RNA was extracted from frozen colorectal cancer clinical isolates and normal mucosa specimens followed by cDNA synthesis and real-time PCR for expressional analysis of the genes. Labelled rat colorectal cancer cells (CC531) were transplanted into the rat liver via the hepatic portal vein and were re-isolated by FACS after discrete time intervals (3, 6, 9, 14 and 21 days) followed by RNA extraction and cDNA microarray analysis. A fraction of re-isolated cells was cultured *in vitro* for 14 and 22 days to compare the results with those from tumor cells grown *in vivo*. Primary (SW480 and HCT116) and metastatic (SW620) colorectal cancer cell lines were exposed to riproximin (10 and 20ng/ml, 48 hours) followed by RNA extraction, cDNA synthesis, expressional profiling of the genes (ITIH3 and ITIH4) and fold change identification by $2^{\Delta\Delta}$CT method. The results were compared with those of untreated control cells.
Results: Both members of the ITIH family were continuously down-regulated in the clinical isolates. However, ITIH3 gene was more substantially down-regulated (-26fold average, Stage II) in the tissue samples of colorectal cancer patients as compared to ITIH4 gene (-9fold average, Stage II). *In vivo* model mimicking the colorectal cancer liver metastasis depicted a marked increase in the expression of both genes throughout the experimental period (21 days). Precisely, a maximum induction was observed in ITIH3 gene at day 03 of implantation (295fold), while ITIH4 was maximally induced at day 21 (246fold). Exposure with the plant protein (riproximin) induced the expression of ITIH3 gene in the three colorectal cancer cell lines. In contrast, riproximin exposure inhibited the ITIH4 gene in the three colorectal cancer at all applied concentrations.
Conclusion: ITIH3 and ITIH4 genes were consistently down-regulated in clinical isolates. In contrast, a substantial induction was observed in metastatic colorectal liver cancer animal model. Riproximin induced expressional alterations in gene specific format in the colorectal cancer cell lines. Further investigations are needed to understand substantial high levels of ITIH genes during colorectal cancer liver metastasis and potential targeting via riproximin.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolism and Signaling

#6646 Fibroblast growth factor receptor signaling modulates cholesterol storage in a SOAT1-dependent manner to promote mammary tumor cell invasion.

Jennifer E. Tuokkola, Lyndsay E. Reese, Ying Wang, Christine H. O'Connor, Annisa H. Rumahorbo, Kathryn L. Schwertfeger

Laboratory Medicine and Pathology, University of Minnesota Medical School, Minneapolis, MN

Signaling by fibroblast growth factor receptors (FGFRs) is active in up to 85% of breast cancers and results in enhanced proliferation, migration, and invasion of tumor cells. Here, we show that FGFR signaling regulates cholesterol metabolism in breast cancer. Specifically, we demonstrate that FGFR activation promotes cellular cholesterol storage by upregulating expression of the enzyme sterol O-acyltransferase 1 (SOAT1). Moreover, we demonstrate that inhibition of SOAT1 attenuates FGFR-driven colony formation and invasion in tumor cells. Finally, we identify a relationship between SOAT1 inhibition and decreased expression of matrix metalloproteinases by tumor cells. Taken together, these findings suggest a previously undiscovered metabolic role for FGFR signaling in breast cancer and present a therapeutic vulnerability that could be targeted in FGFR-driven cancers.

#6647 Targeting DCLK1-mediated glutamine addiction in chemoresistant ovarian cancer.

Samrita Dogra[1], Cole Hladik[2], Sugantha Priya Elayapillai[1], Bethany Hannafon[1]

[1]OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Ovarian cancer (OC) presents significant therapeutic challenges due to its frequent late-stage diagnosis accompanied by distant metastases and the development of chemoresistance. As existing FDA-approved targeted therapies for OC do not adequately address peritoneal metastases, there is an urgent need for innovative treatment strategies that specifically target the molecular and cellular pathways underlying metastasis and disease recurrence. Doublecortin-like kinase 1 (DCLK1) is a serine/threonine kinase with a demonstrated role in cancer cell stemness, epithelial-mesenchymal transition (EMT), disease progression in gastrointestinal and pancreatic cancers and resistance in ovarian and lung cancer. The study objective is to evaluate the functional role of DCLK1 in the peritoneal metastasis of OC and investigate the associated benefits of antagonizing it as a novel strategy to mitigate OC metastasis. Our prior studies demonstrate DCLK1 inhibition reduces the number of visible metastases in an orthotopic OC model in mice. In this study, we used pharmacological inhibition (DCLK1-IN-1), and genetic manipulation (DCLK1 CRISPR-knockout (KO) and over-expression systems) to assess the role of DCLK1 in promoting OC metastasis. We observed that elevated DCLK1 expression enhanced OC cell adhesion to different extracellular matrices including collagen, fibronectin, and laminin. Furthermore, DCLK1 inhibition effectively reduced mesothelial cell clearance relative to control. Targeted gene expression profiling and pathway analysis revealed DCLK1 inhibition in cisplatin resistant (CPR) OC spheroids upregulated genes involved in glutamine metabolism. Using metabolic flux assays, we demonstrated increased oxygen consumption in DCLK1 KO CPR cells that was abrogated by BPTES (glutamine oxidation inhibitor). Furthermore, we show that combined treatment of OC CPR spheroids with DCLK1 inhibitor (DCLK1-IN-1) and glutamine antagonist (DRP-104) showed a synergistic cytotoxic effect. In addition, the novel combination strategy was significantly effective in reducing OC cell adhesion and mesothelial cell clearance relative to single agent alone. Collectively, our findings establish DCLK1 as a key regulator of metastasis and demonstrate that its inhibition induces glutamine dependency in chemoresistant tumor cells. Thus, the combined use of DCLK1 inhibitors (e.g., DCLK1-IN-1) with glutamine metabolism inhibitors (e.g., DRP-104) represents a rational therapeutic approach to mitigate peritoneal metastases in a chemoresistant setting.

#6648 Novel integrated stress response (ISR) kinase inhibitors have activity in multiple cancer cells.

Aurelien Laguerre, Martin Smrcina, Ivy Nai-Jung Hung, Devin K. Porter, Nathan G. Hedrick, Dmitri Rozanov, Mark R. Hansen, **Vikas K. Goel**

Zafrens Inc., San Diego, CA

The integrated stress response (ISR) is an adaptive cellular program that facilitates survival and proliferation under conditions of cellular stress and can be appropriated to contribute to the tumorigenesis of multiple cancers. ISR is activated in response to various cues in the tumor microenvironment and cell-intrinsic factors but is ultimately regulated by four core serine/threonine kinases: GCN2 (activated by amino acid deprivation), HRI (in response to heme deficiency), PERK (unfolded protein response stress), and PKR (dsRNA stress response of infection and oxidative stress). These four ISR kinases play a central role in cancer cell equilibrium, allowing them to proliferate by adapting to adverse conditions, immune evasion, and metastasis. All ISR kinases phosphorylate a common downstream effector, eIF2a, at Ser51. peIF2a^{S51} shuts down cap-dependent translation and results in the up-regulation of ATF4, a transcription factor that controls the transcription of genes essential for cancer cells to adapt to stress and nutrient deprivation. Due to the observation that adaptive compensation and rewiring in cancer cell pathways can occur in response to inhibition of single signaling nodes, it has been suggested that simultaneous inhibition of multiple ISR kinases may be required to improve anti-cancer response or counteract drug resistance. We developed an initial high-throughput ATF4 immunofluorescence (IF) assay to screen chemical matters in low- to no-glutamine culture conditions. We identified three potential subseries of compounds of the type II kinase inhibitor class. Structure modeling and docking suggested that these subseries differ in inhibitory profiles against four ISR kinases, and we decided to focus on two of these subseries to develop potent ISR inhibitors further. Multiple hits (ZF125, ZF163, ZF284, ZF302) demonstrated low nM potency in the cellular target engagement assay (ATF4 IF) and biochemical kinase assay against three ISR kinases. RNA transcriptomic analysis confirmed that ZF-ISR inhibitors downregulate several ISR kinase target genes, such as DDIT3 and SLC1A5, ATF4, CEBPb, and TRIB3. Our lead molecule has also demonstrated high selectivity in a select kinome screen (40 kinases) at 1uM, except for ISR kinases. Zafren's lead ISR (ZF-ISR) inhibitors have shown a growth inhibitory effect in multiple cancer cells with 10mU/ml of ASNase of ASNase. Interestingly, most of these cancer cell lines harbor RAS/RAF/MPAK pathway mutations. DepMAP analysis revealed other potential gene signatures as combination strategies with ZF-ISR inhibitors. As determined by multiple ADME assays, ZF-ISR inhibitors have also shown favorable drug-like property profiles. In-vivo tumor growth inhibition studies are in progress.

#6649 Pharmacological inhibition of HuR deregulates mitochondrial function and reduces mitochondrial activity in cancer cells.

A. M. Vu[1], M. Mehta[1], S. Jayaraman[1], M. Fuller[2], R. Ramesh[1], A. Munshi[1];
[1]University of Oklahoma Health Sciences, Oklahoma City, OK, [2]Michigan State University, East Lansing, MI

The RNA-binding protein, human antigen R (HuR), is overexpressed in many cancer types, and regulates genes linked to tumor growth, angiogenesis, cell cycle, and chemoresistance. HuR overexpression correlates with increased tumor size, invasiveness, and poor prognosis. Inhibiting HuR through pharmacological or RNA interference (RNAi) methods leads to antitumor activity both *in vitro* and *in vivo* against a broad spectrum of human cancers. Molecular mechanisms of antitumor activity include cell cycle arrest, increased ROS production, and enhanced DNA damage culminating in apoptotic cell death. However, the role of HuR in cancer metabolism and mitochondrial dynamics remains largely unexplored. In the present study we investigated the effects of the HuR inhibitor, CMLD-2, on glycolysis, mitochondrial function, ROS production, and mitophagy in human breast (MDA-MB-231) and lung (H1299) cancer cell lines. Both cell lines were treated with vehicle (DMSO) or CMLD-2 (20 μM or 30 μM) and analyzed at 24 or 48 hours post treatment. CMLD-2 treated cells showed a dose- and time-dependent reduction in markers of glycolysis and oxidative phosphorylation (GLUT1, GLUT4, HK2, LDHA), and a decrease in OXPHOS complex proteins. CMLD-2 treatment also led to a significant reduction in the rate of glycolysis (ECAR) and mitochondrial oxidative phosphorylation (OCR) as measured by Seahorse metabolism assays. Transmission electron microscopy (TEM) analysis showed CMLD-2 treatment increased autophagosome formation, mitochondrial fragmentation, and reduced mitochondrial count. Additionally, CMLD-2 treatment increased ROS production, with a 1.3- and 1.6-fold rise in MDA-MB-231 cells at 20 μM and 30 μM, respectively, and a 1.1- and 1.3-fold increase in H1299 cells at 20 μM and 30 μM, as measured by DCFDA fluorescence. Immunoblotting of AMPK-dependent autophagy signaling showed a time- and dose-dependent increase in LKB1, phospho-AMPK (Thr172), phospho-ULK (Ser555), phospho-FOXO3 (Ser413), p62, and LC3-I cleavage in CMLD-2-treated MDA-MB-231 cells. In H1299 cells, CMLD-2 treatment increased the above-mentioned markers except for phospho-ULK (Ser555), suggesting ULK-independent autophagy activation. Confocal microscopy of mitochondria (using Mitotracker Red CMX Ros) and LC3 (using LC3-GFP expression plasmid) in CMLD-2 treated cells, revealed colocalization of mitochondria with autophagosomes in both cell lines, indicating mitophagy. Our study demonstrates HuR inhibition results in mitochondrial dysfunction and significant metabolic changes in cancer cells, providing insights into the potential of HuR-targeted therapies for cancer treatment.

Funding**:** The study was supported in part by a grant received from the National Institutes of Health (R01 CA 282735-01) and American Cancer Society (ACS-DICR: INTR-23-1253708-01-DICR INTR).

#6650 Targeting the PI3K pathway with alpelisib in patient-derived xenografts: a multi-cancer type approach.

Kapur B. Dhami[1], Chiya-Kuei Mo[1], Zhanfang Guo[1], Richard Kurupi[1], Preet Lal[1], Kazuhito Soto[1], Xiyi Wei[1], Michael C. Wendl[1], Jacqueline Mudd[1], Shunqiang Li[1], Sherri R. Davies[1], Jeff Chuang[2], Bingliang Fang[3], Ryan Fields[1], Hui Zhang[4], Meenhard Herlyn[5], Feng Chen[1], Kian-Huat Lim[1], Kian-Huat Lim[1], Cynthia Ma[1], Li DIng[1]

[1]Washington University in St. Louis, School of Medicine, St. Louis, MO,[2]Jackson Laboratory for Genomic Medicine, Farmington, CT,[3]MD Anderson Cancer Center, Houston, TX,[4]Johns Hopkins University, Baltimore, MD,[5]Wistar Institute, Philadelphia, PA

Phosphoinositide 3-kinase (PI3K) pathway has a crucial role in the regulation of cellular proliferation, survival, and metabolism. Frequent aberrant activation of this pathway is one of the most common oncogenic events across various human cancer types including breast (ER+), colorectal, lung, kidney, and skin cancers. We collected and analyzed baseline tandem mass tag (TMT) proteomics data (protein and phosphorylation levels) for 40 samples from 36 PIK3CA PDX models across five cancer types (RCC, Melanoma, CRC, BRCA, and LUAD). Initial Pearson correlation analysis revealed that most samples clustered by cancer type, indicating that tissue specificity contributes more to molecular similarities than oncogenic mutations. When focusing on components of the PI3K pathway, we observed diverse protein levels and activation statuses across the cohort of PDX models. In breast cancer (BRCA), colorectal (CRC), and kidney (RCC) samples, we noted elevated levels of total and phosphorylated AKT, which were lower in lung squamous cell carcinoma (LUSC) and melanoma samples. Interestingly, we also found heterogeneous activation statuses of components in the PI3K pathway in BRCA samples. A subset of BRCA samples exhibited high levels of total AKT and phosphorylation at T479 and S477, alongside elevated TSC1 and TSC2 activation. Since TSC proteins are known to inhibit PI3K pathway activity, their elevation could indicate feedback inhibition of the pathway even with PIK3CA mutations. To further elucidate the diverse treatment response profile of the PIK3CA mutant PDX lines across cancer types in mice, we assembled a cohort of 3 cancer types, BRCA, ccRCC, and PDAC. Despite the varied mutation profiles, we observed that responses to Alpelisib differed among the RCC PDX lines, with insignificant effects in PDMR-274T, no response in RESL4, and a modest effect in RESL10. In the BRCA study, out of 6 treated ER+ PDX lines, we observed significant responses in WHIM9 and WHIM20. Moderate responses were seen in WHIM84 and WHIM18, while HCI-011 and WHIM16 showed no response. Proteogenomic analyses are ongoing to discern response biomarkers.

#6651 β-catenin-mediated aerobic glycolysis: a marker of poor prognosis in triple-negative breast cancer.

Chandra Prakash Prasad[1], Sheikh Mohammad Umar[1], Shruti Kahol[2], Sandeep R. Mathur[2]

[1]Medical Oncology, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[2]Pathology, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Aerobic glycolysis has emerged as a crucial regulator of cancer cell migration and metastasis in various cancers including TNBCs. Characterization of molecular pathways associated with increased aerobic glycolysis in TNBCs could provide key mechanistic insights into the regulators of TNBC progression. Here, we demonstrated for the first time the theranostic potential of the β-catenin-PFKP-LDHA-MCT1 axis that drives aerobic glycolysis in TNBCs. β-catenin and related glycolytic proteins (PFKP, LDHA, and MCT1) were analyzed in triple-negative breast cancer (TNBC) patients (n=98) using immunohistochemistry (IHC). Prognostic significance was assessed through Kaplan-Meier survival analysis and Cox regression. Additionally, we compared the efficacy of two β-catenin inhibitors, XAV939 and Axitinib, in suppressing β-catenin-driven aerobic glycolysis in both *in vitro* and *in vivo* TNBC models. We showed that β-catenin and its associated glycolytic proteins (PFKP, LDHA, and MCT1) are overexpressed in more than 50% of TNBC cases. Kaplan-Meier survival analysis and Cox regression revealed that elevated β-catenin expression, combined with high levels of other glycolytic proteins (β-catenin+MCT1^{high}; β-catenin+PFKP+MCT1^{high}; β-catenin+LDHA+MCT1^{high}; and β-catenin+PFKP+LDHA+MCT1^{high}), was linked to poor prognosis, highlighting the role of β-catenin-regulated aerobic glycolysis in TNBC aggressiveness. Additionally, we found that Axitinib, compared to XAV939, more effectively reduced β-catenin and glycolytic protein expression, lactate production, cell migration, invasion, and colony formation in TNBC cell lines. In conclusion, this study is the first to identify a novel β-catenin-regulated aerobic glycolysis pathway in triple-negative breast cancer (TNBC). We also demonstrated that Axitinib is a more effective inhibitor of this pathway than XAV939.

#6652 PDCD4/mTORC2 axis regulates tumorigenesis through PFKFB3 in NSCLC.

Elham Zokaei, Qing Wang, Hsin-Sheng Yang

Toxicology and Cancer Biology, University of Kentucky, Lexington, KY

Programmed cell death 4 (PDCD4) is a tumor suppressor whose expression is frequently downregulated in various cancers, including lung cancer. PDCD4 has been shown to suppress tumor cell proliferation, migration, invasion, and metastasis in cultured cells and in mouse models. It has also been suggested to play a role in regulating glucose metabolism; however, the detailed mechanisms remain unclear. Using reverse phase protein array, we found that knockdown of PDCD4 upregulated 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3), a critical enzyme in regulation of glycolysis. PFKFB3 converts fructose-6-phosphate to fructose-2,6-bisphosphate to activate the rate-limiting enzyme, 6-phosphofructo-1-kinase, in glycolysis. PFKFB3 expression is upregulated in lung cancer and correlates with tumor stage progression. Inhibition or down-regulation of PFKFB3 in lung cancer cells induces cell apoptosis and inhibits tumor growth in nude mice. Given that PDCD4 inhibits mTORC2 activity, we next examined how mTORC2 affects PFKFB3 expression. We found that mTORC2 interacted with PFKFB3 in NSCLC cells. Using In vitro kinase assays demonstrated that can phosphorylate PFKFB3. Further analysis pinpointed a Ser residue as the target site, leading to the generation of phosphorylation-deficient (S to A) and phospho-mimetic (S to D) mutants. Stability assays revealed that phosphorylation at this specific Ser is essential for maintaining PFKFB3 protein stability; as the phosphorylation-deficient mutant underwent rapidly degradation, whereas the phospho-mimetic mutant showed increased it's half-life. Functional assays showed that WT PFKFB3 promoted high proliferation rates, whereas the phosphorylation-deficient mutant impaired colony formation and proliferation. Taken together, these findings uncover a key mechanism of metabolic reprogramming in NSCLC, in which mTORC2 drives glycolysis by directly phosphorylating PFKFB3, highlighting the therapeutic potential of targeting the PDCD4/mTORC2/PFKFB3 axis in NSCLC treatment.

#6653 Taurine Transporter *SLC6A6* promotes myeloid leukemia progression by regulating glycolysis.

Sonali Sharma[1], Benjamin J. Rodems[1], Cameron D. Baker[2], Christina M. Kaszuba[3], Edgardo I. Franco[3], Takashi Ito[4], Laura M. Calvi[5], Michael W. Becker[5], Bradley R. Smith[6], Paul S. Brookes[7], Joshua C. Munger[6], Jane L. Liesveld[5], Craig T. Jordan[8], John M. Ashton[2], Jeevisha Bajaj[9]

[1]Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY,[2]Genomics Research Center, University of Rochester Medical Center, Rochester, NY,[3]Department of Biomedical Engineering, University of Rochester, Rochester, NY,[4]Department of Bioscience and Technology, Fukui Prefectural University, Fukui, Japan,[5]Department of Medicine, University of Rochester Medical Center, Rochester, NY,[6]Department of Biochemistry and Biophysics, University of Rochester Medical Center, Rochester, NY,[7]Department of Anesthesiology, University of Rochester Medical Center, Rochester, NY,[8]Division of Hematology, University of Colorado Anschutz Medical Campus, Aurora, CO,[9]Wilmot Cancer Institute, Department of Biomedical Genetics, University of Rochester Medical Center, Rochester, NY

Interactions of stem cells with their surrounding microenvironment are known to be essential for both normal development and for sustaining self-renewing adult stem cells, such as the hematopoietic stem cells (HSCs). Since cancers often hijack developmental signals for their progression, it is likely that niche-driven signals that sustain HSCs also influence the growth of leukemias arising from mutations in HSCs and early hematopoietic progenitors, such as acute myeloid leukemia (AML) and blast crisis chronic myeloid leukemia (bcCML). To identify candidate cell surface receptors essential for myeloid leukemia progression, we employed a comprehensive approach integrating our *in vivo* genome-wide CRISPR screen and our RNA-seq analysis of human LSCs from distinct myeloid leukemia subtypes. Of these, the taurine transporter (TauT), encoded by *SLC6A6*, was of particular interest since its expression is associated with poor prognosis in acute myeloid leukemia (AML) patients. Our experiments using TauT knockout mice indicate that TauT loss significantly impairs myeloid leukemia progression *in vivo*. An RNA-Seq analysis of freshly isolated $TauT^{+/+}$ and $TauT^{-/-}$ leukemia cells identified a striking decrease in glycolysis associated genes in the absence of TauT. Consistent with this, Seahorse analysis showed significantly reduced basal glycolysis and glycolytic capacity in $TauT^{-/-}$ LSCs as compared to $TauT^{+/+}$ controls. In addition, inhibiting TauT reduced the abundance of key glycolytic metabolites as measured by LC/MS spectrometry. Our experiments showing significant downregulation of mTOR pathway in the absence of TauT indicate that mTOR signaling may regulate glycolysis in leukemia cells. Consistent with a functional role of mTOR downstream of TauT function, our data shows that activating mTOR pathway in $TauT^{-/-}$ cells can rescue expression of glycolysis related genes and leukemic cell growth. Importantly, our experiments inhibiting TauT using shRNAs or small-molecule inhibitors identify a key role of this signal in the growth of patient-derived myeloid leukemia cells. Collectively, our data identify a critical requirement of the taurine-TauT axis in myeloid leukemia progression and indicate that the TauT inhibition may be of therapeutic value in myeloid leukemia.

#6654 Investigating the role of fructose-1,6-bisphosphatase in soft tissue sarcoma.

B. Nance, B. Keith, C. Simon;
University of Pennsylvania, Philadelphia, PA

Glucose metabolism is commonly dysregulated in cancer and other pathological contexts. Fructose-1,6-bisphosphatase (FBP) is a key rate-limiting gluconeogenic enzyme that converts fructose-1,6-bisphosphate to fructose-6-phosphate, which produces glucose and glycogen from noncarbohydrate substrates. Two FBP isoforms, FBP1 and FBP2, are differentially expressed in human tissues. FBP1 is expressed in the primary gluconeogenic organs (liver and kidney) to maintain blood glucose levels under fasting conditions. In contrast, FBP2 expression is primarily restricted to striated muscle where it regulates glycogen synthesis. Our recent work demonstrates that both FBP isoforms function as metabolic tumor suppressors and are significantly downregulated in multiple cancers. In sarcoma cells, ectopic FBP2 decreases cytosolic glycolytic flux and FBP2 interacts with nuclear c-Myc to repress transcription of the gene encoding mitochondrial transcription factor A (TFAM), a transcription factor essential for mitochondrial biogenesis. We aim to expand on the roles of FBP2 expression in sarcomas by investigating its binding partners and the role of its catalytic activity in vitro and in vivo. To explore this, we have ectopically expressed wildtype FBP2 and catalytically inactive FBP2-E98A at similar levels to human skeletal muscle in sarcoma cell lines and observed their impacts on proliferation, glucose metabolism, colony formation, invasion, gene expression, and tumor growth. Interestingly, both enzymatically wildtype FBP2 and catalytically inactive FBP2 can suppress proliferation and colony formation in vitro suggesting that FBP2 has additional non-catalytic functions contributing to its repressive role in cancer cells. To explore additional roles of FBP2 outside of its catalytic function, we have developed a FBP2-BioID2 fusion protein and performed immunoprecipitation mass spectrometry to identify novel binding partners of FBP2. Surprisingly, our RNAseq and proteomics data suggest that ectopically expressed wildtype FBP2 may enrich for gene sets and putatively bind with components of the cytoskeleton.

Furthermore, to investigate the role of FBP2 loss in sarcomagenesis, we have also utilized autochthonous and injury-induced murine models of undifferentiated pleiomorphic sarcoma with and without Fbp2 loss. We aim to fully characterize these models to elucidate the possible roles of FBP2 in tumor latency, size, and metastasis in sarcoma.

Overall, our work will further define the moonlighting roles of FBP2 by elucidating its interactome and the role of FBP2 in coordinating metabolic transitions in sarcomagenesis.

#6655 Meta-analysis of 70 cancer studies suggests altered pH-sensitive potassium channeling associated with 7 oncogenes and/or DNA modifiers as initiators of pH reversal via cytosolic proton chains.

Marie E. Beckner

Brain Health Research Institute, Kent State University, Willoughby Hills, OH

The potassium channel (KCN) gene family (≥ 90 members) is influenced by upstream modifiers and encodes interactive proteins, many also pH-sensitive. Regulated KCN proteins channel K^+ flux to mediate optimal K^+ levels in cells. Small monovalent cations, preferentially K^+, can displace protons from inner cell membrane anions. Released free protons rapidly become hydronium ions (H_3O^+) that react with a "Grotthuss" type water matrix of H-bonded chains of $H_9O_4^+$ & $H_5O_2^+$ in a "microaqueous proton chain" (MAPC) cytosol. The chains undergo domino-like conformational changes involving H^+ that permit protons entering the matrix to incite quick release of different H^+ elsewhere from matrix edges (Adelroth P, BBA, 1757(2006)867-70). Putatively, elevated release of H^+ from cytosolic MAPC near cell exit sites (transporters of H^+, etc.) allows pH reversal. Methods. Meta-analysis was performed on cancer studies selected for published gene expression landscapes (not Supplemental Materials), that lacked KCN bias yet yielded differentially expressed genes (DEG) of the KCN family to determine the proportion of KCN DEG affecting pH-sensitive K^+ flux and to identify associated non-KCN DEG. Heat maps (46 studies), Venn diagrams, tables, phylogenetic trees, etc. were analyzed for count data & with Fisher's Exact testing. Results & Discussion. Thus far in 70 expression (E) studies, E1-E70 (1301 authors), of 29 malignancy types, of the 53 KCN DEG detected, 33 (62.3%) encode H^+-sensitive proteins (135 literature references). 52 of 70 studies (74.3%) contained ≥1 KCN DEG encoding H^+-sensitive proteins. The most frequent KCN DEG, *KCNN4* and *KCNMA1* in 9 and 6 studies, respectively, encode H^+-sensitive proteins. The most common cancers, lung, breast, & glioblastoma, had KCN DEG encoding H^+-sensitive proteins detected in 72.7%, 44.4%, & 85.7% of their respective studies. Also, 50 of 70 studies were in 8 author-designated categories which had relevant DEG present in ≥1 study. Categories in decreasing frequency are Histone/Chromatin/Epigenetic, *TP53*, Epithelial Mesenchymal(Mes) Transition/*TGFβ*/Mes, *EGFR*, *MYC*, *RAS*, *BCL2*, & *MET*. Studies in the 8 categories compared to the other 20 studies differed significantly for detection of KCN DEG encoding H^+-sensitive proteins, $p = 0.0325$. Conclusion. Collectively, malignant gene expression landscapes involving 7 oncogenes and/or DNA modifier scenarios are associated with KCN DEGs encoding H^+-sensitive proteins, possibly as downstream effectors. Potentially, dysregulated inner membrane K^+ levels result in release of membrane-bound protons that (1) incite rapid domino-like proton shifts in a MAPC cytosol resulting in proton release elsewhere for (2) enhanced H^+ efflux achieving (3) pH reversal causing enhanced malignancy via altered enzyme activities, cytoskeletal rearrangements, etc.

#6656 Cancer-derived polyamines regulate adipocyte lipolysis and fat waste in cancer cachexia.

Matias Fabregat, Julia K. Hansen, Hoang V. Bui, Andrea Galmozzi

UW Madison, Madison, WI

Cancer Cachexia (CC) accounts for more than 20% of all cancer-related deaths, rising to 30% in pancreatic cancer cases. Current treatments, which focus primarily on nutritional supplementation to address weight loss, are largely palliative and show limited efficacy. No pharmacologic therapy currently exists for CC. While skeletal muscle loss is a defining characteristic of cachexia, fat wasting often precedes muscle loss and is a stronger predictor of survival than overall body weight loss. Recognizing this, our study aims to identify cancer-secreted factors that drive adipocyte dysfunction and development of cachexia. To achieve this, we measured lipolytic activity in primary adipocytes exposed to conditioned media (CM) derived from various cancer cell lines. Remarkably, cancer cells from tumor types with a high incidence of cachexia, such as pancreatic ductal adenocarcinoma (PDAC) and head and neck cancers, induced significantly greater lipolysis compared to cells from cancers linked to lower cachexia incidence, such as breast cancer. Characterization of cancer-cell-secreted factors identified elevated polyamine levels in pro-cachectic CM. Consistently, we found that data from the Cancer Cell Line Encyclopedia also show an upregulation of the polyamine biosynthetic pathway in pro-cachectic cells. Using a syngeneic PDAC model, we observed that, in tumor-bearing mice, increased circulating lipids and fat loss correlated with elevated polyamine levels in the serum and the adipose tissue compared to sham controls. Mechanistically, high polyamine levels in cultured adipocytes and adipose tissue depots led to hyperhypusination of the eukaryotic translation initiation factor eIF5A. This unique post-translational modification activates eIF5A, enabling it to regulate protein translation, including key enzymes involved in lipolysis. Importantly, inhibiting either polyamine synthesis in cancer cells or eIF5A hypusination in adipocytes effectively blocked the pro-lipolytic effects of cancer cell CM, indicating that polyamines act as cancer-derived signaling molecules to promote lipid mobilization in adipocytes. This study sheds light on tumor-adipose tissue crosstalk and identifies cancer-derived polyamines as key drivers of cachexia. Specifically, polyamines promote the hyperhypusination of eIF5A, thereby enhancing lipolysis. These findings offer a foundation for developing anti-cachectic therapies targeting the polyamine-dependent hypusination of eIF5A. When combined with anti-cancer treatments, such therapies could significantly improve the quality of life and clinical outcomes for cancer patients suffering from cachexia.

#6657 ACLY-mediated acetyl-CoA levels drive bladder cancer progression.

H. Kim[1], J. Lee[2], S.-i. Jo[1], D. Suh[1], H. Lee[1], S. Oh[1], C. Jeong[1], J. Ku[1], C. Kwak[1], S. Park[2], J. Han[1];
[1]Seoul National University Hospital, Seoul, Korea, Republic of, [2]College of Pharmacy Seoul National University, Seoul, Korea, Republic of

Background: As cancers progress, elucidating the underlying mechanisms of metabolic reprogramming caused by genetic alteration in cancer cells may provide a key clue for exploring druggable targets. Targeting unique metabolic reprogramming which contributes to aggressive progression in bladder cancer (BC) remains a major challenge. This study aimed to identify metabolic pathways and druggable targets that influence BC progression and remodel the tumor microenvironment.
Methods: Liquid chromatography mass spectrometry-based untargeted metabolomic profiling was performed on low grade (LG) and high grade (HG) BC tissue samples of patients (N=8). The prognostic value of related metabolic genes was assessed using transcriptomic datasets (TCGA and UROMOL). To investigate the biological mechanisms underlying ACLY-acetyl-CoA-regulated BC progression, we utilized proliferation, transwell invasion, wound healing, colony formation assays, western blotting, immunoprecipitation, and immunohistochemistry, employing T24, J82, UMUC3, and MB49 cell lines and tumor tissues. BC mice models were produced by injection of MB49 cells into the bladder wall and subcutaneous tissues of C57/BL6 and BALB/C nude mice and administrated by daily oral gavage or peritoneal injection of BMS-303141. Tumor growth was monitored longitudinally using caliper measurement and bioluminescence imaging. Altered tumor microenvironment was assess by histological analysis.
Results: Acetyl-CoA was one of the most significantly enhanced metabolites in HG tumor tissues compared to LG tumor tissues. In the acetyl-CoA pathway, ACLY which converts citrate to acetyl-CoA, was found to play a critical role in maintaining tumoral acetyl-CoA levels, firmly linking it to poor prognosis in BC patients. Perturbing ACLY activity through genetic knockdown (siRNA or shRNA) and pharmacological inhibition (BMC-303141) significantly reduced intracellular acetyl-CoA levels, impaired cell proliferation, migration, invasion, and colony formation, suppressed EMT marker expressions (N-cadherin, vimentin), and affected PD-L1 protein levels by acetylation. ACLY and PD-L1 protein expression were positively correlated in BC tissue microarray-based analysis. In line with this, BMS-303141 suppressed tumor growth in both immunocompetent and immunodeficient mice, with more pronounced effects observed in immunocompetent mice, suggesting an additional anti-tumor effect through ACLY-acetyl-CoA-mediated immune modulation.
Conclusion: Our findings indicate that acetyl-CoA is a critical metabolite in BC progression, particularly through ACLY, the primary enzyme responsible for producing intracellular acetyl-CoA in BC cells, linked to increased BC aggressiveness. Targeting ACLY holds therapeutic potential for aggressive BC.

#6658 Inhibiting glycolysis for the treatment of HGF/MET/TWIST1 driven NSCLC brain metastases.

Xiaxuan Wu[1], Jason Chen[2], Thomas Hintelmann[1], Andrew Zhao[2], Joseph Dosch[2], Rahul Desai[1], Purva H. Rumde[1], Kasey R. Cargill[1], Riyue Bao[2], Vinod Kumar[3], Laura P. Stabile[4], Timothy F. Burns[5]

[1]School of Medicine, University of Pittsburgh, Pittsburgh, PA,[2]UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA,[3]Department of Pharmacology & Chemical Biology, University of Pittsburgh, Pittsburgh, PA,[4]Department of Pharmacology & Chemical Biology, University of Pittsburgh, University of Pittsburgh, Pittsburgh, PA,[5]Department of Medicine, Division of Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA

Non-small cell lung cancer (NSCLC) has the highest incidence of brain metastases (BM), with ~40% of patients developing BM. We identified a significant enrichment of *MET* amplification (amp) in NSCLC BM compared to primary lung and liver metastases. MET, a receptor tyrosine kinase, and its ligand, hepatocyte growth factor (HGF), promote proliferation, epithelial-mesenchymal transition, angiogenesis, metastasis and metabolic reprogramming through glycolysis. We have found that *MET* amp NSCLC BM and *MET* altered cells have increased glycolysis compared to *MET* wildtype (WT) BM and cells. We have also shown that TWIST1 is regulated by the HGF/MET pathway, essential for MET-driven NSCLC and MET TKI resistance and responsible for HGF/MET-driven hexokinase II (HK2) expression in *MET* altered cells. HK2, a critical node for metabolic regulation, catalyzes the first step in glucose metabolism. Thus, we hypothesize that targeting glycolysis in MET-driven NSCLC may be an effective therapeutic strategy. We have previously shown that metastatic H1993 (*MET* amp) cells which were derived from the same patient as primary lung H2073 (*MET* WT) cells exhibit increased glycolysis and increased glycolytic dependency. We have now found that TWIST1 was sufficient to drive glycolytic dependency as TWIST1 overexpression (OE) in H2073 cells enhanced sensitivity to the HK2 inhibitor 2-deoxyglucose (2DG), while TWIST1 knockdown in H2073 cells decreased sensitivity to 2DG. Interestingly, TWIST1 OE in H1993 cells increased HK2 levels, leading to 2DG resistance but increased sensitivity to the downstream glycolytic inhibitor, PFK158 with similar or decreased sensitivity to oxidative phosphorylation (OXPHOS) inhibitors. To examine whether glycolytic inhibitors would be effective at the time of MET TKI resistance, we used our *MET* altered models of acquired MET TKI resistance, H1993 CR and UW-21 CR. H1993 CR (low HK2) cells exhibited reduced sensitivity to 2DG but increased sensitivity to PFK158 and AT-101, while UW-21 CR (high HK2) cells showed reduced sensitivity to all three inhibitors compared to parental cells. We then examined whether glycolytic inhibition would be effective against *MET* amp driven EGFR TKI resistance. HCC827R2 (acquired *MET* amp) cells demonstrated increased HK2 protein expression and heightened sensitivity to 2DG and AT-101 compared to HCC827 cells. In a more relevant *ex vivo* brain slice model, we found that H1993 brain colonization was inhibited by 2DG and AT-101 but not OXPHOS inhibitors, while H2073 colonization showed limited response to glycolytic inhibitors but more sensitivity to OXPHOS inhibitors, consistent with our previous findings in patient BM. Remarkably, H1993 CR cells which were resistant to glycolytic inhibition *in vitro* were sensitive to 2DG *ex vivo*. These findings suggest that MET-driven glycolytic dependency plays a significant role in BM, highlighting glycolysis as a potential therapeutic target.

#6659 Defective lipid homeostasis induced by QKI loss is a mutator on gliomagenesis.

Y. Guan, T. Shingu, K. J. Lu, E. Kilinc, T. G. Hart, J. Zhang, Y. Chen, B. Y. S. Kim, J. Hu;
UT MD Anderson Cancer Center, Houston, TX

Glioblastoma (GBM) is the most malignant form of primary brain tumor. It is also one of the deadliest and most treatment-resistant cancers with more than 14,490 cases diagnosed in the United States in 2023. Tumorigenesis is a multistep process that starts with the occurrence of an oncogenic mutation in a single somatic cell. Despite extensive information about mutators for many cancers, the specific mutator driving GBM development remains unclear. Interrogating human glioma genomic and transcriptomic data revealed that defective lipid metabolism is associated with increased structural variants, particularly extrachromosomal DNA (ecDNA) formation. Quaking (QKI) is frequently mutated or deleted in human GBMs. Mechanistically, QKI acts as an RNA binding protein to regulate pre-mRNA stability of genes that regulates lipid components of endolysosomes, particularly the unsaturated fatty acids. We identified that QKI modulates neural stem cells and glioma stem cells lipid metabolism and further maintains membrane integrity in mitochondria and nuclear envelope. Deleting Qki on the *Nestin-CreER^{T2}; Pten$^{L/L}$; Trp53$^{L/L}$* background (QPP) strongly enhances gliomagenesis in mice. Using this model, we found Qki loss promoted somatic driver alterations including focal DNA alterations and oncogene amplification on ecDNA, especially *Pdgfra*/*Kit*, which as common oncogenes in ecDNA across both human and QPP mouse GBMs. Collectively, this work elucidates novel mechanisms underlying defective lipid homeostasis induced by QKI loss acts as a mutator in promoting gliomagenesis through inducing genomic instability. Our study provides a deeper insight into lipid metabolic dysregulation of GBM and a candidate for diagnosis and therapy. It will also contribute to the development of therapeutic strategies that specifically target QKI-depleted GBM.

#6660 Fasting-mimicking diet and starvation escape inhibition as novel low-toxic treatments for kidney cancer.

Samuel Lazzeri, Anastasiya Shmahala, Olga Blazevits, Valter D. Longo

IFOM-FIRC Institute of Molecular Oncology, Milan, Italy

Fasting, or fasting-mimicking diet (FMD), can delay tumor growth and promote tumor regression by making cancer cells more vulnerable to conventional therapies, while promoting protection and resistance in normal cells. FMD, which imitates the beneficial effects of fasting while being more tolerated by patients, activates peculiar survival/growth pathways in different cancer types, which can be identified and inhibited leading to tumor regression with low-toxicity. In the present study, we exploited the beneficial effects of FMD in the treatment of kidney cancer, which remains a major challenge despite the significant therapeutic progress of the past years. We developed a protocol that recapitulates in vitro the main molecular effects of FMD, in which cancer cells are exposed to reduced levels of glucose and serum factors. We observed that renal cancer cells subjected to in vitro FMD up-regulate specific starvation escape pathways, including the ERK-MAPK and the mTOR-S6K signalling. We developed a treatment based on FMD and selective inhibitors of these pathways, which induced cell death in a wide range of renal tumor lines, but not in normal cells, through the impairment of the purine metabolism ultimately leading to oxidative stress. We confirmed that the treatment is very effective in delaying tumor growth and in promoting tumor regression in different kidney cancer subcutaneous xenograft mouse models, attesting its safety and low toxicity on mice. The treatment also reduced metastasis formation upon intravenous injection of renal cancer cells in a syngeneic mouse model. We believe that this study represents a promising start to develop innovative and feasible treatments for kidney cancer, which could potentially also be extended to other cancer types.

#6661 Effect of berberine on cholesterol regulation in pancreatic ductal adenocarcinoma via heat shock factor 1.

Ahmad Hegazi, Rejina Shrestha, Shruti Ghai, Kuo-Hui Su

Department of Cell and Cancer Biology, University of Toledo, Toledo, OH

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a malignancy characterized by poor prognosis and elevated metabolic activity, including dysregulated lipid metabolism that supports aggressive growth. Cholesterol homeostasis, involving synthesis, uptake, and efflux, is pivotal for tumor progression. The pro-oncogenic transcription factor heat shock factor 1 (HSF1) has been reported to sustain the increasing metabolic demands of cancer cells by directly inhibiting AMP-activated protein kinase (AMPK), leading to an enhanced de novo cholesterol synthesis process and lipogenic phenotype in human melanoma cells. Berberine, a natural alkaloid with anti-cancer properties, has demonstrated efficacy in modulating cholesterol metabolism. However, its role in cholesterol regulation through HSF1 in PDAC remains poorly understood.
Objectives: To investigate the role of berberine in modulating cholesterol homeostasis in PDAC through the regulation of HSF1.
Methods: Multiple human pancreatic epithelial cells and cancer cell lines were treated with berberine to evaluate its effects on cholesterol regulation. Immunoblotting was used to assess changes in key proteins associated with cholesterol metabolism, focusing on determining berberine's impact on cholesterol efflux pathways.
Results: Berberine treatment significantly reduced total HSF1 levels, phosphorylation at Serine326, and downstream target HSP72 in a dose-dependent manner. Berberine treatment also increased AMPK phosphorylation at Thr172 and decreased cholesterol efflux transporter ATP-binding cassette transporter A1 (ABCA1). However, the expression of another cholesterol efflux transporter, ABCG2, remained unaffected by berberine treatment.
Conclusion: This study reveals a novel mechanism by which berberine exerts an anti-cancer effect in PDAC by modulating cholesterol regulation through HSF1.

#6662 Deciphering molecular network complexity of oncogenic PIK3CA through proximity labeling.

Rong Li, Donghee Lee, Md Abdullah, Eslenur Nipa, **Jong Hyuk Kim**

University of Florida, Gainesville, FL

PIK3CA mutations are major drivers for oncogenesis. Mutant PIK3CA continuously activates the PI3K pathway, transmitting oncogenic signals within transformed cells. Despite decades of efforts to target oncogenic PIK3CA for cancer therapy, the precise molecular and functional machinery remains incomplete due to the molecular complexity of the PI3K pathway. Mapping proximity proteins in the oncogenic PI3K pathway and identifying mutant signals will signify a deep understanding of oncogenesis and a broad range of therapeutic applications. In this study, we show that PIK3CA mutant cells establish a unique molecular program that network with distinct proteins, differing from cells with wild-type (WT) PIK3CA. We have developed a bioengineering approach to decode protein-protein interactions of oncogenic PIK3CA and identify key molecular partners, potentially unveiling therapeutic vulnerabilities in cancer cells. First, we applied the proximity labeling technique, based on the fusion of a protein ligase to a protein of interest (POI), featuring proximity-dependent biotinylation of interacting proteins. The biotin ligase BioID2 was utilized to integrate WT PIK3CA or gain-of-function hotspot mutations in E545K or H1047R residues. To optimize the labeling protocol and biotinylation conditions, the BioID2 plasmids were fused with each POI, incorporating multiple combinations of protein linkers and tags, including myc, and red fluorescence protein. A total of 13 plasmids were constructed in mammalian expression vectors, including pcDNA3.1 vector for transient expression, and pHAGE-puro vector for generating stable cell lines. Next, we used fluorescence microscope to screen RFP signals for transfection efficiency and employed immunofluorescence to verify the situations of protein expression and biotinylation with specific antibodies and fluorescence-conjugated streptavidin. Finally, streptavidin pulldown and LC-MS were utilized to identify the proximity proteins. Our technical approach confirmed a high level of reliability and consistency in LC-MS data between POI replicates. We identified approximately 1,000 proximity proteins, of which 436 were shared between samples labeled with WT and mutant PIK3CA. We found that both H1047R and E545K mutants demonstrated altered interactions with the protein GATAP2A. Furthermore, PIK3CA H1047R uniquely interacted with proteins S100A7, FLG2, LGALS7, and PPIB, while E545R specifically mapped proximal proteins SEPTIN7, SERBP1, SNW1, and RNPS1. To further validate our methods, we engineered two cancer cell lines (DHSA-1426 and COSB) to induce PIK3CA H1047R mutations using CRISPR/Cas9. Our ongoing work involves labeling proximity proteins with mutant PIK3CA in these malignant cells, enabling temporal and spatial molecular sensing of oncogenic PIK3CA and its functional interactome in living cancer cells.

#6664 ATF4 is required for PanIN formation and PDAC via effects on nucleotide metabolism and suppression of p53 activity.

Leah M. Ziolkowski, Kay F. Macleod

The Ben May Department for Cancer Research, University of Chicago, Chicago, IL

Pancreatic ductal adenocarcinoma (PDAC) is increasing in incidence in western society and has a 5-year survival rate of less than 13% which while better than it was several years ago, remains one of the worst for all solid tumors. The development of KRAS inhibitors to block the activity of the dominant activated oncogene in human PDAC brings hope that the mortality rate will improve in the coming years. However, as these new therapeutics enter clinical trials, there is an expectation that resistance to KRAS inhibitors will emerge. Thus, the interrogation of additional pathways and the mechanisms of drug resistance are critical to expand the efficacy of KRAS inhibitors and promote patient survival. Our work focuses on the role of *Activating Transcription Factor 4* (ATF4) in PDAC where an ATF4-like gene signature predicts worse survival outcomes for PDAC patients. We show here for the first time that conditional loss of *Atf4* in acinar cells of the adult mouse pancreas prevents KRas-driven PDAC, such that neither pre-malignant pancreatic intra-epithelial neoplasia (PanIN) lesions nor PDAC develops over the lifetime of the animal. We also show that loss of Atf4 alone in pancreatic acinar cells (absent KRas activation) causes increased pancreatitis and marked pancreas shrinkage following treatment with cerulein. We show that loss of Atf4 in adult pancreatic acinar cells leads to DNA damage, induction of p53 (and both p21 and Bax) and increased cell death, that is exacerbated by cerulein treatment. The increased DNA damage was associated with nucleotide depletion and decreased levels of metabolites involved in 1C metabolism which we attribute to the observed loss of expression of Atf4 targets, such as Mthfd2. Together, our data point to a critical role for Atf4 in maintaining nucleotide pools necessary for tumor cell growth and that its loss promotes p53-dependent cell death preventing PDAC initiation and progression.

#6666 Translocation-dependent regulation of nucleotide metabolism in response to drug-induced nucleotide stress.

Zaffar Iqbal Bhat, Iqra Ishrat, XiaoMi Lu, Justin L. Tan

INSTITUTE OF CANCER RESEARCH, Shenzhen Bay Laboratory, Shenzhen, China

Nucleotide metabolism plays a significant role in cancer development and progression. Cancer cells have an increased demand for nucleotides, which are the building blocks of DNA and RNA, due to their uncontrolled proliferation. Targeting nucleotide metabolism is an important strategy for cancer therapy. However, existing therapies have a small therapeutic window as they induce toxicity in cancer and normal cells alike. Little is known about the mechanisms of nucleotide stress-induced toxicity in cells. In prokaryotes, the PyrR protein senses nucleotide levels by binding UMP. This regulates the ability of PyrR to bind the attenuator region of the *pyr* operon transcript, thus altering transcription of downstream nucleotide metabolism genes. PyrR therefore acts as a nucleotide sensor in prokaryotes. The paralog of this protein in mammals is yet to be discovered. It is unknown if similar nucleotide sensing mechanisms occur in mammalian cells. Our study aims focused to identify new nucleotide binding proteins that regulate nucleotide metabolism in humans. Here, we identified human proteins that had conserved homology to regions of the prokaryotic PyrR protein. We found similar amino acid sequences to the UMP binding site of PyrR in some candidate eukaryotic proteins. We analyzed the effect of nucleotide stress induction, via treatment with two clinical nucleotide biosynthesis inhibitors, on candidate protein P. P is normally localized in the cytoplasm but upon inhibitor treatment, P translocates into the nucleus. Knockdown of P resulted in decreased, cell viability, which could be rescued by nucleotide addition. Computational simulations identified potential nucleotide binding sites on P. We mutated the potential binding site aminos acids of P and expressed P mutant protein in cells. Unlike wildtype P, P mutant did not translocate into the nucleus upon nucleotide stress. Chromatin immunoprecipitation with high-throughput sequencing (ChIP)-seq revealed that P binds to the promoter regions of nucleotide metabolic genes. Through these studies, we have identified a novel mammalian protein sensor that transcriptionally regulates nucleotide metabolism through nuclear localization. These findings suggest an additional pathway by which nucleotide metabolism is directly regulated in response to the availability of end-product nucleotides. Knowledge of this pathway could propose ways to improve the therapeutic window of nucleotide biosynthesis-based chemotherapy.

#6667 Dual inhibition of PIKfyve and KRAS/MAPK targets metabolic vulnerabilities of pancreatic ductal adenocarcinoma.

Jasmine P. Wisniewski[1], Caleb Cheng[1], Sydney Peters[1], Ruya Pakkan[1], Pietro Morlacchi[2], Jennifer P. Morton[3], Yuanyuan Qiao[1], Costas A. Lyssiotis[1], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]Agilent Technologies, Inc., Lexington, MA,[3]CRUK Scotland Institute, Glasgow, United Kingdom

Background: Pancreatic Ductal Adenocarcinoma (PDAC) exists within a harsh, nutrient-depleted microenvironment, and is known to use lysosomal processes, such as autophagy, for maintenance of metabolic function. PIKfyve is a lipid kinase that serves as the single source for PI(3,5)P2, a molecule critical for the process of autophagy. Considering the role of PIKfyve in autophagy, we hypothesized it to be crucial for PDAC pathophysiology.

Methods & Results: To evaluate the significance of PIKfyve in PDAC, we employed RNA-ISH and found that PIKfyve was significantly higher expressed in PDAC tissue compared to normal surrounding cells. Performing viability screens across multiple PDAC cell lines, we observed that they were highly sensitive to PIKfyve inhibitors apilimod and ESK981. This data suggested that PIKfyve is crucial for PDAC development.

We then performed a metabolism-focused CRISPR screen with the selective pressure of PIKfyve inhibition to assess the metabolic role of PIKfyve in PDAC. From this, we identifiedthe function of the de novo fatty acid synthesis pathway as necessary for PDAC survival following PIKfyve perturbation. In addition to this pathway being essential upon PIKfyve inhibition, we also noticed dramatic upregulation of fatty acid synthesis genes FASN and ACACA following the activation of SREBP1, a transcriptional regulator of lipogenesis. To determine if this shift translated to a metabolic phenotype, we performed targeted lipidomics and observed a significant increase in sphingolipids.

KRAS, mutated in the majority of PDAC cases, is known to be a major driver of metabolic homeostasis through MAPK signaling. De novo fatty acid synthesis is one such pathway controlled by KRAS signaling; we noticed decreased expression of FASN and ACACA along with sphingolipids following KRAS/MAPK inhibition. Specifically, KRAS/MAPK inhibition attenuated the increase in FASN and ACACA as well as lipidomic reprogramming seen with PIKfyve inhibition.

We investigated the in vivo potential of this combination using a syngeneic orthotopic model of PDAC. Notably, all but one mouse were cured when treated with both ESK981 and MEK inhibitor trametinib. Then employing a KPC model, we observed that mice treated with both ESK981 and MEK inhibitor selumetinib had an increased median survival time by over 5 times.

Taken together, the concurrent targeting of PIKfyve and KRAS-MAPK disrupts lipid homeostasis and has potent antitumor effects, holding promise as a therapeutic treatment strategy.

#6668 MNK2-dependent activation of *de novo* lipid synthesis drives breast cancer brain metastasis.

Jessie Ling Ai Wong[1], Giselle Sek Suan Nah[1], Fatin Nasha Binte Sulaimi[1], Kian Leong Lee[1], Kassoum Nacro[2], Kaustubh Bhinge[3], Amanda E.D. Van Swearingen[3], Carey K. Anders[3], Sin Tiong Ong[1]

[1]Programme in Cancer Stem Cell Biology, Duke-NUS Medical School, Singapore, Singapore,[2]Experimental Drug Development Centre (EDDC), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,[3]Division of Medical Oncology, Duke Cancer Institute, Duke University Medical Center, Durham, NC; Division of Medical Oncology, Duke Center for Brain and Spine Metastasis, Duke University Medical Center, Durham, NC

Patients with triple-negative breast cancer (TNBC) have poor prognosis, attributed to a ten-fold increased risk of developing brain metastases (compared to patients with other breast cancer subtypes), as well as the limited availability of effective therapies for breast cancer brain metastasis (BCBM). Recent work has revealed that SREBP1, a master transcription factor regulating *de novo* lipid synthesis, is required for BCBM survival in the lipid-depleted brain microenvironment. Given that previous studies have highlighted a link between MAPK interacting protein kinases (MNK) and lipid biosynthetic pathways, we investigated whether MNKs are essential for lipid biosynthesis in BCBM. We found that *MNK2* and *SREBP1* are upregulated in BCBM compared to paired primary cancers (n= 5 pairs, $p<0.05$). This upregulation is also observed in neurotropic 231-Br relative to its parental MDA-MB-231 TNBC cell line. Using a novel brain-penetrant MNK1/2 inhibitor, ETC-501, we show that MNK activity is required for growth of 231-Br cells in lipid-depleted conditions, as well as *de novo* lipid synthesis. Using a combination of immunofluorescence- and immunoblot-based assays, we find that ETC-501 prevents the nuclear translocation of SREBP1 and causes an accumulation of the precursor form of SREBP1 in the endoplasmic reticulum, preventing its processing into the mature form required for nuclear localization, and lipogenic gene activation. Importantly, we find that both genetic & pharmacological inactivation of MNK prevents the establishment of BCBM *in vivo*. In rescue experiments, we find that expression of mature SREBP1c restores lipid droplet levels in ETC-501-treated cells. Our study reveals a critical role for MNK2 in regulating SREBP1 and lipid synthesis, providing new insights into TNBC BCBM. Inhibitors of MNK kinases, such as ETC-501, may offer potential in managing TNBC patients at high-risk for BCBM.

#6669 Vagal perturbation of the gut-brain axis deters cancer-associated cachexia.

Aliesha D. Garrett[1], Xiling Shen[1], Ayelet Erez[2], Naama Darzi[2]

[1]Terasaki Institute for Biomedical Innovation, Los Angeles, CA,[2]Weizmann Institute of Science, Rehevot, Israel

Cancer-associated cachexia (CAC) is a wasting syndrome present in 80% of advanced cancer patients. CAC decreases the quality of life, causes higher mortality, and causes resistance to treatments with increased toxicity. CAC is currently incurable and directly responsible for up to 30% of all cancer deaths.
We find that cancer-induced systemic inflammation disrupts vagal tone via infiltration of innate immune cells into the brain, involving the vagal dorsal motor nucleus of the hindbrain. This disruption leads to CCL2-driven vagal hyperactivation and elevated acetylcholine output to the liver, resulting in the downregulation of hepatocyte nuclear factor 4 alpha (HNF4α), a key regulator of liver metabolism. We further demonstrate that a right cervical vagotomy in mice with lung or pancreatic cancer disrupts the abnormal CNS-liver vagal crosstalk, restoring liver metabolism and feeding behavior, thereby alleviating cachexia symptoms independent of tumor burden. Importantly, electrical, chemical, or surgical disruption of the right vagus nerve, including via a custom wireless implantable device, restores liver metabolism, alleviates CAC manifestations, and synergizes with chemotherapy, significantly improving the overall well-being and survival rates of mice with lung or pancreatic cancer.
Our findings have substantial translational potential for CAC treatment, mainly as non-invasive vagal interventions are already FDA-approved for other therapeutic applications.

#6670 Unraveling bone marrow adipocyte-leukemia interactions: Identifying key signaling pathways for improved leukemia therapies.

J. Rahbani, M. Song, O. Ukomadu, O. Arnold, E. Postich, A. Dhar, C. Saygin;
The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL

Bone marrow, the soft tissue within our bones, plays a vital role in blood production and also houses fat cells called bone marrow adipocytes (BMAs), which are a natural component of its structure. However, recent studies suggest that these fat cells might contribute to leukemia growth by fostering an environment that aids cancer cell survival and enhances their resistance to treatments like chemotherapy. This issue could be exacerbated in individuals with obesity, as they have an increased amount of bone marrow fat cells, potentially creating an even more protective environment for leukemia cells. Here, we study two aggressive types of leukemia: acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL). We believe leukemia cells send specific signals to these fat cells, causing them to change in ways that promote cancer growth and treatment resistance. Our research will investigate these communication signals and the changes in fat cell behavior, with the aim of finding new ways to treat leukemia more effectively. The study has three main goals: (i) understanding how leukemia alters fat cell metabolism; (ii) examining how different eating patterns like calorie restriction and time-restricted feeding affect fat cell activity and (iii) exploring how time-restricted feeding influences leukemia cell survival and metabolism after chemotherapy. Investigating the role of BMAs in leukemia not only deepens our understanding of the bone marrow microenvironment but also opens new avenues for targeted therapies. Over time, this work could revolutionize how we understand and treat leukemia, laying the groundwork for new therapies that target its underlying biochemical mechanisms, and potentially reshaping the future of cancer treatment.

#6671 Metabolic predictors in hepatocellular cancer.

Brandon Mathew[1], Kazufumi Ohshiro[1], Krishanu Bhowmick[1], Xiyan Xiang[1], Srinivasan Dasarathy[2], Adrian R. Krainer[3], Lopa Mishra[1]

[1]The Feinstein Institute for Medical Research, Manhasset, NY,[2]Division of Gastroenterology and Hepatology, Cleveland Clinic, Cleveland, OH,[3]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Background: Obesity and Metabolic dysfunction-associated steatotic liver disease (MASLD) affect nearly a third of the world's population. 20% of MASLD patients progress to Metabolic dysfunction-associated steatohepatitis (MASH). Hepatocellular Cancer (HCC) arises in 4-11% of MASH patients. Recently, we discovered obesity-driven cancers in our mouse models with disruptions to TGF-β signaling (*Cell Rep. 2024.43(9):114676 and Sci Transl Med. 2021.13(624): eabk2267*). Key metabolic enzymes were evaluated in both mouse models and human cirrhotic patients to elucidate their roles in HCC development. Our Mutant mice exhibited significant sarcopenia, with a notable reduction in muscle mass, mirroring the substantial muscle loss observed in human cirrhotic patients. We identified levels of PKM2, Myostatin and SPTBN1 to be significantly altered in our mouse models of obesity driven HCC.
Methods: To investigate the roles of myostatin, SPTBN1, and PKM2 in human HCC progression, serum samples were obtained from 143 patients with cirrhosis and 57 patients diagnosed with HCC. Myostatin and PKM2 serum concentrations were quantified using Somascan proteomic analysis. ELISA was conducted to confirm the observed differences in myostatin and SPTBN1 levels between the cirrhosis and HCC patient cohorts. Additionally, serum samples from 18 cirrhotic patients were longitudinally analyzed over a 5-year follow-up period to monitor their progression to HCC.
Results: Elevated myostatin levels were observed in obese mice. Serum myostatin concentrations were significantly higher in patients with HCC than those with cirrhosis ($p < 0.05$), with a 17% increase in mean levels noted in the HCC cohort. A trend toward increased PKM2 serum concentrations was also observed in HCC patients relative to cirrhosis patients. Somascan proteomic analysis identified elevated myostatin and PKM2 levels in the serum of 18 cirrhosis patients who progressed to HCC over a five-year follow-up period. Validation using ELISA in a prospective cohort ($n = 200$) confirmed the significant difference in myostatin concentrations between HCC and cirrhosis patients ($p < 0.05$). Additionally, serum SPTBN1 concentrations were found to be elevated in patients with virus-related cirrhosis and HCC, further supporting its involvement in disease progression.
Conclusions: These findings highlight the significant role of Myostatin, PKM2, and SPTBN1 in the progression of cirrhosis to HCC. Elevated myostatin levels in obese mice and HCC patients underscore its potential as a biomarker for disease progression. The observed trend of increased PKM2 concentrations in HCC patients further implicates its role in tumorigenesis, particularly in an immunosuppressive tumor microenvironment. Collectively, these results reinforce the importance of these biomarkers in understanding HCC progression and their potential utility in early detection, risk stratification, and targeted therapeutic strategies.

#6672 Lipid droplet accumulation after metformin and 6 aminonicotinamide combinatory treatment of glioblastoma cells.

