N-methyl-D-aspartate receptor (NMDAR) is an ionotropic glutamate receptor that plays an important role in brain development, learning and memory. NMDARs are encoded by *GRIN* genes: *GRIN1*, *GRIN2A-D*, and *GRIN3A-B*. Rare *de novo* mutations in one of the *GRIN* genes lead to *GRIN* disorder, a neurodevelopmental disorder with symptoms of profound intellectual disability, epilepsy, and visual cortical impairment. Most pathogenic variants are missense heterozygous mutations that leads to over- or under-activation of NMDAR. As a result, pharmacological interventions directly targeting NMDAR often show mixed results in patients. Development of gene-based therapies are desired. A functional NMDAR is a heterotetrametric complex consists of two obligatory GluN1 subunits (encoded by *GRIN1* gene). The other two subunits are a combination of any of the GluN2 or GluN3 subunits. We hypothesize that delivery of exogenous *GRIN1* gene is beneficial for missense *GRIN1* variants. The exogenous *GRIN1* gene will lead to excess expression of functional 'wildtype' GluN1 proteins that competes with variant proteins for the assembly into NMDARs. As a result, more NMDARs will contain only wildtype GluN1 subunits and function normally (Figure 1). To test our hypothesis, we developed two genetic constructs. Both constructs contain i) human *GRIN1* cDNA (hGRIN1); ii) a V5 tag sequence at the N-terminus; iii) 5' and 3' inverted terminal repeats (ITRs) for AAV transfer. We used two promoters that drive ubiquitous or neuron-specific expression. The constructs are packaged into an AAVHSC capsid that can cross the blood brain barrier and transduce neurons and glial cells. We generated two mouse models possessing the equivalent heterozygous missense *GRIN1* patient variants, the Grin1$^{Q536R/+}$ and Grin1$^{Y647S/+}$ mice. Electrophysiological studies revealed that, remarkably, AAVHSC-delivered hGRIN1 showed significantly improved NMDAR-mediated synaptic transmission and restored long-term potentiation (LTP) in the hippocampus of both Grin1$^{Q536R/+}$ and Grin1$^{Y647S/+}$ mice (Figure 2). Importantly, the treatment did not negatively impact normal synaptic functions. For systemic transduction, we also administered the vectors intravenously (i.v.). hGRIN1 expression was detected at mRNA and protein levels in the brain of Grin1$^{Q536R/+}$ mice four- and twenty-week after i.v. injection. Efforts are made to determine the optimal dose, promoter, and route of administration for behavioural rescue. In summary, our strategy has translational potential for clinical applications and may serve as a novel one-time treatment for patients with pathogenic *GRIN1* variants.

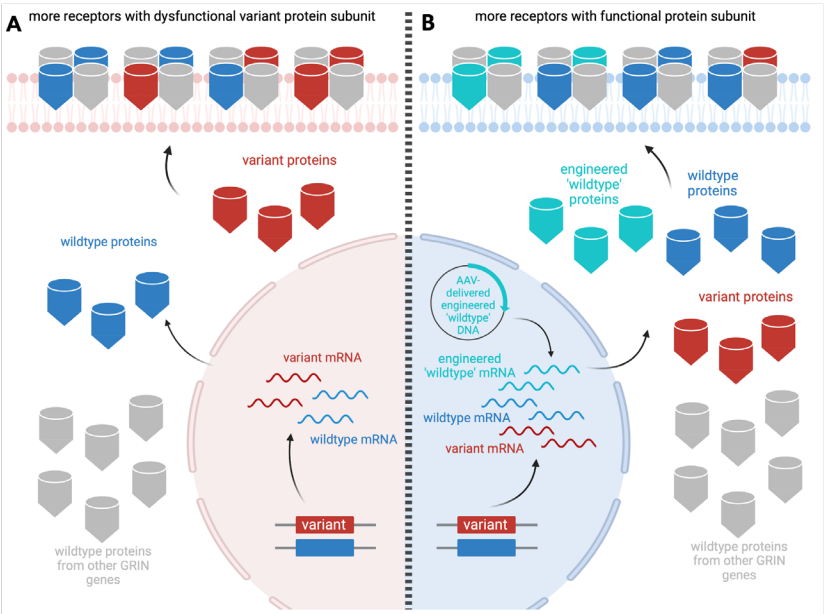

Figure 1. Rationale of *GRIN1* replacement therapy for patients with heterozygous missense variants in *GRIN1* gene, regardless of the locus. (A) Schematic showing a cell from a heterozygous *GRIN1* variant patient that expresses both wildtype (blue) and variant (red) GluN1 protein. **(B)** Delivery of exogenous *GRIN1* cDNA coding for 'wildtype' protein (teal) that competes against variant GluN1.

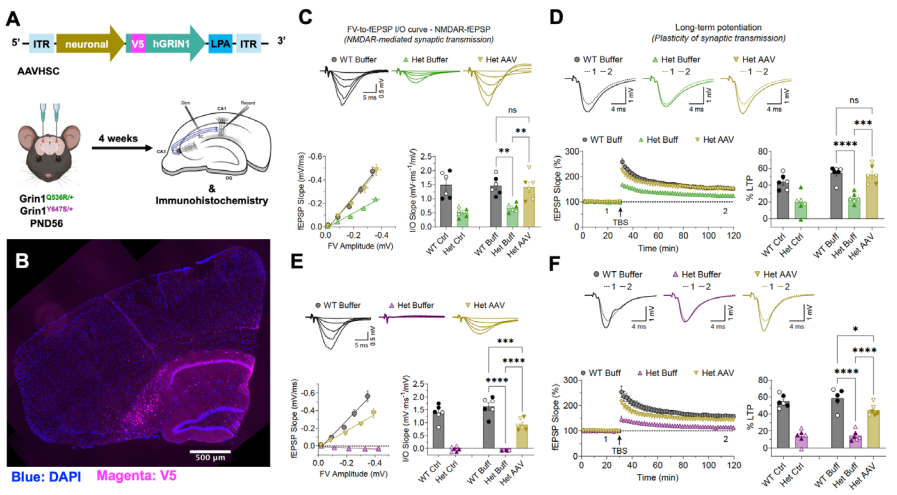

Figure 2. Rescue of NMDAR function following AAVHSC-hGRIN1 expression in the hippocampus of two distinct mouse models of GRIN1 disorder. (A) Design of bilateral intrahippocampal AAVHSC-hGRIN1 injection in Grin1$^{Q536R/+}$ mice (Het, green), and Grin1$^{Y647S/+}$ mice (Het, purple) followed by electrophysiology and immunohistochemistry. WT and Het mice receiving buffer are used as controls. **(B)** V5 immunofluorescence pattern in the hippocampal and surrounding cortical regions. Scale bar=500µm. **(C-F)** Electrophysiological results revealed significant improvement of synaptic NMDAR function in the hippocampus of both Grin1$^{Q536R/+}$ (C-D) and Grin1$^{Y647S/+}$ mice (E-F). Stimulation electrode (Stim) was placed at Schaffer collateral/commissural fibers (SC) and recording electrode (Record) were placed in CA1 stratum radiatum. Baseline recording dataset (no injection) included on the left side of each graph for comparison. (C&E) Representative NMDAR-mediated field excitatory postsynaptic potential (fEPSP) traces, input/output (I/O) function of NMDAR-fEPSP against fiber volley (FV) amplitude, and slope of the I/O curve calculated as a measure of NMDAR-mediated synaptic transmission. NMDAR-mediated responses were recorded in low magnesium (0.1mM) with AMPARs blocker NBQX; (D&F) Representative AMPAR-fEPSP traces before (dotted line) and after (solid line) induction of long-term potentiation (LTP). fEPSP slope (as a percentage of baseline) plotted over time before and after theta burst stimulation (TBS) of LTP. % LTP difference calculated between time points 1 and 2. Filled symbols: males; open symbols: female. One-way ANOVA. Mean±SEM. Tuckey's post hoc. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001, ns = not significant.

549 Recovery in a Mouse model of Tyrosine Hydroxylase Deficiency by Triple Transduction of Striatal Cells with AAV Vectors Expressing Dopamine-Synthesizing Enzymes

Karin Kojima[1], Yo Sato[2], Mika Ito[2], Naomi Takino[3], Takanori Yamagata[1], Hiroshi Ichinose[4], Shin-ichi Muramatsu[1]
[1]Jichi Medical University, Shimotsuke, Tochigi, Japan, [2]Institute of Science Tokyo, Yokohama, Japan, [3]Jichi Medical University, Shimotsuke, Japan, [4]Institute of Science Tokyo, Yokohama, Kanagawa, Japan

Background: For efficient dopamine synthesis, three enzymes are necessary: tyrosine hydroxylase (TH), the rate-limiting agent, first converts tyrosine to l -3,4-dihydroxyphenylamine (l-dopa). Aromatic-l-amino-acid decarboxylase (AADC) then converts l-dopa to dopamine. Guanosine triphosphate cyclohydrolase I (GCH) is the rate-limiting enzyme for synthesizing essential TH cofactor tetrahydrobiopterin (BH_4). TH deficiency caused by variants in *TH* gene presents with dystonia, oculogyric crisis, loss of voluntary movements, developmental delay, and autonomic symptoms. Motor symptoms are treated with l-dopa, but the onset of dyskinesia and hyperactivity requires repeated dose reductions and interruptions, making treatment challenging. We have shown that gene therapy injecting AAV-AADC into the putamen is effective for AADC deficiency, which has symptoms similar to TH deficiency. We have also developed a gene therapy for Parkinson's disease in which AAV vectors expressing TH, AADC, and GCH, respectively were injected into the putamen. **Methods:** We used Dat-Cre×Th-flox mice as a TH deficiency model. In these mice, *TH* gene was deleted in dopamine transporter (Dat) expressing neurons, and the level of dopamine in the striatum was reduced by less than 5 % of those in the wild type mice. The dopamine deficient mice showed hypoactivity in the open field test. These mice were stereotaxically injected with AAV-TH, AAV-AADC, and AAV-GCH (7×10^9, 4×10^9, and 1×10^{10} vector genomes, respectively) in the caudo-putaminal unit (CPU). Control mice were received AAV-GFP. Brain tissues were harvested four weeks after injection for biochemical and histological analyses. **Results:** Three weeks after injection of a mixture of AAV-TH, AAV-AADC, and AAV-GCH into the CPU, treated mice showed a marked behavioral improvement in the open field test, including an increase in locomotion. Immunohistochemistry showed almost all transduced cells were medium spiny neurons. **Conclusions:** We have shown motor symptoms in TH deficient mice are reversible by striatal injection of AAV-TH/GCH/AADC. This approach avoids the surgical risks associated with brain stem infusion. Transduced striatal neurons efficiently synthesize dopamine. These findings support the notion that AAV-mediated TH/GCH/AADC delivery could be a promising therapy for individuals suffering from TH deficiency.

550 GABAergic-Selective AAV Gene Therapy for SLC6A1-Related Disorder

Bryan Gore[1], Rong Guo[2], Emily Luber[3], Robert Christian[4], Jiatai Liu[2], Jessica Trinh[3], Yemeserach Bishaw[5], Meagan Quinlan[6], John Mich[7], Refugio Martinez[6], Travis Hage[4], Kathryn Gudsnuk[4], Tim Jarsky[4], Jonathan Ting[6], Manuel Lopez[8], Justin Ichida[9], Ed Lein[6], Boaz Levi[6]*

**Corresponding Author*

SLC6A1-related disorder is a severe developmental epileptic encephalopathy with an urgent need for an innovative disease-modifying therapy. The disease is caused by the loss of the primary GABA transporter in the brain, GAT1. Endogenous GAT1 neuronal expression is restricted to inhibitory neurons and promotes the clearance of GABA from synaptic and extra-synaptic sites. AAV-mediated gene delivery of *SLC6A1* could provide a one-time curative treatment to patients that suffer from this disease, yet the importance of targeting expression to defined brain cell types is unknown. Here we developed AAV-based therapeutics to express human *SLC6A1* either selectively in inhibitory neurons or in all neurons to test if neuronal subclass-selectivity is essential for the safe rescue of phenotypes. We found that inhibitory neuron-specific expression was better tolerated and reversed major disease-relevant phenotypes, including GABA uptake activity, inhibitory current kinetics, EEG epileptiform activities, seizures, motor dysfunction, and cognitive deficits. In contrast, pan-neuronal expression of *SLC6A1* resulted in increased mortality, significant side effects, and very limited phenotypic rescue. Thus, our findings suggest that the

inhibitory-circuit selective expression of *SLC6A1* is necessary for safe and efficacious gene therapy for *SLC6A1*-related disorder.

551 A Platform for Engineered Cross-Correction of AAV-Expressed Transgenes

Paul Carlson[1], Daniel Dubreuil[2], Swathi Ayloo[1], Shih-Ching Chou[3], Jae Ryu[4], Jeffrey Ardinger, Yashvi Parikh[5], Jie Bu[4], Bradford Elmer[6], Michael Fleming[1], Christian Mueller[7], Shyam Ramachandran[7]
[1]Sanofi, Cambridge, MA, [2]Sanofi, Bridgewater, NJ, [3]Genzyme, a Sanofi Company, Waltham, MA, [4]Sanofi, Waltham, MA, [5]Sanofi, Waltham, MA, MA, [6]Sanofi, Waltham, Massachusetts, [7]Sanofi Genzyme, Waltham, MA

A limitation of many AAV gene therapy approaches is insufficient transduction of target cells and tissues to achieve the necessary therapeutic effect. In some cases, this limitation can be mitigated through capsid engineering and/or increased AAV dosing; however, certain tissues and cell types remain difficult to efficiently transduce. Moreover, increased AAV dosing presents both safety risks and increased manufacturing costs.

To address this challenge, we took inspiration from proteins which are naturally "cross-corrective"; that is, which are produced and secreted from one cell and taken up to exert their action in another. For example, the Arylsulfatase A (ARSA) enzyme - which is implicated in Metachromatic Leukodystrophy (MLD) - is naturally secreted into the extracellular matrix where it is taken up by neighboring and distant cells via the mannose 6-phosphate receptor (M6PR). We have shown that the recombinant human protein can leverage normal ARSA secretion and reuptake mechanisms, facilitating enzyme spread to secondary, non-transduced cells. This results in "cross-correction" in a broad range of cells, including oligodendrocytes and microglia (which are not efficiently transduced in vivo by AAV vectors).

To engineer cross-correction, we first carried out in silico screens to identify possible signal peptides (SPs) for efficient protein secretion as well as efficient cleavage of the SP. In one example, SP optimization of an AAV-delivered human GBA1 transgene (implicated in diseases like GBA-PD and Gaucher Disease) resulted in greatly enhanced GCase protein spread compared to the footprint of AAV-transduced cells; like ARSA, this protein can then be taken up by non-transduced cells, resulting in a functional restoration of enzyme activity in non-transduced cells in vivo. In cases where the secreted protein is not naturally taken up by cells, further modification via the incorporation of a cell penetrating peptide (CPP) may be used to enable uptake. For example, SP- and CPP-modified frataxin protein (for the treatment of Friedreich's Ataxia) demonstrated cross-correction and evidence of cellular uptake across tissue types. Together, these results highlight the exciting potential of engineered cross-correction to overcome AAV transduction limitations across a range of indications.

552 Gene Replacement Therapy for TECPR2-Related Hereditary Sensory and Autonomic Neuropathy

Xin Chen[1], Merve Emecen Sanli[2], Thomas Dong[3], Anjala Jiji[1], Steven Gray[4]
[1]UT Southwestern Medical Center, Dallas, TX, [2]UTSW, Dallas, TX, [3]20000, Dallas, TX, [4]University of Texas Southwestern Medical Center, Dallas, Texas

Background
TECPR2-related hereditary sensory and autonomic neuropathy with intellectual disability (HSAN type 9) is a rare autosomal recessive disorder caused by biallelic pathogenic variants in the gene named TECPR2 (tectonin beta-propeller repeat containing 2). The TECPR2 gene encodes a protein crucial for autophagy regulation, sensory processing, and motor coordination. Clinical manifestations include developmental delay, motor deficits, and autonomic dysfunction, with limited life expectancy. Despite the critical impact of this disorder, no disease-modifying therapies are available, highlighting the need for innovative therapeutic interventions.

Aim
These studies aimed to investigate the feasibility, safety, and effectiveness of adeno-associated viral 9 (AAV9)-mediated TECPR2 gene replacement therapy in a preclinical mouse model.

Methods
For the efficacy study, the AAV9/TECPR2 vector was administered to TECPR2 knock in (KI) and WT mice at 7–10 days (P7-10) or 0-2 days (P0-2) of age. Mice were administered with vehicle or a low (1.25e11 vg), middle (2.5e11 vg), or high (5e11 vg) dose of AAV9/TECPR2 via intrathecal (IT) injection. Efficacy was assessed using body weights, survival and behavioral tests. Behavioral tests including startle response, hot plate, open field, rotarod, hindlimb clasping, and nest building were performed at 3-, 6-, and 9-months post-injection. For the safety study, AAV9/TECPR2 was administrated to WT mice at P7-10 and animal safety was monitored through serum toxicology panels, histopathological and survival analysis.

Results
No obvious adverse effects in body weight and survival were observed in efficacy groups. In behavior testing, p7-10 treatment demonstrated a dose-dependent rescue in startle response. Temperature hypersensitivity at 6-month post injection was rescued with high dose treatment at P7-10. In the open field test, distance and the time spent in the center parameters were partially rescued. Increased front paw lifted times and decreased front right luminance were partially rescued dose dependently. Interestingly, in the mouse cohort treated at P0-2, less therapeutic benefits were observed. No significant adverse effects in body weight, survival, or histopathologic analysis were observed in the safety study.

Conclusion
AAV9-mediated TECPR2 gene replacement therapy shows some promise as a therapeutic approach for TECPR2-related HSAN type 9. Both the efficacy and safety results highlight the potential for clinical translation.

553 Gene Replacement Therapy for MPS IIIC with scAAV9/HGSNAT Vector

Xin Chen[1], Thomas Dong[2], Merve Emecen Sanli[3], Anjala Jiji[1], Jill Wood[4], Srikanth Singamsetty[4], Steven Gray[5]
[1]UT Southwestern Medical Center, Dallas, TX, [2]20000, Dallas, TX, [3]UTSW, Dallas, TX, [4]Phoenix Nest Biotech, Brooklyn, NY, [5]University of Texas Southwestern Medical Center, Dallas, Texas

Background:
Mucopolysaccharidosis type IIIC (MPS IIIC), or Sanfilippo syndrome type C, is an ultra-rare autosomal recessive lysosomal storage disorder caused by mutations in the heparan-α-glucosaminide N-acetyltransferase (**HGSNAT**) gene. This results in lysosomal accumulation of heparan sulfate, leading to progressive neurodegeneration. Clinical manifestations include neuropsychiatric symptoms, developmental delay, and childhood dementia, with most patients succumbing to the disease before adulthood. Current treatment options remain palliative, highlighting the urgent need for therapeutic strategies to address the **HGSNAT** enzyme defect.

Objective:
This study aimed to evaluate the efficacy and safety of an intrathecally delivered **scAAV9/HGSNAT (JLK-247**) vector to treat MPS IIIC in a mouse model.

Methods:
The gene therapy vector was administered to **HGSNAT P304L** mutant mice at postnatal 7–10 days (early dosing) or 150 days (delayed dosing) of age. Efficacy was assessed using behavioral tests, enzymatic activity assays, and histopathological analyses. Safety was monitored through serum toxicity panels, organ weights, and survival analysis.

Results:
Early dosing rescued the urinary retention phenotype significantly better compared to delayed treatment, with a partial restoration of **HGSNAT** enzymatic activity in key organs. Improved survival was noted in treated mice, primarily driven by the need to euthanize the untreated mice for animal welfare due to extreme urinary retention. In behavior testing, impaired novel object recognition was rescued in treated mice irrespective of their age at dosing. No significant adverse effects in body weight, survival, or open-field behavior were observed in **JLK-247** treated mice irrespective of their age at dosing.

Conclusion:
The findings highlight that CNS-directed gene replacement therapy with **JLK-247** is a promising strategy to treat MPSIIIC. Further studies will assess postmortem histological and biomarker changes in these mice. GLP toxicology studies will assess the safety of **JLK-247** to advance this experimental gene therapy approach towards clinical application.

554 Novel Peptide Therapy Targeting Pro-Inflammatory Microglia for Neonatal Hypoxic-Ischemic Encephalopathy in Mice

Rika Zen[1], Tomoko Maeda[2], Shunichiro Tsuji[2], Makoto Urushitani[3], Takashi Murakami[2], Tomoya Terashima[4]*
[1]Shiga University of Medical Science, Otsu-city, Shiga, Japan, [2]Shiga University of Medical Science, Otsu, Shiga, Japan, [3]Shiga University of Medical Science, JAPAN, [4]Shiga University of Medical Science, Otsu,Shiga, Shiga, Japan
**Corresponding Author*

Introduction: Hypoxic-ischemic encephalopathy (HIE) is a neonatal brain disorder caused by perinatal complications such as placental abruption. Neonates born with HIE are at high risk of severe neurological and developmental impairments; however, no effective treatments are currently available. HIE is aggravated by intracerebral inflammation caused by pro-inflammatory microglia. We investigated the therapeutic effects of an apoptotic peptide on HIE due to depletion of pro-inflammatory microglia.

Methods: MG1 homing peptide, which selectively targets and binds pro-inflammatory microglia, was conjugated with the pro-apoptotic peptide $_{D}$[KLAKLAK]$_2$ (KLA), resulting in MG1-KLA. The therapeutic effects of MG1-KLA for HIE were examined *in vitro* and *in vivo*. We administered MG1-KLA into pro- and anti- inflammatory microglia derived from primary cultures of microglia, and examined binding ratio, cell viability and apoptosis assay. Next, HIE model mice were induced in P9 (postnatal day 9) , which corresponds to full-term birth in human, using carotid artery ligation followed by hypoxia. We performed intracerebroventricular (ICV) injection of MG1-KLA or phosphate-buffered saline (PBS) 24 hours after-hypoxic ischemic surgery, and evaluated the therapeutic effects. After conducting behavioral tests such as rota-rod test and open field test on P23–25, histological analysis using MAP2 staining was conducted on P26 to evaluate tissue damage. Additionally, histological analysis using IBA-1 and CD86 was performed on P12 to evaluate pro-inflammatory microglial accumulation, and biochemical analyses with quantitative polymerase chain reaction (qPCR) were performed on P10, 8 hours after ICV injection, and on P11 to examine pro- and anti-inflammatory cytokine changes over time.

Results: MG1-KLA selectively bound to 81.8% of pro-inflammatory microglia and decreased cell viability in a dose-dependent manner. Annexin V apoptosis assay showed that MG1-KLA induced apoptosis in 24.2% of pro-inflammatory microglia. The effect of MG1-KLA was less shown on anti-inflammatory microglia. Next, HIE mice treated with MG1-KLA showed significant improvement in the rota-rod test and open field test, and MAP2 staining results showed significantly reduced brain atrophy compared with the PBS-administered non-treated mice with HIE. MG1-KLA administration improved HIE-induced neuronal and behavioral dysfunction in mice. Furthermore, IBA-1 and CD86 staining showed that accumulation of pro-inflammatory microglia in ipsilateral side of MG1-KLA treated mice was suppressed compared with PBS-administered non-treated mice. The results of qPCR showed that pro-inflammatory cytokines such as TNF-α and IL-1β were suppressed in the ipsilateral hemisphere of MG1-KLA treated mice compared with PBS-administered non-treated mice. This cytokine suppression corresponded with decreased microglial activation.

Conclusions: MG1-KLA selectively depleted pro-inflammatory microglia both *in vitro* and *in vivo*. These findings suggest that the novel MG1-KLA peptide therapy has a high potential for treating neonatal HIE through the selective induction of apoptosis in pro-inflammatory microglia.

555 Extracellular Vesicle Trafficking of Gangliosides Boosts rAAV-Based Correction for GM3 Synthase Deficiency

Sophia Liu[1], Jonathan Valeros[1], Max Zinter[1], Travis Thomson[1], Jessica Spinelli[1], Guangping Gao[1], Phillip Tai[2]
[1]UMass Chan Medical School, Worcester, MA, [2]UMass Chan Medical School, Worcester, Massachusetts
GG and PT are co-corresponding authors.

GM3 synthase deficiency (GM3SD) is a severe infantile epilepsy syndrome with debilitating neurological phenotypes. GM3SD is a monogenic disorder that is caused by mutations in the *ST3GAL5* gene, permitting rAAV-based gene therapy as a promising approach. Using a neuron-specific promoter to drive *ST3GAL5* expression in an AAV9 vector, we have successfully restored both cognitive and motor functions in mouse models for GM3SD. Immunofluorescence staining showed widespread correction of gangliosides across the cortex beyond what is typically achieved by AAV9-based vectors. Widespread expression of gangliosides across the brain suggested that some brain structures may be cross-corrected following gene therapy. We hypothesize that gangliosides use extracellular vesicles (EVs) as a mechanism to cross-correct cells that are not directly transduced by gene therapy vectors. Tunable resistive pulse sensing (TRPS) quantification of EV size and concentration showed that *ST3GAL5* expression influences EV biogenesis. Specifically, loss of *ST3GAL5* resulted in smaller vesicles and lower production of vesicles overall. This result suggests that *ST3GAL5* expression may influence the overall lipid profile of EV membranes. LC/MS measurement of ganglioside content in EVs also confirm that GM3 and GD1a/b gangliosides are present in EVs isolated from brains. The presence of simple and complex gangliosides in these EVs allows them to be viable vehicles for ganglioside trafficking, which enables the EVs to correct nearby cells and other brain structures. Additional experiments to confirm our findings will allow research into increasing rAAV efficiency for the treatment of GM3SD and other neurological disorders.

556 Harnessing AAV-RNAi Technology for the Treatment of Neurodegenerative Diseases

Jessica Hogestyn[1], Bradford Elmer[2], Johanna Adams[3], Yao Chen[1], Jie Bu[1], Erik Wischhof[1], Tiffany Chan[1], Aishwarya Mahendran[1], John Bladon[1], Ye He[4], Robert Jackson[4], Brenda Richards[1], Christian Mueller[5], Shyam Ramachandran[5]
[1]Sanofi, Waltham, MA, [2]Sanofi, Waltham, Massachusetts, [3]Sanofi, Bridgewater, NJ, [4]Sanofi, Cambridge, MA, [5]Sanofi Genzyme, Waltham, MA

Neurodegenerative proteinopathies including Huntington's, Parkinson's, and Alzheimer's disease face significant unmet medical needs. These disorders are driven by the accumulation of toxic proteins, and the structural heterogeneity of protein aggregates complicates therapeutic targeting. RNA interference (RNAi) provides a straightforward method to overcome this complexity, reducing all toxic protein isoforms with a single drug for each proteinopathy. Here, we present three examples of adeno-associated virus (AAV)-mediated RNAi for the sustained reduction of pathogenic proteins, illustrating a platform with transformative potential for neurodegenerative proteinopathies. By employing artificial microRNAs (amiRNAs) against specific targets of interest, AAV-RNAi delivers precise, scalable, and durable gene silencing to address the underlying genetic and molecular pathologies of these diseases.

Huntington's disease (HD) is a fatal, monogenic neurodegenerative disease caused by expanded trinucleotide repeats in the huntingtin gene (*HTT*) resulting in the accumulation and aggregation of huntingtin protein and subsequent neurotoxicity. Partial suppression of *HTT* mRNA in the brain has been shown to be safe and efficacious in animal models, validating *HTT*-lowering as a therapeutic strategy agnostic to allele type. We designed amiRNAs targeting *HTT,* implementing a novel optimization workflow to resolve liabilities associated with inefficient amiRNA strand processing. Potent amiRNAs were identified with robust *HTT* lowering *in vitro* and *in vivo* in a rat model of HD highlighting the promise of AAV-RNAi for the treatment of HD.

Synucleinopathies are a family of diseases, including Parkinson's disease and multiple system atrophy (MSA) characterized by the accumulation of alpha-synuclein protein. Using a brain-penetrant AAV capsid, 50% wild-type *Snca* knockdown in the pre-formed fibril mouse model prevented alpha-synuclein pathology, protected dopaminergic neuron in the substantia nigra, and halted the spread of pathological aggregates. Potency of our gene

therapy candidates was improved through amiRNA concatenation, showcasing scalable design improvements and clinical translation potential.

Similarly, for tauopathies such as Alzheimer's disease and progressive supranuclear palsy (PSP), targeting microtubule-associated protein tau (*MAPT*) with AAV-RNAi reduced tau aggregates, phospho-tau species, and neurodegeneration biomarkers in a tauopathy mouse model. Off-target effects were minimized through rigorous *in vitro* and *in vivo* screening, identifying a lead amiRNA with a wide therapeutic window that achieved clinically relevant target knockdown with no off-target effects. Pharmacology studies in nonhuman primates further demonstrated proof-of-concept for neuronal *MAPT* knockdown.

These studies underscore the versatility and transformative power of AAV-RNAi technology for the treatment of neurodegenerative proteinopathies. Ongoing advancements in vector engineering and capsid optimization, supported by robust *in vivo* preclinical validation, promise to accelerate clinical translation and bring hope to patients facing devastating neurodegenerative diseases.

557 A Computational Model Predicts Treatable Huntington's Disease Patient Population and Minimum Therapeutic Efficacy Requirements for Gene Therapies Targeting Somatic Instability

Paul Ranum[1], P. Peter Ghoroghchian[2], Jang-Ho Cha[3]
[1]Latus Bio, Philadelphia, PA, [2]Latus Biosciences, Downingtown, PA, [3]Latus Bio, Boston, MA

Precise delineation of a treatable patient population is a challenge across indications targeted by gene therapies. Because effective gene therapy intervention requires a viable target cell population, patients must be treated sufficiently early in disease prior to irreversible cell damage or loss. Therapeutic outcomes are determined by the number of viable target cells and efficacy characteristics of the therapy (transduction rate, and transgene functionality). This complex relationship between disease, patient, and therapeutic intervention defines clinical success or failure. Therefore, enrollment of patients who are too advanced in disease may doom an efficacious therapy in clinical trials. This challenge is particularly apparent in Huntington's disease where somatic instability (SI), the stochastic increasing of CAG repeat length in medium spiny neurons, advances with patient age and underlies cellular health and death.

Somatic instability (SI) in the mutant HTT allele is a high value therapeutic target for Huntington's disease (HD). However, rates of SI and the speed of HD progression vary widely with inherited germline CAG repeat lengths across the HD patient population. Understanding this variability and projecting the treatable range of patients for novel SI-directed therapies is critical to their design, preclinical development, and for conferring optimal benefit to HD patients.

Latus has developed a computational model that tracks the percentage of healthy medium spiny neurons (MSNs) across the lifetime of HD patients; the model further predicts changes in MSN survival based on a SI-directed interventional gene therapy. Leveraging the previously reported rates of SI in human MSNs (Handsaker et al., 2025), and inputs describing therapeutic efficacy, the model projects the range of patients treatable using LTS-201 - an MSH3-targeting gene therapy preclinical candidate in development by Latus Bio.

The model predicts that for a hypothetical patient, presenting with a germline CAG length of 40, treated at age 30, a SI-targeting gene therapy with conservative efficacy characteristics achieves substantial therapeutic benefit: a 15 year delay in the onset of motor changes, and 12 and 15 year delays in the onset of HD-ISS Stage 2 and Stage 3, respectively.

To evaluate the treatable range of HD patients, the model has been expanded to predict therapeutic benefit across a spectrum of germline CAG lengths and ages. This analysis predicts that LTS-201 could provide a minimum therapeutic benefit of > 5 years in delay to onset of motor symptoms for the majority of HD patients and that it has the potential to confer the greatest benefit when delivered early, prior to the onset of motor symptoms.

The flexible framework provided by this computational model enables therapeutic performance prediction across the HD patient population and serves as a valuable tool for defining the target populations for SI-directed therapies.

558 Long term safety and efficacy of BGT-DTDS in the DAT-knockout mouse model of Dopamine Transporter Deficiency Syndrome

Riccardo Privolizzi[1], Hester Wing Sum Chu[2], Giulia Leoni[3], Simon Eaglestone[4], Adrien Lemoine[5], Manju Kurian[6], Simon Waddington[6], Joanne Ng[7]
[1]University College London, London, London, United Kingdom, [2]University College London, LONDON, Greater London, United Kingdom, [3]Waterbeach, Cambridgeshire, United Kingdom, [4]Bloomsbury Genetic Therapies, London, United Kingdom, [5]LONDON, United Kingdom, [6]University College London, London, United Kingdom, [7]UCL Queen Square Institute of Neurology, London, Greater London, United Kingdom

Dopamine transporter deficiency syndrome (DTDS) is an inherited, life-limiting childhood neurotransmitter disease caused by biallelic loss-of-function mutations in the solute carrier family 6 member 3 (*SLC6A3)* gene encoding the dopamine transporter (DAT), integral to dopamine homeostasis and neurotransmission. There is an unmet clinical need for paediatric patients presenting with a progressive parkinsonism-dystonia to adults with early-onset Parkinson's disease, who do not respond to currently available medical or neurosurgical treatments. DTDS is likely misdiagnosed as cerebral palsy and underreported worldwide. We previously reported our gene therapy development for DTDS in patient-derived iPSC neuronal model and DAT-knockout (DAT-KO) mice to 3 months post gene therapy.

In the present study, we assessed the long-term efficacy and safety of BGT-DTDS (AAV2.SLC6A3*)* gene therapy: an AAV2-mediated gene therapy delivered to the midbrain of DAT-KO mice to model clinical delivery application. We observed a dose-dependent therapeutic effect demonstrated by normalisation of locomotor behaviours in open field, vertical pole and foot fault tests. Brain immunohistochemical analysis showed sustained DAT expression in the midbrain of treated animals. Neuropathology analysis at 12 months post gene therapy demonstrated safety and no neurotoxic effects with Hematoxylin & Eosin, Nissl, and glial fibrillary acidic protein (GFAP) staining. Our data affirms that stereotactic midbrain-targeted BGT-DTDS gene therapy provides long-term correction of DAT function and safety in a clinically relevant animal model of DTDS. The parallel success of a similar gene therapy approach for aromatic L-amino acid decarboxylase (AADC) deficiency further corroborates the promise of this approach. With this body of preclinical data, BGT-DTDS received Orphan Drug Designation from the European Commission (EC) and the U.S. Food and Drug Administration (FDA) as well as Rare Pediatric Disease Designation (RPDD) from the FDA for the treatment of DTDS and provides further support for clinical trial application.

559 Cross-Species BBB-Penetrant IV-Delivered AAV Gene Therapy Provides Broad and Robust CNS Tau Lowering in Tauopathy Mouse Models and Non-Human Primate

Hechen Bao[1], Maneesha Paranjpe[2], Cansu Colpan[1], Ching-Lien Fang[1], Jeff Thompson[3], Yasuhiro Ito[1], Joydip Kundu[1], Su Jing Chan[1], Bridget Shaughnessy[1], Shiron Lee[4], Joseph Clement[4], Camila Arce[1], Rebecca Spellman[1], Barbara Bueno[1], Anupriya Kulkarni[5], Wenya Yang[1], Munachiso Egbuchulam[4], Amy Bruce[1], Rong Zhao[1], Nilesh Pande[4], Jiachen Liu[4], Manonmani Kumar[1], Elisabeth Knoll[6], Brian Ezell[4], Gretchen Rivera[7], Tyler Moyer[1], Dillon Kavanagh[1], Jordan Routhier[1], Alexander Kubiak[8], Jack Studer[8], Dhiral Shah[9], Kyle Grant[2], Matteo Placidi[8], Netsanet Gebremedhin[4], Jeron Chen[10], Johnny Yao[11], Chanchal Sadhu[12], Mathieu Nonnenmacher[8], Dinah Sah[1], Todd Carter[8], Rajeev Sivasankaran[1], Wencheng Liu[2]*

Progression and spread of tau pathology in the human brain correlates well with cognitive decline in Alzheimer's disease (AD). Pan-tau lowering in the central nervous system (CNS) was recently shown to have favorable clinical

outcomes for the treatment of AD. However, anti-sense oligonucleotides which reduce tau expression and tau pathology in both preclinical and clinical studies require repeated administration via intra-ventricular or intrathecal administration. In contrast, a single intravenous (IV) administration of a blood-brain barrier (BBB)-penetrant, self-complementary adeno-associated virus (scAAV) gene therapy can durably and effectively reduce CNS levels of human tau in tauopathy mouse models, which we previously reported (Bao et al, #1602, ASGCT 2024).

In the present study, we utilized a second-generation, cross-species BBB-penetrant TRACER™-derived capsid to intravenously deliver a vectorized primary artificial microRNA (pri-amiRNA) containing a potent tau siRNA, VY-1706, in tauopathy mouse models as well as non-human primates (NHP). In addition, to further optimize our AAV gene therapy targeting tau, pri-amiRNA driven by two different promoters with distinct cellular tropisms were evaluated head-to-head in rodent and NHP pharmacology studies to compare tau lowering. The results demonstrated a dose-dependent increase in vector genome (VG) and concomitant tau mRNA knockdown, in multiple brain regions of VY-1706 treated hTau and P301S mice at 8 weeks post-injection. In hTau mice, which express all six human isoforms, tau mRNA levels were reduced by 60-80%, and total tau protein levels decreased by 70-80% in the high dose group compared to the vehicle-treated controls across multiple brain regions. Similarly, in P301S mice, a disease model carrying a human tau mutation, reductions in tau mRNA and total tau protein levels in the high-dose group were comparable to those observed in hTau mice within the same brain regions. Additionally, pathological tau protein levels were reduced by up to 80% in these P301S mice, highlighting the promising efficacy of this approach. In the NHP study, broad biodistribution of vector genomes was observed in multiple critical AD related brain regions. Tau mRNA levels were reduced by greater than 50%, and total tau protein levels were reduced by 40-55% at 11 weeks post-injection. In addition, there was no associated perturbation of the endogenous microRNA transcriptome. Importantly, treatment with VY-1706 was well-tolerated, with no notable test article related adverse effects. The overall pharmacological activity and safety profiles were similar between the two promoters driving the pri-amiRNA in both rodent and NHP studies. These findings demonstrate that the combination of a potent and well-tolerated tau targeting pri-amiRNA with a novel cross-species BBB-penetrant capsid holds promise as a one-time, IV treatment option for AD and other tauopathies.

560 Selective targeting of trans-synaptic tau using chimeric antibodies receptors tethered to the synaptic membrane

Trans-synaptic transmission of pathological tau contributes to the spread of tau aggregates and neurofibrillary formation in Alzheimer's disease (AD). Reducing the prevalence of pathogenic tau species within the synaptic cleft may therefore prevent tau propagation and attenuate AD progression. Passive immunotherapy using monoclonal IgG antibodies has been used to target extracellular tau, however these therapies have not achieved clinical success suggesting a failure to target propagating tau species. Additional challenges such as antibody selectivity towards spreading species, availability within the CNS and physical limitations in accessing the narrow synaptic cleft may further prevent immunotherapies from accessing and identifying trans-synaptic propagating tau. To address these limitations, we purified synaptosomes from AD and pathologically negative control patients and used phospho-proteomics to identify tau epitopes present in the AD post-synaptic terminals. Comparison of the AD and normal post-synaptic fractions identified 17 phospho-tau epitopes enriched in the AD fraction, including the PHF1 tau epitope pS396/pS404. Using this information, we developed a novel approach to increase effective anti-tau antibody concentration at the synapse by using AAV9 to deliver a tethered synaptic-chimeric antibody receptor (synCAR) to the post-synaptic membrane. To achieve this aim, we fused the PHF1 small antibody fragment (scFv) with the post-synaptic membrane component neurolignin-1 (NLGN1). Using both murine and hiPSC neuronal models, we show that our PHF1 synCAR effectively expresses at the synaptic membrane and localizes with the post-synaptic marker PSD95 without impacting neuronal viability. Finally, we show that PHF1 synCAR effectively targets pathogenic tau species by observing that tau aggregation in seeded mouse primary neurons increased by ~73%. This indicates that PHF1 synCAR captures and concentrates tau seeds resulting in accelerated seeding pathology. Overall, these data

suggest a novel mechanism for targeting proteins either in the synaptic cleft or within the post-synaptic membrane and provides an effective approach for isolating and identifying propagating tau species.

561 Tuberin Replacement Therapy in Cultured, Patient-Derived Neural Progenitor Cells and a Cerebral *in vivo* Mouse Model of Tuberous Sclerosis Complex Type 2

Zin-Juan Klaft[1], Edwina Abou Haidar[2], Marie Rehm[1], Pauline Martin[2], Shilpa Prabhakar[3], Roberta Beauchamp[2], Alexandra Geffrey[4], Tomeh Tomeh[5], Vijaya Ramesh[2], Chris Dulla[1]*, Xandra Breakefield[3]*

**Corresponding Author*

Tuberous sclerosis complex (TSC) is an autosomal dominantly inherited neurologic disease caused by loss of function of tuberin or hamartin. Affected individuals inherit one defective allele of either the *TSC2* or *TSC1* gene, respectively, with a somatic mutation in cells in a susceptible tissue during development or later life leading to benign tumors (hamartomas) and focal dysplastic lesions affecting the brain, skin, eye, heart, lungs, and kidney. Most serious consequences result from second hits in the brain leading to cortical tubers, subependymal nodules, subependymal giant cell astrocytomas, demyelination, astrogliosis, and epilepsy. There has been some success in treating neurologic and non-neurologic manifestations in symptomatic TSC patients with inhibitors of the mammalian target of rapamycin (mTOR) signaling pathway such as sirolimus/everolimus (rapalogs). Rapalogs have to be continuously taken, compromise immune functions, may cause psychobehavioral problems and are less effective in treating epilepsy than other symptoms. While ketogenic diet and treatment of infantile spasms with vigabatrin can attenuate seizure burden, treatment-resistant seizures remain the major disease burden for patients throughout their life despite the current standard of care. In a previous study we showed that systemic delivery of an adeno-associated virus (AAV) vector (serotype 9) encoding a condensed form of human tuberin (cTuberin) in a

cerebral mouse model of *TSC2* led to extended lifespan and reduction in brain pathology, including normalization of subependymal overgrowths with a decrease in cell proliferation around the ventricles and reduced neuropathology.

Here we show that in these cerebral TSC2-KO mice, AAV-cTuberin rescues ventricular overgrowths and demyelination by magnetic resonance imaging (MRI), as well as decreased proliferation of subventricular cells, reduced size of neurons, and pS6 staining intensity by immunohistochemistry. Chronic *in vivo* electrocorticography (ECoG) recordings revealed that both AAV-cTuberin therapy and everolimus reduced seizures in this animal model, but gene therapy was more effective in normalizing the interictal ECoG in mice, compared to everolimus. These findings support use of AAV-cTuberin as gene replacement to increase survival, normalize brain morphology and reduce seizures in the cerebral TSC2 mouse model.

562 AAV-SynCav1 Administration to the Hippocampus of Cuprizone Mouse Model of Multiple Sclerosis Preserves Hippocampal Myelination

Introduction: Multiple Sclerosis (MS) is a chronic autoimmune demyelinating disease of the brain and spinal cord that causes axonal injury and cerebral atrophy. There exist few interventions that specifically target neuroprotection, neurorepair, and remyelination. Cuprizone ingestion in mice induces white matter pathology similar to MS lesions and thus serves as an excellent model to test potential remyelinating therapies. Six weeks of cuprizone (0.2%) diet results in demyelination of the corpus callosum (CC) and hippocampus (Hpc). Withdrawal of cuprizone results in early-stage re-myelination at 2-3 weeks. We have previously shown that brain delivery of the membrane/lipid raft (MLRS) scaffolding protein caveolin-1 (Cav-1) using a neuron-specific synapsin promoter (synapsin-Cav-1, SynCav1) increased hippocampal axonal myelination of CA3 Schaffer collaterals and augmented cognitive function in aged mice. Moreover, when delivered to the brain of Alzheimer's disease (AD, PSAPP) mice, SynCav1 preserved hippocampal axonal myelination, dendritic arborization, synaptic ultrastructure, and hippocampal-dependent fear conditioning (FC) learning and memory. These findings provide strong support for the potential therapeutic applicability of *SynCav1* in treating de-myelinating neurodegenerative diseases like MS. Current study tested AAV.CAP-MAC, an engineered variant that achieves broad CNS biodistribution in multiple non-human primate species.

Methods: C57Bl/6 mice at the age of 8-week were fed cuprizone diet (0.2%) for 6 weeks. Mice were randomly allocated to normal diet group, cuprizone exposure (CE) sham group, and CE+ SynCav1 group. For CE sham group and CE+SynCav1 group underwent surgery 1 week prior to the CE initiation. 3.0 µL of either 0.9% saline or CAP.MAC SynCav1 was injected at 6 locations (3 locations/hippocampus). The tissue collection was performed at the age of 14 weeks. For the CE+ SynCav1 group, the 2.1E10 (genome copies, g.c.)/animal were given. Fear conditioning (FC) test was performed at the end of diet to evaluate memory function. After CE time point mice were euthanized and the brains were harvested. Black Gold staining was used for myelin evaluation for the hippocampus. **Results**: There was no difference in FC learning (Day 1) between the normal diet group and the CE sham group. In both Contextual recall (Day 2) and Auditory-cue recall (Day 3), the freezing time (%) were significantly lower in CE sham group with the p-value of 0.02 and 0.03 (Unpaired t-test), respectively. Black-Gold myelin histology analysis showed significant decreased signal in the CE hippocampus compared to normal diet ($p < 0.0001$, Unpaired t-test). In FC, CE impaired both context ($p=0.058$) and cue (Figure 1) memory recall. In CE mice that were pre-treated with SynCav1, Black-Gold staining showed obvious myelinated fibers in the hippocampus when compared to the untreated CE mice (Figure.2 A-C). Black Gold density analysis showed significant increased myelin signal in the hippocampus of SynCav1-treated CE mice (mean: 7.4) compared to untreated CE mice (mean: 2.5, Unpaired t-test) (Figure 2D)

Conclusion: Cuprizone diet for 6 weeks induces prominent hippocampal demyelination and resultant fear memory deficits. Direct hippocampal gene delivery of SynCav1 preserved hippocampal myelin in cuprizone mice, suggesting that SynCav1 may be an effective gene therapy to mitigate neurodegeneration in MS.

563 Adeno-Associated Virus Based Therapy to Treat Disease and Reduce Demyelination in an Animal Model of Multiple Sclerosis

Christopher Chan[1], Cristina Gaddie[2], **Geoffrey Keeler[1]**
[1]University of Florida, Gainesville, FL, [2]University of Florida

Multiple Sclerosis (MS) is the prototypical neuro-inflammatory demyelinating disease. In MS, inflammation can result in the development of focal lesions, axonal damage, and eventual axonal death resulting in progressive disability. However, there are currently no clinically available treatments specifically for combating demyelination. Thus, current MS treatments only effectively treat a portion of the disease.

Remyelination is the regenerative process where new myelin sheaths are formed and can result in the restoration of axonal function and prevent axonal death. Within MS, remyelination occurs but is inefficient and ultimately fails in most lesions. Thus, induction of remyelination represents an effective treatment modality for MS, either alone or in conjunction with current therapies.

Astrocytes have been identified as key players in the demyelinating lesion. These cells are responsible for creating an inflammatory environment conducive to demyelination, suppress remyelination by inhibiting oligodendrocyte progenitor cells (OPCs) proliferation and differentiation, show increased GFAP expression, and form glial scars.

Other than astrocytes, OPCs and microglia are considered the two other major cell types directing the demyelinating lesion. Astrocytes are unique in that they can affect both OPCs and microglia in a paracrine fashion through the secretion of neurotrophic factors, cytokines, and other molecules. Thus, it is our opinion that astrocytes represent an ideal cell target to induce remyelination.

Adeno-associated virus (AAV) serotype 9 (AAV9) represents a novel platform to develop a therapy for demyelination as it crosses the BBB and provides widespread biodistribution within the central nervous system (CNS). Though peripheral injections suffer from inefficient BBB crossing, poor CNS transduction, and off-target transduction/expression they are preferred to direct injections as direct injections are invasive and provide less than ideal biodistribution within the CNS.

In this work we show that the AAV platform can be utilized to specifically target activated astrocytes for transgene expression in an animal model of MS. Further, we show that in our model a single i.v. injection of AAV results in robust transgene expression and transduction throughout the CNS of animals. Finally, here we show the first AAV vector to treat demyelination and reduce disease severity in an animal model of MS (Fig 1). The reduction in disease severity was mediated via down-regulation of cytokines transcription levels known to play a role in disease onset and severity (Fig 1A-C). Finally, we show that our vector is capable of significantly reducing the amount of demyelination that occurs in the corpus collosum of treated animals (Fig1D & E). This work represents the first step in developing an effective AAV therapy to treat demyelination in patients with MS.

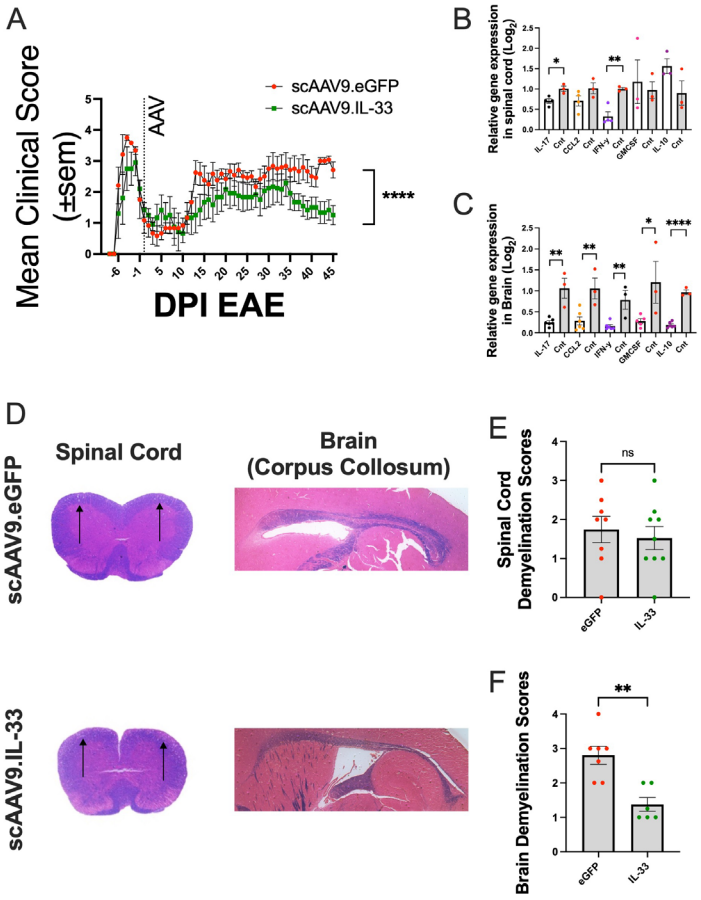

Figure 1: Therapeutic efficacy of IL-33. Either an scAAV9.IL-33 or scAAV9.eGFP vector was administered to animals suffering from RR-EAE. A) The scAAV9.IL-33 vectro resulted in reduced disease severity as compared to the control. B) scAAV9.IL-33 vector resulted in significant down-regulation of IL-17 and IFN-γ mRNA transcript in the spinal cord. C) scAAV9.IL-33 vector resulted in significant down-regulation of IL-17, CCL2, IFN-γ, GMCSF, and IL-10 in the brain. D) Luxol fast blue stains showing demyelination in spinal cord and brain. E) scAAV9.IL-33 vector did not result in significant differences in demyelination in the spinal cords of animals. F) scAAV9.IL-33 vector resulted in significantly less demyelination (lower demyelination scores) in the brains of treated animals as compared to controls. N=3-7, * ≤ 0.05, ** ≤ 0.005, ***≤ 0.0005, **** < 0.0001

564 *A 4-Week Study of Rodent Multiple Sclerosis (MS) Model*

Mele Avilla[1], Alexander Doering[2], Zachery Fetterhoff[3], Megan Rohde[3], Megan Speich[3], Megan Ender[3], Erick Gjertson[3], Stacey Schumacher[3], Nicole June[3], Susan Lynk[3], Vaithinathan Selvaraju[4], Aaron Peterson[3], Jay Herman[2], Brian McIntosh[2]

[1]Labcorp Drug Development, Madison, WI, [2]Labcorp Drug Development - Madison, WI, Madison, WI, [3]Labcorp Early Development Laboratories Inc., Madison, WI, [4]Labcorp Drug Development - Madison, WI, Madison

Introduction: Multiple sclerosis (MS) is a debilitating, chronic, neurological autoimmune disorder affecting 1 in 3,000 people caused by the loss of myelin, and manifests in symptoms ranging from mild to severe paralysis. The primary event leading to symptomatic pathology is the infiltration of peripheral immune cells that have been primed against components of myelin sheath. Peripheral immune cells, primarily T and B lymphocytes and macrophages, infiltrate into the central nervous system (CNS) parenchyma leading to demyelination and neuroaxonal degeneration. The complex nature of MS makes it difficult to fully replicate the human disease. Therefore, the aim of our study was to establish a reproducible MS rodent that mimics serum activity and anatomic pathology of the human disease. We induced MS by administering C57BL/6J female mice with myelin oligodendrocyte glycoprotein peptide 35-55 (MOG)/Complete Freund's Adjuvant (CFA) and pertussis toxin (PTX); which the result is an

experimental laboratory model of myelin destruction, capturing the pathophysiology of autoimmunity and neuroinflammation.

Methods: The CFA is a solution comprised of the antigen, MOG, emulsified in mineral oil composed of inactivated and dried mycobacteria (i.e. mycobacterium tuberculosis) and is used as an immunopotentiator (booster). Pertussis toxin is a toxin produced by the bacteria Bordetella pertussis and is used as an adjuvant to enhance the development of the disease by disrupting the blood-brain barrier and facilitating immune cell infiltration into the CNS; it helps trigger the autoimmune response in the MS model. The study was conducted for 4-weeks and entailed evaluating four groups: Groups 1 and 2 were the control groups and groups 3 and 4 consisted of the test groups. Test articles MOG/CFA and PTX dose levels were chosen to alter and/or reduce ambulation activities. Group 1 was treated with only PBS. Groups 2, 3, and 4 were treated with 200 µg of MOG/CFA; followed by 1x PBS treatment twice for Group 2; 50 ng of PTX twice for Group 3 or 100 ng of PTX twice for Group 4. 100 µL of MOG/CFA (1.0×10^6 ng/mL) or 1xPBS was subcutaneously injected twice on Day 1, followed by 100µL of PTX (500ng/mL or 1000 ng/mL) or 1x PBS intraperitoneally injected once on Day 1 and once on Day 2. To capture changes in locomotor activities, MotorMonitor (Kinder Scientific) was used to evaluate/characterize movement activities. Immunohistochemistry, histology, serum chemistry and cytokine analyses were also deployed to evaluate the MS model.

Conclusion: The development of a consistent rodent MS model, such as that evaluated in this study, will aid in evaluating new candidate cell or gene therapy products for efficacy and human safety. The overarching goal of providing this model to the community is aimed in providing the millions afflicted with MS potential for new autoimmune focused therapies and a healthier life.

565 Endo-Tek™: A Tissue-Engineered Alternative to DMEK/DSAEK for Corneal Endothelial Dysfunction

Wei Wang[1], Emily Lazarus[1], Xiaokun Wang[1], Khoa Tran[2], Christopher Stoeger[2], Albert Jun[1]*
[1]OcuCell, Inc., Baltimore, MD, [2]OcuCell, Inc., Portland, OR
**Corresponding Author*

Introduction: Corneal endothelial dysfunction is a leading cause of corneal transplantation worldwide, traditionally treated by deceased donor tissue transplantation methods such as Descemet Membrane Endothelial Keratoplasty (DMEK) and Descemet Stripping Automated Endothelial Keratoplasty (DSAEK). However, these procedures are limited by donor tissue shortages and associated complications. This study introduces Endo-Tek™, a tissue-engineered graft designed as an alternative to DMEK/DSAEK, utilizing *in vitro* cultured human corneal endothelial cells (HCECs) on a novel hydrogel scaffold.

Methods: Endo-Tek™ grafts were engineered using a transparent, thin collagen hydrogel combined with *in vitro* cultured HCECs. A molded design was developed and added to the scaffold to introduce curvature approximating the posterior surface of the cornea. Cell viability on the grafts was assessed using calcein-AM staining, and corneal endothelial markers were evaluated through immunofluorescence staining. In a feline model with induced corneal endothelial dysfunction, Endo-Tek™ grafts were transplanted to assess *in vivo* functionality. Postoperative outcomes, including corneal clarity and thickness, were monitored over 12 weeks using optical coherence tomography (OCT). *In vivo* confocal microscopy and histological analysis were performed on the enucleated eyes to confirm cell and graft attachment.

Results: The engineered hydrogel scaffold was approximately 15-25 µm in thickness and maintained a high transparency over 90% in the visible light spectrum. A confluent monolayer of HCECs on the Endo-Tek™ graft exhibited typical morphology and marker expression with a cell density of >3000 cells/mm^2. The hydrogel demonstrated superior mechanical properties, facilitating easy handling without breakage, and was compatible with loading into the Straiko-modified Jones tube for injection into the anterior chamber, reopening post-injection on every attempt. By week 6 post-transplantation, treated eyes exhibited substantial corneal clearing. Pachymetry indicated a reduction in corneal thickness towards baseline levels. *In vivo* confocal microscopy confirmed the presence of a healthy endothelial cell layer, and OCT, along with histological analysis, verified firm graft attachment

to the stroma with a graft thickness of less than 25 μm. Additionally, the curved design of the scaffold could potentially reduce detachment rates post-implantation.

Conclusions: Endo-Tek™ presents a promising tissue-engineered alternative to traditional DMEK/DSAEK procedures, addressing limitations related to donor tissue availability and surgical complications. The novel hydrogel scaffold's properties include optimal thickness, high transparency, mechanical strength, biocompatibility, and curved shape.

566 SELECTION OF QUALIFIED TREATMENT CENTRUM FOR CELL THERAPY

Cecilia Marinova[1]*, Eva Vlkova[2], Monika Horackova[3], Magdalena Netukova[4], Cecilia Skalicka[5], Graziella Pellegrini[6], Veronika Sladkova[7], Martina Losova[8]
[1]Medasol, Prague, Praha, hlavní město, Czech Republic, [2]Faculty Hospital Brno,, Brno, Praha, hlavní město, Czech Republic, [3]Faculty of Medicine, Masaryk University Brno, Brno, Praha, hlavní město, Czech Republic, [4]Faculty Hospital Kralovske Vinohrady, Praha, Czech Republic, Praha, Praha, hlavní město, Czech Republic, [5]General University Hospital in Prague, Praha, Czech Republi, Praha, Praha, hlavní město, Czech Republic, [6]Holostem Terapie Avanzate, 41125 Modena, Italy, [7]Medasol sro, Praha, Praha, hlavní město, Czech Republic, [8]Prague, Czech Republic
**Corresponding Author*

Introduction: Unlike established pharmaceutical companies, start-ups lack local presence and structured launch activities, limiting awareness and patient access to treatments. In ophthalmology, Holoclar, a tissue-engineered therapy for moderate-to-severe limbal stem-cell deficiency (LSCD) due to trauma, is an example of a start-up innovation, which lacks wider acknowledgement. Holoclar can be administered only in qualified treatment centers (QTCs) per EMA and Transplantation Centre regulations. Selecting appropriate QTCs is critical to ensuring broad patient access, but challenges include complex certification processes and fragmented referral pathways. To ensure the best outcome for cell therapy, standardized processes need to be established, including the selection of patients based on complex eligibility criteria, the certification and qualification of the Holoclar® treatment center in line with the Transplantation Centre (TC) and EMA regulations and the standardization of biopsy, manufacturing and implantation processes with follow-up. At present, cornea trauma patient treatment is individual. These patients are treated at regional centers, their traumas and treatment outcomes are specific and their long-term tracking is individual. In most cases, patients are referred based on personal requests by attending doctors *via* an established personal contact with the doctor from the Qualified Treatment Center (QTC).

Methods: We mapped current practices to identify patient distribution and referral trends. Key criteria included patient volume, center expertise, specialization, infrastructure, and institutional support. Additional factors such as legal, financial, and logistical readiness were considered.

Results: From 10 centers, three were shortlisted: Prague VFN, Prague Vinohrady, and FN Brno. Despite a lower patient volume, FN Brno was ultimately selected due to its advanced qualification status, strong institutional support, and readiness to complete legal and financial agreements. To address Prague's higher patient concentration, a novel patient-doctor tandem model was implemented, facilitating treatment access at Brno QTC.

Conclusions: Effective QTC selection requires evaluating treatment capabilities, patient pathways, and institutional support. Strong center management and adaptability are essential for overcoming logistical and operational challenges. The structured coordination by Medasol facilitated a streamlined approach to patient access and treatment continuity.

567 Screening of Matrix Gla promoters to drive efficient expression of AAV-delivered Engineered Mechanosensitive Channel in trabecular meshwork for Enhancing Outflow Facility and lowering IOP in TGFβ2 Animal Model of Glaucoma

Adnan Dibas[1], Lucero Garcia[2], Megan Aldape[2], Eman Shamekh[2], SUBRATA BATABYAL[2], Samarendra Mohanty[2]
[1]Nanoscope Technologies, Bedford, TX, [2]Nanoscope Technologies LLC, Bedford, TX

The current standard of care for ocular hypertension associated with Glaucoma relies on daily eye drop medications to lower intraocular pressure (IOP), however, patients exert poor compliance. Previously, we have shown that the intracameral gene therapy using an engineered mechanosensitive channel (EMC) targeted to the trabecular meshwork (TM), provided a sustained IOP lowering through control of the outflow facility. Here, we present the optimization of the specific TM Matrix Glia Protein (MGP) promoter to enhance the EMC expression in human TM cells.

EMC was packaged in self-complementary (sc)AAV2 and produced using the triple transfection method. EMC expression in TM was driven by the Matrix Gla Protein (MGP) promoter upstream, while mCherry downstream served as a biomarker. MGP promoter was modified with proprietary elements, and five MGP promoter derivatives were assessed in NTM7820 cells (a TM cell-line). Our results show successful transduction of human TM cells by scAAV2-EMC, visualized by fluorescence microscopic imaging of mCherry reporter. MGP-3 and MGP-5 promoters were superior to wild-type MGP promoter in driving EMC expression.

Intravitreal Ad5-TGF-β2 (transforming growth factor beta) injection, known to increase IOP, was carried out in adult C57BL/6J mice. IOP was measured by TonoLab. Intracameral injection of scAAV2-EMC was carried out to determine changes in the aqueous outflow facility and IOP due to EMC transduction of TM. The AH outflow measurement was conducted using manometry in EMC-treated and control groups. Visually evoked potential (VEP) measurement was conducted to evaluate the effect of EMC treatment on the health of retinal neurons.

Intracameral delivery of scAAV2-EMC led to EMC expression in TM, lowered the elevated IOP, and restored the AH outflow in the TGFβ2 mouse model. VEP measurement showed a 50% higher amplitude in the scAAV2-EMC treated group as compared to the control.

The number of retinal ganglion cells (RGCs) was quantified by immunohistochemistry analysis using rabbit anti-RBPMS (RNA-binding protein with multiple splicing) and mouse anti-tubulin III on flat-mounted retinas. The observed higher survival of RGCs based on RBPMS and tubulin III labeling, suggests a neuroprotective effect on retinal ganglion neurons owing to reduced ocular hypertension.

Transduction of EMC, a pressure sensor channel, in TM restored its capacity to regulate IOP. EMC, upon activation by increased IOP, enhanced the outflow facility and facilitated pressure relief through the conventional TM pathway. The optimized MGP promoter should enhance the efficacy of the IOP-lowering EMC gene therapy.

568 Local delivery of inflammation-inducible vectorized anti-TNF biologics to treat non-infectious uveitis

Dave Copland[1]*, Philip Langer[2], Alison Clare[1], Ying Kai Chan[3], Andrew Dick[4]
[1]University of Bristol, BRISTOL, Bristol, City of, United Kingdom, [2]BRISTOL, United Kingdom, [3]Cirrus Therapeutics, Cambridge, MA, [4]University of Bristol, Bristol, UNITED KINGDOM
**Corresponding Author*

Introduction: Non-infectious immune-mediated inflammation of the eye (Uveitis) accounts for significant visual loss in adults. A key goal for immunotherapy is to minimize patients' systemic steroid use, which requires more selective, local and targeted approaches. Gene therapy using adeno-associated viral (AAV) vectors offers a step change opportunity to provide sustained and controlled depot delivery of therapeutics in the eye. Our preclinical evaluation targets a critical immune pathway, testing AAV constructs encoding anti-TNF biologics, given their tractable evidence of systemic efficacy in man.

Methods: AAV7m8 constructs, encoding anti-TNF biologics under control of constitutive (CMV) or inflammation-responsive (AP1—NFkB) promotors, were designed and produced. *In vitro*, HEK-293T cells were transfected [MOI 1E5vg/ml] to evaluate transgene expression (ELISA), inducibility (IL-1b stimulation) and bioactivity (HEK-Blue™TNF-α reporter assay). *In vivo*, therapeutic AAV vectors were injected intravitreally [2E9 vg/eye] in mice, with contralateral fellow eye receiving control AAV (NULL). Experimental autoimmune uveoretinitis (EAU), a preclinical model of uveitis was induced to assess inducibility and efficacy in individual eyes by imaging (fundus & optical coherence tomography) and FACS (CD45+ infiltrates).

Results: We were able to detect expression of clinically relevant anti-TNF biologics, including human TNFR1-IgG and Adalimumab, after AAV transfection of HEK-293T with both constitutive and inducible promoters. These products were demonstrated to be bioactive, neutralizing TNF mediated signalling and NFkB activation *in vitro*. *In vivo*, constitutive expression of a murine version of the TNFR1-IgG biologic, which potently neutralizes mouse TNF signalling, reduced clinical inflammation and immune cell infiltrate to the eye during peak disease of the EAU model. Furthermore, we demonstrate effective inducibility of our inflammation responsive promotor to express a bioactive anti-TNF therapeutic transgene, with detectable expression in ocular supernatants (retina and vitreous) at peak inflammation.

Conclusions: Intravitreal delivery of AAV permits expression of clinically relevant, bioactive anti-TNF biologics in mouse eye, and are efficacious in a preclinical model of uveitis. An inflammation responsive promotor driving expression of therapeutic transgenes in response to early clinical signs of inflammation offers a potential for regulated gene therapy, delivering targeted biologics within the eye as and when required during disease for uveitis treatment.

569 AAV-based Gene Replacement Therapy Improves Visual Behavior in a Murine Model of Usher Syndrome Type 1C (USH1C)

Usher Syndrome (Usher) is the leading cause of combined deaf-blindness in the world. There are no current treatments available to address the visual loss in Usher. We created a mouse model of Usher that contains the *USH1C* c.216G>A (216A) mutation responsible for USH1C in patients. The 216A mutation produces truncated harmonin, a key scaffolding protein in the retina and inner ear, leading to dysfunctional photoreceptors and cochlear hair cells. We showed that antisense oligonucleotides targeting this mutation transiently improves gene and protein expression, and retinal function in USH1C mice. To improve upon these results, we developed a gene replacement strategy using adeno-associated virus (AAV) for long-term expression of USH1C in photoreceptors and restoration of visual function. Previously, subretinal injection (SRI) of AAV8-*Ush1c* resulted in transduction of photoreceptors within the injection bleb; however, visual function was not improved. Here, we aim to drive USH1C expression in photoreceptors within and beyond the surgical margins and confer long-term improvements in visual function and behavior using AAV44.9, a novel AAV vector capable of spreading from the site of injection throughout the retina. USH1C and control mice were treated by a single SRI at postnatal day 21 (P21) with AAV44.9(E531D)-hGRK1-*Ush1c-a1*-P2A-GFP vectors (5e11 vg/mL) or saline as vehicle. To assess the extent of the treated area, GFP expression was measured by fundoscopy, fluorescent confocal scanning laser ophthalmoscopy, and immunohistochemistry (IHC). Over a 1-year time-course, *Ush1c* transgene expression was measured using RT-PCR, and retinal function and visual behavior were assessed using electroretinography (ERG) and visual cliff test, respectively. On fundoscopy, AAV44.9(E531D)-mediated GFP expression was observed in >80% of USH1C and control eyes 8-weeks post-injection, and IHC analyses at 3-months-of-age showed transduction of primarily photoreceptors, with robust GFP signals in the inner/outer segments. At 3-months-of-age, RT-PCR analysis showed increased transgene expression in AAV-treated USH1C mice compared with saline-treated USH1C littermates. At 6-months-of-age, visual cliff analysis showed improved visual behavior in AAV-treated USH1C mice compared with saline-treated USH1C littermates. ERG analyses are currently underway. Mice are being aged to determine the

duration of treatment benefit. These results suggest the therapeutic potential of early AAV44.9(E531D)-*Ush1c* intervention to improve gene expression and visual behavior in USH1C mice.

570 Mini-PCDH15 Gene Therapy for Blindness in Usher Syndrome Type 1F

Maryna Ivanchenko[1], Xinlan Chen[1], Daniel Hathaway[1], Muriel Heitsch[1], Alex Klein[1], Jennifer Phillips[2], Kevi Booth[2], Corey Goldstein[1], Andrew Murphy[1], Jeremy Wegner[2], Artur Indzhykulian[3], Sean Megason[1], Monte Westerfield[2], **David Corey[1]**
[1]Harvard Medical School, Boston, MA, [2]University of Oregon, Eugene, OR, [3]Massachusetts Eye and Ear Infirmary, BOSTON, MA

Purpose: Usher syndrome 1F (USH1F), an autosomal recessive disorder caused by mutations in the *PCDH15* gene, is characterized by profound congenital deafness, balance dysfunction, and progressive vision loss due to retinitis pigmentosa. Cochlear implants can compensate for deafness but there are no therapies for blindness. Gene addition therapy is attractive, yet the *PCDH15* coding sequence of ~5.8 kb is too large to fit into a single AAV capsid. We engineered mini-PCDH15 genes in which 5 of the 11 extracellular cadherin repeats were deleted, and delivery by AAV to inner ears successfully rescued hearing in mouse models of USH1F. To evaluate the efficacy of mini-PCDH15 gene therapy to rescue blindness, we used zebrafish and mouse USH1F models.

Methods: With transposon insertion, we introduced *mini-pcdh15b* into USH1F zebrafish. Rescue of visual function was assessed with electroretinogram (ERG) and optokinetic reflex (OKR). Mini-Pcdh15b localization and photoreceptor morphology were analyzed and quantified with immunofluorescence and electron microscopy. In mouse experiments, we injected adult mice subretinally with AAV8-mini-hsPCDH15. Retinas were collected for histological analysis to evaluate the mini-gene expression and localization in photoreceptors.

Results: Untreated *Pcdh15b*-mutant zebrafish exhibited early and progressive defects in photoreceptor morphology and visual function: immunofluorescence and electron microscopy revealed abnormal calyceal processes and distorted outer segments in untreated mutants, and reduced ERG and OKR. In contrast, the treated group showed correct localization of the mini-Pcdh15b, preserved photoreceptor morphology, and improved vision with ERG and OKR restored to wild-type levels. In mouse, immunofluorescence of retinas injected with AAV8-mini-hsPCDH15 confirmed efficient expression and proper localization of mini-PCDH15 in photoreceptors.

Conclusion: *Mini-pcdh15b* expression restores vision in a zebrafish model of USH1F and mediates expression and normal localization of Pcdh15b in zebrafish photoreceptors. In mice, mini-hsPCDH15 is efficiently expressed and correctly localized in photoreceptors. These findings offer a promising approach for treating progressive blindness in humans with USH1F. More generally, they show that shortening proteins based on atomic structure may overcome the packaging limitations of AAV vectors to treat certain forms of vision loss.

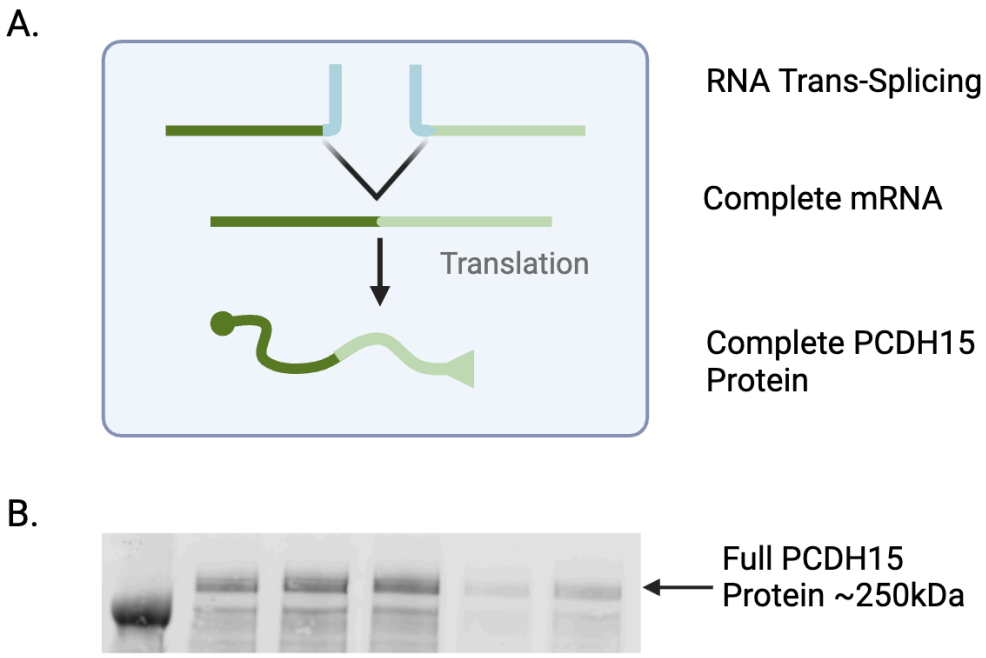
571 AAV Compatible Delivery of Full-Length PCDH15 for Treatment of USH1F via RNA End Joining

Claire Williams[1], Ryan Hsu[2], Lukas Bachmann[3], Kip Hermann[4], Samuel Pfaff[5]
[1]Salk Institute for Biological Studies, San Carlos, CA, [2]Salk Institute & UC San Diego, La Jolla, CA, [3]Insmed Gene Therapy LLC, San Diego, CA, [4]Salk Institute for Biological Studies, [5]The Salk Institute, La Jolla, CA

Usher Syndrome 1F (USH1F) is a debilitating genetic disease where patients experience congenital, bilateral, profound sensorineural hearing loss, vestibular areflexia, and adolescent-onset retinitis pigmentosa. USH1F is caused by mutations in protocadherin-15 (PCDH15) making it an ideal candidate for gene replacement or gene editing strategies for treatment. PCDH15 is a cell-membrane binding protein that is primarily present in stereocilia and the retina and its coding sequence is approximately 5.8 kb, which exceeds the maximum packaging capacity of AAVs. To overcome the size limitations of AAVs for delivery of PCDH15 in a gene replacement strategy, we utilized our novel RNA End Joining (REJ) technology and created five different constructs to optimize the expression of full-length PCDH15 in vitro. REJ is a highly efficient mRNA trans-splicing process, which can be

used in the delivery of multiple DNA constructs, which will scarlessly recombine transcribed RNAs in the nucleus, resulting in a full-length mRNA of the desired protein. The REJ variants were transfected into HEK293T cells and the expression of the 250kDa PCDH15 dimer was validated by Western blot. All screened variants exhibited full-length PCDH15 at varying levels with minimal fragment expression, and an optimal design was packaged into AAV8 driven by the photoreceptor specific GRK1 promoter. Subretinal injections into mice demonstrate robust protein expression and promising histological results. These findings illustrate a promising gene replacement strategy for USH1F.

Figure 1. (A) Schematic of REJ-enabled PCDH15 delivery. RNA dimerization domains are in blue and the split coding sequence is in green. (B) Western Blot depicting PCDH15 successfully reconstituted in wildtype mouse retinas.



572 A novel dual-target gene therapy strategy design with balanced gene expressions

Xuemei Yu[1], Haitao Yang[1], Wen Luo[1], Shuang Luo[1], Qing Xie[1], **Qiang Zheng[2]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotechnology, CHINA

Purpose: Contributors to dry AMD is multifactorial. Dual-target therapeutic strategies have the potential for superior therapeutic outcomes over the single-target approach. Currently, the design of dual-target gene therapy constructs typically employs either a self-cleaving 2A peptide or a multi-promoter tandem construct. However, the 2A peptide structure is plagued by incomplete self-cleavage issues (Fig.1b) and tandem structure design often leads to compromised expression of the transgenes. The purpose of the current study is to develop a dual target gene therapy construct to overcome the above issues.

Methods: A series of dual-target constructs expressing Gefurulimab and sCD59 were constructed (Fig.1a). These constructs were transfected into ARPE19 cells, and the expression efficiency for each construct was evaluated by detecting the target genes' expression using an ELISA method. The high expression single-target constructs were used as benchmark.

Results: Benchmark construct T252 expressed sCD59 level of 106.4 ng/mL, T273 expressed Gefurulimab level of 3969.1 ng/mL. In contrast, the multi-promoter tandem structures of T306 (sCD59: 16.1 ng/mL, Gefurulimab: 2843.7 ng/mL) and T307 (sCD59: 106 ng/mL, Gefurulimab: 175.5 ng/mL) demonstrated imbalance in expression. While the construct with insulator framework of T356 achieved a balanced dual-target expression, with 66 ng/mL and 2349.7 ng/mL for sCD59 and Gefurulimab, respectively (Fig.2).

Conclusion: By employing the insulator framework, we identified a vector construct capable of balancing the expression of dual-target genes. Both target gene exhibited relatively high expression levels. Such a vector design can be utilized for gene therapy of multi-target diseases, such as dry AMD.

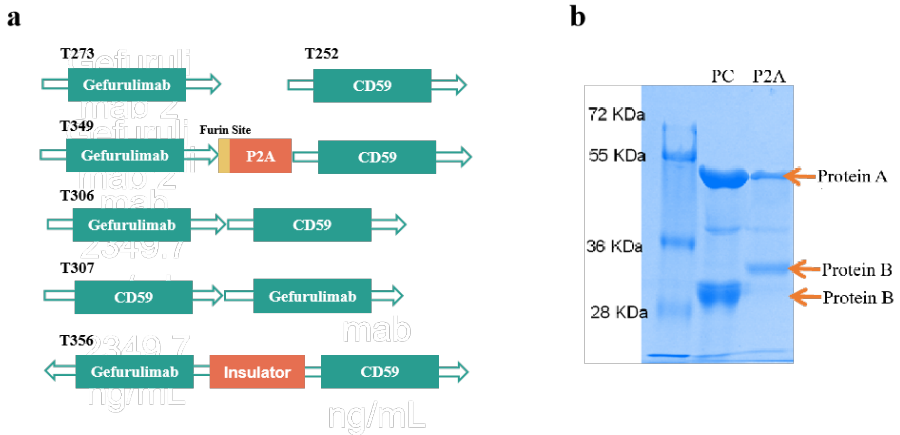

Fig.1: Dual-target gene therapy cassettes.
a Schematic Representation of Construct with Diverse Designs. T349 embodies the 2A peptide structure, T306 integrates an upstream Gefurulimab fused in-frame with a downstream sCD59 expression cassette, T307 is a similar design but with different position of target genes. T356 illustrates the incorporation of an insulator structure in between target genes. **b** Comparative SDS-PAGE analysis of proteins expressed from the self-cleaving 2A peptide construct versus a positive control. PC: positive control, P2A: protein products expressed through a self-cleaving 2A peptide construct.

Introduction
The formation of macular scars is strongly associated with poor visual outcomes in eyes receiving anti-VEGF treatments. Connective tissue growth factor (CTGF), which plays a crucial role in fibrosis, is highly expressed in eyes with wet age-related macular degeneration (wAMD). To address both neovascularisation and fibrosis, we have developed a bicistronic gene therapy vector that targets VEGF, through VEGF Capture 2 (VC2), and CTGF using an anti-CTGF single-chain variable fragment (anti-CTGF ScFv). This study assesses the therapeutic efficacy of this bicistronic vector.

Methods
In vitro co-culture angiogenesis assays (HUVEC/human fibroblast) and *in vivo* laser-induced choroidal neovascularization (CNV) and subretinal fibrosis models were used to evaluate the vectors.

Results
In the co-culture assay, the bicistronic vector (VC2/anti-CTGF ScFv) significantly reduced VEGF-induced angiogenic tubule length and branch points relative to a Null control (3661µm vs 12678µm tubule length, 2.25 vs 33.5 branch points, n=3). However, the anti-CTGF ScFv monocistronic vector was unable to significantly affect tubule length or branching (11157µm and 39.75 branch points, n=3). In the laser CNV model, 90% of lesions were classed as leaky in the Null-treated eyes compared to 4% in the bicistronic vector treated eyes (n=25). Interestingly, the anti-CTGF ScFv monocistronic vector also had a significant effect on vascular leakage with only 36% of the lesions classed as leaky (n=28). In the fibrosis model, the bicistronic vector significantly decreased leakage and fibrosis markers such as fibronectin and α-SMA). Impressively, the anti-CTGF ScFv monocistronic vector also showed a notable reduction in fibrotic markers, highlighting its effectiveness in mitigating fibrotic progression.

Conclusions
The bicistronic VC2/anti-CTGF ScFv vector has been shown to reduce angiogenesis, vascular leakage, and subretinal fibrosis in preclinical models of wAMD, underscoring the therapeutic potential of inhibiting both VEGF and CTGF. Additionally, the anti-CTGF ScFv monocistronic vector demonstrated significant anti-fibrotic effects in vivo, highlighting the importance of targeting CTGF to prevent fibrosis progression. This dual-target strategy represents a promising advancement in wAMD treatment, as it addresses both neovascularization and fibrosis to enhance visual outcomes.

574 IKC159V: A bicistronic AAV gene therapy for Geographic Atrophy delivering dual protein expression and multifaceted protection against retinal damage

Emily Warner[1]*, Laura Vaux[2], Peter Widdowson[3], Andrew Osborne[2], Katie Binley[1]

Background
Age-related macular degeneration (AMD) persists as a predominant cause of blindness on a global scale. The

current standard of care involves frequent, burdensome ocular injections, which exhibit limited success in maintaining vision. Emerging therapies seek to address the intricate pathology of geographic atrophy (GA), a severe form of AMD, with the aim of improving therapeutic outcomes. This research introduces findings on IKC159V, a bicistronic AAV gene therapy designed to co-express two secreted, therapeutically significant proteins: a neuroprotective protein, pigment epithelium-derived factor (PEDF), and anti-complement protein, soluble CD46 (sCD46).

Methods
Human induced pluripotent stem cell-derived retinal pigment epithelium (iPSC-RPE) cells were transduced with the bicistronic AAV-PEDF/sCD46 construct (IKC159V), or monocistronic AAV constructs expressing either PEDF or sCD46, and used to assess expression and the protective effects of PEDF and sCD46 by ELISA and immunohistochemistry (IHC). IKC159V was administered subretinally in the murine eye and secreted PEDF and sCD46 protein levels were quantified from vitreal samples. Successful transduction of the retina was confirmed by RNAscope and IHC on ocular sections. To recapitulate degeneration of photoreceptors and RPE cells, a chemically-induced model of retinal injury (using N-methyl-N-nitrosourea (MNU)) was employed, with the impact on visual function determined using electroretinography (ERG) and histology.

Results
In response to chronic A2E exposure and blue light challenge, transduced human iPSC-RPE cells maintained stable protein expression and exhibited improved RPE cell survival compared to controls (n=6). Subretinal delivery of IKC159V in mice resulted in dose-dependent increases in vitreal concentrations of both PEDF and sCD46 protein (n=10). Transduction of both RPE and photoreceptor cells was confirmed at the DNA and protein level. In the MNU injury model, IKC159V protected against photopic b-wave loss compared to a Null control (IKC159V = 21% loss, Null = 92% loss; n≥11), which was supported by histological data showing preservation of cone cells (IKC159V = 235 cells/FOV, Null = 26 cells/FOV; n≥6), and RPE morphology (IKC159V = 36% RPE damage, Null = 77% RPE damage; n≥6).

Conclusions
IKC159V effectively supports cellular preservation critical for vision in both rodent and human models, highlighting its potential to improve clinical outcomes in AMD-associated GA. IKC159V is a promising gene therapy candidate that may address multiple pathological hallmarks of GA.

575 KRIYA-825 (AAV2.CR2-CR1) for Geographic Atrophy: Characterization of Biological Activity and Biodistribution

Rachel Eclov[1], Pilar Prentiss[1], Angela Ambakhutwala[2], Angela Yang[2], Michael Engles[3], Jessica Raubenolt[1], William Chappell[4], Robert Damitz[1], Yoreh Barak[5], Hagay Drori[6], Jiewu Liu[2], Kara Shumansky[7], Leslee Arwood[2], Lauren Parker[1], Benjamin Johnson[8], James Coyne[1], Uma Karadge[1], David Lally[1], Andrew Murphy[9], Nancy Bordelon[1], Ashlyn Bassiri[10], Michele Stone[11]
[1]Kriya Therapeutics, Morrisville, NC, [2]Kriya Therapeutics, Durham, NC, [3]Eye Soar Inc, Raleigh, NC, [4]Kriya Therapeutics, Inc., Durham, NC, [5]Rambam Health Care Campus, Haifa, Haifa, Israel, [6]Everads Therapy, Tel Aviv, HaMerkaz, Israel, [7]Durham, NC, [8]Kriya Therapeutics, Raleigh, NC, [9]Kriya Therapeutics - Redwood City, CA, Morrisville, NC, [10]Kriya Therapeutics, Morrisville, North Carolina, [11]NA, Morrisville, North Carolina

Therapies that modulate an overactive complement system have shown clinical benefit for retinal diseases including geographic atrophy (GA). Current treatments for GA require intravitreal injection every 1 to 2 months to sustain complement inhibition, resulting in a high treatment burden. KRIYA-825 is an optimized complement receptor 2-complement receptor 1 fusion protein (CR2-CR1) designed to inhibit C3 and C5 convertase activity, encoded and packaged into an AAV2 gene therapy for delivery by suprachoroidal injection. Here, we report KRIYA-825's in vitro complement inhibition, rodent efficacy and non-human primate (NHP) suprachoroidal biodistribution to support clinical development.

KRIYA-825's CR2-CR1 fusion protein was designed based on previously reported CR2-CR1 proteins (Fridkis-Hareli et al. 2019) but modified for number of CR1 activity domains and size of domain linkers and evaluated for

alternative and classical complement inhibition in Wieslab assays. For efficacy assessment of KRIYA-825, C57BL/6 mice (N=10/group) were randomly assigned to bilateral subretinal treatment groups: naïve, vehicle, and KRIYA-825 (8E8 or 3E9 vg/eye). Retinal damage was induced by intraperitoneal sodium iodate ($NaIO_3$) 4 weeks after AAV treatment. Evaluations 10-days after $NaIO_3$ included optimal coherence tomography (OCT), vector genomes (qPCR), transgene mRNA (RT-qPCR), and protein of transgene and complement fragments (immunoassay) in ocular homogenates. Biodistribution of KRIYA-825 was performed in NHPs (cynomolgus monkeys) receiving bilateral suprachoroidal injections (3E11, 1E12, or 3E12 vg/eye; 2-5 animals per group) using the Everads Injector. Animals were monitored for ocular health and at 4- and 12- weeks post injection for ocular (retina, RPE-choroid and sclera) and systemic biodistribution of vector genomes, transgene mRNA, and transgene protein. KRIYA-825 demonstrated classical and alternative pathway complement inhibition with <1 nM IC_{50} values. In mice, KRIYA-825 led to dose-dependent preservation of retinal thickness, vector genomes and transgene mRNA in ocular homogenates, and detectable CR2-CR1 protein levels. Retinal damage by $NaIO_3$ increased C3b and iC3b fragment levels, while treatment with KRIYA-825 reduced iC3b protein to levels comparable to those seen in healthy animals. The Everads Injector was compatible with KRIYA-825 and in NHPs, suprachoroidal delivery was well-tolerated with no unanticipated ocular findings. Vector genomes and transgene mRNA were detected at high levels in ocular tissues including sclera, choroid-RPE and retina, with minimal detectable systemic transgene mRNA. KRIYA-825 preserved retinal structure in an acute retinal degeneration mouse model, and suprachoroidal administration with the Everads Injector achieved targeted biodistribution in NHPs. This CR2-CR1 protein demonstrated complement inhibition in vitro, reduced complement fragment levels in vivo and detectable biodistribution across NHP and mouse ocular tissues. These findings support further clinical development of KRIYA-825 as a potential one-time sustained therapy for GA.

576 Generation of a non-human primate model of Geographic atrophy, Dry Age-related macular degeneration

Pavitra Ramachandran[1], Suzanne Jacobs[2], Shivakumar Vasanth[3], Ryan Boyd[4], Amy Frederick[5], Mikhail Levit[5], Pavithra Krishnaswami[6], Nikita Patel[7], Christian Mueller[8], Catherine O'Riordan[9]
[1]Genzyme, a Sanofi Company - Cambridge, MA, Waltham, MA, [2]Sanofi, Waltham, MA, [3]Charles River Laboratories, Mattawan, MI, [4]Mattawan, MI, [5]Sanofi, Cambridge, MA, [6]Sanofi, Cambridge, [7]Sanofi, Waltham, [8]Sanofi Genzyme, Waltham, MA, [9]Sanofi, Waltham, Massachusetts

Introduction: Age-related macular degeneration (AMD) is a leading cause of vision loss in adults over 60 years of age, with prevalence expected to grow to 288 million in 2030 as the population ages. As AMD progresses, the macula deteriorates and leads to advanced forms of disease – either wet AMD, which is characterized by neovascularization and vascular leakage, or dry AMD [also known as geographic atrophy (GA), which is characterized by the death of photoreceptor and RPE cells. There is a lack of NHP GA models that recapitulate lesion growth- an important therapeutic efficacy readout in patients. Primates are the only species with a macula; therefore, rodent models cannot accurately recapitulate human disease features. Here, we created an NHP model that recapitulates key features of progressive geographic atrophy by inducing outer retinal lesions in the macula.

Methods: In 3 cohorts of cynomolgus macaques, we induced retinal atrophy in specific regions of the macula (sparing the fovea) using different laser settings by altering the power, spot size and duration of laser exposure. The first 2 cohorts of animals were used to optimize the laser settings in 4-week studies. In the 3rd cohort, we induced atrophic lesions using the optimal laser settings identified from cohorts 1 and 2 and tracked laser-induced lesion growth in an 8-week study. We used in-life imaging – cSLO, OCT and FA – to track retinal and macula changes over time and conducted proteomic analyses of aqueous humor collected at baseline, 2 weeks and 4 weeks post laser treatment.

Results: We identified a specific laser setting that reproducibly produced lesions with localized atrophy of the RPE and photoreceptor layers, the main cell types affected in geographic atrophy. Additionally, we observed a significant increase in lesion surface area and decrease in retinal thickness over time, indicating a loss in retinal cells. Importantly, the model did not develop vascular leakage or neovascularization seen with the laser induced CNV model. We also observed an increase in complement proteins in the aqueous humor after laser induction.

Conclusion: This NHP model is a potential efficacy model for dry AMD therapeutics wherein the features of RPE and photoreceptor atrophy and lesion growth in the macula can be assessed.

577 A novel AAV vector delivering sCD59 for the treatment of dry AMD in mice model

Xing Li[1], Tao Yang[1], Wen Luo[1], Jie Zhang[1], Shiping Yang[1], Shuang Luo[1], Qing Xie[1], **Qiang Zheng[2]***

**Corresponding Author*

Purpose: Abnormal activation of the complement system is considered a major cause in the development of dry age-related macular degeneration (dry-AMD). sCD59 is a protective protein that shields the retina from damage mediated by the complement activation, and it holds potential for the treatment of dry AMD. The purpose of the current study is to develop a gene therapy approach that enables sustained and effective expression of sCD59 to mitigate the progression of dry AMD.

Methods: A low-dose laser induced dry-AMD mice model was used in this study to evaluate our therapeutic vectors. A soluble CD 59 (sCD59) was packaged into an engineered AAV capsid variant with high transduction efficiency for ocular tissues and into AAV2 serotype as a control. These two vectors were injected intravitreally into eyes of each animal. Laser induction was performed 2 weeks post injections. Stage 4 lesions were measured for each eye by fluorescein angiography to assess disease severity. Retinal tissues were harvested at the end point and choroidal flat mount was conducted to show the retinal damage for each eye.

Results: the fluorescein angiography data and choroidal flat-mount images indicated that both vectors treated groups greatly reduced the stage-4 lesions in animals' retina, and the AAV-variant-sCD59 group had superior therapeutic effect than AAV2-CD59 group (Fig.1).

Conclusion: Using a novel AAV variant to effectively express sCD59 showed pharmacological effect in low-dose laser induced dry AMD model, providing potential for clinical translation in the treatment of dry AMD.

Identification of cell-type-specific *cis*-regulatory modules (CRMs) in the primate retina:
Globally, at least 2.2 billion people suffer from vision impairment, with over 300 million facing irreversible blindness due to neurodegenerative retinal diseases. Specific retinal diseases are often linked to the degeneration of particular cell types, each associated with unique genetic mutations. For instance, in age-related macular degeneration and retinitis pigmentosa, photoreceptors are primarily lost, while retinal ganglion cells (RGCs) degenerate in glaucoma. Adeno-associated virus (AAV) has emerged as the gold standard vector for gene augmentation- and gene editing- based treatments for retinal disease. However, a key challenge lies in developing AAV tools capable of targeting and manipulating specific cell types or subtypes. Here we report a workflow using *cis*-regulatory modules (CRMs), such as enhancers, promoters, and the 5' UTR region, which exhibit high cell-type specificity, to guide AAV-mediated gene expression in specific retinal cell types.

In this study, we first focused on identifying cell-type-specific CRMs in individual cell types. To achieve this, we generated chromatin accessibility data using scATAC-seq assays and identified differentially accessible regions for the enriched genes in distinct retinal cell types. We refined the potential CRM candidates by applying thresholds to screen these regions, focusing on those with higher conservation scores and greater densities of cell-type-specific

transcription factor binding sites. Next, we inserted these candidate CRMs, each paired with a unique barcode, into AAV vectors to drive the expression of Cre, and packaged them into AAV2-based capsids. We then intravitreally injected mice with a pool of AAVs carrying these CRMs, along with AAVs expressing a Cre-dependent fluorescent reporter (tdTomato). Subsequently, we assessed expression of barcodes uniquely associated with each CRM across different retinal cell types through Fluorescence-Activated Cell Sorting and scRNA-seq analyses. After identifying the CRMs that demonstrated cell specificity, we injected them individually into marmoset retinas to further validate their ability to guide gene expression in specific retinal neurons. Immunofluorescence staining and immunohistochemistry were used to examine the expression pattern of tdTomato.

In conclusion, our research aims to contribute to the development of a versatile toolbox for targeting specific retinal cells by incorporating cell-type-specific CRMs into AAVs, with significant potential for advancing therapeutic treatments for retinal diseases.

579 AAV-delivered engineered suppressor tRNA rescues visual function in mice with an inherited retinal disease

Chengda Ren[1], Li Song[2], Ming Hu[3], Lu Fang[4]*, Yang Yang[5]*
[1]West China Hospital, Chengdu, Sichuan, China, [2]Sichuan University State Key Laboratory of Biotherapy, Chengdu, Sichuan, China, [3]Sichuan university West China hospital Department of Ophthalmology, Chengdu, Sichuan, China, [4]Sichuan University West China Hospital Department of Ophthalomology, CHINA, [5]Sichuan University, Chengdu, Sichuan, China

Nonsense mutations account for 11% of human pathogenic mutations and result in the synthesis of truncated proteins. Nonsense suppression therapies by small molecular drugs or suppressor tRNAs (sup-tRNAs) can introduce an amino acid at premature termination codon, thereby, promote the production of full-length protein. Although nonsense suppression therapies by sup-tRNAs demonstrate promising results in cell culture models, the in vivo delivery still faces the challenges related to efficacy, stability and safety. Here, we engineered the body sequence of sup-tRNA^{Arg} to achieve a 2.2-fold readthrough capacity. The sequence engineered sup-tRNA^{Arg} (SE-sup-tRNA^{Arg}) outperforms the original one at PTCs with all four types +4 nucleotides. By using the recombinant adeno-associated virus (rAAV) delivery platform, we successfully restored production of full-length protein and rescued visual function in a mouse model carrying a nonsense mutation in *RPE65* gene. rAAV.SE-sup-tRNA^{Arg} had limited retinal toxicity and minimal effects on the activation of unfolded protein response pathways, which is related to readthrough on normal stop codons. This study highlights the therapeutic potential of rAAV.SE-sup-tRNA^{Arg} on endogenous transcripts carrying clinically relevant PTC. Moreover, our findings encourage the further application of rAAV.SE-sup-tRNA^{Arg} on other inherited retinal disease models carrying nonsense mutations.

580 Molecular Stability of Human Donor Retinal Gene Expression and Protein Abundance Post-Mortem: Implications for Cell and Gene Therapy Applications

Cerys Easton[1], Megan Criss[2], Phillip Wilmarth[3], Ashok Reddy[3], Mark Ellison[1], Megan Straiko[4], Khoa Tran[1]
[1]VisionGift, Portland, OR, [2]Floragenex, Tigard, OR, [3]Oregon Health & Science University, [4]Legacy Health, Portland, OR

Purpose: The integrity of human post-mortem retinal tissue is critical for advancing retinal cell and gene therapy. This study evaluates transcriptional and proteomic stability in donor retina over two distinct post-mortem intervals to assess their effects on tissue quality and stability for therapeutic research and biomarker discovery.

Methods: Whole eyes were recovered from post-mortem donors (n=7 pairs) under standard US eye banking protocols, with ocular cooling maintained post-mortem. Eyes were stored at 2–8°C until dissection and flash freezing in liquid nitrogen. The OD retina was collected at 12 hours and the OS retina at 18 hours post-mortem. The macular region superior to the fovea was used for RNA sequencing (RNA-seq), while the inferior region was processed for TMT-mass spectrometry. Library preparations were performed simultaneously, and the sequencing of all samples were conducted on the same chip (Floragenex, Inc., Tigard, OR). Gene alignment was performed using the GRCh38 (GENCODE v32/Ensembl 98) human reference genome. Proteins were isolated and labeled with one of 14 TMTPro isobaric tags (OHSU Shared Proteomics Resources), and all 14 samples were analyzed in a single TMT-mass spectrometry run to minimize experimental variability. RNA-seq data were processed using DESeq2 (Bioconductor), and proteomic data were analyzed using the PAW pipeline.

Results: RNA-seq identified 22,446 unique genes, with differential expression analysis revealing only six genes with significant changes between the 12- and 18-hour post-mortem intervals (adjusted p-value < 0.1). Four of the six genes were upregulated and only two were down-regulated in the 18-hour time point compared to the 12-hour. No enriched pathways were represented by the differentially expressed genes. Proteomic analysis identified 6,109 unique proteins (each confirmed by the identification of at least two distinct peptides, 1% FDR), with no significant differences in protein abundance between time points (all $P > 0.05$). Molecular markers for retinal cell types, including those relevant to cell and gene therapy applications, remained detectable and stable in both datasets. Furthermore, genes and proteins associated with retinal diseases including AMD and glaucoma were detectable and exhibited no post-mortem degradation between the two time points.

Conclusions: Retinal gene expression and protein abundance remain stable between 12- and 18-hours post-mortem, ensuring the molecular integrity required for therapeutic development. These findings support expanding the post-mortem interval cut-off from 12 to 18 hours for the use of donor retinal tissues in transcriptomic and proteomic studies relevant to regenerative medicine, gene therapy target validation, and the development of cell-based interventions for retinal diseases.

581 A novel spontaneously immortalised Non-Human Primate Müller glia cell line reveals a population of Müller glia cells with stem cell-like qualities, a potential source for an in situ retinal regeneration

Ahmed Salman[1], Aranxta Bolinches-Amorós[2], Tina Storm[2], Daniela Moralli[2], Paulina Bryjka[2], Stephen Davies[2], Angela Russell[2], Alun Barnard[3], Robert MacLaren[4]
[1]University of Oxford, Oxford, Oxfordshire, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Oxford Biomedica, Oxford, United Kingdom, [4]Oxford University, Oxford, United Kingdom

Purpose
Retinal degenerative diseases are considered the leading cause of blindness worldwide. Cell therapies for ocular diseases aim to replace or restore the degeneration of the light-sensitive cells in the retina, the photoreceptors. Such therapies are often challenging due to low rate of proliferation and/or differentiation of cells in vitro, and poor migration and integration in vivo. Therefore, a stable source of cells within the retina to replace lost photoreceptors is promising for cell replacement therapies.

Methods
A spontaneously immortalised Müller glia cell line was derived from a primary culture of neural retina of a Macaque monkey by dissociation with papain dissociation reagent. The cells were cultured, passaged and eventually immortalised without the presence of growth factors. A differentiation cocktail containing fibroblast growth factor 2 (FGF2), taurine, retinoic acid, and insulin-like growth factor 1 (IGF-1) was used to induce differentiation, followed by characterisation with immunocytochemistry and reverse-transcriptase (RT-PCR) analyses to examine the expression of specific Müller glia, stem cell and neuronal cell markers.

Results
Here we report ~~a~~ spontaneously immortalised Müller glia cell line isolated from rhesus macaque monkey, grown under normal culture conditions and could be expanded indefinitely without the presence of growth factors. The cell line exhibits normal morphology and expressed Müller glia markers such as VIMENTIN, GLUTAMINE SYNTHASE, glutamate-aspartate transporter (GLAST), and CD44. As well as expressing Müller glia specific markers, they also express stem cell-specific markers such as paired box 6 (PAX6) and SRY (sex determinant region)-2 (SOX2). The cell line lacked expression of postmitotic retinal neurons including RHODOPSIN and CD73, however, in the presence of factors that induce differentiation, these cells show a shift in gene expression patterns and start to express retinal-specific markers such as RHODOPSIN, and RECOVERIN, as well as neuronal markers including bIII TUBULIN and 160kDa neurofilament (NEFM). In addition, the cells maintained expression of stem cell markers such as PAX6 and NOTCH1.

Conclusion
Our observations indicate that the non-human primate retina harbours a population of cells that express both Müller glia and stem cell markers, which can undergo a state of de-differentiation, a phenomenon known in reprogrammed Müller glia cells. They also suggest that these cells can be useful to further understand the regeneration potential in the mammalian retina, which represents a major obstacle for potential therapies to restore retinal function in humans.

582 Injury-responsive gene therapy for neuroprotection of retinal ganglion cells

Lucie Guo[1], Rain Wen[2], Xin Xia[3], Haoliang Huang[4], Yinglin Situ[5], Christina Tsien[3], Heather Chang[3], Eeshika Mitra[3], Liang Li[4], Sui Wang[2], Michael Kapiloff[3], Lei Qi[6], Yang Hu[7], J Goldberg[7]*

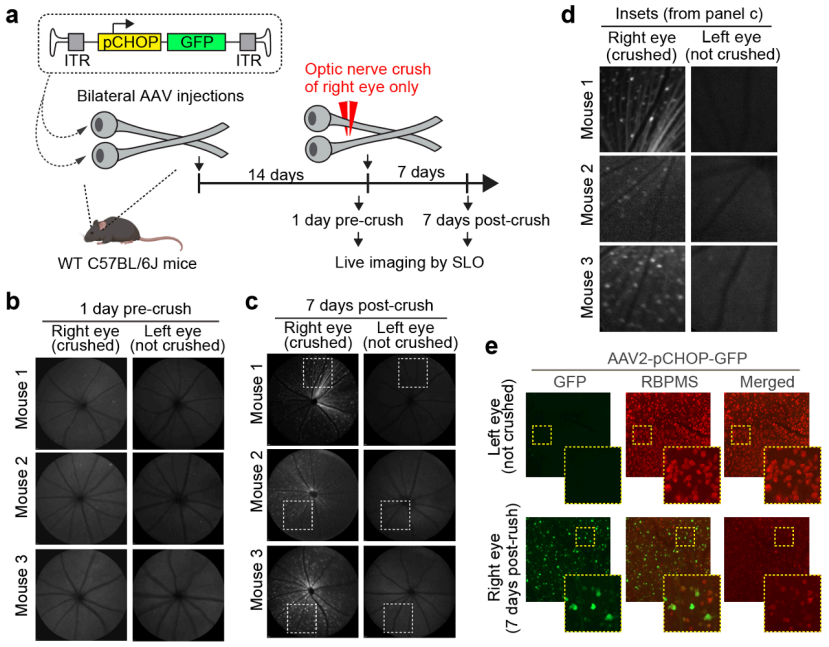
**Corresponding Author*

Purpose: Precise control of gene expression is crucial for safety and efficacy of gene therapies. While AAVs enable long-term gene expression in non-dividing tissues such as the neural retina, uncontrolled expression risks adverse effects. We hypothesize that using injury-specific regulatory elements, such as the endoplasmic reticulum (ER) stress-responsive CHOP promoter ("pCHOP"), can enable "smart" gene therapies to allow cells to sense disease conditions and autoregulate therapeutic gene expression.

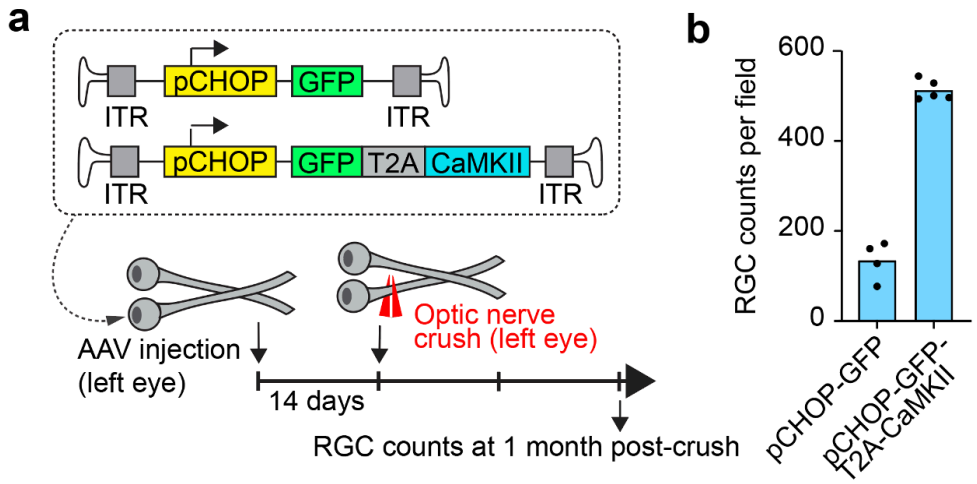
Methods: AAV2 expressing pCHOP driving GFP was intravitreally injected into C57BL/6 mice (N=3 per group). Optic nerve crush was performed on one eye per animal, leaving the contralateral eye uninjured. Live fluorescence imaging with scanning laser ophthalmoscopy (SLO) was conducted at 3- and 7-days post-crush using the Heidelberg Spectralis system. Additionally, AAV2 expressing pCHOP driving Ca2+/calmodulin- dependent protein kinase II (CaMKII) T286D—a gene shown to promote neuroprotection—was tested in C57BL/6 mice (N=5 per group). Optic nerve crush was performed 2 weeks after injection, and retinal ganglion cells (RGCs) were quantified via RBPMS immunostaining 1 month later.

Results: GFP expression was minimal in uninjured eyes but was strongly induced in injured eyes following optic nerve crush. Cryosections revealed GFP expression localized predominantly in the ganglion cell layer. Mice that received AAV2-pCHOP-CaMKII T286D exhibited significantly higher RGC survival compared to those injected with AAV2-pCHOP-GFP ($p<0.05$).

Conclusions: These findings demonstrate that the ER stress-responsive CHOP promoter can drive injury- specific gene expression and confer neuroprotection following optic nerve injury. Given the central role of ER stress in various ocular pathologies, pCHOP offers a promising strategy for developing gene therapies with controlled, injury-responsive expression, potentially confining exogenous gene expression to injured or degenerating cells, and reducing the risks of constitutive overexpression.



a) Mice are injected with AAV2-pCHOP-GFP in both eyes, and optic nerve crush was performed in the right eye only. b-d) Live imaging by SLO of each retina at 1 day before crush (b) and 7 days after crush (c-d). e) Immunohistochemistry on retinal wet mounts, of RGCs (with RBPMS) and GFP.



a) Schematic of mice injected with AAVs before optic nerve crush. b) Quantitation of RGC counts on retinal whole mounts.

583 Intein-based Dual AAV Gene Therapy Restores ABCA4 Function in Stargardt Disease

Xing Wang[1], Weiwei Wu[2], Guixiang Yang[3], Liying Chen[2], Shuna Cui[3], TJ Cradick[4], Alvin Luk[5], Linyu Shi[2], Hui Yang[6]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China, Shanghai, Pudong New Area, China, [2]HuidaGene Therapeutics Co., Ltd., Shanghai, China, Shanghai, Shanghai, China, [3]HuidaGene (Shanghai) Therapeutics Co. Ltd., Shanghai, China, Shanghai, China, [4]HuidaGene Therapeutics, Clinton, NJ, USA; Cholgene Therapeutics, Middletown, DE, USA, Clinton, NJ; Middletown, DE, MA, [5]Huidagene Therapeutics Inc, Clinton, NJ, [6]HuidaGene Therapeutics Co., Ltd., Shanghai, China; Shanghai Institute of Meteria Medica, Chinese Academy of Sciences, Shanghai, China, Shanghai, Shanghai, China

Background: Loss-of-function mutations in the *ABCA4* gene result in the accumulation of toxic bis-retinoid compounds, leading to photoreceptor degeneration and central vision loss in Stargardt disease (STGD1). Due to the large size of the *ABCA4* gene, its delivery via AAV requires a dual-vector approach. We developed an intein-based dual AAV gene replacement therapy (HG005) designed to express the full-length human ABCA4 (FL-ABCA4) protein via protein trans-splicing (PTS). This study evaluates the therapeutic potential of HG005 in a mouse model of STGD1.

Methods: We employed a dual-plasmid system in HEK293T cells to co-express truncated ABCA4 proteins fused with inteins, facilitating PTS production of FL-ABCA4 (Outlined in **Fig. 1A**). Nine split sites and 14 intein types were screened for optimal efficiency, comparing the results with previously reported versions, $C1150^{Npu}$ and $C1150^{Rma}$ (Ruiting 2023). Western blotting (WB) assessed FL-ABCA4 expression and fusion efficiency. Based on the in vitro findings, dual AAV vectors were constructed with promoters, introns, and codon optimization. Subretinal injections of these dual AAV vectors were performed in the *Abca4*-deficient mice ($Abca4^{-/-}$). Expression and localization of ABCA4 protein were assessed by WB and immunofluorescence (IF) at 8 weeks post-injection, using C57BL/6J mice as controls (**Fig. 2A**). The recovery of ABCA4 protein was measured at different HG005 injection doses. Therapeutic efficacy was evaluated by quantifying A2E accumulation in the retina using liquid chromatography-mass spectrometry (LC-MS) at 12 weeks post-injection (**Fig. 2D**).

Results: The WB analysis of HEK293T cell screening identified Site 2 as the most efficient split site for the fusion efficiency of FL-ABCA4, with a significantly higher full-length to truncated protein ratio (**Fig. 1B**). Among the intein types, Intein 4 combined with Site 2 yielded the highest FL-ABCA4 protein expression, exceeding $C1150^{Npu}$ by more than twofold (**Fig. 1C**). In vivo studies showed robust and dose-dependent functional human ABCA4 (hABCA4) protein restoration in the retina of $Abca4^{-/-}$ mice treated with HG005 8 weeks after subretinal injection. WB analysis revealed that HG005 achieved ABCA4 protein expression levels up to 150.4% of those in wild-type (WT) mice, significantly outperforming the previously published $C1150^{Rma}$ expression (**Fig. 2C**). Immunofluorescence results confirmed specific localization of hABCA4 protein to the photoreceptor outer segments (OS), consistent with the WT retinal biodistribution (**Fig. 2B**). Notably, LC-MS analysis demonstrated a dose-dependent reduction in A2E accumulation, with the high-dose group of HG005 achieving 74.5% reduction in A2E compared to controls at 3 months post-injection (**Fig. 2D**).

Conclusions: This study demonstrates the feasibility of using the PTS mechanism to successfully express the FL-ABCA4 protein via a dual-plasmid system. Through rigorous optimization and screening of split sites, intein types, and vector design, HG005 is mediated by Site 2 and Intein 4 and has emerged as a superior candidate. HG005 achieved much higher ABCA4 protein expression at equivalent dosages and significantly reduced the A2E accumulation than previously reported $C1150^{Rma}$ approaches, markedly enhancing the therapeutic potential. These findings establish HG005 as a promising gene therapy for Stargardt disease and support its advancement toward clinical development.

584 Human Retinal Cell Delivery of a Bioengineered, Synthetic Protein Sensitive to Multiple Wavelengths of Light in Patients with Stargardt Disease

Vinit Mahajan[1], Byron Lam[2], Vitaliy Zak[3], Victor Gonzalez[4], Ninel Gregori[2], Chavala Sai[5], SUBRATA BATABYAL[6], Michael Carlson[7], Sanghoon Kim[8], Ananta Ayyagari[5], Joanne Hu[5], Najam Sharif[5], Stephen Tsang[9], Samuel Barone[5], Samarendra Mohanty[10]
[1]Stanford University Laboratory for Cell & Gene Medicine, Palo Alto, CA, [2]Bascom Palmer Eye Institute, Miami, FL, [3]Acuity Eye Group, Palm Desert, [4]Valley Retina Institute, McAllen, TX, [5]Nanoscope Therapeutics, Dallas, TX, [6]Nanoscope Technologies LLC, Bedford, TX, [7]Nanoscope Therapeutics Inc, Dallas, [8]Nanoscope Instruments, Inc., Bedford, TX, [9]Columbia University, New York, NY, [10]Nanoscope Therapeutics Inc, Bedford, TX

Background
Multi-characteristic opsin (MCO), a triprotein fusion complex from non-mammalian sources, has demonstrated high ambient light sensitivity over a broadband light spectrum without compromising kinetics. As an optogenetics approach targeting higher-order retinal neurons (e.g., ON bipolar cells), the initial safety and efficacy of viral-vector-delivered MCO (MCO-010) was clinically evaluated in Stargardt disease (SD), a progressive inherited retinal disease that leads to severe and irreversible vision loss through photoreceptors and retinal pigment epithelial (RPE) cell degeneration.

Methods
A single intravitreal injection of MCO-010 was administered in the worse-seeing eye of SD patients in STARLIGHT, phase 2 open-label study conducted over 48-weeks at two US sites. Six adults (mean age 50 years, range 32-71 years, 4 males) received 1.2E11 genome copies (gc)/eye of MCO-010. The primary outcome was the incidence, nature, and severity of treatment-emergent adverse events (TEAEs). Secondary endpoints included change in best-corrected visual acuity (BCVA), vision-guided mobility, and shape determination accuracy. Visual field perimetry and Michigan Retinal Degeneration Questionnaire (MRDQ) were exploratory endpoints.

Findings
All 6 participants had at least 1 ocular TEAE; non-ocular TEAEs occurred in 3 participants. The most common TEAEs were conjunctival hemorrhage, ocular hypertension, and vitreous cells (2 subjects). There were no deaths, hospitalization, loss of eye, retinal detachment, endophthalmitis, or TEAEs leading to study discontinuation. The mean BCVA of the 6 treated eyes at baseline and 48-week follow-up was 22.8, and 28.3 ETDRS letters respectively. The BCVA change from baseline was 7.2, 4.2, and 5.5at 12, 24, and 48 weeks respectively. With a wearable magnifier (low-vision glasses), the mean BCVA change was 17.8, 15.7, 13.3 at 12, 24, and 48 weeks respectively. The improvement in mean defect in visual field perimetry was 1.02, 2.47, and 2.63 dB at 12, 24, and 48 weeks respectively. Specific improvements were noted in reading, and color and contrast domains of the MRDQ.

Interpretation
MCO is the most bioengineered non-mammalian protein that has been heterologously expressed in humans. Intravitreal MCO-010 was safe, and improvement in on(eye)-chart vision of SD participants with severe low vision was observed. MCO-010 optogenetic phase 2 results support the further investigation for treatment SD.

585 AAV-Mirtron Treatment Preserves Retinal Structure and Function in the Human P23H Knock-In Autosomal Dominant Retinitis Pigmentosa Mouse Model

Qingyun Zheng[1], Imran Yusuf[2], Ahmed Salman[1], Maria Kaukonen[3], Federica Staurenghi[2], Harry Orlans[3], Michelle McClements[2], Robert Maclaren[2]*

Introduction
Mutations in the rhodopsin (RHO) gene are the leading cause of autosomal dominant retinitis pigmentosa (ADRP). The heterogeneity of RHO mutations presents a significant therapeutic challenge, necessitating precise suppression of mutant RHO transcripts while ensuring optimal replacement of codon-modified rhodopsin. Mirtrons, a subclass of short hairpin introns, are processed into functional RNA interference effectors following splicing from precursor mRNA. This study investigates an adeno-associated virus (AAV)-delivered triple mirtron vector to achieve balanced knockdown of mutant RHO and replacement of codon-modified RHO in a humanised ADRP mouse model.

Methods
The lead candidate triple mirtron AAV vector targeting human RHO (RHOp.3xM.coRHO) was administered at a dose of 5×108E genome copies (gc)/eye via subretinal injection in Rho+/−, hP23H+ mice at 3–4 weeks of age. Post-injection assessments included optical coherence tomography (OCT) at 1, 3, and 6 months, electroretinography (ERG) at 4 and 6 months and RNA extraction from harvested retinas for transcript assessments.

Results
In P23H+ mice, the photoreceptor layer thickness in both the superior and inferior retinas remained consistently greater in treated eyes compared to paired uninjected controls at 1, 3, and 6 months post-injection. Functional improvements were also evident, as demonstrated by enhanced scotopic and photopic ERG b-wave amplitudes at both 4 and 6 months post-injection. Quantitative PCR revealed significant reductions in mouse rhodopsin and human P23H rhodopsin transcript levels, with concurrent detection of coRHO transcripts, maintaining total rhodopsin levels at ~50% of uninjected eyes at 6 months. Biodistribution analysis confirmed retinal specificity of transgene expression.

Conclusions
AAV-delivered triple mirtron vector achieved effective knockdown of native rhodopsin transcripts and balanced rhodopsin replacement in the human P23H knock-in mouse model. Structural improvements correlated with enhanced retinal function, supporting the potential of mirtron-based RNA knockdown and replacement as a novel approach for gene therapy of ADRP.

586 12-Month Safety and Efficacy Evaluation of Subretinal Gene Therapy (FT-002) for the Treatment of RPGR Gene Mutation Associated X-linked Retinitis Pigmentosa

Ruyi Han[1], Jiawen Wu[1], Jihong Wu[2], Weihong Yu[3], Gezhi Xu[1], Rongping Dai[3], Li Huang[4], Minghui Xue[4], Chao Ren[5], **Xinyan Li[5]***, Ruifang Sui[3]*
[1]Eye and Ent Hospital of Fudan University, Shanghai, Shanghai, China, [2]Eye and Ent Hospital of Fudan University, Shanghai, China, [3]Peking Union Medical College Hospital, Beijing, Beijing, China, [4]Frontera Therapeutics, Shanghai, Shanghai, China, [5]Frontera Therapeutics, Shanghai, China
**Corresponding Author*

Background: X-linked retinitis pigmentosa (XLRP) is a severe form of retinitis pigmentosa (RP) characterized by early onset and rapid progression of vision loss or even blindness. The majority of XLRP cases are caused by mutations in the retinitis pigmentosa GTPase regulator (RPGR) gene, and currently there is no effective treatment. FT-002 is an investigational gene therapy that uses the adeno-associated virus serotype 5 (AAV5) vector to deliver a codon-optimized human RPGRORF15 gene into retinal photoreceptor cells through subretinal injection. This gene therapy aims to express active RPGR protein, potentially rescuing photoreceptor cell loss due to RPGR gene mutation, thus improving visual function or delaying the progression of visual impairment in XLRP patients.

Methods: A pilot clinical study (NCT05874310) conducted in China is an open-label, dose-escalation trial enrolling males aged 18-45 years with RPGR mutation-associated XLRP who receive a single subretinal injection of FT-002. The safety and tolerability, immunological responses, and efficacy of FT-002 are evaluated. All participants are encouraged to enter long-term follow-up for up to 5 years. This study complied with ICH-GCP, was approved by the IC of each site, and all participants signed the ICF.

Results: As of January 15, 2025, 18 participants enrolled in the pilot study received FT-002 at doses of 5×10^{10}, 10×10^{10} and 20×10^{10} vg/eye and completed 1 year follow-up. FT-002 was well-tolerated, with no DLT or FT-002 related SAE observed. Most AEs were related to the surgical procedure, and signs of FT-002 related ocular inflammation observed in 8/18 (44%) participants but were controllable via topical use of steroids. Vitreous cells were the most common ocular inflammation of grade 1-2 in severity. OCT imaging revealed no retinal pigment epithelium (RPE) atrophy, and pigmentation observed at the retinotomy sites. Notably, it is the first time to report that no significant progression of ellipsoid zone (EZ) loss was noted at 12 months post FT-002 injection compared to baseline, especially for participants who had well preserved EZ. Additionally, immunological findings did not indicate safety concerns. Improvement in microperimetry mean sensitivity across 68 loci was observed in 10×10^{10} vg/eye (1.32 dB) and in 20×10^{10} vg/eye (0.83 dB) at month 12, with 50.0% and 33.3% of participants maintained ≥7 dB improvement in ≥5 loci, respectively. Updated follow-up data in all participants will be presented.

Conclusion: Subretinal injection of FT-002 at doses of 5×10^{10} to 20×10^{10} vg/eye was generally well-tolerated with no RPE changes noted. FT-002 has the potential to provide long-term clinical benefits for XLRP patients with defects in the RPGR gene, including improvements in visual acuity and retinal sensitivity.

587 Optogenetic Therapy for the Treatment of Photoreceptor Degeneration Diseases

Xiaohu Wei[1], Lingjie Cui[2], Min Li[3], XueTing Luo[3], **Kai Wu[4]**, SiJie Sun[3], XiaoHua Liu[3], ZhiPing Cui[3], Chang Tan[3], Hongyang Li[3]
[1]U-genex, Shanghai, Shanghai, China, [2]Ugenex Therapeutics Ltd.Co, shanghai, Shanghai, China, [3]Ugenex Therapeutics Ltd.Co, shanghai, China, [4]UgeneX, Shanghai, China

Photoreceptor degenerative diseases such as retinitis pigmentosa and age-related macular degeneration ultimately lead to photoreceptor degeneration and irreversible blindness. We aim to restore vision in affected patients through optogenetic therapy, specifically by expressing light-sensitive ion channel proteins in the remaining retinal ganglion cells (RGCs).

We have designed light-sensitive ion channels and their variants with high photosensitivity and excellent photodynamic properties, such as low light sensitivity thresholds, fast response speeds, and high maximum response frequencies. Through extensive screening of various ion channel variants, we selected the most optimal version. It covers the entire visible spectrum, achieves optimal absorption at 550 nm, and exhibits exceptionally low phototoxicity. By combining our in-house developed adeno-associated virus (AAV) capsid vectors and RGC-specific promoters, we successfully delivered the constructs into blind C3H mice and induced full-field electroretinograms (ERGs) under ordinary white-light stimulation. Concurrently, visual evoked potentials (F-VEPs) were recorded in the visual cortex, indicating complete restoration of the visual pathway. Furthermore, the AAV vectors we developed exhibited excellent infection efficiency in the retinas of non-human primates (NHP), effectively targeting multiple regions, including the macula and surrounding areas. In addition, promising light-sensing properties were recorded in NHP retinas.

In conclusion, we have developed an optogenetic therapy candidate with high sensitivity, fast kinetics, exceptional safety profiles, coupling with highly efficient AAV capsid vector, which is now progressing into clinical investigation in photoreceptor degenerative patients.

588 Therapeutic Evaluation of a Gamma-Globin Gene Addition Vector System With a Large LCR in Sickle Cell Disease Mice by *In Vivo* HSC Transduction

Chang Li[1]*, Hongjie Wang[1], Anna Anderson[2], Sucheol Gil[3], Darrick Carter[4], Andre Lieber[5]
[1]University of Washington, Seattle, Washington, [2]University of Washington, Sandy, UT, [3]University of Washington, [4]Protein Advances Inc., Seattle, WA, [5]University of Washington, Seattle, WA
**Corresponding Author*

We developed an *in vivo* hematopoietic stem cell (HSC) gene therapy strategy by directly targeting mobilized HSCs inside the body by intravenously delivered helper-dependent adenovirus (HDAd) vectors. This strategy does not require *ex vivo* culture of HSCs and transplantation. It holds the potential for broad applications due to its simplified procedure and affordability. Based on *in vivo* HSC transduction in a sickle cell disease mouse model (CD46/Townes), we have previously reported that *in vivo* prime editing mediated the correction of the sickle cell disease mutation and the amelioration of the disease phenotype. However, the *in vivo* use of prime editors could cause editor enzyme-related adverse effects or/and off-target editing. Here, we therefore evaluated the therapeutic efficacy of a HDAd vector that contained a 29kb g-globin expression cassette including 26kb of the b-globin locus-control region (LCR). After *in vivo* transduction with the HDAd-long-LCR-g-globin vector plus HDAd-SB (for vector integration) and *in vivo* selection with low doses of O^6BG/BCNU to expand transduced HSCs by utilizing an $MGMT^{P140K}$ gene incorporated in the vector, we observed that more than 90% of peripheral red blood cells (RBCs) expressed g-globin. Levels of added g-globin protein were >20% of human b-globin present in CD46/Townes mice. The treated animals demonstrated significantly reduced percentages of sickling RBCs compared to untreated controls. Other disease indicators including reticulocyte counts and histological readouts also showed significant amelioration. No noticeable side effects were observed after *in vivo* transduction/selection. We isolated lineage-negative cells from the *in vivo* transduced mice and transplanted them into irradiated C57BL/6 mice. As of week 12 after engraftment, the gamma-globin expression remained stable. We are following the secondary recipients for one more month for terminal analyses. In summary, the endogenous long LCR in the HDAd-long-LCR-γ-globin vector drove therapeutic levels of gamma-globin expression in SCD mice and demonstrated advantages over mini-LCRs which are widely used in the development of *ex vivo* gene therapy products for sickle cell disease.

589 Novel Lentiviral Vectors Enable Controlled Expansion of Transduced Hematopoietic Stem Cells: Beta-Hemoglobinopathies as disease models

Introduction: Gene therapy holds a significant promise for treatment of beta hemoglobinopathies, although its full therapeutic potential is constrained by several challenges. Clinical approaches employ lentiviral vectors with the truncated beta-globin Locus Control Region (uLCR) driving high-level transgene expression in erythroid cells. However, the large size of the uLCR limits the vector's capacity for multiplex purposes.

Aim: To overcome current limitations and optimize globin vectors for better safety and efficacy, we developed a new lentiviral vector featuring a compact, erythroid-specific enhancer that is significantly smaller than the uLCR, while maintaining strong transgene expression. This modification allows for the integration of two additional functional components; (1) a dual-functioning chromatin insulator, serving both enhancer-blocker and barrier functions to improve transgene expression stability and protect against insertional mutagenesis, and (2) a positive selection ($FKBP^{F36V}$-MPL) cassette that can expand genetically modified cells in vivo upon stimulation in the presence of AP20187. As a therapeutic transgene we have used a short-hairpin RNA (shRNA) targeting the HbF-suppressor BCL11A while a GFP reporter gene was added for normalization and tracking purposes. The $FKBP^{F36V}$-MPL cassette encodes for a fusion protein that initiates proliferation when exposed to its ligand, the chemical inducer of dimerization AP20187.

Methods: After low-MOI transduction, CD34+ HSCs from healthy donors, β-thalassemia and SCD patients were cultured ±AP20187. Transduction efficiency, proliferation during erythroid and myeloid (granulocytic-monocytic) ex vivo differentiation and γ-globin expression in transduced erythrocytes were evaluated by flow cytometry and HPLC, respectively.

Results: Transduction efficiency ranged between 1-30%, depending on the MOI. AP20187-treatment at the end of ex vivo erythropoiesis and granulocytic/monocytic differentiation led to a 2.8±1.6-fold and 58,5±26,5-fold expansion of transduced cells, respectively [GFP+ cells (%): 19,1±9.3 +AP20187 vs 7.5±2,5 -AP20187, p=0.001 and 36.4±24.9 +AP20187 vs 0.67%±0.42 -AP20187, p=0.0001, respectively). Notably, the expanded cells in the granulocytic/monocytic culture exhibited a distinct erythroid signature (CD235a+/CD36+) and were negative for myeloid markers (CD33-/CD13-), indicating that AP20187-mediated expansion is erythroid-specific even in the absence of erythropoietin. Finally, HPLC evaluation of the globin chains at the end of the erythroid differentiation showed a significantly increased γ-globin/β-like-globin ratio after AP20187 treatment in all cultures (healthy donors: 0.30 vs 0.18 (p=0.05), SCD: 0.6 vs 0.41 (p=0.05), thalassemic: 3.49 vs 2.25 (p=0.0001), vs -AP20187).
Conclusions: Our insulated, erythroid-specific lentiviral vector, combined with the FKBPF36V-MPL cassette, provides an optimized system for safe and effective viral vector gene therapy targeting beta hemoglobinopathies. Additionally, it offers the potential for selective expansion of target cells in other hematopoietic stem cell (HSC) gene therapy approaches.

590 Split Intein Lentiviral Vector Hematopoietic Stem Cell Gene Therapy for the Treatment of DOCK8 Deficiency

Vrishti Sinha[1], Joseph Long[2], Ashley Takenami[3], Caroline Kuo[3]
[1]University of California Los Angeles, Los Angeles, CA, [2]UCLA, Los Angeles, California, [3]University of California, Los Angeles, Los Angeles

Introduction: Dedicator of Cytokinesis 8 (DOCK8) Deficiency is a rare autosomal recessive primary immune deficiency caused by loss of function mutations of the *DOCK8* gene including deletions of various sizes, missense

and nonsense mutations. DOCK8 is expressed primarily in cells of the hematopoietic stem cell lineage and encodes a guanine nucleotide exchange factor (GEF) protein responsible for actin cytoskeletal rearrangement and association and translocation of phosphorylated STAT3. While likely underdiagnosed, roughly 1 in 1 million individuals have DOCK8 Deficiency affected by recurrent and often severe infections involving the skin and respiratory tract along with recalcitrant viral infections leading to dysplasia and cancers. Currently, allogeneic hematopoietic stem cell transplantation (HSCT) is the only curative therapy but can be associated with many complications. Therefore, the goal is to provide safe and improved curative treatments for DOCK8 Deficiency patients by utilizing autologous HSCT and *ex vivo* gene correction strategies. To achieve this goal, we have designed and tested multiple lentiviral vectors. Given the large size of *DOCK8*, we developed split intein constructs which independently undergo genomic integration. Upon translation, two protein halves undergo spontaneous protein splicing *in trans* to generate the desired DOCK8 protein.

Methods: To study candidate vectors *in vitro*, we transduced Jurkat, DOCK8 KO Ramos, DOCK8 KO primary peripheral blood stem cells (PBSCs) and DOCK8 KO CD4 T cells from peripheral blood mononuclear cells (PBMCs) with candidate intein vectors in comparison to constructs containing the entire *DOCK8* cDNA. DOCK8 deficient cell lines and primary cells were generated using CRISPR/Cas9 knockout. VCNs achieved by each candidate vector were determined by ddPCR. Expression and pSTAT3 function of DOCK8 were assessed through flow cytometry and Western Blots, respectively.

Results: When transducing cells with each candidate vector, the single lentiviral vectors achieved VCNs below 0.05 whereas the split intein lentiviral vectors achieved VCNs of ~1 in primary PBSCs. Furthermore, split intein vectors had improved DOCK8 expression at lower doses compared to the single vectors. Mock-treated Jurkats do not express DOCK8, but when transduced and stimulated with hIL-21, there is increased pSTAT3 expression via Western Blot. Ongoing studies focus on functional restoration of DOCK8 in KO CD4 T cells.

Conclusion: Thus far, we have been able to overcome the large size of the DOCK8 gene using a split intein lentiviral vector approach. We have demonstrated the promising potential nature of these intein constructs to express a functional and full length DOCK8 protein *in vitro*. Our next steps include characterization of the candidate constructs in *in vivo* murine models to further validate our lentiviral approach. Our split intein approach could serve as a viable alternative option to gene modify other monogenic diseases due to defects in large genes.

591 Comparing Efficacy and Safety of Prenatal versus Neonatal AAV5 Gene Therapy for Hemophilia A in a Sheep Model

Martin Rodriguez[1], Oluwaseun Babatunde[1], Walaa Mohamed[1], Jovanna Perez[1], J Vaughan[1], Andrew Farland[2], John Owen[2], Anthony Atala[3], Christopher Doering[4], H. Trent Spencer[5], Christopher Porada[1], M Graça Almeida-Porada[6]
[1]Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, [2]Wake Forest University Baptist Hospital, Winston Salem, NC, [3]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, [4]Emory University, Atlanta, GA, [5]Emory University School of Medicine, Atlanta, GA, [6]Wake Forest School of Medicine, Winston-Salem, North Carolina

Persons with severe hemophilia A (HA) lack functional factor VIII (FVIII) protein and experience severe and spontaneous bleeding. Clinical trials in adult HA patients receiving AAV gene therapy (GT) have underscored the risk of hepatoxicity and genotoxicity and demonstrated waning FVIII levels post-treatment. Moreover, the presence of pre-existing anti-AAV antibodies in circulation restricts treatment eligibility and negatively impacts clinical efficacy. We hypothesized in utero AAV-based GT (IUGT) would enable correction of HA prior to birth, circumventing both AAV- and FVIII-related immune hurdles. Sheep fetuses at 60-65 gestation days (human 18-20 g.weeks) received an AAV5 vector encoding a codon optimized, bioengineered fVIII variant (ET3) (AAV5-lcoET3) by ultrasound-guided intraperitoneal injection, at a dose of $2x10^{12}$ vg/kg (n=4) (IUGT recipients). Neonatal lambs (3 days old) received the same dose of AAV5-lcoET3 (n=3) via cephalic vein (NNGT recipients). Both groups were evaluated for hematological and hepatic alterations. All IUGT recipients evaluated monthly post-birth had normal complete cell counts (CBCs) and normal liver enzymes, while all NNGT recipients had normal CBCs but increased alanine aminotransferase (ALT) levels by 7 days post-GT, returning to normal by 30d. In addition, one NNGT

recipient maintained elevated gamma glutamyltransferase (GGT) levels up to 30 days post-GT, which subsequently returned to normal (60d) without treatment. ET3 protein in circulation was quantified using an ET3-specific ELISA. IUGT recipients had mean ET3 levels of 7.3+/-3.03 ng/mL at 120d post-IUGT corresponding to 30 days post-birth. Intriguingly, 1 of 3 IUGT recipients exhibited circulating ET3 levels for up to 270d post-IUGT. Specifically, it had plasma ET3 levels of 8.79+/-1.13 ng/mL at 120d, 3.9+/-0.44 ng/mL at 150d, 2.07+/-0.08 ng/mL at 210d, 3.49+/-0.39 ng/mL at 240d, and 24.25+/-0.36 ng/mL at 270d post-IUGT. Circulating ET3 levels in the other two IUGT recipients dropped below the level of detection by 150d post-IUGT. In contrast, all NNGT recipients exhibited an initial spike of ET3 (5.26 +/- 1.6 ng/mL) at 7d post-NNGT, with ET3 levels declining by day 30 to 0-1 ng/mL. ET3 transcripts were detected in circulating mononuclear cells by RT-dPCR in both IUGT and NNGT recipients up to 210 and 120d post-GT respectively. To determine immunogenicity of ET3 and of the AAV vector, ELISAs were performed for anti-ET3 IgG and anti-AAV5 IgG antibodies, respectively. While no anti-ET3 antibodies were detected at any timepoint in the IUGT recipient with sustained ET3 levels, the other IUGT recipients developed anti-ET3 antibodies detectable at 240 and 270d post-IUGT respectively, and two of the NNGT recipients developed anti-ET3 IgG at 120d and 180d post-NNGT. Of note, anti-AAV5 IgG antibodies emerged at similar time points as the anti-ET3 IgG antibodies and were detected in the same IUGT and NNGT recipients that developed anti-ET3 IgG; in one of the animals, a wild AAV-type infection was confirmed prior development of anti-AAV antibodies. Studies are ongoing to elucidate the: 1) molecular mechanism by which therapeutic ET3 persists long-term in the IUGT recipient and 2) cause of the development of anti-ET3 antibodies after waned circulating ET3. These studies will improve our understanding of efficacy and of potential toxicities of IUGT and NNGT using AAV vectors and will pave the way for safer and more effective treatments for HA.

592 Development of a Humanized Immune system mouse supporting primary AML PDX engraftment for drug efficacy studies

Mara Gilardi[1], Paolo Schiavini[1], Laura Griffin[2], Brandon Walling[1], Paul Heverly[1], Stefano Cairo[3], Philip Dube[4], Monika Buczek[5], Marianna Zipeto[1], Michael Ritchie[1]
[1]Champions Oncology, Rockville, MD, [2]Taconic Biosciences, Rensselaer, NY, [3]Champions Oncology Inc, [4]Taconic Biosciences, Rockville, MD, [5]Taconic Biosciences, Rockville

Acute Myeloid Leukemia (AML) is a devastating hematological malignancy with a global incidence of approximately 120,000 new cases annually and a five-year survival rate below 30%. Despite advances in therapeutic strategies, treatment outcomes remain poor. The complexity of AML, characterized by genetic heterogeneity and clonal evolution, presents significant challenges for the development and testing of novel therapeutics in clinically relevant settings.

AML research relies heavily on cell lines and syngeneic rodent models, or immunodeficient rodent models without the inclusion of a human immune system. While these models provide valuable insights, they fail to fully recapitulate the genetic and phenotypic diversity of primary human AML tumors. Traditional models often lack the tumor microenvironment and immune interactions critical for therapeutic evaluation and successful translation to the clinic. Furthermore, existing models generally rely on extensively passaged samples, which lose the heterogeneity and clonal diversity intrinsic to AML, undermining their clinical relevance.

To address these limitations, we developed an in vivo model supporting a primary AML PDX and a humanized immune system derived from CD34+ hematopoietic stem cells (HSCs). The NOG-EXL mouse was selected as the preferred in vivo model as it has been successfully engrafted with primary AML PDXs, albeit not also with a humanized immune system component. The NOG-EXL, transgenic for human IL-3 and GM-CSF, supports engraftment of both human myeloid and lymphoid lineages, making it suitable for diverse therapeutic applications. Additionally, stem cell donors were selected so that HLA-matching to specific AML PDXs was optimized. The model was generated by first engrafting HLA-matched HSCs into NOG-EXL mice followed by engraftment of the primary AML PDX. Human immune cell engraftment and AML cancer progression were assessed at different timepoints via flow cytometry on peripheral blood and bone marrow. A custom flow cytometry panel was used to identify the human immune cells present as well as the main AML sub-populations including the AML progenitors, AML blasts and monoblasts.

This novel approach bridges a critical gap in AML research by offering a robust, clinically relevant platform that reflects real-world disease biology by demonstrating an in vivo model with primary, never-passaged AML PDX in the context of a human immune system. The AML humanized model sets a new standard for preclinical evaluation, promising to accelerate the development of personalized therapies and improve outcomes for AML patients worldwide.

593 Human Liver Tissue Equivalent (hLTE) Models for Studying the Safety and Efficacy of AAV-based Gene Therapy for Patients with Hemophilia A

Sarah Wachtman[1], Ritu Ramamurthy[2], Jonathan Diaz[2], Anthony Atala[3], Christopher Doering[4], H. Trent Spencer[5], Christopher Porada[2], M Graça Almeida-Porada[6]*

Gene therapy (GT) promises long-term-treatment for hemophilia A (HA), a bleeding disorder caused by various mutations in the F8 gene. Ongoing clinical trials with AAV-based GT in adults showed that most patients experienced unexpected hepatoxicity and required subsequent immunosuppression with FVIII levels dropping over time, forcing patients to revert to factor replacement. These data underscore key differences compared to data from pre-clinical animal models and emphasize the need for more accurate models enabling the assessment of the safety and efficacy of GT products in a fully human system. To investigate the impact recipient age has on these variables and whether GT could be safely extended to younger populations, we developed human liver tissue equivalent (hLTE) models to test the efficacy and potential toxicity of AAV-mediated GT at different ages. Using adult-derived hLTE, we have previously shown impaired self-aggregation of hLTE, and a significant dysregulation of genes involved in hepatotoxicity and inflammation. Here, we used pediatric human donors' hepatocytes and stromal cells (Kupffer, stellate, and sinusoidal endothelial cells) to develop a 2000-cell organoid that recapitulates the structure, biology, and functions of the native liver. The cells were transduced using AAV5 or AAV6 encoding GFP in suspension and were plated in U-bottom 96-well plates to self-aggregate into hLTEs, alongside non-transduced (NT) controls. The hLTEs were monitored for 10 days; GFP expression was monitored daily via fluorescence imaging, DNA and RNA were collected on days 5 and 10 for dPCR, viability assays (Live/Dead, ATP) were performed on days 5 and 10, a functionality assay (CyP450) was performed on days 7-10, and media was collected on days 5-10 to perform ELISAs for urea, albumin, transaminases (ALT, AST), and Alpha-1 antitrypsin (AAT). Data from 3 biological replicates of pediatric hLTEs indicate transduction with AAV5 or AAV6 had no significant impact on hLTE function or viability as determined by Live/Dead, ATP, and Cyp450 assays when compared to NT groups. Fluorescence imaging of the GFP transgene demonstrated a continuous increase in GFP signal in both AAV5 and AAV6, with significantly higher levels of GFP expression in AAV6 beginning on day 4 post-transduction. dPCR results indicated significantly higher levels of GFP mRNA in the AAV5-transduced hLTEs compared to AAV6. Interestingly, there was no significant difference in transgene DNA copy number between transduced groups. No significant differences in urea and albumin production were found; however, we observed a large variation in AST and ALT levels between biological replicates, indicating that patient profile plays a significant role in transaminase response to transduction. Additional comparison studies using adult hLTEs to define the impact of recipient age on efficacy and hepatic response to GT are currently underway.

594 An *In Vitro* Air-Liquid Interface Lung Model of Alpha1 Antitrypsin Deficiency for Assessing an Adeno Associated Virus Based Genetic Medicine

Wenkai Jia[1], Roxanne Croze[2], Kenneth McCullough[3], Devi Khoday[1], Thomas Mason[1], Melissa Calton[4], David Kirn[1], An Song[1]*

Alpha1 antitrypsin deficiency (A1ATD) is a rare genetic disease caused by mutations in the SERPINA1 gene, resulting in deficient levels of A1AT. Obstructive lung disease develops when the lack of A1AT in the alveoli leads to uninhibited elastase activity, causing connective tissue breakdown and the development of emphysema in the lungs. Treatment options for individuals with lung diseases associated with A1ATD are very limited and largely mirror those available for patients with non-A1ATD-related chronic obstructive pulmonary disease (COPD), including bronchodilators, steroids, antibiotics and other anti-inflammatory therapies. The only regulatory agency-approved disease-specific therapy for A1ATD is intravenous augmentation therapy with plasma-purified A1AT. Adeno-associated virus (AAV)-based genetic medicine targeting the lung parenchyma has the potential to serve as a long-term approach for the treatment of A1ATD lung disease, by expressing the wild type (WT) allele M-AAT gene in pulmonary cells, which will then secrete the protein into the airway, thereby augmenting the lung levels of A1AT and preventing alveolar proteolytic destruction.

To facilitate assessment and development of translatable therapeutic candidates, we developed an air-liquid interface (ALI) lung model using iPSCs derived from PiZZ A1ATD patient cells. PiZZ and control WT iPSCs were expanded and differentiated into lung progenitor cells, which were then seeded onto transwell membranes to differentiate and mature into an ALI system. The ALI cultures were characterized through immunofluorescent staining targeting biomarkers for key airway epithelial cells, including ciliated, goblet, basal, alveoli and club cells. Disease markers were characterized by protein analysis using gel electrophoresis (PAGE) on cell lysate and enzyme-linked immunosorbent assay (ELISA) on cell culture basal medium.

The PiZZ iPSC-ALI disease model exhibited a decreased secretion of A1AT compared to the WT iPSC-ALI model and showed an increased accumulation of aggregated intracellular A1AT in the total cell lysate. The cells were transduced apically using an AAV carrying the A1AT transgene payload, and the basal medium was collected over time to assess A1AT expression and functionality of exogenously produced A1AT following AAV transduction. Both WT and PiZZ iPSC-ALI models were successfully transduced with AAV, resulting in A1AT secretion in a dose-dependent manner at varied multiplicities of infections (MOIs). In both contexts, functional A1AT was produced and secreted, as demonstrated by the ability of the cell culture basal medium to inhibit neutrophil elastase activity.

In conclusion, a PiZZ iPSC-ALI lung model was developed that replicated key disease characteristics. This A1ATD disease model can serve as a valuable tool for evaluating genetic medicine candidates during their product development process.

595 A Novel Strategy for Treating Gefitinib-Resistant Cancer: Correction of Multiple pathogenic single-nucleotide polymorphism (SNP) Using Adenine Base Editor- expressing adenovirus

A-Rum Yoon[1], Taeyoung Koo[2], Chae-Ok Yun[3]
[1]Hanyang University, Seoul, Korea, [2]Institute for Basic Science, Seoul, Korea, [3]Gene-Medicine, Seoul, Korea

This study presents an innovative strategy for addressing drug-resistant cancers by targeting specific oncogenic mutations. The research focuses on editing targeted mutations. Here we have targeted EGFR-T790M and TP53-R273H, single-nucleotide missense mutations associated with gefitinib resistance in cancer by utilization of an adenine base editor (ABE) coupled with specific single-guide RNAs, delivered via adenovirus. The ABE system demonstrated high accuracy and efficiency in correcting oncogenic mutation sites both in vitro and in vivo. Co-treatment with the ABE system targeting EGFR and TP53 SNPs, combined with gefitinib, showed superior results compared to gefitinib alone. Notably, this combination therapy increased drug sensitivity and more effectively suppressed abnormal tumor growth. Collectively, this approach not only addresses the issue of drug resistance but also offers a more targeted and potentially more effective treatment option for cancer patients.

596 Design and Development of Improved LNP Targeting Ligands for *In Vivo* Hematopoietic Stem Cell Editing

Stephen Sherman[1]*, Katerina Tsiounis[1], Megan Fitzgerald[1], Li Li[2], Peisheng Zhang[1], Ying Shao[1], Tallie Anne Algiere[1], Ryan Santosh[1], He Wang[1], Ramya Viswanathan[3], Swarali Lele[1], Jieni Xu[1], John Zuris[3], Sheryl Bowley[1]

Lipid nanoparticle (LNP) technologies have emerged as effective vehicles for *in vivo* delivery of therapeutics for a variety of diseases. The ability to deliver nucleic acids via LNPs presents an opportunity to leverage CRISPR/Cas-based gene editing machinery *in vivo* to correct genetic diseases with a minimally invasive approach. Although significant progress has been made in adjusting LNP composition to target organs of interest, the specific targeting of subcellular compartments within a given organ remains a challenge. In particular, the hematopoietic stem cell (HSC) compartment represents a minority fraction of the total bone marrow that generates the entirety of an organism's blood system. Enabling LNP transfection of the bone marrow can be broadly met through adjusting lipid composition, however targeting the HSC compartment remains a challenge. Here, we describe the development and optimization of a targeted LNP (tLNP) strategy to enable editing of HSCs *in vivo*.

We designed a screening platform to select targeting ligands that maximize the internalization of cell-surface targets while maintaining cellular specificity for HSCs. This approach utilizes a combination of available omics datasets paired with a flow cytometry-based measurement with the cell target of interest. Potential targeting candidates are further assessed using a tLNP format, which enables selection of an optimal targeting ligand. Using this platform *in vitro*, we identified an improved targeting ligand, Ligand 2, for HSCs that yielded 7 times greater internalization compared with Ligand 1, our first iteration of targeting ligand, as measured by the mean fluorescence intensity of the target. These *in vitro* findings directly translated to LNP efficacy in the NBSGW mouse model engrafted with human hematopoietic and stem progenitor cells (HSPCs). Upon infusion of tLNPs containing our proprietary editing cargo, targeting Ligand 1 achieved 0.25% editing of HSPCs in humanized mice, while Ligand 2 produced 26% editing. While the core LNP remains the same, these data indicate that the targeting ligand is a significant contributor to achieving abundant transfection directed to a discrete cell compartment of the bone marrow. The validation of this *in vitro* testing platform in an *in vivo* context underscores the need for targeting elements to actively promote the uptake of LNPs in the HSC population of the bone marrow, providing an opportunity for target cell-specific editing for the durable treatment of β-hemoglobinopathies.

597 Comprehensive Analysis of ABL1 Variant Resistance to Multiple Kinase Inhibitors via Prime Editing

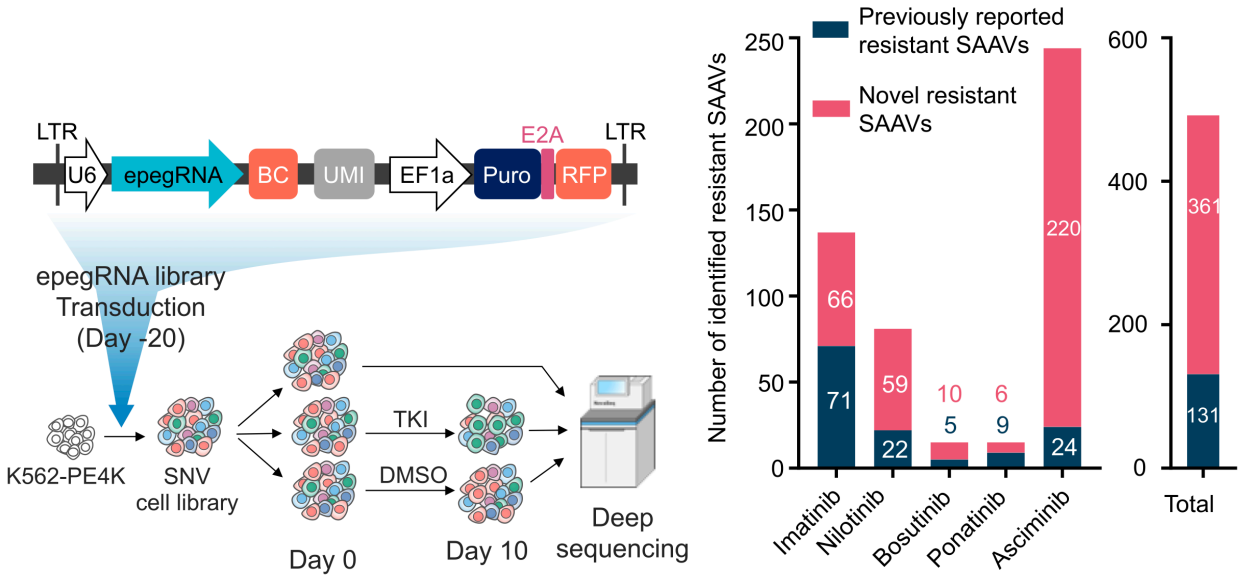
Uncertain significance variants (VUSs) pose a challenge to the clinical utilization of genetic data, particularly in the context of precision medicine. Chronic myeloid leukemia (CML) exemplifies this issue, as treatment relies on tyrosine kinase inhibitors (TKIs) spanning four generations, yet predicting TKI resistance for patients harboring ABL1 mutations remains challenging, especially when these mutations are not accounted for in existing clinical guidelines.

In this study, we employed prime editing to systematically introduce 97% (2,802/2,892) of all potential single nucleotide variants within the ABL1 kinase domain, resulting in the expression of 98% (1,954/1,998) of all possible single amino acid variants (SAAVs). We then assessed the resistance profiles of these SAAVs against a panel of five TKIs—imatinib, nilotinib, bosutinib, ponatinib, and asciminib—representing all four TKI generations, using CML-relevant K562 cells.

Through this approach, we identified 361 previously uncharacterized SAAV-TKI resistance pairs, significantly expanding the current knowledge of mutation-driven drug resistance. The comprehensive resistance landscape generated in this study serves as a valuable resource to refine clinical decision-making and enhance precision

medicine strategies for CML patients by providing an evidence-based framework for drug selection based on ABL1 mutation status.



598 Fixing the Balance: A Dual-Targeted Base Editing approach to reduce α-globin and reactivate Fetal Hemoglobin to treat β-hemoglobinopathies

Mathieu von Joest[1], Pierre Martinucci[2], Panagiotis Antoniou[3], Margaux Mombled[4], Sandra Manceau[5], Mario Amendola[6], Wassim El Nemer[7], Annarita Miccio[8]

[1]Institut Imagine, Paris, Paris, France, [2]Imagine Institute for Genetic Diseases, FRANCE, [3]AstraZeneca Gothenburg, Gothenburg, Gotlands lan, Sweden, [4]UMRS_951 Genethon, Evry, Essonne, France, [5]Biotherapy Clinical Investigation Center, Necker Children's Hospital, Assistance Publique Hopitaux de Paris, InIdex GR-Ex, Paris, France, [6]Genethon, Evry, Essonne, France, [7]Aix Marseille Univ, CNRS, EFS, ADES, Labex GR-Ex, Marseille, France, [8]Imagine Institute, Paris, France

Beta-hemoglobinopathies are caused by a reduced or abnormal synthesis of the adult hemoglobin (Hb) β-chain. In sickle cell disease (SCD), a point mutation in the β-globin gene results in β^S-chain production and leads to Hb polymerization, causing red blood cell (RBC) sickling and organ damage. In β-thalassemia, mutations in the β-globin causes a reduced (β^+) or absent (β^0) β-chain production, α-globin precipitation and death of erythroid precursors. Transplantation of autologous, genetically modified hematopoietic stem cells (HSCs) is an attractive therapeutic option.

Patients affected by these disorders in association with α-thalassemia traits have improved clinical phenotypes. In β-thalassemia, the co-occurrence of α-thalassemia, characterized by a reduced α-globin expression, ameliorates the α/β globin ratio and decreases free α-chains, thus reducing death of erythroid precursors. In SCD, reduced α-globin levels lower Hb concentration decreasing Hb polymerization. Moreover, the lower affinity of β^S-chain for α-chain compared to the wt β-chain generates excess of toxic α-chains, which is diminished with the co-inheritance of α-thalassemia. In parallel, mutations inducing reactivation of fetal β-like γ-globin and expression of fetal Hb

(HbF) can also ameliorate the β-thalassemic and SCD phenotypes by improving the α-/β-globin ratio and preventing Hb polymerization, respectively. Base editing (BE) allows specific DNA mutations (C>T, cytidine base editors, CBEs; A>G, adenine BEs, ABEs) without generating dangerous double strand breaks, thus allowing the multiplexed editing of several targets. We developed a common BE strategy that concomitantly (i) reduce α-globin production by targeting MCS-R2 enhancer, the most critical regulator of the α-globin *HBA* genes and (ii) reactivate HbF expression by disrupting enhancers of BCL11A, a master repressor of γ-globin expression.

First, we used ABEs and CBEs to target either the GATA1 or NFE-2 activator binding sites (BS) present in MCS-R2 *HBA* enhancer. Screening in K562 erythroid cell line showed that disruption of different BS resulted in significant differences in α-globin production, suggesting that some BSs within MCS-R2 enhancer are more critical for α-globin expression. Based on our screening results, we were able to partially down-regulate α-globin synthesis to 50% of its normal levels in both SCD and β-thalassemic RBCs derived from HSCs carrying up to 80% of edited enhancers. This led to a better α-globin/β-like globin ratio in β-thalassemic RBCs. While modulation of α-chains levels may be sufficient for β^+-thalassemic patients, it might be limiting for β^0-thalassemic or SCD patients, as these patients require the additional expression of a β-like chain. Thus, we simultaneously targeted the MCS-R2 enhancer and the GATA1 or ATF4 activators binding motifs within the erythroid-specific *BCL11A* enhancers (+58-kb and +55-kb regions) to reactivate HbF using ABEs. Targeting both regions in HSCs did not alter editing efficiencies at each locus that reached up to 80%. A colony forming cell assay showed no impact on progenitors' viability. Besides reduced α-globin levels, RBCs displayed high HbF levels that were sufficient to ameliorate the pathological phenotype. Overall, we reactivated γ-globin expression and downregulated α-globin, resulting in beneficial effects resembling those observed in patients with co-inheritance of α-thalassemia.

599 eePASSIGE Knock-In of *F8* Exons 23-26 cDNA for Intron 22 Inversion Mutations

Andrew Vanden Heuvel[1], Jackson Bauer[2], Lindsey George[3]
[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Introduction:
Hemophilia A, the most common severe congenital bleeding disorder, is caused by *F8* mutations resulting in deficient function of the coagulation factor VIII (FVIII) protein. Given modest FVIII function imparts large phenotypic improvement, meaning that even low-efficiency *F8* gene correction or integration is expected to be clinically significant. The *F8* intron 22 inversion mutation accounts for nearly 50% of severe hemophilia A cases. In this intrachromosomal recombination event, a gene within intron 22 of *F8* recombines with one of two copies upstream and telomeric to the *F8* sequence. This rearrangement splits *F8* into two parts, separating exons 1-22 from exons 23-26. The unaffected *F8* promoter continues to transcribe the first 22 exons, resulting in a truncated, nonfunctional protein. Knock-in of exons 23-26 cDNA into intron 22, before the site of recombination, could rescue transcription of the full *F8* gene through the sustained use of the endogenous promoter and subsequently restore hemostatic function. Due to the size of exons 23-26 cDNA (627bp), few tools are available for the insertion of a DNA fragment this size without double-stranded breaks. Currently, there are no published findings using twin prime editing, PASSIGE, or any similar derivatives for any *F8* disease-causing mutation, including the intron 22 inversion. We aim to use recently enhanced eePASSIGE (Pandey et al. Nat Biomed Eng 2025) to efficiently insert codon-optimized exons 23-26 cDNA using single-stranded breaks, thus minimizing the risk of genotoxicity, to rescue complete transcription of *F8* and restore FVIII hemostatic function.

