CD82 belongs to the tetraspanin family and regulates several intracellular signaling pathways. We previously found that CD82 is aberrantly expressed on acute myeloid leukemia (AML) cells and plays a role in the adhesion of these cells to the bone marrow microenvironment. Adult T-cell leukemia (ATL) is a lethal peripheral T-cell malignancy in which HTLV-1-infected T cells transform and proliferate by various mechanisms. This study found that ATL cells expressed aberrant CD82 compared to T cells isolated from a healthy volunteer, as assessed by immunocytochemistry. Interestingly, MTT assay found that MT-1 cells derived from ATL patient became more susceptible to growth inhibition mediated by doxorubicin and etoposide when CD82 was knocked down using the CRISPR-Cas9 technique, although the doubling time of CD82 knockdown MT-1 cells was compatible with parental MT-1 cells. These observations suggest that CD82 may be a promising therapeutic target in ATL. Further experiments are required to elucidate the role of CD82 in ATL cells.

#6892 Ribonucleotide reductase is a potential therapeutic target in colorectal cancer.

Federica Invrea, Consalvo Petti, Claudio Isella, **Enzo Medico**

Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy

Colorectal cancer (CRC) is a heterogeneous disease showing significant variability in clinical aggressiveness and treatment response. Primary and acquired resistance limit the efficacy of available treatments, and identification of new therapeutic targets is needed to further improve patients' outcomes. To identify actionable targets, we performed a "drop-out" loss-of-function screening with an shRNA library covering 200 drug-target genes in nine different CRC cell lines, covering the whole spectrum of molecular subtypes of CRC. Multiple screening hits were found. Among them RRM1, encoding a member of the ribonucleotide reductase complex and targeted by the FDA-approved drug clofarabine, was found to be non-dispensable in all cell lines. In vitro drug efficacy studies confirmed sensitivity to clofarabine of most CRC cell lines. In vivo testing on a CRC cell line xenograft confirmed substantial growth inhibition by clofarabine. These results unveil a possible therapeutic opportunity in colorectal cancer.

#6896 A pan-KRAS degrader for the treatment of KRAS-mutant cancers.

Mu-Sheng Zeng[1], Jie Yang[1], Qiao-Li Wang Wang[1], Guan-Nan Wang[1], Jia-Cong Ye[1], Zi-Qian Li[1], Jing-Yun Wang[1], Zhao-Hui Liang[1], Shu-Xin Li[1], Cong Sun[1], Wen-Ting Liao[1], Yi-Jun Gao[1], Jing Wang[1], Yong Mao[2], Chunjing Yu[2], Guo-Kai Feng[1]

[1]Sun Yat-sen University Cancer Center, Guangzhou, China,[2]Affiliated Hospital of Jiangnan University, Wuxi, China

KRAS mutations are highly prevalent in a wide range of lethal cancers, and these mutant forms of KRAS play a crucial role in driving cancer progression and conferring resistance to treatment. While there have been advancements in the development of small molecules to target specific KRAS mutants, the presence of undruggable mutants and the emergence of secondary mutations continue to pose challenges in the clinical treatment of KRAS-mutant cancers. In this study, we developed a novel molecular tool called tumor-targeting KRAS degrader (TKD) that effectively targets a wide range of KRAS mutants. TKD is composed of a KRAS-binding nanobody, a cell-penetrating peptide selectively targeting cancer cells, and a lysosome-binding motif. Our data reveal that TKD selectively binds to KRAS in cancer cells and effectively induces KRAS degradation via a lysosome-dependent process. Functionally, TKD suppresses tumor growth with no obvious side effects and enhances the antitumor effects of the PD-1 antibody and cetuximab. This study not only provides a strategy for developing drugs targeting “undruggable” proteins but also reveals that TKD is a promising therapeutic for treating KRAS-mutant cancers.

#6897 Development of immunomodulatory nanoparticles targeting HER2 for breast cancer therapy.

Mathilde Dacos, Lea Plantureux, Erwan Diroff, Sarah Giacometti, Joseph Ciccolini, **Raphaelle Fanciullino**

Aix-Marseille University, Marseille, France

Nanoparticles (NPs) are emerging as a promising strategy in oncology, offering optimised drug delivery and the potential to modulate immune responses. In this study, we developed an innovative nanoparticle encapsulating docetaxel and functionalised with trastuzumab for the precise targeting of HER2-positive tumours (called ANC for Antibody Nanoparticle Conjufate). Pharmacokinetic analyses were performed using C57BL/6 mice, which were administered free docetaxel (1.6 mg/kg) and trastuzumab (135 ng/kg) via intraperitoneal injection (n = 29), or ANC (nanoparticles at the same docetaxel and trastuzumab doses as the free drugs, n = 40). Blood samples were collected at 0.5, 1, 2, 3, 6, 8, 12, and 24 hours post-injection, and the frozen plasma was analysed using by HPLC-UV. For biodistribution studies, DiR-labelled nanoparticles were administered to C57BL/6 mice, and imaging was performed on a daily basis using an IVIS Spectrum imager. Immunomodulation study was assessed by flow cytometry. The $AUC_{0-\infty}$ for the ANC (4250.79 ng.mL/h) was four times higher than for free docetaxel (1050.3 ng.mL-1.h-1). In addition, the half-life of the liposomal docetaxel (22.14 hours) was significantly three times longer than that of the free docetaxel (7.15 hours). Biodistribution studies in mouse models showed that the nanoparticle remained stable and did not reach the liver until 30 hours after injection. Immunomodulation studies showed that ANC had a different effect on the distribution of lymphocyte subpopulations compared to free drug, with a notable decrease in regulatory T cells (Tregs) in the ANC-treated group, suggesting a potential immunostimulatory effect. The potential immunomodulatory effects of these nanoparticles on anti-tumour immune responses are currently being investigated. These preliminary results demonstrate the dual benefit of targeted drug delivery and immune system engagement offored by these nanoparticles, which could pave the way for novel breast cancer treatments.

Keywords: Nanoparticles, breast cancer HER2 +, immunomodulation, pharmacokinetics, biodistribution

#6898 Identification of a novel first-in-class inhibitor targeting the ADAR1 p150 isoform demonstrates robust anti-tumor efficacy in a syngeneic mouse model.

Avijit Goswami, Sandeep Goyal, Kawaljit Singh, Princy Khurana, **Aditya Kulkarni**

Avammune Therapeutics, Phoenixville, PA

Background: Adenosine deaminase acting on RNA (ADAR1) catalyzes the conversion of adenosine (A) to inosine (I) in double-stranded RNAs (dsRNAs). It exists in two isoforms: nuclear p110 and p150, which shuttles between the nucleus and cytoplasm and is regulated by interferon (IFN) signaling. The p150 isoform contains a Z-DNA/Z-RNA binding domain and suppresses immunogenic dsRNAs and Z-RNAs arising from endogenous retroviral elements. Loss of ADAR1 leads to Z-RNA accumulation, activation of the sensor ZBP1, and RIPK3-driven necroptosis. ADAR1 promotes tumor cell survival and resistance to immune responses, making p150 inhibition a promising strategy to boost anti-tumor immunity. Herein, we report the discovery of a first-in-class Zα-targeted ADAR1 p150 inhibitor for cancer immunotherapy.
Methods: A class of ADAR1 p150 inhibitors (AVA-ADR) were identified through a high-throughput ADAR1p150 binding assay. The ability of these inhibitors to induce interferons was confirmed in various cell-lines. The on-target mechanisms were confirmed by downstream PKR activation and MDA5 mediated upregulation of ISGs. Pharmacokinetic studies demonstrate the oral availability of the AVA-ADR compounds. The anti-tumor efficacy of our ADAR1 p150 inhibitors was evaluated in B16F10 syngeneic melanoma mice model as monotherapy and in combination with anti-PD-1.**Results:** We have identified a potential first-in-class small molecule inhibitor specifically targeting the ADAR1 enzyme via the Zα domain. Our compounds exhibit potent in vitro IFN response via an MDA5-dependent mechanism. Binding studies revealed a series of AVA-ADR compounds with strong sub-micromolar affinity for the Zα-domain. ADME and pharmacokinetic analyses demonstrate favorable PK profiles and oral bioavailability. Our ADAR1 inhibitors demonstrated promising anti-tumor activity in preclinical melanoma models, with notable tumor growth inhibition observed both as monotherapy and in combination with immune checkpoint inhibitors. The combination therapy led to enhanced efficacy compared to either treatment alone. Additionally, markers associated with immune activation were significantly upregulated in tumor samples from the combination group. Target engagement was supported by the development of a PROTAC derivative, which selectively degraded the target protein.**Conclusions:** To our knowledge, our AVA-ADR series of compounds are the first report of a selective small molecule inhibitor of ADAR1 p150. The 2nd generation AVA-ADR compounds described here are stable/orally bioavailable first-in-class ADAR1 inhibitors that demonstrated significant IFN induction in-vitro and in-vivo, demonstrating significant tumor growth inhibition as monotherapy and synergistically in combination with Anti -PD1.

#6899 Investigating the impact of CXCR6 antagonism on Wnt/β-catenin signaling and sorafenib resistance development.

Anastasia G. Chambers[1], Abhishek Shrestha[1], Morgan Reeves[2], Alivia Cullu[1], Lauren Donohue[1], Sergio Duarte[1], Satyamaheshwar Peddibholta[2], Siobhan Malany[2], Ali Zarrinpar[1]

[1]Department of Surgery, University of Florida College of Medicine, Gainesville, FL,[2]Department of Pharmacodynamics, University of Florida College of Pharmacy, Gainesville, FL

Introduction: Due to its heterogeneity, hepatocellular carcinoma (HCC) has a high incidence of resistance and toxicity to its first-line therapy sorafenib. Combinations of drugs can be used to exploit synergistic effects to improve efficacy and reduce adverse events. Upregulation of C-X-C chemokine receptor type 6 (CXCR6) and its ligand has been observed in multiple cancers and has been used as a predictor of cancer recurrence and poor prognosis in HCC. Increased CXCR6 signaling has been shown to promote Wnt/β-catenin signaling, a pathway known to be dysregulated in 50% of HCC and involved in sorafenib resistance. We have developed SBI-457, an orally bioavailable small molecule CXCR6 inhibitor, which decreased tumor growth in a murine HCC model. In this study, we test the efficacy of combining SBI-457 and sorafenib in mitigating the development of resistance and increasing sensitivity to drug treatment in HCC.

Experimental Procedure: An HCC cell line-derived xenograft model was generated by injecting HCC cell line SKHep1 subcutaneously in the flank of male NOD.Cg-Prkdc^{scid}IL2rg^{tm1Wjl}/SzJ (NSG) mice. Mice were treated with vehicle, sorafenib, SBI-457, or sorafenib and SBI-457 in combination; mouse tumor volumes and weights were tracked for the duration of study. Mice were all euthanized at study endpoint, and tissues collected for analysis, including assessment of tumor proliferation, invasion, and CXCR6 and β-catenin expression levels.

Results: SKHep1 tumors treated with sorafenib and SBI-457 in combination were significantly reduced in tumor volume and weight compared to vehicle. Mice treated with SBI-457 alone or in combination with sorafenib maintained stable weight and had no observed toxicity due to treatment. CXCR6 expression was slightly elevated in the sorafenib only treated group and reduced in the groups treated with SBI-457 alone. Western blot and IHC analysis confirmed that treatment with SBI-457 increases active (non-phosphorylated) GSK-3β and decreases β-catenin expression, while sorafenib treatment resulted in an increased phosphorylated GSK-3β and (non-phosphorylated) active β-catenin expression. This sorafenib-induced increase in β-catenin was attenuated by combination treatment with SBI-457.

Conclusion: This study demonstrated that treatment with CXCR6 antagonist, SBI-457, in combination with sorafenib was able to significantly reduce tumor burden compared to vehicle. Additionally, combination therapy seems to attenuate the sorafenib-induced increase in β-catenin expression, indicating that CXCR6 inhibition could help mitigate sorafenib resistance development.

#6901 Imipridones (ONC201, ONC206 and ONC212) modulate MGMT and ClpX expression in DIPG cell lines.

Lanlan Zhou, Shengliang Zhang, Wafik S. El-Deiry

Brown University, Providence, RI

The first-in-class small-molecule imipridone ONC201/Dordaviprone targets mitochondrial protease ClpP to disrupt oxidative phosphorylation and trigger integrated stress response (ISR), TRAIL/DR5, and tumor cell death. ONC201 and analog ONC206 and ONC212 are blood-brain barrier penetrant. Temozolomide (TMZ) is an oral alkylating agent that is generally well tolerated. Epigenetic transcriptional silencing of O6-methylguanine-DNA methyltransferase (MGMT) mediated by MGMT gene promoter methylation is associated with response to TMZ treatment. TMZ has been used in combination with Radiation Therapy (RT) as standard of care for glioblastoma (GBM) with a methylated MGMT promoter since 2005. Our previous studies demonstrated that ONC201/ONC206 synergized with standard-of-care GBM therapies TMZ and RT in GBM cell lines and orthotopic GBM mouse model. Diffuse Intrinsic Pontine Gliomas (DIPG) is a fast growing and highly aggressive pediatric central neural system tumor that starts in the brain stem's glial cells and has a dismal prognosis. DIPG has been recognized to be molecularly distinct from both adult high-grade glioma (HGG) and other non-midline pediatric high-grade gliomas (pHGG). DIPG has almost universally unmethylated MGMT promoters and TMZ has no role in the treatment of this disease. We reported earlier that ONC201 suppresses oxygen consumption rate observed with TMZ alone in DIPG cells, and TMZ has effects on T-cells killing solid tumor cells with high expression of MGMT. In this study we discover that imipridones (ONC201, ONC206 and ONC212) reduce expression of MGMT in DIPG cell lines following treatment with Imipridones -/+ TMZ. ClpX levels were reduced in all glioma cells treated and served as a biomarker of imipridone target engagement. The change of MGMT has the same trend as that of ClpX. These novel findings suggest a potential mechanism of synergy between imipridones and TMZ through suppression of MGMT protein expression in DIPG cells that typically have unmethylated MGMT promoter and are resistant to effects of TMZ. We are going to test this mechanism of synergy and therapeutic efficacy in vivo by treating orthotopic DIPG mouse models with imipridones -/+ TMZ. Our results support further studies combining imipridones (ONC201, ONC206 and ONC212) with TMZ and RT as a reasonable and safe therapeutic option for DIPG.

#6902 Promising therapeutic effects of pyrimidine synthesis inhibition by a novel dihydroorotate dehydrogenase inhibitor in small cell lung cancer.

Bahareh Nourmohammadi[1], Ola A. Elgamal[2], Sandip Vibhute[3], Christopher C. Coss[4], Thomas E. Goodwin[5], Erin Hertlein[2], Joseph M. Amann[6], Chad E. Bennett[4], John C. Byrd[2], David P. Carbone[6]

[1]Biomedical Sciences Graduate Program, College of Medicine, The Ohio State University, Columbus, OH,[2]Division of Hematology and Oncology, Department of Internal Medicine, College of Medicine, University of Cincinnati, Cincinnati, OH,[3]Drug Discovery Shared Resource, Comprehensive Cancer Center, The Ohio State University, Columbus, OH,[4]Drug Development Institute, Comprehensive Cancer Center, The Ohio State University, Columbus, OH,[5]Department of Chemistry, Hendrix College, Conway, AR,[6]Division of Medical Oncology, Department of Internal Medicine, James Thoracic Center, The Ohio State University, Columbus, OH

Small-cell lung cancer is an aggressive subtype of lung cancer with poor prognosis and poor overall survival and comprises approximately 15% of all lung cancers. SCLC, unlike NSCLC, has no known targetable driver mutations and, therefore, targeted therapeutics have been lacking. The frontline therapy for SCLC is platinum-etoposide chemotherapy, a regimen that has been in use for 30 years. Although patients respond well to this combination initially, they almost always relapse shortly after the start of therapy and second line therapies typically provide only a few months of benefit. Clearly, better therapeutics are necessary for the treatment of SCLC. Cancer cells often have dysregulated metabolic pathways. These changes are often necessary to enable the continued proliferation of the cancer cells. Therefore, key metabolic enzymes can have a crucial role in tumor cells survival and can be considered targets for cancer treatment. According to some recent studies, dihydroorotate dehydrogenase (DHODH), which catalyzes the conversion of dihydroorotate to orotate in the pyrimidine *de novo* synthesis pathway, has a particular role in the survival of different types of cancers including leukemia and SCLC. We evaluated the effect of HOSU-53, a novel DHODH inhibitor, on SCLC tumor growth *in vitro* and *in vivo*. We measured IC50s of 18 SCLC cell lines *in vitro* using CellTiter-Glo® Luminescent Cell Viability Assay and most SCLC cells showed sensitivity to HOSU-53 treatment in the low nanomolar range. Additionally, to determine the role of salvage pathway in HOSU-53 sensitivity, we treated the sensitive and resistant cells in parallel with HOSU-53 alone or in combination with exogenous uridine. In the presence of uridine, cell viability was significantly rescued in resistant cells compared to HOSU-53 treatment as single agent. However, we did not observe rescued cell viability in sensitive SCLC cells. These results suggesting that in SCLC cells which are resistant to *de novo* pyrimidine inhibition, activation of salvage pathway may be one of the compensatory mechanisms for tumor cells to sustain their survival. To evaluate the effect of DHODH inhibition on SCLC tumor growth *in vivo*, we treated xenograft mice models with HOSU-53 alone or in combination with etoposide plus cisplatin as the standard chemotherapy for SCLC. We observed a significant decrease of tumor volume when HOSU-53 was used alone and in combination, without significant animal weight loss. Together, these data demonstrated the promising efficacy of HOSU-53 in different SCLC subtypes and support the strategy of targeting DHODH as a potential therapy to treat SCLC. These findings support the initiation of a phase I clinical trial to evaluate the preliminary efficacy and tolerability of HOSU-53; therefore, we have initiated a first-in-human phase I trial of this agent.

#6903 PERMnano: A quick method to develop nanoliposomes and nanosuspensions for oral/parenteral administration to expedite preclinical testing.

Henis Patel, Himaxi Patel, Akanksha Ugale, **Ketan Patel**

St. John's University, Queens, NY

The vast majority of novel drug candidates are hydrophobic in nature, which often presents significant challenges in formulation due to poor aqueous solubility, limiting their drug delivery, systemic concentration, and availability at the target site. Generally, organic solvents (ethanol, PEG, DMSO etc.), cellulose polymers, vegetable oils and surfactants are used to administer drugs for preclinical testing. However, these methods may result in false negative efficacy and poor translational insight. Liposomes (a bilayer phospholipid vesicle) and nanosuspensions (nanostablized drug particles) have emerged as promising delivery systems to overcome these challenges with great translational potential. However, both technologies require a thorough knowledge of excipients, set-up, processing and skilled manpower. This study explores a simple and quick approach for preparing nanoliposomes and nanosuspension of various hydrophobic drugs for oral and parenteral administration. The first objective was to develop an excipient blend for the preparation of liposomes/nanosuspension based on the physicochemical properties of the drug and the route of administration. The second objective was to develop a rapid media milling process using parenterally acceptable zirconia beads. Thus, the study aimed to develop and optimize a premix excipient blend with rapid nanomilling for the preparation of nanomedicine (PERMnano). For liposomes, a pro-liposome powder was prepared through a modified solvent evaporation method, using three different saturated and unsaturated phospholipids, PEGylated DSPE and cholesterol. For nanosuspensions, stabilizer blends (FDA-approved stabilizers for oral and parenteral use) were prepared using a freeze-drying process. Various hydrophobic drugs, including Amphotericin B, Docetaxel, Ibrutinib, BRD4 PROTAC, Sotorasib, Mebendazole, Ebselen, and Irinotecan were suspended into aqueous phase with 1-10% premixed excipient blends for nanoliposomes and nanosuspension. The results demonstrated that both liposomes and nanosuspensions prepared via rapid wet media milling showed desirable physicochemical properties, with particle sizes consistently below 200 nm and with narrow size distribution (PDI < 0.2), indicating uniformity and stability. Entrapment efficiency (%EE) and drug loading (%DL) were significantly influenced by the choice of excipient blend and physicochemical properties of the drug candidate. The resultant formulations were stable and suitable for administration into animals. In conclusion, PERMnano could potentially provide a rapid, translational, and efficient technique for preclinical drug delivery of hydrophobic drug molecules, including beyond the rule of 5 molecules, high dose candidates and PROTACs.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Targets and Pathways
Poster Session

#6906 c-Myc inhibition through targeting MMK3 and c-Myc interaction overcomes acquired resistance to third generation EGFR inhibitors in the treatment of EGFR mutant lung cancer.

Z. Chen, K. Vallega, D. Wang, H. Fu, S. Ramalingam, A. Ivanov, S.-Y. Sun;
Emory University, Atlanta, GA

There is an urgent need to develop effective strategies for overcoming the inevitable acquired resistance to third generation EGFR tyrosine kinase inhibitors (EGFR-TKIs) such as osimertinib, which are approved for the treatment of advanced non-small cell lung cancer (NSCLC) harboring mutant EGFR. Our previous study has demonstrated c-Myc inhibition as a critical mechanism in mediating the therapeutic efficacy of osimertinib against EGFR mutant (EGFRm) NSCLCs/tumors and targeting c-Myc as an effective strategy for overcoming osimertinib acquired resistance. However, lack of specific c-Myc inhibitors restricts the application of this strategy in battling against acquired resistance to third generation EGFR-TKIs. Recently, we developed a novel strategy to inhibit c-Myc via disrupting the interaction of MKK3 and c-Myc, which stabilizes c-Myc protein. In this study, we found that the specific inhibitor of MKK3/c-Myc interaction, SGI-1027, effectively decreased c-Myc levels via disrupting the interaction and promoting c-Myc degradation in different osimertinib-resistant EGFRm NSCLC cell lines that possessed elevated levels of both c-Myc and MKK3 and increased interaction of MKK3 and c-Myc. SGI-1027, but not a p38 (that activates MKK3) or MKK3 kinase inhibitor, when combined with osimertinib or another third generation EGFR-TKI, synergistically decreased the survival of osimertinib-resistant EGFRm NSCLC cells with enhanced induction of apoptosis. In agreement, genetic knockdown of MKK3 led to c-Myc reduction and re-sensitized osimertinib-resistant EGFRm NSCLC cell lines to undergo apoptotic cell death upon osimertinib treatment. Moreover, the combination of SGI-1027 and osimertinib was also significantly more active than either single agent in suppressing the growth of osimertinib-resistant EGFRm NSCLC tumors in mice, indicating enhanced tumor-inhibitory effect *in vivo*. In sensitive EGFRm NSCLC cell lines, osimertinib effectively inhibited MKK3 and c-Myc interaction accompanied with substantial reduction of c-Myc levels, suggesting a critical mechanism by which osimertinib decreases c-Myc levels through promoting c-Myc degradation via disrupting MKK3 and c-Myc interaction. Hence, our findings reveal molecular mechanisms accounting for c-Myc reduction by osimertinib in sensitive EGFRm NSCLC cells and c-Myc elevation in EGFRm NSCLC with acquired resistance; it also suggests a novel strategy to target c-Myc via disrupting MKK3 and c-Myc interaction for overcoming acquired resistance and rationale for developing cancer therapeutic agents that specifically disrupts MKK3 and c-Myc interaction. (This study was supported by NIH/NCI R01 CA245386, UG1 CA233259, U01 CA168449, U01 CA217875, lung cancer SPORE P50CA217691 and Emory Winship Cancer Institute lung cancer research internal funds)

#6907 Novel TACC3 protein-protein interaction inhibitor, AO-252, shows potent activity in prostate, gastric cancers, and triple negative breast cancer with brain metastasis.

Sridhar Vempati, Chaemin Lim, Robbin Frnka, Edward Painter, Sotirios G. Stergiopoulos

A2A Pharmaceuticals, New York, NY

TACC3 (Transforming Acidic Coiled-Coil-Containing 3) is a key player in microtubule and centrosomal processes and is considered to have an important role in causing chromosomal instability, leading to aggressive cancer. TACC3 overexpression is found in multiple cancers and strongly associated with a poor prognosis in those cancer types. TACC3 is a pleiotropic gene which binds to multiple proteins and plays an important role in DNA damage response mechanisms, hematopoiesis, epigenetics, and immune functions. While TACC3 is essential for cancer cells but it is dispensable for normal cells based on conditional knockout in adult mice, making it an ideal treatment target for highly aggressive cancers. We had previously shown that AO-252, a novel small molecule TACC3 protein-protein interaction (PPI) inhibitor, exhibited strong in vivo efficacy in triple negative breast cancer (TNBC) and ovarian cancer. In the present work, we show in vitro and vivo assays that AO-252 shows exceptional efficacy in prostate, gastric cancers and TNBC with brain metastases. In all these cancers, AO-252 exhibited dose dependence on tumor growth inhibition and complete responses in xenograft models. In addition, these responses demonstrated to be durable even after stopping the treatment with AO-252. We also show that AO-252 exerts its activity by destabilizing the C-terminus of TACC3 and disrupting the protein-protein interactions occurring in the C-terminus (EGFR, NOTCH, BRCA1, HIF1b/ARNT, KIFC1, HDAC2, MBD2, DNAPK etc) without blocking the N-terminus interactions. AO-252 is currently in first-in-human (FIH), Phase I clinical trial in TNBC, ovarian and endometrial cancers (NCT06136884). We are in the process of expanding our trial to include prostate, gastric cancer and TNBC with brain metastases.

#6908 Autophagy disruption via PIKfyve inhibition as a novel strategy to enhance immunotherapy responses in multiple myeloma.

Cecilia Bonolo de Campos[1], Dor D. Abelman[1], Ruijuan He[1], Tessa Pelino[1], Ding Yan Wang[1], David S. Scott[1], Zhihua Li[1], Michael St Paul[1], Trevor J. Pugh[1], Olga Issakova[2], Nikolai Sepetov[2], Tak W. Mak[1], Suzanne Trudel[1], A Keith Stewart[1]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]PIKSci, Toronto, ON, Canada

Despite advancements in the treatment of multiple myeloma (MM), most patients ultimately relapse due to innate and acquired drug resistance. Our search for novel therapeutic strategies led to the development of PIK001, a potent and selective PIKfyve inhibitor, as a promising therapeutic approach targeting lysosomal function and autophagy. In addition to its robust single agent anti-MM activity, PIK001 presented synergistic activity with relevant anti-MM therapeutics, including selinexor, venetoclax, and pomalidomide (IMiDs), *in vitro*. Notably, PIK001 retained efficacy in IMiD-resistant isogenic human myeloma cell line (HMCL) models, underscoring its potential in drug-resistant MM. To investigate the determinants of PIKfyve resistance, we generated PIK001-resistant HMCLs by culturing three PIK001-sensitive HMCLs (KMS26, KMS11, and JJN3) in escalating doses of the PIKfyve inhibitor (up to 5uM). These isogenic models of resistance were characterized by whole genome and transcriptome sequencing and mass spectrometry-based proteomics. *Ex vivo* downstream effects of PIK001 treatment with 500nM for 16h were further assessed in patient-derived CD138+ MM samples using single-cell multiomic sequencing. PIK001 resistance was associated with a marked upregulation of genes and proteins involved in lysosomal function, autophagy regulation, and cholesterol homeostasis, along with downregulation of MYC targets. These findings were also found in primary patient samples following PIK001 treatment. KMS26 PIK001-resistant showed a clonal *PIKFYVE* kinase domain mutation, previously described in a resistant diffuse large B-cell lymphoma cell line. Importantly, we observed a two-fold increase in canonical and noncanonical Major Histocompatibility Complex (MHC) class I and a four-fold increase in MHC class II gene and protein expression in the PIK001-resistant compared to PIK001-sensitive KMS11. Increased cell surface expression of MHC Class I and II in KMS11 PIK001-resistant was confirmed by flow cytometry. PIK001-resistant KMS26 and JJN3 also presented an upregulation of cell surface expression of MHC Class I and, to a lesser extent, II. Similarly, PIK001 treatment also resulted in increased in MHC Class I gene expression on primary patient samples. Since downregulation or loss of MHC Class I has been shown as a mechanism of immune evasion in cancer, these findings suggest that PIKfyve inhibition may enhance MM immunotherapy responses by upregulating MHC surface expression. This hypothesis aligns with recent studies demonstrating increased tumor-specific MHC Class I expression and improved cancer immunotherapy efficacy following PIKfyve inhibition in solid tumors. Together, these results highlight the potential of PIKfyve inhibitors to synergize with existing anti-MM therapeutics and sensitize MM cells to MHC-dependent immunotherapies via autophagy disruption.

#6909 Exportin 1 as a novel therapeutic target in gastroenteropancreatic neuroendocrine tumors.

Md. Hafiz Uddin[1], Husain Y. Khan[1], Amro Aboukameel[1], Sahar F. Bannoura[1], Hugo Jimenez[1], Grayson Barker[1], Allan M. Johansen[2], Khalil Choucair[1], Sunil Jaiman[3], Gregory Dyson[1], Yang Shi[1], Mohammed N. Al Hallak[1], Nitin Vaishampayan[1], Steve Kim[1], Eliza W. [1]Department of Oncology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[2]Department of Cancer Biology, Wake Forest University, Winston-Salem, NC,[3]Department of Pathology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[4]Department of Surgery, O'Neill Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL,[5]Henry Ford Cancer Institute, Henry Ford Health System, Detroit, MI,[6]Division of Hematology and Oncology, O'Neill Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL

Background: Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) show minimal response to FDA-approved therapies suggesting an urgent need for the identification of novel and effective therapeutic targets. Aberrant nuclear protein transport to the cytoplasm, often observed in cancer, causes mislocalization-dependent inactivation of critical cellular proteins. The major nuclear exporter exportin-1 (XPO1) has been linked to cancer therapy resistance. Nevertheless, the role of XPO1 in GEP-NETs has not been explored. Major GEP-NETs growth regulators such as MEN1, DAXX and mTOR are recognized cargo proteins of XPO1, which regulates their nucleo-cytoplasmic transport. Here we evaluated the role of XPO1 in pancreatic neuroendocrine tumors (pNET) subsistence and therapy resistance.

Methods: We performed immunohistochemistry (IHC) analysis for XPO1 on 145 low-grade pNET tumors, and 35 normal, and established cell lines. Growth inhibition was determined by MTT, colony formation and apoptosis assays. Gene expression was determined using quantitative PCR, and protein expression using western blotting and immunofluorescence (IF) techniques. The impact of XPO1 inhibitor selinexor and analogs was evaluated in pNET 2D and 3D cultures, xenograft and primary explant cultures.

Results: IHC on TMAs confirmed XPO1 over-expression in pNET tumor tissue. Selective inhibitors of nuclear export (SINE) selinexor and eltanexor suppressed the growth of BON-1 and QGP-1 cells at pharmacologically relevant concentrations. Both inhibitors significantly reduced the number and the area of the colonies, and were able to induce apoptosis. Western blot analysis revealed significant induction of PARP cleavage. The pNET marker Chromogranin A was found to be reduced in the XPO1 inhibitors treated cells in IF assay. Selinexor synergized with everolimus and sunitinib leading to superior pNET cell deaths (combination index<1). IF analysis showed nuclear retention of mTOR and MEN1, and perinuclear accumulation of DAXX in the BON-1 cell line. Selinexor suppressed phosphorylation of mTOR and its downstream targets P70S6K and RICTOR. We observed significant inhibition of MEN1 targets including suppression of FANCD2 and SMAD3 and activation of p53. Selinexor given at low dose (15 mg/kg), twice a week for three weeks suppressed the growth of BON-1 and QGP-1 tumors *in vivo*. An examination of residual tumors showed a reduction in mTOR downstream target pS6 and reduced nuclear expression of pAKT. Six-day treatment with 300 nM selinexor demonstrated a marked reduction in the proliferation marker ki67 and nuclear retention of the well-recognized XPO1 cargo FOXO3a in the pNET explant tissue.

Conclusions: This is the first study to reveal the therapeutic potential of novel XPO1-targeted agents for the treatment of a GEP-NET *in vitro* and *in vivo*. XPO1 could be a novel therapeutic target that warrants further clinical investigations in GEP-NETs.

#6910 Synergistic tumor cell killing with dual inhibition of PARG and USP1.

Ramya Ravindranathan, Alexandre A. da Costa, Benjamin P. Lamarre, Sirisha Mukkavalli, Ozge Somuncu, Kalindi Parmar, Geoffrey I. Shapiro, Alan D. D'Andrea

Harvard Medical School, Dana-Farber Cancer Institute, Boston, MA

Poly (ADP-ribose) glycohydrolase (PARG) is an enzyme that aid in DNA repair primarily through the removal of poly (ADP-ribose) (PAR) chains from PARylated proteins. PARG inhibitors are currently in clinical development for patients with tumors exhibiting homologous recombination deficiency (HRD). Recently, we have demonstrated that similar to PARP inhibitors, PARG inhibitors also promote the formation of single stranded DNA gaps (ssGAPs) in preclinical ovarian cancer models. PARGi treatment increases the levels of toxic S phase PARylation resulting from Okazaki fragment processing (OFP) defects. More importantly the cellular sensitivity to PARGi directly correlates with the formation of ssGAPs. Additionally, our recent findings show that inhibitor of USP1, a deubiquitinating enzyme, also promotes the accumulation of ssGAPs during replication in BRCA1-deficient cells, and this phenotype correlates with the drug sensitivity. Interestingly, a CRISPR screen with USP1 inhibitor (USP1i) KSQ-4279 has identified gRNAs against genes encoding proteins in the OFP and base excision repair (BER) pathways, particularly PARG and PARP1, as key sensitizers. Combining PARP inhibitor (PARPi) with USP1i has shown promise in preclinical setting, extending PARPi benefits to tumors without homologous recombination defects and addressing PARPi resistance. In this study, we provide the evidence that PARGi synergizes with USP1i to maximize vulnerability to drug-induced replication stress in a panel of ovarian cancer and breast cancer cells. The combination treatment exacerbated DNA damage and replication stress as detected by an increase in markers such as pKAP1, pRPA, pCHK1 and γH2AX. Notably, USP1i augmented the PARGi-induced S phase PARylation and specifically PARylation at the replication forks. As predicted, the combination treatment induced ssGAP formation in the sensitive cells. Dual inhibition of PARG and USP1 caused an accumulation of unresolved replication intermediates, resulting in mitotic catastrophe as evidenced by a marked increase in micronuclei formation and chromosomal aberrations. Importantly, PARGi and USP1i combination enhanced tumor cell killing in a subset of PARP-inhibitor-resistant BRCA1-deficient tumors. Overall, these results indicate that the combination treatment with a PARGi and a USP1i causes accumulation of toxic PARylation at the replication fork leading to ssGAPs and replication catastrophe. Both PARG inhibitors and USP1 inhibitors are orally available drugs currently in clinical trials. Our data provides novel mechanistic insights into the therapeutic potential of combining these inhibitors, offering preclinical evidence to support its advancement for treating tumors with HRD and those resistant to PARP inhibitors. This combination strategy holds promise for enhancing treatment efficacy while reducing toxicity, paving the way for more targeted and effective therapeutic options.

#6911 Investigating pharmacological targeting of the SLC1A1 aspartate/glutamate transporter.

Pooneh Koochaki[1], Jesse A. Coker[2], Biao Qiu[3], Nancy Wang[2], Todd Romigh[2], Shaun R. Stauffer[2], Olga Boudker[3], Abhishek A. Chakraborty[1]

[1]Cancer Biology, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[2]Center for Therapeutics Discovery, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[3]Department of Physiology & Biophysics, Weill Cornell Medicine, New York, NY

Background: SLC1A1/EAAT3 functions as a trimeric, Na^+-dependent dicarboxylic amino acids (glutamate and aspartate) transporter. Recent studies have identified SLC1A1/EAAT3 as an oncogenic dependency in several cancers, including clear cell renal cell carcinoma (ccRCC), blood-borne tumors, and lung cancer. Unfortunately, despite this transporter's potential as a therapeutic target, pharmacological inhibition of SLC1A1 has remained elusive due to the absence of potent and selective inhibitors. In earlier studies, we investigated a previously described bicyclic imidazopyridine aniline SLC1A1 blocker (which we synthesized in-house, Compd 3e). Compd 3e bound SLC1A1 directly and promoted its thermal stability. Furthermore, Compd 3e treatment replicated the effects of genetic SLC1A1 blockade in terms of both metabolic changes and cytotoxicity of ccRCCs. Importantly, these fitness defects were rescued by supplementation of cell-permeable Asp and Glu.

Results: Here, we resolved the Cryo-EM structure of Compd 3e-bound SLC1A1. These studies showed that Compd 3e operates through a dual inhibitory mechanism. First, Compd 3e occupies a previously uncharacterized 'hidden' cholesterol-enriched pocket within the transporter, competitively disrupting Na^+ binding that is critical for SLC1A1's transport cycle. Second, Compd 3e wedges itself between the trimeric domains, thereby non-competitively arresting the 'elevator' movements necessary for substrate translocation across the membrane. Compd 3e makes several direct contacts with SLC1A1, including with the F99 residue that is not conserved in the other SLC1A family proteins. Mutating this residue into the SLC1A2/1A3-like (F99M) or the SLC1A5-like (F99L) conferred resistance to Compd 3e. These studies explain the mechanistic basis of Compd 3e's selectivity towards SLC1A1. Compd 3e has poor pharmacological properties (solubility, bioavailability, etc.). In silico molecular docking enabled a structure-activity relationship (SAR) campaign to optimize the Compd 3e scaffold. Our biochemical, structural, and functional studies have identified improved SLC1A1 inhibitors.

Conclusion: Our study provides an understanding of the dual mechanisms by which Compd 3e inhibits SLC1A1. These mechanistic discoveries uncover a novel therapeutic avenue for targeting ccRCC (and other SLC1A1-dependent cancers). More broadly, this work highlights the allosteric targeting of solute carriers outside their substrate-binding pocket, which can be leveraged for several other oncogenic SLCs.

#6912 Resolvin E1 sensitizes tumors to immune checkpoint inhibition by stimulating tumor antigen presentation.

Sui Huang[1], Katherine Quinlinvan[2], Eva Rothenberg[2], Michael Gillespie[2], Nandini Krishnamoorthy[3], Wayne D. Klohs[4], John Parkinson[4], Gary Mathias[4], Dipak Panigrahy[2]

[1]Institute of Systems Biology, Seattle, WA,[2]Beth Israel Deaconess Medical Center, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]Thetis Pharmaceuticals LLC, Essex, CT

Background: Immune-checkpoint inhibitors (ICI) unleash tumor-specific cytotoxic T cells already primed to recognize tumor-associated antigens (TAA). One reason for poor response to ICI is insufficient priming of T cells, which requires cross-presentation of TAA to T cells by innate immune cells. Phagocytosis of apoptotic tumor cell by antigen-presenting innate immune cells is crucial for priming T cells to TAA, but without proper adjuvant signals, it can lead to immunosuppression. The endogenous lipid mediator Resolvin E1 (RvE1), a partial agonist of the BLT1 receptor, promotes phagocytosis of tumor cell debris and has been shown to control solid tumor growth in animal models. However, its effect on antigen presentation remains unknown.
Methods: We studied the efficacy of TP-317, a clinical stage RvE1 drug, in murine tumor models implanted subcutaneously (Lewis Lung carcinoma (LLC), CT26 colon carcinoma, B16F10 melanoma, KPC pancreas adenocarcinoma). After tumor volumes reached ≥ 100mm3, animals were treated with TP-317 (0.3 mg/kg, po, qd; or 300 ug/kg, s.c., q6d) alone or in combination with ICI or chemotherapy or both (n=8-9/group). Tumors were resected at days 9-12 and analyzed by bulk and/or single cell RNAseq.
Results: TP-317 monotherapy suppressed primary tumor growth on average by 31% in LLC, 66% in B16F10, 46% in CT26 and by 36% in KPC, rivaling the canonical ICI + chemo in these models. While TP-317 exhibited additivity when combined with chemotherapy (cisplatin, 5-FU and gemcitabine + paclitaxel in LLC, CT26 and KPC, respectively) or ICI (anti-PD1 +/- anti-CTLA4), TP317 synergistically enhanced tumor control in combination with ICI + chemo or with dual ICI, reducing tumor growth by an additional 60-80% compared to the various dual combinations alone. The effect of TP-317 monotherapy required the presence of CD8 T cells and was largely abrogated in animals co-treated with a BLT1 antagonist. Whole-tumor transcriptomes of resected tumors of TP-317-treated versus control animals displayed a broad upregulation of IFN-γ response genes, including antigen presentation machinery, regulators of MHC loci, immunoproteasome and MHC-I/II, as well as genes activating T-cell, NK cell and dendritic cell interaction. Single-cell RNAseq of B16F10 and LLC located the source of such transcriptional activation to innate immune cells. Intriguingly, antigen presentation genes (including MHC-II) were also markedly induced in tumor cells.
Conclusion: These data demonstrate the potent antitumor activity of TP-317, notably when combined with ICI and chemotherapy. This synergism may be explained by the dual effect of cross-presentation of TAA to prime T cells and presentation of TAA on tumor cells, sensitizing them to cytotoxic T cells. Thus, TP-317 holds promise as novel adjunct treatment for cancers that are currently treated with immunotherapy targeting T cell exhaustion but show limited response.

#6913 Discovery of GSC000580, a novel oral small molecule of MC4R antagonist for treatment of cancer-related body mass loss.

M. Liu, S. Zhao, **B. Lu**, Y. Xia, F. Yang;
Changchun GeneScience Pharmaceutical Co., Ltd., Shanghai, China

Melanocortin 4 Receptor (MC4R) is heavily involved in appetite regulation, body mass and energy homeostasis. MC4R is a GPCR class A receptor that belongs to the melanocortin receptor family. When leptin binds to the receptor, POMC neurons release POMC, which is cleaved to form α-MSH, followed by activating MC4R to result in loss of appetite and weight loss. AGRP released from AGRP neurons inhibits MC4R signaling, which promotes appetite and increases body weight. Weight gain in MC4R KO mice is gene dose dependent. MC4R GOF mutations in human2 are associated with low BMI and LOF mutations are associated with obesity. Agonists of MC4R for treating POMC, leptin receptor and other genetic defects resulting in hereditary obesity, have been approved by the FDA . Antagonists of MC4R are expected to be developed for weight-related disorders like cancer anorexia and other types of anorexia. 27%-58% of patients with advanced cancer have loss of appetite, 33%-75% have anorexia, which significantly increased the risk of postoperative complications and mortality. Current progestogen drugs couldn't offer adequate efficacy and favorable safety. MC4R antagonists with oral convenience may have the potential to recover or increase the appetite and body weight of patients with cancer-related anorexia, thereby improving their quality of life, further promoting the outcome of tumor treatment, and even improving OS. Currently, two MC4R antagonists have progressed to phase I clinical study. TCMCB07, an MC4R antagonist peptide, has shown efficacy in various cancer anorexia rat models but its use is limited due to the requirement for intravenous administration. PF-07258669 is an oral small molecule MC4R antagonist with efficacy in an aged rat model of anorexia.

Here we report the discovery of GSC000580, a novel, highly potent and selective MC4R antagonist that exhibits strong in-vitro activity and has been shown to induce increased food intake and body mass gain in two animal models of anorexia. In vitro, GSC000580 could bind to MC4R receptor with less than 1nM potency with high (500~1000 fold) selectivity across the melanocortin receptor family and potently blocking cAMP production with less than 1nM potency in cellular functional assay. In vivo, GSC000580 demonstrated dose-dependent significant increase of body weight gain and food intake in cisplatin-induced and aging-related anorexia rat models. GSC000580 has a favorable ADME and PK profile in rodents, dogs and NHPs, along with an acceptable safety profile. Additionally, GSC000580 exhibits the ability of brain penetration, with a brain-to-plasma ratio (b/p) of 0.17. GSC000580 demonstrates promise as a potential clinical treatment for cancer-related body mass loss.

#6914 p27 small molecule inhibitors for CDK4/6i-resistant metastatic breast cancer (mBC).

G. Chen, C. Guido, N. Zisman, K. Allamneni, **S. W. Blain**;
Concarlo Therapeutics, Brooklyn, NY

Cyclin-dependent kinases 4/6 (CDKs) are key cell cycle regulators that form trimeric complexes with cyclin D1 and the master regulator p27Kip1, acting downstream of proliferation-driving pathways. CDK4/6 inhibitors (CDK4/6i) like palbociclib have been pivotal for the treatment of ER+ mBC but resistance to these drugs is common. This resistance is due to CDK2 activation, which bypasses CDK4/6 inhibition, restoring cell proliferation and suggesting that effective targeting requires simultaneous inhibition of CDK4/6, and CDK2. CDK4/6i work by dissolving the trimeric CDK4/6-cyclin D1 complex, freeing p27 to inhibit CDK2, initially blocking the activity of all three G1 CDKs, but patients become resistant by reactivating CDK2 by a variety of mechanisms including overexpression of CDK6 and cyclin E or loss of RB and FAT1.

Concarlo's unique approach directly targets the master CDK regulator, p27, to simultaneously inhibit CDK2/4/6 in concert, leveraging p27's ability to turn G1 CDKs ON and OFF during proliferation and quiescence, respectively. Phosphorylation of p27 at Y88 causes p27's C-terminal tail to leave CDK active site, turning the kinases on; without phosphorylation, p27's C-terminal tail remains in the CDK active site, keeping the kinases off. When p27 is phosphorylated at Y88, it becomes a target for ubiquitin-mediated degradation, reducing p27 levels, and reinforcing the unconstrained activity of CDK2. Our studies demonstrated the feasibility and tolerability of targeting p27 in breast cancer in treatment naïve and palbociclib resistant models. Blocking p27 Y-phos with a therapeutic peptide significantly reduced tumor growth in xenograft models, with evidence of CDK2 inactivation, tumor necrosis and increased survival. Moreover, p27 inhibition was well-tolerated during repeat dosing in mice.

Concarlo has identified first-in-class small molecule p27 inhibitors (SMp27i) that act as molecular stabilizers or glues, binding and inactivating the trimeric CDK complex. They block p27 Y-phos and inhibit CDK2/4/6. SMp27i inhibit cell proliferation in treatment-naïve and palbociclib-resistant BC cells but have little effect on normal mammary cells. Target engagement in treated cells showed that Rb, CDK2, and Cdc6 phosphorylation were all inhibited. Total p27 levels increase demonstrating that when p27 Y88-phos is blocked, p27 degradation is reduced and more p27 is present to inhibit CDK2. When combined with approved CDK4/6i, SMp27i enhance their potency. SMp27i have been favorably profiled in in vitro ADME screens, off-target binding screens, and have encouraging in vivo mouse PK. Direct targeting of p27 presents a new treatment paradigm bypassing the challenges of ATP-competitive CDKis, with potential to expand into tumor types with aberrant p27, CDK2/4/6 or RAS/MAPK activity.

#6916 CK2 inhibitor shows anti-tumor activity in Ewing sarcoma preclinical models.

Muhammad Danial, Rajesh Rajaiah, Marudhu Pandiyan Shanmugam, Sholler Chloe, Jeremey Hengst, Abhinav Beeravally Nagulapally, Yasin Uzun, Giselle Saulnier Sholler, Chandrika Gowda behura

Penn State Hershey Cancer Institute, Hershey, PA

Introduction: Ewing sarcoma (EWS) is a highly aggressive bone cancer. EWS-FLI chromosomal fusion is detected in more than 85% of cases and is indispensable for EWS tumor survival and growth. Casein kinase II (CK2) is a serine/threonine kinase encoded by the CSNK2A1 gene that is essential for normal cellular processes and is overexpressed in EWS. Studies report that EWS protein is phosphorylated by CK2 at Ser325 and forced expression of CK2 in 293T cells increased EWS-FL1 protein. Here, we report that CK2 inhibition negatively affects EWS-FLI protein abundance, suppresses its downstream target GLI1, and shows anti-tumor activity in EWS xenografts. CX-4945 (silmitasertib) is a selective small molecule inhibitor of CK2 currently in clinical trial.

Methods: EWS cell lines (n=6) were treated with serial dilution of CX-4945 for up to 48 hours, and cell viability, apoptosis, migration, and invasion potential were analyzed. We measured the mRNA and protein levels of known CK2 and EWS-FLI1 targets. RNA sequencing and gene expression analysis were done to evaluate gene expression changes following treatment with CX-4945. A673 cells were transduced with a clone of GFP+ lentiviral particles expressing CK2a-specific shRNA, and control shRNA, and phenotype was assessed using the above methods. A673 cell line-derived xenograft and patient-derived xenograft of EWS were treated with CX-4945 at a dose of 75mg/kg oral gavage twice daily for 28 days or vehicle. Tumor size and survival was measured.

Results: CX-4945 at inhibitory concentrations of 2-8μM, increased apoptosis, decreased migration, invasion in all cell lines. We confirmed that CX-4945 treatment decreased EWS-FLI protein level, expression of EWS-FLI1 targets (GLI1, RNF2), known CK2 substrates (pAKT s129). Pharmacological and genetic inhibition of CK2 resulted in decreased cell viability, increased apoptosis, and decreased migration and invasion in vitro. Single-drug treatment with CX-4945 achieved 50-80% tumor inhibition and significantly prolonged survival in treated mice after 4 weeks of therapy. Following in vivo treatment with CX-4945, no significant organ toxicity was noted in tumor-bearing mice when compared to vehicle-treated mice. CX-4945 shows synergistic cytotoxic activity with Temozolomide and Irinotecan.

Conclusions: CSNK2A1 expression is high in EWS and correlates with poor overall survival. CK2 inhibition decreases EWS-FLI protein abundance and suppresses its downstream target GLI1. CX-4945 shows excellent anti-tumor activity and target inhibition in EWS xenografts. CX-4945 works synergistically with cytotoxic agents like Temozolomide and Irinotecan. These results support further pre-clinical characterization and clinical development of CX-4945 for treating EWS in combination with cytotoxic therapy. A Phase I clinical trial is evaluating the safety and tolerability of CX-4945 in pediatric solid tumors, including EWS (NCT06541262).

#6917 Developing a novel therapeutic approach to target EGR1 in aggressive breast cancer.

Suguru Ogata[1], Sophia McAneny-Droz[1], Manuel Van Gijsel-Bonnello[1], Verena Martinez-Rodriguez[1], Mark Miller[2], Bingbing Li[2], Naoto T. Ueno[1], Xiangshu Xiao[2], Xiaoping Wang[1]

[1]Cancer Biology Program, University of Hawai'i Cancer Center, Honolulu, HI,[2]Chemical Physiology and Biochemistry, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Introduction: Aggressive breast cancer, e.g., Triple-negative breast cancer (TNBC) and inflammatory breast cancer (IBC), needs novel targeted therapies. The epidermal growth factor receptor (EGFR) is a central signaling molecule that promotes tumor growth and metastasis and creates an immunosuppressive tumor microenvironment (TME) in aggressive breast cancers. Our research has demonstrated that early growth response 1 (EGR1), which EGFR signaling pathway regulates its expression, is a central mediator to an immunosuppressive TME by regulating the expression of immunosuppressive chemokines, indicating EGR1 is a potential therapeutic target for patients with aggressive breast cancer. However, no inhibitors or therapeutic antibodies currently target EGR1, emphasizing the critical need for novel strategies to inhibit its activity. Because EGR1 gene expression is regulated by the cAMP response element-binding protein (CREB), we hypothesize that suppressing EGR1 expression by inhibiting CREB can downregulate immunosuppressive chemokines and lead to reduced tumor growth in aggressive breast cancer. In this study, we evaluated the effect of the novel CREB inhibitor on IBC and TNBC cell growth and the expression of immunosuppressive chemokines by modulating EGR1 expression.

Methods: We evaluated the effects of the CREB inhibitor on EGR1 gene and protein expression in human IBC and TNBC cells (SUM149, HS578T, HCC1806, and HCC1937) and murine TNBC cells (E0771 and PyMT-N) *in vitro* using real-time PCR and Western blot analyses. Cell sensitivity to CREB inhibitor was assessed using the CellTiter-Blue assay. The expression of EGR1-regulated chemokines (*CCL2*, *CCL20*, *CXCL5*, and *CXCL8*) after CREB inhibitor treatment was examined using real-time PCR.

Results: CREB inhibitor suppressed *EGR1* gene expression in all tested cell lines and reduced EGR1 protein expression in SUM149, HS578T, E0771, and PyMT-N cells. The half-maximal inhibitory concentration (IC_{50}) of TNBC cells to CREB inhibitor was 1.067 μM (HCC1806), 2.342 μM (HCC1937), 3.291 μM (E0771), and 1.622 μM (PyMT-N). Compared to DMSO control, CREB inhibitor treatment reduced the gene expression of *CCL2*, *CCL20*, and *CXCL8* in human TNBC cells and that of *CCL2*, *CCL20*, and *CXCL5* in murine TNBC cells.

Conclusions: The CREB inhibitor suppressed the expression of the EGR1 gene and protein and decreased the expression of EGR1-regulated immunosuppressive chemokines, suggesting that a CREB inhibitor can effectively modulate EGR1 expression and function. We will further investigate the impact of targeting EGR1 with a CREB inhibitor on IBC and TNBC tumor growth and TME modulation *in vivo*.

#6918 TEAD inhibition as a therapeutic strategy for diffuse-type gastric cancer.

Lawrence W. Wu[1], Sung Joo Jang[1], Jimyung Park[1], Cameron Shapiro[1], Tracy T. Tang[2], Ryan H. Moy[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Vivace Therapeutics, San Mateo, CA

Introduction: Diffuse-type gastric cancer (DGC) accounts for one third of gastric cancers and is associated with poor differentiation, discohesive growth, chemoresistance, and worse survival compared to intestinal-type tumors. DGC is typically genomically stable, and there are no approved DGC-targeted therapies. Recent studies utilizing multi-omic profiling of patient samples and DGC mouse models have identified a tumor-promoting role for Yes-associated protein 1 and transcriptional coactivator with PDZ-binding motif (YAP/TAZ), which interact with TEAD transcription factors to regulate gene expression. Therefore, we evaluated the activity and mechanism of TEAD inhibitors in DGC preclinical models.

Methods: Gastric cancer patient-derived organoids (PDOs) and cell lines were treated with TEAD inhibitors (VT103, VT107) and/or 5-fluorouracil (5-FU) for *in vitro* assays evaluating cell proliferation or invasion. The *in vivo* activity of VT103 and/or 5-FU was tested with a subcutaneous xenograft model using a genetically engineered mouse model of gastric cancer driven by oncogenic $Kras^{G12D}$ and loss of *Trp53*/*Cdh1*.

Results: TEAD inhibition with VT103 and VT107 reduced proliferation, colony formation, and invasion in DGC cell lines and PDOs. We observed no effect of TEAD inhibitors on the viability of a normal gastric tissue cell line. Combining the TEAD1-selective inhibitor VT103 with 5-FU chemotherapy resulted in further reduction of DGC PDO viability relative to monotherapy. In flank tumors, inhibition of the YAP/TAZ-TEAD pathway using VT-103 in combination with 5-FU significantly reduced tumor growth. We hypothesized that TEAD inhibition blocks an epithelial-to-mesenchymal transition (EMT) program and promotes apoptosis. Consistent with this hypothesis, TEAD1 inhibition with VT-103 reduced expression of the EMT marker Slug and increased expression of the apoptosis marker cleaved caspase 3 in tumor xenografts.

Conclusions: The YAP/TAZ-TEAD pathway is an important driver of gastric cancer growth and metastasis, particularly in DGC where it may promote EMT. TEAD inhibition reduces gastric cancer growth and invasion *in vitro* and *in vivo* in preclinical models and demonstrates synergistic activity with 5-FU chemotherapy. These results suggest a potential role for further investigation of clinical efficacy of TEAD inhibitors in patients with DGC.

#6919 Targeting CLIC3 as a novel strategy to inhibit metastasis in breast cancer.

P. Mellor[1], S. Kendall[1], S. Smith[1], J. Olsen[2], H. Sahile[2], B. Page[2], A. Saxena[1], D. Anderson[3];
[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]University of British Columbia, Vancouver, BC, Canada, [3]Saskatchewan Cancer Agency, Saskatoon, SK, Canada

Women with metastatic breast cancer have a 5-year survival rate of only 28%. This study aims to investigate the role of CLIC3 (chloride intracellular channel 3) in breast cancer metastasis and explore its potential as a therapeutic target. CLIC3, secreted by cancer cells and cancer-associated fibroblasts, promotes tumor invasion and angiogenesis through its oxidoreductase activity that inhibits TGM2 (transglutaminase-2). High CLIC3 levels correlate with poor prognosis across all breast cancer subtypes.
CLIC3 was knocked down in metastatic breast cancer cells, which were evaluated for cell migration and invasion using Boyden chambers, non-adherent growth in soft agar, and tumor formation and metastasis in mice. Small molecule inhibitors of CLIC3 activity were identified using an *in silico* screen of >10 million commercially available small molecules and 94 compounds were tested as possible CLIC3 inhibitors (CLIC3i) using recombinant CLIC3. We synthesized over 70 analogs of the top inhibitor for structure-activity relationship analysis, with the most promising inhibitors also assessed for CLIC3 binding using thermal shift assays and migration in scratch assays.
CLIC3 knockdown significantly reduced cell migration, invasion, and growth in soft agar, effects rescued by shRNA-insensitive CLIC3. In vivo, CLIC3 knockdown decreased tumor growth and completely blocked lung metastasis, underscoring its role in the colonization and growth of macroscopic metastases. Four promising compounds with mid-μM IC50 values for CLIC3 activity inhibition were identified (E5, D1, A5, D5). Among them, HA-22-31 emerged as a lead compound (IC50 = 1.7 μM), demonstrating direct binding to CLIC3 and significant inhibition of migration. In conclusion, CLIC3 enhances metastasis in breast cancer through its enzymatic activity. These findings suggest that further development of small molecule CLIC3 inhibitors may represent a promising new strategy for targeting metastatic breast cancer.

#6920 Targeting the AR co-activator CBP/p300 in metastatic castration-resistant prostate cancer (mCRPC).

Ananya Dutta[1], Beatrice C. Thomas[2], Pelumi Olawuni[1], Erik Soderblom[1], Eric Schadt[3], Bonnie Dougherty[3], Andrew J. Armstrong[1], Jason A. Jason A. Somarelli[1]

[1]Duke University, Durham, NC,[2]Nova Southeastern University, Fort Lauderdale, FL,[3]Pathos, New York, NY

Purpose: Standard treatment for metastatic castration-resistant prostate cancer (mCRPC) includes androgen receptor (AR) pathway inhibitors (ARPIs), such as androgen deprivation therapy or enzalutamide. Despite prolonged survival with ARPI therapies, resistance is nearly universal, highlighting the urgent need to identify new resistance mechanisms and therapeutic targets. Methods: We combined systems-level and experimental approaches to identify and test actionable network nodes linked to ARPI resistance as therapeutic vulnerabilities in prostate cancer. Systems-level analyses were performed using weighted gene co-expression network analysis and Bayesian network inference. Networks were overlaid with experimental data, including ENCODE ChIP-Seq data. The *in vitro* efficacy of pocebrodib was evaluated in a series of enzalutamide-sensitive and -resistant prostate cancer cell lines using CellTiter-Glo, colony forming assays and 3D spheroid assays. The *in vivo* activity of pocebrodib was evaluated in patient-derived xenografts. Proteomics and acetylomics was used to interrogate the potential mechanisms of action for pocenbrodib. Results were validated by RT-qPCR, western blotting and flow cytometry. Knockdown studies were performed using non-targeting and SCP2-targeting siRNAs. Results: Multi-layer network inference pinpointed the CREB binding protein (CBP)/p300 complex as a key regulatory node associated with patient outcomes and ARPI resistance. Consistent with this observation, preclinical testing of the CBP/p300 inhibitor, pocebrodib, demonstrated efficacy in both enzalutamide-sensitive and -resistant lines *in vitro*, with IC50s of ~1 μM. Cell growth inhibition was accompanied by downregulation of AR activity, as indicated by RNA-Seq and RT-qPCR. Pocenbrodib also demonstrated tumor growth inhibition of both enzalutamide-sensitive and -resistant patient-derived xenografts and a durable response in a patient with ARPI-resistant prostate cancer as part of the Phase I COURAGE study. Proteomics and acetylomics identified differential acetylation of both histone and non-histone proteins, including a subset of histone acetylation events altered in enzalutamide-resistant cells that are restored upon treatment with pocenbrodib. These analyses also identified enrichment of fatty acid metabolism proteins, including the sterol carrier protein 2 (SCP2) and fatty acid synthase (FASN), suggesting CBP inhibition may cause cells to sense loss of acetyltransferase activity as a reduction in free acetyl-coA, leading to alteration in fatty acid metabolism as a feedback response. Conclusion: Inhibition of the CBP/p300 axis by pocenbrodib is a promising new approach to treat ARPI-resistant prostate cancer. Future studies are aimed at clinical evaluation of pocenbrodib and exploration of downstream signaling axes to identify key biomarkers of response to pocenbrodib.

#6922 MDM2 inhibitor alrizomadlin induces ferroptosis through p53 dependent and independent pathways in TP53 wildtype NSCLC.

Shan Shi[1], Qiu Yun Luo[2], Wen Tao Pan[3], **Miaozhen Qiu**[4], Da Jun Yang[5]

[1]Department of Experimental Research, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou, China,[2]Department of Clinical Research Center, The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China,[3]Suzhou Ascentage Pharma Inc., Suzhou, China,[4]Department of Medical Oncology, Sun Yat-Sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China,[5]Department of Experimental Research, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou, P. R. China./Suzhou Ascentage Pharma Inc., Suzhou, Jian, Guangzhou, China

Alrizomadlin (APG-115) is a second-generation MDM2 inhibitor that blocks the MDM2-p53 interaction, thereby stabilizing p53 protein and restoring its transcriptional regulatory functions in cell cycle control and apoptosis. Recent study indicated that APG-115 also exerted an anticancer effect in various cancers, but the specific function and underlying mechanism in TP53-wildtype NSCLC has not been elucidated. My project aims to determine whether APG-115 exerts anti-tumor effects by mediating ferroptosis through P53 dependent and non dependent pathways. We repeatedly validated the induction effect of APG-115 on ferroptosis using multiple recognized iron death detection methods, searched for ubiquitinases in public databases, and constructed a mouse tumor model to further verify the in vitro experimental results. In this study, we found that APG-115 exerted potent antitumor efficacy in TP53-wildtype NSCLC both in vitro and in vivo. Further experiments demonstrated that APG-115 induced ferroptosis, thereby facilitating the tumor cell death. Ferroptosis -related pathways genes, such as PTGS2, were significantly enriched after APG-115 treatment. APG-115 promotes PTGS2-mediated ferroptosis through a well-characterized mechanism. Specifically, APG-115 upregulates the expression of the deubiquitinase USP22, a key regulator in protein homeostasis. USP22, once upregulated, acts on PTGS2 by removing its ubiquitin tags through the ubiquitin-proteasome system. This deubiquitination prevents PTGS2 from being targeted for proteasomal degradation, thereby stabilizing the PTGS2 protein. The sustained expression of PTGS2 enhances ferroptosis, ultimately contributing to the cytotoxic effects of APG-115 in tumor cells. Collectively, our study reveals that APG-115 induces ferroptosis in TP53-wildtype NSCLC by stabilizing the expression of PTGS2 protein, providing a new direction for further clinical investigation of APG-115 as a monotherapy or combination therapy.Keywords:Alrizomadlin; Ferroptosis; PTGS2; USP22; Ubiquitin-proteasome system

#6923 The EHD2-Orai1 pro-oncogenic axis is required for calcium-dependent membrane repair in triple-negative breast cancer.

Haitao Luan[1], Azize Cerci[2], Bhopal Mohapatra[2], Timothy Bielecki[1], Matthew Storck[1], Jun-Yul Lim[3], Vimla Band[2], Subu Ramanathan[2], Hamid Band[1]

[1]Eppley Institute for Research in Cancer, University of Nebraska Medical Center, Omaha, NE,[2]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[3]Department of Mechanical & Materials Engineering, University of Nebraska- Lincoln, Lincoln, NE

Background: Triple-negative breast cancer (TNBC) is an aggressive and highly metastatic breast cancer subtype characterized by poor therapeutic outcomes. Increased invasive capabilities expose tumor cells to higher plasma membrane stress resulting in frequent breaches that are incompatible with cancer cell survival and invasiveness. Upregulation of membrane repair mechanisms has been shown to counteract this inherent tumor cell vulnerability and targeting such mechanisms represents a novel potential therapeutic strategy. Previous studies have shown that plasma membrane repair involves multiple calcium-dependent protein complexes. We have previously demonstrated that EHD2, a member of the EHD (Eps15 homology domain-containing) protein family, functions in this role by sustaining the plasma membrane expression of Orai1, which is required to sustain the pro-oncogenic Store-Operated Calcium Entry (SOCE) pathway. EHD2 has been found to accumulate at plasma membrane repair sites in skeletal muscle models, suggesting the potential role of EHD2-SOCE axis in regulating plasma membrane integrity in breast cancer cells.

Methods: We used CRISPR-Cas9 knockout of EHD2 or Orai1 as well as Orai1 inhibition in TNBC cell lines to examine the role of EHD2-Orai1 axis in the repair of mechanical or streptolysin O (SLO) toxin induced plasma membrane disruptions. The role of EHD2 as a mechano-transducer of external plasma membrane stress leading to Orai1 activation was investigated using micro-cantilevers to indent TNBC cells expressing genetic encoded calcium sensors. Functional linkage of EHD2 and Orai1 was assessed by measuring the impact of gene Knockout or complementation on SOCE and cell migration.

Results: EHD2 knockout impaired the ability of TNBC cells to efficiently repair the plasma membrane disruptions induced by mechanical injury or SLO. Orai1 knockout recapitulated the EHD2 knockout phenotype. A functional linkage of EHD2 and Orai1 was demonstrated by the ability of ectopic constitutively active Orai1, but not its dominant negative form, to rescue the cell migration defects of EHD2 knockout TNBC cells. Indenting the plasma membrane with micro-cantilevers induced rapid Ca^{2+} flux in TNBC cells and accumulation of EHD2 at the sites of deformation. Membrane deformation-induced Ca^{2+} entry was markedly reduced by EHD2 or Orai1 knockout. Orai1 inhibitors impaired the repair of mechanical or SLO induced plasma membrane disruption.

Conclusion: Our results reveal an EHD2-Orai1 axis that is a critical regulator of mechanosensitive Ca^{2+} entry in TNBC cells and required for their plasma membrane repair. Our findings support a role of EHD2-Orai1 axis in mechano-sensing and plasma membrane integrity in TNBC cells under stress. These findings suggest that targeting the EHD2-SOCE axis could present a novel therapeutic strategy in TNBC.

#6926 Targeting plasma membrane $K_{Ca}3.1$ channels reduces tumor size and mitigates gemcitabine-induced fibrosis in a PDAC mouse model.

Z. Petho[1], I. Neumann[1], W. Wilczak[1], M. Rugi[1], S. Sargin[1], S. Schimmelpfennig[1], E. Nass[1], G. Mesquita[1], D. Ciechanska[1], A. Oeckinghaus[1], S. Pillozzi[2], N. Prevarskaya[3], V. Lehen'kyi[3], A. Schwab[1], B. Soret[1];
[1]University of Munster, Munster, Germany, [2]University of Florence, Florence, Italy, [3]University of Lille, Lille, France

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive cancer marked by extensive fibrosis and limited therapeutic options. The calcium-activated potassium channel $K_{Ca}3.1$ has been implicated in cancer progression. with Its elevated expression correlatesing with poor survival in PDAC patients. Here, we explored the *in vivo* therapeutic potential of targeting $K_{Ca}3.1$ channels using selective inhibitors in PDAC.

Experimental procedures: Tumor-bearing KPfC ($Kras^{wt/LSL\text{-}G12D}$ $Tp53^{fl/+}$ $PDX1^{Cre+}$) mice were treated with TRAM-34 or maurotoxin, inhibitors of $K_{Ca}3.1$, either alone or in combination with gemcitabine. $K_{Ca}3.1$ expression, and markers of epithelial-to-mesenchymal transition (EMT) were assessed via immunohistochemistry. Tumor progression was evaluated by histological analysis, measuring tumor node size and Sirius Red staining to quantify fibrosis. Distinct effects of plasma membrane and mitochondrial $K_{Ca}3.1$ inhibition were determined by comparing maurotoxin with the membrane-permeable TRAM-34.

Results: $K_{Ca}3.1$ channels were expressed in $CK18^+$ tumor cells and $\alpha\text{-}SMA^+$ cancer-associated fibroblasts. Maurotoxin reduced the tumor node size as compared to vehicle treatment, especially in combination with gemcitabine. In contrast, TRAM-34 and gemcitabine in monotherapy showed no significant impact on tumor node size. Gemcitabine alone induced a marked increase in fibrosis within tumor nodes, an effect not observed with other treatments. Notably, co-treatment with $K_{Ca}3.1$ inhibitors prevented gemcitabine-induced fibrosis and reversed EMT marker expression.

Conclusions: Selective targeting of plasma membrane $K_{Ca}3.1$ channels with maurotoxin reduces tumor node size and mitigates gemcitabine-induced fibrosis in PDAC. These findings highlight the therapeutic potential of $K_{Ca}3.1$ inhibition as a strategy to enhance the efficacy of gemcitabine and limit desmoplasia.

#6927 Novel ferrocene and naphthalene-based analogs block HRH1-signaling to inhibit colon cancer growth.

A. A. Ansari[1], D. Veeragoni[1], A. Azaz[1], S. Bhattacharya[1], H. Ghosh[1], B. Biersack[2], P. Dandawate[1];

Colorectal cancer (CRC) is one of the leading causes of cancer-related deaths worldwide, with over 1.8 million incidences and 900,000 deaths annually. CRC persists as a significant clinical challenge, detailing a 5-year survival rate of 14% for patients with distant metastases. CRC exhibits high genetic heterogeneity, which supplements a rich mutational landscape that gives rise to aggressive phenotypes. Therefore, there is a pressing need to identify novel and effective therapeutics to target CRC alongside identifying niche molecular pathways that contribute to pathogenesis. Here, we report the identification and formulation of novel histamine receptor 1 (HRH1) antagonists that inhibit CRC cell growth. Ferrocene (Fc) analogs are interesting due to their excellent lipophilicity, redox nature and anticancer activity. We synthesized a series of Fc and naphthalene-based compounds and tested them against colorectal cancer (CRC) cells HCT-116 and DLD-1. Compounds C10 and C12 inhibited the growth of CRC cells (IC50 = 0.5-1 mM), colony formation and induced apoptosis by downregulating bcl2 and mcl1 levels. We identified that both C10 and C12 bind to histamine receptor 1 (HRH1) using molecular docking studies. HRH1 is overexpressed in CRC cells and tissues compared to noncancerous colonic tissue. Further, histamine treatment activated ERK and GSK3β phosphorylation time-dependently in CRC cells, suggesting the receptor's functionality. Moreover, preincubation of C10 and C12 with CRC cells inhibited histamine-induced ERK and GSK3β phosphorylation, suggesting that C10 and C12 block HRH1 to inhibit histamine signaling. Further, a cellular thermal shift assay (CETSA) showed protection from thermal denaturation in C10 and C12 treated groups, suggesting a protein stabilization and potential binding of C10 and C12 with HRH1. Finally, C10 and C12 treatment (20 mg/kg, i.p., once daily, 21 days) reduced tumor volume and weight in HCT116-xenograft growth in NSG mice. In conclusion, we discovered novel HRH1 antagonists to inhibit colon cancer growth.

#6928 Combination treatment with cisplatin and PG3 for p53-mutated head & neck cancers.

Xiaobing Tian, Wafik S. El-Deiry

Brown University, Providence, RI

More than 90% of head & neck (H&N) cancers are squamous cell carcinoma (HNSCC) that occur from the mucosal epithelial tissue of the oral cavity, oropharynx, and larynx. About 30~40% of stage I or II HNC patients are curable and show improved survival rates after surgery or radiotherapy alone. However, over 60% of stage III or IV HNC patients require chemotherapy. Cisplatin is one of standard chemotherapy drugs for stage III and IV patients. In addition, the mutation frequency of the p53 gene in HNSCC is 65-85%.
DNA damage following cisplatin treatment can activate apoptosis via p53 in p53 wild-type cancer cells. In p53-mutated/deleted cancer cells, DNA-damage drugs can lead to cell death through other mechanisms, such as integrated stress response (ISR). There multiple cisplatin-resistance mechanisms were reported. Nucleotide excision repair (NER) is known as the primary strategy for repair of cisplatin-induced DNA damage. Elevated ERCC1 and ERCC5 expression enhance NER and are associated with cisplatin resistance in HNSCC patients. It was reported that ATF4 downregulation promoted cisplatin resistance in p53 mutated and deleted gastric cancers.
A small molecule PG3 treatment triggers ISR and leads to cell apoptosis through HRI/eIF2α/ATF4/PUMA pathway in p53-mutated and deleted colorectal cancer cell lines. We hypothesize that (1) combination treatment of PG3 with cisplatin can reduce side effects of cisplatin through reducing the dose of cisplatin, which can be achieved by enhanced induction of integrated stress response, (2) PG3 can sensitize cisplatin-resistant and p53-mutated H&N cancer cells to cisplatin through enhanced induction of integrated stress response. The combination treatment shows synergistic effects in p53-mutated FaDu and Cal27 H&N cancer cells. In combination therapy, use of PG3 allows use of a lower cisplatin dose to achieve a therapeutic benefit. The combined treatment enhances ISR induction, and the ISR contributes to cell apoptosis. We identified that cisplatin or the combination treatment activates the HRI/ATF4/NOXA pathway. NOXA mediates Mcl-1 degradation and is responsible for the combination treatment-induced apoptosis.

#6930 Structure activity relationship (SAR) studies identify novel non-pungent capsaicin analogs which display robust growth-inhibitory activity in human ovarian carcinoma cells.

K. J. Modi[1], R. S. Gadepalli[2], J. R. Rimoldi[2], T. E. Long[3], Y. Chen[4], K. C. Brown[1], S. D. Richbart[1], J. C. Meritt[1], S. L. Miles[1], P. Dasgupta[1];
[1]Marshall University School of Medicine, Huntington, WV, [2]University of Mississippi, University, MS, [3]Marshall University School of Pharmacy, Huntington, WV, [4]Bluefield State University, Bluefield, WV

Purpose of the study: The dietary compound Capsaicin is the hot and pungent ingredient of chili peppers. Preliminary data in our laboratory have found that capsaicin displays robust growth-inhibitory activity in a diverse array of human cancers. However, the clinical applications of capsaicin as a viable anti-cancer drug are hindered by its adverse side effects, such as gastric irritation, nausea, stomach cramps and a burning sensation in the gut. Clinical trials which explored the pain-relieving activity of capsaicin found that patients who orally ingested capsaicin discontinued taking the drug due to its unpleasant side effects. The primary aim of our studies was to rationally design non-pungent capsaicin analogs which would retain the anti-cancer activity of the parent molecule.
Experimental procedures. (SAR) studies have shown that the pharmacophore of capsaicin may be divided into three regions: REGION A, B, AND C. The addition of long-chain unsaturated fatty acyl groups in REGION C of capsaicin generated non-pungent compounds which displayed improved pain-relieving properties, relative to capsaicin. We synthesized a panel of compounds which contained a long chain unsaturated fatty acyl side chain in Region C of the capsaicin molecule. Subsequently, we determined the growth-inhibitory activity of these compounds in human ovarian cancer cells (in cell culture and chicken chorioallantoic membrane (CAM) models.
Results: The non-pungent Region C capsaicin analog DOHEVANIL displayed greater pro-apoptotic activity than capsaicin in human ovarian carcinoma cells. Most interestingly, DOHEVANIL did not impact the growth of normal human liver and kidney cells.
Conclusions: The non-pungent Region C capsaicin analog DOHEVANIL may be a promising non-pungent capsaicin analog which displays robust growth-suppressive activity in human ovarian cancer cells.
Support or Funding Information Funding for our study was supported by the NIH R15-AREA Grant (2R15CA161491-02 and 2R15CA161491-03), the Women's Health T3: 3P20GM103434-23W1 (PI: Dr. G Rankin) to PD and MAV and the NIAID-AI151970 grant to TEL. Furthermore, this study was supported in part by the West Virginia IDeA Network of Biomedical Research Excellence (WV-INBRE) grant (NIH grant P20GM103434; PI: Dr. G. Rankin), the National Institute of General Medical Sciences of the National Institutes of Health under the award number P30GM122733.

#6932 Phloroglucinol suppresses metastasis in CAV1 overexpressing cancer cells.

Layla Simon[1], **Keila Torres**[1], Andrew F. G. Quest[2]

[1]Universidad Finis Terrae, Santiago, Chile,[2]Universidad de Chile, Santiago, Chile

Metastasis is the process by which malignant cells dissociate from a primary tumor and disseminate to distant organs or tissues. This phenomenon presents one of the most significant challenges in oncology, as it is strongly associated with poor clinical outcomes and increased mortality rates. Caveolin-1 (CAV1) plays a crucial role in the metabolic reprogramming of cancer cells, particularly by promoting glycolysis, which enhances tumor cell migration and metastasis. This study aimed to evaluate the anti-metastatic potential of phloroglucinol, a monomer of phlorotannins from brown algae with anti-tumorigenic effects. The effects of phloroglucinol were assessed in metastatic breast (MDA-MB-231) and melanoma (B16-F10) cells expressing or not CAV1. Cell viability, migration, hexokinase activity and L-lactate levels were analyzed. C57BL/6 mice (N=5) were injected with B16-F10 cells pre-treated with phloroglucinol, and after 21 days, lung metastasis was assessed. *In vitro*, phloroglucinol significantly inhibited the migration of CAV1-expressing cancer cells and reduced lactate levels in the supernatants of the treated cells. Additionally, phloroglucinol suppressed CAV1-enhanced glycolysis by inhibiting hexokinase activity. *In vivo*, pre-treatment with phloroglucinol reduced the metastatic potential of CAV1-overexpressing cells. These findings suggest that phloroglucinol holds promise as a novel therapeutic agent for preventing cancer metastasis by targeting cancer cell metabolism.

#6933 Ru(II)-thymine complex inhibits NF-κB activation, suppressing acute myeloid leukemia stem cells.

Maiara de S. Oliveira[1], Ingrid R. S. B. Dias[1], Rafaela G. A. Costa[1], Ana Carolina B. da C. Rodrigues[1], Suellen L. R. Silva[1], Milena B. P. Soares[1], Rosane B. Dias[2], Ludmila F. Valverde[3], Clarissa A. G. Rocha[1], Alzir A. Batista[4], Rodrigo S. Correa[5], Valdenizia R. Silva[1], Eugenia T. G. Pina[1], **Daniel P. Bezerra**[1]

[1]Oswaldo Cruz Foundation, Salvador, Brazil,[2]State University of Feira de Santana, Feira de Santana, Brazil,[3]Federal University of Sergipe, Lagarto, Brazil,[4]Federal University of Sao Carlos, Sao Carlos, Brazil,[5]Federal University of Ouro Preto, Ouro Preto, Brazil

Acute myeloid leukemia (AML) is a deadly blood cancer caused by leukemia blasts that fail to develop properly. AML has a significant relapse rate, which is attributed to a subset of cells known as leukemia stem cells (LSCs). Herein, we evaluated the ability of a Ru(II)-thymine complex (RTC) with the formula $[Ru(PPh_3)_2(Thy)(bipy)]PF_6$ (where PPh_3 = triphenylphosphine, Thy = thymine, and bipy = 2,2'-bipyridine) to suppress AML LSCs. RTC exhibited strong cytotoxicity against solid and hematologic malignancies and inhibited primary AML LSCs, as evidenced by a decrease in the CD34+CD38- cell population. RTC decreased the number of CD34+ and CD123+ cells in the AML cell line KG-1a, which has a similar population to LSC. RTC-treated NSG mice bearing KG-1a xenografts had a reduced number of leukemic blasts in the bone marrow. RTC-treated KG-1a cells showed increased DNA fragmentation, active caspase-3 and cleaved PARP (Asp 214) levels, and mitochondrial superoxide. The pancaspase inhibitor Z-VAD-(OMe)-FMK, but not the antioxidant N-acetylcysteine, partially reduced RTC-induced cell death in KG-1a cells, demonstrating that RTC causes caspase-mediated apoptosis via an oxidative stress-independent pathway. In molecular mechanism investigations, transcripts of the NF-κB inhibitor NFKBIA were increased, and the level of NF-κB p65 phosphorylated at Ser529 residue was reduced in RTC-treated KG-1a cells. This suggests that RTC may block NF-κB signaling. Altogether, these data suggest the anti-AML potential of RTC in AML LSCs via suppression of NF-κB signaling.

#6934 Acetate-induced transcriptomic alterations reveal potential therapeutic targets in triple negative breast cancer.

Gabriel Borges-Velez[1], Diego N. Bracero-Sanchez[2], Liah M. Roman-Calderon[1], Oscar A. Loperena-Gonzalez[1], Ariana S. Garcia-Lopez[1], Angel J. Amaral-Maisonet[1], Jeannette L. Salgado-Montilla[1], Esther A. Peterson-Peguero[3], **Josue Perez-Santiago**[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]University of Maryland, College Park, MD,[3]University of Puerto Rico - Rio Piedras Campus, San Juan, Puerto Rico

Background: Triple Negative Breast Cancer (TNBC) is the most aggressive subtype of breast cancer and lacks effective therapies. The MDA-MB-231 cell line, derived from TNBC, is used to evaluate new therapeutic strategies. Acetate, a microbial short-chain fatty acid (SCFA), is a key source of acetyl-CoA during metabolic stress and plays a critical role in regulating cancer cell epigenetics and transcriptomics. Acetate's signaling functions may be a significant factor in cancer growth and progression, however the role of acetate in TNBC remains unclear. Here, we evaluated the effects of acetate on the gene expression of TNBC cells.
Methods: We used MDA-MB-231 as our cell model for TNBC. Cells were then exposed with sodium acetate at a concentration of 5mM or growth media (negative control) for 24 hours in triplicates. After exposure, total RNA was extracted (Qiagen RNAeasy Mini kit) and sequenced using the Illumina NextSeq (2 X 75bp). The higher-quality reads were aligned, annotated, and quantified to the human genome (hg38) using STAR and RSEM softwares. Gene expression analysis was performed in R statistical software (packages tximport and DESeq2) and genes with an adjusted p-value < 0.05 were considered significant. Functional and enrichment analyses were performed using Metascape (FDR p<0.05).
Results: There were 1410 differentially expressed genes associated with acetate treatment. Adenylosuccinate lyase (A0A1W2PRX2), a novel described protein, was the highest upregulated gene (log2 fold change: 8.25), while dorsal inhibitory axon guidance protein (DRAXIN) was the most downregulated gene (log2 fold change: -2.70). In addition, there was a significant increase in the levels of kinesin family member 12 (KIF12) and protein phosphatase 1 regulatory inhibitor subunit 1B (PPP1R1B), which have been associated with chemoresistance. Significantly impacted biological processes and pathways include regulation of cell projection organization, response to hormone, chromatin remodeling, cytokine signaling in immune system, signaling by receptor tyrosine kinases, epithelial cell differentiation, response to oxidative stress, and DNA damage response.
Conclusion: Acetate can promote TNBC cell growth and disease progression via inflammatory mechanisms and lipid metabolism. The observed increase and decrease in A0A1W2PRX2 in DRAXIN expression, respectively, highlight these genes as potential novel therapeutic targets, given their association with breast cancer through oncogenic signaling cascades and apoptosis regulation. Furthermore, upregulation of KIF12 and PPP1R1B suggest that acetate may potentially mediating therapeutic resistance in TNBC. These findings provide insights into microbial metabolic byproducts can impact TNBC progression and suggest that targeting acetate-driven metabolic and signaling pathways may offer innovative strategies for treatment of TNBC.

#6935 Combinatorial treatment with small molecule inhibitors C26-A6 and MYCi975 in hepatocellular carcinoma (HCC).

Eva Davis, Ali G. Ermi, Devanand Sarkar

Virginia Commonwealth University, Richmond, VA

Hepatocellular carcinoma (HCC) is the most common form of primary liver cancer. The median overall survival of advanced HCC patients is only 6.5-10.7 months. Identifying novel therapeutic targets and developing effective combinatorial treatment is highly relevant to HCC. Two oncogenes, Astrocyte elevated gene-1(AEG-1) and MYC (coding for c-Myc) are co-amplified in HCC patients and cooperate to promote aggressive, metastatic HCC. MYC is a driver oncogene for HCC and overexpression of MYC alone can initiate HCC. AEG-1 overexpression itself cannot induce HCC but it can significantly accelerate tumor progression once initiated. The objective is to evaluate the therapeutic efficacy of the combination of C26-A6 and MYCi975, small molecule inhibitors of AEG-1 and MYC, respectively, for HCC. Human HCC cell lines SNU-449, SNU-182, HuH-7, and Hep3B were treated with C26-A6 and MYCi975, alone or in combination. Optimum concentration of the inhibitors, to be used in combination, was determined by titration experiments. Cell viability was measured by MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] and colony formation assays. Data was analyzed by a two-tailed T-test. Cell invasion was analyzed by Matrigel invasion assay. Differential gene expression was analyzed by RNA-sequencing (RNA-seq) and Ingenuity Pathway Analysis (IPA). In all four cell lines, MYCi975 was more potent than C26-A6 to inhibit cell viability. For MYCi975, MTT assay over 5 days identified the IC_{50} ranging between 2-4 μM, while for C26-A6 IC_{50} was more than 100 μM. A combination of C26-A6 and MYCi975 showed significant and synergistic inhibition in viability. Similarly, the combination treatment showed significant inhibition in cell invasion compared to single agent treatment. SNU-449 cells were treated with C26-A6, MYCi975, or C26-A6+MYCi975 combination for 24 h and RNA-seq was performed. This time point was chosen to identify differentially expressed genes (DEGs) by inhibitor treatment before cell death starts. IPA of DEGs revealed that MYCi975 inhibited pathways associated with cell proliferation, C26-A6 inhibited pathways regulating cell migration, invasion, and metastasis, and the combination inhibited both. Inhibition of several oncogenes, such as STAT3, E2F2, and FOXM1 which are associated with poor prognosis and aggressive HCC, was identified by the combination treatment. MYCi975 inhibited cell proliferation, while C26-A6 inhibited cell invasion indicating that in an *in vivo* setting C26-A6 and MYCi975 combination might inhibit both primary and metastatic tumors and the combination might exert a synergistic inhibitory effect compared to either agent alone. Studies are ongoing to evaluate *in vivo* therapeutic efficacy of the treatment and elucidate the underlying mechanism mediating the effects of the combination treatment.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Protein Kinases and Phosphatases as Targets for Therapy
Poster Session

#6939 MAPKAP kinase 2 regulates inflammatory responses in glioblastoma.

Eleni Panagioti[1], Yi Wen Kong[2], Xueyang Yu[2], Sean E. Lawler[3], Michael B. Yaffe[2], Charles H. Cook[1]

[1]Surgery, BIDMC/Harvard Medical School, Boston, MA,[2]David H. Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, MA,[3]Department of Pathology and Laboratory Medicine, Legorreta Cancer Center, Brown University; The Warren Alpert Medical School, Brown University, Providence, RI

IDH-wildtype glioblastoma (GBM) is the most common and aggressive primary malignant brain tumor in adults, with 5-year survival rates of only 6% and a median survival of 14-22 months, depending on the MGMT promoter methylation status. Despite advances in treatment, GBM remains highly resistant due to its complex molecular landscape, characterized by rapid proliferation, angiogenesis, immune invasion, and metabolic dysregulation. In this study, we investigate the role of MAPK-activated protein kinase 2 (MK2), a critical kinase in the MAPK signaling pathway, as a potential therapeutic target in GBM. MK2 regulates key cellular processes including inflammation, stress response, DNA damage repair, and cell migration, all of which contribute to GBM progression. Notably, MK2 is highly enriched in microglia and peripherally derived macrophages. Our results demonstrate that MK2 is significantly upregulated in GBM tissues compared to normal brain tissue, and its expression correlates with poor survival outcomes. *In vitro,* MK2 inhibition significantly suppresses glioma cell proliferation, induces G1 cell cycle arrest, and promotes apoptosis, suggesting its potential to limit tumor growth and metastasis. To assess the *in vivo* antitumor effects of MK2 inhibition, we orthotopically implanted GL261 and CT-2A gliomas in MK2 knockout (KO) and wild-type C57BL/6 mice. MK2 genomic knockout is well tolerated in immunocompetent C57BL/6 mice. GL261 tumor cells with intact MK2 signaling effectively implant in hosts with global MK2 deficiency and shows more aggressive tumor growth than in hosts with wild-type MK2. In contrast, there was no effect on tumor growth in the CT-2A model, suggesting that tumor immunogenicity may influence the role of MK2 signaling in GBM. Mechanistically, host MK2 deficiency leads to increased circulating $Gr1^{+}CD11b^{+}$ myeloid-derived suppressor cells (MDSCs) and elevated PD-L1 expression on these cells, indicating a tumor-promoting inflammatory response and an altered immune profile within the myeloid compartment. These findings suggest an important role of MK2 in immune responses to GBM tumors that restricts growth. Ongoing studies are investigating the immunoregulatory function of MK2 using conditional knockout models targeting MK2 specifically in myeloid cells, as well as selective silencing of MK2 in tumor cells through CRISPR/Cas9 *in vivo.* Together, our results highlight MK2 as a possible therapeutic target in GBM, and underscores the importance of tumor-selective MK2 inhibitors and targeted therapies. These approaches could serve as adjunctive treatments to overcome therapy resistance and improve patient outcomes in this devastating malignancy.

#6941 Preclinical efficacy of the CK1 alpha/CDK7/CDK9 inhibitor BTX-A51 in *CIC*-rearranged sarcoma.

Q. Odom-Lewis[1], S. L. Davis[1], S. Pieper[1], C. Chu[2], E. Mazzola[2], R. Liu[2], N. Solimini[2], P. C. Gokhale[2], G. I. Shapiro[2], G. D. Demetri[2], **I.-M. Schaefer**[1];
[1]Brigham and Women's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA

CIC-rearranged sarcoma is an aggressive mesenchymal neoplasm characterized by high metastatic potential and poor clinical outcomes with median overall survival of only 12 months. The lack of effective systemic therapies highlights the urgent need to identify biologic vulnerabilities for therapeutic targeting. *CIC*-rearranged sarcoma shows molecular dependence on MYC, which can be targeted indirectly through cyclin-dependent kinase (CDK) 9 inhibition. In leukemia, casein kinase 1 alpha (CK1α) inhibition has been shown to have anti-tumor activity through activation of p53. We here investigated the anti-tumor effect of the CK1α/CDK7/CDK9 inhibitor BTX-A51 in preclinical models of *CIC*-rearranged sarcoma and determined the underlying mechanism of response. To evaluate the anti-tumor effect of BTX-A51 *in vitro*, we treated the CIC01, CIC02, NCC-CDS1-X1-C1 (CDS1), and NCC-CDS2-C1 (CDS2) cell lines with BTX-A51 (dose range 0.49-1000 nM) and performed BrdU cell proliferation, CellTiter-Glo cell viability, and Caspase-Glo 3/7 apoptosis assays. Daudi (MYC-driven Burkitt lymphoma) cells were used as control. IC_{50} values were calculated using an AAT Bioquest IC_{50} Calculator. We also assessed the effect of BTX-A51 on cell cycle progression using flow cytometry analysis and measured cell counts. The expression of key signaling proteins after 3, 6, 12, or 24 hours of treatment with BTX-A51 was determined through immunoblotting studies. *In vivo* studies assessing the anti-tumor effect of BTX-A51 in the CIC01 and CIC02 patient-derived xenografts are currently underway, and results will be reported. The CIC01, CIC02, CDS1, and CDS2 cell lines were highly sensitive to BTX-A51 with proliferation IC_{50} values ranging from 13-50 nM. In all 4 cell lines, BTX-A51 substantially inhibited cell viability and induced caspase 3/7-mediated apoptosis. At the same time, BTX-A51 treatment substantially inhibited expression of MYC, MCL-1, MDM2, phospho-RPB1 CTD Ser2 (a substrate of CDK9), phospho-RPB1 CTD Ser5 (a substrate of CDK7), phospho-RB1 Ser795, and RB1, and induced expression of phospho-histone H2A.X Ser13, p53, cleaved PARP (Asp214), and cleaved caspase 3. BTX-A51 treatment for 12 hours reduced the fraction of cells in S phase in cell cycle phase analysis consistent with G1 arrest and significantly reduced cell counts in all 4 cell lines ($P = 0.0381$ each, Wilcoxon rank-sum test). These findings demonstrate that BTX-A51 has anti-tumor activity in preclinical models of *CIC*-rearranged sarcoma. Treatment with BTX-A51 induces caspase 3-mediated apoptotic cell death through combined stabilization of p53 and inactivation of oncogenic drivers. Together with ongoing *in vivo* studies, our data will provide a compelling preclinical rationale for the evaluation of BTX-A51 in patients with *CIC*-rearranged sarcoma.

#6942 Targeting *CCNE1* amplification in gastric cancer.

Sung Joo Jang[1], Lawrence W. Wu[1], Sho Hangai[1], Cameron Shapiro[1], Jimyung Park[1], C. Gary Marshall[2], Ryan H. Moy[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Repare Therapeutics, Cambridge, MA

Background: Cyclin E (CCNE1) is amplified in multiple cancers including approximately 10% of esophagogastric cancers and 20% of ovarian cancers. *CCNE1* amplification leads to DNA replication stress and chromosomal instability. Prior studies have found that *CCNE1* amplification in gastric cancer is associated with increased liver metastasis, an “immune-cold” tumor microenvironment, and worsened clinical outcomes. At the same time, CCNE1-amplified tumors are vulnerable to loss of membrane-associated tyrosine- and threonine-specific cdc2-inhibitory kinase (PKMYT1). Lunresertib (RP-6306) is a selective, first-in-class, oral PKMYT1 inhibitor that leads to unscheduled mitotic entry and catastrophic DNA damage selectively in *CCNE1*-amplified cells. The purpose of this study is to evaluate the effect of PKMYT1 inhibition in *CCNE1*-amplified gastric cancer.

Methods: Human gastric cancer cell lines derived from patient-derived organoids (PDOs) or mouse CCNE1-overexpressing gastric cancer organoids were treated with lunresertib *in vitro*. Cell proliferation and viability were measured by WST-1, CellTiter-Glo, and colony formation assays. Quantitative reverse-transcription PCR (qRT-PCR) was used to measure RNA expression. Mice bearing syngeneic subcutaneous CCNE1-overexpressing gastric cancer xenografts were treated with lunresertib, anti-PD1, or lunresertib plus anti-PD1. Treatment efficacy was monitored by tumor volume, and tumor-infiltrating immune cells were assessed by flow cytometry.

Results: Lunresertib induced significant cytotoxicity in *CCNE1*-amplified gastric cancer cell lines and organoids measured through multiple cell viability and proliferation assays. Lunresertib induced DNA damage as monitored by increased γH2AX expression in *CCNE1*-amplified gastric cancer cells. Lunresertib also strongly induced *CXCL10* expression, a downstream cytokine of the cGAS-STING cytosolic DNA sensing pathway. While lunresertib or anti-PD1 monotherapy demonstrated moderate tumor growth inhibition *in vivo* in a syngeneic model of CCNE1-overexpressing gastric cancer, the combination of lunresertib and anti-PD1 resulted in the strongest tumor regressions, suggesting possible synergistic activity. Flow cytometry of tumor-infiltrating immune cells identified increased CD4+ T cells and decreased neutrophils with lunresertib plus anti-PD1.

Conclusion: Lunresertib demonstrated synthetic lethality in *CCNE1*-amplified gastric cancer across multiple *in vitro* and *in vivo* experiments. Lunresertib had synergistic effects with anti-PD1 *in vivo* against *CCNE1*-amplified gastric cancer, potentially due to induced DNA damage and inflammatory cytokine induction.

#6943 RV-1521: A broad-spectrum mRNA vaccine targeting KRAS mutations in cancer.

Renxiang Chen[1], Yongsik Bong[1], Wei Liu[2], Ezra Chung[1], David Brown[1], Evan Lewoczko[1], Zachary Dorsey[1], Steven Long[1], Cun Yu Wang[2], **Dong Shen**[1]

[1]RNAimmune, Inc., Baltimore, MD,[2]School of Dentistry, UCLA, Los Angeles, CA

KRAS mutations, particularly G12 and G13 variants, are common in cancers but remain difficult to target therapeutically. While KRAS G12C inhibitors, such as sotorasib and adagrasib, have made significant progress, their mutation-specificity excludes up to 85% of KRAS-mutant cancers, including those with G12D, G12V, and G13D mutations. To address this gap, we developed RV-1521, a broad-spectrum mRNA vaccine targeting multiple KRAS mutations, including G12D and G13D, and evaluated its efficacy in a CT26 colon cancer model in Balb/c mice.

RV-1521 induced robust immune responses, with serum IgG titers increasing 3.5-fold ($p < 0.01$). B cell epitope mapping identified four immunogenic KRAS regions. T cell profiling revealed activation hotspots in peptides P1, P35, and P36, with significant IFN-γ secretion in response to both wild-type and G12D-mutant KRAS epitopes. Flow cytometry analysis showed a 2.7-fold increase in IFN-γ$^+$ CD4$^+$ T cells in splenocytes from vaccinated mice. These results highlight RV-1521's capacity to activate diverse immune mechanisms targeting KRAS-mutant tumor elimination, particularly through CD4$^+$ T cell-mediated responses.

As a monotherapy, RV-1521 demonstrated dose-dependent antitumor efficacy, reducing tumor volume by 50% ($p < 0.001$) and tumor mass by 45%. This was accompanied by a 3-fold increase in CD8$^+$ T cell infiltration and a 2.8-fold increase in granzyme B expression. These findings were consistent with reduced tumor proliferation and enhanced T cell-mediated cytotoxicity. When combined with anti-PD-1 therapy, RV-1521 further amplified its efficacy, achieving a 70% reduction in tumor volume ($p < 0.001$) and a 2.5-fold increase in tumor IFN-γ levels, while preserving cytotoxic T cell activity and reversing T cell exhaustion. Transcriptomic analysis revealed upregulation of immune pathways, including T cell receptor and Th1/Th2 signaling, alongside downregulation of key oncogenic drivers such as EGR1, FOS, and JUN.

Strain-specific analysis revealed stronger immune responses in Balb/c mice compared to C57BL/6 mice, suggesting that genetic background may influence immune activation. Notably, RV-1521 elicited immune responses against both wild-type and mutant KRAS, addressing tumor heterogeneity and minimizing immune escape. The unexpected cytotoxic role of CD4$^+$ T cells further underscores the therapeutic potential of this vaccine.

By targeting multiple KRAS mutations, RV-1521 overcomes the limitations of mutation-specific therapies. Its ability to synergize with anti-PD-1 therapy and elicit a robust, multi-faceted antitumor immune response positions it as a promising strategy for treating KRAS-driven cancers. Ongoing studies will evaluate its safety and adaptability across diverse microenvironments and patient populations.

#6944 Transient pan-RAF inhibitor treatment for melanoma prevention.

Rachel E. Lew[1], Harsha S. Sanaka[2], Venkat R. Chirasani[3], Sharon L. Campbell[3], Christin E. Burd[1]

[1]Cancer Biology and Genetics, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Molecular Genetics, The Ohio State University, Columbus, OH,[3]Biochemistry and Biophysics, University of North Carolina, Chapel Hill, NC

Therapeutic options are currently limited for the 15-25% of cutaneous melanomas driven by an oncogenic *NRAS* mutation. Our previous findings showed that melanoma-associated NRAS substitutions stabilize conformations optimal for BRAF binding, thereby promoting RAF dimerization, proliferative signaling, and ultimately melanomagenesis. Building on these discoveries, we hypothesized that NRAS-mutant melanoma precursors would exhibit substitution-specific sensitivity to pan-RAF inhibition, and that a temporary blockade of RAF signaling would eliminate NRAS mutant-melanocytes in the skin. BRET and NanoBiT complementation assays revealed that pan-RAF inhibitors promote RAS-RAF and RAF-RAF interactions at lower doses in human melanoma cell lines with a weakly melanomagenic NRAS substitution (Q61H) compared to those with a stronger melanomagenic NRAS substitution (Q61R). Surprisingly, these drug-induced RAF complexes were associated with decreased MAPK>ERK signaling and higher drug sensitivity, suggesting that fully inhibited, drug-bound protomers drive increases in NRAS-RAF interactions. To test the mutation-specific sensitivity of NRAS-mutant melanoma precursors in vivo, mouse models of spontaneous NRAS Q61R- or Q61H-driven melanoma were prophylactically treated with a pan-RAF inhibitor for three days and then followed for tumor formation. Consistent with our in vitro data, short-term pan-RAF inhibitor treatment delayed melanoma onset in NRAS Q61H, but not Q61R mice. These findings highlight the critical role of RAF signaling in NRAS-mutant melanoma formation, suggesting that short-term use of effective, targeted therapies could prevent melanoma formation.

#6945 Targeting Chek2-YBX1&3 axis to enhance response to immune checkpoint blockade therapy in gliomas.

Heba Ali[1], Ningjia Zhou[1], Li Chen[1], Vivekanudeep Karri[1], Mahalakshmi Harish[2], Yalu Zhou[3], Vasilios Kalas[4], Karl Habashy[1], Victor A. Arrieta[1], Kwang-Soo Kim[1], Si Wang[1], Joseph Duffy[1], Ragini Yeeravalli[1], Deanna M. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL

Although the immunosuppressive microenvironment of glioblastoma (GBM) is well-established, the tumor-intrinsic mechanisms underlying resistance to CD8+ T cell-mediated killing remain incompletely understood. Our previous study identified Checkpoint Kinase 2 (Chek2) as the top contributor to CD8+ T cell resistance in GBM through an in vivo CRISPR screen. Therapeutic evaluation demonstrated that Chek2 inhibition, combined with PD-1/PD-L1 immune checkpoint blockade, significantly enhanced CD8+ T cell-mediated tumor killing and improved survival in preclinical glioma models. Here, we aimed to elucidate the immunosuppressive function of Chek2. Immunoprecipitation-mass spectrometry (IP-MS) and phosphoproteomics identified the transcriptional repressors and RNA-stabilizing proteins YBX1 and YBX3 as critical interactors of Chek2. Single-gene knockout and overexpression studies of Chek2, YBX1, and YBX3 in multiple glioma cell lines revealed that these proteins positively regulate each other's expression at the protein level. RNA sequencing coupled with ChIP-seq analysis demonstrated that the Chek2-YBX1-YBX3 interaction represses the expression of inflammatory cytokines. Targeting Chek2, YBX1, and YBX3 with the small-molecule inhibitor SU056 enhanced antigen presentation and promoted CD8+ T cell proliferation. Moreover, combining SU056 with PD-1 blockade significantly improved survival in multiple glioma models. Collectively, these findings reveal an immunosuppressive mechanism mediated by the Chek2-YBX1-YBX3 axis and propose its inhibition as a promising therapeutic strategy to enhance responses to immune checkpoint blockade therapies in gliomas.

#6946 Targeting PDGFRa-SHP2 signaling enhances radiotherapy in IDH1 mutant glioma.

Xiaozhou Yu, Xiao Song, Deanna Tiek, Runxin Wu, Maya Walker, Craig Horbinski, Bo Hu, Shi-Yuan Cheng

Northwestern University, Chicago, IL

Background: Isocitrate dehydrogenase mutant (IDH-mut) gliomas represent a distinct subtype of glioma with a somewhat better prognosis. However, despite this, they remain incurable due to the limited availability of effective treatments. Targeting SHP2, a non-receptor protein tyrosine phosphatase, shows promise as a therapeutic strategy for cancers, including IDH wildtype (WT) glioblastoma (GBM). However, it is unknown whether IDH-mutant gliomas respond to SHP2 inhibition.
Methods: Bioinformatic and biological analyses revealed increased expression and activation of the PDGFRα-SHP2-ERK pathway in IDH-mutant gliomas and patient-derived IDH-mut glioma stem-like cells (GSCs). The effects of SHP2 inhibition, alone or with radiation therapy (RT), were assessed through assays including cell growth, sphere formation, cell differentiation, flow cytometry, immunoblotting, orthotopic brain tumor xenografts, and immunohistochemistry.
Results: PDGFRα expression was elevated in IDH-mut gliomas and GSCs, activating the SHP2-ERK pathway. SHP099, a SHP2 inhibitor, reduced GSC tumorigenicity in vitro and in vivo by disrupting SHP2-ERK signaling and promoting differentiation. SHP099 also enhanced cytotoxicity of RT, the standard treatment for IDH-mut glioma, on IDH-mut GSCs and orthotopic glioma models. Mechanistically, the PDGFRα-SHP2-ERK axis is activated in IDH-mut gliomas and RT further activates this pathway. Targeting SHP2 suppressed ERK signaling thereby enhancing the therapeutic effect of RT.
Conclusion: Combining SHP2 inhibition with RT shows promising therapeutic efficacy for IDH-mut glioma by suppressing the activated SHP2-ERK axis.

#6947 CRISPR/Cas9 kinome screen identifies PNKP as a novel fitness gene in HPV-negative head and neck squamous cell carcinoma.

Gurleen Kaur Tung[1], Kate Chatfield-Reed[2], Masaru Miyagi[3], Wendi Quinn O'Neill[4], Quintin Pan[4]

[1]Otolaryngology, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Biology, Yukon University, Whitehorse, YT, Canada,[3]Pharmacology, Case Western Reserve University School of Medicine, Cleveland, OH,[4]Otolaryngology, University Hospitals Cleveland Medical Center, Cleveland, OH

Background: Head and neck squamous cell carcinoma (HNSCC) is the seventh most common malignancy worldwide. Most cases are linked to alcohol, tobacco, and areca nut, while a smaller proportion is driven by high-risk human papillomavirus (HPV). HPV-negative HNSCC is associated with poor prognosis with a 5-year survival rate of 40-50%. This dismal outcome has remained relatively static over the past several decades, highlighting the critical need for the discovery of novel targets and therapeutics to better manage HPV-negative HNSCC patients.**Methodology:** We performed parallel *in vitro* and *in vivo* CRISPR-Cas9 knockout kinome screens to identify kinases essential for the fitness of HPV-negative HNSCC cells. CAL27 Cas9 EGFP cells were transduced with a pooled sgRNA kinome library containing 6,104 sgRNAs at a MOI of ~0.4. After 7 days of puromycin selection, these transduced cells were cultured *in vitro* for either 7 or 14 days or implanted into the flanks of athymic nude mice, with tumor harvesting at 6 weeks. DNA was isolated from both cells and tumors, followed by next-generation sequencing to identify and quantify individual sgRNAs. Fitness genes identified in both the *in vitro* and *in vivo* screens were further validated using shRNA technology in a panel of HPV-negative HNSCC cell lines. **Results:** We identified 24 fitness genes that were common to both our *in vitro* and *in vivo* screening approaches. These kinases are primarily involved in pathways critical for DNA damage and repair, metabolism, and cellular proliferation. Among them, we prioritize the validation of polynucleotide kinase 3'phosphatase (PNKP) as an essential gene in a panel of HPV-negative HNSCC cell lines. shRNA-mediated knockdown of PNKP significantly reduced the cellular proliferation and clonogenic survival of CAL27, Detroit-562 and FaDu cells. Furthermore, PNKP knockdown severely impaired tumorigenicity *in vivo*, with CAL27 and FaDu xenografts showing markedly reduced tumor growth compared to controls. Phosphoproteomic analysis revealed that PNKP knockdown resulted in dephosphorylation of 762 unique sites (log2FC>1.5; FDR p<0.05), with a particular impact on proteins involved in nuclear and mitochondrial DNA repair pathways.**Conclusion:** Our study identified and confirmed PNKP as an essential gene for the survival of HPV-negative HNSCC cells. This discovery highlights the potential of PNKP as a novel therapeutic target, which may lead to the development of innovative therapeutics that could improve the clinical outcomes of HPV-negative HNSCC patients.

#6949 Downregulating the mitotic kinases TTK and NEK2 as a promising approach for the reduction of metastasis in triple-negative breast cancer cell lines.

Alexandra N. Aquino-Acevedo[1], Angel D. Colon-Burgos[1], Marileana Rodriguez-Ruiz[2], Gabriel Rosario-Ortiz[1], Elliott R. Rodriguez-Lopez[1], Esther M. Irizarry-Quintana[3], Gretchen M. Albarran-Acosta[1], Joel A. Orengo-Orengo[1], Melanie E. Cruz-Robles[1], Harold I. Saavedra[1]

[1]Ponce Health Sciences University, Ponce, Puerto Rico,[2]Moffitt U54 Summer Research Program, Ponce Health Sciences University, Ponce, Puerto Rico,[3]U54 REC InterAmerican Undergraduate Program, Ponce Health Sciences University, Ponce, Puerto Rico

Triple-negative breast cancer (TNBC) lacks estrogen, progesterone, and HER2 receptors, making it the most aggressive form of breast cancer. TNBC with distant metastases is nearly untreatable with anti-hormonal or anti-HER2 therapies, leaving chemotherapy as the primary option. TNBC is characterized by uncontrolled cell growth, increased centrosome amplification, genetic instability, and high invasive potential. Non-Hispanic Black (NHB) and Hispanic/Latino (H/L) women have lower 5-year survival rates compared to non-Hispanic White (NHW) women, partly due to later-stage tumor detection and higher TNBC prevalence. Women with a greater proportion of African ancestry exhibit elevated expression of several mitotic kinases, such as TTK and NEK2. TTK helps maintain genomic stability by regulating the spindle assembly checkpoint, while NEK2 regulates centrosome separation and microtubule organization. However, overexpression of these kinases in breast cancer is linked to increased cell growth, chromosomal instability, aneuploidy, and epithelial-to-mesenchymal transition (EMT). Previous data from a tissue microarray confirmed the link between TTK overexpression and markers of proliferation, EMT, and the TNBC subtype. Thus, we aim to measure expression levels of EMT markers and transcription factors, as well as changes in the invasive capacity of metastatic TNBC cell lines, upon downregulation of TTK and/or NEK2. To address this, TNBC cell lines, MDA-MB-231 (NHW) or MDA-MB-157 (NHB), were cultured, followed by TTK and/or NEK2 siRNA-mediated knockdown. Western blot and qPCR analyses measured protein and mRNA expression levels of EMT markers and transcription factors. Invasion assays were performed using Matrigel matrix invasion chambers. Preliminary results indicate that silencing of TTK, NEK2, or both resulted in a reduction of the mRNA expression levels of EMT markers, Vimentin, N-cadherin, or β-Catenin in MDA-MB-231 and MDA-MB-157 cell lines. Western blot results showed a significant decrease in Vimentin protein levels in all treatment groups of MDA-MB-231 cell lines, while TTK/NEK2 knockdown also reduced N-cadherin, β-Catenin, and SNAIL transcription factor. Comparably, results from MDA-MB-157 cell lines showed a significant reduction of β-Catenin protein levels upon NEK2 knockdown. Furthermore, TTK/NEK2 knockdown leads to a decrease in the invasive capacity of both TNBC cell lines. These preliminary data suggest that dual silencing of mitotic kinases TTK and NEK2 may be a promising approach for reducing key proteins involved in EMT processes in TNBC cell lines. Due to their increased expression in women of African descent (e.g. African American and Caribbean Hispanics), targeting mitotic kinases could represent a promising therapeutic strategy, particularly in Afro-descendants with TNBC by limiting tumor growth and metastasis.

#6950 VRK1 as a novel therapeutic target in small cell neuroendocrine carcinoma of the uterine cervix via mitochondrial dysfunction.

Mariya Kobayashi[1], Satoshi Nakagawa[1], Yusuke Ishii[1], Yuji Kamei[2], Mizuki Kanda[3], Tatsuo Masuda[1], Mamoru Kakuda[1], Kosuke Hiramatsu[1], Tadashi Iwamiya[1], Shinya Matsuzaki[1], Masahiro Inoue[4], Yutaka Ueda[1]

[1]Department of Obstetrics and Gynecology, The University of Osaka, Suita, Japan,[2]Department of Obstetrics and Gynecology, Higashiosaka City Medical Center, Higashiosaka, Japan,[3]Department of Obstetrics and Gynecology, Sakai City Medical Center, Sakai, Japan,[4]Clinical Bio-Resource Research and Development, Kyoto University, Kyoto, Japan

[Objective] Small cell neuroendocrine carcinoma of the uterine cervix (SCNEC) is a rare cancer with a poor prognosis, highlighting the pressing need for effective pharmacotherapies. Our previous proteomic analysis identified vaccinia-related kinase 1 (VRK1) as one of the proteins highly expressed in SCNEC compared to squamous cell carcinoma (SCC) and adenocarcinoma (AC). VRK1 is a member of the VRK family of Ser-Thr kinases, and its overexpression is associated with poor prognosis in various cancers. It is also expected to be a potential synthetic-lethal drug target in VRK2-low/null cancers. This study aims to investigate the potential of VRK1 as a therapeutic target for SCNEC.
[Methods] To examine VRK1 and VRK2 expression levels across different histological types of cervical cancer, immunohistochemistry was performed on clinical samples, including five SCNEC cases, 34 SCC cases, and seven AC cases. The effect of VRK1 on tumor growth was assessed in vitro (2D and 3D cultures) and in vivo (xenograft model) by shRNA-mediated knockdown of VRK1 (shVRK1) and its control (shCont). Gene Set Enrichment Analysis (GSEA) was conducted on RNA-seq data extracted from mouse xenograft tumors to compare shCont and shVRK1. Conditions with exposure to reactive oxygen species (ROS) were generated using hydrogen peroxide (H_2O_2). Mitochondrial function was evaluated through changes in mitochondrial membrane potential and mitochondrial protein expression.
[Results] VRK1 expression exhibited variability in SCC and AC but was consistently high across all SCNEC samples. In 2D cultures, VRK1 knockdown demonstrated limited effects on cell proliferation; however, it significantly inhibited tumor growth in 3D cultures and in vivo xenograft models. GSEA revealed that mitochondrial translation and gene expression pathways were the most suppressed in shVRK1 tumors compared to shCont. Subsequent in vitro and in vivo experiments revealed that VRK1 knockdown had a stronger tumor growth inhibitory effect under conditions with exposure to ROS, driven by the combined influence of the tumor microenvironment and the tumor's high energy metabolism, and this was accompanied by mitochondrial dysfunction. Furthermore, VRK2 expression, a potential biomarker of VRK1's effects, was confirmed to be characteristically low in SCNEC.
[Conclusion] SCNEC is characterized by high VRK1 expression and low VRK2 expression. VRK1 knockdown suppresses tumor growth via mitochondrial dysfunction, particularly in vivo. These findings suggest that VRK1 is a promising therapeutic target for the treatment of SCNEC.

#6952 PIM inhibition increases membrane expression of TNFRSF10B(DR5) and combination with recombinant human TRAIL synergizes to reduce renal cell carcinoma cell viability.

Kimberly S. Meza, Wafik S. El-Deiry, Sheldon L. Holder

Brown University, Providence, RI

Renal cell carcinoma (RCC) cases are on the rise globally. RCC tumors' acquired resistance to current RCC therapies necessitates the identification of novel biomarkers and therapeutic strategies. Oncogenic PIM1 kinase is overexpressed in human RCC tissue and cell lines and is associated with worse clinical outcomes in RCC. PIM1 is an emerging clinically relevant biomarker and target in the treatment of RCC. The overexpression of PIM kinases has been previously reported in a glioblastoma model and knockdown or pharmacological inhibition of PIM kinases promoted the increased membrane expression of TNFRSF10B/DR5. Death Receptor 5 (DR5) is the specific receptor to TRAIL, a cancer-selective apoptosis-inducing ligand. A relationship between PIM kinases and regulation of DR5 expression for TRAIL-induced apoptosis is not yet described for RCC. Here we identify a potential link between PIM kinases' involvement in DR5 regulation and TRAIL apoptosis in RCC. RCC and nonmalignant renal epithelial cells were treated with PIM inhibitors (SGI-1776, TP-3654) or vehicle control for 24 hours and then evaluated for membrane DR5 levels via flow cytometry. Low doses (5μM) of PIM inhibitors were sufficient to induce the increased mean membrane expression of DR5 in 786-O cells by more than eleven fold (3.03% control vs 36.07% treated). To investigate synergism between PIM inhibitors and recombinant human TRAIL (rhTRAIL), RCC cell lines were treated with increasing concentrations of SGI-1776 or TP-3654 and rhTRAIL (TLY012) for 24 hours and assessed for viability via Cell Titer Glo assay. Combinations of PIM inhibitors and rhTRAIL reveal that PIM inhibition sensitized RCC cells to TRAIL induced apoptosis. These results reveal novel therapeutic strategies for the treatment of RCC, highlighting PIM kinases as targets to potentiate TRAIL induced apoptosis. Current studies are ongoing to understand the mechanism of PIM kinase involvement in DR5 regulation and sensitivity to TRAIL in RCC.

#6953 Inhibition of Eukaryotic elongation factor 2 kinase (eEF2K) disrupts key processes in colorectal cancer progression and tumor growth.

Nermin Kahraman[1], Ezgi Biltekin[1], Ogun Ali Gul[1], Goknur Kara[2], Izabela Fokt[3], Yasemin M.Akay[4], Waldemar Priebe[3], Metin Akay[4], Bulent Ozpolat[1]

[1]Department of Nanomedicine, Houston Methodist Research Institute, Houston, TX,[2]Department of Neurosurgery, Houston Methodist Research Institute, Houston, TX,[3]Department of Experimental Therapeutics, University of Texas MD Anderson Cancer Center, Houston, TX,[4]Department of Biomedical Engineering, University of Houston, Houston, TX

Colorectal cancer (CRC) is the third most commonly diagnosed cancer with 1.9 million new cases and the second leading cause of cancer-related deaths, with 935,000 deaths reported in 2023. Despite advances in therapy, the 5-year survival rate for metastatic CRC remains as low as 14%, emphasizing the need for novel treatment strategies. Previously, we have validated that Eukaryotic elongation factor 2 kinase (eEF2K) is an atypical alfa kinase as a potential molecular target that is commonly expressed in highly aggressive solid cancers such as triple-negative breast cancer, pancreatic, ovarian, and lung cancers and demonstrated that it acts as a key player in the survival, proliferation, invasion, and tumor growth of cancer cells and promoting cell. In this study, we investigated the role of eEF2K in colon cancer tumorigenesis and progression and its potential as a therapeutic target using a novel eEF2K small molecule inhibitor and siRNA-based knockdown studies. We found that eEF2K expression is highly expressed in CRC cell lines and eEF2K is associated with shorter patient survival and poor prognostic marker in CRC patients (NCI-TCGA patient database), inhibition of eEF2K in various CRC cell lines (HCT116, RKO, COLO320, and with different genetic alterations leads to suppression on cell proliferation, migration, and invasion. Western blot analysis confirmed that treatment with the siRNA and the eEF2K inhibitor reduced the activity of clinically significant signaling molecules including Src, FAK, and Cyclin D1 which are crucial for tumor growth and progression. In vivo, targeting of eEF2K by eEF2K siRNA encapsulated in iron oxide nanoparticles (IONPS) and our novel water soluble small-molecule eEF2K inhibitor suppressed CRC tumor growth of HTC116 and RKO tumors (flank) CRC tumor models in nude mice, with no observed toxicity. Analysis of tumor tissues by immunohistochemistry showed significant inhibition of the Ki-67 proliferation marker and induction of apoptosis by TUNEL staining. Our study provides the first evidence that eEF2K is a clinically significant potential molecular target and contributes to tumorigenesis and progression of CRC. Its effective inhibition is safe and can suppress tumor growth in preclinical CRC models. These promising results lay the foundation for further developing eEF2K-targeted therapies, offering a potential new approach for treating CRC.

#6954 Discovery and characterization of selective mixed-lineage kinase 3 PROTAC degraders for cancer therapy.

D. Mehlich[1], K. Karpinska[1], V. R. Sabbasani[2], M. Lomiak[1], P. Torres-Ayuso[3], K. Wrobel[1], V. Nguyen-Phuong Truong[1], R. Serwa[1], R. E. Swenson[2], J. Brognard[4], A. A. Marusiak[1]; [1]International Institute of Molecular Mechanisms and Machines - Polish Academy of Sciences, Warsaw, Poland, [2]National Heart Lung and Blood Institute, National Institutes of Health, Bethesda, MD, [3]Lewis Katz School of Medicine, Temple University, Philadelphia, PA, [4]National Cancer Institute, National Institutes of Health, Frederick, MD

Mixed-lineage kinase 3 (MLK3) is a member of the MLK family of serine/threonine kinases. MLK3 is well-known to regulate MAPK signaling by acting upstream of ERK, JNK, and p38 pathways. In addition to its canonical role in activating MAPK cascades, MLK3 regulates the activity of various proteins and signaling pathways, including NF-κB, Wnt/β-catenin, and PAK1. Previous studies demonstrated that MLK3 can promote the proliferation, invasive growth, and metastatic potential of human cancers. Triple-negative breast cancer (TNBC) is a subtype of breast cancer that is characterized by poor prognosis owing to its aggressive clinical course and limited targeted treatment options. MLK3 is often upregulated in TNBC and is involved in driving the tumorigenic potential of TNBC cells. Consequently, several small-molecule inhibitors targeting MLK3 were pursued as new investigational drugs for TNBC in preclinical studies. However, the utility of these compounds is limited by their low specificity and multiple off-target effects. Furthermore, recent studies suggested that the pro-oncogenic activity of MLK3 might result from its kinase-independent and scaffolding functions, which are not effectively targeted by conventional small-molecule inhibitors. To overcome the challenges associated with MLK3 inhibition, we developed and characterized first-in-class MLK3 Proteolysis Targeting Chimera (PROTAC) degraders. We synthesized a series of PROTAC compounds by connecting pan-MLK inhibitor CEP-1347 to molecules binding different E3 ligases (VHL, IAP, Cereblon). We found that CEP-1347-VHL-02, a PROTAC based on CEP-1347 and ligand for VHL E3 ligase, was the most potent MLK3 degrader among all candidate compounds. Next, we demonstrated that CEP-1347-VHL-02 effectively degraded MLK3 via the ubiquitin-proteasome system in breast cancer cell lines. By applying biochemical assays and proteomic approaches, we found that CEP-1347-VHL-02 selectively targeted MLK3 but no other MLK kinases. Furthermore, we showed that MLK3 degradation by CEP-1347-VHL-02 led to diminished oncogenic features of TNBC cells, as evidenced by reduced proliferation, migratory potential, cell cycle arrest, and increased apoptosis. These effects were not observed in other breast cancer subtypes upon MLK3 degradation, which indicates the subtype-specific oncogenic functions of this kinase. Collectively, our research provides new opportunities for the selective targeting of MLK3 in cancer and highlights MLK3 degradation as a potential novel treatment strategy in TNBC. In the ongoing studies, we further investigate the pharmacokinetic properties and therapeutic potential of MLK3-targeting PROTACs across various cancer cell lines with high expression of this kinase.

#6955 TTK inhibition as a potential sensitizer to CDK4/6 inhibition in metastatic triple-negative breast cancer cell lines.

Gretchen M. Albarran-Acosta, Magda N. Alvarez Rodriguez, Alexandra N. Aquino-Acevedo, Harold I. Saavedra Lugo

Basic Sciences, Ponce Health Sciences University, Ponce, Puerto Rico

Breast cancer (BC) is the most common and deadly malignant tumor in women worldwide. Triple-negative breast cancer (TNBC) is the most aggressive BC subtype since it is associated with uncontrolled cell proliferation, genetic instability, and metastasis. Advanced TNBC with distant metastasis is untreatable with anti-hormonal or anti-HER2 therapies due to the lack of hormone receptors (estrogen and progesterone) and Human Epidermal Growth Factor 2 receptor (HER2). Therefore, chemotherapy is the primary treatment for this subtype of BC. The main goal of treatment for advanced TNBC patients is to prolong survival while minimizing the toxicities associated with chemotherapy. TNBCs are more prevalent in Non-Hispanic Black (NHB) and Hispanic/Latinas (H/L) with TNBC, who have lower 5-year survival rates when compared to Non-Hispanic White (NHW) women with TNBC. TNBC patients with a higher percentage of African ancestry exhibit increased expression of certain mitotic kinases (e.g. Threonine tyrosine kinase, TTK), which are crucial for genomic stability, relative to NHW. TTK is a mitotic kinase that helps maintain genomic integrity by regulating the spindle assembly checkpoint. In BC, TTK overexpression mediates centrosome amplification, chromosome instability, aneuploidy and early metastasis. Cyclin-dependent kinase (CDK) 4/6 regulates DNA replication by phosphorylating Rb, which signals progression through the G_1 phase of the cell cycle. The CDK4/6 inhibitor Palbociclib, which induces cellular senescence in tumors, is effective in luminal BC patients but not in TNBC patients. Preliminary data indicates that the inhibition of TTK restored levels of the G1/S regulators p21, p27, and Rb. Therefore, our objective is to evaluate if resistant TNBC cells from NHB women may be responsive/sensitive to CDK4/6 inhibition with Palbociclib treatment after inhibition of mitotic kinase TTK, compared to NHW women. We hypothesize that *inhibition of mitotic kinase TTK will restore levels of G1/S regulators, therefore allowing cells to respond to Palbociclib treatment, and decreasing early metastasis and tumor growth.* Inhibitor drug was added at various concentrations 24 hours after seeding MDA-MB-231 and MDA-MB-157 BC cancer cell lines in 96-well plates. After 96 hours, MTT Assay revealed IC_{50} values of 2.52 nM and 5.93 nM for the TTK inhibitor (BAY1217389) and 9.11 nM and 4.95 nM for Palbociclib (PD0332991) in MDA-MB-231 and MDA-MB-157, respectively. These concentrations will allow optimization for dosing in dual therapies. This will allow reducing each drug's levels and toxicity while improving safety and efficacy for clinical use.

#6956 Overcoming stress induced therapy resistance in triple negative breast cancer with the MNK inhibitor EB1.

Marta Cano-Galietero[1], Elena Muro-Blanc[2], Sara Garcia-Ortega[2], Adriana Martinez Cifuentes[1], Jose Ignacio Borrell Bilbao[3], Stefan Hummer[4], Santiago Ramon y Cajal[2]

[1]Spanish Biomedical Research Network Centre in Oncology (CIBERONC), Barcelona, Spain,[2]Translational Molecular Pathology Group, Vall d'Hebron Research Institute (VHIR), Barcelona, Spain,[3]Pharmaceutical Chemistry Group, IQS School of Engineering, Barcelona, Spain,[4]Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain

INTRODUCTION. Therapy resistance and the evasion from immune based therapies represent main caveats of current cancer treatments and both processes critically rely on the activation of stress response pathways, which activate the kinases MNK1/2. While MNKs are non-essential kinases, phosphorylation of eIF4E at S209 is required for oncogenic transformation and correlates with worse prognosis in several human tumors. Targeting MNKs has therefore evolved as a non-toxic strategy in oncology, to improve the efficacy of current treatments. We have identified with EB1 the first in-class Type-II inhibitor of the kinases MNK1/2 with a superior mode of action (Bou-Petit et al, JMC, 2022).
OBJECTIVES. We have previously postulated that targeting MNKs sensitizes cells to therapy induced cellular stress (Martinez et al. PLOSone, 2015). In this work, we describe the impact of EB1 on cell fate in the context of cellular stress and delineate the underling signaling pathways.
METHODOLOGY. The cell line MDA-MB231 was used as model of triple negative breast cancer (TNBC) and results were confirmed in MDA-MB468 and HS578T cells. Effects on cell growth of EB1 alone and in combination with cellular stress or therapeutic agents were studied through crystal violet assay. Alterations in signaling pathways were studied by western blot. Electron and confocal microscopy were used to analyze changes in cellular organelles and their activity. Functional assays on protein translation and the autophagy-lysosomal pathway complement the study. Main results obtained with EB1 were compared to the siRNA mediated knock-down of MNKs and eFT-508 (eFFECTOR Therapeutics, Inc.) as the most advanced Type I MNK inhibitor.
RESULTS. Cell growth assays demonstrate enhanced activity of EB1 in combination with cellular stress or therapeutic agents. Concomitantly, stress response pathways were hyper-activated in the presence of EB1 and protein translation was diminished. Microscopic analysis reveal alterations in the morphology autophagosome/lysosome structures, particularly under cellular stress. Analysis of signaling pathways revealed furthermore a link to the PI3K/AKT/mTOR signaling pathway in stress-compromised cells upstream of protein translation and autophagy. Remarkably, the observed phenotypes could only be observed with EB1 but not with eFT508, suggesting that the mode of action of MNK inhibitors is relevant in this context.
CONCLUSIONS. We demonstrate here that the MNK inhibitor EB1 affects breast cancer cells particularly under cellular stress conditions. We propose that EB1 might represent a novel therapeutic opportunity, to combat cellular stress induced therapy resistance. This might be of particular importance for the treatment of TNBC, in which good initial responses to systemic therapies are in most of cases followed by therapy resistance and tumor relapse.

#6957 Taking a new approach to treating p53 null endometrial and ovarian cancers by combining chemotherapy with tyrosine kinase inhibitors.

Jamie L. Padilla[1], Lane E. Smith[1], Irina V. Lagutina[2], Mara P. Steinkamp[3], Kimberly K. Leslie[4]

[1]Internal Medicine, University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]CRTC Shared Facility, University of New Mexico Health Sciences Ctr., Albuquerque, NM,[3]Pathology, University of New Mexico Health Sciences Ctr., Albuquerque, NM,[4]University of New Mexico Health Sciences Ctr., Albuquerque, NM

Endometrial and ovarian cancers are of the most common gynecologic cancers, and endometrial cancer incidence and mortality rates are rising. The majority of the highest risk forms of these cancers harbor mutations in the central tumor suppressor p53, encoded by the gene *TP53*. Approximately 30% of mutations such as frame shift alterations, result in a p53 null state as distinguished from the other broad category of p53 mutant tumors that are hotspot single amino acid missense alterations. With the loss of p53-dependent cell cycle checkpoints in p53 null cells, these tumors depend exquisitely on a signaling pathway downstream of p38 MAPK to enforce the G2/M checkpoint by phosphorylating cdc2, the G2/M checkpoint gatekeeper, allowing tumor cells to stop and repair DNA before entering mitosis. Using preclinical cell, organoid and PDX studies we report that adding a tyrosine kinase inhibitor to abrogate the p38 MAPK enforced G2/M checkpoint is synergistic with chemotherapy and results in mitotic catastrophe specifically in p53 null cells. Endometrial p53 null Hec50 and ovarian cancer PDX9 organoids were treated with therapeutically relevant doses of the TKIs erlotinib (an EGFR/MAPK inhibitor) or lenvatinib (primarily targeting VEGFR), paclitaxel alone or the combination of each TKI +paclitaxel and assessed for cell viability using both the CyQuant DNA platform and the Incucyte cell imaging platform. Cells expressing either wild type or missense mutated p53 were used in parallel experiments as comparisons to the p53 null models. Our striking results indicate that the combination of erlotinib and paclitaxel was highly synergistic specifically in p53 null cells with a significant reduction in the IC50 of the paclitaxel when erlotinib was added to the regimen. This result was specific for p53 null models, not for wild type or missense mutated models. Furthermore, the active regimen was erlotinib +paclitaxel, not lenvatinib +paclitaxel, indicating that the effective TKI to achieve synergy must target the EGFR/MAPK pathways, and targeting VEGFR pathways does not produce synergy under these conditions. Studies are now underway in additional cell, organoid and PDX models to validate our initial findings. The impacted kinome is also being assessed to further determine the specific targets of each TKI in the p53 null versus p53 wild type and missense mutated models. By exploring the potential of combining a TKI with chemotherapy specifically for patients with p53 null tumors, we hope to provide a more effective treatment option for this challenging subgroup of patients.

#6958 Combined targeting of AURKA and AURKB as a potential therapeutic strategy to decrease the expression of epithelial-to-mesenchymal transition drivers in triple-negative breast cancers.

Joel Alexis Orengo[1], William Frank Rodriguez[2], Selimar Alvarez Velazquez[3], Alexandra N. Aquino- Acevedo[1], Gabriel Rosario Ortiz[1], Melanie E. Cruz Robles[1], Esther M. Irrizary Quintana[4], Harold I. Saavedra[1]

[1]Basic Sciences, Ponce Health Sciences University, Ponce, Puerto Rico,[2]University of Puerto Rico, Ponce U-RISE program, Ponce Health Sciences University, Ponce, Puerto Rico,[3]Cancer Prevention and Control Research Training Program-UPR Comprehensive Cancer Center, Ponce Health Sciences University, Ponce, Puerto Rico,[4]MCC/PHSU U54 PACHE Partnership Undergraduate Research Program, Ponce Health Sciences University, Ponce, Puerto Rico

Studies have shown a significant health disparity between Hispanic/Latino women (H/L) and women of African ancestry (non-Hispanic black (NHB), Black H/L, and Caribbean H/L) compared to non-Hispanic White women (NHW) as they are more likely to be diagnosed with and to die from triple-negative breast cancer (TNBC). At mRNA levels, NHB women diagnosed with TNBC overexpress mitotic kinases such as AURKA and AURKB relative to NHW. Although these mitotic kinases have a pivotal role in the cell cycle, when dysregulated, they can activate epithelial-to-mesenchymal transition (EMT) drivers that can lead to metastasis and therapy resistance. TNBC is the most aggressive breast cancer subtype that lacks the progesterone (PR), estrogen (ER), and the ERBB2 (HER2) receptor. Therefore, it cannot be treated with biological therapies that are known to be effective against the other molecular subtypes. Thus, the purpose of this study is to investigate if AURKA and AURKB are potential therapeutic targets against TNBC in women of African ancestry. Hence, we hypothesize that co-inhibiting AURKA and AURKB will decrease the expression of EMT biomarkers and transcription factors and, therefore, lead to early metastasis. Using The Cancer Genome Atlas Database (TCGA), we identified higher expression of AURKA and AURKB in NHB women than in NHW women and increased expression of AURKB in NHB women with TNBC. After 4-siRNA-mediated knockdown, immunoblotting and Real-Time qPCR were performed using the MDA-MB-231 cells (NHW) and MDA-MB-157 (NHB) mesenchymal TNBC cells. Preliminary data indicates that the expression of AURKA and AURKB decreased in all cell lines compared to the control group. N-cadherin protein level decreased in MDA-MB-231 after a single inhibition, while the levels of ZO-1 increased after combined inhibition. Vimentin decreased in MDA-MB-157 after AURKB inhibition, while the levels of Snail decreased after combined inhibition. At mRNA levels, AURKA and AURKB significantly reduced in both cell lines and levels of Twist decreased in MDA-MB-231 after co-inhibiting AURKA and AURKB. Preliminary data from invasion assays suggest a decrease in invasion ability after single and combined inhibition in both cell lines. We will perform a prolonged transfection using shRNA to evaluate the expression of these EMT biomarkers. Additionally, we will study tumor growth and metastasis rates in vivo models. In conclusion, these results suggest the role of AURKA and AURKB in TNBC and their potential as therapeutic targets to decrease early metastasis.

#6959 CK2 inhibition exhibits synergistic effect with KIT inhibitors in acute lymphoblastic leukemia.

Katarina Dovat, Daniel Bogush, Julia Randazzo, Marjon Rafie, Stephanie Buczkowski, Rabab Husain, Joseph Schramm, Yali Ding, Chingakham Singh, Dhimant Desai

Penn State University, Hummelstown, PA

Survival for pre-B cell Acute lymphoblastic leukemia (B-ALL) has significantly improved, but High Risk (HR) subgroups continue to result in increased death for pediatric oncology patients. Novel treatment strategies are required to conquer chemotherapy resistance and improve life expectancy for HR B-ALL. Deletion of IKZF1, resulting in decreased IKAROS function, is a feature of high-risk B-ALL that is associated with resistance to chemotherapy and a poor prognosis. Casein kinase 2 (CK2) is a protein kinase upregulated in B-ALL, which phosphorylates IKAROS and reduces Ikaros DNA binding affinity. This results in a loss of IKAROS-mediated transcriptional regulation in B-ALL patients. Previous studies have shown that pharmacologic inhibition of CK2 with CX-4945 recovers IKAROS function as a transcriptional regulator. Receptor tyrosine kinase c-KIT is transcriptionally regulated by IKAROS and is often upregulated in B-ALL. The purpose of this study was to determine whether restoration of IKAROS function as c-KIT repressor via CX-4945 would act in a synergistic manner with c-KIT inhibitor imatinib in B-ALL. B-ALL cells were treated with imatinib over 72-hours to demonstrate the half-maximal inhibitory concentration (IC50). The IC50 was used to determine the range of the concentration of imatinib to be used in association with CX-4945 in a 72-hour synergy analysis of cytotoxicity. Cell viability was determined using WST-1 cell proliferation assay. The data was analyzed using Calcusyn and synergy was specified as a combination index below 0.85. The study was repeated with several different drug concentrations to establish a more precise range of synergy. The cytotoxicity of single drug c-KIT inhibitor, Imatinib, in Nalm6 B-ALL produced an IC50 of 25uM while CK2 inhibitor CX-4945 has IC50 of 4uM. When a combination was administered with a constant dose of CX-4945 at 4uM and different concentrations of imatinib, synergy was detected at several dose combinations. In conclusion, our results demonstrate that CK2 inhibitor, CX-4945, and c-KIT inhibitor, imatinib, exhibit a synergistic therapeutic effect on B-ALL cells. Presented data provide a rational for the use of combination therapy with CK2 inhibitors and imatinib for treatment of high-risk B-ALL, including Philadelphia positive (Ph+) B-ALL.

#6960 Specific BaF3 tumor platform for c-KIT and KRAS mutations.

Ziwei Li, Hating Dai, Tianyu Pang, Jiali Liu, Wenbo Du, **Wen-Jen Yu**

ICE Bioscience INC, Beijing, China

BaF3 cell line from mouse pro-B cell is rely on interleukin-3 (IL-3) for survival and widely used to evaluate the efficacy of kinase oncogenes, downstream signaling, and the blocking ability of small molecule kinase inhibitors by site specific mutation of target genes such as KRAS, EGFR, AKT, c-KIT, etc. However, few was known about the in vivo efficacy of BaF3 tumor models and the differences of efficacy from spontaneous mutation human cell lines. ICE bioscience constructed over 300 BaF3 point mutation stable cell lines as a good platform for high throughput screening in vitro. In this study, two specific BaF3 c-kit mutation tumor models (BaF3 c-KIT-V559-V560 del, BaF3 c-KIT-W557-K558 del-T670I) and BaF3 KRAS-G12C tumor models were established for efficacy evaluation of Imatinib, Sunitinib, and Sotorasib. The results showed that Imatinib 100 mpk inhibited BaF3 c-KIT-V559-V560 del tumor growth (TGI=111.10%, T/C=2.68%) and Sunitinib 40 mpk inhibited BaF3 c-KIT-W557-K558 del-T670I tumor growth (TGI=106.13%,T/C=2.03%), respectively. The efficacy of Sotorasib-30 mpk to Ba/F3 KRAS G12C tumor is significant and reached 89.37% TGI and 26.71% T/C. Although ASP3082 is a KRAS G12D inhibitor, the efficacy of ASP3082-3 mpk to KRAS-G12D GP2d CDX model is not relevant, only 37.29% TGI and 73.25% T/C values were found in this study. Western blotting showed that the BaF3 mutation tumor models are suitable for the drug discovery of specific point mutation anti-cancer drugs.

#6961 Characterization of EGFR C797S-mutant, osimertinib-resistant non-small cell lung cancer cells.

Janneke J. T. M. Melis, Kirsten J. W. Kevenaar, Jonne van Eck, Janneke M. van den End, Yvonne Grobben, Jeffrey J. Kooijman, Guido J. R. Zaman

Oncolines B.V., Oss, Netherlands

Osimertinib is a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor that irreversibly binds to active-site cysteine 797 (C797). Originally, it was developed to target the T790M gatekeeper mutation which arises as acquired resistance mechanism to first-generation EGFR inhibitors such as gefitinib. Due to its efficacy and selectivity, osimertinib is now used as first-line treatment for non-small cell lung cancer (NSCLC) patients harboring the activating EGFR mutation L858R or exon 19 deletion. However, a wide range of on- and off-target resistance mechanisms have been observed in clinical settings. Developing relevant models is crucial for designing effective treatment strategies to overcome osimertinib resistance.
The most frequently occurring on-target resistance mechanism against osimertinib is the C797S mutation, which has urged the development of fourth-generation EGFR inhibitors. To enable the profiling of novel EGFR inhibitors and drug combinations on C797S-mutant EGFR models, the mutation was introduced in NCI-H1975 cells via gene-editing with CRISPR/Cas9. NCI-H1975 is an NSCLC cell line harboring the L858R activating mutation and T790M resistance mutation. The cell line is resistant to first-generation EGFR inhibitors such as gefitinib, but remains sensitive to osimertinib. NCI-H1975 cells were transfected with a homology-directed template containing the C797S mutation and were edited via CRISPR/Cas9.
After confirmation that the mutation was introduced in a significant number of cells by DNA sequencing (mutation frequency: 28%), the cell pool was single-cell sorted followed by expansion and analysis of single cell clones. Three cell clones were characterized in detail using whole exome sequencing, quantitative analysis of EGFR surface expression using Quantibrite beads (BD Biosciences), and cell viability assays using ATP as readout in 2D culture and 3D spheroids.
Whole exome sequencing confirmed the presence of the C797S mutation in the three clones. Quantification of cell surface EGFR expression levels revealed two times higher EGFR expression in the clones compared to the parental cell line. In 2D cell viability assays, the C797S-mutant clones were 316-fold less sensitive to osimertinib compared to the parental cell line. In contrast, the fourth-generation EGFR inhibitors BLU-945 and JBJ-09-063 reduced viability of the parental and C797S-mutant clones with similar potency. While potencies in the clones were similar between 2D culture and 3D spheroids, BLU-945 and JBJ-09-063 reached a higher maximum effect in 3D spheroids compared to 2D culture.
The successful generation and characterization of the NCI-H1975 C797S-mutant clones provides a valuable *in vitro* model in which additional next-generation EGFR inhibitors and drug combinations can be profiled to identify therapeutic strategies to overcome osimertinib resistance.

#6963 The impact of aPKC inhibitors on PKC-ι/ζ; and connexin 43 in glioblastoma multiforme.

Grazielly Caroline Teodoro, Mildred Acevedo-Duncan

University of South Florida, Tampa, FL

Glioblastoma multiforme (GBM) is the most aggressive brain cancer in adults, arising from astrocytes. Its treatment is complicated by the blood-brain barrier, tumor infiltration, and genetic diversity, highlighting the urgent need for novel therapies. Our research group focuses on understanding the impact of ICA-S((-Amino-1-[(1R,2S,3R,4R)-2,3-dihydroxy-4-[(phosphonooxy)methyl]cyclopentyl]-1H-imidazole-4-carboxamide), an atypical inhibitor of PKC-ι, and ζ;-Stat (8-hydroxy-1,3,6-naphthalenetrisulfonic acid) inhibitor of PKC- ζ; on GBM proliferation and invasion, as well as their effects on Connexin 43 (Cx43). PKC-ι /ζ; plays a crucial role in GBM tumorigenesis by regulating cell proliferation and invasion. Its overexpression is directly influenced by phosphoinositide 3-kinase (PI3K). PKC-ι/ζ; and its upstream regulator, Src tyrosine kinase, regulate Cx 43, a gap junction protein that facilitates communication between astrocytic cancer cells and surrounding normal cells, thereby promoting cancer progression. The effects of aPKC inhibitors were assessed through proliferation assays on glioblastoma cell lines T98G and U87MG, revealing the impressive efficacy of both ICA-1S and ζ;-Stat. ICA-1S achieved a statistically significant 50% reduction in T98G cell proliferation (p <0.001), while ζ;-Stat resulted in a decrease of approximately 40% in proliferation within T98G cells (p< 0.001). Furthermore, ICA-1S also achieved around 40% reduction in proliferation in the U87 cell line (p< 0.001). Co-immunoprecipitation experiments provided evidence of the association between PKC-ι and Cx 43, as well as between PKC-ζ and Cx 43, in both cell lines. This suggests a direct interaction between these proteins, demonstrating their potential role in mediating cellular signaling and communication in GBM. Western blot analysis showed that ICA-1S downregulated PKC-ι and Cx43, while ζ;-Stat downregulated PKC-ζ and its phosphorylation of Cx43, impacting the PI3K/AKT pathway. Immunofluorescence Analysis of T98G cells showed decreased Cx43 distribution following treatment, suggesting potential disruption of cell communication. Further analysis will investigate the effects of ICA-1S and ζ-Stat on the U87MG cell line, specifically examining the PI3K/AKT pathway using western blotting and immunofluorescence. Moreover, High-Performance Liquid Chromatography-Mass Spectrometry (HPLC-MS) will be essential for identifying phosphorylation sites directly impacted by aPKCs and Src in Cx 43. These innovative therapeutic strategies hold promise for overcoming chemical resistance challenges and may enhance patient survival outcomes.

#6964 Dual inhibition of PKMYT1 and WEE1 kinases as a targeted therapy for ATIP3-deficient breast cancers.

Maria M. Haykal[1], Marie Varin de Lapeyriere[2], Alexis Denis[2], Sylvie Rodrigues-Ferreira[3], Clara Nahmias[1]

[1]INSERM U981 (Gustave Roussy), Villejuif, France,[2]IKTOS, Paris, France,[3]Inovarion, Paris, France

ATIP3, a microtubule-associated protein with tumor suppressor functions, is frequently lost in aggressive breast cancers, particularly in 60-80% of triple-negative breast cancer (TNBC), where its absence correlates with poor prognosis. ATIP3 deficiency is associated with heightened aneuploidy, presenting a vulnerability exploitable by targeted therapies. WEE1 kinase, a critical regulator of the G2/M checkpoint, has demonstrated therapeutic promise in this context. Inhibiting WEE1 with AZD1775 selectively compromises ATIP3-deficient cells by exacerbating DNA damage, mitotic abnormalities and chromosome pulverization, ultimately leading to cell death. However, the clinical application of WEE1 inhibitors is constrained by dose-dependent toxicities, necessitating combination strategies to enhance efficacy while reducing toxicity.

To address these challenges, we explored the complementary targeting of PKMYT1, another G2/M checkpoint kinase with distinct yet overlapping functions to WEE1. Using 3D cultures of breast cancer cell lines, we compared the responses of ATIP3-deficient and ATIP3-expressing cells to three PKMYT1 inhibitors—RP-6306, GSK1520489A, and MYT1-IN-I. ATIP3-deficient cells exhibited heightened sensitivity to all three inhibitors, particularly RP-6306, which achieved significantly lower IC50 values. To maximize therapeutic impact, we combined RP-6306 with AZD1775, resulting in a synergistic reduction in cell viability in ATIP3-deficient cells.

Dual inhibition of WEE1 and PKMYT1 intensified replication stress, DNA damage, and abnormal mitoses, exceeding the effects observed with either inhibitor alone. Importantly, the dual-targeting approach enables the use of lower doses of WEE1 inhibitors, potentially mitigating the toxicities associated with high-dose monotherapies.

Our findings establish PKMYT1 as a complementary target to WEE1 in ATIP3-deficient breast cancers. The synergistic effects of their combined inhibition not only enhance therapeutic efficacy but also address key limitations of current WEE1-based therapies. This dual-targeting strategy holds promise for improving outcomes in aggressive breast cancer subtypes. Furthermore, our work highlights the potential of ATIP3 as a predictive biomarker for patient stratification and the rational development of personalized therapies.

#6965 Atypical protein kinase C-ι inhibitor suppresses the proliferation of malignant pancreatic ductal adenocarcinoma cells.

Shreejana Rimal[1], Mildred Acevedo Duncan[2]

[1]University of South Florida, Tampa, FL,[2]Chemistry, University of South Florida, Tampa, FL

Pancreatic cancer is considered to be one of the most lethal malignant cancers as its diagnosis remains elusive if the disease progresses to an advanced stage. Moreover, pancreatic cancer is the third leading cause of cancer-related deaths in the U.S. Chemoresistance to various drugs for pancreatic cancer is the main reason for its aggressive nature. Atypical protein kinase is the family of protein kinases that contain two isoforms -ι and -ζ. These protein kinases which play a significant role in the signaling pathways have been proven to be involved in cancer cell proliferation and metastasis. (5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methyl cyclopentyl)-1H-imidazole-4-carboxamide-(ICA-1S), one of the specific inhibitors of Protein Kinase C-ι has been reported to inhibit the function of PKC-ι resulting to a decreased cell proliferation, decreased metastasis, and increased apoptosis. Our study focuses on using ICA-1S to inhibit PKC-ι in two pancreatic adenocarcinoma cell lines: ASPC1 and PANC1. Firstly, 50,000 cells were seeded into 6 well plates and treated with different concentrations of ICA-1S (0.5μM, 5μM,10μM,20μM, and 50μM) in every 24 hours for three days. The drug-treated cells and the control were trypsinized to count the number of cells using Cellometer cell counting chambers. The highest percentage of inhibition by ICA-1S was observed at 10 μM for both the cell lines ASPC1 and PANC1 where the proliferation was observed to decrease at 52% in the case of ASPC1 and 49.8% in the case of PANC1 respectively. ICA-1S concentration of 10 μM is now used for further experiments. Western Blot analysis of both ASPC1 and PANC1 cell lines demonstrated the downregulation of the PKC-ι and PKC-ζ proteins. Similarly, the downregulation of apoptosis-related marker, Caspase 3 led us to hypothesize that apoptosis is induced in the drug-treated pancreatic cancer cells compared to the control. Mutation in KRAS is most common in pancreatic cancer where very few drugs have been approved by the FDA for the treatment of pancreatic adenocarcinoma. Thus, we will on the KRAS regulated pathway for further analysis. Further investigations would include the study of aPKC inhibitor-affected pathways using techniques like WST, immunoprecipitation assay, immunofluorescence, and Western blotting.

#6966 Apparent potency of small molecule inhibitors is influenced by the choice of substrate in LIMK biochemical in-vitro kinase activity assays.

Robert Torka, Andreas Gericke, Frank Totzke, Carolin Heidemann-Dinger, Constance Rademann, Thomas Weber, Daniel Mueller

Scientific Office, Reaction Biology Europe GmbH, Freiburg, Germany

Protein kinases are essential for the regulation of many biological processes, e.g. proliferation, differentiation, migration, and apoptosis. Deregulated kinase activity is observed in tumor cells and altered activity of specific kinases is essential for development and progression of cancer and other diseases. Consequently, regulation of protein kinase activity became a target for therapeutic intervention. Intensive research resulted in the development of many small molecule kinase inhibitors (SMI) being clinically approved as targeted therapies. Functional biochemical in-vitro assays are essential requirements to assess SMIs effects on target kinase activity after validation of specific kinases being molecular drivers of a pathological condition. Only limited information is gained by monitoring the interaction of kinase and compound in pure binding assays, but more conclusive data can be generated by in-vitro kinase activity assays. However, the relevance of results from both approaches depends on how well the assay setup responds to the mode-of-action of the compounds. Recombinant proteins and generic substrates are well established in development of protein kinase assays due to cost and technical feasibility considerations. Especially some generic substrates are highly artificial e.g. the commonly used Tyrosine-kinase substrate Poly(Glu/Tyr)4:1 and may be considered as phosphate group acceptors only. However, such generic substrates have successfully been used for development of numerous clinically approved SMIs. Other kinases however are not compatible with generic substrates and can only be established using less artificial substrates or even require their respective physiological in-vivo substrate for in-vitro activity. These kinases include several members of the RAF and MAPK family. Functional in-vitro assay using a generic substrate are rarely replaced by physiological substrate due to more complex assay conditions and increased cost for drug screening. We compared biochemical in-vitro kinase activity assays for the LIM kinases, LIMK1 and LIMK2, using either generic substrates or the published physiological substrates, CFL1 and CFL2. We further evaluated these results by comparing them in different assays, using radiometric and luminescent read-out technologies. Several published LIMK inhibitors displayed significant differences in the relative potency when tested with generic or physiological substrates. Generic substrates for biochemical in-vitro kinase activity assays in preclinical drug development have been well established and successfully applied in the past. However, our data indicate, that the choice of a more physiological substrate should be considered carefully, as it might significantly increase the relevance and therefore value of the results obtained from early-stage compound screening.

#6967 Suppression of protein X-mediated survivin expression enhance the antitumor effect of irinotecan in colorectal cancer.

Se Yong Park[1], Ju-Hee Kang[1], Jung Ho Hwang[2], Sun-Ju Lee[2], Jun-Won Yun[1], Seung Hyun Oh[1]

[1]College of Veterinary Medicine, Seoul National University, Seoul, Korea, Republic of,[2]College of Pharmacy, Gachon University, Incheon, Korea, Republic of

Survivin, an inhibitor of apoptosis protein, contributes to cancer drug resistance. This study investigated survivin's role in irinotecan resistance in colorectal cancer. RT-PCR and western blotting confirmed increased survivin expression in irinotecan-treated colorectal cancer cells. Knockdown of survivin by using siRNA decreased cell viability, confirming its anti-apoptotic function. Screening potential upstream regulators revealed ‘protein X’ but not ‘protein Y’, as a key mediator of survivin expression. ‘Protein X’ is overexpressed in many cancers and associated with drug resistance. We hypothesized that inhibiting ‘protein X’ could enhance irinotecan's effectiveness. Both genetic inhibition by siRNA and pharmacological inhibition with an ‘protein X’ inhibitor enhanced apoptotic effects of irinotecan in colorectal cancer cell lines. The synergistic effect was particularly pronounced in HCT116 cells, which showed the highest sensitivity to irinotecan. These findings suggest that targeting ‘protein X’-mediated survivin expression may be a promising strategy to overcome irinotecan resistance in colorectal cancer. This approach provides a novel perspective on enhancing the efficacy of irinotecan-based therapies and potentially improving outcomes for colorectal cancer patients. Further in vivo studies and clinical trials are warranted to validate these findings and explore the therapeutic potential of this combination approach.

#6968 Targeting overexpressed NEK2 kinase in esophageal adenocarcinoma.

Lei Chen, Heng Lu, Farah Ballout, Wael El-Rifai, Oliver Gene McDonald, **Dunfa Peng**

University of Miami, Miami, FL

The incidence of esophageal adenocarcinoma (EAC) has rising rapidly during the past four decades in the US and Western countries, becoming the dominant type of esophageal cancer and a significant clinical challenge. However, the prognosis of EAC patients is still poor with 5-year overall survival rate about 20%. There is an urgent need to identify novel therapeutic targets associated with EAC biology. NEK2 is a serine/threonine protein kinase of NEK (NIMA related kinase) family which has 11 members, NEK1-NEK11. NEK2 is frequently overexpressed in human cancers, associated with tumor progression and drug resistance. We detected the overexpression of NEK2 in both mRNA and protein levels in EAC cell lines and primary EAC tissues using qRT-PCR, western blotting, immunohistochemistry. Functionally, we demonstrated that overexpression of NEK2 in EAC cells promoted tumor cell growth. Targeting NEK2 using specific siRNAs and a recent NEK2 specific inhibitor NBI-961 in EAC cells significantly inhibited EAC tumor growth in vitro and in vivo in a xenograft mouse model. RNA-seq analyses indicate that NEK2 inhibition using NBI-961 impaired important signaling pathways such as EMT, IL6-JAK -STAT3, mTOR1 and DNA repair, and enhanced interferon alpha response pathway in EAC cells. Our data suggests that targeting frequently overexpressed NEK2 in EAC is a promising approach.

CHEMISTRY: Lead Identification and Optimization
Poster Session

#6972 Discovery of XNW29016, a PARG inhibitor for HRD cancer therapy.
Y. Hu, H. Wei, D. Wan, B. Ma, J. Xu, S. Wang, L. Kong, Z. Zhang, Y. Li, Z. Wu, Y. Hou, W. Wang, X. Liu, M. Le, J. Qiang;
Evopoint Biosciences Co., Ltd., Suzhou, China

DNA damage repair enzymes are promising targets as genomic instability and DNA repair defects are important characteristics of cancer cells PARylation catalysed by PARP1/2 is a kind of reversible protein modification, which has central functions in maintaining genome stability. Poly (ADP-Ribose) glycohydrolase (PARG) is the dominant eraser of PARylation in the cell, whose activity prevents excessive accumulation of PARylation, promotes the dissociation of repair proteins, and ensures the smooth completion of DNA repair process. Deficiency of PARG leads to accumulation of PARylation and deregulation of DNA repair, which in turn causes cells to be sensitive to DNA damage and replication stress. So PARG is considered as a promising target for treating tumors characterized by DNA repair defects. PARG and PARP are in the same biochemical pathway, but their inhibitors inhibit tumor cell growth through different mechanisms, and therefore tumor cells show different sensitivities to the two inhibitors. Since the efficacy of PARP inhibitors is limited by intrinsic or acquired drug resistance in clinical practice, PARG inhibitors can also be used as an effective supplement for PARP inhibitors. XNW29016 is a rationally designed PARG inhibitor which binds directly to the PARG catalytic domain with *in vitro* biochemical IC_{50} of 29nM against PARG. Treating cells with XNW29016 strongly induced the accumulation of intracellular PARylation, activated DNA damage response signaling pathway and caused cell cycle arrest. XNW29016 demonstrated potent *in vitro* antitumor effects in a variety of PARPi-resistant cancer cell lines such as RMUG-S, KURAMOCHI and HCC1428. SNU601 and HCC1806 cells with acquired niraparib resistance or carboplatin resistance continued to be sensitive to XNW29016, but insensitive to niraparib. This result indicates that patients could still benefit from XNW29016 after treatment with PARP inhibitors and platinum drugs. In line with *in vitro* activities, XNW29016 performs antitumor activity in cell derived xenograft models of breast cancer, ovarian cancer, and gastric cancer. *In vivo* efficacy is dose-dependent and test dosages are well-tolerated, with minimum effective dose at 25 mg/kg/dose twice daily. We observed a time-dependent accumulation of PARylation. XNW29016 has good oral bioavailability and excellent exposure in preclinical pharmacokinetic studies. In toxicological studies, XNW29016 exhibits satisfactory safety profile. Altogether, these preclinical findings warrant further clinical evaluation of XNW29016 in patients with HRD cancers.

#6974 Identification of a potent KRAS (ON) inhibitor with selectivity for mutant KRAS over HRAS and NRAS.

Keith Koch, Kim Alley, Karyn Bouhana, Richard Brizendine, Paul Carlson, Mark Chicarelli, Michelle Crow, Brad Fell, Jennifer Fulton, Anna Guarnieri, Jackie Harrison, John Fischer, Ravi Jalluri, Amber Johnson, Cori Malinky, Macedonio J. Mejia, Brad Newhouse, Scott Niman, Rob Rieger, John Robinson, Mareli Rodriguez, Leah Salituro, Vinny Scarato, Aaron Smith, Francis Sullivan, Yang Wang, Shannon Winski, Silas Wodd, Yeyun Zhou

Cogent Biosciences, Boulder, CO

Oncogenic KRAS gene mutations are prevalent across human cancers, including: pancreatic, lung, and colorectal. In the US alone, it is estimated that over 165,000 cancer patients are affected by KRAS mutations annually. Early successes in the discovery of mutation specific therapeutics for KRAS led to the development of marketed agents adagrasib and sotorasib, which selectively inhibit $KRAS^{G12C}$. While these precision medicines address a critical unmet medical need, they only treat ~11% of patients with oncogenic KRAS mutations. Recent efforts to address this disparity have resulted in the identification of pan KRAS inhibitors that target all clinically relevant mutations. Herein, a novel preclinical pan KRAS (ON) inhibitor, demonstrating picomolar cellular activity across a panel of prevalent KRAS mutations is highlighted. This lead series exemplar has a differentiated mechanism of action compared to the tri complex multi RAS inhibitors currently in development, with selectivity over HRAS and NRAS. In vivo characterization to be presented includes pharmacokinetics, pharmacodynamics measuring inhibition of pERK, and efficacy in KRAS mutant tumor bearing mouse models.

#6976 Identification of novel KAT6A/B inhibitors with enhanced antitumor activity and reduced hematologic toxicity.

Rui Liu, Yushi Chi, Xiayan Zhang, Xuemei Tian, Chenqiang Jia, Zhiliang Lv, Huixin Yan, Qian Zou, Liping Han, Wan-Jen Yang, Jijun Yuan, Xiaoling Yuan, Zhiyu Ma, Yi Zhang, Yongqiang Shan, Chen Hu

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: KAT6A/B are promising targets for breast cancer therapy. A phase 1 study of the KAT6A/B inhibitor PF-07248144 showed encouraging clinical results; however, target-associated hematologic toxicity, particularly neutropenia, may hinder dose escalation. KAT6A/B inhibitors that exhibit suboptimal specificity towards other members of the KAT family may lead to increased hematologic toxicity. This study aims to identify potent and highly selective KAT6A/B inhibitors with "fast-on, fast-off" pharmacokinetic profiles *in vivo*, enabling sustained antitumor efficacy while minimizing hematologic toxicity.

Methods: Cytotoxicity of the candidates was evaluated in ZR-75-1 cells using the CellTiter-Glo (CTG) assay. An *in vitro* acetyltransferase assay, employing radiolabeled acetyl-CoA as a substrate, was conducted to assess the inhibitory effects of the candidates. *In vivo* efficacy using mono-agent was tested in a ZR-75-1 breast cancer model, while synergy studies were performed in the patient-derived xenograft (PDX) model LD1-0009-362016, which was resistant to CDK4/6 inhibitors. Top candidates were screened in the WuXi Mini 44 safety panel at a concentration of 10 μM to identify potential off-target effects. Additionally, the inhibition of H3K23 acetylation in ZR-75-1 cells was analyzed by Western blotting.

Results: HLX97-069/053 emerged as the top two candidates, exhibiting superior enzymatic inhibition and enhanced selectivity against KAT5/7/8, along with more potent cytotoxic effects in ZR-75-1 cells, in head-to-head comparisons with PF-07248144. The cytotoxicity of each compound was correlated with their potency to inhibit H3K23 acetylation. Both compounds displayed favorable ADME characteristics, such as high oral bioavailability and excellent pharmacokinetics. In a ZR-75-1 xenograft model, they demonstrated dose-dependent antitumor efficacy with minimal weight loss over a five-week treatment period. Notably, HLX97-069 resulted in less significant reductions in leukocyte, neutrophil, lymphocyte, and monocyte counts compared to PF-07248144 after five weeks of treatment. We propose that the more robust KAT6A/B inhibition and “relatively faster” clearance of HLX97-069 may contribute to its broader therapeutic window. Both compounds were well tolerated at 100 mg/kg in a single-dose acute toxicity study in rats. Additionally, HLX97-069 showed no off-target inhibition in safety panel screening. Compared to PF-07248144, HLX97-053 exhibited significantly stronger synergy with fulvestrant and palbociclib in the LD1-0009-362016 model.

Conclusion: In summary, these preclinical data provide compelling evidence that we have identified novel KAT6A/B inhibitors with best-in-class potential. Confirmation of the final candidate will depend on the outcomes of the forthcoming pilot toxicity studies, with an IND application anticipated by the end of 2025.

#6977 Development of SY-9453, a novel MAT2A inhibitor, for the treatment of MTAP-deficient cancers.

Shuang Liu, Zhenbang Lou, Ying Xin, Chang Lu, Shikang Cheng, Junfen Shi, Yeliu Wang, Sheng Zhao, Yan Zhu, **Hong Luo**, Yinghui Sun

Shouyao Holdings (Beijing) Co., Ltd., Beijing, China

Co-deletion of the *MTAP* gene with the *CDKN2A* gene, which is found in approximately 15% of all cancers, results in sensitization to MAT2A inhibition and provides an option for therapeutic intervention. The encouraging clinical activity of IDE397 provides further proof-of-concept for MAT2A inhibitors in the treatment of MTAP-deficient cancers. Here, we describe SY-9453 as a novel and potent MAT2A inhibitor. In the biochemical assay, SY-9453 potently inhibited the activity of MAT2A enzyme with an IC_{50} of 0.5 nM. In HCT116 $MTAP^{-/-}$ cells, SY-9453 showed very strong inhibition of the cellular SAM production and protein SDMA modification with IC_{50s} less than 10 nM. Moreover, SY-9453 also demonstrated strong inhibitory activity on the proliferation of multiple MTAP-deficient cancer cell lines. Functionally, SY-9453 reduced cellular mRNA splicing, induced cell cycle arrest, and promoted cell apoptosis in a dose-dependent manner. *In vivo* studies showed that SY-9453 has robust anti-tumor activity in several CDX models of colorectal cancer, pancreatic cancer, and non-small cell lung cancer. In the HCT116 $MTAP^{-/-}$ xenograft model, SY-9453 displayed dose-dependent inhibition of tumor growth, and tumor regression was observed after treatment with SY-9453 at 25 mpk, QD. Furthermore, SY-9453 revealed favorable PK properties and tolerability in preclinical studies. In conclusion, the current results demonstrate that SY-9453 is a novel small molecule MAT2A inhibitor with high activity *in vitro* and *in vivo*, providing a rational option for treating cancers with MTAP deficiency.

#6978 Discovery and characterization of BAY-805, a potent and selective DUB inhibitor of ubiquitin specific peptidase USP21.

Norbert Schmees[1], Fabian Goricke[2], Ulrike Scheib[1], Raphael Boehm[1], Namik Akkilic[1], Gerd Wohlfahrt[1], Kirstin Petersen[2], Victoria Vu[3], Leanna Smith[4], Niels Lindner[5], Joerg Weiske[1], Ulf Boemer[1], Krzysztof Brzezinka[1], Philip Lienau[2], Stefan Gradl[2], Hartmut Beck[5], Peter J. Brown[6], Vijayaratnam Santhakumar[3], Masoud Vedadi[7], Dalia Barsyte-Lovejoy[3], Cheryl Arrowsmith[8]

[1]Nuvisan, Berlin, Germany,[2]Bayer AG, Berlin, Germany,[3]University of Toronto, Toronto, ON, Canada,[4]Sickkids Hospital, Toronto, ON, Canada,[5]Bayer AG, Wuppertal, Germany,[6]Structural Consortium SGC, Chapel Hill, NC,[7]Ontario Institute for Cancer Research, Toronto, ON, Canada,[8]UHN Research, Toronto, ON, Canada

Deubiquitinases (DUBs) have recently become of high interest as some members of this protein class show potential for therapeutic interventions. The family of nearly 100 members is divided into 6 sub families. Their action is the cleavage of ubiquitin modifications from proteins, by which the function of the respective protein can change significantly. Due to this catalytic reaction all DUBs share, it is not clear so far how good specificity with potential small molecule inhibitors (SMOLs) can be achieved. Until today, only a handful of selective inhibitors were identified for a small number of protein deubiquitinases. Recent literature suggests that USP21 plays a prominent role in apoptosis, DNA repair, and signal transduction. It down-regulates TNFα-induced NF-κB activation through deubiquitinating of RIP1[15] and was reported to deubiquitinate RIG-I as well as STING to negatively regulate antiviral responses.[16-18] Recent studies indicate the relevance of USP21 in promoting tumor development and growth, including in non-small cell lung cancer[19], bladder carcinoma[20], gastric cancer[21], hepatocellular carcinoma[22], basal-like breast cancer[23], cervical cancer[24], esophageal cancer[25], colorectal cancer[26] and pancreatic cancer[27]. We selected USP21 as an interesting target for oncological treatment with a focus on its immune-oncological potential. A uHTS hit finding campaign on the Bayer 4 million compound library was initiated to identify potential selective inhibitors for USP21. Selectivity was tested against 3 other USP family members and specificity by further interference assays. Binding was cross validated by thermal shift assay (TSA). Surprisingly only a very limited number of compounds passed all criteria, and one cluster was selected for optimization. The poster will show the identification of structural classes, the focus on one series and its optimization starting from the initial 12 µM HTS hit to a single digit nano-Molar probe. The probe BAY-805 shows high selectivity in biochemical assays against a larger number of USP family members and activity in a cell-based NF kB activation assay. This probe gives an opportunity to validate USP21 pharmacology under relevant conditions in cancer.

#6979 Development of orally bioavailable multi-targeted inhibitors of Wnt signaling for the treatment of colorectal cancer.

S. Ginn[1], S. Rokey[1], A. Fistrovich[1], A. McMahon[1], T. Chavez[1], V. Tandon[2], J. Nogales[2], C. Cabel[1], C. Morales[1], S. Daptardar[1], C. Thorne[1], S. Banerjee[2], C. Hulme[1];
[1]University Of Arizona, Tucson, AZ, [2]University Of Dundee, Dundee, United Kingdom

Colorectal cancer (CRC) is a leading cause of cancer-related deaths in the United States, projected to account for 7.6% of all new U.S. cancer cases in 2024. Hyperactivation of the Wnt/β-catenin signaling pathway is a key driver of CRC, with up to 96% of cases showing oncogenic Wnt activation. Increased Wnt activation contributes to tumor stemness, progression, and pathogenesis. Targeted therapies have been developed, but drug resistance can often occur, limiting effectiveness. In this work, a novel series of multi-targeted kinase inhibitors that target downstream members of the Wnt signaling pathway (DYRKs, CLKs, CDK7/8/19), along with PI3Kα, BRAF, and PDGFR have been developed. Our lead compound, DYR895**,** demonstrates improved Wnt signaling inhibition over phase 1b clinical candidate Cirtuvivint (WNT reporter EC_{50}: 5.1 nM vs. 230 nM), while being well tolerated in mouse models (MTD >50 mg/kg) and orally bioavailable (F%: 81%). In an HCT-116 xenograft model, treatment with DYR895 resulted in reduced tumor growth and improved survival. Further optimization of DYR895 with the goal of reducing CNS exposure while enhancing Wnt inhibition led to the discovery of DYR1055, with a 10x improvement in affinity for some target kinases while maintaining key surrogate ADME attributes. Investigations into the efficacy of DYR1055 in disease models are ongoing.

#6980 Discovery of a subtype-selective TEAD inhibitor for cancer treatment.

Won An, YoungKu Kang, Seul Lee, Ye Gi Han, Jiyoon Seok, Sanghoon Kim, Ahreum Kwon, Eunji Ha, **Bora Yoo**, Ji-Duck Kim, Joon Seok Park

Daewoong Pharmaceutical Company Ltd., Yongin-si, Korea, Republic of

The transcriptional enhanced associated domain (TEAD) in the Hippo pathway signaling can regulate development and tumorigenesis. TEAD transcription factors have four subtypes (TEAD1-4) with highly conserved sequence whereas these subtypes show different expression levels depending on the organ. TEAD inhibitors are the emerging therapeutic agents for patients with NF2 mutant tumors. Most TEAD inhibitors block all subtypes of TEAD by targeting palmitoylation site and the interface 3 of YAP and TEAD. Here, we discovered TEAD selective inhibitors targeting the allosteric position of palmitoylation site. Our bicyclic compounds showed the potent in vitro activities on TEAD and cancer cell growth inhibitory effects. We also identified the compound-protein structure through X-ray crystallography and the effect of imidazole part on the TEAD selectivity. Pharmacokinetic properties of TEAD selective inhibitors were acceptable for oral administration. Furthermore, a TEAD selective inhibitor reduced the tumor growth of NCI-H226 xenograft mouse model. Overall, a TEAD selective inhibitor has the potential for developing targeted therapy for NF2 mutant tumors also each TEAD subtype-driven pathologies.

#6981 Discovery and optimization of purine-based CDK11 inhibitors for the treatment of Ewing's sarcoma.

Nada Elkholy, Pompom Ghosh, Hannah Walker-Mimms, Luxin Sun, Dylan Grassie, Ernst Schonbrunn, Derek Duckett, Andrii Monastyrskyi

Drug Discovery, Moffitt Cancer Center, Tampa, FL

RNA splicing, the process of intron removal from pre-mRNA, is a fundamental step in gene expression regulation mediated by the spliceosome. In Ewing's sarcoma, driven by the EWS-FLI1 fusion transcription factor, splicing is essential for generating in-frame fusion transcripts. Cyclin-dependent kinase 11 (CDK11) has been identified as a bona fide kinase responsible for phosphorylating SF3B1, a core component of the U2 snRNP. Both CDK11 and SF3B1 are crucial for EWS-FLI1 pre-mRNA maturation, with inhibition of either impairing splicing and disrupting downstream oncogenic target expression, revealing key therapeutic vulnerabilities in Ewing's sarcoma. These vulnerabilities offer novel therapeutic strategies to target EWS-FLI1-driven malignancy. We have employed structure-based drug design to develop a novel series of purine-based CDK11 inhibitors. Subsequently, machine learning-based quantitative structure activity relationship (QSAR) modeling was employed to optimize the dataset by identifying key structural features correlated with CDK11 activity, enabling a more focused refinement of the inhibitor series. Differential scanning fluorimetry confirmed preferential binding of one series of stereoisomers, indicating a potential for enhanced selectivity across the kinome. Furthermore, radiometric kinase assays further validated the inhibition of CDK11 functional activity. Biochemical and cell-based assays, including NanoBRET target engagement and CellTiter-Glo viability assays were performed to triage compounds. These efforts aim to identify potent and selective CDK11 inhibitors, ultimately advancing our understanding of CDK11's role in Ewing's sarcoma and its therapeutic potential.

#6982 First-in-class inhibitors of the proton-sensing receptor GPR68 for oncology.