Cecilia Gasco[1], Ivan Macharashvilli[1], Daniela Perez Visnuk[1], Marina Perona[2], J. Silvio Gutkind[3], **Marcela Solange Villaverde**[1]

[1]University of Buenos Aires, Buenos Aires, Argentina,[2]The National Atomic Energy Commission, Buenos Aires, Argentina,[3]University of San Diego, Moores Cancer Center, San Diego, CA

Glioblastoma (GBM) has the worst prognosis among primary brain cancers. As in many tumors, GBM proliferation is supported by glycolysis and the pentose phosphate pathway (PPP). The PPP enables cancer cells to adapt to anabolic demands, including lipid synthesis, and to restore antioxidant defenses. Metformin (MET), a worldwide prescribed drug for type-two diabetes, impairs the progression of different malignancies by indirectly inhibiting the mammalian target of rapamycin (mTOR). Our previous results showed that the combination of MET and 6-aminonicotinamide (6AN), a PPP inhibitor, strongly potentiates their individual cytotoxic effects on different tumor cells. Thus, the present work aimed to study the effect of MET alone or in combination with 6AN on the mTOR pathway as well as on the activity of acetyl-CoA carboxylase, a key enzyme in lipid synthesis, in the human GBM cell line U251. Results showed that MET (5 mM) alone or in combination with 6AN (25 μM) decreased the mTOR effector, pS6, and increased the presence of the phosphorylated form of acetyl-CoA carboxylase (24 h of treatment, determined by western blot and immunofluorescence, $p<0.05$). Controversially, we also found an increase in the total cell lipid content (BODIPY and oil red staining, analyzed by flow cytometry (FC), $p<0.01$) of MET/6AN-treated cells, which was accompanied by a mild increase in the content of the lipid transporter CD36 (FC, $p<0.01$). In addition, by fluorescence microscopy, we observed an increase in the number and size of lipid droplets of MET/6AN-treated cells. Finally, we also found that MET/6AN promoted a decrease in mitochondrial potential and an increase in oxidative stress and lipid peroxidation (TMRE, DCF and C11-BODIPY respectively, FC, $p<0.01$). Preliminary results indicated that accumulation of lipids inside lipid droplets may prevent lipid peroxidation. These results deserve to be further investigated to better understand the mechanisms involved in the effectiveness of the combination of MET/6AN as a potential strategy to treat GBM.

#6673 Alternate mechanism of translation initiation in TNBC metabolism.

Emilia F. Carlo[1], Erna Mitaishvili[2], Columba de la Parra[3]

[1]Chemistry, Herbert H. Lehman College, City University of New York, New York, NY,[2]Biochemistry, The Graduate Center, City University of New York, New York, NY,[3]Chemistry, Herbert H. Lehman College & The Graduate Center, City University of New York, New York, NY

Triple-negative breast cancer (TNBC) is a highly aggressive and metastatic subtype of breast cancer. Metastasis is considered one of the primary causes of mortality in cancer patients. TNBC has been shown to exhibit advanced cancer hallmarks, such as metabolic reprogramming and selective mRNA translation, which contribute to metastatic progression. Previous studies show that TNBC utilizes an alternate cap-dependent translation mechanism mediated by Death Associated Protein 5 (DAP5). Our studies indicate this alternate translation plays an essential role in metabolic reprogramming. Analysis from genome-wide translatome studies, qRT-PCR, Western blot analyses, as well as metabolomic assays on the TNBC cell line (MDA-MB-231) with non-silencing controls (shNsi) and DAP5-silenced (shDAP5) samples indicate that this alternate translation plays a significant role in the metabolic reprogramming. DAP5 silencing reduces the translation of several glucose metabolism-related mRNAs, independent of their steady-state abundance, and reduces proteins associated with glycolytic metabolism. Targeted metabolomics shows that DAP5 silencing alters metabolites critical in breast cancer energy metabolism. Our findings also suggest that DAP5-dependent translation may selectively regulate metabolic mRNAs under stress conditions when canonical mTORC1/eIF4E cap-dependent translation is attenuated. This alternative translation initiation mechanism suggests this metabolic switch is necessary for malignant progression and metastasis in TNBC cells. These results provide new insights into the molecular mechanisms underlying metabolic reprogramming in metastatic breast cancer and may offer novel therapeutic targets for TNBC treatment.

#6674 Leucine sensing and mTOR activation drive SNAIL-mediated EMT in pancreatic cancer cells.

Hironori Koga[1], Yasuko Imamura[2], Atsutaka Masuda[1], Hiroyuki Suzuki[1], Toshimitsu Tanaka[1], Takahiko Sakaue[1], Hideki Iwamoto[1], Toru Nakamura[1], Takumi Kawaguchi[1]

[1]Div. of Gastroenterology, Dept. of Medicine, Kurume Univ. School of Medicine, Kurume, Japan,[2]Research Center for Innovative Cancer Therapy, Kurume Univ., Kurume, Japan

Background: Pancreatic cancer, characterized by a highly fibrotic and hypovascular tumor microenvironment, possesses unique metabolic adaptations that enable survival and proliferation in malnourished conditions. Aim: This study aimed to compare the metabolic adaptations of pancreatic cancer cells to glucose deprivation with those of liver cancer cells, which are representative of hypervascular tumors.
Methods: Three pancreatic cancer cell lines (BxPC-3, Panc-1, MIA PaCa-2) and two liver cancer cell lines (HuH-7, Hep3B) were analyzed. We examined transcriptional expression levels of genes involved in amino acid transport, including *LAT1*, *CD98*, *CD147*, *EPCAM*, and *ASCT2*; epithelial-mesenchymal transition (EMT), including *SNAIL*, *SLUG*, and *ZEB1*; and cancer stemness, including *CD24*, *CD44*, and *DCLK1*, under glucose-deprived conditions.
Results: Pancreatic cancer cells displayed significantly lower proliferative activity under glucose deprivation compared to liver cancer cells. While glucose-starved cells did not undergo significant apoptosis, they exhibited cell cycle arrest. Pancreatic cancer cells showed mild arrests in both the G0/G1 and G2/M phases, whereas liver cancer cells exhibited a clear G0/G1 arrest. Among amino acid transporters, *LAT1* was uniquely upregulated in pancreatic cancer cells, correlating with increased *SNAIL* (EMT regulator) and *DCLK1* (cancer stemness marker) expression. *LAT1* knockdown abolished *SNAIL* upregulation in glucose-starved pancreatic cancer cells, indicating a mechanistic link. Stimulation of LAT1 by branched-chain amino acids (BCAAs; valine, leucine, isoleucine) under glucose-free conditions induced dose-dependent *SNAIL* upregulation by leucine, accompanied by increased expression of leucine sensors *SAR1B* and *Sestrin2*. This activation triggered mTOR pathway signaling, as evidenced by phosphorylation of S6K1 and 4E-BP1. Conversely, rapamycin inhibited mTORC1 activation, suppressing leucine-induced SNAIL upregulation.
Conclusion: Pancreatic cancer cells reprogram their metabolism to adapt to energy crises via leucine-mediated upregulation of SNAIL, potentially enhancing metastatic capabilities through EMT. Targeting LAT1 or the mTOR pathway may represent promising therapeutic strategies for pancreatic cancer.

#6675 Are malic enzymes a metabolic drug target in the war against cancer?.

B. Krinkel[1], M. Slayton[2], J. Jeon[2], J. Copping[1], J. Flanagan[1], S. Merajver[2], C. Squire[1], K. Loomes[1];
[1]University of Auckland, Auckland, New Zealand, [2]University of Michigan, Ann Arbor, MI

Background: Cancer continues to be a formidable adversary, claiming countless lives globally and fueling the pursuit of more effective therapies to enhance treatment outcomes and quality of life. A hallmark of cancer is the reprogramming of cellular metabolism, including the aberrant biosynthesis of essential metabolites that support survival and rapid cellular proliferation. This metabolic shift often involves increased reliance on glutamine as a fuel source and elevated expression of malic enzyme 2 (ME2) within the mitochondria. ME2 catalyzes the generation of pyruvate and NAD(P)H and is upregulated in pancreatic, melanoma, and lung cancer, making it a promising yet underexplored therapeutic target. We have solved the structure of the active site small molecule inhibitor NPD-389 in complex with ME2 and used virtual screening to identify novel scaffolds to develop into new drug leads.
Methods: We expressed recombinant human ME1-3 isoforms and detailed their enzymatic kinetics with and without inhibitors. Molecular snapshots of the potent malic enzyme inhibitor were trapped within a complete set of X-ray crystal structures for the three isoforms ME1-3, and this structural data was used to conduct the virtual screening of up to 12 million drug-like and fragment molecules to identify novel, potent malic enzyme inhibitors. To complement the multidisciplinary characterization of malic enzyme inhibition, the efficacy of NPD-389 in treating triple-negative breast cancer was assessed.
Results: Our kinetic analyses reveal unique inhibition patterns, particularly for the least studied isoform, ME3. We detailed its substrate and cofactor binding affinities and inhibitory constants for EA, MDSA, and NPD-389. The revelation of X-ray crystallographic visualization of the potent but isoform non-selective inhibitor NPD-389 in complex is a metal-binding mode and the adoption of an unexpected malic enzyme conformation. Virtual screening based on the unique protein conformation identified several new scaffolds with promising inhibitory activity against ME's. These include molecules confirmed by X-ray crystallography to bind in an allosteric site and that, critically, display distinct isoform selectivity. In triple-negative breast cancer cells, NPD-389 inhibited proliferation in most cell lines, suggesting its potential as a lead compound for further development.
Conclusions: Our studies underscore the potential of ME2 as a therapeutic target in cancer treatment. By detailing the binding mode of NPD-389 and those of newly identified selective inhibitors, we provide a robust platform for the future clinical development of potent inhibitors of metabolic pathways driving cancers. We envisage that isoform selective ME drugs could serve as adjunct therapies alongside existing checkpoint inhibitors or chemotherapy, enhancing treatment efficacy and improving patient outcomes.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: microRNAs and Other Noncoding RNAs 1
Poster Session

#6678 Targeting long non-coding RNA LINC00324 using novel plant-derived exosome-like nanovesicles loaded with anticancer epigenetic modifiers effectively inhibits biomarkers of epithelial-mesenchymal transition in breast cancer.

Alaa Ashraf Al_Aaser, Nourhan El-Sayed El-Feel, Ahmed Samir Sultan

Biochemistry, Alexandria University, Alexandria, Egypt

Despite recent advancements in the diagnostics and therapeutics of breast cancer, it continues to be the second leading cause of death among women worldwide. Therefore, identifying new potential biomarkers and molecular targets is essential for enhancing the diagnosis and treatment of BC patients. A wealth of evidence underscores the significant role of long non-coding RNAs in various biological processes, including tumorigenesis, which might offer new biomarkers and molecular targets for improved cancer detection and treatment. In this context, long intergenic non-coding RNA 00324 (LINC00324) has been associated with advanced cancer stage, larger tumor size, lymph node metastasis, and poorer prognosis across several cancer types. However, its biological function and molecular mechanisms in breast cancer remain largely unexplored. This study adopts an innovative approach aimed at challenging existing knowledge and research methodologies, with the goal of making significant advancements in breast cancer research. By exploring the role of LINC00324 as an oncogene in tumorigenesis and progression, the study may uncover crucial downstream oncogenic signaling pathways related to Epithelial-Mesenchymal Transition (EMT), which are linked to the hallmark features of breast cancer pathogenesis. This research could ultimately lead to the identification of a new biomarker for the diagnosis and prognosis of breast cancer, thereby transforming our understanding and treatment of the disease. In this study, we employed an innovative approach to downregulate the expression of LINC00324 across various breast cancer cell lines, ranging from well-differentiated to poorly differentiated types. This was accomplished using isolated novel plant-derived exosome-like nanovesicles (PELNVs), demonstrating specific biological effects, including anti-inflammatory and anti-tumor properties, while exhibiting minimal toxic side effects. PELNVs were a novel vehicle for delivering anticancer epigenetic modifier drugs and specific siRNA targeting LINC00324. Additionally, we investigated several downstream target biomarkers of epithelial-mesenchymal transition, including oncogenic targets such as *Notch1, Notch4, Nanog, s6 kinase, β-catenin*, and *Stat3*, both *in vitro* and *in vivo*. These findings suggest that LINC00324 could serve as a novel biomarker for diagnosis and prognosis.
Outcome: Identifying the molecular classification of breast cancer subtypes based on the expression of individual biomarkers, such as LINC00324, might lead to the development of novel therapeutic biomarkers/targets for early detection, drug resistance, and personalized cancer treatments. Using PELNVs for drug delivery may inspire future research on plant-derived nanovesicles.

#6679 MicroRNA cargo of extracellular vesicles of pancreatic cancer patients have immunoregulatory potential.

Rupinder Kaur[1], Sandeep Bhoriwal[2], Pramod Kumar Gautam[1]

[1]Biochemistry, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[2]IRCH, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Pancreatic ductal adenocarcinoma (PDAC) is characterized by a dismal five-year survival rate of 5-8%. Extracellular vesicles (EVs), nano-sized membrane-bound particles (30-150 nm) present in the circulatory system, play a crucial role in mediating intercellular communication, regulating immune responses, and driving tumor progression. MicroRNAs (miRNAs), integral components of EVs, function as key mediators in cellular signaling pathways. Although the role of exosomal miRNAs (exo-miRNAs) in cancer pathogenesis is well established, their comprehensive therapeutic, diagnostic, and immunomodulatory potential remains largely unexplored. This study established the differential exoMIR profile of PDAC patients using small RNA sequencing on the Illumina platform, compared with healthy controls, post-surgery and follow-up. Statistical analysis revealed hsa-miR-375-3p, hsa-miR-134-5p and hsa-miR-197-3p miRNAs were downregulated in PDAC patients than controls whereas hsa-miR-126-5p, hsa-miR-7847-3p, hsa-miR-197-3p were upregulated post-surgery. Six-month follow-up sample after surgery had hsa-miR-144-3p, hsa-miR-194-5p, hsa-miR-16-5p, hsa-miR-197-5p upregulated and hsa-miR-125b-3p was downregulated as compared to post-surgery sample. These distinct exoMIRs were identified as key regulators of cytokine translation in immune cells. The altered expression of these cytokines is well-known to significantly influence immune activity within the tumor microenvironment. Bioinformatic analyses revealed that these miRNAs, along with their protein targets, are closely involved in oncogenic pathways, underscoring their potential as valuable tools in cancer therapeutics, diagnostics, and prognosis.

#6680 Androgen-regulated miRNA-mRNA interactions in luminal A breast cancer: Insights into metastasis, anoikis resistance, and metabolic pathways.

Jehad A. Yasin[1], Osama M. Younis[1], Leen A. AlKuttob[1], Ramez M. Odat[2], Sofia Adwan[3], Mohammad Abdulla[1], Afaf Mansour[1], Dana Alsafadi[1], Mamoun Ahram[1]

[1]University of Jordan, Amman, Jordan,[2]Jordan University of Science and Technology, Amman, Jordan,[3]Medical Laboratories, American University of Madaba, Amman, Jordan

Background: Luminal A breast cancer (BC), the most common subtype of BC, often expresses the androgen receptor. This study explores androgen-regulated miRNA-mRNA interactions and their roles in metastasis, anoikis resistance, and metabolism.
Methods: Luminal A cell lines, MCF-7 and T47D, and the luminal androgen receptor (LAR) MDA-MB-453 cells, were treated with dihydrotestosterone for 48 hrs, followed by microarray analysis of mRNA and miRNA expression. Expression data were normalized and differentially expressed (DE) transcripts were identified. Gene Set Enrichment Analysis was utilized, and miRNA-mRNA interaction networks were built using multiMiR. Survival analyses, coexpression, and therapy response comparisons were done on luminal A cohorts in TCGA, 'ROC Plotter', and 'KMplotter'. MAVISTO's algorithm was used for network motif discovery.
Results: Seven DEmiRNAs were found in MCF-7 cells and 20 in T47D, both of which were fewer than the 66 found in LAR. A 17-gene androgen response signature was derived by overlapping DEmiRNA-targeted DEmRNAs in luminal A cells with the 'Hallmark Androgen Response' set, including 16 upregulated mRNAs like FKBP5, a hub mRNA regulated by hsa-miR-429, and TPD52, both of which were in T47D and MCF-7. The mean expression of the signature correlated with better overall survival (OS) in luminal A BC (HR = 0.67, 95% CI: 0.45-0.99, n = 1,504) and was higher in endocrine therapy responders compared with non-responders (p = 0.041). However, only three genes in the signature had significant negative epithelial-mesenchymal transition (EMT) scores, while 11 were EMT-promoting. Bi-fan network motifs in signature-related network, featuring two miRNAs co-regulating two mRNAs, were the most enriched. Negative regulation of anoikis, an enriched term, had two upregulated EMT-promoting genes, SNAI2 and CAV1 in MCF-7, both with significant coexpression with downregulated hsa-miR-429 (correlations ≤ -0.29); DEmRNA signature from this term predicted poor OS (HR = 1.8, p = 0.038). Syndecan-mediated signaling was enriched, with SDC2 upregulated and interacting with the downregulated miRNAs hsa-miR-429, hsa-miR-4490, and hsa-miR-890 upon androgen treatment. Similarly, RND3 GTPase was upregulated and interacted with hsa-miR-429. Syndecan and RND3, linked to metastasis, may share a regulatory pathway. Insulin signaling was also enriched; Insulin Receptor Substrate 1 (IRS1) was downregulated and interacted with hsa-miR-429 and hsa-miR-890. In T47D, estrogen response, linked to DEmRNAs FKBP5 and FASN, and previously related to invasion and anoikis resistance, emerged as a key enriched term from miRNA-regulated mRNAs.
Conclusion: We found significant androgen-regulated miRNA-mRNA interactions influencing anoikis suppression, metastasis, and metabolic shifts in luminal A breast cancer, with hsa-miR-429 as a key regulator.

#6681 Identification of a panel of four exosomal microRNAs driving T cell dysfunction in the tumor-immune microenvironment of high-grade serous ovarian cancer.

Michael Chan[1], Li Yang[1], Nan Xiang[2], Dongbing Gao[1], Jianting Sheng[1], Stephen TC Wong[1]

[1]Systems Medicine and Bioengineering, Houston Methodist Neal Cancer Center, Houston, TX,[2]School of Basic Medical Sciences, Anhui Medical University, Hefei, China

Purpose: High-grade serous ovarian cancer (HGSOC), the most aggressive ovarian cancer subtype, has poor outcomes due to late-stage diagnosis and a complex tumor microenvironment (TME). This study investigates exosomal microRNAs (miRNAs) in HGSOC, focusing on their role in immune evasion mechanisms within the TME and their potential as biomarkers for early detection and therapeutic targets. **Methods:** We conducted comprehensive miRNA sequencing on exosomes derived from nine human ovarian cancer cell lines, including those representing high-grade serous ovarian cancer. Bioinformatics analyses were then applied to identify key miRNAs and their target genes potentially involved in T cell exhaustion, stemness, and modulating immune response pathways. Selected exosomal miRNAs were validated through miRNA transfection and RT-qPCR to evaluate their effects on genes related to immune checkpoints, cytokine expression, and immune modulation. Additionally, ex vivo experiments assessed the functional impact of tumor-derived exosomes on CD8+ T cells, including IFN-γ secretion and T cell stemness. **Results:** A critical panel of four exosomal miRNAs — miR-24, miR-191, miR-181c, and miR-146a — were identified through differential expression and pathway enrichment analyses, highlighting their involvement in immune modulation pathways such as IL-4 and IL-13 signaling pathway. In vitro validation confirmed that these exosomal miRNAs significantly altered the expression of key genes associated with immune checkpoints, T cell exhaustion, and cytokine production, reinforcing their role in facilitating immune evasion. Ex vivo experiments demonstrated that tumor-derived exosomes modulate CD8+ T cell function by reducing IFN-γ secretion and impairing T cell stemness. Notably, the encapsulation of these miRNAs within exosomes allows them to circulate systemically and influence both local and distant components of the tumor microenvironment (TME). These findings emphasize the dual role of exosomal miRNAs in shaping the immune landscape of HGSOC—acting as drivers of immune suppression and as promising candidates for non-invasive biomarkers and therapeutic targets. **Conclusions:** The four miRNAs identified in this study are key modulators of the immune landscape within the TME of HGSOC, engaging critical pathways that promote immune evasion and tumor progression. Notably, their presence within exosomes—a circulating vesicle system capable of long-range transport—position exosomal miRNAs as promising biomarkers for non-invasive early detection and as versatile therapeutic targets, offering new opportunities to improve outcomes in this aggressive cancer subtype.

#6682 Circulating Epstein-Barr virus microRNAs associated with Hodgkin lymphoma prognosis.

Soo Mi Lee[1], Cristina S. Bogsan[1], **Jason T. Howard**[2], Abigail G. Wandoff[3], Meng-Xuan Wu[3], Estelle Verburgh[4], Maxine van der Schyff[4], Frank J. Slack[1], Yujing J. Heng[1], Katherine Antel[3]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]Mirxes US, Durham, NC,[3]Dana Farber Cancer Institute, Boston, MA,[4]University of Cape Town, University of Cape Town, South Africa

Background: Epstein-Barr virus (EBV) infection is an established causal factor for Hodgkin lymphoma (HL). MicroRNAs (miRNAs) are master regulators of gene expression and are ideal biomarkers. We profiled the circulating expression of 42 EBV miRNAs in HL patients to determine if EBV miRNA(s) can be a noninvasive biomarker for EBV+ HL or disease severity.
Method: Plasma was obtained from 11 patients with HL in a tuberculosis and HIV-endemic setting in Cape Town, South Africa. EBV infection in HL tumor cells were confirmed using a clinical PCR assay. The expression of 42 miRNAs were measuring using a qPCR-based Mirxes ID3EAL^{TM} EBV miRNA panel. Wilcoxon test or Fisher's test were used to compare data between two groups. Spearman's rho was used for correlation analysis. Fold changes were calculated using the $2^{\wedge-\Delta\Delta CT}$ method.
Results: EBV+ HL patients were significantly older (p=0.04; Table 1). No miRNA was associated with EBV or prognostic factors at FDR<0.05. Of interest, miR-BART20-3p expression was 33% lower in EBV+ patients compared to EBV- patients (p=0.052) and did not correlate with age (rho=0.39, p=0.23). MiR-BART17-3p was inversely correlated with stage (rho=-0.61, p=0.047). MiR-BART2-5p correlated with International Prognostic Score (IPS; rho=0.72, p=0.01). miR-BART14-3p was inversely correlated with Eastern Cooperative Oncology Group (ECOG) score (rho=-0.60, p=0.049). MiR-BART11-5p and miR-BART14-5p were higher in patients that reported B-symptoms (11.2-fold p=0.01 and 2.5-fold p=0.02, respectively). In contrast, MiR-BART14-3p and miR-BART17-3p were 33% and 41% lower in patients with B-symptoms (both p=0.03). No miRNA was associated with HIV.
Conclusion: Circulating EBV miRNAs were associated with HL disease severity but not EBV status. Further investigations into these candidate miRNAs will increase our understanding of HL disease progression as well as explore the potential of these miRNAs as therapeutics or therapeutic targets. Table 1.

#6683 Melatonin and 17β-estradiol suppress TGFB1 and TGFBR2 in IDCs cells by target miR-93-5p.

Bruna Cristine De Almeida, Kelly Pedrozo Ferreira, Jose Maria Soares-Junior, Juciara Costa Silva, Katia Candido Carvalho, Edmund Chada Baracat

Departamento de Obstetricia e Ginecologia, Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil

miR-93-5p exerts an oncogenic effect in a tissue-specific mode, and its activity is related to cancer progression and development. In breast cancer cells, *miR-93* overexpression was associated with proliferation, invasion, migration, and metastasis. In addition, it targets *TGFB1* and *TGFBR2* genes, which are directly involved in mammary development. Activated TGFB1 is able to directly bind the TGFBR2 promoting the cascade of signaling. *TGFB1* modulates many cellular processes. However, changes in its expression may show a controversial role, both inhibiting the development of early-stage lesions (during carcinoma initiation and progression) and participating in invasion and metastasis (in the late stages of tumor progression). It is known that epigenetics events can silencing *TGFB1* pathway signaling. In this context, melatonin (Mel) has gained notoriety due to its oncostatic activities and mainly to modulate miRNAs. Additionally, estrogen signaling is often associated with the onset of breast cancer and directly interacts with *TGFBR2*. Our goal was to evaluate the effects of Mel and 17β-estradiol (E2) treatments in invasive ductal carcinoma cells (IDC) and to assess the expression of *miR-93* and its target, *TGFB1* and *TGFBR2*. IDC cells (MCF7 (ER+) and MDA-MB231 (triple-negative) were treated with 3000 μM Mel and 100 nM E2 isolated, and the two drugs were combined (M+E2), with daily replenishment. RNA was extracted and reverse transcription synthesis was performed. RT-PCR was carried out for *miR-93*, *TGFB1* and *TGFBR2* detection. Relative quantification was determined with ExpressionSuite Software v1.3. ER-positive IDC cells showed significant suppression of *miR-93* expression with Mel (Fold: 0.494) and M+E2 (Fold: 0.488) treatments, compared to control. In addition, *miR-93* expression was significantly lower with M+E2 treatment compared to E2. Lower expression of *miR-93* leads to an increase of *TFGB1*, after the Mel (Fold: 2.607) and M+E2 (Fold: 3.433) treatments, related to control and E2 treatment. This same effect was observed in *TGFBR2* expression, in which the inhibition of *miR-93* promoted the expression of *TGFBR2* after Mel (Fold: 2.551) and M+E2 (Fold: 2.988) treatments. In triple-negative IDC cells, lower expression of *miR-93* was observed in Mel (Fold: 0.868), M+E2 (Fold: 0.814), and E2 (Fold: 0.780) treatments. Suppression of *miR-93* after Mel and M+E2 treatments, increased *TGFB1* expression by more than seven times (Mel Fold: 7.068, and M+E2 Fold: 7.342). However, even though E2 treatment also decreased the expression of *miR-93*, the expression of *TGFB1* did not show significant changes. In addition, *TGFBR2* also presented great expression with inhibition of *miR-93,* after Mel (Fold: 3.005) and M+E2 (Fold: 2.723) treatments. Overall, our findings provided evidence for the significant role of *miR-93* in regulating the TGFB cascade and also introduced Mel as a new therapeutic agent for targeting oncogenic miRNAs in IDC cells. Supported by: FAPESP 2022/04174-2 and 2018/24224-9.

#6684 Aiolos expression regulates epithelial-mesenchymal transition through repressing miR-424-5p in lung cancer cells.

Ying-Shiun Kao, **Jung-Jyh Hung**

National Yang Ming Chiao Tung University and Taipei Veterans General Hospital, Taipei, Taiwan

Introduction: Epithelial-mesenchymal transition (EMT) is one of the major molecular mechanisms inducing tumor invasion and metastasis. The Ikaros family of DNA binding proteins are zinc finger transcription factors. Aiolos overexpression promotes EMT through upregulating the PI 3-kinase/Akt/Twist/MMP16 pathway in lung cancer. However, the roles of Aiolos regulating EMT and metastasis through miRNAs expression in lung cancer has not been well demonstrated in the literature.
Materials and Methods: qRT-PCR was performed to determine miR-424-5p expression in H1299-Aiolos and A549-Aiolos cells. Knockdown of miR-424-5p was performed in H1299 cells, and transfection of miR-424-5p was performed in A549 cells. Western blotting analysis was performed to demonstrated E-cadherin and vimentin expression. Migration assay and matrigel invasion assay were done to determine the EMT phenotypes after miR-424-5p transfection or knockdown in lung cancer cells.
Results: Down-regulation of miR-424-5p in H1299-Aiolos and A549-Aiolos cells was determined by qRT-PCR. Western blotting analysis showed decreased E-cadherin and increased vimentin expression in H1299 cells after miR-424-5p knockdown. Western blotting analysis also showed increased E-cadherin and decreased vimentin expression in A549 cells after miR-424-5p transfection. Migration assay showed that migration increased in H1299-shmiR-424-5p cells, but decreased in A549-miR-424-5p cells. Matrigel invasion assay showed the invasiveness increased in H1299-shmiR-424-5p cells, but decreased in A549-miR-424-5p cells.
Conclusions: Aiolos expression regulates EMT through repressing miR-424-5p expression in lung cancer cells. The results shed light on further understanding of the mechanisms of metastasis in lung cancer.

#6686 Bioinformatic evidence for the involvement of SP1, MYC, and HIF1A in the regulation of miRNAs and histone H2AZ1.

Kotohiko Kimura, Monika Rajput, John Ho Chun, Ru Chih C. Huang

Biology, Johns Hopkins University, Baltimore, MD

We previously proposed the concept that the inhibitors for SP1, MYC, and HIF1A should induce strong anticancer activity by reducing the expression of stem cell-related proteins (Curr. Issues Mol. Biol. 2023, 45, 9262-9283). Then, it was shown that in LN229 and U87MG glioblastoma cells, either tetra-methyl-O-nordihydroguaiaretic acid (M_4N) or tetra-acetyl-O-nordihydroguaiaretic acid (A_4N) suppressed SP1 and only a few stem cell-related proteins and induced only a small amount of cell death while the combination treatment of M_4N with A_4N greatly suppressed the expression of SP1, MYC, and HIF1A, and all stem cell-related proteins examined, and greatly induced cell death. This data provided the biochemical evidences to support the aforementioned concept. In this study we did bioinformatic analysis to seek for further evidences to support this concept. The ontology analysis showed that the proteins associated with SP1, MYC, and HIF1A were specifically involved in the regulation of transcription and that various miRNAs which had been shown to induce either anti- or pro-cancer activity were associated with SP1, MYC, and HIF1A, which suggested that the inhibition of SP1, MYC, and HIF1A could modulate transcription of both coding and noncoding RNAs and affect cancers. It has been known that nucleosomes, containing histone variants H2AZ1, are important for gene transcription initiation and termination, chromosome segregation and DNA double-strand break repair. The network analysis showed that there were intricate connections between three transcription factors (SP1, MYC, and HIF1A) and H2AZ1. These data overall showed that SP1, MYC, and HIF1A in combination played important roles in transcription regulations via multiple ways (modulations of both coding and non-coding RNAs, miRNAs, and H2AZ1) and that the inhibitions of these transcription factors should have strong negative impacts on cancers which required enhanced production of energy and materials for their rapid proliferation. Thus, these bioinformatic data overall supported our concept as well.

#6687 Micromanaging resistance: microRNA expression and chemoresistance in testicular germ cell tumors.

Ratnakar Singh, Kelly Kries, Aayush Gupta, Amy Li, Zeeshan Fazal, Doha Shokry, Raya Boyd, Brayden Rennels, Sarah J. Freemantle, Michael J. Spinella

Comparative Bioscience, University of Illinois at Urbana-Champaign, Urbana, IL

Testicular germ cell tumors (TGCTs) are the most common type of cancer among young men, and incidence has increased over the past 40 years. Approximately 80% of patients with metastatic TGCTs can be cured with chemotherapy; however, those patients that develop resistance to treatment often have a poor prognosis. Despite efforts to identify clear genetic factors that determine chemotherapy sensitivity and resistance in TGCTs, recent research has shifted focus toward the role of epigenetics in maintaining sensitivity to drugs like cisplatin and decitabine. Epigenetic mechanisms, including DNA methylation, histone modifications, and microRNAs (miRNAs), play a crucial role in regulating gene expression. Prior studies in somatic cancers have linked differential expressions of miRNAs to drug resistance. In this study, we hypothesized that the response of TGCTs to cisplatin and decitabine is partially influenced by miRNA expression. Through miRNA sequencing analysis followed by RT-qPCR validation, we identified distinct patterns of miRNA expression that correlate with resistance to cisplatin and decitabine in TGCTs. Consistent with our previous findings on protein coding gene expression, we observed that 54 miRNAs were reciprocally expressed between cells resistant to decitabine and those resistant to cisplatin. In follow-up analysis, we selected a subset of these reciprocally regulated miRNAs and predicted their target genes using miRDB and TargetScan. Downstream miRNA-RNA interactive analysis, enrichment analysis, and validation assays are ongoing and will be presented. Together, our study aims to elucidate the mechanistic roles of miRNAs in chemosensitivity and chemoresistance in TGCTs. The findings from this study will also support precise diagnosis and personalized treatment strategies for patients with TGCTs.

#6688 Differential serum mirnas in obese and diabetic African American colon adenoma patients.

Hassan Brim, Adeyinka O. Laiyemo, **Hassan Ashktorab**

Howard University, Washington DC, DC

Background: Metabolic syndrome, characterized by obesity, diabetes, and other metabolic disturbances, is associated with an increased risk of colon cancer. There is a critical need for assays that can detect biomarkers to enable risk stratification, early diagnosis, and prevention of colon adenomas and colorectal cancer. Serum miRNAs are emerging as promising biomarkers for this purpose.
Aim: The purpose was to elucidate the role of miRNAs in the pathophysiology of colon adenomas in the context of obesity and diabetes.
Methods: We used serum samples from age- and gender-matched African Americans (n=18 per group) to ensure that the comparison of miRNA expression was not confounded by age or gender differences. The groups included patients without adenomas (Normal), patients with adenomas and obesity, and patients with adenomas and diabetes. RNA extraction and miRNA sequencing was rigorous, utilizing the miRNeasy Serum/Plasma Kit and Lexogen Small RNA-Seq Library Prep Kit, respectively. Illumina NextSeq 500 sequencing provided high coverage (15 million reads per sample). The alignment to the UCSC hg38 human genome and the use of the DESeq2 R package for differential expression analysis ensured robust statistical evaluation of miRNA expression changes. We identified miRNAs with significant fold changes (log2 FC ≥ 2 or ≤ -2) and p-values < 0.05.Results: In the Adenoma-Obese group, miR-455, miR-219b, miR-34a, miR-378a, miR-485, and miR-133b showed significant associations with obesity-related metabolic dysregulation. Notably, miR-34a, involved in cell cycle and apoptosis regulation, was upregulated, highlighting its role in obesity-related cancer pathogenesis. In the Adenoma-Diabetic group, miR-455 was upregulated, suggesting its involvement in insulin resistance and adenoma progression, while miR-219b was downregulated, potentially reflecting a compensatory response to hyperglycemia. Ingenuity Pathway Analysis (IPA) revealed that these miRNAs are linked to pathways involved in cancer, diabetes, and lipid metabolism. Key pathways, including insulin signaling, Wnt/β-catenin, and mTOR, underscore the interplay between metabolic disorders and colorectal adenoma progression.
Conclusion: This study highlights distinct miRNA expression profiles associated with adenoma development in obesity and diabetes. miR-34a, miR-378a, and miR-455 emerged as potential biomarkers and therapeutic targets. Future research should validate these findings in larger cohorts to refine their utility in clinical applications.

#6689 Evaluating the influence of blood collection tubes and extraction kits on miRNA recovery in cancer biomarker research.

Eunju Seong, Nicholas M. George, Jordan LaRue, Jing Li, Lisa Bartron

Research and Development, Streck, LLC, La Vista, NE

Cell-free RNAs, especially microRNAs (miRNAs), are emerging as valuable biomarkers in cancer research and other diseases. These small, non-coding RNA molecules circulate in the bloodstream, offering insights into the physiological and pathological states of various organs and tumors. However, the stability of miRNAs in blood samples can be significantly affected by the type of blood collection tube used and the handling of samples. Here, we determine the optimal workflow for miRNA extraction from blood samples by comparing three types of blood collection tubes - citrate, EDTA, and Nucleic Acid BCT (NAC) - paired with three different extraction kits: A, B, and C. The three selected extraction kits differ in their sample lysis mechanisms, which are crucial for minimizing the effects of highly active innate RNases present in plasma. Kit A uses a proprietary lysis reagent containing phenol, allowing for plasma lysis at room temperature and recovering RNA from the aqueous layer following phase separation. Kit B employs two consecutive heated lysis steps at 60 °C with chaotropic agents while Kit C executes plasma lysis at 37 °C using proteinase K and further purifies RNA on an automated magnet-based platform. We observed that when plasma samples were processed within 24 hrs with Kit A per manufacturer's instructions, both RNA spike-in and endogenous miRNA recoveries were notably compromised regardless of tube type, while the mRNA yield was markedly reduced in samples collected in NAC. We were only able to increase recovery with substantial modifications to Kit A's protocol. In contrast, when we analyzed plasma samples with Kits B and C per manufacturer's instructions, we saw consistent isolation of miRNA and mRNA across all three tube types, albeit with slight variations in reproducibility. These data show that the recovery of miRNA and mRNA from plasma samples is significantly influenced by the combination of RNA extraction kit and blood collection tube. The automation capability of Kit C facilitates higher throughput processing, which is advantageous in clinical settings where sample volume and processing time are critical factors. To demonstrate the compatibility of Kit C with NAC, cancer-associated miRNAs, including miR-21-5p and miR-122-5, were quantified in samples collected into citrate, EDTA, and NAC. We observed that these miRNAs are maintained in samples stored in NAC for up to five days, but not those stored in EDTA or citrate. These data underscore the importance of selecting appropriate blood collection tubes and extraction kits to optimize miRNA recovery from plasma samples. The findings indicate that both components significantly influence miRNA quantification. Careful consideration of these factors is crucial for obtaining reliable results in clinical studies involving circulating miRNAs. Nucleic Acid BCT is For Research Use Only. Not for use in diagnostic procedures.

#6690 A novel B7H3-targeting macrocyclic peptide conjugate efficiently delivers siRNAs to cancer cells and tumor endothelium.

Danyan Li[1], Lincy Edatt[1], Jillian Perry[1], Avery Huber[2], William David Green[1], Jarred Michael Green[1], Justin Milner[1], Albert Bowers[2], Chad Pecot[1]

[1]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[2]Eshelman School of Pharmacy, UNC Chapel Hill, Chapel Hill, NC

Short-interfering RNAs (siRNAs) can treat a wide range of human diseases from viral outbreaks to cancer, however, targeted siRNA delivery remains a significant challenge. Recently, significant efforts have focused on developing novel delivery technologies for siRNAs, targeting tumors and other extrahepatic tissues. B7-H3 (CD276), a B7 family of immune checkpoint proteins, is highly expressed in cancer cells and tumor endothelial cells (TECs). We employed an mRNA display campaign against the hB7-H3 protein and discovered a macrocyclic binding peptide, JP5. Using surface plasmon resonance, we confirmed specific binding of JP5 to both human and murine B7-H3 with a KD of approximately 770nM and 600nM, respectively. Characterization of protease stability showed that greater than 80% of the peptide remains intact after incubation with 50% serum for 24h. Further, our team conjugated JP5 to chemically stabilized siRNAs labeled with a Cy5 fluorophore to observe biodistribution of siRNAs, including cancer cells and and TECs. Mice were implanted with A431 WT or B7H3 KO cells, and upon xenograft tumor formation, mice were given PBS (control) or JP5-siRNA-Cy5 (n=5 mice/group). Gross biodistribution by IVIS imaging was found in the tumors, skin, bowel, liver and kidney, with minimal accumulation in the heart and lungs. Flow cytometry and immunofluorescence revealed that JP5 conjugation directed siRNAs to ~80% of TECs and to 40-60% of cancer cells, with a significant reduction in B7H3 KO cells. In conclusion, the JP5 macrocycle delivers siRNAs to B7H3-expressing cancer cells and TECs in the tumor microenvironment, paving a path forward for sophisticated cancer therapeutics.

#6691 A divalent and chemically modified microRNA-34a with enhanced circulation kinetics and improved endosomal escape for the treatment of triple-negative breast cancer.

Sharjeel Anjum, Shreyas Iyer, Digambar Waiker, Andrea Kasinski

Purdue University Institute for Cancer Research, West Lafayette, IN

Treatment of triple-negative breast cancer (TNBC) remains highly challenging due to the absence of HER2/hormonal receptors and its resistance to conventional therapies. Although surgery, chemotherapy, and radiotherapy are available treatment options, these broad-spectrum therapies are limited by their non-specific targeting and severe side effects, underscoring the need for more precise therapeutic options. Targeted micro RNA (miRNA) therapeutics have gained significant attention in this regard. In most cancers including TNBC, tumor suppressive miRNAs are often lost, leading to unchecked oncogene expression. One such miRNA, miR-34a which is transcriptionally activated by p53, regulates several oncogenic pathways by down-regulating genes like MET, AXL, and C-MYC. Restoring miR-34a in TNBC is therefore being explored as a potential therapeutic strategy. However, clinical use of miRNAs has been limited by their susceptibility to nucleases, immunogenicity, and lack of targeted delivery methods. To address these limitations, our lab developed a chemically modified, folate-conjugated miRNA-34a (FM-FolamiR-34a) that is highly stable and can be specifically delivered to TNBC cells overexpressing folate receptor alpha (FRα). FM-FolamiR-34a effectively downregulated its targets and demonstrated promising antitumor activity. However, due to its small size (~14 kDa), FM-FolamiR-34a was subject to rapid renal clearance, limiting its therapeutic availability. Additionally, endosomal entrapment restricted its cytoplasmic abundance, further reducing its mRNA-targeting efficiency. To overcome these challenges, we developed a novel, chemically modified, folate-conjugated *divalent* miR-34a with enhanced circulation kinetics and improved endosomal escape. This divalent molecule includes two miR-34a duplex copies linked by cleavable deoxythymidine linkers (dT-linkers), which are susceptible to enzymatic cleavage by DNAse II in late endosomes. The dT-linker facilitates miR-34a release from the receptor promoting endosomal escape and increasing cytosolic availability. The dual nature of our construct also raises its molecular weight above the kidney clearance threshold (~30 kDa), preventing rapid excretion and providing additional time for engagement with FRα-expressing cancer cells. Furthermore, delivering two miR-34a strands per receptor doubles the intracellular miR-34a copy number, enhancing cellular availability. We anticipate that our divalent miR-34a will demonstrate superior antitumor efficacy in TNBC compared to the monovalent version (FM-FolamiR-34a). This innovative approach addresses key critical barriers in miRNA-based therapeutics - specifically endosomal entrapment and rapid renal clearance - presenting an effective strategy to target FRα overexpressing TNBC.

#6692 The combination of 5-methyltetrahydrofolate and nigericin enhances the cytosolic release of chemically modified miRNA-34a, significantly boosting its anti-tumoral activity.

Kenan E. Ozcan[1], Sophia A. Matthias[1], Shreyas G. Iyer[1], Ahmed M. Abdelaal[2], Sudarsan R. Kasireddy[3], Philip S. Low[3], Andrea L. Kasinski[1]

[1]Purdue University Institute for Cancer Research, West Lafayette, IN,[2]Microbiology & Immunology, Indiana University School of Medicine, Indianapolis, IN,[3]Department of Chemistry, Purdue University, West Lafayette, IN

A major driver of cancer progression involves the downregulation of tumor-suppressive miRNAs like miR-34a, which regulates key cancer-promoting genes such as MYC, AXL, and BCL-2. Thus, it is not surprising that miR-34a restoration has been proposed as an anticancer strategy. miRNAs, such as miR-34a can precisely target cancer-related genes with limited toxicity, provided they are properly designed. Effective therapeutic design must address RNA specificity, stability, and endosomal escape. Our lab has made significant progress in addressing these unmet challenges, particularly in enhancing specificity and stability of miRNA therapeutics through ligand-mediated delivery and chemical modifications, respectively. Our ligand-mediated delivery strategy capitalizes on overexpression of Folate Receptor 1 (FR1) in cancer cells, and uses the high-affinity FR1 ligand, folate, to deliver miRNAs to cancer cells with high specificity. To overcome the issues with poor instability, we created a fully modified version of miR-34a (FM-34a), increasing its stability by ~400-fold. Despite significant progress in developing FM- 34a as a therapeutic agent, efficient endosomal escape remains a major hurdle. To address this, a small molecule ionophore, nigericin that disrupts endosomal membranes was conjugated to the folate-FM-34a conjugate (Fol-N-FM-34a). However, nigericin alone achieved only modest improvements in escape efficiency, likely due to the inability of folate to dissociate from the receptor at the elevated endosomal pH levels induced by nigericin. To overcome this limitation, a lower affinity ligand of FR1, 5-methyltetrahydrofolate (5-MTHF), was used in combination with nigericin (5M-N-FM-34a). Unlike folate, 5-MTHF retains a similar binding affinity for FR1 at physiological pH but dissociates more effectively at the higher pH levels attainable in the presence of nigericin, thereby enhancing endosomal escape and cytosolic delivery. We validated that the 5-MTHF ligand binds to FR1-expressing cells in both *in vitro* and *in vivo* models and that 5-MTHF-N-FM-34a lead to a higher cytosolic abundance of miR-34a and superior downregulation of miR-34a target genes compared to Fol-N-FM-34a *in vitro*. To evaluate *in vivo* activity both single dose targeting and multi-dose efficacy studies were conducted. 5M-N-FM-34a achieved greater target downregulation and enhanced anti-tumor activity in a $KRAS^{G12D}$ $p53^{-/-}$ genetically engineered mouse model of non-small cell lung cancer in comparison to other ligands. These findings highlight 5-MTHF-nigericin as a promising ligand for targeting FR1-overexpressing tumors.

#6693 Targeting oncogenic miR-135b in colorectal cancer: Computational modeling and small molecule screening for RNA-based therapy.

Berat Demir[1], Lalehan Oktay[2], **Serdar Durdagi**[3]

[1]Department of Molecular Biology and Genetics, Gebze Technical University, Kocaeli, Turkey,[2]Lab for Innovative Drugs (Lab4IND), Computational Drug Design Center (HITMER), Bahcesehir University (BAU), Istanbul, Turkey,[3]Molecular Therapy Lab, Department of Pharmaceutical Chemistry, School of Pharmacy, Bahcesehir University (BAU), Istanbul, Turkey

Colorectal cancer ranks among the leading causes of cancer-related deaths globally. In this study, we identified miR-135b as a differentially expressed microRNA in colorectal cancer through an analysis of datasets from the Gene Expression Omnibus (GEO) database. Target genes associated with miR-135b were subsequently identified, and pathway and functional enrichment analyses were conducted to provide a deeper understanding of the underlying biological processes. We developed a de novo three-dimensional model of miR-135b's tertiary structure, targeting the Dicer cleavage site for small molecule inhibition. Dicer binds to the terminal loop region of the pre-miRNA and cleaves it to produce a double-stranded miRNA duplex. One strand of this duplex, the guide miRNA, is loaded into the RNA-induced silencing complex (RISC), which mediates miRNA-mRNA interactions, leading to post-transcriptional gene silencing. To identify potential inhibitors, molecular docking simulations were conducted using the ChemDiv miRNA-targeted small molecule library (~20,000 compounds). The top-scoring compounds were further explored by screening their commercial analogues in the ZINC library via SwissSimilarity. These analogues were docked at the Dicer cleavage site, and optimized docking scores were obtained. The highest scoring compounds were then subjected to all-atom molecular dynamics simulations, followed by post-simulation analysis to evaluate the dynamic interactions between miR-135b and the selected hit ligands.

#6694 Multiplex RNAi delivers on-versus-off tumor precision in T cells.

Reka A. Haraszti, Xavier Segarra-Visent, Anastasia Kremer, Tatyana Ryaykenen

Department of Medicine II, Hematology, Oncology, Clinical Immunology and Rheumatology, University Hospital Tubingen, Tubingen, Germany

Selective inhibition of graft-versus-host disease (GvHD) while preserving graft-versus-leukemia (GvL) remains a critical challenge in allogeneic stem cell transplantation. More broadly, engineering on-versus-off tumor selectivity represents a central precision medicine problem in T cell-mediated immunotherapies. Evidence suggests that T cell phenotype distributions, defined by transcriptomes and transcriptional regulation, are key determinants of this selectivity. RNA interference (RNAi) therapies, including small interfering RNAs (siRNAs) and microRNA (miRNA) mimics, represent a novel class of precision medicine tools capable of engineering cellular transcriptomes. We identified an siRNA cocktail targeting RAN, WAPAL, and AURKA that achieved GvHD inhibition comparable to approved therapies (35-95% vs. 55-91% reduction in T cell proliferation) while sparing GvL effects (no increase in leukemia proliferation, compared to a 7-20-fold increase with approved drugs). Notably, substituting any siRNA in the cocktail drastically impaired GvHD inhibition (up to a 10-fold reduction), and individual siRNAs against WAPAL and AURKA showed no significant GvHD inhibitory effects. While RAN siRNA alone was highly effective against GvHD *in vitro* (>90% inhibition of T cell proliferation), it compromised bead-activated T cells. Thus, the RNAi-based transcriptome engineering strategy demonstrated that targeting RAN, WAPAL, and AURKA synergistically inhibits GvHD, while also conferring selectivity to this innovative therapeutic approach. The effect of chemical modifications on miRNA function remains poorly understood. In our study, we screened diverse chemical modification patterns to develop miRNA replacement therapies (miR-146a, miR-181a, miR-374b) within the GvHD/GvL context. Silencing performance of miRNA mimics—whether on fully matched reporter targets or natural targets with mismatches—failed to reliably predict miRNA efficacy in inhibiting GvHD *in vitro*. Notably, certain miRNA mimics achieved GvHD inhibition comparable to approved therapies (60-95% vs. 55-91% reduction in T cell proliferation) while either sparing or even enhancing GvL effects (up to an 80% decrease vs. up to a 22-fold increase in leukemia proliferation). Generally, miRNA mimics with higher phosphorothioate content demonstrated stronger GvHD inhibition, whereas no such pattern was observed for GvL outcomes. RNA-Seq analysis revealed that the same marker genes could predict responses to miR-374b mimics in both GvHD and GvL assays, highlighting shared molecular pathways influencing these outcomes. Such analyses may serve as target discovery tool to uncover pathways potentially differentiating between GvHD and GvL. Multiplex RNAi therapies, such as siRNA cocktails or miRNA mimics have the potential to rewrite the T cell transcriptional program and enhance on-versus-off-tumor precision of T cell mediated cancer therapies.

#6695 Lipid nanoparticles with cell specific CRISPR activity against cancer.

Noah Richardson, Sanam Rezaei Benam, Samaneh Maleknia, Reza Shahbazi

Indiana University School of Medicine, Indianapolis, IN

The most prevalent cancer in men is prostate cancer and is the second leading cause of cancer death in men. Initially, metastatic prostate cancer responds to androgen deprivation therapy (ADT) blocking the androgen receptor (AR) signaling pathway responsible for growth and proliferation. Resistance eventually develops however and although systemic androgens are minimal, the androgen receptor remains functional and drives prostate cancer growth in most patients. This advanced form of prostate cancer termed castration-resistant prostate cancer (CRPC) is incurable and largely driven still by the AR. Development of resistance is through several mechanisms including receptor duplications, intratumoral androgen synthesis, constitutively active point mutations, and AR splice variants that confer resistance to current therapies targeting the AR signaling axis The continued biological significance and reliance of AR signaling in CRPC has made the definitive knockout (KO) of the gene an enticing target.

We have developed antibody coated lipid nanoparticles (LNP) to specifically direct CRISPR nanoformulations to cancer cells expressing targetable surface antigens. Our first target is PSMA-expressing CRPC C4-2B cells. Our PSMA-LNP CRISPR formulation has increased safety and specificity with both extracellular and intracellular prerequisites for CRISPR targeting and activity. Intracellular activation of the CRISPR sgRNA complex is mediated by sensing cell-specific miRNA uniquely identified in malignant cells. We have screened miRNA databases and C4-2B cell lines identifying specific miRNA not expressed significantly in other healthy tissues. Using miRNA-flanked sgRNA CRISPR formulations our system once shuttled to PSMA expressing C4-2B cells allows assembly of Cas9 protein and sgRNA in a cell-specific manner causing AR knock out and cell death. In vitro PSMA-LNP delivery of unmodified guides demonstrate 60-95% gene editing efficiency analyzed by T7EI and TIDE analysis in C4-2B cells and control cells. Next using miRNA-flanked sgRNA CRISPR formulations we demonstrate preferrable editing in targeted cancer cell lines. Our time-lapse Incucyte live cell analysis shows preferential targeting of PSMA-LNP to C4-2B cell lines in comparison to control malignant and primary cell lines. Currently, we are continuing our studies through in vivo analysis of PSMA-LNP delivery and gene editing specificity in a CRPC mouse model utilizing our unique CRISPR LNP formulation in addition to exploring other gene targets controllable by microRNA sensing CRISPR therapeutics. Our findings demonstrate the feasibility of targeted CRISPR gene editing to treat prostate cancer and a platform for cancer-cell gene targeting across multiple cancers.

#6696 Exosome delivered combinatorial therapeutic approaches for advanced brain tumors.

Monique Kanitz Ruschel, Isaiah Davis, Karthik Gourishetti, Christian Jacobsen, Deepak Bhere

Dept. of Pathology, Microbiology, and Immunology, University of South Carolina- School of Medicine, Columbia, SC

Glioblastoma (GBM) is an aggressive form of brain cancer that affects over 12,000 people each year in the United States. Current treatments such as surgery, chemotherapy, and radiation have limitations and can often fail to achieve full tumor remission, as the five-year survival rate for this disease is around 7%. Recent research has revealed miRNA (miR), small non-coding RNAs that regulate gene expression, as contributors to the suppression and progression of various cancers, including GBM. Exosomes, tiny vesicles released by cells, show great promise as a cancer therapeutic. Our research focuses on using exosomes enriched with microRNA (miR) to address miR dysregulation in as a delivery system for glioblastoma treatment, as these vessels can cross the blood-brain barrier to deliver the treatment. Our goal is to examine the effectiveness of stem cell-derived exosomes carrying miR-124 and miR-7 as a new approach for treating glioblastoma, as this cancer is known for having downregulation of such microRNAs. Adult human stem cells (SC) are modified with target miR plasmids and then grown in an exosome-depleted medium. The exosomes that carry the miR are then separated, purified, measured, and examined. These exosomes are used in all subsequent research. The effects of exosomes on established and patient derived primary GBM cells are studied using a combination of cell viability tests and microscopy. To understand the molecular mechanisms that underlie the effect of miR modulation on cell proliferation and cell death pathways, a time course immunoblot analysis is carried out. To assess the effects of miR modulation in vivo, orthotopic animal models of GBM will be used.

Our research has shown that stem cell-derived exosomes can be an effective delivery system, asthey can evade the immune system and target specific cells. We have successfully transferred microRNA cargo to our target tumor cells using exosomes. By modulating miR, we have been able to halt tumor progression *in vitro* by targeting multiple pathways involved in GBM growth and progression. Although we are still awaiting the results of our ongoing animal studies, our preliminary data suggests that using stem cell-derived exosomes loaded with miR-124 and miR-7 is a promising approach for treating GBM.

#6697 Role of the miR-101-3p/CALCRL/NEAT1 axis in immune modulation and tumorigenesis in non-small cell lung cancer.

Gulnaz Tabassum, Mansoor A. Syed, Kapil Dev

Department of Biotechnology, Jamia Millia Islamia University, New Delhi, India

Lung cancer (LC), particularly Non-Small Cell Lung Cancer (NSCLC), remains a global health challenge with a five-year survival rate of 17.8%, largely due to delayed diagnosis and limited understanding of tumor progression. MicroRNAs (miRNAs), key regulators of gene expression, play critical roles in immune modulation, metabolism, and tumorigenesis, but their role in immunometabolic reprogramming in LC is underexplored. This study investigated novel molecular targets in LC using integrated bioinformatics and in vitro approaches, focusing on the regulatory interplay between miRNAs, mRNAs, and long non-coding RNAs (lncRNAs). RNA-Seq datasets of lung adenocarcinoma (LUAD) were analyzed to identify differentially expressed genes (DEGs) and miRNAs (DEMs). Immune-related genes (IRGs) were curated and intersected with DEGs to identify differentially expressed immune-related genes (DEIRGs). A protein-protein interaction (PPI) network was constructed, and enrichment analyses were performed to identify hub DEIRGs. A ceRNA regulatory network involving miRNA (miR-101-3p), mRNA (CALCRL), and lncRNA (NEAT1) was constructed and analyzed using survival (KM Plotter) and tumor immune infiltration (TIMER) analyses. Experimental validation included expression analysis of miR-101-3p, CALCRL, and NEAT1 using Real-Time PCR and functional studies involving overexpression of NEAT1 and miR-101-3p via transfection. Real-time PCR, Western Blotting & Dual-luciferase assays confirmed CALCRL as a direct target of miR-101-3p. Functional assays—including cell proliferation (MTT assay), ROS production, mitochondrial membrane potential, ATP content, and apoptosis analysis (FACS)—were performed to assess the biological impact of this regulatory network. This study revealed a novel ceRNA axis involving miR-101-3p, CALCRL, and NEAT1. miR-101-3p was significantly downregulated, correlating with increased expression of CALCRL and NEAT1. Functional studies revealed that NEAT1 overexpression suppressed miR-101-3p while enhancing CALCRL expression, promoting tumor progression. Restoration of miR-101-3p suppressed tumor cell proliferation, induced ROS accumulation, impaired mitochondrial function, reduced ATP levels, and triggered apoptosis, underscoring its tumor-suppressive potential. In conclusion, this study provides a detailed framework for the miR-101-3p/CALCRL/NEAT1 axis, offering novel insights into immunometabolic reprogramming in LC. These findings highlight miR-101-3p as a promising therapeutic target, paving the way for miRNA-based therapies in NSCLC

#6698 Inducible miRNA therapeutics: A multi-targeted strategy for treating diffuse midline gliomas.

Riley Bigger[1], Niloofar Khairkhah[2], Rhea Sridhara[2], Hernando Lopez-Bertoni[3], Stefanie Galban[4]

[1]Departments of Radiology, Surgery, and Biological Chemistry, University of Michigan Medical School, Ann Arbor, MI,[2]Departments of Radiology and Surgery, University of Michigan Medical School, Ann Arbor, MI,[3]Department of Neurology, Johns Hopkins University, Baltimore, MD,[4]Departments of Radiology and Surgery, Center for Molecular Imaging, Rogel Cancer Center, University of Michigan Medical School, Ann Arbor, MI

Diffuse Midline Gliomas (DMGs) are highly aggressive gliomas that account for ~20% of pediatric central nervous system tumors. The H3K27M-altered subset is particularly lethal, with 100% tumor recurrence and no effective long-term treatments. Thus, a desperate need to develop new therapeutic avenues remains. RNA therapies, a new class of therapeutics that include microRNA (miRNA) therapies, utilize RNA mimetics to target and treat cancer and other diseases. Compared to single-target small molecule inhibitors, miRNAs represent potent future tools capable of simultaneously targeting multiple aberrant signaling pathways in DMG to increase therapeutic efficacy and prevent tumor resistance and recurrence. To identify targetable, aberrant gene expression in H3K27M-mutated DMG, we performed RNA sequencing of nascent, newly synthesized RNA in the human DMG cell line SU-DIPG-XIII and its isogenic pair SU-DIPG-XIII-H3K27M-KO, where oncohistone expression is prevented by CRISPR gene editing. We compared transcriptional profiles in isogenic cells to render a list of potential disease/tumor-driving genes, expressed solely in H3K27M DMGs, that can be targeted. Computational analysis using miRNet identified miRNAs hsa-miR-124-3p, hsa-miR-27a-3p, and hsa-miR-146a-5p as promising candidate RNA mimetics to develop as new therapeutic options for DMG H3K27M-altered. These miRNAs are predicted to each target 300-400 genes upregulated specifically in H3K27M DMGs, highlighting the powerful capability of this new class of RNA therapeutics. Notably, preliminary proliferation assays in SU-DIPG-XIII cells showed that DMG-specific miRNAs significantly reduced tumor cell growth, highlighting their therapeutic potential. To evaluate efficacy and cellular consequences of identified miRNAs in a panel of human and murine DMG H3K27M-altered cells, we have employed an inducible lentiviral system that allows for precise on/off gene regulation with miRNA mimetics. This system enables controlled manipulation of gene expression, providing a powerful tool to study the functional consequences of miRNAs in various cellular contexts. Furthermore, the panel of DMGs with inducible miRNA will be utilized for *in vivo* testing in relevant orthotopic models and adapted to the PiggyBac intrauterine electroporation DMG model. Our research will pioneer the use of microRNA mimetics as the first proof-of-concept study of using DMG-specific miRNAs to control aberrant gene expression. While this strategy demonstrates significant promise, we acknowledge that advancements in RNA delivery methods will be essential for translating this approach into a clinical reality in the future. In summary, our findings will provide proof-of-concept for use of a new class of RNA therapeutics for the development of innovative future therapies for DMG.

#6699 Development of a fully modified miR-34a (FM-miR-34a) cancer therapeutic: a translational research study.

Shreyas Ganesan Iyer, Digambar Waiker, Ana C. Betustak, Sharjeel Anjum, Andrea L. Kasinski

Purdue University, West Lafayette, IN

MicroRNAs (miRNAs) regulate gene expression by binding to sites within the 3′ untranslated region (UTR) of target mRNAs and exert negative control through mRNA cleavage or translational repression. In cancer, downregulation of tumor-suppressive miRNAs is common, prompting exploration of miRNA restoration strategies for inhibiting tumor growth and suppressing key oncogenic pathways. MicroRNA-34a (miR-34a), known for its tumor-suppressive properties, has advanced to clinical trials as an anti-cancer agent. However, clinical implementation faces challenges such as precise tumor-targeted delivery, susceptibility to degradation in circulation, rapid renal clearance and hindered cytosolic entry due to endosomal entrapment. We tackled a few obstacles by generating a first-in-class fully modified miR-34a (FM-miR-34a) supported by a ligand-mediated vehicle-free delivery platform which exhibited enhanced stability and sustained target gene repression *in vitro* and *in vivo*. Prior to the generation of FM-miR-34a, the molecule would have degraded in circulation quickly. However, with FM-miR-34a showing increased stability in serum, we can now aim to increase the circulation half-life of the molecule, which would allow more miR-34a to be biologically available. To achieve this, we incorporated an albumin-binding moiety within the delivery ligand, allowing the molecule to bind to human serum albumin, the most abundant protein in blood. This in turn increases the overall molecular weight of the cancer therapeutic, pushing it over the renal clearance limit and thus increasing its circulation half-life. We also observe a potent combinatorial anti-tumor response when FM-miR-34a is combined with paclitaxel, a standard chemotherapy for breast cancer. Paclitaxel induces mitotic arrest at G2/M and apoptosis at G0 and G1/S phases, making it an ideal partner for synergistic effects with miR-34a. This approach will potentially allow for reduced dosing of paclitaxel and contribute to better therapeutic efficacy, thus improving quality of life of triple negative breast cancer patients. The research, thus, aims to contribute to the development of a robust therapeutic agent utilizing the miR-34a restoration strategy, addressing delivery challenges, and exploring synergies with existing treatments for enhanced efficacy against cancer.