Methods and Results:
63 combinations of prime editing RNA guides (pegRNAs) were designed in the first 500bp of intron 22 of *F8* to insert the *attP* sequence. The guides were transfected in Huh7 cells with the prime editor (PE)6d variant. Screening results were analyzed through Next-Generation Sequencing (NGS) to determine precise *attP* insertion, imperfect edits, and non-homologous end joining (NHEJ) indels. Five combinations of guides, varying only by primer binding site lengths, achieved >18% precise insertion with <1.4% imperfect edits and <0.3% NHEJ indels (Figure 1). NHEJ indel percentages were consistent with untransfected control cells and thus considered negative. The highest achieving pegRNA pair, which demonstrated 20.13% precise insertion, 1.27% imperfect edits, and 0.21% NHEJ indels, was used in the following transfection. PE6d, eeBxb1, pegRNAs, and a donor plasmid containing *F8* exons 23-26 cDNA, splice acceptor, and *attB* sequence, were co-transfected in Huh7 cells to assess integration of the

donor. Insertion was evaluated by junction PCR of the region between endogenous intron 22 and the newly introduced exon 23. Sanger sequencing results showed recombination of *attP* and *attB* forming *attL* as well as the correct insertion and orientation of the splice acceptor and the *F8* exons 23-26 cDNA.

Conclusion:
These data indicate the possibility of using eePASSIGE to restore loss of FVIII function for hemophilia A patients with intron 22 inversion mutations. The use of the endogenous *F8* promoter and single-stranded breaks provide significant benefits from a safety and efficacy perspective. Work is ongoing to evaluate the phenotypic outcomes of these methods in an in vitro stable cell line and an in vivo mouse model.

600 Base Editing Rescue of *SOD1* associated ALS

Jenny Gao[1], Nathan Bamidele[2], Erik Sontheimer[2]*, Wen Xue[3]*

**Corresponding Author*

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease with a median survival of 2-5 years after diagnosis. Mutations in the cytosolic superoxide dismutase (*SOD1*) gene, which encodes an antioxidant enzyme, account for ~20% of familial ALS and 2-3% of sporadic ALS. Misfolded SOD1 mutants form toxic aggregates that drive motor neuron degeneration and ultimately lead to respiratory failure. Despite extensive research, treatment options remain limited. Antisense oligonucleotides (ASOs) targeting SOD1, known as tofersen, have been promising in reducing mutant SOD1 protein levels but require repeated administration, limiting their long-term feasibility. Base editors offer a potentially more durable genetic therapy by precisely modifying pathogenic SOD1 transcripts without inducing double-stranded breaks. In this study, we screened a panel of Nme2 base editors to identify one capable of disrupting SOD1 expression via splice site editing.

Methods and Results: We screened a panel of Nme2 base editors with variations in deaminase positioning and linker length to identify the most efficient editor for targeting a splice site in the *SOD1* gene at exon 2. Various linker lengths and deaminase positioning can change the editing window and hence change the editing efficiency at the target adenine. Successful editing induces exon skipping, leading to decreased SOD1 transcript levels. Our most effective editor achieved ~35% editing efficiency. Verification at the endogenous site via plasmid transfection confirmed similar editing efficiency (~35%). An all-in-one version showed ~17% editing, which correlated with a two-fold reduction in total SOD1 RNA by qRT-PCR and a four-fold decrease in protein levels. Analysis of bystander edits showed that the amino acids remained conserved.

Conclusions: A gene-editing therapy that reduces the SOD1 transcript levels could serve as a one-time treatment for ALS patients with *SOD1*-linked disease. Our study demonstrated that Nme2 base editors are promising candidates, effectively reducing both mRNA and protein levels. By targeting a splice site, this approach is mutation-agnostic, making it broadly applicable to a larger ALS patient population. Future studies will focus on optimizing delivery and assessing long-term therapeutic potential in ALS disease models.

601 Base Editing for Precise and Specific Elimination of Lipoprotein(a)

Marcel Chuecos[1], So Park[2], Madhvi Bhakta[3], Ususa Too-Chiobi[4], Daniel Betancourth[2], Anjana Tiwari[5], Donna Palmer[1], Biana Godin[6], Philip Ng[1], Michael Boffa[7], Marlys Koschinsky[8], Gang Bao[9], William Lagor[1]*

Lipoprotein(a) (Lp(a)) is a causal risk factor for cardiovascular disease (CVD), and current therapeutic options are limited. Commercial efforts are currently underway to develop one-time gene editing interventions aimed at permanent inactivation of the *LPA* gene in the livers of high risk patients. In our previous work, we demonstrated that adeno-associated virus (AAV) delivery of CRISPR/Cas9 could reduce liver and plasma apolipoprotein(a) (apo(a)) to undetectable levels in an *LPA* transgenic mouse model. However, due to the highly repetitive nature of the targeted genomic region, we observed frequent chromosomal rearrangements in the treated animals - including large deletions, inversions, and AAV genome insertions. Consequently, we hypothesized that cytosine base editing (CBE) could be used to more precisely introduce premature stop codons in *LPA* to decrease Lp(a) levels, while circumventing double-strand DNA breaks and the associated deleterious chromosomal rearrangements.

Guide RNAs (gRNAs) were designed with BE-Designer to target exon 2 of the *LPA* gene and the latest TadA-derived CBE (CBE6) was utilized to install a premature stop codon. *In vitro* testing in HEK293T cells revealed successful editing by several gRNAs, with guide #1 and #2 exhibiting the highest editing efficiency (23 ±1.9 and 44 ± 1.4 % respectively). gRNAs were also tested in cell lines that stably express apo(a) or an inactive plasminogen protein (PLG-S741C). Both gRNAs reduced secreted apo(a) levels by 50%, and only guide #2 decreased secreted PLG-S741C levels, indicating off-target activity, which was confirmed by DNA sequencing. To test this approach *in vivo,* CBE6 was packaged into helper-dependent gutless adenovirus driven by a liver specific promoter (HDAdV-CBE6). gRNAs 1 and 2 were packaged into AAV and injected separately into *LPA* transgenic mice via tail vein at a dose of 5×10^{11} genome copies (GC), in conjunction with 3×10^{11} viral particles (VP) of HDAdV-CBE6. An 80% reduction of circulating apo(a) was measured 10 days after viral injection.

Ongoing efforts aim to use lipid nanoparticles (LNP) to deliver the CBE6 and evaluate the capacity of this LNP-CBE approach to reduce apo(a) and Lp(a) levels *in vivo*. This approach offers a promising avenue for reducing Lp(a) levels and addressing a significant unmet need in CVD management.

602 High Efficiency Prime Editing of Alzheimer's Disease High Risk APOE4 Allele by Brain-directed AAV Vectors

Caner Günaydin[1], Neil Hackett[1], Victor Wakim[1], Dolan Sondhi[1], Stephen Kaminsky[1], Ronald Crystal[2]
[1]Weill Cornell Medical College, New York, NY, [2]Weill Cornell Medical College, New York

Common variants of the apolipoprotein E gene (APOE) have a major impact on the risk of developing Alzheimer's disease (AD). Relative to homozygotes with the common E3 allele, the APOE4 variant (C112R) increases risk by 3.5-fold in E3/E4 heterozygotes and 13.5-fold in E4 homozygotes. Since the E3 and E4 alleles differ only by a single nucleotide, gene editing is a potential route to reducing AD risk in E4 homozygotes. Because the apolipoprotein E pool in the brain is separate from systemic APOE, editing would ideally be directed to the brain without disrupting the systemic APOE pool. Following *in vitro* optimization of editing guide RNAs, efficient prime editing expression cassettes were inserted in the optimized 6th generation prime editor PE6 split-intein plasmid and

packaged into pairs of adeno-associated viruses (AAV) for *in vivo* editing. TRE4 transgenic mice with replacement of the mouse ApoE gene by the human APOE4 variant were administered AAV vectors and APOE4 to APOE3 editing efficiency was assessed after 4 weeks. We compared editing efficiency in the central nervous system (CNS) using three different delivery routes (intrahippocampal, intracisterna magna and intravenous) and three AAV capsids: AAVrh.10 a clinically tested vector for CNS transduction (Sondhi D et al, Sci Transl Med 2020; 12:eabb5413); AAV.S2 an engineered AAVrh.10 derivative with improved distribution following intraparenchymal brain administration (Karan K et al, Hum Gene Ther 2024; 35:904); and AAV-CAP.B10, an engineered AAV9 derivative designed to enhance transport through the blood brain barrier (Goertsen et al., Nature Neurosci. 2022; 25:06). The same dose (10^{12} genome copies) was used for all vectors and routes. Intrahippocampal administration of AAVrh.10 vector achieved an average of 18.6±5.5% editing across the brain but with higher editing in cortex (28.1±6.1%) than cerebellum (3.4±2.1%). A higher average editing efficiency was obtained by IHC injection of AAV.S2 with an average of 26.7±3.1% editing across the brain with high editing both in cortex (21.2±10.8%) and in cerebellum (41.5±2.3%). Intravenous delivery of AAV-CAP.B10 provided 24.5±4.8% across the brain. Vector DNA levels were the same for all 3 groups ($p>0.05$). However, CNS delivery of either AAVrh.10 or AAV.S2 led to significantly higher vector copies in the liver [1.5±0.6 vector copies/haploid genome (vc/g) for AAVrh.10; 1.47±0.1 vc/g for AAV.S2] while intravenous CAP.B10 mediated only 0.1±0.1 vc/g in the liver. We conclude that the high efficiency APOE4 to APOE3 editing in the brain is feasible using intrahippocampal administration of the clinically proven AAVrh.10 vector. However, a wider distribution of editing in the brain was achieved by both IHC administration of AAV.S2, an engineered AAVrh.10 derivative, and by intravenous delivery of brain-penetrant AAV-CAP.B10. In future studies, these novel engineered capsids may provide the best therapeutic option.

603 In vivo base editing extends lifespan of a humanized mouse model of prion disease

Prion disease is a fatal neurodegenerative disease caused by the misfolding of prion protein (PrP) encoded by the *PRNP* gene. While there is currently no cure for the disease, depleting PrP in the brain is an established strategy to prevent or stall templated misfolding of PrP. We developed *in vivo* cytosine and adenine base strategies delivered by adeno-associated viruses (AAVs) to permanently modify the *PRNP* locus to achieve PrP knockdown in the mouse brain. Systemic injection of dual-AAV PHP.eB encoding BE3.9max and sgRNA installing *PRNP* R37X resulted in 37% average installation of the desired edit, 50% reduction of PrP in the mouse brain, and 52% extension of lifespan in transgenic human *PRNP* mice inoculated with pathogenic human prion isolates representing the most common sporadic and genetic subtypes of prion disease. We further engineered base editing systems to achieve improved *in vivo* potency and reduced base editor expression in non-targeting tissues, resulting in 63% average PrP reduction in the mouse brain from a 6.7-fold lower viral dose, with no detected off-target editing of anticipated clinical significance observed in either human cells or mouse tissues. These findings support the potential of *in vivo* base editing as one-time treatment for prion disease.

604 Targeted Gene Correction Using AAV-Delivered Base Editing Improves Smooth Muscle Cell Function in the Eye of an ACTA2^{R179H} MSMDS Mouse Model: A Promising Surrogate Endpoint For Future Clinical Trials

Claire Fong[1], Elyssa Alber[2], Shruti Gajjar[3], Sabyasachi Das[1], Vijai Krishnan[1], Pazhanichamy Kalailingam[4], Kangsan Roh[1], Christiano Alves[5], Shuqi Yun[2], Lauren Fox[2], Leillani Ha[2], Hannah Stutzman[2], Giulia De Rossi[6], Benjamin Kleinstiver[1], Casey Maguire[7], Mark Lindsay[1], David Chung[2], Patricia Musolino[8]

[1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, North Andover, MA, [4]MGH- Harvard Medical School, Boston, MA, [5]Boston, MA, [6]University College London, London, United Kingdom, [7]The Massachusetts General Hospital, Charlestown, MA, [8]Neurology, Massachusetts General Hostpial, Boston, MA

Introduction: Multisystemic smooth muscle dysfunction syndrome (MSMDS) is a severe, ultrarare disorder caused by pathogenic variants in ACTA2, leading to widespread smooth muscle dysfunction, vascular abnormalities, and life-threatening complications such as early-onset stroke and aortic dissection. A key early diagnostic indicator is congenital mydriasis caused by impaired contractility of iris smooth muscle cells (SMCs). In this study, we evaluated the therapeutic efficacy of CRISPR-Cas9 adenine base editors (ABEs) delivered via a novel smooth muscle–tropic adeno-associated virus (AAVPR-AB8e-VRQR) in rescuing pupillary contractility and retinal vasculature defects in an MSMDS mouse model. Concurrently, we utilized a Cre-inducible tdTomato reporter system (AAVPR-Cre) to assess the *in vivo* tropism and cellular specificity of our AAVPR construct.

Methods: An MSMDS mouse model developed in-house was retroorbitally injected with AAVPR-AB8e-VRQR at postnatal day 3. At 8 weeks, we analyzed pupillary reflex to light and performed conventional histology and immunofluorescence of SMC markers. To validate the targeting specificity of our AAVPR vector, we utilized Cre-inducible tdTomato reporter mice injected with AAVPR-Cre, with retinal tissues harvested 5 weeks post-injection for biodistribution analysis.

Results: Untreated MSMDS mice exhibited dilated, non-reactive pupils and a marked reduction in α-SMA expression in the iris and retinal vasculature. Retinal analysis revealed abnormalities in arteriole branching, vessel caliber, and autonomic innervation. AAVPR-AB8e-VRQR-treated mice demonstrated significant restoration of α-SMA expression, normalization of vascular morphology, and, in a subset of mice, partial recovery of pupillary reflexes—supporting the therapeutic potential of base editing in smooth muscle diseases. To confirm the targeting efficiency of our AAVPR vector, Cre-inducible tdTomato mice injected with AAVPR-Cre exhibited widespread tdTomato expression in retinal smooth muscle cells, endothelial cells, and pericytes, validating the construct's tropism for smooth muscle-rich vasculature.

Conclusions: These findings provide the first evidence that systemic delivery of AAVPR-AB8e-VRQR can restore smooth muscle contractility and vascular integrity in MSMDS mice through CRISPR-based gene correction. The partial rescue of pupillary function suggests that gene therapy may effectively reverse aspects of MSMDS pathology, although residual innervation deficits or dose-response effects may influence outcomes. Importantly, the use of a Cre-inducible tdTomato reporter system confirms the tropism of our AAVPR vector, supporting its potential as a platform for future therapeutic applications. Given the systemic nature of MSMDS, the restoration of smooth muscle function in the anterior chamber and retinal vasculature provides a critical, noninvasive surrogate endpoint for evaluating broader treatment efficacy in clinical trials.

605 Precise Correction of the *Pde6b*-L659P Mutation Causing Retinal Degeneration via Base and Prime Editing

Zhiquan Liu[1], Siyu Chen[2], Jingyu Zhao, Yang Sun[1]*
[1]Stanford University, Palo Alto, CA, [2]Stanford School of Medicine, Palo Alto, CA
**Corresponding Author*

Purpose: Retinitis pigmentosa (RP) is a group of inherited retinal disorders characterized by the progressive degeneration of photoreceptor cells, ultimately leading to blindness. The *Pde6b* gene, which encodes the β-subunit of rod cGMP phosphodiesterase, has been identified as a causative gene for autosomal recessive retinitis pigmentosa (RP40). Currently, no effective treatments are available for this condition. Genome editing technologies offer promising potential for treating inherited genetic disorders. Among these, recently developed base editing (BE) and prime editing (PE) technologies allow precise and efficient genome editing while minimizing the risks of double-strand DNA breaks and associated toxicity. This study explores the potential of BE and PE technologies to rescue retinal degeneration in a mouse model of RP carrying the *Pde6b*-L659P mutation (c.1976T>C, p.L659P).

Methods: A Neuro-2a (N2a) cell line harboring the *Pde6b* (c.1976T>C, p.L659P) mutation was generated using BE-mediated modeling, serving as the N2a cell model. BE or PE vectors were transfected into the N2a cell model, and editing efficiencies were assessed via Sanger sequencing. Plasmids expressing the optimized BE or PE systems were electroporated into the retinas of *Pde6b* mutant mice on postnatal day 0 (P0), with co-expressed EGFP used as a marker for successful electroporation. Electroporated retinas were collected at P30, and the rescue effect was evaluated through sanger sequencing and immunofluorescence (IF) analysis.

Results: We tested four CBE systems, including rA1-CBE, A3G-CBE, CDA1-CBE, and AID-CBE, along with seven sgRNAs in the N2a cell model. Sequencing results revealed that only the A3G-CBE system was able to precisely correct the L659P mutation, while the other three CBE systems generated a high proportion of bystander mutations. The optimal combination of A3G-CBE and sgRNA4 achieved a 15% targeted correction rate. For PE, we tested five PE systems, five epegRNAs, and six nicking gRNAs. The optimal combination of PE7, e2, and n1 achieved an 20% precise correction rate in the N2a cell model. In vivo electroporation of BE or PE plasmids achieved approximately 10% targeted editing, and IF results confirmed the restored expression of the PDE6B protein.

Conclusions: This study provides a proof-of-concept demonstration for precisely correction of Pde6b-L659P mutation causing retinal degeneration by BE and PE tools, paving the way for future translational approaches.

606 Improving the Safety and Efficacy of *In Vivo* Genome Editing in HSCs by Using Strong HSC-Specific Promoters and a Pomalidomide-Induction-System to Regulate the Level and Duration of Editor Expression after HDAd Gene Transfer.

Hongjie Wang[1], Lishan Huang[2], Arpit Mishra[3], Sucheol Gil[2], David Hawkins[3], Andre Lieber[3]*
[1]University of Washington, Seattle, Washington, [2]University of Washington, [3]University of Washington, Seattle, WA
**Corresponding Author*

We are using HDAd vectors for *in vivo* genome editing in HSCs with a focus on therapies of hemoglobinopathies and HIV/AIDS. Our approach requires improvements both in its safety and efficacy. While our HDAd vectors preferentially transduce primitive HSCs after intravenous injection into mobilized CD46-transgenic mice, humanized mice and rhesus macaques, off-target transduction (e.g. other blood cell lineages and cells in the spleen, liver, and lung) was also found. Furthermore, the comparison of the PGK and the relatively strong EF1a promoters to drive ABE8e expression has shown that the editor expression level critically determines the editing rates/percentage of edited cells, specifically in multiplex editing vectors. Our first goal was therefore to develop highly active HSC-specific promoters. First, we generated GFP reporter plasmids containing ~2kb of proximal promoters (encompassing the TATA box, transcription start site and 5'UTR) derived from genes that are expressed in HSCs at high levels (CD164, cKit, DSG2, PROM1, and PROCR). Nucleofection of these plasmids containing these promoters into human $CD34^+$ cells showed the highest GFP expression levels for the cKit and PROCR promoters in $CD34^+$ subsets enriched for HSCs ($CD34^+/CD45RA^-/CD90^+$). We then linked these promoters to distal HSC enhancers that are likely involved in the activation of c-kit (2 enhancers), CD164 (4 enhancers), and PROM1 (2 enhancers). These enhancers were identified using an ENCODE/Hi-C data-based approach. After nucleofection into $CD34^+$ cells, GFP expression levels from the HSC-plasmids in $CD34^+/CD45RA^-/CD90^+$ cells were 3- to 4-fold higher than the those from the EF1a promoter, with the highest GFP levels found for the combination of the proximal cKit promoter with CD164-3, PROM1 or PROM2 enhancers. This activity was specific for $CD34^+/CD45RA^-/CD90^+$ cells. We have generated HDAd vectors using HSC- promoter/enhancers driving an AB8e base editor for reactivation of g-globin to study specificity and efficacy of *in vivo* base editing in in humanized mice and in CD46/bYAC-transgenic mice.

The second problem we tried to address was the prolonged activity of genome editors in slowly dividing/quiescent HSCs after *in vivo* HDAd transduction. Editors are expressed and active as long as the episomal HDAd genomes are present in HSCs, which, on the one hand, increases the rate of biallelic edits, but on the other hand increases the risk of off-target editing. We used a pomalidomide-based "switch-on" approach to control the half-life of an (HBG1/2 promoter-specific) ABE8e base editor and a SCD mutation specific prime editor via a degron-linked to an anti-CRISPR peptide. (Pomalidomide is an anti-cancer drug.) The system was incorporated into an HDAd vector and

transduction/editing studies in cell lines and $CD34^+$ cells were performed. Without pomalidomide no editing of the target site was detectable by next-generation sequencing (NGS) indicating tight suppression in the absence of pomalidomide. Editing rates increased in a pomalidomide concentration-dependent manner. The plateau of editing is reached on day 2 after exposure to pomalidomide. The editor is active for 3 days after removal of pomalidomide. *In vivo* studies are ongoing. Eventually, we will combine the inducible and HSC-specific expression systems for genome editors.

607 Base Editing for Generating a Gain-of-Function Variant in Hemophilia B

Nemekhbayar Baatartsogt[1], Yuji Kashiwakura[2], Takafumi Hiramoto[3], Rina Ito[4], Rikako Sato[4], Yasumitsu Nagao[5], Hina Naruoka[6], Haruka Takata[6], Morisada Hayakawa[3], Khishigjargal Batjargal[7], Tomoki Togashi[5], Atsushi Hoshino[8], Taro Shimizu[9], Yusuke Sato[10], Tatsuhiro Ishida[11], Osamu Nureki[12], Tsukasa Ohmori[13]
[1]Jichi Medical University, Shimotsuke, Japan, Japan, [2]Jichi Medical University, Shimotsuke, Tochigi, Japan, [3]Jichi Medical University, JAPAN, [4]Hokkaido University, Hokkaido, Hokkaido, Japan, [5]Jichi Medical University, Shimotsuke city, Tochigi, Japan, [6]Tokushima University, Tokushima, Tokushima, Japan, [7]Department of Biochemistry, Jichi Medical University, Shimotsuke City, Japan, Japan, [8]Graduate School of Medical Science, Kyoto, Kyoto, Japan, [9]Osaka University, JAPAN, [10]Hokkaido University, Sapporo, Hokkaido, Japan, [11]Tokushima University, Tokushima, Japan, [12]The University of Tokyo, Bynkyo-ku, Tokyo, Japan, [13]Jichi Medical University School of Medicine, Shimotsuke, Tochigi, Japan

Background: Hemophilia B, a congenital bleeding disorder caused by pathogenic variants in the *F9* gene, is often the result of single-nucleotide variants. Although genome editing to correct the disease-causing variant offers a promising strategy, developing a unique therapeutic reagent for each individual variant is impractical.

Aim: We investigated whether base editing could induce a gain-of-function variant in blood coagulation factor IX (FIX), thereby enhancing FIX activity as a strategy for treating hemophilia B.

Methods: We selected several *F9* variants derived from Hemophilia B patients and established HEK293 cells and knock-in mice harboring the patients' variants. The plasmid containing SpCas9 (D10A) conjugated with several cytosine deaminases was transfected into the cells. Base-editing constructs were packaged into adeno-associated virus (AAV) vectors or lipid nanoparticles (LNPs) and administered to the mice. Editing efficiency was determined by next-generation sequencing, and off-target effects were assessed using GUIDE-seq and R-loop assays. FIX activity and antigen levels were measured by one-stage clotting assays and ELISA, respectively.

Results: We engineered a G:C to A:T substitution at c.1151 of the *F9* by cytosine base editing to generate the R338Q variant, known as the Shanghai *F9* variant, which markedly enhances coagulation factor activity. This gain-of-function variant significantly boosted FIX activity in the supernatant of HEK293 cells expressing various pathogenic *F9* variants. Among the base editors tested, the wild-type SpCas9 (D10A) fused to TadCBEd provided the highest C-to-T conversion with minimal bystander edits and negligible off-target effects. AAV-mediated delivery achieved more than 60% conversion of the target G:C to A:T, not only in HEK293 cells carrying different *F9* variants but also in knock-in mice harboring human *F9* cDNA. Additionally, LNP-based delivery of base editor mRNA and guide RNA increased FIX activity in vivo, and repeated dosing further enhanced the therapeutic benefit.

Conclusion: Our results demonstrate that cytosine base editing to introduce the R338Q variant in the *F9* gene represents a promising genome editing strategy for treating various forms of hemophilia B. This approach holds potential for long-term therapeutic benefits and overcomes several limitations of conventional AAV-based gene therapy, including challenges related to re-administration and limited applicability in pediatric populations.

608 A Novel RNA Splicing Therapy for USH2A-Associated Retinitis Pigmentosa

Jiayu Ou[1], **Hui Xu[2]**, Fazhou Zhang[3], Zhengxia Yang[3], Jiaqi Tu[3], Zhendong Xiao[4], Junjiu Huang[5], Junbin Liang[2]*
[1]Reforgene Medicine, Guangzhou, China., Guangzhou, China, [2]Reforgene Medicine, Guangzhou, Guangdong, China, [3]Reforgene Medicine, Guangzhou, China., Guangzhou, Guangdong, China, [4]The Third Affiliated Hospital of

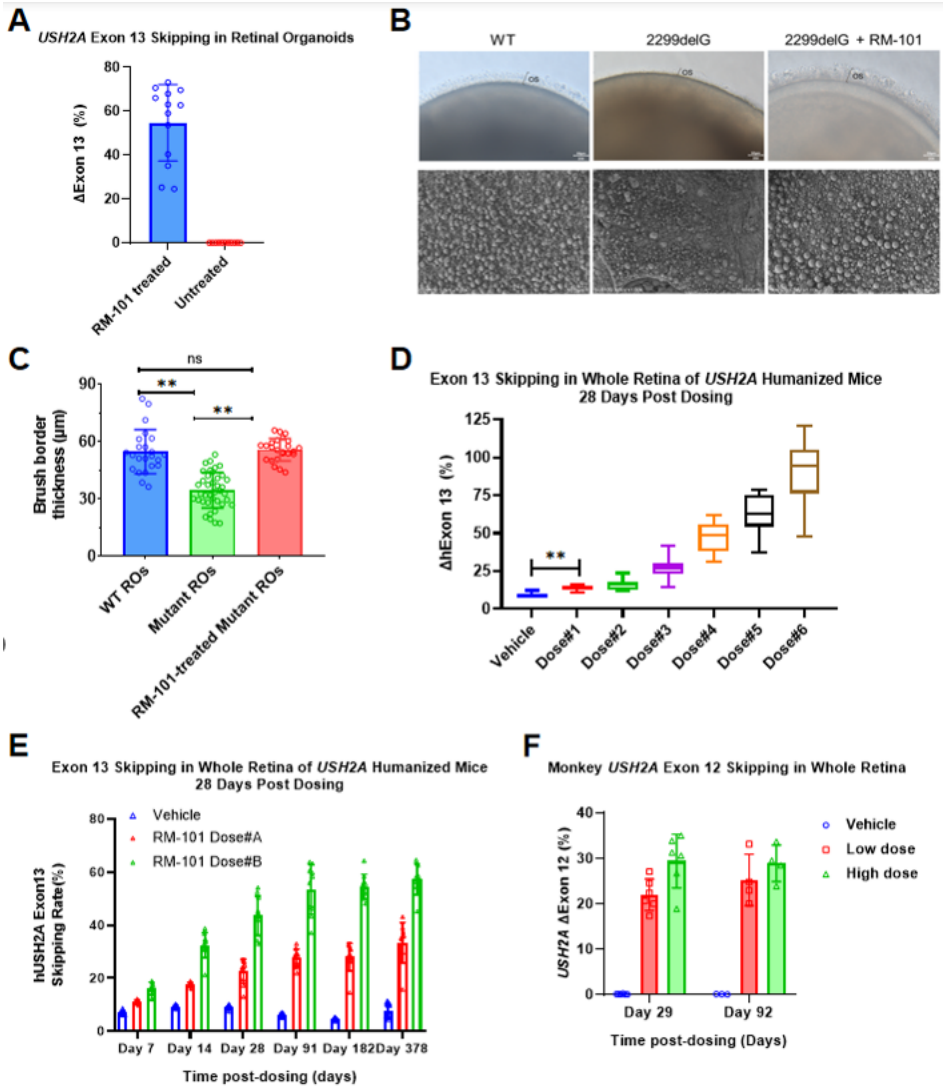
Sun Yat-Sen University Biotherapy Center, Guangzhou, Guangdong, China, [5]Guangzhou, CHINA
**Corresponding Author*

Purpose: Currently, no approved therapies exist for retinitis pigmentosa (RP) associated with the USH2A gene. Antisense oligonucleotide-mediated transient exon skipping has shown promise in treating RP linked to mutations in USH2A exon 13. This study reports on RM-101, a single administration exon-skipping therapy based on adeno-associated virus (AAV) and engineered U7 snRNA.

Methods: Retinal organoids (ROs) with the c.2299delG mutation in both alleles, USH2A humanized mice harboring human USH2A exon 13, and non-human primates were treated with RM-101 to evaluate exon skipping efficiency and efficacy. To assess the safety of RM-101 administration, both biodistribution and toxicology studies were performed. RNA sequencing was conducted on ROs, monkey retina, and choroid samples to analyze off-target local splicing variants (LSVs). Potential binding of RM-101 in surrounding regions was predicted using in silico approaches to evaluate the correlation of LSVs with RM-101.

Results: RM-101 transduction resulted in an average of 52.8% exon skipping in mutant ROs (Fig. A), restoring Usherin protein expression. The brush border, indicative of the photoreceptor outer segment, was restored to normal thickness, as confirmed by microscopy (Fig. B & C). In USH2A humanized mice, subretinal injections of RM-101 induced targeted exon skipping in a dose-dependent manner, with the highest efficiency of 91% observed (Fig. D), peaking at approximately 28 days post-dosing and remaining stable for 378 days (Fig. E). In monkeys, 25% exon skipping was detected in intact retinas (Fig. F). Biodistribution studies in monkeys and rabbits demonstrated that RM-101 was predominantly distributed in the retina and choroid. Ophthalmic examinations in toxicology studies revealed no product-related abnormalities in monkey eyes over a 13-week observation period. RNA-Seq identified 406 unique LSVs. For those with an absolute change in splice frequency >10%, further application of Blastn did not reveal any potential binding sites with >13 bp matches to RM-101 antisense, suggesting an insignificant correlation between these LSVs and RM-101 antisense. Based on these results, the Investigational New Drug (IND) applications for RM-101 were approved by the U.S. Food and Drug Administration and the China National Medical Products Administration.

Conclusions: RM-101 can stably and efficiently reprogram USH2A mRNA splicing, restore functional Usherin expression and rescue retinal outer segment development. This has the potential to improve visual function in patients with USH2A-associated RP. RM-101 is now ready to enter a Phase 1 trial.



609 An RNA Trans-Splicing Strategy to Rewrite mRNAs Implicated in Cardiomyopathy

David Fiflis[1], Abigail Benkert[2], Beatrice Sewell[3], Katie Clements[4], Aravind Asokan[5]
[1]Duke University Pratt School of Engineering, Durham, NC, [2]Duke University Medical Center, Durham, NC, [3]Duke University School of Medicine, Durham, NC, [4]Duke University, Morrisville, NC, [5]Duke University, Durham, North Carolina

RNA trans-splicing is currently being evaluated to edit large sections of defective mRNAs with a corrected sequence. Our lab and others have developed both CRISPR-assisted (CRAFT) and CRISPR-free methods to edit mRNAs implicated in different diseases characterized by multiple mutations. Clinical trials using this platform for treatment of ocular diseases such as Stargardt disease caused by mutations in the *ABCA4* gene and inherited retinitis pigmentosa are either planned or underway.

In earlier work, we introduced CRISPR Assisted mRNA Fragment Trans-Splicing (CRAFT) to edit mRNAs that underly distinct monogenic diseases: *DMD* (Duchenne muscular dystrophy, *DMPK* (myotonic dystrophy type I), *LMNA* (dilated cardiomyopathy), *RYR2* (catecholaminergic polymorphic ventricular tachycardia), and *FXN* (Friedreich's ataxia). Here, we report the design, engineering and characterization of next generation CRISPR-free RNA trans-splicing constructs (simply referred to as RAFT) for rewriting large RNA stretches. To achieve such, we

replaced the Cas13 direct repeat in the trans-splicing RNA with a panel of unique RNA structures and assessed the performance of these CRISPR-free editors using a split fluorescent reporter as a proxy for trans-splicing efficiency. Across all target mRNAs tested (*RYR2*, *DMPK*, and *LMNA*), two of these structures achieved editing levels on par with CRAFT, consistently enhanced trans-splicing efficiency by 3-4-fold over conventional spliceosome mediated RNA trans-splicing (SMaRT). Importantly, RAFT improved both 5' as well as 3' trans-splicing in all targets.

We then utilized the RAFT platform to rewrite *MYH7,* which encodes the cardiac beta-myosin heavy chain. Mutations in *MYH7* are one of the most common inherited causes of Hypertrophic cardiomyopathy (HCM), a prevalent form of genetic heart disease which affects 1:500 individuals with a majority exhibiting autosomal dominant inheritance. For this reason and due to the large gene size of MYH7, conventional AAV gene replacement is not feasible. Using our fluorescent reporter split across a target *MYH7* intron, we individually screened more that 100 unique trans-splicing RNAs, to identify optimal RNA architectures that enable rewriting of either the first (5' trans-splicing) or second half (3' trans-splicing) of the *MYH7* open reading frame. Optimized RAFT constructs achieved editing rates of 35% with the 5' editor and 38% with the 3' editor. Further assessment with AAV-RAFT yielded 8% and 10% for 5' and 3' approaches respectively. Experiments focused on assessing the performance of AAV-RAFT in cardiomyocytes differentiated from normal donors and HCM-patient derived induced pluripotent stem cells (iPSC-CMs) are currently underway. Efficiency of *MYH7* mRNA trans-splicing and functional impact in patient derived iPSC-CMs will be presented. The RAFT approach may be particularly impactful towards editing large genes and/or diseases with autosomal dominant inheritance.

610 Improving mRNA Trans-Splicing Strategies to Repair Extensive Genetic Mutations

Phillip Price[1], Emily Fabyanic[2], Xin Huang[2], Daniel Cohen[2], Francesca Cargnin[2], Elizabeth Ramsburg[2]
[1]Spark Therapeutics, Galesburg, IL, [2]Spark Therapeutics, Philadelphia, PA

Spliceosome-mediated RNA trans-splicing (SMaRT) technology represents a versatile tool for the correction of disease-causing mutations at the pre-mRNA level for genes that are too large for most viral vectors. However, therapeutic application of mRNA trans-splicing has been hindered by low efficiency and difficulty in accurately detecting trans-splicing events. Seeking to enhance the efficiency and accurate detection of SMaRT-mediated repair of transcripts containing large disease-causing mutations, we used *HUNTINGTIN* (*HTT*) transcript as a template. Huntington's Diseases (HD) is a neurodegenerative disease caused by a CAG repeat expansion in exon 1 of the *HTT* gene. Using *in silico* tools, we identified introns 8, 9, and 10 of the *HTT* gene as candidates for trans-splicing. A fluorescence-based reporter was used to screen for optimal trans-splicing modules. Quantitative sequencing methods revealed that our WT-*HTT* pre-mRNA trans-splicing molecules (wtHTT-PTMs) achieved up to 16% splicing with the endogenous *HTT* transcript in HEK293s. Further enhancement was achieved by replacing the self-cleaving ribozyme in our initial wtHTT-PTMs with a *MALAT1* terminator, increasing trans-splicing efficiency up to approximately 30%. These findings represent significant progress toward using trans-splicing as a platform to reprogram large mutated genomic regions, expanding the potential for therapeutic applications.

611 Intronization of Splice Editors Expands Trans-Splicing Toolkit

Samuel DeMario[1], James Griffin[2], Kaisle Hill[1], Kevin Goncalves[1], Nicholas Henninger[1], Changchang Liu[1], Bret Peterson[2], Nicholas Reynolds[2], Awilda Rosario[2], Puloma Sen[2], David Yao[2], Patty Biezonski[1], Kamyab Javanmardi[1], Brigit Riley[2], Jacob Borrajo[3]
[1]Amber Bio, South San Francisco, CA, [2]Amber Bio, South San Francisco, [3]Amber Bio, San Francisco, CA

Classical gene therapy approaches have faced significant challenges due to the size limitations of the cargo that can be effectively delivered into target cells. These limitations have restricted the potential therapeutic applications of gene therapy, particularly for disorders that require the replacement of large transcripts. Multi-kilobase RNA editing (trans-splicing) is an emerging therapeutic strategy which offers a promising solution to these challenges. Splice Editor systems co-opt the endogenous splicing machinery to facilitate multi-kilobase RNA edits via trans-splicing. Splice Editors enable repair of much larger mRNAs by allowing delivery of only a portion of the target mRNA. Additionally, Splice Editor systems mitigate the risks of toxic overexpression by ensuring the protein product is expressed at levels consistent with the endogenous RNA. Another key advantage of trans-splicing is that it does not

make permanent changes to the genome, theoretically making it a safer alternative to traditional gene editing techniques.

Despite its potential, Splice Editors face several unique challenges that need to be addressed for successful therapeutic application. These challenges include: 1) the stability of Splice Editors, 2) the efficient localization of Splice Editors to the target RNA, 3) the overall efficiency of the Splice Editing process, 4) off-target trans-splicing, and, 5) translation of Splice Editor RNA resulting in expression of a truncated peptide. These novel challenges necessitate novel solutions. Recent studies have highlighted the role of intronization in enhancing transgene expression. Intron excision has been previously identified as a key factor for efficient nuclear export of mRNAs. Furthermore, evidence suggests that intronization is a more effective strategy than codon diversification for minimizing the usage of cryptic splice sites in transgene constructs. Additionally, the deposition of exon junction complexes following splicing has been shown to protect exons from post-transcriptional modifications, including m6A methylation.

In this work, we investigate the incorporation of small introns into Splice Editors and explore the context-dependent nature of intron usage. Using machine learning-based tools, we are able to predict optimal placement of introns within a Splice Editor. Furthermore, we examine the impact of intronization on Splice Editing efficiency. Our work expands the toolkit for developing Splice Editing therapeutics.

612 Machine Learning Guided Design of Drug-Inducible Splicing Elements for Gene Therapy

Mark Miller[1], Nicholas Dietrich[2], Justice Lu[3], Aditi Kothari[4], Jennifer Israel[5]
[1]Kriya Therapeutics, Novato, CA, [2]Kriya Therapeutics - Redwood City, CA, Durham, NC, [3]Duke University, Durham, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Kriya Therapeutics, Redwood City, CA

Inducible regulation of gene expression represents an important opportunity to enhance gene therapy, because the ability to modulate therapeutic transgene expression could significantly expand treatment options and precision. We previously demonstrated a novel regulatory system utilizing drug-induced mRNA splicing to modulate gene expression in vitro. To optimize this system for therapeutic applications, we developed a machine learning approach to understand and predict sequence features that govern drug-induced splicing. Our analysis leveraged a comprehensive RNAseq dataset of over 500,000 diverse RNA sequences (50-2000bp, median 235bp) measured across five mammalian cell lines, capturing both de novo splicing induction and modulation of baseline splicing activity in response to a small molecule (log2 fold-change between -7.4 and 10.8).

We designed a deep convolutional regression network incorporating interpretable filters to predict multiple aspects of sequence-dependent splicing behavior. For each input sequence, the model predicts both baseline splicing levels (rank correlation >0.2) and the magnitude of drug-induced splicing changes (rank correlation >0.3). Additionally, the model provides sequence-specific uncertainty estimates for induced splicing levels (rank correlation >0.35), enabling identification of sequences with predictable splicing responses. The neural network architecture was designed to capture both local sequence motifs and longer-range motif interactions that influence whether and to what degree the drug induces or modulates splicing at these sequences. Importantly, the interpretable nature of the model could allow identification of specific sequence patterns and structural elements that determine splicing induction and regulation, thereby potentially providing mechanistic insights into drug-mediated control.

Beyond prediction and optimization of experimentally obtained sequences, the trained regression network can be used to screen large libraries of computationally generated sequences to identify those with promising inducibility and low-baseline profiles. This computational pipeline provides a framework for enhancing the dynamic range and reducing required drug doses in future therapeutic applications of inducible splicing systems.

613 CRISPR assisted RNA trans-splicing for controlled and transient activation of T cells

Harshitha Venugopal Lanvanya[1], David Fiflis[2], Beatrice Sewell[3], Aravind Asokan[4]
[1]Duke, Durham, NC, [2]Duke University Pratt School of Engineering, Durham, NC, [3]Duke University School of Medicine, Durham, NC, [4]Duke University, Durham, North Carolina

Adoptive T cell therapies for various cancers and autoimmune diseases are being used in the clinic. The potency and duration of the T cell response are key to successful outcomes of these therapeutic modalities. Several factors have been implicated in altering T cell state and improving function both broadly and in the context of CAR-T therapies. Amongst these, certain naturally occurring mutations and gene fusions in T cell associated cancers seem to improve the overall robustness and fitness of T cells. However, leveraging these targets through over-expression, stable genomic insertion using lentiviral vectors and other approaches to increase activation and potency of T cell therapies can prove challenging due to oncogenicity risks.

One such example is *VAV1*, a cytoplasmic guanine nucleotide exchange factor (GEF) that is activated upon downstream signaling of T cell receptor activation. *VAV1* plays a role in the activation of certain transcription factors, TCR clustering, calcium flux and polarization of the T cell. Recent studies have identified various activating mutations and fusions in *VAV1* in different T cell cancers such as peripheral T-cell lymphoma (PTCL-NOS), ALK-negative anaplastic large cell lymphoma (ALCL), and angioimmunoblastic T-cell lymphoma (AITL).

Here, using two RNA editing approaches, CRAFT (CRISPR assisted Fragment Trans-splicing) and RAFT (RNA Assisted Fragment Trans-Splicing) recently developed by our lab, we introduce certain activating mutations and fusions into endogenously expressed *VAV1* mRNA. Importantly, our trans-splicing approach limits the maximum number of edited mRNA copies to that of the endogenous transcript in the cell. We first designed a split-GFP reporter for one of the target introns in *VAV1* and carried out guide selection and parameter optimization for high efficiency trans-splicing of exogenous RNA fragments into *VAV1* pre-mRNA. Trans-splicing was quantified by percent of GFP positive cells and mean fluorescence intensity (MFI) through flow cytometry. Lead CRAFT and RAFT constructs were validated in HEK293, Jurkat (human T cell lymphoma) and in primary human T cells, where we achieved up to 56% and 62% GFP positive cells for CRAFT and RAFT respectively. Next, we utilized optimized CRAFT and RAFT constructs to edit endogenous *VAV1* pre-mRNA and achieved efficient trans-splicing as evidenced by molecular analysis. As proof-of-concept for T cell applications, we rewrite *VAV1* mRNA to generate a *VAV1-STAP2* fusion swapped for the C-terminal SH3 domain of VAV1. The latter chimeric protein is thought to increase downstream signaling and T cell activation. Correspondingly, editing *VAV1* mRNA and generation of the trans-spliced product in primary T cells was confirmed using Sanger sequencing and resulted in increased T cell activation as validated by different T cell surface markers. Overall, our work provides the foundational basis for exploring RNA trans-splicing as a strategy to transiently rewrite and tune T cell transcriptomic signatures.

614 Massively Parallel RNA Barcode Screens for CRISPR-Assisted Trans-Splicing

David Fiflis[1], Harshitha Venugopal Lanvanya[2], Beatrice Sewell[3], Aravind Asokan[4]
[1]Duke University Pratt School of Engineering, Durham, NC, [2]Duke, Durham, NC, [3]Duke University School of Medicine, Durham, NC, [4]Duke University, Durham, North Carolina

We recently introduced CRISPR Assisted Fragment Trans-splicing (CRAFT), a novel RNA editing approach that leverages CRISPR-Cas13 systems to introduce exogenous RNA sequences into mRNA transcripts by trans-splicing. CRAFT is an attractive modality for gene therapy, as only a single editing reaction enables precise multi-kilobase rewriting while maintaining the expression profile of the target transcript. We developed a split fluorescent reporter-based assay to screen parameters that can impact trans-splicing efficiency. While this assay provides a simple unambiguous readout, the throughput is limited by the need to individually clone and test each parameter.

To overcome this bottleneck, we developed an RNA barcode-based screening pipeline to efficiently probe the large parameter space across several endogenous transcripts in vitro. To discriminate trans-spliced transcripts arising from distinct variants, we introduced a “barcode” of single nucleotide polymorphisms (SNPs) in the trans-spliced exons that was unique to each trans-splicing RNA. By linking the barcode to the parameter of interest, we successfully applied this platform to first identify efficient trans-splicing RNAs for *LMNA* and *DMPK* from a large, pooled library of guide RNA sequences (415 for *LMNA*, and 172 for *DMPK*) tiled across each intron target within the

transcript of interest. A pool of oligos containing an antisense "spacer" sequence, hemi-intron, as well as a unique spacer that was operably linked to SNP based barcodes located within a fragment of the next downstream exon was generated. This oligo pool embedded within the CRAFT RNA editing construct was transfected along with catalytically dead *Rfx*Cas13d in vitro and targeted amplicon sequencing on the RNA across the splice junction was carried out to determine the relative trans-splicing efficiency of each guide. The latter was calculated as the ratio of abundance of the associated barcode in the mRNA to the corresponding abundance within the plasmid pool delivered to the cells. Using this approach, we identified guide RNA sequences capable of achieving 25% trans-splicing efficiency for *LMNA* and 24% trans-splicing for *DMPK* endogenous transcripts, which corroborated trends observed from the earlier reporter-based assay. Overall, the barcode screen described allows rapid probing of CRAFT construct design parameters that can impact trans-splicing efficiency across diverse endogenous target RNAs, and may be applied for the engineering of other trans-splicing platforms.

615 Exploration of Trans-Splicing Methodologies in AAV Therapeutic Development Targeted at Treating Neurofibromatosis Type-I and Associated Tumors

Corresponding Author

Neurofibromatosis Type 1 (NF1) is a neurologic disease with a complex pathologic burden characterized by widespread tumor formation and various neurological manifestations. As a single gene loss-of-function disorder where more than 50% manifestations are caused by sporadic mutations, NF1 is amenable to gene therapy approaches aiming to restore function. The large size of the NF1 cDNA (~8.5 kb) is a considerable challenge for development of AAV-based gene therapies for this disease.

We have explored alternative gene therapy approaches that maintain NF1 regulation from its native promoter through trans-splicing to the endogenous pre-mRNA. We used a library approach to evaluate the efficacy of spliceosome mediated RNA trans-splicing (SMaRT) whereby a vector encoded mutation free mRNA, also known as a pre-trans-splicing molecule (PTM), hybridizes to the endogenous mutated pre-mRNA and provides splicing machinery with alternative splice signals to generate a chimeric mRNA encoding normal protein. Unfortunately, despite early success in splicing with artificial systems, next generation sequencing showed a lack of chimeric mRNA despite substantial expression of both the PTM and endogenous NF1 gene.

Recently a Cas13-based mRNA trans-splicing system was shown to work across a variety of genes using artificial constructs and endogenous sequences (Fiflis et al, 2024). We investigated this Cas13-based trans-splicing approach for NF1, but it is important to note that due to ineffectiveness of the CMV promoter in our target Neurofibroma cell lines, we transitioned the published CMV promoter to an EF1a promoter that was functional in our cells. Given the large size of the NF1 mRNA and limited packaging capacity of AAV vectors, we designed barcoded AAV gRNA libraries to identify candidates to replace the N- or C-terminus of NF1 CDS by targeting introns 22 and 38, respectively. We screened these libraries by transient transfection of HEK293T cells and identified several candidate gRNAs with significant enrichment between the plasmid library and chimeric trans-splicing derived NF1 mRNAs following RT-PCR and illumina NGS sequencing. We found that 0.7% of NF1 mRNAs were chimeric (carry gRNA-specific barcodes in exon 23) for the N-terminus replacement library but found no evidence of trans-splicing for the C-terminus library targeting intron 38. Enrichment calculations identified ~5 gRNAs for the N-terminus library with an enrichment greater than 10X (**Fig. 1**). We assessed the efficiency of each candidate gRNA and observed a maximum trans-splicing efficiency of 3.2%, ie the percentage of chimeric NF1 mRNAs in the cell.

We sought to analyze the therapeutic potential of trans-splicing in immortalized NF1 patient cell lines (ipN 02.3λ, ipNF 04.4, & ipNF95.6) by measuring changes in Ras pathway activity, cell growth and/or death. AAVD/J vectors encoding Cas13 and individual gRNA-N-terminus NF1 CDS were used to infect NF1 cell lines at 1E6 vg/cell and total RNA isolated to assess trans-splicing efficiency. Despite transducing 80-90% of cells (assessed by transduction with an AAVD/J-GFP vector), we found no evidence of trans-splicing despite our high vector dose. We are investigating different parameters that may influence the overall efficiency of Cas13-mediated trans-splicing, including intron 'targetability' (sequencing-specific accessibility in the pre-mRNA) expression levels of Cas13, gRNA-NF1 CDS, and endogenous NF1 mRNA levels.

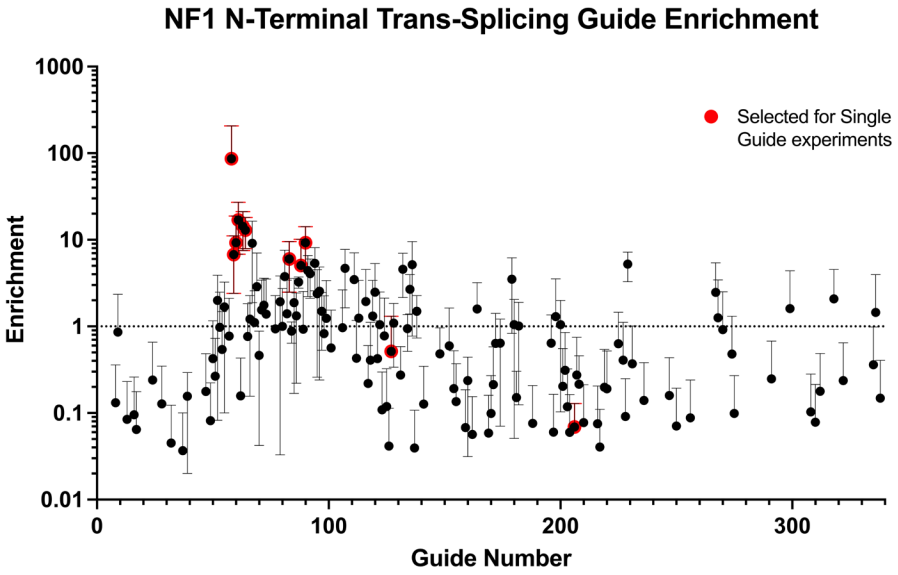

Figure 1. Guide Enrichment for NF1 N-terminal trans-splicing. Guides highlighted in red were cloned as single guides and tested for trans-splicing efficiency.

616 Discovery and Characterization of Novel Epigenome Editing Domains

Gabriel Butterfield[1], Alexandra Garcia-Moreno[1], Dahlia Rohm[1], Nahid Iglesias[1], Charles Gersbach[1]*
[1]*Duke University, Durham, NC*
**Corresponding Author*

Although current epigenome editing technology is able to robustly activate or repress gene expression, only a small subset of mammalian epigenetic marks can be deposited with existing tools. In order to expand the capabilities of epigenome editing, we screened a library of ~2500 full-length human proteins recruited by dCas9 to several promoters for modulation of target gene expression. We found two proteins capable of facilitating target gene activation that have not previously been used to control expression of native genes.

One of these, CITED2, functions by recruiting the H3K27 acetyltransferase p300, and could provide additional specificity relative to overexpression of the p300 catalytic core domain, which can lead to target-independent acetylation. We also demonstrate that dCas9-CITED2 is a robust tool for high-throughput screening via gene activation, similar to the commonly used dCas9-VP64 activator.

This screen also revealed PHF15 as a novel activator. PHF15 functions by depositing H4K12 acetylation, a mark which has not previously been robustly programmable. PHF15 also mediates changes in H3K4 methylation. In cells from Friedreich's Ataxia patients, these marks are decreased at the *FXN* locus as a result of heterochromatin that forms in the first intron due to repeat expansion. This led us to hypothesize that dCas9-PHF15 might increase levels of these marks when targeted to *FXN*, leading to restored expression of its protein product, frataxin. We tested this hypothesis in Friedreich's Ataxia patient-derived iPSC lines and showed that PHF15 was indeed able to both

increase levels of these marks as well as increase expression of the frataxin gene. Ongoing work includes testing this approach in clinically relevant cell types and evaluating strategies for additional gene activation to wild type levels. This work expands the set of epigenetic states that can be robustly programmed and demonstrates the therapeutic potential of specifically reprogramming epigenetic marks.

617 Directed Evolution and Characterization of Cas Effectors in Mammalian Cells for Expanded Epigenome Editing Space

Xiao Yang[1], Melanie Silvis[1], **Courtney Klappenbach[1]**, Chris Still[1], Tabitha Tcheau[1], Blair Gainous[1], Zaki Jawaid[1], Gabriella Alvarez[1], Julia Bachteal[1], Ryan Swan[1], Brandon Liauw[1], Aayushma Gautam[2], Stanley Qi[1], Tim Daley[1], Yanxia Liu[3], Dan Hart[3]*

**Corresponding Author*

CRISPR-mediated transcriptional and epigenetic regulation has broad potential applications in gene therapy and academic research. To improve the epigenome editing efficiency and achieve reduced cargo sizes suitable for delivery via single-AAV, we have previously engineered a compact RNP system with enhanced function (with dCas effectors under 500-amino acid in complex with gRNA scaffolds around 100-nucleotide long). However, the effective epigenome targeting range still desires further expansion from the canonical T-rich PAM recognition of our original dCas effector.

Here, we have established a directed evolution platform in mammalian cells to alter the PAM recognition profile of our dCas effectors towards a new PAM sequence with greater prevalence in the human genome and minimal initial recognition by our dCas effector. Using a CRISPRa synthetic reporter system to detect dCas recognition of the novel PAM, we were able to select and validate beneficial mutations from a site-saturation mutagenesis library of over one thousand variants. Combinatorial engineering of these variants significantly improved recognition of the novel PAM sequence, with top variants demonstrating over 400-fold improvement compared to the parent dCas effector. Recognition of the novel PAM was also observed in the context of CRISPRi when the variant dCas effectors were fused with a compact epigenetic suppressor and targeted to a synthetic reporter. To comprehensively characterize the PAM profile of these engineered dCas effectors in mammalian cells, we also developed a pooled CRISPRa assay which uses the activation of a synthetic target to sensitively query PAM recognition. This assay enabled us to detect the expanded or altered PAM profiles for our new dCas variants.

Overall, this work provides a novel mammalian cell-based platform for both directed evolution and characterization of altering the PAM recognition profile of dCas effectors. The resulting collection of novel dCas variants enables a broader or orthogonal epigenome targeting range when combined with the compact activation/suppression modulators we have developed in house. Increasing the epigenome editing range allows expanded applications in both basic research and therapeutics.

618 Beyond the Dot Blot: A Novel Method for dsRNA Detection for Gene Therapies

Ashish Chougule[1], Sara Bidoui[2], Julien Verdi[2], Olivia Kelada[3]*
[1]Revvity Inc, [2]Revvity Inc, Codolet, Gard, France, [3]Revvity Inc, Hopkinton, MA

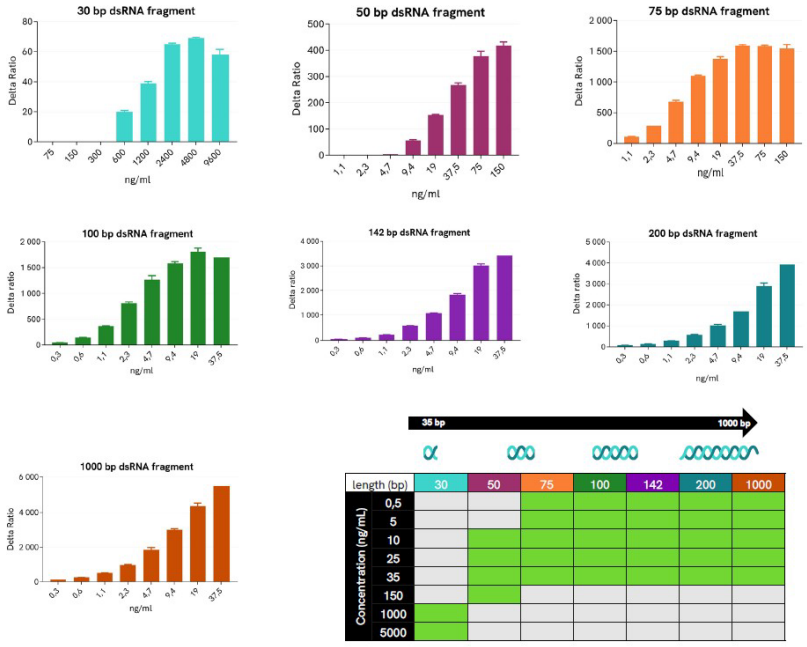
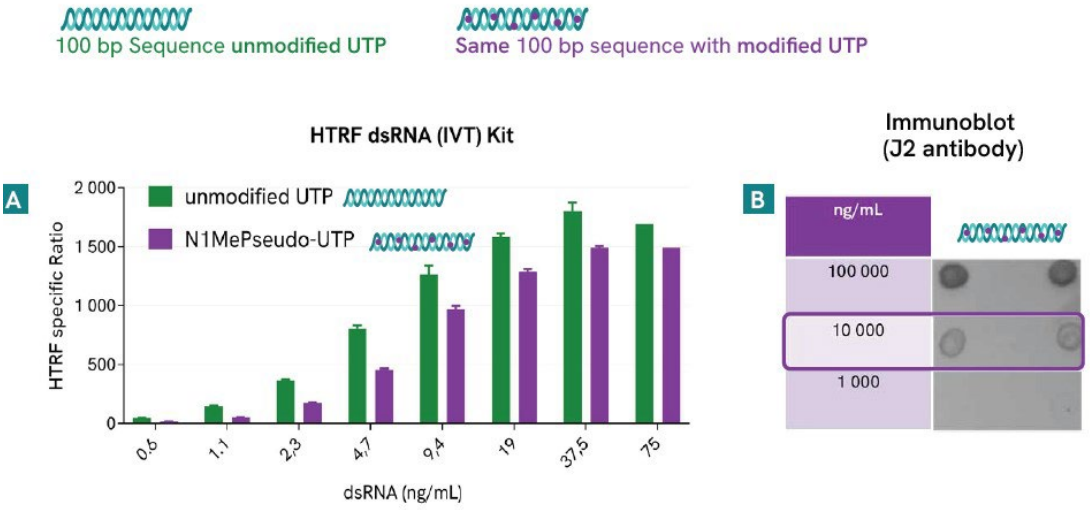
Introduction: In vitro transcription (IVT) is a go-to technique in molecular biology for creating RNA molecules from a DNA template. It is straightforward, precise, versatile, and scalable, making it essential for various research and biotech applications. IVT has been crucial in developing RNA-based therapeutics, like mRNA vaccines and gene therapy. The IVT process includes several steps: selecting and editing the template, setting up the transcription, purifying the RNA, and characterizing the final product. Detection of double-stranded RNA (dsRNA) contaminants, which can form due to secondary structures, self-annealing, or polymerase pausing, is performed using various immunoassay formats, such as ELISA, homogeneous immunoassays, and dot blot. Herein we describe the use of a no-wash homogeneous immunoassays that relies on FRET signaling to test for dsRNA **contaminants.**

Methods: All dsRNA samples were serially diluted in the kit diluent, and 10 µL of each dilution was plated in a 384sv white plate. After addition of 10 µL of HTRF dsRNA detection reagents mix, the HTRF signal was recorded following overnight incubation at room temperature. Two 100 bp dsRNA sequences were synthetized from the N-terminus portion of GFP protein. One sequence was generated without modification, while the other had a substitution of all uridines by N1mePseudo-UTP. The HTRF dsRNA assay was run following the protocol and compared to a dot blot assay using the J2 gold standard antibody.

Results: The novel method detected dsRNA for the whole range of short and mid-length sequences *(Figure 1)*. 50 bp sequences were detectable at low concentrations and detection of 30 bp sequences was possible at higher concentrations. Longer dsRNA sequences improved detection sensitivity, with successful detection of sequences up to 1000 bp at low concentrations. However, sequences of 20 bp and below were not detected due to their small size preventing antibody binding. HTRF signal and dot fluorescence intensity showed that both assays are capable of detecting N1mePseudo-UTP dsRNA *(Figure 2)*. HTRF assay sensitivity for modified dsRNA was in the same range as that of unmodified dRNA, with a similar detection limit ~1 ng/mL. For the immunoblot assay, however, the detection limit was much higher and around 10000 ng/mL. Using modified nucleoside triphosphates, like N1-methylpseudo-uridine, significantly advanced mRNA therapeutics by improving RNA stability and reducing immunogenicity. Comparative assays showed that both HTRF and immunoblot assays effectively detected uridine-modified dsRNA, with the HTRF assay demonstrating superior sensitivity. No detection signal was recorded using for any of the ssRNA, DNA Template, and T7 polymerase samples in comparison with positive controls of dsRNA. In these assay conditions, the kit shows detection specificity for dsRNA over other tested IVT reagents.

Conclusions: Developing robust dsRNA detection assays is crucial for advancing RNA therapeutics and ensuring the safety of biopharmaceutical products. The HTRF dsRNA assay provides a reliable and sensitive method for detecting dsRNA contaminants, supporting the rigorous quality control needed in IVT processes and gene therapy development.





619 Safety Assessment of on-/off-target aberrations in the generation of Universal CAR-T cells

Vidya Chivukula[1], Ryan Mate[2], Vinoy Ramachandran, James Tollitt[3], Leandro Lo-Cascio[2], Claire Kerridge
[1]Medicines and Healthcare Products Regulatory Agency, South Mimms, Hertfordshire, United Kingdom, [2]Medicines and Healthcare products Regulatory Agency, South Mimms, United Kingdom, [3]MHRA, POTTERS BAR, Hertfordshire, United Kingdom

Allogeneic CAR-T cells have shown great clinical promise through the use of healthy donor-derived T-cells with reduced manufacturing times and consistent T-cell qualities. Advancements in gene editing tools such as CRISPR/Cas9 with improved guide design, and on-/off-target prediction tools have enabled the precise editing of genes, including B2M, PD-1 and TRAC, thereby successfully mitigating GvHD. Each Cas9-gRNA (RNP) induced gene editing event for the generation of allogeneic cells is associated with risks of potential off-target activity. The current therapeutic gene editing practices involve *in silico* guide design with off-target prediction, which can be confirmed by experimental validation. However, there is minimal guidance available for risk assessing off-target predictions and little known about variations between *in silico* and cell-based methods.

We aimed to compare *in silico* and experimental determination of on-/off-target editing events for clinically relevant targets in PBMC derived T-cells, to set out a methodical flow for guide selection and help set up clinically relevant thresholds for all editing events. The guide sequences targeting TRAC and B2M genes were categorised as high- and low-risk using the *in silico* tools. These *in silico* risk-assessments will be compared to DIGseq performed with gDNA and targeted NGS on enriched gene-edited populations from donor derived T-cells (n=3).

Analysis using web-based design tools of TRAC_guide1 and TRAC_guide3 targeting the TRAC locus, and B2M_guide1 and B2M_guide3 targeting the B2M gene for hindering the expression of TCR and MHC class I, respectively, have similar on-target editing scores (Table1). Although a variability in the number of predicted off-target sites was observed, a consensus was drawn as TRAC_guide3 and B2M_guide1 being ‘low-risk’ guides, while TRAC_guide1 and B2M_guide3 being ‘high-risk’ guides. However, all the selected guides have a potential for off-target edits in oncogenes (Table2). These guides will be tested further by experimental methods and compared to the *in silico* analysis to determine a methodical flow for performing a risk assessment of all the on-/off-target editing events.

While this work is in progress, we have shown that the *in silico* guide design tools offer a high throughput option for initial screening. However, the variations in predicted off-target sites warrants for the need of a methodical analysis of potentially dangerous off-target editing events.

Label	Chromosome	Locus location	IDT guide design checker scores		Total number of precited off-target sites (4, 3, 2 & 1 base mismatches)

620 Leveraging gene delivery approaches for in vivo target validation and safety assessment

Putianqi Wang, Calico Life Sciences, South San Francisco, CA

At Calico, we aim to advance the understanding of aging or age-related diseases, and to develop therapeutics for these conditions. To understand whether age-related genes or pathways are valid therapeutic targets, we need precise tools to perturb them in live animals and to investigate the physiological consequences of such perturbations. Leveraging viral and non-viral gene therapy vectors, we optimized precise approaches to CRISPR-edit genes selectively in the liver or lung of mice, and applied these approaches to assess target safety or efficacy in early pipeline development. As the first example, we used lipid nanoparticles (LNPs) to perform a target safety assessment. We showed that a single dose of LNPs, through a systematic injection, can deliver genes selectively to >90% hepatocytes. Given the high selectivity and efficiency of liver delivery, we successfully deleted a target gene (X) in the liver by delivering LNP encapsulating gRNAs to Cas9 expressing mice, and confirmed that genetic perturbation of this gene did not induce liver toxicity. This approach allowed quick and robust liver toxicity assessment for pipeline targets without generating transgenic mouse models which is an extremely time consuming process. As the second example, we used adeno-associated viruses (AAVs) to validate the efficacy of a target gene for lung fibrosis. We found that, intranasal or intratracheal delivery of AAV6.2ff, an engineered capsid derived from AAV6, transduced >90% alveolar type 2 cells and >80% large airway epithelial cells. High targeting efficiency to lung epithelial cells made AAV6.2ff a promising tool for gene perturbation selectively in these cell types. Because our target gene (Y) is predominantly expressed by lung epithelial cells, we subsequently showed a successful deletion of gene (Y) in the lung by delivering AAV6.2ff carrying gRNAs to Cas9 expressing mice. This approach allows further investigation of target efficacy in mouse models of lung fibrosis without the need to generate tool compounds/antibodies or transgenic mouse models. Overall, we demonstrated that both viral and non-viral gene therapy vectors are valuable tools in early discovery research.

621 T-Cell Gene Editing via Integration-Free LNP-Mediated Delivery of gRNA and CRISPR Enzyme

Xiulian Sun[1], Sheng Zhao[1], Jie Wang[2], Yulan Liu[2], Qianbo Ma[2]
[1]Richmond, BC, [2]uBriGene Biosciences International Co., Suzhou, China

Background and Aims:
CRISPR technology has revolutionized genetic engineering by enabling precise genome editing. However, translating this potential into clinical applications faces a critical challenge: the efficient delivery of CRISPR components to primary T cells. While conventional viral vectors are effective, they are limited by immunogenicity, toxicity, and the risks associated with genomic integration. Lipid nanoparticle (LNP)-based systems have emerged

as a promising non-viral alternative, offering transient expression, scalability, and enhanced safety for delivering mRNA-encoded gene-editing tools.

Methodology:
This study introduces an optimized LNP platform for co-delivering guide RNA (gRNA), RNA-encoded Cas9 (via mRNA or circular RNA [circRNA]), and DNA donor templates to primary human T cells. By encapsulating the CRISPR machinery within a single formulation, the platform ensures synchronized delivery and temporal coordination of gene-editing components, improving editing precision while reducing off-target effects. To maximize efficacy, the LNP formulation was systematically engineered through rational lipid selection, RNA payload optimization, and refinement of the delivery protocol. Key parameters—including nanoparticle size, zeta potential, encapsulation efficiency, and biocompatibility—were characterized to enhance transfection performance. In vitro validation using primary T cells isolated from human peripheral blood demonstrated robust delivery and editing efficiency.

Results and conclusion:
LNP-mediated transient RNA expression reduced prolonged Cas9 activity, significantly lowering off-target risks and enhancing the safety profile of CRISPR editing. This approach enables precise genetic modifications without compromising cell viability, marking a critical advance for therapeutic applications. The platform holds transformative potential for developing next-generation T cell therapies, including customized CAR-T products with improved efficacy and safety. Future efforts will focus on adapting LNPs for in vivo delivery and exploring multiplexed gene-editing strategies to address complex disease models.

622 High-Fidelity Genome Editing with Cas-CLOVER: A Platform for Advancing Liver-Targeted Therapeutics

Matthew Nitzahn[1], Oscar Alvarez[1], Lucas Homa[1], Khalid Hajj[1], Cindy Negron[1], Mauricio Barajas-Mora[2], Kevin Johnson[1], Sairey Russell[1], Mu Li[1], Bonnie Jacques[1], Joshua Rychak[1], Blair Madison[1]
[1]Poseida Therapeutics, San Diego, CA, [2]Poseida Therapeutics, San Diego

Background
RNA-guided nucleases, such as CRISPR/Cas9, have greatly advanced genome editing by enabling precise genetic modifications, with the potential to address the root causes of genetic diseases. However, concerns about off-target edits, viral vector-related toxicities, and insertional mutagenesis remain significant barriers to clinical translation. To address these challenges, we developed a fully non-viral, liver-directed therapeutic platform using the high-fidelity Cas-CLOVER™ technology and proprietary liver-directed lipid nanoparticles (LNPs). Cas-CLOVER achieves its high fidelity by utilizing a dual gRNA strategy to narrowly restrict double strand breaks to the target site and reduce unwanted off-target edits.

Methods
Proprietary LNPs were engineered to co-encapsulate Cas-CLOVER mRNA and sgRNAs for targeted delivery to hepatocytes through an apoE/LDLR-dependent mechanism. Pharmacokinetic (PK) and safety profiles were evaluated in wild-type (WT) mice and non-human primates (NHPs). PK analysis included LC-MS and qPCR to assess serum clearance, tissue distribution, and persistence. Acute and chronic toxicity studies assessed transaminase levels, cytokines, hematology, coagulation markers, and histopathology. Efficacy was evaluated in humanized mice and NHPs through liver editing efficiency and biomarker reduction.

Results
PK studies in wild type mice dosed with 0.25-3 mg/kg of Cas-CLOVER LNP showed a rapid liver uptake and marked serum reduction of ionizable lipid and Cas-CLOVER mRNA, with minimal exposure of other major organs (80% liver exposure vs 15% in spleen, and 5% combined in lungs, heart, kidney, and testes), suggesting a favorable uptake and clearance profile. ──Safety studies (dose range 0.25-3 mg/kg) revealed transient serum transaminase (AST and ALT) and mild cytokine (IL6, MCP1, MIP-1β) elevations resolving within 48 hours, with no chronic toxicity. In humanized mice, a single administration achieved liver editing saturation (65%) and sustained plasma

biomarker reductions (>90%) for up to 180 days. In NHPs, a single administration achieved up to 45% liver editing and up to 65% reduction in plasma biomarker levels three weeks post-administration.

Conclusion
The Cas-CLOVER platform, delivered via proprietary LNPs, exhibits robust safety, durability, and efficacy in preclinical models. These results underscore its potential as a translatable, liver-directed therapeutic platform for treating rare and complex genetic diseases.

623 Design of Chemically Modified AsCas12a Guide RNAs for Increased Potency of LNP-Delivered Gene Editing Cargos

Bryant Chica[1]*, Alexis Burns[2], Mark Jones[2], Chrysa Latrick[2], Stephen Sherman[3], Jill Fletcher[4], McKenzie Weiss[2], Steven Wolk[2], Paul Wrighton[5], Vikram Soman[6], Stephen Pietrasiewicz[1], Katerina Tsiounis[3], Sheryl Bowley[3]

In vivo therapeutic gene editing via delivery of CRISPR-Cas mRNA and guide RNA (gRNA) containing lipid nanoparticles (LNPs) is emerging as a powerful technology to treat genetic diseases. Establishing a favorable therapeutic index for this technology depends on engineering the gRNA and mRNA payloads for optimal potency. Optimizing the potency of the gRNA can require both sequence and chemical modifications to the gRNA, leading to a rapidly expanding number of gRNA variants to evaluate. Here we present the iterative incorporation of chemical modification motifs into AsCas12a gRNA that increases the potency of LNP gene editing cargos across multiple cell types and gRNA target sequences. We leverage biophysical measurements, including time-resolved DNA cleavage kinetics, gRNA binding affinity, and gRNA stability, coupled with *in cellulo* editing assessments, to inform the rational design of chemical modification patterns for improving gRNA potency. These measurements also provide mechanistic insight into the impact of CRISPR gRNA chemical modifications on specific steps along the pathway to productive gene editing. Identifying potency-enhancing chemical modification patterns for CRISPR gRNAs that translate across multiple cell types and target sequences represents a crucial step towards enabling a strategy for a gRNA target agnostic platform for ‘plug-n-play' *in vivo* gene editing pipeline development.

624 TALEN®- Mediated non-viral Transgene Insertion for the Advancement of Cellular and Gene Therapies.

Gil Letort[1], Aymeric Duclert[2], Diane Leclerre[1], Isabelle Chion-Sotinel[1], Emilie Dessez[1], Margaux Sevin[3], Roman Galetto[4], Marco Rotondi[5], Jordan Skinner[6], Shipra Das, Cosimo Ducani[7], Roger Salvatori[8], Laurent Poirot[2], **Beatriz Aranda-Orgilles[6]**, Philippe Ducha[1], Julien Valton[9]
[1]Cellectis SA, Paris, France, [2]Cellectis, Paris, France, [3]Cellectis SA, Paris, Paris, France, [4]Cellectis SA, Paris, Il de France, France, [5]Cellect, Paris, France, [6]Cellectis Inc, New York, NY, [7]Moligo Technologies, Solna, Sweden, [8]Moligo Technologies, Solna, Sweden, Sweden, [9]Cellectis, Inc., New York, NY

Cell and gene therapy approaches can rely on using gene-editing tools to modify disease-associated genes and introducing transgenes in the genome. These modifications can restore or create new cellular functions, thereby providing a potential therapeutic solution for a wide array of diseases. Despite clinical successes in the immuno-oncology and gene therapy fields, several challenges persist. The traditional application of lentiviral vectors for payload delivery results in random genomic integration, which may pose risks of genomic toxicity or cellular transformation. Advanced techniques use targeted transgene integration facilitated by DNA repair templates with specific homology arms, which can be delivered in AAV particles. These templates are introduced to the cell along with gene-specific double-strand breaks created by gene-editing tools. While more specific, this approach also faces challenges such as manufacturing constraints, potential AAV-associated toxicities or limited payload size. Increasing evidence suggests that non-viral methods, such as single-stranded DNA, to deliver transgenes have the potential to address current efficiency, safety and manufacturing challenges. Consequently, there is a need to integrate these methods into the next-generation of therapies to treat a broad range of diseases.

Here, we explore the combination of TALEN® mediated gene editing and the delivery of non-viral donor templates, particularly single-stranded DNA in its linear (LssDNA) and circular (CssDNA) formats, to mediate gene insertion in T-cells and hematopoietic stem and progenitor cells (HSPCs). We show that non-viral templates are amenable to be used to efficiently edit T-cells with CssDNA leading to higher integration levels. In HSPCs, we also observe an increase in transgene insertion frequency using CssDNA compared to LssDNA, alongside increased viability and insertion specificity. Additionally, we use CITE-seq coupled with long-term engraftment capacity assessment in NCG mice to compare CssDNA with traditional viral DNA repair templates (AAV). Our results demonstrate that CssDNA-mediated cell engineering favors stem-cell fitness and editing stability compared to traditional viral DNA repair templates (AAV). Our comprehensive dataset revealed critical transcriptomic and phenotypic differences regarding the efficacy of non-viral versus viral DNA donor template delivery methods.

Our findings highlight the potential of non-viral ssDNA delivery combined with TALEN® gene editing for gene insertion in long-term repopulating hematopoietic stem cells and primary T-cells. Implementing these advanced gene-editing techniques can pave the way for next-generation of therapies, aiming to provide alternative efficient, and safe therapeutic options for patients with cancer, autoimmune diseases, monogenic disorders, and other conditions.

625 Investigation of Double-Stranded DNA Donors and CRISPR-Cas9 RNP for Universal Correction of Cystic Fibrosis Causing Mutations in Human Airway Cells

Colin Juett[1], Vrishti Sinha[1], Paul Ayoub[2], Ruth Foley[3], Lindsay Lathrop[4], Joseph Long[1], Emily Duggan[1], Beate Illek[5], Brigitte Gomperts[6], Steven Jonas[1], Donald Kohn[1]*

Introduction
Cystic Fibrosis (CF) is caused by disruptive mutations in the Cystic Fibrosis Transmembrane Conductance Regulator (*CFTR*) gene. *CFTR* encodes a chloride ion channel, essential for maintaining proper ion transport in the epithelial layers of the lungs and GI tract. Site-specific insertion of the *CFTR* cDNA into the endogenous locus in airway basal stem cells could prove curative for all disease-causing mutations of the *CFTR* coding region. Typically, approaches have relied on adeno-associated virus mediated delivery of a homology directed repair (HDR) donor, which limits therapies to *ex vivo* treatment. To overcome this limitation, we developed nonviral editing reagents that insert a *CFTR* cDNA cassette just downstream of the *CFTR* promoter with the eventual goal of delivery through lipid nanoparticles *in vivo*.

Methods
Editing reagents were all optimized in the T84 and 16HBE14o- cell lines. Different sgRNA were screened for their Cas9 directed on- and off-target editing profiles. Off-target double strand breaks were identified via GUIDE-seq analysis. Various naked dsDNA HDR donors were assessed for their effect on cell viability by MTT assay and their integration efficiency by droplet digital PCR. Following editing with the best HDR donor candidate in the CFTR-null CF mutant-cell line (16HBEgeG542X), CFTR protein expression was measured by Western Blot. Electrophysiological validation of protein restoration and function utilized the Ussing chamber assay to assess CFTR-dependent chloride ion current in bulk edited cell populations.

Results
An sgRNA that targeted the 5' untranslated region of *CFTR* with a cutting efficiency of 93% and minimal off-target activity was selected to move forward. We first screened potential nonviral HDR constructs that carried mCitrine and found that linear dsDNA had the lowest toxicity and highest rate of integration. To avoid including *CFTR*'s promoter in the homology arms of the HDR donor, we evaluated arm lengths of 500bp to 50bp and found no significant difference in integration. Furthermore, we evaluated the addition of 5' hexamines to our linear dsDNA donors to prevent free end recognition. The integration increased twofold with this modification. Still, with this optimized donor allelic integration was 7.0%, so we evaluated small molecule inhibitors of DNA-PKcs and Polθ,

two early mediators of the nonhomologous end joining and microhomology mediated end joining pathways, respectively. In combination, these inhibitors significantly increased the integration to 13.8% without significantly affecting cell survival. Editing with the full-length *CFTR* cDNA was performed in 16HBEgeG542X cells. Despite just 2% integration, expression of CFTR protein was detectable by Western Blot due to codon optimization. Additionally, bulk edited cell populations measured in Ussing chambers achieved >40% restoration of the chloride ion currents of the wildtype control.

Conclusions
We optimized a linear dsDNA HDR donor and developed a nonviral editing system for CF. Our approach demonstrated functional correction of the CFTR. Importantly, by not utilizing viral delivery the editing reagents can be packaged into lipid nanoparticles. This capability would potentially allow for *in vivo* delivery once targeting to airway basal stem cells is validated.

626 Achieving Therapeutic Endogenous FVIII Levels in Hemophilia A Mice Using Ultrasound-Mediated Gene Delivery of CRISPR/Cas9 Plasmids

Ting-Yen Chao[1], Meng-Ni Fan[1], Yuanyi Xu[1], Xiaohe Cai[2], Savannah Lawton[1], Chun-Yu Chen[1], Carol Miao[3]*

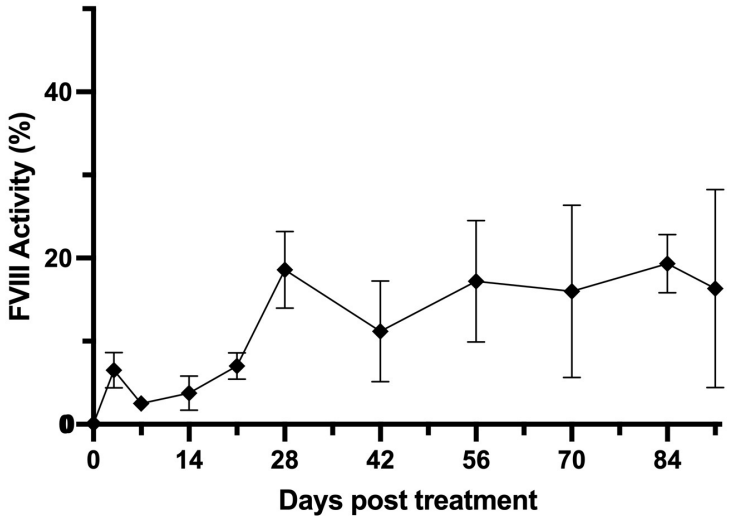
Hemophilia A (HA) is a genetic disorder characterized by the inability to produce functional clotting factor VIII (FVIII). Current treatment with FVIII replacement therapy need to be repeatedly administered that is both costly and inconvenient. Gene editing represents a promising alternative, offering the potential for correction of the underlying mutation. Ultrasound mediated gene delivery (UMGD) has emerged as a safe and effective non-viral method for gene transfer. This approach enables targeted delivery to specific cell types by altering ultrasound parameters and plasmid formulations. In this study, we evaluated the potential of UMGD to deliver CRISPR/Cas9 plasmids targeting liver sinusoidal endothelial cells (LSECs), the native site of FVIII production, to edit mutated FVIII gene and restore endogenous FVIII expression. Building on prior UMGD experiments, we used a therapeutic ultrasound protocol (1.1 MHz frequency, 14 Hz pulse repetition frequency, 50 W power, and 150 μs pulse duration), previously shown to preferentially transfect LSECs in mouse livers. The procedure involved injecting a mixture of MBs and a Cas9 plasmid carrying a single-guide RNA (sgRNA) targeting a 5-base pair deletion in exon 1 of the FVIII gene (NSGHAsgRNA) into the portal vein of NSG HA mice. Blood samples were collected over a 90-day follow-up period, and FVIII activity was assessed via the activated partial thromboplastin time (aPTT) assay. The livers were harvested post-experiment and hepatocytes and LSECs were isolated separately for DNA isolation and sequencing to evaluate gene-editing efficiency. FVIII activity in treated mice (n=5) reached an average of 20% of normal levels over the 90-day period (Fig 1). Next generation sequencing (NGS) analysis of liver DNA revealed an average in-frame editing efficiency of 5% in LSECs, highlighting the preferential targeting of this cell type under the applied ultrasound conditions.

This study demonstrates that UMGD can preferentially deliver CRISPR/Cas9 plasmids to LSECs in a mouse model of HA, enabling gene editing and partial restoration of FVIII activity. These findings provide a promising foundation for further optimization of UMGD as a non-viral approach to treat genetic disorders like HA. With advancements in ultrasound technology and gene-editing tools, UMGD could pave the way for safe, effective, and durable therapies for HA and other genetic diseases.



627 Highly Efficient and Easy-to-Operate HDR Gene Knock-in Editing Is Achieved by 'All-in-One' Delivery Vehicles (AiDVs)

Yawen Fu[1], Erik Bäcklin[2], Juliette Suermondt[2], Zankruti Dave[3], Juan Gao[1], Houze Zhou[4], Xiuming Liang[5]*, Samir El Andaloussi[6]*, Joel Zacharias Nordin[7]*

Introduction: CRISPR-Cas9 genome editing technology has revolutionized the landscape of gene therapy, immunotherapy, and regenerative medicine. Clinical trials using CRISPR-Cas9 for gene therapy are currently in progress or approved, such as in the treatment of patients with hemoglobinopathies. However, repairing a large defect or inserting a whole gene is not possible using CRISPR-Cas9, base editing, or prime editing. Hence, there is growing interest in homology-directed repair (HDR)-mediated precise gene knock-in to correct loss-of-function mutations and ultimately cure genetic diseases. However, the HDR efficiency is currently lower than indels (insertions and deletions), which has become a bottleneck for the application.

Methods: Here, we leverage advanced extracellular vesicle (EV) engineering methods to develop a novel modality for delivering Cas9-ribonucleoproteins (RNPs) as well as templates of a gene to integrate the correcting-cDNA at a specific locus by HDR simultaneously, all of which have been achieved by an 'All-in-One' Delivery Vehicle (AiDV).

Results: Our highly efficient nanoparticles can deliver the complete HDR machinery to multiple clinically relevant cell types, including T cells and hematopoietic stem cells (HSCs). With a simple addition to cell cultures, we achieve robust HDR editing rates (eg. 50% precise gene knock-in in Jurkat cells). Notably, in combination with the small molecule compound M3814, which inhibits non-homologous end-joining (NHEJ) repair, HDR is enhanced to over 90% at one endogenous locus.

Conclusions: This approach significantly improves HDR-mediated gene knock-in efficiency, making it applicable for clinical treatment. The straightforward operation and the possibility of in vivo application would make this treatment more economical than other options, paving the way for its development and improvement as an off-the-shelf treatment.

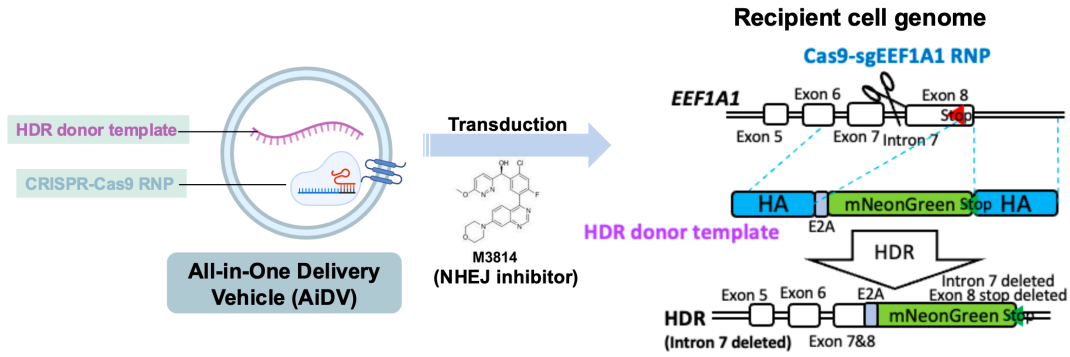

Fig.1 We leverage advanced extracellular vesicle (EV) engineering methods to develop a novel modality for delivering Cas9-ribonucleoproteins (RNPs) as well as templates of a gene to integrate the correcting-cDNA at a specific locus by HDR simultaneously, all of which have been achieved by an 'All-in-One' Delivery Vehicle (AiDV).

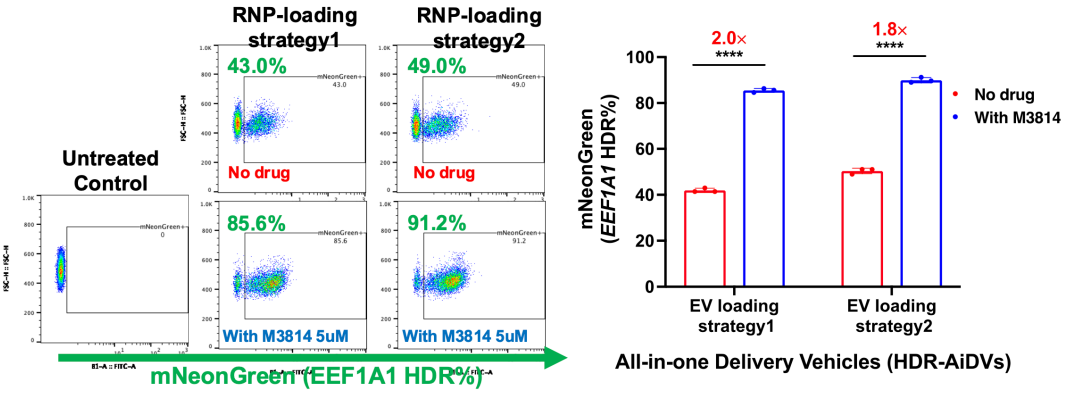

Fig.2 The modified AiDVs that delivered Cas9-RNPs and the HDR template simultaneously achieved efficient HDR in Jurkat cells at the EEF1A1 locus. Here the AiDVs were package with Cas9-RNPs and a mNeonGreen HDR template. The mNeonGreen positive cell percentage reflects HDR efficiency. HDR efficiency was further increased by M3814 (an effective inhibitor of the DNA-dependent protein kinase catalytic subunit, DNA-PKcs, involved in the phosphorylation of NHEJ-associated proteins), which is similar to previous data in Cas9-RNP electroporation and AAV6 delivery.

628 In Vivo Genome Editing with an Ultra-Compact Type V Nuclease for All-In-One AAV Delivery

Adeno-associated viruses (AAV) are an established delivery technology with clinical validation in the field of gene therapy. The benefit of AAV delivery over other approaches, such as lipid nanoparticles, is tropism to organs and

tissues beyond the liver, including the central nervous system (CNS) and muscle. However, gene editing using AAV has been limited due to cargo size constraints, owing to the large size of many gene editing systems. Here, we describe an ultra-compact (488 amino acids) engineered type V nuclease capable of efficient genome editing across multiple cultured cell types and tissues in vivo when delivered using a single AAV vector. In vitro, this nuclease restored dystrophin protein levels by over 50% in Duchenne muscular dystrophy (DMD) model myocytes and achieved complete gene disruption at the SOD1 locus in K562 human cells. In vivo, AAV9-mediated delivery to the mouse central nervous system (CNS) via stereotactic injection resulted in up to 52% editing efficiency in olfactory bulb nuclei, and a significant reduction in target protein levels in the motor cortex. These results highlight the potential of this ultra-compact nuclease for AAV-based therapeutic genome editing beyond the liver, with implications for treating neuromuscular and neurodegenerative disorders.

629 AAV HITI for therapy of dominant Retinitis Pigmentosa

Arjun Padmanabhan[1], Federica Esposito[2], Manuel Rhiel[3], Mariangela Lupo[4], Elena Marrocco[5], Tatjana Cornu[6], Geoffroy Andrieux[7], Manel Llado Santaeularia[8], Ivana Trapani[8], Toni Cathomen[9], Alberto Auricchio[10]

Retinitis Pigmentosa (RP) affects 1 in 3,000 individuals worldwide, with 30-40% of cases having an autosomal dominant (AD) mode of inheritance. The rhodopsin gene (*RHO*) is most frequently mutated in ADRP (RP4), with the P23H mutation being the most common in the US. Traditional gene therapies are ineffective for this condition and eliminating the mutant *RHO* allele is critical to prevent its toxic effect. CRISPR-Cas9 holds promise by targeting the mutant allele while preserving the healthy one; however, its application is limited due to the need for guide RNAs specific for each *RHO* mutation.

We developed an adeno-associated viral vector-mediated homology-independent targeted integration (AAV-HITI) approach targeting the *RHO* locus irrespective of the mutation and demonstrated that HITI donor DNA design is crucial to achieve favourable knock-in events.

Moreover, comprehensive integration analysis at the on-target site revealed that HITI predominantly occurs in the desired direction of integration. Concurrently, we are employing unbiased long-read sequencing to gain deeper insights into the genomic outcomes of our platform. Finally, AAV-HITI tested in a humanized mouse model of RP4 resulted in significant improvements in retinal function and morphology, including visual acuity up to 1-year post-treatment. Overall, this human-centric approach represents a significant advancement toward clinical application of AAV-HITI.

630 A Compact and Potent Type II CRISPR System for CNS Gene Knockdown via AAV Delivery

Adeno-associated viruses (AAVs) are important vehicles for therapeutic genome editing tools but have a restricted cargo capacity. Here we show that MG21-1, a novel type II nuclease that is small enough to be packaged together with its guide RNA in a single AAV, can produce high levels of protein knockdown in the central nervous system (CNS). Potent guides targeting the human ATXN2 gene were identified based on activity measured in K562 cells, with 97% genome editing efficiency measured by formation of insertions and deletions (InDels). These guides were

further validated in human neural progenitor cells (NPCs). Highly active human guides with the greatest similarity to the mouse genome were converted to the mouse sequence and then tested in mNeuro-2A cells, where editing in the range of 50-97% indels were detected. AAV cargo designs were evaluated with plasmid delivery to Neuro-2A cells, and the most active designs were subsequently packaged into AAV9 and CAP-B10 capsids. Stereotactic injections of AAV9 packaged with MG21-1 and guide into the mouse motor cortex showed up to 69% reduction in mean ATXN2 intensity in cells where MG21-1 was detected, as compared to a non-targeting guide control AAV9 delivered contralaterally. Systemic injections of the same editing cargo packaged into the blood-brain barrier-penetrant CAP-B10 capsid recapitulated the results of local injections, with an average 82% knockdown of ATXN2 protein detected in sagittal sections of the brain, validated across three animals by quantitative imaging. These results demonstrate the potential of a small CRISPR nuclease to efficiently knock-down a target in the CNS using a single AAV injected locally or systemically.

631 Improved Prediction and Activation of Homology-Directed Repair in Translational Ex-vivo Systems

[1]Integrated DNA Technologies, Coralville, IA, [2]Integrated DNA Technologies Inc, Coralville, IA, [3]Stanford University, Stanford, CA, [4]Stanford University, Stanford, CA [5]Kamau Therapeutics, South San Francisco, CA, [6]Integrated DNA Technologies Inc, [7]Stanford University School of Medicine, Stanford, CA

CRISPR-Cas enzymes can induce a double-strand break (DSB) at a specific genomic locus, which is subsequently repaired by various endogenous DNA repair pathways. Among these, homology-directed repair (HDR) is particularly crucial for introducing precise sequence alterations into the genome. However, enhancing the efficacy of this repair pathway to achieve therapeutically relevant frequencies is often a time-consuming and challenging process. In this study, we present a series of innovations aimed at optimizing HDR in therapeutically relevant systems, regardless of the format (ssODN, AAV, etc.) or size (small vs. large) of the donor template. Here, we demonstrate that the potential for HDR is dependent on the guide RNA (gRNA) and show predictive indications of non-homologous end joining (NHEJ) repair that are largely conserved to enable high-precision prediction of HDR potential across cell lines. We further demonstrate how HDR potential can be predictably enhanced by using different DNA repair modulation tools to achieve desired outcomes and are developing methods to detect undesired effects. Finally, we demonstrate that new protein-based DNA repair modulation can significantly enhance performance in translational settings without increasing off-target effects.

632 CRISPR Library Design Solutions for Efficient Gene Knockout Screening

Javier Gomez Vargas[1], Morgan Sturgeon[1], Sean West[2], Gavin Kurgan[3], Ashley Jacobi, Garrett Rettig
[1]Integrated DNA Technologies, Coralville, IA, [2]Integrated DNA Technologies, Coralville, [3]Integrated DNA Technologies Inc, Coralville, IA

CRISPR-Cas systems are RNA-guided endonucleases that generate double-strand breaks (DSBs) at targeted loci, which can be repaired by pathways such as non-homologous end joining (NHEJ) to create indels. Leveraging this principle, guide RNA (gRNA) libraries can target large genomic regions for knockout, making them an essential strategy for gene knockouts and functional genomics. However, the lack of well-defined tools for flexible library generation with predictable performance has been a significant challenge. To address this need, we present a customizable gRNA library creation process featuring a customer-facing design interface, allowing parameters such as gRNA spacing and number to be tailored. We also demonstrate support for novel nucleases (e.g., Cas12 systems) and diverse genomes. We demonstrate the optimal number of gRNAs required for consistent, high-efficiency gene editing and identify design strategies that significantly improve frameshift and knockout frequency. To ensure the integrity of our synthesis platform, we synthesized a 96-well plate of select gRNAs (n=18 replicates/gRNA) and used multiplexed rhAmpSeq with UDIs to detect cross-contamination, finding none. Finally, we showcase an offering of advanced screening and analysis capabilities for CRISPR libraries through services available at IDT.

633 Excision of the *C9orf72* Hexanucleotide Repeat Expansion Using a Dual-ARCUS Gene Editing Approach Reduces Neurotoxic RNA Foci and Dipeptides in an *In Vivo* Model of ALS

Spencer McKinstry[1], Adam Mischler, Joanna Dobson, Emily Manzon, Chengwei WANG, Jeff Smith[2], Cassie Gorsuch[1]
[1]Precision Biosciences, Durham, NC, [2]Precision BioSciences, Inc., Durham, NC

Amyotrophic Lateral Sclerosis (ALS) is a progressive, fatal neurodegenerative disease, characterized by the degeneration of upper and lower motor neurons leading to a loss of muscle control and eventual death. The most commonly known cause of familial ALS is a hexanucleotide repeat expansion (HRE) in the first intron of the chromosome 9 open reading frame 72 (*C9orf72*) gene. Bidirectional transcription of the HRE-containing allele generates toxic RNA foci and dipeptide repeats (DPRs), supporting a gain of function mechanism for *C9orf72* in ALS. To prevent production of these toxic species, two ARCUS nucleases were developed and optimized to excise the region of the gene that contains the HREs. Taking advantage of their small size, coding sequences for both ARCUS nucleases were packaged into a single AAV under the control of a neuron-specific promoter. To demonstrate proof of concept for this excision approach, induced pluripotent stem cells from an ALS patient with a *C9orf72* HRE were differentiated into motor neurons and transduced with the dual-ARCUS AAV. The target region of the *C9orf72* gene was excised from ~30% of alleles, which led to a ~30% reduction in toxic RNA foci. To confirm the efficacy of this approach *in vivo*, the dual-ARCUS AAV was administered via intracisternal magna injections to neonatal C9-500 mice, a transgenic mouse line that contains full-length human *C9orf72* with a HRE of 300-500 repeats. These mice display the hallmarks of *C9orf72* ALS, including detectable RNA foci throughout the central nervous system and DPRs in the brain. In both the motor cortex and spinal cord of ARCUS-treated mice, excision of the target region led to reductions in toxic products. These data provide proof of concept that this excision approach using a pair of ARCUS nucleases can remove the HRE region of *C9orf72* in neurons to eliminate the toxic gain of function products that drive degeneration in ALS.

634 Excision of the Expanded GAA Repeats from Fxn^{null}::$YG8s(GAA)_{>800}$Increases Frataxin Expression

Introduction: Appropriate mouse models are essential in the processes of drug discovery and therapy development for Friedreich's ataxia (FRDA). The Fxn^{null}::$YG8s(GAA)_{>800}$ (Jax Stock No. 030395) humanized transgenic mouse is one of the best characterized mouse models of FRDA. It is also the only mouse model that expresses human frataxin encoded by the entire human *FXN* gene. It carries a large GAA repeat expansion of ~800 repeat and develops a mid to late onset progressive phenotype. It is the only FRDA mouse model that can be used for testing "human sequence-specific" therapies such as antisense oligonucleotides or CRISPR-Cas9 editing. Control mice (Y47R) were created by random integration of a human transgene containing the entire *FXN* gene with only 9 GAA repeats. The transgene is inserted in a different chromosomal location than that of the $YG8s(GAA)_{>800}$ model, resulting in very high frataxin expression. Progressive weight gain in these animals presents a concern for motor/behavioral analyses. Therefore, to address these issues and generate an appropriate control strain for $YG8s(GAA)_{>800}$ mice, we utilized CRISPR-Cas9 editing to excise the fragment of intron 1 containing 800 GAAs.

Methods: $YG8s(GAA)_{>800}$ embryos were electroporated with Cas9 protein and four gRNAs (two upstream and two downstream of the GAA repeats) to generate the YG8sD(GAA) strain. Embryos were transferred to pseudo-pregnant female mice.

Results: Genotyping and DNA sequencing of seven surviving pups demonstrated that all carried edited alleles. Two males were selected as founders of the YG8sD(GAA) colony and crossed with B6 wild type females to minimize potential off-target effects of genome editing. One of the seven pups was sacrificed, and RNA and protein analyses demonstrated significant upregulation of frataxin expression after GAA excision compared to the YG8s$(GAA)_{>800}$ strain.

Conclusions: Using CRISPR-Cas9, we generated a novel control mouse strain of critical importance to drug discovery and therapy development for FRDA

635 Single-Cell Genotyping and Transcriptomic Analysis of CRISPR/Cas9 edited hematopoietic stem and progenitor cells for Treating Sickle Cell Disease

Mingming Cao[1], So Hyun Park[1], Cecile Karsenty[2], Gang Bao[3]
[1]Rice University, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Rice University

Sickle cell disease (SCD) is a severe inherited disorder caused by a single nucleotide substitution in the β-globin gene (*HBB*), resulting in the production of sickle hemoglobin (HbS) that leads to chronic complications, including hemolytic anemia, vaso-occlusion, and ineffective erythropoiesis. Gene-editing strategies such as that using CRISPR/Cas9 technology have demonstrated therapeutic potential by correcting the sickle mutation through homology-directed repair (HDR) with a donor template. However, this approach induces DNA double-stranded breaks, which can result in unintended editing outcome including small insertions and deletions (INDELs), and large gene modifications. These editing outcomes can have high genotypic diversity, which is largely overlooked by conventional colony-based genotyping methods due to the limited resolution, particularly at the single-cell level. To address these challenges, we developed a platform combining single-cell RNA sequencing (scRNA-seq) with the Genotyping of Transcriptomes (GoT) to analyze the diverse outcomes due to CRISPR/Cas9 gene editing. This platform was then applied to study the *HBB gene in edited and differentiated* hematopoietic stem and progenitor cells (HSPCs) from patients with SCD.

We first established a genotyping library preparation method to enrich for HBB cDNA and a pipeline to quantify editing-induced alleles and genotypes on *HBB.* This was integrated with standard scRNA-seq analysis to link genotype diversity with functional outcomes. Using this approach, we analyzed editing outcomes in SCD HSPCs edited with ribonucleoproteins (RNP) containing HiFi*Spy*Cas9 and either R-02 or R-66S guide RNA, with or without a corresponding single-strand oligodeoxynucleotide (ssODN) donor template for correcting the sickle mutation. Edited HSPCs were differentiated into the erythroid lineage and analyzed at days 3, 7, 10, and 13. We quantified 30,532 R-02 gRNA edited cells, 27,886 R-66S gRNA edited cells, and 14,688 untreated cells, revealing significant genotypic diversity. For example, on day 7, we identified 702 unique genotypes in 4,847 cells of the sample edited by the R-02 RNP plus ssODN and 1,230 unique genotypes in 4,163 cells of the sample edited by R-66S RNP. These genotypes are composed of unedited SCD mutation, HDR-mediated HBB correction, HBD-conversion, in-frame and out-of-frame INDELs as well as large deletions and insertions.

By linking genotypes to transcriptomic data, we found that while γ-globin expression partially compensates for β-globin deficiency in *HBB*-disruptive genotypes such as out-of-frame INDELs and large deletions, it does not fully restore the normal α/β globin ratio. This imbalance raises concerns about persistent functional deficit and globin dysregulation. We identified a distinct cell cluster in the edited samples that has significantly enriched *HBB*-disruptive genotypes. Cells in this cluster showed characteristics of ineffective erythropoiesis in late polychromatic erythroblasts, early and mid-orthochromatic erythroblasts (OrthoE). Further, they displayed significant upregulation of stress-related genes, severe α/β globin imbalances, and impaired progression into late-stage OrthoE. These findings underscore the importance of a comprehensive evaluation of the functional consequences of gene editing and highlight the urgent need to optimize the gene-editing strategies to improve the efficacy and safety of gene-editing therapies.

636 CasX gRNA Screening and Selection Enables Ex Vivo CD38 Knockout NK Cell Therapy

Seunghee Lee[1], Laura Blaha[2], Jared Getgano[2], Matthew Sullivan[1], Yogesh Bhootada[1], Victoria Qu[1], Monica Wu[1], Dustin Cooper[1], Khang Tran[1], Akimmee Green[3], Jacob Hope[4], Justin Pater[3], Anusha Dias[1], Robert Igarashi[5], Christian Mueller[6], Christopher Borges[1]
[1]Sanofi, Waltham, MA, [2]Sanofi, Waltham, [3]Sanofi employee at the time work was performed, Waltham, MA, [4]Beam Therapeutics, Somerville, MA, [5]Kiadis Pharma, Amsterdam, Netherlands, [6]Sanofi Genzyme, Waltham, MA

Multiple myeloma is a malignant neoplasm originating from plasma cells expressing high levels of CD38. Although several treatments have been developed over the past decades, the 5-year relative survival rate for multiple myeloma is as low as 57%. Sarclisa® (isatuximab), a Sanofi anti-CD38 monoclonal antibody, is reported to increase the 60-month progression-free survival rate by 20% when used in combination with bortezomib, lenalidomide, and dexamethasone. Natural killer (NK) cell combination therapy has been proposed to increase the antigen-dependent cell-mediated cytotoxicity (ADCC) against malignant CD38+ plasma cells, potentially enhancing the efficacy of anti-CD38 antibodies. However, combining these two therapeutic strategies is challenging because NK cells express CD38 on their surface which results in fratricide upon exposure to anti-CD38 antibodies.

To minimize NK cell fratricide, we employed a CasX nuclease based genome editing strategy to eliminate CD38 protein on the surface of NK cells. We assessed the function of 52 CasX guide RNAs (gRNAs) in primary NK cells expanded from 6 unique CD3-depleted PBMC donors. In total, 6 CasX gRNAs achieved greater than 80% knockout (KO), with the top performing candidate reaching 95% KO. Importantly, screening of the lead gRNA was performed with CasX mRNA, obviating the need to produce CasX ribonucleoprotein. We defined gRNA potency across our top candidates by serially titrating CasX mRNA concentrations and found that the lead gRNA is more potent than other highly active gRNA. Surprisingly, while the lead gRNA maintained greater than 93% efficacy even with less than 10% of the amount of CasX mRNA used in the initial screen, other candidates exhibited a 10-35% reduction in efficacy with decreasing concentrations of CasX mRNA. Furthermore, insertions and deletions (indels) at the on-target cut sites for each gRNA correlated well with phenotypic protein KO.

We continue to develop a suite of gRNA off-target discovery and validation tools specifically for CasX using a surrogate gRNA. This gRNA exhibits similar on-target editing to other candidate gRNAs but has a higher *in silico* off-target signature. Using this surrogate gRNA, we detected off-target events in an *in vitro* biochemical off-target assay. One of the off-target sites that was identified in these assays, but not the *in silico* off-target algorithm, was validated to occur at 2% following editing in primary human NK cells using a targeted amplicon based sequencing method. In contrast, the lead gRNA has a more favorable *in silico* off-target signature and fewer off-target sites found in the *in vitro* biochemical off-target assay. Together, we present a robust CasX gRNA screening, gRNA off-target detection and gRNA off-target validation platform that can be used in combination to identify candidate gRNA used for therapeutics.

637 Machine Learning-Informed CRISPR Screening for Enhanced MSC Chondrogenesis

Joshua Graham[1], **Tomas Gonzalez Fernandez**[2], Yu Zhang[2]
[1]Lehigh University, Doylestown, PA, [2]Lehigh University, Bethlehem, PA

Introduction: Traumatic and degenerative cartilage injuries are a leading source of pain worldwide, causing great financial burden and diminished quality of life. Cartilage has limited healing capacity, prompting the need for de novo cartilage regeneration through strategies such as the chondrogenic differentiation of primary mesenchymal stromal cells (MSCs). Yet, clinical translation is challenged by limited chondrogenic capacity in vivo and phenotype instability. CRISPR gene editing adds fine control of cell fate through precise manipulation of gene expression. However, editing a single gene can have a cascading effect throughout gene regulatory networks (GRNs) causing unpredictable phenotypic shifts. We have previously established CRISPR-GEM, a machine learning model that learns GRNs then evaluates CRISPR target genes for specific therapeutic applications. Our objective is to experimentally validate this model by screening CRISPR activation (CRISPRa) target genes to enhance MSC

chondrogenesis. We hypothesize that the identified genes will induce potent chondrogenesis as determined by PCR, high-throughput fluorescent assays and in vivo models.

Methods: mRNA encoding the nuclease null Cas9 fused to the tripartite transcriptional activator VPR (dCas9-VPR) and guide RNAs (gRNAs) were complexed at a 1:2 mRNA:gRNA molar ratio with the RALA peptide at a nitrogen:phosphorous (NP) ratio of 7. Quantitative PCR (qPCR) was performed using TaqMan Fast Advanced Master Mix for qPCR (Applied Biosystems) and specific TaqMan gene expression assays (Applied Biosystems) using the 2-ΔΔCt method with RPL13A as the housekeeping gene. SOX9 reporter knock-in was performed using Cas9 ribonucleic protein (RNP) targeting immediately before the SOX9 stop codon. A pDNA donor template (Genscript USA) containing GFP flanked by homology arms complementary to either side of the cut site was co-delivered with RNP using RALA at an NP ratio of 5 or a 100x RALA:RNP molar ratio, respectively. Finally, knock-in cells were sorted by flow assisted cell sorting (FACS).

Results: CRISPR-GEM identified PRG4, SERPINA3, SERPINA1, MGP, TNP1, and BMP2 as top scoring CRISPRa target genes for the chondrogenesis of MSCs. Multiple gRNA sequences were assessed for each gene using an mRNA/gRNA co-delivery system through the RALA cell penetrating peptide (Figure 1A). Significant activation of each gene was achieved relative to non-transfected controls and non-targeting controls with at least one gRNA for each gene (Figure 1B-G). To assess the functional impact of gene activations, we designed reporter MSCs to fluorescently trace SOX9 protein expression for high throughput analysis of target genes and gene combinations (Figure 2A). As a positive control, SOX9 activation was optimized resulting in a maximum fold change of 15.7 ± 5.5 (p=0.0005)(Figure 2B). Future work will use this reporter system to characterize the effect of CRISPR-GEM target gene activations on SOX9 expression to validate model findings. Optimized activation targets will then be assessed in vivo by embedding transfected reporter MSCs in alginate hydrogels then implanting them subcutaneously in immunodeficient mice and tracking the fluorescent intensity using an in vivo imaging system. In all, these results demonstrate efficient non-viral gene activation for the chondrogenesis of MSCs and presents a novel high-throughput strategy for CRISPR target gene assessment which can be applied to a range of therapeutic applications.

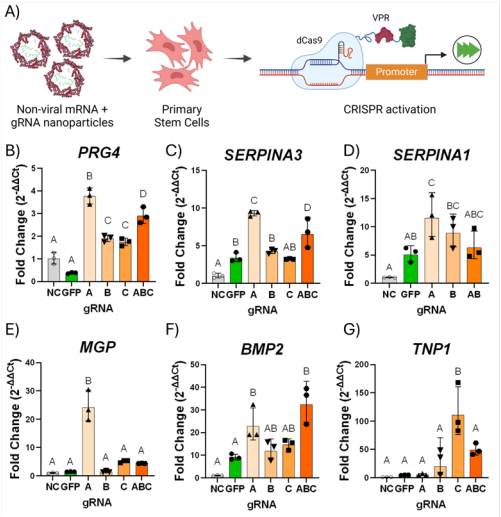

Figure 1. CRISPRa guide RNA (gRNA) Optimization. **A)** Schematic of gene activation strategy. mRNA encoding nuclease-null Cas9 (dCas9) fused to the tripartite transcriptional activator VPR (dCas9-VPR) was co-delivered with gRNA into primary MSCs using the non-viral RALA cell-penetrating peptide. This approach was used to optimize the gRNA sequences for each target gene by delivering three identified gRNA for each gene or two for *SERPINA1*. **B-G)** Using these methods, the top 6 genes were activated, and the fold change after 24 hours was determined via qPCR to identify the optimal gRNA sequences for future chondrogenesis studies. *PRG4, SERPINA1, SERPINA3, MGP, TNP1,* and *BMP2* activation levels corresponded to their basal expression but significant activation was achieved with at least one gRNA combination for each gene. The transfection of GFP was included as a control to determine the transcriptomic effects of the delivery vector. Groups labeled with the same letters within a graph are not statistically significant from each other (p<0.05) as determined by a one-way ANOVA.

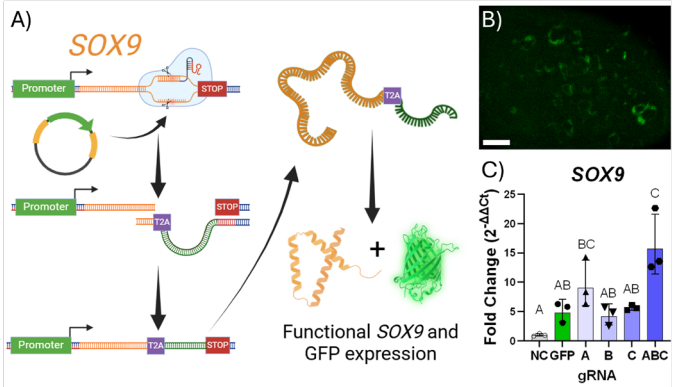

Figure 2. SOX9 reporter MSC experimental design. **A)** Schematic of experimental strategy. Cas9 ribonucleic protein targeting *SOX9* immediately before the stop codon will be delivered to MSCs to create a double stranded break (DSB). pDNA encoding GFP surrounded by homology arms complementary to the *SOX9* sequence was then delivered to align the GFP sequence over the DSB for copying into the *SOX9* transcript. The result is the expression of fully functional SOX9 and GFP allowing a quantification of SOX9 protein production following gene activations. **B)** Fluorescent images of knock-in cells following TGF-β3 treatment. Scale = 100 μm. **C)** *SOX9* activation was performed as a positive control in later studies. The transfection of GFP was included as a control to determine the transcriptomic effects of the delivery vector. Groups labeled with the same letters within a graph are not statistically significant from each other (p<0.05) as determined by a one-way ANOVA.

638 Rapid and Accurate Genotyping of 100 Gene-Edited Cells Using GeneAbacus

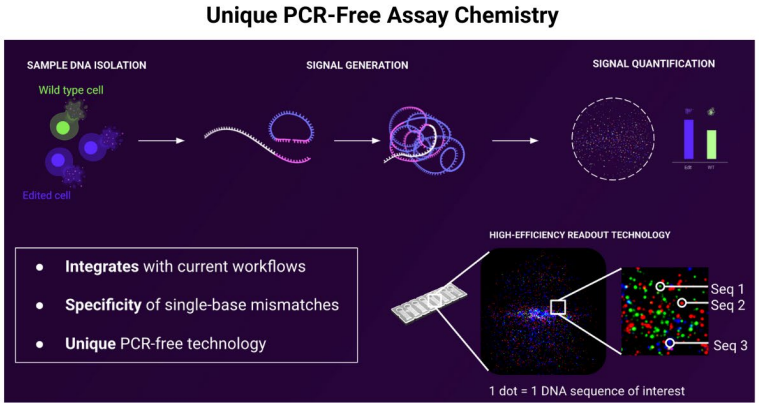
Hamid Sharifi[1], **Leiore Ajuria[1]**, Xuan Droz[2], Allison Whalen[1], Felix Neumann[1], Adele Kerjouan[2], Iván Hernández-Neuta[1]
[1]*Countagen AB, Solna, Sweden*, [2]Cytosurge AG, Glattbrugg, Switzerland

Introduction: Timely genotyping of gene editing outcomes remains a significant challenge, particularly when working with limited cell numbers or single-cell manipulation as long culturing times are needed for sufficient DNA amounts. Traditional PCR-based methods are powerful but prone to nonspecific amplification, especially in samples with low cell count. Here, we present a standardized PCR-free genotyping assay that delivers highly accurate results within a single day, starting from as few as 100 cells/sample.

Method: GeneAbacus leverages padlock probes and Rolling Circle Amplification (RCA) chemistry to convert genotypes into quantifiable signals that can be read out with a fluorescence microscope. The loss of wild type alleles and detection of specific edits are measured by digital quantification of signals obtained from edited and unedited cells. We have developed a sample preparation module for GeneAbacus to handle limited cell number samples without compromising accuracy. Comparative studies were conducted using human HCT 116 and human U-2 OS cell lines, analyzing knock-out efficiency in heterozygous pools and homozygous clones. Results were evaluated using next-generation sequencing (NGS) as a reference method.

Results: We demonstrated functionality of GeneAbacus from samples with a range of 100 to 1,000 cells. The assay achieved equal sensitivity for both cell lines used. Blind testing of knock-out efficiency revealed robust precision and reproducibility with high degree of concordance as confirmed by NGS data (R^2= 0.982) for tested gene editing efficiencies ranging from 20% to 100% edited alleles.

Conclusion and Outlook: With the extended capability of GeneAbacus to handle samples with limited cell numbers, the genotyping process of gene-edited cells can be streamlined.. This addresses not only bottlenecks in PCR-based workflows but can accelerate the gene editing validation step by for instance shortening the cell culture time, enabling cell engineering solutions on single cell level and on cell types with limited dividing capacity.



639 Advances in Cytogenetic Detection of Small Genomic Targets and Transgenes for Cell and Gene Therapy

Erin Cross[1], Christopher Tompkins[2], Stephen Gross, Matthew McGowan[3], Henning Mann[4], Michael Yang[5], Nicholas Sciascia[5], Brenna Fearey[5]
[1]Kromatid Inc, Fort Collins, CO, [2]KromaTiD, Longmont, CO, [3]Kromatid Inc, Longmont, CO, [4]Nikon Instruments, Nikon Bioimaging Lab, Seattle, WA, [5]Nikon Instruments, Nikon Bioimaging Lab, Boston, MA

Cell and gene therapies often require complex editing systems that utilize nuclease-based editing in combination with delivery and/or insertion of one or more transgenes into a target genome. Some examples include in vivo gene therapy using liver-targeting AAV vectors, lentiviral particles to introduce Cas9 RNPs and CAR transgenes into human T-cells, and the use of DNA as a therapeutic agent to replace defective genes or kill tumor cells. While stable transgene integration can have considerable therapeutic benefits, any integration event into genomic DNA could disrupt host gene expression and potentially contribute to secondary malignancies via insertional mutagenesis. Factors such as vector choice (lentivirus versus gammaretrovirus), cell substrate (e.g., T-cells versus CD34+ cells), and even the individual donor can additionally influence this risk. The transgenic DNA sequences integrated into the genome are often smaller than what conventional FISH assays can detect. To address the need to characterize small-target integrations in a cellular-based assay, Kromatid has developed a platform, KROMASURE, with two fit-for-purpose solutions to provide single-cell cytogenetic assessment of transgene integrations. These are KROMASURE inSite and its counterpart, KROMASURE Pinpoint FISH, two advanced cytogenetic assays for identifying and measuring the copy number and true modal distribution of integration events on a single-cell basis. The number (and sometimes location) of the transgenic integration events in these complex edited products can be measured on average by NGS or dPCR methods. However, this averaging divorces structural variant and transgene data from any cellular context, making it impossible to observe co-localization of events or understand the true distribution in a batch of edited cells. For this study, we have combined our advanced DNA probe design strategies that avoid homology, repetitive sequence, and other sources of fluorescent signal noise, with intelligent image acquisition and image analysis technologies available at Nikon BioImaging Lab, to develop a scalable, robust imaging-based cytogenetics assay for small target detection. Briefly, Nikon developed an AI-enhanced “two-pass” approach to scan KROMASURE inSite slides, with the first pass being a low-magnification “large field of view” scan used to identify cells in interphase and metaphase states, and the second pass being a high-magnification Z-stack acquisition of detected interphase and metaphase cells. This imaging workflow was automated through a suite of Nikon NIS-Elements tools including JOBS (for automated imaging), General Analysis 3 (for object detection) and NIS.ai (for segmentation classifier training and noise reduction), to create a robust, scalable imaging solution with limited human intervention. Moreover, the Nikon microscope optics excelled at identifying small, fluorescently dim puncta, a critical requirement for using our DNA probe-based assay to accurately identify and score small genomic targets and transgene insertions. Using the Nikon BioImaging Lab workflow, we were able to obtain high-quality images of approximately 10,000 cells in about a week, a dramatic improvement over conventional, manual imaging workflows and one that enables us to search for and quantify rare genomic events. Using a transgene system as a model we demonstrate the use of KROMASURE inSite for understanding the true structural heterogenicity in batches of edited cells.

640 Personalized Molecular Engineering of CRISPR Systems to Improve Activity and Specificity

Eric Josephs, Stony Brook University, Stony Brook, NY

The challenge of improving the activity and specificity of CRISPR in gene therapies lies in the facts that the human genome is large; that CRISPR effectors like Cas9 that increasingly enter clinical trials for therapeutic gene editing are tolerant to small differences between the intended target and other sites that might be present in an individual’s genome; and the existence of these “off-target” sites in a patient’s DNA may not even be known or detected *a priori.* However, developing CRISPR biotechnologies with extreme specificity would not only eliminate clinical risk for off-target mutation, but would also present new therapeutic opportunities of CRISPR, such as allele-specific gene editing.

Currently, two of the main approaches to reducing the potential for unwanted mutations are (i) computational optimization of the target site determined by a CRISPR effector's guide RNA (or gRNA) to minimize the predicted number of other sites that might be similar to the target of interest, and (ii) using engineered "high-fidelity" Cas9 enzymes with less activity at sites that diverge from the gRNA's target. These approaches suffer from 3 major limitations: (i) "high-fidelity" CRISPR effectors are "high-fidelity" because of their significantly reduced overall activity and effectiveness; (ii) the reduced flexibility and range of potential therapeutic targets that comes from computational optimization; and (iii) that computational optimization is not "personalized" but rather uses the "reference" human genome to predict "off-targets" and can catastrophically miss small but important variations between individuals.

Invisible line

My laboratory has developed an approach to experimentally screen 100's of thousands of gRNA variants known as extended gRNAs or x-gRNAs that we previously have shown can increase specificity in CRISPR activity at specific targets by orders of magnitude with known off-target sites and can significantly outperform CRISPR targeting even when compared to engineered "high-fidelity" Cas9 effectors. We have validated this approach using several well-characterized gRNAs with known-off-targets, including gRNAs for treating inherited metabolic disorders of the liver and others currently in clinical trial for treatment of sickle cell disease (SCD); we believe this approach would have great potential in genetic treatments for many diseases. More recently, we have developed "automated" microfluidic platforms for high-throughput gRNA characterization of both on- and off-target activity – simultaneously characterizing, for example, gRNAs for every possible CRISPR target within an exon of interest – and subsequently applied this approach toward the "hands-fee" discovery of gRNA variants with significantly enhanced activity profiles. Furthermore, we have taken this approach to the extreme: we are now ablet to readily generate gRNA variants capable of discriminating single-nucleotide variants (SNVs), even when the variants are located outside the protospacer adjacent motif (PAM) of the CRISPR effector – something otherwise extremely challenging – completely eliminating detectable activity at one SNV and with no loss of activity at the other SNV of interest; we have demonstrated this extreme level of specificity with two SNVs resulting from common pathogenic somatic mutations. We expect these contributions will not only improve the safety of CRISPR therapies but also enable new applications of CRISPR gene therapies.

641 A Robust Approach for CRISPR-Cas Therapeutic Guide Design and Selection Leveraging Variant-Aware Computational and Biochemical Approaches

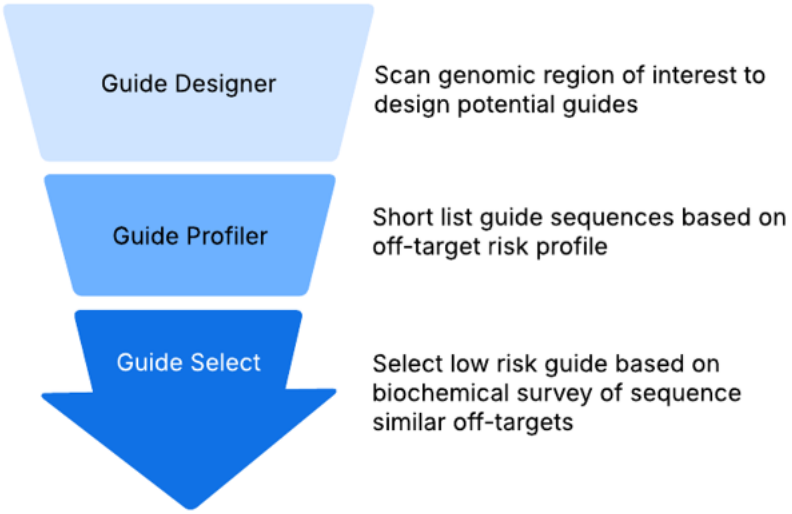
Vijetha Vemulapalli[1], FNU Shankaracharya[2], Alyssa Ferreira[2], Edward Salinas[2], Hongyao Yu[2], L. Ashley Lester[2], Divya Ravindran[2], Elijah Dabney[2], Andrew Hollinger[3], Douglas Smith[4], Thomas Mullen[4]
[1]SeQure DX, Holliston, MA, [2]SeQure Dx, Waltham, [3]Waltham, MA, [4]SeQure DX, Waltham, MA

Guide RNA (gRNA) design for a CRISPR-Cas system routinely begins with computational tools to identify a small set of candidate guide sequences. While currently available computational tools that are designed for guide design take into account factors that impact on-target editing, they do not provide a comprehensive analysis of off-target risk or genetic variation present in human populations. Moreover, any off-target analysis is based on predictions from statistical models with no consideration for biological significance of putative off-target loci. These computational analyses are often followed by selection of a single guide based on experiments evaluating editing efficiency in a relevant model system without any biochemical assessment for off-target specificity. Motivated by experience in reducing off-target gene editing risk in therapeutic applications we have developed a more effective approach.

Here, we present an integrated, multi-step approach that utilizes a combination of computational tools (Guide Designer, Guide Profiler) and an in-vitro biochemical assay (Guide Select) to perform variant and off-target aware guide design, profiling, and selection.

The TRBC1 gene is a well-studied therapeutic target in immunotherapies. Using the Guide Designer software, we performed comprehensive design of candidate guides and profiled them based on several factors such as location within the transcript and previously published metrics of on-target and off-target performance. For the top 25 gRNA

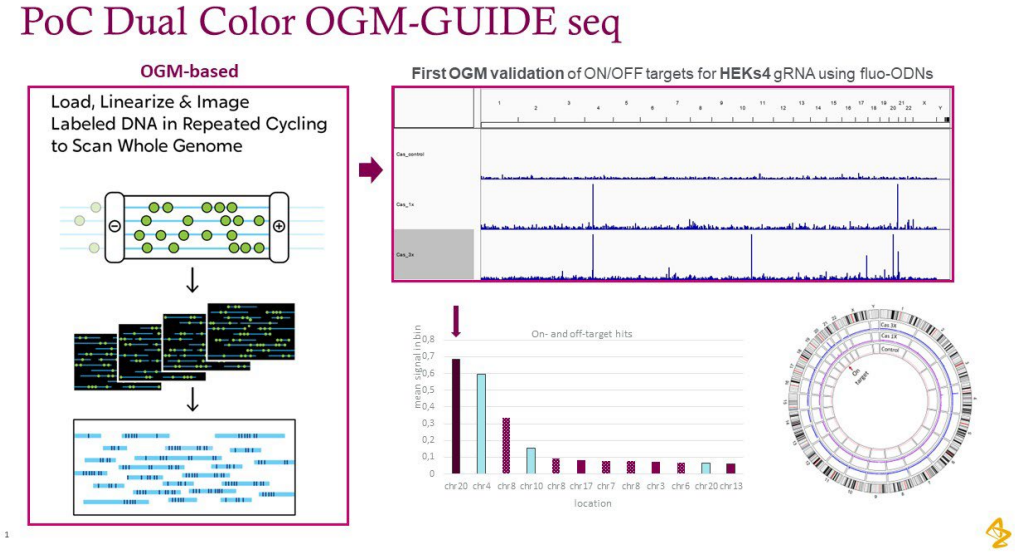
sequences, the Guide Profiler software was used to perform a comprehensive search for on-target variation and candidate off-target sites across 7 human superpopulations, annotation of putative off-target loci with biological features, and finally rank-ordering of their off-target risk profile. For the top 8 guide RNA sequences, this was then followed by empirically defining their biochemical editing specificity using the Guide Select assay. This assay is a multiplexed adaptation of the ONE-seq assay and is designed to biochemically identify off-target sequences with lower edit distance (<5 mismatches and indels) from the guide RNA sequence. Based on the assay read out, the guide RNA with lowest off-target risk is finally selected for downstream efficacy testing. Selection of the optimal candidate gRNA from this approach and comparing to a previously published guide, we present data from off-target characterization using the GUIDE-seq and SAFER-detection assays to underline the impact of this comprehensive guide RNA selection approach. In summary, improving the rigor around the design, profiling, and selection of guides earlier in the discovery process reduces the overall risk of a therapeutic program, prioritizes safety, and improves overall speed of a therapeutic program.



642 Dual-Color Optical Genome Mapping for Enhanced GUIDE-seq Analysis in CRISPR-Cas9 Editing

Roberto Nitsch, AstraZeneca, Mölndal, Vastra Gotalands lan, Sweden

CRISPR-Cas9 genome editing has revolutionized genetic engineering, yet ensuring its precision and safety remains a key challenge. Off-target effects and unintended structural variations, such as large deletions, duplications, and translocations, often evade detection by conventional sequencing-based methods, which rely heavily on small amplicon generation, and overly elaborated computational algorithms for variant calling. Here, we introduce a novel dual-color Optical Genome Mapping (OGM) approach that includes GUIDE-seq applications, providing a direct, PCR-free, bioinformatics-independent method for an all-in-one detection of CRISPR-induced genomic alterations. By leveraging two distinct fluorescent labels, this technique allows for simultaneous visualization of structural variants and the integration sites of GUIDE-seq oligonucleotides, enabling an unbiased, high-resolution assessment of double-strand break (DSB) repair outcomes across the genome. Unlike short-read or long-read sequencing, which can struggle with repetitive regions and complex rearrangements, dual-color OGM provides a single-molecule, high-throughput solution that captures large-scale genomic modifications with exceptional sensitivity and specificity. This approach offers a powerful alternative for evaluating Gene Editing safety, eliminating the need for bioinformatics pipelines and computational artifact corrections. By improving the accuracy of genome integrity assessments, dual-color OGM has strong potential for clinical and translational applications, particularly in the development of genome editing-based therapeutics.



643 Genome-Wide *In Silico* Analysis of Greater than Five Million CRISPR Guide RNAs Reveals Limited Predictive Power of Non-Human Primates for CRISPR Guide RNA Off-Target Activity in Humans

Laura Blaha[1], Victoria Qu[1], Dale Bodian[2], Michael Lyons[2], Michael DeRan[2], Mia Bosinger[3], Christian Mueller[4], Christopher Borges[1]
[1]Sanofi, Waltham, MA, [2]Diamond Age Data Science, Boston, MA, [3]Diamond Age Data Science, Chelmsford, MA, [4]Sanofi Genzyme, Waltham, MA

Non-human primates (NHPs) such as rhesus and cynomolgus macaques are used for pre-clinical modeling of gene editing therapies, leveraging similarities to human anatomy and physiology as well as high sequence homology between NHP and human genomes. However, the functional relevance of NHP genomes in CRISPR guide RNA (gRNA) specificity analysis has yet to be determined. We describe a bioinformatic pipeline to annotate *in silico* genome-wide specificity analysis of over five million Cas9 and Cas12a CRISPR gRNAs with respective on-target sequence similarity across NHP species. We hypothesized that computational intersection of the annotated off-target profiles for each gRNA would reveal the functional relevance of multiple NHP species in modeling CRISPR off-target activity in humans.

CRISPR gRNA design tools were modified to enable prediction of human intragenic Cas9 and Cas12a spacer sequences genome-wide, and a bioinformatic pipeline was developed to annotate the panel of spacers with the names of the candidate human gene targets. Selection of NHP models for CRISPR efficacy and toxicity studies would require the selected NHP genome to exhibit a perfect on-target sequence match for the candidate gRNA, so another bioinformatic pipeline was developed to annotate the human-derived spacers against NHP genomes and characterize the strength of sequence match. Computational intersection of the species-specific spacer annotations produced a list of human spacers with perfect on-target sequence identity in common NHP genomes.

Next, an *in silico* CRISPR off-target analysis pipeline was modified and applied to the list of spacers with pan-species on-target sequence identity. For each spacer, the pipeline produced a list of potential off-target *loci* in each primate species' genome within defined mismatch criteria for both spacer and PAM sequences. Another bioinformatic pipeline was developed to annotate the off-target sites in each genome with the overlapping and nearest neighbor genes.

Comparison of the off-target profiles between species reveals the fraction of human off-targets also found in the off-target predictions in each NHP genome. Results were combined for all spacers stratified by Cas nuclease. The data, representing a robust and inclusive panel of guide RNAs across the human genome, demonstrate that NHP experimental models do not recapitulate a majority proportion of CRISPR guide RNA off-target activity in the human genome despite high overall genomic sequence similarity between primate species. These results highlight the importance of understanding limitations of NHPs for the study of CRISPR gRNA specificity and especially for contextualizing human risk informed by these studies.

644 Leveraging DNA Missing from the Human Genome to Generate CRISPR Targetable Sequences Without Off-Target Effects

Sarah Fong[1], Orry Elor[2], Yelena Guttman[2], Vladyslav Barskyi[2], Benianmin Krupkin[2], Coline Arnould[2], Ofer Yizhar Barnea[2], Nadav Ahituv[3]
[1]University of California San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, [3]University of California, San Francisco, San Francisco, CA

CRISPR off-target effects, including non-specific guide RNA mismatches, are a major hurdle for CRISPR therapy development. To overcome this limitation, we tested whether 15 nucleotide-long DNA sequences missing from human reference genomes and six model organism genomes (including mouse, rat, fly, worm, yeast, E. coli)—termed nullomers—are more precise protospacer targets for the CRISPR machinery. As a proof-of-concept for this approach, we used CRISPR activation (CRISPRa) and inactivation (CRISPRi) to test improvements in nullomer-protospacer targeting. We engineered thousands of previously characterized promoters and enhancers with nullomer-protospacer sequences. Using massively parallel reporter assays (MPRAs), we find that nullomer-protospacer sequences have a minor effect on endogenous regulatory activity and can be safely embedded in these elements. We are currently using these regulatory building blocks to downregulate (CRISPRi) or upregulate (CRISPRa) transgene activity with nullomer-targeting sgRNAs and analyzing them for off-target effects using a variety of genomic tools. In summary, our approach engineering nullomer-protospacer sequences into regulatory elements for CRISPRa/i systems provides a significant advancement in genome engineering by leveraging protospacer sequences absent from the human genome. Our work offers a promising strategy to improve the precision of genetic research tools and gene therapies by ensuring robust gene regulation with minimal off-target effects.

645 TOP-SECRETS Enables Cas9 Nucleases to Differentiate SNVs Outside of PAMs

Ashley Herring-Nicholas[1], Eric Josephs[2]*
[1]UNC Greensboro, Greensboro, NC, [2]Stony Brook University, Stony Brook, NY
**Corresponding Author*

CRISPR-Cas9 has emerged over the past several years as a powerful biotechnological tool that holds tremendous therapeutic potential in treating genetic diseases, including several that have entered clinical trials. However, the possibility of unintended Cas9-induced mutational events raises significant concerns, especially in distinguishing single nucleotide variants (SNVs). To address this, we developed a novel high-throughput *E. coli*-based screening platform entitled, Selection of Extended CRISPR RNAs with Enhanced Targeting and Specificity (SECRETS), designed to quickly screen tens of thousands to hundreds of thousands of extended guide RNAs (x-gRNAs) and identify those that significantly enhance Cas9 specificity while maintaining robust on-target activity. Using an *in vitro* cleavage assay targeting several genes – *EMX1, FANCF, VEGFA,* and *HBB,* we consistently find that x-gRNAs selected through SECRETS outperform high-fidelity Cas9 variants by maintaining on-target activity levels while eliminating cleavage at off-target sequences differing by as few as two mismatches (Fig. 1). Additionally, these x-gRNAs do not generate new off-targets, as evidenced by CHANGE-seq analysis of Cas9 editing in A549 cells.

With further improvement of this system, we also developed Targeting Overlapping Protospacers with SECRETS (TOP-SECRETS) to discriminate between pathogenic and non-pathogenic alleles at SNVs outside the protospacer adjacent motif (PAM) – a capability that is currently unachievable with standard Cas9 approaches. We tested this by

targeting the KRAS G12D mutation, an undruggable oncogenic mutation frequently found in multiple cancers. We find that TOP-SECRETS can identify x-gRNAs that retain high on-target activity *in vitro* at the pathogenic allele with no detectable activity at the healthy allele (Fig. 2a). We also validated this approach with clinically relevant mutations in MED12, which are responsible for ~70% of uterine fibroids, and where mutations abolish a PAM site – the opposite of typical PAM-targeting approaches. Again, x-gRNAs identified via TOP-SECRETS maintain high on-target activity *in vitro* at the pathogenic allele while exhibiting no activity at the healthy allele (Fig. 2b).

These findings show that SECRETS and TOP-SECRETS can be used to robustly generate x-gRNAs in a design-free way that reduces the need for individualized optimization and is streamlined to test any identified on-target/off-target pair. This approach of designing gRNAs with extreme precision opens the door for allele-specific gene editing and has profound implications for personalized medicine, particularly in the treatment of monogenic disorders, cancer, and other genetic diseases where SNV-targeted correction is required, especially outside of a PAM.

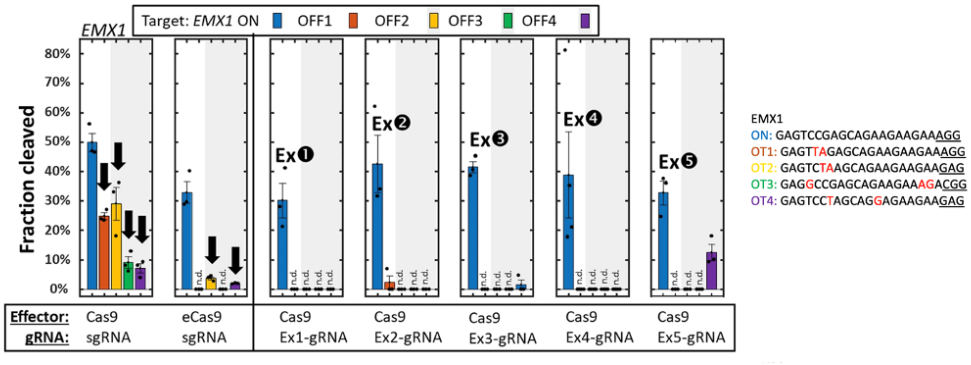


Figure 1. All five x-gRNAs exhibit remarkable on-target activity and greatly reduced off-target activities across four known off-target sites for the standard gRNA during *in vitro* cleavage assays using purified components. (n = 3 replicates each, dots are individual data points. Error bars = standard error of the mean. Black arrows highlight the off-target activity of Cas9 and eCas9 with the sgRNA that was blocked when using x-gRNAs).

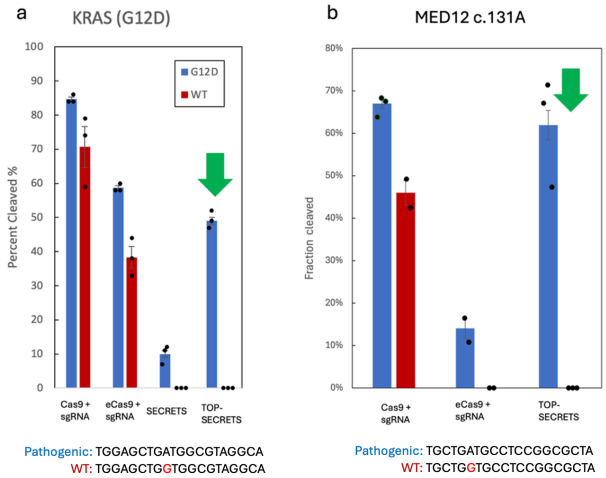

Figure 2. X-gRNAs identified via TOP-SECRETS exhibit increased specificity profiles compared to Cas9 and maintain robust activity as compared to eCas9. (n = 3 replicates each, dots are individual data points. Error bars = standard error of the mean. Green arrows highlight the activities of the x-gRNAs).

646 Reprogramming Large Serine Recombinases for Site-Specific Integration into Mammalian Genomes

Aksana Schneider[1], Liliya Mukhametzyanova[2], Sahithi Seedarala[2], Juliane Sturm[1], Diana Federl[1], Melanie Brux[1], Sven Papsdorf[2], Lukas Schmitt[1], Melania Zauri[3], Teresa Rojo-Romanos[2], Maciej Paszkowski-Rogacz[1], **Felix Lansing[3]***

**Corresponding Author*

Accurate and efficient integration of large DNA sequences into specific genomic sites is essential for numerous medical, agricultural, and research applications. Current methods often rely on inducing double-stranded DNA breaks and relying on cellular DNA repair pathways such as NHEJ or HDR, which have their limitations. Serine integrases, such as Bxb1, offer a promising alternative as they can catalyze precise DNA recombination without generating free DNA ends. However, customizing these integrases for specific genomic targets remains challenging. We have employed directed evolution and rational engineering to generate Bxb1 variants capable of targeting defined genomic loci.

Through directed evolution of rationally designed libraries in bacteria, we successfully generated Bxb1 variants with activity at defined genomic sites in the human genome. Furthermore, we show that that the activity levels achieved in bacteria translate in reporter assays in human cells. Finally, we demonstrate and confirm target integration at the DNA level in the selected genomic locus using our evolved LSR variants.

Our study showcases the reprogramming of Bxb1 for integrating gene-sized DNA cargo into the human genome without requiring the prior integration of WT BxB1 binding sites (attB). Efficient integration was demonstrated for a target site that differs in 17 out of 38 nucleotides from the WT attB target site demonstrating that we do not require pre-existing pseudo recombination sites with high homology to attB. A genome wide analysis with our proprietary search motif revealed flexible targeting across the whole human genome. This novel approach highlights the versatility of Seamless Tx Recombinase Programming technology, offering efficient and precise genome editing capabilities for a wide range of applications.

647 CRISPR Engineered Humanized Albumin Mouse ("hAlb-CR") Achieves Robust Transgene Expression following Liver-Targeted Gene Insertion

Jacqueline Frost[1]*, James Krantz[2], Angela Mote[3], Kelsey Higgins[2], Mason Zlotnik[2], Holly Schroeder[3], Nelly Mettenbrink[4], Sophie Fahlenbock[5], Sören Turan[6], Marco Weinberg[7], Sherif Gabriel[8], Andre Cohnen[6], Prabhakar Bastola[9]
[1]AskBio, Morrisville, NC, [2]AskBio Inc., Morrisville, NC, [3]Askbio, Research Triangle Park, NC, [4]Bayer AG, Berlin, Germany, [5]Bayer AG, Wuppertal, Germany, [6]Bayer AG, Wuppertal, Nordrhein-Westfalen, Germany, [7]ReCode Therapeutics, Durham, NC, [8]AskBio, Durham, NC, [9]AskBio Inc., Research Triangle Park, NC
**Corresponding Author*

Humanized mouse models are crucial for preclinical drug development, particularly in the context of gene editing technologies. These models offer a unique advantage for *in vivo* evaluation of guide RNAs (gRNAs) that target human loci. We developed a CRISPR-engineered humanized mouse model ("hAlb-CR") where the human *albumin* exon 1 and intron 1 locus, a well-characterized safe harbor site, was integrated into the endogenous mouse *albumin* locus. This model allows for the direct evaluation of human-specific gRNAs within a phylogenetically relevant *in vivo* context.

We conducted systematic studies to validate the hAlb-CR mouse model. First, we compared hAlb-CR heterozygotes against age-matched Wild-Type control mice and an existing hAlb model ("hAlb-BAC") featuring a randomly inserted bacterial artificial chromosome containing the human albumin gene. These three models were treated with an AAV-reporter construct, packaged with a liver tropic capsid, and Lipid Nanoparticles (LNPs) containing SpCas9

and either human or mouse-specific gRNAs. This study showed 5-fold higher insertional reporter expression with hAlb-CR heterozygous mice compared to hAlb-BAC homozygous age-matched litter mate controls, while displaying nearly identical editing. The hAlb-CR model secreted similar levels of albumin as their age-matched wild-type littermates. This suggests that a nominal decrement in albumin expression following insertion at this locus is safe and will not adversely affect the maintenance of intravascular oncotic pressure. These models are relevant to evaluate the efficacy of potential clinical candidates utilizing the human albumin insertion approach, which is a predominant therapeutic locus of interest.

Next, we assessed the preclinical relevance of the homozygous hAlb-CR model by evaluating targeted insertion of a therapeutic protein at the human *albumin* locus. cDNA of a therapeutic protein was delivered via AAV, followed by LNP-mediated delivery of multiple nuclease variants and corresponding human gRNAs. All nuclease variants yielded robust therapeutic protein secretion. Notably, expression levels achieved through insertional editing were comparable to those observed with episomal AAV expression at similar doses. No significant changes in albumin levels were observed across treatment groups.

These findings demonstrate the utility of the hAlb-CR model for *in vivo* pre-clinical evaluation of nucleases, guides and therapeutic cassettes targeting the human *albumin* locus for relevant therapeutic applications.

648 A Protein-Guided Modular Integrase (MINT) Platform Enables Compact Therapeutic Payloads and Efficient Targeted Integration in T Cells

Jeffrey Miller[1]*, Friedrich Fauser[2]*, Sebastian Arangundy Franklin[3], Jessica Davis[2], Lifeng Liu[2], Nicola Schmidt[2], Luis Rodriguez[2], Nicholas Scarlott[2], Rakshaa Mureli[4], Irene Tan[2], Yuanyue Zhou[5], Danny Xia[2], Sarah Hinkley[6], Bhakti Kadam[2], Nga Nguyen[2], Stephen Lam[2], Bryan Bourgeois[2], Emily Tait, Mohammad Qasim[2], Vishvesha Vaidya, Adeline Chen[2], Andrew Nguyen, Yuri Bendana[2], David Shivak[2], Patrick Li[7], Andreas Reik[8], David Paschon[8], Gregory Davis[8]

Targeted integration (TI) of large DNA sequences into endogenous genomic loci has numerous potential applications in genomic medicine, agricultural trait development, synthetic biology, and basic research. Large serine integrases (LSIs) such as Bxb1 would represent ideal reagents to perform TI if they could be reprogrammed to integrate with high efficiencies at desired sites. LSIs recognize their targets using a protein-guided mechanism that allows for more compact and therefore more easily deliverable enzymes than the more common RNA-guided approaches. Notably, their covalent serine-DNA strand transfer mechanism is potentially safer than nuclease-based TI methods as it minimizes free DNA ends that can cause translocations and large deletions. However, high-efficiency direct reprogramming of LSIs has yet to be demonstrated.

With our Modular Integrase (MINT) platform we have identified three regions within Bxb1 that have a profound impact on the enzyme's specificity profile. Performing directed evolution upon 6-7 amino acid residues in each region can almost completely reprogram the targeting preferences for the corresponding portions of the target site. We build upon this work by combining our engineered Bxb1 variants with Bxb1 hyperactive mutations to dramatically increase integration efficiency. To enable therapeutic applications, we then explored alternative donor formats such as mini-circles and nanoplasmids.

With these improvements to our MINT platform, we demonstrate high-efficiency direct reprogramming of Bxb1 without relying on other gene editing tools to pre-install a natural Bxb1 recombination site. We further characterized our MINT platform by evaluating its genome-wide specificity profile and adding mini-circle and nanoplasmid donor delivery capabilities or our existing plasmid and AAV donor capabilities. This represents significant progress towards potential therapeutic applications such as integration into safe harbor loci and integration of a corrected coding sequence into introns of disease-causing genes.

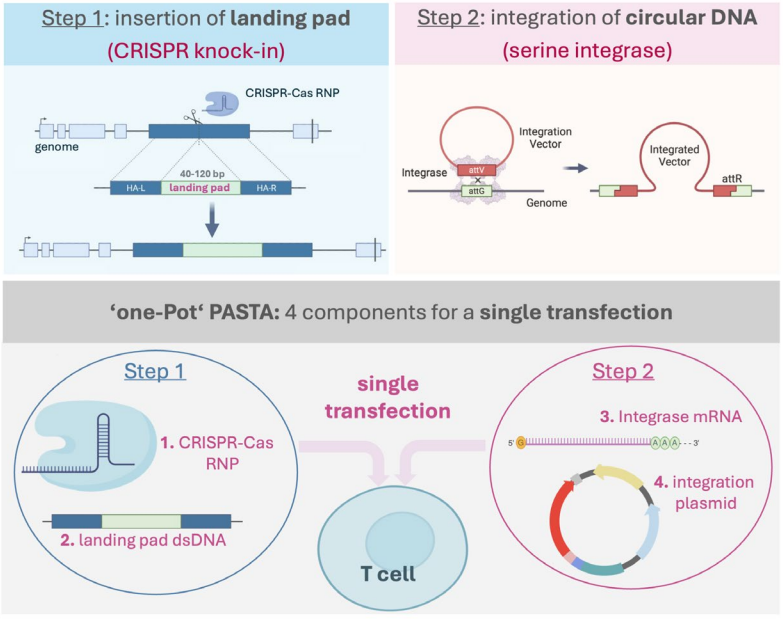
649 PASTA: CRISPR Knock-In Paired with Integrase for Simple, Precise, and Efficient Large Transgene Insertion in T Cells

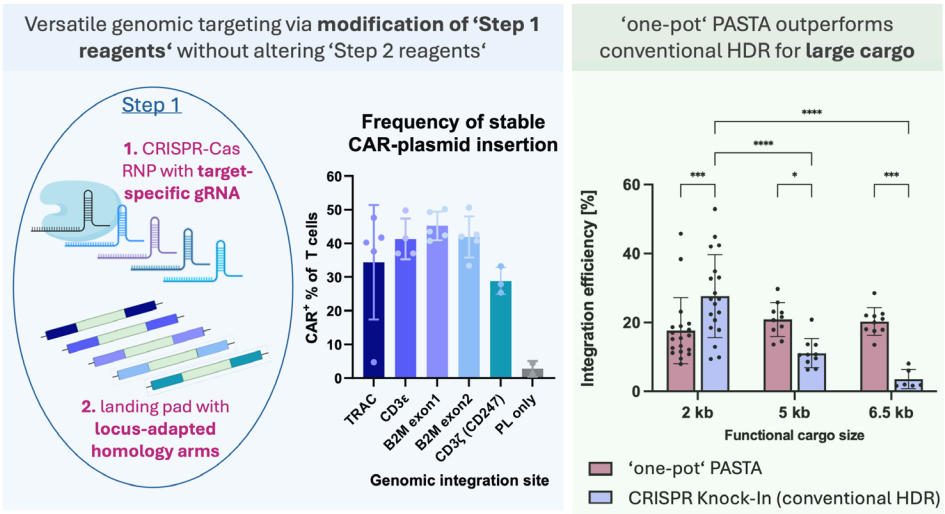
Jonas Kath[1], Isabell Kassing[2], Ana-Maria Nitulescu[3], Viktor Glaser[4], Marie Pouzolles[2], Shona Shaji[5], Yaolin Pu[6], Laura Hartmann[7], Maik Stein[8], Daniel Ibrahim[9], Dimitrios Wagner[5]
[1]Charité - University Medicine Berlin, Berlin, Germany, Germany, [2]Baylor College of Medicine, Houston, [3]Charité - University Medicine Berlin, Berlin, Berlin, Germany, [4]Charite – Universitatsmedizin Berlin, Berlin, GERMANY, [5]Baylor College of Medicine, Houston, TX, [6]BIH Center for Regenerative Therapies, Berlin, GERMANY, [7]Baylor College of Medicine, Berlin, Berlin, Germany, [8]Berlin Institute of Health at Charite, Berlin, Berlin, GERMANY, [9]Charité - University Medicine Berlin, Berlin, Germany

Adoptive cell therapy using gene-modified T cells expressing target-specific receptors has emerged as a powerful treatment for malignancies and autoimmune diseases. However, current gene transfer methods, such as lentiviral transduction and homology-directed repair (HDR), are limited in their ability to efficiently and precisely integrate large DNA sequences, constraining the scope of T-cell engineering.

To overcome these challenges, we developed PASTA (programmable and site-specific transgene addition), a two-phase approach enabling efficient, site-specific integration of large transgene cassettes. In Phase 1, a **small DNA landing pad** is introduced into the genome via CRISPR-Cas-mediated HDR. In Phase 2, a large serine integrase (e.g., Bxb1) precisely inserts a **circular DNA** vector into the landing pad. This streamlined "one-pot" process is initiated by a single transfection, simplifying the procedure and enhancing clinical applicability (**Figure 1**). We demonstrate that 'one-pot' PASTA enables efficient transgene insertion at key genomic loci for T-cell engineering, including TRAC, *B2M*, *CD3E*, *CD3Z (CD247)*, and *GAPDH* (**Figure 2, left**). Compared to conventional HDR, integrase-mediated insertion improves knock-in rates by 9-fold (range: 2.5–14-fold) when integrating a 6.5 kilobase (kb) therapeutic tri-cistronic transgene cassette. This results in targeted knock-in rates exceeding 20% after a single electroporation with an 8.5 kb plasmid (**Figure 2, right**). The transgene cassette contains two antigen receptors for dual-antigen targeting and a safety switch. The resulting dual-antigen targeting CAR T cells are currently being evaluated in mouse models for antigen escape in B-cell lymphoma, a common cause of relapse after mono-targeted CAR T-cell therapy.

Overall, 'one-pot' PASTA is a precise, versatile, and efficient non-viral gene transfer platform for large, multicistronic transgene cassettes. It simplifies T-cell engineering and provides a more flexible alternative to prime editing-based strategies like PASSIGE and PASTE.





650 Large DNA insertion at genomic safe harbors in human cells using a site-directed transposase

James Short[1], Lisa Sharek[1], Joshua Meckler[2], Brian Hew[1], Brandon Johnson[1], David Waller[1], Ilko Stoytchev[1], Shanfu Xie[3], Joseph Higgins[3], **Jesse Owens[1]***

Integrating large DNA sequences at specific genomic locations remains a challenge in gene therapy. Virus-based methods lack insertion site control, raising concerns about insertional mutagenesis. Non-integrating viral vectors like AAV are immunogenic, limiting repeat dosing. Sequence-specific strategies like CRISPR-Cas9 nucleases introduce unprotected double-strand breaks (DSBs), which can lead to deletions, chromosomal rearrangements, and chromothripsis via non-homologous end joining (NHEJ). While homology-directed repair (HDR) enables site-specific insertion, it is inefficient in non-dividing cells and impractical for large DNA sequences. Base editors and prime editors avoid DSBs but have limited edit sizes. CRISPR nucleases can also activate a p53-mediated DNA damage response, selecting for cells with impaired p53 function.

Transposons offer a promising alternative by integrating DNA without unprotected DSBs. Among transposable elements explored for gene therapy, piggyBac, Sleeping Beauty, and Myotis lucifugus transposase (MLT, or piggyBat) can integrate large DNA sequences (>100 kb) at TA or TTAA sites. These elements use a single transposase enzyme to excise and insert transposon DNA without generating unprotected DSBs.

A targeted transposase system could provide a powerful gene therapy tool. Previously, we demonstrated that fusing transcription activator-like effectors (TALEs) or dCas9 to piggyBac transposase enabled targeted DNA insertion, resulting in clonal isolated cells with single, site-specific integrations. However, this approach required extensive screening due to low targeting efficiency (~0.06%). Here, using structural predictions, we introduced mutations that disrupted MLT's native DNA-binding function while preserving its catalytic activity. By linking DNA-binding proteins to MLT, we aimed to restore targeted integration.

We systematically evaluated 10 factors influencing targeted integration: (1) spacing between the DNA-binding protein's target sequence and the target TTAA site, (2) amino acid linker composition (3) target sequence orientation relative to the TTAA site, (4) whether one or two DNA-binding protein target sequences flank the TTAA site, (5) transposase linkage site (N-terminus, C-terminus, or internally), (6) DNA-binding protein type (zinc fingers vs. TALEs), (7) sequence adjacent to the TTAA site, (8) genomic location of the binding protein's target sequence, (9)

whether the binding protein was covalently or non-covalently linked, and (10) mutations in the transposase DNA-binding domain to reduce off-target insertion while maintaining efficiency.

Using a plasmid-based assay, we identified strict targeting rules. Key factors included a non-covalent transposase–DNA-binding protein linkage and strict base-pair spacing between the binding protein's target sequence and TTAA site. Applying these rules to safe harbor sites, we achieved high-efficiency on-target insertions at multiple loci. Our most promising configuration resulted in over 50% of cells containing an on-target insertion. An off-target assay showed near-background activity, indicating DNA-binding domain mutations reduced unwanted insertions.

This programmable transposase system enables site-specific genomic integration without unprotected DSBs, minimizing off-target effects while allowing efficient insertion of large DNA sequences. These findings provide a framework for developing safer, more precise gene integration technologies.

651 Programmable Site-Specific Super piggyBac Transposase for Integration of Large DNA Payloads into Endogenous Genomic Sites

Joseph Lucas[1], **Andres Valderrama[1]**, Ming Lee[1], Michelle Xu[2], Min Tong[1], Brandon Molina[1], Charlie Hatter[1], Dongyang Zhang[1], Olga Batalov[1], Matthew Nitzahn[1], Lucas Homa[1], Oscar Alvarez[1], Ana Carneiro[1], Khalid Hajj[1], Alicia Davis[1], Jacob Reichert[1], Haibin Xi[1], Nikki Nguyen[1], Sang Lee, Fernando Lopez Espinoza[3], Blair Madison[1]
[1]Poseida Therapeutics, San Diego, CA, [2]San Diego, CA, [3]Poseida Therapeutics, San Diego

The site-specific Super piggyBac (ssSPB) is a novel transposase system that combines the advantageous features of the Super piggyBac (SPB) transposase with the precision of targeted integration. The ability of SPB to insert large DNA payloads into mammalian genomes without introducing double-strand breaks (DSBs) in the genome (and thus not relying on endogenous DNA repair machinery) sets it apart from nuclease-based integration approaches using CRISPR-Cas9. The SPB cut-and-paste mechanism minimizes the chance of integrating truncated or mutated cargos. Additionally, SPB's propensity to integrate at TTAA sites in introns and intergenic regions is favorable from a genotoxicity perspective. Nevertheless, the inability to target integration to specific genomic locations can constrain its use in specific therapeutic applications.