Reid Hans Johnson Olsen[1], Michael Prime[2], Bellamy Duncan[2], Berizzi E. Alice[2], Alex Ceroni[2], Fonfria Elena[2], Major Gooyit[3], Mizuho Horioka[2], Katherine Lansu[2], Samuel R. Lawrence[2], Manisha Naik[2], Kostantinos Papachristos[2], Maninder Panesar[2], Martin Redhead[2], Simon Richards[2], David A. Smith-Parkin[2], Piotr Stepien[2], Jake Swadling[2], Diogo M. R. Tomaz[2], Bojan Vilagos[2], Walker S. Andrew[2]

[1]Recursion Pharmaceuticals, Boston, MA,[2]Recursion Pharmaceuticals, Oxford, United Kingdom,[3]Recursion Pharmaceuticals, Chicago, IL

Background: Aggressive tumors are often characterized by a fibrotic and acidic microenvironment. These features are associated with immune dysfunction, reduced survival, and impaired efficacy of chemo- and immunotherapies. One axis mediating these functions acts via GPR68, a proton-sensing receptor thought to be selectively enriched in cancer associated fibroblasts (CAFs). In mouse models, GPR68 deletion is associated with reduced tumor burden and increased overall survival, potentially by reversing immunosuppressive effects of the tumor environment. To date, a single compound purported to be a GPR68 antagonist (FT011) has entered clinical development for fibrosis. There has been limited evaluation of the efficacy of GPR68 antagonists as anti-tumor agents.

Methods: We assessed the efficacy of compounds developed using generative AI on GPR68 signaling pathways, explored GPR68-mediated effects on CAF biology, and evaluated the effects of GPR68 antagonism via CAFs on T-cell mediated cancer cell killing *in vitro.* We evaluated the *in vivo* efficacy of GPR68 antagonism on tumor growth in syngeneic models alone and in combination with immune checkpoint inhibitors.

Results: Expression of GPR68 in patient CAFs was confirmed by qPCR and signaling assays. *In vitro*, GPR68 stimulation induced changes in CAF-secreted factors, which were robustly reversed by GPR68 antagonism. GPR68 activating stimuli had no measured effect on a wildtype fibroblast cell line. GPR68 activation in CAFs led to significant changes in collagen production, which were blocked by GPR68 antagonism. Conditioned media from GPR68-activated CAFs impaired T-cell cytokine release and inhibited the ability of activated primary T-cells to kill PC-3 cancer cells. This effect was reversed by GPR68 antagonism. *In vivo*, GPR68 antagonism significantly reduced tumor growth in multiple aggressive syngeneic models. Tumor material from the 4T1 tumor-bearing animals treated with GPR68 antagonist revealed significantly increased tumor necrosis, suggesting more pronounced effects than those indicated by tumor volume alone. In support of GPR68 antagonism promoting an adaptive anti-tumor immune response, we observed enhanced efficacy when GPR68 antagonism was combined with different immune checkpoint inhibitors in a colon cancer model.

Conclusions: GPR68 acts via CAF signaling to suppress the adaptive immune response to cancer cells. GPR68 antagonism *in vivo* shows anti-tumor activity across multiple syngeneic models suggesting a broad range of potential indications. These effects are improved in combination with immune-checkpoint inhibitors supporting an immune-targeting axis between GPR68, acidic tumors, and the adaptive immune response. We are currently progressing our first-in-class lead molecules through preclinical development and validating potential *in vivo* biomarkers for future human clinical trials.

#6983 Innovative oral STING agonists for cancer therapy.

Zhiyong Qin, Limin Jia, Chengyu Yang, Chuanyun Yu, Yang Lv, Yujie Wang, Pan Li

Henan Genuine Biotech Limited Inc, Henan, China

STING, functioning as an adaptor protein, plays a pivotal role in the induction of type I interferons (IFN) and pro-inflammatory cytokines subsequent to the detection of cytosolic DNA. The development of a non-nucleotide STING agonist amenable to oral administration holds the promise of expanding the clinical utility of STING agonists among cancer patients. Leveraging computer-aided drug design strategies, a cohort of non-nucleotide STING agonists endowed with oral antitumor activities was meticulously designed and synthesized, with the overarching goal of exploring uncharted druggability domains. Among the array of investigated compounds, ZSSW21040164 manifested remarkable IFN-β (Interferon-β) activities within the tumor microenvironment. Rigorous experimental validation unequivocally demonstrated that ZSSW21040164 activates the downstream signaling cascade of STING via a STING-dependent modality. Moreover, ZSSW21040164 exhibited favorable pharmacokinetic (PK) characteristics, notably high oral bioavailability. In murine tumor models bearing H22, MC38, and CT-26 tumors, oral administration of ZSSW21040164 was well-tolerated and had a significant anti-tumor effect with more tumors achieved complete remission, which accompanied by the establishment of durable antitumor immunity. Notably, when ZSSW21040164 was co-administered with a fully murinized anti-mouse PD-1 antibody, the antitumor efficacy of single-agent therapy was substantially augmented. Collectively, these findings strongly suggest that ZSSW21040164 harbors considerable potential for development as an efficacious antitumor agent, warranting further preclinical and clinical investigations. Within this work, a series of aryl-fused heterocycles STING agonists with significant potency towards STING were investigated. The investigation comprised multiple aspects, namely, the identification methodology, pharmacokinetic (PK) properties determination, evaluation of in vitro and in vivo antitumor activities, and the elucidation of relevant structure-activity relationships (SARs). ZSSW21040164, an orally available human STING agonist, emerged as a crucial finding. It is anticipated that this compound will serve as a valuable reference for the discovery and design of human STING agonists suitable for systemic administration in a clinical setting, thereby contributing to the advancement of cancer therapeutics.

#6984 Discovery of selective SMARCA2 inhibitors for the treatments of SMARCA4 mutated cancers.

Seong Heon Kim, Hyuntae Kim, Sukho Lee, Minou Choi, Jong Woo Park, Hyosun Choi, Goeun Yang, Daehoon Kim, Doo-Young Kim, Sunhee Lee, Min Ah Park

Hyundai Pharm, Suwon, Korea, Republic of

BRM and BRG (SMARCA2/4) are two mutually exclusive catalytic ATPase subunits of the BAF complexes. SMARCA4 is frequently mutated in multiple cancers, including about 10% of non-small cell lung cancer (NSCLC). As a result, SMARCA4 deficient cancer cell becomes more dependent on its paralog, SMARCA2, for their survival. Consequently, a selective inhibitor targeting SMARCA2 is a potentially effective therapeutic option for SMARCA4-mutant cancers. We identified HD-10991 and HD-11030 as selective SMARCA2 inhibitors and evaluated their potency in SMARCA2 and SMARCA4 biochemical assays, as well as in Cell Titer-Glo assays using melanoma and NSCLC cell lines. HD-10991 and HD-11030 effectively inhibited SMARCA2 activity with single-digit nanomolar potency by binding to the ATPase domain. Both compounds demonstrated excellent selectivity, showing over 30-fold greater potency against BRM compared to BRG1 in chromatin remodeling assays. HD-10991 and HD-11030 possess desirable drug-like properties for oral administration, including favorable physicochemical characteristics and pharmacokinetic profiles. Systemic exposure through oral administration resulted in dose-dependent anti-tumor effects, consistently leading to tumor growth arrest and regression in SMARCA4-mutant xenograft models, such as SK-MEL-5 and A549 CDX models. Additional in vitro and in vivo studies in SMARCA4-mutant cell lines are ongoing to support the further development of these compounds. These findings, highlighting the anti-tumor efficacy and promising drug-like properties of HD-10991 and HD-11030, underscore their potential as candidates for preclinical studies aimed at therapeutic intervention for patients with SMARCA4-mutant cancers.

#6985 Discovery of potent and selective USP1 inhibitors for the treatments of BRCA-deficient tumors.

Seong Heon Kim, Hwa Sil Kim, Sukho Lee, Jieun Kim, Jinwoo Lee, Jong Woo Park, Yukyung Kim, Daehoon Kim, Doo-Young Kim, Min Ah Park

Hyundai Pharm, Suwon, Korea, Republic of

Poly (ADP-ribose) polymerase 1 (PARP1) inhibitors are the first successfully approved synthetic lethal cancer treatments targeting BRCA1/2-mutated breast and ovarian cancers. However, limited responsiveness among patients with BRCA1/2 mutations and the emergence of resistance to PARP inhibitors highlight the growing need for alternative synthetic lethal drugs, either as monotherapy or in combination with PARP inhibitors. Ubiquitin-Specific Protease 1 (USP1), a member of the deubiquitinating enzyme (DUB) family, plays a crucial role in DNA repair processes. USP1 inhibitors induce cancer cell death by blocking Translesion Synthesis (TLS) and the Fanconi anemia pathway, both of which have been identified as synthetic lethal partners with BRCA1/2 mutations or other homologous recombination deficiencies (HRD). We identified HD-12093 and HD-12136 as potent and selective USP1 inhibitors. Both compounds exhibited strong potency in the BRCA1-mutant triple-negative breast cancer (TNBC) cell line, MDA-MB-436, and demonstrated excellent selectivity for BRCA1-mutant cells over BRCA wild-type cells. HD-12093 and HD-12136 also induced the accumulation of mono-ubiquitinated PCNA, a known substrate of USP1. In PARP inhibitor-resistant cells, these compounds showed synergistic growth-inhibitory effects when combined with a PARP inhibitor, highlighting their strong potential to effectively overcome PARP inhibitor resistance. HD-12093 and HD-12136 exhibit favorable drug-like properties and pharmacokinetic profiles suitable for once-daily oral administration. These results support further development of HD-12093 and HD-12136 as potential best-in-class USP1 inhibitors for BRCA-deficient cancers resistant to PARP inhibitors either as monotherapy or in combination with PARP inhibitors.

#6986 Discovery of trihydroxyflavone from botanical sources targeting the epigenomic driver NSD3 in lung squamous cell carcinoma.

Betty Yangari, Kelsey Zou, Kala Mignone, Huisheng Xie, **Jianliang Zhang**

Chi University, Reddick, FL

Lung squamous cell carcinoma (LSCC) represents a highly aggressive subtype of non-small cell lung cancer, accounting for approximately 30% of all lung cancer cases. Despite its significant prevalence, effective targeted therapies for LSCC remain elusive, contributing to poor clinical outcomes. Recent molecular research has identified NSD3 as a critical oncogenic driver, with gene amplification observed in 60% of LSCC cases. NSD3 catalyzes the di-methylation of histone H3K36, leading to the epigenetic upregulation of key oncogenes such as MYC, CDK1, and CCNB1. Furthermore, the hyperactive NSD3-T1232A mutation has been implicated in accelerating tumor progression. This study aimed to develop and characterize novel small-molecule inhibitors targeting both wild-type NSD3 and the hyperactive NSD3-T1232A mutant in LSCC. Using AI-assisted molecular docking, kaempferol, an anticancer compound derived from medicinal plants, emerged as a promising lead. Comprehensive *in silico* drug design, cellular cytotoxic screening, surface plasmon resonance (SPR) assays, NSD3 chemiluminescent assays, and immunoblotting were employed to identify potent NSD3 inhibitors among kaempferol derivatives. Trihydroxyflavone (THF), one such derivative, demonstrated top DiffDock Confidence and SMANA Affinity scores, indicating a strong potential for NSD3 binding. SPR analysis confirmed the physical interaction between THF and NSD3, yielding favorable binding kinetics with a dissociation constant (KD) of 6.9 μM. Additionally, THF inhibited NSD3-catalyzed histone H3K36 methylation and disrupted critical oncogenic pathways involved in chromatin remodeling, cell cycle control, and mTOR signaling. Cell viability assays revealed that THF significantly reduced the proliferation of LSCC cell lines with NSD3 amplification or gain-of-function mutations, achieving an IC50 of 2.3 μM. In conclusion, our findings demonstrate the therapeutic potential of THF as a targeted inhibitor for NSD3-driven LSCC, laying the groundwork for future preclinical studies aimed at developing selective NSD3 inhibitors to improve outcomes for LSCC patients.

#6987 MYC condensate-modulating small molecules demonstrate robust antitumor activity in animal models of ovarian cancer and other solid tumors.

Ann Boija, Bede Portz, Yingda Ye, Jian-Guo Ren, Thomas Durand-Reville, Kip West, Isaac Klein

Dewpoint Therapeutics, Inc., Boston, MA

The transcription factor MYC is a critical driver of cancer, implicated in 70% of malignancies and amplified in approximately 30% of ovarian cancers, where it contributes to aggressive tumor progression. Despite its pivotal role in oncogenesis, MYC has eluded traditional structure-based drug discovery efforts due to the absence of well-defined drug binding sites and its dependence on highly dynamic interactions. Here, we are deploying condensate biology and phenotypic screening to identify and optimize small molecule condensate modulators (c-mods) to modify MYC oncogenic function. *In vitro*, MYC c-mods dissolve MYC nuclear condensates, selectively repress MYC-driven gene expression, and induce cell killing in a spectrum of ovarian cancer and esophageal cancer cell lines. Advanced MYC c-mods optimized using Dewpoint's AI/ML-powered end-to-end platform are orally bioavailable and yield tumor stasis and regression in *in vivo* models of ovarian cancer at tolerated daily doses. We demonstrate that the antitumor activity of the MYC c-mods extends to additional *in vivo* models from multiple indications and correlates with repressed MYC activity in tumors.

#6989 Advancing AOH1996: Enhanced anticancer activity of next-generation small molecule PCNA inhibitors.

Pouya Haratipour[1], Maryam Zangi[1], Mahshid Yaghoubi[1], Long Gu[2], Jennifer Jossart[2], John J. P. Perry[2], Linda H. Malkas[2], Robert J. Hickey[1]

[1]Cancer Biology and Molecular Medicine, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Molecular Diagnostics & Experimental Therapeutics, Beckman Research Institute of The City of Hope, Duarte, CA

Proliferating cell nuclear antigen (PCNA) plays a critical role in at least nine distinct cellular pathways, including DNA replication and repair, transcription, cell cycle control, apoptosis induction, transcription-replication conflict resolution, and immune surveillance. Tumor cells express an acidic isoform of this protein (caPCNA), whereas non-cancer cells express only a basic isoform (nmPCNA). The absence of the caPCNA isoform in non-cancer cells makes it an ideal target for selectively killing cancer cells while preserving the viability of non-cancer cells. To this end, we developed a small molecule, AOH1996, that selectively inhibits the caPCNA isoform in cancer cells, inducing cell death in these cells while showing no detectable effects on non-cancer cells. AOH1996 directly binds to caPCNA, stabilizes its trimer structure, reduces chromatin association, and selectively inhibits tumor cell growth. Currently, in several phase I and phase Ib clinical trials, AOH1996 exhibits highly selective anti-cancer properties with essentially no off-target toxicities. This study describes our efforts to improve the clinical characteristics, potency, and stability of AOH analogues through a scaffold-hopping strategy that employs structure-activity relationship (SAR) studies and bioisostere replacement. SAR analysis and modification of four unique scaffolds related to AOH1996 led to the discovery of several additional analogues exhibiting enhanced potency, selectivity, and metabolic stability compared to the clinical lead. Over one hundred AOH analogues were designed, synthesized, and initially evaluated for effects on cell growth across eight tumor cell lines. Our results identify top analogues featuring unsymmetrical 3-methoxy-5-methyl groups on the terminal phenoxy moiety, combined with fluorine, nitrile, or chlorine substitutions at the #6 position of 1-naphthoic acid. Among these, AOH-3M5Me-6F and AOH-3M5Me-6CN emerged as the lead analogues, demonstrating up to nine- and seven-fold improved potency and 38% and 68% higher liver microsome stability, respectively. These findings position these analogues for further development as selective PCNA-targeting cancer therapies.

#6990 Profiling Ras inhibitors for effects on GTP hydrolysis using the Transcreener GDP assay.

Camdon Yemm, **Robert Lowery**

BellBrook Labs, Madison, WI

Ras family GTPases are the most frequently mutated proteins in human cancers, most notably missense mutations at G12 and G13 that prolong the activated, GTP-bound state of the protein. Inhibitors that shift the equilibrium toward GDP-bound Ras, such as sotorasib, are proving effective clinically, and efforts to expand upon this strategy are widespread. Current strategies for biochemical screening and analysis of Ras inhibitors rely on the use of fluorescent GTP and GDP analogs to detect effects on GDP release and GTP binding. Though robust and widely used, these methods do not provide information on GTP hydrolysis, a critical part of the GTPase signal transduction process. We have developed methods for detecting GTP hydrolysis by small GTPases using the Transcreener GDP^2 assay, a homogenous, competitive immunoassay for GDP with far-red fluorescence readout. Because GDP release is generally rate limiting, stimulation by GEFs can also be measured by monitoring GDP formation. We have optimized these assays for initial velocity detection of GTPase activity for wild type (WT) and mutant Ras proteins with robustness suitable for high throughput screening and tested a number of compounds reported to inhibit GTP and/or GDP binding. Consistent with expectations, the Ras G12C-specific covalent inhibitor, Sotorasib, potently inhibited KRas G12C (IC_{50} = 9.6 nM) and did not inhibit the wild-type enzyme. MRTX1133, which binds noncovalently to GDP-bound KRas G12D, inhibited the G12D mutant with an IC_{50} of 8.4 nM, and was less potent with the G12V and WT enzymes; IC_{50} = 48 nM and 69 nM, respectively. BI-2865, a pan KRas inhibitor, showed much weaker inhibition of all KRas variants tested, with IC_{50} values of 427 nM, 228 nM and 236 nM for WT, G12D and G12V KRas. We note that these GTPase assays require nanomolar concentrations of protein, and therefore cannot be used to accurately determine the potency of covalent inhibitors, such as sotorasib, that bind with picomolar affinity. However, for non-covalent inhibitors, such as MRTX1113 and BI-2865, measuring GTPase activity is a robust approach for selectivity profiling and may yield mechanistic insights different from those gleaned from guanine nucleotide binding/release assays or biophysical methods, e.g. SPR.

#6991 Targeting NONO as a therapeutic strategy for metastatic castration-resistant prostate cancer (CRPC).

Brian McEllin, Yang Gao, Bodhi Hueffmeier, Andrea Gutierrez, Julia Robbins, Lillian Tatka, Tonibelle Gatbonton-Schwager, Carolyn Allen, Erin Broderick, Daniele Canzani, William Fondrie, Gaelle Mercenne, Lindsay Pino, Alex Federation

Talus Bioscience, Inc., Seattle, WA

Prostate cancer is among the most prevalent cancers among men, with approximately 300,000 new cases diagnosed annually. While androgen deprivation therapy (ADT) is effective in controlling early-stage prostate cancer, treatment options are considerably limited once the disease advances to metastatic castration-resistant prostate cancer (CRPC). This progression underscores the critical need for innovative therapeutic strategies to address this difficult-to-treat stage. Resistance to ADT arises when androgen receptor (AR) signaling becomes active even in the absence of ligands. This resistance is often driven by mutations in the ligand-binding domain (LBD) of AR or the expression of alternative AR isoforms that lack the LBD, with ARv7 being the most prominent. ARv7, plays a crucial role in the progression and treatment resistance of advanced prostate cancer, and is a high priority target for drug development.

A recent report identified an indirect mechanism for inhibiting the AR pathway through targeting NONO (non-POU domain-containing octamer-binding protein), an RNA binding protein which plays various roles in the nucleus, including transcriptional regulation and RNA splicing. Talus Bio has developed a groundbreaking technology, TF-Scan, the first cell-based global screening platform specifically designed to target transcription factors (TF). TF-Scan integrates functional proteomics, automated cell processing, and machine learning to evaluate a drug's ability to modulate the activity of DNA-bound proteins in live human cells. Using our platform, we identified several compounds that bind NONO at the residue C145, stabilizing the protein on the RNA, and blocking splicing.

Ongoing cross-functional studies aim to validate that NONO inhibition can effectively reduce AR and ARv7 splicing, suppress subsequent protein production, and disrupt the AR- and ARv7-dependent transcriptome. This disruption can potentially impede the growth and survival of prostate cancer cells that rely on these pathways. While these findings are promising, the application of NONO inhibition as a treatment for mCRPC is still under investigation. Further studies are necessary to confirm its efficacy and safety in clinical settings.

#6993 Development of synthetic lethal compounds targeting RB1-SUCLA2 deletion in advanced prostate cancer.

Susumu Kohno, Chiaki Takahashi

Kanazawa University, Kanazawa, Japan

The deletion of the tumor suppressor gene RB1 frequently occurs upon metastatic and/or castration-resistant conversion in prostate cancer. This extensive chromosomal loss associated with RB1 deletion also results in the loss of additional neighboring genes. Inhibition of gene products that compensate for these defective deletions can induce tumor-specific synthetic lethality. Our previous research demonstrated that SUCLA2 is collaterally deleted with RB1 often in advanced prostate cancer and that 5-Isopropyl-2-methyl-1,4-benzoquinone (TQ) selectively kills SUCLA2-deficient tumors. In this study, we explored the target of TQ and the mechanism of action. To determine the binding targets of TQ, we synthesized a biotinylated alkyl TQ enabling target identification via mass spectrometry analysis. Four mitochondrial enzymes were identified (W, X, Y, and Z). Enzymatic assays revealed that only enzyme X was inhibited by TQ in a dose-dependent manner. Enzyme X composes qn enzymatic complex consisting of six alpha and six beta subunits, which TQ dissociated. Notably, TQ irreversibly depleted 2-oxoglutarate and glycine in SUCLA2 knockout (KO) cells, while TQ did not affect these metabolites in SUCLA2-reconstituted cells. Adding cell-permeable 2-oxoglutarate prevented TQ-induced apoptosis in SUCLA2 KO cells, suggesting that TQ induces apoptosis by depleting tricarboxylic acid (TCA) cycle intermediates, likely through the inhibition of enzyme X. We are currently developing new TQ derivatives to improve IC50 and pharmacokinetics. This research opens avenues for novel therapeutic strategies targeting metabolic pathways through this distinctive mechanism.

#6994 Reversal of cancer gene expression for novel compound discovery in diffuse midline glioma.

Dmitry Leshchiner[1], Savneet Kaur[2], Eita Uchida[2], Kentaro Mineji[2], Yasuhide Makino[2], Katerina Petrosky[2], Bilal Aleiwi[3], Edmund Ellsworth[3], Rintaro Hashizume[2], Bin Chen[1]

[1]Michigan State University, Grand Rapids, MI,[2]University of Alabama at Birmingham, Birmingham, AL,[3]Michigan State University, East Lansing, MI

Background: Diffuse midline glioma (DMG) H3K27-altered is an aggressive incurable brainstem tumor that targets very young children. Median survival rate of patients is 9 months with 5-year survival rates of less than 1%. Complete resection is not possible due to the tumor location close to vital areas of the brain, and chemotherapy and radiotherapy are only symptomatic treatments used for palliative care. Through the reversal of cancer gene expression, we previously identified mycophenolate mofetil as a repurposed candidate for DMG; however, the clinical applicability of this candidate is limited due to its poor brain penetration. This study aims to identify new potent agents that can cross blood-brain barriers through the screening of a large compound library and lead optimization.

Method: For the screening we used our custom pipeline Gene expression Prediction from chemical Structure (GPS) that allows us to predict gene expression profiles of millions of compounds from chemical structures. With the predicted profiles, we scored compounds based on their reversal of disease gene expression. By screening the Enamine CNS library, we identified novel compounds with the ability to reverse the DMG gene signature we previously identified. Compounds were validated in DMG cell lines using MTS assays. Top hits were then selected for PK studies and maximum tolerated dose studies. To optimize our lead compounds, we ran MolSearch, a multi-objective optimization AI pipeline. We evaluated the final lead in a panel of patient-derived DMG cell lines as well as conducted PK and toxicity studies.

Results: We selected 30 compounds with the lowest reversal score for validation. Out of the 30 compounds selected, 19 had favorable ADME properties such as rule-of-5 compliance, solubility, potential toxicity, synthetic accessibility and predicted metabolic stability. Out of the 19 compounds, 7 showed reduction in cell viability in DMG cell lines. We chose the compound with the lowest IC50 as our lead. PK studies showed acceptable blood barrier penetration but significant clearance of the drug in plasma. To improve these properties, we ran our lead optimalization pipeline MolSearch to generate potential compounds that will retain reversal ability and ADME properties of the lead compound while improving metabolic stability. We are currently evaluating these new
analogs. Together, we have demonstrated that reversal of cancer gene expression could lead to the discovery of novel therapeutic in DMG.

#6995 Novel 4,6-disubstituted-7*H*-pyrrolo[2,3-*d*]pyrimidines as dual mEGFR/AURK inhibitors for non-small cell lung cancer.

Sonali Kurup[1], QiQi Hu[1], Kexin Zheng[1], Samantha Satawa[1], Felix Amissah[1], Erika Lisabeth[2]

[1]Ferris State University, Big Rapids, MI,[2]Michigan State University, East Lansing, MI

The epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) constitute the recommended therapy for non-small cell lung cancer (NSCLC) expressing mutant epidermal growth factor receptor (mEGFR). Resistance to first-generation EGFR-TKIs was addressed by osimertinib, an irreversible EGFR-TKI. However, newer mutations and redundant signaling pathways continue to drive resistance to osimertinib in mEGFR+ NSCLC. There are currently no viable EGFR-mediated treatments for osimertinib-resistant NSCLC. The aurora kinases (AURKA, AURKB) are mitotic kinases involved in centrosome maturation and separation during mitosis and can contribute to tumorigenesis. The AURK inhibitors have resensitized osimertinib-resistant mEGFR+ NSCLC cells when combined with osimertinib. Thus, dual mEGFR/AURK inhibition provides a unique approach for mEGFR+NSCLC. Kurup et al. previously investigated 4-substituted-7*H*-pyrrolo[2,3-*d*]pyrimidines as dual mEGFR/AURK inhibitors. Compounds **1-8** were developed as 4,6-disubstituted-7*H*-pyrrolo[2,3-*d*]pyrimidines to determine their effects as dual mEGFR/AURK inhibitors. The design, synthesis, and evaluation of compounds **1-8** will be presented and discussed. The anticancer effects of dual mEGFR and AURK inhibition in osimertinib-resistant mEGFR+ NSCLC cells will also be presented.

#6996 Integrating high-throughput screening with ligand-based pharmacophore modeling and virtual screening strategies to optimize exonuclease 1 inhibitor design.

J. Hess, L. Zheng, B. Shen;
Beckman Research Institute of The City of Hope, Duarte, CA

Pharmacophores are the specific steric and electronic features of a small molecule that are necessary to ensure interaction with a specific biological target and to trigger or block its biological response. Three-dimensional quantitative structure-activity relationship (3D-QSAR) pharmacophore modeling is a computational approach that utilizes data collected from *in vitro* experiments and molecular docking to map the shared features of known actives, producing a template that can be used to optimize the physical and chemical properties of lead compounds. Our goal is to generate a 3D-QSAR model for exonuclease 1 (EXO1) inhibition to support the pre-clinical development of a potent, EXO1-specific, small molecule inhibitor and define the molecular interactions that drive inhibitor specificity toward EXO1 instead of related nucleases. Construction of this model will facilitate the development of a potent EXO1 inhibitor that is selective, cancer-specific, and synthetic lethal with BRCAness. Additionally, it will establish a structural foundation for enhancing the selectivity of inhibitors targeting highly similar 5' nuclease family members, such as FEN1. Here, we describe our approach to integrating the high-throughput and virtual screening data we have collected for ~365,000 small molecule compounds to map a preliminary 3D-QSAR hypothesis for EXO1 inhibition.

#6997 Impact of KRAS^{G12C} oxidation state on non-small-cell lung cancer response to targeted therapeutics.

Yismeilin R. Feliz Mosquea[1], Maria Luiza Carneiro Buchele[1], Derek Parsonage[2], Jingyun Lee[1], Surbhi Mundra[3], Sharon L. Campbell[3], Leslie B. Poole[2], Cristina M. Furdui[1]

[1]Internal Medicine, Section on Molecular Medicine, Wake Forest University School of Medicine, Winston-Salem, NC,[2]Department of Biochemistry, Wake Forest University School of Medicine, Winston-Salem, NC,[3]Department of Biochemistry and Biophysics, University of North Carolina School of Medicine, Chapel Hill, NC

RAS proteins are critical signaling nodes that regulate cellular growth, with activating mutations in KRAS found in approximately 25% of human cancers. These mutations lead to chronic KRAS activation and sustained oncogenic signaling. Among >130 cancer-associated point mutations in KRAS, 99% cluster at hotspots (G12, G13, and Q61), with G12C mutations predominant in non-small cell lung cancer (NSCLC, ~80%). The G12C mutation introduces a reactive cysteine, enabling covalent drug discovery strategies. Therapeutics such as AMG510 (Sotorasib) target KRAS^{G12C} by locking it in an inactive state; however, resistance arises in ~60% of treated patients. To address this challenge, we aim to investigate how oxidation of KRAS and at Cys12 in KRAS^{G12C} influences its ability to bind covalent inhibitors, potentially offering insights into resistance mechanisms and novel therapeutic strategies. To explore the effects of oxidative modifications on KRAS^{G12C} function, we have started by engineering a recombinant KRAS^{G12C} protein that lacks other cysteines (denoted KRAS$^{G12C\text{-}CL}$) and introduced a Trp substitution (Y137W) to enable fluorescent kinetic analyses (KRAS$^{G12C\text{-}CLW}$; CL stands for cysteine-light). Recombinant protein samples were exposed to oxidants (H_2O_2) in the presence or absence of GDP, subsequently desalted using Bio-Spin Chromatography columns, and then analyzed by mass spectrometry to quantify the kinetics of oxidation to sulfinic acid state (-SO_2H) under these conditions. Further fluorescent kinetic assays of reduced and oxidized KRAS^{G12C} with AMG510 and other KRAS inhibitors showed complex profiles distinguishing inhibitor binding to the reduced and oxidized KRAS^{G12C}. Additionally, we conducted targeted analyses of endogenous KRAS^{G12C} oxidation in Calu-1 non-small cell lung cancer cells. Calu-1 cells treated with 1 mM H_2O_2 for 5 minutes demonstrated rapid oxidation of KRAS^{G12C}. Data will be presented showing the impact of KRAS^{G12C} oxidation on the therapeutic efficacy of clinical and experimental inhibitors. These approaches aim to better evaluate the impact of KRAS^{G12C} oxidation state on inhibitor engagement and therapeutic outcomes, addressing mechanisms of resistance and optimizing treatment strategies.

CHEMISTRY: Targeted Protein Degradation
Poster Session

#7002 Discovery of DXTX-1464: A first-in-class, highly potent and selective degrader of CCNE1/CCNE2 and CDK2 for cancer therapy.

Tim Dwight, Andrew Allen, Vivian Guo, Justin Radatti, Stephane Corbel, Stephane Billotte, Paul Greenspan, MIke Wood, Humphrey Gardner, **Bryce Kenneth Allen**

Differentiated Therapeutics Inc, Oceanside, CA

Introduction: Cyclin E1 (CCNE1) and E2 (CCNE2) when amplified are a hallmark of several aggressive cancers, including ovarian, gastric, and endometrial. These cyclins, when overexpressed, bind and activate CDK2, driving uncontrolled cell cycle progression and contributing to treatment resistance, particularly to CDK4/6 inhibitors in breast cancer. The persistent activation of CCNE1/CCNE2-CDK2 complexes is also linked to poor clinical outcomes in many solid tumors. In addition, kinase-independent functions of Cyclin E have been demonstrated to regulate cell cycle and affect genome stability. Selectively targeting the degradation of CCNE1, CCNE2, and CDK2 offers a promising strategy to dismantle this oncogenic axis, overcome therapeutic resistance, and improve patient outcomes.
Results: Prospective design informed by Auto/dx, a proprietary platform for predicting degrader pharmacology, elucidated multiple series of dual Cyclin E and CDK2 degraders designed to enable preferential stabilization of a ternary complex conformation enabling lysine-specific targeting of a ubiquitination zone between CDK2 and CCNE1/CCNE2, selectively targeting these proteins for degradation via the ubiquitin-proteasome system. These bivalent degraders incorporate a ligand that binds CDK2 and a cereblon-binding moiety, connected by an optimized linker that induces cooperativity and novel protein-protein interaction surfaces between CDK2 and cereblon. Functional studies demonstrated that these degraders effectively eliminated CCNE1, CCNE2, and CDK2 while sparing other cyclins and CDKs. Selective degradation of CCNE1/CCNE2-CDK2 complexes by development candidate DXTX-1464 resulted in potent inhibition of downstream signaling, including phosphorylation of Rb, a critical mediator of cell cycle progression and resulted in the upregulation of p21 and p27. This led to cell cycle arrest, the induction of apoptosis in some contexts, and significant antiproliferative effects in cancer models with CCNE1/CCNE2 dependencies. In vivo studies further validated these results, achieving robust depletion of CCNE1, CCNE2, and CDK2 in tumor models, leading to measurable tumor regression. 14 day DRF studies have indicated DXTX-1464 is well tolerated in rat and dog at doses exceeding the DC90.
Conclusions: Targeted degradation of CCNE1, CCNE2, and CDK2 represents a novel therapeutic approach for cancers characterized by Cyclin E dependencies or CDK2 hyperactivation. By eliminating CCNE1/CCNE2-CDK2 complexes, we propose this strategy will circumvent resistance to CDK4/6 inhibitors in HR+/HER2– breast cancers and will address oncogenic signaling in Cyclin E-amplified or overexpressed solid tumors. These findings support the further development of CCNE1/CCNE2 degraders and provide a rationale for their clinical application in patients with Cyclin E-driven malignancies.

#7003 NX-5948 is a CNS-penetrant catalytic Bruton's tyrosine kinase (BTK) degrader that breaks established design rules for CNS drugs.

Wylie Palmer, Mark Noviski, Paul Auger, Karthik Arumugam, Danielle Bautista, Nivetha Brathaban, Robert Cass, Ming Liang Chan, Ganesh Cherala, Philip Keyes, Aishwarya Kumar, Saloni Malla, Mitchell Lavarias, Filippo Marchioni, Jenny McKinnell, Jun Ma, Ryan Rountree, May Tan, Alexandra Trotier, Sarah Whelan, Davorka Messmer, Frederick Cohen, Gwenn M. Hansen

Nurix Therapeutics, Inc., San Francisco, CA

NX-5948 is a targeted protein degrader of Bruton's Tyrosine Kinase (BTK) in Phase 1 clinical development for the treatment of B cell malignancies. Heterobifunctional degraders, such as NX-5948, occupy beyond Rule-of-Five chemical space where established guidelines for physicochemical properties associated with drug-likeness cannot easily be applied. In contrast to approved central nervous system (CNS) drugs, NX-5948 exceeds several recognized chemical property metrics, such as molecular weight, polar surface area, and hydrogen-bond donor count. In addition, NX-5948 does not conform with in vitro permeability and transporter efflux ratio guidelines that would predict for CNS penetration. Despite these unfavorable properties, NX-5948 shows CNS exposure in preclinical models. As a bifunctional degrader with an event-driven mode of action, NX-5948 induces potent degradation of BTK in primary human B cells and malignant B cells. By performing a series of *in vitro* experiments measuring cellular partitioning and degradation kinetics, we calculated the catalytic efficiency of NX-5948 and demonstrate that one degrader molecule can promote degradation of thousands of copies of target protein. This enables a very low concentration of free drug to sustain pharmacodynamic activity and efficacy *in vivo*. NX-5948 shows dose-dependent brain exposure in rodents with an unbound brain-to-plasma partition coefficient, or Kp,uu, value consistent with CNS penetration. Additionally, NX-5948 degrades BTK in microglia in naive mice and rats with intact blood-brain barriers. NX-5948 also degrades BTK in intracranially-implanted tumor cells and extends survival in an intracranial TMD8 mouse model of CNS lymphoma. In the clinic, NX-5948 is detectable in cerebrospinal fluid of patients with CNS-involved B-cell malignancies, with concentrations that exceed the minimum free plasma level that correlates with BTK degradation. NX-5948 has also demonstrated clinically meaningful responses in patients with primary CNS lymphoma or chronic lymphocytic leukemia with CNS involvement (Hansen, G., AACR San Diego, 2024; Linton, K., EHA Hybrid Congress, Madrid, Spain, 2024), supporting the therapeutic potential of NX-5948 in B-cell malignancies with CNS involvement.

#7004 CT7439 an oral first-in class selective CDK12 and 13 inhibitor and cyclin K degrader: Profiling activity and combination efficacy in an ovarian cancer model.

A. K. Bahl[1], M. Carr[2], S. Thompson[3], A. Campbell[4], A. Leishman[5], E. Ainscow[5];
[1]Bahl (Individual), Dublin, Ireland, [2]Sygnature, Nottingham, United Kingdom, [3]Sygnature Discovery, Nottingham, United Kingdom, [4]Sygnature Disciovery, Nottingham, United Kingdom, [5]Carrick Therapeutics, Dublin, Ireland

CT7439 is a small molecule kinase inhibitor of cyclin-dependent kinases CDK12/CDK13 that received FDA IND approval in 2023. In addition to inhibiting CDK12/13, CT7439 acts as a monovalent glue degrader of cyclin K (CCNK), the cyclin required for CDK12/13 function. Proteomics quantification by DIA LCS/LCSMS mass spectrometry was conducted after exposure to 30 nM CT7439 at 4 & 24 hr. OV-90 cells were cultured in media and exposed to CT7439 at various concentrations and time points. Combination studies were conducted with the PARP inhibitors and Carboplatin. The following parameters were assessed: proliferation/cell survival, confluency formation, CCNK protein levels and DNA damage and repair (DDR) genes. CT7439 inhibited OV-90 cell growth with an IC50 of 4.4nM and this impact on cell growth was significantly attenuated by co-treatment of the cells with proteasome inhibitor. Proteomics analysis revealed that 99 proteins were found to be differentially abundant between samples from CT7439 (30 nM) treated and vehicle at 4 hrs. At 24 hrs 1,666 proteins were found to be differentially abundant. CCNK was the only cyclin impacted by CT7439. Pathway and ontology analysis showed reduced abundance for proteins involved in DDR. DDR genes (BRCA1, ERCC4, RAD51C and POLQ) are inhibited by treatment with CT7439, at concentrations consistent with inhibition of CDK12/13-Cyclin K in the cells. CT7439 activity in OV-90 in cellular assays:

OV-90	Growth	CCNK**	BRAC1*	ERCC4*	RAD51C*	POLQ*	MCL-1*
IC_{50} nM (SD)	4.4	0.66 (0.1)	1.7 (0.4)	0.82(0.3)	1.2 (0.7)	1.9(0.2)	>20

Data is mean ± SD (**Western blot, *qPCR) In addition to single agent activity of CT7439 a strong combination activity between CT7439 and the PARP inhibitors Olaparib, Niraparib and AZD10530 as well as the carboplatin was observed in an OV-90 cellular confluency assay. CT7439 is an orally bioavailable selective CDK12/13 inhibitor and degrader of CCNK. Pre-clinical studies demonstrates clinical potential for monotherapy use in solid tumors and as a combination therapy with agents known to cause a DNA damage response.

#7005 Discovery and characterization of DAC-1522, a novel Trop2-targeting degrader-antibody conjugate for precision oncology.

Chuanjie Chen[1], Qianqian Shen[1], Xinhui Cai[1], Yaqi Ding[1], Xiaoyu Yang[1], Yanfen Fang[1], **Jiangnan Luo**[2], Jian Ding[1], Yi Chen[1], Xuan Zhang[1]

[1]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China,[2]DaCure Therapeutics, Shanghai, China

Antibody-drug conjugates (ADCs) have revolutionized cancer therapies by enabling the targeted delivery of cytotoxic payloads to tumor cells. However, their efficacy and safety heavily rely on the toxins as their payloads, and the rare availability of toxin types often limits their efficacy and broader expansion of indications. Combining the precision targeting feature of ADCs and diverse options of protein degraders, degrader-antibody conjugates (DACs) have emerged as a next-generation therapeutic modality and offer a promising strategy to overcome these challenges. The human trophoblast cell surface antigen 2 (Trop-2) is a transmembrane glycoprotein widely expressed in various types of tumors. It has been clinically proven as a well-suited antigen for ADCs with its widespread overexpression in cancer cells and much lower expression in normal cells. Despite the clinical success of Trop2-targeting ADCs like IMMU-132 (sacituzumab govitecan-hziy), their dependence on topoisomerase inhibitors as payloads has exposed significant limitations, particularly in addressing both intrinsic and acquired drug resistance. This has created an urgent need for innovative therapeutic solutions. Here we introduce DAC-1522, a novel Trop2-directed DAC, that can potentially overcome the limitations of ADCs. *In vitro* studies have shown that DAC-1522 efficiently degrades the target protein in a dose-dependent manner and exhibits potent antiproliferative activity against multiple human cancer cell lines. Its efficacy is strongly correlated with the level of Trop2, ensuring selective cytotoxicity in Trop2-positive cells and sparing Trop2-negative cells, resulting in a favorable therapeutic window. Notably, DAC-1522 retains uncompromised antiproliferative activity in an ADC-induced acquired drug resistance model, underscoring its potential to overcome the drug resistance after ADC treatments. *In vivo*, DAC-1522 achieves complete tumor regression with a single intravenous injection in mice (human pancreatic cancer BXPC-3 xenograft model), significantly outperforming IMMU-132 in terms of efficacy. No obvious safety concerns were observed. These findings support further preclinical and clinical development of DAC-1522 as a highly promising therapeutic candidate for the Trop2-expressing cancers.

#7006 TY-2719, a potent and selective broad-spectrum mutation-effective EGFR-PROTAC molecule, attenuates acquired resistance to 3rd-generation EGFR TKIs.

Apeng Liang*,#[1], Shengli Dong*,#[1], Shaoqing Chen*[1], Shunxun Han[1], Hongqiang Li[1], Guangbin Liu[1], Xi Wang[1], Zhengfei Guo[1], Yanyan Liu[1], Ling Fang[1], Yi Long[1], Xiang Zhang[1], Wei Wu[1], Chengshan Niu[2], Mingyu Jiang[3], Jun Li[3], Yusheng Wu[3]

[1]TYK Medicines, Inc., Changxing county, Huzhou City, China,[2]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, Henan, China,[3]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China

Introduction: The epidermal growth factor receptor (EGFR) is a well-known oncogenic driver of non-small cell lung cancer (NSCLC). Approximately 15~50% of NSCLC patients carrying EGFR mutations is reported. Despite the substantial therapeutic efficacy of EGFR tyrosine kinase inhibitors (TKIs), acquired EGFR-TKI resistance presents a significant challenge in the clinical management of NSCLCs. Proteolysis-targeting chimera (PROTAC) represents a novel technology with the capacity to degrade oncogenic proteins, and exhibits significant potential for overcoming drug resistance. Recently, several EGFR PROTAC antitumor drugs have successfully progressed to clinical trials with the aim of addressing drug-resistant EGFR mutations in NSCLC. These included CFT8919 (NCT06641609), HSK40118 (NCT06050980), and HJ-002-03 (CTR20241691). TY-2719 is an oral, highly selective, broad-spectrum EGFR-PROTAC designed by TYK Medicines Inc., to overcome the resistance of 3rd -generation EGFR TKIs.

Results: TY-2719 did not suppress the growth of normal cells, such as NHEK, and NSCLC cells, such as A549 and A431 cells harboring wild-type EGFR. However, TY-2719 has excellent in vitro antiproliferative activity against a number of EGFR mutants, including common mutations, post osimertinib-resistant mutations, and rare mutations. Our data suggest that TY-2719 has superior selective activity in cells containing EGFR mutants compared to wild-type EGFR-expressing cells. It efficiently degraded EGFR carrying L858R/T790M/C797S and 19del/C797S mutations in BaF3 cells with single-digit nanomolar range activity, as evidenced by EGFR-HTRF and western blot assays. Toxicity is an important factor limiting the efficacy of protac therapy, and many toxic effects are caused by ImiD-mediated degradation of CRBN neosubstrates. For example, GSPT1 plays an essential role in the majority of cells; however, GSPT1 may be accidently degraded by PROTACs recruited CRBN. Using a western blot assay, we found that TY-2719 did not degrade IKZF1/2/4, CK1α, and GSPT1. The IC50 values of TY-2719 were greater than 10 μM in the inhibition assays for all eight important CYP450 isoforms involved in drug metabolism. The DMPK characteristics of TY-2719 were excellent in the rat experiments. TY-2719 showed significant antitumor activity and tolerability in xenograft mouse models.

Taken together, we have identified a potent and highly selective, broad-spectrum mutation-effective new EGFR-PROTAC molecule which may grant new therapeutic opportunities to overcome drug resistance of 3rd -generation EGFR TKIs in NSCLC patients.

#Shengli Dong and Apeng Liang contributed equally to this work.

#7007 Identifying novel non-allosteric PIM1 degraders to overcome treatment resistance in triple negative breast cancer.

Sanjay V. Malhotra[1], Benedikt W. Grau[1], Dhanir Tailor[1], Abel Bermudez[2], Fernando Jose Garcia Marques[2], Juliana Geppert[1], Sharon Pitteri[2]

[1]Cell, Development and Cancer Biology, Center for Experimental Therapeutics, Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Department of Radiology, Canary Center at Stanford for Cancer Early Detection, Stanford University School of Medicine, Palo Alto, CA

Background: Breast cancer (BC) is the most common cancer among women, with triple-negative breast cancers (TNBC) being the most aggressive type. Resistance to current mainline therapies is one of the major reasons for increased mortality. PIM1 oncoprotein has been implicated in causing treatment resistance, and therefore, associated with the development and progression of this disease. Several attempts have been made to develop inhibitors of PIM1. However, these inhibitors are not specific and can lead to toxicity by inhibiting the activity of other kinases. Therefore, there is an unmet need to develop a non-orthosteric inhibitor or non-allosteric degrader, which would be more specific and could help in effective treatment of TNBC.
Methods: We synthesized a novel class of PIM1 degraders and confirmed their non-allostatic mode of action experimentally *in vitro*, *in silico* and *in vivo*.
Results: Our lab has designed indole-based compounds and identified initial hits on their PIM1 inhibition properties in a luciferase reporter assay. Further optimization improved the PIM1 inhibition up to 80-90%. However, the *in silico* analysis suggested that the compounds do not interact with the orthosteric center of the protein. This was confirmed by a kinase assay, which revealed that the new compounds do not interfere with PIM1 kinase activity. On the other hand, Bio-layer interferometry (BLI) studies confirmed the physical interaction of our compounds with the PIM1 protein, concluding non-allosteric interaction. The top three compounds were tested further *in vitro*. Treatment with our top candidate(s) inhibits cell proliferation and arrests the cells in G1 phase. This was followed by apoptotic cell death. These findings suggest that our newly designed compounds can indeed interact with PIM1 and hinder its protein function while leaving its kinase activity unaffected. Furthermore, *in vivo* study in the EMT6 orthotopic mice model of the top three compounds suggest that treatment inhibits tumor progression and lung metastasis.
Conclusion: Preliminary results merit the optimization of 'Hit-to-Lead' and development of a suitable candidate to treat TNBC, where PIM1 is the cause of treatment resistance. Successful completion of the proposed work will enable a new combination therapy to reverse chemoresistance.

#7008 Development of a potent SOS1 degrader exhibiting superior combination effects with anti-cancer drugs in various tumor models.

Jiyoung Kim, Ji Youn Park, Yeajin Woo, Soohyun Lee, Beomseon Suh, Han Wool Kim, So Hyuk Kim, Yongdae Kwon, Heejung Moon, Yeeun Kim, Jungmin Ahn, **Jihye Lee**, Je Ho Ryu, Song Hee Lee

Background: Son of Sevenless 1 (SOS1) is a crucial guanine exchange factor (GEF) for KRAS, facilitating the activation of RAS family proteins by promoting the exchange of GDP for GTP at its catalytic site. It also binds GTP-bound KRAS at an allosteric site, enhancing its GEF activity through positive feedback. Loss or genetic inactivation of SOS1's GEF function reduces the survival of tumor cells with KRAS mutations. Additionally, SOS1 is subject to MAPK-mediated negative feedback inhibition and drugs targeting upstream and downstream nodes relieves SOS1 from this inhibition resulting in pathway reactivation.
Results: UBX-144 demonstrated superior degradation activity, achieving sub-nanomolar DC50 levels in the NCI-H358 NSCLC (non-small cell lung cancer) cell line and in transiently transfected SOS1 mutant cells, where it effectively degraded SOS1. A time-course degradation assay demonstrated half-maximal degradation of SOS1 within 2 hours of treatment. A mechanism of action (MOA) study revealed that UBX-144 degrades SOS1 via the ubiquitination-proteasome system, mediated by CRBN E3 ligase. Both UBX-144 and UBX-164 inhibited cell proliferation across various cancer types, including gastric, colon, breast, lung, brain cancers, and chronic myeloid leukemia (CML). A combination synergy study showed that UBX-204 synergized with various inhibitors in NCI-H358 and MIA-PaCa-2 cell lines. In vivo pharmacodynamic (PD) data showed that UBX-144 effectively degraded SOS1 protein in tumors in a U87-MG xenograft model. Experiments using the glioblastoma cell line derived xenograft model demonstrated a compelling in vivo profile, with 10 mg/kg administration of UBX-144 resulting in significant tumor growth inhibition (TGI: 101%) and maximal degradation values exceeding 95% in tumors.
Conclusion: We have successfully discovered novel SOS1 degraders exhibiting remarkable anti-tumor activities. In particular, the superior anti-cancer effects of combination treatments with other drugs were confirmed across various cancer cell lines, highlighting its potential as an excellent combination partner. We demonstrate that SOS1 degraders provide a promising therapeutic option for RTK/RAS/MAPK-dependent cancer patients.

#7009 Discovery of UBX-306 as a potent, selective, and orally bioavailable HPK1 degrader.

Ae-Ran Choi[1], Na-rae Jeong[1], Sun-Mi Yoo[1], Han Wool Kim[1], So Hyuk Kim[1], Hyun-Hwi Kim[1], Sun-Kyoung Im[2], Miyoung Jang[1], Hohyun Lee[1], Jungmin Ahn[1], Je Ho Ryu[1], **Song Hee Lee**[1]

[1]Ubix Therapeutics Co., Ltd., Seoul, Korea, Republic of,[2]NeoImmuneTech, Inc., Rockville, MD

Background: Hematopoietic progenitor kinase 1 (HPK1), part of the MAP4K family, is a serine/threonine kinase critical for modulating immune cell signaling and function. HPK1 is predominantly expressed in hematopoietic cells, where it acts as a negative regulator of T-cell receptor (TCR) signaling and other immune pathways. Upon activation, HPK1 dampens immune responses by phosphorylating key adapter proteins, such as SLP-76, and promoting their degradation, ultimately inhibiting T-cell activation, proliferation, and cytokine production. Given the critical role of T-cells in anti-tumor immunity, HPK1 has emerged as an attractive target in immuno-oncology for enhancing immune responses.
Results: UBX-306;NT2020 demonstrated robust HPK1 protein degradation, achieving single-digit nanomolar DC_{50} levels in the Jurkat cell line in a dose-dependent manner. The degradation effect of UBX-306-1 is strongly dependent on the ubiquitin-proteasome system (UPS). Both UBX-306-1 and UBX-306-3 significantly enhanced IL-2 secretion in Jurkat cells, demonstrating superior EC_{50} values compared to the warhead of UBX-306, AZ1, or reference HPK1 degrader. Treatment with UBX-306-1 increased IL-2 production in a concentration-dependent manner, even in the presence of immunosuppressive molecules such as PGE2 and NECA. UBX-306-2 effectively degrades HPK1 protein in Ramos, Raw264.7, THP-1, and KG-1 cell lines. In vivo pharmacodynamic (PD) data demonstrated that UBX-306-1 efficiently degraded the HPK1 protein in the mouse blood. UBX-306-1 induced peak degradation of HPK1 at 6 hours after oral administration, with the degradation activity sustained for up to 24 hours. The antitumor efficacy of UBX-306-1 was evaluated in the CT-26 (Colorectal cancer) syngeneic tumor mouse model. Daily oral administration of UBX-306-1 at doses of 10 mg/kg and 30 mg/kg resulted in robust tumor growth inhibition.
Conclusion: We demonstrate that potent HPK1 degraders, effectively activate immune cells and inhibit tumor growth in mouse syngeneic tumor models as single agents. These degraders enhance IL-2 and IFNγ production while overcoming immunosuppressive factors. Further, in vivo studies will deepen our understanding of HPK1 degradation as a promising immunomodulatory strategy for enhancing anti-tumor immunity.

#7010 HDB-82: A promising PROTAC degrader for KRAS G12D mutant cancers.

Mohammad Hassan Baig[1], Yun Seong Jo[1], Sagar Dattatraya Nale[2], Chang Joong Kim[2], Tae Hwan Park[2], Ju Han Bok[3], Dong Min Kim[3], Hye Mi Kim[3], Ji Min Park[3], Jae June Dong[1], Jae Hee Cho[1], Sung Ill Jang[1], Byoung Gon Moon[3]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]BNJ Biopharma Inc., Incheon, Korea, Republic of,[3]Handok Inc., Seoul, Korea, Republic of

KRAS G12D mutations, occurring in approximately 30% of solid tumors, represent a significant therapeutic target. While selective KRAS G12C inhibitors have achieved clinical success, effectively targeting the more prevalent G12D mutation remains an unmet medical need. This study investigates the potential of proteolysis-targeting chimeras (PROTACs) as a promising avenue for KRAS G12D-driven cancers, potentially offering advantages over traditional inhibitors through catalytic protein degradation. Targeted protein degradation of mutant KRAS may yield greater efficacy than simply inhibiting the protein. This study focuses on the design, synthesis, and biological evaluation of novel KRAS G12D-targeting PROTAC degraders. Through rigorous optimization, we developed HDB-82, a highly potent and selective PROTAC compound targeting KRAS G12D. HDB-82 effectively induced degradation of the KRAS G12D protein, leading to significant antiproliferative activity against KRAS G12D-mutant cancer cells *in vitro* and *in vivo*. HDB-82 demonstrated potent anti-cancer activity against various KRAS G12D-mutant cell lines, achieving low nanomolar IC_{50} values. It effectively degraded the KRAS G12D protein in various KRAS G12D-expressing cell lines (DC_{50} value ranges from picomolar to sub-nanomolar range). Mechanistic studies revealed significant suppression of downstream MAPK and PI3K/AKT signaling pathways, accompanied by robust induction of apoptosis, and superior antiproliferative activity compared to existing inhibitors. Furthermore, HDB-82 exhibited favorable pharmacokinetic and pharmacodynamic properties in mice. Intravenous administration of HDB-82 (10 mg/kg, q.w.) resulted in substantial tumor growth inhibition across multiple KRAS G12D-positive tumor models. These findings establish HDB-82 as a promising therapeutic candidate for KRAS G12D-mutant cancers, warranting further preclinical investigation and potential clinical development.

#7011 Humanized CRBN knockin mice enable in vivo assessment the efficacy and toxicity of CRBN-targeted protein degraders.

Yi Li, Xiaolei Qiu, Liping Feng, Dongxiao Feng, Ruilin Sun

GenoBioTX, Sugar Land, TX

Protein degraders have emerged as a transformative therapeutic approach in the past decade, enabling targeted degradation of proteins, including traditionally undruggable targets, by facilitating the recruitment of E3 ubiquitin ligases. Among these, molecular glues such as thalidomide and its derivatives, and PROteolysis TArgeting Chimeras (PROTACs), have gained significant attention. Cereblon (CRBN), a key component of the Cullin 4 RING E3 ubiquitin ligase (CRL4), is the most extensively studied target in protein degrader research. CRBN interacts with DDB1, Cullin 4 (CUL4A/B), and RBX1 to form the CRL4^CRBN complex, which mediates substrate recognition and degradation. Thalidomide derivatives bind to CRBN, modulating substrate specificity and promoting substrate degradation.

However, differences at the V388 and E377 residues between human and mouse CRBN proteins (94% homology) impede the antitumor efficacy and teratogenicity of thalidomide in mice, limiting suitable preclinical models. To address this, we developed a humanized CRBN knockin mouse model by inserting the human CRBN coding region (exon 2-11) and a WPRE/polyA cassette into the mouse Crbn locus using ES cell-based gene targeting. This model expresses full-length human CRBN in targeted cells.

We validated human CRBN (hCRBN) expression across multiple tissues, including spleen, liver, brain, and intestines, via RT-PCR and western blot. Lenalidomide and CC-885 treatments of hCRBN splenocytes demonstrated the degradation of substrate proteins CK1α and GSPT1. Pharmacokinetic analysis revealed no significant differences between hCRBN knockin and wild-type C57BL/6 mice. In vivo CC-885 treatment induced on-target toxicity, as evidenced by rapid lethality, GSPT1 degradation, and increased pathological scores in hCRBN knockin mice.

Our humanized CRBN mouse model serves as a robust preclinical platform for evaluating the efficacy and toxicity of CRBN-targeted protein degraders, offering valuable insights for drug development.

#7013 RGT-61159, best-in-class oral small molecule inhibitor of MYB via selective RNASplicing alteration, synergistic anti-tumor aActivity when combined with standards of care in leukemia disease models harboring AML common genetic lesions and with NOTCH inhibitors in ACC disease models.

Norman Lu, **Patricia Soulard**, Xiubin Gu, Chris Yates, Kai Li, Sam Hasson, Ibrahim Kay, Zhiping Weng, Travis Wager, Simon Xi

Rgenta Therapeutics, Inc., Woburn, MA

The oncogenic transcription factor MYB is a master regulator of self-renewal, differentiation and proliferation of hematopoietic cells. MYB is frequently aberrantly expressed in hematologic malignancies and has been revealed to be a central component of oncogenic complexes maintaining aberrant gene expression programs in AML. RGT-61159 is a potent, selective oral small molecule inhibitor of the oncogene MYB via the inclusions of a cryptic exon into MYB RNA transcripts, resulting in the activation of the nonsense-mediated decay pathway promoting MYB mRNA depletion and sequentially MYB protein degradation. The RGT-61159 Phase 1 study in adults with relapsed/refractory ACC or CRC has been initiated (NCT06462183).
Here, we report genomic analyses of different AML cell lines treated with RGT-61159 that provided further insight into key oncogenes (e.g., BCl2, NOTCH, MYC) directly regulated by MYB. To further evaluate RGT-61159's potential to treat leukemia, RGT-61159 single agent was profiled in a battery of murine models of AML harboring the most common genetic lesions (e.g., Flt3 ITD, MLL-fusion and NPM1 mutation). RGT-61159 showed significant anti-tumor activity across the different AML tumor models tested along with robust MYB RNA depletion in tumor cells at tolerated doses.
In addition, the benefit of combining RGT-61159 with a panel of standard-of-care agents for AML treatment was explored in vitro across a panel of AML cell lines harboring different genetic alterations. The data revealed synergistic cell killing activity when RGT-61159 was combined with Flt3 inhibitors (e.g. gilteritinib and midostaurin) in MOLM-13 and MV4.11 cell lines harboring Flt3 IDT mutation, and with menin inhibitors (e.g. KO-539, revemenib) in AML cell lines with NPM1 mutant) or MLL-fusion. Finally, RGT-61159 combination with a Bcl2 inhibitor (venetoclax) resulted in synergistic cell killing activity in AML cell lines carrying NPM1 mutations or AML-1-ETO fusion protein. These studies provide compelling supportive evidence for combining RGT-61159 with standards-of-care for AML treatment in the relevant population of patients with AML. .

#7014 Characterization and validation of PROTACs that recruit KLHL12.

Zoe A. Petros, John Lee Sensintaffar, Anish Kizhakkekkara Vadukoot, Kwangho Kim, Manikandan Thangaraj, Alex G. Waterson, Stephen W. Fesik

Vanderbilt University, Nashville, TN

Proteolysis targeting chimeras (PROTACs) have emerged as a promising strategy for cancer therapy in the field of drug discovery. PROTACs are heterobifunctional small molecules that bind to both a target protein and an E3 ubiquitin ligase, thus facilitating degradation of the target protein of interest. Benefits of PROTACs as an alternative therapeutic strategy include the ability to target inaccessible proteins, the regulation of target protein signaling pathways, and overcoming drug resistance in certain types of cancer. There are more than 600 known E3 ligases in the human genome, but current PROTAC technology has been limited to the use of CRBN, VHL, XIAP, and MDM2. Therefore, the discovery of novel ligands for different E3 ligases could further improve current PROTAC technology. An application that our research group has focused on is exploring the possibility of tissue selective E3 ligases that are overexpressed in cancer cells compared to normal tissue to design tissue selective PROTACs for a target of interest. We have observed that protein levels of the E3 ligase KLHL12 are low in normal tissue and high in cancer cells. Using structure-activity relationship (SAR) by nuclear magnetic resonance (NMR), we identified hits that bound to the KLHL12 E3 ligase, which were then optimized to bind in the range of 10-100 nM K_d by SPR. We then generated KLHL12 based PROTACS that target BRD4 and Bcl-xL using thalidomide and A-115463 derivatives, respectively. PROTAC activity was optimized by measuring protein target degradation in HT29 cells by an in-cell western experiment where our most potent degrader had an average DC_{50} of 5.05 nM and achieved 89.65% degradation. Mechanism studies were carried out to verify that the PROTACs behaved in both a proteasome and target dependent manner. Future studies will support further characterization of KLHL12 by investigating its expression patterns across various cancer tissues, its functional essentiality in cells, and its involvement in protein-protein interactions.

#7015 Intelligent molecular glue discovery by identifying glueable ligase-target pairs at scale.

Phil Burke, Arpita Sen, David Noble, Abhishek Dogra, Ruchi Bansal, Dasha Krayushkina, Natasha Seelam Murakowska, Kerry McGowan, Charles Lin, Yeweon Lee, Randolph Lopez

A-Alpha Bio, Seattle, WA

Targeted protein degradation can be induced by monovalent small molecules, called molecular glues. These molecules modify the substrate-binding interface of E3 ubiquitin ligases and reroute their binding to novel targets, opening the possibility of therapeutically inhibiting proteins previously considered “undruggable”. However, for a molecular glue to sufficiently stabilize a ligase-target interaction and induce degradation, the two proteins must exhibit proper shape complementarity and contain productive amino acid contacts - two proteins selected at random are unlikely to be glued by any small molecule. Identifying novel “glueable” ligase-target pairs requires the discovery and characterization of weak interactions (likely in the micromolar affinity range) between thousands or more potential pairs of human E3 ligases and therapeutically relevant target proteins. The need to evaluate vast numbers of potential protein interactions while maintaining exquisite sensitivity for weak interactions presents a major technical roadblock. To address this challenge, we apply *AlphaSeq*, a high-throughput and highly sensitive experimental platform for measuring protein-protein interactions, to discover and structurally characterize weak interactions between ligases and target proteins. We validate our approach by characterizing known ligase-target interactions, such as between the E3 ligase MDM2 and the tumor suppressor protein p53. We then leverage *AlphaSeq* for the discovery of molecular glues for novel ligase-target pairs and orthogonally validate these interactions with surface plasmon resonance (SPR). Finally, we use *AlphaSeq* mutational data to structurally characterize the interaction interface and inform the intelligent discovery of molecular glues.

#7016 PROTiNb: A novel platform for developing biodegraders targeting intracellular proteins.

Hongzhuan Gu, Lijun Ye, Zexiu Huang, Dan Xu, Lizhen Zhan, Tian Wang, Liang Xiao, Yue Huang, Baiguang Ren, Chang Zhou, Ke Chen, Xiaodong Wu, Di Lu

Guangdong Fapon Biopharma Inc, Dongguan, China

Since the concept of targeted protein degradation (TPD) was first introduced in the 1990s, innovative technologies such as PROTACs and molecular glues have rapidly emerged and advanced, leveraging pathways including the ubiquitin-proteasome system, lysosome-mediated degradation, and autophagy. A notable limitation of PROTAC technology is its dependence on small molecule ligands to engage the target protein or the E3 ligase. These small molecules are often vulnerable to target mutations, which can interfere with binding and are considered a major cause of drug resistance. Furthermore, most existing TPD technologies rely on a limited set of endogenous E3 ligases, primarily CRBN and VHL.Nanobodies, on the other hand, provide larger binding surfaces and greater structural flexibility, allowing for a broader range of target proteins and potentially mitigating resistance risks. Recognizing these advantages, we established PROTiNb (Proteolysis Targeting intra-Nanobody) platform. This platform integrates engineered E3 ligases with VHH nanobodies in RNA form to be translated in the cells, enabling highly efficient and specific protein degradation.

For instance, in GFP-overexpressing cell lines, LaG16-SPOPm (modified SPOP) and GFP enhancer-RNF4m (modified RNF4) demonstrated higher degradation efficiency compared to their wild-type E3 ligase counterparts. Similarly, when fused with KRAS-specific VHH RT22, RT22-SPOPm showed superior degradation activity over RT22-SPOPwt, leading to enhanced inhibition of tumor cell proliferation. Furthermore, the fusion of RNF4m with the PCNA-specific VHH efficiently degraded PCNA in cancer cells, inducing cell cycle arrest and significantly suppression of tumor cell growth in vitro. We inoculated Nude mice with HCT116 cells overexpressing doxycycline-induced KRAS PROTiNb and induced PROTiNb expression by feeding doxycycline. The induction of KRAS PROTiNb significantly inhibited tumor growth. To translate this platform into a therapeutic application, we used a tumor-targeted lipid nanoparticle (LNP) for in vivo delivery. In vitro studies revealed that tumor-targeted LNPs enhanced the delivery specificity and increased the tumor-suppressive potency. Most notably, these nanobody-based degraders exhibited robust activity in vivo, effectively suppressing tumor growth.

In summary, our study demonstrates the versatility of the PROTiNb platform in rapidly generating degraders against intracellular targets once considered undruggable, with promising potential for clinical therapy for cancers.

#7017 Discovery and development of a highly co-operative and potent pan-KRAS degrader.

Dinesh Chikkanna, Madhu Aeluri, Leena Khare, Ravindra MV, Debajyoti Basak, Uday Bhat, Suraj T. Gore, Narmatha V, Shailesh V. Jadhav, K. Y. Vasantha, Sivapriya Marappan, Megha Goyal, R. N. Raghavendra, Amit A. Dhudashiya, Kiran Aithal, T. Jagadeesh Kumar, D. S. Suhas, K. B. Charamanna, P. Dharani, R. Naveenkumar, Rahul B. Chavan , Randeep Bokalial, D. S. Samiulla, Subhendu Mukherjee, Thomas Antony, Kavitha Nellore, Rajesh Eswarappa, Girish Chandrappa Daginakatte, Sanjeev Giri, Susanta Samajdar, Murali Ramachandra

Aurigene Oncology Limited, Bangalore, India

KRAS is one of the most frequently mutated oncogenes in various cancers. KRAS G12D mutation is prevalent in 39% of pancreatic ductal adenocarcinoma (PDAC), 27% of colorectal cancer, 11% of non-small cell lung adenocarcinoma as well as in a subset of other solid tumors. KRAS G12V mutation is found in 31% of PDAC, 20% of colorectal cancer and 19% of non-small cell lung adenocarcinoma. KRASG12C mutations are found in 41% of non-small cell lung adenocarcinoma and 3-5% of colorectal cancers. Despite recent advances in small molecule KRAS inhibitors, a majority of KRAS alterations are not yet addressed. Further, in cases where inhibitors are available, resistance rapidly emerges. Eliminating all mutant KRAS using a targeted protein degradation approach may lead to superior efficacy relative to inhibiting the protein. We have identified a series of degraders through structure-based drug design and our Directed Neo-substrate Degrader (DN_sD) approach, with very high co-operativity, potent pan-KRAS degradation activity and a desirable pharmacokinetic profile. The high co-operativity of pan-KRAS degraders was confirmed though Surface Plasmon Resonance (SPR) analysis. These degraders demonstrated significant degradation of KRAS in multiple KRAS mutant cell lines and showed mechanistic activity via the modulation of pERK levels leading to significant anti-proliferative activity. The KRAS degraders were found to be selective against HRAS and NRAS which was also confirmed using global proteomic analysis. Further, the development candidate molecule demonstrated significant and dose dependent tumor growth inhibition in multiple KRAS mutant xenograft models which was accompanied by sustained KRAS degradation. Notably, the development candidate compound has demonstrated excellent PK and tolerability in rodent and non-rodent tox species. IND enabling studies are ongoing to support clinical development.

#7018 Antibody-degrader conjugates unlock the therapeutic potential of heterobifunctional degraders through antibody-like pharmacokinetics and excellent in vivo efficacy.

Jan G. Felber, Anil P. Jagtap, Philipp Ochtrop, Saskia Schmitt, Isabelle Mai, Sarah Herterich, Paul Machui, Dietmar Konig, simon vogt, Dominik Schumacher, **Jonas Helma-Smets**, Annette Vogl, Marc-Andre Kasper

Tubulis GmbH, Martinsried, Germany

Heterobifunctional small molecules recruiting the proteasomal machinery enable the targeted protein degradation (TPD) of selected proteins and considerably broaden the druggable space for therapeutic use. Many such molecules have seen fantastic success in preclinical and clinical developments, e.g., for targeted degradation of specific oncoproteins that were previously inaccessible for cancer therapy. Even though early hits are quickly generated by adapting the modular concept of bifunctional degraders, most of such molecules are against the central rules of a “drug-like” molecule: they are usually larger in size (800-1500 Da) and often lack sufficient solubility. These early bifunctional degraders hits require exhaustive structure optimization in each case to optimize pharmacokinetics (PK) profiles and bioavailability.
Here, we report Tubulis’ antibody-degrader conjugates that exploit bifunctional degraders as high-potency bioactive payloads to be released specifically inside cells that are targeted by the antibody. Our linker technology ensures high degrader-to-antibody ratios (DARs) and excellent linker stability in blood plasma. Moreover, we liberate the degrader after receptor-mediated uptake of the ADC and show high efficiencies in target protein degradation. Most importantly, our conjugates exhibit antibody-like PK properties that ensure long-lasting plasma circulation of high DAR constructs over weeks, even when bifunctional degraders are employed that have not been optimized for PK properties. Taken together, these factors allow impressive in vivo efficacy of the conjugates after single dose application in preclinical animal models.

#7019 Identification of first-in-class paralog selective SMARCA4 degraders for treatment of hematological and prostate malignancies.

Chandrasekhar Abbineni, Kiran Aithal, Bilash Kuila, Sandeep Vitthal Dukare, Arya Desai, Megha Goyal, Khaji Abdul Rawoof, Gauri Rahul Petkar, Gopinath CH, T Jagadeesh Kumar, Charamanna KB, Rahul B. Chavan, Nandish C, Suraj Tgore, Leena Khare, Samiulla DS, Subhendu Mukherjee, Thomas Antony, Kavitha Nellore, Sanjeev Giri, Rajesh Eswarappa, Girish Daginakatte, Susanta Samajdar, **Murali Ramachandra**

Aurigene Oncology Limited, Bengaluru, India

The BAF (SWI/SNF) chromatin remodeling complex comprises of two mutually exclusive ATPases, SMARCA2 (BRM) and SMARCA4 (BRG1), that affect the mobilization and positioning of nucleosomes on DNA and thereby regulates important cellular functions including transcription, DNA recombination, DNA repair and chromosome decatenation during mitosis. SMARCA4 is frequently overexpressed in several types of cancers. Overexpression has been linked to increased proliferation and survival, as well as aggressive tumors and poor prognosis. SMARCA4 knockdown in these tumors lead to inhibition of proliferation and increased sensitivity to known chemotherapeutic agents, supporting the validity of targeting SMARCA4. In addition, PTEN and SMARCA4 appear to share synthetic lethality relationship based on reported in vitro and in vivo knockdown studies. Considering this well-established biological rationale, selective degradation of SMARCA4 should offer significant clinical benefit in multiple disease settings. Here, we report first-in-class SMARCA4 selective degraders that demonstrate distinct cellular phenotype. As part of the initial design plan, selective SMARCA2/4 Bromodomain inhibitors and specific ligands of several E3 ligases were chosen to arrive at different degrader designs. Several linkers and different exit vectors were considered to construct a variety of hetero-bifunctional degrader molecules. Our proprietary ternary complex modeling algorithm, ALMOND^4 (ALgorithm for MOdeling Neosubstrate Degraders) helped in prioritizing the designs. Shortlisted compounds were synthesized and profiled in multiple cellular assays to understand their potential to degrade SMARCA4 selectively. These compounds exhibited very potent anti-proliferative activity in cell lines of hematological and prostate cancer origin (e.g. MV-4-11, VCaP, etc.) whereas no significant potency is observed in SMARCA4 mutant cell lines. Identified compounds have shown selective degradation of SMARCA4 over SMARCA2 in multiple cell lines. Few potent SMARCA4 selective degraders were optimized for pharmacokinetic properties and further evaluation of tolerability and efficacy in rodents is in progress.

#7020 Chemical probe discovery for PAX3::FOXO1 via small-molecule microarrays.

Y. Xiang, M. Ramos Sala, B. Wu, D. Rana, K. Motoyama, B. Leifer, M. Toure, S. Doyle, A. N. Koehler;
Massachusetts Institute of Technology (MIT), Cambridge, MA

PAX3::FOXO1 (P3F) oncoprotein is a driver of poor patient outcome, contributing to tumorigenesis by dysregulating protein complexes that result in altered chromatin structure and gene expression. We conducted Small-Molecule Microarray (SMM) screening of approximately 10,000 compounds using engineered HEK293 cell lysates, identified KI-P3F-032, a compound that binds silently to the fusion protein, forming the basis for PROTACs development. With this initial results, there is a need to revalidate this preliminary screening result with biophysical data, we validated binding with SPR and developed biologically relevant high-throughput secondary assays to evaluate PROTACs efficacy. We have now developed a PROTAC with strong selective cytotoxicity against P3F positive RMS cell lines. At the same time, we also explored the possibility of indirect targeting of P3F via inhibiting and degrading other transcription regulators such as CDK9. We also developed new SMM assays to identify novel P3F binders using a library of approximately 65,000 small molecules under native P3F positive cell lysates, identifying 90 potential binders. We then developed functional recombinant P3F protein production and purification in our lab to enable pure protein based assays. We hope our research strategy can further advance the current progress on targeting the conventionally undruggable P3F oncogenic fusion and bring insight to targeting disordered oncogenic fusions in other pediatric cancers.

#7021 Discovery of a highly potent and orally bioavailable ER PROTAC degrader for the treatment of breast cancer.

Guan Zhou, Yuanli Wang, Wei Xue, Yongzheng Ding, Jing Cheng, Kanghua Wang, Weiwei Yu, Wenmin Chen, **Fuming Xu**

Gan & Lee Pharmaceuticals, Beijing, China

Breast cancer is the most prevalent invasive cancer among women globally and approximately 70-80% of newly diagnosed breast cancer cases are ER-positive (ER+). Estrogen receptor α (ERα) is a prime target for the treatment of ER+ breast cancer. Despite the development of several effective therapies targeting ERα signaling, clinical resistance remains a major challenge. A promising therapeutic strategy to overcome endocrine resistance in ER+ breast cancer is the development of ER degraders using the proteolysis targeting chimera (PROTAC) technology. Facilitated by our new cereblon ligand library, we have discovered a potent and orally bioavailable ER PROTAC degrader GLR203801, with its binding affinity to cereblon increased by 20-fold than that of ARV-471. GLR203801 exhibited robust protein degradation in both ER wild-type cell lines (DC_{50} < 1 nM, D_{max}> 90%) and mutant cell lines harboring Y537S or D538G mutation (DC_{50} 2-10 nM, D_{max} > 80%). Profound inhibition of the expression of ER-regulated genes GREB1 and PR was observed with GLR203801 in all the tested cell lines. GLR203801 shows more potent cell growth inhibition activity and maximum inhibition is 20%-30% higher than that of ARV-471 in all the tested ER wild-type and mutant cell lines.

GLR203801 was characterized with favorable PK profile *in vivo*, with longer $T_{1/2}$ and higher plasma exposure than ARV-471. GLR203801 displayed significantly enhanced antitumor efficacy than ARV-471 in five ER+ xenograft models (MCF-7, T-47D, ZR-75-1, MCF-7^{Y537S}, and T-$47D^{D538G}$), with tumor regression observed in wild-type xenograft models. PK/PD studies demonstrated that the tumor exposure of GLR203801 was 10 to 20-fold higher than that of ARV-471, and GLR203801 degraded >95% of ER in MCF-7^{WT} and T-$47D^{D538G}$ tumor tissue. In addition, GLR203801 in combination with CDK4/6 inhibitors showed synergistic anti-tumor efficacy in T-47D xenograft model. GLR203801 also effectively inhibited the viability of breast-cancer patient derived ER+ organoids. The good tolerance of GLR203801 in toxicity study both in SD rats and beagle dogs supports it as a promising preclinical candidate for further clinical development.

#7022 Discovery of GLR203701, a highly potent AR PROTAC with favorable PK profile and optimized tissue distribution characteristic.

Xiaobing Liu, Qianqian Zhao, Yuna Zhang, Yichao Ma, Licong Bu, Kanghua Wang, Weiwei Yu, Fuming Xu, **Wenmin Chen**

Gan & Lee Pharmaceuticals, Beijing, China

Prostate cancer is a hormone-dependent tumor, and the androgen receptor (AR) signaling axis drives all stages of prostate cancer, including the lethal, drug-resistant form of the disease termed metastatic castration-resistant prostate cancer (mCRPC). The development of PROTAC targeting AR has become a promising therapeutic strategy to solve the problem of mCRPC drug resistance of prostate cancer.

PROTAC drugs generally have both low solubility and permeability, which often lead to poor oral bioavailability and saturated drug absorption, with the systemic exposure reaching a plateau at lower dose. Phase 1 dose escalation trial showed systemic exposure of ARV-766 reached maximum at 320 mg/day in humans. 100 mg/day and 300 mg/day, were selected as the RP2D. The maximum or saturation exposure determines the window in which PROTAC drugs can be ramped up in clinical trials, which is of great significance to the clinical efficacy.

Recently, our drug discovery campaign led to the discovery of a potent AR PROTAC, named GLR203701. GLR203701 has good FaSSIF (Fasted State Simulated Intestinal Fluid) solubility, which contributed to a significant improvement of oral bioavailability. Moreover, the maximum exposure of GLR203701 was 5-fold higher than that of ARV-766 in rats and its exposure in beagle dogs reached up to 10-fold higher. In VCaP, LNCaP and 22RV1 cells, GLR203701 could degrade more than 90% of AR, with half-maximal degradation concentration (DC_{50}) < 10 nM. Profound tumor growth inhibition (TGI>90%) was observed in all the three xenograft models, even when the compound was dosed once every other day.

GLR203701 was chosen from a STAR (structure-tissue exposure/selectivity-activity relationship) analysis of over 100 pre-screened molecules because of its ideal tissue distribution. GLR203701 had reduced accumulation in liver and kidneys, while achieved 2.7-fold higher exposure in tumor than in plasma. Drug concentration detected in the epididymis and prostate was similar to the blood. Our refined STAR approach has enabled a harmonious balance of drug concentrations among visceral tissues, tumor and disease related organs, benefiting the efficacy/safety. No significant adverse effects were observed when GLR203701 was administered at 120 mg/kg to rats and dogs. Taking the high exposure level and good bioavailability, GLR203701 is expected to generate a board therapeutic window. These preclinical data support the clinical development of GLR203701 for the treatment of mCRPC.

#7023 A phenotypic screening method identifies a potent anti-cancer PROTAC targeting MAP3K1.

Lelisse T. Umeta[1], Jayapal R. Mallareddy[1], Sarbjit Singh[1], Smitha Kizhake[1], Lidia Boghean[1], Amritha Kizhake[1], Suchita Vishwakarma[2], Katelyn L. O'Neill[1], Lisa Humphrey-Brattain[1], Adrian Black[1], Xu Luo[1], Andrew S. Boghossian[3], Matthew G. Rees[3], Melissa M. Ronan[3], Jennifer A. Roth[3], Amarnath Natarajan[2]

[1]UNMC Eppley Institute, Fred & Pamela Buffett Cancer Center, Omaha, NE,[2]Department of Pharmaceutical Sciences, UNMC Eppley Institute, Fred & Pamela Buffett Cancer Center, Omaha, NE,[3]Broad Institute of MIT and Harvard, Cambridge, MA

The identification of Thalidomide, Lenalidomide, and Pomalidomide as Cereblon (CRBN) binders spurred the development of proteolysis-targeting chimeras (PROTACs). PROTACs with CRBN-binding moieties are heterobifunctional molecules that form a ternary complex with CRBN, which recruits the CUL4-DDB1 ubiquitin ligase protein complex, and a protein of interest (POI) and targets it for degradation. Despite numerous ongoing efforts, the structure-based design of PROTACs remains elusive. The current approach relies on the synthesis of a PROTAC library and screening the library in the chosen assay format to identify viable hits. Here, we propose a viability-based phenotypic screening system using HCT116 wild type (WT) POI knock-out ($POI^{-/-}$) and CRBN knock-out ($CRBN^{-/-}$) cells to identify PROTACs that display activity in both a POI and CRBN-dependent manner. For this study, we selected MAP3K1, an oncogenic signaling activator, as our POI and conjugated an ATP-competitive MAP3K1 inhibitor with thalidomide using various linkers to generate the library. The library was subjected to a 3-day viability screen using the above WT, $MAP3K1^{-/-}$, and $CRBN^{-/-}$ cell lines. The screen identified 50-008 as a hit that selectively inhibited the viability of the WT cells but not $MAP3K1^{-/-}$ or $CRBN^{-/-}$ cells. 50-008 was chemically validated in a colorectal cancer cell line and organoid model by making single changes that affect either CRBN binding, MAP3K1 binding, or the linker. Follow-up studies showed that 50-008 inhibits cancer cell proliferation, induces apoptosis, and an S-phase cell cycle arrest in a CRBN and MAP3K1-dependent manner. Furthermore, A Profiling Relative Inhibition Simultaneously in Mixtures (PRISM) screen of 50-008 across ~900 cancer cell lines identified 267 sensitive cancer cell lines (IC_{50} < 0.1μM), including luminal B breast cancer cell line T47D and 131 resistant cancer cell lines (IC_{50} > 10 μM). Mechanistic studies in T47D cells demonstrated that 50-008 degrades MAP3K1 and modulates the activation of key downstream effectors, such as ERK and IKKβ.

#7024 Discovery of highly selective, potent and orally bio-available SMARCA2 degraders.

Chandrasekhar Abbineni, Kiran Aithal, Bilash Kuila, Sandeep Vitthal Dukare, Prasath Kothandaraman, Arya Desai, Megha Goyal, Khaji Abdul Rawoof, Dhaytadak Bhagwan Mahadeo, Gopinath CH, T Jagadeesh Kumar, Charamanna KB, Rahul B. Chavan, Nandish C, Suraj Tgore, Leena Khare, Samiulla DS, Subhendu Mukherjee, Thomas Antony, Kavitha Nellore, Sanjeev Giri, Rajesh Eswarappa, Girish Daginakatte, Murali Ramachandra, **Susanta Samajdar**

Aurigene Oncology Limited, Bengaluru, India

The BAF (SWI/SNF) chromatin remodeling complex comprises of two mutually exclusive ATPases, SMARCA2 (BRM) and SMARCA4 (BRG1), that affect the mobilization and positioning of nucleosomes on DNA and thereby regulate important cellular functions including transcription, DNA recombination, DNA repair and chromosome decatenation during mitosis. Genetic silencing studies have established that the oncogenic activity of tumors lacking SMARCA4 is primarily driven by SMARCA2-containing residual SWI/SNF complex. Thus, targeting SMARCA2 in a SMARCA4 mutant setting is synthetically lethal. Considering this well-established biological rationale, selective targeting of SMARCA2 could be a precision oncology opportunity to meet an unmet medical need. Here, we report the identification and development of highly selective SMARCA2 degrader with oral bioavailability that have demonstrated robust efficacy in SMARCA4 mutant CDX models. SMARCA2 selective degraders were identified by optimizing an assembly of SMARCA2/4 Bromodomain binders, degron connecting linkers and several ligands of specific E3 ligases. Design prioritizations were done using a proprietary ternary complex modelling algorithm, ALMOND (ALgorithm for MOdeling Neosubstrate Degraders). Prioritized designs were synthesized and profiled in multiple cellular assays to understand the mechanistic and functional readouts. Several compounds that potently and selectively degrade SMARCA2 were identified with a distinct phenotype in a panel of SMARCA4 mutant cell lines. ADME optimization led to development of compounds with encouraging oral bioavailability in rodent as well as non-rodent species. Global proteomics indicated highly selective SMARCA2 downregulation in a SMARCA2/4 proficient cell line. Further, the identified degrader demonstrated robust efficacy supported by SMARCA2 degradation in multiple SMARCA4-mutant CDX models, at well-tolerated doses. Repeat dose tolerability profile of the lead compound in non-rodent species is ongoing towards candidate nomination.

#7025 Novel Insights into anti-tumor mechanisms of small-molecule ID antagonists.

Sergey Yaklichkin[1], Yohannes Ambaw[2], Michelle Saoi[3], Justin Cross[3], Robert Benezra[1]

[1]Cancer Biology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Cell Biology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Donald B. and Catherine C. Marron Cancer Metabolism Center, Memorial Sloan Kettering Cancer Center, New York, NY

Inhibitors of Differentiation (ID) proteins (ID1-4), members of the helix-loop-helix (HLH) transcription regulator family, play critical roles in cancer progression and metastasis. Previously, we developed AGX51, a small-molecule ID antagonist, and its more potent derivative, AGX-A, which target ID proteins for degradation. Loss of ID proteins induces reactive oxygen species (ROS) accumulation and promotes lipid peroxidation, leading to non-ferroptotic cell death in breast cancer (BC) cells. This cell death can be rescued by the lipid scavenger alpha-tocopherol, implicating lipid ROS in the mechanism. To investigate changes in lipid composition, we performed non-targeted LC-MS lipidomic profiling of AGX-A-treated BC cells. This analysis revealed significant increases in specific lipid classes, including phosphatidylinositols (PI) (+47.06%), lysolipids (+23.53%), and phosphatidylcholine (PC) (+6.5%) correspondently, indicating a distinct lipidomic signature compared to classical ferroptotic inducers. Importantly, co-treatment with alpha-tocopherol restored lipid composition to basal levels, supporting the hypothesis that non-ferroptotic lipid peroxidation is a key mechanism underlying these changes. Furthermore, combining AGX-A with the general lipase inhibitor Orlistat significantly enhanced its cell-killing effects. Lipidomic profiling of this combination revealed notable increases in triacylglycerol species, which are likely susceptible to lipid peroxidation, amplifying AGX-A's cytotoxic activity. These findings highlight the therapeutic potential of ID antagonists in inducing a unique, non-ferroptotic cell death pathway. By altering lipid metabolism and exploiting lipid peroxidation, ID antagonists represent a promising strategy for targeting aggressive and drug-resistant tumors.

#7026 Nanobody-PROTACs: Method development towards using single-domain antibodies to target undruggable proteins for degradation.

Caroline Cope, Cristina Tufarelli, Robert Britton

University of Leicester, Leicester, United Kingdom

Proteolysis targeting chimeras (PROTACs) are bifunctional molecules that can bring an E3 ligase (e.g. VHL) into the vicinity of a protein of interest (POI). The E3 ligase poly-ubiquitinates the POI, marking it for degradation via a proteasome. Uniquely, PROTACs have the ability to bind to any chosen amino acid region, meaning there is tailored targeting of the POI, followed by subsequent degradation. This means that PROTACs have the potential to degrade targets previously considered 'undruggable', such as the oncogene, *KRAS*, which is historically difficult to therapeutically target due to lack of deep binding pockets. Typically, PROTACs utilize small molecules to target the POI, however, our work aims to uncover the potential of nanobodies to replace these small molecules. The gold standard for protein targeting remains monoclonal antibodies, however, nanobodies possess the same antigen binding site specificity, whilst possessing a tertiary structure only a tenth of the size. Our work focuses on identifying whether the nanobody-PROTAC has the potential for cellular entry, and thus degradation of its POI. For proof of concept, we utilized an anti-GFP nanobody tagged with AZdye647, synthesized using the Michael addition reaction, followed by SDS-PAGE analysis to assess successful conjugation. This conjugate was then used to treat fixed and live cells expressing enhanced green fluorescent protein (EGFP), followed by fluorescent microscopy to confirm cellular entry and POI targeting. Initial SDS-PAGE analysis revealed the successful conjugation of the AZDye647 to the nanobody. Specific binding within fixed cells was confirmed using fluorescent microscopy, as co-localization of EGFP and the AZdye647-tagged anti-GFP nanobody was revealed. Our data also confirmed that liposomal encapsulation of the AZdye647-tagged anti-GFP nanobody yielded efficient delivery into live EGFP expressing cells. Together, this data provides confirmation that a nanobody-PROTAC would be capable of passing through the cellular membrane, maintaining its integrity and degrading its POI. Further understanding of whether the replacement of AZDye647 with an E3 ligase ligand could result in the degradation of 'undruggable' oncogenes such as *KRAS*, *in vitro*, will confirm whether this is a viable therapeutic approach to patients with *KRAS*-mutant cancers.

#7027 Mass spectrometry-based proteomics for accelerating PROTAC and molecular glue drug discovery.

Michael J. Ford, Ravi Amunugama, David L. Allen, Richard C. Jones

MS Bioworks, LLC, Ann Arbor, MI

Targeted protein degradation (TPD) platforms, including PROTACs and molecular glues, have revolutionized drug discovery as transformative therapeutic strategies. Recent advancements in mass spectrometry-based proteomics have dramatically improved assay speed and sensitivity, providing actionable insights into degradation profiles and drug efficacy on timescales compatible with discovery chemistry. This study evaluates the practical utility of advanced proteomic assays in supporting TPD research, focusing on their role in streamlining drug discovery pipelines. State-of-the-art proteomic workflows were employed to quantify the proteome-wide effects of PROTACs and molecular glues across diverse cellular models. Assay sensitivity, reproducibility, and throughput were rigorously assessed to determine their real-world applicability. Our findings reveal that these enhanced technologies generate robust, high-resolution datasets, capturing the dynamic interplay between target degradation, protein interactions, and cellular responses. This enabled the rapid identification of optimal degrader candidates and informed structure-activity relationship (SAR) studies. Mass spectrometry-based proteomics has emerged as an essential tool for advancing TPD strategies. By combining heightened sensitivity with operational feasibility, these assays offer critical insights that accelerate the development of PROTACs and molecular glues, bridging the gap between foundational research and clinical application.

CLINICAL RESEARCH: Advances in Translational Pediatric Cancer Research
Poster Session

#7031 The role of atypical protein kinase C (aPKC) in the cellular invasion mechanism of diffuse intrinsic pontine glioma (DIPG) and diffuse midline glioma (DMG) and its regulation by ICA-1S and temozolomide (TMZ) inhibitors.

Radwan Ebna Noor[1], Nuzhat Nowshin Oishee[1], Mahfuza Marzan[1], Javad Nazarian[2], Mildred Acevedo-Duncan[1]

[1]Chemistry, University of South Florida, Tampa, FL,[2]Center for Cancer and Immunology Research (CCIR) at Children's National Health Systems (CNHS), Washington, D.C., Children's National Health System, WA

The DIPG develops in the human brainstem area (pons) and the DMG develops in the region covering the pons, midbrain, and thalamus. Due to their locations, surgical resection is not available and sample collection through biopsy is also limited. Moreover, the lack of knowledge of cell signaling regulations is one of the major challenges in treating these lethal pediatric gliomas. To understand the cellular characteristics like migration and invasion of these gliomas our research focuses on the atypical PKC-ι, which plays a major role in tumorigenesis due to its overexpression directly impacted by phosphoinositide 3-kinase (PI3K), phosphatase and tensin homolog (PTEN) and other pathways. In this ongoing research, we are investigating the role of the aPKC-ι/ζ expression levels in correlation with the malignancy of two incurable pediatric gliomas DIPG (SU-DIPG-IV) and DMG (CNMC-D-1008). The study sheds light on a regulatory connection between the isoenzyme-specific signaling pathway for invasion [PKC-ι /Focal Adhesion Kinase (FAK) / Paxillin] and its inhibition by a potent aPKC inhibitor, ICA-1S (5-Amino-1-[(1R,2S,3R,4R)-2,3-dihydroxy-4-[(phosphonooxy)methyl]cyclopentyl]-1H-imidazole-4-carboxamide), alone or in combination with Temozolomide (TMZ) *in-vitro*. In a previous study, we demonstrated that ICA-1S in combination with TMZ decreased the invasion of glioma cell lines by lowering the FAK and paxillin phosphorylation in the PKC-ι/ FAK/ Paxillin pathway. In our current study, we have observed the presence of an immunoprecipitation (IP) complex formation between PKC-ι and FAK indicating the presence of a direct phosphorylation event in SU-DIPG-IV cells during the invasion mechanism. Unlike SU-DIPG-IV, the CNMC-D-1008 cells have shown no such phosphorylation events in the IP experiments. Moreover, the study of the PKC-ι expression level with cellular overgrowth, cell cycle progression, cell migration, apoptosis, and toxicity study of the drugs will also be reported based on different experiments such as western blot, scratch assay, flow cytometry, WST-1 assay, etc. These studies bring insights into cellular processes like invasion and proliferation after the mono/combination therapy of ICA-1S and TMZ in these cell lines. The results presented here shed light on two prospects: that PKC-ι expression level may be established as a biomarker to perform anti-PKC therapy and as an inhibitor of PKC-ι the prospect of ICA-1S as a form of novel personalized treatment for these pediatric gliomas.

#7032 The role of general control nonderepressible 2 (GCN2) kinase in leukemogenesis and therapeutic response to L-asparaginase.

R. Claude, S. Srivastava, M. Zhong, C. Chen, S. Batra, U. Dave, C. Zhang, Y. Fang, K. Staschke, R. A. Wek, J. Zhang;
Indiana University at Indianapolis, Indianapolis, IN

Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer, affecting the lymphoid cells of both B and T lineages. Most ALL cells are auxotrophic for asparagine, a nonessential amino acid for protein synthesis, due to the low expression of asparagine synthetase (ASNS), a rate-limiting enzyme for *de novo* biosynthesis of asparagine. Standard ALL treatment takes advantage of this vulnerability by giving patients L-asparaginase, a bacterial enzyme that depletes the circulating asparagine. However, previous work from our lab and others has shown that some ALL cells become resistant to L-asparaginase treatment through the induction of ASNS expression. Mechanistically, amino acid starvation activates the general control of nonderepressible 2 (GCN2) kinase, leading to the accumulation of the ATF4 transcriptional factor. ATF4, in turn, is recruited to the promoter of the *ASNS* gene to activate its transcription. However, the role of GCN2 kinase in the process of leukemogenesis under nutrient limiting environment has not been established. Here, we found that, in a mouse T-ALL model driven by a KRas(G12D) mutation, ATF4 and ASNS expression were strongly elevated in leukemic tissues. However, germline deletion of the *Gcn2* did not delay leukemogenesis in primary T-ALL and secondary T-ALL generated by transplanting the pre-leukemic bone marrow cells into *Gcn2* wildtype recipient mice. Although GCN2 inactivation does not affect leukemogenesis, it sensitizes T-ALL cells to L-asparaginase treatment *in vitro* and *in vivo*. In addition, a small molecule inhibitor of GCN2, GCN2iB, synergistically inhibits leukemic growth and survival in the mouse T-ALL model and human T-ALL lines where the basal expression of ASNS is low. Finally, we tested a newly developed inhibitor of ASNS (ASX-173), which selectively killed leukemic cells in the absence of exogenous asparagine even though their basal level expression of ASNS is high. Taken together, our results suggest that targeting GCN2 or ASNS will have therapeutic implications in ALL patients who become resistant to L-asparaginase treatment.

#7033 Unraveling *Kiaa1549-Braf* driven brain tumors: From modeling to therapy.

Ylenia Cendon Florez[1], Ram Kannan[2], Matthias A. Karrajannis[1], Darlene Dela Cruz[3], Udi Segal[3], Danilo Maddalo[3], Scott Foster[4], Robert Benezra[1], Andrea Ventura[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Asset and Pipeline Strategy, Schrodinger, New York, NY,[3]Department of Translational Oncology, Genentech, San Francisco, NY,[4]Department of Research Oncology, Genentech, San Francisco, NY

The *KIAA1549-BRAF* (*KB*) fusion is a prevalent genetic event in two distinct central nervous system tumors: pilocytic astrocytomas (PAs) and diffuse leptomeningeal glioneuronal tumors (DLGNTs). This chromosomal rearrangement, consisting of a 2 Mbp tandem duplication at 7q34, results in the formation of a fusion protein absent in normal cells. The KB fusion protein has been described to dimerize the BRAF kinase in a RAS-independent manner, leading to a constitutive activation of the MAPK pathway and promoting tumorigenesis. Despite its significance, the lack of pre-clinical models limits our understanding of how *KB* promotes DLGNTs and PAs development, so effective therapeutic strategies remain elusive. To address this, we aimed to model the KB fusion at its endogenous chromosomal location.

Overcoming the challenges of modeling chromosomal rearrangements, we used the CRISPR-Cas9 gene-editing technique to model the fusion event *ex vivo* and *in vivo* in the mouse brain, leveraging *p53*- or *Arf*-deleted backgrounds. These models allow us to investigate the molecular mechanisms by which *KB* promotes tumor initiation and progression and test the therapeutic potential of Belvarafenib, a class II BRAF inhibitor that targets BRAF dimers.

Our results demonstrate that CRISPR-mediated engineering of KB in *p53*- or *Arf*-deficient backgrounds, both *ex vivo* and *in vivo*, generates CNS tumors resembling human DLGNTs in their histology and growth patterns. Furthermore, targeting the robust MAPK pathway activation in these KB-driven tumor models with Belvarafenib significantly reduced ERK phosphorylation and tumor growth, and significantly increased the survival of treated mice.

These findings demonstrate that *KB* promotes tumor initiation and progression, and highlight the therapeutic potential of Belvarafenib targeting this oncogenic event. Thus, our *KB*-DLGNTs model emerges as a valuable tool to evaluate the efficacy of novel pre-clinical BRAF inhibitors.

#7034 The impact of EphA2 in the malignancy of CIC-DUX sarcomas.

Lisa Toracchio[1], Alberto Bavelloni[1], Caterina Mancarella[1], Lorena Landuzzi[1], Andrea Morini[1], Elisa Simonetti[1], Pier Luigi Lollini[2], Andrea Morrione[3], **Katia Scotlandi**[1]

[1]IRCCS Rizzoli Orthopedic Institute, Bologna, Italy,[2]University of Bologna and IRCCS Azienda Ospedaliera Universitaria di Bologna, Bologna, Italy,[3]Sbarro Institute for Cancer Reseach, Temple University, Philadelphia, PA

Capicua (CIC)-rearranged sarcomas (CDS) are rare and highly aggressive undifferentiated small round cell sarcomas and patients with CDS have a dismal prognosis. Despite being recognized as a distinct entity by WHO 2020, these tumors are still treated according to Ewing sarcoma regimens and new more specific treatment options are urgently needed. Previous work, including data from our group, has identified the IGF-AKT-mTOR signaling pathway as particularly active in these tumors. Here, we highlight the role of the Ephrin system, particularly the EphA2 receptor, in CDS. EphA2-mediated signaling emerged from a core set of 71 genes that clearly distinguish CDS from Ewing sarcoma (PMID: 34903601). Functional studies on three CDS cell lines obtained from patient-derived xenografts (PDX) confirmed the high expression of the receptor, which was constitutively activated on serine residue 897 (S897). EphA2 is highly expressed in embryos during development, declines in later stages and can be re-expressed in cancer. EphA2 is implicated in self-renewal, chemoresistance, and metastasis and its expression correlate with poor patient outcome in several tumors (PMID:33686241). The targeting of EphA2 is thus under investigation. However, EphA2 signaling is complex, occurring through canonical, ligand-dependent mechanisms and/or non-canonical ones mediated by crosstalk with other receptors, kinases or activated by different ligands. In CDS, AKT is hyper-active due to the constitutive activation of IGF2/IGF1R signaling and the intrinsic inhibition of MAPK. AKT induces strong phosphorylation of EphA2 at S897, which leads to a conformational change of EphA2, promoting cell migration and metastasis. This mechanism renders CDS cells resistant to traditional anti-EphA2 tyrosine kinase (TK) inhibitors used as single agents. Therefore, we have successfully tested the efficacy of a combination between ALW-II-41-27, a widely used inhibitor of EphA2 kinase activity, and IGF-1R/AKT inhibitors in preclinical models. In addition, we are testing EphA2 targeted degradation by using HaloPROTAC3 approaches to confirm the impact of targeting EphA2 on CDS cell migration and metastasis.

The research leading to these results has received funding from AIRC under IG 2019—ID. 22805 project—P.I. K. Scotlandi. For HaloPROTAC studies support was provided by the Italian Ministry of Health through the Executive Programme of Cooperation in the field of Science and Technology between Italy and the USA 2023-2025, MAECI-2023-23683465, to C. Mancarella.

#7035 Targeting Ewing sarcoma with a novel RBM39 degrader: DNA damage repair pathway effects.

F. Liu[1], Y. Zhang[1], B. Wang[2], J. Finn[1], J. Tonra[1], L. Huang[1], D. Liu[1], H. Jin[3], X. Liu[1], **D. Lu**[1];
[1]Seed Therapeutics Inc., King of Prussia, PA, [2]University of Washington, Seattle, WA, [3]Vitsgen Therapeutics, Portland, OR

Patients with metastatic Ewing Sarcoma have a five-year survival rate of 15-30%. For 30 years, there are limited approved therapies, including chemotherapy, radiotherapy and surgery, which are associated with significant morbidities and secondary cancers, supporting the need for new impactful therapies. Analysis of the RNA splicing factor RNA Binding Motif Protein 39 (RBM39) in the Cancer Target Discovery and Development (CTD^2) Network showed that Ewing sarcoma cell lines are especially sensitive to RBM39 loss. Here we demonstrate effects on mediators of DNA damage repair in association with significant anti-cancer effects of an orally administered novel RBM39 degrader, ST-00937.
Methods and Results: A next generation RBM39 degrader ST-00937 was designed through structure-based drug design and prioritized based on in vitro anti-cancer potency, metabolic stability and oral pharmacokinetics in mice. Human Ewing sarcoma A673 cells were utilized to explore the effects of ST-00937 in this cancer type. Tumor cell viability was evaluated by CellTiter-Glo® Luminescent Cell Viability Assay (CTG) and anti-tumor efficacy was evaluated in nude mice bearing tumors established with A673 cells. Protein levels in cell lysates and tumor homogenate were measured by Western Blot. Target gene RNA splicing was evaluated by RT-PCR.ST-00937 degraded RBM39 by 6 hours of treatment and reduced in vitro A673 Ewing sarcoma cell viability with an IC50 of 170 nM. These in vitro effects translated to complete A673 tumor regressions in mice by the 11th day of twice daily ST-00937 oral dosing at 30mg/kg, without an effect on body weight. By the third day of treatment, RBM39 was undetectable in A673 tumors. Mechanically both the EWS-FLI1 driver gene fusion in A673 cells and RBM39 degradation are reported to reduce DNA damage repair pathways. Here we report RBM39 degradation in A673 cells significantly increases phosphorylated γH2Ax, a marker of DNA double strand breaks. This DNA damage is thought to contribute to the induction of cell apoptosis detected as increased cleaved caspase-3. Increased DNA double strand breaks is furthermore associated with negative effects on 3 proteins involved in homologous recombination repair of DNA double strand breaks; mis-splicing of BRCA1 (Breast cancer type 1) and ATM (ATM Serine/Threonine Kinase), and reduced protein levels of RAD51D (recombination repairing regulator Recombinase homolog D).
Conclusion: The RBM39 molecular glue degrader ST-00937 therefore demonstrates total tumor regression in a model of Ewing sarcoma. Mechanistic studies indicate that the robust activity of ST-00937 involves deficient homologous recombination repair. Continued research in our lab will add further insights into the mechanism of action of RBM39 degraders in this cancer of high unmet need.

#7036 Co-targeting AR, mTOR, and PI3K inhibitors in DSRCT as a novel therapeutic approach.

Roberto Cardenas-Zuniga, Asmaa G. Ahmed, Kien Ryan Cao, Abid Raza, **Clement Agyemang**, Danh Truong, Joseph Ludwig

UT MD Anderson Cancer Center, Houston, TX

DSRCT (Desmoplastic Small Round Cell Tumor) is a rare soft tissue sarcoma that appears in the abdominal and pelvic area of mainly young males. There is little information about the molecular mechanisms involved in its pathology. Despite existing treatment options such as surgery, chemotherapy, and radiation, the NIH estimates that the five-year survival rate is only 15%, with frequent recurrence. Thus, new molecular targets and more effective therapeutic strategies are needed. Due to the high prevalence in males during puberty and the fact that AR (Androgen Receptor) is expressed in DSRCT, we hypothesized that AR plays an essential role in DSRCT development. We evaluated sensitivity to DHT (Dihydrotestosterone) and its effect on proliferation in the presence of different FBS (Fetal Bovine Serum) concentrations. For this approach, the LNCaP (prostate cancer) cell line was used as control. Our results indicated that DSRCTs responded differently to DHT at different FBS concentrations. We observed that DHT stimulates AR phosphorylation and increases total AR, pS6, and total S6 protein levels. Next, we explored the sensitivity of DSRCT cell lines to Enzalutamide and Darolutamide inhibitors; Temsirolimus (an mTOR inhibitor); Alpelisib (a PI3K inhibitor); and Gedatolisib (a dual mTOR and pan-PI3K inhibitor). Individual drug sensitivity was evaluated using in vitro exposure via the classic dose-response curve assays, measuring viability with CellTiterGlo2.0 reagent to calculate IC50 values. DSRCTs were more sensitive to Darolutamide than Enzalutamide, two different AR inhibitors. Dual targeting PI3K and mTOR with Gedatolisib was more effective than Alpelisib or Temsirolimus alone. Taking lessons learned from prostate cancer, we studied combination assays of AR antagonists combined with PI3K/mTOR inhibitors. Those assays suggested that Darolutamide and Gedatolisib effects were mainly additive, with a slight synergy. We conclude that DSRCT cell lines are responsive to AR blocking and highly sensitive to PI3K/mTOR inhibitors. A co-targeting strategy that jointly inhibits the AR and PI3K/mTOR pathways is being investigated in murine models and might be considered for future studies if the regimens have non-overlapping toxicity profiles.

#7038 Direct targeting of DNMT1 inhibits high-risk neuroblastoma growth through epigenetic reprogramming.

Danielle C. Rouse, Saurabh Agarwal

Department of Pharmaceutical Sciences, College of Pharmacy and Health Sciences, St. John's University, Queens, NY

DNA Methyltransferase 1 (DNMT1) mediated hypermethylation represents a crucial epigenetic modification implicated in neuroblastoma (NB), a devastating pediatric cancer with a 60% relapse rate. DNMT1, a prominent member of the DNA methyltransferase family of enzymes, catalyzes the transfer of methyl groups to the 5-carbon position of cytosine residues within DNA sequences. While extensive research has established that hypermethylation of CpG islands leads to transcriptional silencing of tumor suppressor genes across various cancer types, the specific molecular mechanisms and therapeutic implications of DNMT1-mediated hypermethylation in NB remained largely unexplored. In this study, we analyzed the publicly available R2 genomic dataset, which revealed the direct correlation between *DNMT1* overexpression and decreased overall NB patient survival rates. Further, we performed a small molecule screening and identified a highly potent and selective DNMT1 inhibitor. Therapeutic targeting of DNMT1 with this inhibitor resulted in significant dose-dependent reductions in multiple hallmarks of cancer progression, including overall cell proliferation, colony formation capacity, and 3D spheroid development. Furthermore, the DNMT1 inhibitor induced cell cycle arrest in the G2/M phase checkpoint and significantly enhanced apoptotic cell death in NB cells. These promising *in vitro* findings were validated through *in vivo* tumor xenograft studies, where the DNMT1 inhibitor significantly inhibited NB tumor growth without any observable toxicity in preclinical models. Further, we employed MethylFlash technology to quantify 5-methylcytosine (5-mc) levels, which verified a significant reduction ($p < 0.0001$) in global DNA methylation status following exposure to increasing concentrations (5, 10, and 20 μM) of the DNMT1 inhibitor. Further molecular analyses revealed profound effects on vital gene and protein expression patterns alongside an enhancement of NB cell sensitivity to conventional chemotherapeutic agents. These findings collectively establish DNMT1 inhibition as a promising therapeutic strategy for NB patients. Our data demonstrates the role of DNMT1-mediated hypermethylation in NB tumorigenesis while establishing that targeted DNMT1 inhibition effectively reduces hypermethylation, thereby suppressing malignant proliferation, inhibiting colony formation, and preventing both 3D spheroid development and in vivo tumor growth. Our data also highlights that the direct DNMT1 targeting approach is a promising epigenetic-based approach for NB treatment. Further mechanistic research of DNMT1 inhibition in NB progression is essential to facilitate the clinical translation of this promising therapeutic strategy.

#7039 Synergistic antitumor activity of the combined PARP1 inhibition and alkylating DNA damage in malignant rhabdoid tumors.

Elena Mironova[1], Sebastian Molinas[1], Vanessa Del Pozo[1], Abhik Bandyopadhyay[1], Zhao Lai[1], Dias Kurmashev[1], Eric L. Schneider[2], Daniel V. Santi[2], Yidong Chen[1], **Raushan Kurmasheva**[1]

[1]UT Health San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX,[2]Prolynx, Inc., San Francisco, CA

Background: Malignant rhabdoid tumors (MRTs) are among the most aggressive and treatment-resistant malignancies affecting infants, originating in the kidney, brain, liver, and soft tissues. The 5-year event-free survival rate for these cancers is a mere 20%. In nearly all cases of MRT, the *SMARCB1* gene (occasionally *SMARCA4*) - a pivotal component of the SWI/SNF chromatin remodeling complex - is homozygously deleted, although the precise etiology of these tumors remains unknown. While young patients with localized MRT generally show improved outcomes, especially those who are older and have early-stage disease, the overall prognosis remains poor despite optimal standard treatments. This highlights the urgent need for more effective treatment strategies. PARP1 is a widely targeted molecule in cancer treatment and, beyond its role in DNA repair, it participates in transcriptional regulation by recruiting chromatin remodeling complexes to modulate DNA accessibility for RNA polymerases.

Methods: We evaluated the antitumor activity of the PARP1 inhibitor talazoparib (TLZ) in combination with the DNA alkylating agent temozolomide (TMZ) across six MRT xenograft models in CB-17 scid mice. The dosing schedule for this combination followed a previously reported protocol (iScience 2021; 25(2):103725). Time-to-event was defined as 4-fold increase in tumor xenograft volume from the treatment initiation date. Event-free survival (EFS) between treated and control groups was analyzed using Kaplan-Meier method. Objective response categories including partial (PR), complete (CR), and maintained complete responses (MCR), were determined based on previously established criteria (Ped Blood Cancer 2007;49:928). To widen the therapeutic window of the drug combination, we employed PEGylated TLZ (PEG-TLZ), which has been reported to reduce systemic toxicity through slow drug release.

Results: Remarkably, our findings indicate that five out of six MRT xenografts exhibited objective response to PEG-TLZ+TMZ therapy. Notably, *SMARCB1* loss was found to confer a protective effect, correlating with elevated expression of DNA damage and repair proteins in *SMARCB1*-deficient MRT cells. Additionally, MGMT emerged as a potential biomarker predictive of in vivo MRT response to PEG-TLZ+TMZ treatment. In addition, our analysis revealed alterations in signaling pathways associated with the observed antitumor activity.

Conclusions: This study presents a novel and efficacious therapeutic approach for MRT, along with a promising candidate biomarker for predicting tumor response.

#7040 The B7-H3 targeting antibody-drug conjugate (ADC) vobramitamab duocarmazine (vobra duo) is potently effective against a broad panel of pediatric solid tumor xenograft models: A study from the Pediatric Preclinical In Vivo Testing (PIVOT) Consortium.

Haiying Tang[1], Edward Favours[1], Samson Ghilu[1], Peyton Wong[1], Vanessa Del Pozo[1], Abhik Bandyopadhyay[1], Elena Mironova[1], Eric J. Earley[2], Stephen W. [1]Greehey Children's Cancer Research Institute, UT Health San Antonio, San Antonio, TX,[2]Genomics Ltd, Oxford, United Kingdom,[3]RTI International, Durham, NC,[4]Children's Hospital of Philadelphia, Philadelphia, PA,[5]National Cancer Institute, Rockville, MD,[6]The Leukemia & Lymphoma Society, The Leukemia & Lymphoma Society, PA,[7]Macrogenics, Onc., Rockville, MD,[8]The Jackson Laboratories, Bar Harbor, ME,[9]The Jackson Laboratories, Farmington, CT,[10]The Jackson Laboratories, Davis, CA,[11]National Cancer Institute, Bethesda, DC,[12]UT MD Anderson Cancer Center, Houston, TX

Introduction: Vobra duo, a duocarmycin-based humanized ADC (drug-to-antibody ratio is ~2.7) targeting B7-H3, shows robust *in vivo* activity against a range of adult cancer models, and a favorable pharmacokinetic and safety profile in cynomolgus monkeys. Initial results from the single agent phase 1 clinical trial of vobra duo (NCT03729596) showed manageable side effects and promising objective response rates in metastatic castration-resistant prostate cancer. B7-H3 is highly expressed in pediatric solid tumors, and it is emerging as a key target for pediatric oncology. Here we report the antitumor activity of vobra duo against preclinical xenograft models of pediatric solid tumors.

Methods: Ewing sarcoma (ES), rhabdomyosarcoma (RMS), and neuroblastoma (NB) xenograft models were tested with n=1 or n=2 designs. Osteosarcoma (OS) models, due to their slower growth kinetics and lower rates of tumor regression, were tested with n=10 mice per arm. The study was extended to include malignant rhabdoid tumor (MRT), hepatoblastoma (HB), and Wilms tumor (WT) models using n=5 mice per treatment group. vobra duo and control ADC (SYD988 anti-CD20 ADC with the same linker and payload as vobra duo) were provided by MacroGenics, Inc., and were administered at 6 mg/kg as a single administration IP. Time-to-event was defined as 4-fold increase in tumor xenograft volume from the day of treatment. The Kaplan-Meier method was used to compare event-free survival (EFS) between treated and control groups. Objective response categories were determined as described previously (Ped Blood Cancer 2007;49:928-940), with objective responses including partial, complete, and maintained complete responses (PR, CR, and MCR).

Results: Vobra duo induced objective responses in 4 of 11 NB models (3 CR and 1 MCR) and in 3 of 5 OS models (2 MCR). ES models showed objective responses in 2 of 6 models (1 MCR) and 4 of 6 RMS models showed objective responses, all MCR. Control ADC was less active than vobra duo and showed objective responses in 0 of 11 NB, 1 of 5 OS, 1 of 6 ES, and 2 of 4 RMS models. The study was extended to MRT, HB, and WT models. Vobra duo induced objective responses in 2 of 4 MRT with 1 MCR, 2 of 5 HB with 2 MCR, and 3 of 4 WT with 3 MCR. Control ADC only induced objective responses in 1 of 4 MRT and 2 of 4 WT models (all PR), with no objective responses for the 5 HB models.

Conclusions: Vobra duo is potently efficacious across a broad panel of pediatric solid tumor xenograft models supporting clinical development of this agent and other agents targeting B7-H3 for children with cancer.

#7041 The CLK/DYRK inhibitor SM09419 shows potent efficacy across a broad panel of pediatric preclinical xenograft models - A report from the Pediatric Preclinical In Vivo Testing Consortium (PIVOT).

Key[3], Daniella Cofini[1], Miguel Agoncillo[1], Steven Neuhauser[4], Timothy M. Stearns[4], Emily L. Jocoy[5], Jee Young Kwon[6], Jeffrey H. Chuang[6], Beverly A. Teicher[7], Richard Gorlick[8], Yael P. Mosse[9], John M. Maris[9], Peter J. Houghton[2], Carol J. Bult[4], Malcolm A. Smith[7]

[1]Children's Cancer Institute, Lowy Cancer Research Centre, School of Clinical Medicine, UNSW Medicine & Health, UNSW Centre for Childhood Cancer Research, UNSW Sydney, Sydney, Australia,[2]University of Texas Health at San Antonio, Greehey Children's Cancer Research Institute, San Antonio, TX,[3]The Children's Hospital of Philadelphia, Philadelphia, PA,[4]The Jackson Laboratory for Mammalian Genetics, Bar Harbor, ME,[5]The Jackson Laboratory, Sacramento, CA,[6]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[7]National Cancer Institute, Bethesda, MD,[8]The University of Texas MD Anderson Cancer Center, Houston, TX,[9]The Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Introduction: SM09419 is an experimental small-molecule pan-inhibitor targeting CLK and DYRK kinases, which play a key role in RNA splicing and other oncogenic processes. SM09419 exhibited promising activity in preclinical models of *TP53*- and *FLT3*-mutated acute myeloid leukemia, and its analog cirtuvivint (SM08502) exhibited broad preclinical activity and evidence of therapeutic benefit in solid tumors. Cirtuvivint is in clinical trials in adults with AML (NCT06484062) and sarcomas (SELNET-7-2/EuCT#: 2024-511987-10-00). To evaluate the role of CLK and DYRK kinase inhibition in pediatric cancers, SM09419 was tested against panels of pediatric solid tumor and leukemia patient-derived xenografts (PDXs).
Methods: SM09419 was provided by Biosplice Therapeutics and administered orally at 25 mg/kg daily for 5 days per week x 3 weeks for the acute lymphoblastic leukemia (ALL), neuroblastoma (NB), sarcoma (SARC) and hepatoblastoma (HB) models. Tolerability was assessed in groups of 3 non-tumor bearing immune-deficient mice (NSG, CB17 SCID) at 100%, 75% and 50% of the recommended dose of 25 mg/kg. For efficacy testing, a single mouse trial (SMT) design (one vehicle control, one drug treated mouse per PDX) was used for ALL (n=30 PDXs), NB (n=14), HB (n=7), Ewing sarcoma (ES, n=8), rhabdomyosarcoma (RMS, n=5), Wilms tumor (WT, n=2) and malignant rhabdoid tumors (MRT, n=3). For the osteosarcoma (OS, n=6) models a conventional study design of 10 mice per group (vehicle or drug) was employed. Standard PIVOT methods were used to assess event-free survival (EFS T/C = ratio of median EFS for treated versus control animals). Stringent objective response measures (ORMs) modeled after the clinical setting were also used to evaluate activity (Houghton et al., Pediatr Blood Cancer, 2007).
Results: SM09419 was well tolerated at all dose levels with <20% weight loss observed, irrespective of the mouse strain. SM09419 showed objective responses (ORMs of partial response, PR; complete response, CR; maintained CR, MCR) against 20/28 evaluable ALL, 6/14 NB, 2/7 HB, 2/8 ES, 0/2 WT, 0/5 RMS, 0/3 MRT PDXs tested. EFS T/C values ranged from 0.4-9.3 (ALL), 1.2-7.0 (NB), 0.64-2.7 (HB), 1.0-5.9 (ES), 0.37-0.81 (WT), 0.65-1.8 (RMS) and 1.7-2.0 (MRT). No objective responses were observed in the 6 OS models, with 4 showing growth delay (EFS T/C >2).
Conclusions: SM09419 exhibited broad antitumor activity across several pediatric cancers (e.g., ALL and NB), with activity also observed for ES and HB. Lower activity was seen in the RMS and OS models. The promising results support further evaluation of CLK/DYRK as therapeutic targets. Future research directions for these cancers include identifying biomarkers that predict sensitivity to CLK/DYRK inhibition as well as efforts to identify effective combinations with targeted and/or standard-of-care drugs.

#7043 HMGA1 Epigenetic Regulators Drive Relapse in Pediatric B-Cell Leukemia By Amplifying ETV5 and Stemness Networks.

Linda M. S. Resar[1], Jung-Hyun Kim[1], Andrei Thomas-Tikonenko[2], Sarah Tasian[2]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Childrens Hospital of Philadelphia, Philadelphia, PA

Despite advances in therapy for pediatric B-cell acute lymphoblastic leukemia (pB-ALL), relapse remains a leading cause of death in children with cancer. The gene encoding the High Mobility Group A1 (HMGA1) chromatin regulator is highly expressed in stem cells and hematologic malignancies where high levels portend poor outcomes. In pB-ALL, *HMGA1* is overexpressed with highest levels at relapse. Transgenic mice overexpressing *Hmga1* in lymphoid cells develop aggressive leukemia. To determine how HMGA1 functions in relapsed pB-ALL, we performed multiomic analyses. Here, we uncover a previously unknown role for HMGA1 as an epigenetic gatekeeper of stemness transcriptional networks at relapse. Strikingly, silencing *HMGA1* expression via *CRISPR* or short hairpin RNA decreases proliferation and clonogenicity in vitro while disrupting engraftment and prolonging survival in vivo. Multiomics analyses revealed transcriptional networks governed by HMGA1 that regulate proliferation (G2M checkpoint, E2F), RAS/ERK signaling, hematopoietic stem cells (HSCs), and ETS variant 5 transcription factor (ETV5) targets. *CRISPR*-mediated *ETV5* gene silencing recapitulates effects of *HMGA1* silencing in pB-ALL cell lines. Further, restoring *ETV5* expression in pB-ALL cell lines with *HMGA1* silencing partially rescues anti-leukemogenic effects of *HMGA1* depletion. Mechanistically, HMGA1 binds to AT-rich regions within the *ETV5* promoter and recruits activating histone marks to induce *ETV5*. Moreover, *HMGA1* and *ETV5* are co-expressed and up-regulated in primary blasts from children with relapsed pB-ALL where high *HMGA1* correlates inversely with time to relapse. Artificial intelligence predicted that the histone deacetylase inhibitor (HDACi), vorinostat, targets HMGA1-ETV5 gene networks. In PDX models with pB-ALL blasts from relapse, we found that vorinostat enhances responses to standard B-ALL therapy (dexamethasone, vincristine), depleting circulating blasts and disrupting leukemic engraftment. Our findings reveal HMGA1 as an epigenetic switch that activates *ETV5* and HSC gene networks in relapsed pB-ALL and rational therapeutic target to treat or prevent relapse.

#7044 *In vitro* and *in vivo* activity of the CD127 monoclonal antibody 4A10 in preclinical models of childhood acute lymphoblastic leukemia.

Gisele O. L. Rodrigues[1], Priscila P. Zenatti[2], Joao M. S. Feitoza[2], Robert K. Chen[3], Uksha Saini[4], Julie A. Hixon[1], Ross A. Hamilton[4], Michael J. Heffernan[4], Jose A. Yunes[2], Phillip P. Breitfeld[4], Atul Varadhachary[4], Sarah K. Tasian[3], Scott K. Durum[1]

[1]National Cancer Institute, Frederick, MD,[2]Boldrini Research Center, Campinas, Brazil,[3]Children's Hospital of Philadelphia, Philadelphia, PA,[4]Allterum Therapeutics, Houston, TX

Background: 4A10 is a monoclonal antibody targeting CD127 (IL-7R alpha) under planned clinical development for treatment of patients with relapsed/refractory (r/r) acute lymphoblastic leukemia (ALL). CD127 is endogenously expressed on normal/malignant T cells as a heterodimer with CD132 to form the IL-7 receptor. CD127 is also aberrantly expressed in *CRLF2*-rearranged B-ALL as part of the heterodimeric thymic stromal lymphopoietin receptor (TSLPR). 4A10 binds the extracellular domain of both wild type and mutant CD127 with high affinity and mediates its anticancer activity through a dual mechanism of action: (i) inhibition of IL-7 signaling, as assessed by phospho-STAT5 production, and (ii) induction of receptor-mediated cytotoxicity through antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP), which can facilitate the killing of CD127+ cells. The role of CD127 in the development, maintenance, and relapse of T-ALL is well described. Extensive preclinical data with 4A10 have demonstrated robust anticancer activity in human T-ALL cell lines and patient-derived xenograft (PDX) models of early T-cell precursor (ETP) and other more mature subtypes. 4A10 has demonstrated single agent activity in chemo-naïve, chemo-resistant, and steroid-resistant T-ALL models, as well as augmented activity in combination with chemotherapy. As CD127 is expressed in other hematological cancers, we tested the hypothesis that 4A10 would also have robust anticancer activity across B-ALL subtypes.

Results: In these preclinical studies, we first detected high expression of CD127 in six B-ALL genetic subtypes and potent 4A10-mediated ADCC *in vitro* against KOPN8, REH, and NALM6 cell lines. We then observed robust inhibition of leukemia proliferation and increased survival with 4A10 monotherapy treatment of *CRLF2*-rearranged Ph-like and Down syndrome-associated, *BCR::ABL1*, *TCF3::PBX1*, *ETV6::RUNX1*, and high-hyperdiploid ALL PDX models compared to vehicle. Single agent 4A10 treatment of steroid-resistant KOPN8 cell line xenograft mice further demonstrated *in vivo* activity with some augmentation on dexamethasone addition.

Conclusions: CD127 is an attractive target with a low risk of 'bystander toxicity' given limited CD127 expression in normal tissues as assessed by tissue cross-reactivity studies. In recent non-human primate studies, 4A10 therapy had a tolerable clinical profile with modest and reversible reduction in normal peripheral blood T-lymphocytes. Given the robust activity of 4A10 against multiple B-ALL subtypes, we will seek to extend our planned Phase 1/2A clinical trial assessing the safety and therapeutic efficacy of single agent 4A10 in adults and children with r/r ALL. Ongoing preclinical studies are also evaluating the therapeutic potential of 4A10 against lymphoma and AML based on promising pilot efficacy data.

#7045 Anti-tumor effects following BET inhibition in preclinical models of pediatric and AYA osteosarcoma.

Ryli E. Justice[1], Niknam Riyahi[1], Barbara J. Bailey[1], Erika A. Dobrota[2], Rada Malko[1], Harlan E. Shannon[2], Keiko E. Kreklau[2], Melissa A. Trowbridge[1], Kathryn L. Coy[1], Felicia M. Kennedy[1], Melinda R. Ervin[1], Anthony L. Sinn[1], Christopher Davis[3], Kyle W. Jackson[3], Brian D. Weiss[3], Steven D. Angus[3], M. R. Saadatzadeh[3], Pankita H. Pandya[3], Karen E. Pollok[1]

[1]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[2]Department of Pediatrics, Herman B Wells Center for Pediatric Research, Indianapolis, IN,[3]Department of Pediatrics, Indiana University School of Medicine Pediatric Hematology, Oncology and Stem Cell Transplant, Indianapolis, IN

Osteosarcoma (OS) is the most common primary malignant bone sarcoma in pediatric, adolescent, and young adult patients with a five-year survival rate of <30%. This is due, in part, to genomic complexities arising from moderate levels of oncogenic replication stress (RS). While moderate levels of RS cause genome instability that contributes to OS progression, high levels of RS can lead to cell death. Notably, bromodomain and extra-terminal domain (BET) proteins (BRD2,3,4) are epigenetic readers that regulate not only transcriptional networks but also DNA replication and repair. Targeting RS through utilization of BET inhibitors (BETi) is an underexplored treatment option in OS and little is known about BETi-induced molecular changes and adaptive responses in OS. We hypothesize that BETi leads to decreased OS cell growth via not only remodeling of gene expression but also increased DNA damage and non-tolerated RS levels. Effect of BETi (AZD5153, BMS-986378, ZEN-3694) in clinical trials for pediatric and adult solid tumors were investigated. In vitro BETi screening of OS cell lines indicated that bivalent AZD5153 was the most potent BETi compared to monovalent BMS-986378 and ZEN-3694. However, in a longitudinal cell growth delay assay with repeat exposure of BETi at clinically relevant doses, all BETi decreased OS cell growth at similar rates. To interrogate mechanisms of action, RNA-seq analysis of BET/BRD4 inhibition via AZD5153, PROTAC (ARV-825), and BRD4 siRNA in OS cell lines revealed distinct and overlapping patterns of alterations in gene expression. A major challenge in OS therapy is mitigation of invasiveness and targeting OS metastatic foci. In all treatment groups, RNAseq analysis indicated upregulation of tumor suppressor DHRS2 an inhibitor of tumor invasion but also TMPRSS9, a promoter of tumor invasion. This observed duality in tumor invasion mechanisms is an example of the intra-heterogeneity of the tumor response and indicative that a second therapeutic hit is likely necessary for suppression of tumor invasiveness in remaining OS cells following BETi therapy. In vivo studies demonstrate that bivalent AZD5153 significantly suppressed tumor growth in OS patient-derived xenografts (PDXs) derived from both treatment-naïve (patient status: alive-PDX112, PDX124; deceased- PDX96, PDX115) and pre-treated metastatic (patient status: deceased-TT2/HT77) OS compared to vehicle ($p<0.05$). Therapy was well tolerated with similar drug sensitivities in female and male mice. Analysis of in-vivo PDX96 response following AZD5153 therapy indicated increased γ-H2AX, and expression of pro-apoptotic genes, indicative of increased RS and cell death. At the transcript level, increased DHRS2 was evident with no changes in TMPRSS9. These data sets reveal the promise of BETi for treatment of OS PDX derived from treatment naïve patients some of which go on to relapse, and in OS PDX derived from metastatic sites.

#7046 Payload and linker selection in novel osteosarcoma antibody-drug conjugate (ADC) targeting CADM1.

Caterina Longo, Zhongting Zhang, Yifei Wang, Wendong Zhang, Zhaohui Xu, Yanhua Yi, Jonathan B. Gill, Micheal Roth, Xin Zhou, Richard Gorlick

The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Our efforts in developing new therapies for osteosarcoma have focused on CADM1 as a novel target for ADC development. After successful proof of principle in vitro and in vivo tests, we developed three GMP manufactured CADM1-targeting ADCs with different linker and payload combinations: CADM1-PEG-Exatecan, CADM1-GGFG-Exatecan (a topoisomerase I inhibitor), and CADM1-Tesirine (a BPD-dimer).
Materials and Methods: We tested 15 of our own osteosarcoma PDX-derived cell lines for cytotoxicity using AlamarBlue and Incucyte Sartorius assays. CADM1-Tesirine was tested at 500 nM and the other two ADCs at 1000 nM due to different cytotoxicity profiles, all three with a 10x dilution. The cells were incubated with the drugs for 120h. Internalization was assessed using Incucyte and Fabfluor Red Labeling Reagent at 2.5 µg/ml for all ADCs and controls, including an isotype control IgG1, bound to the respective linker-payload. The bystander effect was evaluated by incubating CADM1-negative cells with media derived from the 5-day incubation of both CADM1-positive and CADM1-negative cells.
Results: CADM1-Tesirine showed significant cytotoxicity across all tested cell lines (IC50: 0.014 - 5.4 nM). CADM1-GGFG-Exatecan exhibited potent activity in most cell lines (IC50: 1.28 - 115 nM). CADM1-PEG-Exatecan had higher IC50 values (2.15 - 222 nM) but had better internalization than CADM1-GGFG-Exatecan. The fluorescence intensity increased over time, with a significant rise within the first 24 hours, which was not as consistently observed for CADM1-GGFG-Exatecan. CADM1-Tesirine displayed robust internalization across all cell lines, following a trend comparable to CADM1-PEG-Exatecan but often achieving even higher fluorescence intensity, thus proving to be the most internalized of the three ADCs. The bystander effect analysis showed that only the media derived from treated CADM1-positive cells induced cytotoxicity, as evidenced by the decreased growth rate using the Incucyte assay.
Conclusions: All three ADCs demonstrate significant anti-tumor activity, however, CADM1-Tesirine had superior IC50 values and internalization. Results from the bystander experiments indicate target dependent internalization and linker cleavage. We are currently conducting in vivo tests to further evaluate their performance anticipating the conduct of a phase 1/2 trial in patients with recurrent osteosarcoma.

#7047 Impact of MYCN inhibition on lineage state and GD2 expression in neuroblastoma.

Angelle L. Brown[1], Sridhar Veluvolu[1], Matthew Shapiro[1], Connor Hennessey[2], Adam Wolpaw[3]

[1]Center for Childhood Cancer Research, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Cancer Biology Graduate Group, University of Pennsylvania, Philadelphia, PA,[3]Department of Pediatrics, Division of Oncology, Perelman School of Medicine, Philadelphia, PA

Neuroblastoma (NB) is a malignant cancer that originates in the developing peripheral nervous system and accounts for ~15% of all childhood cancer deaths. Some NBs are easily cured, but those classified as high risk require treatment that includes chemotherapy, surgery, autologous stem cell transplant, radiation, and immunotherapy with antibodies targeting the disialoganglioside GD2. Despite this extensive therapy, only ~50% of children survive. Even in these high-risk cases, most of the NB cells respond to initial therapy, but a subset of cells survives (persister cells) and grows back into resistant relapsed disease. Two important factors in relapse are *MYCN* amplification and intratumoral heterogeneity. MYCN, a transcription factor of the MYC family, is amplified in about 40% of high-risk NB cases and is associated with a particularly poor prognosis. Intratumoral heterogeneity is also thought to contribute to relapse. NB cells can exist in two different lineage states: a chemosensitive adrenergic (ADRN) state and chemoresistant mesenchymal (MES) state. With the development of improved pan-MYC inhibitors and the advancement of MYC-targeting therapies into clinical trials, there is a new need and opportunity to investigate how NB responds to MYCN inhibition, how this impacts lineage state, and how this changes GD2 expression.

We investigated the effects of MYCN inhibition in MYCN-amplified ADRN cell lines using the small molecule pan-MYC inhibitor MYCi975. Cell viability assays, western blot analysis, quantitative PCR, and flow cytometry analysis were conducted to evaluate the impact of MYCN inhibition.

We found that treatment with MYCi975 results in a rapid decrease in the protein levels of MYCN, MYCN target genes, and ADRN state markers, but not in new expression of MES state markers or changes in the expression of the immunotherapeutic target GD2. Doses that effectively decrease MYCN result in a loss of cell viability after 3-5 days. However, rare cells survive prolonged treatment (persister cells) and are able to resume proliferation once MYCi975 is removed. These recovered cells demonstrate relative resistance to retreatment with MYCi975 with a ~2-fold increase in the IC50 compared to naïve cells. Additionally, these resistant cells recover basal levels of MYCN and ADRN markers but have decreased surface GD2.

Our findings support the likelihood that some NB cells will survive therapies that inhibit MYCN and provide a model to investigate the identity and potential vulnerabilities of these cells. Furthermore, we find a role for MYCN in maintaining the ADRN lineage state but not in maintaining GD2 expression. However, GD2 is downregulated in resistant cells with implications for the relative timing of MYCN-targeting and GD2 targeting therapies. Ongoing work will be presented on transcriptomic changes after MYCi975 treatment and in resistant cells.

#7048 Molecular and immune landscape of extracranial malignant rhabdoid tumors (eMRT) and atypical teratoid rhabdoid tumors (ATRT): Insights into disease mechanisms.

Maria D. Hernandez Ramirez[1], **Marlena Mucha**[1], Victoria E. Fincke[1], Martin Hasselblatt[2], Christian Vokuhl[3], Michael C. Fruhwald[1], Pascal D. Johann[1]

[1]Pediatrics and Adolescent Medicine, Swabian Children's Cancer Center, University Hospital Augsburg, Augsburg, Germany,[2]Institute of Neuropathology, University Hospital Munster, Munster, Germany,[3]Section of Pediatric Pathology, Department of Pathology, University Hospital Bonn, Bonn, Germany

Rhabdoid tumors are aggressive pediatric cancers characterized by significant alterations in gene expression and tumor microenvironment composition. Our study aims to investigate the molecular mechanisms driving tumor aggressiveness and relapse in extracranial malignant rhabdoid tumors (eMRT) and atypical teratoid rhabdoid tumors (ATRT). Using high-resolution single-cell RNA sequencing and spatial transcriptomics, we analyzed gene expression patterns and cellular interactions within the tumor microenvironment, with a particular focus on immune cell composition and activity.

Previous research has identified distinct DNA methylation subgroups in eMRT, associated with clinical outcomes such as high- and standard-risk profiles. These subgroups, linked to differences in survival rates, relapse frequencies, and SMARCB1 genetic alterations, provide a foundational framework for understanding tumor heterogeneity. Building on this framework, we explored subgroup-specific gene expression profiles and tumor microenvironmental dynamics, moving beyond methylation-based stratification. Pathway enrichment analysis identified key molecular pathways associated with immune evasion and tumor progression, providing insights into the tumor microenvironment and its role in disease progression. We observed enrichment in pathways such as nuclear-transcribed mRNA catabolic process (nonsense-mediated decay), and cytoplasmic translation, which are crucial for sustaining the high proliferative rates of tumor cells. Unique to the high-risk group in eMRT is the enrichment of pathways such as protein phosphorylation and plasma membrane-bounded cell projection assembly, which are critical for oncogenic signaling and invasive mechanisms. Immune cell characterization revealed a higher macrophage count in the eMRT high-risk group compared to the standard-risk group, aligning with their aggressive phenotype, as macrophages facilitate invasion and immune evasion. The high-risk eMRT group also showed elevated levels of growth factors (FGF9, HGF, PDGFC) and invasion-related proteins (SEMA3D, IL1RAPL1), with reduced ALB levels, which suggest enhanced proliferation and metabolic alterations characteristic of aggressive tumors. These findings offer a deeper understanding of the unique molecular and cellular landscapes of rhabdoid tumors, providing valuable insights to inform potential therapeutic targets.

#7049 Harnessing phosphoproteomic profiling for target discovery in high-risk osteosarcoma: A pathway to novel therapies?.

C. M. Perkins[1], Z. Barger[1], A. Fordham[1], A. Salib[1], T. Lim Kam Sian[2], R. J. Daly[2], P. Ekert[1], E. Fleuren[1];
[1]Children's Cancer Institute, Sydney, Australia, [2]Monash Biomedicine Discovery Institute, Melbourne, Australia

Background and Aims: Osteosarcoma (OS) is the most common primary malignant tumor of the bone in children and adolescents and young adults (AYAs). Currently there are no effective targeted treatments for advanced disease, and tumours rarely possess actionable, genomic alterations. Activated (phosphorylated) protein kinase signaling has been identified as a key driver event in subsets of human osteosarcoma. This study aims to utilize a phosphoproteomic approach to identify aberrantly activated kinases in OS, which novel targeted therapies can be directed against.
Hypothesis: Activated kinase signaling is a key driver event in subsets of human OS. Phosphoproteomic profiling of OS tumours will identify aberrantly activated kinases, which if targeted by matched drugs could indicate novel, effective, patient-specific OS therapies.
Methods: Eighteen unique patient-derived xenograft (PDX) models from high-risk (<30% chance of survival) sarcoma patients enrolled in the ZERO Childhood Cancer Precision Medicine Trial (ZERO), including four OS (one with matched disease samples), were subjected to Mass Spectrometry-based phosphoproteomic profiling. Selected activation signatures in OS were validated by Western Blot (WB) and linked to molecular genomics/transcriptomics. Eight drug targets were selected for functional validation in vitro in short and long-term drug viability assays across standard OS (n=3) and newly established OS PDX cell lines from ZERO patients (n=6). Two top-performing novel agents underwent further in vitro combination testing using ZERO's clinically applicable 150-compound drug library and in vivo exploration. Drug mechanism-of-action was investigated by WB and cell cycle analysis.
Results: In OS, we identified ~4900 phosphosites, corresponding to 1843 unique proteins. Eight novel drug targets with elevated phosphorylation across OS patient models were selected for further validation with ten kinase inhibitors. Two clinically applicable inhibitors demonstrated remarkably low IC50 values of <0.05uM or <0.1uM across standard OS and OS PDX cell lines in short-term in vitro assays and were selected for further validation. On-target drug activity and mechanism-of-action was confirmed by WB, where reduced expression of CDK downstream targets was observed. Clonogenic assays further confirmed the remarkable sensitivity of tested cell lines to these drugs. In vitro combination testing revealed synergy with at least three targeted agents.
Conclusion: Our study demonstrates significant anticancer activity of two novel kinase inhibitors in vitro in OS and newly established high-risk ZERO PDX cell lines. Studies exploring the in vivo efficacies of these drugs as single agents and in combinations are underway. This study demonstrates the potential application of phosphoproteomics for the discovery of actionable targets in high-risk OS.

#7050 Preclinical evaluation of the AKR1C3-activated alkylator OBI-3424 in hepatoblastoma: A report from the Pediatric Preclinical In Vivo Testing Consortium (PIVOT).

Jocoy[5], Yu-Jung Chen[6], Ming-Chen Yang[6], Beverly Teicher[7], Carol J. Bult[3], Malcolm A. Smith[8]

[1]Department of Pediatrics, Memorial Sloan Kettering, New York, NY,[2]Greehey Children's Cancer Research Institute, UT Health San Antonio, San Antonio, TX,[3]The Jackson Laboratory, Bar Harbor, ME,[4]The Jackson Laboratory, Farmington, CT,[5]The Jackson Laboratory, Sacramento, CA,[6]OBI Pharma, Taipei City, Taiwan,[7]Molecular Pharmacology, National Cancer Institute, Bethesda, MD,[8]CTEP, National Cancer Institute, Bethesda, MD

Introduction: OBI-3424 is a DNA alkylating prodrug activated by aldo-keto reductase family 1 member C3 (AKR1C3). Elevated AKR1C3 expression is observed in a variety of tumors including prostate cancer, T-cell acute lymphoblastic leukemia (T-ALL), hepatocellular carcinoma (HCC) and hepatoblastoma. Interim Phase 2 data of OBI-3424 in advanced HCC patients showed encouraging survival benefit and a good safety profile. Evaluation of AKR1C3 expression across a spectrum of pediatric tumors showed highest expression in T-ALL and hepatoblastoma. Prior preclinical testing of OBI-3424 in T-ALL patient-derived xenograft (PDX) models showed significant activity with prolonged complete remissions. Hence, we evaluated the anti-tumor activity of OBI-3424 across a panel of hepatoblastoma PDXs and examined AKR1C3 expression as a response biomarker.

Methods: Tumors from 8 hepatoblastoma PDXs were evaluated for AKR1C3 expression by immunohistochemistry and H-scores assigned following pathology review. OBI-3424 was provided by OBI Pharma and administered intravenously at 2.5 mg/kg weekly for 3 weeks. Tolerability testing was performed in 3 non-tumor bearing immunodeficient mice at 100%, 75% and 50% of the recommended dose (2.5 mg/kg). In efficacy studies, 3-6 mice were treated per treatment group (vehicle, OBI-3424) across the 8 hepatoblastoma PDXs profiled for AKR1C3 expression. Previously described measures assessing event-free survival (EFS T/C = ratio of median EFS for treated versus control animals) and overall objective response measures (ORMs) modeled after the clinical setting were used to evaluate activity (Houghton et al., Pediatr Blood Cancer, 2007).

Results: H-scores for AKR1C3 expression ranged from 50 - 255 (median: 158) with 5 of 8 models having H-scores ≥100. AKR1C3 transcript expression was well correlated with protein expression. OBI-3424 was well tolerated at all dose levels tested with no significant weight loss in 2 different immunodeficient mouse strains. Among 8 models tested, partial responses (PRs) were observed in 3 models and 1 model showed stable disease (SD). Three models were categorized as progressive disease with tumor growth delay (PD2), and 1 model continues to undergo testing. EFS T/C values ranged from 2.34-5.62. Preliminary assessments of response do not appear to consistently correlate with AKR1C3 expression level (e.g., PR and PD2 observed in models with H-scores of 250 and 255, respectively).

Conclusions: OBI-3424 shows promising preclinical activity in hepatoblastoma PDX models inducing objective responses. The role of AKR1C3 expression as a response biomarker for hepatoblastoma requires further investigation. Results from this study along with encouraging interim Phase 2 clinical data for advanced HCC patients may provide rationale for future clinical development of OBI-3424 in hepatoblastoma.

#7051 CCL21 therapy in conjunction with low-dose metronomic cyclophosphamide generates superior responses against neuroblastoma in vivo.

Benjamin Gephart, Gabrielle Brumfield, Donald W. Coulter, Joyce Solheim

University of Nebraska Medical Center, Omaha, NE

Neuroblastoma is a pediatric malignancy that arises from aberrant neural crest progenitor cell division and proliferation. Relapsed and refractory disease often has a poor prognosis, with the long-term survival rate less than 30%. Neuroblastoma is canonically considered to be an immunologically cold and non-immunogenic tumor type, with dense populations of immune suppressive cell populations that have been shown to impair anti-tumor immunity. Despite the significant clinical response in other tumor types, immune checkpoint inhibitors have only shown limited clinical efficacy in neuroblastoma. Superior treatment modalities are needed to increase overall survival with less severe toxicity in the treatment of neuroblastoma. CCL21 is a chemokine that mediates the migration of immune cell populations such as T cells, NK cells, and dendritic cells, which are key immune cell populations for robust anti-tumor immunity. Prior preclinical studies have highlighted the effectiveness of CCL21 therapy as a potential treatment modality for multiple solid tumor types; however, CCL21's effectiveness against neuroblastoma is poorly understood. We sought to investigate the effectiveness of intratumoral delivery of CCL21 therapy against neuroblastoma in vivo. We desired to also characterize the immunomodulatory properties of the alkylating agent cyclophosphamide against neuroblastoma both in vitro and in vivo. Cyclophosphamide is part of the standard-of-care treatment protocol for neuroblastoma and has been shown to possess unique immunomodulatory properties at low doses. Herein, we demonstrate that CCL21 therapy in conjunction with metronomic low-dose cyclophosphamide chemotherapy generates superior controlling of neuroblastoma tumor growth in an immunocompetent, syngeneic Neuro2a mouse model. In our in vitro studies, we show that low-dose cyclophosphamide up-regulates cell surface calreticulin expression, as well as cell surface PD-L1 expression on neuroblastoma tumor cells, suggesting that it has potential to facilitate sensitization to anti-PD-L1 checkpoint blockade. In short, this research shows the therapeutic potential of CCL21 and metronomic low-dose cyclophosphamide chemotherapy in the treatment of non-immunogenic tumor types such as neuroblastoma. Furthermore, this research supports the technical feasibility of a novel in situ tumor immunotherapy strategy for neuroblastoma in a preclinical setting.

#7052 Istiratumab exhibits antiproliferative activity in Ewing sarcoma and rhabdomyosarcoma.

Jerome Salmon[1], Sarah Cherkaoui[2], Floriane Braye[1], Raphael J. Morscher[2], Luc Friboulet[1], Alexandre Bobard[1], Jean-Paul Alves[3], Jean-Pierre Armand[1], **Birgit Geoerger**[1]

[1]Gustave Roussy, Villejuif, France,[2]Kinderspital, Zuerich, Switzerland,[3]Pegascy, Villejuif, France

Istiratumab (prior MM-141) is a fully human tetravalent bi-specific antibody that binds and co-inhibits IGF-1R and ErbB3 (HER3). Istiratumab inhibits ligand binding to abrogate PI3K/AKT signaling resulting in antiproliferative activity in various cancers alone and in combination with mTOR inhibitor everolimus or chemotherapy, including in a human Ewing sarcoma model. Following Phase I and Phase II trials in advanced solid and pancreatic cancer, the molecule was abandoned by Merrimack Pharmaceuticals and was subsequently acquired by Pegascy. To consolidate our decision to proceed with a pediatric study, we explored our MAPPYACTS sequencing data on recurrent or refractory pediatric cancers for alterations in both pathways. Mutations in IGF-1R and HER3 occur rarely in pediatric cancers, some tumors exhibit IGF-1R amplification. Most tumors expressed moderate levels of IGF-1R with high expression in neuroblastoma samples and amplified osteosarcoma; IGF-2R is expressed in most cancers. IGF1 was lowly expressed in neuroblastoma and sarcoma but highly in choroid plexus carcinoma whereas IGF2 was highly expressed in most tumor types, particularly rhabdomyosarcoma, hepatoblastoma and ependymoma that are known to exhibit LOH. HER3 was found expressed in RMS, hepatoblastoma, a proportion of high grade glioma and carcinomas, its ligand NRG1 was found high only in single samples of sarcoma subtypes. Moreover, we observed IRS2 and IRS1 overexpression in about 80% of Ewing sarcoma samples. Overall, the activity of these pathways encouraged us to explore further the antitumor activity of istiratumab in pediatric cancers. We evaluated antiproliferative activity in Ewing sarcoma (TC-71, TC-106, CHLA-99, TC-205), alveolar (Rh41, Rh30) and embryonal (RD) rhabdomyosarcoma of istiratumab alone and in combination with the IRS1/2 inhibitor NT219 or HDAC inhibitor panobinostat. Istiratumab exhibited antiproliferative activity at 0.1 and 1 µM against most cell lines as determined by WST-1 assay. Strong growth inhibition (60-70%) was noted in TC-71 and TC-106, moderate inhibition (26%) in CHLA-99, whereas TC-205 was not sensitive. 35-45% growth inhibition was achieved in rhabdomyosarcoma RD, Rh30 and Rh41, similar to EBV-positive nasopharynx carcinoma C666, which co-expresses both pathways. Antiproliferative effects of istiratumab were enhanced by addition of NT219 at 0.1 µM or panobinostat in the 3 Ewing sarcoma cell lines tested. Similarly, the addition of IGF1 but not NRG1 in low serum growing conditions reinforced the observed activity of istiratumab in Ewing sarcoma cell lines. Evaluations to determine biomarkers for sensitivity are ongoing. Conclusion: Istiratumab has antiproliferative activity in sarcomas and will be evaluated in molecularly selected pediatric malignancies and Ewing sarcoma within the AcSé-ESMART trial.

#7053 Proteomics and integrative pathway analysis to understand the mechanism of action of mithramycin and etoposide combination induced cell death in Ewing sarcoma cells.

Christoffer B. Lambring[1], Khadiza Zaman[1], Elin Stone[1], Natalie Gierat[1], Ameya Bhargava[2], Laszlo Prokai[1], **Riyaz Basha**[1]

[1]University of North Texas Health Science Ctr., Fort Worth, TX,[2]Purdue University, West Lafayette, IN

Ewing's sarcoma (ES) is a highly aggressive cancer that primarily originates in the bones or soft tissues and is predominantly diagnosed in adolescents and young adults. The EWS-FLI1 fusion protein is considered a hallmark of ES, being expressed in approximately 85% of cases. Prognosis for advanced ES remains poor, with survival rates around 30%, and current chemotherapy regimens are associated with severe long-term side effects. Mithramycin has emerged as a promising inhibitor of EWS-FLI1; however, its clinical application is limited by dose-dependent toxicities. We hypothesize that combining mithramycin with standard chemotherapy could enhance therapeutic outcomes through synergistic effects, potentially allowing for reduced doses of both agents to maximize efficacy while minimizing toxicity. To investigate this, we evaluated the combined impact of mithramycin and etoposide on ES cell lines. Using TC205 cells, we further explored the underlying mechanisms through proteomics and integrative pathway analysis (IPA). In this study, we assessed the dose- and time-dependent effects of mithramycin and etoposide in ES cell lines (CHLA10 and TC205) and non-cancerous cardiomyocytes (H9C2) to optimize treatment conditions. In vivo assays demonstrated a significant reduction in tumor growth with combination therapy compared to single-agent treatment. Using TC205 cells, we assessed the impact of mithramycin and etoposide both as monotherapies and in combination. Cells were plated in triplicate for each group (control, mithramycin, etoposide, and mithramycin + etoposide) and treated with optimized doses. After 48 hours, cells were harvested, and protein samples were subjected to proteomics and IPA to elucidate the mechanisms of action of both mono- and combination therapies. The combination of mithramycin and etoposide significantly inhibited cell viability compared to individual treatments. Proteomics analysis identified 517 altered proteins (t-test with BH correction), with 142 upregulated and 375 downregulated. IPA revealed significant changes in markers associated with disease and physiological function networks, including homologous recombination, cytostasis of sarcoma cell lines, cell movement of sarcoma cell lines, and osteoclastogenesis of limb bones. More than 70 disease and function networks and over 200 canonical pathways were significantly affected. Key pathways included eukaryotic translation initiation, cell cycle checkpoints, neutrophil degranulation, and cell cycle control of chromosomal replication. Overall, these findings reveal that the combination of mithramycin and etoposide alters critical networks and pathways, enhancing therapeutic efficacy in ES cell lines.

#7054 Mithramycin and chemotherapy combination induces apoptosis in Ewing sarcoma cells by upregulating reactive oxygen species and associated pathways.

Christoffer B. Lambring[1], Kayla Fure[1], Z'Niyah WIilson[2], Gisel Gutierrez[1], Umesh Sankpal[1], **Riyaz Basha**[1]

[1]University of North Texas Health Science Ctr., Fort Worth, TX,[2]Old Dominion University, Norfolk, VA

Ewing's Sarcoma (ES) is a rare and aggressive bone cancer that primarily affects children and adolescents. The disease is characterized by the presence of the EWS-FLI1 fusion protein, a transcription factor found in 85% of ES tumors that drives oncogenesis and tumor progression. Advanced ES has a grim prognosis with survival rates below 30%. Standard chemotherapy often results in significant long-term morbidities due to side-effects. Mithramycin has shown promise in inhibiting EWS-FLI1, however, its clinical application has not been established due to dose-dependent toxicities. We hypothesize that combining mithramycin with chemotherapy could offer a potential strategy to achieve synergistic effects, enabling lower dosages of both drugs to enhance efficacy while minimizing toxicity. We tested the combination effect of Mithramycin and Etoposide using ES cell lines and determined the response on inducing higher apoptosis through altering reactive oxygen species (ROS). Cardiomyocytes were used to test systemic toxicity against non-cancerous cells. Ewing Sarcoma cells (CHLA 10 and TC205) and cardiomyocytes (H9C2) were cultured and treated with Mithramycin, Etoposide, and their combination using optimized concentrations determined for each drug. Cell viability, Caspase 3/7 activity and ROS production were measured using respective luminescence-based assays. Flow cytometry with Annexin V/7AAD staining evaluated apoptosis levels, and protein expression of apoptosis-related markers, such as c-PARP, was analyzed using a capillary-based Simple Western system. Statistical analyses were performed using GraphPad Prism to evaluate significance. The combination of Mithramycin and Etoposide significantly inhibited ES cell viability compared to either agent alone. Apoptotic markers were markedly elevated in the combination-treated cells and associated with an upregulation of Caspase 3/7 activity and ROS production. Flow cytometry analysis confirmed an elevated apoptotic response, with a higher percentage of Annexin V-positive cells in the combination group. Additionally, Western blot analysis revealed increased c-PARP expression, consistent with enhanced apoptosis. In H9C2 cardiomyocytes, no treatment exhibited significant toxicity at equivalent concentrations, indicating the potential for no cardiac side effects. These results demonstrate the synergistic effects of Mithramycin and Etoposide in targeting cancer cells while sparing healthy tissue. Protein samples were subjected to proteomics and Integrative Pathway Analyses are currently being conducted to precisely elucidate the involvement of ROS-associated markers in understanding the mechanism of action and in vivo efficacy of this combination. Investigating additional biomarkers of response and resistance may provide further insights for personalized therapy.

#7055 An IL1RAP ADC is efficacious in distinct oncofusion-driven pediatric cancers.

Haifeng Zhang[1], Wei Li[2], Xiaqiu Yang[1], Qingfeng Huang[1], Yue Zhou Huang[1], Alberto Delaidelli[1], Andrew Lytle[1], Melanie Rouleau[1], Christian Steidl[1], Dimiter Dimitrov[2], **Poul Sorensen**[3]

[1]BC Cancer Research Institute, Vancouver, BC, Canada,[2]University of Pittsburgh, Pittsburgh, PA,[3]University of British Columbia, Vancouver, BC, Canada

Our recent studies identified the cell surface protein IL-1 receptor accessory protein (IL1RAP) as a crucial regulator of redox homeostasis and a suppressor of ferroptosis (iron-mediated cell death) in Ewing sarcoma (EwS). IL1RAP directly binds to the CD98/xCT plasma membrane antiporter to enhance cystine uptake, thereby replenishing cysteine and glutathione (GSH) pools in EwS cells. Moreover, when extracellular cystine is limited, IL1RAP induces cystathionine gamma lyase (CTH) to activate the transsulfuration (TSS) pathway for *de novo* cysteine synthesis. IL1RAP depletion diminishes GSH pools and induces oxidative stress to trigger *anoikis* and ferroptosis, thereby inhibiting EwS metastatic capacity. Importantly, IL1RAP is minimally expressed in normal tissues, including blood and bone marrow, with placenta as the only normal tissue to express IL1RAP, nominating this protein as a promising immunotherapy target. Here, we uncover that distinct fusion oncoproteins activate IL1RAP expression in cancers of different lineages, including EWS-ETS fusions in Ewing sarcoma (EwS), the ETV6-NTRK3 fusion in diverse tumor types, and the NPM-ALK fusion in anaplastic large cell lymphoma (ALCL). To target IL1RAP in these cancers via immunotherapy, we identified a highly specific IL1RAP binder from phage-display biopanning, and engineered an IL1RAP-directed human IgG based antibody-drug conjugate (ADC; X12-IL1RAP-PBD) linked to the DNA damaging agent, pyrrolobenzodiazepine (PBD). In proof-of-concept studies, our proprietary X12-IL1RAP-PBD induced potent DNA damage, apoptosis, and bystander cell killing in *in vitro*. In preclinical mouse models, X12-IL1RAP-PBD induces dramatic and durable regression of tumor xenografts expressing of the oncofusions at dosing of only 0.2mg/kg. Moreover, essentially no signs of toxicity were noted, with stable body weights and no histological evidence of toxicity in vital organs such as liver, lung, kidney, and brain. Moreover, X12-IL1RAP-PBD fully blocked tail vein injected EwS cell-induced liver changes *in vivo*, again without any toxicity. Thus, this first-in-class IL1RAP-targeting ADC is highly efficacious in preclinical models of multiple oncofusion-driven cancers, warranting further clinical translation.

#7056 The impact of aberrant ZMIZ1 protein expression in pediatric acute lymphoblastic leukemia.

Caroline S. Greenstone[1], Jessica Krugman[2], Danielle W. Cohen[3], John Easton[4], Heather Mulder[4], Ying Shao[4], Xiaotu Ma[5], Nikki A. Evensen[6], William L. Carroll[7]

[1]Barnard College, New York, NY,[2]Pediatric Hematology-Oncology, The Mount Sinai Hospital, New York, NY,[3]Pediatric Hematology-Oncology, NYU Grossman School of Medicine, New York, NY,[4]St. Jude Children's Research Hospital, Memphis, TN,[5]Computational Biology, St. Jude Children's Research Hospital, Memphis, TN,[6]NYU Langone Health, New York, NY,[7]NYU Grossman School of Medicine, New York, NY

While the outcomes for pediatric acute lymphoblastic leukemia (ALL) have improved dramatically over the past 30 years, up to 20% of patients relapse and their prognosis is poor. Collaborators at St. Jude's Research Hospital discovered that mutations in *ZMIZ1* are highly enriched at relapse in a subset of patients. Subsequent studies showed that the transcript level is correlated to event-free survival. Thus, our objective is to study the function of ZMIZ1 in cancer survival under the selective pressures of chemotherapy. To accomplish this, we generated a panel of B-ALL cell lines overexpressing either wild-type (WT), or two different mutant forms of ZMIZ1 found in patients (A291-A305 deletion (Del), or A297T substitution (Sub)) and compared them to an empty vector (EV) control. We performed reverse transcription quantitative PCR (RT qPCR) to confirm mRNA expression, western blots to determine expression of ZMIZ1, as well as cell viability, apoptosis, and proliferation assays to assess functional impact. While full length transcripts were confirmed in all three lines, full length protein was only detected in the WT overexpressing line. All lines expressing the mutant forms of ZMIZ1 demonstrated a lower molecular weight product, suggesting post-translational modification. Phenotypically, we observed profound resistance to prednisolone, a cornerstone of ALL therapy, upon WT (IC50 >1e-1mM) expression compared to EV (IC50=3e-4mM), while cell lines expressing the Del or Sub showed no difference in drug sensitivity (IC50s=3e-4mM). No differences were seen with other commonly used chemotherapies. Since these experiments were done in cell lines with two WT alleles, we then used CRISPR-cas9 to knock out endogenous *ZMIZ1*. Allele specific sequencing for individual clones was confirmed using IDT's rhAmpSeq^{TM} CRISPR kit. *ZMIZ1* complete knockouts (KO) showed no detectable protein expression and had increased sensitivity to prednisolone (IC50=3e-5mM) compared to the Rosa control (IC50=5.7e-5mM) in both cell viability and apoptosis assays. Subsequently, we reintroduced ZMIZ1 (WT and mutants) into KO cells and again only WT had detectable full length protein expression, but now all three lines showed the lower molecular weight product. Resistance to prednisolone was restored completely upon rescue with WT ZMIZ1 (IC50>1e-1mM) compared to the complete KO cells and Rosa. In contrast, mutant cell lines now showed modest resistance to prednisolone (IC50s 4.9e-5mM Del; 5.6e-5mM Sub) compared to KO. Collectively our results indicate a complex relationship between the products of WT and mutant alleles mediated in part by a post-translationally modified species involved in glucocorticoid resistance. A more thorough understanding of how mutations in *ZMIZ1* affect the regulation and drug resistance is vital in determining the clinical significance and evaluating ZMIZ1 as a potential therapeutic target in patients.

CLINICAL RESEARCH: Early Detection Biomarkers 2
Poster Session

#7060 Semi-quantitative lateral flow immunoassay for HPV serology for detection of HPV+ oropharyngeal cancer.

Akshansh Kaushik, Tej Patel, Joshua Eger, Ching Wen Hou, Jennifer Blain Christen, Karen S. Anderson

Arizona State Univ. Biodesign Institute, Tempe, AZ

Background: HPV (human papilloma virus) is a leading cause of 60-70% of oropharyngeal cancer in the US. Antibodies to HPV early antigens are detectable in serum samples up to two decades prior to diagnosis, so that HPV serology are potential biomarkers for screening. We have developed a rapid colorimetric lateral flow assay (LFA) for the semi-quantitative detection of antibodies for HPV16 CE2 and HPV16 E7 antigens.
Methods: Recombinant his-tagged proteins (HPV16 CE2 184-365aa and HPV16 E7) were printed separately on nitrocellulose membranes, with human IgG as a control line. Plasma samples from newly diagnosed HPV+ or p16+ oropharyngeal cases (n=38) and controls (n=46) were selected for assay development and image analysis based on known serostatus. The plasma was applied to the membranes, washed and blocked with casein, and antibodies were detected using a gold-conjugated protein G secondary antibody. A Python program was developed using the OpenCV library for image processing and the scipy.signal library was used to detect bands on the strip as peaks. The area under the curve for these peaks was calculated, with a threshold >700 unit squares. The seropositivity of the LFA was compared with laboratory-based RAPID ELISA HPV serology.
Results: By RAPID ELISA, the sensitivity of CE2 serology was 84% and E7 was 78.9% at >97% specificity for the plasma samples specifically selected for the assay development (not a random or matched cohort). On the LFA, the sensitivity of CE2 serology was 52.6% and E7 was 76.3% at >97% specificity. By LFA, 89.5% of cases were positive for either CE2 or E7 serology at 95.6% specificity, with strong concordance with RAPID ELISA (κ=0.853).
Conclusion: The LFA test demonstrated high concordance for detecting antibodies in plasma samples compared to RAPID ELISA, providing a promising point-of-care tool for large-scale screening of oropharyngeal cancer.

#7061 Biomarkers in TGF-β and corresponding Immune pathway stratify HCC-risk in cirrhotic patients.

Xiyan Xiang[1], Richard L. Amdur[2], Kirti Shetty[3], Herbert Yu[4], Linda L. Wong[5], Nyasha Chambwe[6], Sanjaya K. Satapathy[7], James M. Crawford[8], Lopa Mishra[9]

[1]The Feinstein Institute for Medical Research, Manhasset, NY,[2]The Institutes for Health Systems Science & Bioelectronic Medicine, The Feinstein Institute for Medical Research, Manhasset, NY,[3]University of Maryland, Baltimore, MD,[4]University of Hawaii Cancer Center, Honolulu, HI,[5]Department of Surgery, University of Hawaii, Honolulu, HI,[6]The Institute of Molecular Medicine, The Feinstein Institute for Medical Research, Manhasset, NY,[7]Division of Hepatology, Northwell Health and Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY,[8]Department of Pathology and Laboratory Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY,[9]The Feinstein Institute for Medical Research, New York, NY

Purpose: Hepatocellular carcinoma (HCC) is a leading cause of cancer deaths worldwide, which is mostly diagnosed at advanced and incurable stages. The suboptimal performance of current screening approaches including serum alpha-fetoprotein testing and ultrasound, highlights the urgent need for novel biomarkers to enable risk stratification and early detection of HCC. Based on our previous mechanistic insights with data from human genomic studies available in The Cancer Genome Atlas (TCGA) and from animal models (*Cell Rep. 2024.43(9):114676 and Sci Transl Med. 2021.13(624): eabk2267*), we have identified functional protein markers associated with HCC such as TGFBR2, MSTN, and PKM2. In this study, we present a model based on the TGF-β and associated immune pathways for the HCC stratification in cirrhotic patients that incorporates biologically relevant proteins to capture ongoing pathophysiological changes that drive hepatocarcinogenesis.
Experimental Procedures: A proteomic analysis of 7,000 proteins (SomaScan) utilizing serum samples (55 uL/each) from 311 individuals with cirrhosis, 18 of whom developed HCC by imaging criteria during the median 5-year follow-up. Using a multivariable logistic regression method, we conducted an unsupervised clustering analysis of TGF-β and the corresponding immune pathway and combined with well-described serum biomarkers to create a risk prediction model. We followed this with ELISA validation of the most promising biomarkers.
Results: In our prospective cirrhosis cohort (n=311), 18 HCC cases (5.8%) developed over a median follow-up of 5 years. Using unsupervised hierarchical clustering, we analyzed TGF-β pathway (n=28) and inflammatory/immune response proteins (n=36), grouping patients into two subgroups based on serum protein expression. Among HCC cases, 77.8% showed higher SMAD3 and 66.7% showed higher TGFBR2 expression. Cirrhotic patients with elevated expression of serum HMGB1/IL34/CCL3L1/IL37/SMAD3/TGFBR2 had a six-fold higher HCC risk (10.64% vs. 1.76%). A TGF-β model combining TGFBR2, GPC3, ANGPTL8, and GZMK outperformed the AFP model, with AUCs of 0.88 vs. 0.60 and better sensitivity (0.61 vs. 0.11) at 0.90 specificity. ELISA validation confirmed that MSTN, TGFBR2, and HMGB2 levels were significantly elevated in HCC ($p<0.05$).
Conclusions and Next Steps: This study successfully demonstrates the high performance of our TGF-β and corresponding immune pathway biologically related biomarkers for HCC risk stratification in cirrhotic patients. The next steps will be large-scale validations of this biomarker panel in cirrhotic patients across all racial and ethnic subgroups in Phase II/III studies.

#7062 Potential biomarker role of LCN2, MMP9 and LCN2/MMP9 complex in OSCC.

Smriti Suri[1], Sushmita Ghoshal[2], Jaimanti Bakshi[3], **Arnab Pal**[4]

[1]Biochemistry, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[2]Radiotherapy and Oncology, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[3]ENT, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[4]Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: Oral Squamous Cell Carcinoma (OSCC) is considered as a major morbidity and mortality in LMICs, with five-year survival rate of less than 50%. Limited availability of early diagnostic markers is one of the important causes of this abysmal outcome. We identified 135 differentially regulated candidate proteins using LC/MS-based shotgun proteomics in the saliva of OSCC patients, of which LCN2 and MMP9 were also found to be significantly upregulated. Dysregulated levels of LCN2, MMP9, and LCN2/MMP9 complex have also been reported in OSCC. To establish the potential role as biomarkers, we evaluated them in OSCC patients.

Methodology: 356 biopsy-proven treatment-naïve OSCC, 26 Oral Pre-Malignant Diseases (OPMDs) and 118 healthy subjects were recruited for the study. 5 ml of unstimulated saliva and 3 ml of whole blood were collected at baseline and during follow-ups. Salivary and serum levels of LCN2, MMP9 and LCN2/ MMP9 complex were estimated using sandwich ELISA. The levels were analysed in various groups and were also correlated with the therapy response and the disease outcome.

Results: Significantly higher (*p≤0.0001*) levels of LCN2 in saliva and serum (median- 609.15ng/ml & 186.18ng/ml) of patients compared to OPMD (median-358.47ng/ml & 124.05ng/ml) and healthy controls (median-95.70ng/ml & 85.53ng/ml) respectively. Salivary and serum levels of MMP9 (median-194.03ng/ml & 3476.755ng/ml) were also found to be significantly higher (*p≤0.0001*) than their levels in OPMD (median-206.50ng/ml & 404.08ng/ml) and control group (median-188.05ng/ml & 540.18ng/ml) respectively. Also, the level of complex of LCN2/MMP9 in saliva and serum (median-145.65ng/ml, median-94.37 ng/ml) was observed to be significantly higher (*p≤0.0001*) than OPMD (median-90.66ng/ml & 55.20ng/ml) and healthy controls (median-70.88ng/ml & 52.76ng/ml) respectively. The increased level of these proteins also correlated with staging and was also found to have a decreasing trend with successful therapy. On ROC analysis, for identifying the ability as a diagnostic marker, significant AUCs for LCN2 in saliva and serum of patients compared to healthy controls were found (0.7446 & 0.6802) with a sensitivity of (88.64% & 77.25%) and specificity of (60.17% & 60.17%) respectively. For MMP9, the AUC for serum was significant (0.9326), with a sensitivity of 85.01% and specificity of 95.54%. AUC for LCN2/MMP9 complex for saliva and serum were also found to be significant (0.7415 & 0.7266) with a sensitivity of (86.74% & 78.80%) and specificity of (52.54% & 63.56%) respectively. Survival curve analysis revealed that pretreatment salivary LCN2 can be used as a predictive marker for OS of OSCC patients with an HR of 1.915 (CI 1.173 to 3.127) and salivary levels of MMP9 for DFS with HR of 2.823 (CI 0.9813 to 8.122).

Conclusion: Baseline LCN2, MMP9, and LCN2/MMP9 complex can be used as potential biomarkers for the diagnosis and prognostication of patients with OSCC.

#7063 Monoclonal antibody evaluation of oxidative DNA base damage in normal and neoplastic breast tissues: development of antibodies specific for 8-OH-adenine and 4,6-diamino-5-formamidopyrimidine (FAPY-adenine).

Zenzeale A. Hudson[1], Sarah McLaughlin[2], Alfredo A. Paredes[3], Gary K. Ostrander[1], Eric H. Holmes[1]

[1]Biomedical Sciences, Florida State University, Tallahassee, FL,[2]Department of Surgery, Mayo Clinic, Jacksonville, FL,[3]Tallahassee Plastic Surgery Clinic, Tallahassee, FL

Breast cancer affects 1 in 8 women and often results from mutations caused by oxidative DNA damage from reactive oxygen species. Two key lesions, 8-hydroxy-adenine (8-OH-Ade) and 4,6-diamino-5-formamidopyrimidine (FAPY-Ade), exhibit two distinct patterns: FAPY-Ade lesions are predominant in normal tissues, while 8-OH-Ade lesions are abundant in cancerous tissues. These shifts reflect tissue redox status, which may provide a pathway to assess future breast cancer risk. Quantitation of these lesions by chemical detection methods is precise but time-intensive and impractical for high-throughput clinical applications. To address this, monoclonal antibodies have been developed and offer a rapid, scalable, and clinically practical alternative for efficiently detecting and quantifying these biomarkers. This innovation can potentially support personalized breast cancer screening strategies. BALB/c mice were immunized with 8-OH-Ade or FAPY-Ade haptens coupled to Keyhole Limpet Hemocyanin (KLH). After three monthly immunizations, the serums of IgG and IgM titers were evaluated. The mice having the highest IgG titer for each antigen were given an intravenous boost, and the spleens were removed three days later for fusions according to standard methods. Using hapten-conjugated BSA-coated 96-well Pro-Bind plates, the ELISA results demonstrated 30-40 positive wells for each antigen. Up to ten positive wells for each antigen were selected and cloned to yield monoclonal antibody-producing hybridomas. The ELISA of the anti-FAPY-Ade antibody, FA5, showed concentration-dependent reduced binding to immobilized BSA-FAPY-Ade hapten conjugate in increasing FAPY-Ade, confirming its FAPY-Ade binding specificity. Immunohistochemistry using normal and cancerous breast tissue revealed significant staining of normal breast tissue compared to cancerous breast tissue using the FA5 antibody. Conversely, the anti-8-OH-Ade antibody, 8A6, displayed weak staining of normal breast tissue with higher staining of cancerous breast tissues. The results demonstrate that monoclonal antibodies specific for 8-OH-Ade and a novel antibody specific for the ring-opening reactive oxygen product, FAPY-Ade, are practical and rapid alternatives to chemical detection methods for their analysis. Immunohistochemistry mirrored past results using chemical detection methods for these oxidized bases, with high FAPY-Ade compared to 8-OH-Ade in normal tissues and the opposite result in cancer-derived tissues. The potential for high-throughput analysis of 8-OH-Ade and FAPY-Ade levels in the DNA of breast tissues may provide information on future breast cancer risk. Further research is underway to evaluate this hypothesis.

#7064 Minimally invasive detection of advanced adenomas in colorectal cancer screening through circulating epithelial cells and somatic DNA aberrations.