#6700 Ligand-directed delivery of chemically modified miR-34a to prostate cancer: enhanced targeting and extended pharmacokinetics.

Digambar Kumar Waiker[1], Ahmed M. Abdelaal[1], Shreyas G. Iyer[1], Ikjot Singh Sohal[1], Esteban A. Orellana[2], Kasireddy Sudarshan[1], Kenan E. Ozcan[1], Andrea P. dos Santos[3], Philip S. Low[4], Andrea L. Kasinski[1]

[1]Department of Biological Sciences, Purdue University, West Lafayette, IN,[2]Department of Molecular and Systems Biology, Geisel School of Medicine, Dartmouth College, Hanover, NH,[3]College of Veterinary Medicine, Purdue University, West Lafayette, IN,[4]Department of Chemistry, Purdue University, West Lafayette, IN

Prostate cancer is a leading cause of cancer-related mortality in men. Current therapeutic options include surgical intervention, chemotherapy, immunotherapy, and localized or systemic radiation therapy. However, advanced metastatic prostate cancers are challenging to treat, underscoring the critical need for more effective strategies. Prostate-specific membrane antigen (PSMA), a transmembrane glycoprotein, is overexpressed up to 1000-fold in ~90% of prostate cancers. The high expression level of PSMA, coupled with highly specific targeting ligands, makes it a promising target for diagnostic and therapeutic applications. While various modalities can be delivered via PSMA, delivery of microRNAs has many advantages including the ability to overcome resistance often observed with single-agent treatments due to the ability of miRNAs to downregulate multiple genes simultaneously. Among the miRNAs with anti-cancer properties, miR-34a is among the most promising. Our work and that of others has determined that restoring miR-34a leads to tumor regression. Unfortunately, *in vivo* delivery challenges remain a bottleneck in advancing miR-34a to the clinic. These challenges can be subclassified into three key issues: 1. achieving specific delivery, 2. avoiding nuclease-mediated degradation, and 3. overcoming poor circulation half-life of the miRNA conjugates. Our lab is dedicated to overcoming these challenges. To address these issues, we developed a miRNA-34a vehicle-free strategy that delivers miR-34a to prostate cancer that comprises three critical attributes. Firstly, a peptidomimetic ligand (PSMA-617) was selected based on its selective specificity for PSMA binding, reducing delivery to non-tumorigenic cells. Secondly, the miR-34a is fully modified (FM-miR34a), containing an alternating pattern of 2′-O-methyl and 2′-fluoro modified sugars and phosphorothioate linkages at the 3′ and 5′ ends of each strand to reduce immunogenicity and to provide exonucleases resistance *in-vivo*. Thirdly, 4-(p-iodophenyl)butyric acid, a small molecule that exhibits high affinity for serum albumin, was added to the conjugate, enhancing the pharmacokinetic properties. Through binding to serum albumin, systemic circulation of the PSMA-617-miRNA-34a conjugate is prolonged, providing additional time to achieve receptor saturation, leading to increased bioavailability and therapeutic efficacy. Overall, our data indicates that bringing all three of these components together into a holist vehicle can enhance the clinical utility of miR-34a for treating prostate cancer.

#6701 CircRNA-derived neoantigen identification in cancer vaccine development.

Yi-Cian Zheng, Chun-Kan Chen

Cell Biology & Physiology, Washington University School of Medicine in St. Louis, St. Louis, MO

Immunotherapy has been a popular topic in combating cancer for its great performance in specificity, versatility and durability recently. Cancer vaccines targeting neoantigens have shown clinical efficacy against cancer, eliciting long-lasting immune response and offering a more selective therapeutic approach with less side effects. However, rare mutation rates and low expression levels of neoantigen make it challenging to identify suitable neoantigens. Traditionally, researchers focus on the canonical mRNA transcriptome and proteome to find potential targets. Recent studies suggest that exploring the non-canonical transcriptome and proteome, particularly circular RNAs (circRNAs), can expand the search. CircRNAs, endogenously formed by the unique back-splicing events during pre-RNA processing, can serve as templates for protein synthesis. Some of these non-canonical peptides are specifically expressed in cancer cells, making circRNAs a valid source for neoantigen discovery. We have developed high-throughput circRNA reporter screening methods and mass spectrometry-based peptidomic workflow to pinpoint translating circRNAs and their derived peptides. Using these techniques, we have identified circRNA-derived neoantigens in breast cancer (BC) cell lines that can be used as possible targets for cancer vaccines. These circRNA-derived neoantigens are immunogenic and can trigger dendritic cell (DC) maturation and T cell activation in vitro. Next, we will test these findings by transferring to in vivo mouse system. We will assess cancer vaccine efficacy by targeting the neoantigens using syngeneic mouse tumor models. Our long-term goal is to apply the circRNA neoantigen identification technology to BC patient samples to facilitate cancer vaccine development and improve cancer immunotherapy. Our work will demonstrate the potential of circRNA-derived non canonical neoantigens in cancer vaccines, serving as a crucial first step to prove their effectiveness in therapy. By expanding our search beyond the traditional transcriptome and proteome, we will explore new targets and transform the neoantigen-based treatment. This innovative effort shifts the current understanding of neoantigen sources and opens up new possibilities for targeted cancer therapy strategies.

#6702 Characterization of the microRNA landscape during airway epithelial differentiation and the key role of the miR-34c-5p-FOSL1 regulatory axis in the transformation to squamous metaplasia.

Dalton Hill[1], Phillip Clapp[2], Ying Du[3], Scott Randell[2], Neil Hayes[4]

[1]Medicine, University of Tennessee Health Science Center, Memphis, TN,[2]University of North Carolina School of Medicine, Chapel Hill, NC,[3]TwinStrand Biosciences, Seattle, WA,[4]University of Tennessee Health Science Center, Memphis, TN

MicroRNAs (miRNA) regulate many cellular functions, including proliferation, differentiation, immune regulation, and apoptosis. Dysregulation of miRNAs plays a key causal role in carcinogenesis across a wide variety of cancers. The miRNA family miR-34/449 has been shown to be important for airway epithelial multiciliogenesis and is down-regulated in asthma. Yet, much remains to be learned about the role of miRNAs in airway epithelial development and differentiation. Moreover, specific causal roles of these miRNAs in the development and progression of airway disease states, such as COPD and squamous cell cancer, is largely unknown. In this study, we characterized the expression of miRNAs and their target mRNA during airway epithelial differentiation. We utilized primary human bronchial epithelial cells grown on an air-liquid interface coupled with mRNA and miRNA sequencing at multiple timepoints to robustly characterize the miRNA-mRNA expression landscape of the airway epithelium throughout differentiation. We identified dynamic changes in expression of many miRNAs and their mRNA targets, including several members of the miR-34/449 family. Within this family, we observed highly induced expression of the family member miR-34c-5p throughout differentiation, while its target FOSL1 - a transcription factor - demonstrated decreased expression throughout differentiation. Furthermore, we demonstrated that inhibition of miR-34c-5p resulted in not only increased expression of FOSL1, but also induced the transition to a squamous metaplasia phenotype. Finally, we showed that in human COPD airway tissue samples, miR-34c-5p is significantly downregulated and FOSL1 is significantly upregulated compared to healthy airway, demonstrating the key role the miR-34c-5p-FOSL1 regulatory axis plays in the transition to squamous metaplasia. This study builds a strong foundation and offers promising future directions for the role of miRNAs in both normal airway epithelial differentiation as well as their role in disease. The discovery of the miR-34c-5p-FOSL1 regulatory axis in the transformation to squamous metaplasia uncovers a key molecular regulator of this preneoplastic state. Further, given the increasing understanding of the role of FOSL1 in carcinogenesis as well as its well-established high expression across many different types of cancers, the tight regulation of FOSL1 by miR-34c-5p uncovers a promising avenue for both further understanding the molecular drivers of carcinogenesis as well as potential therapeutic targets.

#6703 LncRNA UCA1 modulates LDHA expression and drives glucose metabolism in colorectal cancer cells.

Salique H. Shaham, Ricardo Pequeno Bracho, Manish K. Tripathi

Medicine and Oncology ISU, University of Texas Rio Grande Valley, McAllen, TX

Background: Colorectal cancer (CRC) ranks as the third most commonly diagnosed malignancy globally and is the second leading cause of cancer-related deaths in the United States. In 2024, an estimated 152,810 new cases of CRC are projected, with 53,010 fatalities. The prognosis for metastatic CRC (mCRC) remains grim, with a survival rate of less than 15%. Urothelial cancer-associated 1 (UCA1), a long noncoding RNA (lncRNA), is dysregulated in CRC and has been implicated in tumor progression. Our research highlights significantly elevated UCA1 expression in metastatic CRC cells, where its association with the GLUT1 and the metabolic enzyme lactate dehydrogenase A (LDHA) suggests a critical role in promoting the Warburg effect —a metabolic hallmark of cancer.
Methods: To evaluate the oncogenic phenotype, assays for migration, invasion, colony formation, and proliferation were conducted. Lentiviral vectors with puromycin selection were used to generate UCA1 overexpression and knockdown cell lines, and fluorescence-activated cell sorting (FACS) was performed to enrich GFP-expressing cells. Anoikis resistance was induced using PolyHEMA plates, and glucose metabolism markers were analyzed at specific time points through RT-PCR and western blotting. Immunofluorescence was used to assess the localization and expression of relevant proteins. Metabolic assays were performed using the Seahorse xFp.
Results: Metastatic CRC cells (SW620) exhibited significantly higher UCA1 expression compared to oncogenic CRC cells (SW480), particularly after 36 hours of anoikis induction. Enhanced expression of GLUT1, YAP1, and FDFT1 was also observed in SW620 cells. UCA1 overexpressing cell line (SW480+UCA1) also showed enhanced expression of GLUT1, YAP1, and FDFT1 correlating with glucose metabolism modulation during anoikis. The expression of LDHA, a key enzyme in the Warburg effect that converts pyruvate to lactate despite oxygen availability, was markedly elevated in SW620 cells compared to SW480 cells. Similarly, LDHA expression was significantly higher in UCA1-overexpressing SW480 cells compared to vector controls. This suggests a functional link between UCA1 and LDHA in metastatic CRC, supported by published studies linking LDHA with GLUT1 and YAP1.
Conclusion: These findings underscore the pivotal role of lncRNA UCA1 in regulating LDHA expression and driving glucose metabolism via the Warburg effect during anoikis resistance, a critical step in metastasis. Targeting the UCA1-LDHA axis may offer novel therapeutic opportunities for combating metastatic CRC.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Pathological Impact of Oncogenes and Tumor Suppressors
Poster Session

#6707 Direct *in vivo* CRISPR screen identifies *BAP1* and *FAT1* as potent tumor suppressors in sarcomagenesis.

Jianguo Huang[1], Xingliang Liu[1], Warren Floyd[2], William Haugh[1], Andrea R. Daniel[2], Zhaoyu Sun[1], Nerissa T. Williams[2], Melissa J. Kasiewicz[1], Yaping Wu[1], Diana M. Cardona[2], Brian Piening[1], John T. Welle[1], Wesley K. Rosales[1], Venkatesh Rajamanickam[1], So Young Kim[2], Eric Xu[2], Lixia Luo[2], Yan Ma[2], Kristianne M. Oristian[2], Omar Lopez[2], Nicholas E. S. Sibinga[3], Rutulkumar Patel[2], Ziqiang Zhang[4], Alexander J. Lazar[5], Corinne M. Linardic[2], Brady Bernard[1], William L. Redmond[1], Walter J. Urba[1], David G. Kirsch[6]

[1]Providence Cancer Institute, Portland, OR,[2]Duke University Medical Center, Durham, NC,[3]Albert Einstein College of Medicine, Bronx, NY,[4]Tongji University School of Medicine, Shanghai, China,[5]University of Texas MD Anderson Cancer Center, Houston, TX,[6]University of Toronto, Toronto, ON, Canada

Undifferentiated pleomorphic sarcoma (UPS) is among the most common soft tissue sarcomas (STS) in adults. For decades, little therapeutic progress has been made for STSs, including UPSs. Targeted therapies for tumors driven by specific genetic mutations have proven to be more effective than standard chemotherapies. However, the molecular pathogenesis of UPSs remains unknown, hindering the development of targeted therapies for UPSs. Approximately 65% of UPSs harbor *TP53* mutations, but somatic mutation of *Trp53* alone is insufficient to induce sarcomas in vivo. The addition of *Rb1* mutation alongside a *Trp53* mutation induces sarcomas in vivo, though with low frequency of tumor onset and slow growth. The role of other genes in facilitating *Trp53*-driven sarcomas is largely unknown. Through a customized *in vivo* CRISPR/Cas9 screen of 35 genes commonly mutated in UPSs, followed by individual gene validation in vivo, we discovered that *Bap1* knockout cooperates with *Trp53* knockout to induce sarcomas in vivo. Furthermore, we demonstrated that *Fat1* deletion increased the onset frequency and growth of *Trp53* and *Rb1*-driven sarcomas in a genetically engineered mouse model. Through multiplex immunohistochemistry and flow cytometry, we found that mouse sarcomas induced by *Trp53* and *Rb1* mutations are significantly enriched with immune cells compared to other mouse sarcomas we generated in vivo. Finally, we show that PARP inhibition may be a potential targeted therapy for *RB1*-loss STSs and BRD4 inhibition may be a potential targeted therapy for *FAT1*-loss STSs.

#6708 RUNX3 restoration in breast tumors leads to profound growth regression via c-Myc inhibition.

Nawaphat Jangphattananont[1], Junichi Matsuo[1], Wei Peng Yong[2], Linda SH Chuang[1], Yoshiaki Ito[1]

[1]Cancer Science Institute of Singapore, Singapore, Singapore,[2]Department of Haematology-Oncology, National University Cancer Institute, National University Health System, Singapore, Singapore

Genetic alterations in the RUNX family genes and their co-factor CBFB are frequently observed in cancer. In breast cancer, RUNX1 and CBFB are identified as significantly mutated genes, while RUNX3 expression is often silenced through hypermethylation. These observations highlight the importance of RUNX genes in mammary homeostasis. Previous studies on luminal-type breast cancer demonstrated that RUNX3 restoration inhibits tumor progression by destabilizing the estrogen receptor α (ERα) protein. However, despite the therapeutic promise of reactivating RUNX3 in breast cancer, its role in hormone receptor-negative subtypes remains inadequately understood. Furthermore, RUNX3 has been reported to exhibit dualistic roles and depending on the cancer type and stage, may function as either tumor suppressor or oncogene. Yet, the molecular mechanisms underlying this duality remain unclear. To investigate the role of RUNX3 in breast pathogenesis, we developed the MMTV-PyMT; Krt8-CreERT2; Rosa26-lsl-RUNX3 mouse model and analysed the effect of conditional induction of RUNX3 expression in Krt8+ mammary epithelial cells and tumor cells within the MMTV-PyMT-driven breast cancer. Without RUNX3 induction, MMTV-PyMT mice developed an average of eight tumors per mouse, and transcriptomic analyses revealed robust activation of the Myc-signaling pathway. Conversely, the induction of RUNX3 significantly suppressed tumor growth, concomitant with a diminished c-Myc expression. This observation underscores the tight relationship between RUNX3 and c-Myc and identifies RUNX3-mediated suppression of Myc pathway as a major aspect of RUNX3 tumor suppressive role. Remarkably, histological analyses of RUNX3-induced breast tumors showed two distinct clusters of cancer cells: proliferating RUNX3-positive cells and non-proliferating RUNX3-positive cells. Spatial transcriptomic profiling revealed elevated c-Myc expression and suppressed RUNX1 expression in the proliferating RUNX3-positive cells compared to non-proliferating RUNX3-positive cells. This observation raises the intriguing possibility that interplay between RUNX1 and RUNX3 determines cellular proliferative potential and implicates RUNX1 as a regulator of RUNX3's paradoxical traits. Consistently, overexpression of RUNX3 in human breast cancer cells induced significant cell death and upregulated RUNX1 expression. Our findings suggest the convergence of RUNX1 and RUNX3 pathways in driving cell states within the tumor microenvironment and establish a causal link between RUNX3, c-Myc activity, and tumor growth dynamics. This study provides critical insights into dual roles of RUNX3 in breast cancer pathogenesis.

#6709 *NF1* mutations in lung adenocarcinoma preclinical models and potential targeted therapies: The crucial role of the RAS-MAPK pathway.

Jean-Stephane Giraud[1], Doriane Gorret[1], Manuela Ye[1], Dominique Lallemand[1], William C. Reinhold[2], Didier Decaudin[3], Ingrid Laurendeau[1], Eric Pasmant[1], Camille Tlemsani[1]

[1]Institut Cochin, Paris, France,[2]Genomics and Pharmacology Facility, National Cancer Institute, Bethesda, MD,[3]Institut Curie, Paris, France

Targeting tumor suppressor genes, such as *NF1,* is a major challenge in cancer. Somatic *NF1* mutations are found in ~15% of lung adenocarcinoma (LUAD) cases. Still, the molecular vulnerabilities and cellular adaptations associated with these mutations remain unclear. Therefore, we aimed to study the functional consequences of *NF1* loss in LUAD and its impact on the RAS/MAPK pathway, as well as potential therapeutic strategies. We established isogenic *NF1*-mutated cellular models (mono- and bi-allelic *NF1* mutations) using CRISPR-Cas9 technology on the HBE4-E6/E7-C1 human bronchial epithelial cell line. Our studies included transcriptomic, phenotypic, and pharmacological studies, utilizing RAS/MAPK and PI3K-AKT-mTOR pathways inhibitors. Differential expression analysis was performed with the “limma” R-package with a 2 × 2 factorial design. We also computed *in silico* data from public drug sensitivity databases of LUAD cell lines. We tested pharmacological combinations in a patient-derived xenograft mouse (PDX) obtained from a LUAD tumor with a homozygous nonsense mutation of *NF1:* c.943C>T, p.(Gln315*) (Variant Allele Frequency ~94%). We confirmed that *NF1* loss-of-function led to the RAS/MAPK pathway activation, while the PI3K-AKT-mTOR pathway was not activated. We observed distinct transcriptomic clusters based on *NF1* mutation status (wild-type [WT], heterozygous, and homozygous). Gene Set Enrichment Analysis found significant *KRAS* signaling down-regulated gene enrichment in *NF1*-mutated clones (q-value=0.059). Moreover, homozygous *NF1*-mutated lung cells exhibited more aggressive characteristics *in vitro* than heterozygous or WT cells: higher proliferation, higher adhesion, and greater migration capacities. In our *in vitro* pharmacological tests, only homozygous *NF1* mutated cells were sensitive to Trametinib (a MEK inhibitor). No sensitivity was observed in these models when treated with the mTOR inhibitor AZD8055 or the PI3K inhibitor Buparlisib alone. Trametinib appeared to modulate the RAS/MAPK pathway more significantly at the transcriptomic level in cells with homozygous *NF1* mutations than in *NF1* WT. Trametinib and Buparlisib synergistically affected the *NF1*-/- model. Analysis of public drug sensitivity databases indicated that inhibitors of the RAS/MAPK and PI3K-AKT-mTOR pathways are effective against *NF1*-mutated LUAD cell lines. We then performed *in vivo* pharmacological tests on the LUAD PDX: Trametinib alone and in combination with Buparlisib resulted in significant tumor volume reductions of 72% and 84%, respectively. Collectively, these findings establish a promising possible efficacy of MEK inhibitors for LUAD patients with *NF1* homozygous mutation.

#6710 The oncogene MYC drives circadian clock disruption and regulates cell plasticity in early lung carcinogenesis.

Juliana Cazarin[1], Cody Naccarato[1], Jamison Burchett[1], Siti Noor Ain Binti Ahmad Shahidan[1], Min Yee[2], Michael O'Reilly[2], Brian J. Altman[1]

[1]Department of Biomedical Genetics, University of Rochester, Rochester, NY,[2]Department of Pediatrics, University of Rochester, Rochester, NY

Circadian rhythms coordinate the compartmentalization of biological processes, such as cell division and metabolism, to the time of the day. Disruption of these rhythms has been implicated in lung carcinogenesis. Circadian disruption accelerates tumor growth in lung adenocarcinoma (LUAD) mouse models, suggesting an oncogenic role of disrupted rhythms. A disrupted circadian clock has been reported in human LUAD, with alterations in circadian gene expression linked to poor prognosis. However, the origins of clock disruption in LUAD and how it supports tumor growth remain unclear. The oncogene MYC has been linked to circadian disruption in cancer cells. MYC or its related family members are mutated or amplified in more than 30% of LUAD cases, with higher MYC expression associated with worse survival. An analysis of public datasets reveals an inverse correlation between MYC expression and the circadian clock gene BMAL1 in human LUAD. BMAL1, a critical component of the mammalian circadian clock, is indispensable for maintaining circadian rhythms, as its deletion leads to their complete disruption in both mice and cells. However, whether MYC directly drives clock disruption in the lung and the extent to which clock dysfunction contributes to MYC-driven carcinogenesis remain unknown. Using organoids derived from alveolar type II cells (ATII), the cell of origin for LUAD, we showed that MYC suppresses BMAL1 expression. MYC also reduced the expression of ATII cell-lineage markers, suggesting activation of a dedifferentiation program. In a LUAD mouse model, three days of MYC overexpression in ATII cells suppressed molecular clock genes, including BMAL1. This was accompanied by increased *Ki67* expression, a marker of proliferation, and the loss of cell-lineage markers early events in lung carcinogenesis. Similarly, in human LUAD, molecular subtypes with reduced epithelial identity markers and poorer survival showed lower BMAL1 expression. These findings suggest a role for the circadian clock in regulating differentiation and tumor progression. Pharmacological restoration of the circadian clock *in vivo* using the RORα agonist SR1078 reduced MYC-induced *Ki67* expression in the lung, indicating that circadian disruption mediates some of MYC's oncogenic effects. Further analysis using CUT&TAG in a mouse lung epithelial cell line revealed that BMAL1 binds to promoters of ATII identity genes (*Sftpb, Abca3*) and cell cycle regulators (*Cdk4*), suggesting that the circadian clock influences both lung epithelial cell identity and proliferation. Overall, we identify MYC as a driver of circadian clock disruption in lung alveolar cells, which may contribute to MYC-induced proliferation and dedifferentiation in early lung cancer. Restoring circadian clock function could represent a potential therapeutic strategy for targeting tumors with MYC amplification.

#6711 Investigating competitive advantage of mismatch repair loss in colonic organoids.

C. Guild, A. Rath, C. Heinen;
University of Connecticut Health Center, Farmington, CT

Lynch syndrome (LS) is an inherited predisposition to developing colon, endometrial, ovarian, and other cancers, affecting about one in 300 people. It is caused by inheriting a pathogenic variant in one copy of a DNA mismatch repair (MMR) gene. Cancers that arise in LS patients are MMR deficient, meaning the cancer cells have lost the remaining, functional MMR allele and thereby lost MMR function. It is known that losing MMR function leads to a drastically increased mutation rate. Additionally, cells in culture that lose MMR function become unresponsive to normally lethal DNA damage caused by alkylating agents. However, the question remains whether this immediate, aberrant DNA damage response contributes to cancer development in LS patients. We hypothesize that loss of this MMR-dependent damage response function provides a competitive advantage to colonic progenitor cells. Importantly, we predict that the strength of this advantage depends on the amount and type of DNA-damaging agents in the environment, such as oxidative stress, that promote expansion of MMR-deficient cells. If this hypothesis is true, it would provide insight into how this selective pressure could be mitigated using chemoprevention, and thereby decrease the incidence of colon cancer in this population.

To test this, we are using stem cell-derived human colonic organoids and CRISPR gene editing to examine differences in survival and proliferation between otherwise syngeneic MMR-deficient (dMMR) and MMR-proficient (pMMR) colonic organoids. We observe that in atmospheric oxygen, dMMR colonic organoids exhibit enhanced budding compared to pMMR colonic organoids, consistent with our hypothesis of a competitive advantage of dMMR colonic cells. Addition of the antioxidant vitamin C decreases the difference in budding between pMMR and dMMR organoids suggesting this difference is mediated by oxidative stress. Additionally, mixed dMMR and pMMR colonic organoid cultures in ambient oxygen become increasingly dMMR overtime, suggesting dMMR colonic progenitor cells have a competitive advantage over pMMR colonic progenitor cells. To explore the mechanism behind this finding, we are analyzing differences in gene expression between pMMR and dMMR colonic organoids. Preliminarily, we have observed increased expression of the senescent marker gene *CDKN2A* (p16) and decreased expression of the colonic stem cell marker *LGR5* in pMMR organoids compared to dMMR organoids. These results suggest that the MMR pathway may promote senescence and/or terminal differentiation in colonic organoid cultures grown in ambient oxygen. Taken together, these results are consistent with our hypothesis that loss of MMR function imparts a competitive advantage in colonic cells in non-transformed colonic organoids that could contribute to cancer formation in LS patients.

#6712 Epigenetic reactivation of a tumor suppressor program in leukemia.

E. Wang[1], C. Han[1], A. Calderon[1], I. Aifantis[2], A. Tsirigos[2], A. Lawal[1], S. H. Rajendran[1], S. Karma[1], H. A. Abbas[3], M. Y. Yassouf[3], Z. Zhang[4], P. Miura[4];
[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [2]NYU School of Medicine, New York, NY, [3]MD Anderson, Houston, TX, [4]UConn Health, Farmington, CT

Tumor suppressor genes (TSGs) impart a cellular fitness in human cancers, including acute myeloid leukaemia (AML). In contrast to genetic alterations, silencing of TSGs without direct mutations lacks genomic scars, thereby complicating the clinical management of AML. Here we conducted genome-scale phenotypic CRISPR/Cas9 screens to uncover genes that suppress leukaemia differentiation. We identified ZBTB7A, a transcriptional repressor that is downregulated in leukaemia stem cells (LSCs) and associated with poor survival outcomes in AML patients. Our results show that the mRNA decay factor ZFP36L2 binds to the 3'-untranslated region (UTR) of *ZBTB7A* to induce its mRNA degradation. Mechanistically, the loss of ZBTB7A promotes a dysregulated inflammatory state that drives leukaemia progression. To explore the translational potential, we coupled *in situ* Flow-FISH readout with CRISPR-based screening which identified KDM4 as a therapeutic vulnerability to restore the tumor suppressive function of ZBTB7A. Pharmacologic inhibition of KDM4 elevated ZBTB7A levels, induced terminal leukaemia differentiation, and broad anti-leukemic efficacy across AML subtypes. Inhibition of KDM4 *in vivo* prolonged survival of leukemic mice while sparing normal haematopoiesis. Together, our findings reveal regulatory circuits underlying the tumor suppressive role of ZBTB7A and highlights an epigenetic therapy to restore its function in myeloid malignancies.

#6714 GPR109A expression provides a molecular link between the colonic microbiome and the associated reduced risk of colon cancer formation.

Muthusamy Thangaraju[1], Nanditi N. Thangaraju[1], Sonia Batan[1], Jabuneesa Khanom[1], Kunal Kumar[1], Snigdha Ganjikunta[1], Subash Sundaram[1], Sathish Sivaprakasam[2], Nikhil Patel[3], Santhakumar Manicassamy[4], Puttur D. Prasad[1], Vadivel Ganapathy[2]

[1]Biochemistry and Molecular Biology, Augusta University, Augusta, GA,[2]Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX,[3]Pathology, Augusta University, Augusta, GA,[4]Medicine, Augusta University, Augusta, GA

Obesity is associated with an increased risk of colorectal cancer (CRC) in both men and women. It has been shown that a body mass index (BMI) of more than 30 has almost twice the risk of early-onset CRC compared with a BMI of 18 - 23. Although the obesity-associated increase in both CRC risk and progression is associated with several systemic and localized factors, the microbiome could play a critical role in obesity-associated CRC. Using mouse models of CRC, we found that dietary patterns shift the normal colonic microbiota populations. Interestingly, the colonic probiotic *Lactobacillus* abundance negatively correlated with body fat composition, providing evidence that obesity interacts with diet to regulate bacterial populations in the colon. Body fat composition is negatively associated with colonic bacteria-derived host cometabolites, Hippurate, and Butyrate, two agonists of the G-protein coupled receptor 109A (GPR109A). We have shown that GPR109A expression is significantly reduced in human CRC compared to the normal colonic epithelium, and GPR109A activation limits CRC growth and progression. Low GPR109A expression in human CRC limits overall survival. Our preliminary studies show that GPR109A expression is negatively associated with increasing BMI, which in turn reduces the bacterial metabolites Hippurate and Butyrate, especially in African-American (AA) CRC patients than in Caucasian (CA). Dietary supplementation of Hippurate and Butyrate significantly reduced CRC formation, and this effect is mediated through GPR109A. *Gpr109a* knockout mice are more prone to chemical carcinogens, and genetically engineered mouse models (GEMM) of CRC and dietary supplementation of Hippurate and Butyrate do not show significant beneficial effects. Similarly, the ketogenic metabolite beta-hydroxybutyrate (BHB), an endogenous agonist of GPR109A, levels are significantly lower in obese AA CRC patients than in lean AA CRC and CA CRC patients. Dietary supplementation of the ketogenic diet significantly increases the *Lactobacillus* abundance and Hippurate, Butyrate, and BHB levels in *Gpr109a* wild-type mice, but this effect is blunted in Gpr109a knockout mice. Overall, our study provides a novel role of GPR109A in the regulation of the colonic microbiome and its metabolites and associated CRC prevention. Further, our study provides evidence that GPR109A expression links to obesity-associated CRC formation, and GPR109A agonists could have a significant clinical impact on the prevention and treatment of CRC.

#6715 Cross-species investigation of gene copy number and cancer resistance.

Morla Phan[1], Thompson Worden[1], Sarah Adamowicz[2], Stephane Lair[3], Mauricio Seguel[1], Claire Jardine[1], Geoffrey Wood[1], Dirk Steinke[2]

[1]Pathobiology, University of Guelph, Guelph, ON, Canada,[2]Integrative Biology, University of Guelph, Guelph, ON, Canada,[3]Sciences Cliniques, Universite de Montreal, Montreal, QC, Canada

Low cancer incidence rates are observed in large mammals such as elephants and whales, despite their mass and long lifespan hypothetically contributing to a higher lifetime probability of acquiring oncogenic mutations. Few studies have investigated cancer-related genes in these animals. One reported that bowhead whales possess two functional copies of PCNA. Multiple studies have investigated the presence of multiple retrogene copies of TP53 in elephants. Extra copies of genes involved in DNA damage detection and repair could contribute to cancer resistance. Droplet digital PCR (ddPCR) was used to quantify gene copy number for TP53, PCNA, HER2, DLG1, and DLG2 in genomic DNA extracted from frozen skin samples of beluga, narwhal and bowhead whales (n=20 each). Results showed that all 3 whale species had more than one copy of PCNA. Agarose gel PCR showed the simultaneous presence of wild-type PCNA (possessing introns) and variable numbers of pseudogene sequences (lacking introns) within individuals for belugas, narwhals, and bowheads. ddPCR found that elephants did not have increased PCNA copy number, but agarose gel PCR showed the presence of PCNA pseudogenes. Similar patterns were also observed in rhinos, horses, cows and other ungulate species. To investigate copy number loss in cancer, ddPCR was performed on formalin-fixed, paraffin embedded normal and matched tumor tissue of 7 individual belugas from the St. Lawrence estuary, an area that was historically contaminated with industrial carcinogens. Copy number loss was not observed for any investigated tumor suppressor gene in tumor tissue compared to normal tissue. Our results show that bowhead whales are not unique in having multiple copies of PCNA. The presence of incomplete copies with unknown function may influence copy number quantification. Further study is required to understand the significance of the variable PCNA pseudogene copies. Understanding natural copy number variation in tumor suppressor genes may provide insight into risk factors and prevention methods across species.

#6716 Effect of ZFHX3 in endometrial cancer progression.

Sanjeev Ganesh, Areebah Qazi, Swornalata Pukhrambam, Sophia Agrusa, Jessica Long, Katherine Gurdziel, Michael Wilson

Wayne State University School of Medicine, Detroit, MI

Endometrial cancer (EC) is the most prevalent gynecological cancer and the 4th most common cancer in women globally. The frequency of EC is increasing in contrast to other prevalent cancers driven by lifestyle choices and metabolic conditions. Currently, research is focused on molecular mechanisms of tumor initiation and tumor microenvironment. ZFHX3 (ATBF1), is a transcription factor that has roles in embryogenesis steroid hormone regulation. It has been identified as a tumor suppressor gene in multiple cancer types. ZFHX3 mutations have been observed in normal endometrium and reports suggest it is mutated in about 20% of EC cases. Despite these frequent mutations, very few studies fully comprehend the molecular mechanisms behind ZHFX3 inactivation and its subsequent role in initiating EC. Our study aims to find the role of ZFHX3 in initiating EC. We knocked down ZFHX3 in 12Z cells via siRNA, followed by mRNA-seq, to examine its function in the endometrial epithelium. Our preliminary data suggests that ZFHX3 regulates c-MyB, a proto-oncogene, suggesting its role as a tumor suppressor gene in EC. We performed transcriptomic analysis on endometrial cells following the knockdown of ZFHX3 and identified differential expression of cell cycle and cell adhesion-related genes, suggesting important roles for ZFHX3 in oncogenic processes. We also overexpressed ZFHX3 expression in Ishikawa cells and treated them with estrogen and progesterone. These cells were subjected to RNA-seq analysis to identify the different signaling pathways affected by the presence of progesterone. Comparing the 2 RNA-seq data, we found EGR1 to be a common gene. We also investigated the effects of ZFHX3 knockdown in the endometrial epithelium *in vivo* and found an increase in the Ki67 expression and endometrial gland number, indicating endometrial hyperplasia. Future studies will focus on the relation between ZFHX3 and EGR1, its subsequent signaling pathways, and elucidating its role as a tumor suppressor.

#6718 Analysis of the pathological significance of CD109 in pancreatic cancer using the mouse model.

Y. Murakumo, Y. Sakurai, M. Ichinoe;
Kitasato Univ. School of Medicine, Sagamihara, Japan

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with a high fatality rate. Because there are few effective treatments for advanced pancreatic cancer, the development of new molecular targeted therapies is desired. CD109 is a glycosylphosphatidylinositol-anchored glycoprotein, whose expression is upregulated in some types of malignant tumors. We recently reported that positive expression of CD109 in tumor cells was significantly associated with poor prognosis in PDAC. In addition, CD109 expression was also detected in the stroma surrounding the tumor cells, suggesting its expression in cancer-associated fibroblasts. The stromal CD109 expression significantly correlated with tumor progression in PDAC. In the present study, we aimed to further investigate the histopathological and prognostic significance of CD109 in PDAC using the mouse model. In the normal mouse pancreas, CD109 expression was almost undetectable by X-gal staining and in situ hybridization. In the PDAC tissues, CD109 expression was detected not only in the tumor cells but also in the surrounding stromal cells, which was similar to that in human PDAC. CD109 expression was predominantly detected in undifferentiated tumor cells rather than differentiated tumor cells. In addition, we generated a CD109-deficient PDAC mouse model line, KPC-CD109KO, and it was revealed that CD109-deficinet KPC mice tended to develop differentiated adenocarcinomas compared with KPC mice with wild-type CD109. However, CD109 deficiency did not affect the survival of KPC mouse. Taken together, CD109 is expressed not only in the tumor cells but also in the stroma in PDAC, and is associated with tumor differentiation in PDAC.

#6719 GULP1 knockout promotes carcinogen-induced bladder cancer by regulating the NRF2-KEAP1 signaling axis.

Chonji Fukumoto[1], Naveen C. Pandey[2], Sylvia S. Sanchez[2], Pritam Sadhukhan[1], Christopher M. Koenig[2], Susmitha R. Pagadala[2], Fenna C. M. Sille[2], Mohammad O. Hoque[1]

[1]Department of Otolaryngology-Head and Neck Surgery, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD

Urothelial carcinoma of bladder (UCB) is the ninth most commonly diagnosed cancer worldwide. Some key genetic and epigenetic alterations are hallmarks on the initiation and progression of UCB. The nuclear factor E2-related factor 2 (NRF2)-Kelch-like ECH-associated protein-1 (KEAP1) signaling pathway, essential for detoxifying reactive oxygen species, is normally regulated by the interaction of NRF2 with KEAP1and the actin cytoskeleton in the cytoplasm. However, genetic and epigenetic alterations can lead to a constitutive activation of NRF2 through the loss of KEAP1 function. This dysregulation results in NRF2 translocation to the nucleus, triggering the expression of numerous genes. We recently reported that phosphotyrosine binding (PTB) domain-containing engulfment adaptor protein 1 (GULP1) is frequently silenced in UCB by promoter hypermethylation, and interacts with the KEAP1-actin cytoskeleton complex to regulate NRF2. Furthermore, the loss of GULP1 expression led to uncontrolled NRF2 signaling, driving cancer progression and resistance to chemotherapy. Here, to strengthen our previous findings that GULP1 acts as a tumor suppressor gene (TSG) in UCB, we exposed GULP1 knockout (KO) mice to a most commonly used carcinogen for generating UCB model in mice. To this end, we exposed 4-week-old GULP1 KO and wild type (WT) C57BL/6 mice to N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN) for 6 to 20 weeks. We then analyzed the resulting bladder tumors using various methods to investigate the NRF2-KEAP1 axis, tumor subtype, and several tumor immune microenvironment (TIME) factors. Our data demonstrates that GULP1 KO exhibits a higher frequency of carcinogen-induced UCB and muscle invasion compared to WT counterparts via regulating the NRF2-KEAP1 axis. Furthermore, GULP1 KO carcinogen-induced tumors appear at earlier time point compared to WT mice. Interestingly, GULP1 KO mice exhibited a characteristic subtype and TIME dynamics that differed from those of WT. In conclusion, our pilot in vivo data suggested that GULP1 may regulate the NRF2-KEAP1 signaling pathway in UCB. Further experiments are ongoing to understand the comprehensive mechanisms of GULP1 involvement in UCB and its association with chemo and immunotherapy response.

#6720 The role of the Co-chaperone UNC45A in breast and prostate cancer.

Asif Elahi, Taoufik Llbiyi, Vamsi Krishna Kommalapati, Yasmeen Jilani, **Ahmed Chadli**

Augusta University Medical Center, Augusta, GA

UNC45A is a key co-chaperone supporting cancer cell proliferation and tumorigenesis. Interestingly, UNC45A is essential for cancer cells but not for normal cell proliferation. However, the mechanism underlying UNC45A regulatory function is not well studied. We have previously shown that UNC45A functions as a glucocorticoid receptor (GR) co-activator to drive the mitotic kinase NEK7 gene transcription. NEK7 is essential for centrosome separation, mitotic spindle formation, and cytokinesis. GR has been implicated in promoting aggressive prostate tumor growth and resistance to therapy. Indeed, GR upregulation is an established mechanism to bypass the androgen receptor blockade therapy in metastatic-resistant prostate tumors. Here, we tested the hypothesis that UNC45A promotes GR-mediated resistance to hormonal therapy. To this end, we used shRNA-mediated gene silencing to evaluate the impact of UNC45A loss on PC3 prostate tumor progression. Our results show that silencing UNC45A reduces cell proliferation *in vitro* and tumor growth *in vivo*. TUNEL analysis and Ki67 staining show that loss of UNC45A triggers DNA damage, reduced cell proliferation, and apoptosis in PC3 tumors grown in the NOD SCID mice model. Immunofluorescence analysis shows a remarkable disorganization of centrosomes in tumor cells expressing UNC45A shRNA. The importance of UNC45A in promoting enzalutamide resistance is being tested in tridimensional spheroid culture and *in vivo* and will be discussed in this meeting. Overall, our results support the hypothesis that UNC45A is a promising cancer therapeutic target and highlight the need for developing UNC45A small molecule inhibitors to treat aggressive diseases such as prostate and breast cancers.

#6721 NUAK2: The key player in ovarian cancer progression - Unraveling the impact of expression and nuclear localization.

Cong Xu, O.G.W Wong, Annie.N.Y Cheung

The University of Hong Kong, Pokfulam, Hong Kong

Background: NUAK2 is a kinase related to the catalytic α-subunits of the AMP-activated protein kinase (AMPK) complexes. Although NUAK2 is amplified in several human cancers, its role in cancer is poorly understood. By immunohistochemical study, we demonstrated that elevated nuclear expressed NUAK2 is associated with poor ovarian cancer patient survival and more aggressive cancer cell behaviour. Exploring the implications of NUAK2 in ovarian cancer could offer valuable perspectives on disease development and patient prognosis.
Aim: To delineate the impact of NUAK2 nuclear localization on cellular mechanisms crucial for tumor proliferation, and metastasis.
Methods: Lentiviral expression vectors harbouring wild type NUAK2 (NUAK2-WT) and NUAK2 NLS mutant (NUAK2-^{375}AAAA^{378}) were used to transduce KF and OVCA420, two ovarian cancer cell lines expressing low level of endogenous NUAK2. Cytoplasmic localization of NUAK2-^{375}AAAA^{378} was confirmed by immunoblotting and immunofluorescence microscopy. The impact on cell growth was evaluated by CCK8 assay and colony formation assay. The ability of the transduced cells in migration and invasion was compared with wound healing assay and transwell assay.
Results: Mutating the NLS excluded NUAK2 from the nucleus. Cells expressing NUAK2-^{375}AAAA^{378} proliferated significantly slower and migrated significantly slower than cells expressing NUAK2-WT.
Conclusion: The study's outcomes indicated nuclear localization is crucial for NUAK2's oncogenic functions in enhancing the proliferation and migration capabilities of ovarian cancer cells. These results underscore the crucial role of NUAK2 in ovarian cancer progression.

#6722 OFD1 as a novel biomarker in cholangiocarcinoma: insights into ciliary dysfunction and tumor growth.

Fabiola Piscopo[1], Anna Barbato[2], Massimiliano Salati[3], Carla Pollastro[2], Giorgia Gitano[2], Alberto Marino[2], Lorenzo Evangelista[2], Luigi Ferrante[2], Antonella Iuliano[4], Luca Reggiani-Bonetti[5], Maria Salatiello[6], Pasquale Pisapia[6], Umberto Malapelle[6], Giancarlo Troncone[6], Massimo Dominici[3], Brunella Franco[1], Pietro Carotenuto[1]

[1]Department of Translational Medical Science, Telethon Institute of Genetics and Medicine (TIGEM), Medical Genetics, University of Naples "Federico II", Naples, Italy,[2]Telethon Institute of Genetics and Medicine (TIGEM), Naples, Italy,[3]Division of Oncology, Department of Oncology and Hematology, University Hospital of Modena, Modena, Italy,[4]Department of Mathematics, Informatics and Economy (DIMIE), University of Basilicata, Potenza, Italy,[5]Department of Medical and Surgical Sciences for Children and Adults, University Hospital of Modena, Modena, Italy,[6]Department of Public Health, University of Naples "Federico II", Naples, Italy

Cholangiocarcinoma (CCA) is a rare and aggressive solid tumor originating from cholangiocytes lining the biliary ducts. It is the second most common primary hepatic malignancy, with an increasing global incidence and limited therapeutic options. Recent studies suggest that the primary cilium acts as a tumor suppressor in the biliary tract by regulating key cancer-related signaling pathways. Moreover, evidence links the reduction or loss of primary cilia to increased aggressiveness in various human cancers. Here, we aimed to identify and functionally characterize primary cilia-associated genes with potential translational relevance for CCA prognosis and treatment. Our study included 120 CCA patients, comprising 51% (36) with intrahepatic CCA and 49% (34) with extrahepatic CCA. Whole-transcriptome and whole-exome profiling were conducted on laser micro-dissected formalin-fixed paraffin-embedded (FFPE) tissue specimens. Bioinformatic analysis identified OFD1 as the top-ranked cilium-associated gene (fold-change ≥ 2.5, $p < 0.01$) among differentially expressed genes in tumor, stromal, and normal tissues. We investigated the role of OFD1 in cilia formation and cell proliferation through in vitro experiments in healthy human cholangiocytes and CCA cell lines. Immunofluorescence staining with ciliary markers revealed that OFD1 silencing promoted ciliogenesis and inhibited tumor growth in CCA cell lines. Western blot analysis confirmed a significant upregulation of ciliary proteins, including PCM1, ARL13B, and acetylated tubulin, following OFD1 silencing. Furthermore, CRISPR/Cas9-mediated OFD1 depletion in CCA cells led to a marked reduction in cell proliferation and restored ciliogenesis. Conversely, OFD1 overexpression in normal cholangiocytes resulted in increased cell proliferation and migration, along with suppression of ciliogenesis. Clinically, higher OFD1 expression was significantly associated with poorer overall survival in CCA patients (10 vs. 39 months; HR 2.33, 95% CI 1.01-5.31, $p = 0.03$). In conclusion, we demonstrated that OFD1 functions as an oncogene in CCA, influencing primary cilia formation and tumor cell growth. Higher OFD1 expression is a significant predictor of worse survival outcomes, identifying OFD1 as a promising biomarker and potential therapeutic target in CCA.

#6723 Targeting RAS in angiosarcoma.

Donghee Lee[1], Eslenur Nipa[1], Erin B. Dickerson[2], Jong Hyuk Kim[1]

[1]University of Florida, Gainesville, FL,[2]University of Minnesota, Minneapolis, MN

Angiosarcomas are aggressive, rare soft tissue sarcomas that form in the lining of blood vessels. Although recurrent mutations in oncogenic drivers, including VEGFR/TIE2 (*KDR*, *FLT4*, *PTPRB*, and *PLCG1*), RAS-MAPK (*KRAS, HRAS*, *NRAS*, and *NF1*), and PI3K (*PIK3CA* and *PTEN*) have been identified in angiosarcomas, attempts to target these pathways using selective or multi-kinase inhibitors have generally failed to produce meaningful clinical responses. RAS proteins act as critical molecular switches that regulate cell signaling, and oncogenic mutations in RAS or VEGFR/TIE2 proteins are strongly implicated in the development of angiosarcoma. However, the mechanisms that govern these mutant pathways and the challenge of developing effective therapeutic interventions have remained elusive. A promising advancement for targeting RAS mutant tumors has been the development of the tri-complex RAS(ON) multi-selective inhibitor, RMC-7977, which simultaneously targets wild-type and mutant KRAS, NRAS, and HRAS in their active, GTP-bound state, offering a potential treatment for angiosarcoma. In this study, we identified *HRAS* Q61R and *NRAS* Q61L mutations in KU-CAS3 and KU-CAS5 angiosarcoma cell lines using Nanopore sequencing. Additionally, we detected *FLT4* amplification and an *NF1* frameshift deletion in HAMON cells, as well as a *PTPRB* deletion in ISO-HAS-B cells. Our results show that RMC-7977 and MEK1/2 inhibitor mirdametinib exhibit strong potency against angiosarcoma cell lines harboring mutations in RAS and VEGFR/TIE2 pathways. Notably, RMC-7977 showed significantly greater anti-proliferation effects in RAS wild-type and *PTEN* frameshift deletion AS5 angiosarcoma cells compared to midrametinib or VEGFR inhibitors. Furthermore, long-term treatment with RMC-7977 inhibited the colony-forming capacity of angiosarcoma cells. These findings suggest that RMC-7977 effectively inhibits the proliferation and survival of angiosarcoma cells. Our ongoing work involves studies to evaluate the *in vivo* effects of RMC-7977 on the the growth of angiosarcomas xenografts containing RAS mutations. We will also investigate the molecular mechanisms underlying oncogenic signaling to elucidate RAS dependency and strengthen the rationale for using RAS inhibitors to treat angiosarcoma. This approach aims to demonstrate that targeting RAS through RAS(ON) multi-selective inhibitors is effective, highlighting the urgent need for clinical trials to advance treatment options for angiosarcoma patients.

#6724 The role of human leukocyte antigen F adjacent transcript 10 in the tumorigenesis of nasopharyngeal carcinoma.

Yusi Liang, Ngar Woon Kam, Zhuoyou YU, Ho Fun LEE

University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Nasopharyngeal carcinoma (NPC) is a highly aggressive malignancy prevalent in Southern China and Southeast Asia related to Epstein-Barr virus (EBV) infection and genetic variations at the Human Leukocyte Antigen (HLA) locus. Human leukocyte antigen (HLA)-F adjacent transcript 10 (FAT10) is a ubiquitin-like protein modifier that can modulate its substrates by (1) mediating degradation via the 26S proteasome or (2) altering function through Fat10ylation. Previously studies have found FAT10 overexpression in various cancers, including gliomas and hepatocellular carcinoma, promoting tumorigenesis by altering cell proliferation, metastasis, and angiogenesis. Nevertheless, the precise role of FAT10 in NPC remains ambiguous. NPC public cohort GSE150430 showed high expression of FAT10 in NPC malignant cells. We also found overexpression of FAT10 in both NPC cell lines and patient-derived xenografts (PDXs) by real-time polymerase chain reaction (RT-PCR) and western blot at mRNA and protein level respectively. FAT10 overexpression in both NPC cell line C666-1 and immortalized normal nasopharyngeal cell line NP460 by lentiviral transduction increased proliferation proved by XTT assay, colony formation assay, and ki67 staining assay. Transwell migration and wound healing assay were performed in FAT10 overexpression cancer cell line and normal cell line to show the enhancement of migration ability. ROS production was also increased in these FAT10 overexpression cell lines by using the CellROX Green reagent. However, the western blot result showed that stemness ability cannot be changed in NP460. To conclude, our findings indicated that FAT10 may play a significant role in the tumorigenesis of NPC. Its underlying mechanism will be further explored.

#6725 Introducing new technology for high performance whole exome sequencing with unparalleled hybridization time flexibility and capability for low to high capture-input.

Daniel Saatman, Jinglie Zhou, Ekaterina Star, Roshani Codipilly, Alexandra Wang

Integrated DNA Technologies, Inc., Redwood City, CA

Whole exome sequencing (WES) via hybridization capture is a targeted sequencing approach to specifically enrich the protein-coding regions of the human genome. The human exome comprises ~1% of the entire genome but contains the majority of relevant variants for researchers. Targeting this region saves on sequencing costs and data storage while also allowing greater sequencing depth of regions of interest. However, current hybridization capture workflows are challenging to execute in the laboratory due to high-temperature sample and reagent handling, pre-heating of multiple buffers, long hybridization times, and narrow library input ranges. Widening the input range is desirable because it can allow for fewer PCR cycles in library preparation or enable high multiplexing during hybridization capture, the latter of which can lower reagent costs.

To evaluate targeted sequencing performance across a wide range of sample inputs and hybridization times, we used low to high total input—1-plex 100ng to 12-plex 6000ng—and hybridized for as short as 1 hour up to overnight. We used the Integrated DNA Technologies (IDT) novel xGen™ Hybridization and Wash v3 kit, which features a user-friendly workflow without hot-liquid handling or temperature-sensitive urgency. This performance is benchmarked side-by-side with a current commercial hybridization-capture kit.

Using these methods, we achieve similar targeting, coverage, uniformity, and GC-balance across all samples with minimal impact from low inputs and short hybs. Further, we calculated the reference/alternate (ref/alt) allelic fraction and found no considerable differences between capture conditions, indicating the potential of this workflow for genotyping applications with low-input samples and/or short hybridizations. This flexibility in hybridization time and library input along with the streamlined workflow allows researchers to meet diverse experimental demands and effectively capture the human exome.

#6726 Investigating the tumor suppressive role of LRIG1 in breast cancer disparities.

Amber Yu, Angel H. Pajimola, Kayla S. Ingram, Brittany Jenkins-Lord

Biochemistry and Molecular Biology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: Within the U.S. population, African American (AA) women have a staggering 40% higher mortality rate from breast cancer than European American (EA) women, despite having a lower incidence rate. This disproportionate mortality burden imposed on AA women is rooted in both environmental and genetic causes. We are interested in elucidating molecular and environmental mechanisms that may be contributing to these breast cancer health disparities. Our recent study identified that higher neighborhood-level socioeconomic deprivation was associated with hypomethylation and decreased gene expression for LRIG1 (Leucine-rich repeats and immunoglobulin-like domains 1) in AA women, but not in EA women. LRIG1 has been shown to act as a tumor suppressor, associating with members of the ErbB family of receptor tyrosine kinases (RTKs), which includes the epidermal growth factor receptor (EGFR), HER2, HER3, and HER4. This association of LRIG1 with ErbBs is predicted to result in the degradation of these proteins and the suppression of pro-growth signaling.
Objective: This project aims to determine differences in the protein expression of LRIG1 and ErbB proteins within breast epithelial cell lines (normal epithelial cells, estrogen receptor-positive (ER+), and estrogen receptor-negative (ER-)) derived from both AA and EA women. We hypothesize that there are differences in the protein expression of LRIG1 and ErbB proteins within breast epithelial cell lines derived from AA women and EA women.
Methods: The levels of protein expression of LRIG1 and ErbB proteins in the cell lines were assessed using Western immunoblotting and densitometric analysis. The colocalization of LRIG1/EGFR and LRIG1/HER2 in non-tumorigenic, ER+, and ER- cell lines was assessed through immunofluorescence (IF) cell staining.
Results: Western immunoblotting revealed substantial variation in target protein levels, with notable differences in LRIG1 protein levels by estrogen receptor status, with greater LRIG1 protein expression in ER+ cell lines. IF staining demonstrated limited colocalization between LRIG1 and EGFR as well as LRIG1 and HER2. Future experiments, including co-immunoprecipitation, will aim to determine how LRIG1 and the ErbB proteins are interacting and what factors may be influencing their binding and downstream signaling.
Conclusions: Our results provide insight into LRIG1 and ErbB co-expression in several breast cell lines from AA and EA women. Our next steps will include identifying distinct differences between these cell lines that might be a result of variations in environmental factors, the tumor microenvironment, and genetic ancestry.

#6727 Ecdysoneless (ECD) as a key estrogen-regulated protein driving progression in ER-positive breast cancer.

Farshid Oruji, Asher Rajkumar Rajan, Mohsin Raza, Bhopal Mohapatra, Hamid Band, Vimla Band

Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE

Background: Breast cancer (BC) is a heterogenous disease, with estrogen receptor-positive (ER+) BC accounting for over 70% of cases. ER+ BC depend on estrogen signaling for oncogenesis and metastasis. Even though treatments targeting ER pathway have improved patient's outcome, factors driving ER+ BC progression particularly in metastatic remain unclear. One of these factors is Ecdysoneless (ECD), a highly conserved protein from yeast to human. ECD expression correlates with ER expression, ECD overexpression is observed in ER+ BC and ECD overexpression correlates with poor patient survival. In this study, we assessed the relationship of ECD and ER, and the role of ECD in ER+ BC oncogenic traits.
Methods: Bioinformatic analysis of publicly available datasets were explored for the relationship between ER and ECD and survival analysis was performed to examine the link between ECD, ER, and ER target MYC expression. ECD promoter analysis followed by chromatin immunoprecipitation (ChIP) and promoter-luciferase assays were used to assess estrogen-dependent ER recruitment to the ECD promoter. Estradiol (E2) treatments were performed to examine how estrogen signaling affects ECD levels. The effects of ECD overexpression were performed in ER+ breast cancer cells to evaluate changes in in vitro tumorigenic traits.
Results: ECD expression correlated with ER levels in publicly available datasets. Survival data showed patients with elevated levels of ECD in ER+ BC had worse outcome. The ECD promoter contained estrogen response elements, and ChIP assays confirmed E2 mediated recruitment of ER to the ECD promoter. E2 treatment enhanced ECD promoter-luciferase activity. Overexpression of ECD in ER+ cells enhanced oncogenic traits.
Conclusions: We have identified ECD is a novel estrogen regulated protein that plays a critical role in ER-driven oncogenesis in ER+ BC. Current studies are exploring the role of overexpressed ECD in in vivo preclinical mice models and therapy resistance.

#6728 Investigating the effect of male-specific lysine demethylase 5D alteration on oncogenic behavior in human prostate cancer cells.

Sarah Ann S. King, Nabila Zaman, Prathiksha Prabhakaraalva, Goutam Chakraborty

Urology, Icahn School of Medicine at Mount Sinai, New York, NY

Prostate cancer (PC) is the most common urological malignancy, with approximately 11% of men being diagnosed with it during his lifetime and is the second leading cause of cancer-related fatalities in males. One of the challenges in treating advanced, symptomatic prostate cancer is the limited effectiveness of the standard care, androgen deprivation therapy (ADT), in late-stage disease. While somatic Y chromosome (ChrY) loss in men has been associated with an increased risk of several diseases, including prostate cancer, the role of ChrY genes in prostate cancer progression and chemotherapy resistance remains understudied. Based on significant epidemiological and genomic data generated by multiple teams, including ours, this present study critically examines the contributions of the loss of the chromosome Y gene lysine demethylase 5D (KDM5D) to chromosome Y-null prostate cancer progression and resistance to ADT. In our approach to investigating this phenomenon we have employed a number of advanced techniques which interrogate the epigenomic, transcriptomic, proteomic, and behavioral landscape of defined prostate cancer lines with genetically altered levels of KDM5D RNA and protein. Herein, lentiviral transduction was employed to perform CRISPR-mediated KDM5D knockout with three novel gRNAs in each castration sensitive and insensitive prostate lines (LNCaP and 22RV1, respectively). Single cell-derived clones from each of the six lines infected with this CRISPR knockout virus have been isolated and individually expanded to measure the impacts of KDM5D knockout accurately with respect to target expression and Cas9 copy number; to date, several subclones have shown satisfactory reductions in KDM5D expression and are now being subjected to functional and behavioral assays pursuant to analyzing its malignant characteristics, alterations in gene expression, and changes in androgen deprivation and/or chemotherapeutic agent sensitivity. Moreover, we have employed KDM5D addback to create an overexpression model in ChrY-null PC3M cells. Thus far, the loss of KDM5D has been shown to contribute to increased oncogenic behavior in prostate cancer cells and may be associated with a poor patient prognosis. Our preliminary data provide mechanistic evidence that KDM5D expression influences several DNA damage repair pathways in prostate cancer cells .Ultimately, the goal of our group is to identify alternative therapeutic targets, chemotherapeutic agents, and ultimately characteristics of clinically consequential prognostic value in KDM5D/ChrY-null prostate cancers where currently no treatments are available.

#6729 The role of L-MYC in prostate cancer.

Jeyaluxmy Sivalingam, Xiuping Yu

Biochemistry and Molecular Biology, LSU Health Sciences Center - Shreveport, Shreveport, LA

The MYC family of transcription factors, comprising MYC, N-MYC, and L-MYC, regulates essential cellular processes, including proliferation, metabolism, differentiation, and apoptosis. While MYC and N-MYC have been extensively studied in prostate cancer (PCa), the role of L-MYC remains underexplored. To investigate the expression patterns of these MYC family genes across different stages of PCa, we analyzed publicly available mRNA expression data from normal prostate tissues, adenocarcinoma prostate cancer (AdPCa), neuroendocrine prostate cancer (NEPCa), and PCa cell lines representing AdPCa, castration-resistant prostate cancer (CRPCa), and NEPCa (H660). Our analysis revealed elevated MYC expression in AdPCa patients and AdPCa/CRPCa cell lines, whereas N-MYC showed no significant expression across PCa stages. In contrast, L-MYC was prominently expressed in NEPCa patients and the NEPCa cell line H660. RNA-seq data from patient biopsies (PMID: 26855148) further confirmed increased L-MYC levels in CRPCa-NE compared to CRPCa-Adeno. Additionally, neuroendocrine markers (NCAM1, INSM1, ASCL1, and NEUROD1) were co-expressed with L-MYC in NEPCa, underscoring its association with neuroendocrine differentiation. The expression of L-MYC in H660 cells was further validated by RT-qPCR and Western blot. Despite their shared genomic structure and high sequence homology, MYC family genes exhibit mutually exclusive expression patterns in PCa. Transcription factor binding site (TFBS) analysis revealed unique regulatory elements that may contribute to this differential expression, warranting further investigation. Ongoing RNA-seq analysis of L-MYC knockdown in H660 cells aims to identify pathways regulated by L-MYC and provide insights into its potential as a therapeutic target in NEPCa. These findings suggest that L-MYC plays a pivotal role in NEPCa progression and highlight the importance of understanding the regulatory mechanisms driving its unique expression.

#6730 Oncogenic ASPP2kappa (k) drives leukemic transformation and disease progression.