Site-specificity expands the possibilities of transposase-based genome engineering by enabling gene replacement, promoter-less transposon designs, and expression uniformity among edited cells. By fusing a TAL effector DNA-binding domain (DBD) to the SPB transposase, we created a reprogrammable tool capable of integrating transgenes into specific genomic loci. Previous site-specific transposases suffered from low integration rates, making these systems inadequate for cell and gene therapy applications. In contrast, our structure-based design, informed by cryo-EM and AlphaFold simulations, precisely positions the DBD and transposase domains, resulting in efficient site-specific integration into mammalian genomes. Furthermore, re-engineering the transposase to function as a dimer rather than a tetramer, along with incorporation of additional thermostability and hyperactive substitutions resulted in a 2-log improvement in integration efficiency.

Given the DSB-free integration, the ssSPB platform is particularly well-suited for targeting repetitive loci, with observations that the integration efficiency scales with the number of target sites. By swapping its TAL DBD domain, ssSPB can be readily reprogrammed to such repetitive sites. Unlike nuclease-based methods that generate DSBs, ssSPB can target repetitive sequences like rDNA, without any genotoxicity. Targeting rDNA offers several advantages: high integration rates, safe harbor characteristics, species-to-species conservation, and the ability to enhance trafficking through fusion with nucleolar localizing proteins. In resting primary T-cells, 1-10 integrations per 100 haploid genomes were achieved using this enhanced trafficking strategy delivering a CAR expression cassette.

We next demonstrated the efficacy of the ssSPB system in vivo, utilizing a hybrid delivery strategy involving LNP-mediated mRNA delivery of the transposase targeting rDNA and AAV-mediated delivery of the transgene. This approach resulted in high editing efficiencies in juvenile mice of up to 5 integrations per 100 haploid genomes, quantified by ddPCR, with greater than 99% on-target integration fidelity as assessed by ligation-mediated PCR

(LM-PCR). Integration rates remained stable for the duration of the study (up to 56 days). We also demonstrate the feasibility of full non-viral delivery (utilizing nanoplasmid DNA-LNP transposon donors).

The ssSPB system offers a versatile and efficient platform for precise genome engineering holding great promise for the development of novel in vivo and ex vivo therapeutic strategies.

652 Site-Specific Integration of Therapeutic Transgenes with a Type V-K CAST System Engineered for Efficient and Targeted Human Genome Editing

Gene editing technologies capable of efficient and specific integration of large transgenes into the human genome have the potential to bring curative treatments to diverse patient populations by providing a single approach that could cover the majority of disease-causing mutations. Recently, we and others demonstrated that CRISPR-associated transposases (CAST) discovered from microbes can be repurposed and programmed for site-specific, targeted integration of gene-sized DNA cargoes into the human genome. Here, we demonstrate that CAST protein engineering and delivery optimization enable efficient integration of diverse cargo designs across different cell types and target loci, including with therapeutically-relevant delivery approaches that are expected to be required for in vivo editing. Through structure and AI-guided protein design, we show that integration efficiency of a compact type V-K CAST system derived from uncultivated microbes can be improved by >50x compared with the natural system. Furthermore, an 'all-in-one' mRNA expressing multiple protein components can be used to deliver the system for efficient editing in primary hepatocytes. Combined with the fact that CAST integration uses a transposase to circumvent double-stranded DNA breaks, these advancements suggest important advantages over other gene editing approaches, especially those that are dependent on DNA repair machinery that may not be active in cell types targeted in vivo. Given their programmability and efficiency integrating large DNA cargoes, CAST systems have the potential to treat any genetic disease caused by a loss-of-function mutation, and contribute to other important advances in biotechnology and synthetic biology.

653 Proof of Concept for Automated Ntensify Manufacturing platform of mRNA: Productivity and Quality Assessment

Michaël Lambin[1], Jérôme Laval[2], Pol Harvengt[1], Mélanie Duyck[1], Maha Dridi[2], Wei Rong[1], Olivier Frère[1], Vasily Medvedev[3], **Hanna Lesch[4]***

The field of mRNA therapeutics requires scalable, efficient, and Good Manufacturing Practice (GMP)-compliant production platforms to meet the increasing demands of both R&D and clinical applications. A proof-of-concept study was conducted to evaluate the first automated, standardized mRNA manufacturing platform, Quantoom's Ntensify™ system. Robust analytical assays were developed alongside production advancements to ensure the quality and regulatory compliance of mRNA therapeutics.

Key attributes like yield, purity, integrity, capping efficiency, poly(A) tail length, and residual contaminants are rapidly assessed using techniques such as High-Performance Liquid Chromatograph HPLC, (capillary) electrophoresis, and mass spectrometry. Integrating these GMP-compliant platforms with automated manufacturing has enhanced quality control and streamlines the transition from R&D to production.

Ntensify™ platform utilizes silica bead-based single-step purification and GMP-ready premixes, eliminating the need for custom process development while minimizing material variability. Robust scalability was demonstrated, with volumes ranging from 50 µL to 20 mL optimized for both R&D and GMP production. Linearized and purified plasmid DNA was used as a template, and the Ntensify™ in vitro transcription (IVT) process was first tested manually at small scale (125µL), achieving a total RNA productivity after one-step purification of 4.30 mg/mL with an RNA integrity of 89%. Scaling the manual process to a "Midi" scale (20ml) yielded 4.71 mg/mL with 91% RNA integrity. Applying the same process in the “Midi” automated system resulted in 4.77 mg/mL yield with 93% RNA integrity. Capping efficiency and poly(A) tail length were consistent between manual and automated processes, with capping efficiencies of 96% and 94%, and poly(A) tail lengths of 90% and 91%, respectively.

Quality assessments of the RNA drug substance produced in Midi automated system showed residual plasmid DNA levels of 0.18 ng/mg RNA and dsRNA content of <0.01%. Large-scale manufacturing is achieved through a scale-out strategy, bypassing the need for additional scale-up steps. These results highlight the advantageous of the automated Ntensify™ platform to streamline mRNA production, supporting a wide range of applications such as vaccinations, personalized cancer vaccines, and other therapeutics.

654 Development of a SMARTvector™ Multiplex shRNA Platform for Complex Cell Therapy Engineering with a Single Vector

Amanda Haupt[1], Shannon Hinsdale[2], Zaklina Strezoska[3], Emily Anderson[2], Hidevaldo Machado[4], Jesse Stombaugh[3], Immacolata Porreca[5], Kevin Hemphill[3]
[1]Revvity, Superior, CO, [2]Revvity, Lafayette, CO, [3]Revvity, UNITED KINGDOM, [4]Revvity, Lafayette, [5]Revvity, CAMBRIDGE, Cambridgeshire, United Kingdom

Chimeric antigen receptor (CAR) T cell therapy represents a new era of cell-based immunotherapies, allowing for targeted killing of cancer, often blood cancers, expressing a specific antigen. Despite the success of several CAR T cell therapies achieving FDA approval, these therapies often suffer from T cell exhaustion, which can present as reduced cytolytic activity, increased expression of inhibitory receptors, and reduced proliferative capacity. These outcomes render the treatment less potent, pointing towards a need to develop more advanced and tunable methods of modulating CAR T cells to be more robust and reliable. Gene editing approaches such as CRISPR-Cas9 have successfully been used for disruption of genes such as PDCD1, an inhibitory receptor involved in CAR T cell dysfunction, to enhance CAR T cell performance ex vivo. Despite the efficiency of CRISPR-Cas9, the number of targets that can be edited in a single sample is partially limited by increased cytotoxicity associated with DNA double-strand breaks (DSBs), thus limiting the therapeutic applicability. Additionally for some targets a knockdown approach might be favorable over a knockout approach. Here we present the SMARTvector lentiviral shRNA technology, a method for simultaneous introduction of a genetic payload, such as a CAR, with multiplex gene knockdown in immune cells from delivery of a single expression vector. We show that up to eight shRNAs and an anti-CD19 CAR can be expressed after a single lentiviral transduction, thus providing a safe alternative of targeting multiple genes while maximizing CAR T cell engineering.

We developed the SMARTvector multiplex shRNA technology with multiple repeats of a patented microRNA scaffold, flanking artificial DNA sequences that target mRNA transcript(s) of interest for efficient gene knockdown. The vector design includes a tunable promoter and optional selection markers for specific targeted development. Here, an array of multiple shRNAs was generated in a single expression vector with efficacy measured by RT-qPCR to assess relative mRNA transcript knockdown or flow cytometry for assessment of functional protein knockdown.

We have demonstrated that up to eight shRNAs can be expressed from a single expression vector, resulting in sustained expression and efficient gene knockdown in HEK cells, primary T cells, and iPSCs. In addition to achieving high knockdown efficiency, we have engineered a vector with optimal linker length between each microRNA-based shRNA encoding region and evaluated position related impacts of each shRNA on the multiplexed cassette. We demonstrate that the SMARTvector multiplex shRNA technology is highly modular and adaptable, making it primed for use in a wide range of cell therapy applications, such as generation of allogenic CAR T cell therapies.

655 CircVec: a powerful circular RNA expression platform to enhance viral and non-viral gene and cell therapies

Eoghan O'Leary[1], Juan Zhang[2], Summer Stefanelli[2], Erik Digman Wiklund[3], Victor Levitsky[4], **Thomas Hansen[2]**
[1]Circio AB, HASSELBY, Sweden, [2]Circio AB, Huddinge, Stockholms lan, Sweden, [3]Circio AB, Hässelby, Stockholm, Sweden, [4]Circio AB, Huddinge, Sweden

Circular RNA (circRNA) is a stable, endogenous class of non-coding transcripts found across most eukaryotes. Unlike mRNA, circRNA resists exonucleolytic RNA turnover, ensuring greater stability and persistence within cells. Advances in understanding circRNA biogenesis, functionality, and its engineering for efficient protein translation have established circRNA as a next-generation therapeutic RNA, with the potential to surpass conventional linear mRNA technologies.

Circio technology platform, circVec, is a novel powerful modular genetic cassette for potent and durable spliceosome-mediated intracellular circRNA expression from viral and non-viral DNA vectors. *In vitro* studies show that circVec achieves nearly 10x higher protein expression levels than conventional mRNA-based vectors one-week post-transfection.

In vivo, intramuscular injections of circVec DNA vectors have demonstrated up to 15x higher and substantially more durable protein expression compared to mRNA vector systems, with the most significant effects observed at low doses, reflecting the most clinically relevant conditions.

Bioinformatic modelling of RNA half-lives from long-term experimental *in vivo* data showed statistically inferred circRNA half-life of over 600 hours, compared to just 9 hours for mRNA, representing 70-fold improved RNA durability *in vivo*. This prolonged half-life results in a fundamentally distinct temporal expression profile, where the closed-loop circular structure enables a sustained accumulation and persistence of expression over a long period of time.

Continued optimization of the circVec genetic cassette has identified several critical genetic elements leading to significant enhancements in therapeutic protein expression compared to both mRNA expression vectors and earlier circVec generations These new genetic components impact the current understanding of gene expression biology in general and may be further modified to potentiate both viral and non-viral gene therapy vectors.

Systemic delivery of circVec has been tested in vivo using AAV9 viral constructs and LNP-packaged DNA vectors. Current results indicate tissue specific accumulation of circRNA expression particularly in extra-hepatic organs, such as muscle, heart and spleen. Ongoing experiments aim to further characterize and quantify the expression profile of the latest optimized circVec vector design and identify target tissues best suited for circRNA expression and accumulation. These data will support the identification of the most promising targets and tissues for development of future circVec-based therapeutic candidates.

With its ability to drive robust, durable circRNA biogenesis and sustained protein expression across a variety of vector systems and tissue types, the circVec platform offers transformative potential for next-generation gene and cell therapies. Circio is currently testing and optimizing circVec AAV and DNA vectors for gene and cell therapy applications, with the aim to advance one or more candidates towards clinical development.

656 Next-Gen Circular RNA: A Promising mRNA Alternative with Enhanced Stability and Therapeutic Applications

Minju Park[1], Jeong-Ki Kim[2], Sunhee Lee[3], Yeonjin Yoo[3], Junyoung Choi[3]
[1]ST Pharm, Ansan-si, Korea, [2]ST Pharm, Ansan-si, Gyeonggido, South Korea, [3]ST Pharm, Ansan-si, South Korea

Circular RNA (circRNA) is a type of single-stranded RNA with a covalently closed loop structure, which confers resistance to exonuclease-mediated degradation. This circular structure offers several advantages over linear

mRNAs, including a longer half-life, enhanced protein expression, functional stability, and reduced immunogenicity. To harness circRNA for therapeutic purpose, we have developed a novel method for producing circRNAs with efficient protein expression, utilizing ribozymes and RNA ligase. Our technology significantly improves circularization efficiency compared to traditional Group I permuted intron-exon (PIE) systems, especially for large genes. Using firefly luciferase as a model, we demonstrated that the activity of the protein by the circRNA was 80-fold and 7.6-fold higher compare to conventional mRNA *in vitro* and *in vivo*, respectively. Additionally, our circRNA technology has been successfully applied into CRISPR/Cas9 gene editing and Bio-PROTAC systems. Furthermore, we have developed and established a process for the mass production of GMP grade circRNAs. Taken together, the circRNAs generated by our technology hold great potential as a new class of therapeutics, offering a promising alternative to traditional mRNA-based therapies for a variety of diseases.

657 Advanced Capillary Electrophoresis Techniques for Monitoring mRNA-based Vaccine and Therapeutic Development: From Plasmid DNA to mRNA Encapsulation

Tyler Davis[1], Tingting Li[2], Sahana Mollah[1], Elliott Jones[1]
[1]*SCIEX, Redwood City, CA,* [2]*Sciex, Brea, CA*

The flexibility and diversity of capillary electrophoresis (CE) have proven to be invaluable tools in the characterization of mRNA-based vaccines and therapeutics during the discovery and development process. Evaluations of key characteristics like purity, integrity, stability, and encapsulation efficiency play an important role in ensuring the safety and efficacy of the final product. This poster spotlights some of the CE-based analyses and kits used for this characterization, starting with the high-resolution separation of plasmid isoforms and linear DNA fragments for the analysis of plasmid DNA topology and purity. This is followed by the rapid assessment of mRNA poly(A) tail length and distribution. Additionally, stability is measured by monitoring the purity and integrity of mRNA molecules over time. Lastly, the encapsulation efficiency of mRNA-LNP is accurate determined utilizing size-based separations.

These studies can be performed using both the single-capillary PA 800 Plus system and the multi-capillary BioPhase 8800 system, providing valuable insights and comprehensive characterization of mRNA-based vaccines and therapeutics.

658 Repurposing CRISPR Knock Out Screens to Identify Cancer-Killing sgRNAs.

Alexis Bennett[1], Selina Shiqing Teh[1], Kirsten Bowland[1], James Eshleman[1], Hong Liang[1]
[1]*Johns Hopkins University School of Medicine, Baltimore, MD*

Background: CRISPR/Cas9 is a prokaryotic adaptive immune system used widely for its programmable ability to induce double-strand DNA breaks (DSB) in the presence of a target sequence and protospacer adjacent motif (PAM). Our lab has previously shown inducing more than 12 DSBs simultaneously with CRISPR/Cas9 results in more than 95% cancer cell death. Hundreds of cancer-specific PAMs can be identified via alignment of a patient's normal whole genome sequencing (WGS) data to their tumor WGS data. How to best identify safe and therapeutically effective sgRNAs that induce a single DSB remains unknown.
Hypothesis: We hypothesize that CRISPR knock-out (CRISPRko) screens, where toxicity of a DSB-inducing sgRNA within cells is inferred from a decrease in abundance of the sgRNA over time, are sufficiently sensitive to identify top performing and safe sgRNAs for selective killing of cancer cells.
Methods: Cancer-specific PAMs were identified by aligning the patient's genome with their tumor's genome, identifying a set of mutations present in the patient's tumor and absent in their normal tissues. Mutations from the tumor genome were assessed for novel tumor-specific PAM formation, and novel PAMs were analyzed for potential off-target activity using Cas-OFFinder. Oligonucleotide libraries of cancer-specific sgRNAs were produced by Twist Biosciences and shotgun-cloned into a lentiGuide-puro (without Cas9) or lentiCRISPR-V2 (with Cas9) plasmid backbone. The patient's tumor-derived cancer cell line was transduced with the corresponding lentiviral sgRNA library and grown for 21 days. Genomic DNA was extracted from day 1 and day 21 samples of the transduced cell population, and PCR-amplified sgRNA loci were deep sequenced. A log-fold change (LFC) value was calculated based on the change in sgRNA abundance from day 1 to day 21. This procedure was repeated with

the same sgRNA library on a non-targeted cell line lacking the tumor-specific PAM to assess safety of the sgRNAs. *Results*: The Panc10.05 cancer-specific sgRNA library resulted in significant LFC of several sgRNAs when targeting Panc10.05 cells, however, most sgRNAs did not produce a significant LFC. The same sgRNA library was screened in TS0111, a cancer cell line lacking the Panc10.05-specific PAMs, and while most sgRNAs were non-toxic, a small number of sgRNAs did prove slightly toxic to TS0111 despite the lack of a corresponding PAM sequence. TS0111 cancer-specific sgRNAs were screened in a large library format as well as smaller cohort pools. These TS0111-specific libraries were cloned into a vector lacking Cas9 and screened in TS0111-Cas9^{+}, TS0111 without Cas9, and Panc10.05-Cas9^{+} cell lines. The libraries identified sgRNAs that were toxic in TS0111-Cas9^{+} but not the other two cell lines. Similar to the Panc10.05 sgRNA library, most TS0111-specific sgRNAs demonstrated no significant LFC.
Conclusions: Large library screens of cancer-specific sgRNAs were generally tolerated in cells, however, for both Panc10.05 and TS0111 cancer cells lines, a small number of cancer-specific sgRNAs were identified as both toxic to the target cell line and less toxic to the non-targeted cell line. Overall, CRISPRko screens were able to identify toxic sgRNAs that induce a single DSB, however, it remains unknown if identification of 5-10 slightly toxic sgRNAs is sufficient for a robust anti-cancer response.

659 Gene Expression Assays for PD Readout for siRNA Therapeutics: Validation Strategy to Support Clinical Studies

Maryse Proulx[1], Ginette Desilets[1], Obed Coulibaly[1], Maude Marie Leblanc[1], Marie-Soleil Piché[1]*
[1]*Charles River Laboratories, Senneville, QC*
**Corresponding Author*

Purpose: Quantitative reverse transcriptase-real time polymerase chain reaction (RT-qPCR) is a common approach to monitor the target gene expression modulation induced by a RNAi-based therapeutic. Despite the published guidelines for the qPCR analyses, the methodologies are not standardized across laboratories and there is an overall lack of harmonization on assay design, validation parameters and appropriate acceptance criteria for these assays. This case study presents the validation of a two-step RT-qPCR method including three duplex reactions for the quantification of a target gene mRNA expression relative to three housekeeping genes, in human liver biopsies.

Methods: Total RNA was isolated from naïve and diseased human liver samples and quantified by spectrophotometric measurement. RNA samples were then diluted with or without yeast carrier RNA and analyzed in parallel in three RT-qPCR duplex reactions. The comparative Ct method was used to normalize the target gene mRNA expression from each duplex to the corresponding housekeeping gene. The following parameters were assessed: range of response (linearity), intra- and inter-assay precision, reference range, multiplex interference, and RNA stability.

Results: The RT-qPCR assay performance was best in the presence of yeast carrier RNA when compared to nuclease-free water. Based on the linearity assessment and on the specificity evaluation (No RT controls), samples can be analyzed from 1000 to 1.40 ng per reverse transcription (RT) reaction, although a target concentration of 100 ng per RT reaction was selected for sample analysis, where possible. The intra-assay and inter-assay precision of the method was within 2.5% CV (coefficient of variation). A human liver RNA pool was also created and characterized (Ct range, Delta Ct range) to be used as quality control (QC) sample for sample analysis. No multiplex interference was observed for two out of the three duplex assays but differences between the single plex and duplex assay were seen in the third duplex assay. The Ct values for the target gene were lower in the duplex assay, compared to the single plex assay, and the maximum fold change observed between the single plex and the duplex assay was of 1.02 fold, indicating that the interference remained minimal and the sensitivity of the assay was not affected.

Conclusions: A two-step RT-qPCR assay combining three duplex assays for the quantification of a target gene mRNA expression relative to the expression of three housekeeping genes in human liver biopsies was successfully validated and used to support the PD assessment for a siRNA in a clinical study.

660 Harnessing Functional Genomics to Advance the Discovery and Development of Oligonucleotide-Based Therapies Targeting the Regulatory Genome

Introduction: Chronic diseases are driven by complex pathophysiology, and the limited efficacy of single-gene targeting approaches has prompted a shift toward disease-modifying strategies that reprogram pathogenic cells back to a healthy state. Long non-coding RNAs (lncRNAs) are tissue- and cell type-specific regulators of disease, making them promising therapeutic targets within this emerging paradigm of more effective treatments achieved through cell state reprogramming. Unlike protein-coding mRNAs, lncRNAs do not encode proteins but modulate gene expression through epigenetic, transcriptional, and post-transcriptional mechanisms. While lncRNA functions are often conserved, their sequences can vary across species, challenging the use of a single antisense oligonucleotide (ASO) across preclinical stages. Thus, developing ASO-based therapeutics targeting lncRNAs requires a tailored approach. **Methods:** The development of ASO-based drugs targeting protein-coding mRNAs traditionally involves assessing ASO potency through dose-dependent target knockdown, with potency defined as the maximal target downregulation achieved at the lowest concentrations. However, this approach is not directly applicable to lncRNAs due to their broad regulatory functions and diverse mechanisms of action (MoAs). To design potent ASOs targeting lncRNAs, we developed a platform that leverages functional genomics across the entire drug development pipeline, from discovery to preclinical validation. Our platform combines genomic, epigenomic and transcriptomic profiling to comprehensively understand lncRNA MoAs and pinpoint optimal target regions to maximize ASO efficacy. This multi-omics approach allows the selection of ideal candidates from a vast in silico-generated ASO sequence pool by predicting disease-modifying target pathways and defines its downstream target engagement panel (TEP). As a result, it enables the selection of ideal candidates based on their ability to reprogram pathogenic cells back to a healthy state, while also incorporating off-target analysis and tolerability studies to optimize both therapeutic efficacy and safety. **Results.** Using our platform, we designed and selected ASO candidates targeting therapeutically relevant lncRNAs across multiple disease areas, including cardiac and pulmonary fibrosis. These ASOs exhibited potent on-target effects, efficient dose-dependent downregulation of TEP genes, and significant modulation of genes within predicted disease-modifying pathways, validating the efficacy of our platform. Through this approach, we identified a potent and safe ASO targeting WISPER, a cardiac fibroblast-specific lncRNA responsible for the fibrotic burden in cardiac diseases. The selected ASO demonstrated effective WISPER knockdown and dose-dependent downregulation of the WISPER TEP, leading to remarkable cell-state reprogramming of tissue-specific pathological myofibroblasts back into quiescent-like fibroblasts in the heart. IND-enabling activities are ongoing. **Conclusions.** Integrating multi-omics profiling and functional genomics assays provides a comprehensive approach to developing ASO-based therapeutics targeting lncRNAs. We have successfully designed ASOs targeting tissue-specific lncRNAs across multiple disease areas, demonstrating their therapeutic potential and safety, with promising prospects for advancing ASO-based disease-modifying treatments toward clinical applications.

661 Humanized INHBE Mice Provide a Robust *In Vivo* Platform for Evaluating RNAi Therapies.

Jean Huang[1], Jinyi Ma[1], Zhixia Li[1], Xiao Liu[1], Rufeng Zhang[2], Xiaofei Zhou[1]
[1]Biocytogen, Waltham, MA, [2]Biocytogen, Beijing, Beijing, China

Introduction: Activin E, encoded by the INHBE gene, is a growth factor that belongs to the transforming growth factor-β (TGF-β) family. As part of the liver-adipose feedback loop, activin E is released from hepatocytes in response to elevated hepatic triglycerides and serum-free fatty acids. It then signals in adipose cells via ALK7 to suppress lipolysis, reducing the efflux of free fatty acids to the liver and preventing excessive hepatic lipid accumulation. Preclinical studies have shown that targeting INHBE with RNAi therapy can reduce fat mass and preserve lean muscle mass compared to currently approved obesity therapies. The drug with the fastest progress at present has initiated a Phase 1/2a clinical trial Biocytogen has developed a humanized INHBE mouse model, B-hINHBE mice, which exclusively express human INHBE but not mouse Inhbe. This model provides a valuable tool for preclinical studies of INHBE-related diseases.

Methods: To develop humanized B-hINHBE mice, exons 1-2 of the mouse *Inhbe* gene, which encode the entire molecule (from ATG start codon to STOP codon) including the 3'UTR, were replaced with their human counterparts. The promoter and 5'UTR regions of the mouse gene were retained. Human *INHBE* expression is driven by the endogenous mouse *Inhbe* promoter, while transcription and translation of the mouse *Inhbe* gene are disrupted. For mRNA expression analysis, liver RNA was isolated from wild-type C57BL/6 mice (+/+) and homozygous B-hINHBE mice (H/H). cDNA libraries were synthesized by reverse transcription, followed by PCR using mouse or human *INHBE* primers. For protein expression analysis, tissue lysates were collected from wild-type C57BL/6 mice (+/+) and homozygous B-hINHBE mice (H/H), and analyzed by western blot with anti-INHBE antibody. 40 µg total proteins were loaded for western blot analysis. To establish the diet-induced obesity (DIO) model, C57BL/6 and B-hINHBE mice (male, 7 weeks old) were fed a high-fat diet (60 kcal% fat) for 12 weeks to induce obesity. During the 9th week, mice were intraperitoneally injected with 15% glucose (1.5 g/kg) for glucose tolerance tests (IPGTT). During the 10th week, mice were intraperitoneally injected with 0.5 U/kg insulin for insulin tolerance Test (ITT). To evaluate the *in vivo* efficiency of RNAi therapy, DIO B-hINHBE mice were treated weekly with an siRNA drug targeting INHBE (provided by client; synthesized based on patent) at a dose of 9 mpk subcutaneously.

Results: RT-PCR results demonstrated that human *INHBE* mRNA was detectable only in homozygous B-hINHBE mice but not in wild-type mice. Western blot analysis showed that INHBE was present in the liver and kidney of wild-type and homozygous B-hINHBE mice, as the antibody cross-reacted with both human and mouse INHBE. The growth curve of DIO B-hINHBE mice closely resembled that of DIO C57BL/6 mice. No significant differences were observed in IPGTT and ITT between DIO B-hINHBE and DIO C57BL/6 mice. In the *in vivo* efficiency test, siRNA targeting INHBE inhibited body weight gain in DIO B-hINHBE mice compared to the saline-treated group. Treatment with siRNA targeting INHBE also resulted in fat mass loss while preserving lean mass.

Conclusions: B-hINHBE mice successfully express human INHBE, which functions normally. They serve as a powerful *in vivo* platform to evaluate RNAi therapy in obesity treatment and muscle preservation.

662 Developing Humanized APOC3 Mice As a Robust *In Vivo* Model for RNAi Therapy Assessment

Jean Huang[1], Suman Zhao[2], Ying Zhao[3], Rufeng Zhang[3], Zan Zhang[1], Xiaofei Zhou[1]
[1]Biocytogen, Waltham, MA, [2]Biocytogen, Waltham, [3]Biocytogen, Beijing, Beijing, China

Introduction: APOC3 (Apolipoprotein C3) is primarily expressed by hepatocytes, with minor expression in intestinal epithelial cells. In the bloodstream, APOC3 is associated with triglyceride-rich lipoproteins (TRLs), which include chylomicrons (CM) produced in the intestine, very-low-density lipoproteins (VLDL) produced in the liver, and high-density lipoproteins (HDL). A small amount of APOC3 is also bound to low-density lipoproteins (LDL). APOC3 increases plasma triglyceride levels by inhibiting lipoprotein lipase (LPL) activity and raises triglyceride and cholesterol levels by interfering with the clearance of TRLs and their remnants through hepatic LDL receptors (LDLR) and low-density lipoprotein receptor-related protein 1 (LRP1). Reduced clearance of TRLs is strongly correlated with elevated plasma APOC3 levels, making APOC3 a promising therapeutic target for reducing the risk of dyslipidemia and cardiovascular disease. Biocytogen has developed a humanized APOC3 mouse model, known as B-hAPOC3 mice. These mice exclusively express human APOC3, with the mouse Apoc3 gene inactivated. This model provides a valuable tool for preclinical research on APOC3-associated diseases.

Methods: To develop humanized B-hAPOC3 mice, exons 2-4 of the mouse *Apoc3* gene, which encode the entire molecule (from ATG to STOP codon), including the 3'UTR, were replaced with their human counterparts. The promoter and 5'UTR regions of the mouse gene were retained. Human *APOC3* expression is driven by the endogenous mouse *Apoc3* promoter, while expression of the mouse *Apoc3* gene is disrupted. For mRNA expression analysis, liver RNA was extracted from C57BL/6 mice and B-hAPOC3 mice. cDNA libraries were synthesized by reverse transcription, and PCR was performed using primers specific to mouse or human APOC3. For protein expression analysis, serum from B-hAPOC3 mice was collected and analyzed using species-specific APOC3 ELISA kits. Lipid metabolism analysis: plasma levels of triglycerides (TG), total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and high-density lipoprotein cholesterol (HDL-C) were measured in B-hAPOC3 and C57BL/6

mice at 5 weeks of age. LDL-C, TC, and HDL-C levels in B-hAPOC3 mice were similar to wild-type. The efficacy of nucleic acid drugs in inhibiting human APOC3 was assessed in B-hAPOC3 mice. B-hAPOC3 mice were randomly divided into two groups. Each group received a subcutaneous injection of either 10 mg/kg of nucleic acid drugs targeting human APOC3 (synthesized as per the patent) or PBS. The nucleic acid drugs were delivered in a PBS solution.

Results: RT-PCR results indicated that human *APOC3* mRNA was detectable only in B-hAPOC3 mice but not in wild-type mice. Protein analysis showed that APOC3 was present in B-hAPOC3 mice. Lipid metabolism analysis showed that TG levels in male B-hAPOC3 mice were significantly higher than those in C57BL/6 mice. Compared to the control group, the treatment group showed a significant decrease in TG levels. Human *APOC3* mRNA expression in the treatment group was also significantly reduced, with an inhibition rate of 73.4%. These results show that B-hAPOC3 mice provide a powerful preclinical model for *in vivo* evaluation of human APOC3-targeted nucleic acid drugs.

Conclusions: B-hAPOC3 mice effectively express human APOC3 and maintain normal functions. These mice offer a robust in vivo model for assessing RNAi therapy in research on APOC3-associated lipid disorders.

663 Optimizing Purification Strategies for sgRNA and Therapeutic Oligonucleotides

Songjun Xiao, LGC Axolabs, Petaluma, CA

The development of CRISPR-based therapies and therapeutic oligonucleotides has opened new avenues for treating genetic disorders and rare diseases. Solid-phase synthesis is a key step in producing these molecules, but it generates impurities that necessitate rigorous purification. This study focuses on optimizing purification strategies for long single-guide RNA (sgRNA), particularly those over 90 nucleotides, to address these challenges. We employed a multi-step purification process, including DMT-on purification, detritylation, and a secondary purification step, to enhance the quality and scalability of these therapeutics. We compared different ion-pair reagents, such as triethylamine (TEA) and hexylamine (HA), for reverse-phase (RP) chromatography, as well as various buffer conditions, including chloride, bromide, and perchlorate, for anion-exchange (AEX) chromatography. Our results demonstrate significant improvements in purity and yield, with sgRNA purity exceeding 80%. Additionally, we are exploring enzymatic ligation as an alternative method for sgRNA production and testing oligo-antibody conjugates to expand the scope of therapeutic applications. The optimized process demonstrates robustness and reproducibility, making it suitable for both research and industrial applications. These advancements are particularly impactful for the rare disease community, where the demand for precise and effective therapies is growing. This work underscores the importance of innovative purification strategies in ensuring the safety and efficacy of next-generation genetic medicines.

664 Validated Impurity Test for Chemical Synthesized sgRNAs using NGS Detection Method

Xia Sheng[1], Luyao Chen[1], Jiyan Wu[1], Chun Guo[1], Claire Zhou[2], Hong Li[3]
[1]GenScript USA Inc., Nanjing, Jiangsu, China, [2]Genscript, Piscataway, NJ, [3]GenScript USA Inc., Piscataway, NJ

Introduction: GMP (Good Manufacturing Practice)-grade single-guide RNA (sgRNA) is used for gene and cell therapy in clinical trials. In a seminar in 2024, the FDA has suggested that sgRNA for IND purposes should report sequence impurities with a frequency higher than 1%. Purity assessment and sequence confirmation for sgRNAs are typically performed with HPLC and Mass spectrometry. However, it is a difficult task for HPLC or Mass Spectrometry to distinguish sequence impurities of N+1 and N-1. Moreover, it is almost impossible to detect point mutations, especially when the mass difference between C and U is only 1 g/mol. Next-generation sequencing (NGS), on the other hand, is widely used for sequence detection. Discriminating between different nucleotide bases is a routine task for NGS. However, it has its own shortcomings where reads induced by PCR bias or sequencing bias can cause the quantification to be quite inaccurate.

In this study, we have developed a semi-quantitative NGS method to analyze sequence impurities in chemical synthesized sgRNAs.

Methods: 5'rApp and T4 RNA ligase are applied to ligate the sequencing adaptors to the single-stranded sgRNA molecule. The adaptors at both ends contain UMIs (Unique Molecular Identifiers) to reduce PCR bias during amplification. Reverse Transcriptase is then used to generate a reverse complement DNA chain. The library constructed through PCR amplification is then sequenced on an Illumina platform. The data analysis process is similar to the genome sequencing except that only UMIs with more than three reads are counted in our analysis pipeline. Tables and pie charts are drawn to display the sequence impurities and their distribution.

Results: Since there is only one reference sequence in the solution, the sequencing depth of the method can reach as high as 100,000X. To validate this method for quality control purposes, we have designed experiments to test the characteristics including specificity, linearity, accuracy, LOQ, and precision. The method was validated to detect N+1/N-1 or point mutations with an LOQ of 1%, which meets the FDA's requirement for IND sgRNA quality control. R^2 of the linear curve of variants with frequencies between 1% and 30% is higher than 0.99. N+1/N-1 in both ends of the sequence can also be detected with this method.

Conclusions: After neutralizing biases that occur in PCR amplification and sequencing, NGS is able to meet FDA requirements and serve as a QC method for synthesized IND sgRNA.

665 Optimizing VHH Ligand Density in T Cell-Targeted LNPs: An Inverted U-Shaped Relationship for Effective *In Vivo* CAR T Cell Generation

Kazuki Hashiba[1], Masahiro Fukasaka[2], Chisa Okuma[1], Akinori Sugiyama[1], Tomonari Mizuno[1], Yoshimitsu Shimomura[1], Taisuke Enoki[1], Yasuyo Ooka[1], Keiko Kajiwara[1], Yoshiki Maeda[1], Jumpei Sasaki[1], Hirofumi Ebe[1], Hiroshi Yamada[3]*
[1]Nitto Denko Corporation, Ibaraki, Osaka, Japan, [2]Nitto Denko Corporation, Ibaraki City, Osaka, Japan, [3]Nitto Denko Corporation, Ibaraki,, Osaka,, Japan
**Corresponding Author*

Chimeric antigen receptor (CAR) T cell therapy has shown remarkable clinical success in treating B-cell malignancies. This approach also holds promise for autoimmune diseases, given its ability to efficiently target and profoundly eliminate pathogenic B cells expressing CD19. However, challenges such as cytokine release syndrome (CRS), neurotoxicity, and the complexity of the manufacturing process—resulting in high costs and extended production times—remain significant barriers. To address these issues, we developed T cell-targeted lipid nanoparticles (ctLNPs) loaded with CD19 CAR mRNA, enabling *in vivo* CAR T cell generation. By optimizing biodegradable ionizable lipids, we designed anti-human CD8 VHH-conjugated LNPs that efficiently and selectively deliver mRNA to CD8+ T cells. In this study, we emphasize the critical role of VHH ligand density on the LNP surface for enhancing mRNA delivery efficiency. The functional VHH ligands on the LNPs were visualized by their interaction with fluorescently labeled recombinant CD8 receptors (Figure 1A), and unbound receptors were excluded using size exclusion chromatography (SEC). Using a nano flow cytometer, we simultaneously measured particle size and fluorescence intensity at the single-particle level, allowing precise quantification of VHH ligand density (Figure 1B, 1C). We explored ligand density-activity relationships by preparing LNPs with varying VHH densities and assessing mCherry reporter mRNA delivery to activated T cells from human peripheral blood mononuclear cells (hPBMCs). The results revealed an inverted U-shaped relationship, with an optimal VHH density identified for maximum efficiency. At this optimal density, more than 80% of CD8+ T cells expressed mCherry at only 4 ng/mL of mRNA. This optimal VHH density was consistent across different VHH clones, lipid compositions, and LNP concentrations. To further validate the targeting efficiency of VHH-conjugated LNPs, *in vivo* studies in hPBMC-engrafted NSG mice were conducted. The results confirmed that the optimal VHH density for mRNA delivery to CD8+ T cells *in vivo* mirrored the findings from *in vitro* studies, with minimal off-target delivery on CD4+ T cells, Tregs, or B cells. The CD8+ T cell-targeted LNPs, loaded with CD19 CAR mRNA, led to dose-dependent CAR expression and B cell depletion. Moreover, intravenous administration of these ctLNPs induced dose-dependent efficacy (0.5–2.0 mg/kg) in Nalm6-Luc/GFP-bearing hPBMC-engrafted NSG mice and substantial depletion of splenic B cells in hPBMC-engrafted NSG mice (0.05–0.25 mg/kg). Notably, the ctLNPs containing our

proprietary biodegradable lipids did not affect mouse body weight at these doses, and we are planning non-human primate (NHP) studies and scale up production to advance this platform toward clinical proof of concept. We believe that these off-the-shelf ctLNPs with optimal VHH density have the potential to revolutionize autoimmune disease therapies.

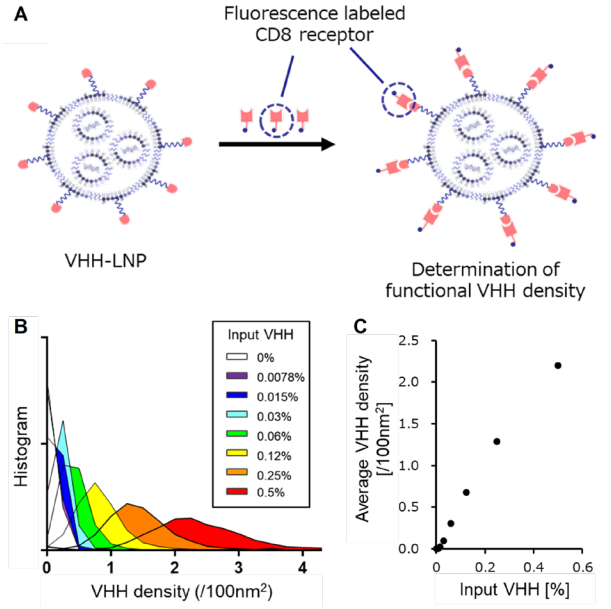

Figure 1. Quantification of the anti-human CD8 VHH Ligand Density of T Cell-Targeted LNP. A) Available VHH ligands on the LNP surface were visualized by interacting with Alexa Fluor 488 labelled recombinant CD8 receptors. B) The quantified VHH ligand density of each particle is represented as a histogram. C) The VHH density on the LNP surface increases with higher input VHH [mol%] relative to the total lipid.

666 T cell specific CAR-T mRNA Design for in situ T Cell Engineering

Cafer Ozdemir[1], BURAK YILMAZ[2], Joseph Parrella[3], Yusuf Erkul[1], Manfred Kraus[1]
[1]Kernal Biologics, Cambridge, MA, [2]Cambridge, MA, [3]Kernal Biologics, Cambrdige

Current CAR-T therapies are challenged with prohibitive cost, manufacturing difficulties and timelines, immune effector cell-associated neurotoxicity syndrome (ICANS). In addition, the malignant cells may lose their antigen that CAR-T cells are binding. Even with permanent genetic engineering CAR-T cells may get exhausted. Depending on the antigen, CAR-T cells may constantly attack healthy B cells. These limitations motivate versatile T cell engineering, that can be redosed if needed. Particularly for autoimmune disease therapy, temporary CAR-T treatment would be sufficient induce immune reset. At Kernal Bio, we have T cell targeted lipid nanoparticles that have higher than 90% transfection efficiency. To complement targeted delivery, we develop CAR-T expressing mRNAs that are translated specifically in T cells. With durable translation of mRNA temporary modification of T cells is sufficient to trigger malignant cell killing. Due to our tolerable ionizable lipids, it can be dosed multiple until the B-cells is fully cleared.

In order to eliminate ex vivo cell engineering, we need to constrain mRNA translation to target T cells upon intravenous administration of mRNA- LNPs, while sparing off-target cells. Using our proprietary computational and synthetic biology pipelines, Kernal Bio combs through large omics data sets to identify sequences that have the potential to shift activity away from off-target cell types into target cells. With this innovative approach of integrated omics analyses, we mechanism agnostically identify sequences of interest. Then the sequence hits are further altered for high throughput screening where the cells dictate what sequences are optimal. We can synthesize, purify, and

screen hundreds of putative cell-specific mRNA elements a week using this methodology and automated mRNA manufacturing. Using this approach, we identified RNA elements that boost translation up to 10-fold in T cells compared to monocytes. Omics driven mRNA design has the potential to time and dose the protein payload with synthetic mRNA. We use the data to fine-tune generative artifical intelligence models to extrapolate into untested combinations of sequences. Our iterative design strategy makes astronomic RNA sequence combinations tractable.

667 Improved T Cell Delivery and Expression of mRNA Using CD8-Targeted Lipid Nanoparticles with Athebody® Designed Ankyrin Repeat Proteins (DARPins)

Fan Yan[1], Sherry Weppler[2], Thomas Chamberlain[3], Grayson Wong[3], Ghania Chikh[3], Nora Guidotti[4], Raffaella Capozzoli[5], Julien Hiblot[5], Rohan Eapen[5], **Ying Tam[3]**, Barbara Mui[6]
[1]Acuitas Therapeutics, Vancouver, BC, [2]Acuitas Therapeutics, Inc., Vancouver, BC, [3]Acuitas Therapeutics Inc, Vancouver, BC, [4]Athebio AG, Schlieren, Zurich, Switzerland, [5]Athebio AG, Zurich, Zurich, Switzerland, [6]Acuitas Therapeutics Inc

Lipid nanoparticles (LNPs) administered intravenously primarily accumulate in fenestrated tissues (e.g., liver, spleen, bone marrow) due to vascular permeability. In the liver, endogenous apolipoprotein E (apoE) binds to the LNP surface, mediating hepatocyte uptake and nucleic acid payload delivery via low-density lipoprotein receptors. While LNP delivery to the liver is well established, expanding delivery to extrahepatic tissues remains a challenge. One approach is "active" targeting, where ligand-conjugated LNPs facilitate direct uptake by target cells in the blood compartment. Here, we evaluate Athebody® designed ankyrin repeat proteins (DARPins), antibody mimetics generated through synthetic combinatorial libraries and *in vitro and in silico* selection methods, as high affinity and specificity ligands for targeted LNP delivery.

Using DiD-labeled LNP containing a fluorophore-expressing mRNA, we first evaluated binding and fluorescent protein expression in mouse splenocytes after IV injection of non-targeted LNPs. At 24 hours after administration, splenic macrophages (33%) and dendritic cells (29%) exhibited notable LNP uptake and payload mRNA expression, while granulocytes, B cells, and T cells showed minimal engagement (<2%). Similar trends were observed *in vitro* using human whole blood. To enable T cell targeting, we conjugated a murine CD8-targeting DARPin to LNPs, and injected these IV into mice to assess *in vivo* targeting efficiency. CD8 DARPin-targeted mRNA-LNP showed dose-dependent, target-specific binding (44%) and transgene expression (34%) in CD8 T cells, with no impact on viability (>90%). Using LNPs with extended circulation, *in vivo* targeting efficiency increased to 86% binding and 59% expression in CD8 T cells, with additional uptake in $CD8^+$ dendritic cells (88% binding, 61% expression). There was no significant increase in targeting to $CD8^-$ cells ($CD8^-$ DCs, CD4 T cells, B cells, or myeloid cells) compared to unconjugated LNPs. Translating this to human cells, a human CD8-targeting DARPin-LNP showed ~98% binding and 46–90% expression in CD8 T cells from healthy human donor whole blood. These findings highlight DARPin-conjugated LNPs as a promising strategy for highly specific mRNA delivery to hard-to-transfect cells accessible within the vascular compartment.

668 *In Vivo RNA Delivery to T Cells and Hematopoietic Stem Cells in Humanized Mice and Non-Human Primates using Targeting Lipid Nanoparticles*

Michael Monte[1], Rahul Palchaudhuri[2], Lorenzo Tozzi[1], Han Gu[1], Giulia Schiroli[3], Apiwat Wangweerawong[1], Yu Cao, Mohit Gupta, Rebecca Goldman[1], William Salomon[1], Lei Liu[1], Aaron Zannini[1], Gun Su Han[1], Christina Ferren[1], Alyssa Sanfilippo[1], Tiffany Morales[1], Jessica Desmond, James Rottman[4], Jason Rodriguez[5], Bill Querbes[1], Hari Pujar[1], Michael Holmes[3], Jane Wang[1]
[1]Tessera Therapeutics, Somerville, MA, [2]Tessera Therapeutics - Somerville, MA, Somerville, MA, [3]Tessera Therapeutics, Cambridge, MA, [4]Tessera Therapeutics, Inc., [5]tessera therapeutics, Cambridge

We believe that non-viral delivery of genetic medicines to cells and tissues *in vivo* could pave the way for new therapeutic possibilities and enhance patient access. However, achieving effective *in vivo* delivery requires development of safe, efficient delivery vehicles capable of transporting genetic medicines to their intended target tissues and cells. While lipid nanoparticles (LNPs) have emerged as a strong platform for delivering RNA

therapeutics to the liver, targeting extrahepatic tissues remains challenging. Tessera Therapeutics is advancing novel LNPs designed to deliver RNA-based gene editing payloads to T cells and hematopoietic stem cells (HSCs) *in vivo*.

Our approach to LNP design incorporates several strategies to enhance tissue-specific delivery, including the optimization of lipid chemistry and composition to skew LNP biodistribution. Our advancements are exemplified by our HSC-targeting LNPs. In B6 mice, after a single intravenous (IV) administered dose, our HSC-targeting LNPs reduced liver delivery by 11-fold compared to liver-tropic LNPs, as measured by transient green fluorescent protein (GFP) levels in various tissues. Addition of a targeting moiety to enhance cell-type specific delivery increased GFP expression in bone marrow by 55-fold, while minimizing liver delivery. In cynomolgus macaques, our LNPs also favored bone marrow, achieving 3-fold greater beta-2 microglobulin (B2M) gene editing in bone marrow versus the liver, and nearly 2-fold longer blood half-life compared to liver-tropic LNPs, enhancing exposure in difficult-to-reach tissues.

By combining our passive and active targeting strategies, we have previously presented efficient delivery to T cells and HSCs in humanized mice and non-human primates (NHPs). We have furthered these efforts by pairing Tessera's novel Gene Writing platform with our proprietary delivery system to enable *in vivo* gene editing. Tessera's Gene Writers facilitate a range of genetic edits, from transgene insertions to single nucleotide changes, using target-primed reverse transcription. Using HSC-targeting LNPs with a Gene Writer and a beta-2 microglobulin (B2M) template in an all-RNA format, we achieved an average of 74% and 76% B2M knockout in long-term HSCs (LT-HSCs, defined as Lin-CD34+CD38-CD90+CD45RA- cells) in humanized mice and cynomolgus macaques, respectively. Similarly, with T cell-targeting LNPs, we observed an average of 30% B2M knockout in splenic T cells of humanized mice.

Beyond successfully achieving reporter protein expression and editing in the B2M locus, we demonstrated robust editing of therapeutically relevant targets. For sickle cell disease, with a single IV administered dose of Gene Writer encapsulated in HSC-targeting LNPs, we achieved 62% HBB Makassar installation in LT-HSCs of humanized mice and an average of 24% in LT-HSCs of cynomolgus macaques. Separately, in the pursuit of developing an *in vivo* CAR-T therapy, a single dose of T cell-targeting LNPs with a Gene Writer and CD20 CAR template resulted in ~30% CAR-expressing T cells, and subsequent elimination of B cells in humanized mice. Together, we believe these results demonstrate our LNP delivery platform is capable of efficiently delivering RNA payloads to edit HSCs and T cells *in vivo*, providing a potential delivery platform for the application of genomic medicines in extra-hepatic tissues.

669 In vivo Targeting of Hematopoietic Stem Cell Receptor cKit by Lentivirus Particles Pseudotyped with chimeric VSV-G proteins

Melissa Moy[1], Tatenda Kadungure[2], Yumeng McDaniel[3], Chia Hsuan Chin[2], Aravind Kancharla[2], Gopal Naik Nenavath[1], Stephen Russell[4], Nandakumar Packiriswamy[5]
[1]Imanis Life Sciences, Rochester, MN, [2]Imanis Life Science, Rochester, MN, [3]Imanis Life Science, Rochester, [4]Vyriad, Rochester, MN, [5]ImanisLife sciences, Rochester, MN

Sickle cell disease (SCD) and beta-thalassemia (beta-thal) are high prevalence hemoglobinopathies resulting from abnormal or reduced production of beta globin, a component of adult hemoglobin. Persistent production of fetal hemoglobin (via continued postnatal gamma globin production) can strongly mitigate both diseases. Casgevy, recently approved by FDA, is an ex vivo hematopoietic stem cell (HSC) editing treatment that uses CRISPR/Cas9 to disrupt the erythroid-specific enhancer region of BCL11A, thereby restoring fetal hemoglobin production in adults with SCD or transfusion dependent thalassemia (TDT). To reduce the cost, complexity and toxicity of this highly effective "ex vivo" therapy we seek to develop virus like particles that can efficiently and specifically deliver BCL11A editing complexes directly to HSCs in vivo. To this end we engineered lentiviral vectors and lentivirus-derived virus-like particles (VLPs) to target the HSC receptor cKit. This was achieved by displaying stem cell factor, the natural ligand for cKit, as an N-terminal extension of the VSV-G protein with which our lentiviral particles were pseudotyped. Specific transduction of cKit positive cell lines and primary hematopoietic progenitor cells was demonstrated following their ex vivo exposure to the SCF-displaying cKit targeted vectors. Subsequently, cKit-targeted and control nontargeted, LDLR-blinded or EGFR-targeted vectors encoding the cre recombinase were

administered intravenously to Ai14 (loxP flanked STOP-tdTomato reporter) mice, following which tdTomato expression in PBMCs was monitored on days 17, 27, 57 and 80 post-infusion. Interestingly, tdTomato expression was clearly identified, initially in myeloid and later in lymphoid PBMCs (approximately 0.4% of circulating cells) from mice that had been infused with the cKit targeted vector, whereas no expression was detected in any of the control mice. Analysis of the tissue distribution of tdTomato positive cells was conducted in a smaller cohort of animals on day 7 post vector administration. Unexpectedly, and in striking contrast to the control vectors, sinusoidal endothelium in the bone marrow, spleen, and liver was transduced with high efficiency following administration of the cKit targeted vector. Further studies are underway to explore the HSC targeting potential of alternate ligands and combinations of ligands displayed on the lentiviral surface.

670 Efficient In Vivo Gene Editing of T Cells Utilizing Novel Targeted Lipid Nanoparticles

Esther Chen[1], Xianghong Li[1], Ferran Soldevila-Casals[1], Theresa Hunter[1], Aaron Beams[1], Goutam Mondal[1], Diti Desai[1], Duy Nguyen[1], Donald Jhung[1], Stuart Sievers[1], Daiki Matsuda[1], Yanjie Bao[1], John Li[1], David Chu[1], Michelle Nguyen[1], Michael Pica[1], Jack Lee[1], Duncan Ugland[1], Claudia Fernandez[1], James Vestal[1], Jeffrey Chen[1], Josephine Nguyen[1], Michael Rosenzweig[1], Gregor Adams[1], Priya Karmali[1], Adrian Bot[1], Haig Aghajanian[1]
[1]*Capstan Therapeutics, San Diego, CA*

Background: Immunotherapy in general and T cell therapy in particular have revolutionized the oncology field. Despite these successes, challenges such as cell manufacturing complexity, limited efficacy, and T cell dysfunction persist. In the study, we present results from a novel T cell-targeting lipid nanoparticle (tLNP) designed to deliver gene editing payloads to T cells in vivo, with potential applicability including next generation immunotherapies. These tLNPs are a product of our CellSeeker™ platform technology and comprise a novel LNP conjugated with a recombinant protein binder designed to deliver RNA payloads to specific cell types in vivo.

Methods: A gene editing payload, consisting of an mRNA encoding for Cas9 and a sgRNA targeting T-cell receptor alpha constant (TRAC), were encapsulated separately (single-payload) or co-encapsulated together (combined-payload). tLNPs were targeted to either pan-T cells via an anti-CD5 antibody, or a T cell subset via an anti-CD8 antibody. Single- and combined-payload tLNPs were administered to primary human T cells in vitro and intravenously to NSG mice engrafted with human T cells. T cell gene editing efficiencies were evaluated in vitro and in vivo.

Results: In vitro we observed robust gene editing of T cells with either single- or combined-payload tLNPs. Both CD5- and CD8-targeting combined-payload tLNPs demonstrated high targeting specificity and up to 55% editing efficiency. Interestingly, co-administration of CD5- and CD8-targeting combined-payload tLNPs resulted in an increase in gene editing efficiency (up to 71%) compared to CD5- or CD8-targeting alone at the same dosage. Delivering the Cas9 mRNA and TRAC sgRNA separately by single-payload tLNPs with either the same targeting antibody or different targeting antibodies, resulted in high editing rates in T cells and T cells subsets, reaching 93%. Single-payload tLNPs have the added benefit of easily titrating the mRNA/guide ratio to find the optimal dose. To test the translatability of this targeted gene editing to an in vivo setting, we intravenously administered combined-payload CD5- and/or CD8-targeting tLNPs to humanized NSG mice. After dosing, we observed robust gene editing consisting in target gene knockout in CD5+ and/or CD8+ T cells in vivo, dependent on targeting binder. Additionally, repeat dosing revealed enhanced editing efficacy in the targeted T cell population, highlighting the tolerability and redosability of the platform.

Conclusions: In this study, we demonstrate the applicability of our CellSeeker™ platform to genomic medicine. T cell targeted tLNPs could deliver gene editing payloads specifically and effectively to targeted cells, resulting in a robust genomic editing (target gene knock out) of T cells in vitro and in vivo providing a springboard for future development including gene knock in. These results demonstrate the flexibility of this platform, including customizability of multiple payload delivery, tunable payload ratio, adaptable dosing regimen, and potential for repeat dosing. These features position the platform as a possible solution for developing more accessible, effective and scalable in vivo cell and gene therapies.

671 Compositional Screening of Lipid Nanoparticles for Intracellular Delivery of Gene-Editing Proteins to T cells

Statement of Purpose: Protein-based therapeutics targeting intracellular entities, such as the CRISPR-Cas9 system, have been employed in gene and immune therapies for diverse diseases. Despite considerable efforts, an efficient delivery system for the in vivo intracellular delivery of protein therapeutics remains elusive. Lipid nanoparticles have been engineered as carriers for mRNA-encoding antigens with validated biosafety profiles. However, their applications in protein delivery have been relatively umexplored. Previously, our lab has developed a multi-step screening method to optimize the type of helper lipid and component ratios in an LNP formulation for gene delivery. In this study, we aim to leverage this platform to optimize LNP formulations for the delivery of gene-editing proteins, including RNPs and Cre recombinase. Specifically, we will employ *in vitro* screening using the HEK293 Ai9 cell line and in vivo cluster-mode screening in Ai9 mice to identify formulations that effectively target the spleen for T-cell gene editing.

Methods: As shown in Figure 1a, we generated a 486-formulation LNP library with DLin-MC3-DMA as ionizable lipid, cholesterol, DMG-PEG2000, and one of six helper phospholipids that were previously used in FDA-approved or experimental LNP formulations. By varying the following parameters: (1) combined molar percentage of DLin-MC3-DMA and helper lipids; (2) weight ratio of cholesterol to DMG-PEG2000; (3) weight ratio of DLin-MC3-DMA to helper lipid; and (4) the weight ratio of total weights of lipid to protein, formulations were generated with RNP and Cre to screen in vitro on HEK293 Ai9 cell line. The top 50 formulations encapsulating RNP were then divided into 10 clusters and administered intravenously (*i.v.*) into Ai9 mice for in vivo cluster-mode screening. Analyzed by flow cytometry, the top three clusters with the highest gene editing efficiency in spleen immune cells were selected and tested individually on Ai9 mice. The most effective formulation F48 was then tested on C57BL/6 mice through i.v. injection to reduce CCR5 expression on T cells, and the results were validated through flow cytometry and western blot.

Results: To select LNP formulations that can deliver proteins with intracellular targets, we evaluated gene editing efficiency of the whole library treated with RNP with sgAi9 and measured the percentage of tdTom expression in the cells (Fig. 1b). The composition variation has generated different gene editing efficiencies under each helper lipid. Of 486 LNP formulations, the 50 top-performing LNPs are shown in Figure 1c. For in vivo systemic gene-editing evaluation, the most effective in vitro formulations were tested via i.v. injections in Ai9 mice with cluster-mode screening. In the following individual formulation assessment, the selected formulation F48 showed significant tdTom expression levels, specifically in T cells within spleens (Fig. 1d). We have also demonstrated the successful CCR5 reduction in T cells from blood 5- and 10-day post-injection, and from spleen 15 days post-injection shown in Figure 1e.

Conclusion: This LNP screening platform allows for the identification of the best-performing LNPs for intracellular delivery of protein for gene editing. In the study, we achieved promising gene editing in T cells in the spleen treated with the selected formulation. These findings highlight the potential of optimized LNP formulations for gene-editing proteins and their applications.

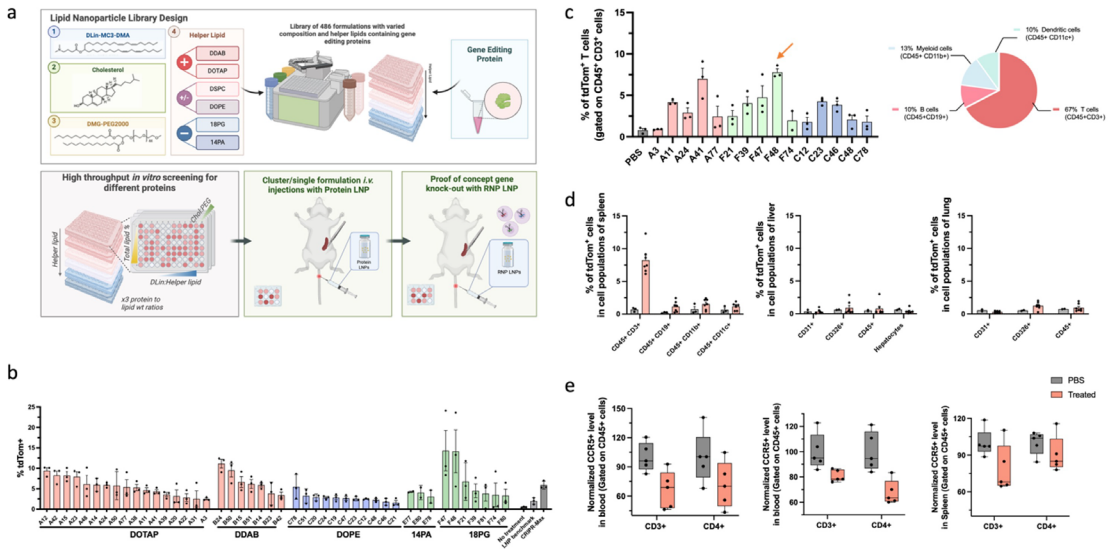

Figure 1. a) Schematic of multi-step screening for intracellular delivery of gene editing proteins **b)** Gene editing efficiency of RNP LNPs in HEK293 Ai9 cells via high-throughput screening platform ($n = 3$). Assessed with tdTom expression. **c)** The top 15 formulations were selected. **d)** FACS was used to quantify the percentage of tdTom$^+$ cells in spleen, liver and lung. **e)** CCR5 expression of CD3$^+$ and CD4$^+$ T cells were quantified 5-day and 10-day post-injection in blood, and 15-day post-injection in spleen.

672 Lipid nanoparticles- a game changer for primary B cell engineering mediated by mRNA-based Crispr/Cas9.

Delivery of mRNA to immune cells has emerged as a promising strategy for engineering and harnessing the therapeutical power of immune cells, especially T, natural killer and B cells. However, current methods, such as viral vectors or electroporation, have limitations in terms of safety, efficiency and scalability. Lipid-based nanoparticles evolved as an appealing alternative, offering a versatile platform for efficient and biocompatible mRNA delivery to these cells. Nevertheless, there is still a necessity for improving the performance and comprehending the underlying mechanisms of efficacy. Currently, there is a growing industrial and clinical interest in B cell engineering and subsequent adoptive B cell transfer, which already displayed good preclinical data. Efficacious, simple & scalable solutions to engineer B cells, particularly by utilization of CRISPR-Cas, remain to be uncovered and are a significant research priority. Thus, we aim to leverage the lipid nanoparticles (LNPs) for improved mRNA delivery to B lymphocytes and achieve therapeutic potency through CRISPR-Cas engineering. To achieve this, we assessed and further optimized our LNPs that we previously developed and described to have superior efficiency in transfecting NK cells. After validation that those LNPs achieved 100% GFP transfection efficiency without inducing toxicity in B cell lines, we exploited the Design Of Experiment approach by finely tuning production parameters to further improve the overall LNP potency. As a result, we obtained high and stable expression of GFP in the B cell lines. Then, we focused on the CRISPR-Cas system for B cell engineering with our model featuring GFP-expressing BL41 lymphoma cells. Cas9 mRNA and sgRNA targeted against the GFP gene were loaded into LNPs, resulting in more than 80% of GFP knock-out. Building on the promising results with cell lines, we next evaluated efficiency in primary B (pB) cells. Pre-activated cells treated with LNPs achieved over 90% transfection of pB cells that were positive for activation markers without notable mortality. This donor-independent efficiency was contrasted with the transfection failure of benchmark formulation, LNP SM102. Finally, as a proof-of-concept, we successfully delivered Cas9 mRNA and two sgRNAs encapsulated in LNPs to induce class switching recombination (CSR) in the antibody heavy chain locus of pB cells, showcasing the high potency of our approach.

Overall, our LNPs provide a scalable platform for highly efficient transfection of B cells, enabling a versatile utilization of the CRISPR-Cas system - a key approach to fully harness the therapeutical potential of B cells.

Formulation & characterizations of LNPs

Thermo Fisher Scientific, Carlsbad, CA, United States

Lipid nanoparticles (LNPs) have proven themselves to be a potent delivery system for mRNA, demonstrating clinical efficacy and safety for several therapeutic applications, including vaccination for infectious diseases and genome editing for rare genetic disorders in the liver. Increasingly, ex vivo and in vivo delivery of nucleic acids to immune cells is highly attractive for the development of immunotherapies including CAR-T and novel cancer vaccines. Here, we have identified and characterized Invitrogen™ Vivofectamine™ LNPs suitable for high delivery efficiency to *ex vivo* human primary T-cells and NK cells as well as different immune cell populations *in vivo* without the need for active targeting.

Our leading LNP candidates were selected from **a library of over 6000 lipids that underwent iterative rounds of *in vitro* and *in vivo* screening and formulation optimization**. Different LNPs were evaluated for immune cell delivery using two desired use cases: 1) high levels of genome editing and protein expression in primary T cells and NK cells *ex vivo* 2) efficient delivery to immune cells after systemic administration *in vivo*.

To identify **LNPs for *ex vivo* mRNA delivery to T-cells**, efficiency of genome editing and protein expression was tested. We demonstrate >90% delivery of reporter eGFP mRNA at low doses of mRNA. Following a co-delivery of Cas9 mRNA and sgRNA to T cells, we observed >90% editing of the TRAC locus in primary human T cells, while maintaining higher cell viability compared to electroporation. Using CD19 CAR mRNA to generate CAR-T cells, we achieved >95% CAR+ expression and confirmed CAR-T functionality in cell killing assays. Additionally, **LNPs demonstrated ~60% transfection efficiency in primary NK cells**. To identify **LNPs for *ex vivo* DNA delivery to**

T-cells, we did multiple iterative screening to identify LNP formulation that can deliver DNA to human primary T-cells with ~60% transfection efficiency.

For identifying ***in vivo*** **immune cell targeting LNPs**, immune cell transfection efficiency was analyzed after systemic administration of selected LNPs to mice. Flow cytometry revealed that a single injection of 1 mg/kg dose of eGFP mRNA-LNPs can target up to 30% of CD11b+ myeloid cells and up to 28% CD11c+ MHCII+ dendritic cells in the spleen. Furthermore, when immune cell LNPs were administered to non-human primates (NHP), they showed efficient eGFP expression in CD11b+ myeloid cells (approx. 80%) and CD3+ T cells (approx. 40%) in peripheral blood. eGFP expression was durable being still detected in over 20% of myeloid and T cells after 2 weeks post-injection (collaborator generated data). Our data indicates that Vivofectamine™ LNPs are suitable for specific and efficient delivery of nucleic acids to a variety of immune cells in vivo and ex vivo for development of immunotherapeutic applications. **The immune cells specific delivery is driven by novel chemistry and LNP composition without utilizing active targeting** overcoming manufacturing and scale-up challenges for development of therapeutic applications.

674 Rational Design and Preclinical Applications of Novel Unshielded Lipid Nanoparticles (uLNPs)

Grishma Pawar[1], Daniel Kurek[2], Jessica Silva[1], Maryam Osooly[1], Japneet Kaur[1], Anthony Tam[3], Rupsa Gupta[1], Rafaela Marodin[1], Kevin An[1], Deaglan Arnold[1], Huy Tran[1], Dominik Witzigmann[2], Jayesh Kulkarni[2]
[1]NanoVation Therapeutics, Vancouver, BC, [2]NanoVation Therapeutics, [3]NanoVation Therapeutics, Vancouver

Lipid nanoparticles (LNP) have revolutionized non-viral gene therapy and represent the most clinically advanced delivery modality. Onpattro, the first-ever approved RNAi therapeutic, is an siRNA-LNP against transthyretin and is indicated for the treatment of hereditary transthyretin amyloidosis. The LNP applied is a 4-component system composed of ionizable lipids, phosphatidylcholine, cholesterol and PEG-lipid (50/10/38.5/1.5 mol%, respectively). This composition is now the de facto gold-standard for intravenously administered nucleic acids for delivery to hepatocytes. The specificity arises from an endogenous targeting mechanism and lipid design that enables rapid unshielding of the LNP following i.v. administration. In particular, the PEG-lipid is designed in a manner so that it dissociates from the particle surface and allows for increased adsorption of Apolipoprotein E to the LNP surface thus promoting uptake into hepatocytes. During manufacturing and storage, PEG-lipid is required to promote LNP stability. Specifically, the amount of PEG-lipid within a formulation determines the particle size, and formulations lacking PEG-lipid rapidly flocculate post-production; the existing paradigm suggests that PEG-lipid or a relevant steric barrier is required to prevent particle aggregation. Comparatively, in vivo, this steric hinderance limits delivery. The hydrophilic coating of PEG-lipid has been reported to inhibit interactions with endosomal membrane resulting in prevention of endosomal escape and decreased formulation efficacy. It has been reported that PEGylated LNPs can induce hypersensitivity through complement activation and can cause undesirable immune responses in vivo against PEG. Additionally repeat dosing of PEGylated LNPs can results in anti-PEG antibodies that can clear subsequent PEG LNPs thereby reducing bioavailability. Therefore, there is a need for designing LNPs that have the desirable properties and stability for hepatic and extrahepatic delivery but do not suffer from the aforementioned issues associated with PEG-lipid.

He we report that we have rationally designed a novel set of LNP formulations termed unshielded LNPs (uLNPs) that comprise of 3 components namely ionizable lipids, phosphatidylcholine and cholesterol and eliminated the need for a fourth component. Our 3-component uLNPs lacking PEG-lipid in their compositions exhibit stable physicochemical properties and long term stability. We have demonstrated promising results with our uLNP technology for intramuscular vaccine applications, ex vivo immune cell applications and intravenous in vivo extrahepatic targeting. Firstly, several of our uLNP compositions resulted in similar or enhanced T and B cell responses against spike mRNA at 1 microgram dose in comparison to benchmark formulations. Secondly, we demonstrated enhanced mRNA delivery and efficient editing of ex vivo CD4+ and CD8+ cells and demonstrated 80% base editing of primary human hematopoietic stem cells (HSCs). Furthermore, we were also able to

demonstrate that uLNPs when administered intravenously, can deliver nucleic acid payloads to extra hepatic tissues of interest compared to LNPs with PEG. Our findings demonstrate that LNPs can be formulated without PEG that was previously thought to be essential LNP component. These novel 3-component uLNPs show excellent physicochemical properties and long-term stability making them an exciting platform to explore for range of other therapeutic applications.

675 *Mobilize*: A modular and versatile targeted LNP delivery platform for extra-hepatic RNA therapeutics

Amit Singh[1]*, Zhiwei Luo[2], Anthony Cura[1], Ting Lan[2], Feng Lin[2], Sanpeng Li[3], Bob Crooker[1], Justin Fang[1], Fei Jiang[4], Wei Qin[4], Roxi Mitrut[1], Nikhita Khanna[1], Cassidy Purrington[5], Jack Norton[5], Alina Zhankulov-Nguyen[5], KieuDuyen Tran[1], Qiujie Cai[2], Rujia Wang[2], Annie Xue[5], Andrea Graham[5], Maria-José Araneda Rubio[1], Yongting Huo[2], Alex Wesselhoeft[1]

Introduction: Lipid nanoparticles, or LNPs have demonstrated tremendous potential as a nonviral drug delivery system with successful clinical translation for both hepatic tissue and vaccine delivery. However, their utility for extrahepatic tissue delivery *in vivo* has been limited. Growing interest in *in vivo* chimeric antigen receptor (CAR) and genome editing technologies have led to a push for development of tissue-specific delivery methods with minimal off-target effects. Selective Organ Targeting (SORT) or CellSeeker™ technologies are prime examples that have demonstrated success in tissue-specific delivery *in vivo*. However, these approaches have specificity, scalability and translational challenges. We have developed *Mobilize* as a modular, versatile and scalable targeted LNP platform that solves the manufacturing challenges while retaining high efficacy.

Methods: *Mobilize* is a delivery system that enables the development of scalable, one-step assembly of a targeted LNP system. *Mobilize* produces high quality LNPs without typical limitations of downstream chemical functionalization, multistep production processes and variability in product quality. We have developed this platform with circular RNA (circRNA) encoding Green Fluorescent Protein (GFP) as payload, and three different targeting ligands for T cell specific delivery. The formulations are characterized by size, polydispersity index (PDI), encapsulation efficiency (EE) and stability using DLS and the Ribogreen assay. We further assess the impact of targeting ligand surface functionalization and fluorescence signal as a function of targeting ligand density *in vitro* in Jurkat cells, primary human T cells, and human PBMCs. *In vivo* efficacy of the *Mobilize* platform is confirmed in both a humanized mouse model and non-human primates (NHP), demonstrating the promise of the platform towards clinical translation.

Results: The *Mobilize* platform demonstrates physicochemical stability, dosing reproducibility and excellent efficacy in relevant *in vitro* and *in vivo* models. We confirm that our surface modification strategy provides the ability of LNPs to de-target from the passive LNP sinks in the liver and improve re-targeting to the cell of interest. As proof of concept, we validate the targeting ability of our platform using three independent ligands to target receptors on the surface of T cells with high efficiency. In humanized mouse models, we observe delivery to up to 55% of quiescent T cells at single and low doses. Finally, we validate our platform for successful delivery to quiescent NHP T cells with ~20% GFP positive population using a single dose of the *Mobilize* LNPs. Clinical observations, liver enzymes levels and extensive monitoring of cytokine/chemokine panels did not show any signs of overt toxicity in any of our mice or NHP study even at the highest tested dose.

Conclusions: Together, we demonstrate that the *Mobilize* LNP platform is versatile, modular and simple technology that is capable of efficient delivery of RNA payloads to extrahepatic tissues with high specificity. Our approach to developing this targeted delivery platform avoids several challenges and pitfalls faced by the industry to ensure product scalability, consistency, quality, efficacy and safety. Our data demonstrates that *Mobilize* provides a potential platform for *in vivo* delivery of RNA therapeutics to extrahepatic tissues.

676 Self-amplifying RNA-lipid nanoparticles for long-term protein expression in liver

Francesca Ferraresso[1], Irafasha Casmil[1], Lih Jiin Juang[2], Katherine Badior[3], Chad Skaer[4], Mitchell Dyer[5], Pieter Cullis[6], Anna Blakney[7], Christian Kastrup[8]
[1]The University of British Columbia, Vancouver, BC, [2]University of British Columbia, Vancouver, [3]Versiti Blood Research Institute, [4]Versiti Blood Research Institute, Milwaukee, [5]Medical College of Wisconsin, [6]University of British Columbia, Vancouver, BC, [7]University of British Columbia - Vancouver, Vancouver, BC, [8]Versiti Blood Research Institute, Milwaukee, WI

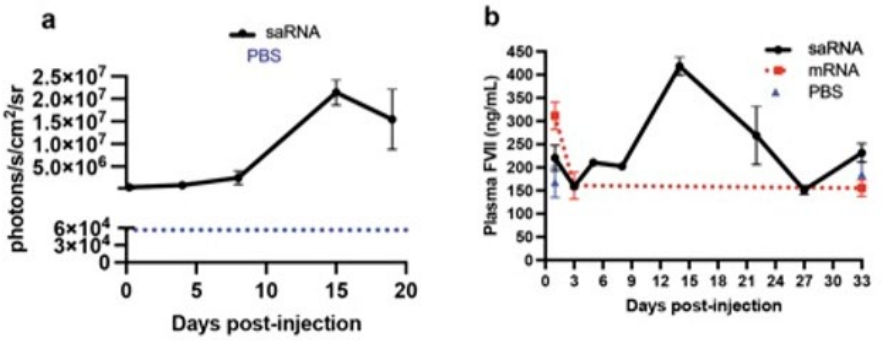
Background: Protein replacement therapies are used to treat over 50 disorders spanning a wide range of diseases including coagulation disorders, cancer, and rare diseases. Current protein replacement therapies have major limitations, including the need of continuous dosing due to the short half-life of proteins, and the risk of developing antibody inhibitors against the recombinant and natural protein. For example, in actively bleeding patients, including those with protein deficiencies, intravenous administration of recombinant activated coagulation factor VIIa (rFVIIa) decreases bleeding. rFVIIa has a short half-life of 2-3 hours and it increases risk of thrombosis due to the initial supra-physiological FVIIa concentration and because FVIIa is the enzymatically activate form of the zymogen protein FVII that normally circulates in blood. RNA therapies provide an opportunity to endogenously synthesize the missing protein from an exogenous RNA transcript, using the liver as a bioreactor following intravenous delivery of the RNA. mRNA therapies are an emerging technology that have potential to replace some protein replacement therapies, however, exogenous protein expression typically only lasts about one day and near-daily repeat injections is inconvenient and potentially dangerous. Self-amplifying RNA (saRNA) has the potential to produce exogenous proteins for up to a month, however its potential has been hindered by immunotoxicity concerns and lack of expression in the liver. saRNA uses a non-infectious, self-replicative viral replicase to enhance transcript lifespan of a therapeutic RNA.

Aims: Develop a protein replacement platform using saRNA encapsulated in lipid nanoparticles (LNP) for intravenous delivery and long-term protein expression in the liver.

Methods: We developed a novel immunosuppressant LNP formulation for the systemic delivery of saRNA and tested it by encapsulating an saRNA construct encoding for reporter protein, firefly luciferase (saFLuc). Protein expression was determined through in vivo imaging system (IVIS). Subsequently, we developed an mRNA (mFVII) and saRNA (saFVII) construct encoding for FVII and determined their therapeutic potential in vivo in mice. Plasma FVII levels were determined through an ELISA assay.

Results: saFLuc-LNP expressed exogenous protein in the liver for more than 20 days. mFVII increased circulating FVII by two-fold for up to 48 hours in mice and rats while saFVII-LNP increased circulating FVII for more than 32 days in mice. mFVII decreased blood loss in a bleeding injury model in both mice and rats. To determine therapeutic feasibly, swine were injected intravenously with mFVII encoding human FVII.

Conclusion: The novel saRNA-LNP platform may offer a more effective, longer-acting and safer treatment option for protein replacement therapies than standard mRNA. saFVII-LNP provides a more consistent replacement of FVII and an alternate treatment option for patients with rare bleeding disorders.



Hepatic delivery of saRNA using LNPs. A) Mice were injected intravenously with LNP containing saRNA expressing firefly luciferase, or PBS vehicle. Luminescence was measured by IVIS up to 20 days. **B)** C57BL/6J mice were treated with LNP containing saRNA encoding mouse FVII and euthanized 1, 3, 5, 8, 14, 22, 27, and 33-days post-injection. The plasma concentration of FVII was measured using ELISA.

677 Lipid Nanoparticle-Based Non-Viral Delivery of FVIII for Hemophilia A Gene Therapy

Meng-Ni Fan[1], Xiaohe Cai[2], Carol Miao[3]
[1]Seattle Children's Research Institute, Seattle, WA, [2]Seattle Children's Research Institute, [3]Seattle Children's Research Institute, Seattle, WA

Viral vector-based gene therapy has shown promise in treating hemophilia A (HA), but its application is limited by pre-existing neutralizing antibodies and the challenge of vector re-administration for maintaining therapeutic coagulation factor levels. Lipid nanoparticles (LNPs) represent a promising non-viral alternative for hemophilia gene therapy that can potentially overcome these limitations.

In this study, we evaluated various LNP formulations using either a biodegradable cationic lipid (LipidA) or FDA-approved MC3 lipid at different doses. Initial screening utilized a plasmid encoding secreted luciferase (pCAG-scLuc). For in vivo assessment of HA gene therapy efficacy, we treated both immunocompetent HA mice (mixed C57BL/6 and SV129 background) and immunodeficient HA mice (HA-NSG) with LNPs encapsulating FVIII-X10 plasmid (pCAG-FVIIIX10) at doses of 0.5 or 1 mg/kg. FVIII activity was measured using a one-stage clotting assay, while hepatotoxicity was evaluated through plasma alanine transaminase (ALT) levels and liver histology.
Mice receiving LipidA-LNPs encapsulating pCAG-scLuc demonstrated a 10-fold higher luciferase expression compared to MC3-LNP treated groups at both 0.25 and 0.5 mg/kg doses, with expression levels correlating with dosage. Luciferase activity persisted for approximately three months. Although LNP administration caused a transient elevation in ALT levels on day one, levels returned to baseline within one week, and liver histology at one-month post-treatment showed no evidence of sustained damage. Based on this superior transgene delivery efficiency, LipidA-LNPs were selected for subsequent HA gene therapy studies.

HA mice treated with LipidA-LNPs encapsulating FVIII-X10 variant at 0.5 mg/kg had therapeutic FVIII levels for approximately one month before declining due to inhibitor development. Given that inhibitor formation frequently occurs in HA mouse models but affects only about 30% of HA patients, we utilized immunodeficient HA-NSG mice to evaluate efficacy without inhibitor interference. HA mice produced FVIII activity above 10% for 6- and 12-weeks following administration at dosage of 0.5 and 1.0 mg/kg, respectively. Notably, subsequent re-administration achieved FVIII activity levels and duration comparable to the initial treatment. To extend the expression duration, we optimized the formulation by adjusting the molar ratio of lipid composition. Mice treated with optimized formulation had 60% FVIII activity in average for about a month. The expression level maintained above 20% for more than 8 months. Transiently elevated ALT level was observed one day post treatment but returned to baseline

level within one week. These findings demonstrate the potential of LNPs as a re-administrable, non-viral platform for HA gene therapy with minimal hepatotoxicity, offering a promising alternative HA gene therapy.

678 P-FVIII-101 is a Non-viral Genetic Medicine with the Potential for Controlled Modulation of FVIII Transgene Expression to Match Patient Needs

Khalid Hajj[1], Johannes Schwerk[1], Mauricio Barajas-Mora[2], Johnnatan Tamayo[2], Hua Wang[1], Alicia Davis[1], Lijun Huang[1], Gopi Nath Vemuri[1], Kevin Johnson[1], Sang Lee, Mu Li[1], Pranavanand Nyshadham[1], Fernando Lopez Espinoza[2], James Yen[2], Min Tong[1], Joseph Lucas[1], Bonnie Jacques[1], Joshua Rychak[1], Blair Madison[1]
[1]Poseida Therapeutics, San Diego, CA, [2]Poseida Therapeutics, San Diego

The standard of care for patients with severe hemophilia A (HemA) has dramatically improved in recent decades with the advent of prophylactic bispecific antibodies such as emicizumab. However, patients still face the risk of breakthrough bleeds, chronic joint damage, and pain. Thus, a need exists for transformative therapies, such as genetic medicines, that may offer functional cures. Current AAV-based gene therapies for HemA are yet to consistently achieve such outcomes, with FVIII activity often failing to reach curative levels and/or declining over time. Moreover, pediatric patients and those with pre-existing AAV immunity are likely to be excluded from treatment.

To overcome these challenges, we deployed the Super piggyBac (SPB) transposon system for DNA insertion delivered via non-viral proprietary lipid nanoparticles (LNPs) to enable genomic integration of a human FVIII (hFVIII) transgene. This results in durable hFVIII expression in neonates, juveniles, and adults in which hFVIII expression is maintained for at least 13 months with full restoration of hemostasis in mouse models of HemA. In light of these promising data, we sought to further understand hepatocellular tolerability and explore potential titratability that may better tailor therapies to differing patient needs.

One benefit of transgene integration with SPB is the high level of hFVIII expression obtained from a relatively small number of modified cells. To understand the impact robust hFVIII expression and secretion may have on the health of targeted liver cells, we conducted experiments to assess ER stress in hepatocytes. Transcriptional responses in primary human hepatocytes and HepG2 cells showed no significant induction of the ER-stress pathway by hFVIII-X5, suggesting there is minimal hepatocellular burden to overexpressing and secreting hFVIII, confirming the feasibility of our low-VCN integration strategy.

To provide a more customizable approach to varying patient needs, we are pursuing technological innovations that enable either repeat dosing to titrate up to desired hFVIII levels, or the ability to step down expression through an inducible modulator switch.We previously demonstrated the feasibility and success of a hFVIII-LNP-SPB repeat dose approach in mice. Further exploration of translatability using rats, a larger representative species, revealed favorable tolerability and ~50% FVIII expression at low dose (0.5 mpk) and approaching 100% at 0.75 mpk after a single dose.Importantly, repeat administration 14 days after initial dose achieved over 100% hFVIII expression at 0.5 mpk and ~500% at 0.75 mpk with no added toxicity or tolerability concerns following the second administration.

To explore optionality to dial down FVIII in the event of supraphysiological levels, we incorporated an inducible modulator switch into the transposon. Delivery of small molecule rimiducid induces activation of iCasp9 in transduced cells triggering their death. In adult mice we show that circulating levels of hFVIII protein can be dose-responsively reduced or titrated down with no apparent impact to liver health. This innovation allows precise control over desired FVIII levels or, alternatively, the elimination of all transposed cells should an unwanted transformation event ever occur. Future preclinical studies will further explore the tunability of these systems to deliver tailored therapeutic levels that provide a durable solution for FVIII restoration in HemA patients.

679 Lipid Nanoparticle Delivery of Minicircle DNA for *LAMA2* Gene Replacement in Muscle

Carles Bayod[1]*, Maria Pallares Masmitja[2], Núria Rafel[3], Marc Güell[4]*
[1]Pompeu Fabra University, Barcelona, Barcelona, Spain, [2]Vall D'Hebron Institut de REcerca, Barcelona, Barcelona, Spain, [3]Pompeu Fabra University, Barcelona, Spain, [4]Pompeu Fabra University Department of Medicine and Life Sciences, Barcelona, Catalonia, SPAIN
**Corresponding Author*

Laminin-α2-related congenital muscular dystrophy (LAMA2-CMD) is a severe neuromuscular disorder caused by mutations in the *LAMA2* gene, leading to progressive muscle degeneration. Gene replacement therapy offers a promising strategy for restoring laminin-α2 expression; however, the large coding sequence (CDS) of *LAMA2* (~9 kb) presents a major delivery challenge. Here, we harness minicircle DNA (MC-DNA) technology in combination with lipid nanoparticles (LNPs) to enable efficient and sustained transgene expression in muscle tissues.

We engineered a human *LAMA2* minicircle construct designed for high expression and long-term stability. Optimized LNP formulations were developed to enhance transgene uptake and endosomal escape in muscle cells, ensuring robust delivery. We evaluated *hLAMA2* expression following intramuscular (IM) and hydrodynamic limb vein injection (HLVI) in murine models, comparing conditions with and without the inclusion of random insertion machinery. Insertion machinery components were delivered as RNA encapsulated in independent LNPs to facilitate genomic integration while potentially reducing genomic vandalism. Preliminary analyses suggest that this approach enables sustained transgene expression, with *LAMA2* detected for up to four weeks post-treatment in wild-type mice. Ongoing experiments aim to quantify and compare endogenous and transgenic *LAMA2* expression levels, as well as evaluate the therapeutic potential in an *LAMA2*-deficient mouse model.

Overall, these findings highlight the potential of MC-DNA with LNP-based delivery as a viable, non-viral alternative for *LAMA2* gene replacement therapy. Future efforts will focus on optimizing LNP formulations, refining dosing regimens, and assessing long-term efficacy and safety in preclinical models.

680 Protease enhanced gene therapy of squamous epithelial stem cells in the oral cavity and skin

Markus Grompe[1], Craig Dorrell[2], Gaurav Sahay[3], Deepak Sahel[4]
[1]Oregon Health & Science University, Tualatin, OR, [2]Oregon Health & Science University, Portland, OR, [3]Oregon Stare Univ, Portland, OR, [4]Oregon State University, Portland, OR

Squamous epithelium is an important tissue that covers the inner and outer surfaces of the body. Squamous cell epithelium is a stem cell driven tissue, characterized by rapid turnover. The stem cells express cytokeratin 14 (K14) and reside on a basement membrane. The progeny of the stem cells move upward from the basement membrane and become progressively differentiated and amitotic. The top layer cells are heavily keratinized and are continuously shed. Because of the rapid turnover, any correction of genetic diseases of the squamous cell epithelium needs to target the basement membrane resident K14+ stem cells. Unfortunately, current vectors and technologies have been unable to efficiently perform durable gene therapy in squamous epithelial stem cells (SESC) *in vivo*. To overcome this limitation, *ex vivo* gene therapy, followed by grafting of gene corrected skin is the current approach. Efficient delivery of genetic payloads to the epidermal stem cells *in vivo* would be much preferable. The situation is even more difficult for mucous membrane stem cells. There currently are no reports at all of gene therapy in that tissue, even in animal models, let alone humans.

Our laboratory has been exploring oral cavity gene therapy in the DNA repair disease Fanconi's anemia in an effort to prevent or reduce the incidence of head & neck malignancies in this disease. Initially, we were completely unsuccessful in targeting the SESC with any of the gene therapy vectors tried, including LNPs, lentivirus, AAV and DNA transposons. Vectors injected into the tongue targeted the musculature and cells below the basement membrane, but not the epithelium.

Reasoning that the basement membrane was the principal obstacle to targeting the stem cell compartment, we combined gene therapy with *in vivo* collagenase treatment. Importantly, collagenase injections are widely used in clinical medicine and considered safe. Using this approach, we achieved highly efficient (90%) stem cell targeting with lipid nanoparticle (LNP) mediated mRNA delivery and AAV vectors in the tongue after a single injection. Similarly, collagenase enabled highly efficient *in vivo* targeting of epidermal stem cells in the skin with LNPs.

We conclude that gentle proteolytic disruption of the basement membrane dramatically enhances the efficiency of gene transfer into squamous epithelial stem cells in vivo. This approach has clear clinical potential.

681 Peptide-Assisted Lipid Nanoparticles for DNA Delivery in Pulmonary Gene Therapy

Jinzhen Hu[1], Millicent Sullivan[1]*
[1]*University of Delaware, Newark, DE*
**Corresponding Author*

Purpose: Alveolar type 2 cells (AT2) in the lung epithelium play a crucial role in maintaining lung function, and their dysfunction contributes to diseases across all age groups. Lipid nanoparticles (LNPs) are the gold standard for non-viral nucleotide delivery. While DNA offers superior stability and sustained transgene expression, its therapeutic application is constrained by lower delivery efficiency. Additionally, conventional systemic injection presents challenges for targeting lung-specific gene therapy. This study aims to develop and optimize LNP-based delivery systems tailored for local lung delivery and enhanced DNA therapy efficiency. In collaboration with clinicians focusing on improving nanoparticle distribution using perfluorocarbon (PFC) liquid, we are optimizing DNA delivery to AT2 cells and expanding the application of DNA-LNP for lung-associated diseases.

Methods: A layer-by-layer design was employed to formulate LNPs consisting of a peptide-DNA complex core, lipid shell, and serum coating (Fig. 1A). A histone peptide sequence, inspired by histone tail signaling, was incorporated to facilitate DNA unpacking and nuclear uptake. LNPs were synthesized via microfluidic mixing, and various peptide-to-DNA charge ratios (NP) were tested to optimize encapsulation efficiency. LNP size, encapsulation efficiency, and stability were assessed using dynamic light scattering (DLS), gel electrophoresis, and a PicoGreen assay. Transfection efficiency and gene expression levels were analyzed in AT2 cell lines by delivering GFP pDNA. To enable local lung delivery in the absence of blood serum, serum pre-coating conditions were examined through size measurement and transfection efficiency. Off-target uptake and expression in a lung macrophage cell line were investigated by delivering Cy5-tagged DNA LNPs and measuring fluorescent intensity through flow cytometry. Lastly, the role of serum exosomes in facilitating peptide-enhanced LNP transfection was examined.

Results: Optimization of NP ratios revealed that an NP 0.5 formulation maintained DNA encapsulation with minimal size increase (Fig. 1B,C). Serum pre-coating remained stable after 16 hours and produced maximum reporter gene expression at 6% serum concentration (Fig. 2C). Transfection studies demonstrated that, despite no direct sequence-specific effects, the inclusion of the peptide in LNPs significantly enhanced overall gene expression. Peptide-modified LNPs achieved nearly 100% cell transfection efficiency, with a 17-fold increase in GFP expression compared to standard LNPs, while maintaining low cytotoxicity at 6% serum concentration (Fig. 2A,B). This improvement suggests a synergistic effect arising from serum pre-coating and peptide inclusion for lung cell delivery. Mechanistic investigations indicated that exosome interactions played a crucial role in enhancing gene expression (Fig. 2D). Macrophage studies confirmed minimal off-target expression.

Conclusion: The peptide-enhanced LNP system demonstrated significant improvements in DNA delivery efficiency to AT2 cells. Optimization of NP ratios and serum pre-coating conditions led to high transfection rates with minimal off-target gene expression. Exosome interactions were identified as a key factor in boosting gene expression. These findings provide a strong foundation for future in vivo testing and the development of targeted gene therapies for lung diseases.

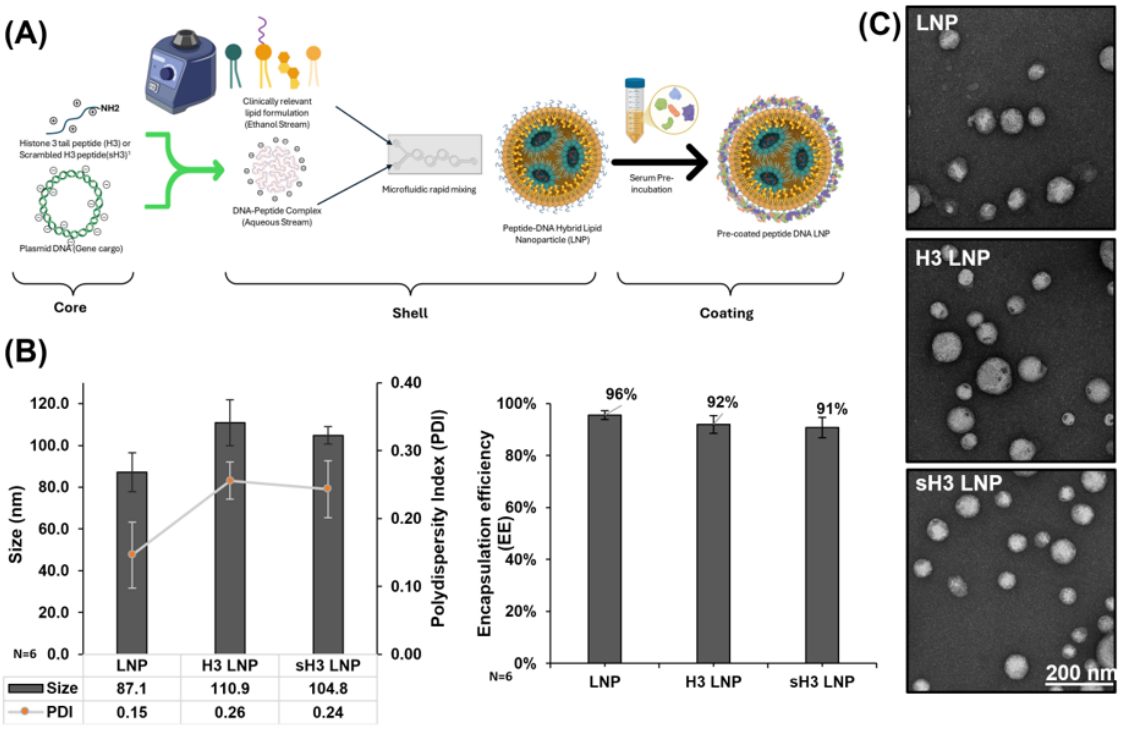


Figure 1: Layer by layer formulation of peptide inclusion LNP schematic and characterization. **A)** LNP is constructed by combining DNA and peptide through electrostatics interaction, then microfluidic mixed the DNA peptide complex with lipid mixture, and precoated with optimized serum protein for lung local delivery. **B)** LNP size and encapsulation measurement through DLS and picogreen assay. **C)** Representative TEM image of the LNPs.

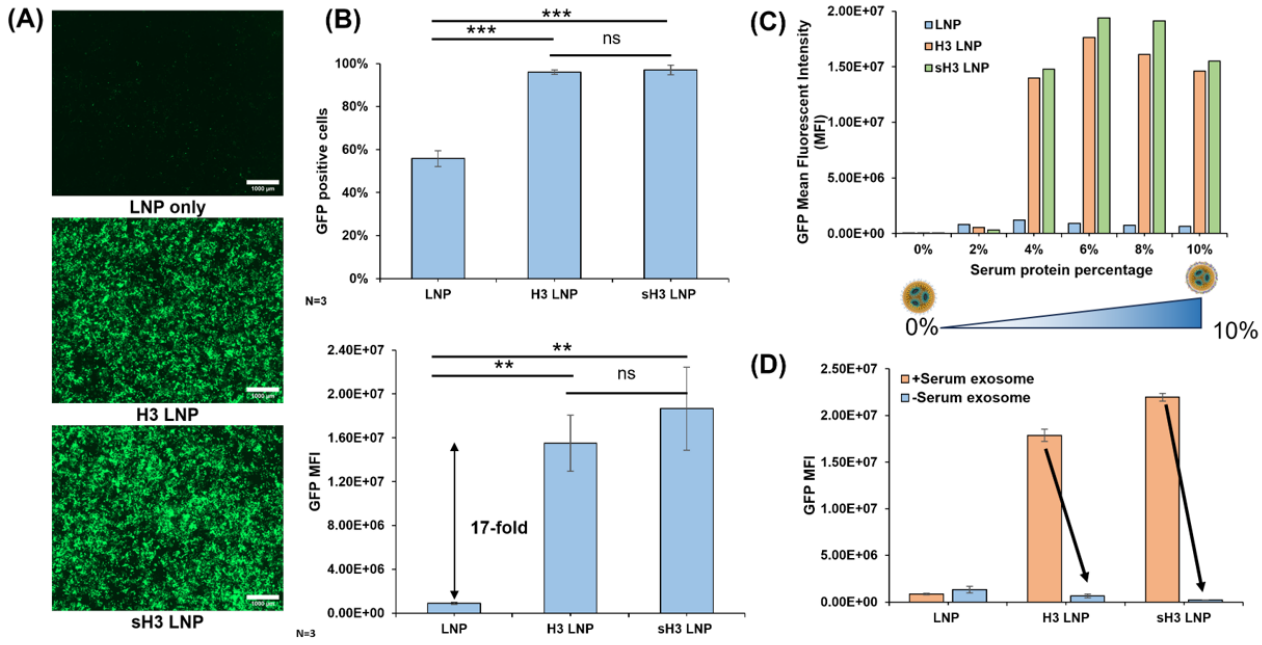

Figure 2: In vitro transfection investigation conducted using MLE-12 lung AT2 cells line. **A)** Representative fluorescent image of transfection study using the three DNA LNPs with GFP as reporter. **B)** Corresponding flow cytometry measurement on MLE-12 transfection efficiency at 6% and gene expression (N=3 for technical replication). **C)** Pre-coating condition testing varying pre-coating serum amount ranging from 0-10% FBS in culture media. **D)** Peptide LNP exosome interaction study using exosome depleted serum for pre-coating.

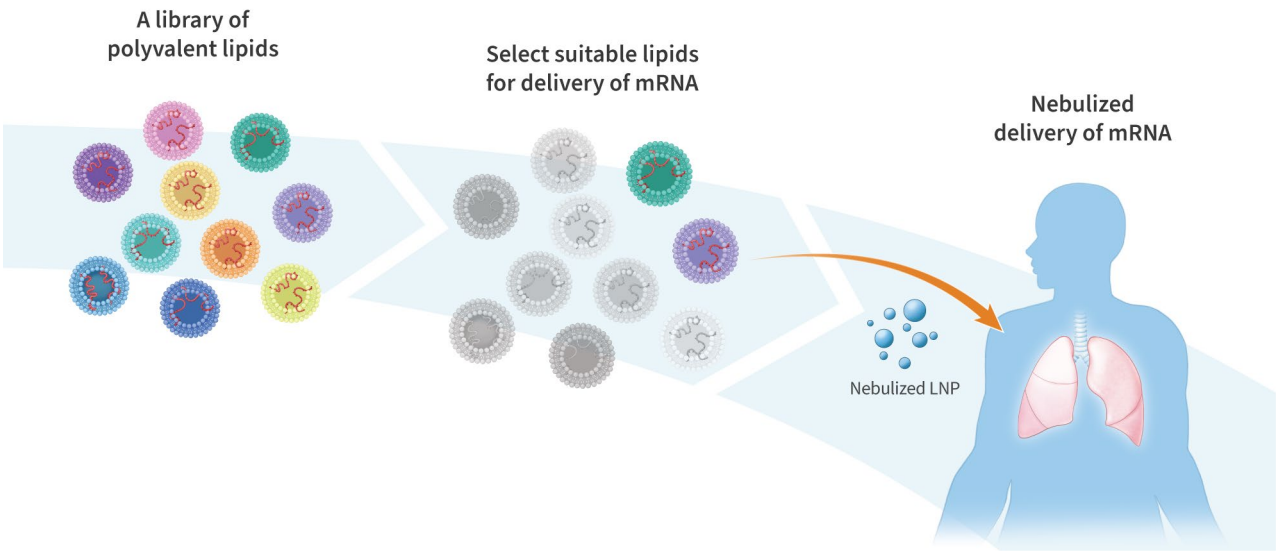
682 A Novel Polyvalent Ionizable Lipid Library for Nebulized Delivery of mRNA to Lung Cells

Joseph Pisano[1], Sean McCarthy[2], Lanzhi Liu[3], Daniel O'Toole, Christopher Rohde[4], Matthew Angel[4]
[1]Factor Bioscience Inc, Cambridge, MA, [2]University of Galway, Galway, Ireland, [3]University of Galway, IRELAND, [4]Factor Bioscience Inc., Cambridge, MA

Nucleic acid delivery systems containing ionizable lipids enable non-viral gene expression and are being explored in numerous gene and cell therapy applications. These systems are typically administered intramuscularly (IM) or intravenously (IV), however these routes are not suitable to address diseases of the lung, such as cystic fibrosis (CF), idiopathic pulmonary fibrosis (IPF), or chronic obstructive pulmonary disease (COPD). Inhaled delivery of nebulized mRNA lipid nanoparticle (LNP) formulations is one of the most promising methods for lung cell targeting, however many nebulized mRNA LNP formulations are limited by nanoparticle disruption and aggregation induced by the nebulization process. Here we demonstrate novel ionizable lipids that enable efficient delivery of nebulized mRNA to lung cells.

From a previously synthesized library, we selected 10 lipids that exhibited high delivery efficiency and cell viability in vitro. LNPs were formulated by mixing 0.1 µg mRNA encoding green fluorescent protein (GFP) with 0.25 µg ionizable lipid, nebulized using a vibrating mesh nebulizer, and administered to 40,000 A549 lung epithelial cells. GFP expression and cell viability was assessed 24h after delivery by flow cytometry. 9 out of 10 lipid formulations outperformed a commercially-available lipid in both nebulized and non-nebulized experiments while maintaining cell viability above 85% in all cases. The top-performing lipids produced 93% GFP-positive cells without nebulization and 63% GFP-positive cells following nebulization, outperforming the commercial lipid, which produced 37% and 8% GFP-positive cells, respectively. Median GFP fluorescence intensity of GFP-positive cells in top-performing lipids was also up to 7 times higher than the commercial lipid without nebulization and up to 4 times higher following nebulization. Formulations maintained high delivery efficiency after being frozen at -80°C for 4 weeks. Lipids containing the dihydroxyspermine headgroup exhibited the strongest performance in nebulization experiments, possibly due to the enhanced capacity for intermolecular complexation with mRNA, increasing the resistance to nebulization induced disruptions.



683 Novel Physical Gene Delivery Method Enhances Expression in Skeletal Muscle

Nadezhda Korostyleva[1], Michael Francis[2], Alex Otten[1], Jacob Hensley[1], **Anna Bulysheva[1]**
[1]University of South Florida, Tampa, FL, [2]Embody Inc, Tampa, FL

Gene electrotransfer (GET) is an established physical method for gene delivery to various tissues and organs *in vivo*, including melanoma tumors, skin, cardiac muscle, and skeletal muscle. GET offers advantages such as nonimmunogenic and nonintegrative gene delivery to targeted tissues. However, limitations include low expression levels, short-lived/transient expression, and muscle contractions.

We investigated a novel physical method for gene delivery based on electrotransfer without applying external current to induce cell membrane permeabilization. We hypothesized that exposing tissues to a strong electric field—without external current—could enhance gene delivery while avoiding muscle stimulation.

Preliminary *in vitro* experiments involved exposing cells to an electric field without current in the presence of propidium iodide or Sytox Green dyes to assess whether electric fields alone could permeabilize mammalian cell membranes. Cells were then fluorescently imaged to determine permeabilization efficiency.

For *in vivo* studies, we developed a custom insulated surface electrode for monopolar gene transfer. In Sprague Dawley rats, skeletal muscle was exposed, and plasmid DNA encoding Firefly luciferase was injected, followed by pulsed electric fields. Muscle contractions were measured using an accelerometer, and pulse delivery was monitored with an oscilloscope. Negative control groups received only plasmid DNA injections, while traditional monopolar, monophasic pulses were used as positive controls for gene expression and muscle twitching. Bioluminescence imaging was performed periodically for over three months to quantify gene expression.

Our *in vitro* experiments demonstrated that cell permeabilization was possible without external current. *In vivo*, contactless electrotransfer significantly enhanced gene expression over injection alone—by more than 100-fold

($p<0.001$)—while completely eliminating muscle stimulation. The elimination of muscle stimulation could reduce pain responses and mitigate the risk of ventricular fibrillation.

This proof-of-concept study did not yet optimize pulsing parameters; therefore, future studies optimizing applied voltage, electrode design, and pulse number may further enhance gene delivery efficiency. Overall, our preliminary work introduces a novel physical method for *in vivo* gene delivery, opening the door to a new platform technology with potential applications in protein replacement therapies. While still in its early stages, this platform could also have broader applications in tissue ablation, as well as gene and drug delivery.

684 Continuous-flow electroporation platform for rapid optimization and seamless scalability for cellular therapy manufacturing

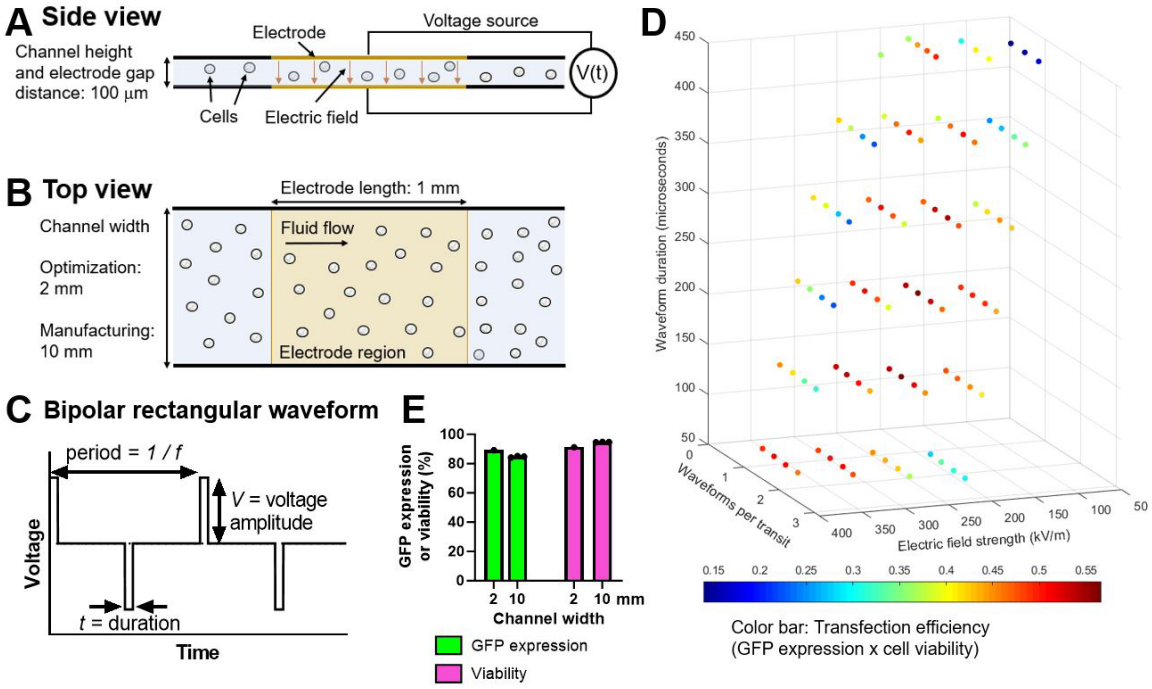
Jacob VanderBurgh[1], **Michael Stehnach**, Grant Corso, Stephen Levy, Harold Craighead
[1]*Cytequest, Ithaca, NY*

Electroporation has become an important tool to introduce genetic edits for cell therapies. However, current instrumentation is unable to address difficulties associated with electroporation such as limited throughput and arduous empirical process optimization. Here, we address these issues with our continuous-flow, microfluidic electroporation platform designed for rapid (3 seconds/well) process optimization in 96-well plates with low volumes (20 µL / well) of cell solution. Our platform combines automated liquid handling with computer-controlled electronics to enable rapid convergence on optimal parameters for electroporation such as cargo/cell concentration or voltage waveform. Once optimized, we can scale our volumetric throughput by swapping to a channel with a larger channel width without re-optimization because of the thin slab geometry of our microfluidic flow chip (Fig. 1A-B). Specifically, the thin flow channel height ensures each cell is subject to the same electric field for reproducibility whereas the width of the channel can be manufactured to match the desired volumetric throughput without changing the electric field strength experienced by the cells.

To demonstrate our optimization capabilities, we transfected Jurkat cells with plasmid DNA-GFP. We screened 93 different bipolar, rectangular waveforms with varying amplitude (V), duration (t), and frequency (f) over a single 7-minute experiment (Fig. 1C). The transfected cells were assigned a unifying efficiency value - calculated as the product of GFP expression and viability (GFP * Viability) - by measuring the GFP expression and viability 24-h post-transfection using flow cytometry. The optimized values were determined by plotting the electric field strength, the number of waveforms cells experience as they transit through the electrodes, waveform duration, and efficiency (Fig. 1D). Overall, we rapidly converged on the optimal waveform ($t = 225$ µs, $V = 18$V, $f = 63$ Hz) using small volumes of cells.

Scaling capabilities were demonstrated by transfecting Jurkat cells with nanoplasmid DNA-GFP using identical parameters in a flow chip with either 2- or 10-mm channel width. To keep the cells' linear velocity constant, we proportionally increased the volumetric flow rate with channel width. Fixing the cells' linear velocity and channel height creates identical electrical environments, providing identical transfection performance. Notably, we found that GFP expression and viability were less than 5% different between cells transfected in the 2 mm and 10 mm channel widths, showing our ability to scale without re-optimization (Fig. 1E).

These results demonstrate the capabilities of our electroporation platform for rapid optimization, which can be easily scaled to high-volume cell manufacturing without re-optimization. These capabilities bypass limitations of current instrumentation, making it a promising platform for non-viral cellular reprogramming for cell therapies.



685 Non-Viral Delivery of DNA Template and Gene Editing Components for Targeted Gene Insertion in Human Primary T-Cells: Electroporation vs. Lipid Nanoparticles

Aaron Hoover[1], Ming Jin[1], Sharlene Amador[1], Elena Stoyanova[2], Tom Adie[3], Chesney Michels, Jeff Cram[1], Mercedes Segura Gally[1], Michael Paglia[1]
[1]ElevateBio, Waltham, MA, [2]Touchlight Genetics, Hampton, London, United Kingdom, [3]Touchlight Genetics, London, Greater London, United Kingdom

Chimeric Antigen Receptor (CAR)-T cell therapy has revolutionized cancer and autoimmune disease treatment. Emerging non-viral delivery methods, such as electroporation (EP) and lipid nanoparticles (LNPs), enable precise nucleic acid delivery for targeted gene insertion. This study investigates the use of RNA-guided nuclease (RGN) mRNA, TRAC sgRNA, and synthetic DNA HDR templates (GFP and CD19-CAR) to achieve precise gene integration in human primary T-cells, comparing the efficiency of EP and LNPs for delivering these components.

Cryopreserved T-cells from healthy donors were activated and split into two transfection arms: EP and LNP delivery. Following transfection, cells were assessed for knockout and knock-in efficiency, viability, and phenotype. Electroporation achieved TRAC knockout efficiencies of 81–99% and HDR knock-in efficiencies of 19-39% for GFP and 10-31% for CD19-CAR. LNP-treated cells achieved TRAC knockout efficiencies of 48–87% and HDR knock-in efficiencies of 12–22% for GFP and 6–21% for CD19-CAR. HDR enhancers improved knock-in efficiencies in electroporated cells but had no effect on LNP-treated cells. Electroporated cells exhibited reduced viability (~60%) and slower growth (PDL = 3), while LNP-treated cells maintained higher viability (~89%) and faster growth (PDL = 5). CD4/CD8 ratios and memory T-cell phenotypes were consistent across EP and LNP conditions.

Both non-viral delivery methods demonstrated the feasibility of RGN-mediated gene editing in primary T-cells, with trade-offs in editing efficiency and viability. Electroporation achieved higher editing efficiencies under the conditions tested, while LNP delivery supported superior viability and expansion potential. These findings underscore the potential of novel non-viral approaches for CAR-T cell manufacturing and the need for further optimization to enhance efficiency and scalability.

686 Optimizing transposon-based gene delivery for cell therapy applications with the MaxCyte® ExPERT™ scalable electroporation platform

Maxwell Van Buskirk[1], Isabel Daher[2], Ashley Strickland-Dietz[3], Lauren Unsworth[4], Diwash Acharya[1], Rama Shivakumar, James Brady
[1]MaxCyte, Rockville, MD, [2]MaxCyte, Inc., Washington, DC, [3]Na, Montgomery Village, MD, [4]MaxCyte, Inc., Rockville, MD

Transposons are an efficient and proven method of gene transfer for cell engineering and have a wide range of applications from cell line engineering to generation of autologous cell therapies. Transposon systems, like piggyBac™, can support insertion of large DNA templates and achieve seamless editing with minimal disruptions to genomic integrity. Compared to gene delivery using viral vectors, transposons are more cost-effective and present fewer manufacturing complexities. Transposons are transfected into cells in the form of plasmids or linear dsDNA and the corresponding transposase enzyme is co-transfected as plasmid, mRNA or protein. Electroporation is a primary *ex vivo* method for delivering transposons due to its ability to load large cargoes with minimal impact on cell health and functionality. In this study we sought to optimize the delivery of the piggyBac™ (PB) transposon system for engineering of cell lines and primary T-cells using MaxCyte's® GMP-compliant ExPERT GTx™ platform with a specific focus on maximizing transposition efficiency, cell expansion, recovery and functionality while limiting vector copy number.

We first generated a PB transposon plasmid encoding a reporter gene (GFP) to study the relative effects of loading agent concentrations, electroporation parameters and other variables on transgene expression and integration efficiency. We initially electroporated K562 cells with a range of concentrations of PB GFP transposon plasmid and PB transposase mRNA to test different ratios and total quantities of transposon and transposase. Following expansion, a GFP expression of over 97% by flow cytometry was achieved at day 17 post-electroporation. Vector copy number (VCN), normalized to human albumin copies when analyzed by QIAcuity™ dPCR, varied in accordance with the relative amounts of transposon plasmid and transposase mRNA that were transfected. We also generated a PB Nanoplasmid™ transposon encoding a second generation anti-CD19 BB-z CAR and co-electroporated it with PB transposase mRNA into primary activated T-cells and we achieved over 50% CAR transposition efficiency by Day 5 post-EP. As with GFP, CAR expression and VCN correlated with the relative transposon and transposase concentrations in the electroporation reaction. These results support previously published data showing how MaxCyte® can enable efficient delivery of transposons with minimal impact on cell health for CAR-T cell manufacturing workflows.

687 Cell Engineering Solutions for T Cell-Based Immunotherapy Manufacturing: From Resting to Activated T Cell Editing

Akshaya Chandrasekaran[1], **Ranganatha Somasagara**[1], Arseny Smirnov[1], Gregory Bonello[1], Namritha Ravinder[2]
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]ThermoFisher Scientific, Carlsbad, CA

Recent advancements in chimeric antigen receptor (CAR) T-based immunotherapies and the push for efficient, cost-effective cell therapies have increased the need for improved manufacturing workflows to enhance patient access while ensuring quality and performance. Traditional CAR T cell manufacturing involves T cell activation, payload delivery, and ex vivo expansion, which often leads to T cell differentiation, exhaustion, and resistance to therapy. Evidence from both murine and human studies indicates that T cell differentiation inversely impacts long-term anti-tumor efficacy, with early memory T cells providing sustained anti-tumor responses. A novel manufacturing approach that activates T cells post-Cas9 delivery has been shown to reduce chromosome loss in the final product. Using non-activated cells as the starting material also offers the benefits of shorter workflow times, crucial for point-of-care and decentralized therapy production, and reduced costs. We present a closed and modular system for producing CAR T cell products from both non-activated/resting and activated T cell populations.

We use an automated counterflow centrifugation method where PBMCs are isolated from fresh leukopaks using the CTS Rotea™ Counterflow Centrifugation system and then downstream T cell enrichment is performed. Electroporation (EP) reactions for payload delivery are set up and optimized at small scale using the Neon™ NxT™

electroporation platform and then scaled up using the CTS™ Xenon™ Electroporation System. Transfection efficiency and cell viability are measured by flow cytometry and resting T cell phenotype is monitored pre- and post-EP to monitor maintenance of stemness in comparison to the starting population. Electroporations are performed using the CTS™ Xenon™ Lower Conductivity Buffer that enables higher energy setting on the Xenon electroporation system for hard-to-transfect cell types thereby providing a wider design space for process development and commercial manufacturing. Cells are activated post-electroporation using CD3/CD28 CTS™ Dynabeads™ and expanded for downstream functional assays. For the activated T cell protocol, PBMCs are isolated from frozen leukopaks and activated prior to cell editing in the CTS™ Xenon™ Genome Editing Buffer. Post-expansion, electroporated cells are washed and concentrated using the CTS Rotea™ Counterflow Centrifugation system and analyzed for transgene expression and cryopreserved for downstream functional studies. Targeted Amplicon-seq validation assay (TAV-seq) confirmed no detectable off-targets in CAR T cells and functional cancer cell cytotoxic assays against CD19 presenting-Nalm-6 cells showed effective killing by anti CD19 CAR-T cells.

In summary, we established a closed modular workflow for CAR T cell generation using automated instrumentation for cell processing and gene delivery thereby minimizing human intervention in the cell therapy manufacturing process. The transfection reagents and gene editing payloads in combination with the closed automated workflows described here will help reduce labor-intensive open system hurdles and improve the engineering of hard-to-transfect primary cells used for the development of efficient adoptive immunotherapies.

688 Transfecting iPSCs Robustly and Safely Using Photothermal Electrospun Nanofibers

Amin Ahmad[1], Chloë De Clercq[2], Stefaan Smedt[3], Kai Ling Liang[4], Tom Taghon[4], Koen Raemdonck[5], Kevin Braeckmans[6]
[1]Ghent University, Gent, Oost-Vlaanderen, Belgium, [2]Laboratory of General Biochemistry and Physical Pharmacy, Ghent University, 9000 Ghent, Belgium, Ghent, Belgium, [3]Laboratory for General Biochemistry and Physical Pharmacy, Ghent University, Ghent, Belgium, [4]Department of Diagnostic Sciences, Ghent University, 9000 Ghent, Belgium, Ghent, Belgium, [5]Ghent University, Ghent, Oost-Vlaanderen, Belgium, [6]Ghent University, Gent, Belgium, Belgium

Introduction: Photoporation is an emerging gentle transfection technology that combines laser stimulation with photothermal nanoparticles. It has been successfully used to deliver a wide range of payloads, including siRNA, mRNA, and proteins, into cells. To address concerns about potential toxic effects of nanoparticles on cells, we recently developed an alternative system in which the photothermal nanoparticles are embedded in biocompatible electrospun nanofibers (PEN). Cells can be cultured on the nanofiber substrate without direct contact with the embedded nanoparticles. At the same time, the nanoparticles are sufficiently close to the cell membrane to become permeabilized upon laser irradiation, allowing external payload molecules to enter and transfect the cells.

Having previously demonstrated that PEN photoporation can transfect cells with siRNA, we aimed to explore the possibility of delivering larger compounds into cells, including in iPSCs. First, we investigated how the physicochemical properties of the PEN substrate and laser fluence affect the delivery yield of FITC-dextran molecules of 10 kDa (FD10) and 500 kDa (FD500) in a model HeLa cell system. We then examined if repetitive laser activation of the PEN substrate increases the intracellular delivery efficiency. After that, we cultured induced pluripotent stem cells (iPSCs) on PEN nanofibers while maintaining high viability and the expression of pluripotency surface markers. Finally, we investigated the intracellular delivery of FITC-dextran molecules of 150 kDa and mRNA into iPSCs.

Methods: PEN nanofibers, composed of PCL and photothermal iron oxide nanoparticles (IONPs), were synthesized by electrospinning. A surface response methodology was used to simultaneously optimize the nanofiber diameter, IONP concentration, and fluence for optimal delivery of FD10 and FD500 into HeLa cells. The viability of iPSCs cultured on PEN substrates was assessed using a metabolic activity assay, while pluripotency markers were monitored via flow cytometry. The intracellular delivery of FD150 and the expression of eGFP after mRNA transfection were also investigated via flow cytometry.

Results: The delivery of FD10 and FD500 into HeLa cells demonstrated that laser fluence is the most significant factor influencing the delivery yield (57.3 ± 3.6% yield for FD10, and 35.3 ± 2.1% for FD500), while nanofiber diameter (400 – 600 nm) and IONP concentration (0.2-5%) had a minor effect. The delivery yield could be significantly improved by repetitively activating the PEN substrates, reaching 46.8 ± 7.2% for FD500). Next, PEN nanofibers were coated with Matrigel for iPSC culture. The concentration of Matrigel was titrated to optimize iPSC viability. The maintenance of pluripotency markers was confirmed with > 99% of cells expressing the TRA1-60, TRA1-81, and SSEA4 markers. Finally, PEN nanofibers were successfully used to deliver FD150 into iPSCs, achieving an efficiency of more than 80%. Additionally, iPSCs were transfected with eGFP mRNA, reaching a transfection efficiency of 25%.

Conclusion: PEN nanofibers are suitable for iPSC culture and enable the delivery of large payload molecules up to 150 kDa into cells without affecting pluripotency. Thus, they offer an attractive system for the safe engineering of iPSCs.

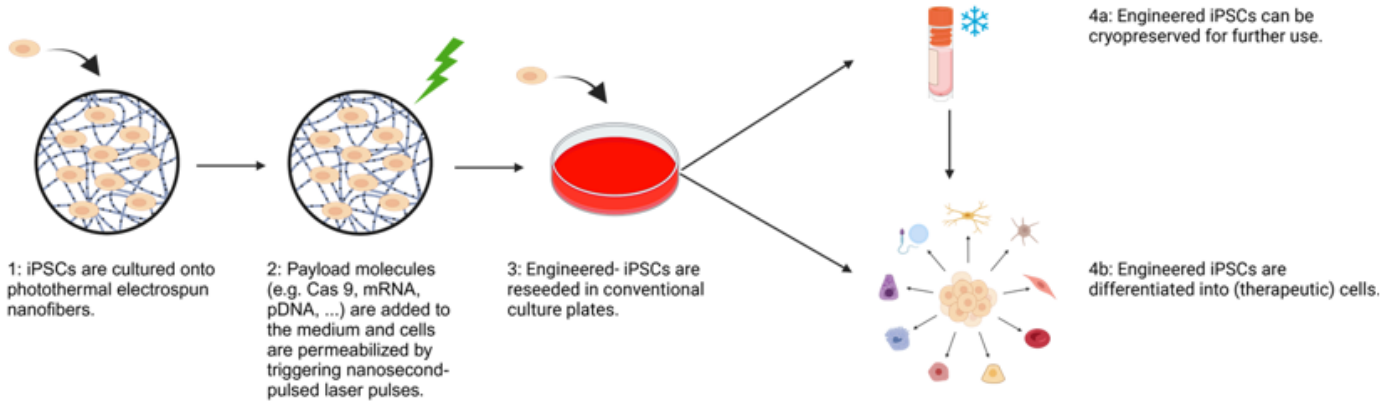


Figure 1: Schematic overview of iPSCs being transfected by photothermal electrospun nanofibers, and used as an off-the-shelf cell therapy product.

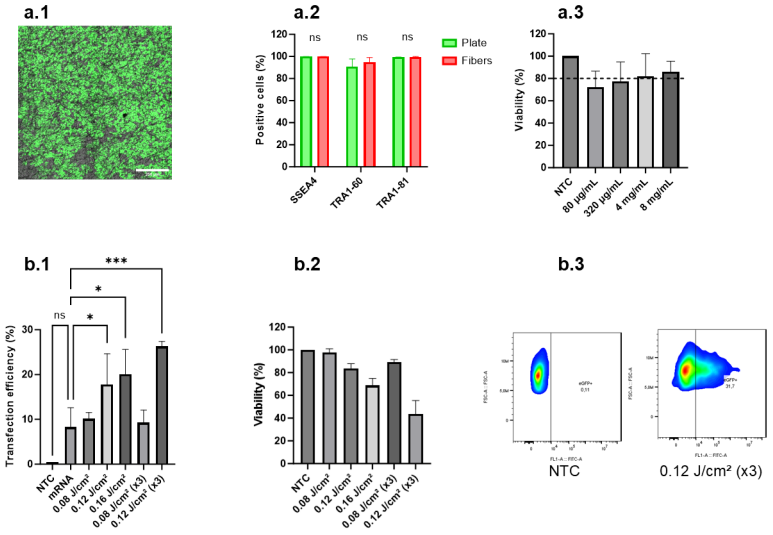

Figure 2: (a) iPSCs can be cultured onto PEN substrates while maintaining their viability and pluripotency. (a.1) Confocal microscopy image showing a monolayer of iPSCs labeled with calcein AM and cultured onto PEN nanofibers (transmission). (a.2) iPSCs cultured onto PEN substrates retain the expression of pluripotency markers similar to iPSCs cultured onto a conventional well plate. **Corresponding Author*

Introduction: Glioblastoma is considered the most aggressive form of brain cancer with a poor prognosis. While various treatment options exist, the rapid disease progression requires more effective and targeted strategies. Currently, there is growing interest in using mesenchymal stem cell (MSC) therapy, because they can self-renew, differentiate into specific tissues, modulate the immune system and target tumor sites. MSCs offer an attractive option for delivering chemotherapeutics and other relevant effector molecules to the tumor site, thanks to their tumor-homing capacity. When using MSCs as drug delivery carriers to treat glioblastoma, there is a need for a technology that can efficiently and gently load MSCs with the relevant effector molecules before transferring them into the patient. Over the past decade, photoporation has emerged as an efficient and gentle cell transfection technology with translational potential for cell-based therapies. This technique uses cutting-edge laser and nanotechnology to permeabilize the plasma membrane with high precision and has been proven quite versatile in terms of cell type and cargo molecule (**Fig 1**). In this study, we aim to investigate whether photoporation can be used for drug loading of MSCs and to explore the potential of these drug loaded MSCs for the treatment of glioblastoma.

Methods: We first optimized photoporation (laser pulse fluence, AuNP concentration) for the delivery of payload molecules into human adipose-derived MSCs (hMSCs). For optimized conditions, we continued investigating the cell functionality after photoporation, e.g. by measuring cell proliferation.

Results: We optimized photoporation parameters using hMSCs from three different donors. FITC-dextran of 10 kDa (FD10) served as the model payload molecule. The percentage of FD10 positive cells was determined by flow cytometry, while the Cell Titre Glo assay was used to assess cell viability. The product of delivery efficiency and cell viability results in a yield value that expresses the overall percentage of viable positive cells. As the data in **Fig 2A** show, for a fixed laser fluence the delivery efficiency increases with higher AuNP concentration, at the expense of cell viability. A laser fluence of 0.53 J/cm^2 performed better than 0.21 J/cm^2, but there was no benefit using higher fluences. An optimal delivery yield of 62% was reached for 8×10^7 AuNPs/mL and a laser fluence of 0.53 J/cm^2. Next, we assessed cell proliferation after photoporation with four different AuNPs concentrations and a laser fluence of 0.53 J/cm^2. The cell proliferation rate was calculated as the fold change compared to day 1. As indicated in **Fig 2B**, there were no significant delays in cell proliferation 7 days after photoporation compared to untreated cells. In ongoing experiments, we are investigating important hMSC criteria (hMSC adhesion to plastic, expression of specific surface markers and multilineage differentiation potential) and hMSCs' immunomodulatory functions.

Conclusion: Our data so far indicate that photoporation can be successfully used for delivering macromolecules into hMSCs. Undelayed cell proliferation after photoporation suggests that it is a gentle approach, although further work is needed to assess its impact on hMSC functionality. Collectively, our results highlight the promise of using photoporation as an efficient technology for MSC engineering and drug loading.

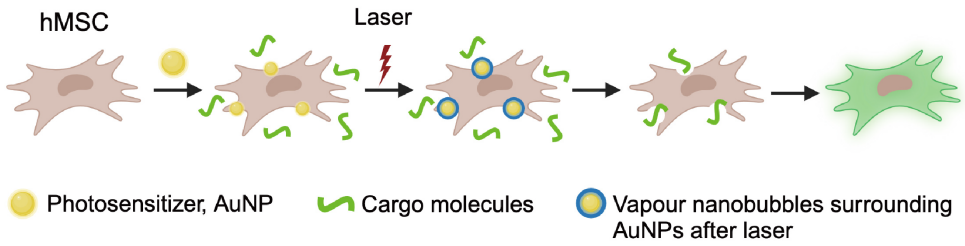

Figure 1. Illustration of the photoporation process. Photosensitizers, such as AuNPs, first bind to the cell membrane through electrostatic interactions. Applying nanosecond pulsed laser light leads to fast heating of the nanoparticles, resulting in heat and mechanical forces which locally disrupt the plasma cell membrane, allowing external payload molecules to enter the cytosol.

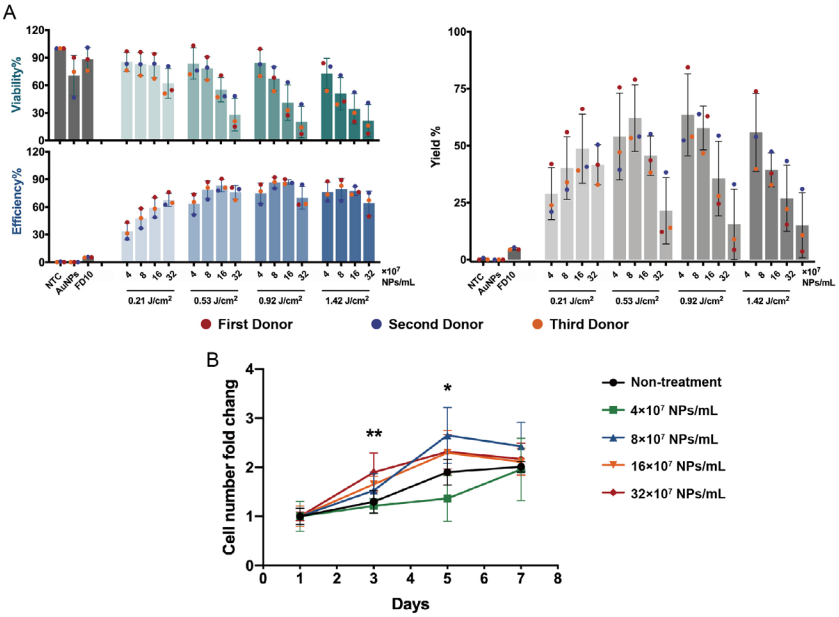

Figure 2. (A) The delivery of FD10 by photoporation into hMSCs from three different donors. Cell viability was measured by the Cell Titer Glo assay, delivery efficiency was measured using flow cytometry, yield was calculated by multiplying viability with efficiency. **(B)** The cell number fold change (relative to cell numbers on day 1) of hMSCs at different time points after photoporation with different AuNPs concentration under optimal laser fluence of 0.53 J/cm2. Statistical analysis was performed using One-way ANOVA with Tukey's multiple comparisons test. (n = 3, *p < 0.05, **p < 0.01).

690 Scalable Non-Viral Gene Editing and Feeder-Free Production of CAR-NK Cells

Deepak Kumar[1], Olga Cohen[2], Lee Sung[1], Ranganatha Somasagara[1], Pushpalatha Chaluvappa[1], Gregory Bonello[1], Namritha Ravinder[3]
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]Thermo Fisher Scientific - Carlsbad, CA, Carlsbad, CA, [3]ThermoFisher Scientific, Carlsbad, CA

Engineered primary human natural killer (NK) cells demonstrate significant potential in immuno-oncology due to their proven safety and potent anti-tumor effects, particularly against solid tumors. Unlike primary T cells, NK cells do not rely on a matching human leukocyte antigen to function, reducing the risk of graft-versus-host diseases in allogeneic therapies. Gene delivery into NK cells is crucial for studying NK cell biology and developing NK cell-based immunotherapies. However, efficient, and safe non-viral gene delivery methods for NK cells remain limited. In this study, we describe non-viral based closed modular automated methods for CAR-NK cell engineering methods for clinical scale manufacturing.

We first optimized the electroporation parameters using the Neon™ NxT Electroporation System 8-channel, emphasizing gRNA, buffers and payload concentrations to enhance gene delivery efficiency and cell viability. We isolated PBMCs using CTS™ Rotea™, a closed counterflow centrifugation system. Isolated NK cells from PBMCs, were then expanded in feeder-free culture using CTS™ NK-Xpander™ Medium. The expended cells were washed, concentrated in genome editing buffer and subjected to cell engineering using CRISPR/Cas9 RNP and electroporation. First, we optimized conditions for small-scale cell editing using the Neon™ NxT, and successfully translated to a clinically relevant scale using the CTS™ Xenon™ Electroporation System. Our results showed that electroporation system efficiently achieved knockout (60-80%) and knock-in (15-25%) of different genes including site-specific CAR knock-in at AAVS1 locus. The edited NK cells maintained their viability and phenotypic characteristics and achieved clinically relevant levels of cell expansion. Further, we performed functional cytotoxicity assays of CAR-NK cells and showed enhanced cytotoxicity against target cells compared to unmodified NK cells.

In conclusion, this study presents closed, scalable, non-viral gene delivery methods for primary NK cell engineering that enables efficient transgene expression without compromising NK cell immunophenotyping or function. The ability to efficiently modify primary NK cells will facilitate further studies on NK cell biology and enable the development of NK cell-based immunotherapies.

691 Enhanced Gene Delivery with High-Frequency Asymmetric Biphasic Pulses: Balancing Efficiency and Reduced Muscle Contractions

Nadezhda Korostyleva[1], Richard Heller[2], Mark Jaroszeski[3], Michael Francis[1], Jacob Hensley[4], Alex Otten[1], Tina Gagliardo[1], Anna Bulysheva[1]
[1]University of South Florida, Tampa, FL, [2]University of South Florida, Tampa, Florida, [3]Univ. of South Florida, Tampa, FL, [4]University of South Florida, Inverness, FL

Introduction: Gene electrotransfer (GET) was first described in 1980s and since then emerged as a promising tool for non-viral gene delivery used for long-term cancer therapies and vaccine integration. One of the major obstacles hindering the transition of the GET and other electroporation approaches into the medical field is the pain and risk of ventricular fibrillation. One of the pulsing modalities shown to mitigate these effects is high-frequency biphasic waveforms, also known as H-FIRE pulses, used for tissue ablation. Due to bipolar cancellation, H-FIRE pulses are not well suited for gene delivery applications. In this study, we hypothesize that if an asymmetric, biphasic pulse sequence is applied to targeted tissue, then gene delivery will be enhanced while reducing skeletal muscle stimulation.

Methods: We studied microsecond-scale asymmetric biphasic waveforms with two opposite pulses (Fig. 1). *In vitro*, mouse myoblasts were exposed to luciferase reporter plasmid followed by immediate exposure to biphasic pulses. Gene expression was measured over the next two days. *In vivo*, Sprague-Dawley rats were subjected to intramuscular injections of luciferase plasmid followed by direct pulsing of skeletal muscles. Rats were then imaged for bioluminescence periodically over the next 3 months. Muscle contraction was measured with an accelerometer during pulsing. Additionally, gene delivery to the skin was assessed in guinea pigs, which received intradermal injections of luciferase encoding pDNA followed by surface application of pulses with either a monopolar platinum electrode or a four-plate electrode. All quantitative data were compared statistically with a two-way ANOVA and a multiple comparisons analysis, $p<0.05$ was considered statistically significant.

Results: Statistical analysis of in vitro results revealed that expression of luciferase in several biphasic pulse groups was significantly higher than the negative control of cells exposed to the DNA but not the pulses ($p<0.05$). Several biphasic groups had comparable expression levels with corresponding monophasic pulsing parameters ($p>0.05$). Similar results were demonstrated in muscle and skin where several biphasic groups showed a significant expression enhancement compared to negative control($p<0.05$). Biphasic pulsing parameters significantly reduced muscle contractions compared to monophasic pulses ($p<0.01$). The acceleration of hind and fore limb movement during several monophasic pulses exceeded acceleration under high-frequency biphasic conditions in both the maximum amplitude and the number of occasions at which maximum amplitude occurred.

Conclusion: This proof-of-concept study demonstrates the feasibility of using asymmetric biphasic pulses as an alternative to classic monophasic GET for gene delivery applications. More work remains on optimizing delivery parameters to reach gene expression levels within physiologically relevant ranges for specific therapeutic applications.

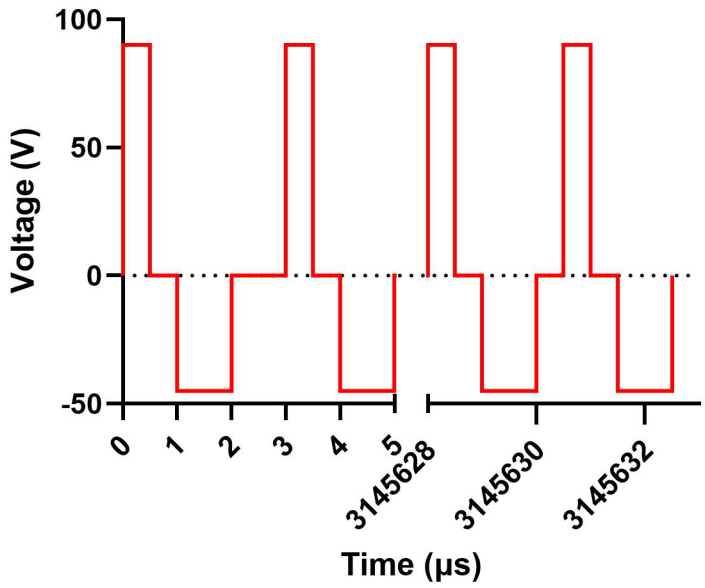

Figure 1: Asymmetric biphasic pulses were used to achieve luciferase plasmid transfection *in vivo* and *in vitro*.

692 Electroporation and LNP-mediated delivery of HPAI HA antigens supports robust anti-influenza immunity *in vivo*

Ebony Gary[1], Nicholas Tursi[2], Robert Vendramelli[3], Casey Hojecki[4], Yangcheng Gao[5], Elizabeth Parzych[1], Darwyn Kobasa[3], David Weiner[5]
[1]The Wistar Institute, Philadelphia, Pennsylvania, [2]The Wistar Institute, Moorestown, NJ, [3]The Public Health Agency of Canada, Winnipeg, MB, [4]Wistar Institute, Philadelphia, PA, [5]The Wistar Institute, Philadelphia, PA

Highly pathogenic avian influenza (**HPAI**) viruses of the H5 subtype are responsible for an increasing number of zoonotic events, including an ongoing outbreak of clade 2.3.4.4b H5N1 influenza in North America. These viruses can infect a wide range of hosts, including humans, representing an ongoing threat to public health and agriculture. Synthetic DNA (**synDNA**) antigens are non-live, non-replicating antigens which are easily produced and do not require cold-chain transport. We designed plasmid-encoded H5 hemagglutinin (HA) antigens representing clades 2.3.2.1c (**pCamb**) and 2.3.4.4b (**pMich**), which have caused the most human zoonoses, and delivered them via electroporation (**EP**) or in optimized lipid nanoparticles (**DNA-LNP**). pCamb-immunized mice had high titers of clade 2.3.2.1c specific binding and pseudovirus neutralizing antibodies in their sera. We also detected significantly increased frequencies of clade 2.3.2.1c-specific IFNγ secreting T cells via ELISpot. Importantly, two immunizations with this plasmid via EP delivery supported complete protection from matched lethal challenge with clade 2.3.2.1c H5N1. Interestingly when mice were immunized with this construct alone, or co-immunized with pCamb and the mucosal adjuvant pCTACK, we observed intermediate protection from heterologous clade 2.3.4.4b H5N1 challenge. We designed a second construct expressing clade 2.3.4.4b HA (pMich) and delivered this plasmid as a single immunization formulated in lipid nanoparticles (**LNP**). A single immunization with pMich DNA-LNP resulted in significant increases in clade 2.3.2.1c and 2.3.4.4b specific serum binding and neutralizing antibodies and supported strong cellular responses 30 days post-immunization. These data suggest that DNA-delivered H5N1 HA antigens can have significant impact on HPAI challenge in vivo and support the continued translation of these antigens.

693 A FIH dose-escalation trial of the safety and pharmacokinetics of anti-SARS-CoV-2 DNA-encoded monoclonal antibodies (DMAb) formulated for delivery by CELLECTRA in healthy adults

Pablo Tebas[1], Ami Patel[2], Joseph Agnes[3], Elizabeth Parzych[4], Amanda Baer[1], Maria Caturla[1], Sukanya Ghosh[5], Mansi Purwar[5], Nicole Bedanova[6], Chungdhak Tsang[7], Knashawn Morales[8], Dinah Amante[9], Paul Fisher[10], Joseph Francica[11], Laurent Humeau[12], Jesper Pallesen[2], Paul Leon, Mark Esser[13], Trevor Smith[10], **David Weiner[2]***

Background: Local intramuscular administration of synthetic plasmid DNA (pDNA) encoding monoclonal antibodies (mAbs) offers an alternative to recombinant protein technology. The dMAb platform has been developed preclinically in infectious disease and cancer immunotherapy models. However, no clinical trial data on this approach have been previously reported. This study advances a first-in-human (FIH) trial evaluating a two-dMAb formulation from preclinical small animal models to a non-human primate (NHP) pharmacokinetics (pK) and challenge study, ultimately leading to an Investigational New Drug (IND) application for assessing safety and pharmacokinetics in healthy individuals.

Methods: This multi-group Phase 1 dose-escalation study (NCT05293249) investigates the intramuscular (IM) administration of a pDNA cocktail encoding AZD5396 and AZD8076, modified for in vivo delivery and expression of the SARS-CoV-2 neutralizing mAb cocktail Evusheld. The vaccine is delivered using CELLECTRA™ electroporation technology. Participants received varying doses across multiple cohorts, and serum samples were analyzed for pharmacokinetics, durability, anti-drug antibody (ADA) responses, and SARS-CoV-2 neutralization activity. The study's primary endpoints include safety and pharmacokinetics of in vivo-expressed DMAbs.

Results: Muscle-expressed DMAbs were detected in the serum of all dosed participants (N=39), with concentrations reaching 1.11 µg/mL. In 24/24 participants who have completed 72 weeks of follow-up, DMAb levels remained stable. Functional assays confirmed SARS-CoV-2 receptor-binding domain (RBD) binding and neutralization activity in pseudovirus assays. No ADA responses were detected, suggesting sustained expression without immune-mediated clearance. Safety assessments revealed no serious adverse events, with mild injection site reactions being the most commonly reported.

Conclusion: This study provides the first clinical proof-of-concept for synthetic pDNA DMAb technology, demonstrating durable in vivo production of functional monoclonal antibodies. The findings underscore the importance of synthetic design, formulation, and delivery in achieving biologically relevant gene-encoded biologics expression. The DMAb platform may represent a valuable strategy for targeting a wide range of diseases treatable with monoclonal antibodies or their derivatives.

694 Enhanced Gene Therapy for Tay-Sachs Disease Using the PP6D5 Polymer and CRISPR/nCas9

Jacky Guerrero[1], Andrés Leal[2], Ivonne Diaz[3], Leon Perez[4], Angela Espejo-Mojica[5], **Carlos Javier Alméciga-Díaz[6]**
[1]Inborn Errors of the Metabolism, Bogotá, Distrito Capital de Bogotá, Colombia, [2]Nemours Children's Hospital Delaware, Wilmington, DE, [3]Universidad Nacional de Colombia, Bogota, Distrito Capital de Bogotá, Colombia, [4]Universidad Nacional de Colombia, Bogota, Amazonea, Colombia, [5]Pontificia Universidad Javeriana, Bogota, Distrito Capital de Bogotá, Colombia, [6]Pontificia Universidad Javeriana, Bogota, Bogot, Colombia

Tay-Sachs disease (TSD) is a fatal neurodegenerative disorder caused by a deficiency of β-hexosaminidase A (HexA), leading to GM2 ganglioside accumulation in the central nervous system. This study explores the use of the PP6D5 polymer as a non-viral vector for CRISPR/nCas9-mediated correction of HEXA mutations, assessing its transfection efficiency and therapeutic potential in TSD GM00515 fibroblasts.

Comparative analysis with Lipofectamine 3000 in healthy cell lines revealed that PP6D5-mediated transfection significantly enhanced HexA activity. In 3T3 cells, PP6D5 achieved a 1.5-fold increase in HexA activity compared to 1.16-fold with Lipofectamine after 30 days. Co-transfection with HEXA/HEXB cDNAs via PP6D5 nearly tripled HexA activity relative to HEXA alone. In U87MG cells, HEXA cDNA transfection using PP6D5 led to a fivefold increase in HexA activity after 25 days, surpassing Lipofectamine. Similarly, in SHSY5Y cells, PP6D5 induced a 2.3-fold enhancement after 15 days, with a striking 45-fold surge upon HEXA/HEXB co-transfection, stabilizing at 27.9-fold after 25 days.

In TSD fibroblasts, HEXA transfection improved HexA activity but did not fully restore normal levels. HEXA/HEXB transfection with Lipofectamine resulted in an eightfold increase after 15 days, whereas PP6D5-mediated transfection reached 3.5-fold after 30 days. Regarding lysosomal dynamics, Lipofectamine increased lysosomal mass intensity, while PP6D5 induced a 1.13-fold reduction. Both vectors effectively reduced ROS levels. Lipid compartmentalization exhibited contrasting patterns: neutral and polar lipid content decreased with Lipofectamine but increased with PP6D5. Additionally, autophagic flux analysis indicated partial recovery with Lipofectamine, while PP6D5 promoted autolysosome formation.

These findings underscore the potential of PP6D5 as a non-viral vector for gene therapy, demonstrating robust CRISPR/nCas9 delivery and sustained therapeutic efficacy across multiple cell models. The distinct cellular responses highlight PP6D5 as a promising, safer alternative to viral vectors for treating TSD.

695 High-Throughput Screening and Data-Driven Evolution of Polymeric Nanoparticles for Efficient Gene Delivery

Cherry Gupta[1], Ashlee Colbert[2], Caleb Hillrich[1], Emma Schmitz[1], Molly Kaufman[3], Sam Farrar[1], Dean Constantine[1], Deeann Wallis[4], Erik Westin[5], Robert Kesterson[6], Nick Andrioff[7], Miguel Pedrozo[7], Brian Smith[7], Andrea McCue[1], Danielle Huk[7], Allison Secard[3]
[1]Battelle Memorial Institute, Columbus, OH, [2]Battelle Healthcare Products, Blacklick, OH, [3]Battelle, Columbus, OH, [4]University of Alabama At Birmingham, Birmingham, AL, [5]Pennington Biomedical Reseach Center, Baton Rouge, LA, [6]Pennington Biomedical Research Center, Baton Rouge, LA, [7]Battelle Memorial Institute, Columbus

Polymeric nanoparticles (PNPs) are modular delivery systems that can be optimized for targeted delivery of therapeutics. The design and development of nanoparticles has been greatly accelerated by recent advancements in rational design approaches, such as high-throughput methods and computational techniques. These strategies move away from a trial-and-error model to a more structured, data-driven approach, improving the efficiency of preclinical discovery pipeline for nanomaterials. Here, we employ a high-throughput design-build-test-learn platform to enhance the delivery efficiency of PNPs for the treatment of Neurofibromatosis Type 1 (NF1), a genetic disorder caused by the loss of functional neurofibromin, a tumor suppressing protein. NF1 gene replacement therapy holds immense clinical potential but is hindered by challenges in delivering the large 8.5 kbp *NF1* gene using viral vectors.

To overcome this, we used cationic diblock PNPs for encapsulating and delivering the full-length human NF1 plasmid (EF1a-NF1-2A-EGFP, ~20 kbp) to human Schwann cells (SCs). However, designing the perfect PNP is difficult because of the vast chemical landscape, the complexity of biological systems, and the limitations of current modeling techniques. To address this, we used our High-Throughput Synthesis, Characterization, and Assessment of Nanoparticles (HIT SCAN™) platform to systematically test over 500 different PNPs and identify the most promising "hit" candidates. The polymers were synthesized using a reversible addition-fragmentation chain-transfer (RAFT) polymerization process, and self-assembled into PNPs. Our approach consisted of two rounds of iterations: in the first round, we screened a diverse library of ~450 first-generation (G1) PNPs, synthesized from six carefully selected monomers, to assess plasmid loading, transfection efficiency (TE), and cytotoxicity in immortalized human NF1-null SCs (hTERT NF1-/- ipNF97.4). *Select PNPs with specific combinations of three monomers emerged as highly effective in encapsulating the large plasmid and delivering it to SCs.* Twenty of these PNP hits were used to demonstrate partial neurofibromin restoration *in vitro* in SCs. Efficacy of the best performing PNP hit was confirmed with *in vivo* testing which showed gene expression in mouse and rat cortex. The overall TE of G1 PNPs was however not sufficient in fully restoring functional neurofibromin *in vitro.* In the second round, we leveraged a machine learning (ML) guided approach to refine the design space. The ML model, trained on successful G1 candidates, identified key structural and compositional features, which was used to generate a second-generation (G2) of 96 PNPs. *The resulting G2 PNPs exhibited a marked 5x increase in TE in SCs, from ~4% in G1 PNPs to ~20% in G2 PNPs.* Functional assays to assess biodistribution, delivery efficacy and restoration of neurofibromin function and downstream signaling pathways (e.g., pERK) both *in vitro* and *in vivo* are ongoing.

In conclusion, the combined use of our HITSCAN™ platform and a data directed evolution approach of PNPs led to the identification of a group of chemically distinct PNPs that were uniquely capable of carrying and delivering the large *NF1* gene to human SCs *in vitro*. The TE of second generation PNPs improved 5x over the first generation PNPs, highlighting the potential of high-throughput screening platforms for accelerating the development of novel nanomedicines for genetic diseases like NF1.

696 Improving Hematologic Gene Therapy by Mapping the Structure/Activity Relationship of Poly(Beta-amino ester) mRNA Nanoparticles

Michael Triebwasser[1], Grant Dominic[1], Taysia Morioka[1], Josh Flint[1], Martina Plank[2], Joerg Lahann[1]
[1]University of Michigan, Ann Arbor, MI, [2]Karlsruhe Institute of Technology, Karlsruhe, Baden-Wuerttemberg, Germany

Introduction: Disorders of the blood, including malignant conditions, such as leukemia, and non-malignant conditions, such as hemoglobinopathies, can be treated by blood cell (hematologic) gene therapy. Delivery of genes encoding chimeric antigen receptors to T-cells or gene editors to hematopoietic stem cells have offered new curative therapies to patients. However in most cases, delivery of these gene therapies to cells has relied upon viral vectors or electroporation. Viral vectors are difficult to scale up due to their high cost; electroporation toxicity reduces the recovery of modified patient cells. Non-viral, nanoparticle (NP)-based delivery is a promising alternative delivery method to hematologic cells. NP are chemically defined, easily scaled, and may have reduced toxicity. One such class of NP is polymeric NP made from poly-beta amino esters (PBAE). The plug-and-play chemistry used to synthesize PBAE allows a large, combinatorial design space. However, the intrinsic variability in the uncontrolled polymerization used to make PBAE polymers has limited wider adoption. The structure-activity relationship (SAR) between PBAE NP and delivery of mRNA to cells of the blood system is not well understood.

Methods: A new synthetic method for PBAE synthesis has been developed allowing highly reproducible polymers to be made. Using this methodology, three different length co-polymers of butanediol diacrylate and amino-butanol were made and then functionalized with three prototypical monomers (a diamine, a piperazine, or an amino-alcohol). Polymer-nucleic acid affinity was probed using fluorescent assays. mRNA transfection of human embryonic kidney (HEK/293) cell line, hematologic cell lines (K562 and HUDEP2) and primary human peripheral blood mononuclear cells (PBMC), and hematopoietic stem and progenitor cells (HSPC, CD34+) were investigated using luciferase and green fluorescent protein (GFP). Additionally, cas9 mRNA and gRNA PBAE NP-mediated gene editing of *B2m* was investigated with flow cytometry.

Results: Size characterization of PBAE polymers with gel permeation chromatography correlated with polymer size by NMR. Nucleic acid binding affinity correlated inversely with polymer length, and amino-alcohol functionalized polymers had lower binding affinity (Figure 1). From a library screen of PBAE-mRNA NP, the top performing candidate had 607-fold higher delivery of luciferase mRNA than a lipid nanoparticle based on a clinically used ionizable lipid. High activity of the best-performing PBAE polymer was conserved across HEK293 cells, HUDEP2, K562 (Figure 2A), PBMC, and CD34+ cells (Figure 2B). Delivery of cas9 mRNA and gRNA with PBAE NP is being studied in these cell types, as well as primary human T-cells.

Conclusions: PBAE NP are a promising non-viral delivery platform for delivery of mRNA to hematologic cells, including primary CD34+ cells. In this series, the profile of the best-performing polymer was conserved across cell types. Further studies of more diverse chemical structures are still needed to better understand the structure-activity relationship (SAR) between PBAE NPs and cell tropism. A better understanding of the SAR will allow the design of improved NP formulations for gene delivery, specifically to primary CD34+ cells and T-cells.

Efficacy of top-performing PBAE mRNA NP in primary human hematopoieitic stem and progenitor (CD34+) cells with similar conditions as in (A), N=2.

697 Optimizing Poly (Amine-Co-Ester) Polymeric Nanoparticles for Enhanced Nucleic Acid Delivery to Endothelial Cells

Jianlei Wu[1], Laura Bracaglia[2]
[1]*Villanova University, King of Prussia, PA,* [2]*Villanova University, Villanova, PA*

Introduction: The intricate, multi-step process of non-viral gene delivery is highly sensitive to the alterations in the structure and properties of the vehicles (1). The interaction between vehicle material and drug delivery may be cell specific. Here, we explore the use of spherical poly-amine-co-ester (PACE) polymeric NPs to deliver therapeutic nucleic acids, including siRNA and mRNA (2), to endothelial cells, an understudied target for drug delivery. In this study, we modify the base cationic PACE polymer to affect the resulting NP surface chemistry and measure the impact on endothelial cellular uptake and total drug encapsulation, developing a correlation between surface chemistry and drug delivery in this cell type. We hypothesize that an increase in ionizable groups on the polymer backbone will result in enhanced nucleic acid loading, cell uptake, endosomal escape, due to stronger electrostatic interactions (3).

Methods: PACE polymers were modified from previously described polymers with (4) with various molecular groups such as carboxylic acid (COOH), polyethylene glycol (PEG), NH-NH2, NH2-OH and NH-OH (5). Fluorescent dyes and short-chain nucleic acid oligomers were encapsulated into NPs formed from these polymers. Dynamic light scattering and zeta potential measured the NP size and surface charge. An Optical Photothermal Infrared (O-PTIR) Spectroscopy characterized functional groups and the amino group density via mapping among different PACE NPs under the wavenumber set at 1173 (cm-1). A picogreen assay measured cargo encapsulation efficiency and TNS assay tested pKa values of PACE NPs. Flow cytometry was used for quantifying cellular uptake of different PACE NPs in Human Umbilical Vein Endothelial Cells (HUVECs).

Results: A library of NPs was formulated from an identical base polymer, each modified to exhibit different surface charges. Fig 1 illustrates PACE50 NPs with distinct end groups and surface charge variations. The amino group density on these NPs was characterized (Fig. 1B). PACENH-NH2 NPs contain more amines, making them more positively charged than base PACECOOH NPs, and enter endothelial cells more rapidly (Fig 2). Surface charge (Fig. 2B), pKa values (Fig. 2D) and nucleic acid loading (Fig. 2C) shift with amine incorporation. Increased charge density results in a greater nucleic acid loading (Fig. 2C) when additional amine groups are introduced. The differences in surface charges of PACE NPs also impact their uptake by endothelial cells (Fig. 2E). Thus, surface charge and pKa values corresponding to ionization of PACE NPs have significant correlation to the cellular uptake. A higher surface charge—excluding pegylated NPs owing to their hydrophilic properties—enhances the electrostatic interaction between the NP surface and the cell membrane, promoting faster cellular uptake and making them effective carriers for nucleic acid delivery.

Conclusions: The PACE NPs with various ratios of monomers can affect the surface charge values. The polymer can also be modified further by adding different end groups to affect the surface charge. The change of surface charge values and distribution of surface charge demonstrate the versatility of PACE NPs and their potential for tailored nucleic acid delivery to endothelial cells, offering promising applications in treating inflammatory conditions.

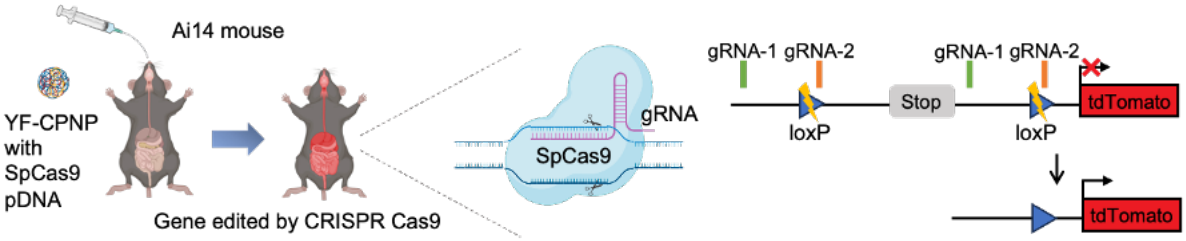
698 Polymeric Nanoparticles Targeting Gut-Associated Lymphoid Tissue for Oral CRISPR/Cas9 and dCas9 Delivery

Huiyi Liang[1], Suwan Ding[2], Veronica Farag[1], Chai Hoon Quek[1], Mengkun Yang[1], Yang Xiao[1], Shannon Weng[1], Yeh-Hsing Lao[3], Satya Nayagam[1], Kam Leong[1]
[1]Columbia University, New York, NY, [2]Columbia University, New York, [3]University at Buffalo, The State University of New York, Buffalo, NY

Effective delivery of CRISPR-Cas9/dCas9 elements is crucial to maximize therapeutic potential. Despite extensive efforts globally to improve the delivery of gene editing elements for somatic genome editing, achieving gene editing via oral delivery has remained an elusive challenge. Here, we present an innovative orally-administered, nonviral gene editing system that opens exciting new avenues for addressing the demands of both localized gene editing in the gastrointestinal (GI) tract and systemic gene editing in a patient-friendly, non-invasive, and repeatable manner. By incorporating yeast fragments into the polyplex, our oral polymeric nanoparticle (NP) platform YF-CPNP for gene editing plasmids can efficiently traverse tightly packed mucosal epithelium via intestinal microfold cells. Its subsequent endocytosis occurs in local and Peyer's patch macrophages, leading to a further accumulation in mesenteric lymph nodes (MLN). With these advantages, YF-CPNP can achieve gene editing in the macrophages, dendritic cells, T cells and B cells in the lymph nodes. This strategy not only prolongs gene editing within the local GI tract and gut-associated lymphoid tissues but also facilitates NP transport through the gut-associated lymphoid pathway to the systemic circulation, ultimately modulating the genome of distal organs such as the liver. This culminates in the manifestation of titin gene activation in the small intestine and liver through oral administration with YF-CPNP with dCas9 VPR plasmid. Our engineered delivery platform offers promise for oral gene editing and activation, representing a significant advancement with potential therapeutic applications.