Shai Friedland[1], Drew Watson[2], **Zhen Zhang**[3], Alexander Atkins[2], Huangpin Ben Hsieh[2], Jr-Ming Lai[2], Stephen Su[2], Hung-Jen Shao[2], Jen-chia Wu[2], John Sninsky[2], Rui Mei[2]

[1]Standford University, Stanford, CA,[2]CellMax Life, Sunnyvale, CA,[3]Johns Hopkins University, Baltimore, MD

Aim

Advanced adenomas (AAs), precursors to colorectal cancer (CRC), affect 5% of individuals under 50 and 8% of those 50 and older. Current blood-based tests have limited AA sensitivity (12-13%) compared to FIT (23.8%), highlighting the need for improved detection methods. The FirstSight assay combines circulating tumor DNA (ctDNA) and circulating epithelial cells (CECs) to enhance AA detection. Initial results show that FirstSight achieves higher sensitivity and specificity than existing blood-based tests. Here we analyze the contributions of ctDNA and CEC in the detection of AA.

Methods

FirstSight was validated in a study of 1,038 prospectively collected, diverse subjects from a majority screening cohort. CEC data were analyzed using a multi-dye machine learning algorithm. The FirstSight algorithm incorporated patient age, sex, and CRC incidence from SEER statistics to adjust baseline risk and refine probability distributions for improved predictive performance. We estimated the contribution of ctDNA and CEC in the detection of AA, and as an example, the cumulative effect of ctDNA and a single CEC-derived marker GM1.

Results

CEC ($p < 0.01$) and ctDNA ($p < 0.0001$) biomarkers were significant predictors of AA. A CEC marker, GM1, improved specificity for AA. At a prespecified 90% specificity for the detection of advanced neoplasia (CRC+AA), the best single ctDNA marker and the CEC marker GM1 individually had a sensitivity of 20% and 16%, respectively, for AA. The combined use of all ctDNA markers had a sensitivity of 39% for AA and the further addition of GM1 raised the sensitivity to 49% for AA. Finally, the integration of ctDNA, CEC markers, their interaction, and demographics improved FirstSight sensitivity to 54.5% for AA.The contribution of GM1 was significant ($\chi^2 = 9.7272$, $p = 0.02103$); removing GM1 reduced the AUC for AA from 0.8165 to 0.745. Consistent with the CRC dysplasia-malignancy continuum, FirstSight demonstrated higher sensitivity for stage I CRC compared to first-generation blood-based tests (92.3% vs. 54.5%).

Conclusions

The multimodal FirstSight test, combining ctDNA and CEC biomarkers, achieved 54.5% sensitivity and 90.6% specificity for AA detection in a 1,038-subject study. CEC signals are found to be most contributory to the detection of AA and the interaction of a single CEC marker, GM1, with ctDNA further improves AA sensitivity, making the performance not simply additive. FirstSight demonstrates the potential for superior AA detection and effective colorectal cancer prevention strategies. This minimally invasive test offers a patient-friendly alternative, with ongoing validation to confirm its clinical utility.

#7065 Desmocollin3 and tumor immune infiltrate: A bioinformatics evaluation.

Bakulesh M. Khamar[1], Sanjay V. Malhotra[2]

[1]Research & Development Division, Cadila Pharmaceuticals Limited, Ahmedabad, India,[2]Cell, Development and Cancer Biology, Center for Experimental Therapeutics, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Introduction: Desmocollin-3 (DSC3), a transmembrane glycoprotein is expressed in various cancers like squamous lung, head & neck, Cervical, Melanoma, bladder cancer etc. DSC3 is also a predictive biomarker for efficacy of Mycobacterium w (Mw) vaccine, a heat-killed suspension of a non-pathogenic mycobacterium. It induces a DSC3-specific cell-mediated (CD8+ T cells) immune response and considered to be a barrier for immune infiltrate. Efficacy of anti-PD1/PDl1 therapy depends on tumor infiltrating immune cells. Present study focuses on the key immune genes and their relationship with DSC3 gene.
Materials and Methods: DSC3 and other genes encoding various immune functions (Table) were evaluated across 17 cancers using cBioPortal TCGA PAN CANCER data set. For correlation between DSC3 and other immune genes, samples with a positive Z score for DSC3 or upper quartile DSC3 (lower of two) were used.
Results: DSC3 expression in Squamous lung cancer, Cancer cervix, head & neck, melanoma, colorectal cancer, mesothelioma and adenocarcinoma stomach were found to have major impact with negative Z score for majority of CD8, M1, Th1, T exhaust, M2 and Th2 genes suggesting lower infiltration of immunosuppressive and immunostimulant immune cells. Following genes had negative Z scores in all seven cancers:1. CD8 group: CD8A, CD8B, GZMA, GZMB, GZMK, GZMM, PRF1, TBX12. M1 group: CCL15, CCL20, CCR7, CXCL10, FCGR1BP, CYBB, Il15, 1I15RA3. Th1 group: CXCR3, IL274. Texhast; BTLA, LAG3, PDCD1, SLAMF6, TIGIT 5. Th2: BATF, CXCR6, SOCS1 6. M2: CD163Similar finding of lower magnitude were also seen in bladder cancer, ovarian cancer, thyroid cancer, pancreatic cancer, adenocarcinoma lung, uterine cancer, testicular germ cell cancer, renal cancer, sarcoma, hepatocellular cancer.
Conclusion: DSC3 expressing tumours are likely to have lower TIL (immunostimulant as well immunosuppressive) and may not be ideal candidate for check point inhibitors.

#7066 RING1 inhibits smoking-induced lung cancer tumorigenesis by ubiquitination and degradation of CIP2A.

In-ho Jeong, Peter Chang Whan Lee

University of Ulsan College of Medicine, Seoul, Korea, Republic of

Lung cancer is the second incidence rate of all new cancer diagnoses and the leading cause of cancer-related deaths globally. To develop novel diagnostic and therapeutic targets for lung cancer, there are emerging needs for molecular biological research on the occurrence and progression. Among the targets, CIP2A has been studied for promoting various cancer types, but detailed underlying mechanisms are needed to be further investigated. In this study, it was verified that CIP2A is overexpressed in lung cancer tissues, particularly amongst those with a smoking history, compared to adjacent normal tissues. CIP2A knockdown in lung cancer cells efficiently reduced cell proliferation and migration capacity. Through the mass spectrometry analysis on A549 cells overexpressing CIP2A, RING1 was identified as a candidate for E3 ligase of CIP2A. The interaction of the two proteins and ubiquitin chain regulation by RING1 was verified by immunoprecipitation. RING1 knockdown enhanced proliferation and migration of lung cancer cells, and these effects result from the upregulation of CIP2A and its downstream molecules, c-Myc and cyclin B1. To further study a trigger for RING1 expression changes in lung tumorigenesis, cigarette smoke extract (CSE) was applied for the following experiments. CSE treatment depleted RING1 mRNA, including protein expression. Decreased RING1 level led to upregulation of CIP2A and c-MYC. Collectively, these results reveal novel roles of the RING1 and CIP2A in lung cancer progression caused by smoking and propose a potential biomarker candidate for the therapeutic and diagnostic targets.

* Keywords: Lung cancer, UPS, CSE

#7067 Integrating blood-based biomarkers and RNA-Seq Data for enhanced colorectal cancer screening.

Elba V. Caraballo-Rivera[1], Hilmaris Centeno-Girona[1], Camille Zenon-Melendez[1], Sheila Lopez -Acevedo[1], Brenda Torres-Velasquez[1], Josue Perez-Santiago[1], Madeline M. Martir-Ocasio[1], Maria Gonzalez-Pons[1], Marcia R. Cruz-Correa[2]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]School of Medicine, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

Colorectal cancer (CRC) is the second cause of cancer-related deaths in the United States and the first leading cause for Puerto Rican Hispanics (PRH). Despite its preventability through screening, compliance still needs to improve due to the invasiveness of current tools. There is a growing demand for validated molecular biomarker panels for minimally invasive blood-based CRC screening. This study evaluated the diagnostic accuracy of four promising blood-based biomarkers and incorporated RNA-seq data from an independent cohort to provide biological insights into biomarker performance. A retrospective case-control study was conducted in plasma samples from 124 CRC cases and 124 age- and sex-matched controls recruited through the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR). Biomarkers tested included methylated DNA encoding the Septin-9 gene (*mSEPT9*) using Epi proColon® 2.0 CE, insulin-like growth factor binding protein 2 (IGFBP2), dickkopf-3 (DKK3), and pyruvate kinase M2 (PKM2) by ELISA. Diagnostic accuracy was measured using the receiver operating characteristic (ROC) area under the curve (AUC) and sensitivity and specificity. For the RNA-seq (Illumina) assay, a case-case study was performed on 15 tumor and 15 adjacent mucosa samples from 7 early and 8 advanced-stage CRC cases. Differentially expressed genes (DEGs) with an adjusted p-value < 0.05 were identified between tumor and adjacent mucosa across stages. Pathway enrichment was performed using Gene Set Enrichment Analysis (GSEA) and KEGG databases. Biomarkers and gene expression patterns were cross-validated to identify shared pathways. Diagnostic accuracy for individual biomarkers *mSEPT9*, IGFBP2, DKK3, and PKM2 was 62.9%, 69.7%, 61.6%, and 50.8%, respectively. Combined biomarkers AUC was of 74.4%, outperforming all individual markers except IGFBP2 in advanced-stage CRC. RNA-seq identified 481 DEGs unique to early-stage and 849 to advanced-stage CRC. Genes DKK3 and PKM2, were differentially expressed in both stages. Additionally, DKK1 and DKK2, were uniquely upregulated in early-stage tumors. Dysregulation of *Wnt* signaling, PI3K-Akt signaling, and cytokine-cytokine receptor interaction pathways were observed across stages. Our results show that integrating plasma biomarker analysis with RNA-seq data enables the identification of critical shared pathways, supporting the utility of a multi-omics approach for CRC screening. Plasma biomarkers demonstrated promising diagnostic accuracy, with IGFBP2 as the most accurate individual marker across CRC stages. The differential expression of DKK1 and DKK2 in early-stage tumors highlights their potential as early CRC biomarkers, warranting validation in plasma samples. These findings support the development of minimally invasive blood-based screening tools for CRC, offering a promising strategy for early detection and improved patient outcomes for PRH.

#7068 Diagnostic and prognostic application of blood and tissue cadherin-17 biomarker in pancreatic cancer.

William C. Cho[1], Wing Shan Yu[2], Tsz Chun Hon[2], Elaine T.Y. Cheung[3], Xiao Qi Wang[4], Qi-Hua Zhang[5], Hui-Yan Luo[5], Dennis Anthony Wong[6], Wah Cheuck[3], John M. Luk[6]

[1]Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong SAR, China,[2]Tiberias Technology (HK) Limited, Hong Kong SAR, China,[3]Department of Pathology, Queen Elizabeth Hospital, Hong Kong SAR, China,[4]Caleb BioMedical Company Limited, Guangzhou, China,[5]Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, China,[6]Arbele Corp., Seattle, WA

Background: Pancreatic cancer (PC) is one of the most lethal cancers, with a 5-year overall survival (OS) rate of ~10%. CA19.9 remains the gold standard biomarker for detecting PC, but its performance is poor, necessitating the exploration of better alternatives. Cadherin-17 (CA17) is overexpressed in several gastrointestinal cancers but shows limited expression in normal tissues, indicating potential diagnostic and prognostic applications in PC. This study aimed to evaluate the diagnostic and prognostic value of CA17 in PC.
Methods: We have newly developed an immunohistochemistry (IHC) platform to compare CA17 expression in PC tissues (n = 127), tumor-adjacent tissues (n = 86), and normal pancreatic tissues (n = 22) obtained from 50 retrospective PC cases, alongside a commercial tissue microarray of PC and normal samples. Digital imaging analysis was performed to quantify CA17 expression with an IHC scoring algorithm that combines the percentage of positive cells and staining intensity (M score). Additionally, 86 retrospective plasma samples were collected from asymptomatic donors and 49 patients with paired pre- and post-treatment plasma. CA17 and CA19.9 levels in plasma were measured using our newly developed highly sensitive and specific CA17 immunoassay and a commercial CA19.9 ELISA kit, respectively.
Results: Normal pancreatic tissues showed negative CA17 IHC results. A significantly higher CA17 M score was observed in PC compared to both normal and cancer-adjacent tissues (median M score: 5.83, 0.38, 0.85, respectively; $p < 0.001$). We observed a significant elevation in blood CA17 levels from asymptomatic donors to pre-treatment stage I/II PC patients, with a decrease in CA17 expression in stage III/IV patients (median in ng/mL: 1.45, 7.14, 2.58, respectively; $p < 0.0001$). Compared to pre-treatment plasma, CA17 levels decreased in post-treatment samples from stages I/II patients, while remaining stable in stages III/IV patients (median in ng/mL: 4.02, 2.42, respectively). Similarly, CA19.9 expression increased progressively from normal donors to stages I/II and stages III/IV patients (median in U/mL: 43, 56, 1446, respectively, $p < 0.0001$). The ROC curve of the CA17 assay showed an AUC of > 0.92, with both sensitivity and specificity of 86% in detecting stages I/II PC, surpassing CA19.9 (55% and 90%, respectively). Stage III/IV PC patients were stratified based on median-high and low CA17 and CA19.9 levels for a 2-year OS analysis, indicating that combining CA17 and CA19.9 in predicting prognosis outperforms each biomarker individually. Patients with both median-high CA17 and CA19.9 levels had a significantly worse OS than those with median-low CA19.9 (median OS: 7 vs 13 months, $p = 0.04$).
Conclusion: CA17 shows promise as a biomarker for early PC detection and prognosis prediction, potentially improving the screening of high-risk individuals for PC and aiding in disease management.

#7069 HPV-related oropharyngeal cancer: Circulating and salivary DNA-based biomarkers for early diagnosis and recurrence monitoring.

Ondrej Bouska[1], Vladimira Koudelakova[1], Zuzana Horakova[2], Marian Hajduch[1]

[1]Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic,[2]Department of Otorhinolaryngology and Head and Neck Surgery, University Hospital Olomouc, Olomouc, Czech Republic

Background: The incidence of oropharyngeal squamous cell carcinoma (OPSCC) has surged worldwide in recent decades. In the Czech Republic, annual OPSCC cases have more than tripled over 30 years, with nearly 800 new cases diagnosed in 2021, surpassing cervical cancer. OPSCC is now predominantly linked to high-risk HPV infection, with about 25% of patients experiencing recurrence within five years. Liquid biopsies (plasma and saliva) are being investigated for their potential in diagnosis, treatment monitoring, and recurrence detection. These efforts focus on DNA-based biomarkers, such as circulating tumor HPV DNA (ctHPV DNA) and oral HPV DNA.
Methods: HPV tumor status was assessed in newly diagnosed OPSCC patients and those in remission using high-risk HPV DNA detection in primary tumor tissue and p16 immunohistochemistry. Only cases positive for both high-risk HPV and p16 were classified as true HPV-related OPSCC. Oral HPV DNA and ctHPV DNA testing were conducted on liquid biopsies (gargle lavage, oropharyngeal swabs, and plasma) before and after treatment, with regular follow-up sampling.
Results: A total of 169 OPSCC patients were enrolled in the study, with 81.8% classified as HPV-related, predominantly involving the HPV16 genotype (98% of cases). Pre-treatment detection of tumor-derived high-risk HPV genotypes in liquid biopsies demonstrated excellent sensitivity: 92% in gargle lavage, 96.3% in oropharyngeal swabs, and 96.3% for ctHPV DNA in plasma, all achieving 100% specificity across sample types. Concordance in high-risk HPV genotype detection between gargle lavage and oropharyngeal swabs reached 94.2% in pre-treatment samples. Among recurrent HPV-related OPSCC cases, ctHPV DNA was detected in 75% (3/4) of cases, with 50% (2/4) also testing positive for oral HPV DNA.
Conclusion: This study aims to validate the combined use of liquid biopsy collection, oral HPV DNA detection, and ctHPV DNA detection for early diagnosis and recurrence monitoring in HPV-related OPSCC patients. Preliminary findings are encouraging, demonstrating the potential for early detection, including in early-stage OPSCC, and highlighting the clinical applicability of these methods for HPV-related OPSCC screening.

#7070 A deeper evaluation of cytokeratin fragment 21-1 as a lung cancer tumor marker and comparison of different assays.

Dianna J. Rowe[1], Timothy A. Khalil[1], Michael N. Kammer[1], Caroline M. Godfrey[1], Yong Zou[1], Cindy Vnencak-Jones[2], David Xiao[1], Stephen Deppen[3], Eric L. Grogan[3]

[1]Allergy, Pulmonary, and Critical Care Medicine, Vanderbilt University Medical Center, Nashville, TN,[2]Pathology, Microbiology and Immunology, Vanderbilt University Medical Center, Nashville, TN,[3]Thoracic Surgery, Vanderbilt University Medical Center, Nashville, TN

Studies show CYFRA 21-1 fragments of cytokeratin 19 (CK19) to be promising biomarkers for non-small cell lung cancer (NSCLC). Although previous literature identifies specific CYFRA 21-1 antibody binding epitopes, the exact molecular weight of the CK19 fragment being detected by current assays is not well-documented. It is believed that during apoptosis, CK19 is cleaved by caspases and resulting fragments are released into the serum. A proposed caspase cleavage site is located between amino acids 235 and 238 of its sequence. Upon cleavage, two fragments are released; the fragment bearing the C-terminus of CK19 is characterized as CYFRA 21-1. Two specific antibodies bind to epitopes localized to the CYFRA 21-1 fragment upstream of the caspase cleavage; KS 19.1 is located at aa 311-335 and BM 19.21 at aa 346-367. Although this antibody binding pattern suggests specific targeting of the CYFRA 21-1 fragment, there is no clear consensus on the molecular weight of the CYFRA 21-1 fragment being detected through currently available assays, suggesting that perhaps different assays detect different fragment lengths. Serum samples from 58 patients (lung cancer (N=36), control (N=22)) were used to measure CYFRA 21-1 across four different quantification assays: enzyme-linked immunosorbent assay (ELISA), chemiluminescent assay (ChLIA), electrochemiluminescence immunoassay (ECLIA), and compensated interferometric reader (CIR). In the cancer group, correlation between ECLIA and ELISA was high ($R_{(Pearson)}$=0.948, $r_{(Spearman)}$=0.868) while correlation between ECLIA vs ChLIA and ECLIA vs CIR was low (R = 0.005, r= -0.0593), (R=0.0275, r= 0.167), respectively. In the control group, correlation between ECLIA and ELISA was high (R=0.948, r=0.868) while correlation between ECLIA vs ChLIA and ECLIA vs CIR was low (R= 0.005, r= -0.0593), (R=0.0275, r= 0.167), respectively. Compared to ECLIA, concordance coefficients (p_c) were poor (p_c <0.90) across all assays except for cancers group in ELISA (p_c = 0.913). ECLIA was the only assay to report ranges above 1 ng/mL CYFRA 21-1 (ECLIA, 1.14-21.59 ng/mL; ELISA, 0.79-24.26 ng/mL; ChLIA, 0.062-0.691 ng/mL; 0.08-7.68 ng/mL). Differing sizes of the protein being measured by each assay may have a role in the discrepancies observed. Based upon structural information, a CK19 protein cleaved at one caspase site would result in 18.4 kDA CYFRA 21-1 and 25.8 kDa N-terminus fragments, while many manufactured methods report molecular weights of approximately 30kDa. Given the different CYFRA 21-1 concentration estimates among assays, further characterization of the fragment and its release during epithelial malignancies, such as NSCLC, is imperative to developing effective biomarker assays.

#7072 Lung cancer risk prediction in Asian populations: A study of immune signatures from the Singapore Longitudinal Ageing Studies.

J. Ye[1], J. Meng[1], G. Lai[2], X. Lim[1], D. Goh[1], W. Xu[1], Y. Wu[1], L. Chong[1], D. S. Tan[3], D. W. Lim[1], R. Ho[4], **J. Yeong**[5];
[1]Agency for Science, Technology And Research, Singapore, Singapore, [2]National Cancer Centre Singapore, Singapore, Singapore, [3]National Cancer Centre Singapore, SingHealth Duke-NUS Medical School, Singapore, Singapore, [4]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [5]Agency for Science, Technology And Research, Singapore General Hospital, Singapore, Singapore

Background: The immune system plays a crucial role in the development and progression of cancer, particularly during aging. Given the distinct genetic and environmental variations in Asian populations compared to Western cohorts, we aimed to evaluate the predictive significance of immune markers for early lung cancer detection in an Asian population.
Methods: Two independent cohorts of elderly Asians from the Singapore Longitudinal Ageing Studies (SLAS I/II, NCT03405675) were investigated for immune markers related to lung cancer. Subjects aged 55 years or older, capable of self-ambulation were recruited in 2003 for SLAS I and 2008 for SLAS II (median follow-up period of 17 and 12 years, respectively). Presence of lung cancer served as the clinical endpoint for analysis. Lung cancer diagnoses (69 in SLAS I and 59 in SLAS II) were confirmed through the Singapore National Cancer Registry. Baseline plasma cytokine levels were measured using a 65-plex Human ProcartaPlex Luminex panel (SLAS I: 43 cases, 70 controls; SLAS II: 11 cases, 11 controls). Feature selection was conducted by bootstrapping the summary of 500 differential expression analyses between cases and controls (P<0.05, t-test). Four machine learning algorithms, Logistic Regression, Random Forest, XGBoost, and Support Vector Machine, were used to train models for the prediction of lung cancer using SLAS I, and validated using SLAS II. Characterization of peripheral blood mononuclear cells were performed using a 24-plex flow cytometry on a subset of SLAS II (8 cases, 8 control).
Results: A total of 28 cytokines showed significant differences between cases and controls, with TSLP emerging as the most important in the Random Forest, XGBoost models and Logistic Regression model. Comparing models based solely on demographic factors (age, sex, smoking, and presence of COPD) to models that incorporate demographic and Luminex factors, the mean AUC increased from 0.65 to 0.71. External validation showing an AUC improvement from 0.68 to 0.85. Immuno-profiling using flow cytometry revealed a significantly reduced proportion of γδ T cells and reduced CD57-expression in γδ T cell subsets in lung cancer cases.
Conclusions: The cytokine TSLP may be a biomarker for assessing the risk of lung cancer. TSLP and its interaction with γδ T cells and CD57-expressing γδ T cells may play key roles in aging-related lung cancer development.

#7073 Development and validation of a high-specificity PCR algorithm for ovarian cancer diagnosis.

Eunyong Ahn[1], Se Ik Kim[2], Sungmin Park[1], Sarah Kim[1], Hyunjung Kim[1], Hyejin lee[1], Heeyeon Kim[3], TaeJin Ahn[1], Yong-Sang Song[4]

[1]ForetellMyHealth, Inc., Pohang-si, Gyeongsangbuk-do, Korea, Republic of,[2]Department of Obstetrics and Gynecology, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Department of Obstetrics and Gynecology, Myongji Hospital, Gyeonggi-do, Korea, Republic of

Ovarian cancer (OC) remains one of the most lethal gynecologic malignancies, largely due to difficulties in achieving early diagnosis. To address the limitations of next-generation sequencing (NGS) platforms, particularly their high cost, we developed a qPCR-based method tailored for the early detection of ovarian cancer. Building on our previous research, we systematically selected and evaluated a refined panel of biomarkers optimized for qPCR detection. This study focuses on the development and validation of a highly specific PCR-based diagnostic algorithm, with particular emphasis on detecting high-grade serous ovarian cancer (HGSOC), the most common and aggressive subtype. A total of 30 samples were utilized to train the diagnostic model, supplemented by additional validation using QC-passed (5 benign and 1 cancer samples) and QC-failed samples (1 benign and 9 cancer samples). Biomarker selection prioritized transcripts with low expression in normal and benign tumor samples but significant outliers in ovarian cancer cases. A panel of 12 diagnostic markers and 1 reference marker was finalized based on statistical parameters such as variance, quantiles, and coverage of ovarian cancer-specific aberrations. PCR data were normalized using ACTB as the reference marker. Marker-specific cutoffs were determined from the training data, and a scoring system was devised to effectively differentiate ovarian cancer from non-OC samples. The algorithm achieved 100% specificity within the training set, missing one cancer sample out of 14, resulting in a sensitivity of 92.9%. Validation using QC-passed samples demonstrated a reasonable separation between OC and non-OC groups. The algorithm's robustness was further evaluated using QC-failed samples with challenges such as gDNA contamination and low RNA integrity (RIN), where performance for key markers was largely preserved. In the validation dataset, the algorithm missed one benign sample from the QC-passed group and one cancer sample from the QC-failed group, yielding an overall specificity of 83.3% and sensitivity of 90.0%. To address variability and refine score thresholds, synthetic datasets were generated, enabling the definition of "grey zone" ranges to manage overlapping distributions between OC and non-OC samples. The developed PCR-based diagnostic algorithm achieved exceptional specificity for ovarian cancer detection. This platform shows promise for clinical application in early ovarian cancer diagnosis, particularly for HGSOC, through precise molecular profiling of platelet RNA. Future work will focus on expanding sample diversity and exploring integration with broader biomarker panels.

#7074 Expression and clinical impact of the prostate specific membrane antigen and programmed death-ligand 1 on disseminated tumor cells from early triple negative breast cancer patients.

Anastasios Tolios[1], Vasileios Vardas[1], Ann-Kathrin Bittner[2], Oliver Hoffmann[2], Rainer Kimmig[2], Galatea Kallergi[1], **Sabine Kasimir-Bauer**[2]

[1]Department of Biology, Laboratory of Biochemistry/Metastatic Signaling, Patras, Greece,[2]Gynecology and Obstetrics, Essen University Hospital, Essen, Germany

Background: Triple-negative (TN) breast cancer (BC) is the most aggressive BC subtype resulting in worse outcome. Currently, neoadjuvant chemotherapy (NACT) in combination with an immune checkpoint inhibitor is the standard of care in cases of high-risk early (e)TNBC. With regard to the unmet need of new biomarker research, we recently demonstrated that the presence of the prostate specific membrane antigen (PSMA) as well as the programmed death-ligand 1 (PD-L1) on circulating tumor cells in the blood of TNBC patients (pts) were poor prognostic factors for disease outcome. The present study aimed to investigate the presence and persistence of these markers on disseminated tumor cells (DTCs), already present in the bone marrow (BM) of eTNBC pts, to elucidate their value for current and future treatment strategies.

Methods: 10-20 ml BM of 55 pts (n=55 before and n=48 after NACT; N=44 paired samples) diagnosed between 2014 and 2017, were aspirated and underwent Ficoll-Hypaque density gradient centrifugation, followed by Immunofluorescence triple staining experiments (CK/PSMA/CD45 and CK/PD-L1/CD45) and subsequent VyCAP analysis to identify PSMA and PD-L1 expression on epithelial, cytokeratin (CK)-positive DTCs. Statistical analysis was conducted using the IBM SPSS Software.

Results: In general, PSMA and PD-L1 were upregulated in TNBC pts' DTCs. Before NACT, the $PSMA^+CK^+CD45^-$ phenotype was identified as the most predominant one in 38/55 pts (69%) but rarely present after NACT [4/47 pts (9%); (69% vs 9%, *p<0.001*)]. In 3/4 pts, the $PSMA^+CK^+CD45$ phenotype persisted over the course of NACT, while only in one patient, PSMA-positive DTCs were present exclusively after therapy. The $PD\text{-}L1^+CK^+CD45^-$ phenotype was detected in 21/50 pts (42%) before and in 13/48 pts (27%) after NACT with a persistence of these cells in 6/21 pts. In 13/21 pts, $PD\text{-}L1^+CK^+CD45^-$ DTCs were only present before NACT and 6/13 pts expressed this phenotype after NACT but not at primary diagnosis. The presence of $PSMA^+CK^+CD45^-$ DTCs before NACT was associated with a shorter progression-free (log-rank *p=0.002*, HR=16.1) and overall survival (log-rank *p=0.016*, HR=2.1), respectively. The presence and/or persistence of PD-L1-positive DTCs did not result in any significant correlations with regard to outcome.

Conclusions: PSMA-positive DTCs were identified as a poor prognostic factor with regard to outcome which confirms our data in circulating tumor cells of TNBC. The presence and persistence of PD-L1-positive DTCs is a promising biomarker to stratify pts for checkpoint inhibition and estimate its success.

#7075 Association between homologous recombination deficiency (HRD)-related biomarkers and signatures in advanced solid tumors.

Xiao Yang Jin, Cai Chen, **Xiao Qiao Liu**, Ping Qiu, Alexander Gozman, Razvan Cristescu, Matthew J. Marton

Merck & Co., Inc., Rahway, NJ

Background: Antitumor activity was observed with olaparib plus pembrolizumab in participants with HRD-positive or homologous recombination repair (HRR)-mutated advanced solid tumors. We assessed HRD-related biomarkers and their association with biomarkers that are predictive of response to pembrolizumab.

Methods: HRD-related biomarkers (BRCA mutations, genomic loss of heterozygosity [gLOH], Signature 3 [Sig3; SigMA score]), tumor mutational burden (TMB), and microsatellite instability-high (MSI-H) were analyzed with FoundationOne®CDx using tumor tissue from participants screened for enrollment in KEYLYNK-007 (NCT04123366). Calculation of SigMA score from FoundationOne CDx data was validated using an internal training set (ovarian cancer, n = 44; breast cancer, n = 96) by comparison with deconstructSigs-based Sig3 from paired whole exome sequencing data as a gold standard. Area under the receiver operating characteristic curve (AUROC) was used to assess the association between HRD-related markers and BRCA biallelic mutation. A Wilcoxon rank sum test was used to compare gLOH and SigMA with BRCA biallelic mutation. Associations between all other biomarkers were evaluated using a Spearman correlation coefficient. The data cutoff date was July 14, 2023.

Results: Tumor samples from 2529 participants screened in KEYLYNK-007 were evaluable by FoundationOne CDx; gLOH was evaluable in 1595 participants. Biallelic BRCA mutations were most prevalent in ovarian (8%), prostate (7%), pancreatic (7%), and breast tumors (5%). Among these 4 tumor types, the SigMA score had higher evaluability than the gLOH (100% vs 72%); compared with HRR wild-type tumors, the gLOH and the SigMA score were higher in tumors with biallelic BRCA mutations versus HRR wild-type tumors (P <0.001) with comparable AUROC (0.76 vs 0.71). gLOH (P = 0.036) but not SigMA score (P = 0.092) was also higher in tumors with monoallelic BRCA mutations versus HRR wild-type tumors. Weak to moderate correlations were observed between gLOH and SigMA score, regardless of BRCA mutation status (ρ <0.5). gLOH and SigMA score were not correlated with TMB (ρ = 0.127 and 0.239, respectively) or MSI-H (ρ = –0.091 and 0.026, respectively) across all tumor types.

Conclusions: SigMA score had a similar association with BRCA biallelic mutations when compared with gLOH with higher evaluability. Thus, SigMA score may feasibly provide orthogonal information to detect HRD and should be evaluated further as a potential tool to identify patients who may benefit from treatment with a PARP inhibitor.

#7077 Immunofluorescence microtissue array (IMA) for detection of prognostic cancer stem cell biomarkers.

Madhumita Das[1], Kymkecia Henry[2], Djarie Armstrong[2], Charle Truman[2], Charlie Kendrick[2], Maya S. Saunders[2], Juan E. Anderson[2], **Malcolm J. Lovett**[2], Rose Stiffin[2], Ayivi Huisso[2], Donrie Purcell[2], Marco Ruiz[1], Paulo Chaves[1], Jayanta Kumar Das[2]

[1]Florida International University, Miami, FL,[2]Florida Memorial University, Miami, FL

Cancer is an intricate disease accountable for the deaths of over 10 million people per year in the United States of America. Several scientific studies showed that the cancer stem cell (CSC) markers have prognostic significance in various cancers and are crucial for designing anticancer drugs to lower cancer death. However, there was a lack of rapid, accurate identification, and analysis, of the prognostic cancer stem cell (CSC) biomarkers in numerous cancer patients. In our laboratory, we identified and analyzed prognostic lung cancer stem cell markers (LCSCs) by using the Immunofluorescence microtissue array (IMA) technique in different lung cancer patient's tissue biopsy samples and observed that the increased expression of LCSCs principally, CD44 and CD80 in stage IIIA lung cancer tissues compared to normal lung biopsy tissues. We also investigated pancreatic cancer stem cell biomarkers (PAN CSCs) namely CD44 and CD80 with the IMA technique in pancreatic biopsy tissues. The CD44 fluorescence proved an increased expression in adenocarcinoma pancreatic cell tissues when compared to CD80. We also studied and analyzed the stage progression with ovarian cancer stem cell biomarkers (OCSCs) chiefly CD54 and CD44 using the IMA technique in ovarian cancer patients and normal biopsy tissues. The increased expression of CD44 and CD54 were observed in Stage III ovarian cancer tissues compared to normal ovarian tissue indicating the potential role of these OCSC's biomarkers for the prognosis of ovarian cancer pathogenesis. Our results of prognostic cancer stem cell biomarkers of lung, pancreatic, and ovarian cancers have been analyzed by one-way ANOVA and bioinformatics software (Reactome, Cytoscape PSICQUIC services, STRING) to find underlying molecular mechanism of target gene regulation of increased expression of prognostic CSCs which may give a clue for the prevention and treatment of these cancers. Further research is warranted for these lung, pancreatic, and ovarian CSCs which could be valuable for clinical trials and drug discovery against these CSC biomarkers at early-stage development.

#7079 DNA methylation profiles classifies dysplasia degree in colorectal adenomas.

J. Higareda-Almaraz[1], F. Mancuso[1], P. Canal-Noguer[1], K. Kruusmaa[2], **A. Bertossi**[2];
[1]Universal Diagnostics SA, Madrid, Spain, [2]Universal Diagnostics d.o.o., Ljubljana, Slovenia

Background: Advanced precancerous lesions (APL), precursors to colorectal cancer (CRC), progress from low-grade dysplasia (LGD) to high-grade dysplasia (HGD) through a stepwise accumulation of genomic alterations. Those alterations include mutations, structural variants, and altered methylation patterns, driving dysplastic cells to carcinogenic transformation. Herein, we present a comprehensive analysis of differential DNA methylation profiles to classify dysplasia severity in colorectal adenomas.
Methods: Whole-genome methylation sequencing libraries from 9 HGD and 6 LGD tissue samples were prepared using the NEBNext Enzymatic Methyl-seq kit (EM-seq). To identify differentially methylated regions (DMRs) we have employed two distinct computational tools (DMRcaller and MethylKit) and divided the genome into 1kb bins. DMRs identified by both methods were mapped to genomic features such as genes, gene promoters, CpG islands, and enhancers. Gene ontology and pathway enrichment analyses were performed to elucidate affected biological processes. The identified methylation signature was subsequently investigated in plasma-derived whole-genome EM-seq data from 30 adenoma patients (26 LGD and 4 HGD) and 30 normal samples. Principal component analysis (PCA) and statistical tests were employed to assess its discriminatory power for group classification.
Results: Differential methylation analysis identified 3,751 significant DMRs, with 626 overlapping between both strategies, achieving significant separation of samples by dysplasia grade (FDR = 1.73e-05). The analysis revealed epigenetic changes in genomic clusters regulating DNA-binding transcription factors, tissue morphogenesis, and the Wnt signaling pathway, linking methylation disruptions to dysplasia severity. Furthermore, our methylation signature, when applied to independent plasma samples from HGD and LGD patients, significantly separated the adenoma samples according to their dysplasia grade (FDR = 4.93e-34).
Conclusions: Our analysis enhances the understanding of the molecular biology underlying high- and low-grade dysplastic adenomas. The identified methylation signature, reflecting epigenetic alterations and disruptions in genomic context, allows for the distinction between HGD and LGD in both tissue and plasma samples. This approach advances risk stratification and personalized management for adenoma patients. Further studies are necessary to validate our findings in larger cohorts and to evaluate the potential of this signature in predicting CRC progression.

#7080 Association between atherogenic index of plasma and cancer risk: A prospective cohort study.

Mengbo Xing, Zhangyan Lyu, Wenxuan Li, Yue Cong, Chao Sheng, Hongru Shen, **Kexin Chen**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Introduction: Cardiovascular disease (CVD) and cancer are among the leading causes of morbidity and mortality globally, with shared mechanisms and risk factors. Patients with CVD face higher risk of multiple cancer subtypes and cancer-related death. The initiation of atherosclerotic plaque formation frequently underlies CVD. Atherogenic index of plasma (AIP), a marker of plasma atherosclerosis, had proved to be a powerful biomarker of CVD. However, few studies have investigated the association between AIP and the risk of overall cancer and common site-specific cancers incidence and mortality in the general population.
Methods: Participants were from the UK Biobank database, a prospective population-based cohort. The exposure variable was the AIP, which was defined as log10 (triglycerides/high-density lipoprotein cholesterol) and participants were categorized into four groups based on their AIP values. The main outcomes included the incidence and death of 20 site-specific cancers: oral, esophagus, stomach, colorectum, liver, pancreas, lung, melanoma, breast, uterus, ovary, prostate, kidney, bladder, brain, thyroid, lymphoma, myeloma, leukemia and mesothelioma cancers. Follow-up time was measured in person years from the baseline enrollment time to the date of cancer diagnosis, death, or the end of follow-up (whichever comes first). We used COX proportional hazards regression model to evaluate the association between AIP and main outcomes. Restricted cubic spline was used for further evaluating the non-linear association.
Results: 401,499 participants were included in this study after excluding baseline cancer and covariates missing, and a total of 55,886 and 14,457 cases of primary cancer and cancer deaths were documented during the median follow-up period of 12.6 years and 14.3 years, respectively. The correlation between AIP and overall cancer risk was not significant. For site-specific cancers, higher AIP was positively associated with lung cancer (LC), endometrial cancer (EC), leukemia and mesothelioma risk, and negatively associated with oral cancer, malignant melanoma and ovarian cancer risk. Especially, higher level of AIP was significantly correlated with higher LC risk, (for Q4-Q1, incidence: 1.19, 95% CI:1.07-1.32, $P = 0.001$, mortality: 1.21, 95% CI:1.07-1.37, $P = 0.002$). Compared to the Q1 group, the higher AIP level group (Q2-Q4) had a higher incidence risk of EC (HR range of 1.25 to 1.39, $P < 0.001$). Furthermore, a U-shaped association was found between AIP and colorectal cancer both in incidence (P for non-linear = 0.012) and mortality (P for non-linear 0.024).
Conclusions: AIP was significantly associated with various cancers risk, especially with higher risk of LC and EC. The results suggested that daily monitoring and management of AIP levels are necessary to reduce cancer risk.

#7081 Body roundness index and its association with cancer incidence and mortality: prospective analyses in the UK Biobank.

Wenxuan Li, Zhangyan Lyu, Mengbo Xing, Haodong Liu, **Kexin Chen**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Obesity is a well-established risk factor for cancer, yet traditional metrics like Body Mass Index (BMI) have limitations in capturing fat distribution. The Body Roundness Index (BRI) is a novel measure designed to better reflect body fat distribution and its health impacts. This study aims to explore the associations between BRI, cancer incidence, and cancer mortality, and to compare the predictive performance of BRI and BMI in assessing cancer-related risks.

Methods: We utilized data from the UK Biobank to investigate the associations between the Body Roundness Index (BRI) and both cancer incidence and cancer mortality. BRI was calculated using waist circumference and height according to the following formula: $BRI = 364.2 - 365.5 \times \sqrt{(1 - (\text{waist circumference} / (2\pi))^2 / (\text{height} / 2)^2)}$. Cox proportional hazards models were used to evaluate the relationships between BRI and these outcomes. To evaluate the predictive capabilities of BRI and BMI for cancer outcomes, receiver operating characteristic (ROC) analysis and area under the curve (AUC) metrics were employed. The DeLong test was used to statistically compare the AUCs of BRI and BMI.

Results: This study included 315,876 participants, among whom 42,405 (13.42%) cancer cases and 10,519 (3.33%) cancer-related deaths were identified. The mean BRI was significantly higher in individuals with cancer incidence compared to those without (4.33 ± 1.56 vs. 4.05 ± 1.53, $p < 0.05$), and similarly higher in the cancer mortality group compared to the non-cancer mortality group (4.50 ± 1.62 vs. 4.08 ± 1.54, $p < 0.05$). Adjusting for age, sex, ethnicity, household income, education level, smoking status, alcohol consumption, physical activity, and family history of cancer, BRI showed a positive association with both cancer incidence and mortality ($HR_{incidence}$= 1.04, 95% CI: 1.03 - 1.05, $p < 0.05$; $HR_{mortality}$= 1.07, 95% CI: 1.06 - 1.09, $p < 0.05$). Participants were further categorized into five groups based on BRI quintiles. Compared to the lowest quintile (Q1: -0.15 to 2.81), individuals in Q4 (4.24 to 5.19) and Q5 (5.19 to 23.56) showed a 1.08-fold (95% CI: 1.05 - 1.12) and 1.15-fold (95% CI: 1.11 - 1.19) increased risk of cancer incidence, respectively, as well as a 1.09-fold (95% CI: 1.01 - 1.16) and 1.25-fold (95% CI: 1.17 - 1.34) higher risk of cancer mortality. ROC analysis revealed that BRI ($AUC_{incidence}$= 0.55, $AUC_{mortality}$= 0.58) outperformed BMI ($AUC_{incidence}$ = 0.53, $AUC_{mortality}$= 0.54) in predicting both cancer incidence and mortality ($p < 0.05$).

Conclusions: This study demonstrates that BRI is a significant predictor of both cancer incidence and mortality, outperforming BMI in predictive accuracy. These findings highlight the potential of BRI as a more effective tool for cancer risk assessment and prevention strategies.

#7082 Differentially expressed genes as potential biomarkers in patients with suspected prostate cancer in a population of Colombian men.

Dayanne M. Rodriguez-Hernandez[1], Jovanny Zabaleta[2], Alba L. Combita[1], Rafael S. Parra-Medina[3], Carmen L. Roa[3], Mateo Barros Barraza[1], Alvaro Gutierrez[4]

[1]Grupo de Investigacion en Biologia del Cancer, Instituto Nacional de Cancerologia, Colombia, Bogota, Colombia,[2]Stanley S. Scott Cancer Center - Interdisciplinary Oncology, Louisiana Cancer Research Center, New Orleans, LA,[3]Departamento de patologia del Instituto Nacional de Cancerologia, Instituto Nacional de Cancerologia, Colombia, Bogota, Colombia,[4]Clinica Urologica, Urobosque - Clinica Urologica, Bogota, Colombia

Prostate cancer (PCa) is the second most common type of cancer in men worldwide. In Colombia, PCa ranks first in incidence, with an estimated crude rate of 52.6 cases per 100,000 men. A large proportion of PCa are latent and do not progress or affect the lives of patients. The prostate-specific antigen (PSA) test remains the most widely adopted primary screening biomarker for the presumptive diagnosis of PCa. However, PSA testing demonstrates limited utility as a screening tool due to its low specificity, which increases the risk of unnecessary biopsies and the potential for overdiagnosis. Our overarching goal is to identify specific biomarkers that allow the early detection of patients with suspected PCa. We conducted an exploratory study to identify genetic expression profiles associated with the aggressiveness of the disease in a cohort of Colombian patients attending the Urology clinic for the first biopsy at the National Cancer Institute and Urobosque recruited from 2021 to 2024 in Bogotá, Colombia. We performed transcriptome analysis using Illumina high-throughput RNA sequencing (NextSeq2000 system) on 75 paraffin-embedded tissues (FFPE): 36 Gleason-positive cancer samples (Patients) and 39 PCa-negative samples (Controls). Histopathological results according to Gleason Grade Group (GG) were distributed as follows: (GG1 n=1, GG2 n=2, GG3 n=15, GG4 n=5, and GG5 n=13). The mean age was 65 years, and the PSA ranged between 4.34 ng/ml and 191 ng/ml. We first identified differentially expressed genes (DEGs) by status (patient vs. control), and the DEGs were then correlated with age and PSA. Four hundred and seventy-three (473) genes were differentially expressed between patients and controls, 55 of which were identified as putative biomarkers of PCa using the Key Pathways Advisor software (KPA, Clarivate). Of those, 173 DEGs were correlated with PSA levels and 203 with age. We identified 113 DEGs common to the 3 variables (status, PSA, and age). According to the pathway enrichment analysis performed through KPA, *SPON2*, *SERHL*, *KCNA2*, *PKP3*, and *SLC29A2* genes were the most significant ($p < 0.001$). We found that 6 out of the 10 most significant pathways in which our identified DEGs participate are associated with diseases of the genito-urinary tract, including prostate neoplasms, genital diseases, neoplasms, and male urogenital diseases. This is the first Colombian report that performs transcriptome analysis in a cohort of patients with suspected prostate cancer, showing very specific differences between patients diagnosed with prostate cancer versus patients with negative results. The development of strategies that will lead to a decrease in diagnostic biopsies and overtreatment of indolent disease remains a challenge for early detection of prostate cancer. Additional validations are needed to confirm these data.

#7083 Classical and basal like cells in donor tissues reveal phenotypic heterogeneity of pancreatic intraepithelial neoplasia.

Jude O. Okoye, Rosina Carr, Ahmed M. Elhossiny, Alberto C. Olivei, Imade Williams, Lei Sun, Yaqing Zhang, Eileen S. Carpenter, Timothy L. Frankel, Marina Pasca Di Magliano

Surgery, University of Michigan, Ann Arbor, MI

Pancreatic ductal adenocarcinoma (PDAC) is a deadly disease that affects individuals of all ages, with marginal improvements in patient survival rates over the years despite available treatments. Although Pancreatic Intraepithelial Neoplasia (PanIN), an early lesion, is known to precede PDAC, identifying individuals at risk of developing PDAC remains a challenge for clinicians. Recent studies have demonstrated both inter- and intra-heterogeneity of PDAC, as well as the aggressive nature of its phenotypes, but little is known about the heterogeneity of PanIN and its risk of progression in humans. To address this gap, we investigated transplant-incompetent samples from 89 male and female White and African-American patients, ages 21 to 76 years, collected through the Gift of Life program. Pathologic analyses using basic histological techniques revealed an average burden of three PanINs per 2 cm x 2 cm of donor tissue. Single-cell RNA sequencing and protein validation identified distinct classical and basal-like cells, along with expression of cytokines that correlate to the phenotypes previously reported in PDAC. In some patients, subpopulations within the already-established aggressive basal cells were identified. Regardless of cell phenotype, the senescence state of most of the identified PanINs may explain why these patients were not diagnosed with PDAC during their lifetimes. Given that most PDAC develop from PanIN and PanINs are often found adjacent to tumors, we are currently probing upregulated and downregulated pathways in tumor-associated PanINs and donor PanINs with tumor-like features, as well as crosstalk between classical and basal PanINs and their microenvironments. We are also developing a model to provide further insight into the risk of disease progression using spatial transcriptomic analysis. This knowledge could lead to more effective methods for early detection and treatment of the lethal disease.

#7084 Multi-omics information from tumor-derived extracellular vesicles enables biomarker discovery and early detection in non-small cell lung cancer.

Kelley Van Vaerenberghe, Margie Kinnersley, Claire Seibold, Tre Blohm, Riley Kemp, Sean Lodmell, Amanda Mast, Tia Seibold, Rachel Short Miller, Katie Havranek

FYR Diagnostics, Missoula, MT

Liquid biopsy plays an increasingly influential role in clinical decision making by supporting earlier cancer detection, diagnosis, patient stratification, and treatment monitoring. The most common approaches utilize cell-free circulating tumor DNA or circulating tumor cells in the peripheral blood of cancer patients. However, these methods are impeded by miniscule analyte abundance leading to unfavorable signal to noise ratios. As a promising alternative, extracellular vesicles (EVs) have emerged as a complementary liquid biopsy analyte. EVs are cell-derived lipid membrane encapsulated particles carrying diverse protein, nucleic acid, and metabolite cargos. Blood plasma of cancer patients contains EVs from healthy cells and tissues throughout the body, but also contains a population of EVs derived directly from tumor tissue. These tumor-derived EVs (TDEVs) serve as rich sources of insight into tumor biology and disease pathology. To detect TDEVs amongst background noise, we have developed a clinically applicable, multi-omic EV subpopulation interrogation pipeline that robustly profiles TDEVs in blood plasma. We have demonstrated the ability of the pipeline to enrich cancer markers and detect activation of pathways driving oncogenesis across several different cancers, including non-small cell lung cancer (NSCLC). There is a particularly compelling need for liquid biopsy-based solutions in early detection and screening applications, when patient adherence to standard of care screening regimens could be improved by simplifying the procedure to a routine blood draw. Here, we have applied our EV-omic pipeline in combination with machine learning in a cohort of NSCLC patients to robustly identify Stage I and II disease using blood-based EV proteomic and transcriptomic signatures. Biomarker profiles found to be most important for patient stratification combine markers known to be relevant in tumor tissue along with novel features. This work highlights our EV subpopulation technology and its ability to address the major challenge of early cancer detection in liquid biopsy.

#7085 Analysis of gene expression pattern of glycosphingolipid synthases using tumor tissues from breast cancer patients to identify key targets for early diagnosis and protection of recurrence.

Kanchan Chakma[1], Robiul Hasan Bhuiyan[1], Farhana Yesmin[2], Koichi Furukawa[3]

[1]University of Chittagong, Chittagong, Bangladesh,[2]New York University, New York, NY,[3]Chubu University, Kasugai, Japan

Breast cancer become the most common types of cancer in Bangladesh (female), and accounted 13028 new cases and 6783 deaths in 2020. No efficient therapy has been developed although anti-HER2 antibody therapy has been tried, showing some effects. We need to detect breast cancers at early stage of evolution and also of recurrence, and develop more effective way than the current approaches to eradicate breast cancers. In order to achieve these purposes, it seems essential to find breast cancer-specific antigens as a marker and/or therapeutic targets. Recently, some interesting and promising findings on breast cancers have been reported. For example, ganglioside GD2 was reported to be a marker of breast cancer stem cels, and also play roles in the carcinogenesis. GD3, Gb3 have an association in tumorigenesis as well as cel proliferation, adhesion and migration. More important marker antigens of breast cancers might be present. Aims of the study are to identify novel breast cancer-associated glycolipids including their synthetic enzyme genes, using many surgical specimens and sera from breast cancer patients. Tumor and healthy tissues were collected after surgical resection from hospitals and clinics. Samples are immediately transferred to the laboratory. mRNA was extracted using TRIzol method. cDNA was converted from mRNA using Reverse Transcriptase. qRT-PCR was performed to analyze glycosyltransferase gene expression pattern. Expression of glycolipid GD3-synthase (ST8SIA1), GD2-synthase (B4GALNT1), and Gb3 synthase (A4GALT) are analyzed by RT-PCR using tumor tissues from breast cancer patients. GD2-synthase expression level found significantly higher in tumor tissues compared to healthy tissues. GD3 and Gb3 synthases did not show significant difference between tumor tissues and healthy tissues. GD2 are upregulated in breast cancer patients. This gene may be a novel biomarker for breast cancer and may be useful to design therapeutic drug.

#7086 Serological assays for early detection of HPV-associated oropharyngeal cancer.

Mingyue Wang[1], Jermaine Brown[1], John C. Smith[1], Leonid Dzantiev[1], Anu Mathew[1], Martin Stengelin[1], George Sigal[1], Padhma Yuvaraj[2], Karen S. Anderson[2], Jacob Wohlstadter[1]

[1]Meso Scale Diagnostics, LLC, Rockville, MD,[2]Center for Personalized Diagnostics, Biodesign Institute, Arizona State University, Tempe, AZ

Research Use Only (RUO) sample-sparing MULTI-ARRAY serology immunoassays have been developed for human antibodies to several HPV-16 early antigens. These assays are intended to support research of oropharyngeal cancer (OPC) linked to the human papillomavirus (HPV).The HPV virus can infect the mouth and throat and cause cancers of the oropharynx, i.e. the back of the throat, including the base of the tongue and tonsils. HPV-related cancer incidence is increasing dramatically among men and is unlikely to decrease in the foreseeable future, despite vaccination efforts. As a result, this may become one of the most common cancers in middle-aged men in the United States by 2045. The HPV16 genome consists of six early genes (E1, E2, E4, E5, E6, and E7) and two late genes (L1 and L2) that constitute the viral capsid. Antibodies to early HPV-16 antigens are commonly present in those with OPC but are detected in only approximately 1% of the general population. These antibodies are present many years before cancer develops; thus, they are ideal biomarkers for early detection of OPC.Immunoassays for antibodies against HPV-16 early antigens E1, E2, E6, and E7 were developed in a high-throughput multiplexed format using electrochemiluminescence (ECL) detection, and MULTI-ARRAY 10-spot 96-well plates. Each well has an array presenting recombinant antigens manufactured by Meso Scale Diagnostics, LLC. The assay uses 25 uL of 2,500x diluted serum or plasma. The assay format is simple: diluted sample is incubated in the well with the antigen array followed by a wash and detection of bound anti-HPV antibodies using an anti-human IgG antibody labeled with the SULFO-TAG ECL label. Assay performance was evaluated with approximately 200 commercially sourced samples from apparently healthy individuals and 14 samples from individuals known to be positive for at least one HPV-16 early antigen using an established reference method (Programmable Protein (RAPID) ELISA, Anderson 2015). There was excellent agreement between the two methods.This high-throughput MULTI-ARRAY assay may be useful in research applications requiring screening of a large number of samples for HPV-16 antibodies.For Research Use Only. Not for use in diagnostic procedures.

#7087 Sample-sparing immunoassays for early detection of cancer.

Mingyue Wang[1], Jermaine Brown[1], Daniel Lee[1], Salvia Misaghian[1], Taron Gorham[1], Leonid Dzantiev[1], Anu Mathew[1], Martin Stengelin[1], Ji Qiu[2], Karen Anderson[2], Joshua LaBaer[2], George Sigal[1], Jacob Wohlstadter[1]

[1]Meso Scale Diagnostics, LLC, Rockville, MD,[2]Arizona State University, Tempe, AZ

Research Use Only (RUO) sample-sparing MULTI-ARRAY immunoassays have been developed for several well-established cancer markers. The primary focus of this project is the development of assays to support research of suspicious lung nodules, but many of these selected markers are also relevant to other cancer types. These immunoassays include a serology panel, two biomarker panels, and a single-marker assay. The serology panel includes assays to detect autoantibodies to p53, CTAG-1, and CTAG-2. This panel requires 25 µL of 2,500-fold diluted serum or plasma. A biomarker panel requiring 25 µL of 100-fold diluted serum or plasma detects the following biomarkers: CA15-3, SCFR/Kit, ErbB2, IGFBP-2, MIF, MMP-2, MMP-9 (total), REG4, S100A6, and TNF-RI. A second biomarker panel requiring 25 µLof 10-fold diluted serum or plasma detects the following biomarkers: CA125, Ca19-9, CEACAM-5 (CEA), EGFR, VEGFR-1/Flt-1, FLT3L, HE4, MMP-3 (total), and osteopontin. Finally, an assay for the core lung cancer biomarker cytokeratin-19 was developed. All assays had dynamic ranges that span 3-4 logs and are sufficiently sensitive to measure native levels in commercially sourced samples from apparently healthy individuals. The assays were preliminarily evaluated using more than 100 commercially sourced serum or plasma samples from apparently healthy individuals and more than 100 commercially sourced serum or plasma samples from patients with lung or other cancers. Many of the biomarkers had significantly different concentrations in several cancers compared to samples from apparently healthy individuals. These RUO assays may be useful in identifying biomarkers for a multi-marker panel to study early cancer.

#7091 Disparities in non small cell lung cancer treatment and outcomes among Native Hawaiian and other Pacific Islander populations.

Chalothorn Wannaphut[1], Manasawee Tanariyakul[1], Jared Acoba[2]

[1]Internal Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI,[2]University of Hawaii Cancer Center, Honolulu, HI

Background:The American Cancer Society and National Cancer Institute, emphasize the critical need to disaggregate data for Asian, Native Hawaiian, and Other Pacific Islander (NHOPI) populations to better understand racial disparities in cancer. NHOPI populations are highly diverse, with distinct genetic, cultural, and socioeconomic backgrounds that can influence cancer outcomes. This study aims to analyze Native Hawaiian, and other Pacific Islander patients with non-small cell lung cancer (NSCLC) to identify disparities in prognostic factors, treatment, and outcomes.
Methods:Data were abstracted from 4,143 NSCLC patients treated at Queen's Medical Center in Honolulu, Hawaii, between 2000 and 2022. Patients were grouped by race: White, Asian, Native Hawaiian, and other Pacific Islander. Kaplan-Meier survival estimates, and Cox proportional hazards models were applied to adjust for demographic, clinical, and treatment-related factors.
Results:Among the 4,143 patients diagnosed with NSCLC, the racial distribution included 971 White patients, 2,324 Asian patients, 637 Native Hawaiian (NH) patients, and 211 Pacific Islander (PI) patients. PI patients were generally younger, more likely to present with late-stage disease, and more often underinsured compared to other racial groups including Native Hawaiians. Median overall survival (OS) was 20.9 months for whites, 20.1 months for Asians, 15.8 months for NH, and 10.3 months for PI ($p<0.001$). Both NH and PI patients were less likely to undergo surgery despite having stage I disease (NH HR 0.52, 95% CI 0.33-0.84; PI HR 0.29, 95% CI 0.12-0.70). Additionally, PI patients less often received systemic therapy for advanced-stage disease (PI HR 0.56, 95% CI 0.38-0.81) compared to whites. In adjusted models without treatment, NH and PI
patients exhibited worse survival compared to whites (NH HR 1.12, 95% CI 1.01-1.26; PI HR 1.16, 95% CI 0.97-1.39). However, when treatment was included in the model, these differences were no longer significant.
Conclusion:Native Hawaiian (NH) and Pacific Islander (PI) patients with cancer should be studied independently due to their unique sociodemographic characteristics and treatment patterns. Both groups showed lower survival rates compared to whites, largely due to disparities in treatment.

#7092 The change in Asian American/Native American/Pacific Islander demographics in interventional clinical trials in Hawai'i.

Aiesha Pradhan, Jangsoon Lee, Naoto T. Ueno, Toshiaki Iwase

University of Hawai'i Cancer Center, Honolulu, HI

Asian Americans, Native Hawaiians, and Pacific Islanders (AA/NH/PI) contribute significantly to the state's ethnic diversity. Despite their substantial presence, these groups face considerable health disparities, particularly in access to and participation in clinical trials. Furthermore, detailed accrual data based on ethnicity is missing as national datasets often aggregate AA/NH/PI populations into a single racial category. The aim of this study is to investigate change in accrual rates to interventional oncology clinical trials over time and determine the patient demographic factors that caused disparities in the trial participation. Through the Clinical Trial Management System at the University of Hawai'i Cancer Center, we collected patient enrollment data for NCI-funded interventional clinical trials (i.e., National Cancer Trials Network, NCTN and NCI Community Oncology Research Program, NCORP trials) conducted within the Hawai'i Cancer Consortium (HCC) between 2005 and 2020. The HCC is constituted by seven entities, including 2 major healthcare organizations in Hawai'i. The dataset comprised of demographic details such as biological sex, age, and race. Among 2,341 study participants who were identified by screening, 870 were enrolled in non-therapeutic studies, while 1,471 were involved in therapeutic trials. Nearly 50% identified as Asian American, 25% as White, and 12% as Native Hawaiian, and 3% as Pacific Islander. The remaining 10% were categorized as Black, American Indian, Multiracial, Other, or Unknown. The number of Asian American participants showed a declining trend until 2014, after which it began to recover. The number of Native Hawaiian and Pacific Islander participants has been stable over this time period. Female participation consistently exceeded male participation over the study period. The annual enrollment of all participants remained low until 2014 but steadily increased, reaching its peak in 2019. This study revealed that local AA/NH/PI accrual has a different trend from the national accrual over time. While the findings suggest that local, continuous community outreach efforts have been effective, male patient accrual remains inequitable. To address this disparity, our center is currently implementing an educational program aimed at Native Hawaiian men to help eliminate mistrust in clinical trial participation.

#7093 Assessing financial toxicity as a correlate of symptom burden in Latina breast cancer patients.

Melissa Gaviria[1], Bharat Narang[1], Ashley M. Rodriguez[1], Francesca Gany[1], Eida M. Castro-Figueroa[2], Victoria Blinder[1], Rosario Costas-Muniz[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Ponce Health Sciences University, Ponce, Puerto Rico

Background/Objective: Depression, anxiety, insomnia, and fatigue often occur concurrently in cancer patients, with Latinos reporting higher burdens compared to non-Latino Whites. These symptoms adversely affect cancer progression and are associated with elevated cancer mortality. Financial toxicity, the financial distress of patients after a cancer diagnosis, has been linked to poorer cancer outcomes. This study aims to explore the relationship between financial toxicity and depression, anxiety, insomnia, and fatigue in Latina breast cancer patients.
Methods: Data was collected from 30 Spanish-speaking Latina breast cancer patients at Memorial Sloan Kettering Cancer Center who endorsed symptoms of depressed mood, insomnia, and fatigue. Depression and anxiety were assessed through the Hospital Anxiety and Depression Scale (HADS), fatigue was measured through the Fatigue Symptom Inventory (FSI), and insomnia was measured using the Insomnia Severity Index (ISI). Financial toxicity was assessed using the FACIT-Cost scale. An independent samples t-test was employed for the analysis, with a p-value of 0.05.
Results: The study participants included 30 Latina breast cancer patients with an average age of 58.9 years. 46.7% of patients were married, and most reported limited English proficiency (86.7%). Most patients had stage 1 or 2 breast cancer (86.7%), were currently receiving treatment (56.7%), and were within five years of their breast cancer diagnosis (73.3%). Patients experiencing higher financial toxicity had significantly higher anxiety scores ($\bar{x}$ = 8.1, SD = 4.5, p = 0.003), depression scores ($\bar{x}$ = 7.6, SD = 3.2, p = 0.001), insomnia levels ($\bar{x}$ = 12.0, SD = 7.0, p = 0.035) and fatigue ($\bar{x}$ = 66.2, SD = 31.0, p < 0.001) compared to those with lower financial toxicity (respectively, $\bar{x}$ = 4.1, SD = 2.5; $\bar{x}$ = 3.5, SD = 2.6; $\bar{x}$ = 8.1, SD = 3.9; $\bar{x}$ = 26.3, SD = 22.9).
Conclusion: Latina breast cancer patients experiencing financial toxicity reported higher levels of depression, anxiety, insomnia, and fatigue compared to those with less financial toxicity, suggesting that financial toxicity has a relationship with symptom burden. Our findings highlight the need to understand how to mitigate financial toxicity to improve cancer care outcomes, or to improve symptom management to reduce financial hardship. Possible interventions might include financial planning with healthcare professionals; leveraging social networks to disseminate financial resource and symptom management information; engaging community health workers and navigators to guide patients and their families toward available financial resources and better symptom management strategies; and building financial self-efficacy and involving family members in financial planning may help lessen the financial distress and symptom burden experienced by Latina breast cancer patients.

#7094 Financial risks in southeast asian patients with cancer.

Nguyen H. Tran, Jordan Mason, Wendy Hanson, Kimberly Steinbert, Minji Lee, Robert McWilliams

Mayo Clinic, Rochester, MN

Background: Financial toxicity can have devastating long-term effects for cancer patients (pts) and their family members which may impact their access to care, adherence and, ultimately, outcomes. Identifying those at greatest risk is key to mitigating costs and distress to pts. Here we report results from a screening questionnaire on financial risks among Southeast Asian (SE-A) pts.

Methods: This retrospective review included pts on the cancer patient registry at Mayo Clinic (Arizona, Florida, Minnesota, Wisconsin, and Iowa) who had completed a clinical visit in an oncology-related department (hematology, medical oncology, radiation oncology, etc) within the past 270 days prior to 6/4/24. Pts completed an electronic social determinant of health questionnaire of which financial risks and transportation needs are the focus of this study: 1) how hard is it for you to pay for the very basics like food, housing, medical care, and heating? 2) in the past 12 months, has lack of transportation kept you from medical appointments or from getting medications. Our primary endpoints include the association between financial risks, active bad debts (defined as having >$5000 owed for high active bad debt, $0-$5000 for some active bad debt), pre-appointment review (PAR) flag status and transportation needs. Descriptive statistics and Chi-square were used to analyze factors associated with financial risks.

Results: We identified 81,731 pts who completed the questionnaire, among whom 387 were SE-A. Compared to non-SE-A and White, 6.5% have some active bad debt vs 3.3% and 3.6% ($p<0.001$), and 1.0% had high active bad debt vs 0.8% and 0.7% ($p<.001$); 58.4% had low financial risk vs 60% and 66% ($p<0.001$) and 2.3% with high risk vs 1.5% and 1.6% ($p<0.001$), 4.1% declined to answer and 29.7% were unknown. Bad debt was associated with PAR flag ($P <0.001$) and financial risk ($P<0.001$). For transportation among SE-A, 2.3% had unmet transportation needs, 1.8% declined/unable to answer, while 17.8% were unknown. Those with transportation needs were associated with active debt and financial risk ($p<0.001$).

Conclusion: In this cohort, we identified SE-A with highest rates of active debt and higher financial risks compared to Non-SE-A and White. A large percentage of patients declined to answer or are unknown. Future pilot questionnaire is in development to identify pts concerns for medical costs, financial strain and the receptivity to be connected to resources/referrals to address them.

#7095 Effectiveness of a breast cancer screening program among non-adherent women in Puerto Rico: A community-based participatory research effort of the Puerto Rico CEAL Community Outreach and Engagement Group.

Norangelys Solis-Torres[1], Karelys Canales-Birriel[1], Nashaly Saldana-Santiago[1], Alondra Mercado-Andino[1], Christian Rivera-Catala[1], Cecilia Marino-Nieto[1], Hector Contreras-Mora[1], Cynthia Perez[2], Vivian Colon-Lopez[1]

[1]Cancer Control and Population Sciences, UPR - Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Biostatistics and Epidemiology, Graduate School of Public Health, University of Puerto Rico, San Juan, Puerto Rico

Background: Breast cancer is the most common cancer (31%) and the leading cause of cancer death (19%) among women in Puerto Rico. The United States Preventive Service Task Force (USPSTF) recommends biennial breast cancer screening by mammography for women aged 40-74. Evidence has documented that Community Health Workers (CHWs) can help increase breast cancer screening rates and improve health equity through community-based approaches.
Objective: The purpose of the study was to assess the effectiveness of a CHW-delivered intervention to increase mammography screening among non-adherent Hispanic women in Puerto Rico.
Methods: PR-CEAL's Community Outreach and Engagement Group conducted an island-wide community-based randomized controlled trial from December 2023 to June 2024. Eligible non-adherent women for breast cancer screening aged 50-74 years were recruited. CHWs collected baseline information on participants' barriers and intentions to schedule an appointment for overdue breast cancer screening using a survey and were randomly assigned to the intervention or a comparison condition. The intervention consisted of a session led by a CHW, where participants received education on breast cancer screening. Participants were randomly allocated into an intervention group, which received information on cancer screening, or a comparison group, which received general health information. Follow-up calls assessed screening status at weeks four and eight, changes in reported barriers, and intent to screen by self-reported confirmation of scheduled appointments. The main outcome variable was having scheduled an appointment for their overdue mammography. Pearson's test was conducted to evaluate the association of having scheduled an appointment among intervention groups.
Results: A total of 89 participants were recruited with an overall median age of 59 (range 55-63) years. Women who received the intervention were RR=1.08 (95% CI: 0.35-3.36) times more likely to report having a higher intent to screen in comparison to the control group; however, the magnitude of this effect was not statistically significant, p-value = 0.898. A positive trend in intent to screen was observed over three time points: baseline (10%), first follow-up (16%), and second follow-up (20%), p-value=0.115.
Conclusion: The intervention demonstrated a positive influence of CHWs on mammography appointment scheduling, but the effect was not statistically significant. Future studies with larger sample sizes are needed to further increase power size estimations and evaluate the impact of CHW-mediated initiatives for cancer prevention and screening promotion in community-based settings.

#7096 Barriers and intention to screen for colorectal cancer among non-adherent women in Puerto Rico: an assessment from the Puerto Rico Community Engagement Alliance (PR-CEAL)..

Karelys I. Canales-Birriel[1], Cynthia M. Perez[2], Norangelys Solis-Torres[1], Nashaly M. Saldana-Santiago[1], Alondra K. Mercado-Andino[1], Christian Rivera-Catala[1], Cecilia Marino-Nieto[1], Hector Contreras-Mora[1], Vivian Colon-Lopez[1]

[1]Cancer Control and Population Sciences, UPR - Comprehensive Cancer Center, San Juan, PR,[2]Department of Biostatistics and Epidemiology, Graduate School of Public Health, University of Puerto Rico, San Juan, PR

Background: Colorectal cancer (CRC) ranks among the top three most diagnosed cancers in men (11.1%) and women (9.5%) in Puerto Rico (PR). Despite efforts to promote early detection, screening rates remain suboptimal, likely due to cultural beliefs, socioeconomic disparities, and limited healthcare access.
Objectives: This study assessed the barriers and intentions for screening among Hispanic women in PR who are non-adherent to FOBT and colonoscopy guidelines.
Methods: PR-CEAL conducted a community based participatory research across various community settings in PR from December 2023 to June 2024, targeting women aged 45-75 who were non-adherent to CRC screening according to the USPSTF guidelines. Eligible women completed an in-person baseline survey where participants provided information about barriers they faced regarding screening and their intentions to screen. To encourage adherence to CRC screening recommendations, community health workers (CHWs) distributed educational materials aligned with USPSTF guidelines. Log-binomial regression models assessed the associations between test modality, barriers, and readiness for screening; *how ready do you feel to schedule an appointment to get tested?* controlling for age and health insurance.
Results: Enrolled women had a median age of 59, 31.2% held a bachelor's degree or higher, 64.9% earned $15,000 or less, 68.2% had public health insurance, and 43.4% married or cohabitating. Readiness for CRC screening differed by test modality ($p < 0.001$), with the highest readiness observed among women in the FOBT group (95.2%, n=118), followed by the colonoscopy group (71.2%, n=84) and the dual modality group (71.4%, n=110). Log-binomial models showed that women in colonoscopy group and women in dual modality group were less likely to be ready for screening compared to FOBT group (RR=0.76, 95% CI: 0.67-0.85; RR=0.74, 95% CI: 0.67-0.83; respectively). Key barriers to CRC screening included the lack of physician recommendation (50.0%, n=198) and being too busy (18.7%, n=74). Women in the dual modality group were more likely than those in FOBT group to report barriers such as not having symptoms (RR=2.15, 95% CI: 1.14-4.04) and being too busy to undergo screening (RR=1.81, 95% CI: 1.07-3.06).
Conclusions: Findings show varying readiness and barriers for CRC screening by test modality. Women in FOBT group demonstrated higher readiness, highlighting the importance of non-invasive tests in promoting screening. Tailored interventions using CHW should address barriers while highlighting the benefits of screening for asymptomatic individuals. Strategies to improve readiness could include enhancing patient education, increasing awareness of screening, and emphasizing the simplicity and accessibility of FOBT.

#7097 Predictors of physician recommendations on cancer screening in women aged 21 to 75 an analysis of sociodemographic, clinical and psychosocial characteristics.

Nitza E. Malave-Velez[1], Ana C. Sala[1], Cecilia Marino Nieto[1], Christian Rivera Catala[1], Cynthia M. Perez[2], Vivian Colon Lopez[1]

[1]Cancer Control and Population Sciences, UPR- Comprehensive Cancer Center, San Juan, PR,[2]Department of Biostatistics and Epidemiology, Graduate School of Public Health, University of Puerto Rico, San Juan, PR

Background: Lack of physician recommendation for cancer screening tests is a critical determinant of cancer screening uptake and remains a major barrier in screening and prevention efforts. This study aims to analyze the sociodemographic, psychosocial, and clinical factors related to lack of physician recommendation in women living in Puerto Rico, ages 21 through 75.
Methodology: A cross-sectional study was conducted by the Puerto Rico Community Engagement Alliance. A total of 500 women, non-adherent to either breast, cervical or colorectal cancer screening were recruited island wide for a randomized controlled trial (RCT) from December 2023 to June 2024. Follow-up calls assessed willingness to undergo either breast, colorectal and cervical cancer screening at four and eight weeks. The main outcome for this analysis was physician recommendation as barrier for screening, categorized as those whose physician did not recommend cancer screening (53%) and those whose physician recommended it (47%). Sociodemographic, clinical, and psychosocial data was collected at baseline. Regression models were conducted to assess the associations between these characteristics and physician recommendation using binary logistic regression. The analysis included models adjusted for age, chronic diseases and high cholesterol. Group differences were analyzed using Mann Whitney u test, alpha 5%.
Results: Participants who lack physician recommendation for cancer screening were significantly older (median=58 years) when compared with those that have received a recommendation (median = 55 years, $p < 0.001$). Significant differences in provider recommendation were also observed among participants reporting chronic diseases in which those participants who lack a physician recommendation are more likely to have diagnosis of heart disease, (15.47% p-value= 0.027), asthma (27.55%; p-value), and high cholesterol (37.74%; p-value). Participants who reported not receiving physician recommendation at baseline had higher willingness to undergo colonoscopy (baseline = 78.88%; first follow-up = 90.30%) in comparison to those who received recommendation (baseline = 63.96%; first follow-up = 78.08%) at both baseline ($p= 0.015$) and during the first follow-up ($p = 0.014$). No significant differences were observed in willingness to undergo other cancer screening test and physician recommendation ($p>0.05$).
Conclusion: Lack of physician recommendation for cancer screening is associated with differences in sociodemographic and clinical characteristics, such as older age and higher prevalence of chronic diseases. We observed statistical differences between willingness to colonoscopy screening at baseline and first follow-up, which highlight missed opportunities during clinical encounters for the promotion of cancer screening in these participants.

#7099 Development of HPV awareness and prevention education materials for Hispanic/Latinx community health educators.

Daisy Montoya[1], Laura Adame[2], Jesus Bastian[1], Najla Dabbagh[1], Yelitza Campos[1], Julie Dang[2], Laura Fejerman[2]

[1]UC Davis, Davis, CA,[2]Comprehensive Cancer Center, UC Davis, Davis, CA

The human papillomavirus (HPV) is the most common sexually transmitted infection in the United States. Although there is no cure for HPV infections, implementation of highly effective preventable measures (screening tests, HPV vaccination) has reduced the incidence of HPV-related cancers. However, the Hispanic/Latinx (H/L) community continues to experience high incidences of HPV infections and some of its related cancers. H/L underutilization of preventative health services can be partly explained by limited health care access, low health literacy levels, and language barriers. To address some of these determinants, the program 'Mas Vale Prevenir' aims to develop culturally and linguistically appropriate HPV related cancer prevention educational materials to train community health educators (Promotores) in California. To inform material development, we conducted 4 informal feedback sessions (N=24) and 2 focus groups with Promotores (N=12) which were analyzed using qualitative methodology (Thematic Analysis). We identified insights related to pre-determined themes: learning preferences (e.g., use medical terminology) and opinions related to content (e.g., liked narrative format, relatability) as well as two emerging themes: importance of content (e.g., normalizing the material, H/L-specific statistics) and the role of Promotores (e.g., bridge between doctors and community). Results from the focus groups analysis were used to refine materials in an iterative manner. Engaging H/L Promotores in the development of health educational materials is essential for their effectiveness as community educators. The next step will be to implement and evaluate the 'Mas Vale Prevenir' program to assess its effectiveness in reducing HPV related cancer health disparities.

#7100 The relationship between social deprivation and immune suppression in Hispanic/Latina patients with breast cancer.

Elexa P. Rallos[1], Sabrina Carrel[2], Michelle Li[3], Batul Al-Zubeidy[4], Edgar Gonzalez[4], Aaron G. Baugh[4], Matthew Jacobo[4], Cheol Park[4], Robert Hsu[4], Dominic Zavala[4], Steven Do[4], Michael F. Press[5], Ming Li[6], Anastasia Martynova[4], Priya Jayachandran[4], Daphne Stewart[4], Chanita Hughes-Halbert[6], Mariana C. Stern[6], Evanthia T. Roussos Torres[4]

[1]Eastern Virginia Medical School, Norfolk, VA,[2]University of South Carolina School of Medicine, Greenville, SC,[3]New York Medical College, New York, NY,[4]Department of Medicine, Division of Oncology, Keck School of Medicine of USC, University of Southern California, Los Angeles, CA,[5]Department of Pathology, Keck School of Medicine of USC, University of Southern California, Los Angeles, CA,[6]Department of Population and Public Health Sciences, Keck School of Medicine of USC, University of Southern California, Los Angeles, CA

Immunosuppressive cells, such as myeloid-derived suppressor cells (MDSCs), prevent tumor infiltrating-lymphocytes (TILs) from mounting an anti-tumoral immune response in solid tumors, including breast cancer. Even though genetic factors, such as race and ethnicity, are suspected to contribute to immunosuppression, social determinants of health—non-medical factors including economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context—may also contribute to observed differences in tumor growth and therapeutic response across different racial and ethnic groups. We hypothesized that the combined effects of Hispanic/Latina origin and higher social deprivation contribute to an increased proportion of immunosuppressive cells in circulation. In this study, our IRB-approved cohort consisted of 131 patients with varied histologic subtypes and stages of breast cancer including 71 Hispanic/Latina (H/L), 37 Non-Hispanic White (NHW), 15 Asian, and 8 African American/Black (AAB) individuals. To assess the proportion of immunosuppressive cells in circulation, we performed flow cytometry analysis of peripheral blood mononuclear cell (PBMC) samples obtained from our cohort. To study social determinants of health across racial and ethnic groups, we utilized the Social Deprivation Index (SDI) as a proxy using each patient's ZIP Code and stratified SDI values into quartiles (where lower quartile indicates less social deprivation). Preliminary data suggested that H/L groups have a greater percentage of circulating suppressive granulocytic (G)-MDSCs (0.31% vs. 0.14%) compared to NHW groups. A similar trend was noted for regulatory T cells with 1.51% in H/L and 1.22% in NHW. This finding also appeared to continue when further adding social deprivation, where groups with both higher social deprivation and H/L origin demonstrated a trending increase in G-MDSCs and monocytic (M)-MDSCs. Preliminary differences in circulating immune cells in in the H/L group could be driven by genetic differences in one or more of the ancestral components and/or by specific exposures that may be more prevalent among H/L women, such as stress, environmental exposures, or others. We are investigating additional data from patient surveys to further inform the observed correlations between SDOH and immune cell differences. Studies are also underway to examine differences in intratumoral immune suppressive cell types in a subset of 13 tumor specimens from 3 H/L and 9 NHW patients with early-stage hormone receptor positive breast cancer. These findings demonstrate the importance of further investigation of the multi-level determinants of response to treatment, especially in patients receiving immune checkpoint inhibitors across diverse racial and socioeconomic populations.

#7101 Envisioning leadership for Latino cancer health equity in prevention and control.

R. F. Trejos, K. Liller;
University of South Florida, Tampa, FL

Background: Latinos are the second-largest ethnic population in the United States of America (USA), and although their cancer rates, for most cancer types, have significantly decreased over the last decade, Latino cancer inequities and disparities continue to result in late cancer diagnosis, cancer treatment-related burden, cancer-related complications, and poor quality of life. Leadership training and skills are needed to adequately prepare healthcare professionals to respond to the complex and ever-evolving nature of cancer inequities. Therefore, this presentation will evaluate current curricular offerings discussing leadership and/or health equity to provide evidence-based recommendations to inform future clinical and community-based curricular and educational approaches.

Methods: We reviewed multiple trainings and educational opportunities currently offered in the USA that discussed or included leadership and/or health equity components and a focus on cancer. Programs were evaluated to understand current gaps in leadership training and the relevance of competency-based education as an effective curriculum development approach to inform the development of future curricular offerings. The literature on leadership for health equity in cancer among Latinos was summarized using the PubMed, Embase (Elsevier), and Scopus (Elsevier) databases following the PRISMA guidelines.

Results: The existing programs in the evidence included the Cancer 101, Éxito Latino Cancer Research Leadership Training, Redes en Acción, and Minority Training in Cancer Control Research programs. Results suggest the importance of developing, implementing, and evaluating formal and informal training programs on leadership that can equip healthcare professionals to respond to the complex and ever-evolving nature of Latino cancer inequities. Most programs included post-baccalaureate youth interested in doctoral-level training. However, absent from the identified curricular offerings are capacity-building training and leadership training, as well as skills that would enable researchers and cancer care providers with the necessary tools to become advocates and patient-driven supporters of patients plagued by cancer and cancer care-related disenfranchisement.

Discussion and Conclusion: Leadership education efforts to tackle Latino cancer inequities are necessary to ensure responding to the unique and complex needs and realities of Latinos in the USA, which can inform clinical and community-based initiatives recognizing the historical and intergenerational factors that shape Latino health.

#7103 p16 predictiveness for HPV-associated head and neck cancer in African Americans compared to Non-Hispanic Whites.

Maria Christiene Lawas[1], Mei-Chin Hsieh[2], Siddhi Patil[3], Anju Duttargi[4], Aishani Kulshreshtha[1], Lucia Martinez Cruz[3], Bailey Garb[1], Shiting Li[1], Nisha D'Silva[1], Maureen Sartor[1], Laura Rozek[5]

[1]University of Michigan Medical School, Ann Arbor, MI,[2]Louisiana Tumor Registry, New Orleans, LA,[3]Georgetown Lombardi Comprehensive Cancer Center, Washington, DC, DC,[4]Georgetown University Medical Center, Washington, DC, DC,[5]Georgetown University Medical Center, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC, DC

This project addresses the need for precision biomarkers for HPV-associated oropharyngeal squamous cell carcinoma (OPSCC) in diverse populations. The immunohistochemistry (IHC) test for the protein p16 is the only clinically approved biomarker for HPV-status in OPSCC and is incorporated into the AJCC v8 staging for OPSCC. It is also used as inclusion criteria for clinical trials, determining the eligibility of patients to receive de-intensified treatment. Literature demonstrates that p16 IHC is estimated to have a sensitivity of 94% and a specificity of ~85-90%. However, the predictive value is lower in populations with lower HPV prevalence, and for these reasons, it is important to study the predictive value of p16 in subpopulations. We investigated the reliability of p16 IHC as a surrogate for HPV+ in a cohort of OPSCC comprised of African Americans (AA) (n=58) and Non-Hispanic Whites (NHW) (n=88) from the Louisiana Tumor Registry (LTR) and University of Michigan (UM). HPV testing was performed on FFPE DNA using bulk RNA sequencing and mapping to high-risk HPV types. Twenty-nine percent (17/58) of AA and 88% (77/88) of NHW were HPV-positive based on RNA. However, 25/58 (43.1%) AA were p16+ and 77/88 (87.5%) of NHW were p16+. The sensitivity of the test for AA and NHW was estimated to be 94.1% and 94.8%, respectively. The specificity of the test for AA and NHW was estimated to be 78.0% and 63.6%, respectively. The positive predictive value (PPV) was significantly lower in AA patients (0.64) compared to NHW (0.948) (p-value = 0.00024, proportions test). In all, the correspondence of p16 and RNA HPV+ was 16/25 in AA OPSCC. Differential expression analysis confirmed that the expression of CDKN2A, the gene responsible for producing p16, was significantly different in HPV RNA positive status versus HPV RNA negative status of any race (logFC ~2-fold, $p < 0.05$) and was not significantly different between NHW HPV RNA positive and AA HPV RNA positive groups (logFC = -0.49, p-value > 0.05). ROC analysis demonstrated that CDKN2A expression had predictive ability for HPV RNA status across all patients (AUC = 0.92), with subgroup analyses showing even higher predictiveness in AA patients (AUC = 0.96) compared to NHW patients (AUC = 0.90). These results indicate that use of p16 IHC for patient stratification in AA OPSCC cases could lead to p16+ HPV-negative cases inappropriately treated as HPV+ tumors, leading to adverse outcomes. This highlights the need for confirmatory HPV testing in OPSCC patients, especially in subpopulations that have a low attributable fraction of HPV, to avoid undertreatment. Our ongoing work will address the use of other HPV-related biomarkers and characterization of pathways that differ between AA and NHW OPSCCs. Prioritizing diversity in patient populations and outcomes research ensures advancements in cancer research reflects all populations, especially those historically underserved.

#7104 Variation in breast cancer molecular sub-types prevalence among ethnic groups within Ghana and implication for tumor biologic studies among African-Americans.

Moses A. Dokurugu[1], Moses Kamita[2], Sylvester Antwi[2], Rose Dampson[3], Patrick K. Akakpo[4], Harriet Larrious-Lartey[2], Valerie Ofori Aboah[2], Foster Amponsah[5], Josephine Nsaful[3], Michael Nortey[6], Kwabena Agbedinu[7], Samuel Mensah[8], Mohammed Sheriff[1], Nelson Affram[9], Ijeoma Aja[10], Alex Mremi[11], Theresia Mwakyembe[11], Mohammed Bharmal[12], Veneranda Nyarko[3], Ali Haythem[12], Eleanor Walker[12], Jessica Bensenhaver[12], Albert Levin[12], Evelyn M. Jiagge[2]

[1]Tamale Teaching Hospital, Tamale, Ghana,[2]Henry Ford Health System, Detroit, MI,[3]Korle Bu Teaching Hospital, Accra, Ghana,[4]Cape Coast Teaching Hospital, Cape Coast, Ghana,[5]Eastern Regional Hospital, Koforidua, Ghana,[6]Cape Coast Teaching Hopsital, Cape Coast, Ghana,[7]Komfo Anokye Teaching Hospital, Kumasi, Ghana,[8]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,[9]Ho Teaching Hospital, Ho, Ghana,[10]Eastern Regional Hospital, Ho, Ghana,[11]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of,[12]Henry Ford Health, Detroit, MI

Background: Triple negative breast cancer (TNBC) is most prevalent in women with Western sub-Saharan African ancestry, including African Americans (AAs) and continental African women. This similarity in risk has been shown to be due in part to the shared genetic ancestry resulting from the trans-Atlantic slave trade. To understand the role of genetic African ancestry in the risk and tumor biology of TNBC in AAs, we established a research collaboration in Ghana (West African, WA), Precision Medicine for Aggressive Breast Cancers (PMABC), to access WA female patients and their tumors for comparative studies with AAs. A principal goal of the PMABC study is to take a more inclusive approach to broadly capture the epidemiologic and tumor biologic characteristics of breast cancer within Ghana.

Methods: To achieve this objective, PMABC is based on a collaborative network of six Ghanaian institution, representing the entire country, and in this first analysis, we describe how patient characteristics, including ethnicity, are related to molecular subtypes of breast cancer in this prospectively collected cohort. We used multinomial logistic regression to evaluate the associations between the molecular breast cancer sub-types (Luminal A, Luminal B, HER2+, TNBC) and patient characteristics.

Results: Sociodemographic data, clinical/pathologic characteristics, and biological samples were collected from a total of 690 consented cases. Among these women the mean age (SD) was 51.37 (13.5) years and mean BMI was 27.9. Importantly, nine different ethnicities were captured in the sample, and 79% of the patients belonged to one of the four main Ghanaian ethnic groups: Akan (Southern, n=352, 51%), Dagomba (Northern, n=36, 5.2%), Ewe (Southeastern, n=93, 13.5%), and Ga (Southwestern, n=61, 8.8%). 38.4% of all the cases were TNBC. There was a significant difference in the risk of developing TNBC among the different ethnic groups; in particular, the Ga ethnic group had the lowest TNBC proportion at 23.7%. Relative to the Akan TNBC prevalence (42.8%) and the Luminal A subtype, the Ga had a 61% decreased risk of TNBC (odds ratio =0.39; p=0.007). Additionally, being menopausal was associated with a decreased risk of developing Luminal B (p=0.029), HER2+ (p=0.018), and TNBC (p=0.027), relative to luminal A subtype. There was also a significant decrease in the age of diagnosis for those with the Luminal B (p=0.008) and HER2+ (p=0.025) subtypes when compared with those who had Luminal A subtype.

Conclusion: These findings are among the first to indicate significantly different risk of TNBC among the geographically diverse ethnicities within Ghana, and they suggest the need for a more refined sub-continental genetic ancestry analysis to effectively determine the impact of genetic African ancestry on the biology of both WA and AA breast cancer.

#7105 Analyses of real-world clinico-genomic and demographic data highlight the multifactorial causes of poor colorectal cancer outcomes in patients of African ancestry.

Sharafudeen D. Abubakar, Henry Walch, Christina I. Lee, Chin-Tung Chen, Kanika Arora, Farheen Shah, Tejiri Agbamu, Michele Waters, Christopher Fong, Justin Jee, Michael F. Berger, Karuna Ganesh, Debyani Chakravarty, Walid K. Chatila, Nikolaus Schultz, Rona Yaeger, Julio Garcia-Aguilar, Francisco Sanchez-Vega

Memorial Sloan-Kettering Cancer Center, New York, NY

Background: Colorectal cancer (CRC) patients of African ancestry (AFR) have been reported to have shorter overall survival (OS) than patients of non-African ancestry (non-AFR). We analyzed real-world clinico-genomic data from a single tertiary cancer center, including treatment and outcomes, to investigate this disparity.
Methods: We analyzed data from 4,310 CRC patients diagnosed after 2014 and treated at Memorial Sloan Kettering Cancer Center (MSKCC), including 270 AFR and 4,040 non-AFR patients. Patients had their tumors sequenced with MSK-IMPACT, a targeted DNA sequencing assay that identifies genomic alterations in 341-505 genes. Genetic ancestry was inferred from sequencing data, and patients with >80% African ancestry were classified as AFR. OncoKB was used to identify clinically actionable genomic alterations, as well as alterations associated with treatment resistance. Type of medical insurance and Yost index based on billing address were recovered from institutional databases. Covariates used in our analyses included primary tumor location, stage at diagnosis, time from diagnosis (Dx) to arrival at MSK and metastatic burden. OS was measured from the time of Dx.
Results: AFR patients had shorter OS (median 39.1 vs. 60.2 months, p<0.001) and presented with more advanced disease: they were more often diagnosed with stage IV disease (51.5% vs 44.3%, p=0.034), tended to arrive later at MSKCC (21.5% vs. 10% arriving >1 year after Dx, p<0.001), more often received prior treatment (29.5% vs 22.1%, p=0.01), and had higher rates of right-sided colon tumors (37.9% vs 21.1%, p<0.001). AFR patients exhibited higher metastatic burden during their clinical history, including higher frequency of liver (70.3% vs 59.3%, p<0.001), lung (57.8% vs 48.6%, p=0.005) and CNS (14.9% vs 8.5%, p=0.001) metastases. They also had lower rates of MSI tumors (6.6% vs 11.1%, p=0.073), fewer FDA-approved targetable alterations (6.1% vs 11.5%, p=0.006 - driven by BRAF), and more alterations resistant to FDA-approved drugs (60.7% vs 45.5%, p<0.001 - driven by KRAS). Overall, Medicaid usage was independently associated with shorter OS (median 29.3 vs. 59.9 months, p<0.001) and later arrival at MSKCC (17.7% vs. 10.4% arriving >1 year after Dx, p=0.024). AFR patients had a higher rate of Medicaid users (7.9 vs. 2.6%, p<0.001), which can partially explain their shorter OS. However, even when Medicaid and non-Medicaid users were analyzed separately, AFR patients still had worse OS (median 26.1 vs. 34.5 months, p=0.069, and 43.7 vs. 60.4 months, p=0.002, respectively).
Conclusions: AFR ancestry and Medicaid use were additive factors associated with poor prognosis. This disparity could be at least partially explained by a combination of clinico-genomic factors, including more advanced disease at diagnosis and delayed arrival at the treating tertiary care center.

#7106 Comprehensive spatial profiling of the tumor immune microenvironment in triple negative breast cancer from Black women.

Felipe Segato Dezem[1], Matt Ingalls[2], Omotoso Ayodele[3], Destiny Burnett[3], Priscila Coelho[3], Carmen Gomez[3], Sara Bodbin[4], Judith Hurley[3], Agata Zieba Wicher[4], Arne Christians[2], Jannik Boog[2], Daniel Jimenez Sanchez[2], Oliver Braubach[2], Sophia George[3], Jasmine Plummer[1]

[1]Center for Spatial OMICs, St. Jude Children's Research Hospital, Memphis, TN,[2]Bruker Spatial Biology, Seattle, WA,[3]Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL,[4]Navinci Diagnostics, Uppsala, Sweden

Normal tissues from Black individuals, regardless of their country of birth or residence, remain critically understudied. This gap in research is particularly concerning, as Black individuals disproportionately experience aggressive pathological diseases, often exhibit resistance or refractoriness to treatment, and face higher rates of premature death. In women, breast cancer is not only more common among U.S. Black women, but it also tends to develop at a younger age compared to other ancestral groups. Furthermore, U.S. Black women are approximately twice as likely as White women to be diagnosed with triple-negative breast cancer (TNBC), a subtype characterized by higher recurrence rates and poorer survival outcomes. To investigate the biological factors contributing to these disparities, we spatially profiled TNBC tumors from U.S. Black and White patients. Our analysis revealed significant differences in the tumor immune microenvironment (TiME). Tumors from Black women exhibited higher immune infiltration, particularly among macrophage and T cell populations. To explore how differences in key immune cell populations could impact immunotherapeutic outcomes, we employed a multiomic spatial proteomics approach, aimed at (1) identifying immune cell populations, (2) mapping their activation states, and (3) revealing PD-1/PD-L1 checkpoint activity. All of this was accomplished with a novel serial CellScape^{TM} workflow, which allows the integration multiplex immunofluorescence (mIF) with and *in situ* Proximity Ligation Assay (*is*PLA). Our mIF assay consisted of more than 30 Vistaplex^{TM} antibodies and efficiently labeled immune cell lineages, activation states and checkpoints. Cell-to-cell interactions and protein-protein interactions at immune checkpoints were then surveyed throughout the TiME using *is*PLA, which enables the imaging-based identification of checkpoint activation via detection of protein-protein interactions. The assay is based on a 40 nm proximity of the interacting partners and uses rolling circle amplification (RCA) to amplify the signal, ensuring high sensitivity and specificity of the detected interaction, in this case, that of PD1 and PDL1. Collectively these results affirmed heightened immune infiltration in tumors from Black woman and, crucially, allowed us to map checkpoint activation on a cell-by-cell phenotypic basis. By leveraging multiomic spatial phenotyping, we detected distinctions in the TNBC TiME from Black women compared to White women. Linking together the occurrence of certain cell phenotypes, their spatial signatures, and their checkpoint activation states. These findings underscore the importance of studying diverse patient populations to better understand tumor biology and inform more equitable therapeutic strategies.

#7107 Racial, gender and socioeconomic disparities in survival outcomes of gastrointestinal stromal tumors: a retrospective analysis from 2000 to 2021.

Asfand Yar Cheema[1], Oboseh J. Ogedegbe[2], Muhammad Faisal Aslam[3], Serhan Unlu[1], Mishaal Munir[4], Kai He[5], Utkarsh Acharya[5]

[1]Cleveland Clinic Foundation/Fairview Hospital, Cleveland Clinic, OH,[2]Trinity Health Ann Arbor Hospital, Ypsilanti, MI,[3]UAB St. Vincent's East Hospital, Birmingham, AL,[4]Lahore Medical and Dental College, Lahore, Pakistan,[5]The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Gastrointestinal stromal tumors (GISTs) are rare mesenchymal neoplasms that originate in the interstitial cells of Cajal or precursor cells within the gastrointestinal (GI) tract, predominantly affecting the stomach and small intestine. GISTs represent the most common type of GI mesenchymal tumors, accounting for approximately 1-3% of all GI tumors. In this study, we explored the effect of gender, race/ethnicity, and socioeconomic factors on survival outcomes among patients with GISTs in the United States.
Methods: We extracted data on patients with a histological diagnosis of GISTs from the Surveillance Epidemiology and End Result (SEER) Registry from 2000-2021. The primary outcome of interest was cause-specific survival. According to the International Classification of Disease for Oncology, Third Edition (ICD-O 3) system, the histological code of GISTs is 8936/3. We excluded patients of missing or unknown race, income, location, and patients outside the years of study. Kaplan-Meier methods were used to estimate 5-year survival rates. Cox proportional hazards regression was used for multi-variable modeling of the survival database. The difference between the observed number of events between each group was compared using a log-rank statistical test. Patients were followed up for 5 years, and survival analysis results were censored at this point, with hazard ratios reflecting 5-year overall survival (OS) between groups.
Results: 11,247 patients met the inclusion criteria. The gender split was 5,719 males (50.9%) and 5,528 females (49.1%). Based on gender, males as compared to females have significantly worse outcomes hazard ratio was 1.18 (95% CI 1.1-1.26, p<0.001). Races were categorized into non-Hispanic Black (n=2092, 18.6%), Non-Hispanic White (n=6027, 53.6%), non-Hispanic Asian or Pacific Islander (n=1616, 14.4%), Hispanic (n=1490, 13.2%), and Alaskan-Native/American Indian (n=22, 0.2%). Compared to Hispanic patients, White and Black patients had significantly worse outcomes (HR 1.13, 95% CI 1.01-1.26, HR 1.38, 95% CI 1.22-1.56, p=0.028, p<0.001, respectively), with no significant difference in outcome among other races. Compared to patients with distant metastasis (n=2403), patients with localized disease had significantly better outcomes (HR 0.26, 95% CI 0.24-0.28). When household income was categorized above and below $60,000 per annum, higher household income was also associated with better outcomes (HR 0.86 95% CI 0.78-0.94, p<0.001).
Conclusions: Gender, race/ethnicity, and income disparities all played a significant role in cause-specific survival in patients with GISTs, with improved survival in females, higher household income (>$60K), and Hispanic patients as compared to Whites and Blacks. More efforts and research are needed to elucidate the root cause and mitigate these survival disparities.

#7108 Leveraging race-informed biological models for disparities research in colorectal cancer.

Xiang Han, Stefanie Gerstberger, Kathleen Luckett, Francesco Cambuli, Jaeyop Lee, Andres Rettig, Ahmed Mahmoud, Jonathan Bermeo, Asha Saxena, T.Peter Kingham, William Jarnagin, Philip Paty, Martin Weiser, Michael D'Angelica, Rona Yaeger, Julio Garcia-Aguilar, Francisco Sanchez-Vega, Karuna Ganesh

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Non-Hispanic Black (NHB) patients have a 20% higher incidence of colorectal cancer (CRC) and a 40% higher CRC mortality than non-Hispanic white (NHW) patients. Disparities may be explained by socioeconomic variables (such as smoking or obesity) and access to health care. However, the role of potential biological differences remains unclear. Patient-derived organoid models (PDOs) provide an ideal model system to study biological differences and avoid confounding clinical variables by focusing on the genomic, phenotypic and functional differences in CRC cells *ex vivo*. There is currently a lack of patient-derived preclinical models from NHB populations. We aim to build a public biobank of NHB patients with detailed clinical annotation, chemosensitivity and biological characterization, examining intrinsic tumor cell states in different genomic backgrounds as potential variables in CRC outcomes.
Methods: PDOs were established from surgically resected primary and metastatic CRC samples from NHB and NHW patients, processed through enzymatic digestion and filtration, and cultured in Matrigel in human intestinal stem cell (HISC) media. Genomic features of the corresponding patients were analyzed using the MSK-IMPACT targeted DNA sequencing assay. We assessed the responses of NHB and NHW PDOs to FOLFOX chemotherapy through drug sensitivity assays with 5-FU:oxaliplatin (concentration of 25:1). Dose-response curves were fitted using the two-parameter logistic regression model to calculate median IC50. After dissociation into single cells, PDOs were cultured in HISC and Base (media without intestine-specific growth factors) conditions for 11-14 days and analyzed by bulk RNA-sequencing to capture phenotypic differences associated with canonical intestinal (less aggressive) and non-canonical (more aggressive) cell states.
Results: We aim to establish a biobank of 10 NHB and 10 comparative NHW patients with similar clinicogenomic profiles. To date, 12 PDOs derived from 5 NHB (3 primary and 2 metastasis samples) and 7 NHW (2 primary and 4 metastasis samples) patients are characterized with further PDO collection ongoing. Four samples with KRAS missense mutations were present across the NHB and NHW patient groups (NHB: 80%, NHW: 57%). IC50 of five NHB and five NHW PDOs revealed no significant differences in sensitivity to FOLFOX (median IC50 NHB: 70.3uM; median IC50 NHW: 59.92uM). ssGSEA scores derived from bulk RNA-seq data of five PDOs, comparing three NHB and two NHW patients, exhibited greater variation across lines than within racial groups, with no significant differences between NHB and NHW patients.
Conclusions: Ongoing work is focused on building a larger cohort for wider comparative characterization. The future completed biobank will become a public resource for scientists to access racially diverse PDOs for drug testing and further biological characterization.

#7109 Understanding race-specific differences in the predictive performance of computational outcome models for breast cancer.

William Asinger, Sarah Eskreis-Winkler, Armaan Kohli, Enrico Moiso, Anika Begum, Mehnaj Ahmed, Andrew Aukerman, Jianjiong Gao, Jian Carrot-Zhang, Arfath Pasha, Hong Zhang, Elizabeth Sutton, Sohrab Shah, Pedram Razavi, **Francisco Sanchez-Vega**

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Neoadjuvant chemotherapy (NACT) is the standard of care for locally advanced breast tumors and pathologic complete response (pCR) is the most prominent determinant of favorable outcomes. We built computational predictors of pCR for breast cancer patients (pts) treated with NACT using different data modalities acquired at baseline (clinical, genomic, pathology and radiology) and investigated race-specific differences in their predictive value when pts were stratified into hormone receptor subtypes.
Methods: We analyzed data from 1,135 breast cancer pts who self-identified as Asian (n=151, 13%), Black (168, 15%), Hispanic (154, 14%) or White (662, 58%). Patients were treated with NACT at Memorial Sloan Kettering (MSK) between 2014 and 2021. The cohort included HR-/HER2+(n=183, 16%), HR+/HER2- (353, 31%), HR+/HER2+(339, 30%) and TNBC (260, 23%) pts. Digital pathology whole-slide images from H&E stained pre-NACT tumor biopsies were analyzed for 863 pts. Pre-NACT MRIs were analyzed for 608 pts. Targeted DNA sequencing from MSK-IMPACT was analyzed for 302 pts. Predictors of pCR were built using penalized regression models for the clinical and genomic modalities, and deep learning (DL) architectures for pathology and radiology. Genetic ancestry was computed for pts with sequencing information using published methods. Model performance was quantified as the area under the receiver operating characteristic curve (AUC).
Results: Genetic ancestry labels and self-reported race were highly concordant (297/302, 98% match). The overall pCR rate was 38.5% and varied strongly by receptor subtype, being lowest for HR+/HER2- (13%) and highest for HR-/HER2+ (75.4%). pCR rate also varied across races, being highest for Asians (45%) and lowest for Black pts (34.5%), although this can be at least partially explained by the different representation of receptor subtypes across races (e.g., Black pts had significantly higher rates of TNBC tumors, 37.5% vs. 20.3%, $p < 0.0001$). After controlling for subtype, Hispanics tended to be diagnosed at a younger age (median 46 vs. 50 years, $p=0.02$). We identified several combinations of subtype and data modalities where AUCs varied by race: for example, AUCs for the clinical predictor were higher for Asian pts in the TNBC subtype (0.64 AUC vs. 0.49 mean AUC across all races), while the predictor based on the same modality overperformed among Hispanics of the HR-/HER2+ subtype (0.84 AUC vs. 0.65 mean AUC across all races). Training subtype-specific models instead of a pan-subtype model only improved overall cross-type AUC for Black pts (mean AUC increase of 0.07).
Conclusions: Racial background can impact the predictive performance of computational outcome models in breast cancer and should be factored for method design. The influence of race-specific differences varies across data modalities and receptor subtypes.

#7110 Exploring cardiovascular comorbidities in cancer-directed therapies for patients with breast cancer in the southwestern United States: A two-center analysis.

T. Escobar-Gil[1], E. Sherry[2], A. C. Millhuff[1], V. Ayodele[3], A. Baig[3], V. G. Hanson[1], O. F. Borja-Montes[1], J. M. Nemunaitis[4], M. Mazo-Canola[3];
[1]University of New Mexico Health Sciences Ctr., Albuquerque, NM, [2]University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]University of Texas Health San Antonio Mays Cancer Center, San Antonio, TX, [4]University of New Mexico Comprehensive Cancer Center, Albuquerque, NM

Background: In 2024, approximately 43,700 women in the U.S. are expected to die from breast cancer. This disease is a leading cause of cancer-related mortality, especially among Hispanic women, who face unique risks, including higher cardiotoxicity rates from treatments like anthracyclines and trastuzumab. Nearly 40% of breast cancer patients experience cardiovascular comorbidities such as hypertension and heart failure, worsened by treatment-related toxicities, and cardiovascular disease has emerged as a leading cause of death among breast cancer survivors. Health disparities contribute to these outcomes, with Hispanic women facing barriers to care and a slower decline in cancer-related fatalities compared to non-Hispanic White women. This study investigates these factors within the Southwestern U.S., where the burden of breast cancer is significant.
Methods: This retrospective cohort study analyzed 394 breast cancer patients from two medical centers located in the Southwestern U.S. (195 from the UNMCCC in Albuquerque, New Mexico, and 199 from UTHSCSA Mays Cancer Center in San Antonio, Texas) treated between January 2022 and December 2023. Inclusion criteria encompassed adult patients diagnosed with stage I-III breast cancer, receiving treatment with curative intent, excluding those with incomplete records. Data was extracted from electronic health records, covering demographics, treatment regimens, radiation use, and cardiovascular conditions while adhering to HIPAA regulations.
Results: The study included 394 breast cancer patients, with a mean age of 59.94 years (SD = 12.11) and a mean BMI of 30.12 kg/m² (SD = 6.58). Women comprised 99% of the cohort (n=389). Patients from UTHSCSA had a mean BMI of 31.00 kg/m² (SD = 6.45), while those from UNMCCC had a mean BMI of 29.25 kg/m² (SD = 6.62). Approximately 84.1% identified as Latino (White), with 61.3% (n=241) pre-menopausal and 83.0% (n=327) having hormone receptor-positive cancer. Anthracyclines were given to 21.1% (n=83), and HER2-directed treatments were administered to 14.7% (n=58) of patients. Radiation therapy was utilized in 58.5% (n=113) of the cohort. Hypertension was the most prevalent cardiovascular condition, affecting 46.5% (n=184), followed by diabetes mellitus (26.1%) and hyperlipidemia (29.7%). Cardioprotective medication usage varied, with around 50% not receiving any such treatments.
Discussion: The findings highlight the health challenges of the Latino population, especially concerning hormone receptor-positive breast cancer. The high rates of obesity and cardiovascular comorbidities underscore the need for targeted interventions. Treatment plans should be individualized for each patient's cardiovascular comorbidities while receiving cancer treatment and delivered through a multidisciplinary approach.

#7111 A cross-sectional survey of genomics infrastructure at six NHGRI-funded Diversity Centers for Genome Research.

X. Wang[1], F. A. Fernandez-Lima[1], Z. Bursac[1], S. Black[1], M. Baum[1], J. W. Pettit[1], D. Bedi[2], H. Wang[2], B. Karanam[2], M. B. Davis[3], M. Rachel[3], E. L. Johnson[3], B. Rivers[3], A. Winkler[4], J. Galan[4], J. Blangero[4], S. Williams-Blangero[4], M. Tiirikainen[5], L. Wu[5], Y. Deng[5], G. Pan[5], O. Korolkova[6], A. Ivanova[6], H. Rajakaruna[6], T. Kanagasabai[6], D. B. Borza[6], R. Singh[6], S. Chirwa[6], L. Stewart[6], S. T. Miller-Hughes[6], A. Ramesh[6], E. Madden[7], A. Shanker[6], **Q. Wang**[6];

[1]Florida International University, Miami, FL, [2]Tuskegee University, Tuskegee, AL, [3]Morehouse School of Medicines, Atlanta, GA, [4]University of Texas Rio Grande Valley School of Medicine, Brownsville, TX, [5]University of Hawai'i at Mānoa, Honolulu, HI, [6]Meharry Medical College, Nashville, TN, [7]National Human Genome Research Institute, Bethesda, MD

Background: With the rapid advancements in human genetics and genomics research, it is crucial to build genomics capacity at minority-serving institutions (MSIs), which play a key role in developing diverse workforce in genomics and precision medicine, driven by their commitment to educating and training underrepresented students and trainees. Moreover, MSIs are instrumental in tackling chronic diseases, including cancer, that disproportionately affect minority and underserved populations.

Methods: A comprehensive cross-sectional survey was conducted from August to October 2024 across six MSIs within the Diversity Centers for Genome Research (DCGR) Consortium, established by the National Human Genome Research Institute (NHGRI), to assess their genomic infrastructure and capacity. The surveyed institutions included the Pacific Center for Genome Research at the University of Hawai'i at Mānoa,the University of Texas Rio Grande Valley, Florida International University, Morehouse School of Medicine, Meharry Medical College, and the Carver Genomic Research Center at Tuskegee University, with the last three being Historically Black Colleges/Universities (HBCUs). These MSIs serve diverse and historically underrepresented minority populations, including Native Hawaiian and Pacific Islander, Asian Americans, Hispanic/Latino communities, and African Americans. The survey consisted of 32 questions covering a wide range of topics, including DCGR budget allocations, available sequencing equipment, proteomics instruments, biorepository sample collection and management, etc.

Results: An important aspect of the survey is MSIs' access to cutting-edge next-generation sequencing technologies, a critical component of genomic research infrastructure. Among the six MSIs surveyed, four currently have Illumina short-read sequencers, and three have long-read sequencers, either Nanopore or Ion Torrent. However, none of the institutions owns a PacBio long-read sequencer, an increasingly popular platform for applications where accuracy, read length, and the ability to resolve complex genomic regions outweigh throughput needs. The six MSIs also vary in their computing infrastructure, proteomics instruments, and mass spectrometers, among other resources. Furthermore, all six MSIs own or plan to establish human tissue biorepositories. The survey reveals two common challenges regarding biorepositories across these institutions: (1) effective biorepository management and (2) securing sustainable funding.

Conclusion: These results provide valuable insights into the genomic infrastructure and capacity of the six MSIs in the DCGR Consortium. The data collected and insights gained lay a strong foundation for supporting MSIs and fostering future collaborations among them to tackle the common challenges they face in building robust genomics programs.

#7112 Pattern of beef consumption and prostate cancer risk among males in the United States.

Opeyemi Oreoluwa Bolajoko[1], Daniel W. Lee[1], Catherine Adebukola Oladoyinbo[2], Ernie Kaninjing[3], Samuel O. Antwi[4], Dee M. Glaser-Boivin[4], Robert J. Turesky[5], Folakemi T. Odedina[6]

[1]Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL,[2]Nutrition and Dietetics, Federal University of Agriculture, Abeokuta, Nigeria,[3]School of Health and Human Performance, Georgia College, Milledgeville, GA,[4]Mayo Clinic, Jacksonville, FL,[5]Masonic Cancer Center, University of Minnesota, Minneapolis, MN,[6]Cancer Health Equity Research Program, Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL

Background: Epidemiology studies have linked frequent consumption of well-done cooked red meat with aggressive prostate cancer (CaP) risk, whereas rare intake or consuming medium-cooked meat is not. Providing public information about the impact of well-done cooking and its potential role in CaP risk may foster the adoption of evidence-based lifestyle modification of meat consumption to lower CaP risk. This pilot study aimed to provide preliminary data on the occurrence of CaP and the pattern of consumption of cooked red beef among ethnically diverse males in the US.

Methods: The proposed project is an exploratory study focused on the assessment of the consumption of various beef dishes among ethnically diverse males in the United States. The study included 408 ethnically diverse males from Florida, Georgia, and Texas. Participants were recruited primarily from partnering restaurants, pharmacies, barbershops and collaborating community businesses using QR codes on the study flyer. Participants completed the self-administered survey that captured demographics, as well as information on beef consumption patterns, including cooking methods, frequency and degree of cooking, and the occurrence of CaP. The data were analyzed using descriptive statistics (frequency and percentages) to summarize demographics and variables on beef dishes. Chi-square was employed to determine the relationship between beef consumption patterns, demographic variables, and CaP occurrence.

Results: The study showed that about half (49.8%) of the participants were between ages 44-63 years and 34.2% were 30-43 years old. The participants were quite diverse, as 51.7%, 16.3%, 13.1%, 11.%, and 2.7% were African American, African immigrants, White, Caribbean immigrants, and Hispanics, respectively. Rural dwellers comprised 34.2%, 26.8% were suburban, and 35.7% lived in urban areas. Educational status showed that 22.7%, 27.8%, and 22.7% were completed high school, college graduates, and associate degrees. The beef consumption pattern shows that 23.6%, 33.3%, 40.1%, and 30.3% regularly had boiled, fried, grilled, and barbequed beef, respectively, but 63,2% reported never eating boiled beef. Doneness preferences differed among participants; 26%, 43.9%, 49.3, and 45.1% preferred well-done, while 1.7%, 1.5%, 2..9%, and 2.7% preferred rare, and 9%, 14.5%, 17.4%, and 15.7% preferred medium boiled, fried, grilled, and barbeques beef, respectively. Only 4.4% of the participants reported being diagnosed with CaP in the past. The pattern of beef consumption, such as the degree of doneness, was found for boiled ($p=0.045$), fried ($p<0.001$), grilled ($p<0.001$), and barbequed ($p<0.001$) beef, as well as frequency of consumption of ($p<0.001$), fried ($p<0.001$), grilled ($p=0.001$), and barbequed ($p<0.001$) to be associated with CaP.

Conclusion: Beef consumption pattern was found to be associated with the risk of CaP among participants.

#7113 Barriers to cancer diagnosis and treatment among women in low- and low-middle-income countries.

Sylvester Antwi[1], Kwabena Agbedinu[2], Livingstone Aduse-Poku[3], Foster Amponsah[4], Harriet Larrious-Lartey[1], Samuel Mensah[5], Josephine Nsaful[6], Patrick Akakpo[7], Veneranda Nyarko[6], Michael Nortey[7], Alex Mremi[8], Theresia Mwakyembe[8], Valerie Ofori Aboah[1], Moses Dokurugu[9], Mohammed Sheriff[9], Nelson Affram[10], Evelyn M. Jiagge[11]

[1]Henry Ford Health, Detroit, MI,[2]Komfo Anokye Teaching Hospital, Kumasi, Ghana,[3]University of Florida, Gainesville, FL,[4]Eastern Regional Hospital, Koforidua, Ghana,[5]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,[6]Korle Bu Teaching Hospital, Accra, Ghana,[7]Cape Coast Teaching Hospital, Cape Coast, Ghana,[8]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of,[9]Tamale Teaching Hospital, Tamale, Ghana,[10]Ho Teaching Hospital, Ho, Ghana,[11]Henry Ford Health System, Detroit, MI

Introduction: Globally, the risk of death from cancer is higher in lower to middle income countries despite a reported lower incidence in these countries. This is attributed not only to biological factors, but to limited access to resources for screening, diagnosis, and treatment. We conducted a scoping review to identify barriers to cancer diagnosis and treatment among women in low- and low-middle-income countries, focusing on breast, colorectal, lung, cervix uteri, thyroid, corpus uteri, and stomach cancers.
Methods: Using the Joanna Briggs Institute approach and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) extension for scoping reviews, we systematically searched PubMed, Embase, Cochrane Library, PsycInfo, CINAHL, Scopus, and Web of Science. Eligible studies, published in English, reported barriers to cancer care in low- and low-middle-income countries. Screening and data extraction were conducted in Covidence by two independent reviewers. A total of 29 studies involving 7031 participants were included, employing quantitative, qualitative, and mixed methods designs.
Results: Most studies (79.3%) were conducted in low-middle-income countries, with Sub-Saharan Africa (82.76%) as the predominant region. Breast cancer was the most studied cancer type (59.38%). On average, diagnosis occurred 7.39 months after symptom onset, and treatment began 4.9 months later. Patients traveled an average of 62 km (172.5 minutes) to health facilities. The most common barriers to cancer care were financial difficulties (71.45%), healthcare system challenges (55.17%), health literacy gaps (51.72%), geographical barriers (68.5%), and sociocultural factors. Financial challenges, reported in 65.52% of studies, included limited resources, high costs, and socioeconomic strain. Healthcare system issues, documented in 55.17% of studies, involved resource shortages, misdiagnosis, and delayed referrals. Geographical barriers, noted in 34.48%, included long travel distances and transportation costs. Health literacy gaps, reported in 51.72% of studies, stemmed from inadequate awareness and education among patients and providers. Sociocultural and stigma-related barriers, highlighted in 41.38% of studies, included cultural beliefs, fear of stigma, and spiritual attributions of illness.
Conclusion: This review underscores the multifaceted barriers to cancer care in low-resource settings, emphasizing the need for interventions addressing financial, health system, educational, and sociocultural challenges. Enhanced healthcare infrastructure, community education, and socioeconomic support are critical to improving cancer outcomes in these regions.

#7114 Carboplatin in combination with etoposide for advanced small cell lung cancer complicated with idiopathic interstitial pneumonia: A single-arm phase II study.

M. Matsumoto[1], Y. Minegishi[2], K. Higa[1], A. Fukuizumi[1], N. Onda[1], S. Takeuchi[1], A. Miyanaga[1], A. Gemma[1], M. Seike[1];
[1]Nippon Medical School, Tokyo, Japan, [2]Mitui Memorial Hospital, Tokyo, Japan

Background: Acute exacerbation (AEx) of interstitial pneumonia is the most common lethal adverse event related to the pharmacological treatment of patients with lung cancer complicated with interstitial pneumonia. Although small cell lung cancer (SCLC) is linked to poor prognosis, it exhibits good response to chemotherapy. Few previous research studies have investigated the safety and efficacy of treatment for advanced SCLC complicated with idiopathic interstitial pneumonia (IIP). We conducted a single-arm phase II study to evaluate the safety and efficacy of carboplatin plus etoposide for the treatment of patients with SCLC complicated with IIP.
Methods: Chemotherapy-naïve patients with advanced SCLC complicated with IIP were enrolled. Patients received carboplatin every 21-28 days at a dose of area under the curve 4-6 on day 1 and etoposide at a dose of 80-100 mg/m^2 on days 1-3.
Results: Thirty-one patients were enrolled between December 2009 and December 2022. A median of four cycles of carboplatin plus etoposide were administered. Acute exacerbation of idiopathic interstitial pneumonia was not observed; the rate of AEx was 0% (95% confidence interval [CI]: 0-9.6%, p=0.038). The objective response rate was 83.9% (95% CI: 82.5-85.2). The median progression-free survival and overall survival were 5.9 (95% CI: 4.7-6.8) months and 14.0 (95% CI: 7.6-27.6) months, respectively. The 1-year survival rate was 61%.
Conclusions: The carboplatin plus etoposide treatment was tolerable and effective in SCLC patients complicated with IIP.

#7115 PredicineDIRECT: a one-stop “from sample to result” workflow for improved sample management in oncology clinical trials.

Yong Huang[1], Ao Zhou[1], Pan Du[1], Shidong Jia[1], Qin Luo[2], Alexander Kuklin[1], Myles Walsh[1]

[1]Predicine Inc., Hayward, CA,[2]Huidu Shanghai Medical Sciences, Ltd., Shanghai, China

Background: Liquid biopsy is now a standard in clinical trials, improving therapy selection, prognosis, and biomarker discovery. However, reliance on CROs for sample collection, processing, and storage often leads to delays and inefficiencies. PredicineDIRECT, a genomics-based biorepository system, addresses these challenges by centralizing sample management, enabling rapid and accurate support for clinical trials.

Methods: Using ISO13485-certified GMP kits, Predicine collects and processes blood, urine, and tissue samples globally and manage samples using BioLIMS. Patient-specific SNP barcodes and bioinformatics analyses detect errors like mislabeling or sample swaps. Tumor Fraction (TF) is measured via low-pass whole-genome sequencing to assess tumor burden efficiently. This workflow enables real-time quality control, longitudinal tumor burden evaluation, and optimized sample selection for downstream analysis. Sponsors access data through a client portal, while securely stored samples remain ready for immediate in-house genomic testing.

Results: In a trial cohort, SNP barcoding identified sample mismatches, including one between plasma and buffy coat samples and another at a longitudinal time point. Predicine promptly resolved these discrepancies, communicating actionable solutions to the sponsor before long-term storage. TF analysis of plasma samples revealed molecular progression, guiding selection of key time points for deep sequencing. A case study also demonstrated SNP inconsistencies between plasma and buffy coat samples, highlighting the robustness of PredicineDIRECT's error-detection system.

Conclusion: PredicineDIRECT provides a streamlined, cost-effective solution for clinical trial sample management by centralizing processes in a single laboratory. With integrated SNP barcoding and TF analysis, the system ensures error-free handling, accelerates downstream sequencing, and delivers actionable insights into tumor burden, supporting efficient and informed decisions in oncology trials.

#7117 Short-term surgical outcomes for colon adenocarcinoma: Racial-ethnic comparisons in the Military Health System.

Yvonne L. Eaglehouse, **Sarah Darmon**, Michele M. Gage, Craig D. Shriver, Kangmin Zhu

Surgery, Uniformed Services University of the Health Sciences, Bethesda, MD

Background: Racial-ethnic disparities in receipt of treatment and survival outcomes of colon cancer have been documented in the general U.S. population, with access to care identified as a contributor to the disparities. Less is known about disparities in quality aspects of colon cancer surgery, such as achievement of negative surgical margins, adequate lymphadenectomy, and complication rates. We aimed to study colon cancer surgery and postoperative outcomes in the Military Health System (MHS), which provides access to care regardless of patient demographic or socioeconomic characteristics, to better understand racial-ethnic disparities in surgical oncology care in an equal access setting.
Material and Methods: We used the MilCanEpi database to identify patients aged 18 or older who were diagnosed with stage I-III colon adenocarcinoma between 2001 and 2014 and received colectomy as primary surgical treatment. The occurrence of positive surgical margins, inadequate lymphadenectomy (&lt12 nodes examined), 30-day complications (general: surgical site infection, hemorrhage, myocardial infarction, stroke, thrombosis; or gastrointestinal: bowel obstruction or intra-abdominal abscess), and 30-day inpatient admissions were captured. Multivariable logistic regression models estimated the adjusted odds ratios (AORs) and 95% confidence intervals (CIs) in association with race-ethnicity for each outcome.
Results: The study included 157 Asian, 257 non-Hispanic Black, 110 Hispanic, and 1115 non-Hispanic White patients. Overall, the frequency of positive margins (7.6%), inadequate lymphadenectomy (28.9%), 30-day complications (33.1%), or 30-day inpatient admissions (14.3%) did not differ significantly between racial-ethnic groups (all AORs and their 95% CIs included 1.00). By complication type (general or gastrointestinal), Hispanic patients had a significantly lower likelihood of bowel obstruction (AOR=0.48, 95% CI=0.25, 0.95) compared to non-Hispanic White patients, with no other statistically significant racial-ethnic differences.
Conclusions: In the equal access MHS, there were no overall significant racial-ethnic differences in margins, lymphadenectomy, or 30-day outcomes of colectomy for non-metastatic colon cancer. Our findings highlight the role of access to care in minimizing racial or ethnic disparities in colon cancer surgery and postoperative outcomes in the U.S.

#7118 Clinical characteristics and survival outcomes of ovarian cancer among South Asian women in United States.

Aditi Karki[1], Sumeet Kumar Yadav[2], Muhammad Rafiqul Islam[3], Raja Pramanik[4], Ramila Shilpakar Dangol[5], Zeba Aziz[6], Sandhya Pruthi[7], Maryam Shahi[8], Jamie N. Bakkum-Gamez[9], Scott H. Kaufmann[10], Fergus J. Couch[11], Siddhartha Yadav[12]

[1]Oncology, Mayo Clinic Comprehensive Cancer Center, Rochester, MN,[2]Internal Medicine, Mayo Clinic Health System, Mankato, MN,[3]Oncology, National Institute of Cancer Research and Hospital, Dhaka, Bangladesh,[4]Oncology, All India Institute of Medical Sciences, New Delhi, India,[5]Oncology, National Academy of Medical Sciences, Kathmandu, Nepal,[6]Oncology, Hameed Latif Hospital, Lahore, Pakistan,[7]General Internal Medicine, Mayo Clinic, Rochester, MN,[8]Anatomic Pathology, Mayo Clinic, Rochester, MN,[9]Gynecologic Oncology, Mayo Clinic, Rochester, MN,[10]Oncology Research, Mayo Clinic, Rochester, MN,[11]Experimental Pathology and Laboratory Medicine, Mayo Clinic, Rochester, MN,[12]Oncology, Mayo Clinic, Rochester, MN

Background: Ovarian cancer is the sixth leading cause of cancer deaths among women in the United States. South Asians in the USA, including Asian Indians and Pakistani Americans (AIPA), are a rapidly growing yet under-researched group. This study aims to analyze the clinical features, survival rates, treatment, and outcomes of ovarian cancer among AIPA women in the United States.

Methods: Adult women diagnosed with ovarian cancer between 2000 and 2023 within the Surveillance, Epidemiology, and End Results (SEER) registry were identified utilizing ICD codes. The analysis focused on comparing clinical characteristics and outcomes between AIPA and Non-Hispanic White (NHW)women and excluded all women of other races/ethnicities or unknown race/ethnicity. Baseline characteristics, including age at diagnosis, disease stage, and treatment, were compared between AIPA and NHW women utilizing a chi-squared test for categorical variables and a t-test for continuous variables. The 5-year overall survival (OS) was estimated for each race/ethnicity by the Kaplan-Meier method, and the OS was further compared between AIPA and NHW in a cox-proportional hazard regression analysis adjusting for age at diagnosis, grade, histology, TNM stage, surgical debulking, completeness of debulking surgery, and receipt of chemotherapy. Similar comparisons of baseline characteristics and OS were also performed in the subset of women with high-grade serous ovarian cancer (HGSOC).

Result: A total of 86,485 women met the inclusion criteria, of which 1,179 were AIPA and 85,306 were NHW. AIPA had a significantly younger median age at diagnosis compared to NHW women in the overall population (57 vs. 65 years, $p<0.001$) and among 448 AIPA and 29,677 NHW women with HGSOC (58 vs. 65 years, $p<0.001$). Approximately two-thirds of women in both groups presented with Stage III or IV ovarian cancer at diagnosis and had a serous subtype of ovarian cancer. Similarly, after the exclusion of unknown grade, high-grade tumors accounted for more than two-thirds (75 vs. 72%) of the ovarian cancer cases in both groups. AIPA were more likely to undergo debulking surgery (85 vs. 80%, $p<0.001$) and receive chemotherapy (77 vs. 72%, $p<0.001$) compared to NHW women. The unadjusted 5-year OS for AIPA and NHW women were 56% vs. 43% in the overall population, and 53% vs. 41% among women with HGSOC, respectively. In multivariate analysis of the entire study population, AIPA women had a significantly better OS than NHW women (HR: 0.86, 95%CI: 0.79 - 0.94, $p<0.001$). Among women with HGSOC, a similar trend of better OS was noted in multivariate analysis among AIPA women compared to NHW (HR: 0.88, 95%CI: 0.77 - 1.01, $p=0.07$), although this did not reach statistical significance.

Conclusion: The younger age at diagnosis, along with a generally better prognosis, among AIPA women compared to NHW women, suggests a possible enrichment of DNA-repair gene alterations among AIPA women.

CLINICAL RESEARCH: Immune Monitoring / Clinical Correlates
Poster Session

#7122 Accelerating immuno-oncology research with flexible workflows using modular flex-fit CyTOF panels.

Shakir Hasan, **Ling Wang**, Stephen Li, Christina Loh

Standard BioTools, Markham, ON, Canada

Deep functional profiling of immuno-oncology markers and cytokines in whole blood (WB) reveals immune signatures that inform disease prognoses, immunotherapy selection, and outcomes in cancer patients. WB is best analyzed within 24 hours of collection to capture clinically relevant immune signatures; however, WB collection and cytometric analysis are often performed at different sites, which can lead to significant delays. WB stabilizers can overcome this challenge, yet not all antibody panels are compatible with these reagents. To enable flexible experimental workflows for deep profiling of immuno-oncology markers and cytokines in WB, we developed modular Flex-Fit CyTOF™ panels compatible with stabilizers. High-parameter flow cytometry mediated by CyTOF technology enables single-tube staining to identify 50-plus markers at the single-cell level. CyTOF technology provides exceptional resolution without spectral unmixing or compensation, while Flex-Fit CyTOF panels allow simple and quick panel design by combining a customizable selection of pre-validated subpanels. We built two high-parameter antibody panels for analysis of fresh and stabilized WB. The first panel has 21 markers and identifies 12 immuno-oncology markers in 10 major cell subsets. The second panel has 31 markers and identifies 10 cytokines in 32 cell subsets. Stimulated WB samples from two healthy donors were either freshly stained or stabilized with PROT1, RBC lysed and stained. Liquid antibodies in the panel were pooled together and frozen (-80 °C) as single-use aliquots for surface and intracellular staining to reduce technical variability from staining. Optimal panel design ensured that all markers in both panels could be used to accurately identify target cell populations in PROT1-stabilized WB. Following stabilization, nonspecific staining was not observed when compared with freshly stained samples. Cell populations maintained the anticipated co-expression of markers in PROT1-stabilized WB. Prominent cytokines such as IL-17A, TNF-α, IL-10, etc., could be detected in stabilized WB. Overall, we show that PROT1-compatible high-parameter antibody panels enable functional profiling of immune cells by identifying immuno-oncology markers and cytokines. Compatibility with WB stabilization reagents provides workflow flexibility for carrying out functional profiling in longitudinal and multi-center studies in clinical research and healthcare settings. Furthermore, freezing antibody cocktails is a unique feature of CyTOF flow cytometry, ensuring staining consistency. Together, flexible CyTOF workflows enable fast and convenient panel design for high-parameter cytometric analysis of WB and can facilitate biomarker discovery, immunotherapy selection and tracking disease prognoses in cancer.

#7123 Unravelling temporal dynamics of GD2-CAR T cell therapy in H3K27M-mutant diffuse midline glioma through comprehensive single-cell and multi-omic profiling.

Yiyun Chen, Moksha H. Desai, Zachary J. Ehlinger, Kun Wei Song, Skyler Rietberg, Hossein Daghagh, Mark P. Hamilton, Snehit Prabhu, Sonia Partap, Jasia Mahdi, Elena Sotillo, Bita Sahaf, Sneha Ramakrishna, Zinaida Good, Michelle Monje, Crystal Mackall

Stanford University, Stanford, CA

H3K27M-mutant diffuse midline gliomas (DMG) are aggressive pediatric brain tumors with dismal prognoses and no effective treatments. GD2, a disialoganglioside overexpressed on DMG cells, is a promising target for chimeric antigen receptor (CAR) T cell therapy. In Arm A of the Phase I clinical trial (NCT04196413), 12 patients (11 on study) received GD2-CAR T cells through an initial intravenous (IV) infusion, and if patients had clinical or radiographic improvement, they subsequently received intracerebroventricular (ICV) administrations. This regimen achieved clinical benefit in ten patients, with >50% tumor volumetric reductions in 5 patients and a durable ongoing complete response in one patient (Majzner, Ramakrishna et al. Nature 2022; Monje et al. Nature 2024). However, disease progression ultimately occurred in 11 patients underscoring challenges in therapeutic optimization. To elucidate mechanisms underlying treatment responses and resistance, we performed a comprehensive multi-omic analysis, integrating single-cell RNA and TCR sequencing, mass cytometry, and clinical and molecular datasets. Sequencing 1,062,398 cells from patient apheresis, CAR T products, and cerebrospinal fluid (CSF) samples collected longitudinally at pre-defined trigger events, we reconstructed the dynamic landscape of immune and tumor cell populations in 12 DMG patients. Our analysis revealed profound CAR T cell infiltration into the CSF after treatment, accompanied by increases in endogenous T cell, mast cell, and monocyte populations and a relative decrease in microglia evident in CSF. This works sought to deeply characterize the lymphocyte profiles in these samples. Inflammatory and proliferation pathways were elevated in CAR T cells at early post-ICV time points, transitioning into an NK-like state and TGF-β receptor signaling at later stages. TCR clonal tracking identified persistent CAR T clones, alongside endogenous T cell activation and expansion. Moreover, non-responders to the therapy showed elevated Treg signatures in the CSF. Using CellChat-based cell-cell communication analysis, we uncovered differential cytokine-receptor interactions in responders versus non-responders, offering novel insights into immune-tumor interactions in the context of CAR T cell therapy. By contextualizing single-cell data within multi-omic frameworks and clinical outcomes, this study advances our understanding of the GD2-CAR T cell therapy, the tumor microenvironment, and biomarkers of response and resistance. These findings provide critical insights for optimizing CAR T cell therapies in CNS malignancies and inform the development of next-generation immunotherapies.

#7124 Imaging mass cytometry (IMC) reveals distinct intratumoral B and T regulatory cell populations in responder versus non-responder soft tissue sarcoma (STS) patients before treatment with immune checkpoint blockade (ICB).

Laurence P. Diggs, Elise Nassif Haddad, Susmita Kumari, Varshini Arunkumar, Sammy Ferri-Borgogno, Samuel Mok, Duncan Mak, Angelique Lin, Madeline McAllister, Akshay Basi, **Manoj Chelvanambi**, Javier Gomez, Jared Burks, Davis Ingram, Khalida Wani, Natalie Duarte, Trevor McKee, Alexander Lazar, Jennifer Wargo, Christina Roland, Emily Keung

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: STS are poorly understood cancers for which systemic therapy options are limited. Recent evidence suggests that some patients with two types of STS (undifferentiated pleomorphic sarcoma, UPS; dedifferentiated liposarcoma, DDLPS) benefit from ICB. Presence of tertiary lymphoid structures (TLS) and B cells within the sarcoma tumor immune microenvironment (TME) is associated with response to ICB and longer survival. It remains unclear how immune populations within this TME interact with each other and how they evolve upon ICB exposure. We characterized the TLS composition and spatial relationships between immune populations in untreated biopsies of UPS/DDLPS of responders (R) versus non-responders (NR).

Methods: We completed a phase 2 trial of patients with resectable primary UPS (n=10) and DDLPS (n=17) who received ICB prior to surgery. Pre-ICB treatment biopsies were collected, and IMC was performed using a 34-plex antibody panel to characterize the TME of R vs NR. TLS composition, densities of immune cell subsets, and their spatial relationships were assessed across baseline biopsy specimens within 3 pre-defined regions-of-interest (ROIs): TLS, non-TLS, and TLS-non-TLS interface regions.

Results: We identified distinct TME profiles in R compared to NR prior to ICB treatment. Intratumoral B cell density was higher in R compared to NR patients across pre-treatment biopsies (502 vs 277 cells/mm2, p=0.45) and within interface (1155 vs 710 cells/mm2, p=0.42) and non-TLS (458 vs 257 cells/mm2, p=0.17) regions but lower in TLS regions (506 vs 729 cells/mm2, p=0.52). NR patients tended to have higher densities of Tregs across pre-treatment samples (81 vs 37 cells/mm2, p=0.44) and in TLS (981 vs 824 cells/mm2, p=0.59), interface (119 vs 53 cells/mm2, p=0.14), and non-TLS (66 vs 15 cells/mm2, p<0.01) regions. When examining spatial distributions of TME immune populations, we noted a trend towards greater distances between B cells and T regs in the tumors of R compared to NR patients (78 vs 45 microns, p=0.13) which was also observed in TLS (116 vs 40 microns, p=0.05), non-TLS (76 vs 44 microns, p=0.14), and interface (179 vs 41 microns, p<0.01) regions.

Conclusion: Although presence of intratumoral TLS is associated with ICB response and longer survival among patients with UPS/DDLPS, not everyone benefits. Response to ICB appears to be associated with the immune profile both within and beyond TLS regions of pre-treatment tumors. Lower Treg, higher B cell populations, and greater distances between Tregs and B cells within pre-treatment biopsies may help predict response to ICB for UPS and DDLPS. Studies are ongoing to assess the evolution of these spatial relationships after ICB treatment.

#7125 Distinct CD8+T cell subsets in advanced melanoma patients with liver metastasis.

Shao Tao, Zang Han, Asha Bunyan, Adil Daud, Ajay Maker, James Lee

UCSF - University of California San Francisco, San Francisco, CA

Background: Liver metastases (LM) in melanoma are linked to poor prognosis, reduced immunotherapy efficacy, and survival, likely due to a suppressive liver immune microenvironment. We hypothesized that LM induces distinct, detectable immune changes in blood and tumor biopsies, supported by our prior preclinical findings. We set to immunophenotype tissues from stage IV melanoma patients to identify systemic and local immune changes, uncover immune tolerance mechanisms, and define biomarkers distinguishing LM-associated suppression. These insights aim to inform strategies to overcome liver-specific immune tolerance, enhance immunotherapy predictability and efficacy, and improve clinical outcomes for LM+ melanoma patients.
Methods: Peripheral blood and tumor samples were longitudinally collected from advanced melanoma patients pre, during, and post treatment clinic visits and/or surgeries. Clinical data, including imaging, treatment, and bloodwork, were obtained. Stage IV patients were stratified into two cohorts: LM+ and LM-. Fresh tumor and blood tissues were immunophenotyped by 12-24 color flow cytometry.
Results: In tumor specimens, ICOS expression on CD8+ subsets were significantly reduced in LM+ patients. Three distinct CD8+ T cell subsets were identified correlating with LM status. In peripheral blood, LM+ patients exhibited significantly lower frequencies of HLA-DR+CD8+ and HLA-DR+CD11c+CD11b-CD8+ subsets compared to LM- patients, while the CD11c+CD11b-CD8+ subset was significantly higher. Similarly, in tumor tissue, LM+ patients showed an increased frequency of CD11c+CD11b-CD8+ subset and a decreased frequency of HLA-DR+CD8+ subset. These observations underscore potential functional differences in immunity between LM+ and LM- patients. These subsets warrant further studies on the immune dynamics of melanoma LM.
Conclusions: Our parallel immunophenotyping of melanoma clinical samples is a foundational step towards developing predictive/prognostic biomarkers to distinguish between LM+ and LM- patients and their outcomes. We identified distinct T-cell subsets with differential representation between cohorts, with reduced expression of ICOS in CD8+ subsets and enrichment of CD11c+CD11b-CD8+ subset in LM+ patients. The functional roles of these subsets require further investigation. Given the immune-regulatory nature of the liver tumor microenvironment and clinical manifestations in LM+ patients, we hypothesize that the CD11c+CD11b-CD8+ subset exhibits a regulatory phenotype, contributing to immune suppression and tumor progression. We aim to characterize this subset at phenotypic, transcriptional, and functional levels, elucidating its role in LM-mediated immune modulation. These findings will inform the development of novel biomarkers and therapeutic strategies for melanoma patients with metastatic disease.

#7126 Divergent molecular features associated with immune checkpoint blockade response.

Travis D. Kerr[1], Patrick G. Pilie[2], Hui Dai[2], Amy B. Heimberger[3], Renata Ferrarotto[2], Jeffrey M. Rosen[4], Shiaw-Yih Lin[2], **Daniel J. McGrail**[1]

[1]Center for Immunotherapy & Precision Immuno-Oncology, Cleveland Clinic, Cleveland, OH,[2]MD Anderson Cancer Center, Houston, TX,[3]Northwestern University, Chicago, IL,[4]Baylor College of Medicine, Houston, TX

The advent of immune checkpoint blockade (ICB) has revolutionized cancer management. However, not all patients will benefit from this powerful therapy, necessitating clinical biomarkers and combination treatment strategies to enhance therapeutic efficacy. Recently, high tumor mutation burden (TMB-H) was FDA-approved as a pan-cancer biomarker for treatment with ICB based on a limited sample size and diversity of tumors. In systematic analysis across cancer types, we observed that immune cell infiltration was only associated with TMB in a subset of cancers. Based on this, we divided cancers into “Category I” cancers where TMB is associated with increased immune infiltration, and “Category II” cancers where TMB is not associated with immune infiltration. Using these classifiers, we analyzed the ability of TMB to predict ICB outcomes across over 2,000 patients. We found that TMB-H predicted ICB outcomes in Category I, but not Category II, cancers. As Category II cancers represent many of the most common cancers in the United States, including those of the breast, prostate, kidney, and brain, we next sought to identify biomarkers relevant to this subset of cancers. We identified that defects in DNA replication stress response predicts ICB response in 12 cohorts of Category II cancers, but not Category I cancers. Furthermore, induction of replication stress response defects sensitized otherwise resistant tumors to ICB. Based on these divergent molecular correlates of ICB response, we hypothesized that different mechanisms may underlie ICB activity in these tumors. Using single-cell RNA sequencing, we identified a non-canonical PD1+ dendritic cell population uniquely in mouse and human Category II cancers, and that this population undergoes extensive transcriptional rewiring following treatment with ICB. Together, this work illustrates the need for context-specific biomarkers for treatment with immune checkpoint blockade.

#7127 The correlation between immune status and the therapeutic efficacy of immune checkpoint inhibitors in patients with non-small cell lung cancer with sarcopenia.

Ryo Yamazaki, Satoshi Watanabe, Takaaki Masuda, Tomoya Wakabayashi, Yumi Ando, Kunihiro Shono, Naohiro Yanagimura, Masashi Arita, Miyuki Sato, Tomohiro Tanaka, Koichiro Nozaki, Yu Saida, Kenjiro Shima, Yosuke Kimura, Nobumasa Aoki, Yasuyoshi Ohshima, Toshiyuki Koya, Toshiaki Kikuchi

Department of Respiratory Medicine and Infectious Diseases, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Our previous prospective study demonstrated that non-small cell lung cancer (NSCLC) patients (pts) with pre-sarcopenia or sarcopenia exhibited poor responses to immune checkpoint inhibitors (ICIs). In this study, we evaluated the relationship between immune status and the efficacy of ICIs in NSCLC pts with sarcopenia.
Method: Pts with stage IV or recurrent NSCLC receiving ICI as first-line treatment at Niigata University Medical and Dental Hospital were eligible. Sarcopenia and pre-sarcopenia were diagnosed with physical performance and skeletal muscle mass. Before ICI treatments, peripheral mononuclear blood cells (PBMCs) were collected, and immune phenotypic data was obtained by flow cytometry.
Result: PBMCs were obtained from 34 pts from December 2021 through September 2024. Six patients and 7 patients were diagnosed with sarcopenia and pre-sarcopenia, respectively. Pts with a higher percentage of Lineage$^-$CD11b$^+$CD14$^+$CD33$^+$DR^{low} monocytic myeloid-derived suppressor cells (M-MDSCs) or Lineage$^-$CD11b$^+$CD15$^+$CD33$^+$DR^{low} polymorphonuclear (PMN)-MDSCs significantly shorter OS (median, 12 months (95% CI, 2.9-26.5) vs 33.1 months (95% CI, 11.4-NR); HR 2.7; P=0.035) after ICI treatments. Further, pts with PD-L1$^+$ cells in MDSCs also had poor OS (median, 12 months (95% CI, 2.9-26.5) vs 33.1 months (95% CI, 11.4-NR); HR 2.6; P=0.0387). The higher percentage of M-MDSC (P=0.0534) and the presence of PD-L1$^+$ cells in MDSCs (P=0.0473) tended to be associated with pts with sarcopenia or pre-sarcopenia.
Conclusion: MDSCs may play a critical role in immune suppression in NSCLC pts with sarcopenia and could be associated with poor OS following ICI treatment. To improve the survival outcome of pts with sarcopenia, it is essential to establish strategies to overcome MDSC-mediated immune suppression.

#7128 Neoantigen expression and expansion of cytotoxic T cell clonotypes in multiple myeloma patients receiving a personalized cancer vaccine post-transplant: Insights from the BM CTN 1401 multicenter trial.

Giulia Cheloni[1], Dimitra Karagkouni[1], Shivani Nanda[1], Lina Bisharat[1], Isabella Saldarriaga[1], Yuling MA[1], Shuoshuo Wang[1], Xanti-Lida Katopodi[1], Yered Pita-Juarez[1], Jessica Liegel[1], Hazal Toros[1], Prateek Pophali[1], David Chung[2], Nina Shah[3], Natalie Callander[4], Binod Dhakal[5], Thinle Chodon[6], Nikhil Munshi[7], Kenneth Anderson[7], Yvonne Efebera[8], Peiman Hematti[5], Hillard Lazarus[9], Ehsan Malek[9], Philip McCarthy[10], Ajay Nooka[11], Krina Patel[12], Aaron Rapoport[13], Robert Soiffer[7], Edmund Waller[11], Marcelo Pasquini[5], Jacalyn Rosenblatt[1], Ioannis Vlachos[1], David Avigan[1]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]AstraZeneca; University of California San Francisco, San Francisco, CA,[4]University of Wisconsin, Carbone Cancer Center, Madison, WI,[5]Medical College of Wisconsin, Milwaukee, WI,[6]Roswell Park Cancer Institute, Buffalo, NY,[7]Dana Farber Cancer Institute, Harvard Medical School, Boston, MA,[8]OhioHealth, Columbus, OH,[9]Case Western Reserve University, Cleveland, OH,[10]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[11]Emory University, Winship Cancer Institute, Atlanta, GA,[12]MD Anderson Cancer Center, Houston, TX,[13]University of Maryland School of Medicine, Baltimore, MD

Background: BMT CTN 1401 is a phase II trial of 140 multiple myeloma (MM) patients undergoing autologous hematopoietic cell transplant (HCT) followed by lenalidomide maintenance with or without a personalized DC/MM vaccine. Vaccination was associated with increased MM-reactive T cells and clonotypic expansion of activated T cells 1-year post-HCT. Here, we identify private or shared antigenic targets in pre-HCT bone marrow (BM) samples, along with corresponding T cell clonotypic patterns. We also further analyzed the peripheral blood (PB) immune landscape of the study patients, exploring the correlation between disease response and the T cell repertoire, including dominant clonotypes.
Method: Pre-HCT BM samples from 16 patients underwent bulk RNAseq and whole exome sequencing. With an in silico-experimental framework developed by our team, we predicted tumor antigens by considering factors including translation potential, RNA expression, peptide-MHC binding affinity, immunogenicity, clonality, and physicochemical properties. 10 samples were further analyzed by single cell (sc) immunoprofiling to assess the antigens expression in MM cells. Additionally, PB samples from 40 study patients underwent sc immunoprofiling to investigate the T cell repertoire in stringent complete response/complete response (sCR/CR, N=26), very good partial response (VGPR, N=9), partial response (PR; N=4) or progressive disease (PD; N=1).
Results: We observed a high prevalence of tumor-specific (neo)antigens, with 50% shared among more than 2 patients. 19 neoantigens were prioritized based on high immunogenicity and expression in multiple patients, including four expressed in immune-privileged tissues (MAGEC1, TPTE, UCHL1). UCHL1 showed an 80-fold higher median expression in MM samples than in healthy controls. We observed a significant enrichment of shared tumor antigenic peptides (n=33) across up to 10 patients, originating from regions not typically expressed or translated, such as retroelements and downstream/upstream open reading frames. PB T cells immunoprofiling revealed higher T cell clonotypic expansion in sCR/CR and VPGR, with sCR/CR associated with higher proportion of cytotoxic CD8 T cells and fewer Tregs 1-year post-HCT. A high degree of TCR sharing between clonally expanded T cells in the PB and BM was observed.
Conclusions: To identify novel immunotherapy targets for MM, we characterized the MM antigenic landscape, identifying personal and shared tumor antigens. In addition, we demonstrated that sCR/CR is associated with clonal expansion of cytotoxic T cells with clonal dynamics in the PB reflecting those in the BM. We are correlating the dominant T cell clonotypes with the identified antigens and assessing the impact of DC/MM fusion vaccination in this setting.

#7129 PDL1 expression on immune cells from solid tumor patients: Implications for tumor immunity and immunotherapy.

Angelina Bisconte, Rachel Owen, Jackie Benko, Jorge Pardo, Samantha Splitt, Deb Phippard

Precision for Medicine, Frederick, MD

Programmed death-ligand 1 (PD-L1) is a key immune checkpoint molecule that regulates immune responses by binding to PD-1 on T cells, contributing to immune tolerance and suppression. PD-L1 expression in solid tumors has become an important biomarker for evaluating the efficacy of immune checkpoint inhibitors in cancer therapy. Characterization of PD-L1 expression on immune cells, particularly CD8+ T cells, in patients with various solid tumors, including melanoma, non-small cell lung cancer (NSCLC), and breast cancer was performed using cryopreserved peripheral blood mononuclear samples using flow cytometry. In addition to PD-L1, co-expression of markers of T cell activation (e.g., CD69, CD86, Ki67) and exhaustion (e.g., PD-1, LAG3) was analyzed to gain a comprehensive understanding of immune cell status. PD-L1 expression was highly variable across patients within solid tumor indications, with elevated expression found on CD8+ T cells, suggesting an upregulation in response to persistent tumor antigenic stimulation. Furthermore, PD-L1+ CD8+ T cells often co-expressed markers of exhaustion, such as PD-1 and LAG-3, indicating a potential role for PD-L1 in T cell dysfunction and immune evasion. These findings underscore the complexity of PD-L1 expression by immune cells and its role in shaping immune responses in solid tumor patients. Through integrating PD-L1 profiling with other markers of immune activation and exhaustion, this highlights the potential of PD-L1 as a predictive biomarker for immunotherapy response and provides insights into the mechanisms of immune evasion in solid tumor cancers.

#7130 Spatially resolved single-cell analysis reveals cGAS-STING-mediated tumor-immune interactions via IFNα as determinants of pembrolizumab sensitivity in triple-negative breast cancer.

Yi Liu[1], **Saranya Chumsri**[2], Yaohua Ma[1], Jodi M. Carter[3], Aziza Nassar[4], Edith Perez[2], Roberto A. Leon-Ferre[5], David Zahrieh[6], David W. Hillman[6], Judy C. Boughey[5], James Ingle[5], Krishna R. Kalari[7], Fergus J. Couch[7], Matthew P. Goetz[5], Keith L. Knutson[1], E. Aubrey Thompson[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Hematology/Oncology, Mayo Clinic Florida, Jacksonville, FL,[3]Laboratory Medicine & Pathology, University of Alberta, Edmonton, AB, Canada,[4]Pathology and Laboratory Medicine, Mayo Clinic Florida, Jacksonville, FL,[5]Hematology/Oncology, Mayo Clinic, Rochester, MN,[6]Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[7]Mayo Clinic, Rochester, MN

Purpose: While an addition of immune checkpoint inhibitor (ICI), pembrolizumab, has improved outcomes of patients with TNBC, early-stage TNBC patients with residual cancer burden (RCB) II/III after neoadjuvant chemotherapy in combination with pembrolizumab (NAP) still have poor outcomes. Previously, we demonstrated that intratumoral HLA-DRA expression and interferon-alpha (IFNα) responses were associated with immune-inflamed phenotype and better outcomes in TNBC patients receiving chemotherapy. This study utilized the CosMx™ SMI to investigate in early-stage TNBC treated with NAP.

Methods: Of 151 samples from TNBC patients treated with NAP at Mayo Clinic, 8 pre-treatment biopsy samples (5 pCR and 3 RCB II/III were analyzed using the CosMx™ SMI platform. Linear mixed models to assess differential expression (DE), adjusting for hierarchical data structures. DE analyses were expressed as log2-fold changes (logFC), with the Benjamini-Yekutieli method. GSEA and IPA for signaling pathway exploration.

Results: 1.7 million cells were identified across 8 samples after stringent quality control. Immune cell profiling revealed higher B cells, plasma cells, plasmablasts, and T cells (CD4 and CD8) in responders, whereas fibroblasts and myeloid cells were enriched in non-responders. DE analysis showed significantly elevated expression of HLA-DRA (logFC 1.955, $p<0.001$), other MHC class I and II components, and IFNα in responders. Tumor cells in responders exhibited the highest IFNα expression across cell types. GSEA and IPA analysis revealed enrichment in interferon signaling, antigen presentation, and the cGAS-STING pathway, which drives IFNα production. Spatial analysis categorized cells by their proximity to tumor cells: within 50 µm, 50-100 µm, and over 100 µm. T cells, particularly CD8 T cells, showed a distance-dependent distribution, with a higher abundance near tumor cells in responders. CD8 T cell activation scores declined with increasing distance from IFNα-positive tumor cells but remained consistently low near IFNα-negative tumor cells. IFNγ-positive CD8 T cells exhibited higher activation compared to IFNγ-negative cells, with activation levels influenced by proximity to tumor cells. Lastly, MHC expression in tumor cells was examined relative to CD8 T cell proximity. HLA-DRA and CIITA expression decreased as tumor cells were farther from CD8 T cells.

Conclusions: This spatially resolved single-cell analysis highlights the pivotal role of tumor-immune interactions in response to pembrolizumab in TNBC. Our data suggest that tumor cells secrete IFNα through the activation of the cGAS-STING pathway, which activates T cells within close proximity, highlighting the potential role of cGAS-STING agonist as well as IFNα signaling and antigen presentation in augmenting TNBC responses to ICIs.

#7131 Integrative single-cell transcriptomic and epigenomic immune profiling reveals parallel insights into cancer research.

Errile Pusod[1], Patricia Schnepp[1], Srikanth Perike[2], Angelica Olcott[2], Elizabeth Dreskin[2]

[1]Bio-Rad Laboratories, Ann Arbor, MI,[2]Bio-Rad Laboratories, Hercules, CA

Introduction: Single-cell technologies have revolutionized immune profiling by enabling the detailed analysis of individual cells, uncovering cellular heterogeneity and complex regulatory mechanisms. Two common single-cell omics include single-cell RNA-sequencing (scRNA-seq) which profiles gene expression by capturing mRNA transcripts, and single-cell ATAC sequencing (scATAC-seq) which profiles gene regulation using hyperactive Tn5 transposase to assess chromatin accessibility. In this workflow, we demonstrate integrative analysis of both technologies that provides comprehensive view of a cell's transcriptomic and epigenomic landscapes.
Methods: Two independent scRNA-seq and scATAC-seq workflows were performed on peripheral blood mononuclear cells (PBMCs) and various cancer cell lines to provide accessible and convenient model system for various oncology applications. Libraries were prepared using Bio-Rad ddSEQ 3' scRNA-seq and scATAC-seq Kits, which uses droplet-based ddSEQ technology for capturing cells with high sensitivity and recovery. Libraries were sequenced using Illumina NextSeq 2000. Data quality was assessed using the Omnition Analysis Software and Seurat was used for downstream tertiary analyses.
Results: Here, we present an integrated analysis of scRNA-seq and scATAC-seq for comprehensive immune profiling of peripheral blood mononuclear cells (PBMCs) and various cancer cell lines. Our findings show consistent correlation of cell types and subtypes identified from each pair of samples. Furthermore, specific differentially expressed genes (DEGs) and differentially accessible regions (DARs) were found to be shared in corresponding cell types such as chromatin peak and increased gene expression of Epiregulin (EREG) in CD14+ monocytes.
Conclusion: Bio-Rad ddSEQ 3' scRNA-seq and scATAC-seq kits provide affordable and scalable method for profiling immune response from thousands of individual cells with increased sensitivity and accuracy. Combined analyses from these two approaches show strong potential for oncology applications. For example, the ability to identify novel immune cell subsets, discover tumor biomarkers, characterize tumor-infiltrating lymphocytes, and reveal regulatory elements driving immune responses in the tumor microenvironment can all be achieved.

#7132 Estimated post-test probabilities of cancers for individuals receiving multi-cancer early detection (MCED) tests.

Candace Westgate[1], Christina Clarke Dur[2], Eric Klein[2], Alpa V. Patel[3], Earl Hubbell[2]

[1]Adventist Health, Saint Helena, CA,[2]GRAIL, Inc., Menlo Park, CA,[3]American Cancer Society, Atlanta, GA

Background: Individuals and their physicians receiving MCED tests may need to interpret the results they receive in the context of their particular cancer risks, both for positive ("cancer signal detected") and for negative ("no cancer signal detected") test results. Using estimated performance characteristics of an on-market MCED test we modeled post-test probabilities after receiving an MCED test result for a variety of typical populations stratified by five year age group and sex, and adjusted for smoking status (unadjusted, ever, former, never), as well as the duration of reduced cancer risk in those who tested negative.

Methods: Using (1) 2006-2015 data (cancer incidence by age, sex) from the Surveillance, Epidemiology and End Reports (SEER) 17, (2) adjustments to incidence by smoking risk factors (3) test sensitivity from the third sub-study of the Circulating Cancer Genome Atlas, and (4) duration of detectable window from the American Cancer Society Cancer Prevention Study III and an exponential distribution for the detection window, we computed post-test probabilities of detection (for positive tests), and depletion of future cancers over various time intervals (for negative tests).

Results: Individuals receiving a negative MCED test result had 42-56% (min-max) the level of late stage (III+IV) cancer diagnosis in the year following blood draw, rising to 72-82% the second year if they did not return for an annual test. Individuals receiving a positive MCED test result with a cancer-signal origin (CSO) returned, had a cancer at that signal location if cancer is confirmed (97% of individual-CSO combinations), with sufficient positive predictive value at each CSO justifying workup (97% of individual-CSO combinations) with few exceptions, such as a breast CSO in males. An important complicating factor is the utilization of conventional screening or imaging tests which can significantly alter the pre-test probability of having certain cancers, for which we provide the example of colonoscopy and its effects over the ten-years post-negative screen.

Conclusions: For common clinical covariates of age, sex, and smoking status this model provides important clinical context for interpreting test reports, including the potential for a significant increase in late stage, deadly interval cancers when testing at longer intervals than one year. Following the CSO estimate in the majority of individuals with positive test results is justified by comparison to usual clinical decision thresholds.

#7133 Detection of early stage colorectal cancer using cell-free oncRNA biomarkers and AI.

Amir Momen-Roknabadi[1], Mehran Karimzadeh[1], Nae-Chyun Chen[1], Taylor B. Cavazos[1], Jieyang Wang[1], Jeremy Ku[1], Alex Degtiar[1], Akshaya Krishnan[1], Martha Hernandez[1], Alice Huang[1], Selina Chen[1], Dang Nguyen[1], Ti Lam[1], Rose Hanna[1], Lisa Fish[1], Magdalena Gebala[1], Alexx J. Smith[1], Sukh Sekhon[1], Jennifer Yen[1], Jeff Gregg[2], Hani Goodarzi[3], Helen Li[1], Fereydoun Hormozdiari[1], Babak Behsaz[1], Anna Hartwig[1], Lee Schwartzberg[1], Babak Alipanahi[1]

[1]Exai Bio Inc., Palo Alto, CA,[2]UNR School of Medicine, Reno, NV,[3]UCSF, San Francisco, CA

Background
Colorectal cancer (CRC) is the second leading cause of cancer-related mortality worldwide. Early detection offers the best opportunity for effective treatment. Although CRC screening methods exist, there remains a need for a high performing blood test to both improve adherence and detect early stage disease. We have previously identified and developed a novel category of cancer-associated, small orphan non-coding RNAs (oncRNAs), and combined them with generative AI modeling to develop a liquid biopsy platform. This platform has demonstrated high sensitivity and specificity for detection of early stage disease across several types of cancer. In this study, we developed an oncRNA- and AI-based assay and analyzed it in a separate, independent test set to evaluate its generalizability and its ability to detect CRC across different cancer stages.
Methods
We utilized The Cancer Genome Atlas (TCGA) small RNA profiles to discover a library of pan-cancer oncRNAs that were significantly enriched among tumors compared to adjacent normal tissues spanning multiple tissue sites. The diagnostic performance of these oncRNAs was evaluated in plasma using a training and independent test cohort. Our training cohort included 613 samples (388 CRC and 225 asymptomatic controls) from six different sources (mean age: 63.7 years, 35.9% female). 37.6% of the cases were classified as stage I/II and 60.8% as stage III/IV. Further, we acquired 192 samples (113 CRC and 79 asymptomatic controls) from a separate cohort for testing (average age: 62.6 years ; 51.6% female). In the test set, 52.2% of cases were classified as stage I/II and 47.8% as stage III/IV. We processed 1 ml of plasma for each sample through our universal, automated cell-free RNA workflow and sequenced at an average depth of 58 million 100-bp single-end reads. A generative AI model was trained using 5-fold cross-validation (CV) to predict CRC, and then applied on the separate, independent test set.
Results
Our oncRNA-based generative AI model achieved an overall AUC of 0.93 (95% CI: 0.91-0.95) for prediction of CRC versus cancer-free controls in CV, and an overall AUC of 0.95 (0.93-0.98) in the independent test set. At 90% specificity, overall model sensitivity was 81.7% (77.5%-85.4%) by CV in the training data, and 88.5% (81.1%-93.7%) in the test set. For stage I CRC, the model has a sensitivity of 72.1% (59.9%-82.3%, N=68) by CV in the training data, and 80.0% (51.9%-95.7%, N=15) in the test set, both at 90% specificity.
Conclusions
We demonstrate that blood-based cell- free RNA can be used for accurate and generalizable early stage detection of CRC. This approach, leveraging a distinct RNA biomarker, has the potential to overcome performance plateaus seen with conventional DNA-based methods in early-stage CRC detection. It offers a promising alternative for blood-based CRC screening in patients and could complement existing DNA- and methylation-based platforms.

#7138 Whole genome sequencing-based detection of minimal residual disease using individual-specific features.

Jun Hyeok Lim[1], Jeong-Seon Ryu[1], Ji Won Byun[1], Jongsuk Chung[2], **Hyun-Tae Shin**[1]

[1]Inha University College of Medicine, Incheon, Korea, Republic of,[2]Gencurix Inc, Seoul, Korea, Republic of

The detection of minimal residual disease (MRD) following cancer treatment is critical for preventing recurrence and improving patient prognosis. However, existing MRD detection methods often lack the sensitivity required for precise monitoring. We have developed a highly sensitive method for MRD detection using whole-genome sequencing (WGS) analysis of cell-free DNA (cfDNA) with individual-specific features. The approach begins by identifying consensus single nucleotide variants (SNVs) and fusions that are consistently detected by multiple variant callers in the patient's tumor WGS. Using a novel algorithm, we quantify supporting reads at the consensus SNV positions and assess their statistical significance based on the error distribution in the patient's plasma WGS. Additionally, unique sequences corresponding to the consensus fusion positions in the plasma WGS are detected to diagnose MRD. Validation through cancer cell-line mix experiments demonstrated a sensitivity of less than 1:12,800. Furthermore, the method effectively detected MRD in clinical samples from various cancer types, including lung, melanoma, breast, and liver. The limit of detection for the SNV quantification method was determined by the error rate in the individual BAM file, while the fusion sequence detection method exhibited no detection limit due to a limit of blank of zero. This algorithm has been implemented on a cloud platform, allowing individual users to analyze their data by uploading it. This highly sensitive approach for detecting MRD offers the potential to improve cancer patient prognosis significantly. Moreover, this technology holds great promise for broad applicability across various cancer types where cfDNA-based monitoring can provide clinical benefits.

#7139 An optimized extraction and library preparation workflow for sensitive mutation detection in clinical cfDNA samples.

Lauren P. Saunders[1], James Erickson[1], Margaret R. Heider[2], Jian Sun[2], Adrian Reich[2], Ben Lepene[1]

[1]Ceres Nanosciences, Manassas, VA,[2]New England Biolabs, Ipswich, MA

Monitoring cell-free DNA (cfDNA) - small DNA fragments circulating in the bloodstream - provides valuable insights into various tissues throughout the body and diverse health conditions. cfDNA has been particularly useful in tracking cancer progression, although its low abundance can lead to low mutation copy frequencies, especially in early-stage cancers where limited tumor presence yields minimal cfDNA in circulation. Optimizing molecular biology techniques for maximal cfDNA recovery and purity as well as high NGS library conversion efficiency is essential to improve detection of low-frequency cancer mutations.

In this study, several cfDNA next generation sequencing (NGS) library preparation workflows were evaluated for sensitivity and workflow efficiency. The NEBNext UltraExpress DNA library prep kit is a new, fast library prep that has not yet been optimized for cfDNA analysis. We compared it with the NEBNext Ultra II DNA Library Prep Kit, which performs well with cfDNA. Both kits were evaluated downstream of the NEAT Liquid Biopsy kit, which is optimized for gDNA removal using Nanotrap Particle technology and results in a highly concentrated DNA elution. With the ability to concentrate down to 20 µL, this extraction kit pairs well with the NEBNext UltraExpress DNA kit which has a 15 µL input. This allows more of the sample to be analyzed, leading to higher detection of low frequency alleles. Initial workflow assessments were analyzed with mutation spike-ins of 0-5% allele frequency in healthy plasma, then confirmed with clinical samples containing known mutations. All workflows produced high complexity libraries with high quality data and successfully detected spike-in mutations, with expected variant allele frequencies. Mutations were also successfully detected in clinical plasma samples demonstrating the essential need for efficient extraction and library prep methods.

#7140 Non-synonymous mutations in the IFN-γ pathway are predictive of response to immune checkpoint inhibition in NSCLC.

Alexander Azizi[1], Arvind Ravi[1], Marzia Capelletti[2], Nicholas Haradhvala[1], Natalie Vokes[3], Stephen-John Sammut[4], Steven Ressler[2], Milan Radovich[2], Justin Gainor[5], Gad Getz[1]

[1]The Broad Institute, Cambridge, MA,[2]Caris Life Sciences, Dallas, TX,[3]Department of Thoracic/ Head and Neck Medical Oncology, MD Anderson Cancer Centre, Houston, TX,[4]Breast Cancer Now Toby Robins Research Centre, The Institute of Cancer Research, London, United Kingdom,[5]Center for Thoracic Cancers, Massachusetts General Hospital, Boston, MA

Introduction: Baseline disruptions in interferon gamma (IFN-γ) signalling enhance tumor immune elimination post-checkpoint blockade in murine models. In the Stand Up to Cancer-Mark Foundation (SU2C-MF) NSCLC clinical cohort, non-synonymous mutations in IFN-γ pathway genes (IFNGR1, IFNGR2, JAK1, JAK2, STAT1, IRF1 & IRF9; n=26, 8%) associated with better outcomes following PD-(L)1 inhibitors (ICI), including improved radiological responses, progression-free survival, and overall survival (OS) (AACR 2024). Here, we aimed to validate these results in an independent dataset and examine predictive vs. prognostic significance.

Methods: The Caris Life Sciences (CARIS) dataset includes NSCLC patients with standard-of-care biopsies and multi-omic testing. Outcomes were tracked using claims. IFN-γ pathway disruption was defined as non-synonymous mutations in the genes available from CARIS's curated whole exome sequencing data (WES) and deep panel of 592 cancer-associated whole-genes: IFNGR1, JAK1, JAK2 & IRF1. Cox proportional-hazards models (CoxPH) assessed OS from ICI initiation. Co-variables had to be dichotomized: age (<65/≥65), PDL1 TPS (0%/>0%), smoking history (non-smoker/ever smoker), and continuous, including TMB, by median.

Results: Among 1070 patients with pretreatment WES, ICI treatment, and OS data, 88 (8.2%) had IFN-γ pathway mutations. Disruption was associated with significantly improved OS (HR 0.63, p=0.028*). Median OS for patients with disrupted vs. intact pathways was 60.0 months (95% CI: 27.6-NA) vs. 26.2 months (95% CI: 20.5-29.7).

Clinical multivariable CoxPH models incorporating TMB and PDL1 TPS confirmed pathway disruption as independently significant (HR 0.27, p=0.030*); this persisted when including sex, age and smoking (OS: HR 0.66, p=0.05). Biological models, including TMB, PDL1 TPS, and immune biomarkers (CXCL9, CD8A, GZMA, PRF1, IFNG), supported survival benefits (HR 0.65, p=0.046*). Correlation coefficients between pathway disruption and covariates were low (e.g., IFNG, 0.005; PDL1 TPS, -0.04; TMB, 0.14).

To assess prognostic effects, in the CARIS dataset, we evaluated analogous patients with NSCLC who had pretreatment WES, no prior or concurrent immunotherapy, but were treated with chemotherapy (disrupted: n=15; intact: n=143). Pathway disruption did not associate with OS [univariable: HR 1.64, p=0.42; multivariable with TMB and PDL1: HR 1.86, p=0.22]. TCGA lung data also failed to suggest a prognostic impact on OS (disrupted: n=40; intact: n=902) [univariable: HR 0.96, p=0.88; multivariable - continuous TMB, histology, stage, purity, age and sex: HR 1.86, p=0.70].

Conclusion: In the SU2C-MF and CARIS NSCLC cohorts, non-synonymous IFN-γ pathway mutations predict improved ICI outcomes, independently of TMB and other variables, but are not prognostic. IFN-γ pathway disruption could guide immunotherapy stratification in NSCLC.

#7141 Final analysis of the randomized Phase 2 cohort of CM24 with nivolumab and chemotherapy in pancreatic cancer & potential serum biomarkers.

Background: CM24 (mAb) blocks CEACAM1 interactions between cancer cells, immune cells and neutrophil extracellular traps (NET), involved in tumor immune evasion, metastasis and cancer-associated thrombosis, affecting patient (pts) survival. We present the final data for the randomized Phase 2 study (NCT04731467) and significant efficacy in a biomarker-enriched subgroup.

Methods: Advanced/metastatic PDAC pts (n=31) progressing after first line treatment, were randomized to receive CM24 (20mg/kg q2wk), nivolumab (240mg/kg q2wk) and chemotherapy (liposomal irinotecan/5FU/LV) (EXP) vs chemotherapy only (CON; q2wk). Pre-dose serum samples (n=30) were collected. Serum CEACAM1 and myeloperoxidase (MPO; a NET marker) levels were evaluated by ELISA. Biomarkers were analyzed post-hoc and HRs for various thresholds were correlated with survival outcomes to select the greatest range providing a statistical benefit. The selected ranges exclude pts with extremely low or high levels of CEACAM1 and NETs.

Results: Final analysis of EXP vs CON shows OS 7.9m vs 5.6m (Δ=2.3m) HR 0.81 (P 0.575, CI 0.38-1.71), PFS 3.9m vs 2.0m (Δ=1.9m) HR 0.75 (*P* 0.46, CI 0.35-1.61), ORR 25% vs 6.7%, DCR 62.5% vs 46.7%. Most frequent Grade ≥3 adverse events were diarrhea; 4 vs 1 pts, fatigue; 2 vs 0 pts and neutropenia; 2 vs 0 pts. Subgroup analysis of pts with serum CEACAM1 level of 6K-15K pg/mL (n=11/30) demonstrates statistically significant benefits in terms of OS: HR 0.21 (*P* 0.04, CI 0.04-1.06), ΔOS=5.1m, PFS: HR<0.1 (*P* 0.003, CI 0-inf), ΔPFS=2.9m, and ORR 50% vs 0%. Statistically significant results were also seen for 80% of the pts (24/30) with serum CEACAM1 (5-16K pg/mL) or serum NET marker MPO (200-600 ng/mL) demonstrating OS HR 0.39 (*P* 0.039, CI 0.16-0.98) and PFS HR 0.28 (*P* 0.006, CI 0.11-0.73).

Conclusions: Final data show that adding CM24 and nivolumab to chemotherapy improved all efficacy parameters and had a manageable safety profile. Subgroup analyses demonstrate statistically significant reduction in the risk of OS and PFS, and suggest serum CEACAM1 & NET marker as predictive biomarkers for CM24-based therapy, corresponding with CM24 mechanism of action

#7142 Mutations in PBAF, especially in PBRM1, enhance immune checkpoint inhibitor response in lung adenocarcinoma.

Sung Feel Kim[1], Hong Sook Kim[2], Hongui Cha[3], Hyemin Kim[1], Yeong Hak Bang[1], Cheolyong Joe[1], Jun-Gi Jeong[1], Eunjoo Oh[1], Na-Eun Lee[1], Hyun Ae Jung[1], Jong-Mu Sun[1], Jin Seok Ahn[1], Myung-Ju Ahn[1], Sehhoon Park[1], Se-hoon Lee[1]

[1]Division of Hematology-Oncology, Departments of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[2]Department of Biological Sciences, Sungkyunkwan University, Suwon, Korea, Republic of,[3]University College London Cancer Institute, Cancer Research UK Lung Cancer Centre of Excellence, London, United Kingdom

Introduction: The SWI/SNF chromatin remodeling complex plays a pivotal role in regulating gene expression and maintaining genomic integrity, with three distinct complexes identified: BAF, PBAF, and ncBAF (also known as GBAF). Each complex contributes uniquely to cellular processes and cancer development. Within the PBAF complex, PBRM1, a key component, has garnered significant interest for its potential to influence the efficacy of immune checkpoint inhibitors (ICIs) in Non-Small Cell Lung Cancer (NSCLC). Despite the critical implications, there remains considerable controversy regarding whether mutations in PBRM1 and other components of the SWI/SNF complexes enhance or impair responses to ICIs. This study seeks to resolve these conflicting perspectives by elucidating the impact of mutations in these key components on the outcomes of ICI therapy in patients with NSCLC, especially lung adenocarcinoma.
Methods: We conducted a retrospective analysis of 4,166 NSCLC patients treated with ICIs at Samsung Medical Center. Among these, 745 met strict inclusion criteria including pre-treatment biopsy and complete RECIST and clinical data. Whole-exome sequencing was performed on 514 patients, focusing on mutations in all the SWI/SNF complex subunits such as ARID1A, ARID1B, ARID2, BRD7, SMARCA4, and PBRM1. Survival analysis techniques were employed to evaluate the association between these mutations and ICI therapy outcomes, calculating median progression-free survival (mPFS) and overall survival (mOS) using hazard ratios (HRs) and log-rank tests.
Results: In the lung adenocarcinoma subset, PBAF complex mutations were significantly associated with improved ICI outcomes, with an mPFS of 3.8 months (HR: 0.71, 95% CI: 0.52-0.98, p = 0.034) and an mOS of 19.4 months (HR: 0.69, 95% CI: 0.50-0.95, p = 0.022). PBRM1 mutations, in particular, resulted in favorable outcomes, with an mPFS of 4.2 months (HR: 0.58, 95% CI: 0.35-0.94, p = 0.018) and an mOS of 24.7 months (HR: 0.54, 95% CI: 0.33-0.91, p = 0.026). These associations were not significant in lung squamous cell carcinoma and other NSCLC subsets.
Conclusion: This study provides evidence that PBAF complex mutations, especially in PBRM1, are associated with improved ICI outcomes in lung adenocarcinoma patients. These findings suggest the potential utility of these mutations as predictive biomarkers for personalizing immunotherapy in this subset of NSCLC patients. Prospective studies are needed to validate these observations and explore the underlying biological mechanisms.