Alessia Ruiba[1], Anna-Lena Ahrens[1], Vanessa Aellig[1], Reka Haraszti[2], Marcus M. Schittenhelm[1], **Kerstin Maria Kampa-Schittenhelm**[1]

[1]Kantonsspital St. Gallen, St. Gallen, Switzerland,[2]Universitatsklinikum Tuebingen, Tuebingen, Germany

Introduction: Despite tremendous efforts and new therapeutics, acute myeloid leukemia (AML) remains difficult to treat and therapy outcome is far from satisfactory for many patients. We have recently identified a novel, oncogenic isoform of the tumor suppressor ASPP2, named *ASPP2k,* which is expressed in >50% of AMLs, and have demonstrated that deregulation of the ASPP2/ASPP2k - p53 axis associates with drug resistance and a more aggressive tumor biology. We now show that ASPP2k drives leukemic transformation and disease progression *in vivo* and proves to be a potent therapeutic target.
Methods: Isogenic AML ASPP2κ silenced (KD) (Molm14, HL60 and ex vivo patient blasts) were established and xenotransplanted into NSG mice. Ba/F3 interleukin-3 dependent pro-B cells, engineered to overexpress ASPP2k were transplanted into immunocompetent C3H mice to study the influence of ASPP2k on the tumor microenvironment. Disease development and progression were monitored using an IVIS Lumina imaging system. In addition, we designed and tested novel, fully chemically modified ASPP2k-specific siRNAs for in vivo application.
Results: All in vivo models demonstrate earlier leukemia development and engraftment as well as a more aggressive course of disease in dependency of ASPP2k expression (lifespan 30 vs 42 days pi for EV and KD, 22d for KI, p<0,001), underlined by higher WBC count (p<0,001), spleno- and hepatomegaly (p<0,0001) early weight loss (p<0,01) and dissemination into brain and lungs (p<0,001). Importantly, Ba/F3 cells lost their IL-3 dependency upon over-expression of ASPP2k, considered a first step of malignant transformation (proliferation +120 fold-change at 96h for KI vs EV). C3H mice transplanted with ASPP2k overexpressing Ba/F3 cells demonstrated higher organ infiltration (eg liver p<0,001) and a strong immune response, as evidenced by upregulation of secretion of pro-inflammatory cytokines like MIP-2, STNFRI, VCAM-1, PF-4, L-selectin, OPG, CD26, MIG proteins, among others as well as significant T-cell infiltration (p<0,01). Most importantly, employing novel, fully chemically modified ASPP2k-specific siRNAs, we were able to silence ASPP2k *in vivo* and again attenuate leukemia progression.
Summary: In summary, we here show that ASPP2k directly contributes to aggressiveness of the disease in vivo and provide a first rational to further develop ASPP2k specific siRNAs as a novel therapeutic approach to combat leukemia. Future studies evaluating ASPP2k as a potential target for therapy are warranted.

#6731 Oncogenic ASPP2k: a key regulator of classical hallmarks of cancer in triple negative breast cancer (TNBC).

Alessia Ruiba[1], Anna-Lena Ahrens[1], Lara Aldinger[1], Lea Stiehl[1], Reka Haraszti[2], Wolfram Jochum[1], Christoph Driessen[1], Marcus M. Schittenhelm[1], **Kerstin Maria Kampa-Schittenhelm**[1]

[1]Kantonsspital St. Gallen, St. Gallen, Switzerland,[2]Medizinisches Universitatsklinikum Tubingen, Tubingen, Germany

ASPP2 is a tumor suppressor, originally characterized as direct p53-binding protein. More recently, ASPP2 was shown to also directly interact with BCL-2 and NFkB, putting ASPP2 in a central position to orchestrate major cancer related pathways. In this context, we have recently reported the identification of a novel, oncogenic isoform of *ASPP2*, named *ASPP2kappa (k),* which is highly and frequently expressed in TNBC. As ASPP2k is characterized by loss of the p53- as well as partial loss of BCL-2 and NFkB-binding sites, its expression impairs major pathways controlling cellular fate, resulting in accelerated proliferation and resistance to chemotherapy. We now show that expression of ASPP2k modulates all classical hallmarks of cancer - fueling a highly aggressive tumor biology in TNBC. Importantly we demonstrate that silencing of ASPP2k slows down tumor growth and inhibits metastasis *in vivo*. Employing our isogenic TNBC ASPP2κ interferenced (KD) cell models (MDA-MB-231 and HS-578T, n=18 per model) we studied the role of ASPP2κ in NSG xenotransplant models. Mice were xenotransplanted with EV or ASPP2k KD cells and tumor engraftment, progression, angiogenesis and metastasis were monitored using an IVIS Lumina imaging system. Tumor engraftment and growth were found to be significantly attenuated in the KD strains (representative data for MDA model: doubling times EV: 7.3d; KD: 12.8d; p<0,0001). EV mice had to be sacrificed between day 40-60 after injection due to tumor size (median OS 51d) while ASPP2k KD only presented with small, localized tumors at day of termination (d72, OS<0,0001). Importantly, 100% of mice bearing ASPP2k expressing (EV) tumors, presented with distant metastasis in multiple different sites at time of sacrifice, while in ASPP2k KD mice, metastasis could be detected in max. one site and only 30% of mice. Regulation of pro-angiogenic and EMT markers as well as involvement of the NFkB pathway were confirmed to play a role in ASPP2k-mediated metastasis. Most importantly, we were able to silence *ASPP2k in vivo,* employing novel, fully chemically modified ASPP2k-specific siRNAs generated for *in vivo* use and confirm potent inhibition of tumor growth also in these models. In summary, we here provide absolutely novel insights into TNBC tumor biology in dependency of ASPP2k and demonstrate first successful attempts to silence *ASPP2κ* employing highly specific siRNAs to target *ASPP2k in vivo.*

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody-Based Cancer Therapeutics 4
Poster Session

#6735 E-cM-Topi, a potent EGFR-cMET bispecific antibody drug conjugate, with superior anti-tumor effect in non-small-cell lung cancer (NSCLC).

Huihui Chen, Le Sun, Bing Hu, Zhiping Zhao, Ziheng Liu, Guangbao Qiu, Dongmei Bai, Ying Li, Ziwei Ren, **Ting Zhang**, Xin Ye, Lingfeng You, Zhendong Xue, Yuchang Mao, Huaixin Dang, Shuyu Cai, Jun Feng, Min Hu, Feng He

Shanghai Hengrui Pharmaceutical CO., LTD., Shanghai, China

EGFR-tyrosine kinase inhibitors (EGFR-TKIs) are standard clinical treatment for NSCLC patients with activating EGFR mutations. However, both intrinsic and acquired resistance to EGFR-TKIs limited their long-term efficacy, posing a significant unmet medical need. The protein overexpression of c-MET has been observed in 5-22% of EGFR-TKIs resistant NSCLC patients. Therefore, a bispecific ADC targeting EGFR and c-MET will shed a light on the management for EGFR-TKI resistance. E-cM-Topi is an EGFR and cMET bispecific ADC, consisting of a Fc-silenced EGFR-cMET bispecific antibody, a cleavable linker and a topoisomerase I inhibitor payload (Topi) with superior bystander effect. The binding affinities to EGFR and c-MET were optimized to enhance tumor-cell-selectivity, increase endocytosis, and improve pharmacokinetics (PK). Considering the wide expression of EGFR in normal tissue, the binding affinity to EGFR was adjusted to be weaker than that to c-MET, thereby enhancing the selectivity for EGFR-cMET-co-expressing tumors while minimizing the toxicity on normal tissues. E-cM-Topi demonstrated strong EGFR/cMET-dependent growth inhibition in various NSCLC cell lines. In HCC827 and EBC-1 xenograft models, E-cM-Topi inhibited tumor growth in a dose-dependent manner. Tumor regression was observed at a single dose of 4.5 mg/kg and sustained till day 35 in HCC827 model and day 20 in EBC-1 model. In addition, E-cM-Topi showed good human plasma stability and favorable cyno PK profile. Less than 0.5% of payload was released in human plasma after a 14-day incubation. Half-life of E-cM-Topi was more than 3 days in cyno monkey. In summary, by fine-tuning the EGFR-cMET bispecific antibody affinity and incorporating a superior bystander effect of payload, E-cM-Topi represents a best-in-class potential. It holds promise as an effective treatment option for EGFR-TKI resistant NSCLC patients.

#6736 Preclinical development of ADCT-241, a novel exatecan-based antibody-drug conjugate targeting PSMA for the treatment of prostate cancer.

Ben Leatherdale, Beccie Martin, Banusha Rajeenthira, Cecile Oblette, Lara Montolio, Abigail Kimpalu, Pedro L. Alves, Hafsah Omar, Alison Faid, Elizabeth Horsley, Lina Baxter, Valenti Gomez, Charlie Britten, Lolke de Haan, Paul W. Hogg, Chris Pickford, Patrick H. van Berkel

ADC Therapeutics, London, United Kingdom

Prostate specific membrane antigen (PSMA) is a 750 amino acid, homodimeric type II transmembrane glycoprotein expressed mainly in prostate tissues, but also at low levels in renal proximal tubules, the small intestine, and the brain. PSMA is known to have two enzymatic functions, firstly in the removal of glutamate from dietary folates in the small intestine, and secondly in hydrolysis of the peptidic neurotransmitter N-acetylaspartylglutamate. In the oncology setting PSMA is a clinically validated target with its expression being upregulated in prostate cancer as well an association with progression and aggressiveness of the disease. Here, the generation and preclinical characterization of ADCT-241, a novel antibody-drug conjugate (ADC) targeting PSMA is described. ADCT-241 is composed of a fully human IgG1 antibody directed against PSMA (anti-PSMA mAb), to which the PL2202 payload, containing the topoisomerase I inhibitor exatecan, has been stochastically conjugated via a cleavable valine-alanine linker with a drug:Ab ratio of 4 (DAR 4). In vitro, anti-PSMA mAb showed good binding affinity for human PSMA and cross-reactivity to rat and cynomolgus monkey PSMA. In addition, ADCT-241 showed specific and potent killing of prostate cancer cell lines, including LNCaP and C4-2, in *in vitro* cytotoxicity assays when compared to a non-binding control DAR 4 ADC containing the PL2202 payload. ADCT-241 showed bystander activity in *in vitro* assays employing PSMA-positive prostate cancer cell lines and PSMA-negative PC-3 cells. *In vivo*, administration of a single intravenous (IV) dose of ADCT-241 was associated with potent anti-tumor activity in prostate cancer xenograft models. Finally, in toxicology studies in rats and cynomolgus monkeys, ADCT-241 was well tolerated at dose levels up to 150 and 75 mg/kg, respectively, following dosing on Day 1 and 22. Circulating serum total antibody, total ADC, and free exatecan concentrations were determined, and showed good *in vivo* stability for ADCT-241 and a half-life of ~8.5 days in cynomolgus monkeys. In summary, ADCT-241 is a novel, stable PSMA-targeting ADC that mediates potent and specific anti-tumor activity in mouse xenograft models and exhibits an excellent tolerability profile in rats and cynomolgus monkeys. The data presented support future clinical development of ADCT-241 for the treatment of prostate cancer indications.

#6737 RAS inhibitors as payloads of ADCs to treat RAS-mutant tumors.

Boyu Zhong, Tony Zhang, Zuyong Deng, Guangming Chen, Chunlan Dong, Liangbao Lai, Erchang Shang

Tyligand Bioscience (Shanghai), Ltd., Shanghai, China

Background: Ras mutation has been identified as one of the major oncogenes in many cancers. Recent breakthroughs in regulating the activity of RAS proteins have led to the discovery of several clinical therapeutic molecules, such as Sotorasib and Adagrasib. However, for patients with RAS mutations, drugs with broader indications, higher potency, better tolerability, and longer efficacy are urgently needed. On the other hand, ADC, as a new precise and efficient drug delivery method, provides a potential solution to the above unmet needs. Here, we disclose a new class of ADCs whose payloads target RAS variant proteins and exhibit excellent antitumor effects and tolerability both *in vitro* and *in vivo*.

Method: Both selective and pan-RAS inhibitors were conjugated to various antibodies via cleavable peptide linkers and ancillary groups to improve druggability. The primary biological activities of payloads and ADCs were examined in a series of cellular proliferation assays. The *in vivo* antitumor effects of the ADCs were evaluated on selected cell-derived xenograft (CDX) mice models, where body weight changes of the test animals were used to estimate the tolerability of the molecules. Both *in vitro* and *in vivo* PK properties of the ADCs were also studied.

Results: The potent KRAS G12D selective inhibitor P1 or pan-RAS inhibitor P2 (KRAS-G12C, G12D, G12S, G12V, G13D, etc.) was successfully conjugated with antibodies such as anti-Her2, Trop2, Claudin18.2, etc., with a maximum DAR value of 8. By optimizing the linker and ancillary group, ADC-1 maintained the high potency of its payload P1 in the antigen-specific cancer cell line GP2D (IC_{50} for P1: 0.5 nM vs ADC-1: 0.4 nM). ADC-1 exhibited excellent anti-tumor effects in animal models. For example, in the GP2D CDX model, a single dose at 10 mpk intravenous injection, 104% TGI (tumor growth inhibition) was observed on day 21. In addition, there was no significant difference in the weight change of the test animals in the ADC treatment group compared with the vehicle group. In both mouse and human plasma, the release of payload P1 from ADC-1 was less than 2% for up to 72 hours. Considering the drug load of approximately 3%wt on ADC, no payload-related safety issues emerged in the study.

Conclusion: ADC containing RAS inhibitor is a new approach to treat RAS mutant tumors. It has shown good selectivity and potency in both *in vitro* and *in vivo* studies on a variety of tumors. It exhibits good PK and physicochemical properties. It also shows an acceptable safety profile. It is a promising measure for treating patients with RAS mutations in the clinic.

#6738 Towards developing a novel therapy for pain: A monoclonal antibody that specifically inhibits voltage-gated sodium channels $Na_v1.7$.

Debin Li, Na Lu, Rui Song, Meimei Liu, **Gavin Zhang**, Huihui Xu, Yuting Xue, Liyan Su, Huaxing Zhu

Novoprotein Scientific Inc., Su Zhou Shi, China

Background: Pain is caused by the transmission of action potentials through nerve fibers to the dorsal root ganglia, ultimately reaching the higher nervous system. Voltage-gated sodium channels (VGSCs) member $Na_v1.7$, encoded by *SCN9A* and primarily localized to the dorsal root ganglion neurons, has been explored as a prominent target for pain management. The $Na_v1.7$ protein is structurally complex. Composed of about 2000 amino acids,this protein possesses four homologous domains, each containing six transmembrane alpha helices. In addition, the Nav family has nine members that share high sequence homology. This structural complexity makes it particularly challenging to develop antibodies that bind to epitopes that cause inhibitory effects on the target. And it's high sequence homologymakes it particularly challenging to develop antibodies with high specificity. Leveraging on our NovoiSMART® technology, we successfully developed NP067, a highly specific and functional monoclonal antibody against $Na_v1.7$.

Methods: It was previously shown that IL-1β upregulates the expression of *ADAMTS1*, and this upregulation is disrupted by the inhibition of $Na_v1.7$. Therefore we measured the expression of *ADAMTS1* under IL-1β induced upregulation, with or without our new antibody NP067. We also compared several known $Na_v1.7$ antagonists and NP067 for their effects to influence the expression of *ADAMTS1*. The specificity of NP067 against $Na_v1.7$ was confirmed by flow cytometry experiments on two cell lines. MCF-7 cells were used for negative confirmation as this cell line expresses SCN5A/SCN7A/SCN8A antigens but not SCN9A. And A549 cells were used for positive confirmation and this cell line expresses SCN5A/SCN7A/SCN8A as well as SCN9A.

Results: NP067 inhibited IL-1β-induced *ADAMTS1* gene expression, and the effects were stronger than other reference molecules. Flow cytometry data showed that NP067 was highly specific to $Na_v1.7$, and the affinity were higher than other reference molecules.

Conclusions: NP067 is a functional and specific $Na_v1.7$ antibody that have great potential in pain treatment. NP067 also shows great potential both as a monotherapy or coupling with other drugs.

#6739 Antibody-drug conjugates with novel payloads are enabled by an ultra-high DAR platform.

Emmalyn Lecky[1], Adam Voelker[2], Isabella Ranieri[1], Andrew Kassick[2], Cassandra Crihfield[2], Christopher Fried[2], Destiny Carpenter[2], David Wilson[2], Robert Fryberger[2], Jingyi Li[2], Amanda Mincey[2], Matthew Cummings[2], Alex Toker[1], Krzysztof Matyjaszewski[3], Antonina Simakova[2], Laura E. Benjamin[2]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]BioHybrid Solutions, Pittsburgh, PA,[3]Carnegie Mellon University, Pittsburgh, PA

Antibody-drug conjugates (ADCs) have emerged as a powerful modality to increase the therapeutic index of potent chemotherapy drugs by selectively increasing drug delivery to tumor cells while minimizing exposure to non-tumor tissue. Recent advances have improved efficacy by increasing the drug-antibody ratio (DAR) and optimizing linkers to reduce payload release in plasma and increase release within tumor tissue. Despite this significant progress and the clinical success of recent ADCs, particularly in breast cancer, challenges persist, including managing toxicity and diversifying payload classes to broaden the clinical applications of ADCs. This study demonstrates the engineering and biological potency of ADCs comprised of 50-200 single or mixed kinase inhibitors, enabling the utilization of previously unusable payloads. Small molecules are linked to a specialized polymer scaffold using cathepsin-cleavable linkers and internalized by tumor cells in an antibody target-dependent manner, where they inhibit signaling pathways essential for survival. These HER2-targeted biomolecules combined with payloads inhibiting PI3K/mTOR (apitolisib) or MEK (cobimetinib) demonstrate the use of ADCs as precision medicine to selectively target cancer cells via antibody and payload. For example, many HER2-positive tumors also carry oncogenic mutations in the PI3K pathway rendering those tumors exquisitely sensitive to these ADCs, especially when HER2 expression is low. As shown in Table 1, PI3K pathway mutations can increase the sensitivity to ADCs with apitolisib as a payload, in some cases surpassing the potency of the exatecan derivative DXd in trastuzumab-DXd (DAR8). We will also present data supporting the *in vivo* safety and efficacy of these ADCs which may provide a novel solution to expand the therapeutic landscape, particularly for HER2-positive cancers.

Table 1:

Cell Line	PI3K pathway mutation	HER2 expression	DS-8201 (T-DXd) (IC50 nM)	BHS T- apitolisib DAR100 (IC50 nM)
SUM159	PIK3CA (H1047L)	1+	159.7	9.365
T47D	PIK3CA (H1047R)	1+	12.44	3.859
MCF7	PIK3CA (E545K)	1+	239	4.944
ZR751	PTEN Missense	2+	11.09	9.451
AU565	WT	3+	0.3521	4.28
SKBR3	PIK3CA (H1047)	3+	0.4009	3.346

#6740 Dual targeting of amyloid precursor protein with α-secretase inhibitor and antibody-drug conjugate synergistically reduces tumor progression in colorectal cancer.

Rongzhang Dou[1], Hanwen Xu[2], Ricardo A. Leon-Letelier[1], Ali H. Abdel Sater[1], Yihui Chen[1], Jody Vykoukal[1], Makoto Kobayashi[1], Clemente Aguilar-Bonavides[3], Johannes F. Fahrmann[1], Hiroyuki Katayama[1], Samir M. Hanash[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]MSD R&D (China) Co, Shanghai, China,[3]SK Life Science Labs, Greater Philadelphia, PA

Background: Amyloid precursor protein (APP) is a type I transmembrane glycoprotein that is overexpressed in various cancer types and has been reported to play key roles in promoting tumor progression. In this study, we investigated the subcellular expression, biological function, and potential therapeutic strategies targeting the ADAM10-APP axis in colorectal cancer (CRC).
Methods: Single-cell RNA sequencing and spatial transcriptomic analysis were performed to elucidate the enrichment of APP expression in CRC. Liquid chromatography-mass spectrometry (LC-MS) surfaceome analysis was conducted on 14 CRC cell lines to validate APP expression on the cell surface. A tissue microarray (TMA) was used to validate the surface expression of APP. Western blotting, 3D culture, invasion and migration assays, as well as a nude mouse model, were utilized to investigate the biological function of APP. Additionally, an antibody-drug conjugate (ADC) assay targeting APP was utilized to explore its therapeutic potential in CRC.
Results: Multi-omics data revealed that APP is highly expressed in CRC and is specifically enriched in epithelial cells. Through proteomic profiling of human CRC cell lines and validation in a tissue microarray consisting of 140 CRC tumors, we identified APP as significantly enriched on the cell surface. Functional studies showed that knockdown or knockout (KO) of APP in CRC cells led to marked reductions in cell proliferation, colony formation, and invasiveness, effects that were in part reversible upon the addition of soluble APP (sAPP). In xenograft models of colorectal cancer (CRC), APP-KO HCT116 tumor-bearing mice exhibited significantly reduced tumor growth and tumor initiation frequency compared to control HCT116 tumor-bearing mice. We further demonstrated that treatment of CRC cells with GI254023X, a selective ADAM10 inhibitor, increased cancer cell surface APP expression. A combination therapy of GI254023X with an APP antibody conjugated to monomethyl auristatin F (APP-ADC-MMAF) resulted in superior anti-cancer efficacy compared to either treatment alone.
Conclusion: APP is highly expressed on the surface of CRC cells and promotes tumor progression, making it a potential target for ADC therapies. Inhibition of ADAM10 reduces APP cleavage and further enhances its surface expression, highlighting a promising treatment strategy for CRC.

#6741 AT65474, a highly selective anti-CLDN6 ADC with a proprietary payload.

Chen Zhong, Yin Wen Cheng, You Xue Wu, Xi Yun Zhang, Rui Yang Zhao, Qian Wang, Ping Du, Shao Jun Liu, Bin Zou

Axcynsis Therapeutics, Singapore, Singapore

CLDN6 is a membrane-bound oncofetal protein and a promising target for cancers such as ovarian and testicular cancer. AT65474 is an antibody drug conjugate (ADC) candidate composed of a highly selective humanized anti-CLDN6 antibody conjugated to a proprietary payload, namely TCS132, with a drug-to-antibody (DAR) ratio of 4. The antibody is engineered to incorporate AxcynCYS^{TM} technology for site-specific conjugation which can reproducibly achieve high DAR4 ratios of greater than 97% by HIC analysis. The payload, TCS132, is derived from an FDA approved drug and when compared to the parent drug, demonstrates increased potency with broad sub-nanomolar activities across a wide range of cancer cell lines including those resistant to paclitaxel, DM1, MMAE and DXd. Additionally, TCS132 was chemically optimized for better PK properties and demonstrates a much-improved safety profile despite its increased potency over the parent drug. *In vitro*, AT65474 specifically binds to CLDN6 presenting tumor cells and upon internalization into lysosomes, releases the payload effectively inhibiting tumor cell proliferation. AT65474 displays a bystander killing effect that enables it to kill surrounding CLDN6-negative tumor cells, further enhancing its anti-proliferative effects. *In vivo*, AT65474 shows strong anti-tumor activity in CLDN6-positive CDX and PDX models at low doses and long intervals, which reflects the elevated payload levels in the tumors. Furthermore, safety assessment of AT65474 including GLP-compliant toxicology studies in Cynomolgus monkeys and SD rats reveals a good safety profile of AT65474. Taken together, the results of the nonclinical studies support the intended clinical trial, dose selection, and regimen in humans.

#6742 High-affinity human IgG1 antibody against GUCY2C for ADC development: Identification, characterization, and efficacy.

Yunxia Zheng, Xiafen Wu, Junxiang Jia, Huihui Guo, Xiangfei Kong, Gengxiang Zhao, Yuanyuan Huang, Hangbo Ye, Xiaolei Liu, Yi Luo, Xiaoqiang Xie, Xia Zhou, Lu Bai, Wenjun Li, Binbin Chen, Qingliang Yang, **Robert Yongxin Zhao**

HANGZHOU DAC BIOTECHNOLOGY CO., LTD, Hangzhou, China

Colorectal cancer (CRC) is the third most common cancer and the second most common cause of cancer mortality worldwide. Despite the early disease screening techniques could reduce the number of deaths, the treatments for metastatic CRC still remains limited. GUCY2C, a receptor predominantly found in the intestinal epithelium, is a tumor-associated antigen that is overexpressed in gastrointestinal malignancies, particularly colorectal cancer (CRC). GUCY2C offers a super clean therapeutic target, due to restricted expression in normal tissues and high expression in CRC cells, with significantly reduced the on-target-off-tumor toxicities. A high-affinity, high-specificity human IgG1 monoclonal antibody against GUCY2C was obtained from a 100 billion-capacity human Fab phage display library. This antibody, after recombinant expression in CHO cells, was extensively validated both in vitro and in vivo for its suitability in antibody-drug conjugate (ADC) development. The recombinant antibody demonstrated high affinity for its specific antigen, as confirmed by Bio-Layer Interferometry (BLI) and Enzyme-Linked Immunosorbent Assay (ELISA) methods. Flow cytometry further confirmed that the antibody had picomolar (pM) affinity for gastric and colorectal cancer cell lines expressing high levels of GUCY2C. Cellular internalization experiments indicated that the antibody possesses excellent endocytic capabilities, making it particularly suitable for ADC development. The antibody was then conjugated with a linker-payload complex containing a topoisomerase I inhibitor and an antimetabolite moiety, and subjected to a series of in vitro and in vivo evaluations. The ADC achieved in vitro proliferation inhibition in the picomolar range of IC50. Several in vivo CDX model experiments also demonstrated significant tumor suppression efficacy. Moreover, acute toxicity evaluation of the GUCY2C-ADC in diverse preclinical models indicated favorable safety profiles and tolerability. Overall, these compelling preclinical data supports the promising therapeutic potential of this ADC in targeted treatment of CRC.

Keywords: Human IgG1 Antibody, GUCY2C, ADC, High Affinity, Tumor Suppression, In Vitro and In Vivo Validation

#6743 Patient-derived organoids: an *in vitro* platform for evaluating ADC efficacy, potency, and specificity.

Daniele Mori, Claudia Beaurivage, Eider Valle Encinas, Yara Hendriksen, Anna Schepers, Foteini Gkogkou, Joris Maas, Ka Wai Lai, Mariana Silva, Sumeyra Mucuk, Vineeta Adegbenro, Ricardo Korporaal, Merel Derksen, **Sylvia F. Boj**

HUB Organoids B.V., Utrecht, Netherlands

Antibody-drug conjugates (ADCs) are pharmaceutical drugs that selectively deliver cytotoxic agents to cells expressing a specific target antigen (TA). Structurally, ADC consists of a highly specific monoclonal antibody linked to a cytotoxic payload. HUB patient-derived organoids (PDOs) are a unique *in vitro* 3D adult stem cell-based model. They closely resemble the architecture and physiology of the tissue of origin, maintaining the patient-specific genetic and phenotypic characteristics, including surface marker expression. This unique feature makes them a patient-relevant *in vitro* model for ADC screenings. The work presented here demonstrates the potential of the HUB PDO platform in an *in vitro* basket trial. Organoids derived from 7 different tissue origins were used for ADC screening, showcasing the platform's reliability and ability to assess ADC specificity, potency, and efficacy. ADCs directed to different TAs, such as Tissue Factor (F3) or trophoblast antigen 2 (TROP2), were tested, and organoid viability was assessed with CellTiter Glo® 3D after 7 days of treatment.
Further parameters, such as TA expression and the percentage of the cell population expressing TA in each organoid, were evaluated by flow cytometry. The analysis of ADCs targeting F3 revealed an ADC-dependent organoid-killing correlation with F3 expression for a subset of PDOs across all different tumor tissue types. However, as observed in clinical trials, the impact of ADC on the viability of some PDOs was unrelated to F3 expression. The lack of correlation between ADC efficacy and target antigen expression was more evident for the TROP2 ADC. These findings underscore the importance of the study in understanding the differential activity between ADCs. Altogether, these results highlight the value of the PDO platform in assessing ADC target specificity and as a patient-relevant model to study the mechanism behind differential activity between ADCs such as antibody internalization dynamics or bystander effects.

#6744 Why the analytical development of agonistic antibodies is challenging? A comprehensive strategy to unlock their characterization for immunotherapy and autoimmunity.

Gaurav Agrawal, Venkatesh Chari, Luhan Yang, Jennifer Lin-Jones, Alpana Prasad, Jane Lamerdin

Eurofins DiscoverX, Fremont, CA

Checkpoint blockade antibodies, or checkpoint inhibitors, are established as effective cancer therapeutics. A contrasting class of therapeutics, agonistic checkpoint antibodies, has recently emerged for attenuating inflammation in autoimmune diseases. Despite showing clinical promise, their development remains challenging due to limitations in conventional checkpoint assay designs that often fail to replicate physiologically relevant conditions *in vitro* and are sometimes confined to assessing only inhibitory responses.
Here, we introduce a novel checkpoint assay design in a co-culture format involving Fcγ receptor-expressing cells, directly measuring the stimulatory activity of agonistic antibodies. Through testing various classes of Fcγ receptors and diverse cell backgrounds, we have established a specific and robust assay design for several key checkpoint receptors such as CD40, CD137, PD-1, and BTLA. Notably, we have identified previously unrecognized agonistic activity in a clinically approved blockade antibody, underscoring the importance of exploring similar activity in other therapeutics of this nature. The assay is optimized as a thaw-and-use format, exhibiting high reproducibility with ease of execution, and qualified for potency and stability studies as needed for commercial release testing in a quality-controlled environment.

#6745 Generation and validation of a recombinant monoclonal antibody to PAX8: a multi-assay approach.

Amber Miller[1], **Danielle Fails**[1], Jessica Tracy[2], Hailey Wooten[3], Michael Spencer[1]

[1]Immunohistochemistry and Digital Pathology, Fortis Life Sciences, LLC, Montgomery, TX,[2]QC and Validation, Fortis Life Sciences, LLC, Montgomery, TX,[3]QC and Validation, ELISA, Fortis Life Sciences, LLC, Montgomery, TX

Introduction: Paired box 8 (PAX8) is a nuclear protein involved in thyroid follicular cell development and expression of thyroid-specific genes. While primarily associated with thyroid follicular carcinomas and atypical follicular thyroid adenomas, recent research has indicated that this marker is prognostic in small cell lung cancer and positively correlated with Ki67 expression (Tao et al., 2024) -- perhaps opening PAX8 up as a future therapeutic target. Studies such as these, though, require the use of extremely reliable antibodies to generate reproducible and trustworthy data. In congruence with the International Working Group for Antibody Validation's (IWGAV) pillars of antibody validation, a program has been implemented to enhance our existing validation principles including the recombinant monoclonal PAX8.
Methods: Four unique PAX8 peptides were synthesized, purified, and used for rabbit immunization and B-cell sorting. Clones were screened for baseline activity and assessed microscopically for specificity using variable tissue and cell microarrays. Specificity was further assessed via reciprocal IPs, western blot, and flow cytometry. Finally, multiplex immunofluorescence staining was conducted utilizing two separate approaches. First, staining and imaging was done using the Lunaphore COMET™ followed by traditional TSA sequential staining methods and imaged with the Akoya PhenoImager® HT system.
Results: Over 40 clones were screened against OVCAR3 cell lysate using ProteinSimple Simple Western™ technology and stained in tandem across target-specific microarrays using chromogenic immunohistochemistry. This dual screen approach allowed for the narrowing of the substantial clone set down to 8, which was reduced further after in-depth CTWB/IP studies eliminated an additional 5 clones. The remaining 3 clones were examined through expanded chromogenic testing on large (80+ cores) human, mouse, and rat tissue and cell microarrays. Throughout the various assays, PAX8 specificity was assessed utilizing other external antibodies, PAX8-overexpressing cells, and known target localization via literary sources.
Conclusions: In utilizing a multi-assay approach, we were able to narrow the original 40+ clone set to a single, highly-specific monoclonal antibody. This approach is one that the International Working Group for Antibody Validation has been emphasizing as a superior way to produce antibodies that foster reproducibility across research. In future studies, multiplex immunofluorescence staining will be conducted using PAX8 in combination with PAX5 and Ki67 across small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC) to evaluate expression rates.

#6746 Multi-modal assessment of an anti-HER2 (trastuzumab) antibody-drug conjugate screening assay for breast cancer models.

Michael Steffey, Stacey Roys, **Anita J. Zaitouna**, Philip Lapinski, Kerry-Ann Bright, Sheri Barnes, David Draper, Scott Wise

Labcorp, Ann Arbor, MI

Antibody-drug conjugates (ADCs) represent groundbreaking advancement in the cancer treatment landscape. ADCs combine the specific binding capacity of a monoclonal antibody with a cytotoxic payload that can kill target and bystander cells. The antibody moiety of ADCs confers payloads with the ability to target cancer cells with minimal damage to healthy tissues.
A key consideration in defining appropriate breast cancer treatment regimen is the expression level of human epidermal growth factor receptor 2 (HER-2), targeted with the antibody Trastuzumab. Breast cancers are classified as high, low, or negative for HER-2, which dictates the therapeutic approach. Trastuzumab alone may not be an effective treatment because tumors can either be initially resistant or develop resistance over time. Around 70% of patients experience resistance within the first year of treatment. To overcome this, ADCs such as Trastuzumab-Emtansine (DM1) or Trastuzumab-Deruxtecan (Dxd) can be used at lower doses, reducing the risk of resistance and potentially enhancing treatment efficacy.
Assessment of Trastuzumab ADCs in multiple murine breast cancer models can be costly, but *in vitro* evaluation of various cancer histotypes facilitates the selective identification of the best murine model. Having a robust screening tool is an important asset. To assess Trastuzumab ADCs, we screened five breast cancer cells (BT-474, Hs 578T, MDA-MB-231, MDA-MB-361, SK-BR-3) with varying levels of HER-2 expression. They were evaluated for binding efficiency, competitive inhibition, and cytotoxicity of ADCs. Additionally, the ability of the ADC to kill bystander cells (HER-2 low or negative cells) was assessed using two bystander assay methods.
The half maximal effective concentration (EC_{50}) values for Trastuzumab and Trastuzumab-Dxd were measured on two cell lines. The HER-2 high cell line had a tenfold higher EC_{50} value.
Competitive inhibition of Trastuzumab-ADC binding was tested with a PE labeled Trastuzumab on two cell lines. The Trastuzumab-ADC was able to outcompete Trastuzumab on HER-2 high cells but not on HER-2 low/negative cells. Proliferation assays on multiple cell lines were used to assess the ability of Trastuzumab-DM1 to inhibit cell growth in comparison to DM1 (payload alone) or Trastuzumab (antibody alone). Overall, Trastuzumab-DM1 was better able to inhibit growth of HER-2 positive cells compared to payload or antibody alone.
Two ADC bystander assays were developed and tested. The first involved flow cytometry and the second a luciferase assay. In both assays, bystander cells were more effectively targeted only in the presence of HER-2 positive cells. The ability of ADCs to target bystander cells suggest that even in heterogenous HER-2 expressing tumors, these therapies may still be effective.
Our cutting-edge approaches provide precise insights into the activity and efficacy of Trastuzumab ADCs.

#6747 A next generation ADC: AR153, pH-dependent anti-B7H3 MMAE.

wonhwa kang

Ybiologics, Daejeon, Korea, Republic of

Antibody-drug conjugates (ADCs) demonstrate significant anti-cancer efficacy, but their therapeutic index (TI) can be restricted due to toxicity in normal tissues. To address this limitation, pH-dependent antibodies have emerged as a promising solution. These antibodies exhibit weak binding to their target under physiologically neutral pH conditions but show strong binding in the acidic environment of the tumor microenvironment (TME), improving tumor selectivity and reducing off-target toxicity, thereby increasing the TI of ADCs. B7-H3, a member of the B7 family, is overexpressed in various solid tumors, making it a promising therapeutic target for ADC development. We screened a recombinant human antibody library (Ymax-ABL) and identified pH-dependent antibodies against B7-H3. We developed a pH-dependent anti-B7-H3 antibody (pH-B7-H3 Ab) that shows strong binding under acidic conditions such as TME, and reduced binding under neutral pH, as seen in healthy tissues. We generated ADCs by conjugating a pH-independent anti-B7-H3 antibody (Non-pH-B7-H3 Ab) and the pH-B7-H3 Ab with GGFG-Dxd and vc-PAB-MMAE, achieving drug-to-antibody ratios (DAR) of 3.8, 3.8, 3.5 and 3.9, respectively. Comparative studies revealed that pH-B7-H3-MMAE exhibited lower cytotoxicity than Non-pH-B7-H3-MMAE under neutral pH conditions typical of normal tissues. However, under acidic conditions (pH 6.0), both ADCs displayed comparable cytotoxicity. Additionally, in a B7-H3-expressing CDX model, ADCs demonstrated similar anti-cancer efficacy. Notably, pH-B7-H3 Ab exhibited superior penetration into tumor tissues compared to Non-pH-B7-H3 Ab, highlighting its potential to improve therapeutic outcomes by selectively targeting tumor cells while minimizing harm to normal tissues.

#6748 Comparison of activities and identification of predictive genomic biomarkers of response to trastuzumab and the trastuzumab deruxtecan ADC using the OncoPanel® platform.

Luciano Galdieri[1], Steven Garner[1], Brogan Epkins[1], Emily Schultz[1], Daria Clucas[1], Kaitlyne Powers[1], Justin Lipner[1], Elsa Liu[2], ChunYao Lee[2], Alastair J. King[1]

[1]Eurofins Discovery, Saint Charles, MO,[2]Eurofins Discovery, Taipei, Taiwan

Antibody-drug conjugates (ADCs) represent a novel class of therapeutic agents that allow the targeted delivery of cytotoxic payloads to tumor cells via the selectivity afforded by monoclonal antibodies (mAbs) directed against tumors expressing particular antigens. When the mAb component of the ADC binds to its cell surface antigen, the ADC-antigen complex is internalized by the cancer cell. Once inside the cell, the drug payload is released from the mAb either through a chemical reaction or enzymatic digestion within lysosomes, ultimately allowing the exertion of its cytotoxic effects. In 2013, the first ADC approved for treating solid tumors was the Her2-targeted ado-trastuzumab emtansine, which was developed for metastatic breast cancer. As of June 2024, the US Food and Drug Administration has approved thirteen ADCs, with many more currently undergoing preclinical development and clinical trials. The anti-Her2-targeted ADC trastuzumab deruxtecan (TDxd) features a cleavable enzymatic linker, unlike trastuzumab emtansine, which utilizes a non-cleavable thioether linker. This cleavable linker enables deruxtecan, a topoisomerase I inhibitor, to diffuse out of cells following cleavage, thereby inducing cytotoxic effects even in tumors with low Her2 expression levels. Solid tumors overexpressing Her2—including breast, colorectal, and gastric cancers, as well as Her2-mutated lung cancers—have shown significant responses to TDxd. We evaluated the activity and selectivity of TDxd, along with the unmodified antibody and free payload when administered separately, against a panel of 300 human tumor cell lines. Potencies were assessed from ten-point dose response curves using a four-parameter log-logistic model with custom curve-fitting software to determine IC_{50} and EC_{50} values. In this study, we compare and contrast the potency and efficacy of each tested agent and explore the genomic biomarkers associated with sensitivity and resistance to each of these treatments. Additionally, we have also evaluated the effect of these agents from a broader tissue biology perspective, including use of the BioMAP® cellular phenotypic platform.

#6750 QLS5132, a highly selective anti-CLDN6 ADC with broader therapeutic window.

Ying Huang[1], Zhongcui Sun[1], Shuyong Zhao[2], Xinmei Wang[3], **Ling Zhang**[1], Yang Yang[1], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., jinan, China,[3]Qilu Pharmaceutical Co., Ltd., Jinan, China

Background: Claudin-6 (CLDN6), a member of the claudin family, is localized in the tight junctions of epithelial cells to regulate permeability, barrier function and polarity of epithelial layers. CLDN6 is notably upregulated in multiple solid tumor types, including ovarian cancer, testicular cancer, endometrial cancer and non-small cell lung cancer, while exhibiting minimal or no expression in healthy adult tissues. Therapeutic potential of CLDN6 as a target for ADC was unraveled by TORL-1-23, a clinical stage ADC drug with MMAE as the payload from TORL BioTherapeutics, LLC, while QLS5132, a novel CLDN6-targeting ADC in IND-enabling stage, demonstrates superior efficacy and tolerability to TORL-1-23.

Method: QLS5132 is composed of a humanized anti-CLDN6 hIgG1 antibody with no cross-reactivity to CLDN9 conjugated to Qilu's proprietary topoisomerase-1 inhibitor, QLS6916, via a hydrophilic cleavable linker. The payload QLS6916 showed nanomolar activity across a wide range of cancer cell lines in vitro and rapid systematic clearance in rodent models.

Result: QLS5132 showed sub-nanomolar activity in CLDN6-positive cancer cell lines, with faster internalization efficacy and stronger bystander killing activity than TORL-1-23. In *in viv*o pharmacology studies, QLS5132 demonstrated superior antitumor efficacy to TORL-1-23 across a panel of ovarian cancer cell line-derived xenograft (CDX) models with varying levels of CLDN6 expression. Furthermore, QLS5132 displayed synergistic activity when combined with PARP inhibitors in CLDN6-expressing ovarian CDX models, indicating its potential for possible combination with PAPR inhibitors in ovarian cancers. QLS5132 was well tolerated in cyno monkeys, with HNSTD up to 60 mpk Q3W x 4 in non-GLP toxicity study, which is 5 folds higher to TORL-1-23.

Conclusion: QLS5132 showed an expanded therapeutic window with superior efficacy and tolerability to TORL-1-23 in preclinical models. QLS5132 also demonstrated great potential to combine with PARPi in CLDN6 positive ovarian cancers. QLS5132 is expected to offer a novel and promising treatment option either as a single agent or combo with PARPi or other SoCs for patients with CLDN6 expressing tumors. QLS5132 will enter clinical trials.

#6751 AT2604 is a highly efficacious ADC targeting alkaline phosphatases ALPP and ALPPL2.

Bryan K.S. Yeung, Wei Qi Tan, You Xue Wu, Xi Yun Zhang, Yin Wen Cheng, Shao Jun Liu, Chen Zhong, Bin Zou

Axcynsis Therapeutics, Singapore, Singapore

Placental alkaline phosphatases, ALPP and ALPPL2, are highly homologous, membrane-bound proteins involved in fetal development. Despite having limited expression in normal tissues, they are highly differentiated in multiple tumor cells making them ideal targets for antibody drug conjugate (ADC) development. AT2604 is an ADC incorporating an anti-ALPP/ALPPL2 antibody conjugated to monomethyl auristatin E (MMAE) with high DAR 4 homogeneity; and displays strong tumor growth inhibition at low doses in CDX models of gastric and pancreatic cancer. In patient-derived xenograft models of gastric cancer with moderate- and low-antigen expression, AT2604 achieves near-complete tumor regression at 3 and 6 mg/kg (QWx3), respectively. A preliminary toxicity assessment in non-human primates concluded a well-tolerated dose of 10 mg/kg (Q3Wx3) without exhibiting any non-reversible adverse effects.and good plasma stability; implying that AT2604 possesses an improved safety profile over other vedotin-based ADCs.

#6752 Identification and validation of human antibodies targeting a novel pan-adenocarcinoma target discovered via spatial transcriptomics.

MinKyu Kim, Jinyeoung Choi, Jae Eun Lee, Hongyoon Choi, Hyung-Jun Im

Portrai, Inc., Seoul, Korea, Republic of

Background: Adenocarcinoma (ADCA) is a type of cancer that originates in glandular epithelial cells in various organs such as pancreas, colon and lung. Spatial transcriptomics enables the high-resolution mapping of gene expression within the tumor microenvironment, preserving spatial context. This allows for the identification of tumor-specific targets in the context of complex tumor microenvironment, providing insights critical for precision oncology. Through a data-driven target discovery platform which leverages large scale transcriptomic data including ST, a novel target, POR-ADCA-001, was identified. Here, we developed human antibodies that have superior specificity and binding affinity to POR-ADCA-001.
Methods: Panning phage display, filter lift assay, and Solid Phase Extraction Enzyme-Linked Immunosorbent Assay (SPE ELISA) were utilized to screen hit antibodies with strong binding potential to the target protein. Furthermore, ELISA and Surface Plasmon Resonance (SPR) analysis were used to identify lead candidate antibodies (POR-ADCA-001-01, POR-ADCA-001-02) that can effectively target POR-ADCA-001 at low concentrations. Moreover, a cell line overexpressing POR-ADCA-001 (cell-1) and a non-expressing cell line (cell-2) were validated using western blot and immunofluorescence. At last, we examined the effectiveness of the antibodies using flow cytometry, immunofluorescence, and internalization assay.
Results: Spatial and differential expression analyses revealed POR-ADCA-001 as highly expressed in various ADCA tissues with low expression in normal tissues. On ELISA, 28 hits were found and the half maximal effective concentration (EC50) values of them were one or two digit nM. Among them, POR-ADCA-001-01, 02 were selected for further development and demonstrated the binding affinity of 0.84 and 14.8 nM. We demonstrated using flow cytometry and immunofluorescence that the two antibodies bind strongly to cell-1 but hardly bind to cell-2. Internalization assays confirmed substantial uptake of the antibodies in cell-1, with minimal activity in control cell lines.
Conclusion: Our research identified POR-ADCA-001 as a target specific to pan-adenocarcinoma and discovered two human IgG antibodies that demonstrate high specificity and effective internalization in cells that express the target. These antibodies could be utilized for the development of targeted therapeutics such as antibody-drug conjugates (ADCs) or radiopharmaceutical therapies (RPTs). This study emphasizes the promise of ST in uncovering new therapeutic targets and improving cancer treatment.

#6753 Exploring new approaches to widening of the therapeutic index of ADCs with dual-payload design and combination with a novel HMA.

Younghwa Chun, Areum Go, Byeong Sung Lee, Seunggun Shin, Sohui Kweon, Hyemin Han, JaeHyeon Lee, Suhyun Park, Ha Young Lee, Min Young Lee, Hyun Yong Cho, Doo Young Jung

PINOTBIO Inc., Suwon-si, Korea, Republic of

Antibody-drug conjugates (ADCs) have revolutionized targeted cancer therapy by delivering potent cytotoxic agents directly to tumor cells. Recent approvals of ADCs such as trastuzumab deruxtecan, sacituzumab govitecan have significantly improved patient treatment options, underscoring the clinical potential of this therapeutic class. However, single-payload ADCs often face limitations in efficacy. Tumor heterogeneity poses a significant challenge, as targeting cancer cells with a single cytotoxic mechanism may not sufficiently overcome resistance or achieve optimal therapeutic outcomes. These limitations call for the development of novel strategies that widen the therapeutic index by increasing the Maximum Tolerated Dose (MTD) and lowering the Minimum Effective Dose (MED). We have designed and synthesized a novel dual-payload ADC combining two distinct cytotoxic agents: a potent topoisomerase I inhibitor (Top1i) and a microtubule-disrupting agent. This innovative approach allows for a synergistic therapeutic effect, leveraging the complementary mechanisms of action of both payloads within a single ADC. *In vitro* cell viability was determined using the CellTiter-Glo assay against the NCI-N87 and MDA-MB-468 cell lines. These studies demonstrated robust potency of the dual-payload ADC across multiple cancer cell lines. *In vivo* efficacy studies were conducted in HER2-expressing NCI-N87 gastric cancer xenograft model. The tumor-bearing mice were treated with various doses of dual-payload ADC, single-payload ADC, or saline control. Notably, dual-payload ADC displayed superior efficacy compared to single-payload ADC, achieving a tumor growth inhibition (TGI) of 103% ($p < 0.05$). This demonstrates superior tumor growth inhibition of the dual-payload ADC compared to a Top1i-based single-payload ADC and a more favorable safety profile compared to a microtubule inhibitor-based single-payload ADC. Pharmacokinetic (PK) profiling and non-GLP toxicity studies are currently underway to further characterize its suitability for clinical development. Moreover, we have explored combination strategies to further augment the therapeutic index. One promising approach involves the combination of the ADC with NTX-301, a novel 4′-thio-modified analog of decitabine (DAC). NTX-301 enhances p53 stabilization more effectively than DAC, potentially improving the ADC's efficacy through synthetic lethality with BCL2 inhibition. Preliminary data suggest that the ADC+NTX-301 combination produces greater synergy and a more favorable therapeutic index than ADC combinations with traditional hypomethylating agents (HMAs). In this study, we present novel strategies to enhance the therapeutic index of ADCs through a dual-payload design and combination with NTX-301. These results highlight the potential of both approaches for further development in cancer treatment.

#6754 A payload screening and ADC evaluation platform for STING agonist antibody drug conjugates.

Ying Meng, Li Li, Min Kang, Xiao Li, Haiting Dai, **Tj (Tiejun) Bing**

ICE Bioscience, Inc., Beijing, China

Antibody drug conjugates (ADCs) are a class of rapidly developing targeted biotherapeutic drugs, which consist of three elements: antibody, linker, and payload. ADCs combine the high specificity of antibodies with the potency of payloads, delivering the highly efficient small molecule within the target tumor cells.
As one of the new payload types, stimulator of interferon genes (STING) agonist can initiate the innate immune response, enhancing the attack on tumor cells. STING agonist ADCs, allowing tumor-localized activation of STING, may achieve greater anti-tumor activity and better tolerability.
By combining the STING binding assay, different THP-1 reporter assay, we can support for STING agonist activities screening. RT-qPCR assay and WB assay can be applied for demonstrating the molecular mechanisms of candidates. For specific screening and evaluation of HER2 STING agonist ADCs, HER2 overexpression reporter assay, co-culture assays of tumor cell lines or STING knockout tumor cell lines with THP-1, hPBMC, as well as whole blood can be utilized at different project stages.

#6755 Discovery of the synergistic dual-payload antibody-drug conjugate (CTPH-02) by combination of MMAE and novel payloads.

Chang-Sun Lee, Myeong Joo Kim, Da hyun Kim, Soyeon Lim, Jiwoo Lee, Eunseok Choi, Wonbin Ha, Han ah Kim, Jaebeom Park, Seung Chan Kim

Celltrion Pharm, Inc., Incheon, Korea, Republic of

Many ADC drugs in clinical trials are showing poor performance without providing sufficient dose due to dose-limiting toxicity, which is rooted from on-target toxicity related to payload itself. There are many efforts to increase the therapeutic index (TI) of ADC, but research on discovering novel payloads based on unique anticancer mechanisms of action is relatively limited. We have developed unique ADC platform technology by adopting multi-drug payloads concept, where we aim to achieve three different goals, (1) increasing MTD and lowering MED (2) showing cytotoxic activity in antigen low-expressed cell lines (3) overcoming resistance cell lines with better cytotoxic effects. This study began with the search for a drug combination that could maintain or increase efficacy of MMAE even with lower dose of MMAE. Drugs with various mechanisms of action were tested to select a combination that showed a high synergy effect with MMAE, and a cell cycle regulating drug was found to offer the most synergistic combination efficacy with MMAE. By conjugating a dual-payload with two-different mechanisms of action to HER2 antibody(trastuzumab), the resulting ADC(CTPH-02) was confirmed to show synergistic effect in terms of cytotoxicity. Very excitingly, CTPH-02 shows significantly high synergistic efficacy in the case of cell lines with low HER2 antigen expression. These findings based on the right combination of two-different payloads open a new paradigm for ADC drug design strategies in cancer therapy in order to provide treatment options to wider range of cancer patients such as low TPS % with low IHC score.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Cellular Responses to Anticancer Drugs
Poster Session

#6759 *In vivo* tumor growth control by general control nonderepressible 2 targeting agents results from kinase activation.

F. Tameire[1], P. Wojnarowicz[1], C. Dudgeon[1], S. Fujisawa[1], S. Ramurthy[1], O. Reilly[1], C. G. Thomson[2], B. Sherborne[2], S. Taylor[2], F. He[2], P. Pan[2], B. Li[2], E. May[3], A. C. Rigby[1], M. J. Mulvihill[1], N. Bose[1], D. Surguladze[1], **E. S. Lightcap**[1];
[1]HiberCell, Boston, MA, [2]Pharmaron UK Ltd, Hoddesdon, United Kingdom, [3]Watertown Biosciences LLC, Watertown, MA

General Control Nonderepressible 2 (GCN2; *EIF2AK4*) is a serine-threonine kinase in the integrated stress response (ISR) signaling pathway that initiates adaptive responses during nutrient stress conditions. While pharmacological inhibition of GCN2 under nutrient stress conditions induces apoptosis and inhibits tumor growth, GCN2 inhibition without nutrient stress has been reported to have no effect on tumor growth. By exploring an array of GCN2 inhibitors, we demonstrate that multiple agents in fact activate GCN2 in biochemical and cell-based assays at low concentrations and inhibit GCN2 at higher concentrations. Unexpectedly, it is this activation, and not inhibition, of the GCN2 pathway that is associated with decreased viability *in vitro* and tumor growth inhibition *in vivo* across multiple models. Knockdown and knockout experiments show that activation of the ISR by GCN2-targeting agents is dependent on GCN2. We also uncover that Type 1 GCN2-targeting agents do not activate GCN2 whereas non-Type 1 agents activate GCN2 in the absence of stress. We demonstrate that a Type 1 GCN2-targeting agent does not have the same viability effects as the non-Type 1 GCN2-targeting agents. These results provide a clearer understanding of the challenges and opportunities for the clinical development of compounds targeting GCN2.

#6760 Anticancer mechanisms of quercetin revealed via a systems biology approach.

A. Goraieb[1], A. Aggarwal[1], **K. W. Yip**[2];
[1]University of Toronto, Toronto, ON, Canada, [2]University of Toronto, Anticancer.ca, Toronto, ON, Canada

Introduction: Quercetin is a dietary flavonoid found in apples, onions, and berries. Previous *in vitro* and *in vivo* studies have identified its pro-apoptotic, anti-angiogenic, antioxidant, and anti-inflammatory activities, in addition to its ability to sensitize cancer cells to traditional chemotherapies. However, there has not yet been a comprehensive evaluation of its anticancer properties on a large panel of cancer cell lines. We hypothesized that quercetin exhibits varied anticancer effects depending on the particular cell line and its tissue of origin.
Methods: For cell survival assessments, 77 cancer cell lines from the NCI60 dataset were seeded into 96-well plates and incubated for 24 hours. DMSO control or quercetin was then added at 5 ten-fold concentrations to a maximum of 100 µM. 48 hours later, the cells were fixed and stained, and cell viability measured with CellTiter-Glo. Next, for transcriptomic profiling, the L1000 assay from The Broad Institute was used. For these experiments, 10 µM of quercetin was added to 9 core cell lines seeded in 384-well plates. Then, the Affymetrix GeneChip HG-U133 Plus 2.0 Array was used to generate a gene expression signature for quercetin, which was then compared with signatures from other compound and genetic perturbations. Connectivity scores were used to classify the L1000 signatures according to similarity to the gene expression changes produced by quercetin. The data for cell survival and transcriptomic profiling were extracted from PharmacoDB and Clue.io, respectively.
Results: The most sensitive cell line to quercetin was the glioblastoma cell line U-87/H.Fine (IC_{50}=5.03 µM), and the least sensitive was the renal cell carcinoma cell line TK-10 (IC_{50} = 5780.61 µM). Overall, quercetin was most potent against myeloid and prostate cancers and least potent against ovary and fallopian tubes cancers. As indicated by high median tau scores, quercetin administration induced gene expression changes similar to NFKB2, PTK2 and EPCAM knock-downs, which are associated with reductions in inflammation, cell proliferation, and cancer growth and progression. The cellular effects of quercetin were analogous to the administration of other anticancer compounds such as CP466722, rhamnetin, and piceatannol. CP46672 can sensitize tumors to ionizing radiation, rhamnetin acts as an antioxidant, and piceatannol is a naturally occurring anticancer agent.
Conclusions: This study provides a comprehensive *in vitro* examination of the impact of quercetin on the viability and gene expression profiles of cancer cells of various origins. Further research on the molecular changes induced by quercetin in animal models and human subjects would help inform the applicability of quercetin in human cancers and guide its use in cancer prevention and treatment.

#6762 Baseline multiomics and chemotherapy efficacy in preclinical trials using patient-derived xenograft models of cholangiocarcinoma can reveal distinct signatures of chemotherapy response.

Amro M. Abdelrahman[1], Danielle M. Carlson[2], Ellen L. Larson[1], Erik Jessen[3], Dong-Gi Mun[4], Isaac Lynch[5], Alessandro Fogliati[6], Stella Konadu Adjei Antwi[1], Aushinie Abeynayake[2], Akhilesh Pandey[4], Mark J. Truty[1], Gregory J. Gores[2], Rory L. Smoot[1]

[1]Surgery, Mayo Clinic, Rochester, MN,[2]Internal Medicine, Mayo Clinic, Rochester, MN,[3]Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[4]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[5]College of Medicine, University of Iowa, Iowa City, IA,[6]Surgery, University of Milano-Bicocca, Milan, Italy

Background: Cholangiocarcinoma (CCA) is a diverse type of cancer. For several years, platinum-based chemotherapy (Gemcitabine and Cisplatin) has been the standard treatment and serves as the foundation for current immunotherapy combinations. The typical response rates are generally between 20% and 30%. In this study, we present the results of preclinical efficacy trials conducted on CCA patient-derived xenograft (PDX) models, correlating them with the baseline multiomics profiling of these models to identify molecular characteristics linked to treatment response.
Methods: Tumor samples from twenty-eight CCA PDX were used to isolate RNA and protein to be included in multiomics analysis (Phosphoproteomics, Proteomics, and Transcriptomics). A subset of PDX models were treated with various doses of Gemcitabine and Cisplatin. The Median Efficacy Index (MEI) was calculated as the ratio of the difference in median of delta in tumor volume at the last day of the study between the treatment and the control arms divided by the median of delta in tumor volume of the control at the last day of the treatment (positive= growth, negative=inhibition, and 0=no efficacy). A Hierarchical All-Against-All algorithm was utilized to compare multiomics features to the MEI and pathway analysis completed for identified molecular features. Pathway enrichment was calculated using the KEGG database, and random-forest variable selection chose the pathways most influential in predicting sensitivity or resistance.
Results: After conducting preclinical efficacy trials, the 11 tested CCA PDX models were classified into sensitive, moderately sensitive, and resistant models based on the MEI on each treatment arm. The top up-regulated genes were identified for Gemcitabine response (SRPK2, GLK2, and RIOK2) and Cisplatin response (NTRK1, PRPF4B, and SRPK2). The top up-regulated genes related to Gemcitabine resistance were NTRK1, PIP5K1C, and CSNK2A2, while those related to Cisplatin resistance were SRPK1, PRPF4B, and CSNK2A1. Downregulation of the anti-folate resistance pathway is a strong predictor of gemcitabine sensitivity, and the lysine degradation pathway is a strong predictor of cisplatin sensitivity.
Conclusion: Multiomics signatures of cholangiocarcinoma can forecast responses to standard chemotherapy in preclinical models. New markers of resistance to Gemcitabine and Cisplatin were discovered, linked to NTRK1, SRPK1, and SRPK2. These resistance profiles will be tested using suitable targeted therapies on the resistant CCA patient-derived xenograft (PDX) models.

#6763 A cellular platform for systematic comparison of RAS inhibitors using PRISM multiplexed screening.

Matthew G. Rees, Mustafa Kocak, Matthew J. Emmett, Colleen T. Harrington, Anthony Fazio, Alvin Kalathungal, Ursula Widocki, Claudine Mapa, Dennie T. Frederick, Jillian N. Eskra, Laura Doherty, Blanche C. Ip, Melissa M. Ronan, William R. Sellers, Jennifer A. Roth

Broad Institute, Cambridge, MA

The discovery and development of direct inhibitors of KRAS is transforming therapeutic options across diverse cancer types. Here, we use the PRISM collection of nearly 900 cancer cell lines, including more than 150 KRAS-mutant cell lines, to characterize 19 KRAS-targeting inhibitors or degraders, including G12C-, G12D-, and pan-KRAS inhibitors. Agents were tested at 8 doses (threefold dilution) for 5 days across a median of 883 cell lines. For each agent, we assessed its selectivity and correlation with KRAS mutation status and genetic dependency. For each cell line, we categorized its sensitivity to each individual agent and in aggregate by comparing across RAS modulators. For example, all 10 KRAS G12C inhibitors or degraders tested showed significant selectivity for cell lines harboring the G12C mutation, with RMC-6291, adagrasib, divarasib, and sotorasib showing the greatest enrichment. Among G12C-mutant cell lines, all 10 G12C-targeting agents were preferentially active against NCIH358 cells (rank 1-3, median 1.5) while OV56 cells showed much more variability in response (rank 5-623, median 92). Similar trends were observed for pan-KRAS inhibitors (NCIH358: median rank 7; OV56: median rank 655). Further, we characterized a panel of downstream (MEK, ERK) or upstream (SHP2, SOS1, RTK) RAS/MAP kinase pathway modulators in the PRISM assay to understand similarities and differences between direct and indirect RAS pathway suppression. Finally, we also explored orthogonal assay formats, including ultra-low adherent and extended-duration (10-day) screening, to investigate kinetic and environmental factors associated with inhibitor response. Collectively, our work provides a comprehensive profile of the cellular effects of current RAS-targeting therapeutics, and provides a foundation for the characterization of newly-emerging agents.

#6764 Lipophagy-dependent fatty acid oxidation is a metabolic vulnerability for KRAS signaling inhibition in pancreatic cancer.