699 In Vivo CAR Delivery as Supercoiled DNA with Lymphatic Tropism Polyasparagine Nanoparticles

Claudia Lee[1], Chris Coker
[1]*Velvet Therapeutics, Houston, TX*

Viral vector and lipid nanoparticles had undoubtedly demonstrated enormous success as single dose gene therapy and annual vaccines, respectively. There remains a gap for a redosable, safe yet durable vector to address the need for in vivo immune reprogramming which has shown much promise to expand the use of CAR-T cell therapy to indications such as solid tumor and autoimmune disease. We produced and characterized a non-viral, biodegradable poly-asparagine nanoparticle for DNA delivery. When the GFP encoding DNA-nanoparticle was injected intravenously, the expression was found in thymus and surprisingly evaded the liver. T cells and lung resident macrophage were found to be GFP positive. We evaluated the delivery platform's utility for in vivo reprogramming using DNA encoding an anti-CD19 chimeric antigen receptor (CAR) in C57B/6 mice. The b cell population in blood and in spleen consistently reduced following tail vein injections. T cell expansion was modest and returned to near baseline within two weeks of the initial dosing. The mice exhibited no signs of distress under a biweekly dosing schedule, which was sufficient to result in significant b cell ablation. We deployed an in-silico binder optimization platform to design a single-chain antibody as the binder of a solid tumor targeting CAR in silico and deliver the CAR as a DNA-nanoparticle polyplex to evaluate the anti-cancer efficacy.

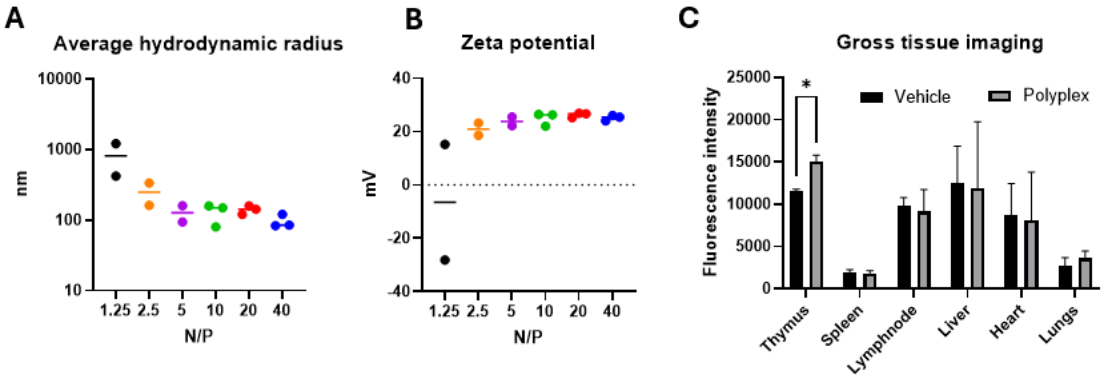


Figure 1, the physical properties and biodistribution of DNA polyplex. A) and B) are the hydrodynamic radius measured by dynamic light scattering and the zeta potential as the function of the asparagine to DNA ratio (N/P). The biodistribution of N/P 10 polyplex encoding GFP is shown in C).

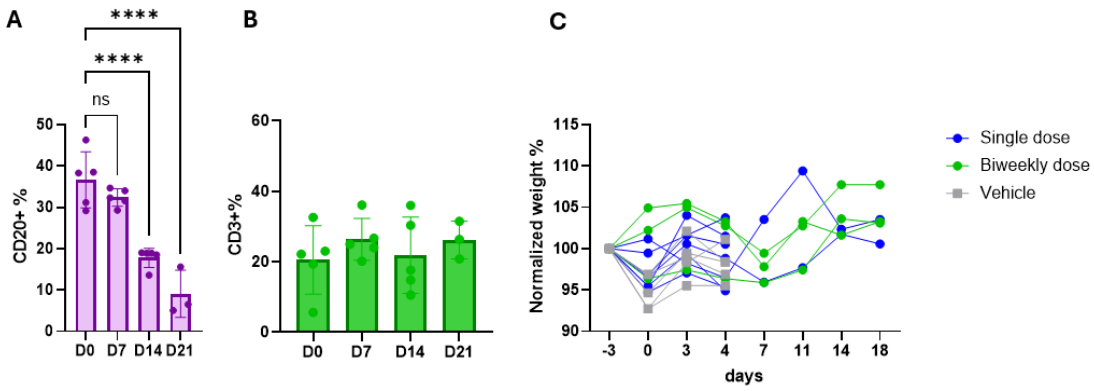

Figure 2, the b cell, t cell populations and weight changes observed in immune competent mice injected biweekly with DNA-nanoparticle encoding anti-CD19 chimeric antigen receptor. A) B cell population in PBMC steadily declined while B) T cell population undulates periodically coinciding the injection frequency. C) The normalized weight compared to baseline suggests no safety concerns.

700 In Vitro and In Vivo Delivery of Nucleic Acids using Poly(glycerol ester)

Brian Ginn[1], Gianna Marinacci[2], Benjamin Roadarmel[2], Scott Radzinski[2], Caroline Costello[2], Jeremy Harris[3]
[1]Secant Group, LLC, Telford, PA, [2]Secant Group, LLC., Telford, PA, [3]Telford, PA

Introduction: Poly(glycerol ester) (PGE) can be used to produce next-generation polyplex for cell and gene therapy and ocular delivery. PGE nanoparticles have performance based on (1) the selection of the diacid structure and the amine functionality used; (2) the type and molar ratio of the polyol; and (3) the complexation buffer and parameters. We investigated use of PGE polymers for delivery of mRNA and pDNA in serum-free, serum containing, and in vivo environments.

Method: PGE was synthesized through a polycondensation reaction followed by amine functionalization of hydroxyl groups using CDI coupling chemistry. Nanoparticle complexes were prepared using varied ratio of nucleic acid to polymer mass and particle size and zeta potential were measured (Zetasizer Ultra, Malvern). Transfection of HEK293T cells used a GFP mRNA or pDNA reporter (Aldevron). After 24 hours, cells were characterized using a flow cytometer (Cytoflex, Beckman Coulter) for viability, percentage of transfected cells (%TE), and expressed protein level (MFI). PGE formulations showing success in serum-free media were further tested in serum-containing media before being selected for testing in vivo in a mouse tail vein injection model to determine efficacy in vivo and localization of particles.

Results: PGE polyplex was able to successfully transfect HEK293T cells at a variety of PGE : nucleic acid ratios ranging from 20:1 to 40:1. Over 90% of cells were transfected with PGE in this range which was near the level seen with Lipofectamine 3000. Expression levels of the GFP reporter were high across the ranges tested and were able to exceed the expression levels seen with Lipofectamine 3000. A slight increase in expression occurred with the 20:1 group when serum was present, suggesting that serum had beneficial impact on the stability of the particle and its uptake by cells. PGE polyplex reagent was able to show notable pDNA and mRNA expression as early as 6 hours post tail vein injection in mouse models, with expression occurring primarily in the spleen of the animals.

Conclusions: Gene delivery using PGE polyplexes was demonstrated for the first time as having comparable in vitro performance to Lipofectamine 3000. PGE was able to maintain its performance in the presence of 10% FBS containing media. Furthermore, the PGE nanoparticle complex was able to transfect cells of the spleen in mouse model, indicating that they are able to protect mRNA from enzymatic degradation in vivo. These results show that the PGE nanoparticles have potential to provide an alternative to conventional delivery vehicles used for pDNA and mRNA both in vitro and in vivo.

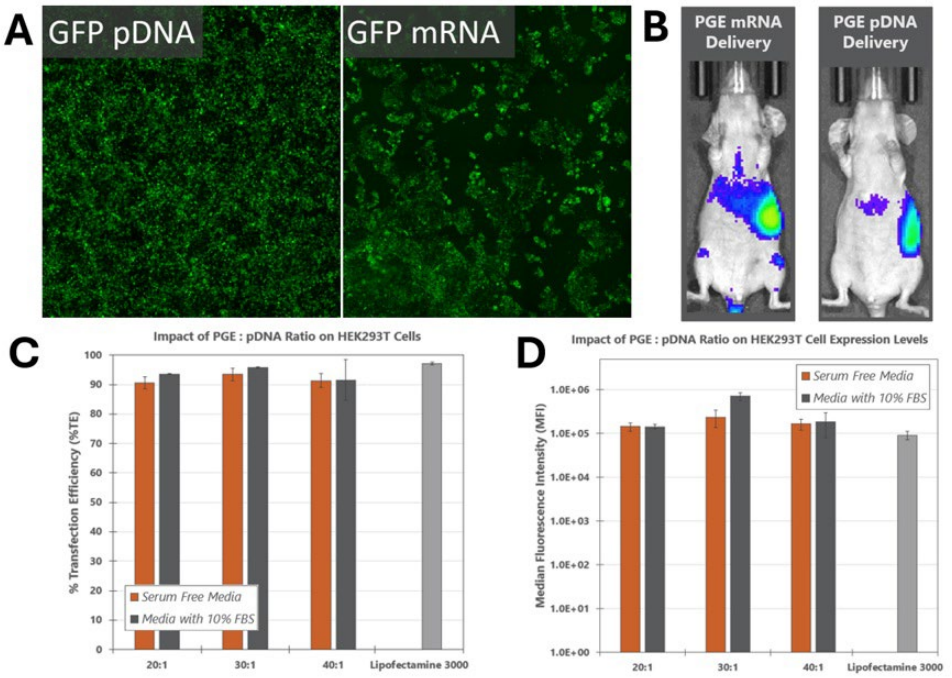

Figure 1: Poly(glycerol ester) (PGE) polyplex nanoparticles are able to deliver GFP reporter pDNA and mRNA to HEK293T cells (**A**). When delivered through a tail vein injection into mice, expression of either pDNA or mRNA is seen within 6 hours in the spleen (**B**). PGE is able to perform at or exceeding the performance of Lipofectamine 3000 across a range of PGE : pDNA ratios in both serum free and serum containing media (**C, D**).

701 High Level Persistent In Vivo Production of an anti-HIV Antibody via the Delivery of Plasmid DNA by a Polymer Nanoparticle

John Fisher[1], Olivia Heynes[2], Shannon Petersen[1], Suteja Patil[2], Teresa Tamayo-Mendoza[2], Felipe Oviedo[3], Gustavo Guzman[1], Jared Van Reet[2], Jeffrey Ting[4], Sean Kevlahan[5], Thomas Neenan[6], **Shashi Murthy[2]**
[1]Nanite, Inc., Boston, [2]Nanite, Inc., Boston, MA, [3]New York, NY, [4]Nanite, Boston, MA, [5]Nanite, North Andover, MA, [6]Nanite Inc., Boston, MA

While monoclonal antibodies are a prominent class of pharmaceutical products there remain significant issues of cost, complexity and especially delivery: concepts that overcome the need to infuse antibodies frequently are a desirable objective. An attractive approach is to deliver non-integrating DNA directly to tissue, allowing the patient to act as their own so-called "protein factory". Demonstrations of this concept have been made using LNPs and viral vectors, but these delivery methods face significant challenges, including extrahepatic delivery, cargo compatibility, safety, redosability and cost. Polymer nanoparticles (PNPs) offer a solution to these problems, but face their own challenges, such as a vast number of possible polymer structures, and polyplex formulation conditions. However, advances in machine learning, materials informatics, and high-throughput chemical synthesis techniques provide a foundation for addressing these challenges by efficiently exploring the polymer design space. Our SAYER platform utilizes a large computational dataset of pDNA polymer interactions to facilitate targeting agent discovery and refinement via deep learning, and to drive discovery of novel polymeric nanoparticles (PNPs) for a wide variety of target tissues. In this work, we demonstrate our ability to design PNPs that can deliver pDNA encoding for PGT121, a broadly neutralizing anti-HIV antibody that targets a V3 glycan-dependent epitope site on the HIV-1 envelope glycoprotein. SAYER-designed polymers formed small and stable PNPs with PGT121-encoding plasmids. Intravenous delivery demonstrated strong serum PGT121 protein levels at 1-day post-transfection and higher levels of protein expression when compared to other state-of-the-art DNA-delivery vehicles. More importantly, intramuscular delivery of Nanite PNPs showed greater than 1.0 ug/mL peak protein expression levels, with meaningful expression levels at > 56 days post-injection. Further, we showed that we can

increase antibody levels and durability by redosing. A general trend of lower dose and lower N/P ratio providing higher antibody levels is seen when PNPs were delivered intramuscularly. These parameters, separate from polymer structure, provide different mechanisms to optimize PNP in vivo delivery performance using machine learning techniques. Extension of the concept to the continuous production of other antibodies, proteins or enzymes are possible, suggesting the broad applicability of pDNA depoting via PNPs as a therapeutic modality. Finally, we emphasize that this strategy of delivering a DNA-encoded secreted proteins via a safe and effective PNP in vivo could be applicable to a wide range of other disease modalities.

702 Branched Polymers with a Crosslinked Core Offer Nanoparticle Size Retention and a Novel Method of Safe and Effective Non-Viral Gene Delivery

Andrea McCue[1], Tony Duong[1], Kenneth Sims[1], Ashlee Colbert[2], Molly Kaufman[3], Emma Schmitz[1], Dean Constantine[1]

Introduction: The delivery of nucleic acids remains a major hurdle in the development of innovative therapeutics. Adeno-associated viruses (AAVs) remain the gold standard, but they come with payload capacity limits and risks of myriad off-target effects. As such, non-viral delivery vehicles, such as polymeric nanoparticles (PNPs) and lipid nanoparticles (LNPs) are attractive alternatives for gene delivery solutions. PNPs represent a potential improvement beyond other non-viral vehicles such as LNPs, due to their increased compositional diversity, which confers the ability to fine tune physical properties beyond the traditional limits of LNPs. These physical properties include features such as size, charge, and shape, features which may be critical in biodistribution, cell uptake, payload release, reduced immunogenicity, and excretion.

Methods: We have developed the HIT SCAN^{TM} (High-Throughput Synthesis, Characterization, and Assessment of Nanoparticles) Platform, a design-build-test-learn PNP screening platform to guide the quick discovery of PNP delivery vehicles. It combines automated PNP library synthesis, in vitro and in vivo screening, and machine learning models to process generated data and direct new PNP synthesis. *Using the HIT SCAN platform, we have developed a family of novel polymer compositions that are designed to produce PNPs that are biodegradable, have a low elastic modulus, have a long half-life and have the potential to achieve a sustained release and/or slowed cellular uptake of their nucleic acid cargo.* The core of these PNPs is a copolymer of a cationic acrylic acid monomer containing tertiary amines, crosslinked with a dialkene functional monomer where the two vinyl groups are connected by an ethylene oxide oligomer linkage. Though most typical lipid nanoparticles and polymer micelles rely on self-assembly of amphiphilic molecules, to form nanoparticle structures, the cross-linked nanostructure of these branched PNPs may allow them to be smaller and maintain size under various formulation conditions. Moreover, the inclusion of the ester groups in the crosslinked core gives these nanoparticles the feature of biodegradability not present in most other polymer and lipid nanoparticles. Finally, the corona of the PNP may be tailored with various functional groups to tune the half-life of the nanoparticles, potentially resulting in sustained action nucleic acid drugs.

Results: We designed and synthesized a diverse of branched polymers, all of which were small (<50nm in diameter) when hydrated as unloaded PNPs in PBS. From this diverse library, a specific compositional family sharing a common functional group on the corona yielded PNPs that formed polyplexes with a small size (<50nm) upon loading with an eGFP circular RNA payload under conditions that often result in aggregated PNPs. In vitro transfection efficiency in HEK293T cells was assessed for the entire diverse library of branched polymer PNPs loaded with the same eGFP circular RNA payload above. Interestingly, there was an overlap between the compositional family of PNPs that formed small polyplexes with RNA, and those with high in vitro transfection efficiencies. We show that the crosslinked core polymers are useful for small polyplexes with nucleic acids that also demonstrate efficient transfection in cell culture. Future work will include evaluation of the in vivo delivery efficiency of this PNP family.

703 Programmable Polymer Nanoparticles Co-Package and Deliver Dual mRNA and pDNA Cargo to Cells

[1]Nanite Inc, Boston, MA, [2]Nanite, Inc., Boston, [3]Nanite, Boston, MA, [4]Nanite, Inc., Boston, MA, [5]New York, NY

Clinical success in the field of gene therapy underscores the importance of identifying affordable gene delivery options for broader public access to life-changing treatments. Lipid nanoparticles (LNPs) have emerged as the leading choice for mRNA-based therapies with the deployment of COVID vaccines, but are limited by their immunogenicity, inability to deliver pDNA and inadequate extra-hepatic delivery. In addition, viral vectors carrying DNA are particularly hindered by cargo capacity and inability to re-dose. Furthermore, virtually no nanocarrier system has shown potential for multi-cargo gene delivery. Polymer nanoparticles (PNPs) offer safe and resorbable capabilities for delivering mRNA or pDNA cargos in an economical way to achieve tissue targeted expression of transgenes. Nanite's proprietary AI-powered platform, SAYER™, rationally designs polymers across hundreds of thousands of collected datasets for effective mRNA or pDNA delivery to target tissues. Here we present optimally designed polymer candidates that can co-package mRNA as well as pDNA within a single nanoparticle, achieving >80% encapsulation efficiency. We also report successful transfection of dual cargo to human bronchial epithelial cell lines, and primary human basal cells with minimal cytotoxicity. The unique ability of Nanite's PNPs to co-deliver mRNA and pDNA into the same cell allows tunable and combinatorial gene expression control that is important across the gene and cell therapy landscape, including gene editing and gene silencing with simultaneous protein replacement, thereby offering competitive advantages over LNP and viral-based delivery systems.

704 Engineering Fusion Proteins to Enhance Efficacy of Adoptive Cell Therapy for Solid Tumors

Miranda Lyons-Cohen[1], Ryma Toumi[1], Valentina Grillo Alvarado[1], Shannon Oda[1]*
[1]Seattle Children's Research Institute, Seattle, WA

Adoptive cell therapy (ACT) is a "living drug" that provides the opportunity to genetically modify T cells to recognize and kill tumors. While this therapy has shown incredible curative potential in hematologic cancers, engineered immune cells can struggle to overcome immunosuppressive barriers in solid tumor microenvironments (TME), which has necessitated the development of novel engineering strategies. The TME presents obstacles that reduce T cell persistence and function, including hypoxia, upregulated inhibitory/death ligands, and immunosuppressive immune cells that promote tumor progression. Here, we describe the development of novel engineered fusion proteins called transform switch receptors (TSRs), that promote T cell persistence and antitumor efficacy against solid tumors by converting inhibitory signals to stimulatory signals to enhance T cell function. We developed Fas-TSRs that combine a negative receptor "decoy" ectodomain (Fas) with a toolbox of different costimulatory endodomains. FasL is a death receptor ligand highly expressed in many cancers that induces T cell apoptosis via FasL/Fas interaction and is a known limiting factor for ACT. We evaluated an array of novel Fas-TSRs in a murine model of pancreatic cancer and identified a leading Fas-TSR candidate that significantly outperformed all costimulatory domains tested – including the Fas-4-1BB that is currently in clinical trials. In preliminary studies, our leading Fas-TSR candidate significantly enhanced survival and improved tumor control *in vivo*. Fas-TSR T cells showed enhanced expansion in the blood, greater poly-functional cytokine expression, and reduced expression of markers associated with T cell exhaustion in the tumor. *In vitro*, Fas-TSR T cells showed enhanced proliferation and function under hypoxic conditions, demonstrating increased function in the immunosuppressive TME. Collectively, these data show that the Fas-TSR engineering strategy provides a safe and durable antitumor T cell response that significantly improves therapeutic efficacy against solid tumors. These data provide novel insights in ACT pre-clinical models to support the advancement of novel Fas-TSRs to clinical trials.

705 DNA delivery by lipid nanoparticles induces CD8$^+$ T cell-dependent antitumor responses and synergizes with anti-PDL1 antibodies in mouse models of hepatocellular carcinoma

ALBA RODRIGUEZ-GARCIA[1], Seoyun Yum[2], Joan Castellsagué[3], Marta Gimenez-Alejandre[4], Guillem Colell[5], Salut Colell[1], Teresa Lobo-Jarne[5], Rui Zhang[6], Xavier Anguela[7], Ali Nahvi[8], Matt Walsh[2], Pedro Cejas[2], Sean

Armour[2], Sonia Guedan Carrio[9]
[1]FCRB-IDIBAPS, Barcelona, Barcelona, Spain, [2]Spark Therapeutics, Philadelphia, PA, [3]August Pi I Sunyer Institute of Biomedical Research, Spain, [4]August Pi I Sunyer Institute of Biomedical Research, Barcelona, Barcelona, Spain, [5]IDIBAPS, Barcelona, Spain, [6]XGen Bio, Winchester, MA, [7]Spark Therapeutics, Inc., Philadelphia, PA, [8]Nava Therapeutics, Cambridge, MA, [9]IDIBAPS, Barcelona, PA, Spain

Background: The introduction of immune checkpoint inhibitors (ICIs) into frontline therapy has reshaped the treatment landscape of hepatocellular carcinoma (HCC). However, only a small subset of patients benefit from these therapies. Nucleic acid-based therapies, particularly those utilizing lipid nanoparticles (LNPs) as delivery vehicles, offer promising avenues for cancer treatment. In this study, we hypothesized that intracellular delivery of non-coding double-stranded DNA (dsDNA) via LNPs can activate innate immune signaling pathways to induce antitumor immune responses and potentiate ICI.

Methods: DNA-LNPs were formulated by combining promoterless plasmid and lipid components using a microfluidic device. Their antitumor efficacy, as monotherapy or in combination with anti-PD-L1 antibodies, was interrogated in two mouse models of HCC. The first involved genetic induction of HCC through hepatic overexpression of c-Met and ΔN90-β-catenin using the Sleeping Beauty transposon/transposase system. The second model involved chemical induction of HCC using diethylnitrosamine (DEN). Serum cytokine levels were measured 4 hours after DNA-LNPs intravenous administration. At study endpoints, livers were analyzed for macroscopic changes, immunohistochemistry staining, and gene expression. Survival outcomes were also assessed.

Results: Treatment with DNA-LNPs triggered a rapid, dose-dependent increase in serum cytokines including IFN-γ, TNF-α, IL-6 and IFN-β. This immune activation led to the recruitment of $CD8^+$ T cells to the tumor microenvironment, which mediated a significant antitumor effect as indicated by increased survival and reduced liver-to-body weight ratios in the genetically induced HCC model. The antitumor efficacy was abolished by $CD8^+$ T cell depletion. Transcriptomic analysis revealed downregulation of pathways associated with HCC progression in treated mice, alongside reduced expression of the oncogenes, β-cat and c-MET, and the proliferation marker Ki67, underscoring the therapeutic impact of DNA-LNPs. No cytokine elevation or antitumor effects were observed after administration of empty LNPs, suggesting that these responses were triggered by the activation of cytosolic DNA-sensing pathways. DNA-LNPs also demonstrated robust antitumor activity in the chemically induced HCC model, as evidenced by a significant reduction in tumor nodule count at the endpoint. The combination of DNA-LNPs with anti-PDL1 antibodies resulted in a synergistic effect, with 90% of treated mice remaining disease-free at the endpoint, compared to 20% and 50% with either treatment alone, respectively.

Conclusions: DNA-LNPs represent a promising therapeutic strategy for HCC, capable of eliciting potent antitumor immune responses. Their efficacy, particularly in combination with ICI, highlights their potential for clinical translation in the management of HCC.

706 Successful Treatment of Recurrent Respiratory Papillomatosis with INO-3107 is Irrespective of Papilloma Microenvironment and Molecular Subtype

Albert Sylvester[1], **Elisabeth Gillespie[2]**, Sarah Marcus[1], Emma Reuschel[1], Kathryn Reed[1], Sadie Wisotsky[1], Grace Tan[1], Jeffrey Skolnik[1], Matthew Morrow[3]
[1]Inovio Pharmaceuticals, Plymouth Meeting, PA, [2]Inovio Pharmaceuticals, Inc. - Plymouth Meeting, Plymouth Meeting, PA, [3]Inovio Pharmaceuticals, Inc., Plymouth Meeting, PA

Introduction: Recurrent respiratory papillomatosis (RRP) is a chronic disease of the airway characterized by recurrent papilloma growth caused by Human Papillomavirus (HPV) infection. The current standard of care consists of multiple surgeries, which often lead to lasting damage to the airway and impaired vocal function. Treatments that minimize or eliminate the necessity for these surgeries while ideally targeting the known etiological agents of RRP (HPV-6 and/or HPV-11) are thus an area of need. Various molecular aspects of papilloma tissue are known to have immune suppressive/regulatory activity, inclusive of high viral load, cytokine/chemokine expression profiles and molecular subtype status. Such aspects may present hurdles to efficacy of an immune

therapy based on T cell activity. Here we report successful clinical treatment of RRP irrespective of these variables in a Phase 1/2 trial of INO-3107, a DNA therapy designed for the treatment of adults with RRP (NCT04398433).

Methods: INO-3107 was administered on study Weeks 0, 3, 6 and 9. Formalin-fixed paraffin-embedded papilloma tissue obtained prior to treatment was assessed by RNA sequencing. Data analyses were performed via R and Gene Set Enrichment Analysis (GSEA) platforms. Patients were classified as clinical responders if the frequency of required surgery during the 52-week trial was lower than the 52-week period prior to treatment.

Results: The overall clinical response for the trial was 81.3%. Pre-treatment papilloma tissue exhibited diverse viral loads in both HPV-6 and/or HPV-11 infected patients, and reductions in surgical interventions were observed irrespective of either HPV type or viral replication. GSEA driven assessment of pre-treatment papilloma tissue did not identify significant elevations of hallmark Interferon Alpha (IFNa) signaling or Inflammatory modules in patients who responded clinically as compared to those who did not. Likewise, individual assessment of cytokines such as IL-1b, IL-15 and IL-18 did not show elevations specific to patients who exhibited clinical responses, nor did expression of chemokines such as CXCL9 or CXCL10. Regression analyses of VEGFA and PD-L1 expression versus change in surgical intervention while on trial did not reveal a significant correlation. Additionally, categorization of pre-treatment papilloma tissue into Basal (immune permissive) or Differentiated (immune exclusionary) molecular subtypes did not trend with clinical benefit.

Conclusions: Reduction in surgical interventions for the management of RRP after immunotherapy were not contingent on low viral loads, a pre-inflamed papilloma status or reduced expression of modulators such as VEGFA or PD-L1. Presence of a Differentiated molecular papilloma subtype did not preclude clinical efficacy. Taken together these data indicate that INO-3107 was able to effectively reduce surgical burden in RRP patients irrespective of papilloma microenvironment and molecular subtype.

707 Platelet-hitchhiking Delivery of MSA-2 and Mn^{2+}-loaded Nanoparticles for Preventing Post-surgical Tumor Recurrence

Xiao Han[1], Bryan Bell[1]*, Di Wen[1]*
[1]*Earle A. Chiles Research Institute, Portland, OR*
**Corresponding Author*

As a critical innate immune activation pathway in cancer immunotherapy, the cyclic GMP-AMP synthase (cGAS)-stimulator of interferon genes (STING) pathway enhances anti-tumor responses by promoting the release of type-I interferons (IFN) and other proinflammatory cytokines. MSA-2, an orally administered small molecule STING agonist, binds to human and mouse STING through dimer formation. However, systemic administration of MSA-2 requires high doses, which may cause off-target toxicity and limit its clinical application. Meanwhile, manganese ions (Mn^{2+}) have been shown to synergistically enhance STING activation when combined with STING agonists. Based on that, we propose to co-deliver Mn^{2+} and MSA-2 using spontaneously formed nanoparticles that could increase local drug concentration and amplify anti-tumor immune responses. Inspired by the wound-targeting ability of platelets, we hypothesized that platelet-hitchhiking delivery of MSA-2-loaded nanoparticles to the post-surgical tumor bed would improve drug accumulation at the tumor site, thereby preventing recurrence.

Here, we synthesized Mn^{2+}-coordinated tannic acid (TA) nanoparticles for MSA-2 delivery using a one-pot method. TAs serve as crosslinkers and anchoring sites for attaching nanoparticles to platelet membranes *via* polyphenol groups. We demonstrated that co-delivery of Mn^{2+} and MSA-2 through nanoparticles induced a stronger type-I IFN release compared to free-form drugs. Additionally, the TA-Mn-MSA-2 nanoparticles exhibited high drug-loading efficiency and pH-responsive disintegration, allowing controlled drug release. When administered intratumorally, these nanoparticles significantly enhanced dendritic cell (DC) maturation, T cell infiltration, and activation, leading to the efficient tumor eradication in the mouse CT26 tumor model. In an incomplete surgery model, particle-loaded platelets effectively targeted tumor residues and induced tumor regression. Our findings offer a promising alternative for systemic delivery of STING agonists to prevent post-surgical tumor recurrence.

708 Ex Vivo Modified Extracellular Vesicles as a Novel Immunotherapeutic Strategy in Glioblastoma

Introduction: Despite significant advancements, the effectiveness of immunotherapy in treating glioblastoma remains unsatisfactory. Oncolytic virus (OV) therapies can kill tumor cells and stimulate the immune system. However, they face challenges posed by the tumor microenvironment. Our research investigates the use of extracellular vesicles (EVs) from glioblastoma stem-like cells (GSCs) following OV infection (EVOV) as vehicles to transport tumor antigens and activate immune signals.

Methods: We developed a spheroid model to assess EVOV's impact on immune responses by co-culturing GSCs with immune cells pre-treated with EVs or EVOVs. Patient-derived GSCs (n=6) were infected with OV (MOI 0.1), and 12 hours later, EVs/EVOVs were isolated and analyzed by Ultra Deep DIA-MS, then used to treat PBMCs. Immune responses and cytokine production were measured using multiparameter flow cytometry. Treated PBMCs were co-cultured with GSC spheroids for three days and analyzed for immune cell infiltration using Rarecyte™ technology and multiparameter flow cytometry. In a final in vivo study, humanized NSG mice (n=16) were injected with PBMCs and GSCs, with GSCs injected into the brain to create a glioblastoma disease model, and the ability of EVOV to activate immune cells circulating in the blood and recruit them to tumors was evaluated.

Results: Our findings revealed significant alterations in the EVOV proteome/peptidome profile upon OV infection. Bioinformatic analysis identified deregulated immunopeptides/proteins (n=879 and 2156; $p<0.05$, FC>1.5) linked to immune responses. Functional tests demonstrated that EVOV significantly enhanced cytokine production (IL-12p70, IFN-γ, MCP-1), activating NK cells, DCs, CD4+ and CD8+ T cells. EVOV-pre-treated PBMCs co-cultured with GSCs had increased activated immune cells (NKT, CD8+ T, and NK cells) and monocytes switching to DCs. The co-culture setup also demonstrated a higher percentage of GSC death when exposed to EVOV-pre-treated PBMCs, emphasizing the cytotoxic potential of this approach. UMAP analysis highlighted distinct activation states induced by EVOV. Using Rarecyte™, we observed significant infiltration of CD8+ T cells expressing granzyme B and TBX21 in tumor spheroids treated with EVOVs. Notably, these spheroids exhibited lower levels of PD-L1+ CD11C+ cells, indicating a reversal of the immunosuppressive microenvironment.

In a humanized NSG mouse model, EVOV treatment reduced CD8+ PD1+ CD25+ T cells and increased activated helper T cells in the blood, indicating enhanced immune responses and decreased T-cell exhaustion. The cytometric analysis also showed a more structured CD3+ T-cell population in the EVOV group, reflecting targeted activation in response to tumor antigens in EVOV.

Conclusions: Our findings suggest that EVOVs represent a promising platform for glioblastoma immunotherapy, potentially overcoming immune evasion mechanisms characteristic of glioblastoma and offering a new avenue for durable therapeutic responses. Thus, this approach can potentially establish similar therapies for other hard-to-treat cancers.

709 Safety and efficacy evaluation of retroviral vectors GEN-1018 and GEN-1013 toward clinical translation for *in vivo* immuno-gene therapy and combined suicide gene therapy

Carli Burns[1], Laura Strauss[1], Akihito Inagaki[1], Stephanie Lees[1], Cecilia Roh[2], Noriyuki Kasahara[3], **Robert Johnson[4]***
[1]GenVivo, Inc., San Marino, CA, [2]GenVivo Inc, San Marino, CA, [3]4D Molecular Therapeutics, San Francisco, CA, [4]GenVivo Inc, Lafayette, CA

Interleukin-12 (IL-12) is a potent anti-tumor cytokine which enhances tumor infiltration and cytotoxic activity of natural killer (NK) cells and cytotoxic T lymphocytes (CTL), activates T_H-1-type immune responses [1-2], and exhibits anti-angiogenic properties [3]. However, systemic administration of IL-12 as a biologic therapy has never achieved approval due to life-threatening toxicities, primarily mediated by induction of IFN-γ overproduction [4-6]. IL-12 gene therapy represents an alternative therapeutic strategy which can be combined with prodrug-activated suicide gene therapy approaches. Our previous preclinical studies supported initiation of clinical trials for *in vivo* cancer gene therapy with GEN2, a retroviral vector for combined delivery of granulocyte-macrophage colony stimulating factor (GM-CSF) and an enhanced gain-of-function variant of the herpes simplex virus thymidine kinase suicide gene (HSV-eTK). Here, we performed a preliminary evaluation of GEN-1018, a retroviral vector encoding both p35 and p40 subunits of human IL-12 (hIL-12), and GEN-1013, encoding both HSV-eTK and IL-12, as well as corresponding surrogate vectors encoding murine IL-12 (mGEN-1018 and mGEN-1013, respectively).

Preliminary evaluation of therapeutic efficacy was performed by intratumoral (IT) or systemic (IV) administration of mGEN-1018 and mGEN-1013 to subcutaneous CT26 murine colorectal cancer models in syngeneic BALB/c mice, with mGEN-1013 experimental arms also treated with ganciclovir (GCV) prodrug. General health, body weight, and tumor growth were monitored over time, followed by immunophenotyping of peripheral blood, spleen, and tumor infiltrating immune cells. Additionally, preliminary safety evaluation of GEN-1013 was performed with pre-transduced A375 subcutaneous human melanoma models in immunodeficient athymic nude mice, enabling measurement of serum hIL-12 levels produced by a predetermined percentage of vector-transduced tumor cells.

Preliminary efficacy data showed that in the aggressive CT26 murine colorectal cancer model in immunocompetent mice, both IT and IV administration of mGEN-1018 and mGEN-1013 induce local and systemic antitumor immune responses by stimulating production of IFN-γ and Granzyme B from NK cells and CTL. Combined gene delivery of both mIL-12 and HSV-eTK by mGEN-1013 followed by GCV prodrug resulted in increased survival compared to control animals. Antitumor effects of systemic IL-12 gene therapy were not associated with visible signs of toxicity, as indicated by lack of significant body weight loss. In the preliminary safety study, increasing serum hIL-12 levels observed in the GEN-1013 pre-transduced A375 tumor model correlated with increasing tumor size over time. However, at all assessed time points, serum hIL-12 concentrations were found to be within the range previously reported to be well-tolerated in humans and non-human primates.

Overall, our results indicate the potential for in vivo gene therapy with retroviral vectors delivered by systemic or IT routes gene delivery to elicit a potent anti-tumor response through antigen release from cancer cells killed by HSV-eTK/GCV suicide gene therapy, leading to anti-tumor CTL responses that are further enhanced by IL-12-mediated activation of both CTL and NK cells. Based on these results, GEN-1013 is currently being further evaluated in definitive preclinical studies to support clinical translation and Investigational New Drug (IND) application.

710 Generation of allogeneic CAR-NKT cells from hematopoietic stem and progenitor cells using a clinically guided culture method

Yanruide Li[1], Lili Yang[2]
[1]University of California, Los Angeles, North Hills, CA, [2]University of California Los Angeles, Los Angeles, CA

Cancer immunotherapy utilizing autologous chimeric antigen receptor (CAR) T cells encounters challenges in manufacturing and patient selection that could be circumvented by employing 'off-the-shelf' products, such as allogeneic CAR natural killer T (^{Allo}CAR-NKT) cells. Previously, we reported a system for differentiating human hematopoietic stem and progenitor cells into ^{Allo}CAR-NKT cells; however, the reliance on three-dimensional culture and xenogeneic feeders limited its clinical applicability. In this study, we describe a clinically guided method to differentiate and expand IL-15-enhanced ^{Allo}CAR-NKT cells, achieving high yield and purity. We generated ^{Allo}CAR-NKT cells targeting seven different cancers and demonstrated their antitumor efficacy, expansion, and persistence in a multiple myeloma model. These cells selectively depleted immunosuppressive cells within the tumor microenvironment and counteracted tumor immune evasion through triple targeting via CAR, TCR, and NK receptors. Additionally, they exhibited a stable hypoimmunogenic phenotype, which is associated with epigenetic and signaling regulation, and did not induce detectable graft-versus-host disease or cytokine release syndrome. These favorable characteristics of ^{Allo}CAR-NKT cells underscore their potential for clinical translation.

711 Allogeneic CD33-directed CAR-NKT Cells for the Treatment of Bone Marrow-resident Myeloid Malignancies

Ying Fang[1], Yanruide Li[2], Siyue Niu[3], Yichen Zhu[4], Yuning Chen[4], Zibai Lyu[5], Lili Yang[1]
[1]University of California Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles, North Hills, CA, [3]UCLA, [4]Los Angeles, CA, [5]University of California Los Angeles

Chimeric antigen receptor (CAR)-engineered T cell therapy holds promise for treating myeloid malignancies; however, challenges remain in bone marrow (BM) infiltration and targeting BM-resident malignant cells. Current autologous CAR-T therapies also face manufacturing and patient selection issues, underscoring the need for off-the-shelf products. In this study, we characterize primary patient samples and identify a unique therapeutic opportunity for CAR-engineered invariant natural killer T (CAR-NKT) cells. Using stem cell gene engineering and a clinically guided culture method, we generate allogeneic CD33-directed CAR-NKT cells with high yield, purity, and robustness. In preclinical mouse models, CAR-NKT cells exhibit strong BM homing and effectively target BM-resident malignant blast cells, including CD33-low/negative leukemia stem and progenitor cells. Furthermore, CAR-NKT cells synergize with hypomethylating agents, enhancing tumor-killing efficacy. These cells also show minimal off-tumor toxicity, reduced graft-versus-host disease and cytokine release syndrome risks, and resistance to allorejection, highlighting their substantial therapeutic potential for treating myeloid malignancies.

712 Reinvigoration of Exhausted T Cells Towards Improved Immunotherapy

Brandon Simone[1], Leo Torres[2], Junwei Shi[3], Edward Wherry[1], Saar Gill[4]
[1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania School of Medicine, Philadelphia, PA, [3]University of Pennsylvania, Bethesda, PA, [4]University of Pennsylvania, Philadlephia, PA

Cellular immunotherapies, including adoptive T cell transfer and genetically engineered T cell therapies, have transformed the treatment of hematologic malignancies and are showing increasing promise in solid tumors. However, the efficacy of these therapies is often compromised by **T cell exhaustion**, a dysfunctional state characterized by progressive loss of cytotoxicity, proliferation, and cytokine production. While immune checkpoint inhibitors (ICIs) can reinvigorate progenitor-exhausted T cells (T_{pex}) in some cancers, ICIs have shown little efficacy in hematologic malignancies despite their susceptibility to T cell immunity. Since **terminally exhausted** T cells are

thought to be refractory to checkpoint blockade, we sought to discover novel means of reversing deeply exhausted T cells.

To address this challenge, we developed a **CRISPR screening approach specifically designed to uncover genes that reverse T cell exhaustion**, rather than merely prevent its onset. A key innovation of this work is the ability to genetically modify **already-exhausted human T cells**, which required the development of a robust and tractable in vitro model of human T cell exhaustion. In this system, naïve human CD8+ T cells were redirected against a B cell acute lymphoblastic leukemia (B-ALL) cell line using a commercially available anti-CD19 × anti-CD3 bispecific T cell engager (BTE) and were subjected to repeated antigenic stimulation every 48 hours until they exhibited hallmark features of exhaustion, including loss of cytotoxicity, proliferation, and cytokine production (approximately 20 days). This model was then leveraged to perform functional genetic screening, employing both a pooled CRISPR sgRNA library targeting ~240 epigenetic modifiers via lentiviral transduction and a novel, non-viral cell-penetrating peptide (CPP)-mediated CRISPR/Cas9 system.

As a proof-of-concept, we first demonstrated efficient single-gene knockout in highly exhausted T cells. We then applied our CRISPR screen in "**exhaustion prevention" mode**, recovering known regulators of exhaustion such as components of the SWI/SNF chromatin remodeling complex, validating the fidelity of our model. More importantly, using our system in "**exhaustion reversal" mode**, we identified novel genetic hits, including genes known to enhance T cell persistence, as well as previously uncharacterized regulators of T cell function.

By identifying genes that may actively restore function in exhausted T cells, we hope to gain new insights into the molecular mechanisms of exhaustion reversal. Such findings could shift the focus from exhaustion prevention toward active rejuvenation of dysfunctional T cells, opening new therapeutic avenues to enhance the durability and efficacy of adoptive T cell therapies.

713 Vectorized Interferons Provide a Robust and Sustained Transcriptional Response Over Traditional Non-Vectorized Recombinant Cytokine Therapies in Human High-Grade Glioma Cells

Tian Lee[1], **Chris Lovejoy[1]**, Ethan Fenton[1], Akela Kuwahara[1], Nathalie Clement[1], Lauren Kelly[1], Nicole Paulk[1]*
[1]Siren Biotechnology, San Francisco, CA
**Corresponding Author*

BACKGROUND: Interferons are pleiotropic immunomodulatory cytokines that drive anti-tumor functions and show promise as cancer therapies. However, their short half-lives limit their ability to mount sustained anti-tumor responses. Siren Biotechnology has developed an AAV immuno-gene therapy platform that delivers vectorized engineered interferons to overcome half-life challenges seen with traditional cytokine therapies. Our first program with this new modality targets high-grade gliomas (HGGs), aggressive brain cancers with no effective therapeutic options. We developed an *in vitro* model to measure cytokine durability and transcriptional responses in human HGG cells. Here, we compared the transcriptomic response of HGG cells when treated with a pulse of recombinant human interferon beta (hIFNβ) cytokines versus vectorized hIFNβ.

METHODS: Two human HGG cell lines (GBM6-FL and U251-FL) were treated with either an AAV carrying an engineered human IFNβ (AAV9-hIFNβ, 4e5-5e5 vg/cell), AAV9-GFP (4e5-5e5 vg/cell), recombinant hIFNβ protein (114-158 pg/mL), or media alone followed by a 24h washout period. Cell culture media and cells were collected 24, 48, 72, and 96h post-treatment for quantification of hIFNβ protein and mRNA purification, respectively. Bulk transcriptomic profiling was performed by RNA-sequencing on an Illumina NovoSeq 6000 with 150 bp paired-end reads. Reads were aligned to the human genome (GRCh38.p14) using STAR v2.7.11b and counted using subread v2.0.6. Differentially-expressed genes (DEGs) were identified relative to media alone and were considered significant if p-adj<0.01.

RESULTS: As expected, treatment with recombinant hIFNβ resulted in media hIFNβ levels below detectable limits (<23 pg/mL) within 24h due to progressive treatment washout. However, cells treated with vectorized hIFNβ induced hIFNβ protein as early as 15h, with expression above 2,000 pg/mL within 48h. Despite daily media

exchanges, hIFNβ levels in the transduced HGG cells were sustained for the 96h time course, demonstrating that vectorized delivery can induce durable supraphysiological levels of hIFNβ expression, directly overcoming half-life challenges of protein-based cytokine therapy. Importantly, measured media levels of hIFNβ protein treatments corresponded with time-matched transcriptional effects in the HGG cells. Cells treated with vectorized hIFNβ exhibited a robust and durable hIFNβ response, evidenced by sustained and increasing DEGs for the entire experiment (96h). Conversely, the response induced by recombinant hIFNβ cytokine was short-lived, with peak DEGs at 24-48h (2,600-5,000 DEGs, p-adj<0.01), followed by a 20-80X DEG reduction by 96h (30-260 DEGs, p-adj<0.01) for each cell line. Importantly, Type I IFN and TNFa signaling pathways were the most significantly enriched pathways in both cell lines treated with recombinant hIFNβ and vectorized hIFNβ when compared to their media alone treatments (p-adj<0.01), suggesting an immunostimulatory and anti-tumoral transcriptomic response specifically induced by the hIFNβ payload, which was absent in the AAV9-GFP control treated cells.

CONCLUSION: Taken together, our data suggests that vectorized hIFNβ induces sustained hIFNβ expression and an IFN-specific anti-tumoral transcriptomic response in HGG cells. Excitingly, this data supports cytokine vectorization as a powerful new modality class that overcomes the half-life challenges seen with traditional cytokine immunotherapy approaches.

714 Hemato-Chimeric Mice Hosting Human Liver-Resident Macrophages for Translational Studies Using In Vivo Gene Therapy of Liver Metastases

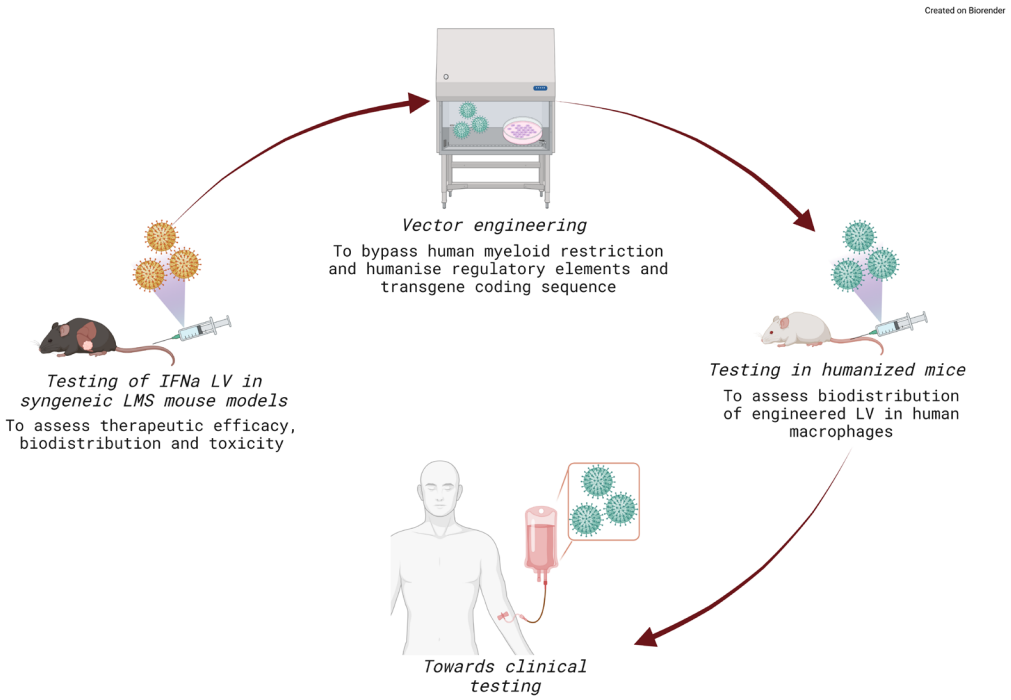
The liver hosts an immunosuppressive environment favoring occurrence of liver metastases (LMS), which render pharmacological treatments often ineffective, leading to poor patient prognosis. We have previously described an *in vivo* gene therapy platform, based on lentiviral vectors (LVs) to selectively engineer liver macrophages, including both liver-resident Kupffer cells (KCs) and tumor associated macrophages (TAMs), to secrete type I interferon (IFNα) within liver metastases. Selective transgene expression was achieved by a macrophage specific promoter and microRNA target sequences that, upon systemic delivery of the LV to mice, led to selective transgene expression in hepatic macrophages which was enhanced in areas surrounding LMS. Gene-based IFNα delivery caused reduced metastatic volume of both colorectal and pancreatic ductal adenocarcinoma liver metastases in mice. Therapeutic response was associated with macrophage immune activation, increased antigen presentation and increased CD8 T cell infiltration and cytotoxicity. In a subset of mice, we detected resistance to IFNα therapy, associated with increased IL-10 signaling, expansion of *Eomes* CD4+ T cells, a cell type displaying features of type I regulatory T (Tr1) cells, and CTLA-4. Combination of *in vivo* IFNα gene therapy with CTLA-4 immune checkpoint blockade expanded tumor-reactive T cells, attaining complete response in most mice. These findings support a promising therapeutic strategy with feasible translation to patients, however human-specific myeloid restriction to LV transduction poses a challenge. Among other mechanisms, SAMHD1-mediated interference with LV retrotranscription and integration in the human genome limits the potentiality of our platform. Here, we introduce a novel mouse model featuring human KCs, alongside LVs customized for human macrophage-specific transgene expression. We enabled the engraftment of human KCs in mice by administering *in vivo* LVs expressing human myeloid-specific growth factors, followed by transplantation of human hematopoietic stem cells. Compared at single cell-RNA level, human KCs predominated in the livers of hemato-chimeric mice and exhibited transcriptional profiles akin to patient-derived KCs. Additionally, we developed and characterized a human macrophage specific MRC1 promoter, which yielded significant transgene output, with heightened expression observed in M2-polarized macrophages. Engineered LVs, packaging the HIV-2 accessory protein VPX, bypassed SAMHD1 restriction enabling *in vivo* human KC engineering in humanized mice. The development of this humanized mouse model,

coupled with VPX-loaded LVs, represents a pivotal advancement for LV-based *in vivo* gene therapies. Humanised models not only enhance our understanding of LV-mediated transduction in human macrophages but also accelerate the translation of preclinical findings to clinical applications.



715 Recombinant Newcastle Disease Virus Expressing PTEN as a Novel Therapeutic Approach for Pancreatic Ductal Adenocarcinoma

Seonhee Kim[1], Hyun Jang[2]

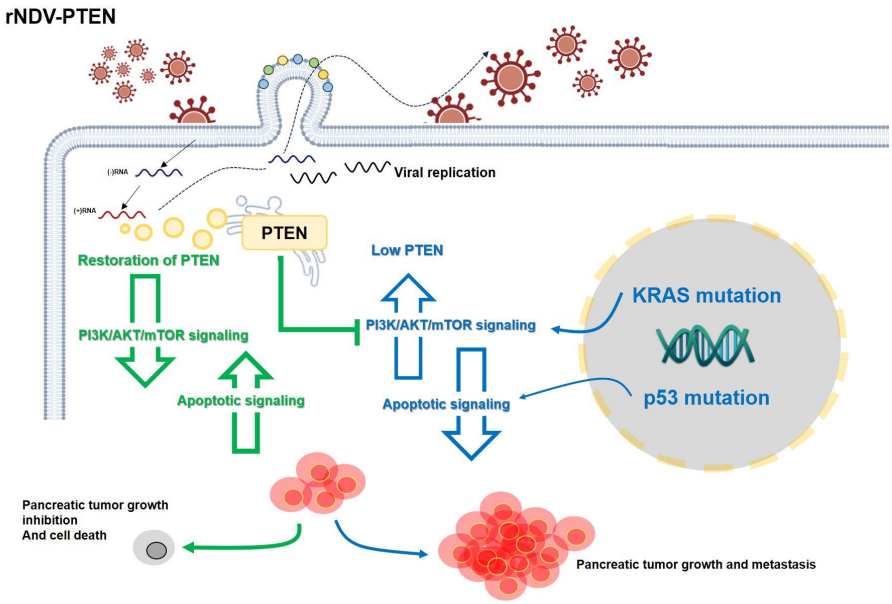
Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest and most treatment-resistant cancers, requiring innovative therapeutic approaches to improve outcomes. Genetic alterations such as KRAS mutations and reduced expression of the tumor suppressor PTEN are pivotal drivers of PDAC progression, leading to dysregulated PI3K/AKT/mTOR signaling and aggressive tumor behavior. To address these challenges, we developed a recombinant Newcastle disease virus engineered to express the PTEN gene (rNDV-PTEN). In vitro, rNDV-PTEN infection of KRAS-mutated PDAC cells significantly restored PTEN expression, suppressing PI3K/AKT/mTOR signaling, inducing apoptosis, and inhibiting cancer cell proliferation. *In vivo*, treatment with rNDV-PTEN effectively reduced tumor growth in orthotopic xenograft models, prolonged survival, and activated apoptotic pathways in PANC-1 cells. Importantly, rNDV-PTEN exhibited mild immune response without abnormal changes in blood glucose, triglycerides, or cholesterol levels. These findings highlight rNDV-PTEN as a dual-action oncolytic virotherapy and gene therapy, offering a novel, safe, and effective treatment option for PDAC patients with highly activated PI3K/AKT/mTOR signaling. This study provides a strong foundation for further clinical development of rNDV-PTEN in combating the devastating burden of pancreatic cancer.



716 More is Less: Cytotoxic Activity of Oncolytic Adenovirus Influences Therapeutic Efficacy in Disseminated Lung Cancer

Jia Yao[1], Svetlana Atasheva[2], Dmitry Shayakhmetov[3]
[1]Emory University, Atlanta, Georgia, [2]Emory University, [3]Emory University, Atlanta, GA

Oncolytic viruses have emerged as a promising therapeutic approach for cancer patients who fail to respond to existing treatments. We developed AVID-317, a novel engineered oncolytic adenovirus with targeted capsid mutations that significantly improved safety following systemic administration. In a preclinical model, systemic administration of AVID-317 (5×10^{10} v.p. per mouse) to NCr/Nude mice with disseminated lung adenocarcinoma significantly slowed tumor progression and extended survival compared to controls, with approximately 25% of mice achieving complete tumor rejection. However, dose escalation of AVID-317 did not yield additional therapeutic benefits. Instead, tumor-bearing mice treated with higher doses exhibited reduced median survival.

To investigate the mechanism underlying the reduction in median survival following dose escalation, we established an *in vitro* model using single-cell suspensions derived from the lungs of tumor-bearing mice. Cells were treated with escalating doses of AVID-317 and analyzed 48 hours post-infection. Flow cytometry revealed dose-dependent tumor cell elimination; however, pro-tumorigenic factor PD-L1 expression was upregulated in non-CD45+ stromal cells in a dose-dependent manner. Furthermore, inflammatory cytokines and tumor-promoting growth factors in the culture media increased with higher virus doses. These findings suggest that tumor cell killing by AVID-317 activates cellular components in the tumor microenvironment, which in turn produce pro-tumorigenic factors, leading to accelerated tumor growth.

To further dissect the mechanism of AVID-317-mediated tumor suppression and to design more effective therapies, we analyzed disseminated tumors from the lungs in NCr/Nude mice using single cell RNA-seq and Mass Cytometry (Cy-TOF) following virotherapy. scRNA-seq analysis revealed that in a subset of mice responding poorly to AVID-317 therapy, tumor-associated CSF1R-expressing myeloid cells expressed higher levels of MHC-II, Ctsb, and Arg1. Additionally, CD3e+ T cells from these mice expressed the exhaustion marker PD-1, a feature not observed in mice with favorable responses to virotherapy. Cy-TOF analysis using 37 metal isotope-labeled antibodies further confirmed increased expression of activation markers on myeloid cells following virotherapy. Based on these findings, we designed a combination therapy strategy to overcome immune suppression and enhance efficacy. In addition to AVID-317 administration, tumor-bearing mice were treated with anti-PD-1 antibody to block immune checkpoint signaling, anti-CSF1R antibody to inhibit CSF1R signaling, and anti-Asialo GM1 antibody to deplete antiviral natural killer (NK) cells.

Overall, our study uncovers complex mechanisms that limit the therapeutic efficacy of adenovirus vectors in treating disseminated cancer and demonstrates the potential of combining virotherapy with immunotherapy to improve outcomes.

Conflict of interest statement: DSH is a co-founder, shareholder, and officer of AdCure Bio, LLC, which develops adenovirus technologies for therapeutic use.

717 *In vitro* and *in vivo* efficacy of novel "armed" oncolytic viruses derived from adenovirus species B for breast cancer therapy

Katrin Schröer[1], Katrin Bronder[2], Montaha Alshawabkeh[3], Erwan Sallard[4], Firas Hamdan[5], Jacopo Chiaro[6], Vincenzo Cerullo[5], Maximiliane Finkbeiner[2], Christine Engeland[7], Anja Ehrhardt[8], Wenli Zhang[9]*

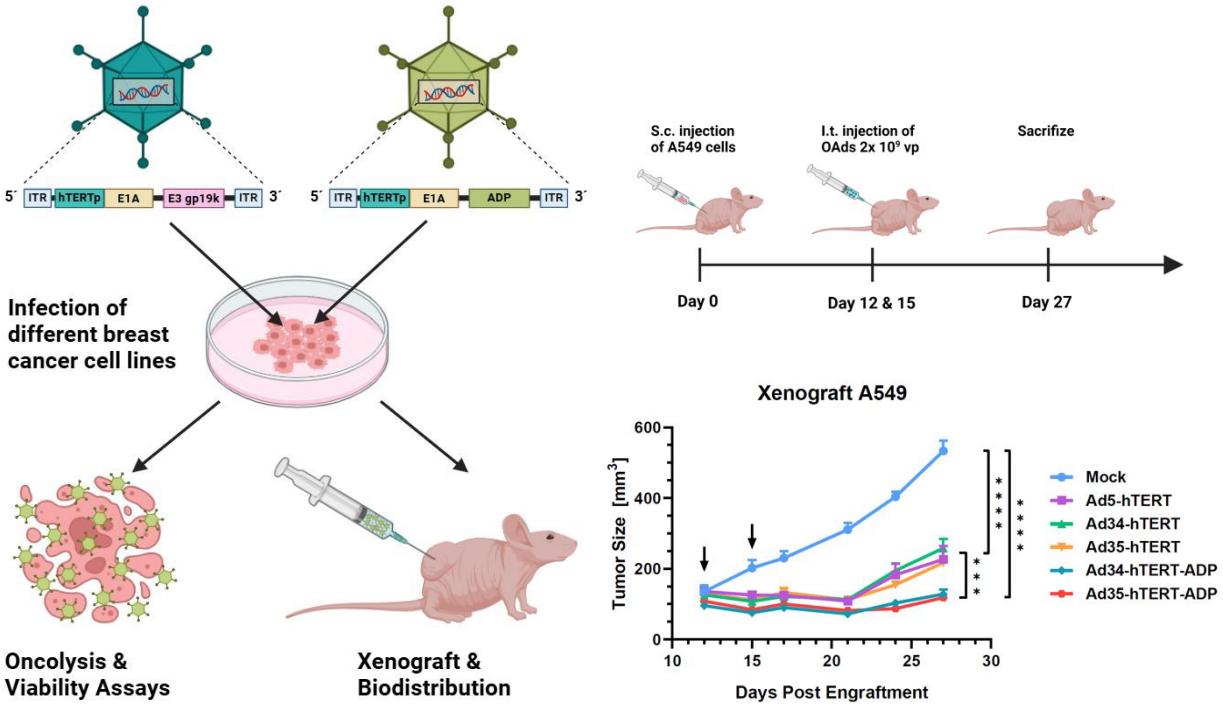
**Corresponding Author*

Oncolytic adenoviruses (OAds) are promising candidates for cancer therapy. Current studies focus on human adenovirus type 5 (Ad5), but robust therapeutic effects are hindered due to low expression of its main receptor, coxsackie and adenovirus receptor (CAR), on many tumor types and high seroprevalence among the population. Here, we explore species B Ads with low seroprevalence and different receptor usage. Based on our previous work, comparing several Ads regarding uptake and lysis of human breast cancer cell lines, two Ads were selected: Ad34 and Ad35, which utilize CD46 as receptor, and especially Ad34 with low seroprevalence and no binding to PF4. Here, the original Ad E1A replication unit promoter was replaced by the human telomerase reverse transcriptase promoter (hT). To obtain the strong lytic effect of Ad5 and to "arm" the non-Ad5 OAds, the adenovirus death protein (ADP) from Ad5 was inserted into the E3gp19k gene of Ad34 and Ad35 (hTA). As a control Ad5-hT was generated and all OAds were analyzed for infectivity, lytic effects and cell viability *in vitro* and explored *in vivo* in tumor-bearing mice.

The constructed OAds Ad5-hT, Ad34-hT, Ad35-hT, and Ad34-hTA and Ad35-hTA (ADP-OAds) were analyzed in four breast cancer cell lines (Hs578T and MDA-MB-231 (triple negative, TNBC), MCF-7 and SKBr3) and in A549 cells. To analyze replication of these novel OAds, TCID50 assays were performed. In SKBr3 and MCF-7 cells, ADP-OAds showed 50-fold higher plaque forming ability compared to Ad5-hT. In the TNBC cell lines, Ad5-hT and both ADP-OAds showed similar plaque forming units. For tumor cell viability, the ADP-OAds showed 30% and 75% reduced cell viability 3 days post-infection in SKBr3 and MCF-7 cells, respectively, compared to Ad5-hT which displayed no reduction in cell viability. For the A549 and TNBC cells, the ADP-OAds showed superior cell killing on day 5 compared to Ad5-hT. The results regarding lytic activity were confirmed by oncolysis assays. Next we performed neutralization assays with anti-human-Ad5 serum using 1/16,000 to 1/125 dilutions. Results revealed neutralization of Ad5 but not of Ad34- and Ad35-OAds, demonstrating that both Ad34 and Ad35 vectors are interesting candidates for *in vivo* applications. *In vivo* experiments in nu/nu NMR1/FoxN1 mice bearing subcutaneous A549 xenografts showed a significant decrease in tumor growth with the Ad34- and Ad35-based ADP-OAds compared to hTERT-only-OAds (Ad5-, Ad34-, Ad35-hT) 15 days after intratumoral application of 1x10e9 viral particles (vp) and 27 days post-engraftment. To examine if the OAds can reach the tumor site when injected intravenously, three additional OAds based on Ad5, Ad34 and Ad35 were generated encoding firefly luciferase (fLuc) driven by the SV40 promoter instead of E3gp19K transcription unit. Biodistribution experiments showed high replication activity in the tumors after intravenous injection of 1x10e9 vp as quantified by qPCR. Moreover, viral DNA for Ad34 and Ad35 was detected in lymph nodes in close proximity to the tumor, pancreas and spleen. To address the safety profile of the OAds and transduction properties in human blood cells, non-activated and activated T-cells from 9 donors were infected. 5 days post-infection no significant T-cell lysis was observed.

In summary, “armed” Ad34- and Ad35-hTERT-ADP OAds are promising candidates for breast cancer therapy that overcome Ad5 limitations by alternative cellular entry receptor usage and low seroprevalence.



718 Adenovirus Type 6 Expressing GM-CSF Exhibits Oncolytic Activity and Induces Antitumor Immunity in an Immunocompetent Syrian Hamster Model of Cholangiocarcinoma

Daria Zabelina[1], Ivan Osipov[2], Denis Maslov[2], Anna Kovner[3], Valeriia Vasikhovskaia[2], Stanislav Romanov[2], Julia Davydova[4], Sergey Netesov[2], **Margarita Romanenko[5]**
[1]Novosibirsk State University, Novosibirsk, Novosibirsk, Russia, [2]Novosibirsk State University, Novosibirsk, Russia, [3]Institute of Cytology and Genetics, Novosibirsk, Russia, [4]UMN, Minneapolis, Minnesota, [5]University of Minnesota, Minneapolis, MN

Cholangiocarcinoma (CCA), the second most common liver cancer, is highly resistant to chemotherapy and radiotherapy, leaving patients with unresectable tumors in urgent need of innovative therapies. Oncolytic adenoviruses (OAds) are a promising cancer treatment strategy due to their ability to induce direct oncolysis, activate the host's immune system, and their strong safety profile demonstrated in clinical trials. Adenovirus type 6 (Ad6), a species C human adenovirus, stands out for its low seroprevalence compared to a “standard” Adenovirus type 5 (Ad5) and its ability to evade Kupffer cells, enhancing its potential for liver cancer therapies such as CCA. To study oncolytic activity and antitumor immunity, an immunocompetent model permissive for OAd replication is essential. Syrian hamsters are one of the few such models, though limited by compatible cancer cell lines. Recently, a tumorigenic hamster CCA cell line, CCA-OF, was developed from tumors induced by Opisthorchis felineus infection. This cell line exhibits morphological characteristics and phenotypes similar to those of human carcinomas. In this study, we evaluated the efficacy of a novel Ad6-based vector, Ad6-d24-GM, against CCA in this immunocompetent, replication-permissive Syrian hamster model.

We have constructed Ad6-d24-GM to incorporate two critical modifications designed to enhance its therapeutic potential: 1) Expression of GM-CSF from the E3-6.7k/gp19k region, which stimulates both innate and adaptive

antitumor immune responses by recruiting and activating antigen-presenting cells; 2) A 24-bp deletion in the E1A gene, enabling tumor-selective replication and enhancing its specificity for cancer cells. We introduced a novel, efficient technology that leverages CRISPR-mediated genome digestion followed by in vitro recombination with a PCR product carrying the desired modifications.

Ad6-d24-GM exhibited dose-dependent cytotoxicity against the CCA-OF cell line, with reduced toxicity to normal human fibroblasts compared to wild-type Ad6 (Ad6wt). The secretion of GM-CSF was significantly higher in CCA-OF hamster cells infected with Ad6-d24-GM than in A549 cells at 24 and 48 hours post-infection. We further investigated in vivo antitumor effects of both Ad6-d24-GM and Ad6wt. Hamsters bearing CCA-OF subcutaneous tumors received 2 intratumoral injections of either Ad6-d24-GM, Ad6wt (3×109 TCID50 infection units), or PBS. The treatment effect was evaluated by comparing tumor growth rates using a linear mixed-effects model. Both viruses reduced tumor growth rate with only Ad6-d24-GM causing significant tumor growth inhibition. Furthermore, Ad6-d24-GM significantly increased the median survival to 34 days compared to 20 days in the PBS-treated group. Immunohistochemical quantification of immune markers revealed that both Ad6-d24-GM and wild-type Ad6 induced robust infiltration of CD4+ and CD8+ T cells and CD68+ macrophages in tumors, indicating activation of antitumor immunity 14 days after the first injection. Notably, the Ad6-d24-GM group exhibited a statistically significant increase in CD68+ macrophages compared to the Ad6wt, highlighting the immunomodulatory effect of the GM-CSF transgene.

These results demonstrate the oncolytic and immunostimulatory potential of Ad6-based vectors for CCA treatment and validate the Syrian hamster syngeneic CCA-OF model as a novel valuable platform for studying oncolytic adenovirus therapies.

719 Oncolytic adenovirus mediated antitumor immune response for the treatment of bladder cancer

A-Rum Yoon[1], Ao Jiao[2], JinWoo Hong[3], Chae-Ok Yun[4]
[1]Hanyang University, Seoul, Korea, [2]Hanyang University, Seoul, South Korea, [3]GeneMedicine, Seoul, South Korea, [4]Gene-Medicine, Seoul, Korea

To overcome the limited therapeutic outcome of conventional treatments in non-muscle-invasive bladder cancer (NMIBC), oncolytic adenovirus (oAd) co-expressing interleukin 12 (IL12), granulocyte-macrophage colony-stimulating factor (GMCSF) and relaxin (RLX; oAd/IL12-GMCSF-RLX) with a clinical stage GSK3β inhibitor (9-ING-41; elraglusib; iGSK3β) was investigated. Our findings demonstrate that oAd/IL12-GMCSF-RLX and iGSK3β combination therapy (oAd/IL12-GMCSF-RLX+iGSK3β) exerted superior inhibition of tumor growth compared with respective monotherapy in a syngeneic NMIBC tumor model. oAd/IL12-GMCSF-RLX+iGSK3β induced superior degradation of tumor extracellular matrix (ECM) and antitumor immune response over the respective monotherapy. In detail, oAd/IL12-GMCSF-RLX+iGSK3β induced superior accumulation of intratumoral T and NK cells, prevention of immune cell exhaustion, and induction of tumor-specific adaptive immune response. Collectively, these results demonstrate that the combination of oAd/IL12-GMCSF-RLX and 9-ING-41 may be a promising approach to elicit a potent antitumor immune response against immunologically 'cold' bladder cancer.

720 Overcoming Barriers to Effective Cancer Therapy with Oncolytic Adenoviruses

Svetlana Atasheva[1], Jia Yao[2], Dmitry Shayakhmetov[1]
[1]Emory University, Atlanta, GA, [2]Emory University, Atlanta, Georgia

Oncolytic adenovirus vectors are an excellent platform for targeting cancer cells and enhancing the anti-tumor immune response. Adenoviral vectors have been used in clinical trials since the late 1990s. However, we still lack a universally effective oncolytic adenovirus to treat cancer. The answer lies in understanding the complex interplay of adenovirus and cancer biology, as well as immune system interactions.

To understand the molecular processes after adenovirus vector infusion, we used a nude mouse model with orthotopic disseminated xenografts in the lungs. This particular nude mouse line had low levels of T cell production, insufficient to mount an anti-tumor response, which allowed slow tumor growth, resulting in a complex cellular composition in the tumor sites. In this model, systemic intravenous treatment with oncolytic adenovirus AVID-317 cured 20% of treated mice, completely clearing cancer cells from the lungs. However, in 80% of tumor-bearing mice, tumor growth was largely unaffected, and the mice succumbed to cancer. Analysis did not show differences in tumor burden, nor were there differences in the amount of virus in the tumor-bearing lungs.

This led us to hypothesize that oncolytic virus-mediated cell death can cause a dysregulated response in tumor-associated cells, dictating treatment outcomes. If cancer cell death leads to an enhanced tissue repair response, cancer cells that escaped the virus proliferate, and the tumor progresses. However, if virus treatment repolarizes the tumor-associated cells to a non-tumor-supporting state, immune cells can clear the cancer cells.

To test this hypothesis, we compiled a signature list of genes known to enhance tumor progression as a "reparative call." The genes in the list included well-known mediators of cancer progression: Pdgfb, Vegfa, Igf1, Arg1, Tgfb1, Fgf, cytokines, chemokines and other genes. To understand which cellular populations were responsible for mounting this reparative call, we performed scRNA-seq on tumor-bearing lungs from mice treated with either buffer or AVID-317 oncolytic adenovirus. We selected mice exhibiting either a responder or non-responder phenotype at 2 weeks after virus infusion.

The scRNA-seq and flow cytometry analysis showed that the tumor cell composition in responder mice was similar to human lung tumor explants, with an abundance of myeloid, lymphoid, and stromal cells. In responder mice, expression of chemokines (Ccl3, Ccl5, Ccl6, Ccl9, Cxcl10) was lower, as was expression of Pdgfb, Vegfa, Tgfβ1, Fgf in stromal cells and macrophages. Wound healing markers like Arg1, Fn1, Chil3, Spp1, Retnla, and Psap were lower in various macrophage clusters. Moreover, lower expression of IL4, IL5, and IL13 in ILCs highlighted the role of these cytokines.

In conclusion, the major role of the reparative call response is played by the macrophage, and stromal compartments. In response to virus-mediated cancer cell death, these cells activate a reparative call that leads to tumor growth and disease progression. However, if these cells are silenced or absent, virus-mediated cancer cell death leads to complete clearing of tumor cells. Our study underscores the importance of the multi-lateral interactions of different immune and stromal cellular populations at the tumor site, highlighting the critical need to develop treatments targeting the myeloid and stromal involvement in the reparative call.

721 A Novel Method For Generating Unprecedented, Unbiased, Ultra-High-Sequence Diversity Libraries Of Plasmids And Recombinant Viruses (With Validation) For High-Throughput Screening, data for machine learning (AI) And Targeted Therapy.

Praveensingh Hajeri[1]*, Masato Yamamoto[1]*
[1]University of Minnesota, Minneapolis, Minnesota
**Corresponding Author*

Background: A typical drug discovery pipeline needs good libraries of potential therapeutic candidates with high-sequence diversity. The probability of finding a good hit primarily depends on the quantity (diversity) and quality (distribution) of candidates in libraries used for screening. They include libraries of peptides, single-chain antibodies, nanobodies, CRISPRs, shRNAs, phage display, yeast display, Ribosome display, DARPins, BiKEs, TriKEs, CAR-T cells, and recombinant viruses (including adenoviruses, lentiviruses, AAVs, and other oncolytic viruses, etc.). Screening them for specific interaction with the target of interest to narrow down to fewer candidates, which can be further validated, are the basic steps in the generic discovery pipeline. Lately, artificial intelligence (AI)-based designing has also been used to design candidates for targeted interaction. However, the quality of such prediction depends on the data used in machine training. Since the current libraries are known to be biased, such libraries may not be as good as unbiased libraries.

Current limitations: Generating high-sequence diversity libraries is very challenging. Several published studies and industries claim to have very high diversity libraries ranging over 10^9 sequence diversity. However, most of those libraries lack validation by stringent experimental standards, and the diversity claimed is mainly based on sequencing a small number of candidates in the library and statistical extrapolations. Most of the time, we found that those who claim very high diversity (over 10^8) did not validate their libraries with stringent next-generation sequencing (NGS) based methods, and those who used stringent NGS methods for validation usually do not claim such big diversity. Therefore, there is an imminent need for a method to generate genuine high-sequence-diversity libraries of high quality.

Methods and results: We have developed a novel method to generate such libraries with very high sequence diversity and validated them with stringent NGS-based methods. Compared to other established methods, our libraries are at least 100 to 1000 times better in diversity (quantity) and have a more uniform and unbiased distribution (quality). Through benchmarking studies, we validated total diversity, duplication rate, sequence bias, and the ability to scale up. As a proof of concept, we generated libraries of plasmids (shuttle vectors to make recombinant adenoviruses) and recombinant adenoviruses with high sequence diversity in a structural protein (Fiber). We also used them for screening against a cancer-specific cell–surface protein.

Applications: Our methods can generate quantitatively and qualitatively better (100-1000 times) libraries. They can be used in high-throughput screening against targets of interest to narrow down to fewer candidates. Smaller libraries resulting after serial and multiple rounds of screening can serve as a dataset for machine training to aid AI-based design. Our unbiased, high-diversity libraries provide a high-quality dataset to improve Ai-based design criteria. We expect our libraries may help in avoiding AI-based design altogether in some cases.

722 Assessment of Oncolytic Properties of the Chimeric Poxvirus HOV-2 in Cholangiocarcinoma Models

Jennifer Cillis[1], Courtney Chen[2], Yoya Vashi[1], Sang-In Kim[3], Yuman Fong[1], Shyambabu Chaurasiya[1]
[1]City of Hope, Duarte, CA, [2]Cedars Sinai, Los Angeles, CA, [3]City of Hope National Medical Center

Introduction: Cholangiocarcinoma is a neoplasm of the biliary system and the second-most common primary hepatic malignancy. It has a highly unfavorable prognosis, regardless of type and location. Neoadjuvant chemotherapy has become mainstay, but five-year survival rates remain poor, prompting the need for more treatment options. Oncolytic viruses can selectively replicate in cancer cells and lyse them, representing a novel class of cancer therapeutics. We have developed a chimeric poxvirus that has enhanced oncolytic properties compared to other poxvirus strains. In this study, we evaluated the oncolytic properties of this chimeric poxvirus (HOV-2) in cholangiocarcinoma models.

Methods and Results: We infected four human cholangiocarcinoma cell lines (KMC-1, KMBC, KMCH and MzChA1) with the oncolytic virus HOV-2 at various multiplicities of infection and measured virus-mediated cytotoxicity at different timepoints. Dose- and time-dependent killing was observed in all four cell lines. Further analysis by flow cytometry revealed that the majority of cells died through apoptosis, as indicated by Annexin V staining. Next, we assessed the growth kinetics of the virus in these cell lines *in vitro*. While virus replication was observed in all cell lines, the levels of replication varied between them. The KMCH cell line supported the highest level of virus replication with 1e5-fold increase in virus titer 72 hours post-infection, while KMBC cells supported the lowest replication with only ~10-fold increase in virus titer over the same period. We tested the safety and therapeutic efficacy of this virus using murine models of cholangiocarcinoma. The KMBC and KMC-1 cell lines were used to generate two distinct xenografts models of cholangiocarcinoma in athymic nude mice. Bilateral subcutaneous tumors were generated by injecting the cells in either side of the lower flanks. Once the tumors reached 50-100 mm^3 in volume, mice were divided into four treatment groups (5 mice/group) such that each group had similar average tumor volume. Next, the mice were administered a single dose of virus (1e6 plaque forming units) either through intra-tumoral (I.T.) or intra-venous (I.V.) route. Tumor volume and weight of the mice were measured twice weekly. In the KMBC model, the I.V. treatment only resulted in mild delay in tumor growth whereas the I.T. treatment resulted in significant tumor regression. However, in the KMC-1 model, both I.T. and I.V. treatments were found to be equally efficient, resulting in almost complete tumor control. In a separate

experiment, mice treated as above, were euthanized on day seven post-infection and virus biodistribution was assessed using plaque assays. In all virus-treated groups, virus was detected in the tumors but was mostly undetectable in all normal organs.

Conclusions: The oncolytic virus HOV-2 can replicate within and kill human cholangiocarcinoma cells. In a human xenograft cholangiocarcinoma tumor model, HOV-2 causes significant tumor regression while remaining localized to the tumor microenvironment. These results signify that HOV-2 displays potential for treatment of patients with unresectable cholangiocarcinoma.

723 Using an Oncolytic Virus to Expand the use of GPC3-targeted Experimental Cancer Therapeutics

Shyambabu Chaurasiya[1], Sang-In Kim[2], Cheng Liu[3], Pei Wang[4], Yuman Fong[1]
[1]City of Hope, Duarte, CA, [2]City of Hope National Medical Center, [3]Eureka Therapeutics Inc, Emeryville, CA, [4]Eureka Therapeutics, Emeryville, CA

Glypican-3 (GPC3) is a membrane-associated oncofetal protein that is overexpressed in hepatocellular carcinoma (HCC). In adult humans, GPC3 is not expressed in normal tissues making it an ideal target for HCC diagnosis and treatment. Several experimental therapeutics targeting GPC3 are currently under investigation, with some already in clinical trials. Among the most advanced GPC3-targeted therapies are GPC3-directed chimeric antigen receptor (CAR) T cells, bispecific T cell engagers (BiTEs), and the GPC3-directed monoclonal antibody, Condrituzumab. Although GPC3 expression is tumor-restricted, its presence within HCC tumors is heterogeneous, and many HCC patients are GPC3-negative. To address this, we have engineered an oncolytic virus capable of delivering a non-functional GPC3 to cancer cells. We hypothesize that this oncolytic virus could make GPC3-negative HCC tumors responsive to GPC3-targeted therapeutics. Additionally, this oncolytic virus could be applied to other solid tumors to render them susceptible to GPC3-targeted treatments. Our results show that the oncolytic virus effectively converts GPC3-negative tumor cells into GPC3-positive. The GPC3 expressed by the virus is specifically recognized by GPC3-targeted therapies, including GPC3 CAR-T cells, GPC3 BiTE, and condrituzumab. When GPC3 CAR-T cells were co-cultured with virus-infected cancer cells, they exhibited activation markers including cytokine secretion and demonstrated cytolytic activity.

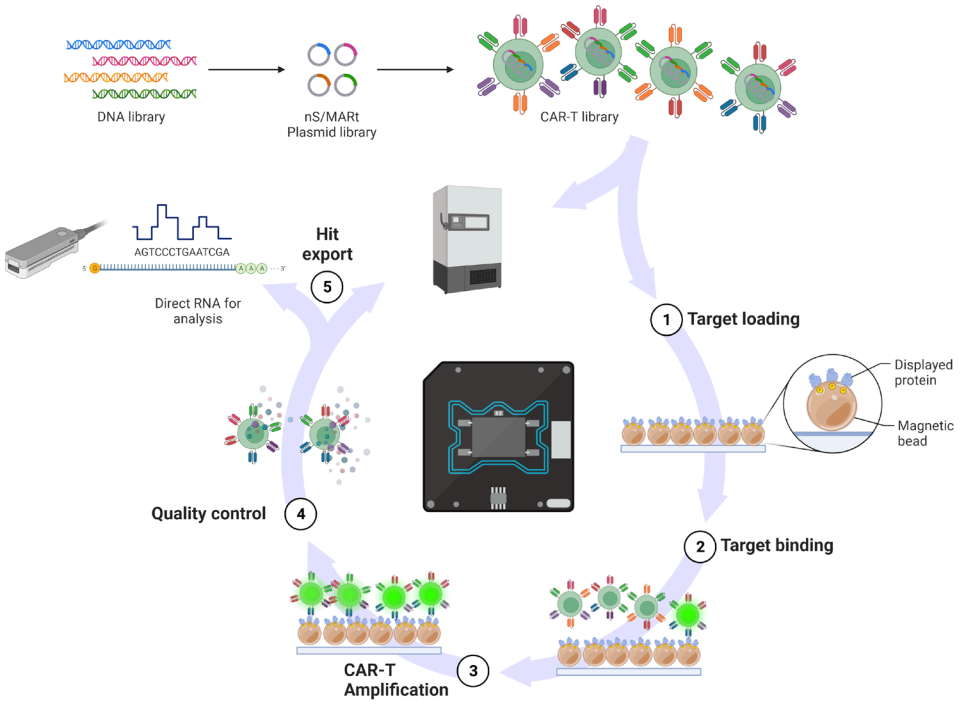
Consequently, the combination of oncolytic virus and GPC3-CAR T cells significantly increased cancer cell killing compared to either treatment alone. Similarly, the bispecific T cell engager, composed of single-chain variable fragments (scFvs) targeting both GPC3 and CD3, activated T cells when co-cultured with virus-infected cancer cells, leading to potent tumor cell killing. Additionally, the monoclonal antibody Condrituzumab recognized the virus-encoded GPC3 on cancer cells and facilitated killing of virus-infected cancer cells by natural killer cells through antibody-dependent cellular cytotoxicity. More importantly, the combination of the oncolytic virus and GPC3-CAR T therapy improved therapeutic efficacy in murine tumor models. In conclusion, our findings indicate that GPC3 expression from an oncolytic virus can improve the effectiveness of GPC3-targeted therapeutics and broaden their potential applications.

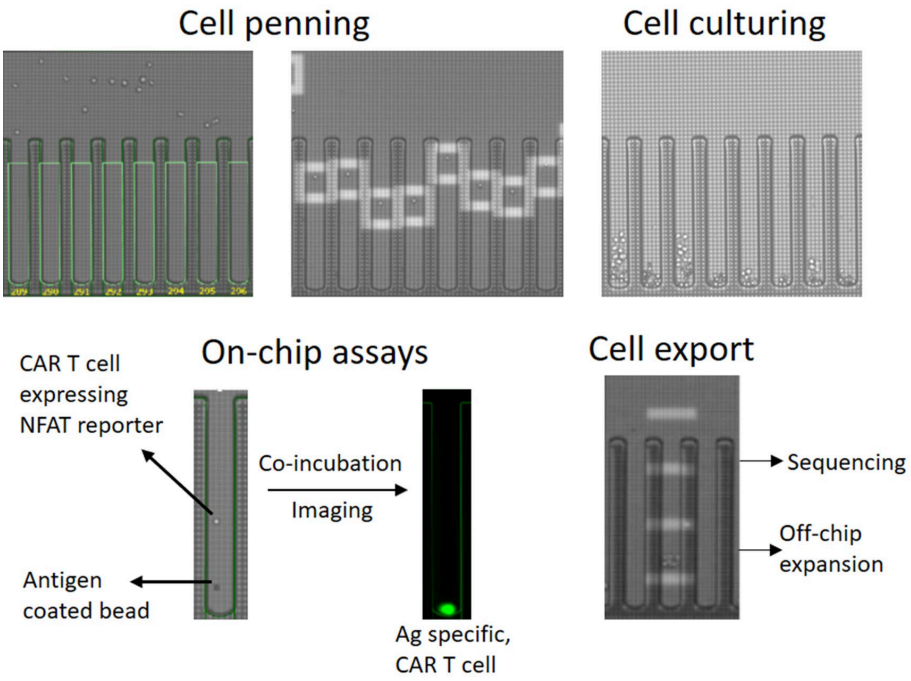
724 A living CAR-T library combined with optofluidics and single cell sequencing for the rapid selection of functional CAR constructs.

Patrick Schmidt[1], Eren Boga[2], Alexandra Tuch[2], Katharina von Werthern[3], Alexandra Mayr[2], Inka Zoernig[2], Dirk Jaeger[2], Richard Harbottle[4]
[1]National Center for Tumor Diseases, Heidelberg, Baden-Wuerttemberg, Germany, [2]NCT Heidelberg, Heidelberg, Germany, [3]NCT Heidelberg, Heidelberg, Baden-Wuerttemberg, Germany, [4]German Cancer Research Center, Heidelberg, Germany

Chimeric antigen receptor (CAR)-T cell therapy has shown remarkable success in treating hematological malignancies, particularly B-cell leukemias and lymphomas, by addressing CD19 and BCMA as target. However, its application to solid tumors faces significant challenges that limit therapeutic efficacy under which antigen heterogeneity plays a prominent role. Recent advances in personalized medicine i.e. the exploitation of tumor neo-antigens as therapeutic target have opened an unprecedented window of opportunity to speed up and refine cancer treatments. Unfortunately, cellular therapies yet cannot hold pace with that development. Classically, CARs (i.e. the scFv binding domain) have been derived either from existing antibodies or are discovered via Phage-Display and subsequent CAR cloning, a process that can last up to several months.

Here, we propose an innovative platform, which can accelerate isolation of functional CAR constructs. In this approach, we generate a “living” fully human CAR library by engrafting a plasmid DNA library into a reporter cell line. Screening and selection of hits is performed on an optofluidic chip at single cell resolution using Bruker´s Lightning device. Oxford Nanopore sequencing of exported hits reveals the incorporation of less than 30 individual CAR constructs per single cell, which are accessible for validation. This novel method of quick identification and selection narrows the CAR discovery process down to maximum 14 days and therefore will allow the discovery of patient individual CAR-Ts for personalized treatment.





725 Enhancement of the Multimodal Cancer Therapeutic Efficacy in Non-Small Cell Lung Carcinoma by Hypoxia Reversal using Hemoglobin-Loaded Biomimetic Nanoparticles as Oxygen Delivery System

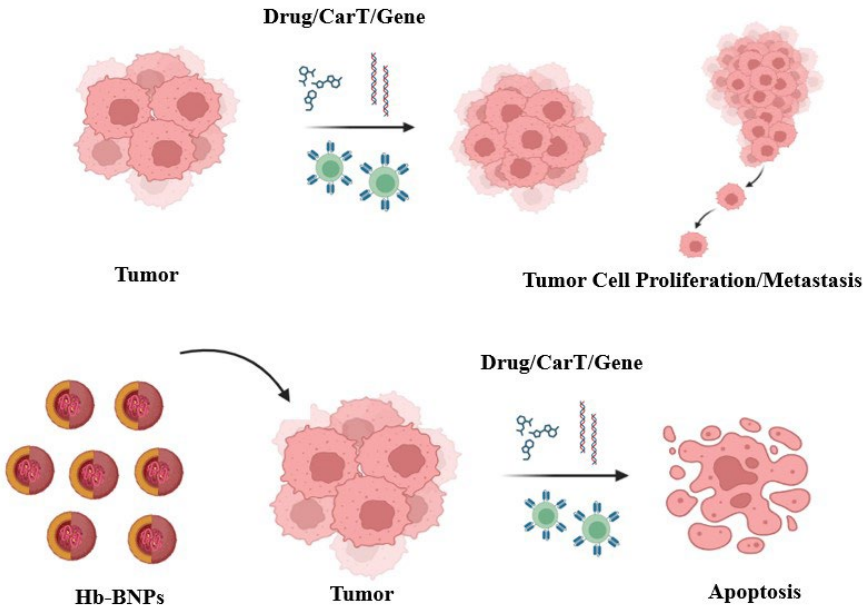
HARSH GANDHI[1], JAYDEEP BHATTACHARYA[2]*
[1]School of Biotechnology, Jawaharlal Nehru University, New Delhi, India, India, [2]SCHOOL OF BIOTECHNOLOGY JAWAHARLAL NEHRU UNIVERSITY, NEW DELHI, Delhi, India
**Corresponding Author*

Cancer is a complex disease marked by uncontrolled cell growth that further leads to metastasis. Lung cancer results in most mortality globally, with non-small cell lung carcinoma (NSCLC) comprising about 85% of the cases. Tumor hypoxia generated by low oxygen levels in the tumor microenvironment poses a significant challenge, as it reduces the effectiveness of treatments like chemotherapy and immunotherapy. This further leads to the therapeutic resistance and poorer treatment outcomes. To address this challenge, we have developed cell membrane-camouflaged biomimetic nanoparticles loaded with natural oxygen carrier hemoglobin (Hb-BNPs) for controlled oxygen delivery to hypoxic tumor cores.

Our study demonstrated that the hypoxia-induced chemoresistance for the anticancer drug paclitaxel can be effectively reversed by delivering oxygen through Hb-BNPs, resulting in significantly improved therapeutic outcomes. Beyond chemoresistance, hypoxia in the tumor microenvironment also poses a major challenge for CAR-T cell therapy in solid tumors. Hypoxia impairs T-cell infiltration, persistence, metabolism, and effector function, all of which limit the therapeutic efficacy of these advanced immune therapies. To address this, we co-administered oxygen through Hb-BNPs alongside LunX CAR-T cells (an immunotherapy candidate for lung solid tumors). This strategy enhanced cytotoxicity under hypoxic conditions, effectively overcoming the functional limitations of immune therapies. Furthermore, hypoxia-induced reduced cellular uptake of gene and diminished transgene expression hinder therapeutic success of gene therapy. By delivering oxygen through Hb-BNPs, improved cellular uptake and transgene expression, can be achieved. Collectively, these findings underscore the broad potential of Hb-BNPs in overcoming hypoxia-driven limitations across multiple solid tumor therapies.

In addition to this, we have demonstrated and elucidated the role of KANK1, a gene associated with cytoskeleton organization in hypoxia. Our study revealed that KANK1 regulation can synergistically enhance the effectiveness of Hb-BNPs in chemotherapy and immunotherapy. By combining oxygen delivery through Hb-BNPs with KANK1

modulation, we are able to address both the oxygen deficit and the structural challenges within tumor cells. Hb-BNPs alleviate hypoxia, boosting oxygen-dependent therapies, while KANK1 modulation enhances cytoskeletal stability, increasing drug uptake and immune cell infiltration. Together, these mechanisms enhance therapeutic efficacy in hypoxic environments. This combined oxygen and KANK1 delivery approach holds the potential to reverse hypoxia-induced therapeutic resistance and enhance clinical outcomes in NSCLC patients.



726 Combining AI-Based Target Discovery with CRISPR/Cas9 Editing: Validating GBC-11004 as a Novel Target to Combat Osimertinib-Resistant NSCLC

Hat Nim Jeon[1]*, Ji Young Bae[2], Hyunsun Na[2], Ji Hwan Park[2], Seung Hyun Ahn[2], Bada Pyo[2], Jihye Ryu[2], Jinguen Rheey[2]

Non-small cell lung cancer (NSCLC) is one of the leading causes of cancer-related mortality worldwide, accounting for approximately 85% of all lung cancer cases. Despite advances in early detection and treatment, the prognosis for advanced NSCLC remains poor due to metastasis and therapeutic resistance. To address this challenge, an advanced artificial intelligence (AI)-driven target discovery platform was employed to identify novel therapeutic targets from Osimertinib-resistant NSCLC patient-derived organoids (PDOs).

A novel kinase target, designated GBC-11004, was identified as one of the top-ranked target genes that were found to be overexpressed in PDOs resistant to Osimertinib. The selection of an appropriate delivery system for CRISPR/Cas9 cargo is a pivotal aspect in the advancement of gene editing for the treatment of diseases. Thus, four delivery systems were evaluated for their efficiency in introducing CRISPR/Cas9 into NSCLC PDOs: (1) plasmid-based transfection, (2) electroporation-based transfection, (3) lentiviral transduction, and (4) a newly developed delivery system. Following the optimization of the delivery system, CRISPR/Cas9-mediated gene editing was performed to assess the functional role of GBC-11004. Indel frequency was measured to confirm gene editing efficiency, and cell viability assays were conducted to determine the therapeutic impact of GBC-11004 inhibition.

Utilizing the most effective gene-editing platform identified, we successfully established PDOs with high efficiency, enabling precise functional validation of therapeutic targets. The present study has identified a new therapeutic target, GBC-11004, which has the potential to circumvent resistance to Osimertinib. In summary, the findings of this

study demonstrate the potential of integrating AI-driven target identification to advance therapeutic strategies in epidermal growth factor receptor-mutated NSCLC, providing a novel prospect for improved patient outcomes.

727 Lipid Nanoparticle Delivery of CRISPR/Cas9 Reagents for Disruption of Oncogenic Translocations in Alveolar Rhabdomyosarcoma

Amadu Tadesse[1], Ruby Sims[2], Matthew Romero[3], Emily Skuratovsky[4], Marlene Ruiz[5], Noah Federman[4], April Pyle[4], Steven Jonas[5]
[1]UCLA, San Diego, CA, [2]University California Los Angeles, Los Angeles, CA, [3]University of California, Santa Cruz, Santa Cruz, CA, [4]UCLA, Los Angeles, CA, [5]University of California, Los Angeles, Los Angeles, CA

Alveolar rhabdomyosarcoma (aRMS) is a rare and aggressive soft tissue cancer arising from skeletal muscle stem cells in children and young adults. This project leverages nanotechnology-based strategies to develop a lipid nanoparticle (LNP) platform designed to deliver CRISPR/Cas9 reagents configured to disrupt the PAX3-FOXO1 translocation that drives the most aggressive phenotypes of aRMS and mitigate its oncogenic effects. Here we present a two-pronged approach: first, designing and validating single guide RNA (sgRNA) sequences configured for the targeted knock out of PAX3-FOXO1 translocations; second, engineering LNPs for the efficient delivery of these gene-editing reagents for the direct therapeutic engineering of aRMS tumors. PAX3-FOXO1-targeting sgRNA sequences were first engineered by identifying conserved PAX3-FOXO1 fusion gene regions from ChimerDB's 4.0 fusion gene database and the UCSC Human Genome database. After targeting regions were identified, guides were then engineered via Benchling's guide design tool. Integrated DNA Technologies (IDT) guide design tool was then used to leverage on-target potential and off-target risk to maximize efficiency and minimize risk. Guide candidates were then tested in a representative PAX3-FOXO1 positive aRMS cell line (RH30) by electroporating Cas9 ribonucleoprotein complexes assembled with PAX3-FOXO1 sgRNA constructs and validated *via* qPCR analysis. Prior to packaging CRISPR/Cas9-based cargoes (*i.e.,* Cas9-mRNA and PAX3-FOXO1-targeting sgRNA), LNPs carrying green fluorescent protein (GFP)-encoding mRNA cargoes were applied to screen for nanoparticle formulations that maximize delivery to RH30 cells. Nanoparticles were prepared *via* microfluidic mixing with mean diameters <200 nm as measured by dynamic light scattering (DLS), nanoparticle tracking analysis (NTA) and cryo-transmission electron microscopy (cryo-TEM) with mRNA cargo encapsulation efficiencies >80% determined by Ribogreen fluorescence-based assay. Our best performing formulations achieved >90% GFP expression 24 h post treatment. In preliminary studies applying LNPs carrying PAX3-FOXO1 CRISPR/Cas9 cargoes, we observe a >50% reduction in PAX3-FOXO1 expression in targeted aRMS cells, as confirmed by qPCR. These findings highlight the potential for developing new CRISPR/Cas9 LNP-based cellular therapeutic strategies for directly augmenting high risk childhood malignancies through the manipulation of cancer driving mutations.

728 Tumoricidal Potential of CRISPR-Cas9 against Pancreatic Cancers

Selina Shiqing Teh[1]*, Alexis Bennett[1], Jingyao Ma[2], Yining Zhu[3], Chien-Fu Hung[3], Hai-Quan Mao[3], **James Eshleman**[1]*
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins Univ, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD
**Corresponding Author*

Introduction: Pancreatic cancer (PC) is the third leading cause of cancer-related deaths in the U.S. with a dismal 5-year survival rate of 13%. Most patients present with advanced cancers at the time of diagnosis, and current treatment options are ineffective with most patients experiencing relapse or resistance. We have previously demonstrated the tumoricidal potential of CRISPR-Cas9 by targeting somatic mutations in PC cell lines. However, its ability to eliminate PC *in vivo* remains elusive. We hypothesize that CRISPR-Cas9 can eliminate PC *in vivo* by inducing multiple double strand breaks, provided that the cells receive the CRISPR-Cas9 therapeutic.

Methods: In a double-blind study, we transduced Panc10.05 Cas9-expressing cells with non-targeting sgRNA (NT), 715F(5) and 230F(12) sgRNAs (multi-target sgRNAs with 5 and 12 target sites in the human genome, respectively), ALU_112a sgRNA (positive control sgRNA targeting Alu repetitive elements), and a pool of 9 sgRNAs targeting 9 different noncoding mutations unique to Panc10.05 and absent in other cell lines (Panc10.05 pool, designed using a

novel protospacer adjacent motif-based, cancer-specific approach previously published[1]). After puromycin selection, we injected them into athymic, nude mice, and measured tumor growth and body weight for 6 weeks. Tumors were then surgically extracted and weighed. Genomic DNA extraction and next generation sequencing (NGS) were performed to detect CRISPR-Cas9 activity / mutations in tumors. Additionally, we developed an mNeonGreen-, Cas9-expressing Panc10.05 cell line, conditioned for *in vivo* growth, to screen lipid nanoparticles (LNPs) for *in vivo* transfection efficiency through intratumoral injection. We identified nine top LNP formulations from previous *in vitro* screening, and tested them in subcutaneous murine xenograft models using luciferase reporter assay. Tumors and organs (liver, spleen, and kidneys) were also harvested post-mortem to examine for off-target transfection. Flow cytometry was performed to identify PC cells in tumors.

Results: Tumor volumes decreased between NT and 230F(12) or Panc10.05 pool as early as week 4 (Dunn-Sidak tests, NT and 230F(12): $P=0.010$, NT and Panc10.05 pool: $P=0.043$, all N=10). By week 6, significant decreases in tumor volumes and tumor weights between NT and the remaining treatment groups were observed (all $P<0.0001$), but no differences in body weight were detected. While tumor growth after treatment with the 12-cutter sgRNA was significantly inhibited, we found that the mutation frequency of the two outlier 230F(12) tumors was extremely low (0.97% and 0.64%), suggesting that lack of CRISPR-Cas9 activity allowed tumor growth. In two separate LNP screening experiments, the LNP formulation used by Moderna mRNA-1273 (containing SM-102) consistently showed high *in vivo* transfection efficiency with some luciferase expression detected in liver. We were also able to identify PC cells from the tumors through mNeonGreen expression.

Conclusion: Our results show that CRISPR-Cas9 is tumoricidal *in vivo*. We have established a subcutaneous mouse model that allows for future optimization and delivery of CRISPR-Cas9 therapeutic to PC tumors.

729 CRISPR/Cas9 knockout of *c-Met* to evaluate its effects on reducing drug resistance against gemcitabine in pancreatic cancer

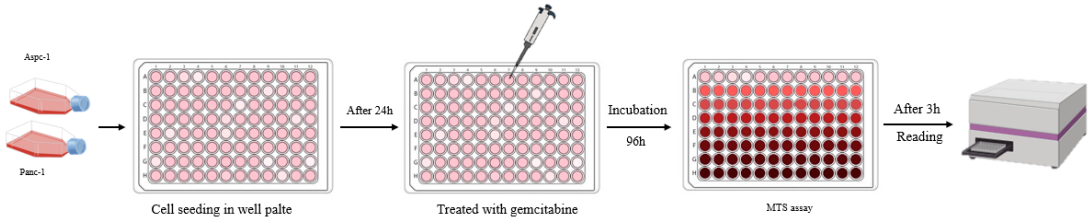
Nasim Hejazi[1], Mahboobeh Forozanfer[2], Ali Valipor[2], Kianoush Dormiani[3]*
[1]Royan Institute, Isfahan, Esfahan, Iran, [2]Royan institute, Isfahan, Iran, [3]Isfahan, Iran
**Corresponding Author*

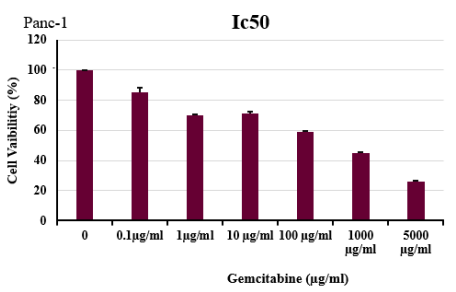
Background: Pancreatic cancer is one of the most lethal malignancies, with drug resistance to gemcitabine posing a significant therapeutic challenge. The c-Met receptor tyrosine kinase has been implicated in tumor progression and drug resistance. This study aimed to knock out the c-Met gene in Panc-1 cells using the CRISPR-Cas9 system and evaluate its effect on reducing drug resistance to gemcitabine in pancreatic cancer.

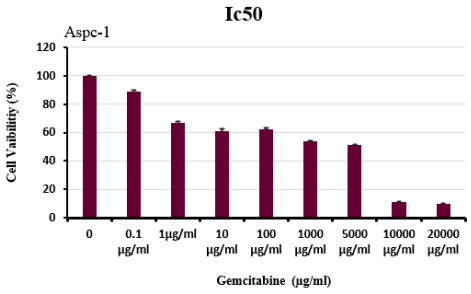
Methods: Initially, c-Met expression levels were measured in Panc-1 and Aspc-1 cell lines by RT-qPCR. Subsequently, the IC50 values of gemcitabine were determined in these cell lines using the MTS assay with varying concentrations of the drug (Fig. 1)Additionally, a vector encoding two designed gRNAs and the spCas9 nuclease was constructed, and transfected into the cell line with a high c-Met expression. The transfected cells were then treated with puromycin to select genetically modified clones, followed by single clonal selection and evaluation using genomic PCR and Sanger sequencing (Fig.2).

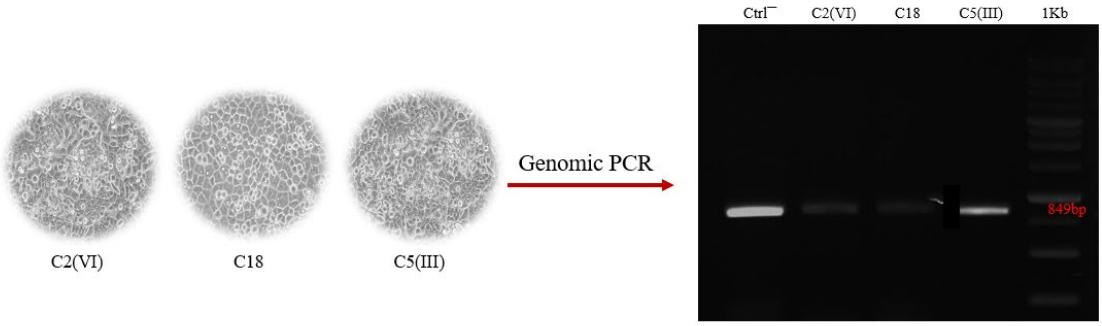
Results: After evaluating the expression level of c-MET using real-time PCR, the PANC-1 cell line was selected for the continuation of the resserch. Following the confirmation of the successful knockout of the c-MET gene through genomic PCR and Sanger sequencing, a notable decrease in cell growth and proliferation was observed. The gemcitabine IC50 values in the c-MET knockout clones were also significantly reduced.

Conclusions: Knockout of the c-Met gene in Panc-1 cells using the CRISPR/Cas9 system significantly decreased drug resistance to gemcitabine. This research underscores the potential therapeutic advantage of targeting c-Met to overcome chemoresistance in pancreatic cancer, offering a hopeful path for enhancing gemcitabine treatment results.









730 mRNA Aggregate Analysis using SEC-MALS

Yinan Zhang[1], Linting Li[1], **Minxin Wang[1]**, Konstantin Musiychuk[1]
[1]*Sepax Technologies, Newark, DE*

The recent developments in mRNA vaccines, therapeutics and CRISPR-Cas9 genome editing technologies call for a robust, accurate and reliable analytical quantification and characterization methods for critical quality attributes of mRNA to ensure the quality of mRNA-based therapeutics and vaccines.

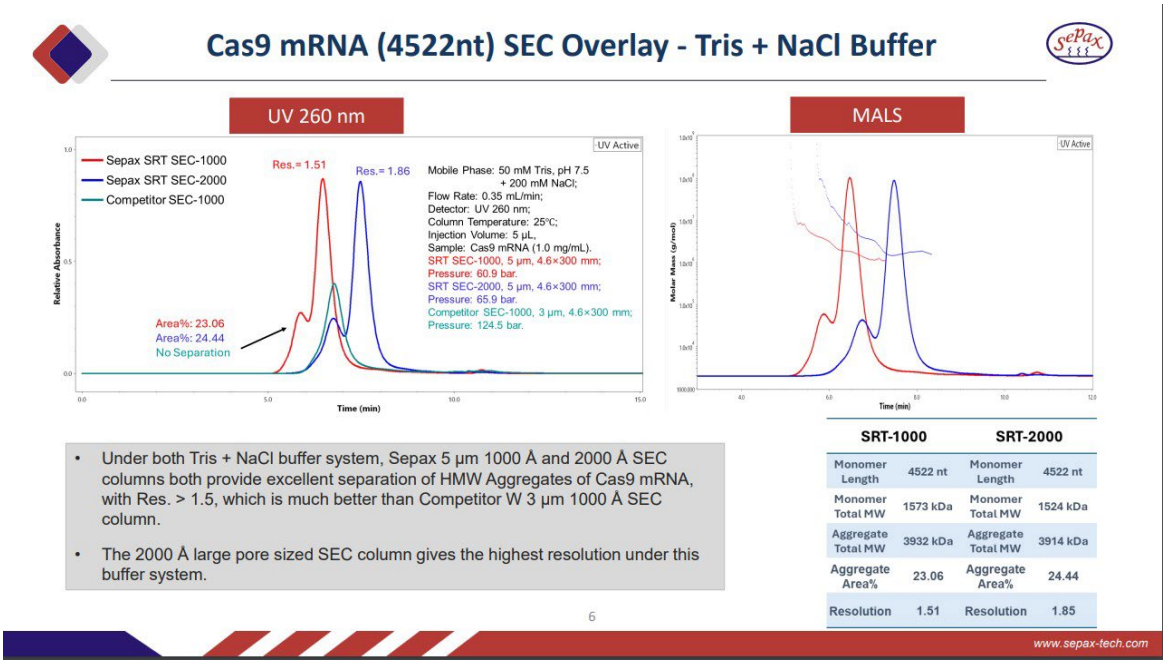
Size Exclusion Chromatography (SEC) along with MALS is one of the methods which can quickly quantify amount of mRNA, its size and amount of high molecular weight aggregates and evaluate its purity.

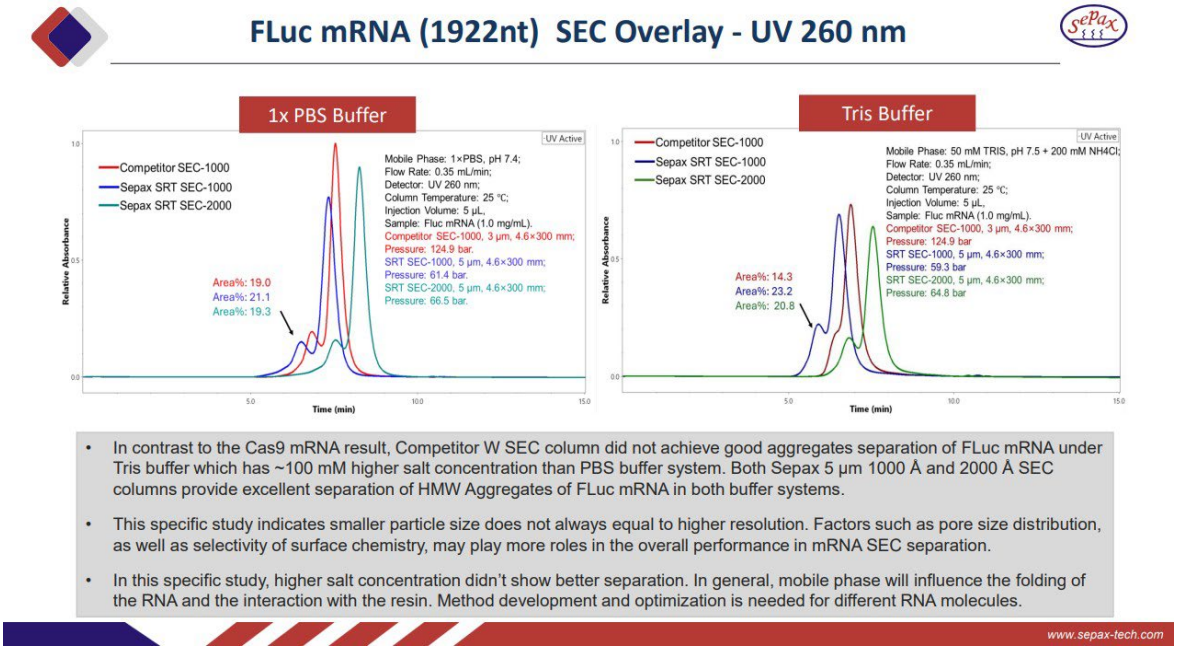
Large size of the modern RNA based therapeutics requires adequate pore size resins with suitable surface chemistry for selectivity and hydrophilicity to achieve high resolution and efficiency separation. It is important to choose adequate column for separation of mRNA – size and sample dependent. Smaller particle size of the resin may not always equal to higher resolution. Factors such as pore size distribution, as well as selectivity of surface chemistry, may also play an important role in the overall performance in RNA SEC separation.

In this study, we present SEC HPLC and MALS data to analyze the effect of pore size, surface chemistry, type of buffer system, salt concentration and temperature on the monomer and aggregate separation of Cas9 mRNA (4500

nt) with estimated molecule weight of 1449 kDa and FLuc mRNA (1922nt) with estimated molecular weight of 616 kDa.

Sepax SRT SEC-1000Å and SEC-2000Å, 5µm particles columns outperform one 3 µm SEC-1000Å column from other branded vendor under all buffer systems with significantly higher resolution. The 2000Å pore sized SEC column provides the highest resolution among the three columns being screened. Conditions such as buffer system, ionic strength and temperature can affect the folding of the mRNA species, and its interaction with the resin separation. Method development and optimization are needed for different RNA molecules. Sepax SRT SEC unique surface chemistry provides more universal buffer compatibility, which is important for developing a robust, accurate and reliable analytical method.





731 Improved ApoptiCIDe™ Safety Switch Provides a Novel, Controllable Therapeutic Platform for Regulated Klotho Anti-Aging Gene Therapy

Keshav Karki[1], Daniel Jasinski[2], Kevin Slawin[1], **David Spencer[1]**
[1]Phoenix-SENOLYTIX, Houston, TX, [2]Eos-SENOLYTIX, Houston, TX

Background: Just as the increasing complexities of cell therapies has demonstrated the need for a rapid, safe and effective safety switch, novel gene therapies that extend past gene replacement for rare pediatric diseases would benefit from the same level of controllability. It remains difficult to control systemic levels of novel proteins produced by newer types of gene therapies simply by modifying gene therapy dose. Therefore, a regulatable gene therapy platform that could be used for such products would be advantageous. Currently, the rimiducid/inducible Caspase-9 (ApoptiCIDe™) system remains the most clinically validated attenuator for cell and gene therapy; however, it's broadest adoption is limited by the burden of a 2-hour infusion of the rim activating agent, along with infusion reactions that can occur as a result of the current excipient, Solutol hydroxy stearate (HS) 15. To improve efficacy and broaden potential applications of the ApoptiCIDe system, we reformulated rimiducid that can be administered quickly and easily *via* the subcutaneous or intramuscular route. Moreover, we demonstrated its broad utility *in vivo* by regulated attenuation of both reporter genes and therapeutically relevant anti-aging candidate therapeutics, Klotho and Follistatin-344.

Results: We screened a large number of combinations of excipient combinations and chose one formulation compatible with subcutaneous and intramuscular injection, with bioavailability above 30%, named PTC-1202, for further clinical development. Formal stability testing revealed 99.8% stability under accelerated conditions (40°C, 75% relative humidity) over 3 months. To demonstrate *in vivo* utility, bioluminescent (BLI) reporter, N-Luc, was co-expressed with ApoptiCIDe under the constitutive CMV promoter/enhancer and delivered to mice using AAV2 and AAV9 vectors via IV, IM, IP and SQ routes. In each case, administration of as little as 10 mg/kg rimiducid (0.3 mg total) led to ~ 90% elimination of BLI within days.

To demonstrate utility with a therapeutically useful gene target, we replaced N-Luc with human secreted Klotho (sKL1), associated with longevity or Follistatin (FST) 344, associated with maintaining muscle mass and delaying sarcopenia or overcoming muscular deficiencies. In both cases, levels of human proteins were easily detectable in the serum at physiological levels and elimination of protein(s) of up to 100% was achievable with one or more rimiducid administration. After a second injection, 60% of mice had undetectable human Klotho and the remaining animals revealed >90% decreased peak protein levels. Ongoing experiments are evaluating the use of lower PTC-1202 doses as a "rheostat" to enable turning down rather than turning off the production of the therapeutic protein.

Discussion: We demonstrated that our improved formulation of rimiducid, PTC-1202, the activating agent for our ApoptiCIDe cell elimination technology, could rapidly and effectively turn off production and reduce systemic levels of Klotho using our controllable gene therapy platform. PTC-1202 should not only provide a new controllable gene therapy platform to improve the safety for patients treated with novel agents, but it should also enhance the ease of use of CaspaCIDe in cell therapies as a safety switch.

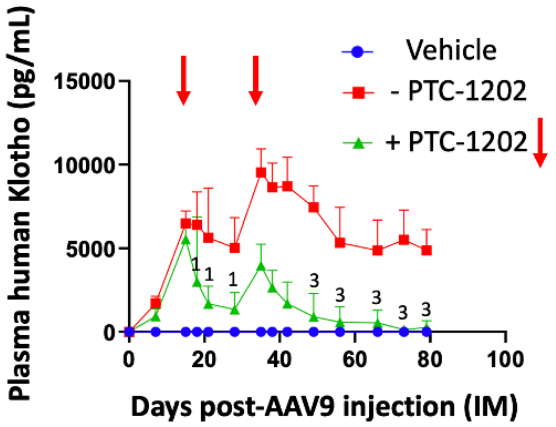


Figure Legend: On day 0, cohorts of mice (n = 5) received vehicle alone (circle), or a single IM injection of AAV9 encoding a bicistronic vector encoding CMV-driven ApoptiCIDe (rimiducid inducible Caspase-9) and secreted human Klotho (square and triangle). Vector-injected mice received reformulated rimiducid on days 19 and 39 (triangle) or control excipient (square) and serum Klotho was analyzed by ELISA at the indicated timepoints. *Note:* Number shown represents the number of animals (of 5) with serum Klotho below the lower limit of quantification (LLoQ).

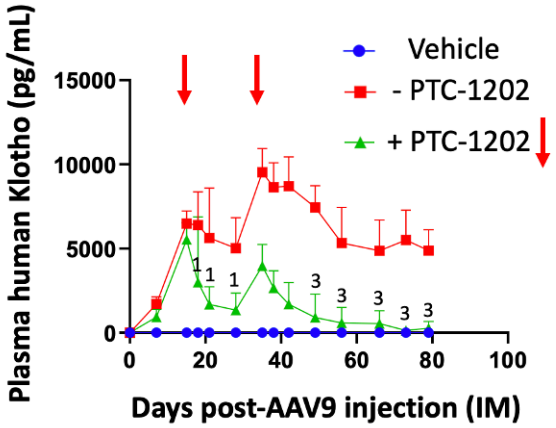

Figure Legend: On day 0, cohorts of mice (n = 5) received vehicle alone (circle), or a single IM injection of AAV9 encoding a bicistronic vector encoding CMV-driven ApoptiCIDe (rimiducid inducible Caspase-9) and secreted human Klotho (square and triangle). 732 Gene Studies About Development of Renal Cell Carcinoma

Leili Niu, Nova Southeastern University, Troy, MI

Background: Renal cell carcinoma (RCC) is a widespread and dangerouos disease. The clear-cell renal cell carcinoma (ccRCC) is the most prevalent type of RCC and is highly malignant. The ccRCC is associated with the loss of the von Hippel-Lindau tumor suppressor gene VHL. The VHL protein (pVHL) binds and stabilzes the renal suppressor protein Jade-1 and plays important growth suppressive roles through Jade-1. Previous studies found that many solid tumors, such as ccRCC, exhibit chromosomal instability and hence have defects in DNA double-strand breaks (DSBs) repairs, we sought to investigate on Jade-1 and pVHL to illustrate mechanisms of cancer development.

Methods: Primary clear cell adenocarcinoma 786-O was the renal cancer cell model. 786-O HAVHL and 786-O HAV0 were transfected by vectors with and without VHL gene respectively. The human embryonic kidney cell line 293T was the healthy renal cell model. Gamma irradiation, doxorubicin, or neocarzinostatin was applied to cause DSBs in renal cells, which were labeled by γH2AX antibodies. The overlapping between Jade-1 and DSBs under the impact of pVHL was visulized in immunofluorescence microscope. The impact of pVHL on Jade-1 expression and transcription levels was innvestigated by immunoblotting and qPCR.

Result: Irradiation and doxorubicin treatments accumulated Jade-1 inside nucleus. DSBs increased Jade-1 protein level in cells without VHL gene, but caused no changes in cells with VHL gene. The colocalization coefficient value between Jade-1 and DSBs did not increase in cells with VHL gene.

Conclusion: Jade-1 participated in DSBs process, and pVHL did not enhance the overlapping between Jade-1 and DSBs. This implies that Jade-1 may not require pVHL in DNA repair process. DSBs upregulated Jade-1 protein level, and pVHL inhibited this elevation. A possible explanation is that pVHL stabilizes the amount of Jade-1 diffusing in cells. More experiments are needed to consolidate these results.

733 Drug-responsive Domains Coupled with Cognate Small-molecule Ligands Drive Synthetic Gene-ON or -OFF Circuits to Regulate Expression of Therapeutic Proteins

Michael Gallo[1], Najmia Amirina-Nave[1], Dan Jun Li[1], Dexue Sun[1], Zheng Ao[1], Grace Olinger[1], Mara Inniss[1], Jan ter Meulen[1], **Dhruv Sethi[1]***

Development of increasingly powerful biological drugs, such as cytokine-armored cell therapies, requires tight control of in vivo protein expression to avoid severe side effects and thereby expand the therapeutic window. We have previously shown that the activity of different classes of therapeutic proteins can be regulated via fusion to drug-responsive domains (DRDs) that can be stabilized with FDA-approved small molecules (Inniss et. al. *Commun Biol* 2025). Currently, this approach is showing promising activity in a Ph1 clinical trial (NCT05470283) in patients with immune checkpoint inhibitor-resistant melanoma treated with engineered tumor-infiltrating lymphocytes expressing regulatable membrane-bound interleukin 15 (OBX-115; Amaria ASCO 2024). While direct fusion of a DRD to proteins of interest can yield effective functional regulation in many cases, in other cases a DRD fusion might affect protein function by interfering with protein binding or post-translational processing. Further, when regulating a secreted protein therapeutic it might be desirable to secrete the native protein rather than a DRD-fused protein. Here, we show that by using a DRD to regulate an artificial transcription factor consisting of a fusion of the chimeric DNA binding domain, ZFHD1, and the transcription activation domain of p65 (Fig 1a) we can construct genetic circuits to regulate expression of either mRNA or short inhibitory RNA. By stabilizing the DRD with ligand, we increase the abundance of the artificial transcription factor, which recruits to the cognate DNA binding sites placed upstream of a minimal promoter. By placing a transgene-encoding protein downstream of the minimal promoter (Fig 1b), mRNA will be transcribed in the ligand-ON state, thereby expressing the protein of interest (ligand-ON/gene-ON circuit). If a short inhibitory RNA is placed downstream of the minimal promoter (Fig 1c), in the ligand-ON state, we can potentially downregulate the expression of any gene in the genome by altering the specificity of the inhibitory RNA (ligand-ON/gene-OFF circuit). The capabilities of the ligand-ON/gene-ON circuit were demonstrated with the in vitro cellular regulation of protein in the cytoplasm (GFP), mitochondria (frataxin) and a secreted protein (interleukin 12 [IL12]). IL12 secretion shows a ligand dose-dependent rheostat-like regulation, with proportional increases in IL12 levels with increases in ligand dose (Fig 1d). Differential basal secretion states for IL12 in the absence of ligand were enforced by altering the composition of the artificial transcription factor (v1-v4, Fig 1d), whilst using fully human components. The capability of the ligand-ON/gene-OFF circuit was demonstrated by dampening the expression of tool proteins like GFP, neuronal proteins such as ApoE (Fig 1e), HTT and members of the TCR signaling pathway, ZAP70 and LAT in a drug-dependent manner. The gene-ON and gene-OFF circuits have the potential to be important tools for gene and cell therapies where precise and variable control of delivered gene product is needed to manage disease and repeat dosing of biologics or anti-sense oligonucleotides is challenging.

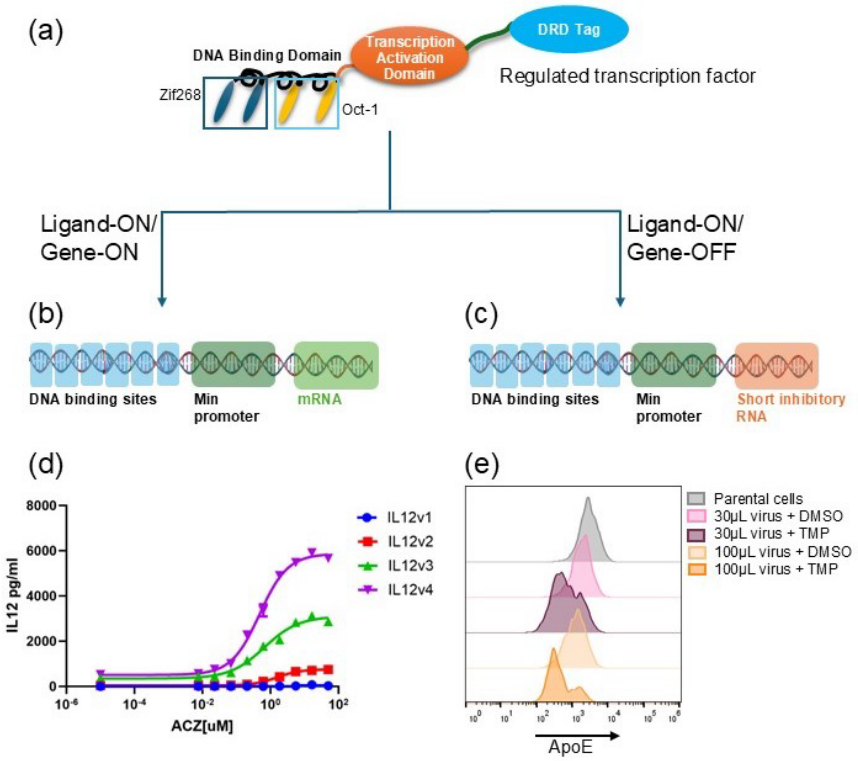

Fig 1. DRD-regulated chimeric transcription factor **(a)** can enable a ligand-ON/gene-ON functionality if combined with an mRNA under the control of a minimal promoter **(b)**. The ligand-ON/gene-OFF switch functionality is enabled when the DRD regulated chimeric transcription is combined with a modified short inhibitory RNA under the control of the minimal promoter **(c)**. Ligand dose-response curves for secreted IL12 using the ligand-ON/gene-ON circuit using trimethoprim (TMP) as the ligand **(d)**. Downregulation of ApoE using the ligand-ON/gene-OFF circuit in a TMP-dependent manner in transduced cells **(e)**.

734 Alectinib Enhances Anti-tumor Efficacy of Disialoganglioside 2 Chimeric Antigen Receptor T Cells in ALK-Mutated Neuroblastoma by Suppressing Programmed Death-Ligand 1

Yuya Sugitatsu[1]*, Akimasa Tomida[2], Tomoya Inoue[3], Yozo Nakazawa[4], Shigeki Yagyu[5], Tomoko Iehara
[1]Kyoto Prefectural University of Medicine, Kyoto City, Kyoto, Japan, [2]Kyoto Prefectural University of Medicine, Kyoto, Japan, [3]Shinshu University School of Medicine, Matsumoto city, Nagano, Japan, [4]Shinshu University School of Medicine, Matsumoto, Japan, [5]Shinshu University, Kyoto, SA, Japan
**Corresponding Author*

Background: High-risk ALK-mutant neuroblastoma (NB) presents significant therapeutic challenges due to drug resistance and an immunosuppressive tumor microenvironment (TME). Chimeric antigen receptor T (CAR-T) cell therapy, particularly targeting disialoganglioside 2 (GD2), has shown potential against NB, but its efficacy is limited in solid tumors by immune evasion mechanisms, such as the upregulation of programmed death-ligand 1 (PD-L1). Aberrant ALK signaling is implicated in the regulation of PD-L1 expression, contributing to immune escape. Alectinib, a second-generation ALK inhibitor, has demonstrated efficacy in ALK-driven malignancies. This study investigates the synergistic potential of Alectinib with GD2 CAR-T cells to enhance anti-tumor activity in ALK-mutant NB. **Methods:** GD2 CAR-T cells were generated by retroviral transduction using a second-generation CAR construct. Their phenotype and function were assessed using flow cytometry and real-time impedance-based cytotoxicity assays. ALK-mutant and wild-type NB cell lines were stimulated with interferon-gamma (IFN-γ) to induce PD-L1 expression, which was measured via flow cytometry and Western blotting. The effects of Alectinib on ALK downstream signaling pathways (STAT3, Akt, Erk1/2) were evaluated by Western blotting. Sequential co-

culture assays were performed to assess the synergistic effects of Alectinib and GD2 CAR-T cells over multiple tumor rechallenges. In vivo efficacy was evaluated using an ALK-mutant NB xenograft model, with tumor growth and survival analyzed across treatment groups. PD-L1 expression in tumor tissues was assessed by immunohistochemistry.

Results: Flow cytometry confirmed that 95.9% of GD2 CAR-T cells expressed GD2, with 35.6% displaying a naïve/stem cell memory phenotype and 44.6% expressing PD-1, indicative of early T-cell exhaustion. In ALK-mutant NB cell lines, IFN-γ stimulation robustly induced PD-L1 expression, significantly suppressed by Alectinib pretreatment. Alectinib inhibited phosphorylation of key ALK downstream signaling molecules, including STAT3, Akt, and Erk1/2, disrupting PD-L1 upstream signaling. Sequential co-culture assays demonstrated enhanced anti-tumor efficacy of GD2 CAR-T cells in the presence of Alectinib, with combination indices improving from 1.0 to 0.77 over three rounds (Figure). Notably, Alectinib did not compromise CAR-T cell phenotype or function. In vivo, the combination therapy of Alectinib and GD2 CAR-T cells significantly suppressed tumor growth and extended survival in ALK-mutant NB xenografts compared to monotherapies ($p < 0.01$). Immunohistochemical analysis revealed reduced PD-L1 expression in tumor tissues from the combination group, suggesting that Alectinib mitigated immune evasion by disrupting the PD-1/PD-L1 axis.

Conclusion: Alectinib synergistically enhanced the anti-tumor efficacy of GD2 CAR-T cells against ALK-mutant NB by suppressing PD-L1-mediated immune evasion and preserving CAR-T cell function. This combination therapy represents a promising strategy to improve outcomes in refractory ALK-mutant NB, warranting further clinical investigation.

735 Developing Novel Chimeric Antigen Receptor Therapies for Glioma

Misty Jenkins AO, Walter and Eliza Hall Institute, PARKVILLE, VIC, Australia

High-grade gliomas remain one of the most formidable challenges in oncology, characterised by aggressive progression and dismal survival outcomes. Despite remarkable advancements in cancer therapies over the past two decades, treatment options for brain cancers, such as glioblastoma (GBM) and diffuse midline glioma (DMG), have stagnated. Current standards, including surgery, chemotherapy, and radiotherapy, offer limited efficacy; GBM patients face a stark 5% five-year survival rate, while DMG, tragically, leaves no survivors, particularly in paediatric cases.

Our research addresses the urgent need for innovative therapeutic strategies. Leveraging the transformative potential of immunotherapy, our program focuses on designing personalised Chimeric Antigen Receptors (CARs) to enhance T cell immunotherapy for brain cancer. Through cutting-edge cell-surface proteomics, we have identified novel brain cancer antigens and established a robust discovery pipeline for therapeutic targets.

We have evaluated the efficacy of CAR T cells in preclinical models, demonstrating significant therapeutic activity both in vitro and in vivo. Recent findings from our group highlight the successful targeting of EphA3 and HER2 in DMG models. In both adult and paediatric models of high-grade glioma, we show that not only do EphA3-targeted CAR T cells eliminate brain tumours, but also persist and form a memory, that can be successfully recalled and clear subsequent tumours.

In humans, recognising the limitations of single-target approaches, we are advancing EphA3-targeted CAR T in combination therapies by engineering CAR T cells to target multiple antigens simultaneously, including GD2, EGFR, HER2, EphA3, CD276, and CD63. Furthermore, we have integrated CAR T cell therapy with immune-modulating strategies, such as checkpoint inhibitors and co-stimulatory agonists, to enhance therapeutic outcomes. We show that systemic administration of anti-41BB in PDX models improves the clearance of syngeneic orthotopic brain tumours.

We have developed innovative methods for tracking CAR T cell dynamics in vivo to address tumour heterogeneity and improve precision. These efforts reflect our commitment to delivering novel therapeutic options for patients with high-grade gliomas, offering hope to individuals and families facing these devastating diseases.

736 GITRL Coexpression in Anti-GD2 CAR-T Cells Results in Persistent Antitumor Activity and Exhaustion Resistance in a Glioblastoma Model

[1]University of São Paulo, Ribeirão Preto, Brazil/ SP, Brazil, [2]University of Sao Paulo, Ribeirao Preto, São Paulo - Brazil, Brazil, [3]Ribeirão Preto, Brazil, [4]University of São Paulo, Ribeirão Preto, Brazil, [5]University of São Paulo, [6]Fundação Hemocentro de Ribeirão Preto, Ribeirão Preto, São Paulo, Brazil, [7]Mie University, Tsu, Japan, [8]Mie University Graduate School of Medicine, JAPAN, [9]University of Sao Paulo, Ribeirão Preto, Brazil, Brazil

Background: CAR-T cell therapy for solid tumors is impaired by the complex tumor microenvironment, which limits cell infiltration and sustained antitumor activity. Thus, enhancing persistance and resistance to suppressive cells will be crucial for improving the efficacy of CAR-T cells against solid neoplasms. Full activation of T cells requires the engagement of costimulatory molecules, as CD28, expressed constitutively, and GITR, expressed right after the initial activation of T cells. GITR engagement with its ligand GITRL promotes enhanced effector functions, as a consequence of T cell proliferation, cytokine production, and antiapoptotic signals. Besides that, GITR activation on Treg cells was found to repress their immunosuppressive functions, which may help to sustain the antitumor activity of CAR-T cells in situ. Thus, our hypothesis is that CAR-T cells coexpressing GITRL will display enhanced antitumor effects.

Aim: The aim of this study was to evaluate in vitro and in vivo the antitumor efficiency of anti-GD2 CAR-T cells coexpressing GITRL in a glioblastoma model.

Methods: To test our hypothesis, we generated human anti-GD2 CAR-T cells coexpressing GITRL (CAR.GD2/GITRL) or the CAR molecule alone (CAR.GD2). In order to investigate the functional activity in vitro of the CAR-T cells, we performed a coculture assay with glioblastoma cells T98G-luciferase (GD2+) and the HCT-166-luciferase (GD2-) using two effector-to-target cell (E:T) ratios. Also, the levels of secreted IFNy were measured by ELISA. Also, T cells recovered from coculture were stained with antibodies against four exhaustion markers (PD-1, CTLA-4, TIM-3, LAG-3) and analyzed by flow cytometry. The persistence of lysis capacity was evaluated by additional rechallenges of coculture. Finally, to access the antineoplastic effect of CAR-T cells in vivo we

induced tumors in NSG mice using T98G-luciferase cells and treated them with both CAR-T cells, untransduced T cell and vehicle.

Results: The lentiviral particles were able to efficiently transduced primary T cells resulting in 30-60% of CAR+ cells. In coculture assays, both CAR-T cells demonstrated a potent cytotoxic activity, with around 90% of T98G cell lysis, while sparing HCT-116 cancer cells, demonstrating GD2-restricted cytotoxic activity. Additionally, CAR.GD2 cells showed higher secretion in coculture in 1:1 ratio, but not in the 2:1 ratio, demonstrating that IFNy secretion by CAR.GD2/GITRL cells was less susceptible to the higher proportion of tumor cells compared to CAR.GD2 cells.The analysis of exhaustion markers revealed an upregulation in all four markers observed in CAR-T.GD2 cells. When comparing the double-positive cell populations for the most expressed markers (PD-1 and LAG-3), we identified a higher frequency of CAR-T.GD2 cells expressing both markers simultaneously (38%) than CAR-T.GD2/GITRL (13%). Also, after three rounds of coculture with T98G tumor cells, CAR-T.GD2/GITRL cells displayed a higher cytotoxic activity than CAR.GD2 cells. In the NSG xenograft model, we observed that both CAR-T cells demonstrated similar in vivo tumor regression and increased survival.

Conclusion: These data suggest that the coexpression of GITRL in anti-GD2 CAR-T cells might enhance T cell resistance to exhaustion and contribute to functional activity. These findings could also be applied to enhance the cytotoxic activity and persistence for other CAR constructs.

Neuroblastoma is the most common malignant (cancerous) extracranial (outside the cranium) solid tumor of childhood that accounts for 15% of cancer deaths in children, and is the primary cause of death from pediatric cancer in children ages 1–5. Disalogangliosid (GD2) is a sialic acid-containing glycosphingolipid uniformly expressed in neuroblastomas. Common challenges of CAR-T cell therapies in solid tumors, such as the limited survival due to the activation induced cell death (AICD), the decreased expansion by their development of a depletion stage and the repressed activation in the immunosuppressive tumor microenvironment (TME). To overcome these challenges, we developed an anti-GD2 Turbo CAR-T which is an enhanced anti-GD2 CAR-T cells with the addition of encoded armored elements of persistence, expansion and shielding modules. The anti-GD2 Turbo CAR-T cells shows enhanced cytotoxicity and increased cytokine release than regular GD2 CAR only when co-cultured with tumor target cells *in vitro*. In addition, the anti-GD2 Turbo CAR-T cells shows enhanced persistence to activation induced T cell apoptosis, increased survival without further stimulation and exogenous cytokines, and potent shielding of anti-tumor activity and cytokine release after TGFβ1 treatment. Evaluation of anti-GD2 Turbo CAR-T in the subcutaneous SY5Y (GD2+ human neuroblastoma cell line) xenograft model demonstrate the significant increase anti-tumor efficacy. The anti-GD2 Turbo CAR-T is more effective at low dose (1e6 or 3e5) to remove tumor due to the addition of encoded armored elements. Compared with regular sc-Fv anti-GD2 CAR-T, the turbo CAR-T also increases the median survival by one week. In summary, these results demonstrate that anti-GD2 Turbo CAR-T as a promising approach for cancer immunotherapy could overcome multiple suppressive mechanisms in the solid tumor microenvironment.

738 Orthogonal IL-2/IL-2Rβ Armoring is Superior to TGF-β Receptor Blockade in Overcoming TGF-β-Driven Inhibition of GPC3 CAR T Cells in Hepatocellular Carcinoma

Inyoung Jung[1], Daniel Park[1], Marie Semana[1], Ivan Cheng[1], Deepti Rokkam[1], Woei Chang[1], Somya Singh[1], Yiling Luo[1], Patrick Lupardus[1], Martin Oft[1], **Paul-Joseph Aspuria[1]**

CAR T therapy has demonstrated success in treating certain hematologic malignancies, achieving deep and durable responses. However, efficacy of CAR T cells is limited, particularly in solid tumors, due to factors contributing to an inhospitable tumor microenvironment. The immunosuppressive cytokine Transforming Growth Factor-beta (TGF-β) accumulates in many cancers. TGF-β inhibits T cell activity by direct inhibition of T cell proliferation, inhibition of Interleukin 2 secretion by T cells, and the inhibition of the cytolytic activity of effector T cells. Strategies to overcome the intratumoral inhibition of T cells by TGF-β are therefore essential to achieving the full potential of CAR T therapy.

IL-2 promotes the proliferation and activity of T cells and has been shown to counteract the inhibitory effects of TGF-β on T cell function. In addition, IL-2 induces IFNγ, which directly inhibits TGF-β signaling. However, therapeutic use of IL-2 is limited by systemic toxicity due to its non-specific activation of lymphocytes. To overcome this challenge, we previously developed a human orthogonal IL-2/IL-2R system consisting of a pegylated, IL-2 mutein (STK- 009) that does not significantly signal through the wild-type IL-2 receptors and a mutated IL-2 Receptor Beta (oRb) that does not significantly respond to wild-type IL-2. This system provides a private IL-2 signal for engineered oRb-expressing cells while avoiding IL-2 signaling in bystander immune cells and IL-2 related toxicities. We have demonstrated STK-009/oRb's ability to selectively expand oRb-expressing CAR T cells (SYNCAR T cells) targeting antigens in both hematological (SYNCAR-001, CD19) and hepatocellular (HCC) malignancies (SYNCAR-002, GPC3) . STK-009 significantly improved anti-tumor efficacy, yielding lasting responses in lymphoma and hepatocellular carcinoma models. In non-human primates, STK-009 did not activate wild-type T or NK cells and showed no drug-related clinical symptoms. Currently, STK-009 + SYNCAR-001 is in Phase I trials (Palomba et al., ASH 2024; NCT05665062, and NCT06544330).

Here, we evaluated the inhibition of CAR T mediated tumor efficacy by intratumoral TGF-β using human anti-GPC3 CAR T cells and GPC3$^+$ TGF-β expressing HCC xenograft models. We compared CAR T cells armored with the orthogonal IL-2/IL-2R system with CAR T cells, whereby TGF-β signaling was abrogated by the expression of a dominant negative TGFBRII (DNTGFBRII). To assess TGF-β accelerated CAR T dysfunction CAR T cells were subjected to continuous antigen exposure of GPC3$^+$ HCC cells engineered to overexpress TGF-β (HEPG2-TGFβ). While DNTGFBRII armoring improved effector cytokine secretion, proliferation, and suppressed exhaustion during chronic CAR stimulation, STK-009 treated SYNCAR-002 T cells demonstrated a greater and more durable enhancement. Both armoring strategies were then tested in HCC xenograft mouse models expressing significant amounts of TGF-β. STK-009/SYNCAR-002 treatment demonstrated superior tumor control, cell proliferation, and better cell fitness compared to the DNTGFBRII armored CAR T cells.

These findings support the advantage of an orthogonal IL-2/IL-2R system that selectively drives and sustains potent T cell effector function even in an adverse tumor microenvironment saturated with TGF-β.

739 JW004: An Armored anti-GPC3 CAR T Therapy for Hepatocellular Carcinoma Enhanced through Multiple Modules

Haihhua Gu[1]*, **Yuling Zhang[1]**, Qi Cao[2], Ji Liu[1]
[1]JW Therapeutics, Shanghai, Shanghai, China, [2]JW Therapeutics, Shanghai, China
**Corresponding Author*

Introduction: Hepatocellular carcinoma (HCC) is an aggressive malignancy, resulting as the third cause of death by cancer each year. Advanced therapeutics have dramatically changed the systemic treatment landscape of advanced HCC. CAR T therapies have become the current focus of treatment investigation in advanced HCC, and show remarkable therapeutic potential. Glypican-3 (GPC3) is a glycosylphospatidyl inositol-anchored membrane protein, is overexpressed in HCC tissues but not in the healthy adult liver. Thus, GPC3 is becoming a promising candidate for HCC diagnosis and immunotherapy. However, the effectiveness of CAR T cells is limited due to the complex tumor microenvironment (TME) and immune-suppressed. To overcome these challenges, we explored JW004, the multiple armored modules to enhance CAR T's function in TME including resistance activation-induced cell death (AICD) and enhance T cell persistence and proliferation.

Methods: Enriched primary CD4$^+$ and CD8$^+$ T cells were used for the generation of CAR-T cells by lentiviral transduction. In vitro, flow cytometry was used to assess the expression level of anti-GPC3 CAR and armored modules' overexpression. The xCELLigence RTCA was used to measure CAR cytotoxic activity post co-culture with target cells from Day0 to Day6, CAR-T cell proliferation was calculated by cell counter. For the function verification of armors were validated by cytotoxic activity and T cell proliferation under non-activation cytokine cell culture medium and soluble TGFb1 treatment which is simulating the TME. In vivo JW004's efficacy was evaluated in NCG xenograft models HCC (via HepG2 and Hu7 two human HCC tumor cell line inoculation), tumor elimination was calculated by tumor volume post CAR T cell dosing. The CAR T cell number and percentage were assessed from mice blood leukocyte by flow cytometry post CAR T cell dosing.

Results: JW004 showed higher potent of cytolysis, T cell proliferation and persistence than anti-GPC3 CAR only when co-cultured with GPC3 expression (low and high level) HepG2 cells in vitro. Furthermore, JW004 improved tumor clearance, also enhanced T cell persistence and proliferation compared to anti-GPC3 CAR only in HepG2 (low GPC3 expression) NCG mice model.

Conclusion: These results demonstrate that armored modules enhance GPC3 CAR T cells' potency and proliferation to support the continuous expansion in vitro and in vivo. JW004 demonstrated more antitumor immunity, potent CAR targeting, resilience to attenuation by TGFβ, reduced activation induce T cell apoptosis, and favorable preclinical efficacy and safety characteristics compared to anti-GPC3 CAR only. Supported by these data, JW004 has potential to address GPC3+ advanced HCC.

740 Armoring iPSC-derived allogeneic therapies with a TGF-b neutralizing synthetic receptor that enhances solid tumor elimination in TME-mimicking conditions in vitro.

Raisa Uchurova[1], Olivia Carton[2], Alexander Goncea[3], Nicholas Alexander[1], Arina Perez[1], Rachel Bernard[1], Ilayda Erkan[4], Sydney Bucher[1], Luis Cocka[1], Daniel Perry[4], John Wheeler[1], Jill Carton[1]
[1]Century Therapeutics, Philadelphia, PA, [2]Drexel University, Collegeville, PA, [3]Century Therapeutics, Reading, PA, [4]Century Therapeutics, Philadelphia

Allogeneic immunotherapy holds immense promise for solid tumor treatment with significant challenges remaining in overcoming the barriers imposed by the solid tumor microenvironment (TME). Extensive preclinical research has led to the pharmacological targeting of the Transforming Growth Factor Beta (TGF-β) pathway, which plays a key role regulating TME. TGF-β drives immunosuppression, stromal remodeling, and angiogenesis to support tumor progression. Here we describe solid-tumor-targeted induced pluripotent stem cells (CAR-iPSC) armored with a synthetic dominant negative receptor (DNR) that neutralizes TGF-β in the environment, thereby potentially inhibiting tumor growth and enhancing immune responses against cancer. We established compatibility of TGF-β DNR engineering with iPSC differentiation and successfully generated TGF-β DNR CAR-iT cells. We confirmed that TGF-β DNR-engineered CAR-iPSCs have reduced SMAD signaling in the presence of soluble TGF-β compared to non-engineered CAR-iPSC by flow cytometry. We evaluated CAR-iT (+/- TGF-β DNR) function in the presence of inhibitory TGF- β (5ng/mL) signals in a repeat-killing assay across multiple Nectin-4 positive target cells. We observed significant advantages of TGF-β DNR CAR-iT in maintaining prolonged cytotoxic activity against labeled target cells by Incucyte in the presence of TME-mimicking conditions. Killing capacity was observed to be 4 times higher with expression of the TGF-β DNR (1.05x10e10 for CAR-iT and 2.5x10e9 CAR-iT with TGF-β DNR). Moreover, we observed a similar effect in a spheroid tumor model, indicating the ability of TGF-β DNR to sustain cytotoxic activity in a 3D culture system. Additionally, we've observed improved function in armored Peripheral blood mononuclear cell-derived iPSC-derived CAR-iNK with TGF-β DNR. In summary, we can improve cytotoxic activity of targeted CAR-iT and CAR-iNK engineered with TGF-β DNR against solid tumor cell lines in the presence of recombinant human TGF-β. These findings highlight a modality that can confer improved anti-tumor activity of future iPSC-derived immunotherapies designed to withstand the immunosuppressive nature of the TME.

741 Preclinical Development of CTSR-Armored B7H3 CAR-T Cells for Pediatric Solid Tumors

Babak Moghimi[1], Michael Hadjidaniel[2], Tania Porrsas[2], Jianping Sun[2], Shawn Barman[3], Devon Bell[2], Emily Hsieh[4], Fariba Navid[2], Shahab Asgharzadeh[2]
[1]Children's Hospital Los Angeles (CHLA), Los Angeles, CA, [2]CHLA, Los Angeles, [3]USC/CHLA, Valencia, CA, [4]CHLA, Los Angeles, CA

Background: TGF-β-targeted CAR-T cells that seek to overcome TME's immunosuppression remain a major opportunity to improve current CAR-T cell therapies. B7-H3, a pan-cancer antigen found to be highly expressed in many pediatric solid tumors, is currently being explored in several trials. Interim reports suggest that the treatment was tolerated with mediocre responses. We proposed to arm these B7-H3 CAR-T cells with a novel chimeric TGF-β switch receptor (CTSR) to convert the immunosuppressive TGF-β signal to a Toll-like receptor (TLR)-mimicking response. We expected that TLR activation in these CAR-T cells would boost their efficiency in TGF-β-rich tumors such as Neuroblastoma (NB), Ewing's sarcoma (EWS), and osteosarcoma (OS).

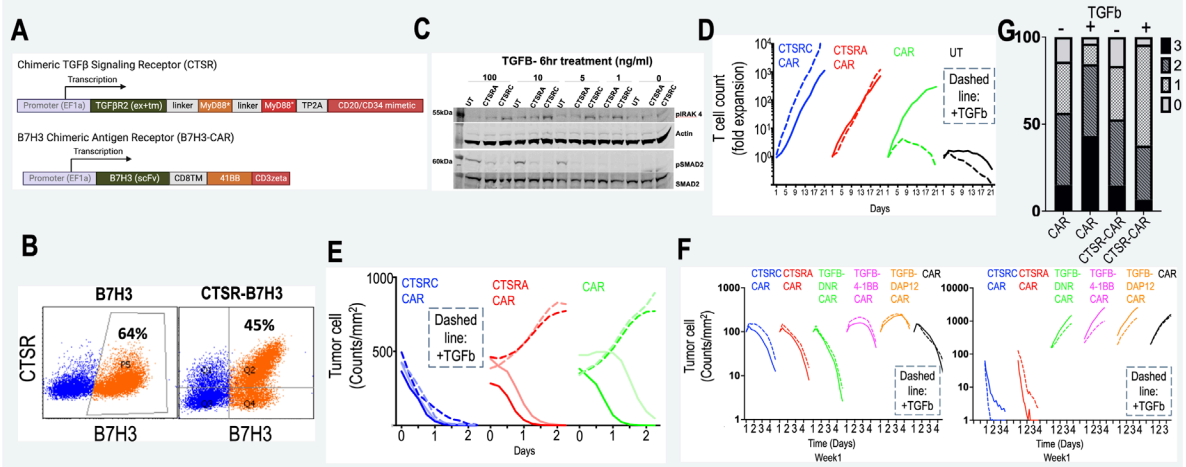
Methods: We engineered the CTSR by fusing the extracellular TGFBR2 domain with the activating domains of MYD88. Human T cells were engineered to express a second-generation CAR against B7-H3 (B7H3-4-1BB-CD3ζ), with or without CTSR.

Results: First, we successfully engineered variations of CTSR and demonstrated a dose-dependent suppression of TGF-β signaling (lower SMAD2/3) and activation of the TLR response (higher IRAK4) upon exposure to TGF-β. We then showed that CTSR reversed the inhibitory effect of TGF-β on CTSR B7-H3 CAR-T cells. While B7-H3 CAR-T cells alone failed to control NB in vitro when exposed to physiological doses of TGF-β, CTSR B7-H3 CAR-

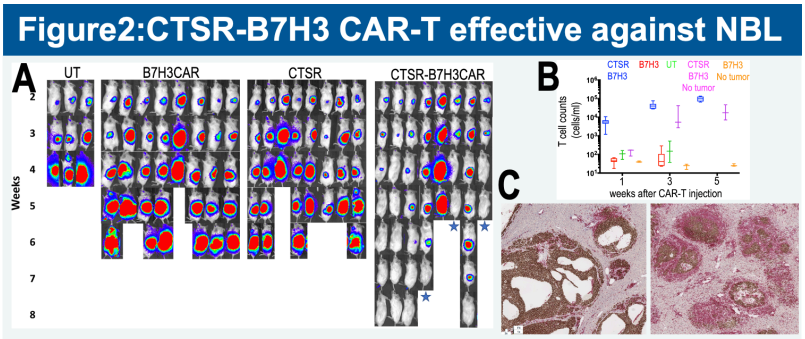
T cells maintained effective tumor control despite increasing doses of TGF-β. More importantly, we observed that CTSR B7-H3 CAR-T cells retained superior anti-tumor efficacy in repetitive tumor exposure, where B7-H3 CAR-T cells alone or armed with alternative switch receptors such as TGFβR2-4-1BB, TGFβR2-DAP12, or TGFB-DNR eventually failed. CTSR B7-H3 CAR-T cells subjected to repetitive tumor exposure showed augmented expansion profiles, enhanced CD4 populations, and longer-lasting T cell memory phenotypes. In an orthotopic disease model of NB, CTSR B7-H3 CAR-T cells demonstrated impressive tumor penetration and disease control, whereas B7-H3 CAR-T cells alone universally failed. The extent of disease control correlated with higher levels of human inflammatory cytokines and several-fold higher T cell counts in the peripheral blood of the mice receiving CTSR CAR-T cells. These findings were similarly replicated in orthotopic models of pediatric EWS and OS.

Conclusions: CTSR armored B7-H3 CAR-T cells have demonstrated superior efficacy against TGF-β-rich pediatric solid tumor disease models and are poised to overcome the immunosuppressive TME barrier, a critical roadblock to the success of CAR-T cells in solid tumors. Our preliminary data provides the rationale for a first-in-human phase I trial of this promising product.

Figure1:CTSR switches TGF-B signaling and reverses its inhibitory effect on CAR-T cells



A-B, Construct design, and CAR expression profile. **C,** CTSR CAR-T cells activate the TLR pathway (via IRAK4) and downregulate the TGF-β signaling pathway (via SMAD2/3). **D,** CTSR-CAR variants demonstrate sustained expansion even under TGF-β treatment. **E,** CTSRC-CARs effectively control tumor cells, overcoming the suppressive effects of high-dose TGF-β. **F,** CTSR-CARs maintain robust, long-term tumor killing, while other CAR variants fail within one week under physiological TGF-β conditions. **G,** CTSR-CAR-T cells exhibit lower cumulative expression of exhaustion markers PD-1, LAG-3, and TIM-3 in response to TGFB exposure.



A, BLI images reveal that CTSR-B7H3 CAR-T cells successfully treat aggressive orthotopic NBL, whereas B7H3 CAR-T cells fail to achieve this outcome. **B,** CTSR CAR-T cells show significantly greater expansion in the peripheral blood of treated mice. **C,** IHC images (brown indicating NBL, red indicating T cells) illustrate strong tumor infiltration and potent anti-tumor effects of CTSR-B7H3 CAR-T cells (right), as compared to the limited efficacy of B7H3 CAR-T cells in the orthotopic model.

742 Nrf2 Deficiency Improves CAR-T Cell Survival and Function in Breast Cancer Models

Yuna Jo[1], Changwan Hong[2]
[1]Pusan National University School of Medicine, Yangsan, Gyeongsangnamdo, KOREA, [2]Pusan National University, Yangsan, Korea

$CD8^+$ cytotoxic T lymphocytes play a pivotal role in tumor rejection but frequently face dysfunction and exhaustion within the immunosuppressive tumor microenvironment (TME). Elevated levels of reactive oxygen species (ROS) in the TME exacerbate T cell impairment, yet the precise molecular mechanisms underlying this phenomenon remain unclear. Nuclear factor erythroid 2-related factor 2 (Nrf2), a transcription factor activated by ROS, is associated with tumor progression. We hypothesized that ROS might influence the anti-tumor activity of $CD8^+$ T cells via Nrf2-mediated pathways. Our study revealed that tumor growth was significantly reduced and reversed in Nrf2-deficient mice upon T cell depletion. We observed increased Nrf2 expression in tumor-infiltrating (TI) T cells, suggesting a role in regulating their function. Importantly, Nrf2 deficiency in $CD8^+$ T cells enhanced their effector functions and resistance to ROS in a murine solid tumor model, enabling sustained activity in a ROS-rich TME. Furthermore, Nrf2 knockdown in human chimeric antigen receptor (CAR)-T cells improved their survival and functional activity in a humanized breast cancer model, resulting in effective tumor control. These findings uncover a novel mechanism linking oxidative stress to immune suppression in cancer and identify Nrf2 as a promising therapeutic target for enhancing T cell-based immunotherapies in ROS-rich solid tumors.

743 Metabolic Reprogramming of HER2 CAR-T Cells Under Hypoxic Conditions: Insights from a multi-omics approach.

Jesus Miguens Blanco[1], Jon Bezney[2], Lei Qi[2], Lawrence Steinman[2], Rogelio Hernandez Lopez[2]*

Background: Chimeric Antigen Receptor (CAR) T-cell therapy has revolutionized hematological cancer treatment, yet its efficacy in solid tumors remains constrained by the challenging tumor microenvironment. Solid tumors characteristically exhibit oxygen levels ranging from 0.5% to 5%, dramatically different from normoxic conditions. This hypoxic environment profoundly impacts immune cell function, particularly T cell metabolism and persistence. Previous research has demonstrated that T cells undergo metabolic reprogramming in low-oxygen conditions,

transitioning from oxidative phosphorylation to glycolytic metabolism. However, the precise metabolic adaptations of CAR-T cells in hypoxic environments and their consequent anti-tumor efficacy remain incompletely understood.

Methods: Our comprehensive investigation utilized an integrated multi-omics approach to characterize HER2 CAR-T cell responses under varying oxygen conditions. Human T cells were isolated from healthy donors, transduced with a HER2-specific CAR construct, and cultured under normoxic (21% O2), moderate hypoxic (5% O2), and severe hypoxic (1% O2) conditions for 24 and 72 hours. We performed 10x Genomics single-cell RNA sequencing to capture transcriptional dynamics, Seahorse metabolic flux analysis to assess cellular energetics, and mass spectrometry to quantify intracellular metabolite profiles. Restimulation assays with HER2-expressing K562s cells evaluated functional capabilities, while advanced computational approaches enabled integrative analysis of the multi-dimensional datasets.

Results: Our analysis revealed nuanced transcriptional and metabolic variations across different hypoxic conditions. Significant differences emerged in gene expression patterns, metabolic pathway utilization, and functional capacities between normoxic and hypoxic environments. These variations were particularly pronounced when comparing moderate and severe hypoxic states, suggesting complex cellular adaptation mechanisms. Metabolic pathway analysis highlighted dynamic shifts in cellular energetics, with notable focus in glycolytic and mitochondrial metabolic nodes.

Conclusion: By integrating single-cell sequencing, metabolomics, and functional data, we have uncovered critical metabolic adaptation mechanisms of CAR-T cells in hypoxic conditions. Our findings provide a foundational framework for developing synthetic biology approaches to engineer more resilient and effective CAR-T cell therapies. Future research will focus on translating these insights into targeted metabolic modifications that enhance CAR-T cell performance in challenging solid tumor microenvironments.

744 EGFR-Targeting Ligand-Based CAR-T Cells Demonstrate Favorable Antitumor Activity Against Gynecologic Malignancies.

Manaka Shinagawa[1], Koichi Hirabayashi[2], Marina Fujioka[3], Kyosuke Kamijo[3], Natsuki Uchiyama[3], Yusuke Yokokawa[3], Yasuhiro Tanaka[3], Motoki Ono[3], Thanyavi Chinsuwan[4], Ryoichi Asaka[5], Aiko Hasegawa[5], Miyuki Tanaka[6], Takashi Murakami[7], Shigeki Yagyu[4], Tsutomu Miyamoto[5], Tanri Shiozawa[5], Yozo Nakazawa[5]
[1]Shinshu University Obstetrics and Gynecology, Nagano, Japan, Japan, [2]Shinshu University, Matsumoto, Nagano, Japan, [3]Shinshu University School of Medicine, Matsumoto, Nagano, Japan, [4]Shinshu University Graduate School of Medicine School of Medicine, JAPAN, [5]Shinshu University School of Medicine, Matsumoto, Japan, [6]Department of Pediatrics, Shinshu University School of Medicine, Matsumoto, Japan, [7]Saitama Medical University, Iruma, Saitama, Japan

Objective. In recent years, the introduction of PARP and immune checkpoint inhibitors has improved the treatment outcomes of maintenance therapy and recurrent cases of gynecological malignancies. However, there is still no new treatment for cases that are resistant to these treatments. Epidermal growth factor receptor (EGFR) is reported to be overexpressed in gynecologic malignancies. However, the clinical efficacy of existing molecular EGFR-targeted therapies against gynecological malignancies has not been demonstrated. This study investigated the antitumor effects of ligand-based EGFR chimeric antigen receptor (CAR)-T cells on gynecological malignancies.