#7143 Development of a peripheral dazostinag (TAK-676) activation RNASeq signature to evaluate STING pharmacodynamic modulation in human solid tumor clinical trials.

Kai Ding, Xin Tong, Radha Ramesh, Samanthi Perera, Yu-Chung Huang, Alex Parent, Jeffrey Raizer, John Gibbs, Neil Lineberry, Vicky Appleman, Somnath Bandyopadhyay, Richard C. Gregory

Takeda Development Center Americas, Inc. (TDCA), Lexington, MA

Dazostinag, a novel STimulator of INterferon Genes (STING) agonist, is currently being evaluated with pembrolizumab for colorectal and head & neck cancers (iintune-1, NCT04420884). RNA sequencing (RNASeq) is a valuable tool for pharmacodynamic (PD) biomarker development, offering comprehensive transcriptome profiling and a wide dynamic detection range. For the iintune-1 Phase 1/2 study, we developed an RNASeq peripheral PD signature for STING activation and demonstrated its utility as a secondary endpoint to measure biological responses to dazostinag.

To develop the PD signature, peripheral blood mononuclear cells (PBMCs) from 7 healthy donors were treated *ex vivo* with vehicle or dazostinag (0.33-10 μM, 6 hours, 3 replicates) and samples were processed for RNASeq. Protein-coding genes with a maximum FPKM ≥ 1 and low variance between replicates were filtered and analyzed utilizing dose-response mixed model for repeated measures. Genes with significant dose responses (FDR ≤ 0.05 and fold change ≥ 1.5 at 0.33 μM) underwent network analysis to identify biologically connected genes.

A 19-gene network with significant response to dazostinag was identified and termed STING_19. Among these genes, 17 are in the interferon (IFN) pathway, consistent with the known IFN activation effect of STING agonists. An independent RNASeq dataset from human PBMCs treated *ex vivo* with dazostinag (0.12-10 μM) was used to evaluate STING_19 against hallmark IFN-α and IFN-γ signatures. STING_19 demonstrated a robust dose-dependent induction by dazostinag, with a median 70-fold increase at 10 μM, greater than the 4 to 6-fold induction of IFN-α and IFN-γ signatures. Additionally, STING_19 induction was confirmed in a syngeneic mouse model, showing a 55-fold increase at 6 hours post-treatment with 1 mg/kg dazostinag.

In the iintune-1 study, for dazostinag single agent arm, STING_19 exhibited a dose-dependent induction in blood, starting from 0.8 mg/kg with a median 18-fold increase at the highest dose of 14mg/kg, indicating a robust PD response. Pembrolizumab combination arm showed a similar induction of STING_19 in response to dazostinag, with pembrolizumab alone at low dazostinag dose (as a surrogate for monotherapy) showing minimum STING_19 induction. Within 0 to 24-hours post-treatment, maximum induction of STING_19 was typically at 24 hours for doses up to 5 mg, and at 10 hours for doses between 7-14 mg, suggesting dose-dependent STING activation dynamics by dazostinag. This induction returned to baseline prior to subsequent weekly doses.

In summary, we developed a robust RNASeq-based peripheral STING activation PD biomarker using *ex vivo* treated PBMCs to evaluate the biological response to STING agonist treatment. This framework could be applied for the development of RNASeq based peripheral PD biomarkers for other investigational assets.

#7144 Integrative analysis of immunogenetics of the HLA-KIR-MIC system to predict clinical outcomes for checkpoint immunotherapy.

Hyun-Sung Lee[1], Priyanka Ranchod[1], Sonali Mitra[1], Hee-Jin Jang[1], Claire Lee[1], Sung Wook Kang[1], Ji Seon Shim[1], Ito Atsushi[1], Gena Lee[1], Tannaz Armaghany[2], Michael Byrd[2], Aihua Yen[2], Quillan Huang[2], Rafee Talukder[2], Shalini Makawita[2], Benjamin Musher[2], Peter Jindra[1], Jinyoung Byun[3], Younghun Han[3], Daniel Wang[4], Bryan Burt[5], Meera Patel[2]

[1]Surgery, Baylor College of Medicine, Houston, TX,[2]Medicine, Baylor College of Medicine, Houston, TX,[3]University of New Mexico, Albuquerque, NM,[4]Medicine, UT South Western Medical Center, Dallas, TX,[5]Surgery, University of California Los Angeles, Los Angeles, CA

Background: Immune-related adverse events (irAEs) have been associated with improved survival during checkpoint immunotherapy in thoracic cancers. However, the relationship between irAEs and survival across various solid tumors remains unclear. This study aims to validate the association between irAEs and prognosis in patients with solid tumors treated with immune checkpoint inhibitors (ICIs) and to identify predictive determinants of irAEs.

Methods: This prospective observational cohort study included 138 patients with solid tumors receiving ICIs or chemo-ICIs, with a median follow-up of 27 months. The primary outcome was the association between irAEs and overall survival (OS). Clinically meaningful irAEs were defined as those requiring treatment delay or discontinuation of ICIs and/or systemic corticosteroids for management of toxic effects. High-resolution HLA/MIC/KIR genotyping and high-throughput plasma proteomics were performed from pre-ICI blood samples to identify determinants to predict irAEs.

Results: Of the 138 patients, 43 (31%) developed irAEs. irAEs were more frequent among responders (12/20 CR (60%) and 4/7 PR (57%)) compared to those with SD (10/31 (32%)) and PD (17/80 (21%)). irAEs were associated with improved OS (median OS with irAEs: 25.8 mo.; without irAEs: 18.5 mo.; HR = 0.56 [95% CI, 0.33-0.95]) and disease-free survival (DFS) (median DFS with irAEs: 17.3 mo.; without irAEs: 4.8 mo.; HR = 0.49 [95% CI, 0.31-0.77]). Furthermore, patients with both durable clinical benefit (DCB) and irAEs demonstrated superior OS (median: 58 mo.) and DFS (median: 34.6 mo.) compared to DCB without irAEs (median OS: 33.4 mo.) and PD (median OS: 13.5 mo.; $P = 1.5 \times 10^{-6}$). Integrated immunogenetic analyses of HLA-A, -B, -C, -E, -F, -G, DRB1, DP, and DQ alleles, as well as MHC-I/II heterozygosity, Bw4/Bw6 (HLA-B), C1/C2 (HLA-C), and centromeric/telomeric KIR groups (AA vs. Bx), revealed distinct clusters for patient stratification. Patients with DCB and irAEs were enriched in more activating immunogenetic genotypes including Bw4 homozygosity, C2 homozygosity, and telomeric Bx KIR genotypes. Furthermore, proteomic analysis of pre-treatment plasma samples showed significant decreases in immunoregulatory proteins and cytokines in patients with DCB and irAEs. Multivariable regression analysis adjusted for cancer type and treatment modality demonstrated that integrative immunogenetics profiles (P=0.004) and circulating proteomic signatures ($P=3.2x10^{-4}$) independently predicted benefit from ICIs while identifying patients at higher risk for irAE development.

Conclusion: This study highlights the utility of integrating immunogenetics and systemic immunity profiling to stratify patients receiving ICIs. Blood-based biomarkers may predict clinical benefit and irAE development, warranting further prospective validation.

#7145 The pan-cancer landscape of *RIT1* genetic alterations.

Matteo Repetto[1], Pier Selenica[2], Soo-Ryum Yang[1], Britta Weigelt[2], Alexander Drilon[1]

[1]Early Drug Development, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Advancements in drug design have resulted in the development of approved and investigational agents targeting KRAS-driven tumors. RIT1 is a GTPase protein that shares homology and oncogenic activation mechanisms with KRAS and plays a role in cell division and resistance to apoptosis. In this study, we aimed to characterize the landscape of *RIT1* alterations across a pan-cancer cohort to assess its frequency and potential as an oncogenic driver.

Methods: Tumor content, ploidy and allelic specific copy number of 86,039 tumor-normal matched samples sequenced clinically with a targeted sequencing panel (MSK-IMPACT) were analyzed with FACETS. Low purity (<20%) and indetermined copy number samples were excluded. Presence of *RIT1* amplifications (Amp), structural variants, oncogenic mutations (Mut), and concurrent OncoKb oncogenic/likely-oncogenic alterations in other genes were evaluated. Co-occurrence and mutual-exclusivity (Co-Me) analyses were performed using DISCOVER. *RIT1*-altered samples were evaluated for genomic complexity compared to wild-type (WT) samples. False discovery rate correction was applied when appropriate.

Results: After removing low-quality samples, 63,270 cancer samples were included, and 1.32% (n=838) were found to harbor *RIT1* oncogenic alterations. Most *RIT1*-alterations observed were Amps (735/838) followed by somatic mutations (Muts) (83/838), concomitant Mut and Amp (2/838) and structural variants (18/838). The most frequent *RIT1* Mut was p.M90I (n=40), followed by p.F82C (n=17), p.A77T (n=11) and R122Q (n=9).Uterine carcinosarcomas (5.5%), hormone receptor-positive breast cancer (4.9%) and triple-negative breast cancer (4.7%) had the highest prevalence of *RIT1* alterations. Restricting the analysis only to Muts, lung adenocarcinoma (LUAD) (n=15; 0.22%) and bladder cancers (n=13; 0.51%) had the highest number of oncogenic *RIT1* Muts. *RIT1*-mutant samples had higher TMBs than *RIT1*-WT samples ($p<0.01$). This association was conserved when accounting for histology in bladder cancer and LUAD ($p<0.01$). *RIT1* Amps were associated with higher fraction of genome altered ($p<0.01$) and co-occurred with amps of neighboring genes *NTRK1* ($p<0.01$) and *AKT3* ($p<0.01$) across most tumor types. DISCOVER assisted Co-Me analysis identified *RIT1* Muts as mutually exclusive with *EGFR* Muts in LUAD ($p<0.01$). Among *RIT1*-mutant samples, 10/15 (66%) LUADs harbored *RIT1* as the sole identifiable oncogene driver alteration, whereas only 3/13 (23%) bladder cancers were otherwise driver negative.

Conclusion: *RIT1* alterations appear to be rare across most tumor types. Higher TMB and rarity of *RIT1* Muts and the observation of *RIT1* Amps frequently co-amplified with other chromosome 1 arm q genes, suggest that these alterations might be primarily passengers. These results have implications for stakeholders interested in developing potential therapies for RIT1 as the landscape of these alterations has not been previously explored.

#7146 Unmasking host immune complexity: Single-cell transcriptomic analysis of circulating PBMCs in non-small cell lung cancer treated with immunotherapy based first line - I3LUNG study.

Arsela Prelaj*[1], Monica Ganzinelli*[1], Alessandro Guidi*[2], Chiara Cavalli*[1], Cecilia Silvestri[1], Antonino Belfiore[2], Laura Mazzeo[1], Claudia Proto[1], Mario Occhipinti[1], Marta Brambilla[1], Teresa Beninato[1], Leonardo Provenzano[1], Luca Inverizzi[2], Giulia Bertolini[3], Daniele Lorenzini[2], Filippo De Braud[1], Luca Agnelli#[2], Andrea Vingiani#[2], **Sabina Sangaletti#**[3], Giuseppe Lo Russo#[1]

[1]Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[2]Department of Diagnostic Innovation, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[3]Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background and Purpose: Biomarkers for immunotherapy in NSCLC remain inadequate, with PD-L1 continuing to underperform despite its ongoing use. "Ghost biomarkers", such as circulating immune profiling, hold potential to reveal host immunity dynamics and identify ways to enhance immune fitness for improved therapeutic outcomes. This study uses single-cell technologies to analyse circulating immune cells in stage IV NSCLC patients (pts) receiving first line mono-immunotherapy (IO) or chemo (CT)-IO, aiming to identify subpopulation who might benefit or not from treatment.
Methods: Blood samples from 33 stage IV NSCLC pts were collected at the baseline of first-line IO or CT-IO, as part of the Horizon Europe-funded I3LUNG study (NCT05537922) conducted at IRCCS Istituto Nazionale dei Tumori of Milan. Single-cell RNA sequencing was performed by Chromium Single Cell 5' v2 kit (10X Genomics) on PBMCs, enriched for neutrophils sorted by FACS (CD66b+CD15+). After quality control, 30 samples were included in the analysis.
Results: Among 30 pts, 27 were treated with CT-IO and 3 with mono-IO, 25 were adenocarcinoma, 4 squamous and 1 NOS carcinoma. UMAP analysis revealed distinct "swan neck" clusters of immature neutrophils, predominantly expressing LCN2 gene, in pts with disease progression (p-value <0.05, logFC -3,67). These cells were notably absent in pts with complete response or partial response. Conversely, responders showed the enrichment of a mature subset of IGHM TCL1A, IGHD expressing B cells ("smart" B cells) (all genes with p-value <0.05 and logFC >2.5). Of note, TCL1A gene is involved in the formation of tertiary lymphoid structures, which are positively correlated with IO responses. Although based on a very small cohort in which no progressive disease occurred, we observed T and NK cells enrichment in mono-IO treated pts with high PD-L1 expression.
Conclusions: To our knowledge, this is the largest prospective cohort that analyses circulating single-cell PBMCs in stage IV NSCLC pts treated with a first-line IO based. We identified novel circulating immune subsets, such as "swan neck" neutrophils and "smart" B cells, which emerged as promising host biomarkers. These subsets consistently acted as negative and positive predictors, respectively to first-line IO-based therapy.

#7147 Ultra-high throughput single-nuclei RNAs sequencing of malignant pleural mesothelioma samples in the BEAT-MESO clinical trial.

Background: Malignant Pleural Mesothelioma (MPM) is a rare cancer with limited treatment options. Large-scale deep biological description of intratumor heterogeneity at single-cell resolution is still missing. Recent studies of fresh tumor biopsies analyzed only a few patients, limiting resolution of population heterogeneity.
Objective: To describe at single-cell resolution in FFPE tissues the cancer cell and tumor microenvironment heterogeneity of untreated MPM patients.
Method: Of the 400 enrolled patients in the BEAT-MESO clinical trial (NCT03762018), 220 patients had available tumor blocks for single-nuclei preparation. The study compared the chemotherapy and bevacizumab combination with and without atezolizumab (anti-PD-L) treatment. All patients signed the ICFs and approved the translational study. Single nuclei were prepared using the snPATHO protocol followed by 10x Genomics FLEX pipeline. Samples were sequenced on a Novaseq X platform.
Results: 179 of the available 220 samples had sufficient tumor content to perform the assay. In total, we detected 792'000 cells. We defined cell type identities using singleR with a combined reference map from non-small cell lung cancer (NSCLC) and a small mesothelioma cohort. We could readily identify cell types of the tumor microenvironment. The most abundant cell types beside tumor cells were cancer associated fibroblast/CAFS (median of 22% of all cells) and macrophages (14% of all cells). We could also define T cell heterogeneity, whereas CD4 T_{CM} cells were the most abundant and detected in all patients, in contrast with proliferating CD4 or CD8 T cells which were absent in 68% of patients, suggestive of rich abundance of tumor reactive T cells. Among immune checkpoints, the expression of TIGIT was the highest, followed by LAG3 and PD1 expression. Tregs were rare and most frequently expressed TIGIT similar to $CD8_{EM}$ and $CD4_{CM}$ cells. We could also define an important heterogeneity of cancer-associated fibroblasts as well as of endothelial cells. Endothelial cell heterogeneity reflected on the proximity to B cells and tertiary lymphoid structures. In contrast, to previous single-cell RNA seq analysis of a small cohort of MPM, we could readily detect neutrophil granulocytes in the tumors. We will also provide data on matching H&E evaluation of TLSs. Depending on the maturation of clinical data, we will also present comparison with clinical parameters.
Conclusions: Our results show the outstanding power to perform snRNAseq of fixed tissues from clinical trials. The method is readily compatible with large phase III clinical trials, and provide a much deeper insight into tumor heterogeneity than bulk RNAseq with deconvolution would do.

#7148 Exploratory biomarker analysis of trastuzumab deruxtecan (T-DXd) treatment for HER2-positive (HER2+) metastatic colorectal cancer (mCRC) in DESTINY-CRC02 (DC-02).

Background: T-DXd showed clinically meaningful antitumor activity in patients (pts) with HER2+ mCRC in the phase 2 DC-02 trial (NCT04744831). Exploratory baseline circulating tumor DNA (ctDNA) analyses of *HER2 (ERBB2), PIK3CA,* and *RAS* mutation (mut) status and blood-based tumor mutational burden were reported previously (Raghav et al. 2024). This study reports the relationship between other CRC-related genes and efficacy of T-DXd in HER2+ mCRC.

Methods For this analysis, data were combined from 122 pts enrolled in the 5.4 and 6.4 mg/kg T-DXd cohorts. Transcriptome analysis by RNA sequencing with ribosome depletion was performed on 102/107 available baseline (BL) archival tissue samples. ctDNA from blood collected at BL (n = 120/120) and after 2 T-DXd treatment cycles (C3D1; n = 97/103 paired BL/C3D1 samples) was analyzed at Guardant Health to determine genomic landscape (OMNI, ~500 genes) and molecular response (MR; G360, ~74 genes).

Results: By ctDNA, alterations (any) in *TP53* (84.2%), *APC* (77.5%), *FLT3* (63.3%), and *PREX2* (52.5%) were most common; 82.5% and 24.2% of pts had *HER2* amplification (amp) or mut, respectively. Pts with *APC* mut or ≥ median *ABCB1* (P-gp) transporter gene expression tended to have lower objective response rate (ORR) and shorter median progression-free survival (PFS; Table). PFS appeared to be shorter in pts with *EGFR* amp (Table), although this group also had higher ctDNA levels, which is negatively prognostic. Complete MR at C3D1 was associated with the highest ORR and longest PFS, while ORR was lowest and PFS shortest when MR was absent (Table).

Conclusions: Several genetic biomarkers with known prognostic effects in CRC, including *EGFR* or *APC* alterations, were potentially associated with T-DXd efficacy. MR analyses suggested magnitude of ctDNA reduction at C3D1 could be predictive of T-DXd clinical response. Further analysis is needed to assess these biomarkers' predictive vs prognostic value.

Table

	ORR			**PFS**		
	ORR (95% CI), %	OR (95% CI)	*P* value[a]	Median (95% CI), months	HR (95% CI)	*P* value[a]

AMR[d] (n = 25)	20.0 (6.8-40.7)	NA	NA	4.2 (2.9-5.5)	NA	NA

AMP, amplification; AMR, absent molecular response; BEP, biomarker evaluable population; C3D1, after 2 T-DXd treatment cycles; CMR, complete molecular response; ctDNA, circulating tumor DNA; HR, hazard ratio; MR, molecular response; mut, mutation; NA, not available; ND, not detected; NE, not estimable; NS, not significant; OR, odds ratio; ORR, objective response rate; PFS, progression-free survival; PMR, partial molecular response. [a]*P* ≥ 0.05 is the significance threshold; subgroups were compared using the Fisher exact test for ORR and log-rank test for PFS. [b]CMR = 100% reduction in ctDNA levels. [c]PMR = 50 to <100% reduction in ctDNA levels. [d]AMR = <50% reduction in ctDNA levels.

#7149 The role of TROP2 in the MoA of Dato-DXd and how it underpins the biologic rationale of the novel AI-guided biomarker TROP2 normalized membrane ratio.

Matthew S. Sung[1], Matthew Wilson[2], Dominik Vonficht[3], Armin Meier[3], Chetan Rane[1], Charlie Dunlop[2], Gopi Patel[1], Anna Przybyla[1], Yann Wallez[2], Xiaochuan Liu[4], Ross Hill[2], James Harper[2], Markus Shick[3], Hadassah Sade[3], Danielle Carroll[2]

[1]AstraZeneca US, Waltham, MA,[2]AstraZeneca UK, Cambridge, United Kingdom,[3]AstraZeneca Germany, Munich, Germany,[4]AstraZeneca US, Gaithersburg, MD

Datopotamab deruxtecan (Dato-DXd) is an antibody drug conjugate (ADC) comprised of a humanized anti-TROP2 IgG1 monoclonal antibody attached to DXd, a topoisomerase I inhibitor, via a plasma stable cleavable linker. Dato-DXd is currently under clinical investigation for the treatment of patients with solid tumors including non-small cell lung cancer (NSCLC), hormone receptor positive and triple negative breast cancer. Recently, TROP2 Normalized Membrane Ratio (NMR) was identified as an exploratory predictive biomarker for Dato-DXd, in patients with non-squamous (NSQ), non-actionable genomically altered (AGA) NSCLC in the phase 3 TROPION-Lung01 study. TROP2 NMR is a quantitative scoring algorithm that measures membrane TROP2 expression relative to the combined sum of cytoplasmic and membrane TROP2 expression for every tumor cell in a TROP2 immunohistochemistry (IHC) stained tissue sample. Herein, we further describe the role of TROP2 in the mechanism of action (MoA) for Dato-DXd and the biological rationale linking TROP2 NMR to its pharmacological mode of action. Utilizing an isogenic cell line series in NCI-H322, a NSQ, non-AGA NSCLC cell line, where TROP2 was either knocked-out (KO) or over-expressed, we demonstrate that Dato-DXd binding and efficacy is dependent on TROP2 expression. TROP2-KO resulted in complete loss of Dato-DXd binding, delivery of intracellular DXd, in vitro cytotoxicity and in vivo efficacy of Dato-DXd implicating the MoA of Dato-DXd requires TROP2. However, TROP2 expression was not sufficient to predict Dato-DXd activity in a broad panel of cell lines across multiple indications including NSCLC. In 34 NSCLC cell lines, TROP2 mRNA expression generally correlated with Dato-DXd activity, however, among the TROP2-high NSCLC cell lines (n=17), there was a mixture of Dato-DXd sensitive and insensitive cell lines. As internalization of the Dato-DXd-bound TROP2 complex is central to its MoA, we measured the internalization capacity of Dato-DXd in NSCLC cell lines (n=15). Dato-DXd internalization required binding to cells, however, there was a differential capacity for Dato-DXd internalization across cell lines despite similar levels of Dato-DXd binding. Importantly, characterization of the TROP2 IHC staining pattern revealed a strong correlation between TROP2 NMR, but not membrane nor cytoplasmic TROP2, and Dato-DXd internalization capacity and efficacy across these NSCLC cell lines. This suggests TROP2 NMR can predict the innate internalization capacity of Dato-DXd from TROP2 IHC stained samples. Collectively, these data highlight the key role TROP2 plays in the MoA of Dato-DXd in preclinical NSCLC models and provides the molecular basis underpinning the biological rationale for TROP2 NMR as an innovative biomarker for Dato-DXd activity in NSCLC.

#7150 Elucidating co-mutation landscapes in ALK fusion subtypes: implications for targeted therapy in non-small cell lung cancer (NSCLC).

Yang Zebo[1], Yuanyuan Zhang[2], Songlin Zhang[1]

[1]Department of Cardiothoracic Surgery, Yichang Central People' s Hospital, Yichang, China,[2]Three Gorges University Renhe Hospital, Yichang, China

Background: EML4-ALK is a prevalent ALK fusion variant with diverse breakpoints and subtypes. Different fusion partners and subtypes exhibit varied responses to ALK tyrosine kinase inhibitors (TKIs) and unique resistance mechanisms. Co-mutated genes influence the efficacy of targeted therapies. This study explores the molecular characteristics and co-mutation profiles of NSCLC with non-EML4-ALK fusions and various EML4-ALK subtypes.

Methods: We analyzed 615 NSCLC samples harboring ALK fusions, confirmed by next-generation sequencing (NGS) using a 733-gene panel. Tumor mutational burden (TMB) was defined as the total count of nonsynonymous somatic mutations in coding regions.

Results: Of 615 patients with ALK fusions, 543 had EML4-ALK fusions, with V1 as the most common subtype (40.88%, 222 cases), followed by V3 (36.46%, 198) and non-V1V3 subtypes (22.65%, 123). In the 72 non-EML4-ALK cases, intergenic-ALK fusion(ALK-IR)was the most prevalent (44.44%), followed by HIP1-ALK, KIF5B-ALK, and STRN-ALK.

Analysis of co-mutations showed similar rates across EML4-ALK subtypes [V1: 85.14% (189/222); V3: 83.3% (165/198); non-V1V3: 87.0% (107/123)], while non-EML4-ALK fusions displayed a lower rate (79.16%, 57/72). In V1 and V3 substitutions were the predominant mutation type, whereas amplifications and substitutions were more common in non-EML4-ALK fusions. TP53 was the most frequently co-mutated gene across all EML4-ALK subtypes [~30%]. Apart from TP53, the distribution of co-mutated genes varied among subtypes, with CDKN2A and ALK-IR showing relatively high mutation frequencies across multiple subtypes.

To explore resistance mechanisms, we analyzed mutations associated with ALK-TKI resistance pathways, including RTKsMET, EGFR, SRC, IGF-1R, HER2, and HER3. The non-V1V3 subtype had the highest rate of resistance-related mutations (14.63%), while V1 and V3 displayed similar rates (10.81% and 10.1%). In V1, MET amplification was the primary resistance mechanism (3.15%), absent in other subtypes. Conversely, EGFR mutations were most common in non-V1V3 (5.69%) and V3 (2.53%) and less frequent in V1 (0.90%). ERBB3 amplification was more prevalent in V3 [V1 (0.45%) vs. V3 (1.01%) vs. non-V1V3 (0.81%)], while KRAS mutations were highest in non-V1V3 [V1 (1.35%) vs. V3 (1.52%) vs. non-V1V3 (3.25%)]. These findings indicate subtype-specific resistance patterns, potentially impacting treatment choices and prognosis.

TMB analysis revealed a higher proportion of TMB-H (TMB ≥10) in V3 patients (9.10%) compared to V1 (5.86%) and non-V1V3 (6.21%), suggesting differential responses to immunotherapy among EML4-ALK subtypes.

Conclusion: Distinct co-mutation and resistance patterns among EML4-ALK subtypes, providing insights that support personalized treatment strategies and prognostic assessments for NSCLC patients with various EML4-ALK fusion subtypes.

#7152 High-dimensional, single-cell analysis and transcriptional profiling reveal novel correlatives of response to PARP inhibition plus PD-1 blockade in triple-negative breast cancer.

Alexander P. Gottlieb[1], Gregory J. Baker[2], Jia-Ren Lin[2], Ricardo Pastorello[3], Yu-An Chen[2], Tuulia Vallius[2], Janae Davis[3], Clarence Yapp[2], Sarah E. Church[4], Eric Miller[4], Anniina Farkkila[2], Shaveta Vinayak[5], Melinda L. Telli[6], Sara M. Tolaney[3], Filipa Lynce[3], Joan S. Brugge[7], Alan D'Andrea[7], Geoffrey Shapiro[7], Sandro Santagata[7], Peter K. Sorger[7], Elizabeth A. Mittendorf[1], Jennifer L. Guerriero[1]

[1]Department of Surgery, Division of Breast Surgery, Brigham and Women's Hospital, Boston, MA,[2]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA,[3]Breast Oncology Program, Dana-Farber Cancer Institute, Boston, MA,[4]Nanostring Technologies, Seattle, WA,[5]Fred Hutchinson Cancer Center, University of Washington, Seattle, WA,[6]Stanford University School of Medicine, Palo Alto, CA,[7]Ludwig Center for Cancer Research, Harvard Medical School, Boston, MA

Background: TOPACIO was a phase I/II study evaluating the PARP inhibitor (PARPi) niraparib in combination with the anti-PD-1 antibody pembrolizumab in patients with locally advanced or metastatic triple-negative breast cancer (TNBC, n=55), irrespective of *BRCA* status. In the efficacy-evaluable population (n=47) the objective response rate (ORR) was 21% and disease control rate (DCR) 49%. Although activity was greater in *BRCA*-MUT patients (7/15, ORR=47% and 12/15, DCR=80%), durable clinical benefit was seen in patients with *BRCA*-WT tumors (3/27, ORR=11% and 9/27, DCR=33%). Patients with PD-L1^{+} tumors (28/47, 60%) achieved higher ORR (9/28, 32%) than those with PD-L1^{neg} tumors (1/13, 8%). It remains unstudied whether tumor gene expression or immune composition in baseline biospecimens is predictive of treatment response. We conducted exploratory biomarker analyses to uncover gene expression patterns and immune states associated with treatment response.

Methods: Transcriptional profiling of baseline samples was performed using the BC360 (n=41) and PanCancer IO360 (n=42) panels (Nanostring) and multigene signatures were used to measure tumor and immune activities. Transcriptional analysis was paired with high-dimensional, single-cell cyclic immunofluorescence (CyCIF) of samples with adequate tissue for analysis (n=22) to characterize the immune microenvironment at single-cell resolution.

Results: *BRCA*-MUT tumors showed increased downstream interferon signaling and immune infiltration relative to *BRCA*-WT tumors ($p < 0.05$). Downstream interferon and immunoproteasome scores were elevated in objective responders ($p < 0.05$). Genes involved in WNT signaling (*TANKS1*, *TANKS2*, *PARP4*, and *NETO2*) associated with long-term response, defined by those still on therapy and responding at data cut off. Low *NETO2* gene expression strongly associated with better ORR ($p = 0.01$). CyCIF analysis performed on whole tissue sections accounting for 2.97×10^6 single cells revealed that in *BRCA*-WT patients, baseline infiltration of immune cells - cells expressing CD45, CD3 (T cells), CD20 (B cells) or CD68/CD163 (macrophages) positively correlated with favorable PFS ($R=0.81$, $p=0.0004$, Spearman's correlation). Further, increasing fractions of CD8+ and PD-1+ CD4+ T cells strongly associated with favorable PFS ($R > 0.71$, $p < 0.0041$). In *BRCA*-MUT patients, baseline immune composition did not correlate with clinical outcome.

Conclusions: *NETO2* expression, WNT pathway, and interferon signaling associate with response to niraparib plus pembrolizumab. While *BRCA*-MUT tumors showed higher baseline immune cell abundance compared to *BRCA*-WT, immune and T cell infiltration was predictive of PFS duration only in *BRCA*-WT patients, suggesting divergent mechanisms of response to PARPi and ICB dependent on *BRCA* status.

#7153 Subclonal mutation load predicts survival and response to immunotherapy in cancers with low to moderate TMB.

Immune checkpoint inhibitors (ICI) have revolutionized cancer treatment, yet current biomarkers like tumor mutation burden (TMB) and mismatch repair deficiency identify responders in only a small fraction of patients, particularly in low-to-moderate TMB cancers. This is critical as the majority of cancer patients (ex. approximately 90% of TCGA) have TMB<10, the FDA-approved threshold for ICI therapy. As such, there is need to identify biomarkers to predict immunotherapy response in these currently overlooked patients.We developed CliPP, a novel statistical machine learning approach that performs subclonal reconstruction through regularized regression. CliPP achieves 100 - 1000 fold faster computation than existing methods while maintaining accuracy in both simulated (n=5,515) and real patient datasets (n=1,582 whole-genome sequences). To facilitate broad adoption, we deployed CliPP as a user-friendly web application (CliPP-on-web, companion AACR abstract, Wu et al.) facilitating use by clinicians and researchers without computational expertise. Using CliPP, we analyzed 7,279 tumors across 32 cancer types from TCGA, 42 samples from two ICI clinical trials in metastatic prostate cancer, and 613 esophageal adenocarcinomas (EAC) from the OCCAMS consortium. Subclonal mutation load (sML) was calculated as the fraction of subclonal mutations, with comprehensive survival analyses performed.High sML showed opposing effects on survival based on TMB: beneficial in 14 cancer types with low-to-moderate TMB (HR=0.06-0.69, P<0.05), but detrimental in 4 high-TMB cancers (HR=1.48-2.70, P<0.05). In two separate metastatic prostate cancer trials (NCT02113657 and NCT02703623) where TMB failed to predict response, high sML predicted favorable outcomes to ipilimumab (NCT02113657: HR=0.18, P=0.004, NCT02703623: HR=0.1, P=0.007) and was associated with increased CD8+ T cell density (P=0.008). Validation in 613 WGS EAC samples with standardized clinical follow-up confirmed improved survival with high sML in moderate-TMB cancers (HR=0.6, P<0.0001), with effects persistent across disease stages.These findings identify sML as a key feature of cancer and reveal an important relationship between evolutionary dynamics and the tumor microenvironment. Furthermore, sML may serve as an orthogonal approach to identify likely responders to ICI in low-to moderate TMB tumors complementing existing biomarkers and potentially broadening the therapeutic reach of checkpoint inhibitors.

#7154 Phenotypic screening from patient-derived organoids to predict therapeutic response.

Emilie Gontran[1], Leo Fillioux[2], Jerome Cartry[1], Ryme Bouyakoub[3], Sabrina Bedja[1], Alice Boileve[3], Ali Mouawia[3], Anna-Rose Gryspeert[4], Mia Cabantous[4], Gizem Altay[4], Maria Vakalopoulou[2], Stergios Christodoulidis[2], Jacques RR Mathieu[1], Paul-Henry Cournede[2], Fanny Jaulin[5]

[1]Gustave Roussy - INSERM U1279 - Universite Paris-Saclay, Le Kremlin-Bicetre, France,[2]CentraleSupelec - Universite Paris-Saclay, Gif-sur-Yvette, France,[3]Gustave Roussy - INSERM U1279 - Universite Paris-Saclay, Villejuif, France,[4]Orakl Oncology, Le Kremlin-Bicetre, France,[5]Gustave Roussy - INSERM U1279 - Universite Paris-Saclay - Orakl Oncology, Le Kremlin-Bicetre, France

Functional precision medicine (FPM) aims to personalize cancer treatment through ex vivo drug testing on patient tumor cells. Classical biochemical tests (like ATP assay) provide limited insight into how patient cells respond to treatment. Phenotypic markers based on imaging features called "radiomics" offer a promising approach to understanding tumor response. Combining FPM with phenotypic screening (PS), we evaluate the predictive power of biomarkers derived from brightfield time-lapse imaging of patient-derived organoids (PDO) from digestive cancer patients.

We screened 24 patients, including 5 with colorectal (CRC) and 19 with pancreatic (PDAC) cancers, each with varying treatment histories (1 to 8 treatments prior to PDO biopsy and 12 different treatments). PDOs were exposed to the corresponding clinical treatments, and 96-hour post-treatment videos allowed for individual tracking of PDO responses. A total of 103 image features (18 intensity, 75 texture, 10 morphology) were extracted from each PDO. Predictive analysis was conducted at 24h, 48h, 72h, and 96h post-treatment, using single timepoints and time-averaging methods. PDO responses were assessed at 3 treatment doses, and area dose-response (ADR) was calculated using trapezoid estimation. Univariate and multivariate Cox models were applied to assess the association of image features with progression-free survival (PFS) and develop an image-based signature for PFS prediction.

We compared image features extracted from entire movie sequences (49 frames), 24h-averaging (13 frames), 4h-averaging (3 frames), and single timepoints (24h, 48h, 72h, 96h). We found similar results from univariate Cox analyses and focused on single timepoint method, which identified 24 features significantly associated with PFS as early as 48 hours. These included intensity (7), texture (11), and shape (6) features (median C-index=0.63, 95% CI [0.60-0.67]). When combining each feature with clinical factors (disease and treatment), 7 features remained significantly associated with PFS. A subset of 3 non-correlated interpretable features was selected (one per category). A signature built from a texture feature measuring pixel intensity homogeneity, combined with disease and treatment best predicted PFS (C-index=0.72, HR=27.43 95% CI [1.89-399.28], p-value=0.046).

Integrating image biomarkers with clinical variables enhances the predictive power of PDO-based functional drug screening. Extracting features from individual timepoints provides earlier insights than biochemical assays, which typically require 5 days post-treatment. This study encourages further exploration of how PS-based FPM could be implemented in a clinical setting. Future work will focus on validating the image-based signature in an independent cohort and across diverse experimental setups.

#7155 A PD-L1-independent phenotype uncovers responders to combined therapy with immune checkpoint inhibitors in kidney cancer.

Florian A. Buttner[1], Viktor Grunwald[2], Elfriede Noessner[3], Igor Tsaur[4], Jens Bedke[5], Matthias Schwab[1], Elke Schaeffeler[1]

[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany,[2]Department of Urology and Medical Oncology, University Hospital Essen, Essen, Germany,[3]Tissue Control of Immunocytes, Helmholtz Munich, Munich, Germany,[4]Department of Urology, University Hospital Tuebingen, Tuebingen, Germany,[5]Department of Urology and Transplantation Surgery and Eva Mayr-Stihl Cancer Center, Klinikum Stuttgart, Stuttgart, Germany

Immunotherapy with immune checkpoint inhibitors (ICI) has substantially improved the treatment of advanced renal cell carcinoma (aRCC). Since treatment effects vary among patients, identifying biomarkers to predict response is crucial for optimizing clinical management. Expression of programmed death ligand 1 (PD-L1) is associated with better response to ICI treatment, but is not a valid biomarker. To advance patient stratification for aRCC, we analyzed molecular and clinical data from the JAVELIN Renal 101 (n=726) and IMmotion151 (n=823) trials, both of which compared a combination of PD-L1 inhibitors and anti-angiogenic treatments with sunitinib monotherapy. In JAVELIN Renal 101, we found correlations between genes and progression-free survival (PFS) in PD-L1-positive tumors treated with sunitinib. These associations were independent of variations in the proportion of PD-L1-positive immune cells present in the tumors. Clustering of PD-L1-positive tumors based on PFS-related genes revealed an IMmune CHeckpoint Inhibitor-responsive Phenotype (IMCHIP). In PD-L1-positive tumors with IMCHIP, combined therapy with ICI led to significantly longer PFS relative to sunitinib (13.3 months vs. 4.4 months median PFS), while in PD-L1-positive tumors without IMCHIP, PFS was comparable for both treatments (11.1 months). By de-correlating gene expression measurements from PD-L1 expression, the clustering could be extended to PD-L1-negative tumors resulting in two groups (aRCC1/2) that were independent of PD-L1 status. Stratification based on aRCC1/2 and PD-L1 status allowed treatment effects to be categorized into four groups. A significant difference in PFS between treatments arms was only observed in patients with tumors of type aRCC2/PD-L1-positive, which corresponded to the IMCHIP profile and covered 32.4% of JAVELIN Renal 101. These findings could be validated in the IMmotion151 trial, where IMCHIP represented 20% of the cohort. Compared to other biomarkers currently being investigated, the combination of aRCC1/2 with PD-L1 status exhibited the greatest potential as a predictive biomarker for patient selection, which was confirmed in both cohorts. The prognostic potential of the aRCC1/2 subdivision was evaluated in 476 clear cell RCC from TCGA. Here, aRCC2 was associated with significantly worse overall survival and cancer-specific survival in both univariate and multivariable analyses, accounting for age, sex, and clinicopathological parameters (TNM). In summary, categorization into aRCC1/2 proved to be a new risk stratification of aRCC which, in combination with PD-L1 status, enabled the retrospective identification of responders who benefited from combined therapy with ICI relative to sunitinib monotherapy. The analysis of IMmotion151 trial data utilized data generated by Genentech/Genentech Research and Early Development.

#7156 Spatial single-cell transcriptomics identifies tumor niches predictive of response to TKI therapy in non-small cell lung cancer.

Haochen Li, Joseph Lownik, Simeon Mahov, Matthew Gayhart, Jean Lopategui, Karen Reckamp, Akil Merchant

Cedars-Sinai Medical Center, Los Angeles, CA

Non-small cell lung cancer (NSCLC) is the tumor with the highest mortality in the world. Tyrosine kinase inhibitors (TKI) are commonly used treatment options for NSCLC, albeit with significantly different mechanisms of action. Responses to TKIs vary greatly among patients. Biomarkers for determination of response in patients treated with these therapies are needed to improve outcomes for patients and allow for more personalized therapeutic approaches.

In this study, we retrospectively collected 34 patients with stage III or IV EGFR-mutated NSCLC. These patients were treated with TKIs. Responses to TKI therapies were dichotomized to early progression (<12 month) and late progression (>12 month) based on their progression free survival data. We performed 10X Xenium spatial single-cell-resolution transcriptomics and imaging mass cytometry (IMC) on tissue microarrays (TMAs) generated from these patients, representing a total of 91 cores.

In this cohort, we detected an enrichment in low tumor infiltrating lymphocyte (TIL) numbers with high epithelial proportions in early progressors using niche detection methods and neighborhood analysis algorithms. The proportion of tumor cells in these immune cold regions is significantly higher in early-progression patients than the late-progression patients. Amphiregulin, encoded by *AREG*, was significantly upregulated in immune cold tumor regions associated with TKI resistance. *AREG* has been demonstrated to inhibit TKI-induced apoptosis with multiple mechanisms. Additionally, we found increased myofibroblast-like cancer-associate fibroblasts (Myo-CAFs) surrounding the tumor region in the early-progressor group.

We next unbiasedly extracted >144,000 features, including gene expression data, cell types, spatial correlations, and gene correlations. We then used Stabl, which is a feature selection algorithm for isolating a sparse and reliable set of features in predictive models when the number of features is significantly greater than the number of patient samples. Using this platform, we identified a 6-feature program which had an AUC of 0.973 in predicting early vs. late progression in TKI-treated EGFR-mutant NSCLC patients. One of the identified features was the expression level of *ARL14* in Myo-CAFs. We further found these *ARL14*$^{+}$ Myo-CAFs with higher tendency to form spatial niches with tumor cells than other CAFs. The *AREG*$^{+}$ immune cold tumor regions and their surrounding *ARL14*$^{+}$ Myo-CAFs commonly form the spatial niches determining TKI responses.

We identified novel spatial features leading to the TKI resistance in NSCLC using the highly multiplexed nature of spatial single-cell transcriptomics. These spatial biomarkers have a high predictive power in predicting response to TKI treatment and provide a basis for the precise treatment of lung cancer and provide potential targets to overcome treatment resistance.

#7157 Development of a comprehensive multigene assay to predict the prognosis of localized or locally advanced prostate cancer.

Jiyoung Ahn[1], Hyunho Han[2], Jang Hee Han[3], Jongkeun Lee[1], Danbi Lee[1], Kyung Chul Moon[4], Young Deuk Choi[2], Chang Wook Jeong[3], Nam Hoon Cho[5], **Woosung Chung**[1]

[1]DCGen Co., Ltd., Seoul, Korea, Republic of,[2]Department of Urology, Urological Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Urology, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Department of Pathology, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[5]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Prostate cancer is the most prevalent malignancy in men worldwide. However, the absence of reliable biomarkers for metastasis due to intra- and inter-tumor heterogeneity complicates the establishment of personalized treatment guidelines. To address tumor heterogeneity, a next-generation sequencing (NGS)-based multigene assay, including gene expression, tumor-related pathways and fusion variants, is proposed for developing a new assay. This study aims to develop and validate a metastasis risk prediction model and a molecular subtype classification model to enable personalized treatment.
Methods: This study included surgical specimens from patients with localized or locally advanced prostate cancer at Seoul National University Hospital and Severance Hospital. Patients were stratified into three cohorts: NED (no evidence of disease; no metastasis within seven years), BCR (biochemical recurrence; PSA elevation within five years), and METS (metastasis within five years). Propensity score matching (PSM) balanced clinical risk factors, and whole transcriptome sequencing was performed on formalin-fixed paraffin-embedded primary tumor tissues to identify differentially expressed genes (DEGs) associated with metastasis. The cancer-related pathways were selected using DEGs in the following methods: Gene Ontology term enrichment analysis and curated pathways, and their scores were calculated using Gene Set Variation Analysis. A Metastasis prediction model was developed using classification and regression algorithms to predict metastatic risk based on DEGs and pathway scores. For molecular subtyping, a improved model was optimized by incorporating previous model with fusion status. Both models were validated using an independent cohort of 172 patients.
Results: Following PSM matching, 354 patients were analyzed, resulting in the identification of 103 DEGs and 33 pathways. Using these features, the metastasis prediction model achieved the highest performance (AUC = 0.904) with the Random Forest algorithm and 0.82 in the validation cohort. This performance surpassed that of regression models and joint models combining classification and regression features. Kaplan-Meier (KM) analysis confirmed the clinical relevance, showing significant differences in 5-year metastasis-free survival (MFS) between high- and low-risk groups ($p < 0.0001$, hazard ratio [HR]: 4.958). The improved subtyping model classified samples into two subtypes: Luminal (69%) and aggressive variant prostate cancer (AVPC, 31%). The 5-year MFS by molecular subtype for all patients (n=526) showed that the AVPC tended to have a worse prognosis (p=0.084, HR: 1.389)
Conclusion: This study can be used to advance risk stratification models for metastasis risk and to inform treatment decisions by comprehensively evaluating gene expression and gene fusion events in prostate cancer.

#7158 Molecular residual disease detection via CAPP-Seq in PTCL patients undergoing stem cell transplantation.

Chandan Sanghera[1], Josie Ford[2], Ruwan Gunaratne[1], Kusha Chopra[2], Anna B. Rider[3], Aliyah R. Sohani,[3], Sean M. McCabe[2], Ronald A. Nemec[2], Yi-Bin Chen[2], Steven McAfee[2], Ephraim Hochberg[2], Jeffrey A. Barnes[2], Caroline MacVicar[2], Eric D. Jacobsen[4], Mwanasha H. Merrill[4], Michael S. Khodadoust[1], David Kurtz[1], Salvia Jain[2]

[1]Department of Medicine, Stanford University, Stanford, CA,[2]Department of Medicine, Massachusetts General Hospital Cancer Center, Boston, MA,[3]Department of Pathology, Massachusetts General Hospital, Boston, MA,[4]Dana-Farber Cancer Institute, Boston, MA

Introduction: Despite advances in therapy, improved biomarkers are needed to guide stem cell transplantation (SCT) in peripheral T-cell lymphoma (PTCL). We hypothesized that molecular residual disease (MRD) detection in pre-SCT apheresis T-cells via Cancer Personalized Profiling by Deep Sequencing (CAPP-Seq) could predict relapse post-SCT.
Methods: Eligible patients had diagnostic FFPE tissue and underwent either autogenic or allogenic SCT from 2005-2024. Autologous stem cells (ASC) harvested at the end of induction chemotherapy were sorted into T-, myeloid, NK/B-cell populations. Whole exome sequencing (WES) was performed on DNA isolated from FFPE, with NK/B-cells as the germline control to identify patient-specific single nucleotide variants (SNVs) and design hybrid-capture panels. A PTCL focused canonical gene panel was designed to capture emerging pathogenic SNVs. The ASC fractions and cell-free DNA (cfDNA) samples were interrogated with both panels as a composite approach to quantify MRD.
Results: 20 AITL and 2 PTCL-NOS cases were included. Median age at diagnosis was 61.3y (IQR 55.4-67.5). In the frontline setting, 6 (27.3%) patients received CHOP, 3 (13.6%) CHOP-azacitidine, 9 (40.9%) CHOEP, 3 (13.6%) BV-CHP, and 1 (4.5%) azacitidine-romidepsin. A median of 25 (IQR 17-37.5) SNVs were recovered per patient. Across all cases *RHOA* was most frequently mutated (86.5%), followed by *IDH2* (54.5%) and *PLCG1* (27.3%), consistent with the known mutation profile of PTCL. MRD+ was defined as the detection of tumor-specific SNVs in the ASC T-cell fraction (T-ASC) as previously described (Newman et al, *Nat Biotechnol* 2016). When limited to canonical PTCL genes, 6/22 patients were T-ASC MRD+. In contrast, when using all SNVs, 14/22 were T-ASC MRD+, demonstrating the benefit of tracking multiple patient-specific SNVs. Shared mutations between hematopoietic lineages, including variants associated with clonal hematopoiesis (CH), are frequently observed in PTCL. Similarly, we found multiple mutations were shared between cell compartments, which limited MRD specificity. To account for this and the effect of CH, SNVs detected in the myeloid and B-cell populations were removed. This significantly improved MRD detection, with 9/10 (90%) T-ASC MRD+ patients relapsing post-SCT, compared to 3/12 (25%) T-ASC MRD- patients (specificity 88.9%, sensitivity 75%, PPV 90%). T-ASC MRD- was associated with superior PFS (p=0.007, HR 5.1, 95% CI 1.4-19.2). Higher levels of T-ASC MRD tumor burden were also associated with inferior PFS (p=0.006, HR 1.4, 95% CI 1.1-1.7). MRD analysis in longitudinal cfDNA samples was performed in a subset of cases and correlated with clinical disease status.
Conclusion: Our PTCL-CAPP-Seq approach enables highly sensitive MRD detection, with T-ASC MRD+ predicting high relapse risk post-SCT. In addition, MRD monitoring in cfDNA samples can help facilitate early treatment decisions.

#7159 Characterizing the role of a *KDM3C* germline polymorphism in chemoradiotherapy outcomes for rectal and head and neck cancers.

Adria Hasan[1], Pragya Priyadarshini[2], Elena V. Demidova[1], Philip Czyzewicz[1], Takahiko Murayama[3], Shreya Shah[1], Mark Andrake[2], Yan Zhou[1], Roland Dunbrack[2], Israel Canadas[3], Thomas J. Galloway[4], Margret B. Einarson[2], Barbara Burtness[5], Erica A. Golemis[6], Joshua E. Meyer[4], Sanjeevani Arora[1]

[1]Cancer Prevention and Control Program, Fox Chase Cancer Center, Philadelphia, PA,[2]Cancer Signaling and Microenvironment, Fox Chase Cancer Center, Philadelphia, PA,[3]Nuclear Dynamics and Cancer, Fox Chase Cancer Center, Philadelphia, PA,[4]Department of Radiation Oncology, Fox Chase Cancer Center, Philadelphia, PA,[5]Department of Internal Medicine, Yale Cancer Center, Yale School of Medicine, New Haven, CT,[6]Department of Cancer and Cellular Biology,, Lewis Katz School of Medicine, Temple University, Philadelphia, PA

Background: Predictive biomarkers for chemoradiotherapy (CRT) are crucial for personalized cancer treatment. We have identified a germline missense polymorphism in lysine modifier, *KDM3C* that significantly associates with CRT outcomes in locally advanced rectal cancer (LARC) and head and neck squamous cell carcinoma (HNSCC). KDM3C regulates cellular processes including double-strand break (DSB) repair and is the first lysine modifier to directly influence BRCA1-mediated DSB repair. We hypothesized that the identified polymorphism, a serine to threonine substitution, modulates CRT responses by altering protein interactions necessary for BRCA1-recruitment to DSB sites.

Methods: Isogenic rectal (RCM-1) and head and neck (Cal-27, SCC9) cancer lines were generated via CRISPR/Cas9-editing; wild-type (WT) and SNP pairs. Immunofluorescence (IF) staining of DSB repair proteins, bulk RNA-sequencing, and colony survival assays were performed. Structure-function studies were conducted using AlphaFold-Multimer (v2.3) and AlphaFold3.

Results: SNP-bearing cells exhibited significantly reduced survival compared to WT cells following treatment with various DNA-damaging agents, including irradiation, platinum-based and other chemotherapeutics, and PARP inhibitors ($p<0.001$, one-way ANOVA). RNA-sequencing revealed downregulation in DNA repair and upregulation in immune response genes in SNP-bearing cells compared to the WT ($q<0.05$). To elucidate the mechanisms behind these results, we explored the regulation of the RNF8-RAP80-BRCA1 pathway in DSB repair, directly influenced by KDM3C. AlphaFold modeling of the FHA domain of RNF8 in complexes with KDM3C peptides (Ser/Thr at SNP position, with/without phosphorylation) showed significantly more stable complexes with KDM3C phospho-peptides, with an order of stability pT>pS>>T>S; aligning with prior studies on FHA peptide binding showing a preference for pThr over pSer. In fact, multiple proteins in BRCA1-mediated DSB repair involve FHA-phospho-peptide interactions, and *KDM3C* SNP region is implicated to play an important role in modulating this process. Supporting AlphaFold predictions, significantly reduced colocalization of RAP80-BRCA1 was observed in SNP-cells versus WT upon irradiation, indicating deficiency in DSB repair ($p<0.01$, Mann-Whitney test). Further, SNP-bearing cells exhibited increased colocalization of cGAS with micronuclei, a marker of genomic instability ($p<0.05$, one-way ANOVA), alongside an upregulated expression of genes associated with innate immune response ($p<0.05$, unpaired t-test).

Conclusion: Results highlight the role of the *KDM3C* SNP in DSB repair, influencing the response to DNA-damaging therapy and triggering broader genomic and immune responses. These findings position this polymorphism as a potential stratification marker to improve CRT efficacy in LARC and HNSCC.

#7160 The distribution of tertiary lymphoid structures serves as a hallmark of hot tumors and is associated with long-term survival and the efficacy of immune checkpoint inhibitors in patients with small cell lung cancer: A retrospective and prospective analysis.

Chaoqi Zhang[1], Peng Wu[1], Le Wang[2], Dexin Shang[1], Junhan Zhou[1], Jingjing Liu[1], Chunqi Lin[1], Nan Sun[1], Jie He[1]

[1]Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, China,[2]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Tertiary lymphoid structures (TLSs) are ectopic lymphoid organs capable of predicting the outcome and therapeutic response in various tumors. Nevertheless, the distribution and clinical significance of TLSs in small cell lung cancer (SCLC) have never been explored. Here, we enrolled over 1500 cases from 6 centers in this retrospective and prospective analysis to elucidate the immune landscape and predictive value of TLSs in SCLC. By employing immunohistochemistry (CD3, CD20, CD21, and CD23) and RNA-seq analysis, we discovered that a high abundance of TLSs was associated with a lower recurrence rate and long-term survival in patients with resected SCLCs. Univariate and multivariate analyses indicated that the status of TLSs was significantly correlated with a lower risk of relapse and cancer-specific death ($P<0.01$), independent of clinicopathological and molecular classifications (ASCL1, NEUROD1, POU2F3, and YAP1). Through the analysis of single-cell RNA sequencing data from 6 patients and whole slide digital pathology analysis of immunohistochemistry (CD45RO, CD4, CD8, CD14, CD68, CD163, CD57, CD66b, Foxp3, and PD-L1) from more than 600 patients, we found that tumors with a high abundance of TLSs were characterized by a high proportion of effector T cells and a high infiltration of anti-tumor immune cells. More importantly, we demonstrated that the status of TLSs was associated with an improved objective response rate, progression-free survival, and overall survival independently of CD8+ T-cell density in SCLCs with immune checkpoint inhibitors from 2 independent retrospective cohorts and a prospective cohort. In summary, our findings highlight that TLSs is a hallmark of hot tumors in SCLC and represents a promising biomarker for long-term survival and immunotherapy.

#7161 HMGA2 predicts treatment outcome in pancreatic cancer.

N. Yamamoto[1], S. Dobersch[2], I. Loveless[3], A. Samraj[1], G. Jang[4], M. Haraguchi[2], R. Fields[5], D. DeNardo[5], F. Notta[6], H. Crawford[3], N. Steele[3], S. Kugel[2];
[1]University of Washington, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]Henry Ford Health System, Detroit, MI, [4]PanCuRx Research Initiative, Toronto, ON, Canada, [5]Washington University in St. Louis, St. Louis, MO, [6]University of Toronto, Toronto, ON, Canada

The recognition of distinct transcriptional subtypes in pancreatic ductal adenocarcinoma (PDAC) has defined a group of poorly differentiated tumors with worse prognosis, but these findings have yet to reach clinical application. These tumors, termed “basal,” are unique for their loss of epithelial identity and relative chemoresistance compared to “classical” tumors. To develop a prognostic biomarker for the basal subtype, we have identified that the chromatin architectural protein HMGA2 is highly expressed in this subset of cancers. Using a tumor microarray of 580 primary biopsies from a diverse set of PDAC patients undergoing surgical resection, we performed multiplex immunohistochemistry for HMGA2, previously published markers of basal and classical disease, and immune subsets. We then associated patient outcome and known clinical data from 491 of these samples to staining patterns. We found that expression of HMGA2, but not published basal markers CK5 or CK17, predicted overall survival in our cohort. Combination of HMGA2 status with GATA6 status allowed for identification of two key study groups: an HMGA2+/GATA6- cohort with worse survival, decreased CD8+ T cells, and poorer response to gemcitabine-based chemotherapies (n=94, median survival = 11.2 months post-surgery); and an HMGA2-/GATA6+ cohort with improved survival, increased CD8+ T cell infiltrate, and improved survival with gemcitabine-based chemotherapy (n=198, median survival = 21.7 months post-surgery). Importantly, these findings were also true for Black patients, who have been underrepresented in previous subtyping studies. HMGA2 was also predictive of overall survival in RNA sequencing from metastatic tumors in an independent cohort. As a positive nuclear marker for basal disease, HMGA2 complements GATA6 as a dual-indicator test for disease subtype in PDAC. We aim to introduce this novel biomarker in a prospective multi-center clinical trial to further validate its use in selecting chemotherapy regimens and across other under-represented racial groups.

#7162 Association between circulating B cell subtypes and treatment response in patients with metastatic renal cell carcinoma (mRCC).

Zeynep B. Zengin[1], Marice Alcantara[2], Hedyeh Ebrahimi[2], Luis Meza[1], Nazli Dizman[3], Christian Nenninger[2], Jeremy Hall[2], Regina Barragan-Carrillo[2], Joann Hsu[2], Daniella Castro[2], Benjamin Mercier[2], Miguel Zugman[2], Salvador Jaime-Casas[2], Alex Chehrazi-Raffle[2], Abhishek Tripathi[2], Peter Lee[2], Motomichi Takahashi[4], Tanya B. Dorff[2], Marcin Kortylewski[2], Sumanta K. Pal[2]

[1]Yale School of Medicine, New Haven, CT,[2]City of Hope Cancer Center, Duarte, CA,[3]MD Anderson Cancer Center, Houston, TX,[4]Miyarisan Pharmaceutical, Tokyo, Japan

Background: While immune checkpoint blockade (ICB) has transformed the treatment of mRCC, response rates remain suboptimal. Most studies of ICB in cancer have focused on T cells as mediators of antitumor responses, but recent evidence highlights B cells' role in modulating ICB efficacy. CD5+ B cells, a small subset with potential immunosuppressive properties, may contribute to immune evasion through mechanisms such as IL-6/STAT3 signaling. This study investigates the prognostic significance of circulating CD5+ B cells in mRCC patients (pts) treated with cabozantinib/nivolumab with or without CBM588, a live bacterial product.

Methods: This open-label, randomized trial enrolled pts aged ≥18 years with histologically verified advanced or mRCC who had not received prior systemic therapy for metastatic disease. Pts were randomized in a 1:2 ratio to receive either cabozantinib/nivolumab alone (control arm) or in combination with CBM588 (experimental arm). Peripheral blood samples were prospectively collected at baseline and week 13. Samples were incubated with matched patients' sera, diluted to 50% in culture media at 37°C with 5% CO2 for a minimum of 2 hours prior to immunostaining of surface markers, phospho-STAT3, and spectral cytometric analysis using the Cytek Aurora system. A two-sided Wilcoxon and two-sided Mann-Whitney U tests were used to compare B cells levels at the two prespecified time points and between the two arms, respectively. Progression-free survival (PFS) was estimated using the Kaplan-Meier method.

Result: In total, 30 pts (20 male, 10 female) with mRCC were randomized to the control arm (10 pts) or the experimental arm (20 pts). The objective response rate in the control arm was 20%, compared to 79% in the experimental arm (p=0.004). The median PFS in the control arm was 13.4 months and was not reached in the experimental arm at the data cut-off (June 1, 2024; median follow-up: 25.8 months). Of the 30 pts, 27 had evaluable blood samples for the final analysis (8 pts in the control arm and 19 pts in the experimental arm). Pts with <75% CD5+ B cells at baseline (n=13) had a median PFS that was not reached, compared to 13.4 months in those with ≥75% CD5+ B cells (n=14 pts; p<0.01, HR=6.47, 95% CI: 1.40-29.88). Of note, CD5+ B cell levels did not differ significantly at baseline between treatment arms (p=0.43). Additionally, no significant difference in circulating CD5+ B cell levels was observed between baseline and week 13 in either arm (p>0.99 in the control arm vs. p=0.25 in the experimental arm).

Conclusions: High baseline levels of CD5+ B cells are associated with inferior outcomes in patients with mRCC treated with cabozantinib and nivolumab. These findings suggest that CD5+ B cells may serve as a prognostic biomarker and a potential target to improve ICB outcomes in mRCC.

#7163 Noninvasive magnetic resonance imaging measured quantitative perfusion as predictive and prognostic biomarker in glioblastoma.

Durga Udayakumar[1], Limin Zhou[2], Marco Pinho[2], Yiming Wang[2], Ben Wagner[2], Michael Youssef[3], Joseph Maldjian[2], Ananth Madhuranthakam[1]

[1]Radiology, Mayo Clinic, Rochester, MN,[2]Radiology, UT Southwestern Medical Center, Dallas, TX,[3]Neurology and Hematology and Oncology, UT Southwestern Medical Center, Dallas, TX

Glioblastoma is highly vascularized with increased perfusion and prognosis remains dismal, despite improved diagnosis and aggressive multimodal treatment. The current standard of care is maximal surgical resection when feasible, followed by adjuvant radiation with concurrent chemotherapy, temozolomide. However, treatment resistance and tumor recurrence pose a considerable challenge for stratifying patients for optimal treatment planning. Current radiological assessment of glioblastoma therapy response predominantly relies on morphological measures; that may not accurately capture early microscopic changes or therapeutic efficacy. We have developed and validated an advanced imaging method, Arterial Spin Labeling (ASL) MRI that enable noninvasive spatial assessment of the entire tumor. ASL-MRI uses water within the blood as an endogenous tracer and measures perfusion without the need for exogenous gadolinium-based contrast agent. The objective of this study was to investigate ASL measured quantitative perfusion after surgery to predict survival in glioblastoma patients undergoing the standard of care chemoradiation treatment. In this prospective, IRB-approved study, twenty-three adults with glioblastoma participated for longitudinal MRI. Progression-free survival (PFS) and overall survival (OS) were recorded for each patient. A baseline MRI scan was performed prior to chemoradiation treatment and after surgery utilizing a 3D ASL sequence. All structural images were co-registered to T1 post-contrast images. Tumor regions of interest (ROIs) such as enhancing tumor (ET), tumor core, whole tumor, and necrosis were manually segmented. Cerebral blood flow maps were calculated and mean perfusion values (MPV) within ET ROIs were extracted. Scatter plot of MPV and Kaplan-Meier graphs were generated using GraphPad Prism. Based on median survival of 420 days, patients were categorized into short (≤420 days) or long (>420 days) survival. A threshold ASL measured perfusion value of 30 mL/100g/min distinguished survival groups; hyper-perfusion correlated with shorter OS, while hypo-perfusion linked to longer OS. The mean±SD of PFS and OS for patients with shorter survival were 119±42 days and 230±117 days respectively, while for longer survival were 624±285 and 726±210 days respectively, and the values were statistically different (P<0.001for both). Kaplan-Meier curves showed significant OS and PFS differences (p<0.015, Hazard Ratio=3.056). Our data indicate that ASL measured baseline perfusion, after surgery and before chemoradiation treatment can benefit in predicting survival and treatment stratification in glioblastoma patients. ASL measured perfusion can be performed during radiation treatment and could provide valuable information that can be incorporated into emerging treatment strategies such as adaptive radiation.

#7164 Predictive biomarkers and immune dynamics in MSS metastatic colorectal cancer treated with regorafenib, ipilimumab, and nivolumab.

Jian Ye[1], Chongkai Wang[1], Colt Egelston[2], Weihua Guo[2], Peter Lee[2], Mawan Fakih[1]

[1]Department of Medical Oncology and Therapeutics Research, City of Hope Comprehensive Medical Center, Duarte, CA,[2]Department of Immuno-Oncology, Beckman Research Institute of the City of Hope, Duarte, CA

Background: Microsatellite-stable (MSS) metastatic colorectal cancer (mCRC) is largely resistant to immune checkpoint inhibitors (ICIs), posing a significant therapeutic challenge. Our phase I trial of regorafenib, ipilimumab, and nivolumab (RIN) demonstrated a 27.6% overall response rate (ORR) and a median overall survival (OS) of 20 months, with better outcomes in patients without liver metastases. This study aims to identify predictive biomarkers and elucidate the immunological mechanisms associated with response and resistance to RIN therapy in MSS mCRC patients.
Methods: Tumor biopsies from eight patients and peripheral blood samples from 29 MSS mCRC patients undergoing RIN therapy were collected at baseline and during treatment. Comprehensive molecular and immune profiling was performed using RNA sequencing, multiplex imaging (CODEX), flow cytometry, and cytokine assays. Gene expression analyses, immune cell phenotyping, cytokine profiling, and T cell receptor (TCR) repertoire analyses were conducted to characterize the tumor microenvironment (TME) and systemic immune responses.
Results: At baseline, tumors from responders exhibited enhanced cellular proliferation, active DNA repair pathways, and increased expression of stimulator of interferon genes (STING) pathway, indicative of a more immunogenic TME. In contrast, non-responders showed aberrant vascular remodeling and a pro-inflammatory TME. In the peripheral blood, responders displayed a Th1-skewed cytokine profile, while non-responders showed markers of DNA damage, elevated immune checkpoint expression, and upregulation of pathogen-response genes, suggesting immune aging and chronic inflammation. Patients with liver metastases displayed significant immune senescence and metabolic hyperactivation, correlating with poor responses to RIN therapy. Following RIN therapy, responders demonstrated increased infiltration of immune effector cells into the TME, associated with a transient reduction of peripheral $CD8^+$ T cells and natural killer (NK) cells, suggesting their migration into the tumor. This was accompanied by increased markers of proliferation, activation, and exhaustion in peripheral immune cells. Furthermore, RIN therapy induced clonal expansion and diversification of $CD8^+$ T cells in responders, along with upregulation of immune activation signatures.
Conclusions: The RIN regimen can reshape the immunological landscape of MSS mCRC by modulating the TME and systemic immunity. Distinct immune profiles between responders and non-responders, especially in patients with liver metastases, highlight the importance of predictive biomarkers for personalized therapy. Addressing immune senescence and metabolic dysregulation may be key to overcoming resistance in this challenging patient population.

#7165 AI-driven vascular structure analysis predicts immunotherapy response in non-small cell lung cancer.

JunHyeong Park[1], Jaesung Heo[1], Jun Hyeok Lim[2], Woo Kyung Ryu[2], Jeong-Seon Ryu[2], Jeong-Seok Choi[3], Lucia Kim[4]

[1]Department of Radiation Oncology, Ajou University School of Medicine, Suwon, Korea, Republic of,[2]Division of Pulmonology, Department of Internal Medicine, Inha University College of Medicine, Incheon, Korea, Republic of,[3]Department of Otorhinolaryngology-Head and Neck Surgery, Inha University College of Medicine, Incheon, Korea, Republic of,[4]Department of Pathology, Inha University College of Medicine, Incheon, Korea, Republic of

Immune checkpoint inhibitors (ICI) have become the standard treatment for advanced non-small cell lung cancer (NSCLC). PD-L1 immunohistochemistry (IHC), the only approved biomarker for predicting ICI treatment response, shows limited predictive value, particularly in patients with low expression (1-49%). Abnormal tumor vasculature in NSCLC correlates with poor prognosis and hampers treatment efficacy by obstructing drug delivery and suppressing immune cell activation. We developed an AI-based biomarker that predicts immunotherapy response by comprehensively analyzing tumor vascular patterns on contrast-enhanced CT. We developed and trained our model using contrast-enhanced CT data from 1,051 NSCLC patients, focusing on both tumor-associated vasculature and normal lung vessels. We developed the Vessel Risk Score (VRS) based on the Mahalanobis distance between the feature distributions of tumor vessels and normal vessels in immunotherapy-treated patients. For external validation, we analyzed pre-treatment CT images from 321 patients who received immunotherapy at two independent institutions (Ajou University Hospital: 218 patients, Inha University Hospital: 103 patients). All images were reviewed by radiation oncologists. VRS effectively stratified patient outcomes. The VRS Low group (n=160) showed significantly longer progression-free survival (PFS) compared to the VRS High group (n=161) (mPFS: 4.9 vs 2.8 months, p=0.013). In multivariate analysis, VRS proved to be an independent prognostic factor alongside PD-L1 expression for both PFS (HR=1.63, 95% CI=1.26-2.10, p<0.001) and OS (HR=1.60, 95% CI=1.18-2.17, p=0.003). Notably, in patients with low PD-L1 expression (1-49%), where clinical decision-making is challenging, VRS demonstrated superior predictive performance with AUROC of 0.68 (95% CI: 0.60-0.77) for treatment response (CR, PR, SD) and 0.70 (95% CI: 0.60-0.78) for durable clinical benefit (DCB), while PD-L1 showed predictive power below 0.5. VRS showed no significant correlation with PD-L1 (p=0.354), suggesting its complementary role in assessing vascular abnormality. The combination of VRS and PD-L1 expression enhanced prognostic stratification: PD-L1 High/VRS Low patients showed mPFS of 7.2 months and mOS of 23.9 months, while PD-L1 Low/VRS High patients showed mPFS of 2.3 months and mOS of 9.8 months, demonstrating marked prognostic differences. Our CT-based vascular structure biomarker provides an effective, non-invasive method for predicting immunotherapy response in NSCLC patients. VRS is particularly useful in predicting treatment outcomes for patients with low PD-L1 expression and complements PD-L1 expression data. These findings underscore the significance of tumor vascular patterns in NSCLC immunotherapy, potentially enhancing patient selection and facilitating personalized treatment strategies.

#7166 Spatially resolved protein profiling of tumor and immune microenvironment in EGFR mutant NSCLC with transformation to SCLC.

Hong Chen, Bingnan Zhang, Alejandra Serrano, Sharia Hernandez, Wei Lu, Santiago Trevino, Natalie Vokes, Ximeng Liu, Yanhua Tian, Bo Zhu, Monique B. Nilsson, John V. Heymach, Jianjun Zhang, Luisa Solis Soto, Carl M. Gay, Lauren A. Byers, Xiuning Le

UT MD Anderson Cancer Center, Houston, TX

Background: Approximately 3-10% of EGFR-mutant non-small cell lung cancer (NSCLC) cases transform into small cell lung cancer (SCLC) as a resistance mechanism to third-generation EGFR tyrosine kinase inhibitors (TKIs). The mechanisms driving this transformation are poorly understood. This study investigates proteomic differences between pre-transformed EGFR adenocarcinoma (preADC) and post-transformed SCLC (postSCLC) to identify underlying mechanisms and therapeutic vulnerabilities.
Methods: Nanostring GeoMx® Digital Spatial Profiling (DSP) technology was used to analyze seventy protein biomarkers in FFPE patient samples. Two patient cohorts were analyzed: Cohort one included seven patients, with one patient having a preADC sample and six patients having postSCLC samples. Cohort two included three patients, each providing paired preADC and postSCLC samples (3 preADC and 4 postSCLC samples in total). Up to 12 regions of interest (ROIs) were selected by expert pathologists from tumor areas, segmented into Tumor and TME compartments based on the expression of morphology markers (pan-CK, synaptophysin, and CD45).
Results: After integrating both cohorts and correcting for batch effects, UMAP and heatmap visualizations showed clear separation between preADC and postSCLC tumor segments. Differential protein expression analysis revealed that preADC tumors exhibited increased expression of immune regulatory proteins, including IDO1, VISTA, INPP4B, MET, Tim-3, CD45 and STING, indicating active immune evasion. In contrast, postSCLC tumors showed elevated expression of CD56, PARP, BIM, Ki-67 and pan-AKT, which aligns with the high CD56 expression characteristic of SCLC, dysregulated DNA damage repair pathways, and AKT pathway activation implicated in NSCLC to SCLC transformation. Further comparison of protein expression in the TME segments revealed more abundant expression of CD45, CD11c, and CD4 in preADC TME, while postSCLC TME exhibited higher levels of GZMB, CD56, and PARP. FDR < 0.05 was used as the cut-off. These TME findings indicate an "immune-cold" phenotype in SCLC, characterized by scarce immune cell infiltration and increased resistance to apoptosis. In addition, protein expression panels identified promising immune checkpoint as potential therapeutic targets including B7H3 and LAG3 in both preADC and postSCLC samples.
Conclusions: These results highlight molecular and immune changes during the preADC to postSCLC transformation. The shift in tumor and TME protein expressions in postSCLC reflects an increasingly aggressive tumor phenotype, with changes in immune suppression, DNA damage and apoptosis pathways. These findings suggest potential therapeutic targets for EGFR-mutant NSCLC with SCLC transformation.

CLINICAL RESEARCH: Molecular Genetics and Epigenetics of Tumors
Poster Session

#7170 Differential prognostic impacts of the germline APOBEC3B deletion polymorphism in hepato-pancreato-biliary and genitourinary cancers.
Ahmadreza Niavarani, Peyvand Parhizkar Roudsari, Roya Noorbakhsh, Melineh Markarian, Reza Malekzadeh

Digestive Oncology Research Center, Digestive Disease Research Institute, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of

The mutational signatures related to apolipoprotein B mRNA-editing enzyme catalytic polypeptides (APOBECs) are found in many cancers. We aimed to assess the impact of *APOBEC3B* deletion variant on the risk and prognosis of various cancers in the Golestan Cohort Study, Iran, comprising 1,393 cancer cases and 1,806 controls (median age: 69.2 years). The population predominantly consisted of the Turkmen ethnicity (77.5%), with 49.6% of individuals deceased during the study period. The TaqMan genotyping assay was used as a proxy to identify the rs12628403-A/C (linked to intact/deleted *APOBEC3B*) alleles. The *APOBEC3B* deletion was identified in 29.8% of individuals. Cancer cases exhibited a higher frequency of *APOBEC3B* deletion compared to controls, particularly among Turkmen individuals (32.9% vs. 28.5%, OR = 1.23, *P* = 0.019). Increased frequencies were observed for gastric cancer (OR = 1.61, *P* = 0.001) and collective *gastrointestinal (esophageal, gastric, small intestinal,* and *colorectal) cancers* (OR = 1.31, *P* = 0.012) among *APOBEC3B*-deleted individuals. In head and neck cancer, *APOBEC3B* deletion was more prevalent among cases of all origins (OR = 1.83, *P* = 0.036). Survival analyses revealed contrasting effects of the *APOBEC3B* deletion. *APOBEC3B* deletion was significantly associated with longer survival in pancreatic (4.0 vs. 2.7 months; *P* = 0.025) and biliary (29.3 vs. 3.1 months; *P* = 0.047) cancers, as well as the collective *hepato-pancreato-biliary (hepatocellular, pancreatic, gallbladder,* and *biliary) cancers* (4.2 vs. 2.5 months; *P* = 0.002). By contrast, it was predictive of shorter survival in bladder (2.1 vs. 32.8 months; *P* = 1.1e-4) and cervical (5.7 vs. 53.7 months; *P* = 0.017) cancers, and the collective *genitourinary (bladder, cervical, uterus,* and *prostate) cancers* (5.7 vs. 32.8 months; *P* = 1.9e-5). Multivariate Cox regression analyses confirmed a favorable prognostic impact of the *APOBEC3B* deletion in the collective *hepato-pancreato-biliary cancers* (HR = 0.634; *P* = 0.039), while an adverse prognostic impact in the *genitourinary cancers* (HR = 2.45; *P* = 1.9e-4) and meningioma (HR = 6.750; *P* = 0.025). These findings suggest the *APOBEC3B* deletion as a susceptibility and prognostic biomarker in specific cancers, with differential effects based on tumor type. Further studies are warranted to elucidate underlying mechanisms and potential therapeutic implications.

#7171 Comparison of clinical next generation sequencing and whole genome sequencing for acute myeloid leukemia characterization and classification.

Annette A. Prah[1], Derek Van Delden[1], Joan Alexander[2], Asya Stepansky[2], Erin Boyle[3], Nicholas Chiorazzi[3], Jonathan Kolitz[3], Stephanie Boisclair[3], Steven L. Allen[3], David Chitty[3], Andrea B. Moffitt[1]

[1]Department of Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, GA,[2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[3]R.J. Zuckerberg Cancer Center, Northwell Health, Lake Success, NY

Acute myeloid leukemia (AML) is a hematopoietic neoplasm characterized by uncontrolled proliferation of myeloid blast cells. AML is the most common acute leukemia, with over 20,000 new U.S. cases diagnosed annually. The 5-year survival rate varies greatly by age, from 63% in younger patients to 11% in older patients. AML is a genetically heterogeneous disease, with over 25 genes implicated in classification. Clinical next-generation sequencing (NGS) is crucial for AML management, aiding in relapse risk assessment, therapy guidance, and understanding of the genetic landscape. In AML, this typically involves sequencing a panel of 50-500 genes. In practice, only diagnostic samples are tested, without germline controls. In research settings, whole genome sequencing (WGS) is performed on paired diagnosis and remission samples, with remission serving as a germline control. This study assessed the accuracy and utility of AML clinical NGS reports by comparing with matched WGS data. We explored the benefits of germline controls and how discrepancies impact risk classification. 65 AML patients treated in the Northwell Health System and enrolled in an IRB-approved biospecimen study were analyzed. Clinical NGS testing was performed using FoundationOne Heme (n=51) or GenPath OnkoSight (n=14). We analyzed mutation data from clinical NGS reports (median 12 variants per report; range 1-26), identifying DNMT3A, FLT3, TP53, and NPM1 as the most frequently mutated genes, consistent with prior studies. Matched WGS data from 15 patients classified clinically reported variants as somatic (27%; n=57), germline (65%; n=135), or not observed (8%; n=17), using variant allele frequencies (VAFs). There was a strong but imperfect correlation between somatic/germline labels and known/unknown status, provided in the clinical NGS reports: 89% of germline variants were of unknown significance (n=120), while 83% of somatic variants were of known significance (n=43). Clinical NGS reports lacked data such as population variant frequency, pathogenicity scores, and VAFs. Germline and unknown significance variants had higher population frequencies and lower pathogenicity scores than somatic and known significance variants ($p<0.0001$). European LeukemiaNet (ELN) risk groups assigned using clinical NGS data (Adverse: 51%, n=33; Favorable: 29%, n=19) were affected by the inclusion of germline or unobserved variants; excluding those reclassified two patients from Adverse to Intermediate risk. This study finds general agreement between AML clinical NGS and WGS in the overlapping genes. The clinical NGS reports studied here lack annotation of germline and subclonal variant status. We highlight the limitations of clinical NGS without germline controls and its implications for AML classification, clinical decision making, and broader scientific understanding.

#7172 Comprehensive whole genome sequencing (WGS) assay provides diagnostic insight into clinically relevant genomic alterations across myeloid malignancies.

Robert Huether[1], Derick Hoskinson[1], Pavana Anur[1], Raul Torres[1], Karl R. Beutner[1], Kristiyana Kaneva[1], Yan Yang[1], Kelly A. Potts[1], Andrew Frazier[1], Iris Braunstein[1], Brett M. Mahon[1], Michael A. Thompson[1], Kate Sasser[1], Halla Nimeiri[1], Lewis J. Kraft[1], Francisco M. De La Vega[1], Guillermo Garcia-Manero[2]

[1]Tempus AI, Inc., Chicago, IL,[2]M.D. Anderson Cancer Center, Houston, TX

Identification of NCCN and WHO guideline-indicated genetic variation is crucial for diagnosis, risk assessment, and therapeutic decision-making in patients with myeloid malignancies. Current practice often utilizes small mutation panels, cytogenetics (CG), and/or fluorescence in situ hybridization—independent tests that require a separate specimen and have timeline and performance limitations. Whole-genome sequencing (WGS) is a promising alternative with rapid turnaround times and low sample requirements, but evidence showing concordance with other methods is still limited. Here, we report the performance of a WGS assay on patients with acute myeloid leukemia (AML), chronic myelogenous leukemia (CML), myelodysplastic syndromes (MDS) and other hematological malignancies (HM). We show high concordance with matched findings using Tempus xT-Heme (a 648 gene targeted DNA-seq panel), Tempus xR (a whole transcriptome RNA-seq assay), and available cytogenetic results.

All 230 patients in our cohort had targeted DNA panel results, 215 had RNA-seq results, and 10 had cytogenetic data. For the WGS assay, DNA obtained from blood or bone marrow aspirates was used to construct paired-end libraries via tagmentation and WGS to 80X mean coverage with the Illumina NovaSeq-X platform. Data were analyzed using the DRAGEN Platform with custom post-processing filters. We filtered SNV/Indel alterations to 40 genes with VAF ≥10%, 608 recurrent rearrangements, and CNAs greater than 5MB.

In our cohort (68% AML, 18% MDS, 12% CML and 2% other HM) the WGS assay identified 504 reportable SNV/indels, 119 SVs, and 14 large CNAs, which were highly concordant with other assays. Specifically, 99.4% of SNVs/indels and 95.1% of SVs were concordant between xT-Heme and WGS. A subset of guideline-recommended SVs (e.g. RUNX1-RUNX1T1, ELN adverse risk fusion) detected by WGS were not identified by xT-Heme (10.7% [13/121]) but were confirmed via RNA-seq. Large CNAs detected by WGS were 100% concordant (14/14) with available clinically reported CG. Notably, our cohort included 26 FLT3 internal tandem duplications (ITDs) ranging from 12 to 97 nucleotides in length, and 24 of these were identified by WGS —the missed ITDs had xT-Heme VAFs of less than 4%. WGS was less sensitive at low VAFs (targeted sequencing depths of ~600x) that were likely subclonal.

We demonstrate high concordance (97%) between our WGS assay and conventional methods in identifying guideline recommended genomic alterations, including large CNAs, in myeloid malignancies. The ability to obtain large CNA results, historically reserved for CG testing, has the potential to save costs and fill an unmet clinical need globally where cytogenetic resources are limited. Additionally, WGS can identify unique SVs that may be missed by conventional methods and may enhance personalized treatment strategies.

#7173 Comprehensive genomic profiling reveals novel insights into the genomic landscape of extraskeletal myxoid chondrosarcomas.

Carl Philipp Schmitthenner[1], Franziska Evelt[1], Lucas Sebastian Scholl[1], Jessica Janke[1], Anna Kuntze[1], Santina Kirmse[1], Kim Falkenberg[1], Ilka Isfort[1], Ruth Berthold[1], Kornelius Kerl[2], Inga Grunewald[1], Eva Wardelmann[1], Wolfgang Hartmann[1], **Marcel Trautmann**[1]

[1]Gerhard-Domagk-Institute of Pathology, Munster University Hospital, Munster, Germany,[2]Department of Pediatric Hematology and Oncology, Munster University Hospital, Munster, Germany

Background: Extraskeletal myxoid chondrosarcomas (EMCs) are rare mesenchymal neoplasms comprising less than 3% of all soft tissue tumors. EMCs arise mainly from the deep soft tissues of the extremities, accompanied by high rates of recurrence and metastases. The molecular hallmarks of EMCs are cytogenetic *NR4A3* rearrangements, generating chimeric NR4A3 fusion oncoproteins. The most common reciprocal translocation t(9;22)(q22;q12) results in a fusion of the EWS RNA-binding protein 1 gene (*EWSR1*) to the nuclear receptor subfamily 4 group A member 3 gene (*NR4A3* or *TEC*; approximately 75% of cases). Although the oncogenic *NR4A3* fusion transcripts appear to play a crucial role in EMC tumorigenesis and progression, the specific biological function and the mechanism of action remains to be defined. Comprehensive genomic profiling (CGP) and reliable molecular characterization of solid tumors using Next-Generation-Sequencing (NGS) technology has become a key tool to facilitate biomarker-matched therapy selection. With a broad spectrum of therapies already approved or currently tested in clinical trials, rapid and scalable detection of an evolving number of therapeutically relevant genomic alterations and complex biomarkers is required.
Methods: This study combined NGS-based CGP and fusion gene analysis of 69 paraffin-embedded EMC tissue samples to systematically map the genomic landscape of EMC. We used the all-in-one OncoDEEP® in-house kit, integrating both (i) an DNA NGS panel larger than 1MB powered by Twist Bioscience hybrid capture technology in combination with (ii) OncoDNA's bioinformatic data analysis and clinical interpretation software suite (OncoKDM) resulting in an integrated theranostic report. The CE-IVD approved assay covers single-nucleotide variants (SNVs), copy number variants (CNVs), deletions and insertions (indels) and loss of heterozygosity (LOH) in 638 genes and facilitates the assessment of key complex biomarkers / signatures such as homologous recombination deficiency (HRD), tumor mutational burden (TMB), or microsatellite instability (MSI).
Results: Overall, more than 13,600 variants have been identified, categorized as: pathogenic (0.1%), likely pathogenic (1.9%), variant of unknown significance (VUS; 13.3%), likely benign (6.3%) and benign (78.3%). TMB, HRD and MSI status were successfully assessed in more than 88% of all EMC samples. Furthermore, a novel *NR4A3* fusion rearrangement was identified with the majority of EMC samples expressing the chimeric t(9;22) *EWSR1::NR4A3* fusion transcript.
Conclusions: This study provides a comprehensive genomic profile of EMC and uncovers novel genetic alterations, enhancing our understanding of its underlying pathogenesis. Gained genomic insights are anticipated to inform and refine future diagnostic criteria, potentially leading to more precise targeted therapies.

#7174 Multiomics analysis of lung adenocarcinoma manifesting as radiological part-solid features in female never-smokers.

Junsu Choe[1], Noeul Kang[1], Jinyeong Lim[2], Eun Seop Seo[2], Mina Hwang[1], Se-Hoon Lee[1], Myung-Ju Ahn[1], Yoon-La Choi[1], Hong Kwan Kim[1], Woong-Yang Park[2], Sang-Won Um[1]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]SAIHST, Sungkyunkwan University, Seoul, Korea, Republic of

Purpose: Early-stage lung adenocarcinomas (LUADs) manifesting as part-solid radiological features have a slowly progressive course to invasive malignancy, but its genomic alterations and tumor microenvironment are poorly understood.
Methods: We analyzed eleven part-solid type LUADs from female never-smokers. Whole-exome sequencing and whole-transcriptome analysis were conducted on samples from seven patients. Single-cell RNA sequencing was performed on samples from four patients, and spatial transcriptomics was conducted on a sample from one patient.
Results: Both the ground-glass and solid components of LUADs exhibited similar characteristics of malignant cells, sharing mutations and showing no significant differences in tumor mutation burden. Compared to the GG component, the solid component showed up-regulation of epithelial-mesenchymal transition (EMT)-related and hypoxia pathways. We identified a cancer-associated secretory (CAS) cell cluster characterized by the expression of the cancer-related gene CEACAM6. CAS cells showed an increasing trend from normal to tumor regions. Interleukin (IL)-1β+ macrophages, a distinct subtype characterized by a pro-inflammatory M1-dominant gene signature, were abundant in solid components. Spatial transcriptomic analysis revealed that IL-1β+ macrophages and CAS cells were co-localized in specific invasive regions of the solid components, which had elevated EMT and hypoxia signatures.
Conclusion: We identified that CAS cells and IL-1β+ macrophages are crucial during the progression from the pre-invasive (GG) to invasive adenocarcinoma (solid component). Targeting CAS cells and IL-1β+ macrophages could be preventive or therapeutic strategies for early LUADs.

#7175 *STAT3/STAT5* mutation predicts shorter overall survival in patients with plasma cell myeloma.

M. T. Ye, Z. Zuo, S. Calin, Y. Yang, M. You;
The University of Texas MD Anderson Cancer Center, Houston, TX

Plasma cell myeloma is a heterogeneous hematological neoplasm characterized by clonal expansion of malignant plasma cells in the bone marrow. Mutations in the RAS-MAPK pathway, such as *KRAS*, *NRAS*, and *BRAF*, have been identified as high-risk factors associated with poor prognosis. However, the clinical impact of *STAT3/STAT5* mutations in plasma cell myeloma has not been well studied. We assessed the clinicopathologic and molecular genetic features and clinical outcomes of 16 myeloma patients with *STAT3/STAT5* mutations identified by next-generation sequencing, including 9 with *STAT3* mutation, 5 with *STAT5A* mutation, and 2 with *STAT5B* mutation, and compared with 32 matched patients without any mutation. *STAT3/STAT5* mutations were detected at initial diagnosis in all 8 patients with initial mutation status available, suggesting *STAT3/STAT5* mutation is an early event in pathogenesis in plasma cell myeloma. *STAT3/STAT5* mutation was the sole mutation in 5 cases and accompanied by other co-existing mutations in 10 cases, with *KRAS/NRAS* (n=5) and *TP53* (n=3) being the most common; in the latter group, *STAT3/STAT5* represented the dominant clone in 4 cases and co-dominant clone in 6 cases. All were missense mutations, with 10 of 16 (63%) located at the SH2 domain. The median variant allele frequency was 9.1%. *STAT3/STAT5*-mutated patients had higher level of serum lactate dehydrogenase, lower level of serum albumin, higher proportion of IgA type paraprotein, and more advanced R-ISS stage. *STAT3/STAT5* mutations were associated with complex karyotype and gain/amplification of *CKS1B*. The median overall survival was significantly shorter for *STAT3/STAT5*-mutated patients (42 months vs 72 months, p<0.0001). In summary, *STAT3/STAT5* mutations are often early events and represent dominant clones in plasma cell myeloma. These mutations are associated with a complex karyotype, more advanced R-ISS stage, and shorter overall survival. Our findings support the routine testing for *STAT3/STAT5* mutations in patients with plasma cell myeloma, highlighting their role in disease pathogenesis and their potential as therapeutic targets.

#7176 ROR1-dependent mutant TP53 and cyclin A1 increases, via NRF2 activation, potentially potentiate genomic instability in chronic lymphocytic leukemia cells with del(17p).
Emanuela M. Ghia, Can Huang, Michael Y. Choi, George F. Widhopf, Thomas J. Kipps

University of California San Diego, La Jolla, CA

Deletion of 17p (del(17p)) and/or TP53 mutated ($p53_{MU}$) and/or complex karyotype (CK) are adverse prognostic factors with chemotherapy or targeted therapy that define high-risk chronic lymphocytic leukemia (CLL). Del(17p) causes loss of one allele of *TP53*. Somatic mutations occur in the other allele of TP53 in about 80% of del(17p) CLL. ROR1 is an embryonic receptor for Wnt5a, which can induce ROR1-signaling leading to activation of ERK1/2, NF-κB and NRF2 target genes in CLL cells. Anti-ROR1 antibody (zilovertamab) therapy, which blocks ROR1-signaling, inhibited expression of such target genes in CLL cells of patients (pts) treated in a phase I study. Prior work also found that pts with CLL cells with high-level ROR1 ($ROR1^{Hi}$) had an inferior progression-free survival and overall survival compared to pts with CLL cells with low-levels of ROR1 ($ROR1^{Lo}$). Our gene set enrichment analysis revealed that NRF2 target genes and cell-cycle control genes were significantly enriched in $ROR1^{Hi}$ versus $ROR1^{Lo}$ CLL cells or in pre-treatment CLL cells (D0) versus CLL cells of the same pts treated with zilovertamab (D28). Most pronounced was CCNA1, which encodes cyclin A1 and is transcriptionally activated by wild-type p53 or most $p53_{MU}$. NRF2 activation can enhance cyclin A1 activation by inducing NRF2 target genes such as NQO1, which can bind $p53_{MU}$ and mitigate its proteasomal degradation. We assessed 493 untreated CLL for ROR1 expression, FISH, and cytogenetics. We found that cases with $ROR1^{Hi}$ CLL had a significantly higher proportion of del(17p) and/or CK than cases with $ROR1^{Lo}$ CLL. This suggests that high-level ROR1-signaling may be conducive to the survival of CLL cells with del(17p) and genomic instability associated with high-level oxidative stress. We examined for this using a CLL-cell line, MEC1, which lacks ROR1 but makes high levels of Wnt5a and has $p53_{MU}$ (Q317fs*29) with del(17p). We also used $MEC1^{Wnt5a-/-}$ cells, in which we deleted *WNT5A*. MEC1 or $MEC1^{Wnt5a-/-}$ cells were transduced with a lentivirus vector encoding ROR1 to generate MEC1-ROR1 or MEC1-$ROR1^{Wnt5a-/-}$ cells. Relative to MEC1 or MEC1-$ROR1^{Wnt5a-/-}$, MEC1-ROR1 cells had significantly increased expression of NRF2 target genes and cell-cycle control genes, NQO1, $p53_{MU}$, and cyclin A1, and increased resistance to drug induced oxidative stress. Similarly, we found that culture of $ROR1^{+}$ del(17p) CLL cells with Wnt5a increased expression of NQO1, cyclin A1, and $p53_{MU}$, and enhanced their resistance to drug induced oxidative stress; this effect of Wnt5a could be blocked by concomitant treatment with zilovertamab. As such, inhibiting ROR1-signaling may reduce resistance to oxidative stress and prove selectively deleterious to CLL cells with del(17p) and CK, thereby mitigating their adverse prognostic implications for pts with CLL.

#7177 Deep genomic analysis of undifferentiated sarcoma.

Jef Baelen[1], Raphael Sciot[2], Ruben Cools[3], Jonas Demeulemeester[3], Isabelle Vanden Bempt[1]

[1]Center of Human Genetics, KU Leuven, Leuven, Belgium,[2]Imaging and Pathology, KU Leuven-UZ Leuven, Leuven, Belgium,[3]Oncology, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium

Introduction: Undifferentiated sarcomas (USrc) are aggressive mesenchymal tumors that do not show characteristic features and therefore remain a diagnosis of exclusion. USrc typically have a low tumor mutational burden but are genomically complex, carrying many large structural variants (SVs) and copy number aberrations (CNAs). Improving diagnostic practice by adding novel whole genome-technologies based on high molecular weight DNA could increase the sensitivity for detecting genetic alterations in USrc, allowing identification of recurrent aberrations or patterns with clinical implications.

Methods: Snap-frozen tissue from 41 USrc in 38 patients were analyzed by both conventional karyotyping and Optical Genome Mapping (OGM). Chromothripsis was determined based on OGM data and defined as more than eight copy number segments with oscillating copy number in co-occurrence with more than eight chromosomal rearrangements within 50 Mb, or more than 20 rearrangements within 50 Mb. These rearrangements should be interleaved and approximately half of them should be inversion-type aberrations. In addition, we identify known cancer genes (COSMIC Cancer Gene Census) which are amplified/lost or show evidence of disruptive SVs. DNA methylation profiling using EPIC arrays was done on 15 USrc followed by sarcoma classification with the Deutsches Krebsforschungszentrum (DKFZ) sarcoma classifier (v12.3).

Results: 32 out of 41 USrc karyotypes showed at least subclonal whole genome-doubling with complex patterns of SVs and CNAs, including double minutes, ring chromosomes and giant markers. OGM was performed on all USrc biopsies yielding an average coverage of 352X. 25 out of 38 patient samples presented with chromothripsis with an average of 4.3 chromosomes affected (1-13 chromosomes). 70% of amplifications (CN greater than or equal to 5) and 83% of high, focal amplifications (CN greater than or equal to 10) occurred in regions with chromothripsis. Aberrations in 590 COSMIC cancer genes were detected. The most frequently altered cancer genes were *CDKN2A* (42%), *RB1* (34%), *PTPRD* (29%), *MGMT* (26%), and *ARHGEF12* (24%). For 3 patients, biopsies from two different time points were profiled, showing a high proportion of shared aberrations. DNA methylation patterns classified 8 out of 15 analyzed samples as USrc, and the remaining 7 showed no match to any reference sarcoma group. Copy number profiles derived from OGM and DNA methylation arrays were near identical. MGMT promotor hypermethylation was observed in 5 out of 16 cases.

Conclusion: Implementation of OGM improves the detection of SVs and CNAs over standard-of-care. This is demonstrated by the detection of chromothripsis regions and novel recurrent aberrations in USrc. Further investigation to confirm these findings and to identify single nucleotide variants and allele-specific copy numbers are currently ongoing using long-read HiFi sequencing (PacBio).

#7178 Advancing WGS and WTS diagnostic testing for pediatric leukemia: fast-tracking CNV, ploidy, and fusion oncogene detection in 5 days.

Rebecca K. Voss, Maria Cardenas, Meiling Jin, Yen-Chun Liu, Alexa N. Siskar, Stephen V. Rice, Michael N. Edmonson, Jennifer L. Neary, Caleb Gallops, Jiali Gu, Jamie L. Maciaszek, Michael Rusch, Mark R. Wilkinson, David Rosenfeld, Priya Kumar, Jeffery M. Klco, Charles G. Mullighan, Jinghui Zhang, David A. Wheeler, Lu Wang

St. Jude Children's Research Hospital, Memphis, TN

Leukemia is the most common cancer in children, with ~75% being acute lymphocytic leukemia (ALL) and most of the rest acute myeloid leukemia (AML). More than half of pediatric acute leukemias are characterized by chromosome translocations, 40% of B-ALLs by ploidy changes, and a subset of AMLs harbor adverse cytogenetic aberrations defined by large-scale copy number changes (LS-CNV). Whole genome (WGS) and whole transcriptome sequencing (WTS) enable comprehensive molecular diagnosis, but often take weeks. We introduce a rapid workflow integrating WGS and WTS for tumor profiling, using advanced bioinformatic tools to evaluate LS-CNVs, tumor ploidy, and gene fusions, yielding results within 5 working days. Samples with >30% tumor content were used for WGS and WTS. We developed tumor-only WGS-based copy number profiling (WGS-CNP) using the Illumina DRAGEN CNV pipeline and an internal post processing analysis to generate genome-wide CNV results within 2-3 hours post-sequencing. Further on, we developed and automated an algorithm which compares test samples to a normal diploid reference, factoring in DNA gains/losses identified by WGS-CNV analysis to calculate DNA index (DI) for tumor ploidy estimates within minutes. We also implemented Fuzzion2, a rapid pattern-matching algorithm, to identify fusion transcripts from WTS data within ~1 hour. This integrated rapid approach was tested in a total of 117 AML and ALL cases previously diagnosed using standard WGS/WTS pipelines (CREST/CICERO/CONSERTING) and flow cytometry for DI, including 67 cases with characteristic fusion oncogenes, 40 ALLs defined by ploidy change, and 65 cases with LS-CNVs.

For gene fusion detection, Fuzzion2 identified all expected fusion oncogenes with no false positives, according to the established criteria. For LS-CNV, findings between WGS-CNP and the standard pipeline were concordant in all tested cases. For tumor ploidy, WGS-DI showed values concordant with Flow-DI in 33/40 cases. The 7 remaining cases were identified as masked low-hypodiploid by WGS-based CNV and B-allele frequency profiling, of which Flow-DI values were above 1.1 representing the actual tumor DNA content due to genome doubling. When using post-genome doubling (4n) as the ploidy baseline to generate CNVs, the calculated WGS-DI was below 0.75, reflecting the original clone before genome doubling.

Our pilot studies show that the WGS-CNP reliably reproduced previously observed LS-CNVs, accurately established tumor ploidy changes and distinguished masked low-hypodiploidy from hyperdiploidy. Together with the implementation of Fuzzion2 algorithm for gene fusion detection, this integrated rapid approach may detect 80-90% of disease-defining genetic alterations in pediatric acute leukemia with high sensitivity and specificity within 5 days, dramatically expediting the diagnostic process using WGS and WTS.

#7179 Streamlined Glioma diagnosis from formalin-fixed paraffin-embedded (FFPE) tissue: One assay, a fraction of the cost and turnaround time.

M. L. Mimosa[1], J. T. Simpson[1], S. Patel[2], K. Boissinot[2], M. Tiab[2], R. Fattouh[1], R. M. Saleeb[1];
[1]University of Toronto, Toronto, ON, Canada, [2]St. Michael's Hospital, Toronto, ON, Canada

We developed a single diagnostic assay to detect Glioma biomarkers including whole chromosomal and gene copy number variations (CNVs), and single nucleotide variations (SNVs). CNVs and SNVs are traditionally detected using different large/high-throughput platforms that can only exist in big genomic facilities. This leads to very high molecular costs and long turnaround times. The current complex diagnostic algorithm creates delays in patient management while increasing inequity in healthcare as smaller non-centralized labs are unable to conduct glioma molecular testing. To streamline glioma diagnosis and address these challenges, we aimed to use a third-generation sequencing platform called nanopore sequencing. It can simultaneously detect both CNVs and SNVs using small inexpensive tools, but is not yet compatible with formalin-fixed paraffin-embedded (FFPE) DNA.

Therefore, we developed a PCR based assay to create clean nanopore compatible FFPE DNA copies to detect CNVs and SNVs. We established a single nucleotide polymorphism (SNP) microarray-based approach to detect the CNVs. Approximately 300 amplicons were included in the assay design including unique SNP-rich areas to detect the chromosomal heterozygosity. We included all glioma markers required by World Health Organization's (WHO) guidelines including chromosomal CNVs on chr 1, 7, 10, 19; gene CNVs on *CDKN2A, CDKN2B*, *EGFR*; and SNVs on *IDH1, IDH2*, *TERT* promoter, *TP53, ATRX, H3-3A* and *H3C2*. We optimized the testing conditions, and reduced cost and turn-around including streamlining the data analysis using a custom shell script. Lastly, we conducted a mini validation as well as a cost and turn-around time analysis using 40 Glioma FFPE samples.

All our samples had a concordant molecular classification status with the reference results. The concordance, sensitivity and specificity (total accuracy) of the assay were all at 100%. A loss status of chr 1p, chr 19q and chr 10 were determined via a loss of heterozygosity (LOH), and gain status of chr 7 was observed as an allele gain 2:1 SNP pattern. Our total turnaround time (from DNA extraction to data analysis) is 3 business days for an entire batch of samples, which is at least 1/3rd the turnaround time of conventional methods. Our material cost is $150 CAD/sample (including DNA extraction, library preparation and sequencing) which is ~10% of the existing assay costs.

This is the first single streamlined diagnostic test to detect CNVs and SNVs in Gliomas using FFPE DNA. Our assay will increase healthcare equity by allowing smaller labs to adopt molecular testing due to its low assay/capital cost, shorter testing time, and streamlined workflow, helping to overcome many of the existing cancer diagnostic challenges.

#7180 DNA methylation profiling of peripheral blood mononuclear cells from small-cell lung cancer patients treated with hypomethylating agent plus carboplatin.

Elnaz Abbasi Farid[1], Zhen Fu[2], Collin M. Coon[1], Shadia I. Jalal[3], Kenneth P. Nephew[1]

[1]Indiana University School of Medicine, Bloomington, IN,[2]Van Andel Institute, Grand Rapids, MI,[3]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Small-cell lung cancer (SCLC), representing 15% of lung cancers, is one of the deadliest malignancies, with a 5-year survival rate under 7%. Despite initial sensitivity to platinum-based chemotherapy, rapid recurrence and treatment resistance remain hallmarks. Epigenetic modifications, particularly DNA methylation, play a critical role in tumor heterogeneity and resistance. Guadecitabine, a hypomethylating agent (HMA), has shown potential when combined with carboplatin. Building on these findings, we conducted a phase II single-arm trial to evaluate this combination as a second-line treatment for extensive-stage SCLC (ES-SCLC). Peripheral blood mononuclear cells (PBMCs) serve as a minimally invasive source to study systemic epigenetic changes, reflecting tumor-specific modifications. To investigate therapy-associated methylation changes, we analyzed PBMCs from 31 patients on NCT0391345 clinical trial testing guadecitabine and carboplatin: 20 paired pre- and post-treatment samples, 6 pre-treatment samples, and 5 post-treatment samples. DNA was extracted using the DNeasy Blood and Tissue Kit, quantified with NanoDrop™ and Qubit spectrophotometry, bisulfite-converted, and analyzed using the Infinium HumanMethylationEPIC v2.0 platform. Data were processed with SeSAMe to generate β-value matrices. Differentially Methylated Positions (DMPs) were identified using a β-value cutoff of 0.2 and an adjusted $P < 0.05$. Functional analysis of significant DMPs was conducted via Ingenuity Pathway Analysis (IPA).Guadecitabine treatment induced 334 hypomethylated and 9 hypermethylated CpG loci, with pathway analysis revealing significant changes in SCLC and NF-kappa B signaling. Key pathways included Rho GTPase signaling (metastasis), pulmonary fibrosis signaling (lung remodeling), p75 NTR signaling (cell survival), and several other signaling pathways (ID1, MYC mediated apoptosis, immunogenic cell death). Deconvolution analysis showed decreased B cells, NK cells, monocytes, eosinophils, and a trend toward reduced CD4+ and CD8+ T cells post-treatment. Conversely, neutrophils significantly increased, suggesting an inflammatory shift in the tumor microenvironment. These findings demonstrate that guadecitabine treatment induces significant CpG methylation changes in PBMCs, impacting genes and pathways critical to cellular signaling, tissue remodeling, and survival mechanisms. The identification of key pathways, including those involved in metastasis, lung remodeling, and tumor cell survival, highlights the potential role of HMAs in modulating epigenetic and biological processes relevant to SCLC progression and therapy.

#7181 Gene enhancers as novel rationale therapeutic targets for impeding colorectal cancer progression.

Flavia Genua[1], Xinxin Shao[2], Ellen Finnegan[2], Christina Caragine[3], Sarah Maguire[4], Paulien Van Minsel[5], Grainne Kirwan[1], Bernard Thienpont[5], Neville Sanjana[3], Weipeng Wang[6], Sudipto Das[1]

[1]Department of Pharmacy and Biomolecular Sciences, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[2]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[3]Department of Biology, New York University, New York, NY,[4]Patrick G Johnston Centre for Cancer Research, Queen's University, Belfast, United Kingdom,[5]Department of Translational Genetics, VIB, KU Leuven, Belgium,[6]Soochow University, Soochow, China

Half of of colorectal cancer (CRC) patients develop metastatic CRC (mCRC) with a low survival rate. Epigenetic abnormalities in promoters and enhancers play a significant role in CRC advancement and hold promise for diagnosis and therapy and over 5,000 variable enhancer loci (VELs) have been shown to be gained/lost in mCRC. Here, the functional impact of these VELs on driving CRC progression was explored. We designed a CRISPRi library including 1,524 VELs gained or lost specifically in CRC cell lines, the top 500 essential genes for the cell line as positive controls, 1,000 non-targeting guides as negative controls and 6 sgRNAs per site, cloned into a lentiviral plasmid. CRISPR screen was applied to the HCT116-dCas9-KRAB-MeCP2 cells for NGS. Anticancer potentials of silenced VELs were evaluated by in vitro assays (i.e MTT assay, apoptosis, cell cycle assay, 3D bioprinting). Chromosomal interactions and epigenetic state were analyzed by Chromosome conformation capture (3C) coupled with sequencing (Hi-C), chromatin immunoprecipitation (ChIP) with massively parallel DNA sequencing (ChIP-seq) and RNA sequencing. We identified 12 depleted VELs causing a significant decrease in HCT116 proliferation after CRISPR-mediated silencing. VEL_1243 and VEL_1084 caused the highest level of cell growth inhibition as well as increased apoptosis and cell cycle arrest in HCT116 cells. After silencing both enhancers, 3D bioprinting showed a reduction in key markers of metastasis. HiC-Seq and transcription factor binding data showed long-range interaction of both enhancers with genes such as MYO3B, UBR3 and GINS3 and enrichment for disease-associated TF including RFX7, and ELF3. RNA seq results showed significant transcriptome-wide expression alterations regulated by VEL_1243 and VEL_1084, exemplified by their impact on disease-associated signaling pathways including PI3K-Akt and MAPK. IFNγ response pathway -which is a critical aspect of anti-tumor immunity - was downregulated following both VEL_1243 and VEL_1084 silencing. Given that immune/inflammatory cells (e.g., tumor-associated macrophages (TAMs), T-cells, natural killer (NK) and cancer-associated fibroblasts (CAFs) are the important components of the tumor microenvironment (TME), we further examined if VELs mediated regulation of TAMs or immune cells controls the TME in a way that promotes tumour growth. M1 were co-cultured with CRC cells knock-down of VELs. Both VELs repression could induce M1 polarization in HCT116 and SW620 cells. Considering M1 macrophages have the capability to promote the Th1 response and engulf and kill target tumor cells, VEL_1084 and VEL_1243 could be potential therapeutic targets for CRC by affecting the polarization of macrophages. VEL_1243 and VEL_1054 regulate CRC-associated phenotypes and warrant further exploration to determine their regulatory role and potential as a novel therapeutic target in CRC.

#7182 EZH2 inhibition as a therapeutic strategy for castration resistant prostate cancer in combination with AR-antagonist enzalutamide.

Shikhar Sharma[1], Jelena Petrovic[1], Sara Linker[1], Whijae Roh[1], Joan Cao[1], Sean Uryu[1], Zhenxiong Wang[1], Yong Zhang[1], Colin A. Flaveny[1], Conglin Fan[1], Tao Xie[1], Kimberly H. Kim[1], Xiaoli Wang[1], Robert A. Rollins[1], Gail P. Risbridger[2], Renea A. Taylor[2], Mitchell G. Lawrence[2], Thomas A. Paul[1], Pei-Pei Kung[1]

[1]Pfizer, Inc., San Diego, CA,[2]Monash Biomedicine Discovery Institute, Monash University, Melbourne, Australia

The histone methyltransferase EZH2 is an epigenetic transcriptional repressor which mediates gene silencing through methylation of H3K27 residues. EZH2 is overexpressed in castration-resistant prostate cancer (CRPC) and has been associated with prostate cancer progression and resistance to anti-androgen therapies. We have developed a potent, selective, SAM-competitive EZH2 inhibitor, PF-06821497 (Mevrometostat). Using genetic and pharmacological approaches, we demonstrate an epigenetic dependency in CRPC to EZH2 inhibition. EZH2 was identified as a hit in a genome-wide CRISPR screen in AR-positive, but not in AR-negative, CRPC models and was further confirmed in independent CRISPR-competition assays. Consistent with genetic data, long-term PF-1497 treatment showed selective anti-tumor activity in AR-positive CRPC cell lines. Anti-tumor activity of PF-1497 was further validated in vivo with dose-dependent tumor growth inhibition observed in correlation with H3K27me3 biomarker inhibition in CRPC xenograft models. EZH2 inhibition induced cell cycle arrest concomitant with transcriptional upregulation of tumor suppressor genes. Interestingly, we found a subset of genes induced upon enzalutamide treatment are also upregulated upon PF-1497 treatment. Transcriptional and epigenetic profiling revealed that genes repressed by AR show enrichment for H3K27me3 indicating a co-repressor function for EZH2. Combination in vitro treatment of PF-1497 with enzalutamide showed synergistic upregulation of such co-repressed genes associated with robust inhibition of proliferation, survival, cell cycle and stem cell pathways. This transcriptional synergy was associated with robust in vivo anti-tumor combination activity of PF-1497 with enzalutamide inducing durable tumor regressions. Similar combination benefit of PF-1497 and enzalutamide was observed across a panel of CRPC PDXs with anti-tumor activity enriched in AR-positive prostate cancer models, including tumors from patients who were refractory to anti-androgen therapies. Taken together, these data highlight the promise of EZH2 inhibition in treating prostate cancer and provide support for ongoing clinical study of PF-06821497 in combination with enzalutamide in mCRPC.

#7183 METTL1-mediated m7G modification promotes 5-FU resistance in colorectal carcinoma.

Silei Sui[1], Yuan Li[1], Rui Su[1], Man Li[2], Ajay Goel[1]

[1]Beckman Research Institute of The City of Hope, Monrovia, CA,[2]The Second Affiliated Hospital of Dalian Medical University, Dalian, China

Background: Colorectal cancer (CRC) ranks among the most common malignancies worldwide. Despite 5-fluorouracil (5-FU) being a cornerstone of CRC therapy, resistance to this chemotherapeutic agent occurs in approximately 50-60% of patients, significantly contributing to poor prognosis. Emerging studies have highlighted the role of METTL1, a methyltransferase mediating N7-methylguanosine (m^7G) modifications, in promoting tumor progression and drug resistance. However, the specific regulatory mechanisms by which METTL1 contributes to 5-FU resistance in CRC remain poorly understood.

Methods: METTL1 expression was analyzed in paired tumor and adjacent normal (AN) tissue specimens in publicly available datasets. Validation of METTL1 dysregulation in CRC tissues and cell lines was performed using qRT-PCR and western blotting (WB), while m^7G levels were assessed by northwestern blot. Functional assays, including cell viability, colony formation, apoptosis, and invasion assays, were conducted to evaluate the role of METTL1 in CRC. RNA sequencing (RNA-seq) and m7G Methylated RNA Immunoprecipitation sequencing (MeRIP-seq) were used to identify downstream targets of METTL1 associated with chemoresistance.

Results: METTL1 was significantly overexpressed in CRC tissues compared to AN tissues ($p<0.001$), with high METTL1 levels correlating with unfavorable clinical outcomes in both public datasets and our clinical cohort ($p<0.05$). Biologically, genetic depletion of METTL1 via CRISPR-Cas9 markedly led to reduced cell proliferation and enhanced apoptosis after 48 hours of 5-FU treatment in HCT116 and SW480 5-FU resistant cell lines. *In vivo*, METTL1 knockdown significantly enhanced the efficacy of 5-FU in a xenograft mouse model, leading to decreased tumor growth. Mechanistically, METTL1-mediated m^7G methylation influenced the translation of mRNAs, including those involved in the TNF and NOTCH1 signaling pathways, both of which are critical in driving 5-FU resistance.

Conclusion: This study identifies METTL1-mediated m^7G modifications as a pivotal mechanism underlying 5-FU resistance in CRC. By regulating the translation of components in the NOTCH1 signaling pathway, METTL1 drives chemoresistance, presenting a potential therapeutic target to enhance the effectiveness of 5-FU-based treatment regimens in CRC patients.

#7184 Novel role of INCB057643, a bromodomain and extra-terminal (BET) protein inhibitor, in myeloid cell regulation and immunosuppressive tumor environment remodeling in myelofibrosis (MF).

Gaurang Trivedi[1], Pat Feldman[2], Natalia Pardo[3], Erin Crowgey[2], Brittney Wass[1], Hamza Celik[1], Betty Lamothe[2], **Diana Alvarez Arias**[2]

[1]Incyte Research Institute, Wilmington, DE,[2]Incyte Corporation, Wilmington, DE,[3]Discovery and Translational Science (DTS), Clarivate Plc, Barcelona, Spain

Dysregulated epigenetic gene expression is a cancer hallmark. BET proteins can bind to acetylated chromatin to regulate transcription factor activity (eg, NF-kB), leading to overproduction of inflammatory cytokines (Kleppe. *Cancer Cell*. 2018). The BET inhibitor (BETi), INCB057643, has been assessed in MF and other cancers (NCT02711137; NCT04279847 [Study 103]). Although NFkB inhibition is proposed as one of the key mechanisms of BETi-mediated activity in MF, the mechanism of BETi is unresolved. This study assessed cellular and molecular mechanisms of BETi in MF. Total RNAseq was performed on whole blood from commercial MF samples treated ex vivo with INCB057643 and samples from patients (pts) enrolled in Study 103 (dose escalation, monotherapy). Differential gene expression (DGE) and gene set enrichment analysis (GSEA) were performed. Plasma biomarkers were analyzed using HuMAP 2.0 (IQVIA^{TM} panel). The impact of INCB057643 on ex vivo differentiation of pt-derived CD34^{+} cells expressing MPN driver mutations was tested at clinical doses. INCB057643 inhibited pathogenic megakaryopoiesis by reducing megakaryocyte (MK) differentiation and proinflammatory cytokine levels, including neutrophil (etc) chemo-attractants, IL-8 and ENA-78. Although IL-8 was produced at similar levels by wild-type and mutant MK progenitors, ENA-78 was produced only by mutant cells. Both cytokines were inhibited by INCB057643. Contrasting with MK, the proportion of erythroid cells was increased. RNAseq of clinical samples showed INCB057643 dose-dependent effects on gene expression. DGE analysis showed differential expression of epigenetic genes, and genes involved in platelet biogenesis; both are known BET functions. DGE analysis of a myeloid gene set representing monocytes, macrophages, dendritic cells, and neutrophils showed dose-dependent decreases in functional genes (*MGST1*, *IDO2*) and immunosuppressive protumorigenic genes (*MARCO*, *SIGLEC11*), but representative T- or B-cell gene expression was either unchanged or elevated (*PRF1*). Consistent with DGE, INCB057643 inhibited proinflammatory cytokine production (eg, RANTES, IL-18 produced by myeloid cells) as well as ENA-78, suggesting reduced inflammatory cell trafficking in bone marrow. Increased expression of MYC is associated with MPN progression; DGE and GSEA showed that hallmark *MYC* targets signatures were reduced by INCB057643. In summary, INCB057643 decreased malignant MK precursors that drive MF. Although data confirmed INCB057643 regulates epigenetic gene expression globally, selective inhibition of myeloid and MK cells, but not other lineages, was observed. INCB057643 inhibited myeloid cells by downregulating immunosuppressive receptors and proinflammatory cytokines, leading to tumor microenvironment remodeling and reduced inflammation.

#7185 Optimization of an epigenetic based combination platform for patients with peripheral t cell lymphoma.

Kallesh D. Jayappa[1], Andrea Joyner[2], Archana Thakur[1], Owen A. O'Connor[1]

[1]Department of Medicine, Division of Hematology/Oncology; Comprehensive Cancer Center, University of Virginia School of Medicine, Charlottesville, VA,[2]Department of Medicine, Division of Hematology/Oncology, University of Virginia School of Medicine, Charlottesville, VA

Introduction: Our previous work demonstrated that combinations of HDAC and DNMT3 inhibitors were synergistic in preclinical models of T-cell lymphoma, and produced compelling activity in patients with relapsed or refractory disease. This combination was identified based on high-throughput chemical screening seeking to identify synthetically lethal combinations in a disease directed fashion. Here, we present a similar approach to rationally identify a third drug to complement the epigenetic-based combinations established to date.

Results: First, we optimized the schedule of an HDACi [romidepsin, (Romi)] and a DNMT3i [5-azacytidine, (Aza)] across T-cell lymphoma lines. Results revealed that simultaneous exposure to Aza+Romi exhibited superior synergistic cytotoxicity compared to all other schedules tested *in vitro*. Using this schedule, we screened a library of drugs for synergy with the cornerstone combination of Aza + Romi. These drugs included agents targeting HMTs, KDMs, SWI/SNF, BET, CDK9, JAK, PI3K, Bcl-2, Bcl-xL, and Mcl-1. The combination drug screen was performed in three representative PTCL lines [H9 (CTCL), SMZ1 (PTCL-NOS), and FEPD (ALCL-ALK^{NEG})] using cell proliferation assay. The synergy between drugs was determined based on excess over Bliss (EOB) scores established using the *Bliss* model of independence (EOB ≥10, synergy; EOB ≥0-10, additive). The results revealed potent synergy between Aza+Romi and drugs targeting HMTs [PRMT5i (mean EOB, 18.5), EZH1/2i (mean EOB, 9.0)], SWI/SNF [SMARCA2-SMARCA4-PBRM1-degrader (mean EOB,15.1)] and kinases [JAK1i (mean EOB, 17.6), PI3Ki (mean EOB, 15.5)]. In further characterization of schedule dependent activity, we noted that preexposure to PRMT5i, EZH1/2i, SWI/SNFi, or JAK1i followed by Aza+Romi treatment produced superior synergy in PTCL cells *in vitro*. The flow cytometric analysis revealed that these combinations induced apoptotic cell death in PTCL cell lines *in vitro* and these drug combinations, except Aza+Romi with SWI/SNFi and PI3Ki, exhibited a broad therapeutic window inducing preferential cell killing in the PTCL lines (cleaved PARP, 66-80%) compared to healthy PBMCs (cleaved PARP, 27-36%). Ongoing studies will decipher mechanisms of action using RNA-Seq and explore the ideal combinations in *in vivo* model of PTCL.

Summary: The development of combination therapy for PTCL patients has been largely predicated on random ad hoc combinations. We describe herein a rational approach to the optimization of a new backbone for the disease. Simultaneous exposure of Aza and Romi coupled to a preexposure to drugs targeting PTMT5, EZH1/2, and JAK1 inhibitors produced potent synergy with a broad therapeutic window. We believe our ongoing investigation on these combinations will soon lead to the development of a new, chemotherapy free combination tailored to treat PTCL.

#7186 Anti-cancer activity of potent and selective EP300 degradation in hematological malignancies.

Claudia Dominici, Qianhe Zhou, Laura La Bonte, Mark Zimmerman, Mei Yun Lin, Wesley Austin

Foghorn Therapeutics, Cambridge, MA

E1A binding protein (EP300) and CREB binding protein (CBP) are highly homologous acetyltransferase paralogs with demonstrated roles as transcriptional co-activators. Dual inhibition of EP300 and CBP has been reported to have anti-proliferative effects in several cancer types. However, it has also been reported to elicit thrombocytopenia, a toxic reduction in the number of platelets in the blood (Nicosia et al., 2023). Hematological malignancy lineages are particularly susceptible to EP300 loss (DepMap, Broad 2024), therefore, developing chemical matter that selectively targets EP300 has the potential to broaden the therapeutic window and improve tolerability. Historically, selectivity has been difficult to engineer due to the high sequence similarity between EP300 and CBP. Using the targeted degradation approach, we have developed a potent and selective heterobifunctional degrader of EP300 with biological activity in hematological malignancy. We observed that selective degradation of EP300 has anti-proliferative activity in a broad range of hematological malignancies in vitro, including diffuse large B-cell lymphoma, multiple myeloma, and follicular lymphoma. We also achieved in vivo efficacy in a Karpas422 GCB-DLBCL xenograft model. Importantly, an investigational safety study was performed in mice at efficacious doses, and no thrombocytopenia was observed. Therefore, leveraging targeted protein degradation to achieve selective EP300 degradation shows promise to be a well-tolerated and effective treatment strategy for advanced hematological malignancies.

#7187 Epigenetic drugs inhibit the oncogenic activity of methyl CpG binding protein 2 (MECP2).

Manish Neupane[1], **Mukesh Kumar**[1], Malela M. Werner[1], Colleen M. Donnelly[1], Alsu Ibragimova[1], Brian Curcio[2], Inna Chervoneva[2], Irina Vasilevskaya[1], Daniel P. Silver[3]

[1]Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA,[2]Division of Biostatistics, Department of Pharmacology and Experimental Therapeutics, Thomas Jefferson University, Philadelphia, PA,[3]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Purpose of the study: MECP2 amplification plays a role similar to activated oncogenic RAS in tumorigenesis, activating the MAPK and PI3K signaling pathways. MECP2 amplification and RAS mutations are mutually exclusive across human cancers; solid tumors such as high-grade serous ovarian cancer (HGSOC), triple-negative breast cancer (TNBC) and lung adenocarcinoma have 38%, 33% and 29% rates of MECP2 amplification respectively. The MECP2 protein has DNA- binding activity which is required for oncogenic transformation and binding is dependent on cytosine methylation. Therefore, MECP2 DNA binding may be targeted by inhibiting cytosine methylation with DNMTi. Additionally, since MECP2 protein requires HDAC activity for its stability, treatment with either HDACi and/orDNMTi could be therapeutic strategies in MECP2- dependent tumors.

Experimental Procedures and Results: The MDAMB468 (TNBC) cell line was modified stably with a doxycycline-inducible shRNA construct targeting the 3'UTR of MECP2 (shMECP2-3'UTR) and growth was dependent on MECP2 in culture. The cells were then implanted in nude mice subcutaneously and tumors allowed to reach approximately 150 mm^3 before shRNA was induced. Tumor growth in doxycycline-treated mice immediately ceased whereas tumors in vehicle-treated mice continued to grow, showing dependence on MECP2 activity *in vivo*. To verify that this was an on-target effect, the modified cell line was further infected with lentiviruses carrying both splicing isoforms of MECP2 without the 3'UTR shRNA target. This reconstitution allowed growth as a xenograft at a similar rate regardless of shRNA induction, confirming inhibition was on-target. We then assessed the therapeutic efficacy of HDACi and DNMTi alone and in combination in xenograft (for TNBC and lung) or PDX (HGSOC) models of MECP2-dependent and independent tumors. To determine if growth inhibition was an on-target effect of these drugs, MDAMB468 was stably transduced with activated KRAS or GFP as a control and was injected in nude mice. Activated KRAS rescued the epigenetic drug sensitivity of xenografts, demonstrating that these drugs inhibit tumor growth by preventing the ability of MECP2 to induce RAS-activated growth factor pathways.

Summary: The antitumor effects of the commonly used epigenetic drugs are thought to result from cell reprogramming through re-expression of tumor suppressors that had been silenced by hypermethylation or by repressive chromatin marks. However, in this context, we show that these epigenetic drugs can act directly by interfering with the oncogenic activities of MECP2, culminating in inhibition of key growth factor pathways for transformation.

Conclusion: Targeting MECP2 function with epigenetic drugs provides an unanticipated therapeutic opportunity for treating the subset of tumors that overexpress MECP2.

#7188 INCB057643, a bromodomain and extra-terminal (BET) protein inhibitor, improved bone marrow function and shifted megakaryopoiesis to erythropoiesis in patients with myeloproliferative neoplasms (MPNs).

Hamza Celik[1], Angelo Albertoni[1], Brittney Wass[1], Sarita Sehra[1], Lea Burke[2], Melody Diamond[1], Matthew Stubbs[1], **Diana Alvarez Arias**[1]

[1]Incyte Research Institute, Wilmington, DE,[2]Incyte Corporation, Wilmington, DE

Patients with MPNs share common characteristics, including overproduction of myeloid cells and dysplastic megakaryocytes (MK) in bone marrow. Aberrant cell differentiation results in chronic inflammation, development of bone marrow fibrosis, and ineffective hematopoiesis, often leading to anemia. Dysregulated gene transcription can drive these disease characteristics (AACR 2023; Abs 6274). BET proteins are key epigenetic factors of oncogene transcription. INCB057643, a novel, orally bioavailable BET inhibitor, is being evaluated in clinical trials as monotherapy and in combination with ruxolitinib in patients with MPNs (NCT02711137; NCT04279847). To understand the INCB057643 mechanism of action including MK differentiation and biomarkers of inflammation and fibrosis, we used a physiologically relevant patient-derived mouse xenograft (PDX) model of myelofibrosis transplanted with patient $CD34^+$ JAK2-$V617F^+$ cells. MK and erythroid progenitors in bone marrow were quantified by flow cytometry for CD61 and CD71 markers, respectively. Reticulin staining was used to assess fibrosis. INCB057643 treatment elicited a robust decrease in JAK2 V617F+ hematopoietic stem progenitor cells and MK in bone marrow. Concordant with depletion of pathogenic cells, a significant reduction in serum proinflammatory cytokines and fibrosis was observed in treated mice. Bone marrow samples from patients enrolled in NCT04279847 (monotherapy) were analyzed for CD61 and CD71 by immunohistochemistry. Patient plasma biomarker analyses were performed using HuMAP 2.0 (IQVIA^{TM} panel); total RNAseq was performed on whole blood samples. Consistent with the preclinical models, CD61 staining was decreased in bone marrow after INCB057643 treatment. Moreover, tight MK clusters changed into looser structures with increased distance between MK cells; dysplastic MK morphology changed to a more normal appearance in some patients. Fibrosis score decreased ≥1 grade in 3/5 patients receiving INCB057643 10 mg qd. Moreover, expression of soluble biomarkers and genes associated with fibrosis, such as *TIMP3* and *Col4A2*, were decreased, while adiponectin expression in plasma was increased, especially at ~week 12, suggesting improved bone marrow function. Notably, erythroid progenitors in patient bone marrow were increased at both doses tested (6 mg qd, n=3; 10 mg qd, n=5). Although all patients who received INCB057643 10 mg qd had anemia at screening, treatment resulted in hemoglobin response in 3/5 patients. In conclusion, the results show that INCB057643 specifically inhibits pathogenic MK differentiation, reduces inflammatory cytokine production, and decreases fibrosis. INCB057643 treatment also improves bone marrow function, which results in increased erythroid differentiation and reduced anemia symptoms.

#7189 EED inhibitor APG-5918 renders vulnerability to immunotherapy by rewiring sphingolipid metabolism via nSMase2-ceramide pathway in pancreatic cancer.

Jing Yang[1], Fan Chen[1], Qiuyun Luo[2], Mingyu Lai[1], Jiachen Lu[1], Dajun Yang[3], Miaozhen Qiu[1]

[1]Department of Medical Oncology, Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China,[2]The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China,[3]Department of Experimental Research, Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Background: Pancreatic cancer has a poor prognosis and is primary resistant to immune checkpoint inhibitors (ICIs) partially due to the inhibitory immune microenvironment. To improve the responsiveness of pancreatic cancer to ICIs, researchers have explored various combination therapies, including the use of epigenetic inhibitors. Embryonic Ectoderm Development (EED), a regulatory component of the PRC2 histone modification complex, has emerged as a target of interest. This study aims to investigate the potential effects of combining EED inhibition with PD-1 blockade in treating pancreatic cancer.

Methods: Allograft models of murine pancreatic cancer cell lines, KPC and Panc02, were used to evaluate the combined anti-tumor effects of PD-1 antibody and a novel EED inhibitor, APG-5918. To determine how EED inhibition and PD-1 blockade influenced immune responses, *in vivo* tumor samples underwent single-cell sequencing and flow cytometry to assess immune cell infiltration and gene expression changes. Additionally, lipidomic metabolic sequencing and ELISA were used to measure changes in ceramide levels *in vitro* following EED or SMPD3 inhibition. Macrophage polarization phenotypes were further characterized using RT-qPCR and flow cytometry in the human monocyte lines THP1 and Raw264.7.

Results: Our study demonstrated that the EED inhibitor APG-5918 synergizes with PD-1 antibody to exert anti-tumor effects in immune-competent murine pancreatic cancer allograft models. Single-cell sequencing of mouse tumor tissues revealed, and subsequent flow cytometry confirmed, a significant increase in M1 macrophages and CD8+ T cells in tumors from the combination treatment group compared with other groups. Transcriptomic analysis showed that EED inhibition significantly upregulated SMPD3 expression, which encodes the ceramide-producing enzyme nSMase2, and enriched the sphingolipid metabolic pathway. Quantitative lipidomic analysis revealed an increase in ceramide C16 levels in KPC and Panc1 cells treated with APG-5918, and ELISA confirmed that ceramide levels could be restored following treatment with the SMPD3 inhibitor GW4869. Furthermore, EED knockdown or supplementation with exogenous ceramide significantly promoted macrophage polarization toward the M1 phenotype in the human monocyte lines THP1 and Raw264.7 *in vitro*.

Conclusions: Taken together, our results demonstrate that the novel EED inhibitor APG-5918 can reshape the tumor immune microenvironment by activating the nSMase2-ceramide pathway, overcoming immunotherapy resistance in pancreatic cancer. This promising approach, combining EED inhibition with PD-1 blockade, will be further explored in translational and clinical studies.

#7191 Targeted genomic and epigenomic dual analysis of the same region for an entire single gene.

Grace Q. Zhao[1], Heng Wang[1], Alexandra Harris[2], Yingmin Wang[1], Yingzhen Wang[1], Ling Su[3], Ashraf Wahba[1], Josh Wang[4], Yun Bao[1], Carole Durand[1], Bram Herman[5], Tiffany Dorsey[2], Shengrong Lin[1], Xiaolin Wu[3], Stefan Ambs[2]

[1]Agilent Technologies, Inc., Santa Clara, CA,[2]Molecular Epidemiology Group, Laboratory of Human Carcinogenesis, National Cancer Institute, Bethesda, MD,[3]Cancer Research Technology Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Agilent Technologies, Inc., Annapolis, MD,[5]Agilent Technologies, Inc., Harwell, United Kingdom

Omics analysis for cancer research is increasingly focusing on integrating both genomic and epigenomic data. While most studies often limit methylation analysis to promoter regions and genomic analysis to exons, research suggests the importance of examining omics information for entire genes, including UTRs and introns. Current whole-genome technologies for simultaneous genomic and epigenomic analysis require costly deep sequencing for low tumor content and may suffer from limited coverage in high CG content regions. To address these challenges, we developed a novel strategy that enables simultaneous genomic alteration and methylation dual analysis of the same region within a single gene, offering an affordable solution with improved uniformity, including high CG regions. ARID1A, a critical component of the SWI/SNF complex, is frequently mutated in breast cancer. Low ARID1A expression is associated with poor outcomes in luminal A and HER2-positive subtypes, making it an ideal candidate for investigating genomic alterations and potential methylation-related gene inactivation. To achieve this, we utilized the novel strategy for simultaneous genomic and epigenomic analysis using the Agilent Avida Duo target enrichment system. This approach allowed us to sequentially capture and analyze both genomic and methylation information across the same promoter, intron, and exon regions of the entire gene from a single DNA input without sample splitting. Moreover, the sequencing depth can be independently optimized for each modality. To optimize sequencing budget and coverage uniformity, we divided the panels (90kb) into high-quality and low-complexity regions, primarily introns, and experimented with different panel mixture ratios. With 10ng of fragmented gDNA, we achieved good coverage for both genomic (>1000x unique molecules) and methylation (>100x unique molecules) analysis, using less than 5M PE reads (sequencing clusters) for each omics in the Avida Duo workflow. For uniformity, the percentage of regions with coverage greater than 0.2x of the mean coverage is >90%. Our pilot studies, using tumor genomic DNA, formalin-fixed paraffin-embedded (FFPE) tissue from various cancer types, and cell-free DNA (cfDNA) control samples, successfully
demonstrated the feasibility of our approach for simultaneous targeted genomic and epigenomic analysis of the same region within the entire single gene, even with limited DNA input.
For Research Use Only. Not for use in diagnostic procedures.

CLINICAL RESEARCH: Targeted Therapies and Combinations 4
Poster Session

#7195 Real-world patient characteristics, treatment patterns, and healthcare resource use in patients with metastatic melanoma (mMEL) treated with BRAF-MEK inhibitor targeted therapies (TTS) in the US.

Gino K. In[1], **Kristina Chen**[2], Gautam Sajeev[3], Mu Cheng[3], Jingyi Chen[3], Joanne Chukwueke[3], Jessie J. Lan[3], James Signorovitch[3]

[1]Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Pfizer, Inc., New York, NY,[3]Analysis Group, Inc., Boston, MA

Background: Real-world evidence on treatment patterns and healthcare resource use (HRU) in patients receiving the targeted therapies encorafenib+binimetinib (ENCO+BINI) and dabrafenib+trametinib (DAB+TRAM) in mMEL is limited.

Methods: Patients initiating ENCO+BINI or DAB+TRAM between June 2018 and March 2023 as first-line (1L) or second-line (2L) treatment for mMEL in the IQVIA Pharmetrics® Plus commercial claims database were included. Patients judged to have received neoadjuvant or adjuvant therapy or treatment for another cancer prior to TT initiation (index date) were excluded. Treatment discontinuation and melanoma-specific HRU were compared between TTs, in 1L and 2L separately. Analyses were adjusted for age, sex, region, index year, time from mMEL diagnosis to index, sites of metastases, NCI score, baseline all-cause HRU and prior immunotherapy (2L analysis only).

Results: In 1L, at baseline, compared to the DAB+TRAM group (n=137), the ENCO+BINI group (n=117) was younger (mean age: 50.6 vs. 54.9 years) and had more patients with lymph node (63.2% vs 49.6%) or bone/bone marrow metastases (28.2% vs 17.5%). In 2L, the ENCO+BINI group (n=60) had higher melanoma-specific emergency room (ER) and outpatient (OP) visit rates than the DAB+TRAM group (n=56) during the baseline period. Treatment discontinuation for ENCO+BINI relative to DAB+TRAM was significantly lower in 1L (adjusted hazard ratio with 95% confidence interval: 0.70 [0.51, 0.96]), and numerically lower in 2L (0.69 [0.43, 1.12]). More ENCO+BINI patients remained on treatment through 12 months (36% vs 21% in 1L; 39% vs 26% in 2L) and 24 months (20% vs 9% in 1L; 27% vs 15% in 2L).Melanoma-specific inpatient (IP) admissions for ENCO+BINI relative to DAB+TRAM were significantly lower in 1L (21% versus 30% with IP admissions in IL; incidence rate ratio [IRR]: 0.45 [0.29, 0.70]) and numerically lower in 2L (37% vs 50% with IP admissions in 2L; IRR: 0.73 [0.43, 1.22]). Rates of OP visits were significantly lower for ENCO+BINI in 1L (IRR: 0.83 [0.77, 0.89]) but significantly higher in 2L (IRR: 1.33 [1.21, 1.46]). There were no differences between the groups on rates of ER visits in either 1L or 2L.

Conclusion: ENCO+BINI was associated with better treatment persistence, lower IP admissions, and lower OP visits in 1L compared to DAB+TRAM, while OP visits for ENCO+BINI were higher than for DAB+TRAM in 2L. This may suggest potential differences in effectiveness or tolerability between TT regimens across treatment settings in this mMEL population. Further contextualization of reasons for resource use in these patients warrant exploration in future studies to help understand their clinical and economic implications.

#7196 Synergistic effect of sotorasib plus trametinib in patients with KRAS^{G12C}-mutated metastatic colorectal cancer.

Silei Sui[1], Marwan Fakih[2], Yuan Li[1], Caiming Xu[1], Ajay Goel[1]

[1]Beckman Research Institute of The City of Hope, Monrovia, CA,[2]City of Hope Medical Center, Duarte, CA

Background: KRAS is altered in approximately 40% of colorectal cancer (CRC), with the KRAS^{G12C} mutant (MUT) being particularly notable for its high prevalence in certain cancers that directly activates the MAPK pathway. Sotorasib, an irreversible, selective KRAS^{G12C} inhibitor, showed promising antitumor activity in *KRAS*^{G12C}-MUT colorectal cancer. However, despite recent FDA approval, the response rate of Sotorasib monotherapy in CRC remains below 10%. Herein, we aimed to investigate the synergistic efficacy for the combination of a MEK1 inhibitor (Trametinib) and Sotorasib in CRC.

Methods: We conducted an integrative analysis of genomic and transcriptomic data, comparing pretreatment cases and those obtained following the development of resistance to Sotorasib. Dose-response curves were generated to determine the IC_{50} values of Sotorasib and Trametinib in CRC cell lines with distinct mutational profiles: SW837 (KRAS^{G12C}) and SW1463 (KRAS^{G12C} and MEK1 MUT). To further investigate the effects of the combination compared to the monotherapy of each drug, we performed a series of functional assays by focusing on perturbations within the MAPK/ERK/AKT signaling pathway.

Results: Among the 27 patients analyzed, 10 were identified with putative resistance phenotype, of which 9 (37%) had acquired MEK1 mutations or amplifications. The Kaplan-Meier analysis for overall survival in CRC patients harboring wild-type and mutant MEK1. Functional analysis demonstrated a synergic effect of combined Sotorasib and Trametinib treatment in SW837 and SW1463 CRC cell lines. In MTT assays, the combination therapy significantly enhanced cytotoxicity compared to either monotherapy alone. Similarly, colony formation assay revealed a marked reduction in the proliferative capacity of CRC cells when treated with the combination therapy. Mechanistically, combination treatment with Sotorasib and Trametinib led to enhanced inhibition of the MAPK/ERK/AKT signaling pathway compared to monotherapy in SW837 and SW1463 cell lines. Furthermore, the introduction of activating mutations in MEK1 (MEK1^{K57T} and MEK1^{K57N}) demonstrated that combinatorial therapies of KRAS^{G12C} inhibitor and MEK1 inhibitors could effectively overcome the drug resistance acquired by these activating mutations.

Conclusion: The combined treatment of Sotorasib and a MEK1 inhibitor, Trametinib, exhibit synergistic effects in drug-induced cytotoxicity and inhibition of MAPK pathways in colorectal cancer lines.

#7197 Targeting FAK exhibits therapeutic effects on interstitial lung disease induced by trastuzumab deruxtecan.

B. Zhang, R. Pang, J. Cheng, J. Gao, N. Qin, L. Liu, Z. Wang;
Inxmed, Shanghai, China

Interstitial lung disease (ILD) is a common pulmonary complication associated with cancer therapy. Several antibody-drug conjugates (ADCs), including trastuzumab deruxtecan (Enhertu), have been implicated in the induction of ILD, thereby limiting their clinical application. Treatment with ADCs must be permanently discontinued if grade 2 or higher ILD-related adverse effects occur. The standard approach for managing Enhertu-induced ILD involves the use of corticosteroids, which can exacerbate the toxicities faced by cancer patients. Our previous studies demonstrated that targeting focal adhesion kinase (FAK) enhances the efficacy of Enhertu and other ADCs in solid tumor treatment. Notably, we have now identified that FAK inhibition by the small molecule inhibitor Ifebemtinib (aka IN10018, Ifebe) can mitigate Enhertu-induced ILD. In an animal model of Enhertu-induced ILD, Ifebe showed recovery trends comparable to those observed with corticosteroids across multiple physiological parameters of mouse respiration. Both inflammatory and ILD injury biomarkers which were activated by Enhertu were significantly reduced with Ifebe monotherapy. Collectively, the combination of FAK inhibition and Enhertu may offer improved therapeutic efficacy while mitigating ILD-related toxicities. These findings warrant further clinical investigation.

#7198 Preclinical efficacy of the combination of MEK inhibitor plus KRAS G12D inhibitor for non-small cell lung cancer with *KRAS G12D*.

Yu Tanaka, Mirai Tsukuda, Gaku Yamamoto, Eri Sugiyama, Hiroki Izumi, Tetsuya Sakai, Shigeki Umemura, Yoshitaka Zenke, Shingo Matsumoto, Kiyotaka Yoh, Koichi Goto, Hibiki Udagawa

National Cancer Center Hospital East, Kashiwanoha, Kashiwa-shi, Chiba, Japan

KRAS G12D is observed in 3 - 8% of non-small cell lung cancer (NSCLC). Currently, no targeted therapies are approved for solid tumors including NSCLC with *KRAS* G12D. MRTX1133 is a selective KRAS G12D inhibitor in advanced development. A previous preclinical data showed that MRTX1133 was effective in pancreatic carcinoma, but might not in NSCLC. Thus, we evaluated the efficacy of MRTX1133 monotherapy and investigated potential therapeutic strategies for NSCLC with *KRAS* G12D using *in vitro* and *in vivo* models. Cell viability assays demonstrated that MRTX1133 was less effective in *KRAS* G12D-mutated NSCLC cell lines. MRTX1133 suppressed phosphorylation of ERK in KRAS G12D-mutated NSCLC cell lines at 2 - 4 hours, but rebound of phosphorylation of ERK was observed at 24 - 48 hours. To identify potential combination drugs that can enhance the efficacy of MRTX1133, we evaluated phosphorylation of receptor tyrosine kinases in *KRAS* G12D-mutated NSCLC cell lines treated with MRTX1133 monotherapy and performed a drug combination screening for *KRAS* G12D-mutated NSCLC cell lines. Although no phosphorylation of receptor tyrosine kinases that could be combination drug candidates were observed, several MEK inhibitors, such as trametinib, selumetinib and binmetinib, enhanced the efficacy of MRTX1133 in cell viability assays. MEK inhibitors suppressed rebound of phosphorylation of ERK by MRTX1133 monotherapy at 24 - 48 hours. The combination of trametinib with MRTX1133 suppressed tumor growth compared to MRTX1133 monotherapy with tolerable toxicity in KRAS G12D-mutated NSCLC *in vivo* models. In conclusion, our findings indicate that the preclinical efficacy of MRTX1133 monotherapy was limited for NSCLC with *KRAS* G12D, and therapeutic potential of MEK inhibitors in combination with MRTX1133.

#7199 Synergistic anticancer effects of milciclib and mirdametinib: mechanistic insights into cell cycle arrest, DNA damage, and senescence.

Xinyu Pei[1], Juifang Fan[2], Anh Nguyen Nguyen[3], Hannah Neiger[3], Imran A. Khan[2], Vladimir Bezrookove[2], Yu Zhou[1], Maureen Veilleux[4], Lily S. Wang[5], Valerie A. Gerriets[3], John K. Cusick[3], Pierre Y. Desprez[2], Li Zheng[1], Mohammed Kashani-Sabet[2], Binghui Shen[1], **Yihui Shi**[2]

[1]Cancer Genetics and Epigenetics, City of Hope, Duarte, CA,[2]California Pacific Medical Center Research Institute, San Francisco, CA,[3]California Northstate University, Elk Grove, CA,[4]University of Lyon, Lyon, France,[5]University of Berkeley, Berkeley, CA

Milciclib, a cyclin-dependent kinase (CDK) inhibitor, has recently been identified as a modulator of pre-mRNA splicing, broadening its therapeutic potential. However, resistance to CDK inhibitors frequently arises due to activation of compensatory pathways, such as the MEK-ERK signaling cascade, which drives unchecked cell cycle progression and circumvents critical checkpoints. RNA sequencing of Milciclib-treated cells revealed significant upregulation of the MEK pathway, highlighting a potential resistance mechanism and supporting the strategy of targeting MEK in combination therapy. To address this challenge, we investigated the combination of Milciclib with the MEK inhibitor Mirdametinib (PD-0325901) across various cancer types, including colorectal cancer. The combination synergistically inhibited cancer cell proliferation by inducing cell cycle arrest at G0/G1 and G2/M phases. It also impaired homologous recombination repair, as evidenced by reduced RAD51 levels, and enhanced DNA damage (γH2AX). Furthermore, Mirdametinib alone and in combination with Milciclib promoted cellular senescence, characterized by the upregulation of p16 and p21. In vivo, the combination treatment significantly inhibited tumor growth in animal models. These findings highlight the complementary mechanisms of action of Milciclib and Mirdametinib. The synergy observed in this combination therapy provides a strong rationale for further clinical investigation.

#7200 PREMOST: an organoid-based functional precision medicine trial in osteosarcoma.

Rina Kuznets[1], Maite Calucho[2], Huyen T. L. Nguyen[2], Scott D. Nelson[3], Sarah M. Dry[3], Jane Yanagawa[4], Arun S. Singh[5], Joseph G. Crompton[4], Lauren E. Wessel[2], Alexander B. Christ[2], Nicholas M. Bernthal[2], Noah C. Federman[6], Bartosz Chmielowski[7], Alice Soragni[8]

[1]Department of Pediatrics, Division of Hematology/Oncology, UCLA, Los Angeles, CA,[2]Department of Orthopedic Surgery, UCLA, Los Angeles, CA,[3]Department of Pathology, David Geffen School of Medicine, UCLA, Los Angeles, CA,[4]Department of Surgery, Division of Thoracic Surgery, David Geffen School of Medicine, UCLA, Los Angeles, CA,[5]Department of Medicine, Division of Hematology & Medical Oncology, UCLA, Los Angeles, CA,[6]Department of Pediatrics, Division of Hematology Oncology, David Geffen School of Medicine, UCLA, Los Angeles, CA,[7]Division of Hematology-Oncology, David Geffen School of Medicine, UCLA, Los Angeles, CA,[8]Department of Orthopaedic Surgery, David Geffen School of Medicine, UCLA, Los Angeles, CA

Pediatric sarcomas are a diverse group of malignancies accounting for ~15% of all childhood solid tumors. Osteosarcomas constitute the most common bone tumor in the pediatric patient population. There are about 1,000 new cases diagnosed each year in the United States, with greatest incidence in adolescence and in the sixth decade of life. Overall, 5-year survival rates are ~60% and as low as ~20-30% for metastatic disease. In the primary setting, neoadjuvant MAP chemotherapy including methotrexate, adriamycin (doxorubicin), and cisplatin combination therapy is the standard of care. However, ~30% of all patients are resistant to MAP therapy, resulting in low degree of necrosis at time of surgery, and rapid recurrences. For recurrent and metastatic disease, NCCN guidelines include several different possible regimens, which have shown some activity in the clinic. For both the neoadjuvant MAP setting and second line therapies, there is no clinically validated biomarker of response to help stratify patients and improve outcomes by selecting the most effective therapy. Our overarching goal is to leverage short-term, patient-derived sarcoma organoids to provide actionable information for treatment guidance. Patient-derived organoids (PDOs) are increasingly used both to investigate tumor growth and for precision medicine, as they recapitulate patients drug responses in many settings (Zhao et al, Nature Reviews Methods Primers 2022). We have an established pipeline to establish and characterize sarcoma patient-derived organoids using an approach that allows us to perform high throughput drug screenings to find individual susceptibilities (Al Shihabi et al, Science Advances 2022; Al Shihabi et al, Cell Stem Cell 2024). Our preliminary correlative studies highlight how sarcoma PDOs can recapitulate therapy outcomes (Al Shihabi et al, Cell Stem Cell 2024). In a small dataset, responses of osteosarcoma organoids established from diagnostic biopsies to MAP neo-adjuvant therapy were found to correlate with both short-term histologic response (necrosis at time of surgery) and long-term patient outcomes (progression-free survival). As such, we have initiated a clinical trial to evaluate the feasibility of developing organoids from these cases and to assess the prognostic accuracy of our platform in predicting treatment outcomes. Here we will discuss the design and preliminary findings of PREMOST (An Organoid-based Functional Precision Medicine Trial in Osteosarcoma, NCT06064682), currently open to patients either suspected of having osteosarcoma (Arm 1) or who have recurrent/metastatic osteosarcoma (Arm 2). Clinical validation of organoid-based platforms is a critical step to deploy these technologies for therapy guidance in the future.

#7201 Targeting SLC38A1 non-conventional glutamine transporter in high risk MDS/AML.

Introduction: Myelodysplastic syndrome (MDS) is a malignant clonal hematopoietic disorder characterized by ineffective hematopoiesis, bone marrow dysplasia, and a tendency to transform into acute myeloid leukemia (AML) in about 30% of cases. Cancer cells are known to rely on glutamine as a source of energy. We have reported that inhibition of glutaminase (GLS), a key enzyme in glutaminolysis, with CB-839 combined with 5-azacytidine has synergistic activity in AML/MDS *in vitro* and *in vivo* models and is associated with durable responses in patients with advanced MDS (DiNardo et al., Nat Cancer 2024). Glutamine uptake is tightly regulated by members of the large solute carrier (SLC) superfamily. We found that SLC38A1, a non-canonical glutamine transporter, is significantly and selectively overexpressed in long-term hematopoietic stem cells (LT-HSCs) in patients with MDS and AML and associated with reduced overall survival. Based on these findings, we hypothesize that SLC38A1 represents a promising therapeutic target and that inhibiting critical tumor-specific metabolic pathways will selectively target MDS stem cells responsible for AML transformation.

Methods: Intracellular metabolites were extracted using a modified Bligh-Dyer procedure and analyzed by ultra-high-performance liquid chromatography tandem ultra high-resolution mass spectrometry (UHPLC-HRMS) technology. SiRNA and CRISPR mediated knockdown of SLC38A1 were done in cell lines and patient samples using Amaxa nucleofection. Colony forming assay was done using human methylcellulose enriched media.

Results: Functional relevance of SLC38A1 was shown by metabolic flux analysis of siRNA-mediated SLC38A1 depletion in HEL cells and knockdown of OCI-AML-3 with CRISPR guide RNAs which demonstrated reduced glutamine transport with corresponding reduction of glutamate and aspartate levels. MeAiB (α-(methylamino)-isobutyric acid), a non-metabolized amino acid analogue and competitive inhibitor of system “A” SNAT family transporters including SLC38A1, reduced AML cell viability in MOLM14 and MV4-11 cell lines. Knock-down of SLC38A1 reduced the number of surviving colonies by 37%, 42% and 43% in MOLM13, THP-1 and MDS-L cells, respectively. SLC38A1 KO in MOLM13 and THP-1 cells attenuated cell proliferation and reduced cell viability compared to control cells. SLC38A1 KO in primary AML and high risk MDS patient samples (n=4) reduced cell viability and colony formation. Additional primary samples are being tested and will be reported.

Conclusion: These findings suggest that inhibition of the import function of glutamine transporter SLC38A1 may be therapeutically beneficial to target the metabolic reprogramming in high risk MDS/AML. Chemical library screening is ongoing and has identified initial tool SLC38A1 inhibitors.

#7202 Real-world data and clinical experience from over 100,000 multi-cancer early detection tests.

Marc Matrana[1], Vershalee Shukla[2], Dallas Kingsbury[3], Martin Poliak[4], Jordan Lipton[5], Louis B. Malinow[6], Oliver Venn[7], John Beausang[7], Geoff Stanley[7], Earl Hubbell[7], Kathryn N. Kurtzman[8], Jeffrey M. Venstrom[8], Rita Shaknovich[8], **Candace Westgate**[9]

[1]Ochsner Cancer Institute, New Orleans, LA,[2]Vincere Cancer Center, Scottsdale, AZ,[3]Fountain Life, Naples, FL,[4]Medical Clinic of Houston, Houston, TX,[5]Signature Healthcare, Charlotte, NC,[6]MDVIP, Baltimore, MD,[7]GRAIL, Inc., Menlo Park, CA,[8]GRAIL, Inc. (Affiliation at time of study completion), Menlo Park, CA,[9]Adventist Health, Saint Helena, CA

Background: A multi-cancer early detection (MCED) test, which has been commercially available since April 19, 2021, detects a cancer signal and predicts cancer signal origin (CSO) by analyzing methylation patterns in cell-free DNA. Here, we report real-world clinical experience with >100,000 MCED tests ordered and processed through October 14, 2023.
Methods: A Quality Assurance program was set up to characterize use of MCED testing in a real-world setting and included voluntarily reported outcome data from healthcare providers to assess cancer signal detection rate (CSDR; cancer signal detected results [true + false positives] divided by all tests) and CSO accuracy. This real-world data analysis included 111,080 tests returned to individuals ≥22 years (56% male, median age 58 y [IQR 50-67]). All data were de-identified following the HIPAA-compliant, independent expert determination method. Only the first test administered to each individual was used in this analysis. CSDR was compared to an independent model of CSDR based on estimated cancer incidence from SEER. When available, the proportion of reported diagnosed cancers is broken down by asymptomatic patients (ie, without clinical suspicion of cancer) and stage. CSO prediction accuracy was calculated for reported diagnosed cancers with a known cancer type.
Results: The overall real-world CSDR was 0.91% (1,011/111,080) and increased with age ($p<1e-10$), consistent with the independent CSDR model prediction and previously published data. Among asymptomatic patients with a positive MCED test and a reported cancer status, 49.4% (128/259) received a cancer diagnosis with a median time to diagnosis of 43 days (IQR: 21-94). Excluding recurrences and cases with multiple diagnoses, cancer stage was available for 69 asymptomatic patients, with 59% [41/69] diagnosed with stages I-III. CSO prediction accuracy across the 19 different CSO categories in this dataset was 89% (201/227) and represented 30 distinct AJCC-defined cancer types ultimately diagnosed. Many cancer diagnoses (60.8% [138/227]) were types without recommended screening guidelines, including 18 cases of head and neck, 15 pancreas and gall bladder, and 9 stomach and esophagus cancers.
Conclusions: Real-world CSDR was consistent with previously reported large-scale clinical studies and an independent CSDR model. Although outcomes data is limited by incomplete reporting, a known issue in clinical surveillance data, these data provide valuable insight into real world use of MCED tests. The MCED test reliably detected a cancer signal across a wide range of cancer types, including unscreened cancers. High CSO prediction accuracy guided diagnostic workups, resulting in typically rapid cancer diagnoses. These real-world data demonstrate the successful detection of both conventionally screened and unscreened cancers using the MCED test.

#7203 Systematic pan-cancer functional patient stratification to advance therapy personalization in rare solid tumors.

Introduction: To date, comprehensive omics sequencing has greatly advanced cancer therapies and precision oncology. However, rare cancers remain challenging due to unique genetic profiles and low prevalence, limiting molecular mechanism-oriented treatment strategies. Comprehensive precision oncology programs enable molecularly informed treatments, benefiting many patients with advanced rare cancers. Nevertheless, therapeutic target selection remains complex, particularly in cases with no or multiple targetable alterations. To improve patient stratification for rare cancers, we developed a high-throughput drug testing strategy that rapidly identifies actionable therapeutic vulnerabilities to support molecular sequencing-based target identification in precision oncology.

Methods: We developed a workflow to generate 3D patient-derived cancer models (PCM) and conduct drug sensitivity testing (DST) from viable patient tissues. Tumor tissue was processed into 3D short-term (ST-PCM) or expandable 3D long-term PCM (LT-PCM), such as organoids and spheroids. Dissociated PCM were seeded on pre-spotted drug test plates containing 87 FDA-approved or clinical trial drugs in five concentrations. Cell viability and drug sensitivity scores (DSS) were assessed after 72 hours for hit identification, followed by discussion in a molecular tumor board.

Results: DSS correlation in replicates across entities and PCM types showed consistent hit classification with low variance (~2.3-8.3%). High DSS values for mutation-targeting drugs validated assay sensitivity, while lack of response in controls confirmed specificity. Screening of >100 PCMs (76 from precision oncology patients) from 17 distinct rare and common tumor entities, including sarcomas, CUP, and others, revealed high feasibility: all LT-PCMs and 97% of ST-PCMs derived from surgical specimens allowed partial or full DST. Despite limited material from small biopsies, i.e., fine needle biopsies, successful screening of drug subsets was achieved in 78% of cases with direct seeding as ST-PCM. Additionally, 24 patient samples were screened after tumor cell expansion in LT-PCM, further expanding the cohort of patients eligible for functional testing. Among all tested PCMs, 91% responded to at least one of the tested drugs ex vivo (range 1-38, median 8). Molecular analysis linked pathway alterations with a higher likelihood of pathway inhibitor response. Importantly, preliminary analysis suggests concordance between ex vivo predictions for drug sensitivity and patient responses.

Conclusion: We established a robust DST strategy that identifies potential therapeutic vulnerabilities to guide personalized treatment recommendations in precision oncology. This approach, feasible even with limited material, has the potential to enhance treatment decision-making and improve outcomes for adults with rare solid tumors.

#7204 Stimulator of interferon genes (STING) protein expression in resected non-small cell lung cancer with EGFR mutation.

Atsushi Osoegawa, Yohei Takumi, Kento Inoue, Eika Kudo, Kazuki Ota, Yuta Abe, Takahiro Sato, Daiki Noda, Miyuki Abe, Naoki Haratake, Kenji Sugio

Oita University, Yufu, Oita, Japan

Background and Objective: In lung cancer with epidermal growth factor receptor (EGFR) mutations (mEGFR), the expression of programmed death-ligand 1 (PD-L1), a predictive marker for the efficacy of immune checkpoint inhibitors (ICI), is generally low, and the effectiveness of ICIs is considered limited. However, a subset of mEGFR cases exhibits high PD-L1 expression, and in such cases, EGFR-tyrosine kinase inhibitors (EGFR-TKIs) have been reported to show reduced efficacy. PD-L1 expression in lung cancer tissue can result from tumor immune responses against neoantigens but may also be induced by the initial immune response via the stimulator of interferon genes (STING) pathway. Moreover, ICI efficacy is reported to be poor in STING-deficient mice. This study, therefore, aimed to analyze the relationship between STING expression and clinicopathological factors, PD-L1 expression, and prognosis in resected mEGFR cases.
Materials and Methods: This study included 40 cases of mEGFR-positive lung cancer surgically resected at our institution between November 2018 and May 2020. Immunohistochemical staining of tumor tissues was performed using an anti-STING antibody (D2P2F), and expression levels were evaluated using the H-score method. EGFR amplification was assessed by qPCR.
Results: Among the 40 cases, 29 were female, with a median age of 72.5 years (range: 42-84 years), and 25 were never-smokers. Pathological stages included stage I in 36 cases and stage III in 4 cases. The EGFR mutation types comprised exon 19 deletions in 16 cases, L858R in 17 cases, and other mutations in 7 cases. PD-L1 expression was negative in 16 cases, 1-49% in 20 cases, and high (≥50%) in 4 cases. STING was expressed in the cytoplasm of tumor cells, with a median H-score of 180 (range: 50-290). When cases were classified into high and low STING expression groups using a cutoff H-score of 150, no significant differences in clinicopathological factors or PD-L1 expression were observed between the two groups. However, a significant correlation was noted between STING expression and EGFR copy number. Prognostic analysis revealed that the high STING expression group had significantly worse outcomes compared to the low expression group (5-year recurrence-free survival: 93% vs. 56%, $p = 0.038$).
Discussion: High STING expression was identified as a poor prognostic factor in mEGFR cases. STING expression correlated with EGFR copy number, suggesting that EGFR copy number may influence STING expression and the malignancy of mEGFR. Further studies are required to investigate the impact of EGFR copy number on STING expression and the malignant potential of mEGFR.

#7205 Targeting diverse pathways for the treatment of KRAS driven non-small cell lung cancer.

R. Stanley[1], S. Flanagan[2], S. Tan[1], E. Dillion[3], A. P. Armstrong[4], J. Naidoo[1], K.-k. Wong[4], G. Cagney[3], T. Ni Chonghaile[1], C. M. Dowling[1];
[1]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland, [2]University of Limerick, Limerick, Ireland, [3]University College Dublin, Dublin, Ireland, [4]New York University, New York, NY

Non-small cell lung cancer (NSCLC) accounts for nearly 85% of lung cancer cases. 32% of patients with NSCLC harbour a KRAS mutation, and these patients have poor clinical outcomes. The newly approved KRAS inhibitors (KRASi) have shown clinical promise, however most patients eventually develop resistance. Hence, it is critical to understand the mechanism of resistance to KRAS inhibition to fuel effective combinational therapy strategies. We recently demonstrated enhanced sensitivity to Histone deacetylase 6 (HDAC6) inhibitors (HDAC6i) in KRAS driven NSCLC. Hence, we sought to explore the benefit of combining HDAC6i with KRASi in KRAS driven NSCLC. Using two separate cell viability assays, we demonstrated a synergistic response to the KRASi and HDAC6i in combination in KRAS driven NSCLC cell lines. Moreover, we observed a decrease in the migration rate with this combination in comparison to the single drug treatment. We also demonstrated a significant reduction in colony formation following the combination of KRASi and HDAC6i. Finally, we confirmed enhanced sensitivity to this drug combination in three-dimensional (3D) cell cultures. To further decipher the specific mechanism of action of HDAC6 in KRAS driven NSCLC we performed a co-immunoprecipitation of HDAC6 in NSCLC cell lines and analysed by liquid-chromatograph mass spectrometry (LC/MS). We found several epithelial-to-mesenchymal transition (EMT) associated proteins such as Yes Association Protein (YAP) and Vimentin (VIM) bound to HDAC6 in KRAS driven NSCLC cells. Interestingly, bulk RNA sequencing revealed a down-regulation of the EMT pathway in cells treated with a HDAC6i compared to the control. Specifically, in this data, YAP and VIM were down regulated following treatment with HDAC6i, among other EMT markers such as Snai1, Twist, and Zeb1/2. Interestingly, we observe a significant reduction in response to HDAC6i in NSCLC cells overexpressing YAP. Given this data combined with recent literature demonstrating an upregulation of EMT proteins associated with KRAS resistances, we purpose that HDAC6 inhibition could be a mechanism to overcome KRAS resistance. In conclusion, we have demonstrated HDAC6i and KRASi as an effective combination strategy for KRAS driven NSCLC. We also propose that the mechanism of action may be through HDAC6's regulation of EMT, and this may help overcome resistance to KRASi, however this warrants further investigation.

#7206 STING agonist ADU-S100 in combination with vemurafenib induces STING upregulation, immune-stimulatory cytokine modulation and enhancing NK-mediated cytotoxicity in BRAF V600E-mutant melanoma.

Vida Tajiknia, Matthew Hadfield, Andrea Schmidt, Connor purcell, Claire Lin, wafik El Deiry, Sean Lawler

Legorreta Cancer Center at Brown University, Providence, RI

Background: Targeting the mitogen-activated protein kinase (MAPK) pathway with BRAF inhibitors, has significantly advanced the treatment of melanoma patients whose tumor harbor a BRAF V600E/K mutation. therapeutic resistance occurs in the majority of patients, highlighting the need for combination strategies to improve treatment outcomes. The activation of the Stimulator of Interferon Genes (STING) pathway has emerged as a promising approach to boost anti-tumor immunity. This study explores the potential efficacy of combining the STING agonist ADU-S100 (ADU) with vemurafenib in human melanoma cell lines harboring the BRAF V600E mutation, focusing on its impact on tumor signaling, cytokine profiles, and NK-cell-mediated cytotoxicity.

Methods: Human melanoma cell lines with BRAF V600E mutation—SK-MEL-28, SK-MEL-24-SH4, RPMI7951, and SK-MEL-3—were treated with ADU, vemurafenib, or both in combination. Cell viability was assessed, while changes in total STING were measured by Western blot. Cytokine profiles were analyzed using a multiplex Luminex panel. NK cell-mediated cytotoxicity was assessed through co-culture experiments.

Results: Cell viability assays demonstrated treatment with ADU alone did not significantly reduce cell viability. Western blot analysis revealed minimal baseline STING levels in the SH4 cell line, with a marked increase following ADU, vemurafenib, or their combination. The most pronounced upregulation of STING occurred when ADU & vemurafenib were used together. In SK-MEL-28, the combination treatment was the only condition to result in substantial STING upregulation and a corresponding reduction in pERK. Cytokine analysis showed that the combination treatment significantly increased the levels of beta-2 microglobulin (B2M) across all three cell lines, suggesting modulation of immune checkpoint inhibitor resistance. Additionally, the combination treatment led to a marked reduction in CXCL-8, a key mediator of melanoma progression and metastasis, and decreased VEGF levels across all three cell lines. The CXCL5/CXCL13 axis, known to influence responses to targeted immunotherapies, was most favorably modulated under the combination condition. Co-culture with NK cells revealed an increase in tumor cell death in all three cell lines following combination treatment.

Conclusion: The combination of STING agonist ADU-S100 and vemurafenib effectively enhances immune-stimulatory cytokine profiles in BRAF V600E-mutant melanoma. Notably, this approach may be used to promote NK cell-mediated cytotoxicity and modulation of key cytokines associated with immune resistance. This strategy shows promise for overcoming resistance and improving outcomes, warranting further clinical investigation.

#7207 Targeting TGFBR2 neddylation suppresses metastatic/immunosuppressive abilities and enhances responsiveness to BRAF inhibitor in melanoma with BRAF V600E mutation.

Leon Tsung-Ju Lee, Hui-Wen Chiu, Yuan-Feng Lin

Graduate Institute of Clinical Medicine, Taipei Medical University, Taipei, Taiwan

Background: Approximately 50% of melanomas harbor activating BRAF mutations (over 90% V600E). BRAF V600E mutation promotes melanoma progression, including metastasis and immunosuppression. While targeted therapies for metastatic BRAF V600E melanoma exist, resistance limits their efficacy. Crosstalk between TGF-β and receptor tyrosine kinase (RTK) signaling pathway is considered a possible mechanism for drug resistance to RTK inhibitors in melanoma with BRAF V600E mutation. In addition, the post-translational modification of TGFBR2 through a non-canonical protein neddylation pathway has been shown to prevent its proteolytic degradation by the proteasome system, which reinforces the activation of TGF-β signaling axis. This study explores whether targeting TGFBR2 neddylation suppresses metastasis/immunosuppression and enhances BRAF inhibitor response.
Methods: Gene Set Enrichment Analysis (GSEA) was performed to predict the possible pathways suppressed by the treatment with the protein neddylation inhibitor MLN4924 in melanoma cells. Site-directed mutagenesis was employed to generate a TGFBR2 variant with mutation at its neddylation sites Lys556 and Lys567. MTT assays assessed cell survival post-treatment. Transwell cultivation and co-culture with activated T cells were utilized to estimate the cellular migration and immunosuppressive abilities of melanoma cells, respectively. Xenograft implantation was established to estimate tumor growth and metastatic ability of melanoma cells.
Results: GSEA results demonstrated that the treatment with neural precursor cell-expressed, developmentally downregulated gene 8 (NEDD8)-activating enzyme inhibitor MLN4924 significantly suppresses epithelial-mesenchymal transition (EMT) progression and the activity of TGF-β signaling pathways in melanoma cells with BRAF V600E mutation. Conversely, TGFBR2 knockdown in the highly metastatic/BRAF V600E mutation melanoma cell lines RPMI7951 and A2058 suppressed migration and immunosuppressive abilities, but its overexpression in the poorly metastatic/BRAF V600E mutation melanoma cell lines A375 and C32 promoted cellular migration/immunosuppressive abilities and drug resistance to the BRAF inhibitor PLX4720 in vitro. The restoration of wild-type, not Lys556Arg/Lys567Arg mutant, rescued the cellular migration/immunosuppressive abilities and drug resistance characteristics of the TGFBR2-silenced RPMI7951 and A2058 cells. Animal experiments revealed that the overexpression of wild-type, not Lys556Arg/Lys567Arg mutant, enhances the metastatic ability and promotes drug resistance to PLX4720.
Conclusion: Our data suggest that targeting TGFBR2 neddylation might be a novel strategy to combat the metastatic/immunosuppressive and BRAF inhibitor-resistant melanoma with BRAF V600E mutation.

#7208 PLK1 inhibition as a novel therapeutic strategy in HER2+ breast cancer with germline METN375S mutation.

Arpita Datta[1], Calista Jia Ling Ow[1], Charlie Marvalim[1], Natasha Gandasasmita[1], Joline Si Jing Lim[2], Soo Chin Lee[2]

[1]Cancer Science Institute, Singapore, Singapore,[2]Cancer Science Institute, Department of Haematology-oncology, National University Health System and National University Cancer Institute, Singapore, Singapore

Introduction: Germline MET polymorphism (N375S), a variant common in Asians but rare in Caucasians (7.9% in South Asians vs 1-2% in Caucasians), has been previously reported to enhance the aggressiveness of squamous cell carcinoma. Germline MET^{N375S} polymorphism was more prevalent in metastatic compared to early-stage hormone receptor negative (HR-) HER2+ breast cancer (BC) patients in Singapore (19.2% vs 9.2%; p=0.058; n=201) and is significantly associated with poorer relapse-free (p=0.015) and overall survival (p<0.001). In HER2+ BC cell lines, MET^{N375S} enhances an aggressive malignant phenotype *in vitro* compared to MET^{WT}. MET^{N375S} expressing HER2+ clones were not sensitive to MET inhibitors but displayed higher sensitivity to HER2 inhibitors. In this study, we aim to (1) Identify drug classes that are effective against MET^{N375S} HR-/HER2+ BC through high-throughput anticancer drug screening; and (2) establish the molecular mechanism that maintains the vital pro-survival signals in MET^{N375S} HR-/HER2+ BC.

Methods: We generated isogenic HR-/HER2 +BC cell models (SKBR3, AU565) expressing either wild-type MET^{WT} or mutant N375S MET^{N375S} and carried out high-throughput drug screening comprising 414 compounds. Bliss scores were calculated using Synergy Finder to determine the interaction of drugs in combination studies. Immunoprecipitation and immunoblotting analysis evaluated interaction partner and expression of protein in the cell lines.

Results: High-throughput drug screening identified 6 compounds with selective sensitivity to MET^{N375S} cells. Intriguingly, 4 out of 6 compounds target PLK1 (Polo-Like Kinase1), a key mitotic kinase downstream of HER2. The IC50 of the four PLK1 inhibitors was (range is for MET^{WT} 0.2 to 1.1 μM and for MET^{N375S} 0.02 to 0.1 μM) 10-fold reduction in MET^{N375S} cells. Western blot analysis revealed that the N375S mutation led to increased phosphorylation of both MET and HER2, which in turn activated downstream signaling pathways, including SRC and MAPK kinases. MET^{N375S} cells demonstrated elevated PLK-1 protein expression. Co-immunoprecipitation confirmed the interaction between MET^{N375S} and HER2, resulting in hyperactivation of HER2 signaling and enhanced MAPK pathway activation. Notably, HER2 knockdown disrupted this signaling, reduced PLK1 levels, and decreased the cells' sensitivity to PLK1 inhibitors. The combination of the PLK1 inhibitor volasertib with HER2 inhibitor lapatinib was highly synergistic in MET^{N375S} cells, significantly enhancing apoptosis at nanomolar concentrations.

Conclusions: Our findings suggest that MET^{N375S} variant promotes tumorigenesis by hyperactivating HER2 signaling and enhancing PLK1 pathway. These findings highlight the potential of PLK1 inhibitors, as a novel therapeutic option for MET^{N375S} mutant HER2+ BC and supports further evaluation of PLK-1 in HER2+ BC.

#7209 Status-agnostic therapy of breast cancer using antibodies targeting O-glycosylated proteins.