Junzhang Zhao[1], Ravi Thakur[1], Dezhen Wang[2], Tuo Hu[2], Chunbo He[1], Surendra K. Shukla[1], Kirsten L. Bryant[3], Kamiya Mehla[1], Channing J. Der[3], Pankaj K. Singh[1]

[1]Oncology Science, University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE,[3]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Pancreatic ductal adenocarcinoma (PDAC) is frequently driven by activating mutations in KRAS, which promote tumor progression through sustained activation of the MAPK (RAS/RAF/MEK/ERK) signaling pathway. This study investigates the metabolic vulnerabilities associated with PDAC by examining the metabolic reprogramming that occurs upon KRAS signaling inhibition via targeting MEK/ERK/KRASG12D, and utilizing metabolomic, lipidomic, and isotope-tracing approaches. Our findings reveal that MEK/ERK/KRASG12D inhibition results in enhanced lipid turnover and fatty acid oxidation while suppressing glycolysis, glucose oxidation, and glutamine metabolism in PDAC cells. Notably, we observed that the increased lipid turnover and fatty acid oxidation are mediated by lipophagy, rather than cytosolic lipolysis. Furthermore, these processes are driven by enhanced nuclear translocation and transcriptional activity of TFEB, a key regulator of lysosomal biogenesis and autophagy. Pharmacological inhibition of fatty acid oxidation, when combined with MEK/ERK/KRASG12D inhibitors, exhibited synergistic anti-tumor effects, significantly reducing the growth of PDAC cell lines and organoids. This combination therapy also decreased tumor burden and improved overall survival in orthotopic cell line-derived and patient-derived xenograft (PDX) mouse models. These results provide novel mechanistic insights into the metabolic adaptations underlying resistance to KRAS signaling inhibition. These studies highlight fatty acid oxidation as a critical metabolic vulnerability in PDAC, offering a promising therapeutic target to enhance the efficacy of KRAS pathway inhibitors.

#6765 Antitumor activity of Selenopsammaplin A analog by targeting histone methyltransferase DOT1L in prostate cancer cells.

Jaeho Han, Sehun Yang, Woong Sub Byun, Sung Chul Jang, Eun Seo Bae, Chae Won Ock, Hyen Joo Park, Hyeung-geun Park, **Sang Kook Lee**

College of Pharmacy, Seoul National University, Seoul, Korea, Republic of

The overexpression of the disruptor of telomeric silencing 1-like (DOT1L), which is a specific methyltransferase for histone H3 at lysine residue 79 (H3K79), has been related to poor outcomes in patients with Castrate-resistant prostate cancer (CRPC). Therefore, targeting DOT1L is considered a potential therapeutic approach to overcome the significant medical challenges of CRPC. In our previous study, we designed selenopsammaplin A (SPA) analogs as non-nucleoside DOT1L inhibitors to suppress human breast cancer cell proliferation and metastasis. However, the antitumor activity and the precise underlying mechanism of SPA analogs in prostate cancer cells remain unclear. Herein, we administered SPA-10091-HCl, a DOT1L-targeting degrader, to effectively hinder the growth and DOT1L-mediated H3K79 methylation in CRPC (PC3 and DU145) cells. Mechanistically, SPA-10091-HCl selectively degrades DOT1L protein through the nuclear ubiquitin-proteasome pathway, thereby suppressing H3K79 methylation in CRPC cells. SPA-10091-HCl inhibits CRPC cell proliferation, migration, and invasion, with the E-cadherin expression upregulation and N-cadherin and vimentin expression downregulation. Additionally, prolonged SPA-10091-HCl treatment induced apoptosis by regulating apoptosis-associated protein expressions. Moreover, SPA-10091-HCl effectively inhibited tumor growth in the PC3 cells-implanted xenograft mouse model without any overt toxicity. These results indicate SPA-10091-HCl as a potential candidate for further development as a chemotherapeutic agent against CRPC.

#6766 Tetraarsenic hexoxide augments the anticancer effects of Artemisia annua polyphenols on both naive and oxaliplatin-resistant HCT116 colorectal cancer cells by downregulating CD44, EGFR and cyclinD1, and increasing DNA damages and intracellular vesicles.

Won Sup Lee[1], Eun Joo Jung [1], Hye Jung Kim[2], Sung Chul Shin[2], Gon Sup Kim[2], Jin-Myung Jung[1]

[1]Gyeongsang National Univ. Hospital, Jinju, Korea, Republic of,[2]Gyeongsang National Univ., Jinju, Korea, Republic of

We previously demonstrated that polyphenols extracted from Korean Artemisia annua L. (pKAL) exerted stronger anticancer activity on oxaliplatin-resistant HCT116 colorectal cancer cells (Oxp-R-HCT 116 cells) than parental HCT116 cells (p-HCT 116 cells). We also demonstrated tetraarsenic hexoxide exerts anticancer activity of pKAL on several cancer cell lines by suppressing NF-κB activity. In this study, we found that tetraarsenic hexoxide significantly enhanced the anticancer activity of pKAL on both Oxp-R-HCT 116 cells and p-HCT 116 cells. The aim of this study is to elucidate how tetraarsenic hexoxide enhance the anticancer effects of pKAL on Oxp-R-HCT 116 cells. CCK-8 assay, phase-contrast microscopy analysis, and morphological analysis with hematoxylin stain revealed that the anticancer effect of pKAL is more enhanced by tetraarsenic hexoxide on Oxp-R-HCT 116 cells even though anticancer effect of tetraarsenic hexoxide alone was not prominent on Oxp-R-HCT 116 cells. This phenomenon was not associated with suppression of some of oxaliplatin resistance-related upregulated proteins (Oxp-RR-Proteins) (β-catenin, neuclephosmin, and SOD), but was associated downregulation of cell survival- and stemness-related proteins (NF-κB, cyclin D1, EGFR, and CD44) that were not up-regulated in Oxp-R-HCT 116 cells. In addition, tetraarsenic hexoxide and pKAL combination treatment enhanced anticancer effect by induction of DNA damage and intracytoplasmic vesicles suggesting autophagic cell death.The detailed western blot analysis for anti-cancer effects of tetraarsenic hexoxide alone did not strongly suppress the expression of β-catenin(one of oxaliplatin resistance-related upregulated proteins) in p-HCT 116 cells as well as Oxp-R-HCT 116 cells while pKAL alone strongly suppressed it. In addition, tetraarsenic hexoxide and pKAL combination treatment enhanced LC3B and P62 while pKAL alone did not enhance them. N-acetylcysteine (NAC) strongly suppressed anticancer effect of induction of DNA damage and intracytoplasmic vesicles that suggested autophagic cell death on Oxp-R-HCT 116 cells. In conclusion, this study suggests that tetraarsenic hexoxide enhanced the anti-cancer effects pKAL by suppressing CD44, EGFR, and cyclin D1, and increasing DNA damages and intracellular vesicles that suggested autophagic cell death. In addition, the anticancer effects of tetraarsenic hexoxide on OXP-R-Hct 116 cells might be associated with cell survival related and ROS pathway, but not associated with downregulating Oxp-RR-Proteins of Oxp-R-HCT 116 cells.

#6767 Apurinic/apyrimidinic endonuclease 2 (APE2) mediates cisplatin ototoxicity by triggering MYH9-dependent mitochondrial toxicity in outer hair cells.

E. Irons[1], Q. Wang[2], W. Zhang[2], F. Zhao[1], M. Yin[2], B. Willard[2], Q. Zheng[1], B. Hu[3], J. Beach[4], R. Prayson[2], J. Yu[2], J. Lin[2], J. Zhao[2];
[1]Case Western Reserve University, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]University at Buffalo, Buffalo, NY, [4]Loyola University Chicago, Chicago, IL

Platinum compounds remain the backbone of chemotherapy regimens for a variety of solid tumors, despite their well-described adverse effects of nephrotoxicity, ototoxicity, and neurotoxicity. Cisplatin ototoxicity results from damage to the cochlear outer hair cells and remains a key dose-limiting toxicity in pediatric cancers, where its incidence reaches as high as 90% in testicular cancer patients. However, the mechanistic underpinnings of cisplatin ototoxicity remains incompletely understood and no treatments exist to prevent its onset. Here we describe a novel pathway mediating cisplatin-induced cell death in outer hair cells dependent on the base excision repair (BER) enzyme apurinic/apyrimidinic endonuclease 2 (APE2). APE2 was highly expressed in cochlear hair cells of patients with cisplatin ototoxicity compared to healthy controls. This was reproduced in vitro, where cisplatin rapidly upregulated APE2 expression and promoted its movement into the mitochondria within hours. APE2 suppressed the activation of ATR and p53 in response to cisplatin, instead promoting the mitochondrial translocation of p53 and intrinsic apoptosis. Knockdown of APE2 protected hair cells from cisplatin-induced apoptotic and non-apoptotic cell death in vitro. In a tamoxifen-induced Cre-lox transgenic mouse model, selective APE2 overexpression in cochlear outer hair cells resulted in loss of outer hair cells, disruption of cochlear architecture, and high-frequency hearing loss. Remarkably, this hearing loss was completely abrogated in mice that also harbored a knockout of MYH9, a non-muscle myosin that is mutated in rare genetic syndromes with hearing loss. We have observed MYH9 to be a binding partner of APE2 and now report that a specific interaction with the proximal coiled-coil domain of MYH9, adjacent to binding sites of its regulatory light chains, mediates this interaction. Consistent with the role of MYH9 in suppressing mitochondrial fission, we found that APE2 incapacitated oxidative phosphorylation and contributed to smaller, fragmented mitochondria. Our data demonstrate a novel mechanism in which the non-canonical DNA repair enzyme APE2 triggers cell death by inhibiting the DNA damage response and triggering MYH9-mediated mitochondrial damage, leading to the cochlear hair cell damage responsible for cisplatin ototoxicity. This work highlights a new therapeutic approach of targeting APE2 to mitigate the off-target toxicities associated with platinum medications.

#6768 Targeting the Her2 and ERα receptors has a significant impact on therapy-resistant ER-positive breast cancer.

DeZha Robinson[1], Hogyoung Kim[1], Alexandra Caroline Selico Dunn[1], Clark Jules Perkins[2], Sihyoung Kim[3], Sichan kim[3], Emily Lauren Schenk-Smith[1], Simak Ali[4], Matthew Burow[5], Emma Elkins[1], Christopher Williams[1]

[1]Division of Basic Pharmaceutical Science, Xavier University of Louisiana - College of Pharmacy, New Orleans, LA,[2]Biology, Xavier University of Louisiana College of Arts and Sciences, New Orleans, LA,[3]Xavier University of Louisiana College of Arts and Sciences, New Orleans, LA,[4]Department of Surgery and Cancer, Imperial College London, London, United Kingdom,[5]Medicine Hematology Medical Oncology, Tulane University School of Medicine, New Orleans, LA

Background: Resistance to endocrine therapy remains a significant clinical hurdle to the management of breast cancer. Mutations in the ESR1 gene (most frequently Y537S) are associated with metastatic disease recurrence in patients previously treated with endocrine therapy. We have shown that silmitasertib, a clinical phase CK2 inhibitor, can inhibit the proliferation of tamoxifen-sensitive and tamoxifen-resistant breast cancer cells in part by disrupting ERα/ERα variant expression. As such, we investigated the antiproliferative and antimigratory efficacy of silmitasertib in CRISPR-edited MCF-7 cells expressing ERαY5237S. Our findings suggest that pharmacological targeting of CK2 may represent an effective strategy in treating ERα-mutated, endocrine therapy-resistant BCa.
Methods: Using parental MCF-7 and MCF-7 ERαY537S cells, we assessed cell proliferation in the monolayer cultures, as well as 3D spheroid growth and wound healing activity using live cell imaging in the presence of silmitasertib. We measured the impact of CK2 inhibition on established mitogenic pathways by RT-PCR and/or immunoblot analysis (Her2, Cyclin D1, S6/pS6, S27, ERK/pERK). Subsequently, we assessed the efficacy of combined exposure to the HER2/EGFR inhibitor lapatinib with or without silmitasertib in both MCF-7 and MCF-7 Y537S cells.
Results: Our studies show that MCF-7 Y537S cells exhibit enhanced sensitivity to both antiproliferative and anti-migratory effects of silmitasertib compared to parental MCF-7 cells. HER2 was also overexpressed in MCF-7 Y537S, and the combination of lapatinib and silmitasertib, revealed an additive effect on cell proliferation.
Conclusion: Our studies suggest that the development of ERαY537S mutations in BCa results in enhanced sensitivity to growth inhibition elicited by CK2 blockade. Our studies provide a convincing rationale for the therapeutic targeting of CK2 in the context of ERα-mutated, endocrine-resistant breast cancer.

#6769 Zanubrutinib (zanu) overcomes BTK V416L resistance in B cell lymphoma models.

Haitao Wang[1], Xiaoyu Feng[2], Jinhong Ren[1], Lanyue Bai[2], Lin Li[1], Chao Cui[2], Lei Shi[2], Yang Li[1], Yangyang Wang[2], Jessica Li[3], Teiko Sumiyoshi[3], Yangbo Yue[2], Wei Jin[1], Zhirong Shen[2]

[1]BeiGene Ltd., Beijing, China,[2]BeiGene Ltd., Shanghai, China,[3]BeiGene Ltd., San Mateo, CA

Introduction: The second-generation BTK inhibitors (BTKis), e.g., zanu, acalabrutinib (acala), have further transformed the therapy landscape of chronic lymphocytic leukemia (CLL). However, acquired mutations in BTK (mainly at position C481) results in covalent BTKi resistance and disease progression. Non-covalent BTKi e.g., pirtobrutinib (pirto) can overcome C481 mutations, but is susceptible to other BTK mutations like the recently described kinase impaired V416L and L528W mutations, which both maintain downstream signaling. However, the impact of V416L on BTKi therapy remains not well characterized. Here, we investigated how V416L affects acala, zanu, and pirto response in B cancer cells.

Method: TMD8 BTK V416L cell lines were generated by CRISPR-Cas9 mediated gene editing. Kinase activity and phosphorylation of BTK Y223 were evaluated in V416L and wildtype (WT) TMD8 cells by Western blot. Structural modeling of human BTK was performed. Viability of TMD8 cells with V416L or WT was measured with CellTiter-Glo assay. Tumor growth inhibition (TGI) was measured in V416L and WT xenograft models. BTK occupancy in TMD8 cells was measured via ELISA with biotinylated probes.

Results: Western blot analysis demonstrates that V416L encodes a kinase with lower enzymatic activity compared to WT indicated by reduced phosphorylation of BTK Y223. However, BTK downstream signaling remains intact. Structural modeling predicts V416L leads to clashes in ATP binding, supporting impairment of kinase activity. TMD8 cells expressing V416L were more sensitive to zanu (IC50=0.8 nM) than to acala (IC50=144.4 nM) and pirto (IC50=2074.8 nM) in cell viability assays. Administration of a clinically relevant dose of zanu (20 mpk BID) resulted in significant regression of TMD8 V416L xenografts compared to vehicle ($p<0.0001$), while a clinically relevant dose of acala (4 mpk BID) did not achieve significant TGI. Neither a higher dose of acala (12 mpk BID) nor 50 mpk BID of pirto showed significant efficacy. Computational structural modeling predicts that V416L creates steric clashes with acala and pirto at the binding site, whereas zanu binding remains unaffected. Consistently, a BTK occupancy assay demonstrated that zanu, but not acala, can efficiently bind to V416L. Furthermore, western blot analysis shows efficient BTK downstream signal inhibition in V416L expressing TMD8 cells treated with zanu, whereas downstream signals are maintained in cells treated with acala and pirto.

Conclusion: These data demonstrate that zanu retains potent antitumor activity against TMD8 cells expressing BTK V416L, whereas acala and pirto may be attenuated by steric clashes. Thus, we hypothesize that clonal expansion of V416L is less likely to occur in patients with CLL treated with zanu, whereas it may lead to resistance in patients treated with acala or pirto. This hypothesis should be validated in clinical studies.

#6770 TFEB-dependent signals confer resistance against chemotherapeutic drug-induced nucleolar stress.

Marjorie Rolland, Florence McDuff, Laure Bessy, Benoit Marchand, **Marie-Josee Boucher**

University of Sherbrooke, Sherbrooke, QC, Canada

In addition to their main role in inhibiting cell growth, chemotherapeutic agents are also known to trigger protective signals that equip cancer cells with resistance mechanisms. Notably, treatment with chemotherapeutics has been associated with increased lysosome-related functions, such as autophagy, which protect cells from death. Our previous research showed that gemcitabine enhances autophagy and lysosomal function, particularly in HeLa and pancreatic cancer cells. However, the precise mechanisms through which this nucleoside analog elicits a protective autophagic response are still elusive. While gemcitabine is designed to interfere with DNA replication, it has also been noted to cause nucleolar stress. In our current study, we sought to determine if gemcitabine induces nucleolar stress and, if so, to examine whether this stress mimics the effects of gemcitabine by triggering a cytoprotective response. Our findings show that: 1) Gemcitabine induces nucleolar stress, indicated by the nucleoplasmic localization of nucleolin and nucleolar morphological changes. 2) Treatment of cells with the nucleolar stress inducer CX5461 leads to an autophagy and lysosomal response, monitored by increased LC3 and LAMP1 puncta, along with elevated levels of mature cathepsin B. 3) Additionally, CX5461-treated cells show an enriched nuclear localization of TFEB, the master regulator of autophagy and lysosomal function, detected by immunofluorescence and subcellular fractionation. The nuclear enrichment of TFEB correlates with the enrichment of faster migrating forms of TFEB (indicative of post-translational modification changes), as detected by immunoblotting. 4) Like gemcitabine, CX5461 impairs cell growth. 5) Nonetheless, clonogenic assays indicate that cells with reduced TFEB function (shTFEB) are more sensitive to CX5461 than control cells. 6) In parallel, shTFEB cells exhibit higher levels of apoptotic markers in response to CX5461 treatment, suggesting that TFEB confers resistance to nucleolar stress. Overall, our data provide the first evidence that nucleolar stress triggers a TFEB-dependent protective response. Conducted in cells without functional wild-type p53 signaling, our findings suggest that TFEB could act as a sensor of nucleolar stress, relaying a protective response and helping cells engage in timely and coordinated actions to cope with stress. Therefore, our results support the involvement of TFEB in chemoresistance. These TFEB-protective signals may be particularly relevant to cancers with high TFEB expression levels, such as pancreatic cancer.

#6772 Heterogeneity of *ex-vivo* tumor responses in primary ovarian cancer tissues.

Chiara Maestri, Ivan Trus, Rajeshwar Nitiyanandan, Jahanvi Kumar, Ricardo J. Parker, William Cance, **Christian Apfel**

SageMedic Corp., Redwood City, CA

Background: While most stage III and IV ovarian cancer patients respond to neo-adjuvant carboplatin and paclitaxel, not all do. Some experience recurrence within 6 months (platinum-resistant), others after 6 months, and a minority achieve remission beyond 5 years. Apart from BRCA mutations, genomic testing offers little guidance on patient-to-patient heterogeneity in tumor responses. To address this, we developed an internally validated functional profiling platform in a CLIA-certified and CMS accredited lab. Our goal was to measure in-vitro heterogeneity of tumor responses to NCCN-recommended treatments to identify the most suitable therapies for patients.

Methods: Ovarian cancer biopsies were shipped overnight and processed the same day using our proprietary functional profiling platform in a physiological culture system with around 2,000 viable cells per well. Tissues were exposed to up to 24 NCCN recommended therapies on the day after for 4 days, cytotoxicity readout with dose response curves within 7 days. Heterogeneity was assessed by the interquartile ratios of the EC50 drug concentrations. Not requiring organoid-like cell growth offers two advantages: a) actionable results for almost all patients and b) a fast turnaround time with an issued report within 10 days. Heterogeneity was evaluated using interquartile ratios of EC50 drug concentrations.

Results: A total of 17 ovarian cancer tissues were processed and exposed to up to 24 NCCN recommended therapies. Interquartile ratios (IQRs) of carboplatin and paclitaxel were 3.62 and 5.22 for the individual drugs, the IQR for the carboplatin/paclitaxel combination was 91.1, suggestive for synergy between both drugs in some, but not other cancer tissues. Gemcitabine's and cisplatin/gemcitabine IQRs were 39.8 and 17.9, respectively, suggestive that patient benefits to gemcitabine or platinum/gemcitabine combination may vary greatly. IQRs for doxorubicin and olaparib were only 5.8 and 3.2, owing to many tissues not showing any tumor response. All p-value comparisons for EC EC50s heterogeneity of tumor responses were <0.001.

Conclusions: Consistent with the clinically known patient-to-patient heterogeneity of tumor responses, such heterogeneities were also observed in our *in-vitro* tissue culture platform. Thus, these results warrant external validation of this already internally validated laboratory developed test (LDT).

#6776 Biological characterization of small molecule eIF4E inhibitors to assess their therapeutic potential in cancer.

Rachel L. O'Rourke[1], Emilio L. Cardenas[1], Jesse Duque[2], Amanda Falzetta[3], Jim Clauwaert[3], Jason Rech[4], John R. Prensner[3], Amanda L. Garner[1]

[1]Medicinal Chemistry, University of Michigan, Ann Arbor, MI,[2]Michigan Center for Therapeutic Innovation, University of Michigan, Ann Arbor, MI,[3]Pediatrics and Biological Chemistry, University of Michigan, Ann Arbor, MI,[4]Medicinal Chemistry, Vahlteich Medicinal Chemistry Core, University of Michigan, Ann Arbor, MI

The dysregulation of translation is a hallmark of cancer that enables rapid changes in the cell proteome to shape oncogenic phenotypes that promote tumor survival. The predominant signaling pathways leading to dysregulation of translational control in cancer are the PI3K-AKT-mTORC1, RAS-RAF-MAPK, and MYC pathways, which all converge on eukaryotic translation initiation factor 4E (eIF4E), an RNA-binding protein which binds to the m^7GpppX cap structure at the 5' end of mRNAs to initiate cap-dependent translation. eIF4E is the rate-limiting factor of translation initiation, and its overexpression is known to drive oncogenic transformation, progression, and chemoresistance across many cancers, establishing it as an attractive therapeutic target. Traditionally, target transcripts of eIF4E have been characterized as mRNAs with long 5'-UTR motifs, but recent studies point to context-dependent translation of eIF4E-sensitive transcripts that is contingent on the regulation status of eIF4E. Therefore, we hypothesize that mechanistically distinct eIF4E inhibitors will elicit different phenotypic responses in tumors based on the dysregulation of select pools of eIF4E-sensitive transcripts. Research in our laboratory focuses on developing mechanistically distinct eIF4E inhibitors, including m^7GpppX prodrug derivatives which bind directly to the cap-binding pocket of eIF4E. Efforts to characterize the effects of these molecules on cap-dependent translation regulation through cell-based phenotypic assays and ribosome profiling will be discussed.

#6777 Characterization of the dual MCT1 and MCT4 inhibitor MCT-IN-1 in MOC1 cell line demonstrates increased apoptosis and compensatory upregulation of glutathione conjugation gene sets.

E. V. Mastrolonardo, V. Diaz Barros, Z. Lin, **H. Samarah**, J. Jackson, A. J. Luginbuhl, A. Linnenbach, U. Martinez-Outschoorn, J. M. Curry;
Thomas Jefferson University, Sidney Kimmel Cancer Center, Philadelphia, PA

Background: Head and neck squamous cell carcinoma, like many solid tumors, upregulates glycolysis regardless of O2 availability via the Warburg effect, which results in accumulation of intracellular lactate. To avoid apoptosis from the resultant decreased pH, these cells export lactate via monocarboxylate transporters (MCT), primarily MCT1 and MCT4, with overexpression of MCT1 and MCT4 having been linked to poor prognosis.
Methods: Mouse Oral Cancer (MOC1) cells were treated with MCT-IN-1, a dual MCT1 and MCT4 inhibitor. Flow cytometry was utilized to characterize apoptosis and S-phase of the cell cycle. Bulk RNAseq data were obtained from both MCT-IN-1-treated and untreated MOC1 cells and analyzed with unbiased gene set enrichment analysis (GSEA). Leading edges of enrichment were analyzed by using the STRING database of protein-protein interactions.
Results: Treatment of MOC1 cells with MCT-IN-1 resulted in decreased tumor cell count ($p<0.01$), increased apoptosis ($p<0.01$), and reduced S-phase of the cell cycle ($p<0.01$) compared to untreated cells. Unbiased GSEA of bulk RNAseq data, contrasting MCT-IN-1 treated versus untreated cells, revealed upregulation of endoplasmic reticulum (ER) stress (NES 1.79, FDR=0.012), suggesting possible mechanism of cell death. In addition, the glutathione conjugation gene set was found to be upregulated (NES 1.75, FDR=0.016), suggesting a possible compensatory response mechanism. Further, GSEA revealed significant enrichment of the oxidative stress and redox pathway (NES 1.74, FDR=0.016), including glutathione transferase and oxidoreductase activities. STRING analysis of upregulations in gene expression revealed a dense protein-protein interaction network, suggesting coordinated roles in detoxification (FDR = 1.00e-16) and cellular stress response mechanisms (FDR = 2.61e-41) in MOC1 cells treated with MCT-IN-1.
Conclusions: We report the first characterization of the dual MCT1 and MCT4 inhibitor MCT-IN-1. Treatment of MOC1 cells in vitro with MCT-IN-1 induces tumor cell apoptosis possibly via upregulation of ER stress and further demonstrates upregulation of glutathione conjugation gene sets, suggesting a possible compensatory mechanism. Validation with in vivo studies and further evaluation of the exact mechanism of these findings are required.

#6778 Targeting the YAP-TEAD interaction in brain metastatic breast cancer cells.

Caitlyn C. Castillo, Mohamed Haloul, Philana Phan, Zongmin Zhao, Ekrem E. Er

University of Illinois at Chicago, Chicago, IL

Breast cancer metastasis to the brain is a devastating stage of breast cancer that presents with cognitive decline and seizures, and currently there are no treatments available. Brain metastases are resistant to immunotherapy, chemotherapy, and targeted therapies. This is partly because the blood-brain barrier and the blood-tumor barriers prevent effective delivery of these treatment modalities at clinically safe doses and partly because we do not know enough about the molecular mechanisms that govern breast cancer brain metastasis. Recent work in mouse models of breast cancer brain metastases revealed that the interaction between Yes Associated Protein (YAP) and Transcriptional Enhanced Association Domain (TEAD) family of transcription factors is an essential step in outgrowth of disseminated cancer cells. Here, we demonstrate a series of time-lapse imaging assays and luminescence based viability assays that we optimized to investigate the impact of YAP-TEAD inhibitors and chemotherapeutic agents on the viability of brain metastatic breast cancer cells *in vitro*. Our results will guide the prioritization of these treatment modalities in pre-clinical *in vivo* models. We will specifically investigate whether one or more of these agents can be loaded onto nanoparticle-engineered macrophages to better overcome blood-brain and blood-tumor barriers for effective delivery and targeted destruction of brain metastases.

#6779 The plant derived compound Simalikalactone D is a potent anticancer agent in triple negative breast cancer cells.

Joshua Nieves[1], Annelis Sanchez[1], Claudia Ospina[2], Pablo Vivas-Mejia[1]

[1]Biochemistry, University of Puerto Rico - Medical Sciences Campus, San Juan, Puerto Rico,[2]Natural Sciences and Mathematics, Interamerican University of Puerto Rico - Bayamon Campus, Bayamon, Puerto Rico

Despite recent advances in systemic therapy, Triple Negative Breast Cancer (TNBC)—accounting for 10-20% of breast cancer cases—remains the subtype with the worst prognosis, marked by a high risk of distant recurrence and death; thus, novel treatments are urgently needed for this deadly disease. Simalikalactone D (SKD) is a potential anticancer compound from *Simarouba tulae*, an endemic plant of Puerto Rico. We observed that the TNBC cells, MDA-MB 231 and MDA-MB 468 respond differently when treated with SKD. Thus, it is critically important to investigate the mechanism of action of SKD in TNBC cells. This study involved a comparative analysis in MDA-MB 231 and MDA-MB 468 cells, and their differential response to treatment with SKD. We performed Tandem Mass Tag (TMT)- based quantitative proteomics, followed by Ingenuity Pathway Analysis (IPA) protein expression analysis to identify distinctly active networks and signaling pathways along with different cellular behaviors between the TNBC cell lines.In the MDA-MB 468 cell line, SKD appeared to play a role in inducing apoptosis through Caspase 3 activation, with apparent PD-1/PD-L1 signaling in Death Receptor pathways. This correlates with reduced cell migration and adhesion in this cell line, which could suggest an apoptotic-mediated loss of integrity. Alternatively, the MDA-MB 231 cells did not show Caspase 3 activation, instead they exhibited an activation of autophagy pathways, including Macroautophagy and Late Endosomal Microautophagy (LEMA). After treatment of cells with SKD, LEMA appeared to act as a compensatory mechanism of survival when Autophagy was impaired. This emphasizes the role of cellular stress responses for maintaining cell viability under SKD treatment.This study highlights the influence of genetic and molecular differences on TNBC cell responses to SKD, reinforcing the clinical importance of personalized medicine. Therapeutic strategies using the genetic and molecular profiles of a patient's tumor could enhance treatment efficacy and improve outcomes, particularly for aggressive cancers like TNBC.

#6780 Discovering novel inhibitors of the chaperone Hsp90 for cancer treatment: A plant-based approach..

Chidera P. Ogbu, Taoufik Llbiyi, Vamsi Krishna Kommalapati, Ahmed Chadli

Augusta University, Augusta, GA

We investigated the effect of small molecules extracted from the latex of Calotropis procera (CPPE) to act as inhibitors of Heat Shock Protein 90 (HSP90), a key molecular chaperone co-opted by cancer cells for survival and proliferation. Current HSP90 inhibitors often activate the heat shock response, reducing their long-term efficacy. While CPPE has been shown to have toxic effects on cancer cells, its exact mechanism of action, including its potential to inhibit HSP90, has yet to be evaluated. Using flow cytometry, gene expression and protein quantification analysis, and mass spectroscopy techniques, we evaluated the effects of CCPE small molecules on triple-negative breast cancer cells (TNBCs) compared to 17-AAG, a known HSP90 inhibitor. We observed a dose-dependent increase in cell death with graded doses of CPPE compared to 17-AAG. Additionally, our findings from the MTT assay and flow cytometry demonstrated that treatment with CPPE led to a decrease in cell viability and the initiation of cell death pathways such as apoptosis and necrosis. Notably, western blot analysis suggests the absence of heat shock responses in cells treated with CPPE compared to 17-AAG. These findings support our hypothesis, indicating that small molecules present in CPPE show promise as candidates for HSP90 inhibitors. Further investigations to gain deeper insights into CPPE mechanisms as well as characterizing its bioactive compounds are ongoing. This research highlights the importance of natural product-based drug discovery in cancer treatment

#6781 Effect of Qingre Lishi Huoxue prescription on pyroptosis and the expression of related proteins caspase-3/GSDME in esophageal cancer cells.

Fuchun Si[1], Gao Si[2]

[1]Hunan University of Chinese Medicine, Henan, China,[2]Peking University Third Hospital, Beijing, China

Introduction: Esophageal carcinoma (EC) is one of the most common malignant tumors posing a threat to human's health, with a high disease incidence and the highest death rate in China. This study aims to screen out the Chinese herbs with strong inhibitory effects on the proliferation of four kinds of EC cells EC9706, EC-1, TE-1 and Eca109 from 300 Chinese herbs, and study the effect of Qingre Lishi Huoxue Prescription(QRLSHXP) on the proliferation and on pyroptosis-related proteins such as Caspase-3 and GSDME of four EC cells.
Methods: The MTT assay was used to assess the effects of 300 Chinese herbs alcohol extracts on the proliferation of the four esophageal cancer cell lines. Based on efficacy and safety profiles, selected herbs were combined to formulate a prescription. Dose-response relationships were determined. Cell morphology changes were observed under an inverted microscope. DNA damage was assessed using TUNEL staining. Lactate dehydrogenase (LDH) release was measured to evaluate cell membrane integrity. Cell death was analyzed using Annexin V/PI staining and flow cytometry. Western blotting and ELISA were performed to detect the expression levels of pyroptosis-related proteins and cytokines.
Results: Eight herbs significantly inhibited all four esophageal cancer cell lines in the initial screening. Toxic herbs were excluded. Four herbs—Sanye Danshen, Jiuguanxue, Shanchagen, and Huaxuedan—were chosen to create the Qingre Lishi Huoxue Prescription (QRLSHXP). This prescription inhibited the proliferation of the cancer cells in a dose- and time-dependent manner.QRLSHXP treatment induced severe cellular swelling, rupture, and content leakage in EC cells. TUNEL staining revealed increased DNA double-strand breaks, indicating enhanced DNA damage. Elevated LDH levels in supernatants suggested compromised membrane integrity. Flow cytometry showed a significant rise in Annexin V/PI double-positive cells, confirming cell death. Western blot analysis indicated increased Cleaved-Caspase-3 and GSDME-N expression, with unchanged total GSDME levels. ELISA results demonstrated significantly higher IL-1β and IL-18 levels in treated groups.
Conclusion: QRLSHXP effectively inhibited the proliferation of EC cells and induced pyroptosis, which was likely associated with the activation of the Caspase-3/GSDME pathway.

#6782 ACADS as a novel target of selinexor activity in diffuse large B cell lymphoma.

K. L. Trkulja[1], W. Tong[1], D. V. Tran[1], L. Meng[1], E. Teh[2], S. Penny[2], D. M. Pinto[2], A. Keating[1], J. Kuruvilla[1], R. C. Laister[1];
[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]National Research Council, Halifax, NS, Canada

Background: Diffuse large B cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma (NHL), with poor outcomes in the relapsed/refractory (R/R) setting. Recent years have identified nuclear export protein Exportin-1 (XPO1) as a negative prognostic factor in several cancer types such as DLBCL. Selinexor is an orally available inhibitor of XPO1 with activity in R/R DLBCL, but knowledge gaps in understanding how XPO1 drives DLBCL are preventing the drug's effective use in the clinic. Here, we analyzed selinexor's effects on DLBCL metabolism and conducted a mass spectrometry analysis of mitochondrial proteins to determine which proteins and pathways relevant to bioenergetics are modulated by selinexor in DLBCL.
Methods: DLBCL cell lines (HBL-1, OCI-Ly2, OCI-Ly8) were treated with selinexor for 24 hours and an XFe96 bioanalyzer was used to measure changes in mitochondrial and glycolytic ATP production. To identify factors driving changes in cellular metabolism, mitochondria were purified from DLBCL cell lines with and without treatment with selinexor. The mitochondrial preparations were digested with proteases and the resulting peptides were identified by mass spectrometry (MS). The sequences of metabolic proteins of interest were analyzed using the LocNES nuclear export sequence identifier (Xu et al., 2014) to determine which of these proteins might be canonical XPO1 cargo molecules. Additional validation of potential XPO1 cargo was performed via nuclear-cytoplasmic fractionation.
Results: Selinexor significantly reduced both glycolytic and mitochondrial ATP production in all cell lines, as measured by extracellular acidification rate and oxygen consumption rate. MS analysis identified 4224 proteins, of which 92 showed a statistically significant change in mitochondrial abundance with selinexor treatment; 61 of these were downregulated, while 31 were upregulated. Several metabolic proteins were affected by selinexor treatment, most notably short-chain acyl-CoA dehydrogenase (ACADS), which catalyzes lipid metabolism via short-chain fatty acid oxidation. ACADS showed a decreased mitochondrial abundance in response to selinexor treatment, suggesting a mechanism by which the drug exerts its metabolic effects via the inhibition of short-chain fatty acid oxidation. Upon further analysis, the primary sequence of the protein was predicted to contain a nuclear export sequence, and subcellular fractionation analysis showed nuclear accumulation of ACADS following selinexor treatment, identifying it as a potential novel XPO1 cargo molecule in DLBCL.
Conclusion: Selinexor inhibits glycolytic and mitochondrial metabolism in DLBCL, in part by blocking the nuclear export of enzymes involved in metabolism such as ACADS, which catalyzes short-chain fatty acid oxidation. Future work will further validate these targets of interest to reveal how selinexor exerts its cytotoxic effects in DLBCL.

#6783 ATM inhibitor AZD1390 sensitizes nasopharyngeal cancer cells to chemotherapy by reversing chemotherapy-induced autophagy.

Syrus Pak Hei Lai, Ngar Woon Kam, Victor Ho-Fun Lee

Department of Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong

Background: Nasopharyngeal carcinoma (NPC) is renowned for its high sensitivity towards chemotherapeutic agents. Nonetheless, chemoresistance remains a major reason for treatment failure in NPC. Ataxia telangiectasia mutated (ATM) has a diverse role in cellular homeostasis, regulating DNA damage response, apoptosis and autophagy. Pharmacological inhibition of ATM is hypothesized to disrupt the DNA damage response towards chemotherapy-induced DNA breaks, which in turn enhances the chemosensitivity of tumor cells. However, given the multifaceted role of autophagy in various cell death mechanisms, the interplay between autophagy and DNA damage response remains elusive. Therefore, we aim to investigate the therapeutical potential of ATM inhibitor AZD1390 in NPC via the regulation of autophagy.
Methods: Antitumor effects of AZD1390 in conjunction with cisplatin were evaluated on two NPC cell lines, NPC43 and C17. Cell lines were pretreated with AZD1390 for 2 hours prior to the administration of cisplatin for 72 hours. We assessed the anti-proliferative effects through annexin V/propidium iodide, CellTiter-Glo, XTT, clonogenic assay and cell cycle analysis. The mechanism of action and autophagic activity upon treatment of AZD1390 were examined by means of a combination of mass spectrometry, western blot, autophagy detection kit and immunofluorescence approaches.
Results: Cisplatin treatment with concurrent AZD1390 pretreatment enhanced the anti-proliferative effect in NPC cell lines compared to cisplatin alone. XTT, cell cycle analysis and colony formation assay revealed a reduced tumor cell clonogenicity and proliferation with an accumulation of cell population in the G0/G1 phase upon the combined treatment. However, no significant changes were observed in terms of apoptosis and necrosis. We observed that cisplatin treatment alone induced autophagy, whereas, in conjunction with AZD1390 pretreatment, the cisplatin-induced autophagy was reversed, indicated by the reduced autophagic activity detected by autophagy detection kit and the increased colocalization of LC-3 and lysosome in immunofluorescent staining. These findings were further supported by our mass spectrometry data that the mTOR signaling pathway, indicative of autophagy inhibition, was significantly enriched in cells treated with AZD1390 in combination with cisplatin as compared to cisplatin alone.
Conclusions: Our findings demonstrated that AZD1390 augments the sensitivity of NPC cell lines to chemotherapy through the reversion of chemotherapy-induced autophagy. Therefore, AZD1390 could potentially serve as a chemosensitizer in NPC treatment.

#6784 Effect of novel gold(I) compounds on cell proliferation and signaling protein expression in MDA-MB-231 breast cancer cells.

Alexis Pawlak, Talitha T. Rajah

DePaul University, Chicago, IL

Gold(I) compounds have been gaining prominence in research as alternative metallo-chemotherapeutic strategies against chemo-resistant tumors. However, the cellular and molecular mechanisms by which gold(I) compounds disrupt cellular processes critical to breast cancer cell proliferation are largely unknown. Our study evaluated the effect of eight novel gold(I) chloride compounds (Table 1) on MDA-MB-231 breast cancer cell proliferation and their mechanistic action on signaling proteins (Bax, Bcl_2, pERK1/2). Cell proliferation was assessed by the MTT assay for 24 to 72 hours, and protein expression was analyzed by western blotting and immunodetection after exposure to gold(I) chloride compounds at their respective IC_{50} concentrations. Our results indicate that except for PEt_3AuCl, all compounds inhibited cell proliferation across all exposure times. PCy_3AuCl, $PiPr_3AuCl$, PPh_3AuCl and PMe_3AuCl exhibited the greatest efficacy at low micromolar doses. PPh_3AuCl (2-fold) and PBu_3AuCl (2.5-fold) displayed high Bax/Bcl_2 ratios suggesting proapoptotic effects. All other compounds showed either decreased or unaltered Bax/Bcl_2 ratios. Each compound inhibited pERK1/2, with $PiPr_3AuCl$ (70%), PMe_3AuCl (64%), and PCy_3AuCl (52%) showing the greatest inhibition. Overall, our results suggest PCy_3AuCl, $PiPr_3AuCl$, and PMe_3AuCl inhibited cell proliferation at low micromolar doses most effectively in MDA-MB-231 cells and the cellular mechanism of action likely varies by compound. These could be through altered status of the cell proliferative pERK1/2 protein and/or the apoptotic proteins Bax or Bcl_2 in this cell line. This study provides new insights into the cellular mechanism by which these gold(I) compounds may exert their effects in this triple negative human breast cancer cell line and contributes to the growing evidence supporting the potential of gold(I) compounds in cancer therapeutics.

Table 1. Effect of Gold(I) Compounds on Cell Proliferation

Gold(I) Compound Name	**Concentration Range Tested (µM)**	**48 Hour IC_{50} (µM)**	**Proliferation Inhibition (48 hours) (%)**
PMe_3AuCl	0.1 - 7.5	0.94 ± 0.19	15.8 - 88.4
PEt_3AuCl	1 - 300	-	0 - 1.9
$PiPr_3AuCl$	0.1 - 7.5	0.56 ± 0.36	7 - 99.2
PBu_3AuCl	0.01 - 2.5	6.3 ± 0.39	0 - 45.7
$PtBu_3AuCl$	0.1 - 7.5	2.3 ± 1.2	0 - 98.6
(PTA)AuCl	1 - 100	69 ± 0.78	0 - 68.3
PCy_3AuCl	0.1 - 7.5	0.37 ± 0.21	16.3 - 98.6
PPh_3AuCl	1 - 15	1.78 ± 0.40	15.4 - 99.5

#6785 MicroRNA-lincrna cross-talk in BRCA1-mutated breast cancer and its therapeutic implications.

Olalekan Fadebi, Zodwa Dlamini, **Rahaba Makgotso Marima**

University of Pretoria, Pretoria, South Africa

Breast cancer remains one of the leading causes of cancer-related mortality, characterized by its complexity and resistance to therapy. Triple-negative breast cancer (TNBC), a particularly aggressive subtype, lacks targeted therapies, making it challenging to treat. Long intergenic non-coding RNAs (lincRNAs) have emerged as critical regulators in cancer biology, with lincRNA-BC7 identified as a potential modulator of BRCA1. However, the exact mechanisms through which lincRNA-BC7 interacts with BRCA1. This study investigated the functional role of lincRNA-BC7 in regulating BRCA1 activity and its contribution to the biological response of TNBC cells to Olaparib. Using in breast cancer *in vitro* models. The cell biological response of TNBC cell line (MDA-MB-231) to Olaparib compared to the control group was evaluated. Gene expression analyses by RT-qPCR was done using LincRNA-BC-7 and BRCA1 specific primers. Furthermore, *in silico* bioinformatics analysis to map the molecular pathways involved was employed. This study revealed that miR-663a (has-miR-663a) could act as a sponge for lincRNA-BC7, thereby influencing its stability and expression levels. This interaction leads to alterations in the expression of target genes involved in key cancer hallmarks such as epithelial-mesenchymal transition (EMT), invasion, and metastasis. The competitive endogenous RNA (ceRNA) networks provide a framework for understanding how these non-coding RNAs interact at the post-transcriptional level, potentially affecting the progression of BRCA1-related breast cancer. Notably, both LincRNA-BC7 and BRCA1 gene expression levels were downregulated in Olaparib treated TNBC cells. Understanding the interplay between miR-663a and lincRNA-BC7and how this ceRNA network affects BRCA1 mutated TNBC may open avenues for novel therapeutic interventions.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance in Molecular Targeted Therapies 5
Poster Session

#6789 Identification of DGKA as a regulatory factor for paclitaxel resistance in lung cancer based on CRISPR screen and transcriptome sequencing.

Jiang Luo, Mini Zhang, Jiawen Tang, Qingwei Wang, Yu Yuan, Min Xia, Yufei Yan, Yushuang Tan, Conghua Xie, **Yan Gong**

Zhongnan Hospital of Wuhan University, WuHan, China

Background: Lung cancer is the second most prevalent cancer with the highest mortality rate in the world. Paclitaxel (PTX) is one of the most effective clinical chemotherapeutic agents for the treatment of lung cancer, but a variety of mechanisms induce its chemoresistance including alterations in microtubule-associated proteins, up-regulation of drug efflux systems. Lipid metabolism was reported to impact chemosensitivity, but the underlying mechanisms are to be clarified. Therefore, this study aims to exploring the molecular mechanisms of PTX resistance regulated by lipid metabolism, and to discover novel PTX resistant targets and therapeutic agents.
Methods: Lipid metabolism related sgRNA library was used for CRISPR screen. PTX-resistant lung cancer cells were constructed for transcriptome sequencing. The key regulators were identified via integrating negative enriched genes in CRISPR screen and the differential ones in transcriptome sequencing. The regulation of PTX sensitivity by the key regulators was confirmed in deficient lung cancer cells. Transcriptome sequencing was applied to find downstream pathways, and immunoblotting and RT-qPCR were used to confirm the molecular mechanisms. Mouse models were used to investigate the safety and effectiveness of its inhibitors combined with PTX for lung cancer treatments in vivo.
Results: DGKA is highly expressed in PTX-resistant lung cancer cells, and its deficiency significantly induced PTX sensitivity in lung cancer cells. DGKA knockdown significantly inhibited lung cancer cell proliferation, invasion and migration. In addition, DGKA depletion promoted PYX-induced cell apoptosis and G2/M-phase arrest in lung cancer cells. Transcriptomics showed that the MAPK signaling pathway was significantly enriched after DGKA knockdown, and further experiments confirmed that DGKA inhibition increased lung cancer cell sensitivity to PTX via inhibiting ERK phosphorylation. DGKA inhibitor (R59022) could induce the PTX sensitivity of lung cancer cells safely and effectively *in vivo*.
Conclusion: DGKA promotes PTX sensitivity of lung cancer cells and alleviates PTX resistance through the MAPK pathway, providing preclinical evidence for targeting DGKA as a novel strategy for lung cancer therapy against PTX resistance.

#6790 Exploring sensitivity and resistance to proteasome inhibitors in *TP53* mutated non-small cell lung carcinoma.

Victoria Neely[1], Kranthi Kumar Chougoni[2], Bin Hu[3], Jennifer E. Koblinski[4], Guangrong Zheng[5], Daohong Zhou[6], Swati Palit Deb[7], Sumitra Deb[7], Jorge J. Nieva[2], Senthil K. Radhakrishnan[4], Steven R. Grossman[2], Hisashi Harada[8]

[1]Philips Institute for Oral Health Research, School of Dentistry, Virginia Commonwealth University, Richmond, VA,[2]Department of Medicine, Keck School of Medicine of USC, USC Norris Comprehensive Cancer Center, University of Southern California, Los Angles, CA,[3]Massey Comprehensive Cancer Center, Virginia Commonwealth University, Richmond, VA,[4]Department of Pathology, Massey Comprehensive Cancer Center, Virginia Commonwealth University, Richmond, VA,[5]Department of Medicinal Chemistry, College of Pharmacy, University of Florida, Gainesville, FL,[6]Department of Biochemistry and Structural Biology and Center for Innovative Drug Discovery, Long School of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX,[7]Department of Biochemistry & Molecular Biology, Massey Comprehensive Cancer Center, Virginia Commonwealth University, School of Meicine, Richmond, VA,[8]Philips Institute for Oral Health Research, School of Dentistry, Massey Comprehensive Cancer Center, Virginia Commonwealth University, Richmond, VA

Background: Non-small cell lung cancer (NSCLC) is the most common histologic subtype of lung cancer (~80%), with ~50% of tumors carrying a missense mutation in the *TP53* tumor suppressor gene (Onc-p53). These mutants often lead to the acquisition of oncogenic traits such as tumorigenesis and chemoresistance, as well as vulnerabilities that can be targeted for treatment, one of which being elevated basal levels of proteotoxic stress. We have previously shown that NSCLC cells expressing Onc-p53 exhibit elevated 20S proteasome activity which serves as a vulnerability for proteasome inhibitors (PIs) to further augment the proteotoxic stress levels, leading to the accumulation of reactive oxygen species (ROS). However, despite initial effectiveness, these Onc-p53 NSCLC cells develop resistance to PIs with the underlying mechanisms of this resistance remaining largely unknown.

Methods and Results: We have elucidated that bortezomib (BTZ)-induced ROS initiates a cascade including the activation and nuclear translocation of NRF2, followed by the induction of ATF3 and NOXA, and ultimately apoptosis. Furthermore, the combination of BTZ with the dual BCL-X_L/BCL-2 targeting BH3-mimetic compound (ABT-263) or a novel BH3-mimetic PROTAC (753B) synergizes with carboplatin, a standard of care chemotherapy, to selectively kill Onc-p53 NSCLC cells *in vitro* and *in vivo*. A second-generation PROTAC (WH244) also shows efficacy *in vitro*. We now show that the inductions of NRF2, ATF3, NOXA, and apoptosis are strongly suppressed in BTZ-resistant Onc-p53 NSCLC cells, generated by continuous culture in suboptimal doses of BTZ up to double its IC_{50}. Interestingly, the combination of BH3-mimetics with BTZ showed cytotoxicity even in BTZ-resistant cells, suggesting that higher doses of BTZ can be used to overcome BTZ-resistance. Bulk-RNA sequencing of BTZ-sensitive vs. BTZ-resistant cells further identified the induction of PD-L1. This induction was abrogated by BTZ-resistant cells, suggesting that immune checkpoint activation may be playing a role in the resistance to PIs observed in previous clinical settings.

Conclusion: In summary, our findings show that resistance to PIs such as BTZ in NSCLC tumors expressing Onc-p53 involves adaptations that reduce proteotoxic stress and may leverage immune checkpoint pathways. However, combining PIs with BH3-mimetics effectively restores cytotoxicity, even in BTZ-resistant cells. This suggests that targeting anti-apoptotic pathways alongside traditional therapies (e.g. the combination of BTZ, carboplatin, with either ABT-263 or 753B/WH244) could offer a powerful approach to overcome PI resistance in NSCLC, supporting the potential for PI-based precision combination therapies in NSCLC patients.

#6791 Evaluation of apoptotic and immune mediators in responsecurrent chemotherapeutic agents using murine breast cancer cell lines: The role of HSP70 and S100A9.

F. Ozcan[1], H. Alkan[2], F. Koksalar Alkan[2], A. Caglayan[2], S. Ozdatli Kurtulus[3], C. Jones[2], H. Korkaya[2];
[1]Faculty of Science, Istanbul University, Istanbul, Turkey, [2]Karmanos Cancer Institute, Wayne State University, Detroit, MI, [3]University of Health Science of Turkey, Istanbul, Turkey

Doxorubicin, Cytoxan and Docetaxel are commonly used chemotherapeutic agents in breast cancer treatment, primarily inducing cell death by different mechanisms. Combining these with novel compounds may enhance efficacy and reduce resistance. 4-HCP, active metabolite of Cytoxan has shown potential as an anticancer agent, and HSP70 and S100A9 are linked to cancer progression, immune response, and apoptosis. JG-231 is a small-molecule inhibitor targeting HSP70, disrupting its chaperone activity and inducing apoptosis, particularly in cancer cells. This study explores the effects of Doxorubicin, Docetaxel, and 4-HCP, combined with JG-231, on apoptosis and immune responses in EMT6 and 4T1 metastatic breast cancer cell lines, focusing on HSP70 and S100A9. Effective doses were determined by MTT assays based on dose-response curves. EMT6 and 4T1 cells were treated with Doxorubicin, Docetaxel, 4-HCP and JG-231, combined with JG-231 for 24 hours, and apoptotic/immune responses were analyzed through gene expression (Caspase-3, Caspase-7, Bax, Bcl-2, myc, Stat-1, TNF, HSP70, S100A9) using RT-PCR. Protein levels were validated by Western Blot, apoptotic cell death and changes in cancer stem cell populations by flow cytometry.Treatment with Doxorubicin, Docetaxel, and 4-HCP, combined with JG-231 significantly induced apoptosis in EMT6 and 4T1 cells. Increased Caspase-3 and Caspase-7 expression and a higher Bax/Bcl-2 ratio confirmed activation of apoptosis. Annexin V-positive cells were higher in treated groups, validating apoptosis induction. Furthermore, the cancer stem cell population was reduced, especially in the 4-HCP-treated group. HSP70 and S100A9 expression levels increased after treatment, highlighting their roles in stress response and immune modulation. These treatments elevated Stat-1, Caspase-3, Caspase-7, TNF, HSPA1A, HSPA1B, HSPA2 and S100A9, demonstrating a broader effect on apoptosis and immune response. While increased levels of Caspase indicate programmed cell death, higher Stat-1 and TNF levels may suggest immune mediated cytoprotection. These effect when combined with the elevated levels of stress-induced HSP1A/B, HSPA2 and inflammatory S100A9 correlates with inflammation and immune modulation. Together our findings may provide some evidence for stress-induced pathways and immune mediated cytoprotection in response commonly used chemotherapeutics in breast cancer and thus combining molecularly targeted therapeutics like JG -231 with standard of care may be more effective. This study was supported by the Scientific and Technological Research Council of TURKEY (TUBİTAK) Project no: 1919B022410990; 1059B192301226.

#6792 Understanding and enhancing cancer persister cell ferroptosis sensitivity.

Anna E. Stuhlfire, Masayoshi Higuchi, August F. Williams, Ariel H. Nguyen, David A. G. Gervasio, Claire E. Turkal, Suejean Chon, Matthew J. Hangauer

Department of Dermatology and Moores Cancer Center, UC San Diego, San Diego, CA

Cancer persister cells are a diverse subset of tumor cells that survive cytotoxic targeted therapy and contribute to tumor relapse. Identifying and exploiting persister cell vulnerabilities is a promising strategy to prevent acquired drug resistance. We previously showed inhibition of the antioxidant GPX4 selectively induces persister cell ferroptotic death.[1] However, the mechanism for persister cell sensitivity to ferroptosis is poorly understood. First, to address whether low cell density underlies persister cell ferroptosis sensitivity,[2] we generated high density persister cells using prolonged cytostatic drug treatments and found chronic drug stress induces ferroptosis sensitivity independent of cell density. We also performed scRNAseq analysis of persister cells treated with GPX4 inhibitor RSL3 and observed downregulation of oxidative phosphorylation (OXPHOS) genes and upregulation of antioxidant NRF2 target genes among persister cells which survive RSL3 treatment, indicating that OXPHOS and ROS are critical for persister cell ferroptosis sensitivity. Consistent with this, we found that inhibition of OXPHOS with metformin protects persister cells from ferroptosis. Therefore, persister cells depend on OXPHOS for survival[3] yet OXPHOS sensitizes persister cells to ferroptosis. We also explored how disulfiram, which has a wide variety of reported mechanisms of action, selectively kills persister cells.[4] We found that disulfiram-induced persister cell killing cannot be rescued by anti-ferroptosis antioxidants such as ferrostatin, but can be rescued with other antioxidants, indicating that persister cells are vulnerable to additional forms of oxidative death beyond ferroptosis. We then sought to identify additional drugs which could sensitize persister cells to ferroptosis and found that inhibition of the oxidoreductase FSP1, which serves as a backup anti-ferroptosis mechanism to GPX4, enhances GPX4 inhibitor-induced persister cell death. We also found that transient, nontoxic pretreatment with HDAC inhibitors sensitizes persister cells to subsequent single agent GPX4 inhibitor treatment in part by increasing persister cell ROS levels. These findings provide additional mechanistic understanding of the disabled persister cell antioxidant state and reveal therapeutic strategies which may be used to selectively induce ferroptosis in persister cells and potentially spare normal tissue.

#6793 Characterizing glucose transport at incremental stages of chemoresistance in melanoma.

Emily T. Wang[1], Abbey Michaelson[1], Amy E. Nielson[2], Rock J. Mancini[1]

[1]Miami University, Oxford, OH,[2]Astante Therapeautics, Cincinnati, OH

Multidrug resistance (MDR) presents major challenges in cancer treatment as cancer cells evolve to evade the effects of chemotherapy. This resistance is driven by various cellular mechanisms, including the overproduction of transport proteins that regulate the intake of essential nutrients and the removal of xenobiotics. While the mechanisms underlying drug efflux in MDR cancers are well studied, the role of carbohydrate transport proteins, like glucose transporters (GLUTs), remains poorly characterized as cells become increasingly resistant to chemotherapy. As interest grows in using glycoconjugation for targeted drug delivery, understanding how sugar transport and metabolism are altered in MDR cancers could be crucial for enhancing the specificity and efficiency of these strategies. In this study, we investigated GLUT expression in a melanoma cell line (B16-F10-Luc2) that was subjected to incremental concentrations of the anthracycline doxorubicin (DOX), ranging from 1 nM to 1 μM. As the cells acquired an MDR phenotype, we observed increased efflux activity and decreased cell proliferation rates. At the proteomic level, our analysis showed that GLUT1 and GLUT3 remain stable over the range of resistance levels, while GLUT2 exhibited minimal expression. Interestingly, GLUT4 was transiently upregulated at the 1 μM resistance level and demonstrated insulin responsiveness. We then evaluated GLUT activity and functionality by comparing glucose uptake under normal and starvation conditions and found that glucose deprivation had a limited impact on uptake in both non-resistant and resistant melanoma. To gain a comprehensive analysis into the genomic regulation of GLUTs and metabolic factors associated with MDR, we performed RNA-seq to reveal differential gene expression across various intermediate levels of DOX resistance. Collectively, our findings provide insights into the modular metabolic adaptations of MDR cancers, which could aid in the development of targeted therapies that address GLUT-related defects with drug resistance.

#6794 Elucidating mechanisms of cancer cell persistence to lorlatinib in ALK positive NSCLC.

Toshio Fujino[1], Darlan C. Minussi[2], Christina L. Anastasia[1], Emily Hensley[1], Satoshi Yoda[1], Mari Mino-Kenudson[3], Wei Ping[2], Katya Marjon[2], Xinmeng J. Mu[2], Marco Maruggi[2], Aaron N. Hata[1]

[1]Cancer Center, Masachussets General Hospital, Boston, MA,[2]Pfizer Inc., San Diego, CA,[3]Department of Pathology, Masachussets General Hospital, Boston, MA

ALK fusion-positive lung cancers exhibit deep and durable responses to ALK tyrosine kinase inhibitors (TKIs), however the emergence of acquired drug resistance is inevitable. Current targeted therapies are insufficient to eliminate all cancer cells within a tumor. So called drug tolerant “persister” cells (DTPCs) evade initial treatment, subsequently evolve mechanisms of acquired resistance, and drive disease relapse. Currently, our understanding of the underlying mechanisms driving DTPC survival and evolution in ALK+ fusion NSCLC, especially during treatment with the most advanced ALK lorlatinib, remains incomplete. To identify mechanisms and therapeutic vulnerabilities of DTPC survival in ALK+ NSCLC, we performed bulk and single-cell RNA-seq and ATAC-seq on ALK+ NSCLC patient-derived cell lines and PDX tumors before, during and after treatment with lorlatinib. Tumors exhibited robust initial responses to lorlatinib (> 50% of tumor reduction) followed by a stable residual disease phase and in some cases tumor regrowth after extended treatment, mimicking clinical treatment trajectories. Transcriptomic analysis revealed progressive upregulation of MAPK pathway signaling in DTPC cells in residual tumors and resistant cells in relapsing tumors. Furthermore, we discovered a sub-population of cells with stem-like features present in untreated and residual tumors, potentially representing a pre-existing cell state poised to evade lorlatinib treatment. Finally, we identified several tumor surface proteins upregulated in residual and relapsing tumors that could serve as potential targets for antibody drug conjugate therapies. These results reveal mechanisms driving survival and evolution of DTPCs and identify potential therapeutic targets to prevent resistance of ALK+ NSCLCs to lorlatinib.

#6795 Cystine deprivation overcomes protective effects of hypoxia on ferroptosis in high-grade serous ovarian cancer.

Zonghao Tang, Anil Sood

MD Anderson Cancer Center, Houston, TX

Iron is known to be crucial for high-grade serous ovarian cancer (HGSC) proliferation. HGSC tumors exhibit elevated iron levels compared to normal tissues, making it more susceptible to ferroptosis. Previous studies have shown that ferroptosis inducers can reduce both tumor growth and metastasis in ovarian cancer mouse models. Hypoxia is a prevalent feature of the tumor microenvironment and may protect HGSC from ferroptosis. Induction of ferroptosis can be triggered by inhibitors of GPX4 (GPX4i) or xCT (xCTi), prompting us to consider whether hypoxia may abrogate the induction of ferroptosis in HGSC cells. We tested multiple ovarian cancer cell lines (e.g., OVCAR3, OVCAR4, and OVCAR8) under normoxia and hypoxia. We used both hypoxia chamber (1% oxygen) and CoCl2 to mimic hypoxic conditions and found that both methods significantly inhibited GPX4i-induced ferroptosis by more than twofold (e.g. 5uM RSL3 decreased OVCAR4 cell viability by 80% under normoxia but only 50% under hypoxia), while only having a minimal effect on xCTi-induced ferroptosis. Given that xCTi blocks cystine import, we also examined whether hypoxia affects cystine deprivation-induced ferroptosis. Hypoxia did not protect HGSC cells from cystine deprivation-induced ferroptosis. In conclusion, our study suggests that hypoxia selectively blocks GPX4i-induced ferroptosis in HGSC, while cystine deprivation-induced ferroptosis remains effective, highlighting the potential of targeting cystine import as a more robust approach for treating HGSC.

#6798 Targeting SMAD4^{L535fs} in LNCaP prostate cancer cells: Implications for therapy resistance and sensitivity.