Methods. EGFR expression in patient surgical samples was evaluated using immunohistochemistry. Ligand-based EGFR CAR-T cells were generated via piggyBac-mediated gene transfer. EGFR CAR-T cells were co-cultured with six EGFR-positive gynecologic malignancy cell lines, and their antitumor effects were assessed via flow cytometry. In addition, to check the serial killing activity of CAR-T cells, a long-term culture was performed by repeatedly adding malignancy cells. In our in vivo study, tumor-bearing mice implanted with gynecological malignancy cell lines expressing firefly luciferase in their intraperitoneal cavity were administered EGFR CAR-T cells, CD19 CAR-T cells, or phosphate-buffered saline (PBS) intraperitoneally. Similarly, a subcutaneous transplantation model was created, and CAR-T or PBS was injected into the tail vein. Tumor growth was monitored using an IVIS® Lumina II in vivo imaging system.

Results. EGFR positivity was observed in 41%, 82%, and 79% of ovarian, endometrial, and cervical malignancies in patient samples, respectively. EGFR CAR-T cells were successfully generated with high CAR positivity and a high proportion of naïve/stem cell memory-like T cells. On the other hand, there was almost no expression of the PD-L1 exhaustion marker. In the co-culture experiment, the growth of all six gynecologic malignancy cell lines was significantly suppressed by EGFR CAR-T cells compared to mock T cells. In long-term culture, CAR-T cells also showed favorable cytotoxic activity. In intraperitoneal gynecological malignancies mouse models, mice treated with EGFR CAR-T cells displayed significantly decreased tumor burden compared to those treated with either CD19 CAR-T cells or PBS. Tail vein intravenous injection of CAR-T cells proved effective against cervical malignancies in a subcutaneous transplantation model.

Conclusions. Ligand-based EGFR CAR-T cells may be a promising therapy for various gynecological malignancies.

745 Development of GMP-Compliant Processes for Novel Mesothelin Targeting hYP218 CAR Lentiviral Vector and T Cell Production

Development of GMP-Compliant Processes for Novel Mesothelin Targeting hYP218 CAR Lentiviral Vector and T Cell Production

Hui Dong[1], Lianghua Bin[1], Cynthia Ng[1], Xiaoyi Yang[1], Warren Rowe[1], Tanusree Sen[1], Chinatsu Mukai[1], Brian Browser[1], John Roach[1], Ray Harris[2], Jason Yovandich[2], Mitchell Ho[3], Raffit Hassan[4], Vinay Vyas[1]

Mesothelin is a cell-surface antigen overexpressed in a variety of solid malignant tumors, making it an attractive target for chimeric antigen receptor (CAR) T cell therapy. Here, we report the development and optimization of a novel CAR T cell therapy process based on a humanized hYP218 antibody targeting the membrane-proximal epitope of mesothelin[i]. This study focused on production of replication-defective lentiviral vectors encoding hYP218 CAR and the subsequent engineering and expansion of CAR T cells in both small-scale and Good Manufacturing Practice (GMP)-scale setups.

Lentiviral vectors were produced using a third-generation lentiviral platform, involving four-plasmid co-transfection, tangential flow filtration (TFF), chromatography, and sterile filtration. These vectors demonstrated a physical p24 titer of 6.72 $x10^6$ pg/mL and an infectious titer as 1.79 $x10^8$ TU/mL. This lentivirus process was further scaled up and GMP grade lentiviral vectors were produced in a GMP facility.

CD4+/CD8+ enriched T cells from peripheral blood apheresis were transduced using purified hYP218 CAR lentiviral vectors and further expanded. T cell process was developed in a small-scale laboratory setup starting at $1x10^6$ cells and scaled up to starting at 55 $x10^6$ cells in an automated device CliniMACS Prodigy (Miltenyi Biotec). The resulting hYP218 CAR T cells achieved CAR expression levels ranging from 47.64% to 57.58% across donors, with a multiplicity of infection (MOI) of 2.06 and a vector copy number (VCN) of 2.1-2.7 copies/transduced cell. The CAR T process produced 2.17-2.19 $x10^9$ hYP218 CAR T cells starting from 55 $x10^6$ CD4+/CD8+ enriched T cell. These CAR T cells demonstrated robust dose-dependent killing potency against mesothelin-expressing cancer cells in cytotoxicity assays.

In summary, we successfully developed and scaled up the production of high-quality hYP218 CAR lentiviral vectors and CAR T cells under GMP conditions, demonstrating high-quality outputs suitable for clinical use. These advancements establish a robust GMP-compliant manufacturing platform for hYP218 CAR T cell therapy into clinical trials for mesothelin-positive solid tumors.

Chimeric Antigen Receptor (CAR) T cell therapy has demonstrated remarkable clinical success for the treatment of hematological malignancies and holds great promise for expanding its application to other types of cancer and autoimmune disease. However, extending CAR T cell therapy to solid tumors presents significant challenges including limited efficacy, poor expansion and persistence of the engineered cells and potential on-target off-tumor toxicity. Furthermore, the severity of the adverse effects may be enhanced by strategies to improve the efficacy by e.g. co-expression of cytokines. In order to address both, safety and efficacy questions, a tight control of the engineered cells would be favorable. We have developed a drug-inducible ON-switch system that allows transcriptional regulation of either the CAR or a booster factor in presence of an orally available small molecule.

Our novel drug-inducible switch system consists of a split synthetic transcription factor (sTF) that can be functionally reconstituted in presence of caffeine. To generate the split sTF, we made use of an anti-caffeine nanobody heterodimer pair and fused a zinc finger DNA binding domain to one of the nanobodies and a transcriptional activator to the other. Transcription of the gene of interest is regulated via an engineered inducible promoter specifically targeted by the sTF.

We demonstrate the versatility of the system, being functional with a wide range of different DNA binding domains and activation domains used in different sTFs, leading to different expression levels of the regulated gene. We also show that response of the inducible promoter can be modulated by modifying the number of sTF binding sites, expanding the design features available to tune our transcriptional switch. All of these, together with the drug dose, highlight the potential to tailor our system to meet specific requirements of the therapy in terms of the expression level of the gene of interest (e.g. CAR or booster molecule).

Using primary human T cells *in vitro,* we demonstrate caffeine dose-dependent expression and cytolytic activity of inducible anti-CD20 CAR and, importantly, no background expression in the absence of the inducer. Furthermore, we investigated the ON-OFF kinetics of the transcriptional switch to prove that the expression of the anti-CD20 CAR can be re-induced after complete shutdown of the system. In contrast to suicide switches, this allows to resume the therapy in case of e.g. relapse. Moreover, we explored the drug-inducible control of additional factors with the potential to enhance efficacy, expansion and persistence of engineered cells constitutively expressing a CAR. Our results reveal improved persistence and efficacy *in vitro* of anti-CD20 CAR cells expressing an active mutant of STAT5B in a caffeine-regulated manner. Importantly, this effect was strictly dependent on the presence of inducer and the strength of the response correlated with the caffeine dose.

We expect that our novel drug-inducible transcriptional switch will enable the development of more potent CAR T cell therapies by regulating the expression of booster proteins while preserving safety and mitigating side effects.

Additionally, when applied to control the expression of the CAR, it allows for a tight regulation of CAR T cell activity to finetune response and enhance safety.

747 Computationally Guided Point Mutations for Screening of Enhanced CAR T cells

Shoji Hisada[1], Atsushi Okuma[2], Yoshihito Ishida[1], Taketo Kawara[3], Daisuke Ito[3], Kei Yoshida[3], Takuya Yamashita[3], Tomohiko Okuda[3], Hiroko Hanzawa[1], Shizu Takeda[3]

Chimeric antigen receptor (CAR)-T cell therapy has transformed cancer treatment, showing substantial promise against various malignancies. However, the optimization of CAR constructs remains an ongoing challenge. While most clinically approved CAR-T cell therapies rely on combinations of CD3ζ, CD28 and 4-1BB, there is growing interest in refining CAR design through more targeted engineering approaches. Traditional methods, such as domain shuffling, have been used to generate CAR diversity, but we propose a more precise method involving point mutations to enhance CAR function. In this study, we computationally selected mutation sites and amino acid substitutions based on their evolutionary conservation, aiming to introduce beneficial changes without disrupting the receptor's structural integrity. This strategy allows for the targeted optimization of specific regions within the CAR, such as the hinge and co-stimulatory domains, for improved signaling and overall CAR-T cell performance. We constructed a library of ~10^8 CAR variants, all featuring second-generation CD28-based receptors targeting CD19. Point mutations were introduced into the hinge and co-stimulatory domains to enhance CAR-T cell activity. From this library, 500 unique CAR variants were selected, transfected into human T cells and tested for their anti-tumor activity against CD19+ tumor cells. Several CAR-T cell clones expressing mutated receptors demonstrated significantly improved anti-tumor responses compared to control CAR-T cells expressing the parental CD28-based construct. These findings highlight the potential of using point mutations as a precise tool for optimizing CAR-T cell therapies and advancing cancer immunotherapy.

748 ICANS and CRS Following Lymphodepletion in CAR-T Therapy: A Real-World Data Analysis

Nancy Lunney[1]*, Vladimir Otasevic[2], Karina D'Angelo[2], Kausik Maiti[3], Chris Learn[2]
[1]Parexel, Doylestown, PA, [2]Parexel, Durham, NC, [3]Parexel, Hyderabad, Telangana, India

Lymphodepletion (LD) chemotherapy is an essential preparatory regimen employed prior to CAR-T cell infusion to enhance the body's ability to accept and proliferate infused CAR-T cells. While overall response rates (ORR) for both LD regimens are reported to be similar, varying rates of Immune effector Cell-Associated Neurotoxicity Syndrome (ICANS) and Cytokine Release Syndrome (CRS) have been reported. This study investigates the relative risk of ICANS and CRS post LD with these regimens as represented in Real-World Data (RWD) from 2018 through 2024.

RWD analysis utilizing the TriNetX database including data from over 229 million patients worldwide was employed to analyze the relative incidence of ICANS and CRS in patients undergoing LD via either Benda or Flu/Cy within 10 days prior to CAR-T infusion with any FDA-approved CAR including group matching and propensity analysis.

Results from 3,730 patients (3240 Flu/Cy and 490 Benda) with identical median follow-up times of 180 days indicate no significant difference in rates of ICANS or CRS between LD regimens. ICANS risk was slightly higher in the Flu/Cy group (16.7%) compared to Benda (14.3%) but this difference was not statistically significant ($p = 0.184$). Survival analysis showed similar results with no significant difference in survival probabilities (83.39% vs 86.32%, $p = 0.118$) or hazard ratio (1.227, $p = 0.551$). CRS risk was similar between Flu/Cy (37.0%) and Benda (38.8%) with no statistically significant difference ($p = 0.458$). Survival analysis showed no significant differences with similar survival probabilities (62.71% vs 61.76%, $p = 0.492$) and hazard ratio (0.947, $p = 0.075$). The number of instances of CRS was also not significantly different.

Propensity score matching was employed to balance demographic characteristics. The matching process reduced both cohorts to 480 patients each effectively balancing most demographics with minor residual differences in some racial categories. Follow-up times were similar between cohorts with a median of 180 days for both before and after matching. For ICANS Flu/Cy showed a slightly higher risk (18.8% vs 14.6%) and lower survival probability (82.00% vs 86.27%) but these differences were not statistically significant. CRS risks were identical (39.6%) with very similar survival probabilities but again not statistically significant.

This study found no significant differences between the rates of ICANS and CRS post-CAR-T with Benda vs Flu/Cy LD per RWD, even after propensity matching . This RWD analysis re-confirms earlier findings although additional confound analysis is needed to clarify the comparative safety profiles of these LD regimens.

749 Epidemiology and Impact of Acute Gastrointestinal Hemorrhage on Outcomes of Chimeric Antigen Receptor T-Cell Therapy in Patients With Hematologic Malignancies: Insights From a Nationwide Database

Abdu Mohammed[1], Adamsegd Gebremedhen[2], Saqib Peracha[3], Waqas Haq[1], Gabriel Urbelz[2], Samson Teka[2], Ahmed Ali[4]
[1]Trinity Health System, Steubenville, OH, [2]Marshall University School of Medicine, Huntington, WV, [3]Trinity Health System, Steubenville, OH, OH, [4]Howard University Hospital, Washington DC, DC

Introduction: Patients with hematologic malignancies are predisposed to both bleeding and thrombotic events due to a range of risk factors. Following chimeric antigen receptor T-cell (CAR-T) therapy, these risks may be amplified by hematologic abnormalities such as impaired hematopoietic recovery, coagulation defects, and increased thrombotic tendencies. Additionally, cytokine release syndrome (CRS), a common CAR-T-related complication, can exacerbate coagulopathy. Despite these risks, limited data are available regarding the epidemiology of gastrointestinal hemorrhage (GIH) and its influence on CAR-T therapy outcomes. This study evaluates the impact of GIH on clinical outcomes in CAR-T recipients using data from the National Inpatient Sample (NIS) database.

Methods: We analyzed data from the NIS to identify adults diagnosed with non-Hodgkin's lymphoma (NHL), B-cell acute lymphoblastic leukemia (ALL), and multiple myeloma (MM) who underwent CAR-T therapy between 2018 and 2021, as identified by ICD-10 codes. Patients were stratified based on the presence or absence of GIH. To ensure national representativeness, complex sampling weights were applied. Sociodemographic characteristics and comorbidities were compared across groups. The primary outcome was all-cause in-hospital mortality, with secondary outcomes including various complications. Multivariate regression models were used to assess outcome disparities, with statistical significance defined as $p < 0.05$.

Results: Out of 4,120 adults who received CAR-T therapy, 82.5% had NHL, 12.6% had MM, and 4.9% had ALL. GIH occurred in 1.46% of these patients. Baseline demographic characteristics were similar between the GIH and non-GIH groups; however, atrial fibrillation was significantly more prevalent in the GIH group (41.67% vs. 11.33%, $p < 0.001$). While the overall in-hospital mortality rate was 3.0%, patients with GIH had markedly higher mortality (16.7%). After adjusting for confounders, GIH was associated with significantly increased odds of all-cause mortality (adjusted odds ratio [aOR] 5.04, 95% CI 1.01–29.01) and higher risks of complications, including acute kidney injury (aOR 4.41, 95% CI 1.07–18.21), respiratory failure (aOR 9.17, 95% CI 1.88–44.79), and shock (aOR 5.29, 95% CI 1.19–23.58). No significant differences were observed between groups regarding the incidence of immune effector cell-associated neurotoxicity syndrome, deep venous thrombosis, pulmonary embolism, intracranial hemorrhage, acute blood loss anemia, acute heart failure, or acute pulmonary edema. Additionally, there were no significant differences in length of hospital stay (LOS) or mean hospitalization costs, which were 16.96 days and $1,196,413, respectively, across the entire CAR-T cohort.

Conclusion: Among patients with hematologic malignancies undergoing CAR-T therapy, the development of GIH was associated with significantly higher in-hospital mortality and increased rates of severe complications. These findings highlight the detrimental impact of GIH on CAR-T therapy outcomes and emphasize the need for targeted management strategies in this high-risk population.

750 A United States Population-Based Study on the Epidemiology and Impact of Hemophagocytic Lymphohistiocytosis on In-Hospital Outcomes in Patients Receiving Chimeric Antigen Receptor T-Cell Therapy

Adamsegd Gebremedhen[1], Abdu Mohammed[2], Mamdouh Souleymane[3], Subigya Thapa[1], Samhitha Gundakaram[1], Abraham Titus[4], Omar Alkharabsheh[5]
[1]Marshall University School of Medicine, Huntington, WV, [2]Trinity Health System, Steubenville, OH, [3]Marshall University Joan C. Edwards School of Medicine, Huntington, WV, [4]University of South Alabama, Mobile, AL, [5]University of South Alabama Mitchell Cancer Institute, Mobile, AL

Introduction: Hemophagocytic Lymphohistiocytosis (HLH) is a life-threatening hyperinflammatory state characterized by uncontrolled immune cell activation, leading to a cytokine storm and hemophagocytosis. This cascade results in cytopenia, coagulopathy, progressive multi-organ failure, and potentially death. In patients undergoing chimeric antigen receptor T-cell therapy (CAR-T), HLH has emerged as a recognized complication and is termed immune effector cell-associated HLH-like syndrome (IEC-HS). While efforts have been made to define its characteristics, pathogenesis, and treatment options, studies examining its epidemiology and population-level impact on CAR-T outcomes remain limited. In this study, we investigate the epidemiology of HLH and its impact on in-hospital outcomes in CAR-T patients using United States population data.

Methods: We used the National Inpatient Sample to identify adults with non-Hodgkin's lymphoma (NHL), B-cell acute lymphoblastic leukemia (ALL), and multiple myeloma (MM) who underwent CAR-T from 2018 to 2021 using ICD-10 codes. The cohort was stratified by HLH status, and complex sampling weights ensured national representation. We compared sociodemographic characteristics and comorbidities between groups, with all-cause mortality as the primary outcome and various secondary outcomes also examined. Multivariate regression assessed outcome disparities, with statistical significance set at $p < 0.05$.

Results: We identified 4,120 adults who received CAR-T (82.5% NHL, 12.6% MM, 4.9% ALL), of whom 50 (1.2%) had a concurrent diagnosis of HLH. The HLH group had a higher proportion of female patients (80.0% vs. 39.7%, $p < 0.05$); otherwise, there were no significant differences in demographic characteristics or comorbidities between the groups. Overall mortality was 3.0%, but 20.0% in HLH patients. HLH was associated with higher odds of all-cause mortality (aOR 7.1, 95% CI 1.1–44.2). Moreover, patients with HLH had higher odds of experiencing shock (aOR 6.3, 95% CI 1.5–25.3), disseminated intravascular coagulation (aOR 21.6, 95% CI 4.2–110.5), intracerebral hemorrhage (aOR 51.3, 95% CI 3.8–685.3), and tumor lysis syndrome (aOR 10.0, 95% CI 2.7–37.3). They also had higher odds of requiring mechanical ventilation (aOR 18.2, 95% CI 4.5–73.0) and vasopressor support (aOR 24.2, 95% CI 6.0–97.9). There were no increased odds of respiratory failure, acute kidney injury, gastrointestinal hemorrhage, acute liver failure, or immune effector cell-associated neurotoxicity in patients with HLH compared to those without HLH. Patients with HLH had longer hospital stays (32.4 vs. 16.8 days, $p < 0.05$; adjusted incidence rate ratio [aIRR] 1.9, 95% CI 1.3–2.6). The mean hospitalization charges for CAR-T patients in general were $1,196,413, with no significant difference between the groups.

Conclusion: HLH in CAR-T patients is linked to higher odds of all-cause mortality, adverse outcomes, a greater need for intensive care, and extended hospital stays. Based on the findings of this study, we stress the importance of early identification and prompt management of HLH in CAR-T patients to reduce its negative impact on outcomes and alleviate the associated healthcare burden.

751 Does the Occurrence of ICANS After CAR-T Therapy Increase the Risk of Late Neurological Complications: A Real-World Data Analysis

Kausik Maiti[1], **Nancy Lunney[2]***, Chris Learn[3]
[1]Parexel, Hyderabad, Telangana, India, [2]Parexel, Doylestown, PA, [3]Parexel, Durham, NC
Corresponding Author

A common and challenging adverse event (AE) associated with CAR-T cell therapy is immune cell-associated neurotoxicity syndrome (ICANS) occurring in 20–60% of patients. ICANS typically occurs within hours to weeks of CAR-T therapy presenting with a wide range of neurological symptoms ranging from mild confusion to severe encephalopathy and potentially life-threatening cerebral edema. While the acute management of ICANS has improved concerns persist about potential long-term neurological sequelae. This study aims to evaluate whether ICANS after CAR-T therapy is associated with the development of Parkinson's disease (PD), in the months and years following treatment.

The TriNetX Real-World (RW) global dataset comprising electronic health records (EHR) of 229 million patients from diverse healthcare organizations worldwide was utilized for this analysis. A total of 4,700 patients in this dataset received one of the US FDA-approved CAR-T therapies, including axicabtagene ciloleucel, tisagenlecleucel, lisocabtagene maraleucel, brexucabtagene autoleucel, and idecabtagene vicleucel. Among these, 820 patients developed ICANS (Cohort 1), while 3,880 patients did not develop ICANS (Cohort 2). Lifetime follow-up data from this RW dataset as of January 10, 2025 revealed that 10 patients (1.22%) in Cohort 1 developed Parkinson's disease (PD) any time after three months of CAR-T therapy whereas 30 patients (0.77%) in Cohort 2 developed PD in the same timeframe. Although the incidence of PD was higher in Cohort 1, the difference was not statistically significant (p-value = 0.2095; Fisher’s Exact Test).

This real-world data analysis revealed that there is no significant association between the development of PD and ICANS post-CAR-T therapy. While the analysis of this large RW dataset reconfirms the findings from earlier studies the slightly higher incidence of PD in the ICANS group while not statistically significant warrants further investigation with longer follow-up- periods and larger patient cohorts. Future studies should consider potential confounding factors including age, prior cancer treatment, and underlying cancer type which could impact the risk of developing neurodegenerative disorders after CAR-T.

Table- 1

Patient Cohorts

Cohort	Cohort Description	Sample size (# of patients)	# of patients developed Parkinson Disease (anytime after 3 months of CART therapy)	Percentage of patients
Cohort 1	Patients who developed ICANS within 3 months following CART	820	10	1.22
Cohort 2	Patients who did not develop ICANS within 3 months of CART	3880	30	0.77

752 Social Determinants Hindering CART Access in Civilian and Military Life

Nancy Lunney[1]*, **Jamie Pierson[2]**, Karina D'Angelo[3], Grace Tierney[3], Chris Learn[3]
[1]Parexel, Doylestown, PA, [2]Parexel, Prosper, TX, [3]Parexel, Durham, NC
**Corresponding Author*

Chimeric Antigen Receptor T-cell (CART) therapy represents a promising advancement in the treatment of certain hematologic malignancies. Underserved patient populations, including veterans, face unique challenges linked to service-related disabilities, mental health conditions, patient financial barriers and reliance on limited healthcare availability, limiting access to CART. Analysis of real-world data (RWD) on Social Determinants Health (SDOH) was conducted to identify factors impacting access to CART.

Review of RWD from the TriNetx claims database covering 4,990 patients across 35 Health Care Organizations (HCOs) from 2019-2025 was conducted together with analysis of clinical trial data on Veteran Affairs (VA) centers from Citeline.

Results of this analysis indicate significant impact due to lack of CART availability in community-based treatment facilities with zero of the 88 United States facilities providing CART at community-based centers. Across the United States, there are 300 academic medical centers, but a small portion—13%—offer CAR-T therapy to patients. Citeline data shows that oncology clinical trials involve only 18 VA centers. Within the extensive network of the Veterans Health Administration (VHA), compromising of 170 medical centers and 1,193 outpatient clinics, the capability to provide CAR-T therapy is limited to a single facility. The VA serves 9.1 million veterans each year with approximately 56,000 veterans in the VHA system being diagnosed with cancer annually. TriNetx data brought to light that of the 4,990 patients undergoing CART treatment 75.75% of those were white with 8.0% black or African American and 12.21% Asian, Other or Unknown. Ethnicity analysis reveals 74.14% not of Hispanic or of Latino descent 7.61% Hispanic or Latino and 18.43% of unknown ethnicity. Differences in gender appear but may be explained by disease state.

For the general population challenges to CART access are multifaceted. The high cost of CART therapy which can exceed $500,000 per treatment creates significant barriers. High insurance deductibles, out-of-pocket expenses along with limited insurance coverage present challenges to patients with health insurance while the uninsured are often excluded from CART access outside of clinical trials. Geographic disparities also play a critical role, as CART therapy is only available at a limited number of certified treatment centers primarily located in urban or academic medical centers. Patients in rural or underserved areas often face significant travel burdens, logistical challenges, and delays in receiving care. The availability of only one VHA facility equipped to administer CART exacerbates the problem. While CART has been proven to extend the life of many patients access to this life-saving treatment must be adapted to meet the needs of underserved populations as RWD demonstrates that the impact of SDOH disproportionately effects vulnerable populations. This analysis highlights the urgent need to integrate SDOH considerations into the deployment of novel therapies to bridge gaps in healthcare delivery for underserved populations.

753 CD45 as a Universal Target for Adjuvant TCR-T Cell Therapy Following Allogeneic Hematopoietic Cell Transplantation

Kostadin Petrov[1], Stephen Carroll[1], Kenneth Jahan[1], Rakshi Bala[1], Debanjan Goswamy[1], Hannah Bader[1], Alok Mahopatra[1], Shubhangi Kamalia[1], Drashti Shah[1], Nivya Sharma[1], Victor Ospina[1], Sanket Revadkar[1], Ryan Kritzer[1], Hana Husic[1], Shobitha Jillela[1], Shoshana Bloom[1], Jackson Lirette[1], Rachel Lent[2], Prachi Dhanania[1], Chandan Pavuluri[1], Carolyn Hardy[1], Alexander Cristofaro[1], Zhonghua Zhu[1], Livio Dukaj[1], Kimberly Cirelli[1], Antoine Boudot[3], **Mollie Jurewicz[1]**, Cagan Gurer[1]

Engineered cell therapies have transformed the treatment of B-cell malignancies, but myeloid malignancies like AML, MDS, and some forms of ALL remain a high unmet need. To date, allogeneic hematopoietic cell transplantation (HCT) remains the only curative option for patients with these malignancies, but up to 40% of patients relapse post-HCT, with >80% mortality within 2 years of relapse. One way to prevent relapse is to administer donor-derived TCR-engineered T cells (TCR-T cells) immediately following transplantation that target antigens presented on patient-derived, but not donor-derived, hematopoietic cells. This provides a way to eliminate residual malignant and pre-malignant hematopoietic cells while sparing normal, donor-derived cells. Early data from the ALLOHA trial suggest that TCR-T cells targeting HA-1 or HA-2, antigens presented on HLA-A*02:01, reduce relapse rates in patients with AML, MDS, and ALL undergoing allogeneic HCT with reduced intensity conditioning (Al Malki, ASH 2024). To expand this trial to include TCR-Ts targeting additional HLA types, we report a novel strategy in which TCR-Ts are developed that target antigens derived from the universal heme-restricted protein CD45 (PTPRC). We demonstrate preclinical proof-of-concept studies using a lead, HLA-A*03:01-restricted, CD45-targeted TCR identified using novel in vitro stimulation and screening platforms. We show that the TCR-T candidate is target-specific, with good safety and efficacy profiles, sparing HLA-A*03:01-negative hematopoietic cells and HLA-A*03:01-positive non-hematopoietic cells, while eradicating HLA-A*03:01-positive, CD45-positive hematopoietic cells of normal and transformed origin in vitro and in vivo. This TCR-T candidate has now been advanced to IND-enabling studies and will be incorporated into the ongoing ALLOHA Phase 1 study.

754 Impact of Protein-Energy Malnutrition on Outcomes of Chimeric Antigen Receptor T-Cell Therapy in Patients with Hematologic Malignancies: Insights from a National Database

Adamsegd Gebremedhen[1]*, Abdu Mohammed[2], Ibrahim Shanti[1], Kriti Dhamija[3], Love Kumar[1], Samhitha Gundakaram[1], Mamdouh Souleymane[4]

Introduction: Protein-energy malnutrition (PEM) is common in cancer patients, including those with hematologic malignancies, and can affect multiple organ systems, including cardiovascular, immune, and cognitive functions.

PEM is linked to poorer outcomes and longer hospital stays across various cancer types. In patients with hematologic malignancies receiving chimeric antigen receptor T-cell (CAR-T) therapy, PEM is associated with prolonged hospitalizations. However, limited research exists on how PEM influences CAR-T outcomes and related complications. This study aims to assess the impact of PEM on CAR-T complications and outcomes using United States population data.

Methods: We used the National Inpatient Sample to identify adults with non-Hodgkin's lymphoma (NHL), B-cell acute lymphoblastic leukemia (ALL), and multiple myeloma (MM) who underwent CAR T-cell therapy between 2018 and 2021, based on relevant ICD-10 codes. The cohort was stratified by the presence or absence of PEM, and complex sampling weights ensured national representation. We compared sociodemographic characteristics and comorbidities between PEM and non-PEM patients. The primary outcome was all-cause in-hospital mortality, with secondary outcomes including complications also examined. Multivariate regression models assessed outcome disparities between the groups, with statistical significance set at $p < 0.05$.

Results: We identified 4,120 adults who received CAR-T therapy (82.5% with non-Hodgkin's lymphoma, 12.6% with multiple myeloma, and 4.9% with acute lymphoblastic leukemia), of whom 790 (19.2%) had concurrent PEM. The PEM group had a higher proportion of patients with anemia (92.4% vs. 76.7%, $p < 0.001$); otherwise, there were no significant differences in demographic characteristics or comorbidities between the groups. Overall mortality was 3.0%, but 10.8% in the PEM group. PEM was associated with higher odds of all-cause mortality (adjusted odds ratio [aOR] 9.4, 95% confidence interval [CI] 3.7–23.8). Additionally, PEM patients had higher odds of acute kidney injury (aOR 2.1, 95% CI 1.3–3.4), respiratory failure (aOR 4.3, 95% CI 2.3–8.0), shock (aOR 2.8, 95% CI 1.4–5.7), immune effector cell-associated neurotoxicity syndrome (aOR 2.7, 95% CI 1.7–4.2), disseminated intravascular coagulation (aOR 10.1, 95% CI 4.0–25.4), and gastrointestinal hemorrhage (aOR 6.5, 95% CI 1.7–24.8). PEM was also associated with higher odds of renal replacement therapy (aOR 5.1, 95% CI 1.5–16.6), mechanical ventilation (aOR 4.7, 95% CI 2.3–9.7), and vasopressor use (aOR 3.4, 95% CI 1.7–7.0). Furthermore, PEM patients had longer hospital stays (24.7 vs. 15.1 days, $p < 0.001$; adjusted incidence rate ratio [aIRR] 1.6, 95% CI 1.4–1.8) and higher mean hospitalization charges ($1,638,050 vs. $1,092,026, $p < 0.001$; aIRR 1.4, 95% CI 1.2–1.6).

Conclusion: Our study found that patients with hematologic malignancies and concurrent PEM who received CAR-T therapy had significantly higher odds of all-cause mortality, adverse outcomes, increased need for intensive care, longer hospital stays, and higher hospitalization charges. These findings emphasize the critical need to address the nutritional needs of this population to improve in-hospital outcomes and reduce healthcare burdens.

755 Comprehensive Immune Reconstitution Profiles Following Chimeric Antigen Receptor T-Cell Therapy

Introduction: Chimeric Antigen Receptor T (CAR-T) cell therapy has revolutionized the treatment of hematologic malignancies. Significant challenges persist regarding disease relapse and infection-related morbidity, impacted by delayed immune reconstitution (IR). Detailed characterization of CAR-T therapy IR remains limited.

Methods: We conducted a single-center retrospective study analyzing IR patterns in CAR-T patients treated between 1/2016 and 9/2024. Comprehensive flow cytometric analysis assessed immune cell subsets, including myeloid cells, monocytes, dendritic cells, T cells (CD4+, CD8+, Treg, αβ, γδ, naïve, memory, activated, and exhausted), B cells, NK cells, and NK-T cells. Planned measurements were prior to lymphodepletion, at CAR-T infusion, and at defined intervals (days 30, 90, 180, year 1, month 18, and year 2) post-infusion. Clinical data were

collected to analyze IR differences. Response rates and survival analyses with landmark analysis at days 30, 90, and 180 post-CAR-T infusion were performed to evaluate patient outcomes with differing IR profiles.

Results: A total of 319 patients were enrolled, including 220 B-cell lymphoma (BCL) and 39 acute B lymphoblastic leukemia (B-ALL) patients who received CD19-CAR-T cells, and 60 multiple myeloma (MM) patients receiving BCMA CAR-T cells. Early recovery (day 30) was observed in monocytes, dendritic, CD8+ T, NK-T, and T-REG cell subsets, while CD4+ T and B cells showed delayed recovery influenced by underlying disease (Fig 1). Median CD4+ T cell count reached 200 cells/μL by day 180 in BCL and day 365 in MM patients, while B-ALL patients failed to achieve this threshold by day 365. B cell recovery patterns varied by disease type. MM patients showed earliest recovery at day 90, followed by BCL patients at day 180, while B-ALL patients showed minimal B cell recovery even at day 365. In BCL patients, CD4+ T cells <100 cells/μL correlated with significantly reduced progression-free survival (PFS) and overall survival (OS) across multiple timepoints, with day-30 landmark analysis hazard ratios (HR) of 3.35 for OS (95% CI 1.73-6.37, p<0.001) and 1.88 for PFS (95% CI 1.14-3.08, p=0.013) (Fig 2). T-cell activation peaked at day 30, coinciding with maximum exhaustion marker expression. At day 30, patients exhibited variable T cell expansion patterns, ranging from high T cell expansion, particularly in γδ T cells, while others lacked T cell recovery (<300 cells/μL). Patients without T cell reconstitution demonstrated significantly lower OS (30-day landmark analysis HR 2.24, 95% CI 1.28-3.93, p=0.005). Patients receiving bendamustine lymphodepletion demonstrated lower depth of immune suppression at CAR-T infusion in all immune subsets vs fludarabine/cyclophosphamide. However, B cells were low at baseline, presumably from prior therapy. Despite less suppression, all immune subsets were further suppressed, except dendritic cells, which remained unsuppressed in some patients receiving bendamustine. MM patients with unsuppressed myeloid dendritic cells at infusion demonstrated reduced PFS (HR 2.29, 95% CI 1.02-5.14, p=0.045).

Conclusions: This study provides the first comprehensive characterization of CAR-T IR through a detailed analysis of multiple immune cell subsets and identifies key immune subset thresholds that may predict survival outcomes. These findings could inform personalized post-CAR-T monitoring strategies and guide interventions to improve clinical outcomes.

756 Stage-specific Expression and Signaling of a CAR in TRAC$^{-/-}$ iPSC-ATOs Rescues Positive Selection and Produces More Naïve and Cytotoxic CAR T Cells

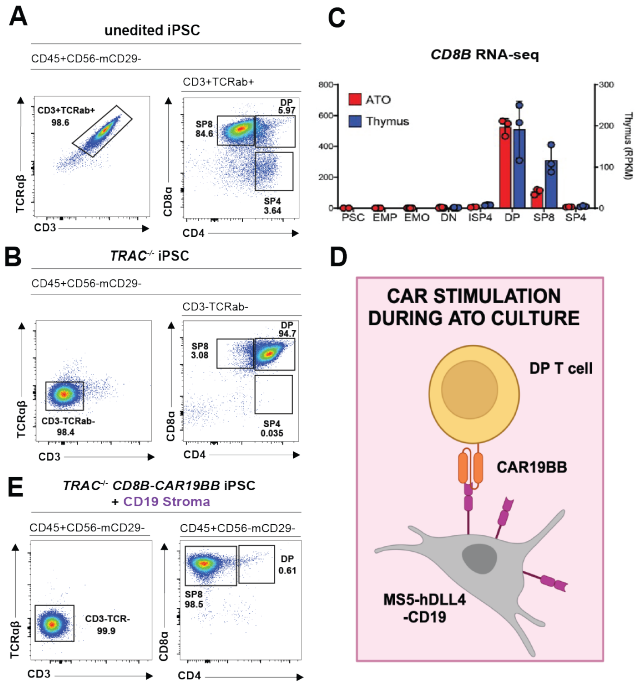
[1]UCLA Molecular and Medical Pharmacology, Los Angeles, California, [2]David Geffen School of Med at UCLA, Los Angeles, CA, [3]UCLA, Los Angeles, CA, [4]UCLA Health, Pasadena, CA, [5]UCLA, Santa Clara, CA

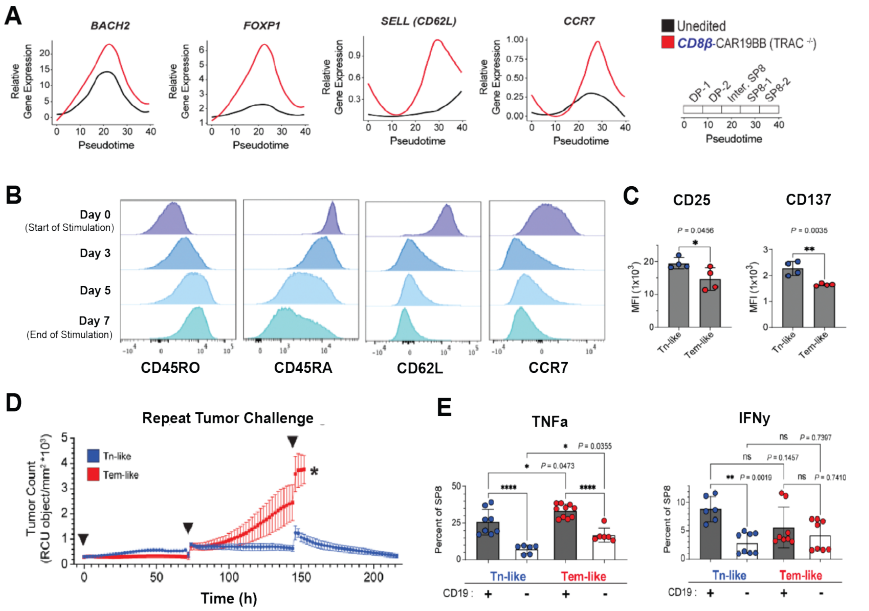
A primary barrier to Chimeric Antigen Receptor (CAR) adoptive T cell therapies is the ongoing reliance on autologous T cell sources and the resulting and unpredictable response rates due to inconsistent T cell potency and *in vivo* exhaustion of cancer patient-derived T cells. Thus, an important goal for the field is to develop strategies to enhance T cell effector function. Induced pluripotent cells (iPSCs) serve as a unique tool in this effort as they can undergo complex multi-gene editing and unlimited clonal expansion. Genetic alterations can be introduced in iPSC to create a universal non-alloreactive transgenic CAR T cell source that is functionally optimized and readily available. However, genetic modifications performed in iPSC may negatively impact subsequent T cell development. Most critically, the elimination of cell surface expression of endogenous T cell receptor (TCR) to prevent graft versus host disease also blocks positive selection, the critical developmental process required to generate mature T cells. During positive selection double positive (DP) T cells mature into single positive CD4+ (SP4s) and CD8+ (SP8s) after a productive interaction between the TCR and a major histocompatibility complex (MHC)-peptide. Our group has developed a method to overcome the block in positive selection through gene editing strategies that produce stage-specific expression of an exogenous TCR or CAR in iPSCs. After differentiation of these engineered iPSC lines in the Artificial Thymic Organoid (ATO) platform, it was observed that mature SP8 T cells that underwent CAR-mediated positive selection were phenotypically and transcriptionally uniformly like naïve T cells (Tn), whereas TCR-mediated positive selection induced mostly effector T cells (Teff). Further, naïve-like CAR T cells produced from the iPSC-ATO when compared to effector memory (Tem) like CAR T cells showed higher *in vitro* tumor killing capacity. In future studies we aim to further define CAR signaling during positive selection and to interrogate the impact of specific CAR signaling on development of mature SP8 phenotype and function.

Figure 1: Stage-specific expression & signaling of a CAR rescues positive selection and T cell development of SP8s.



(A) At 6 weeks of unedited iPSC-ATO development, TCR/CD3 is expressed and primarily single positive CD8+ (SP8) T cells are seen. **(B)** T cells from *TRAC*$^{-/-}$ iPSCs do not express the TCR/CD3 and cannot undergo positive selection. **(C)** RNA-seq data of normal Thymus and ATO differentiation was used to identify candidate genes that were developmentally regulated. *CD8B* was expressed at the DP and SP8 stages of T cell development. Using a CRISPR/-Cas9 editing strategy, a CAR targeting CD19 (CAR19BB) was introduced into the 3' UTR of the *CD8B* gene in the iPSCs, introducing CAR expression during the same expression window as the endogenous *CD8B* gene. **(D)** The CAR was stimulated throughout positive selection by CD19 antigen provided in the stroma within the ATO. **(E)** Delayed expression and stimulation of CAR19BB at the developmental stage of *CD8B* expression completely rescued positive selection in *CD8B-CAR19BB TRAC*$^{-/-}$ iPSCs.

Figure 2: SP8 CAR T cell transcriptional phenotype and impact of culture and stimulation on T cell phenotype and function.



(A) Multiomic analysis of week 3 iPSC-ATOs identified five major clusters as T cells developed from DP stages to mature SP8s. Comparison of gene expression within the defined clusters identified common naïve transcription factors and genes were differentially upregulated in the *CD8B-CAR19BB TRAC*$^{-/-}$ (red) T cells versus unedited T cells (black). **(B)** SP8s from the ATO were stimulated by CD19 expressing K562s (CD19-K562) across 7 days of co-culture. By day 7, naïve markers were largely downregulated, mimicking a more effector memory-like T cell (Tem) phenotype. **(C)** Activation phenotypes of Tem-like *CD8B-CAR19BB TRAC*$^{-/-}$ T cells (red) were compared to the naïve-like *CD8B-CAR19BB TRAC*$^{-/-}$ T cells (Tn) (blue) produced directly from the ATO culture. **(E)** After a 6h co-culture with either CD19-K562s (black bar) or antigen negative K562s (white bar), quantification of T cell effector cytokines was assessed in both Tem-like and Tn-like SP8s. **(D)** *In vitro* cytotoxicity was assessed using an Incucyte repeated tumor challenge assay of CD19-K562 growth during co-cultures with Tn-like or Tem-like SP8 T cells at a Target:T cell ratio of 1:1.

757 Targeting CCL2 to Improve Efficacy and Reduce Toxicity of CAR T-cell Therapy

Wiktoria Parol[1], Georgina Anderson[2], Michael Chapman[3]
[1]University of Cambridge (MRC Toxicology), CAMBRIDGE, Cambridgeshire, United Kingdom, [2]University of Cambridge, UNITED KINGDOM, [3]MRC Toxicology Unit, University of Cambridge, Cambridge, United Kingdom

Chimeric antigen receptor (CAR) T-cell immunotherapy has emerged as a transformative treatment for haematological cancers. However, it is not effective in all patients, and it has still not found use in solid tumours, largely because of their immunosuppressive microenvironments. Furthermore, its clinical application may be limited by severe toxicities, most notably cytokine release syndrome (CRS). A unifying axis regulating these processes is that mediated by the chemokine, CCL2, also known as monocyte chemoattractant protein-1 (MCP-1). CCL2 activates its target cells by binding its receptor, CCR2. CCR2 is expressed on regulatory T-cells (Tregs), a key driver of immunosuppression in the tumour microenvironment. It is also expressed on monocytes, a central player in the pathophysiology of CRS; where CCL2 binding leads to chemotaxis to the tumour site, interleukin-6 secretion, and recruitment and activation of surrounding immune cells. CCL2 is thus a major driver of CRS. Indeed, it is found at elevated levels in the serum of patients receiving CAR T-cell therapy and it is a reliable predictor of high-grade CRS. Targeting CCL2 therefore represents a promising therapeutic strategy, enhancing efficacy by inhibiting Tregs at the tumour site, and reducing toxicity by preventing excessive monocyte recruitment. However, it is important to demonstrate that this strategy does not impair the activity of the CAR T-cells themselves.

To explore this approach, we developed fourth-generation, CD19-directed, armoured CAR T-cells that secrete proteins to modulate the effects of CCL2 in the tumour microenvironment. These proteins include both single-chain variable fragments (scFvs) and nanobodies directed against CCL2, plus eotaxin-3, a natural antagonist of CCL2.

These proteins neutralize CCL2 and block the CCR2 receptor on monocytes and Tregs. To overcome the challenge of poor transduction efficiency in primary T-cells, we employed an antisense vector in which the CAR is under a constitutively active CMV promoter, while therapeutic protein secretion is regulated by a T-cell activation-inducible NFAT promoter. Each gene in the vector is separated by polyadenylation sites to minimize transcriptional interference. We demonstrated that this optimized vector could be efficiently transduced into primary T-cells, at a level similar to the parental, unarmoured vector. To ensure that armouring these CAR T-cells did not impair their cytotoxicity, we co-cultured them with CD19+ Ramos B-cells and assessed target cell killing via flow cytometry. Indeed, the armoured CAR T-cells demonstrated equivalent cytotoxicity to control, parental, non-armoured second-generation CAR T-cells. Importantly, we confirmed that these CAR T-cells effectively secreted scFv/nanobody proteins against CCL2 and that these armouring proteins had binding and functional blocking activity. Further studies are ongoing to confirm inhibition of monocyte migration.

In conclusion, this study presents a novel, unified approach to improving CAR T-cell therapy by enhancing efficacy, whilst targeting one of the major axes of toxicity.

758 Alloimmune Defense Receptor Combined with Genetic Ablation of Adhesion Ligand CD58 is a Comprehensive Approach to Promote Functional Persistence of Allogeneic Cell Therapies without Conditioning Chemotherapy

Alan Williams[1], Rina Mbofung[1], Daniel Morales-Mantilla[1], Brian Groff[1], Alison O'Connor[1], Betsy Rezner[2], Ramesh Janani[1], Binzhong Li[3], Yijia Pan[1], Mark Jelcic[1], Hui-Yi Chu[4], Bi-Huei Yang[1], Tom Lee[1], Karl-Johan Malmberg[5], Maksim Mamonkin[6], Eigen Peralta[1], John Goulding[1], Bob Valamehr[1], Jode Goodridge[1]
[1]Fate Therapeutics, Inc., San Diego, CA, [2]Fate Therapeutics, [3]Fate Therapeutics, Inc., San Diego, [4]Fate Therapeutics, Inc, San Diego, California, [5]Oslo University Hospital, Oslo, Norway, [6]Baylor College of Medicine, Houston, Texas

Clinical administration of chimeric antigen receptor (CAR) T-cell therapy relies on conditioning chemotherapy (CCT) to deplete host immune cells and maximize homeostatic cytokines to promote CAR T cell expansion and functional persistence. However, CCT also requires hospitalization and costly administration of therapy in tertiary healthcare settings. Providing off-the-shelf CAR T cell therapy without requiring CCT has the potential to significantly reduce treatment-related toxicities, cost of care, and extend patient reach. To this end, we established Sword and Shield Technology, a unique approach combining a novel synthetic alloimmune defense receptor (ADR), which targets 4-1BB and evades alloreactive immune cell response, and knock-out of CD58 ($CD58^{KO}$) to disrupt the ability of alloreactive immune cells to form a functional synapse. Both ADR and $CD58^{KO}$ were engineered into a clonal master iPSC line that can be used for consistent and uniform production of off-the-shelf multiplexed-edited CAR T cells. $ADR^{+}CD58^{KO}$ CAR iT cells demonstrated resistance to allo-rejection and uniquely expanded in cell number over the duration of an MLR assay with unmatched donor PBMCs, whereas control CAR iT cells (ADR^{null} $CD58^{wt}$) were eliminated. Notably, $ADR^{+}CD58^{KO}$ CAR iT cells exhibited similar levels of host T cell evasion observed with HLA I/II deficient controls. In addition, $ADR^{+}CD58^{KO}$ CAR iT cells avoided NK cell-mediated rejection, an observation not seen with controls. The $ADR^{+}CD58^{KO}$ CAR iT cells proved capable of persisting even in supraphysiologic conditions, co-cultures with primed alloreactive T cells (pAllo-T) generated from an unmatched donor, where in these very stringent conditions, control CAR iT cells were depleted in a few days. Upregulation of 4-1BB on pAllo-T was observed in co-cultures with control CAR iT cells but not in co-cultures with $ADR^{+}CD58^{KO}$ CAR iT cells, indicating that $ADR^{+}CD58^{KO}$ CAR iT cells are hypoimmunogenic to highly reactive pAllo-T. To confirm $ADR^{+}CD58^{KO}$ CAR iT cells retain potent anti-tumor activity under alloreactive pressure, we used a serially challenged tri-culture assay combining the pAllo-T MLR with daily-dosing of tumor cells. Control CAR iT cells showed rapid loss of tumor control and expansion of $4\text{-}1BB^{+}$ pAllo-T. In contrast, $ADR^{+}CD58^{KO}$ CAR iT cells prevented expansion of $4\text{-}1BB^{+}$ pAllo-T (not detected vs 47% $4\text{-}1BB^{+}$ in control) and maintained potent anti-tumor activity and durable persistence. Similar results were observed in a xenograft tumor model where $ADR^{+}CD58^{KO}$ CAR iT showed enhanced tumor control compared to controls in vivo in the presence of pAllo-T ($p < .05$). To demonstrate that $ADR^{+}CD58^{KO}$ CAR iT cells do not inhibit the host immune response against tumor cells, a tri-culture set up was investigated consisting of Nalm6 tumor lacking CAR antigen, host anti-tumor T cells, and $ADR^{+}CD58^{KO}$ CAR iT cells. Anti-tumor T cells co-cultured with Nalm6 tumor reduced tumor burden by 5-fold and in tri-cultures using $ADR^{+}CD58^{KO}$ CAR iT cells, we observed no inhibition of the anti-tumor T cell activity or

associated 4-1BB expression. Importantly, these results show that ADR^{+}CD58^{KO} CAR iT cells do not aberrantly target or disrupt the anti-tumor activity of non-alloreactive T cells. In conclusion, the potential of ADR^{+}CD58^{KO} CAR iT cells to elicit robust cytotoxic responses against diseased cells in immune competent settings shows promise for the use of cell-based immunotherapies without administration of CCT to patients.

759 Single Cell RNA-seq Detection of AAV in Circulating Leukocytes via Antibody-Derived Tags

Todd Yoder[1], Sushmita Paul[1], Minnal Gupta[1], Gaelle Mardy[1], Blake Rust[2], Stacy Webb[3], Cheyenne Hellard[4], Mengyan Du[4], Sinclair Cooper[5], Kate Krontz[4], Eisha Clyde[3], Gavin George[4], Vyohm Neel, Greg Gojanovich[3], Scott Hammond[6], Ross Fraser[7], Canwen Jiang[7], Daniel Hui[1], Simon Lacey[8]
[1]AskBio, Philadelphia, PA, [2]AskBio, Morrisville, NC, [3]AskBio, Durham, NC, [4]AskBio, Research Triangle Park, NC, [5]AskBio UK Ltd, Edinburgh, Edinburgh, City of, United Kingdom, [6]Asklepios Biopharmaceutical, Research Triangle Park, NC, [7]AskBio, Durham, North Carolina, [8]AskBio, Milton, DE

Introduction: The presence of anti-AAV antibodies pose a potential obstacle to AAV-mediated gene therapy. Recent reports have highlighted the innate immune compartment's role in response to recombinant AAV vectors – often facilitated by anti-AAV antibody opsonization and Fc receptor-mediated uptake. These reports were proteomic-based, namely conventional[1] or high-dimensional[2] flow cytometry with a capsid reporter for single cell AAV detection. While impactful in identifying the reactive populations of the immune system and demonstrating intervention strategies, these methods were limited by the number of cellular biomarkers characterizing the immune response. Single cell RNA-sequencing (scRNA-seq) provides unparalleled phenotyping of individual cells with potential to generate molecular and proteomic data through antibody-derived tags (ADTs). Herein we leveraged this multimodal platform with the first of its kind viral detection using anti-AAV ADTs to identify reactive leukocytes via *sequencing of extracellular protein targets from AAV* (SEPTA) to address fundamental questions in AAV immunology.

Methods: Three AAV8 seropositive individuals were recalled from a healthy donor pool screened in the Philadelphia area. Whole blood draws were stimulated *ex vivo* for 24 hours with AAV8 empty capsid or AAV8 expressing nano-luciferase paired with unstimulated control. Post hemolysis, cells were stained with a panel of antibody-derived tags for surface protein quantification. An additional anti-AAV monoclonal antibody, ADK8, was conjugated with a molecular barcode and spiked in during surface staining to label extracellular AAV+ cells. Cells were then fixed and permeabilized, followed by intracellular stain with ADK8 conjugated to a second unique molecular barcode to identify AAV+ phagocytes.

Results: The characterization of neutrophils is technically challenging due to rapid cellular degradation and paucity of gene expression. Using SEPTA, we captured ~50,000 cells and defined >12 distinct neutrophil states acutely post *ex vivo* stimulation, with >600 molecular and protein markers per leukocyte. Molecular signature-based computation clustering resolved neutrophil heterogeneity ranging from immunosuppressive to interferon-inducible viral responsive, degranulating, or neutrophil extracellular trap (NET) priming. Consistent with previous reports, capsid uptake was observed in neutrophils and monocytes. These frontline populations exhibit upregulation of toll-like receptor (TLR), cytosolic DNA sensing, NOD-like receptor, and chemokine signaling pathways in AAV-stimulated conditions. We observed variation in antiviral response between agonists and donors categorized as tolerant or moderate-to-highly immunogenic. Interestingly, a greater magnitude and proportion of leukocytes expressed activation markers in the AAV8 nano-luciferase stimulation compared to donor-paired AAV8 empty capsid.

Conclusion: The complexity and heterogeneity of human response to AAV warrants the use of the most sophisticated tools at our disposal. Though ephemeral in nature and understudied in the context of AAV, neutrophil states may correlate to several clinical outcomes including disease severity and thrombotic microangiopathy (TMA). Here we demonstrate the utility of our multimodal scRNA-seq method with viral detection, SEPTA, in resolving the initial immunological populations and pathways ensuing from AAV administration in seropositive individuals.

760 Characterization of Antigen-specific Memory B Cell Repertoire in Human Tissues by Single-Cell Tools (LIBRA-Seq)

Larisa Pereboeva[1], Eddie-Williams Owiredu[1], Rodney King[1], Frances Lund[1], Troy Randall[1]
[1]*University of Alabama at Birmingham, Birmingham, AL*

Memory B cells (Bmem) play a critical role in generating antibodies upon repeated pathogen exposure. Research on human B memory cells has predominantly focused on their circulating pool, which poorly reflects the true B memory repertoires in other immunological sites. There remains a significant knowledge gap regarding tissue-resident Bmem, which constitute over 90% of the total Bmem pool. To address this gap with a closer focus on antigen (AG)-specific B cells, we investigated AG-specific Bmem in multiple tissues of an organ donor seropositive for SARS-CoV-2 and OC43 antibodies. We leveraged the LIBRA-seq tool, which integrates single-cell RNA sequencing (scRNA-seq), V(D)J sequencing, and barcode-enabled antigen mapping, to evaluate the tissue residence and transcriptome profile of OC43 and SARS2-reactive Bmem from human spleen, mediastinal, and mesenteric lymph nodes.

Methods: Lymphocytes were isolated from the spleen, mediastinal, and mesenteric lymph nodes of an organ donor. The cells were stained with an antibody panel, including barcoded OC43 and SARS-CoV-2 Spike tetramers. CD19+/IgD− AG++ cells were bulk sorted for single-cell analysis. 10,000 cells were submitted for 10X libraries GEX, VDJ, and FB. Libraries were sequenced on an Illumina platform, and the final reads were processed using the Cell Ranger multi pipeline, followed by various single-cell tools to calculate LIBRA-scores, analyze gene expression and molecular characteristics.

Results: Our findings reveal that subsets of AG-specific Bmem exhibit distinct transcriptional profiles driven partly by antigen specificity. Significant differences in repertoire characteristics (clonality, abundance, and diversity), gene usage, VH-VL pairing, CDR3 length, and frequency of somatic hypermutations (SHM) were observed between the OC43- and SARS-CoV-2-reactive subsets. The OC43 subset demonstrated highly biased V gene usage, predominated by IGHV1-69**01, IGHD6-19**01, and IGHJ4*02 gene combinations, VH:VL gene pairing, longer CDR3 lengths (up to 30 amino acids), and a higher frequency of SHM. In contrast, the SARS-CoV-2 reactive receptors exhibited greater clonal diversity exhibiting broader (unbiased) VH gene utilization with lower mutation frequencies. The OC43 repertoire displayed features of a well-developed adaptive response, with broad clonal expansion and affinity maturation, while the SARS2 repertoire likely reflects the response to a new infection, characterized by minimal clonal expansion, shorter CDR3 regions, higher diversity, and lower mutation frequency.

Conclusions: Our high-throughput single-cell analysis enables the study of the diversity and distinctive characteristics of OC43 and SARS-CoV-2 -specific B memory cells within human lymphoid tissues. This study provides detailed insights into the molecular characteristics of OC43- and SARS-CoV-2 -reactive antibody repertoires, including clonal structure, antibody specificity, and the functional potential of memory B cell subsets. These insights are crucial for understanding the immune response to coronaviruses in general. For instance, the available pool of OC43-reactive Bmem can now be evaluated for cross-reactivity to SARS-CoV-2, suggesting the potential for recalling pre-existing OC43 Brem to combat a new coronavirus infection. Additionally, our study provides a wealth of paired sequences of human antibody genes, with potential applications in therapeutic or diagnostic fields, particularly in gene therapy.

761 *Pre-Existing Immunity to AAV - A Qualitative Comparison Between Different Neutralization Assay Methods*

Joshua Baal[1], Kirsten Prestel[2], Lea Hupe[2], Klaus-Ingmar Pfrepper[2], Martin März[3], Dana Holzinger[4]
[1]*PROGEN Biotechnik GmbH, Heidelberg, Baden-Wuerttemberg, Germany,* [2]*PROGEN, Heidelberg, Germany,* [3]*PROGEN, Heidelberg, Baden-Wuerttemberg, Germany,* [4]*Progen Biotechnik GmbH, Heidelberg, Germany*

Adeno-associated virus (AAV)-based gene therapy continues to offer transformative potential for treating a wide array of genetic disorders. However, natural exposure to AAV has resulted in the development of antibodies in a

significant portion of the population. These pre-existing antibodies can pose challenges by neutralizing AAV vectors or eliciting immune responses, which may compromise the efficacy and safety of gene delivery. Thus, screening patients for AAV-specific antibodies prior to treatment is crucial. To evaluate whether patients possess pre-existing neutralizing antibodies (NAbs), neutralization assays are performed. These assays determine the ability of antibodies to inhibit AAV genetic payload delivery into target cells. Complementary to neutralization assays, total antibody (TAb) assays—such as TAb ELISAs—offer a broad assessment of AAV antibodies. Positive results from TAb assays may warrant further investigation using specific NAb assays, which are more selective but usually also more cost-intensive.

In this study, data from three distinct NAb assays with distinct read-outs were compared for AAV2 and AAV8. The assays include a system using AAV vectors encoding Renilla luciferase (Luc), a system employing AAV-NanoLuc® and a solution utilizing the iLite® AAV Nab platform. With each method the neutralization potential of three monoclonal antibodies, that recognize intact AAV particles, have been evaluated by determining their half-maximal effective concentration (EC_{50}) values. The EC_{50} represents the antibody concentration at which 50% of viral infectivity is neutralized, serving as a quantitative measure of neutralizing activity. Additionally, ten human serum samples were tested using the before mentioned systems. The results were qualitatively compared among the three NAb assays and further evaluated against data from a total antibody (TAb) ELISA, which detects general AAV antibody presence.

The assays exhibited variations in their evaluation methodologies, driven by the distinct technical requirements inherent to each system. Nevertheless, the resulting order of magnitude for the EC_{50} values obtained from the tested monoclonal AAV antibodies demonstrated qualitatively comparable outcomes across all three NAb assays. Similarly, the results generated for the tested human serum samples were qualitatively consistent among the three assay systems and showed strong alignment with the outcomes derived from the TAb ELISA. These findings demonstrate the overall methodological comparability of the tested systems.

762 Characterization of the Immune Landscape of the AML Bone Marrow Microenvironment by Cellular Indexing of Transcriptomes and Epitopes (CITE-Seq)

JunHyeong Kim[1], Uthpala Wijayaratna[2], Jacob Du[3], Brittany Davidson[1], Tammie Tam[1], Alexis Combes[1], Karin Gaensler[1]*

Single-cell technologies have enabled important advances in acute myeloid leukemia (AML) by characterizing the heterogeneity of tumor cell populations; however, the immunological landscape of the bone marrow microenvironment (BMME) in AML has not been as extensively explored at the single cell level. In these studies, flow cytometric and high-dimensional single-cell technologies were applied to characterize immune states in the AML BMME. Preliminary analysis of the AML BMME was initially performed using multiparametric flow cytometry of bone marrow (BM) samples from 17 AML patients at diagnosis (Dx) and following remission (Rm) induction (total 34 samples). The frequency of 11 BM resident immune cell subsets was determined. Hierarchical clustering of this data revealed 3 major patterns of immune configurations and included, 1) a group exhibiting a high frequency of monocytes and myeloid derivatives, 2) a group characterized by high frequency of plasma cells, and 3) a group composed predominantly of $CD4^+$ and $CD8^+$ T lymphocytes. These immune cell patterns remained consistent in Dx and Rm stages, indicating the conservation of certain immune profiles. To enable a more detailed mapping of the immune profiles in the BMME, single-cell level proteomic and RNA analysis was performed using Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITE-seq). This approach, combined with unsupervised clustering, enables an unbiased characterization of both individual cells and the overall immune landscape of the BMME. CITE-seq enabled us not only to move beyond traditional immune cell types, but also to identify 20 distinct transcriptomic cell states—both immune and non-immune. Among these, we observed several $CD8^+$ T cell and NK cell subtypes that have been previously associated with anti-tumor functions.

To identify the primary axis of cell composition variation, we applied principal component analysis (PCA) to uncover recurrent immune patterns in the BMME across Dx and Rm samples using CITE-seq data. Each group was

analyzed independently, and in both cases, three principal components captured a significant portion of the heterogeneity—accounting for approximately 50% of the total variation. Specifically, we observed four distinct immune patterns in the Dx samples, whereas the Rm samples appeared largely homogeneous. In both groups, the variation was primarily driven by monocytes (MO), B cells, and plasmacytoid dendritic cells (pDCs). This suggests that while the immune environment is initially heterogeneous at Dx, various chemotherapy regimens may reset the BMME to a more homogeneous state.

In light of these findings, we investigated whether the trajectory of immune composition changes between Dx and Rm could serve as a robust classifier for AML patients. Using PCA on paired biopsies, we identified four primary classes of immune compositional shifts following chemotherapy. Notably, $CD8^+$ T cell subtypes emerged as a key feature, independent of treatment type or AML subtype. These results suggest that the immune compositional shifts between Dx and Rm biopsies define distinct immune archetypes, driven by the transcriptomic profile of bone marrow-associated $CD8^+$ T cells, and may serve as an orthogonal disease classifier. We anticipate that this BMME-based classifier could enhance the prediction of disease trajectories and therapeutic responses to AML.

763 Understanding and characterizing the immune response to adeno-associated virus (AAV) in the central nervous system (CNS)

Ashley Harkins[1], Amanda Tutto[2], Katelyn Sylvia[3], Meghan Blackwood, Motahareh Arjomandnejad[4], Acadia Kopec[1], Allison Keeler-Klunk[1]
[1]UMass Chan Medical School, Worcester, MA, [2]Worcester, MA, [3]Umass Medical School, Worcester, MA, [4]UMass Chan Medical School, Worcester, Massachusetts

Evaluating immune responses to adeno-associated virus (AAV) is critical for safe and durable gene therapy. AAV is a leading viral vector for the delivery of therapeutic cargo in part because pre-clinical data has demonstrated low immunogenicity compared to other viral vectors. However, immune responses have been observed in clinical trials for AAV gene therapies including capsid-specific T cell responses that led to clearance of transduced cells. Striking differences in immune responses to AAV gene therapies from different administration routes have been observed. Intravenous (IV) delivery of Zolgensma provoked elevated liver enzymes, acute liver failure, and cardiac dysfunction, whereas intraparenchymal (IP) delivery of Upstaza elicited little to no adverse immune responses, suggesting that direct brain injections of AAV may have a safer immune profile for central nervous system (CNS) indications. The clinical data further highlighted that the mechanisms underlying the differential immune response to routes of delivery, capsid and transgene are not fully understood.

To investigate this further, we injected 6–12-week-old mice bilaterally in the thalamus (IP) or IV with either PBS, a low immunogenic capsid, AAV9, or a highly immunogenic capsid, AAVrh32.33. These capsids further delivered either an immunologically inert transgene, secreted embryonic alkaline phosphatase (SEAP), or a highly immunogenic transgene, Ovalbumin (OVA). At 2-weeks post IP injection, serum IFNγ and CXCL10 spiked in animals in the rh32.33-OVA group, indicating potential recruitment of immune cells to the brain. 6-weeks post injection, animals injected with AAVrh32.33, but not AAV9, exhibited an increase in the percentage of CD3+ T cells in the brain. Interestingly, CD4+CD25+FoxP3+ regulatory T cells were observed in the brain of all animals treated IP and not IV, indicating stimulation of an immunoprotective response. IFNγ ELISPOTs performed on splenocytes isolated at 6-weeks demonstrate capsid-specific T cells in IP-delivered rh32.33-SEAP treated animals, but not those treated with rh32.33-OVA. However, 25% of the animals in the rh32.33-OVA group reacted to the immunogenic OVA peptide, SIINFEKL. In the brain, 25% of rh32.33-SEAP animals clearly demonstrated capsid-specific T cells as measured by capsid dextramer staining. IV-injected animals in the rh32.33-SEAP group however, all had circulating capsid-specific T cells at 6-weeks post-injection. Surprisingly, all animals in the IV-injected AAV9-SEAP group also had capsid-specific T cells. Serum expression of rh32.33-OVA was higher in animals injected IP compared to animals that received rh32.33-OVA IV, where there were no detectable transgene levels, indicating that Treg recruitment to the brain may allow for transgene expression. In IP injected animals, vector genomes at 6-weeks are higher in the brain than in the liver and are similar across all capsid- and transgene-groups. IV injected animals, however, have no detectable vector genomes in the brain and low-levels in the liver.

Overall, we found an interplay of route of delivery, transgene and capsid elicited surprising T cell responses in AAV treated mice. Future work will include testing the role of Tregs in transgene expression through Treg depletion and further elucidating the mechanism of T cell recruitment to the brain for the creation of safer and more effective AAV gene therapies.

764 Elucidating the efficacy and immune response to retinal gene therapy in non-human primates using spatial transcriptomic and single-cell approaches

Celia Sourd[1]*, Joel Quinn[2], Molly John[2], Cristina Martinez-Fernandez Dela Camara[2], Moustafa Attar[3], Hoda Shamsnajafabadi[2], Ahmed Salman, Calliope Dendrou[3], Jasmina Cehajic-Kapetanovic[2], Robert MacLaren[4], Kanmin Xue

Adeno-associated viral (AAV) vector-mediated gene therapies to treat inherited retinal degenerations have gained momentum since the approval of *voretigene neparvovec* (Luxturna), a subretinally-administered AAV2 vector encoding human *RPE65*. A wide range of AAV-based gene therapies are in advanced stages of development for treating both rare and common retinal diseases. While the eye is considered relatively immune-privileged due to the blood-retinal barrier, chronic intraocular inflammation has been reported in both preclinical and clinical studies following AAV gene therapy, which has become a major clinical concern for the broader application of this treatment modality.

To better understand the primate ocular immune response to AAV gene therapy, we treated two wildtype non-human primates (NHPs) with subretinal gene therapy: NHP1 received the clinical dose of *voretigene neparvovec* (AAV2-CAG-*RPE65*) in both eyes; while NHP2 received an engineering grade AAV8 vector encoding a human codon-optimised retinitis pigmentosa GTPase regulator (*coRPGR*) transgene under the control of a photoreceptor-specific promoter (*GRK1*), alongside an equivalent vector encoding *mScarlet* reporter transgene, in separate subretinal blebs of both eyes.

Retinal structure and function were monitored for 3 months by *in vivo* retinal imaging and electroretinograms. At three months, retinal punches from treated and untreated areas were harvested for histological, spatial transcriptomic and single-cell transcriptomic analyses. The results revealed the subretinal gene therapies to be clinically well-tolerated with minimal perturbation of retinal structure and function. Robust expression of human *RPE65* and *coRGPR* transgenes were identified in the treated retina. Single-cell RNA-seq indicates that AAV8 vectors transduced ~80% of cones and rods within the bleb area, while AAV2 transduced 30% of rods and RPE cells. No correlation was found between the expression levels of the viral transgene and apoptotic marker. Single cell analysis also identified retinal infiltration by significant populations of macrophages, T cells and B cells at 3 months post-gene therapy, indicating a subclinical but prolonged type 1 cell-mediated response. Moreover, spatial transcriptomic data revealed migration of retinal microglia to the subretinal space following gene therapy. This, when combined with marked upregulation of pro-inflammatory pathway genes (including TNFα, IL1b, CXCL8, CCL2 and CCL5), implicates resident and infiltrating monocytic phagocytes as key orchestraters of retinal inflammation.

Our findings provide mechanistic understanding of clinical observations of gene therapy-associated uveitis (GTAU) and reveal molecular targets for controlling these deleterious immune responses.

765 Transient Treg Expansion Mitigates Cas9-Specific Immune Responses to Enhance Durability of AAV Gene Editing Therapy in Duchenne Muscular Dystrophy

Dongqi Liu[1], Chen Zhang[2], Di Cao[3], Shuang Li[1], Weidong Xiao[2], Moanaro Biswas[4], Roland Herzog[5], Jamie Spangler[6], Renzhi Han[1]*

Adeno-associated virus (AAV)-mediated CRISPR editing offers transformative potential for Duchenne muscular dystrophy (DMD), but immunotoxicity directed against AAV and the bacterial-derived Cas9 nuclease remains a critical barrier. To reach therapeutic efficiency, high therapeutic doses are used which could exacerbate the humoral and cytotoxic T lymphocyte (CTL) responses. Particularly, the Cas9-induced immunotoxicity leads to elimination of edited muscle fibers and promotes muscle inflammation, reducing the long-term efficacy and safety of AAV-mediated gene editing therapy for DMD. Here we explored an immunomodulatory strategy using F5111-IC, a single-chain human IL-2/antibody fusion protein, to selectively expand regulatory T cells (Tregs) while minimizing CD8+ T cell and NK cell activation—key drivers of AAV/transgene-directed immunity.

Male *mdx*^{4cv} mice were primed with four consecutive intraperitoneal doses of F5111-IC followed by intravenous administration of MyoAAV4A-CMV-SpCas9-ABE (1E+14vg/kg) one day after priming. At the time of AAV administration, F5111-IC selectively expanded peripheral blood FOXP3 CD25 Tregs to ~60% in CD4 while suppressing CD8+ and NK cell populations. This immunosuppressive state persisted for ~7 days, after which Tregs levels returned to physiological baseline at 10%. IFN-γ ELISpot analysis of splenocytes at 5 weeks post-AAV injection revealed a 54% reduction in Cas9-specific T cell responses compared to untreated AAV controls, though residual immunity remained detectable.

To further improve the regime, we include rapamycin that synergizes with IL-2 on Treg expansion and immune suppression. Treatment was extended to twice weekly for 4 weeks post-AAV administration. Preliminary data showed sustained Treg expansion and suppression of CD8+, NK, and CD19+ populations in peripheral blood. Additionally, the treatment group exhibited an 83% reduction in serum AAV-specific IgG levels compared to untreated AAV-only controls at Day 5 post-AAV treatment, highlighting its strong immune suppression potential. Our ongoing experiments are investigating whether this combinatorial regimen can yield stronger or even full suppression of Cas9-directed CTL activity, thereby improving the durability and safety of AAV-CRISPR therapy in DMD.

We expect that this study will provide critical insights into the potential of transient, targeted Treg modulation to overcome immune toxicity in AAV-mediated gene editing and to enhance long-term therapeutic outcomes in DMD.

766 AAV cross reactivity elicits a serotype specific response and complement activation in type I SMA patients post Zolgensma treatment

Tomas Baldwin[1], Ivan Doykov[2], Pierpaolo Ala[3], Nikki Cornell[4], Mariacristina Scoto[4], Giovanni Baranello[5], Haiyan Zhou[2], Francesco Muntoni, Kevin Mills[5], Wendy Heywood[6]
[1]UCL Institute of Child Health, LONDON, Greater London, United Kingdom, [2]University College London, London, United Kingdom, [3]University College London, United Kingdom, [4]Great Ormond Street Hospital, London, Greater London, United Kingdom, [5]University College London, London, Greater London, United Kingdom, [6]University College London, HAYWARDS HEATH, West Sussex, United Kingdom

Gene therapy offers lasting benefits but also faces hurdles in the form of seropositivity to AAV vectors from prior exposure. This includes generation of neutralising antibodies that can reduce efficacy and complement activation that can trigger adverse immune reactions. In this study, we have developed and applied a fully quantitative, multiplexed targeted proteomic method to measure and profile anti-AAV antibody responses and complement binding. In a pilot study of 20 spinal muscular atrophy patients who received Zolgensma, an AAV9 based gene therapy, we examined the cross-reactivity of antibody/complement responses against AAV2, AAV8, and AAV9.

When assessing antibody response longitudinally against AAV9, we observe shifts from an IgM dominant response towards a complement activating IgG1 profile from 2 months post dose. We detected cross-reactivity of IgG1, IgG2, IgG3, IgG4, IgM, and IgA1 against all three serotypes, despite no known exposure to AAV2 or AAV8. Notably, AAV8 exhibited significantly lower complement deposition than AAV9, with reduced levels of C1Qc ($p=0.0049$), C4b ($p<0.0007$), and C9 ($p=0.0012$). Additionally, immunocomplex responses were assessed in 3 patients pre-

treatment, demonstrating serotype specific evolved immune responses. In post-treatment samples, we observed a complement response to AAV2 from 0.5 months. This indicates a non-IgG associated response either driven instead by IgM through the classical pathway or with also a notable absence/reduction of C1q could indicate activation of the lectin pathway against AAV2 in AAV9 exposed individuals.

By applying a novel targeted proteomic based methodology to profile the immune complex to AAV vectors we can achieve a significant advancement in assessing a patient's immune response to AAV compared to traditional methods. We demonstrate here that not only can we determine cross-seropositivity against a range of capsids, but also determine whether these antibody responses are likely to stimulate complement deposition. This allows for a more informative, fully quantitative analysis of individual patients immunocomplex raised against varying capsids. This could potentially open the door towards a personalised medicine approach and re-dosing.

767 Classical Complement Ablation Leads to Divergent Lymphocyte Activation by Antigen Presenting Cells in Response to AAV

Robert Jimenez[1], Blake Williams[2], Alejandro Espinoza[3], Philip Farahat[4], Matteo Pellegrini[3], OLUWATAYO Ikotun[5], Armando Villalta[6], Perry Shieh[1], Melissa Spencer[1]
[1]UCLA, Los Angeles, CA, [2]UCLA, Foster City, CA, [3]University of California Los Angeles, [4]University of California, Irvine, Irvine, CA, [5]University of California, Los Angeles, Los Angeles, CA, [6]University of California Irvine, Irvine, CA

Systemically delivered adeno-associated viral vectors (AAV) activate classical and alternative complement pathways. Excessive complement activation leads to thrombotic microangiopathy (TMA). While drug interventions can dampen TMA, the split products that arise from complement activation cannot be completely eliminated. These split products act as anaphylatoxins that modulate downstream immune responses that limit the safety and efficacy of AAV-based therapies. Prior work demonstrated that dual dosing AAV in mice, with a 4-week interval, can recapitulate some immune responses observed in humans dosed with AAV such as anti-AAV antibody formation, chemokine signaling, and classical complement activation (Emami, et al, 2023). To mechanistically understand how split products of classical complement influence downstream immune responses to AAV, we used C1qa knockout mice (C1q KO) (*B6(Cg)C1qatm1d*(EUCOMM)Wtsi/TennJ) lacking the first component of classical complement. Homozygous C1q KO knockout mice and C57Bl6/J wildtype mice were given an initial dose of AAV9 empty vector to prime adaptive immunity and four weeks later administered a second dose of AAV9_CMV_mCherry (1.16 E14 vg/kg). Splenocytes were isolated from singly dosed mice after 1 and 2 weeks as well as from dual dosed mice. Splenocytes were subjected to single cell RNA sequencing. B-cell, CD4 T-cell and CD8-cell frequencies were delayed after a single dose of AAV in C1q KO mice at 1 week compared to wildtype splenocytes. However, T follicular helper cell populations increased two weeks post dosing and presented signs of enhanced activation at 2 weeks post dose and after dual dosing. C1q KO monocytes upregulated activation markers at 1- and 2-weeks post dosing. Following a second dose of AAV, the difference in cellular frequencies observed between the two genotypes previously was reduced. However, select immune activation markers persisted including those on monocytes, T follicular helpers and B cells. Chemokine protein levels were significantly elevated for Cxcl10, Ccl4, and Ccl2 in both genotypes at the 5-hour post dose 2 timepoint and were significantly elevated in C1q KO mice compared to wildtype at this same time point. Blood samples were collected from DMD patients treated with Elevidys (AAV Rh74-microdystrophin) prior to dosing and on days 4, 7, and 14 post dosing, revealing significantly elevated levels of CXCL10 and CCL2 from plasma. The chemokines detected are suggestive of macrophage activation, therefore we examined how antibodies and complement C3 influence THP-1 macrophage activation in vitro after exposure to AAV-immune complexes. These studies showed that AAV-antibody complexes increased both viral entry and activation, in an Fc receptor dependent manner, while complement C3b or iC3b did not influence uptake or activation. We tested whether increased chemokines observed in C1q KO mice was due to higher antibody levels but found equivalent anti-AAV IgG levels between genotypes. However, we observed evidence of continued complement activation in the mice, demonstrated by enhanced iC3b generation in C1q KO mice 5 hours post dose 2, suggesting activation of the alternative pathway. These results suggest that inhibition of classical complement pathway could lead to increased activation of compensatory immune mechanisms that worsen downstream immune responses. Studies are needed to determine if acute inhibition of classical complement results in similar responses.

768 AAV2 Delivery of the saCas9 Gene Results in MHC I Presentation of an HLA-A*02:01 Restricted T cell Epitope Potent to Induce T Cell Cytotoxicity.

Susana Najera[1], Annalisa Nicastri[2], Sojin Bing[3]
[1]FDA, Silver Spring, MD, [2]Oxford University, oxford, United Kingdom, [3]FDA, Silver Spring, Maryland

In vivo genome editing with CRISPR-Cas9 systems is generating worldwide attention and enthusiasm for the possible treatment of genetic disorders. However, the consequences of potential immunogenicity of the bacterial Cas9 protein and the AAV capsid have been the subject of considerable debate. Here we model the antigen presentation in cells after in vivo gene editing by in vitro transduction of a human cell line with an AAV2 vector that delivers the Staphylococcus aureus Cas9 transgene. Through HLA class I enrichment, peptide elution and highly sensitive LC-MS interrogation, we identified a highly conserved saCas9-derived T cell epitope that is restricted to HLA-A*02:01 and induces CD8+ T cell activation and killing. We conclude that AAV delivery of Cas9 protein results in presentation of a T cell epitope that can activate CD8+ cells and induces killing of the transduced cell, with important ramifications for in vivo genome editing strategies.

769 All-in-one AAV Vectors Delivering Compact *Dbp*-CasX, *Plm*-CasX, *Un1*Cas12f and *As*Cas12f Nucleases as Antiviral Gene Editing Therapeutics for the Treatment of Hepatitis B Virus

Daniel Stone[1]*, Michelle Loprieno[1], Harrison Dulin[1], Keith Jerome[1]
[1]Fred Hutchinson Cancer Center, Seattle, WA
**Corresponding Author*

In recent years much research effort has gone towards the development of curative therapies for highly prevalent but uncurable chronic infectious diseases that place a high burden on public health systems globally. Pathogens including malaria, tuberculosis, human immunodeficiency virus (HIV), herpes simplex virus (HSV) and hepatitis B virus (HBV) are now being targeted for 'cure'. To this end, we and others are developing targeted nucleases including CRISPR family nucleases as antiviral therapeutics, and we are using AAV vectors to deliver these nucleases to sites of persistent viral infection, a process made challenging by the large size of the commonly used *Sp*Cas9 nuclease. Previously we showed that administration of an HBV-targeted AAV-*Sa*Cas9 vector containing a 3345 bp *Sa*Cas9 ORF expressed from a short EFS promoter resulted in gene editing of viral genomes in chronically HBV infected liver-humanized FRG mice. However, the gene editing efficiency was low, which was likely due to low nuclease expression levels from a suboptimal AAV-*Sa*Cas9 vector in HBV infected human hepatocytes. Here we describe the development of compact all-in-one AAV vectors expressing engineered Cas family nucleases derived from *Dbp*-CasX (*Dbp*-CasX-R3), *Plm*-CasX (*Plm*-CasX-R1), *Un1*Cas12f (CasMINI_v3.1) and *As*Cas12f (en*As*Cas12f-HKRA), plus their respective sgRNAs. Compact all-in-one AAV vectors contain nuclease ORFs of 3078, 3063, 1737 and 1329 bp respectively so can accommodate increasingly larger promoters and additional regulatory elements to facilitate improved nuclease expression in human hepatocytes and subsequently HBV gene editing. Strong ubiquitous or liver-specific promoters, as well as post-transcriptional regulatory elements or microRNA binding motifs can now be accommodated to optimize nuclease expression. Compact all-in-one AAV vectors express a sgRNA from the U6 promoter containing a 3' 20-23bp protospacer that can recognize target sequences with adjacent 5'TTTR, 5'NTTR, 5'TTCN and 5'TTCN PAM sequences respectively. We generated compact all-in-one vectors expressing either *Dbp*-CasX-R3, *Plm*-CasX-R1, CasMINI_v3.1 or en*As*Cas12f-HKRA from the strong ubiquitous CBH promoter and complementary sgRNAs targeting 9 conserved HBV genome sequences within essential HBV ORFs, plus previously validated sgRNAs targeting either the human VEGF or β2-microglobulin genes as internal controls (40 total targets). CpG-motif deleted non-coding GAPDH intron 2 stuffer DNA was included in CasMINI_v3.1 and en*As*Cas12f-HKRA all-in-one vectors to create AAV vector genomes of comparable length to *Dbp*-CasX-R3 and *Plm*-CasX-R1 all-in-one vectors (4002-4631). We then tested the ability of each compact nuclease to edit a HBV genotype D genome in HEK293 and HepG2 cells. Efficient gene editing by compact nucleases was detected at HBV target sites via TIDE analysis and NGS sequencing of target site PCR amplicons at levels comparable or greater than our previously used AAV-*Sa*Cas9 vector. HBV-specific compact all-in-one AAV vectors packaged into the human hepatocyte-tropic AAV.LK03 capsid are currently being tested for their antiviral efficacy in HBV infected primary human hepatocytes and in HBV infected liver-humanized NSG-PiZ

mice. Preliminary results suggest all-in-one compact nuclease AAV vectors can be viable alternatives to previously used AAV-*Sa*Cas9 vectors as antiviral therapeutics targeting replicating and persistent HBV.

770 In Vivo Generation of CAR-T Cells for the Treatment of B-Cell Mediated Autoimmune Diseases

Chimeric antigen receptor T cell (CAR-T) therapy has demonstrated remarkable success in treating hematological malignancies [1]. Building on the achievements of anti-CD19 CAR constructs in oncology, there is increasing interest in adapting these approaches for autoimmune disorders driven by autoreactive B cells, such as rheumatoid arthritis, systemic lupus erythematosus, and multiple sclerosis, to restore immune tolerance. Notably, ex vivo–manufactured CD19 CAR-T cells have shown robust B cell depletion, inducing complete remission in patients with treatment-refractory systemic lupus erythematosus and dermatomyositis [2].

Despite these impressive outcomes, ex vivo CAR-T cell therapies face significant challenges, including the need for lymphodepletion, a complex production process, and limited control over peak CAR-T cell levels due to uncontrolled expansion of cells in vivo, which can lead to adverse events such as cytokine release syndrome [3]. To address these limitations and harness the full potential of CAR-T therapy for autoimmune diseases, we are developing an in vivo CAR-T cell engineering platform. This system employs an antibody-based ligand targeting strategy to direct lipid nanoparticles (LNPs) carrying mRNA encoding CD19 CAR to specific T cell populations in vivo, enabling controlled, transient CAR expression without the need for ex vivo manipulation or lymphodepletion. Our approach demonstrated dose-dependent mRNA delivery to resting T cells from both human and non-human primate (NHP) sources in vitro, resulting in the generation of highly functional, antigen-specific CAR-T cells. These CAR-T cells exhibited strong cytotoxic activity, antigen-induced proliferation, and effective B cell depletion in peripheral blood mononuclear cells from multiple donors. In vivo, in a $CD34^+$ humanized mouse model, single and multiple doses of targeted LNPs delivering CD19 CAR mRNA produced significant, dose-dependent B cell depletion. Additionally, the LNP platform demonstrated robust cargo mRNA expression in non-human primates, highlighting its potential for clinical translation.

In summary, our in vivo CAR-T engineering platform offers a simpler, scalable, and potentially safer alternative to traditional ex vivo CAR-T therapies, with broad therapeutic implications for treating autoimmune diseases and beyond.

771 Chemokine-Engineered CAR-T Cells for Autoimmunity: Multiplexed mRNA Technology for Improved Mode of Action and Safety

Samira Picht[1], Lisa Hemmerling[2], Antonia Klaas[3], David Simon[3], Manfred Gossen[4], Hans-Dieter Volk[5], Gerhard Krönke[3], Michael Schmueck-Henneresse[6]*, **Norman Drzeniek[7]***

Chimeric antigen receptor (CAR)-T cells have recently emerged as a potential cure for systemic autoimmune diseases [1] but their widespread application is limited by manufacturing cost, lymphodepletion and poor control over biodistribution and pharmacodynamics.
As an immune reset in autoimmunity does not appear to require long-term CAR-T engraftment, mRNA technology bears the promise for transient CAR-T cells with an improved safety and treatment controllability [2].
We aim to design such mRNA-CAR-T cells for deeper B cell depletion. We optimize mRNA delivery to human T cells and co-express mRNA-based CD19-CAR or stable CRISPR/Cas9 CAR knock-in (KI) alongside mRNA-encoded chemokine receptors for targeting lymphatic tissues (CCR7) and inflammation (CXCR3A; Figure 1A) [3].

mRNA was transcribed in vitro [4], LNPs were formulated using microfluidic mixing. Primary human T cells were activated and transfected by LNPs vs electroporation with CAR-mRNA and CCR7- or CXCR3-mRNA. For stable CAR-T cells, CAR was knocked into the T cell receptor alpha chain locus using CRISPR-Cas9 and CXCR3 mRNA was transfected 6 days later.
Transfection efficacy and cell viability, mRNA expression kinetics (flow cytometry) and changes in cytokine production (ELISA) were quantified. CAR-T cell functions were compared between migration-engineered CAR-T cells, concentional CAR-T and untreated T cells: killing of B cells, CAR-T cell migration toward target cytokines (CXCL11; CCL21), and a combination of migration and target elimination were quantified in cell-based human in vitro assays.

Both mRNA transfection methods resulted in effective transfection (>80%) and high T cell viability (>90%). In CRISPR/Cas9-engineered CAR-T cells, CAR-KI rate was >20% and cells could be re-transfected with mRNA 6 days post-KI without significant viability loss. In "mRNA-only" CAR-T cells, co-expression of CAR and chemokine receptor mRNAs could be achieved in 80% of cells upon single treatment and lasted ~3d, whereafter cells assumed their original phenotype.
Transfection with CCR7-mRNA increased receptor expression (Figure 1B) and strongly boosted the migration of (CAR-)T cells toward the CCL21 chemokine, a marker of secondary lymphoid organs (Figure 1C), while CXCR3A-mRNA increased migration toward the inflammatory mediator CXCL11 (Figure 1D).
Chemokine-engineered CAR-T cells functionally outperformed T cells transfected with "CAR only" in a combined killing and migration assay (Figure 1E).

We demonstrate mRNA-based CAR-T cells with a transient phenotype and no transfection-related toxicity. Their elimination of tissue-resident B cells may be enhanced by the co-expression of tissue-targeting chemokine receptors. Such products promise improved controllability and safety through re-dosing and a mode of action tailored to deep B cell depletion in autoimmunity.
Validation in relevant disease models and transition to GMP-compatible manufacturing are ongoing.

772 Innovative Lipid-Based Delivery Solution: Unlocking New Opportunities in Manufacturing Genetically Modified Immune Cell Therapies

Brooke Benson[1], Claire Gueguen[2], Mélodie Seiler[2], Marine Fenat[2], Priya Anandakumaran[3], Patrick Erbacher[4]
[1]Sartorius Stedim Biotech GmbH, San Diego, CA, [2]Sartorius Polyplus, Illkirch, France, [3]Sartorius, Marlborough, United Kingdom, [4]Polyplus-transfection, ILLKIRCH GRAFFENSTADEN, France

Gene-modified cell therapies, such as engineered T cells or Natural Killer (NK) cells expressing chimeric antigen receptors (CARs), are among the most promising treatments for cancer and autoimmune diseases. Traditionally, these therapies rely on lentiviral vectors to transfer the gene of interest; however, this approach is associated with lengthy manufacturing timelines, high costs, and potential safety risks. To overcome these limitations, our research focuses on lipid-based solutions as a promising alternative for producing CAR-T and CAR-NK cells.

773 Cell Targeted Lipid Nanoparticle (ctLNP)-based CAR-T Therapy: A Novel Strategy for B cell Malignancies and Autoimmune Diseases

Chimeric antigen receptor (CAR)-T cell therapy, which can be engineered to target pathogenic B cells, has demonstrated clinical success in treating B cell malignancies and is now being explored for B cell–driven autoimmune diseases. However, current genome-integrated *ex vivo* CAR-T therapies face multiple limitations, including the risk of cytokine release syndrome (CRS) and neurotoxicity, as well as complex manufacturing and high costs that restrict broader clinical implementation. Nitto has pioneered targeted lipid nanoparticle (LNP) technology (Nat Biotechnol, 2008, PMID: 18376398; Hepatology, 2022, PMID: 34605045) and developed a cell-targeted LNP (ctLNP) platform to enable the *in vivo* generation of mRNA-based CAR-T cells. Because CAR expression is driven by ctLNP-delivered mRNA, the dosing can be flexibly adjusted and repeated, allowing efficient regimens that minimize the risk of CRS while maximizing therapeutic efficacy. Furthermore, this off-the-shelf formulation shortens production timelines, lowers costs, and improves accessibility by circumventing the need for labor-intensive *ex vivo* procedures. Our ctLNPs comprise three principal components: (i) a VHH (the variable heavy domain of the heavy chain) that specifically binds CD8 T cells, for which we precisely optimized its surface density on the LNP to maximize delivery efficiency; (ii) Nitto's biodegradable lipids, formulated to support safe and

efficient *in vivo* delivery; and (iii) an mRNA payload encoding a CD19-specific CAR. To evaluate this system, we activated human peripheral blood mononuclear cells (hPBMCs) with CD3/CD28 beads and IL-2, then transfected them at varying ctLNP doses. We observed robust, dose-dependent mRNA expression in CD8 T cells, which yielded efficient CAR-T cell generation. These CAR-T cells exhibited potent cytotoxicity against primary B cells across ctLNP concentrations of 0.003–3 µg/mL. To further characterize CAR-mediated activity, we co-cultured ctLNP-transfected T cells (0.3 or 3 µg/mL) with the CD19-expressing Nalm6 leukemia cell line at effector-to-target (E:T) ratios of 1:1 to 1:9 for 72 hours. The results demonstrated clear dose-dependent target cell elimination and corresponding IFNγ production, underscoring the efficacy and specificity of this mRNA-based CAR-T platform. In *in vivo* studies, intravenous ctLNP administration (0.05–0.5 mg/kg) in humanized NSG mice (bearing hPBMCs) achieved complete B cell depletion. In a separate Nalm6 tumor model, ctLNP treatment (0.5–2 mg/kg) yielded dose-dependent tumor suppression (Fig. 1) without evident toxicity such as weight loss. Collectively, these findings demonstrate that ctLNP-based *in vivo* CAR-T therapy is a promising new modality. We are now preparing for non-human primate studies and GMP Production to advance this platform toward clinical proof of concept, ultimately broadening therapeutic options for patients with B cell malignancies or B cell–driven autoimmune disorders.

Background: Early clinical data with autologous lentiviral chimeric antigen receptor (CAR) T cell therapy in autoimmune disease (AID) has been paradigm shifting with potential to transform patient care. However, traditional

CAR-T has limitations on scalability, access, procedure complexity, and safety associated with conditioning that may limit its potential reach. SAIL is developing a targeted LNP-eRNA platform to enable *in vivo* transient programming of a patient's immune cells with an off-the-shelf IV injectable product.

In vivo CAR-T platform: SAIL's in vivo CAR-T platform is composed of three key components: (1) circular, Endless RNA™ (eRNA™) designed for enhanced stability and durable expression of CD19 CAR in T cells; (2) optimized nanoparticle (NP) compositions to maximize endosomal escape and expression of eRNA in T cells; and (3) surface functionalization of NPs with binding moieties to increase the efficiency and selectivity of T cell-targeted LNPs.

Results: Delivery of a GFP reporter-encoded payload resulted in efficient and selective expression in 60% to 80% of CD4 and CD8 T cells in blood and lymphoid tissues across C57BL/6 WT mice, hPBMC and hCD34+-humanized mice, and NHPs. *In vivo*-engineered T cells with eRNA-encoded hCD19 CAR expressed ~1,000-7,000 CAR molecules per cell; a level of expression above the threshold to effectively mediate target cell killing *in vitro*. Accordingly, single administration of SAIL's targeted LNP-eRNA at a dose as low as 0.01mg/kg led to deep depletion of naïve, memory B cells and plasmablasts in PBMC-humanized mice. In a more translational B-cell repopulating CD34-humanized model, a short cycle of injections achieved deep depletion of B cells in both blood and lymphoid tissues; the latter of which is known to be critical to achieve long-lasting immune reset in autoimmune disease (AID) patients.

Conclusion: SAIL's targeted LNP-eRNA technology platform enables *in vivo* transient programming of T cells with a superior dose efficiency profile, with the potential to replace a complex, costly, and genome-integrative cell therapy product by an off-the-shelf and non-integrative IV injectable product that does not carry the safety risks associated with lymphoablative conditioning. Plans are in place to rapidly advance a first-generation *in vivo* eRNA-encoded CAR product to human clinical studies for autoimmune diseases, such as systemic lupus erythematosus, rheumatoid arthritis, idiopathic inflammatory myositis, and systemic sclerosis.

775 Next-generation synthetic signal peptides Cell and Gene Therapies

Pamela O'Neill, SynGenSys, SHEFFIELD, South Yorkshire, United Kingdom

For secreted or cell-surface proteins, signal peptides are short sequences (15-30 amino acids) that target the nascent polypeptide into the secretory pathway. They are cleaved during co-translational translocation into the endoplasmic reticulum at specific recognition sites. Signal peptides are inherently diverse and protein-specific (~3,700 sequences/genome). Critically, at the intersection of key cellular processes – mRNA translation and protein-folding - signal peptide mediated translocation can significantly impact the rate at which proteins are transited through the secretory pathway. Importantly, signal peptides are highly context specific: alternation of a signal peptide sequence may significantly increase cellular production of one target protein whilst reducing the production of another.

In cell and gene therapy, signal peptides used often face limitations such as inefficient targeting, degradation, immunogenicity, context-dependent activity, and potential interference with cellular functions. Whilst most therapies utilise endogenous sequences, directed engineering of signal peptide sequence can substantially improve the efficiency of protein production from an introduced recombinant DNA or mRNA sequence. Moreover, relevant to the quality of the encoded therapy, correct cleavage of a signal peptide to yield the predicted protein product cannot be assured in the therapeutic context, even when using endogenous sequences.

We have developed a proprietary computational platform that integrates large-scale 'omics data with advanced feature analysis, which enables protein product-specific design and engineering of novel signal peptides. Based on in-house comparative empirical analysis of a large library of natural signal peptides, we designed novel, patentable, synthetic compositions with enhanced functionality. Our approach confers expression control, with validated peptide cleavage, and provides a flexible, efficient solution for various therapeutic needs. To exemplify application of our platform, for both Factor VIII (FVIII; Hemophilia A) and a CD19 CAR-T (B-cell malignancies), we used proprietary algorithms to curate and select libraries of 200 signal peptides in each case. Protein expression was measured in HepG2 and Jurkat T-cells, respectively, with reference to the homologous FVIII and CD28 CAR-

T/GM-CSFRα signal peptide controls. Demonstrating the effect of signal peptide sequence, across all signal peptides tested, ~10-fold range of expression was observed for FVIII and >100-fold range for CD19 CAR-T. Based on these data, key sequence features were computationally identified and utilised to derive novel synthetic signal peptides, which exhibited 2.5-fold increases in both FVIII expression in HepG2 cells and CD19 CAR-T expression in Jurkat cells. For CD19 CAR-T, signal peptide cleavage was measured by mass spectrometry. Whilst control signal peptides were correctly cleaved with 60% efficiency, synthetic signal peptides were cleaved at up to 90% efficiency.

In summary, we demonstrate that computational design can be successfully deployed to yield novel protein-specific synthetic signal peptides that can significantly improve cellular protein production and processing. For gene and cell therapies, this is a powerful tool to increase the cellular efficiency of therapeutic protein production.

776 Leveraging Immuno-STAT stimulation via TCR and IL-2 signaling to specifically control CAR T cell expansion and persistence *in vivo*

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Dana-Farber Cancer Institute, Brookline, MA, [3]Cue Biopharma, Boston, MA, [4]Dana Farber Cancer Institute, Boston, Massachusetts
**Corresponding Author*

***Introduction*:** CAR-T cell therapy (CAR-T) has remarkable success in hematologic malignancies but limited persistence remains a challenge contributing to disease relapse. IL-2 signaling through a CAR-independent circuit uniquely eradicated solid tumor models [1], but the clinical utility of non-specific cytokine CAR-T support (e.g. IL2; aldesleukin) is limited by toxicity. Immuno-STATs^{TM} are designed to activate and expand antigen-specific CD8^{+} T-cells via co-delivery of peptide/HLA-based TCR stimulation and an IL-2 mutein (*Fig. 1A*; [2]). The first clinical-stage Immuno-STAT, CUE-101, selectively activates and expands HPV-specific CD8^{+} T-cells and is associated with durable anti-tumor responses in HPV+ recurrent/metastatic head and neck cancers, with the objective response rate more than doubled in combination with pembrolizumab vs historic control of pembrolizumab alone (NCT03978689, [3]). While IL-2 signaling pathway remains a major component of T-cell persistence, combining natural TCR signaling could lead to optimal expansion and persistence of CAR-T cells. Here we report pre-clinical proof-of-concept for genetic engineering of combined exogenous-TCR co-expression plus a CAR (*E*xogenous-*T*CR; E.T. or E.T.CAR) paired with TCR and IL-2 signaling from an Immuno-STAT to enable direct regulation of E.T.CAR expansion and persistence in vivo (*Fig. 1A*).

***Methods*:** Human CD8^{+} T cells were transduced with an HPV-E.T., spiked into autologous PBMCs and cultured in the presence of increasing concentrations of CUE-101 or irrelevantly targeted Immuno-STAT. For in vivo studies, multi-cistronic viral vectors were engineered to encode E.T.CAR (TCRα/β + CAR) and nano-luciferase. HPV-E.T.CAR T-cells or irrelevantly-targeted CMV-E.T.CAR T-cells were transferred into immunocompromised mice, followed by 3 weekly-doses of CUE-101. T-cell expansion/persistence was measured by bioluminescence imaging (BLI) and flow cytometry.

***Results*:** *In vitro*, in contrast to an irrelevant-peptide/HLA Immuno-STAT, CUE-101 treatment resulted in selective and dose-dependent expansion of HPV-E.T.-transduced T-cells (enrichment from 3% to ~30% E.T.+ of CD8+ T cells; *Fig. 1B–C*). In a tumor-free (to assess CUE-101/E.T. contribution, without confounding by CAR signaling) *in vivo* model, CUE-101 treatment induced dramatic and selective expansion of HPV-E.T.CAR T-cells compared to irrelevant control CMV-E.T.CAR T-cells (>80-fold E.T.CAR+ increase at day 21 post transfer; *Fig. 2*).

***Conclusion*:** We demonstrate that Immuno-STAT treatment together with engineering co-expression of cognate exogenous TCR can specifically control the expansion and persistence of CAR-T cells. Leveraging the clinical experience with CUE-101, we anticipate future evaluation of this approach to determine whether Immuno-STAT-controlled expansion of E.T.CAR-T can enhance and control expansion/persistence of adoptive cellular therapies in patients.

777 Exploration of Allogeneic Shielding Strategies by Precise CRISPR/Cas9 Genome Engineering of Primary Human B Cells to Enable Off-the-shelf B Cell Medicines for Sustained Delivery of *in vivo* Biologics

Xuqing Zhang[1], Anja Hohmann[1], Tracy Huang[1], Wesley Wong[1], Alexis Hubaud[1], Leandra Wilson-Patrick[2], Shivani Bhawsar[2], Neva DiBlasi[2], Winnie Nguy[1], Connor Malloy[2], Shamael Dastagir[2], Sean Arlauckas[3], Adam Lazorchak[3], Hanlan Liu[1], Lea Hachigian[2], Richard Morgan[1]
[1]Be Biopharma, Cambridge, MA, [2]Be Biopharma, Cambridge, [3]Be BioPharma, Cambridge, Massachusetts

B cells can be precisely genetically engineered to produce therapeutic proteins and further differentiated into plasma cells (PCs) that secrete the target proteins (referred to as a B Cell Medicine, BCM). BCMs have the potential for longevity, capacity for high protein secretion, the ability to engraft without preconditioning and to be re-dosed[1], making them an attractive platform for the sustained supply of biologics. To expand BCM accessibility, we explored allogeneic models to test the potential of BCMs as an allogeneic therapy, and ways to enhance hypoimmunogenicity by multiplexed CRISPR/Cas9 genome engineering.

Engineered BCMs are currently being clinically evaluated as an autologous cell therapy for hemophilia B[2]. The natural hypoimmunogenicity of plasma cells has been observed in the clinic, including detection of patient-derived PCs 9-month post allogeneic bone marrow transplant[3], suggesting the potential of BCMs as an allogeneic cell therapy. Herein we first present data using both *in vitro* and *in vivo* assays to determine the potential of BCMs as an allogeneic off-the-shelf cell therapy without additional engineering. We determined changes to cell surface markers relevant to allogeneic rejection during the process of B cell to PC conversion and observed major histocompatibility complex (MHC) downregulation and modulation of other immunologically relevant molecules. We used mixed lymphocyte reactions (MLR) to compare BCM recognition and, relative to activated B cells, noted reduced CD4 (>80%) and CD8 (40-90%) T cell activation. To evaluate allogeneic resistance *in vivo*, we used immunodeficient mice that express human IL-15 (NOG/NSG-hIL15) which were further humanized with either NK or CD34 cells. Human cell chimerism was >3% for NK and > 12% for T cells and both human T and NK cells were demonstrated to be functional in the CD34 humanized mice.

We used CRISPR/Cas9-based B cell engineering to introduce potential allogeneic shielding strategies. Three categories of shielding prototypes were evaluated: 1) “Don’t-eat-me” signals; 2) MHC modulation; and 3) Immune synapse modulation. With engineering optimization, we demonstrated multiplexed gene knock-out (>85% at 3 loci)

and multiplexed transgene knock-in (up to 25% dual positive cells without selection). *In vitro* all prototypes showed complete CD4 T cell resistance and increased CD8 T cell resistance compared to unedited BCMs in the MLR assay, with the MHC modulation category facilitating the most NK resistance.

Top prototypes in each category, along with control BCMs with luciferase as a surrogate transgene, were evaluated *in vivo*. In the NOG-hIL15 NK model, the Don't-eat-me and MHC modulation categories showed complete NK resistance as demonstrated by equivalent bioluminescence with or without NK cells at week 7. Both T and NK resistance was evaluated in the hCD34-NSG-hIL15 model. All prototypes were well tolerated, and persistence was observed at week 7 for all prototypes except for the MHC knockout approach. Consistent with human clinical observations, unedited BCMs shared many of the survival advantages observed with the allo-engineered cell prototypes.

In summary, we demonstrated BCMs are immunologically stealthy and can be further engineered to evade host immune responses, opening the possibility of exploring them as off-the-shelf cellular therapies without HLA matching to serve broader patient populations.

778 A Differentiated and Durable Allogeneic T cell Strategy by Leveraging Orthogonal Cas9 Enzymes and an AAV & LNP Delivery Platform

Utsav Jetley[1], Yong Zhang[2]*, Aaron Prodeus[3], Ishina Balwani[1], Palak Sharma[3], Ian Miller[3], Allie Luther[3], Ivy Dutta[3], James Peter[3], Qingzhan Zhang[3], Biao Liu[3], Birgit Schultes[3], BO HAN[4]

Autologous chimeric antigen receptor (CAR) T cell therapies have shown great success for treating several types of hematological malignancies, but their widespread use has been hindered by several challenges, including manufacturing failures and the high cost of individualized products. This has sparked a strong desire for "off-the-shelf" allogeneic products. A key safety concern with allogeneic T cells, the risk of graft-versus-host disease (GvHD), has largely been addressed by removing the endogenous T cell receptor (TCR) using gene editing technologies. However, key challenges remain for generating persistent allogeneic T cells due to the recognition of mismatched human leukocyte antigen (HLA) alleles by host T cells or the recognition of cells lacking HLA class I (e.g., when removed via beta-2-microglobulin (*B2M)* knockout) by NK cells, both of which can lead to rejection of such allogeneic T cells by the host immune system. Other approaches involving deep or prolonged lymphodepletion of the host can improve allogeneic T cell persistence but come with an increased risk of infections. To address these challenges, we developed an allogeneic T cell strategy by leveraging a dual CRISPR/Cas9 cleavase/base editor and lipid nanoparticle (LNP) delivery platforms to perform one site-specific insertion for a targeting CAR or TCR and four knockouts, removing the endogenous TCR (via *TRAC*) to prevent GvHD, and disrupting *HLA-A*, *HLA-B*, and the class II transactivator (*CIITA*) to prevent T and NK cell rejection. Edited donor T cells did not induce GvHD in an immunocompromised mouse model over a 90-day evaluation period. Cells knocked out for *HLA-A*, *HLA-B*, and *CIITA* were protected from rejection by alloreactive T cells and NK cells when the residual HLA-C allele was matched to the hosts. The matching approach is further simplified using donors homozygous for *HLA-C*, achieving HLA matching across a broad patient population with a minimal number of donors. Using our proprietary T cell engineering process, we successfully generated allogeneic T cells incorporating four gene knockouts plus site-specific insertion of a tumor-specific TCR or CAR, with high yields and efficiency. Importantly, these allogeneic T cells had comparable functional activity to the control cells engineered without the *HLA-A*, *-B*, and *CIITA* edits in *in vitro* and *in vivo* assays, suggesting no unfavorable functional impact from these gene edits. In summary, we have successfully developed a differentiated "off-the-shelf" approach for CAR-T and TCR-T therapies, which is expected to be cost-effective to produce and durable without requiring intense lymphodepletion. This promising strategy is being applied to our cell therapy pipeline, and its implementation in other cell types is being investigated.

779 Electroporation-free delivery of CRISPR enzymes for efficient multiplex genome editing of primary human immune cells and repair of patient mutations in the rare disease hemophagocytic lymphohistiocytosis (HLH)

Srishti Sahu[1], Joseph Muldoon[2], Dror Assa[1], Alzbeta Ressnerova[3], Justin Eyquem[2], David Nguyen[2], Ross Wilson[4]
[1]Innovative Genomics Institute, Berkeley, CA, [2]UCSF, San Francisco, CA, [3]UCB, Berkeley, CA, [4]University of California Berkeley, Berkeley, CA

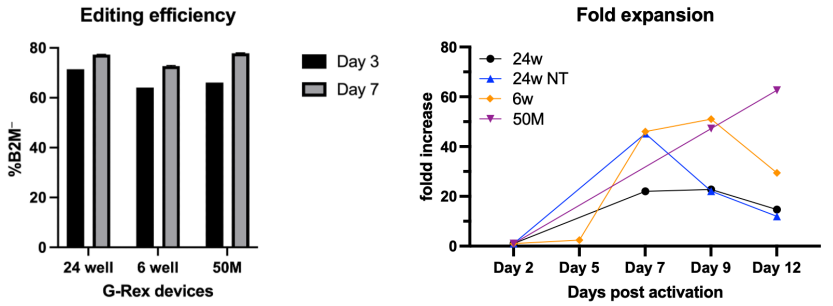
Peptide enabled ribonucleoprotein delivery of CRISPR enzymes (PERC) is a new approach for delivery of genome editing enzymes to primary human immune cells, an important cell type in the field of cell-based genetic therapies. Currently, the predominant mode of CRISPR enzyme delivery is electroporation, which has several disadvantages including reliance on dedicated hardware, incompatibility with repeat dosing, and negative impacts to cell phenotype and viability. In contrast, PERC relies on an amphiphilic peptide that is combined with CRISPR enzymes in their GMP-friendly ribonucleoprotein (RNP) format and applied on to cells in a cultured (ex vivo) setting to mediate high-efficiency editing. PERC has been shown to be compatible with Cas9 and Cas12a as well as adenine base editors and could potentially work well with any CRISPR enzyme. When paired with an AAV carrying a homology directed repair template (HDRT) DNA, PERC can produce high efficiency knock-in of desired transgenes.

Cells edited using PERC have improved viability, resulting in significantly higher edited cell yields, which can be critical in a clinical setting. PERC preserves naïve phenotype, minimally impacting the transcriptome as compared to electroporation. It does not require dedicated hardware and is gentle on cells, which allows for sequential multiplex editing, reducing the risk of chromosomal translocations. PERC is especially appealing because it is "lentivirus"-like in practice: PERC reagents are simply applied to the cells. This is in stark contrast to the cumbersome electroporation approach to CRISPR delivery that has been used out of necessity in recent years. PERC is compatible with the transformational G-Rex technology, which enables culturing and expansion of T cells with minimal handling. Cell health and editing efficiencies are well maintained as we scale from 24 well to 6 well to larger G-Rex vessels. These findings suggest a clear path towards manufacture of precisely edited CRISPR-based cell therapies, potentially involving a "closed loop" approach, requiring minimal handling while maintaining sterility and quality of manufacturable chimeric antigen receptor (CAR)-T cells.

Mutations in the gene *PRF1*, which encodes for the protein perforin, is among the leading causes for familial Hemophagocytic lymphohistiocytosis (HLH), a rare immunological disease. Gene variants may have an unknown effect on its function, and therefore on the disease. To study the effects of these variants of unknown significance (VUS), we introduce a patient mutation in healthy donor cytotoxic T cells by electroporation of CRISPR RNPs and homologous-directed repair templates (HDRTs).This leads to a reduction of perforin levels, which is associated with decreased efficiency in a target cell killing assay. Because PERC can easily be paired with other methods of delivery where repeated sequential editing would not be possible, here we utilize PERC to deliver base editors and revert the simulated patient mutation in cells that were previously electroporated.

In conclusion, we show PERC as a versatile delivery method that can be paired with G-Rex technology for multiplex genome editing and scalable manufacture of CAR-T cells. PERC can also be paired with other delivery technologies such as electroporation, and thus enable the study and correction of disease-causing mutations.

PERC can be readily scaled up in G-Rex® to edit T cells



PERC editing of primary human T cells can be readily scaled in different G-Rex® devices starting with initial cell counts of $1x10^6$ (24 well G-Rex®), $5x10^6$ (6 well G-Rex®), and $25x10^6$ cells (50M G-Rex®) resulting in efficient editing rates and ~50-fold expansion in 9 days. This technology can be applied to multiplex editing of T cells to efficiently manufacture high quality CAR-T cells with minimal handling.

780 Adapter-targeted lentiviral vectors for gene transfer *in vitro* and *in vivo*

Selective gene delivery to the desired cell type using targeted lentiviral vectors (LV) is an effective and safe strategy for immunotherapeutic applications such as chimeric antigen receptor (CAR) T cell therapy. Current CAR-T cell production processes lasts up to two weeks and include several *ex vivo* cell modification steps. By shortening the manufacturing process or directly generating CAR-T cells *in vivo*, the field aims to eliminate this laborious process while improving product quality. Furthermore, T cell subsets and phenotypes have been shown to have a significant impact on CAR T cell anti-tumor efficacy, therefore, understanding the functional differences between T cell subsets may promote shorter production processes and *in vivo* approaches.

Previously, we described the development of a modular gene delivery system called Adapter-LV, which is based on universally targeted LVs, as directed by adapter specificity. Additionally, a single chain variable fragment (scFv) specific for an artificial tag on the adapter molecule (e.g. an antibody or a fragment thereof) is fused to the viral attachment protein (H) of the LV. In general, transduction of a specific cell type expressing a certain target antigen is dependent on the concentration and specificity of tagged adapter molecules. We optimized Adapter-LV by employing engineered envelope proteins from the canine distemper virus (CDV) to overcome low viral vector yield and limited functionality targeting non-activated cells, as with the previously used measles virus (MV) pseudotype. With the CDV based Adapter-LV, the productivity is improved while the selectivity and flexibility of the system are maintained.

We successfully generated CAR-T cells with varying CD4:CD8 ratio *in vitro* and confirmed CAR-T cell function by specific lysis of tumor cells with all generated CAR-T cell products. Next, we evaluated the functionality *in vivo* by injecting a single dose of CDV-Adapter-LV into PBMC-transplanted NSG mice to generate CD8+ CAR-T cells using a CD8-specific adapter. CD8+ T cells were selectively transduced, while B cells were depleted, confirming the generation of functional CAR-T cells *in vivo*. Furthermore, we investigated adapter-mediated gene transfer to generate CD4+ CAR-T cells or a mix of CD4+ and CD8+ CAR-T cells *in vivo*. In the presence of CD4 and CD8 specific adapter molecules, CAR-T cells of both T cell subsets were successfully generated.

In conclusion, we can confirm that our improved targeted gene delivery system is suitable for both, *in vitro* and *in vivo* use, by selectively generating for example CD4+ and CD8+ CAR-T cells using the Adapter-LV platform. This system can also be used to analyze and optimize effective CD4:CD8 T cell combinations, as well as to better understand their individual and bystander importance for CAR-T cell and non-CAR-T cell therapy applications.

781 Long-acting Circular RNA CAR Drives Potent and Durable Tumor Elimination In-vivo

Kshitij Sharma[1], Ashlesha Odak[1], Rio Boothello[1], Weiyu Zhao[1], Kelvin Muriuki[1], Monica Jaffee[1], Eric Lebish[1], Shivani Gaikwad[1], Brett Rickeard[1], Aidan Simpson[2], Britt DiMarzio[1], Sanjana Manja[1], Danish Ansari[1], Akshay Mavani[3], Sarah Bening[1], Alexander Lemaire[1], Wuhbet Abraham[1], Ryan Sowell[1], JASPREET KHURANA[1], PRASHANT NAMBIAR[1], Jacob Becraft[1], Tasuku Kitada[1]*

In vivo engineered mRNA-based cell therapies can overcome many of the limitations of current stably integrated cell therapies such as Chimeric antigen receptor (CAR) T cell therapy. Broader patient access, ease of manufacture, significantly lower cost, immediate availability of drug product, ease of repeat dosing and improved safety profile with the absence of stable integration and debilitating lymphodepletion regimens are some of the key advantages of an in vivo engineered mRNA cell therapy approach. However, due to the short-lived nature of RNA expression, levels of CAR protein expression and duration must be improved to match the effectiveness observed with stable integration-based cell therapy.

We previously demonstrated the development of circular RNA (circRNA) IRES sequences that enable 10x higher levels than the current state of the art IRES and up to 25 days of CAR expression when transfected into non-activated primary human T cells. These circRNA CAR-T cells drove multiple rounds of robust repeat tumor cell killing *in vitro* over 15 days in culture. When adoptively transferred into a tumor bearing mouse the circRNA CAR-T cells effectively controlled tumor burden up to 7 days post transfer.

Building on this work, we show that our circRNAs can transfect T cells with up to 80% efficiency within the mononuclear cell (MNC) population in fresh leukopaks using lipid nanoparticle (LNP) based delivery. These transfected cells when adoptively transferred into tumor bearing mice showed complete tumor elimination, comparable to lenti-virus transduced T cells, with sustained tumor control lasting 21 days post transfer. We also demonstrate here, the ability of miRNA-based genetic circuits within circRNA to be highly effective in de-targeting expression in non-target cells while preserving expression in target cells. By integrating Strand's proprietary circuit platform for highly specific payload expression, advanced circRNA production processes, and enhancements in expression duration and levels, we are developing an in vivo engineered circRNA CAR platform for potent and long-lasting CAR therapy.

782 Development and Evaluation of Two BCMA-Targeted CAR-T Cell Products for Multiple Myeloma Treatment: A 2nd vs. 4th Generation Approach with IL-15 Production in Brazil

Larissa Zanetti[1]*, Caroline suzuki[2], Thiago Mitsugi[3], Cleyson Barros[3], Erica vidal[3], Jamile Ramos[3], Lays Trajano[3], Ingrid ferreira[3], Nelson Hamerschlak[3]*, Lucila Kerbauy[3]*

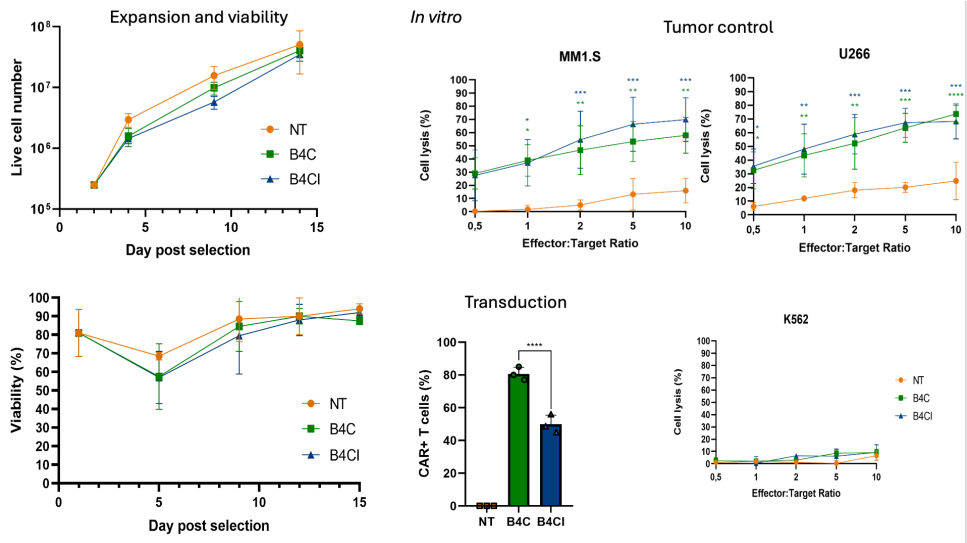
Introduction: B cell maturation antigen (BCMA)-targeted chimeric antigen receptor (CAR)-T cell therapy has emerged as a breakthrough treatment for multiple myeloma. However, disease relapse remains a significant challenge following therapy. In this context, fourth-generation CAR-T cells, which include cytokine production, have emerged as a potential strategy to enhance both tumor cell eradication and CAR-T cell persistence. In Brazil,

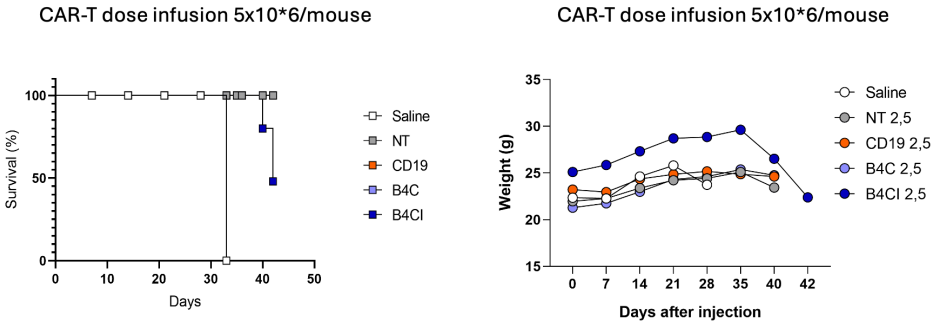
however, access to CAR-T cell therapy is constrained by prohibitively high costs and lengthy production timelines. This study aimed to develop two BCMA-targeted CAR-T cell products: a 2nd generation and a 4th generation CAR with sIL-15 production, for the treatment of multiple myeloma patients.

Methods: We developed two BCMA-targeted CAR constructs: one 2nd generation CAR (BCMA-4-1BB-CD3ζ) and one 4th generation CAR (BCMA-4-1BB-CD3ζ-IL-15). Lentiviral particles containing the CAR sequences were generated and used to transduce primary T cells. The functionality of the CAR-T cells in vitro was assessed through cytotoxicity and cytokine production assays against BCMA-positive (MM1.S, U266) and BCMA-negative (K562) cell lines. Additionally, T cell memory and exhaustion profiles were evaluated. For in vivo efficacy, luciferase-labeled BCMA+ tumor cells (MM1.S) were intravenously injected into immunodeficient mice, followed by CAR-T cell infusion. Control groups included saline, non-transduced T cells, and CD19-targeted CAR-T cells. Tumor progression was monitored through weight tracking, bioluminescence imaging, and survival analysis.

Results: Both 2nd and 4th generation BCMA-targeted CAR-T cells achieved high transduction rates (40-85% CAR+ cells) in primary T cells derived from healthy donors. In vitro assays revealed BCMA-specific cytotoxicity, with both CAR-T products effectively killing BCMA+ target cell lines (MM1.S, U266) and producing TNFα and IFNγ. No cytokine production or cytotoxicity was observed against the BCMA-negative K562 cell line. Notably, no significant increase in T cell exhaustion markers (PD-1, TIM-3, LAG-3) was observed on CAR-T cells compared to non-transduced T cells. Moreover, IL-15-producing CAR-T cells exhibited a higher proportion of memory T cell populations. In vivo, both CAR-T products exhibited strong anti-tumor activity compared to the control groups. The 4th generation CAR-T cells provided superior tumor control relative to the 2nd generation CAR-T cells. However, mice treated with the 4th generation CAR-T cells experienced significant toxicity, leading to mortality within 35 days, despite no tumor progression. In contrast, mice treated with the 2nd generation CAR-T cells remain alive to this day, demonstrating nearly 3 months of survival, while all control animals did not survive.

Conclusion: We developed two novel BCMA-targeted CAR-T cell products: a 2nd generation CAR and a 4th generation CAR with sIL-15 production. Both showed strong BCMA-specific cytotoxicity and cytokine production, with favorable memory and exhaustion profiles in vitro. In vivo, both CAR-T products controlled tumor growth, but the 4th generation demonstrated superior efficacy at the cost of significant toxicity. Further research is needed to address these toxic effects. Notably, CAR-T production and testing were completed in just 10 days, marking a key advancement in reducing production timelines and improving access to CAR-T therapy for multiple myeloma patients in Brazil.





783 Development of a Method for the Gene Editing of T-cells in a Closed Single-Use System

Lyne Khair[1], **Katie Campbell[2]**
[1]Saint-Gobain Life Sciences, Worcester, MA, [2]Saint-Gobain Life Sciences, Northborough, MA

The genetic modification of T-cells involves viral transduction for the delivery of the Chimeric Antigen Receptor (CAR), which is often inefficient. In this study, we present a method to ensure a robust T-cell transduction rate in a closed single-use system, the VueLife® cell culture bags from Saint-Gobain. VueLife® bags are highly permeable to oxygen and carbon dioxide, while being impermeable to water. VueLife® C Series bags are designed for culture and expansion of suspension cells, including T-cells. The VueLife® AC Series are composed of a treated film. This proprietary surface treatment results in the VueLife® AC bag having a higher surface energy and is intended to promote better cell and protein adhesion to the bag surface, a feature than can be leveraged for transduction applications.

VueLife® C and AC bags were used to perform the lentiviral transduction using a viral concentration of 10^9-10^{10} TU/ml and an MOI of 1, 5, 10 and 20. To identify the optimal transduction conditions, we tested different coating combinations in VueLife® C and AC bags prior to transduction. We evaluated coating with a range of RetroNectin® concentrations, both in the presence or absence of the blocking agent BSA. T-cells were incubated in the coated bags along with the GFP-labelled lentiviral vector for an additional two days. We obtained 20%, 70%, 80% and 85% GFP positive cells with an MOI of 1, 5, 10 and 20, respectively, in the presence of 20ug/cm^2 RetroNectin® for T-cells transduced in both VueLife® C and AC bags. The effect of BSA coating, in the presence or absence of RetroNectin®, did not have a significant impact on transduction rates.

Using a lentiviral vector with an MOI of 10, we found that, in the absence of RetroNectin®, the T- cell transduction rate in VueLife® C bags was 35%, while it was 50% in VueLife® AC bags, two days post-transduction. Following a ten-day expansion, transduced T-cells were collected and analyzed. The GFP levels were found to range between 60 and 70%. We also performed cell surface staining, to assess the distribution of CD4 and CD8 cells, as well as the distribution of effector, effector memory and central memory T-cells, which were the dominant population in all conditions tested. VueLife® C bags require RetroNectin® coating to achieve high transduction rates (>50%), while VueLife® AC bags can be used without coating. In summary, these results demonstrate the capabilities of the VueLife® bags series for efficient T-cell transduction.

784 Improved Genetic Engineering of Primary Human Hematopoietic Stem and Progenitor Cells Using SMAR DNA Nanovectors

Transplanting hematopoietic stem and progenitor cells (HSPCs) that have been electroporated with cytotoxic drug-resistance genes could enable robust anticancer therapy without compromising adequate hematopoiesis. Achieving sustained genetic modification in HSPCs is critical for this approach. While recombinant integrating viruses are commonly used, their propensity for random genomic integration raises concerns about insertional mutagenesis. In addition, inherent viral immunogenicity complicates clinical implementation.

To address these challenges, we developed a non-viral DNA vector platform incorporating Scaffold/Matrix-Associated Regions (S/MAR). Unlike viral or CRISPR/Cas9-based systems, these SMAR DNA nanovectors (nSMAR) remain episomal and avoid the risk of integration-mediated genomic damage. Their large cargo capacity also facilitates the delivery of complex therapeutic transgenes, making them suitable for advanced gene therapy applications. Notably, the mitotic stability of nSMAR-based constructs provides the potential to lower manufacturing costs for genetically engineered HSPCs. Here, we assessed the efficiency and longevity of reporter gene expression mediated by nSMAR constructs in the K562 cell line and in primary HSPCs. We also generated nSMAR vectors carrying a mutant human dihydrofolate reductase (hDHFR) gene to confer resistance to methotrexate (MTX). All electroporations were performed with the MaxCyte ExPERT® platform, and transfection efficiency along with cell viability were evaluated via flow cytometry.

We observed persistent reporter transgene expression in K562 and primary HSPCs. In primary HSPCs from three donors, transfection efficiencies reached up to 82% with acceptable viability (75–93%) three days post-electroporation. Cells maintained reporter expression for at least 21 days in culture. Furthermore, in K562 cells, the nSMAR vector containing double-mutant *hDHFR* effectively conferred MTX resistance. Ongoing work aims to adapt these nSMAR vectors for primary HSPC modification and to investigate engraftment potential and MTX resistance in more detail. These findings highlight nSMAR vectors as a promising strategy for stable and safe gene modification of HSPCs. This platform may serve as a powerful tool for hematopoietic cell transplantation, potentially benefiting patients with malignancies or inherited hematological disorders.

785 Epitope Editing of CD90 Protects Hematopoietic Stem Cells from Immunotherapy and Enables Targeted Enrichment for Gene Therapy

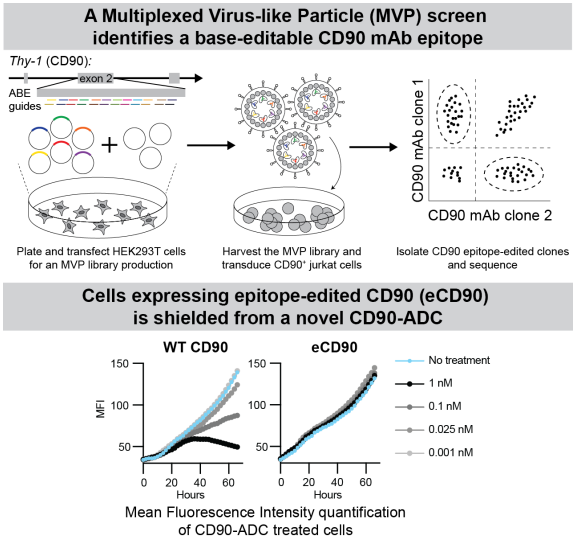
Seunga Choo[1], Stefan Radtke[2], Peter Rupert[3], Kyle Swing[1], Alvin Tong[1], Theo Humphreys[4], Anvesh Dasari[4], Roland Strong[3], Hans-Peter Kiem[2]
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, Washington, [3]Fred Hutchinson Cancer Center, [4]Fred Hutch Cancer Center, Seattle, WA

Introduction: Hematopoietic stem cell (HSC) gene therapy holds immense potential to cure blood and immune disorders. Its success and long-term efficacy depend on the treated HSCs' ability to efficiently repopulate the hematopoietic system. However, current cytotoxic conditioning regimens used to deplete host HSCs and enable engraftment of ex vivo gene-modified HSCs are associated with significant toxicities. To address this issue, non-genotoxic approaches utilizing cell type-specific antibody-drug conjugates (ADCs) have been developed to selectively target specific cell populations. Building on this concept, gene editing of epitope sites can prevent ADC binding, protecting edited cells from ADC-mediated depletion and enabling selective enrichment of desired cells to reach the therapeutic threshold. Here, we present an epitope editing strategy targeting the long-term HSC (LT-HSC) marker CD90. This approach shields edited cells from a novel CD90-ADC, allowing for selective elimination of unedited CD90-expressing LT-HSCs from the bone marrow niche and supporting improved HSC gene therapy outcome.

Methods: To identify epitopes for a CD90 monoclonal antibody (mAb), a guide RNA library targeting all adenine base-editable sites in exon 2 of the *Thy1* gene (encoding CD90) was packaged into virus-like particles containing adenine base editors. The resulting multiplexed virus-like particle (MVP) guide library was used to transduce CD90-dependent Jurkat human lymphoblastic cells. Viable clones with reduced mAb binding were isolated and sequenced to identify epitope-edited CD90 variants (eCD90). HSCs and cell lines expressing eCD90 were evaluated for proliferation, differentiation potential, and resistance to a novel CD90-ADC.

Results: The MVP screen identified an eCD90 variant with reduced binding to the CD90 mAb while retaining recognition by a different antibody, indicating preserved CD90 protein structure. Cryo-electron microscopy localized the epitope to the mAb interaction site. Human HSCs expressing eCD90 demonstrated normal engraftment, proliferation, and multilineage potential in an in vivo immunocompromised mouse model. Upon exposure to a novel CD90-ADC, eCD90-expressing cells were protected and proliferated normally, whereas wild-type CD90-expressing cells were effectively eliminated.

Conclusions: The eCD90 variant provides complete protection from a CD90-ADC without disrupting CD90 protein structure or functionality in HSC engraftment and proliferation. This approach offers a robust strategy to enrich gene-corrected LT-HSCs by removing uncorrected HSCs and creating niche space for corrected cells to engraft, ultimately enhancing the efficacy of HSC gene therapy. Further investigations are underway to assess eCD90 functionality, its long-term effects in vivo, and eCD90-mediated HSC enrichment using the CD90-ADC and chimeric antigen receptors.



786 NK cells derived from expanded cord blood HSCs provide an optimal source for allogeneic cell therapy

Ece Canan Sayitoglu[1], Everardo Hegewisch-Solloa[1], Grace Eppolito[1], **Rui Tostoes**, Miguel Maduro[1], Nina Horowitz[1]
[1]*ImmuneBridge, San Francisco, CA*

Natural Killer (NKs) cells are a promising allogeneic immunotherapy for several malignancies. Their natural anti-tumor activity is orchestrated by a diverse array of activating and inhibitory receptors, enabling potent effector function against heterogeneous tumors while maintaining a favorable safety profile. However, there have been several roadblocks in their production as cell therapies: (1) lack of scalable cell sources platforms for clinical-scale manufacturing, (2) significant donor-to-donor variability, and (3) need for robust and predictive preclinical assays to validate NK efficacy. We developed an integrated screening and manufacturing platform that leverages a proprietary small molecule, IBR403, to achieve 1E3-1E6 fold expansion of cord blood unit (CBU)-derived hematopoietic stem cells (xHSCs). This platform enables use of CBU segments, containing less than 300 µL of

blood, while leaving the 25 mL CBU cryopreserved and intact for selective manufacturing. xHSCs from segments are differentiated into NK cells (xHSC-NKs) and characterized using flow cytometry, xCELLigence, and advanced assays (e.g. serial rechallenge, organoid co-culture, and in vivo models). xHSC-NKs from optimal donors express high levels of canonical activating receptors including NKG2D and DNAM-1, and degranulate and produce inflammatory cytokines upon stimulation with target cells similarly to peripheral blood (pb) NK cells. xHSC-NKs exert cytotoxicity against diverse tumor cell lines, allowing us to identify optimal donors for downstream clinical applications. Serial rechallenge assays show NKs exhibit significant donor-derived variability in their responses to repeated tumor exposures. xHSC-NKs also eradicate 3D patient-derived cancer organoids comparably to pbNKs. Finally, xHSC-NKs acquire a mature phenotype (KIR^+CD16^+) and exhibit long-term persistence and high killing capacity after 10 weeks in vivo. Overall, xHSC-NK cells demonstrate high efficacy against tumor cells and clear therapeutic potential, with our platform enabling scalable, cost-effective manufacturing and rigorous donor prescreening to produce thousands of potent allogeneic NK doses from a single CBU - providing access to durable therapies and improving patient outcomes.

787 Enhanced Ex Vivo Expansion of Hematopoietic Stem Cells by a Novel Compound Cocktail

Javed Manesia[1], Bert Wognum[2], Wing Chang[2], Marta Walasek[3], Allen Eaves[4], Sharon Louis[3]
[1]STEMCELL Technologies, Vancouver, BC, [2]STEMCELL Technologies Inc., Vancouver, BC, [3]STEMCELL Technologies, Vancouver, [4]STEMCELL Technologies Inc, Vancouver, BC

A major challenge in utilizing hematopoietic stem cells (HSCs) for cell and gene therapies in blood and immune disorders is the loss of self-renewal and potency during in vitro culture. Developing optimized cell culture conditions that preserve and expand functional HSCs is essential to overcome this limitation. To address this, we tested the effects of more than 40 compounds either individually or in combination for their capacity to expand and maintain long-term hematopoietic stem cells during in vitro culture. We identified a novel combination of compounds (CMs) that improved the expansion and maintenance of HSCs derived from human cord blood (CB), bone marrow (BM), and mobilized peripheral blood (mPB). CB-derived CD34+ cells or CD34+CD38-CD45RA-CD90+ cells (an HSC enriched population) were cultured in StemSpan™ SFEM II, a serum-free medium containing SCF, FLT3L, TPO, IL-3, and IL-6, with or without CMs (control). After 7 days of culture, cells were counted and analyzed for expression of CD34, CD45RA, CD90, CD133, and EPCR by flow cytometry. The results demonstrate that supplementation with CMs significantly increased the frequency of CD34+ cells relative to the control (75.6% ± 10.8% vs. 59.2% ± 9.9%, respectively; n=24, $p < 0.0001$). More importantly, the HSC population, as defined by CD34+CD45RA-CD90+CD133+EPCR+ marker expression, showed significantly higher fold expansion (4.6 ± 1.92 vs 0.12 ± 0.07, n=24, $p<0.0001$) and frequency (10.5% ± 3.7% vs 0.19% ± 0.11%, n=24, $p< 0.0001$) compared to control. The effects of CMs on HSC frequency and expansion were similar in cultures initiated with mPB and BM-derived CD34+ cells. When CMs were added to cultures initiated with CD34+CD38-CD45RA-CD90+ cells, it resulted in 18-fold increase in expansion and 64-fold higher frequency of HSCs compared to cultures without CMs after 12 days of culture. Finally, to determine whether CMs preserve in vivo engraftment potential of HSCs, 2,500 uncultured CB CD34+ cells or the progeny of 2,500 CB CD34+ cells expanded for 7 days with CMs were transplanted into immunodeficient NSG mice. Bone marrow analysis at 20 weeks post-transplantation demonstrated higher levels of human leukocyte engraftment in mice transplanted with CM-expanded cells compared to those receiving uncultured CD34+ cells (19.2% ± 15.14% vs 11.23% ± 8.76%; n=8 mice/group). Together, these findings demonstrate that supplementation with this novel combination of compounds improves HSC expansion, preserves self-renewal capacity and enhances their in vivo repopulation potential. This novel approach provides a promising solution for preserving functional HSCs during in vitro culture, facilitating their application in cell and gene therapies for hematological and immune disorders.

788 Transcription Factor-Wide Screens to Identify Regulators of Tissue Resident Memory T cell States

Tomer Rotstein[1], Michael Brown[1], Sean McCutcheon[1], Charles Gersbach[1]
[1]Duke University, Durham, NC

Memory T cells exhibit distinct functional characteristics depending on their location within the body. Recent advancements have unveiled a significant population of memory T cells residing in non-lymphoid tissues. These resident memory T cells are critical for combating infections and their abundance has a positive correlation with improved survival rates across many solid tumor types. Motivated by this observation, we aimed to harness the potential of resident memory T cells for adoptive cell therapy. However, isolating these cells from donor-derived tissues is impractical. Therefore, we focused on epigenetic reprogramming of blood-derived T cells towards a tissue resident state. We conducted two cDNA overexpression screens, using open reading frames (ORFs) encoding all known transcription factors, in primary human CD8 T cells to identify genetic regulators of *CD103* (a residency marker) and *IL7R* (a memory marker). The intersection of these screens identified the transcription factor *TGIF2LX*, capable of upregulating both markers. Interestingly, this transcription factor is not expressed in human T cells. As opposed to the reported effects of TGIF family members in other cell types, we show that *TGIF2LX* overexpression potentiates the effect of TGF-b and retinoic acid signaling in T cells. Varying levels of these signaling pathways have been demonstrated to control the generation of tissue resident memory T cells in the skin, small intestine, and liver. Bulk RNA-sequencing revealed that *TGIF2LX* overexpression in T cells leads to widespread transcriptional reprogramming, including activation of genes associated with increased tissue residency programs (e.g. *ITGAE*, *CD69*, *CXCR6*) and decreases in genes associated with circulation programs (e.g. *KLF2*, *S1PR1*). We further characterized *TGIF2LX* overexpression in T cells using a multimodal single cell readout, pairing scRNA-seq with a CITE-seq library of 134 unique cell surface markers. This demonstrated a distinct cell state with *TGIFL2X*-overexpressing T cells existing in clusters unique from those containing unedited cells. Of note, these cells also clustered separately from T cells overexpressing *RUNX3*, a transcription factor previously identified to enhance tissue residency and improve tumor control, suggesting a novel axis for controlling tissue residency.

789 Targeting UPAR With Multiplexed-Engineered iPSC-Derived CAR T Cells to Reverse Age- and Insult-Related Fibrotic Disease

Sean Sherman[1], Olena Kolesnichenko[1], Mochtar Pribadi[1], Thomas Dailey[1], Hui-Yi Chu[2], Alex Garcia[3], Somayeh Pouyanfard[4], Martin Hosking[1], Tom Lee[1], Jodie Goodridge[1], Bob Valamehr[1], Eigen Peralta[1]
[1]Fate Therapeutics, Inc., San Diego, CA, [2]Fate Therapeutics, Inc, San Diego, California, [3]Fate Therapeutics, San Diego, CA, [4]UCSD, San Diego, CA

Urokinase plasminogen activator receptor (UPAR) is a component of the plasminogen system, contributing to diverse biological processes including fibrinolysis, cell adhesion, and cell migration. Increased UPAR expression has been implicated in cancer and inflammatory disease. Recent work has demonstrated that treatment with anti-UPAR CAR T cells can eliminate fibrosis and restore liver function in models of metabolic dysfunction-associated steatohepatitis (MASH). Here, we present the development of novel anti-UPAR CAR constructs, characterization of UPAR as a target in MASH and radiation induced pulmonary fibrosis (RIPF), and development of iPSC-derived CAR T cells for treatment of fibrotic diseases.

To select an optimal binder sequence for targeting UPAR in human disease, we profiled a set of candidate binders across several parameters. The UPAR protein is comprised of three domains and is highly susceptible to cleavage between domains 1 and 2. To assess the binding location of our binders, we generated target lines overexpressing either full-length or cleaved UPAR for use in cytotoxicity assays. Two of our candidate binders showed activity only against full-length UPAR, while two other binders effectively targeted both full-length and cleaved UPAR. In addition to mapping domain specificity, we generated a series of target cell lines expressing specific amounts of UPAR to compare the relative binding affinity of each of our candidate CAR binders. From these experiments we selected the two binders that recognized the post-cleavage UPAR domains, with two distinct binding affinities, for further development. To characterize UPAR expression in human disease, we analyzed patient samples of MASH, hepatocellular carcinoma-related cirrhosis, and pulmonary fibrosis, as well as normal adjacent tissue for comparison. UPAR expression was elevated in diseased tissues, with the highest expression found in fibrotic regions. Staining with cell identity markers revealed that UPAR+ cells express markers of either macrophages (CD68) or activated fibroblasts (αSMA), cell types known to drive fibrotic disease progression. Profiling UPAR across a panel of 30 normal tissues revealed consistently low levels of expression, demonstrating the potential of UPAR as a potent CAR target to treat fibrotic disease with low risk of cross-reactivity.

In addition to developing CAR T cells targeting human UPAR, we have developed a new mouse model for targeting UPAR in RIPF. In humans, RIPF is a common side effect of radiation therapy with minimal treatment options. In preclinical studies, after a single dose of radiation to the left lung, we observed significant fibrosis in the irradiated tissue within two weeks (Fig. 1). As in models of liver fibrosis, UPAR expression was upregulated in the fibrotic region following irradiation, evidence that targeting UPAR+ cells with CAR T-cell therapy will be widely applicable to a range of fibrotic diseases with few current therapeutic options. Moreover, targeting fibrotic diseases such as MASH and RIPF with iPSC-derived CAR T cells will avoid drawbacks of traditional CAR T-cell therapy including manufacturing challenges overcome by our off-the-shelf approach and the need for conditioning chemotherapy mitigated by our sword and shield technology. We are now investigating iPSC-derived anti-UPAR CAR T cells in various preclinical models, with the goal of developing an off-the-shelf CAR T-cell therapy for fibrotic disease and cancer.

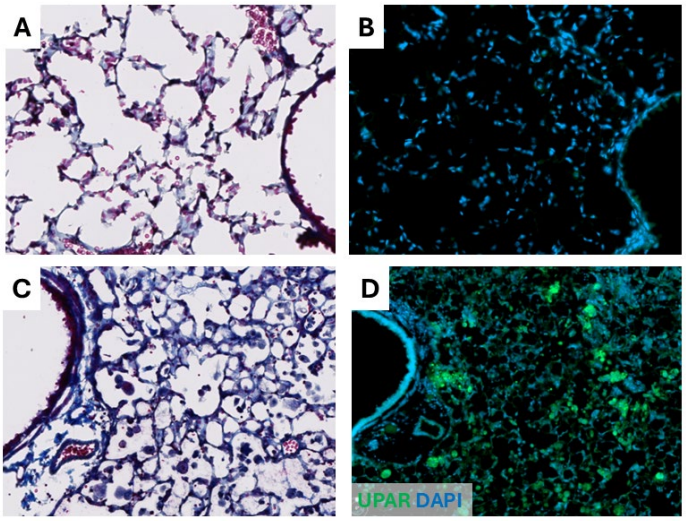


Figure 1. UPAR is upregulated in fibrotic regions in a mouse model of RIPF. Two weeks after irradiation of the left lung (90 Gy), fibrosis was observed by trichrome staining of collagen (**C**). UPAR expression was increased in the fibrotic regions of irradiated lungs (**D**) compared to naïve lung (**A, B**)

790 Role of integrins in engineered plasma cell localization and function

Nikita Trivedi[1], Nathan Camp[2], Aaron Ramonett[3], Gregory Asher[2], David Rawlings[4], Richard James[1]
[1]Seattle Children's Research Institute, Seattle, WA, [2]Seattle Children's Research Institute, [3]1. Seattle Children's Research Institute, Seattle, WA, [4]University of Washington, Seattle, WA

Introduction: Plasma Cells (PCs) play an integral role in long-term humoral protection. After antigen exposure, PCs are formed in the peripheral organs, migrate into the bone marrow (BM) and secrete large amounts of antibodies (Abs) for several decades. Due to their longevity and high secretion capacity, engineered PCs are being developed as cell-based protein-secreting therapeutics. Engraftment of PCs in the BM depends on the interactions between the donor PCs and the host BM niche. It is therefore important to assess the surface proteome of PCs to characterize potential interactions that enhance or inhibit engraftment into the BM.

Methods: Here, we employed mass spectrometry-based proteomics to define the proteins expressed on the surface of engineered PCs and undifferentiated B cells. To determine whether identified proteins were required for PC biology, we used CRISPR-Cas9-based gene editing to knock out specific proteins and studied PC functions *in vitro*. To study the *in vivo* functions of edited PCs, we utilized luciferase tracking in a murine model to determine their localization and engraftment in various immune compartments, and ELISA to quantify human Abs secretion in the murine serum. Finally, we characterized the phenotype of the engrafted PCs upon sacrifice via flow cytometry.

Results: With the surface proteomics approach, we identified several adhesion proteins that were expressed on the membrane of PCs, some of which were not found in undifferentiated B cells. We found that adhesion proteins belonging to the Integrin and SLAMF family were predominantly expressed on PCs. Specifically, PCs highly expressed integrin proteins ITGA4 and ITGB1, which form a heterodimer known as Very Late Antigen-4 (VLA-4), previously shown to be necessary for PC retention in the BM. In *in vitro* studies, upon CRISPR-Cas9 based knock out of ITGB1, we discovered that surface expression of ITGB7 is upregulated, due to pairing with ITGA4, which would otherwise be complexed with ITGB1. Assessment of the engrafted PCs demonstrated that, in contrast to published literature, neither ITGB1 nor ITGB7 are necessary for engraftment or function of PCs in the BM niche. These findings suggest that integrin proteins either play a redundant role or are dispensable for driving and retaining edited PCs into the BM niche.

Conclusions: Contrary to existing literature, VLA-4 is dispensable for migration to or retention of PCs in the BM niche. This challenges existing paradigms and requires a reevaluation of PC-BM interactions. The ITGA4 and ITGB7 heterodimer is believed to be a homing marker that drives immune cells to gut-associated mucosal sites. Future experiments will compare the differential localization of ITGA4 and ITGB7 co-expressing PCs to that of ITGA4 and ITGB1 co-expressing PCs in the BM and gut-associated lymphoid tissues.

791 SR-02, a Novel Islet Replacement Therapy for Insulin-Requiring Diabetes

William Rust[1], Rosemary Mazanet[2], Carole Welsch[3]
[1]Seraxis Inc., Germantown, MD, [2]Seraxis, Chestnut Hill, MA, [3]Seraxis Inc, Germantown, MD

Islet replacement therapy is the best option to improve long-term health outcomes for patients of type 1 diabetes (Rickels 2019). Allogeneic cadaveric islets infused to the portal hepatic circulation with concurrent immune suppression (Lantidra) and an experimental, embryonic stem cell-derived product (Zimislecel), also infused to the portal circulation with immune suppression, have both resulted in insulin independence in patients of type 1 diabetes.

Regardless of their source, pancreatic cell clusters infused to the portal vein can cause microvascular obstruction injury that stimulates a local inflammatory reaction harmful to the infused cells. This uncertainty complicates the delivery of a calculated therapeutic dose and likely reduces the potency of the cell product. Furthermore, the surviving cell clusters are dispersed throughout the liver parenchyma, making their tracking, or removal (for safety reasons) impossible.

SR-02, a novel stem-cell derived Islet replacement therapy have advantages that are described here.

- The cells were reprogrammed from mature islet tissue of a pancreas from a highly compatible, healthy organ donor. Administration of this cell product will not be limited to patients of certain ABO blood types.
- The SR-02 cells differ from pluripotent cells (including embryonic stem cells and induced pluripotent stem cells) in that they retain pancreatic character that restricts their fate potential, yielding a purer endocrine pancreatic product.
- SR-02 is administered into an omental pouch in lieu of the portal vein. This allows a precise application of a calculated dose, which can be visualized radiographically and retrieved without causing long-term complication to the patient. SR-02 is manufactured to meet 21 CFR part 210 and 211 requirements and is currently being evaluated in a phase 1/2 clinical study (NCT06651515).

A required feature of omental administration is the ability to remodel the implant site to form a niche, including microvascularization, capable of supporting a functional extra-pancreatic endocrine pancreas. Nonclinical studies have shown that the implant coordinates with host omental tissue to create a graft with structural features of a native pancreas. In particular, the bolus of implanted endocrine cell clusters become the organized endocrine cell clusters and ribbons separated by host stroma reminiscent of the distribution of islets in the pancreas. This implies coordination between host and implant to remodel the combined graft.

The retrievability of the graft without immune suppression withdrawal enables the implant of clusters to patients on immune suppression therapy due to an existing organ transplant and enables the implant of clusters that have been modified to reduce or eliminate immune-targeted rejection. SR-03, a version of the Seraxis stem cell line has also been modified and is in nonclinical development. Omental administration and elimination of de novo systemic immune suppression therapy will make islet replacement therapy widely accessible to millions of patients in need.

792 MxV Glycoproteins: A Novel Fusogen for In Vivo CAR-T Generation

Xiaojiang Fan[1], **Shuangshuang Zhang[2]**, Yantao Li[3], Qiaoyong Yi[3], Ruidong Hao[4]*, Minmin Sun[3]

Chimeric antigen receptor (CAR) T-cell therapies have revolutionized cancer treatment, yet their widespread use is hindered by complex manufacturing processes and high costs. To overcome these challenges, we developed a novel lentiviral vector pseudotyped with MxV glycoprotein (MxV-G), demonstrating promising efficacy for in vivo CAR-T generation. First, we observed that MxV-G significantly outperformed the traditional VSV-G pseudotyped vectors, achieving 2-5 fold higher viral titers, both for reporter gene construct GFP and CAR constructs. Additionally, the MxV-G pseudotyped vector exhibited superior CAR-T transduction efficiency at equivalent multiplicities of infection (MOI). We next utilized this vector, incorporating a T-cell targeting module, to generate CAR-T cells in vivo. In a MHCI/II knockout NSG mouse model bearing Nalm6-Luc tumors, intraperitoneal injection of the vector one day after peripheral blood mononuclear cell (PBMC) infusion resulted in complete tumor eradication. Notably, high levels of CAR-T cells were detected post-virus administration. To abolish natural tropism and enhance specificity of MxV-G, we designed a number of mutants with single and multiple amino acid mutation based on an AI-Driven protein model and a Large Language Model. Our results showed that a mutant with multiple AAs mutation diminished infectivity in non-T cells, while the T-cell targeting module restored comparable transduction efficiency on T cells, similar to the wild-type MxV-G vector. These findings collectively highlight mutated MxV-G as a novel fusogen for in vivo CAR-T generation, offering a potentially more efficient and cost-effective approach for CAR-T therapy.

793 ENaBL, a Novel Lentiviral Vector Platform for In Vivo Engineering of Therapeutic Anti-BCMA CAR T Cells, Shows Effective T Cell Transduction and Tumor Control in a Humanized Murine Model

Laura Galvis[1], Bastien Doix[2], Laura Weerens[3], Melissa Drappier[4], Alexia Fiévet[3], Brian Webster[4], Sylvia Pecenko[3], Alessio Cantore[5], Jishuai Zhang[6], **Philippe Parone[7]***

**Corresponding Author*

Chimeric antigen receptor (CAR) T-cell therapies have transformed treatment for B-cell malignancies, though their availability is restricted by manufacturing limitations, logistical demands, long waiting time and high cost of treatment. To address these challenges, we developed ENaBL, a nanobody-targeted, immune-shielded lentiviral vector platform for *in vivo* cell engineering. The ENaBL-T vector, specifically designed to transduce T cells, is a third-generation, self-inactivating lentiviral vector encoding a BCMA-targeted CAR under the control of a T cell-specific synthetic promoter to minimize off-target expression. The envelope of ENaBL-T is MHCI-depleted and enriched with human CD47 to reduce complement-mediated inactivation and vector phagocytosis (Milani et al., 2017 & 2019). T-cell-specific transduction is achieved through a llama-derived, membrane-anchored nanobody (VHH) targeting the TCRαβ receptor, combined with a targeting deficient VSV-G protein for envelope stability and efficient membrane fusion. *In vitro*, ENaBL-T effectively transduced both activated and resting CD4+ and CD8+ T cells from healthy donors and multiple myeloma patients. Exposure of resting T cells to ENaBL-T induced T-cell activation, expansion, and enrichment of transduced cells. In human CD34+ hematopoietic stem cell humanized

NCG mice, a single intravenous administration of ENaBL-T led to selective T-cell transduction, achieving clinically-relevant levels of circulating BCMA CAR-T cells, complete tumor clearance in a systemic multiple myeloma model, and no observed toxicity. Biodistribution of ENaBL-T transduced cells was consistent with the intravenous route of administration, with integrated vector copies detected in liver, spleen, and bone marrow, while CAR expression remained specific to human T cells, confirming the specificity of the T cell synthetic promoter. These results demonstrate that ENaBL-T can support safe and effective *in vivo* generation of functional CAR-T cells, potentially expanding patient access to cost-effective, off-the-shelf CAR-T therapies without the need for apheresis, lymphodepletion or *ex vivo* cell manufacturing. We have successfully manufactured ENaBL-T encoding a clinically validated BCMA CAR construct (referred to as ESO-T01) at clinical scale using adherent fixed bed bioreactor and first in human testing was initiated in 4Q2024 (NCT06691685).

794 A Vivo CAR T Producer (HN2301) for Autoimmune Disease Enables B cell Depletion in NHP Tissues and Performs Therapeutic Effect in an SLE Mouse Model

Tina Xiao[1], Gaofeng Zha[2], Lina Shi[2], Wanyin Fang[2]
[1]Shenzhen MagicRNA Biotech, Shenzhen, Guangdong, China, [2]Shenzhen MagicRNA Biotech, Shenzhen, China

Background: Autologous chimeric antigen receptor (CAR) T cell therapies demonstrated clinical efficacy in various autoimmune diseases through the “B cell reset”. But the challenges of CAR T therapy involved in manufacturing costs, including time and economy, expandability, risk of the integrating viral vectors, and the process of lymphodepleting chemotherapy, highlight the necessity for an “off the shelf” substitution CAR T therapeutic. To this aim, we developed an in vivo CD19 CAR T producer, HN2301. It is an engineered CD8 T cell lipid nanoparticle (EnC-LNP) encapsulated with CD19 CAR mRNA. HN2301 reprogrammed CD19 CAR T cells in vivo and depleted the B cells, inducing a “B cell reset” to cure the B cell-involved autoimmune diseases. We tested the activity of HN2301 to eradicate B cells from systemic lupus erythematosus (SLE) patients and healthy adults. Then we explored the murine cross-reactive CD19 CAR surrogate 1 (HN2301S1) in a SLE murine model to test the therapeutic effect of HN2301 on lupus and evaluated the “B cell reset” by a NHP cross-reactive CD20 CAR surrogate 2 (HN2301S2) in non-human primates (NHPs).

Methods: To test the activity of HN2301, peripheral blood mononuclear cells (PBMC) from patients with SLE and healthy control adults (HC) were treated with HN2301, and CAR T cell reprogram efficiency and B cell depletion efficiency were evaluated for the function of HN2301 invitro. Therapeutic effects were testified in a SLE murine model that utilized HN2301S1. HN2301S2 was used for the CAR T cell reprogramming, “B cell reset” verification, and safety evaluation in Cynomolgus macaques.

Results: HN2301 holds the regular morphology under an electron microscope and has almost the same characteristics as conventional LNP. The production of HN2301 is controllable and repeatable, and the scalable production of HN2301 reached 500 mg for now. HN2301 efficiently and specifically engineered the CAR T cells in vitro and eliminated the autologous B cells of the HC and SLE patients. HN2301S1 is a surrogate of human CD8 EnC-LNP that carried anti-mouse CD19 CAR mRNA, successfully reprogrammed the CAR T cells and induced “B cell reset” in CD8 humanized SLE model mice, and significantly decreased the level of anti-dsDNA antibody, ameliorating the lupus nephritis manifestations of the SLE model mice. HN2301S2 efficiently enabled the CD20 CAR T cells reprogrammed in cynomolgus macaques in a dose-dependent manner (0.05-1 mpk), inducing profound B cell depletion in peripheral blood (PB). In addition, a low dosage of 0.2 mpk*3 doses induced B cell elimination in the spleen, bone marrow, and lymph nodes of NHP. B cells recovered in PB within 10 days after the HN2301S2 administration, and the repopulated B cells were predominantly naïve (CD27-), demonstrating the “B cells reset” after the administration of HN2301. In addition, HN2301S2 demonstrated excellent safety and tolerability in NHPs.

Conclusion: The vivo CAR T producer HN2301 is a safe "off-the-shelf" product that reprogrammed the CAR T cells in vivo, eliminated the B cells quickly in different tissues, induced the “B cell reset” in NHPs, and performed excellent therapeutic efficacy on SLE mice. HN2301 holds the controllable, repeatable, and scalable production. HN2301 brings limitless potential for autoimmune diseases involved by the autoantibody produced by auto-reactive B cells and enables the autoimmune diseases patients to achieve a durable, drug-free remission.