Aaron C. Groen[1], Nisha Shrestha[1], Boris Klebanov[1], Byeongjun Yu[2], Beom Yong Lee[2], Yun-Hee Park[2], Chul-Woong Chung[2], Constantine Theodoropulos[1], Hans H. Wandall[3]

[1]GO Therapeutics, Natick, MA,[2]LigaChem Biosciences, Daejeon, Korea, Republic of,[3]Department of Cellular and Molecular Medicine, Center for Glycomics, University of Copenhagen, Copenhagen, Denmark

We have developed a novel antibody-drug conjugate (ADC), based on the mAb L100, that selectively targets a O-GalNAc-glycoprotein expressed in approximately 20% of all breast cancer. Unlike many ADC programs targeting Breast Cancer, L100 recognizes cancer-specific O-glycosylated versions of proteins do not present on normal tissues circumventing adverse events from on target off tumor binding to healthy tissues. The crystal structure of L100 provides insights into its binding specificity and affinity. L100 exhibits low nanomolar affinity (0.83nM) to the glycoprotein target and has also been developed as a companion diagnostic assay, further validating its potential as a therapeutic target. L100 is conjugated to the microtubule-disrupting agent MMAE and the topoisomerase inhibitor exatecan via a site-specific β-glucuronidase-cleavable linker. This linker is stable in plasma, but selectively releases the payload in tumor tissues, which exhibits a high expression pattern of beta-glucuronidase. In preclinical studies, the L100 ADC (LCB22A) demonstrated potent and selective cytotoxicity against various cancer cell lines (EC50=~4.4 nM) and effectively eliminated tumors in breast cell-derived xenograft (CDX) and patient-derived xenografts (PDX) with MED = ~2mpk. Importantly, L100-MMAE (LCB22A-MMAE) and L100-exatecan (LCB22A-exatecan) were well-tolerated in cynomolgus monkey toxicity studies, with no significant adverse events observed. Additionally, the ADC selectively killed target cells in a human mixed organotypic cancer model without affecting healthy cells, indicating excellent tolerability and safety. By specifically targeting cancer-specific O-glycans expressed only in cancer tissues and employing a tumor-selective payload release mechanism, L100 ADC (LCB22A) offers a promising and safe therapeutic option for treating breast cancer while avoiding the on-target off-tumor toxicity that plague other ADC therapies.

#7210 Predicting drug response heterogeneity in AML: novel AI-enabled proteomics model for a prospective clinical trial.

James T. Sorrentino[1], Salvador Martinez-Bartolome[1], **Afshin Mahmoudi**[1], Antonious Koller[1], Mahan Abbasian[1], Christina Lamm[1], Mohamed Rdait[1], Mary-Elizabeth Percival[1], Jasmine Naru[2], Derek L. Stirewalt[1], Pilgrim Jackson[1]

[1]Yatiri Bio, Inc., San Diego, CA,[2]Fred-Hutch, Seattle, WA

Acute myeloid leukemia (AML) is an aggressive blood cancer with a significant chance of relapse and only a 17% 5-year survival rate for patients refractory to first-line therapy. Current therapies, even when combined with newer agents, have not significantly enhanced long-term survival for many AML patients. One major barrier in the development of effective therapies for AML and their successful deployment for patients, has been the lack of accurate model systems to identify and predict therapeutic efficacy in patient subsets. Current AML cell lines do not predict drug sensitivity because the cell lines harbor strong driver alterations that occur in only a small fraction of patients and their biology has drifted from that of an AML patient. With state-of-the-art culture conditions, we have created over 50 patient-derived hematopoietic stem/progenitor cell (HSPC) models and have measured cellular response across 40 AML therapeutics. Leveraging our pipeline for LC-MS/MS and innovative data integration, we have created a patient landscape with embedded cell models for prospective therapeutic positioning. HSPCs were evaluated using a panel of cell surface markers, and preliminary results show marginal drift from the original patient samples. Unbiased proteomics were generated with peripheral blood samples from 100 AML patients and all ex-vivo models. Pathway overrepresentation and correlation analysis are used to confirm that patient-derived HSPCs are closer in biological context to patient subpopulations than commercially available cell lines. Additionally, global proteomics data from over 2500 samples from 11 public and 5 private datasets across 8 different cancer indications were collected to perform a molecular functional analysis to guide a transfer learning model for matching patients to ex vivo HSPCs. A custom deep learning architecture was built to (1) define global cancer mechanism enrichments of the AML samples and (2) integrate paired ex vivo treatment response. To drive a prospective clinical trial at FHCC, our model was used to select a minimal set of proteins that can accurately separate patient subsets for which there are differential sensitivity profiles across 4 AML therapeutics. For this trial, 40 patients with relapsed/refractory AML or other high-grade myeloid neoplasms will be enrolled and randomized to one of two arms. Arm A: receive standard of care hypomethylating agent therapy (20 patients). Arm B: undergo an ex vivo MS-based targeted assay on the peripheral blood to predict response to various treatment regimens; if a drug is identified through the assay, patients will receive that treatment (20 patients). The primary objective of the trial is to assess the feasibility of a single MS-based assay for the selection of the ideal AML therapeutic for each patient to be used in combination with azacitidine to achieve response, extend survival, and improve quality of life.

#7211 Proteolysis targeting chimeras (PROTACs) of oncogenic RET protein.

Shriya Pandey[1], Yafeng Wang[2], Xueqing Hu[1], Ujjwol Khatri[1], Tao Shen[1], Vivek Subbiah[3], Blaine H. M. Mooers[4], Ting Chao[2], Shaohui Wang[5], Huaxuan Yu[2], Xingmin Sun[6], Jianfeng Cai[2], Jie Wu[1]

[1]Department of Pathology, Peggy and Charles Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Department of Chemistry, University of Southern Florida, Tampa, FL,[3]Early-Phase Drug Development, University of Oklahoma Health Sciences Center, Sarah Cannon Research Institute, TN,[4]Department of Biochemistry and Physiology, Peggy and Charles Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK,[5]Department of Biochemistry and Physiology, University of Southern Florida, University of Southern Florida, FL,[6]Department of Biochemistry and Physiology, University of Southern Florida, Tampa, FL

The REarranged during Transfection (RET) kinase is an oncoprotein and a therapeutic target for RET alteration-positive cancer. Two RET-selective protein tyrosine kinase inhibitors, selpercatinib (LOXO-292) and pralsetinib (BLU-667), have been approved for treating RET-alteration-positive cancer. However, achieving a complete response with a RET kinase inhibitor remains a challenge in most patients. In cell cultures, these inhibitors increase the expression of CCDC6-RET fusion protein, which may affect their effectiveness at low concentrations. To tackle this problem, we synthesized and characterized a panel of RET PROTACs for the dual action of inhibiting RET kinase activity and degrading the oncogenic protein. A lead compound, YW-N-7, was selected based on *in vitro* PROTAC analyses and *in vivo* PK data. YW-N-7 exhibited the dual action of specifically inhibiting and degrading RET protein. Proteomic analysis identified RET as the only significantly down-regulated protein in the entire proteome by YW-N-7 compared with the RET kinase inhibitor. In the BaF3/KIF5B-RET tumor model, YW-N-7 inhibited and degraded KIF5B-RET oncoprotein in xenograft tumors in animals, and significantly inhibited tumor growth. This work illustrates the potential of developing a RET PROTAC for simultaneously inhibiting and degrading oncogenic RET kinase for cancer therapy.

#7212 Preclinical analysis of ONC206 and ONC212 with lurbinectedin in pancreatic cancer.

Tej Tummala, Ashley S. S. Uruchurtu, Abbas E. Abbas, Christopher G. Azzoli, Wafik S. El-Deiry

Legorreta Cancer Center at Brown University, Providence, RI

Pancreatic cancer is a devastating disease with a poor five-year survival rate of approximately 12%. Given the poor prognosis of the disease, it is vital to develop novel improved therapeutic regimens. Lurbinectedin is a chemotherapeutic that stalls and degrades RNA Polymerase II after binding to guanine-rich sequences in the minor groove of DNA, stalling transcription and inducing single- and double-stranded DNA breaks. Our group recently described lurbinectedin's potency as both a single agent and combinatorial agent with irinotecan and 5-fluorouracil in pancreatic cancer cell lines. Our group also recently described a synergistic interaction between lurbinectedin and imipridone ONC201/Dordaviprone, an anticancer compound that induces the TRAIL apoptotic pathway, in small cell lung cancer cell lines. We now demonstrate that a combination of lurbinectedin and ONC212, a chemical derivative of ONC201, results in highly efficient and synergistic killing of pancreatic tumor cells in vitro. Under combinatorial conditions, cells seemingly exhibit an upregulation of DR5 and γH2AX and a downregulation of ClpX in the presence of ONC212. Future studies will analyze whether a combination of lurbinectedin and ONC212 or lurbinectedin and ONC206, another imipridone and chemical analogue of ONC201, proves more efficient at killing pancreatic tumor cells in vitro. Our results are developing insights into novel combinatorial therapeutic regimens while investigating the molecular mechanisms underlying synergism.

#7213 Targeting XPO1 to enhance the durability of response of MRTX1133 in pancreatic ductal adenocarcinoma.

Husain Yar Khan[1], Amro Aboukameel[1], Sahar F. Bannoura[1], Md Hafiz Uddin[1], Fulya Koksalar Alkan[1], Ahmet B. Caglayan[1], Hilmi K. Alkan[1], Bin Bao[1], Hugo Jimenez[1], Mohammed Najeeb Al Hallak[1], Khalil Choucair[1], Steve Kim[1], Rafic Beydoun[2], Gregory Dyson[1], Yang Shi[1], Misako Nagasaka[3], Azeddine Atfi[4], Hasan Korkaya[1], Muhammad Wasif Saif[1], Philip A. [1]Oncology, Wayne State University School of Medicine, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Pathology, Wayne State University School of Medicine, Detroit, MI,[3]University of California Irvine School of Medicine, Orange, CA,[4]Oncology, Massey Cancer Center, Virginia Commonwealth University, Richmond, VA,[5]Henry Ford Cancer Institute - Henry Ford Health System, Detroit, MI,[6]Hematology and Oncology, University of Alabama at Birmingham, Birmingham, AL

Introduction: The KRASG12D inhibitor MRTX1133, which targets KRAS in the OFF-state, is currently under evaluation in pancreatic ductal adenocarcinoma (PDAC) patients. However, as seen with other OFF-state KRAS inhibitors, MRTX1133 may provide only limited improvements in disease-free survival due to the emergence of drug resistance. This highlights the need for strategies to enhance the efficacy of KRAS inhibitors in PDAC. The nuclear transport protein, XPO1, plays a significant role in several pro-tumorigenic pathways and has been identified as a therapeutic vulnerability in KRAS-mutant cancers. It is overexpressed in many cancers, including PDAC, and its inhibition causes robust synthetic lethal interaction with oncogenic KRAS, indicating that targeting both XPO1 and KRAS may be beneficial. In this study, using several preclinical PDAC models, we have demonstrated that the second generation XPO1 inhibitor KPT8602 synergizes with and enhances the efficacy of MRTX1133.

Methods: We generated KRASG12D inhibitor-resistant PDAC cells and assessed the effect of KPT8602 on their survival. We further tested different combinations of MRTX1133 and KPT8602 for their antiproliferative effects in 2D and 3D *in vitro* PDAC models. To test the *in vivo* antitumor efficacy of the combination, we used KRASG12D-mutant human PDAC cell-derived xenograft (CDX) and murine PDAC transgenic KPC cell-derived allograft models.

Results: KPT8602 sensitized MRTX1133-resistant PDAC cells to growth inhibition, establishing that KRASG12D inhibitor-resistant cancer cells can potentially respond to KPT8602. Furthermore, treating multiple PDAC cell lines in 2D and 3D cultures with KPT8602 and MRTX1133 at different dose combinations resulted in synergistic inhibition of their viability. At the molecular level, the combination downregulated p-ERK, mTOR, p-4EBP1, DUSP6 and cyclin D1 expression in PDAC cells. Kinome analysis revealed reduced kinase activity for several kinases related to MAPK signaling in the combination treated PDAC cell lysates. Combining subtherapeutic doses of KPT8602 (15 mg/Kg BIW) and MRTX1133 (30 mg/Kg QD) caused significant tumor growth inhibition in multiple subcutaneous and orthotopic PDAC mouse models ($p<0.001$). Also, the combination treatment resulted in significantly enhanced survival in an immunocompetent orthotopic PDAC allograft model ($p<0.001$). Moreover, we have also demonstrated that maintenance with KPT8602 in combination treated mice prevented tumor relapse and resulted in a durable antitumor response in a PDAC CDX model.

Conclusion: This is the first study showing that KPT8602 treatment can overcome resistance to MRTX1133 and synergistically augment the antitumor effects of MRTX1133 in PDAC preclinical models. This combination regimen can potentially prevent or delay drug resistance by making it feasible to achieve a more durable response at a lower dose of KRASG12D inhibitor.

#7214 Real-world concordance analysis of a combinatorial functional precision medicine platform, Optim.AI™, in both solid and hematological cancers.

Masturah Mohamed Abdul Rashid[1], Jhin Jieh Lim[1], Weng Tong Ho[1], Su Pin Choo[2], Donald Yew Hee Poon[3], Daryl Chen Lung Tan[4], William Ying Khee Hwang[5], Yvonne Loh[2], Jeffry Beta Tenggara[6], Chin Hin Ng[7], Hugo Saavedra[1], **Edward Kai-Hua Chow**[1]

[1]KYAN Technologies Pte Ltd, Singapore, Singapore,[2]Curie Oncology, Singapore, Singapore,[3]Dr D.Y.H Poon & Associates Medical Oncology Clinic, Singapore, Singapore,[4]Clinic for Lymphoma, Myeloma and Blood Disorders, Mount Elizabeth Novena Hospital, Singapore, Singapore,[5]National Cancer Centre Singapore, Singapore, Singapore,[6]Division of Hematology and Medical Oncology, Department of Internal Medicine, MRCCC Siloam Hospitals Semanggi, Jakarta, Indonesia,[7]Centre for Clinical Haematology, Singapore, Singapore

PURPOSE: Functional precision medicine aims to expand the landscape of effective drug treatment options beyond standard of care through additional insights from ex vivo phenotypic drug response data. In our previous work, we have demonstrated the clinical feasibility of Optim.AI™, a combinatorial functional precision medicine platform, in identifying effective and resistant treatment options for non-Hodgkin lymphoma and acute myeloid leukemia (AML). This study further investigates the clinical utility and concordance of Optim.AI™ in predicting treatment sensitivity or resistance in a variety of hematological and solid cancers processed at KYAN's clinical laboratory, with notable case studies highlighted.

METHODS: Optim.AI™ utilizes efficiently designed experiments of less than 200 ex vivo combinations to interrogate over 530,000 possible treatment permutations from a 12-drug panel. Optim.AI™ then ranks all clinically actionable treatments within the tested drug panel based on predicted sensitivity or resistance. In this study, we investigated 66 cases from a total of 20 cancer types (5 hematological and 15 solid cancer) and a range of tissue sample sources, including bone marrow aspirate, peripheral blood, tissue biopsy or resections, and pleural or peritoneal fluid. Retrospective concordance analysis was performed by evaluating Optim.AI™-generated tumor cell viability results against the prior lines of treatment for each sample. Prospective data of patients administered with Optim.AI™-predicted treatment were also collected, where applicable.

RESULTS: With an established viability cut-off of 0.5, Optim.AI™ demonstrated a correlation of 88% with prior therapies, which included a range of 36 targeted treatments and chemotherapy agents. Among the 37 solid cancer cases evaluated, 86.5% (p-value < 0.0001) demonstrated concordance to prior line(s) of treatment, while for hematological cancers, 89.7% of the 29 cases (p-value = 0.0005) were concordant with previously observed resistance. Additionally, platform-predicted treatments were associated with positive clinical responses in several cases of hematological and solid cancers, where prospective data were available.

CONCLUSIONS: Our retrospective concordance results demonstrate the clinical applicability and robustness of Optim.AI™ in predicting sensitivity or resistance to cancer treatments. In line with previous prospective clinical studies, these findings illustrate the platform's potential to positively impact treatment recommendations across a broad range of hematological and solid cancers. Future prospective studies to evaluate Optim.AI™-guided treatments are warranted to further confirm the predictive value of the platform and provide evidence for incorporating such functional assays in clinical oncology.

#7215 Targeting EZH2 in castration-resistance prostate cancer using a novel PROTAC.

Qi Chu[1], Wanqing Xie[1], Galina Gritsina[1], Xiaodong Lu[1], Ka Wing Fong[2], Zhiquan Lei[2], Hongshun Shi[1], Lourdes Brea[2], Jonathan Zhao[3], Gary Schiltz[4], Jindan Yu[1]

[1]Urology, Emory University, Atlanta, GA,[2]Department of Medicine, Northwestern University, Chicago, IL,[3]Human Genetics, Emory University, Atlanta, GA,[4]Chemistry, Northwestern University, Evanston, IL

Background: EZH2, a core subunit of the Polycomb Repressive Complex 2 (PRC2), is significantly upregulated in advanced Prostate Cancer (PCa), especially in Castration-Resistant Prostate Cancer (CRPC). However, enzymatic inhibitors of EZH2, such as EPZ-6438, have shown limited efficacy in PCa, while EZH2 knockdown has previously shown to lead to cellular senescence and major growth suppression, warranting the development of Proteolysis Targeting Chimera (PROTAC) to degrade all EZH2 proteins.
Methods: Medicinal chemistry was utilized to develop a plethora of EZH2 PROTACs. Mass spectrometry and western blotting were used to assess target protein levels. RNA-seq and H3K27me3 ChIP-seq analyses were performed in PCA cells to evaluate transcriptional and histone modification changes. Senescence staining and flow cytometry were used to evaluate cellular senescence and analyze cell cycle progression. Cell proliferation was assessed in vitro using CellTiter-Glo and live-cell proliferation assays. In vivo efficacy was evaluated using 22Rv1 and VCaP xenograft mouse models.
Results: Among several EZH2 PROTAC degraders, 6272 was chosen as the lead candidate due to its high specificity and efficiency in degrading EZH2. We showed that 6272 significantly inhibited 22Rv1 and VCaP cell proliferation compared to EPZ-6438, although this effect was not observed in LNCaP cells. RNA-seq analysis revealed that 6272 readily induced cellular senescence pathways, such as CDKN1A (p21) expression, in 22Rv1 and VCaP, but not LNCaP cells. Further, ChIP-seq showed no changes in H3K27me3 at the CDKN1A gene locus, indicating that 6272 regulates these genes in a catalytic function-independent manner. Lastly, we confirmed that 6272 also significantly reduced 22Rv1 and VCaP xenograft tumor growth.
Conclusion: In this study, we developed a novel EZH2 PROTAC with superior efficacy compared to EPZ-6438 in suppressing some prostate cancer cells via rapidly promoting cellular senescence.

#7217 Synergistic anti-cancer effects of dual IGF-1R and EGFR targeting in uveal melanoma.

Pei-Chi Tsai, Charles G. Eberhart, **Su-Chan Lee**

Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

Uveal melanoma arises from melanocytes in the eye, with approximately 7,000 patients reported worldwide every year. IGF-1R plays an important role in uveal melanoma metastatic progression, and promotes tumor cell proliferation and survival. However, in previously reported clinical trials, targeting IGF-1R did not significantly inhibit uveal melanoma metastatic spread or patient survival. This could be due to compensatory activation of other receptor signaling pathways. Therefore, the aim of this study is to find other activated receptors in uveal melanoma cells following IGF-1R inhibition which could be co-targeted in a novel combination treatment for metastatic uveal melanoma. Using several uveal melanoma cell lines (Mel202, Omm2.3, Omm2.5, Omm1, 92.1, MP38 and MM28), we found that treatment with linsitinib, an IGF-1R inhibitor, increased EGFR protein expression and activity. Targeting IGF-1R alone with linsitinib, or EGFR alone with gefitinib, did not significantly inhibit growth of uveal melanoma cells. However, combination treatment with linsitinib (10μM) and gefitinib (5μM) significantly inhibited both cell growth and anchorage-dependent/independent colony formation abilities in uveal melanoma cultures. Moreover, Linsitinib and gefitinib co-treatment dramatically increased cleaved PARP protein, an apoptotic maker. Our research suggests that dual targeting of IGF-1R and EGFR could be a novel treatment strategy to inhibit uveal melanoma metastatic dissemination and growth.

#7218 Preventive use of trilaciclib in Chinese patient with extensive-stage small cell lung cancer (ES-SCLC) receiving chemotherapy: A multi-center, single-arm, observational real-world study.

Ying Liu[1], Jianqiang Bi[2], Jianxin Chen[3], Meifang Chen[4], Xuesong Chen[5], Yongxing chen[6], Yinghua Ji[7], Yujie Jiang[8], Lu Li[9], Qin Liao[10], Sheng Lin[11], Jie Liu[12], Yi Liu[13], Yu Liu[14], Zhaoting Meng[15], Zhuqing Mu[16], Yunxiang Qi[17], Yanhong Shang[18], Ling Xu[19], Shufeng Xu[20], Lu Zheng[21], Jin Zhou[17], **Ying Cheng**[1]

[1]Jilin Cancer Hospital, Changchun, China,[2]CangZhou Hospital of Integrated Traditional Chinese and Western Medicine, Cangzhou, China,[3]Quzhou People's Hospital, Quzhou, China,[4]Taizhou Hospital of Zhejiang Province, Taizhou, China,[5]Jiangsu Province Hospital, Nanjing, China,[6]Hainan General Hospital, Haikou, China,[7]The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China,[8]Affiliated Hospital of Youjiang Medical University for Nationalities, Baise, China,[9]West China Hospital of Sichuan University, Chengdu, China,[10]Shulan (Hangzhou) Hospital, Hangzhou, China,[11]The Affiliated Hospital of Southwest Medical University, Luzhou, China,[12]Henan Cancer Hospital, Zhengzhou, China,[13]Shaanxi Provincial People's Hospital, Xi'an, China,[14]HanDan Central Hospital, Handan, China,[15]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China,[16]Xinxiang Central Hospital, Xinxiang, China,[17]Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China,[18]Affiliated Hospital of Hebei University, Baoding, China,[19]Anhui Chest Hospital, Hefei, China,[20]First Hospital of Qinhuangdao, Qinhuangdao, China,[21]Ningbo Medical Center Lihuili Hospital, Ningbo, China

Background: Extensive-stage small cell lung cancer (ES-SCLC) is a highly aggressive disease characterized by rapid progression and development of extensive metastases. Standard chemotherapy-based regimens for ES-SCLC often lead to myelosuppression, compromising medication compliance and prognosis. Trilaciclib is a CDK4/6 inhibitor, approved by NMPA in 2022 to decrease the incidence of chemotherapy-induced myelosuppression (CIM) in adult with ES-SCLC. This study aims to evaluate the efficacy and safety of preventive use of trilaciclib prior chemotherapy in Chinese ES-SCLC population under real-world settings.

Methods: ES-SCLC patients suitable for combined treatment of trilaciclib and chemotherapy were enrolled in this study. Eligible participant received 240 mg/m^2 of trilaciclib IV 4 h prior chemotherapy. The primary endpoint was the incidence rate of severe neutropenia (SN). The secondary endpoints included the occurrence of grade 3/4 hematologic adverse events (HAEs), administration rate of G-CSF and ESA, safety, and anti-tumor efficacy of chemotherapy.

Results: A total of 201 ES-SCLC patients receiving at least one dose of trilaciclib combined with chemotherapy were included from 60 centers in China during March 10 2023 to August 10 2024, with median age of 65 (58, 71). Metastases occurred in 90.0% of the subjects at baseline, in which brain metastases accounted for 16%. 92.5% of the patients adopted platinum plus etoposide (E/P) regimen. The mean number of completed chemo-cycle was 3.0 (1.4). In Cycle 1, 1 case (0.6%) of SN occurred in patient receiving second-line (2L) treatment with E/P therapy. Grade 3/4 HAEs were reported in 5.4% of the patients in Cycle 1, including neutropenia (3.6%), anemia (1.2%) and thrombocytopenia (1.8%). During the whole treating period, a total of 5 cases (2.6%) of SN occurred, 4 of which received 2L treatment with E/P, while the remaining one received first-line cis-platinum therapy. 17.5% participants experienced grade 3/4 HAEs during the study, in which neutropenia, anemia and thrombocytopenia accounted for 8.2%, 9.3% and 3.1%, respectively. G-CSF and ESA were used in 2.6% and 1.0% of the patients. As for safety, grade ≥3 AEs were reported in 20.9% of the participants. No AEs-related treatment discontinuation happened. No serious AEs and death occurred. Among 48 patients included into tumor response analysis, the best response to chemotherapy was CR (8.3%), PR (43.8%), SD (39.6%) and PD (8.3%). The objective response rate (ORR) and disease control rate (DCR) reached 52.1% and 91.7%, respectively.

Conclusions: Prophylactic administration of trilaciclib (240 mg/m^2) prior chemotherapy exhibits superior myeloprotective effect and were well-tolerated in Chinese ES-SCLC population, providing evidence for clinical benefit of trilaciclib as a myelo-protectant.

#7219 Targeting the RAS pathway with MEK and pan-RAF inhibition in Philadelphia-like acute lymphoblastic leukemia.

Hong A. De Sa, Isabel Kenna, Jeffrey W. Tyner, Bill H. Chang

Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Philadelphia-like (Ph-like) acute lymphoblastic leukemia (ALL) afflicts close to 30% of adolescents and young adults with ALL and portends a poor response to standard chemotherapy. Ph-like ALL often harbors CRLF2-rearrangements (CRFL2-R) and JAK2 mutations. CRLF2-R and JAK2 can further activate RAS signaling with or without RAS pathway mutations, suggesting a role to target this pathway in Ph-like ALL. Here, we report our results using a novel combination of the MEK inhibitor trametinib (tram) and the pan-RAF inhibitor tovorafenib (tovo) in a CRLF2-R ALL patient-derived xenograft. We identified a CRLF2-R ALL sample from our institution's biorepository. The sample had an IGH-R by cytogenetics, CRLF2 overexpression by flow cytometry, and JAK2 by NGS. The sample was injected into immunodeficient (NSG) mice. Peripheral blood flow cytometry for human CD19 and human CD45 vs mouse CD45 expression was monitored. Following engraftment >20%, mice were sacrificed and mononuclear cells isolated from the spleen were exposed to drugs to assess *in vitro* response. *In vivo* response was then tested in cohorts of 5 mice injected per condition. Upon engraftment, cohorts were treated with vehicle, 1mg/kg/day tram, 12.5mg/kg/day tovo, or the combination daily until moribund. CRLF2-R ALL cells showed *in vitro* sensitivity to tram as assessed by viability and phosphorylation of ERK at low nM concentrations. These cells showed minimal response to tovo at μM concentrations. Combination with tram and tovo did not show added benefit. Upon injection, mice engrafted within 1 month and rapidly succumbed to disease. *In vivo* treatment with single agent or combinations briefly, but significantly improved survival compared to control (Table 1). Targeting the RAS pathway in CRLF2-R ALL has therapeutic potential. Interestingly, addition of the pan-RAF inhibitor tovorafenib to trametinib did not have further therapeutic benefit. These findings begin to shed insight into novel targets for CRLF2-R ALL.

Survival Outcomes

	Median survival (days)	Log-rank p-value to control	Log-rank p-value to combination
Control	3		
Tovorafenib	8	**0.0035	*0.0116
Trametinib	15	**0.0035	ns 0.4235
Combination	13	**0.0035	

#7220 Zongertinib demonstrates potent efficacy against cancer cells harboring HER2 non-tyrosine kinase domain mutations.

Y. Shibata[1], M. B. Nilsson[1], H. Udagawa[2], J. P. Robichaux[1], J. He[1], X. Yu[1], J. V. Heymach[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]National Cancer Center Hospital East, Kashiwa, Japan

Activating mutations in HER2 are found in approximately 2-4% of non-small cell lung cancer (NSCLC). Recurrent activating mutations most commonly occur in the tyrosine kinase domain (TKD) encoded by exons 18-21, with exon 20 insertions being the most frequent, followed by non-TKD mutations in the transmembrane domain (TMD) and juxtamembrane domain (JMD). While tyrosine kinase inhibitors (TKIs) such as the HER2-selective inhibitor zongertinib and the pan-HER inhibitors poziotinib, pyrotinib, and afatinib have been tested primarily in patients harboring TKD mutations, their efficacy against non-TKD mutations has been less well characterized. To systematically evaluate HER2 TKI activity against HER2 non-TKD mutations, we established a panel of Ba/F3 cell lines expressing various HER2 mutations including common TKD mutations (e.g. exon 20 insertions YVMA, GSP, and VC), TMD mutations such as V659E, and JMD mutations such as R678Q and evaluated drug sensitivity by Cell Titer Glo assay. Among HER2 TMD mutations, zongertinib showed potent activity with an average IC50 value of 8.72 nM. For HER2 JMD mutations, zongertinib demonstrated an IC50 value of 0.35 nM, and among HER2 TKD mutations, zongertinib treatment yielded an average IC50 value of 6.14 nM. Moreover, calculation of the relative IC50 value, representing the ratio of IC50 values between HER2 mutations and wild-type EGFR, revealed that zongertinib which had an average log IC50 mutant HER2/wild-type EGFR ratio of -2.31, -3.71, -2.46, for TMD, JMD, and TKD HER2 mutations, respectively, exhibited superior selectivity compared to pyrotinib (TMD -1.00, JMD -4.85, TKD -0.55) and poziotinib (TMD 0.09, JMD -3.13, TKD 0.48). This suggests zongertinib has high efficacy and a potentially lower risk of EGFR inhibition-associated toxicity. In addition, we generated a HER2 TMD mutant NSCLC cell line model by expressing HER2 V659E in HCC4006 cells and knocking out endogenous mutant EGFR. Consistent with our results obtained using Ba/F3 models, HCC4006 HER2 V659E cells were sensitive to HER2 inhibition with zongertinib. Our findings indicate that zongertinib demonstrates comparable or more potent inhibitory activity for HER2 non-TKD mutants (e.g TMD and JMD) as HER2 TKD mutations, providing a potential therapeutic option for patients with these HER2 non-TKD mutant cancers.

#7221 Whole genome and transcriptome sequencing can be introduced into the diagnostic workup of sarcoma and pediatric cancer patients.

Svetlana Nikic[1], Kristine N. Jinnett[2]

[1]Precision Oncology Consulting, Barcelona, Spain,[2]Kristine Jinnett Consulting, Dublin, Ireland

Introduction: Limited molecular diagnostics in pediatric cancers and sarcomas hinder accurate diagnosis and therapy selection, due to an inability to detect some clinically relevant large and rare rearrangements. This meta-analysis evaluates the potential of WGS/WGTS to overcome these limitations and improve personalized oncology care.
Methods: A systematic review and meta-analysis of English-language studies (PubMed; 01/08/2024-5/11/2024) was conducted per PRISMA guidelines to evaluate the clinical impact of WG(T)S in pediatric cancers and sarcomas. Included studies were primary research articles with data on clinical impact, validity, utility, and/or feasibility.
Results: A total of 14 studies (5 sarcoma and 9 pediatric) were deemed eligible for inclusion in the study. Analysis revealed a wide turnaround time (TAT) range of 9-71 days. Sequencing depths ranged from 45-100X for tumor and 30-40X for normal samples, whilst feasibility of WG(T)S ranged from 62-100%. Our analysis found that WG(T)S demonstrated significant clinical utility in sarcoma patients leading to a refined/changed diagnosis in 18.6%, actionable findings in 64%, and therapy-informing findings in 36% of cases, on average. In pediatric cancers, WG(T)S led to a refined/changed diagnosis in 22.9%, actionable findings in 42.6%, and therapy-informing findings in 38.5% of cases, on average. We also found that, on average, 7.3% of both sarcoma and pediatric cancer patients harbored germline findings (Table 1).
Conclusions: WG(T)S enhances diagnostic yield by detecting large rearrangements (e.g., structural variants, gene fusions) critical for accurate diagnosis and risk stratification in pediatric cancers and sarcomas. Our meta-analysis demonstrates the clinical utility of WG(T)S, suggesting its potential for routine use in oncology.

Analysis of clinical utility of WG(T)S in sarcoma and pediatric cancer patients. N/A, not availab

Initial Patient Cohort **(No. of patients/samples that underwent genomic profiling)**	Refined Diagnosis	Actionable Alterations	Therapy-informing Findings	Germline Findings	Cancer Type

IMMUNOLOGY: Novel Animal Models / Tumor Antigenicity/Processing and Presentation
Poster Session

#7225 The secreted cytokine Chitinase 3-like-1 promotes breast cancer metastasis.

Adeline Masse[1], Tarek Taifour[2], Yu Gu[1], Virginie Sanguin-Gendreau[1], Dongmei Zuo[1], Bin Xiao[1], Hailey Proud[1], Nancy U. Lin[3], Melissa E. Hughes[3], Kalie Smith[3], Rinath Jeselsohn[3], William J. Muller[1]

[1]Biochemistry, McGill Univ. Goodman Cancer Ctr., Montreal, QC, Canada,[2]Experimental Medicine, McGill Univ. Goodman Cancer Ctr., Montreal, QC, Canada,[3]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Breast cancer is the second most common cancer and a major cause of mortality affecting women worldwide. Immunosuppression is a key hallmark of cancer progression, whereby cancer cells suppress the immune system that is programmed to fight the disease. This suppressed tumor immune microenvironment (TIME) facilitates cancer metastatic spread to distant organs, which is associated with treatment resistance, recurrence, and poor prognosis. The Signal transducer and activator of transcription 3 (Stat3) suppresses the immune system, drives cancer progression and metastasis. Genetic ablation of Stat3 in the murine inducible breast tumor model expressing polyoma virus middle T (PyMT), results in delayed tumor onset and reduced tumor growth and metastasis. We have also previously demonstrated that the secreted protein Chitinase 3-like-1 (Chi3l1) is a direct target of Stat3 which promotes immunosuppression through its actions on neutrophils. Chi3l1 recruits neutrophils and induces the formation of Neutrophil Extracellular Traps (NETs) that block T cells from infiltrating the tumor. Targeting both Chi3l1 or neutrophils resulted in increased T cell infiltration and delayed tumor onset. However, the roles of Chi3l1 during the metastatic cascade remained unclear. To further investigate the role of Chi3l1 in metastasis, we generated a novel inducible mouse model that overexpresses Chi3l1 specifically in the mammary epithelial cells. Overexpression of the Chi3l1 protein in the Stat3 knockout PyMT model showed a rescue of the delay in tumor onset. Consistent with our previous studies, Chi3l1 overexpression caused a dramatic influx of neutrophils and the generation of an immune suppressed TIME. In addition, we observe an increase in circulating tumor cells which correlated with a quicker onset and increased incidence of pulmonary metastasis. These results hint that in breast cancer, Chi3l1 overexpression creates a pro-tumorigenic TIME which favorizes tumor initiation and progression as well as induces intravasation of tumor cells into the blood stream, which leads to metastasis to distant sites. Our future studies will investigate whether this phenotype is driven through neutrophils and whether targeting neutrophils would inhibit Chi3l1-mediated metastasis.

#7226 Development of syngeneic tobacco associated oral cancer models using *Trp53* and *Cdkn2a* mutant mice.

Roberto Rangel[1], Roberto Rangel Jr[1], Alanis E. Rodriguez-Rosario[1], Nicholas Balbin[1], Liping Dong[1], Arnoldo Corona[1], Ahmed Tajmim Noor[1], Guillermina Lozano[2], Andrew G. Sikora[1], Jeffrey N. Myers[1]

[1]Head and Neck Surgery, UT MD Anderson Cancer Center, Houston, TX,[2]Genetics, UT MD Anderson Cancer Center, Houston, TX

Background: Immunotherapy has revolutionized cancer treatment by leveraging therapeutic antibodies to block immune checkpoint inhibitors (ICIs). However, despite numerous clinical trials, success remains limited, likely due to tumor models lacking the appropriate genetic mutations or being studied in non-orthotopic sites factors critical to tumor response. To address these limitations, we developed syngeneic oral cancer models featuring defined mutations in *Trp53* and *Cdkn2a*, the most frequently altered genes in human papillomavirus-negative head and neck squamous cell carcinoma (HNSCC). This mutation combination correlates with aggressive disease and poor survival outcomes in HNSCC patients. Using a carcinogenesis approach in single- and double-mutant *Trp53/Cdkn2a* mice, we established a preclinical platform to study HNSCC, a malignancy with limited therapeutic options.

Methods: *Krt14-Cre* transgenic mice carrying *Trp53*-LOF, *Trp53R172H*, *Trp53R245W*, and *Cdkn2a*-LOF mutations were backcrossed onto a C57BL/6 genetic background. Oral carcinogenesis was induced via 16 weeks of low-dose 4-nitroquinoline 1-oxide in drinking water. Tumors from the tongues of treated mice underwent histopathological analysis and tissue culture immortalization. Orthotopic injections of immortalized tumor cells into C57BL/6J mice enabled validation of tumorigenic cell lines. RNA profiling quantified ICIs, cytokines, chemokines, and immune cell markers via qPCR. Sensitivity of the resulting genetically defined ROC tongue tumors to cisplatin, gemcitabine, and anti-PD-1 immunotherapy was assessed.

Results: Mutations in *Trp53* and *Cdkn2a* significantly accelerated tongue tumor development. Mice harboring double germline mutations exhibited more aggressive tumor progression compared to single-mutation or wild-type controls. From these tumors, we established eight syngeneic ROC cell lines, each harboring distinct *Trp53/Cdkn2a* co-mutations confirmed through sequencing. These cell lines, free of mycoplasma and verified to have unique mouse-origin STR profiles, were tumorigenic in C57BL/6J mice. The cell lines displayed variable expression levels of ICIs, cytokines, chemokines, and immune cell markers, and exhibited differential responses to chemotherapy and anti-PD-1 immunotherapy. Importantly, the models demonstrated immune "hot" and "cold" tumor microenvironments, including immune-excluded phenotypes.

Conclusions: Our study establishes syngeneic oral cancer models with *Trp53* and *Cdkn2a* mutations as robust platforms for investigating oral cancer immune evasion and optimizing immune-based therapies. These models provide a complementary tool for human clinical trials by facilitating hypothesis testing and advancing therapeutic strategies targeting the tumor microenvironment and immune system.

#7227 An inducible, spatially restricted mouse model of lung cancer.

Israel Ifeoluwa Odekunle, Sydney Remington, Allison Racela, David J. Seward

Department of Pathology and Laboratory Medicine, University of Vermont Cancer Center, Burlington, VT

Accurately modeling human lung tumor initiation and progression in genetically engineered mouse models (GEMMs) remains a challenge. In contrast to human lung cancer development, where patients typically present with a solitary tumor nodule, the majority of GEMMs produce numerous independent primary lung lesions. Each of these lesions then evolves as an independent tumor, a situation not relevant to human lung cancer biology. The Cre-loxP recombination system is widely used to generate GEMMs, including the inducible, tamoxifen-dependent systems that allow cell-specific conditional activation via promoter regulation. We have used this system extensively to generate KRAS-driven Lung adenocarcinomas arising from club cells via the club cell secretory protein (CCSP) Cre-ERT2 system. While powerful, this model has limitations. Specifically, limiting tumor induction to a single location within the lung is impossible. To address this limitation, we have combined the highly efficient photoactivable Cre (PA-Cre) recombinase mouse (JAX: 033544) with a novel CCSP-FlpO mouse to spatially limit tumor formation based on targeted blue-light exposure. Exploiting the CCSP promoter enables us to limit FlpO recombinase expression to club cells, thereby confining the two light-activatable Cre halves to club cells. Following focal trans-cutaneous blue light exposure, the PA -Cre halves dimerize and induce the oncogenic alleles, KRAS p.G12D, and Serine Threonine Kinase 11 loss, respectively. We assert that utilizing this approach will overcome major limitations inherent in current GEMMs used to study lung cancer and provide a paradigm-shifting platform to study lung cancer initiation and progression.

#7228 Long-term humanization of NOG mice and next-generation NOG strains to induce lineage-specific differentiation of immune cells for assessment of novel immune cell therapies, check point inhibitors, and immune cell engagers for translational immuno-oncology research.

Maria Stecklum[1], Louise Baskin[2], **Jens Hoffmann**[1]

[1]EPO GmbH, Berlin, Germany,[2]Taconic Biosciences, Inc., New York, NY

Background: The preclinical evaluation of novel immune therapies requires humanized immune system (HIS) mouse models. In previous studies we have demonstrated that either peripheral blood mononuclear cells (PBMC), subsets of PBMCs like T and NK cells or CD34+ hematopoietic stem cells (HSC) can be used to establish a HIS model. With the development of next-generation NOG mice, lineage-specific differentiation of immune cell sub-populations of interest can be supported. Transplantation of cell line-derived (CDX) or patient-derived (PDX) tumor xenografts on HIS mice provides a full model for human tumors for the investigation of checkpoint inhibitors (CPI), as well as novel cell therapies and immune cell engagers.
Methods: HSC-humanized mice were generated by i.v. transplantation of CD34+ stem cells to immunodeficient mice. For humanization, NOG mice and next-generation NOG strains were used: NOG, NOG-EXL, hIL-2 NOG, hIL-6 NOG and FcResolv™ NOG mice were compared to each other for lineage-specific differentiation using single donors or a mixed HSC donor pool. Long-term survival was monitored and engraftment of immune cells was analyzed by FACS of blood every four weeks. After termination, spleen, bone marrow and thymus was also screened for human immune cells. In humanized NOG mice, CDX and PDX from different entities were s.c. transplanted and used to evaluate CPI.
Results: Humanized hIL-2 NOG mice showed significantly decreased survival after HSC transplantation in comparison to the other mouse strains and had to be sacrificed within the first 6-8 weeks after HSC transplantation. In the other mouse strains, transplanted HSCs engrafted and differentiated mainly into B and T cells. NOG-EXL mice displayed the highest engraftment, with up to 80% of human cells in the blood, including a higher portion of myeloid cells after 8 to 12 weeks. Humanized NOG, hIL-6 NOG and FcResolv™ NOG mice showed the longest survival rate with over 400 days for single donor transplantation. In humanized NOG mice, selected CDX and PDX tumors successfully engrafted without significant differences in tumor growth compared to non-humanized mice. CPI treatments with Nivolumab or Ipilimumab induced tumor growth delay in selected models.
Conclusions: Next-generation NOG mouse strains are characterized by a lineage-specific differentiation of immune cells depending on integrated human cytokines. Furthermore, we established a human tumor-immune-cell model for NOG mice using different entities of CDX or PDX in combination with CPI. Our human tumor-immune cell models allow preclinical translational studies on tumor immune biology as well as evaluation of new therapies, drug combinations and biomarker identification and validation.

#7229 Humanized mouse models of γδ T engraftment for the testing of cell based anti-cancer therapeutics.

Kevin Tsai, Nancy Zheng, Beau Parry, Destanie Rose, James G. Keck, Li-Chin Yao

Innovation and Product Development, The Jackson Laboratory, Sacramento, CA

One of the major hurdles of T cell-based immune therapy is identifying a T cell receptor that works for all patients. The γδ T cells, which express T cell receptors that can recognize several evolutionarily conserved cell surface molecules commonly become elevated in cancer cells, may solve this problem. There is currently no mouse model capable of expanding these γδ T cell subsets *in vivo*. Using human peripheral blood mononuclear cells (PBMC) engrafted NSG mouse strains, we compared γδ T cell engraftment in mice with or without irradiation to explore whether irradiation can aid the expansion of human γδ T cells and if so, which of our new NSG derivatives is best suited for human γδ T cells expansion.

Non-irradiated or irradiated NSG-MHC I/II double knock-out (DKO), NSG-FLT3- MHC I/II DKO (FDKO), and NSG-SGM3-IL-15 × MHC I/II DKO (SDKO) mice were engrafted with PBMCs. For non-irradiated studies, 7 different donors were used. For irradiated studies, 3 different donors were used. In the irradiated studies, mice were taken down 9 days post engraftment. In the non-irradiated studies, human leukocyte engraftment was monitored via flow cytometry staining of retro-orbital blood for up to 93 days. At indicated time points following engraftment, tissue samples were collected to enumerate the frequency and number of γδ T cells. Robust and rapid γδ T cell expansion was observed in all irradiated NSG derivatives with the SDKO mice showing the highest concentration of circulating γδ T cells 9 days post engraftment (40-70 γδ T cells/μL of blood) followed by the FDKO mice (20-50 γδ T cells/μL of blood) with the DKO mice showing the lowest (1-10 γδ T cells/μL of blood). The frequency of γδ T cells within the hCD45 population was 1-5% in all three strains, which is physiologically similar to that in humans. In addition, γδ T cells were found in the spleen and mucosal sites (e.g. colon and lungs) of engrafted mice. In non-irradiated mice, both SDKO and FDKO mice showed higher γδ T cell engraftment rates relative to the DKO mice up to 93 days post engraftment. However, the expansion rate was slower than that of the irradiated mice: reaching the highest percentage of engraftment 28-42 days post engraftment. The γδ T cells could be recovered from the blood, spleen, and lungs of SDKO and FDKO mice but almost devoid in the DKO mice. Interestingly, with some donors, more γδ T cells were found in the SDKO mice whereas with other donors, in the FDKO mice.

Irradiated SDKO mice showed maximal expansion and recovery of γδ T cells from the spleen, blood, and mucosal sites. By comparison, the γδ T cell expansion was slower in the blood, spleen, and lungs of SDKO and FDKO non-irradiated mice but remained detectable even up to
93 days post engraftment while up to 80% of the DKO mice had lost their γδ T cell engraftment. Studies to investigate anti-tumor capacity of γδ T cells are currently underway.

#7230 New mouse strains NSG-SGM3xIL15xDKO and NSG- FLT3LxDKO are superior to NSG-MHC I/II DKO mice for humanization of peripheral blood mononuclear cells.

Nancy (Xiaoqing) Zheng, Kevin Tsai, Guoxiang Yang, Beau Parry, **Destanie Rose**, James Keck, Li-Chin Yao

The Jackson Laboratory, Sacramento, CA

Background: Peripheral blood mononuclear cells (PBMC)-humanized mice serve as important platforms to evaluate efficacy and toxicity. NSG-MHC I/II double-knock out (DKO) mice have been widely used due to being a humanized T cell model with delayed graft-versus-host disease. However, achieving at least 5% engraftment within a week requires 10-15e6 PBMCs per mouse with irradiation, which accelerates PBMCs to engraft compared to non-irradiated mice. Additionally, engraftment of certain cell populations, such as natural killer (NK) cells and monocytes from PBMC has been challenging in the DKO strain. Therefore, we aimed to develop new mouse strains that can be better humanized with lower PBMC cell counts while gaining a variety of cell subtypes. Next generation DKO strains including NSG-SGM3xIL15xDKO (SDKO) and NSG-FLT3LxDKO (FDKO) engrafted with multiple PBMC donors were compared.
Methods: Nonirradiated SDKO, FDKO, and DKO mice were intravenously (IV) injected with 10e6 (5 donors) or 15e6 (2 donors) PBMCs and retro-orbital breeds were collected for engraftment comparisons for up to 70 days. Additionally, we compared PBMC engraftment of SDKO, FDKO, and DKO with and without irradiation (2 donors) for 70 days.
Results: When mice were engrafted with 10e6 PBMCs without irradiation, SDKO and FDKO achieved higher human CD45+ cells engraftment level in the periphery blood compared to DKO. Depending on the PBMC donors, SDKO or FDKO can achieve the highest engraftment rate sooner and reach the highest human CD45+ cell count among all the three strains. The peak engraftment levels of hCD45+ cells in SDKO or FDKO were 1.5-2.6 times higher than that in DKO. When mice were engrafted with15e6 PBMCs without irradiation, SDKO was engrafted rapidly and reached the highest engraftment level compared to the other two strains. FDKO was engrafted faster and showed a higher level than DKO mice before 28 days post-humanization. hCD3+T cells and hCD19+ B cells were the major cell populations post PBMC engraftment with significantly higher levels in SDKO and FDKO, compared to DKO. In addition, hCD8+ T cells and hCD56+ NK cells were engrafted at significantly higher numbers in SDKO compared to FDKO and DKO. Irradiation helped B cells to engraft at higher levels in SDKO and DKO for short term studies.
Conclusions: The two new mouse strains, SDKO and FDKO, are engrafted with human PBMCs at a faster rate, and higher levels compared to DKO mice. In addition, SDKO provides better engraftments of CD8+ T cells and NK cells. Irradiated SDKO mice reach a higher hCD45+ peak engraftment level compared to the DKO. Thus, SDKO and FDKO may serve as new and improved platforms to assess preclinical immuno-oncology efficacy and toxicity.

#7231 Immuno-oncology drugs fast in vivo efficacy test IO-FIVE for research and precision medicine.

Bin Xie[1], Yang Liu[1], Yu Di[1], Xiaorong Gu[1], Kaimeng Hu[1], Song Xu[1], Loc Van[2], Josh Caggiula[2], Diandong Jiang[1], Danyi Wen[1]

[1]Shanghai LIDE Biotech Co., Ltd., Shanghai, China,[2]LIDE Biotech Co., Ltd., Doylestown, PA

Immunotherapy is becoming a promising cancer treatment for microsatellite-instability-high (MSI-H) pan-cancers, and combination therapy with IO drugs and anti-angiogenesis or antibody-drug-conjugates is considered as a first-line therapy for advanced or unresectable hepatocellular carcinoma and bladder cancer respectively. Though human CD34+HSC and PBMC humanized models are valuable tools to investigate the *in vivo* function and mechanism of immuno-oncology drugs, the allogeneic reaction between targeted cancer tissue and human immune system is a serious issue. Obviously, this could interfere with the fundamental reaction of the testing drugs particularly with mismatched HLA donors. Thus, there is an urgent and unmet need for a preclinical *in vivo* model that effectively mimics patients through autologous immune systems. LIDE's Mini-PDX (mini-patient-derived xenografts) model has been widely applied to test the *in vivo* chemosensitivity of chemical and targeted compounds for more than 3000 clinical biopsies in the last decade. Leveraging this *in vivo* organoid system, we have developed the immuno-oncology version of MiniPDX, named "Immuno-Oncology drugs Fast *In Vivo* Efficacy" test or IO-FIVE. This assay uses patient cancer cells with its microenvironment immune cells and stroma cells isolated from the same fresh biopsy, well mixed and co-inoculated in mini-capsules before implantation into immune deficient mice. Total tissue viability and phenotyping of each cell subsets could be assessed within 2 weeks by Celltiter Glo and flow cytometry analysis respectively. Furthermore, omics study would shed new light for deeper understanding about the mechanism. Using this model, we found that Daratumumab (CD38-Ab) had a tumor suppression effect in less than half of CD38+ acute myeloid leukemia patients (response rate is around 30% in all AML N>60), and laboratory IO-FIVE data guided clinical Sintilimab (PD1-Ab), bevacizumab and capecitabine combo-therapy leads to a stable disease (SD) type for one advanced lung metastatic colon cancer patient with microsatellite stable genotype. Consistent to clinical trials, PD1 antibody (e.g., Sintilimab) monotherapy seems have limited tumor control effect in around one-fourth of ovarian cancer patients (N=11), IO and PARP inhibitor combo-therapy or novel drugs (bispecific antibody, ADCs) may enhance the immunotherapy efficiency and sensitivity. Our IO-FIVE model is offered as a unique *in vivo* functional assay to help do patient stratification as well as MOA studies.

#7232 KDM1A/UTX Mutations Modulate Innate Immune Responses to Influence Immunotherapy Outcomes in Lung Squamous Cell Carcinoma.

Feifei Na, Xiaofeng Deng, Yuying Wang, Zhenkun Zhang, Yang Yang, Liting You, Zuoyu Liang, Yu Liu, Chong Chen

West China Hospital, Sichuan University, Chengdu, China

Introduction: Immunotherapy has come of age for lung cancers, especially lung squamous cell carcinoma (LUSC), which lacks targeted therapies . *KDM6A/UTX* is frequently mutated in LUSC and is associated with poor prognosis. However, the mechanisms by which *KDM6A/UTX* mutations influence the efficacy of immunotherapy in LUSC remain unclear. **Methods:** We developed genetically engineered murine models of LUSC by culturing lung organoids from adult C57B/L6 mice, using Cas9 and sgRNAs to introduce driver mutations of LUSC. These organoids were then orthotopically transplanted into the lungs of recipient C57B/L6 mice to establish in vivo LUSC models. Tumor growth and progression were monitored through live imaging and micro-CT. Histopathological assays were performed to validate the models' accuracy in representing human LUSC. Multi-omics methods were used to analyze the the biological behavior of Kdm6a-mutant tumor cells, their response to immunotherapy, and identify key regulatory target genes. Potential therapeutic targets identified through these analyses are currently under further validation. **Results:** A LUSC mouse models with sg*Trp53*; sg*Pten*; *SOX2*; *Myc; Cas9* (TPSM) was established. Histopathological analyses showed that these models represented the features of human disease. Tumor organoids were successfully developed from these models and serial transplantation confirmed that these organoids remained the characteristics of the original models. Loss of *Kdm6a/UTX* significantly enhanced the growth of LUSC tumor organoids in vivo and promoted metastasis. Notably, LUSC tumors with *Kdm6a/UTX* mutations exhibited a poor response to immune checkpoint inhibitors (ICIs), and showed significantly shortened survival in treated mice. Multi-omics analyses revealed that Kdm6a/UTX mutations upregulated several pathways associated with tumor progression, including focal adhesion, epithelial-mesenchymal transition (EMT), and epithelial cell migration. In contrast, immune-related pathways such as virus response and interferon-β signaling were downregulated. These mutations also resulted in a decreased recruitment of immune cells, including cytotoxic T cells (CD8+), into the tumor microenvironment, potentially contributing to immune evasion and the poor response to immunotherapy. **Conclusion:** The new LUSC mouse models developed in this study provide a platform for investigating the mechanisms of LUSC progression and response to immunotherapy. Our results suggest that *Kdm6a/UTX* play a critical role in modulating the tumor immune microenvironment, promoting immune evasion, and reducing the efficacy of immunotherapy. Further validation of the identified molecular targets and their therapeutic potential is underway.

#7233 An in vivo co-injection model for studying macrophage polarization and therapeutic repolarization in tumor development.

Philipp Metzger, Valerie Oberhardt, Carla N. Castro, **Holger Weber**

Reaction Biology Europe GmbH, Freiburg, Germany

Macrophages play a critical role in tumor development by shaping the tumor microenvironment. In particular, the M2-polarized macrophage phenotype is associated with pro-tumoral functions such as promoting angiogenesis, immune suppression, and tumor progression. Consequently, numerous therapeutic approaches aim to repolarize M2 macrophages to mitigate their tumor-supportive behavior. While these effects are consistently and effectively demonstrated in vitro in our laboratory, translating these findings into in vivo models remains a significant challenge. Here, we present an in vivo co-injection model that allows the detailed study of macrophage-tumor cell interactions and the evaluation of potential therapeutic agents targeting macrophage polarization. First, we isolated monocytes from heathy donors and differentiated them in vitro into various phenotypes (M0, M1, and M2) according to our established protocols. We selected a tumor cell line that secretes high levels of macrophage survival promoting factors and has good in vivo growth characteristics. In this model we co-injected the tumor cells together with macrophages in NXG animals. Our results demonstrate that the co-injected M2 macrophages remains stable for over a week in the tumor microenvironment, closely mimicking the persistence observed in human tumors. Additionally, M0 macrophages undergo differentiation under the influence of the tumor microenvironment, reflecting the dynamic and plastic nature of macrophage polarization in vivo. Marker expression as well as functional properties, such as phagocytotic activity of pHrodo Zymosan particles ex vivo, was analyzed by flow cytometry.
This model provides a biologically relevant system for studying macrophage-targeting therapies, complementing the robust and reproducible in vitro experiments routinely conducted in our laboratory. The presence of the M0 and M2 macrophages over a significant period of time enhance the model's utility for evaluating substances designed to repolarize macrophages in vivo.
In conclusion, this in vivo co-injection model represents a valuable tool for preclinical research into macrophage polarization and its impact on tumor progression. Its potential ability to replicate key aspects of macrophage-tumor cell interactions enables comprehensive investigations of therapeutic strategies targeting the tumor microenvironment. This approach has the potential to accelerate the development of novel treatments aimed at disrupting the pro-tumoral functions of M2 macrophages and enhancing anti-tumoral immune responses.

#7234 Unveiling the role of B7H3 in driving the tumor immune microenvironment and progression of small cell lung cancer.

Mahek Fatima[1], Parvez Khan[2], Md Arafat Khan[2], Asad Ur Rehman[2], Laiba Anwar[2], Aatiya Ahmad[2], Jaewon Lee[3], Imayavaramban Lakshmanan[2], Anish Thomas[4], Dinesh Pradhan[5], Apar K. Ganti[6], Brad St Croix[3], Surinder K. Batra[2], Mohd Wasim Nasser[2]

[1]University of Nebraska Medical Center, Omaha, NE,[2]Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE,[3]Tumor Angiogenesis Unit, National Cancer Institute, Frederick, MD,[4]Developmental Therapeutics Branch, National Cancer Institute, Bethesda, MD,[5]Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE,[6]Department of Hematology-Oncology, University of Nebraska Medical Center, Omaha, NE

Lung cancer is the leading cause of cancer-related deaths globally, with small cell lung cancer (SCLC) representing a highly aggressive subtype. The prognosis for SCLC remains dire due to early metastasis, chemoresistance, high recurrence rates, and limited therapeutic options. Despite the approval of some immunotherapeutic drugs for SCLC, their efficacy is restricted to a small subset of patients. This limited success is attributed to low expression of PD-L1 and the immune-cold tumor microenvironment in SCLC, underscoring the urgent need for new therapeutic targets. Bioinformatic analysis of SCLC datasets, focusing on immune checkpoint regulators, identified B7H3 (CD276) as a promising candidate upregulated in SCLC. This finding was confirmed in SCLC cell lines and human tissue samples. B7H3 is a cell surface protein overexpressed in multiple tumor types, functioning as both an immune modulator and an oncogenic driver. However, its role in SCLC tumorigenesis remains unclear. To investigate the functional involvement of B7H3 in SCLC, we employed CRISPR-Cas9 to knock out the *B7H3* gene in SCLC cell lines. B7H3 knockout significantly reduced transwell migration and wound-healing abilities in SCLC cells. When co-cultured with T-cells, B7H3-proficient SCLC cells suppressed T cell activation, unlike their B7H3-deficient counterparts. To therapeutically target B7H3, we used the antibody-drug conjugate (ADC) m276-SL-PBD in the spontaneous SCLC mouse model RPM (Adeno-CGRP-Cre; $Rb1^{flox/flox}$; $TP53^{flox/flox}$; $LSL\text{-}Myc^{T58A}$) which significantly reduced tumor burden, metastasis, angiogenesis, and increased T cell infiltration. To further elucidate the role of B7H3 in SCLC progression, we generated a novel spontaneous mouse model, RPMC (Adeno-CGRP-Cre; $Rb1^{flox/flox}$; $TP53^{flox/flox}$; $LSL\text{-}Myc^{T58A}$; $Cd276^{fl/fl}$). These mice exhibited a marked decrease in tumor burden, tumor-associated angiogenesis, and metastasis, with a significantly increased T-cell infiltration compared to controls. Transcriptomic analysis of B7H3-proficient/-deficient cells revealed NFIB among the top 50 downregulated genes following B7H3 deletion. NFIB, a key driver of SCLC metastasis, was significantly reduced in B7H3-deficient human and syngeneic (RPMC) cell lines. Metastatic tissues from RPMC mice also showed lower NFIB expression compared to the RPM model. In conclusion, this study highlights the critical role of B7H3 as well as modulation of NFIB expression in regulating SCLC progression. Our findings establish B7H3 as a promising therapeutic target and demonstrate the potential role of CD276 ADCs in overcoming the limitations of current treatments of SCLC. By advancing our understanding of B7H3's role in promoting tumor growth, this study paves the way for designing more effective therapeutic strategies to combat SCLC.

#7235 New mouse strain NSG-SGM3xIL15xDKO is better for PBMC engraftment in Raji-bearing mice of minor immune subsets compared to NSG-MHC I/II DKO mouse.

Nancy (Xiaoqing) Zheng, Guoxiang Yang, James Keck, **Li-Chin Yao**

The Jackson Laboratory, Sacramento, CA

Introduction: PBMC-humanized MHC I/II double knock-out (#025216, DKO) strain has shown strong T cell engraftment with minimal acute GVHD. We recently have developed two new mouse strains, NSG-SGM3xIL15xDKO (SDKO) and NSG-FLT3LxDKO (FDKO), and their engraftment comparison data will be presented in the same meeting. Here we aimed to investigate the engraftment of various immune cell types in SDKO and FDKO mice in the presence of tumor stimulation.
Methods: We assessed PBMC engraftment levels and immune subtypes in irradiated SDKO, FDKO, and DKO implanted with lymphoma (Raji-luc and Nalm6-luc) and breast cancer (MDA-MB-231-luc) xenografts. In addition, we investigated the differences between irradiated and non-irradiated mice of the above three strains implanted with Raji-Luc cells. Whole blood via retro-orbital bleeds and spleen were collected to analyze engraftment and immune cell populations by flow cytometry. Five different PBMC donors were used.
Results: We found irradiated SDKO and FDKO achieved higher PBMC humanization levels compared to DKO. Interestingly, Raji-luc cells stimulated PBMCs to engraft at a significantly higher level compared to PBS, MDA-MB-231-luc and Nalm6-luc cells. hCD3+ T cells were activated (HLA-DR+) in Raji-luc groups. The stimulatory effect of Raji-luc cells was also validated in the three strains without irradiation. PBS treated irradiated mice without tumor stimulation, both SDKO and FDKO had approximately 9-15 folds engraftment of CD19+ B cells and CD56+ natural killer (NK) cells, and some donors showed 2-4 folds engraftment of CD11c+HLA-DR+ dendritic cells and CD64+ macrophages compared to what was seen in DKO mice in early engraftment. After Raji-luc cells stimulation, the engraftments of above cell types were enhanced 3-4 folds over the DKO. Non-irradiated SDKO and FDKO showed a 2-3 folds increase in B cells and NK cells compared to those in DKO mice in early engraftment in peripheral blood in the PBS group. With Raji-luc cells, the engraftments of B cell and NK cells were enhanced 2-4 folds in SDKO and FDKO over DKO mice. Other tumor data will also be presented.
Conclusion: Both PBMC-humanized SDKO and FDKO show improved NK cells and myeloid cells engraftment compared to DKO after tumor antigen stimulation. The response may vary based on PBMC donors and cancer cell lines. Irradiation also helps certain cell types like myeloid cells to engraft compared to no irradiation in the cancer models.

#7236 First successful engraftment of human pancreatic cancer cells in an immunocompromised porcine model to test tumor ablation by high-frequency irreversible electroporation (H-FIRE).

Manali Powar[1], Tamalika Paul[1], Edward Jacobs[2], Sherrie Clark-Deener[1], Christopher Byron[1], Sheryl Coutermarsh-Ott[1], Katie Orr[1], Maxx Steinmann[1], levente Gal[1], Cassandra Poole[1], Carley Elliott[3], Mackenzie Woolls[1], Madeline Mott[1], Julio Arroyo[2], Zaid Salameh[2], Hannah Ivester[1], Rafael V. Davalos[2], Irving Coy Allen[1]

[1]Virginia Tech, Blacksburg, VA,[2]Georgia Tech, Atlanta, GA,[3]Graduate Program in Translational Biology, Medicine and Health, Virginia Tech, Blacksburg, VA

Pancreatic tumor is difficult to treat due to late diagnosis, critical tumor location, limited surgical options, and high metastatic potential. High-frequency irreversible electroporation (H-FIRE) is a non-thermal ablation technique that uses high-voltage electric pulses to create permanent nanopores in cell membranes, disrupting homeostasis and inducing cell death. This study established the feasibility of using H-FIRE to ablate pancreatic tumors in an immunocompromised porcine model were RAG2/IL2RG double knockout pigs. Panc1 human pancreatic cancer cells were orthotopically injected into the pancreas of these pigs. 3 weeks post-injection, successful tumor engraftment and growth were observed during treatment. We successfully accessed and treated the tumors using H-FIRE, with clear ablation zones and preservation of surrounding tissue confirmed by histopathology. The treatment also showed minimal local muscle contraction. This study demonstrated the first robust large-animal model of H-FIRE-treated human pancreatic cancer with safety and efficacy. Future work will explore the potential of these immunocompromised porcine models for developing advanced therapeutic strategies to enhance tumor ablation by H-FIRE.

#7237 Rapid-onset squamous cell carcinoma and spontaneous regression following papillomavirus infection.

Andrea Bilger[1], Ella T. Ward-Shaw[1], Denis L. Lee[1], Renee E. King[1], Shwu-Yuan Wu[2], Michael A. Newton[3], Cheng-Ming Chiang[4], Darya Buehler[5], Kristina Matkowskyj[6], John P. Sundberg[7], Rong Hu[5], Paul F. Lambert[1]

Squamous cell carcinoma (SCC) development in mammals is thought to require months or years from the time that initial changes occur. We show that SCCs induced by the mouse papillomavirus MmuPV1, which are generally diagnosed 4-6 months post infection, can be found as soon as 2 weeks post infection. SCCs developed within 2 weeks in immune-competent, adult FVB (FVB/NTac) mice at sites prone to human papillomavirus (HPV)-induced tumors and cancers in human patients: the base of the tongue, the anus, and the skin. The anterior tongue, less susceptible than the base of the tongue to HPV-induced cancer in humans, was resistant to rapid-onset cancer. The presence of invasive cancer in histological tissue sections was verified by multiple pathologists. These diagnoses were corroborated by the results of a classic test of malignancy: skin tumors obtained two weeks post infection grew ectopically as subcutaneous grafts in immune-deficient hosts. Preventative treatment with a novel BRD4 inhibitor dramatically reduced the frequency of ear skin SCCs present 2 weeks post infection and significantly reduced overall disease severity. Like many human papillomaviruses, MmuPV1 lacks an E5 gene. Expression of HPV16 E5 driven by the Keratin 14 promoter in FVB mice (FVB/NTac-Tg(KRT14-HPV16E5*)33Plam/Plam) significantly increased the frequency of rapid-onset invasive cancers caused by MmuPV1 at the base of the tongue and in the anus. In an E5-transgenic mouse with a persistent MmuPV1-induced ear skin lesion, we detected a lymph node metastasis at 38 weeks - further demonstrating a cancer phenotype. Cancers and less severe dysplasia induced by infection at the base of the tongue or the anus spontaneously regressed within 4 to 8 weeks of infection; however, ear lesions persisted. When CD4+ and CD8+ T cells were depleted, lesions at the base of the tongue and anus also persisted, indicating that spontaneous regression involves a T cell-mediated immune response. These results indicate that papillomavirus infection alone is sufficient to induce rapid onset of invasive cancer, and that persistence of disease depends on the tissue-specific immune microenvironment.

#7238 Quantitative profiling of HLA class I and II antigens and neoantigens in tissue and PBMC samples with an improved mass spectrometry approach.

A. Viode, A. Pfeiffer, L. Raess, M. Tognettti, T. Temu, O. M. Bernhardt, **D. Redfern**, Y. Feng, R. Bruderer, L. Reiter;
Biognosys AG, Schlieren, Switzerland

Human leukocyte antigen (HLA) molecules are critical mediators of immune surveillance, functioning to present antigenic peptides derived from self and non-self proteins to T cells. By facilitating the recognition of pathogenic or abnormal cells, such as cancer cells, HLA molecules play a pivotal role in guiding immune responses and enabling targeted immune interventions. In oncology clinical trials, the use of peripheral blood mononuclear cells (PBMCs) offers significant advantages for immunopeptidomics (IMPX) and potential neoantigen discovery. Unlike solid tissue biopsies, which may be limited in availability and require invasive procedures, PBMCs can be routinely isolated from blood, allowing for serial sampling. PBMCs comprise a diverse population of immune cells, including lymphocytes (T cells, B cells, and NK cells) and monocytes, which collectively serve as a holistic snapshot of the body's immune status, enabling the tracking of immune modulation, and providing pharmacodynamics readout across various disease contexts.

We developed and optimized an unbiased IMPX profiling workflow leveraging native lysis and magnetic bead-based immunoprecipitation for isolating both class I and class II immunopeptides. By refining the lysis and pulldown conditions, we ensured effective extraction and enrichment of HLA complexes from minimal starting material, achieving robust profiling across varying sample types, including cell lines, tissues, and PBMCs. To accommodate the often limited PBMC availability in real-world clinical settings, we tested this pipeline with inputs as low as 5 million PBMCs, achieving high-quality, reproducible IMPX data. Further downstream, LC-MS setup and AI-based bioinformatics solutions were optimized to support streamlined data generation and analysis. Overall, the developed workflow demonstrated high reproducibility and specificity across sample types, identifying robust immunopeptide profiles: (1) For class I immunopeptides, >60% of peptides identified were 9-mers, with >80% predicted as strong binders, exhibiting expected amino acid enrichment at anchor residues; (2) For class II immunopeptides, >50% of peptides were 14-to-16-mers, with >50% predicted as strong binders. Input material ramping tests showed that >2,800 class I immunopeptides could be consistently identified from 2.5 mg of fresh-frozen tissue, and 2,000-3,000 class I immunopeptides from as few as 5 million PBMCs. Moreover, we profiled the immunopeptidomes of several representative cancer cell lines (e.g. SHP77, OV56) with known HLA subtype(s) that are commonly used in TCR therapeutics target discovery.

In summary, we have developed a high-sensitivity, robust pipeline for class I and II immunopeptidome profiling that is compatible with low-input samples, making it suitable for both target discovery and clinical applications.

#7239 Investigating the role of topoisomerase IIB in the regulation of antigen presentation pathway in high-grade serous ovarian cancer.

Shraddha G. Gupta, Sangeeta Kumari, Adam Karami, Aisha Jamil, Sergey Karakashev

Temple University, Philadelphia, PA

Epithelial ovarian cancer (EOC) is the deadliest gynecologic malignancy and accounts for 90% of ovarian tumors. High grade serous ovarian cancer (HGSOC), an aggressive subtype of EOC, develops rapidly and is correlated with poor prognosis. Importantly, HGSOC accounts for 70-80% of deaths related to ovarian cancer. Immunotherapies that have revolutionized the field of cancer therapy demonstrate limited therapeutic efficacy in HGSOC. HGSOC tumors are characterized by low immune cell infiltration and reduced anti-tumor immune response. Hence, it is crucial to develop new therapeutic strategies that improve anti-tumor immune response in HGSOC. Epigenetic suppression of antigen processing and presentation pathway (APP) is one of the major mechanisms adopted by cancer cells to escape T-cell cytotoxicity. APP entails binding of the cytotoxic CD8+ T cells to neoantigen presented by Major Histocompatibility Complex Class I (MHC class I) on the membrane of cancer cells. Neoantigen recognition by CD8+ T cells lead to activation of CD8+T cells and subsequent killing of the antigen-presenting cells (APC). Previous studies have demonstrated that defects in the expressions and functions of APP components correlate with reduced T-cell infiltration, metastasis, and poor overall survival. Our bioinformatics analysis of publicly available ovarian cancer patient dataset from The Cancer Genome Atlas (TCGA) and ovarian cancer cell line database (Depmap) revealed DNA topoisomerase 2-beta (TOP2B) as a potential negative regulator of APP. TOP2B is a topoisomerase that regulates the transcription of its target genes by altering the topological state of DNA. Recently, a small molecule inhibitor, CX-5461, was discovered to specifically target TOP2B. It has also completed Phase I clinical trials for solid tumor and hematological malignancies demonstrating its safety and efficacy in human patients. Understanding the role of TOP2B in cancer progression may lead to the development of a novel therapeutic strategy to improve overall survival of HGSOC patients.

#7240 The role of myeloid cell derived HMGB1 in the development of hepatocellular carcinoma.

Sai Santosh Babu Komakula, Xiaodong Ge, Wei Chen, Romain Desert, Hui Han, Zhuolun Song, Sukanta Das, Dipti Athavale, Nithyananthan Subramaniyam, Chao Wang, Daniel Lantvit, Abid Anwar, Natalia Nieto

Pathology, University of Illinois at Chicago, Chicago, IL

Background: High mobility group box 1 (HMGB1) is a non-histone chromatin-associated protein involved in the pathogenesis of chronic liver disease. HMGB1 is expressed in myeloid cells, including conventional dendritic cells (cDCs), which play a major role in the tumor microenvironment. However, whether intracellular myeloid cell-derived HMGB1 is involved in hepatocellular carcinoma (HCC) is unknown. We hypothesize that intracellular HMGB1 drives cDC maturation towards LAMP3^{+} DCs, allowing effective cytotoxic CD8^{+} T cell responses to reduce HCC.
Methods: We analyzed publicly available scRNA-seq datasets from human HCC for the expression of HMGB1 in all subsets of DCs in HCC tumor and non-tumor tissues and in hepatic draining lymph nodes (dLNs). We generated mice with conditional ablation or overexpression of *Hmgb1* in myeloid cells (*Hmgb1*$^{\Delta Mye}$ and *Hmgb1*$^{KI\ Mye}$). To induce HCC, 14-day-old male mice were injected i.p. with diethylnitrosamine (DEN) and were sacrificed at 5, 6, 8, and 10 months. Histopathological analysis of livers was performed using H&E staining. Immune cell populations were analyzed in tumor and non-tumor tissues using flow cytometry. cDCs were isolated from tumor and non-tumor tissues by FACS, and RNA-seq analysis was performed.
Results: Analysis of scRNA-seq datasets revealed LAMP3^{+} DCs increased in human HCC tumor tissue and hepatic dLNs. LAMP3^{+} DCs displayed increased activation and migration scores. Moreover, HMGB1 was highly expressed in cDCs (CLEC9A^{+} and CD1C^{+}), which can differentiate to LAMP3^{+} DCs. *Hmgb1*$^{KI\ Mye}$ mice were protected from HCC, whereas control mice developed HCC after 8 months, and *Hmgb1*$^{\Delta Mye}$ mice started developing HCC at 5 months. Macroscopic analysis and H&E staining of the livers from *Hmgb1*$^{\Delta Mye}$ mice showed more tumors and higher tumor volume than control and *Hmgb1*$^{KI\ Mye}$ mice. Immunohistochemistry of HCC tumor sections revealed that *Hmgb1*$^{\Delta Mye}$ mice have fewer LAMP3^{+} DCs in tumor tissues than control and *Hmgb1*$^{KI\ Mye}$ mice. Flow cytometry analysis showed that *Hmgb1*$^{KI\ Mye}$ mice had significantly increased cDCs in tumor tissues and dLNs than control and *Hmgb1*$^{\Delta Mye}$ mice. In addition, there was enhanced CD8^{+} T cell apoptosis in the HCC tumor tissues from *Hmgb1*$^{\Delta Mye}$ mice. RNA-seq data of cDCs unveiled that pathways involved in antigen presentation were downregulated in *Hmgb1*$^{\Delta Mye}$ mice and upregulated in *Hmgb1*$^{KI\ Mye}$ mice compared to control mice.
Conclusions: Ablation of myeloid-derived HMGB1 accelerates HCC development in mice. Enhancing HMGB1 expression in myeloid cells increased the number and the antigen presentation activity of cDCs. Therefore, increasing HMGB1 expression in cDCs could be a therapeutic approach to protect from HCC.

#7241 Tumor-derived APi1 inhibits antigen cross-presentation in dendritic cells and impairs anti-tumor immunity in breast cancer.

Erwei Song, Di Huang, **Ruxin Wang**

Sun Yat-sen University, Guangzhou, China

Tumor mutational burden (TMB), usually representing high immunogenicity, could not always predict treatment response of immune checkpoint blockade (ICB). Here, we showed that defective antigen cross-presentation in type 1 conventional dendritic cells (cDC1) was responsible for lacking tumor-specific cytotoxic T lymphocytes (CTLs) in triple-negative breast cancer (TNBC) patients. Mechanistically, we found a tumor-derived protein, termed antigen presentation inhibitor 1 (APi1) , was shuttled via extracellular vesicles (EVs) into the endosomes of intratumor DCs, inhibited antigen cross-presentation by locking antigen binding to HSP90 and precluding their translocation from endosomes to cytoplasm. APi1 knockdown in tumor cells or inhibiting APi1/HSP90 interaction in DCs efficiently promoted antigen translocation and enhanced their cross-presentation, which improved ICB therapeutic responses. Clinically, high tumor APi1 expression was associated with low infiltration of antigen-specific CTLs and poor ICB efficacy in TNBC patients. Therefore, tumor EV-shuttled APi1 locks antigen/chaperone interaction and impairs antigen cross-presentation in DCs. Moreover, targeting APi1 is promising to enhance anti-tumor immunity and reverse ICB resistance.

#7242 Inhibition of ULK1/2-mediated autophagy augments antigen processing and presentation promoting increased antigen specific CD8+ T-cell cytotoxicity.

Jhansi L. Leslie, Umida Djakbarova, Samantha S. Hodge, Logan Chinn, Natalie Hill, Kayla Walzer, Hyunyoung Moon, Xuelei Yan, Anne Van Abbema, Yihong Guan, Connor Rosen, Jenna L. Jeffrey, Ester Fernandez-Salas, Susan L. Paprcka

Arcus Biosciences Inc., Hayward, CA

BACKGROUND: High levels of ULK1/2-mediated macroautophagy (autophagy) are associated with immunologically cold tumors that respond poorly to therapy. Increased autophagy results in decreased antigen processing and presentation (APP) mediated by autophagosomal degradation of neoantigen-generating immunoproteasomes and MHC-I. Here, we demonstrate that inhibition of ULK1/2-mediated autophagy restores APP and increases antigen-specific CD8+ T-cell cytotoxicity.
METHODS: Levels of APP machinery were assessed at baseline and after ULK1/2 inhibition using qPCR, western blot, and/or flow cytometry in both murine and human cancer cell lines. Autophagic flux was evaluated using mCherry-GFP-LC3B reporter cell lines imaged in Incucyte. Localization of MHC-I and LC3B following inhibition of ULK1/2 were assessed by immunofluorescence via microscopy. Levels of peptide-loaded MHC-I were assessed by flow cytometry using antibodies that detected either OVA loaded MHC I or KRAS-peptide loaded MHC I. Antigen-specific CD8+ T-cell cytotoxicity was evaluated utilizing MC38-OVA-mCherry tumor cells and OT-1 CD8+ T-cells in the absence or presence of ULK1/2 inhibition.
RESULTS: Inhibition of ULK1/2 decreases basal levels of autophagy in multiple cancer cell lines. Subcellular localization of MHC-I is dramatically altered by inhibition of ULK1/2 as evidenced by decreases in co-localization of MHC-I with the autophagosome marker LC3B and increases in both total and surface levels of MHC-I. Moreover, levels of peptide-loaded MHC-I increased in multiple cancer cell lines upon ULK1/2 inhibition demonstrating that inhibition of autophagy restores antigen processing and presentation. To determine the functional impact of these changes to AAP, we utilized the OT-1 OVA co-culture system. Inhibition of ULK1/2 results in significantly enhanced killing of the MC38-OVA tumor cells by OT-1 CD8+ T cells. Importantly, the killing is antigen specific since ULK1/2 inhibition did not result in increased killing of non-OVA expressing tumor cells by OT-1 CD8+ T cells.
CONCLUSIONS: Tumors with elevated levels of autophagy are associated with reduced antigen processing and presentation resulting in low immune infiltration and poor responses to therapy. Decreasing autophagy by inhibiting ULK1/2 results in increased antigen processing and presentation, leading to enhanced antigen specific CD8+ T-cell cytotoxicity. Together, these results demonstrate that targeting ULK1/2 enhances antigen presentation and antigen-specific T cell mediated killing of cancer cells.

#7243 Mapping the isoaspartylation site(s) in the N-terminal region of ELAVL4 by using deletion constructs and testing against SCLC patient sera.

Shiori Fukutome, Diego A. Velarde, Davin Pan, Chunli Yan, Pamela R. Duarte, Provati Devi, Ite A. Offringa

University of Southern California Keck School of Medicine, Norris Comprehensive Cancer Center, Los Angeles, CA

Small cell lung cancer (SCLC) is the most aggressive type of lung cancer. Standard of care consists of a platin-based therapy with etoposide, combined with immune checkpoint inhibition. While 2/3 of patients respond, the cancer usually recurs, and patients have a 5-year survival rate of only 8%. New therapies are urgently needed. About 15% of SCLC patients spontaneously develop a low-titer immune response against Embryonic Lethal, Abnormal Vision Drosophila-like 4 (ELAVL4). This protein is expressed throughout the nervous system but in the lung is unique to pulmonary neuroendocrine cells (the main cells of origin of SCLC) and is present on the surface of SCLC cells. Patients with low titer anti-ELAVL4 antibodies show improved response to chemotherapy and significantly improved survival. Our previous work indicates that the anti-ELAVL4 immune response is triggered by isoaspartylation of the unstructured N-terminal ELAVL4 region; asparagine or aspartic residues spontaneously form a succinimide intermediate, followed by hydrolysis resulting in an isoaspartyl link. This creates an antigenic kink in the protein, an appears to favor dimerization/aggregation. The unstructured N-terminal region of ELAVL4 contains 6 asparagine residues and 2 aspartic acid residues. Here we aim to understand which asparagine/aspartic acid residues in the N-terminal region undergo isoaspartylation and contribute to the anti-ELAVL4 immune response. To this end, we have constructed four deletion clones with different regions of the ELAVL4 N-terminal region carrying one or two possible sites of isoaspartylation (residues 1-13, 8-18, 16-29, and 28-38). Recombinant proteins generated from these constructs will be incubated under isoaspartyl-inducing conditions (neutral pH, 37ºC) and will use Western Blot and ELISA assays todetermine reactivity of SCLC patient sera as well as sera from mice immunized with Elavl4 $_{(1\text{-}117)}$. Understanding the sites of isoaspartylation in ELAVL4 will help identify the optimal target for the development of anti-isoaspartylated ELAVL4 monoclonal antibodies, which may provide a novel, targeted immunotherapy for SCLC patients. Supported by the Robert E. and May R. Wright Foundation Transformative Cancer Research Grant, USC's Undergraduate Research Associates Program, and the Norris Comprehensive Cancer Center core grant, award number P30CA014089 from the NIH/NCI.

#7244 Detection of gene fusion-induced neoepitopes and cognate T cell receptors in liposarcoma.

Peter Horak[1], Jonas P. Becker[2], Sven Blobner[1], Julian Hlawatsch[3], David Weber[4], Jonas Forster[2], Annika Baude[1], Johanna Wagner[1], Isabel Poschke[3], Inka Zornig[5], Michael Volkmar[6], Michael Platten[3], Dirk Jager[7], Priya Chudasama[8], Stefan Frohling[1], Angelika Riemer[2]

[1]Translational Medical Oncology, German Cancer Research Center, Heidelberg, Germany,[2]Immunotherapy & Immunoprevention, German Cancer Research Center, Heidelberg, Germany,[3]Immune Monitoring Unit, German Cancer Research Center, Heidelberg, Germany,[4]Expression & Cell Biology, TRON Mainz, Mainz, Germany,[5]Clinical Cooperation Unit Applied Tumor Immunity, German Cancer Research Center, Heidelberg, Germany,[6]Cellular Therapies Platform, Helmholtz Institute for Translational Oncology, Mainz, Germany,[7]Medical Oncology, Heidelberg Univesrity Hospital, Heidelberg, Germany,[8]Precision Sarcoma Research Group, German Cancer Research Center, Heidelberg, Germany

Introduction: Dedifferentiated liposarcomas (DDLS) are malignant soft tissue tumors characterized by focal amplifications on chromosome 12q. Using whole genome and RNA sequencing, we found that these structural alterations generate open reading frames that may lead to potential gene fusions and immunogenic neoepitopes. These may serve as potential therapeutic targets. We present the results of the detection and validation of fusion-derived neoepitopes in eight liposarcoma patient samples. In addition, we investigate the patients' T cell repertoires against the identified fusion-derived (FD) neoepitopes.

Methods: Two variant calling pipelines were employed to identify gene fusions. The FD peptides were used as input for HLA binding prediction. We used mass spectrometry (MS)-based immunopeptidomics for HLA presentation analysis. We performed untargeted MS analysis using data-independent acquisition MS combined with ion mobility separation by high-field asymmetric waveform ion mobility spectrometry. The mass spectra were compared with the human proteome, FD sequences, and libraries of in silico predicted fragment spectra. Targeted MS analysis was performed using the ultra-sensitive parallel reaction monitoring workflow (optiPRM). All identified FD neoepitopes were subjected to Epitope-SPecific Expansion Cultures (ESPEC) testing and the TCR repertoire of expanded T-cells analyzed by deep sequencing for candidate peptide selection.

Results: We identified 17 to 123 fusion events on chromosome 12, resulting in 122 to 1126 neoepitope candidates per patient by sequence analysis. The MS workflow successfully identified neoepitopes in six of the eight samples tested. All neoepitope candidates identified by the untargeted approach were subjected to targeted analysis, regardless of their predicted HLA binding ability. In addition, we targeted the top 20 FD candidates from each patient based on the in silico binding prediction. The targeted analyses confirmed the results of the untargeted approach and provided additional detections in five of the six patients analyzed. The validated FD peptides were used to stimulate autologous peripheral blood mononuclear cells from four patients in ESPECs to identify reactive TCRs. T cell expansion was observed in ESPEC cultures against one to 15 peptides per patient, which were subjected to TCR repertoire analysis by deep sequencing.

Conclusions: We detected bona fide HLA-presenting FD neoepitopes and identified neoepitope-specific T cells in the peripheral blood of DDLS patients. These data may further aid the process of identifying and selecting candidate immunogenic peptides, thereby facilitating the clinical development of personalized treatments for DDLS patients, including cancer vaccines and TCR-based therapies.

#7245 Reversible downregulation of HLA class I in adenoid cystic carcinoma.

Annie Li[1], Bianca L. Gonda[1], Elizabeth M. Codd[1], Adam von Paternos[1], Dawn R. Mitchell[1], Markus D. Herrmann[1], Prinjali Kalyan[1], Samantha E. Flynn[1], Thuc Q. Dzu[1], Chengzhou Gao[1], Edwin Zhang[1], Julia J. Mendel[2], Julia C. Thierauf[1], Peter M. Sadow[1], Thomas Denize[1], Diane Yang[1], Florian J. Fintelmann[3], Ross D. Merkin[4], Atul K. Bhan[1], William C. Faquin[1], Daniel L. Faden[2], Xin Gao[4], Jong Chul Park[4], Lori J. Wirth[4], Stefan T. Kaluziak[1], Anthony John Iafrate[1]

[1]Pathology, Massachusetts General Hospital, Harvard Medical School, Boston, MA,[2]Otorhinolaryngology, Head and Neck Surgery, Massachusetts Eye and Ear, Harvard Medical School, Boston, MA,[3]Radiology, Massachusetts General Hospital, Harvard Medical School, Boston, MA,[4]Medicine, Hematology-Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Adenoid cystic carcinoma (ACC), a rare and lethal cancer, has shown low response rates to systemic therapies, such as cytotoxic chemotherapy, tyrosine kinase inhibitors and immune-checkpoint inhibitors (ICIs). Despite numerous clinical trials, no effective treatments for patients with recurrent or metastatic ACC have emerged, and ACC mortality rates remain stagnant. Therefore, we aimed to characterize the ACC immune landscape to understand the poor response rates to ICIs.
Experimental Design: We leveraged automated multiplex immunofluorescence (mIF), RNA in-situ hybridization, scRNAseq Gene Expression analysis and spatial transcriptomics analysis to identify pathways supporting the cold ACC immune environment and molecularly characterize ACC tumors, ACC metastasis, adjacent normal tissues, and normal tissues from regions where ACCs arise. Based on results from these studies, we treated freshly resected ACCs with interferon-γ or a STING agonist in vitro.
Results: mIF demonstrated that ACC tumors are immunologically 'cold', with few tumor-infiltrating T-lymphocytes (TILs) and low PD-L1 expression. The most striking finding, however, was a very low B2M expression in almost all ACCs, with focal expression found in some metastatic cases. Spatial transcriptomics of these focally B2M-positive ACC metastases further identified significantly upregulated genes, including *IRF1*, *GBP1* and *TAP1*, indicating an interferon-γ program that mediated reintroduction of HLA-I/B2M. Upon short-term treatment of primary ACC tissues in vitro with interferon-γ or a STING agonist, we observed strongly upregulated HLA/B2M class I expression. mIF and RNAseq analyses of normal salivary gland and breast tissues revealed a p63+, NFIB+, basal duct cell population with similarly low B2M/HLA class I expression.
Conclusions: Low B2M/HLA class I expression may explain why ACCs are immunologically cold and the lack of response to ICIs. Our findings suggest that the normal cell of ACC origin exists in a B2M/HLA-class I low state, and that pharmacologic manipulation with immune activators, such as STING agonists, can restore HLA/B2M in ACCs, creating a path to urgently needed, effective immunotherapies.

#7246 A natural antibody response associated with improved survival of SCLC patients can be actively induced in a SCLC mouse model and leads to significantly improved survival.

Diego Alejandro Velarde[1], Joseph Valdes[2], Chunli Yan[1], Sarah Elmalh[1], Hannah Lee[1], Daniel J. Mullen[1], Angie Moreno[1], Matthew A. Gladstone[1], Nicky Nie[1], Ming Li[1], Martin Kast[1], Ite A. Offringa[1]

[1]University of Southern California, Los Angeles, CA,[2]University of California San Diego, Los Angeles, CA

Background: Small cell lung cancer (SCLC) has a 5-year survival of just 8%, killing over 20,000 Americans annually, thus new therapies are urgently needed. ~15% of SCLC patients naturally develop anti-Hu (an antibody response against ELAVL4) and show improved response to therapy with significantly extended survival. Rare SCLC patients develop a severe and sometimes lethal autoimmune response against ELAVL4 and can show complete SCLC regression. We determined that the antibody-initiating antigenic epitope consists of ELAVL4 isoaspartylated (isoAsp-ELAVL4) in its unstructured N-terminal region (aa 1-38). Isoaspartylation is an immunogenic type of protein damage that is normally repaired but appears abnormally persist in ELAVL4 in SCLC. IsoAsp-ELAVL4 constitutes a cancer-specific neo-antigen. ELAVL4 has been shown to be expressed on the outside of SCLC cells. In rare cases the anti-isoAsp-ELAVL4 antibody response can lead to autoimmunity through epitope spreading to unmodified ELAVL4.

Methods: Here we tested whether actively inducing an immune response against recombinant isoaspartylated Elavl4 in a mouse SCLC model improves survival. We used a *Trp53*$^{fl/fl}$; *Rb1*$^{fl/fl}$ inducible SCLC mouse model to examine both: whether immunization with isoAsp-Elavl4 prior to SCLC induction is protective, and whether immunization with isoAsp-ELAVL4 extends survival following completion of cisplatin+etoposide therapy. Mice were immunized with a recombinant N-terminal fragment of Elavl4 (aa 1-117) generated in Clear Coli and incubated under isoaspartyl-inducing conditions (phosphate-buffered saline at 37°C for 7 days), then emulsified in incomplete Freund's adjuvant (IFA). The negative control was phosphate-buffered saline in IFA; recombinant Elavl4 naturally undergoes isoaspartylation even after short periods at physiological conditions, preventing its use as a negative control. The trajectories of mice were closely monitored with a detailed body metric score and serum was collected from blood draws every 2 weeks to monitor the anti-Elavl4 antibody response.

Results: ELISA data showed that all isoAsp-Elavl4-immunized animals became immune responsive against isoAsp-Elavl4, and just as in human SCLC patients, a small fraction of control-immunized animals spontaneously developed anti-Elavl4 reactivity. Immunization alone before SCLC induction in the absence of chemotherapy did not improve survival. In contrast, immunization following cisplatin+etoposide therapy significantly extends overall survival ($p = 0.00088$).

Conclusions: An immune response against isoAsp-Elavl4 can be actively induced, and when given after chemotherapy can significantly improve SCLC overall survival in a mouse model.

#7247 Leveraging advanced mass spectrometry for enhanced immunopeptidomics in human and murine cells.

Richard C. Jones[1], Michael J. Ford[1], Daneil A. Bochar[2], Michael R. Pisano[2]

[1]MS Bioworks, LLC, Ann Arbor, MI,[2]AnchorBio Solutions, Ann Arbor, MI

Immunopeptidomics is the study of peptides presented by Class I and Class II Major Histocompatibility Complexes (MHC). Presented peptides originate from a complex intracellular processing pipeline, culminating in the presentation of proteolytically derived fragments on the cell surface bound to MHC molecules. Advances in our understanding of the immune system have spurred significant interest in identifying these peptides and characterizing the immunopeptidome. Recent advances in mass spectrometry have significantly increased sensitivity, enabling unprecedented depth of immunopeptidome coverage and facilitating assays with reduced starting material requirements. To build on recent advancements, we utilized the Orbitrap Astral mass spectrometer, a cutting-edge technology offering superior sensitivity and resolution, to profile immunopeptidomes from human and murine cell lines. Comparative analyses with traditional immunopeptidomics workflows highlighted the Orbitrap Astral's remarkable ability to enhance peptide identification, particularly for low-abundance peptides that were previously challenging to detect. This advancement enabled a deeper and more comprehensive characterization of the immunopeptidome, unveiling valuable insights into antigen presentation. The integration of the Orbitrap Astral represents a major advancement in the field of immunopeptidomics, facilitating unprecedented sensitivity in the profiling of antigen presentation. These findings have important implications for cancer research, particularly in the development of targeted immunotherapies and the broader understanding of immune responses in oncology.

#7248 Expression profiles of 10 common cancer-specific antigens collected for the development of cancer vaccines and T cell therapies applicable to most solid cancer patients.

Tetsuya Nakatsura, Kazumasa Takenouchi, Jun Kataoka, Yusuke Ito, Sae Kikuchi, Hiroki Kinoshita, Kazunobu Ohnuki,, Toshihiro Suzuki, Nobuo Tsukamoto

National Cancer Ctr. Japan, Kashiwa, Japan

We clinical trialed a peptide vaccine derived from the cancer-specific antigen, glypican-3 (GPC3). There have been cases of multiple patients with advanced cancer who responded to the peptide vaccine after just a few doses, and seven patients with refractory pediatric cancer have survived for 10 years without a recurrence, so the peptide vaccine is also expected to be effective in preventing recurrence. On the other hand, we have also seen several cases of GPC3 expression negative cancer recurrence, revealing the limitations of peptide vaccines with a single antigen. To overcome the heterogeneity of individual cancers and apply the antibody to a wide range of solid cancer patients, we collected 10 common cancer-specific antigens, such as GPC3. In this study, we performed immunohistochemical analysis of various solid cancer specimens using antibodies against ROBO1, TGFBI, AFP, EphB4, CLDN1, and LAT1 in addition to GPC3, HSP105α, FOXM1, and SPARC, which we have previously studied. These antigens were frequently expressed in various solid cancers but shown to be rarely expressed, with some exceptions, in non-cancerous normal organs adjacent to the cancer. Even if a normal cell expresses an antigen protein, if the cell does not express HLA class I on its cell membrane, it can escape attack by cytotoxic T lymphocytes (CTL). Many non-cancerous normal cells, including hepatocytes that express HSP105α and pancreatic acinar cells that express CLDN1, do not express or only weakly express HLA class I, and it has been determined that the risk of adverse events from CTLs induced by vaccines containing these antigens or from T cell receptor (TCR)-engineered T cell therapy is low. In our other study, we have identified many peptides derived from these 10 common cancer-specific antigens with higher CTL induction capacity than the GPC3 peptide used in the clinical trial. We are currently developing peptide vaccines and mRNA vaccines. Identifying many TCRs that react to peptides and developing TCR-T cell therapy is also possible. For CTLs to be effective, HLA class I must be expressed on the surface of cancer cells. It was revealed that most solid cancers, except for lung adenocarcinoma and pediatric cancer, frequently express HLA class I on the cell membrane. In addition, it was revealed that the cell membrane antigens EphB4, CLDN1, and LAT1 are frequently expressed in various solid cancers. CAR-T cell therapy targeting these antigens may be a savior for many solid cancer patients. In this study, we clarified the expression profiles of 10 common cancer-specific antigens collected to develop cancer vaccines and T cell therapies that can be applied to most solid tumor patients. We will continue to develop cancer immunotherapies that target these multiple common cancer-specific antigens.

#7249 TME hypoxia drives immunopeptidomic deficiencies in non-small cell lung cancer by blocking translation of interferon stimulated genes within the MHC I pathway.

Matthew G. Smith, Alexis Ramos, Heena Panchal, Adam Mailloux

Microbiology and Immunology, University of Iowa, Iowa City, IA

Loss or reduction in the expression of interferon stimulated genes (ISGs) which augment the MHC class I presentation pathway (MHC1PP) predict poor responsiveness to immunotherapy as these genes are required for tumor rejection mediated through $CD8^+$ T cells. Understanding how these MHC1PP components are regulated is critical for the design of strategies to enhance immunotherapy responses in solid tumors, particularly those deemed "cold" and poorly immunogenic through low-level expression of the MHC1PP. Here, we present evidence that tumor hypoxia, a hallmark of solid cancers, blocks the translation of ISGs comprising the MHC1PP. We first established that tumor hypoxia *in vitro* (2% O_2) blocks IFN-γ induction of MHC1PP components including the immunoproteasome (IP) proteolytic subunits and ER chaperones and transporter proteins involved in generating a peptide-MHC I complex (p-MHC I) via Western blot analysis of human (A549) and murine (LLC) non-small cell lung cancer (NSCLC) lines cultured at normoxia (20% O_2) versus hypoxia. We then assessed the immunopeptidome of A549 cells through immunoprecipitation of intact p-MHC I and analysis of presented antigen via LC-MS based immunopeptidomic workflows. We showed that under normoxia, IFN-γ induction of the MHC1PP results in significantly enhanced antigen diversity and a three-fold increase in total unique tumor antigens, while hypoxia completely abolishes this augmentation of the immunopeptidomic landscape. Mechanistic studies indicate that while MHC1PP components are blocked at the protein level, mRNA transcript levels are largely unaffected as determined by RT-PCR of A549 cultures. 5-methylcytosine (m5C) ELISA experiments showed that hypoxia significantly increases the abundance of m5C modifications on RNA and reversing this accumulation through RNA but not DNA specific methyltransferase inhibitors corresponds with restored protein expression of MHC1PP components in hypoxic A459 cells, suggesting a potential epitranscriptomic mechanism of translation regulation. *In vitro*, restoring oxygen to A549 cells rapidly reverses the blocked induction of MHC1PP components. To corroborate this *in vivo*, subcutaneous LLC tumors were grown on C57Bl/6 mice subjected to whole body hyperbaric oxygen therapy (HBOT) versus controls. Compared to controls, HBOT treated mice had significantly smaller tumors, showed prolonged survival, and exhibited greater $CD8^+$ tumor infiltrating lymphocyte (TIL) activation status. Overall, these studies indicate that tumor hypoxia regulates the translation of ISGs comprising the MHC1PP, potentially driving or contributing to immunologically “cold” TME in solid cancers such as NSCLC, and restoring tumor oxygen *in vivo* is a potential strategy to augment tumor immunogenicity and improve responses to additional treatment modalities.

#7250 Extracellular acidity in the TME interferes with the IFN-γ induction of the immunoproteasome.

Matthew G. Smith, Alexis Ramos, Heena Panchal, Adam Mailloux

Microbiology and Immunology, University of Iowa, Iowa City, IA

The immunoproteasome (IP) is a component of the MHC class I presentation pathway (MHC1PP) that is induced by IFN-γ, functions to augment the immunogenicity of cancer cells by generating optimal tumor antigens from polypeptide precursors, and is correlated with favorable responses to immunotherapy. Understanding tumor intrinsic factors that regulate the IP in cancer is essential for addressing immunologically cold tumors which respond poorly to immunotherapy. Extracellular acidity (pH 6.5) is a hallmark of solid tumors and despite being shown to impair $CD8^+$ anti-tumor immunity, remains understudied as a driver of immune-evasion in cancer. Here, we present data that extracellular acidity *in vitro* can restrict the induction of the catalytically active subunits of the IP, in particular 20s proteasome subunit beta type 9 (β1i) and 20s proteasome subunit beta type 10 (β2i). Various human and murine cancer cell lines (Human: pancreatic ductal adenocarcinoma PANC1, hepatocellular carcinoma HEPG2, non small cell carcinoma A549; Murine: non small cell carcinoma LLC) were cultured in control media (DMEM pH 7.4) versus acidic media (DMEM pH 6.5) and stimulated with IFN-γ to induce the IP. Cell lysates were assessed by Western blot and demonstrated a sharp reduction in the protein induction of β1i and β2i, which are both required for the formation of the mature IP, under acidic conditions compared to controls. RT-PCR analysis of A549 cells indicates that these proteins are blocked transcriptionally as well as translationally. Mechanistically, we demonstrate via Western blot that activation of signal transducer and activator of transcription 1 (STAT1), the critical transcription factor required for IFN-γ induction of the IP, is delayed in acidic conditions compared to controls. We further show that signal transducer and activator of transcription 3 (STAT3), a pro-tumorigenic transcription factor and antagonist of STAT1 transcriptional activity, is activated under acidic conditions in A549 cells and furthermore IFN-γ enhances this STAT3 activation but only under acidic conditions. Functionally, we show via flow cytometry that downstream of the blockade in IP subunit induction that occurs under acidic conditions, surface MHC I expression is diminished. Overall, these studies indicate extracellular acidity in the TME restricts the induction of IP components potentially through a STAT3 dependent mechanism, suggesting that targeting STAT3 activation in acidic tumors may improve tumor immunogenicity and responses to immunotherapy.

IMMUNOLOGY: Novel In Vivo, In Vitro, and In Silico Models
Poster Session

#7254 Mouse models for alleviating GvHD and assessing on-target off-tumor toxicity of bispecific T-cell engagers.

Hongyan Sun[1], Bei Zhang[1], Yunlong Jiang[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Bispecific T cell engagers (TCEs), which simultaneously target CD3 on the surface of T cells and a tumor-associated antigen (TAA) located on cancer cells, have shown great promise in tumor treatment. However, multiple factors including targets, indications, dosage and immunogenicity influence the efficacy and safety of TCEs. Furthermore, the intricate mechanism of action may limit the translatability from preclinical study to clinical application. To improve the translation of early research findings into effective therapeutic strategies, we introduced two optimized mouse models for preclinical evaluation of TCEs.

Due to poor cross-species reactivity of anti-CD3 and anti-TAA antibodies, mice that express wild type murine CD3 molecules are not suitable for the evaluation of TCEs. Severe immunodeficient animals engrafted with both human T cells and cancer cells represent an ideal model. However, graft-versus-host disease (GvHD) is often observed, which can make data interpretation challenging. To this end, the NCG-MHC-dKO mouse model was developed by knocking out both murine MHC class I and II molecules in the NCG background. Compared to conventional NCG mice, NCG-MHC-dKO mice alleviated the GvHD response and prolonged the life span of PBMC-engrafted animals, thereby extending the therapeutic window. We have verified the efficacy of talquetamab, a GPRC5D-directed T cell engager, in huPBMC-NCG-MHC-dKO mice inoculated with NCI-H929 cell line. Talquetamab could significantly inhibit tumor growth in NCG-MHC-dKO mice, with the animals maintaining stable body weight and healthy condition throughout the treatment period. These findings highlighted NCG-MHC-dKO mice as an ideal platform for evaluating the efficacy of TCEs.

Although the huPBMC-NCG-MHC-dKO model is very powerful for the efficacy evaluation of TCEs, it cannot be used to evaluate on-target off-tumor toxicity due to the absence of human TAA in mouse tissues with compromised immune systems. To this end, the BALB/c-hCD3EDG mouse model was developed by inserting the entire gene regions including regulatory sequences of the human CD3E, CD3D, and CD3G genes into the mouse genome, while simultaneously deleting the endogenous mouse CD3e, CD3d, and CD3g genes. Replacing the murine CD3 molecules with human counterparts did not impact the immune system of BALB/c-hCD3EDG mice. In addition, we have developed multiple human TAA knock-in mouse models in the BALB/c-hCD3EDG background. The expression of TAAs in these mice resembled that in humans. Together, these models can be used not only to evaluate the efficacy, but also on-target off-tumor toxicity of TCEs.

In conclusion, our mouse models provide valuable tools to increase the translatability of preclinical models to evaluate TCEs.

#7255 Novel anti-PD(L)1 resistance models for post-anti-PD(L)1 drug development.

Hongyan Sun[1], Yan Wang[1], Zhu Fang[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Although cancer immunotherapy utilizing blockade of the PD-1/PD-L1 checkpoint has revolutionized the treatment of a wide variety of malignancies, leading to durable therapeutic responses, it is ineffective in many patients who developed drug resistance after initial response. Therefore, the establishment of robust preclinical anti-PD-1 resistance models is of paramount importance for unraveling drug resistance mechanisms and developing novel treatment strategies.

The mechanisms of anti-PD-1/anti-PD-L1 resistance include insufficient presentation of tumor antigens, downregulation of MHC class I molecules, dysregulated IFN-γ signaling pathways, and the immunosuppressive tumor microenvironment.

GemPharmatech has established 3 models of anti-PD-1 resistance. (1) Drug induced model: BALB/c-hPD1 mice were subcutaneously transplanted with CT26 cells and treated with anti-PD-1 (KEYTRUDA®) twice weekly. Non-responsive tumors were excised, dissociated, cultured, and then re-implanted into naïve mice for anti-PD-1 treatment to maintain screening pressure. The induced model of anti-PD-1 resistance was obtained after repeated screening cycles. (2) Genetically engineered model: Engineered anti-PD-1 resistant models were established by knocking out either B2M or STK11 in CT26, which are known to confer specific genetic alterations to anti-PD-1 resistance. (3) Primary resistance model.

CT26 cells acquired anti-PD-1 resistance after a series of KEYTRUDA treatment and re-implantation demonstrated a stable anti-PD-1 resistant phenotype. Compared with parental cell lines, drug-resistant CT26 cell showed a significantly faster tumor growth kinetics in vivo. RNA sequencing data revealed a set of genes disregulated between the resistant and parental cell lines, providing insight into the resistance mechanism to anti-PD-1 therapy. In the engineered PD-1-resistant CT26 model, knocking out STK11 dampen CT26's response towards anti-PD-1 treatment. After ablation of STK11, CD8+ cytotoxic T lymphocyte infiltration was decreased, and myeloid-derived suppressor cells (MDSCs) significantly accumulated in the tumor microenvironment. Additionally, STK11 deletion was associated with reduced PD-L1 expression in tumor cells, suggesting that immunosuppressive microenvironment contributed to the development of resistance.

In conclusion, preclinical anti-PD-1 resistance models are valuable tools for researchers to dissect the complexity of anti-PD-1 resistance mechanisms and provide important guidance for the biomarker discovery as well as development of innovative therapeutic strategies.

#7256 Development of a human immune system reconstituted mouse model without the function of FcγRs expressed on mouse innate immune cells.

Jay Zhang, Yanhui Nie, Dexuan Huang, Xiao Liu, Qingqing Xu, Qiang Liu, Shuangshi Liu, Xiaofei Zhou

Biocytogen, Waltham, MA

Severe immunodeficient mice have been widely used in xenotransplantation research and for validating various immunotherapy methods. We utilized gene editing techniques to knock out the IL2rg gene in NOD scid mice, resulting in a severe immunodeficient mouse model that lacks mature T, B and NK cells, but retains most of the myeloid cells, which we named B-NDG mice (#110586). Human immune cells can be successfully reconstituted in B-NDG mice (#110586). However, due to the lack of effective support from human cytokines, only human T cells can be reconstituted in B-NDG mice (#110586). IL15 is a key cytokine in the development and maturation of NK cells and also promotes the survival of memory CD8+ T cells. When validating the *in vivo* efficacy of therapeutic IgG antibodies using a mouse model with a reconstituted human immune system, the antibodies may not only bind to the reconstituted human immune cells to exert pharmacodynamic activity but also bind to various Fcγ receptors expressed on mouse innate immune cells, such as macrophages and neutrophils. This interaction may lead to antibody neutralization or antibody-dependent cellular phagocytosis (ADCP), affecting the accuracy of the efficacy validation.Biocytogen developed B-NDG hIL15, FcγR KO mice (#112653) in which the mouse IL15 gene was replaced by human IL15 gene. Then the mouse genes Fcgr1, Fcgr2b, Fcgr3 and Fcgr4 were knocked out. Mouse FcγRI, FcγRIIb, FcγRIII and FcγRIV were not detectable in B-NDG hIL15, FcγR KO mice (#112653). Human IL15 was detectable in homozygous B-NDG hIL15, FcγR KO mice (#112653). The concentration of human IL15 in the serum was 112 pg/mL, similar to that in B-NDG hIL15 mice (#110600). The frequency of mouse granulocytes, monocytes, macrophages and DCs in the blood and spleen of B-NDG hIL15, FcγR KO mice (#112653) are similar to that in B-NDG hIL15 mice (#110600). Binding analysis of rituximab analog (in-house) showed that rituximab-bound cells were not detectable in B-NDG hIL15, FcγR KO mice (#112653). B-luc Daudi cells (#310677) were intravenously injected into B-NDG hIL-15, FcγR KO mice (#112653). After 3 days, mice were grouped when the intensity of the imaging signal reached approximately 1.2×10^6 p/sec, at which time human NK cells expanded *in vitro* were engrafted into the mice and the mice were treated with anti-human CD20 antibody rituximab. The results showed that rituximab was efficacious in controlling B-luc Daudi growth in human NK cells engrafted B-NDG hIL15, FcγR KO mice (#112653).

#7257 Humanized GDF15 model for simulating weight loss induced by GDF15 secretion in tumors.

Jay Zhang, Suman Zhao, Ruili Lv, Yongshun Li, Saina Ma, Yanling Wang

Biocytogen, Waltham, MA

GDF15, also known as growth differentiation factor-15, is expressed by multiple tissues and secreted into the serum. It regulates numerous physiological processes, such as affecting food intake and causing weight loss, by binding to the receptor GFRAL. Under normal physiological conditions, GDF15 levels are low; however, its expression significantly increases under pathological conditions such as diabetes and cancer. In some special types of advanced cancers, GDF15 levels can rise and trigger anorexia-cachexia syndrome. We created humanized B-hGDF15 mice by replacing the mouse GDF15 gene with the human GDF15 gene in situ. Additionally, we established a B-hGDF15 MC38 cell line by inserting an exogenous promoter and the human GDF15 CDS sequence at the mouse GDF15 locus in MC38 cells. RT-PCR was conducted to detect mRNA levels of hGDF15 in B-hGDF15 mice, confirming the absence of mouse *Gdf15* expression and the presence of human *GDF15* expression. We performed ELISA to detect the protein expression levels of hGDF15 in B-hGDF15 mice and B-hGDF15 MC38 humanized cell line, confirming successful expression of the hGDF15 protein. When B-hGDF15 mice were inoculated with B-hGDF15 MC38, tumor model was developed successfully, and a trend of body weight loss was observed compared with the wild-type MC38 group. Subsequently, we performed an efficacy experiment in B-hGDF15 mice inoculated with B-hGDF15 MC38. After 7 days of inoculation, the mice were grouped based on body weight and tumor size, and the treatment group received 10 mg/kg of a ponsegromab analog on the same day. We observed significant weight gain in the treated group compared to the control group, indicating that B-hGDF15 mice and B-hGDF15 MC38 provide an excellent preclinical in vivo model for testing GDF15-targeted drugs.

#7258 Enhancing TIL efficacy in NSCLC through epigenetic reprogramming and computational modeling.

Daniel R. Plaugher[1], Avery R. Childress[1], Christian M. Gosser[1], Dave-Preston Esoe[1], Xuilong Song[1], Jinpeng Liu[2], Christine F. Brainson[3]

[1]Toxicology and Cancer Biology, University of Kentucky, Lexington, KY,[2]Cancer Biostatistics, Markey Cancer Center, University of Kentucky, Lexington, KY,[3]Toxicology and Cancer Biology, Markey Cancer Center, University of Kentucky, Lexington, KY

Novel therapeutic protocols are desperately needed to treat non-small cell lung cancer (NSCLC), the deadliest cancer world-wide. Recently, utilizing a patient's tumor-infiltrating lymphocytes (TIL) is proving to be a viable and highly personalized approach. Despite its promise, many obstacles remain, such as refining expansion protocols for better *in vivo* TIL proliferative potential, improving T cell ability for homing-to and targeting tumor cells upon re-infusion, and avoiding IL-2/lymphodepletion related side effects. We hypothesize that inhibiting epigenetic enzyme EZH2 (EZH2i) will improve both TIL expansion and infusion outcomes in NSCLC patients. Yet, there are likely mechanisms of T cell suppression that EZH2i may not overcome. To address and identify these mechanisms, stochastic mathematical modeling of gene signaling in cancer has risen as a useful tool. Thus, we further hypothesize that modern sequencing data and mathematical biology can discover alternative mechanisms of T cell suppression that will suggest novel targets for TIL-combination treatment.

To test these hypotheses, we have tested the EZH2 inhibitor valemetostat with anti-PD1 in a murine model of non-small cell lung cancer. We observed tumor regression and strong IFN-gamma T cell responses in combination treated animals. We also observed up-regulation of both major histocompatibility complexes, greater pro-T cell cytokine signaling, and myeloid populations became more tumor-eliminating. To translate these findings to TILs, we are currently securing NSCLC samples from our Biospecimen Core, establishing patient-derived tumoroids, and expanding TILs *ex vivo*. TILs will be expanded with/without EZH2 inhibitor valemetostat (Val) under "young" protocols. At *ex vivo* endpoint TILs will be assessed for Val-driven differences in viability, differentiation state, and reactivity via flow cytometry. To complement or studies with an *in silico approach*, we are utilizing libraries of publicly available NSCLC data to perform bioinformatic analysis and implemented equation learning techniques to infer NSCLC tumor signaling networks from clinical data between immunotherapy responders and non-responders. Differentiation patterns will be assessed as a function of pseudo-time-course data to inform predictions of signal transduction pathways. Lastly, mathematical phenotype control theory will be used to uncover potential targets within the tumor to boost TIL response in NSCLC.

Given that advanced stage lung cancers remains refractory to most treatments, determining methods to improve precision medicine options such as TIL therapy is an important goal for the field. Our blending of classic bench science with bio-informatics has the potential to deepen our understanding of TIL therapy and to identify new way to improve therapeutic responses.

Funding: T32 CA165990 (DRP), R01 CA237643 (CFB), R01 HL170193 (CFB), P30 CA177558 (Markey Shared Resources).

#7259 An in vivo humanized mouse model for human dendritic cell reconstitution to evaluate efficacy of tumor immunotherapy by B-NDG Flt3 KO mice.

Fengqian Chen, Shujin Zhang, Fengxing Gu, Shaozu Fu, Yanling Wang

Biocytogen, Waltham, MA

Fms-like tyrosine kinase receptor 3 (Flt3) is a membrane protein that is strongly expressed on hematopoietic stem cells (HSCs). FLT3LG (FLT3 ligand) is a growth factor that can stimulate the proliferation, differentiation, and survival of these cells when it binds to its receptor FLT3. The Flt3/Flt3L signaling axis indeed plays an important role in the production of conventional dendritic cells (cDCs) and plasmacytoid dendritic cells (pDCs). Knockout of mouse Flt3 results in a reduction of mouse dendritic cells (DCs), which increases the availability of mouse Flt3L to the human receptor after human HSCs transplantation, thereby supporting the development of human immune cells, particularly dendritic cells.
Biocytogen developed B-NDG Flt3 KO mice by knocking out the Flt3 gene in the NDG background. mFLT3 was detectable in DCs and CD117+ cells of B-NDG mice, but not in homozygous B-NDG Flt3 KO mice. To determine whether the knockout of Flt3 will affect the expression of FLT3LG. Serum were isolated from B-NDG mice and homozygous B-NDG Flt3 KO mice. Expression level of mouse FLT3L were analyzed by ELISA. Mouse FLT3L was detectable in B-NDG mice and homozygous B-NDG Flt3 KO mice. Levels of mFLT3L were substantially elevated in homozygous B-NDG Flt3 KO mice compared to B-NDG mice. To evaluate whether the knockout of Flt3 impacts the frequency of leukocyte subpopulations, Bone marrow cells were isolated from B-NDG mice and homozygous B-NDG Flt3 KO mice, Frequencies of T cells, B cells, NK cells, granulocytes, monocytes, macrophages in B-NDG Flt3 KO mice were like those in B-NDG mice. Frequencies of DCs in B-NDG Flt3 KO mice were lower than those in B-NDG mice.
In summary, the significant decrease of DCs in B-NDG Flt3 KO mice creates an opportunity for the successful reconstruction of human DCs, which could have a significant positive impact on tumor immunotherapy.

#7260 Predicting the starting dose and step-up regimen for first-in-human trial of T-cell engagers using mechanistic mathematical modeling.

Oleg Demin Jr, Galina Kolesova, Dmitry Shchelokov

InSysBio CY, Paphos, Cyprus

The minimal anticipated biological effect level (MABEL) approach is recommended for selecting a safe clinical starting dose for T-cell engagers (TCEs). This approach estimates the minimal recommended starting dose (MRSD) by setting predicted drug exposure in humans below the concentration that results in a desirable percentage of maximal pharmacological activity (PA) observed in vitro (in the range of 20%-50%, e.g., EC20). However, this method may lead to a low MRSD and multiple dose escalations, resulting in sub-therapeutic doses (Saber et al. ***Regul Toxicol Pharmacol***. 2017 Nov;90:144-152). The aim of our study was to apply quantitative systems pharmacology (QSP) modeling to predict the MRSD and step-up dosing regimen for HPN536, a T-cell engager targeting mesothelin (MSLN).

The translational QSP model consists of two parts: an *in vitro* model and a pharmacokinetic (PK), receptor occupancy (RO), and PA model. The *in vitro* model was developed to describe published data on T-cell dependent cytotoxicity, cytokine secretion, and T-cell activation in the presence of various HPN536 concentrations, and to identify EC50 expressed in terms of the number of trimers—complexes of HPN536 with CD3 and MSLN in the immunological synapse (IS) between T-cells and cancer cells. PK parameters were fitted using data on cynomolgus monkeys and translated to humans using a standard allometric scaling approach. The PK/RO/PA model for cancer patients includes the distribution of TCE into the tumor (ovarian cancer), binding of HPN536 with CD3 and MSLN, trimer formation in IS, and PA based on EC50 values identified in the *in vitro* model. PA depends on the number of trimers in the tumor. Variability was implemented in the model, including MSLN expression, PK, T-cell density in the tumor, and tumor size.

Starting dose estimates were calculated as a dose range corresponding to 20%-50% PA. The MRSD range predicted by the model was higher than the range calculated by the conventional MABEL PK-driven approach. The starting dose predicted by the model is 40 ng/kg based on cytokine assays, whereas the starting dose in the phase 1 trial was 6 ng/kg (established by the MABEL PK-driven approach), and CRS grade 3 was observed at 54 ng/kg without dexamethasone pretreatment. The optimal step-up regimen is the one that minimizes peak trimer levels and results in the highest trough trimer level at the target dose. Considering once-weekly administration of the HPN536 target dose, the optimal regimen with two step-ups was as follows: 0.001 mg/kg given on day 1, 0.003 mg/kg given on day 4, and 0.01 mg/kg QW started on day 8 (target dose).

Applying QSP modeling to predict MRSD in addition to the MABEL PK-driven approach might help reduce the number of dose escalation steps, exposing patients to sub-therapeutic doses in first-in-human trials, and optimize step-up dosing regimens.

#7261 Dynamical mathematical models reveal that cell cycle inhibitors promote immunogenicity and T cell cytotoxicity when combined with IL-15 in estrogen receptor positive breast cancer cell lines.

Jiyeon Park[1], Frederick R. Adler[1], Aritro Nath[2], Jason I. Griffiths[2], Patrick A. Cosgrove[2], Kimya Karimi[2]

[1]Department of Mathematics, University of Utah, Salt Lake City, UT,[2]Department of Medical Oncology and Therapeutics Research, Beckman Research Institute, City of Hope National Medical Center, Monrovia, CA

Advanced estrogen receptor positive (ER+) breast cancers are typically treated with endocrine therapy (ET) plus cell cycle inhibitors (CCI); however, nearly 20% of these cancers recur due to treatment resistance. Our previous study of tumor intrinsic properties during CCI plus ET treatment found that CCI-resistant cancer cells are associated with diminished immune-activating signals to cytotoxic CD8+ T cells due in part to reduced interleukin-15 (IL-15) signaling, a potent immunostimulatory cytokine. This finding motivates our study of combination IL-15/T-cell based immune-activating treatment regimen development. However, the fact that CCI also inhibit immune cells challenges this immunotherapy development, creating complex interactions that require mathematical modeling in collaboration with *in vivo* experiments to analyze. To study these complex interactions, we develop a nonlinear ordinary differential equation mathematical model that describes the tumor ecosystem of interacting cancer cells and cytotoxic T cells linked with pharmacokinetics of ribociclib (CCI) and IL-15. We design experimental model using 3D spheroids of CCI-sensitive and resistant cancer cell lines in monoculture or co-cultured with patient-derived cytotoxic T cells and tracked over 5 days of growth. These spheroids were treated with CCI alone or in combination with IL-15. This dynamical model accurately fits experimental data by quantifying the effects of both treatments on the growth rates and interactions between cancers and T cells. Key parameters of our model quantify how treatments impact the promotion of T cell recruitment and T cell activation by cancer cell antigens. These combine to lead to the subsequent killing of cancer cells. Analyzing these parameters under various dose drug combinations drives to three main findings: (1) proliferation of both cell types are suppressed by CCI, while only T cells are activated by IL-15, (2) CCI, despite slowing T cell proliferation, promote immunogenicity and immune cell toxicity in combination with IL-15, and (3) the enhanced immune capacity under this combination treatment is higher in ribociclib-resistant cancer cell lines than in sensitive cell lines. The mathematical modeling reveals that combining immune-activating treatment (IL-15) with a cell cycle inhibitor (ribociclib) outperforms single therapy in limiting cancer cell growth. Furthermore, cancer cells resistant to cell cycle inhibitors are more effectively targeted by this combination therapy. For future work, we will use the mathematical model to propose optimal therapy regimens that minimize the total dosage of the two drugs and maximize treatment response with long-term goal of overcoming recurrence due to drug resistance by strengthening immune surveillance in ER+ breast cancers.

#7262 Organoid-based prediction of immune checkpoint inhibitor response in gastric cancer: A correlation with clinical outcomes.

H. Kim[1], S. Chang[2], H. Jun[2], U.-J. Yun[3], J. Kim[2], H. Kim[4], T. Kim[5], M. Jung[6];

[1]Department of Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Podo Therapeutics, Seongnam-si, Korea, Republic of, [3]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of, [5]Division of Gastroenterology, Department of Internal Medicine, Yonsei cancer center, Yonsei University College of Medicine, Seoul, Korea, Republic of, [6]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Research and development in immune checkpoint inhibitor (ICI) therapy are rapidly advancing across various cancer types. However, accurately predicting treatment responses remains a significant challenge due to factors such as patient-specific immune system variability, tumor heterogeneity, and genetic differences. Current model systems for evaluating ICI efficacy also face limitations. While organoids replicate patient-specific tumor characteristics, their lack of immune components hinders their ability to assess the complexity of immunotherapy. To address these challenges, we developed a co-culture platform combining tumor organoids with immune cells to evaluate ICI drug efficacy and predict patient-specific therapeutic responses. We collected ascites and pleural effusion samples from 88 gastric cancer patients, obtaining 109 samples and successfully establishing 63 organoids, achieving an establishment rate of 80.7%. Immunohistochemical staining and next-generation sequencing (NGS) confirmed the organoids' molecular and histological similarity to the corresponding patient tumors. Peripheral blood mononuclear cells (PBMCs) were isolated from matched blood samples and activated using cytokines such as IL-2. Patient-derived immune cells were then co-cultured with tumor organoids and treated with ICI drugs, including nivolumab, pembrolizumab, and atezolizumab, as well as chemotherapy drugs, to evaluate their anticancer efficacy. Our results showed immune cells localizing around the organoids and inducing concentration-dependent tumor cell death following ICI treatment. Drug response evaluations were conducted on 25 different organoids, and the findings were compared with the clinical responses of the corresponding patients. Among 17 patients who underwent follow-up after anticancer treatments, including immunotherapy, the co-culture platform demonstrated high predictive performance, with an accuracy of 94.12%, sensitivity of 83.33%, and specificity of 100%. Notably, sequential analysis of samples from the same patients revealed that in vitro predictions of resistance to nivolumab corresponded with clinical progression as assessed by the Response Evaluation Criteria in Solid Tumors (RECIST). These findings highlight the robustness of our co-culture platform in predicting ICI responses and underscore its potential to guide personalized immunotherapy strategies for gastric cancer patients. Related patents and rights belong to Podo Therapeutics.

#7263 Development and validation of a machine learning framework for immune phenotype classification and immunotherapy response prediction in lung cancer.

Hyun Woo Park[1], Ki Wook Lee[1], Ji Won Lee[1], Sehhoon Park[2], Young-Jun Jeon[1]

[1]Sungkyunkwan University, Suwon, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of

Tumor immune microenvironment composition significantly influences immunotherapy outcomes in lung cancer, with immune-inflamed tumors demonstrating higher response rates compared to immune-non-inflamed tumors. This study aimed to develop a machine learning framework to classify immune phenotypes in lung cancer using TCGA data and validate its utility in predicting immunotherapy response with real-world patient samples. Existing approaches, such as the Lunit SCOPE technique, have been employed for immune phenotype characterization but face limitations in handling tumor heterogeneity and adapting to diverse datasets, underscoring the need for more robust tools. A baseline machine learning model was constructed using six tree-based classifiers: Random Forest, Extremely Randomized Trees, AdaBoost, Gradient Boosting, XGBoost, and LightGBM. Feature importance scoring identified critical immune-related gene expression profiles, including markers from interferon signaling, T-cell activation, and cytokine regulation pathways. Model optimization incorporated 15 classifiers, leveraging advanced hyperparameter tuning and ensemble learning strategies to improve accuracy, Matthew's correlation coefficient (MCC), and area under the ROC curve (AUROC). Classification training and validation were performed on 447 TCGA lung cancer samples, divided into 80% training and 20% validation subsets, stratified into immune-inflamed and immune-non-inflamed phenotypes based on bulk RNA-seq gene expression datasets. The final model demonstrated robust adaptability to tumor heterogeneity and was independently tested on 87 patient samples labeled through the Lunit SCOPE framework, stratified into immunotherapy responders and non-responders. Correlation analysis assessed the relationship between immune phenotypes and therapeutic outcomes. The optimized model exceeded the performance of Lunit SCOPE, achieving an AUROC >0.90 in classifying immune-inflamed versus immune-non-inflamed samples in the TCGA dataset. Testing on real-world patient samples further confirmed its ability to accurately predict immunotherapy response, supporting the hypothesis that immune-inflamed tumors derive greater benefit from treatment. This machine learning framework demonstrates superior accuracy and adaptability compared to existing techniques, offering significant potential to improve patient stratification, reduce ineffective treatments, and guide precision immunotherapy in lung cancer. Future directions include integrating multi-omics datasets to further refine predictive capabilities and assess its generalizability across other cancer types.

#7264 AI-guided engineering and preclinical characterization of anti-PD1/IL15 mutein bifunctional fusion proteins.

Yun Zhang, Liang Tian, Chenpeng Su, Xiangyu Sun, Ran Hao, Tianhong Li, Dandan Liu, Jiyuan Tian, Xiaoqian Chen, Jian Peng, Zhenping Zhu

Helixon US Inc., New York, NY

IL15, a cytokine of the IL2 family, is pivotal for activating natural killer cells and effector/memory CD8 T cells. Clinical application with various IL15 formulations for cancer therapy, however, has been greatly hindered by its pharmacokinetics and dose-dependent systemic toxicity. A promising approach involves the fusion of IL15 with an anti-TAA antibody or an immune checkpoint antibody, in an attempt to specifically target IL15 to the tumor and its microenvironment while reducing peripheral exposure and toxicity. In this study, we generated a panel of stable IL15 variants (IL15v), utilizing an internally developed AI algorithm, with attenuated binding affinity to IL2Rβ and biological activity. We then engineered a panel of fusion proteins each comprising of a disulfide-bond stabilized IL15v, the IL15Ra sushi domain, and an anti-PD1 antibody IgG. Several lead molecules were produced with good expression level, stability and drugability. These anti-PD1/IL15v fusions not only fully retained their PD1-blocking activity, but also were significantly more potent in promoting the activation of PD1-expressing T cells, comparing to those of PD1-negative cells. In vivo pharmacokinetics and antitumor activity of these anti-PD1/IL15v fusions are currently being investigated. Anti-PD1 targeted delivery of stabilized and attenuated IL15v may provide an effective approach, with an improved safety profile, to reverse the suppressive state of tumor-infiltrating antigen-specific PD1-expressing CD8 T cells.

#7265 Using PBMC-humanized mice to identify optimal autologous CAR T products for maximized efficacy and minimized toxicity at an individual level: a study of CD19, CD22, and CD19x22-specific constructs in multiple PBMC donors.

Won Lee[1], Destanie Rose[1], Beau H. Parry[1], Joshua Gustafson[2], Rebecca Gardner[3], Heather Gustafson[4], James G. Keck[1], Jiwon Yang[1]

[1]Innovation & Product Development, The Jackson Laboratory, Sacramento, CA,[2]Seattle Children's Therapeutics, Seattle Children's Hospital , Seattle, WA,[3]Oncology, St. Jude Children's Research Hospital, Memphis, TN,[4]UW Department of Pediatrics, Ben Towne Childhood Cancer and Blood Disorders Research; Seattle Children's Research Institute; University of Washington, Seattle, WA

Chimeric antigen receptor T-cell (CAR T) therapy has revolutionized cancer treatment by providing targeted eradication of cancer cells. However, the efficacy and toxicity of CAR T cells can vary widely between individuals, posing challenges for patient-specific optimization. To address these gaps, we evaluated the efficacy, expansion, and cytokine induction profiles of CAR T using PBMC-humanized mice. Three autologous CAR T products with 4-1BB co-stimulation were manufactured from the PBMCs of three healthy human donors: CD19-specific, CD22-specific, and CD19x22-specific (dual) CAR T cells. The dual CAR T cells were transduced with lentiviral vectors encoding either CD19- or CD22-specific CARs, resulting in three distinct CAR T cell compositions: those targeting CD19 alone, CD22 alone, or both CD19 and CD22. NSG-MHC Class I/II double knock-out (DKO) mice were irradiated and engrafted with 10 million PBMCs from the same donors used for the autologous CAR T cells. Six days post-humanization, the mice were treated with one of the three autologous CAR T cells. We found that all CAR T products effectively eliminated B cells in vivo within three weeks post-treatment, while CD19 CAR Ts achieved clearance significantly faster than CD22 CAR Ts. Expansion levels of CAR T cells differed significantly by donors and constructs. Overall, mice treated with CD19 CAR Ts showed peak expansion earlier than those treated with the other two CAR Ts. Mice treated with CD22 CAR Ts reached the highest expansion across all donors during the 28-day study period. Notably, one donor treated with CD22 CAR Ts displayed more than a 10-fold higher expansion compared to the other two donors, which corresponded to decreased survival and significant body weight loss. In dual CAR T-treated mice, CAR T cells targeting CD19 alone showed more robust expansion than the others (54 to 99% of total CAR T cells, depending on timepoints and donors). Cytokine induction was both donor-dependent and CAR construct-dependent, particularly for IL-1β, IL-2, IL-3, IL-5, IL-6, and IL-10. In summary, PBMC-humanized mice are a valuable platform to assess individual variability in CAR T efficacy and toxicity. These insights highlight the need for personalized preclinical evaluations to optimize CAR T construct selection and predict patient-specific outcomes.

#7266 Nanotechnology-enabled photochemical immune stimulation in clinical veterinary models of head and neck cancers.

Michael S. Valic[1], Charly J. McKenna[2], Mark Zheng[1], Jason L. Townson[1], Harley H. L. Chan[1], Layla Pires[3], Bridget Bane[2], Sharon Tzelnick[1], Alessandra Ruaro[1], Axel Sahovaler[4], Brian C. Wilson[1], Michelle L. Oblak[2], Jonathan C. Irish[1], Gang Zheng[1]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Ontario Veterinary College, Guelph, ON, Canada,[3]Biomedical Engineering, Texas A&M University, College Station, TX,[4]University College London Hospitals, London, United Kingdom

Background: Photodynamic therapy (PDT) is a non-surgical treatment using light to activate the cytotoxicity of a photosensitizing drug in cancer cells. PORPHYSOMES (PS) are lipid-porphyrin nanoparticles with high tumor uptake and PDT efficacy as well as low skin sensitivity. We have shown that activating PS with 'sub-therapeutic' PDT light dose in mouse models of head and neck (H&N) cancer stimulates immunogenic cell death and generates robust and transferable anti-tumor immunity. Here, we demonstrate the first evidence of this photochemical immune stimulation (PCIS) using PS in veterinary patients with spontaneous H&N tumors.

Methods: Clinical veterinary trials were conducted at the Ontario Veterinary College (AUP# 4548) in companion dogs with resectable H&N cancers. PS were injected IV at 3 mg/kg. Subjects in Arm 1 of the trial underwent surgery 24-48 h post injection. Subjects in Arm 2 underwent sub-therapeutic PDT treatment (671 nm, 12.5~50 J interstitial fiber or 12.5~25 J/cm^2 surface) at 6 or 24 h post injection, followed by resection at 48 h post injection. Blood samples were collected for hematology, biochemistry, pharmacokinetic analysis and immune profiling. During surgery, the tumor and neck lymph nodes were imaged by fluorescence for PS localization before submission for pathology. Cytokine and chemokine levels were measured in plasma/serum pre and post PDT, and tumor and lymph nodes were analyzed to compare for immune cell changes between Arms 1 (control) and 2.

Results: Eight veterinary patients were recruited: 6 thyroid carcinomas, 1 oral squamous cell carcinoma, 1 oral melanoma. Three subjects were enrolled in Arm 1 and 5 in Arm 2. No significant changes in blood counts or biochemistry were detected in any dog post PS injection. The PS half-life in plasma was ~57 h, and the tumor uptake varied between 6 and 60 µg/g (mean 28 µg/g). PDT was well tolerated in all cases, with no treatment-related adverse effects reported. Increases in multiple proinflammatory cytokines and chemokines were detected within 24 h of PDT, including significant increases in IL-8 and TNF alpha. Histology confirmed enrichment in CD68$^+$ macrophages and CD16$^+$ neutrophils in the PDT-treated tumors and in multiple T cell populations in lymph nodes. The relative magnitude of immune responses post PDT correlated weakly with PDT light dose in this small dataset. Of the subjects treated with PDT (7 mo. longest follow-up to date), only 1 tumor recurrence (in lung) was reported.

Conclusions: PS injection and PDT treatments were well tolerated. Sub-therapeutic PDT simulated measurable immune responses in these spontaneous veterinary tumors, analogous to the early responses seen in mouse models, in which the impacts on tumor progression, metastasis and survival were significant. These data provide key proof of concept evidence for PS PCIS in H&N cancers and motivate the continue translation of PS into human clinical studies.

#7267 Development and validation of a novel humanized B-hTRBC1/hTRBC2 mouse model for T cell activation.

Hannah Horton, Zhixia Li, Shufeng Wang, Zhenlan Niu, Lei Zhao, Yanling Wang, Xiaofei Zhou

Biocytogen, Waltham, MA

The gene encoding the TCR constant β chain (TRBC) has two isoforms: TRBC1 and TRBC2. Each TCR (and therefore each T cell) irreversibly selects a TCR β-chain constant region encoded by either TRBC1 or TRBC2 for expression in a mutually exclusive manner. Normal T cells consist of both TRBC1 and TRBC2; however, malignant T cells contain only one of the two isoforms. In the treatment of TRBC1+ or TRBC2+ T cell malignancies, selectively targeting TRBC1 or TRBC2, respectively, can effectively eliminate the malignant clone without significantly compromising the integrity of the T cell compartment, thereby preventing severe immunosuppression.

This study introduces a novel B-hTRBC1/hTRBC2 mouse model for the investigation of T cell activation and includes an extensive analysis of its phenotypic and immunological characteristics. Gene and protein expression of human TRBC1/TRBC2 in these mice were confirmed using RT-PCR and flow cytometry, respectively. The study also found comparable development, differentiation, and distribution of immune cells in the spleen, blood, and lymph nodes between B-hTRBC1/hTRBC2 mice and wild-type C57BL/6 mice. Notably, normal T cell proliferation and cytokine production were observed in vitro in response to anti-mCD3E and anti-hTRBC1 antibody treatments, demonstrating the functionality of humanized T cells in these mice.

In summary, our data indicate that B-hTRBC1/hTRBC2 mice provide a powerful preclinical model for *in vivo*/*ex vivo* evaluation of T cell activation.

#7268 A novel immunocompetent tumor model reveals the immunomodulatory effects of trastuzumab deruxtecan.

J. Steele, J. Balko;
Vanderbilt University School of Medicine, Nashville, TN

The αHER2 antibody-drug conjugate, trastuzumab deruxtecan (T-DXd), has revolutionized the treatment of breast cancer. However, it is being combined with immunotherapy in clinical trials without rigorous preclinical validation. Few studies have explored T-DXd's immunologic impact, and comprehensive preclinical data supporting immunotherapy combinations is lacking. This gap stems from trastuzumab's inability to bind to rodent HER2. Consequently, many existing models rely on human-derived cell lines or xenografts transplanted into immune-deficient mice, thus overlooking T-DXd's adaptive immunologic effects. Other strategies involve inoculating murine tumors expressing human HER2 into immunocompetent mice; however, this approach increases the immunogenicity of the model and often leads to tumor rejection or delayed growth due to xenoantigens arising from sequence differences between mouse and human HER2. To address this, we have developed a robust, immunocompetent tumor model to study trastuzumab-based therapies by minimally editing the mouse HER2 trastuzumab binding region. This tumor model, which we termed HER2^{X}, binds trastuzumab, is nonimmunogenic, and is sensitive to T-DXd treatment. Here we demonstrate the use of this HER2^{X} tumor model to elucidate the immunologic effects of T-DXd. Cytometry by time of flight (CyTOF) analysis revealed significant shifts to proinflammatory, antitumor immune populations, including T cells, NK cells, and M1-like macrophages, in T-DXd treated versus untreated EMT6 HER2^{X} tumors from immunocompetent mice. Accordingly, the proportion of M2-like macrophages, neutrophils, and monocytes were significantly lower in the T-DXd treated tumors. Notably, 60% of T-DXd complete responder mice were also resistant to rechallenge with EMT6 HER2^{X} tumor cells, indicating immunologic memory and potential involvement of adaptive immunity. Furthermore, T-DXd treatment potentiated EMT6 HER2^{X} antitumor responses in immunocompetent mice compared to athymic nude mice. Finally, co-administration of αPD-L1 and T-DXd treatment further increased survival and response compared to either monotherapy in HER2^{X} tumors. Together, these data suggest T-DXd induces a proinflammatory tumor-immune microenvironment, necessitates adaptive immunity for effective antitumor response, and may provide combinatorial benefit with immunotherapy in clinical settings. Further work is needed to determine the mechanism behind these immunomodulatory effects, and how we can leverage this knowledge to inform and improve treatment strategies in patients.

#7269 The humanized CRBN mice model facilitates PROTACs studies based on CRBN ligands.

Mari Kuraguchi, Ying Zhao, Chonghui Liu, Xiao Liu, Jiansu Zhang

Biocytogen, Waltham, MA

CRBN ligands, which have become increasingly popular as E3 ligase ligands, are important in designing PROTACs (Proteolysis Targeting Chimeras) and molecular glue degraders, aiding in targeted protein degradation. CRBN, part of the CRL4 E3 ubiquitin ligase complex, binds to specific proteins and promotes their degradation, a process essential for cell regulation and apoptosis. In multiple myeloma (MM) treatment, drugs targeting CRBN, like thalidomide and lenalidomide, show effectiveness by altering substrate specificity of CRBN, targeting tumor-associated proteins for degradation. CRBN-based PROTACs are emerging as promising cancer treatments by directing CRBN to target proteins for degradation. Biocytogen has developed the B-hCRBN mouse model, engineered to express human CRBN instead of the mouse version by inserting the full-length human *CRBN* CDS into the mouse *Crbn* exons 2-3. Expression of human CRBN mRNA and proteins were exclusively detected in homozygous humanized mice and these mice also demonstrated increased IL2 production in CD4+ T cells in response to lenalidomide treatment, confirming successful generation of the model. In summary, B-hCRBN mice are effective tool for preclinical *in vivo* efficacy and safety evaluation of CRBN-targeted drugs, including CRBN-based small molecules, molecular glues, and PROTAC drugs.

#7270 Novel humanized cell and murine models expressing tumor-associated antigens for ADC toxicity and IO combination evaluation.

X. Wang, R. Wang, K. Lian, R. Lu, J. Feng, J. Zhou, X. Tu, X. Feng, J. Lin, F. Xu, L. Bourre, J. Wang;
Crown Bioscience, Inc., San Diego, CA

Introduction: Antibody-drug conjugates (ADCs) represent a breakthrough therapeutic class that provides tumor-targeted cytotoxicity while stimulating immune responses, offering promising potential when combined with immunotherapies and particularly with PD-1 inhibitors. Traditional xenograft tumor models developed in immunodeficient mice are employed to evaluate ADCs' anti-tumor efficacy. However, these models lack competent immune systems and human antigen expression in normal tissues, limiting their capacity to assess immune responses and toxicity. To address these limitations, we developed HuCell, mouse tumor cells engineered to express tumor associated antigen (hTAA) such as HER2, and HuGEMM, humanized for a specific drug target within mice with a functional immune system. In this study HuCell/HuGEMM humanized mouse models were developed to evaluate the efficacy of ADCs in combination with anti-PD-1 immunotherapy and toxicity.

Methods: Surface expression of human HER2, Trop2, and Nectin-4 on MC-38 HuCell was verified using flow cytometry before and after inoculation on mice. 5×10^6 HuCells were subcutaneously inoculated into hHER2, hTrop2, hNectin4 and hHER2/hPD-1 models in C57BL/6 background or wild-type (WT) models. Tumor-bearing models were treated with monotherapy of trastuzumab-deruxtecan (T-Dxd), sacituzumab govitecan or enfortumab vedotin, or combination therapy with anti-PD-1 antibodies. For the toxicity study, 180 mg/kg T-Dxd and 100 mg/kg trastuzumab-emtansine (T-DM1) were injected into hHER2 mice weekly for two doses by intravenous injection.

Results: A highly HER2-expressing HuCell line (clone #2) successfully grew in hHER2 models but not in WT models, with tumors displaying nearly 100% of human Her2 positive cells with high surface expression (2×10^5 molecules per cell). In dose response study, T-Dxd significantly inhibited tumor growth at 5 mg/kg and 10 mg/kg in C57BL/6-hHER2. Combination treatment of T-Dxd (4 mg/kg+2 mg/kg, QW) with Keytruda (5 mg/kg, BIW×2) resulted in a complete response rate (8/8) with 87% TGI ($p<0.01$) compared to T-Dxd monotherapy (7/8) with 96% TGI ($p<0.001$) in hHER2/PD-1 double knock in mice. In a toxicity study, T-DM1 showed liver toxicity, whereas T-Dxd did not. Both T-DM1 and T-Dxd exhibited notable hematological toxicity, consistent with clinical observations. In the Trop2 and Nectin-4 HuCell/HuGEMM studies, similar results were observed. HuGEMM models demonstrated superior positive cell rate and single-cell antigen expression levels. Furthermore, a synergistic effect was observed when PD-1 therapy was combined with monotherapy.

Conclusion: HuCell and HuGEMM models provide an advanced platform to evaluate ADC drug monotherapy and combination therapies with immune checkpoint inhibitors. Additionally, they offer a sophisticated solution to assess both on-target and off-target toxicity of ADCs.

#7271 SENTI-202 CD33 OR FLT3 NOT EMCN logic-gated gene circuit components selectively target AML while protecting human HSC/HPCs from off-tumor toxicity in a humanized mouse model.

Muharrem Muftuoglu[1], Li Li[1], Mahesh Basyal[1], Jiangxing Lv[1], Lauren B. Ostermann[1], Han Deng[2], Priscilla Wong[2], Tim Lu[2], Brian Garrison[2], Kanya Rajangam[2], Michael Andreeff[1]

[1]Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Senti Biosciences, San Francisco, CA

There are no approved chimeric antigen receptor (CAR) natural killer (NK) or T cell therapies for acute myeloid leukemia (AML), due in-part to the scarcity of tumor-specific cell surface targets, which creates potential safety challenges with on-target off-tumor toxicity. SENTI-202 is an innovative CAR NK cell therapy that expresses a potent CD33 OR FLT3 NOT EMCN logic-gated gene circuit, in conjunction with IL-15. The bivalent CD33 OR FLT3 activating CAR targets 2 AML antigens, CD33 & FLT3, enabling targeting of AML stem cells & blasts (Gonzalez, 2023; Kaveri, 2024) and venetoclax-resistant AML cells (Muftuoglu, 2023). The NOT EMCN inhibitory CAR (iCAR) protects hematopoietic stem and progenitors (HSC/HPCs) from off-tumor toxicity (even if the healthy cells are $FLT3^+/CD33^+$), which is a major technological advancement that could enhance safety and hematopoietic recovery in patients. The iCAR recognizes the healthy cell marker endomucin (EMCN), which is expressed on up to 76% of HSCs (Reckzeh, 2018) but not AML cells. Here, we used CD33 OR FLT3 NOT EMCN CAR NK cells to validate iCAR-driven HSC/HPC protection in a humanized mouse model by comparing CD33 OR FLT3 NOT EMCN NK (88% CAR^+) to (1.) Non-engineered NK and (2.) CD33 OR FLT3 NOT HER2 (iCAR control) NK (89% CAR^+). First, we confirmed expected in vitro anti-AML activity (observed 50-70% killing; E:T=1:1) and iCAR-mediated model healthy cell preservation activity (observed ~50% preservation; E:T=1:1), using $EMCN^-$ and $EMCN^+$ cell lines, consistent with our prior results showing the EMCN iCAR preserves primary human HSCs from off-tumor toxicity in vitro (Garrison, 2022). Here, using a humanized mouse model we demonstrated iCAR-mediated in vivo protection of human HSC/HPCs from off-tumor toxicity for the first time in the field. Following successful human HSC/HPC engraftment, mice were given 2 CAR NK cell injections on d0 & d7, then HSC/HPC frequency was assessed on d14. While treatment with the iCAR control NK cells led to a significant decrease in HSC/HPC frequency compared to non-engineered NK (18.15% versus 28.6% of $hCD45^+$; p value=0.00015), treatment with CD33 OR FLT3 NOT EMCN NK cells resulted in a significantly increased HSC/HPC frequency versus iCAR control NK cells (34.2% versus 18.15% of $hCD45^+$; p value=0.00000355). This demonstrates that the EMCN iCAR protects human HSC/HPCs from off-tumor toxicity in vivo, and suggests that the EMCN iCAR may increase the SENTI-202 therapeutic window. In conclusion, the SENTI-202 CD33 OR FLT3 NOT EMCN logic-gated gene circuit enables exceptional efficacy against AML while protecting HSC/HPCs from off-tumor toxicity, demonstrating the potential of SENTI-202 as a targeted and precise therapy for AML. SENTI-202 is currently in Phase 1 clinical development in patients with relapsed/refractory hematologic malignancies including AML (NCT06325748).

#7272 aPD1 response prediction in a human *ex vivo* tumor model: A case study in multiomic approaches for preclinical drug evaluation.

Adam Yalin, Andras Sziraki, Devin Mediratta, Andrew Shuparski, Andy Tu, Mirko Andreoli, Patrick Petrossian, Konstantinos Vlachos, Tomas Zikmund, Dagmar Schierova, Alena Molnarova, Anna Dostalova, Eleni Mimitou, Adeeb Rahman, Lisa Freinkman, Florian Uhlitz, **Evgeny Kiner**

Immunai, New York, NY

Background: Anti-PD1 (aPD1) and other immunotherapies have demonstrated significant clinical impact in cancer treatment. However, the inability to accurately predict which patients will respond to specific therapies and to determine the correct indications or combinations for many immunotherapy drugs has led to clinical trial failures across many tumor indications. To address this, we developed a preclinical *ex vivo* patient derived-tumor fragment (PDTF) platform that leverages single-cell multiomics data and our expansive patient-derived single-cell database AMICA™ to dissect drug mechanism of action (MOA), and identify baseline determinants of molecular *ex vivo* response, which can be used to predict therapeutic response in clinical samples. Using pembrolizumab as a use case, this approach identifies patient-level baseline predictive features of aPD1 therapeutic response and predicts the relative clinical efficacy of aPD1 across patient subgroups.

Methods:

PDTFs from a cohort of renal cell carcinoma (RCC) patients were treated with 10 ug/ml aPD1 or isotype control for 48 hr. Multiplex ELISA was performed on culture supernatants, while pre-culture and treated PDTFs were dissociated and sorted on live immune cells for CITE-seq analysis. The resulting multiomic dataset includes cell abundances, cell type specific RNAs and proteins, clonality of T cell subsets, and secreted proteins. These features were used to stratify patients into molecular responders and non-responders. The pre-culture samples from the same patients were then analyzed using the ImmunoDynamics Engine™, a proprietary machine learning (ML) framework, to determine the baseline features of molecular response. To validate our approach, these baseline features were contextualized using samples from patients with known clinical response to PD1 blockade.

Results:

•aPD1 elicits cytotoxicity and interferon pathway upregulation in PD1-expressing cell types. The MOA of aPD1 in our *ex vivo* system is consistent with several clinical datasets.
•Individual donors could be classified by molecular response to aPD1 across several multiomic features.
•Immune features correlating with response to aPD1 at baseline were identified and found to be predictable of molecular response with reasonable accuracy.
•Molecular response features were validated on baseline tumor samples from patients treated with PD1 inhibitors in the clinic and were found to be predictive of therapeutic prognosis.

Conclusions:

Our *ex vivo* model system and analytical framework uses several modalities to establish the MOA and clinical response features of an immunotherapy agent. Recapitulating the known biology and response of aPD1 builds conviction that extending this framework to
other immunomodulatory drugs and their combinations could enhance patient selection and clinical trial design, ultimately improving clinical outcomes.

#7273 CCR8/CCL1 humanized model for efficacy assessment of CCR8/CCL1-targeting therapies.

Fabiane Sonego, Angela Pappalardo, Gaelle Martin, Yacine Cherifi, Patricia Isnard Petit, Kader Thiam

genOway, Lyon, France

Modulation of tumor microenvironment has shown to be a promising approach to treat cancer. Among diverse mechanisms responsible for tumor immunosuppression, those mediated by regulatory T cells (Treg) infiltrating in tumor are well identified and known to reduce the efficacy of anti-tumor therapies. CCR8 has been identified as a potential therapeutic target due to its role in the immunosuppression induced by Treg. CCL1 is the major CCR8 ligand and CCL1 / CCR8 interaction induces STAT3-dependent up-regulation of FoxP3, CD39, IL-10 and Granzyme B, leading to the enhancement of the suppressive activity of Treg cells. A major challenge in the development of new therapeutic approaches relies on the choice of the right preclinical model, which could mimic the complexity of interactions among different cell types and closely predict the effects of therapeutics in humans. The current therapeutic approaches directed towards the CCR8/CCL1 axis target the receptor CCR8, requiring its humanization for assessment of therapeutics displaying species-specific activity. The development of a physiologically relevant model depends, among others, on the maintenance of a proper interaction of the receptor and ligand. CCR8 has 2 ligands in mouse: CCL1 and CCL8. Mouse CCL8 is able to induce specific calcium flux in human CCR8-transfected mouse cells (Islam *et al.*, Nat Immunol, 2011), suggesting that humanization of CCL8 is not mandatory. However, in *vitro* studies showed that murine CCL1 was unable to interact with human CCR8, leading to the conclusion that the CCR8 / CCL1 axis needs to be humanized. Prior to the mouse model generation, an *in vitro* functional assessment confirmed the functionality of human CCR8 in murine cells. Herein, we describe a novel CCR8 and CCL1 double humanized model. Briefly, CCR8 and CCL1 were humanized. Both human genes are under the control of their endogenous mouse promoter, enabling physiological and regulated expression (no regulatory elements were altered by the gene editing process), which is key for the interpretation of the data obtained with the model. CCL1 is produced and detected in the serum from CCR8/CCL1 humanized mice. CCR8 was expressed on approximately half of the MC38 tumor infiltrated Tregs, while very low or absent expression was observed on Treg in the periphery (spleen, skin and blood). Expression of human CCR8 enabled activity of CCR8-targeting antibodies, as a collaborator has shown that treatment with a CCR8 antibody induces tumor volume reduction ($400mm^3$ vs. $750mm^3$) and increased survival (80% vs 30%) 20 days post MC38 inoculation. Therefore, this model is a valuable tool for efficacy assessment of CCR8-targeting drugs, enabling the investigation of immunomodulatory mechanisms at the tumor microenvironment. This is possible because the mouse immune system is functional and its interplay with mouse stroma and tumor cells enables the assessment of a finely regulated microenvironment.

#7274 A preclinical *in vitro* platform for evaluating the potency of bispecific T cell engagers in 2D and 3D models.

Xuefei Yan, Shiqi Guo, Saskia De Man, Yifan Chen, Jiawei Meng, Michelle Kop, Valeria Teodosieva, Haijuan Yu, Gera Goverse, **Jun Zhou**, Peng Wang

Crown Bioscience, Inc., San Diego, CA

Introduction: Bispecific T-cell engagers (BiTEs) are innovative cancer therapeutics designed to harness the immune system by linking T cells to cancer cells, inducing tumor-specific cytotoxicity, which enhances specificity and reduces off-target effects on normal tissue. In this study *in vitro* assays were established to evaluate the tumor cell-killing and T cell activation of BiTEs, specifically using a claudin18.2-targeted BiTE AMG910 and the monoclonal antibody zolbetuximab.

Methods: Target expression on tumor cells for claudin18.2 and AMG910/zolbetuximab binding to tumor and T cells was evaluated via flow cytometry. Tumor cell killing was assessed after 48h co-culture of tumor cells with human T cells upon treatment by FACS and LDH release assays. T cell activation was evaluated by IFN-γ and IL-2 supernatant release, along with FACS (CD25, CD69, IFN-γ, and Granzyme B). AMG910 was further tested in 3D pancreatic patient-derived xenograft organoid (PDXO) models employing high content imaging (HCI) to assess immune cell activation, infiltration, and organoid killing.

Results: NUGC4-hClaudin18.2 cells exhibited the highest Claudin18.2 protein levels compared to NUGC-4 and SNU-620 cells, despite similar mRNA levels. RNA-seq and FACS showed that Claudin18.2 expression was absent in AGS cells. AMG910 displayed stronger binding to SNU-620 cells and T cells compared to zolbetuximab, while zolbetuximab exhibited stronger binding to NUGC4-hClaudin18.2 cells, with no significant binding difference observed between the two Abs on NUGC-4 cells. In a co-culture with human T cells and tumor cells, AMG910 demonstrated significant dose-dependent killing of SNU-620, NUGC-4, and NUGC4-hClaudin18.2 cells compared to untreated samples, along with elevated IFN-γ and IL-2 secretion. T cell activation was further confirmed by increased expression of CD25, CD69 and intracellular Granzyme B and IFN-γ. No effects were observed in co-culture with AGS cells. Furthermore, AMG910 did not activate T cells in the absence of tumor cells, indicating AMG910's Claudin18.2-dependent T cell activation. In 3D co-cultures, treatment with the T cell engager enhanced migration of activated immune cells (CD69) into the organoids, inducing organoid killing analyzed via HCI.

Conclusion: Successful *in vitro* assays were developed for preclinical BiTEs testing. 2D co-cultures efficiently assess direct tumor cell killing and T cell activation mediated by antibody treatments. Additionally, 3D organoid co-cultures offered a more physiologically relevant setup, mimicking the tumor microenvironment and representing patient diversity. Moreover, the HCI analysis revealed enhanced infiltration of activated T cells upon treatment with the T cell engagers before killing of the organoids. This combination offers a robust platform for in-depth preclinical evaluation of BiTEs.

#7275 A novel PD-1, IL12Rβ1 and IL12Rβ2 humanized mouse model for evaluating the combined efficacy of anti-tumor therapies.

Jade Hsu, Linlin Wang, Fengxing Gu, Meiqi Zhang, Jing Guo, Xiaofei Zhou

Biocytogen, Waltham, MA

PD-1 is an inhibitory immune checkpoint that reduces T cell activity by binding to its ligand PD-L1, which facilitates immune evasion in the tumor microenvironment. In recent years, targeting PD-1 has become a key component of cancer immunotherapy. Interleukin-12 (IL-12) serves as a crucial regulatory factor in both innate and adaptive immunity; it promotes cell proliferation, activates cytotoxic lymphocytes and natural killer (NK) cells, boosts the production of interferon (IFN)-γ, and supports cell differentiation, thereby enhancing the generation of TH1-related immunoglobulins. Given its role in pro-inflammatory responses and immune modulation, IL-12 has the potential to convert tumors from a "cold" state to a "hot" state. Therefore, the combination of IL-12 and PD-1 inhibitors represents a promising strategy for advancing cancer immunotherapy. Biocytogen has developed B-hPD-1 plus/hIL12RB1/hIL12RB2 mice by breeding humanized PD-1mice with humanized IL12RB1 and IL12RB2 mice. To validate the PD-1 expression, splenocytes were collected from C57BL/6 mice and homozygous B-hPD-1 plus/hIL12RB1/hIL12RB2 mice stimulated with anti-mouse CD3ε antibody *in vivo* for 24 hrs. Mouse PD-1 was only detectable in C57BL/6 mice. Human PD-1 was exclusively detectable in homozygous B-hPD-1 plus/hIL12RB1/hIL12RB2 mice, but not in C57BL/6 mice. To validate the functionality of the humanized IL12Rβ1 and IL12Rβ2 receptor complex, $CD4^+$ T cells sorted from splenocytes of C57BL/6 and homozygous B-hPD-1 plus/hIL12RB1/hIL12RB2 mice were stimulated with human IL-12 *in vitro*, and IFN-γ production was detected by ELISA. Mouse IFN-γ were both increased after responsiveness to mIL-12 in C57BL/6 mice and homozygous B-hPD-1 plus/hIL12RB1/hIL12RB2 mice. Mouse IFN-γ were increased after responsiveness to hIL-12 in homozygous mice but not in wild-type mice.

In summary, the PD-1, IL12RB1, and IL12RB2 genes have been successfully humanized in B-hPD-1 plus/hIL12RB1/hIL12RB2 mice, allowing us to assess the combined efficacy of anti-tumor drugs.

#7276 Accurate prediction of clinical immunotoxicity of oligonucleotide therapeutics using ex vivo circulating fresh human whole blood test system.

Erika A. K. Fletcher, Gunilla Tornqvist, Helena Harlin Laven, **Sakthi Srinivasan**

Immuneed AB, Uppsala, Sweden

Few oligonucleotide (ONDs) therapeutics are currently approved for cancer treatment due to their ability to modulate gene expression and protein function and their reduced toxicity compared to traditional chemotherapeutics. Existing preclinical animal models demonstrate varied sensitivities to ONDs for detecting clinical immunotoxicity. Non-Human Primates (NHPs) show a higher sensitivity to phosphorothioate oligonucleotides and tend to overpredict the risk of complement activation. Additionally, NHPs were unable to predict antisense oligonucleotide (ASO) induced cytokine release prior to first-in-human (FIH) trials. A notable example is ISIS 353512 (a 2' methoxyethyl ASO, 2' MOE ASO), which unexpectedly induced IL-6 release in human volunteers. Here, we describe the use of a physiologically relevant ex vivo model based on circulating fresh human whole blood, to accurately predict the clinical immunotoxicity of two FDA-approved ONDs: imetelstat (OND) and inotersen (a 2' MOE ASO). Both ONDs were tested in six donors at three concentrations each 1, 5 and 25 uM), covering the clinical Cmax for both inotersen (at the lowest concentration) and imetelstat (at the highest concentration). This ex vivo test system enables the study of early human immune responses by preserving all blood immune cells, immunoglobulins, and active coagulation and complement cascade systems. The system has previously been validated for predicting infusion reactions of antibody-based drugs prior to FIH trials.Both inotersen and imetelstat are known to cause clinical side effects such as flu-like symptoms. The model system reflects these symptoms with a significant increase in pro-inflammatory cytokine release (IL-8, and TNF-α) observed at the highest dose of both ONDs. Imetelstat demonstrated significant activation of granulocytes and monocytes, correlating with the observed high release of IL-6 and IL-8 cytokines in this model system and its intended action against myeloid tumors. In contrast, inotersen only triggered B cell activation, correlating with the IL-6 release caused by Toll-like receptor (TLR) stimuli in B cells, a response previously observed in patients treated with ISIS 353512. Previous studies indicate that both the investigated ONDs result in complement activation in NHPs, while imetelstat alone caused significant complement activation in the clinic. In line with clinical observations, the high dose of imetelstat (but not inotersen) in our test system showed significantly increased activation of complement factors (C3a, and C5a). Additionally, imetelstat caused a decreasing trend with platelet counts, which correlates with its clinical manifestations of thrombocytopenia. Taken together, the data show that our ex vivo circulating whole blood test system has the potential to predict human immunotoxicity responses to ONDs before FIH trials.

#7277 Development of a macrophage-based screening pipeline to evaluate the immunomodulatory effects of small molecule inhibitors.

Marie Durr, Manasa Suresh, Bryan Weselman, David Quiceno-Torres, Megan Winakur, Satish Noonepalle, Alejandro Villagra

Georgetown University, Washington, DC

Introduction: Immunotherapies targeting adaptive immunity have shown promising results in solid tumors; however, many patients are either unresponsive or develop resistance. Emerging interest in innate immunity has driven novel strategies to target myeloid cells, including tumor-associated macrophages (TAMs). TAMs primarily have an anti-inflammatory, pro-tumoral M2-like phenotype secreting growth and angiogenic factors to promote an immunosuppressive tumor microenvironment (TME). Modulating the TAMs towards a more proinflammatory M1-like elicits anti-tumor responses with enhanced antigen presentation and phagocytic activity. Therefore, understanding the molecular mechanisms driving macrophage phenotype plasticity is essential to maintaining the phenotypic switch from M2-like to M1-like in an immunosuppressive TME. Current high-throughput pipelines for screening and optimizing anticancer drugs focus on the cytotoxic and antiproliferative effects of these compounds, underestimating or ignoring their immunomodulatory effects. In this study, we developed drug screening pipelines to identify small molecule inhibitors impacting the macrophage functional phenotype to identify leading candidates with immunoregulatory properties.
Methods and Analysis: Mouse bone marrow-derived macrophages were polarized to M1-like or M2-like phenotypes and applied in bulk RNA sequencing to identify specific genes associated with each phenotype. We created stable RAW264.7 macrophages expressing luciferase under the control of phenotype-specific promoters to identify targets modulating the macrophage phenotype. Additionally, THP-1 reporter cell lines driven by response elements of inflammatory signaling pathways were used to further evaluate the mechanistic role of small molecule inhibitors on the phenotypic switch in macrophages[MS1] following stimulation of the pathway with appropriate cytokines.
Results and Conclusions: RNA sequencing data identified exclusive genes upregulated with M1 and M2 polarization of macrophages. Based on the gene expression changes and successful validation of the plasmids in RAW264.7 cells, we selected TNF and CXCL5 as genes for M1 and Arg1 and CCL24 for M2 markers. Using the stable reporter RAW264.7 cell lines and the THP-1 reporters for specific pathways, we screened several epigenetic modifiers, including novel HDAC inhibitors. Using this approach, we found selective HDAC6 inhibitors diminished the anti-inflammatory phenotype of macrophages and, upon stimulation with appropriate cytokines, increased pro-inflammatory pathways, such as NFkB. These efforts could enable high-throughput screenings of novel small molecule inhibitors for their immunomodulatory effect on macrophages.

#7278 Non-clinical toxicity studies of S-CP201.

Michael Ahrweiler, Wolfgang Meyer, Daniel Perrissoud, Axel Zander

RDP Pharma AG, Romanshorn, Switzerland

Edelfosine, an anticancer alkylphospholipid, has been widely investigated. Inter alia, it integrates into cell membranes (including mitochondria and ER) and acts via CD95-driven apoptosis, AKT3/PI3K inhibition, phospholipase C and protein kinase C inhibition, and impacts cholesterol metabolism. It exhibits antiangiogenic and antimetastatic effects, selectively targets malignant cells, and has shown efficacy in preclinical xenograft models, (e.g metastatic breast and prostate cancers), and in phase 2 trials across tumor types. The main adverse event was dose-dependent, reversible gastrointestinal toxicity. Many non-clinical toxicity reports on edelfosine are available. Since edelfosine is racemic, its S-enantiomer (S-CP201) was chosen for development due to PK/ PD advantages over the R-counterpart. Key data of a GLP-/ICH S9 and M3-conform, IND-enabling toxicity package for S-CP201 is stated below. In addition to a 4-week dose range-finding (DRF) study, S-CP201 was given in a 13-week rat toxicity study per os (p.o.) at 3, 9, 27, and 40 mg/kg/day (d) (15 rats per sex and group). The 2 high dose groups showed reversible liver enzyme increases. One female in the 27 mg/kg group exhibited an enlarged pituitary; 9/15 males showed seminal vesicle atrophy, and 10/15 tubular vacuolation in the testes. In the 40 mg/kg group, dilated intestines, cecum, and reddened duodenal mucosa were observed. The NOAEL was set at 9 mg/kg/d. In a maximum tolerated dose (MTD)/DRF study in minipigs, escalating doses reached 96 mg/kg/d for 3 d in the DRF phase and 12 mg/kg/d for ≤6 d in the MTD phase. Doses ≥12 mg/kg/d resulted in soft feces, dark duodenal mucosa, and reduced appetite/body weight (BW) loss. MTD was 6 mg/kg/d. Safety pharmacology tests of S-CP201 (core battery) were also conducted. In Wistar rats, single oral doses ≤40 mg/kg showed no notable respiratory effects (whole-body barometric plethysmography). Similarly, single doses ≤14 mg/kg in telemetered male Beagle dogs showed no adverse effects on blood pressure, heart rate, ECG, or body temperature, confirming prior negative hERG assay results. Soft feces were found at doses ≥9 mg/kg, but no other changes in BW or food consumption were noted. In a modified Irwin test, single oral doses ≤100 mg/kg in Sprague-Dawley rats produced no signs of behavioral, neurological, or autonomic effects. A pilot Ames fluctuation test showed no mutagenic potential across a broad concentration range. In a standard Ames test, low mutagenic effects were seen only at high concentrations in 3 of 4 tested S. typhimurium strains. A new Ames test under similar conditions did not reveal mutagenic effects. An in vitro micronucleus assay showed no effects at therapeutic concentrations, and an in vivo micronucleus test in male rats receiving S-CP201 (≤200 mg/kg/d p.o.) showed no clastogenic or aneugenic effects. An in vitro hemolysis test (up to 20 µM) was negative for S-CP201. Overall, this S-CP201 non-clinical safety package supports proceeding to Phase 1 studies.

#7279 A novel humanized IL2 and IL15 receptor mouse model enables preclinical efficacy studies for IL-2 cancer therapeutics.

Kelvin Yin, Alexander Sercel, Linlin Wang, Suman Zhao, Zan Zhang, Zhenlan Niu, Yanling Wang, Xiaofei Zhou

Biocytogen, Waltham, MA

Recombinant human interleukin 2 (IL-2) is effective in treating metastatic renal carcinoma and melanoma, however, severe dose-limiting toxicity restricts patient treatment. There is conflicting evidence from human and murine studies on whether activation of natural killer (NK) cells leads to efficacy or toxicity and if activation of T or NK cells is associated with therapeutic benefit. The development of a humanized mouse model for this system is imperative to evaluate the safety and efficacy of IL-2 targets.

Here, we generated a homozygous humanized hIL-2RB/hIL-2RG/hIL-15/hIL-15RA mouse model which constitutively expresses human IL-2RB, IL-2RG, IL-15, and IL-15RA proteins. The distribution of basal leukocyte subpopulations of blood, spleen, and lymph nodes in humanized B-hIL-2RB/hIL-2RG/hIL-15/hIL-15RA mice is similar and comparable to the distribution found in wild-type C57BL/6 mice. Functionally, the human IL-2 and IL-15/IL-15RA complex elicits a dose-dependent induction of pSTAT5 in humanized mice. Furthermore, using this model, we have detected modest efficacy of a human IL-2 drug in inhibiting MC38 tumor growth *in vivo*.

In summary, B-hIL-2RB/hIL-2RG/hIL-15/hIL-15RA mice provide a powerful preclinical model to clear roadblocks towards *in vivo* evaluation of IL-2 drugs for cancer treatment.

#7280 A novel IL12Rβ1 and IL12Rβ2 humanized mouse model for preclinical toxicity evaluation of human IL-12 analogs.

Kelvin Yin, Alexander Sercel, Fengxing Gu, Jing Guo, Meiqi Zhang, Saina Ma, Jiansu Zhang, Xiaofei Zhou

Biocytogen, Waltham, MA

Interleukin 12 (IL12), a heterodimer cytokine composed of IL12A (p35) and IL12B (p40), is mainly produced by dendritic cells and macrophages in response to antigenic stimulation and its receptor is a protein complex encoded by IL12Rβ1 and IL12Rβ2. IL12 signaling regulates innate and adaptive immunity, influencing the proliferation and activation of cytotoxic lymphocytes and natural killer (NK) cells, stimulating the production of interferon (IFN)-γ, and promoting the differentiation and production of Th1-associated immunoglobulins. IL12 is a promising anti-tumor drug capable of transforming the tumor microenvironment from “cold” to “hot”. To accelerate discovery in this space, Biocytogen has independently developed IL12RB1 and IL12RB2 single KI mice and mated them to subsequently B-hIL12RB1/hIL12RB2 double KI mice to develop a fully humanized model for testing IL12-analog drugs. First, the mRNA expression levels of human IL12RB1 and human IL12RB2 in B-hIL12RB1/hIL12RB2 mice were quantified using RT-qPCR. Additionally, immunophenotyping by flow cytometry shows that the humanization of IL12RB1 and IL12RB2 did not affect the proportions and distribution of immune cells. To validate the functionality of the humanized IL12Rβ1 and IL12Rβ2 receptor complex, $CD4^+$ T cells sorted from splenocytes of C57BL/6 and homozygous B-hIL12RB1/hIL12RB2 mice were stimulated with human IL12 *in vitro*, and IFN-γ production was detected by ELISA. The results indicated that human IL12 induced a significant increase in IFN-γ levels in the B-hIL12RB1/hIL12RB2 mice, while no such effect was observed in wild-type mice. Furthermore, to evaluate the *in-vivo* toxicity of human IL12 analogs, B-hIL12RB1/hIL12RB2 mice were treated with human IL12 at different doses and for varying durations. Body weight was measured daily during treatment. At the end of the experiment, the weights of the liver and spleen were measured, and pathological changes in the liver and spleen were assessed through HE staining. Meanwhile, serum levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in the mice were detected using ELISA. In the *in vivo* toxicity study, human IL-12 administration resulted in a progressive decline in body weight in treated mice over time. Additionally, human IL12 treatment was associated with an increase in the ratios of liver weight to body weight and spleen weight to body weight. Pathological changes in the liver and spleen were also observed, alongside an upward trend in ALT and AST activity. These results suggest the successful humanization of IL12RB1 and IL12RB2 signaling in B-hIL12RB1/hIL12RB2 mice, enabling evaluation of the preclinical toxicity of human IL12 analogs.

#7281 Predicting clinical checkpoint inhibitor responses with TumorGraft3D PBMC co-culture.

Mara Gilardi, BanuPriya Sridharan, Veena Jagannathan, Brandon Walling, Stefano Cairo, Marianna Zipeto, Michael Ritchie

Champions Oncology, Inc., Hackensack, NJ

Although immunotherapy-based therapeutics such as checkpoint inhibitors (CPI) have revolutionized cancer therapy, a lot needs to be done in the field. In preclinical settings, ex vivo models still face significant challenges in translating the results into clinical responses. Traditional approaches, including cell-lines, are limited by their lack of genetic heterogeneity. Similarly, 2D systems fail to capture spatial complexity, significantly reducing their translational relevance. Clinical data on CPI are not available for commercially available cell lines since they were developed before CPI treatments were approved. These limitations hinder the accurate modeling of CPI efficacy and the prediction of therapeutic responses. To address these issues, Champions Oncology leverages a tumor bank of 1500 patient-derived xenograft (PDX) models across solid tumors and hematological malignancies offering 3D co-culture assays specifically tailored for different mechanisms of action. To provide a clinical translational platform that retains human tumor heterogeneity, we developed Champions TumorGraft3D (CTG3D) low-passage 3D PDX-organoid models. The use of proprietary, indication-specific media enabled CTG3D to preserve the genetic, proteomic, and phenotypic diversity of the original tumors. Additionally, their 3D architecture accurately models the cell-cell interactions that are crucial for mimicking immune cell engagement. The in-depth clinical annotation of our bank, which includes detailed patients' clinical history, enables this system to provide predictive insights into the CPI efficacy. In this project, we assessed the translational value of our CTG3D co-culture system, based on its ability to recapitulate the clinical response in patients. We selected models derived from patients displaying resistance or sensitivity to CPI, by leveraging the data collected in Champions Oncology Tumor Bank. Then, we optimized the CTG3D-PBMCs co-culture settings including media and cell ratios. High throughput flow cytometry was used to interrogate the model. We profiled the co-culture with a custom-designed panel allowing for cancer cell killing and immune phenotyping readout in parallel. Beyond immune activation, we were able to determine the correlation of the data obtained from the co-culture with the clinical records of the original patients. In summary, we developed a cutting-edge ex vivo CTG3D PBMC co-culture platform allowing for dynamic evaluation of immune engagement and checkpoint inhibitor responses, therefore providing valuable translational datasets. By overcoming the limitations of traditional assays, CTG3D co-culture systems represent a transformative step forward in preclinical immunotherapy research and the development of personalized cancer treatments.