Chizhe Yi, Cindy Sin Ting Chow, Stephen Kwok Wing Tsui

The Chinese University of Hong Kong, Shatin, NT, Hong Kong

Introduction: Prostate cancer is the most common form of cancer and a leading cause of cancer-related death in men worldwide. This disease progresses from an androgen-dependent, non-metastatic state to a highly aggressive, metastatic, androgen-independent phenotype through various intrinsic genetic alterations. One crucial genetic alteration involves SMAD4, a tumor suppressor in the TGF-β signaling pathway, which plays a significant role in promoting aggressive tumor progression. Recent studies have reported that the knockdown of SMAD4 in prostate cancer cells, such as LNCaP, promotes resistance to therapies, including androgen deprivation therapy (ADT) and chemotherapy. The SMAD4^{L535fs} mutation has been implicated in altering cellular proliferation dynamics in LNCaP prostate cancer cells. This study investigates the impact of the SMAD4^{L535fs} mutation on LNCaP prostate cancer cell proliferation and response to chemotherapeutic agents.

Methods: LNCaP prostate cancer cells expressing SMAD4^{WT} and mutant SMAD4^{L535fs} were used to evaluate cell proliferation and viability. Cells were cultured under androgen deprivation conditions and treated with enzalutamide, gemcitabine, or ferroptosis inducers (erastin, ferrostatin-1). Cell viability and spheroid proliferation were assessed using CCK-8 and CellTiter-Glo assays over 72 hours. Apoptosis induction by enzalutamide was evaluated using Annexin V/PI staining. To assess the effects of DNA damage, LNCaP cells were treated with gemcitabine (10 μM), a DNA-damaging agent. For ferroptosis assessment, LNCaP cells were treated with ferroptosis inducers, including erastin (10 μM) and ferrostatin-1 (10 μM), for 72 hours.

Results: SMAD4^{L535fs} significantly enhanced the proliferation of LNCaP spheroids compared to the wild type under androgen deprivation and enzalutamide treatment.Viability assays demonstrated increased resistance to gemcitabine in SMAD4^{L535fs} cells, suggesting a role for SMAD4^{L535fs} in mediating chemoresistance.LNCaP cells treated with ferroptosis inducers showed differential responses, indicating that SMAD4^{L535fs} may influence susceptibility to ferroptosis.

Conclusion: SMAD4^{L535fs} enhances the proliferation and chemoresistance of LNCaP prostate cancer cells, providing insight into potential therapeutic targets for overcoming drug resistance. Further studies are required to elucidate the molecular mechanisms underlying SMAD4^{L535fs}-mediated ferroptosis resistance.

#6799 The interaction of notch signaling and P53 reactivation in endometrial and ovarian cancer therapy.

Daisy Belmares-Ortega[1], Lane E. Smith[1], Jamie L. Padilla[1], Geneva L. Williams[1], Robert J. Lake[1], Hua-Ying Fan[1], Kimberly K. Leslie[2]

[1]Division of Molecular Medicine, University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]University of New Mexico Health Sciences Ctr., Albuquerque, NM

Across all cancer sites, uterine and uterine cervix cancers have worsened in survival outcomes within the last few decades. Among cancers of the female reproductive organs, endometrial cancer remains the most commonly diagnosed malignancy and is now the most lethal. Deaths from endometrial cancer surpassed those from ovarian cancer just this year. The most aggressive endometrial cancers, serous adenocarcinomas, arise from mutations in p53, leading to loss of the tumor suppressive functions of wild type p53. Endometrial serous adenocarcinomas and ovarian cancers are both associated with an increased recurrence risk. Another aberrant pathway involved in endometrial cancer cell proliferation is Notch signaling, which is hyperactive in the most aggressive endometrial and ovarian cancers. MicroRNA (miRNA) expression profiles have been studied and reveal a signaling protein, NOTCH2 is a likely target related to recurrence. To study the relationship between p53 mutations and Notch signaling, endometrial adenocarcinoma and recurrent ovarian cancer cell lines including KLE, AN3CA, and PEO4 were employed for these studies due to their overexpression of Notch signaling (AN3CA), mutated p53 status (KLE, AN3CA, and PEO4), and as a cancerous recurrence model (PEO4). The curcumin-analogue AKT-100 was utilized as a mutant p53 reactivator agent in our studies to recreate the wild type p53 pro-apoptotic transcriptome. Additionally, our studies included a key down-regulator of the Notch-signaling pathway, auranofin. Auranofin as a Notch inhibitor can be used to prevent recurrence. While AKT-100 and auranofin were active in both cell lines as single agents, KLE cells were less sensitive to Auranofin due to low Notch signaling at baseline compared to AN3CA cells with high baseline activation of Notch. Interestingly, single agent AKT-100 treatment of KLE cells resulted in enhancement of the Notch signaling pathway as a resistance mechanism. This finding set the stage for the dual treatment of KLE cells with AKT-100 and Auranofin to prevent Notch upregulation. The combination of AKT-100 and Auranofin was highly synergistic (Combinatorial Index = 0.25). To confirm the mechanism of drug synergy, RNA sequencing, target protein expression and chromatin immunoprecipitation studies will be employed to confirm the effect of each agent on p53 and Notch signaling. These studies identify a novel combinatorial drug regimen tailored for the treatment of the most aggressive endometrial and ovarian cancers and identify an important mechanism underlying drug synergy.

#6800 Extracellular ATPase inhibitor-chemotherapy treatment of macrophages increases danger signal extracellular ATP to induce inflammatory pyroptotic cell death.

Jasmine M. Manouchehri, Mathew A. Cherian

The Ohio State University Wexner Medical Ctr., Columbus, OH

Among cancers in women worldwide, breast cancer has the highest incidence and takes the most women's lives. Patients with triple negative breast cancer (TNBC) experience worse outcomes than the patients diagnosed with hormone-dependent and human epidermal growth factor receptor-positive breast cancers because of the aggressive and rapidly progressive nature of breast cancer and the shortfall in the availability of specifically targeted therapies for TNBCs. Therefore, there is a demand for unique and fresh therapeutic approaches especially for TNBCs. Extracellular ATP (eATP) has been demonstrated to cause cell death in an autocrine and paracrine manner and is also a known danger signal that causes immune activation. Our previously published data reveals that at high micromolar concentrations eATP can induce cell death through the purinergic P2RX7 and P2RX4 receptors. We also demonstrated that eATP modulates TNBC cell death in the presence of chemotherapy. Despite this, eATP is rapidly degraded to adenosine by extracellular ATPases (eATPases). It should be noted that eATP release and activation of its receptor, P2XR7, are prerequisites for the activation of a complex of proteins known as the NLRP3 inflammasome and subsequent activation of caspase 1 which can lead to the induction of a highly inflammatory form of programmed cell death known as pyroptosis. It is particularly notable that the cell type most associated with this inflammatory form of cell death is macrophages, so we found it compelling to evaluate the effects of ATP signaling in macrophages. The objective of this study was to examine if the application of eATPase inhibitors will augment eATP release from chemotherapy-treated monocytic THP-1 and differentiated THP-1 cells and induce an inflammatory form of cell death known as pyroptosis. We previously showed that heparan sulfate inhibits multiple families of extracellular ATPases. Hence, we treated differentiated THP-1 cells with increasing concentrations of paclitaxel in the presence and absence of five different heparinoids that inhibit heparinase with cell viability and eATP being assessed. Furthermore, we found that there was an increase in caspase 1 activity, indicating increased pyroptosis, in monocytic THP-1 and differentiated THP-1 cells with the combined treatment of the E-NTPDase inhibitors PSB 069 or POM-1 and paclitaxel compared to paclitaxel treatment alone. These results show that eATP modulates monocytic THP-1 and differentiated THP-1 cells responses to chemotherapy, which could be advantageous to sensitize the anticancer effects of macrophages on TNBC cells. The development of efficacious therapies could stimulate an increase the depth and length of responses to chemotherapy and immunotherapy in TNBCs through pyroptosis induction of tumor associate macrophages through enhanced eATP.

#6802 RLIP depletion promotes apoptosis in ovarian cancer.

S. S. Singhal, M. Krishna, P. Kulkarni, D. Horne, R. Salgia;
City of Hope National Medical Center, Monrovia, CA

Ral interacting protein (RLIP) is a multifunctional protein localized and distributed in the plasma membrane, cytosol, and nucleus of the cell. RLIP is ubiquitously expressed in various tissues, including the ovary. In tumorigenesis, RLIP emerges as a common feature for solid tumor growth. RLIP is an anti-apoptotic non-ABC glutathione (GSH)-conjugate transporter involved in receptor-ligand endocytosis, as well as in multispecific drug transport and resistance. The presence of RLIP appears to be indispensable for cancer cells as indicated by its overexpression in various malignant cell lines. Partial inhibition and or depletion of RLIP using antibodies or antisense in the absence of chemotherapy drug causes apoptosis in multiple ovarian cancer (OC) cell lines; in the presence of carboplatin, marked synergy is observed *in vitro* as well as *in vivo*. These findings indicate that RLIP is a good target for cancer cell killing, and that its down-regulation would promote apoptosis through both drug-dependent and drug-independent effects. To examine the effect of specific RLIP depletion on apoptosis, we tested the effect of RLIP antisense in a number of OC cell lines. Growth inhibition and apoptosis were observed in all cases upon RLIP depletion. Cytotoxic synergy between RLIP antisense, RLIP antibodies, and carboplatin was examined in cell culture and xenografts of OVCAR8 OC cells. RLIP inhibition by antibodies was equally as effective as antisense and enhanced carboplatin efficacy in OC xenografts. Taken together, these results show that RLIP is a rational and promising new target for OC therapy. (This work was supported in part by the Department of Defense grant W81XWH-22-1-0331. Funding from the Beckman Research Institute of City of Hope is also acknowledged).

#6803 RNF5-DNAJA1 axis dictates selinexor sensitivity of multiple myeloma by regulating mitochondrial function.

Mengqi Wang

Tianjin Medical University, Tianjin, China

Selinexor is a First-in-Class XPO1 Inhibitor approved for relapsed or refractory multiple myeloma (RRMM), but the overall response rate remains unsatisfactory. The main mechanism by which Selinexor kill MM cells is to suppress the export of tumor suppressor proteins and oncoprotein mRNAs, however other key underlying mechanisms need to be investigated. Here, using a proteomics of nucleocytoplasmic separation assay, we discover that a ring finger containing E3 ligase, RNF5, is a cargo substrate of XPO1 and its nuclear-cytoplasmic transport is correlated with poor clinical therapeutic response. In the interactome of XPO1, we identify that DNAJA1 is a new partner of RNF5 and catalyzes K29-linked polyubiquitination of DNAJA1, which strengthens the interaction between DNAJA1 and HSP70, consequently and antagonizes the interaction of HSP70 and HSF1, therefore activates UPR^{mt} activation and mitochondrial protection. Thus, administration of RNF5 inhibitor inh-02 and DNAJA1 inhibitor 116-9e disrupts UPR^{mt} balance and sensitizes selinexor *in vitro* culture cell lines and in the xenograft and Vk*Myc mouse models. Collectively, our study elucidates the machinery of XPO1-RNF5-DNAJA1 axis in regulating mitochondrial function, and sheds light on developing new strategies to improve the efficacy of treating RRMM patients.

#6804 Sanguinarine overcomes osimertinib resistance by inducing HMOX1-related ferroptosis in osimertinib resistant cells lines and tumors.

Rongzhong Xu, Liubing Lin

Shanghai Municipal Hospital of Traditional Chinese Medicine, Shanghai, China

Epidermal Growth Factor Receptor (EGFR) gene, as a crucial oncogenic driver, plays a significant role in the occurrence and progression of non-small cell lung cancer (NSCLC). Osimertinib, as the latest generation of EGFR tyrosine kinase inhibitors (TKIs), has shown remarkable efficacy not only in patients with EGFR-sensitive mutations but also in those with rare EGFR mutations. However, similar to patients treated with first- or second-generation EGFR-TKIs, those treated with osimertinib eventually develop resistance Therefore, it is crucial to investigate the mechanisms of resistance and identify novel, rational strategies and drugs to overcome acquired resistance. Here we demonstrated that Sanguinarine, a natural benzophenanthridine alkaloid derived from rhizomes of the plant species Sanguinaria canadensis, which induces ferroptosis in osimertinib-resistance cells, leading to cell death. In this study, we found that sanguinarine induced more cell death in osimertinib-resistant cell lines, compared to osimertinib-sensitive EGFR-mutant cell lines. RNA-seq showed that sanguinarine increased higher expression level of HMOX1 in osimertinib-resistant cell lines than osimertinib-sensitive EGFR-mutant cell lines. Moreover, compared to osimertinib-sensitive cell lines, sanguinarine induces more ROS production, increases Fe^{2+} concentration, and promotes more ferroptosis in osimertinib-resistant cell lines. Interestingly, we found that HMOX1 levels are elevated in tissues from patients with EGFRm NSCLC who relapsed from EGFR-TKI treatment. Also, Osimertinib and other EGFR-TKIs up-regulate HMOX1 expression in EGFRm NSCLSC cells and tumors. Enforced expression of an ectopic HMOX1 gene in Osimertinib-sensitive EGFRm NSCLC cells increased the sensitivity of cells to sanguinarine by inducing more ferroptosis, whereas knockdown of HMOX1 in Osimertinib-resistant cell lines conferred resistance to sanguinarine. Importantly, sanguinarine inhibited more effective in osimertinib resistant EGFRm NSCLC xenograft in vivo than in osimertinib sensitive models. Together, compared to osimertinib-sensitive cell lines, sanguinarine induces more ROS production and increases Fe^{2+} concentration results in more ferroptosis in osimertinib-resistant cell lines. This difference may be due to the overexpression of HMOX1 in Osimertinib-resistant cells, making them more susceptible to the effects of sanguinarine.

#6805 DKC1 promotes colorectal cancer progression and therapy resistance by dysregulating sphingolipid biosynthesis.

U. K. Khan[1], A. Goel[1], S. Nigam[1], N. Chaudhary[2], A. Bajpai[1], A. Praveen[1], A. Shendre[1], S. Carskadon[3], A. Kapoor[4], A. Tewari[4], A. Chandra[5], S. N. Dalal[2], N. Palanisamy[6], B. Ateeq[1]; [1]Indian Institute of Technology Kanpur (IIT Kanpur), Kanpur, India, [2]Advanced Centre for Treatment, Research and Education in Cancer, Tata Memorial Centre, Navi Mumbai, India, [3]Vattikutti Urology Institute, Henry Ford Health System, Detroit, MI, [4]Regency Hospital, Kanpur, India, [5]King George's Medical University, Lucknow, India, [6]Henry Ford Health System, Detroit, MI

Colorectal cancer (CRC) is the second most frequent lethal malignancy globally. It has been associated with limited treatment effectiveness in most cases, leading to modest clinical outcomes with first-line therapies. Despite the recent advancements in the treatment modalities, most patients fail to respond by switching to alternative bypass mechanisms and acquiring drug resistance. This emphasizes an urgent need to discover the underlying mechanistic circuitry in CRC pathogenesis and explore alternative robust drug targets to overcome the lack of treatment response thereby improving the patient's survival. In addition, molecular heterogeneity associated with tumor profiles also influences treatment outcomes, prompting a fundamental need for molecular characterization of colorectal tumors to design targeted therapies. Here, we used a bottom-up approach to delineate the clinical significance of *Dyskerin pseudouridine synthase 1* (*DKC1*) in CRC patients. We observed elevated DKC1 levels in tumor specimens compared to adjacent normal tissue, associated with aggressive disease and poor recurrence-free survival. Moreover, patients acquiring resistance against standard treatment regimen (FOLFOX/FOFIRI) showed increased expression of DKC1. Importantly, loss-of-function studies suggest high DKC1 imparts oncogenicity by promoting cell cycle progression, suppressing cell death, and conferring stem cell-like phenotype. Notably, gene signature profile from DKC1-high patient tumors exhibit similarity to Consensus Molecular Subtype 2 (CMS2) of CRC. We deciphered a positive feedback loop operating between canonical WNT signaling and DKC1, responsible for orchestrating DKC1 expression and its associated tumorigenicity. Comprehensive lipidomic and transcriptomic analyses reveal perturbed sphingolipid metabolism and an abundance of very-long-chain fatty acid ceramides, particularly Cer(d18:2/23:0) and Cer(d18:1/24:0) in DKC1-positive CRC. Mechanistically, Co-IP and ChIP-PCR results confirmed that DKC1 and SOX2 together drive the expression of *SGPP2,* modulating sphingolipid biosynthesis and targeting *SGPP2* in DKC1-positive CRC alleviates oncogenic properties. Taken together, we demonstrate that elevated DKC1 expression imparts chemoresistance, and pharmacological inhibition of DKC1 and WNT signaling effectively attenuates the growth of therapy-resistant patient-derived organoids as well as CRC cells in a synergistic manner. Conclusively, we propose the DKC1/WNT axis as a promising therapeutic target for chemotherapy non-responding CRC patients. The study also highlights the utility of complex sphingolipids as a plasma-based biomarker providing a new paradigm for the non-invasive diagnosis of advanced-stage CRC patients.

#6806 Deciphering the role of BRD2 in acute adaptive response to BET inhibitors across cancers.

Suyakarn Archasappawat, Eunjung Lee, Chang-il Hwang

University of California, Davis, Davis, CA

Bromodomain and extraterminal motif (BET) inhibitors, such as JQ1, are a promising therapeutic strategy against cancer, targeting key epigenetic regulators, particularly BRD4. However, resistance to BET inhibitors poses a significant challenge, necessitating a deeper understanding of adaptive mechanisms. Here, we identified the upregulation of BRD2, another member of the BET protein family, as a conserved response to BET inhibition across multiple cancer types. We hypothesize that this upregulation facilitates cellular adaptation to treatment, reducing drug efficacy and potentially contributing to resistance over time. To test this, we performed BRD2 knockdown, demonstrating that BRD2 depletion sensitizes pancreatic cancer cells to BET inhibitors in vitro. Furthermore, a combination of BRD2 knockdown with JQ1 treatment significantly impaired tumor growth in vivo. Mechanistically, ChIP-seq analysis of BRD2 and BRD4 occupancy upon JQ1 treatment revealed that BRD2 and BRD4 share common binding sites. JQ1 caused a substantial loss of BRD4 from chromatin, while BRD2 was modestly affected. Although JQ1 has a higher affinity for BRD4 than for BRD2, our data suggest that higher cellular abundance of BRD2 compensates for BRD4 function under BET inhibitor treatment, thereby contributing to adaptive resistance and sustaining essential transcriptional programs. These findings highlight BRD2 as a key player in the adaptive response to BET inhibition and a potential therapeutic target to enhance the efficacy of BET inhibitors in pancreatic cancer and other malignancies.

#6807 Targeting EZH2 to overcome osimertinib resistant non-small cell lung cancer.

Christian M. Gosser[1], Xiulong Song[1], Dave-Preston Esoe[1], Avery R. Childress[1], Daniel R. Plaugher[1], Kassandra J. Naughton[1], Riya J. Patel[1], Ryan A. Goettl[2], Jinpeng Liu[2], Christine F. Brainson[3]

[1]Department of Toxicology and Cancer Biology, University of Kentucky, Lexington, KY,[2]Department of Internal Medicine, Markey Cancer Center, University of Kentucky, Lexington, KY,[3]Department of Toxicology and Cancer Biology, Markey Cancer Center, University of Kentucky, Lexington, KY

Non-Small Cell Lung Cancer (NSCLC) is a continual issue across the United States as the leading cause of cancer-related mortalities. Within NSCLC, Epidermal Growth Factor Receptor (EGFR) mutations have emerged as a main genetic driver. Treatment for EGFR mutated lung cancers has evolved over the past two decades, starting with the EGFR tyrosine kinase inhibitors gefitinib and erlotinib, and more recently moving to osimertinib. These treatments are typically successful initially, but resistance to EGFR inhibitors is inevitable for many patients. Findings ways to overcome the myriads of resistance mechanisms that can occur is the key improving treatment outcomes. Our lab studies the Polycomb Repressive Complex 2 (PRC2) that contains the subunit Enhancer of Zeste Homology 2 (EZH2). PRC2 is an epigenetic methyltransferase that facilitates histone H3 lysine 27 tri-methylation (H3K27me3) to silence gene expression. EZH2 has been implicated in many cancers may potentially drive treatment resistance. Our hypothesis is that inhibition of EZH2 will overcome osimertinib resistance by blocking the oncogenic signaling driven by the transcription factor c-MYC. To test our hypothesis, PC9, PC9GR4, and HCC4006 were all made resistant to osimertinib with IC_{50}s of 1μM and above. Following generation of acquired resistance, we found that treatment with the EZH2 inhibitor tazemetostat (EPZ6438) was able to resensitize cell lines to osimertinib. In PC9GR4OR this re-sensitization was accompanied by increased apoptosis. We next tested two cell lines, PC9GR4OR and HCC4006OR, as *in vivo* xenografts, and showed that combination of osimertinib and EPZ6438 led to significant tumor regression that was not achieved by either drug alone. Next, to understand mechanisms of resistance, we performed RNA sequencing on both parental and osimertinib resistant lines treated with vehicle, EPZ6438, osimertinib, or both. GSEA analyses showed that resistance mechanisms for the three lines were not the same. PC9OR upregulated cell cycle targets and c-MYC targets, HCC4006OR upregulated oxidative phosphorylation and c-MYC targets, and PC9GR4OR had an increase in cholesterol homeostasis. RT-qPCR analyses also showed that combination treatment increased antigen presentation (*HLA-A*) and lowered PD-L1 (*CD274*). This combination of changes may produce tumors that are more susceptible to immune surveillance, or that respond better to immune checkpoint inhibitors. Overall, this work highlights the ability of inhibiting EZH2 to overcome multiple osimertinib resistance mechanisms in human lung cancer cells and suggests that this drug combination may prolong the treatment benefit for many lung cancer patients. This work was funded by: Markey Women Strong, Markey STRONG Scholars Program through the American Cancer Society IRG-22-152-34 (HY), T32 CA165990 (DRP), R01 CA237643 + Cure Supplement (CFB, CMG), R01 HL170193 (CFB), P30 CA177558 (Markey Shared Resources)

#6808 DOCK1 as a therapeutic target for EGFR resistance in cholangiocarcinoma.

Kishor Pant[1], Kory Engelstad[1], Estanislao Peixoto[1], Ainhoa Lapitz[2], Jesus M. Banales[3], Adrian Mansini[4], Sergio A. Gradilone[1]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]Biodonostia Health Research Institute - Donostia University Hospital, University of the Basque Country (UPV/EHU), San Sebastian, Spain, San Sebastian, Spain,[3]Biodonostia Health Research Institute - Donostia University Hospital, University of the Basque Country (UPV/EHU), San Sebastian, Spain,[4]Rush University Medical Center, Chicago, IL

Cholangiocarcinoma (CCA) is an aggressive cancer of the bile ducts, characterized by poor prognosis and limited treatment options due to late-stage diagnosis and resistance to targeted therapies. Mutations in critical pathways, including the Epidermal Growth Factor Receptor (EGFR) and Fibroblast Growth Factor Receptor (FGFR), drive CCA progression, while resistance mechanisms and mutation weaken the effectiveness of available therapies. Dedicator of Cytokinesis 1 (DOCK1), a guanine nucleotide exchange factor, has emerged as a key player in cancer progression, particularly in modulating cell signaling. In this study, we investigated the therapeutic potential of targeting DOCK1 in CCA via modulating EGFR signaling. Our assessment across five distinct patient cohorts demonstrates that DOCK1 is significantly overexpressed in CCA tumors compared to normal cholangiocytes, underscoring its pivotal role in promoting tumor growth and aggressiveness. Pharmacological inhibition of DOCK1 using the small-molecule inhibitors CPYPP and TBOPP, as well as siRNA-mediated knockdown, resulted in a marked reduction in HuCCT1 and EGI1 CCA cell lines proliferation and migration. This was accompanied by an increase in tumor suppressor proteins p53 and p21, along with a decrease in proliferation markers PCNA and cyclin D1. Moreover, siRNA-mediated reduction of DOCK1 expression significantly induced apoptosis and cytotoxicity, accompanied by elevated levels of cleaved caspase-3 and PARP1, highlighting its role in driving cell death resistance in CCA. Furthermore, DOCK1 inhibition disrupted EGF-stimulated EGFR phosphorylation and downstream signaling through Erk1/2, a critical pathway supporting tumor growth, survival, and therapeutic resistance. These findings position DOCK1 as a central enhancer of EGFR-mediated oncogenic signaling, playing a key role in the aggressive phenotype and therapeutic resistance of CCA. Targeting DOCK1 not only suppressed tumor cells proliferation but also enhanced cell death, offering a dual therapeutic advantage. Our study provides strong evidence supporting DOCK1 as a promising therapeutic target and suggests that its inhibition, particularly in combination with EGFR-targeted therapies, could overcome EGFR mutant and drug resistance mechanisms and improve clinical outcomes in CCA. By unveiling this novel therapeutic strategy, our research lays the foundation for advancing more effective and stable treatments for this aggressive and often deadly malignancy.

#6809 IFITM3/MET axis drives osimertinib resistance through Akt pathway activation in *EGFR*-mutant lung cancer.

Ritsu Ibusuki[1], Eiji Iwama[1], Atsushi Shimauchi[1], Hiroyuki Inoue[2], Daisuke Shibahara[1], Kohei Otsubo[1], Yasuto Yoneshima[1], Isamu Okamoto[1]

[1]Department of Respiratory Medicine, Kyushu University, Fukuoka, Japan,[2]Department of Respiratory Medicine, Fukuoka University, Fukuoka, Japan

EGFR-mutant non-small-cell lung cancer (NSCLC) patients often experience significant clinical benefits from EGFR tyrosine kinase inhibitors (TKIs). However, resistance to these therapies inevitably emerges over time through various mechanisms, limiting the long-term effectiveness of the treatment. The mechanisms of resistance and the duration required for resistance to emerge are highly variable and difficult to predict, highlighting the need for new therapeutic strategies to suppress resistance. In this study, we elucidated the mechanism by which IFITM3, a membrane protein whose expression is upregulated by cytokine stimulation, contributes to reduced sensitivity to the EGFR-TKI osimertinib and promotes the development of resistance through Akt pathway activation. Additionally, we demonstrated that IFITM3 levels are elevated in pre-treatment clinical specimens from *EGFR*-mutant NSCLC patients who developed early resistance to osimertinib, supporting its role in resistance development. Furthermore, Combined treatment with osimertinib and MET inhibitor results in synergistic growth inhibition in NSCLC xenograft mouse models with high IFITM3 expression. These findings provide a rationale for clinical trials investigating the co-administration of MET and EGFR inhibitors in patients with elevated IFITM3 levels to address the heterogeneity of EGFR-TKI resistance mechanisms.

#6810 The mechanism of PRMT5 in causing smoking-induced lung cancer and development of EGFR Tyrosine kinase inhibitor resistance.

Ayesha Khan, Usama Altayeh, Subaranjana Saravanaguru Vasanthi, Mohammad Fazle Alam, Neelu Puri

University of Illinois College of Medicine (Rockford), Rockford, IL

In 2024, lung cancer accounts for 20% of US cancer deaths and 80-90% of NSCLC patients are smokers. PRMT5 (protein arginine methyl transferase 5) is involved in various normal cellular pathways and activates the PI3k-Akt signaling pathways that increase lung tumorigenicity. In NSCLC, EGFR-TKI treatments with Osimertinib initially reduce tumor growth but often lead to resistance in about 19 months. Currently, PRMT5 inhibitors are in clinical trials for several malignancies; further studying PRMT5's role in EGFR-TKI resistance could reveal if these inhibitors enhance TKI efficacy in NSCLC.

We hypothesize that modulating PRMT5 could reduce tumorigenicity and overcome OR resistance. We studied the expression of PRMT5 in both drug-resistant (OR) and drug-sensitive (parental) H3255 and PC9 NSCLC cell lines after treatment with CSE for 24 and 48 hours, followed by western blotting and qPCR. Also, using qPCR the effects of PRMT5i after CSE treatment were studied on inflammatory cytokines.The efficacy of PRMT5i (GSK591) on PC9OR cells were studied using bioprinted with GelMA with a R-Gen 200 bioprinter.

After 24 and 48 hours of CSE treatment PRMT5 gene expression was increased as observed using qPCR in TKI-resistant H3255P/OR (1.5-11 fold) and PC9/OR (1.5-17 fold) ($p<0.05$) cells respectively. Immunoblotting results also indicated a 1.3-2.1-fold ($p<0.01$) upregulation of PRMT5 in these cell lines. PC9P/OR cells were treated with GSK591, and the MTT assay revealed a significant decrease in cell viability to 49% and 46% ($p<0.01$) respectively, in the GSK591 plus OR group as compared to OR treatment group. The cell viability was significantly lowered by 49% in the siRNA plus OR group compared to the siRNA group alone. The treatment groups in both siRNA and PRMT5i treated cells had additive inhibitory effect ($p<0.01$). Studies on inflammatory cytokines in PC9OR cells first treated with CSE and then with PRMT5i showed that CSE alone caused an upregulation of cytokines: TNFα (4-5 fold), IL-1β (1-2.3 fold), and IL-8 (7-9 fold) ($p<0.05$). However, treatment with PRMT5i resulted in a downregulation of these cytokines: TNFα (0.4-0.5 fold), IL-8 (0.5 fold), and IL-1β (0.4-0.6 fold) ($p<0.05$). These findings indicate that inhibiting or downregulating PRMT5 may be effective in reducing CSE-induced oncogenicity. To replicate patient lung tumor microenvironment and enhance the clinical relevance of our findings, we employed 3D bioprinting by accurately layering cells onto biological scaffolds. Preliminary results with PC9OR along with HLF (Human lung fibroblasts) bioprinted spheroids showed 40% inhibition of spheroid count/microscopic field by a combination of PRMT5i and OR compared to OR alone.

In conclusion, we infer that PRMT5 is overexpressed in TKI-resistant cells, leading to increased oncogenic potential. Modulating PRMT5 levels could enhance the effectiveness of EGFR TKIs in NSCLC patients.

#6811 Overcoming temsirolimus resistance in renal cell carcinoma: The potential of bAP15 inhibitor combination therapy.

YI-JU Kao[1], Kuan-Lin Kuo[1], Shih-Ming Liao[1], Chen-Hsun Hsu[1], Yen-ling Chiu[2], Wei-Chou Lin[3], Kuo-How Huang[1], Po-Ming Chow[1]

[1]Department of Urology, National Taiwan University Hospital, Taipei City, Taiwan,[2]Department of medical research, Far Eastern Memorial Hospital, Taipei, Taiwan,[3]Department of Pathology, National Taiwan University Hospital, Taipei City, Taiwan

Renal cell carcinoma (RCC) is a prevalent form of kidney cancer with a high mortality rate, especially in advanced stages. While treatments like tyrosine kinase inhibitors, mTOR inhibitors, and immune checkpoint inhibitors exist, they often have limited efficacy. Temsirolimus, a clinically used mTOR inhibitor, provides a therapeutic option for advanced RCC by hindering cell growth and proliferation, but resistance to this drug can emerge. This study investigated the role of deubiquitylating enzymes UCHL5/USP14 in RCC progression and the potential of their inhibitor, bAP15, to overcome Temsirolimus resistance. bAP15 demonstrated potent anti-cancer activity in RCC cells by inducing apoptosis and cell cycle arrest. Importantly, bAP15 synergized with Temsirolimus in vitro, likely by inhibiting proliferating cell nuclear antigen (PCNA), and enhanced Temsirolimus efficacy in vivo. This combination therapy suppressed tumor growth more effectively than either agent alone. These preclinical findings highlight the potential of bAP15 to overcome Temsirolimus resistance in RCC by targeting UCHL5/USP14. Further research, including clinical trials, is necessary to evaluate the safety and efficacy of bAP15 in RCC patients.

#6812 The third-generation FLT-3 inhibitor, PLM-102, is a promising therapeutic option for venetoclax-resistant AML.

Yun Sun Lee, Min Ji Park, Bongki Ko, Soo Jin Kim, Miran Moon, Soo Yeon Jang, Yong-Chul Kim

Pelemed, Seoul, Korea, Republic of

Venetoclax, a selective inhibitor of the anti-apoptotic protein Bcl-2, has been used as a first-line treatment for acute myeloid leukemia (AML). However, the long-term administration of the drug generally leads to the development of resistance, thereby limiting its therapeutic efficacy. This study aims to evaluate whether PLM-102, an orally available selective and potent FLT3 inhibitor, can overcome venetoclax resistance (VR) in a drug-resistant AML model. To prepare venetoclax-resistant AML cells, the FLT3-ITD-positive MOLM-14 cell line was exposed to increasing concentrations of venetoclax, starting from 10 nM to 1 μM over a period sufficient to induce appreciable resistance. The venetoclax-resistant (VR) cells showed increased phosphorylation of FLT3, AKT, and STAT3 compared to the parental cells. Treatment of the VR cells with PLM-102 ameliorated all activated signaling pathways, restoring them to basal levels more effectively than either tuspetinib or gilteritinib. Additionally, venetoclax, an inhibitor of the anti-apoptotic protein Bcl-2, is known to upregulate MCL-1 as a bypass mechanism. Treatment with PLM-102 reduced MCL-1 and Bcl-2 expression levels and concurrently led to a significant increase in cleaved caspase-3, indicating that PLM-102 induces apoptosis in VR cell lines. In-vivo anti-cancer activities of venetoclax, various FLT3 inhibitors and PLM-102 were compared in the MOLM-14 VR xenograft mouse model. In contrast to the in-vivo study with the parental MOLM-14 model, venetoclax did not show anti-cancer activity in the MOLM-14 VR model, confirming the resistance of VR AML cells in vivo. Notably, PLM-102 demonstrated the highest tumor growth inhibitory (TGI) efficacy compared with those of other FLT3 inhibitors including tuspetinib, gilteritinib and PHI-101. In conclusion, PLM-102 completely inhibited FLT3 kinase and its downstream signaling including AKT and STAT3, inducing apoptosis in VR AML cells along with significant inhibition of the tumor growth in the VR xenograft mouse model. These findings suggest that PLM-102, a third-generation FLT-3 inhibitor, is a promising candidate for overcoming venetoclax resistance and could serve as a therapeutic option for venetoclax-resistant AML.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanisms of Cancer Therapeutics
Poster Session

#6816 Synergistic targeting of nonsense-mediated mRNA decay and heat shock protein 90α for treating lethal prostate cancer.
J. Liu, X. Wang, H. Maasoumyhaghighi, M. Nouri, X. Liu;
University of Kentucky, Lexington, KY

Background: Androgen receptor signaling inhibitors (ARSI) provide modest survival benefits for metastatic castration-resistant prostate cancer (CRPC), but most patients eventually develop resistance, with some progressing to neuroendocrine prostate cancer (NEPC), a highly aggressive form of the disease. There are no effective treatments for ARSI-resistant patients, underscoring the need for new therapeutic strategies. Synthetic lethality, where the combined loss of two genes causes cell death, has shown promise in cancer therapy, as demonstrated by the success of PARP inhibitors. However, synthetic lethal CRISPR-Cas9 screens in prostate cancer (PCa) remain underexplored.
Methods: A combinatorial CRISPR-Cas9 knockout screen was employed to identify synthetic lethal (SL) pairs in ARSI-resistant prostate cancer. Identified SL pairs were validated using in vitro cell viability assays and in vivo models, including cell line and patient-derived xenografts. A luminescence-based nonsense-mediated mRNA decay (NMD) sensor system was utilized to investigate the role of heat shock protein 90α (HSP90α) in NMD. The molecular mechanisms by which NMD components and HSP90α maintain protein and RNA homeostasis in advanced PCa were elucidated using immunohistochemistry, immunofluorescence, immunoblotting, and immunoprecipitation assays.
Results: (1) The combinatorial CRISPR-Cas9 knockout screening identified NMD components and HSP90α emerged as a top novel synthetic lethal pair in ARSI-resistant PCa. (2) Dual knockout of NMD regulators and HSP90α led to cell death in ARSI-resistant PCa. (3) Inhibitors targeting both NMD and HSP90α synergistically suppressed the growth of advanced PCa cells in both in vitro and in vivo models, with minimal effects on normal cells. (4) HSP90α interacts with the NMD regulator, protecting it from aggregation and facilitating its function.
Conclusions: Our research, utilizing an unbiased combinatorial CRISPR-Cas9 double-knockout screen, is the first to identify synthetic lethal pairs in ARSI-resistant prostate cancer. This study not only provides a new therapeutic approach for overcoming drug resistance in advanced PCa but also deepens our understanding of cellular homeostasis by elucidating the interaction between NMD components and heat shock proteins in the context of advanced prostate cancer.

#6817 Targeting XPO1 eliminates cancer stem-like cells and abrogate hepatic metastasis in uveal melanoma.

B. Jin, H. Zou, J. Pan;
Sun Yat-sen University, Guang Zhou, China

Uveal melanoma originating from the uveal tract are a rare form of the malignancy with a biology and clinical feature distinct from its more common cutaneous counterparts. Yet, UM is the most common primary intraocular tumor in adults. Despite effective treatment in primary UM with eye-sparing radiation-based techniques or enucleation, ~50% of UM patients ultimately develop distant metastasis, most commonly in the liver. UM patients with hepatic metastasis have dismal prognosis owing to the limited efficacy of the available treatments. It is fundamental to find new therapeutic targets and develop novel treatment approaches for metastatic UM. XPO1 (also referred as CRM1), a key member of the importin β superfamily of nuclear transport receptors, mediates nuclear export of tumor suppressors and growth factors. We found that XPO1 was highly overexpressed in UM cells and positively correlated with poor prognosis of UM. Depletion of XPO1 by shRNA or its small molecular inhibitor KPT-330 significantly inhibited growth of UM cells *in vitro* and *in vivo*. Treatment with KPT-330 markedly induced apoptosis in UM cells via reducing the protein level of Survivin. Meanwhile, silencing of XPO1 by lentiviral shRNA or incubated with KPT-330 significantly decreased the percentage of ALDH+ cells and dampened self-renewal capacity in UM cells. Targeting XPO1 by KPT-330 profoundly alleviated liver metastasis burden in liver metastasis mouse model. These results suggest XPO1 may be a potential therapeutic target for patients with metastatic UM.

#6818 GPR34-driven damage-response macrophages underlie therapeutic resistance to surufatinib.

Xiaofan Guo, Yuxiao Liu, Yiping Zou, Wenbo Zhu, Peijun Xu, Yuning Song, Jing Huang, Xiaopeng An, **Song Gao**, Jihui Hao

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Pancreatic cancer, an immunologically "cold" tumor, poorly responds to immunotherapy. TAMs, key immune cells in its microenvironment, drive tumor progression. Despite recent progress in macrophage-targeted therapies like CSF1R inhibitors, clinical results in pancreatic cancer are disappointing, with unclear mechanisms. Surufatinib, a CSF1R inhibitor, hinders macrophage differentiation into an immunosuppressive state. Surufatinib alters macrophage differentiation pathways, but resistance is mediated by the emergence of damage-associated macrophages. A subset of these macrophages, characterized by high GPR34 expression, is enriched in refractory pancreatic cancer patients. Through activation of the LysoPS-GPR34 axis, these macrophages enhance efferocytosis and subsequently downregulate MHC-I, leading to $CD8^+$ T cell exhaustion.
Method: Tumor immune microenvironment alterations in pancreatic cancer patients after surufatinib treatment were analyzed via scRNA-seq. Multiplex immunofluorescence staining and flow cytometry were performed on tumor tissue microarrays and fresh surgical specimens. GPR34 conditional knockout mice with orthotopic tumors were analyzed via flow cytometry. The mechanisms of $CD8^+$ T cell exhaustion were investigated using in vitro co-culture systems of macrophages and $CD8^+$ T cells. The efficacy of GPR34 antagonists in combination with immunotherapy and chemotherapy was evaluated in spontaneous tumor models.
Result: Single-cell RNA sequencing (scRNA-seq) was performed on tumor specimens from patients enrolled in clinical trials receiving surufatinib plus chemotherapy. The analysis revealed changes in the tumor immune microenvironment, identifying a subset of damage-response macrophages characterized by high GPR34 expression. Notably, this macrophage population was significantly enriched in treatment-resistant patients. These high expression GPR34 macrophages activated damage-response signaling via the lysophosphatidylserine (LysoPS)-GPR34 axis, promoting $CD8^+$ T cell exhaustion through the release of chronic inflammatory factors and enhanced efferocytosis. Furthermore, efferocytosis further promotes the formation of autophagolysosomes in macrophages, leading to increased degradation of MHC-I, thereby suppressing the antigen-presenting function of macrophages. Targeting $GPR34^+$ macrophages significantly improved the efficacy of both immunotherapy and chemotherapy.
Conclusion: Surufatinib alters macrophage differentiation pathways, but resistance is mediated by the emergence of damage-associated macrophages. A subset of these macrophages, characterized by high GPR34 expression, is enriched in refractory pancreatic cancer patients. Through activation of the LysoPS-GPR34 axis, these macrophages enhance efferocytosis and subsequently downregulate MHC-I, leading to $CD8^+$ T cell exhaustion.

#6819 TOMM40/FADS2 expression ratio predicts the sensitivity to mTOR inhibitors in triple-negative breast cancer.

Salman Mohamed Farah[1], **Yuan-Feng Lin**[2]

[1]International Ph.D. Program in Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan,[2]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

Background: Triple-negative breast cancer (TNBC) is a subtype of breast cancer that does not express the estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor-2 (HER2). Because of the negative to ER, PR and HER2, the current targeted therapy is not fully working for TNBC. Deregulated mTOR signaling has been reported to have implications in several human diseases, including cancer. This study aimed to explore the prognostic significance of the mTORC1 gene set and identify potential biomarkers for predictive the therapeutic effectiveness of mTOR inhibitors on TNBC.
Methods: The transcriptional profile of normal tissues and primary tumors derived from TNBC patients was obtained from The Cancer Genome Atlas (TCGA) database and used to generate the differentially expressed genes (DEGs) of mTORC1 gene set from Molecular Signatures Database. Cox regression analysis for the DEGs against overall survival of TNBC patients was employed to identify independent prognostic factors. The Chi-square test of independence was used to study the association among the identified prognostic genes and the clinicopathological characteristics of TNBC patients. RT-PCR, immunohistochemistry (IHC) staining and Western blot experiments were used to detect endogenous expression levels of the identified prognostic genes in a panel of TNBC cell lines. MTT assay were used to assess the sensitivity/resistance of TNBC cells to mTOR inhibitors.
Results: Two potential prognostic genes FADS2 and TOMM40 were identified from 56 differentially expressed genes (DEGs) between normal tissues and primary tumors of TCGA TNBC patients. Where FADS2 is a protective factor (HR= 0.652), TOMM40 (HR= 2.243) serves as a risk factor under overall survival condition. The signature of TOMM40 downregulation and FADS2 upregulation was associated with a favorable overall survival; conversely the higher TOMM40/FADS2 ratio was referred to a poor outcome in TNBC patients. Under overall survival condition, the TOMM40/FADS2 ratio was shown to significantly ($p < 0.05$) associate with age, tumor size, lymph node metastasis, pathologic stage and overall survival event. Notably, cell-based cytotoxicity assay revealed that TNBC cells harboring a higher TOMM40/FADS2 ratio compared to TNBC cells with a lower TOMM40/FADS2 ratio are more sensitive to mTOR inhibitor treatment.
Conclusion: Our results provide the expression ratio of TOMM40/FADS2 genes as a useful biomarker to predict the therapeutic efficacy of mTOR inhibitors in TNBC.

#6820 Artificial intelligence (AI) assisted analysis of plasma cytokine levels in a phase II trial using metronomic chemotherapy on gastrointestinal (GI) cancer patients.

Ryley Stewart[1], Juan C. Silva Espinoza[2], Briana Elise Pinales[2], Cuipeng Qiu[1], Jiangying Zhang[1], Paola Orlandi[3], Vladimir Georgiev[3], Alessandro Michelangeli[4], Kazumasa Fujiwara[5], Giacomo Allegrini[6], Giulio Francia[1], Guido Bocci[3], Maria L. Manca[3]

[1]Biolosciences, The University of Texas at El Paso, El Paso, TX,[2]The University of Texas at El Paso, El Paso, TX,[3]The University of Pisa, Pisa, Italy,[4]Bonn University, Bonn, Germany,[5]Ryukoku University, Kyoto, Japan,[6]Biolosciences, The University of Pisa, Pisa, Italy

We previously reported a metronomic chemotherapy regimen (UFT, a 5-fluorouracil prodrug; 100 mg/twice per day p.o.; plus cyclophosphamide as an i.v. bolus on day 1 and then 50 mg/day p.o.; plus celecoxib 200 mg/twice a day p.o.); evaluated in the COMET trial (ID NCT02926911; Allegrini et al. Angiogenesis 2012: 15(2):275-86) of GI cancer patients. At AACR 2024 we reported analysis of 75 cytokines in the plasma of these patients. Here, we report levels of 22 not previously evaluated cytokines, analyzed for clinical correlations in this trial, in 34 out of the 38 patients. We used AI to perform part of the statistical analysis. AI assisted in the writing of the R or Python programs implemented. We report the identification of baseline plasma levels of soluble Tie-2 (sTie2) and osteopontin as potential predictive biomarkers for the overall survival (OS) of participants to this trial. sTie 2 values showed a positive correlation with OS ($r = 0.43$; $p = 0.019$), while osteopontin was inversely related ($r = -0.41$; $p = 0.024$). Having defined cut-off levels (389 pg/ml for sTie 2 and 412 pg/ml for osteopontin), we observed a stronger association with OS in subgroups of patients above or below the thresholds, as detected by Kaplan-Meier analysis and log-rank tests ($p < 0.01$, in both tests). The chosen cut-offs also were predictive for patients with better Progression Free Survival (PFS). Patients with osteopontin levels below the cut-off had a PFS of 5.5 months, compared to 2 months in patients above the cut-off ($p=0.002$). For sTie2 patients with above cut-off levels had a PFS of 5.9 months versus 2.2 months in patients below the cut-off ($p=0.002$). We also used cytokine levels to generate predictive patient scores. A score of 1 was assigned for each of sTie2 ≤ 388.8 pg/mL, Osteopontin > 412.5 pg/mL, and sHer3 > 185.4 pg/mL baseline levels. We then arranged patients with relation to Stable and Progressive Disease as follows: A) Low Risk (Score 0): Stable Disease at Recist criteria: 62.5% Progressive Disease: 37.5%. B) Intermediate Risk (Score 1): Stable Disease: 45.8% Progressive Disease: 54.2%. C) High Risk (Score 2-3): Stable Disease: 23.1% Progressive Disease: 76.9%. Our results demonstrate an approach using AI to assist in biomarker analysis of clinical trials, and to stratify patients to identify those likely to benefit from metronomic chemotherapy.

#6821 The anticancer effects of polyisoprenylated phosphonyl ester inhibitors (PPEIs) of PMPMEase in pancreatic cancer cells.

Jahnissi Odoom, Amarender Burra, Kweku Ofosu-Asante, Justin Mensah-Mamfo, Joshua Ablordeppey, Nazarius Lamango

Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Monomeric G-proteins such KRAS, CDC42, RHOA, and RAC1 are polyisoprenylated and methylated to become fully functional. Polyisoprenylated protein methyl transferase (PPMTase) and polyisoprenylated methylated protein methyl esterase (PMPMEase) appear to regulate G-protein function. Previous studies showed that PMPMEase inhibition causes cancer cell death. In the current study, polyisoprenylated phosphonyl ester inhibitors (PPEIs) were developed as *t,t,*-farnesyl-targeted irreversible PMPMEase inhibitors. Experiments were conducted with two pancreatic cancer cell lines, MIA PaCa-2 and PANC-1. NSL-AB-01, NSL-AB-02, and NSL-AB-03 suppressed pancreatic MIA PaCa-2 cells cancer cell viability with EC_{50} values of 4.5, 4.8, and 4.6 μM, respectively, and 5.0, 6.4, and 5.1 μM for PANC-1 cells, respectively. Proliferation was inhibited by 99% and 95% for MIA PaCa-2 and PANC-1 cells at low micromolar PPEIs concentrations, respectively. PPEIs induced caspase activity by over 150% for both cell lines. Phosphorylation of MAPK proteins ERK1/2, MEK1/2, and CRAF were reduced by 77%, 50%, and 42% for MIA PaCa-2 cells, respectively. In PANC-1 cells, ERK1/2 phosphorylation decreased by 75%, while MEK1/2 increased by 140%. The PI3K/AKT proteins, S6 Kinase, PI3K, and AKT, were activated through phosphorylation by 19, 20, and 94%, in MIA PaCa-2 cells. However, opposing effects were observed in PANC-1 cells whereby PDK1 and PI3K phosphorylation were significantly decreased by 30 and 40%, respectively. PPEIs treatment caused actin filaments to become diffused, retracted, and clustered, causing the cancer cells to lose shape and become rounded. These findings show the potential role of PPEIs in disrupting cancer cell proliferation and, consequently, cancer progression.

#6823 Dynamics of KMT2D modulation of the PI3K-Akt pathway and the impact on metastasis in prostate cancer.

Abbas Jawadwala, Surrendra Gulla, Remi Adelaiye-Ogala

University at Buffalo, State University of New York, Buffalo, NY

Despite advances in the treatment of prostate cancers, such as androgen receptor (AR) inhibitors and androgen depreivation therapies (ADT), relapse often occurs, which leads to drug resistant forms of prostate cancer. Understanding the mechanism behind resistance thus becomes important for developing effective treatments. Epigenetic regulators such as KMT2D, a histone 3 lysine 4 methlytransferase, have been implicated in modulating signature pathways associated with cell progression and survival. The PI3K-AKT-mTOR pathway has been studied by many in the field on its role in cancer progression and treatment resistance. However, not as much is known about it being epigenetically regulated. Our preliminary studies demonstrate an association of KMT2D expression/activity and the PI3K-AKT signaling pathway. Interestingly, enrichment analysis in KMT2D knockout treatment-resistant prostate cancer models and their respective controls, demonstrated enriched signatures associated with tumor metastasis and cell adhesion downregulated. While these studies are still preliminary, our results provides an insight to the role of KMT2D in a context dependent mannar, where in an already acquired treatment-resistant state, KMT2D may be promoting a tumor-suppressor-like program and help improve the existing treatment regimen. Ongoing studies will validate our preliminary findings and provide a better understanding of the correlation between KMT2D and these genes along with the PI3K-Akt-mTOR signaling pathway..

#6824 Efficacy and mechanism of surufatinib combination with PD-1 monoclonal antibody and chemotherapy for the treatment of pancreatic cancer with liver metastasis in animal models.

Mengjiao Fan, **Ru Jia**, Guanghai Dai

The Fifth Medical Center, Chinese People's Liberation Army General Hospital, Beijing, China

Background: The phase 1b/2 study of surufatinib plus camrelizumab, nab-paclitaxel and S-1 (NASCA) as first-line therapy has demonstrated superior clinical efficacy compared with nab-paclitaxel and gemcitabine (AG) for metastatic pancreatic adenocarcinoma (PDAC) (NCT05218889), especially in patients with liver metastasis (LM). To delve deeper into the underlying mechanism behind NASCA's effectiveness in the LM group, we conducted animal experiments and utilized multiplex immunohistochemistry (mIHC) technology.
Methods: Two animal models of pancreatic cancer (subcutaneous and LM) were established using KPC cells in C57BL/6 mice. The animals were then randomly assigned to receive placebo, AG, NASCA, and PD-1 plus nab-paclitaxel and S-1 (AS). Human primary pancreatic lesions (PL) and LM lesions were collected, and organ-specific differences were analyzed by using mIHC.
Results: LM changes the effectiveness of NASCA in mice. NASCA outperformed than AG in subcutaneous model. In subcutaneous and LM model, NASCA and AG showed the comparable tumor regression to placebo in subcutaneous tumor, but better than AG in liver tumor. NASCA boosts anti-tumor efficacy in LM by improving immunosuppressive microenvironment. Flow cytometry of peripheral tissues revealed reduced MDSC and PDL1+ macrophages infiltration ($p < 0.05$) and increased NK and activated T cells infiltration ($p < 0.05$) in liver tumors with NASCA. Treg infiltration decreased in both subcutaneous and liver tumors from early (d5) to late (d14) treatment time points. Higher fractions of Treg cells were infiltrated in LM than PL by mIHC: A total of 59 patients with PDAC were enrolled to evaluated the organ-specific response of NASCA therapy. MIHC detected significantly higher fractions of $FOXP3^+$ cells in stroma of LM compared with PL ($p < 0.05$). Patients with $CD68^+CD163^-$ (percent) and FOXP3+ (percent) in stroma may benefit more from NASCA regimen.
Conclusion: LM could alter the efficacy of NASCA in KPC mice through improving immunosuppressive microenvironment. The heterogeneity of mIHC is limited in LM and PL, but patients with $CD68^+CD163^-$ and $FOXP3^+$ in the stroma may benefit more from NASCA regimen, which may contribute to developing precise immunotherapy strategies for PDAC patients with LM.

#6825 Novel therapeutic strategies targeting MECOM rearranged AMLs discovered by unbiased drug screen.

Christine E. Birdwell[1], Warren C. Fiskus[1], Christopher P. Mill[1], Tapan M. Kadia[1], Naval Daver[1], Courtney D. DiNardo[1], Koji Sasaki[1], John A. Davis[1], Kaberi Das[1], Hanxi Hou[1], Surbhi Sharma[1], Rashmi K. Shamanna[1], Michele Ceribelli[2], Kapil N. Bhalla[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]NCATS, Bethesda, MD

The MECOM locus at chromosome 3q26.2 encodes for the transcriptional regulator EVI1. In ~10% of *de novo* AML, aberrant overexpression of EVI1 is observed. In approximately 50% of these it is due to inv(3)(q21;q26.2) or due to the chromosomal rearrangement [3q26.2-r], in which GATA2 enhancer is dislocated and drives EVI1 overexpression. 3q26.2-r AMLs tend to be more stem-like, exhibit therapy resistance and poor patient survival. To determine potential druggable targets, we conducted an unbiased drug screen in 3q26.2-r AML cell lines. We screened a library of over 2400 mechanistically annotated drugs (NCATS Mechanism Interrogation Plates), against seven AML cell lines (four 3q26.2-r and three non-3q26.2-r AML). Exploiting the mechanistic redundancy in the library, we identified target-level sensitivities in 3q26.2-r AML cells and relative activity as compared to other AML subtypes. Corroborating previous studies, in 3q26.2-r AMLs, BET protein inhibitors showed absolute sensitivity. We conducted RNA-seq and mass spectrometry analyses after BET inhibitor (BETi) mivebresib (ABBV-075) treatment. The findings revealed a significant overlap with the expression signature determined by RNA-seq and mass spectrometry performed after CRISPR knockout (KO) of EVI1. The dysregulated proteins included MYC, mTOR and TNF-alpha, indicating them to be potential targets or co-targets with BETi in 3q26.2-r AMLs. Since mTOR, PIK3CA, XIAP and Bcl-xL were also identified as druggable sensitivities in 3q26.2-r AML, we tested the activity of the combined mTOR/PI3K inhibitor dactolisib (BEZ235). Exposure to BEZ235 for 48 hours induced moderate levels of apoptosis in 3q26.2-r AML cell lines and patient-derived (PD) AML cells. This was associated with a decrease in the levels of the EVI1 targets, ERG, Bcl-xL, and c-Myc, as well as of c-Myb and EVI1, with simultaneous increase in the cleaved PARP levels. Combination of dactolisib with mivebresib exerted synergistic in vitro lethality in 3q26.2-r AML cell lines and PD AML blasts. Co-targeting with BETi and other identified sensitivities such as the IAP family inhibitor (LCL161) or Bcl-xL inhibitor (navitoclax or A1155463) also exhibited synergistic lethality in 3q26.2-r AML cell lines and PD AML cells. Importantly, compared to the vehicle control, monotherapy with mivebresib (BETi), dactolisib or LCL161 significantly reduced the AML burden and improved survival of the NSG mice in the xenograft models of 3q26.2-r AML. Co-treatment of mivebresib with dactolisib or LCL161 was superior than each drug alone in reducing AML burden and improving survival. These findings demonstrate promising preclinical activity of novel BETi-based combination with IAP or Bcl-xL inhibitor against AML with EVI1 overexpression.

#6826 PRMT5 inhibition is a promising therapeutic strategy for high-risk neuroblastoma.

Parul Suri, Saurabh Agarwal

St. John's University, Queens, NY

Neuroblastoma (NB), a pediatric solid tumor originating from the extracranial sympathetic nervous system, frequently persists as a metastatic, drug-resistant cancer despite recent improvements in dose-intensive chemotherapy, radiation, and surgical approaches. Identifying novel molecular targets and developing effective therapeutic regimens for NB is crucial. PRMT5, an arginine methyltransferase, has emerged as a potential target, with its inhibition demonstrating therapeutic effects in various cancer models. Multiple potent, small-molecule PRMT5 inhibitors are currently in clinical trials or development. In this study, we investigated the pre-clinical effects of a specific PRMT5 targeting small molecule inhibitor, PM5i, on NB growth. Analysis of multiple NB patient datasets revealed an inverse relationship between PRMT5 expression and NB patients' overall survival, underscoring PRMT5 as a potential therapeutic target. Our cytotoxicity and clonogenic assay data demonstrate that PM5i significantly inhibits NB proliferation and colony formation in a dose-dependent manner with IC50 values ranging from 1 to 4 μM across different NB cell lines ($p<0.01$). PRMT5 inhibition by PM5i significantly induced apoptosis with a 2-fold increase in Annexin V-positive cells compared to controls ($p<0.05$) and inhibited cell cycle progression by arresting cells in the S phase with the percentage of cells in the S phase increasing from 22% in controls to 45-50% in treated cells ($p<0.01$). These effects were consistent across different NB cell lines. To recapitulate *in vivo* tumor growth, we employed 3D spheroid models of NB. PM5i treatment significantly inhibited 3D spheroid growth and volume in a dose-dependent manner with about a 2-fold reduction compared to control treatments ($p<0.01$). Molecular analysis revealed that PM5i treatment downregulated the expression of genes involved in critical cell processes by 2 to 3-fold, including AKT, MAPK, and MYCN pathways in NB cells. These pathways are known to play crucial roles in NB pathogenesis and progression. Collectively, our data provide compelling evidence that PRMT5 targeting represents an effective therapeutic strategy for high-risk NB. The potent effects of PM5i on NB cell growth, survival, and key oncogenic pathways highlight the potential of PRMT5 inhibitors in NB treatment. Further development of PRMT5 inhibition strategies and their combination with current chemotherapies may pave the way for efficient clinical translation, holding significant promise for improving outcomes in high-risk NB patients.

#6827 Developing lung adenocarcinoma cell lines to test new drugs and mitigate lung cancer health disparities.

Kweku Ofosu-Asante[1], Sofia Lugo[2], Bianca Dal Bo[2], Matthew A. Gladstone[2], Chunli Yan[2], Daniel J. Mullen[2], Kyle R. Philips[3], Benjamin J. Ryder[3], Yong Huang[3], Ite A. Offringa[2], Nazarius S. Lamango[1]

[1]Florida A&M University College of Pharmacy & Pharmaceutical Sciences Institute of Public Health, Tallahassee, FL,[2]University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Department of Mechanical and Aerospace Engineering, University of Florida, Gainesville, FL

Lung cancer continues to be the number one cause of cancer-related deaths worldwide and remains a prominent source of cancer health disparities. Black/African American (B/AA) males exhibit a 12% higher lung cancer incidence rate and a 15% higher lung cancer death rate when compared to white males. Lung adenocarcinoma (LUAD) is the most common histological subtype of lung cancer in all ethnic/racial groups, including B/AA individuals. To further examine this phenomenon, we want to create a collection of lung cancer cell lines that would be useful for molecular studies of lung cancer development, progression, development of new targeted therapies, and pre-clinical drug testing. After reviewing the literature (Leon *et al.* 2023, Frontiers in Oncology, Vol. 13, p. 1187585, 2023), we identified only 30 unique B/AA cell lines out of ~800, the majority being from White and Asian patients. Moreover, only 6 of the 30 cell lines are LUAD. In order to mitigate this disparity, we are creating a collection of multiple independent isogenic cell line variants from the existing NCI-H23 lung cancer cell line. NCI-H23 was derived from a B/AA male LUAD patient and harbors a *KRAS*^{G12C} heterozygous mutation. G12C is the most common *KRAS* mutation in LUAD (~40% of *KRAS* mutations) followed by G12V (~20%), G12D (~15%), G12A (~10%), and G13C (~6%). We used CRISPR/Cas9 genome-based editing to replace the *KRAS*^{G12C} mutation with *KRAS*^{G12V}, *KRAS*^{G12D}, *KRAS*^{G12A}, and *KRAS*^{G13C}. We have derived independent cell lines for most mutations. We have performed whole genome sequencing of these cell lines to assess possible off-target effects that may have arisen from the CRISPR/Cas9 engineering. In addition, we will carry out whole genome RNA sequencing to examine the effect of the engineering and/or *KRAS* mutation switching. As a control, we have sequenced the genomes and transcriptomes of three monoclonal cell lines we derived from NCI-H23 cells, to determine what variability ensues with the derivation of monoclonal lines, since that is required to obtain the CRISPR/Cas9 edited cells. We will use this collection of cell lines to study the efficacy of polyisoprenylated cysteinyl amide inhibitors (PCAIs). PCAIs were developed in the Lamango lab to target and suppress hyperactivities of G-proteins in cancers driven by mutant *KRAS*. We will test PCAIs alone, in comparison and in combination anti-KRAS drugs on the new cell lines bearing diverse *KRAS* mutations. Our efforts will provide new cell lines to study lung adenocarcinoma in B/AA subjects addressing a key shortcoming and disparity in the lung cancer research toolkit, thereby facilitating the testing of potential new therapies such as PCAIs in an African ancestry background.