795 Preclinical Development of UB-VV400, a Surface Engineered Lentiviral Vector for the In Vivo Generation of CD22-Directed CAR T Cells

Travis Friesen[1], Chris Nicolai[2], Nikole Perdue[1], Seungjin Shin, Timothy Gervascio[1], Alyssa Sheih, Amber Turner[3], Molly DePoy[3], Jessica Freeman[3], Alissa Brandes[4], Jeffrey Teoh, Laurie Beitz, Ryan Larson[1]
[1]Umoja BioPharma, Seattle, WA, [2]Seattle, WA, [3]Umoja Biopharma, Louisville, CO, [4]Umoja Biopharma Seattle, Washington

BACKGROUND: Autologous CD19 CAR T therapies have transformed treatment paradigms for B-cell malignancies (BCMs); however, many challenges remain that limit patient access to these therapies, including operational and logistical complexity, and high manufacturing and distribution costs. Furthermore, there is a need for alternative treatment strategies for patients who are refractory or relapse following CD19 CAR T therapy. CD22 is a B-cell specific antigen expressed on most BCMs and autoreactive B cells and is a validated target for CD22-directed CAR T products. Umoja is developing UB-VV400, an off-the-shelf, multidomain fusion (MDF) protein surface engineered lentiviral vector (VivoVec^{TM}) designed to generate fully human anti-CD22 CAR T cells *in vivo* without the need for lymphodepletion. In addition to the anti-CD22 CAR, UB-VV400 encodes the rapamycin-activated cytokine receptor (RACR^{TM}) system as part of the payload delivered to T cells. The RACR system enables rapamycin-activated enrichment and expansion of CAR T cells *in vivo* through the delivery of IL-2/IL-15-like signaling to transduced cells. Here, we describe preclinical studies demonstrating that UB-VV400 ± rapamycin is well-tolerated and generates anti-CD22 CAR T cells *in vivo* that deplete CD22-expressing B cells and tumor cells.

METHODS: UB-VV400 lots were manufactured in a clinical scale suspension process at Umoja's manufacturing facility (Louisville, CO). In vitro studies with UB-VV400 used PBMCs from healthy donors and patients with hematologic malignancies or autoimmune disease. Functional assays were performed by co-culturing UB-VV400-generated CAR T cells with target cell lines. In vivo studies were performed in PBMC-humanized NSG MHC-I/II DKO mice bearing systemic tumor and in non-tumor bearing CD34-humanized NSG mice, which contain CD22+ human B cells.

RESULTS: In vitro culture of PBMCs with UB-VV400 demonstrated MDF surface engineering mediated selective binding and activation of T cells and subsequent transduction of T cells resulting in expression of RACR and the anti-CD22 CAR. UB-VV400 generated CAR T cells mediated antigen-specific tumor cell killing and cytokine secretion in response to CD22^{hi} (Raji) and CD22^{lo} (Nalm6) cells, but not CD22-negative cells (K562, Raji-CD22^{KO}). In PBMC-humanized NSG MHC-I/II DKO mice bearing systemic tumor, UB-VV400 generated CAR T cells that mediated anti-tumor activity. In non-tumor bearing CD34-humanized NSG mice, UB-VV400 generated CAR T cells that resulted in B-cell depletion in the circulation, spleen, and bone marrow. Combination treatment of UB-VV400

with rapamycin further enriched and expanded CAR T cells *in vivo* in both humanized mouse models and corresponded with complete target cell eradication and prolonged survival in tumor-bearing mice. UB-VV400 ± rapamycin was well tolerated in both mouse models.

CONCLUSIONS: UB-VV400 demonstrated specific and efficient transduction of T cells, which corresponded with the generation of CD22-directed CAR T cells capable of killing both $CD22^{hi}$ and $CD22^{lo}$ tumor cells *in vitro* and *in vivo*. Moreover, the administration of rapamycin promoted RACR-mediated enrichment and expansion of CAR T cells *in vivo* resulting in complete tumor clearance and B-cell depletion. Overall, nonclinical studies of UB-VV400 ± rapamycin demonstrated a favorable safety profile, with no associated adverse events. These data support active, ongoing clinical studies in R/R LBCL and autoimmune disease.

796 Development of In Vivo CAR T Cell Therapy Using Nanoparticle and RNA-Based Gene Delivery Systems

Minkyeom Kim[1], Dae-Hyuk Kweon[2], Wonbeom Park[3]
[1]Sungkyunkwan University, Suwon-si, Gyeonggido, Korea, [2]Sungkyunkwan University, Suwon, Gyeonggido, South Korea, [3]Sungkyunkwan University, Suwon, Kroea, Republic of, Korea

Introduction: CAR-T cell therapy has demonstrated groundbreaking efficacy in relapsed or refractory malignant hematologic tumors, such as leukemia and lymphoma. Currently, most CAR-T cell therapies require a complex ex vivo manufacturing process, involving T cell extraction, activation, genetic modification, expansion, and purification before administration to the patient. This process is time-consuming and costly, limiting its feasibility for rapid, patient-specific treatment and broad clinical application. To overcome these challenges, an alternative strategy is to directly deliver CAR genes into immune cells, eliminating the need for ex vivo manipulation. Among various gene delivery systems, mRNA@LNP has emerged as a promising alternative due to its advantages, including ease of large-scale production, high delivery efficiency and flexibility, excellent safety. However, since LNPs can be absorbed by various cell types indiscriminately, non-specific mRNA delivery has been reported to cause significant side effects. Although antibody-mediated active targeting can address this issue, existing chemical conjugation strategies typically involve multi-step reactions, toxic reagents, and PEG detachment problems, highlighting the need for simpler and more stable alternatives.
To this end, we developed a chemical-free platform by fusing apolipoprotein A1 (ApoA1) directly to an antibody, termed “Grab Antibody” (GrAb). Due to the strong lipid-binding affinity of ApoA1, GrAb spontaneously assembles into a stable protein corona on the LNP surface, ensuring proper antibody orientation while maintaining stability. In this study, we applied the GrAb approach by fusing ApoA1 to the Fc domain of a CD3 antibody (Foralumab) or a CD5 antibody (5D7). CD3 and CD5 are highly expressed on T cells, enabling receptor-mediated delivery of mRNA to this cell population. We demonstrate that CD3- or CD5-targeted GrAb-LNPs efficiently deliver CAR mRNA to T cells, leading to a strong antitumor effect.

Results: We generated modified nucleoside-containing mRNA encoding a CAR targeting CD19 (a marker of B cells) and encapsulated it in CD3- or CD5-targeted GrAb-LNPs (hereafter referred to as aCD3LNP or aCD5LNP, collectively T-LNP) (Fig. 1A). As a proof-of-concept experiment, we incubated NBD-PE-labeled T-LNPs with freshly isolated human Peripheral Blood Mononuclear Cells (hPBMCs) in vitro. T-LNPs exhibited selective binding to lymphocytes, resulting in an increased NBD-PE fluorescence signal in this population. In contrast, LNPs without antibody coating (ConLNP) and isotype control antibody-coated LNPs (IsoLNP, non-targeting LNPs) did not show this increase (Fig. 1B). Next, we incubated T-LNPs containing modified mRNA encoding Green Fluorescent Protein (GFP) with hPBMCs in vitro. T-LNPs successfully delivered mRNA to most lymphocytes, with 50.2% of cells expressing GFP following aCD3LNP-GFP treatment and 21.9% following aCD5LNP-GFP treatment (Fig. 1C). In in vitro experiments, GFP protein expression peaked at 12 hours and declined over 24 and 48 hours. Furthermore, GFP expression increased in a dose-dependent manner (Fig. 1D, E). Finally, we generated T-LNPs encapsulating CAR-encoding modified mRNA. After co-culturing PBMCs with luciferase-expressing NALM-6 cells (a CD19-expressing cancer cell line), we delivered aCD3LNP-CAR or aCD5LNP-CAR. These LNP-generated CAR-T cells effectively eliminated CD19-expressing target cells in vitro (Fig. 1F).

797 Efficient and Effective *in Vivo* CAR T Generation Using Recombinase-Based, Precise, High-Capacity, Off-the-Shelf, LNP-Based *In Vivo* Genomic Engineering

Zhongxiao Wang[1], Samya Bhaduri[1], Ryan Tassone[1], Andrés Álvarez[1], Jack Blank[1], Christopher Geisert[1], Ozgun Kilic[1], Laura Swenson[1], Ria Guha[1], Tae-Gon Cha[1], Xiaoming Lu[1], Jason Donald[2], Srinivas Chollangi[1], Christopher Wilson[1], **Celeste Richardson[1]***
[1]Stylus Medicine, Cambridge, MA, [2]Stylus Medicine, Lexington, MA
**Corresponding Author*

Engineered cell therapies are revolutionizing medicine. However, problems of high cost and high complexity associated with *ex vivo* manufacturing are restricting access by patients and threatening the commercial viability of these life-saving therapies. *In vivo* cell engineering with off-the-shelf medicines offers the solution.

Herein, we describe an elegant, efficient, and low-cost approach to *in vivo* CAR T therapy using recombinase-mediated, site-specific genomic insertion of high-capacity payloads by non-viral, targeted lipid nanoparticle (LNP) delivery. This strategy avoids fundamental obstacles to potency, safety and accessibility including viral vector immunogenicity, random genomic insertion, payload limitations and transient expression.

CAR T cell engineering using a built-for-purpose large serine recombinase targeted to a safe harbor in the human genome was first analyzed *in vitro*. Using transfection of a mRNA-encoded recombinase and a CAR-encoding DNA donor, we observed precise, efficient, and reproducible payload integration. Cell-surface analysis of engineered T cells revealed uniform and high CAR expression - consistent with the recombinase's defined insertion profile. Functional analysis of recombinase-engineered CAR T cells *in vitro* and *in vivo* demonstrated potent anti-tumor cytotoxicity, polyfunctional cytokine production, and stable long-term CAR expression.

Recombinase-mediated *in vivo* CAR-T generation using targeted-LNP and subsequent anti-tumor activity was next evaluated in a NSG mouse model engrafted with Nalm6-luciferase tumor cells. Following transfer of human PBMCs, mice were treated with a single intravenous dose of CD3-targeted LNP co-encapsulating an mRNA-encoded recombinase and a DNA donor encoding a CD19-specific CAR (or appropriate LNP controls). Subsequent analysis of peripheral blood revealed cell surface CAR-expression (FACS) on T cells and genomic integration (ddPCR) of the CAR construct indicating successful *in vivo* CAR T generation. IVIS-based tumor analysis demonstrated potent and sustained anti-tumor responses consistent with efficient *in vivo* CAR T generation and stable long-term CAR expression.

In summary, we have developed a recombinase-based platform capable of precise, polygenic, off-the-shelf, LNP-based *in vivo* cell engineering. We demonstrate efficient and effective *in vivo* generation of CAR T cells using this approach. This work lays the foundation for genomic medicines that are differentiated, effective, safe and broadly accessible.

798 Development of a Scalable HEK293/HEK293T Suspension Cell Line Platform for Efficient Viral Vector Production

Saet Byoul Lee[1], Kate Bruening[1], Austin Anderson[1], Aishwarya Nair[1], Trent Lyman[1]
[1]Matica Biotechnology, College Station, TX

Introduction: HEK293/HEK293T cell lines are widely used in viral vector production processes. However, their tendency to form aggregates during scale-up or high-density culture poses challenges in suspension process development compared to CHO cell lines. This study presents a scalable, regulatory-compliant cell line platform for viral vector production using the MatiMax HEK293T suspension cell line. It addresses the challenges through experimental screening by DOE and statistical analysis, without any genetic modifications or engineering of the cells.

Methods: The cell line was generated through serum-free, suspension adaptation from an adherent cell line. The effects of throw diameter, agitation speed, media composition, media supplements, and different flask types were tested to identify the optimal condition for HEK293T suspension cell line. The effects of different throw diameters for agitation were evaluated and compared in terms of P/V ratio. Cell density, viability, cell size distribution, cell aggregates, and cell cluster formation were assessed using an automatic cell counter (Vi-cell, Nucleocounter), flow cytometry, and microscopy. Productivity was evaluated through the lentiviral vector production process.

Results: Agitation conditions were found to play a critical role in HEK293T cell aggregate formation and aggregate size during culture in Erlenmeyer flasks. The experimental results demonstrate that conditions which reduced the aggregate formation and allow only smaller-sized aggregates not only enhanced viability but also led to more stable and robust process data. Approaches involving supplementation or physical modifications, such as changes in flask type, were effective in reducing aggregate formation. However, due to potential risks on productivity and viability, these conditions were not incorporated into the final setup.

Conclusions: This study presents a cell line platform that can be used to develop processes for viral vector production, which is essential for gene therapy product manufacturing. We successfully identified the optimal high-density culture conditions for cell expansion in Erlenmeyer flasks that minimize aggregate formation. This platform not only provides valuable insights into overcoming challenges associated with HEK293T cell culture in viral vector production but also offers potential as a host cell line for advanced technologies, such as stable packaging cell lines or stable producer cell lines.

799 Breaking the Bottleneck in Lentiviral Production: Achieving Ultra-Low Infectivity-to-Particle Ratios and Cost Efficiency for Transformative Gene Therapies

Pouria Motevalian[1], Uma Lakshmipathy[2], Clifford Froelich[3], Ritika Garg[1], Yasmin Hajimirza[1], Brandon Tse[4], Sergio Ita[5], Amy Correia[1]
[1]Thermo Fisher Scientific, Plainville, MA, [2]Thermo Fisher Scientific, San Diego, CA, [3]ThermoFisher Scientific, Plainville, MA, [4]ThermoFisher Scientific, Milford, MA, [5]Thermo Fisher Scientific, Plainville

Lentiviral vectors (LV) are increasingly favored for both *in vivo* and *ex vivo* gene therapy due to their distinct advantages over other viral vectors such as adeno-associated virus (AAV). These advantages include a larger genetic cargo capacity, efficient transduction of both dividing and non-dividing cells, stable integration into the host genome for long-term expression, and relatively low immunogenicity. As a result, lentiviruses have emerged as a powerful platform for delivering therapeutic genes across various clinical applications.

We employed a Design of Experiments (DoE) approach, integrated with advanced high-throughput process technologies and state-of-the-art analytical characterization tools, to optimize the upstream production of lentiviral vectors. This multi-pronged strategy enabled us to systematically assess critical process parameters and refine manufacturing conditions for enhanced LV yield and quality.

In this work, we present an optimized approach to produce LV encoding the CD19 gene of interest, benchmarked against a green fluorescent protein (GFP) control. Our process achieved high upstream LV titers while consistently maintaining an infectivity-to-particle ratio below 1:1000. Moreover, we observed a notable reduction in manufacturing costs without compromising infectivity, highlighting the potential of this platform to streamline LV production for both clinical and research applications. This optimized approach for producing lentiviral vectors encoding the CD19 gene of interest demonstrates a key advance in establishing robust, scalable, and cost-effective manufacturing processes. By consistently achieving high upstream LV titers with infectivity-to-particle ratios below 1:1000, our method addresses one of the critical barriers in lentiviral vector production—ensuring product potency while controlling costs. These findings underscore the promise of this platform for accelerating clinical and research applications, and the potential to extend these optimization strategies to other gene targets and therapeutic indications.

800 Systematic Assessment and Scalable Bioreactor Process Development of Lentiviral and Gamma-Retroviral Vectors for CAR-T and TIL Therapies

Cathy Wang[1], Subhashini Ramgopal[2], Forrest Kan[2], Margie Harris[1], Feroza Iffat[1], Priya Balasubramanian[1]
[1]CTMC, Houston, TX, [2]CTMC, Houston

Genetically modified immune cell therapies such as CAR-T and TIL have shown great promise in treatment of hematological and solid tumors. Lentiviral vectors (LVV) and gamma-retroviral vectors (RVV) are mainstay platforms for genetic modification in CAR-T and TIL manufacturing processes, however, cost and timeline associated with viral vector manufacturing often presents a significant hurdle to new therapies during early and late stages of development.

CTMC, a joint venture between National Resilience and MD Anderson Cancer Center, is uniquely positioned to address the unmet need of viral vector supply chain in CAR-T and TIL product development. CTMC has taken the two-pronged approach of 1) from a technical perspective, identifying and prioritizing the development of viral vector platforms most suitable for CAR-T and TIL processes with the greatest benefit in cost and scalability dependent on the phase of clinical development; and 2) from an organizational perspective, reducing white space in the product development timeline through robust platform building and vertical integration of development activities.

Here we present a systematic assessment of LVV and RVV performance attributes in T cell processes, and evaluation of RVV manufacturing in multiple bioreactor platforms. Using in-house representative constructs, we generate like-for-like LVV and RVV with multiple envelopes and compare them in T cell transduction. Vector- and envelope-specific differences are observed in transduction efficiency and expression pattern, highlighting differences in performance attributes and informing selection of suitable vector system for specific applications. Furthermore, we evaluate a stable cell line-based RVV process in manual and bioreactor production platforms including hollow fiber and fixed-bed bioreactors and show that such a process is highly scalable with maintenance of productivity over multiple harvests. We compare attributes of different bioreactor platforms tested and show that a manual RVV process can readily transition to a suitable bioreactor platform with comparable or superior unit and total batch yield. Bioreactor platforms drastically reduce hands-on time and operational complexity, enabling the scaling of stable cell line-based RVV processes through product development stages. Through this work, we aim to reduce the viral vector supply chain bottleneck, accelerate development timeline, and expand accessibility of innovative cell therapies.

801 From bench to dose: building a robust and scalable cGMP manufacturing process for non-replicative Herpes Simplex Virus 1 (nrHSV-1) vector as a powerful gene therapy platform

Michela Gentile, ReiThera, Rome, Italy

Viral vectors have become one of the leading delivery systems for genetic medicine in humans. The specific combination of their key properties offers several advantages tailored to a broad spectrum of gene therapies for both acute and chronic diseases (K. Lundstrom, 2023). nrHSV-1 vectors are attractive for gene therapy mainly due to the large HSV genome (152 kb) which can accommodate therapeutic transgenes larger than 30 kb in size. Moreover, they are particularly useful in nervous system (NS) gene therapy applications due to their innate neural tropism and ability to establish latent infections with prolonged transgene expression (D. R. Knop and H. Harrel, 2007). Many of these indications address large patient populations necessitating efficient, large-scale production to reach scale and lower COGS per dose. Thus, developing a highly productive, scalable and completely closed production process represents a critical requirement to manufacture the vector under cGMP conditions to cover the clinical demands. This study describes the development of a fully scalable production process for a nrHSV-1 viral vector using the Fixed-bed Scale-X technology from the bench up to the Scale X Carbo 30 m^2, using a derivative clone from an adherent Vero cell line. The upstream and downstream process parameters were initially investigated by small-scale studies using a Cell Stack system, then the optimal parameters were adapted and transferred to the Scale-X Hydro

2.4m^2. A number of optimization runs were executed to increase productivity and maximize the yield and clearance of the final process. By infecting the cells at a density of >1.2E+05 cell/cm^2, a productivity comparable to the values obtained in Cell Stack systems was achieved. In terms of downstream, the release of the virus from infected cells was coupled to an endonuclease digestion in recirculation mode inside the bioreactor, ensuring an efficient system to recover the intracellular virus, while reducing the host cell DNA released from the cells. Furthermore, a 0.45 µm clarification step was introduced to reduce cell debris and aggregated impurities, while the TFF with hollow fiber was carried out to formulate the final DS. Our modular purification platform ensured optimal overall yield (≥50% in terms of PFU/mL) and good impurities clearance (up to 785-fold HCP reduction and HCDNA amount ≤10 ng/dose) in final product. To prove the full scalability of the process, additional runs were executed on both Scale-X Carbo 10m^2 and Carbo 30m^2 bioreactors, as demonstration and engineering runs respectively, to mimic the final process implemented during GMP manufacturing. The process parameters were linearly scaled-up based on the higher fixed bed surface, while the same seeding and infection cell densities were applied. Although a higher fixed bed scale was used, both vector-specific productivity (pfu/cm^2) and process yield (~ 50%) were achieved. The manufacturing of the clinical lot was successfully executed, proving the development of a robust and scalable platform fulfilling clinical dose expectations and satisfying regulatory requirements for the release of the drug product.

802 Implementation of an Institutional Gene Therapy Safety Committee at the University of Utah

Julie Porter[1], Sarah Moldt[2], Brian Shayota[2], Russell Butterfield[2]
[1]University of Utah Salt Lake City, UT, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT

Gene therapy has rapidly expanded with hundreds of active clinical trials and 14 FDA-approved non-oncologic therapies. Safety events, including death, are a significant consideration with gene therapy products and without proper prevention and management can limit their use and benefit. Management of systemically delivered AAV gene therapies, including management of adverse events, crosses established medical disciplines. Many of these adverse events are immunologically mediated and a better understanding of immunology, the effects on various organ systems, and appropriate interventions is critical for providers administering gene therapy. Thus, a multidisciplinary framework is needed to review, monitor, and mitigate risks associated with gene therapy treatments.

At the University of Utah, we recently initiated an institutional Gene Therapy Safety Committee (GTSC) to (1) build a base of knowledge and experience among providers regarding care for patients and research subjects receiving gene therapy, (2) create an established forum for individuals to discuss gene therapy, including in-depth review of adverse events , and (3) develop a set of institutional guidelines and practices for implementation of systemically delivered gene therapies including standards for pre-treatment evaluation, treatment, and post-treatment surveillance and management. The GTSC integrates expertise from diverse medical specialties including Neurology, Genetics, Gastroenterology/ Hepatology, Nephrology, Hematology/ Oncology, Cardiology, Dermatology, and Ophthalmology. Clinical research coordinators and nurses are invited to participate, ensuring a comprehensive evaluation of complex patient cases. The GTSC meets bi-monthly to discuss internal cases as well as those from the literature. Previous and planned meeting topics typically relate to a particular adverse event type, such as acute liver injury, thrombotic microangiopathy, or acute cardiac injury; or management strategies such as immune modulation beyond steroids. Additional resources of include a listserv, which members can use to ask questions or get advice outside of regular meetings, and a literature archive containing relevant articles relating to gene therapy safety. The GTSC is also available to help review potential clinical trial opportunities as our institutional confidentiality agreements allow. Early outcomes demonstrate the GTSC's effectiveness in reducing adverse event severity, improving interdisciplinary communication, and enhancing the ethical and scientific rigor of gene therapy treatment. We likewise anticipate that further development of the Gene Therapy Safety Committee will allow for expanded implementation of both FDA- approved and clinical trial gene therapies as physicians and primary investigators feel more empowered and supported in managing potential safety concerns, ultimately leading to more opportunities for patients.

803 Case Study: Resilience's SnapLVV™ Program from Bench Scale to GMP (USP Process and Lessons Learned)

Nicole Nohilly[1], Kevin Keating[2], Catherine Siglin[3], Yvette Valenzuela[4]
[1]Resilience, Inc., Allston, MA, [2]Resilience, Boston, [3]Resilience, Boston, MA, [4]Resilience, Watertown, MA

Lentiviral vector production is a highly sensitive gene delivery system. The execution of bench-scale bioreactors, scale-up runs, and the technology transfer for GMP manufacturing of a 4-plasmid transient transfection system can be difficult without proper procedures and templates in place. This case study exemplifies the lentiviral vector platform process performance from 2L to 50L, while also including the at-scale technology transfer to a GMP manufacturing facility. In six months, we utilized scale-up methods and templates for all process parameters, including but not limited to, gassing strategy, agitation, PID tuning, media warming procedure, and cell counting. Executing the process at a smaller scale allows for identifying potential issues before the commitment to large-scale manufacturing. With the benefit of lesser consumption of process material, there is also faster process optimization, and higher confidence in at-scale operations, all while maintaining viral vector yield and titer. Following successful process evaluation, an at-scale demonstration run was executed while the technology transfer was ongoing between the development team and the manufacturing counterparts. The result was the maintenance or increase in the recovery yield across scales. We will highlight lessons learned from this program, upstream processes, execution, and templates from thaw to harvest.

804 Development of Cell-Based Functional Assays to Predict CAR-T Potency and Persistence

David Draper[1], Evan Massi[2], Yelena Bronevetsky[2], Garcia Candy[2], Long Le[2], Hadia Lemar[2], Shannon Eaker, James Lim[2]
[1]Labcorp Drug Development, Ann Arbor, MI, [2]Xcellbio, San Francisco, CA

Introduction: Cytokine secretion assays are routinely deployed to predict the effectiveness of adoptive cell therapy products. Cytokine secretion occurs when effector cells bind to target tumor cells, with secreted factors such as IFNg, TNFa, and IL-2 assessed to determine the 'potency' of manufactured CAR-T cells. However, secretion assays lack direct functional information on the status of the target cell (cytolysis, viability), relying solely on the activation of status of the effector cells to determine its effectiveness. Furthermore, secretion assays are limited in their ability to predict the 'persistence' of the adoptive cell therapy product, a critical factor for determining long-term in vivo effectiveness in patients. To overcome these limitations, we have developed a set of functional and phenotypic assays that can be deployed in all phases of development to accurately predict the potency and persistence of both autologous and allogenic adoptive cell therapy products.

Methods: Utilizing the AVATAR platform (Xcellbio), effector and target cell populations (CD19 CAR-T, Nalm6) were screened under hypoxic and hyperbaric culture conditions to mimic the in vivo tumor microenvironment. Oxygen and pressure levels of 1% O2 and 2.0 PSI were used for screening conditions, along with effector to target ratios (E:T) that ranged from 1:4 to 1:32. Serial tumor-restimulation was performed up to 5 challenges to measure the persistent killing capacity of CD19 CAR-T cells. Functional assays were paired with immunophenotyping to determine populations of central memory (CD45RA-CCR7+), effector memory (CD45RA-CCR7-), naïve/stem cell memory (CD45RA+CCR7+) and terminally differentiated effector memory cells (CD45RA+CCR7-).

Results: CD19 CAR-T cells manufactured with the AVATAR platform exhibited improved tumor killing potency compared to conventionally manufactured cells (CO2 incubator, control), particularly at E:T ratios below 1:4. AVATAR expanded CD19 CAR-T cells also maintained high levels of killing at fourth and fifth tumor challenges, whereas conventionally expanded cells exhibited consecutive 50% decreases in tumor killing capacity across the same set of tumor challenges. Further analysis of the AVATAR expanded CD19 CAR-T cells showed two-fold higher percentages of naïve/stem cell memory and terminally differentiated effector memory cells, whereas both central memory and effector memory were decreased when compared to conventionally manufactured cells.

Conclusions: In this study, we have shown that cell-based functional assays can be used to measure the killing persistence of an adoptive cell therapy product and can be complemented by immunophenotyping efforts to improve manufacturing strategies to produce cell therapies with long-term persistence in patients.

805 Point of Care Automated Manufacturing Enables Rapid Translation of Both Novel TCR-T Cell Therapies as well as Conventional CAR T Cell Therapies into the Clinic

Isabella Ogusuku[1], Johannes Wellershoff[2], Eva Argiro[2], Vera Herbel[3], Caroline Brandes[4], Sabrina Veld[2], Lois Hageman[2], Marieke Griffioen[2], Rosa de Groot[2], Mirjam Heemskerk[2], Dominik Lock[5], **Ian Johnston[5]**
[1]Miltenyi Biotec BV & Co KG, Köln, Nordrhein-Westfalen, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Miltenyi Biotec BV & Co KG, GERMANY, [4]Bergisch-Gladbach, Germany, [5]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Nordrhein-Westfalen, Germany

Although cell and gene therapies are showing impressive efficacy, a number of serious barriers to widespread patient access remain, including manufacturing logistics, manufacturing upscaling and the cost of the therapies themselves. One possible solution to reduce costs and improve patient access is to manufacture using a local point of care (PoC) model.

Using closed, GMP-compliant, automated manufacturing systems, it is possible to standardize ATMP manufacturing procedures to greatly accelerate and simplify the translation of novel therapies into the clinic. To illustrate this, 2 different manufacturing protocols for generating TCR-modified T cells were established on the CliniMACS Prodigy® at a PoC clinical manufacturing site in the Netherlands. The first of these was a T cell Transduction large-scale (TCT-LS) 8-day protocol to generate T cells modified with a lentiviral vector encoding an HLA-A*02:01 restricted recombinant ΔNPM1 neoantigen-specific TCR to be used in a clinical trial targeting relapsed or refractory AML. The second was a standard scale (TCT) 6-day shortened protocol to enable expression of an HLA-B*07:02 restricted recombinant BOB1-specific TCR, which will be used in a trial for treatment of relapsed or refractory B-cell malignancies. BOB1 is a B-cell lineage-specific transcription coactivator shown in studies to be essential for survival of certain B cell malignancies and therefore provides an attractive novel target.

Method transfer and process establishment was simplified due to a high level of automation. During process validation runs using healthy donor material, a suitable yield of TCR-modified CD8+ T cells for clinical application was reached: 5.6E9 ± 1E9 ΔNPM1.TCR+ CD8+ T cells (n=4) and 9.4E8 ± 3.1E8 BOB1.TCR+CD8+ T cells (n=3). As all processes are performed at the clinical site and a fresh product is infused into the patient, a short vein-to-vein time is readily achievable. The ΔNPM1-TCR trial is currently recruiting patients in the Netherlands (NCT06424340) while the BOB1-TCR trial is in preparation.

A complementary strategy will be discussed which is focused less on novel therapies but on more established approaches using CAR T cells. A concept has recently been implemented to supply “blueprints” for manufacturing and quality control along with GMP-quality reagents, consumables, GMP lentiviral vector encoding a selection of clinically-relevant CAR constructs as well as regulatory documentation packages to academic clinical centers. This approach has enabled rapid establishment of PoC manufacturing either for early-phase CAR T cell clinical trials or for treatment of patients under hospital exemption. First clinical results have been reported by investigators in several countries including India and Thailand. These examples demonstrate how the use of functionally-closed, automated technologies along with robust manufacturing and quality control procedures can greatly simplify the establishment of manufacturing ATMPs in a PoC setting. It has the potential to foster innovation, improve patient access to life-saving therapies in areas where treatment is not available while giving the treating physician more control of the patient treatment and therapeutic scheduling.

806 Expansion and Characterization of Natural Killer Cells in a Closed Single-Use System

Lyne Khair[1], Katie Campbell[2]
[1]Saint-Gobain Life Sciences, Worcester, MA, [2]Saint-Gobain Life Sciences, Northborough, MA

Nature Killer (NK) cells are innate immune cells that belong to the same family as T and B cells. They account for 5-10% of peripheral blood mononuclear cells (PBMCs). Their role is to control tumor growth as well as microbial infections. NK cells are cytotoxic and do not require prior antigen exposure to mediate their anti-tumor effects, making them a cell of choice for both autologous and allogeneic immunotherapies. NK cell therapies require a large number of cells per infusion (10^7-10^8 cells). The establishment of a robust, reproducible protocol for *in vitro* expansion of NK cells from PBMCs, without the need for feeder cells or serum supplementation, will have significant implications for the number of cancer patients who will potentially benefit from this therapeutic option.

In this study, we present a method to ensure robust NK cell expansion in a closed single-use system, the VueLife® cell culture bags from Saint-Gobain. VueLife® bags are highly permeable to oxygen and carbon dioxide, while being impermeable to water. VueLife® C Series bags are designed for culture and expansion of suspension cells, including NK cells. Cells were cultured in serum-containing and serum-free media, following isolation from PBMCs. There were no significant differences between the two growth conditions in terms of fold increase over a 14-day expansion (70-80-fold). However, cells expanded in serum-free conditions had a lower overall viability (75% vs. 90% for serum-containing media). In addition to expansion from freshly isolated cells, we also performed a successful NK cell expansion from a cryopreserved stock, with similar fold increase and viability to cells freshly isolated from PBMCs.

Finally, we performed an extensive flow cytometry analysis of cell surface markers. In all examined conditions, cytotoxic NK cells were expanded ($CD56^{bright}$ $CD16^{+}$). The activation marker NKG2D was consistently expressed, with the largest population recorded in the frozen NK cells. Exhaustion markers (PD-1 and TIGIT) remained at low levels in all conditions. Functional markers Granzyme B and Perforin showed the highest level of variability, with the largest population recorded in the NK cells expanded from the cryopreserved stocks. Using the current protocol for a 14-day expansion, this set of experiments show that VueLife C bags can support the ex-vivo expansion of functional NK cells with little to no effect on their viability and exhaustion markers.

807 G-Rex (Gas Permeable Rapid Expansion) Technology used for T regulatory Cell Culture

Dana Margittai[1], Tsutomu Ikeda[1], James Dinh[1], Gabriella Zucchiatti[2], Feleke Takele[1], Yong Bin Kim[3], Alexander Anneling[1], Guangwen Wang[1], Everett Meyer[4]
[1]Stanford Medicine, Laboratory for Cell and Gene Medicine, Palo Alto, CA, [2]Stanford Laboratory for Cell and Gene Medicine, Palo Alto, CA, [3]Stanford University, Chemical Engineering, Palo Alto, CA, [4]Stanford Medicine, Blood and Marrow Transplantation and Cell Therapy, Palo Alto, CA

Introduction: Finding robust methods to culture T regulatory (Treg) cells can be challenging when looking to develop a clinical scale cell and gene therapy process. Examples of popular methods used for GMP manufacturing are T-Flasks, gas permeable culture bags, and WAVE bioreactors. These methods allow for gas exchange and nutrients via diffusion. The G-Rex unit tested in our studies shows that the technology of nutrient and gas exchange via convection with the G-Rex technology produces similar or higher expansion fold for Treg cells compared with conventional methods mentioned above.

Methods: In our study, we tested seeding densities ranging from 0.5 x 10^6 – 4 x 10^6 cells /cm^2 with Treg cells across 4 donors. The G-Rex 24 well units were used where each well is 2cm^2. Cells were cultured for 5 days with X-VIVO™ 15 Chemically Defined Medium with gentamicin supplemented with 10% heat inactivated Human male AB serum and 10% L-glutamine, 10% Sodium Pyruvate and 10% non-essential amino acids (NEAA) in the presence of recombinant human IL-2 (500 IU/ml), and stimulated using Dynabeads® Human T-Activator CD3/CD28 at 1:1 Cell:Bead ratio. Cell counts were completed/performed with Nexcelom's Cellometer Auto 2000.

***Results*:** Culture seeded at 0.5 x 10^6 cells /cm^2 had fold expansion of 1.79 with cell viability dropping from 94.6% to 88.6%. Cultures seeded at 1.0 x 10^6 cells /cm^2 had fold expansion ranging from 2.63 to 7.9 while maintaining viability between 93.5% to 98%. Cultures seeded at 2.0 x 10^6 cells /cm^2 had fold expansion ranging from 2.6 to 6.3 while maintaining viability from 93.9% to 95%. Cultures seeded at 4.0 x 10^6 cells /cm^2 had fold expansion of 3.78

while maintaining viability at 92%. When comparing to tissue culture plastic, fold expansion of Tregs is similar ranging from 2.47 to 3.47 with viability ranging from 93.2% to 94.3%.

***Conclusion*:** Across 4 seeding densities that were cultured in the G-Rex 24 Well plate we were able to conclude that it is feasible to scale up T regulatory cell culture using the G-Rex culture technology with a seeding density ranging from 1 x 10^6 cells /cm^2 - 4 x 10^6 cells /cm^2.

808 Development and Translation of PPL-001, an autologous, gene-edited $CD34^+$ HSPC Therapy for Friedreich's Ataxia

Anusha Sivakumar[1], Colin Exline[2], Alexis Corl[1], Keneth Munoz[3], Angelyn Solis[4], Lilas El-Hachim[4], Rishika Murthy[5], Rafael Badell-Grau[6], Rita Wan[4], Eric Thai[1], VEENITA KHARE[4], Stephanie Cherqui[7]*
[1]University of California, San Diego, La Jolla, CA, [2]Papillon Therapeutics, San Diego, CA, [3]University of California San Diego, Perris, CA, [4]UCSD, San Diego, CA, [5]UCSD, Santa Clara, CA, [6]UC San Diego, La Jolla, CA, [7]University of California, San Diego, La Jolla, California
**Corresponding Author*

Friedreich's ataxia (FRDA) is a multi-systemic, autosomal recessive, neurodegenerative disorder caused by homozygous GAA repeat expansion mutation in intron 1 of frataxin (*FXN*) gene.This leads to reduced FXN expression, a mitochondrial protein essential for cellular homeostasis. FRDA is characterized by ataxia, areflexia, sensory loss, muscle weakness, and cardiomyopathy, which is the leading cause of mortality.Currently, there are no effective treatments for FRDA. We previously showed complete rescue of neurologic, muscular, and cardiac complications in YG8R FRDA mouse model with a single, systemic infusion of wild-type hematopoietic stem and progenitor cells (HSPCs).This rescue was mediated by FXN transfer from engrafted HSPC-derived microglia/macrophages to neurons/myocytes.We next developed an autologous transplantation therapy using an ex-vivo CRISPR/Cas9 gene-editing strategy that excises GAA expansion in CD34+ HSPCs from patients (PPL-001).Here, we present IND-enabling studies evaluating pharmacology, manufacturing, and safety of PPL-001, aimed at initiating first-in-human HSPC and genome editing clinical trial for FRDA.To evaluate therapeutic efficacy, we generated murine analogous, bone-marrow derived Sca1+ HSPCs (mPPL-001) from YG8s(GAA)>800 mice (YG8JR) carrying human FXN with >800 GAA repeats, using the same gene editing components as PPL-001.Two-month-old myeloablated YG8JR mice were transplanted with either mPPL-001 or mock HSPCs and analyzed 6-7 months post-transplant.With a mean gene editing efficiency of 18.5% in mPPL-001, hematopoietic tissues maintained a substantial proportion of mPPL-001 derived cells: ~7.24% in bone marrow cells, ~8.8% editing in blood, 25.05% in spleen and 16.68% in thymus. mPPL-001-derived cells were also present in FRDA-affected organs, such as the heart(2.78%), spinal cord(1.49%), cerebellum(0.85%), and skeletal muscle(3.33%).Mice transplanted with mPPL-001 exhibited significant preservation of cerebellar architecture and granular cell layer neurons, compared to untreated or mock-transplanted mice. Additionally, cardiac mitochondrial ultrastructure was significantly preserved in mPPL-001 transplanted mice compared to mock.These findings demonstrate that single infusion of mPPL-001 engraft in the bone marrow niche to become a reservoir of healthy cells that can engraft into injured organs for their long-term preservation.We next optimized a robust and reproducible manufacturing process for PPL-001 using G-CSF/Plerixafor mobilized apheresis products from two healthy adult donors (<36 GAA), Cas9 protein, two single guideRNAs (sgRNA) flanking the mutation (UP4, DN4), an electroporation facilitator and Xenon electroporator. CD34+ HSPCs were isolated using the CliniMACS Plus system with >80% viability and >98.75% purity, pre- and post-electroporation.7 days post-electroporation, gene editing efficiency of PPL-001 from the two donors were 19.31% and 22.35%.To evaluate potential off-target effects, comprehensive ONE-Seq analysis of the two sgRNAs identified <5 Tier 1 sites (>1% rate of on-target with functional annotation) and <71 Tier 2 sites (>1% rate of on-target with low functional annotation), confirming low number of potential off-target sites. The nominated off-target sites will be validated using rhAMP-Seq in PPL-001 cells. In summary, these promising results of scale-up feasibility, efficacy and safety support our efforts in clinical translation of CRISPR/Cas9 gene corrected HSPCs for FRDA.

809 Expansion of human T cells with greater quantity and quality via small molecule (CMT-01)

Ling Wu, ChemT Biotechnology, Singapore, Singapore

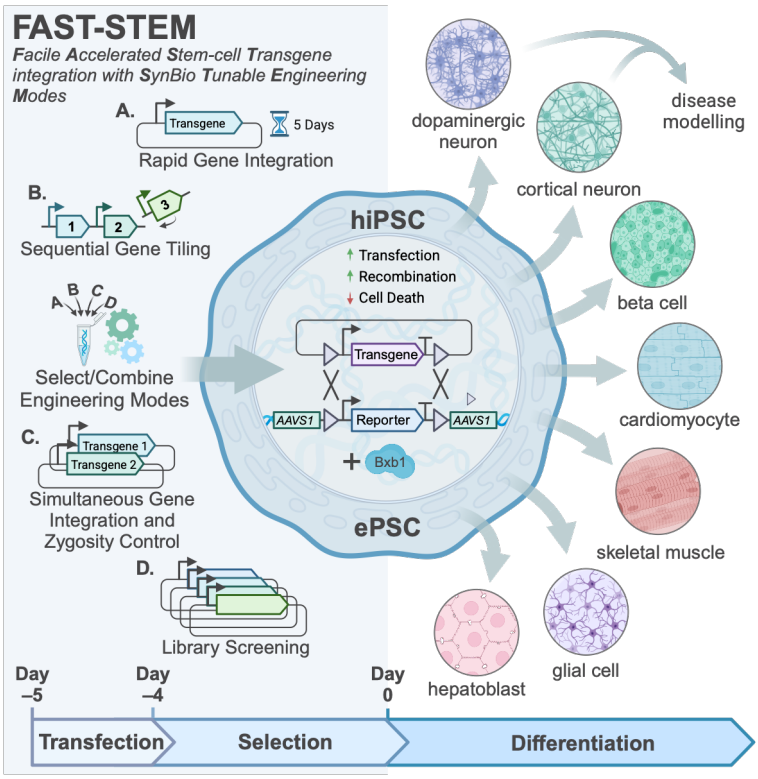
T cell therapy products require ex vivo modification and expansion to reach the necessary cell numbers and quality before being administered to patients. Traditionally, this process has relied heavily on serum and cytokine-based culture systems, which present challenges such as variability, batch-to-batch inconsistencies, and high costs. As the field transitions toward large-scale allogeneic T cell manufacturing to meet growing demand, selecting the appropriate culture reagents is increasingly critical to achieving robust and reproducible yields. Small molecules have emerged as a promising alternative, offering distinct advantages over traditional reagents, including enhanced stability, scalability, and cost-effectiveness. Despite their potential, small molecules remain underexplored in the context of T cell production, creating an opportunity to innovate and optimize this critical step in T cell therapy development.

Our discovery, CMT-01, exemplifies this potential by small molecules to significantly improve T cell culture outcomes. In preclinical studies, CMT-01 has consistently demonstrated a remarkable 5-10x increase in T cell expansion compared to conventional methods, while preserving key functional characteristics such as a naïve memory phenotype. This is crucial for maintaining long-term efficacy, as it enhances T cell persistence and activity in vivo. Moreover, CMT-01 has been shown to augment the functional capabilities of expanded T cells, resulting in improved therapeutic performance in vivo. These findings position CMT-01 as a transformative solution for next-generation T cell therapy manufacturing, addressing industry challenges and paving the way for more efficient, scalable, and cost-effective production processes.

810 FAST-STEM: A Synthetic Biology Landing-Pad Toolkit for Next Generation Stem Cell Engineering and Regenerative Medicine

Aaron Rosenstein[1], Michael Garton[1]
[1]*University of Toronto, Toronto, ON*

Very recent clinical advancements in human stem cell (hPSC) based tissue replacement have opened a new frontier of possibility: *therapeutically augmented human cell* engraftment. Therapeutic augmentation requires the design of synthetic gene circuits that are compatible with hPSCs. Such design is highly challenging due to: (a) poor translation of circuits developed in immortalized cell lines; (b) absence of effective tools for synthetic human stem cell development. To address this, we developed FAST-STEM (*Facile Accelerated Stem-cell Transgene integration with SynBio Tunable Engineering Modes*), a landing-pad platform that enables *design–build–test–learn* style hPSC engineering. FAST-STEM facilitates fast iterative synthetic cell evolution, zygosity manipulation, and highly controlled library screening. While previous site-specific methods involve laborious multi-step engineering protocols which take weeks to complete prior to expansion, FAST-STEM enables generation of *differentiation ready* engineered stem cells in 5 days. We demonstrate the potential for FAST-STEM to accelerate stem cell synthetic biology by creation of engineered human liver, glial-cells, muscle, cardiomyocytes, pancreatic beta-cells, and cortical neurons in addition to dopaminergic neuron Parkinson's disease models.



811 Feeder-Free Expansion of iPSC-derived NK Cells to Clinical Scale

Daniel Terheyden-Keighley[1], Boris Greber[2]
[1]Catalent Cell & Gene Therapy, Langenfeld (Rheinland), Germany, Germany, [2]Catalent Cell and Gene Therapy, Düsseldorf, Germany, Rheinland, Rheinland-Pfalz, Germany

Background & Aim: Natural killer (NK) cells play a critical role in immune surveillance, targeting and eliminating transformed cells before they develop into life-threatening cancers. Unlike T cells, NK cells can be used as allogeneic therapies without the risk of graft-versus-host disease. This enables large-scale manufacturing from a single donor for off-the-shelf therapies, potentially offering improved safety compared to T-cell-based treatments. Traditional donor-derived NK cell manufacturing faces challenges, including donor-to-donor variability and reliance on bulk gene delivery methods such as viral vectors, leading to inconsistent production. iPSC-derived NK cells offer a consistent and practically unlimited source material, requiring only a single precise gene-editing step at the master cell bank level. However, current methods using iPSCs often depend on embryoid body-based differentiation and cancerous feeder cells, creating additional complexities for clinical scalability.

Methods: An iPSC-derived NK cell platform was developed to address these challenges by enabling feeder-free expansion at clinical scale. This process uses defined media to expand and bank NK precursor cells at small scale before transitioning to cost-effective media for large-scale expansion. The approach eliminates the need for feeder cells and uses GMP-compatible protocols. NK cell purity and functionality were assessed through the expression of KIR receptors, NK activation markers, and cytotoxic efficacy against K562 cells.

Results: The developed protocol successfully expanded up to several billion NK cells per cm² of seeded iPSCs in a feeder-free process. The resulting NK cells exhibited high purity, robust KIR receptor and activation marker expression, and potent cytotoxic activity against target cells. To our knowledge, this is the first method to achieve the expansion of iPSC-derived NK cells without feeder cells, using a GMP-compatible process, and at scales sufficient for clinical applications.

Conclusions: This feeder-free iPSC-derived NK cell platform offers a consistent, scalable, and GMP-compatible solution to produce NK cells for clinical use. By overcoming the limitations of traditional donor-derived methods and current iPSC-based approaches, the platform supports the development of off-the-shelf NK cell therapies with enhanced safety, reliability, and manufacturing efficiency.

812 Generation of Functional BCMA CAR-iNKT Cells from Clinical-Grade iPSCs via a GMP-Compliant Manufacturing Process with Capacity for Linear Scale-Up

Akane Urakami[1]*, Tomokuni Shigeura[2], Noriko Watanabe[2], Mio Shiraishi[2], Yu-Chin Lin[2], Koichiro Shioya[3], Aki Naito[2], Tomio Matsumura[3], Kanto Nakajima[2], Ryoko Kuniyoshi[2], Yuta Ohira[3], Yoshie Sasako[4], Sachiko Kira[4], Satoko Sasaki[4], Hiroko Okura[4], Munechika Yamaguchi[4], Momoko Okoshi[4], Haruhiko Koseki[4], Lilin Zhang[3]*

Induced pluripotent stem cells (iPSCs) have emerged as a consistent cell source for 'off-the-shelf' CAR-T or CAR-NK cell therapies. This study presents the first successful establishment of an iPSC line engineered with a BCMA-targeting CAR, derived from invariant natural killer T (iNKT), and subsequently differentiated into functional iNKT cells suitable for clinical application. We also demonstrate, for the first time, the efficient production of functional CAR-iNKT cells from an iPSC platform with the capacity for linear scale-up to clinical-scale production.

iNKT cells are a rare subset of T lymphocytes with an invariant Vα24-Jα18 TCR (Vα24 TCR) that recognizes glycolipids presented by the monomorphic MHC-like molecule CD1d, which enables allogenic use without inducing graft-versus-host disease. The uniqueness of iNKT cells as a cell therapy platform lies in their dual anti-tumor functionality: direct cytotoxicity via TCR and NK receptors, and indirect tumor suppression through the activation of tumor antigen-specific T cells. The induced endogenous host immune cells are expected to persist within the patient even after the administered allogeneic cells are eventually cleared. We previously reported that iPSC-derived iNKT cells retained these functional properties of native iNKT cells, irrespective of CAR gene editing.

To establish a parental iPSC source for further engineering, we established iNKT cell-derived iPSC banks. iNKT cells were enriched from leukapheresis products obtained from qualified healthy donors and subsequently reprogrammed into iPSCs. The resulting colonies were screened and evaluated based on the pluripotency markers, TCR gene rearrangement, differentiation potential, and genetic integrity. These iPSC lines successfully differentiated into CD34+ hematopoietic progenitor cells (HPCs) and subsequently into iPSC-derived iNKT (ipsNKT) cells, achieving robust proliferation with an expansion capacity of up to 6,000-fold. Successively, we developed a BCMA-targeting CAR-iPSC line. Using CRISPR-Cas12a-based technology, iPSCs were engineered to knock out beta-2-microglobulin (ß2M) and knock in BCMA CAR along with human IL-15. This modification resulted in BCMA CAR expression, IL-15 secretion, and the loss of MHC Class I expression. The edited cells were cloned, screened by PCR, and evaluated for genetic characteristics and differentiation potential. The gene-edited iPSCs retained robust differentiation capability, and the resulting BCMA CAR-ipsNKT cells exhibited high purity (>95% CD3+/Vα24-Jα18 TCR+ cells) with CAR expression reaching up to 99.5%. This established manufacturing process utilized feeder-free culture conditions, with all reagents being xeno-free and GMP-compliant.

BCMA CAR-ipsNKT cells demonstrated potent in vitro cytotoxicity against multiple myeloma cell lines. In a xenograft model, mice treated with BCMA CAR-ipsNKT cells showed significantly prolonged survival compared to those treated with controls or non-CAR-engineered ipsNKT cells.

In summary, we successfully established clinically compliant iNKT cell-derived iPSC lines and a GMP-compliant, scalable manufacturing process for gene editing and large-scale production of CAR-ipsNKT cells. This study highlights the potential of iPSC-derived CAR-iNKT cells as a versatile and scalable platform for allogeneic cell therapies.

813 Formulating recombinant proteins with chemically defined ingredients to replace human-derived proteins for mesenchymal stem cell culture

Yingying Li[1], **Chu Han Hoh[2]**, Kavitha Rajasekhar[3], Eva Loo[3]
[1]Evonik, Singapore, Singapore, Singapore, [2]Evonik Corporation, Singapore, Singapore, [3]Evonik, Singapore, Singapore

Introduction: Xeno-free (XF) media containing human blood-derived proteins is state-of-the-art for manufacturing mesenchymal stem cells (MSC). However, a recent Food and Drug Administration (FDA)'s 2024 draft guidance highlighted the risks of disease transmission and ingredient impurities arising from the use of human derived materials, there is increasing regulatory scrutiny of raw ingredients used in cell therapy manufacturing. To address the unmet need for alternatives to human derived proteins with lower risk profile, we screened, optimized, and evaluated different formulations comprising of recombinant proteins and other chemically defined ingredients.

Methods: An in-house xeno-free (XF) MSC medium formulation was used as a basis to evaluate our recombinant protein formulations. In internal tests, this XF formulation, containing human proteins, performed favorably in comparison to commercial xeno-free media in terms of cell growth and stemness. In a first step, the human proteins were removed from formulation, and combinations of recombinant proteins with other chemically defined ingredients were screened for their ability to re-create the effect of human-derived proetins. The most promising combinations were then used to prepare chemically defined version of the XF media to be tested in small scale experiments. The best performing media were identified and further evaluated using MSC derived from different donors and tissue sources for three passages. The critical quality attributes of cell growth, stemness and senescence were assessed.

Results: In order to understand how to formulate recombinant proteins as alternatives for human proteins in cell media, we first tried to directly change from human-derived proteins with recombinant proteins. This proved inadequate for MSC cell survival and growth (Figure 1). Moving ahead, combinations of recombinant proteins and chemically defined ingredients were designed and tested. Out of the tested formulations, four demonstrated the ability to support MSC growth over four passages in small-scale experiments. The best-performing formulation was subsequently validated in T25 flasks across multiple donors. This recombinant protein based formulation exhibited superior performance in cell growth and stemness maintenance across two donors over four passages, indicating stable efficacy (Figure 2). This formulation was also added to umbilical cord MSCs cultured in commercial low-serum media. This supplementation supported stem cell expansion in later passages (>P6) and significantly increased the production of cellular antioxidant glutathione while reducing the percentage of senescent cells.

Conclusions: The incorporation of additional chemically defined ingredients alongside recombinant proteins successfully replaces human proteins in MSC media. This combination may also be applicable to other cell types as an alternative of human-derived proteins, significantly aiding in addressing regulatory challenges associated with the use of human-derived materials in cell therapy production.

Figure 1. Directly replace human derived protein with recombinant proteins provide inadequate for Mesenchymal cell survival and growth

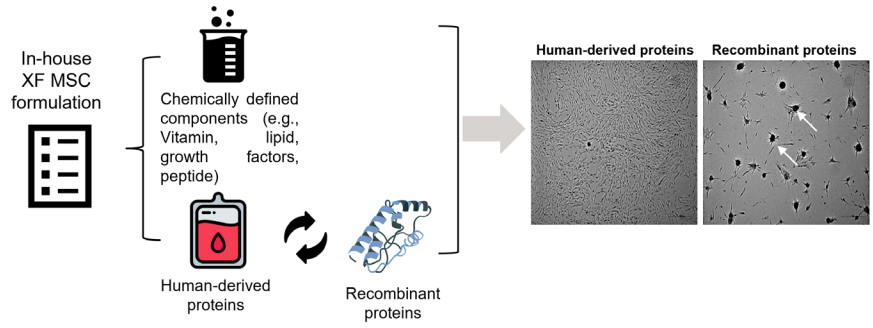

Figure 2. Recombinant protein-based formulation with chemically defined ingredients successfully re-create the effect of human derived proteins and exhibited superior performance in cell growth and stemness maintenance.

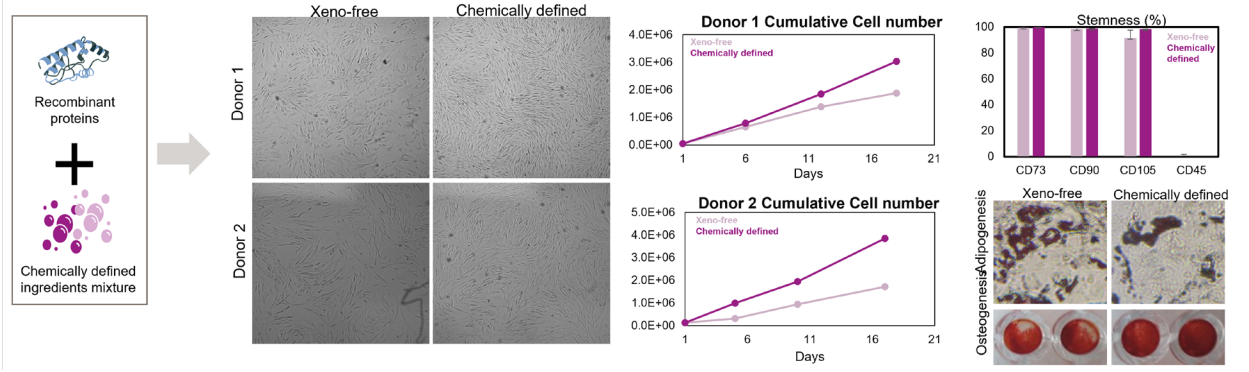

814 Development of Tools to Support Coating-Free Adherent Culture of Human Mesenchymal Stromal Cells Under Reduced-Serum and Serum-Free Conditions

Josh DiGiacomo[1], Isha Dey[2], Rayees Ahamed[2], Kanika Singh[3], Arafat Fasuyi[1], Debra Johnson[4], Sune Sporring[5], Matthew Dallas[1]

[1]Thermo Fisher Scientific, Frederick, MD, [2]Thermo Fisher Scientific, Bengaluru, India, [3]Thermo Fisher Scientific, Bengaluru, Karnataka, India, [4]Carlsbad, CA, [5]Thermo Fisher Scientific, Roskilde, Denmark

Human mesenchymal stromal cells (hMSCs) have found applications in cell therapies for a wide variety of diseases such as bone and cartilage disorders, diabetes, neurological disorders, and more due to their capabilities in differentiation, immune regulation, tissue repair, and cell signaling. As with all cell therapies, high quantities of hMSCs are required to prepare therapeutic doses. Therefore, the process of expanding hMSCs needs to be efficient, reliable, and consistent to provide adequate quantities of cells for both research purposes and therapeutic development. Adherent hMSCs cultures generally require extracellular matrix (ECM) coatings and/or media containing animal-derived serum. These factors reduce the efficiency and reproducibility of the hMSC expansion process by introducing variable culture conditions from animal-origin components, requiring additional time for coating, and adding extra costs.

To support progress towards more efficient and less animal-dependent processes for expanding hMSCs, we have developed an animal-origin free (AOF) version of Insulin-Transferrin-Selenium (ITS) supplement. Through multiple experiments, we demonstrated that this supplement supports the culture of adipose-derived hMSCs (as well as other primary cell types) under reduced-serum conditions on coating-free surfaces over multiple passages.

To support complete serum-free expansion of adherent hMSCs under coating-free conditions, we developed the Nunclon™ Supra cell culture surface and applied it to a wide variety of cell culture vessels ranging from 96-well plates to T175 flasks. Using hMSCs derived from adipose tissue, bone marrow, and Warton's jelly, we demonstrated that serum-free, coating-free culture on the Nunclon™ Supra cell culture surface allows for similar cell culture metrics (including viability, doubling time, and morphology) as compared with serum-free, ECM-coated culture on a standard cell culture surface. In addition, we also demonstrated that hMSCs expanded under serum-free, coating-free conditions on the Nunclon™ Supra surface maintain equivalent expression of multipotency markers and demonstrate comparable differentiation into chondrocytes, osteocytes, and adipocytes when compared to hMSCs cultured under serum-free, ECM-coated conditions. Taken together, these results indicate that the enhanced Nunclon™ Supra cell culture surface can play an important role in reducing hMSC culture workflow demands and easing the expansion of hMSCs into large volume cultures.

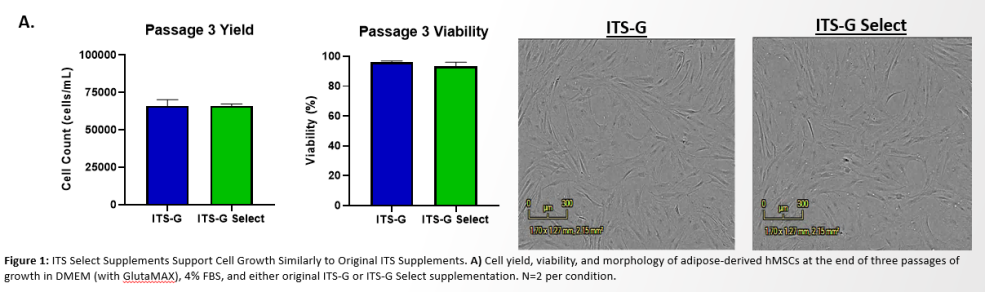

Figure 1: ITS Select Supplements Support Cell Growth Similarly to Original ITS Supplements. **A)** Cell yield, viability, and morphology of adipose-derived hMSCs at the end of three passages of growth in DMEM (with GlutaMAX), 4% FBS, and either original ITS-G or ITS-G Select supplementation. N=2 per condition.

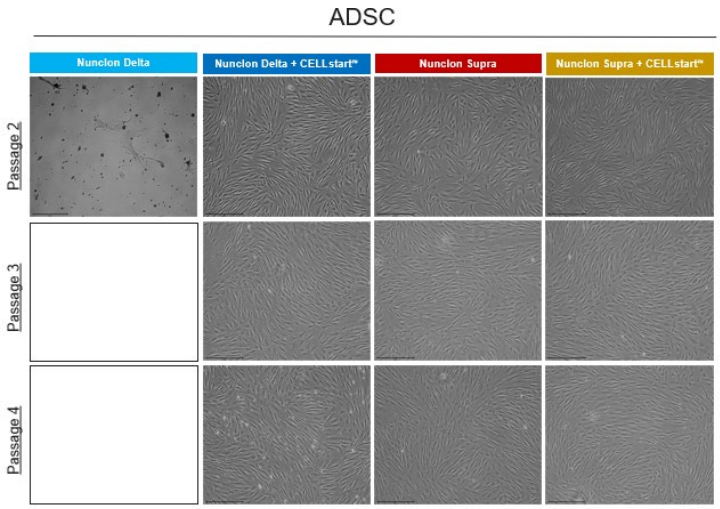

Figure 2. Morphology of hMSCs derived from adipose tissue (ADSC) over multiple passages when cultured without serum on the Nunclon™ Delta or Nunclon™ Supra surface with or without CELLstart™ coating. hMSCs cultured serum-free on the Supra surface without coating are viable unlike hMSCs cultured serum-free and coating-free on the Delta surface. This experiment was repeated with similar results for bone marrow-derived and Wharton's jelly-derived hMSCs.

815 Bioinspired Microbeads for Boosting Feeder-free Manufacturing of Immune Cells

Cheng-Tai Chen[1], Chien-An Chen[2], Nien-Tzu Chou[2], Chih-Hung Lee[2], Ching-Fang Lu[2], Su-Feng Chiu[2], Wen-Ting Chiang[2], Hsiang-Yuan Huang[1]
[1]Industrial Technology Research Institute, Chutung, Hsinchu, Taiwan, [2]Industrial Technology Research Institute, Hsinchu, Taiwan

Introduction: Cell-based immunotherapy carries significant potential for treating cancer and other diseases; however, it faces substantial challenges in immune cell manufacturing. The intricate processes, especially for T and NK cells, demand careful selection of raw materials to ensure safety and quality. To address these challenges, we are thrilled to introduce iKNOBeads—a magnetic microbead with a unique bioinspired design engineered explicitly for immune cell activation.

Methods: We meticulously fabricated iKNOBeads, focusing on size and shape to ensure optimal design. Their bumpy surface, which enhances the contact area for cell interactions, significantly improves activation efficiency while minimizing the required bead amount. To validate the effectiveness of our new technology, we rigorously compared the iKNOBeads-based platform with commercially available products for manufacturing CAR-T and NK cells, implementing our optimized processes and carefully selected reagents.

Results: Our compelling results reveal that the iKNOBeads platform substantially elevates CAR-T and NK cell products' quality, quantity, and functionality. When scaled up using a 500 mL G-rex bioreactor, we achieved an

impressive milestone: successfully producing up to 2 billion functional NK cells in just two weeks. Moreover, we have validated the efficacy of our innovative feeder-free platform in producing CAR-NK cells in vitro.

Conclusion: iKNOBeads represents a transformative leap in immune cell manufacturing efficiency. Its unique bioinspired design and superior performance promise more effective and affordable cell-based immunotherapies. With iKNOBeads set for commercial release this year, we are excited to continue our research and explore its potential in preclinical and clinical applications.

Manufacturing of GPC-3 CAR-NK cells in 14 days from 3 healthy donors using the iKNOBeads-based platform

816 Serum- and Feeder-Free Generation of Multipotent Hematopoietic Progenitors from Pluripotent Stem Cells in a 3D Culture System

Tim Le Fevre[1], Diana Golubeva[2], Brandon Wong[1], Tinya Wang[2], Patrick Brauer[2], Andy Kokaji[1], Allen Eaves[3], Sharon Louis[4], Nooshin Tabatabaei-Zavareh[1]
[1]STEMCELL Technologies, Inc., Vancouver, BC, [2]STEMCELL Technologies, Inc., Vancouver, [3]STEMCELL Technologies Inc, Vancouver, BC, [4]STEMCELL Technologies, Vancouver

Hematopoietic stem and/or progenitor cells (HSPCs) and their derivatives, including natural killer (NK) cells, T cells, and B cells, show immense potential for the treatment of various malignancies and diseases. However, generating therapeutically relevant yields of HSPCs remains a major challenge.The derivation of HSPCs from human pluripotent stem cells (hPSCs) provides an alternate source of unlimited cells to overcome this bottleneck and enable their use in diverse cellular therapies.

We have developed a scaleable, serum- and feeder-free 3D culture system capable of generating large numbers of functional, multipotent HSPCs. hPSC aggregates (5 independent cell lines) were seeded into either 6-well non-treated tissue culture plates on an orbital shaker or into a 100 mL PBS-MINI MagDrive Bioreactor containing STEMdiff™ Hematopoietic - EB Medium to form embryoid bodies (EBs) in 3D suspension cultures. After 12 days, both cultures were filtered with 37 µm reversible filters to remove the EBs and harvest the hPSC-derived HSPCs

remaining in the supernatant as single cells. HSPCs were assessed for yield and frequency of CD34+ cells by flow cytometry. The differentiation potential of these hPSC-derived HSPCs was assessed by colony-forming unit (CFU) assay and by lineage-specific differentiation to myeloid cells, erythroid cells, and lymphoid cells.

The 6-well 3D suspension cultures yielded 1.3 x 10^6 ± 1.6 x 10^5 CD34+ cells per 1 mL of culture vessel volume, with a CD34+ frequency of 73 ± 2% (mean ± SEM; n = 36). The scaled-up 100 mL bioreactor cultures performed comparably, producing 1.6 x 10^7 - 1.1 x 10^8 CD34+ cells (n = 4). In the CFU assay, hPSC-derived HSPCs generated 116 ± 14 CFU per 5,000 cells seeded, with 101 ± 16 granulocyte/macrophage colonies and 9 ± 4 erythroid colonies (n = 8) counted.

Lineage-specific differentiation confirmed that these hPSC-derived HSPCs were capable of differentiating to myeloid cells (macrophages, megakaryocytes, and microglia), erythroid cells, and importantly, lymphoid cells (B, NK, and T cells), indicating that these cells are definitive multipotent HSPCs. Lymphoid-specific differentiation resulted in 27 ± 14% CD19+ B cells (8 ± 4 per input hPSC, n = 6), 79 ± 2% CD56+ NK cells (1504 ± 394 per input hPSC, n = 25), and 54 ± 7% CD4+CD8+ double positive T cells (701 ± 293 per input hPSC, n = 9). Of note, 33 ± 5% of the CD4+CD8+ double positive T cells were also CD3+TCRαß+ indicative of a more differentiated phenotype.

These results demonstrate that our 3D suspension culture system can generate functional and multipotent HSPCs from hPSCs in both 6-well plate and larger-scale bioreactor formats to support the manufacturing of clinically relevant yields of HSPCs. This system is a valuable tool for researchers to aid in the study and development of cellular therapies.

817 Metabolic Profiling to Predict In-Vitro T-cell Fitness

Anthony Lauer[1], Kayla Sylvester[2], Natasha Karassina[2], Jolanta Vidugiriene[3]
[1]Promega Corporation, Fitchburg, WI, [2]Promega, Madison, WI, [3]Promega Corporation

Adoptive T-cell therapies rely on the expansion of functional and metabolically fit T-cells to ensure therapeutic efficacy. Comprehensive evaluation of T-cell fitness in vitro is critical for optimizing these approaches, yet predictive metabolic metrics are not fully established. In this study, we employed luminescent plate-based assays to measure key metabolic and functional parameters in human T-cells as a model for cell expansion in CAR-T or other cell therapy applications.

Cellular reducing capacity, NAD(H)/NAD(P)(H) concentration, ATP levels, dehydrogenase activity, and markers of differentiation were measured at multiple timepoints in the activation and expansion process. IFN-γ/TNF-α cytokine secretion and T-cell-dependent cell killing served as functional metrics of cell fitness.

Correlations between these metrics and differing cell culture conditions revealed distinct metabolic signatures associated with T-cell functional fitness. Increased reducing capacity highlighted stronger activation when using one distinct culture medium, while increased proliferation in another medium correlated with higher ATP levels and increased dehydrogenase activity. Differentiation markers, analyzed alongside metabolic profiles, showed expected increases in glycolysis during T-cell activation and differentiation, and provided insights into the relationship between metabolic states and lineage commitment (e.g., effector vs. memory-like cells).

Collectively, these metabolic parameters serve as predictive biomarkers for T-cell fitness, demonstrating their potential utility in screening T-cell products for CAR-T and other therapeutic applications, and highlighting the importance of metabolic profiling in the optimization of T-cell expansion protocols.

818 Microfluidic Magnetic Bead Capture of Target Cells for In-Process Phenotyping of CAR T Cells

Aleksandra Nikoniuk[1], Koki Lilova[2], Nicolas Szita[3], Michael Thomas[3]
[1]University College London, LONDON, London, United Kingdom, [2]Autolus Ltd, London, London, United Kingdom, [3]University College London, London, United Kingdom

Chimeric antigen receptor (CAR)-T cell therapies have in the past decade revolutionized the treatment of haematological cancers with impressive long-term remission rates achieved in clinical trials resulting in seven US Food and Drug Administration (FDA) approvals as of November 2024. However, the establishment of CAR T cell therapy as a standard of care is limited by complex logistics and manufacturing protocols, which contribute to their high prices. Producing a drug of consistent quality is critical in reducing the overall costs, which requires tight control of process parameters. To monitor them robust technologies are necessary to inform of critical quality attributes (CQAs), highlighting the importance of quality control (QC) in manufacturing of CAR T cell therapies.

Flow cytometry, a great research tool widely used for in-process CAR T cell phenotyping, does have limitations when implemented in Good Manufacturing Practice (GMP) environment. It is typically a highly manual procedure in both assay execution and data analysis and so is prone to human error and therefore not reliable. Some attempts have been made to automate flow cytometry assays, using robotic arms or microfluidic cartridges. These, however, do not offer online, inline or at-line testing, nor are they affordable. This highlights the lack of Process Analytical Technology (PAT) for determination of cell phenotype. To truly introduce PAT into CAR T cell manufacturing, there is a need for novel approaches that not only accurately measure cell marker expression levels but also integrate with cell processing equipment.

Here, we evaluate effective approaches to incorporate magnetic bead-based cell detection in microfluidic devices. Preliminary results show efficient cell capture on antibody-functionalised magnetic beads. The fabrication of microfluidic devices using a hard polymer allows not only for rapid prototyping but also aligns with the needs of low-cost mass manufacture. Efficient CNC machine milling of the chips enables screening of a range of designs to best fit the proposed analytical assay. The use of a clear, hard polymer allows for stable tubing connection of the chip device with syringe pumps for automation of fluid flow as well as on-chip cell visualisation. Small footprint of the chip paves way for its integration with CAR T cell manufacturing equipment. All these aspects strive to challenge the status-quo of analytical testing in advanced therapy processing by creating a viable, low-cost alternative.

819 Recirculated Tumor Chip Platform to Study How Microenvironmental Factors Affect Kinetics of Immune Cells and Immunotherapeutics

Chun-Wei Chi[1], AH Rezwanuddin Ahmed[2], Sihong Wang[2]*, Yeh-Hsing Lao[1]*
[1]University at Buffalo, The State University of New York, Buffalo, NY, [2]CUNY – City College of New York, New York, NY
**Corresponding Author*

Microenvironmental factors, including mechanical, chemical, immune, and stromal components, control tumor development. However, there is yet little understanding of how these factors affect the kinetics of cancer therapeutics and the downstream drug response, although there have been multiple models reported to study tumor microenvironment and to screen new therapeutics. Patient-derived xenograft (PDX) and high-throughput 2D screening are the most representative in vivo and in vitro models used for cancer drug development, respectively. Despite their popularity in cancer drug screening, PDX mouse models only offer murine physiological microenvironment to transplanted human tumors, while conventional 2D culture models provide very limited insights as 2D culture lacks many components seen in tumor. In light of these limitations, we develop a tumor chip platform that enables control and measurement of certain microenvironmental variables, including physiological flow, endothelial barrier and stroma compositions, along with live-cell imaging to understand the dynamics between tumor-microenvironment-cancer therapeutics and to evaluate how these components respond to the treatment. This multi-layered tumor chip reconstructs the tumor architecture and microvessel. Recirculation in this platform is

controlled by the recirculating circuit unit we created, consist of four one-way valves to generate the unidirectional flow. Through our optimization, our platform could recapitulate the tumor-microvascular interface and physiologically relevant interstitial flow in the reconstructed triple-negative breast cancer (TNBC) tumor compartment. To understand the role of tumor microenvironment in affecting the dynamics of immune cells and the efficacy of immunotherapeutics, we created different stromal compositions on chip with recirculation of CD8+ cytotoxic T cells. Tumor endothelium was found to be the key barrier for T cell infiltration, and cancer-associated fibroblasts in the tumor stroma further impeded this cell infiltration. In addition, affected by the cancer-associated fibroblasts in tumor stroma, tumor microvasculature reconstructed on chip showed a different expression pattern of endothelin B receptor (ET_BR) and intercellular adhesion molecule-1 (ICAM-1), thereby inhibiting T cell infiltration. Treatment of anti-PD-L1 antibody therapeutics could overcome these barriers and enhanced T cell's cytotoxicity against the TNBC cancer cells, while additional treatment of the ET_BR antagonist (BQ788) could tackle the negative dynamics between ET_BR and ICAM-1 in tumor microvasculature. Taken together, our results confirm that our chip recapitulates the characteristics of tumor-microvascular interface as well as tumor stoma. This platform could potentially serve as an ex vivo toolkit to optimize immunotherapeutics for cancer treatment.

820 Development of Potency Assays for Recombinant AAV vectors Independent of both the Promoter and Transgene as well as for AAV Encoded Transgenes Regulated by Photoreceptor and Retina Specific Promoters

Jordi Rodo[1], Lue Huang[2], Lone Bovin[3], Christophe Lallemand[4], **Michael Tovey[5]***
[1]Svar Life Science, Cambridge, MA, [2]Svar Life Science, VILLEJUIF, Val-de-Marne, France, [3]Svar Life ScieScience, Malmö, Sweden, [4]Svar Life Science, Paris, France, [5]Svar Life Science Nces, Villejuif, AL
**Corresponding Author*

Current methods for quantifying the potency of recombinant AAV vectors are laborious, imprecise, and time consuming. A universal AAV potency assay based on the i*Lite*® reporter-gene technology has been developed that is rapid, precise, and independent of both the transgene and its promoter. Data will be presented illustrating the utility of this assay. An essential safety requirement for the successful development of therapies based on AAV-encoded transgenes is that the transgene is expressed exclusively in the target tissue. This can be accomplished by the use of tissue or even cell-type specific promoters. This poses significant challenges, however, for the development of appropriate potency assays that accurately reflect tissue or cell-type specific expression of the transgene.

The i*Lite*® reporter-gene technology has been used to develop potency assays for AAV encoded transgenes regulated by both photoreceptor-specific promoters and retina-specific promoters that reflect to a high degree the mechanism of action of the AAV-encoded transgene. The development of one such assay for the quantification of the potency of the retina-specific guanylate cyclase GUCY2D regulated by the hGRK1 promoter derived from the rhodopsin kinase G-protein coupled receptor kinase will be described. The assay is based on the stable co-transfection of ARPE-19-HPV-16 cells, derived from the retina pigmented epithelium, with a cGMP responsive reporter-gene construct and guanylyl cyclase-activating protein-1 (GCAP-1) to obtain maximal GUCY2D activity. The resulting cell line was also stably transfected with the Renilla luciferase (RL) reporter-gene under the control of a constitutive promoter that allows both FL and RL activity to be quantified sequentially in the same well of a microtiter plate. FL activity can thus be normalized with respect to RL expression rendering the assay independent of cell number and allowing non-specific effects to be detected.

The resulting i*Lite*® cell line has been used to quantify the potency of an AAV5 encoded GUCY2D transgene under the control of the hGRK1 promoter. A dynamic range of some 750-fold was obtained in a 4PL potency assay and a relative potency assay without the need to add live Adeno virus or other external stimuli. The cells have been converted into a frozen ready-to-use format that confers both ease of use and low coefficients of variation. Data will be presented illustrating the utility of this assay.

821 A Novel and Reliable *In Vitro* Copper-Excretion Potency Assay with Engineered Huh-7-CuEP Cells for Evaluating Gene Therapy Candidates in Wilson Disease

Chenming Lu[1], Yuzhe Peng[1], yi Zhang[1], Ya Wang[1], Yixiong Chen[2]*, Qing Lin[3]*
[1]Lingyi Biotech, Shanghai, China, [2]Lingyi Biotech, Shanghai, China, China, [3]Lingyi Biotech, Lutherville, MD
**Corresponding Author*

Wilson disease (WD) is a rare autosomal recessive disorder caused by mutations in the *ATP7B* gene, leading to impaired copper excretion by the dysfunctional ATP7B protein and resulting in systemic copper accumulation, primarily affecting the liver, brain, and kidneys. LY-M003, an investigational adeno-associated virus serotype 8 (AAV8)-based gene therapy, was designed to produce a modified miniATP7B^{LY} protein in the liver, thereby reducing copper accumulation in WD. The development of a biological potency assay that accurately mimics the endogenous mechanism of action of the target gene/protein is essential for advancing gene therapy products. In this study, we developed a robust in vitro potency assay utilizing a Cu^{2+}-dependent luciferase reporter system in an engineered Huh-7-CuEP^{TM} cell line, providing a sensitive tool to evaluate the copper-excretion capacity of therapeutic candidates for WD.

In this Huh-7-CuEP^{TM} cell line, a metal responsible luciferase reporter cassette was stable integrated into Huh-7 cell line, with the endogenous *ATP7B* gene being inactivated. Upon the addition of excess CuSO4 to the culture medium, cellular copper levels increased significantly and the luciferase expression was markedly increase under the activation of the copper responsible cassette. The luciferase signal showed a correlation with excess $CuSO_4$ concentration, ranging from 10 μM to 100 μM (4-PL, $R^2 = 0.98$). Following infection with LY-M003, cellular copper concentration decreased as ATP7B expression was restored, which was reflected by a substantial reduction in luciferase activity. At specific concentrations of $CuSO_4$ in the medium, the inhibition of excess copper response can be used to quantify the biological potency of the gene therapy products. The inhibition curve demonstrated a strong correlation with LY-M003 multiplicity of infection (MOI), from 1.0×10^4 to 3.0×10^6 (4-PL, $R^2 = 0.97$), simulating different levels of functional product. This assay has been established and validated for specificity, linearity and range, precision and robustness in accordance with GLP guidelines. Specificity testing confirmed that the luciferase signal was exclusively induced by excess Cu^{2+} and inhibited by LY-M003. The quantitative range was found to be between MOI 1.2×10^4 and 2.7×10^6. When performed by two analysts on separate days, the coefficient of variation (CV) for six replicates per analyst and twelve replicates across both analysts was less than 20%, indicating high precision.

In conclusion, the Huh-7-CuEP-based copper-excretion potency assay has been successfully established and validated. It is a suitable tool for release testing and stability evaluation of Wilson disease products, particularly gene therapy candidates.

822 Functional Potency-Based Bioactivity Characterization of Viral Vectors with Supportive Physical and Genomic Titer Analyses

Jessica Stone[1], Cassandra Moshfegh[1], Gustavo Rivas[1], Uyen Nguyen[1], Samantha Schrecke[1], Kevin Mc Manus[1], **Christina McKenna[2]**, Daniel Mitchell[1]*, Ismaeel Muhamed[2]*
[1]Matica Biotechnologies, College Station, TX, [2]Matica Biotechnology, College Station, TX
**Corresponding Author*

Abstract: The field of Cell and Gene Therapy (C>) has generated a variety of novel solutions to the treatment of certain diseases such as cancer and genetic disorders. In this space, viral vectors are employed as the drug product itself, or a critical reagent to generate the therapeutic cell. These viral vectors require a variety of analytics to be performed for the evaluation of their critical quality attributes. Among these attributes are genomic titer, particle titer, and vector potency. While the analytics for genomic and particle titer, often PCR and ELISA-based, respectively, vary modestly among viral vectors, potency analytics are more varied. As each viral vector is unique in its intended bioactivity, no one-size-fits all potency assay is in place and therefore each program must develop product specific potency assays.

Despite the commonality of the physical and biochemical techniques applied to evaluate genomic and particle titer, there are some differences that necessitate one or more augments to these methods. For instance, while qPCR and ddPCR can be utilized to titer DNA-carrying vectors, RNA-containing ones require the addition of a reverse transcriptase step. Moreover, to evaluate particle titer, due to the variation in particle size and composition of the base vector, ELISA, HPLC, microscopy, and light scattering techniques are employed. Each of these methods require some variation in their execution to accommodate for these vector differences.

Potency assays, however, require the greatest variation among vectors to characterize their bioactivity. Vector potency refers to the construct's ability to exert its intended therapeutic effect upon the target cell type. As such, the potency assay must be developed to directly evaluate the therapeutic effect of the vector whether this effect is oncolytic for the treatment of cancer cells, or transducing, resulting in short, or long, term expression of a specific gene product. Incompatible, or inefficient, methods to determine potency can lead to program complications and regulatory delays.

At Matica, we have developed a variety of potency assays to support our clients' programs. These include one of multiple different viral vectors generated using Lentiviruses, AAV's, Adenoviruses, and others. Each vector exhibits its own characteristics which determine the analytical techniques that are applicable. For instance, Adenoviruses, often employed as oncolytic vectors, allow for a more direct characterization through traditional plaque assays, as these vectors are cytopathic. Whereas AAV's, due to their nonpathogenic nature, traditional infectivity assays are not applicable. Instead, to evaluate an AAV vector's infectivity, a TCID50 can be employed, where the readout is by qPCR or ddPCR after a short infection period.

We show here multiple methods developed and executed at Matica, on different representative vectors systems, to demonstrate the variety of techniques available to interrogate viral vector potency along with data showing characterization of genomic and particle titer.

823 Functional cell-based models for gene therapies that utilize cell-specific promoters are enabled through CRISPR-activation

SN Sarah Morris[1], Akshata Korgaonkar[2], Tirthasree Das[2], Jerrod Denham[2], Jenny Holt[3], Paul Bresge[3], Peter Francis[3], Jon Melnick[2]
[1]Ray Therapeutics, Inc., Berkeley, CA, [2]Ray Therapeutics, Inc., Berkeley, [3]Ray Therapeutics, San Francisco, CA

As the field of AAV gene therapy evolves, payload design strategies have begun to focus on minimizing potential off-target toxicity that may be associated with systemic transgene expression. One approach to address this issue is the use of cell type-specific promoters that restrict payload expression to therapeutically relevant cell types, as exemplified by use of the synapsin promoter[1] to minimize non-neuronal expression in brain-targeted AAV gene replacement.

While this specificity is desirable for maximizing the therapeutic index of a gene therapeutic, it introduces challenges in designing functional cell-based assays principally due to the lack of readily-culturable cell lines that both express the specific cell type promoter and are tropic to AAV. To address this issue, we used CRISPR-activation[2], coupled with promoter-specific guides to enable transgene expression in HEK293T cells. In this approach, a panel of guides spanning the human promoter sequence are transiently co-transfected into HEK293T along with CRISPR-activation components (dCAS9-VP64, gRNA-MS2, MS2-p65HS1) in 96-well plates. AAV harboring a promoter-GFP payload is introduced into the wells, followed by outgrowth and imaging. The guide yielding the highest and most consistent GFP expression is then used to make a monoclonal derived stable cell line suitable for gene therapy expression, potency and functional assays.

In the representative system described here, we focused on an appropriate cell line that can express transgenes tied to a proprietary ON bipolar mGluR6 (metabotropic glutamate receptor 6) promoter. After identifying an active mGluR6 promoter guide and establishing a clonal CRISPR-activator cell line, we demonstrate the use of this cell line in an optogenetic potency assay suitable for GMP lot release. This allows potency assays previously developed for the universal CAG promoter to be seamlessly repurposed for the mGluR6 promoter.

This strategy should be applicable to any promoter whose activation in HEK293T is tolerated and potentially enhanced via guides that span artificial junctions in synthetic promoters, overcoming one of the practical roadblocks hindering the implementation of next-generation AAV gene therapies.

BGT-DTDS and BGT-PD (AAV2-SLC6A3) are first-in-class gene therapies expressing dopamine transporter (DAT) evaluated for different indications. DAT is a key regulator of dopamine homeostasis, and perturbations have

been associated in genetic and idiopathic Parkinson's disease (PD). Dopamine transporter deficiency syndrome (DTDS) is caused by biallelic loss-of-function mutations in *SLC6A3* gene encoding DAT, and is a form of childhood parkinsonism disorder similar to AADC deficiency. We have previously shown preclinical efficacy of BGT-DTDS in a DTDS mouse model, and efficacy in managing debilitating levodopa-induced dyskinesia (LID) in PD with complete LID suppression in a rat model. We aim to progress with these promising preclinical data to clinical application.

One of the challenges in translation is AAV scale-up manufacturing to current good manufacturing practice (cGMP). In this study, we successfully scaled up BGT-DTDS/BGT-PD production to a 2L feasibility batch with Viralgen, and evaluated potency *in vivo*. Pre-cGMP batch had an improved empty:full capsid ratio than research grade vector, in absence of aggregates. *In vivo* potency assay was performed in neonatal DTDS mice by bilateral intracerebroventricular injections at two-log dose range ($1.7x10^9$-$1.7x10^{11}$vg/pup), and research grade at $1.7x10^{10}$vg/pup (n=7-9/group). Compared to dose-matched research grade vector, pre-cGMP vector had increased potency showing significant improvements in open field parameters at 4 and 12 weeks. No in-life adverse effects were observed in both pre-cGMP and research vectors, and at all doses evaluated. Overall, our data demonstrates pre-cGMP vector superiority in purity and *in vivo* potency, supporting successful scale-up manufacturing towards cGMP applications.

825 Optimized Automated DNA Extraction: A Pathway to Improved Patient Monitoring in CAR-T Trials

Joël Meyboom[1], Sjoerd Ingelse[1], Ilse Wolters[1], **Karthikeyan Devaraju[1]***
[1]Cerba Research, Rijswijk, Zuid-Holland, Netherlands
**Corresponding Author*

Chimeric Antigen Receptor T- cell (CAR-T) therapies are key gene therapy for both oncology and autoimmune diseases. CAR T-cells as well as TCR-T therapies are produced by stable integration of the CAR/TCR transgene constructs in the genome predominantly by lentiviral /retroviral vector transduction. The use of viral vectors and transgene integration in the genome need monitoring of patients treated with CAR -T therapies for replication competent lentivirus/retrovirus (RCL/R) and vector copy numbers (VCN).

CAR therapies can be autologous or allogeneic cell therapies. In both cases, patients must undergo lymphodepletion before being treated with CAR-T therapies. As a result of this lymphodepletion, patients have little to no nucleated cells within the first few days' post infusion of therapy. RCL/R and VCN are monitored at specific time points before and after CAR administration. In particular, VCN is done from the first few days to 4 weeks of CAR therapy. In this window, only a limited amount of DNA is available before recovery of the lymphocytes including the CAR-T cells in the subject. To ensure sufficient DNA is available for CAR monitoring during the first 2 weeks, DNA should be extracted using as much sample input volume as possible. This poses challenges to any automated extraction procedure as well as for efficiency of downstream molecular assays.

We optimized our standard automated DNA extraction procedure with sample input volumes <0.5 mL and managed to increase sample input volumes above 1 ml and elute DNA in volumes sufficient to enable efficient RCL/R and VCN detection directly (n=5 different donor samples). The RCL/R results showed a CV <20% for all copies tested within the quantification range, while the VCN data showed a CV <20% for >50 copies/PCR and a CV< 40% for copies <50 copies/PCR. The results from both our standard and optimized workflows are comparable and demonstrate no impact on molecular assay performance. This provides us with a scalable workflow that can handle different volumes of clinical samples, both above and below 1 ml. The workflow is being tested for other sample matrices and being validated for clinical sample testing.

826 Assessment of an Automated, Multi-dimensional Digital PCR Workflow for the Rapid Evaluation of Recombinant AAV Genome Integrity.

Jens Stolte[1], Thierry Schuepbach[2], **Luca Nanni[3]**, Alexandre Felix[4], Nicolas Mermod[4], Efrain Guzman[3]
[1]NewBiologix SA, Epalinges, Vaud, Switzerland, [2]NewBiologix SA, Epalinges, VD, Switzerland, [3]NewBiologix, Epalinges, Vaud, Switzerland, [4]NewBiologix SA, Epalinges, Switzerland

Digital PCR (dPCR) is the gold standard for quantifying recombinant adeno-associated virus (rAAV) vector following production because of its ability to deliver absolute and precise measurements of viral genome titers without a need for external standards. Its multiplexing capability enables the simultaneous detection of multiple genomic regions, providing critical insights into rAAV genome integrity through co-localization analysis. However, dPCR has a narrow dynamic range primarily due to the fundamental principles of its operation and the statistical constraints of its partitioning-based quantification method, which necessitates testing multiple dilutions of each sample to avoid errors from subsampling or saturation.

After capsid lysis, the released single-strand rAAV genome is fragile and prone to degradation. It is hypothesized that the measured integrity by multi-dimensional dPCR underestimates the actual rAAV integrity due to sample treatment during and after capsid lysis. Manual preparation of dPCR samples is further complicated by the need for custom multiplexed primer/probe sets for different rAAV genomes and for varying dilution strategies for both crude and purified samples across different production stages. This complexity makes manual workflows labor-intensive, error-prone, and difficult to scale.

To overcome these challenges and obtain consistent results, variations in sample preparations must be minimized, highlighting the need for robotic systems. We have developed an automated workflow using a cost-effective benchtop robotic system to streamline dPCR sample preparation for rAAV quantification. The system automates DNase digestion of the cellular DNA, capsid lysis, serial dilutions, and the preparation of dilution-optimized samples with the appropriate dPCR mix, ready for analysis. By eliminating manual preparation challenges, this method improves efficiency, consistency, and accuracy while enabling the simultaneous processing of diverse rAAV sample types on a single dPCR plate. This approach, together with a custom downstream data analytics software, makes dPCR workflows more accessible and scalable in the context of rAAV production analytics.

This automated workflow for multi-dimensional PCR is used alongside long-read sequencing technologies for the quality assessment of AAV-based gene therapy product candidates.

827 High-Coverage Whole-Genome Sequencing Reveals Adverse CRISPR Editing Events in Human HSPCs Targeted by Therapeutic gRNAs

Ayal Hendel[1], **Nechama Kalter[2]**, Michael Rosenberg[3], Gila Lithwick-Yanai[4], Sarah Pollock[4], Zohar Shipony[4]
[1]Bar Ilan University, Ramat-Gan, Tel-Aviv, Israel, [2]Bar-Ilan University, Ramat-Gan, Israel, Israel, [3]Bar-Ilan University, Ramat-Gan, Israel, [4]Ultima Genomics, Newark, CA

CRISPR-Cas genome-editing technology is rapidly advancing into diverse clinical applications for the treatment of various diseases. However, its therapeutic use requires a thorough assessment of potential adverse editing outcomes at both on-target and off-target sites. These outcomes include insertions and deletions at target and non-target sites, as well as structural variations (SVs) such as long deletions, inversions, translocations, and copy number variation (CNV). Such events can result in harmful genomic rearrangements, which, if they confer a selective advantage, may promote clonal expansion and drive tumorigenesis. Therefore, precise and robust detection methods are essential to evaluate the safety and efficacy of CRISPR-based genome-editing therapeutics.

The gold-standard approach for quantifying adverse genomic effects relies on targeted amplification followed by deep sequencing of pre-selected sites. However, this method requires an extensive preliminary nomination of potential off-target sites, is limited to analyzing only a few hundred regions, and demands the design and optimization of custom primers for each target. Furthermore, targeted sequencing is inherently constrained in its

ability to detect all types of large-scale genomic rearrangements, such as inversions and chromosome loss. Fish-and-bait methods enable broader detection but are restricted to pre-designed bait sequences. Amplification-based long-read sequencing (LRS) can identify large-scale SVs but remains limited to selected targets and is subjected to amplification bias. While amplification-free LRS eliminates this bias, it suffers from low read yield and is still target-specific, further limiting its utility for unbiased, genome-wide analysis.

A promising solution to the challenges of detecting adverse genomic effects lies in the application of whole-genome sequencing (WGS). This unbiased, genome-wide approach is versatile, applicable to all cell types, and capable of detecting a comprehensive range of CRISPR-editing events. However, traditional WGS methods have been constrained by high costs and insufficient coverage, limiting their utility for identifying low-frequency events. We have advanced WGS capabilities by utilizing Ultima, a sequencing technology that delivers dramatically reduced costs, enabling ultra-high coverage (up to 1000×) as the new standard for evaluating and understanding Cas9 on-target and off-target effects.

Leveraging this technology, we conducted high-coverage WGS on CRISPR-edited human hematopoietic stem and progenitor cells (HSPCs) modified with CRISPR-ribonucleoprotein (RNP) complexes, with gRNAs used in clinical studies, including the Casgevy gRNA—the first FDA-approved CRISPR-based therapy. This analysis revealed a diverse spectrum of genomic aberrations, including various genomic rearrangements at the cut-sites, that are challenging to identify using targeted approaches. This study highlights the wide range of potential genomic alterations caused by CRISPR editing and emphasizes the vital role of unbiased, high-coverage approaches in their detection. By enabling a streamlined, one-step, and comprehensive assessment of genomic integrity, WGS-based approach represents a major advancement in ensuring the safety of CRISPR-based cell therapeutics.

828 Simultaneous measurement of viral vector titer and genome integrity with long-read amplicons enabled by Countable PCR

Michael Balamotis[1], **Eleen Shum[1]**, Haeun Lee[1], Emily Blair[1], Kyle Kim[1]
[1]Countable Labs, Palo Alto, CA

We introduce Countable PCR, a novel platform that enables genome integrity and viral titer characterization, including long-read amplicons, within a single assay, with high sensitivity and low variability. Current methodologies in the field present notable drawbacks for providing reliable viral titer measurements: qPCR is too variable; and dPCR suffers from a narrow dynamic range, high Poisson errors, and arbitrary thresholding. Further, it is impossible to conduct both titer and genome integrity assessments in a single assay, as dPCR has partitioning limitations. Countable PCR overcomes these challenges by directly counting single molecules.

Here, we demonstrate the value of direct molecule counting by designing a novel multiplex assay that interrogates different regions of the gene of interest (GOI) to accurately quantify the ratio of partial vs. complete transgene while simultaneously measuring titer in the same sample. Unlike dPCR, this single-molecule approach prevents false co-occupancy of fragmented, unlinked targets, ensuring accurate genome integrity data. Full genome integration is further validated with the ability to analyze long-read amplicons, which we demonstrate here up to 2000 bp. Together, this work demonstrates how Countable PCR makes gene therapy viral characterization workflows more versatile and approachable compared to legacy methods.

829 The Good, the Bad, & the Chimeric: Using Nanopore Sequencing to De-Risk rAAV Genome Packaging

Kathrin Breunig[1], Florian Dunker-Seidler[2], Magdalena Haubner[3], **Florian Sonntag[2]**, Markus Hoerer[4], Rebecca Feiner[5]
[1]Ascend Advanced Therapies GmbH, Planegg, Bavaria, GERMANY, [2]Ascend Advanced Therapies GmbH, Planegg-Martinsried, Bayern, Germany, [3]Ascend Advanced Therapies GmbH, Planegg-Martinsried, GERMANY, [4]Ascend Advanced Therapies GmbH, Planegg-Martinsried, Germany, Germany, [5]Ascend Advanced Therapies GmbH, Planegg, Germany

Adeno-associated virus (AAV) vectors are widely used in gene therapy due to their efficacy and safety. The vast majority of AAV capsids contain the correct vector transgene ("the good"), but a small fraction harbors unwanted DNA sequences. These packaged DNA impurities ("the bad") are derived from the biological starting materials used to manufacture AAV, e.g. plasmids used in transient manufacturing platforms, or viruses used for infection-based manufacturing and from the manufacturing cells. Fortunately, their safety implications are mitigated to some extent by the absence of inverted terminal repeats (ITR) which prevent episomal persistence in the transduced cells, reduce the risk of double-strand formation of DNA impurities and, therefore, limit the risk of (persistent) expression of impurities in patient´s cells.

However, chimeric reads, i.e. hybrid DNA sequences with ITRs and contaminants arising from vector recombination or bidirectional ITR packaging, could be rapidly transcribed into translationally active double-stranded DNA molecules that may persist in transduced cells for years raising safety concerns with respect to immunogenicity and cell transformation when comprising oncogenic sequences. To this end, a deeper understanding of their origins and implications is needed. Here, we report a thorough characterization of more common DNA impurities derived from plasmid backbone and host cell DNA sequence packaging, and of very rare sequences such as HCD-ITR and rep-ITR fusion sequences in a rAAV9 vector batch.

Using Illumina and nanopore deep sequencing we examined the identity, origin, and abundance of various classes of chimeric reads using proprietary analysis pipelines. We speculate on their biological relevance and potential to impact gene therapy. Finally, we present strategies demonstrating how comprehensive analytical approaches can mitigate risks associated with packaged DNA impurities.

830 A Novel Reference Standard for Assessing AAV Titer and Genome Integrity

Andrzej Noyszewski[1], Alex Deiulio[1], James Qin[2], James Brown[1]
[1]Agathos Biologics, Fargo, ND, [2]QIAGEN Sciences LLC, Germantown, MD

Introduction: Viral vectors hold great promise for treating a broad array of genetic conditions by enabling the delivery of therapeutic genes into target cells. We developed a reference standard for evaluating adeno-associated virus (AAV) titer and genome integrity, incorporating polymerase chain reaction (PCR) target sites, including the Bovine Growth Hormone Polyadenylation Signal (bGHpA), Woodchuck Hepatitis Virus Posttranscriptional Regulatory Element (WPRE), Cytomegalovirus (CMV) Enhancer and Promoter, Green Fluorescent Protein (GFP) reporter gene, Simian Virus 40 Polyadenylation Signal (SV40pA) and Promoter, and Human Growth Hormone Polyadenylation Signal (hGHpA). These targets, evenly distributed across the AAV genome, allow for comprehensive titer and genome integrity assessment (GIA). The reference standard also incorporates the Green Fluorescent Protein (GFP) reporter gene.

Material and Methods: A cross-site evaluation of genome titer and GIA of the rAAV8 lot produced in AE1-BHK cell line containing the reference standard as the genome was performed. Titer and genome integrity were assessed with the use of QIAcuity Cell and Gene Therapy (CGT) dPCR Assays, with use of QIAcuity Digital PCR System. Qiagen CGT Viral Vector Lysis Kit was used to perform capsid lysis, and no restriction digestion was performed. Titer was measured in duplex reactions with the following target sets (Figure 1): Duplex 1 (CMV Promoter, GFP, fragment length ~1.5kbp), Duplex 3 (WPRE, SV40 Promoter, fragment length ~2.6kbp), and Duplex 4 (bGHpA, hGHpA, fragment length ~3.5kbp).

Results: The mean AAV genome titer based on all targets was determined to be 1.13×10^{13} vg/mL ± SD 2.98×10^{12}. We compared results of our standard analytics that accompany a certificate of analysis (COA) and partnered with Qiagen as an outside vendor to validate in parallel. These data showed reproducibility between both groups and the percentage differences in titer obtained from duplex reactions for Duplex 1, 3, and 4 between Agathos Biologics and Qiagen laboratories ranged from ~2% to ~15%. dPCR targets located at the distal ends of the AAV genome (bGHpA, hGHpA, near the ITR regions) were lower than those determined for regions positioned closer to the center of the AAV genome. Genome integrity analysis showed similar percentages of AAV genome intactness, with cross-site precision (%CV) of 11%, 4%, and 53% for Duplex 1, 3, and 4, respectively. Intra-assay precision (%CV) was below 20% for both Agathos and Qiagen data. The results indicated the highest percentage of intact

genomes for shorter fragments (fragments 1.5 kbp and 1.9 kbp (Agathos Biologics data only)) near the position of the gene of interest (GFP), with lower percentages of genome intactness for targets located near the ITR region.

Conclusions: Cross-site evaluation of the rAAV8 sample with the reference standard showed similar titer and genome intactness results. The lower percent genome intactness at distal regions may indicate PCR inhibition from ITR secondary structures, as reported previously, and/or AAV genome truncation. Further optimization and standardization of genome integrity protocols are needed to reduce inter-laboratory variation.

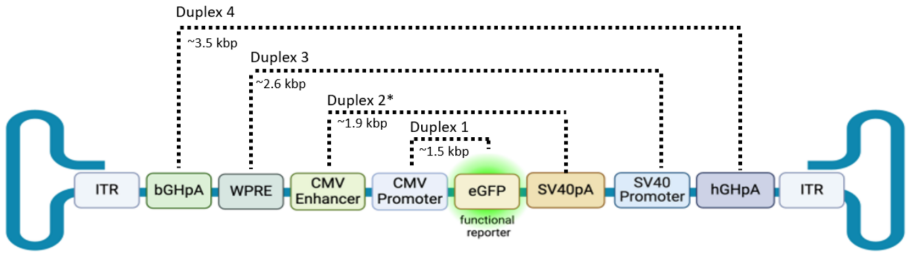

Figure 1. Graphical representation of the rAAV standard and dPCR assays used. The figure illustrates the types of duplex assays employed to evaluate titer (vg/mL) and genome integrity of the rAAV standard in a cross-site evaluation (*Duplex 2 not included in the cross-site evaluation). The duplex assays include Duplex 1: CMV Promoter and GFP (fragment length ~1.5 kbp); Duplex 2: CMV Enhancer and SV40pA (fragment length ~1.9 kbp); Duplex 3: WPRE and SV40 Promoter (fragment length ~2.6 kbp); Duplex 4: bGHpA and hGHpA (fragment length ~3.5 kbp). Image not drawn to scale.

831 Nanopore Sequencing and Screening of AAV Genomes for Optimal Production and Function

Dhruv Prasad[1], Keith Connolly[2]
[1]Modalis Therapeutics, Watertown, MA, [2]Modalis Therapeutics Inc., Cambridge, MA

Adeno-associated virus (AAV) has become a popular tool for gene therapy due to its ability to safely and efficiently deliver genetic elements to multiple tissue types in vivo. Genetic elements with a total size within ~4.7 kilobases (kb) can be assembled between two ITRs, packaged into AAV particles, and be used to deliver expression cassettes to animal and human tissues.

Production of AAV particles can be challenging and result in a heterogeneous mixture of capsids with complete and incomplete genomes, which can increase the amount of virus needed to achieve the desired expression in vivo. Indeed, sequence elements have been shown to impact packaging of complete AAV genomes, though a thorough characterization of how sequence affects AAV genome packaging is not available. Here we sought to develop a system to 1) identify truncated AAV genomes and the underlying sequence elements responsible for inefficient AAV genome packaging, and 2) evaluate how these sequence elements impact AAV manufacturing and transduction using a high-throughput assay system. To this end, we have established a pipeline where AAV genomes are evaluated by gel electrophoresis and sequencing using the Oxford Nanopore Technology (ONT) platform, and pooled libraries of AAV plasmid constructs are evaluated for manufacturing and transduction potential using bulk and single-cell sequencing. This pipeline identified a promoter sequence element that was detrimental to AAV manufacturing and transduction. The approach presented herein can be used to select AAV constructs with properties needed for safe and effective gene therapies destined for the clinic.

832 Improved Quantification of Adeno-Associated Virus (AAV) Viral Genome Using Nanoneedle Technology for Enhanced Molecular Specificity

Qimin Quan[1]*, Angad Garg[2], Tal Raz[3], Eli Litton[3]
[1]NanoMosaic LLC, Waltham, MA, [2]NanoMosaic LLC, Newton Highlands, MA, [3]NanoMosaic, Waltham, MA
**Corresponding Author*

Introduction: Recombinant adeno-associated virus (rAAV) exhibits significant heterogeneity throughout the manufacturing process. Accurate quantification of capsid and genome titers, particularly the integrity of the viral genome, is crucial for ensuring the efficacy and safety of gene therapies. Current methodologies (analytical ultracentrifugation [AUC], electrophoresis, and molecular assays, such as PCR and ELISA), often fall short in distinguishing between full-length viral genomes and truncated or partial genome fragments, which impacts the interpretation of AAV vector quality.

Methods: We developed a novel viral genome assay utilizing a nanoneedle technology on the Tessie platform. Tessie enables accurate and highly reproducible quantification of full-length transgenes and offers molecular specificity to distinguish those from long partial genomes of similar sizes. In our study, Tessie's performance was compared to established methods, including ELISA for capsid titer, droplet digital PCR for genome titer, and AUC and electrophoresis for assessing viral genome integrity. A reference AAV sample, potentially containing a high level of full-length genomes along with a certain level of contamination from long partial genomes, was analyzed using all platforms. This comparison aimed to evaluate Tessie's ability and accuracy in identifying and quantifying distinct viral species within heterogeneous AAV preparations.

Results: The AUC characterization displayed a single peak (**Fig. 1a**), suggesting that the predominant species accounts for 70% of the total population. In contrast, electrophoresis revealed multiple side bands, highlighting the heterogeneous nature of the sample. When quantifying the area under the curve within the 3-5 kb size range, electrophoresis indicated that less than 11% of the total population corresponds to the full-length viral genome size **(Fig. 1b**). We hypothesize that the discrepancy between AUC and electrophoresis results arises from the presence of a significant population of long partial genomes that are similar in size to the full-length viral genome. On the Tessie platform, we developed two assays: the full-length transgene assay, which specifically quantifies the titer of the full-length viral genome (4.3 kb), and the long partial transgene assay, which quantifies left-truncated partial transgenes (3.9 kb). Additionally, we quantified the capsid titer on the same platform, enabling us to calculate the empty/full/partial ratio. When accounting for the long partial genome populations, the empty/full ratio aligns well with the AUC characterization. Furthermore, the pure full-length population corresponds more closely with the electrophoresis results.

Conclusions: Our results demonstrate that traditional methods, such as AUC, can misclassify long partial genome subpopulations as full-length viral particles due to their limited ability to distinguish between full-length genomes and truncated transgene variants. In contrast, Tessie's quantification method exhibited a high degree of correlation with molecular methods, including ELISA and ddPCR, and effectively reconciled the discrepancies observed between different biophysical methods, such as AUC and electrophoresis. The new methodology enables accurate quantification of viral genomes, distinguishing full from partial genomes, thus enhancing the development and production of AAV-based gene therapies.

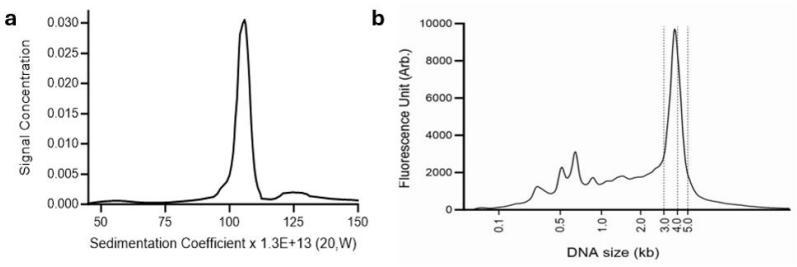

Fig. 1: **a**. AAV9 samples were analyzed using a sediment velocity analytical ultracentrifuge at 20,000 rpm, equilibrated at 20°C for 1 hour. Absorbance at 230 nm was then measured. **b**. AAV9 sample was DNase I treated, lysed by heat treatment, purified by AMPure XP beads, and analyzed on the Tapestation with a denatured double-stranded DNA size ladder. The sizes of the dsDNA ladder are shown and should serve as a rough approximation of fragment sizes. The dotted lines specify the region overlapping the peak.

833 Comprehensive Integrity Assessment of rAAV Batches Through an Integrated Workflow Coupling Long Read Sequencing with Multiplex dPCR

Matteo Franco[1]*, Maria Intermaggio[1], Emilia Esposito[2], Zachary Murphy[1], Manuel Philip[3], Paul Byrne[4], Saira Afzal[5], Raffaele Fronza[6], Richard Gabriel[5]
[1]ProtaGene US Inc., Burlington, MA, [2]Heidelberg, Germany, [3]ProtaGene CGT GmbH, Heidelberg, Baden-Wuerttemberg, Germany, [4]ProtaGene, Burlington, MA, [5]ProtaGene CGT, Heidelberg, Baden-Wuerttemberg, Germany, [6]Tessera Therapeutics, Somerville, MA
**Corresponding Author*

While recombinant adeno-associated viral vectors (rAAV) are one of the leading platforms for gene therapy, the manufacturing process remains complex. The assessment of potential incomplete or truncated genomes and their effects on the safety and efficacy of the therapy is crucial. Several methods have emerged to support rAAV integrity analysis. Digital polymerase chain reaction (dPCR) allows for absolute quantification of AAV genomes and assessment of integrity by multiplexing up to six targets to cover the whole genome. While faster and cheaper, dPCR requires an upfront setup to establish primer sets and can only be used for quantification of known and expected targets. Long-read sequencing technologies extensively characterize the AAV genome, including sequence identity and identification of all packaged species, without the need for known targets. However, these methods only provide a relative quantification of full-length genomes. Here, we present a study where we evaluate the integrity of the AAV genomes packaged within a research-grade AAV9 control batch, with an expected length of 2,996bp.

We sequenced the rAAV batch on an Oxford Nanopore MinION. The vector capsids were sequentially digested with a combination of DNases and Proteinase K to release only the packaged DNA. The size distribution was assessed using automated electrophoresis before and after the material was converted into double stranded form. Results showed a reliable and consistent conversion, without alteration of the size distribution when looking at the single-stranded profile versus the double stranded profile. Next, the library was prepared for long read sequencing following the sequencing kit instructions for the V14 chemistry, with several optimizations for the expected size and type of molecule. A total of >2,5 million reads were obtained and further analyzed using an in-house pipeline. Most reads mapped to the genome (>85%), and most were at full length (2,900-2,996 bp). The second most frequent length size identified was at 100-200bp pointing to a possible presence of additional ITRs or truncation.

In parallel to the Nanopore efforts, to leverage dPCR multiplexing, we designed five primer sets spanning the whole AAV genome (ITR-UTR junction, 5' region of the promoter, promoter-transgene junction, transgene-polyA junction, and polyA-ITR junction). After establishment, these primers were used in a multiplex dPCR assay with part of the material extracted for the previous method, which was serially diluted down to 1E+03 cp, and added to a QIAcuity Nanoplate 8.5k 96-well plate. dPCR results were used to confirm the findings from the Nanopore data. Efforts to refine the accuracy of the quantification are currently ongoing, focusing on the de-multiplexing of occupancy data.

In summary, we have shown that coupling the long-read sequencing and dPCR enables an extended characterization of the vector particles and the genomes packaged, as well as accurate quantitation of full-length vectors.

834 Leveraging Next-Generation Sequencing for CMC of Gene and Cell Therapy Products

Thipa Asvarak[1], Ziwei Li[1], David Killen, Marcell Veidner[2], Thomas Hartsch[2], Qiu Ruan[3]
[1]Genedata Inc., Lexington, MA, [2]Genedata AG, Basel, Switzerland, [3]Genedata, Lexington, MA

In the rapidly evolving field of gene and cell therapies (CGTs), Chemistry, Manufacturing, and Controls (CMC) is instrumental. The development and production of these therapeutics present significant challenges, including shorter shelf life, Critical Quality Attributes (CQAs) assessment, manufacturing complexity, complex logistics and higher costs, and stringent regulatory compliance requirements. By harnessing the power of NGS technology, biopharmaceutical companies can produce high-quality CGTs that meet good manufacturing practice (GMP) requirements and clinical standards, ensuring that CMC concerns are addressed. Biopharma and biotech organizations can significantly reduce development timelines and improve product quality by using the NGS multi-attribute method (MAM) to monitor several CQAs of CGTs simultaneously for e.g., adventitious agent detection, vector integration, and genome integrity assessment.

Having a validated in-house environment is vital for the successful implementation of overarching NGS platforms. However, to successfully validate such platforms, teams need to consider variability in methods, instruments, and protocols, as well as robust data handling, and adherence to regulatory compliance. Strategic partnerships are crucial for success.

In this poster, we present three use cases from leading biopharmaceutical companies showing best practices for validation of NGS platforms in-house for CGT development.

835 Advancing rAAV Manufacturing with Long-Read Sequencing

Esko Kautto[1], Thomas Gregory[1], Dakota Sizemore[1], Apollinaire Ngankeu[1], Adam Davis[1], David Dismuke[1]
[1]Forge Biologics, Grove City, OH

Recombinant adeno-associated virus (rAAV) vectors require robust quality control to ensure patient safety and therapeutic efficacy. Conventional assays, such as restriction enzyme digests, denaturing alkaline gels, and PCR-based quantification, while valuable, often fall short in fully characterizing genome integrity, confirming sequence identity, and detecting contaminants. Many current sequencing-based approaches, particularly those based on Sanger and Illumina sequencing, rely on targeted or amplification-based methods, which may introduce biases or fail to capture the full complexity of vector populations. Next-Generation Sequencing (NGS), particularly long-read sequencing, offers a more comprehensive analytical approach to enhance detection of partial genomes, structural abnormalities, and unexpected contaminants throughout the rAAV production lifecycle.

Long-read sequencing using Nanopore technology serves as a key component of our rAAV characterization strategy throughout the manufacturing process, from research-grade plasmid screening to final cGMP drug product testing. This approach enables full-length genome characterization, structural variant detection, and contaminant analysis. By avoiding amplification biases, native DNA integrity is preserved, ensuring a more accurate representation of vector composition. Long-read sequencing offers detailed insights into plasmid integrity and rAAV vector composition, identifying partial genomes, heterogeneous populations, and unexpected structural variations.

For GMP-grade rAAV drug product testing, Illumina sequencing serves as an orthogonal method to confirm sequence identity and improve confidence in variant detection. Its lower per-base error rate allows for the precise identification of small sequence variants, including single-nucleotide polymorphisms (SNPs) and small insertions or deletions (indels).

Optimized DNA extraction and library preparation protocols maximize data accuracy and reproducibility within sequencing workflows. The data analysis workflow is performed using Forge's proprietary bioinformatics pipeline, which integrates read alignment, variant calling, and contaminant screening to provide a comprehensive assessment of genome integrity, purity, and sequence identity. These methodologies support both research applications and regulatory compliance, ensuring the reliability of rAAV vector characterization from early development through commercial manufacturing.

This approach enables comprehensive rAAV characterization throughout production, supporting confirmatory release testing and early detection of manufacturing inconsistencies before cGMP batch production. The ability to assess genome integrity, sequence identity, and contaminants provides valuable insights for refining vector production, guiding risk assessments, and ensuring regulatory compliance

836 Full Length Transgene Quantification Utilizing NanoMosaic Tessie Technology

Isabella Pajevic[1], Peter Webster[2]
[1]Solid Biosciences, Charlestown, MA, [2]Solid Biosciences, Cambridge, MA

Product characterization is a critical aspect of adeno-associated virus (AAV)-based gene therapy development, where accurate quantification of full-length transgenes and capsid titers is essential for maintaining consistent quality, safety, and efficacy. Currently the AAV field utilizes several approaches to quantify product integrity, including both molecular and biophysical methods. However, none of the currently available methods allow for genome integrity and capsid titer measurements on the same sample utilizing the same device. Combining data obtained from multiple systems compounds assay variability resulting in decreased accuracy, thereby lessening the value of the obtained results.

Traditional methods, such as qPCR and ddPCR, are limited in their ability to distinguish full-length genomes from truncated or fragmented sequences, and when combined with ELISA for capsid titer, suffer from compounded variability. Similarly, current methodologies for analyzing the empty/full capsid ratio, such as analytical ultracentrifugation (AUC), are not just labor-intensive, with a low assay throughput, they cannot identify what is being packaged. While these methods provide value at specific stages in the AAV production process, newer technologies are needed that can provide a more accurate quantification of true full-length vector genome. This abstract discusses advantages of using NanoMosaic's Tessie technology to identify full-length transgene and capsid titers in one platform.

The Tessie nanoneedle platform enables measurement of AAV transgenes and AAV capsids in one platform. The Tessie nano-plate nanoneedles are densely integrated on a silicon chip and are configured into 96 or 384 well format for high throughput workflows.

We report the development of a viral genome assay utilizing two affinity-tagged oligonucleotide probes to selectively bind specific regions of the transgene. Through limited primer extension, these probes incorporate into a double-stranded DNA product, enabling differentiation between full-length and truncated transgenes. Full-length genomes were detected by probes positioned at opposite ends of the therapeutic region, while truncated variants were identified using probes targeting suspected breakpoints. The resulting labeled DNA was quantified with high sensitivity using Tessie nanoneedle sensors, having more than 20,000 nanoneedles in each well, resulting in an accurate and scalable method for assessing AAV genome integrity.

Improvements to both the transgene and capsid assays for use on our custom capsid platform were made over traditional methods with the goal of providing an accurate and fast measurement of the empty/full ratio of our AAV products. For example, for the transgene assay, DNA probe sequences and locations along the transgene were enhanced to allow for quantification of full-length transgene; and capsid titer assay developed ligand/antibody identification, and standard curve. A combination of assays capable of characterizing the titer, genome integrity, capsid titer and empty/full ratio of AAV products compatible with samples from various process stages was developed.

837 Impact of Sample Collection Container Material, Hold Time, and Storage Temperature on Adeno-Associated Virus Endotoxin Testing

Amanda Zhang[1], Ayda Mayer[2]
[1]REGENXBIO Inc., Rockville, MD, [2]Regenxbio, Rockville, MD

Endotoxins are components of the outer membrane of gram-negative bacteria, and they are released upon cell lysis of the intact bacteria. The Inspection Technical Guide with the title "Pyrogens, Still a Danger" issued by U.S. Food and Drug Administration (FDA) in 1979, described the severe impacts of this pyrogen when injected in sufficient amount. Since endotoxin is a common contaminate found in biopharmaceutical product and that the amount of endotoxin in the product dose is critical, it is crucial to test the drug product samples to ensure the endotoxin level in parental solution is within the FDA's guideline of acceptance level. The questions we are trying to answer for the produced adeno-associated virus (AAV) material are: what would be the ideal sample collection container material, sample hold time, and sample storage temperature to safeguard the endotoxin data as consistently and accurately reflecting the endotoxin concentration in drug material? Also, do AAV serotypes play a role in endotoxin recovery in solution? Endotoxin recovery means the amount of endotoxin measured under different conditions versus the starting endotoxin measurement. There is limited literature on these topics, hence this study was conducted to better understand the best endotoxin testing practice for AAV.

Two common AAV serotypes were selected to verify any differences in endotoxin recovery between them. AAV samples were spiked in with an appropriate amount of Control Standard Endotoxin (CSE) to achieve comparable endotoxin concentration at time 0 of this study. A negative and a positive buffer control were included, where the positive control had similar starting endotoxin level as the spiked-in AAV samples. All these samples were tested in polypropylene and polystyrene collection containers because these two plastic materials are two of the commonly used sample collection container types. The samples were stored at three different temperatures: room temperature, 2-8ºC, and -80ºC. Then, they were measured at different time points in replicates. After all data was collected, statistical analyses were applied to check for outliers, significant differences between the data, and if there was a trend for the endotoxin recovery under different parameters.

Data indicates there is minimal difference for endotoxin recovery between polystyrene and polypropylene at 2-8ºC and -80ºC. However, at room temperature, endotoxin recovery in polypropylene sample collection containers is impacted more prominently than in polystyrene material. Data suggests the presence of AAV reduces the impact of storage temperature on endotoxin measurements for both plastic materials. This is particularly noticeable at -80ºC. Finally, regardless of which type of plastic material was used for the collection tube, or storage temperature, the endotoxin values reduced with time for both serotypes.

In summary, endotoxin measurements can be affected by sample container material, time of exposure to the container material, and storage temperature. The recovery differences between serotypes are not evident. Polystyrene is the preferred sample storage container, and testing time plays a role on the endotoxin levels measured. This study helped to determine the parameters to better test AAV samples that will yield results to more accurately reflect the endotoxin content in drug material.

838 Ultra-Cold Storage of Lentiviral and Adenoviral Vectors in Cyclic Olefin Polymer Containers

Vidya Murthy[1], Krishnendu Khan[2]
[1]West Pharmaceutical Services, Inc., Hokinton, PA, [2]West Pharmaceutical Services, Radnor, PA

Adenoviral (AdV) and Lentiviral (LV) vectors are major platforms for developing vaccines and cell and gene therapies. Ultra-cold storage of the adenoviral viral vectors can be helpful to ensure uninterrupted supply of vaccines in critical times such as a pandemic and in oncologic and advanced therapies. Lentiviral vectors are commonly used in cell therapy, in particular CAR-T cell generation. Thus, well-controlled ultra-cold storage of viral vector plays an important role in ensuring the quality of cell products.

Polypropylene (PP) vials and tubes have been commonly used as the primary container in research, but they may be not suitable for clinical manufacturing of drug products, due to concerns related to container closure integrity of the snap cap- or screw cap-based systems and high particle generation from the material. Cyclic olefin polymer (COP) vials may be helpful to overcome these challenges and maintain better drug safety, purity and efficacy.

2 mL Daikyo Crystal Zenith® (CZ) cyclic olefin polymer (COP) vials with bromobutyl serum stoppers and aluminum seals were compared to 1.8 mL PP screw cap vials and evaluated for the ultra-cold storage of Ad5-CMV-eGFP and Ad5.F35-CMV-eGFP viral vectors for 1 to 14 days. In a separate experiment, the vials were compared for the functional recovery of Lenti-GFP viral vectors, imitating a short-term storage condition and addressing potential concerns related to pH excursions upon exposure to and after removal from a dry ice-based shipping condition.

STUDY FINDINGS

- AdV physical recovery was higher from COP vials than PP vials particularly upon shorter terms of ultra-cold storage. In either vial types, functional recovery was comparable to fresh sample after 1 day but declined before 7 days.
- LV functional recovery was comparable between COP and PP vials, in ultra-low freezer or dry ice. There was significant functional titer loss after filling and immediately dispensing from the PP vials, whereas there was no significant loss from COP vials.
- COP vials can be a suitable alternative to PP vials for the cold chain containment of the growing generation of viral vector-based therapeutics.

Crystal Zenith is a registered trademark of Daikyo Seiko, Ltd. Crystal Zenith technology is licensed from Daikyo Seiko, Ltd.

839 Recombinant Animal Origin Free Albumin in Downstream Wash and Cryopreservation for CAR-T Cell Therapy Manufacturing

Andrew Hamann[1]*, Mark Stathos[2]
[1]InVitria, Junction City, KS, [2]Junction City, KS
**Corresponding Author*

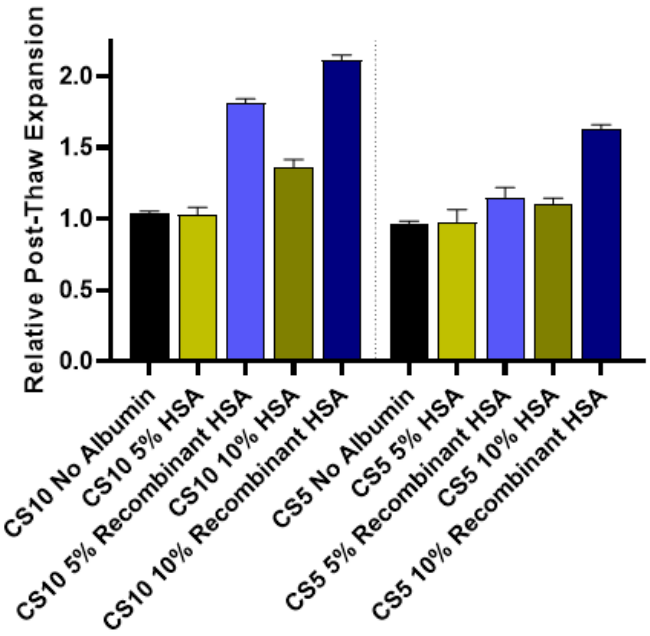
Background and Aims: Cryopreservation and cell washing are critical steps in T cell therapy manufacturing, where preserving T cell viability and key phenotypes is essential for therapeutic success. Traditional cryopreservation media and washing buffers often use clinical blood-derived human serum albumin (HSA), which presents safety, regulatory, and supply chain challenges. Recombinant human serum albumin (rHSA) produced in an animal free expression system, offers a safer, more consistent alternative. This study aimed to evaluate the efficacy of rHSA in enhancing T cell cryopreservation and improving post-wash T cell retention while maintaining CD4/CD8 ratio, memory phenotype, and proliferative capacity.

Methodology: Primary human T cells from two healthy donors were cryopreserved in commonly used formulations containing 5 or 10% DMSO with varying concentrations of rHSA (0%, 5%, or 10%) or clinical HSA. Post-thaw, T cell viability, proliferation, and memory phenotypes (Tscm, Tcm, Tem, Temra) were assessed over 72 hours using live-cell imaging and flow cytometry. For cell washing, T cells were thawed, activated, and washed three times with 1% or 5% rHSA or clinical blood-derived HSA solutions in PBS. The CD4/CD8 ratio, memory phenotypes, cell retention, and post-wash proliferation were evaluated immediately after washing and after three or six days of culture.

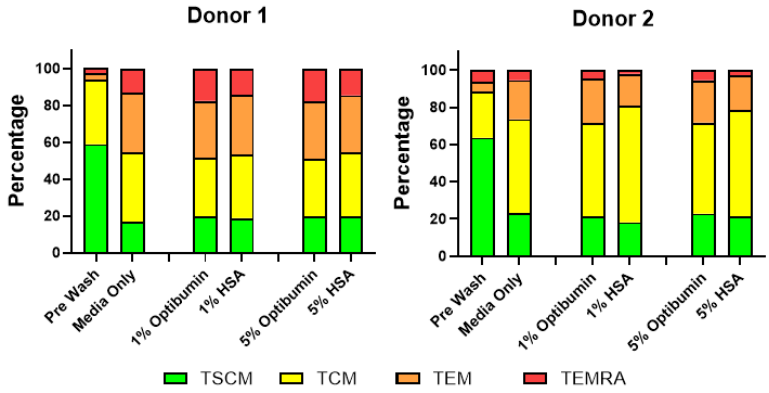
Results: In cryopreservation, rHSA significantly improved T cell recovery and proliferation compared to controls. Animal origin free rHSA also reduced final DMSO concentrations, improving the safety profile. The rHSA preserved early memory phenotypes (Tscm and Tcm) comparably to clinical HSA and helped maintain a balanced CD4/CD8 ratio by mitigating CD8+ T cell loss. In the washing process, rHSA significantly improved cell retention,

preserved the CD4/CD8 ratio, and maintained early memory phenotypes (Tscm and Tcm). These cell washing experiment results were also comparable to clinical HSA.

Conclusion: Animal origin free rHSA significantly improved T cell cryopreservation outcomes by enhancing viability, proliferation, and preserving phenotype, while reducing DMSO concentrations. It also improved cell retention during washing and preserved T cell phenotype, supporting critical early memory phenotypes essential for CAR-T therapies. As an animal origin free alternative, rHSA addresses regulatory and safety concerns, providing consistent performance for both cryopreservation and washing steps in cell therapy manufacturing.



Normalized T cell expansion after 72 hours post-thaw, comparing cryopreservation conditions inCS10 (10% DMSO) and CS5 (5% DMSO) with no albumin, 5% or 10% rHSA (recombinant human serum albumin), or a clinically used blood-derived HSA. rHSA enhanced post-thaw expansion in a dose-dependent manner.



Proportions of stem cell memory (Tscm, green), central memory (Tcm, yellow), effector memory (Tem, orange) and terminal effector memory (Temra, red) cells in T cells from two different donors. Flow cytometry analysis performed before the wash step (*Pre-Wash*) and on Day 3 post-wash using 1% and 5% concentrations of either *Optibumin* or Clinical HSA.

840 Development of In Vitro Potency Assay for AAV-mediated Gene Therapy for Muscular Dystrophy

Shibi Likhite[1], Jean Zhang[1], Emma Frair[2], Liubov Gushchina[3], Hui Lin[1], Jacob Lay[2], Joseph Beljan[1], Kevin Flanigan[4]
[1]Nationwide Children's Hospital, Columbus, OH, [2]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [3]The Ohio State University and Nationwide Children's Hospital RI, Columbus, OH, [4]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH

Adeno-associated virus (AAV)- mediated gene therapy has accelerated the therapy development for muscle disorders in recent years. AAVs with multiple modalities including gene replacement, knockdown, CRISPR and exon skipping, are at the forefront of delivering these therapeutics for patients with Muscular Dystrophy. With many of these programs gearing up for the in-human clinical trials, potency determination of the clinical grade AAV therapeutic remains one of the crucial aspects of the vector release as well as continued stability testing. For most of the current AAV serotypes, the potency assessment is currently performed in vivo in rodent models of the disease, which is extremely time consuming, labor intensive and expensive. Thus, there is critical need for the development of a robust and quantitative in vitro cell based assay for potency determination. Unfortunately, the current vectors in use (especially AAV9) do not readily transduce the cells in vitro. In the current study, we have developed a method to determine the potency of AAV9 vector in vitro using patients-derived fibroMyoD (FM) cell line from healthy donors and patients with Duchenne Muscular Dystrophy (DMD), as well commercially available primary myoblasts. We show that this method can be utilized to determine the dose dependent increase of expression of the therapeutic protein or exon skipping upon transduction of AAV9 vector at increasing multiplicity of infections (MOIs). This novel method is suitable not only for initial determination of efficacy of the vectors, but also for the potency determination of clinical grade vectors for release testing, lot-to-lot variability testing and stability.

841 pART Platform Process for Plasmid Manufacturing: Scalable, Robust, and Built for Tomorrow's Therapies

Alan Eduardo Castillo[1]*, Dustin Brüske[2], Björn Krüger[3], Sandra Wenzel[2], Carola Schröder[2], Anke Eichmann[3], Michael Schmidt[4], Christoph Köly[4], Carolyn Delto[5], Denis Runge[6], Michael Küchler[2], Sebastian Damerow[7]

The demand for plasmid DNA (pDNA) in different qualities has grown substantially in recent years, as it plays a critical role in the rapidly expanding sector of next generation vaccines and therapies. It acts as an active pharmaceutical ingredient (API) in DNA vaccines and cell and gene therapies (C>), as a critical raw material in the production of viral vectors, and as a template for therapeutic mRNA. Meeting the growing demand for pDNA and securing a reliable supply chain require the development and validation of robust platform manufacturing processes. These processes must deliver consistent quality across various scales, while complying with stringent regulations and remaining cost effective.

Manufacturing processes based on the fermentation of *E. coli* as a host have proven to be the most reliable method for industrial pDNA production, offering flexibility, robustness and scalability to bioreactors of several thousand liters. *E. coli* grows rapidly in inexpensive media and produces large quantities of pDNA within short timeframes. A typical manufacturing process consists of three main stages: the fermentation of *E. coli* in a bioreactor (USP – Upstream processing), cell lysis and clarification of the pDNA containing supernatant (MSP – midstream processing), and the use of advanced purification techniques (DSP – downstream processing) for the recovery of highly purified supercoiled (SC) pDNA, which is widely recognized as the therapeutically most relevant isoform.

The development of a robust and cost-effective platform process involves addressing several challenges in a systematic manner. While growth medium optimization and the use of sophisticated feeding strategies can be used to increase output and volumetric productivity during the USP, the produced pDNA molecules are large and sensitive to mechanical stress, which can ultimately lead to changes in their topological form. This, coupled with the increased viscosity of high cell density lysates, makes standard clarification methods, such as those using depth filters or hollow fibers, particularly difficult. Additionally, the target SC pDNA must be purified from a complex mixture of host cell proteins (HCP), genomic DNA (gDNA), endotoxins and unwanted pDNA isoforms. Some of these contaminants share similar physicochemical properties, comparable sizes, or a net negative surface charge. The pART process was developed to overcome all these issues in a ready-to-use approach, offering tailored solutions for pDNA supply that ensure consistent quality from small to large scales. These results have been demonstrated for plasmid sizes ranging between 3 to 19 kb.

842 Risk Assessment for Cross-Contamination of Plasmids Used for AAV Production

Plasmid transient transfection is a fast and flexible method to produce adeno-associated virus (AAV) used as a gene therapy vector. Recently, health authorities have highlighted cross-contamination between different plasmids produced in multi-product plasmid facilities as a potential safety risk for gene therapy products. This study examines factors influencing the safety risk of plasmid cross-contamination between AAV products.

There are three general types of plasmids used to produce AAV products through triple transfection: 1) gene-of-interest (GOI) plasmids encoding a transgene flanked by inverted terminal repeats, 2) plasmids encoding AAV *rep* and *cap* genes, and 3) plasmids encoding adenovirus helper genes. From a patient safety perspective, the highest risk scenario is cross-contamination of an AAV GOI plasmid into another plasmid used for production of a different AAV product. Such a contamination event results in production of an AAV capsid capable of delivering a contaminant transgene to patients. Within the AAV process, plasmid ratios and relative titer of contaminant and contaminated plasmid both impact the concentration of contaminated AAV product found in an AAV drug substance. The risk to the patient is further influenced by the toxicity of the contaminant transgene and the dose of the contaminated product.

The risk from cross-contamination in multi-product plasmid production facilities can be mitigated by employing cleaning solutions which degrade plasmid DNA. While it is a common practice to use NaOH to clean equipment in plasmid facilities, we provide data demonstrating that NaOH does not robustly degrade plasmid DNA. To address this gap, we will show data on an alternative cleaning solution which degrades plasmid DNA more effectively.

Finally, we consider all these factors in a case study using the GOI plasmid pGOIx as a model contaminant. pGOIx is used to produce the AAV gene therapy product GOIx, and clinical data from the GOIx program was used to perform the safety assessment. The outcome of the pGOIx case study is that the risk to patients from plasmid cross-contamination of pGOIx into other AAV plasmids is low, as long as appropriate cleaning and changeover procedures are used in the plasmid production facility. This safety assessment requires product toxicity data and production process parameters which may not yet be available in other AAV products prior to plasmid production. Thus, it should not be expected that a safety assessment such as this will be performed to justify routine plasmid changeover; rather, this case study is intended to aid plasmid and AAV manufacturers in reducing the risk of plasmid cross-contamination by highlighting relevant risk factors.

843 Advanced Plasmid Linearization Using Type I and Type II Restriction Enzymes: A Scalable, High-Purity Platform for Cell and Gene Therapy Applications

Charlie Fan[1], Justin Chen[1], Philemon Asfeha[2], **Rui Tang[3]***, Pawan Bhatt[4]*, Delicia Henriques[4]

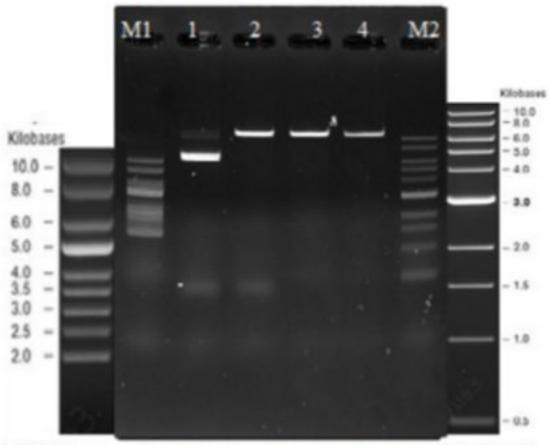
Plasmid DNA serves as a critical starting material for cell and gene therapies due to its ease of design, low production costs and high stability for long term storage.1 Today, plasmids are used to manufacture several advanced therapies which include DNA vaccines, viral vectors (AAV and LVV), mRNA therapies and vaccines, transient protein therapies (mAbs) and gene modified therapies, such as CAR-T.2 For some processes, plasmids are linearized as this can increase transfection efficacy, improve accessibility for transcription and allow for enhanced gene expression for non-viral delivery therapies.1 ProBio has developed a 3-step platform plasmid purification process for the purification of supercoiled plasmid DNA with capabilities of generating greater than 90% supercoiled plasmid with endotoxin levels less than 10 EU/mg. When followed by plasmid linearization, the entire process has a quick turnaround time of 4 weeks.

The linearization process is done by using restriction enzymes to cut circular plasmid DNA at specific sites, which transforms it into a linear plasmid.3 Restriction enzymes are categorized into three classes, Type I, Type II and Type III. In this poster, we demonstrate our plasmid linearization capabilities using Type I and Type II enzymes for three plasmids with our platform process. Type I enzymes were used to linearize LVV plasmid NF04 and pHelper plasmid JGIA, respectively. Type II enzymes were used to linearize a polyA plasmid, referred to as, Plasmid A. The plasmids were incubated with the enzymes for 16-20 hours until digest was completed and purified using mixed modal Capto Core 700 resin. Figure 1 shows Agarose Gel Electrophoresis results for undigested and linearized JGIA respectively. Our Analytical data summarized in Table 1 confirms that the purified supercoiled and linearized plasmids (NF-04, JGIA, Plasmid A) have >95% purity which meets current FDA standards. Further, the current platform plasmid linearization process has a recovery rate of >40%, host cell protein impurities less than 1% and endotoxin level less than 10 EU/mg. In all cases, we were able to remove undigested non linearized plasmid using mixed modal chromatography resin and able to achieve 100% linear plasmid as the final product.



M1: Supercoiled DNA Ladder Marker (NEB:N0472s)
M2:1kb DNA Ladder (NEB:N0550S)

844 Revolutionizing Plasmid DNA Production: A Chromatography-Free, High-Yield, High-Quality Platform

Jizhi Xie[1], **Lijun Wang[2]**
[1]Hangzhou CoJourney Bio Ltd., Hangzhou, Zhejiang, China, [2]CoJourney, Lower Gwynedd, PA

Background: Plasmids are indispensable tools in the cell and gene therapy (CGT) field, serving as critical raw materials for advanced therapies such as viral vector production and enabling the delivery of therapeutic genes. Their ability to carry and express genetic information has revolutionized treatments for genetic disorders, cancers, and infectious diseases. Despite significant advances in plasmid design and delivery systems, downstream processing remains a major bottleneck in plasmid biomanufacturing. Traditional reliance on multiple chromatographic steps often leads to low yields, high costs, and operational complexity, underscoring the need for innovative solutions to streamline production while maintaining high-quality standards.

Methods: In this study, we developed and validated a novel, chromatography-free plasmid purification platform designed to produce therapeutic-grade plasmid DNA with reduced processing complexity and manufacturing costs. The platform was optimized through three key innovations: (1) enhanced alkaline lysis conditions informed by a

mechanistic understanding of cellular disruption and precipitation dynamics, (2) controlled solid-liquid separation to preserve precipitate integrity, and (3) development of control strategies to minimize supercoiled to open circular plasmid conversion and (4) novel approach for selective removal of open circular plasmid during purification.

Results: The optimized platform technology consistently preserved high supercoiled plasmid integrity while efficiently removing host cell-derived contaminants and controlling product-related impurities, such as open circular and linear plasmid DNA forms. The final product met stringent quality specifications, achieving >90% supercoiled purity, endotoxin levels <10 EU/mg, residual host cell protein <0.1%, host cell DNA <0.1%, and RNA content <0.1%. The chromatography-free process achieved a recovery rate of >50%, outperforming traditional chromatography-based methods in both efficiency and cost-effectiveness. Furthermore, the process inherently reduces cross-contamination risks, making it well-suited for large-scale GMP manufacturing and ensuring robust regulatory compliance.

Conclusion: This innovative chromatography-free platform represents a transformative advancement in plasmid DNA manufacturing. By eliminating chromatographic steps, it offers a scalable, cost-effective, and operationally simplified solution for commercial-scale production. Its ability to consistently meet therapeutic-grade quality standards positions it as a powerful tool for accelerating the development of plasmid-based therapeutics, vaccines, and personalized medicine, addressing critical challenges in the rapidly growing CGT field.

845 Animal Origin-free Yeast and Soytone-based Fed batch Fermentation as a Versatile Platform for High-Yield Plasmid Production

The production of plasmids, crucial for gene therapy applications, vaccine development, and biotechnology, often faces yield limitations during the upstream fermentation. Fermentation media design and nutrients screening have been a point of focus in improving overall yield. This study investigates the use of Gibco™ Animal Origin Free (AOF) yeast and soytone to enhance cell growth and plasmid production across various cell lines and plasmid constructs including plasmids destined for viral vector and *in-vitro* transcription applications. The impact of yeast and soytone-based feed approach on plasmid yield was tested under controlled and identical media formulation (CD media), fermentation temperatures, pH, Agitation, and dissolved oxygen conditions across *E. Coli* strains and constructs. The process demonstrated a consistent improvement in both cell growth and plasmid yield, particularly in conditions where traditional media fall short. The findings suggest that Gibco™ AOF yeast and soytone feed can be an effective supplement to standard fermentation media, offering a cost-effective solution to optimize plasmid production and increase yields up to 1 g/L of culture. Data showed that under optimal fermentation conditions the use of yeast and soytone minimizes the accumulation of byproducts such as acetate, regardless of the *E.Coli* strain.

846 Scalable and Efficient Production of Plasmid using Yeast and Soytone Fed batch: Optimizing Single Use Technology Fermentation and Purification Processes for cGMP production

Carson White[1], Jacob Hromyak[1], Gabriel Rivera[2], Neelanjan Sengupta[3], Eva Geygan[1], Brittany Sangiovanni[1], Ryan Heetai[1], Lauren Ruiz[1], Erik Klemp[1], Destiny Jones[1], Myriam Capehart[1], Ned Drey[1], Mahajoub Bello Roufai[4]*

With advances in the biotechnology industry, the demand for plasmid DNA (pDNA) to support viral vectors, mRNA/DNA-based biotherapies and vaccines has significantly increased. As several plasmid-based products

advance towards FDA approval, there is a growing need for cost-effective and safe processes capable of producing plasmids at both gram and kilogram scales. Although specialized production facilities have been developed to meet the increasing demand, the expansion of capacity brings challenges such as large-volume handling and the risk of cross-contamination between production campaigns. These challenges highlight the need for a highly productive fermentation process that utilizes fully disposable product-contact materials to mitigate these risks. Culture metabolic profiles and pDNA production trends were used to design and optimize a Gibco™ yeast and soytone-based feed to supplement Gibco™ CD Media. This process consistently showed high performance across a range of plasmid constructs. The developed process was scaled up using our process transfer strategy from the 0.25L Ambr250M to 5L scale during process development, followed by scaling up to cGMP 50L and 200L single use Fermenters. Results showed scalability in the fermentation process and consistency in cell growth and plasmid productivity. Moreover, downstream purification using a 2-column purification process on our single-use platform demonstrated consistent yields from development through cGMP production. Quality control test results for cGMP grade final formulated plasmids meets release specifications for 5L, 50L and 200L scale batches

847 Advances in Gene Therapy for Profound Hearing Loss: An Update on the CHORD Phase 1/2 Trial

[1]Regeneron Pharmaceuticals, Boston, MA, [2]Columbia University Medical Center, New York, NY, [3]Cambridge University, Cambridge, United Kingdom, [4]University of Washington, Seattle, WA, [5]UCLA, Los Angeles, CA, [6]Great Ormond Street Hospital, London, United Kingdom, [7]Hospital Universitario Ramon y Cajal, Madrid, Spain, [8]Clinica Universidad de Navarra, Pamplona, Spain, [9]Nemours Children's Health, Jacksonville, FL, [10]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [11]Regeneron, Boston, MA, [12]Rgeneron Pharmaceuticals, Inc., Tarrytown, NY

Introduction: Otoferlin plays a critical role in inner hair cell (IHC) signal transmission to auditory nerve fibers. Biallelic pathogenic variants of the *otoferlin* (*OTOF*) gene typically cause severe-to-profound deafness. Preclinical data for DB-OTO, an adeno-associated virus gene therapy carrying the human *OTOF* cDNA (complementary DNA), showed IHC-selective otoferlin expression and auditory brainstem response (ABR) recovery in mutant mice that may translate into high-quality physiological hearing in humans. The ongoing, first-in-human, multicenter phase 1/2 open-label CHORD clinical trial (NCT05788536) is evaluating the safety, tolerability, and efficacy of DB-OTO in pediatric patients with profound *OTOF*-related deafness.

Methods: In this phase 1/2 trial, participants <18 years of age with biallelic pathogenic or likely pathogenic variants in *OTOF*, with profound hearing loss by behavioral pure tone audiometry and no detectable response on ABR testing at maximum stimulus levels, are being enrolled. DB-OTO, at a dose of 7.2×10^{12} vector genomes, was administered as a unilateral or bilateral intracochlear injection using a typical facial recess approach via the round window. Safety and efficacy measurements were performed at multiple timepoints before and after treatment.

Results: Previously, early safety and efficacy data were presented. Surgical delivery has been uneventful in all participants, no dose-limiting toxicities or DB-OTO–related adverse events have been reported, and no persistent vestibular manifestations have been observed to date. Longer-term efficacy and durability data from the first participant, and efficacy data from the first 11 patients enrolled in the trial including initial data from bilaterally dosed patients will be presented.

Conclusion: Gene therapy has recently emerged as a promising approach to treat congenital hearing loss. In this first-in human gene therapy trial, DB-OTO was well tolerated overall. These encouraging data suggest that DB-OTO gene therapy has the potential to enable physiological hearing in children with *OTOF*-related deafness.

848 Initial Results from Gene Therapy for X-linked Retinoschisis *via* Subretinal Delivery of scAAV8-hRS1 in Pediatric Patients

Licong Liang[1], Yang Yang[2]*, **Lu Fang[3]***, Kaiqin She[3]
[1]West China Hospital, Sichuan University, Chengdu, Sichuan, Sichuan, China, [2]Sichuan University, Chengdu, Sichuan, China, [3]Sichuan University West China Hospital Department of Ophthalomology, CHINA
**Corresponding Author*

Introduction: X-linked retinoschisis (XLRS) is an X-linked recessive retinal degenerative disease, resulting from mutations in *RS1* gene. It is the leading cause of macular degeneration in male children. We report the safety and efficacy of subretinal delivery of scAAV8-hRS1 in pediatric patients with XLRS.

Methods: This single-arm, single-center trial enrolled pediatric patients (aged 5–18 years) with confirmed *RS1* mutations. All participants received a single unilateral subretinal delivery of scAAV8-hRS1. The primary outcome was the incidence of treatment-emergent adverse events (TEAEs), while secondary outcomes were best-corrected visual acuity (BCVA) and swept-source optical coherence tomography (SS-OCT). Initial data through the 26-week study period is reported. This trial is registered at the Chinese Clinical Trial Registry, ChiCTR2300076682.

Results: Nine patients completed the 26 weeks of follow-up. They were divided into two dose cohorts: cohort 1 (n=6) and cohort 2 (n=3). A total of 38 TEAEs were reported, with no grade 3 or higher TEAEs. No TEAE was related to the study drug. No ocular inflammation was observed. The treated eyes showed a mean BCVA improvement of 9·3 letters (SD 3·7) in cohort 1 and of 10·0 letters (SD 3·6) in cohort 2. SS-OCT revealed that by week 13, macular schisis cavities completely closed in all patients with no recurrences till the 26-week follow-up. The mean central retinal thickness in treated eyes decreased by 479·3 µm (SD 150·3) in cohort 1 and by 432·7 µm (SD 150·1) in cohort 2. Seven out of nine patients demonstrated restoration of the continuity of outer retinal layers, including the external limiting membrane and ellipsoid zone. Both retinal structure and function were restored in the treated eyes of all 9 participants.

Conclusion: In the 26-week study, the treatment successfully restored both retinal structure and function in the in pediatric patients with XLRS, with no drug-related severe adverse events. These promising results supported the further development of scAAV8-hRS1 gene therapy for patients with XLRS.

849 Safety and Efficacy of ZM-02 Optogenetic Gene Therapy Clinical Study for Advanced Retinitis Pigmentosa

Wenhui Zhou[1], Shiyi Yin[2], Haihan Zhang[3], Menghan Zhou[4], Mojtaba Shirinzadeh[4], Jingyun Liu[1], Wenbin Wei[3], Alvin Luk[1], Yin Shen[1]*
[1]Zhongmou Therapeutics, Wuhan, China, [2]Beijing Tongren Eye Center, Beijing, China, [3]Beijing Tongren Hospital, Beijing, China, [4]Wuahan University, Wuhan, China [7](unknown), WUHAN, China
**Corresponding Author*

Introduction: Retinitis pigmentosa (RP) is the most common inherited retinal disease, affecting over 200 million people globally, with no approved treatment. Advanced RP causes significant decreases in visual acuity, visual field, and quality of life. ZM-02 is an optogenetic gene therapy using an adeno-associated virus to deliver a novel photosensitive protein gene, PsCatCh2.0, via intravitreal injection. Thus, we conducted a clinical study, MOON trial (NCT06292650) to evaluate a single injection of ZM-02 in advanced RP patients with various causative genes.

Methods: MOON trial is a randomized, single-blinded, dose-escalation, first-in-human study investigating the safety, tolerability, and efficacy of ZM-02 (AAV-PsCatCh2.0) in RP patients. Eligible participants had best-corrected visual acuity (BCVA) no better than finger counting (≥ logMAR 2.0), loss of photoreceptor layer, and retained ganglion and bipolar cell layers. Participants were randomly assigned (3:1) to intervention (cohort 1-high dose, Cohort 2-low dose) or control group (Sham injection). Participants were assessed before and after treatment at designated follow-ups for 1 year. The primary endpoints were incidence of adverse events (AEs), serious adverse events (SAEs), and dose-limiting toxicities (DLTs). Secondary endpoints were BCVA, and multi-luminance tests (MLTs).

Results: Eight RP participants (mean 36.25 ± 9.25 years old) were enrolled: Cohort 1 (n=4), 2 (n=2), and 3 (n=2). All participants in Cohort 1 and 3, and one in Cohort 2, completed at least 9 months' follow-up; the other in Cohort 2 completed 6 months. Most AEs were mild (≤ CTCAE Grade 2), resolved with topical treatment, and were attributed to the surgical procedure. No DLTs or SAEs were reported (Figure 1). At the most recent visit, 83.3% of the intervention group (Cohorts 1 and 2) showed clinically significant BCVA improvement (0.54 ± 0.30 logMAR), and 100% had improvement in at least two out of three MLTs. Notably, the intervention group showed progressive improvement in color vision (Figure 2).

Conclusions: This trial indicated that ZM-02 has a notable safety and tolerability profile with no drug-related AEs. Efficacy results showed significant BCVA improvement, supported by MLTs, with an unexpected bonus in color perception. These findings suggest that ZM-02 holds promise in advanced RP treatment.

850 Gene Therapy Clinical Trials Targeting Optic Neuropathies and Other Ocular Diseases until 2024

Niranjana Kesavamoorthy[1], Arshia Arjomandi[2], Hossein Ameri[3]
[1]JFK University Medical Center, Metuchen, NJ, [2]University of Southern California, Los Angeles, CA, [3]USC Roski Eye Institute, University of Southern California, Los Angeles, CA

Introduction: Gene therapy is a promising approach that has the potential to treat incurable conditions such as optic neuropathies. We have compiled and analyzed all gene therapy clinical trials on optic neuropathies and other ocular diseases until 2024.

Methods: The ocular gene therapy clinical trials were searched from the following websites: US National Institute of Health ClinicalTrials.gov, International Standard Randomised Controlled Trial Number Register, EU Clinical Trials Register, Gene Therapy Net, Australia New Zealand Clinical Trials Registry (ANZCTR), EU Deliberate release database on clinical trials (JRC), Chinese Clinical Trial Registry (ChiCTR), US National Cancer Institute Cancer Trials, Belgian Biosafety Server Clinical Trials Database, World Health Organization International Clinical Trials Registry Platform, German Clinical Trials Register, Japan Registry of Clinical Trials (JRCT), UMIN Clinical Trials Registry (UMIN-CTR), Wiley database on Gene Therapy Trials Worldwide, and UK Gene Therapy Research.

Results: There were a total of 260 ocular gene therapy clinical trials from 1998 to 2024. Among these, 30 trials (12%) targeted optic neuropathies, with Leber's hereditary optic neuropathy (LHON) being the most studied condition, comprising 16 trials. Other optic neuropathy trials included 3 for autosomal dominant optic atrophy, 2 for nonarteritic anterior ischemic optic neuropathy (NAION), and 1 for ischemic optic neuropathy. 8 trials targeted systemic disorders affecting the optic nerve such as neuromyelitis optica spectrum disorder (NMOSD) and multiple sclerosis. Of the remaining ocular trials, 221 focused on retinal diseases, 4 on glaucoma, 3 on corneal diseases, and 2 on uveitis.

In terms of therapeutic approach, 174 trials (67%) used gene augmentation, 31 trials used RNA therapy, 9 trials utilized systemic gene therapy, 7 trials used gene therapy targeting pathogenic viruses, and 3 trials used oncolytic viruses. 18 trials were observational extensions of interventional studies. 26 trials used cell-based gene therapy; of these 18 trials used encapsulated cell technology, 7 trials used CAR T cell therapy and 1 trial used another approach. Of the gene augmentation trials, 159 (61%) used adeno-associated virus (AAV) as a vector, 8 used lentiviral (LV) vector, 2 used simian immuno-deficiency virus (SIMV), and 1 used adenoviral vector (AV). Of all the years, 2023 had the maximum number of trials at 53, followed by 2024 with 32 trials. 61 trials (23%) were academic, and 199 trials (77%) were sponsored by industry.

In terms of the trial phase, 65 trials were phase 1, 81 trials were phase 1/2, 43 trials were phase 2, 12 trials were phase 2/3, 25 trials were phase 3, and 1 trial was phase 4, 30 trials did not specify the phase.

Conclusion: Our analysis shows that of the gene therapy clinical trials targeting optic neuropathies, the majority targeted LHON, followed by systemic conditions affecting the optic nerve. Overall, clinical trials on gene therapy for ocular diseases have been increasing vigorously as the years progress with a peak of 53 trials in 2023. This growth highlights the expanding interest and advancements in gene therapy approaches for addressing ocular conditions.

851 Efficacy and Safety of ART002, a Single-dose Gene Editing Therapy, in Patients with Severe Heterozygous Familial Hypercholesterolemia

Pinfang Kang[1], Yi Zhao[1], Qin Gao[2], Qing Chen[1], Ying Tang[1], Meiyang Xu[1], Ziyi Chen[3], Hongju Wang[1], Wenjuan Wu[3], Han Qiu[4], Jialin Tao[5], **Yongzhong Wang[6]**, Ningru Zhang[1], Bi Tang[1], Huan Zhou[1]
[1]The First Affiliated Hospital of Bengbu Medical College, Bengbu, China, [2]Bengbu Medical University, Bengbu, Bengbu, China, [3]Bengbu Medical University, Bengbu, China, [4]AccurEdit Therapeutics, Suzhou, China, [5]AccurEdit Therapeutics, Suzhou, Jiangsu, China, [6]Accuredit Therapeutics US, suzhou, Jiangsu, China

Background and Aims: Heterozygous familial hypercholesterolemia (HeFH) is one of the most common hereditary metabolic disorders. Severe HeFH (LDL-C>5 mmol/L or 190 mg/dL with other risk factors) confers significant increased risk for atherosclerotic cardiovascular disease (ASCVD) but only a small proportion of patients have achieved the LDL-C goal. Statins are the primary treatment but it is not enough to effectively reduce LDL-C, and a significant proportion of patients are unable to tolerate high-intensity statins. PCSK9 inhibitors as an add-on therapy to statins can further reduce LDL-C levels but the real-world reported adherence to PCSK9 antibody therapy is suboptimal. While siRNA has improved drug convenience and adherence, the average LDL-C reduction of Inclisiran over 4 years is only 44% even with maximally tolerated statins. ART002 is an investigational CRISPR/Cas9-based *in vivo* gene editing therapy delivered via lipid nanoparticles (LNP), designed as a single-course treatment to permanently inactivate the liver *PCSK9* gene. We aim to evaluate safety and efficacy for ART002 in patients with severe HeFH.

Methods and Results: In this open-label, single-arm clinical trial (ChiCTR2400093099) in China, 6 adults with HeFH (diagnosed by LDLR or APOB pathogenic mutants) were subjected to single intravenous infusion of ART002 at doses of 0.3, 0.75 or 1 mg/kg, with N=1, 3 or 2, respectively. At study baseline, 4 of 6 patients did not receive statins and mean LDL-C was very high (>6.2 mmol/L or 240 mg/dL). For those without baseline statin use, low- or moderate-intensity statin was initiated as a combination therapy three weeks or more after ART002 treatment. The primary endpoint was safety and tolerability of ART002 in HeFH patients. Secondary endpoints included the assessment of pharmacodynamics, specifically changes in plasma PCSK9 and serum LDL-C levels at week 24. The data cutoff for the analysis was 17-Jan-2025. ART002 demonstrated a favorable safety profile with no serious adverse events (SAEs) or significant immune toxicities reported. No elevations in liver enzymes beyond CTCAE Grade 2 was observed. Adverse events were limited to mild, self-limiting and mostly have resolved without any intervention. The administration of ART002 achieved remarkable reductions in plasma PCSK9 levels reaching up to 91% with mean reductions of 73%, 86% and 86% in the 0.3, 0.75 and 1 mg/kg groups, respectively. Similarly, LDL-C levels were reduced by up to 68%, with mean reductions of 62%, 57% and 56% across the same dose groups at the latest follow-up (8–24 weeks post-infusion). Notably, a patient with a challenging heterozygous LDLR-negative mutation demonstrated a substantial 81% reduction in PCSK9 and 43% in LDL-C. Patients with heterozygous

LDLR or APOB-defective mutations in the 0.75 and 1 mg/kg groups achieved noteworthy reductions of 87% in PCSK9 and 59% in LDL-C. Overall, an impressive 83% of patients successfully reached the target of ≥50% LDL-C reduction, underscoring the efficacy and potential impact of ART002 in effectively lowering LDL-C levels across diverse patient populations.

Conclusions: ART002 is the first single-course gene-editing therapy targeting PCSK9 that has been clinically proven to be safe and effective for the treatment of severe HeFH across all treated patients to date. This innovative therapy may potentially revolutionize the treatment landscape for hypercholesterolemia and ASCVD.