#7282 Development of an HLA-matched humanized immune system mouse model with primary AML patient samples for immunotherapy testing.

Mara Gilardi[1], Paolo Schiavini[1], Laura Griffin[2], Brandon Walling[1], Paul Heverly[1], Stefano Cairo[1], Philip Dube[2], Monika Buczek[2], Marianna Zipeto[1], Michael Ritchie[1]

[1]Champions Oncology, Inc., Hackensack, NJ,[2]Taconic Biosciences, La Jolla, CA

Acute Myeloid Leukemia (AML) is a devastating hematological malignancy with a global incidence of approximately 120,000 new cases annually and a five-year survival rate below 30%. Despite advances in therapeutic strategies, treatment outcomes remain poor. The complexity of AML, characterized by genetic heterogeneity and clonal evolution, presents significant challenges for the development and testing of novel therapeutics in clinically relevant settings. AML research relies heavily on cell lines and syngeneic models, or immunodeficient models without an added human immune system component. While these systems provide valuable insights, they fail to fully recapitulate the genetic and phenotypic diversity of primary human AML tumors. Traditional models often lack the tumor microenvironment and immune interactions critical for therapeutic evaluation. Furthermore, existing models generally rely on extensively passaged samples, which lose the heterogeneity and clonal diversity intrinsic to AML, undermining their clinical relevance. To address these limitations, we developed an in vivo AML platform using human CD34+ engrafted NOG-EXL mice. NOG EXL was selected as the preferred in vivo model as it has been successfully engrafted with primary AML PDXs, albeit not also with a humanized immune system component. This novel platform was built on a bank of over 50 patient-derived AML models that have been passaged, preserving their native tumor characteristics. Humanized NOG-EXL mice, transgenic for human IL-3 and GM-CSF, were used to promote primary AML engraftment as well as CD34+ stem cell differentiation into a wider repertoire of human myeloid and lymphoid lineages. The models are fully characterized with RNA sequencing, proteomics, diagnostic data, and detailed clinical histories. By retaining the complexity and clonal architecture of primary AML tumors, these models provide a truly translational system for preclinical drug testing. AML donors were evaluated in humanized NOG-EXL. CD34+ engraftment was confirmed in humanized NOG-EXL mice followed by engraftment with AML primary cells. Human immune cell engraftment and AML cancer progression were assessed at different time points through flow cytometry on peripheral blood and bone marrow. A custom flow cytometry panel was used to identify the human immune cells present as well as the main AML sub-populations including the AML progenitors, AML blast,s and monoblasts. This novel approach bridges a critical gap in AML research by offering a robust, clinically relevant platform that reflects real-world disease biology by demonstrating an in vivo model with primary never-passaged AML PDX in the context of a human immune system. The Champions AML humanized model sets a new standard for preclinical evaluation, promising to accelerate the development of personalized therapies and improve outcomes for AML patients worldwide.

IMMUNOLOGY: Overcoming Checkpoint Inhibition and Tumor Suppression
Poster Session

#7286 A first-in-class αPD-1/αVEGF/IL-2v tri-specific fusion protein demonstrates promising anti-tumor efficacy in immune checkpoint inhibitor-resistant tumor models.

Sunjung Cho, Jun-Eui Park, Yongjun Jung, Hyojoo Bang, Jeongseok Heo, Seokchan Kang, Suna Kim, Minwoo Kim, Young Jin Park

Mustbio, Suwon-si, Korea, Republic of

Immune checkpoint inhibitors (ICIs), including anti-PD(L)1 monoclonal antibodies, have been widely approved and used for various cancer types. However, the response rate to ICIs is limited to certain cancer types, largely attributed to the absence or low presence of immune cells within the tumor microenvironment (TME). αVEGF antibodies not only facilitate immune cell infiltration into tumors but also improve the immunosuppressive conditions of the TME. Notably, the combination of αPD-1 and αVEGF antibodies and αPD-1/αVEGF bispecific antibody therapy have demonstrated improved efficacy compared to αPD-1 monotherapy across various cancer types. Despite such advances, boosting immune cell proliferation within the TME remains crucial for achieving superior efficacy in ICI-resistant or refractory patients. αPD-1/αVEGF/IL-2v is a highly TME-selective tri-specific fusion protein comprising αPD-1, αVEGF, and IL-2v. This compound was engineered to activate T cells continuously via αPD-1, enhance tumor-infiltrating lymphocytes (TILs) via αVEGF, and proliferate effector T cells strongly via novel IL-2v. We evaluated the intrinsic activity of each functional arm of the αPD-1/αVEGF/IL-2v fusion protein individually. The αPD-1/αVEGF/IL-2v exhibited blocking activity against PD-1/PD-L1 binding comparable to pembrolizumab, showed VEGF/VEGFR blockade activity similar to that of αVEGF antibody, and effectively induced $CD8^+$ T cell activation comparable to aldesleukin. In vitro trans-endothelial migration assay demonstrated that αPD-1/αVEGF/IL-2v significantly enhanced T cell migration compared to the combination of αPD-1 and αVEGF or αPD-1/αVEGF bispecific antibody. This tri-specific fusion protein also improved the $CD8^+$ T cell/Treg ratio and reduced exhausted $CD8^+$ T cell population during in vitro immune cell expansion in TME mimic condition. Furthermore, αPD-1/αVEGF/IL-2v showed TME selective immune cell activation and cytokine release while exhibiting minimal effects on immune cells in peripheral blood. The murine surrogate of αPD-1/αVEGF/IL-2v demonstrated dose-dependent anti-tumor efficacy, superior to αPD-1 or αPD-1/αVEGF bispecific antibody in both ICI-resistant MC38 and B16F10 tumor models without body weight loss. In conclusion, αPD-1/αVEGF/IL-2v represents a first-in-class tri-specific fusion protein with therapeutic potential to overcome the limitations of αPD-1 or αPD-1/αVEGF therapies.

#7287 Association between *LAG3* expression and immune checkpoint inhibitor (ICI) efficacy in advanced melanoma.

Inderjit Mehmi[1], Jacob mercer[2], Adam Dugan[2], Binyam Yilma[2], Catherine Hegarty-Traverso[2], Calvin Chao[2], Stamatina Fragkogianni[2], Omid Hamid[1]

[1]The Angeles Clinic and Research Institute, Los Angeles, CA,[2]Tempus, Chicago, IL

Predictive biomarkers for first-line (1L) ICI therapy in advanced melanoma are lacking. aLAG-3/PD1 is approved regardless of *LAG3* expression despite evidence of poorer RR and PFS (Relativity-047). The relationship between *LAG3*expression and clinical benefit to 1L non-aLAG-3 ICIs is unknown. We evaluated *LAG3* expression as a biomarker for benefit towards 1L non-aLAG-3 ICIs in a real-world (rw) advanced melanoma cohort.De-identified NGS data from patients (pts; N=367) with stage III-IV (advanced) cutaneous melanoma was analyzed in the Tempus Database. Pts were treated with 1L ICIs, aCTLA4/PD1 (n=222) or aPD1 (n=145). Pts treated with 1L aLAG-3/PD1 were limited and not included. Tissue was collected prior to 1L and sequenced with xT DNA (648-gene panel) and xR RNA assays. *LAG3* high (*LAG3*-H) and low (*LAG3*-L) expressors were defined by median *LAG3* RNA transcripts per million. PD-L1 was determined by IHC. QuanTIseq was used to estimate immune cell proportions. Rw overall survival (rwOS) was calculated from treatment (tx) start to death from any cause. Rw objective response rate (rwORR) was defined as the proportion of pts with a documented complete or partial response within 90 days of tx start. Hazard ratio (HR) was calculated using a Cox proportional hazards (CoxPH) model and p-values using the Wald test. *LAG3*-H was associated with PD-L1+ status (*LAG3*-H 52% vs *LAG3*-L 5.5%) and higher proportions of adaptive immune cells, including CD8+ (2.7% vs 0.1%), B (4.3% vs 3.1%), and inhibitory Treg cells (4.5% vs 2.9%; p<0.001 for all). In the aPD1 cohort, *LAG3*-H (n=77) had higher rwORR vs *LAG3*-L (n=68; 67% vs 15%, p=0.002). In the aCTLA4/PD1 cohort, *LAG3*-H (n=109) had similar rwORR vs *LAG3*-L (n=113; 46% vs 37%, p=0.42). CoxPH analysis found a significant interaction between *LAG3* and 1L ICIs on rwOS (p=0.02), suggesting the ICI effect on rwOS differs between *LAG3*-L and *LAG3*-H (p=0.02). In the *LAG3*-L group, pts treated with aPD1 had reduced rwOS compared to the aCTLA4/PD1 cohort (HR, 1.88, p=0.03), while in the *LAG3*-H group pts treated with aPD1 had higher rwOS compared to the aCTLA4/PD1 cohort (HR, 0.67, p=0.2). *LAG3* was associated with immune microenvironment changes and modulated 1L aPD1 but not aCTLA4/PD1 efficacy in pts with advanced melanoma. Similar to the Relativity-047 trial that showed *LAG3* alters aLAG-3/PD1 efficacy, pts with *LAG3*-H treated with aPD1 had improved outcomes vs pts with *LAG3*-L. However, pts with *LAG3*-H treated with aCTLA4/PD1 had similar outcomes vs pts with *LAG3*-L. Differences in rwOS observed between aCTLA4/PD1 and aPD1-treated pts within the *LAG3* expression subsets indicates potential predictive value of this biomarker. Future studies will prospectively validate these novel findings in pts with advanced melanoma to confirm the finding that aCTLA4/PD1 is optimal for pts with *LAG3*-L and alternative 1L ICIs are best for pts with *LAG3*-H.

#7288 Targeted degradation of mobile immune checkpoints to advance cancer therapy.

[1]Department of Molecular and Cellular Biology/Department of Chemistry, The Scripps Research Institute, La Jolla, CA,[2]Department of Molecular and Cellular Biology, The Scripps Research Institute, La Jolla, CA,[3]Department of Immunology and Microbiology, The Scripps Research Institute, La Jolla, CA,[4]Department of Chemistry, University of Alberta, Edmonton, AB, Canada,[5]Department of Chemistry, The Scripps Research Institute, La Jolla, CA,[6]Laboratory of Molecular Genetics and Immunology, The Rockefeller University, New York, NY,[7]Department of Molecular Medicine, The Scripps Research Institute, La Jolla, CA,[8]Division of Gastroenterology, Hepatology and Nutrition, Boston Children's Hospital, Harvard Medical School, Boston, MA,[9]Department of Chemistry/Department of Medical Microbiology and Immunology, University of Alberta, Edmonton, AB, Canada

Immune checkpoint inhibitors (ICIs) targeting T cell-intrinsic checkpoints, such as CTLA-4 and PD-1, have shown promising outcomes across diverse cancer patient populations. However, resistance to these ICIs remains prevalent, especially in patients with an immunosuppressive tumor microenvironment (TME), suggesting the existence of additional immune checkpoints that act through orthogonal mechanisms. To overcome therapeutic resistance, there is an unmet need to identify novel immune checkpoints involved in cancer progression and to develop innovative therapeutic strategies capable of reprogramming the TME by neutralizing tumor-promoting factors. Here, we identify sialic acid-binding immunoglobulin-like lectin (Siglec)-7 and -9 as mobile immune checkpoints acquired by T cells from myeloid cells via trogocytosis in the TME. These trogocytosed Siglec checkpoints suppress T cell activity by dephosphorylating T cell receptor (TCR)-related signaling pathways through engagement with tumor-associated sialoglycans. To target these mobile checkpoints, we leveraged sulfur(VI) fluoride exchange (SuFEx) click chemistry to develop a high-affinity Siglec-7/-9 ligand and converted it into a degrader for lysosomal degradation of both Siglecs. This degrader efficiently reduced Siglec levels in T cells and myeloid cells, significantly restoring T cell function and enhancing anti-tumor immunity. The degrader, particularly when combined with anti-CTLA-4, remodeled the TME and generated durable T cell memory, resulting in excellent tumor control in multiple murine models. These findings underscore the significance of degrading exogenously acquired Siglec checkpoints on T cells as a novel strategy to overcome resistance to established ICIs in cancer therapy.

#7289 High CD8+ T cell TIM-3 expression predicts for sensitivity to TIM-3 based triplet checkpoint inhibitor combinations.

Manali S. Phadke[1], Jiannong Li[1], Sathya Sriramareddy[1], Paulo Rodriguez[1], Brian Ruffel[1], Vincent Luca[1], Ann Chen[2], Keiran S.M. Smalley[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]Huntsman Cancer Foundation, Salt Lake city, UT

Background: Melanoma response to the immune checkpoint inhibitor (ICI) combinations such as anti-PD-1, anti-PD-1+LAG-3 and anti-PD-1+CTLA-4 is not durable. The triplet combination of anti-PD-1+CTLA-4+LAG-3 is being studied clinically in multiple cancers, including advanced melanoma. This study comprehensively describes the mechanism of action of this ICI triplet, and a second triplet of anti-PD-1+LAG-3+TIM-3, in 3 mouse melanoma models with varying levels of sensitivity to ICI.
Methods: Syngeneic mouse models of SM1, SW1 and B16-10 melanoma flank tumors were used to explore the response to anti-PD-1+LAG-3, anti-PD-1+CTLA-4, anti-PD-1+LAG-3+CTLA-4 triplet and anti-PD-1+TIM-3 doublet and anti-PD-1+LAG-3+TIM-3 triplet. We performed flow cytometry on the responding and resistant tumors, tetramer bindings assays, T-cell depletion and IHC to determine the mechanisms of action of these ICI combinations. Additionally, we analyzed scRNA-Seq data from sensitive and ICI resistant human melanoma to determine the overlap in immune checkpoint expression across T -cell subsets.
Results: The PD-1+CTLA-4+LAG-3 triplet combination demonstrated good efficacy in the SM1 and B16-F10 models and was associated with a more favorable immune response such as increased CD69+ CD8+ T cells, reduced exhausted T cells and increased GP100-tumor specific T cells than either doublet. The ICI-resistant SW1 model, did not respond to the PD-1+CTLA-4+LAG-3 triplet and exhibited accumulation of TIM-3+ exhausted CD8+ T cells. Targeting elevated TIM-3 on CD8+ T cells, using the anti-PD-1+LAG-3+TIM-3 triplet, but not the PD-1+TIM3 doublet, restored T cell activity and led to a remarkable anti-tumor activity in SW1 model, with some mice showing complete tumor regression. The PD-1+LAG-3+TIM-3 triplet was also highly effective in the SM1 model showing increased percentage of CD69+ CD8+ and tumor specific T cells and reduced exhausted T cells. scRNA-Seq analysis showed that TIM-3 levels were significantly higher in the CD8+ T cells of melanoma patients failing PD-1 therapy. We also observed a good correlation between LAG-3 and TIM-3 expression in the CD8+ T cells. Hence, co-targeting these two checkpoints may possibly reverse the T cell exhaustion.
Conclusion: In conclusion, our results demonstrate that ICI resistance associated with high TIM-3 expression in the CD8+ T cells can be overcome through use of a PD-1+LAG-3+TIM-3 combination. The observation that high TIM-3 expression in CD8+ T cells is associated with PD-1 resistance suggests the potential to use anti-TIM3 based ICI combinations as a second-line treatment strategy in patients with advanced melanoma.

#7290 Targeting APP with GENA-119B31: A novel approach to overcoming immune checkpoint inhibitor resistance in cancer immunotherapy.

Mi Young Cha, **Kitae Park**, Hyunuk Kim, Hyunkyung Yu, Bu-Nam Jeon, Jiyeong Lee, Youngeun Ha, Sang-Moo Park, Gyeongyeon Kim, Suah Choi, Han-Sol Kim, Hyonam Kim, Sang-Gyun Kim, Hansoo Park

Genome & Company, Suwon-si, Gyeonggi-do, Korea, Republic of

Immunotherapy has profoundly transformed the treatment of advanced cancers, leading to improved clinical outcomes. Despite these successes, many patients remain unresponsive to immune checkpoint inhibitors (ICI). Consequently, there is an urgent need for novel treatments for patients who fail to respond to ICI or develop resistance. We previously identified amyloid precursor protein (APP), a type I transmembrane protein present in T cells. APP interacts with the novel immune checkpoint protein contactin 4 (CNTN4), expressed in tumor cells, and plays a central role in mediating CNTN4's immunosuppressive signal to T cells. Moreover, profiling APP expression in tumor-infiltrating T cells from NSCLC patients treated with anti-PD-1 and chemotherapy, we observed that $CD8^+$ Teff cells of non-responding (SD) patients predominantly exhibited elevated *APP* levels, while those of responding (PR) patients manifested higher levels of *IFNG* and *PDCD1*. Here, we present the *in vitro* and *in vivo* efficacy of GENA-119B31, a humanized monoclonal antibody targeting APP. GENA-119B31 binds strongly to human APP at both protein and cellular levels and effectively blocks the interaction between CNTN4 and APP. The *in vitro* biological activities of GENA-119B31 were evaluated using co-culture conditions with $CD4^+$ or $CD8^+$ T cells and A549 human cancer cells engineered to overexpress OKT3 and CNTN4. GENA-119B31 treatment demonstrated promising T cell-mediated cytotoxicity. For the *in vivo* study, we established CNTN4-overexpressing murine cancer cell lines (CT26/Cntn4 and Pan02/Cntn4) due to the low CNTN4 expression in mouse cells compared to human cells. This allowed for more clinically relevant conditions in efficacy assessment. GENA-119B31 showed strong anti-tumor activity in the CT26/Cntn4 syngeneic liver metastasis murine model, which has been internally confirmed to be resistant to anti-PD-1 therapy and closely mirrors clinical outcomes. The efficacy was demonstrated by a marked reduction in metastatic nodules and a decrease in hepatic damage markers in serum. In our previous study using human cancer TMA slides, pancreatic cancer, known for its resistance to ICIs, was identified as having high CNTN4 expression. In the Pan02/Cntn4 syngeneic subcutaneous murine model, GENA-119B31 showed significant anti-tumor activity, with reductions in tumor volume and weight, whereas no such effects were observed in the Pan02 WT model, which has low CNTN4 expression. These findings indicate that GENA-119B31's anti-tumor activity is mediated through the APP/CNTN4 axis, with CNTN4 expression potentially serving as a biomarker for therapeutic response. This study confirms the potential of APP as a target for cancer immunotherapy through the use of the anti-APP antibody GENA-119B31. Our findings provide preclinical evidence supporting GENA-119B31 as a promising novel therapeutic strategy.

#7291 Advancing cancer immunotherapy: characterizing and leveraging bispecific antibodies targeting immune checkpoints.

Jun Wang, Denise Garvin, Jonathan Mitchell, Pete Stecha, Michael Beck, Jim Hartnett, **Kai Hillman**, Gopal Krishnan, Frank Fan, Julia Gilden, Mei Cong, Jamison Grailer

Promega, Madison, WI

Bispecific antibodies targeting immune checkpoints are transforming cancer immunotherapy by enabling novel mechanisms of action unattainable by monospecific antibodies. These engineered molecules simultaneously engage two distinct epitopes, such as PD-1 and CTLA-4 or TIGIT, to amplify anti-tumor immune responses while minimizing off-target effects. Here we demonstrate the use of cell-based reporter bioassays to provide a robust platform for assessing the functional potency, stability, and specificity of bispecific antibodies. Combination bioassays, such as PD-1 + TIGIT and PD-1 + LAG-3, evaluate synergistic effects on T-cell activation. Additionally, Fc effector function bioassays, including ADCC and ADCP assays, assess the cytotoxic potential and receptor-mediated activity of bispecific formats. These assays ensure precise characterization of mechanisms of action, guiding the refinement of antibody designs.

#7292 HY05350: A trispecific T-cell engager with immune checkpoint inhibitor targeting mesothelin for solid cancer.

Yan Hu, Sanyou Guo, Yujing Zhang, Mengyun Zhang, Bo An, Dan Sun, Ao Fu, Xiaoqiang Chai, Jiangshan Dai, Qing Xiong, Tao Wei

Sichuan Huiyu Seacross Pharmaceutical Technology Co., Ltd, Chengdu, China

Objective: Limited efficacy is the major road block when developing T cell engager (TCE) for solid cancers, which is partly due to the suppressive tumor microenvironment (TME) created by the expression of inhibitory immune checkpoints, such as PD-L1. To enhance anti-tumor activity of T cells, we engineered a trispecific T cell engager (HY05350), targeting CD3 and tumor-associated antigens Mesothelin (MSLN) and PD-L1 for solid cancers.
Methods: CD3 antibody obtained by optimizing affinity of SP34. Alpaca was immunized with MSLN and PD-L1. VHH antibodies were obtained and humanized. Various trispecific formats evaluated by T cell activation, T cell-dependent cytotoxicity (TDCC), cytokine release and PD-L1 checkpoint blockade assays. Anti-tumor efficacy was studied in CDX mouse models, MoA studied by single cell NGS in the CD3xPD1xPDL1 transgenic mice, PK/TK and GLP toxicity evaluated in cynolmogus.
Results: HY05350 in the format of 2(MSLN)+1(PD-L1)+1(CD3) was selected. It could induce strong target- & dose-dependent cytotoxicity in MSLN+ cancer cells and effectively block binding of PD-L1 to T cell PD1. It demonstrated a strong anti-tumor activity in a variety of the mouse CDX models. Cynomolgus GLP toxicity study demonstrated HY05350 was well-tolerated with a toxicity profile comparable to typical CD3 based bispecific antibodies and had an acceptable PK/TK profile with a T1/2 of 12-35 hours. We explored MoA of HY05350 in vitro and in vivo. Our in vitro experiments showed (1) HY05350 could induce a stronger 2nd signal than the bispecific antibody (CD3xMSLN), consistent with the observation by Liu et al (2019) that the CD3xPD-L1 arm of HY05350 could target the PD-L1+ APC cells to activate T cells and induce more effective antitumor immunity than directly bridging T cells to cancer cells; (2) As expected, activation of T cells induced PD-L1 expression in most tested cancer cells. Furthermore, HY05350 showed more potent TDCC activity against MSLN and PDL1 double-positive than single-positive tumor cells, suggesting PD-L1, together with MSLN, could enhance stronger TDCC activity, presumably via a feedforward mechanism, than the bispecific antibody CD3xMSLN; (3) HY05350 induced strong cytotoxicity against PD-L1+ DMSC, suggesting remodeling TME potential. Single cell sequencing analysis of ~10K immune cells of MC38 tumors revealed that in pre- and post-dosed CDX mice, HY05350 induced a wide range of immune responses. In particularly, it significantly increased proportions of three major anti-tumor groups of lymphocytes: T cells, NK cells and interestingly gamma-delta T cells.
Conclusion: We engineered a trispecific T cell engager HY05350 targeting CD3, MSLN and PD-L1 to treat solid cancers. Our in vitro and in vivo studies demonstrated that HY05350 was well-tolerated, induced strong T cell activation, cytotoxicity and potent antitumor efficacy, supporting for further clinical investigation.

#7293 First in class Anti-CLEC-1A myeloid checkpoint antibodies for the treatment of solid tumors with monotherapy and combination therapy efficacies.

Etienne Foucher[1], Mylene Derame[1], Justine Durand[1], Marion Drouin[1], Camille Ligeron[2], Caroline Mary[1], Vanessa Gauttier[1], Isabelle Girault[1], Emmanuelle Wilhelm[1], Virginie Thepenier[1], Cecile Batty[1], Geraldine Teppaz[1], Ariane Desselle[1], Marine Malloci[1], Irene Baccelli[1], Marion Colonello[1], Stephanie Neyton[1], Elise Chiffoleau[3], Aurore Morello[1], Nicolas Poirier[1]

[1]OSE Immunotherapeutics, Nantes, France,[2]OSE Immunotherapeutics and Nantes Universite, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France, Nantes, France,[3]Nantes Universite, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France

The immune checkpoint CLEC-1 (C-type lectin domain family 1 member A) expressed by dendritic cells, macrophages, and endothelial cells, has been shown as a necrotic receptor playing a critical role in immune response modulation during sterile inflammation. Several studies have highlighted CLEC-1's potential as a target for immunotherapeutic strategies. Absence of CLEC-1 signaling by genetic ablation or antibody blockade has been shown to promote anti-tumor response by increasing the cross-presentation of dead cell-associated antigens by type 1 conventional dendritic cells and by enhancing T-cell activation. Furthermore, this CLEC-1 signaling blockade has also recently been shown to increase an acute inflammatory response in a model of liver tissue damage induced by the acetaminophen (APAP) intoxication by exacerbating the recruitment of neutrophils at the site of inflammation. Using LC/mS, we discovered different CLEC-1 ligands, such as TRIM21, HRG and other intracellular or plasma membrane molecules. Although their biological activities following interaction with CLEC-1 remain to be fully investigated, we observed that a cell stress induced by radiation or by different chemotherapeutic class agents such as cyclophosphamide (CPA), oxaliplatin, vorinostat and others, increase the expression of CLEC-1 ligand(s) on necrotic and live cells. Consequently, we found *in vivo* that CPA treatment combined with the absence of Clec1a gene more strongly induced tumor volume reduction than in the presence of Clec1a in fibrosarcoma (MCA) and colorectal (MC38) mouse models. We developed and selected two anti-CLEC-1 antagonist antibodies harboring different properties (e.g. affinity, epitope). Using humanized CLEC-1 mice, we showed, in a orthotopic mouse model of hepatocarcinoma (Hepa1.6) exhibiting resistance to anti-PD1/PDL1 mAb therapy, that these anti-CLEC-1 antibodies in monotherapy significantly increase overall mice survival compared to corresponding isotype control treatment (3 independent experiments, n=32 for each treatment, $p<0.002$). Moreover, we confirmed also the therapeutic effect of these anti-CLEC-1 antibodies in combination with CPA in the ectopic MC38 model (n=18, 2 independent experiments). Altogether, our results further dissect the mechanism of action of the myeloid checkpoint CLEC-1 in its ability to impair anti-tumor immunity and support its target with antagonist antibody for cancer immunotherapy.

#7294 Neuropilin-1 specific antisense oligonucleotides exhibit anti-tumor activity in vivo and significantly increase the efficacy of checkpoint inhibitors.

Andre Maaske[1], Sven Michel[1], Daniel Kokotek[1], Nicole Kirchhammer[2], Anne Sadewasser[1], Julia Festag[1], Melanie Buchi[2], Monika Schell[1], Janani Sekar[1], Stefanie Raith[1], Alfred Zippelius[3], Frank Jaschinski[1], **Richard Klar**[1]

[1]Secarna Pharmaceuticals GmbH & Co. KG, Planegg, Germany,[2]Cancer Immunology, Department of Biomedicine, University Hospital Basel, Basel, Switzerland,[3]Cancer Immunology, Department of Biomedicine; Medical Oncology, University Hospital Basel, Basel, Germany

Introduction: Immune checkpoint inhibitors (ICI) revolutionized the treatment of cancer. However, most patients do not respond to the currently available therapies, or become refractory, which demonstrates the need for the development of novel therapeutic strategies. The transmembrane protein Neuropilin-1 (NRP1) interacts with various receptors and ligands and contributes to an immunosuppressive tumor microenvironment (TME) through multiple mechanisms. NRP1 facilitates the migration of tumor associated macrophages (TAMs), is important for the stability of regulatory T cells, correlates to exhaustion of effector T cells and plays an important role in neoangiogenesis. Furthermore, in several cancers including pancreatic, breast and gastric cancer, high expression of NRP1 has been associated with a poor prognosis. Here we demonstrate the anti-tumor effects of downregulation of NRP1 by locked nucleic acid (LNA) modified antisense oligonucleotides (ASOs) in murine cancer models as monotherapy and in combination with anti-PD-(L)1 antibodies. Furthermore, we provide insights into the potential underlying mechanisms of the observed therapeutic efficacy.
Methods: Highly active and well tolerated NRP1-specific ASOs were identified with our OligoCreator oligonucleotide discovery platform. These were tested in different syngeneic tumor models, after a palpable tumor was established, as monotherapy or in combination with ICIs. Survival, immune infiltration, NRP1 expression, and transcriptomic changes were analyzed.
Results: A robust knockdown of NRP1 was seen in tumor tissue and in individual infiltrating cell types, including T cells and macrophages, which was accompanied by transcriptomic changes in pathways related to inflammation and extracellular matrix remodeling. Mice treated with NRP1 specific ASO had delayed tumor growth up to complete tumor eradication, which was further increased when combined with ICI, whereas ICI alone showed only a low efficacy. The complete responders were re-challenged with the same cancer cell line, alongside previously untreated mice. While the treatment-naïve mice showed rapid tumor growth, all re-challenged mice eradicated tumors quickly, without the need for an additional treatment.
Conclusion: NRP1 specific ASOs are a promising new approach for the treatment of solid cancers. Our data show that the limited efficacy of ICI in the models tested could be improved significantly when combined with the ASO-treatment. Target knockdown was observable in various infiltrating cell types, accompanied by upregulation of genes involved in inflammation and downregulation of genes involved in extracellular matrix organization, which is currently being further analyzed. Based on these promising results, we started preparation for first in human trials to treat patients with solid cancers.

#7295 Reversing resistance to checkpoint inhibitors by treatment with claudin-1 specific antibodies in an orthotopic in vivo model for cholangiocarcinoma.

Romain Desert[1], Zeina Nehme[1], Bocar Kane[1], Emilie Crouchet[1], Frank Juhling[1], Vikas Ranvir[2], Alberto Toso[3], Mathias Heikenwalder[2], Catherine Schuster[1], **Thomas Baumert**[1]

[1]University of Strasbourg, Inserm, Institute for Translational Medicine and Liver Disease (ITM), UMR_S1110, Strasbourg, France,[2]Division of Chronic Inflammation and Cancer, German Cancer Research Center (DKFZ), Heidelberg, Germany,[3]Alentis Therapeutics, Allschwil, Switzerland

Background: Resistance to immunotherapy is a major challenge in the treatment of solid tumors. Cholangiocarcinoma (CCA) exemplifies this challenge by poor outcome and very limited response to approved checkpoint inhibitors (CPI). Claudin-1 (CLDN1) is a transmembrane protein overexpressed in epithelial cancer cells and shown to be a mediator of carcinogenesis, invasion and metastasis. However, the functional role of CLDN1 for the tumor microenvironment (TME) is largely unknown. Using CCA as a model disease, we aimed to study the impact of CLDN1 for the TME and its potential role as a therapeutic target to address CPI resistance.
Methods: CLDN1 expression and its association with TME was analyzed by spatial transcriptomics in CCA patient tissues. Immunocompetent orthotopic animal models of intrahepatic CCA were generated by hydrodynamic tail vein injection (HDTV) of proto-YAP/AKT or the KRAS/p19 oncogenes together with a CLDN1 expressing plasmid. Following tumor development within the liver, mice were treated with monoclonal antibodies (mAbs) targeting CLDN1 and/or PD-1.
Results: Spatial analyses of patient tissues revealed that CLDN1 was overexpressed in cancer cells and CLDN1 expression was associated with oncogenic signaling and reduced T cell infiltration. In orthotopic mouse models for CCA, CLDN1 gain-of-function studies showed enhanced tumor growth and decreased survival. Treatment with CLDN1 mAbs markedly and significantly reduced tumor burden and intratumoral fibrosis and resulted in increased intratumoral CD3+ and CD8+ T cell infiltration as well as modulation of peritumoral macrophage distribution. Gene expression analyses revealed down-regulation of pathways for fibrogenesis, carcinogenesis and up-regulation of pathways for T cell activation and proliferation. Whereas PD1 mAb single agent therapy did not show significant efficacy, the combination of PD-1 with CLDN1 mAbs markedly and significantly improved overall survival.
Conclusions: CLDN1 plays a functional role in the TME by modulating tumor fibrosis and immune cell infiltration. Treatment with CLDN1 mAbs provides an opportunity to overcome resistance and improve the efficacy of CPIs by enhancing tumoral immune responses.

#7296 PF-08046049 synergizes with checkpoint inhibitors to drive CD8+ T cell effector differentiation and tumor clearance in an IO-resistant model.

L. Shehata, M. Ulrich, L. Gutierrez, J. Hartsuyker, R. Giraddi, R. A. Heiser, B. P. O'Connor;
Pfizer, Inc., Bothell, WA

The checkpoint inhibitors anti-PD-1 and anti-CTLA-4 have been clinically successful as therapeutics for melanoma due to their ability to reinvigorate the immune system. However, about half of patients do not benefit from these treatments, suggesting there are still barriers to CD8+ T cell activation or infiltration into the tumor microenvironment (TME). Additionally, while the combination therapy of anti-CTLA-4 and anti-PD-1 (Ipilimumab-Nivolumab) improves response rate and overall survival compared to monotherapies, it also leads to increased toxicity and immune-related adverse events. Recent studies have demonstrated that CD8+ T cell co-stimulation through the 41BB axis is critical for PD-1/PD-L1 blockade efficacy in melanoma, yet those signals may be limited or unavailable to tumor-associated antigen-specific T cells within the TME. However, nontargeted 4-1BB signaling poses a risk of widespread peripheral immune activation and liver toxicity, as was the case for the 4-1BB agonist Urelumab. PF-08046049 (BB228) is a bispecific molecule comprised of a CD228-specific antibody and 4-1BB-directed Anticalin proteins. CD228 is highly expressed in several cancer indications but is low on normal tissues, thus BB228 targets 4-1BB co-stimulation to T cells within the TME. We tested the efficacy of BB228 as a monotherapy and in combination with the current melanoma standard of care (SOC) treatments, anti-PD-1 and anti-PD-1/anti-CTLA-4. In an IO-resistant LL2 model, neither BB228 nor anti-PD-1 monotherapy led to tumor control. However, in combination, BB228 synergized with anti-PD-1 and anti-CTLA-4 to promote tumor clearance. We found that while anti-PD-1 and anti-CTLA-4 can target and expand stem-like CD8+ T cells in both the tumor-draining lymph node and TME, BB228 is able to drive the differentiation of those stem-like cells into effectors, resulting in tumor killing. These data illustrate that BB228 has a distinct and complementary mechanism of action from the current melanoma SOC treatments.

#7297 Enhanced efficacy of CTX-471, a CD137 agonist antibody, in models of immune checkpoint failure via simultaneous blockade of neo-angiogenesis.

Amy Daniel Ulumben[1], Diana I. Albu[1], Rachael Duffy[1], Tristan Lubinski[2], Jason Kong[3], Jessica Zolotaresvsky[3], Melissa Brundin[3], Mei Su[1], Ruturaj Jadhav[3], Bing Gong[3], Thomas Schuetz[4], Kris Sachsenmeier[2], Alberto Visintin[1]

[1]Preclinical Research, Compass Therapeutics, Boston, MA,[2]Translational Research, Compass Therapeutics, Boston, MA,[3]Antibody Discovery, Compass Therapeutics, Boston, MA,[4]CEO and Co-founder, Compass Therapeutics, Boston, MA

CTX-471 is a monoclonal agonistic anti-CD137 antibody currently under investigation in solid tumors. To increase the breadth and duration of response of CTX-471 we set out to investigate its anti-tumor efficacy in combination with anti-angiogenesis agents in murine models. CTX-009 is a bispecific antibody targeting VEGF-A and DLL4 which is undergoing clinical investigation in multiple cancer types, including biliary tract and colorectal cancers. Encouraged by early findings showing activity of the combination in a B2m negative mouse tumor model, engineered to mimic HLA loss in patients, we broadened the exploration of the combinatorial treatment in an additional B2m knockout model using a different murine genetic background ($CT26^{B2m-/-}$, Balb/c). Furthermore, we developed two novel mouse models of immunotherapy resistance without the enhanced NK cell susceptibility bias conferred by complete MHC-I loss due to B2m deletion. CT26 cells with an engineered deletion of the B2m gene were passaged in CT26 tumor-experienced mice and a line of $CT26^{B2m-/-}$ cells that escaped immune rejection was established (CT26 B2m knockout escapers, $CT26^{B2m-/-E}$). For the second model, the H-2k1 MHC-I locus was knocked out in the MC38 cells, resulting in targeted homozygous loss. Using this approach, the expression of the other MHC-I alleles, and therefore natural resistance to NK cells, are expected to be left intact.

Results: Coupling VEGF-A/Dll4 targeting with CD137 agonism markedly increased the anti-tumor efficacy of the individual treatments alone in the $MC38^{B2m-/-}$, $MC38^{H-2k1-/-}$, $CT26^{B2m-/-}$ models as well as in the highly IO resistant $CT26^{B2m-/-E}$ model. Tumor growth inhibition was accompanied by pharmacodynamic evidence consistent with decrease of vascular bed density and enhancement of cellular cytotoxic immunity. CTX-471 monotherapy was still efficacious, albeit blunted, in these IO resistant models. The latter preclinical results mirrored data from a Ph1 clinical trial of CTX-471, where evidence of NK activation following CTX-471 treatment was seen in both blood and tissue samples of patients with known defects in the antigen presentation machinery. The findings presented here suggest that an agonistic anti-CD137 antibody may provide enhanced clinical benefit when employed alongside an anti-angiogenesis agent, such as CTX-009, in tumors where immune checkpoint inhibitors had previously failed.

#7298 DUSP11 is an intracellular innate immune checkpoint in lung adenocarcinoma.

Brian J. Thomas, Xue Bai, Benjamin J. Cryer, Mark A. Daniels, Margaret J. Lange, Donald H. Burke

Molecular Microbiology and Immunology, University of Missouri School of Medicine, Columbia, MO

The major success of immune checkpoint inhibitors (ICIs) to treat cancer highlights both the efficacy of inhibiting immunosuppressive proteins as a means of re-activating the anti-tumor immune response and the generalizability of targeting such proteins (i.e., therapies are clinically useful across many cancer types). While the major focus in immuno-oncology has been to manipulate the adaptive immune system, recent attention has been given to manipulating the innate immune system to treat cancer and/or enhance adaptive responses. In this work we detail the intracellular protein, Dual Specificity Phosphatase 11 (DUSP11), as an innate immune checkpoint (iIC) in lung adenocarcinoma (LUAD), among other cancers. LUAD remains a leading cause of death worldwide, largely due to mutant oncogene acquired therapeutic resistance and a lack of effective alternative therapeutic options, including ICIs. There is a clear unmet need for new methods to treat refractory LUAD. In this work we targeted DUSP11, a phosphatase with high affinity for 5' triphosphate RNA (3pRNA) that has readily been reported as a host factor that aids viruses escape of immune detection. As many cancers show dysregulated RNA transcript processing, we hypothesized that DUSP11 knockdown would increase the presence and detection of immunostimulatory RNA by pattern recognition receptors (PRRs) and activate anti-cancer immune mechanisms. To do this, we engineered multiple Dicer substrate small interfering RNAs targeting DUSP11 and showed that decreased expression at the mRNA and protein levels had significant impacts on cell viability for multiple cancer cell types, including LUAD. The decrease in LUAD cell viability was due to induction of apoptosis, and innate immune responses were significantly upregulated, evidenced by increased expression of interferon-stimulated genes (ISGs), release of type I IFN, and paracrine stimulation of cells expressing IFNAR1. As retinoic acid inducible gene I (RIG-I) was an ISG that was upregulated upon DUSP11 knockdown, we speculated that, as in viral studies, RIG-I was responsible for the anti-cancer phenotype. Indeed, the knockdown of RIG-I, but not other intracellular PRRs, recovered the cell viability and innate immune response phenotypes. To corroborate this, we showed that knocking down DUSP11 enhances the effect of RIG-I agonizing 3pRNA, and we showed that LUAD cells engineered to be deficient in RIG-I do not respond to DUSP11 knockdown. Ongoing studies in mice appear to show that the anti-cancer effect of modulating DUSP11 activity is conserved *in vivo*. Overall, our preclinical studies suggest that DUSP11 is an excellent target to modulate innate immunity and induce LUAD cell death. Early studies suggest that this target and mechanism is generalizable to other cancer types; however, understanding which cancers respond and why, as well as assessing the safety and toxicity of targeting this protein warrant further investigation.

#7299 CS2009: A first-in-class trispecific antibody targeting PD-1, CTLA-4, and VEGFA with potential to be a next-generation backbone therapy with combined checkpoint inhibition and anti-angiogenesis.

Chuan Wang, Ning Zhang, Yilin Huo, Xinling Zhang, Yongwang Li, Jingyu Sun, Xuelian Liu, Yongli Yang, Xueqin Dai, Yuxin Qian, Fei Ma, Yi Sun, Yujuan La, Jianxin Yang

CSTONE Pharmaceuticals, Suzhou, China

Background: CS2009 is a first-in-class trispecific antibody designed to target PD-1, CTLA-4, and VEGFA, with potential to replace current anti-PD(L)1 therapies. CS2009 consists of three functional arms including anti-PD-1, anti-CTLA-4, and anti-VEGFA. Clinical evaluations of bispecific molecules and combination therapies targeting PD-1/CTLA-4 and PD-1/VEGFA have shown favorable synergistic effects. For instance, cadonlimab (targeting PD-1/CTLA-4) and ivonescimab (targeting VEGFA/PD-1) have been approved in China for the treatment of advanced cervical carcinoma, gastric or gastroesophageal junction adenocarcinoma, and EGFR-mutant non-small cell lung cancer, respectively. Here, we present preclinical data that demonstrate CS2009 preferentially targets and reinvigorate PD-1/CTLA-4 double-positive tumor-infiltrating T lymphocytes (TILs); and its anti-VEGFA arm inhibits tumor angiogenesis and promotes vascular normalization, helping to convert an immune-suppressive tumor microenvironment (TME) to an immune-active TME, hence enhancing the tumor growth inhibition mediated by effector TILs.
Methods & Results: The lead molecule of CS2009, J30, was constructed with a bivalent anti-VEGFA arm, a monovalent anti-PD-1 arm, and a monovalent anti-CTLA-4 arm. Preclinical characteristics of J30 have been published previously. To further validate J30 as the lead molecule, J30 was assessed in primary PBMCs assays, which demonstrated its potent checkpoint inhibitory function. Its cross-species binding to PD-1, CTLA-4, and VEGFA were evaluated by Octet (BLI). Its functionality of interrupting the interaction of PD-1/PD-L1, CD80/CTLA4, and VEGFR2/VEGFA was evaluated in the competitive ELISA assays. Its cross-reactivity supported selection of cynomolgus monkey as the relevant species for nonclinical safety assessment. A single-dose PK study (5, 15, or 50 mg/kg, 30-minute IV infusion) and a GLP-compliant 4-week repeat-dose toxicity and safety pharmacology study (0, 25, 50, or 100 mg/kg, 30-minute IV infusion, QW*5) with a 4-week recovery were conducted in cynomolgus monkeys. J30 demonstrated a monoclonal antibody-like PK profile, with terminal half-lives ($t_{1/2}$) around 4 days, with no observed gender differences. All dose levels were well tolerated with the highest non-severely toxic dose (HNSTD) at 100 mg/kg. Further pharmacodynamic analysis demonstrated J30's biological activity in periphery with dose dependency. Both ICOS/Ki67 expression level on CD8 & CD4 T cells were upregulated.
Conclusion: CS2009 is a promising trispecific antibody for the treatment of various advanced solid tumors, with potential to be a next-generation backbone therapy with combined checkpoint inhibition and anti-angiogenesis. Current preclinical data support further clinical investigation of CS2009.

#7300 Resolvin E1 in solid tumor cancer: towards clinical translation of a novel oral agonist targeting the LTB4-BLT1 pathway to sensitize tumors to immune checkpoint inhibition.

Joyce Steinberg[1], Richard Newman[2], Beverly Paperiello[1], Tracy Jennings[1], Wayne D. Klohs[1], Sui Huang[3], Dipak Panigrahy[4], Gary Mathias[1], John Parkinson[1]

[1]Thetis Pharmaceuticals LLC, Essex, CT,[2]CMAX Clinical Research, Adelaide, Australia,[3]Institute of Systems Biology, Seattle, WA,[4]Beth Israel Deaconess Medical Center, Boston, MA

Background: Resolvin E1 (RvE1) and leukotriene B4 (LTB4) are both agonists of the BLT1 receptor (aka LTB4R1) but elicit distinct biological outcomes due to biased agonism. Activation of BLT1 promotes CD8+ T cell recruitment to the tumor, which enables effective immune checkpoint inhibitor (ICI) immunotherapy. However, LTB4, a pro-inflammatory lipid mediator, also promotes tumor progression through neutrophilic inflammation and is found at elevated levels in human cancers. In contrast, RvE1 selectively activates BLT1 to promote phagocytosis of tumor debris without causing inflammation. TP-317, a stabilized RvE1 molecule, effectively suppresses solid tumors in various murine models (CT26 colon carcinoma, Lewis lung carcinoma, B16F10 melanoma, KPCy pancreatic adenocarcinoma) when administered once daily, both alone and with ICI +/- chemotherapy. The effect of TP-317 as monotherapy required the presence of CD8 T cells and was largely abrogated in animals co-treated with a BLT1 antagonist. Whole-tumor transcriptomes of resected tumors of TP-317-treated versus control animals displayed broad upregulation of IFN-γ response genes and antigen presentation machinery, consistent with the synergism observed when given in combination with ICI. TP-317 is being developed as oral therapy for colorectal cancer and non-small cell lung cancer. The present study describes the pharmacokinetics, pharmacodynamics and safety profile of oral TP-317 given as an enteric-coated tablet to healthy volunteers.

Methods: Twenty-four subjects were randomized 3:1 to single oral doses of TP-317 at 10, 40 and 80 mg (n=8/group). Safety, tolerability and PK/PD were assessed using standard methods. Subjects receiving the 80 mg dose underwent frequent CBC testing to assess short-term fluctuations in circulating neutrophils.

Results: Oral TP-317 was well tolerated, achieving peak plasma concentrations of RvE1 that exceeded the EC_{50} for BLT1 activation (~10 nM) by 1.2, 2.8, and 6.7 times at 10, 40, and 80 mg doses, respectively. All subjects receiving the 80 mg dose exhibited transient neutropenia, with neutrophil counts dropping below 1500/mL near plasma tmax and recovering to normal range within about 2 hours. A similar pattern, also without safety concerns, was previously observed in healthy subjects receiving an oral RvE1 drug (150 mg bid) for 10 days.

Conclusions: Oral TP-317 demonstrates good tolerability and achieves adequate systemic RvE1 levels to engage the BLT1 receptor, suggesting a dose range of 40 to 80 mg once per day for patient studies. Transient neutropenia, a known effect of BLT1 activation by RvE1, indicates target engagement in humans. TP-317's unique ability to promote antigen presentation in myeloid and tumor cells offers a novel approach to sensitize tumors to ICI, warranting clinical investigation in cancer patients.

#7301 FP011, A tri-specific immune checkpoint inhibitor targeting PD-1 × TIGIT × PVRIG for cancer immunotherapy.

Yuanyuan Wang, Liang Xiao, Fan Wu, Baiguang Ren, Chang Zhou, Peipei Hu, Ke Chen, Xiaodong Wu, Di Lu, Yongting Huo

Guangdong Fapon Biopharma Inc., Dongguan, China

Immune checkpoint inhibitors, such as anti-PD-1/PD-L1 antibodies, have rapidly changed the treatment paradigm for multiple tumor types. Unfortunately, many patients still remain unresponsive or acquire resistance after initial response to treatment. The complex network of immunosuppressive molecules and their upregulation after initial treatment may contribute to such resistance, and lead to terminal exhaustion and fixed loss of effector functions of T cells. Here, we developed FP011, a tri-specific antibody which can simultaneously block the inhibitory signals of PD-1, PVRIG and TIGIT on effector T cells, so as to better activate T cells to kill tumor cells.

In vitro, by interacting with T cells *in cis*, FP011 can act on T cells with higher avidity, exerting synergistic blockade of these three immunosuppressive signals. In a tri-target reporter assay, both FP011 and the combination group induced much stronger luminescence signal than those induced by bi-specific antibodies and monoclonal antibodies. In an antigen-specific (CMV) T cell activation assay, in which T cells were induced to exhaustion after long-term stimulation with CMV antigens, FP011 also induced a more significant degree of T cell activation than what bi-specific antibodies, pembrolizumab and the combination of anti-PD-1, anti-PVRIG and anti-TIGIT monoclonal antibodies could do. In a PBMC-engrafted NOD-dKO-A375 mice model, FP011 inhibited tumor growth (93%, $P < 0.0001$) in a way significantly better than anti-PD-1 antibody (39.45%, $P = 0.0627$), the combination of anti-PD1, anti-PVRIG and anti-TIGIT antibodies (90% $P < 0.0001$), and another tri-specific positive control (66.18%, $P = 0.0007$). The inhibition of tumor growth was associated with an increase of tumor-infiltrating T cells following the FP011 treatment.

In conclusion, these data provide insight into the efficacy of FP011, both in vitro and in vivo, which indicates that targeting three immune checkpoints simultaneously can synergistically enhance T cell activation to achieve a better tumor-killing effect.

#7302 A Novel Therapeutic Approach : New Drug Candidate with are potent and safe next-generation multi-target immune checkpoint inhibitor.

B.-R. Lee[1], S.-B. Lee[1], C. Yoon[1], H. Hwang[1], S. Jung[1], J. Heo[1], K.-M. Lee[2], H. Kim[1];
[1]Cellemedy Co., Ltd., Seongnam, Korea, Republic of, [2]Korea University College of Medicine, Seoul, Korea, Republic of

Immune checkpoint inhibitors play a crucial role in current cancer treatments, serving as promising therapeutic options across various cancer types. In particular, PD-L1/PD-1 immune checkpoint inhibitors have been at the forefront of this field. However, recent concerns have been raised regarding the risk-benefit ratio of treatment based on PD-L1 expression levels, prompting the need for the development of immune checkpoint therapies that demonstrate high efficacy regardless of whether PD-L1 expression is high or low. Cellemedy's T-sphaera platform based multi-target immune checkpoint inhibitors that simultaneously act on multiple immune targets, regardless of target expression levels. This platform offers several advantages: 1) it introduces biologically active domains that exhibit therapeutic effects, 2) it demonstrates high avidity based on protein structural characteristics, 3) it inherently possesses a cancer-T cell engaging effect when introducing multi-targets, and 4) being human protein-based results in reduced immune-related side effects, contributing to a favorable safety profile and therapeutic index. Cellemedy's multi-target immune checkpoint inhibitors exhibit target-specific cytotoxicity against melanoma cancer cell line. In a non-human toxicity study, those compounds were well tolerated during repeated dosing, providing evidence of a superior safety profile without noticeable side effects. Furthermore, we verified strong efficacy in in vivo studies through T/NK cell engagement and high target avidity following a single-dose administration. Rapid and durable anti-tumor responses have been observed in vivo models. In summary, Cellemedy's T-sphaera is promising multi-target immune checkpoint inhibitor platform that can be designed for various target, not only immune checkpoint blockade but also other tumor receptors, aiming at multiple cancers.

#7303 A novel anti-PD-L1/VEGF bispecific antibody (HLX37) with immune checkpoint inhibition, anti-angiogenic, and antineoplastic activities.

Ge Song, Yu-Syuan Chen, Xiaoling Yuan, Chunlei Ge, Xiansong Xiong, Seng Zhu, Hongqing Wei, Jijun Yuan, Chen Hu, Qingyu Wang, Jun Zhu

Shanghai Henlius Biotech, Inc, Shanghai, China

Introduction: Dual blockade of PD-L1 and VEGF has demonstrated significant clinical benefits in advanced hepatocellular carcinoma (HCC) and non-small cell lung cancer (NSCLC). However, efficacy remains suboptimal in certain indications, potentially due to insufficient levels of anti-VEGF inhibitors within the tumor, as well as vascular dysfunction caused by the disruption of vascular homeostasis via the anti-VEGF inhibitor. The bispecific antibody targeting PD-L1 and VEGF enhances anti-VEGF delivery to the tumor site by binding to tumor PD-L1, promoting synergistic effects of blood vessel normalization and T cell activation within the tumor microenvironment, thus improving anti-tumor activity.

Methods: Flow cytometry and Biacore were employed to evaluate the binding of the bispecific antibody. PD-L1 or VEGF blockade assays were conducted using PD-1-Jurkat cells/PD-L1-APC-CHOK1 or KDR cells. Efficacy was assessed in CDX models with immune humanization, including MDA-MB231 (human breast cancer cell line), NCI-H292 (human lung mucoepidermoid carcinoma cell line), HCT116 (human colon cancer cell line), and SK-MES-1 (human lung cancer cell line) tumor cell lines. Pilot pharmacokinetic and toxicity studies were performed in cynomolgus monkeys.

Results: *In vitro* assays demonstrated that the anti-PD-L1/VEGF bispecific antibody exhibits high binding affinity for both PD-L1 and VEGF, showing dual blockade activity against PD-1/PD-L1 and VEGF/VEGFR2. The anti-PD-L1/VEGF bispecific antibody was shown to possess superior ability to reverse T cell exhaustion. It conferred robust tumor inhibition activity and dose-dependent tumor suppression in the MDA-MB231, NCI-H292, HCT116, and SK-MES-1 models. Compared to the combination group of anti-PD-1 monoclonal antibody and anti-VEGF monoclonal antibody, the anti-PD-L1/VEGF bispecific antibody showed enhanced tumor enrichment. The distribution of anti-PD-L1/VEGF is mediated by both PD-L1 and VEGF, HLX37 was well tolerated in cynomolgus monkeys after three weekly intravenous doses of 100 mg/kg.

Conclusion: HLX37 is an anti-PD-L1/VEGF bispecific antibody with immune checkpoint inhibitory, anti-angiogenic, and antineoplastic properties. It demonstrated strong preclinical efficacy and a favorable safety profile, with enhanced tumor enrichment. It holds promising potential for further application in various types of tumors.

#7304 Cytotoxic PD-L1/PD-L2 dual-specific antibodies couple tumor stroma remodeling with checkpoint blockade to drive rejection of "cold" cancers.

Ahmad Salameh[1], Coline Couillault[2], Anupallavi Srinivasamani[2], Qinying Liu[2], Elisabetta Bolli[3], Christine Gagliardi[1], Guillaume Trusz[2], Nadthakarn Boland[4], Paul Blezinger[1], Dongxing Zha[2], Manuela Iezzi[5], Bianka Prinz[4], Federica Cavallo[3], Federica Pericle[1], **Michael A. Curran**[2]

[1]ImmunoGenesis, Inc., Houston, TX,[2]Immunology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy,[4]Adimab, Inc., Lebanon, NH,[5]D'Annunzio University of Chieti-Pescara, Chieti-Pescara, Italy

Introduction: Antibody blockade of either the Programmed Death 1 (PD-1) immune checkpoint receptor on T cells or its cognate ligand PD-L1 on tumor cells and stroma has revolutionized oncology but fails to regress "cold" tumors lacking T cell infiltration. We leveraged the iterative selection capacity of yeast-displayed fully human antibody selection to identify dual PD-L1/PD-L2 specific antibodies (DIPDL) that block their engagement of both PD-1 and B7-1. Finally, we engineered these DIPDL to efficiently kill PD-L1 and PD-L2 expressing tumors and stroma.
Materials and Methods: Antibody binding to PD-Ligands was measured by Octet. The Promega PD-1 assay system was used to measure EC50s for reversal of PD-1 driven T cell inhibition. Retrogenix microarray technology was used to determine specificity of target binding. Surrogate and direct assays were used to measure ADCC and ADCP efficiency. Murine syngeneic tumor models were tested for PD-1 blockade versus DiPDL antibodies to mediate tumor regression. Flow cytometry was used to characterize changes in the tumor immune microenvironment. Human tumor xenografts were implanted into immunodeficient mice to study the cytotoxic potential of these antibodies.
Results: We leveraged multiple antibody engineering technologies to generate dual PD-L1/PD-L2 specific antibodies capable of blocking ligand interactions with PD-1 and B7-1, and also mediating efficient tumor and stromal depletion. These Fc engineered DIPDL kill human PD-L1$^+$ and/or PD-L2$^+$ cells *in vitro* using both NK and myeloid effectors. *In vivo* studies of murine syngeneic tumor models revealed that these DIPDL antibodies significantly outperform PD-1 blockade across both "hot" and "cold" cancers. Tumor microenvironment analysis showed that myeloid stromal depletion correlates with T cell and dendritic cell expansion and therapeutic response. Lastly, treatment of immunodeficient mice bearing human triple negative breast cancer with these cytotoxic DIPDL significantly inhibited tumor growth and reduced myeloid stromal density.
Conclusions: These DIPDL represent a new generation of immunotherapeutic which couple superior PD-1 pathway blockade with direct depletion of both immunosuppressive and T-cell exclusionary stroma and tumors. Across murine models, these DIPDL deliver transformative efficacy overcoming limitations of simple PD-1 blockade and have moved to an ongoing Phase I clinical trial.

#7305 Increasing TCR/antigen sensitivity using anti-CD3 Fabs enhances anti-tumor effects but not immunotoxicity of immunotherapies blocking T cell checkpoint receptors.

Onyekachi Juliet Okpasuo, Chandrashekara P. Mahadevappa, Hien Huynh, Christa Cheatam, Vijay Radhakrishnan, Adam Schrum, Diana Gil

University of Missouri - Columbia, Columbia, MO

Cancer patients treated with immune checkpoint inhibition (ICI), such as monoclonal antibodies (mAbs) that block the inhibitory functions of the T cell receptors, CTLA-4 and PD-1, are at risk of experiencing immune-related adverse effects (IRAEs). These effects may require interruption, neutralization, or discontinuation of treatments, potentially hindering control of cancer progression. The risk for IRAEs is elevated in individuals with underlying autoimmune diseases (AIDs), resulting in this subpopulation of cancer patients being undertreated with ICI therapies. Establishing novel approaches to enhance anti-tumor control by T cells using ICI without increasing concomitant immunotoxicity could benefit a broad range of cancer patients, including those with autoimmune pathologies. Targeting the CD3ε subunit of the T cell antigen receptor (TCR) with a Fab fragment that strictly controls monovalence (Mono-Fab) improves sensitivity to TCR/antigen stimulation and T cell effector function. We have demonstrated that anti-CD3ε Mono-Fabs are effective immunotherapies against murine melanoma, depending on the presence of functional T cells and the availability of tumor-associated antigens (TAAs) in melanoma cells. Here, the efficacy of the anti-mouse CD3ε Mono-7D6-Fab and its potential to induce IRAEs has been compared to ICI therapies using the mAbs anti-PD-1 and anti-CTLA-4 in mice implanted with subcutaneous melanoma. Results indicate that Mono-7D6-Fab enhances the performance of ICIs based on the level of tumor immunogenicity. However, Mono-7D6-Fab did not increase the immunotoxicity risk of either anti-CTLA-4 or anti-PD-1 monoclonal antibodies when combined with these treatments, nor in experiments involving the three types of immunoglobulins, as seen in mice with experimental autoimmune encephalomyelitis (EAE), which reported a worsening of T cell-mediated immune pathology. Additionally, T, B, and innate immune cell subpopulations found in peripheral lymphoid and CNS tissues, which could mediate EAE, were down-modulated in mice treated with Mono-7D6-Fab alone or combined with ICIs while elevated in mice treated solely with ICIs. Similarly, treatment with ICIs alone failed to control tumor growth in the context of underlying autoimmune disease; however, combining Mono-7D6-Fab with ICIs restores the anti-tumor benefit of ICI without further exacerbating autoimmune toxicities. These promising findings justify further experimentation for the eventual translation of anti-human CD3 Mono-Fabs, potentially enhancing and broadening the application of cancer immunotherapies that target T-cell anti-tumor responses.

#7306 Selective and novel ALDH1 inhibitor enhances immune checkpoint blockade therapy in preclinical models of MSS colorectal cancer.

Akinchan Kumar[1], Andrada Constantinescu[2], Ismail Ceylan[2], Mileidys Perez-Alea[2], **Bassam Janji**[3]

[1]Department of Cancer Research, Luxembourg Institute of Health, Luxembourg City, Luxembourg,[2]Advanced BioDesign, Saint-Priest, France,[3]Luxembourg Institute of Health, Luxembourg City, Luxembourg

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths globally and the third most frequently diagnosed cancer type, according to the Global Cancer Observatory. While the emergence of immune-checkpoint inhibitors (ICI) in the past decade has transformed cancer treatment paradigms, their efficacy in CRC is limited, particularly in the microsatellite-stable (MSS) subtype, which constitutes 85% of cases. MSS CRC is characterized by a low mutation burden and an immunosuppressive tumor microenvironment (TME), resulting in poor responsiveness to ICIs. Recent studies have identified elevated ALDH1 expression and its enzymatic products in MSS tumors, with retinoic acid (RA) produced by ALDH1 playing a pivotal role in fostering an immunosuppressive TME. This RA-mediated immunosuppression arises not only from tumor cells but also from tumor-associated immune cells, such as M2 macrophages and myeloid-derived suppressor cells (MDSCs), both of which exhibit high ALDH1 activity. Using syngeneic mouse models of MSS CRC, including MC38-CEA and CT26 cell lines, we evaluated the therapeutic potential of combining ABD0171, a selective ALDH1 inhibitor (ALDH1i), with anti-PD-1 therapy. Our findings reveal that ABD0171 significantly enhances the efficacy of anti-PD-1 therapy, leading to improved survival outcomes in MSS CRC models. This synergistic effect is associated with substantial alterations in the TME immune landscape, including an increase in pro-inflammatory M1 macrophages and reductions in both M2 macrophages and regulatory T cells (Tregs). Mechanistically, ALDH1 inhibition significantly reduces intratumoral RA levels, disrupting a key pathway responsible for the differentiation of immunosuppressive macrophages from monocytes. Ongoing studies are exploring the molecular mechanisms underlying these effects. Overall, our work underscores the potential of selective ALDH1 targeting as a strategy to overcome immunotherapy resistance in MSS CRC, offering new therapeutic opportunities for patients with this challenging cancer subtype.

#7307 Potential role of alpha-2-macroglobulin in versican proteolysis regulation in colorectal cancer.

Yousef H. Gadalla, Somak Chaudhuri, Sean G. Kraus, Anna M. Field, Katherine A. Johnson, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin - Madison, Madison, WI

Background: Versican is a large extracellular glycoprotein that acts as a barrier for immune cell infiltration in colorectal cancer (CRC). The V1 isoform of versican can be cleaved by ADAMTS 4 and 5 into the bioactive fragment versikine with immune stimulatory properties. Despite overexpression of ADAMTS 4 and 5 in CRC, versican may be poorly proteolyzed. ADAMTS 4 and 5 may be inhibited by the presence of an extracellular endopeptidase inhibitor, alpha 2 macroglobulin (A2M). Here we investigate A2M expression in CRC, its correlation with versican proteolysis status, and immune cell infiltration.

Methods: The Cancer Genome Atlas (TCGA) Colorectal Adenocarcinoma PanCancer Atlas dataset was used to stratify CRC patients (n=594) into two cohorts: $A2M^{hi}$ (n=57) (mRNA expression Z-score >1) and $A2M^{lo}$ (n=341) (Z-score <0). Clinical characteristics and differences in gene expression were analyzed between the two groups. CRC patient-derived tumor samples (n=306) were analyzed for protein-level expression of versican (VCAN), versikine (Vkine), A2M, CD8A and CD4 via immunohistochemistry (IHC). A binning scale of 0 - 3 was used to assess staining intensity with 0/1 being low and 2/3 being high expression. The number of CD8A and CD4-positive lymphocytes in direct contact with tumors (tumor-infiltrating lymphocytes; TILs) were counted per high power field (HPF). Th1 (T helper 1 cell) and Treg (T regulatory cell) subsets of CD4+ TILs were further evaluated per 20X field of view (FOV) via dual immunofluorescence.

Results: $A2M^{hi}$ and $A2M^{lo}$ groups have no differences in disease staging (q=.109), sex (q =0.992) or age distribution (q= 0.368). The $A2M^{hi}$ group has higher mRNA expression of VCAN (log_2fold change = 2.40, q <.01), ADAMTS1 (2.3, q<.01), ADAMTS4 (1.74, q <.01), ADAMTS5 (1.47, q<.01), CD8A (1.48, q<.01), CD4 (1.91, q<.01), CXCL9 (1.88, q<.01), and CXCL10 (1.32, q<.01). Out of 306 patient-derived tumor samples, 82.9% of versican proteolytic prominent (VPP) ($VCAN^{Lo}$ $Vkine^{Hi}$) were $A2M^{Hi}$, 76.8% of versican proteolytic weak (VPW) ($VCAN^{Hi}$ and $Vkine^{Lo}$ or $Vkine^{Hi}$) were $A2M^{Hi}$, and 85.1% of versican versikine low (VVL) were $A2M^{Hi}$. There is a trend towards significant interaction between A2M, versican and Th1 cells (p=0.0531), but none exist between A2M, versican and CD8+ T-cells/ Tregs. VPP and $A2M^{Hi}$ samples have significantly higher median Th1s/FOV than VPW and $A2M^{Hi}$ samples (VPP and $A2M^{Hi}$median: 24.5 Th1s/FOV, VPW and $A2M^{Hi}$ median: 9, p = .009).

Conclusion: The expression of A2M can regulate ADAMTS protease function but does not appear to prevent VCAN proteolysis or impact T cell infiltration in CRCs.

#7309 Investigating IL-1β signaling axis and inhibition strategies with small molecules in canine metastatic osteosarcoma: Insights for translational medicine.

Matheus Moreno Passos Barbosa[1], Vishnu V. Krishnamurthy[2], Timothy M. Fan[3]

[1]Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL,[2]High-Throughput Screening Facility, School of Chemical Sciences, University of Illinois at Urbana-Champaign, Urbana, IL,[3]Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL

Introduction: Osteosarcoma (OS) is the most common bone tumor in pet dogs and people. While localized therapies, including surgery and ionizing radiation, effectively control bone-related events, options for slowing metastatic progression remain limited and only marginally active. Advances in drug delivery highlight the need for predictive animal tumor models to accelerate therapeutic development for humans. The clinical features, behavior, histopathology, treatment response, and genetics of OS in dogs closely mirror those in humans, making dogs an ideal comparative model. Dogs with spontaneous OS offer valuable insights into OS biology and are particularly useful for evaluating immunotherapeutic strategies. The pro-inflammatory effects of interleukin-1-beta (IL-1β) in the tumor microenvironment may hinder immunological responses against OS in both species. IL-1β is upregulated in the myeloid compartment of canine OS patients and facilitates metastatic progression in other cancers, including breast cancer. This study investigates the biological sources and role of IL-1β in OS metastatic biology and potential blocking strategies with small molecule inhibitors, offering insights for translational medicine.
Methods: Canine OS cells, primary monocytes, monocyte-derived macrophages, and DH82 cells were used to investigate IL-1β secretion and receptor expression. Immunological and proliferative factors under IL-1β exposure were assessed by ELISA and clonogenic assays. RNA NanoString profiling was employed to characterize gene transcripts in both healthy canine lungs and metastatic OS lesions. A high-throughput screening approach evaluated the ability of 80,000 small molecules to inhibit IL-1β intracellular downstream signaling and to inhibit IL-1β biological release and inflammasome activity.
Results: Canine OS cells express receptors related to IL-1β signaling and secrete pro-metastatic factors upon IL-1β exposure. However, OS cells do not secrete IL-1β. Primary monocytes and DH82 cells secrete IL-1β in response to inflammasome and caspase activator molecules. Monocyte-derived M1 macrophages were found to release significantly higher amounts of IL-1β compared to M0 and M2 macrophages. Metastatic lesions in canine OS exhibited distinct gene transcript profiles. Small molecules and structure-related molecules with potent IL-1β inhibition activities were identified.
Conclusions: Our study showed that IL-1β is secreted by monocytes and macrophages, not by OS cells. IL-1β induces the release of pro-metastatic factors by canine OS cells, suggesting its role in OS metastasis. Targeted inhibition of IL-1β may be a potential therapeutic strategy for controlling metastatic progression in OS and collectively underscore the potential value of comparative oncology approach towards successful translation medicine.

#7310 PTPN1/2 inhibition with AC484 inhibits tumor metastasis.

Yue Liu, Im-Meng Sun, Marc Creixell, Jordan S. Brown, Tuan Andrew Nguyen, Jiaxi Wang, Nianxin Yang, Ka Man Li, John Balibalos, Samir Kharbanda, Kayley Hake, Varahram Shahryari, Aaron W. Stebbins, Patrick M. Godfrey, Jonghyeob Lee, Chirag H. Patel, Po-Han Tai, Evangelia Malahias, Wenjun Kong, Kenneth J. Finn, Marcia N. Paddock, Fiona A. Harding, Jonathan D. Powell

Calico Life Sciences, South San Francisco, CA

ABBV-CLS-484 (AC484) is a novel small molecule based immunotherapeutic drug that inhibits both PTPN2 and PTPN1 and is currently under clinical investigation for treating solid tumors. In preclinical syngeneic tumor models, AC484 has been shown to be efficacious as a monotherapy, in conjunction with checkpoint inhibitors (ICBs) in ICB-resistant tumors, as well as in adoptive cellular therapy (Baumgartner et al, Nature 2023). Given the potent efficacy of this immunomodulatory compound, we sought to investigate the potential role of PTPN1/2 inhibition as a means of preventing metastasis. To this end, we established spontaneous metastatic murine models of 4T1 breast cancer and CMT167 lung cancer. In both models, AC484 treatment was able to inhibit metastasis. Notably, AC484 reduced circulating tumor cells and suppressed tumor cell seeding and outgrowth in the lungs. Genetic deletion of PTPN1/2 in tumor cells failed to recapitulate this effect, indicating that PTPN1/2 inhibition was tumor cell extrinsic. Indeed, AC484 was ineffective in inhibiting metastasis in NSG mice, suggesting that it exerted its effects on immune cells. Antibody depletion experiments further demonstrated that both T cells and NK cells play critical roles in AC484-mediated anti-metastatic activity in the C57BL/6 CMT167 model, with NK cells appearing more dominant in the BALB/c 4T1 model. Careful kinetic analysis of these models demonstrated accumulation of myeloid cells, particularly neutrophils and monocyte-derived macrophages, both systemically and locally in the lungs. Importantly, this increase in myeloid population was observed prior to the formation of micro metastases and continued to escalate as lung metastasis advanced. These findings support a role for myeloid cells in altering the microenvironment to promote seeding, survival, and growth of metastatic tumor cells. Interestingly, while AC484 treatment prevented lung metastasis, it did not decrease myeloid cells. Rather, single-cell RNA sequencing of lung tissue from 4T1-bearing mice showed an increase in activation markers of myeloid cells, supporting a role for AC484 in modifying the metastatic microenvironment. Taken together, our data demonstrate the ability of PTPN1/2 inhibition to inhibit metastasis by enhancing anti-tumor immunity and altering the metastasis niche. These data provide the preclinical rationale for pursuing AC484 treatment in the neoadjuvant/adjuvant setting as a means of promoting the efficacy of cancer therapies with curative intent.

#7311 Targeting STAT3 to prevent non-small cell lung cancer in patients with chronic obstructive pulmonary disease.

Katherine E. Larsen[1], Leticia G. Hamana Zorrilla[2], T. Kris Eckols[3], Moses M. Kasembeli[3], Michael J. Clowers[1], Avantika Krishna[1], Maria T. Grimaldo[1], Nastaran Karimi[1], Shanshan Deng[1], Vignesh Gunasekharan[4], Luisa M. Solis Soto[2], David J. Tweardy[1], Seyed Javad Moghaddam[1]

[1]Pulmonary Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[3]Infectious Diseases, UT MD Anderson Cancer Center, Houston, TX,[4]Division of Cancer Prevention, National Cancer Institute, Rockville, MD

Non-small cell lung cancer (NSCLC), primarily caused by cigarette smoking, is the leading cause of cancer-related deaths worldwide. Smokers with chronic obstructive pulmonary disease (COPD) face a 3-10 fold increased risk of developing NSCLC compared to smokers without COPD. Lung inflammation and functional deterioration persist in COPD patients, and the risk of developing NSCLC remains elevated. This notes the importance of targeting inflammatory pathways to prevent cancer progression. In COPD patients, lung adenocarcinoma (LUAD) is the most common subtype of NSCLC, with about 30% of cases featuring activating mutations in the Kirsten rat sarcoma viral (*KRAS*) oncogene. Current treatments for *KRAS*-mutant LUAD (KM-LUAD) are often ineffective, warranting novel preventive and therapeutic methods. Our group previously developed a COPD-like mouse model through weekly exposure to an aerosolized lysate of non-typeable *Haemophilus influenzae* (NTHi), a common airway colonizer in COPD patients. Using this model, we showed that COPD-like inflammation promotes KM-LUAD with an essential role for the pro-inflammatory cytokine, IL-6, and activation of signal transducer and activator of transcription 3 (STAT3). Here, we investigated the effects of STAT3 inhibition on KM-LUAD promotion by COPD. We utilized $CCSP^{Cre}$/LSL-$Kras^{G12D}$ (CC-LR) mice, a genetic model of LUAD that develops early-stage lung lesions starting at six weeks of age. Six-week-old CC-LR mice were exposed to aerosolized NTHi lysate or PBS weekly to induce COPD. At ten weeks of age, they received one of three doses (25, 50, or 100 mg/kg) of TTI-101, a selective STAT3 inhibitor, or vehicle control daily for 14 days by oral gavage. We then collected blood, bronchoalveolar lavage fluid (BALF), and lung tissues for complete blood counts, blood chemistry tests, tumor burden, inflammation analysis, and histopathology. Results indicated no significant weight changes or toxicity from TTI-101 treatment. NTHi exposure induced COPD-type neutrophilic inflammation in vehicle treated cohorts that was reduced following the treatment with TTI-101. Tumor burden, both multiplicity and area, also showed a significant decrease in TTI-101-treated mice. Inflammation and levels of tyrosine phosphorylated STAT3 (pY-STAT3) in lung tissues were significantly reduced post-treatment. These findings suggest that STAT3 contributes to KM-LUAD promotion in COPD and that its inhibition with TTI-101 may effectively prevent KM-LUAD associated with COPD. Further research will determine the effects of TTI-101 in preventing NSCLC promotion and identify candidate biomarkers that correlate with NSCLC development and the preventative efficacy of TTI-101. Funding: This project was funded by Federal funds from the National Cancer Institute, National Institutes of Health, Department of Health and Human Services, under contract No. 75N91019D00021/75N91022F00002

IMMUNOLOGY: T Cell Engagers and Novel Antibody-Based Therapies
Poster Session

#7315 Engineering and characterization of novel T cell engagers (TCEs) directed against colorectal cancer-associated antigens (CEACAM5, CDH17).

Jinxiu Hou, Liang Tian, Chenpeng Su, Rui Shen, Dandan Liu, Jiyuan Tian, Tingting Gu, Xiaoou Xu, Xiaoqian Chen, Lisha Dong, Chuan Chen, Yongxin Shang, Maowei Wang, Jian Peng, Zhenping Zhu

Helixon US Inc., New York, NY

Colorectal cancer (CRC) is one of the most prevalent and deadliest oncological diseases worldwide. Carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5) and cadherin-17 (CDH17) have been shown to be selectively expressed in colorectal tissues, and their level of expression and/or co-expression are significantly up-regulated in malignant diseases. Various experimental therapeutic modalities addressing these TAA targets are currently under active exploration. In this study, we engineered several T cell engagers (TCEs) directed against these targets, in multiple molecular formats, such as TAA/CD3 (1+1), TAA/TAA/CD3 (bivalent or biparatopic, 2+1), and TAA1/TAA2/CD3 (trispecific, 1+1+1), and characterized these TCEs in a battery of assays, including binding, T cell activation and tumor cell-killing, production and developability, as well as anti-tumor efficacy in vivo in various animal models. '1+1', '2+1' bivalent, and '2+1' biparatopic formats were designed and constructed for both CEACAM5/CD3 and CDH17/CD3 bispecific TCEs. A trispecific TCE, CEACAM5/ CDH17/CD3 (1+1+1) was also produced. The cell-binding, cytotoxicity, T cell activation and cytokine release mediated by these TCEs were investigated in vitro. The anti-tumor activity of these TCEs were examined in vivo in human PBMC-reconstituted immune-deficient mice implanted with human CEACAM5- and/or CDH17-expressed tumor xenografts. In these TCE molecules, each building blocks, i.e., αCEACAM5, αCDH17, and αCD3 antibodies, were designed and selected regarding their antigen binding affinity and specific epitope. These are followed by various designing of the molecular formats of the TCEs to ensure the balance of multiple parameters, including antigen/cell binding, T cell activation vs tumor cell killing, production and developability, etc. Our studies identified a CEACAM5/CDH17/CD3 trispecific TCE that was more potent than the bispecific TCEs in killing tumor cells, and was broadly effective in killing tumor cells that either express only CEACAM5 or CDH17, or both. The trispecific TCE was also more efficacious than the single-target based TCEs in inhibiting xenograft tumor growth in animal models. Taken together, these findings support further development of the CEACAM5/CDH17/CD3 trispecific TCE as a promising modality for the treatment of CRC patients.

#7316 QL615, a tetraspecific T cell engager with highly restricted activity on MET and EGFR-positive tumors while providing co-stimulation via CD2.

Yanan Wang, Meihua Luo, Guangjie Guo, Shenda Gu, Joshua Morrissette, Nathan Ngo, Shihao Chen

QLSF Biotherapeutics, South San Francisco, CA

Effective targeting of solid tumors using T cell engagers remains challenging due to the lack of tumor specific antigens (TSA), and the difficulty in achieving sustained anti-tumor response. Frequently, target antigen expression is upregulated on cancer, yet low expression on normal tissues limits the therapeutic window. Moreover, the lack of co-stimulatory signals paired with CD3 in the tumor microenvironment often leads to T cell exhaustion and non-durable responses. To overcome these shortcomings, we have developed a tetraspecific T cell engaging platform, termed TECAD "T Cell Engager with Co-Stimulation Avidity Driven", to address both tumor selectivity and potency by (1) activating T cells only when bound to tumor cells expressing paired antigens, and (2) providing CD3 co-stimulation via conditional CD2 activation. The latter enhances antitumor immune response and overcomes resistance to immune checkpoint blockade therapies. QL615, our lead TECAD candidate, targets MET and EGFR, two clinically validated targets limited by expression on normal tissues. MET and EGFR are typically expressed on non-overlapping normal tissues but frequently colocalized on tumors cells. We have optimized the affinity of MET and EGFR binding domains such that only dual engagement on the target cell provides high avidity binding AND-gated activation. Cell binding assays showed nanomolar EC_{50} on tumor cells expressing both MET and EGFR, whereas binding was negligible on cells expressing only low levels of either MET or EGFR. In vitro killing assays demonstrated over a 1000-fold selectivity in the lysis of double-positive tumor cells. The TECAD's CD2-mediated co-stimulation enhanced in vitro killing of tumor cells ~30-fold over constructs with CD3 redirection alone and showed superior tumor growth control in vivo. QL615 is currently advancing toward a development decision and clinical evaluation.

#7317 A novel LY6G6D x CD3 bispecific T-cell engager demonstrates better tumor killing and minimal cytokine release than a benchmark molecule.

Lini Huang, Mengting Chen, Yu Zhang, Dong Wu, Shiyong Gong, Xuan Wu, Danqing Wu, Chengbin Wu

EpimAb Biotherapeutics, Shanghai, China

Colorectal cancer (CRC) poses a significant global health challenge with high morbidity and mortality rates. Immune checkpoint inhibitors (ICI) have shown remarkable clinical efficacy in patients with mismatch-repair deficient (dMMR) or microsatellite instability-high (MSI-H) colorectal cancer. However, the vast majority of patients with microsatellite-stable (MSS) or microsatellite instability-low (MSI-L) colorectal cancer cannot benefit from ICI treatment. Recently, lymphocyte Antigen 6 Family Member G6D (LY6G6D) has emerged as a tumor associated antigen selectively expressed in MSS and MSI-low colorectal cancers. By using EpimAb's proprietary anti-CD3 antibody panel and bispecific antibody platform, we developed EM1034, a novel LY6G6D x CD3 bispecific T-cell engager (TCE). Compared to a clinical stage benchmark TCE which has monovalent target binding arms and asymmetrical knob-into-hole geometry, EM1034 demonstrated hundred folds increased tumor lysis potency while it induced much lower cytokines *in vitro*. *In vivo* efficacy studies further demonstrated that EM1034 is more potent than the benchmark molecule in xenografted models with different LY6G6D expression levels. Taken together, this study support EM1034 as a promising molecule for the treatment of mCRC patients with LY6G6D positive MSS/MSI-L tumors.

#7318 ZW209, a DLL3 targeted trispecific T cell engager with integrated CD28 co-stimulation, demonstrates safety and potent preclinical efficacy in models of small cell lung cancer.

Desmond Lau, Peter Repenning, Diana Canals Hernaez, Alec Robinson, Diego Perez Escanda, John Zhang, Hamed Shirvani, Catherine Wu, Kurt Stahl, Aditi Deshmukh, Nichole Escalante, Mariana Rocha, Begonia Silva Moreno, Lisa Newhook, Purva Bhojane, Paul A. Moore, Nina E. Weisser, Thomas Spreter von Kreudenstein

Zymeworks BC Inc., Vancouver, BC, Canada

Small cell lung cancer (SCLC) is a highly aggressive and difficult-to-treat malignancy with limited treatment options. Delta-like ligand 3 (DLL3), a cell surface protein overexpressed in SCLC, has emerged as a promising therapeutic target. Bispecific T cell engagers (TCE) targeting DLL3, including tarlatamab which has received accelerated approval, have demonstrated anti-tumor activity in the clinic with an improved duration of response compared to current standard of care, including chemotherapy and immunotherapy. Despite these advances, we believe there is opportunity to improve the rate and depth of response as the clinical activity of bispecific T cell engagers may be limited by low T cell infiltration and poor T cell function characteristic of SCLC tumors, and by the emergence of treatment-related T cell anergy due to T cell stimulation via signal 1 (CD3) only. The incorporation of signal 2 co-stimulation, via CD28 signaling, has the potential to improve response rates by stimulating increased T cell activation, proliferation and survival. To address treatment challenges and enhance the durability and sustainability of T cell activation, we engineered ZW209, a trispecific co-stimulatory T cell engager (TriTCE Co-stim) that optimally engages CD3 and CD28 and redirects and enhances cytotoxic T cell responses to DLL3-expressing tumor cells while maintaining a desired safety profile.

Our development candidate, ZW209, is designed to optimally engage CD3 and CD28 in an obligate *cis* manner, supported by a lack of T cell cross-linking and fratricide. The addition of CD28 co-stimulation in ZW209 demonstrated enhanced DLL3-dependent cytokine induction and T cell proliferation with improved antitumor activity relative to clinical bispecific TCEs benchmarks. In a serial, repeated challenge *in vitro* cytotoxicity assay, ZW209 displayed superior T cell fitness and anti-tumor activity to a bispecific control and clinical benchmark. *In vivo*, ZW209 exhibited potent anti-tumor activity in multiple humanized SCLC xenograft models. In aqueous and solid phase cytokine release assays, ZW209 exhibited minimal DLL3-independent cytokine production. Importantly, a ZW209 cynomolgus cross-reactive surrogate molecule displayed a favorable safety profile as it was well tolerated in non-human primates with repeat dosing at 10 mg/kg with no abnormal clinical signs.

In summary, these preclinical data support that ZW209 promotes improved anti-tumor activity against DLL3-positive cancer cells relative to competitor bispecific TCEs. By integrating CD28 co-stimulation into our trispecific T cell engager, ZW209 has the potential to improve the rate and duration of response for better clinical outcomes.

#7319 AI-guided engineering and development of anti-DLL3-targeting T cell engagers (TCEs).

Chuan Chen, Yue Wu, Liang Tian, Chenpeng Su, Zhaohui Chen, Dandan Liu, Jiyuan Tian, Xiaoou Xu, Xiaoqian Chen, Yang He, Yongxin Shang, Jian Peng, Zhenping Zhu

Helixon US Inc., New York, NY

The aggressive nature of small cell lung cancer (SCLC) and other neuroendocrine cancers (NECs), coupled with their poor prognosis and limited therapeutic options, represent significant challenges in clinical settings. Current first-line treatments, which often include platinum-based chemotherapy combined with programmed cell death protein 1 (PD-1) axis blockade, are associated with short-lived remission and rapid development of resistance, underscoring the critical need for novel therapeutic strategies. Delta-like ligand 3 (DLL3) has emerged as a promising tumor-associated biomarker, with specific overexpression on NECs, particularly SCLC. An anti-DLL3 x CD3 bispecific T-cell engager (TCE), tarlatamab, has demonstrated significant clinical benefits and was recently approved by the US FDA for the treatment of DLL3-expressing SCLC. In this study, we have generated several novel DLL3/CD3-targeting TCEs through the application of our streamlined AI-guided multi-specific development platform. Our AI-driven approach facilitates the engineering and optimization of multiple parameters, including antibody binding epitope, affinity, expression level, stability, and further developability of the candidates in a high-throughput fashion. Our biparatopic TCEs were designed to simultaneously engage two distinct epitopes on DLL3 on tumor cells, and mono-valency binding to CD3 on T cells with moderate to low affinity, in an attempt to enhance T cell-mediated specific cytotoxicity while minimizing potential side effects due to T cell over activation and cytokine production. The affinities and activities of the TCE building-blocks, i.e., the individual anti-DLL3 and CD3 antibodies, and the overall TCE molecules, were fine-tuned through both sequence and molecular format engineering under the guidance of our in-house AI algorithm. Our leading TCE molecule demonstrated a robust DLL3-specific T cell-dependent cellular cytotoxicity towards several tumor cell lines with various DLL3 expression levels, including both cisplatin-sensitive (e.g., NCI-H209, NCI-H526, DMS153) and cisplatin-resistant (e.g., SHP-77) cell lines. The biparatopic DLL3-target TCE also showed significant tumor inhibitory activity in tumor xenograft models including SHP-77, NCI-H82, and DMS-53. Taken together, our data underscore the significant utility of AI-guided platform in antibody/protein engineering, and support further development of our biparatopic anti-DLL3 x CD3 TCE in the treatment of DLL3-expressing SCLC and other NECs.

#7320 KGX105, a conditionally active prodrug of EGFRxCD3 T cell engager induces anti-tumor potency.

Y. Gao, J. Wang, S. Yang, J. Huang, H. Chen, H. Jiang, H. Wu, Y. Wu, **W. Jiang**;
Shanghai KangaBio Co., Ltd., Shanghai, China

T cell engagers (TCEs), are highly potent antitumor therapeutics to trigger T cell cytotoxicity, which have shown clinical benefit in hematologic malignancies while far been less successful in solid tumors. The development of TCEs against solid tumors has been limited by the significant on-target toxicity in normal tissues and cytokine release syndrome. Epidermal growth factor receptor (EGFR) is expressed in a variety of solid tumors. Several EGFR-targeted therapeutics have been approved for the treatment of cancer with either limited efficacy or induction of resistance. EGFR-targeting TCEs offered an alternative solution to overcome these issues. To address these challenges, we have developed KGX105, an EGFRxCD3 TCE prodrug with masked EGFR and CD3 antibody, which could be conditionally activated by tumor-specific proteases, and an albumin binding domain to extend the half-life. This design prevents on-target toxicity in normal tissues and systemic activation of T cells in circulation. Once masks are cleaved by tumor microenvironment (TME)-specific proteases, KGX105 could effectively trigger T cell cytotoxicity toward EGFR-positive tumor cells. To confirm KGX105's masking effect, we compared KGX105 and unmasked KGX105 for their ability in binding, T cell activation and T-cell-induced tumor cytotoxicity. KGX105 showed significantly reduced binding to CD3 and EGFR by >1000-fold and >200-fold, compared to the unmasked KGX105. KGX105 also showed reduced potency by >3000-fold in the T cell activation and by >1000-fold in the tumor cell cytotoxicity, which could be fully recovered after protease digestion, comparable to the unmasked KGX105. Then we conducted *in vivo* antitumor studies in human colorectal cancer HCT116 and COLO205 xenograft models using hPBMC-reconstituted M-NSG mice. KGX105 showed significant anti-tumor efficacy in both tumor models with the TGI% in HCT116 of 95% at 0.3 mg/kg and the TGI% in COLO205 of 68% at 3 mg/kg. No obvious body weight change was observed during the dosing period. The pilot toxic study to evaluate the safety and toxicokinetics of KGX105 is ongoing in *Cynomolgus* monkeys. The studies presented herein support KGX105 as a promising novel therapeutic to target a wide range of EGFR-expressing cancers with the potential to avoid the life-threatening on-target toxicities and systemic cytokine release.

#7321 A novel gamma-delta T cell engager platform for cancer immunotherapy.

Lei Ding, Sadhak Sengupta, Mariska ter Haak, Kate Rochlin, Yanjie Li, Lawrence S. Lamb

IN8bio, Birmingham, AL

Bispecific T cell engagers (TCE) bring effector T cells in contact with cancer cells by binding a pan-T cell receptor sequence and a tumor-associated antigen (TAA) simultaneously, thereby initiating activation and killing properties of the T cell. One of the foremost challenges for the clinical use of TCE is tumor heterogeneity, specifically, the limited expression of specific tumor antigens on the cancer cell surface. Gamma-delta (γδ) T cells are unique in that they recognize multiple stress-associated antigens common to most malignancies regardless of origin. This function is independent of MHC restriction, enabling them to target a broad range of tumors. Here, we report initial findings from a novel γδ T cell engager platform (γδ-TCE), specifically two γδ-TCEs targeting hematologic malignancies, CD33-TCE (CD-33, AML) and CD19-TCE (CD19, B_ALL), while also enabling γδ T cells to engage tumor-associated stress ligands with innate surface receptors such as NKG2D, PVR, and others.

Preliminary in vitro characterization revealed properties suggestive of pan-δ chain binding, such as competing with isoprenyl pyrophosphate activation of Vδ2+ T cells, yet efficiently driving both activation and expansion of Vδ1+ and Vδ2+ T cell subsets from peripheral blood mononuclear cells (PBMC). Robust expansion of a diverse repertoire of γδ T cells in the tumor environment is critical for continued pressure and a persistent anti-tumor response. Cytotoxicity assays show that both CD33-TCE and CD19-TCE measurably enhanced γδ T cell-mediated lysis of CD33+ AML and CD19+ ALL tumor cells, respectively, in a dose-dependent manner. In co-cultures with tumor cells, γδ-TCE- armored γδ T cells showed markedly increased degranulation and the release of pro-inflammatory cytokines, such as IFN-γ, TNF-α, granzymes, and perforin, further highlighting the activation of γδ T cells into a potent cytotoxic state and amplifying their tumor-eradicating abilities.

This novel γδ T cell engager platform represents a promising new approach to cancer immunotherapy, offering an effective strategy for enhancing γδ T cell-mediated tumor cell lysis. Furthermore, the platform's modular and flexible design suggests applications in treating a broad range of malignancies by combining the innate recognition properties of γδ T cells with the targeting of specific tumor-associated antigens, thus expanding its therapeutic potential.

#7322 LBL-058, A novel T cell engager conjugate (TEC) targeting DLL3 with dual tumor suppressive functions..

Sun Jianming, Huang Xiao, Huang Jing, Zhang Peng, Ding Mi, Qin Yurong, Wu Guojin, Mi Ye, Yang Ye, **Jordan Zhu**, Yue Zhao, Shoupeng Lai, Xiaoqiang Kang, Hong Ling

Leads Biolabs, Nan Jing Shi, China

Background :Small cell lung cancer (SCLC) is a highly malignant tumor and accounts for approximately 15% of lung cancer cases. The prognosis of invasive SCLC is poor, with a 5-year survival is 7%. SCLC has a high response to chemotherapy but tends to relapse and resist. In recent years, immune checkpoints have brought breakthroughs in first-line treatment and prolonged OS, but options after the second line are still lacking. Delta-like ligand 3 (DLL3) is an inhibitory Notch ligand that is highly expressed in SCLC and other neuroendocrine tumors, and its expression is limited in normal cells. Nowadays, many DLL3-targeting therapies are in development among them Tarlatamab, which is a T cell engager (TCE), has been approved by FDA for the treatment of adult patients with extensive-stage small cell lung cancer (ES-SCLC) with disease progression on or after platinum-based chemotherapy, at the same time several DLL3 targeting ADCs were also showing some promising results. Thus makes DLL3-targeting therapy an attractive strategy to treat SCLC.
Methods :Here we report a T cell engager conjugate (TEC), LBL-058, comprised of a DLL3-targeted T cell engager conjugated to a novel topoisomerase I inhibitor (TOP1i) payload. Moreover, LBL-058 was designed with a higher affinity targeting DLL3 and a lower affinity targeting CD3 to avoid potential cytotoxicity to T cells mediated by binding to T cells. The binding affinity of LBL-058 to DLL3 and CD3 was determined with Fortebio, while the T cell based activity was measured using several cell-based assays including reporter gene and TDCC assays. Binding of LBL-058 to DLL3 or CD3 induced Internalization and cytotoxicity were also evaluated by several cell-based assays. The anti-tumor activity of LBL-058 was investigated in xenograft mouse model.
Results :The affinity difference between CD3 and DLL3 has been fine-tuned, LBL-058 binds more easily to DLL3-positive cells. In CD3 reporter gene assay, LBL-058 could activate the NFAT reporter element through DLL3 antigen-dependent CD3 cross-linking. LBL-058 not only induce potent TDCC and T cell activation but also selectively deliver cytotoxicity payload to DLL3-positive tumor cells. In animal models, LBL-058 treatment induced durable tumor regression in xenograft tumor model.
Conclusion:LBL-058 has the potential to be a First-In-Class DLL3-targeted TCE ADC, which combines the anti-tumor properties of TCE and ADC, and shows a potent and durable anti-tumor activity and is expected to provide clinical benefits for the treatment of patients with SCLC.

#7323 LBL-043, a novel LILRB4xCD3 T cell engager, for the treatment of relapsed/refractory multiple myeloma.

Yujia Dang, Xiao Huang, Yurong Qin, Xiaoya Liu, Min Chen, Duqing Jiang, Guojin Wu, Mi Ye, Jianming Sun, **Hong Ling**, Shoupeng Lai, Xiaoqiang Kang, Jordan Zhu

Leads Biolabs, Nanjing, China

Background: Multiple myeloma (MM) is a clonal plasma cell proliferative disorder characterized by abnormal increase of monoclonal immunoglobulins. Despite newly developed novel therapeutic agents have greatly improved the outcome of MM patients in the past decades, MM is still an incurable hematological malignancy. Several CD3 bispecific immunotherapies that harness T cells against MM are at various stages of preclinical and clinical development, but most of them are hampered by the refractory and resistant mechanisms. Leukocyte immunoglobulin-like receptor B4 (LILRB4) is an immune checkpoint inhibitory receptor, which is highly expressed on monocytic blasts of AML and myeloid-derived suppressive cells. Most recently it is discovered also highly expressed in MM, in particular rrMM(relapsed/refractory MM). It does not express on hematopoietic stem cells and progenitor cells, therefore make it a promising target for hematological malignancies. Herein a novel T cell engager targeting LILRB4, LBL-043, is developed to specifically kill LILRB4 expressing MM cells.

Methods: LBL-043 is a bispecific antibody targeting LILRB4 and CD3, designed using proprietary LeadsBody^{TM} platform, which is a 2:1 format with two VHH arms targeting LILRB4 with high affinity and one scFv arm targeting CD3 with fine-tuned affinity. The binding affinity of LBL-043 was determined with Fortebio and flow cytometry, and the function activity was measured using reporter gene and TDCC assays on MM cell lines. The anti-tumor activity was investigated in B-NDG/hu-PBMC reconstructed mice implanted with NCI-H929. In addition, the potential toxicity profile of LBL-043 was examined in a non-GLP dose range finding (DRF) study in cynomolgus monkeys via IV infusion, once a week for a total of 4 doses.

Results: The binding affinity of LBL-043 to LILRB4 and CD3 protein was 0.724 nM and 35.7 nM, respectively. In CD3 reporter gene assays, LBL-043 could activate the NFAT signaling only in the presence of LILRB4+ cells. And LBL-043 was shown a potent TDCC activity in different LILRB4 expression level MM cells. In NCI-H929 CDX mouse model, LBL-043 was shown significant anti-tumor activity. DRF Study in Drug Toxicology Assessments demonstrated that LBL-043 has good safety profile in cynomolgus monkeys. There were no LBL-043 related changes of cardiac parameters, clinical chemistry, hematology, urinalysis, organ weight and gross pathology (except for decreased size of thymus).

Conclusion: LBL-043, a novel bispecific antibody targeting CD3 and LILRB4, redirecs T cells to effectively kill MM cells by simultaneously binding MM cells and T cells. It is also shown a great anti-tumor efficacy in NCI-H929 CDX mouse model. DRF of LBL-043 (0.2~10 mg/kg) in cynomolgus monkeys was well tolerated, and HNSTD was 10 mg/kg. These data for the first time show LBL-043 as a promising therapeutic bispecific antibody for the treatment of MM patients.

#7324 ONO-4685: A novel PD-1/CD3 bispecific T-cell engager (TCE) for the treatment of T-cell malignancies.

N. Tateshita[1], N. Watanabe[2], T. Shimbo[1], A. Morimoto[2], K. Takeda[1], T. Tanihiro[2];
[1]Ono Pharmaceutical Co., Ltd., Mishima-gun, Japan, [2]Ono Pharmaceutical Co., Ltd., Tsukuba-shi, Japan

Mature T and NK-cell neoplasms are of mature T-cell or NK-cell origin and comprise approximately 10% to 15% of non-Hodgkin's lymphomas (NHLs) all over the world. While new therapies with novel mechanisms of action have become available, their therapeutic outcomes are limited and most subtypes of the neoplasms have a poor prognosis. Therefore, identification of new therapeutic approaches is still an unmet medical need.Programmed cell death 1 (PD-1) is an inhibitory receptor expressed and increased on normal activated T and B cells that promotes T-cell apoptosis, anergy and functional exhaustion. PD-1 is also expressed on multiple different cancer types including major T-cell lymphomas/leukemias: Angioimmunoblastic T-cell lymphoma (AITL); Nodal T-cell lymphoma with T follicular helper (Tfh) phenotype; Follicular T-cell lymphoma; Peripheral T-cell lymphoma (PTCL) not otherwise specified (PTCL-NOS); Cutaneous T-cell lymphoma (CTCL) mycosis fungoides (CTCL-MF); CTCL Sézary syndrome (CTCL-SS), and; Adult T-cell leukemia/lymphoma (ATLL). Thus, PD-1 is a novel potential therapeutic target for T-cell lymphomas/leukemias.ONO-4685 is a first-in-class bispecific TCE antibody that binds to human PD-1 and CD3 to engage T-cells with PD-1 expressing tumor cells. TCEs have recently shown clinical anticancer success with some hematologic malignancies and solid tumor types.Here we performed preclinical studies to evaluate the therapeutic value of ONO-4685 to treat PD-1 expressing T-cell malignancies.To evaluate the effect of ONO-4685 on the cytolytic activity of T-cells, peripheral blood mononuclear cells (PBMCs) from healthy donors as well as PD-1 expressing T cell lymphoma/leukemia cell lines (ILT-Mat, HPB-ALL, and SUP-T1) were co-cultured in the presence of ONO-4685. ONO-4685 induced potent cytolytic cell killing of the cell lines. To assess the effect of ONO-4685 on T-cells, the intracellular expression of T-cell granzyme B was evaluated in *in vitro* cytotoxicity assay. ONO-4685 induced granzyme B expression in $CD4^+$ and $CD8^+$ T cells in the presence of PD-1-expressing target cells (ILT-Mat). Moreover, ONO-4685-mediated cytotoxicity on PD-1 expressing target cells was observed in the PBMCs from ATLL patients. *In vivo* anti-tumor activity of ONO-4685 was evaluated in PBMC-humanized mice xenograft models using PD-1 expressing human T cell lymphoma/leukemia cell lines (SUP-T1 and TL-Mor). ONO-4685 treatment showed suppressive effects on tumor growth in a dose-dependent manner.Taken together, these preclinical data support the clinical development of ONO-4685 as a novel TCE targeting PD-1 expressing hematologic malignancies. A Phase I clinical study in the USA is ongoing to evaluate the safety and tolerability of ONO-4685 in relapsed or refractory patients with PTCL and CTCL (NCT05079282).

#7325 Pharmacologic characterization of a highly specific and potent CLDN6xCD3 T cell engager (TCE), ARC101, for the treatment of CLDN6+ cancers.

Sanjaya Singh, Danlin Yang, Joseph Erhardt, Theresa McDevitt, Scott R. Brodeur, Bridget Larkin, Cassandra Lowenstein, **Desmond Lewis**, Tabitha Soto, Brinda Shah

Third Arc Bio, Spring House, PA

Claudin 6 (CLDN6) is an oncofetal protein involved in tight junction formation and is responsible for regulating cell polarity, adhesion and permeability. CLDN6 has recently emerged as an ideal target for novel oncology therapeutics, given the expression in various solid tumors, with limited normal tissue expression. High-levels of CLDN6 cell-surface protein expression are commonly detected in testicular cancer and epithelial ovarian cancer (EOC), with lower frequency expression in additional solid tumors such as gastric-, cervical-, endometrial-, and lung cancer. Using normal human tissue microarrays (TMA) and a highly selective commercially available CLDN6 antibody, minimal staining of CLDN6 was confirmed across a large panel of normal tissues by IHC, where sparse and limited apical staining of CLND6 was detected in pancreas, stomach, salivary gland, kidney and uterine tissues. High CLDN6 expression in ovarian tumors was demonstrated with the same selective antibody, confirming CLDN6 as a unique solid tumor target with limited normal tissue expression. ARC101 is a bispecific antibody that targets CLDN6 on tumor cells and CD3 on T cells, leading to T-cell-mediated tumor cell lysis. Generation of CLDN6-specific therapeutic antibodies has been challenging given the high degree of homology that exists between CLDN6 and CLN9, and to a lesser extent CLDN4. ARC101 was selected as a therapeutic candidate, due to the high degree of specificity obtained with this molecule. ARC101 bound to and induced cytotoxicity of a CLDN6 overexpressing SKOV3 ovarian cell line. No significant binding or cytotoxicity was observed for CLDN9 or CLDN4 overexpressing SKOV3 cell lines, underscoring the high specificity of ARC101 for CLDN6 over other highly homologous claudins. ARC101 bound to CLDN6-positive human ovarian cancer cell lines OVCAR3, PA1, and OV90, while binding to OVCAR3 cells was completely abolished when CLDN6 expression was deleted via knock out. ARC101 induced potent T cell activation and cytotoxicity at low effector to target (E:T) cell ratios across the panel of CLDN6-positive cells (2D and 3D models), with no activity observed on the CLDN6-negative OVCAR3 knock out cell line. In vivo, ARC101 demonstrated potent and dose-dependent anti-tumor activity in an ovarian tumor xenograft model. Overall, ARC101 is a highly specific CLDN6-directed T-cell engager with significant therapeutic potential for CLDN6-positive solid tumors. A Phase 1 first-in-human (FIH) clinical trial of ARC101 (NCT06672185) is planned to commence in 2025.

#7326 ATG-201, a novel T-cell engager (TCE) effectively depletes B cells with reduced risk of CRS for the treatment of B cell malignancies and B cell related autoimmune diseases.

Gang Bian[1], Huiling Liu[2], Tengteng Li[1], Zaoshun Hu[2], Peng Chen[1], Jay Mei[3], **Bing Hou**[3]

[1]Shanghai Antengene Corporation Limited, Shanghai, China,[2]Antengene (Hangzhou) Biologics, Hangzhou, China,[3]Antengene Corporation, Shaoxing, China

Background: CD19-targeted therapies, such as chimeric antigen receptor (CAR)-T or T-cell engagers (TCE), have been approved for the treatment of B cell malignancies. By depleting autoreactive B cells, CD19-targeted CAR-T have shown early yet promising efficacy in treating patients with B cell-driven autoimmune diseases. However, the clinical application of TCE continues to be greatly hindered by the unfavorable pharmacokinetics and toxicity associated with cytokine release syndrome. Here we developed a "2+1" CD19 x CD3 TCE, ATG-201, which effectively depletes B cells with minimal risk of CRS and IgG-like PK profile. It demonstrates potent anti-disease *in vivo* efficacy in mouse models for lymphoma and autoimmune diseases.
Methods: ATG-201 was constructed by introducing a high affinity, novel conformational epitope-targeted anti-CD3 single chain fragment variable (scFv) to the hinge region of one of the heavy chains of a CD19 monoclonal antibody. It was evaluated in a series of *in vitro* studies for binding affinity, T cell dependent cytotoxicity (TDCC) cytokine release, and drug developability. The *in vivo* anti-lymphoma efficacy and pharmacodynamic effect were evaluated in Raji xenograft model. The tissue reside B cell depletion was assessed in CD34+ hematopoietic stem cells humanized NDG-hIL-15 mice. Pharmacokinetic parameters of ATG-201 was evaluated in normal Balb/c mice.
Results: ATG-201 showed limited CD3+ T cell binding before CD19-crosslinking. It activated T cells and only in the presence of CD19+ cells. It induced potent TDCC against CD19 positive cells with pM range IC50. ATG-201 demonstrated stronger naïve B cell depletion activity with much lower cytokine release compared to benchmark TCEs *in vitro*. ATG-201 showed potent anti-lymphoma activity in PBMC-humanized subcutaneous Raji xenograft model with significant augment of infiltrated CD8+ T cells in tumor microenvironment and limited proinflammatory cytokines detected in plasma. Single dose ATG-201 completely and deeply depleted B cells in blood, bone marrow and spleen of CD34+ cells humanized NDG-hIL-15 mice. ATG-201 exhibited a mAb-like pharmacokinetic profile in Balb/c mice with a T1/2 of ~300h. ATG-201 was stable at high concentration (125mg/ml) and under stress conditions. The surrogate CD19xCD3 TCE demonstrated potent efficacy in mouse systemic lupus erythematosus model, inhibiting the lymph node swelling and auto-antibody producing.
Conclusion: ATG-201 demonstrates CD19-dependent CD3 binding and activation, inducing effective B cell depletion *in vitro* and *in vivo* with low cytokine release, which provides potential for the treatment of B cell malignancies and B cell related autoimmune diseases.

#7327 Harnessing FcγR glycoengineering to enhance anti-tumor monoclonal antibody efficacy.

Bowie Yik-Ling Cheng, Raquel M. Centeio, David Kung-Chun Chiu, Taia T. Wang

Stanford University, Stanford, CA

New strategies to enhance the activity of anti-tumor monoclonal antibodies (mAbs) that mediate cytotoxicity are needed. Glycoengineering of certain anti-tumor mAbs has been employed to increase their cytotoxic activity; however, the benefits of this approach are limited to specific patient groups. Beyond mAb engineering, an additional strategy involves modifying Fc gamma receptors (FcγRs), the receptors for IgG antibodies on effector cells, to augment specific antibody effector functions including cytotoxicity. One method for improving FcγR binding to mAbs is through glycoengineering, though the potential to modulate anti-tumor mAb activity via *in vivo* FcR glycoform engineering remains unexplored. We investigated the impact of FcγR glycosylation on therapeutic mAb activity and demonstrated that modifying FcγR glycoforms can enhance antibody-mediated anti-cancer responses. Underprocessed N-linked glycoforms were associated with improved binding affinity of Rituximab and Trastuzumab to FcRs, which enhanced the antibody-dependent cellular cytotoxicity activity of human peripheral blood mononuclear cells against target cells expressing CD20 or HER2, respectively. In vivo, glycoengineering of FcγRs improved the therapeutic efficacy of both a wild-type and an afucosylated anti-tumor mAb, demonstrating that this approach can further potentiate the activity of mAbs that have already been engineered for increased cytotoxicity. These findings underscore the potential of FcγR glycoengineering as a strategy to optimize mAb-based cancer immunotherapy.

#7328 Anti-tumor activity of anti-body drug conjugates in patient-derived xenografts of metastatic breast cancers patients.

Elodie Montaudon[1], Rania El Botty[1], Heloise Derrien[1], Ahmed Dahmani[1], Laura Sourd[1], Gabriel Champenois[2], Andre Nicolas[2], Didier Meseure[2], Guillaume Dutertre[3], Anne Vincent-Salomon[2], Laura Courtois[4], Julien Masliah Planchon[4], Ivan Bieche[4], Florence Coussy[5], Luc Cabel[5], Elisabetta Marangoni[1]

[1]Translational Research Department, Institut Curie, Paris, France,[2]Department of Pathology, Institut Curie, Paris, France,[3]Surgery Department, Institut Curie, Paris, France,[4]Genetics Department, Institut Curie, Paris, France,[5]Medical Oncology Department, Institut Curie, Paris, France

Background: Antibody-drug conjugates (ADCs) have emerged as highly effective new therapeutics for metastatic breast cancer (mBC). Sacituzumab govitecan (SG), an anti-TROP2 ADC, has been approved for the treatment of ER+/HER2- and triple negative mBC and trastuzumab deruxtecan (T-DXd), an anti-HER2 ADC, has been approved for HER2-amplified and HER2-low mBC. Despite the significant improvement in patients' survival, several hurdles remain to overcome, including the development of predictive biomarkers and the optimal sequential strategy. The aim of this study was to evaluate the response to SG and T-DXd ADCs in PDX models established from mBC and to identify potential biomarkers of response and resistance.
Material and Method: Biopsies from metastases or breast tumors from stage IV patients progressing on standard of care treatments were engrafted in nude mice. PDX were characterized at the genomic level and by RNAseq. HER2 expression was scored by IHC analysis by a clinical pathologist. The anti-tumor efficacy of T-DXd and SG was tested *in vivo* on 20 and 8 PDX respectively as compared to standard care treatment (endocrine therapy, CDK4/6 inhibitors, PARP inhibitors and chemotherapy).
Results: Forty-two PDXs were established, 33 (79%) from metastases and 9 (21%) from breast tumors of mBC. At the genetic level, PDX exhibited the typical molecular pattern of mBC with frequent alterations in the *PIK3CA*, *AKT1*, *ESR1* and *FGFR1* genes. Both T-DXd and SG treatment resulted in strong anti-tumor activity in multiple PDX, with 70 % and 75% of the models showing partial or complete response, respectively. Most of the models show similar responses to T-DXd and SG, with few PDX showing a different response pattern. Among these, a *BRCA1* mutated PDX showing cross resistance to talazoparib, CDK4/6 inhibitor, chemotherapy and T-DXd, was found to be a highly responder to SG treatment. T-DXd and SG were also highly efficient in *ESR1* mutated PDX established from patients progressing on aromatase inhibitors, including a model with cross resistance to different SERD. HER2 expression at baseline did not predict response to T-DXd. GSEA analysis identified different gene sets associated with T-DXd resistance, including KRAS signaling, EMT and hypoxia. Pharmacodynamic experiments in PDX responder and resistant to T-DXd and SG are ongoing to identify pharmacodynamic biomarkers.
Conclusion and Perspective: In summary, we established PDX of mBC, characterized for HER2 expression, genomic alterations and response to T-DXd and SG. Both ADCs showed high anti-tumor activity in multiple PDX with resistance to standard treatments including CDK4/6 inhibitors, SERD and PARP inhibitors. Response to T-DXD was not correlated with HER2 expression while T-DXd resistance was associated to an enrichment of EMT and hypoxia gene sets.

#7329 Overcoming systemic toxicity of IL-12-based immunotherapy by tumor-targeting and IL-12 attenuation.

Jihoon Chang, **Byoung Chul Lee**

Kanaph Therapeutics, Seoul, Korea, Republic of

With the recent success of immune checkpoint inhibitors, there is a renewed interest in cytokines as promising agents for cancer immunotherapy. Cytokines are well-established immunomodulators, and several inflammatory cytokines, including IL-12, have demonstrated potent anti-tumor activity. However, systemic administration of IL-12 has been associated with severe immune related adverse events, significantly limiting its therapeutic application. To overcome such narrow therapeutic window, we developed KNP-101, a bispecific Fc-fusion protein consisting of anti-FAP and attenuated IL-12. KNP-101 accumulates in the tumor microenvironment via anti-FAP and thus induces IL-12 activity at the tumor site. In addition, additional mutations were introduced into IL-12 to further mitigate systemic toxicity. Although the IL-12 activity was attenuated, KNP-101 mouse surrogate maintained significant anti-tumor potency in various mouse syngeneic models with a single intravenous injection. In combination therapies with anti-PD-L1, KNP-101 mouse surrogate demonstrated a synergistic anti-tumor effect. Analysis of tumor infiltrated lymphocytes via FACS demonstrated that the effects were mediated by immune cell infiltration. In naïve mouse toxicity test, KNP-101 mouse surrogate was tolerable up to 150 ug/head and no survival issue was observed. Similar toxicity studies were performed in tumor-bearing mice and, KNP-101 mouse surrogate showed safe profiles being tolerable up to 500 ug/head with no survival issues. Noticeably, KNP-101 mouse surrogate induced far less IFNg in serum compared to null/IL-12 suggesting that systemic toxicity was greatly reduced. Furthermore, KNP-101 was tolerable at doses up to 2.4 mg/kg in repeat-dose non-GLP studies conducted in cynomolgus monkey. Notably, KNP-101demonstrated that systemic toxicity of IL-12 therapy can be overcome by tumor-targeting and IL-12 attenuation strategies. KNP-101 exhibited a wide therapeutic window, by showing potent anti-tumor activities and significantly improved safety profiles. These attributes position KNP-101 as a promising therapeutic option for patients facing resistance to current cancer therapies.

#7330 MDNA113: A tumor targeting and conditionally activated anti-PD1-IL2^{SK} to enhance the therapeutic index.

Scott Rowlinson, Minh D. To, Qian Liu, Rosemina Merchant, Fahar Merchant, **Aanchal Sharma**

Medicenna Therapeutics, Toronto, ON, Canada

Background: To improve systemic tolerability of potent cytokines including anti-PD1/IL2 immunocytokines, conditional activation using tumor associated proteases have been gaining attention. MDNA113 (masked anti-PD1-IL2^{SK}), a Bifunctional SuperKine for Immunotherapy (BiSKIT), offers key distinguishing features including (i) next-generation IL2 Superkine (IL2^{SK}) with 'β-enhanced not-α' receptor selectivity, and (ii) a masking domain that also functions as a tumor targeting domain. MDNA113 incorporates an IL-13Rα2 selective IL13 superkine (IL13^{SK}) that facilitates tumor targeting and promotes durable accumulation within IL-13Rα2 expressing tumors thereby amplifying activation and therapeutic activity at the tumor site. In addition, the IL13^{SK} partially masks the IL2^{SK}, sterically hindering its systemic activity to improve tolerability while maximizing localization and activity of anti-PD1-IL2^{SK} within the tumor microenvironment (TME) which promotes synergy between IL2 receptor (IL-2R) agonism and immune checkpoint blockade by cis binding.

Methods: IL-2R signaling and PD1/PD-L1 blockade were evaluated using in vitro cell based reporter assays and human PBMCs. Tolerability, pharmacodynamics, efficacy and mechanistic studies were conducted in mouse syngeneic tumor models.

Results: MDNA113 demonstrated reduced IL-2R agonism while maintaining PD1/PD-L1 blockade compared to non-masked anti-PD1-IL2^{SK} in cell-based assays. This was reflected in reduced p-STAT5 signaling in human CD8+T cells, accompanied by decreased PBMC proliferation. Upon in vitro cleavage by proteases, full IL-2R agonism was restored as intended. In mice, MDNA113 exhibited better tolerability than naked anti-PD1-IL2^{SK}, correlating with reduced peripheral lymphocyte expansion. Systemic administration of MDNA113 showed comparable efficacy to anti-PD1-IL2^{SK} in mouse syngeneic tumor models, consistent with the designed protease mediated activation of MDNA113 through release of the IL13^{SK} mask within TME. Furthermore, MDNA113 achieved complete tumor regression in mice harboring IL-13Rα2 expressing solid tumors. These mice were also resistant to tumor growth when rechallenged with the same tumor antigen in the absence of any additional treatment, indicative of an underlying tumor specific memory response. Tumors from mice treated with a single dose of MDNA113 showed an elevated influx of CD8^{+}GrzB^{+} T cells, consistent with synergy between IL-2R agonism and immune checkpoint blockade. In addition, MDNA113 demonstrated superior efficacy compared to single-agent anti-PD1 when tested in a neo-adjuvant setting in an orthotopic 4T1.2 triple negative breast tumor model.

Conclusion: MDNA113 is conditionally active anti-PD1-IL2^{SK} designed by leveraging IL13^{SK} as a dual tumor targeting and masking domain for enhanced tolerability and robust efficacy in both therapeutic and neoadjuvant settings.

#7331 Antitumor activity of amivantamab in diffuse pleural mesothelioma.

Shinichiro Suzuki, Lin Yang, Jennifer Ayers-Ringler, Ezequiel J. Tolosa, Kuan-Li Wu, Janet L. Schaefer-Klein, Farhad Kosari, Aaron S. Mansfield

Mayo Clinic, Rochester, MN

Background: Diffuse pleural mesothelioma (DPM) is a rare and aggressive cancer arising from mesothelial cells of the pleura. Over 2,500 new cases are diagnosed annually in the United States, mainly attributable to asbestos exposure. The prognosis is poor, and while nivolumab (PD-1 inhibitor) and ipilimumab (CTLA-4 inhibitor) have been approved for first-line treatment of unresectable DPM, the three-year survival rate is only 23%. DPM tumors express high levels of epidermal growth factor receptor (EGFR) and mesenchymal-epithelial transition (MET), but targeted therapies like erlotinib (EGFR tyrosine kinase inhibitors) have shown no clinical benefit. We hypothesized that amivantamab, a bispecific antibody that targets both EGFR and MET, may have activity against DPM through antibody-dependent cellular cytotoxicity (ADCC).
Objective: The purpose of this study was to assess the potential of amivantamab to mediate ADCC in tissue culture experiments with DPM cell lines.
Methods: We assessed DPM for the expression of EGFR and MET using available data from bulk RNA sequencing. We also examined protein expressions of EGFR and MET by Western blot analysis in five epithelial (EM-Meso, H2452, H2461, Mero-41 and Mero-95), three sarcomatoid (H2373, H2596 and ONE58), and one normal mesothelial (MeT-5A) cell lines. Co-culture experiments were performed with the DPM and normal cell lines and NK cells in the presence of amivantamab to evaluate ADCC.
Results: We identified high levels of EGFR and MET expression in both epithelial and sarcomatoid cases of DPM from 183 patients. This finding was corroborated by Western blot analysis of all eight DPM cell lines. In vitro experiments demonstrated that amivantamab induced dose-dependent ADCC in DPM cell lines, with robust NK cell-mediated ADCC observed across all tested DPM lines. Notably, sarcomatoid-type DPM cells were more sensitive to amivantamab-induced ADCC than epithelial-type cells. These findings suggest that amivantamab may offer therapeutic benefits for DPM tumors with high EGFR and MET expression.
Conclusion: This study provides preclinical evidence supporting the potential of amivantamab as a novel therapeutic option for DPM, especially in sarcomatoid tumors. Ongoing in vivo studies including in patient-derived xenograft (PDX) models will further evaluate the efficacy of amivantamab in DPM.

#7332 Investigating genes and pathways determining sensitivity or resistance to anti-L1cam ADCs in lymphomas.

Filippo Spriano[1], Giulio Sartori[1], Chiara Tarantelli[1], Luciano Cascione[1], Sara Napoli[1], Flavio Mehli[2], Gunther Spohn[2], Francesco Bertoni[1]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]Elthera AG, Zurich, Switzerland

Background: L1 cell adhesion molecule (L1CAM) is a glycoprotein initially characterized for its role in neuronal migration, cell adhesion, axonal growth, and synaptogenesis. In recent years, it has been identified in various solid tumors, in which it promotes invasion, metastasis, and resistance to therapies. We previously demonstrated the expression of L1CAM in a subset of lymphomas, mainly mantle cell lymphoma (MCL) and cutaneous T-cell lymphomas, determining *in vitro* and *in vivo* sensitivity to anti-L1CAM antibody-based therapies (Spriano et al., AACR-NCI-EORTC 2023). This project aimed to define genes and pathways contributing to the anti-lymphoma activity of L1CAM targeting antibody-drug conjugates (ADCs) in L1CAM-positive lymphomas. We used the Z138 MCL cell line as a model system exposed to two ADCs, sharing the same antibody backbone but with different payloads, the DNA targeting SG3199 (ADC6) and the tubulin targeting MMAE (ADC4), respectively.
Methods: We generated stable Cas9 or dCas9-VP64 expressing Z138 cells, then infected them with the Brunello (LOF) or the Calabrese (GOF) library. After the appropriate selection, cells were split to obtain the baseline representation of sgRNA distribution (T0) and then left untreated or treated with either of the two anti-L1CAM ADCs (exp arms) for two weeks. MAGeCK-MLE was used to model sgRNA read counts and assess the sgRNA β values and statistical enrichment (FDR<0.1). Combination treatments were performed, exposing cells to increasing concentrations of both drugs for three days, followed by an MTT assay.
Results: L1CAM expression was strongly associated with sensitivity to ADC4 but not to ADC6. As already reported and demonstrated also by us, the SG3199 payload is highly potent, rendering its activity less dependent on L1CAM levels. Among the genes sustaining resistance to ADC4, we identified FBXW7 and SOX11 (known L1CAM regulators), kinesins involved in microtubule assembly, MDR1, BCL2, CASP9, and ARID1A; TP53, BAX, CD20, CD19, RC3H1, and FCGR1B were identified as genes providing sensitivity to ADC4. Among the genes promoting resistance to ADC6, we identified RAD51B, ATR, BCL2, CHD4, and genes involved in the mitochondrial respiratory chain. Among the genes related to ADC6 sensitivity, we identified CDKN2B, RIPK1, MAPK9, RC3H1, NFKB1A, and RIF1. Finally, due to the observed involvement of ATR and BCL2 in the resistance to ADC6, we tested the addition of an ATR inhibitor (elimusertib) or a BCL2 inhibitor (venetoclax) to ADC6 in the Z138, achieving a strong synergism and additivity/synergism, respectively.
Conclusion: LOF and GOF CRISPR-Cas9 screenings identified genes related to resistance or sensitivity to anti-L1CAM ADCs that could be potentially used as therapeutic targets or biomarkers.

#7333 PD-L1-directed ISACs target host immune cells to drive powerful antitumor immune responses in a manner distinct from conventional PD-1/PD-L1 blockade.

Po Y. Ho, Rishali K. Gadkari, Shahid Khan, David T. Omstead, Jennifer E. Melrose, Matthew N. Zhou, Katelynn A. McEachin, Karla A. Henning, William G. Mallet, Steven J. Chapin, Romas A. Kudirka, Shelley E. Ackerman, Michael N. Alonso, **Justin A. Kenkel**

Bolt Biotherapeutics, Redwood City, CA

Background: Monoclonal antibodies targeting PD-1/PD-L1 have demonstrated clinical activity in numerous indications, but a large proportion of patients do not respond to anti-PD-(L)1 therapy, underscoring the need for alternative strategies. PD-L1 can be expressed by tumor cells as well as immune cells in the tumor microenvironment (TME) and tumor-draining lymph nodes. In particular, antigen-presenting cells (APCs) including macrophages and dendritic cells (DCs) can express high levels of PD-L1 and play a key role in regulating T cell responses through the PD-1/PD-L1 pathway. We are developing a novel class of molecules called Immune-Stimulating Antibody Conjugates (ISACs) that consist of tumor- or TME-targeting antibodies coupled to innate immune stimuli such as TLR7/8 agonists. Here, we present preclinical data demonstrating that PD-L1-targeted ISACs can engage both PD-L1-expressing tumor cells and APCs to drive robust immune responses and antitumor activity. Our results indicate a critical role for immune cell-expressed PD-L1 in antitumor activity and suggest a mechanism of action uncoupled from PD-1/PD-L1 blockade.

Methods: ISACs were prepared using proprietary anti-human PD-L1 antibodies and TLR7/8 agonist payloads. Anti-mouse PD-L1 ISACs were made using antibodies from Bioxcell. In vitro activity was assessed in human whole blood, tumor/DC cocultures, and purified PD-L1+ myeloid cell populations. In vivo efficacy studies were performed in syngeneic and xenograft tumor models. PD-L1 knockout tumor cells were generated using CRISPR/Cas9.

Results & Conclusions: PD-L1 ISACs induced robust, target-dependent activation of human myeloid cells cocultured with PD-L1-expressing tumor cells, as measured by secretion of cytokines such as IL-12 and TNFα. PD-L1 ISACs also strongly activated macrophages and DCs polarized to express high levels of PD-L1, demonstrating the ability to directly activate PD-L1-expressing APCs. Systemically administered PD-L1 ISACs were well tolerated in mice and showed improved efficacy over anti-PD-L1 antibodies, with tumor regression including complete responses observed in syngeneic and xenograft models. Mice with complete responses in syngeneic models rejected tumors upon rechallenge, indicating induction of immunological memory. Knockout of tumor PD-L1 expression in a syngeneic model had no impact on efficacy, suggesting that targeting of PD-L1-expressing host immune cells is critical for antitumor activity. PD-L1 ISACs exhibited similar efficacy whether or not the anti-PD-L1 antibody used blocked binding to PD-1, indicating that checkpoint blockade is not a major mechanism of action. These data demonstrate that PD-L1 ISACs represent a compelling new approach to treat cancer, leveraging mechanisms that are distinct from and potentially complementary to conventional PD-1/PD-L1 blockade.

#7334 Targeting Nectin-4 with a first-in-class triple MMAE/dual TOP1i payload ADC showing synergistic and durable activity across all target expression levels and favorable tolerability.

Isabella Attinger-Toller, Philipp Probst, Romain Bertrand, Rachael Fay, Lia Kallenberger, Patrick Maurhofer, Ramona Stark, Emma Renard, Roger Santimaria, Dragan Grabulovski, Bernd Schlereth, Philipp R. Spycher

Araris Biotech AG, Au, Switzerland

The Araris' site-specific and one-step linker conjugation technology aims at generating stable, safe and highly potent ADCs without the need for antibody engineering prior to payload conjugation. We here present a novel Nectin-4 targeting triple-warhead ADC using a combination of MMAE and two different topoisomerase-1 inhibitors (TOP1i, DAR2+2+2) designed to treat a broad range of Nectin-4 expressing solid tumors. With this novel ADC we aim to 1) effectively kill heterogenous and resistant tumors by delivering multiple cytotoxic payloads to the same tumor cell, 2) control and limit bystander activity to avoid excessive toxicities and 3) maximize payload delivery through stable linker-payload coupling resulting antibody-like ADC pharmacokinetic exposure profiles. The triple-warhead ADC was shown to be highly homogenous and pure with a DAR of 6, as desired. The ADC showed high stability under stressed conditions with no signs of aggregation, which we attribute to the hydrophilic nature of the peptide-linker-payload design. On target-positive cancer cell lines, the ADC showed high and target-specific cytotoxic activity. It further showed excellent stability in mouse, cyno and human sera with no linker-payload deconjugation or linker cleavage, and the DAR remaining unchanged. Most importantly, the ADC was extremely stable in circulation showing an exposure profile like the unmodified parent antibody in rodents. Notably, the tolerability in rats showed an HNSTD of more than 20 mg/kg in a dose-range-finder study (vs. Enfortumab vedotin (EV): 5mg/kg). No significant skin or hematological toxicities were observed, implying that the triple warhead did not result in toxicities exceeding the mono-payload toxicity profiles in rats. Strikingly, in a receptor high-expressing breast cancer SUM-190PT xenograft model, the triple warhead ADC administered as a single dose at 0.5 mg/kg on day 0 led to long-lasting and complete tumor regression (more than 100d), indicating synergistic activity of the different payloads. Interestingly, the combination using the respective MMAE (DAR2) and TOPi (DAR2+2) ADCs, each dosed at 0.5 mg/kg, showed no response whatsoever and neither did Enfortumab vedotin (EV) at this dose, the current Nectin-4 targeting standard of care in mUC. Further, in a low Nectin-4-expressing TNBC PDX model, the high anti-tumor activity was confirmed leading to high and complete anti-tumor responses at 2.5 mg/kg compared to EV and Sacituzumab govitecan, the FDA-approved ADC for TNBC. In conclusion, the first-in-class Nectin-4 targeting triple-payload ADC leads to very high anti-tumor efficacy in CDX and PDX models and is well tolerable in rats. We show for the first time, that combination of multiple payloads in one ADC can lead to synergistic effects in mouse models while still being well tolerable.

#7335 Comparison of ADCC-mediated efficacy of zolbetuximab in hCD16A-CB17SCID humanized mice and CB17SCID WT mice bearing the SNU-601 tumor model.

Rong Wang, Xiaoze Wang, Kaixia Lian, Rongfei Lu, Haijuan Yu, Jie Lin, Ludovic Bourre, Jingjing Wang

Crown Bioscience, Inc., San Diego, CA

Introduction: The mechanisms of action of cytotoxic monoclonal antibodies (mAbs) include FcγR-dependent mechanisms to induce antibody-dependent cell cytotoxicity (ADCC). In mice, ADCC relies on mFcγRIII expressed on NK cells, while human NK cells depend on hFcγRIIIA (hCD16A). However, human IgG1 display significant affinity differences between mouse and human FcγRs, which can impact their efficacy in preclinical models. Additionally, testing an affinity-enhanced Fc-engineered antibody in a mouse without the human FcγR counterparts provides limited predictive value. Therefore, preclinical mouse models expressing human FcγRs are essential to evaluate clinical Fc potent antibody. In this study, a hCD16A-CB17SCID humanized (HuGEMM) mouse model, featuring hCD16A knock-in on mouse NK cells, was used to evaluate the ADCC function of the CLDN18.2 mAb zolbetuximab. Using SNU-601 cell line, a high expression hCLDN18.2 model, the efficacy of zolbetuximab in hCD16A-CB17SCID mice was compared to CB17SCID WT mice in SNU-601 xenograft.

Methods: Surface expression of human CD16 on NK cells from peripheral blood (PB) and spleen of hCD16A-CB17SCID HuGEMM mice was verified by flow cytometry. *In vivo* studies involved 1×10^7 SNU-601 cells subcutaneously inoculated into hCD16A-CB17SCID HuGEMM models or CB17SCID WT models. Tumor-bearing models were treated with zolbetuximab (10 mg/kg, i.p., BIW×13 doses) or hIgG1 (10 mg/kg, i.p., BIW×13 doses) as an isotype control. At the study endpoint, NK cell function related markers in PB, tumor tissues and hCLDN18.2$^+$ tumor cell apoptosis from SNU-601 tumors were assessed by flow cytometry.

Results: hCD16A expression was confirmed on NK cells from PB and spleen in hCD16A-CB17SCID HuGEMM mice. SNU-601 tumor showed similar growth profile as was observed in hCD16A-CB17SCID HuGEMM and WT models. Significant tumor growth inhibition (TGI) of SNU-601 tumor was observedwith zolbetuximab compared to the isotype control, with hCD16A-CB17SCID HuGEMM models showing 55% TGI, higher than the 33% TGI observed in CB17SCID WT models. At the study endpoint, similar percentages of mNKp46$^+$ mCD49b$^+$ NK cells, mCD107a$^+$ mNKp46$^+$ mCD49b$^+$ NK cells, and mKi67$^+$ mNKp46$^+$ mCD49b$^+$ NK cells were observed between hCD16A-CB17SCID HuGEMM and CB17SCID WT models. Apoptosis analysis indicated that zolbetuximab induced apoptosis in hCLDN18.2$^+$ tumor cells compared to control groups in both hCD16A-CB17SCID HuGEMM and CB17SCID WT models.

Conclusion: This study indicates that hCD16A-CB17SCID HuGEMM models exhibit enhanced tumor growth inhibition in response to zolbetuximab treatment compared to CB17SCID WT models, demonstrating the potential of this model as a more effective preclinical model for evaluating ADCC-mediated therapies.

#7336 B7-H7 is a novel ADC target for solid tumors and shows potent activity with multiple payload-linker technologies.

Emilien Loeuillard, Bijan A. Etemad-Gilbertson, Susannah L. Hewitt, Jamie L. Strand, Riale T. Gilligan, Silvia Ferrati, Tatiana I. Novobrantseva, Matthew Rausch

NextPoint Therapeutics, Boston, MA

Introduction: B7-H7 is a member of the B7 family, with strong expression in multiple cancer indications in addition to its known role as an immune regulator. B7-H7 upregulation is correlated with poor patient outcomes. Furthermore, its normal tissue expression is limited making B7-H7 very attractive for targeting tumors. NextPoint has therefore explored B7-H7 as a novel antigen to target antibody drug conjugates (ADCs) to solid tumors. Antibodies previously raised against distinct B7-H7 epitopes, with cross-reactivity to the cynomolgus protein, were produced as ADCs and multiple distinct payload-linker technologies were applied. These were tested for *in vitro* and *in vivo* activity, and for their developability characteristics enabling lead selection of the most potent compounds.

Methods: ADC binding efficacy was assessed by flow cytometry on endogenous B7-H7+ and overexpressing B7-H7 cell lines. Internalization was tracked with Fabfluor-pH reporter conjugated to ADCs using Incucyte® imaging. *In vitro* cytotoxicity was evaluated by luminescence-based cell viability assays with CellTiter-Glo® to detect ATP in the media. The pharmacokinetics of each ADC was assessed in rats by measurement of both total and drug-conjugated antibody. The *in vivo* activity was tested against B7-H7-expressing xenograft tumors in immunodeficient mice.

Results: The majority of B7-H7-targeted ADCs had similar on-cell binding capacities as parental antibodies. Internalization analyses showed that after 4h, over 50% of cells had internalized the compounds with an optimal concentration of 0.3 nM ADCs. Multiple B7-H7 targeted ADCs demonstrated cytotoxicity against tumor cell lines, with an *in vitro* EC50 under 0.3 nM on average and under 0.1 nM for the most potent compounds. Rat pharmacokinetics demonstrated half-lives above 7 days for the lead compounds and acceptable payload stability across technologies. *In vivo*, ADC leads were tested in several *in vivo* tumor models that cover a wide range ofB7-H7 protein expression. Selected ADC leads with distinct linker-payload technologies demonstrated tumor activity in multiple *in vivo* tumor models. Body weight changes were minimal following dosing of the most active ADCs in these mouse systems.

Conclusions: Collectively, these preclinical studies establish B7-H7 as an attractive ADC targeting antigen and demonstrate its activity with multiple clinically relevant payload-linker technologies. These data support further development of lead compounds as a promising treatment for patients with B7-H7-expressing tumors.

#7338 Evaluation of a novel target Claudin1 in preclinical models of nasopharyngeal carcinoma.

K. Chin[1], C. Hui[1], C.-H. Wong[1], G. Chung[1], W. Lai[2], A. Toso[3], L. Manenti[3], L. Lili[1], C. Tsang[1], Q. Tao[1], E. Hui[1], A. Chan[1], K. Lo[1], B. Ma[1];
[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Prince of Wales Hospital, Hong Kong, Hong Kong, [3]Alentis Therapeutics AG, Allschwil, Switzerland

Introduction: Epstein-Barr virus (EBV)+ve nasopharyngeal carcinoma (NPC) is prevalent in Southern China where patients with recurrent/ metastatic disease can be treated with chemotherapy and/or immune-checkpoint inhibitors. Claudin 1 (CLDN1) is a member of the tight junction (TJ) family of proteins that is overexpressed in some cancers with their non-junctional (NJ) epitopes exposed at the epithelium. This study investigated CLDN1 as a novel therapeutic target in NPC and evaluated the preclinical activity of ALE.C04 - a first-in-class, highly specific monoclonal antibody targeting NJ-CLDN1, in NPC models.
Method: Expression of NJ-CLDN1 was assessed in three EBV+ve NPC cell lines (C666-1, NPC43 and C17C), four patient-derived- xenografts (PDXs) and NPC biopsies (n=44). The anti-proliferative effect of ALE.C04 was evaluated in NJ-CLDN1+ve NPC cell lines by clonogenic and invasion assay, co-cultured with or without human-derived natural killer (NK) cells. Results are validated in PDX models (C15, C17). ALE.C04 was administrated either as a single agent or in combination with chemotherapy or bevacizumab.
Results: NJ-CLDN1 were overexpressed in two NPC cell line (NPC43 and C17C), three PDXs (C15, C17 and X2117) and biopsies (80%). Interestingly, NJ-CLDN1 was not detected in PDX Xeno-666 and its derived cell line, C666-1. A non-significant correlation trend was found between h-score with overall survival. Treatment with ALE.C04 suppressed colony formation of NJ-CLDN1+ve cell lines, with more significant effect observed in C17C. Effect of ALE.C04 as a single agent is modest on the growth of NJ-CLDN1+ve positive cell lines and C17 PDX model. Whilst in combinatorial approach, ALE.C04 showed synergism with gemcitabine as tumor growth was suppressed in C17 PDX. In contrast, ALE.C04 monotherapy significantly suppressed growth in C15 PDX, resulting in substantial changes in gene expression profile (via RNA-Sequencing) compared to the control group. The results of the *in vitro* coculture assay and *in vivo* combination with gemcitabine and bevacizumab will be presented.
Conclusion: The results generated to date provide a proof-of-concept of targeting NJ-CLDN1 signaling in NPC using ALE.C04, especially in combination with chemotherapy or anti-vascular agent. ALE.C04 is now being evaluated in patients with NPC and other head and neck cancers in a phase 1 clinical trial (NCT06054477).

#7339 A highly efficacious next-generation CEACAM5 (CEA)-targeted Boltbody™ ISAC for the treatment of colorectal, pancreatic and lung tumors.

Background: CEACAM5 is a well-characterized cell-surface antigen highly expressed on multiple solid tumors, particularly colorectal, pancreatic, and non-small cell lung cancers. Despite its favorable properties as a cancer target, no therapies targeting CEA have been approved to date. We are developing a novel class of molecules, Immune-Stimulating Antibody Conjugates (ISACs) with next-generation TLR7/8 agonists to activate tumor-infiltrating myeloid cells and initiate a broad innate and adaptive anti-tumor immune response.[1]
Methods: A panel of anti-CEACAM5 antibodies was tested for binding affinity and specificity; CEACAM5-mediated antibody-dependent cellular phagocytosis (ADCP) by myeloid cells; and myeloid-mediated tumor cell killing. A subset of the antibodies was chemically conjugated to a proprietary next-generation TLR7/8 agonist and assessed in myeloid cell activation assays in vitro and tumor growth inhibition in vivo.
Results: Our lead CEA-targeted ISAC binds with high affinity and selectivity to CEACAM5+ cell lines and tumors. In vitro, ISAC binding to tumor cells drives efficient ADCP by myeloid cells and stimulates production of critical immune-activating cytokines including IL-12p70, IFNγ, and TNFα. The next-generation TLR7/8 agonist payload is active in mice where it inhibits the growth of CEACAM5+ xenograft tumors in immune-compromised mice. In CEACAM5 transgenic mice, treatment with the CEA-targeted ISAC results in complete tumor regression of CEACAM5+ syngeneic tumors including models with low CEACAM5 expression. Failure of CEACAM5+ cell lines and CEACAM5-parental cell lines to form tumors upon rechallenge demonstrates development of immunological memory and epitope spreading during initial treatment. In cynomolgus monkeys the CEA-targeted ISAC was well-tolerated with no significant drug-related adverse events up to 15 mg/kg, the highest dose tested.
Conclusions: This pre-clinical data set demonstrates the antigen-dependent induction of a robust innate and adaptive immune response by a next-generation CEA-targeted ISAC and the potential to treat CEACAM5+ human cancers.

#7343 Factors associated with self-reported fatigue among long-term metastatic breast cancer survivors.

Chloe M. Hery, Juan Peng, Ashley Pariser Davenport, Michelle J. Naughton

The Ohio State University Wexner Medical Center, Columbus, OH

Purpose: Fatigue is one of the most often reported symptoms among breast cancer patients and affects patients' quality of life and emotional and physical functioning. This study aimed to examine the association between self-reported fatigue and sociodemographic, clinical, and psychosocial factors among metastatic breast cancer (MBC) survivors.
Methods: 232 patients from the Ohio State University Stefanie Spielman Comprehensive Breast Center, who had been diagnosed with MBC for ≥1 year, were asked to complete a one-time, online survey. The survey assessed the patients' quality of life, self-rated health, symptoms, supportive care needs, and reflections on their cancer diagnosis and treatment. Participants were asked to rate their level of fatigue in the past 7 days on a scale of 0 (no fatigue) to 10 (very severe fatigue). A multivariate generalized linear model (GLM) was used to determine the sociodemographic (age, race, education, income, rural/urban residency), psychosocial (self-rated health, quality of life, social support, sleep quality, anxiety), and clinical factors (time since diagnosis, treatment types, pain, symptoms) associated with patients' fatigue.
Results: Patients were on average 59.6 years old (±12.7) and 5.3 (±4.8) years from their diagnosis with MBC. Most were non-Hispanic and white (91%), approximately half had a college education (51.7%), and over a quarter resided in rural counties (28%). The results indicated that overall, 53% rated their quality of life as very good or excellent. The patients' average level of fatigue was 4.3 points (±2.4) out of 10 points possible. In multivariate models, self-rated quality of life, pain, and sleep quality were significantly associated with fatigue after controlling for age, time since diagnosis, self-rated health, education level, rural/urban residency, and treatment type (oral therapy only vs. IV therapy). Higher quality of life (β=-0.35, p=0.0003) and better sleep quality (β=-0.14, p=0.02) were associated with lower levels of fatigue. In contrast, higher levels of pain were associated with greater fatigue (β=0.37, p<0.0001).
Conclusions: Understanding and treating the long-term symptoms and unique experiences of MBC survivors is important in improving their quality of life and long-term survival. Fatigue does not necessarily resolve after treatments have concluded and MBC patients are often on treatment for long periods of time. Addressing methods to improve patients' sleep quality and pain levels may improve their fatigue and quality of life and alleviate the symptom burden experienced by these patients.

#7344 Family history of hematologic malignancy and prognosis across lymphoma subtypes: Novel association with poor outcomes in follicular lymphoma.

George Cholack[1], Raphael Mwangi[2], Thomas M. Habermann[3], Verena Hinder[2], Rosalie Griffen[2], Dennis Robinson[2], Andrew L. Feldman[4], Thomas E. Witzig[3], Stephen M. Ansell[3], Brian K. Link[5], Yucai Wang[3], Carrie A. Thompson[3], Susan L. Slager[2], Matthew Maurer[2], Anne J. Novak[2], James R. Cerhan[2]

[1]Internal Medicine, Mayo Clinic School of Graduate Medical Education, Rochester, MN,[2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[3]Department of Medicine, Division of Hematology, Mayo Clinic, Rochester, MN,[4]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[5]Department of Medicine, University of Iowa Hospitals and Clinics, Iowa City, IA

Family history of hematologic malignancy (FHHM) is an established risk factor for developing lymphoma, but studies examining associations between self-reported FHHM and lymphoma prognosis during the recent treatment era are limited. Utilizing a prospective cohort study, we evaluated associations between FHHM and prognosis for common lymphoma subtypes, including diffuse large B-cell (DLBCL), follicular (FL), marginal zone (MZL), mantle cell (MCL), Hodgkin (HL), and T-cell (TCL) lymphomas. We used the Mayo Clinic component of the Molecular Epidemiology Resource, a prospective cohort study of newly diagnosed lymphoma patients enrolled from 2002 to 2015. Self-reported FHHM (HL, NHL, leukemia, or multiple myeloma) in a first-degree relative was obtained via questionnaire. Primary outcomes were overall survival (OS) and event-free survival (EFS; time from diagnosis to disease progression, initiation of second-line therapy, or all-cause death). Secondary outcomes were failure to achieve 24 months of event-free survival (EFS24; associated with aggressive disease and poor outcomes) and lymphoma-specific survival (LSS; time from diagnosis to death from lymphoma or lymphoma treatment-related complications). We used multivariable Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% confidence intervals (CI) for the association of FHHM with OS, EFS, and LSS, and logistic regression to estimate odds ratios (ORs) and 95% CI for the association with failure to achieve EFS24. All models were adjusted for sex and a lymphoma subtype specific prognostic index. The cohort consisted of 650 DLBCL, 679 FL, 291 MZL, 178 MCL, 254 HL, and 196 TCL patients. The prevalence of FHHM ranged from 9.7% in TCL to 14% in FL. FHHM was not associated with OS in any subtype, but MCL patients with FHHM showed an inferior EFS (HR=1.70, 95% CI 1.02-2.85; p=0.04). For EFS24, FHHM was associated with failure to achieve EFS24 only in FL (OR=1.57, 95% CI 0.99-2.48; p=0.05). Similarly, FHHM was associated with inferior LSS in FL patients (HR=1.98, 95% CI 1.11-3.53; p=0.02). In a treatment subgroup analysis of FL patients, the FHHM associations with failure to achieve EFS24 (OR=2.48, 95% CI 1.04-5.74; p=0.04) and inferior LSS (HR=2.68, 95% CI 1.09-6.58; p=0.03) strengthened among those treated with frontline immunochemotherapy (IC). In summary, there were no evidence of associations between FHHM and OS across lymphoma subtypes, but MCL patients with FHHM displayed inferior EFS. FL patients with FHHM were more likely to not achieve EFS24 and to ultimately die of their lymphoma or a lymphoma treatment-related complication. This finding was stronger in more aggressive FL requiring frontline IC. This novel finding would suggest that genetic or environmental factors associated with FHHM may underlie pathways that impact disease aggressiveness and early clinical failure in FL.

#7345 Differences in complete screening adherence across age, income, and education groups.

Kierstin M. Faw, Jamal R. Winn, Robert A. Smith, Ahmedin Jemal, Parichoy Pal Choudhury, Priti Bandi, Jordan A. Baeker Bispo, Alpa V. Patel

American Cancer Society, Atlanta, GA

There is limited knowledge of the sociodemographic characteristics of individuals who are fully adherent to all recommended cancer screening tests. Understanding these cancer screening gaps may provide insights into subpopulations who may benefit from interventions to increase overall early cancer detection. The Cancer Prevention Study- 3 is a prospective cohort study established by the American Cancer Society (enrollment 2006-2013). Between enrollment and 2018, cancer-free participants reported cancer screening tests (mammography, colonoscopy, sigmoidoscopy, stool testing, and low dose lung computed tomography (CT) scans) and year(s) of each screening. Eligibility for each test was determined using 2018 American Cancer Society guidelines. For each person, an adherence score was calculated based on the number of eligible screenings and whether they were adherent. Patterns of adherence were compared across age, education, and income groups using an ANOVA to determine statistical significance. 129,927 individuals were included in this analysis. Men had a higher proportion of no screening adherence (17%), and complete adherence (81%) compared to women, 8% and 67%, respectively. For those 45-55 years old (N=37,393), approximately 46% were not completely adherent, compared to only 24% of those > 55 years old. Likewise, study participants who had an annual income <$50,000 or a high school degree or less, had a higher proportion of individuals with partial or no adherence versus those who had an annual income ≥$100,000 or a college degree or higher.

	No Adherence N (%)	**Partial Adherence N (%)**	**Complete Adherence N (%)**	**p-value**
Age				
45- 55 years old	6,977 (18.66)	10,044 (26.86)	20,372 (54.48)	
>55 years old	5,282 (5.71)	17,231 (18.62)	70,021 (75.67)	<0.0001
Income				
<$50,000	2,354 (11.73)	5,290 (26.35)	12,429 (61.92)	
$50,000-100,000	3,809 (8.74)	9,480 (21.76)	30,271 (69.49)	
≥$100,000	5,783 (9.12)	11,884 (18.74)	45,733 (72.13)	<0.0001
Education				
≤High School Graduate	1,168 (11.38)	2,611 (25.44)	6,485 (63.18)	
Some or technical college	3,522 (9.91)	8,573 (24.11)	23,457 (65.98)	
≥ College Graduation	7,079 (8.97)	15,014 (19.03)	56,804 (72.00)	<0.0001

Given the significant differences in adherence by age, income level, and education, consideration of bundled screening (getting multiple screenings during a single visit), especially for some populations, may provide an opportunity to increase complete screening adherence, potentially reducing the number of cancers diagnosed at an advanced stage and increasing survival.

#7346 Disparities in sarcoma care prior to initiation of treatment among patients with newly diagnosed sarcoma.

Lauren Li, Nam Bui, Kristen Ganjoo, Minggui Pan

Division of Oncology, Stanford University School of Medicine, Saratoga, CA

Purpose: Disparities in the outcomes for patients with sarcoma have been reported, however, few studies have investigated the disparities in sarcoma care and the related etiologies. We investigated the care disparities and associated factors along the segments of the adult sarcoma care journey from the onset of symptoms to the establishment of diagnosis and sarcoma consult prior to the initiation of treatment.

Patients and Methods: This cohort included patients with newly diagnosed soft tissue or bone sarcoma (including benign musculoskeletal neoplasms) who were referred to Stanford Medicine for establishing sarcoma care, from July 2020 to April 2024. We investigated the interval from the onset of symptoms (pain and/or palpable mass) to the first appointment with a primary care provider (PCP wait-time), the interval from first PCP appointment to obtaining the first imaging study for workup such as MRI, PET/CT or a Ct scan (imaging wait-time), the interval from the initial PCP appointment to obtaining the tissue biopsy for establishing the diagnosis (biopsy wait-time), and the interval from the referral date for sarcoma consult to obtaining the sarcoma consult (sarcoma consult wait-time. We also performed a survey among the physicians and non-physician staff within the Stanford sarcoma program to understand the perception of acceptability of wait-time more than 5 weeks.

Results: Among 402 eligible patients, approximately one third had PCP wait-time longer than 5 weeks, young adults and Hispanic patients had the highest rate of such long wait-time. Approximately 20% of patients had imaging wait-time longer than 5 weeks, young adults had the highest rate of such long wait-time (30%). There were approximately 5% of patients with sarcoma consult wait-time longer than 5 weeks. However, nearly 80% of patients had biopsy wait-time longer than 5 weeks, African American and Hispanic patients had the highest rate of such long wait-time. In addition, compared to public insurance, there were more patients with private insurance that were associated with PCP wait-time, imaging wait-time, sarcoma consult wait-time and biopsy wait-time longer than 5 weeks. Our survey among the physicians and non-physician staff within the Stanford sarcoma program showed that wait-time longer than 5 weeks was considered unacceptable by a vast majority of responders.

Conclusion: Substantial disparities in sarcoma care related to age group, ethnicity and insurance type appear to exist in the multiple segments of sarcoma care journey prior to the initiation of treatment. Biopsy wait-time appears to be the segment of sarcoma care with the highest rate of long wait-time and significant ethnicity disparities.

#7347 Disparities in breast cancer outcomes among South Asian women: A comparative analysis with White patients.

Jasmin Hundal, Yanwen Chen, Abhay Singh

The Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH

Background: South Asians (SA) are among the fastest-growing racial and ethnic immigrant populations in the United States. Despite this, limited research exists on their breast cancer (BC) outcomes compared to other populations. This study examines disparities between SA and White breast cancer patients.
Methods: Data from female BC patients aged 18 years or older, diagnosed between 2004 and 2021 were obtained from National Cancer Database. For “RACE”, code “15”, “16”, “17” [“Asian Indian or Pakistani, NOS (formerly code 09)”, “Asian Indian”, “Pakistani”] were considered as the “South Asian”; the code “01” as “White”. Cox proportional hazards models were used to estimate the effect of race/ethnicity on OS unadjusted, or adjusted for age group, insurance status, Charlson-Deyo comorbidity score, socioeconomic indicators (percent without a high school degree, and median income quartiles), facility type, urban or rural residence, treatment types (chemotherapy, radiation, surgery, hormone therapy), and year of diagnosis. All analyses were done via SAS/STAT 15.3, or R 4.2.2.
Results: SA were significantly younger at diagnosis, with 37.5% under the age of 50 compared to 21.5% of White (p-value<0.001). A larger proportion of SA were privately insured (62.9%) compared to White (53.7%), with fewer relying on Medicare (17.3% vs. 36.9%) (p-value<0.001). SA were also more likely to reside in areas with higher median income and education levels. Regarding clinical presentation, SA had higher advanced-stage diagnoses (12.8% Stage III-IV) compared to White (11.6%) (p-value<0.001). Tumor subtype distributions revealed that 45% of South Asians had HR+/HER2- cancers compared to 43.3% of Whites, and the prevalence of Triple-Negative breast cancer was slightly higher in SA (7.9%) than in White (6.0%) (p-value<0.001). Treatment patterns showed nearly identical rates of 63.1% SA and 63.2% of Whites received hormone therapy (p-value=0.741), with slightly different surgery rates (93.0% vs. 93.7%) (p-value<0.001). However, SA was less likely to receive chemotherapy (24.7% vs. 17.4%) (p-value<0.001) but had comparable radiation therapy rates (57.1% vs. 57.8%) (p-value=0.055). Survival analyses indicated better outcomes for SA in HR+/HER2- cancers across all stages (e.g., Stage I: HR 0.560, p<0.001) and in HR-/HER2+ cancers at advanced stages (e.g., Stage IV: HR 0.528, p=0.002). Mortality greater than 90 days after surgery was lower for South Asians (81.9%) compared to White (86.1%) (p-value<0.001).
Conclusion: SA exhibit several distinctive characteristics compared to White BC patients, including a younger age at diagnosis, higher socioeconomic status, and better survival outcomes. These findings underscore potential differences in tumor biology, healthcare access, and treatment patterns. Future research should explore systemic, genetic, and social determinants underlying these distinctions.

#7348 Long-term outcomes of pediatric craniopharyngiomas: multi-center comparative study.

Vitor Nagai Yamaki[1], Jai Sidpra[2], Bruno Santana Peres[3], Catuto Domingos Alexandre Quianga[1], Guilherme Jose Costa Borsatto[1], Joao Paulo Mota Telles[1], Ines Nobrega Silva[4], Asthik Biswas[4], Kshitij Mankad[4], Hani Marcus[5], Noor ul Owase Jeelani[6], Sueli Mieko Oba-Shinjo[1], Hamilton Matushita[1], Suely Kazue Nagahashi Marie[1], Kristian Aquilina[6]

[1]Neurology, University of Sao Paulo, Sao Paulo, Brazil,[2]Development Biology and Cancer section, University College of London, London, United Kingdom,[3]Radiology, University of Sao Paulo, Sao Paulo, Brazil,[4]Neuroradiology, National Hospital for Neurology and Neurosurgery, London, United Kingdom,[5]Neurosurgery, National Hospital for Neurology and Neurosurgery, London, United Kingdom,[6]Neurosurgery, Great Ormond Street Hospital, London, United Kingdom

Background: Craniopharyngioma (CP) account for 80% of childhood hypothalamo-pituitary tumors and, though benign, their proximity to the visual pathways, hypothalamus, and pituitary incurs significant long-term neurologic and endocrine morbidity. Informed surgical decision-making has the potential to reduce morbidity and improve outcomes. There remains a high degree of variability in how these lesions continue to be managed.
Methods: This multicenter retrospective observational study aimed to compare long-term outcomes of CP at two pediatric neurosurgery units (GOSH, UK, and USP, Brazil), delineating management paradigms associated with better prognosis. CP treated over a 20-year period were identified and standardized clinical outcomes recorded for comparative analysis.
Results**:**123 patients were identified (USP=52; GOSH=71). No demographic differences were identified between series (mean age: USP=9.2±4.6; GOSH=8.2±4.1 years). Headaches (USP=75%; GOSH=62%) and visual deficits (USP=46%; GOSH=38%) were the most common presenting symptoms. Growth hormone deficiency at presentation was more common in the USP cohort (USP=62.5%; GOSH=35%; p=0.009). There was significantly more hypothalamic invasion in the GOSH cohort (Paris grade 2: GOSH=67.0%; USP=37.5%; p=0.026), but significantly larger cystic volumes in the USP cohort (USP=27.5±37cm^3; GOSH=10.5±8.9cm^3; p=0.004). These differences led to different surgical approaches, with more subtotal resections at USP (78%) and more cyst aspirations at GOSH (62%). 80% of patients at GOSH received RT compared to 32% at USP. Mean follow-up at GOSH was 7.5±4.8 years compared to 10.1±5.6 years at USP. Cognitive outcome did not vary. GOSH cohort presented higher rates of levothyroxine replacement (USP=67%; GOSH=86%; p=0.017). GOSH exhibited better hypothalamic outcomes (p=0.08) and better visual outcomes (field deficits: GOSH=44%; USP=66%; p=0.01). In multivariate analysis (n=123), subtotal/gross-total resection (OR=0.17; 95%CI:0.05-0.55, p<0.01) and older age at diagnosis (OR=0.91, 95%CI:0.82-0.99, p=0.04) were associated with longer progression-free survival.
Conclusions: Comparative analysis of two large craniopharyngioma series identified different paradigms of surgical management driven by clinical-radiological presentation with similar long-term outcomes. Subtotal/gross-total resection was not related to worse clinical outcome or better progression-free survival.

#7349 Impact of HLA loss on NK cell infiltration and resistance to immunotherapy.

Olamide Adefioye, Youngsoo Han, Lucas Yeung, Aidan Shen, Jesse Wang, Zhaohui Wang, Cheng-chi Chao, **Chongming Jiang**

Terasaki Institute for Biomedical Innovation, Los Angeles, CA

Background: Clinical resistance to immunotherapy remains a significant challenge in cancer treatment, with many patients requiring combination therapies to achieve optimal therapeutic outcomes. Tumor cells often evade immune detection by down-regulating Major Histocompatibility Complex (MHC)-I or Human Leukocyte Antigen (HLA) expression, effectively escaping T-cell-mediated immunity. However, this loss may enhance tumors susceptible to Natural Killer (NK) cells, which are capable of recognizing and targeting cells with diminished HLA expression. Elucidating the interplay between HLA heterogeneity, NK cell infiltration, and the tumor immune microenvironment (TIME) is critical for addressing resistance and improving immunotherapy efficacy. This study investigates the HLA loss and its impact on tumor-infiltrating NK cells in the TIME.

Methods: Utilizing single-cell RNA-seq data from human pan-cancer datasets, we crafted 18 distinct pan-cancer NK signatures reflective of NK presence. Pan-cancer datasets, including lung squamous cell carcinoma (LUSC) and lung adenocarcinoma (LUAD), were analyzed using gene set enrichment analysis (GSEA), correlation heatmaps, and survival analyses to evaluate NK cell activity, HLA expression, and immune microenvironment characteristics. The T and NK cell ratio was explored as a potential biomarker of HLA heterogeneity. Linear Discriminant Analysis (LDA) was also employed to evaluate the separation of high and low NK activity groups, though these results were inconclusive.

Results: HLA loss patients exhibited increased NK cell infiltration, likely driven by diminished inhibitory signaling in the absence of HLA molecules. Significant correlations between the T and NK cell ratio and HLA heterogeneity were observed, suggesting its potential as a biomarker for immune profiling. High NK activity was associated with improved survival outcomes, underscoring the protective role of NK cells in the TIME. Hot tumors showed higher NK cell infiltration and lower HLA heterogeneity compared to cold tumors, highlighting distinct patterns of immune cell recruitment.

Conclusion: Tumor-infiltrating NK cells represent a promising target for overcoming therapy resistance associated with HLA loss. Although the LDA results were inconclusive, the observed associations between NK signatures, HLA heterogeneity, and the T and NK cell ratio lay a solid foundation for further investigation. These findings suggest that NK cells and the T and NK ratio could serve as both biomarkers and therapeutic targets in immunotherapy-resistant cancers. Future studies should validate these findings across independent datasets and explore NK-targeted combination therapies.

#7350 Association between radioactive iodine treatment for hyperthyroidism and incident cancer.

Harry D. Momo[1], Megan R. Haymart[2], Xu Shi[3], Alison M. Mondul[1]

[1]Department of Epidemiology, University of Michigan, Ann Arbor, MI,[2]Division of Metabolism, Endocrinology, and Diabetes, University of Michigan, Ann Arbor, MI,[3]Department of Biostatistics, University of Michigan, Ann Arbor, MI

Background: Radioactive iodine (RAI) has been one of the main treatments for hyperthyroidism since the 1940's. However, its long-term safety, particularly regarding cancer risk, remains unclear and controversial. This study aimed to evaluate the association between RAI treatment for hyperthyroidism and overall cancer risk as well as risk of site-specific cancers.
Methods: We conducted a retrospective cohort study using the University of Michigan Precision Health database, which integrates clinical and administrative data from multiple sources, including records from electronic health records, pharmacy, cancer registries, and death registries. Our analytic sample included Michigan Medicine primary care patients aged 18 and older newly diagnosed with hyperthyroidism between 2006 and 2019 with no previous cancer diagnosis. Information on types of treatment for hyperthyroidism (RAI, anti-thyroid medications or thyroidectomy) was abstracted from electronic health records. Participants were followed until cancer diagnosis, death, or end of study (December 2022). Data for key covariates including age, sex, race, comorbidities, BMI, smoking and alcohol history were extracted. Associations between hyperthyroidism treatment and risk of overall and site-specific cancers with at least 20 cases (Breast, Melanoma, Cervix, Prostate, Brain/CNS, Bladder and Colon) were estimated using Cox proportional hazards models. Treatment type was modeled as a time-dependent variable (RAI vs. other treatment) and the analysis included both age-adjusted (age adj) models and multivariable (mv) models which adjusted for age, sex, BMI, comorbidities and severity of hyperthyroidism. MV models for breast, cervix, and prostate cancer did not include sex as these models were restricted to women or men, as appropriate.
Results: A total of 6435 participants were included in the analysis, contributing 52,782 total person-years of follow-up. A total 487 cases of cancer were diagnosed. Compared to patients treated with either medication or thyroidectomy, RAI treatment was not significantly associated with an increased risk of overall cancer (age adj-HR = 0.93 [95% CI: 0.77-1.13], p=0.46; mv-HR= 1.02 [95% CI: 0.73-1.41], p=0.93). In site-specific cancer analyses, RAI treatment was associated with a significant increase in risk of breast cancer in the age adj-HR = 1.70 [95% CI: 1.16-2.40], p=0.04 and remained significant in the multivariable model HR = 2.24 [1.21-4.17], p=0.03). No significant associations were identified between RAI treatment and other site-specific cancers.
Conclusions: In this cohort study, RAI treatment for hyperthyroidism was associated with a significantly increased risk of breast cancer but showed no consistent association with overall cancer risk.

#7351 Financial toxicity and satisfaction with cancer treatment among patients with multiple myeloma: An analysis of the MMRF's CureCloud initiative.

M. A. Fiala[1], E. Lepisto[2], C. Amadi-Mgbenka[2], J. Schulman[2], G. Mulligan[2], H. Cho[2];
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Multiple Myeloma Research Foundation, Norwalk, CT

Background: Multiple myeloma (MM) is one of the most expensive cancers to treat and many patients with MM experience financial toxicity. However, there are limited studies of financial toxicity and its sequalae in this population. In this study, we aimed to explore financial toxicity in a national cohort of patients with MM. Moreover, we aimed to determine if financial toxicity was associated with satisfaction with one's cancer treatment.
Patients and Methods: This study analyzed data from the Multiple Myeloma Research Foundation (MMRF) CureCloud initiative (NCT03657251). CureCloud is a longitudinal study which collected biospecimens, clinical data, and patient reported outcomes (PROs), the COmprehensive Score for Financial Toxicity (COST) and the Cancer Therapy Satisfaction Questionnaire (CTSQ).
Results: In total, 214 participants completed the PROs. The mean age was 68, 60% were male, and 94% were white. The median time from MM diagnosis to the baseline survey completion was 6 months. The mean COST score was 29 (SD=10) and 37% had a COST score less than 26 and were considered to be experiencing financial toxicity. Younger patients were more likely to be experiencing financial toxicity than older patients. For each 10 years decrease in age, the odds of financial toxicity increased by 52% (aOR 1.52; 95% CI 1.20-1.87; p<0.01). Patients who resided in less affluent neighborhoods were also more likely to be experiencing financial toxicity. For each $10,000 decrease in median household income of one's home census tract, the odds of financial toxicity increased by 87% (aOR 1.87; 95% CI 1.20-2.49; p=0.01). Participants experiencing financial toxicity had a mean CTSQ score 6.7 points lower than those without (b = -6.7; 95% CI [-2.7]-[-10.6]; p < 0.01). A subset of patients (n = 75) completed a second COST survey approximately one year later. Financial toxicity status was relatively stable; the status of 81% of patients was the same at both time points. In patients experiencing financial toxicity at baseline, 67% (18/27) were still experiencing it at the later time point. An additional 10% (5/48) of patients not experiencing financial toxicity at the initial survey were at the later time point.
Conclusions: Over one-third of patients with MM experienced financial toxicity and financial toxicity was associated with reduced satisfaction with MM treatment. Younger patients and those who live in less affluent neighborhoods were more likely to experience financial toxicity. These segments of the MM population can be targeted for interventions aimed to reduce financial toxicity.

#7352 Gemcitabine-docetaxol-cisplatin and everolimus in advanced soft tissue sarcomas: Clinical outcomes and prognostic biomarkers.

Wen-Chi Wu, Chueh-Chuan Yen

Taipei Veterans General Hospital, Taipei, Taiwan

Background: Soft tissue sarcomas (STSs) are rare mesenchymal tumors with poor prognosis. While anthracycline-based regimens remain first-line treatment, subsequent options are limited. This study evaluated a novel combination regimen of gemcitabine, docetaxel, cisplatin with everolimus (G-GTC/E), which combines conventional cytotoxic agents with targeted therapy.
Methods: A retrospective analysis was conducted between June 2009 and September 2024 on STS patients treated with G-GTC/E at our institution. The regimen was administered every three weeks: Day 1 - gemcitabine 800 mg/m2 and everolimus 10 mg; Day 8 - gemcitabine 60 mg/m2, cisplatin 60 mg/m2, docetaxel 60 mg/m2, and everolimus 10 mg; Day 15 - everolimus 10 mg. We analyzed baseline characteristics, inflammatory markers, and treatment outcomes. Statistical analyses included Kaplan-Meier survival estimates and Cox proportional hazards models for prognostic factors.
Results: Among 74 enrolled patients with advanced STSs, the ORR was 46% (CR 2.7%, PR 43.2%) with a DCR of 68.9%. The mOS was 16.2 months (95% CI: 10.9-21.4) and mPFS was 5.9 months (95% CI: 3.3-8.5). Histological subtypes included LMS (32.4%), UPS (18.9%), angiosarcoma (6.8%), synovial sarcoma (6.8%), LPS (5.4%), MPNST (5.4%), and others (24.3%). Survival varied significantly across subtypes, with synovial sarcoma showing the most favorable mOS at 29.8 months (95% CI: 0-76.3), followed by LMS at 21.7 months (95% CI: 9.6-33.9), while UPS showed the poorest survival of 8.6 months (95% CI: 0-20.8). Primary sites included extremities (40.5%), abdominal/thoracic visceral organs (29.7%), retroperitoneum (13.5%), trunk (10.8%), and head and neck (5.4%). Head/neck sarcomas had the longest mOS at 27.4 months (95% CI: 12.2-42.6), followed by retroperitoneal (24.8 months; 95% CI: 16.5-33.0) and visceral sarcomas (23.6 months; 95% CI: 14.0-33.3). For prognostic factors, elevated CRP, neutrophil-lymphocyte-ratio, platelet-lymphocyte-ratio, and systemic inflammatory index predicted poor OS. Monocyte-lymphocyte-ratio showed similar trend without significance (p=0.119). All inflammatory markers suggested inferior PFS without statistical significance. Low albumin levels predicted poor outcomes in both OS and PFS. Grade 4 hematological toxicities included neutropeniq (40%), thrombocytopenia (35%), and anemia (10%). Grade 3/4 diarrhea and skin rashes occurred in 16.2% and 25% of patients, respectively.
Conclusion: G-GTC/E demonstrated promising efficacy as a second-line treatment for advanced STS. Careful monitoring for thrombocytopenia, diarrhea and skin reactions is essential. Elevated inflammatory markers and low albumin levels predicted poor outcomes, suggesting their potential utility in patient stratification for G-GTC/E therapy in advanced STS.

#7353 Evaluating the LinC CHW program's effect on emergency department visits and health outcomes in cancer patients.

Tishiya Carey, Alexis Roach, Elizabeth Hansen

University of Chicago, Chicago, IL

This study examines the impact of the Liaisons in Care (LinC) Community Health Worker (CHW) program on emergency department (ED) utilization and survival outcomes among cancer patients at the University of Chicago Medicine. Designed to reduce ED visits by enhancing patient engagement, the LinC program provides targeted support through follow-ups, resource provision, and coordinated care. Our cohort included 72 cancer patients enrolled in LinC from January 2022 to December 2023, each with at least one recorded home visit or extensive engagement through other encounters. Key engagement metrics indicated that 83% of all encounters were CHW-initiated, with 77% conducted virtually. ED utilization decreased, with the average number of visits per patient dropping from 1.68 visits before program enrollment to 0.81 visits post-enrollment. Patients experienced an average interval of 102 days between ED visits and a 30-day readmission rate of 35.3%. The median survival time for the cohort was 557 days, with a one-year survival probability of 66.7%. Kaplan-Meier analysis revealed a significant difference in survival outcomes based on diagnosis timing: patients diagnosed within six months of enrollment had a lower median survival time (284 days) compared to those diagnosed before six months of enrollment (835.5 days; $p = 0.005$).These findings highlight the potential of CHW programs to improve healthcare outcomes for high-risk cancer populations by enabling timely interventions and providing access to resources. The results support the expansion of similar CHW-led initiatives to reduce health disparities and enhance the quality of life for cancer patients. Future analyses will incorporate social determinants of health (SDOH) to further refine engagement strategies and optimize CHW allocation across service lines.

#7354 Patient reported outcome validation within the Voyage Study cohort.

E. J. Kirsch, J. A. Grimm, S. M. Stoddard, W. Z. Fan, K. A. Bohn, K. J. Yost, L. J. Finney Rutten, J. E. Olson;
Mayo Clinic, Rochester, MN

Background: Epidemiologic studies commonly obtain important exposure and outcome information from patient self-report although these may be influenced by imperfect understanding and/or faulty recall. The Voyage Study is a large-scale, prospective cohort study of long-term health outcomes among participants with a valid multi-target stool DNA (mt-sDNA) test order (N=150,047). The purpose of this analysis was to evaluate the validity of participant reported mt-sDNA tests, colorectal cancer (CRC), and/or aerodigestive cancers (ADC, including cancers of the head, neck, oral, esophageal, lung, liver, stomach, pancreas, anus) among respondents.

Methods: Participants from across the Unites States enrolled in the study completing questionnaires at enrollment and 1 year. The year 1 questionnaire collected data on completion and outcome of their mt-sDNA test, follow up colonoscopies and other procedures as well as a diagnosis of CRC or ADC. The study team contacts those who reported either CRC or ADC for permission to obtain copies of medical records. Records are then reviewed by a trained nurse abstractor and evaluated for validity. Mt-sDNA test results were available from Exact Sciences.

Results: At the time of this analysis, year 1 questionnaire data were available on 135,035 participants. Abnormal mt-sDNA results (n=12,928) were self-reported by 13,420 participants with 96.3% accuracy. Of the 111,556 self-reported normal results, 93.4% (n=104,150) were reported correctly. The validation process for the Voyage Study is ongoing with 860 self-reported CRC and 318 self-reported aerodigestive cancer diagnoses to date. Complete data are available on 155 individuals with a self-report of a new CRC diagnosis and 63 individuals with a self-report of aerodigestive cancer. Abstraction confirmed 47% (n=73) of those reported as true CRC diagnoses. Participants were better at correctly reporting at least one aerodigestive cancer (73%, n=46).

Discussion and Conclusions: Patient reported medical record validation poses a unique challenge in today's world. The process of requesting participant authorization followed by institutional requests to release the medical records to the research team is slow and painstaking. We found that patients are able to correctly report their mt-sDNA tests but found a relatively low proportion of reported cancer diagnoses reported correctly. This underscores the need to continue to validate key outcomes rather than relying solely on participant responses. As the number of outcomes validated increases, the study team will look at a variety of social and economic factors to better understand what contributes to or hinders an accurate self-report.

#7355 Understanding health belief profiles and their role in medication adherence and quality of life among cancer survivors: insights from a multimethod study.