#6828 Therapeutic potential of novel polyisoprenylated phosphonyl ester inhibitors in triple-negative breast cancer.

Joshua K. Ablordeppey, Amarender Burra, Kweku Ofosu-Asante, Jahnissi Odoom, Nazarius S. Lamango

Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL

Hyperactive monomeric G-proteins such as RAS are dominant “drivers” in cancer. In triple negative breast cancer (TNBC), RAS hyperactivity is due to low levels of the RAS-GTPase activating protein, RASA1, a tumor suppressor. KRAS is polyisoprenylated and methylated to become functional. Polyisoprenylated methylated protein methyl esterase (PMPMEase) is overexpressed in various cancers and its specific inhibition causes cancer cell death. Polyisoprenylated phosphonyl ester inhibitors of PMPMEase (PPEIs) were designed to suppress hyperactive RAS-promoted cancers through PMPMEase inhibition. Here, we evaluated the anti-proliferative properties of the PPEIs against two TNBC cell lines, MDA-MB-468 and MDA-MB-231. The PPEIs, NSL-AB-01, NSL-AB-02 and NSL-AB-03 inhibited TNBC cells with EC_{50} values of 3.3 μM, 4.0 μM and 3.6 μM for MDA-MB-468 and 4.1 μM, 5.6 μM and 5.6 μM for MDA-MB-231, respectively. Following 48 h exposure to 1 μM NSL-AB-01, the proliferation of MDA-MB-231 and MDA-MB-468 cells was inhibited by 48% and 8%, respectively. At 2 to 3 μM concentrations, the proliferation of both cell lines was completely blocked. In addition, NSL-AB-01 inhibited the migration of MDA-MB-231 and MDA-MB-468 cells by 95% at 5 μM and 73% at 3 μM, respectively, thereby suggesting potential antimetastatic effects of the PPEIs. Further investigations are in progress to ascertain the molecular mechanisms underlying these effects. Overall, these findings suggest the therapeutic potential of PPEIs as novel agents for TNBC and other cancers with activated G-protein signaling.

#6829 Allele frequency of DPYD genetic variants for fluoropyrimidines metabolism in a Northeast Mexican population.

Maria L. Garza-Rodriguez, Francisco J. Villarreal-Alvarado, Axa N. Vega-Garcia, Valeria J. Gomez-Ordaz, Irasema Martinez-Ramos, Vanessa N. Ortiz-Murillo, Azalea E. Urdiales-Ordonez, Alan Burguete-Torres, Fernando Alcorta-Nunez, Carlos H. Burciaga-Flores, Moises Gonzalez-Escamilla, Oscar Vidal-Gutierrez, **Diana C. Perez-Ibave**

Oncology, Centro Universitario Contra el Cancer UANL, Monterrey, Mexico

Background: Fluoropyrimidine-based (FP) chemotherapy is used to treat solid cancers, including colorectal and breast cancer. The dihydropyrimidinedehydrogenase (DPD) enzyme is in charge of the metabolism of FP; this enzyme is coded by the dihydropyrimidine dehydrogenase (*DPYD*) gene. Genetic variants in*DPYD* have been related to an increased risk of severe toxicity. FP toxicity affects about 30-40% of patients, which in some cases may be lethal. *DPYD* genotyping aims to identify variants that lead to DPD deficiency. The allele frequency of most of the*DPYD* variants in the Mexican population is currently unknown. Variant identification in the Mexican population can help oncologists in the treatment of patients by reducing the chances of toxicity by adjusting treatment without comprising the antitumoral activity. The aim was to describe the frequency *DPYD* gene variants associated with FP toxicity in northeastern Mexico's oncologic population.

Methods: We analyzed seven *DPYD* variants by real-time PCR and Sanger sequencing. Two related to reduced activity (c.1129-5923C->G and c.2846A->T)associated with increased risk for toxicity, and four with null activity (c.1156G->T,c.1905+1G->A, c.1679T->G, c.1898delC, and c.299_302delTCAT) with a higher and severe risk for toxicity. Genomic DNA was isolated from 361 subjects: 117 cancer patients and 244 non-cancer subjects. Allele frequency was calculated for each variant and correlated with clinical data.

Results: We analyzed a total of 361 subjects, including 117 cancer patients, of which68% had an oncological diagnosis of colorectal cancer, followed by breast cancer with 14%. Metastasic and clinical stage III were present in 42% and 34%, respectively. Grade III (G3) gastrointestinal toxicity was the most common, with a presence of31.9%. The variant c.1129-5923 C>G was found in the heterozygous state in 1.2295%(n=3) of non-cancer patients, the c.2846 A>T variant was found in one non-cancer patient 0.4098% (n=1), and in a 1.7094% (n=2) of cancer patients. The rest of the variants were found in a state of native homozygosity. The two patients carrying the c.2846A>T variant presented a G3 and G4 respectively; one patient required dose adjustment, and the other patient suspended the FP treatment.

Conclusions: The allele frequency for two of the seven analyzed variants (c.1129-5923C>G, and c.2846A>T) was higher than reported for the global population (0.00476and 0.005166). *DPYD* genotyping may help to identify people who are at higher risk of developing severe FP toxicity. Personalized medicine allows oncologists to modify the treatment before it begins.

#6830 JZP815, a potent and selective pan-RAF inhibitor, is effective against a spectrum of mutant KRAS and NRAS solid tumor cancers, as monotherapy and in combination, generating a gene expression profile of MAPK inhibition.

Robert Hauptschein[1], Ankur Karmokar[2], Emanuele Loro[2], Yang Yuan[1], Graham Brock[1], **Robin C. Humphreys**[1], Alexey Sorokin[3], Preeti Kanikarla[3], Scott Kopetz[3]

[1]Jazz Pharmaceuticals, Inc., Palo Alto, CA,[2]Jazz Pharmaceuticals, Inc., Cambridge, United Kingdom,[3]University of Texas MD Anderson Cancer Center, Houston, TX

Activation of the mitogen-activated protein kinase (MAPK) pathway by oncogenic mutations in RAS and RAF are frequent drivers of human cancer. Targeting specific components of the MAPK pathway is a precise and rational route to deliver benefits to cancer patients. RAS and RAF proteins are core pathway components that interact directly to mediate MAPK signaling. Direct and indirect inhibition of this key MAPK pathway intersection is critical in driving responses in patients with RAS and RAF mutations. JZP815 (flezurafenib) is an oral pan-RAF inhibitor under development by Jazz Pharmaceuticals. We examined in vitro and in vivo effects of JZP815 pan-RAF inhibition as a single agent and in combination, in multiple RAS and RAF mutant cell and tumor model systems, and those arising from KRAS G12C inhibitor therapy. Lastly, we established a pharmacodynamic (PD) profile indicating JZP815 MAPK pathway engagement. Specifically, in vitro studies in a broad KRAS and NRAS mutant tumor cell line dataset revealed a complex and extensive potency profile of JZP815. Mutant NRAS lines demonstrated significant anti-proliferative response, whereas KRAS mutant lines showed a more diverse response profile. JZP815 inhibited cell proliferation in KRAS mutant cell lines with acquired resistance mutations known to arise in patients after KRAS inhibitor therapy, including acquired KRAS and BRAF mutations. JZP815, in combination with a MEK inhibitor, generated synergistic antiproliferative activity in mutant NRAS melanoma cells lines. In vivo CDX and PDX models showed JZP815 activity against KRAS, NRAS, and BRAF mutant (class 1, 2, 3) xenografts. In BRAF class 1 melanoma PDX models, JZP815 monotherapy generated a more robust antitumor effect compared to 2nd-generation RAF inhibitors. JZP815 demonstrated activity alone and in combination with SOC agents in CRC PDX models, derived from patients who had progressed on KRAS G12C inhibitors. Using bioinformatic analysis, PD profiles were generated that indicated direct impact of JZP815 in MAPK signaling on xenograft tumors bearing KRAS mutations. Whole transcriptome profiling of a KRAS G13D mutant tumor model showed JZP815 suppressed a clinically relevant transcriptional biomarker of MAPK pathway inhibition (MPAS). In addition, the suppression of MPAS gene signature was associated with JZP815 exposure. These PD data support dose- and time-dependent MAPK pathway and target engagement by JZP815 in preclinical models. In summary, JZP815, a potent selective pan-RAF inhibitor, is active against a variety of KRAS, NRAS, and BRAF mutants, and KRAS inhibitor generated mutants, as a single agent and in combination. JZP815 elicits a clinically verified PD profile that could be used to confirm target engagement in patients. JZP815 is currently in phase 1 testing (NCT05557045).

#6831 Systems biology analysis of vitamin D_3 reveals new anticancer properties.

A. M. Sunderji[1], S. Roy[1], A. Aggarwal[1], **K. W. Yip**[2];
[1]University of Toronto, Toronto, ON, Canada, [2]Anticancer.ca, University of Toronto, Toronto, ON, Canada

Introduction: Vitamin D_3 (also known as cholecalciferol) is an essential nutrient and hormone that is obtained through both sunlight-mediated cutaneous synthesis and direct dietary intake. Vitamin D_3 functions to inhibit tumor cell growth by arresting the cell cycle at G0/G1 phases, increasing apoptosis, and reducing nuclear β-catenin levels to prevent the formation of cancer-promoting T-cell factor complexes. This study identified the cancer cell lines most responsive to *in vitro* treatment with vitamin D_3, as well as the compounds and genetic perturbations that are most similar to treatment with vitamin D_3.

Methods: For cell line response analyses, the NCI60 dataset from the US National Cancer Institute was used. Human cancer cell lines were incubated for 24 hours and treated with cholecalciferol for 48 hours at 5 different ten-fold serial dilution concentrations. Sulforhodamine B was used to measure cell survival. To identify genetic and compound perturbations similar to vitamin D_3, data was obtained from the L1000 gene expression assay and CLUE. In this assay, mRNA transcript abundance was measured in 978 human landmark genes and inferred for over 11,000 others to compare gene expression levels to those induced by vitamin D_3.

Results: The least sensitive cell line to vitamin D_3 was the multiple myeloma cell line RPMI-8226 (IC_{50}=56.3 μM), and the most sensitive was the colorectal cancer cell line HCT-116 (IC_{50} = 18.2 μM). Overall, vitamin D_3 was most potent against lymphoid, renal, and melanoma cancer cell lines, and least potent against myeloma cell lines. As indicated by high median tau scores, administration of vitamin D_3 induced gene expression changes similar to OTX2 and ZNF114 knockdowns; OTX2 is a transcription factor associated with neurological organ development while ZNF114 is a zinc-finger protein important for transcription regulation, and both have a biological network connection to vitamin D_3. Vitamin D_3 treatment has similar genetic effects to known therapeutic compounds like VX-702, nelfinavir, and calcipotriol.

Conclusions: This study provides a comprehensive *in vitro* examination of the cancer cell lines most impacted by treatment with vitamin D_3. Further research will help better inform the use of vitamin D_3 in nutrition plans and guide its use in cancer prevention and treatment.

#6832 SYS6041, a next-generation Folate Receptor α-targeted antibody-drug conjugates for the treatment of FRα-expressing malignancies.

Jieru Liu[1], Huan Li[2], **Mo Dan**[1], Xiwu Hui[2], Bin Yao[2], Yang Zhang[1], Linlin Xiao[1], Bin Kang[1], Can Yuan[2], Bin Bao[2], Miaomiao Wei[1], Chunqing Qu[1], Yanling Li[1], Wei Yang[1]

[1]CSPC Pharmaceutical Group Ltd., Beijing, China,[2]CSPC Megalith Biopharmaceutical Technology(Shijiazhuang) Co., Shijiazhuang, China

Folate Receptor α(FRα)exhibits an increased expression on cell surfaces in multiple solid tumors, including ovarian, lung, endometrial cancer, with limited expression in normal tissues. Recently, an antibody drug conjugate (ADC) with a microtubule inhibitor (MTI) payload, was approved by FDA for FRα-expressing platinum-resistant ovarian cancer. However, it can cause severe ocular toxicities and show therapeutic efficacies only in patients with high expression. In order to address the unmet needs of additional patient populations, we sought to develop a next generation FRα-targeting ADC, SYS6041, actively targeting tumors with a broad range of FRα expression, especially moderate or low expression levels. SYS6041 was developed adopting a novel ADC platform with a camptothecin-based topoisomerase 1 inhibitor payload, Exatecan, tethered to a cleavable linker. The drug-to-antibody ratio standed 8.0. Upon binding to FRα, SYS6041 underwent receptor-mediated internalization. Subsequent proteolytic cleavage released the cytotoxic payload Exatecan, leading to DNA strand breaks and consequently disrupting DNA replication and transcription. SYS6041 demonstrated potent cytotoxicities against FRα expressing cancer cell-lines and effective bystander activities towards tumor cells without FRα expression. It demonstrated superior antitumor effects across ovarian endometrial and lung cancer CDX models compared to the MTI-ADC especially in models with low or moderate FRα expression, with a minimum effect dose(MED) at 0.75 mg/kg. In a FRα moderate ovarian PDX model with Olaparib resistance, SYS6041 significantly inhibited tumor growth at 3 mg/kg, whereas the MTI-ADC showed no inhibitory effect at 6 mg/kg. Furthermore, Exatecan demonstrated a significant enrichment in the tumors of mice bearing tumors, achieving a tumor-to-blood ratio of 182 following a dosage of 6 mg/kg of SYS6041.SYS6041 exhibited a stable PK profile with AUC of Exatecan less than 0.01% of that of total Exatecan in ADC. In a GLP toxicity study in cynomolgus monkey, SYS6041 demonstrated an encouraging tolerability with an HNSTD of 50 mg/kg, and favorable PK and DAR stability, and presented a good tolerability profile with therapeutic window (TW)>66 (HNSTD/MED). In conclusion, the distinct mode of action along with the proprietary drug-linker platform resulted in an excellent in-vivo antitumor potency and safety, which supports the potential of SYS6041 as a novel therapeutic agent that may help address unmet needs in patients with moderate and low FRα expressing malignancies.

#6833 Influence of g*uthation S transferase* T1 and M1 polymorphisms on tamoxifen metabolism in malian women with breast cancer.

Brehima Diakite[1], Yaya Kassogue[1], Mamoudou Maiga[2], Oumar Kassogue[1], Fousseyni Diarra[1], Kadidiatou Cisse[1], Aissata Coulibaly[1], Cheick B. Traore[1], Madani Ly[1], Jane L. Holl[3], Lifang Hou[2]

[1]Univ. of Sciences, Techniques & Technologies of Bamako (USTTB), Bamako, Mali,[2]Northwestern University, Chicago, IL,[3]University of Chicago, Chicago, IL

Background: The metabolism of tamoxifen, used in breast cancer treatment, is influenced by the *GSTT1* and *GSTM1* genes. Women were classified as poor (inactivated genes), intermediate (reduced enzyme activity), or rapid (functional genes) metabolizers. This classification helped to understand how genetic variations affected treatment efficacy and side effect risk, promoting a personalized therapeutic approach. This study aimed to analyze the impact of *GSTT1* and *GSTM1* genetic variations on tamoxifen metabolism in Malian women with breast cancer.
Methods: A cohort study was conducted involving 109 Malian women (ages 18-50) diagnosed with ER/PR (+) breast cancer and eligible for tamoxifen treatment. *GSTM1* and *GSTT1* genotypes were determined using multiplex PCR.
Results: A significant correlation was observed between the *GSTM1* gene and family history of breast cancer ($p = 0.026$) as well as tumor size ($p = 0.031$). The genotypic frequencies were 75.2% for functional *GSTM1* and 24.8% for inactive; for *GSTT1*, 56.9% were functional and 43.1% inactive. The categories of metabolizers were distributed as follows: 42.2% (rapid), 14% (intermediate), and 11% (poor), with a significant difference ($p < 0.0001$).
Conclusion: This study highlights the correlation between the *GSTM1* and *GSTT1* genes and factors related to breast cancer. Genotypic variations affect tamoxifen metabolism, emphasizing the importance of genetic factors in optimizing treatment.

#6834 The Region C non-pungent capsaicin analogs ARVANIL and DOHEVANIL sensitize human ovarian cancer cells towards the growth-inhibitory activity of gemcitabine.

K. B. Conley[1], S. D. Richbart[1], K. J. Modi[1], R. S. Light[1], R. S. Gadepalli[2], J. R. Rimoldi[2], T. E. Long[3], Y. Chen[4], P. Dasgupta[1];
[1]Marshall University School of Medicine, Huntington, WV, [2]University of Mississippi, University, MS, [3]Marshall University School of Pharmacy, Huntington, WV, [4]Bluefield State University, Huntington, WV

Purpose of the Study: Ovarian cancer (OC) is the second most common gynecologic cancer in the United States. Ovarian cancer causes more deaths than any other cancer (of the female reproductive system) in women. Combination chemotherapy involving cisplatin and taxanes is the cornerstone for ovarian cancer treatment. The challenge with ovarian chemotherapy is that patients develop cisplatin-resistance (and/or taxane-resistance) upon prolonged exposure to the drug. Gemcitabine is one of the second-line therapies for relapsed ovarian cancer. Several convergent studies show that nutritional phytochemicals can often improve the therapeutic response of chemotherapeutic drugs. The long-term objective of our laboratory is to identify dietary chemicals that may improve the anti-cancer activity of chemotherapeutic drugs. Our published data show that capsaicin (the spicy component of chili peppers) enhanced the pro-apoptotic activity of the chemotherapy drug camptothecin in human small-cell lung cancers. Apart from capsaicin, we have also identified non-pungent capsaicin analogs namely ARVANIL and DOHEVANIL which display greater growth-inhibitory activity in human Ovarian carcinoma cells relative to capsaicin. The objective of the present research project was to explore the combinatorial activity of gemcitabine and these capsaicin analogs in ovarian cancer.
Experimental Procedures: Caspase-3 Activity Assays and Cell Death ELISA assays were used to measure the pro-apoptotic activity of the combination of gemcitabine and Arvanil in human ovarian cancer cells. We also determined the combinatorial pro-apoptotic activity of gemcitabine and dohevanil in human ovarian cancer cells. The results obtained from the apoptosis assays were confirmed using the soft agar assay and the chicken chorioallantoic membrane assay.
Results: Both arvanil and dohevanil sensitized human ovarian cancer cells towards the growth-inhibitory activity of capsaicin
Conclusions: The combination of platinum drugs with capsaicin and capsaicin-like compounds may improve the pro-apoptotic activity of cisplatin in human ovarian cancer.
Support or Funding Information Funding for our study was supported by the NIH R15-AREA Grant (2R15CA161491-02 and 2R15CA161491-03), the Women's Health T3: 3P20GM103434-23W1 (PI: Dr. G Rankin) to PD and MAV and the NIAID-AI151970 grant to TEL. Furthermore, this study was supported in part by the West Virginia IDeA Network of Biomedical Research Excellence (WV-INBRE) grant (NIH grant P20GM103434; PI: Dr. G. Rankin), the National Institute of General Medical Sciences of the National Institutes of Health under the award number P30GM122733.

#6835 Inhibition of platelet activation and antibody-dependent cellular cytotoxicity by the tyrosine kinase inhibitor dasatinib in an *ex vivo* human whole blood system.

Sakthi Srinivasan[1], Ali Zirakzadeh[1], Sofia Ramstrom[2], Erika A. K. Fletcher[1], **Helena Harlin Laven**[1]

[1]Immuneed AB, Uppsala, Sweden,[2]School of Medical Sciences, Orebro University, Orebro, Sweden

Dasatinib is a second-generation tyrosine kinase inhibitor approved for therapeutic use in patients with Philadelphia-positive (Ph+) chronic myeloid leukemia. Dosing of dasatinib is limited by the potential for side effects, including pleural effusion and bleeding disorders. The propensity for bleeding problems is at least in part due to dasatinib inhibiting normal platelet functions. While dasatinib is effective in treating leukemia, the challenge in dosing is associated with a risk for emergence of the T315I mutation of BCR-ABL and potential tumor escape. Thus, the ability to combine dasatinib with other therapeutic agents is desirable and currently under investigation. We have developed an ex vivo test system using circulating fresh human whole blood, enabling direct study of the effects of various compounds on platelet aggregation and activation in a physiologically relevant environment. To see whether the clinical effects of dasatinib could be recapitulated in the test system, we incubated blood from healthy donors in the system with dasatinib prior to stimulation with Thrombin Receptor (PAR1) Activating Peptide 6 (TRAP-6). As predicted, dasatinib significantly inhibited TRAP-6-mediated platelet aggregation and activation as measured by whole blood free platelet counts, platelet expression of CD62P, and the formation of platelet-white blood cell conjugates. At the Cmax concentration, alemtuzumab (anti-CD52) results in antibody-dependent cellular cytotoxicity (ADCC) and release of large amounts of cytokines in the test system, mimicking clinical effects of the drug. We also see a drop in platelet count and platelet activation, correlating with acute effects of alemtuzumab observed in patients. Based on these observations, alemtuzumab was used in the system to investigate whether dasatinib could inhibit platelet activation by a therapeutic drug with known effects on platelets. Dasatinib significantly inhibited the drop in free platelet count and platelet activation seen in response to alemtuzumab. As dasatinib could potentially inhibit multiple signaling pathways, we also investigated whether it had effects on ADCC of CD52+ cell types (lymphocytes and monocytes) by alemtuzumab in the ex vivo system. The decreased lymphocyte and monocyte counts observed in alemtuzumab-treated samples were significantly increased by the addition of dasatinib, whereas non-CD52 expressing cells (such as neutrophils) were not affected. Taken together, the data suggest that the ex vivo test system can be used to investigate the effect of different therapeutic agents on platelet activation and that dasatinib at concentrations that inhibit platelet activation may also inhibit ADCC. Combination therapies involving dasatinib and antibodies with predicted ADCC-dependent effects may thus require further investigation prior to clinical use.

#6836 Analysis of 81 plasma cytokine levels in a phase II trial of gastrointestinal cancer patients treated with metronomic chemotherapy: Incorporation of artificial intelligence and mathematical modeling.

Maria L. Manca[1], Briana E. Pinales[2], Juan C. Silva Espinoza[2], Ryley D. Stewart[2], Diana L. Prospero[2], Mariana N. Frias[2], Mia E. Montelongo[2], Hector M. Padilla[2], Claire E. I. Perucho[2], Brianna E. Ortega[2], Valeria V. Lopez[2], Paola Orlandi[1], Arianna Bandini[2], Mariana J. Silva[2], Marta Banchi[1], Vladimir Georgiev[1], German Rosas-Acosta[2], Kazumasa Fujiwara[3], Alessandro Michelangeli[4], Guido Bocci[1], Giacomo Allegrini[1], **Giulio Francia**[2]

[1]The University of Pisa, Pisa, Italy,[2]The University of Texas at El Paso, El Paso, TX,[3]Ryukoku University, Kyoto, Japan,[4]Bonn University, Bonn, Germany

Metronomic, or continuous low-dose, chemotherapy can inhibit tumor growth via inhibition angiogenesis and immune system activation. At AACR 2024, we reported multiplex analysis of 75 cytokines in 34 out of 38 patients with gastrointestinal (GI) tumors, who were evaluated in a phase II clinical trial of metronomic UFT (a 5-fluorouracil prodrug; 100 mg/twice per day p.o.) and cyclophosphamide (an i.v. bolus on day 1 of 500mg/mq2 and then 50 mg/day p.o.) plus celecoxib (200 mg/twice a day p.o.); the COMET trial (CLINICAL ID NCT02926911; Allegrini et al. Angiogenesis 2012: 15(2):275-86). We now present analysis, including Artificial Intelligence (AI) input (Claude AI built by Anthropic, and Gemini AI built by Google), and mathematical modeling, of plasma levels of 81 cytokines in 34 of the 38 patients. Our analysis included baseline (day 0), days 28 and 56, and days 84 and 112 of the trial, and correlated specific cytokines levels with Overall Survival (OS) and Progression Free Survival (PFS). We now report previosly not evaluated potential biomarkers for this trial, including soluble Her-3 (sHER3). We used AI as confirmatory analysis of data elaboration, firstly performed by R and Stata packages. Building on our previous report of plasma levels of TRAIL and MCP-4 cytokines showing positive correlations with OS, we now report that sHER3 showed an inverse relationship with OS. Patients with sHER3 values ≤185.4 pg/ml presented better prognosis (median OS: 12.1 months) compared to the group with higher levels (median OS: 5.8 months). With regards to PFS, patients with sHER3 levels below the cut-off of 185pg/ml had a better PFS (5.8 months), compared to those above the cut-off (2.3 months; p=0.005). These results add to our previous reporting that TRAIL and MCP-4 levels had a direct association with PFS. As a proof of concept multifaceted analytical approach, we also built mathematical modeling assisted by AI. This approach developed a mathematical model for PFS prediction based on three interacting components: tumor dynamics (by using RECIST measurements), relative pro-angiogenic activity (using baseline VEGF as proxy), and immune response (using baseline IL2 as proxy). AI helped us to optimize the parameters of Ordinary Differential Equations and to predict PFS. Our approach could allow the stratification of GI patients for future metronomic chemotherapy trials, and the potential identification of patients that should instead be offered alternative therapies. Limitations of the present study are that all methods are calibrated on retrospective single-center data. Additional validation will be needed to confirm the robustness of our model.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Nonclinical Models for Targets
Poster Session

#6840 FGFR cell lines: A comprehensive approach to drug discovery and evaluation, from small molecules to biologics, covering binding to activation.

Siyu Li, Yao Peng, Yu Wang, Maimaitiming Nuermanguli, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Fibroblast growth factors (FGFs) bind to their receptors (fibroblast growth factor receptors, FGFRs), activating downstream signaling pathways, which play crucial roles in both mitogenic processes, such as embryogenesis and growth, and non-mitogenic processes, such as neuroregulation and metabolic regulation. FGFRs primarily consist of four subtypes: FGFR1, FGFR2, FGFR3, and FGFR4. Abnormalities like high expression or mutations in these receptors can lead to the aberrant activation of their signaling pathways, resulting in tumorigenesis. Consequently, targeting FGFR is a promising strategy for cancer therapy. Current FGFR-targeting drugs, either in clinical use or under development, include small molecule inhibitors, antibodies, antibody-drug conjugates (ADCs), CAR-T therapies, and soluble FGFR receptors. Different cell models are required for efficacy evaluation of various drug types. Kyinno has developed a comprehensive series of FGFR-related cell lines, which include Ba/F3 kinase cells, FGFR overexpression cells, knockout cells, and reporter cells. Among these, Ba/F3 cells have been meticulously engineered to depend on various FGFR point mutations and fusion mutations for survival, showcasing robust capabilities in evaluating FGFR small molecule inhibitors. The FGFR overexpression and knockout cells are crucial for assessing antibody binding, ADC drug endocytosis, and certain radioimmuno conjugates (RICs). Reporter cells, designed based on FGFR downstream signaling pathways, cover a spectrum of wild-type and point-mutated FGFR subtypes, thus effectively evaluating the impact of drugs on downstream signaling pathways. This strategic array of cell models collectively enhances the development and validation of FGFR-targeted therapies, providing invaluable insights and tools for advancing cancer treatment research. By leveraging these diverse cell models, researchers can better understand the mechanisms of FGFR-targeted interventions, ultimately contributing to more effective therapeutic strategies.

#6841 Improved Ba/F3 kinase engineered cell lines: an innovative in vivo screening platform.

Hao Huang, Yunpeng Zhai, Xuyang Duan, Na Li, Siyu Li, Guoqian Wang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Background: Ba/F3 engineered cells commonly cause tumor metastasis when implanted into immune-deficient mice, resulting in reduced survival time and narrower dosing windows. To overcome this limitation, we have developed a novel approach that modifies these cells without compromising target pathway activation while significantly reducing their metastatic potential. This modification extends both the survival duration and the therapeutic window available for treatment interventions.
Methods: We utilized two distinct cell lines, KC-2400 Ba/F3-TPR-Met-D1228A and KC-4183-Ba/F3-plus-TPR-MET-D1228A respectively. Both cell types were implanted subcutaneously (SC) into NOD SCID female mice. Key parameters such as time to staging at 100 mm^3, time to reach 1000 mm^3, time to first death, dosing window duration, and average tumor volume (ATV) at the point of first death were meticulously recorded and compared between the two groups.
Results: The modified cell line demonstrated a slower progression rate, taking 28 days to reach 1000 mm^3 compared to 18 days for the unmodified group. Survival time increased by 11 days, from 24 days to 35 days, while the therapeutic dosing window expanded from 14 days to 25 days. Futhermore, the ATV at the time of first death was reduced from approximately 1700 mm^3 to around 1300 mm^3, reflecting better tumor growth control.
Conclusion: Engineering Ba/F3 cells to diminish their metastatic capability effectively prolongs survival and broadens the therapeutic window in immune-deficient mouse models. This strategy offers a promising enhancement for preclinical research and holds potential for improving therapeutic outcomes in related clinical applications.

#6842 LgBiT-HiBiT engineered cell lines for protein degradation detection: Comprehensive PROTACs evaluation platform with endpoint and real-time kinetic analysis.

Siyu Li, Shi Qin, Yao Peng, Yunpeng Zhai, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Small molecule drugs have long been integral to disease treatment, but but their limitations have become increasingly apparent over time. The advent of proteolysis-targeting chimeras (PROTACs) offers a promising solution to some of these challenges. PROTACs, also known as hetero-bifunctional compounds, represent a new therapeutic class that includes a specific ligand to bind the target protein, a suitable linker, and an E3 ubiquitin ligase substrate. Upon binding to target proteins, PROTACs recruit an E3 ligase and induce the degradation of target proteins through the ubiquitin-proteasome system. This mechanism allows PROTACs to address protein targets with small-molecule binding ligands that exhibit limited efficacy, broadening the scope of druggable proteins. Additionally, unlike traditional small molecules that merely inhibit protein activity, PROTACs eliminate both enzymatic and non-enzymatic functions of target proteins, reducing the likelihood of drug resistance. Currently, Western Blot (WB) technology is widely used to validate target protein degradation and evaluate the efficacy of PROTACs. While effective for detecting significant protein level changes, WB is time-consuming, lacks precise quantification, and is impractical for monitoring protein degradation at multiple time points due to its high cost and labor intensity. To efficiently and accurately evaluate PROTACs, Kyinno have developed a series of cell models based on the LgBiT-HiBiT technology. LgBiT and HiBiT are high-affinity protein subunits that together constitute NanoLuc luciferase, catalyzing the luminescence of a luciferin substrate detectable by a microplate reader. We have achieved stable overexpression of LgBiT protein in cells and utilized CRISPR-Cas9 gene editing technology to insert HiBiT tags at the N- or C-terminal of endogenous target genes. These cell models are suitable for both endpoint and pharmacokinetic studies. Using a luciferase substrate appropriate for live-cell detection, the luminescence value reflects the current level of HiBiT protein, which correlates with the level of the target protein. Additionally, employing a long-term luciferase substrate allows real-time monitoring of protein levels at each time point. Currently, these cell lines target proteins such as IRAK3, GSPT1, GSPT2, ELAVL1, and GRK2. They support high-throughput screening of PROTACs, molecular glues, lysosome-targeting chimeras (LYTACs), and antibody-based PROTACs (AbTACs), offering a robust platform for advancing drug discovery and development.

#6843 MegaScreen, a useful platform for ADC drug evaluation.

Guoqian Wang, Yao Tang, Jingxiao Xu, Tingduo Lv, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Since the approval of the first antibody-drug conjugate (ADC) , Mylotarg, in 2000, there are now 15 approved ADCs on the market, with over 210 in clinical trials. The development of ADC drugs has entered a flourishing stage, particularly showing significant efficacy and good safety in targets such as HER2, EGFR, Trop2, CLDN18.2, and Nectin-4. The application prospects of ADC therapy in cancer treatment are very broad. ADCs are drugs composed of three parts: a monoclonal antibody, a linker, and a toxin. Among these, the ADC toxin, also known as the ADC payload, is a crucial component of ADC drugs. The toxin is the key to determining the potency of the ADC drug. The payloads of approved ADC drugs are highly toxic, primarily including MMAE/MMAF, calicheamicin, DM1/DM4, SN38/Dxd, etc. These payloads are 1-2 orders of magnitude more toxic than chemotherapy drugs, with some even reaching pM levels. The mechanisms of action of the payloads currently under development mainly include DNA alkylating agents, DNA topoisomerase inhibitors, microtubule disruptors, and RNApolII inhibitors. We have established a substantial cell bank, containing over 800 human tumor cell lines and 100 animal tumor cell lines, covering all types of cancers. Based on this rich cell bank, we are building an Megascreen platform. Through extensive testing, we obtain efficacy data for different ADC payloads across various cell lines, guiding us in selecting suitable cell lines for in vitro evaluation of ADCs. To date, we have tested more than 200 commonly used cell lines particularly breast cancer cell lines. with several ADC palyloads, such as MMAE, SN38, Dxd, exatecan. Our plan is to complete testing of all cells within a year. This Megascreen platform is a large-scale project that will significantly contribute to the screening and evaluation of ADCs.

#6844 In vitro and in vivo screening platform for discovery of JAK2 inhibitors.

Na Li, Xinyu Zhong, Hao Huang, Guoqian Wang, Xuyang Duan, Yunpeng Zhai, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Background: The JAK-STAT signaling pathway functions as a widely utilized mechanism triggered by cytokines, playing a crucial role in regulating various key biological activities , including cell proliferation, cell differentiation, cell apoptosis, and immune response. JAK (Janus Kinase) kinases belong to a family of intracellular non-receptor tyrosine kinases. This family consists of four core members: JAK1, JAK2, JAK3, and TYK2. Among them, JAK2 is particularly significant in mediating signal transmission for hematopoietic growth factor receptors. It facilitates signaling for various cytokines, such as Thrombopoietin (TPO), Erythropoietin (EPO), and Macrophage colony stimulating factor (GM-CSF), thereby regulating the proliferation of hematopoietic cells. Consequently, abnormalities in JAK2 are closely are strongly linked to various diseases, notablypolycythemia vera (PV), myelofibrosis (MF), and essential thrombocythemia (ET). The objective of this study is to assess the effectiveness of JAK2 inhibitors, investigate their underlying mechanisms of action, and determine the optimal dosing regimen to maximize therapeutic benefits while minimizing adverse effects..

Method: The study utilized several cell lines, including Ba/F3-MPL cell line, Ba/F3-EPER-JAK2-V617F cell line, Ba/F3-EPER-JAK2-V617F-mJAK-KO cell line, Ba/F3-MPL-W515L-JAK2 and Ba/F3-MPL-JAK2-V617F cell lines to investigate the effects of fluconazole. *In vitro*, these cell lines were treated with different concentrations of fluconazole and used p-STAT5 alphaLISA to detect the inhibitory effect of fluconazole on downstream signaling pathways. *In vivo*, the cell lines were inoculated into BABL/c nude mice through tail vein injection to form a mouse model of bone marrow proliferative disease caused by JAK2 abnormal activation. We weighed and photographed the liver and spleen, and detected the blood biochemistry and routine of the model mice. We also detected the pathological changes of the spleen through HE staining and reticular protein fibrosis staining.

Results: *In vitro* finding demonstrated that Ruxolitinib significantly inhibited the phosphorylation level of STAT5 downstream of JAK2 in a dose-dependent manner. The *in vivo* experiments revealed that, compared with the sham group, the disease model mice exhibited significantly increased spleen and liver weights. Additionally, higher cell inoculation levels led to shorter survival times, elevated serum ALT and AST levels, and aggravated spleen fibrosis. Treatment with Ruxolitinib significantly alleviated the burden on the liver and spleen and prolonged the survival of the treated mice.

Conclusion: We successfully established both *in vitro* and *in vivo* screening platform for JAK2 inhibitors, providing a valuable tool for optimizing therapeutic strategies for diseases associated with abnormal JAK2 activation.

#6845 Evaluation of individual drug response to tyrosine kinase inhibitor treatment in precision-cut tumor slices of gastrointestinal stroma tumors.

Dina Monch[1], Julia Thiel[1], Meng Dong[1], Annika Maa?[1], Annette M. Staiger[2], Katrin Kurz[2], German Ott[2], Philipp Renner[3], Tobias Leibold[3], Thomas Murdter[1], Matthias Schwab[1], Marc-Hendrik Dahlke[3], Jana Koch[1]

[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany,[2]Department of Pathology, Robert-Bosch-Hospital, Stuttgart, Germany,[3]Department of General and Visceral Surgery, Robert-Bosch-Hospital, Stuttgart, Germany

Gastrointestinal stromal tumors (GIST) are the most prevalent mesenchymal tumor entity of the gastrointestinal tract and serve as a key example for targeted therapies with tyrosine kinase inhibitors (TKI) such as imatinib, in tumors with the most frequent mutations in PDGFRA or c-Kit. Although TKIs have significantly improved the overall survival rates of GIST patients, there are currently no treatment options for imatinib-resistant tumors and tumors without identifiable driver mutations. So far, current sarcoma research mostly relies on expensive mouse models or 2D cell culture that do not integrate the tumor microenvironment (TME). Therefore, clinically relevant, patient-derived 3D GIST models that include cells of the TME are urgently needed. In this study, we tested the feasibility of precision-cut tumor slices (PCTS) as a preclinical model for personalized GIST research. PCTS are patient-derived 3D tissue slices that enable the study of interactions between tumor cells and cells of the surrounding TME. For this, primary GIST tumors were cut into 250µm thick slices and cultured for up to two weeks with or without standard TKI treatment. Tumor morphology and cell composition was analyzed via immunohistochemical (IHC) and multiplex immunofluorescence (mIF) staining, which enabled the simultaneous detection of up to six different markers on one FFPE tissue section. The downstream analysis included a machine-learning based workflow that allowed the comparison of biomarker expression and spatial immune cell distribution in the PCTS stromal and tumor areas before and after treatment. Comparison between primary tumor and PCTS revealed a preserved tumor morphology and heterogeneous cell composition throughout culture. In addition, serum levels of various cytokines were assessed with LEGENDPlex assays and correlated with the PCTS cell composition. The *in vitro* response of PCTS to TKI-based therapies was analyzed via IHC staining and ATP-based viability assays. PCTS from tumors with PDGFRA mutations were expected to be imatinib-resistant, while PCTS from tumors with c-KIT mutations were considered imatinib-sensitive. Sequencing analyses determined the PDGFRA or c-KIT mutational status showing that all patients harbored either a PDGFRA or a c-KIT mutation. PCTS treatment response was compared to the mutational status and if available to clinical follow-up data. Of all PCTS that responded to imatinib therapy, two cases matched the anticipated clinical outcome. PCTS provide a clinically relevant new model system for GIST to explore the development of therapy response to TKI-based treatment and to investigate novel GIST treatments such as immunotherapies and combination treatments. The work is supported by the Robert Bosch Stiftung, Stuttgart, Germany

#6846 Using CRISPR/Cas9 to edit KRAS in a small cell lung cancer cell line.

Myra Elise Castel[1], Neil T. Conlon[1], Georg F. Bischof[2], Ke Wei Gong[3], Neil A. O'Brien[3], John P. Crown[4], **Denis M. Collins**[1]

[1]School of Biotechnology, Dublin City University, Dublin, Ireland,[2]Puma Biotechnology, Inc., Los Angeles, CA,[3]Division of Hematology/Oncology, University of California, Los Angeles, Los Angeles, CA,[4]Department of Medical Oncology, St Vincent's University Hospital, Dublin, Ireland

Introduction: Small cell lung cancer (SCLC) accounts for 10-15% of lung cancers and is the most aggressive subtype. Approximately 16% of SCLCs contain mutations in the *KRAS* oncogene. The $KRAS^{G12C}$ activating mutation is now clinically targetable. There are limited SCLC models containing the $KRAS^{G12C}$ mutation available to generate pre-clinical rationale for clinical studies. This study aimed to develop a protocol for the insertion of the $KRAS^{G12C}$ mutation in the KRAS wild-type SCLC cell line NCI-H1048 using CRISPR/Cas9 technology.

Methods: A protospacer adjacent motif (PAM) was identified near the $KRAS^{G12C}$ mutation site and a single guide RNA (sgRNA) was designed using SnapGene software. The efficiency and specificity of the sgRNA were determined using CRISPRon and CRISPRoff webservers (https://rth.dk/resources/crispr/). A repair template containing the nucleotide substitution was created. The CRISPR/Cas9 plasmid pSpCas9(BB)-2A-GFP (PX458, Addgene) was assembled with a single-stranded DNA oligo matching the sgRNA sequence. The NCI-H1048 cell line was transfected with the DNA assembly product (pKRASm) or the PX548 empty plasmid (control) using Lipofectamine 3000. Cells were sorted by GFP fluorescence 3 days after transfection using a BD FACS Aria III cell sorter. pKRASm- and PX458-transfected cells were seeded for colony formation in 10 cm tissue culture plates. Several pKRASm and PX458 clones were isolated and Sanger sequenced to determine $KRAS^{G12C}$ mutation status. Codons affected by genetic alterations were determined by DNA local alignment using SnapGene software. Cell line growth rates were assessed over 7 days using the Incucyte® live-imaging system.

Results: The transfection efficiency in NCI-H1048 was 0.6% for pKRASm and 1.2% for PX458. No clones with a $KRAS^{G12C}$ mutation were isolated. However, two clones had alterations in the *KRAS* exon 2 sequence. Clone NCI-H1048-29 contained a 15bp in-frame deletion (impacting codons 9-13), and clone NCI-H1048-32 had heterozygous alleles from position 27 (impacting codons 9-37). The regions affected are the P-loop (codons 10-14, phosphate-binding loop) and switch I (codons 30-40, binding interface for KRAS effectors and regulators). The growth of clones NCI-H1048-29 and NCI-H1048-32 was compared to a control clone (PX458-transfected NCI-H1048-9). The *KRAS* alteration significantly reduced the growth of NCI-H1048-29 ($p=0.023$) and NCI-H1048-32 ($p=0.004$) compared to the NCI-H1048-9 control confirming phenotypic impact of the *KRAS* alterations.

Conclusion: The CRISPR/Cas9 method employed resulted in the creation of novel SCLC cell lines with *KRAS* alterations, but further optimization of the protocol is needed to introduce *KRAS* point mutations. The CRISPR/Cas9-edited cell lines created will be used for further *in vitro* study of KRAS biology in SCLC.

#6847 Development and application of DTR mouse models for immune cell ablation and tumor immunotherapy studies.

Yang Yu, Yi Li, Hechun Ma, Shuang Li, Ruilin Sun

GenoBioTX, Sugar Land, TX

Inducing the selective ablation of specific cell types is a powerful approach for studying complex cell-cell interactions, particularly within the immune system. While systemic depletion of immune cells can be achieved using chemicals or cytotoxic antibodies, the diphtheria toxin receptor (DTR)-diphtheria toxin (DT) system provides a more targeted, cost-effective, and minimally invasive alternative. The system leverages the fact that human DTR has a 10^3-10^5 times higher affinity for DT compared to rodent cells. This allows selective cell ablation in mice by introducing the human DTR gene into specific cell populations and subsequently administering DT in vivo.

Using CRISPR/Cas9 technology, we generated a series of DTR mouse models targeting immune cell types, including CD8, Ncr1, Foxp3, CD11c, and seven additional cell-specific targets. These models were created on C57BL/6 or BALB/c genetic backgrounds, with the human DTR coding sequence driven by murine endogenous promoters. Successful gene insertions were validated using GFP or Tomato fluorescent reporter expression. Upon DT administration, these engineered DTR mice exhibited transient immune cell ablation within 48 hours, with cell levels recovering to baseline within 96 hours in the absence of repeated DT dosing.

For functional validation, we used the Ncr1-DTR mouse model in an MC38 tumor inoculation study. DT treatment effectively depleted natural killer (NK) cells in the blood, highlighting the model's utility for immune cell depletion in specific experimental contexts.

Overall, these results demonstrate that DTR mouse models are robust tools for dissecting immune cell functions, exploring intercellular interactions, and evaluating the mechanisms of immune-based therapies.

#6848 Development of a humanized C3 mouse model for preclinical evaluation of therapeutics in C3 glomerulopathy.

Andrei Golovko, Shuang Li, Xiaolei Qiu, Yi Li, Ruilin Sun

GenoBioTX, Sugar Land, TX

C3 glomerulopathy (C3G) is a rare and progressive kidney disease, encompassing C3 glomerulonephritis and dense deposit disease, both driven by dysregulation of the alternative pathway of complement activation. Approximately 50% of patients progress to end-stage kidney disease (ESKD) within 10 years, with limited treatment options currently available.
To address this unmet need, we developed a novel humanized C3 (hC3) mouse model that exhibits a pronounced C3G-like phenotype, characterized by early progression to ESKD and increased mortality. Compared to wild-type mice, hC3 mice display significantly reduced circulating C3 levels, alongside liver and kidney dysfunction confirmed by biochemical and pathological analyses. These mice also demonstrate reduced body weight, elevated morbidity early in life, and a shortened lifespan of approximately 5-6 months. To evaluate potential therapies, we treated hC3 mice with the small interfering RNA drug ARO-C3 at high and low doses. ARO-C3 treatment led to a reduction in serum hC3 levels as early as one week post-administration, with a single dose maintaining suppression for at least five weeks. Importantly, ARO-C3 treatment significantly prolonged survival and improved liver and kidney function, as demonstrated by molecular and histopathological analyses. This hC3 mouse model provides a robust platform for studying complement-mediated diseases such as C3G and for preclinical evaluation of novel therapeutic strategies targeting the complement system.

#6849 RIT1^{M90I} is a driver of lung adenocarcinoma tumorigenesis and resistance to targeted therapy.

Ashley DiMarco, **Mirunalini Ravichandran**, Jeffery Lau, Anthony Lima, Eva Lin, Julie Weng, Luca Gerosa, Pablo Saenz-Lopez Larracho, Thomas Hunsaker, Yang Xiao, Monika Mis, Charles Havnar, Kai Barck, Klara Totpal, Oded Foreman, Mark Merchant, Nicole Sodir, Danilo maddalo

Genentech, Inc., South San Francisco, CA

RIT1 is a RAS-family GTPase that is mutated in 2.4% and amplified in up to 14% of lung adenocarcinoma patients. Yet, the oncogenic potential of RIT1 in the lungs is not completely understood. Many patients with RIT1 alterations are considered 'oncogene-negative', hence they are not eligible for any targeted therapy in the clinic. The role of RIT1 in cancer has been historically understudied due to the lack of *in vitro* and *in vivo* models harboring RIT1 alterations. In this study, we generated the first murine model of RIT1^{M90I}-mutant lung cancer. We found that RIT1^{M90I} was tumorigenic in the lungs and the tumors displayed histopathological features similar to lung adenocarcinoma. We leveraged this new model to assess both *ex vivo* and *in vivo* sensitivity of RIT1 tumors to the SHP2 inhibitor, migoprotafib, in combination with other targeted therapies. Finally, we showed that RIT1^{M90I} can also drive resistance to the KRAS^{G12C} inhibitor, divarasib, and that the combination with migoprotafib can revert this phenotype. Our data shows that RIT1^{M90I} is a bona fide oncogenic driver of NSCLC and mediator of targeted therapy resistance as a co-occurring mutation. Taken together, our study suggests that RIT1-altered cancer patients may benefit from combination treatment with SHP2 inhibitor in the primary and resistance setting.

#6850 A new syngeneic lung cancer model with KRAS and LKB double mutations for evaluating the efficacy of combined KRAS mutation targeted therapy and immunotherapy.

Lei Ci[1], Derek Reznik[1], Kai Zhou[1], Minghui Sun[2], Yi Li[2], Qin Huang[2], Ruilin Sun[1]

[1]GenoBioTX, Sugar Land, TX,[2]Shanghai Model Organisms Center Inc., Shanghai, China

Background: Lung cancer, particularly non-small cell lung cancer (NSCLC), remains the leading cause of cancer-related deaths globally. Genetically engineered mouse models are vital for replicating the genetic and histopathological characteristics of NSCLC, enabling precise manipulation of tumor suppressors and oncogenes. These models facilitate the development of autochthonous tumors within their natural tissue environment. Mutations in LKB1 and KRAS, which frequently co-occur, are associated with resistance to immune checkpoint inhibitors (ICIs) in NSCLC. However, challenges in detecting and quantifying spontaneous lung tumors in mouse models persist. Therefore, there is a critical need for preclinical models with intact immune systems that allow for effective detection and quantification of spontaneous lung cancers. Such models are essential for evaluating the efficacy of therapies targeting KRAS and LKB1 double-mutant NSCLC.
Methods: We developed a novel mouse model (KLL mouse) on the C57BL/6 background, incorporating the KRAS(G12D) mutation, LKB1 deficiency, and firefly luciferase expression. Spontaneous lung cancer was initiated via intranasal delivery of an adeno-associated virus (AAV)-based Cre recombinase system. Tumor progression was monitored longitudinally using micro-CT imaging. From this model, we derived the 279# tumor cell line from spontaneous lung tumors in one mouse (279#). This cell line was used to establish both subcutaneous and orthotopic lung tumor models for therapeutic efficacy studies.
Conclusion: We successfully established a comprehensive preclinical platform for studying NSCLC with KRAS and LKB1 dual mutations. This platform includes a spontaneous lung cancer mouse model, a derived KLL cell line, and associated subcutaneous and orthotopic tumor models. These resources provide valuable tools for investigating optimal treatment strategies for NSCLC, particularly the combination of targeted therapies and immunotherapies.

#6851 An integrated preclinical platform for antibody-drug conjugate development.

Stefano Cairo, Mara Gilardi, Marianna Zipeto, Michael Ritchie

Champions Oncology, Inc., Hackensack, NJ

Antibody-drug conjugates (ADCs) are an innovative class of targeted cancer therapeutics that combine the specificity of monoclonal antibodies with the potent cytotoxic effects of small-molecule drugs. The development of ADCs requires an integrated approach to identify targets, optimize payload delivery, and validate efficacy across ex vivo and in vivo preclinical models. Selecting the right pipeline supporting ADC development is essential. Cell lines often fail to express the specific target antigens leading to discarding or retaining the wrong targets causing clinical failure. For these reasons, ADC development needs clinically relevant models such as patient-derived xenograft (PDX) reflecting clinical trial populations. Champions Oncology has generated a comprehensive preclinical platform to support ADC development by integrating molecular profiling, multi-omics integration and histology data along with functional assays and patient-derived ex-vivo and in vivo models. Champions' PDX bank includes over 1500 models, extensively characterized at a molecular level, and highly reflective of the current clinical trial populations. The deep multi-omics characterization, which includes a proteomic dataset in addition to transcriptomics data, provides a unique advantage in model selection for ADC development. The platform identifies novel targets by analyzing and correlating gene and protein expression in PDX models and validating these findings in clinical tumor samples and normal tissue. This ensures that potential ADC targets exhibit limited overlap with known ADC targets and are differentially expressed in tumor tissues compared to normal tissues, thereby minimizing off-target toxicity. Following target identification, the platform includes steps enabling the discovery and development phase, leveraging Champions' cell-based assays, proprietary ex vivo TumorGraft3D organoid platform, and in vivo model. These models, derived from primary patient tumors, retain the molecular and histopathological characteristics of human cancers enabling a deeper understanding of target biology, ADC internalization, and downstream cytotoxic effects. These analyses are integrated into the workflow to inform ADC construct design, including optimizing antibody specificity, and payload potency. Here we show an example of how Champions Oncology's integrated preclinical ADC development pipeline offers a comprehensive approach for identifying and validating new targets during ADC optimization for therapeutic success. This platform accelerates ADC discovery while ensuring translational relevance, paving the way for next-generation cancer therapeutics.

#6852 Targeted administration of lactate dehydrogenase inhibitor during transarterial of hepatocellular cardinomas in a rat model.

Ryan Baron[1], Ariful Islam[2], George McClung[2], Ryan El Ghazal[2], Nicholas Perkons[2], Alexey Gurevich[2], Jennifer Crainic[2], Daniel Ackerman[2], Nicolas Skuli[2], Gregory Nadolski[2], Stephen Hunt[2], Terence Gade[2]

[1]Drexel University College of Medicine, Philadelphia, PA,[2]Radiology, University of Pennsylvania, Philadelphia, PA

Introduction: Despite improvements in locoregional therapy, recurrence of hepatocellular carcinoma (HCC) remains common, as tumor cells can respond to therapy by undergoing metabolic reprogramming to utilize anaerobic glycolytic pathways via lactate dehydrogenase. In this work, we assessed the growth rates and recurrence rates of HCC in target tumors undergoing transarterial embolization (TAE) with an LDH inhibitor (LDHi), bland TAE (BLAND), and sham therapy (SHAM).

Methods and Materials: Development of autochthonous HCC was induced in 25 Wistar rats using DEN and tumor progressions were tracked with serial MRI until the target tumor reached a volume of 100-300 mm^3. TAE with LDHi were performed using sequential administration of 10 µg/kg LDHi followed by 40-120 µm Embosphere (Merit Medical Systems) (n=13), while bland TAE were performed using Embosphere alone(n=8). An additional cohort underwent a sham TAE procedure without the administration of Embosphere (n=4). Following surgery, rats were serially imaged using T2 MRI, where tumor growth was tracked and monitored for treatment response and potential recurrence. Rats were classified as progressive disease (PD) if there was no decrease in tumor volume by <20%, PR if tumor volume decreased by >20%, and CR if the tumor was eradicated. Recurrence following PR was classified by a >20% increase in tumor volume from the lowest post-treatment volume.

Results: LDHi target tumors had an average %change in tumor volume of -64% from treatment volume, while the BLAND showed a -38% decrease (p=0.068). Results of a Kaplan-Meier survival analysis with a log-rank test showed a significant difference in survival between the groups (p=0.006). All SHAM rats showed no response to treatment and were classified as PD. Treatment responses in the BLAND cohort were2/8 PD and 6/8 PR, while responses in the LDHi cohort were 1/13 PD, 11/13 PR, and1/13 CR. All rats classified as PR experienced recurrence and the time of progression free survival was significantly longer in the LDHi cohort (24 days) as compared to the BLAND (13 days) (p = 0.036).

Conclusion: Administration of LDHi during TAE yields a larger decrease in targeted tumor volume as compared to BLAND TAE, while also providing a statistically significant improvement in progression free survival.

#6853 A standardized drug selectivity profiling platform with a proteome coverage of more than 5,000 proteins.

Tomas Friman, Tuomas Tolvanen, Tove Bostrom, Ying Sun, Alexey Chernobrovkin, Yasmin Andersson, Christina Velasco, Daniel Martinez Molina

Pelago Bioscience AB, Solna, Sweden

Drug hunters typically rely on a combination of biophysical/biochemical binding and efficacy assays to find and prioritize hit compounds in their drug discovery efforts. These activities are pivotal for success where the right assay combination can correlate productive binding (target engagement) with a biological effect. The earlier such correlations can be established, the better, as that speeds up the prioritization process and builds confidence in the lead series that are progressed to lead optimization. Currently, at that stage, selectivity assays for specific protein classes, typically including safety panels of up to 200 proteins, are applied. However, a limited number of proteins will result in a biased selectivity assessment. Instead, an unbiased and proteome-wide selectivity profiling assay, employed early in the drug discovery process, contributes to the correct prioritization of lead compounds. Pelago Bioscience has established a standardized assay for selectivity profiling, based on the Cellular Thermal Shift Assay (CETSA) with mass spectrometry (MS) detection, which enables discrimination between selective and more promiscuous molecules at the proteome level. As an example, we have profiled over 100 different drugs and probes used in clinical oncology and tumor biology research. Investigated drug classes include antimetabolites, alkylating agents, DNA intercalating agents, epigenetic modifiers, kinase inhibitors, and microtubule inhibitors. In the work presented here, we will show how compounds with similar structures and mode of action also display similar CETSA protein shift profiles with regards to intended targets and off-targets. Such reference data allows comparison of novel chemical hits to compounds with an established mode of action. High throughput and data quality, with an assessment of more than 5,000 proteins, enables large compound batches to be assayed also during early phases of drug discovery. This speeds up the process and increases the confidence in lead series and future lead candidates.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 4
Poster Session

#6857 The novel transcriptional inhibitor ecubectedin demonstrates strong antitumor activity in patient-derived xenograft models of soft tissue sarcoma.

Daniel Gorgels[1], Chao-Chi Wang[1], Karo Wyns[1], Lore De Cock[1], Luna De Sutter[1], Kimberly Verbeeck[1], Ulla Vanleeuw[1], Maria Jose Guillen Navarro[2], Pablo Manuel Aviles Marin[2], Agnieszka Wozniak[1], Patrick Schoffski[3]

[1]KU Leuven, Leuven, Belgium,[2]PharmaMar, Madrid, Spain,[3]General Medical Oncology, UZ Leuven, Leuven, Belgium

Objective: Soft tissue sarcoma (STS) is a heterogenous group of rare, malignant, mesenchymal tumors. Doxorubicin (DOX)-based chemotherapy is standard of care for advanced/metastatic disease, despite low response rates and poor disease control. We explored the antitumor activity of ecubectedin (ECU; PharmaMar), a novel transcriptional inhibitor related to the ecteinascidin family, in patient-derived xenograft (PDX) models of STS, representing sarcomas with complex genomes and translocation-related entities.

Methods: ECU was studied *in vivo* in 6 PDX models, including two leiomyo- (LMS; UZLX-STS22_2, STS111), two dedifferentiated lipo- (DDLPS; STS204, STS112), one synovial (SySa; STS336) and one *CIC*-rearranged sarcoma (CRS; STS134). Xenografts were transplanted on both flanks of female NMRI *nu/nu* mice (n=257). Mice were randomized to 5 experimental groups and treated by tail vein injection once weekly: 1) vehicle (VEH) (5% dextrose) 5 mL/kg; 2) DOX 5 mg/kg; 3) trabectedin (TRA) 0.15 mg/kg; 4) lurbinectedin (LUR) 0.18mg/kg; 5) ECU 1.2 mg/kg. Treatment lasted 16 days; antitumor activity was assessed by tumor volume (TV) analysis, histopathology and western blot. Group comparisons used the Mann-Whitney U test, and baseline comparisons used the Wilcoxon test. A $p < 0.05$ was considered statistically significant.

Results: ECU-treated tumors were statistically significantly smaller compared to VEH control in all models except STS22_2 on day 16. In 4 out of 6 models the drug caused TV stabilization and in one (STS134) it led to TV shrinkage to 41% compared to baseline. Histopathological analysis confirmed antitumor effects, showing significant changes in mitotic and apoptotic activity compared to VEH-treated tumors (Table 1).

	Relative tumor volume as compared to baseline						Mitotic activity						Apoptotic activity					
Subtypes	**STS22_2**	**STS111**	**STS204**	**STS112**	**STS134**	**STS336**	**STS22_2**	**STS111**	**STS204**	**STS112**	**STS134**	**STS336**	**STS22_2**	**STS111**	**STS204**	**STS112**	**STS134**	**STS336**
VEH	349%	155%	205%	273%	387%	259%	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a
DOX	243%	170%	148%	154%	177%	161%	↓	↓	↓		↓*		↑*	↑*	↑		↑*	
TRA	254%	137%	172%	135%	230%	167%	↓	↓	↓		↓*		↑*	↑*	↑*		↑*	
LUR	232%	126%	173%	175%	202%	169%	↓*	↓*	↓		↓*		↑*	↑*	↑*		↑*	
ECU	181%	104%	143%	104%	41%	97%	↓*	↓*	↓		↓*		↑*	↑*	↑*		↑*	

Conclusion: ECU has antitumor effects in PDX models of STS, with the most prominent activity seen in STS134. Next step includes investigating the role of DNA repair mechanisms in response to ECU treatment.

#6858 The next generation transcriptional inhibitor PM54 demonstrates strong antitumor activity in patient-derived xenograft models of soft tissue sarcoma.

Daniel Gorgels[1], Chao-Chi Wang[1], Karo Wyns[1], Lore De Cock[1], Luna De Sutter[1], Kimberly Verbeeck[1], Ulla Vanleeuw[1], Maria Jose Guillen Navarro[2], Pablo Manuel Aviles Marin[2], Agnieszka Wozniak[1], Patrick Schoffski[3]

[1]KU Leuven, Leuven, Belgium,[2]PharmaMar, Madrid, Spain,[3]General Medical Oncology, UZ Leuven, Leuven, Belgium

Objective: Soft tissue sarcoma (STS) is a heterogenous group of rare, malignant mesenchymal tumors. Doxorubicin (DOX)-based chemotherapy is standard of care for advanced, metastatic STS, despite low response rates and poor disease control. We explored the antitumor activity of PM54 (PharmaMar), a next generation transcriptional inhibitor related to the ecteinascidin family of agents, in patient-derived xenograft (PDX) models of STS.

Methods: Female NMRI *nu/nu* mice (n=258) were transplanted on both flanks with 6 different PDX models of leiomyo- (LMS; UZLX-STS22_2, STS111), dedifferentiated lipo- (DDLPS; STS204, STS112), *CIC*-rearranged (CRS; STS134) and synovial sarcoma (SySa; STS336). Mice were randomized to 5 treatment groups and treated by tail vein injection once weekly: 1) vehicle (VEH) (5% dextrose) 5 mL/kg; 2) DOX 5 mg/kg; 3) trabectedin (TRA) 0.15 mg/kg; 4) lurbinectedin (LUR) 0.18 mg/kg; 5) PM54 1.2 mg/kg. Treatment lasted 16 days. Antitumor activity was assessed by tumor volume (TV) analysis, histopathology and western blot. The Mann-Whitney U test was used to compare groups, the Wilcoxon test to compare with baseline. A p value of <0.05 was considered statistically significant.