852 Initial clinical results from OTC-HOPE, the first *in vivo*, liver directed, AAV-mediated gene insertion study in neonatal OTC deficiency: complete clinical response observed in first male infant to receive ECUR-506 and complete 24-week Phase 1/2 study

Julien Baruteau[1]*, Gabriel Cohn[2], Anil Dhawan[3], Anupam Chakrapani[4], Stephanie Grunewald[5], Molly Abbott[6], Helen Ashton[5], Sophie Foxall[7], Ai-Ling Koh[5], Christos Lazaridis[5], Havea Navarro-Kennedy[5], Hamza Patel[5], Siyamini Sivananthan[5], Eleni Tamvaki[5], Katy Vecchiato[6], Matthew Hall[8], Karen Kuhn[9], Thomas White[10], Barbara Pinho[11], George Diaz[12]
[1]Great Ormond Street Institute of Child Health University College London, London, Kent, United Kingdom, [2]iECURE, Blue Bell, PA, [3]King's College Hospital, London, United Kingdom, [4]Great Ormond Street Hospital, London, London, United Kingdom, [5]Great Ormond Street Hospital for Children, London, London, United Kingdom, [6]Great Ormond Street Hospital, London, United Kingdom, [7]Great Ormond Street Hospital foe Children, London, London, United Kingdom, [8]IECURE, Inc., Plymouth Meeting, PA, [9]iECURE, Inc., Coatesville, PA, [10]iECURE, Inc., Blue Bell, [11]Fortrea, Inc., Princeton, [12]IECURE, Inc., Blue Bell, PA
**Corresponding Author*

Background: Ornithine transcarbamylase deficiency (OTCD) results in impaired ureagenesis and hyperammonemia due to congenital deficiency of the urea cycle enzyme, ornithine transcarbamylase (OTC). Severe neonatal onset OTCD patients have marked reductions in OTC activity resulting in severe hyperammonemia and low blood urea nitrogen (BUN). Males with severe neonatal onset OTCD typically become hyperammonemic within the first 48-72 hours of life and are commonly misdiagnosed. Current standard of care includes limiting protein intake and administration of nitrogen scavenger drugs. While this aids in lowering plasma ammonia, impairment of ureagenesis and risk for hyperammonemia persist. Despite aggressive medical management, repeat hyperammonemic events are common and mortality rates are high thereby necessitating liver transplantation for some patients. ECUR-506 is a liver-directed, investigational gene editing product being developed for the treatment of neonatal onset OTCD. ECUR-506 is a mix of two AAVrh79 vectors, one encoding a meganuclease, M2PCSK9, for targeted editing of the human PCSK9 gene, and the other, a codon-optimized human OTC donor gene co-administered intravenously in a 1:3 ratio, respectively. Dual vector administration is designed to guide OTC transgene integration into the hepatocyte genome which may result in the durable production of functional OTC enzyme.

Materials and Methods: The OTC-HOPE clinical trial (NCT06255782) is a 24-week, first in human, single arm, Phase 1/2, open-label, global, multi-center trial designed to assess safety and efficacy of ECUR-506 in males with neonatal onset OTCD who are <9 months of age and 3.5 kg to 10 kg at the time of dosing. Planned dose levels were informed by non-clinical studies. Study participants will be included in a 14.5-year follow-up study. Herein, initial clinical and biomarker data of the first study participant to complete the 6-month clinical trial are described.

Results: The participant experienced 2 hyperammonemic events by 3.5 months of age and underwent ECUR-506 (1.3×10^{13} GC/kg) infusion at 6.5 months of age. Asymptomatic transaminitis was observed between weeks 4-8 post-infusion, and a liver biopsy confirmed an acute T-cell inflammatory response, which resolved with immunosuppression. Normal ammonia and reduced glutamine levels prompted nitrogen scavenger medication discontinuation and liberalization of protein intake by weeks 12 and 15, respectively. Subsequently, mean ammonia levels were normal, no hyperammonemic events were observed, mean BUN levels and urinary nitrogen were increased relative to pre-treatment levels, and normal infant growth trajectory were observed over the remainder of the 6-month study.

Conclusion: These are data from the first infant to undergo in-vivo, liver directed, AAV-mediated gene insertion and to complete the OTC-HOPE clinical trial. The observed increase in BUN and urinary nitrogen along with normal mean ammonia levels and increased protein intake following ECUR-506 administration in conjunction with scavenger medication discontinuation are suggestive of increased nitrogen flux through the urea cycle and restoration of at least partial functional hepatic OTC enzyme activity. The complete clinical response, as defined in the OTC-HOPE clinical protocol, achieved in this patient support the continued evaluation of low dose ECUR-506 (1.3×10^{13} GC/kg) in the clinical trial.

853 Durable Efficacy and Safety of DTX301: Long-term Follow Up (LTFU) of a Phase 1/2 Trial in Adults with Ornithine Transcarbamylase Deficiency (OTCD

Cary Harding[1], Janet Thomas[2], Margo Breilyn[3], Maria Couce[4], Tarekegn Geberhiwot[5], Nathalie Guffon[6], Leticia Hualde[7], Aneal Khan[8], Laura Konczal[9], Melinda Peters[10], Lipika Ghosh[11], J Lawrence Merritt[12], Eric Crombez[12]
[1]Oregon Health & Science University, Portland, OR, [2]University of CO School of Medicine and the Children's Hospital Colorado, Aurora, CO, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]University of Santiago de Compostela, Santiago de Compostela, Spain, [5]University of Birmingham, Birmingham, United Kingdom, [6]Hospices Civils de Lyon, Bron, Rhône, France, [7]Cruces University Hospital, Biocruces Bizkaia Health Research Institute, Barakaldo, Spain, [8]MAGic Clinic Ltd, Calgary, AB, [9]University Hospitals of Cleveland Medical Center, Cleveland, OH, [10]Boston Children's Hospital, Harvard Medical School, Boston, MA, [11]Ultragenyx Pharmaceutical Inc., Novato, [12]Ultragenyx Pharmaceutical Inc., Novato, CA

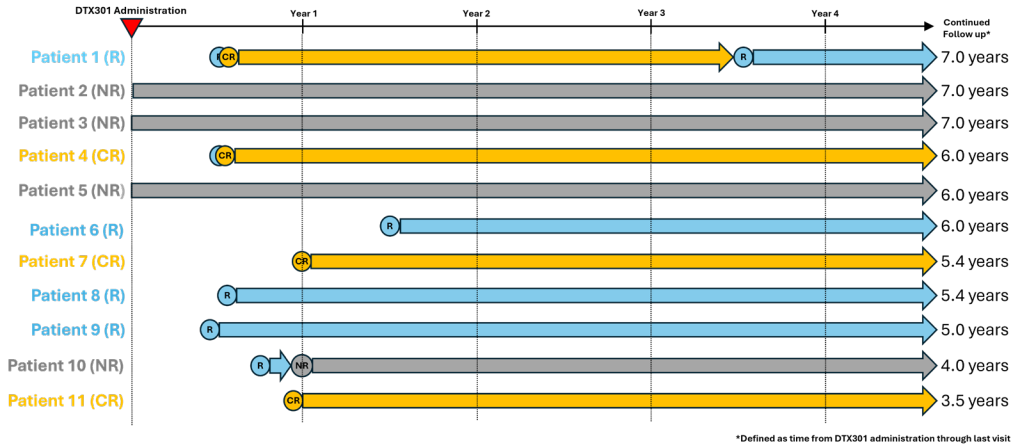
Introduction: OTCD is an X-linked urea cycle disorder resulting in a life-long risk of episodic hyperammonemia that can lead to cumulative brain damage, coma, or death. DTX301 is an AAV8 vector containing the OTC transgene being investigated for treatment of OTCD. We report the LTFU of 11 adults with late-onset OTCD who received a single IV infusion of DTX301 in the Phase 1/2 trial (NCT02991144).

Methods: The initial study was a global, multicenter, open-label phase 1/2 dose-finding study that lasted 52 weeks with an ongoing long-term extension for an additional 8 years. Patients received one IV infusion of DTX301. Relative to baseline in the Phase 1/2 trial, Complete Responders discontinued all ammonia-scavenger medications and protein-restricted diet, and Responders had ≥50% reduction in medications and dietary protein restriction.

Results: Eleven patients were enrolled in the Phase 1/2 trial. All have continued in the extension study, with up to 7 years of follow up to date. No treatment-related serious AEs, dose-limiting toxicities, or infusion-related events have been reported. During the primary study, six patients experienced transient changes in liver function due to AAV8 vector administration. All resolved following corticosteroid administration. During LTFU, three patients experienced mild ALT elevations and two experienced hyperammonemia or hyperammonemic crises, all considered unrelated to DTX301. Corticosteroids were not associated with increased ammonia, hyperammonemia, or hyperammonemic crisis. Five patients had corticosteroid-related AEs. Most were mild (grade 1), though one patient had grade 3 AEs of bone infarction, osteonecrosis, and subcortical collapse that led to knee replacement. As of 09 December 2024, 10 of 11 patients have remained clinically stable and 7 have shown a meaningful clinical response to DTX301. 3 patients were Complete Responders, 4 were Responders, and 4 were Nonresponders at last follow up (**Figure 1**). The overall mean rate of ureagenesis increased as early as Week 6 after DTX301 administration and increases were maintained. The rate of ureagenesis increased from baseline to last visit for 10 patients (91%); only 1 Nonresponder showed no increase over this time. From Baseline to last visit, mean 24-hour plasma ammonia area under the curve (AUC) values decreased in 8 patients (73%), 2/3 Complete Responders, 3/4 Responders, and 3/4 Nonresponders. One patient was reclassified from Responder to Nonresponder at W52 due to the need to decrease protein intake. This patient continues to experience recurrent hyperammonemia and HACs not considered related to DTX301. For the remaining 3 Nonresponders, no changes were made to ammonia scavenging drugs or dietary protein restrictions. Another patient was reclassified from Complete Responder to Responder after restarting an ammonia-scavenging drug at Week 182 due to personal preference despite being clinically stable and experienced two serious AEs at Week 300 and Week 333 with hyperammonemia although no elevated ammonia levels of clinical significance were reported. All other patients have maintained their Complete Responder or Responder status (**Figure 1**).

Conclusions: DTX301 continues to show manageable safety and durable improvements in clinical responses. The Phase 3 trial (NCT05345171) is currently evaluating DTX301 in adults and children ≥12 years of age.

Figure 1. Clinical response to DTX301 over time



854 First patient treated in the first phase 1–2 trial of AAVLK03hOTC gene therapy for ornithine transcarbamylase deficiency in children

Anupam Chakrapani[1], Julien Baruteau[2], James Blackstone[3], Berna Seker Yilmaz[3], Srividya Sreekantam[4], Louise Van Dorp[5], Siyamini Sivananthan[3], Katy Vecchiato[5], Molly Abbott[5], Havinder Hara[3], Agnieszka Kubat[6], Alison Evans[3], Jaami Yusuf[6], Blair McLennan[3], Andrew Embleton-Thirsk[3], Hakim-Moulay Denbi[3], Iona Cullen-Stephenson[3], Harriet Quartley[3], Nick Freemantle[3], Adrien Lemoine[7], Marjorie Dixon[5], Sharon Cunningham[8], Leszek Lisowski[9], Ian Alexander[10], **Paul Gissen[6]**

[1]Great Ormond Street Hospital, London, London, United Kingdom, [2]Great Ormond Street Institute of Child Health University College London, London, Kent, United Kingdom, [3]UCL, London, United Kingdom, [4]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom, [5]Great Ormond Street Hospital, London, United Kingdom, [6]UCL, London, London, United Kingdom, [7]LONDON, United Kingdom, [8]Children's Medical Research Institute (CMRI), Westmead, NSW, Australia, [9]Sendatu Therapeutics, Westmead, NSW, Australia, [10]Sydney Children's Hospitals Network, Westmead, NSW, Australia

Ornithine transcarbamylase deficiency (OTCD) is a rare X-linked urea cycle disorder with recurrent metabolic decompensations characterised by hyperammonaemia, high glutamine levels, liver dysfunction and encephalopathy causing long-term neurological damage. Conventional treatments have limited efficacy and whilst liver transplantation is effective, it has associated morbidity and mortality, requires lifelong immunosuppression and is challenged with a shortage of organ donors. We developed the adeno-associated virus (AAV)-based gene therapy AAVLK03hOTC encoding a human codon-optimised OTC gene and pseudoserotyped with highly human hepatotropic LK03 capsid to target the liver and restore functional expression of OTC enzyme. Preclinical in vitro and in vivo studies demonstrated restoration of functional OTC activity in OTC deficient hepatocytes following treatment with AAVLK03hOTC. A 26-week GLP toxicity and biodistribution study in naïve Cynomolgus monkeys demonstrated elevated liver OTC activity 26 weeks after administration of AAVLK03hOTC in the absence of notable toxicological alterations. AAVLK03hOTC was expressed in almost all fluids and organs analysed, highest levels were in the liver. "Halting Ornithine transcarbamylase deficiency with Recombinant AAV in ChildrEn" (HORACE) is a UK based phase I/II clinical trial with a single administration of AAVLK03hOTC to paediatric OTCD patients with severe phenotype which aims to achieve normalisation of liver metabolism, thus reducing acute risk of morbidity and mortality from hyperammonaemic decompensations. Three doses (6x10^11vg/kg, 2x10^12vg/kg and 6x10^12vg/kg) are proposed in the dose escalation part of the trial. For dose-escalation cohorts, all patients will be 6-16 years to ensure homogeneity between cohorts. Based upon predicate data from other AAV gene therapy trials, there is a risk of asymptomatic transaminitis likely caused by T-cell mediated immune response to AAV, readily controlled by immunosuppression. Following escalation, recruited patients will be adaptively allocated to dose according to model-based simulation. After the initial 12 month-follow

up period participants will enter a 4-year follow up. The first patient treated with low dose (6x10^11vg/kg) AAVLK03hOTC gene therapy was a 10-year-old male with late-onset OTCD. Previous history included recurrent episodes of hyperammonaemia treated with dietary protein restriction and daily ammonia scavengers. The patient tolerated the gene therapy administration remarkably well. Two weeks after administration he presented with hyperammonaemia and encephalopathy caused by mycoplasma pneumonia encephalitis unrelated to gene therapy, followed by excellent recovery. Significant reduction in ammonia and glutamine levels were noted 6 and 8 weeks after gene therapy administration respectively, which allowed initiation of ammonia scavenger withdrawal. 7 months after gene therapy administration the patient developed raised liver transaminases >2 times above upper limit of normal. He remained asymptomatic but treated with prednisolone and tacrolimus which achieved normalisation of the transaminases within 2 weeks. 12 months post infusion glutamine and ammonia levels remain below the lower limit of normal and withdrawal of ammonia scavengers with normalisation of dietary protein intake was achieved whilst maintaining metabolic stability.

855 rAAV Gene Therapy for Classic Fabry Disease: ZS805 Results from An Ongoing Investigator-Initiated Clinical Trial

Biao Dong[1], Ke Wan[1], Siwu He[2], Hoi Yee Chow[3], C. Valencia[4], Aliah Abuammah[5], Yucheng Chen[6]
[1]Sichuan University, Chengdu, Sichuan, China, [2]Sichuan University, 成都市, Sichuan, China, [3]Sichuan University, CHINA, [4]Sichuan Real & Best Biotech Co., Pilot Rock, OR, [5]King Saud University, Riyadh, Saudi Arabia, Saudi Arabia, [6]Sichuan University, Chengdu, China

Introduction: Fabry disease is a lysosomal storage disorder, caused by the pathogenic mutations in the *GLA* gene located on the X chromosome, which results in the progressive accumulation of GL3 and Lyso-GL3 in multiple cells, tissues and organs. ZS805 is a rAAV genetic drug carrying the *GLA* gene with an engineered signal peptide driven by a liver specific promoter, which was packaged in the AAV5 capsid (ChiCTR2300073886). Patients with Anti-α-Gal and Anti-AAV5 were enrolled, and the efficacy with or without prophylactic treatment of immunosuppressant was compared.

Study Design: Dose escalation was performed at two doses: 1.0×10^{13} vg/kg (low dose) and 2.0×10^{13} vg/kg (high dose). Eleven participants were enrolled into dose escalation and dose expansion cohorts (Figure 1). Ten patients were given a prednisone prophylactic treatment one week prior to injection while one patient had no prednisone prophylactic treatment. Data from nine participants with relatively long treatments were presented. The key patient eligibility criteria included male classic participants aged ≥18 years without ERT (enzyme replacement therapy) within 45 days prior to enrollment. The primary objectives was safety and tolerability, and the secondary objectives included the assessment of PK/PD (α-Gal A activity and vector shedding), immunogenicity (α-Gal A antibody, T cell response, anti-AAV5 antibody) and efficacy (GL-3 and Lyso-GL3 level, renal function, BPI and QOL scores).

Results: **Plasma α-Gal A Activity**
At low dose, plasma α-Gal A activity levels increased to 2.2 to 14 times the normal median level (8.1 nmol/h/mL) one week after administration, remaining stable with peak levels reaching 4.8 to 29.5 times the normal. After one week of high-dose administration, plasma α-Gal A activity levels increased to 4.4 to 16.1 times the normal median level, and remained stable, achieving peak levels that were 5.5 to 62.6 times the normal. All four participants who had either anti-α-Gal A antibody or anti-AAV5 antibody showed the elevated plasma α-Gal A activity.

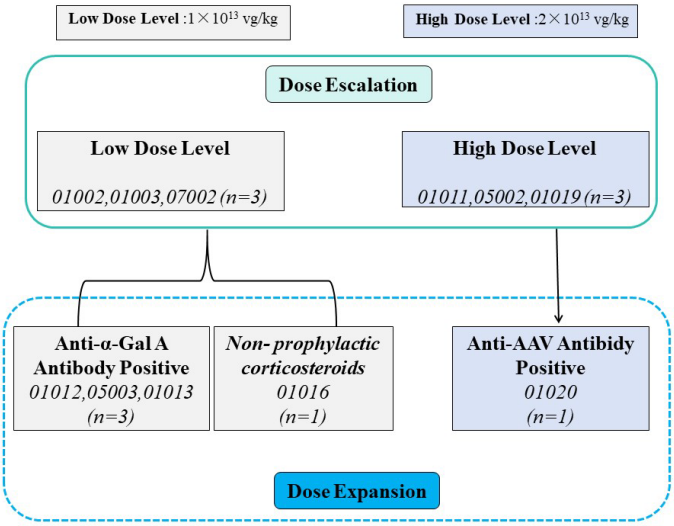
Substrates Lyso-GL3 and GL-3
Plasma Lyso-GL3 in all participants showed a significant reduction, with the **maximum decrease ranging from 20.1% to 66.6% in the low dose group and 9.2% to 67.6% in the high dose group.** The changes in plasma GL-3 levels exhibited a similar trend to that of Lyso-GL-3.

Safety and Tolerability
ZS805 was well-tolerated with no dose-limiting toxicity (DLT) among the eleven participants enrolled, which indicated a favorable safety profile. Two participants experienced three adverse events (AEs), but of all of them recovered without any lasting effects.

Vector shedding
Vector DNA levels in the blood peaked within 10 minutes, rapidly declined by the end of week 1, and were

completely cleared by about 6 months. Full clearance periods of the vector were as follows: week 1-3 for urine, week 3-7 for saliva, week 3-12 for semen.

Conclusions:
ZS805 was well tolerated at both dosage levels.
The α-Gal A activity remained stable and sustained in two participants for more than 52 weeks.
The level of plasma Lyso-GL-3 significantly decreased.



856 Title: Patient Centered Work on Considerations for Outcomes in Cerebral Creatine Deficiency Syndromes Trial Design

Heidi Wallis[1], Audrey Thurm[2]
[1]*Association for Creatine Deficiencies, Carlsbad, CA,* [2]*National Institute Of Mental Health, Bethesda, MD*

This poster will present findings and ongoing work from two related Patient Centered Outcomes Research Institute (PCORI) grants led by the Association for Creatine Deficiencies. We established a Core Outcome Set for patients with Cerebral Creatine Deficiency Syndromes (phase 1), and work is now underway on considerations for how to choose optimal outcome measures for clinical trials in these conditions (phase 2). In this second phase, we also focus on identification of Clinically Meaningful Differences.

This process is important for our patients and families because oftentimes individuals with genetic conditions associated with neurodevelopmental disorders score at the floor of the standardized tests used or in some cases no tests have been validated for the population. The FDA is interested in meaningful differences in areas relating to functioning and feeling, but when parents observe small improvements and repeat testing, the metrics utilized may not be sensitive to these changes. This issue is exacerbated when the "symptom" under evaluation is neurodevelopment itself, which is critically important since many neurodevelopmental domains (e.g. expressive communication, cognitive functioning) were prioritized in the core outcome set established by the first phase of this work. We aim to promote disease understanding and prevent the use of inadequate endpoints in clinical trials by working ahead of potential upcoming trials to establish the considerations necessary for selecting appropriate measurement tools. Another complexity that we consider in this work is that very different neurodevelopmental phenotypes are observed within the same disease (for example, early versus later diagnoses in guanidinoacetate methyltransferase deficiency, and female versus male phenotypes in X-linked creatine transporter deficiency).

Understanding differences based on heterogeneity in presentation and clinical meaningfulness will be important to consider when selecting outcome measures.

857 Initial Safety Results from the PROPEL Trial Evaluating SBT101 as a Potential Gene Therapy for Spinal Cord Disease in Adult Males with X-linked Adrenoleukodystrophy

Marc Engelen[1], **Lawrence Hayward[2]**, Philip Yin[3]*, Pamela Foulds[4]
[1]Amsterdam Leukodystrophy Center, Department of Pediatric Neurology, Amsterdam, Netherlands, Amsterdam, Netherlands, [2]Umass Chan Medical School, Worcester, MA, [3]Spur Therapeutics, Somerville, MA, [4]Freeline Therapeutics, STEVENAGE, Hertfordshire, United Kingdom
**Corresponding Author*

Introduction: X-linked adrenoleukodystrophy (ALD) is a progressive neurodegenerative disorder caused pathogenic variants in the *ABCD1* gene, which is localized to the X chromosome and encodes ABCD1 protein that transports very long chain fatty acids (VLCFA)-CoA esters into the peroxisome for degradation. Pathogenic variants in *ABCD1* result in accumulation of VLCFA in all tissues. Patients with ALD can develop a leukodystrophy, adrenal failure, progressive peripheral neuropathy and spinal cord disease with or without cerebral involvement. When cerebral involvement has not been documented, this phenotype has historically been referred to as adrenomyeloneuropathy (AMN). There are currently no treatments for AMN, leaving patients with a progressive disease that leads to lifelong physical disability. SBT101 is a recombinant AAV9 vector encoding the functional *ABCD1* gene. Preclinical studies demonstrated dose-dependent ABCD1 protein expression, reduction of VLCFA levels, and functional improvements as measured by grip strength following administration of SBT101 in models of AMN. SBT101 has progressed to the clinic and has the potential to address the primary cause of AMN by restoring expression of the ABCD1 protein in spinal cord cells, potentially halting progression of disease and/or leading to improvements in the neurological pathology.

Methods: PROPEL is a Phase 1/2 dose-finding study in adult males with ALD and no cerebral involvement (historical AMN phenotype) to evaluate the safety and efficacy of a single intrathecal administration of SBT101 in two dose cohorts: low dose (LD: 1.0E14 vg) and high dose (HD: 3.0E14 vg). All patients receive prophylactic immune management (IM). The primary endpoint is safety. Secondary endpoints include multiple clinical assessments of mobility, bladder/bowel impairment, imaging, patient reported outcomes, and biomarkers of response. A natural history study, CYGNET is also ongoing with 65 patients enrolled and duration of follow up 3-36 months.

Results: Eight patients have been dosed to date (4 LD, 4 HD). Patient age ranged from 19-36 years, with disease duration at time of treatment of 2-14 years. Duration of follow up after dosing was 1 week-20 months. All patients tolerated the infusion well with 2 receiving a blood patch after the procedure. The most common adverse drug reaction (ADR) reported more than once was positive ELISPOT test. To date, no serious adverse events (SAEs) deemed related to SBT101, the procedure, or IM have occurred. One patient in the LD cohort died during the trial due to underlying disease, which was deemed unrelated to study product, study procedures, or IM. Evidence of transduction from droplet digital PCR will be presented along with early read out of markers of axonal damage in plasma and cerebral spinal fluid (CSF) (ie., neurofilament light chain; NfL).

Conclusion: Initial results from the PROPEL trial in adult, male ALD patients, show SBT101 has been well tolerated to date at both low and high doses, with cellular evidence of transduction in the relevant tissues and encouraging biomarkers of response. Patient outcomes will be analyzed and compared to natural history databases including those of the ongoing CYGNET study. The current data support the development of SBT101, a one-time, first-in-class investigational gene therapy to treat the high unmet medical need in individuals with AMN.

858 AlloNK® Cell Therapy ± Rituximab in Patients with Relapsed or Refractory Non-Hodgkin Lymphoma

Umar Farooq[1], Amitkumar Mehta[2], Erin Dean[3], Jennifer Saultz[4], Joseph Maly[5], Bassam Mattar[6], Adam Olszewski[7], Ruthee-Lu Bayer[8], Valerie Chacon[9], Gina Chu[10], Gilad Gordon[11], Heather Kelley[9], Thorsten Graef[9]*, Rashmi Khanal[12]

**Corresponding Author*

Introduction: AlloNK is a non-genetically modified, allogeneic, off-the-shelf, cryopreserved natural killer (NK) cell therapy candidate in development for the treatment of cancer and autoimmune diseases. A highly scaled manufacturing process enables production of thousands of 1 billion cell doses from a single donor cord blood unit (CBU). AlloNK has been optimized for combination with monoclonal antibodies (mAbs) to enhance antibody-dependent cellular cytotoxicity (ADCC) and anti-tumor responses through selection of CBUs with the natural high-affinity variant of CD16 (158V/V polymorphism) and a killer cell immunoglobulin-like receptor (KIR)-B haplotype.

Methods: The objectives of this Phase 1/2 clinical trial (NCT04673617) were to assess the safety and anti-tumor activity of AlloNK alone and in combination with rituximab in patients with CD20 positive relapsed or refractory (R/R) non-Hodgkin Lymphoma (NHL) of B-cell origin. Patients received a standard lymphodepleting (LD) regimen and were administered up to 4 cycles (4 weekly doses per cycle) of AlloNK at doses of $1x10^9$or $4x10^9$ cells/dose in an outpatient setting. Efficacy was evaluated using the Lugano response assessment criteria (2014).

Results: Sixteen patients received AlloNK across 3 different monotherapy cohorts, and 29 patients received AlloNK + rituximab across 4 different combination cohorts. Most patients were white (82%), male (62%), with a median age of 68 years, had aggressive NHL subtypes (84%), and had received a median of 4 prior lines of systemic therapy (range: 1-9). In line with the usage of LD regimens, the most common treatment-emergent adverse events (TEAEs) were hematologic, including neutropenia (84%), leukopenia (82%), and lymphopenia (71%). Infusion related- reactions (IRRs) and febrile neutropenia (n=3; 7% each) were the only related serious TEAEs reported in more than 1 patient. TEAEs of cytokine release syndrome (CRS) were reported in 4 patients (9%; 3 Grade 1 cases and 1 Grade 2 case) and were attributed to IRR as they happened within 24 hours of cell infusion, resolved without specialized treatment, and no cytokine elevations were noted. Other cell therapy-associated toxicities such as immune effector cell associated neurotoxicity syndrome (ICANS) and graft-versus-host disease (GVHD) were not observed. There have been no deaths related to AlloNK, and no patients have discontinued from the study due to AEs related to AlloNK. The objective response rate (ORR) in the monotherapy treatment group was 37.5%, including 4 (25.0%) complete responses (CRs) and 2 (12.5%) partial responses (PRs). In the combination treatment group, the ORR was 55.2%, including 13 CRs (44.8%) and 3 PRs (11.1%). In the 14 patients who were naïve to prior CAR-T therapies, 64% had CRs, with a median duration of response of 19.3 months.

Conclusions: AlloNK cell therapy is a safe and effective cellular therapy for B cell lymphomas. Given its alternative mechanism of action, AlloNK has the potential to enhance the ADCC response, thereby increasing anti-tumor activity without the safety challenges associated with T cell approaches, including high rates of CRS and ICANS. The combination of AlloNK and rituximab has demonstrated promising safety and efficacy in a heavily pretreated R/R NHL patient population, including older patients. The low risk of acute toxicities and preliminary efficacy results support the administration of AlloNK in the outpatient setting.

859 Trial in progress: Phase I study of non-viral gene-modified CAR-T cell therapy for malignant solid tumors with expression of EPHB4 receptor（CARTiEr）

Chikako Funasaka[1], Yoichi Naito[2]*, Hitomi Kubota[1], Yukiko Ishiguro[1], Nozomu Fuse[1], Masashi Wakabayashi[1], Junichiro Yuda[3], Genichiro Ishii[1], Toshihiro Suzuki[4], Kazumasa Takenouchi[4], Tetsuya Nakatsura[4], Konomi Morita[5], Yoichi Inada[5], Yozo Nakazawa[6], Shigeki Yagyu[7], Toshihiko Doi[1]

Background: EPHB4 has been reported to be overexpressed on the surface of tumor cells in various tumors, including malignant bone and soft tissue tumors. AP8901 is a CAR-T cell that can specifically recognize and kill EPHB4 receptor-expressing malignant tumor cells by modifying the ephrin-B2 protein, the natural ligand for the EPHB4 receptor. AP8901 is being developed using a genetic manipulation technique called the "piggyback transposon method" and the "genetically modified feeder cell method", which enables the stable expression of CAR proteins in T cells and prevents T cell exhaustion. A preclinical study demonstrated the therapeutic efficacy and tolerability of AP8901 in mice transplanted with a rhabdomyosarcoma cell line. We planned Phase I study evaluating safety and efficacy of AP8901 for metastatic solid tumors.

Methods This is a single-center, single-arm Phase I study of a single intravenous dose of AP8901 to evaluate the safety, tolerability, pharmacokinetics/pharmacodynamics and preliminary antitumor activity in patients with Ewing's sarcoma or solid tumors expressing the EPHB4 receptor. This study is a dose escalation study with a 3+3 design. Doses are calculated on the basis of body weight at the time of peripheral blood mononuclear cell collection. Key inclusion criteria include: (1) Subjects must have histologically diagnosed Ewing's sarcoma or solid tumor with confirmed metastasis or recurrence/no standard treatment for metastasis or recurrence or refractory or intolerant to standard treatment. (2) Subjects have a most recent biopsy or surgical resection specimen with a pre-screening immunohistochemical stain positive for EPHB4 in at least 1% of tumor cells. (3) ECOG performance status of 0 or 1. Major exclusion criteria include (1) Subjects being treated with systemic corticosteroids or systemic immunosuppressive drugs. (2) Subjects with symptomatic or uncontrolled brain metastases requiring concurrent treatment, impaired major organ function, active autoimmune disease, or active infection. (3) Subjects with a history of allogeneic hematopoietic stem cell transplantation. Primary endpoint is percentage of dose-limiting toxicities from the start of lymphocyte depletion therapy to 28 days after AP8901 administration. The maximum number of subjects to be enrolled is 18. This study is being conducted at the National Cancer Center Hospital East, Japan. (jRCT2033230299)

860 Phase I Open-label Single-arm Study to Evaluate the Safety, Tolerability and Preliminary Efficacy of CHT102, an Allogeneic Mesothelin-targeted CAR-T Cell, in Patients with Advanced Solid Tumors (CHAPTER)

Background: CHT102, an allogeneic CAR-T therapy targeting mesothelin (MSLN), enhanced by proprietary ROBUS-T technology, demonstrates remarkable preclinical specificity, cytotoxic efficacy and persistence. This report presents preliminary results from a Phase I, open-label, single-arm trial evaluating the safety and efficacy of CHT102 in patients (pts) with advanced solid tumors. **Methods:** The primary objective was to assess safety and tolerability, with secondary objectives of evaluating efficacy and pharmacokinetics (PK) via flow cytometry and qPCR. Eligible pts included those with advanced/metastatic MSLN-expressing tumors, progressive disease despite systemic therapy, and ECOG status ≤1. Pts underwent lymphodepletion with cyclophosphamide and fludarabine,

with/without nab-paclitaxel, followed by CHT102 infusions on Days 1, 5 and 9. Dose escalation employed accelerated titration and a 3+3 design across four cohorts (3×10^8, 6×10^8, 12×10^8 and 18×10^8 CAR+ T cells). **Results:** Between August 9, 2024, and January 27, 2025, seven pts (4 pancreatic cancers,1 gastric cancer, 2 ovarian cancers) were enrolled. Six pts completed CHT102 infusions and were evaluated for safety and efficacy. One pancreatic cancer pt in cohort 2 received a second infusion on D43. The 7th pt is awaiting lymphodepletion, and cohort 4 enrollment is set for February 2025. The six infused pts had a median age of 66 years (range: 57-68) with a median of two prior systemic therapies (range: 2-5). No dose-limiting toxicities were observed. Common treatment-emergent adverse events (TEAEs) were hematologic: leukocytopenia (100%, Grade 3/4 83.3%), neutropenia (100%, G3/4 83.3%), lymphopenia (100%, G3/4 100%), anemia (66.7%, G3 50%), and thrombocytopenia (66.7%, G3/4 33.3%). One pt in cohort 3 experienced Grade 2 CRS on D1, resolved with tocilizumab and steroids. No neurologic toxicities or GVHD occurred. A Grade 3 cerebral infarction was reported in a cohort 2 pt on D35, attributed to pre-existing hypercoagulability. Non-hematologic TEAEs, including nausea (100%) and fever (50%), were Grade 1-2. At a median follow-up of 56 days (range: 11-99), no objective response rate (ORR) was observed. However, five pts (83.3%) showed 5-27% target lesion reduction, achieving a disease control rate (DCR) of 83.3%. Pancreatic cancer pts had a DCR of 75%. PK analysis demonstrated robust CHT102 expansion, with a median peak of 10,909 cells/ml (range: 1,040–15,819) and a median time to peak of 10 days (range: 7-13). **Conclusions:** The CHAPTER study indicates CHT102 has a favourable safety profile and encouraging efficacy in advanced solid tumors. Most AEs were transient and manageable. With an 83.3% DCR, CHT102 shows promise as a therapeutic option, particularly in pancreatic cancer pts, who demonstrate a DCR of 75%.

861 Improved HDAd Vector Design for Multiplex Editing and Gene Addition

Akshara Velmurugan[1], Karthik Karuppusamy[1], Hongjie Wang[2], Donna Palmer[3], Philip Ng[3], Andre Lieber[1]*

We are using capsid-modified, helper-dependent adenovirus (HDAd) vectors for *in vivo* transduction of hematopoietic stem cells (HSCs) with the goal to treat hemoglobinopathies, neurodegenerative diseases, or HIV. HDAds have an insert capacity of 35kb and are produced in HEK293 cells expressing Cre recombinase (116 cells). During HDAd amplification, massive amounts of transgene products are produced in 116 cells, which can affect their viability, greatly reduce the yield of produced HDAds, and/or cause HDAd genome rearrangements that mostly involve the deletion of the transgene. This problem is more acute for HDAd vector expressing genome editors (CRISPR Cas9, base editors, and prime editors), specifically for multiplex editing HDAd vectors containing more than one sgRNA or sg/peg RNAs. We speculate that this is due to enhanced cytotoxicity, associated with off-target editing together with high-level expression of the editors containing dCas9. Our goal was therefore to suppress editor expression in 116 cells, while allowing it in target HSCs. In addition to microRNA regulation (PMID: 2605252), we use here two approaches: *i)* We expressed a natural anti-CRIPR peptide (Acr) from the helper vector, from 116 cells, and also used an Acr-expressing plasmid for transfection together with the pHDAd plasmid in the beginning of the rescue process. *ii)* To completely suppress base or prime editor expression in 116 cells, we employed proteasomal degradation of the anti-CRISPR peptide AcrIIA4 using the chimeric degron ZFP91-IKZF3 (superdegron) and pomalidomide. Addition of pomalidomide restores the function of the dCas9 domain within the base or prime editors. After addition of pomalidomide base or prime editor editing rates in HSCs increased in a pomalidomide concentration-dependent manner. The plateau of editing is reached on day 2 after exposure to pomalidomide. The editor is active for 3 days after removal of pomalidomide. These improvements allowed us to produce HDAds vector with two prime editors (to truncate tEpoR for erythroid cells auto-expansion and to simultaneously correct the sickle mutation in the b-globin gene) or with two Tad CBE base editors (for tEpoR truncation and reactivation of g-globin). Furthermore, we improved HDAd vectors for gene addition (GFP, g-globin) by using a novel hyperactive Sleeping Beauty transposase (SB200x) that allowed for a higher integration rate than its predecessor SB100x. We are currently testing whether this will allow us to reduce the intensity of *in vivo* selection of stably transduced HSCs with O^6BG/BCNU. Overall, these improvements make HDAd vector more suitable for *in vivo* HSC gene therapy.

862 Cross-Species Enhancer AAV Platform for Targeting Spinal Motor Neurons and Cardiomyocytes

The spinal cord contains a diverse array of cell types that work together to coordinate motor and sensory functions by relaying information between the brain and the rest of the body. Understanding and targeting these specific cell types is critical for advancing knowledge and developing therapeutics for movement disorders such as Amyotrophic Lateral Sclerosis (ALS). These conditions, characterized by motor neuron (MN) degeneration, currently lack effective cures. Recent advances in single-cell transcriptomics have provided deeper insights into the cellular diversity, however selective targeting of these cell types remains a significant challenge. To address this gap, we aimed to create an adeno-associated virus (AAV) toolkit for targeting spinal motor neurons. We expanded our single-cell epigenetic datasets to include mouse and macaque spinal cords to identify putative cell-type-specific enhancer elements compact enough to fit into an AAV backbone while providing ample room for therapeutic cargos. From these datasets, we identified novel enhancer elements that target broad motor neuron populations as well as specific spinal cord motor neuron (SMN) subtypes (α and γ). Each enhancer was cloned into an AAV backbone and validated using fluorescence reporter expression *in vivo*. We further tested the top pan-MN enhancers in rats and macaques through various routes of administration, confirming the conservation of enhancer activity across species. Additionally, we combined enhancers targeting both upper motor neurons (UMNs) and SMNs into a single AAV vector for simultaneous labeling of the corticospinal target. This approach demonstrates the capability to target multiple cell types within a single viral vector and could be directly applied to diseases like ALS. Beyond the central nervous system, we developed enhancer AAVs for other targets. Specifically, we identified putative cardiomyocyte-specific enhancers derived from human epigenetic data and validated enhancer AAVs in mouse hearts. Overall, our enhancer AAV platform enables precise, cell-type-specific targeting, which can drive therapeutic cargos for a range of diseases affecting the CNS and other organ systems.

863 A New Generation of Inducible All-In-One Tet-On-ORF/shRNA Vectors

Dezhong Yin[1], Mao Fu[2], Hua Su, Justin Fellows[2], Julian Heller[3], Brian Park[2], Laily Jaghori[2], Wei Fu[2]
[1]OriGene Technologies, Inc., Rockville, MD, [2]OriGene, Rockville, MD, [3]OriGene Technologies, Inc., Germantown, MD

Tet-On is a powerful inducible system and also a classical tool to regulate gene expression in mammalian cells. It has also been applied to regulate Pol III-driven transcription, such as shRNA or gRNA driven by U6 or H1 promoter. However, there are unresolved technical issues that limit its applications. 1). The Tet-On inducible system is composed of Tet regulatory protein and inducible gene expression cassettes, however co-transfection of two vectors will cause the imbalance of the two functional groups in transfected cells. 2). Due to the limited insert size and the unique structure of the lentivector, it poses a great challenge to incorporate all functional cassettes into a single lentiviral transfer plasmid. Our All-in-one new system is built upon the tetracycline activator protein, Tet-On 3G, combined with a new plasmid structure, which could tightly regulate the downstream transcription of gRNA or shRNA. The responsiveness of our system to Doxycycline regulation is also dramatically improved compared with the current versions. The new Tet-On system is further optimized into a compact structure to be compatible with the Lenti-virus package (All-In-One Lenti-Tet-On system), which still keeps the leaky expression at an undetectable

level. Combined with all these features, the new generation of the system imposes a wide application in the genomic editing fields.

864 AAV-Based Cell Type-Specific Targeting (ACTStar) System: A Novel Method for Brain Cell Access

Aykut BOSTANCI[1], Kyung Whan Yoo[2], Yingxi Lin[3], Huaiyu Hu[4], Baisong Lu[5]
[1]Wake Forest University School of Medicine, Winston Salem, NC, [2]Wake Forest University School of Medicine, [3]UT Southwestern Medical Center, Dallas, TX, [4]Syracuse, NY, [5]Wake Forest Medical School, Winston Salem, North Carolina

Determining cell types and their function in the brain enables understanding of the complex structure of the brain, developing treatments, and illumination of cellular mechanisms. Current methods depend on transcriptomic methods, compact promoter isolation, the Cre-loxP system, and germline modifications and are usually of low efficiency and high cost. Thus new methods are needed. The aim of this study is to design a method, AAV-based Cell Type-Specific Targeting system (ACTStar), to overcome the limitations of the current methods. Specifically, the system should access brain cells of multiple species without the need of germline modification and promoter isolation. ACTStar enables brain cell access via CRISPR/Cas9-mediated targeted integration of recombinase DNA into the 3'UTR of marker genes for brain cells. The system consists of three AAV vectors: a gene-specific recombinase driver, a Cas9-expressing vector, and a reporter vector, the latter two vectors are shared between all genes and specifies. The gene-specific recombinase driver vector expresses a sgRNA targeting the 3'UTR of the marker gene and a sgRNA to target both ends of an IRES-recombinase DNA template on the vector for integration into the marker gene. The gene-specific recombinase driver and the Cas9-expressing vector work together to integrate IRES-recombinase into the 3'UTR of the marker gene to enable marker gene-specific expression of the recombinase, which will then activate reporter expression from the reporter vector. We tested targeting IRES-Cre to the 3'UTR region of mouse *Gad1* and *Slc17a7* in mouse N2a neuroblastoma cells, and observed Cas9-dependent integration of IRES-Cre in the expected loci. Off-target analysis and in vivo validation of the method are under way.

865 GRAd as Vaccine Platform for COVID-19 and HIV

Angelo Raggioli, ReiThera, Rome, Roma, Italy

The GRAd platform, based on a low-seroprevalent gorilla-derived adenoviral vector, represents a transformative approach for the rapid generation of vaccines against a variety of pathogens, proving especially suitable for outbreaks and experimental medicine. ReiThera's pioneering efforts in the development of simian adenoviral (SAd) vector vaccines have led to the isolation of several SAds from chimpanzees and gorillas, belonging to different genetic groups. Among these, Group C adenoviral vectors stand out as the most potent inducers of T cell responses, owed to their lower induction of innate immunity (type 1 IFNs) and higher, prolonged antigen expression.

GRAd-COV2, a GRAd-based COVID-19 vaccine, has been the first product based on this platform technology, tested in humans and demonstrated to induce a potent and broad CD8 and Th1-skewed CD4 response, associated to a good safety profile and elevated productivity.

Building on the success of GRAd-COV2, we are now leveraging the GRAd vector technology to develop a potent T-cell inducing HIV vaccine, relying on an innovative T cell immunogen design based on mutationally constrained CD8 epitopes. These epitopes are selected from several clade C and B HIV proteins by structure-based network analysis, are commonly targeted by highly functional CD8 T cells in HIV elite controllers and provide broad coverage of prominent HLA class I alleles.

Preclinical immunogenicity in inbred and HLA-A2.1 knock in mice have confirmed the successful induction of high magnitude, broad and functional CD8+ T cell responses, and the GRAdHIVNE1 vaccine manufacturing and release for the IAVI C-114 phase I clinical trial scheduled for Q1 2025 in Southern Africa are underway. This innovative approach underscores GRAd's potential as a versatile and potent vaccine platform for addressing global health challenges.

866 Differential expression from reconstituted AAV hybrid dual vector systems with splicing enhancers is dependent on tissue specific SRSF protein expression

Chitra Gopinath[1], Joy Dhinakar[2], Sharath Babu[3], Trailokyanath Panigrahi[4], Ruchita Selot[5], Barathi Veluchamy Amutha[6], Arkasubhra Ghosh[7]*
[1]GROW Research Laboratory, Bangalore, India, India, [2]Narayana Nethralaya, Banglore, India, India, [3]Grow Research Lab, [4]Narayana Nethralaya Foundation, Bangalore, India, India, [5]GROW LAB NNF, Bangalore, Karnataka, India, [6]Singapore Eye Research Institute, [7]Narayana Netralaya Foundation, Bangalore, Karnataka, India
**Corresponding Author*

The limited packaging capacity of recombinant AAV presents a major challenge, which is effectively addressed by the hybrid dual (HD) vector system. However, splice signals flanking the overlapping sequence play a crucial role in intron removal, directly impacting final protein expression levels. To overcome this bottleneck, we developed a novel 90bp recombinogenic splice enhancer intron (SEI) to improve splicing efficiency. When compared to the previously reported 297bp AP sequence (OAP), the SEI dual vector demonstrated significantly higher reporter gene expression *in vitro.* We observed a higher percentage of LacZ positive cells with SEI (13.51% ± 3.28) compared to that of OAP (7.29 % ± 0.56) upon cytological staining. Similarly, the β-galactosidase activity obtained from the SEI vectors (0.0082 ± 0.0009 U/µg protein) were significantly higher ($p < 0.0001$) when compared to levels from the OAP vectors (0.0034 ± 0.0006 U/µg protein).

Molecular analysis of splicing *in vitro* revealed that the SEI dual vectors achieved (23.83% ± 4.68) a significantly higher ($P \leq 0.05$) percentage of spliced to unspliced mRNA ratio compared to OAP (6% ± 1.21). To validate that the spliceosome factors are indeed contributing to the higher expression from SEI, we used splicing inhibitors during transfections with pDNA containing SEI or OAP in cis, flanked by the 5' and 3' halves of the *LacZ* reporter gene on either side. The effect of pre-mRNA splicing inhibitors was partially mitigated by SEI, yielding a higher percentage of spliced/unspliced product ratio (7.245% ± 1.892) compared to OAP (3.898% ± 0.9235) upon quantitative PCR analysis, confirming the interaction with splicing factors.

The SEI and OAP dual vectors were tested for stable gene expression *in vivo* in C57BL/6 mice. Percentage of LacZ positive TA muscle fibres were significantly ($P \leq 0.01$) higher with SEI vectors (86.09% ±3.41) compared to OAP (42.63% ±8.94). In retina, LacZ expression were significantly ($P = 0.03$) higher with SEI (45.75 ±0.84) vs. OAP (40.53 ±1.39). We further validated the efficiency of the SEI vectors in retinal and muscle disease mouse models. AAV dual vectors administered *Abca4*$^{-/-}$ retina demonstrated reduced lipofuscin deposits (~60-70%) and significantly recovered retinal function on ERG (n=6/group, $P < 0.05$) with the SEI vectors. In the D2.mdx mice, the SEI vectors yielded 65.19 ± 4.984 dystrophin positive fibers and the OAP vectors yielded 49.52 ± 3.818 fibers.

Interestingly, in all experiments the expression efficacy from the SEI vectors was significantly higher in the muscle compared to the retina. We observed higher expression levels of the spliceosome factors such as SRSF1 and SRSF2 in muscle compared to the retina. The SEI contains enriched binding sites for these factors. These SR proteins bound to SEI (acting as an Exonic Splice Enhancer) stabilize U2AF-65kDa recruitment to the polypyrimidine tract via U2AF-35kDa and aid interactions across intron and the U1 snRNP-specific 70kDa, further promoting efficient intron removal. Gene expression driven by this enhanced splicing mechanism is likely independent of reconstitution efficiencies from the ITR and overlap-mediated concatemerization.

In conclusion, our results in Stargardt disease and Duchenne muscular dystrophy models further validate the application of this novel dual vector system for gene expression across various tissues.

867 *Purified Anelloviral Capsid Proteins can Bind and Encapsidate Different Nucleic Acids Payloads into Anellovectors for Gene Delivery*

Andrew Keezer[1]*, Yue Zhang[1], Nidhi Acharekar[1], Eli Miller[1], Ethan LaFrance[1], Stephanie Thurmond[1], Geoffrey Parsons[1], Erik Hansen[1]*, Timsi Rao[1]*

Human anelloviruses are an abundant and highly divergent class of commensal viruses with no known disease association. In addition, their diversity and abundance in all tissues presents a potential for tissue tropism. These features position them as ideal candidates for potentially safe and efficient gene delivery of a diverse range of therapeutic nucleic acid payloads for various disease indications. We have developed a cell-free, in vitro assembled genetic medicines platform which is composed principally of two components: recombinant anellovirus capsid protein and a nucleic acid payload (e.g., DNA, RNA), offering payload diversity while also simplifying production to conventional and readily scalable systems at dramatically lower cost.

Here we've tested assembly of various sizes and types of nucleic acids with recombinant anellovirus capsid protein for Anellovector formation. Using electrophoretic mobility shift assays followed by electron microscopy, we evaluated the binding and encapsidation of different nucleic acid structures with purified capsid proteins. The tested payloads included single and double stranded DNA and RNA with different structures and sizes. Successful formation of an anellovirus vector (ANV) was achieved with DNA and RNA payloads as confirmed by electron microscopy. Several of these novel ANVs were tested in in vitro transductions of HEK293s and found to be functionally active.

This work has allowed us to better understand the permissiveness of ANVs to potentially deliver an unprecedented diversity of nucleic acid payloads. Such a uniquely versatile genetic medicines platform opens the possibility to more finely tailor the viral delivery product to the gene-delivery need.

868 Development of Novel T Cell-Specific Synthetic Promoters for Safer and More Effective In Vivo CAR-T Cell Therapies

Laura Weerens[1], **Bastien Doix[2]**, Brian Webster[3], Michael Roberts[4], Philippe Parone[5]*
[1]EsoBiotec, Mont-Saint-Guibert, Brabant Wallon, Belgium, [2]EsoBiotec, Mont Saint Guibert, Be, Belgium, [3]EsoBiotec, Mont-Saint-Guibert, Belgium, [4]Chromatin Bioscience Ltd, NORTH BERWICK, East Lothian, United Kingdom, [5]Esobiotec, Mont Saint Guibert, brabant wallon, Belgium
**Corresponding Author*

In vivo reprogramming of Chimeric Antigen Receptor (CAR) T cells holds transformative potential for cell therapy. A major challenge of this approach is the risk of off-target toxicity due to CAR transgene expression in non-T cell populations. To address this, EsoBiotec has developed ENaBL-T, a T cell-targeted lentiviral vector that induces CAR transgene expression under the control of a T cell-specific promoter derived from endogenous human gene regulatory elements. This synthetic promoter is engineered to achieve functional expression of the CAR transgene exclusively in T cells while maintaining a compact size compatible with lentiviral vector packaging constraints.

Core promoters and enhancers from genes specifically expressed in T lymphocytes were identified from functional genomics datasets using proprietary bioinformatics pipelines developed at Chromatin Bioscience. The selected regulatory sequences were assembled into synthetic promoters with a size below 1kb and initially tested in a dual reporter expression assay on a panel of cell lines and primary cells from different tissues. Synthetic promoters were selected based on specificity and potency of expression compared to the constitutive promoter EF1a and subsequently tested for functional expression of a CAR construct in primary T cells and for impact on lentiviral titer during production.

Mining of functional datasets for T cell specific regulatory sequences yielded multiple proximal-core promoters and enhancers sequences which were assembled in 35 synthetic promoters each containing one core and 2 enhancer sequences. Promoters including regulatory sequences from CD3δ and TCRab induced expression of reporters significantly above those of EF1a in lymphocyte cell lines as well as in primary T cells, while minimizing expression in non-target cells. In repeated co-culture of primary CAR-T cells expressing a BCMA CAR under the control of selected synthetic promoters (SYN), cytotoxicity and cell expansion of SYN BCMA CAR-T cells were higher compared to EF1α BCMA CAR-T cells when exposed to target tumor cells. In addition, infectivity and production yield of ENaBL-T SYN BCMA CAR vectors were significantly higher compared to ENaBL-T EF1α BCMA CAR and correlated with a reduced level of BCMA CAR on the surface of lentiviral producer cells.

These findings demonstrate that ENaBL-T synthetic promoters drive potent and selective CAR expression in T cells, outperforming constitutive promoters, while also enhancing vector production yield and infectivity. As a key component of the ENaBL-T vector, the synthetic promoter plays a critical role in building a platform for cost-effective, safe, and efficacious in vivo CAR-T cell therapies.

869 Optimization of Plasmid Cloning Methodology to Support Continued Development of the Pinnacle PCL™ Gene Therapy Platform

Samuel Bartlett[1], Nicholas Richards[2], Julie Aguiar[3], Matthew Fuller[4]
[1]Ultragenyx Pharmaceutical Inc., Somerville, MA, [2]Ultragenyx, Novato, California, [3]Ultragenyx Pharmaceutical Inc., Novato, CA, [4]Ultragenyx, Somerville, MA

As Ultragenyx continues to advance its portfolio of gene therapy programs, there is continual investment in iterative improvement of plasmids supporting rAAV generation. Here, we report advancements in the Triple-Play Plasmid (pTP), which contains AAV *Rep* and *Cap* genes, and the therapeutic vector construct, and is stably integrated into the Pinnacle Producer Cell Line (PCL) system. The Pinnacle PCL system is capable of supporting scalable 2000L clinical grade rAAV production and has been used to generate material for the ongoing UX701 clinical trial for Wilson Disease. Cloning techniques to facilitate faster, more efficient cloning with a higher probability of technical success have been optimized. This effort has culminated in “pTemP 2.0”, a method for scarless cloning of an insert into a standardized pTP template backbone in a single step, bypassing subcloning and generation of intermediate plasmids, thereby saving time and resources. We have also focused on improvement of supplying helper virus functions; however, the traditional, widely used pAD helper plasmid has proven challenging to modify due to its large size (~15-20 kb) and lack of available restriction sites. We have successfully employed the use of Gateway Cloning technology to overcome historic challenges observed with pAD Helper cloning workflows. This work has facilitated ongoing efforts to improve rAAV productivity and quality via higher throughput plasmid cloning.

870 High-Quality Engineered Plasmid Vectors for Advancing Therapeutics Development

Daksha Patel, GenScript USA Inc., Piscataway, NJ

High-quality plasmid vectors are critical for biologic manufacturing, next-generation cell and gene therapies, and vaccine development. Vector purity and the integrity of inverted terminal repeats (ITRs) are essential for genome replication, packaging, and regulatory compliance in therapeutic applications.

Our engineered ssAAV and scAAV vectors with customizable features, including two distinct backbone options, three ITR sequence variations, and multiple restriction sites on both sides of the ITRs enable scientists to meet diverse research and clinical needs. These vectors ensure superior ITR stability and plasmid yield, outperforming traditional systems to deliver consistent and reliable results.

For mRNA research, our optimized plasmid vectors that outperform conventional systems such as pUC57 and pVAX1, offering improved cloning efficiency, enhanced poly(A) tail stability, and higher plasmid yields. With two unique backbones and four poly(A) sequence variations, these new state-of-the-art vectors incorporate dual

restriction enzyme sites, providing exceptional flexibility and precision for diverse and complex mRNA applications.

Combining innovative design with robust performance, these plasmid solutions empower researchers to achieve scalable, high-quality viral vector and mRNA-based therapeutic development. In this poster, we show how these innovations enhance the transition from discovery to commercialization and ultimately advance the field of precision medicine.

871 Enhancing Gene Transfer Efficiency in Viral and Non-Viral Vectors for Therapeutic Delivery

Michael Karney[1], Andrea O'Hara[2], Crystal Richardson[2], Sumit Kumar[1], Haythem Latif
[1]Genewiz From Azenta Life Sciences, South Plainfield, NJ, [2]Azenta, Burlington, MA

Maximizing the efficacy of therapeutic delivery while minimizing risks is key to improving therapeutic development. Viral vectors, such as lentivirus and adeno-associated virus (AAV), are noted for their high efficiency and stable integration, but pose risks such as immunogenicity and insertional mutagenesis. Non-viral methods, including lipid-based nanoparticles (LNPs) and CRISPR/Cas9-based delivery offer safer alternatives with lower immunogenic risks; however, the typical payload can have limited bioavailability. Each of these methods has a critical component of either the delivery vehicle or payload which governs experimental success. Here we describe optimized workflows to minimize screening time while maximizing successful research results across the top three delivery vectors of choice: lentivirus, AAV, and mRNA.

Lentiviral vectors are powerful cell engineering tools used to infect target cells followed by integration of the gene of interest into target cell genome. For difficult-to-infect target cells including hematopoietic stem cells and neuronal cells, high viral titer is critical for efficient transduction. We describe an efficient lentiviral packaging method with robust packaging to produce high-titer lentiviral vectors, tailored for difficult-to-transduce cells and high-throughput packaging in 96-well plates suitable for CRISPR screening.

The ITR regions in AAV plasmids are notoriously unstable, prone to full or partial deletions during propagation in bacteria. As a result, a significant portion of clones after transformation may contain mutated ITRs, and plasmid DNA preparations from a liquid culture may contain a mixed population. Our results show that proprietary plasmid synthesis and preparation techniques maintain ITR integrity through AAV packaging and improve gene delivery.

Lastly, sequence accuracy of the DNA template and integrity of transcribed mRNA are crucial factors in determining the success of downstream experiments for mRNA therapies. Here we illustrate a streamlined gene-to-mRNA workflow to overcome these limitations in mRNA production. This includes rapid synthesis with optimization of long polyA regions in mRNA for enhanced LNP encapsulation and efficient delivery, in vitro transcription, and novel sequencing of mRNA constructs for complete characterization of critical components such as the polyA tail.

872 Gene Delivery Vector Comparison Study Using the Celigo™ Image Cytometer

Bo Lin[1], Mackenzie Pierce[1], Yongyang Huang[2]
[1]Revvity, Lawrence, MA, [2]Lawrence, MA

Recombinant adeno-associated virus (rAAV) is one of the preferred gene delivery vectors due to its safety and efficacy attributes for cell-based therapies. To develop effective gene delivery vectors, scientists need to consider multiple elements, such as the promoter, insertion location, genetic target, and target gene to name a few. Green fluorescent protein (GFP), or other detection markers are often used to measure vector transduction and gene expression efficiency. Using fluorescent microscopy and flow cytometry, cell samples can be analyzed, however, both methods can be quite time consuming, labor intensive, and lack high-throughput capabilities to quickly monitor gene expression over the time course of the experiment. In this work, we developed and employed the Celigo™

cytometer to screen different gene delivery vectors including, plasmid, mRNA, AAV with or without gene integration element, to determine the GFP gene delivery efficiency in SupT1 cells. GFP signal intensity was monitored 24-, 48-, 72-, and 96-hours following transduction and the viability was tested at 96 hours. Using the Celigo™ image cytometer we were able to monitor transient and integrated GFP expression amongst multiple gene delivery vectors. SB-P-AA-101-07 displayed stronger expression levels at 24- and 48-hours as transient gene delivery reagent. With stable gene expression, both plasmid and rAAV with gene integration element mRNA exhibited over ~90%+ GFP transduction efficiency at 96-hours. The end-point viability assay used a duo fluorescent staining method with Hoechst 33342 and Drag 7™ dyes to display various results ~60-95% amongst gene delivery vectors used, while untransduced samples displayed high viability 95%. Based off this study, the Celigo™ cytometer may prove useful for other researchers developing and screening gene delivery vector efficiency and viability in a high throughput manner.

For Research Use Only. Not for use in diagnostic procedures.

873 New gene therapy vehicle for the expression of multiple transgenes with distinct kinetics of expression

Justine Basset[1], Alexandra Seraffin[2], Teddy Jégu[2], Alberto Epstein
[1]EG 427, PARIS, Paris, France, [2]EG 427, PARIS, France

During the last decade, viral delivery systems for gene therapy have undergone significant improvements, enabling the introduction, replacement, or counteraction of genes to treat a variety of human diseases. However, current systems are not adapted for the expression of multiple transgenes with distinct expression kinetics.

Herpes simplex virus type 1 (HSV-1) is a non-integrative virus that establishes a life-long, latent infection within sensory neurons. Its 152kb double-stranded DNA genome is packed into chromatin and organized in two distinct epigenetic programs: Heterochromatin marks repress all the viral lytic genes, while euchromatin marks allow expression within a specific genomic region called the Latency-Associated Transcript (LAT).

We developed a single, non-replicative HSV-1 (nrHSV-1) vector bearing two transgenes inserted in two different epigenetic regions of the HSV-1 genome. *In vitro* studies using glutamatergic cortical neurons derived from iPS cells showed that this unique vector allows the two transgenes to be expressed with different durations. (Figure 1) The transgene inserted in the heterochromatin region (Fig. 1B) displays shorter expression while the one inserted in the euchromatin counterpart (Fig. 1A) is stably expressed over the tested time points. The expression pattern of these transgenes from this single nrHSV-1 vector is currently being assessed *in vivo* in mouse DRG sensory neurons after footpad injection.

This innovative dual-payload nrHSV-1 vehicle represents a promising approach for next-generation gene therapy products, enabling the delivery of multiple transgenes with distinct expression dynamic within the same cell. This research paves the way to *in vivo* gene deletion and replacement by a long-term expression of the corrected gene, as a therapeutic tool for autosomal dominant diseases.

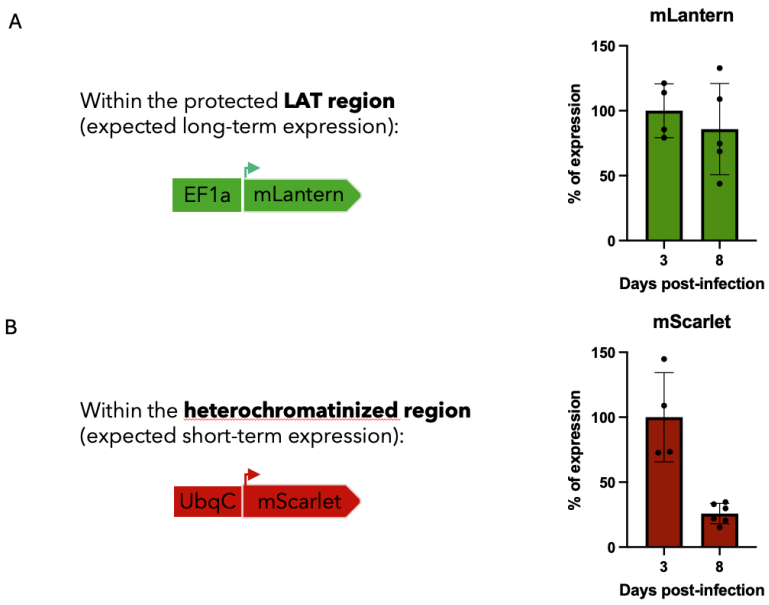

Figure 1: Distinct kinetics of transgene expression in iPS-derived cortical glutamatergic neurons infected with nrHSV1 dual-payload vectors. **A.** RT-PCR quantification of the mGreen Lantern reporter gene inserted within the protected LAT region, showed a stable expression level overtime. **B.** RT-PCR quantification of the mScarlet reporter gene inserted in the heterochromatin region of HSV1 genome presented a strong decrease of expression overtime.

874 Comparison of dual AAV vector strategies for lung gene therapy

Brenna Stevens[1], Madison Hughes[1], Yanlong Pei[2], Jeff Caswell[3], Khalil Karimi[2], Bernard Thebaud[4], Sarah Wootton[1]
[1]University of Guelph, Guelph, ON, [2]University of Guelph, [3]University of Guelph, Guelph, [4]Ottawa Hospital Research Institute, Ottawa, ON

Introduction: Cystic Fibrosis and other monogenic lung diseases have long been a pertinent target for AAV-vectored gene therapies. However, the limited coding capacity of AAV has been a serious barrier to delivering larger transgenes. To overcome this issue, two AAVs can be co-administered, each carrying one half of the gene, effectively doubling AAV's coding capacity. Many dual vector strategies have been developed to achieve recombination of the full-length transgene. The overlap method uses homologous recombination, while the hybrid method uses this in addition to splicing. The novel mRNA transplicing (MTS) method involves mRNA transcript binding and splicing.

Methods and Results: Here, we engineered dual AAV vectors employing either the overlap or novel MTS strategy to deliver the Cre-recombinase gene, with eGFP in the 5' AAV and mCherry in the 3' AAV as reporter genes. These AAV vectors were delivered to mouse-derived precision-cut lung slices (PCLS) as a lung modelling system, and fluorescence was monitored via fluorescence microscopy. Both eGFP and mCherry expression in single cells were observed after co-transduction, suggesting both AAVs had transduced single lung cells (Figure 1). PCLS generated from the Rosa-LacZ strain will be used to evaluate successful Cre expression via LacZ staining and quantification. These vectors will then be co-administered intranasally to Rosa-LacZ mice to evaluate their efficiency *in vivo* in the lungs. The lungs will be harvested, stained, and LacZ quantitative assays will be run. Additionally, we developed dual AAV vectors using the overlap and hybrid method to deliver the clinically relevant CFTR gene (tagged with eGFP). Mouse PCLS were transduced with these vectors and GFP expression monitored. Both the overlap and hybrid vectors resulted in GFP-CFTR expression; however, the overlap method outperformed the hybrid method (Figure 2). These CFTR dual vectors have been administered to Balb/c mice intranasally. At 3 weeks post-AAV administration, the lungs will be harvested, and GFP-CFTR expression will be quantified by flow cytometry.

Conclusion/Relevance: Dual vectors are vital to expanding AAV's coding capacity. This study suggests that the overlap method may be an effective option for delivering the oversized CFTR gene to lungs.

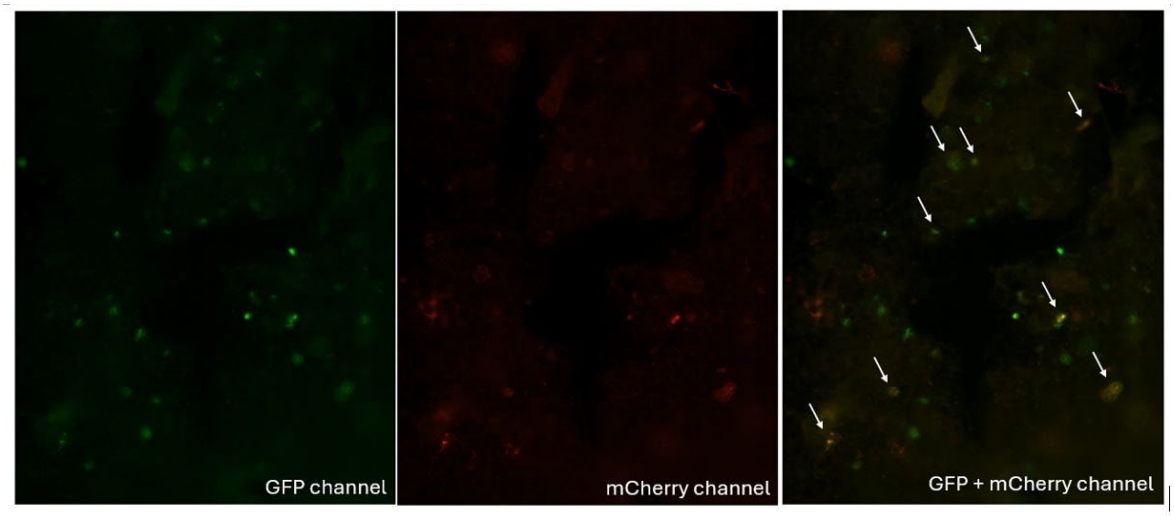

Figure 1. Mouse-derived PCLS were transduced with dual AAV Cre mRNA transplicing vectors. Five days post-transduction, slices were imaged using fluorescence microscopy to detect GFP and mCherry, and images were merged to identify co-transduced cells (white arrows).

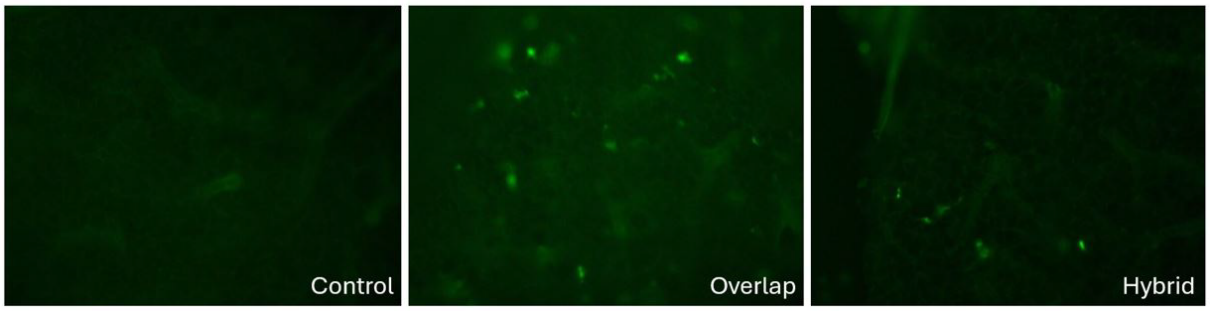

Figure 2. Mouse-derived PCLS were transduced with dual AAV vectors expressing eGFP-tagged CFTR using either the overlap or hybrid method. PBS-administered slices were used as a negative control. Five days post-transduction, slices were imaged under fluorescent microscopy to detect GFP.

875 AAV Vectors in Focus: Overcoming Challenges in Gene Delivery Systems

Shohreh Ghasemi, Augusta University, Atlanta, GA

Adeno-associated virus (AAV) vectors have become a cornerstone of gene therapy due to their safety, versatility, and ability to achieve long-term gene expression. However, challenges such as limited cargo capacity, pre-existing immunity, and off-target effects continue to hinder their full potential. This abstract examines recent advancements aimed at overcoming these obstacles to enhance the efficiency and applicability of AAV-based gene delivery systems. Innovations in capsid engineering have resulted in vectors with improved tissue specificity and reduced immunogenicity. Novel strategies, including the development of hybrid AAV systems, enhanced manufacturing

processes, and immune modulation techniques, are enabling more effective delivery of therapeutic genes. These breakthroughs have significant implications for treating a wide range of genetic disorders and chronic diseases, underscoring the potential of AAV vectors to transform the future of gene therapy.

876 Biomechanical Assessment of the Impact of Adenoviral Delivery of Three VEGF Isoforms on Rotator Cuff Tendon-to-Bone Healing in Mice

Victor Wakim[1], Dolan Sondhi[1], Hirotaka Iura[2], Camila Carballo[3], Meghan Herlitzka[1], Monica Gertz[1], Yuki Suzuki[2], Neil Hackett[1], Stephen Kaminsky[1], Scott Rodeo[4], Ronald Crystal[5]
[1]Weill Cornell Medical College, New York, NY, [2]Hosptial for Special Surgery, New York, NY, [3]Hosptial for Speical Surgery, New York, NY, [4]Hospital for Special Surgery, New York, NY, [5]Weill Cornell Medical College, New York

Tendon healing is the main limiting factor of recovery after rotator cuff repair. Outcomes from surgery may be enhanced by faster healing and a reduced rate of repeated injury. This study assesses the local administration of an adenovirus vector (Ad) expressing multiple isoforms of vascular endothelial growth factor (VEGF) to promote recovery from rotator cuff repair in a mouse model. We used Ad serotype 5 to express a hybrid cDNA/genomic VEGF gene coding for the 3 major VEGF isoforms: VEGF121, 165, and 189. *In vitro* and *in vivo* studies established that the highest VEGF expression was achieved with Ad5VEGF(3i), $E1^{-}E3^{-}$ Ad5 with an expression cassette in the 3' to 5' configuration driven by the CAG promoter in the deleted E1 region. This vector expresses VEGF 189>165>121. The C57Bl/6 mice (n=10, per time point, per treatment condition) underwent complete transection of the supraspinatus tendon, followed by immediate surgical repair using a modified Kessler suture pattern with a 6-0 prolene suture. The potential utility of Ad5VEGF(3i) was assessed by its administration into the deltoid muscle at a total dose of 10^8 or 10^9 particle units at the time of rotator cuff repair. To assess the impact on recovery, biomechanical testing of the tendon attachment site was assessed at 1, 2, 4 and 8 weeks post-surgery. Rotator cuff injury and subsequent repair had a profound impact on many biomechanical parameters, with a >2.5-fold decrease in stiffness at all time points. However, the tendons of the animals treated with Ad5VEGF(3i) showed a faster recovery compared to untreated surgical mice with a higher load to failure ($p<0.05$), higher maximum stress ($p<0.03$) and higher energy absorbed by the tendon ($p<0.02$) 2 weeks following surgery. The biomechanical properties of the tendon were maintained at 4 weeks after surgery. At 8 weeks, the high dose treated tendons also showed higher energy absorbed ($p<0.01$). We conclude that the delivery of Ad5VEGF(3i) at the time of surgery has the potential to accelerate recovery following rotator cuff repair and maintain a better biomechanical phenotype.

877 A novel miniaturized filamentous phagemid as a gene delivery vehicle to target mammalian cells

Roderick Slavcev[1], Shirley Wong[1], Salma Jimenez[2], Deborah Pushparajah[2], Rohini Prakash
[1]University of Waterloo, Waterloo, ON, [2]University of Waterloo, Waterloo

The filamentous phage M13 is a single-stranded DNA phage with several attractive characteristics for gene delivery, including a capsid amenable to the display of foreign peptides and a simple well-characterized genome that is easy to genetically modify. Previously, we constructed a targetable DNA minivector production system based on M13 (a miniphagemid), called *'intelligent Phage-Assembled Gene Expression'* (iPhAGE) which minimized the inflammatory bacterial and phage DNA content in the vector. In general, DNA minivectors, devoid of their prokaryotic components have shown improved gene transfer and safety. We examined the miniphagemid system's capacity for *in vitro* transgene delivery to target cells through phage display of epidermal growth factor (EGF) to target its cognate receptor. The absence of the prokaryotic backbone and minimized vector size conferred dramatically improved transgene expression of both the targeted miniphagemid virion particles as well as purified single-stranded phagemid miniDNA compared to their 'full' counterparts. We further optimized this system to improve the packaging efficiency of DNA minivectors by deleting the packaging signal and introducing multiple novel mutations to the helper plasmid used for miniphagemid production. These enhancements resulted in higher yields and exceptional purity of the miniphagemids. In all produced lysates, contamination of prokaryotic backbone DNA in iPhAGE lysates was $< 2.0 \times 10^{-8}$ and contamination from helper phage/plasmid was $< 1.0 \times 10^{-10}$. Another notable improvement was the yield of miniphagemids and hence retrievable miniDNA, which was between 1.0–10 mg/L/OD_{600} depending on the packaged sequence. The improved system further enhanced phage-mediated gene

expression in mammalian cells by >100-fold as assessed *in vitro*. In summary, we present a highly pure, scalable, and efficient vector production system that combines cell-targeting ligand display with high capacity, minimized DNA vector capabilities.

878 An *E. coli*-based platform for the production and assembly of anellovirus vectors in *vitro* for gene therapy platform

Roderick Slavcev[1], Rohini Prakash, Deborah Pushparajah[2], Shirley Cheung[2]
[1]University of Waterloo, Waterloo, ON, [2]University of Waterloo, Waterloo

Gene therapy (GT) offers immense potential for treating various acquired and inherited diseases, but the safety and efficacy of this treatment modality largely depends on the vector. Generally, viral vectors show high transduction efficiency along with transgene expression, but their use is limited by challenges such as insertional mutagenesis, immune responses, and high manufacturing costs. While non-viral vectors may offer the possibility of improved control and redosability, and often easier to produce, they tend to exhibit lower transgene delivery efficiency. These limitations underscore the need for novel and more effective delivery systems that are safe, efficacious, and provide greater transgene expression control via vector redosability and titratability.

Anelloviruses are ssDNA orphan viruses with the ability to transfect a wide range of human cells and tissues. As they naturally contribute to the human virome, they offer a safer and potentially redosable/controllable alternative to more conventional viral vectors. The application of these viruses as gene therapy vectors has been limited by the dearth of efficient propagation systems that permit the exploitation of anelloviruses as suitable gene therapy vectors.

Here, we describe a novel prokaryotic system for a two-step *in vitro* of TTV19 anellosomes in *E. coli*. This work successfully demonstrates the expression and assembly of anellovirus capsid proteins, leading to the production of ssDNA viral gene delivery vectors *in vitro*. Self-assembled particles were capable of efficiently transducing mammalian cells with a 100- to 1000-fold improvement in gene expression compared to the molar equivalent of dsDNA and ssDNA in HEK 293T cells respectively. This two-step anellovirus vector production was further enhanced into a single-step production system enabling fully formed anellosomes in *E. coli*. The proposed *E. coli*-based anellovirus system represents a novel and highly scalable/cost-effective platform for the development of anellovirus-based viral vectors for gene therapy applications.

879 Engineering T Cell-Specific Lentiviral Vectors for Safe and Effective In Vivo CAR-T Therapy

Bastien Doix[1], Melissa Drappier[2], Alexia Fiévet[3], Brian Webster[2], Jishuai Zhang[4], Philippe Parone[5]*
[1]EsoBiotec, Mont Saint Guibert, Be, Belgium, [2]EsoBiotec, Mont-Saint-Guibert, Belgium, [3]EsoBiotec, Mont-Saint-Guibert, Brabant Wallon, Belgium, [4]Shenzhen Pregene Biopharma, Shenzhen, China, [5]Esobiotec, Mont Saint Guibert, brabant wallon, Belgium
**Corresponding Author*

Ex vivo Chimeric Antigen Receptor (CAR)-T cell therapy is constrained by a complex manufacturing process and a high cost of goods, significantly limiting patient accessibility. In vivo generation of CAR-T cells offers a cost-effective, “off-the-shelf” approach by reprogramming a patient’s own cells directly in situ, addressing the challenges of both autologous and allogeneic ex vivo CAR-T therapies. However, translating this approach into the clinic requires overcoming key hurdles, such as ensuring precise T cell transduction to minimize off-target toxicity and effectively reprogramming a sufficient number of T cells to achieve meaningful clinical outcomes. To address these challenges, EsoBiotec has developed a 3rd generation self-inactivating Engineered NanoBody T cell-specific Lentiviral vector (ENaBL-T). ENaBL-T features an engineered viral envelope incorporating a T cell-specific nanobody binder (VHH) that enables precise targeting of T cells and induces their activation and expansion. Efficient internalization of the vector into T cells is achieved through a newly designed targeting-deficient mutant of VSV-G.

VSV-G mutant envelope proteins were created via site-directed mutagenesis and candidates were screened to identify mutations that abrogate the natural tropism of VSV-G for the LDL receptor while retaining its membrane fusion activity. Selected VSV-G mutants were paired with T cell-specific nanobody binders (VHH) including CD8 and TCRαβ and tested on panels of cell lines and primary cells. The optimized vector, combining anti-TCRαβ VHH and VSV-G^{I331E} targeting deficient mutant, demonstrated a high level of T cell specific transduction with minimal off-target transduction in TCR-negative cells. VSV-GI^{331E} TCRαβ VHH ENaBL-T efficiently transduced both resting and activated human primary T cells, inducing significant T cell activation and expansion compared to broad tropism VSV-G^{WT} lentiviral vectors. BCMA CAR-T cells generated using VSV-G^{I331E} TCRαβ VHH ENaBL-T (referred to as ESO-T01) exhibited potent antitumor activity *in vitro* against target tumor cells.

These findings demonstrate that the ENaBL-T vector, incorporating the VSV-G^{I331E} targeting deficient mutant and a VHH targeting TCRαβ, achieves precise T cell targeting while also inducing T activation and expansion through the stimulatory activity of the TCRαβ VHH, resulting in high levels of T cell transduction. This engineered lentiviral vector enables the generation of potent CAR-T cells with robust antitumor activity. ENaBL-T represents a promising step toward the clinical translation of cost-effective, scalable, and safe in vivo CAR-T cell therapies.

880 Infectivity, Expression and Redosing in mice of an Anellovirus vector produced by in vitro assembly.

Isabella Gold[1], Riana Pozsgai[1], Erik Hansen[1], Timsi Rao[1], Andrew Keezer[1], Yue Zhang[1], Nidhi Mukund Acharekar[1], Hyun Jung Jun[1], Geoffrey Parsons[1], Christopher Wright[1], Ashley Mackey[1]
[1]*Ring Therapeutics, Cambridge, MA*

Recent advances in gene therapy have led to FDA approvals of several treatments for a wide range of genetic disorders. Despite these successes, significant challenges remain, including issues with immunogenicity, redosing, serious adverse events, and high manufacturing costs. To address these limitations, Ring Therapeutics is developing a novel class of gene delivery vectors (ANVs) derived from Anelloviruses. Anelloviruses are a diverse family of commensal, single-stranded DNA (ssDNA) viruses that constitute >97% of the human virome. Anelloviruses are widely distributed across vertebrate species, are immune evasive, and exhibit broad tissue tropism in humans, making them promising candidates for therapeutic gene delivery. Here we show that ANVs are amenable to production via assembly in vitro, which has the potential to dramatically reduce manufacturing costs for genetic medicines.

We recently demonstrated that these engineered vectors can be produced at research scale by assembly in vitro combining purified capsid proteins and nucleic acid payloads in a highly controlled encapsidation reaction. Further, ANVs have been shown to be functionally active exhibiting transduction in cell cultures using a marker gene, green fluorescent protein (GFP). Here, we demonstrate, for the first time in vivo (in mice), the activity of an ANV assembled in vitro containing ssDNA payloads encoding GFP under the control of a CMV promoter (ANV.CMV.GFP). Local injections in eye and muscle of mice were performed to evaluate the expression of the ANV.CMV.GFP vector. Initial repeat dosing experiments were also conducted. For the ocular study, C57BL/6 mice received bilateral subretinal injections of ANV.CMV.GFP, AAV2.CMV.GFP, or vehicle control on Day 0. A repeat unilateral intravitreal injection was administered on Day 21. Retinas and posterior eyecups were harvested on Days 21 and 42 for analysis of DNA, mRNA, and protein. For the muscle studies, Balb/c mice were injected intramuscularly with ANV.CMV.GFP, AAV2.CMV.GFP, or vehicle control on Day 0, followed by a repeat intramuscular injection on Day 21. Caudal muscles were harvested on Days 21 and 42 for analysis.

GFP DNA, mRNA, and protein was detected, and redosing was well tolerated in the mice. This study represents the first demonstration in vivo of the infectivity, expression, and repeat-dosing potential of ANV assembled in vitro and data are consistent with our transduction results in cell culture. These findings support further studies in vivo of ANV assembled in vitro and highlight the potential of ANVs to offer a more versatile therapeutic, with substantially less cost than traditional viral therapeutics, possibly overcoming key limitations of current gene therapy.

881 Detyrosinated Microtubules Limits AAV2 Trafficking and Regulates Gene Transduction Efficiency

Shefali Tripathi[1], Shamshul Huda[2], Joydipta Kar[1], Dinesh Chandra[3], Jayandharan Rao[4]*, Nitin Mohan[1]*
[1]Indian Institute of Technology Kanpur, India, Kanpur, Uttar Pradesh, India, [2]Indian Institute of Technology Kanpur, India, [3]Dept of Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India, [4]Indian Institute of Technology Kanpur, India, Kanpur, India, India
**Corresponding Author*

Introduction: Adeno-associated virus (AAV) is a widely utilized vector for gene delivery due to its safety and efficacy. However, its transduction limitations lie in its interaction with host cell machinery, particularly its trafficking through the endosomal compartments and routing toward degradation pathways. This study investigates the role of microtubule detyrosination—a microtubule post-translational modification (Mt-PTM)—in regulating AAV2 trafficking, and its transduction efficiency.

Methods: By using super-resolution Structured Illumination Microscopy (SIM) and correlative live-cell and STochastic Optical Reconstruction Microscopy (STORM), we studied the interaction between AAV2 and detyrosinated microtubules and the impact of microtubule detyrosination on AAV2 motility. Microtubule tyrosination was enhanced by overexpressing tubulin-tyrosine ligase (TTL) and the detyrosinated tubulin was modulated pharmacologically by using parthenolide. Transduction efficiency was quantified, and preclinical models of hemophilia B were used to evaluate the therapeutic potential of dimethylamino parthenolide (DMAPT) in enhancing AAV2-mediated factor IX expression.

Results: AAV2 infection led to an increase in microtubule detyrosination, which hindered the cytoplasmic motility of the virus and delayed its nuclear entry. Either overexpression of tubulin-tyrosine ligase (TTL) or the pharmacological inhibition of microtubule detyrosination using parthenolide, improved the AAV2 motility by two-fold and its perinuclear accumulation. These modulations facilitated the early escape of the virus, resulting in a three-fold improvement in transduction efficiency. DMAPT enhanced AAV2-mediated factor IX expression in hemophilia B preclinical models, demonstrating its potential as a co-therapeutic agent.

Conclusion: These findings underscore the critical role of detyrosinated microtubules in managing AAV2 trafficking and transduction efficiency. The pharmacological targeting of microtubule detyrosination with modulators like DMAPT offers a promising strategy for improving the effectiveness of AAV-based gene therapies. This study establishes the foundation for novel therapeutic interventions that enhance AAV transduction by modulating host-cell microtubule dynamics.

882 The influence of VP1 N-termini on heat-induced genome release of adeno-associated virus serotype 8

Recombinant adeno-associated virus (rAAV) is used as a gene delivery vehicle for gene therapy. rAAV encapsidates the designed genome flanked by the two inverted terminal repeats in the wild-type genome, that contains a promoter and gene of interest to treat diseases. rAAV capsid consists of 60-mers of three major viral proteins (VPs), VP1, VP2, and VP3. VP1 contains the VP1 unique (VP1u) region at the N-terminus that is not present in other VPs and possesses phospholipase A2 activity for endosomal escape. The VP2 N-terminus, which is shared with VP1, is called the VP1/VP2 common region and contains a nuclear localization signal. Although the stoichiometric ratio of VPs composing the capsid has been considered to be VP1:VP2:VP3 = 5:5:50, recent studies have shown that rAAV is a mixture of heterogeneous particles with various VP stoichiometric ratios, and that the incorporation of VP1 or VP1/VP2 into total VPs is highly correlated with rAAV transduction efficiency.

Here, we focused on the VP stoichiometric ratio of rAAV serotype 8 (rAAV8) and investigated the heat-induced genome release and the capsid thermal stability using several biophysical methods, mass photometry, nano differential scanning fluorimetry, hydrogen/deuterium exchange mass spectrometry, and sedimentation velocity analytical ultracentrifugation. We prepared three rAAV8 samples with different VP stoichiometric ratios, including particles with a high VP1/VP2 to VP3 ratio (FP_{LD}), a low VP1/VP2 to VP3 ratio (FP_{HD}), and only VP3 ($FP_{VP3only}$). All the samples were extensively purified to remove empty particles (EPs) with no encapsidated genome inside the capsid using two cycles of CsCl density gradient ultracentrifugation. As a result, upon heating to the point of capsid disassembly, most rAAV8 particles remain as monomers in three states: capsids encapsidating their ssDNA, capsids that fully eject the genome while tethering the genome on the capsid surface, and empty capsids that have fully released their encapsidated genome. The ratio of VP1 and/or VP2 to total VPs barely altered the extent of genome release, whereas the possession of VP1 and/or VP2 influenced on the extent of genome release. Importantly, thermal unfolding of the VP1u and VP1/VP2 common region, i.e., VP1 N-terminus was closely monitored at about 60°C, lower than the VP3 denaturation initiation temperature of 71-72°C. Interestingly, $FP_{VP3only}$ had a greater proportion of empty particles (EPs) than did FP_{LD} and FP_{HD} after incubation at 45–55°C, whereas when incubated at 65°C, the FP_{LD} and FP_{HD} had a significantly greater proportion of EPs than did $FP_{VP3only}$. This result indicates that the unfolding VP1 N-terminus related to the genome release upon the heating; folded VP1 N-termini prevented the genome release at temperatures below 60°C, whereas the unfolding of the globular structure in VP1 N-termini facilitated the genome release.

This study provide us the new insights into heat-induced genome release with a focus on VPs and contribute to a better understanding of the rAAV particles at a molecular level.

883 A Single Conserved F-to-Y Mutation at the 5-Fold Interface Is Exclusively Required for an AAP-Dependent-to-Independent Capsid Assembly Switch

Anusha Sairavi[2], Swapna Kollu[1], Hiroyuki Nakai[2]*

Assembly activating protein (AAP) facilitates a multitude of functions resulting in AAV capsid assembly. However, the process through which AAP assists VP subunit assembly resulting in the formation of AAV capsids is not completely understood. Data from our group and others have shown that certain AAV serotypes (AAP-independent serotypes; AAPi serotypes: AAV4, 5, 11, 12 and rh32.33) can assemble capsids independently of AAP's involvement while the rest are AAP-dependent serotypes (AAPd serotypes) that include but are not limited to AAV2,3,6,7,8,9, and 10. To uncover amino acids underlying AAP requirement, we had previously focused on AAV2. Our iterative evolution study on an AAV2 mutagenesis library identified AAV2F370Y as a mutant capable of assembling capsids without AAP. However, this observation does not exclude the possibility that there are alternative pathways that contribute to the transition from AAPd to AAP-independent AAPd serotype capsid mutants because directed evolution approaches do not necessarily capture all potential pathways leading to the desired phenotype. Here, by extending our directed evolution approach to AAV9, we reveal that the F-to-Y mutation at the position corresponding to AAV2F370 is an exclusive requirement for the phenotype switch from AAV9, an AAPd serotype, to an AAP-independent AAV9 capsid mutant. To uncover the amino acids underlying AAP requirement in AAV9, we generated an AAP knockout of AAV9 utilizing an ITR2-Rep2-AAV9CapAAP9KO-ITR2 plasmid. The plasmid was subjected to error-prone PCR to generate an AAV9 mutagenesis library. The library was selectively enriched for AAP independent mutants by cycling through HEK293 over three rounds of selection in the absence of AAP9. Similar to the finding with AAV2, arbitrarily chosen mutants after third round showed a common AAV9F372Y mutation (corresponding to AAV2F370Y) and were capable of assembling capsids in the absence of AAP. The AAV2F370Y and AAV9F372Y mutants exhibited transduction efficiency in HEK293 cells comparable to their respective wild-type capsids, indicating that the F-to-Y mutation does not impair function. This suggests that the mutation is neutral, apart from its role in determining AAP dependence in capsid assembly. As this F-to-Y mutation lies on the 5-fold axis interface, we propose that VP subunit assembly at this axis requires conformational changes promoted by AAP, while the F-to-Y mutation alone induces these changes even in the absence of AAP. Importantly, our finding that the same F-to-Y mutation emerged as the sole mutation capable of conferring AAP independence in two independent directed evolution studies conducted on two separate serotypes (AAV2 and

AAV9) strongly indicates that, within the AAPd serotypes, this F-Y mutation is the only viable pathway to AAP independence and no alternative pathways can confer AAP independence. This F residue is fully conserved across the AAPd and AAPi serotypes while the F-Y mutation appears to have a neutral effect on infectivity, indicating that there are evolutionary constraints that strongly disfavor reversion to AAP independence once capsid assembly becomes reliant on AAP. Further investigation of AAP-independent mutants derived from AAPd serotypes will help better understand how AAP participates in AAV capsid assembly and why AAP has become an indispensable factor in this process.

884 Functional Orthogonality of Parvoviral Phospholipase A_2 (PLA_2) Domains in Recombinant AAV Vector Transduction

Dependoparvoviruses are a genera of Parvoviridae which are of interest in viral vector development for gene therapy applications. Engineering approaches that modify the AAV capsid surface have been employed to retarget vectors and enhance transduction efficiency in desired tissues. Separately, buried capsid protein domains that are not surface exposed, such as the viral protein 1 unique (VP1u) region or nuclear localization signals (NLS), have been shown to play a critical role in viral infectivity and post-entry trafficking. However, functional exploration and engineering of these domains with the goal of improving vector potency has lagged that of the capsid surface. Within this framework, the conserved group XIII phospholipase A_2 domain (PLA_2) within the VP1u of parvoviruses, which must be externalized during infection is particularly noteworthy. Here, we describe a library-based approach to evaluate a diverse panel of both rationally engineered and natural parvoviral PLA_2 domains by replacing the adeno-associated virus serotype 9 (AAV9) enzymatic domain. Key findings highlight which parvoviral genera contain PLA_2 domains that exist in sequence space compatible with the VP1u region of AAV9 capsid proteins. Notably, a selection of Avian dependoparvovirus/AAV9 chimeras deemed high performers based on infectious library cycling *in vitro* demonstrate improved transduction efficiency compared to both single-stranded (ss) and self-complementary (sc) AAV9 vectors. The best performing chimeric isolate is equivalent to AAV9 with regard to cell surface binding but shows improved uptake into the cytoplasm as well as nuclear entry as evidenced by sub-cellular fractionation and confocal microscopy. The lead identified avian PLA_2 domain is also functional in the context of serologically distinct AAV5 vectors, demonstrating broader compatibility within the genera. Overall, this study underscores the functional orthogonality of antigenically distinct PLA_2 core enzyme domains derived from Parvoviridae in commonly utilized AAV capsids with prospects for improving post-entry trafficking and AAV vector potency in gene therapy.

885 Identification of key amino acids near the N-terminus of AAV AAP essential for driving its degron function

Anusha Sairavi[2], Swapna Kollu[1], Hiroyuki Nakai[2]*

Assembly activating protein (AAP) interacts with AAV VP subunits and plays a critical role in AAV capsid assembly. It has been shown that AAP binds to VP through the domain near its N-terminus. This AAP-VP interaction, however, cannot remain persistent as prolonged binding may hinder VP oligomerization. Studies have shown a decline in AAP steady-state levels over time during capsid assembly, and capsid structural and biochemical analyses have revealed that AAP is absent from the capsid. Together, these findings strongly indicate that AAP indeed dissociates and is ultimately degraded. To understand the mechanism by which AAP degrades, our group has

conceived an AAP degron model wherein AAP undergoes facilitated degradation triggered through its degron motif. We have previously shown that the Hydrophobic Region (HR) for AAP1, 2, 3, 5, 6, 7, 8, 9 and 12 and the Conserved Core (CC) for AAP 4 and 11, both of which are present near the N-terminus, contain a degron. Here we further extend our observations and uncover key amino acids within the HR or CC region that are critical for AAP's degron function. To pinpoint the key amino acids within each of HR and CC critical for AAP's degron function, we utilized two approaches, with each tailored to the respective region. For the HR region, we scanned overlapping motifs across its entirety, and for the CC region, we manually selected a residue based on the AAP sequence alignment. For the HR region, we chose AAP9 as the representative serotype and divided HR into 7 subregions (R1 to R7) wherein each subregion had 5 overlapping residues with the adjacent region(s). To assess the degron function of these subregions, each subregion was fused to FLAG-GFP, and GFP expression from each subregion construct was compared against controls. Interestingly, both R5 and R6 showed substantial decrease in GFP expression comparable to that from the full-length HR, whereas the other subregions showed GFP expression comparable to the FLAG-GFP control. The overlapping 5 residues between R5 and R6 was found to be QWLQV, indicating its critical role in HR degron function. For the CC region, sequence alignment of AAPs revealed that most residues are conserved exhibiting similar biochemical attributes except at position 135(AAP4 numbering), where AAV4 and11 have V while all other serotypes have E. Accordingly, we generated AAP4CCV135E-FLAG-GFP and assessed its GFP expression against controls. True to our hypothesis, we found AAP4CCV135E retained GFP expression albeit at a level lower than the FLAG-GFP control, indicating a critical role of this residue for the degron function in CC. These findings confirm that AAPs are inherently prone to degradation, while previous studies including ours have consistently shown that AAP can stabilize in the presence of VP, indirectly indicating that AAP-VP complex formation prevents AAP degradation. Taken altogether, we postulate a hypothetical model where the formation of AAP-VP complex masks the AAP degron motif thereby suppressing its function and supporting AAP's function for assisting VP oligomerization. Once VP oligomerization begins, it induces a conformational loosening of the AAP-VP interaction, leading to degron exposure. This, in turn, facilitates AAP degradation, promotes AAP-VP dissociation and ultimately VP oligomerization into a fully assembled capsid.

886 Understanding DNA host cell factors as potential restriction factors to efficient AAV gene transfer in skeletal muscle cell

[1]GENETHON, EVRY-COURCOURONNES, Essonne, France, [2]GENETHON, EVRY, France, France, [3]Institut Cochin, Paris, Seine-Saint-Denis, France, [4]Institut Cochin, Paris, Paris, France, [5]Institut Cochin, Paris, France, [6]GENETHON, EVRY, Essonne, France

Adeno-Associated Viral (AAV) vector mediated gene therapies are at the forefront of novel treatments for muscular dystrophies. In recent years, the number of clinical trials and approved AAV-based treatments have increased. Nonetheless, certain roadblocks still arise during clinical trials, such as immune responses due to the high doses administered. While efforts to reduce the dose by capsid engineering are being made, investigating cellular to responses to AAV transduction would enable us to define new strategies to improve gene therapies. Studies have been conducted to help understand the cells innate viral responses, such as DNA damage response pathways. However, most of these studies have been performed in dividing cells where these pathways are more abundant and might not reflect the environment in post-mitotic skeletal muscle fibers. Using next generation sequencing technologies such as RNA-Seq and single-nuclei RNA-Seq, we aimed to investigate changes in the transcriptional landscape of myogenic cells following rAAV transduction. The aim was to identify known and potential new host cell restriction factors which might restrict efficient AAV gene transfer in skeletal muscle fibers. A preliminary study was performed in immortalized differentiated human myotubes transduced with LICA1 or AAV9 encoding a GFP-Luciferase gene at MOI 5,000. Cells were harvested at 24h post-transduction and analyzed by bulk RNA-Seq comparing differential gene expressions to control vehicle infected cells. In the LICA1 transduced cells, but not the AAV9 cells, we observed an increase in DNA damage response genes linked to p53 class mediator resulting in cell cycle arrest. These findings are being further investigated by single-nuclei RNA-Seq in immortalized human myotubes to assess for potential limitations due to heterogeneous transduction of myonuclei. Additionally, co-localization studies by confocal imaging allow to validate the interaction between AAV transduction and the observed molecular changes. These results allow us to further understand the interactions between AAV genome and host cell factors, leading to an improved knowledge of factors influencing efficient AAV gene transfer in

muscle fibers. Additionally, they will pave the way to develop novel therapeutic strategies to increase gene transfer and potentially lower doses in muscular dystrophies gene therapy.

887 EGFR Inhibition Reduces AAV8 Capsid Entry to Hepatocytes, Posing a Potential Liver De-Targeting Strategy

Adeno-associated virus (AAV) based therapies hold great promise for the treatment of rare genetic diseases through their ability to deliver genetic cargo to a variety of tissues. However, their applicability has been hindered by liver toxicity in several otherwise-successful gene therapy trials. One of these, the ASPIRO trial for X-linked myotubular myopathy (XLMTM), was placed on clinical hold after four patient deaths due to liver failure. This led to the discovery that cholestatic liver disease is a clinically significant feature of XLMTM, which has been further demonstrated in both zebrafish and mouse models of the disease. This pre-existing liver phenotype is further exacerbated by AAV viral treatment. Therefore, it is important that gene therapies for XLMTM can be delivered in a way that protects the liver from further injury. With this goal in mind, we performed a high-throughput drug screen in hepatocyte spheroids to find small-molecules that would block AAV8 entry. Our screen yielded 13 hits, one of which was Osimertinib, a previously approved EGFR inhibitor. After further validation and testing of small-molecule drugs, monoclonal antibodies, PROTACs, and siRNAs against EGFR, we found that approaches that target the intracellular domain of EGFR are sufficient to reduce GFP fluorescence but do not reduce viral entry as measured by ddPCR. On the other hand, extracellular targeting or siRNA knockdown effectively reduce both viral entry and transgene expression. We are currently testing our lead candidate, a GalNAc-conjugated siRNA against EGFR, in a mouse model of XLMTM to assess whether viral entry is reduced and whether signs of liver toxicity following AAV8 injection are ameliorated. This therapeutic strategy holds promise because we can specifically de-target the liver while boosting expression to desired tissues, which may even allow for dosing at an overall lower viral titer. Additionally, compared to approaches where the viral capsid is altered, this strategy is compatible with existing AAV-based therapies.

888 Interrogating the Dependency of AAV Capsids on AAVR for Retinal Transduction following Intravitreal or Subretinal Injection

Valerie Hinsch[1], Patrick Kellish[2], Emily Xu[3], Diego Fajardo[4], Hannah Friend[3], James Peterson[4], Sanford Boye[5], Shannon Boye[6]
[1]Division of Cellular and Molecular Therapy, Department of Pediatrics, University of Florida, Gainesville, FL, USA, Gainesville, FL, [2]Kincell Bio, Gainesville, FL, [3]Division of Cellular and Molecular Therapy, Department of Pediatrics, University of Florida, Gainesville, FL, Gainesville, FL, [4]Division of Cellular and Molecular Therapy, Department of Pediatrics, University of Florida, Gainesville, FL, [5]Powell Gene Therapy Center, University of Florida, Gainesville, FL, Gainesville, Florida, [6]Division of Cellular and Molecular Therapy, Department of Pediatrics, University of Florida, Gainesville, FL, Gainesville, Florida

While there have been successes using adeno-associated virus (AAV)-based gene therapies to treat human disease, certain indications remain unaddressed, in part because the target tissue is relatively difficult to transduce. We continue to learn more about the underlying mechanisms of transduction by various AAV capsids and, in so doing, expand the AAV vector toolkit to overcome these hurdles. Recently a factor involved in transduction, AAV Receptor (AAVR), was discovered. The purpose of our study was to determine the role of AAVR in retinal transduction by different AAV capsids following either intravitreal (IVtI) or subretinal (SRI) injection in mice. Vectors containing CBA-GFP, were injected in littermate $AAVR^{+/-}$ and $AAVR^{-/-}$ mice at either high (5e9vg/eye) or low (5e8vg/eye) dose and transduction was evaluated at 3 and 6 weeks post-injection (p.i.) via fluorescent fundoscopy. For IVtI, retinal transduction by AAV2, AAV6, and AAV9 was completely dependent on the presence of AAVR. Retinal transduction by SRI AAV2 required AAVR, whereas AAV6, AAV8, and AAV9 demonstrated partial dependency. In contrast, AAV5 exhibited robust retinal transduction following SRI that was independent of AAVR at the high dose and partial dependency at the low dose, indicating this dependency can be overcome at high

doses. The observation that AAV8 and AAV5 both transduced photoreceptors and retinal pigmented epithelium (RPE) in an AAVR-independent manner following SRI contrasts the observation that these capsids rely on AAVR to transduce various tissues following systemic injection. To further explore this discrepancy, $AAVR^{+/-}$ and $AAVR^{-/-}$ mice were intraperitoneally injected with AAV5, AAV8, or AAV9 vectors (1e11 to 2e11 vg) containing smCBA-luciferase to determine if this observation was unique to the retina. At both 3 and 7 weeks p.i., fluorescent imaging revealed that AAV8 and AAV9 were partially dependent on AAVR for transduction of systemically targeted tissues. AAV5 remained completely independent, a result that contrasts previous in vitro research. We also investigated the relationship with known AAV capsid cellular receptors and AAVR dependency. AAV6ΔHS and AAV2ΔHS capsid mutants devoid of heparin sulfate proteoglycan (HSPG) binding sites, [AAV6 (K531E) and AAV2 (R487G, R585S, R588T), respectively] were subretinally injected in $AAVR^{+/-}$ and $AAVR^{-/-}$ mice. AAV6ΔHS (4e9vg) displayed reduced transduction in $AAVR^{-/-}$ mice compared to $AAVR^{+/-}$ mice, similar to parental capsid, AAV6. Interestingly, SRI of AAV2ΔHS (5e9vg) displayed strong transduction in $AAVR^{-/-}$ mice, in stark contrast to its parental capsid, AAV2, indicating a potential co-dependency of HSPG and AAVR for transduction by AAV2. Future retinal gene therapies will need to consider how to leverage the requirement for AAVR depending on the route of administration.

889 Non-Invasive Monitoring of rAAV-Mediated Gene Expression Using Chemical Exchange Saturation Transfer (CEST) MRI

Zinia Mohanta[1], Aruna Singh[1], Hernando Lopez-Bertoni[2], Sophie Sall[3], Julia Stabinska[1], Irini Manoli[4], Hilary Vernon[5], Charles Venditti[6], Assaf Gilad[7], Michael McMahon
[1]Kennedy Krieger Institute, Baltimore, MD, [2]Johns Hopkins School Of Medicine, Baltimore, MD, [3]Johns Hopkins University School of Medicine - Baltimore, MD, Baltimore, MD, [4]NIH, Bethesda, Maryland, [5]Johns Hopkins University School of Medicine, Baltimore, MD, [6]NIH, Bethesda, MD, [7]Michigan State University, East Lansing, MI

Introduction: Recombinant adeno-associated virus (rAAV)-mediated gene therapy is a promising strategy for treating genetic disorders. To enable detection of rAAV transgene expression in vivo, we developed a superCESTide reporter gene, engineered to generate contrast in chemical exchange saturation transfer (CEST) MRI. This novel approach enables non-invasive, real-time, in vivo monitoring of gene expression using MRI. The objective of our study was to determine the efficacy of rAAV-mediated delivery of the superCESTide for CEST MRI-based imaging of transgene expression in the liver.

Methods: rAAV vectors were engineered to express either superCESTide or tdTomato genes, both under the enhanced chicken beta-actin (CBA) promoter and pseudotyped with an AAV8 capsid (Figure 1a). Five groups of C57Bl/6 mice were studied across two experimental rounds. In Round 1, two groups received either 8×10^{12} gc/kg of tdTomato (Group 1 Td, n=5) or a combination of superCESTide + tdTomato (Group 1 SCT, n=5). In Round 2, two additional groups were injected with a higher dose (1.4×10^{13} gc/kg) of tdTomato (Group 2 Td, n=4) or superCESTide+tdTomato (Group 2, SCT, n=4), with an untreated control group (n=5). In vivo CEST MRI experiments were conducted using a Bruker 11.7 T scanner with steady-state saturation via a Gaussian pulse (saturation power, 2.4 μT; pulse length, 100 ms) and interleaved FLASH readouts with radial sampling. Transgene expression was verified using fluorescence imaging with IVIS Spectrum CT. Gene expression levels were quantified through reverse transcriptase-polymerase chain reaction (RT-PCR). CEST contrast was assessed using magnetization transfer ratio asymmetry (MTR_{asym}) analysis, with regions of interest (ROIs) drawn over the liver to evaluate superCESTide expression.

Results: Fluorescence imaging confirmed hepatic expression in rAAV-injected mice (Figure 1b). CEST MRI scans showed significantly higher contrast in the superCESTide groups compared to controls (Figures 1c-h). Mean MTR_{asym} values were significantly different across groups (One-Way ANOVA, $P = 0.0054$). Upon pairwise comparison between all groups using unpaired parametric t-tests with Welch's correction (Figure 1i), the MTR_{asym} for the mice injected with higher dosage of superCESTide+ tdTomato, had significantly higher values. RT-PCR was performed to determine superCESTide transgene expression levels relative to actin (Figure 2a, difference between Group 2 SCT to other groups, *, $P<0.05$), tdTomato expression level relative to actin and groups with higher dosage of both transgenes (Figure 2b, no statistical difference). Also, the superCESTide gene expression levels were significantly higher in the liver compared to the kidneys, showing organ specific targeting (Figure 2c). Linear

regression analysis between MTR_{asym} values and log_{10} values of superCESTide expression revealed a strong linear relationship ($R^2 = 0.6$), with non-zero slope ($m=0.8P < 0.0001$) (Figure 2d).

Conclusion: This study demonstrates a clear correlation between CEST MRI contrast and superCESTide expression, supporting its potential as an MRI reporter gene for non-invasive gene therapy monitoring. The findings highlight the feasibility of real-time, in vivo tracking of rAAV-mediated transgene expression, advancing the field of molecular imaging in gene therapy.

Synthetic gene circuits offer considerable potential for engineering human cells to perform complex functions for innovative therapeutic applications. However, current approaches are limited by the lack of versatile, scalable and modular molecular components compatible with the limited packaging capacity of viral vectors used in gene therapy, such as AAV. We overcame these barriers by developing a novel class of Modular Artificial Dimerizing transcription factors (MADTFs) whose activity is dynamically regulated through interaction with competitive inhibitory proteins (ΔTFs). These DTFs competitively heterodimerize with MAD-TFs preventing their homo-dimerization and thus their function. This dual strategy enables dynamic and reversible regulation of gene expression, establishing a novel technological platform to build synthetic circuits and program cell behaviour. The compact and modular design of MADTFs and ΔTFs not only facilitates their integration into a variety of biotechnological applications but also enhances their potential for clinical translation.

We first implemented two different biomolecular circuits for doxycycline-inducible gene expression using the MADTF/DTF technology and then tested them by transient transfection in HEK293T cells. These circuits rely on the Coherent Inhibitory Loop (CIL) topology, which can be used to achieve high-performance inducible gene expression in mammalian cells while reducing "leaky" basal gene expression. Thanks to the combination of low leakiness and high maximal expression, the CIL circuit confers a 200-fold higher increase in gene expression, in response to doxycycline administration, while the state-of-the-art TRE3G tet-on system's performance is one order of magnitude lower.

After having demonstrated the capabilities of the technology, as a proof of concept for potential applications to gene therapy, we are now building a gene dosage compensation circuit (GDC), i.e. a synthetic circuit capable to regulate the expression of a gene within a cell in a specified range independently of plasmid copy number or virus uptake. The GDC is able to mitigate the overxpression-related toxicity risks associated with gene replacement therapy approaches for some conditions such as RETT syndrome and Friedrich's Ataxia. In our implementation, MADTF drives expression of the gene of interest (in our case a GFP fused to a transcriptional activator), which in turns control the expression of the ΔTF. The construct fits within the AAV packaging capacity allowing the whole circuit to be delivered in a single AAV vector. The balance between MADTF and ΔTF ensures that the expression of the

gene of interest is maintained within a tight expression window independently of the plasmid copy number. Our work aims to establish a foundational technology for precision-engineered synthetic circuits enabling transformative advances in both biotechnology and medicine.

891 Small Molecule Inhibition of SUMOylation Increases Expression from AAV Vectors Both During and Long After Initial Transduction in Mice

Recombinant adeno-associated virus-based vectors (rAAV) are in clinical development for human gene therapy, but a common limitation is a low level of transgene expression after vector delivery. Multiple mechanisms have been proposed that silence expression of unintegrated DNA, such as AAV episomes. This makes it challenging to maintain therapeutic levels of gene expression, particularly because readministration with AAV is not feasible due to immune responses. One potential silencing mechanism is the conjugation of the small ubiquitin-like modifier (SUMO) to proteins. Previous studies have suggested that SUMOylation may influence both AAV capsid function and host cellular antiviral pathways. We thus set out to identify clinically relevant modulators of SUMOylation useful in improving AAV transduction. TAK-981 is a small molecule inhibitor of the SUMO-activating enzyme (SAE) complex in clinical development. We thus tested TAK-981 for potentially boosting expression from AAV vectors. To test this in vitro, HeLa or IMR90 cells were treated with TAK-981 prior to transduction with AAV-eGFP and expression was quantified with microscopy and flow cytometry. Boosting of GFP expression was observed, with a 14-fold (HeLa) and 26-fold (IMR90) increase at the highest optimal dose. Vector DNA copy number was not significantly altered, and the ratio of mRNA copies to vector template was increased. To evaluate the effect of TAK-981 in vivo, BALB/cJ or Hemophilia A/CD4KO mice were treated with TAK-981 or vehicle control. TAK-981 was administered during or long after AAV delivery of vectors expressing luciferase (AAV-luc) or human factor VIII (AAV-hFVIII). Expression was quantified by bioluminescence (luciferase) or hFVIII antigen ELISA. DNA vector copies and transgene mRNA from mouse livers were measured by qPCR and RT-qPCR. In BALB/cJ mice treated with TAK-981 at time of AAV-luc delivery, luciferase expression increased 200-fold over controls at 3 days post-AAV administration and returned to control levels by day 7. When BALB/cJ mice were delivered AAV-luc with no drug and treated with TAK-981 a month after transduction, luciferase expression increased 100-fold over controls for 2-3 days, decreasing thereafter to control levels. A similar increase was observed with repeated dosing of TAK-981 at later times. Mice treated with drug during AAV delivery were later exposed to TAK-981 or vehicle at 1.5 months post transduction. All mice receiving TAK-981 had a 150-fold boost in luciferase expression, regardless of initial treatment. In hemophilia A/CD4KO mice transduced with AAV-hFVIII in the presence of TAK-981, treatment boosted hFVIII expression 4-fold and increased hFVIII RNA copies per DNA template. Integration site distributions were quantified using ligation-mediated PCR and the AAVengeR pipeline. Analysis of human cell lines and mouse livers did not show significant changes in integration frequency or distribution, or vector DNA rearrangements at integration junctions. In summary, SUMOylation inhibition with TAK-981 can boost expression when given during or long after AAV transduction. Repeated dosing with TAK-981 results in enhanced transgene expression at each administration. We postulate that TAK-981 modulates AAV transcription, rather than vector genome synthesis or integration. As TAK-981 is undergoing clinical testing in human patients, this may represent a strategy for boosting AAV transgene expression to improve human gene therapy outcomes.

892 An Enhancer-based AAV Toolbox for Precise Neuronal Targeting

Yating Wang, Broad Institute of Mit And Harvard, Cambridge, MA

Recombinant AAV (rAAV) can drive long-term gene expression in vivo and has become a popular gene delivery vector for research and gene therapy. However, to better leverage rAAV as a research and therapeutic tool, the

expression of transgene needs to be regulated in a cell-type specific or context dependent manner. To address this, significant efforts have been made to modify the AAV capsid. However, the extent of specificity capsid choice can offer is relatively limited. Enhancers are non-coding elements that can regulate gene expression and control the activity or spatial-temporal pattern of gene expression. In recent years, we and others have identified a number of enhancers that, when incorporated into rAAV vectors, can restrict the transgene expression to particular neuronal populations. Yet, viral tools to access and manipulate fine neuronal subtypes are still limited. Here, we developed a highly efficient computational pipeline to identify cell-type specific enhancers from single-cell ATAC-seq and RNA-seq data. We incorporated these regulatory elements into rAAV vectors and built a set of viral tools that are highly specific for distinct neuronal populations. Importantly, we showed that the route and age of injection can have significant impacts on the performance of these enhancer-based rAAV vectors. These enhancers, when used in the context of different effectors, can target (fluorescent proteins), observe activity (GCaMP) and manipulate (opto- or chemo-genetics) specific neuronal subtypes. We also validated our enhancer-AAV tools across species. Thus, we provide the field with a powerful set of tools to study neural circuits and functions and to develop precise and targeted therapy.

893 Novel Rationally Designed Promoters Surpass CAG in Mouse and Human Models

Ann Lettko[1]*, Dustin Lee[1], Chenjin Jin[1], Edgar Hernandez[2], Jeroen Bastiaans[1], Ce Feng Liu[1], Josefa Sullivan[1]*

Introduction: Promoters are essential for gene expression and can be engineered to develop optimized gene therapies. Ideal promoters are short in length and confer tissue specificity as well as potent transgene expression. Approximately 50% of gene therapy clinical trials rely on the CAG or CMV promoters. However, high doses of gene therapies have recently led to serious adverse events in patients. Thus, there is a need to increase gene therapy vector potency to improve the safety profile of gene therapies. Accordingly, we aimed to engineer novel CAG-based constitutive promoters which are both shorter than the original sequence and lead to stronger transcriptional activity. CMV was excluded because it reportedly inactivates *in vivo.* These optimizations would allow for a lower effective dose which could potentially reduce immune responses after treatment and lower the cost of goods for gene therapy applications.

Methods: The CAG promoter is a hybrid promoter, 1.8 kb in length, consisting of the CMV immediate early enhancer, the chicken β-actin promoter, and a hybrid rabbit β-globin intron. We rationally designed a series of 82 new CAG promoter variants by systematically introducing modifications to each of the promoter elements and tested them in human and mouse *in vitro* and *in vivo* models. In our library of engineered CAG promoter variants, 51 are smaller than the original CAG, of which 22 are fewer than 1000 base pairs in length.

Results: In HEK293T cells, 67 CAG promoter variants are stronger than the original CAG sequence with the strongest promoter exhibiting 13-fold improvement in potency. In both primary human hepatocytes and primary human myotubes, four CAG variants drove 15-fold higher transgene expression than the original while being ~40% shorter in length. These four variants and an additional strong CAG variant were packaged into AAV9 and administered either systemically or directly into the gastrocnemius muscle of C57BL/6 mice. After systemic administration, one variant in particular, C178, was found to be stronger than the original CAG in the muscle, liver, heart, and brain while being 700 base pairs shorter in length. In the mouse muscle, four of these variants led to 0.5 to 2.5-fold stronger transgene expression three months after direct injection. In contrast, muscle-specific promoters that are used in the clinic such as Ck8e are significantly weaker than the original CAG promoter when assessed using the same bioimaging paradigm. Expression will continue to be evaluated to determine if these potent promoters have durable activity *in vivo*.

Conclusions: Here, we have shown several rationally designed CAG-based constitutive promoters which are both shorter than the original CAG sequence and yield higher transcriptional activity in human and mouse *in vitro* and *in vivo* models. These promoters show potential for the development of future gene therapies. In particular, these smaller, more potent CAG variants could be advantageous for the design of gene therapies for the muscle and central nervous system where transgenes are typically large, and packaging constraints are of major concern.

894 KT-Splice: Regulation of AAV Transgene Expression by Manipulation of Alternative Splicing

Nicholas Dietrich[1]*, Jennifer Israel[2]
[1]Kriya Therapeutics - Redwood City, CA, Durham, NC, [2]Kriya Therapeutics, Redwood City, CA

In the development of gene therapies using Adeno-associated viral (AAV) vectors, engineered capsids and tissue-specific promoters allow drug developers to restrict vector expression to specific tissue types. While these advancements in vector design offer some control over where the therapy is expressed, they lack the ability to regulate the level or the timing of therapeutic transgene expression. Further modifications to AAV vectors to allow for sequence-specific regulation of transgene expression would improve safety and efficacy while expanding potential indication options. To address this need, we have developed KT-Splice, which is a system to regulate transgene expression through control of alternative splicing. This system uses delivery of a small molecule to induce a targeted change in RNA splicing thereby altering expression of an AAV transgene in a sequence-specific manner.

We first conducted an RNA-sequencing based small molecule screen to identify candidate small molecules that demonstrated splice-switching of RNA in a sequence-dependent context. We then generated the KT-Splice system by cloning the splice-switches (i.e. sequences that demonstrated alternative splicing upon drug treatment) into a Green Fluorescent Protein (GFP) reporter construct and assessed induction of GFP in vitro after small molecule treatment. Following further optimization of the splice-switch sequence, we examined the activity of KT-Splice in vivo.

The KT-Splice switch was packaged into AAV9 and systemically injected into mice at 2 vector doses, 1e11 or 1e12 vector genomes per animal, and 4 weeks post-injection the small molecule was introduced by oral gavage at two concentrations, 10 or 20 milligrams per kilogram. We collected liver and hearts from these animals and tested for levels of vector DNA and alternative slicing of the switch sequences in these tissue types in animals treated with drug versus vehicle. We observed a significant increase in RNA splicing of the optimized KT-Splice vector in mice only after small molecule delivery in both vector doses. These data demonstrate that KT-Splice is potentially a transformative system to control the timing, location, and expression level of an AAV transgene and provides a mechanism for the next generation of AAV gene therapies to treat more common diseases.

895 Ultra-Compact Synthetic Transcription Factor Platform for Small-Molecule Regulated Control of AAV Transgene Expression

Amparo Cosio[1], Amy Weiss[1], Gabriela Cosenza[1], Hailey Edelstein[2], Paul Carlson[3], Shyam Ramachandran[3], Joshua Leonard[1]*

Gene therapies rely on ubiquitous or tissue-specific promoters to drive constitutive transgene expression, but these approaches lack the flexibility needed for precise therapeutic control. In many applications, the ability to fine-tune transgene expression in response to patient-specific needs is crucial for optimizing efficacy. Dynamic control over gene expression allows for dose adjustment and temporal regulation of therapeutic activity, reducing the risk of under- or over-treatment. Inducible gene expression systems offer this level of precision, yet the packaging constraints of widely used AAV vectors limit the implementation of existing systems. Developing compact, small-molecule-inducible systems would address these challenges and enhance the versatility of gene therapies across a range of clinical applications.

In this study, we describe the development of new ultra-compact, potent, and tunable, small molecule-induced gene regulation systems optimized for use in AAV vectors. We pioneered the adaptation of minimal zinc finger transcription factors based on previous technology[1] to make them controllable by FDA-approved drugs[2], which we termed minimal inducible synthetic transcription factors (mini-synTFs). We demonstrated the ability to employ

multiple small-molecule controllable modalities to conditionally regulate transgene expression. These demonstrations include initial prototyping via transient transfection of plasmids to explore design space, followed by validation of promising designs via transduction of neuronal cells with a single AAV vector encoding both the transgene and regulatory components. This approach identified promising small-molecule controllable systems that enable dynamic and regulatable AAV-mediated gene expression. Our toolkit offers valuable solutions for researchers and drug developers seeking precise control over transgene expression in gene therapy applications.

AAV-based gene therapy is a growing field with recent approvals for diseases ranging from hemophilia B to aromatic L-amino acid decarboxylase (AADC) deficiency. However, the majority of AAV vectors employed in clinical trials use constitutive vectors with expression profiles that cannot be altered after vector administration. The lack of post administration control of the transgene limits the applicability of the AAV delivery in cases where clinical success requires precise protein expression within a narrow therapeutic window. In previous work, we have demonstrated that the expression profiles of AAV vectors can be controlled by the co-localization of endogenous transcriptional machinery and AAV genomes through chemically induced proximity (CIP). Specifically, by embedding a small, humanized synthetic DNA binding protein (DBP) and cognate binding array in the AAV transgene cassette, we show in human cells that the epigenetic and transcriptional activator protein BRD4 can be recruited to the AAV genome through the use of a heterobifunctional small molecule with affinity for both BRD4 and the DBP. Here, we extend this work by screening seven different organizations of the CIP AAV dose control platform, and identify a new lead vector with a balanced profile of dynamic range and total gene expression. For the first time, we show that the CIP approach to controlling AAV expression after transduction can be applied to biologically impactful transgene cargo in the context of VEGF blocking therapy. The VEGF decoy receptor is an efficient inhibitor of VEGF signaling and subsequent angiogenesis that has been explored for applications including diseases of the eye such as wet age-related macular degeneration and cancers such as metastatic colorectal carcinoma. However, toxicity associated with VEGF decoy receptor therapy has contributed to the slow adoption of this therapeutic strategy to a gene delivery platform such as AAV. In this work we apply the lead CIP AAV control vector to the delivery of the VEGF decoy receptor, and show dose-dependent activation of the transgene payload in colorectal cancer cells and primary human endothelial (HUVEC) cells concentrations. To measure the impact of the CIP-controlled VEGF decoy receptor on angiogenesis, we performed a tube formation assay with primary HUVEC cells. We show that CIP activation of AAV-mediated delivery of the VEGF decoy receptor significantly reduced HUVEC tube network formation compared to AAV treatment alone. These studies provide evidence that chemical recruitment of endogenous upregulating machinery to AAV genomes can be used to titrate the expression of therapeutically relevant transgenes in human cells. Future preclinical *in vivo* studies will determine the extendibility of this platform to the development of a new class of dynamically-dosable AAV vectors.

897 Differential Usage of Transcription Factor Binding Sites to Boost Synthetic Promoter Activity

Camilla Belamarich[1], Chenjin Jin[1], Alexandria Forbes[1], Josefa Sullivan[1], Enrico Mossotto[1]*
[1]*MeiraGTx, New York, NY*

Transcription factor binding sites (TFBS) play a crucial role in regulating gene expression and can either enhance or repress expression depending on their function and context. Here, we designed a library of short synthetic promoters to evaluate the effect of differential TFBS usage in N2A, mouse neuroblastoma, and C2C12, mouse myoblasts, cell lines.

A massively parallel reporter assay was created to assess the transcriptional strength of 244,000 synthetic promoter sequences. These 182 bp sequences include a variable regulatory upstream region and one of six core promoters with known tissue specificity. Two ubiquitous, JeT and AdML, two muscle-specific, MCK and DES, and two liver-specific promoters, mTTR and AAT, were chosen to assess the impact of alternative TFBS usage on promoter specificity. Regulatory regions were generated to evaluate (i) the effect of each TFBS in isolation, and (ii) the combinatorial effect of selected and tissue-enriched TFBS. Promoter activity in each cell line was calculated as a normalized expression score, referred to as SoR, using Illumina-based sequencing data. Subsequently, the TFBS fold change, or Boost SoR, over the activity of the parent core promoter without any regulatory region was calculated.

Using Boost SoR, we categorized all TFBS as activators (Boost SoR $\geq$ 0.1, n=85,711), repressors (Boost SoR $\leq$ -0.1, n=53,146), or as having minimal impact on promoter performance (Boost SoR between -0.1 and 0.1, n=13,814). The top five activating TFBS tested with muscle-specific MCK achieved a four-fold or greater increase in expression compared to MCK alone, with the top boosting TFBS exhibiting a six-fold Boost SoR. The five most repressive TFBS tested with MCK reduced transcription by over five-fold. For JeT, the five strongest activating TFBS increased expression by three-fold or more, while the five most repressive TFBS decreased expression by four-fold or more. In total, 21.6% of all TFBS combined with JeT were characterized as activators with the strongest activators boosting expression by more than four-fold. Except for DES, all core promoters exhibited the highest boost in expression through homotypic, or repetition of the same TFBS, designs rather than through combinatorial approaches. Amongst the two hundred strongest activating homotypic TFBS designs for each of the core promoters, only six were consistently observed across promoters, emphasizing their high degree of selectivity. To further evaluate TFBS-promoter selectivity, we correlated the Boost SoR of TFBS across core promoters. On average, TFBS tested with JeT and MCK exhibited a lower correlation with other core promoters (R^2_{JeT} = 0.14, R^2_{MCK}=0.23), suggesting a higher TFBS selectivity of those promoters. Conversely, the constitutive promoter, AdML, showed a significantly higher correlation with the liver promoter, mTTR, and MCK, a muscle promoter (R^2_{mTTR} = 0.29, p_{mTTR}=1.4E-81; R^2_{MCK} = 0.28 p_{MCK}= 9.6E-77).

We successfully characterized TFBS that positively and negatively boost the expression of core promoters. By quantifying the boosting effects of differential TFBS, we demonstrated the ability to enhance the performance of the widely used and optimized JeT promoter. Furthermore, we identified TFBS uniquely associated with each promoter and sequences that should be excluded from active regulatory element design. This analysis represents a key asset when designing stronger synthetic promoters for gene therapy.

898 Characterization of AAV ITR-proximal regions (IPRs) from different AAV serotypes reveals tissue-specific enhancer and promoter activities

Jianghui Wang[1], Suk Namkung[2], Ritika Sudhin Bhattacharya[3], Phillip Tai[4], Guangping Gao[1]
[1]*UMass Chan Medical School, Worcester, MA,* [2]*University of Massachusetts Medical School, Worcester, Massachusetts,* [3]*Gateway Institute for Brain Reseach, Davie, FL,* [4]*UMass Chan Medical School, Worcester, Massachusetts*

While AAV-based gene therapy has made significant strides through capsid engineering and regulatory cassette optimization, the functional contributions of native AAV genetic elements have received relatively little attention. Previous studies have shown that inverted terminal repeats (ITRs) possess weak promoter-like activity, while the ITR-proximal region (IPR) at the 3' end of the wildtype AAV2 genome exhibits tissue-dependent enhancer-like function. These findings suggest that native AAV elements can be harnessed to improve gene therapy vectors. Building upon our unpublished work, which demonstrated that IPRs from AAV8 and AAVrh.39 can enhance transcription *in vitro* and *in vivo*, we expanded our investigation to systematically evaluate the enhancer and promoter activities of IPRs from multiple AAV serotypes (AAV1, AAV2, AAV3, AAV3b, AAV4, AAV5, and AAV6) in human hepatocytes and HEK293 cells.

We cloned IPR sequences (IPR1, IPR2, IPR3, IPR3b, IPR4, IPR5, and IPR6) into three distinct configurations: 1) at the 5' end, upstream of the human phosphoglycerate kinase (*hPGK*) promoter; 2) at the 3' end, downstream of the polyA signal in *hPGK*-driven luciferase expression cassettes; and 3) at the 5' end, in a promoter-less luciferase expression cassette. These designs allowed us to systematically evaluate the enhancer and promoter activities of the IPRs in regulating transgene expression. Our initial transfection studies in HEK293 cells revealed distinct enhancer activities for specific IPR elements. When positioned at the 5' end of the *hPGK* promoter, IPR1, IPR2, IPR3, IPR3b, IPR4, and IPR5 enhanced transgene expression by approximately two- to four-fold relative to controls. Similarly, placement of IPR1, IPR2, IPR3, IPR3b, IPR4, and IPR6 at the 3' end of the polyA signal yielded comparable increases in expression. However, none of the IPRs exhibited significant promoter activity in HEK293 cells. In human hepatocytes, all IPRs except IPR5 functioned as enhancers at both the 5' end of the *hPGK* promoter and the 3' end of the polyA signal, increasing expression at levels similar to those observed in HEK293 cells. Notably, IPR1 demonstrated dual functionality in hepatocytes, acting as an enhancer and exhibiting promoter-like activity when placed upstream of a promoter-less luciferase cassette. Expression levels conferred by IPR1 was comparable to those achieved by the *hPGK* promoter. Our current findings are consistent with previous observations by Ian E. Alexander's group, which focused on IPR2. These results underscore the tissue-dependent regulatory potential of IPRs, particularly their ability to fine-tune transgene expression in hepatocytes. While further validation is ongoing, these *in vitro* findings provide a robust framework for further translational gene therapy studies. Based on their consistent enhancer activity and hepatocyte-specific promoter capability, IPR1, IPR3b, and IPR4 have been prioritized as lead candidates for *in vivo* validation, which is currently in progress to assess their capacity in optimizing gene expression.

In conclusion, our work reveals the untapped potential of native IPRs to precisely modulate transgene expression in a tissue-specific manner. These findings underscore the value of mining native AAV biology, a strategy that complements capsid engineering and promoter optimization, to develop next-generation gene therapy vectors with tailored efficacy. 899 A Platform for Next-Generation Synthetic Promoter Design and Engineering

David James[1], Thilo Pohle[2], Abayomi Johnson, Cristina Alexandru-Crivac, Francesca Taglini, Molly Smith
[1]SynGenSys, SHEFFIELD, South Yorkshire, United Kingdom, [2]SynGenSys, Sheffield, United Kingdom

The promoter is a critical component of any gene therapy payload, determining cell and tissue specificity, transgene expression levels, and stability. Its selection directly impacts safety and efficacy. Synthetic promoters enable precise control to maximize therapeutic benefits, minimize off-target effects, can reduce dosing, and repress transgene expression during manufacturing.

We have created a proprietary computational platform that enables rapid generation of highly tissue-targeted synthetic promoters with controllable activity. Our platform quantitatively surveys the different transcriptional landscapes of all human cell types to mine subsets of transcriptionally active building-block DNA sequences that are assembled *in silico* into novel, patentable, synthetic promoters with desirable functionality. Our synthetic promoters are designed to be specific to a given cellular/disease context, possessing functional characteristics that overcome the inherent limitations of natural and viral promoters.

To demonstrate its function and versatility, we applied our platform to engineer synthetic promoters for immunotherapeutic payload expression in natural killer (NK) cells exhibit a broad range of activity (between 5 to 100% of hCMV-IE), in B-lymphoma and liver cell lines (Ramos and HepG2, respectively). Liver-targeted synthetic promoters exhibit a >10-fold activity range from ~17% to ~200% of hCMV-IE in HepG2 cells and up to 27-fold that of liver-specific promoter currently used in a commercial gene therapeutic. Negligible activity in differentiated muscle C2C12 cells was observed and promoter activity in HepG2 cells correlates well with promoter activity in cultured primary hepatocytes ($r2 = 0.97$, $p<0.0001$). In contrast, skeletal muscle targeted synthetic promoters exhibit high activity in C2C12 cells (up to 93% of hCMV-IE) with minimal activity in HepG2 cells (3.4% of hCMV-IE).

Importantly, these novel synthetic promoters were designed for high transcriptional efficiency (small DNA footprint to minimise utilization of the limited AAV payload) and minimal interference with the host-cell transcriptional landscape.

In summary, synthetic promoters rationally engineered *de novo* for disease-specific targeted expression offer significant advantages over the limited repertoire of natural (endogenous/viral) promoters with poorly-defined activity and specificity. As a key component of the therapy, the use of safe and efficacious synthetic promoters should be a primary consideration for vector design.

900 A novel AAV2 variant designed for targeting of retinal tissue via intravitreal injection

Shiping Yang[1], Yu Xie[1], Tao Yang[1], Fusen Ding[1], Shuang Luo[1], Qing Xie[1], **Qiang Zheng[2]***

Purpose: Eyes possess unique autoimmune privilege properties that make them favorable targets for gene therapy. However, current gene therapy methods utilizing adeno-associated virus (AAV) vectors face challenges. For example, AAV vectors demonstrate limited transduction efficacy in retinal tissue and RPE-choroid when administered via intravitreal injection. The purpose of the current study is to develop a AAV variant with high transduction efficiency to retina tissue.

Methods: Guided by rAAV viral structural biology principles and receptor binding, a 7-peptide sequence was "rational design" and incorporated into variable region VIII of AAV capsid to augment its binding affinity for cellular receptors. AAV variants were screened and AAV2.M1 was found to have high transduction efficiency and selected to do further assessment.

Results: An EGFP report gene was packaged into wild-type AAV2, AAV2.M1 and a positive control AAV variant. Compared with wild-type AAV2 and the positive control AAV variant, the M1 variant exhibited comparable packaging efficiency but demonstrated a marked increase in transduction efficiency to ARPE19 cells. Following intravitreal injection at a dose of 2e9 vg/eye, the AAV2.M1 variant outperformed both wild-type AAV2 and the positive control AAV variant in mice, achieving higher transduction levels in RPE and photoreceptor cells. In rhesus monkeys, the transgene expression was found 1915.64 ng/g in the animals' retinal tissue in AAV2.M1 variant group after intravitreal injection, significantly higher than the positive control group which is 11.8 ng/g.

Conclusion: The AAV2.M1 variant represents a promising vector candidate in ophthalmic gene therapy. Its potential to advance the gene therapy industry is substantial.

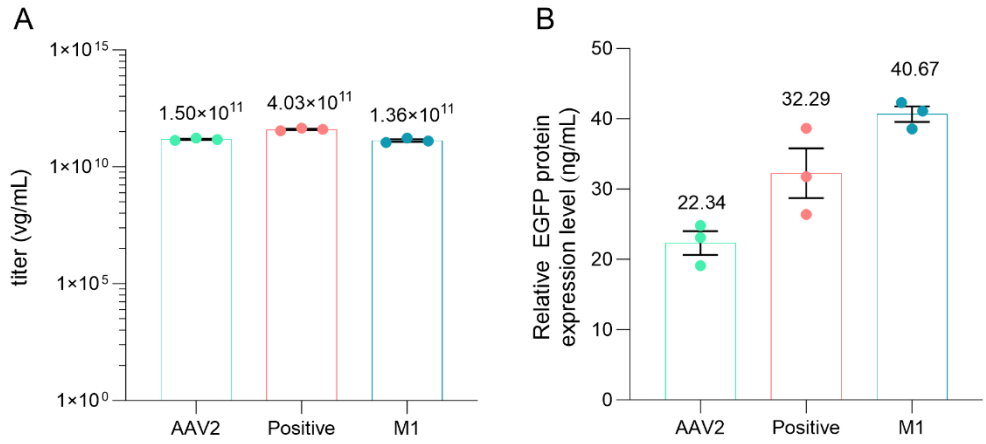

Fig.1 A, packaging efficiency of three AAV vectors; **B**, EGFP reporter gene was packaged into three AAV vectos and ARPE19 cells were transduced with these vectors the EGFP protein expression was detected by ELISA.

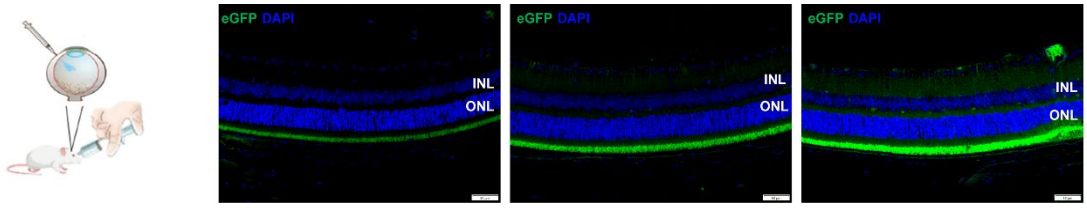

Fig.2 Intravitreal injection of different AAV variants vectors include AAV2-EGFP, Positive control, and AAV2.M1-EGFP were performed in mice eyes at a dose of 2.5E9 vg/eye. Mice were sacrificed at day 14 post-injection, retinal cross-sections and immunofluorescence (EGFP, green) analyses were conducted. (Scale bars: 50 μm; INL: inner nuclear layer, ONL: outer nuclear layer)

901 Identification of a novel AAV capsid variant with enhanced transduction efficiency in mice

Purpose: The transduction efficiency of AAV vectors to retinal tissues has not yet met the expectations of researchers when administrated via intravitreal injection. The purpose of this study is to identify AAV variants with high transduction efficiency to the retina tissue. **Methods:** A capsid library was constructed using a rational design approach. This library underwent three rigorous rounds of screening in cellular, murine, and primate models, to identify highly enriched candidate rAAV capsids (Fig.1). **Results:** the AAV variant M4 exhibited the highest enrichment score during the screening process and was subsequently confirmed to have a higher transduction efficiency than positive benchmark variant in ARPE19 cells (Fig 2A). A transgene of sCD59/EGFP were packaged into this novel AAV variant to generate the AAV2.M4-sCD59 AAV2.M4-EGFP vectors. In a head-to-head study the sCD59 expression level in AAV2.M4-sCD59 group was 2.45 times higher than wild-type AAV2-sCD59 vector group when transduced these vectors into ARPE19 cells (Fig.2B). Following intravitreal injection into C57BL/6 male mice of these two vectors, the transgene expression was found 2.46 times higher than that of AAV2-sCD59 in animals' retinal tissues (Fig.2C). Immunofluorescence staining revealed significantly higher EGFP fluorescence intensity in the AAV.2M4-EGFP group compared to the AAV2 group (Fig.2D). **Conclusion:** Our newly isolated

AAV2.M4 variant has high transduction efficiency to the retinal tissues in mice, making it a promising vector candidate for advancing rAAV-based gene therapy in clinical applications.

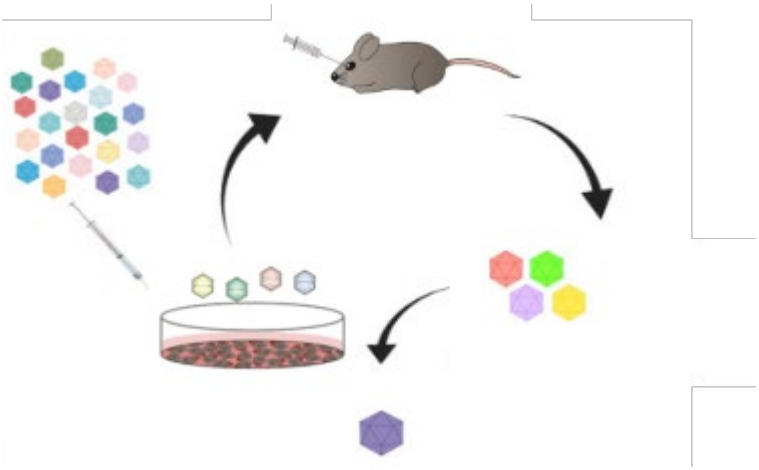

Fig.1 Schematic flowchart for the screening of rAAV variants

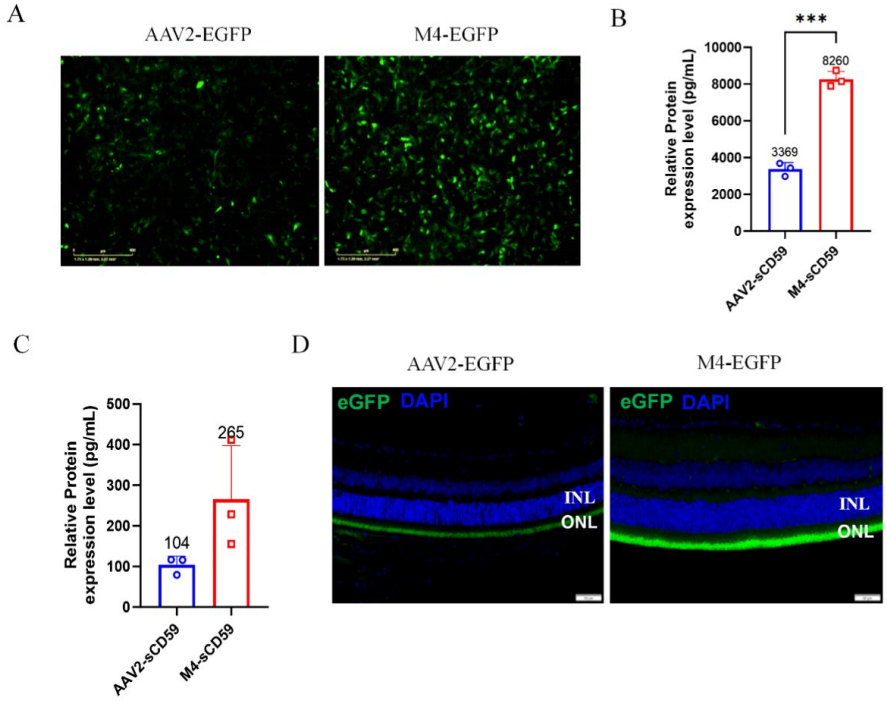

Fig.2 A. The AAV2-EGFP and AAV2.M4-EGFP vectors were transduced into ARPE19 cells, and the fluorescence images were taken 48 hrs post transduction. **B.** The cells were harvested and the EGFP protein level was measured in cell lysis. **C** AAV2-sCD59 and AAV2.M4-sCD59 vectors were administrated into mice eye via intravitreal injection. Mice retinal tissues were collected at day-13, the relative sCD59 expression level was measured by ELISA. **D** Cross-section and immunofluorescence (EGFP, Green) analyses of mice retina treated with IVT injection of AAV2-EGFP(left) and M4-EGFP(right). 902 A Novel AAV Variant for Efficient RPE Transduction via Intravitreal Injection

Jiawei Li[1], Shiping Yang[1], Yingjian Tang[2], Shuang Luo[1], Qing Xie[1], **Qiang Zheng[3]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotechnology Co., Ltd, Chengdu, China, [3]Chengdu Origen Biotechnology, CHINA
**Corresponding Author*

Purpose: Effectively delivering of therapeutic drugs to target cells, particularly RPE and photoreceptor cells, poses a significant challenge in AAV-mediated gene therapy for ophthalmic diseases. Intravitreal (IVT) injections offer a simpler method to directly deliver the therapeutic drug into retina in an outpatient clinic setting. However, IVT injections necessitate a high transduction efficiency of the AAV vector to effectively target the key cells. The aberrant activation of complement cascade is believed to play a key role in the development of Dry age-related macular degeneration (AMD). CD59 is a complement regulator which is capable of protecting RPE cells from complement-induced cell destruction. The purpose of this study is to investigate the transduction efficiency of our novel AAV variant when administered via IVT injection.

Method: A novel AAV2 variant was created by capsid engineering technology. And a soluble CD59 (sCD59) was packaged into this capsid to generate a recombinant AAV-sCD59 vector. The parental AAV2 wild-type serotype was used as control. The transduction efficiency was evaluated in nonhuman primates (Rhesus Monkey). Basically, intravitreal injection was performed at a dose of 1E11 vg/eye in both the experimental group (n=4) and control group (n=2) respectively. At 14- and 28-days post-injection, retinal tissues were collected, the vector genome copies and the transgene expression level were measured by qPCR and ELISA respectively.

Result: On the 28th day post-injection, the concentration of sCD59 protein in animals' aqueous humor tissues, retina and vitreous humor were significantly higher than in the wild-type AAV2 group. Besides, our novel AAV variant showed 11 times higher than that of the wild-type AAV2 capsid in terms of vector genome copies. (Fig. 1)

Conclusion: We report a novel AAV2 variant with high transduction efficiency following IVT injection in a Rhesus Monkey model. The evaluation of the therapeutic effect of the AAV-sCD59 in the treatment of dry-AMD is ongoing.

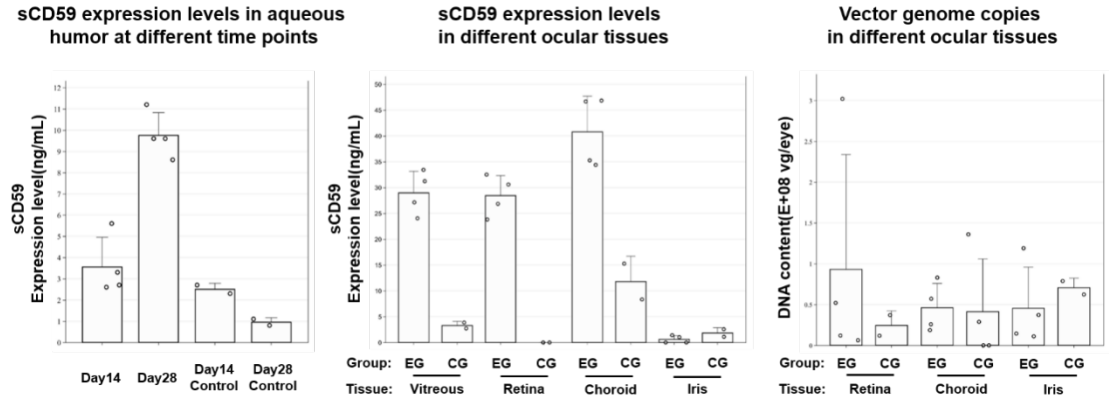

Figure 1. The expression levels of sCD59 protein at various time points (left) and in diverse ocular tissues (middle), as well as the vector genome copies in the aqueous humor (right) of monkey eyes, were detected by ELISA and qPCR following transduction. EG stands for the Experimental Group, and CG stands for the Control Group (wild-type AAV2).

903 Engineered AAV capsids for transduction of the retina by intravitreal injection

Florian Schmidt[1]*, Konstantin Schneider-Heieck[2], Szilard Sajgo[3], Rick Farouni[1], Janis Koester[4], Jacek Krol[5], Sascha Fauser[5], Randall Platt[6]*

Recombinant adeno-associated viruses (rAAV) are a promising gene therapy candidate, in particular for treating Inherited retinal diseases (IRDs). While subretinal delivery of curative transgenes via AAV vectors is well established, exemplified by the market approval for Luxturna, it remains a complex procedure performed by highly trained specialists. To address broader needs, many IRDs will require delivery of the AAV capsid via the simpler and more accessible route of intravitreal (IVT) injection. This is particularly relevant for those IRDs that compromise the structure of the retina, resulting in a pathology that renders it highly sensitive to complications following subretinal injection. AAV capsids available to date display limited transduction of the retina following IVT administration leaving patient needs unmet and increasing the demand for novel AAV capsids. To fill this gap, we performed RNA-driven biopanning of AAV peptide libraries following intravitreal injection in mice. We deployed this approach performing three rounds of selection, isolating a variety of lead capsid candidates that confer strong retinal tropism. Several of these candidates, delivered intravitreally, substantially outperform AAV2.7m8, a leading candidate for retinal gene therapy, achieving up to 10-fold increased retinal transduction. Furthermore, our candidate capsids show distinct transduction profiles towards different layers of the retina. A head-to-head comparison of our lead candidate FSp0026 with AAV2.7m8 revealed a 7-fold greater transduction of the inner nuclear layer at an equivalent viral dose also outperforming AAV2.NN and AAV2.SS. Beyond this, FSp0026 displayed high production fitness, yielding titers about 40-fold higher than AAV2.7m8, demonstrating the translational potential of our lead candidate candidates isolated via our RNA-driven biopanning pipeline.

Our pipeline yielded additional candidates outperforming AAV2 and AAV2.7m8, following intravitreal injection at a low titer (1E+08 vg/eye) quantified via immunohistochemistry (IHC) and automated image quantification. Moreover, one capsid was able to efficiently transduce anterior eye structures including stroma cells and keratocytes. To the best of our current knowledge, this would be the first AAV capsid that could be leveraged to address corneal diseases or open the opportunity for keratocytes to serve as a cellular factory for the production of therapeutic proteins.

These experiments confirmed that lead candidates outperform the literature references in both the outer and inner nuclear layer and retinal ganglion cells, showcasing our ability to derive novel AAV-capsids from our pipeline in an in vivo context. Following this selection we further expanded our biopanning pipeline to human retinal organoids, demonstrating its capacity to rapidly evolve novel AAV capsids in clinically relevant model systems.

904 Systematic Evaluation of AAVs in Two Non-human Primate Models Following IVT Injection Identifies AAV(Eye) as a Promising Candidate for Further Capsid Engineering

Bing Wang[1], Haniya Zaidi[2], Lemin Wang[3], Yuyan Wang[3], Yu Liu[2], Yuling Dai[4], Cheng Xu[5], Daozhan Yu, Qizhao Wang[6]
[1]AAVnerGene Inc, Rockville, MD, [2]AAVnerGene Inc, Rockville, [3]AAVnerGene Inc., Rockville, MD, [4]AAVnerGene INC., Germantown, MD, [5]AAVnerGene, North Bethesda, MD, [6]AAVnerGene Inc

Gene therapy holds great promise for the treatment of eye diseases. Adeno-associated virus (AAV) serotypes, such as AAV2, AAV5, and AAV8, are widely used for retinal gene delivery. AAV2 is predominantly utilized for intravitreal injection (IVT), while AAV5 and AAV8 are often used for subretinal injection (SRI). Due to its minimally invasive nature and the ability to be performed in an outpatient setting, IVT represents a safe and promising approach for ocular gene therapy. IVT delivers AAV vectors into the vitreous space, primarily targeting the ganglion cell layer (GCL) and other inner retinal cells. However, the inner limiting membrane (ILM) poses a significant barrier, restricting the penetration of natural AAV serotypes into deeper retinal layers beyond the GCL.

To overcome these limitations, engineered AAV2 variants such as AAV2-YFs, AAV2-7M8, and AAV-4D-R100 have been developed through directed evolution, enabling improved delivery to the outer retina. However, significant challenges remain when translating these advancements to large-animal retinas, which differ substantially from rodent retinas. Large-animal retinas, such as those in dogs and non-human primates (NHPs), feature specialized high-acuity regions (e.g., the area centralis in dogs and the fovea in primates), a thicker vitreous, and a more robust ILM. Consequently, AAV2 may not be the optimal serotype for retina-targeting capsid engineering in NHPs using the IVT route.

To identify potential AAV capsids for further engineering, we systematically evaluated commonly used AAV serotypes (AAV2, AAV5, AAV6, AAV8, AAV9, and AAVrh.74) and a series of AAV2 variants (AAV2-Y444F-Y500F, AAV2-Y444F-A493V-Y500F, AAV2-GL, AAV2-NN, and AAV2-7M8) in the whole retina of Rhesus Macaque using barcode technology. The results showed that among the commonly used serotypes, AAV2 exhibited the highest DNA levels in the retina, followed by AAV5, AAV9, AAV8, and AAV6. AAV2-YFs slightly increased DNA levels. AAV2 variants selected from large-animal models (AAV2-7M8) demonstrated a ~10-fold increase in DNA levels compared with AAV2. However, AAV2 variants evolved using mouse models (AAV2-NN and AAV2-GL) showed either comparable or reduced DNA levels.

At the RNA level, AAV6 exhibited an ~8-fold increase in expression compared to AAV2. Notably, AAV2-7M8 demonstrated a several-hundred-fold increase in RNA expression relative to AAV2. Moreover, we identified a novel AAV capsid, designated AAV(Eye), which achieved a 3.4-fold increase in DNA levels and a 47-fold increase in RNA expression compared to AAV2. Additionally, AAV(Eye) demonstrated greater specificity in the retina compared to AAV2-7M8. Importantly, AAV(Eye) also exhibited a ~12-fold increase in RNA expression in Cynomolgus Monkeys compared to AAV2. Using single-cell molecular sequencing, we aim to identify the specific target cells for this capsid.

In summary, AAV(Eye) demonstrates strong potential as a template for future AAV capsid engineering efforts, providing an efficient platform for targeted retinal gene delivery especially in NHP models.

905 Development of a Novel Antibody Targeting Engineered AAV2 Capsids for Gene Therapy Applications

Sameera Peraramelli[1], Ningguang Luo[2], Eduardo Santillan[3], Derrick Huynh[4], Shengjiang Liu[5]
[1]Avirmax, Inc., Hayward, CA, [2]Avirmax, [3]Avirmax Inc, Oakland, CA, [4]Avirmax, 22710 Zaballos Ct., CA, [5]Avirmax Inc., Hayward, CA

Introduction: Wild-type AAV2 is commonly used in gene therapy but has limited tropism to deeper retinal regions, which hinders its effectiveness in treating retinal diseases. To address this, we engineered a novel capsid, AAV2.N54, that exhibits enhanced specificity and efficiency in targeting these regions. The ability to accurately detect engineered capsids is crucial for evaluating their therapeutic potential and ensuring safety in clinical applications. Here, we present an antibody that specifically recognizes AAV2.N54, enabling precise monitoring of its distribution following intravitreal administration.

Methods: To engineer the novel AAV2.N54 capsid, we employed directed evolution techniques, optimizing its tropism for deeper retinal regions. An antibody specific to AAV2.N54 was generated using hybridoma technology, enabling the isolation of high-affinity clones. Characterization of the antibody was conducted through ELISA and Western blot assays to confirm its specificity and binding affinity to AAV2.N54, demonstrating no cross-reactivity with wild-type AAV2 or any other AAV serotypes. Statistical analyses were performed to validate the significance of the observed differences in antibody binding and tropism across different capsids.

Results: Results indicate that AAV2.N54 demonstrates improved tropism compared to wild-type AAV2 and the engineered capsid AAV2.7m8 across all four species studied. This is evidenced by efficient delivery to the macular retina and reduced targeting of the ciliary body. AAV2.N54 has been successfully utilized in toxicology studies and clinical trials, with comprehensive analysis conducted to determine the identity and empty-to-full ratio of the capsid. Developing a specific antibody for the AAV2.N54 capsid is crucial; it exhibits high specificity with no cross-

reactivity with wild-type AAV2 or any other AAV serotypes (1, 2, 3, 5, 6, 7, 8, 9, and 10). This has been validated through indirect and sandwich ELISA assays. Additionally, we possess an antibody that recognizes wild-type AAV2, creating an optimal combination for quantifying AAV2.N54 while ensuring accurate measurement in various applications. The antibody's specificity and sensitivity position it as a valuable tool for monitoring AAV2.N54 in both research and therapeutic contexts.

Conclusions: In conclusion, the engineered AAV2.N54 capsid represents a significant advancement in ocular gene therapy, offering enhanced tropism for deeper retinal regions and improved therapeutic potential. The development of a specific antibody that accurately detects AAV2.N54, without cross-reactivity to wild-type AAV2 or other serotypes, facilitates precise monitoring of this novel capsid's distribution and efficacy in clinical applications. Together with the wild-type AAV2 antibody, these tools enhance our ability to quantify and assess the safety and effectiveness of AAV2.N54 in therapeutic settings, paving the way for future advancements in retinal disease treatment.

906 Directed Evolution of an Intravitreally Delivered Random Mutagenesis Library of the AAV2 VP1u Region Generates Novel Capsids with Enhanced Retinal Transduction by Increasing Cellular Trafficking and Transcription Efficacy

Mengtian Cui[1], Jianghui Wang, Jackson Mcgowan[2], Mitchell Yip, Andras Komaromy[3], Claudio Punzo, Phillip Tai[4], Guangping Gao*
[1]Umass Chan Medical School, Worcester, MA, [2]UMass Chan, Worcester, MA, [3]Michigan State University, East Lansing, MI, [4]UMass Chan Medical School, Worcester, Massachusetts

MC and JW are co-first authors

Adeno-associated virus (AAV) vectors are the most utilized vehicle for gene therapy. Thus, there is a growing demand for capsids with specific tropism profiles, high transduction efficacies, and enhanced safety. To meet these demands, the field continues to discover novel capsids by engineering the viral protein sequence of AAVs, specifically the variable regions within the VP3 region. Our previous study has shown that AAV2.MC1, an AAV2 capsid variant with naturally mutated residues in the VP1 unique (VP1u) region, significantly increases retinal cell transduction in murine and canine retinas following intravitreal (IVT) injections. The VP1u region, located at the N-terminus of the VP1 protein, is a poorly characterized sequence involved in AAV cellular trafficking and transgene transcription. The sparse knowledge of VP1u constrains efforts to rationally modify the region, highlighting the need for further investigation.

To explore the role of VP1u in enhancing vector transduction and uncover its underlying mechanism, we constructed a VP1u-specific mutagenesis library by introducing random mutations into the region via error-prone PCR, yielding 4.93×10^5 unique VP1u variants. The resulting plasmid library was packaged into the first AAV library, which was intravitreally injected into mouse eyes. Four weeks post-injection, retinal tissue transcripts of enriched VP1u variants were extracted, converted to cDNA, repackaged into a second AAV library, and subjected to the IVT injection. Following another four weeks, transcripts from enriched VP1u variants in the retina were converted to cDNA and analyzed by NGS to estimate variant diversity and enrichment. NGS analysis identified six VP1u variants with better enrichment scores than wild-type AAV2 VP1u. These variants were then individually evaluated in mouse retinas via IVT injection. The top-performing capsid (VP1u1) showed a ~6-fold higher transduction than the parental AAV2 capsid and ~ 3-fold higher transduction than the well-established retinotropic capsid, AAV2.7m8. VP1u1 also showed a ~2-fold higher increase in photoreceptor transduction compared to AAV2.7m8. A second variant, VP1u2, showed ~4-fold and ~2-fold higher transduction than AAV2 and AAV2.7m8, respectively. Interestingly, VP1u1 has a single amino acid mutation in a poorly described N-terminal region of AAV2 VP1u with an unknown function. To uncover this region's function, we tested its impact on transcription by luciferase reporter assays. Overexpressing the VP1u region of AAV2 increased reporter expression from the hPGK promoter in different cell lines, while VP1u1 and VP1u2 further increased reporter expression by 2- to 2.5-fold compared to AAV2. We are currently validating these findings with ChIP assays.

This study demonstrates that VP1u is a promising target for AAV capsid engineering, offering significant potential for improving vector performance. Moreover, our results provide further insights into the previously uncharacterized domains of the AAV capsid, expanding opportunities for innovative applications in gene therapy.