Meng-Jung Wen[1], Olayinka O. Shiyanbola[2]

[1]Health Services Research in Pharmacy, University of Wisconsin-Madison, Madison, WI,[2]Clinical Pharmacy, University of Michigan, Ann Arbor, MI

Background: More than half of cancer survivors don't engage in taking oral anticancer medications (OAMs) due to negative perceptions, leading to relapse, hospitalizations, and higher medical costs. This multimethod study explored cancer survivors' health belief schemas to understand their decision-making processes around OAM adherence and its impact on quality of life.
Methods: This cross-sectional study surveyed 323 cancer survivors nationally to assess beliefs about cancer, OAM adherence, and health-related quality of life (HRQoL), using latent profile analysis to identify subgroups based on health beliefs. Hierarchical regression examined subgroup associations with adherence and HRQoL, while qualitative content analysis of eight interviews provided deeper insights into participants' cancer experiences.
Results: Three health belief profiles were identified: **(1)** optimistic and adaptive (n = 43, 13%), **(2)** conscious but hesitant (n = 99, 31%), and **(3)** overwhelmed and unaware (n = 181, 56%), with significant differences in belief patterns. Regression analysis showed that health belief profiles explained 49.1% of the variance in medication adherence and 28.6% in HRQoL, adjusted for clinical and demographic factors. Cancer survivors in Profile 3 had the lowest adherence (mean = 20.98, SD = 9.0, P<.001) and HRQoL (mean = 14.45, SD = 7.8, P<.001), with *Risk of Recurrence* (β = -.15, p = .01), *Cancer Consequences* (β = -.17, p = .01), and *Personal Control* (β = -.12, p = .05) as significant strong predictors of nonadherence. Qualitatively, participants reported key consequences of cancer including fatigue and medication side effects, social and structural barriers such as altered dynamics with friends and family, social isolation, and financial strain caused by unaffordable healthcare costs and reduced work capacity. Those who perceived a higher risk of recurrence showed greater tolerance for uncomfortable side effects and adhered more consistently to OAMs. Additionally, compared to the overwhelmed and unaware group, participants who maintained optimism and adaptability in managing their cancer, embraced positive thinking and actively engaged in self-management practices, such as maintaining a healthy diet, exercising, and setting alarms for medication taking.
Conclusion: This study identified distinct health belief profiles among cancer survivors, highlighting their impact on medication adherence and HRQoL. Survivors with overwhelmed and unaware beliefs exhibited the lowest adherence and HRQoL, emphasizing the importance of addressing negative perceptions and enhancing personal control to improve outcomes. Tailored interventions targeting specific belief profiles, particularly those at higher risk of nonadherence, may foster better self-management and adherence, ultimately improving quality of life for cancer survivors.

#7356 Feasibility, acceptability, and preliminary efficacy of acceptance and commitment therapy in women living with metastatic breast cancer.

Ashley Hatch[1], Joanna B. Torzewski[2], Jessica L. Thomas[3], Heidy N. Medina[1], Fiona S. Horner[4], William J. Gradishar[5], David Victorson[3], Frank J. Penedo[6], Michael H. Antoni[6], Patricia I. Moreno[1]

[1]Department of Public Health Sciences, University of Miami Miller School of Medicine, Miami, FL,[2]Department of Psychiatry and Behavioral Sciences, Northwestern University Feinberg School of Medicine, Evanston, IL,[3]Department of Medical Social Sciences, Northwestern University Feinberg School of Medicine, Evanston, IL,[4]Department of Psychology, Carnegie Melon University, Pittsburgh, PA,[5]Department of Medicine, Northwestern University Feinberg School of Medicine, Evanston, IL,[6]Department of Psychology, University of Miami, Miami, FL

Purpose: While metastatic breast cancer (BC) has no cure, treatment advances are helping women live longer. However, these women often experience debilitating treatment symptoms and emotional distress. Acceptance and commitment therapy (ACT) is an evidence-based intervention that improves mood and quality of life while allowing for the feelings of grief and loss that are expected when facing a life-limiting prognosis. There is a paucity of randomized controlled trials of ACT among women with metastatic BC. This study examined acceptability, feasibility, and preliminary efficacy of a tailored ACT intervention in a randomized pilot trial.
Procedures: Women with stage IV BC (N=30) were randomized 1:1:1 to ACT, usual care, or Cognitive and Behavioral Stress Management (CBSM). ACT and CBSM included 8 weekly group sessions (90 minutes each) delivered via videoconference. Participants completed FACT-B and PROMIS measures at baseline, mid-intervention, post-intervention and 1-month follow-up. Cohen's D effect sizes were calculated.
Results: On average, women were 59.7 years old and 5.6 years from metastatic BC diagnosis. Enrollment rate was 88.5% (31/35), randomization rate was 96.8% (30/31), and retention rate was 90% (9/10 for ACT, 9/10 for usual care, 9/10 for CBSM). 100% of women in both ACT and CBSM attended at least half of the 8 sessions and 88.8% attended at least 6 sessions. 94.4% of women in ACT and 88.2% in CBSM would recommend the intervention to another woman living with metastatic BC. The effect sizes at post intervention were greater than .8 for ACT vs. usual care, while only anxiety and meaning were greater than .8 in CBSM vs. usual care (Table 1).
Conclusion: Findings demonstrate high feasibility and acceptability for ACT and CBSM in metastatic BC. A full-scale randomized control trial is needed to determine the stability of effects and whether ACT has robust effects on outcomes of interest and optimizes HRQoL among women with metastatic BC.

#7357 Mediators of inflammation modify the association between clonal hematopoiesis and incident hematologic malignancy in ARIC.

Elizabeth A. Platz[1], Vernon A. Burk[1], Meng Ru[1], Sergiu Pasca[2], Lukasz P. Gondek[2], Katherine Y. King[3], Ajibike D. Lapite[3], Anna Prizment[4], Corinne E. Joshu[1], Pradeep Natarajan[5], Margaret A. Goodell[3], Christie M. Ballantyne[3], Koichi Takahashi[6]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD,[3]Baylor College of Medicine, Houston, TX,[4]University of Minnesota, Minneapolis, MN,[5]Harvard Medical School, Boston, MA,[6]MD Anderson Cancer Center, Houston, TX

Background: Clonal hematopoiesis (CH) is associated with a higher hematologic malignancy (HM) risk, and risk increases with variant allele frequency (VAF). We determined whether inflammatory factors modify the association between CH and HM.

Methods: We conducted a prospective cohort analysis of 9,978 participants (55.9% female, 29.5% Black) in the Atherosclerosis Risk in Communities (ARIC) study who were 44-80 years old and did not have a cancer history. Median follow up was 20.9 years. CH (VAF≥2%: 9.8%; VAF≥10% [large CH]: 4.7%) was identified from whole exome sequencing data constrained to 74 genes (Bick et al. *Nature* 2020). Incident HM (N=434) was ascertained mainly by cancer registry linkage. Aspirin was assessed at study visits by review of containers of prescribed and over the counter drugs used in the last 2 weeks. Plasma proteins were measured by SomaScan® 5K assay. We prespecified interleukin (IL)-6, interferon-gamma (IFN-gamma), IL-8, IL-1beta, and tumor necrosis factor (TNF)-alpha. We estimated the association between CH and HM stratified by aspirin use and plasma protein levels (median; 8,693 participants) using Cox regression adjusting for age, sex, race, and risk factors for HM.

Results: The association between large CH (vs no CH) and HM was weaker in aspirin users (HR=1.58, 95% CI 0.91-2.72, p-trend [across no, small, large CH]=0.26) than in non-users (HR=2.02, 95% CI 1.29-3.15, p-trend=0.008). The association between large CH and HM was stronger in participants with higher (HR=2.11, 95% CI 1.29-3.44, p-trend=0.10) than lower (HR=1.38, 95% CI 0.77-2.48, p-trend=0.56) plasma IL-6. Median VAF in those with large CH was comparable between higher (18%) and lower (16%) IL-6 strata, as was percentage of common genes mutated (*DNMT3A:* higher 48%, lower 48%; *TET2:* higher 21%, lower 23%). Patterns of association between CH and HM by strata of IFN-gamma (higher: p-trend=0.014; lower: p-trend=0.46) and IL-8 (higher: p-trend=0.01, lower: p-trend=0.46) were similar to IL-6. In contrast, for TNF-alpha strata, the association between large CH and HM was weaker in participants with higher (p-trend=0.20) than with lower (p-trend=0.06) levels, and the percentage with mutated *DNMT3A* appeared to differ by TNF-alpha level (higher 51%, lower 43%). Associations between large CH and HM were comparable in the higher (p-trend=0.05) and lower (p-trend=0.12) IL-1beta strata.

Conclusions: Regular aspirin use may dampen CH-associated hematologic malignancy risk. Higher plasma levels of some pro-inflammatory cytokines, especially IL-6, may exacerbate CH-associated hematologic malignancy risk. While IL-6 is produced by immune cells with *DMNT3A* and/or *TET2* mutations, the similar VAF and percentage of mutated gene by IL-6 level suggests that IL-6 is not simply marking CH extent. Laboratory experiments are needed to establish cause for these inflammation mediators. Support: NHLBI, NCI, NPCR

#7358 Cigarette smoking is associated with worse prognosis in myelodysplastic syndromes and causes inflammation and hematopoietic alterations in murine models.

T. Verma[1], D. Verma[1], S. Sahu[1], K. Pradhan[1], R. Aggarwal[1], S. Jasra[2], S. S. Dehghani[1], H. Zhang[1], M. Spodek[1], I. Mantzaris[1], M. Konopleva[1], M. Goldfinger[1], A. Verma[1], D. Hosgood[1], A. Shastri[1], Y. Zou[1];

[1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Vermont Medical Center, Burlington, VT

Introduction: Cigarette Smoking has been associated strongly with solid tumors but the causative links with myeloid malignancies have not been well elucidated. Also, the effects of smoking on hematopoiesis have not been explored in vivo.

Results: A highly diverse cohort of Myelodysplastic syndrome (MDS) patients (N=128) including 37% Hispanic and 29% African American subjects was studied. Overall survival was found to be significantly reduced in subjects with previous smoking histories (N=78) when compared to never smokers (N= 58), (P value = 0.04; Median Survival 2130 days vs 4620 days). This was not due to significant differences in age, sex, IPSS, blast counts, mutations between the groups. Next, to determine the effects of smoking in vivo, we optimized a cigarette smoke machine that allowed us to expose mice (C57B/6) to 6 cigarettes a day, 3 times a week for one month. Mice exposed to cigarette smoking exhibited signs of reduced activity and showed raised levels of inflammatory mediators, Interleukin-1β (IL1β) and histamine, while the anti-inflammatory protein Interleukin -10 decreased when compared to controls. Mice exposed to cigarette smoking showed reduced white cell counts. Increased hemoglobin was also seen reflecting exposure to smoke. To assess for qualitative stem cell alterations we performed competitive transplantation experiments using CD45.2 donors exposed to smoking using CD45.1 recipients. Smoking exposure led to reduced donor chimerism at 4 months after transplants, when compared to controls. This difference was reduced at 8 and 12 months, demonstrating that smoking exposure led to reduced progenitor functionality, reflected in early chimerism defects. Cigarette smoke condensate (CSC) collected from the smoke machine's artificial lung was chemically analyzed and showed high levels of nicotine and known carcinogens Acetaldehyde, Formaldehyde, Benzo(a)pyrene, Toluene, Benzene, and Nitrosamines (NNN, NAT, NAB, NNK). We administered CSC via intratracheal injections chronically for 4 months (3 times a week) to an independent cohort of mice. Mice again demonstrated an increase in inflammatory IL-1β and histamine and murine bronchial macrophages treated with CSC exhibited to an inflammatory transcriptomic signature and proteomic validation of increased IL-1β. Lastly, treatment of primary human CD34+ stem and progenitors with CSC resulted in a decreased production of hematopoietic cell colonies, validating the in vivo findings of bone marrow suppression.

Conclusion: We demonstrate that history of cigarette smoking is associated worse overall survival in MDS. We also demonstrate that exposure to cigarette smoking leads to inflammation and hematopoietic alterations in vivo, potentially accounting for adverse clinical outcomes in hematologic malignancies.

#7359 Systemic chronic inflammation is associated with quality of life in the Cancer Disparities Research Network.

Holli Ann Loomans-Kropp[1], Yengeniya Gokun[2], Priya Das[2], Aaliyah Beneby[3], Ting-Yuan Cheng[2], Electra Paskett[2], Cancer Disparities Research Network Cohort Workgroup

[1]The Ohio State University Wexner Medical Ctr., Columbus, OH,[2]The Ohio State University, Columbus, OH,[3]Central State University, Wilburforce, OH

Purpose: The objective of this study was to examine the association between chronic inflammatory (CI) biomarkers and self-reported quality of life (QoL) measurements among medically underserved and minority individuals in the Cancer Disparities Research Network (CDRN).
Methods: We utilized 190 plasma samples collected as part of the CDRN. Briefly, the CDRN was a nationwide initiative intended to improve participation of minority and underserved populations in biobanking research. Eligibility criteria for CDRN was age 40-74, living in an Appalachian County or self-identified as African American (AA)/Black, Hispanic, or Asian, and meeting one of the following criteria: living in a medically underserved area, low literacy, a household income below the federal poverty level in 2015 or being uninsured or receiving subsidized health insurance. For inclusion in the current study, participants needed to have a completed baseline survey and provided a blood sample. CI biomarkers were measured using the ProcartaPlex Human Inflammation Panel 20plex. Concentrations were log-transformed prior to analysis. Self-reported QoL in the past week was measured using a Likert scale (0-10) for anxiety, fatigue, and distress, which were categorized as none, mild, moderate, and severe. Spearman correlation coefficients and adjusted generalized linear regressions were used to assess the relationships between QoL measures and biomarkers. Model covariates included socioeconomic status, age, sex, race, aspirin and nonsteroidal anti-inflammatory drug use, frequency of moderate exercise, and history of arthritis, asthma, depression, high cholesterol, and diabetes.
Results: Among the participants included in our study, 32% were White, 34% were AA/Black, 30% Asian, and 4% Other. We found statistically significant positive correlations between 10 (30.3%) CI biomarkers and anxiety, 6 (18.1%) biomarkers and fatigue, and 4 (12.1%) biomarkers and distress. gp130 was strongly correlated with anxiety and APRIL, MMP-1, and IL-19, were correlated with all three measures (anxiety, fatigue, distress). Adjusted results showed that moderate distress was associated with higher concentrations of APRIL ($p<0.01$), while mild and moderate anxiety were associated with higher concentrations of MMP-1 ($p=0.01$ and $p=0.04$, respectively). Mild ($p=0.03$), moderate ($p=0.04$), and severe ($p=0.02$) anxiety was associated with higher gp130 concentration. Race was a significant covariate in our models, suggesting baseline differences in CI markers across self-reported race.
Conclusions: We demonstrated the association between CI biomarkers APRIL, MMP-,1 IL-19, and gp130 with self-reported QoL measures, specifically anxiety and distress. Moreover, we showed that subjective QoL perceptions was associated with systemic CI, suggesting the importance of understanding the mind-body inflammatory connection.

#7360 Characterizing the immune microenvironment of Nigerian breast tumors by subtype.

Jovita Byemerwa[1], Drew Neish[1], April Deveaux[1], Omolola Salako[2], Adetola Daramola[3], Olusegun Alatise[4], Gabriel Egun[5], Tomi Akinyemiju[1]

[1]Population Health Sciences, Duke University School of Medicine, Durham, NC,[2]College of Medicine & Lagos University Teaching Hospital, Lagos, Nigeria,[3]Lagos University Teaching Hospital, University of Lagos, Lagos, Nigeria,[4]Population Health Sciences, Obafemi Awolow University Teaching Hospital, Ile-Ife, Osun State, Nigeria,[5]University College Hospital, University of Ibadan, Ibadan, Oyo State, Nigeria

Background: Breast cancer (BC) bears significant and well-established disparities in aggressiveness and mortality, disproportionally affecting women of African descent. While socioeconomic factors might explain disparities in BC outcomes in women of African descent, intrinsic tumor biology is now recognized as a contributing factor in BC mortality. Clinical and molecular features of breast tumors in African American women strikingly resemble those of West African women, both characterized by early onset and a high prevalence of the aggressive triple-negative breast cancer subtype, suggesting the shared West African genetic ancestry might play a factor in BC aggressiveness. However, there is a paucity of studies that have clearly characterized the breast tumor microenvironment (TME) in West African women, a critical knowledge gap whose addressing might open therapeutic opportunities to address BC disparities in women of African descent. In this study, we characterized the immune repertoire of BC from Nigeria by receptor subtype.
Methods: We used the Nanostring technology Immune Exhaustion (IE) Panel to characterize the immune repertoire of Nigerian breast tumors by subtype. The Nanostring IE panel targets 785 genes across 47 pathways involved in immune activation, suppression, exhaustion and memory. RNA was isolated from breast tumors of 48 newly diagnosed, treatment naïve breast cancer patients with either estrogen receptor-positive (ER+), HER2-enriched, and Triple-negative Breast Cancer (TNBC) subtypes from Nigeria. After hybridization of the RNA with fluorescent barcoded IE panel probes and counting of hybridized probes, quality control and normalization of the raw data were performed using the Nanostring nSolver Software. Analysis of differential gene expression, pathway scoring, cell type profiling, and gene set enrichment by receptor subtype was performed using the nSolver Software Advanced Analysis Package 2.0, NanostringTM).
Results: Six differentially expressed genes (DEGs) were significantly upregulated or downregulated in ER+ breast cancers vs TNBC. The CHRD gene (associated with TGF-beta signaling) was the most significantly upregulated in ER+ BC vs TNBC. In contrast, the SHC4 gene (associated with cytotoxicity) was the most significantly downregulated in ER+BC vs TNBC. Pathway scoring indicated that ER+ BC had decreased fatty acid metabolism, hypoxia response, and glycolysis and glucose import pathway scores compared to TNBC. No differences in B, T, and NK cell immune exhaustion scores were observed between various BC subtypes.
Conclusion: We observed differences in gene expression and metabolic pathways by subtypes, with the ER+ BC subtype having lower fatty acid metabolism, and glycolysis and glucose import pathway scores in comparison to TNBC. Our findings highlight new insights that could open therapeutic opportunities to improve BC outcomes among women of African descent.

#7361 Scientific rationale and successful implementation of biospecimen collection in the NCI Connect Cohort for Cancer Prevention.

Nicolas A. Wentzensen[1], Stephanie Weinstein[1], Amanda Black[1], Erin Schwartz[1], Hannah P. Yang[1], Michelle Brotzman[1], Paul Albert[1], Laura Beane-Freeman[1], Amy Berrington[2], Jonas De Almeida[1], Jonine D. Figueroa[1], Montserrat Garcia-Closas[2], Nicole Gerlanc[1], Gretchen Gierach[1], Rena Jones[1], Peter Kraft[1], Charles Matthews[1], Habib Ahsan[3], Brisa Aschebrook-Kilfoy[3], Chun-Hung Chan[4], Robert Greenlee[5], Stacey Honda[6], Ben Rybicki[7], Blythe Ryerson[8], Katherine Sanchez[9], Mark Schmidt[10], Kevin Sykes[9], Larissa White[11], Jeanette Ziegenfuss[12], Stephen Chanock[1], Christian Abnet[1], Mia Gaudet[1]

[1]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]ICR, London, United Kingdom,[3]University of Chicago, Chicago, IL,[4]Sanford Health, Sioux Falls, SD,[5]Marshfield, Marshfield, WI,[6]KP Hawaii, Honolulu, HI,[7]Henry Ford Health System, Detroit, MI,[8]KP Georgia, Atlanta, GA,[9]Baylor Scott and White, Dallas, TX,[10]KP Northwest, Portland, OR,[11]KP Colorado, Denver, CO,[12]Health Partners, Minneapolis, MN

Introduction: The Connect for Cancer Prevention Study is a new prospective cohort with repeated exposure assessment and long-term follow-up to study the cancer continuum from initiation, multi-step carcinogenesis, diagnosis, to outcomes in a diverse US population. Over 50,000 participants towards the goal of 200,000 have been recruited so far at 10 integrated healthcare sites across the United States. Goals of Connect include studies of cancer etiology, risk prediction, and early detection. Biospecimens are a critical component for exposure assessment and biomarker measurement. We summarize the scientific rationale and successful implementation of biospecimen collections in Connect.

Methods: A biospecimen collection protocol was informed by literature review, expert consultations, and pilot studies evaluating how different blood collection tubes and processing protocols influence DNA yield and quality, as well as nucleic acid and protein-based biomarkers. Baseline biospecimens include a 45ml blood draw, a urine collection, and a mouthwash sample. Biospecimens are collected in dedicated research labs or at clinical sites with home collection of mouthwash samples. A cell-free DNA collection for multi-cancer early detection is implemented at research collection sites. All biospecimens are shipped to an NCI laboratory for processing and long-term storage. Process metrics include sample completeness, sample deviations, temperature logging, and needle-to-freezer time, among others.

Results: As of November 2024, 35,790 participants of 53,005 enrolled (68%, ranging from 57% to 75% across sites) donated blood and urine samples, with baseline collections still ongoing. Among collections, 58% were from clinical sites, and 42% from research labs. Over 80% of biospecimens collected at research labs were received at NCI within one day, while 70% of biospecimens collected at clinical sites were received within 2 days. Over 95% of all biospecimens were received within 4 days. The return of home-collected mouthwash samples was 77%. Among 276,228 biospecimen tubes collected, 87% were complete with no deviations recorded. Over 90% of participants submitted a short survey relevant for sample collection after the biospecimen visit. Blood collections are planned every three years to study different exposure windows and biomarker changes within individuals. More frequent collections are considered among participants at high risk of cancer.

Conclusions: Connect combines EHR data, state-of-the-art surveys, and biospecimen collections to address critical questions of cancer etiology and prevention. We successfully implemented a robust and efficient biospecimen collection approach at 10 recruitment sites across the U.S. The timeline and process for biospecimen access for the research community and initial biospecimen activities will be presented at AACR.

#7362 Connect for Cancer Prevention Study: a modern prospective cohort.

Mia M. Gaudet[1], Amy Berrington de Gonzalez[2], Christian C. Abnet[1], Paul Albert[1], Jonas S. Almeida[1], Stephanie Weinstein[1], Amanda Black[1], Hannah P. Yang[1], Michelle Brotzman[1], Laura Beane-Freeman[1], Laura Beane-Freeman[1], Jonine Figueroa[1], Neal D. Freedman[3], Nicole M. Gerlanc[1], Gretchen L. Gierach[1], Rena R. Jones[1], Peter Kraft[1], Charles Matthews[1], Habibul Ashan[4], Briseis Aschebrook-Kilfoy[4], Chun-Hung Chan[5], Robert T. Greenlee[6], Stacey A. Honda[7], Benjamin Rybicki[8], Katherine Sanchez[9], Kevin Skyes[9], Mark A. Schmidt[10], Larissa L. White[11], Jeanette Y. Ziegenfuss[12], Stephen J. Chanock[1], Montse Garcia-Closas[2], Nicolas A. Wentzensen[1]

[1]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]Institute of Cancer Research, London, United Kingdom,[3]NCI DCCPS, Bethesda, MD,[4]University of Chicago, Chicago, IL,[5]Sanford Health, Sioux Falls, SD,[6]Marshfield Clinic, Marshfield, WI,[7]Kaiser Permentae - Hawaii, Honolulu, HI,[8]Henry Ford Health, Detroit, MI,[9]Baylor, Scott and White Health, Dallas, TX,[10]KP Northwest, Portland, OR,[11]KP Colorado, Denver, CO,[12]Health Partners, Minneapolis, MN

Background: Reaching the national goal of reducing cancer mortality by 50% within 25 years will require improvements in cancer early detection and prevention in addition to treatment. Modern prospective cohorts that capture new and emerging exposures to research cancer etiology are critical to achieve these goals. Profound societal and technological changes in the last decade present opportunities and challenges for the recruitment, engagement, and retention of participants in new cohorts.
Methods: The Connect for Cancer Prevention Study is a modern cohort of adults, 30-70 years old without a prior cancer diagnosis, recruited from 10 U.S. integrated health care systems. Participants provide information and biospecimens at enrollment and at regular intervals during at least 20 years of follow up. Exposure and outcome information will be captured through online surveys, electronic medical records, medical imaging, geospatial linkages of 20-year residential histories, wearable sensors, and linkages with the National Death Index and the state cancer registries. Collected biospecimens include blood, urine, saliva, and fecal samples, as well as precursor and tumor tissue specimens. Data systems follow F.A.I.R. (findability, accessibility, interoperability, and reuse of digital assets) principles to maximize data and tool re-usability.
Results: In 2021, recruitment commenced among an eligible catchment population of more than 3.2 million patients. As of November 2024, over 53,000 of the expected 200,000 participants consented; 87% completed at least some baseline activities to date. Baseline recruitment is expected to be complete in 2027. The current study population has a median age of 53 (IQR: 42-61) years, 67% are female, 63% completed at least a bachelor's degree, and 88% report good to excellent overall health. Among the cohort, 61% of participants self-report as White, 14% self-report as multi-racial, 11% as Black, African American or African, 5% as Asian, and 4% as Hispanic, Latino, or Spanish among other categories. The portion of the latter category is expected to increase as recruitment ramps up at a site with a high Hispanic catchment population, which started enrollment in 2023. The proportion of individuals who have ever smoked cigarettes is 30%, whereas 9% have ever used marijuana, 3% have ever smoked cigars, and 2% have ever vaped nicotine containing electronic cigarettes. The median body mass index of participants is 30 kg/m^2 (IQR: 24-36 kg/m^2). Approximately, 30,000 incident precursor and 8,000 cancer diagnoses are expected to occur during the first 10 years of follow up.
Conclusions: Connect for Cancer Prevention Study combines novel approaches in epidemiology and data science to provide a valuable resource for the scientific community to study cancer etiology, natural history, risk prediction, early detection, and survivorship. Individual-level data is expected to be released to the scientific community in 2026.

#7363 Providers' beliefs, perceived skill, and perception of organizational norms relate to their delivery of cigarette smoking intervention to patients seen in healthcare centers serving rural and medically underserved areas of Texas.

A. D. Siddiqi[1], M. Britton[1], T. A. Chen[2], I. Martinez Leal[1], A. Bergey[2], T. Goulbourne[2], T. Ousley[2], T. Williams[3], K. Casey[3], L. R. Reitzel[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Houston, Houston, TX, [3]Integral Care, Austin, TX

Rural and medically underserved populations have elevated smoking rates, yet evidence-based cessation care is not often provided in healthcare settings serving these communities, leading to a greater burden of smoking-related cancers. Social cognitive theory (SCT) factors - cognitive, behavioral, and environmental - influence providers' smoking intervention delivery. Here, we examine the veracity of these relations in a novel setting, healthcare centers serving rural and medically underserved areas of Texas, to inform workplace capacity building to improve care for smokers and prevent cancers. Providers (N=347) from 19 healthcare centers took an e-survey and reported on 1) their beliefs about smoking: whether their patients a) are concerned about smoking and b) want to quit (cognitive); 2) perceived treatment skills: whether they a) have the skills to help their patients quit smoking and b) are knowledgeable about referral options (behavioral); and 3) workplace norms: whether tobacco cessation counseling is an important part of their center's mission (environmental). Smoking intervention practices (the 5A's: Ask, Advise, Assess, Assist, Arrange) for past-month patient contacts were self-reported. Linear mixed models tested for associations between SCT constructs and the 5A's, controlling for center type. Overall, 31.41% of providers believed their patients were concerned about smoking and 29.11% thought they wanted to quit; 48.99% endorsed treatment skills and 53.89% were knowledgeable of referral options; and 48.99% endorsed that tobacco treatment was an important part of their center's mission. Providers Asked 68.31% of patients about their smoking status; of the smokers seen, providers Advised 58.68% to quit, Assessed interest in quitting among 51.90%, Assisted 35.87% to quit, and Arranged follow-ups for 22.79%. Relative to those who did not, providers who believed patients wanted to quit Asked a greater proportion of their patients about their smoking status. Providers who reported having the skills to help patients quit smoking or knowing about referral options delivered Ask to more patients and Advise, Assess, Assist, and Arrange to more smokers. Providers who believed that tobacco cessation was an important part of their center's mission delivered Ask to more patients and Advise and Assess to more smokers. All ps <0.02. Workplace interventions providing education to improve the accuracy of providers' smoking-related beliefs, training to bolster their smoking treatment and referral skills, and efforts to reflect the importance of a shared smoke-free mission may reduce gaps between the current and the recommended best practices in smoking care provision in centers serving patients in rural and medically underserved areas of Texas.

#7364 Culturally sensitive, virtually supervised, home exercise improves cognition in Latina and Hispanic breast cancer survivors: results from the ROSA Trial.

Elizabeth Cox[1], Paula Gonzalo-Encabo[2], Rebekah L. Wilson[1], Mary K. Norris[3], Danny Nguyen[3], Cami N. Christopher[4], Jocelyn Greer[3], Christina M. Dieli-Conwright[4]

[1]Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA,[2]Dana-Farber Cancer Institute/Universidad de Alcala, Madrid, Spain,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Dana-Farber Cancer Institute/Harvard Medical School/Harvard T.H. Chan School of Public Health, Boston, MA

Background: Breast cancer diagnosis and treatment contribute to cognitive impairment, including executive and memory dysfunction, which reduce quality of life. Breast cancer is the most common cancer diagnosis in Hispanic and Latinas, who are often diagnosed at later stages, requiring more aggressive treatment that can increase severity of cognitive impairment. Exercise can safely and effectively improve cognition in cancer survivors, but Latina/Hispanic breast cancer survivors (LHBCS) often do not meet physical activity guidelines and face exercise barriers such as lack of enjoyment and knowledge, self-consciousness, and discouragement. Previous research on exercise and cognition is inconclusive among LHBCS, possibly due to inadequate attention to these barriers. Culturally sensitive, virtually supervised, home exercise interventions may reduce barriers and improve cognition in LHBCS.
Aim: This exploratory analysis aims to determine the efficacy of virtually supervised, home exercise to improve cognition in LHBCS enrolled in the ROSA Trial (NCT04717050).
Methods: LHBCS (n=64) were randomized to a 16-week progressive aerobic and resistance exercise group (EG) or attention control group (CG). The EG completed ~90 min sessions led virtually by an exercise trainer, and the CG completed static stretching 3 days/week. Barriers were addressed with Spanish-language materials and staff, and delivery in the home. At pre- and post-intervention, participants completed NIH Cognition Toolbox tasks: i) List Sort Working Memory to assess working memory (ability to hold and manipulate information in mind, a component of executive function), and ii) Picture Sequence Memory to assess episodic memory (ability to learn and recall experiences in daily life). Residual change scores quantified pre- to post-intervention changes in performance. T-tests assessed changes within and between groups; when model assumptions were violated, Mann-Whitney U tests were applied.
Results: Thirty-nine LHBCS were included in the analysis ($\bar{x}_{age}$=55.39, SD=10.18). The EG (n=21) showed significant improvement on List Sort Working Memory (p=0.05, d=0.40) and Picture Sequence Memory (p=0.01, d=0.50) tasks from pre- to post-intervention, while the CG (n=18) showed no significant changes (p>0.05). No significant differences were detected between groups (p>0.05).
Discussion: The findings suggest culturally sensitive, virtually supervised, home, progressive combined exercise improves components of executive function and episodic memory in LHBCS. Our results align with evidence that exercise enhances these cognitive domains in BCS. Lack of differences between groups may reflect limited power or variability in individual responses. Future analyses will assess additional cognitive domains and effect mediators (e.g., cardiorespiratory and physical fitness).

#7365 Use of wearable technology for physical activity and health monitoring in individuals diagnosed with cancer.

Gillian Gresham[1], Cami N. Christopher[2], Rikuta Hamaya[2], Aditi Hazra[2], JoAnn E. Manson[2], Howard D. Sesso[2]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Brigham and Women's Hospital, Boston, MA

Background: Wearable devices provide an opportunity to remotely collect objective data on a patient's physical activity (PA) and sleep patterns, blood pressure (BP), blood glucose, and other health-related metrics. To date, the prevalence of use and role of wearable devices in older adults diagnosed with cancer remains unclear. We sought to evaluate patterns and characteristics associated with wearable device use.
Methods: A cross-sectional survey on wearable device use was nested within the COSMOS trial, a completed randomized trial of cocoa extract and multivitamin supplementation among U.S. older adults that began in 2015. A 2023 follow-up survey included questions about the usage and frequency of use of any wearable device (activity tracker, BP monitor, or glucose monitor), and willingness to share data for future research. We included participants who completed the 2023 survey and had a self-reported history of cancer diagnosis at baseline, except for non-melanoma skin cancers and compared survey responses to individuals who did not report a history of cancer. Multivariable logistic regression analyses were conducted to assess characteristics associated with wearable device usage adjusted for age, sex, race, income, body mass index (BMI), PA level, and diet quality.
Results: Of the 18,552 COSMOS participants with 2023 survey data, 3,045 reported a cancer history, 62% were female with a median age 73 years (interquartile range=8.3). There were 780 (26%), 1161 (38%), and 60 (2%) participants with a cancer history reporting usage of an activity tracker, BP monitor, or glucose monitor, respectively. Activity tracker usage was lower in those with vs without a cancer history (n=15,507) (26% vs 29%, p=0.0003), while BP monitor usage was higher (38% vs 36%, p=0.023). Among those with a cancer history and reporting any wearable device usage, 78% used activity trackers, 19% used BP monitors, and 66% used glucose monitors most or all of the time. The percentage of individuals willing to share their data was higher for those with a history of cancer compared to those without, for all devices, with statistically significant differences for activity trackers (84% vs. 81%, p=0.02). In multivariable logistic regression, age (Odds ratio (OR): 1.04 per 1-year decrease), female sex (OR: 1.55), higher income (OR: 2.03), BMI (OR: 1.02), and PA level (OR: 1.07) were each statistically significantly ($p<0.05$) associated with increased odds of activity tracker use. BMI also was significantly associated with use of BP and glucose monitors ($p<0.05$).
Conclusions: Older adults with a history of cancer have a high prevalence of wearable device usage, and are willing to share their data for research purposes. This highlights the potential to leverage existing trials to recruit participants in future studies involving wearables and collect valuable insights on their daily activity and biometric data.

#7366 Associations of inflammatory dietary patterns and predicted pro-inflammatory hs-CRP scores with health-related quality of life among breast cancer survivors.

Ji Yeong Kim[1], Sang-Eun Moon[1], Hyun Jeong Cho[1], Zisun Kim[2], Hyun Jo Youn[3], Jihyoung Cho[4], Jun Won Min[5], Yoo Seok Kim[6], So-Youn Jung[7], Eun Sook Lee[7], Young Bum Yoo[8], Se Kyung Lee[9], Seho Park[10], Jung Eun Lee[1]

JYK and S-EM contributed equally to this study.

Backgrounds: Diet may modify chronic inflammation, which has a potential link with health-related quality of life (HRQoL) and cancer prognosis. This study investigated the associations of inflammatory dietary patterns and predicted pro-inflammatory hs-CRP scores with HRQoL levels among breast cancer survivors.

Methods: This cross-sectional study included a total of 717 breast cancer survivors recruited from nine hospitals in Korea. Dietary intake was assessed using 3-day dietary records (DRs) or a validated food frequency questionnaire (FFQ). The HRQoL of the participants was assessed using the Short Form-36 (SF-36) Health Survey, which comprises eight domains. To examine the inflammatory dietary pattern, the reduced rank regression (RRR) was performed with the intake amount of each food group and the plasma levels of five inflammatory biomarkers (high-sensitivity C-reactive protein (hs-CRP), Interleukin (IL)-6, IL-8, adiponectin, and tumor necrosis factor (TNF)-α). The factor loadings were multiplied by the standardized daily intake (g) of each food group to calculate the inflammatory dietary pattern scores. The least square-means (LS-means) and 95% confidence intervals (95% CIs) of the HRQoL scores were estimated according to the quartiles of the inflammatory dietary pattern score using the general linear model (GLM). Additionally, a predicted pro-inflammatory hs-CRP score was derived using a previously developed model and its association with HRQoL was examined by using the GLM.

Results: The inflammatory dietary pattern was characterized by high intakes of refined rice, noodle, seafood (excluding fish), sugar-sweetened coffee, carbonated or sugar-sweetened beverages, along with low intakes of salted vegetables and processed fish. Higher inflammatory dietary score was associated with lower scores on HRQoL mental health domain (p for trend = 0.034), physical functioning domain (p for trend = 0.017) and bodily pain domain (p for trend = 0.057). Higher predicted pro-inflammatory hs-CRP score was associated with lower scores on HRQoL physical component summary domain (p for trend = 0.001), physical functioning domain (p for trend = 0.003) and bodily pain domain (p for trend = 0.018).

Conclusions: The inflammatory dietary pattern score and the predicted pro-inflammatory hs-CRP score may be inversely associated with the HRQoL levels in breast cancer survivors.

#7368 Serum concentrations of per- and polyfluoroalkyl substances and mosaic loss of chromosome Y among men in the Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening Trial.

Jongeun Rhee, Vicky C. Chang, Weiyin Zhou, Mitchell J. Machiela, Jonathan N. Hofmann, Mark P. Purdue, Sonja I. Berndt

Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD

Per- and polyfluoroalkyl substances (PFAS) are persistent organic pollutants detectable in the serum of most U.S. adults. Some PFAS are established or possible human carcinogens. Mechanistic studies in human cells and animals suggest PFAS may have genotoxic effects through indirect DNA damage caused by induction of oxidative stress or other mechanisms; however, evidence from human populations is limited. We investigated the relationship between serum PFAS concentrations and mosaic loss of chromosome Y (mLOY) as a biomarker of genotoxicity and genomic instability among men. We analyzed blood-derived DNA from 2,377 men (aged 55-76 at blood collection) in three nested case-control studies within the PLCO Cancer Screening Trial. mLOY was detected using high-density genotyping array intensity data for chromosome Y. Pre-diagnostic serum concentrations of four PFAS [perfluorooctanoate (PFOA), perfluorooctane sulfonate (PFOS), perfluorohexane sulfonate (PFHxS), perfluorononanoate (PFNA)] were measured. Using study-specific multivariable logistic regression, we estimated odds ratios (ORs) and 95% confidence intervals (CIs) for the associations between serum PFAS and any detectable mLOY (overall mLOY) or mLOY affecting ≥10% of cells (expanded mLOY) among cases and cancer-free controls, separately. Results stratified by study and case-control status were summarized using a random-effects meta-analysis. Overall mLOY was detected in 22% of all men and 8.3% of all men had expanded mLOY. We found a suggestive positive association between serum PFHxS concentrations and mLOY (doubling in serum concentration, summary $OR_{continuous}$=1.14, 95%CI=0.93-1.40; summary OR highest vs. lowest quartile=1.22, 95% CI=0.55, 2.69, P-trend=0.09). The magnitude of the association was stronger for those with a higher proportion of affected cells (expanded mLOY; doubling in serum concentration, $OR_{continuous}$=1.19, 95% CI=0.89-1.59). No associations were observed with other PFAS. In conclusion, in this large population-based study, we observed suggestive evidence of a positive association between elevated serum PFHxS concentrations and mLOY. As the first study to evaluate PFAS in relation to mLOY, our findings, if confirmed, may provide new insight into PFHxS effects affecting genome maintenance, relevant for cancer development.

#7369 Self-reported barriers to healthcare and cancer screening rates: results from the All of Us Research Program.

Kevin H. Kensler[1], Anjile An[1], Aaron Gurayah[2], Faith Morley[1], Meenakshi Davuluri[2], David M. Nanus[3], Bashir Al Hussein Al Awamlh[2], Rulla M. Tamimi[1]

[1]Population Health Sciences, Weill Cornell Medicine, New York, NY,[2]Urology, Weill Cornell Medicine, New York, NY,[3]Medicine, Weill Cornell Medicine, New York, NY

Introduction: Identification of healthcare access-related factors linked to lower use of cancer screening can inform targeted policies and interventions to mitigate these barriers and ameliorate screening disparities. We evaluated how barriers to healthcare influence cancer screening rates for five cancer types in a diverse population.

Methods: We identified cohorts of participants within the *All of Us* Research Program (2017-2022) meeting U.S. Preventive Services Task Force (USPSTF) guideline eligibility criteria for breast, colorectal, cervical, lung, or prostate cancer screening. Participants self-reported whether nine potential barriers had led them to delay seeking medical care in the past year. Using these items, a barrier burden was calculated by summing the number of affirmative responses (range 0-9), and exploratory factor analysis was performed to identify latent classes of barriers. USPSTF guideline-concordant receipt of cancer screening was assessed in the linked participant electronic health record. Multivariable-adjusted odds ratios (OR) were estimated for the association between each barrier, the barrier burden, and factor scores and receipt of cancer screening, accounting for participant sociodemographic characteristics.

Results: Compliance with screening guidelines varied by cancer site: breast (42%, n=31,827 eligible), cervical (28%, n=37,770), colorectal (42%, n=68,895), lung (11%, n=2,737), and prostate (36%, n=8,807). The most cited barriers were concerns about out-of-pocket costs, nervousness about seeing a provider, and inability to get time off work, though barrier frequency varied across cancer sites. Participants who were younger, female, had lower income or educational attainment, or identified as Hispanic or non-Hispanic Black were more likely to report 3+ barriers to care. Participants reporting 3+ barriers to care had lower screening rates relative to those who reported no barriers for breast (OR 0.66, 95% CI 0.60-0.72), cervical (OR 0.77, 95% CI 0.72-0.83), colorectal (OR 0.77, 95% CI 0.72-0.82), lung (OR 0.65, 95% CI 0.37-1.09), and prostate cancer (OR 0.78, 95% CI 0.64-0.95). Three latent factors were consistently identified across cancer sites reflecting cost concerns, logistical barriers (e.g. transportation), and competing obligations (e.g. time off work). In multivariable analyses, cost concerns were associated with lower screening rates for breast, cervical, and colorectal cancer, logistical barriers for breast, cervical, colorectal, and prostate cancer, and competing obligations for breast and prostate cancer.

Conclusions: The cumulative burden of barriers to access and barriers related to cost concerns, logistics, and competing obligations were associated with lower cancer screening rates. Policies and interventions are needed to target multiple dimensions of access simultaneously to increase cancer screening uptake.

#7370 Evaluations of lifestyle factors with biliary tract cancer risk in cohort studies including 742,906 Asian adults.

Valerie Gunchick, Wei Zheng

Department of Medicine, Division of Epidemiology, Vanderbilt University Medical Center, Nashville, TN

Biliary tract cancer (BTC) is a rare, aggressive malignancy and incidence has globally increased 76% from 1990 to 2017. BTC incidence is higher in Asia than Europe and North America, yet studies evaluating BTC risk in Asian populations are limited. Herein we evaluate tobacco smoking, alcohol consumption, BMI, physical activity, and dietary factors with BTC risk. We evaluated 742,906 adults enrolled in 14 cohort studies as part of the Asia Cohort Consortium. Represented countries include China, Japan, Korea, Bangladesh, India, and Iran. Participants completed baseline surveys which collected demographics, lifestyle characteristics, and medical histories, and were followed to identify cancer diagnoses. Participants were removed due to data only on cancer death, a baseline history of cancer or stroke, among other reasons. Cox regression was used to estimate hazard ratios and 95% confidence intervals describing risk of first primary incident BTC in pooled cohort data. Models were adjusted for age, sex, education, cohort study, diabetes, and BMI, where applicable. Some evaluations were stratified by sex due to differing smoking and drinking behaviors. The analyzed cohort includes 451,053 participants with a median age of 54 years, follow-up time of 15.0 years, and 1,300 incident BTC cases. More men than women reported ever smoking or drinking (76.9% vs 7.0%, 63.3% vs 8.0%, respectively). Alcohol consumption was positively associated with BTC risk in men [HR (95% CI) comparing >=60 to 0 grams/day was 1.48 (0.99-2.20), p-trend=0.02]. In both sexes, duration of smoking was positively associated with BTC risk [comparing >40 to 0 years: 1.40 (0.81-2.43), p-trend=0.008] as was high BMI [comparing ≥27.5 to 18.5-22.9: 1.36 (1.11-1.66), p-trend=0.002]. Physical activity was not associated with BTC risk [comparing moderate to minimal activity: 1.00 (0.77-1.28), p-trend=0.76]. Given that our study suggests that obesity, alcohol, and smoking may play an important role in the etiology of BTC, mitigating these conditions could combat the rising incidence of this fatal malignancy. Future plans include dietary evaluations, study-specific estimates combined with meta-analysis, and sensitivity analysis studying BTC death.

POPULATION SCIENCES: Socioeconomic, Lifestyle, and Biological Drivers of Cancer Risk and Survival: Clinical Outcomes and Treatment Guidelines
Poster Session

#7373 The dual influence of treatment and age on survival in patients with glioblastoma.

James Fahey[1], **Manon Penco**[2], Emma Federico[1], Erica Power[1], Michael Egozi[1], Dayna Sloane[1], Isaac Ng[1], Kayeromi Gomez[3], Kristen L. Lauing[4], Ishan Roy[5], Theresa Walunas[6], Kevin P. Barton[7], Douglas E. Anderson[1], Anand V. Germanwala[1], Vikram C. Prabhu[1], Jigisha Thakkar[1], Derek A. Wainwright[1]

[1]Department of Neurological Surgery, Loyola University Medical Center, Maywood, IL,[2]Department of Cancer Biology, Loyola University Medical Center, Maywood, IL,[3]Biostatistics Collaborative Core, Clinical Research Office, Loyola University Medical Center, Maywood, IL,[4]Department of Cancer Biology, Loyola University Chicago Stritch School of Medicine Loyola Medicine, Maywood, IL,[5]Department of Physical Medicine and Rehabilitation, Shirley Ryan Ability Lab, Northwestern University Feinberg School of Medicine, Chicago, IL,[6]Department of Medicine, Division of General Internal Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL,[7]Division of Hematology/Oncology, Loyola University Medical Center, Maywood, IL

Background: Glioblastoma (GBM; IDHwt) is primarily diagnosed at ≥65 years of age with a peak incidence between 70-79 years old. Increased age is a strong detrimental factor. Older patients have significantly poorer treatment outcomes for both immune-based- and standard of care (SOC)-therapies. In addition to treatment response, maladaptive age-dependent effects have been attributed to decreased physical resilience, immune system alterations, and lack of tolerance to therapies. Yet, there is insufficient research investigating age-dependent prognostic factors in electronic health record (EHR) patient data, particularly in the diverse cohort of patients that Loyola University Medical Center (LUMC) serves.
Methods: Patients were identified through ICD-9/10 definitions for brain cancer and 192 IDHwt GBM patients were chart reviewed and confirmed. Demographic, co-morbid, mutational, and treatment data was compiled. Analysis of overall survival (OS) was performed using the survminer package in R 4.0.2. Data were stratified by patient age and used to construct univariate and multivariate Cox proportional-hazard models with statistical significance assessed using log-rank tests.
Results: GBM patients ≥65 years old (n=103, median OS=221 days) experienced worse OS ($p<0.001$) compared to those<65 years of age (n=89, median OS=464 days). Older patients declined treatment more frequently ($p=0.002$) (OR=2.95) and had higher Charlson Comorbidity Index (CCI) scores ($p<0.001$). After removing patients who declined treatment (n=143), this age-influenced outcome disparity persisted ($p=0.019$). After further restricting to only patients who completed a full course of SOC radio-chemotherapy (n=125) (young: n=71, median OS=543 days) (old: n=54, median OS=495 days), OS differences between age groups lost significance ($p=0.061$). Among patients in this cohort, MGMT methylation ($p=0.027$) and initial tumor resection ($p<0.001$) was associated with increased OS. The development of neurocognitive symptoms within 6 months of diagnosis ($p<0.001$), higher initial CCI ($p=0.019$), and initial KPS under 80 ($p=0.002$) were independently associated with poorer OS. When accounting for initial KPS and resection status, OS differences between age groups were significant ($p=0.01$). Unlike the older cohort, younger patients had a significant association between increased body mass index and improved OS ($p=0.017$) while cachexia/significant weight loss was associated with worse OS ($p=0.015$).
Conclusion: Though the statistical significance is missing in the completed treatment cohort, likely due to sample size, clinical trends show younger patients have better survival outcomes. The older cohort's decreased physical resilience, as evidenced by the increased pre-existing comorbidities and higher CCI scores, could be driving their decreased participation and may suggest additional biological etiologies for the discrepancies in OS.

#7374 Body size and composition in relation to PI3K/AKT/mTOR signaling: insights into cancer risk and outcomes - a systematic review.

Rand Lucine Talal Akasheh[1], Cuthbert Mario Mahenge[1], Faiza Kalam[1], Anita Adib[1], Stephanie Schulte[2], Ting-Yuan David Cheng[1]

[1]Department of Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Health Sciences Library, The Ohio State University, Columbus, OH

Objective: To synthesize evidence from studies investigating the relationship between body size and composition with PI3K/AKT/MTOR signaling in the context of cancer risk and outcomes.
Methods: A systematic search of the literature was conducted in Web of Science, Embase, and Pubmed as of January 2019. The inclusion criteria entailed studies that reported any anthropometric measure of body size and/or composition; and any measure of gene, RNA, or protein expression in PI3K/AKT/MTOR signaling, or that directly or indirectly interacts with the pathway in tumors, precancerous lesions, adipose, or muscle tissue; and included people with cancer or precancerous lesions, cancer survivors, high-risk populations, or/and populations with average risk for studying cancer risk.
Results: The search strategy resulted in 6258 studies, of which 1198 studies were excluded by deduplication. Titles and abstracts of the remaining 5087 studies were screened and 4471 studies were found irrelevant and therefore excluded, leaving 316 studies for full-text screening. Of these, 173 studies were excluded leaving 143 studies that met the inclusion criteria and were used in full-text extraction. The included studies focused on gastrointestinal cancers (n = 50: 35 colorectal, 2 upper GI, 3 gastric, 4 esophageal with 1 on Barrett cases, 5 pancreatic, and 1 hepatic); gynecological cancers (n = 34: 32 endometrial with 4 on normal endometrium of at-risk women, 1 cervical, 1 ovarian); breast cancer (n = 31: with 2 on normal breast tissue of at-risk women); male reproductive cancers (n = 7: 6 prostate, 1 Leydig cell); lung cancer (n = 6); thyroid cancer (n = 6); renal cancer (n = 2); skin cancer (n = 1); and cancer cachexia across cancer sites (n = 6). Body size and composition modulate many components of PI3K/AKT/MTOR pathway, in addition to upstream and downstream effectors. Numerous studies indicate that obesity modifies the relationship between molecules in the PI3K/AKT/MTOR pathway and cancer survival, while alterations in this pathway may also affect how body size and composition relate to cancer survival. However, inconsistency in findings was observed due to heterogeneity in study design, exposure variables, reported effect estimates, population characteristics, cancer and tumor features, and methods of outcome measurements. This heterogeneity precluded a meta-analysis. Instead, a qualitative synthesis was conducted to integrate key insights and trends.
Conclusions: The review highlights the broad impact of obesity on cancer biomarkers and outcomes and emphasizes the need for standardized study design and consistent reporting in future research to facilitate meta-analyses and robust conclusions. Most studies relied solely on BMI as a measure of body size, revealing a substantial research gap in examining the relationship between body adiposity and muscularity with PI3K/AKT/mTOR signaling.

#7375 The epidemiology and outcomes of protein-energy malnutrition in lung cancer patients admitted with sepsis: A population-based study.

Adamsegd Isac Gebremedhen[1], **Abdu Osman Mohammed**[2], Mamdouh Souleymane[1], Reesha Bodiwala[1], Awasi Marcel[1], Avantika Thapa[3], Muhammad O. Jamil[1]

[1]Marshall University Joan C. Edwards School of Medicine, Huntington, WV,[2]Trinity Health System, Wintersville, OH,[3]Anwar Khan Modern Medical College, Dhaka, Bangladesh

IntroductionLung cancer patients are at high risk for infection-associated complications. Protein-energy malnutrition (PEM) is common among lung cancer patients. PEM is associated with worse outcomes and longer hospital stays in various cancers, but its impact on lung cancer patients with sepsis is not well studied.This study aims to explore how PEM affects in-hospital outcomes in lung cancer patients admitted with sepsis.MethodWe identified adult patients with lung cancer from the National Inpatient Sample who were admitted with sepsis as the principal diagnosis from 2018 to 2021, using ICD-10 codes. The cohort was categorized based on the presence or absence of protein-energy malnutrition (PEM), and complex sampling weights were applied to ensure national representativeness. Our primary outcome was all-cause mortality, and we analyzed several secondary outcomes. Multivariate regression models evaluated outcome disparitiesbetween the groups, with statistical significance set at $p < 0.05$.ResultsWe identified a total of 186,275 adults with lung cancer who were admitted with the principal diagnosis of sepsis from 2018 to 2021. Among these, 51,065 patients (27.4%) had a concurrent diagnosis of PEM.The PEM group had a higher proportion of male (57.9% vs 53.9%, $p<0.001$) and non-white (28.3% vs 22.1%, $p<0.001$) patients. Patients with PEM had higher odds of all-cause mortality with an aOR (adjusted odds ratio) of 1.11 (95% confidence interval [CI] 1.05-1.18). They also had higher odds of respiratory failure (aOR 1.15, 95% CI 1.10-1.21), mechanical ventilation use (aOR 1.11, 95% CI 1.02- 1.21), septic shock (aOR 1.15, 95% CI 1.09-1.21) and vasopressor use (aOR 1.17, 95% CI 1.04-1.31).Furthermore, they experienced longer hospital stays (8.9 vs 6.5 days) with an adjusted incidence rate ratio (aIRR) of 1.32 (95% CI 1.30-1.35) and higher hospitalization charges ($109,925 vs $81,376) with aIRR of 1.27 (95% CI 1.23-1.31).ConclusionOur study revealed that lung cancer patients with PEM admitted with sepsis had significantly higher odds of all-cause mortality and other adverse outcomes compared to those without PEM. They also experienced longer hospital stays and higher hospitalization charges. These results underscore the critical need to address PEM in lung cancer patients and adjust inpatient care to minimize complications in this high-risk population.

#7377 Intrauterine device use and ovarian cancer risk among 11 case-control studies and 7 prospective cohort studies.

Chan School of Public Health, Boston, MA,[2]Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA,[3]Department of Obstetrics and Gynecology, Brigham and Women's Hospital, Boston, MA,[4]Division of Oncological Sciences and the Knight Cancer Institute, Oregon Health & Science University School of Medicine, Portland, OR,[5]Department of Cancer Epidemiology, Moffitt Cancer Center, Moffitt, FL,[6]Slone Epidemiology Center, Boston University Chobanian and Avedisian School of Medicine, Boston, MA,[7]Program in Epidemiology, Fred Hutchinson Cancer Center, Seattle, WA,[8]Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[9]Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT,[10]Biostatistics and Epidemiology Core, Children's Mercy Kansas City, Kansas City, MO,[11]Epidemiology Branch, National Institute of Environmental Health Sciences, National Institutes of Health, Durham, NC,[12]Department of Oncology, Faculty of Medicine and Health Sciences, McGill University, Montreal, QC, Canada,[13]Department of Research, Cancer Registry of Norway, Norwegian Institute of Public Health, Oslo, Norway,[14]Department of Epidemiology, Emory University, Rollins School of Public Health, Atlana, GA

Introduction: Recently, intrauterine device (IUD) use has increased and oral contraceptive (OC) use has decreased. While OC use is known to reduce epithelial ovarian cancer (EOC) risk, previous studies of IUD use and EOC risk have shown inconsistent associations. Here, we examined the association between primarily non-hormonal IUD use and EOC risk by leveraging harmonized individual-level data from 11 case-control studies, 10 in the Ovarian Cancer Association Consortium and the African American Cancer Epidemiology Study, and 7 prospective cohort studies from the Ovarian Cancer Cohort Consortium.

Methods: Contraception use was self-reported through questionnaires. Study-specific odds ratios (OR) and 95% confidence intervals (CI) were estimated using unconditional logistic regression (case-control studies) or time varying polytomous logistic regression models (cohort studies), adjusted for age, duration of OC use, parity, and family history of breast or ovarian cancer. Heterogeneity between studies was assessed for case-control and cohort studies separately using Cochran *Q*. There was no evidence of heterogeneity between studies, thus, data were pooled within each study design. Case-control and cohort pooled results were combined by random effects meta-analysis. Associations were estimated for overall EOC risk and by histotype (high-grade serous, low-grade serous, endometrioid, clear cell, mucinous). Heterogeneity across histotypes was evaluated using a Wald test for case-control and cohort models separately.

Results: Among case-control studies, data were pooled for 11,033 cases and 13,358 controls. A total of 1,933 (17.5%) cases reported ever IUD use compared to 2,656 (19.9%) controls. Among cohort studies, data were pooled for 629,008 participants with 3,549 incident cases. A total of 72,546 (11.5%) participants reported ever IUD use at enrollment. The associations of ever vs. never IUD use and EOC risk were similar in case-control (pooled OR: 0.92; 95% CI: 0.86-0.98) and cohort studies (pooled OR: 1.00; 95% CI: 0.88-1.13). When meta-analyzed, there was a suggestive 5% lower odds of overall EOC among IUD users (OR: 0.94; 95% CI: 0.88-1.01; p-het = 0.26). We observed heterogeneity by histotype in case-control studies (p=0.0001) but not in cohort studies (p=0.77). After meta-analysis, results suggested that IUD use was associated with a lower risk of mucinous (OR: 0.85; 95% CI: 0.73-0.98), clear cell (OR: 0.69; 95% CI: 0.64-0.86), and low grade serous EOC (OR: 0.75; 95% CI: 0.55-1.01).

Conclusion: IUD use was not associated with an increased risk of EOC in this analysis of over 12,000 ovarian cancer cases. Our findings suggest there may be an inverse association between IUD use and risk of mucinous, clear cell, and low grade serous EOC. Analyses are ongoing and will include assessment of effect modification by parity and birth cohort, as well as consideration of timing of IUD use.

#7378 Trends in head and neck cancer: Incidence, mortality and distant metastasis disparities from SEER data.

L. Mazhar, L. Zhang, J. Ireland, V. Walter, L. Wang, J. M. Yingst, S. I. Allen, J. Foulds, J. Muscat;
Penn State College of Medicine, Hershey, PA

Introduction: Head and neck cancer (HNC) is the seventh most common cancer globally. Approximately 10% of HNCs present with distant metastases (DM) at diagnosis, with a median survival of less than one year. Lower socioeconomic status (SES) has been associated with advanced stage HNCs. Socioeconomic disparities have been reported in HNC incidence and mortality. However, the role of SES among individuals with HNC who develop DM remains less explored. We analyzed trends in the HNC incidence and mortality rates in the U.S. and identified sociodemographic predictors of DM using data from the Surveillance, Epidemiology, and End Results (SEER) database.
Methods: This study used publicly available SEER Data from 2000-2022. Descriptive statistics were calculated for the full incident cohort (N=303,196: human papilloma virus (HPV) related HNC: 85,531; non-HPV: 217,665) and the subset of cases with DM (n=33575). Age-adjusted incidence and mortality rates per 100,000 population and annual percentage changes (APC) were calculated using SEER*Stat version 8.4.4. Poisson regression was used to identify sociodemographic predictors of DM such as age, sex, race/ethnicity, marital status, income, and metropolitan/non-metropolitan status using SAS version 9.4. The 95% confidence intervals (CIs) and p-values for incidence rate ratios (IRR) were reported.
Results: Age-adjusted incidence and mortality rates of HNC were 14.9 and 2.6 per 100,000 population, respectively. Slight decreases in incidence (APC: -0.2; 95% CI: (-0.4, -0.1); p<0.0001) and mortality (APC: -0.6; 95% CI: (-0.8, -0.4); p<0.0001) were observed. Oropharyngeal cancers (HPV-related) exhibited increased incidence (APC: 3.9; 95% CI: (3.1, 4.7); p<0.0001) and mortality (APC: 3.0; 95% CI: (2.5, 3.5); p<0.0001). Laryngeal cancers had decreased incidence (APC: -2.6; 95% CI: (-2.7, -2.4); p<0.0001) and mortality (APC: -2.1; 95% CI: (-2.2, -2.0); p<0.0001). About 11% of HNC cases had DM, with higher rates for individuals aged 50-64 years (IRR: 1.09; 95% CI: (1.06, 1.13) ; ref: 20-49 years), males (IRR: 1.21; 95% CI: (1.18, 1.24)), non-Hispanic (NH) Asian or Pacific Islanders (IRR: 1.50; 95% CI: (1.44, 1.56)); ref: NH White) and those with an income of $40K-$74,999 (IRR: 1.61; 95% CI: (1.48-1.75); ref: $75K or more). Advanced age at diagnosis (80+ years: IRR: 0.89; 95% CI: (0.85, 0.93)), being married or partnered (IRR: 0.84; 95% CI: (0.82, 0.86); ref: others) and living in non-metropolitan areas (IRR: 0.89; 95% CI: (0.86, 0.92); ref: metropolitan areas) were associated with lower rates of DM.
Conclusions: The incidence and mortality rates of HNCs have declined since 2000 whereas the rates have increased for HPV associated HNC. Our study highlights the need for understanding the causes of more advanced disease in subgroups of the population, and to refine the risk categories such as specific Asian or Pacific Islander populations and geographic classification.

#7379 Exploring the epidemiology, clinical outcomes, and healthcare burden of multiple myeloma patients with atrial fibrillation hospitalized for sepsis: a population-based study.

Adamsegd I. Gebremedhen[1], Abdu Mohammed[2], Mamdouh Souleymane[1], Yifang Song[2], Yonas Fetle[1], Mahmoud Abdallah[3], Muhammad O. Jamil[3]

[1]Internal Medicine, Marshall University Joan C. Edwards School of Medicine, Huntington, WV,[2]Internal Medicine, Trinity Health System, Steubenville, OH,[3]Hematology and Oncology, Marshall University Joan C. Edwards School of Medicine, Huntington, WV

Introduction: Multiple myeloma (MM) patients face a high risk of infection-related complications, and many also develop atrial fibrillation (AF), partly due to disease-driven inflammation and treatments like chemotherapy and immunotherapy. While AF is known to worsen outcomes in various cancers, its specific impact on MM patients with sepsis remains unclear. This study investigates how AF influences outcomes in MM patients hospitalized with sepsis, shedding light on an important yet underexplored aspect of their care.
Methods: We identified adult patients with MM from the National Inpatient Sample who were admitted with the principal diagnosis of sepsis from 2018 to 2021, using ICD-10 codes. We divided the cohort based on the presence or absence of AF and applied complex sampling weights to ensure national representativeness. Our primary outcome was all-cause mortality, and we analyzed several secondary outcomes. We used multivariate regression models to evaluate outcome disparities between the groups, with statistical significance set at $p < 0.05$.
Results: We identified 56,970 adults with MM admitted with sepsis between 2018 and 2021, of whom 15,565 (27.3%) had AF. The mortality rates were 14.0% for the entire cohort and 17.9% for the AF group. Patients with AF were older (74.7 vs. 69.0 years, p<0.001), had a higher proportion of male patients (63.2% vs.56.2%, p<0.001), and a higher proportion of white patients (71.5% vs. 59.6%, p<0.001). They also had a higher comorbidity burden (Charlson Comorbidity Index > 3: 89.8% vs. 79.2%, p<0.001). Patients with AF had higher odds of all-cause mortality with an adjusted odds ratio (aOR) of 1.60 (95% confidence interval [CI] 1.41-1.81). They had higher odds of respiratory failure (aOR 1.50, 95% CI 1.36-1.64), mechanical ventilation use (aOR 1.66, 95% CI 1.41-1.96), septic shock (aOR 1.60, 95% CI 1.45-1.78) vasopressor use (aOR 1.64, 95% CI 1.33-2.01), and renal replacement therapy use (aOR 1.69, 95% CI 1.43-2.01). Furthermore, they experienced longer hospital stays (8.6 vs. 7.8 days) with an adjusted incidence rate ratio (aIRR) of 1.14 (95% CI 1.09-1.19) and higher hospitalization charges ($110,329 vs. $99,756) with aIRR of 1.20 (95% CI 1.13-1.28).
Conclusion: This study indicates that MM patients with sepsis and AF have worse outcomes, such as higher mortality, increased need for critical treatments (including mechanical ventilation, vasopressors, and renal replacement therapy), longer hospital stays, and higher medical expenses. These results highlight the necessity for careful and individualized management of MM patients with AF, especially when they develop sepsis.

#7380 Association of weight loss promoting medications with male breast cancer incidence, tumor grade, and stage: a SEER-Medicare nested case-control study.

Aniruddha B. Rathod[1], Biai Dominique Elmir Digbeu[2], Jenil R. Patel[3], David S. Lopez[4]

[1]Department of Epidemiology, Fay W. Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Department of Biostatistics and Data Science, University of Texas Medical Branch, Galveston, TX,[3]Department of Epidemiology, Human Genetics and Environmental Sciences, UTHealth Houston School of Public Health, Dallas, TX,[4]Peter O'Donnell Jr. School of Public Health,, University of Texas Southwestern Medical Center, Dallas, TX

Background: Obesity has been associated with an increased incidence of male breast cancer (MBC), including the high-grade and advance-stage of the disease. With the rising use of weight loss-promoting medications (WLPMs), including the use of metformin, there is a growing interest in their potential to positively influence cancer outcomes. Yet, there is a poor understanding about the impact of WLPMs and metformin on the incidence of MBC, stage and grade, presenting a significant gap in research.
Methods: We conducted a nested case-control study using the Surveillance, Epidemiology, and End Results (SEER)-Medicare database. The cohort included 2,444 MBC cases and 12,068 matched controls (1:5 by birth year and diagnosis date), all of whom had continuous Medicare Part A/B enrollment for at least one year between 2008 and 2019. Pre-diagnostic exposure to WLPMs and metformin was determined through prescription records. Multivariable weighted conditional logistic regression models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for MBC incidence, advanced-stage cancer (stage 4), and high tumor grade (grade 3).
Results: Among MBC cases, 83% were Non-Hispanic White, 34% were >=80 years, 75% had hypertension, 56% had hyperlipidemia, 36% had diabetes and 16% used metformin over 6 months prior to index date. Metformin use was associated with a reduced risk of MBC incidence (OR 0.64, 95% CI 0.54-0.74), and high tumor grade (OR 0.57, 95% CI 0.41-0.78). However, it was linked to an increased likelihood of advanced-stage cancer (OR 1.79, 95% CI 1.26-2.56). WLPMs did not significantly affect the incidence, tumor grade and stage of MBC.
Conclusion: Our findings suggest that metformin may reduce the risk of MBC incidence but could be associated with advanced-stage disease at diagnosis. Further research is needed to explore the effects of WLPMs on MBC outcomes.

#7381 Esophageal carcinoma association with chronic liver disease and cirrhosis mortality risk: A population based retrospective study.

Olanipekun Lanny Ntukidem[1], Oboseh John Ogedegbe[1], Sakshi Bai[2], Asfand Yar Cheema[3], Ayobami Gbenga Olafimihan[4], Nosakhare Paul Ilerhunmwuwa[5], Utkarsh Acharya[6], Kai He[6]

[1]Trinity Health Ann Arbor, Ypsilanti, MI,[2]Henry Ford Jackson Hospital, Jackson, MI,[3]Taussig Cancer Center, Cleveland, Ohio, Cleveland, OH,[4]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL,[5]University of Pittsburgh, Pittsburgh, PA,[6]The Ohio State University Comprehensive Cancer Center, Columbus, Ohio, Columbus, OH

Introduction: The American Cancer Society estimates about 22,370 new esophageal cancer (EC) cases and about 16, 130 deaths in the United States for 2024. While the rates of esophageal cancer have decreased slightly in recent years, the chronic liver disease and cirrhosis (CLD & C) mortality rates are upwardly trending. We holistically analyzed the CLD & C mortality risk in EC patients given the multiple risk factors that are common to these diseases.

Methods: Using the Surveillance, Epidemiology and End-Result (SEER) Research Data, 17 registries and Multiple Primary Standardized Incidence Ratio (MP-SIR) registries, a retrospective study of patients diagnosed with esophageal cancer between 2000 and 2021 was conducted. We estimated the standardized mortality ratios (SMR) by dividing the observed chronic liver disease and cirrhosis death rates in our sample over expected dates of the general population, matched to age, gender and ethnicity.

Results: Analysis of the risk based on race revealed a much higher risk of CLD & C in American Indian/Alaska Natives compared to other races. American Indian/Alaska Natives had SMR 555.37 (CI 114.53-1623.04, $p < 0.05$), Asian/Pacific Islanders SMR 89.56 (CI 32.87-194.94, $p < 0.05$), Black SMR 44.52 (CI 21.35-81.88, $p < 0.05$), Whites SMR 20.49 (CI 17.27-24.14, $p < 0.05$). Females had a higher risk of CLD & C mortality (SMR 36.46, CI 22.84-55.18, $p < 0.05$) compared to males (SMR 20.98, CI 17.65-24.76, $p < 0.05$). We also analyzed mortality risk based on staging of esophageal cancer. Localized EC SMR was 24.12 (CI 17.78-31.98, $p < 0.05$), Regional EC SMR 16.09 (CI 11.98-21.26, $p < 0.05$), Distant EC SMR 47.03 (CI 30.43-69.42, $p < 0.05$). Based on age, patients aged <60 years SMR 31.09 (CI 24.10-39.49, $p < 0.05$), patients aged 60-69 years SMR 24.71 (CI 18.99-31.61, $p < 0.05$) and patients aged 70+ years SMR 12.45 (CI 8.51-17.57, $p < 0.05$).

Conclusion: These data should inform screening and preventive strategies for esophageal cancer patients. It is well known that esophageal cancer and CLD & C share multiple risk factors. American Indian/Alaska Natives was noted to have a much higher SMR compared to other races. Primary and Secondary preventive modalities must be strategized to tackle these disparities.

#7382 Trends in next generation sequencing (NGS) testing by social determinants of health for metastatic cancer patients, 2016-2022.

Clementine Adeyemi[1], Louise B. Murphy[2], Tim Bancroft[3], Kristin Moore[2], Stephanie Gallagher[3], Amy Nguyen[2], **Gieira S. Jones**[1]

[1]351 N Sumneytown Pike P.O. Box 1000, Merck, North Wales, PA,[2]Optum Life Sciences, Eden Prairie, MN,[3]Optum Life Sciences, North Wales, PA

Introduction: Next Generation Sequencing (NGS) testing is a precision medicine tool that uses genomic information from patient tumors to inform treatment decisions and direct patient access to targeted therapies. Social determinants of health (SDOH) *partially explain* barriers to healthcare access, which can impact clinical outcomes. Real-world studies examining impact of SDOH on receipt of genomic testing are limited. Objective: To examine annual incidence rates (IR) of NGS testing overall and by SDOH indices in endometrial, lung, and colorectal cancer patients.
Methods: This retrospective cohort study included patients diagnosed with advanced and recurrent endometrial cancer (aEC), metastatic non-small cell lung cancer (mNSCLC), or metastatic colorectal cancer (mCRC), from July 2016 to September 2022, in the Optum Research Database. Annual incident rates (per 365,000 person-days) were calculated for NGS testing and stratified by 5 SDOH domains: social isolation, financial stress, food insecurity, housing insecurity, and transportation difficulty. SDOH measures were categorized as low, medium, or high unmet needs. Full-year NGS testing IRs are reported for trend analysis.
Results: The study examined 14,624 aEC, 33,608 mNSCLC, and 20,437 mCRC mostly White patients (69%), with median age (years): 69 aEC, 72 mNSCLC, and 70 mCRC. NGS testing rates varied across tumors during the study follow up-period with the highest overall rates observed in mNSCLC (146.9), followed by CRC (73.8) and aEC (19.3). IRs increased over time for all cancer groups (1.5X higher in 2021 than 2017 for mNSCLC, and 2X higher for aEC and mCRC). Annual NGS testing trends were similar for racial/ethnic groups in aEC and mCRC, but, Black and Hispanic mNSCLC patients had the two lowest testing rates (IR: 139.3 and 134.8 respectively) compared to White (IR: 147.3), and Asian patients (IR: 186.3). In mCRC patients, those with the highest level of unmet need had the lowest IRs for all SDOH domains except food insecurity; a similar pattern was seen in mNSCLC. Before 2019, rates were lower in aEC patients with high financial stress and food insecurity vs. with those with low unmet need; this trend reversed from 2019-2021. Changing testing trends in aEC patients may result from the issuance of a Medicare national coverage determination for NGS testing.
Conclusion: NGS testing rates have increased for mCRC, mNCSLC and aEC patients since 2017, however, rates differed by level of SDOH. Targeted interventions focused on increasing NGS testing among patients with more unmet SDOH needs could be impactful. Further investigation into the social factors that influence patient access and treatment decisions may help remove existing barriers to optimal patient care.

#7383 Plant-based diet index and risk of hepatocellular carcinoma: Findings from a prospective cohort study.

Yen Thi-Hai Pham[1], Renwei Wang[1], Jaideep Behari[2], Jian-Min Yuan[1], Hung N. Luu[1]

[1]UPMC HIllman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA,[2]Division of Gastroenterology, Hepatology, and Nutrition, Department of Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Hepatocellular carcinoma (HCC) accounts for ~90% of primary liver cancer cases, one of leading causes for cancer incidence (>900,000 new cases/year) and mortality (>800,000 deaths/year) worldwide. The established risk factors for HCC are chronic infection with hepatitis B virus (HBV), hepatitis C virus (HCV), alcohol abuse and obesity; among which about two-thirds of HCC cases are attributable to viral hepatitis. Recently, plant-based diets, including overall plant-based dietary index (PDI) and healthful plant-based dietary index (hPDI), which were based on overall intake and sub-categories of food items that deem to be “healthfulness” to better account for the quality of plant foods, have received a great attention due to their potential benefits to chronic diseases. Data on the association between PDI and risk of HCC are sparse. We, thus, prospectively evaluated the associations between PDI and hPDI scores and HCC risk.

Methods: We used data from the Singapore Chinese Health Study, a prospective cohort study of 63,275 participants aged 45-74 living in Singapore. Both PDI and hPDI scores were derived from the semi-quantitative food frequency questionnaire at baseline. The HCC incident cases were identified through record linkage analysis with the Singapore Cancer Registry. Cox proportional hazard regression method was used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) for HCC in relation with PDI and hPDI scores. A nested case-control study (197 HCC incident cases and 465 matched controls) was also performed among the cohort participants. Conditional logistic regression model was used for the case-control analysis to examine the association between PDI and hPDI scores with risk of HCC with further adjustment for HBsAg seropositivity status.

Results: After 17.6 years of follow-up with 819,573 person-years, we identified 561 incident HCC cases. We found an inverse association between PDI and HCC risk ($HR_{per\text{-}SD\ increment}$=0.87, 95% CI: 0.79-0.95; P_{trend}=0.009). Compared with the lowest quartile, the HRs (95% CIs) of HCC for quartiles 2, 3, and 4 of PDI score were 0.81 (0.64-1.01), 0.75 (0.59-0.95), and 0.73 (0.56-0.93), respectively. Similar pattern was also found between hPDI and HCC risk ($HR_{per\text{-}SD\ increment}$=0.86, 95% CI: 0.79-0.94; P_{trend}=0.002). Furthermore, this inverse association pattern between PDI and HCC risk was found only in HBsAg-negative individuals in the case-control study ($OR_{per\text{-}SD\ increment}$=0.79, 95% CI: 0.64-0.98; *P*trend =0.04).

Conclusions: Our findings showed that higher plant-based dietary index score was associated with lower risk of HCC. Our findings have public health implications for primary prevention against the development of HCC, particularly relevant in populations such as the United States where HCC incidence rate has been increasing in the past 3 decades dur to high prevalence of obesity, but not due to HBV and/or HCV infection.

#7384 Population attributable fraction of cancer incidence obesity and physical inactivity, in 2020 in the Republic of Korea.

SuJung Byoun

National Cancer Center - Korea, Goyang-si, Korea, Republic of

Abstract Purpose: Cancer is the leading cause of death in Korea. This study aimed to analyze the impact of two major risk factors, obesity and physical inactivity, on cancer incidence and to estimate the population attributable fraction (PAF) for cancers attributable to these factors in Korea as of 2020.
Materials and Methods: For obesity-related cancers, 13 types of cancers (e.g., pharyngeal cancer, gastric cancer, pancreatic cancer, liver cancer) were selected based on the World Cancer Research Fund (WCRF) recommendation. Obesity was categorized using BMI as follows: 16.0 ≤ BMI < 18.5 (underweight), 18.5 ≤ BMI < 23.0 (normal weight; reference), 23.0 ≤ BMI < 25.0 (overweight), 25.0 ≤ BMI < 30.0 (obesity), and BMI ≥ 30.0 (severe obesity). Physical inactivity was defined as having activities less than 600 MET·min/week. Exposure prevalence for obesity and physical inactivity in 2005 was derived from the Korea National Health and Nutrition Examination Survey (KNHANES) assuming 15 years of latency. Relative risks (RR) for cancer types were derived from meta-analyses of relative risks (RR) estimated from the four Korean cohort studies, including the Korean Genome and Epidemiology Study (KoGES), KNHANES, the health examination data from National Health Insurance Service (NHIS), and the Korean Cancer Prevention Study-II (KCPS-II) using Cox proportional hazards models. Confounding variables such as age, smoking status, alcohol consumption, and BMI were adjusted The PAF for each cancer type and overall cancer incidence was calculated using Levin's formula.
Results: For obesity-related cancers, the PAF for overall cancer incidence was 2.35% (5,794 cases attributed to obesity in 2020) for the total population, 2.26% (2,935 cases) for men, and 2.45% (2,859 cases) for women. Among specific cancers, the highest PAFs were observed for kidney cancer (21.09%, men), pharyngeal cancer (27.07%, men), and endometrial cancer (29.38%, women). For physical inactivity, the PAF for overall cancer incidence was 0.39% (464 cases) for the total population, 0.47% (78 cases) for men, and 0.97% (387 cases) for women. Among cancer types, colorectal cancer showed the highest PAF (0.50%, 399 cases) for the total population, while breast cancer in women accounted for 65 cases (PAF 0.26%).
Conclusion: Obesity and physical inactivity significantly contribute to cancer incidence in Korea, particularly for cancers such as kidney, endometrial, colorectal, and breast cancer. These findings underscore the need for targeted public health strategies to manage obesity and promote physical activity as part of comprehensive cancer prevention efforts. Further research should focus on refining risk estimates and exploring additional environmental and genetic factors affecting cancer incidence.
Key Words: Obesity, physical inactivity, population attributable fraction, cancer risk, BMI, physical activity

#7385 Shifting landscapes of cancer-related lifestyle risk factors among U.S. young adults under age 50.

Sina Azadnajafabad, Xiaoyu Zong, Nicholas Jeschke, Yichen Sun, Duo Ren, Yin Cao, on behalf of Cancer Grand Challenges Team PROSPECT

Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO

Introduction: The rising incidence of early-onset cancers among younger adults in the U.S. and globally has been alarming over the past decades. Understanding the evolving patterns of cancer-related lifestyle factors in younger populations is crucial for identifying key risk factors for targeted prevention and emerging exposures for etiological research.
Methods: We utilized the National Health and Nutrition Examination Survey (NHANES) (1999-2023) to characterize age-specific patterns and trends of established risk factors for multiple cancers, including body mass index (BMI), current smoking, alcohol consumption, and physical activity, among adults under age 50. We also examined emerging dimensions of these behaviors, such as weight history, e-cigarette use, binge drinking, and sedentary behaviors.
Results: Across all age groups under 50, mean BMI steadily increased (27.7 to 29.5 kg/m^2), with a sharper increase in later survey cycles for age groups 30-39 and 40-49. The proportion of overweight/obese children and adolescents increased (30.0% to 33.8%). Trends for highest self-reported lifetime weight also followed an upward trajectory (185 to 202 lbs), with 30-39 age group reporting the highest figures in the past decade. Current smoking prevalence decreased across all age groups throughout this period (29.0% to 14.2%), but 30-39 age group exhibited a stabilizing trend recently. While the mean age of smoking initiation among current smokers decreased slightly (17.5 to 17.0 yrs), adolescents reported smoking a full cigarette at a much younger age in the past decade (14.8 to 13.1 yrs). Meanwhile, prevalence of recent e-cigarette use rose sharply (2.8% to 9.0%), with the highest rates in 20-29 age group. While alcohol consumption decreased slightly across all age groups (3.3 to 3.0 drinks/day among drinkers), prevalence of binge drinking more than doubled (11.4% to 27.5%). The 20-29 age group consistently reported highest levels of alcohol intake and binge drinking. Younger adults showed higher prevalence of moderate/vigorous physical activity (58.5% to 61.3%); however, the daily time spent on such activity declined (229 to 206 minutes), particularly among 20-29 and 30-39 age groups. Sedentary behavior time increased for all age groups (342 to 371 minutes), with the highest level observed in adolescents and recent rising trends in 20-29 and 30-39 age groups.
Conclusion: Analyses of nationally representative data in the U.S. revealed substantial shifts in the landscape of cancer-related lifestyle risk factors, underscoring the urgent need to understand the biological impact of age of initiation, cumulative and peak exposures, emerging behaviors, and age-specific exposure patterns on cancer initiation and progression in younger populations. These insights are crucial for informing the development of tailored, life-stage-focused prevention strategies to combat early-onset cancers.

#7386 Economic deprivation and cardiovascular disease risk among long-term breast cancer survivors.

Robina Josiah Willock[1], Daniel Parks[2], Samah Nabi[3], Desiree Rivers[1], Chaohua Li[4]

[1]Community Health and Preventive Medicine; Cancer Health Equity Institute, Morehouse School of Medicine, Atlanta, GA,[2]Community Health and Preventive Medicine, Morehouse School of Medicine, Atlanta, GA,[3]Undergraduate Medical Education, Morehouse School of Medicine, Atlanta, GA,[4]National Center for Primary Care, Morehouse School of Medicine, Atlanta, GA

Background and Purpose: Disparities in cardiovascular disease (CVD) mortality among breast cancer (BC) survivors are well documented. There has been notable progress in identifying and mitigating risk factors for poor health outcomes and improved quality of life for long-term BC survivors. However, the unique impact of structural determinants of health, and the intersections of the community-level and individual-level economic deprivation that perpetuate inequities in BC incidence, screening, treatment options, and risk of comorbidities, are still not cogently described in the literature. Persistent, chronic, or transient poverty exacerbates CVD risk and poor health outcomes among BC survivors. This observational study examined the associations between measures of economic deprivation and CVD outcomes in a national sample of female BC survivors.

Methods: This study used National Health Interview Survey 1999-2022 cohort data to examine the prevalence of CVD, (*angina, stroke, myocardial infarction and coronary artery disease*) among female BC survivors. We evaluated correlational and logistic models of association between socio-demographic characteristics, health behaviors, comorbid conditions, and family poverty-income ratio (PIR) as well as interaction terms between PIR and select predictor variables.

Results: The impact of family PIR varied across different age cohorts and race/ethnicity categories. Race was not independently associated with CVD risk in this population, but significantly moderated the relationship between poverty status and CVD risk among Black breast cancer patients compared to White and Asian breast cancer patients OR=0.08 (95% CI 0.01-0.65) Additionally for middle-aged breast cancer survivors (45-64 yrs), higher socioeconomic status offers substantial protection against CVD (OR=0.0405; 95% CI 0.17-0.96) compared to patients <45yrs and older patients (≥65yrs). While at very advanced ages (>85yrs), the protective effect of higher socioeconomic status becomes less relevant in determining CVD risk. Higher PIR (>5 and 1-4) confers strong protective effects against CVD particularly during the initial seven-year period after BC diagnosis and even among women who seek routine follow-up care (OR=0.52; 95% CI 0.30-0.92).

Conclusions and Implications: Economic deprivation as measured by the poverty income ratio is signaled as an important determinant of cardiovascular disease (CVD) risk among certain subpopulations of breast cancer patients, and its effect is magnified when intertwined with other determinants and sociodemographic characteristics.

#7387 Trends in cancer prevalence among people with type 2 diabetes: an analysis using National Health Interview Survey.

Pranali G. Patel[1], Chaitali S. Dagli[1], Nada Al-Antary[2], Mrudula Nair[2], Abdulghafoor Alani[2], Oluwole A. Babatunde[3], Nosayaba Osazuwa-Peters[4], **Eric Adjei Boakye**[2]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]Henry Ford Health System, Detroit, MI,[3]Prisma Health, Greer, SC,[4]Duke University School of Medicine, Durham, NC

Background: Type 2 diabetes (T2D) is associated with an increased risk of cancers including colorectal (CRC), breast, endometrial, liver, pancreatic, kidney, bladder, lung, and esophageal. Research indicates that individuals with T2D experience a higher incidence of CRC, potentially due to shared risk factors or biological pathway. This study aims to examine and compare trends in the prevalence of CRC to other cancers (in this study includes breast, endometrial, liver, pancreatic, kidney, bladder, lung, and esophageal) among respondents diagnosed with T2D.
Methods: We analyzed data from the 2013-2023 National Health Interview Survey (NHIS), a nationally representative, cross-sectional survey of the U.S. non-institutionalized population that employs a multistage probability sampling design. Adults aged >18 years with a T2D diagnosis, currently on medications, and diagnosed with cancer were included. Joinpoint regression was used to estimate trends in CRC prevalence compared to other cancers among individuals with T2D through annual percent change (APC).
Results: The study included a total weighted sample of 11,766,072 respondents, consisting of 1,893,687 individuals with CRC and 9,872,385 individuals with other cancers. Most respondents were aged 65+ (70%), female (66%), non-Hispanic White (71%) and married (56%). Overall, we observed an increase of 9% per year in the proportion of CRC cases between 2013 and 2015, although not statistically significant, followed by a significant decrease of 4% per year between 2015 and 2023. In contrast, the proportion of other cancer cases remained relatively stable. For females with CRC, the proportion increased by 25% per year from 2013 to 2015, although not statistically significant, but significantly decreased by 8% per year from 2015 to 2023. While among females with other cancers, the proportion decreased by 4% per year between 2013 and 2015, although not statistically significant, but significantly increased 1% per year between 2015 and 2023. The proportion of males with CRC increased 1% per year from 2013 to 2016 and later decreased by 4% per year from 2016 to 2023; neither of which were statistically significant. The proportion of other cancers among males significantly increased by 2% per year from 2013 to 2021 and remained stable between 2021 and 2023.
Conclusion: CRC prevalence has declined overall since 2015 among individuals with T2D. However, sex differences persist, with notable decrease among females in the same time frame. Meanwhile, other cancer trends have remained stable. These findings highlight the complex relationship between T2D and cancer, which may be influenced by various factors such as gender, age, and possible common underlying mechanisms. Further research is needed to explore the underlying causes of these trends and disparities among males and females.

#7388 Trends of diagnosis disclosure among individuals with plasma cell disorders.

Akshay Dalvi[1], Maria Malik[2], Andriy Derkach[3], Ana Sahagun[4], Jorge A. H. Martinez[4], Gia Merlo[5], Jennifer Ahlstrom[4], Jay R. Hydren[4], Saad Z. Usmani[6], Susan Chimonas[7], Robin Ortiz[8], Urvi Shah[6]

[1]Department of Chemistry, University of Illinois Chicago, Chicago, IL,[2]Department of Internal Medicine, New York University Langone Health, New York, NY,[3]Department of Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[4]HealthTree Foundation, Lehi, UT,[5]Departments of Nursing and Psychiatry, New York University Grossman School of Medicine, New York, NY,[6]Multiple Myeloma Division, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Center for Health Policy and Outcomes, Memorial Sloan Kettering Cancer Center, New York, NY,[8]Departments of Pediatrics and Public Health, New York University Grossman School of Medicine, New York, NY

Multiple myeloma, along with precancerous conditions such as monoclonal gammopathy of undetermined significance (MGUS) and smoldering myeloma, represent the most common plasma cell disorders (PCDs) around the world. Coping with such disorders is often a challenging prospect for patients, and the disclosure or withholding of information pertaining to the patient's diagnosis or prognosis may have a significant impact on the patient's perception of their care. We hypothesize that patient perceptions of diagnosis disclosure will be largely positive due to the various psychosocial benefits conferred by the sharing of information with friends and family. In order to investigate these diagnosis disclosure patterns among individuals with PCDs and determine areas for interventions that utilize social support strategies to help patients navigate their diagnosis, we invited participants with PCDs through the HealthTree Cure Hub to complete a 34-question online survey regarding their disclosure trends (n= 510). Participants generally reported sharing their diagnosis with at least one person (98%), with the most common responses being a spouse, domestic partner or significant other (60%) and friend(s) (10%). Most participants that chose to disclose their diagnosis experienced a positive impact in their coping (79%) and became closer with others (55%), whereas patients who chose not to disclose their diagnosis generally reported feeling more isolated in their relationships (56%). Despite some reports of certain negative experiences associated with sharing a PCD diagnosis, the majority of participants expressed no regrets over sharing their diagnosis (87%). Based on these findings, patients generally perceive sharing their diagnosis among their primary social networks to be beneficial to their coping. Oncologists may also be advised to promote the utilization of social support to navigate a PCD diagnosis.

#7389 Examining ovarian cancer disparities: The influence of demographics, insurance coverage, and travel distance on survival outcomes.

Sejong Bae

Medicine, University of Alabama at Birmingham, Birmingham, AL

Background: Ovarian cancer continues to be a devastating disease despite advancements in medicine. Significant disparities in care and outcomes exist, particularly among marginalized populations, due to limited healthcare access and the considerable impact of travel distance. Patients in remote or underserved areas often face delays in diagnosis and treatment, adversely affecting survival rates. This study underscores the critical need for ongoing research into early detection methods and personalized treatment strategies, aiming to enhance survival rates and quality of life for ovarian cancer patients while addressing barriers to equitable healthcare access.
Methods: For the national-level analysis, data from the National Cancer Database (NCDB) was utilized, focusing on ovarian cancer patients in the East South-Central region treated at Academic/Research programs, diagnosed between 2004 and 2017, with a minimum of five years of follow-up. At the local level, data was sourced from the Tumor Registry at the O'Neal Comprehensive Cancer Center. Travel distance in the O'Neal data was determined using zip codes and categorized into tertiles—short, intermediate, and long distances. Multivariable logistic regression models were employed to identify factors associated with five-year mortality, adjusting for distance, demographics, cancer stage, and insurance status at the national level.
Results: Both national and local analyses revealed that being Black, older age, and having a higher cancer stage were associated with poorer odds of survival. Nationally, Medicaid recipients (vs. those with private insurance) had worse survival odds. Travel distance was not significantly associated with five-year mortality in the South at the national level. However, data from O'Neal showed that among ovarian cancer patients diagnosed from 2006-2015, longer travel distance was associated with lower five-year mortality compared to those with shorter travel distances to the treatment center.
Discussion: Ovarian cancer remains a lethal disease with significant disparities, affecting Black patients, older individuals, and Medicaid recipients the most. While travel distance did not impact survival rates nationally, the O'Neal data revealed an unexpected association between longer travel distances and better survival rates, likely due to access to specialized care. These findings highlight the urgent need for equitable healthcare access and continued research to improve early detection and treatment strategies.

#7390 Differences in cancer and all cause mortality among non Hispanic Black American adults by nativity and duration of U.S. residence: Findings from the 1997-2018 NHIS-NDI record linkage study.

A. K. Abubakar[1], P. T. Nguyen[2], M. Rahman[1];

[1]St. Luke's International University, Tokyo, Japan, [2]Hitotsubashi Institute for Advanced Study (HIAS), Hitotsubashi University, Tokyo, Japan

Background: Non-Hispanic Black (NHB) Americans bear a high burden of cancer and all-cause mortality. Previous studies show that foreign-born individuals generally have lower cancer mortality rates, though declines are more pronounced among U.S.-born NHBs. This study examined differences in cancer and all-cause mortality risk between U.S.-born and foreign-born NHB adults as well as by duration of U.S. residence among the foreign-born.

Method: We used pooled data from the 1997-2018 National Health Interview Survey, linked to the National Death Index with follow-up through December 31, 2019, including 90,487 adult NHB participants. Cox regression models were used to estimate hazard ratios by place of birth and duration of residence in the U.S. after adjusting for sociodemographic and health behavior factors.

Result: The intra-racial disparity in cancer mortality has been continuously observed over the past several decades among NHBs by their place of birth (foreign-born versus US-born). Multi-pronged research strategies are needed to understand this disparity as well as to plan appropriate interventions to address this gap among NHB.

#7391 Longitudinal changes in the gut microbiome among newly diagnosed colorectal cancer patients.

Maria F. Gomez[1], Stephanie R. Hogue[1], Jessica R. Burns[1], Seth I. Felder[2], Esther Jean-Baptiste[1], Adetunji T. Toriola[3], Jane C. Figueiredo[4], Christopher I. Li[5], David Shibata[6], Victoria Damerell[7], Christoph Kahlert[7], Erin M. Siegel[1], Rashmi Sinha[8], Emily Vogtmann[8], Sheetal Hardikar[9], Mary Playdon[9], Leigh Greathouse[10], Biljana Gigic[7], Cornelia M. Ulrich[9], Doratha A. Byrd[1]

[1]Cancer Epidemiology, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Department of Gastrointestinal Oncology, H. Lee Moffitt Cancer Center, Tampa, FL,[3]Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine and Siteman Cancer Center, St. Louis, MO,[4]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Public Health Sciences Division, Fred Hutchinson Cancer Research Center, Seattle, WA,[6]Department of Surgery, University of Tennessee Health Science Center, Memphis, TN,[7]Department of General, Visceral and Transplantation Surgery, Heidelberg University Hospital, Heidelberg, Germany,[8]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institute of Health, Rockville, MD,[9]Department of Population Health Sciences, University of Utah, Salt Lake City, UT,[10]Department of Human Sciences and Design, , Robbins College of Health and Human Sciences, Baylor University, Waco, TX

Background: The gut microbiome may be linked to colorectal cancer (CRC) prognosis. Few studies characterized the gut microbiome longitudinally across CRC treatment. Herein, we investigated the gut microbiome dynamics before and up to two years after surgery among newly diagnosed CRC patients.
Methods: We extracted DNA from stool collected longitudinally at baseline (pre-surgery) and at 6, 12, and 24-months after in the ColoCare Study. We characterized fecal bacteria using 16S rRNA gene sequencing (16S; N=133; baseline and 6 months only) and whole-genome shotgun sequencing (WGS; N=41; all timepoints). We estimated rarefied alpha diversity (richness and Shannon index) and beta diversity (Bray Curtis). We calculated centered-log ratio transformed relative abundances of *a priori*-selected taxa and functional genes (WGS only). We used permutational multivariate analysis of variance to estimate the percentage explained in variability of the Bray Curtis distance matrix. We estimated average differences in the microbiome metrics across time using linear mixed effects models adjusted for study center and treatment.
Results: In total, 43% of the cohort received adjuvant therapy and 24% received neoadjuvant therapy. On average, from baseline to 6 months, alpha diversity decreased, with statistically significant declines in the Shannon index for 16S (β = -0.32, 95% CI = -0.47, -0.17; *P* <0.001) and WGS (β = -0.38, 95% CI = -0.56, -0.20; *P* <0.001). WGS alpha diversity tended to somewhat recover at 12 and 24 months. Bray Curtis distance variation was primarily explained by subject (e.g., for 16S: 75%, *P*=0.03); whereas timepoint explained about 3% of variation in 16S and WGS Bray Curtis distance (all *P* < 0.05). Among 16S genera (presented per 1-unit increase in log ratio), there was an average 0.33-unit increase in *Fusobacterium* (95% CI = 0.05, 0.62; *P*= 0.02) and a -0.98-unit decrease in *Prevotella* (95% CI = -1.41, -0.56; *P* <0.001) abundance over 6 months. At the species-level (WGS), there were progressively stronger decreases from baseline up to 24 months in multiple potentially pathogenic *a priori* bacteria. For example, the changes β's (95% CIs) in *Porphyromonas asaccharolytica* were -1.33 (-2.11, -0.57; *P*<0.001) at 6 months, -1.53 (-2.33, -0.74; *P*<0.001) at 12 months, and -1.18 (-2.05, -0.31; *P*=0.01) at 24 months. Acetolactate synthase gene abundance, involved in branch chain amino acid synthesis, increased on average from baseline to 6 and 12 months.
Conclusion: We found that microbial diversity tended to decrease over time, recovering somewhat around a year. We found that the abundance of multiple oral-originating species previously associated with CRC presence and prognosis tended to decrease over time (except *Fusobacterium* in the less detailed 16S data). Overall, our intriguing findings highlight that the microbiome may shift after tumor removal. Next steps will interrogate these shifts as they relate to clinical outcomes.

#7392 The effects of socioeconomic deprivation on the tumor microenvironment of bladder cancer.

Tom Marco[1], Kenneth Barker[1], Jesse Ritter[1], Numaan Mahmood[1], Rishab Srivastava[1], Amith Rao[2], Isaac Zarif[1], Ricardo Estrada Mendizabal[3], Sachin Deshmukh[4], Edgar Tapia[4], Jose Guillen-Rodriguez[1], Juan Chipollini[1], Alejandro Recio-Boiles[1]

[1]University of Arizona, Tucson, AZ,[2]Banner University Medical Center, Tucson, AZ,[3]Mayo Clinic, Phoenix, AZ,[4]CARIS Life Sciences, Phoenix, AZ

Background: Bladder cancer patients with lower socioeconomic status (SES) often present with more aggressive disease and face poor outcomes, likely due to complex interactions with risk factors linked to lower SES. However, little is known about the effect of low SES on bladder tumor biology at the molecular level. This study sought to characterize better the impact of low SES on the bladder tumor microenvironment.

Methods: This is a retrospective analysis of 93 patients (63 male and 30 female) ranging from age 33 to 92 presenting to the University of Arizona Cancer Center with bladder cancer from 2016-2023. Each patient's neighborhood level of SES was scored using the Area Deprivation Index on a scale of 1-100, with 1 representing the highest SES and 100 the least. These patients were then split into tertile 1: 1-33 (T1: N=16), tertile 2: 34-67 (T2: N=43), and tertile 3: 68-100 (T3: N=34), and each patient's tumor microenvironment and mutational landscape was characterized and compared utilizing NGS (592, NextSeq; WES, NovaSeq) and WTS Sequencing (NovaSeq) (Caris Life Sciences, Phoenix, AZ). Statistical significance was determined using chi-square and Mann-Whitney U ($p<0.05$).

Results: Our study had no significant difference between age, sex, and race between the three tertiles. Hispanic ethnicity was significantly higher in T3 (26.5%) when compared to T2 (7%) and T1 (0%), p=0.013. The frequency of TMB-H (≥10 mutations/megabase) was significantly lower in T3 (15.6%) when compared to T2 (51.2%, p=0.02) and T1 (50%, p=0.01). There was significantly less T cell CD8+ infiltration in tertile 3 (0.02%) when compared to T2 (0.43%, p=0.04) and T1 (0.37%, p=0.08), and less dendritic cell infiltration in T3 (0%) when compared to T2 (0.1%, p=0.13) and T1 (0.64%, p=0.008). T regulatory cells were lower in T3 (1.37%) compared to T2 (2.13%, p=0.09) and T3 (2.02%, p=0.24). IHC-PD-L1 and gene expression for immune checkpoint genes, MHC-Class I, and MHC-Class II did not vary significantly between tertiles. KMT2C-mt was highest in T2 (21.1%) compared to T1 (3.12%, p=0.03) and T3 (6.67%). There was no other significant differences in mutation prevalence between the three tertiles.

Discussion: In our study, lower SES bladder cancer patients had a lower amount of CD8+ cells, dendritic cell infiltration, and a low frequency of TMB-H, indicating a lower level of adaptive immune response present in the tumor microenvironment. Lower levels of adaptive immune activity have been associated with more aggressive tumor behavior and worse outcomes in bladder cancer patients. These findings provide a partial explanation of the molecular mechanisms underlying the poor prognosis observed in low SES patients with bladder cancer. Larger-scale studies exploring the impact of SES on tumor biology are essential as they hold significant therapeutic and preventive implications.

#7393 Occupational benzene exposure and solid cancers: A systematic review and meta-analysis.

P. Boffetta[1], M. Seyyedsalehi[2];
[1]Stony Brook University, Stony Brook, NY, [2]University of Bologna, Bologna, Italy

Benzene, an aromatic hydrocarbon, is an established cause of leukemia. The association between benzene exposure and solid cancers is currently being investigated. We conducted a systematic review and meta-analysis to assess the association between occupational benzene exposure and the incidence and mortality of breast, female genital, kidney, bladder, prostate, testis, esophageal, gastric, colorectal, liver, gallbladder, pancreas, lung, head and neck, brain, and skin cancers. We included cohort and case-control studies referenced in the 2018 IARC Monograph on benzene and also reviewed studies published up to April 2024 in PubMed, SCOPUS, and EMBASE. We evaluated the quality of the studies using a modified version of the Newcastle-Ottawa Scale. We used forest plots of relative risk (RR) to present and analyze the data and employed a random-effects model to address heterogeneity between studies. Stratified analyses were performed to explore potential effect modification. Our meta-analysis included 80 independent studies, and the findings are summarized in Table 1. The results of our study indicated an association between overall occupational benzene exposure and breast, kidney, colorectal, head and neck, and brain cancer and a dose-effect association between benzene exposure and lung, hepatobiliary, bladder cancer. In addition, non-significant RR>1.25 were derived for ovarian and gallbladder cancer. Additional well-designed studies, incorporating detailed exposure assessment and control for potential confounders, are required to clarify these relationships. It is essential to implement occupational safety measures, such as proper ventilation, personal protective equipment, and workplace monitoring, to minimize exposure and safeguard workers in industries where benzene is present.

Table 1: The combined relative risk (RR) of occupational benzene exposure and various types of solid cancer.

Cancer type	**RR (95%CI), I2, p value**	**Number of risk estimates**	**Publication bias**
Breast	**1.08 (1.03-1.14), I^2=38.6%, p=0.03**	23	0.03
Cervix	1.24(0.89-1.73), I^2<0.001%, p=0.21	6	0.43
Endometrium	1.21(0.87-1.68), I^2=0.001%, p=0.26	4	0.36
Ovary	1.28(0.77-2.14), I^2=57.7%, p=0.35	6	0.50
Kidney	**1.20(1.03-1.39), I^2=91.6%, p<0.001**	31	0.81
Bladder	1.07(0.97-1.18), I^2=44.4%, p=0.003	35	0.75
Prostate	1.00 (0.93-1.08), I^2=12.6%, p=0.27	29	0.12
Testis	1.09(0.53-2.23), I2=1.09%, P=0.80	5	0.32
Esophagus	1.06(0.87-1.30), I^2=68.7%, p<0.001	27	0.004
Stomach	1.07(0.85-1.33), I^2=89.5%, p<0.001	35	0.60
Colorectal	**1.10 (1.06-1.14), I^2=0.0%, p=0.95**	28	0.90
Liver	0.94 (0.80- 1.11), I^2=13.0%, p=0.31	15	0.23
Gallbladder	1.48 (0.86- 2.53), I^2=71.9%, p<0.001	8	0.37
Pancreas	0.97 (0.87- 1.09), I^2=21.6%, p=0.16	26	0.28
Lung	1.00(0.93-1.07), I^2=84.9%, p<0.001	45	0.16
Head and neck	**1.27(1.00-1.64), I^2= 0%, P =0.05**	29	0.10
Brain	**1.14(1.01-1.29), I2=22.1%, p=0.13**	32	0.05
Skin melanoma	0.98(0.79- 1.22), I^2=21.2%, p=0.22	14	0.70
Skin non-melanoma	1.14(0.90- 1.43), I^2=40%, p=0.01	18	0.08

#7394 Investigating the synergistic carcinogenic effect of tobacco and marijuana smoke: A retrospective chart review study.

Ryan P. Kimball[1], Paul J. Wilkinson[1], Eric C. Lis[1], Jacqueline W. Poole[2], Ryan W. Walters[3]

[1]Creighton University School of Medicine, Omaha, NE,[2]Division of Pulmonology, Critical Care, and Sleep Medicine, Creighton University, Omaha, NE,[3]Department of Clinical Research and Public Health, Creighton University, Omaha, NE

Introduction: Tobacco is the leading preventable cause of lung cancer, and both duration and quantity of tobacco smoking are positively correlated with risk of lung cancer.[1-2] Marijuana has long been speculated to increase the risk of developing lung cancer due to many shared carcinogens with tobacco and its ability to cause cancer cells to grow in vitro.[3] While a potential synergistic carcinogenic effect of marijuana and nicotine has been suggested, no clinical studies have yet confirmed this.[4-5]

Methods: The electronic medical record system was utilized to identify patient age at diagnosis and lung cancer stage at diagnosis in patients with biopsy-confirmed lung cancer in the CHI Health System (Omaha, NE) from January 1, 2017 to December 31, 2022. A total of 156 patients with a history of smoking both tobacco and marijuana concurrently met inclusion criteria. Another 135 patients with a history of smoking tobacco (but not marijuana) were matched as controls according to shared demographic data as well as quantity and duration of tobacco use. One way analysis of variance (ANOVA) and chi-square analysis was used to compare data between groups.

Results: The average age at diagnosis of patients who smoked tobacco and marijuana was 61.3 ± 7.5, compared to 64.0 ± 7.8 for patients who smoked only tobacco (p-value = 0.041). Of patients who smoked tobacco and marijuana, 83 (53%) had stage III or IV lung cancer at time of diagnosis, compared to 75 (56%) patients who smoked only tobacco (p-value > 0.05).

Conclusions: These results suggest that the concurrent use of marijuana and tobacco is associated with a lower age at diagnosis of lung cancer compared to the use of tobacco alone. There was no difference in proportion of patients with advanced stage lung cancer at time of diagnosis between groups. These findings warrant further research into a potential additive carcinogenic effect of smoking tobacco and marijuana concurrently.

PREVENTION / EARLY DETECTION / INTERCEPTION: Genetic and Environmental Determinants of Risk and Screening Methods
Poster Session

#7397 A multi-ancestry polygenic risk score improves lung cancer risk stratification across diverse populations.

Chan School of Public Health, Boston, MA, [3]University of New Mexico, Albuquerque, NM, [4]National Cancer Institute, Bethesda, MD, [5]International Agency for Research on Cancer, World Health Organization, Lyon, France, [6]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [7]University of Hawaii Cancer Center, Honolulu, HI, [8]University of Toronto, Toronto, ON, Canada, [9]Stanford University, Stanford, CA

Background: Currently implemented lung cancer risk prediction models consider a limited set of risk factors and insufficiently stratify patients for screening, leaving a large proportion of lung cancer patients, particularly those from non-European ancestries, ineligible for low-dose CT scans. Polygenic risk scores (PRS) have demonstrated potential for improving lung cancer risk prediction, but are predominantly derived from participants of European-ancestry, limiting their applicability to other populations. This study aims to develop a novel multi-ancestry PRS for lung cancer and evaluate its ability to enhance equitable risk stratification.

Methods: We constructed multi-ancestry PRS using the largest available lung cancer genome-wide associate studies (GWAS), which include 33,023 European cases and 339,471 controls, 11,506 East Asian cases and 179,654 controls, and 2,379 African American cases and 6,908 controls. We trained four genome-wide multi-ancestry PRS models (PRS-CSx, JointPRS, CT-SLEB, and PROSPER) using a reference panel of 1,287,077 SNPs, and compared them to a previously published 128-SNP PRS based on known lung cancer risk loci. PRS models were validated in 1,047 lung cancer cases and 214,403 controls from the All of Us Research Program biobank and their performance was evaluated in a pooled multi-ancestry analysis as well as stratified by genetic ancestry.

Results: PRS-CSx demonstrated the highest performance among all tested methods, with an adjusted-AUC (conditional on sex, age, and the top 16 principal components) of 0.60 (95% CI: 0.58-0.62) and an OR of 1.43 (95% CI: 1.35-1.52) in the pooled analysis. Comparable performance was observed in the European ancestry subgroup (OR: 1.48, 95% CI: 1.37-1.59, 697 cases, 112,145 controls). The PRS-CSx PRS also performed well in the African American population (OR 1.36, 95% CI: 1.17-1.58, 178 cases, 47,701 controls), and in the Admixed American/Latino population (OR: 1.34, 95% CI: 1.03-1.74, 55 cases, 32,936 controls). Individuals in the top decile of the PRS distribution had a 1.96-fold increased risk of lung cancer (95% CI: 1.60-2.40) compared to the average group in the 40-60th percentile. Furthermore, on average, individuals in the top decile reached a 1.5% 5-year absolute risk of lung cancer 8 years earlier than those with average PRS values.

Conclusions: Multi-ancestry PRS outperform a single-ancestry PRS model. Integrating a multi-ancestry PRS into a lung cancer risk prediction model can improve risk stratification, addressing disparities in screening eligibility across diverse populations. This approach has the potential to improve early detection and reduce lung cancer mortality equitably across ancestry groups.

#7398 Defining prostate cancer polygenic risk score categories: Reference populations and methods used impact risk interpretation.

B. Guo[1], A. Sahimi[2], X. Sheng[3], S. Cheng[4], F. Chen[3], C. A. Haiman[3], D. V. Conti[3], B. Darst[1];
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]New York University Grossman School of Medicine, New York City, NY, [3]University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA, [4]University of Washington School of Public Health, Seattle, WA

Background: Polygenic risk scores (PRS) could effectively identify individuals at higher risk of prostate cancer (PCa) and may have notable implications for screening. However, PRS risk classification depends on the comparison population.
Objective: We investigated how different reference populations and methods for defining PRS risk categories affect interpretation.
Methods: We evaluated a multi-ancestry PCa PRS in 6,194 cases and 24,693 controls from self-identified non-Hispanic White (WH), African American (AA), Japanese American (JA), and Latino American (LA) populations in the Multiethnic Cohort (MEC). The PRS was based on 451 variants identified in a prior PCa GWAS across four ancestries. MEC participants were categorized into PRS deciles using 1) PRS distribution of MEC controls within each population or across all populations combined; 2) MEC controls' PRS distribution adjusted for the first 10 principal components (PCs); 3) PRS distribution from external reference populations within each matched continental ancestry or across all ancestries; and 4) individualized PRS deciles calculated as a linear combination of ancestral proportions and external reference populations' decile cutoffs. Reference populations for methods 3 and 4 included 1,890 EUR, AFR, EAS, and AMR individuals from 1KGP and the PAGE Global Reference Panel, chosen for their close genetic resemblance to respective populations based on PCA. Additionally, 41,825 EUR, 18,636 AFR, 1,263 EAS, and 9,888 AMR individuals from All of Us (AoU), defined by genetic ancestry, were also used as reference population for methods 3. Logistic regression models adjusted for age and the first 10 PCs were used to evaluate the association between PRS deciles and PCa risk.Results: Non-population-specific reference group cutoffs approaches consistently had higher PRS predictive ability than population-specific cutoffs for the top 90%-100% PRS decile across all methods and populations. For instance, the OR for AA men in the top 90%-100% PRS decile was 4.37 [3.49-5.48] and 5.29 [3.85-7.27] when using the PRS distribution of MEC controls within each population and across all populations combined, respectively. Similarly, the OR was 4.60 [3.35-6.30] and 5.32 [4.18-6.79] when using 1KGP/PAGE, and 4.73 [3.74-6.00] and 5.41 [4.14-7.07] when using AoU as reference population. There was high variability in cases and controls selected in the top 90%-100% PRS decile across methods. For instance, the top decile included 9,447/1,264, 485/440, and 750/872 cases/controls when using MEC controls, 1KGP/PAGE, and AoU, respectively, to define non-population-specific PRS decile cutoffs for AA men.
Conclusion: PRS interpretation and individual risk categorization are highly dependent on reference populations and methods used to define risk categories, which have critical clinical implications when implementing PRS.

#7399 Polygenic risk score-based smoking and drinking behaviors and head and neck squamous cell cancer risk by HPV status.

T. Hou[1], A. Thakral[2], K. Hueniken[1], T. Dudding[3], M. Gormley[3], S. Virani[4], A. Olshan[5], B. Diergaarde[6], T. Waterboer[7], K. Smith-Byrne[8], P. Brennan[8], D. Neil Hayes[9], E. Objective: HPV-positive and HPV-negative head and neck squamous cell carcinoma (HNSCC) are distinct entities from an epidemiological and biological standpoint. We aimed to evaluate the predictive performance of polygenic risk scores (PRS), which could be a surrogate when behavioral data are missing or deemed unreliable, for tobacco smoking (Smoking Initiation [SI], Age of Smoking Initiation, Cigarettes Per Day [CPD], Smoking Cessation) and alcohol consumption (Drinks Per Week [DPW]) and their impact on HNSCC risk stratified by HPV status.
Methods: We analyzed data from 8013 participants in the VOYAGER consortium, including 4716 HNSCC cases and 3297 controls. PRS for the 5 phenotypes were generated based on the genome-wide significant variants ($P < 5\times10^{-8}$, $r^2 < 0.001$) from the GSCAN consortium. Logistic regression models were used to evaluate the association between PRS and HNSCC risk, separately in HPV-positive and negative patients. A corresponding phenotype analysis based on actual smoking and alcohol behaviors is included for comparison.
Results: All 5 PRS significantly predicted corresponding behaviors in the expected direction. For HPV-positive patients, higher PRS for SI and DPW were associated with a higher HNSCC risk. For HPV-negative patients, higher PRS for SI, CPD, and DPW had a higher risk of HNSCC. Phenotype analyses confirmed the predictive value of PRS and showed strong correlations between all 5 behaviors and HNSCC risk in both HPV-positive and negative patients.
Conclusion: PRS-based models of smoking and drinking behaviors and are associated with HNSCC risk in both HPV-positive and negative patients. These findings highlight the role of a genetic predisposition to these behaviors as a surrogate marker influencing the risk of HNSCC.

Table. PRS Analyses for Smoking and Drinking Behaviors in Predicting HNSCC Risk by HPV Status.

PRS of smoking and drinking behaviors predicted HNSCC risk				
HPV status	Behaviors	OR	95% CI	*P*
Positive	Smoking Initiation	1.10	1.05-1.16	1.18×10^{-4}
	Age of Smoking Initiation	1.01	0.96-1.06	0.681
	Cigarettes Per Day	0.99	0.94-1.04	0.676
	Smoking Cessation	1.02	0.97-1.07	0.495
	Drinks Per Week	1.24	1.18-1.30	3.50×10^{-16}
Negative	Smoking Initiation	1.07	1.01-1.13	0.041
	Age of Smoking Initiation	0.98	0.93-1.05	0.595
	Cigarettes Per Day	1.06	1.01-1.13	0.047
	Smoking Cessation	1.05	0.99-1.12	0.090
	Drinks Per Week	1.24	1.16-1.32	1.82×10^{-11}

#7400 Prevention outpatient clinic: evidence-based, risk-stratified counseling and prevention research.

Ursula M. C. Will

Prevention Outpatient Clinic, German Cancer Research Center, Heidelberg, Germany

The Prevention Outpatient Clinic (POC), the centerpiece of the National Cancer Prevention Center (NCPC), is being established in Heidelberg through a long-term partnership between the German Cancer Research Center and the German Cancer Aid. This initiative aims to systematically expand evidence-based, personalized cancer prevention across Germany, integrating all essential elements of prevention, from basic research and clinical trials to public counseling and the training of prevention specialists, under one roof. Inspired by the Comprehensive Cancer Centers model, the NCPC seeks to create a comprehensive and sustainable framework for cancer prevention. At the POC, visitors complete a digital questionnaire before engaging in a personalized consultation with medical experts. A specialized prevention counseling guide is used to develop tailored, evidence-based recommendations aimed at improving overall health and addressing specific cancer risk factors. This guidance encourages positive lifestyle changes, such as smoking cessation, healthier dietary choices, weight management, and increased physical activity. To further support these changes, the POC provides programs that focus on behavioral therapy, motivational techniques, psychoeducation, group nutritional counseling, and physical activity initiatives. The clinic collaborates with external partners to offer additional services, such as specialized smoking cessation programs, dietary advice, targeted exercise opportunities, age-appropriate cancer screenings, and genetic counseling, ensuring a comprehensive approach to prevention. In addition to its counseling services, the POC is deeply integrated into cancer prevention research. Participants are invited to contribute biosamples (e.g. blood, urine, stool, saliva) for a long-term registry study, forming a valuable resource for future research. Collaborative studies with DKFZ and partner institutions explore areas such as genetic risk profiling, biomarker discovery, innovative early detection methods, and digital prevention tools. Dedicated research studios enable in-depth exploration of the roles of nutrition and physical activity in cancer prevention. Data collected from these activities feed into a comprehensive database, driving the ongoing refinement of prevention strategies and the development of innovative interventions. Regular follow-up appointments ensure sustained support and allow the POC to monitor the effectiveness of its services, adapting them based on emerging scientific evidence. Once piloted and refined, the POC model will be scaled to other locations across Germany. This expansion will make personalized prevention counseling and participation in cutting-edge research accessible to all, empowering citizens nationwide to actively engage in reducing cancer risks and improving long-term health outcomes.

#7401 Ancestral impact on family history of breast cancer and high-risk mutations among women from Lima, Peru.

Amanda F. Corpuz[1], Xiaosong Huang[1], Elad Ziv[2], Susan L. Neuhausen[3], Laura Fejerman[1], Tatiana Vidaurre[4]

[1]University of California, Davis, Davis, CA,[2]University of California San Francisco, San Francisco, CA,[3]City of Hope Comprehensive Cancer Center, Duarte, CA,[4]Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru

Family history of breast cancer (FHBC) and carrying a high penetrance mutation are strong predictors of breast cancer risk. Breast cancer associated genes have been characterized and pathogenic/likely pathogenic variants (P/LP) identified in different populations. However, characterization of family history and high-risk mutations within the Indigenous American genomic background is still understudied. The Peruvian Genetics and Genomics of Breast Cancer Study (PEGEN-BC) is a case cohort of ~2,000 breast cancer patients from Lima, Peru. Demographic, and clinical information was collected from all participants. Targeted sequencing of 40 susceptibility genes was performed in 1,364 women from the PEGEN-BC study. Variants were called by GATK HaplotypeCaller and annotated by ANNOVAR with the ClinVar database (v20240611). Global ancestry proportions (Indigenous American, European, African, and East Asian) were estimated for another project using the program Admixture (v1.3.0, k = 4). Mean differences of proportions between groups based on FHBC (1st to 3rd degree relatives) were tested using t-test and chi-squared test respectively. The association between FHBC and P/LP mutation status was tested using a logistic regression model stratified by ancestry (dichotomized: above and below the median European genetic ancestry), including age at diagnosis as a covariate. The average age of the study participants was similar between those with FHBC (49.6 years, standard deviation (sd)=11.1) and those without FHBC (49.9 years, sd=11.1). Average Indigenous American ancestry was 77% (sd=16) among participants with FHBC and 70% (sd=19) among those without ($p<0.0001$) and European ancestry was 21% (14) and 17% (11) respectively ($p<0.0001$). There were 62 (4%) carriers of P/LP variants among individuals without FHBC and 44 (10%) among those with FHBC ($p<0.0001$). Among participants with European ancestry below the median (<18%), the association between FHBC and P/LP status was not significant. However, among women with European ancestry above the median, the odds of carrying a P/LP variant if they had FHBC were 4.1 times (95%CI 2.16-7.77) higher than if they did not have FHBC ($p<0.0001$). These results may reflect disparities in patients knowledge of family history by ancestry, which correlates with factors such as socioeconomic status and level of education, as well as difference in the proportion of genetic variants contributing to familial aggregation of risk in different genetic ancestry backgrounds.

#7402 High frequency of germline mutations among breast cancer patients in Jamaica.

Patrick Roberts[1], Rory Thompson[2], Richard Shaw[1], Alison Ayoub[3], Imani Hewitt[3], Derria Cornwall[1], Natalie Guthrie-Dixon[4], Camille Ragin[5], Simone Ann Marie Badal[3]

[1]Department of Surgery, Radiology, Anesthesia & Intensive Care, Univ. of the West Indies - Mona Campus, Kingston, Jamaica,[2]Department of Pathology, Univ. of the West Indies - Mona Campus, Kingston, Jamaica,[3]Basic Medical Sciences, Univ. of the West Indies - Mona Campus, Kingston, Jamaica,[4]Caribbean Institute for Health Research, Univ. of the West Indies - Mona Campus, Kingston, Jamaica,[5]Fox Chase Cancer Center, Philadelphia, PA

Breast cancer (BCa) is the most common cancer among Jamaican women, with 60-70% presenting at advanced stages (III or IV). Incidence rates are slightly lower (43.1 per 100,000) than global rates (47.8 per 100,000) and mortality rates are notably higher (18.1 per 100,000 versus 13.6 per 100,000). This study investigated germline testing in Jamaican women with BCa to examine clinicopathologic associations and to compare the utility of two genetic testing panels within this population. A retrospective, cross-sectional study was conducted on 178 Jamaican women with pathologically confirmed BCa at 8 hospital sites during 2018 - 2024. Cancer data extracted from patients' medical records included BCa type, cancer surgeries performed, metastatic sites, tumor stage, molecular markers (ER, PR, HER2, Ki67) and documentation of family history of cancer. Germline genetic testing was performed using comprehensive multigene panel tests from either Invitae (n=126) or Blueprint Genetics (n=52). The Invitae panel assessed 84 genes associated with hereditary cancer syndromes, while the Blueprint panel examined 160 genes. Both panels included core BCa susceptibility genes (BRCA1, BRCA2, PALB2, CHEK2, ATM). Data underwent quality control measures including removal of duplicates, standardization of formats, appropriate handling of missing values, and validation of outliers prior to statistical analysis using STATA 18 Software. The mean age was 44.5±10.5 years with most patients having at least one variant classification (36.5%). Just over 40% and 34% had Luminal A/B and triple negative molecular subtypes respectively, and 36% had advanced stage. Variants classified as pathogenic or likely pathogenic (P/LP) were identified in 15.7% of cases. P/LP status was significantly associated with multiple variant status ($p<0.001$) with 57.1% of cases with P/LP status having two or more gene variants overall when compared to 42.4% with VUS status. Of the 75 genes examined amongst the cases, 10.7% had mutations in *BRCA2*. Thirty-two of the 255 variants classified were unique P/LP variants. Of these variants, *BRCA2* had the most positive (30.6%); c.3109C>T p.(Gln1037*) being the most common P/LP variant overall (8.3%). Other high frequency variants were c.303T>G p.(Tyr101*) in *BRCA1* and c.258+2T>C in *SBDS*. A greater proportion of patients carried P/LP variants when tested by Blueprint Genetics (19%) in contrast to 14% when tested by Invitae. No genetic variants were identified for 32.6% of participants. Our findings reveal a high frequency of germline mutations in Jamaican BCa patients. This supports the need for implementing germline testing as part of treatment planning and to ensure the utilization of targeted therapies. Further investigations of broader gene panels beyond the traditional BCa susceptibility genes may be warranted for better understanding of the germline mutation landscape in this population.

#7403 Colorectal neoplasia rates in Li Fraumeni syndrome.

Sophia R. Spiegel[1], Caitlin Orr[1], Mikia J. Croom[2], Nicolas U. Edgar[3], Sophie R. Cahill[4], Anh N. Le[1], Madeline Good[1], Jo Anson[3], Soren Feola[3], Casey Mehrhoff[5], Anne Naumer[3], Jennie Vagher[3], Luke D. Maese[5], Judy E. Garber[4], Asaf Maoz[4], Bryson W. Katona[6], Suzanne P. MacFarland[2], Kara N. Maxwell[1]

[1]Division of Hematology-Oncology, Department of Medicine, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA,[3]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[4]Division of Cancer Genetics and Prevention, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[5]Department of Pediatrics, University of Utah School of Medicine, Primary Children's Hospital, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[6]Division of Gastroenterology, Department of Medicine, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA

Background and Aims: Li Fraumeni Syndrome (LFS) is an inherited cancer predisposition syndrome with up to 90% lifetime cancer risk and is caused by *TP53* pathogenic germline variants (PGVs). Current NCCN guidelines for LFS recommend colonoscopy for colorectal cancer (CRC) screening every 2-5 years, beginning at age 25 or 5 years before earliest known familial CRC, based on recent literature suggesting ~5-7% of LFS patients develop CRC. However, no data exists on findings of screening colonoscopy in LFS patients to support use of earlier and more frequent screening. In this study, we determined colon neoplasia detection rates of colonoscopy in LFS patients.

Methods: We analyzed CRC diagnoses from our entire LFS cohort (n=220 adults) and fully documented screening colonoscopies (n=123) from January 2019 - August 2024 in a cohort of adult LFS patients (n=90). *TP53* PGVs were classified based on variant type and functional effect into dominant negative (DN) loss of function (LOF) missense, truncating LOF variants, or hypomorphic variants. Analysis is ongoing of validation cohorts at Huntsman Cancer Institute and Dana Farber Cancer Institute and of pediatric data at these institutions.

Results: Of 220 adult LFS patients, 15 (6.8%) had a diagnosis of CRC at a median (IQR) age of 39(32-46). Compared to LFS patients without CRC, patients with CRC were more likely to be male (73% vs 26%, p=0.0004), but not more likely to have a DNLOF/LOF vs hypomorphic PGV (30% vs 39%, p=0.78). Of 90 adult LFS patients with fully documented colonoscopies, the average age at time of data abstraction was 42.6 ± 12.5 y/o, 72% were female, and 73% of patients had a prior malignancy. 31% of PGVs were DNLOF missense, 24% were LOF truncating variants, 38% were hypomorphic, and 7% were unknown. Overall detection rates for any neoplastic finding, adenoma (ADR), serrated lesion (SDR), advanced precancerous polyp, and CRC were 34%, 24%, 9%, 4%, and 0.8% respectively. Detection rates for any neoplastic finding, adenoma, advanced adenoma, serrated lesion, advanced serrated lesion, and CRC were similar between patients aged 25-44 (34%, 32%, 8%, 13%, 0 and 3% respectively) and 45-75 (36%, 28%, 6%, 6%, 0 and 2%), with no significant difference by gender. No significant difference in precancerous polyp (p=0.8438) and colon neoplasia (p=1) detection rates was found in patients with hypomorphic *TP53* PGVs compared to DNLOF/LOF PGVs.

Conclusion: Our data show that LFS patients have a lower ADR (24%) but similar SDR (9%) to the endoscopic benchmarks in standard risk adults (35% and 6%, respectively); however, LFS patients undergo earlier and more frequent screening, suggesting that LFS patients have comparable polyp burdens at an earlier age. These data support the NCCN guidelines for earlier and more frequent colonoscopy in LFS patients.

#7404 Screening patterns among high-risk individuals for pancreatic cancer at a tertiary academic center.

Alice Ahyoung Lee, Naoko Fushimi, Audrey Sutton, Andrea Leung, Sharon Pneh, Walter Park

Stanford University, Palo Alto, CA

Background: Multiple guidelines have developed in the last decade on recommendations for pancreatic cancer screening among high-risk individuals (HRIs). The International Cancer of the Pancreas Screening (CAPS) Consortium, American Gastroenterology Association (AGA), and American Society for Gastrointestinal Endoscopy (ASGE) are three widely known societies that have each published screening guidelines. At our tertiary care hospital, we perform annual pancreatic cancer screening for individuals meeting high-risk screening criteria by any of the 3 above guidelines. We aimed to describe real-world screening patterns within our cohort.

Methods: Patients followed by Stanford's Benign Pancreas Clinic were identified as HRIs if they met screening criteria per the 2019 CAPS, 2020 AGA, and/or 2022 ASGE guidelines and either underwent at least 1 screening modality or were counseled on pancreatic cancer screening. Screening was deemed completed for a calendar year if the HRI underwent either an abdominal MRI with contrast or an EUS of the pancreas. Patterns of annual pancreatic cancer screening were reviewed retrospectively.

Results: A total of 341 HRIs were identified from March 2009 to July 2024. 97 (28.4%) met high-risk criteria due to family history only, while 244 (71.6%) met high-risk criteria due to a high-risk hereditary mutation. The mean follow-up time from first screening encounter was 4.6 years. 51.4% of patients completed at least 50% of their recommended annual screenings. There were no significant differences in gender, race/ethnicity, age at first encounter, or risk factor among those in the lowest quartile of successfully screened patients compared to the entire cohort.

Conclusions: It is difficult to achieve high compliance rates for annual pancreatic cancer screening of high-risk individuals as recommended by the CAPS, AGA, and ASGE. Analysis of our lowest performing quartile suggest no disparity by gender, race/ethnicity, age at first encounter, or risk factor.

	All HRIs (n=341)	Lowest quartile of screened patients (n=86)	P-value
Gender (%)			0.51
Female	268 (78.6)	71 (82.6)	
Male	73 (21.4)	15 (17.4)	
Race/Ethnicity (%)			0.88
Non-Hispanic White	224 (65.7)	60 (69.8)

#7405 Temporal evolution of early signs and symptoms of early-onset colorectal cancer in diverse populations: Insights from the All of US Research Program.

Ruiyi Tian, Chongliang Luo, Xiaoyu Zong, Cassandra D. L. Fritz, Philip R. O. Payne, Yin Cao

Washington University In St. Louis, St. Louis, MO

Introduction: The incidence of early-onset colorectal cancer (EOCRC, diagnosed before age 50) has risen sharply over the past three decades. Current screening guidelines are inadequate for detecting EOCRC in individuals under the recommended screening age, emphasizing the urgent need for identifying pre-diagnostic signs and symptoms and their temporal evolution patterns to inform early detection.
Methods: A total of 347 incident EOCRC cases within the NIH All of Us Research Program (1991-2022) with ≥1 year of pre-diagnostic electronic health record (EHR) were matched with up to four controls. Signs and symptoms were classified as chronic (vs non-chronic) based on whether required ongoing medical care or impacted daily functioning for ≥12 months. Poisson regression models and dynamic network analyses were used to identify signs and symptoms from 1 year to 3 months before diagnosis and characterize their co-occurrence network within 2 years to diagnosis. Longitudinal trajectory analysis was used to examine the evolution of symptom intensity over 3-month sliding windows from 2 years to diagnosis.
Results: From 1 year to 3 months pre-diagnosis, 16 non-chronic signs and symptoms were significantly associated with increased EOCRC risk, with the highest incidence rate ratios (IRRs) for blood in stool (IRR 12.9, 95% CI 4.4-38.1) and hemorrhage of rectum and anus (11.4, 5.0-26.0). Network analysis identified three symptom clusters centered on abdominal pain: (1) hemorrhage of the rectum and anus, which connects to blood in stool, acute pain, and anal/rectal conditions; (2) benign neoplasm of the colon; and (3) nausea and vomiting, back pain, syncope and collapse, and urinary tract infection, which interconnect. Clusters 1 and 2 co-occurred increasingly from 2 years to 3 months pre-diagnosis, with connections between clusters 1 and 3 emerging in the final 3 months. Longitudinal trajectory analysis demonstrated a steady increase in symptom intensity, accelerating 9 months before diagnosis, for abdominal pain, hemorrhage of rectum and anus, blood in stool, benign neoplasm of colon and anal and rectal conditions.
Conclusion: Mapping symptom networks and their temporal evolution offers a promising path to enhance EOCRC detection. Integrating these insights into precision diagnostics can align with advanced prevention frameworks, improving outcomes for younger at-risk populations.

#7406 Noncontrast screening whole body MRI with diffusion-weighted imaging for multi cancer detection: a retrospective case series study.

Candace Westgate[1], Rebecca Nayeri[2], Madhurima Datta[3], Jeffrey Venstrom[3], Rodrigo S. Pompa[3], Pratik Shingru[3], Saqib Basar[3], Sam Hashemi[3], **Yosef Chodakiewitz**[3]

[1]Adventist Health - St. Helena Women's Center, St. Helena, CA,[2]Department of Medicine, Division of Hematology/Oncology, Greater Los Angeles VA Healthcare Center, Los Angeles, CA,[3]Prenuvo, Redwood City, CA

Introduction: Single-cancer screening (SCS) methods improve survival in some cancers but miss ~70% of cancer deaths from unscreened cancers. Multi-Cancer Detection (MCD) strategies aim to broaden early detection. We evaluate the MCD yield of screening WB-MRI (sWB-MRI) in a real-world clinical setting.
Methods: In this retrospective single-center study, we reviewed sWB-MRI cases from 2022 with 12 months follow-up, excluding active cancer patients. The noncontrast, multiparametric sWB-MRI with Diffusion-Weighted-Imaging (1.5T) covered head to ankles. Radiologists provided structured reports for primary care physician (PCP) review. Follow-up data was gathered through direct-to-patient phone calls, focusing on capturing any interval history of biopsy and histopathologic outcomes.
Results: Of 1,011 subjects (52% male, mean age 56 ± 28 years, median follow-up 14 ± 2 months), indications included proactive health (64%), general concerns (18%), and specific symptoms (18%). 9 radiologists reported the scans, with 5 reporting 90% (12%, 15%, 15%, 16%, & 32%). Results were reviewed with PCPs in 92.3% of cases. sWB-MRI led to targeted Tissue Sampling (TS) in 50 cases (4.9%). To isolate simple diagnostic-motivated TS (dTS) for further focused analysis, we excluded TS from clinically-indicated procedures beyond simple diagnostics: dTS = 41 (4.0%).
Histopathology-confirmed Cancer Detection Percentages (CDP) with 95% CI were: Overall sWB-MRI CDP (O-CDP) = 2.2% (1.37-3.28%); dTS CDP = 51% (35-67%).
O-CDP by age (# subjects, CDP %): <35 years (36, 0), 35-49 years (288, 1.4), 50-64 years (393, 2.6), 65-79 years (265, 3.0), >79 years (29, 0). Two false negatives (0.2%) were breast cancers. Of 22 detected cancers, 64% were retrospectively estimated localized, 36% regional/distant. 86% of cancers detected occurred in patients who did *not* indicate specific symptoms for their sWB-MRI reason. Of sWB-MRI detected cancer, 68% lacked SCS methods, while 32% had SCS options.
Non-cancer clinically significant diagnoses (CSDs) included benign masses, aneurysms, liver disease, and pneumonia, prompting clinical action. Study limitations included reliance on patient-reported outcomes and lack of comprehensive medical records, limiting analysis of intermediate diagnostics and follow-up testing.
Conclusions: sWB-MRI prompted pathologically-proven cancer diagnoses across diverse anatomical regions, including those outside standard SCS coverage. Prospective studies involving standardized sWB-MRI reporting frameworks (such as ONCO-RADS), larger cohorts, and designs that capture comprehensive intermediate diagnostic processes and long-term health outcomes, are essential to refine protocols and assess clinical validity (e.g., sensitivity, specificity, predictive values) and utility (e.g., patient outcomes, healthcare system impact).

#7407 Generalizability of an AI-based mammogram risk score (MRS) for breast cancer among racially and ethnically diverse women.

Shu Jiang[1], Debbie L. Bennett[2], Peter Kraft[3], **Graham A. Colditz**[1]

[1]Surgery, Public Health Sciences, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Radiology, Washington University School of Medicine in St. Louis, St. Louis, MO,[3]National Cancer Institute, Bethesda, MD

Breast cancer remains the most common cancer diagnosed among women worldwide. While risk prediction models hold great promise for enhancing preventive breast cancer management, a major challenge lies in accurately identifying women at elevated risk across diverse racial and ethnic groups. Mammogram risk scores (MRS), an AI-driven feature summarizing mammographic texture, have shown potential to accurately classify 5-year breast cancer risk in racially diverse populations.[1] However, similar prediction performance across groups does not necessarily ensure the model's generalizability. To address this, we analyzed data from two large North American cohorts—Emory and British Columbia—encompassing over 226,000 racially diverse women, including Non-Hispanic White (NHW), Non-Hispanic Black (NHB), East Asian, South Asian, and Indigenous women. We assessed the distribution of MRS by race and ethnicity and observed little variation in median MRS between the two cohorts overall, among race and ethnicity groups within each cohort, or between cohorts within race and ethnicity (where such comparisons were feasible). We further examined the association between MRS and breast cancer risk both overall and stratified by race/ethnicity. Statistically significant associations were found, with hazard ratios (HR) per standard deviation increase in MRS ranging from 2.03 (95% CI: 2.00-2.06) to 2.15 (95% CI: 1.93-2.40) after adjusting for age. This significant association was consistent across racial/ethnic groups: NHB (2.12, 95% CI: 1.92-2.51), East Asian (2.10, 95% CI: 2.02-2.18), South Asian (2.09, 95% CI: 1.72-2.49), and Indigenous women (2.19, 95% CI: 1.65-2.79). Prediction accuracy, as assessed using the 5-year AUC, also showed no statistically significant differences by race/ethnicity within each cohort. Our findings indicate no clinically meaningful differences in MRS performance across these groups, suggesting broad applicability. The MRS could be effectively used in clinical practice to estimate age-specific breast cancer incidence, including for individuals with mixed ancestry or self-reported identities commonly encountered in real-world settings. 1. Jiang S, Debbie B, Rosner B, Tamimi R, Colditz G. Development and validation of dynamic 5-year breast cancer risk model using repeated mammograms. JCO Clinical Cancer Informatics, In press. 2024.

#7408 Factors influencing false positive low-dose computed tomography-based lung cancer screening in an urban, safety-net system.

Rutu Rathod[1], Urooj Wahid[2], Asha Kandathil[3], Mary Gwin[4], Sheena Bhalla[4], Song Zhang[2], Andrea Semlow[5], Vijaya Natchimuthu[5], Sarah Malone[2], George Oliver[6], David H. Johnson[4], Megan A. Mullins[2], David Gerber[2], Rasmi Nair[2]

[1]Department of Epidemiology, Fay W Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Peter O'Donnell Jr. School of Public Health, UT Southwestern Medical Center, Dallas, TX,[3]Radiology, UT Southwestern Medical Center, Dallas, TX,[4]Internal Medicine, UT Southwestern Medical Center, Dallas, TX,[5]Parkland Health, Dallas, TX,[6]Parkland Center for Clinical Innovation, Dallas, TX

Background: False-positive results from low-dose computed tomography (LDCT)-based lung cancer screening can result in unnecessary follow-up tests, increased patient anxiety, and higher healthcare costs. We evaluated the prevalence of false-positive LDCT results and assessed factors associated with these LDCT results within an integrated, urban safety-net healthcare system serving a diverse and underserved population. Design: Retrospective cohort study.
Setting: Electronic health records data from Parkland Health, an integrated safety-net provider in Dallas, Texas (January 1, 2017-May 31, 2022), with a 1-year follow-up period through May 31, 2023.
Outcome: False-positive LDCT was defined as positive screen (lung RADS 3, 4A, 4B or 4X) followed by a negative completed work-up or no diagnosis of lung cancer after 12-month follow-up.
Analysis: Univariable and multivariable logistic regression models were used to assess the associations between patient characteristics (patient age, sex, race/ethnicity, preferred language, insurance status, comorbidity score, smoking status and smoking pack-years) and a false-positive LDCT.
Results: A total of 2525 LDCTs were included from 2029 patients. Of these, lung cancer was diagnosed in 12 patients (0.6%), and 394 (19.4%) were classified as false-positive. Median age was 62 years, 59% were men, 49% were non-Hispanic Black, 16% were Hispanic, and the median pack-years were 40. In both univariable and multivariable analyses, age was significantly associated with false positive LDCT results. Patients aged 65-70 years (OR=1.81, 95% CI: 1.06-3.10) and >70 years (OR=2.02, 95% CI: 1.15-3.54) had higher odds of false-positive results compared to those aged 50-54 years.
Conclusion: In our integrated safety-net healthcare system, approximately one in 5 patients had a false-positive LDCT result, and age was a significant contributor. Patients aged 65 years and older were more likely to experience false-positive findings, suggesting that age-related factors may influence the diagnostic accuracy of LDCT. Future studies are needed to replicate these findings and further minimize unnecessary follow-up interventions, particularly in older populations.

#7409 Effectiveness of lung cancer screening by sex and tumor histology: Extended, pooled analysis of the ITALUNG and LUSI trials, with comparison to findings in the NLST.

Rudolf Kaaks[1], Francisco O. Cortes-Ibanez[1], Stefan Delorme[1], Erna Motsch[1], Verena Katzke[1], Claus-Peter Heussel[2], Hans-Ulrich Kauczor[3], Giulia Picozzi[4], Giuseppe Gorini[4], Francesca Maria Carozzi[5], Laura Carrozzi[6], Eugenio Paci[4], Donella Puliti[4], Mario Mascalchi[7]

[1]German Cancer Research Center, Heidelberg, Germany,[2]Thoraxklinik, Heidelberg University Hospital, Heidelberg, Germany,[3]University Hospital Heidelberg, Heidelberg, Germany,[4]Institute for Cancer Research, Prevention and Clinical Network (ISPRO), Florence, Italy,[5]University of Pisa, Pisa, Italy,[6]University Hospital of Pisa, Pisa, Italy,[7]University of Florence, Florence, Italy

Introduction: Low-dose computed tomography (LDCT) screening can reduce lung cancer (LC)-related mortality, but questions remain about the duration of this effect and differences by sex and tumor histology.
Methods: Extended follow-up data from the ITALUNG and LUSI trials were pooled to examine screening-related tumor stage-shifts and to estimate relative hazards for LC-related mortality, by sex and histology. Findings were compared to, and additionally combined with, those from the US National Lung Screening Trial (NLST).
Results: In ITALUNG-LUSI, screening yielded a 30% reduction of overall LC mortality up to 8 years after final screening (dilution-adjusted HR=0.70[0.51-0.96]). This reduction, however, was more pronounced for women (HR=0.49[0.25-0.96]) than men (HR=0.78[0.54-1.11]), which was confirmed in combined data of ITALUNG-LUSI plus NLST (6 years post-screening, women: HR=0.74[0.61-0.90], men: HR=0.93[0.80-1.06]; $p_{heterogeneity}$=0.06). Analyses of stage-shifts and relative mortality hazards suggested that screening reduced mortality by non-small cell and non-squamous tumors in both sexes. In women (18-20%), more than among men (5-9%), screening also resulted in frequent detection of adenocarcinomas with lepidic growth. Finally, in both ITALUNG-LUSI and NLST, LDCT screening reduced the incidence and mortality for small-cell lung cancer (SCLC) among women (HR=0.63[0.43-0.94], all trials combined) but not among men ($p_{heterogeneity}$=0.04).
Conclusion: LC-related mortality reduction by LDCT screening may last until 8 or more years after cessation, and appears to be stronger for women than men, due to reduced incidence and mortality of SCLC in women only. The latter might be caused by removal of (likely EGFR-mutated, and slowly growing) adenomatous precursor lesions that over time would transform into SCLC (lineage plasticity). These findings may have major implications for the optimization of screening programs in terms of eligibility criteria and screening intervals

#7410 Make it better and faster: a retrospective study examining the introduction of an agnostic, reflexive, and expanded pathological protocol for lung cancer patients in Saskatchewan, Canada.

Nicholas Jette[1], John Decoteau[2], Hui Wang[3], Darryl Yu[2], Mary Kinloch[2]

[1]Department of Surgery, University of Saskatchewan, Saskatoon, SK, Canada,[2]Department of Pathology, University of Saskatchewan, Saskatoon, SK, Canada,[3]Department of Chemical and Biological Engineering, University of Saskatchewan, Saskatoon, SK, Canada

Background: Lung cancer evaluation for Saskatchewan patients involves an initial histologic or cytologic diagnosis rendered to the thoracic surgeon, followed by an oncologist consult. The oncologist initiates tissue biomarker testing for advanced stage patients at the first patient visit, and treatment guidance is determined once this is available. This multi-step process ranges 25-39 days from biopsy to treatment-critical information. We sought to reduce this delay and increase actionable mutation rates by implementing stage-agnostic, pathologist-initiated, expanded biomarker reflex testing. We also sought to determine if these changes would lead to improved times to treatment amongst the various populations throughout our unique provincial population considering pathologic testing for lung cancer patients occurs in one of the major population centers, Saskatoon.
Methods: 1064 patients were included in the study and examined 18 months of data pre-and post-algorithm change. The differences between actionable mutation rate were examined using a T-test. Multivariable logistic regression models were used to estimate confidence intervals (CI) for the associations between independent factors and time to treatment from biopsy. The initial algorithm of advanced stage, parallel immunohistochemistry (IHC) for ALK, ROS, 22c3 PDL1 and DNA next-generation sequencing with ThermoFisher Oncomine for KRAS/BRAF/EGFR was updated to stage agnostic DNA triage panel for KRAS/BRAF/EGFR and PDL-1 IHC with all driver-negative patients reflexed to a ThermoFisher Oncomine Fusion panel with 49 actionable mutational targets.
Results: 394 patients (pre algorithmic change) and 670 (post change) were examined. An increased detection rate of actionable mutation of 6.7% was noted with post-algorithmic changes. This included an increase of X ALK and Y ROS patients and X MET14 and NTRK patients. Biopsy to biomarker reporting decreased from 40.4 days to 29.7 days (-26%). Furthermore, prior to the implemented change, biopsy to treatment time was 30 days for patients residing near or in Saskatoon, and 37 days for those residing near or in Regina, and 28 and 30 days post algorithmic change, respectively.
Conclusions: Patient biomarker results at the first oncologist visit are paramount to timely treatment of the patient. Saskatoon was able to maintain the same turnaround time (TAT) despite an increased number of patients being tested. Regina, despite being a major center, still shows an increased TAT due to the time it takes to transfer the patient material across the province. While an updated protocol increases biomarker equity for patients across the province, interventions need to be targeted to ensuring patients do not suffer untimely delay by not being in a biomarker testing center.

#7411 Screening of nasopharyngeal cancer in a multi-ethnic healthy Singaporean cohort.

Ashlynn Chen[1], Arthur Tan[2], Jia Hui Isabelle Jang[2], Song Tar Toh[2], Wei Yee Wan[3], Chwee Ming Lim[4]

[1]Duke-NUS Medical School, Singapore, Singapore,[2]Department of Otolaryngology-Head and Neck Surgery, Singapore General Hospital, Singapore, Singapore,[3]Department of Pathology, Singapore General Hospital, Singapore, Singapore,[4]Singapore General Hospital, Singapore, Singapore

Background: Epstein-Barr Virus (EBV)-positive Nasopharyngeal Cancer (EBV-NPC) is highly prevalent in Asia, with annual incidences of 20-100 per 100,000. In Singapore's multi-ethnic population, EBV IgA serologies targeting viral capsid antigen (VCA) and early antigen (EA) are commonly performed for NPC screening. However, the longitudinal variability of EBV IgA serologies and its relationship with NPC risk remains unclear. This study evaluates the longitudinal patterns of EBV IgA serologies and NPC development in a tertiary medical center.
Methods: Retrospective analysis of asymptomatic individuals referred for NPC screening at Singapore General Hospital between 2008-2021 was performed. Demographics, EBV IgA serologies titers, plasma DNA PCR, nasoendoscopy, biopsy, and MRI post-nasal space (PNS) findings were collected. A positive family history was defined as any first-degree relative with a prior history of NPC. Patients with only one serology test and screening of less than 1 year were excluded.
Results: 4586 patients had EBV IgA serologies performed and 1977 met our inclusion criteria. Patients (45.6% male, 54.4% female; aged 12-90) had a median follow-up of 207.1 months (range: 12-5125 months) and were predominantly Chinese (95%), with 1.16% Indian, 1.66% Malay, and 2.17% from other ethnicities. All were screened using nasal endoscopy examination (n=11,423) and 725 biopsies were performed. Adjunctive tests including MRI PNS (n=876) and EBV DNA-PCR (n=392) were also performed as per physician's discretion. EBV serologies were repeated in 2-5 times (61%), 6-10 (21.3%), or >10 (18.1%) over the screening period. Titre fluctuations showed no clear pattern: 61.96% were positive for only one serology type, 12.13% were persistently positive for both, 23.4% had decreasing titers, and 2.42% had increasing titers. Six patients (0.3%) developed NPC, all ethnic Chinese, asymptomatic, and aged 50 on average. Among these, 3/6, 1/6, and 2/6 had Stage I, III, and IV NPC at diagnosis, respectively. Two had a family history of NPC. The mean detection time was 61 months, and follow-up averaged 12.7 years. Serology titer patterns were persistently positive or increasing. Increased EBV EA-IgA (2/6) or VCA-IgA (2/6) titers were observed 1-2 years before diagnosis. One patient had a normal biopsy but suspicious MRI, leading to repeat biopsy and NPC diagnosis.
Conclusion: In this longitudinal heterogeneous healthy multi-ethnic NPC screening cohort, the NPC detection rate was 0.3%. Fluctuation of EBV IgA serologies was variable, and increasing titers of both Ea and VCA serologies were identified in 33.3% of NPC. Future evaluation of high risk cohorts and cost-effectiveness of NPC screening are warranted.

#7412 The relationship between lifestyle factors and polygenic risk score with prostate cancer risk in the Multiethnic Cohort.

R. W. Hughley IV[1], A. Wang[2], P. Wan[3], X. Xiong[4], W. Xiong[3], D. Bogumil[3], S. Park[5], L. Wilkens[5], L. Le Marchand[5], D. Conti[3], C. Haiman[3], F. Chen[4];
[1]USC - University of Southern California, Waldorf, MD, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]USC - University of Southern California, Los Angles, CA, [4]USC - University of Southern California, Los Angeles, CA, [5]University of Hawaii Cancer Center, Honolulu, HI

Introduction: Behavior modifications for men at high genetic risk of prostate cancer (PCa) have the potential to prevent or delay disease onset. In this study, we evaluated whether the association of a previously developed healthy behavior score with PCa risk varies across levels of genetic susceptibility, as measured by a multi-ancestry polygenic risk score (PRS) in the Multiethnic Cohort (MEC).
Methods: We conducted a nested case-control analysis of 6,096 incident PCa cases and 24,684 controls among African American (13%), Latino (23%), Japanese American (35%), Native Hawaiian (7%), and White (22%) men in the MEC. Among the PCa cases, 2,049 were aggressive cases and 776 were lethal cases. We calculated the 2015 Prostate Cancer Behavior Score from the baseline questionnaire, which comprised six modifiable factors (smoking, BMI, physical activity, intake of tomatoes, processed meat, and fatty fish), with each factor scored as 1 for meeting healthy thresholds and 0 otherwise. This score ranged from 0 to 6 with a higher score indicating a healthier behavior pattern. The PRS of 451 risk variants was constructed with weights from the largest multi-ancestry genome-wide association study for PCa. In the overall study and within each racial/ethnic group, we evaluated the association of the behavior score (categorized as 0-2, 3, 4, 5-6) with risk of overall, aggressive, and lethal PCa in logistic regression analyses and assessed interactions between the behavior score and PRS (categorized as 0-50%, 50-75%, and 75-100%) on PCa risk using the likelihood ratio test (LRT). A $P < 0.05$ was considered statistically significant.
Results: Comparing the highest to the lowest category of the behavior score (5-6 vs. 0-2), there was a suggestive 29% (95% CI: 0.47-1.04, P=0.09) lower risk of lethal PCa in the overall study. Although not statistically significant, a similar inverse association was observed in Whites (OR=0.36), Japanese Americans (OR=0.26), and Latinos (OR=0.26) but not in African Americans (OR=1.62). When stratified by PRS category in the overall study, this inverse association appeared to be stronger for men in the 75-100% PRS category (OR=0.55, 95% CI: 0.27-1.04, P=0.07) than those in the lower PRS categories (ORs 0.72-0.97, P >0.9). These differences in the association of behavior score with risk of lethal PCa across PRS categories were not statistically significant ($P_{LRT} = 0.56$). No interaction was observed between the behavior score and PRS on risk of overall and aggressive PCa.
Conclusion: Findings from this multiethnic study provided further support that the 2015 Prostate Cancer Behavior Score was associated with a reduced risk of lethal PCa. However, there was limited evidence that this association was modified by PCa PRS, which could be due to the relatively small number of lethal PCa cases in our study. Further investigations in larger diverse populations are warranted to confirm our findings.

#7413 Germline susceptibility to single and multiple primary cancers utilizing an ancestry adjusted case-control analyses.

Vignesh Ravichandran, Ying Liu, Irina Ostrovnaya, Kaitlyn Tkachuk, Aliya Khurram, Yelena Kemel, Alicia Latham, Diana Mandelker, Chaitanya Bandlamudi, Michael Conry, Saloni Sinhas, Syed Aijazuddin, Nikolaus Schultz, Michael Berger, Mark Robson, Zsofia Stadler, Kenneth Offit, **Vijai Joseph**

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Germline pathogenic variations (PV) increase heritable risk for cancer and are utilized to target tumor-specific prevention and early detection. However, inherited cancer associations may be pleomorphic, penetrance and expressivity may vary and may be modified by location of the PV, ancestry and polygenic or non-genetic factors. This study aims to determine the magnitude and spectrum of risk for specific tumor types and multiple primary cancer (MPC) for genes commonly tested in patients at familial risk for cancer or undergoing tumor-normal analysis for a cancer diagnosis.

Methods: We conducted a retrospective cohort study of patients consenting to MSK-IMPACT, a matched tumor-normal sequencing assay, over a five-year period. We collected data on cancer onset, race, ethnicity, and, where consent was obtained, clinical information through cBioPortal and the MSKCC clinical databases. MPC were classified using IARC guidelines. Non-cancer control data was sourced from gnomAD. Clinically actionable pathogenic variants in cases and controls were identified using the automated variant curator PathoMAN and manual curation in a subset. Ancestry adjusted weighted generalized linear model was used to estimate risk for single primary (SP), MPC, and MPC-pairs. Biallelic losses were analyzed from paired tumors and normal.

Results: 28,000 individuals across 22 cancer types were tested for 100 cancer predisposition genes (CPG). MPC had a higher rate of carrier frequency for germline PV in known or novel CPG compared to single primary (SP) cases (SP =15%, MPC=21%). In the analysis including MPC cases, we discovered or replicated novel associations including *BRCA2* and biliary cancer (OR=4.5, CI=2.2-8), *ATM* (OR=4.8, CI=2.1-9.2) and *BRCA2* and mesothelioma (OR=8, CI=3.1-16.6); *NBN* (OR=4.2, CI=2.3-6.9) and lung cancer, *PALB2* and germ cell cancer (OR=7.8, CI=1.9-20.8). Novel associations were observed with *RECQL4* and breast, bowel, cervix, lung cancers and uveal melanoma, and *RECQL* with breast, lung and bowel cancers. *SLX4* was associated with prostate, soft tissue and ovarian cancers. PV in *RECQL4, MSH2* and *MLH1* were enriched in patients with two independent compared to single bowel tumors. In the MPC group, as expected, mismatch repair genes *MSH2, MSH3* and *MLH1* were associated with increased risks for stomach, bowel, and uterine cancer, and TP53 with multiple breast cancer primary tumors. The MPC cohort demonstrated pleiotropy of *BRCA1/2*, *NF1, ATM, TP53 and RECQL4* with several tumor types, with biallelic losses in tumors supporting several of these associations. We did not replicate reported associations of *PALB2* and ovarian cancer and *CHEK2* and colon cancer.

Conclusions: Ancestry adjusted risk estimates among a real-world case-cohort of primary and multiple primary cancer cases revealed several novel associations and did not confirm some prior associations with cancer phenotypes.

#7415 Association between sleep traits and risk of non-Hodgkin's lymphoma subtypes: a mendelian randomization study in the International Lymphoma Epidemiology (InterLymph) Consortium.

Introduction: With over 80,000 new cases of non-Hodgkin's lymphoma (NHL) diagnosed annually, modifiable risk factors remain unclear. Circadian disruption, linked to cancers like breast and prostate, affects immune cells (e.g., natural killer cells and T-helper cells) by altering their trafficking and proliferation. Some studies (PMID: 30566672, 27611440) suggest long sleep may increase overall NHL risk, including a Mendelian randomization (MR) study (PMID: 32895918). However, no research has examined the causal relationship between sleep traits, including long sleep, and NHL risk, by subtypes. We hypothesize that sleep traits are causally associated with NHL subtypes in European populations, testing this using MR with data from the International Lymphoma Epidemiology Consortium (InterLymph).

Methods: We conducted two-sample MR using genome-wide association studies (GWAS) summary data for sleep traits and NHL subtypes. Only independent, genome-wide significant ($p < 5\times10\text{-}8$) Single Nucleotide Polymorphisms (SNPs) were selected as valid instruments, sourced from the UK Biobank. Sleep traits included chronotype (153 SNPs), insomnia (48 SNPs), sleep duration (78 SNPs), excessive daytime sleepiness (37 SNPs), short sleep (27 SNPs), and long sleep (8 SNPs). NHL subtype data were from InterLymph: follicular lymphoma (6,508 cases / 64,183 controls), mantle cell lymphoma (1,169 cases / 61,603 controls), Waldenstrom macroglobulinemia/lymphoplasmacytic lymphoma (WM/LPL: 1,697 cases / 59,333 controls), and chronic lymphocytic leukemia (8,522 cases / 67,653 controls). The primary analysis used inverse-variance weighted (IVW) random-effects, with MR-Egger for pleiotropy adjustment.

Results: Using the IVW method, we did not identify any statistically significant causal association between sleep traits and the risk of NHL subtypes, but did yield several intriguing trends. Long sleep (sleep duration >= 9 h per night) showed a marginally increased NHL risk [Odds ratio (OR) range: 1.51 - 247.9] across each subtype. Short sleep (sleep duration < 7 h per night) showed a similar trend [OR range: 1.25 - 1.81], except for WM/LPL, where we noticed a negative trend. The confidence limit for long sleep was imprecise due to the small number of variants. We did not notice any significant directional horizontal pleiotropy or weak instrument bias.

Conclusions: We found no conclusive evidence of a relationship between sleep traits and four NHL subtypes. However, we see suggestive trends of long and short sleep associated with higher risk of some NHL subtypes. These findings align with the previous studies, which showed long sleep was associated with higher risk of NHL overall. Future directions include expanding our analysis to additional NHL subtypes, generating polygenic risk scores, and conducting stratified analyses.

#7416 Prevalence of IL28B single nucleotide polymorphism Rs12979860 and cytomegalovirus (CMV) among allogeneic stem cell transplant in leukemia children.

Mohamed A. Eltokhy[1], Israa Gamal[2], Omar A. Eltoukhy[3], Youssif Madney[4], Mohamed M. Farag[5], Tarek Mansour[6], Sanjay K. Srivastava[1], Sahar Radwan[7]

[1]Department of Immunotherapeutics and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX,[2]Faculty of Pharmacy, Al-Azhar University, Cairo, Egypt,[3]Department of Clinical Pharmacy, Misr International University, Cairo, Egypt,[4]Department of Immunotherapeutics and Biotechnology, National Cancer Institute, Cairo University, Cairo, Egypt,[5]The Regional Center for Mycology & Biotechnology, Al-Azhar University, Cairo, Egypt,[6]Department of Virology and Immunology, National Cancer Institute, Cairo University, Cairo, Egypt,[7]Microbiology and Immunology Dept., Faculty of Pharmacy, Al-Azhar University, Cairo, Egypt

Cytomegalovirus (CMV) remains a significant cause of morbidity and mortality among allogeneic stem cell transplant (allo-SCT) recipients especially in pediatric leukemia patients. IFN-λ family: interleukin (IL)-28A, -28B, and -29 and IFN-λ4. All have antiviral properties similar to IFN-α. In vivo, IFN-λs are mostly secreted by dendritic cells (DC) and macrophages. IL-28B signals through a heterodimeric receptor consisting of IL-28R1 chains and IL-10Rβ, hence inducing an antiviral state. It has been shown that screening allo-SCT recipients for the presence of defined polymorphisms in genes involved in the regulation and activation of innate and adaptive immune responses may help to predict their individual risk of viral infection and disease. Our study aims to investigate the prevalence of single nucleotide polymorphism (SNP) (rs12979860), upstream of the IL28B gene among allo-SCT recipients and to investigate whether that SNP has any effect on the incidence rate and the features of active CMV infection in cancer children receiving stem cell transplantation. Thirty-five patients undergoing allo-SCT in 57357 children's cancer hospital were included in the study (age range,2-20 years). A total of thirty-five whole blood samples were collected. DNA Extraction from Blood Samples was performed by using ThermoScientific GeneJet genomic DNA purification kit, IL28B SNP Analysis L28B (rs12979860) genotyping was performed by RT-qPCR (Applied Biosystems TaqMan SNP genotyping assay) using QuantStudio ViiA7 system, and routine screening of CMV was performed once a week by real-time PCR (ViroGene real-time CMV quantification kit). The prevalence of single nucleotide polymorphism (SNP) (rs12979860), upstream of the IL28B gene among allo-SCT in cancer children was as follows: C/C carriers were 34.3%, C/T carriers were 42.8% and T/T carriers were 22.8%, 37.1% of patients had one or more episodes of active CMV infection during the first 100 days following allo-SCT. Patients carrying the homozygous T allele had a shorter duration of initial active CMV infection than those carrying the homozygous or heterozygous C-allele. Also, Patients carrying the homozygous T allele show a lower magnitude of CMV DNA viral load within their initial episodes of CMV infection compared to the C/C and C/T groups. Data from the current study showed a protective effect of the homozygous T allele of IL28B SNP (rs12979860) against CMV infection in cancer patients undergoing allo-SCT, T/T carriers showed a lower incidence of active CMV infection episodes occurring within 100 days after allo-SCT, those episodes were shorter in duration and lower in magnitude compared to patients carrying C/C and C/T allele. These findings emphasize the potential for personalized risk assessment and management strategies in pediatric allo-SCT recipients based on IL28B SNP profiling.

#7417 Biological, clinical and epidemiological risk factors for oropharyngeal cancers in people with HIV in Puerto Rico.

Juliana M. Serrano-Rodriguez[1], Jurelis Torres-Reyes[1], Yakshi N. Ortiz-Maldonado[1], Carlos A. Sola-Morla[2], Gabriel Borges-Velez[1], Jeannette Salgado-Montilla[1], Maria M. Sanchez-Vazquez[1], Magaly Martinez-Ferrer[1], Ramon F. Gonzalez-Garcia[3], Josue Perez-Santiago[1]

[1]Division of Clinical and Translational Cancer Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]School of Medicine, Universidad Central del Caribe, San Juan, Puerto Rico,[3]School of Dental Medicine, University of Puerto Rico Medical Science Campus, San Juan, Puerto Rico

Background: People with HIV (PWH) are at a higher risk of developing cancers. Periodontal disease (PD), which is highly prevalent in PWH, is a chronic inflammatory disease associated with increased risk factor for oropharyngeal cancers as well as lung, pancreatic and colorectal cancers. Dysbiosis of the oral microbiome and oral human papillomavirus (HPV) infection can increase cancer risk. Puerto Rico (PR) has disparities in HIV infection and HPV-related malignancies, and socio-economic disadvantages that further increase cancer risk, but none of these risk factors have been evaluated altogether in PWH, particularly in PR. In this study, we evaluated the prevalence of PD in Puerto Rican PWH and analyzed other risk factors associated with oropharyngeal cancers in relation to PD.
Methods: We collected saliva and oral rinse samples as well as PD status from 165 sexually active and virally suppressed PWH. We also collected sociodemographic, clinical and lifestyle variables through a questionnaire. In a subset of participants, we evaluated HPV infection and genotype (DNA ELISA kit HPV SPF10 and RHA kit HPV SPF10-LiPA2, n=135), the oral bacteriome (16s sequencing, n=98) and oral mycobiome (ITS sequencing, n=32), in relation to PD as factors for increased oral cancer risk. Diversity, taxonomic assignments, differential abundance analysis and statistical analysis were performed using QIIME2 and R-statistical software.
Results: High prevalence of PD (86%) was observed, with moderate (60%) and severe (27%) being the most abundant. PWH with PD had significantly lower median CD4 count than PWH without PD (753cells/µl vs. 895cells/µl p=0.029). HPV+ PWH had a 95% prevalence of PD, with the prevalence of severe PD increasing to 35%. Furthermore, PD was also significantly associated with higher bacterial and fungal phylogenetic diversity (p=0.048 and p=0.028, respectively) and higher bacterial richness (p=0.063). In addition, significantly higher abundance of fungal pathogenic species was observed in PD, characterized by higher relative abundance of *Candida*.
Conclusion: Overall, high prevalence of PD significantly associated with lower median of CD4 count was observed in Puerto Rican PWH, which may contribute to a higher risk for oropharyngeal cancers, as well as other distal cancers. Moreover, dysbiosis of the oral microbiome and oral HPV infection associated with PD could contribute to subsequent inflammation and oral tissue damage which can further increase cancer risk. Understanding the mechanistic interplay between these cancer risk factors is essential to establish targets for early prognosis and personalized treatment approaches and better preventive public health strategies to reduce oropharyngeal cancers.

#7418 HPV and EBV coinfection in Puerto Rican people with HIV: insights into oropharyngeal cancer risk.

Jurelis Torres-Reyes[1], Oscar A. Loperena-Gonzalez[1], Jeyra L. Perez-Lozada[2], Juliana M. Serrano-Rodriguez[1], Gabriel Borges-Velez[1], Maria M. Sanchez-Vazquez[1], Magaly Martinez-Ferrer[1], Josue Perez-Santiago[1]

[1]UPR - Comprehensive Cancer Center, San Juan, Puerto Rico,[2]San Juan Bautista School of Medicine, Caguas, Puerto Rico

Background: People with HIV (PWH) are disproportionately affected by Human papillomavirus (HPV), a major risk factor for oropharyngeal cancers. Additionally, PWH are more susceptible to acquiring opportunistic infections, such as Epstein-Barr Virus (EBV). EBV may lead to the development and progression of Burkitt's and Hodgkin's lymphoma and other types of cancers. HPV-related malignancies coupled with EBV infection have been associated with an increased risk of cervical cancer, however the relationship between EBV and HPV in in the oral cavity, particularly in PWH has not been investigated. In this study, we evaluated the prevalence of EBV in PWH and assessed their relationship with oral HPV infection due to their potential impact in immune suppression and oropharyngeal cancer development.
Methods: Saliva samples, sociodemographic, and clinical data from 91 sexually active subjects (68 PWH and 23 people without HIV [PWOH]) from a community clinic in San Juan, Puerto Rico. We analyzed for oral HPV infection (34 HPV+ and 57 HPV-) and genotyped HPV using the DNA ELISA kit HPV SPF10 and RHA kit HPV SPF10-LiPA25 that detects 40 HPV subtypes. We quantified EBV levels in saliva using qPCR. Statistical analyses of levels of EBV were assessed in relation to HPV status using R-statistical software.
Results: PWH had a median CD4 count of 791 cells/µL. The prevalences of EBV in PWH was 88% (60/68) vs in PWOH was 74% (17/23). In addition, the prevalence of EBV was higher in males than females (90% vs 63%). PWH with HPV had a 62% (21/34) of high-risk HPV genotypes, with HPV-18 being the most prevalent subtype 38% (8/21). Furthermore, EBV detectability had a trend with HPV status (p=0.07), especially in males with HPV showed higher detectability of EBV (p=0.002). In a multivariate model, EBV detectability was associated with biological sex after adjusting for HIV status and HPV status (p=0.004).
Conclusions: Higher prevalence of EBV were observed in males than females. The trend observed between EBV detectability and HPV status, suggest a potential association between these viral infections, which could have implications for immune regulation in PWH. The high prevalence of HPV in PWH, and the association with EBV, particularly in males may indicated a need to underline the importance of HPV vaccination and regular screening in this population. We aim to increase the sample size to further validate the association of EBV and HPV in Puerto Rican PWH and include sociodemographic and lifestyle variable to investigate how socio-cultural characteristics may influence this association.

#7419 Polygenic risk scores and risk of second cancers among older adult cancer survivors.

Clara Bodelon, Adriana Lori, Christina C. Newton, Ying Wang, Parichoy Pal Choudhury, Hyuna Sung, Ahmedin Jemal, Lauren R. Teras, Alpa V. Patel

American Cancer Society, Atlanta, GA

Background. The etiology of second primary cancers among survivors of older adult-onset cancers is largely known. There is limited data as to whether genetic predisposition increases the risk of second cancers among older adult-onset cancer survivors.
Methods. This analysis was conducted among men and women enrolled in the Cancer Prevention Study II Nutrition cohort who were diagnosed with a first non-metastatic incident cancer between 1992 and 2015. Survivors were followed-up until 2017 for the diagnosis of a second primary cancer at a different organ. Analyses were restricted to participants with genetic data, younger than 85 years at their initial diagnosis, unrelated and of European ancestry. We used externally validated polygenic risk scores (PRSs) for the prediction of overall (overall-PRS; 179 variants), breast (BC-PRS; 313 variants) and prostate (PC-PRS; 451 variants) cancers in the general population. Adjusted Cox proportional regression models were used to compute hazard ratios (HRs) and 95% confidence intervals (CIs) to estimate the risk of second primary cancers associated with the PRSs, modeled as continuous and quartile variables.
Results. This cohort included 16,356 survivors of a first primary cancer (58.1% male). The median age at this diagnosis was 73 years (interquartile range (IQR): 68, 77), with 72.2% of the cancers being localized. The most common first primary cancers were prostate (35.0%), breast (19.1%) and colorectal (9.5%). Cancer survivors were followed-up for a median of 8.6 years (IRQ: 4.1, 13.9) for the incidence of a second primary cancer. We found that the PRSs were associated with significant increased risks of second cancers. Specifically, 1-standard deviation (sd) increased of the overall-PRS increased the risk of any second cancer by 7% (HR=1.07, 95% CI: 1.03, 1.12); 1-sd increased of the BC-PRS increased the risk of breast cancer among female survivors of a non-breast cancer by 59% (HR=1.59, 95% CI: 1.35, 1.86); and 1-sd increased of the PC-PRS also increased the risk of prostate cancer in male cancer survivors of a non-prostate cancer by 59% (HR=1.59, 95% CI: 1.39, 1.82). Compared to the lowest quartiles of each of the PRSs, those in the highest quartile of the overall-PRS had a 16% increased risk of any second cancer (HR=1.16, 95% CI: 1.04, 1.30); those in the highest quartile of the BC-PRS had a 4-fold increased risk of breast cancer (HR=4.07, 95% CI: 2.43, 6.80); and those in the highest quartile of the PC-PRS had a 3-fold increased risk of prostate cancer (HR=3.05, 95% CI: 2.10, 4.43).
Conclusions. In this cohort of older cancer survivors, we found that externally validated PRSs for the prediction of overall and breast and prostate cancers in the general population were associated with higher risks of developing second primary cancers. These PRSs may provide valuable information to improve clinical risk stratification among survivors and opportunities to enhance surveillance for second cancers.

#7423 Modelling COPD to lung cancer progression using machine learning frameworks.

Tej Pandya[1], Marcellus Augustine[1], Kevin Litchfield[1], Nuno Rocha Nene[2], Charles Swanton[1]

[1]The Francis Crick Institute, London, United Kingdom,[2]University College London, London, United Kingdom

Background
Chronic obstructive pulmonary disease (COPD) is a lung condition characterised by chronic respiratory symptoms due to abnormalities of the airways that causes persistent, often progressive airflow obstruction and independent risk factor for lung cancer. However, the mechanisms linking COPD to lung cancer remain poorly understood, particularly the role of mutual risk factors such as air pollution and smoking. Emerging evidence challenges that environmental carcinogens can be purely mutagenic, and suggests that chronic inflammation also facilitates cancer progression and can be compounded in genetically susceptible individuals. This study aimed to investigate any gene-environment interactions contributing to lung cancer development in patients with COPD.
Methods
We used machine learning frameworks to solve this problem given the limitations of conventional methods on this high-dimensional and multi-modal data. Using germline SNPs, measurements of air pollution through PM 2.5, and clinical information from the UK Biobank, a cohort of 488,377 participants, we created models to predict whether patients with COPD would get lung cancer. We tested multiple frameworks optimised for tabular data such as eXtreme Gradient Boosting (XGBoost) and TabNet, in addition to Elastic Net, to be able to independently capture different facets of the data and account for potential non-linear interactions not modelled in linear approaches. As a secondary aim, we focussed on COPD patients with at least a ten-year post-diagnosis survival, minimizing bias from mortality effects on cancer progression.
Results
In (n=24,094) individuals with COPD, 1,312 progressed to develop lung cancer by the date of censorship. Patients progressing to lung cancer were significantly older at enrolment, had greater exposure to air pollution, and smoked more heavily (all $p < 0.001$). Using an 80:20 train-test split, XGBoost and Elastic Net models outperformed TabNet ($p< 0.01$ by DeLong's test) in predicting lung cancer risk, with XGBoost achieving the highest ROC-AUC on the held-out test set (0.73, 95% CI: 0.72-0.75). Restricting the inclusion criteria to ten-year COPD survivors notably improved prediction accuracy (ROC-AUC = 0.87, 95% CI: 0.85-0.90) and identified SNPs related to lung function and inflammation (such as RAGE) as important risk factor of lung cancer in patients in COPD patients.
Conclusions
This study demonstrates that integrating machine learning with epidemiological data enables high-accuracy modelling of lung cancer risk in patents with COPD, emphasizing a potential role of inflammation mediating PM 2.5 gene-environment interactions. These findings underscore the need for research on the biological mechanisms driving inflammation-associated cancer risk in COPD for patient stratification, as well as the potential for applying machine learning frameworks methods to other cancers to explore tumorigenic inflammation.

#7424 Simplifying oncology terminology: Leveraging large language models for patient education.

Yuqing Wang[1], Inae Park[1], Simo Du[2], Zhengrui Xiao[1], Yizhou Chen[3]

[1]Montefiore Medical Center, Albert Einstein College of Medicine, The Bronx, NY,[2]Jacobi Medical Center, Albert Einstein College of Medicine, The Bronx, NY,[3]Neuroscience Institute, Carnegie Mellon University, Pittsburgh, PA

Introduction: Large language models (LLMs), such as OpenAI's ChatGPT-4, are designed to process natural language and generate responses to text-based prompts. While these models have shown promise in addressing clinical and patient-related inquiries, they are not specialized in medicine and lack integration with dedicated medical knowledge databases, leading to potential inaccuracies. On the other hand, healthcare professionals and models explicitly trained in medical texts frequently rely on specialized terminology, which can create significant barriers to clear and patient-friendly communication. This study aims to utilize LLMs to translate complex medical terminology into easy-to-understand explanations, focusing on hematology and oncology fields where communicating medical concepts to the public is particularly challenging. Our objective is to develop a solution that ensures explanations are both accurate and accessible, bridging the gap between technical medical knowledge and patient comprehension.