Results: PM54-treated tumors were statistically significantly smaller when compared to VEH-treated PDX on day 16. TV stabilization on day 16 was seen in 5 out of 6 models, while in STS134 the experimental compound led to TV shrinkage to 76% of the baseline (table 1). Histopathological analysis supported the TV analysis showing that PM54 exerted the strongest antitumor effect in all models analyzed thus far, compared to VEH-treated tumors.

	Relative tumor volume as compared to baseline						Mitotic activity						Apoptotic activity					
Subtypes	**STS22_2**	**STS111**	**STS204**	**STS112**	**STS134**	**STS336**	**STS22_2**	**STS111**	**STS204**	**STS112**	**STS134**	**STS336**	**STS22_2**	**STS111**	**STS204**	**STS112**	**STS134**	**STS336**
Vehicle	349%	155%	205%	273%	387%	259%	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a
DOX	243%	170%	148%	154%	177%	161%	↓	↓	↓*		↓*		↑*	↑*	↑		↑*	
TRA	254%	137%	172%	135%	230%	167%	↓	↓	↓*		↓*		↑*	↑*	↑*		↑*	
LUR	232%	126%	173%	175%	202%	169%	↓*	↓*	↓*		↓*		↑*	↑*	↑*		↑*	
PM54	162%	113%	145%	125%	76%	100%	↓*	↓*	↓*		↓*		↑*	↑*	↑*		↑*	

Conclusion: PM54 has strong antitumor activity in PDX models of STS, with the most pronounced effects in STS134. Further steps include investigation of the role of DNA repair mechanisms in response to treatment with PM54 and the clinical development of this next generation transcriptional inhibitor in STS.

#6859 Targeting scaffold/matrix associated regions in pancreatic ductal adenocarcinoma.

Jack Prochnau[1], Daisy Medina[1], Xena Huang[1], Panneerdoss Subbarayalu[1], Deepika Singh[1], Stanton McHardy[2], Manjeet Rao[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]University of Texas at San Antonio, San Antonio, TX

Pancreatic cancer is the tenth most common cancer in the United States and is projected to become the second leading cause of cancer-related death by 2030. Most cases arise in exocrine cells and are driven by genetic mutations, such as *KRAS* and *CDKN2A*, as well as modifiable risk factors, including alcohol use, chronic pancreatitis, and obesity. The aggressive nature of pancreatic ductal adenocarcinoma (PDAC), coupled with its complex tumor microenvironment, leads to late-stage diagnoses and a five-year survival rate of 13%. Despite advances in treatment, which include surgical resection, radiotherapy, and chemotherapeutic regimens like gemcitabine and FOLFIRINOX, therapy-related toxicity and chemotherapy resistance remain significant barriers to improved outcomes. One promising therapeutic approach involves exploiting vulnerabilities in the DNA damage response (DDR) pathways unique to cancer cells. While cancer cells rely on an aberrant DDR to sustain unchecked replication, their increased mutational burden renders them particularly susceptible to DNA-targeting therapies. However, existing DNA-targeting treatments are limited by off-target effects, resulting in toxicity and the emergence of resistance. This underscores the need for novel, selective drugs capable of targeting DNA processes specific to cancer cells. We report on a novel carbazole-derived compound that represents a significant advancement in PDAC therapy. Carbazole, a nitrogen-containing heterocyclic molecule, serves as a pharmacophore in therapeutics with diverse applications, including antitumor, antiviral, and anti-inflammatory agents. Our compound demonstrates potent inhibition of PDAC growth and metastasis in both *in vitro* and *in vivo* models while sparing normal cells. Our results reveal that our compound blocks PDAC growth and progression by selectively targeting Scaffold/Matrix Associated Regions (S/MARs), which play critical roles in several processes including increasing the rate of transcription initiation, providing support to origin of replication as well as chromatin organization. By disrupting S/MARs and their associated binding proteins, our compound inhibits specific genes that support replication and DNA repair processes. This study will set the stage for a new paradigm of treating PDAC using a carbazole-derivative that is highly potent, has unique mechanism of action and shows minimal toxicity. Furthermore, its potential to complement existing treatments positions it as a promising candidate for PDAC therapy.

#6860 MTL-004, a promising new therapeutic for post-resection treatment of glioblastoma.

Mike Hudson[1], Elisabeth Bertrand[2], **Sylvie Maubant**[2], Marie Lux[2], Elodie Marie Dit Chatel[2], Jordan Longin[2], Sophie Chaumeron[2], Maxime Beauchet[2], Anne-Pascale Luzy[2], Pauline Bornert[2], Olivier Duchamp[2]

[1]Gordian Pharma LTD, Pentre Bach, Brecon, United Kingdom,[2]Oncodesign Services, Dijon, France

Objectives:
Glioblastomas (GBM), are exceptionally hard to treat, aggressive and genetically heterogeneous tumors. We report the tolerance, biodistribution and excretion of MTL-004 (5-(aziridine-1- yl)-4 hydroxylamino-2-nitrobenzamide) in healthy animals, along with data its effect when delivered as a single intra-cranial dose in a bioresorbable paste (poly DL-lactic acid-co-glycolic acid and poly ethylene glycol (PGLA/PEG)) following surgical resection of primary GBM, on tumor growth and survival.
Experimental procedures
Tolerance and biodistribution of MTL-004:
Healthy Wistar Han male and female rats were subjected to intravenous (IV) escalating or repeated doses of MTL-004. Body weight and behaviour of animals were monitored to assess toxicity. Healthy Wistar Han female rats were subjected to single intracranial (IC) or IV administration of radiolabelled ^{14}CMTL004 to assess its excretion and biodistribution. Sequential collection of blood and organs were performed and radioactivity was measured.
Efficacy of MTL-004 on tumor bearing rats:
On day 0, tumors were orthotopically induced by implanting 9L fragments into the brain of Fischer 344 female and male rats.On day 5, developing tumors were surgically resected, and rats were subsequently treated with either temozolomide (TMZ), the current standard of care model, orally (PO) for 5 consecutive days, a single application of a bioresorbable paste containing MTL-004, or both treatments combined.
Results:
Tolerance and biodistribution of MTL-004:
Based on IV dosing, 5 mg/kg/day was considered to be the maximum tolerated dose of MTL-004. A dose of 1 mg/kg/day was considered to be the highest dose suitable for repeated IV treatments, and was the safe dose selected for all *in vivo* studies.Following IC and IV administration of ^{14}CMTL004, plasma exposure profile and pharmacokinetic half-life were similar. The retention / half-life of ^{14}CMTL004 in brain was longer than in plasma, suggesting
that its elimination, along with metabolites, took longer in brain than in plasma. MTL-004 was mainly excreted through urine.
Efficacy of MTL-004 on tumor bearing rats:
Male and female rats treated with a single IC dose of MTL-004 following tumor resection demonstrated a significantly higher survival compared to both placebo and TMZ groups and remained in apparent good health for the duration of the study.Combination of both PO TMZ and IC MTL-004 doses was assessed in female rats, where no significant increase of survival was observed compared to IC administered MTL-004 alone.
Conclusions:
MTL-004 was found to be safe and well-tolerated at a dose of 1 mg/kg, and was excreted mainly through urine.Following resection, PO TMZ seemed to have a transient impact on tumor growth, but minimal survival gains compared to placebo. In contrast, a single IC treatment with MTL-004 in paste provided prolonged control of tumor recurrence leading to a significantly increased survival of animals.

#6863 Development of MYCN/MYC inhibitors.

Satyanarayana Gadde[1], Sin Wi Ng[1], Natalie Chung[1], Qian Wang[1], Larissa Doughty[2], Tracey Nero[2], Maria Tsoli[1], David Ziegler[1], Louis Chesler[3], Michael Parker[2], Naresh Kumar[4], Belamy Cheung[1], Glenn Marshall[1]

[1]Children's Cancer Institute Australia, Sydney, Australia,[2]Bio21 Institute, University of Melbourne, Melbourne, Australia,[3]The Institute of Cancer Research, London, United Kingdom,[4]School of Chemistry, University of New South Wales, Sydney, Australia

Background: Deregulated expression of MYC family transcription factors is present in more than 70% of human cancers. MYC is an intrinsically disordered protein without known drug binding pockets and is essential for adult cell replication, making clinical development of MYC inhibitors challenging. MYCN amplification and overexpression generate driver signals in the childhood cancers, neuroblastoma (NB), medulloblastoma (MB) and diffuse intrinsic pontine glioma (DIPG).
Methods and Results: We previously reported a small molecule compound, SE486-11, which reduced MYCN protein levels in combination with suberoylanilide hydroxamic acid. We developed more potent analogues of SE486-11 with improved single agent potency, selectivity towards cancer cells and solubility (UNSW-SC compounds). Our lead compound, UNSW-SC-22 is highly effective *in vitro* against MYCN-driven NB and MB cells with sub-micromolar IC_{50} values and displayed a wide therapeutic index. UNSW-SC-22 displayed MYCN- and c-MYC-dependent cytotoxicity and decreased MYCN and c-MYC protein levels in NB and MB cell lines. MYCN and c-MYC protein half-life was decreased ~2-fold, while K-48-linked ubiquitination of MYCN protein was increased by UNSW-SC-22. We show UNSW-SC-22 bound to full length MYCN and c-MYC proteins directly, with KDs of 62.7 µM and 60.5 µM, respectively, by surface plasmon resonance. In-cell target engagement was further confirmed by drug affinity responsive target stability and cellular thermal shift assays. Total RNA from NB and MB cells treated with UNSW-SC-22 showed down-regulation of MYC target genes on GSEA analyses. On *in-vitro* pharmacology profiling against 47 intracellular signalling targets (78 assays) known to cause adverse drug reactions in humans, UNSW-SC-22 demonstrated no significant target activation at <20 µM. UNSW-SC-22 freely crossed the blood-brain barrier, reaching a concentration of 10.8 µM in brain tissue, with a half-life of 1.22 hours. UNSW-SC-22 significantly reduced the tumour burden and improved overall survival of MYCN-driven NB and MB mice. MYCN protein expression was downregulated in tumours collected from mice treated with UNSW-SC-22.
Conclusion: Collectively, our data suggest that MYCN and c-MYC are the direct molecular targets of UNSW-SC compounds. These compounds have strong potential to serve as specific targeted therapy to treat MYCN/c-MYC driven paediatric and adult cancers.

#6864 Overcoming resistance to tubulin-targeting drugs with PM534: an innovative microtubule-targeting compound.

Maria Jose Guillen[1], Maria Jose Munoz[1], Maria Angela Oliva[2], Daniel Torralba[1], Marcelo Lima Ribeiro[1], J. Fernando Diaz[2], Carmen Cuevas[1], **Pablo M. Aviles**[1]

[1]Pharma Mar, S.A., Madrid, Spain,[2]Centro de Investigaciones Biologicas Margarita Salas, CSIC, Madrid, Spain

Tubulin, a GTP-regulated protein essential for microtubule assembly, is a critical target in cancer therapy. However, current tubulin-targeting drugs face limitations due to toxicity and resistance mechanisms, associated with overexpression of either P-glycoprotein or β-III tubulin isotype. This study aimed to evaluate PM534, a novel compound targeting the colchicine-binding domain (CBD) on tubulin, for its potential to overcome these challenges. PM534´s transport properties were investigated applying MDR1-mediated transport assays in Abcb1KO-MDCKII cells. *In vivo*, PM534's antitumor efficacy was assessed in athymic nude mice bearing xenografts of resistant tumors, including LoVo-Doxo cells with Pgp overexpression and HeLa βIII cells with β-III tubulin overexpression. Each xenograft group received a single intravenous (i.v.) dose of PM534 (5 mg/kg), and tumor growth was monitored over a 7-day period. The Km and Vmax kinetic parameters of human MDR1-mediated PM534 transport were determined to be 12.84 µM and 10.3 pmol/min/pmol transporter protein, respectively. *In vivo* data showed that PM534 significantly reduced tumor volumes in resistant models, achieving median tumor volumes of 131.4 mm^3 in LoVo-Doxo xenografts and 163.4 mm^3 in HeLa βIII xenografts by day 7, compared to placebo-treated controls (410.6 mm^3 and 257.4 mm^3, respectively). PM534's efficacy surpassed paclitaxel in these resistant models, as its activity remained unaffected by Pgp overexpression or β-III tubulin presence—both common resistance mechanisms that limit other tubulin-targeting drugs. In conclusion, PM534 demonstrates potent antitumor activity in drug-resistant cancer models, effectively bypassing Pgp-mediated efflux and β-III tubulin-related resistance. These findings support PM534's potential as a promising therapeutic candidate capable of overcoming the limitations of current tubulin-targeting agents in oncology.

#6865 Discovery and characterization of small molecule inhibitors targeting EXO1 for BRCAness cancer therapy.

Yixing Wang, Jessica Hess, Li Zheng, Binghui Shen

City of Hope National Medical Center, Duarte, CA

Human exonuclease 1 (EXO1), a member of the structure specific nuclease family, plays a critical role in maintaining genome stability by processing DNA double-strand breaks (DSBs), nicks, and replication intermediates during DNA replication and repair. As its exonuclease activity is essential for homology-directed repair and replication fork processing, EXO1 has emerged as a compelling therapeutic target, especially in cancers marked by heightened DNA damage and replication stress. Through high-throughput screening of 45,000 compounds, we identified eight distinct scaffolds of EXO1 inhibitors that demonstrated effective and selective inhibition. Two lead compounds, C200 and F684, underwent structural and mutagenesis studies, which confirmed their binding mechanisms. Biochemical assays further validated their potent and selective inhibition of EXO1 activity. Tumor cell profiling revealed that these inhibitors exploit synthetic lethality in BRCA1-deficient cells, emphasizing their specificity and therapeutic potential for targeting BRCAness cancers. Mechanistically, EXO1 inhibition suppressed DNA end resection, increased the accumulation of DSBs, and triggered S-phase PARylation, effectively disrupting DNA repair pathways essential for cancer cell survival. These findings establish EXO1 inhibitors as promising candidates for the treatment of BRCAness cancers and lay the groundwork for further optimization and development of these compounds as targeted therapeutics.

#6867 Triplet combination of monzosertib, a potent CDC7 inhibitor, with DNMT and BCL2 inhibitors is highly active in human AML xenograft mouse models.

Hatsuo Furuichi[1], Hiroko Endo[1], Akinori Arimura[2], Yu Nishioka[1], Masaaki Sawa[1]

[1]Carna Biosciences, Inc., Kobe, Japan,[2]CarnaBio USA, Inc., South San Francisco, CA

Introduction: Cell division cycle 7 (CDC7) is a highly conserved serine-threonine kinase that plays an important role in the initiation of DNA replication and cell cycle progression. Aberrant expression of CDC7 has been reported in many cancers and is thought to promote abnormal proliferation of cancer cells. Thus, CDC7 has been recognized as a potential drug target for treating cancers.Monzosertib (AS-0141) is a potent, selective, orally bioavailable small molecule inhibitor of CDC7, currently under Phase I clinical study in patients with advanced, metastatic, relapsed or refractory malignancies. In the previous studies, we demonstrated that monzosertib exerted strong synergy effects with DNA methyltransferase inhibitor (DNMTi; azacitidine or decitabine) or BCL2 inhibitor (venetoclax) in human acute myeloid leukemia (AML) cell lines.In this study, we evaluated the antitumor efficacy of monzosertib, DNMTi and venetoclax “triplet” therapy in human AML xenograft models.
Method: Fa-CI plot (the Chou-Talalay method) was used to assess combination effects of monzosertib with DNMTi and venetoclax in human AML cell lines. Effects of drug combination on cellular signaling pathway were examined by western blotting. In vivo antitumor activity of monzosertib alone or in triplet combination with DNMTi and venetoclax were evaluated in human AML tumor-bearing mice.
Results: Triplet combination of monzosertib with DNMTi (azacitidine or decitabine) and venetoclax resulted in a synergistic effect on antiproliferative activity in human AML cell lines. Treatment of MV4-11 cells (human AML cell line) with the triplet combination significantly increased in γH2AX, a biomarker of cellular response to DNA damage (DNA double strand breaks). Combining monzosertib with DNMTi (azacitidine or decitabine) and venetoclax resulted in enhanced tumor growth inhibition in a MV4-11 xenograft mouse model without body weight loss.
Conclusions: Monzosertib demonstrated significant synergistic activity in combination with DNMTi (azacitidine or decitabine) and venetoclax in both in vitro and in vivo human AML models. The triplet combination of monzosertib with DNMTi (azacitidine or decitabine) and venetoclax was well-tolerated in these mouse AML models, suggesting the triplet therapy of monzosertib combined with the standard of care (DNMTi plus venetoclax) for AML patients may provide a new therapeutic opportunity in AML.

#6868 Targeting glycolysis in cancer.

Sucheta Telang, Renita Ranjan, Joseph Burlison

University of Louisville, Louisville, KY

The reprogramming of metabolism to increase reliance on glycolysis is a recognized phenomenon in tumors and is frequently driven by oncogenic mutations. In breast cancer, one of these genetic alterations, the increased activity of the human epidermal growth factor receptor 2 (HER2/*ErbB2*) is observed in ~30% of tumors. HER2 activate a variety of downstream effectors (*e.g.* Ras, HIF-1α) that stimulate glycolysis, in part through the activity of a family of enzymes, the 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatases (PFKFB1-4). The PFKFBs produce fructose-2,6-bisphosphate (F26BP) which activates a rate-limiting glycolytic enzyme, 6-phosphofructo-1-kinase (PFK-1) and therefore important regulators of glycolysis. Preliminary data from our laboratory have determined that the PFKFB4 enzyme was highly expressed in a series of patient - derived $HER2^+$ breast tumors relative to normal breast and additionally found higher expression in paired metastases. We found that silencing PFKFB4 expression in $HER2^+$ breast cancer cells caused a marked reduction in their glycolytic flux and survival. Through in silico screening and optimization, we have identified a small molecule inhibitor of PFKFB4 that selectively inhibits PFKFB4 activity with a resultant decrease in glycolysis and cancer cell growth. We have found that PFKFB4 inhibition also caused a significant decrease in the invasion and migration of $HER2^+$ breast cancer cells *in vitro,* importantly at concentrations well below levels that affect cell viability. We have now examined the effects of PFKFB4 inhibition in a relevant transgenic model of HER2-driven spontaneous mammary tumor formation and have found that the inhibitor caused marked suppression in the growth of $HER2^+$ mammary tumors without signs of systemic toxicity. We additionally have found in preliminary studies that PFKFB4 inhibition decreased the development of metastases in these mice. Taken together, our data strongly support the further evaluation of these inhibitors as a potential strategy for the successful treatment of $HER2^+$ breast cancer.

#6869 A quantitative, conformation-driven screening approach for identification of RNA-targeting small molecule modulators of MYC expression in cancer.

Michelle Kriner, Chuhern Hwang, Brett Israels, Fusayo Koyanagi, Isha Gupta, Wanling Kratzman, Jason Fontana, David Sparkman-Yager

Wayfinder Biosciences, Seattle, WA

Targeting RNA molecules that encode for undruggable proteins involved in cancer is an emerging strategy for small molecule drug development. While a handful of compounds have entered the clinic, progress has been slow due to longstanding challenges in identifying molecules that are both functional and selective. Wayfinder Biosciences has developed an RNA-based sensor technology that addresses these bottlenecks and deployed it to discover compounds that bind to structured elements in the *MYC* mRNA, which is deregulated in a majority of human cancers. The *MYC* 5' UTR is known to contain RNA structures that regulate translation of the c-Myc protein. Using Wayfinder's proprietary computational pipeline, we selected three targetable RNA motifs and designed Wayfinder sensors for each. Wayfinder sensors couple folding of the target RNA motif to folding of a fluorogenic RNA domain and are designed to only generate fluorescence when the target RNA adopts a specific conformation. By screening compound libraries against our sensors, we can identify small molecules that selectively bind to each target RNA structure. Notably, one of the *MYC* motifs we selected represents an alternative conformation that we predict will inhibit interaction with regulatory RNA-binding proteins, enabling us to discover a novel class of modulators of *MYC* expression.

We screened a panel of sensors encoding the *MYC* elements or off-target RNA structures against a library of 50,000 drug-like small molecules to identify compounds that selectively target each *MYC* motif. Hits were validated via dose-response experiments and surface plasmon resonance, an orthogonal biophysical method. Top binders were tested for their ability to reduce cell viability and c-Myc protein levels in a small cell lung cancer cell line (NCI-H82) and a mesothelioma cell line (MSTO-211H), both of which harbor large *MYC* gene amplifications. To date, we have identified multiple hit series that bind to the *MYC* 5' UTR and modulate c-Myc protein levels, leading to significantly reduced proliferation of Myc-amplified cancer cells.

Together, our results validate the ability of Wayfinder's platform to identify selective RNA-binding small molecules that engage their target in *in vitro* models and offer promise for development of cancer therapeutics. Top compounds from this study are currently undergoing medicinal chemistry optimization for potency and selectivity in preclinical models. Future studies will focus on defining the indication space that can be addressed by our *MYC*-targeting molecules and further characterizing their antiproliferative mechanism of action.

#6871 T-Cell redirection to EGFR positive solid tumor with α-TCR nanobody chemically self-assembled nanorings.

Debasmita Paul, Freddys F. Rodriguez, Declan Dahlberg, Abhishek Kulkarni, Lakmal Rozumalski

Department of Chemistry, University of Minnesota, Twin Cities, MN

Cancer immunotherapy involves utilizing a patient's own immune system to identify and destroy cancer cells. Recent advances in this field involve bispecific monoclonal antibodies, genetically engineered T-cells, and immune cell engagers, which have shown success in clinical settings. In this regard, the Wagner Lab has shown that prosthetic antigen receptor (PAR) T-cells, which use chemically self-assembled nanorings (CSANs) can be successfully used to redirect T-cells to target antigens upregulated on cancer cells. CSANs are composed of glycine linked dihydrofolate reductase molecules (1DD) that self-assemble into nanorings upon addition of a chemical dimerizer. This self-assembly can be reversed by the addition of the FDA approved drug, trimethoprim, thus disengaging the T-cells from tumor cells. Bispecific CSANs consisting of alphaCD3 single-chain variable fragment (scFv) recognizing CD3 on T-cells and scaffolds targeted to tumor associated antigens have shown effective eradication of solid tumors such as breast cancer and medulloblastoma both in vitro and in vivo. However, the scFvs pose challenges such as hydrophobicity, aggregation, low stability, and immunogenicity. The structural complexities make production challenging in popular bacterial expression systems. Camelid heavy-chain variable domains, also called nanobodies, have been established as a popular alternative to the scFvs due to their smaller size, increased tissue penetration, low immunogenicity, and ease of production, while retaining similar antigen binding properties. In this project, CSANs composed of 1DD units fused to an antiTCR nanobody, which binds to the T-cell receptor (TCR) on the surface of T-cells, will be used to redirect T-cells to solid tumors. Ongoing experiments show that the antiTCR nanobody has lower binding affinity as compared to antiCD3 scFv. This is beneficial as the non-specific activation of T-cells, which is a drawback of high affinity binders, is weaker in case of the antiTCR nanobody. Further, due to the stability and smaller size of nanobodies, antiTCR-1DD has been genetically modified to fuse a tumor targeting scaffold, thus generating bispecific proteins which can simultaneously engage T-cells and tumor cells. Experiments have shown that perhaps due to its geometry, the bispecific protein is highly potent even at very low doses. Bispecific proteins are clinically translatable, reduction in production load being one of the reasons. The bispecific constructs also lay the foundation of higher order immunotherapeutic tools.

#6872 Repurposing the DNA labeling agent EdU for glioblastoma treatment.

H. Kaanoglu[1], A. Adefolaju[1], C. Fraley[2], M. Shobande[2], R. Dasari[1], B. Mann[1], N. Bell[1], S. Keir[2], S. Hingtgen[1], A. Sancar[1], A. B. Satterlee[1];
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Duke University, Durham, NC

Glioblastoma (GBM) is the most common and aggressive type of malignant central nervous system tumors, with over 300,000 new cases diagnosed globally each year. Despite intensive efforts to improve survival with different treatment regimens, GBM is still deemed largely incurable. We previously found that 5-ethynyl-2'-deoxyuridine (EdU), which is commonly used in laboratories to study DNA replication, is recognized by mammalian cells as DNA damage, removed from the genome by nucleotide excision repair, and causes death of proliferating cells. Here, we evaluate the therapeutic potential of EdU for treatment of GBM, as EdU has been shown to cross the blood-brain barrier and incorporate into proliferating GBM cells but not into post-mitotic neurons. We tested the efficacy of EdU against several different model systems, including not only GBM cell lines in *in vitro* cell culture and *in vivo* orthotopic mouse models of GBM, but also living, uncultured GBM patient tumor tissues grown within our Organotypic Brain Slice Culture (OBSC) *ex vivo* platform. In all three model systems, EdU was effective in killing GBM cells. When compared to the standard of care drug Temozolomide (TMZ) in *in vitro* GBM cell survival assays, EdU displayed ED50 values orders of magnitude lower than TMZ in all five GBM tumor cell lines tested. Against two *in vivo* orthotopic brain tumor models, EdU significantly extended survival relative to controls. Using our OBSC *ex vivo* platform, we were able to quantify the capability of EdU to potently kill rapidly dividing cells within heterogeneous GBM patient tumor tissues without harming the healthy OBSC-associated brain tissue. EdU efficacy against a panel of patient GBMs largely correlated with the clinical Ki-67 status of each tumor, save for one tumor that remained unresponsive to treatment with both EdU and TMZ. Overall, these data suggest that (1) EdU has potential to be repurposed as an anticancer therapeutic and is especially adept at killing rapidly proliferating cells with low off-target toxicity; (2) the OBSC platform can measure nuanced differences in efficacy of experimental therapeutics on heterogeneous patient tumor tissues; and (3) OBSCs can continue to help identify potential responders and non-responders to EdU treatment via functional precision testing of patient tumors *ex vivo*. [HK and AA contributed equally to this work.]

#6873 Discovery and characterization of novel ULK1/2 inhibitors and their ability to degrade ATG13, inhibit autophagy, and treat lung cancer.

Patrick Martin Hagan, Allison Limpert, Douglas Sheffler, Huiyu Ren, Nicholas Cosford

Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA

Lung cancer is the leading cause of cancer-related mortality across all populations. Autophagy (ATG) is a cell survival process by which dysfunctional cellular components are removed and recycled to maintain homeostasis through a lysosomal dependent degradation mechanism. ATG upregulation is implicated as a bad actor in several diseases, particularly K-Ras driven non-small cell lung cancer (NSCLC), where it provides nutrients to lung cancer cells in the nutrient poor and hypoxic tumor microenvironment. ATG also contributes to chemotherapeutic resistance, making it a viable pathway for therapeutic intervention. However, the only clinically available drugs targeting ATG are chloroquine and hydroxychloroquine, which are not ATG-specific and have multiple adverse side effects. ATG is an intricate, multistep process beginning with the Unc-51-like autophagy-activating kinases 1 and 2 (ULK1/2) initiation complex. The supramolecular assembly of this complex relies on the adaptor protein ATG13, which binds ULK1/2. Knockout of ATG13 significantly reduces the viability of lung cancer cell lines, indicating that ATG13 is a viable therapeutic target for lung cancer. Furthermore, our group has characterized other autophagy inhibiting compounds that also robustly degrade ATG13 in cells and tissues, leading to cancer cell death. We have developed and optimized a high throughput screening (HTS) assay whereby ATG13 is HiBit tagged in A549 NSCLC cells (ATG13 HiBit assay) to allow identification of compounds that induce ATG13 protein loss, and therefore inhibit ATG. We have also developed a testing funnel that employs multiple assays to characterize compounds that degrade ATG13 independent of cellular toxicity (cell viability assay), confirm their activity against our protein of interest (In Cell Western blot ATG13 assay), measure their ability to inhibit autophagy (GFP-LC3-RFP-LC3ΔG ATG flux assay) and eliminate compounds that cause assay interference (HiBit counterscreen). Using these assays we have identified a novel lead compound which degrade ATG13 and inhibits autophagy resulting in cell death in NSCLC.

#6874 Bkt300, a novel small molecule targeting the protein regulator of cytokinesis 1 pathway in hepatocellular carcinoma.

Amnon Peled[1], **Lika Gamaev**[1], Hanna Wald[2], Rakefet Rosenfeld[2], Orly Eizenberg[2], Arnon Aharon[2], Michal Abraham[2]

[1]Goldyne Savad Institute of Gene Therapy, Hadassah Hebrew University Hospital, Jerusalem, Israel,[2]AlonBio Ltd, Ness Ziona, Israel

Hepatocellular carcinoma (HCC) remains a major cause of cancer mortality worldwide, largely due to its high recurrence rate and chemoresistance. The microtubule-associated protein regulator of cytokinesis 1 (PRC1) has been implicated in HCC progression, associated with poor prognosis, enhanced cancer proliferation, stemness, metastasis, and chemoresistance. PRC1 functions as an oncogenic driver, particularly in HCC cases with elevated expression, where it promotes Wnt signaling and the expression of genes linked to early recurrence. BKT300, a novel targeted anti-cancer agent, was found to inhibit PRC1, offering a potential treatment option for advanced, difficult-to-treat cancers that express high levels of PRC1, such as HCC. This study investigated the effects of BKT300 on HCC cell migration and survival pathways. BKT300 selectively inhibited HCC cell migration, induced G2/M cell cycle arrest, and triggered mitotic catastrophe and apoptosis through the caspase 3 pathway. BKT300 targeted PRC1 by arresting it in a phosphorylated state at T481, concurrently downregulating CDC25C and upregulating p21. siRNA-mediated suppression of PRC1 in HCC cells prevented the activity of BKT300, indicating that BKT300's efficacy is dependent on PRC1 expression. Direct binding of BKT300 to PRC1 was further confirmed through multiple assays. In vivo studies in two HCC mouse models demonstrated significant tumor growth inhibition and tumor regression, underscoring the therapeutic promise of BKT300 for HCC. Overall, BKT300 presents a novel approach to tackling HCC by directly targeting PRC1, potentially improving outcomes in HCC cases with high PRC1 expression and resistance to conventional therapies.

#6875 Preclinical development of a novel small molecule multitarget inhibitor LCI133 for endometrial adenocarcinoma.

Qi Zhang, Vaidehi Mujumdar, Ritchie Delara, Krishnaiah Maddeboina, Dhananjaya Pal, Bharath Yada, Hailey Dryden, Wendel Naumann, Yovanni Casablanca, Erin Crane, Jubilee Brown, Cody Mchale, Donald Durden

Atrium Health Levine, Charlotte, NC

Objective: Endometrial cancer (EC) is the most common gynecologic malignancy with rising mortality and limited targeted therapies. LCI133, an in silico-designed triple inhibitor of CDK4/6-CDK9-AURK, has demonstrated nano-molar potency against PTEN-mutant EC cells lines and favorable in vivo tolerability. Genetically engineered mouse model (GEMM) is the optimal approach to investigate cancer therapeutics in an immunocompetent setting. The objective of this study is to: 1) describe the physiochemical and pharmacokinetic properties of LCI133, 2) establish and characterize the Pgr-Cre; Pten fl/fl GEMM of EC, 3) assess the preliminary effect of LCI133 on GEMM disease burden.
Methods: 1) LCI133 was profiled for target inhibition by cell-free screen and KinomeSCAN. In vivo PK/ADME properties were assessed as described by Veena Bala.5 In vitro potency was assessed by IC50 assay, cell cycle assay, qRT-PCR and immunoblotting at the indicated timepoints for target biomarkers. 2) Pgr-Cre;Ptenfl/fl mice with conditional PTEN deletion were generated by crossbreeding PTEN floxed mice (Ptenflox)with mice expressing Cre under the regulation of the progesterone receptor promoter (PgRCre). Alterations of PTEN/PI3K/AKT pathway were validated by qRT-PCR and immunoblotting. Histopathologic features of female reproductive tract (FRT) were characterized by H&E and immunohistochemistry staining. FRT relative size was normalized to mouse body mass. 3) Beginning at 4-5 weeks of age, formulated LCI133-HCl was administered to Pgr-Cre;Ptenfl/fl mice intraperitoneally daily for 21 days. Animal weight was recorded during treatment. Relative FRT size, pathology and target inhibition were assessed at endpoint.
Results: 1) LCI133 demonstrates favorable preclinical PK/ADME profile. LCl-HCl salt form is superior to free form. 2) We confirmed loss of PTEN in Pgr-Cre;Ptenfl/fl FRT with concomitant increases in pAKT. Endometrial adenocarcinoma with serosal and lympho-vascular invasion in a background of hyperplasia was identified at 7-8 weeks of age with high penetrance. Conditional loss of PTEN correlates with expression of Pgr, predominantly in the endometrium and myometrium. 3) LCI133 treatment was associated with decreased relative FRT size, reduced angiogenesis and target suppression.
Conclusion: In silico-designed LCI133, as a highly selective inhibitor against CDK4/6-CDK9-AURK with nano-molar potency and favorable PK/ADME properties, demonstrated promising in vivo therapeutic index in immunocompetent mouse models.

#6876 A novel PCNA inhibitor AOH1996 demonstrates pre-clinical efficacy in pancreatic ductal adenocarcinoma models.

Sahar F. Bannoura[1], Husain Y. Khan[1], Md Hafiz Uddin[1], Amro Aboukameel[1], Bin Bao[1], Khalil Choucair[1], Yang Shi[1], Rund Nimri[2], Eliza W. Beal[1], Hugo Jimenez[1], Mohammad Najeeb Al Hallak[1], Muhammad Wasif Saif[1], Philip A. Philip[2], Bassel El-Rayes[3], Ramzi M. Mohammad[1], Boris C. [1]Wayne State University, Karmanos Cancer Institute, Detroit, MI,[2]Henry Ford Cancer Institute, Henry Ford Health, Detroit, MI,[3]Department of Hematology and Oncology, University of Alabama at Birmingham, O'Neill Comprehensive Cancer Center, Birmingham, AL,[4]Beckman Research institute of City of Hope, Duarte, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive disease with a dismal prognosis. It is the 9th most common cancer, and the 3rd leading cause of mortality in cancer patients in the United States. PDAC poses a significant clinical challenge partly due to advanced disease stage at diagnosis, poor response to chemotherapeutics, and common recurrence. Proliferating cell nuclear antigen (PCNA) is a ring-shaped clamp protein that encircles DNA and regulates replication and repair. Cancer cells depend on PCNA-mediated DNA repair, and transcription-replication conflict resolution to tolerate DNA damage, thus promoting proliferation. AOH1996 is a novel selective PCNA inhibitor in phase I clinical trials for solid tumors. AOH1996 disrupts the association between PCNA and its numerous binding proteins, thereby inhibiting PCNA functions such as DNA replication, and damage repair. In this study, we investigated the use of AOH1996 in preclinical models of pancreatic ducal adenocarcinoma (PDAC).

Methods: We determined cell viability and growth inhibition by MTT, colony formation and spheroid assays. Drug combinations of AOH1996 with KRAS inhibitors and chemotherapy were analyzed using synergy finder.

Results: We demonstrated that AOH1996 inhibits the growth of a panel of PDAC tumor cells in a dose-dependent manner, in 2D and 3D culture models and clonogenic assays. Cell cycle analysis revealed that AOH1996 causes S-phase arrest in PDAC cells, indicating that S-phase arrest prevents tumor cell growth by targeting DNA replication and repair processes supporting further investigation into AOH1996 to target PDAC. Transcriptomic analysis using RNA sequencing is ongoing to examine the underlying molecular mechanisms of AOH1996 activity. KRAS is the most common oncogenic driver in PDAC and is one of the main synthetic lethal targets with PCNA. Therefore, we examined the combination of emerging KRAS inhibitors with AOH1996 on PDAC models. We found that KRAS G12D inhibitor (MRTX1133) in combination with AOH1996 enhanced cytotoxicity in several PDAC cell lines at lower MRTX1133 concentrations, potentially reducing toxic side effects. We also observed enhanced efficacy of the chemotherapeutic agent oxaliplatin, which is a platinum compound in the FOLFIRINOX regimen, in combination with AOH1996. This indicates that AOH1996 has great potential at improving responses to current and emerging treatments for PDAC patients.

Conclusion: Collectively, our results show that AOH1996 is a promising agent for PDAC treatment which potentiates chemotherapy, and targeted KRAS G12D inhibitors. *In vivo* xenograft studies combining AOH1996 and KRAS inhibitors are ongoing.

#6877 Oxidative stress induced lipid peroxidation as a mechanism of topoisomerase II alpha poisoning by chemotherapeutic agents.

Amy C. Flor, Don Wolfgeher, Stephen J. Kron

Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL

Topoisomerase II alpha (TOP2A) is an ATPase essential for maintaining optimal genomic DNA topology in cells. By relaxing DNA supercoils and entanglements, TOP2A relieves torsional stress to facilitate transcription, replication, and mitosis. In cancer cells, TOP2A is often overexpressed, enabling abnormally rapid genomic replication, in turn facilitating cellular hyperproliferation and driving tumor progression. Thus, TOP2A is a key target of several chemotherapeutic drugs, including etoposide and doxorubicin. While etoposide has long been proposed to stabilize the TOP2A-DNA cleavage complex (TOP2Acc) via interfacial inhibition, we have elucidated a complementary oxidative stress mediated pathway involving lipid peroxidation (LPO) and subsequent generation of reactive lipid electrophiles (LDEs). The LDE 4-hydroxynonenal (HNE) covalently modifies TOP2A at cysteine residues in its ATPase domain, in a DNA-dependent manner. HNE modification inhibits TOP2A catalytic activity and traps TOP2Acc, leading to accumulation of lethal DNA double strand breaks (DSBs). Induction of reactive oxygen species (ROS) by etoposide and doxorubicin were shown by flow cytometry assays, and LPO and HNE-protein adducts were imaged using fluorescence microscopy. Several chemotherapeutic TOP2A poisons significantly depleted reduced glutathione, a key antioxidant. *In vitro*, HNE inhibited DNA decatenation and relaxation activities of purified human TOP2A in kDNA and plasmid DNA assays. Mass spectrometry revealed sites of covalent HNE modification, including Cys216 within the ATPase domain. Malachite green ATPase assays demonstrated that HNE reduced ATP hydrolysis, consistent with disruption of ATP binding. In cell-based studies, HNE directly induced TOP2Acc and DSBs, as detected by trapped in agarose DNA immunostaining (TARDIS) assays and neutral comet assays, respectively. TOP2Acc and DSBs induced by etoposide or doxorubicin were mitigated by a lipid antioxidant, implicating LPO as a mediator of TOP2A targeted drug poisoning. An etoposide resistant cancer cell line exhibited cross resistance to HNE-induced toxicity, further supporting a shared mechanism involving redox metabolism. Proteasome inhibitors including bortezomib exacerbated the persistence of HNE-induced DSBs, indicating that repair of HNE-induced TOP2Acc primarily depends on the proteasome for degradation.

Conclusion: Taken together, our data suggest an underappreciated role for TOP2A as a redox sensor in tumor cells, connecting oxidative stress to DNA damage signaling and creating a target for redox active drugs. This work suggests novel opportunities for improving chemotherapeutic strategies, by leveraging proteasome inhibitors or designing covalent inhibitors targeting Cys216 to optimize therapeutic outcomes and minimize off target toxicities.

#6878 Ag5: a novel quantum cluster therapy targeting mitochondria and antioxidant systems in glioblastoma.

Jayesh Telang[1], Marleen Derweduwe[1], Vanesa Porto[2], Blanca Dominguez[2], Ross Breckenridge[3], Martin Treder[3], Fernando Dominguez[2], Annelies Claeys[1], Isabel Aguirre Alcolea[1], Frederik De Smet[1]

[1]KU Leuven, Leuven, Belgium,[2]Universidade de Santiago de Compostela, Santiago de Compostela, A Coruna, Spain,[3]Arjuna Therapeutics, Novo Milladoiro, A Corunã, Spain

Despite extensive efforts from drug developers, physicians, and patients, the prognosis for glioblastoma (GBM) remains one of the poorest in adult oncology. Current oncology drug development often revisits established technologies, with few truly novel treatments emerging to tackle challenging diseases like GBM. ARJUNA Therapeutics is breaking new ground with quantum cluster technology, creating a unique family of small molecules. The first of these, Ag5, consists of five silver atoms (a quantum cluster) with demonstrated drug-like qualities, including the ability to cross the blood-brain barrier. Ag5 penetrates cells and specifically catalyzes the irreversible inactivation of both glutathione and thioredoxin antioxidant systems in cancer cells, rapidly depleting mitochondrial glutathione and inducing cell death with minimal off-target effects at therapeutic doses. In collaboration with ARJUNA, the Laboratory for Precision Cancer Medicine at KU Leuven, Belgium, screened 20 patient-derived glioma stem cell lines from adult GBM tumors. Ag5 demonstrated cell-killing effectiveness at submicromolar concentrations in approximately 50% of these models, showing activity in both newly diagnosed and recurrent tumor models, as well as in cells from both the core and infiltrating regions. Importantly, tumor cell lines taken from individual patients at various disease stages retained their Ag5 sensitivity, even as they acquired resistance to radiotherapy and/or TMZ. Biomarkers defining sensitivity and resistance to Ag5 in patient-derived GBM lines have been identified, supported by promising preclinical in vivo data. Ag5 has the potential to benefit a significant proportion of GBM patients. A clinical phase 0 neuro-oncology trial at University Hospitals Leuven, Belgium, is planned to test both the biomarker and therapeutic hypothesis for Ag5 in adult GBM patients.

#6879 Inhibition of triple-negative breast cancer progression via ribosomal protein(s) modulation.

Arpit Dheeraj[1], Fernando Jose Garcia Marques[2], Dhanir Tailor[1], Abel Bermudez[2], Praveen Kumar[1], Benedikt Grau[1], Carrsyn B. Haley[1], Sharon Pitteri[2], Sanjay V. Malhotra[1]

[1]Center for Experimental Therapeutics, Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Department of Radiology, Canary Center at Stanford for Cancer Early Detection, Stanford University, Palo Alto, CA

Background: Triple-negative breast cancer (TNBC) is a highly heterogeneous disease with distinct features at the pathological, molecular and clinical levels that are associated with lower survival rates than other subtypes of breast cancer (BC). TNBC is a highly aggressive subtype of breast cancer and represents for 15-20% of all breast cancer cases. TNBC cancers present myriad clinical challenges due to their heterogeneity, poor prognosis, high recurrence, and high incidence of metastasis. Dysregulation of protein translation is a frequent feature of cancer. Translation of mRNAs to proteins i.e., protein synthesis *via* ribosomes, is a fundamental cellular activity. Increased levels of translation, necessary to support rapid cell proliferation, have been reported across different cancer types including TNBC.
Methods: Cell viability and clonogenic assays were performed on a range of TNBC cells, including MDA-MB-231, MDA-MB-468, SUM159, HCC1395, HCC1806, EMT6, and 4T1. Cell cycle distribution was assessed through flow cytometry. LC-MS/MS analysis was performed on TMT-labeled samples for global proteome profiling. CETSA assay was performed to identify the target of CET019. The efficacy of CET019 (30 mg/kg) was tested using tumor (mouse and human cells) and patient derived xenograft studies.
Results: Our studies show CET019 suppresses the clonogenic potential and growth of various triple-negative breast cancer cells. The CET019 treatment causes cell cycle arrest in TNBC cells at the G2/M phase. Proteomics analysis suggests that CET019 specifically affects the protein translation associated pathways. CETSA assay identified the thermal shift of various translation associated proteins, including RPLs and RPS. *In vivo* studies with CET019 found an inhibition of tumor growth kinetics in the mouse xenograft study with different TNBC models, as compared to the control group. We also observed that CET019 inhibited metastatic lung nodules. The results were further substantiated in four Patient Derived Xenograft (PDX) models.
Conclusion: In summary, our study has strong preclinical evidence of CET019 as a promising lead candidate for TNBC treatment. “The complete chemical structures of the compounds used will be disclosed at the time of presentation at the meeting.”

#6880 Rinatabart sesutecan (PRO1184) in combination with standard-of-care therapy exerted potentiated antitumor activity in preclinical cancer models.

Lei Wang, Wanwan Shen, Wenke Qi, Qilin Wu, Yang Xiao

Genmab, Suzhou, China

Background: Rinatabart sesutecan (Rina-S) is an investigational antibody-drug conjugate composed of a human monoclonal antibody that selectively binds to folate receptor alpha (FRα), a novel protease-cleavable highly hydrophilic linker, and a topoisomerase 1 inhibitor, exatecan. Preclinical studies have demonstrated potent antitumor activity of Rina-S monotherapy in a broad range of tumors. In the phase 1/2 GEN1184-01 study (NCT05579366), treatment with Rina-S monotherapy resulted in antitumor activity in patients with heavily pretreated platinum-resistant ovarian cancer (PROC) and endometrial cancer (EC) across various FRα expression levels, with a manageable safety profile. Here we evaluate the combinability and antitumor activity of Rina-S with standard-of-care (SOC) therapies in preclinical cancer models.

Methods: To evaluate the effect of Rina-S on immunogenic cell death (ICD), FRα-expressing cell lines (KB and 3LL-FRα cells) were treated with either Rina-S or exatecan for 24 to 72 hours and then assessed for markers of ICD, including extracellular ATP, HMGB1, and calreticulin. To assess the antitumor activity of Rina-S alone or in combination with SOC therapies, multiple in vivo studies were conducted in various mouse models. Xenograft mouse models inoculated with OC (OVCAR-8 cells) or EC (HEC-1-A cells) received either phosphate-buffered saline (PBS) alone or Rina-S alone, with or without carboplatin (OC), bevacizumab (OC), or olaparib (EC). Syngeneic mouse models of lung cancer or colorectal cancer received either PBS alone or Rina-S alone, with or without an anti-PD1 agent nofazinilmab (CS1003). Antitumor activity was assessed by measuring tumor volume over 30 days and the evaluation durations for lung cancer and colorectal cancer were 20 and 28 days, respectively.

Results: In vitro incubation of FRα-expressing cells with Rina-S or exatecan resulted in upregulation of ICD overall, as measured by ATP, HMGB1, and calreticulin levels. In models of OC and EC, Rina-S combined with carboplatin, bevacizumab, or olaparib produced potentiated antitumor activity compared with single-agent treatment. Combination of Rina-S with an anti-PD1 agent in syngeneic models of lung and colorectal cancer showed a potentiated effect compared with single-agent treatment.

Conclusions: These preclinical studies provide evidence for combination therapy with Rina-S and various SOC therapies and suggest that Rina-S may be investigated in different treatment settings in the clinic. A phase 1/2 study (NCT05579366) is currently ongoing to study the efficacy and safety of Rina-S in combination with carboplatin, bevacizumab, or pembrolizumab for the treatment of platinum-sensitive OC, PROC, and EC, respectively.

#6881 Discovery of ACE-232: a novel and highly potent non-steroidal CYP11A1 inhibitor.

Kuo-Long Yu[1], Hongbin Yuan[2], Sanjeev Kumar[1], Kai Kang[2], Wenming Li[2], Manhua Li[2], Weitao Pan[1], **Wenqian Li**[1], Junmei Wang[1], Zhiming Wen[1], Genshi Zhao[1], Tinggui Yin[1]

[1]Acerand Therapeutics, US, Carmel, IN,[2]Medicinal Chemistry, Acerand Therapeutics, Shanghai, China

CYP11A1 is the first and rate-limiting enzyme in steroid hormone biosynthesis, catalyzing the conversion of cholesterol to pregnenolone and isocaproic aldehyde. Inhibition of this enzyme blocks the entire steroid hormone biosynthesis pathway, including androgens and their precursors, which activate the androgen receptor (AR) and promote prostate cancer growth. Targeting CYP11A1 has led to therapies like ODM-208 (MK-5684), which shows antitumor activity in heavily pretreated mCRPC patients, especially those with AR ligand binding domain (LBD) mutations. Here we report the discovery of ACE-232, a novel, highly potent, and selective CYP11A1 inhibitor. ACE-232 is significantly more potent than ODM-208 (>15x) in inhibiting CYP11A1 in human adrenal adenocarcinoma H295R cells, with an IC_{50} of 0.17 nM compared to ODM-208's IC_{50} of 2.82 nM. Additionally, ACE-232 demonstrates superior potency (>10x) in suppressing testosterone biosynthesis in H295R cells. Preclinical pharmacokinetic studies show that ACE-232 has significantly lower clearance and a longer half-life across multiple species (mouse, rat, and dog), resulting in a flatter pharmacokinetic (PK) curve compared to ODM-208. Together, these properties may enable sustained target engagement with once-daily dosing while minimizing hormone level fluctuations in patients. In castrated mouse models, ACE-232 showed equal or superior efficacy in inhibiting tumor growth at 0.3 mg/kg QD in both VCaP and enzalutamide-resistant xLNCaP models, compared to ODM-208 at 30 mg/kg BID. Furthermore, in a non-castrated mouse model, ACE-232 showed significant efficacy at 1.5 mg/kg BID, whereas ODM-208 at 30 mg/kg BID did not. ACE-232 also demonstrates favorable ADME properties suitable for drug development. In a safety panel screening across 93 targets at 5 μM, ACE-232 exhibited minimal off-target effects. GLP toxicology studies demonstrated a wide safety margin in both rats and dogs, with primary effects observed in the endocrine and reproductive organs, consistent with CYP11A1 inhibition. Based on these findings, an IND filing for ACE-232 with the FDA is planned for December 2024.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Cancer Therapeutic Targets and Drug Delivery Technologies
Poster Session

#6885 Plectin as a novel therapeutic target for pancreatic cancer.

Cody L. Wolf[1], Roxanne K. Ruiz[2], Julien Dimastromatteo[1], Samantha Perez[1], Matthew J. Reilley[3], Kimberly A. Kelly[1]

[1]Biomedical Engineering, University of Virginia, Charlottesville, VA,[2]Department of Molecular Physiology and Biological Physics, University of Virginia, Charlottesville, VA,[3]Department of Medicine, University of Virginia, Charlottesville, VA

Pancreatic ductal adenocarcinoma (PDAC) is the 3rd deadliest cancer in the United States with only a 5-year survival rate of 13%, demonstrating a desperate need for novel therapeutic targets to significantly enhance options for patients. In 2008, *Kelly et al.* pioneered a phage-display-based functional-proteomic approach and identified a cytolinker protein, plectin, which was mislocalized and ubiquitously expressed on the membrane of PDAC. This unique localization of plectin, called cell surface plectin (CSP), has since been found to be expressed on the cell surface of many cancer subtypes, including PDAC, ovarian carcinoma and cholangiocarcinoma, but remains cytoplasmic in normal tissues. Knockdown of plectin and an anti-CSP functional monoclonal antibody revealed the importance of CSP to proliferation, migration, and invasion in cancers. Recently, a phase 1 clinical trial using an anti-CSP antibody, ZB131 (NCT05074472) in CSP positive cancer subtypes showed ZB131 as a viable and safe drug candidate for treatment. In the trial, treatment with ZB31 led to stable disease in 3 out of 9 PDAC patients. In order to more fully understand the mechanism of action of ZB131 and to obtain comprehensive understanding of molecular signaling of CSP in cancer we have employed bioinformatic strategies as well as knock outs using CRISPR/Cas9 inducible systems. Transcriptomic data from bulk and single cell RNA-seq data from human PDAC revealed that CSP overexpressing tumors were enriched for integrin-extracellular matrix interactions, suggesting CSP plays a major role in matrix remodeling and metastasis. Additionally, treatment with anti-CSP antibody led to a decrease in classic signaling cascades associated with cancer progression such as SRC, PRAS40, STAT3, AKT, and ERK1/2. The cumulative work from this research highlights the role of CSP in PDAC and suggests a desperate need for an anti-CSP therapeutic for patients.

#6886 Pharmacokinetics of paclitaxel and cyclopamine co-administered via polymeric micelle in HCC mice.

Emanuel R. Baltrip[1], Lu Dai[1], Diana S-L Chow[1], Chun Li[2]

[1]Pharmacological and Pharmaceutical Sciences, University of Houston, College of Pharmacy, Houston, TX,[2]Cancer Systems Imaging, University of Texas MD Anderson Cancer Center, Houston, TX

Hepatocellular Carcinoma (HCC) is a highly aggressive form of liver cancer that is typically diagnosed at an advanced stage, leaving limited treatment options. The current non-surgical, first-line treatment, Sorafenib, is non-curative and does not improve patient quality of life. Our study involved pharmacokinetic (PK) analysis of Paclitaxel (PTX) and Cyclopamine (CPA) in an HCC mouse model. PTX is a microtubule-stabilizing drug, while CPA is a Hedgehog signaling pathway inhibitor. Together, the compounds arrest the cell cycle at the M and G phases, preventing tumor cell proliferation. The compounds were co-administered using a polymeric micelle formulation, termed M-CPA/PTX, which contained 2.5 mg each of PTX and CPA, with size of 70.63 ± 3.4 nm, PDI of 0.122 ± 0.038, and encapsulation efficiency of ≥80% for both compounds. The PK was evaluated in HCC transgenic mice expressing the C-MYC oncogene, after IV dosing of M-CPA/PTX at 5 mg/kg/drug every other day for 1, 2, and 3 doses, respectively. The injection volume ranged from 100 - 200 µL based on body weight. The mice were randomized into four groups: vehicle (n = 10), 1 dose (n =8), 2 doses (n=7), and 3 doses (n = 10). After the last dose of each group, PK blood samples were withdrawn at specified time points up to 24 hours when the tumor and organs were harvested. Samples were analyzed using a validated LCMS/MS method with an LLOQ of 0.5 ng/mL, following a liquid-liquid extraction with a volume ratio of 5:1 ACN: H_2O (1:1 v/v) to blood sample or tissue homogenates. PK analysis was performed by both 1 and 2-compartment models using Phoenix WinNonlin™ to derive the PK parameters. ANOVA with the Tukey post hoc test was used to compare data across dosing groups with p-value <0.05 for significance. For PTX, the clearance (CL) was 43.17 ± 11.0 L/h/kg, not changing significantly after multiple dosing. The AUC had a notable, but insignificant, increase from 177.1 ± 44.23 h*ng/mL to 193.05 ± 31.76 h*ng/mL. The volume of distribution (V_d) was 91.3 ± 61 L/kg with no appreciable trend across the three groups. For CPA, the CL increased from 23.02 ± 10.34 L/h/kg to 63.48 ± 35.82 L/h/kg and 52.81 ± 31.45 L/h/kg after two and three doses, respectively. The AUC was 253.53 ± 103.2 h*ng/mL after one dose, which decreased to 230.55 ± 99.67 h*ng/mL and 153.96 ± 67.19 h*ng/mL after two and three doses, respectively. The V_d increased from 77.77 ± 12.91 L/kg to 130.57 ± 41.83 L/kg after three doses; however, this increase was not statistically significant. Tumor drug accumulation was also analyzed. In blood, the drug concentrations at 24 hr were below the LLOQ, so the absolute tumor concentration was evaluated. The concentrations were 9.24 ± 5.91 ng/g for PTX and 8.99 ± 4.1 ng/g for CPA. In conclusion, the PK of PTX and CPA in HCC mouse model from single and multiple dosing of M-CPA/PTX were characterized. Multiple dosing yielded no changes in CL and V_d of PTX, but increased CL and decreased AUC in CPA.

#6887 Targeting JMJD6: A Novel Approach in Cancer Therapy?.

Mathilde Calmels, Dorian Brager, **Christophe Marcireau**

Sanofi, Vitry-Sur-Seine, France

The Jumonji Domain Containing 6 protein (JMJD6) is part of the Jumonji C domain-containing protein family and functions as an arginine demethylase and lysine hydroxylase. JMJD6 facilitates demethylation of arginine and hydroxylation of lysine in both histone and non-histone proteins. Its activity on histones is primarily mediated by the JMJC domain, which is involved in demethylating H3R2me2 and H4R3me2. These demethylation events at histone H3 arginine 2 (H3R2me2) and histone H4 arginine 3 (H4R3me2) are crucial for regulating chromatin accessibility and gene transcription. JMJD6 also targets non-histone proteins such as TRAF6, STAT1, RNA helicase A, ERa
, HSP70, EIF3B, EIF3C, etc. Additionally, more than 150 sites of JMJD6-catalyzed lysine hydroxylation on 48 protein substrates have been identified. JMJD6 plays an important role in transcriptional regulation, RNA splicing, inflammation, and immune responses. It downregulates pathways and activities like p53, TGF-β signaling, and Myc-induced apoptosis, while upregulating processes such as CDKs, WNT, MAPK, and autophagy pathways. Abnormal JMJD6 expression is linked to various diseases, including cancer. Elevated JMJD6 expression has been reported in many tumor types, including breast invasive carcinoma (BRCA), lung adenocarcinoma (LUAD), liver hepatocellular carcinoma (LIHC), colon adenocarcinoma (COAD) and rectum adenocarcinoma (READ). High JMJD6 levels are also associated with poor prognosis, making it an attractive target for cancer therapy. In this study, we confirmed the critical role of JMJD6 in a NSCLC cell line and a liver cancer cell line. Using CRISPR/Cas9, we replaced the endogenous JMJD6 promoter with a doxycycline-regulated promoter, creating conditional JMJD6 cells. We will examine the effects of JMJD6 depletion in these cells and assess the complementation results with various JMJD6 alleles.

#6888 Targeting melanoma cells through G-quadruplex formation: mechanism and enhanced efficacy of T-oligo in combination therapy.

Rose Bahari[1], Stephanie M. Lopez[1], Archit Agnihotri[1], Hyatt Alaraj[2], Lawrence Miller[3], Neelu Puri[1]

[1]Biomedical Sciences, University of Illinois College of Medicine Rockford, Rockford, IL,[2]Biomedical Sciences, University of Illinois Chicago, Chicago, IL,[3]Chemistry, University of Illinois Chicago, Chicago, IL

Melanoma is one of the deadliest skin cancers in the world, estimated to cause 7,990 deaths annually. Telomerase binds to the 3' overhang of the telomere, causing telomere elongation and cell survival. Treatment against melanoma aims at targeting the 3' telomere overhang using T-oligo, which is a guanine-rich oligonucleotide homologous to the telomere overhang, preventing the growth of melanoma cells by inducing apoptosis. As a guanine-rich oligonucleotide, T-oligo can form G-quadruplexes (G4), secondary structures of nucleic acids, which we aim to detect using FRET microscopy in melanoma cells. Currently, vemurafenib and trametinib are agents that are used to treat melanoma. We were also interested in studying the combinational treatment of T-oligo with vemurafenib/trametinib to determine if it improves the efficacy of these drugs as compared to monotherapy in melanoma cells. We hypothesize that T-oligo forms G-quadruplexes in the nucleus of melanoma cells, and combination therapy of vemurafenib/Trametinib with T-oligo would be efficacious compared to monotherapy.

#6889 A gold-based antibody-drug conjugate with theranostic potential for synovial sarcoma.

Jeffrey Okojie, Bridger Kearns, Melanie I'anson-Holton, Andralyn McKell, Josh Hanosek, Jared James Barrott

Brigham Young University, Provo, UT

Synovial sarcoma is a rare form of cancer that occurs in the soft tissue adjacent to bones in adolescents and young adults. Although rare, it is ranked as the second most common malignant soft-tissue tumor in children. This cancer has a high metastatic rate with 50% of all cases exhibiting metastasis at the time of diagnosis. The first line of therapy for this cancer is surgery which is effective for the primary tumor, but in patients with metastatic disease, chemotherapy and radiation are the main therapeutic options. These therapies tend to have negative side effects due to their lack of specificity. Antibody-drug conjugates are a promising class of cancer therapeutics due to their specificity and reduced side effects. Of particular interest are gold-based antibody-drug conjugates due to their laser-induced temporal control and theranostic (diagnostic and therapeutic) capabilities. This work sought to develop a novel gold-based antibody-drug conjugate for synovial sarcoma with limited side effects. To accomplish this goal, a potential target receptor, Oncostatin M Receptor (OSMR), was identified. This receptor has been shown to be involved in cancer proliferation and migration when activated by its ligand, Oncostatin M(OSM). OSMR is highly expressed in various cancers including breast cancer. The mRNA and protein expression of OSMR in synovial sarcoma tumors was compared to normal tissues. An anti-OSMR antibody was conjugated to a fluorophore and the conjugate was injected into synovial sarcoma-bearing mice to assess the specificity and targeting ability of the antibody in vivo. Gold nanorods were then synthesized, characterized, and conjugated site-specifically to the anti-OSMR antibody. The over-expression of OSMR in synovial sarcoma tumors as compared to normal tissues was validated. An anti-OSMR antibody conjugated to a fluorophore targeted OSMR-expressing tumors and metastatic cells and discriminated between tumor and normal tissue in vivo. Gold nanorods were successfully synthesized and conjugated site-specifically to an anti-OSMR antibody. These findings suggest OSMR as a viable candidate for a targeted treatment of synovial sarcoma. They also suggest that an anti-OSMR conjugate can target both primary and metastatic tumors. The successful conjugation of gold nanorods to the anti-OSMR antibody opens the possibility of a theranostic approach to synovial sarcoma.

#6890 Knockdown of CD82 sensitizes adult T cell leukemia cells to anti-cancer agents-induced growth inhibition.

K. Fukuchi, T. Ikezoe, I. Ogahara, S. Zhao;
Fukushima Medical Univ., Fukushima, Japan