Methods: We curated a dataset of cancer-related terms and their explanations from two sources: the National Cancer Institute (NCI) Dictionary, which provides detailed medical definitions, and simplified explanations based on National Comprehensive Cancer Network (NCCN) guidelines for patients. Using Meta's LLaMA 7 B-based chat model, we implemented retrieval-augmented generation (RAG) to enable the model to access the NCI Dictionary as needed. To fine-tune the model to generate patient-friendly explanations, we applied LoRA-based supervised fine-tuning (SFT). Readability was measured using the Flesch Reading Ease Score (FRES) and Dale-Chall Readability Formula (DCRF). Improvements in accessibility were quantified through a two-sample t-test, comparing the mean readability scores of the model's outputs against the baseline.

Results: The fine-tuned model demonstrated significant improvements in both accessibility and readability, achieving a 5% and 4% increase in the FRES (baseline: 69.25; output: 72.60, $P < 0.01$) and DCRF (baseline: 9.50; output: 9.15, $P < 0.01$), respectively. Preliminary results also indicate the model's capability to translate entire paragraphs of dense medical text into patient-friendly explanations. Expert validation on a larger scale is currently underway, further solidifying the model's potential to revolutionize patient communication in oncology. This innovative approach sets a new standard for leveraging advanced language models in healthcare education.

Conclusion: We successfully trained a large language model specifically designed to simplify complex oncology medical terms into patient-friendly language. By serving as a reliable tool for delivering precise and accessible medical information, it holds the potential to reduce the workload of healthcare providers and enhance patient understanding in clinical settings.

#7425 AttentionAML: An attention-based deep learning model for accurate identification of childhood acute myeloid leukemia subtypes.

L. Li, J. D. Khoury, J. Wang, S. Wan;
University of Nebraska Medical Center, Omaha, NE

Acute myeloid leukemia (AML) is a rapidly progressing hematopoietic malignancy characterized by aberrant clonal expansion of abnormal myeloid progenitor cells, typically leading to bone marrow failure and compromised hematopoiesis. Pediatric AML encompasses over 20 molecular subtypes defined by genetic alterations, such as chromosomal alteration, gene fusions, mutations, or tandem duplications. Each subtype exhibits a specific response to treatment and prognosis, underscoring the critical need of accurately identifying subtypes for effective clinical management and tailored therapeutic approaches. Traditional wet lab approaches to identify AML subtypes primarily rely on morphological analysis, cytogenetic analysis, immunophenotyping, or molecular profiling, which can be labor-intensive, costly, and technically challenging for clinical practice applications. To address these challenges, we propose AttentionAML (Attention-based Multilayer Perceptron Model for Identifying Acute Myeloid Leukemia Subtypes), a novel deep learning approach that leverages the power of attention mechanisms and multilayer perceptron (MLP) to accurately classify AML subtypes based solely on transcriptomic profiling. Compared with standard MLP models, the attention-based MLP model can capture both global and local information within high-dimensional gene expression data by focusing on the most relevant features, enhancing the performance of the model in AML subtyping. Our model is trained on different cohorts of 1,656 AML patients with known subtypes, utilizing RNA-seq data from publicly available databases such as Therapeutically Applicable Research to Generate Effective Treatments (TARGET) initiative and the St. Jude Cloud Genomics Platform. To evaluate the performance and generalizability of AttentionAML, we conducted rigorous 100 times five-fold cross-validation tests. Our results suggested that AttentionAML consistently outperformed both conventional machine learning models (e.g., ensemble SVM) and standard deep learning models (e.g., MLP model), with remarkable performance across different metrics, including the accuracy of 97.15%, precision of 97.13%, recall of 97.15%, F1 score of 97.02%, and the Matthews correlation coefficient (MCC) of 0.9674. In addition, by leveraging the hidden layer embedding information, AttentionAML gave clearer and more insightful visualization of the global landscape of all AML patients compared to tSNE, providing better separation of AML subtypes and preserving both local and global data structures. We believe that AttentionAML represents a significant progression in characterizing pediatric AML, which can potentially improve downstream risk stratification, optimize treatment strategies, and advance precision medicine for AML as well as other pediatric, adolescent, and young adults (AYA).

#7426 Leveraging deep learning to enable precision medicine via the IMPROVE benchmarking framework.

Natasha Koussa[1], Sara Jones[1], Jeremy Jacoboson[2], Yannick Mahlich[2], M Ryan Weil[1], **Sara J. C. Gosline**[2]

[1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Pacific Northwest National Laboratory, Seattle, WA

The rise of targeted therapies for cancer treatment has fueled the development of algorithms that take the molecular profile (e.g. mutations, transcripts, etc.) of a tumor and predict the effect a drug has on this tumor. Recent advancements in deep learning have enabled the prediction of a cell's response to untested, potentially novel drugs using molecular measurements [1]. To assess the clinical reliability of these algorithms, we first need to measure their performance across a range of data and model systems (e.g. cell lines, organoids, etc.). Toward this end, we introduce a benchmarking framework that enables the comparison of deep learning models for drug response across both cell line and organoid datasets.

We built a fully provenanced, federated data collection pipeline that standardizes gene names, chemical structure information, and recalculates drug response curves for 10 different datasets from 4 different model system types, each accessible via our coderdata Python package (https://pnnl-compbio.github.io/coderdata/) which properly formats and processes the data for machine learning ingest. We integrated this package into the IMPROVE benchmarking framework (https://github.com/JDACS4C-IMPROVE) to evaluate the performance of eight machine learning algorithms that either leverage gene expression data alone [2-5], or with copy number [6,7], mutation[8], and methylation data[9] added. For each algorithm we calculate the performance when using different data splitting methods as well as within-dataset and cross-dataset performance, including multiple model system types.

To date, we have collected over 4,100,000 drug-cell datapoints across ~55,000 drugs and ~1600 samples and 4 types of model system. Using our framework we evaluate (1) the effects of proper data splitting in cross-dataset analysis within a single dataset, (2) cross-dataset predictions within model systems, and (3) the ability to predict across different model systems. We are currently extending the organoid data to better enable the benchmarking of tools across the model systems and add algorithms to our benchmarking framework. We plan to use this framework to perform robust assessment of clinical applicability of AI/ML in precision medicine.

#7427 Use of large language models for clinical data abstraction from oncologic medical records.

Jillian Nelson[1], Monica Agrawal[2], Den E Bloodworth[1], Divya Gopinath[2], James Mullenbach[2], Peter J. Briggs[1], Dominique Connolly[2], David Sontag[2], Alpa V. Patel[1]

[1]American Cancer Society, Atlanta, GA,[2]Layer Health, Boston, MA

Introduction: Abstraction of clinical data from unstructured medical records is a labor-intensive process. Large language model (LLM)-based systems can accelerate the availability of data for research use.

Participants and Methods: The American Cancer Society's Cancer Prevention Study-3 is a large, nationwide prospective cohort study of ~300,000 cancer-free participants enrolled between 2006-2013. Participants who self-reported a diagnosis of breast, colorectal, ovarian, or any blood cancer on the 2021 follow-up survey were consented for the retrieval of medical records (available as a single PDF) from diagnostic and treatment facilities. Guidelines, e.g. ontologies and decision trees, were generated to precisely define abstraction tasks, and relevant research data were annotated via human abstraction. This project then used 300 breast cancer-related medical records to develop (n=200) and test (n=100) the performance of Layer Health's LLM-based platform Distill to abstract seven data elements from the medical record: cancer behavior, laterality, neoadjuvant therapy status, and presence of key biopsy or surgery with associated procedure dates. Both an answer and corresponding evidence from the record were provided by their algorithms; this evidence was used to conduct quality control on a small fraction of data points that were automatically flagged by inter-variable consistency checks. An ACS oncology data specialist adjudicated disagreements between human and LLM-based abstraction to update ground truth labels. Accuracy and F1 statistics were then calculated between ground truth and LLM-derived results.

Results: Results on the test set (n=100) were available on the same day; adjudication of 25 discrepancies between human and LLM-based abstraction found 12 LLM errors and 13 human errors. Cancer behavior and laterality were abstracted with 100% accuracy by the LLM system. Neoadjuvant therapy (yes/no) was abstracted with 99% accuracy (F1=0.99). Surgical and biopsy procedures (yes/no) were abstracted with 98% (F1=0.99) and 96% (F1 = 0.98) accuracy, respectively. 94% of identified key biopsy dates were accurate within 1 day, and 96% were accurate within 30 days. 96% of identified key surgery dates were accurate within 1 day, and 97% were accurate within 30 days.

Conclusion: LLM-based systems offer a time-efficient and accurate solution to accelerate abstraction of key data elements for use in oncologic research, including complex multi-step variables.

#7428 Predicting acute care utilization following cancer treatment using machine learning: A patient-centered approach to precision oncology.

Arman Koul[1], Mohana Roy[2], Behzad Naderalvojoud[1], Tina Hernandez-Boussard[1]

[1]Biomedical Informatics, Stanford University School of Medicine, Stanford, CA,[2]Medical Oncology, Stanford University School of Medicine, Stanford, CA

Introduction: Unplanned acute care utilization (ACU) after receipt of cancer treatment is a significant challenge in oncology, often reflecting care gaps and driving higher costs. To address this, the Centers for Medicare & Medicaid Services (CMS) have designated ACU as a critical quality metric (OP-35). Predicting patients at risk and understanding root causes of ACU can enable interventions that improve outcomes for patients. This work applies advanced machine learning models, integrating structured and unstructured data, to predict ACU in diverse patients across varying malignancy categorizations and treatments.

Methods: This study utilized data on 18,143 patients from a comprehensive, multisite cancer center, to develop machine learning models predicting ACU within 30 days of cancer therapy initiation per OP-35 criteria. Predictions for each therapy line were generated separately. Predictions utilized structured data from medical records and when earlier therapy lines were received outside the center, large language models were applied to clinical notes to encode this unstructured data into the model. Demographic variables, including race, ethnicity, and insurance, were included to identify potential biases. The model, trained on 2010-2019 data and validated on 2020-2024 data, used mean imputation for missing values and employed XgBoost and Random Forest algorithms for supervised learning with hyperparameter tuning to ensure the best trade-off between bias and variance in the model.

Results: The 30-day ACU prediction model showed strong predictive performance, with an XGBoost model achieving an Area Under the Receiver Operating Characteristic Curve (AUROC) of 0.84 (95% CI: .82-.85). Performance was further analyzed across OP-35 categories, with the highest accuracy in predicting ACU due to anemia (AUROC: .87, 95% CI: .86-.88) and infection (AUROC: .86, 95% CI: .85-.87). Incorporating later therapy lines enhanced predictive accuracy by capturing the complexities of advanced disease.

Conclusions: This study highlights the potential of ML to advance precision oncology by predicting ACU following cancer therapy—a critical indicator of patient-centered care quality. By incorporating data from multiple therapy lines and leveraging advanced modeling techniques, it addresses complexities such as disease progression and diverse treatment histories. Decomposing predictions by ACU causes offers actionable insights for timely interventions. These findings highlight the importance of integrating advanced analytics into clinical workflows to improve outcomes, reduce costs, and support data-driven decision-making in oncology.

#7429 Illuminating the dark genome in cancer using artificial intelligence.

M. Alvarez-Torres, X. Fu, R. Rabadan;
Columbia University Irving Medical Center, New York, NY

Understanding the role of noncoding regions of the human genome in cancer requires innovative, high-resolution approaches. Artificial intelligence (AI) is transforming cancer research by providing advanced tools to identify, analyze, and interpret cancer genomes. This study aims to 1) discuss how noncoding mutations in key regulatory elements and other regions can contribute to cancer development, and 2) evaluate the leading AI models used for analyzing noncoding variants, focusing on their evolution and application in cancer research. We present examples of mutations in promoters, e.g. TERT [Huang et al., Science 2013] APC [Snow et al., Clin Gen 2015]), enhancers (a SNP in gliomas [Yanchus et al., Science 2022]), and super-enhancer hypermutation in B-cell lymphomas [Bal et al., Nature 2022; Leeman-Neil et al., Nat Gen 2023]. These cases demonstrate the functional impact of noncoding variants in tumorigenesis. However, for many noncoding regions and mutations, our understanding of the underlying mechanisms, binding motifs, and their roles in gene regulation remains limited. Here, AI can play a crucial role by analyzing large genomic datasets to uncover hidden patterns and interactions. This study compares AI models developed over the past decade, including DeepSEA[Zhou et al., Nat Meth 2015], DeepBind [Alipanahi et al., Com Bio 2015], DeltaSVM [Lee et al., Nat Gen 2015], Basset [Kelley et al., Gen Res 2015], CADD [Rentzsch et al., Nuc Ac Res 2018], Expecto [Zhou et al., Nat Gen 2018], DeepC [Schwessinger et al., Nat Meth 2020], Enformer [Avsec et al., Nat Meth 2021], and GET [Fu et al., Nature 2024 (in press)]. We assess and scored key factors such as model complexity, data integration, cell-type specificity, interpretability, and usability within cancer research. Older models (2015-2018) score lower in complexity than recent ones (2018-2024), reflecting simpler architectures due to earlier computational limitations. In contrast, newer models leverage advanced computational power and deep learning, enhancing their ability to capture complex biological patterns and improve data integration and cell-type specificity. However, usability in practical research does not correlate with publication year, as user-friendly interfaces and comprehensive documentation play crucial roles in application, regardless of model complexity. In conclusion, AI has proven instrumental in elucidating the role of noncoding mutations in cancer, revealing intricate regulatory patterns and previously unknown mechanisms. Over 11,000 publications cite the models discussed, underscoring their scientific impact. Such efforts will support predictive models that can generalize across diverse contexts, advancing genomic research and its implications for cancer biology. Our work highlights the potential of these AI models to assist researchers, particularly those less familiar with computational techniques, in advancing cancer genomics.

#7430 Multicenter study on an artificial intelligence model for predicting NSCLC recurrence.

Junho Lee[1], Daehwan Lee[2], Kiwon Lee[2], Ho Yun Lee[3], Tae Jung Kim[3], Yeong Jeong Jeon[3], Junghee Lee[4], Seong Yong Park[4], Jong Ho Cho[4], Hong Kwan Kim[4], Yong Soo Choi[4], Sehhoon Park[5], Jong-Mu Sun[5], Se-Hoon Lee[5], Jin Seok Ahn[5], Myung-Ju Ahn[5], Hyun Ae Jung[5]

[1]Division of Medical Oncology-Hematology, Department of Internal Medicine, Kyung Hee University Hospital, Kyung Hee University College of Medicine, Seoul, Korea, Republic of,[2]Spidercore Inc., Daejeon, Korea, Republic of,[3]Department of Radiology and Center for Imaging Science, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[4]Department of Thoracic and Cardiovascular Surgery, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Korea, Republic of,[5]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Background:Accurate and practical prediction of recurrence in early-stage NSCLC is essential for managing patient outcomes and tailoring personalized treatment strategies. This study updated and validated a previously developed transformer-based model for NSCLC recurrence prediction, which integrates clinical, pathological, laboratory, and radiologic data, while proposing strategies to enhance its generalizability.Methods:The model was developed and internally validated using data from Samsung Medical Center (SMC) and Kyung Hee University Hospital (KH) collected from 2008 to 2024. The primary outcome was predicting recurrence within one year after the monitoring point. This study demonstrates the timely provision of risk scores (RADAR score) and determined thresholds and the corresponding area under the curve (AUC).
Results:A total of 16,828 patients was enrolled (12,208 with stage I; 2,702 with stage II; and 1,918 with stage III) Development set was 11,341 and validation set was 5,487. The median age was 64 years (range: 13-96). Females accounted for 44.3%, while males made up 55.7%. The median follow-up duration was 32.9 months, and 18.7% of patients experienced recurrence. The percentage of never-smokers was 49.7%, and ex-smokers or current smokers comprised 50.3%. Median RFS in total population was 140.9 months (95% CI, 134.0-147.9). The AUC for predicting relapse within one year of the monitoring point was 0.804. However, depends on the institute, AUC was 0.855 for SMC data (2008-2022), however 0.756 for SMC data (2023-2024) and 0.719 for KH data. We developed updated version of RADAR model by using multi-center data and validation. The updated RADAR model showed 0.858 of AUC with sensitivity of 74.5% and specificity of 82.1% (AUC=0.865 in stage I, AUC=0.756 in stage II, and AUC=0.731 in stage III).Conclusions:This study addresses the challenges of generalizability in NSCLC recurrence prediction models across diverse data sources. The integrated model showed improved overall performance, emphasizing the importance of multi-institutional data integration for enhancing prediction reliability. Future work will focus on feature selection to mitigate data heterogeneity and optimize model performance. Further external validation and refinement are necessary to support the implementation of precision medicine tailored to individual patients.

#7432 Transformer-based glioma patient recurrence prediction model infers novel genetic markers.

Ko-Hong Lin, Kai Zhang, Dung-Fang Lee, Xiaoqian Jiang

UT Health Houston, Houston, TX

Approximately 90% of glioma patients experience recurrence after initial treatment, leading to poor prognosis and short survival time. While established genetic markers, such as IDH mutation and 1p/19q codeletion, are linked to glioma prognosis, there is a critical need to identify novel targets associated with recurrence to overcome therapeutic challenges. In this study, we developed a transformer-based deep learning model to predict glioma recurrence by integrating multi-omics data, including mutations and copy number variations, from the Glioma Longitudinal Analysis (GLASS) Consortium. Our model outperformed traditional machine learning approaches, including support vector machines, logistic regression, and decision trees, achieving the best performance when utilizing mutational features alone, while copy number variations were less informative. Feature importance analysis identified key contributors to glioma recurrence, including frequently mutated genes such as TP53, ATRX, and PTEN, as well as novel markers like MUC16, TTN, and CIC. Our approach represents an early application of state-of-the-art deep learning to dissect the genomic drivers of glioma recurrence, offering valuable insights for developing targeted therapies to improve patient outcomes.

#7433 Predicting overall survival (OS) differences using longitudinal AI-driven imaging-based prognostication (IPRO) in patients with advanced non-small cell lung cancer (aNSCLC).

Mohammed A. Alvi[1], John Riskas[1], Shahid A. Haider[1], Vignesh Sivan[1], Oleksandra Samorodova[1], Jay Hennesy[1], Duoaud Shah[1], Felix Baldauf-Lenschen[1], Marina Salluzzi[2], Ronald Bridges[3], **Omar F. Khan**[4]

[1]Altis Labs, Inc., Toronto, ON, Canada,[2]Calgary Image Processing and Analysis Centre, University of Calgary Cumming School of Medicine, Calgary, AB, Canada,[3]Department of Medicine, University of Calgary Cumming School of Medicine, Calgary, AB, Canada,[4]Department of Oncology, University of Calgary Cumming School of Medicine, Calgary, AB, Canada

Background: Early prediction of overall survival benefit associated with cancer treatments remains a key challenge in clinical trials and patient care. Standardized measures such as the Response Evaluation Criteria in Solid Tumours (RECIST) v1.1 are used in clinical trials to define tumour response and progression, but are subject to inter- and intra-observer variability, and are infrequently used in day to day clinical practice. Imaging-based prognostication delta (IPRO-Δ) is an artificial intelligence system trained on longitudinal changes in rich features extracted from serial real-world imaging data, automatically predicting survival from pairs of baseline (BL) and follow up (FU) thoracic computed tomography (CT) scans.

Methods: IPRO-Δ was evaluated in an external real-world dataset of 194 aNSCLC patients treated with first line systemic therapy at 17 cancer centers, with pretreatment BL and FU (8±4 weeks after treatment initiation) scans. IPRO-Δ generated survival predictions at week 8 for each patient. Kaplan-Meier analyses and hazard ratios (HR) evaluated the association of IPRO-Δ quartiles with OS, with the highest quartile representing progressive disease, the lowest treatment response, and the middle stable disease.

Results: The cohort included 19 stage IIIB (9.8%) and 175 stage IV (90.2%) aNSCLC patients, with 94 females (48.5%) and a median age of 64 years. Most tumours were adenocarcinoma (n = 147, 75.8%), followed by squamous cell (n = 18, 9.3%), large cell (n = 5, 2.6%) and other histologies (n = 24, 12.4%). Table 1 shows survival stratification amongst IPRO-Δ quartiles for the overall population and the subgroup of EGFR+ patients.

Conclusion: IPRO-Δ successfully predicted survival differences amongst aNSCLC patients using BL and week-8 CT scans. Future work will compare IPRO-Δ to RECIST v1.1, potentially leading to IPRO-Δ's use as a surrogate endpoint in aNSCLC trials.

Table 1. Overall survival based on IPRO-Δ quartile risk stratification.

	Overall Population (n = 194)			**EGFR Positive Population (n = 79)**	
	Median OS, mths (95% CI)	*HR (95% CI)*		*Median OS, mths (95% CI)*	*HR (95% CI)*

Stable Disease Quartiles	14.75 (12.3 - 19.2)	1.31 (0.91 - 1.89)	**Stable Disease Quartiles**	20.2 (16.93 - 24.8)	1.58 (0.89 - 2.8)
Progression Quartile	7.43 (5.03 - 10.9)	2.11 (1.39 - 3.2)	**Progression Quartile**	10.2 (7.43 - 26.6)	2.71 (1.41 - 5.19)

#7434 Cloud-based machine learning for enhanced tumor classification in cancer genomics: an end-to-end solution for whole slide imaging data.

Jovana Babić, Nevena Nikolić, Milan Kovačević, Rowan Beck, **Tariq Khoyratty**, Zelia Worman

Seven Bridges Genomics Inc., Boston, MA

The digitization of histological slides into high-resolution Whole Slide Images (WSIs) has revolutionized pathology workflows, providing unparalleled insights into tissue morphology and playing a vital role in advancing cancer diagnostics and treatment. Tasks that were once time-consuming and subjective can now be automated and enhanced with machine learning (ML) and artificial intelligence (AI) solutions. These include image analysis systems capable of extracting diagnostic insights such as tumor classification, subclassification, and grading, aiming to improve accuracy, reproducibility, and efficiency in histopathology workflows. To lower the technical barrier to researchers in accessing and utilizing advanced ML, we developed a comprehensive solution for classifying WSIs by disease or tumor subtype, based on the morphological characteristics of the tissue. Building on the NCI Cancer Research Data Commons' (CRDC) cloud infrastructure, we take advantage of hosted data from the Imaging Data Commons (IDC) and Human Tumor Atlas Network (HTAN) paired with the computational resources available in the Cancer Genomics Cloud (CGC), powered by Velsera and funded by the NCI, to host a reproducible WSI ML solution. This solution includes data preparation and preprocessing, model training, evaluation, and predictions, within an interactive analysis environment. The analysis harnesses the computational capabilities of the CGC platform to efficiently process large-scale datasets. To facilitate data preparation, we integrated tools previously developed on the CGC to extract regions of interest (ROIs) from WSIs, enabling the creation of expanded datasets by generating tumor tissue patches for model training. To further enhance classification performance, a consensus model approach was employed—combining predictions from multiple models to improve robustness and accuracy. This work demonstrates the power of coupling AI-ready harmonized imaging data, available from within the CRDC, with advanced ML techniques, and showcases an end-to-end ML workflow on the CGC. By hosting the solution on an accessible and interactive system, users will be able to seamlessly apply the analysis to their own datasets, gaining meaningful insights with minimal technical barriers. The combination of best practices in data preparation, model development, and consensus-driven accuracy improvement makes ML for histopathology more accessible to users, enabling further research and deeper insights into cancer etiology and diagnostics.

#7435 CRCFound: A colorectal cancer CT image foundation model based on self-supervised learning.

Jing Yang[1], **Du Cai**[2], Junwei Liu[3], Zhenfeng Zhuang[1], Fengao Wang[3], Chenghang Li[4], Chuling Hu[2], Baowen Gai[2], Yiping Chen[5], Yixue Li[3], Liansheng Wang[1], Feng Gao[2], Xiaojian Wu[2]

[1]Xiamen University, Xiamen, China,[2]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China,[3]Guangzhou National Laboratory, Guangzhou, China,[4]The Hong Kong University of Science and Technology, Guangzhou, China,[5]Sun Yat-sen University, Guangzhou, China

Background: Colorectal cancer (CRC) is a significant global health threat. Accurate risk stratification is essential for determining the optimal treatment plan, yet existing deep learning models perform poorly in the preoperative diagnosis of CRC and lack generalizability due to insufficient annotated data. To address these issues, we propose CRCFound, a self-supervised learning-based CT image foundational model for CRC.
Methods: A total of 6,332 CRC patients with preoperative CT images were collected from 2008 to 2019 at the Sixth Affiliated Hospital of Sun Yat-sen University. Among them, 5,137 unlabeled CT images were used for pretraining, and 1,195 images were reserved for fine-tuning and validation. Comprehensive benchmark tests were conducted on six diagnostic and two prognosis tasks in comparison with other models. Model interpretation was also explored to gain a more profound understanding of the model's behavior and decision-making process.
Results: CRCFound demonstrated excellent performance and generalization ability. For preoperative diagnosis of TNM stage, the average AUC of CRCFound for T, N, M, and overall TNM stage reached 0.889, 0.847, 0.830, and 0.774. In the MSI and CMS diagnosis tasks, it also showed good predictive performance (AUC 0.952 and 0.810, respectively). For prognosis prediction, CRCFound_CT was an independent risk factor for disease-free survival (hazard ratio (HR)= 4.62, 95%CI = 2.7-7.88, P < 0.001) and overall survival (HR = 7.78, 95%CI = 4.12-14.7, P < 0.001). Feature visualization using the t-SNE algorithm demonstrated that CRCFound could effectively differentiate samples in multiple tasks. Visualization of the attention map indicates that CRCFound can focus more effectively on the critical areas of the tumor than traditional supervised learning models, thus providing more accurate predictions.
Conclusion: CRCFound addresses the challenge of insufficient annotated data and performs well in a wide range of downstream tasks, offering a promising solution for accurate diagnosis and personalized treatment of CRC patients.

#7436 DeepSomatic: A SNV and small-indel somatic caller using deep neural networks.

Daniel E. Cook[1], Jimin Park[2], Pi-Chuan Chang[1], Alexey Kolesnikov[1], Lucas Brambrink[1], Juan C. Mier[1], Joshua Gardner[2], Brandy McNulty[2], Samuel Sacco[2], Ayse Keskus[3], Asher Bryant[3], Tanveer Ahmad[3], Jyoti Shetty[4], Yongmei Zhao[5], Bao Tran[4], Giuseppe Narzisi[6], Adrienne Hellend[6], Byunggil Yoo[7], Irina Pushel[7], Lisa Lansdon[7], Chengpeng Bi[7], Adam Walter[7], Margaret Gibson[7], Tomi Pastinen[7], Midhat S. Farooqi[7], Nicolas Robine[6], Karen H. Miga[2], Andrew Carroll[1], Mikhail Kolmogorov[3], Benedict Paten[2], Kishwar Shafin[1]

[1]Google, Mountain View, CA,[2]UC Santa Cruz Genomics Institute, Santa Cruz, CA,[3]Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD,[4]Sequencing Facility, Cancer Research Technology Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[5]Sequencing Facility Bioinformatics Group, Biomedical Informatics and Data Science Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[6]New York Genome Center, New York, NY,[7]Children's Mercy Hospital, University of Missouri-Kansas City School of Medicine, Kansas City, MO

DeepVariant is a highly accurate germline variant caller that applies deep dearning to classify germline variants with high accuracy. Here, we present DeepSomatic, which applies DeepVariant's convolutional neural network (CNN) to accurately call somatic mutations from paired tumor-normal sequencing and tumor-only sequencing. To develop DeepSomatic, we adapted the input pipeline to accommodate tumor-normal pairs. DeepVariant model inputs consist of a set of pileup images, also referred to as "channels", that represent features extracted from sequence data at candidate sites. Features include base, base quality, mapping quality, and haplotype. Channel sets from both tumor and normal samples are combined. In this way, our model can compare tumor and normal reads and learns to distinguish germline variants from somatic mutations.

For training, DeepSomatic uses sequence data from the SEQC2 consortium, which has established a benchmarking dataset for HCC1395 (a triple-negative breast cancer cell line) across a variety of sequencing technologies. Additionally, we have supplemented the SEQC2 data with additional sequencing from cell lines (H2009, H1437, HCC1954, HCC1937, Hs578T) to further improve our training datasets and enable benchmarking across different cancer types. We have also developed in silico samples that replicate varying levels of tumor purity and normal-sample contamination. Using these data, we have trained models on whole-genome data from Illumina, PacBio, and Oxford Nanopore (ONT).

We report that DeepSomatic outperforms existing somatic callers across sequencing technologies. For example, we observe that our DeepSomatic Illumina model has a SNP F1 score of 0.983 on held-out chr1 HCC1395 data, which outperforms ClairS (F1=0.969), and Strelka2 (F1=0.952). Similarly, our PacBio model has a SNP F1=0.95 compared to ClairS (F1=0.935). Finally, our ONT model achieves an F1=0.869, which is an improvement over ClairS (F1=0.863). We similarly observe that DeepSomatic outperforms on F1 scores for indels as well for Illumina, PacBio, and ONT models. We plan to continue improving DeepSomatic through improvements to the software, models, and training data. We welcome community feedback.

#7437 AI-guided discovery of small molecules targeting eIF4F complex to inhibit oncogenic mRNA translation in castration-resistant prostate cancer.

Fengze Jin, Puja Singh, Hanyong Chen, Yibin Deng

Department of Urology, The University of Minnesota Medical School, Minneapolis, MN

Effective treatment of castration-resistant prostate cancer (CRPC) remains a significant clinical challenge. Our structure-guided biochemical studies have revealed that the interaction between eukaryotic initiation factors eIF4A and eIF4G within the eIF4F complex plays an essential role for prostate cancer cell survival and CRPC tumor growth. Genetic disruption of the eIF4A-eIF4G interaction in cancer cells selectively inhibits oncogenic mRNA translation, significantly reduces prostate cancer cell survival, and suppresses the *in vivo* growth of xenografted CRPC tumors. Despite its promise as a therapeutic target, no chemical drug has been developed that effectively disrupts the eIF4A-eIF4G complex to block oncogenic mRNA translation for cancer therapy. To enhance the likelihood of discovering highly biologically active compounds targeting the eIF4A-eIF4G complex, we are developing and utilizing artificial intelligence (AI)-guided “Deep Docking (DD)” algorithms with Schrödinger Molecular Docking platform. This approach enables to develop 'end-to-end' algorithms for structure-based virtual screening (SBVS) of ultra-large chemical libraries containing billions of synthesizable molecules, including novel and unchartered areas of the chemical universe. Building on our resolved structure of the human eIF4A-eIF4G complex, we performed AI-guided SBVS of a chemical library containing 1.5 billion of molecules. By integrating our optimized computational filtering and validation approaches, we identified and selected top-ranked promising candidates for chemical synthesis. Experimental validation of the synthesized compounds demonstrated their abilities to disrupt the eIF4A-eIF4G interaction, block the translation of oncogenic mRNAs such as MYC, MDM2, BCL2, and MCL1, and significantly reduce the survival of CRPC cells. These results demonstrate the effectiveness of our AI-guided platform for structure-based ultra-high chemical library screening, highlighting its potential to accelerate the discovery of drug-like molecules targeting the eIF4F complex. Translationally, the experimentally validated compounds could be advanced into first-in-class therapies for castration-resistant prostate cancer (CRPC) characterized by aberrant activation of the eIF4F complex.

#7438 Mapping T cell reactivity against the human genome using machine learning uncovers target specific TCRs against novel tumour antigens.

Nathaniel J. Davies[1], Amalia Martinez[1], Maria Busz[1], David Cook[1], Xiaoyan Pan[1], Juan Bolivar[1], Simon Wright[1], Eleanor Bagg[1], Graham Ogg[2], Sophie Johnson[1], Sophie Wells[1], Sophie Richard[1], Samantha Drennan[1], Samuel Ward[1], Sarah Leonard[1], Thomas L. Andresen[1]

[1]T-Cypher Bio Limited, Oxford, United Kingdom,[2]MRC Translational Immune Discovery Unit, University of Oxford, Oxford, United Kingdom

Introduction: T cell engagers (TCEs) are a class of targeted therapies with demonstrated clinical potential in solid tumors. A main challenge currently facing TCEs is the availability of clean cancer targets with a wide therapeutic window. Intracellular targets presented to T cells by HLA complexes are strongly linked to disease mechanisms and are therefore very attractive, but drugging HLA-presented targets has been challenged by our ability to map the specificity of T cell repertoires. We here present the T-Cα platform, which represents a fundamental change in TCR discovery methodology, enabling us to discover >10,000 TCRs per week against 100s of targets. This data has enabled us to train machine learning (ML) models and to demonstrate the ability of these models to extrapolate beyond the training data. In effect, this results in the discovery of novel therapeutically relevant TCRs and enhances our understanding of the interface between T cell reactivity and the human genome.

Experimental Procedures: We used the T-Cα platform to discover more than 50 novel targets across all areas of the genome, including regions previously considered non-coding. We screened billions of T cells from 100s of donors against these targets and other targets of interest. We generated single-cell transcriptomic data as part of the screens and predicted the potency of each TCR at the discovery stage. For the purposes of model development, we generated matched negative data with non-binding TCRs during the course of the screens. These datasets, representing 10,000s of TCR-epitope pairs, were collated alongside available public data and a machine learning model was trained to predict TCR specificity. The TCRs were functionally validated downstream for potency and cross-reactivity.

Results: We have generated, to our knowledge, the largest high-quality database of TCR-epitope pairs against 100s of targets. We demonstrate that with this data, alongside matched negatives, we can train models that are able to predict TCR specificity with high concordance with known epitope pairings. We used the model to predict the specificity of unseen TCRs against novel targets of therapeutic interest in oncology. We further demonstrate that the model can extrapolate beyond the training data and identify novel target-specific TCRs suitable for the development of TCEs.

Conclusions: We have developed a uniquely high-throughput, high-content TCR discovery platform with which we are able to discover >10,000 specific TCRs per week against 100s of targets. We have trained a machine learning model which can accurately extrapolate to unseen TCRs, enhancing our understanding of T cell reactivity against the human genome. With the T-Cα platform, we have built a pipeline of novel T cell engagers for the treatment of solid tumors, the first of which we expect to enter IND enabling studies mid 2025.

#7439 Label-free 3D virtual papanicolaou staining of urine cytology using deep learning and holotomography.

Tal Lifshitz[1], Geon Kim[1], Su-Jin Shin[2], Kwang Suk Lee[3], YongKeun Park[1]

[1]Physics, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Department of Pathology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Urology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

The Papanicolaou stain is commonly used to assess cells for carcinoma in urine cytopathology. However, due to the nature of cytology, cells are often imaged overlapping one another, which makes them hard to distinguish and complicates the assessment process. The staining procedure not only introduces changes to the cells, but it is also lengthy and expensive. Here, we present a deep learning model that creates virtual Papanicolaou stained 3D images from label-free 3D holotomography images of urine cytology. We acquired 38 3D holotomography images of urine cytology samples using the Tomocube HT-X1, after which the samples were stained and 38 matching whole slide images were acquired. The image pairs were preprocessed to flatten the 3D holotomography images into 2D, and image registration to align the image pairs. This produced 10,693 image pairs of size 256x256 px, 8670 of which were used to train a modified version of the CycleGAN model. After the model was fully trained, the z-stack 3D holotomography images were input into the model one by one, resulting in a 3D virtual stained image. Our results show that our model was able to virtually stain the test sample (SSIM = 0.691 ± 0.097, PSNR = 19.9 ± 5.8, MSE = 0.017 ± 0.011) to produce an accurate 2D image, and also virtually visualize the Papanicolaou stained test samples in 3D. The presented work has potential in aiding practitioners by shortening the standard staining process. Through visualizing virtually stained urine cytology samples in 3D, our work provides the information needed to accurately assess cases of overlapping cells and cell clusters.

#7440 Natural language processing algorithms allow retrospective glioblastoma phenotyping by identifying true wild-type isocitrate dehydrogenase gliomas in electronic health records.

V. Guggilla[1], N. Forrest[1], A. Bell[1], K. Nandoliya[1], E. Houskamp[1], S. Tran[1], R. Lukas[1], J. Johnson[1], I. Roy[1], D. Wainwright[2], T. Walunas[1];
[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL, [2]Loyola University Stritch School of Medicine, Maywood, IL

Background: Glioblastoma (GBM), the most common primary brain tumor in adults with a devastating median overall survival time of 12 months, was reclassified by the World Health Organization in 2021 to only include gliomas with wild-type isocitrate dehydrogenase (IDHwt). This presents a challenge in studying retrospective cohorts of patients diagnosed with outdated definitions of GBM, which may include tumors with IDH mutations. To address this, we developed and validated natural language processing-based models in electronic health record (EHR) data designed to identify patients with IDHwt gliomas. We also developed models for identifying important prognostic markers in GBM, such as the methylation status of the O6-methylguanine-DNA-methyltransferase (MGMT) promoter, to further demonstrate the utility of these tools and EHR data in studying GBM.
Methods: We manually adjudicated 1,500 pathology documents from Northwestern Medicine (NM) containing the case-insensitive word, “glioblastoma”, for the presence of a diagnosis of IDHwt glioma as well as the methylation status of MGMT. In parallel, we implemented the National Library of Medicine’s MetaMap tool on these documents to identify biomedical concepts contained within the text. These biomedical concepts were used as features in training a series of regularized logistic regression models that identify the IDH mutation and MGMT methylation status. We next constructed Kaplan-Meier survival curves, stratifying patients by MGMT methylation. Finally, we evaluated the performance of these models at Loyola University Medical Center (LUMC) to determine their efficacy at a secondary healthcare institution.
Results: The best performing model in identifying IDHwt gliomas had an F1-measure of 0.88 in the holdout test set of documents from NM. Comparing patients with hyper-methylated and unmethylated MGMT showed significant differences in median overall survival times regardless of the MGMT identification method used ($p < 0.001$). Finally, the best performing IDHwt glioma identification model had an F1-measure of 0.96 when implemented at LUMC. 15% of patients identified at LUMC were Hispanic or Latino, compared to only 5% at NM ($p < 0.05$).
Discussion: Our results suggest that we successfully designed and implemented models to identify patients with true IDHwt gliomas. Importantly, these models displayed excellent performance at a secondary healthcare institution, demonstrating that they can be utilized to identify ethnically diverse and multi-site GBM cohorts. Furthermore, our characterization of the NM GBM cohort recapitulated known trends in survival patterns, serving as a secondary validation metric and demonstrating the utility of EHR data in studying GBM in clinical settings.

#7441 Machine-learning-based inference of clinical metadata from gene expression data.

Valentin Bernu, Guillaume Appe, **Abdelkader Behdenna**, Antoine Gaston, Julien Haziza, Akpeli Nordor

Epigene Labs, Paris, France

Secondary analysis of omic datasets holds great potential in accelerating precision oncology research and drug development. Despite this potential, a major challenge lies in harmonizing clinical information across diverse data sources. Although natural language processing techniques perform well in harmonizing many clinical variables, their performance diminishes when dealing with more intricate ones (e.g., histological type). Here, we introduce a method to infer clinical information directly from molecular data.

We identify the most informative genes from the gene expression data using an analysis of variance for each clinical variable. Then, we train machine learning classifiers (XGBoosts) on the selected features. The Cancer Genome Atlas (TCGA) pancancer database is used for training and Gene Expression Omnibus (GEO) database is used for independent testing. Expert scientists labeled clinical variables from both sources. Due to underrepresentation in TCGA, some classes of clinical variables are excluded from the training and test sets. TCGA encompasses 11,000 transcriptomic profiles spanning 33 cancer types, while the 210 aggregated GEO datasets include 7,077 transcriptomic profiles across 13 cancer types. A total of 15,430 genes are profiled in both TCGA and these GEO datasets.

We assessed our methods on five clinical variables. The encouraging accuracy of current models for biopsy site, sample type, and histological subtype suggests that they are effectively capturing the underlying patterns. For primary site and histological type classifications, the models achieved high accuracies and macro-averaged F1 scores: 93% accuracy with a 0.89 F1 score across 11 classes for primary site, and 96% accuracy with a 0.91 F1 score across 6 classes for histological type.

This method offers a significant opportunity to complement expert data labeling, addressing the challenge of scaling clinical data harmonization for the secondary analysis of omic data across multiple applications in cancer drug discovery and development. Our findings are particularly encouraging for inferring clinical details related to primary sites and histological types, with cross-database training and testing further boosting its generalizability. The strong performance across these two clinical variables underscores the potential of our approach. Nonetheless, the performance has been evaluated on a limited subset of classes of the clinical variables, highlighting the need for further validation with more diverse datasets to further unlock the potential of the method.

#7442 Transforming breast cancer treatment decisions: AI tools improve Ki67 risk assessments with 90 pathologists.

Amanda Dy[1], Ngoc-Nhu Jennifer Nguyen[2], Melanie Dawe[3], Dimitrios Androutsos[1], Susan Done[3], April Khademi[1]

[1]Electrical, Computer, & Biomedical Engineering, Toronto Metropolitan University, Toronto, ON, Canada,[2]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[3]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

A Ki67 proliferation index (PI) of ≥20% determines high-risk status and guides treatment decisions in HR+/HER2− early breast cancer. The Ki67 PI, defined as the ratio of Ki67+ tumor cells to total malignant cells, is labor-intensive and subjective to score. AI support is necessary for routine and reliable clinical use. This is the first large-scale, international study on AI-aided Ki67 PI risk assessments in breast cancer. Ninety pathologists scored the continuous PI from 0% to 100% for 10 breast cancer tissue microarrays (TMA) with and without AI support. The AI tool provided a continuous PI and a Ki67+/- tumor nuclei overlay. The AI tool was developed and validated independently of the pathologists and data used in this study (PMID: 38218973). Using gold-standard manual counts, two pathologists established the ground-truth (GT) PI scores for each TMA, ranging from 7% to 28%. The pathologists' PI scores were classified into low (<20%) and high risk (≥20%). The risk classification accuracy, sensitivity and specificity relative to the GT were obtained for manual and AI-aided scores, yielding 900 paired classification metrics (90 pathologists × 10 TMAs). Table 1 summarizes the classification metrics showing improvements with AI support for all demographics. The AI tool achieved 100% risk classification accuracy. Manual misclassification and AI-aided correction rates are also summarized in Table 1. The overall manual misclassification rate was 26%, and AI support successfully corrected 95% of these cases. The McNemar's test, a nonparametric statistical test for paired binary data, assessed statistical differences in risk classification between manual and AI-aided scoring, an asterisk denotes significance (p<0.05). AI support can improve the clinical reliability of PI scoring for risk classification and treatment decisions. AI integration into routine practice can ensure consistent Ki67 use, improving drug response predictions and patient outcomes.

Risk classification metrics, misclassification rates and correction rates, (*) denotes p<0.05.

#7443 Feasibility of automatic spleen volumetry from 3D ultrasound images of mice using deep learning.

Adam M. Aji[1], Thomas M. Kierski[1], Juan D. Rojas[1], Bincy John[2], David Harris[2], Ryan C. Gessner[1], Craig McMannus[1], Jeffrey Peterson[1], Tomasz J. Czernuszewicz[1]

[1]Revvity, Durham, NC,[2]Charles River Laboratories, Morrisville, NC

The spleen plays a critical role in immune function and blood filtration. Interestingly, the spleen's volume changes in response to various diseases. For example, enlargement of the spleen (splenomegaly) can arise because of cancer (solid and liquid tumors), liver diseases (MASH), Lupus, or various infections. Conversely, atrophy or shrinking of the spleen can arise from conditions such as graft-versus-host-disease, inflammatory bowel, or sickle cell disease. Though the size of the spleen is a relatively well-established biomarker that may be useful in several preclinical studies, it is currently difficult and costly to measure for large cohorts of mice over multiple timepoints.

It is possible to measure spleen volume and weight ex vivo at a terminal timepoint, but this approach is not amenable to longitudinal tracking. Alternatively, imaging using ultrasound or magnetic resonance can be used to interrogate the spleen noninvasively and repeatedly, but this method requires data to be segmented in 3D. Segmentation often creates a bottleneck in study design because it is time consuming. Furthermore, measurements derived from human-annotated data are prone to inter-user variability and user error.

Towards addressing these challenges with measuring spleen volume in longitudinal preclinical studies, we trained an AI model to segment spleens from a diverse set of 3D ultrasound images. In total, 180 images were acquired in mice from a Vega ultrasound scanner (Revvity, Waltham, MA, USA). These images were varied in terms of animal strain, positioning, field of view, and disease state with splenic volumes ranging between approximately 20 mm^3 and 150 mm^3. These data included samples from healthy controls and mice with conditions including solid tumors, blood cancer, Lupus, and graft versus host disease which were annotated by expert human readers. Data were shuffled and split into training and validation groups with an 80-20 split and the training set was used to train a modified U-Net model.

Inference on the validation set after training yielded a Dice coefficient of 0.86, and the total processing time for the 36 images was 49.0 seconds (1.36 sec/image) on an NVIDIA RTX 3090 GPU. A linear regression analysis between the ground truth volumes and the volumes predicted by the model resulted in a R^2 value of 0.85. These results suggest that this problem is an excellent candidate for automation using artificial intelligence, particularly with an automated ultrasound scanner such as the Vega where positioning is highly reproducible. The training set size (N=144 images) is quite small by conventional deep learning standards, and we expect the segmentation accuracy to increase further as more images are added to the training pool. Future work will focus on collecting more in vivo images from a variety of murine models.

#7444 Automated quantification of small animal liver tumor volume in longitudinal MR imaging using deep learning.

Thomas M. Kierski[1], **Adam M. Aji**[1], Juan D. Rojas[1], Ryan C. Gessner[1], Laura Beretta[2], Suet Ying Kwan[2], John Hazle[3], Kiersten L. Maldonado[3], Charles Kingsley[3], Richard R. Bouchard[3], Tomasz J. Czernuszewicz[1]

[1]Revvity, Durham, NC,[2]Department of Molecular and Cellular Oncology, MD Anderson Cancer Center, Houston, TX,[3]Department of Imaging Physics, MD Anderson Cancer Center, Houston, TX

In preclinical imaging studies with small animals, tracking tumor growth accurately over time can be challenging due to the time-consuming, labor-intensive, and error-prone nature of manual segmentation of 3D images. Orthotopic and metastatic cancer models can be particularly problematic as additional radiologic expertise is required to detect tumors within the context of deep anatomy, and individual animals may contain many nodules (ten or more) requiring many hours of segmentation effort. Therefore, the goal of this study was to develop and validate a deep learning model for automatic volumetric measurement of murine liver tumors in MR images to increase the practicality and adoptability of longitudinal imaging in preclinical research.

We describe a method for automatically quantifying tumor volume over time using a dataset of 4.7T T2-weighted MR images taken from a study involving a genetic model of spontaneous liver cancer. The dataset included 894 images from 198 unique animals collected using a Biospec 47/40 (Bruker, Kontich, Belgium) over a span of 30 weeks. Each image was manually segmented by an expert annotator and tumor burden was tracked longitudinally to generate growth curves. A modified U-Net model built on the MONAI framework was trained to segment tumors.

On a held-out test subset of 177 images (20% of the overall dataset), the model's predicted overall tumor burden showed a strong correlation with the human ground truth, achieving an R^2 value of 0.88. The model processed each image in 0.34 seconds on a machine with an NVIDIA RTX 3090 GPU, significantly faster than the 5-10 minutes required for manual annotation. This efficiency translates to a substantial reduction in overall annotation time for studies with large datasets.

This study demonstrates the feasibility of using deep learning for liver tumor segmentation in MR images. The proposed method offers a reliable and efficient alternative to manual segmentation, potentially improving the accuracy and speed of volumetric measurements in preclinical cancer research.

#7445 Deep learning prioritizes cancer mutations that alter protein nucleocytoplasmic shuttling to drive tumorigenesis.

Z.-X. Liu, K. Yu, Y. Zheng, J.-F. Lin;
Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Genetic variants can affect protein function by driving aberrant subcellular localization. However, due to limitations in existing computational tools, comprehensive analysis of how mutations promote tumor progression by influencing nuclear localization is currently lacking. Here, for the first time, we systematically characterized potential shuttling-attacking mutations (SAMs) across cancers. The deep learning model Predicting Shuttling-Attacking Mutations (pSAM) was the leading tool constructed for the *ab initio* decoding of protein sequence determinants essential for subcellular shuttling, including classical nuclear localization signals and unconventional sequences such as fragments embedded in DNA/RNA-binding domains. Leveraging cancer mutations across 11 cancer types, we found that SAMs constitute about 6.7% of the mutations and enrich functional genetic variations and critical genes in cancer; for example, SAMs in transcription factors prevent them from entering the nucleus and subsequently cause abnormal expression of downstream targets. We experimentally validated a dozen SAMs, among which R14M in PTEN, P255L in CHFR, R674C in NFE2L1 and R144C in KAT8 were identified to disrupt the nuclear localization through interfering their interactions with importins. Further studies confirmed that the altered nucleocytoplasmic shuttling triggered by SAMs in PTEN and CHFR rewired the downstream signaling pathways and eliminated their function of suppressing cancer progression. Thus, this study greatly contributes to the understanding of the molecular details of nucleocytoplasmic shuttling and reveals the variants mediating aberrant protein subcellular localization and dysfunction in cancers and diseases.

#7446 Stratification of cell therapies in solid tumor organoids using deep learning-derived imaging metrics.

Luca Lonini[1], Madhavi Kannan[1], Geoffrey Schau[1], Stanislaw Szydlo[1], Vignesh Krishnaraja[1], Sonal Khare[1], Daniel Rabe[1], Michael Streit[1], Mary Flaherty[1], Brandon Mapes[1], Mark Prytyskach[2], Stefan Kiesgen[3], Gurpanna Saggu[2], Megan McAfee[2], Kate Sasser[1], Justin Guinney[1], Richard Klinghoffer[1], Chi-Sing Ho[1]

[1]Tempus AI, Inc., Chicago, IL,[2]Takeda, Cambridge, MA,[3]BioNTech, Cambridge, MA

Background. High-throughput screening of immunotherapies is crucial for identifying promising candidates against various cancer indications and accelerating the pre-clinical development of cell therapies. Two technologies have shown promise in quantifying therapy effectiveness: patient-derived organoid (PDO) models co-cultured with cell therapies, and deep learning-based computer vision, which facilitates large-scale, automated image analysis to extract quantitative metrics of treatment efficacy and cell biology effects. Here, we use deep networks to predict PDO viability from brightfield images and compute explainable features which are used to stratify a large cohort of cell therapies, tested on multiple tumoroid lines and indications.
Methods. Time-lapse confocal microscopy was used to record images of a large cohort of 27 cell therapies co-cultured with 15 different patient-derived tumor organoids (PDO) lines, across 8 cancer indications (breast, colorectal, endometrial, gastric, head and neck, liver, lung, pancreas) over the course of 72 hours, and at 2 different effector-to-target concentrations. PDO viability was measured by terminal TO-PRO-3 staining. A convolutional deep network was trained to perform label-free predictions of PDO viability from brightfield images at each timepoint (N=11,110) and evaluated on a held-out test set (N=2,112). Deep learning segmentation models were further used to co-localize tumoroid and immune cells, and extract a set of 6 explainable features - or spatial phenotypes - which quantified 1) tumoroid area, 2) cell apoptosis intensity and 3) temporal dynamics, as well as 4) immune proliferation, 5) immune infiltration and its 6) temporal dynamics. We fitted a linear model to measure their contribution in predicting terminal viability, and used hierarchical clustering to assess associations with exposure to different therapies.
Results. Our bright-field model of viability was found to be highly concordant with ground truth viability from terminal vital dye stain on a held-out test set, representing 11 TO lines across 8 distinct cancer types (Pearson's r=0.76). A linear model of spatial phenotypes showed high correlation with terminal viability (Pearson's r=0.70), while clustering of spatial phenotypes stratified samples into groups of non-engineered and engineered therapies with and without an additional compound.
Conclusion. Our study highlights that imaging-derived metrics from brightfield imaging can quantify treatment potency and cell phenotypes in ex-vivo screens. The approach pursued here is highly scalable and permits the analysis of large scale screening experiments to assess the impact of cell therapies on PDOs. Using explainable features further allows to stratify therapies into biologically meaningful groups based on the measured phenotypic readouts.

#7448 Developing virtual staining algorithm of colon cancer organoids using holotomography and deep learning.

Juyeon Park, Geon Kim, YongKeun Park

Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Colon cancer organoids hold great potential for studying the development of colon cancer. To assess their physiological and developmental status, both morphological parameters (e.g., cell shape and volume) and functional parameters (e.g., presence of proliferating cells or pluripotent stem cells) are crucial. However, current fluorescence labeling methods are invasive, potentially damaging or altering the organoids, making them disposable. To overcome this limitation, it is essential to develop a non-invasive method for monitoring organoids for long-term. We propose a solution that integrates holotomography and deep learning. Holotomography is a label-free imaging technique that measures the 3D refractive index distribution of samples without requiring any exogenous labeling. While this technique operates within a label-free framework, the resulting images provide only structural information and lack functional information. This limitation makes it challenging for researchers to distinguish cellular and subcellular structures with specific function. We address this challenge by leveraging deep learning to provide both structural and functional information through virtual staining of label-free images. Specifically, we construct a paired dataset using correlative holotomography, which captures both label-free images and their corresponding fluorescence images. Using supervised learning, we train a neural network to map label-free images to their corresponding fluorescence counterparts. Once trained, the neural network can automatically predict virtual fluorescence images from label-free inputs without exposing the organoids to any exogenous chemicals. To validate the accuracy of the trained neural network, we first acquire label-free images of the organoids and input them into the network. After obtaining the network-generated virtual fluorescence images, we chemically stain the same organoids. Finally, we compare the chemically stained images with the virtual images produced by the neural network to evaluate its performance. By combining the safety of label-free imaging with the precision of artificial intelligence, our technology eliminates critical barriers to organoid research and translation. This breakthrough accelerates the development of scalable and safe organoid therapies, bringing us closer to a future where lab-grown organoids revolutionize regenerative medicine and save lives.

#7449 Evaluating the effectiveness of machine learning models using polygenic risk scores and clinical factors for breast cancer risk stratification.

Lannawill Caruth[1], Roukiatou Sore[2], Sarah Ehsan[2], Anne-Marie McCarthy[2], Shefali Setia-Verma[1]

[1]Department of Pathology and Laboratory Medicine, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[2]Dept. of Biostatistics Epidemiology & Informatics, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA

Breast cancer is the most common cancer among women in the United States, aside from skin cancer. Early detection and treatment significantly reduce mortality rates, highlighting the importance of effective risk prediction methods. This study evaluates the predictive performance of multiple machine learning models that include polygenic risk scores (PRS), clinical and demographic factors. We compared three predictive models using 313 SNPs model from PGS catalog and incorporated age, body mass index (BMI), five genetic principal components (PC1-5), and breast density as predictor variables. Logistic Regression (LR), Multilayer Perceptron (MLP), and Probabilistic Graphical Model (PGM) were implemented to assess breast cancer risk. MLPs are a type of artificial neural network that consists of layers of interconnected "neurons" that work together to process and learn from data. Each layer processes the information and passes it to the next layer, allowing the model to learn complex patterns and detect non-linear relationships in the data, which makes it useful for predictions. The selected PGM implementation uses Bayesian statistics to determine feature importance and correlation. The model then uses this information to predict the probability an instance belongs to a group (e.g. case or control). Among 3,000 African ancestry women from the Penn Medicine BioBank, model performance varied. Logistic Regression demonstrated the highest predictive accuracy at 0.69, followed by Probabilistic Graphical Model at 0.64 and Multilayer Perceptron at 0.63. Our study suggests limited interaction between PRS and clinical factors in breast cancer prediction. These findings aligns with prior research demonstrating the largely independent nature of polygenic risk scores from traditional clinical risk factors. These findings underscore the challenges in developing more sophisticated risk prediction models and highlight the need for alternative approaches to capture the complex genetic architecture of breast cancer risk Subsequent research will incorporate moderate and high penetrance genes to enhance the predictive power of our risk assessment models, potentially improving precision in breast cancer risk stratification.

#7450 Leveraging large language models' own knowledge for obtaining and exploring gene embeddings.

Dailin Gan[1], Siyuan Zhang[2], Xin Lu[1], Jun Li[1]

[1]University of Notre Dame, Notre Dame, IN,[2]The University of Texas Southwestern Medical Center, Dallas, TX

Transfer learning is increasingly prevalent in gene expression analysis. Large transformer-based models generate embeddings from genes, which are used to construct machine-learning models for various downstream tasks. Given the high cost of training these large models, recent work has utilized ChatGPT-4, a pre-trained language model, to produce embeddings from manually curated NCBI gene descriptions. However, this method does not leverage the vast pre-trained knowledge of ChatGPT-4. In this work, we propose directly querying ChatGPT-4 about genes and converting its responses into embeddings rather than using static NCBI descriptions. For each gene, we independently asked ChatGPT-4 four specific questions designed to elicit ChatGPT's knowledge about each gene's general characteristics, regulatory functions, gene structure, and implications in cancer research. We evaluate our approach by comparing the embeddings it produces with those derived from NCBI descriptions. The comparison suggests, notably, that ChatGPT-4's knowledge closely aligns with that of NCBI despite differences in presentation. Furthermore, ChatGPT-4 reveals more detailed and comprehensive information about many genes. We also used the ChatGPT-answer-derived gene embeddings to distinguish long and short-range transcription factors, dosage-sensitive and insensitive genes, and bivalent, Lys4-methylated, and non-methylated genes. Results indicate a preference for ChatGPT-answer-derived gene embeddings in downstream applications by machine learning models. Overall, our findings suggest that direct querying of ChatGPT-4 offers clear advantages for generating gene embeddings.

#7451 Efficacy of chemoradiotherapy in older patients with advanced stage head and neck cancer: A propensity and machine learning analysis.

Rasheed Omobolaji Alabi, Alhadi Almangush, Antti Makitie

Research Program In Systems Oncology, University of Helsinki, Haartman Institute, Helsinki, Finland

Background: The rising incidence of head and neck squamous cell carcinoma (HNSCC) is linked with both human papillomavirus and aging population. As a result, there is an emerging need for developing management strategies for older patients with advanced-stage HNSCC. This study aims to use machine learning (ML) techniques to examine the efficacy of definitive, concurrent chemoradiotherapy (CRT) for older patients (≥65 years) with stage III-IV HNSCC. We used permutation feature importance (PFI) to compare the efficacy of CRT with single-modality radiotherapy (RT) for the overall survival (OS) of this HNSCC subgroup. Finally, we compared the results obtained using ML analysis with propensity-score matched (PSM) analysis to clarify the efficacy of CRT in this patient population.
Methods: A total of 3570 patients with HNSCC were obtained from the Surveillance, Epidemiology, and End Results (SEER) Program to build the ML model. We compared voting ensemble and extreme gradient boosting algorithms for stratifying older (≥65 years) HNSCC patients into OS risk groups. Furthermore, the PFI analysis was based on stacked ML models to evaluate the efficacy of CRT regarding OS of older (≥65 years) HNSCC patients. Then, we performed a 1:1 propensity-score matched (PSM) analysis to reduce treatment selection bias and analyze the prognostic role of CRT.
Results: Our ML model showed a performance accuracy of 85.2% in predicting OS in this subgroup of HNSCC. The aggregate feature importance showed that CRT is the most important feature for OS in this group of HNSCC patients. In addition, patients with stage IV disease showed better survival than those with stage III. The PSM confirmed the efficacy of CRT compared to RT alone.
Conclusions: This study showed that CRT may be more feasible and effective than RT alone for older patients with stage III-IV HNSCC. This further emphasized that advanced-stage treatment decisions should rather be made according to other patient-related factors than chronologic (calendar) age alone. Therefore, validating these models with multi-institutional datasets and testing them in the context of clinical trials is warranted to confirm the efficacy of CRT over RT alone for older patients (≥65 years) with stage III-IV HNSCC.

#7452 MAGNETICA: Machine-augmented generation of novel enhanced tomographic imaging for tumor insight and cancer assessment.

Hosein Barzekar, Mahyar Abbasian, **Morteza Rezanejad**, Mohammed Qutaish, Neal Sherkar, Deepti Nagarkar, Karen Stephansen, Scott Ogden, Lauren K. Brady, Brandon W. Higgs

Genmab, Plainsboro, NJ

Background: Quantitative features extracted from radiology images can reveal tumor characteristics beyond what the human eye can detect. While promising for identifying imaging biomarkers, the limited availability of patient 3D CT images in early-phase cancer trials is a major bottleneck. Recruiting patients with specific tumor types is difficult, leading to small, non-diverse datasets that lack statistical power for decisions on drug dosing, safety, and mechanism. Image augmentation could generate diverse, synthetic patient images to simulate tumor profiles, model disease progression, and increase biological variation while preserving patient privacy. However, current models do not meet these goals. To address this, we introduce MAGNETICA, a novel framework that integrates clinical features with anatomical structures for synthetic 3D CT image generation.
Methods: We used the NSCLC-Radiomics (Lung1) dataset - which includes pretreatment CT scans, manual 3D gross tumor volume delineations by radiation oncologists, and clinical outcome data from 422 NSCLC patients, 36% were squamous histology and 68% were stage III - to train our model. A Variational Autoencoder (VAE) processed 3D CT volumes, preserving anatomical structures while compressing them into latent features, which were input into a Latent Diffusion Model (LDM) incorporating key clinical characteristics into its latent space. Clinical variables—including age, gender, tumor stage (T, N, M), histology, and survival time were transformed into textual descriptions using a sentence transformer model. These embeddings were integrated into the LDM to condition image generation. To ensure anatomical consistency, ControlNet was used to condition the generation on organ and lesion maps, producing realistic, patient-specific CT images with lesion labels. Synthetic images were validated with automated anatomical reconstruction scoring to ensure fidelity.
Results: The model demonstrated strong alignment between synthetic and real 3D CT scans. The Mean Absolute Error between synthetic and real images was 0.12. For the radiomic feature “Total Energy,” the Kolmogorov-Smirnov test had a statistic of 0.07, and the Kullback-Leibler divergence was 3.81×10^{-11}, indicating no significant differences. Moreover, an automated anatomical annotation score validated that 98.9% of our VAE-generated CT synthetic images were high-quality, scoring 0.8 or higher.
Conclusions: Consistent with our hypothesis, the synthetic 3D CT scans closely resembled real images, paving the way for capturing key disease characteristics. MAGNETICA advances synthetic imaging by bridging AI-driven generation and clinical needs. By augmenting early-stage trials with diverse, clinically relevant synthetic CT scans, this approach has potential to empower analyses that inform on dose selection, safety monitoring, and precision medicine.

#7456 Overcoming ICI resistance with CXCR1/2 antagonism in advanced HCC.

Jeric Hernandez, Kabeer Munjal, Emma Kartalia, Madelena Brancati, Howard L. Li, James Leatherman, Ervin Griffin, Christopher J. Thoburn, Won Jin Ho, Marina Baretti, Daniel J. Zabransky, Elizabeth M. Jaffee, Mark Yarchoan, Mari Nakazawa

Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Despite the recent success of immune checkpoint inhibitor (ICI) based regimens in advanced stage HCC, clinical outcomes remain poor with a median overall survival (OS) of under two years. There is an unmet need to improve responses to, and durability of, ICI based therapy in HCC. IL-8 is a chemokine promoting the attraction of myeloid cells via receptor CXCR1/2 and has been shown to have numerous pro-tumorigenic roles in the tumor immune microenviroment (TiME). Recent work by others has shown that high plasma IL-8 concentration is associated with inferior outcomes for patients receiving ICI therapy across multiple solid tumors, but its relevance to outcomes in patients with HCC is not well characterized.
Methods: We prospectively collected whole blood from patients with HCC prior to initiation of standard of care immunotherapy-based regimens at Johns Hopkins (IRB #00267960). Plasma cytokines were profiled via Luminex bead-based immunoassay. To profile the local effects of IL-8 on the TiME, we performed IHC (anti-IL8, anti-CD3, anti-CD8, and anti-CD206) on resected HCC tumor tissue from systemic treatment naive patients (n=13). Finally, to understand the consequences of IL-8 inhibition via CXCR1/2 antagonism, we utilized a syngeneic murine HCC model (RIL-175 in female C57BL/6) treated with medicated SX-682 (anti-CXCR1/2) alone and in combination with intraperitoneal injections of anti-PD1+anti-VEGF.
Results: The final clinical cohort included 41 patients with advanced HCC. Patients were predominantly male (82.9%) with Barcelona Clinic Liver Cancer (BCLC) stage C disease (75.6%) who received treatment with atezolizumab + bevacizumab (51.2%). In a multivariable Cox model, baseline plasma IL-8 above or equal to median was associated with inferior progression free survival (PFS; hazard ratio [HR] 3.78, p=0.01) and OS (HR 2.32, p=0.07) after controlling for BCLC stage, albumin-bilirubin (ALBI) index, baseline alpha fetoprotein (AFP), regimen type, and baseline concentration of other cytokines with relevance in HCC (IL-6, IL-10, and VEGF-A). IHC on resected tumor specimens revealed negative correlation between IL-8 staining and CD8 cell density (R=-0.2, p=0.041) and positive correlation with CD206 staining (R=0.24, p=0.05). In our murine model, combination treatment with anti-CXCR1/2, anti-PD1, and anti-VEGF was associated with reduction of tumor volume at day 36 compared to control (p<0.001), anti-CXCR1/2 (p=0.006) and anti-PD1+anti-VEGF (p=0.06).
Conclusions: Consistent with prior reports in other solid tumors, high plasma IL-8 concentration was associated with inferior survival on ICI based regimens in HCC. We hypothesize that IL-8 signaling promotes M2 macrophage polarization and in turn results in reduced effector T cell infiltration in the TiME. These results provide rationale for targeting the CXCR1/2 signaling axis in advanced HCC.

#7457 Personalized treatment for hepatocellular carcinoma (HCC) patients.

Jinhee Kim[1], Miseol Son[1], Da Som Kim[1], Yunjeong Oh[1], Naeun Jeon[1], Inhee Roh[2], Jayeon Kim[2], Vinay Tergaonkar[3], Do-Hyun Nam[4], Pierce Kah-Hoes Chow[5], Yong Jae Shin[4]

[1]Innovative Institute for Precision Medicine, Samsung Medical Center, Seoul, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of,[3]Department of Pathology, Yong Loo Lin School of Medicine, NUS, Singapore,[4]Department of Neurosurgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[5]Duke-NUS Medical School, National Cancer Centre, Singapore, Singapore

Predicting drug response is crucial for personalized medicine, especially in cancer research and drug resistance studies. Accurate prediction of drug response, such as the half-maximal inhibitory concentration (IC50) in cell culture models, is vital for establishing personalized treatment models. In particular, patient-derived cell culture models have garnered increasing attention due to their precise prediction of therapeutic responses in targeted drug therapies. However, the prediction of drug response in hepatocellular carcinoma (HCC) patient-derived cells (PDCs) has not been fully explored. In this study, we aimed to predict personalized drug responses to anticancer drugs in HCC. We characterized hepatic stem-like cancer cells using various human HCC cell lines (Hep3B, SkHep1, PLCPRF5, MHCC-LM3, HepG2, Huh-7). Different types of cell culture media were tested to identify HCC-specific conditions. Anticancer agents such as sorafenib and regorafenib were found to increase drug resistance in 3D cell culture models of HCC. A high-throughput screening of 300 media conditions, each with varying growth factor compositions, was conducted, and cell viability was assessed in 17 HCC patient-derived PDC models. Drug resistance profiles varied among HCC patients, with some demonstrating sensitivity to sorafenib and lapatinib, while others showed resistance to tivantinib. Next-generation sequencing (NGS) revealed unique mutations across different HCC patients. In particular, one individualized HCC patient showed the best drug response to lenvatinib and sunitinib. Furthermore, our prediction model revealed that lapatinib exhibited higher drug resistance, mirroring patterns observed in tumor cells associated with regulatory T cells, tissue-resident memory T cells (TRM), and tumor-associated macrophages (TAMs). These findings suggest that our approach offers a promising framework for predicting drug responses in HCC, supporting its application in personalized medicine.

#7459 The anticancer effects of brusatol are mediated by PPAR-γ/ME1-driven glycolysis in intrahepatic cholangiocarcinoma.

Xiaoqing Wang[1], Caiming Xu[2], Kai Luo[3], Yuhan Fang[1], Goel Ajay[4], Guixin Zhang[3]

[1]Institute (College) of Integrative Medicine, Dalian Medical University, DaLian, China,[2]Department of General Surgery, The First Affiliated Hospital of Dalian Medical University, DaLian, China,[3]Department of General Surgery, The Second Affiliated Hospital of Dalian Medical University, DaLian, China,[4]Department of Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of City of Hope, Biomedical Research Center, Monrovia, Monrovia, CA

Background: Intrahepatic cholangiocarcinoma (ICC) is a malignant tumor characterized by its dense fibrotic microenvironment, which is associated with chemotherapy resistance and poor outcome. Hence, developing novel strategies to improve the outcome of ICC is essential. Brusatol, a steroidal molecule isolated from *Brucea javanica*, exhibits various biological activities, including anti-inflammatory and anticancer effects. Although the molecular mechanisms underlying the anti-cancer effects of brusatol in ICC remain unclear, the present study aims to investigate its therapeutic potential in ICC cells.

Methods: We conducted a series of in vitro experiments on human ICC cell lines (HCCC-9810 and HuCCT1) to assess the impact of brusatol on cell proliferation and glycolysis regulation. Transcriptomic sequencing and pathway enrichment analysis was performed to identify specific signaling pathways associated with brusatol treatment in ICC cells. Furthermore, the pathway was further validated through a series of mechanistic studies.

Results: Brusatol significantly inhibited the proliferation, migration, and invasion of ICC cells in a concentration-dependent manner ($p < 0.05$). Glycolytic activity was markedly suppressed by brusatol, as evidenced by a reduction in glucose consumption, ATP production, and lactate secretion in ICC cells. Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) assay confirmed the downregulation of glycolysis-related genes, including GLUT1, HK2, PFK1, and LDHA. RNA sequencing and pathway enrichment analysis suggested that brusatol inhibits the PPAR-γ/ME1 signaling pathway ($p < 0.05$), which likely regulates glycolysis in ICC cells. Subsequently, RT-qPCR and western blotting results corroborated the RNA-seq findings. Interfering with PPAR-γ expression via siRNA or inhibiting the PPAR-γ pathway with Rosiglitazone resulted in a marked reduction in glycolytic activity ($p < 0.01$), further reinforcing the critical role of the PPAR-γ/ME1 signaling axis in the regulation of glycolysis. These findings underscore the potential of brusatol as a therapeutic agent that effectively disrupts glycolytic metabolism in ICC by targeting the PPAR-γ/ME1 pathway.

Conclusion: Our findings provide compelling evidence that the PPAR-γ/ME1 signaling pathway mediates the anti-cancer effects of brusatol, supporting its potential as a safe and effective integrative treatment approach for ICC. This potential offers hope for the development of new and improved treatments for ICC.

#7460 Unveiling NEPC vulnerabilities through single-cell analysis and drug screening.

Ziyu Zeng[1], Yan Liu[1], Aktar Ali[2], Xin Lu[1]

[1]Biological Sciences, University of Notre Dame, Notre Dame, IN,[2]Chemistry and Biochemistry, University of Notre Dame, Notre Dame, IN

Neuroendocrine prostate cancer (NEPC) represents an aggressive, treatment-resistant disease that emerges following androgen deprivation therapy. Despite growing evidence supporting transdifferentiation from luminal cells, the cellular origins and developmental trajectories remain poorly understood. Through comprehensive integration of single-cell RNA sequencing data from 318 human prostate cancer samples and 179 mouse models, analyzing over one million cells, we identified distinct neuroendocrine subpopulations as well as both convergence and diversity among non-neoplastic cells (especially fibroblasts and immune cells). These ongoing efforts are expected to provide an unprecedented comprehensive view of prostate cancer heterogeneity and unravel critical cellular and molecular differences between treatment-induced and de novo NEPC. Using our established dual-luciferase reporter system in NEPC cells, we screened 290 compounds and identified 19 AR-inducing compounds and 44 NEPC-selective compounds. Among these, several promising candidates showed significant therapeutic windows, including compounds targeting inflammatory pathways and epigenetic regulators, with one compound demonstrating 100-fold selectivity for NEPC cells compared to AR-positive prostate cancer cells. Additionally, we found that while NEPC cells retain basic AR signaling machinery, AR expression alone was insufficient to restore sensitivity to AR pathway inhibitors, highlighting the complexity of targeting cellular plasticity in NEPC. This integrative approach combining computational analysis with experimental validation provides new insights into NEPC development and presents novel therapeutic opportunities for this aggressive disease. Our ongoing work aims to validate these findings through cross-species comparative analyses and detailed mechanistic studies.

#7461 Identifying molecular vulnerabilities in rare cancers using a novel graph-based therapeutic discovery model.

Li Zhao[1], Ying Zhu[1], Randy Chu[2], Haifeng Zhu[2], Stephanie T. Schmidt[1], Yuntao Yang[1], Chunjie Jiang[1], Mark Knafl[2], Xingzhi Song[2], Xiaogang Wu[2], Jianhua Zhang[2], Sabitha Prabhakaran[2], Scott Woodman[2], Timothy Heffernan[3], Elizabeth Burton[2], Rare Tumor Initiative Team, Andy Futreal[2], Bissan Al-Lazikani[1]

[1]Genomic Medicine, Institute for Data Science in Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]TRACTION, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Rare cancers, as defined by the WHO criteria with an incidence of fewer than 6 cases per 100,000 people annually, pose significant challenges in diagnosis and treatment due to their low prevalence, heterogeneity, and limited therapeutic options. Patients with rare cancers represent a historically neglected population. Traditional statistical approaches predominantly focus on altered genes, overlooking molecular vulnerabilities that are not explicitly mutated but could still be exploited therapeutically.
Methods: We analyzed a cohort of over 1,000 patients spanning more than 120 distinct rare cancer types (Futreal, A., "Rare cancer patient profiling and engagement", AACR Annual Meeting 2022). By systematically evaluating whole-exome sequencing and RNA sequencing data, we identified genes representing key alterations across the cohort. To uncover both altered and latent molecular vulnerabilities, we applied an integrative, generalizable graph-based AI model explicitly designed for therapeutic discovery. Unlike traditional methods, this model integrates multimodal patient data into a network-based framework, connects genomic alterations with latent dependencies, and identifies hidden signals of molecular vulnerabilities, irrespective of their mutational status. Results were validated using public resources, including the DepMap dataset, without incorporating cell line data as inputs or for model training.
Results: Unsupervised clustering revealed 15 molecular subgroups across the cohort. Some clusters, such as CNS (Brain and Spine), exhibited high molecular homogeneity (e.g., 92% of cluster members), while heterogeneous diagnoses like sarcoma were distributed across four clusters, reflecting distinct molecular subtypes. For each cluster, we constructed networks to predict molecular vulnerabilities. Each subgroup yielded at least five prioritized targets associated with FDA-approved or late-stage investigational drugs. Additionally, we identified novel targets that hold promise for innovative drug discovery, offering new avenues for therapeutic exploration. Validation using DepMap data confirmed significant enrichment of these predicted vulnerabilities. Further integration with PRISM and the Genomics of Drug Sensitivity in Cancer (GDSC) datasets refined and prioritized key therapeutic opportunities.
Conclusions: This study demonstrates the power of a graph-based therapeutic discovery model to identify key molecular vulnerabilities in rare cancers. By uncovering both altered and latent dependencies, we have laid the foundation for safe and effective therapeutic development in these neglected malignancies. This integrative approach provides a scalable framework for advancing precision oncology in rare tumors, addressing a critical unmet need for novel and repurposed therapeutic options.

#7463 A linker platform for antibody drug conjugates (ADCs): expanding the therapeutic window.

David Yi, Wen Zhang, John Liu, Suk Lee, Alice Chen

Baylink Biosciences Inc., Palo Alto, CA

Although ADCs have demonstrated great clinical promise, their therapeutic window remains limited due to the complexity of this drug format. Factors contributing to this narrow safety window include the instability of the linkers, accelerated plasma clearance due to the hydrophobicity of the ADCs, and off-target toxicity caused by nonspecific uptake by non-antigen expression healthy cells, free payload pre-release in the circulation system, low tumor retention due to heterogeneity of tumor antigen level and ADC DAR value By preserving the essential functions of the antibody and the payload, an optimized linker can significantly enhance ADC therapeutic window by increasing hydrophilicity and stability while reducing non-specific endocytosis by non-tumor cells. We have designed a panel of novel linkers focused on improving hydrophilicity and stability of ADC, with a particular emphasis on reducing its off-target endocytosis. A key feature of our linkers is the inclusion of a negative charged side chain and hydrophilic chaperone, which not only minimizes non-specific uptake by non-tumor cells but also greatly enhances its hydrophilicity. The side chain linker with this special architecture allows efficient enzymatic cleavage to ensure rapid payload release intracellularly, and lead to superior bystander cell killing effect than the ADC with GGFG-Dxd linker system. One example exploiting the proprietary linker is Trastuzumab-BL-001-exatecan with a drug-to-antibody ratio (DAR) of 8, demonstrated hydrophilicity comparable to Trastuzumab-GGFG-Dxd (biosimilar) in HIC analysis, with no aggregation detected by analytical SEC. This ADC exhibited excellent stability, maintaining high solubility, and cytotoxicity under stressed conditions. It also resisted deconjugation in the presence of high concentration of N -acetylcysteine and showed exceptional stability in human and mouse plasma. Pharmacokinetic studies in rats indicated favorable pharmacokinetic properties, while efficacy testing in the NCI-N87 tumor model revealed comparable performance to Trastuzumab-GGFG-Dxd. Additionally, BLB-101 ADC, featuring the same linker, was well tolerated in non-human primates following repeated administration. In conclusion, our novel linker designs offer significant advantages, with features that could expand the therapeutic window of current ADCs by improving their stability, reducing off-target effects, increasing bystander activity, and maintaining efficacy. We are also expanding the utility of this class of linkers to enable ubiquitous design of dual-payload-ADC Degrader-Antibody-Conjugates.

#7465 Clustered macrophages cooperate to eliminate tumors via coordinated intrudopodia.

Dennis E. Discher, Lawrence Dooling

University of Pennsylvania, Philadelphia, PA

Macrophages often pervade solid tumors, but observations that macrophage clusters might associate with patient survival have remained largely unexplored. We observe dynamic macrophage clusters in tumors under conditions that maximize cancer cell phagocytosis, and our reductionist approaches to cluster formation reveal pathways and roles for tumor-intrusive pseudopodia. Aggregates form over hours on low-adhesion substrates after ‘M1’ polarization of macrophages with interferons, including Tcell-derived cytokines, and yet clusters prove fluid on timescales of minutes. Clusters also sort from M2 macrophages which are induced by an interleukin and that disperse on the same substrates. M1’s upregulate cell-cell adhesion receptors but suppress actomyosin contractility, and while both pathways contribute to cluster formation, decreased cortical tension was predicted to unleash pseudopodia. Macrophage neighbors in tumor spheroids indeed extend intrusive pseudopodia or ‘intrudopodia’ in between adjacent cancer cell junctions - at least when phagocytosis conditions are maximized, and coordinated intrudopodia help detach and individualize cancer cells for rapid engulfment. Macrophage clusters thereby provide a cooperative advantage for phagocytosis to overcome solid tumor cohesion.

#7466 Advancing tumor characterization and immune phenotyping through multiomic in situ profiling of RNA and proteins.

Thanutra Zhang, Smritee Dadhwal, Joshua Thao, Anatalia Robles, Cheyenne Christopherson, Suyog Pathare, Kristen Pham, Minkyung Park, Hsin Wen Chang, Janine Hensel, Cedric Espenel, Hayato Ikoma, Gabriele Girelli, Paul Ryvkin, Veronica Gonzalez Munoz

10x Genomics, Inc., Pleasanton, CA

Cancer continues to be one of the leading causes of death and financial burden on public health worldwide. Despite advances in detection and treatments, there is still a significant level of uncertainty in predicting how an individual's cancer will respond to treatment due to tumor heterogeneity among different patients and multiple subclones from the same individual. A more comprehensive understanding of cancer cell populations, their molecular interactions, and their microenvironment can offer valuable insights into optimal treatment strategies and patient stratification. This can be achieved through the integrated detection of both RNA and protein targets, enabling a deeper exploration of the molecular mechanisms driving cancer.

Here, we analyzed formalin-fixed, paraffin-embedded (FFPE) human tissue sections from diverse tissue types using spatial multi-omics technologies from 10x Genomics. A new add-on capability enables visualization and analysis of protein expression for key immuno-oncology markers including markers for immune cell typing, cell structure, proliferation, and differentiation, as well as immune checkpoint markers (e.g., PD-1, PD-L1, LAG-3, and VISTA). Simultaneous spatial profiling of 480 genes and 28 proteins, integrated with H&E imaging, provided detailed insights into tissue architecture, tumor origins, immune cell infiltration, and the immune status of the tumor microenvironment.

The combined RNA and protein profiling method is a powerful approach for validating RNA-based findings and providing definitive evidence at the functional biological level. Protein data also offers critical insights into the expression and function of different isoforms that are challenging to discern at the RNA level. For instance, isoforms such as CD45RA and CD45RO, which arise from alternative splicing of the PTPRC gene, are often indistinguishable using RNA profiling alone due to the shared exonic sequences in their transcripts. However, protein-level analysis can differentiate these isoforms and enables a more precise understanding of their distinct roles in the immune response, including the delineation of naïve and memory T-cell subsets.

Furthermore, RNA expression does not always directly correlate with protein levels, underscoring the importance of integrating both data types. For instance, discrepancies between RNA and protein expression were observed for β-catenin, encoded by the CTNNB1 gene, across tissues. β-catenin plays a pivotal role in tumor progression through its dual functions in cell adhesion and signaling. By integrating RNA and protein data, researchers can uncover the complexities of post-transcriptional regulation, subcellular localization, and their combined influence on cancer progression, providing deeper insights into disease mechanisms and potential therapeutic targets.

#7467 Unveiling racial disparities in prostate cancer using an integrative genomic and transcriptomic analysis.

Ahmed Fadiel[1], Abdalla Elbialy[1], Akshay Sood[2], Shang-Jui Wang[2], Peng Wang[2], Anil V. Parwani[2], Gennady Shvets[3], Nagireddy Putluri[4], Jenny Li[2], Xuefeng Liu[2]

[1]University of Chicago, Chicago, IL,[2]Ohio State University, Columbus, OH,[3]Cornell University, Ithaca, NY,[4]Baylor College of Medicine, Houston, TX

Significant racial disparities are found in prostate cancer patients. African American (AA) individuals have a ~64% higher incidence and 2.3 times increased mortality rate compared to Caucasian (CA) counterparts. This study integrates RNA and exome sequencing from prostate cancer tissue in both populations to uncover genetic and transcriptomic differences driving these disparities. We analyzed 52 prostate cancer samples (27 AA, 25 CA) using RNA-seq and exome sequencing. RNA-seq analysis revealed 1003 upregulated and 1589 downregulated genes in AA samples compared to CA samples. Pathway analysis showed enhanced activity in immune response and cellular interactions in AA samples, with notable regulation by histone-associated transcription factors (HIST1H1A, HIST1H1D, and HIST1H1B). X2K analysis identified enrichment of EZH2 and SUZ12 transcription factors, core components of the PRC2 complex, suggesting epigenetic regulation involvement in AA prostate cancer. Exome sequencing identified 5419 mutations unique to AA samples and 1146 unique to CA samples. After filtering race-specific variants, we identified 266 unique mutations affecting 20 genes in AA samples and 415 unique mutations impacting 21 genes in CA samples. Key genes with high-impact mutations in AA samples included TP73 (tumor suppression), XYLB (metabolism), ALDH4A1 (oxidative stress), PTPRB (cellular signaling), and HLA-DRB5 (immune response), potentially contributing to disease progression and therapy response disparities. The distinct molecular profiles identified between AA and CA prostate cancers, particularly in immune response pathways and epigenetic regulation, suggest potential therapeutic targets. These findings highlight the importance of considering genetic and epigenetic variations in developing tailored therapeutic approaches to improve treatment efficacy and reduce mortality rates across diverse populations.

#7468 Androgen response and prognostication in luminal androgen receptor-positive TNBC patients: Defining a novel signature.

Osama Mustafa Younis, Jehad Amer Yasin, Afaf Mansour, Mohammad Abdulla, Dana Alsafadi, Mamoun Ahram

University of Jordan, Amman, Jordan

Triple negative breast cancer (TNBC) is an aggressive form of cancer that has been subclassified into six molecular subtypes. One subtype, the luminal androgen receptor (LAR), which is characterized by over-expression of the androgen receptor (AR), confers the worst survival. In this work, we aimed to elucidate the androgen-regulated expression profile and molecular pathways involved in the survival of LAR patients. Microarray and bioinformatic analyses of gene expression and microRNA (miRNA) levels were performed following treatment of MDA-MB-453 cells with 10 nM dihydrotestosterone (DHT) for 48 hours. Differentially expressed genes were overlapped with GSE245554, which treated MDA-MB-453 cells with a selective androgen receptor degrader. Overlapped genes with opposing expression patterns were considered androgen-dependent. Shortlisted genes were run through univariate, multivariate, and Kaplan-Meier-based signature collection using the METABRIC cohort. Validation was conducted across the KMplotter and TCGA cohorts. Finally, gene set enrichment analysis (GSEA) between high and low signature expression was carried out using enrichr, and miRNA-mRNA interactions were identified through multiMiR. An 11 gene signature involving FASN, CYFIP2, HSD11B2, EPS8, DALRD3, NANS, MGAT4A, LRRN1, SPATA13, SSR1, and GPCPD1 (LARsig) was curated. LARsig was prognostically significant in the TNBC and LAR cohorts using overall survival (OS) and recurrence-free survival (RFS) metrics. In the high LARsig cohort, LAR patients had a median RFS of 40 months, in comparison to 120 months of the low LARsig cohort (HR = 2.37, 95% CI: 1.39-4.04, $p < 0.01$). A Cox regression-based risk score was inserted into a multivariate Cox model with age, grade, and tumor stage which revealed a consistent OS prognostic significance (HR = 2.41, 95% CI: 1.30-4.49, $p < 0.01$). GSEA showed an immunosuppressive environment where downregulated genes had terms like TNF-alpha signaling, IFN-gamma signaling, apoptotic processes, and cellular defense response. Upregulated genes showed terms consistent with stress response such as macromolecule catabolic process, autophagy, cell cycle, macro-autophagy, and negative regulation of apoptosis. Lastly, FASN appears to play the biggest biological role in our signature. Six differentially expressed miRNAs had validated interactions with FASN including miR-20b-3p (Fold Change = 3.36, FDR p value = 0.0132). MiR-20b-3p had positive co-expression (R = 0.19, p = 0.01) with FASN in the TCGA TNBC cohort. Overall, our study presents the first androgen response signature in LAR patients, and elucidates the possible mechanisms underlying patient survival and treatment resistance. Employment of our risk score for patient stratification in future androgen blockade-based trials could be of clinical utility.

#7469 Molecular insights and biology of low-PSA high-risk prostate cancer.

Nabila Zaman[1], Adriana M. Pedraza[2], Sarah Ann King[1], Prathiksha Prabhakaraalva[1], Natasha Kyprianou[1], Ashutosh K. Tewari[2], Goutam Chakraborty[1]

[1]Department of Urology, Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Department of Urology, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Aggressive prostate cancer (PCa) often progresses to castration-resistant disease (CRPC), which becomes incurable and lethal. Although most PCa tumors are initially responsive to androgen deprivation therapy (ADT), duration of this response varies, and relapse typically occurs as disease transitions to CRPC in most patients. Although there have been advancements in molecular genetics and genome sequencing, early identification of lethal versus non-lethal forms of PCa remains difficult. A substantial number of PCa patients are present with high-risk tumors that produce low levels of prostate-specific antigen (PSA) at diagnosis. Research suggests that therapeutic outcomes for these patients may be unfavorable, as they may not respond as effectively to ADT or androgen receptor pathway inhibitors (ARPI). As a result, this high-risk PCa with low PSA secretion may represent an understudied subtype of the disease.

Methods: Between 2013 and 2023, a total of 3619 PCa patients underwent robotic-assisted radical prostatectomy (RARP). Patients were divided into four groups based on PSA levels: very low (<2.5 ng/ml), low (2.6-5.0 ng/ml), medium (5.1-8.0 ng/ml), and high (>8.0 ng/ml). ANOVA and Pearson's chi-squared tests were performed to compare clinical characteristics among these groups. In addition, gene expression profiles from TCGA PCa cohort were analyzed to assess differential PSA/KLK3 mRNA expression within cancer cells. To further investigate, single-cell clones from LNCaP parental population were selected to study molecular characteristics of tumor cells with low PSA expression.

Results: We observed that patients with high-risk PCa and very low PSA levels (<2.5 ng/ml) experienced higher rates of biochemical recurrence than those with high-grade cancer who had PSA levels above 2.5 ng/ml. Furthermore, we observed a significantly higher occurrence of seminal vesicle invasion (p=1.058e-05) and neurovascular invasion (p=0.0047) in both very low and high PSA groups compared to other two groups. Notably, very low PSA group showed a higher rate of lymph node invasion (p=0.00095) than other three groups. Transcriptomic analysis of TCGA cohort showed genes upregulated in very low PSA group compared to high PSA group, were significantly enriched (p<0.001) in metastatic castration-resistant prostate cancer (mCRPC). Furthermore, our study of LNCaP-derived naturally occurring low-PSA clones demonstrated enhanced migratory potential and higher expression of EMT markers compared to parental LNCaP cells, which express high levels of PSA.

Conclusions: Our study reveals a distinct subtype of localized PCa characterized by low PSA levels while still displaying high-risk features. This subtype is particularly invasive and linked to potentially poor outcomes, highlighting the necessity for further investigation to gain deeper understanding of its aggressive biology and characteristics that remain largely unexplored.

#7470 Extensive genome sequencing on tissue vs large ctDNA panel: what clinical impact?.

Marie Morfouace, Etienne Rouleau, Marc Deloger, Ludovic Lacroix, Voreak Suybeng, Sofiane Taleb, Claudio Nicotra, Maud Ngo Camus, Fabrice Barlesi, Fabrice Andre, Antoine Italiano, Benjamin Besse, Arnaud Bayle

Gustave Roussy, Villejuif, France

Background: Molecular profiling is critical for personalizing cancer treatments, with approaches spanning from tissue DNA sequencing to liquid biopsy analysis of circulating tumor DNA (ctDNA). While both techniques provide valuable insights, the comparative clinical impact of tissue-based genomic profiling versus ctDNA-based profiling in tailoring treatments remains insufficiently explored.
Methods: We are investigating the comparison between wide genomic sequencing of tissue and ctDNA profiling with a large panel to evaluate their ability to guide treatment decisions in cancer patients. At Gustave Roussy, Comprehensive genomic profiling (CGP) on ctDNA is routinely used to guide treatment selection for patients with advanced metastatic cancers, in therapy failure after 1st line. In the same patient population, Extensive Genome Sequencing (EGS: WGS, WES, WTS) can also be proposed, from fresh frozen material. To assess the relevance of these approaches, we identified a cohort of patients from Gustave Roussy with prescription of both EGS on fresh frozen tumor tissue and CGP on ctDNA, (Foundation One Liquid CDx Assay, 324 genes, tumor mutational burden [TMB], microsatellite instability) and were discussed in Gustave Roussy's molecular tumor board. This study will evaluate and compare the capacity of these methods to tailor treatment strategies in this population
Results: Between April 2021 and Oct 2024, 202 patients with both EGS and CGP were identified. Failure rate of EGS on tissue was 18.8% (due to lack of sufficient tissue for 36 patients and non-contributive for 2 patients). Conversely, failure rate of CGP on ctDNA was 8.4% (non-contributive for 17 patients). Out of the 147 evaluable patients, main tumor types were HNSCC (n=32, 22%), endocrine tumors (n=26, 18%), gynecological tumors (n=16, 11%), sarcoma (n=13, 9%) and pancreatic tumors (n=14, 9%). The median turnaround time between reception of the sample and results from the molecular analysis was 10 [5:37] days for CGP versus 95 [25:724] days for EGS. We compared the therapeutic recommendations provided with both analyses, after discussion during a molecular tumor board. Independently of the time between tissue sampling and liquid biopsy (median: 111 days), treatment recommendations were concordant in 83% of cases. For 13 cases (8.8%), alterations were identified only on tissue (deletion (n=4), mutation (n=6), genomic signature (n=3)).
Conclusion: Our analysis on a small cohort of patient shows that EGS and CGP have a high concordance rate in terms of therapeutic recommendations when both are contributive. Given organizational barriers of EGS on tissue (cost, turnaround time, difficulty to obtain tumor material of sufficient quality), a sequential strategy could be interesting.

#7471 Mutational profiles of pancreatic cancer patients from Eastern Asia using somatic exome sequencing.

Jacquelyn Reuther[1], Taro Shibuki[2], Megan Hawley[1], Hideaki Bando[3], Keir Violaceae[1], Makoto Ueno[4], Kenji Ikezawa[5], Takuji Okusaka[6], Teiichi Sugiura[7], Keiko Kamei[8], Yoshito Komatsu[9], Michiaki Unno[10], Hiroki Yukami[11], Takuji Iwashita[12], Emily Westheimer[1], Kumiko Umemoto[13], Robert Daber[1], Takayuki Yoshino[14], **Jianhua Zhao**[1], Masafumi Ikeda[2]

[1]Labcorp Genetics, Iselin, NJ,[2]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan,[3]Department for the Promotion of Drug and Diagnostic Dev., Division of Drug and Diagnostic Dev., National Cancer Center Hospital East, Kashiwa, Japan,[4]Department of Gastroenterology, Kanagawa Cancer Center, Yokohama, Japan,[5]Department of Hepatobiliary and Pancreatic Oncology, Osaka International Cancer Institute, Osaka, Japan,[6]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan,[7]Division of Hepato-Biliary-Pancreatic Surgery, Shizuoka Cancer Center Hospital, Shizuoka, Japan,[8]Department of Surgery, Kindai University Faculty of Medicine, Osakasayama, Japan,[9]Division of Cancer Chemotherapy, Hokkaido University Hospital, Sapporo, Japan,[10]Department of Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan,[11]Cancer Chemotherapy Center, Osaka Medical and Pharmaceutical University, Takatsuki, Japan,[12]First Department of Internal Medicine, Gifu University Hospital, Gifu, Japan,[13]Department of Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan,[14]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Introduction: Pancreatic adenocarcinoma (PC) is one of the most lethal diseases. The incidence of PC is rising in the Asia-Pacific population, with some of the highest rates in Japan. As such, the utilization of molecular testing has increased, especially for advanced disease, to identify molecular drivers and therapeutic targets.
Methods: 146 patients from Japan (ages 45-81) who were diagnosed with PC underwent exome-based, tumor molecular profiling (TMP) (Labcorp Genetics Inc). 96/146 (65.8%) patients had unresectable tumors. Results were correlated with clinical information. Variants were interpreted according to the AMP/ASCO/CAP guidelines. Signaling pathway analysis was conducted using the Reactome database, with significance determined by binomial test with corrected p-values (FDR; Benjamini-Hochberg procedure). Fisher's exact test was utilized for statistical assessment of clinical parameters.
Results: TMP detected 404 Tier 1/2 somatic variants in 135 (92.5%) patients. Genes known to be frequently mutated in PC were identified in the cohort: KRAS (122/146; 83.6%), TP53 (108/146; 74.0%), SMAD4 (35/146; 24.0%) and CDKN2A (25/146; 17.1%). A potential enrichment of hotspot U2AF1 (5/146; 3.4%) codon 34 mutations was identified, compared to published frequencies in PC in cancer databases (1%) that trended toward statistical significance (p=0.07). Pathway analysis identified a statistically significant enrichment of mutations in several kinase signaling pathways including PI3K/AKT (p-value: 2.1e-11; FDR: 9.8e-09), ERBB2 (p-value: 5.3e-07; FDR: 1.2e-04), and RAS/MAPK (p-value: 4.2e-06; FDR: 5.5e-04). Mutations associated with homologous recombination or mismatch repair pathways were statistically associated with early age of onset (<50 years of age; p= 0.036). Hotspot KRAS mutations were associated with unresectability (p=0.002), late tumor stage (stages 3-4, p=0.026), and metastasis (p=0.010).
Conclusion: Alterations enriched in targetable pathways were identified in the patient cohort in addition to statistically significant findings associated with more aggressive PC. TMP testing can aid in the identification of alterations that are pertinent to the identification of relevant therapies and clinical trials as well as identify PC patients with potentially more aggressive disease.

#7472 Metabolic mechanisms underlying late recurrence in hormone receptor positive breast cancer.

Bryce Ordway, Isabella Vianna, Johannes Kreuzer, Wilhelm Haas, Dennis Sgroi, Leif W. Ellisen

Mass General Cancer Center, Boston, MA

Hormone receptor positive (HR+) breast tumors are anomalous in their tendency for late recurrence. In the clinic, an mRNA ratio of HOXB13 to IL17RB (H/I) from the primary tumor is used to determine a patient's risk for late recurrence and benefit of extended adjuvant hormonal therapy. Little is known about the tie between the H/I ratio and the biology leading to late recurrence. Herein we present data from primary breast tumors, *in silico* analyses and cell-based models that support our hypothesis that dysregulation of one-carbon metabolism and the SAM cycle is linked to the H/I signature and contributes to epithelial-mesenchymal plasticity (EMP), which has been shown to mediate the late recurring phenotype. We conducted proteomics analysis of 86 HR+ breast tumors and identified Choline Dehydrogenase (CHDH) as the most significant differentially expressed protein between HOXB13 high and low groups; with CHDH being associated with HOXB13 low tumors. Notably, RNA expression of CHDH is highly correlated with expression of IL17RB due to a shared promoter region. These links with both HOXB13 and IL17RB led us to hypothesize that CHDH contributes to the phenotype of late recurrence. To determine if signatures of differences in CHDH function could be seen in H/I low and high cell lines we used RNA expression and metabolomics data from the DepMap portal. Betaine, a standard readout metabolite for CHDH function, was significantly elevated in H/I low cell lines, consistent with our previous observations. We also observed that 1-methylnicotinamide, produced by Nicotinamide N-methyltransferase (NNMT), was identified as the metabolite most upregulated in H/I high cell lines. CHDH and NNMT both contribute to one-carbon metabolism in the SAM cycle, with opposing influences. Previous studies have demonstrated that dormancy and late recurrence in the context of HR+ breast cancer is driven by epithelial-mesenchymal plasticity (EMP). To test the association between SAM flux and differing epithelial and mesenchymal phenotypes, we created a CHDH:NNMT score and correlated this against epithelial-mesenchymal phenotypes in patient tumors from the TCGA Firehouse Legacy dataset. A significant association was found in all tumor types, with a conglomerate p-value across tumor types of $<10^{-300}$. We also observed high SAM levels in tumors associated with markers of an epithelial-like state. We then demonstrated that shRNA knockdown of NNMT is sufficient to increase expression of epithelial proteins in cell lines displaying a mesenchymal phenotype. We will next test the ability of CHDH and NNMT to alter EMP in breast cancer cells and identify EMP associated metabolic pathways. In total, we have demonstrated that metabolic enzymes regulating SAM flux are highly associated with late-recurrence in HR+ breast tumors. Ongoing experiments will assess how metabolism controls epithelial-mesenchymal plasticity that may mediate the phenotype.

#7474 Comprehensive multi-omics characterization of gastric cancers with proteogenomic insights.

Lindsey K. Olsen[1], Yuefan Wang[2], Hui Zhang[2], Bing Zhang[1], Clinical Proteomic Tumor Analysis Consortium (CPTAC)

[1]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX,[2]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

Gastric cancers are one of the leading causes of cancer-related mortality worldwide. Characterized by high tumor heterogeneity, the treatment of gastric cancers remains challenging. Prior attempts to elucidate the tumor heterogeneity of gastric cancers have included subtyping it into differing clinical and molecular subtypes. For example, the main histological type, adenocarcinoma, has intestinal and diffuse subtypes. At the genomic level, gastric cancers are classified as either Epstein-Barr virus (EBV), microsatellite instability (MSI), chromosomal instability (CIN), or genomically stable (GS). Transcriptomic subtyping has further revealed subtype and clinical prognosis relationships: MSI, microsatellite-stable microsatellite stable with epithelial-to-mesenchymal transition phenotype (MSS/EMT) (poor prognosis), and MSS/TP53 active or inactive (intermediate prognosis). However, these subtypes are still poorly understood at the functional level. To address this gap, the Clinical Proteomics Tumor Analysis Consortium (CPTAC) conducted a comprehensive multi-omic characterization of 159 gastric tumors and 31 normal adjacent tissues. Moving beyond conventional genomic and transcriptomic analyses, we employed a novel multi-omics approach that encompasses the proteome, phosphoproteome, glycoproteome, metabolome, and additional “omes” such as ubiquitinome, acetylome, and protein-protein interactome. In addition, to better understand the unique role of the microbiota in gastric cancers, we integrated the entire microbiome genome and transcriptome data into the whole analysis. By combining these 12 layers of data and microbiome analysis together, our study provides unprecedented proteogenomic insights, advancing our understanding of the molecular mechanisms of gastric cancer oncogenesis and aiding in the development of novel precision oncologist therapies. In this study, we classified gastric cancers by molecular and clinical subtypes, revealing both shared and subtype-specific biological features at the multi-omic level. We highlight the associations of post-translational modification (PTM) alterations to immune and metabolic pathways. Proteogenomic analysis uncovered promising new surface targets and potential biomarkers for existing targeted therapies. Further in-depth analyses of PTMs and protein-protein interactions have uncovered insights into intracellular signaling pathways and PTM crosstalk with therapeutic potential. Additionally, the impact of microbiome on immune responses and PTM patterns underscores the interplay between microbiota and cancer phenotypes, providing valuable insights for advancing precision medicine in gastric cancers. Overall, our study provides the most comprehensive multi-omics atlas for gastric cancers, offering deep insights into its cancer biology and molecular heterogeneity.

#7475 A comprehensive single-cell atlas of gastric cancer reveals malignant cell state dynamics and plasticity in tumor progression and metastasis.

Enyu Dai, Yanshuo Chu, Yang Liu, Ruiping Wang, Yibo Dai, Jaffer A. Ajani, Linghua Wang

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Gastric cancer exhibits diverse malignant cell states that contribute to intratumor heterogeneity (ITH), a fundamental factor that drive tumor progression, metastasis, and treatment resistance. While previous single-cell RNA sequencing (scRNA-seq) studies have provided novel insights into ITH in gastric cancer, they are often constrained by small sample sizes and limited transcriptional coverage.
Methods: In this study, we curated, annotated, and integrated scRNA-seq datasets from 21 studies, comprising 626 samples from 316 individuals, including healthy donors and patients with precancerous lesions and gastric cancer. Within the epithelial compartment, malignant and non-malignant cells were distinguished using three complementary computational methods. To refine malignant cell subclustering, we developed a novel approach that incorporates patient-specific copy number variations, minimizing the impact of inter-patient heterogeneity on clustering analysis.
Results: Following rigorous quality control and data integration, unsupervised clustering analysis classified 2,088,266 high-quality cells into six major cell types or compartments: B cells, T cells, innate lymphoid cells, myeloid cells, stromal cells, and epithelial cells. Within the epithelial cell compartment, we identified 12 distinct malignant cell states characterized by unique expression profiles and phenotypic characteristics, such as cell proliferation capacity and lineage-specific plasticity. These cancer cell states exhibited substantial variation in the activity of hallmark cancer signaling pathways, with their presence and composition closely linked to tumor aggressiveness and clinical outcomes. Proliferative cancer cells and translationally active cancer cells predominated in intermediate tumor stages, dormant cells were prevalent in advanced stages, and epithelial-mesenchymal transition (EMT) states were enriched in metastatic tumors. Additionally, we identified a malignant cell population with high expression of intestinal lineage markers in patients with signet ring cell carcinoma, and these findings were validated using spatial transcriptomic.
Conclusions: This study presents a comprehensive single-cell transcriptomic atlas of gastric cancer epithelial cells, providing valuable insights into transcriptional ITH. Our findings define distinct malignant cell states, elucidate their dynamics, and highlight their clinical significance, establishing a framework for understanding how these states contribute to disease progression and metastasis.

#7476 Characterizing the molecular drivers of terminal duct lobular unit involution and associations with breast cancer in African American women.

Jeri Danielle Hughes[1], Angel Hokulani Pajimola[1], Brittny Davis-Lynn[2], Sharon Fan[2], Mustapha Abubakar[2], Renata Cora[3], Alexandra Harris[2], Gretchen Gierach[2], Brittany Jenkins[1]

[1]Biochemistry & Molecular Biology, Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[2]National Cancer Institute, Bethesda, MD,[3]Division of Cancer Epidemiology and Genetics, National Instiutes of Health, Bethesda, MD

Background: Terminal duct lobular units (TDLUs) are the functional units of the mammary gland, consisting of a terminal duct and the surrounding lobular tissue. These structures are key in the process of milk production and secretion, particularly in women of reproductive age. TDLUs are important in the context of breast pathology, as they can be sites of various benign and malignant changes, such as fibroadenomas or breast cancer. TDLU involution refers to the process of regression (or shrinking) of TDLUs as women age, particularly after menopause. Incomplete or delayed involution may be associated with an increased risk of breast cancer, as persistent epithelial tissue may remain susceptible to malignant changes. Differences in TDLU involution have been observed in the context of self-reported race, generating a gap in knowledge regarding the differential molecular regulation of TDLU involution by race and genetic ancestry. Our work aims to identify driver genes and pathways that regulate this process, as well as understand how these pathways are epigenetically modified, and possibly differ by race.
Methods: Normal breast tissue from voluntary research biopsies were obtained from 94 pre-menopausal women (47 African American, 47 European American) between 2009-2019 from the Komen Tissue Bank. We performed both bulk RNAseq analyses and the EPIC850K methylation array to determine differences in cancer- and immune-related pathways associated with high and low TDLU counts (counts per mm^2) stratified by self-reported race.

Results: In African American women, 56 genes showed significant changes in gene expression associated with differential expression by TDLU counts per mm^2, indicating differences in TDLU involution. Of these genes, LMOD1 and MFGE8 were associated with TDLU count (high/low) and were more significantly differentially expressed among African American women than European American women. LMOD1 is an actin-regulating protein that regulates cell shape, motility, and cytoskeleton remodeling. MFGE8 is a milk-fat globule epithelial growth factor that also mediates phagocytosis of apoptotic cells. Ingenuity Pathway Analysis revealed LMOD1 and MFGE8 interact via androgen receptor signaling in breast cancer. Further studies will investigate epigenetic modifications in these genes and those related directly to TDLU involution.
Conclusions: Studying TDLU involution is crucial for understanding both the normal aging process of the breast and its implications for breast cancer risk. Understanding the molecular mechanisms behind TDLU involution, such as immune regulation and genetic factors, can help identify individuals at higher risk for breast cancer and inform preventive strategies.

#7477 Conquering overtreatment of ductal carcinoma in situ through integrative team science.

Jelle Wesseling[1], Proteeti Bhattacharjee[2], Esther H. Lips[2], Elinor J. Sawyer[3], E. Shelley Hwang[4], Alastair M. Thompson[5], Grand Challenge PRECISION Consortium[6]

[1]Department of Pathology, Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands,[2]Division of Molecular Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands,[3]School of Cancer and Pharmaceutical Sciences, Faculty of Life Sciences and Medicine, Guy's Cancer Centre, King's College London, London, United Kingdom,[4]Department of Surgery, Duke University School of Medicine, Durham, NC,[5]Department of Surgery, Dan L Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX,[6]Netherlands Cancer Institute, Amsterdam, Netherlands

Ductal carcinoma in situ (DCIS), often misclassified as early-stage breast cancer, rarely progresses to invasive disease. Yet, the inability to distinguish between indolent and aggressive DCIS leads to widespread overtreatment, burdening thousands of women globally. Addressing this, the PRECISION team, under the Cancer Grand Challenges initiative, has achieved remarkable advancements, driving a paradigm shift in DCIS management. PRECISION exemplifies next-level team science, merging expertise from 10 institutions across the USA, UK, and the Netherlands. Spanning disciplines such as epidemiology, molecular biology, AI, pathology, clinical expertise, health outcomes, and patient advocacy, the team's interdisciplinary approach enabled transformative breakthroughs.
Key achievements include:

1. Understanding DCIS Biology: Using innovative patient-derived DCIS-MIND models and single-cell genomic techniques, PRECISION revealed that genetic changes alone do not dictate progression. These findings challenge long-held assumptions, emphasizing the need for comprehensive approaches to assess risk.
2. Risk Stratification Methodologies: Novel biomarkers, AI-driven morphometric analyses, and an RNA-seq classifier reliably differentiate high-risk from low-risk DCIS. For example, the RNA-seq classifier identified low-risk DCIS with a 98% negative predictive value, paving the way for treatment de-escalation.
3. Testing Active Surveillance: Clinical trials embedded in PRECISION' (COMET, LORD, LORIS) explored the safety of active surveillance, potentially replacing invasive treatments for low-risk DCIS with cost-effective outcomes. Patient engagement and shared decision-making tools further enhance personalized care strategies.

PRECISION's success stems from dynamic international collaborations and integration of advanced technologies. Its findings not only redefine DCIS management but also establish a blueprint for addressing other low-risk malignancies. By focusing on biology-based, patient-centered solutions, PRECISION ensures that treatment aligns with the true nature of the disease, paving the path to transform DCIS care worldwide. To do so, the team aims to develop dynamic risk forecasting techniques, powered by evolutionary AI, drawing inspiration from geoscience methodologies. The team also plans to establish a Global Virtual DCIS Monitoring Clinic, enabling worldwide participation. This initiative will support personalized care, foster shared decision-making, and minimize clinic visits through standardized data collection and seamless online follow-ups.

#7478 Lung cancer gene regulatory networks reflect smoking history and age-related metabolic pathway alterations.

Camila Lopes-Ramos[1], Enakshi Saha[2], Jeong Yun[3], Craig Hersh[3], Edwin Silverman[3], Dawn DeMeo[3], John Quackenbush[4], Kimberly Glass[1]

[1]Harvard T.H. Chan School of Public Health; Brigham and Women's Hospital; Harvard Medical School, Boston, MA,[2]University of South Carolina, Columbia, SC,[3]Brigham and Women's Hospital; Harvard Medical School, Boston, MA,[4]Harvard T.H. Chan School of Public Health, Boston, MA

Background: The rising incidence of lung cancer among individuals without a history of smoking highlights the need to explore biological mechanisms underlying this phenomenon. Our study aims to identify gene regulatory mechanisms that drive lung cancer risk among never-smokers by analyzing how gene regulatory networks differ between individuals with and without lung cancer, depending on their smoking history.
Methods: We used RNA-Seq data from the Lung Tissue Research Consortium (LTRC) collected via TOPMed, comprising non-cancerous lung tissue samples from 344 individuals with non-small cell carcinoma and 329 lung tissue samples from individuals without cancer. Across all, 18% reported no history of smoking. We ran differential gene expression analysis by voom, adjusting for age, sex, COPD status, and examining statistical interactions between smoking (never/former) and cancer status. We analyzed sample-specific transcription factor-gene regulatory networks generated by PANDA-LIONESS. We used linear regression to evaluate the association between gene targeting score (measured by gene indegree) and the interaction between smoking and cancer status. We ran gene set enrichment analysis with genes ranked by the corresponding smoking by cancer interaction coefficients.
Results: Differential expression analysis of lung tissues from individuals with and without cancer showed that genes overexpressed in cancer are enriched for canonical cancer pathways, such as p53, MAPK, and WNT signaling pathways (FDR<0.05). We found a significant interaction between cancer and smoking status, indicating these cancer-related pathways had higher enrichment in former-smokers compared to never smokers. Gene regulatory network analysis indicated that these differential expression patterns are possibly driven by increased transcriptional targeting of these cancer-related pathways. Among never-smokers, individuals with cancer showed higher targeting of metabolic pathways (e.g., fructose and mannose, glutathione, phenylalanine, histidine, arginine, and proline metabolism) compared to lung tissue from individuals without cancer (FDR<0.05), highlighting a possible role of metabolic pathways in tumor development, uniquely among never-smokers. A negative correlation between metabolic pathway targeting scores and age was observed exclusively in individuals with cancer without a history of smoking (Mean Pearson R=-0.24).
Conclusion: Our findings reveal transcriptional targeting differences in lung cancer by smoking history. Among individuals without a history of smoking, the increased targeting of metabolic pathways in cancer, which is pronounced in younger compared to older individuals, may contribute to the higher risk of early-onset lung cancer among never-smokers, offering new avenues for understanding and addressing the disease in populations without a history of smoking.

#7479 Single-cell OncoTreat: Novel therapeutic candidates by high resolution inference and validation of drug sensitivities in heterogeneous cholangiocarcinoma tumors.

A. Obradovic[1], L. Tomassoni[1], D. You[2], C. Drake[1], F. Dela Cruz[1], A. Kung[2], A. Califano[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Memorial Sloane Kettering, New York, NY

Cholangiocarcinoma is an aggressive biliary adenocarcinoma with limited treatment options. Stromal infiltration and intratumoral heterogeneity in this tumor type prevents identification of actionable dependencies from bulk-tissue profiles. While cholangiocarcinoma illustrates these challenges, they are common across many other aggressive tumors.To address these challenges, we introduce a single-cell RNA-Sequencing (scRNA-Seq) framework for prioritization of drugs to treat heterogeneous tumor cell subpopulations. Single-cell analyses can bypass limitations of sample size in a precision medicine approach by providing large tumor cell “cohorts” even from individual patients, with the advantage that cell subpopulations can be effectively distinguished. Unfortunately, >80% of genes in each cell profiled by scRNA-Seq are typically undetectable, limiting discoverability of therapeutic targets and drug sensitivities. The VIPER algorithm addresses this by inferring the *transcriptional activity* of a protein from expression of its downstream target genes. By then identifying aberrantly activated proteins, each cell can be matched to an empiric database of cell line drug perturbation RNA-Seq, ranking drugs which empirically inhibit the proteins aberrantly activated in each cell. We refer to this approach as single-cell OncoTreat.Analysis of tumor cells across six patients by this approach has revealed three distinct sub-phenotypes of cholangiocarcinoma cells, with conserved proteomic signatures, and distinct predicted drug sensitivities. A seventh patient recapitulated these phenotypes, with drug predictions validated in a low-passage, patient-derived xenograft (PDX) model. The top-ranked drug by integrated analysis of all tumor cells was plicamycin, which at sub-cluster level only two of three clusters were predicted to respond to. Conversely, dacinostat was inferred to be active against all three tumor-cell sub-phenotypes. Tumor growth studies in PDX demonstrated growth rate control with both plicamycin and dacinostat, but much improved survival time with dacinostat, outperforming gemcitabine + cisplatin standard of care. Post-treatment scRNA-Seq confirmed predicted subpopulation-specific effects, such that dacinostat depleted all three tumor sub-phenotypes, while plicamycin depleted only the two predicted, allowing the third to reconstitute a treatment-resistant tumor. To our knowledge, this is the first report of dacinostat as an HDAC inhibitor effective in cholangiocarcinoma treatment, *in vivo*. Ultimately, this approach suggests promising candidates for follow-up trials in cholangiocarcinoma, and is highly generalizable to elucidate complementary dependencies of other aggressive, heterogeneous tumors.

#7480 Spatial Groups provide a pan-tumor spatial transcriptomic biomarker of immunotherapy response.

Vivek Behera[1], Hannah Giba[2], Ue-Yu Pen[2], Anna Di Lello[1], Benjamin A. Doran[2], Alessandra Esposito[1], Apameh Pezeshk[1], Christine Bestvina[1], Justin P. Kline[1], Marina C. Garassino[1], Arjun S. Raman[2]

[1]Department of Medicine, Section of Hematology/Oncology, University of Chicago, Chicago, IL,[2]Department of Pathology, Duchossois Family Institute, University of Chicago, Chicago, IL

Immune checkpoint blockade (ICB) has transformed cancer therapy and is now approved in every type of cancer, yet it remains difficult to identify the ~ 20% of patients that will benefit from such therapy. Explainable models that predict ICB response can potentially spare ‘responders’ from toxic chemotherapies while identifying alternative options for ‘non-responders’. The only widely approved ICB biomarker of response, PD-L1, treats TME cells as individual components and is only weakly predictive of outcomes. Recent studies have suggested that biomarkers built on cell-to-cell spatial proximity, such as tumor cell to CD8+ T cell distance, can improve upon PD-L1 in predicting ICB efficacy. Yet, there is a lack of generalized approaches for identifying tumor spatial biology relationships relevant to ICB response, especially considering the wealth of information generated by high-resolution spatial biology techniques. Our approach was (1) to integrate spatial transcriptomics datasets from 96 tumors across twelve tumor types and (2) to apply statistical covariation approaches to identify organizing principles of spatial biology that would facilitate the comparison of these datasets. The basis of this approach is our identification of a conserved unit of pan-tumor spatial organization that we termed ‘Spatial Groups’. Spatial Groups (SGs) are multi-cellular units demonstrating coordinated transcriptional programs contained within spatial domains ranging in size from tens of microns (dozens of cells) to mm-scale (large regions of a tumor). SGs are hierarchically organized such that large-scale SGs exert contextual field effects on their nested small-scale SGs. For example, we found that T cell presence in large-scale SGs impacted metabolic pathway shifts occurring within nested medium-scale SGs, which in turn impacted cell adhesion programs within nested small-scale SGs. We found that SGs revealed immune-related spatial biology patterns that we hypothesized would serve as a genome-wide spatial biomarker of ICB response. To test this idea, we performed a retrospective study of 16 patients with metastatic non-small cell lung cancer treated with ICB or chemotherapy-ICB in the frontline setting. Unlike PD-L1 status, our SG-derived biomarker was highly significant in predicting progression-free survival after therapy initiation. Additionally, analysis of SGs in non-responder patients provided insights into patient-specific spatial biology architectures limiting ICB efficacy. In summary, our discovery of Spatial Groups provides a general framework for using spatial biology to identify pan-tumor ICB response.

#7481 Genomic aberration-derived signature in lung adenocarcinoma improves patient prognosis and therapy stratification.

Xiang Wang[1], Zijian Zhang[1], Jian-Rong Li[1], Jianjun Zhang[2], Chao Cheng[1]

[1]ICTR, Baylor College of Medicine, Houston, TX,[2]Department of Thoracic/Head and Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX

Background: Lung cancer is the leading cause of cancer-related mortality worldwide, with a poor prognosis due to late-stage diagnoses. While advances in targeted therapies and immune checkpoint blockade therapies (ICBT) have improved survival outcomes for subsets of non-small cell lung cancer (NSCLC) patients, the clinical heterogeneity and variable response rates to these therapies remain significant challenges in precision medicine. Identifying robust biomarkers for stratifying patients and tailoring personalized treatments remains a critical unmet need.
Methods: We developed the Genomic Aberration-derived Signature for Patient Stratification (GASPS), a novel statistical framework integrating genomic and transcriptomic data. GASPS models the effects of driver genomic aberrations—mutations, amplifications, and deletions—on gene expression to define actionable gene signatures. Using lung adenocarcinoma (LUAD) data from The Cancer Genome Atlas (TCGA), we identified and validated driver gene signatures across independent NSCLC datasets, including TRACERx. The clinical relevance of these signatures was assessed for their ability to predict prognosis and treatment response.
Results: GASPS defined 38 driver genomic aberration signatures, which consistently outperformed genomic aberration status in predicting patient outcomes. Hierarchical clustering of signature scores stratified patients into subgroups with distinct survival patterns. Notably, the EGFR-Mut and EGFR-Amp signatures demonstrated contrasting prognostic and predictive associations: EGFR-Mut was linked to favorable prognosis and chemotherapy sensitivity, whereas EGFR-Amp was associated with poor prognosis and increased tumor proliferation. The STK11-Mut signature emerged as a robust biomarker for resistance to ICBT, correlating with reduced immune infiltration and a "cold" tumor microenvironment. Validation across multiple datasets confirmed the generalizability of these findings.
Conclusion: The GASPS framework provides a powerful tool for integrating genomic and transcriptomic data to derive clinically actionable gene signatures. These signatures offer superior prognostic and predictive capabilities, enabling better patient stratification and advancing personalized treatment strategies for NSCLC. While demonstrated in LUAD, this framework is adaptable to other cancer types, paving the way for broader applications in precision oncology.

#7482 Mapping the temporal landscape of breast cancer using epigenetic entropy.

Daniel L. Monyak[1], Shannon T. Holloway[1], Graham Gumbert[1], Lars J. Grimm[1], Shelley Hwang[1], Jeffrey R. Marks[1], Darryl Shibata[2], **Marc D. Ryser**[1]

[1]Duke University School of Medicine, Durham, NC,[2]University of Southern California, Los Angeles, CA

Background: The age of a newly diagnosed breast cancer encodes valuable etiologic and prognostic information, yet it is considered a known unknown. Here we develop an entropy-based epigenetic clock that measures the age of individual breast cancers and quantifies the evolutionary-ecological forces that modulate growth.
Methods: Using 450K methylation array data from 634 invasive breast cancers and 79 normal breast tissue samples, we identified 500 fluctuating CpG (fCpG) sites whose methylation states exhibit unbiased oscillations. After external validation of the fCpG set in an independent cohort (n=146), we derived an entropy-based epigenetic clock index (ECI) as a measure of tumor mitotic age. We correlated the ECI with tumor features and gene expression (GSEA) and quantified its relationship with the tumor microenvironment (CIBERSORTx). We validated the ECI in 40 patients with paired primary-metastasis samples and used mathematical models to estimate the calendar ages of individual tumors.
Results: Compared to older tumors (higher ECI), younger tumors (lower ECI) had increased proliferation, higher grade, and larger size. Younger tumor age was strongly associated with the fraction of genome altered (R, -0.56; P<0.0001). Luminal A cancers were older compared to luminal B and basal cancers (P<0.001 each, Wilcoxon). Mitotically younger tumors were enriched for gene pathways related to proliferation and cell cycle control, whereas older tumors were enriched for immune pathways and immune-related signaling pathways. The extent of immune infiltration, and T-cell infiltration in particular, increased with mitotic tumor age. These findings suggest that a tumor's effective growth rate is shaped by the competition between intrinsic growth potential and microenvironmental pressures (e.g., immune surveillance). In patients with paired primary-metastasis samples, the 500 fCpGs were strongly correlated within but not between patients (median R, 0.73 vs. 0.08; P<.0001, Wilcoxon). In 36/40 patients, the metastasis was younger than the primary, providing support for the interpretation of the ECI as a measure of tumor age. Anchoring the median age at a consensus estimate of 3 years, the inferred calendar ages among 413 cancers ranged from 0.2 to 35.2 years (IQR: 1.5-5.6 years). There were notable differences in median tumor ages by molecular subtype, ranging from 1.0 years in basal cancers to 6.5 years in luminal A cancers.
Conclusions: This entropy-based epigenetic clock measures tumor growth on a scale of months to years, which contrasts with existing clocks that track longer timescales associated with biologic tissue aging and cancer risk. By delineating old and stable from young and aggressive tumors, the clock has potential applications in risk stratification and early detection. Although developed for breast cancer, the clock provides a scalable technology to characterize the broader temporal landscape of solid tumors.

#7483 A new spatial multi-omics approach to deeply characterize human cancer tissue using a single slide: a new spatial muti-omics approach to deeply characterize human cancer tissue using a single slide.

yasmine adimi[1], clement Levin[2], Emilia Puig Lombardi[2], Marion Classe[2], Cecile Badoual[1]

[1]Inserm U970, Paris, France,[2]Sanofi R&D, Paris, France

Introduction: In digital pathology, extracting comprehensive data from a single tissue sample is critical for enhancing diagnostic precision and therapeutic strategies. Techniques like multiplex imaging and spatial transcriptomics offer unprecedented depth of information. This study introduces a novel and innovative approach combining for the first time Phenocycler® (with a 34-marker panel) and Visium® spatial transcriptomics on the same tissue section of squamous cell carcinoma of the upper aerodigestive tract.
A single tissue section was analyzed using Phenocycler® (PP) for proteomics with a 34-marker panel targeting microenvironment and structural proteins, followed by H&E staining and Visium® spatial transcriptomics (ST) to map RNA expression. This approach allowed for the thorough assessment of immune cell spatial distribution and transcriptomic profiles, while evaluating the impact of proteomic treatment on RNA integrity and gene expression.
Results: Despite initial concerns about RNA degradation due to multiplex staining treatments, RNA integrity in the PP+ST sample was comparable to ST-only samples, as indicated by similar total gene expression distributions. The PP+ST sample exhibited high-density feature points across the tissue, suggesting that proteomic pre-treatment did not impair subsequent transcriptomic analysis. Unsupervised UMAP visualization revealed similar clustering patterns between PP+ST and ST-only samples, indicating preserved cellular heterogeneity and molecular signatures. Consistent spatial distributions and clustering were observed between Phenocycler® pseudospots and Visium® data, with significant correlations in the spatial distribution of key cell types, including malignant clusters and immune cells.
This study is a pioneering demonstration of the feasibility and efficiency of integrating spatial proteomics and transcriptomics on the same tissue section, guaranteeing high fidelity in molecular profiling. This combined method is crucial for deepening the understanding of the tumor microenvironment, with potential implications for improving diagnostics and personalized cancer therapies. The ability to analyze multiple data layers on the same cells enhances the development of precise AI-based diagnostic tools and personalized treatment strategies.

#7487 Genetic and genomic knowledge, attitudes, and beliefs among Hispanic/Latinos with colorectal cancer.

Charite Ricker[1], Daisy Hernandez[1], Itzya Ulloa[2], Elena Taylor[2], Blanca Ovalle[3], Bo Yuan[4], Juan Pablo Lewinger[2], Rosa Barahona[3], Caryn Lerman[2], Julie O. Culver[5], Mariana Stern[3], John Carpten[6], Heinz-Josef Lenz[2], **Lourdes A. Baezconde-Garbanati**[3]

[1]Department of Medicine, Division of Medical Oncology, Keck School of Medicine of USC, Los Angeles, CA,[2]Norris Comprehensive Cancer Center, Keck School of Medicine of USC, Los Angeles, CA,[3]Keck School of Medicine of USC, Los Angeles, CA,[4]Department of Population and Public Health Sciences, Keck School of Medicine of USC, Los Angeles, CA,[5]Department of Medicine, Keck School of Medicine of USC, Los Angeles, CA,[6]City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Knowledge, attitudes, and beliefs (KAB) about genetics impacts engagement in genetics and genomics research, but there is a lack of data about these constructs among Hispanic/Latinos (H/L).
Methods: Adult H/L patients with colorectal cancer were recruited at a public (Los Angeles General) and a private (USC Norris Cancer Hospital) hospital to complete a cross-sectional survey assessing KAB. Recruitment and survey administration was done in Spanish or English.
Results: Preliminary analysis of 56 surveys found that most participants were from the public hospital (93%), born outside the US (84%), Spanish speaking (71%), and male (63%); median age was 55 years and acculturation was low [1.89 (SD 1.25); scale 1-5]. Low to mid-range scores were found for genetic literacy [3.45 (SD 1.49); scale 1-7], genetic knowledge [9.63 (SD 6.03); scale 0-25], cancer knowledge [2.20 (SD 1.24); scale 0-5]; and tumor genomics knowledge [3.62 (SD 0.78); scale 0-6]. Although 51% agreed they would want to be contacted for future research, 33% expressed uncertainty. When asked about genetic research, > 90% agreed it is medical progress. Almost 90% would want to know if their disease was hereditary, >80% would inform relatives about genetic results, and 29% agreed they were concerned about genetic testing impacting their ability to stay in this country.
Conclusion: Participants had limited genetic literacy, genetic, cancer and tumor genomics knowledge. Most expressed interest and positive feelings towards genetic testing and genomic research; however, there were uncertainties and concerns to consider in future research to improve H/L engagement in genetics research.

#7488 Prenatal exposure to chemotherapy increases the mutation burden in human neonatal hematopoietic stem cells.

I. Struys[1], C. Velazquez[1], J. Ubels[2], C. L. LeJeune[1], M. van Roosmalen[2], A. Rosendahl Huber[3], A. van Leeuwen[2], W. Bossuyt[1], B. Thienpont[1], T. Voet[1], K. Van Calsteren[1], L. Lenaerts[1], R. van Boxtel[2], F. Amant[1];

[1]KU Leuven, Leuven, Belgium, [2]Princess Maxima Center, Utrecht, Netherlands, [3]Institute for Research in Biomedicine, Barcelona, Spain

Background. Nowadays, chemotherapy is included in the standard of care for cancer treatment during pregnancy, and is considered clinically safe for the child's cognitive, cardiac and brain development up until early adolescence. However, whether prenatal exposure to maternal chemotherapy treatment has a mutagenic impact on the fetal genome, remains unexplored. Patients and methods. We investigated mutation accumulation in hematopoietic stem and progenitor cells (HSPCs) from neonates born to pregnant cancer patients treated with chemotherapy (n=13), as well as healthy pregnant women (n=9) and untreated pregnant cancer patients (n=4). From every subject, cord blood, as a source for neonatal DNA, was collected at delivery, whereafter single HSPCs were isolated and clonally expanded for subsequent whole-genome sequencing (15ξ). Signature analyses was performed using the MutationalPatterns R package and comparison with the COSMIC database.
Results. The mutational burden identified in HSPCs from neonates born to untreated pregnant cancer patients and to healthy controls was similar (mean of single base substitutions (SBS)=41.2±9.1 and 39.9±14.3 respectively; p=0.97) and reflected the expected mutation burden from healthy individuals at birth. In contrast, HSPCs from neonates prenatally exposed to varying chemotherapy regimens, showed an increased number of somatic mutations (mean SBS=89.7±59.2; p=0.0038). Mutational signature analyses attributed the excess mutations to either clock-like processes, which are active during normal cellular aging, or to direct mutagenesis by platinum-based drugs in the case of neonates prenatally exposed to platinum-containing regimens. Our findings in early neonatal tissue are consistent with mutational signatures previously identified in healthy cells of cancer survivors directly exposed to chemotherapeutic drugs and are validated via direct *in vitro* exposure of cord blood HSPCs from healthy individuals to single chemotherapeutic agents frequently used to treat pregnant women.
Conclusion. This study demonstrates that environmental mutagenic exposure during pregnancy can increase somatic mutation accumulation in the fetus. Given that detrimental early life exposures can adversely affect health outcomes later in life, our study highlights the need for further research into the impact of environmental maternal exposures associated to genomic insults during the perinatal period.

#7489 Archetype analysis links heterogeneity in premalignant lesions to diverging features of lung adenocarcinoma.

Kelley Anderson[1], Linh Tran[2], Kostyantyn Krysan[2], Gregory A. Fishbein[3], William D. Wallace[4], Emily Green[1], Hanqiao Liu[1], Xiaohui Xiao[1], Gang Liu[1], Erin Kane[1], Avrum Spira[1], Steven M. Dubinett[2], Eric Burks[5], Sarah Mazzilli[1], Marc Lenburg[1], Jennifer Beane[1]

[1]Section of Computational Biomedicine, Boston University Chobanian & Avedisian School of Medicine, Boston, MA,[2]Department of Medicine, David Geffen School of Medicine at University of California, Los Angeles, CA,[3]Department of Pathology & Lab Medicine, David Geffen School of Medicine at University of California, Los Angeles, CA,[4]Department of Pathology, Keck School of Medicine of University of Southern California, Los Angeles, CA,[5]Department of Pathology, Boston University Chobanian & Avedisian School of Medicine, Boston, MA

Lung cancer is the leading cause of cancer-related death. Adenocarcinoma (LUAD), the most common form of lung cancer, is a heterogeneous disease with high variability in histopathologic features and clinical outcomes. Atypical adenomatous hyperplasia and adenocarcinoma *in situ* are the premalignant lesions (PML) in LUAD pathogenesis. The molecular features of PML that lead to aggressive LUAD are poorly characterized. We hypothesized that transcriptomic changes in PML are linked to distinct clinicopathologic features that may identify aggressive PML before they become invasive LUAD. We examined lung resections from patients with early-stage LUAD where adjacent tissue contained premalignant histology. Normal, PML, and LUAD areas were laser-capture micro-dissected, and RNA was isolated and then profiled using bulk RNA-sequencing (n=41 patients, n=177 samples). We derived a set of recurrent gene modules (n=9 modules) in LUAD PML using samples from our cohort (n=80 PML samples) and three publicly available data sets (n=57 LUAD PML samples). Using these modules, we identified four PML archetypes, where the vertices of a polytope define each archetype. Based on pathway (Gene Set Enrichment Analysis, FDR <0.01) and signature enrichment, we identified the four archetypes as: normal-like, inflammation, cell adhesion, and proliferation. Analyzing the expression of published gene signatures suggests that the immune environment and epithelial cell plasticity may play different roles in different archetypes. Archetypes also differ with regard to a gene-expression signature for predicted immunotherapy response, with the proliferation archetype predicted to have a poor response, and the inflammation archetype predicted to have a good response to immunotherapy (logistic regression, $p<0.05$). An advantage of the archetyping approach is that archetype space is continuous, and samples from other cohorts can be placed within the PML-derived polytope based on their transcriptomic profile. We found that the PML-derived archetypes were related to clinical features in studies of LUAD. The proliferation archetype was associated with a decrease in disease free survival in multiple datasets (cox-proportional hazard model, $p<0.05$ for each tested cohort), and aggressive LUAD histology (linear model, $p<0.05$ for each tested cohort). While past studies demonstrated transcriptional differences between tumors and PML, our archetyping approach focuses on PML-specific gene expression patterns using multiple cohorts to increase the diversity of PML samples studied. Gene expression differences among archetypes were related to pathway dysregulation and prognosis. Characterizing PML based on transcriptomic features may improve our understanding of divergent mechanisms of carcinogenesis, and enable identification of aggressive PML capable of developing into invasive LUAD.

#7490 Uncovering rare cellular populations in esophageal preneoplasia through genetic perturbation tracking and scRNA-seq.

J. Jang, K.-P. Ko, J. Zhang, J.-I. Park;
UT MD Anderson Cancer Center, Houston, TX

The early detection and characterization of rare cellular populations in preneoplastic lesions are crucial for understanding cancer initiation and progression, as well as for identifying novel therapeutic targets. Rare cell populations, often overlooked due to their low abundance, play pivotal roles in shaping the tumor microenvironment and driving disease development. In this study, we employed a lineage tracing system based on tracing vectors introduced into a 2D cell line model of esophageal preneoplasia. This approach allowed us to track genetic perturbations that accumulate during cell proliferation, enabling precise identification of distinct cellular lineages. By coupling this lineage tracing method with single-cell RNA sequencing (scRNA-seq), we achieved high-resolution transcriptomic profiling, uncovering rare cellular populations with unique molecular and lineage-specific characteristics. The rare populations identified through this integrated approach exhibited a quiescent phenotype, suggesting their involvement in lesion persistence and resistance to therapies targeting proliferative cells. Transcriptomic analysis revealed distinct genetic signatures and key pathways associated with these populations, offering potential avenues for therapeutic intervention and biomarker development. Our findings demonstrate the value of combining genetic perturbation-based lineage tracing with scRNA-seq to uncover rare and functionally significant cellular populations. This study provides new insights into the cellular dynamics underlying esophageal cancer initiation and progression, laying the groundwork for future research aimed at understanding the roles of these populations and developing targeted therapies.

#7492 "Baseline-informed" unsupervised multiplexed CyTOF analysis enhances detection of minimal/measurable residual disease in acute myeloid leukemia.

Mahesh Basyal[1], Muharrem Muftuoglu[1], Li Li[1], Jiangxing Lv[1], Yukun Tan[2], Ken Chen[2], Michael Andreeff[1]

[1]Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX

Multiparameter flow cytometry (MFC) and molecular techniques are the cornerstone for detecting acute myeloid leukemia (AML) minimal/measurable residual disease (MRD). However, some MRD(-) patients relapse, suggesting current methods miss persistent leukemia due to suboptimal detection limits or distinct leukemia-associated phenotypes(LAP). This highlights the need for improved MRD detection methods. Challenges in MFC-based MRD detection include reliance on limited markers, incomplete LAP detection, clonal evolution, surface-marker restrictions, and the need for specialized expertise. These limitations underscore the need for methodologies capable of capturing diverse and dynamic AML proteomic landscape. Single-cell proteomics via CyTOF uniquely dissects high-dimensional features, enabling comprehensive and unbiased leukemic cell characterization. We hypothesized that CyTOF, combined with unsupervised analysis, enhances MRD detection by identifying diverse proteomic features in a feature-agnostic manner. To explore this, we conducted integrated CyTOF analysis of 60 AML patients and 12 bone marrow (BM) samples. This revealed diverse AML proteomic profiles distinct from HSCs/HSPCs indicating unsupervised methods capture aberrant leukemia profiles in a feature-agnostic manner. Next, AML MRD was modeled by mixing barcoded primary AML cells (n=5) and cell lines (Kasumi, Molm13, OCI-AML3) with healthy BM at dilution ratios from 1:10 to 1:100,000. A 50-parameter CyTOF panel and UMAP analysis assessed MRD detection sensitivity. UMAP analysis showed that primary AML cells and cell lines were well-segregated up to a 1:1,000 dilution, with progressive loss of resolution at higher dilutions. At a 1:100,000 dilution, AML cells became indistinguishable from healthy HSCs/HSPCs, highlighting the limitations of UMAP in detecting rare populations. Baseline-informed unsupervised analysis—leveraging phenotypically similar baseline AML cells—restored clustering sensitivity at a 1:100,000 dilution (23 AML cells in 2.3 million BM cells). Furthermore, we extended these findings by conducting integrated CyTOF analysis on pre- and post-therapy primary AML samples (n=5). This "informed" analysis improved AML MRD detection and demonstrated its potential for clinical trials. This approach enabled detailed characterization of metabolic, signaling, apoptotic, and phenotypic features of AML MRD, providing deeper insights into its complexity and surpassing the limited insights of current MRD detection tools. In conclusion, multiplexed CyTOF analysis combined with an "informed" unsupervised analytic approach significantly enhances AML MRD detection and characterization. In addition to enumerating MRD cells with high sensitivity, CyTOF enables detailed proteomic profiling, offering insights that could guide AML MRD therapy.

#7493 Spatially resolved insights into epithelial-stromal co-evolution in pancreatic ductal adenocarcinoma.

Ahmed M. Elhossiny[1], Padma Kadiyala[2], Alexander Bray[3], Jamie Mills[3], Hannah Watkoske[4], Arvind Rao[1], Jude Okoye[4], Atul Deshpande[5], Jiaqi Shi[6], Elana J. Fertig[7], Filip Bednar[2], Yaqing Zhang[4], Eileen S. Carpenter[8], Timothy Frankel[2], Marina Pasca di Magliano[9]

[1]Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI,[2]Department of Surgery, University of Michigan, Ann Arbor, MI,[3]Department of Internal Medicine, Division of Hematology and Oncology, University of Michigan, Ann Arbor, MI,[4]Rogel Cancer Center, University of Michigan, Ann Arbor, MI,[5]School of Medicine, Johns Hopkins University, Baltimore, MD,[6]Department of Pathology, University of Michigan, Ann Arbor, MI,[7]Institute for Genome Sciences, Greenbaum Comprehensive Cancer Center, Department of Medicine, University of Maryland, Baltimore, MD,[8]Department of Internal Medicine, Division of Gastroenterology and Hepatology, University of Michigan, Ann Arbor, MI,[9]Department of Cell and Developmental Biology, University of Michigan, Ann Arbor, MI

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest cancers, with a five-year survival rate of 13%. The tumor microenvironment (TME) in PDAC includes a heterogeneous population of cells. In genetically engineered mouse models, the TME evolves alongside the formation and progression of epithelial precursor lesions to cancer. However, the evolution of the TME in human samples has not been thoroughly characterized, primarily due to limited access to pre-malignant pancreatic tissue. Leveraging a collaboration with Gift of Life Michigan, an organ donor organization, we previously reported that precursor lesions are abundant in the normal human pancreas (*Carpenter et al., Cancer Discovery, 2023*). To date, we have collected over 100 human pancreata, a dataset that enables us to map the characteristics of these lesions and their surrounding microenvironment across variables such as age, sex, and race. Here, we aim to model the co-evolution of the stroma and neoplastic epithelium during tumor progression. We utilized spatial transcriptomics technology with the 10x Visium platform, analyzing over 20 human pancreata during the discovery phase. We applied a spatially aware clustering approach to delineate distinct tissue domains across normal, tumor-adjacent, and tumor samples. We leveraged a previously established single-cell RNA-seq atlas (n=41) to deconvolute cell-type fractions and cell-type-specific gene expression profiles within each spatial transcriptomics spot. As a result, we identified distinct epithelial structures (e.g., Acinar, Ducts, PanINs, tumor) as well as stromal domains (e.g., tertiary lymphoid structures (TLS), fibrotic regions). We hypothesized that stromal gene expression is influenced by the proximity to and the density of different epithelial structures. Therefore, we employed a kernel density estimation approach to model gene expression in stromal cells, specifically fibroblasts and macrophages, as a function of epithelial-specific density. This analysis uncovered distinct characteristics of the stroma surrounding precursor lesions compared to tumor stroma, emphasizing spatially regulated gene expression programs that likely drive TME remodeling in PDAC. Future directions include performing cell-cell interaction analysis to further elucidate epithelial-stromal crosstalk, complemented by in vitro functional experiments to validate the pro- or anti-tumorigenic roles of the identified markers. This work lays the foundation for spatially resolved insights into PDAC biology, informing therapeutic strategies targeting the TME.

#7494 An integrative systems-level framework reveals SMARCD3 resistance regulon signatures vulnerable to MEK1/2 inhibitors in ER+BC cells resistant to everolimus.

Eric F. Medina, Elena Farmaki, Jason I. Griffiths, Vince K. Grolmusz, Andrea H. Bild, Aritro Nath

Beckman Research Institute of The City of Hope, Duarte, CA

Estrogen receptor-positive breast cancer (ER+BC) represents nearly 75% of all breast tumors, with nearly 20-40% patients eventually developing metastases. Everolimus is an mTOR inhibitor which has been approved for use in combination with exemestane in patients with metastatic ER+BC. However, many patients eventually develop resistance to everolimus leading to poor survival outcomes. Systematic characterization of the molecular phenotypes underlying everolimus resistance could reveal new therapeutic targets for metastatic ER+BC. We analyzed transcriptomic profiles from multiple pairs of everolimus resistant or sensitive ER+BC cell lines, to identify signaling mechanisms that distinguish resistant cells both at baseline and under everolimus treatment. Using linear mixed-effects models, we identified strong activation of the growth-factor signaling meta-phenotype in resistant cells at baseline, which persisted even under everolimus treatment. This meta-phenotype included alternate growth signaling mechanisms including IGF1R/insulin, ESR1, RAS and MAPK signaling. To understand the regulatory mechanism behind alternate growth-factor signaling activation, we adopted a network reconstruction architecture to identify SMARCD3 regulons as key transcriptional regulatory networks in resistant cells. In a neo-adjuvant trial for ER+BC patients, the expression levels of SMARCD3 and its regulon's activity were significantly elevated in tumors refractory to everolimus. To develop a therapeutic strategy against everolimus resistance, we used transcriptomic and drug sensitivity profiles of 926 cancer cell lines treated with 395 compounds. We found that the activation of SMARCD3 regulons was consistently associated with sensitivity to several known MEK1/2 inhibitors, including trametinib. To validate these findings, we evaluated the efficacy of everolimus in combination with trametinib and demonstrate that the combination treatment significantly reduced the growth of resistant cells compared to everolimus. Our results demonstrate that everolimus resistant ER+BC cells utilize alternate growth-factor signaling to escape therapeutic control. We found that this phenotype is strongly linked with activation of the SMARCD3 regulons and can be therapeutically targeted using MEK1/2 inhibitors.

#7495 The evolving ECM architecture shapes unique evolutionary trajectories of breast tumor immune escape and elimination.

Yijia Fan, Jason Tomas George

Biomedical Engineering, Texas A&M University, Houston, TX

Purpose: Cancer progression remains a clinical challenge due to tumor heterogeneity. Effective T cell infiltration is critical for mounting an anti-tumor response. Tumors are classified as “hot” or “cold” based on the extent of T cell infiltration. In many cancers, particularly breast cancer, extracellular matrix (ECM) geometry evolves with tumor progression, characterized by Tumor-Associated Collagen Signatures (TACS). Specifically, empirically observed ECM topologies are random fibers (TACS1), circumferentially aligned fibers (TACS2), and radially arranged fibers (TACS3). Clinically, patients with TACS3+ breast cancer exhibit poorer survival compared to TACS3- cases, but the underlying mechanisms and the role of evolving ECM geometry in tumor evolution and tumor-T cell interaction remain unclear. The lack of biomarkers or methods to track TACS evolution underscores the need for physical models linking ECM geometry to tumor-immune co-evolution.
Methods: To address this, we developed the EVO-ACT (EVOlutionary Agent-based Cancer T cell interaction) model, built upon the Gillespie algorithm.
Results: Our analysis of the three TACS geometries revealed distinct T cell migration patterns and efficiencies: TACS3 demonstrated the highest efficiency, TACS1 intermediate, and TACS2 the lowest. While TACS geometry significantly influences T cell infiltration, it does not act as an absolute barrier; stronger chemokine gradients enhance T cell infiltration across all TACS types. Notably, TACS3 facilitates immune recognition and correlates with higher survival in our simulations, which contrasts with the clinically observed lower survival of TACS3+ breast cancer patients. As TACS3 is typically linked to late-stage breast tumors with phenotypic adaptations, we incorporated mechanisms such as EMT into our model to address this discrepancy. The progression from TACS2 to TACS3, coupled with EMT, more accurately reproduced clinical outcomes. Considering the mesenchymal phenotype’s ability to upregulate immune checkpoint molecules such as PD-1/PD-L1, we further explored TACS-specific tumor evolution and its impact on responses to immune checkpoint inhibitors and patient survival. Our findings reveal lower survival in TACS3/EMT+/PD-L1+ cases compared to TACS2/EMT-/PD-L1+ cases, highlighting that TACS3-associated poor survival arises not solely from ECM geometry but from late-stage cancer adaptations such as EMT and upregulated immune checkpoint expression.
Conclusions: This study underscores the complex interplay between evolving ECM geometry and tumor-T cell interaction dynamics, offering a new explanation for TACS-associated survival differences. It also provides novel insights into TACS-specific responses to PD-1/PD-L1 inhibitors and their implications for patient survival.

#7496 Evolutionary trajectories inferred by selective epistasis and phylogenetic analysis reveal the malignant progression of intraductal papillary mucinous neoplasms to pancreatic ductal adenocarcinoma.

Derek C. Song[1], Nic Fisk[2], Margaret Moore[3], Vincent L. Cannataro[4], Jeffrey D. Mandell[1], Luisa Escobar-Hoyos[5], Leanne Brown[5], Lu Qiao[5], John W. Kunstman[5], Jeffrey P. Townsend[3]

[1]Yale University, New Haven, CT,[2]University of Rhode Island, Kingston, RI,[3]Yale School of Public Health, New Haven, CT,[4]Emmanuel College, Boston, MA,[5]Yale School of Medicine, New Haven, CT

Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer death, with high mortality rates attributable to late detection when metastases have already occurred. Early-stage PDAC is challenging to detect due to its frequently asymptomatic nature, lack of biomarker sensitivity, and inaccessible anatomical location. Pre-malignant intraductal papillary mucinous neoplasms (IPMNs) are detectable through imaging and can progress to malignant PDAC, offering a unique opportunity for early interventions such as prophylactic resection. However, identification of IPMNs that will become malignant is challenging, and pancreatic resection comes with significant morbidities. Thus, characterizing the evolutionary trajectories by which IPMNs progress to PDAC could both guide surgical decision-making and reveal targetable mechanisms to prevent malignant development.

Here, we quantify the evolutionary selection for mutations that lead to IPMNs and compare that result to the selection of known drivers of PDAC. We infer a protective effect of KLF4 mutation in IPMNs on subsequent progression to PDAC that arises due to antagonistic selective epistasis with KRAS and other high-impact contributors to PDAC. We then investigate the molecular etiology of IPMNs and PDACs at different histopathological grades, finding that the mutational processes observed in each are markedly alike, suggesting instead that microenvironmental and epistatic dynamics of the heterogenous proto-tumor drive progression. Finally, to detail prospective mutational trajectories by which IPMNs progress to KRAS-positive PDACs, we leverage selective epistatic interactions to map likely mutational orderings in PDACs and compare those orderings to the sequence of mutations reconstructed via phylogenetic analysis of IPMN lineages.

#7499 Driver mutations propel subclonal evolution and spatial patterns of tumor growth in intrahepatic cholangiocarcinoma.

E. John[1], P. Shukla[1], A. Jain[1], A. Lau[1], T. Lesluyes[2], H. Ogilvie[1], M. Tarabichi[3], J. Roszik[1], Y. Yuan[1], P. Van Loo[1], L. Kwong[1], Y. Chun[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University Cancer Institute Toulouse Oncopole, Toulouse, France, [3]Universite Libre de Bruxelles, IRIBHM, Belgium, Belgium

Intrahepatic cholangiocarcinoma (ICC) is a highly lethal cancer of the bile ducts that exhibits a diversity of driver oncogenic mutations, several of which have been shown to be frequently subclonal. However, existing tumor evolution studies in ICC have been limited by either the number of sub-regions assessed or a paucity of driver mutation heterogeneity. Here, we conducted a multi-omic analysis of 90 tumor regions from 11 discrete tumors in 10 patients, identifying subclonal driver mutations in 5 of the patients, in the genes *PBRM1*, *PIK3CA*, *TP53*, *ARID1A*, *BRAF*, *MLH1*, and *CDKN2A*. This high-number multi-region approach also allowed us to unambiguously identify distinct subclonal evolutionary branches and map them to the spatial location of the samples. Importantly, each subclonal driver mutation was tightly associated with these defined branches, implicating them as a frequent mechanism of driving subclonal evolution. Additionally, subclonal branching showed a spatial correlation on surgical resection depicting the strength of multi-region sequencing in treatment. In total, we conclude that while subclonal branching can be driven by a number of factors, the acquisition of bona fide driver mutations strongly propels subclonal evolution and spatial patterns of tumor growth.

#7500 Joint reconstruction of single-cell evolutionary lineages and fate transition trajectories from long-read single cell transcriptomes.

Yueying He[1], Yuanqing Yan[2], Cheng-Kai Shiau[1], Lina Lu[1], Minhua Wang[1], Taisuke Kaihou[2], Chitaru Kurihara[2], Kazutaka Fukumura[3], Rajul K. Ranka[4], Yudai Miyashita[2], Timothy Pan[1], Arvind Bhimaraj[5], Daniel Brat[6], Jason Huse[5], Ankit Bharat[2], Ruli Gao[1]

[1]Department of Biochemistry and Molecular Genetics, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Department of Surgery, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[3]Department of Anatomical Pathology, University of Texas MD Anderson Cancer Center, Houston, TX,[4]Department of Cardiovascular Sciences, Houston Methodist Research Institute, Houston, TX,[5]Department of Cardiology, J.C. Water Jr. Transplant Center, Houston Methodist Research Institute, Houston, TX,[6]Department of Pathology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Computational inference of endogenous genetic alterations from single cell transcriptomic data opens an avenue of measuring both evolution and fate markers in individual cells, in particular, the emerging long-read single cell RNA sequencing (LR-scRNAseq) technologies allowed detection of multi-layered mutations across whole transcript bodies of thousands of genes in thousands of cells in parallel. However, robust tools for integrating single cell genetic evolutionary lineage and fate transition trajectory from these powerful data are missing. To address this, we developed EvoFATE, an unsupervised graph learning model, to automatically reconstruct unified roadmaps of single cell evolutionary lineages and fate transition trajectories by discovering representations using endogenous mutations as evolutionary markers and gene expressions as fate remodeling markers. EvoFATE recovered complex evolutionary fate dynamics in simulations and blood samples where diverse cell types had known lineage orders. We applied EvoFATE onto LR-scRNAseq data of patient-matched lung metastatic tumors and identified the evolutionary fate paths of tumor cells during both metastatic seeding and clonal expansion stages. To summarize, EvoFATE robustly integrates genetic evolutionary lineages with cell fate transition trajectories to resolve complex fate remodeling dynamics and evolution-fate synchronies using cell endogenous markers, enabling precise tracing of temporal changes in cells under real pathophysiology conditions without genetic manipulations.

#7502 Radiation-induced transcriptomic reprogramming of mesenchymal glioblastoma stem cells reveals key pathways and potential targets.

Grace Rosner[1], Abigail Goen[1], Godwin Peasah-Darkwah[1], Jonathan Rodgers Gochicoa[1], Alos Diallo[1], Gokul Srinivasan[2], Elisa Bu Sha[3], Joshua Levy[4], **Kelli B. Pointer**[5]

[1]Dartmouth College, Hanover, NH,[2]UCLA/Caltech, Los Angeles, CA,[3]Rutgers University, New Brunswick, NJ,[4]Computational Biomedicine, Cedars-Sinai, Los Angeles, CA,[5]Radiation Oncology, Dartmouth College, Hanover, NH

Background: Glioblastoma (GBM) is a highly aggressive primary brain tumor with a median survival of less than two years. Despite standard therapy of surgery, radiation, and chemotherapy, GBMs recur. These recurrences may partially be due to glioblastoma stem cells (GSCs). Various subpopulations of GSCs exist, likely attributing to different resistant niches. The mesenchymal (MES) subpopulation may drive radiation (RT) resistance. The transcriptomic shifts that define GSC adaptation to RT remain unknown. This study explores the transcriptomic reprogramming of MES GSCs following RT to identify resistance mechanisms.

Methods: Using dataset GSE162931 from the GEO database and MES gene signatures from PMID:31327527, we analyzed two patient-derived GBM cell lines pre- and post-10 Gy RT. Data for the two cell lines were preprocessed and integrated with Seurat, followed by clustering and UMAP visualization with 2D kernel module-score weighted density plots. Cluster proportion changes between conditions were statistically examined using Chi-squared or Fisher's tests with adjusted p-values. Differential expression analysis revealed conserved and unique gene markers distinguishing treated from naïve conditions, visualized in volcano plots and heatmaps. A final score integrating module scores and cluster proportions quantified MES traits at the single-cell level. All analyses were conducted in R studio version 4.2.3.

Results: UMAP, density plots, and cluster proportion changes indicate significant shifts in MES GSC distributions post-RT, suggesting RT selection for specific transcriptomic profiles. Highly MES subclusters exhibit distinctive RT-responsive gene expression patterns. The final scoring revealed enhanced MES traits in post-RT clusters. Distinct clustering patterns in MES GSCs highlight diverse adaptive strategies. Differential expression analysis reveals upregulation of DNA repair genes (SAT1, NDRG1, GADD45A), enhancing genomic stability post-RT, and stemness markers (NES, GDF15), emphasizing self-renewal capacity. Genes supporting oxidative stress management (SQSTM1, DDIT4) were upregulated, while downregulated metabolic genes (PGK1, LDHA) indicate a shift towards oxidative phosphorylation. Gene Set Enrichment Analysis identified enriched pathways related to DNA repair, cell migration, and differentiation regulation.

Conclusion: These findings underline the transcriptomic plasticity in MES GSCs that drive RT resistance. Potential targets like AKAP12 and S100A4, essential for maintaining stem-like traits and MES phenotypes, present new therapeutic targets that could be used to combat resistant GSC populations, aiming to reduce tumor recurrence and enhance GBM patient outcomes.

#7503 Detection of genomic alterations in lenvatinib-resistant liver cancer cell lines.

JungHyun Kim[1], Ji Young Kim[1], Gamin Han[1], BoYoon Kim[2], Hoon Kim[2], Yeup Yoon[1], Wonseok Kang[3]

[1]Samsung Advanced Institute for Health Sciences and Technology (SAIHST), Sungkyunkwan University, Seoul, Korea, Republic of,[2]Department of Biopharmaceutical Convergence, Sungkyunkwan University, Suwon, Korea, Republic of,[3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Hepatocellular carcinoma (HCC), the most common type of primary liver cancer, is the sixth most prevalent tumor worldwide and the fourth leading cause of cancer-related deaths. Lenvatinib, a multi-targeted tyrosine kinase inhibitor (TKI), is a first-line therapy for HCC patients who are ineligible for immunotherapy. However, like other targeted therapies, its efficacy is often compromised by the development of resistance. Understanding the molecular alterations driving this resistance is critical to improving therapeutic outcomes in HCC. In this study, lenvatinib-resistant human HCC cell lines were established by exposing parental sensitive cells to increasing concentrations of lenvatinib. Resistant Hep3B and Huh7 cell lines were successfully developed, exhibiting higher lenvatinib-specific IC_{50} values compared to their sensitive counterparts. To investigate the mechanisms underlying drug resistance, whole-genome sequencing (WGS, average depth: 30X) was performed, identifying resistance-specific genomic alterations, including copy number variations (CNVs), mutations, and structural variations (SVs). Emerging evidence suggests that chromosomal instability (CIN) plays a critical role in resistance evolution through structural rearrangements and focal amplifications. To reconstruct these amplified regions, we utilized AmpliconArchitect, followed by classification into chromosomal amplification (ChrAmp) and extrachromosomal DNA (ecDNA) using AmpliconClassifier. The number of focal amplifications increased from 4 to 7 in resistant Hep3B cells and from 14 to 18 in resistant Huh7 cells. Notably, newly identified oncogenes were detected within these amplicons, including *ZIC2* in Hep3B and *EGFR* in Huh7. Despite the emergence of new amplicon profiles in resistant cells, most retained their original classifications as ecDNAs or ChrAmps, suggesting that clones carrying these amplicons exhibit an intrinsic resistance phenotype. Ongoing studies involving single-clone isolation and further genomic characterization aim to refine and expand these findings. In conclusion, we successfully established lenvatinib-resistant HCC cell lines and characterized their resistance-specific genomic alterations. Our results highlight the role of CIN in driving resistance under the selective pressure of targeted therapies, offering potential insights for improving therapeutic strategies in HCC.

#7504 Integrated multiomic analysis to infer longitudinal patterns of ecDNA in IDH-wildtype integrated multiomic analysis to infer longitudinal patterns of ecDNA in IDH wild-type glioblastoma.

Dacheng Zhao[1], Kevin Anderson[2], Amit Gujar[1], Megan Costa[1], Djamel Nehar-Belaid[2], Frederick Varn[2], Elise Courtois[2], Paul Gabrie[2], Paul Robson[2], Hyo-Eun Moon[3], Anna Golebiewska[4], Sun Ha Paek[3], Simone Niclou[4]

[1]Yale University School of Medicine, New Haven, CT,[2]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[3]Seoul National University, Seoul, Korea, Republic of,[4]Luxembourg Institute of Health, Luxembourg, Luxembourg

Extrachromosomal DNA (ecDNA), a prevalent mechanism of gene amplification, drives oncogene overexpression and is associated with poor patient survival. Over 60% of primary glioblastoma (GBM) cases harbor ecDNA-mediated oncogene amplifications. To better understand the functional consequences of ecDNA amplification, we performed a comprehensive analysis of ecDNA distribution in tumors using longitudinally sampled multiomic data from 35 GBM patient specimens. This dataset integrates 68 whole-genome sequencing (WGS) datasets, 243,459 transcriptomic and chromatin accessibility profiles derived from the same nuclei. We developed a single-nucleus ATAC-seq-based pipeline to classify ecDNA status at single-cell resolution. To validate the robustness of this pipeline, we utilized patient-derived neurospheres (n = 2), generating multiomic datasets and over 100 fluorescent in situ hybridization (FISH) images per cell line for structural validation. This approach enabled the identification of ecDNA-containing regions in each patient sample through WGS data and the inference of single-cell-level copy number variations. In total, we classified the ecDNA status of over 86,345 malignant cells. Our findings demonstrated that ecDNA copy numbers remain stable during tumor progression, with no significant changes in the proportion of ecDNA-containing cells over time. Notably, we observed that oncogenes amplified on ecDNA are associated with distinct tumor cell states. By applying non-negative matrix factorization and a random forest machine learning algorithm, we extracted gene programs linked to ecDNA that are enriched for cell-cycle regulation and chromatin regulating. These results provide new insights into the regulatory landscape of ecDNA-driven glioblastoma and highlight its potential role in shaping tumor cell identity and progression.

#7505 Comprehensive in-silico molecular analysis of early-onset gastric cancer identifies novel genes implicated in disease characterization and progression.

Fernan Gomez-Valenzuela, Ian Silva, Ignacio Nicolas Retamal, Javiera Garrido, Benjamin Garcia-Bloj, Tomas De Mayo Glasser, Matias Munoz-Medel, Juan Alejandro Godoy, Marcelo Garrido

Centro de Oncologia de Precision, Universidad Mayor, Santiago, Chile

Gastric cancer, a prevalent and fatal form of cancer worldwide, is manifested at different age ranges during the lifespan. Approximately one-third of newly diagnosed gastric cancer cases are early onset gastric cancer (EO-GC), which affects individuals under the age of 50. EO-GC tends to be more aggressive than late-onset gastric cancer (L-GC), with a faster and multifocal disease progression. Moreover, EO-GC is associated with early metastatic disease. Recent research has underscored the need for a deeper understanding of EO-GC that promotes therapeutic approaches specific to EO-GC. These characteristics emphasize the need to understand their differential molecular characteristics deeply. We analyzed The Cancer Genome Atlas Stomach Adenocarcinoma (TCGA-STAD) transcriptomic expression data as a proxy to understand if age may be positioned as a variable associated with a specific gene expression pattern in gastric cancer. Using transcriptomic and clinical data, we performed a comprehensive bioinformatic analysis to explore molecular differences between EO-GC (n = 32) and L-GC (n = 345). Principal component analysis (PCA) revealed distinct transcriptomic clusters separating EO-GC and L-GC cases, particularly when categorized by decades, highlighting their molecular divergence. Next, we performed differential gene expression analysis (DGEA) using the 'DESeq2' and 'edgeR' R packages, identifying several significant genes that distinguish EO-GC from L-GC. Among these, *KLHL4*, *MAGEL2*, *RNLS*, and *CYP8B1* were upregulated in EO-GC, while *CLDN6*, *MIOX*, *PNMA5*, and *ACTL8* were downregulated. Consequently, we performed a functional analysis of differentially expressed EO-GC genes related to cytoskeleton regulation, cell adhesion, and metabolism pathways, which may contribute to its aggressive phenotype. Furthermore, some EO-GC genes were associated with poorer survival outcomes. Last, we observed that the DNA methylation score was higher for EO-GC cases. In conclusion, our findings highlight the critical role of differential genetic and epigenetic landscapes of EO-GC and propose these molecular features for its diagnosis and prognostic evaluation. These insights could inform the development of personalized therapies to improve outcomes for younger GC patients.

#7506 A gene program association study (GPAS) in prostate cancer reveals novel gene modules associated with plasticity and metastasis.

Hanbing Song[1], **Junxiang Xu**[2], Paul Allegakoen[1], Yih-An Chen[1], Hannah N. W. Weinstein[1], Arda Demirci[1], Isaac Salzman[1], Keila Velazquez-Arcelay[1], Margaret Tsui[1], Jon Akutagawa[1], Julia H. Pham[1], Peter R. Carroll[1], Matthew R. Cooperberg[1], Ezequiel Goldschmidt[3], Nancy Greenland[4], Joshua D. Campbell[2], Franklin W. Huang[1]

[1]Department of Medicine, University of California, San Francisco, San Francisco, CA,[2]Department of Medicine, Boston University, Boston, MA,[3]Brain Tumor Center, University of California, San Francisco, San Francisco, CA,[4]San Francisco Veterans Affairs Medical Center, San Francisco, CA

Objective: Prostate cancer (PCa) is a heterogeneous disease both within and across individuals. Genomic alterations, epigenetic changes, and interactions with cells in the tumor microenvironment (TME) contribute to different states in tumor cells. Single-cell RNAseq (scRNAseq) can provide insights into the transcriptional heterogeneity of tumor cells and cell types in the TME. However, most scRNAseq studies are limited by small sample sizes. Here, we performed the first gene program association study in PCa to identify gene modules and immune cell types associated with intra-tumoral heterogeneity and metastasis.
Methods: 14 datasets were merged to create a harmonized scRNAseq atlas. Copy number inference and boosted gradient tree models were trained to identify the tumor cells. Celda was used to identify co-expression modules. Linear mixed effect models were used to associate modules with clinical phenotypes. Finally, a transformer model similar to RoBERTa for annotation of PCa datasets was developed and validated in 2 independent datasets.
Result: We compiled an atlas of 560,492 cells from 128 PCa patients with localized primary PCa, Castration resistant PCa (CRPC), and metastatic PCa from 7 different sites. 166 co-expression modules were identified across 106,998 tumor cells. 2 cell-cycle modules were consistently upregulated across all metastatic sites while prostate lineage and antigen presentation modules were consistently downregulated. Different metastatic sites exhibited unique module expression patterns. For example, a module of FOLH1 and SPON2 was upregulated specifically in brain metastasis while erythroid modules were found in liver metastasis. 4 different modules were significantly higher in neuroendocrine prostate cancers (NEPC). Each NE tumor was not monolithic but expressed a unique combination of these modules. A novel subtype of NEPC tumors was identified which predominantly expresses the HES1 module instead of the canonical NE module. We developed a novel scoring system to identify NEPC tumors in bulk RNA-seq data using a combination of NE-associated modules which performed better than previously established gene set signatures (AUC = 0.938). Within the TME, we detected a T-cell cluster signified by heat shock protein genes enriched in African American PCa patients than European American patients. Furthermore, a transformer neural network was developed for automated annotation of scRNAseq PCa datasets which achieved a 91% accuracy in validation datasets.
Conclusion: We generated a comprehensive atlas of cells from PCa, characterized novel gene programs that defined tumors cells in localized and metastatic samples, identified a novel subtype of NEPC, and developed a robust computational tool to predict these states in new studies. These findings can potentially be used clinically to stratify high-risk patients with localized disease.

#7507 Towards transparent and context-specific annotation of driver and passenger mutations in cancer.

M. Madhumita[1], J. Teague[1], P. Beer[2], Z. Sondka[1];
[1]Wellcome Sanger Institute, Hinxton, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom

Cancer arises from the accumulation of somatic genetic alterations, with only a subset acting as "drivers" that promote malignant transformation. Distinguishing between driver and passenger mutations is fundamental for both clinical and research applications, yet current *in-silico* variant annotation tools often fall short. Our previous evaluation of multiple algorithms revealed a concerning reliance on pre-computed, black-box models that are rarely updated and typically limited to missense mutations. These tools also lack transparency and biological context, leading to inconsistent predictions that hinder effective cancer driver identification.

Building on these findings, our current study emphasizes the need for a new framework in cancer genomics. This framework should be characterized by explainable, unbiased approaches, long-term support, and the integration of recurrence data as a marker of positive selection. To address the above limitations, we leverage 20 years of manually curated COSMIC data. By systematically analysing mutation peaks or hotspots within cancer-associated genes, we uncover patterns indicative of positive selection, a hallmark of driver mutations. Our approach is enriched by integrating additional biological metrics, including dN/dS ratios, which measure selection pressure on genes, and allele frequency data from diverse human populations to account for background genetic variation. Furthermore, we incorporate gene-specific functional insights to enhance the contextual relevance of our predictions.

Our integrative methodology aims to establish a robust, reproducible set of rules for annotating driver mutations, leveraging multiple layers of evidence to reduce biases and increase predictive accuracy. By prioritizing algorithmic transparency and the inclusion of biologically informed data, we lay the foundation for a more reliable classification system that adapts to emerging discoveries in cancer genomics. Ultimately, our work seeks to transform cancer mutation annotation into a reproducible and clinically actionable process, paving the way for better-targeted therapies and more precise diagnostic tools. Through this, we aspire to bridge the existing gaps in driver mutation identification and to propel cancer genomics towards its full potential in precision medicine.

#7508 Transcriptomic analysis of polyisoprenylated cysteinyl amide inhibitors treatment of pancreatic and breast cancer reveals changes in apoptotic and angiogenic factors.

Kweku Ofosu-Asante, Amarender Burra, Jahnissi Odoom, Joshua Ablordeppey, Nazarius S. Lamango

Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

The aggressive nature of KRAS-driven cancers and the lack of effective targeted therapies makes them extremely challenging to manage. The polyisoprenylated cysteinyl amide inhibitors (PCAIs) were designed to mimic the polybasic C-terminal hypervariable (HVR) region of KRAS and related proteins. The HVR and polyisoprene modifications are essential for their functional localization. Disrupting the polyisoprenylation-dependent interactions abrogates RAS signaling interactions, affording opportunities for controlling hyperactive G-proteins in cancers. Previous studies have demonstrated the effectiveness of PCAIs against cancer-progression phenomena various cancer cell lines. Hence, we determined the effect of the PCAIs on the gene expression in PANC-1, MIA PaCa-2 and MDA-MB-231 cells, to better understand biological responses elicited by cancer cells on exposure to PCAIs at gene level. Following 3 µM NSL-YHJ-2-27 treatment of MIA PaCa-2 cells, total RNA was extracted, sequenced and analyzed using Partek Flow. DESeq2 tool was used to analyze a total of 88 genes that were significantly differentially expressed. Out of the 88 genes, 85 were upregulated and 3 downregulated. Notable genes such as tumor suppressor gene, suppressor of cytokine signaling 1 (*SOCS1*) and autophagy-related protein 9 (*ATG9L*) were significantly upregulated by 2-fold and 3-fold, respectively. Moreover, treatment with 3 µM NSL-AB-51 of both PANC-1 and MDA-MB-231 cells resulted in 9 and 28 genes, respectively, being differentially expressed. The gene endothelin-1 (*EDN1*) which promotes cell proliferation, survival and neovascularization was significantly downregulated by one-fold in PANC-1 cells. Genes such as BCL-2 binding component 3 (*BBC3*) that has been shown to promote apoptosis and angiopoietin-like 4 (*ANGPTL4*) that inhibits tumor angiogenesis were significantly upregulated by 2-fold and 4-fold, respectively. These effects on the transcriptome strongly corroborate the phenotypic characteristics of the PCAIs against cell viability and proliferation, migration, invasion and angiogenesis and offers more opportunities to further understand and develop the PCAIs as potential agents to treat KRAS-driven cancers.

#7509 Path-Omics: Elevated plasma cell infiltration into aneuploid epithelium predicts Barrett's esphagus progression to adenocarcinoma.

Caner Ercan[1], **Xiaoxi Pan**[1], Thomas G. Paulson[2], Matthew D. Stachler[3], Carlo C. Maley[4], Yinyin Yuan[1]

[1]Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[3]Department of Pathology, University of California San Francisco, San Francisco, CA,[4]Arizona Cancer Evolution Center, Arizona State University, Tempe, AZ

Background

Barrett's esophagus (BE) is a precancerous condition characterized by the metaplastic replacement of esophageal epithelium in response to gastroesophageal reflux. Although the progression rate to invasive carcinoma is low, identifying high-risk patients remains a critical unmet need, especially as BE prevalence rises. While molecular and immune microenvironment changes associated with BE progression are documented (Nowicki-Osuch 2021), there is a gap in reliable pathology-level indicators to assess cancer risk. This study aims to uncover cancer-relevant changes in BE using computational pathology approaches.

Methods

We analyzed a unique dataset comprising 742 esophageal biopsy slides from 138 patients, and with DNA content abnormalities, including aneuploid (n=125 slides from 26 patients), determined by flow cytometry. Clinical follow-up data for cancer progression was available for 117 of these patients. Using computational pathology models, we trained a multiple-instance learning framework for aneuploid prediction (Lu 2021, Ercan 2024) on 45 slides, and a single-cell detection model based on the ACformer architecture (Huang 2023), fine-tuned on 13,343 cells. Spatial immune cell distribution within the epithelium was quantified using the Morisita-Horn index (MHI), which measures spatial overlap between immune cells and BE cells.

Results

The MIL-based aneuploid prediction model achieved a balanced accuracy of 74.3% and an AUC of 0.81 on the test set (n= 388), while the single-cell detection & classification model reached accuracies of 73.7% for detection and 98.3% for classification (in epithelium, lymphocyte, plasma cell, eosinophil, neutrophil and stromal cell classes). Immune cell MHI was significantly elevated in aneuploid biopsies ($p < 10e-4$, n=125). Aneuploid was found to strongly correlate with cancer progression ($p < 10e-5$, n=33). In aneuploid samples, immune cell infiltration analysis revealed that increased immune cell abundance and higher plasma cell MHI scores were significantly associated ($p < 10e-4$, $< 10e-4$, respectively) with cancer progression in the vicinity of aneuploid BE epithelium, consistent with the observations in (MK Strasser 2023).

Conclusion

This study demonstrates the potential of Patho-Omic tools to predict aneuploid in BE biopsies and identify cancer progression-associated features directly from routine pathology slides. By combining slide-level aneuploid prediction with single-cell detection, we highlight the role of immune cell spatial dynamics in cancer progression. These findings lay the groundwork for stratifying BE patients by progression risk through biopsy image analysis.