907 Breaking Through the ILM: An Evolved AAV Variant for Efficient Photoreceptor Targeting

Subin Cho[1], Han Jeong[2], Junwon Lee[3]*, Jae-Hyung Jang[4]*

Photoreceptors are a compelling target for gene therapy due to their essential role in vision and their involvement in retinal degenerative diseases, such as retinitis pigmentosa, Stargardt disease, and Leber's congenital amaurosis. Effective gene delivery to photoreceptors typically relies on subretinal injection, an invasive procedure that involves penetrating the retinal layers and detaching the neural retina from the retinal pigment epithelium. This approach carries significant risks, including collateral damage, and often fails to achieve widespread photoreceptor transduction. In contrast, intravitreal injection offers a less invasive alternative with the potential for broader retinal coverage. However, efficient gene delivery to photoreceptors via this route remains challenging due to physical barriers such as the inner limiting membrane (ILM), which restricts viral vector penetration. To overcome this challenge, we employed directed evolution to engineer a novel adeno-associated viral (AAV) vector with enhanced tropism for murine photoreceptors via intravitreal injection. Through high-throughput mutagenesis and Darwinian selection, we identified key amino acid residues that improve photoreceptor infection efficiency across retinal layers. Our results demonstrate that the newly developed AAV variant can bypass the ILM and achieve robust photoreceptor transduction via intravitreal administration, offering a promising strategy for non-invasive retinal gene delivery. In this presentation, we will highlight the enhanced transduction specificity of our evolved AAV vector compared to its wild-type parent vector and multiple widely used variants. Furthermore, we will discuss its therapeutic potential in animal models. These findings provide valuable insights into the structure-function relationship of AAV capsid proteins and highlight the potential of engineered AAV vectors for gene therapy applications targeting retinal degenerative diseases.

908 Tailoring AAV Vectors for Gene Therapy of Inner Ear Disorders by Directed Evolution

Josephine Macdonald[1], Hildegard Büning[1], Jennifer Marx[2], Peixin Huang[3], Hinrich Staecker[4], Nico Jäschke[5], Lisa Prager[5], Philipp John-Neek[5], Christoph Arnoldner[6], Axel Schambach[7], Erdem Yildiz[8], Anselm Gadenstaetter[6], Matthias Gerlitz[9], Athanasia Warnecke[7], Odett Kaiser[7], Lutz Wiehlmann[7]
[1]Hannover Medical School, Hannover, Niedersachsen, Germany, [2]Hannover Medical School (MHH), Hannover, Germany, [3]The University of Kansas Medical Center, [4]University of Kansas, [5]Hannover Medical School, GERMANY, [6]Medical University of Vienna, Vienna, Austria, [7]Hannover Medical School, Hannover, Germany, [8]Medical University of Vienna, Vienna, Vienna, Austria, [9]Medical University of Vienna, Vienna, Wien, Austria

There is a pressing need to advance treatments for hearing loss (HL) and deafness, which is a currently incurable disease affecting 20 % of the global population. The treatments most commonly used for HL include hearing aids and cochlear implants. However, they require some functionality remaining in the inner ear of the patient and, furthermore, no hearing restoration is achieved with these treatments. On the other hand, success has been seen in the first clinical trial using Adeno-associated virus (AAV) vectors to treat HL, where the therapeutic transgene, *OTOF*, is being delivered to the inner ear of DFNB9 patients.

Thus far, AAV variants being tested in the inner ear today originate from libraries screened in other target tissues (e.g. CNS, eye), have been *in silico* generated (e.g. Anc80L65), or use the wildtype capsid. In contrast, we are aiming to optimize the AAV vector system for inner ear directed gene therapy by focussing on the inner ear as target structure. Therefore, we generated AAV peptide display libraries based on the AAV1, AAV2 and AAV6 capsid backbones. All libraries presented random unique 7-mer peptide inserts at variable region VIII of the capsid protein

with diversities (number of different capsid variants) ranging from 80,000-622,000 (maximum likelihood estimate, MLE). We conducted high-throughput *in vivo* selection screens in the inner ear of adult mice (n = 4, per library), testing alternative administration routes that demand overcoming robust biological barriers, in order to reduce the invasiveness of the eventual treatment.

Distinct variants were found to be accumulated to up to 5% for AAV2-based variants and up to 2.5% for AAV1-derived capsids after two rounds of *in vivo* selection. A total of 20 top candidates from the AAV1 and AAV2 libraries were produced as vectors packaging the dTomato transgene. Individual administration into the adult mouse ear showed the variants outperformed the parental serotypes and showed distinct expression patterns in the cochlea. Three promising variants had the ability to transduce outer hair cells, a challenging cell type to infect, and many also targeted inner hair cells. Almost half of the variants also strongly transduced all layers of the stria vascularis – a viable target tissue for the treatment of age-related HL – and 4 variants were highly specific for spiral ganglion neurones.

Top AAV candidates have also been confirmed to reach the cells in 10-11 week old pig cochleae (n = 6) using the less invasive administration route, with three clear top performers - Var1, Var3 and Var4. Furthermore, cDNA analysis of the cochleae showed clear and strong expression from Var4 after only 7 days post-administration. Var4 is now being investigated to carry a therapeutic transgene as it works cross-species and in mice has been shown to infect OHCs alongside IHCs and SGNs and shows a mild but widespread transduction of the SV

909 A High throughput, high-efficient AAV evolution system for tissue targeting AAV screening

Shijun Zhang[1], Xiao Li[1], Tiangang Yuan[1], Fengpeng Li[1], **Chunyan He[2]***
[1]Suzhou GenAssist Therapeutics Co., Ltd, suzhou, China, [2]Suzhou GenAssist Therapeutics Co., Ltd, Suzhou, Jiangsu, China

Introduction: Numerous AAV capsid optimization approaches have been developed to improve tissue-specific tropism and expression efficacy, including direct evolution and rational design. These methods suffer from low screening efficiency due to low library abundance or poor underlying science. Only very few valuable capsids specific for muscle or CNS were obtained from these engineering systems. To overcome these issues, we developed an innovative evolution system for tissue specific AAV screening. Human genome contains all the information of the ligands to receptors on cell membrane. We hypothesize that human genome displaying AAV can gain the cell entry function of these ligands. Through appropriate screening systems, any tissue specific AAV capsid can be attained from this library.

Methods: Random peptides from human genome were inserted between amino acids 588 and 589 in AAV9 library capsid. The library was enriched in vitro and in vivo (mice and NHP) for several rounds. Capsid variants enriched relative to the virus library at the DNA and RNA level in various tissues were identified by target-NGS for each round. New motifs from the enriched sequences will be identified by a score-based approach. Leading candidates will be further optimized by combining motif-based machine learning with additional rational design to enhance the targeting properties and transduction efficiencies. Individual capsids with 3 unique barcodes will be further confirmed in NHP.

Results/Outlook: Approximately 8 x 10^{10} unique nucleotide sequences library was packaged into rAAVs. After several rounds of enrichment in iPSC-derived myotubes and muscles of animals (mice or NHP). Multiple new motifs have been enriched with RGD listed as one of TOP 10 motifs. Multiple top new motif-containing sequences exhibited 2-3 times higher specificity to muscles than RGD-containing sequences in mice. Motif-based machine learning was utilized to optimize tissue specificity of the sequences from in vitro and in vivo experiments. Leading candidate sequences specific to muscles are under investigation in DMD mice and the results will be available in Mar 2025. In summary, this innovative Human Originated Peptide Evolution (HOPE) AAV platform enables the findings of new motifs specific to different tissues (CNS, kidney, lung, et al), which can extremely expand the scope of AAV gene therapy in future.

910 Nanobody Incorporation Confers Precise Infectivity to Adeno Associated Virus

Ajay Extross[1], Daniel Schmidt[2], Morrhyssey Benz[1]
[1]University of Minnesota, Minneapolis, MN, [2]Minneapolis, MN

Adeno-associated virus (AAV) is a non-pathogenic virus that is widely used in both research and the clinic for delivery of genetic payloads to cells of interest. Several AAV serotypes are in use because of their slightly varying tissue tropism. Recombinant AAV (rAAV) variants such as AAV-DJ and AAV-PHP.eb have been engineered to expand on AAV's natural tropism. This tropism can be attributed to interactions of the virus with proteoglycans and polysaccharides found on most cell surfaces. Mutating the rAAV capsids at residues that bind to these common polysaccharides results in the virus losing most of its infectivity and by extension its natural tropism. rAAV is amenable to domain and peptide insertions for retargeting to target cells while maintaining capsid integrity and infectivity. Previous work in our lab has revealed positions in the AAV-DJ capsid that tolerate incorporation of various domains. This has been used in combination with antibodies or nanobodies to re-engineer viral tropism. Incorporation of a nanobody targeting the Fibroblast activating protein (FAP) receptor showed a boost in infection for target cells. In this work, we report the incorporation of a nanobody targeting a metabotropic glutamate receptor (mGluR5), a receptor of clinical significance in neuroscience research. First, we show that the nanobody can be incorporated in either the VP1 or VP2 protein of the AAV-DJ capsid without impinging on capsid integrity and packaging efficiency. Mutating the Heparan binding domain (HBD) in the capsid results in a loss in infectivity, seen in both immortalized cell lines and primary hippocampal mouse neurons. However, virus capsids that incorporated the nanobody against the HBD background can rescue infection. In addition, these engineered variants show a preference to infect neurons over glial cells in primary culture. Next, we replicated incorporation of the nanobody in AAV-PHP.eb and show that nanobody mediated infectivity boost can be extended to other AAV serotypes. In conclusion, we show that nanobody incorporation is tolerated in multiple AAV serotypes and confers specificity to virus infection, re-directing AAV tropism and allowing AAV to be used as a precise delivery vehicle to target neural circuits.

911 AAV capsid engineering for improved AAVR binding to enhance transduction efficiency

Travis Bainbridge[1], Jingjie Hu[1], Maciej Paluch[2], Pramila Tamrakar[3], Matthew Johnson[3], Honglin Chen[4], Beyza Bulutoglu[1]
[1]Genentech, Inc, South San Francisco, CA, [2]South San Francisco, CA, [3]Genentech, South San Francisco, CA, [4]Genentech, Inc, South San Francisco, California

Immunogenicity and the consequent toxic side effects present major obstacles to broader AAV usage, and this can become especially problematic with the highest doses used in the clinic (E13-E14 vg/kg). The engineering of adeno-associated virus (AAV) capsids for enhanced transduction would be beneficial for reducing vector dose. AAV transduction includes two key mechanistic events: i) Capsids binding to cell surface receptors, followed by internalization, ii) intracellular trafficking of AAVs including steps such as endosomal escape. The universal AAV receptor, AAVR, was identified as a key receptor for AAV infection, playing an important role in intracellular AAV trafficking. In this study, we generated AAV9 virus-like particles (VLPs) and performed saturation mutagenesis at the receptor-binding interface. We then screened the generated variants bearing single substitutions as well as combinations, via surface plasmon resonance (SPR). Ten single or combinational AAV9 variants with improved AAVR affinity, ranging from ~2-114 fold, were characterized and structures of virus like particles containing these substitutions, in complex with a truncated AAVR, were determined by CryoEM.

We then packaged these variants with a GFP reporter payload to study their transduction efficiency *in vitro*. We observed up to ~15-fold improvement in transduction efficiency (%GFP x Mean fluorescent intensity), compared to cells transduced with WT AAV9. Notably, among the top three AAV9 variants (ER, QK and ER/QK), the degree of improvement in transduction efficiency was correlated with the degree of increased AAVR binding affinity. However, there is not a strong overall correlation between binding affinities of the variants, with transduction efficiency. Particularly the variant AN/ER/QK with the highest AAVR affinity (~114 fold) only showed a low level of improvement in transduction efficiency. This could be due to the existence of an optimal affinity window.

To further investigate the mechanism of action of the top three AAV9 variants (ER, QK and ER/QK), we studied the intracellular trafficking of the virus particles by immunofluorescent imaging of assembled capsids. We observed a trend of increased signal of assembled capsid staining in cells transduced by these three variants at 6hr post transduction, compared to the cells transduced with WT AAV9. The variant AN/ER/QK with the highest affinity showed a similar level of capsid staining as the top three variants with more puncta appearance, some of which co-stained with phagolysosome-like structures in the cytoplasm, which could potentially lead to the degradation of virus particles.

Overall, this study provided insight into the interaction of AAV capsid variants with AAVR and their impact on transduction efficiency. We have demonstrated that engineering the viral capsid to modulate its binding affinity to AAVR can be advantageous. This approach may also be compatible with and complementary to orthogonal capsid engineering efforts focusing on enhanced tropism, and can be used in a broad range of gene therapy applications.

912 Conjugation of Peptide Ligands to AAV Towards Pancreatic Cell AAV Gene Delivery

Stephen Trisno[1], Mark Kay[2]
[1]*Stanford University, Union City, CA,* [2]*Stanford University School of Medicine, Stanford, CA*

Adeno-associated virus (AAV) is a small DNA virus that has been closely studied for its potential for human gene therapy. Multiple serotypes of AAV and recombinant AAV possess differential transduction efficiency and specificity towards different tissues; however, no cell type-specific AAV vectors have been created to date. In order to understand and improve cell/tissue transduction efficiency and specificity, our lab continues to explore unnatural amino acid (UAA) substitution on the AAV capsid that allows for site-specific modification via click-chemistry to conjugate aptamers or a small molecule ligand to the AAV (Puzzo et al., 2023). In this study, we seek to demonstrate an expansion of these capabilities to other cell types, particularly pancreatic cells, by conjugation of peptide ligands that bind to surface receptors known to be expressed on those cells. Specifically, we selected the ligands that bind to GLP1R (glucagon-like peptide 1 receptor, for targeting pancreatic endocrine cells) or SCTR (secretin receptor, for targeting pancreatic exocrine cells). After optimization using the technologies previously developed in our lab (Puzzo et al, 2023), the peptides were successfully conjugated to the UAA-substituted AAV-DJR/A-A587. The secretin peptide-conjugated AAVs (SCT-AAV) demonstrated a several-fold increase in transduction efficiency towards cell lines exogenously expressing SCTR when compared to unconjugated AAVs or when compared to transducing control cell lines not expressing SCTR. We are currently establishing whether the improvement in transduction efficiency was due to an increase in viral entry into the SCTR-expressing cells. In contrast, in transducing GLP1R-expressing cells, the GLP1 peptide-conjugated AAVs demonstrated a decrease in transduction efficiency as compared to unconjugated AAV. This reduction in transduction efficiency was also seen in our control cells (non-GLP1R expressing cells). The cause for this reduction is unclear. Future steps include interrogating how the AAV-ligand-receptor interaction improves transduction, understanding why GLP1 peptide-conjugated AAVs have decreased transduction efficiency overall and if steps can be taken to reverse this, as well as further validating this 1) *in vitro* in cell lines that endogenously express the surface receptors of interest and eventually 2) *in vivo* to evaluate whether this improved transduction efficiency is translatable in tissue/organs and whether this improved efficiency is specific to cells expressing the corresponding receptors.

913 An Approach to Facilitate Multiple Peptide Insertions at Different Locations on the Surface of AAV Viral Particle

Qingshuo Zhang[1], Rui Hao[2], **Zhongya Wang**[3]
[1]*Renoviron (Suzhou) Biotech Co., Limited, Suzhou, Jiangsu, China,* [2]*RenoViron Biotechnology, Suzhou, Jiangsu, China,* [3]*RenoViron, Suzhou, Jiangsu, China*

Adeno-associated virus (AAV) has been successfully used for *in vivo* delivery of gene therapy drugs to treat multiple clinical indications. However, this gene delivery vehicle still faces some limitations and challenges, including low tissue specificity or insufficient transduction in certain target tissues, and/or tissue toxicity due to high accumulation in non-target organs.

One common strategy to overcome these limitations is to insert a peptide into the common VP3 region of AAV capsid proteins to retarget the virus to a specific cell or tissue type. Not all the surface sites of AAV particles are suitable for surface display of foreign peptides. Site I-587, I-588, and I-453 of AAV2 (or corresponding locations in other AAV serotypes) are the most frequently used positions for inserting foreign peptides. These sites can be used either individually or as a combination of two sites. The simultaneous use of three or more sites for inserting foreign peptides in VP proteins is more difficult due to steric hindrance and have not been explored thoroughly.

We sought to utilize multiple affinity tags, including the 8 aa Strep-tag II, the 10 aa c-Myc tag, and the 9 aa HA tag, to explore this possibility. The tags were first individually inserted to 130 surface sites of AAV9 VP3 proteins and every corresponding mutant AAV was generated in 293 HEK cells and purified. The yield of the mutant AAVs was first quantified by qPCR to determine whether the insertion of the foreign peptides interfered with viral production.

The mutant AAVs were further tested in pulldown assays and biolayer interferometry (BLI) assays to determine whether the tags were well presented at the surface of viral particles and retained their original binding properties. In pulldown assays, Strep-tag II, c-Myc tag, and HA tag-containing viral particles were bound to BeaverBeads Magrose Strep-Tactin, Pierce anti-c-Myc magnetic beads, and HA-beads, and were eluted with D-Desthiobiotin, c-Myc peptide, and HA tag elution peptide, respectively. In BLI assays, each tag's binding kinetics to its corresponding antibody was analyzed on the GatorPrime biolayer interferometry system, a label-free analysis instrument based on the biolayer interferometry technology, using anti-c-Myc, anti-HA, and anti-Strep-tag II antibodies.

Through these experiments, we discovered many sites suitable for peptide insertion to the AAV9 VP3 region. Among them, multiple sites could be used together to facilitate simultaneous insertion of two different peptides with a very mild impact on viral production and little interference on peptide presentation. The simultaneous insertion of three tags proved to be difficult, with most of the site combinations leading to either a substantial loss of viral production or a disruption of the inserted tag's antibody-binding property. However, we found that two of the site combinations could be used for the simultaneous insertion of three peptides with a mild loss of viral production and a good presentation of all three inserted peptides at the surface of the viral particles.

Foreign peptides have been successfully introduced into AAV to ablate the binding of a natural receptor, to mediate transduction through a novel AAV receptor, to facilitate downstream purification, to escape pre-existing neutralizing antibody, or to modulate immune response. The above findings could expand our abilities to improve current AAV vectors for a more desirable clinical outcome.

914 Assembly-based RNA Packaging Using Adeno-associated Virus Capsids

Dongxin Wang[1], Yongping Yue[1], Jin Han, Baisong Lu[2], Xiao Heng, Roland Herzog[3], Dongsheng Duan[4]
[1]University of Missouri, Columbia, MO, [2]Wake Forest Medical School, Winston Salem, North Carolina, [3]IU School of Medicine, Indianapolis, IN, [4]Univeristy of Missouri, Columbia, MO

Adeno-associated virus (AAV) is a powerful vector for efficient tissue-specific and bodywide gene delivery. While persistent AAV-mediated gene expression is ideal for many gene therapy applications, this is not desirable for applications which require transient expression. One salient example is CRISPR editing. Long-term expression of the bacterial-derived editing enzyme (such as Cas9) increases the risk of untoward genome modifications and cellular immune responses. Encapsidation of an mRNA into AAV capsids would allow robust delivery and transient expression. Efficient RNA-protein conjugation can be achieved using an RNA aptamer and the corresponding aptamer-binding protein (ABP). We hypothesized that an ABP engineered in the inner surface of the AAV capsids would allow recruitment of an aptamer-containing RNA into AAV capsids during assembly. To test this hypothesis, we inserted N22, a 22 residue ABP to positions 192 and 210 in VP2 of AAVMyo. Structural modeling suggests that these two positions are oriented toward the interior in the assembled capsids. AAVMyo was selected for its superior muscle targeting. Dot blot and western blot suggest that inserting N22 into VP2 did not interfere with AAV assembly and packaging. To evaluate RNA packaging, we extracted RNA from purified AAV particles and quantified the spliced mRNA by TaqMan PCR with or without reverse transcription, in the presence and absence of DNase and/or RNase. No RNA was detected when no plasmid or a conventional ITR-containing plasmid was used

in packaging. Interestingly, we detected a low amount of RNA packaging with a plasmid that did not carry BoxB, the N22-matching aptamer. Similarly, a low amount of RNA was detected using unmodified AAVMyo capsids. Collectively, these results suggest that AAV capsids are permissive to RNA packaging. Strikingly, when the VP2-N22 modified AAVMyo and the BoxB-containing plasmids were used together, we achieved 60 to 90-fold enhancement in RNA encapsidation. In summary, our results suggest that AAV capsids can be adapted to carry RNA. Further development of this technology may broaden AAV gene therapy applications. Recombinant adeno-associated virus (rAAV) has emerged as a leading vector for gene therapy, due to its safety and efficacy. However, current rAAV manufacturing systems are burdened by the excessive production of empty capsids- viral particles lacking the therapeutic gene of interest. These empty capsids are considered as product-related impurities that reduce the infectivity of full particles and may even trigger undesired immune responses. Thus, reducing the empty capsid ratio in rAAV preparations is crucial to enhance the efficiency, safety, and affordability of AAV-based gene therapies. Various techniques, such as analytical ultracentrifugation (AUC) and anion-exchange (AEX) chromatography, are available to quantify and separate empty capsids, however, these methods are labour-intensive, time-consuming, and costly.

Here, we introduced a novel synthetic biology-based approach to enhance AAV2 genome packaging efficiency, thereby increasing the full-to-empty capsid ratio. Using a rational engineering strategy, plasmids encoding novel fusions of native AAV2 proteins were incorporated into standard transfection procedures. Transfections were performed in suspension HEK293F cells at a 1 mL scale in 6-well plates via transient transfection. Viral genome and capsid titers were quantified using crude lysates by quantitative PCR (qPCR) and enzyme-linked immunosorbent assay (ELISA), respectively. The percentage of full capsids was inferred using the qPCR-to-ELISA ratio. Among the 16 novel plasmids tested, 10 exhibited a higher full capsid ratio than WT AAV2, with 7 showing statistically significant improvements, and the highest ratio observed was 19.8%, compared to 7.1% for WT AAV2. Four of the novel capsids, showing the highest full capsid ratios, were scaled up to 50 mL cultures in shake flasks, and crude lysate data from qPCR and ELISA confirmed consistent improvements in full capsid ratios similar to the small-scale experiments. The purification of vectors was then performed using Dynabeads CaptureSelect AAVX magnetic beads, and the full/empty capsid ratio of purified vectors was determined via negative-staining transmission electron microscopy (TEM). TEM analysis, conducted by counting over 500 capsids per vector, revealed that the best-performing fusion capsid brought about a 28.9% full capsid ratio, a 1.9-fold increase compared to WT (15.1%). Despite these promising results, all fusion capsids displayed a significant reduction in transducing unit titers (TU/mL), with reductions ranging from approximately 2-fold to 17-fold compared to WT AAV2, as determined by transduction of HEK293T cells followed by the flow cytometry. Ongoing studies are focused on addressing this reduction by further modifying the variants to rescue their infectious abilities. Overall, our findings showed promise to advance AAV bioprocessing, offering a fresh perspective on developing of more efficient AAV production systems.

916 Advancing AAV Capsid Engineering for Targeted Gene Therapy Using PackGene's π-Icosa Platform

Tiffany Pan[1], **JIn Qiu**[2], Irene Song[3]
[1]PackGene Biotech INC, Houston, TX, [2]PackGene Biotech INC, Houston, MA, [3]Packgene Biotech, Houston, TX

Adeno-associated virus (AAV) is a widely used gene delivery vector, but its clinical utility is constrained by limitations in tissue specificity, immune evasion, and transduction efficiency. To address these challenges, we developed the π-Icosa Capsid Engineering System, a platform combining rational design, directed evolution, and AI-driven prediction models to engineer AAV capsids with enhanced targeting, manufacturability, and reduced off-target effects. The platform integrates an AI-based targeting prediction model, built on a transformer architecture and pre-trained using protein language models, which achieved an AUC of 0.83 on directed evolution datasets for accurate tissue-specific tropism prediction.

Building on these advancements, the π-Icosa platform employs a proprietary algorithm to design and screen diverse capsid libraries, followed by iterative in vivo testing to identify optimized variants. This approach has yielded novel AAV capsids with improved tissue tropism. Muscle-targeting variants PG016, PG017, and PG018 demonstrated superior transduction compared to AAV9 and MyoAAV 4A. CNS-targeting variant PG008 in mice, along with additional ongoing library screening, has resulted in many candidates that achieved 10^3-10^6-fold higher reporter gene expression in NHPs. Retinal-targeting variants PG021 and PG022 efficiently transduced retinal ganglion cells (RGCs), Müller glial cells, and inner nuclear layer (INL) cells. For ex vivo T-cell therapy, variants PG009, PG010, PG012, and PG013 exhibited 10x higher infectivity in primary human T cells compared to wildtype AAV6.

Furthermore, to complement the engineering of these advanced AAV capsids, a manufacturability prediction model was developed to generate AAV mutants with high packaging efficiency (up to 97%), 2-3 times higher yields than wildtype AAV, and enhanced sequence diversity, enabling the discovery of novel capsids with improved properties. These results demonstrate the potential of integrating AI-driven approaches with rational design and directed evolution to overcome key gene therapy challenges. The π-Icosa platform enables the development of highly specific, efficient, and manufacturable AAV variants, advancing the field toward safer and more effective therapeutic applications.

917 Generative Transformer Models for Designing Diverse and Viable AAV Capsid Sequences

Mian Umair Ahsan[1], Kai Wang[1]
[1]*Children's Hospital of Philadelphia, Philadelphia, PA*

Designing novel adeno-associated virus (AAV) vectors is necessary for addressing the limitations of AAV gene therapies, but most AAV capsid sequence variants fail to assemble, creating a major roadblock. High-throughput sequencing of mutational capsid libraries has enabled a data-driven assessment of the fitness landscape of AAV capsids, and some studies have combined machine learning models with ad-hoc algorithms to design novel and viable capsid sequences. Recently, transformer models have revolutionized the field of deep-learning and led to the creation of large language models, such as generative pre-trained transformers (GPTs) from OpenAI, and protein language models (PLMs), such as ESM2 from Meta which excels in a range of protein structure prediction tasks. However, the potential of GPTs and PLMs in designing novel AAV capsids remains largely unexplored. In this study, we adapted ESM2 to predict assembly of AAV2 capsid sequence variants and trained a GPT model to generate diverse and viable capsid sequences.

Methods: We used the AAV2 capsid library data (N=296,970 sequences consisting of 52% viable capsids) from Bryant et al. (*Nature Biotechnology*, 2021) and targeted mutations within amino acid positions 561–588 of the VP1 protein. The data was evenly split into training and validation sets to develop a classifier model, where the ESM2 model was trained on the training set and evaluated on the validation set. We then trained a new generative model, based on OpenAI's GPT-2 architecture, to generate viable or non-viable capsid sequences with user-specified edit distances from the wild-type AAV2 sequence, guided by specific input prompts. Finally, the ESM2 classifier was used to assess the viability of the GPT-2-generated capsid sequences.

Results: On the validation dataset, our ESM2 classifier showed a high accuracy of 96%, with 96.7% precision and 95.4% recall. We prompted the trained GPT-2 model to generate 100k viable and 100k non-viable capsid sequences with edit distances between 2 and 29. After removing any overlaps with the initial capsid library, we kept 74.8k and 53.5k, putatively viable and non-viable novel capsid sequence candidates, respectively. The putative viable and non-

viable sequences had a mean edit distance of 10.2 (SD=4.4) and 15 (SD=6.6) from the wild-type AAV2 sequence, respectively. The ESM2 classifier predicted 99% of the putative viable capsids to be viable and predicted 82% of the putative non-viable capsids to be non-viable.

Conclusions: Our evaluation shows that the ESM2 classifier can accurately assess a capsid sequence for assembly viability, making it suitable for evaluating our generative model. Our GPT-2 model can generate novel capsid sequences that are diverse from the wild-type AAV2 sequence and have a high likelihood of assembly. This approach differs from the previous studies that have used a classifier model to screen billions of randomly mutated capsid sequences and iteratively mutate promising candidates, which makes it difficult to design capsids with multiple desired traits. In contrast, our generative model can directly generate capsid sequences with multiple desired properties, such as viability and edit distance. This highlights the potential of generative transformer models in designing capsids that can simultaneously optimize for other AAV traits such as lower immunogenicity or increased liver transduction, thus accelerating the development of novel gene therapies.

918 Artificial Intelligence Enables Rapid and Efficient Identification of Adeno-Associated Vectors with Improved Transduction of Target Tissues

David Cardoso[1]*, Suzanne Scott[2], **Leszek Lisowski[2]**, Iñigo Jauregi Unanue[3]
[1]Sendatu Therapeutics, Cambridge, MA, [2]Sendatu Therapeutics, Westmead, NSW, Australia, [3]Sendatu Therapeutics
**Corresponding Author*

Introduction: Clinical success has been achieved with several AAV-based therapies; however, the inconvenient truth remains that the current generation of capsids are unsuitable for many target tissues. As a result, there remains a significant unmet burden of disease, meaning gene therapies are either not possible or require large doses – placing patients at risk of serious adverse events (such as immune reactions), and increasing manufacturing costs dramatically. More efficacious vectors are urgently required for tissues that are otherwise ideal targets for gene therapy, including but not limited to the brain, kidney and lungs.

Methods: Sendatu Therapeutics leverages a unique combination of specialised know-how and patent-pending technological approaches to develop novel delivery mechanisms for safe and effective targeted genetic therapies. Synergistically, our artificial intelligence engine accelerates the search for the 'needle in the haystack' by designing optimal peptide libraries not only for the intended cell/tissue target, but also for the desired functional characteristic(s), such as transduction efficiency, titre, immunological properties. This reduces the in vivo experimentation required to find suitable candidates, reducing R&D costs, all while producing AAV capsids with improved chance of clinical success.

Results: To demonstrate the power of our platform, we generated a 10-mer peptide insertion AAV library and performed capsid selection in HuH-7 cells, generating a combined score that uses packaging, cell entry and transgene expression data. Our trained ML models subsequently scored 120 million possible peptides and identified the 1,000 top-performing peptides. We then vectorised the top N=10 ML-designed capsids and N=10 top AAV variants from the physical, lab-based selection. These vectors were used to package a GFP cassette and transduce HuH-7 cells; their performance was monitored by fluorescence activated cell sorting (FACS). All ten ML-designed variants performed better than the original vector (with a median fold-change of 1.8), and all were also better than the median performance of the physical selection group. We additionally tested a 7-mer peptide insertion library in mice, to select for capsids that target the kidney while simultaneously de-targeting from the liver. After training on packaging, cell entry and transgene expression datasets for kidney and liver, our ML models scored 120 million peptides for kidney transduction and liver detargeting. Following synthesis of the predicted top 1000 peptides, several candidate capsids were identified, with kidney expression up to 200-fold higher than liver expression as measured by next-generation sequencing.

Conclusion: Sendatu Therapeutics' functional transduction platform, allowing for parental capsid modification and generation of capsid packaging, entry (DNA) and expression (RNA) datasets in a cell-and tissue-specific manner, combined with artificial intelligence models, has enabled the prediction and validation of capsids that have preferentially demonstrated desired characteristics including enhanced transduction and targeting specific tissues.

919 From Data to Delivery: AI-Driven Design of Optimized AAV Vectors for Gene Therapy

Jinyoung Kim[1], Subin Cho[2], Han Jeong[3], Choi Yoonjae[4], Chanbi Jeon[4], Hongyoung Choi[5], Changmin Kang[6], Junwon Lee[7]*, Jae-Hyung Jang[4]*

Traditional directed evolution with randomized AAV libraries has been a cornerstone of AAV engineering. However, this approach is constrained by the limited diversity of AAV libraries, restricting the exploration of the vast sequence space of capsid, which consists of approximately 735 amino acids. The disparity between the theoretical diversity of capsid and the practical library size (~10^8 variants) presents significant challenges in developing optimized AAV vectors for specific applications. Recent advancements in capsid engineering using artificial intelligence (AI) have shown promise in addressing these limitations by learning and predicting capsid properties, enabling more efficient and targeted capsid design. In this study, we developed deep learning-based AI models to predict capsid properties. These models were employed as cross-validation tools to enhance prediction accuracy and evaluate potential capsid variants *in silico*, significantly narrowing down candidates for *in vitro* and *in vivo* validation. This streamlined approach enhanced the efficiency of variant selection for functional testing. A key focus of this work was analyzing the gradients of feature maps within the trained models to identify key amino acids contributing to specific capsid properties. This analysis provided insights into how individual amino acids influence AAV functionality, guiding rational capsid design. Additionally, we optimized data preprocessing to uncover meaningful patterns, thereby improving model performance. By leveraging AI to explore previously uncharted sequence space, we successfully designed an optimized AAV vector with enhanced cell tropism. This AI-driven vector significantly increased transduction efficiency across several animal models compared to its wild-type parent and several widely used engineered vectors. Our findings highlight the potential of AI as a powerful tool for advancing capsid engineering, overcoming the limitations of traditional engineering approaches, and accelerating the development of next-generation gene therapy vectors. In this presentation, we will introduce and discuss our AI-driven approach and the successful outcomes achieved, providing insights into the future of AI-powered AAV engineering.

920 Machine Learning-Driven AAV Capsid Engineering for Enhanced Tissue Targeting and Optimized Production Efficiency

Adeno-associated viruses (AAVs) are widely used as gene therapy vectors due to their high safety profile and long-term gene expression. However, optimizing AAV serotypes for efficient blood-brain barrier (BBB) penetration, muscle targeting, and other tissue-specific delivery remains a significant challenge. In this study, we employ convolutional neural networks (CNNs) and other machine learning (ML) models to design and predict AAV capsid variants with enhanced tissue tropism and high production efficiency. By training ML models on extensive datasets of AAV sequences and experimentally validated functional capsids, we generate novel serotypes that demonstrate superior targeting efficiency to specific organs while maintaining high viability and full capsid ratio.

Furthermore, our approach optimized to minimize cross-packaging events, ensuring precise vector identity and reducing unwanted recombination. This strategy enhances AAV vector homogeneity and production consistency, critical factors in clinical applications. By integrating ML-driven sequence design with experimental validation, we establish a scalable pipeline for developing next-generation AAV vectors optimized for therapeutic applications.

Our findings provide a robust framework for engineering AAV capsids with tailored tropism, improved manufacturability, and enhanced safety for gene therapy.

921 Investigating the Effect of Age on AAV2 and AAV8 Delivery and Transgene Expression via Subretinal Injection in Mice

Jimin Han[1], Alexander Doering[1], Vaithinathan Selvaraju[2], Heather Flaherty[3], Paul Miller[4], Carol Rasmussen[5], James Ver Hoeve[6], Alex Katz[5], Jenny Plasil[5], Jaime Tesmer[4], T Nork[4], Ellison Bentley[5], Peter Sonnentag[7]

Retinal disorders, such as inherited retinal diseases (IRDs) and age-related macular degeneration (AMD), affect patients of all ages. However, therapeutic options remain limited and thus far are only able to slow disease progression. Gene therapy offers a promising approach and has previously shown great potential to treat retinal disorders, as evidenced by the first FDA-approved ophthalmic gene therapy (Luxturna). Despite the wide range of age in patient demographics, the impact of age on the delivery, expression, and tolerability of adeno-associated virus (AAV)-mediated therapies remains poorly understood. Notably, while younger patients, especially those diagnosed with IRDs, are thought to benefit most from early intervention, clinical practices often prioritize adult patients due to safety and ethical concerns. This leaves pediatric, as well as geriatric, populations underrepresented in gene therapy trials, creating critical gaps in our understanding of how age-specific factors affect the effectiveness of retinal gene therapy.

In this study, we investigate the effect of age on the delivery and safety of two AAV vector serotypes (AAV2, AAV8) when considered independently from the efficacy of specific therapeutic genes that employ the use of these vectors. AAV2 was selected for its previous clinical precedence and established tropism for retinal cells along with AAV8, which has been reported to have greater transduction efficiency, especially in the photoreceptors. We have administered AAV2-CAG-EGFP and AAV8-CAG-EGFP (1 uL; $1x10^{12}$ vg/mL) bilaterally via subretinal injection in C57BL/6J mice at different ages. In Phase I, we investigated AAV2 and AAV8 delivery in adult (6-10 weeks) and aged (≥78 weeks) mice. We evaluated vector delivery and spatial expression of the vector's transgene using fundus autofluorescence imaging and immunohistochemistry. Additionally, tolerability was assessed through ophthalmoscopic examination, optical coherence tomography, and electroretinography to monitor functional retinal outcomes. Phase II will extend this work to young mice at postnatal day 21, a developmental stage comparable to human infants at approximately 2-3 years. At this stage, the mouse retina is sufficiently mature while still reflecting the unique challenges of treating young patients with developing immune and retinal systems. We will evaluate whether the immature retinal environment affects vector tolerability or transgene expression. By systematically analyzing how age affects AAV vector tolerability and transgene expression, this study provides insights for the development of age-specific gene therapies. Results from this research will inform the design of safer and more effective therapies, particularly for pediatric and geriatric populations. Furthermore, the findings will serve as a preliminary step toward translational studies in larger animal models (e.g., minipig, non-human primate). Ultimately, this work aims to help optimize the delivery of gene therapies for diverse patients, from early-onset IRDs to age-related retinal degeneration.

922 A new dosing regimen to treat Bardet-Biedl Syndrome 1 (*BBS1)* retinal degeneration with AXV-101 (AAV9-BBS1) improves histological and functional photoreceptor survival in *Bbs1* M390R mice. Finding the right balance between bleb number, dose per bleb and total dose per eye.

BBS1 patients become blind before they reach adulthood. We have previously demonstrated that AXV-101, an AAV9 vector expressing a human codon-optimised copy of BBS1 (hCOBBS1) was able to rescue retinal degeneration in the *Bbs1* M390R mouse model when deliver subretinally. To improve histological and functional rescue, we devised a new strategy by increasing the numbers of blebs, reducing the dose per bleb while increasing the total viral particles per eye. Retinae from mutant Bbs1 M390R mice were unilaterally dosed subretinally with AXV-101 at day 7 to 9 (P7-9) with two blebs, one superior and inferior regions of the retina, leaving the untreated contraleral eye as control. Three cohorts with three different dosed were injected; 7.5x109, 4x109 and 1.3x109 viral genomes per bleb (vg/bleb), for a total of 1.5x1010, µ and 2.6x109 total genomes per eye (vg/eye). Animals were followed for 6 months, monitoring the structure of the retina with Optical coherence tomography (OCT) and function by Electroretinogram (ERG) and hCOBBS1 transgene expression 6 months after dosing. We tried 3 doses (low-2.6x109 vg/retina) medium 8x1010 vg/retina) and high (1.5x1010 vg/retina), in two blebs of 1ml per retina in treated and M390R animals. At 2 months, low (27.20µm) and medium (25.34µm) M390R treated eyes display thicker ONL thickness compared to buffer treated M390R eyes (21.16µm) with high dose (37.83 µm, $p<0.0001$) showing a significant rescue in ONL thickness (Figure 1). At 4 months M390R treated eyes display a trend in dose response in rescue of mean ONL thickness with low, medium and high dose at 24.43µm ($p=0.0062$), 26.81µm ($p<0.0001$) and 37.55µm ($p<0.0001$), respectively, all showing significant rescue compared to buffer treated M390R eyes (13.38µm). At 6 months post-treatment the treated M390R eyes maintain the increased ONL thickness compared to buffer treated M390R eyes (low $p<0.0001$, medium $p=0.0849$, high $p<0.0001$) (Figure 1). In the WT buffer treated and in M390R treated eyes (in all doses) there is slight decline in ONL thickness with time, but this is not significant while in M390R buffer treated and untreated contralateral eyes show a significant decline in ONL thickness over 6 months. The functional rescue of the M390R animals is even better than the histological rescue of the ONL, showing a clear dose dependent response. The cone responses with of photopic b-wave at maximum stimulus showed significant differences at 4 month after treatment for low, medium and high doses was at 40%, 39%, 83% of WT buffer treated eyes and by 6 months post-treatment these were at 24%, 34% and 65%, respectively. For scotopic b-wave at 6 months we saw a 30%, 40% and 68% of buffer treated WT function compared with the 18% of the M390R buffer treated eyes (Figure 2). To assess level of hCOBBS1 transgene expression in the retinal tissue eyes were collected at 6 months post-treatment and were used for RT-qPCR of hCOBBS1. This analysis showed expression of hCOBBS1 with medium (11564-fold) and high (13522-fold) doses compared to housekeeping genes. These results demonstrate that an increased bleb strategy, with reduced vital titre per bleb but increase total titre per eye is more effective. That the histological rescue and halting of the photoreceptor death can be observed with lower doses than the functional rescue. That AXV-101 can sustain a high level of functional rescue over time and it is a prime candidate for first-in-human clinical trials.

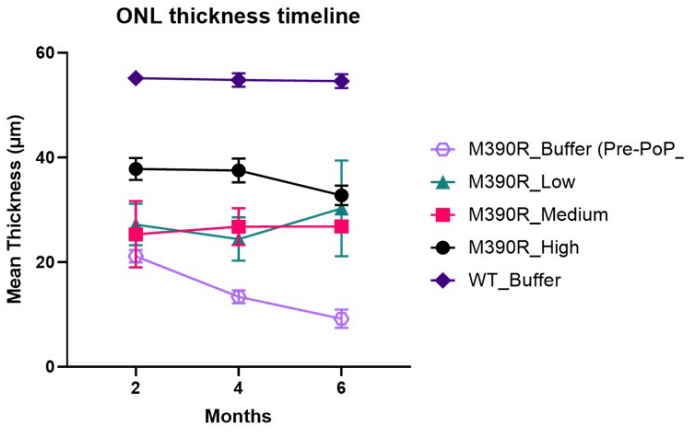

Figure 1. The ONL thickness is sustain over time. Change in mean ONL thickness ±SEM for M390R low, medium and high dosed and WT buffer and M390R buffer treated eyes from 2 months to 6 months post-injection. Data were analysed by 2-way ANOVA with post hoc Šídák's multiple comparisons.

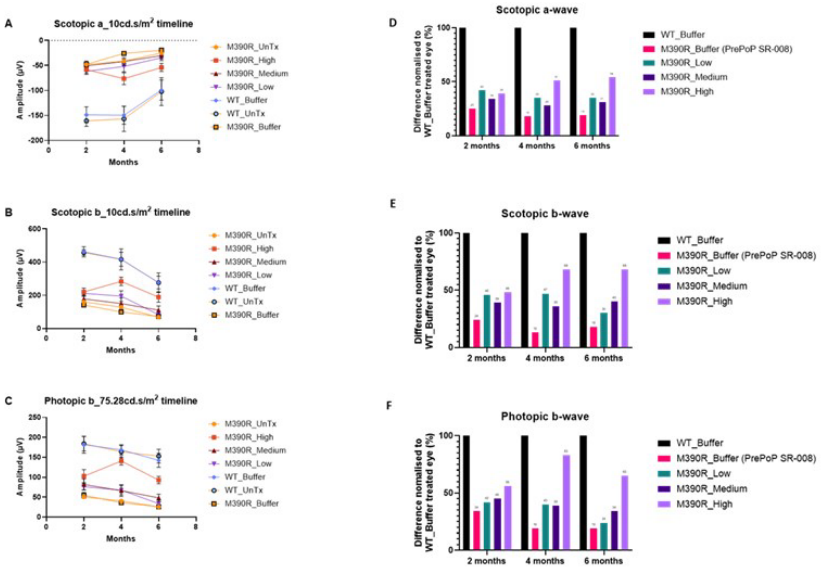

Figure 2. Temporal changes in retinal function measured by ERG at maximum stimulus (A-C) Changes in (A) Scotopic a, (B) Scotopic b, and (C) Photopic b-wave response (mean amplitude ±SEM) at maximum stimulus over 6 months period for untreated contralateral (UnTx), M390R low, medium and high treated and WT buffer treated eyes as well as M390R buffer treated eyes. (D-F) Percentage response of M390R treated eyes for (D) Scotopic a, (E) Scotopic b, and (F) Photopic b-wave at maximum stimulus. Stimulus response is normalised to WT buffer treated eyes at respective timepoints.

923 INS1203: RNA-End Joining Technology Enables Full-length ABCA4 Expression In Mouse and NHP Retinal Photoreceptors

[1]Insmed Gene Therapy LLC, San Diego, CA, [2]Insmed, Inc., San Diego, CA, [3]Insmed Inc., San Diego, CA, [4]Insmed Inc., Bridgewater, NJ

Stargardt Disease is the most prevalent form of inherited childhood blindness, affecting about 1:10,000 individuals in the United States. Stargardt Disease is caused by mutations in the ABCA4 gene encoding a large transmembrane protein that clears retinoids from photoreceptors. Loss of ABCA4 leads to accumulation of toxic byproducts that cause degeneration of the photoreceptors and apposing retinal pigment epithelium. Despite a well characterized disease mechanism, treatment for Stargardt patients is restricted to symptom management, as there is currently no approved cure or method for stalling progressive vision loss. A major challenge in gene therapy has been the ~5-kilobase cargo size limitation of AAV which restricts the ability for efficient and safe delivery of large genes like ABCA4 (6.8kb coding sequence).

The RNA-end joining (REJ) technology described here aims to address the size limitation related to AAV-based gene therapy by delivering a gene of interest as fragments in two (or more) individual AAVs and subsequently reconstituting the full-length coding sequence on the mRNA level in the target cell. In REJ, each half-coding sequence is expressed from a separate AAV vector, refered to as REJ-donor (RD) and REJ-acceptor (RA). The RD and RA transcripts are equipped with short RNA elements that mediate strong non-covalent binding of the two and through recruitment of the cellular splicing machinery efficient joining of the two RNA molecules in trans. REJ is therefore uniquely positioned to potentially address a challenge of conventional gene therapy approaches, and in particular advance the use of AAV strategies in large gene related ocular diseases such as Stargardt disease.

With INS1203, we have developed and characterized a therapeutic REJ-AAV8-ABCA4 gene replacement vector formulation that expresses Abca4 protein from two AAV8 vectors in a 1:1 ratio. Each construct drives expression of the N- or C-terminal half of the protein by the human GRK1 promoter. The two fragments join, and elements designed to inhibit fragment expression function to block translation of truncated protein from either single AAV.

Following subretinal injection in the Stargardt Disease mouse model of INS1203, we have shown that Abca4 protein expression is restored to physiological levels, specifically expressed in photoreceptors, and predominantly localizes to the photoreceptor outer segment, showing the intended biodistribution and cellular localization. Here we report functional studies in the mouse model demonstrating dose-dependent reduction of the disease biomarker A2E in the eye. Additionally, in the non-human primate (NHP) eye, INS1203 was generally well-tolerated when delivered via subretinal injection. Using a junction spanning RNA-probe, the INS1203 derived full-length abca4 transcript is found to be abundant and widespread in the NHP retina. These results demonstrate that REJ can be used to deliver large genes to the mouse and primate retina. Taken together, these results support further study of INS1203 as potential ABCA4 gene replacement therapy for Stargardt Disease.

924 Evaluation of MERTK gene therapy in RCS rats following a single bilateral subretinal injection.

Mayur Choudhary[1], Rozemarijn Verhoeven[2], Benjamin Yerxa[3], George Magrath[4], Ashwath Jayagopal[5]
[1]Opus Genetics, Durham, NC, [2]Little Creek Research, Siler City, NC, [3]Opus Genetics, Raleigh, NC, [4]Opus Genetics, Inc, Durham, NC, [5]Durham, NC

Retinitis pigmentosa (RP), a group of inherited retinal dystrophies affecting 1 in 3000 – 7000 people, is characterized by disruption of rod photoreceptors, leading to rod-cone degeneration. Mutations in the proto-oncogene tyrosine-protein kinase MER (*MERTK*) gene cause ~3% of RP cases. Loss of *MERTK* function leads to disruption of phagocytosis by the RPE, followed by rod cell death. OPGx-*MERTK* (AAV2-VMD2-h*MERTK*) is a gene augmentation approach developed to help patients impacted by *MERTK*-related RP. In this study, we evaluated the efficacy of OPGx-MERTK in Royal College of Surgeons (RCS) rats which exhibit a retinal pigment epithelium (RPE) phagocytosis defect due to a natural mutation in *mertk*, following a single bilateral subretinal injection.

At P14, male and female animals (n=10-12 per group) received a single subretinal injection of vehicle (group 1) or 5E8 (low dose, group 2) or 1E10 (high does, group 3) vg/eye OPGx-MERTK. Study parameters included clinical observations, body weights, ophthalmic examinations (slit lamp microscopy and indirect ophthalmoscopy), optical coherence tomography (OCT), fundus imaging, full field electroretinography (ffERG), and ocular histopathology and immunohistochemistry. Slides from the eye were stained with hematoxylin and eosin (H&E) for histopathology, and duplicate slides were labeled for immunohistochemistry (IHC) for rhodopsin, R/G opsin, and MERTK

There were no test article-related effects on clinical observations or body weights. Ophthalmic exam observations on 1 day post injection (dpi) were associated with the dosing procedure, and included bleb formation, vitreous and sub-bleb hemorrhage, which resolved at 21 dpi. OCT and fundus evaluation showed retinal degeneration of the photoreceptor layer on day 21, historically observed in RCS rats. On day 21, 13/14 eyes, 9/9 eyes and 2/10 from group 1, 2 and 3, respectively showed photoreceptor debris. On Day 42, similar findings of retinal degeneration were noted in Group 1, while in Groups 2 and 3, 8/14 and 1/10 eyes showed photoreceptor debris, respectively. Group 3 animals had detectable outer nuclear layer (ONL) on days 21 and 42, while Group 1 ONL was reduced on day 21 and generally not quantifiable by Day 42, and Group 2 ONL was reduced on day 21 and detectable only in a few eyes on day 42. Measurement of outer nuclear layer thickness exhibited significant preservation of ONL at 42 dpi (Vehicle: 1.870±3.60; Low dose: 3.60±4.51; and High dose: 21.28±12.94 µm) in the high dose cohort ($p<0.0001$, n=10). ffERG measurements showed a significant improvement in scotopic-a (at 39.8 cd.s m^{-2}: Control-18.76±13.79 µV, High dose-53.32±27.93 µV, $p<0.05$, n=10) and scotopic-b (at 39.8 cd.s m^{-2}: Control-44.08±14.90 µV, High dose-170.57±86.38 µV, $p<0.0001$, n=12) amplitudes.

In conclusion, subretinal administration of 0, 5E8, or 1E10 vg/eye OPGx-MERTK on P14 in the RCS rat model of retinal degeneration was well tolerated. Model induction in this pilot study was as expected, with retinal degeneration, photoreceptor debris, thinning of the ONL, and flat ERG waveforms observed in the vehicle group on Days 21 (P35) and 42 (P56). These data demonstrate that in the RCS rat model of retinal degeneration, 1E10 vg/eye OPGx-MERTK effectively preserved the photoreceptors and retinal function.

925 Inhibition of Laser Induced Choroidal Neovascularization (LCNV) by Blocking Complement Activation Cascade Using AAV Vectors Carrying Complement Inhibition proteins

Sameera Peraramelli[1], Jianwu Chen[2], Zhe Yu[1], Alan Chen[3], Eduardo Santillan[4], Derrick Huynh[5], Ningguang Luo[3], Shuyi Li[6], Jin Zhong Li[2], Shengjiang Liu[2]*
[1]Avirmax, Inc., Hayward, CA, [2]Avirmax Inc., Hayward, CA, [3]Avirmax, [4]Avirmax Inc, Oakland, CA, [5]Avirmax, 22710 Zaballos Ct., CA, [6]Avirmax, Hayward, CA
**Corresponding Author*

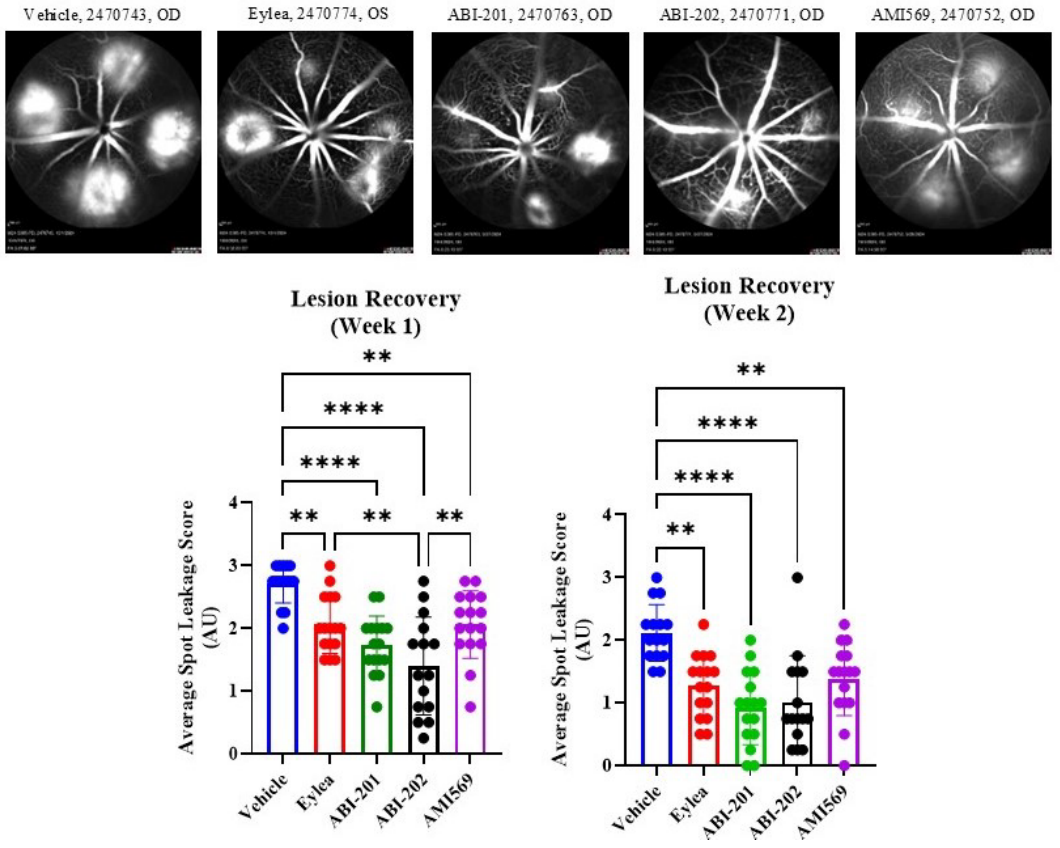
Introduction: This study aimed to determine whether a mouse laser-induced choroidal neovascularization (LCNV) model, treated with constructs carrying the complement protein sCD59 and a complement 3 inhibition (C3i) fusion protein, could elicit non-VEGF-dependent anti-angiogenesis and anti-inflammatory responses. The study also evaluated the localized therapeutic effects of these constructs compared to VEGF inhibition using Eylea as a control.

Methods: C57BL/6J mice received bilateral intravitreal (IVT) injections of either Vehicle, Eylea (40 µg/mL), ABI-201 (sCD59+C3i fusion protein), ABI-202 (sCD59+C3i fusion protein), or AMI569 (C3i+sCD59) at a dose of 1.0E+09 vg/eye. Laser injury was induced in the retinal tissue 28 days after dosing to model choroidal neovascularization (CNV). Lesion recovery was assessed at 7 and 14 days post-injury using fundus angiography and by measuring average spot leakage scores. In vivo protein expression levels in the whole eye, serum, and other organs were quantified using custom in-house ELISA assays to evaluate the localized or systemic distribution of the therapeutic constructs.

Results: Mice treated with the vehicle exhibited the largest lesion sizes and highest intensity of injury, confirming the model's sensitivity. Among the treatments, ABI-202 (sCD59+C3i fusion protein) demonstrated the greatest reduction in lesion size and leakage intensity, likely due to its dual mechanism of complement inhibition and the protective effects of the fusion protein. ABI-201 (sCD59+C3i fusion protein) was the next most effective, showing enhanced lesion healing through a combination of complement inhibition and protective properties of the fusion protein. AMI569 (C3i+sCD59) provided notable reductions in lesion intensity by complement inhibition alone, comparable to Eylea, which served as the VEGF antagonist control. The ranking of treatments based on efficacy revealed: ABI-202 — The most effective, combining complement inhibition with additional protective effects from the C3i fusion protein. ABI-201 — Provided robust healing, coupling complement inhibition with further benefits of the C3i fusion protein. AMI569 — Delivered solid outcomes by targeting complement activation exclusively. At 14 days post-injury, lesion intensity and size reductions remained consistent with trends observed at the 7-day time

point. The highest expression of gene products was observed in ocular tissues, confirming the localized activity of the constructs. Serum and other systemic tissues showed minimal or undetectable protein levels, suggesting a targeted and localized therapeutic effect.

Conclusion: This study demonstrates that complement inhibitors (C3i, sCD59, and their combinations with a C3i fusion protein) are comparable to anti-VEGF treatments like Eylea in reducing laser-induced retinal injury in a mouse LCNV model. These findings highlight the therapeutic potential of complement inhibitors to address inflammation, oxidative stress, and angiogenesis in retinal diseases such as wet AMD. By targeting complement activation, these therapies offer a broader mechanism of action beyond VEGF inhibition, providing new possibilities for standalone or combination therapies. This is especially relevant for patients who do not respond to anti-VEGF treatments. Furthermore, the results validate the LCNV model as an effective tool for studying complement-driven ocular diseases and exploring novel, targeted therapies for preserving vision.



926 Development of Gene Therapy Vectors to Deliver *MYO7A*, *PCDH15*, *CDH23*, and *USH2A*

Seongjin Seo[1]*, Kun-Do Rhee[2], Poppy Datta[3]

Usher syndrome is a genetic disorder that affects both vision and hearing. While at least nine genes are linked to Usher syndrome, mutations in four genes—*USH2A*, *MYO7A*, *PCDH15*, and *CDH23*—account for over 90% of cases in the United States. Adeno-associated virus (AAV) is a safe and efficient gene delivery vehicle and is currently the most broadly used viral vector in retinal gene therapies. However, the aforementioned Usher syndrome

genes are all larger than the AAV vector's packaging capacity, making conventional single AAV-based gene therapies unsuitable for the vast majority of Usher syndrome patients.

We have developed a strategy for delivering large genes using up to four AAV vectors, combined with a CRE-lox-mediated unidirectional DNA recombination system to reconstitute full-length genes. We applied this strategy to the four most commonly mutated Usher syndrome genes and created gene therapy vectors for the treatment of retinal degeneration. For *MYO7A* and *PCDH15*, dual AAV vector systems were designed to deliver the full-length genes, while a tripartite system was developed for *CDH23*. For *USH2A*, which has a coding sequence spanning 15,606 bp, we devised three sets of triple AAV vectors and one set of quadruple AAV vectors to deliver "shortened" *USH2A* (*sUSH2A*) genes with different deletions. *In vitro* studies in 293T cells confirmed that all these AAV vectors successfully produced the intended full-length proteins. *In vivo* studies in mouse retinas are currently underway. These gene therapy vectors provide a foundation for advancing to larger animal models to evaluate their therapeutic efficacies in preclinical studies and future clinical trials.

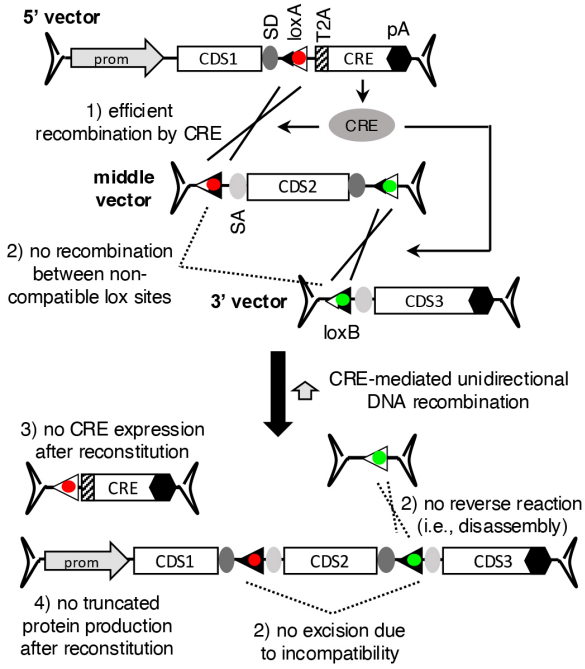

Figure 1. Delivery and reconstitution of large therapeutic genes using multiple AAV vectors and CRE-lox-mediated unidirectional DNA recombination. Advantages of this approach are indicated (1-4).

927 Insulin-Assisted AAV Gene Therapy for Inherited Retinal Diseases

Purpose: Adeno-associated viruses (AAVs) are proven efficient and relatively safe for intraocular delivery with subretinal injections. However, this method is not without therapeutic limitation in that only the retinal area injected has access to AAV and complications arise like detachment of retina, traumatic macular holes, subretinal neovascularization, and late-appearing retinal atrophy in treated patients with voretigene neparvovec-rzyl (Luxturna). Intravitreal injection attempts have largely failed to transduce the retina efficiently and carry concern for inflammatory response with residual virus left in the eye. To treat the retina more completely, without the physical

trauma of subretinal injection and late atrophy, we propose a novel approach that delivers AAV to the pre-retinal surface after removal of the vitreous, accelerates it into the retina with adjuvant insulin coadministration, and then removes the vector 30 minutes later to avoid residual AAV in the eye. With this approach, we hypothesize that insulin-assisted AAV pre-retinal delivery can transduce outer retina photoreceptors. To model parts of this approach pre-clinically, we have conducted in vivo murine intravitreal injections, ex vivo murine retinal explant cultures, and in vitro cell culture that demonstrates an AAV transduction efficiency dose response with increasing doses of insulin.

Methods: Mouse eyes were treated with an intravitreal injection of 7.2x1010 viral genomes/eye of AAV9.CB.GFP in 2 microliters with insulin doses of 10, 20, and 30ng and balanced salt solution as control in contralateral eye for 4 weeks. Ophthalmic exams including in vivo fundus imaging, optical coherence tomography (OCT) and electroretinography (ERG) were performed to assess retinal structural integrity and function, respectively. Retina morphology, GFP transduction and expression were evaluated using immunohistochemistry and GFP-ELISA. To test AAV transduction on the order of minutes, both murine retinal explants and retinal pigment epithelium (RPE) cell lines were treated with AAV9.CB.GFP and the same doses of insulin as above[TM1] for only 30 minutes before rinsing. We evaluated GFP transduction in explants and RPE cultures on the 3rd, 5th and 7th day.

Results: Our results demonstrate a dose response of AAV transduction to increasing concentrations of insulin. GFP expression was observed robustly throughout both inner and outer retinal cells after intravitreal injection, including in the photoreceptors, with increasing transduction as more insulin is added. Retinal integrity and function were retained on OCT and ERG, respectively. In retinal explants and primary RPE cell cultures, only 30 minutes of AAV plus insulin exposure resulted in similar dose response curve.

Conclusions: We developed a novel insulin-assisted AAV gene therapy approach that significantly increases transduction efficiency to the order of minutes and effectively treats the outer retina. The short 30 minutes of residence time on the pre-retinal surface will facilitate successful transduction and then AAV removal in larger pre-clinical models during typical retina surgery time constraints. Our preliminary data from pigs also demonstrated robust transduction in outer retina. This gene agnostic approach may well be applied to any AAV therapy or conceivably non-viral therapy, allowing it to be utilized for genes larger than AAV carrying capacities and future gene editing approaches.

Figure 1

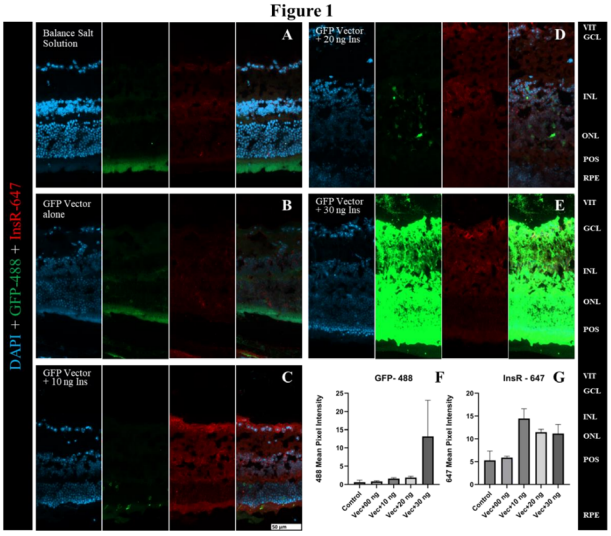

Figure 1. Retinal sagittal sections with dose response curve to insulin. AAV, adeno-associated virus; GFP, green fluorescent protein; InsR, insulin receptor; VIT, vitreous; GCL, ganglion cell layer; INL, inner nuclear layer; ONL, outer nuclear layer; POS, photoreceptor outer segment; RPE, retinal pigmented epithelium.

928 Inhibition of IGF1R with KRIYA-586: A Novel AAV Gene Therapy Expressing an Anti-IGF1R Antibody Demonstrates Comparable Pharmacodynamic Activity to Teprotumumab

Rachel Eclov[1], Ruth Castellanos[2], Angela Ambakhutwala[2], Cigdem Yasar[3], Chris Lassiter[1], William Chappell[4], Lauren Parker[1], Benjamin Johnson[5], Tanika Williamson[6], Chaitali Basole[1], Jiewu Liu[2], Pilar Prentiss[1], Jessica Raubenolt[1], Ashlyn Bassiri[7], Andrew Murphy[8], Andrea Kossler[9], Michele Stone[10]
[1]Kriya Therapeutics, Morrisville, NC, [2]Kriya Therapeutics, Durham, NC, [3]Stanford University, Palo Alto, CA, [4]Kriya Therapeutics, Inc., Durham, NC, [5]Kriya Therapeutics, Raleigh, NC, [6]Durham, NC, [7]Kriya Therapeutics, Morrisville, North Carolina, [8]Kriya Therapeutics - Redwood City, CA, Morrisville, NC, [9]Stanford Univeristy, Palo Alto, CA, [10]NA, Morrisville, North Carolina

Teprotumumab is a human IgG1 monoclonal antibody that inhibits the insulin growth factor 1 receptor (IGF1R) and is approved for treatment of acute and chronic Thyroid Eye Disease (TED). Increased expression and activation of IGF1R on orbital fibroblast contributes to the pathophysiology of TED and leads to fat accumulation and muscle expansion behind the eye, driving the physical phenotypes of the disease. Inhibition of IGF1R in TED reduces orbital inflammation and proptosis. Adverse reactions have been reported with the current intravenous teprotumumab treatment regimen, including hearing impairment, hyperglycemia, and muscle spasms. To address these limitations, we have developed KRIYA-586, an investigational adeno-associated virus (AAV) gene therapy engineered to express an anti-IGF1R similar to teprotumumab. AAV produced anti-IGF1R reduces IGF1R signaling and expression in cancer cell lines and TED patient derived fibroblasts, and KRIYA-586 intratumoral treatment reduces IGF1R in a tumor xenograft model similar to recombinant teprotumumab.

Excreted anti-IGF1R from immortalized human embryonic kidney (HEK293T) cells transduced with KRIYA-586 was evaluated using either supernatant or enriched protein isolated by Protein A Chromatography (verified for heavy and light chain molecular weight (immunoblot) and total protein quantified (Gyros and Electrochemiluminescence method)). The KRIYA-586 produced protein was evaluated for amount bound to IGF1R (Insulin Signaling MSD ELISA), reduction in total IGF1R (flow cytometry and immunocytochemistry) and IGF1R phosphorylation signal in fibrosarcoma (HT1080) cells and/or TED fibroblasts. Fibroblasts were isolated from adipose decompression samples that would have otherwise been discarded from consenting TED patients. To evaluate KRIYA-586 in vivo pharmacodynamic activity, xenografted nude mice bearing IGF1R+ human colon carcinoma (Colo 205) tumors were given a single intratumoral injection of KRIYA-586 (7.75E11 vg/tumor) or weekly intraperitoneal injection of 6 mg/kg recombinant teprotumumab. At Days 7, 14 and 21 (N = 3 per day) and Day 31 (N = 8) post treatment, animals were sacrificed to assess tumors (size, IGF1R protein, anti-IGF1R protein, vector genomes) and serum (anti-IGF1R protein).

KRIYA-586 produced anti-IGF1R had similar detection of human IgG1 heavy and light chains ratios compared to recombinant teprotumumab. A comparable quantity of vectorized anti-IGF1R and recombinant teprotumumab bound to IGF1R with similar inhibitory activity in HT1080 and TED fibroblast cells. In the xenograft model, anti-IGF1R was detected in serum within 14 days of KRIYA-586 administration and a significant and similar decrease of IGF1R levels in tumors between KRIYA-586 or weekly recombinant teprotumumab were observed.

These data demonstrate that KRIYA-586 generates functional anti-IGF1R with pharmacodynamic activity in vitro, ex vivo and in vivo, equivalent to exogenously administrated teprotumumab. This supports further evaluation of the potential translation of KRIYA-586 gene therapy to impact the course of TED.

929 Periorbital Delivery of AAV Therapeutics for the Treatment of Orbital Diseases

Ruth Castellanos[1], Rachel Eclov[2], Michael Engles[3], Angela Ambakhutwala[1], Robin Marjoram[1], Andrew Murphy[4], Uma Karadge[2], Chris Lassiter[2], William Chappell[5], Lauren Parker[2], Benjamin Johnson[6], Jiewu Liu[1], Pilar Prentiss[2], Jessica Raubenolt[2], Nancy Bordelon[2], Ashlyn Bassiri[7], Michele Stone[8]
[1]Kriya Therapeutics, Durham, NC, [2]Kriya Therapeutics, Morrisville, NC, [3]Eye Soar Inc, Raleigh, NC, [4]Kriya Therapeutics - Redwood City, CA, Morrisville, NC, [5]Kriya Therapeutics, Inc., Durham, NC, [6]Kriya Therapeutics, Raleigh, NC, [7]Kriya Therapeutics, Morrisville, North Carolina, [8]NA, Morrisville, North Carolina

Orbital diseases, including thyroid eye disease, orbital cellulitis, idiopathic orbital inflammatory syndrome and dacryoadenitis affect tissues surrounding the eye, which are not typically targeted by intraocular or AAV gene therapies. Some of the tissues involved in these diseases are small and not feasible for intra-tissue injections, such as extraocular muscles. To address this issue, we explored periorbital AAV delivery via retrobulbar injection in Göttingen minipigs as a novel route targeting local delivery of AAV to orbital tissues. We selected Göttingen minipigs due to their anatomical similarities to humans.

Minipigs negative for AAV neutralizing antibodies were administered AAV8.mCherry or AAV9.mCherry via retrobulbar injection into the muscle cone at a dose of 1E12 vg/eye in 250uL, or AAV9.mCherry (3.6E11 vg/eye in 12 uL) via intramuscular (IM) injection to the lateral rectus extraocular muscle. Three weeks post-administration, orbital and systemic tissues were examined for vector genomes (qPCR), transgene expression (RT-qPCR), and mCherry protein via immunohistochemistry (IHC). Retrobulbar administration of either AAV8 or AAV9, yielded robust mCherry staining in >75% of extraocular muscles and 51-75% of adipocytes with limited spread to the optic nerve or peripheral tissues. Vector genome analysis shows that animals treated with retrobulbar AAV8 and AAV9 had high vector genome in the extraocular muscles and adipose tissues (1E5-2E6 vg/µg DNA), both superior to IM AAV9.mCherry at 3E4 vg/µg DNA.

Retrobulbar AAV delivery achieved superior transduction of orbital tissues compared to intramuscular injection in large animal models, with minimal systemic distribution. This targeted approach represents a promising novel therapeutic strategy for treating orbital diseases and establishes proof-of-concept for clinical translation.

930 Intracochlear Administration Methods Across Species

Sebastien Diot[1]*, **Molly Kalker[2]**, Marion Souchal[3], Carolanne Coyat[3], Aurore Marie[4], Elodie Flaszka[3], Véronique Baudoux[3], Sylvie Pucheu[3], Gaëlle Naert[3]

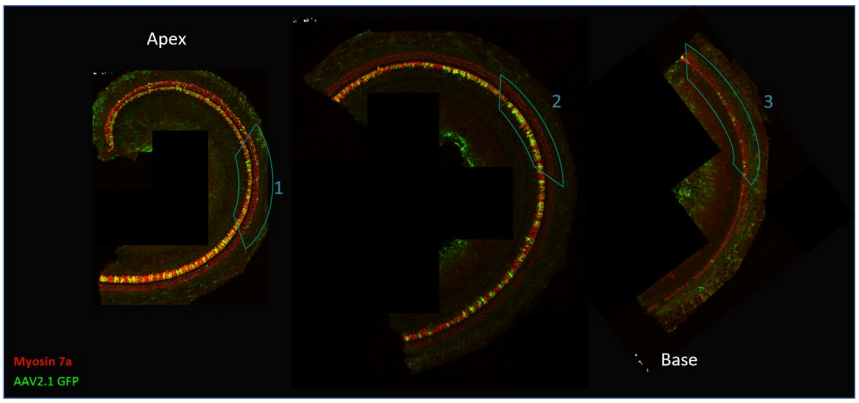
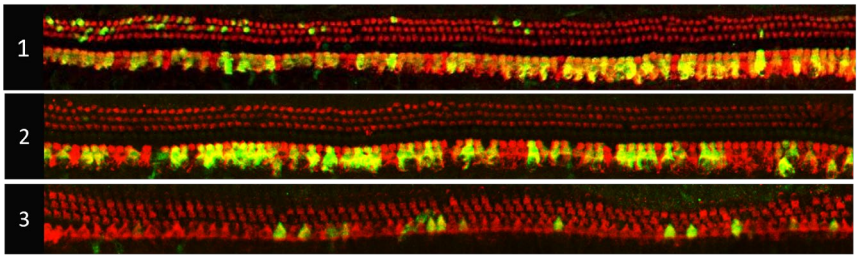
The delivery of gene or cell therapy to the inner ear represents a challenge due to the blood-labyrinth barrier, necessitating local delivery approaches, especially for expensive therapy with limited therapeutic range or susceptibility to systemic side effects. This is particularly relevant for viral gene transfer and cell-based therapies. Adeno-associated virus (AAV) vectors emerge as a prominent choice for gene therapy due to infection efficiency, low toxicity, sustained gene expression, and cost-effectiveness.

This study aimed to compare different intracochlear (IC) injection techniques in mice and guinea pigs. Mice were administered via posterior semicircular canal (PSCC) and round window (RW) injections, while guinea pigs received cochleostomy infusion, RW injection (RWI) or deposit (RWD) due to anatomical differences. Auditory function effects of IC administration were evaluated in both species via auditory brainstem response (ABR) and distortion product otoacoustic emission (DPOAE) measurements.

Following AAV delivery, GFP expression from AAV-mediated cell transfection enabled the identification of transfected cochlear regions. Both PSCC and RW injections successfully targeted hair cells, albeit with variations in transfection patterns and intensity depending on the injection method and AAV subtypes. Finally, impacts on auditory function varied among injection methods, with PSCC and IC routes showing less effect on DPOAE amplitudes and ABR thresholds compared to the RW route.

In conclusion, our study highlights the importance of refined intracochlear delivery method in animals accordingly to the delivered product and targeted inner ear disorders. While all methods effectively reached cochlear hair cells, variations in transfection patterns or in product concentration at targeted cells, and effects on auditory function highlight the need for careful consideration of injection strategies. It is worth mentioning that the posterior semicircular canal (PSCC) and cochleostomy routes, though effective in animals, lack translational relevance to humans. Moving forward, further research into optimizing delivery methods will be essential for advancing therapeutic interventions in auditory disorders.





Injection parameters

931 AAV mediated gene delivery to the aged and young mice lung

Lu Song[1], Agnieszka Anya , Wendorff[2], Alexander Li[2], Varahram Shahryari[2], Aaron Stebbins[2], John Patino[2], Andy Chang[2], Astrid Gillich[2], James Lee[2], Calvin Jan[2], Putianqi Wang[1]
[1]Calico Life Sciences, South San Francisco, CA, [2]Calico Life Sciences

Adeno-associated virus (AAV) mediated gene delivery provides a more rapid method for in vivo validation of aging-related target genes, compared to the development of transgenic animal models. Aging is the primary risk factor for many chronic lung diseases, including idiopathic pulmonary fibrosis, chronic obstructive pulmonary

disease and acute respiratory distress syndrome. Many studies have investigated gene delivery to the lungs of young mice; however, the physiological decline of tissues in aged animals presents a major challenge for gene delivery. Here, we compared two AAV serotypes, AAV6.2FF and AAV9, transduced in young and aged mice. AAV6.2FF shows high transduction efficiency in the epithelial cells of both young and aged mouse lungs. AAV9 is more biased towards infecting fibroblast cells in the lungs of young and aged mice. Comparing AAV-mediated gene transduction in young and aged animals will facilitate understanding of AAV gene delivery in the aged pulmonary system, and define research tools to understand aging-related lung diseases.

932 A Head-to-Head Comparison of AAV9 Biodistribution in Mice: Routes of Administration and Age Dependence

Matthew Rioux[1], Andrea Boitnott[2], Satvik Paduri[3], Yuhui Hu[4], Steven Gray[5]*
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, Texas, [3]UT Southwestern Medical Center, Dallas, TX, [4]UT Southwestern, Dallas, [5]University of Texas Southwestern Medical Center, Dallas, Texas
**Corresponding Author*

Adeno-associated virus serotype 9 (AAV9) has broad systemic delivery, the ability to cross the blood brain barrier, and a low toxicity profile, making it widely used as a gene delivery vector. Despite the extensive use of AAV9 in translational research, variability in vector constructs, injection volumes, treatment ages, and routes of administration make the existing body of work regarding AAV9 biodistribution fractured and often studies are difficult to directly compare. We designed the following study to provide a head-to-head comparison of biodistribution of AAV9 based on the route of administration in mice, with internally controlled groups treated at various developmental timepoints. Due to the emergence of AAV9 as the dominant AAV serotype used to target the central nervous system, we concentrated our analysis on central nervous system tissue (cerebrum, cerebellum, lumbar spinal cord, and cervical spinal cord) with a secondary focus on key peripheral organs (liver, heart, and sciatic nerve). We evaluate transgene expression of a self-complementary AAV9 vector expressing GFP driven by a strong ubiquitous promoter (CBh) via four different routes of administration at four different ages. Bilateral intracerebroventricular, intravenous, lumbar intrathecal, and lumbar intrathecal intracerebroventricular combination injections were performed in C57BL/6J mice at postnatal day 1, 5, 10, and 28. Mice were treated with a total dose of either $2.5x10^{11}$ or $5.0x10^{11}$ viral genomes, which allowed for direct comparison across treatment groups. All tissue was collected at 8 weeks of age to allow for peak gene expression and brain maturation to at least adolescent levels before immunohistochemistry and quantitative polymerase chain reaction analysis. As targeted therapies continue to improve through engineered viral vector optimizations, it will be important to establish standardized benchmarks to gold standards like AAV9, for accurate comparison.

933 *Pre-Clinical Safety and Efficacy of AAV9 gene therapy for Mucolipidosis type IV (ML4)*

Tyler Mola[1], Olivia Morales[2], Simon Wentworth[3], William Callahan[2], McKenna Watson[4], Ananya Uppalapati[2], Ana Rita Batista[2], Miguel Sena-Esteves[2]
[1]UMass Chan Medical School, Leominster, MA, [2]UMass Chan Medical School, Worcester, MA, [3]University of Massachusetts Medical School, Worcester, MA, [4]University of Massachusetts Chan Medical School, Worcester, MA

Mucolipidosis type IV (ML4) is an autosomal recessive lysosomal storage disease caused by mutations in the *MCOLN1* gene, encoding for the transient receptor potential channel, mucolipin 1 (TRP-ML1). Evidence has shown that TRP-ML1 acts as a non-selective cation channel whose channel activity is pH- and Ca^{2+}- dependent and that it regulates lipid trafficking by regulating late endosomal/lysosomal fission and fusion events. However, the exact function of TRP-ML1 and how the mutated versions interfere with lysosomal function is still unknown. It has been shown that AAV-mediated CNS gene transfer of human *MCOLN1* results in rescue of motor deficits and delayed time to paralysis with correction of brain pathology in ML4 mice (*Mcoln1*$^{-/-}$). We are conducting a blinded long-term dose escalation efficacy study in *Mcoln1*$^{-/-}$ mice treated neonatally (P0-P1) by bilateral intracerebral ventricular (ICV) injection of 1E10, 3E10 or 1E11 vg of scAAV9-JeT-h*MCOLN1* vector or PBS. Behavioral performance is assessed at 2 and 6 months of age in the Open Field and rotarod tests to assess efficacy and durability of effect. Interim data analysis of survival (**Fig. 1**) showed that all animals have perished in group B with a median survival of

200 days. The identity of group B was unblinded prior to conclusion of the study and corresponds to mice treated with PBS. For the other groups there appears to be a dose effect with two groups (A and C) with several animals that have reached the humane endpoint (median survival in group C is 251 days), and one group (Group D) where all mice remain alive at 292 days of age. Performance in the rotarod test was comparable across groups at 2 months of age, but it declined significantly in PBS-treated animals by 6 months of age. Performance was significantly better in AAV-treated mice compared to PBS-treated mice at 6-months of age and remained unchanged between 2 and 6 months of age for groups A and D. Importantly there have been no adverse events in age-matched carrier and wild type littermates that also receive AAV vector at birth. Molecular and histological analyses of tissues are ongoing.

Conclusions: Our survival and behavioral data show that neonatal ICV treatment with scAAV9-JeT- h*MCOLN1 vector* has a substantial therapeutic effect, rescuing motor deficits and increasing survival of ML4 mice. We are currently analyzing tissues for MCOLN1 expression and impact of treatment on storage material and myelination, which is defective in ML4 mice. We are also developing a *MCOLN1* knockout HEK293T cell line to assess vector potency across AAV vector batches. The interim results show a durable benefit of neonatal treatment with scAAV9-JeT-MCOLN1 vector and support transition of this AAV gene therapy to a phase I/II clinical trial in ML4 patients.

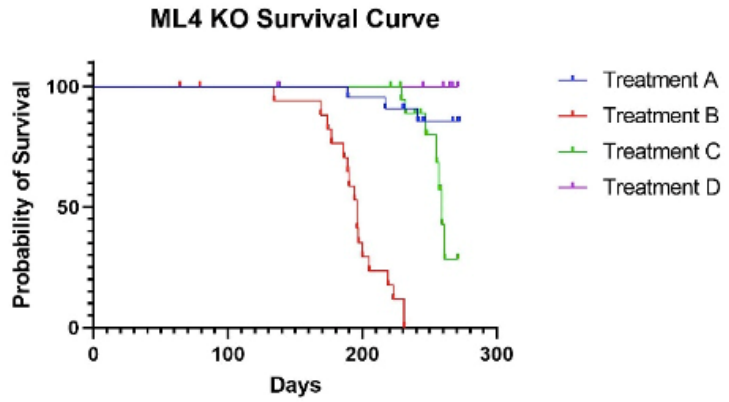

Figure 1. Survival of ML4 mice treated neonatally by ICV injection of AAV9-hMCOLN1 vector or PBS (Group B).

934 *Neonatal Intravenous Delivery of AAV-F in a Gaucher disease mouse model*

Ozge Cetin[1], Anna Keegan[2], Ellie Chilcott[3], Juan Antinao Díaz[4], Amy Geard[5], Giulia Massaro, Ahad Rahim, Simon Waddington, Rajvinder Karda*
[1]University College London, LONDON, UK, United Kingdom, [2]UCL, LONDON, London, United Kingdom, [3]University College London, LONDON, London, United Kingdom, [4]UCL, London, Greater London, United Kingdom, [5]University College London, LONDON, United Kingdom
**Corresponding Author*

While AAV9 has demonstrated clinical success in treating diseases such as Spinal Muscular Atrophy (SMA), there is some limitations. One major challenge is the requirement for high concentrations of AAV9 to achieve therapeutic efficacy, which can lead to off-target effects and dose-limiting toxicity. To address these challenges, the AAV-F capsid has emerged as a promising candidate for gene therapy studies, due to its widespread central nervous system (CNS) targeting capabilities and greater transduction efficiency.

A comparative biodistribution profiles of AAV-F and AAV9 was conducted using a CAG promoter driving the green fluorescent protein (GFP) reporter gene. After administering titre-matched AAV-F and AAV9-CAG-eGFP ($1.9x10^{10}$ vg/pup) via single intravenous neonatal delivery, GFP analysis at six weeks post-injection revealed that AAV-F exhibited significantly greater neuronal and astrocytic transduction targeting throughout the brain compared

to titre-matched AAV9. Additionally, AAV-F demonstrated higher transduction levels in visceral organs including heart and liver, compared to titre-matched AAV9.

The therapeutic efficacy of AAV-F was evaluated using a knock-out (KO) mouse model of Gaucher disease (GD), a severe neurometabolic disorder caused by mutations in the *GBA1* gene. Which manifests with severe neurodegeneration and visceral pathology. The most acute neuronopathic form (nGD), has no effective treatment options and leads to death in early development. The GD KO mice display neurological and visceral pathology, leading to premature death between postnatal days P12-P14.

Newborn GD KO mice were administered with titre-matched AAV-F and AAV9-CAG-*hGBA1* ($6x10^{10}$ vg/mouse), as well as a higher dose of AAV9-CAG-*hGBA1* ($6x10^{11}$ vg/mouse) via a single intravenous injection. The therapeutic outcomes were evaluated based on survival, body weight, enzyme activity, and behavioural assessments. Both AAV-F and AAV9 treatments resulted in a significant extension of lifespan, compared to PBS KO control group. Rotarod behavioural assessment, resulted in comparable results between AAV-F LD (low dose), AAV9 HD (high dose), and WT control group. AI behavioural assessment using DeepLabCut showed similar results. Analysis of GCase enzyme activity in the brain revealed that AAVF-LD resulted in comparable GCase enzyme levels to AAV9-HD.

Our proof-of-concept study showed that a single intravenous administration of AAV-F-CAG-*hGBA1* to a GD KO mouse model demonstrated significant improvement in survival, weight and GCase enzyme activity. Thus, providing early evidence of the use of AAV-F as a potential treatment for nGD at a lower vector copy number compared to AAV9.

935 AAV-Mediated Beta-Cell-Specific Smad2 Silencing: Bridging Transgenic Mouse Evidence to Gene Therapy for Hyperglycemia

Madison Thomas[1], Ashley Diehl[2], Mohammad Tariq[1], Lydia Liszewski[1], Ting Zhang[3], Vinitha Dhamotharan[1], Krishna Prasadan[1], George Gittes[4]
[1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Raleigh, NC, [3]University of Pittsburgh, Pittsburgh, Pennsylvania, [4]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA

Introduction:
Hyperglycemia resulting from beta-cell dysfunction is a hallmark of type 2 diabetes mellitus (T2DM), a leading global health challenge. Chronic high-fat diet (HFD) exposure exacerbates beta-cell exhaustion, leading to dedifferentiation, senescence, and apoptosis. Smad2, a key mediator of TGF-β signaling, negatively regulates beta-cell proliferation while promoting beta-cell dysfunction under hyperglycemic stress. Studies using transgenic mice with congenital beta-cell-specific Smad2 knockout have demonstrated improved beta-cell function and protection against diet-induced hyperglycemia. Furthermore, conditional deletion of Smad2 in adult beta cells showed similar protection against and reversal of diet-induced hyperglycemia. This study aims to translate these findings by employing adeno-associated virus (AAV)-mediated Smad2 silencing as a potential gene therapy for hyperglycemia.

Methods:
Beta-cell-specific Smad2 knockout (Smad2-fx/fx; InsCreERT) mice were fed an HFD (60 kcal/kg) from 6 weeks of age and treated with tamoxifen or vehicle at 18 weeks. Glucose homeostasis was assessed using glucose tolerance tests (GTT), insulin tolerance tests (ITT), glucose-stimulated insulin secretion (GSIS), and HbA1c measurements. Islets were harvested for RNA sequencing and functional assays. Based on these results, to create a therapeutic system applicable to humans with T2DM, we created an rAAV vector expressing Smad2-targeted short hairpin RNA (shRNA) controlled by the rat insulin promoter (RIP) for beta-cell-specific Smad2 gene silencing. The vector included EGFP for tracking. In vitro validation was performed using MIN6 beta cells, and in vivo delivery was achieved via pancreatic ductal infusion in high-fat-fed CD1 mice. Smad2 expression, infection efficiency, and functional outcomes were evaluated.

Results:
Transgenic Smad2 knockout mice demonstrated significant improvements in glucose homeostasis, as evidenced by

enhanced GTT, ITT, GSIS, and reduced HbA1c compared to controls. RNA sequencing of isolated islets revealed upregulation of beta-cell maturity markers and downregulation of ER stress and mitochondrial dysfunction pathways.
In vitro validation of rAAV-mediated Smad2 silencing in MIN6 cells resulted in a 65% reduction in Smad2 mRNA. In vivo, CD1 mice treated with the Smad2-targeted rAAV showed a 75% reduction in Smad2 expression, with viral infection primarily localized to islet peripheries. Ongoing studies aim to evaluate physiological outcomes and optimize infection efficiency.

Conclusion:
AAV-mediated Smad2 silencing effectively mirrors the benefits observed in transgenic models, including enhanced beta-cell function and improved glucose regulation in high-fat-fed hyperglycemic mice. These findings support the potential of AAV-based Smad2 silencing as a therapeutic strategy for hyperglycemia. Future work will focus on optimizing viral delivery and assessing long-term physiological impacts.

936 Functional Elevation of Computationally Designed IL-10 in IL-10 KO mice

Jordan Stokes[1], Sihong Song[1]*, Zhihang Shen[1], Peter Ramdhan[1], Iram Hyder[2], Allison Bayer[1], Clive Wasserfall[1], Li Chenglong[1]
[1]*University of Florida, Gainesville, FL,* [2]*University of Flordia, Gainesville, FL*
**Corresponding Author*

Increasing evidence suggests that IL-10 has therapeutic effect for the treatment of inflammatory diseases. However, it is challenging to use IL-10 as a therapeutic drug since it also has pro-inflammatory functions. To reduce the proinflammation effects of IL10, we have designed 3 IL-10 mutants (A, B and C) using recently developed structure-based computational-design technology. We first tested the function of these mutants in human PBMCs. Western blot analysis showed that intracellular pSTAT3 (mediator of IL-10 signaling) levels in IL-10 mutant treated PBMCs were lower than that in IL-10W treated cells. To quantitatively evaluate the functions of the IL-10 mutants, we have generated 3 cell lines (THP-luc, U937-luc and RAW-luc), in which the reporter gene (luciferase) are responsive to IL-10 signaling pathway through pSTAT3. Using these cell lines, we showed that our IL-10 mutants are functional, yet have lower activity than IL-10W. We next generated recombinant adeno-associated virus (rAAV8) vectors expressing wild type or mutant IL-10 molecules (W, A, B, and C). We tested our vectors in IL-10 knockout (IL-10 KO) mice, which are on Balb/c background (BALB/cAnNTac-Il10em7Tac) and spontaneously develop inflammatory bowel disease (IBD). We IP injected cohorts of IL-10 KO mice with rAAV8 vectors (10^{11}vg/mouse) expressing W, A, B, C, or GFP, or PBS (as model control) at 8 weeks of age. Results from this study showed that our vectors mediated high and sustained levels of transgene expression detected at 2 and 4 weeks after the vector injection. The body weight gains in A, B, and C groups were significantly higher than in GFP (the vector control) group. Importantly, the accumulative disease activity index (DAI) scores in W, A, B and C groups were significantly lower than GFP group and were similar to that in Balb/c mice (normal control group). In addition, the colon injury in W, A, B, C group were significantly lower than that in GFP and PBS group. In summary, our IL-10 mutants have similar protective effect to IL-10W in IL-10KO mouse model. These results indicate that gene therapy of IL-10 mutants may be safer and more effective than IL-10W for the treatment of IBD.

937 InstaGTx Amplifies AAV Tropism and Is Safe in Non-human Primates

Lauren Switala[1], Lin Di[1], Andrei Maiseyeu[1]
[1]*Case Western Reserve University, Cleveland, OH*

Increasing targeting and thereby decreasing off-targeting of systemically-administered AAV remains a challenge for hard-to-transduce sites such as skeletal or cardiac muscle. Typically, this challenge is addressed on an organ-by-organ basis, with engineered capsids meant to be delivered to a single target organ most effectively. Direct evolution or other methods are often employed for this purpose; however, these methods are expensive and time-consuming, and must be replicated for each organ of interest. Here, we present a tool that enhances AAV targeting, agnostic to AAV serotype. We have engineered a cargoless, polymeric nanoparticle enhancer, InstaGTx, that bolsters different AAV serotypes' tropism to their target organ when administered prior to systemic AAV injection. We have

previously demonstrated InstaGTx's efficacy for heart targeting of AAV1 and AAVrh74.[1] Although we have already shown efficacy of InstaGTx, its safety has not yet been demonstrated in non-human primates (NHPs), a necessary step towards clinical translation. Here, we show that InstaGTx exhibits a favorable safety profile in African Green monkeys (Figure 1a). In this non-terminal study, subjects between 5 and 8 years old who were prescreened for anti-AAV neutralizing antibodies had blood drawn after a baseline saline injection. They were injected with InstaGTx 28 days later and their blood was collected and processed for serum 1 hour and 1 week post injection. Serum was analyzed with a clinical chemistry panel for liver enzymes and assays for inflammatory cytokines,chemokines, and complement factors. The results show that InstaGTx injection does not increase liver enzymes or inflammatory cytokines and chemokines, nor does it activate complement C3a and C5a. We have also validated an in vitro-in vivo screening assay, in which NHP serum is added to human iPSC-derived cardiomyocytes simultaneously with AAV1-Luc. The addition of InstaGTx-injected NHP serum increased transduction relative to saline-injection serum control (Figure 1b), suggesting a serum-derived factor as a driving force of increased in vivo transduction. Excitingly, this assay could allow future high-throughput screening of AAV serotypes for tissue-targeting enhancement, by testing InstaGTx-injected NHP serum with serotypes of interest in in vitro transfections. Further, screening nonviral gene delivery vehicles (polymeric or lipid nanoparticles, etc) with this assay will determine whether InstaGTx can bolster uptake of these different modalities as well. Our data from an in vivo-in vitro NHP study suggests that InstaGTx technology may be translatable for human gene therapy. By improving the targeting of existing AAV serotypes and other therapeutic delivery vehicles, the effective administered dose of treatment will be reduced. This dose reduction increases safety and decreases the cost of goods per dose of AAV (or other delivery vehicle) and decreases the cost of manufacturing. InstaGTx technology holds the potential to expand treatable indications for AAV gene therapies—and potentially other delivery modalities—while streamlining candidate screening, improving safety, and accelerating the timeline to IND submission.

938 Broad Biodistribution of AAV5 and AAV9 Following ICV Administration Compared to ICM in Non-Human Primates.

Meriem Bourajjaj[1], Greg Dobrynin[2], Sara Gimeno Peris[3], Margit Lampen[4], Andra Sonea[3], Giorgia Squeri[5], Rudy de Laat, Amila Zuko[4], Madhurima Chatterjee[3], Wouter Kamphuis[6], Angga Kusuma[7], Liesbeth Heijink[8], **Stephane Baudouin[9]**

[1]UniQure, Amsterdam, Noord-Holland, Netherlands, [2]uniQure, Amsterdam, Netherlands, [3]UniQure NV, Amsterdam, Netherlands, [4]Amsterdam, Netherlands, [5]UniQure B.V., Amsterdam, MA, Netherlands, [6]UniQure B.V.,

Amsterdam, Netherlands, [7]UniQure Biopharma, Amsterdam, Netherlands, Netherlands, [8]UniQure Inc., Amsterdam, Noord-Holland, Netherlands, [9]UniQure NV, Basel, Basel-Stadt, Switzerland

Due to the lack of suitable AAV capsids for intravenous delivery, gene therapies for CNS disorders typically rely on local administration routes. Intraparenchymal injections are ideal for targeting specific brain areas, while cerebrospinal fluid (CSF) injections are preferred for diseases affecting multiple, distant brain regions. Delivering AAV to the CSF can be achieved by administration to the lateral ventricles (i.e. intracerebroventricular, ICV) or to the cisterna magna (ICM). The relative benefits of each route in achieving optimal brain biodistribution remains unclear. This study aims to compare the biodistribution of two AAV serotypes, AAV5 and AAV9, following ICV or ICM delivery in non-human primates (NHP) with unilateral intra-thalamic dosing as a control. A tool cargo expressing a secreted protein under the control of a CAG promoter was used to compare the effect of route of administration and serotype on expression of vector DNA and mRNA across brain regions. Additionally, CSF neurofilament and glial fibrillary associated protein levels were measured in NHPs as markers of neuronal damage and gliosis. Overall, the results showed a broad expression of vector DNA and mRNA following ICV administration for both serotype and localized to spinal cord regions following ICM administration. Furthermore, AAV5 administration led to higher vector DNA expression than AAV9, independent of the route, but resulted in similar mRNA expression levels, suggesting potential difference in cellular tropism. Overall, these findings support the preference for ICV administration when targeting higher brain regions, and ICM for lower brain regions and spinal cord.

939 Biodistribution in ocular tissues after suprachoroidal injection of KH658 in cynomolgus monkeys

Hao Jiang[1], QINGWEI LI[2], **Qiang Zheng[3]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotech, Chengdu, China, China, [3]Chengdu Origen Biotechnology, CHINA

Purpose: The suprachoroidal injection is a recent breakthrough in the retinal gene-delivery landscape and may provide a unique opportunity to perform less invasive surgeries. KH658 is an anti-VEGF gene therapy product that employs a novel AAV capsid variant (AAVv128), delivered by suprachoroidal injection for the treatment of neovascular age-related macular degeneration (nAMD). The purpose of the present study was to assess the ocular tissue distribution following a single suprachoroidal injection of KH658 in cynomolgus monkeys.

Methods: Cynomolgus monkeys were sacrificed 13 weeks following a single suprachoroidal injection (100µl/eye) of 1E12vg/eye KH658, and ocular tissues were collected for subsequent analysis. The quantification of transgene and transgene product was performed by qPCR and ELISA, respectively.

Results: The transgene was present at a concentration of 1.81E7 vg/g in the retina, 1.17E10 vg/g in the choroid, and 2.18E10 vg/g in the sclera. The transgene product was found to be 8,700 ng/g in the retina, 7,680 ng/g in the choroid, and 162 ng/g in the sclera. The transgene and transgene product were below the limit of quantification in the other ocular tissues, including the cornea, lens, conjunctiva, vitreous body and optic nerve.

Conclusions: The transgene and transgene product of KH658 were predominantly distributed within the retina, choroid, and sclera, which is consistent with the characteristics of suprachoroidal injection. The high concentration of anti-VEGF transgene products within the retina suggests that suprachoroidal administration of KH658 may represent a treatment option for nAMD.

940 Exploring the Transduction Efficiency of Suprachoroidal Injection of AAV in the Treatment of Neovascular Age-related Macular Degeneration through A Twice-laser Modeling

Qingwei Li[1], Hao Jiang[1], **Qiang Zheng[2]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotechnology, CHINA
**Corresponding Author*

AAV-antiVEGF is a replication-deficient recombinant AAV variant, which is contained a gene that encodes for a VEGFR-Fc fusion protein intended to treatment for neovascular age-related macular degeneration (nAMD) via suprachoroidal space (SCS) injection. SCS injection has lower invasiveness and fewer complications than subretinal injection (SR) and intravitreal injection (IVT). It also has less impact on ocular structure and vision. However, physiological barriers may limit AAV drug diffusion. nAMD is caused by choroidal neovascularization (CNV) that damages the blood - retinal barrier (BRB). Therefore, in the pathological state of nAMD, the retinal permeability may be increased, which is conducive to the transduction of AAV. To explore whether suprachoroidal injection can increase the transduction efficiency of AAV in the pathological state, we have explored a design of a twice - laser modeling. Two lesions were laser induced 14 days prior to the administration of AAV-antiVEGF in rhesus monkey, in order to induce CNV to mimic the compromised barriers of eyes under the pathological state of nAMD.

At Day 0, laser photocoagulation in the peri-macular region of the retina to induce CNV (1st modeling) to mimic the compromised barriers of eyes under the pathological state of nAMD. Single suprachoroidal space injection of AAV-antiVEGF was performed 14 day (Day 14) after the first modeling (1st modeling), with doses of 3E11 vg/eye and 1E12 vg/eye. At Day 42, 28 days after injection, the laser induced CNV will be performed again (2nd modeling). At day 56 and day 70, the percentage of grade-4 lesions, the fluorescein leakage (FL) areas and the retina thickness will be determined to evaluate the efficacy. Compared with the historical data of single - modeling, the results showed that AAV-antiVEGF can effectively inhibit the formation and development of Grade 4 lesions, reduce the area of the fluorescein leakage (FL) region and the thickness of the retina.

The results of this study suggest that in the pathological state of nAMD, suprachoroidal injection of AAV can transduce the retina more efficiently, thereby achieving a therapeutic effect.

941 Biodistribution and Expression of Ixoberogene Soroparvovec (Ixo-vec) in Non-Human Primates: A Comprehensive Study on Intraocular and Systemic Distribution

Kris Poulsen[1], Julio Nieves[1], Kelly Hanna[1], Charles Engbers[1], Jenny Vo[1], Ruslan Grishanin[1], Romuald Corbau[1]
[1]Adverum Biotechnologies, Redwood City, CA

Ixo-vec is an investigational intravitreal gene therapy designed to express aflibercept, a VEGF inhibitor, as a treatment for neovascular age-related macular degeneration (nAMD). Clinical studies, Phase 1 OPTIC (NCT03748784) and Phase 2 LUNA (NCT05536973), demonstrated that a single intravitreal administration eliminated or significantly reduced the need for supplemental anti-VEGF injections in patients who required frequent IVT injections prior to study initiation. LUNA data has confirmed the potential best-in-class profile of Ixo-vec at the 6E10 vg/eye dose, demonstrating robust and sustained aflibercept levels, industry leading annualized reduction in anti-VEGF injection rates, BCVA preservation, CST reduction and a greater than 90% patient preference for Ixo-vec compared to their prior standard of care.

Non-human primate studies reported here evaluated the tissue biodistribution and expression of Ixo-vec using doses of 3E10 vg/eye and 1E11 vg/eye which are the primate doses equivalent to the human doses used in Phase 2 LUNA (6E10 and 2E11 vg/eye). Results showed that aflibercept mRNA was limited to intraocular tissues and was below the limit of detection in all other tissues at both doses, suggesting no systemic exposure to the ectopically expressed aflibercept protein. Aflibercept protein levels were 4- to 7-fold higher in the retina than in the aqueous humor and uvea, suggesting that the retina, where VEGF causes neoangiogenesis, is the tissue location for the highest levels of aflibercept protein production.

Vector genome DNA was shown to be localized to intraocular tissues, including the retina, choroid, anterior chamber tissues, and parts of the visual system containing retinal ganglion cell axons (optic nerve, optic chiasm, optic path, and LGN). Systemic tissue levels were significantly lower, with the highest levels detected in lymphatic

tissues. At the lower dose (3E10 vg/eye), systemic tissue levels were below the limit of quantification while at the higher dose (1E11 vg/eye) only very low levels of vector genome DNA were detected in liver and lung tissues.

An additional study tested whether there is a transfer of Ixo-vec to fellow eyes. Animals were dosed in one eye with supra-therapeutic doses of 2E12, 6E12, and 2E13 vg/eye.. The study found no evidence of vector genome transfer between eyes. This was supported by the absence of aflibercept or anti-capsid antibodies in the un-dosed fellow eyes. These data also support clinical trials to assess dosing the second eye of patients with bilaterial nAMD.

In summary, these data continue to demonstrate the safety profile of Ixo-vec at the 6E10 human equivalent dose, which has been selected for evaluation in registrational studies, as transduction occurred only in ocular tissues with no systemic expression detected. Additionally, these data confirm the potential to safely dose the second eye for patients with bilateral nAMD.

942 Preclinical Safety Evaluation of AAV5-hRORA (OCU410-ST) a Gene Therapy Candidate for Stargardt's disease and other *ABCA4* related retinopathies

Kalpana Rajanala[1], Pushpendra Singh[2], Bart Cosaro[2], Arun Upadhyay[3]
[1]Ocugen Inc, Malvern, PA, [2]Ocugen, Malvern, PA, [3]Ocugen, Inc., Malvern, PA

Background: Mutations of the ATP binding Cassette 4 (*ABCA4)* gene lead to its functional deficiency, resulting in defective processing and transportation of all-trans retinaldehyde from the photoreceptors to retinal pigment epithelium (RPE) cells. This deposition and subsequent accumulation of oxidized products triggers complement activation and leads to retinal degeneration, ultimately resulting in the development of disease phenotypes such as Stargardt disease 1 (STGD1), Cone Rod Dystrophy 3 (CRD), and Retinitis pigmentosa 19 (RP19). Our prior studies revealed that Retinoic acid-related orphan receptor α (RORA) regulates many of the pathways impacted in STGD, including cellular response, metabolism, and complement activation. OCU410ST (AAV5-*hRORA*) is a modifier gene therapy platform that is being developed to treat individuals with Stargardt disease and other *ABCA4* related retinopathies.

Methodology: A total of 12 cynomolgus monkeys were treated with a single dose of either formulation buffer as vehicle control or with OCU410ST at doses of 8.61×10^{10}, 1.75×10^{11} or 3.50×10^{11} Vg/eye, respectively via subretinal injection. Parameters evaluated in this study included clinical observations, body weight, food consumption, clinical pathology (hematology, coagulation, and clinical chemistry), immunogenicity (AAV5 binding antibody, RORA protein binding antibody, antigen-specific T-cell immunoreactivity, and cytokines), tissue biodistribution of vector DNA, target gene mRNA and protein expression, virus shedding. In addition, detailed ophthalmic examinations, including general ocular examination, electroretinography (ERG), intraocular pressure (IOP), optical coherence tomography (OCT), fundus fluorescein angiography (FFA), and fundus photography (FP) were performed throughout the study.

Results: The *hRORA* transgene was mainly distributed in ocular tissues. In tissues positive for OCU410ST, the *hRORA* mRNA expression was at highest levels in the Iris-ciliary complex, retina, and retinal pigment epithelium (RPE)-Choroid Complex. The hRORA specific DNA was detected in tears in a dose-dependent manner up to one-week post-dosing. In toxicological assessment, OCU410ST appeared to be well tolerated at all dose levels. There were no unscheduled deaths or notable changes in body weight, food consumption, hematology, coagulation, or clinical chemistry for the duration of the study. No related systemic toxicity and changes in IOP were observed across different dose groups. Pigment deposition, local depigmentation, local fluorescence leakage, and multifocal pigmentation with blocked fluorescence were observed in all groups, including control, and were related to the subretinal injection procedure. No ADA response was observed against the hRORA protein. A dose dependent response was observed against the AAV5 capsid. However, no systemic clinical signs due to an increase in anti-AAV5 antibodies were observed. There was no immunogenic response detected in the PBMCs against hRORA or AAV5 capsid.

Conclusions: Our results demonstrate that OCU410-ST is safe and tolerable at tested doses. Based on these results, 3.50×10^{11} Vg/eye was identified as the maximum tolerable dose for further planned clinical studies.

943 Bilateral sequential injection of KH631 in rhesus monkeys showed good safety profile

Qingwei Li[1], Hao Jiang[1], **Qiang Zheng[2]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotechnology, CHINA
**Corresponding Author*

Purpose: In the real world, neovascular age-related macular degeneration (nAMD) can occur in either one eye or both eyes, with unilateral onset being relatively more common. As time progresses, the other eye also has a risk of developing the disease. Therefore, it is necessary to investigate the safety of repeated drug administration in the contralateral eye.

Method: KH631 Ophthalmic Injection is a replication-deficient recombinant AAV variant, which is contained a gene that encodes for a VEGFR-Fc fusion protein intended to treatment for nAMD via subretinal injection. In our study, on the first day, KH631 was injected into the rhesus monkey right eyes with dose of 2.5E11 vg/eye, 1E12 vg/eye and 5E12 vg/eye. After a 13-week interval, the left eyes were injected again with same dose. The safety and tolerance of the eye and the whole system after sequential re-administration were examined for 52 weeks.

Results: Throughout the 52-week study period, the results demonstrated that under the conditions of this experiment, there were no statistically significant differences ($P>0.05$) in immune-related indicators such as immunoglobulins (IgM, IgG), complements (C3, C4), T cell subsets (CD45+CD3+, D45+CD3+CD4+, CD45+CD3+CD8+), and circulating immune complexes (CIC) when compared with the control group. No obvious abnormalities were found in cytokines such as IFN-γ, TNF-α, IL-2, IL-4, IL-5, IL-6, and IL-10. There were no test article-related abnormal changes were observed in the general condition, body weight, food intake, body temperature, electrocardiogram and blood pressure, neurological function and behavior, hematology, blood biochemistry, routine urine test, bone marrow smear, organ weight/coefficient, and histopathological examination of organ tissues of each system except the eyeball in monkeys of each dose group.

Conclusions: The research results indicate that after repeated administration to the contralateral eye, the systemic safety is good and no new adverse reactions emerge compared with the first administration. This provides strong support for repeating the administration to patients in the real world.

944 KH631 consistently expressed in rhesus monkey eyes over 152 weeks

Hao Jiang[1], QINGWEI LI[2], **Qiang Zheng[3]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotech, Chengdu, China, China, [3]Chengdu Origen Biotechnology, CHINA

Purpose: KH631 is a clinical-stage anti-VEGF gene therapy product designed to treat neovascular age-related macular degeneration (nAMD). In previous studies, KH631 demonstrated favourable efficacy and safety in pharmacodynamic, pharmacokinetic and toxicological studies in non-human primates (NHPs). The purpose of the present study was to investigate the long-term expression stability of KH631, continuous transgene product assays were conducted in rhesus monkeys.

Methods: Rhesus monkeys 1M002, 1F002 and 3F001 received bilateral administration of KH631 at a dosage of 3E10, 1E11 and 5E11vg/eye, respectively. The transgene product of KH631 in the aqueous humour was collected and detected at 53, 104 and 152 weeks. The aqueous humour, with a volume of between 50 and 100µl per eye, was collected from the eye using a 0.3 mL insulin syringe with a 27G needle. The transgene product was detected by a validated ELISA method.

Results: The transgene product of KH631 at 53, 104 and 152 weeks for 1M002 (3E10 vg/eye) was 19.4, 32.2 and 17.7 ng/mL in OS and 22.6, 27.6 and 17.2 ng/mL in OD. For 1F002 (1E11 vg/eye), the concentrations were 53.0, 43.9, and 31.3 ng/mL in OS and 36.1, 45.5, and 24.9 ng/mL in OD. For 3F001 (5E11 vg/eye), the concentrations were 96.3, 119.5 and 62.5 ng/mL in OS and 126.0, 84.9 and 91.8 ng/mL in OD. Longer expression of KH631 is currently under investigation.

Conclusions: The results demonstrated that KH631 was consistently expressed in rhesus monkey eyes for 152 weeks at all three doses, suggesting that a single subretinal injection of KH631 has the potential to offer a one-time treatment for nAMD patients.

945 Evaluating the impacts of pre-existing NAb and ADA in rhesus monkeys on the efficacy of subretinal injection of KH631

Hao Jiang[1], QINGWEI LI[2], **Qiang Zheng[3]***
[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, Sichuan, China, [2]Chengdu Origen Biotech, Chengdu, China, China, [3]Chengdu Origen Biotechnology, CHINA
**Corresponding Author*

Purpose: Currently, AAV represents the most common vector for the delivery of *in vivo* gene therapy. However, the presence of pre-existing anti-AAV neutralising antibodies (NAb) may impede the ability of AAV to transduce target tissues, potentially leading to unfavorable results. Furthermore, the formation of anti-drug antibodies (ADA) will result in the removal of the therapeutic proteins expressed by AAV, which will consequently impact the final therapeutic outcome. The purpose of the present study was to evaluate the impact of pre-existing NAb and ADA on the therapeutic efficacy of subretinal injection of KH631, a clinical-stage anti-VEGF AAV gene therapy product.

Methods: On day 1, a dosage of between 3E9 and 5E11 vg/eye of KH631 was administered subretinally to rhesus monkeys (26 eyes in total). Serum were collected on days 0 and 27 and analysed for the presence of anti-AAV NAb and ADA. On day 28, a laser photocoagulation procedure was conducted to create a model of laser-induced choroidal neovascularisation (CNV). Subsequently, on day 42 and 56, the percentage of grade-4 lesions was then determined by means of fluorescein fundus angiography (FFA).

Results: On day 0, three rhesus monkeys were identified as exhibiting pre-existing anti-AAV NAbs. On day 27, five rhesus monkeys were found to be ADA positive, one day prior to the laser photocoagulation procedure. Nevertheless, 100% suppression of the CNV grade-4 lesion was observed in these rhesus monkeys on day 42 and 56.

Conclusions: As with other gene therapy products administered via subretinal injection, there was no negative effect of pre-existing anti-AAV antibodies on the therapeutic efficacy of KH631. Moreover, the presence of ADA did not impede the efficacy of KH631 as observed in the monkey CNV model.

946 Prevalence of Neutralizing Antibodies Against Adeno-Associated Virus (AAV) 8 and 9 in a Specific Pathogen-Free (SPF) Colony of Cynomolgus Macaques

Marcela Salazar Werner[1], Jenny Greig[2], Surina Boyd[2], Qiuyue Qin[2], Chelsea Wallace[3], Jessica Chichester[2], James Wilson[2]
[1]Franklin BioLabs, West Chester, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Franklin Biolabs, Philadelphia, PA

Systemic administration of recombinant adeno-associated virus (AAV) vectors is the preferred delivery route to achieve broad vector distribution and therapeutic transgene expression in preclinical and clinical settings. However, pre-existing humoral immunity against wild type AAV negatively affects transduction by systemically administered recombinant AAV vectors, severely impacting treatment efficacy and durability. It is well established that there is a strong negative correlation between the levels of pre-existing anti-AAV neutralizing antibodies (NAb) and AAV

gene therapy efficacy. Screening of NAb titers in preclinical animal models prior to vector dosing is therefore paramount to ensure seronegativity and enable a maximal response to the administered therapy. We screened 132 cynomolgus macaques (*Macaca fascicularis*) from the Bioculture Group®'s 100% specific pathogen-free (SPF) colony in Mauritius to determine pre-existing NAb titers against AAV serotypes 8 and 9. Anti-AAV8 and AAV9 NAb responses were analyzed in the sera using a cell-based assay, with serum dilutions ranging from 1:5 to 1:20, according to standard operating procedures. Our results demonstrate that 45% and 56% of the SPF cynomolgus macaques presented with a titer of <1:5 for both AAV8 and AAV9, respectively, and were seronegative. Forty percent of the animals presented with a low seropositivity titer (1:5 - 1:10) against AAV8, and 11% against AAV9. Only 14% of the animals evaluated presented with a seropositivity rate of ≥1:20 against AAV8, and 33% against AAV9. In conclusion, about 50% of the cynomolgus macaques screened were suitable for preclinical studies involving systemically administered AAV8 and AAV9 serotypes.

947 Integrating Raman Spectroscopy and Genome-Scale Modeling to Enhance AAV Upstream Manufacturing

Itsasne Arangoa[1], Ainara Apezteguia[2], Jens Keune[3], Maria Gonzalez[4], Cesar Trigueros[5]
[1]Viralgen Vector Core - San Sebastian, San Sebastian, Guipúzcoa, Spain, [2]Viralgen Vector Core, San Sebastián, Guipúzcoa, Spain, [3]Viralgen Vector Core, San sebastian, Spain, [4]Viralgen Vector Core - San Sebastian, San Sebastian, Spain, [5]Viralgen, San Sebastian, Spain

Viralgen is a Contract Development and Manufacturing Organization (CDMO) focused on the production of adeno-associated viruses (AAVs). We utilize an innovative and standardized manufacturing platform based on Pro10™ cells, which allows the production of diverse AAVs and the capability to scale up to 2000L bioreactors. This platform is structured into two main phases: upstream (USP) and downstream (DSP). Within the final stage of USP, conducted in a bioreactor, two critical processes take place: cell expansion, which ensures a sufficient cell population, and subsequent virus production, initiated by the transfection of the expanded cells.

In both final stages of USP (cell expansion and viral production), cells require precursors (such as amino acids) and energy (ATPs), generated as outputs from metabolic pathways after metabolizing nutrients from the culture medium. Therefore, the cell's performance in generating biomass and subsequently AAVs should correlate with the levels of precursors and energy produced as a result of cellular metabolism.

Although the manufacturing process is based on a standardized platform, the output exhibits variability associated with several factors, including the product itself (which may vary according to client specifications), measurement inaccuracies, and the degrees of freedom of the Critical Process Parameters (CPPs) within pre-established ranges. Among these CPPs are Viable Cell Density (VCD) and metabolites, which are measured off-line every 24 hours. The consumption of metabolites could serve as a basis for estimating the generation of necessary precursors and energy, correlating them to understand the activities related to cell expansion and AAV production.

However, two main barriers exist to achieve this correlation:

1. A mathematical model is required to simulate cellular metabolism and estimate precursor and ATP levels based on consumption ratios. Such models will not only estimate cell productivity but also help identify active subsystems and metabolic bottlenecks, potentially guiding feeding strategies to alleviate these constraints or inefficiencies.

2. The off-line measurements taken every 24 hours lack the necessary frequency to accurately calibrate and simulate a metabolic model.

To address these barriers, Viralgen has implemented Raman spectroscopy in 3L development bioreactors, generating a chemometric model that estimates the concentration of five essential metabolites (glucose, lactate, glutamine, glutamate, and ammonium) every 30 minutes from the acquired spectra. Additionally, a preliminary version of a

genome-scale metabolic model (GEM) has been developed and simulated using consumption ratios quantified by Raman spectroscopy.

Currently, efforts are focused on calibrating the metabolic model to reduce prediction errors. This involves calibrating the model with flow data from four of the five essential metabolites measured by Raman (leaving lactate free) and with online VCD measurements captured by an ABER capacitance probe. The lactate estimation is compared against actual measurements to assess predictive capabilities.

At present, the prediction error for lactate is approximately 40%, indicating excessive degrees of freedom in the model. Future steps will include incorporating transcriptomics to calibrate reactions governed by genomic regulation and continuing to refine the model with new experimental flow data measured by Raman in upcoming experiments.

948 Improving VP1 Ratios Impact on CQAs in rh10 AAV Manufactured Through Sf9 Platform.

Elena Bianchetti[1], Alexandro Berumen[2], Aileen Rottinger[1], Eric Tompkins[3], Ambryice Riggs[4], Noah Miller-Medzon[1], Eric Lin[1], Christina Pelella[1], Marina Goldfeld[1], David Lin[3], Tim Fenn[5]*

Adeno-associated virus (AAV) capsids can support successful gene therapies, but the impact of VP ratios on product CQAs is still poorly understood. We optimized our Sf9-baculovirus manufacturing process for 3 AAV programs and performed analytical characterization. Vector genome titers were obtained by ddPCR, while capsid purity and VP ratios were analyzed by CE-SDS. Moreover, gene of interest (GOI) potency was evaluated at the mRNA or protein level, depending on the program. Our data demonstrates a linear correlation between VP1 content and GOI potency at a protein level from rh10 AAVs produced by a baculovirus process. The increase in VP1 ratios resulted in higher genome titer and potency expression. Comparability experiments suggest that, after manufacturing process optimization, Sf9 AAVs and HEK293T AAVs are not statistically different in terms of genome titer and potency. The optimization of Lexeo's Sf9-baculovirus process demonstrates that knowledge of the relationship between VP ratios impact on CQAs, improving VP1 amount in the capsids, capsid purity and potency. Moreover, the current baculovirus manufacturing platform at Lexeo yields AAVs that display similar purity and potency profiles as the widely available HEK-based platform. In addition, the ease of production level scaling and the favorable cost-of-goods underscores the many advantages baculovirus platform can offer to address the unmet needs for many rare disease indications.

949 msDNATM: A Superior DNA Vector For Improved rAAV Manufacturing

Olga Zaslaver[1]*, Jamie Lam, Siddarth Chandrasekaran[2], Robyn Binsfeld[3], Peyman Mokarami[1], Ming Zhu[1], Roderick Slavcev[4], **Nafiseh Nafissi[5]***
[1]Mediphage Bioceuticals, Toronto, ON, [2]Mediphage Bioceuticals, Inc., Toronto, ON, [3]Queen's University, Kingston, Ontario, [4]University of Waterloo, Waterloo, ON, [5]University of Waterloo/Mediphage Bioceuticals, TORONTO, ON
**Corresponding Author*

Background: Recombinant adeno-associated viruses (rAAV) are essential and important tools for the treatment of genetic disease. However, the manufacturing of rAAV vectors remains challenging, particularly due to the inclusion of unwanted sequences in the packaging process. These contaminants—such as plasmid backbone or RepCap sequences—result in suboptimal potency, increased immune responses, and difficulties in purification. To address these challenges, we propose the use of a next-generation miniDNA vector, ministring DNA (msDNA™), as a superior alternative to conventional plasmid DNA (pDNA). msDNA™ is a linear, covalently closed, double-stranded DNA vector that is devoid of bacterial sequences, such as antibiotic resistance genes and origins of replication, thereby reducing the risk of erroneous packaging.

Methods: rAAV vectors were produced using a triple transfection approach with either isogenic msDNA™ or plasmid-based vectors for rAAV2 and rAAV9 serotypes. Transfections were performed in HEK293 cells, followed by crude collection at day 2, benzonase treatment of cell lysates, and purification by affinity capture and ion exchange chromatography. Viral genome titers (qPCR), capsid protein expression (ELISA), and in vitro potency (GFP expression via flow cytometry) were assessed. A Design of Experiment (DOE) approach was used to optimize transfection parameters, including DNA mass, reagent type, reagent ratio, and vector molar ratios. Crude and purified rAAVs were analyzed using qPCR and next-generation sequencing (NGS) to detect bacterial sequence mispackaging. Purified vectors were evaluated for in vivo bioactivity in mice via RT-PCR and western blotting.

Results: Optimization revealed that msDNA™ required unique transfection conditions for maximum yield. Using JetOptimus as the transfection reagent led to a 5-fold increase in crude viral genome titer for msDNA™-derived rAAV and a 2-fold increase for pDNA-derived vectors compared to Fectovir-AAV. Adjusting the molar ratio of msDNA-RepCap relative to cis and helper vectors further enhanced crude viral genome titers by 2X, an effect not observed with pDNA. In vitro potency of crude msDNA™-derived vectors was comparable to, or better than, crude pDNA-derived vectors, even in cases where viral genome titers were lower. Alignment of Illumina NGS reads to pDNA backbone collected from of purified rAAV2 vector genomes, demonstrated a dramatic reduction (10^4-fold) in bacterial sequence mispackaging for msDNA™-derived rAAVs compared to pDNA-derived vectors. However, qPCR of crude rAAV vectors revealed residual mispackaging of RepCap sequences in both msDNA™ and pDNA-derived vectors. In vivo studies confirmed equivalent or moderately higher potency of msDNA™-derived rAAVs in liver, central nervous system.

Conclusion: msDNA™ represents a significant advancement in rAAV manufacturing, offering a bacterial-sequence-free DNA vector platform that enhances vector purity and potency. By reducing mispackaging of bacterial sequences, msDNA™ improves the quality of rAAV products, reducing the risk of immune activation and enhancing therapeutic potential. Further optimization, such as increasing RepCap size or modifying the p5 promoter, may further minimize RepCap mispackaging and improve final product purity.

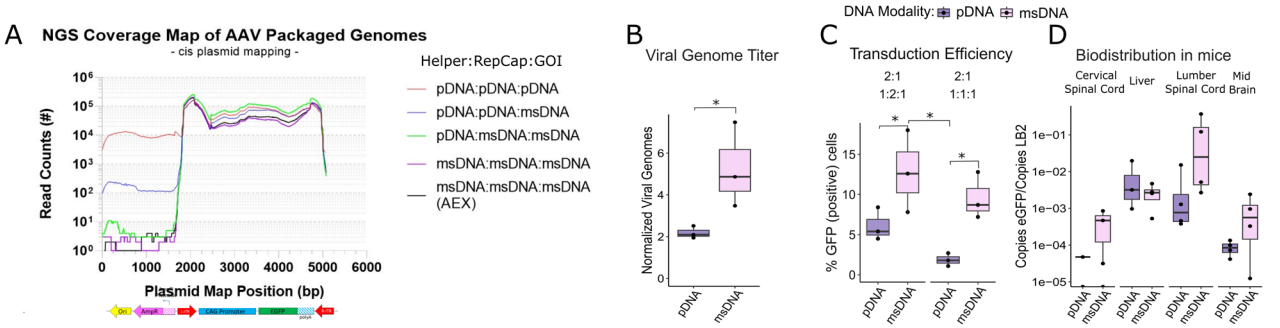

Figure 1: msDNA™-Derived rAAV Vectors Exhibit Negligible Backbone Sequence Packaging and Comparable or Enhanced Bioactivity (A) Illumina read counts aligned to the Cis- Gene of interest plasmid reveal a negligible signal for backbone sequences when msDNA™ vectors progressively replace traditional plasmid (pDNA) vectors in triple transfection. (B) Relative viral genome titer in crude preps of optimized conditions was higher for msDNA-derived rAAV2 vectors. (C) in vitro potency was greater in msDNA™-derived rAAV2 preps. (D) Relative mRNA copy number in liver and CNS tissues of mice treated with msDNA™- or pDNA-derived rAAV2 via intrathecal (IT) injection shows comparable copy numbers in the liver and moderately higher levels in CNS tissue with msDNA-derived AAV2 and AAV9 vectors.

950 Plasmid Engineering and Process Development to Improve Self-Complementary AAV Productivity

Chien-Ting Li[1], Tsai-Yu Chen[2], David Chiu[3], Fernando Lugo[4], Tam Duong[1], Wenling Dong[5], Bingnan Gu[6]
[1]Lonza Houston Inc., Houston, TX, [2]Lonza, Houston, TX, [3]Lonza, Houston, [4]Research & Development, Lonza Houston Inc., Houston, TX, [5]Lonza, Basel, Switzerland, [6]Lonza Houston Inc., Houston, Texas

Self-complementary AAV (scAAV) vectors were developed by mutating one of the ITRs to form double-stranded genome. Unlike traditional single-stranded AAVs (ssAAV), scAAVs can enhance gene expression efficiency by

bypassing the need for second-strand synthesis. Therefore, it has been widely used in clinical and commercial stages. In this study, we first presented design improvements in pHelper and pRepCap plasmids that can increase scAAV titers. We also presented a case study for a client-specific Gene of Interest (GOIs), where we apply our Lonza plasmid system. We further improved the scAAV productivity more than 7 fold at the upstream production stage by significantly decreasing transgene plasmid. In summary, we utilized both plasmid engineering and process development strategy to improve self-complementary AAV productivity with clinically relevant GOI.

951 Investigation of the Variations in Viral Protein 2 Stoichiometric Ratio and Deamidation of Viral Protein 1 and Their Impacts on Transduction Efficiency of Adeno-Associated Virus 8 Vectors

In the upstream process of adeno-associated virus (AAV) vector manufacturing, HEK293 cells, HEK293 cell-derived cells, such as adherent HEK293T cells or suspension HEK293 cells, are employed in the production system via the transient transfection of plasmids. To mitigate the potential risk, HEK293 cells without the T-antigen protein and/or T antigen-encoding nucleotide sequence are preferred for the AAV vector production. However, limited information is available on the variation of quality attributes (QAs), during manufacturing using the HEK293 suspension cell line system, which is suitable for small- to large-scale production using bioreactors.

Although several QAs of AAV vectors that were potential CQAs have been reported, information is limited on the variations in QAs of the AAV vector product under similar production and purification procedures and the corresponding impacts on the transduction efficiency of the produced AAV vector. To better understand these relationships, we manufactured 10 AAV vector products using the HEK293 suspension cell line system under the conditions, with the only differences being the culture volume and container type, and examined 14 QAs, including particle properties, particle size distribution, viral protein properties, impurities, and transduction efficiency.

Obvious variations across products were observed in several QA parameters. We investigated the relationship between QAs with significant variation and the transduction efficiency using the following correlation analysis. To extract the QA parameters that can be used for the correlation analysis, one-way analysis of variance (ANOVA) was used to evaluate significant differences in the mean values of 18 QA parameters obtained from 14 QAs across the 10 products. For the 14 QA parameters that showed a significant difference in mean values, the correlation matrix was used to investigate whether there was a correlation between QA parameters. Correlation analysis of the QAs revealed the attributes that could affect the transduction efficiency. Notably, the VP2 stoichiometric ratio was positively correlated with the transduction efficiency. The deamidation ratios of N57 and N94 in VP1 had a negative tendency to the transduction efficiency. Consistently, the accelerated stability testing showed a negative correlation of the time-dependent increase in the deamidation ratios of the two asparagine residues (N57 and N94) with the transduction efficiency. Our study clearly demonstrated that the VP2 stoichiometric ratio and deamidation ratios of N57 and N94 could be pCQAs of AAV vector products in terms of gene transduction.

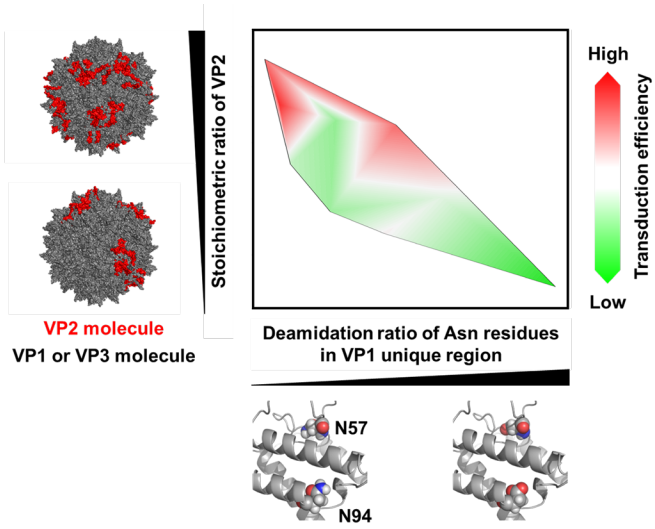

Figure. Schematic representation of the relationship between the stoichiometric ratio of VP2, the deamidation ratio of Asn residues in VP1, and the transduction efficiency.

952 High Productivity HEK293 AAV Production Platform Enabled by Novel Transfection Reagents and Proprietary Plasmid Expression Systems

[1]Tenaya Therapeutics, South San Francisco, CA, [2]South San Francisco, CA, [3]Tenaya Therapeutics, South San Francisco, California

Adeno-associated virus (AAV) continues to be a central modality in vehicles for gene therapy, having a known safety profile, variation in tissue tropism and optionality to dose by local or systemic injections depending on serotype. While many gene therapies have proven to be safe and effective, the primary bottleneck to move the industry to the next phase of maturity is high manufacturing costs. Tenaya conducted studies intended to increase productivity, while preserving safety, purity, and potency of AAV gene therapy drug product. Tenaya HEK293 producer Cell lines utilized in these studies demonstrated comparable productivity to a benchmark commercial cell line and development work with transfection and expression systems combined has notably improved titer up to 6x as well as upstream % full capsid up to 3x controls. These improvements to AAV productivity and quality were achieved through studies testing transfection protocols and reagents, including in-house developed novel transfection complexes, as well as propriety transient expression systems, including triple, dual, and single plasmid formats.

Tenaya demonstrated improvement in productivity with small scale production models which report comparable purity, *in vitro* and *in vivo* protein expression. By using high productivity HEK293 producer cell lines, scaling productivity to stirred tank reactors and *in vivo* data reporting comparable protein expression, Tenaya demonstrated its HEK293 manufacturing process has the potential to support the development of cost-effective AAV gene therapies.

953 A Scalable, DoE-based Approach to Improving Plasmid Ratios for AAV Transfection

Frank Fabian[1], **Mikkal Blick**[2], Hugh Murray[3], Eva Fong[4], Ayan Dey[5], Michael Shen[6]
[1]MilliporeSigma, Carlsbad, CA, [2]MilliporeSigma - Carlsbad, CA, Carlsbad, CA, [3]MilliporeSigma, Vista, CA, [4]Milliporesigma, Burlington, MA, [5]MilliporeSigma - Carlsbad, Carlsbad, CA, [6]Carlsbad, CA

Adeno-associated viruses (AAVs) are a leading modality for gene therapy owing to their safety and broad tropism. As the use of these applicates increase, optimal process development is critical to improve production titers and critical quality attributes. Here, we demonstrate the use of a design of experiment (DoE) approach to investigate the effect of plasmid DNA ratio on capsid and genomic titer using the AAV8 and AAV9 serotypes using an Ambr15 system. For both serotypes, jmp software was used to design a mixture-design experiment to investigate the plasmid ratio used in a triple transfection for AAV production on lysate capsid and genome titer. The results were used to generate a serotype-specific model that uses plasmid ratio to predict titer production. The plasmid ratio that optimizes production was then tested at the bench-scale using the Ambr250 and Mobius 3 L bioreactors.

The DoE analysis led to the generation of predictive models maximizing the desired outcome of increased titer production. A statistical analysis of the actual and predicted log capsid titer returned root mean square error (RMSE) values of 0.2188 and 0.2388 with P values < 0.0001 for AAV8 and AVV9 respectively. Similarly, the genomic titer RSME values for AAV8 and AAV9 with P<0.0001 were 0.4618 and 0.505 respectively. For AAV8, the model-generated pDNA ratio predicts a production of 3.74E+12 capsids/mL and 1.18E+12 genome copies/mL (GC/mL). Similarly, for AAV9, the generated ratio predicts production of 9.30E+11 capsids/mL. and 5.27E+11 GC/mL. When applied to bench scale processes, the plasmid ratios were scalable. Average AAV8 production in the Ambr250 system was 3.74E+12 capsids/mL and 1.18E+12 GC/mL and average production in the 3 L Mobius was 4.35E+12 capsids/mL and 1.38E+12 GC/mL. For AAV9, average production in the Ambr250 was 9.30E+11 capsids/mL and 5.27E+11 GC/mL and average production at the 3 L scale was 1.637E+12 capsids/mL and 5.58E+11 GC/mL.

The DoE approach utilized here resulted in optimal transfection pDNA ratios that maximized AAV8 and AAV9 capsid and genome titer production. The generated models were able to predict the viral production at two different scale bench scale bioreactor systems. Therefore, the systematic use of DoE modeling to assess the pDNA mixture ratio in microbioreactors was able to maximize titer production at larger scale.

954 High-Yield, Pan-Serotype Plasmid System for Manufacturing Adeno-Associated Virus Gene Therapies: Cost and Efficiency Benefits for R&D and Commercial Processes

Paul Freeman[1]*, Michael DiBiasio-white[2], Esther Aribilola[1], Matthew Bennett[1], Patrick Bresnahan[1], Rong Cong[1], Hanna Czeladko[1], Spencer Fielder[1], Ramin Kamran-Sami[1], Graham Lilley[1], Shahrzad Parker[1], Lauren Sargent, Jordan Shufro[1], Matt Edwards[3]*, Robert May[2]

**Corresponding Author*

A major challenge in development of adeno-associated virus (AAV)-based gene therapies is the low manufacturing yield and poor packaging efficiency of AAV capsids. While the enhanced tropism of novel capsids has reduced the total required dose, capsid modifications can have negative effects on manufacturability. Therefore, we design and screen for high yielding capsids during the capsid discovery phase. Even after discovering novel capsids with good manufacturability, a high-yield, capsid-agnostic manufacturing method could drastically decrease the cost and difficulty of screening and production of these capsids and unlock low-yielding capsids, such as AAV2, as viable delivery vehicles.

Affinia therapeutics has developed a plasmid system which led to an increased yield during initial screens for all tested wild-type and novel capsids. Directed optimizations can increase vector genome yield more than 10-fold relative to traditional plasmid systems. Packaging efficiency increases of 4-fold are commonly achieved in poorly packaging serotypes. This system has shown consistent effectiveness across all tested wildtype and novel capsids, all evaluated commercially available helper plasmids and all tested transfection reagents.

These manufacturability enhancements decrease total upstream batch size requirements and increase capacity on the downstream unit operations by minimizing the presence of empty capsids which consume purification yield to remove. In 2024, Affinia Therapeutics implemented this system, achieving transformative results in both capsid discovery and drug development manufacturing. In R&D, the Affinia Therapeutics Vector Core average clonal production titer increased 740% in 2024 when compared to 2023 clonal productions, decreasing average batch size

and increasing production throughput, and thereby significantly reducing cost of goods per unit. For pipeline products with more development focus, even higher yields were achieved; an intensified production process for one of Affinia's lead novel capsid has achieved over 5e15 vg/L at bioreactor harvest which should lead to lower cost of goods manufactured for clinical products.

In summary, this innovative plasmid system addresses critical manufacturing challenges, enabling more efficient production of AAV gene therapies and unlocking the potential of diverse capsid platforms for development, clinical, and commercial use.

955 Overcoming Challenges in AAV Plasmid Preparation: Advanced Solutions for Superior ITR Integrity and High-Yield Production

Andrew Tsao[1], Wenlu Zuo[2], Xiang Zhang[2], Xiangnan Chen[2], Yang Wang[3], Meng Wei[4], Kangming Chen[5]
[1]GenScript USA Inc., Piscataway, NJ, [2]GenScript Biotech Corporation, Nanjing, China, [3]GenScript USA Inc, Piscataway, NJ, [4]GenScript USA Inc., Nanjing, China, [5]GenScript Biotech Corporation, Nanjing

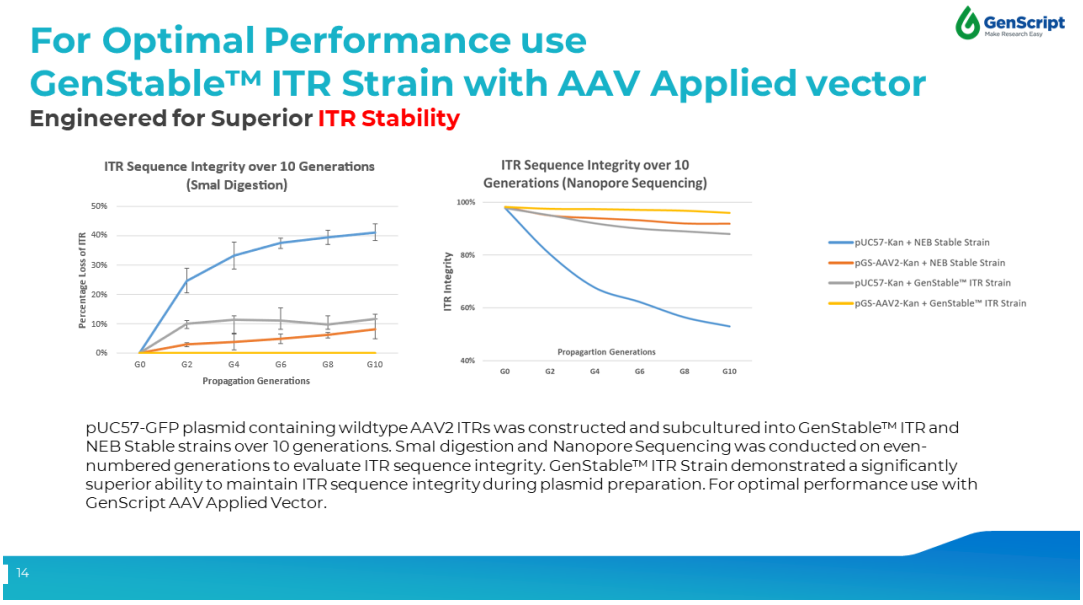
The field of gene and cell therapy, particularly adeno-associated virus (AAV)-based therapies, is revolutionizing the treatment of genetic disorders, cancers, and rare conditions. AAV vectors are highly valued for their ability to deliver genetic material with high specificity and low immunogenicity, making them a cornerstone in therapeutic applications. However, the preparation of high-quality plasmids for AAV production presents unique challenges, particularly in maintaining the integrity of AAV inverted terminal repeat (ITR) sequences due to its repetitive and high GC-content nature.

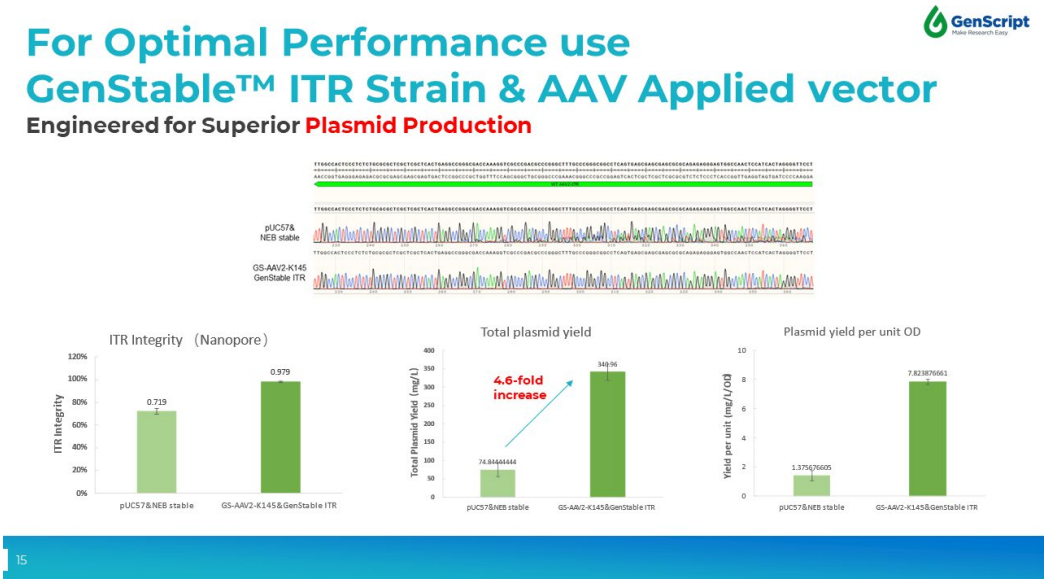
ITRs are essential components of AAV plasmids, playing a critical role in viral genome replication, packaging, and integration. Regulatory agencies such as the U.S. Food and Drug Administration (FDA) and European Medicines Agency (EMA) require verification of intact ITR sequences for clinical applications, as mutations or truncations can compromise vector performance and therapeutic efficacy.

To overcome these challenges, GenScript has developed a comprehensive suite of plasmid solutions specifically designed for AAV plasmid propagation. Our proprietary GenStable™ ITR strain and AAV applied vectors with built-in ITR sequences are engineered to preserve ITR integrity, significantly enhancing sequence stability and plasmid yield. Together, these solutions achieve an impressive >95% success rate in generating ITR intact clones through 10 generations, representing a 100% improvement over conventional tools, while boosting plasmid yields by more than fourfold.

In addition, GenScript offers advanced quality control technologies to ensure precise ITR sequence analysis, addressing the limitations of traditional methods such as standard Sanger sequencing and enzyme digestion, which often fail to accurately evaluate ITR integrity. Our proprietary ITR Sanger sequencing technology provides full reads of the ITR regions with clean and reliable peaks, ensuring comprehensive verification of sequence integrity. Complementing this, ITR Nanopore sequencing delivers detailed insights into sequence purity and population heterogeneity, offering a deeper understanding of plasmid quality.

By integrating cutting-edge plasmid solutions with sequencing technologies, GenScript enables researchers to overcome challenges in AAV plasmid preparation. Our solutions streamline workflows, reduce costs, and facilitate the production of high-quality AAV vectors, accelerating the development of safe and effective gene therapies.





956 Development and Optimization of a Transient Two-Plasmid AAV Manufacturing Platform

Anna Prendeville[1], Omar El-Ghouch[2], Kate Dray[3], Jeffrey McMahan[4], Will Johnson[5], Liliana Wroblewska[1], Ta-Chun Hang[1]
[1]Asimov, Boston, MA, [2]Biotech, Boston, MA, [3]Asimov Inc, Boston, MA, [4]Cambridge, MA, [5]Asimov Inc, Boston

INTRODUCTION: Adeno-associated viral (AAV) vectors are amongst the most widely used viral manufacturing production systems for gene therapies. The current gold standard for transient viral vector manufacturing utilizes a 3-plasmid system. However, this manufacturing process approach has significant limitations, including suboptimal genomic titer and low packaging efficiency. To address these limitations, we combined an optimized refactored 2-plasmid transient process with a proprietary, monoclonal HEK293 cell line possessing properties of minimal aggregation and nutrient consumption. Our 2-plasmid system enables us to conduct design space characterization of

input factors (i.e., plasmid ratio studies) with greater experimental reproducibility compared with the standard 3-plasmid system.

METHODS: The refactored 2-plasmid system consists of the following: the first plasmid contains Rep, Cap, and the gene of interest (GOI). The second plasmid contains the Helper genes along with a genetic booster to improve productivity. We applied a combination of machine learning (ML) and upstream process development approaches to identify optimal transfection and process conditions for 5 different AAV serotypes (AAV2, AAV5, AAV6, AAV8, AAV9) utilizing GFP as the GOI. Bayesian Optimization (BO), Design of Experiments (DOE), and subject matter expert (SME)-driven approaches were assessed in parallel to iteratively evaluate regions of the design space over five experiments (Figure 1, Figure 2A). Experiments were conducted at different scales (e.g., shake flasks, ambr15, and ambr250) to evaluate the impact of transfection conditions (e.g., plasmid ratios, transfection reagent, total DNA) and process conditions (e.g., agitation rates, dissolved oxygen, inoculation densities) on titer (vg/mL) and full capsids (%). After each experimental iteration (Figure 2A), Bayesian Optimization was trained on available data and mapped to a multi-objective acquisition function balancing design space exploration and exploitation.

CONCLUSION: Using our integrated computational and experimental methodology, we identified key levers within the upstream process development area that maximizes key manufacturing metrics of genomic titer (1e+12 vg/mL) and percent full capsid (35%) (Figure 2B). These results demonstrate the utility of BO for PD optimization. Furthermore, we estimate that we were able to reduce experiments by 50% and accelerate timelines to achieve a target spec. We believe our approach can be applied to optimize AAV manufacturing processes and be a tool for SMEs to plan and integrate experimental results. Future work includes using the BO framework to continue optimizing the AAV Edge system performance across an expanded set of GOIs.

Figure 1. Workflow diagram of how BO, DOE, and SME work together.

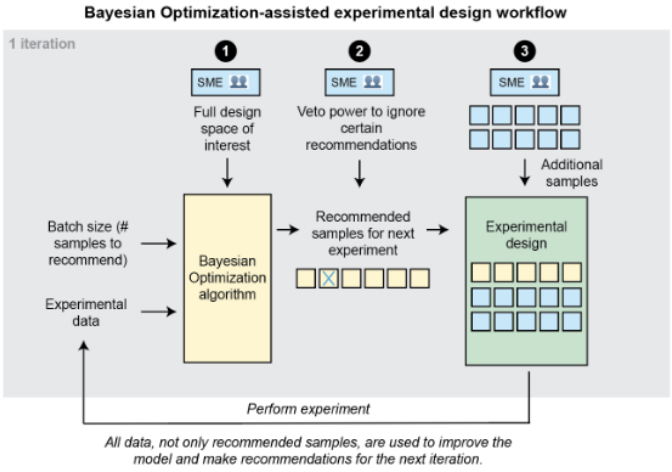


Figure 2. Performance across iterative study designs. Pareto front as a ridge plot visualization of genomic titer demonstrated progressive improvement in identification of design space parameters using BO, DOE, and SME (A). Titer and %full were achieved for all serotypes (B).

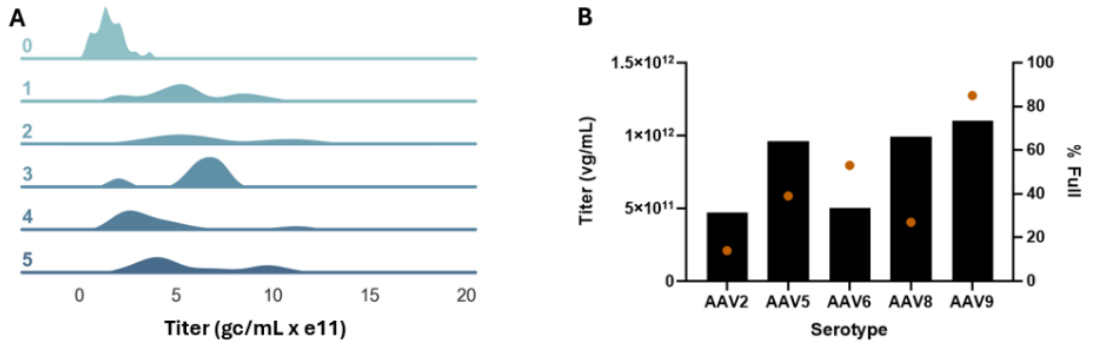

957 Streamlining Recombinant AAV Production: A Single Plasmid Approach for Higher Yields and Reduced Costs

Barbara Martins Fernandes Paes[1], Omar Farnos Villar[2], **Alina Venereo Sanchez[3]**
[1]VVector Bio, Montréal, QC, [2]VVector Bio, Montreal, [3]VVector Bio, Beaconsfield, QC

High manufacturing costs for complex biologics, driven by low product yields, excessive impurities, and scaling issues, currently hinder our ability to meet market demands. To address these challenges, significant resources are being invested into innovative strategies aimed at maximizing yields per cell and enhancing the production of genome-containing capsids. One critical process in manufacturing recombinant adeno-associated virus (rAAV) involves a transfection step that often requires three or four plasmids to be manufactured independently. All these plasmids must enter not only the cell cytoplasm but also the nucleus to enable successful production. Typically, rAAV is produced through a triple transient transfection method, which necessitates the purification of the three plasmids, optimization of their ratios, and complexation of the total plasmid DNA with a transfection reagent. In this context, we demonstrate that combining the adeno helper genes, the AAV replication (rep) and capsid (cap) genes, along with a gene of interest into a single plasmid offers a practical alternative to the conventional triple transfection process and presents a highly advantageous solution to produce rAAV. Around 1E6 cells/mL of HEK293SF-3F6 suspension cells cultured in serum-free conditions, in 20 mL working volume in shake flasks were transfected with various concentrations of plasmid DNA. Triple transient transfection was performed using pAdDeltaF6 helper plasmid, pRepCap6, and pAAV-CAG-GFP (Addgene) at equal molar plasmid ratios. PEI-25K (Polysciences) was used as the transfection reagent at a ratio of 2:1 PEI: DNA. Productions with the conventional triple transfection and the new single transfection methods were assessed at 48 and 70 hours post-transfection (hpt). Clarified crude lysate was used to determine viral genome content (VG/mL) by droplet digital PCR. The functional viral particle quantification (TU/mL) was determined using a cell-based assay where GFP-positive cells are assessed via flow cytometry and the transducing units are calculated. Production of rAAV was carried out using the single plasmid at various DNA concentrations and compared to triple transient transfection. Plasmid DNA concentrations of 1 µg/mL, 0.75 µg/mL, and 0.5 µg/mL were tested with the single plasmid and the control triple transient transfection was performed using 1 µg/mL. A higher viral genome titer was obtained using the single plasmid compared to the control, as well as a higher cell viability at the time of harvest. The single transfection condition using 0.75 µg of plasmid DNA/mL demonstrated an increase of 2 times in viral genome titer compared to triple transfection, for production harvested at 48 hpt and 5 times when harvested at 70 hpt. Also, the production of functional rAAV particles was 2.3 times higher (48 hpt) and 4.6 times higher (70 hpt) using 0.75 µg/mL of the single plasmid than the control triple transfection. We demonstrated significant increases in the viral genome titer of AAV6-GFP and in the functional titer when produced using the single plasmid method. Additionally, we identified a 25% to 50% reduction in the total plasmid DNA required, which also led to a corresponding 25% to 50% decrease in the amount of

transfection reagent needed. Furthermore, since the single plasmid method requires only one purification step, it substantially lowers the cost of transfection, making it more efficient for the successful production of rAAV.

958 Assessment of Novel RepCap Vectors for Improved AAV Titers along with Superior Product Characteristics

Siddhartha Paul[1]*, Ruigong Wang[2], Larry Anderson[3], N'Dea Wheeler[2], Laura Carroll[3], Bhargavi Kondragunta[4]*
[1]Catalent Pharma Solutions, Baltimore, MD, [2]Catalent Cell & Gene Therapy, Baltimore, MD, [3]Catalent Pharma Solutions, Madison, WI, [4]Catalent, Rockville, MD
**Corresponding Author*

Introduction: Recombinant adeno-associated viral vectors (rAAV) are an essential tool in AAV-mediated gene therapy. A continuous challenge in this field is to produce a high-titer, high-potency vector to achieve a better therapeutic effect. Some key aspects of vector production include improved plasmid design, which involves optimizing and configuring AAV genes, promoters, and regulatory elements. The recently discovered membrane-associated accessory protein (MAAP), encoded by an alternative open reading frame within the AAV capsid VP1 protein, has been shown to influence AAV packaging and production. MAAP features an N-terminal basic and hydrophobic region, a central threonine/serine (T/S)-rich domain, and a C-terminal hydrophobic and basic region. This study evaluates over 15 novel RepCap plasmids with single or combinatorial mutations in MAAP within the VP1 ORF protein, termed as RepCapExcel vectors. This evaluation was carried out across four AAV serotypes: AAV5, AAV6, AAV8, and AAVrh10. The goal of this study was to evaluate the impact of the Catalent RepCapExcel vectors on AAV productivity and characteristics.

Methods: The RepCapExcel plasmids were assessed using triple transfection in Catalent's baseline UpTempo^{SM} process in shake-flasks using the Catalent clonal HEK293 suspension cell line, along with Catalent's® Off-the-shelf (OTS) helper plasmid and a model gene-of-interest plasmid (pGalacorin™). AAV particles produced with these RepCapExcel plasmids, were compared to those generated with Catalent OTS RepCap plasmids. Viral genome titer and particle titers were quantified by droplet digital PCR and particle ELISA. A single step affinity purification was completed prior to evaluation of AAV product characteristics.

Results: Several of the novel RepCapExcels demonstrated a 3- to 7-fold increase in AAV vector genome and particle titers across multiple serotypes. Importantly, the several-fold increase in titers was achieved without increasing residual hcDNA (host cell DNA) contaminant or compromising the full capsid percentage. The purity of the viral capsid proteins (VP1, VP2, and VP3) showed consistent ratios (VP1:VP2: VP3) between AAV particles produced with the RepCapExcel plasmids, when compared with the control OTS RepCap plasmids as determined by CE-SDS (Capillary Electrophoresis-SDS). To further ensure product identity, capsid proteins and their post-translational modifications (PTMs) were characterized via intact mass LC-MS (Liquid Chromatography-Mass Spectrometry) and peptide mapping LC-MS analysis respectively. Intact mass analysis confirmed alignment between the observed molecular weights and theoretical predictions for all serotypes, with no significant differences between AAV particles produced with the novel RepCapExcels and OTS control RepCap plasmids. AAV PTMs, including acetylation, deamidation, oxidation, and phosphorylation, were consistent with those obtained using the Catalent OTS RepCap plasmids.

Conclusions: Preliminary findings suggest that novel RepCapExcel vectors are promising candidates for achieving high AAV titers along with superior quality attributes during AAV production for gene therapy applications.

959 One Stone, Two Birds: Engineering Rep-Cap Plasmids to Enhance AAV Manufacturability and Potency

Xiaojun Liu[1]*, Yeonji Kim[2], Chris Brown[1], Jing Zhu[1]
[1]ReciBioPharm, Watertown, MA, [2]Boxborough, MA

Recombinant adeno-associated virus (rAAV) vectors are pivotal in gene therapy due to their proven safety and efficacy for therapeutic gene delivery. However, low production yields and vector heterogeneity remain significant barriers to scalable, high-quality manufacturing. In this study, we introduce a novel strategy to address these challenges through the engineering of Rep-Cap plasmids, a critical component of the triple-plasmid transfection system.

Using rational design and synthetic biology approaches, we optimized Rep-Cap plasmid sequences by incorporating regulatory elements for synchronized gene expression, fine-tuning the VP1/VP2/VP3 protein ratio, optimizing codon usage, and eliminating unstable or recombinogenic regions. Engineered plasmid variants were assessed in proprietary and commercial suspension HEK293 cell platforms across multiple AAV serotypes, including AAV2, AAV6, and AAV8.

Our optimized Rep-Cap plasmids yielded substantial improvements in AAV production and quality. Specifically, vector yields increased by 2- to 10-fold, exceeding 2E15 VG/L, while the ratio of full-to-empty capsids improved by 50%, indicating enhanced vector integrity. Transcriptomic analyses revealed balanced and sustained expression of Rep and Cap proteins, reduced cellular stress, and improved packaging efficiency. Comprehensive characterization, including TEM, AUC, CE, and NGS assays, confirmed the quality of the AAV vectors produced using these plasmids.

Beyond improving production, the engineered Rep-Cap plasmids demonstrated scalability across serotypes in suspension-based systems and retained robust functional performance. In vitro and in vivo functional assays validated the enhanced bioactivity and safety of the resulting vectors, highlighting the translational potential of this approach.

Our findings underscore the dual benefits of engineering Rep-Cap plasmids: enhancing AAV manufacturability and potency. This strategy offers a scalable, versatile solution to current manufacturing challenges, meeting the growing demand for high-quality AAV vectors in clinical and commercial applications.

960 Novel RepCap Vectors with a Mutated Membrane-Associated Accessory Protein for Recombinant AAV Titer Improvement

Ruigong Wang[1], Siddhartha Paul[2], Bhargavi Kondragunta[3]
[1]Catalent Cell & Gene Therapy, Baltimore, MD, [2]Catalent Pharma Solutions, Baltimore, MD, [3]Catalent, Rockville, MD

Introduction: Recombinant adeno-associated viral (rAAV) vectors have emerged as one of the powerful tools in the field of human gene therapy based on their excellent safety profile and ability to achieve long-term efficacy. The single-stranded AAV genome contains genes such as Rep (Replication), Cap (Capsid), and AAP (Assembly), flanked by inverted terminal repeats (ITRs) required for transgene packaging. The Cap gene encodes for the viral capsid proteins (VP1, VP2 and VP3) actively involved in cell binding and internalization. A 119 amino acid viral protein named membrane-associated accessory protein (MAAP) was discovered in 2019 as the expression product of an alternative open reading frame that utilizes an abnormal start codon with Cytosine instead of Adenine in CTG (Cytosine, Thymine Guanine). MAAP functions as an egress factor limiting AAV production through competitive exclusion. In addition, MAAP facilitates AAV replication and has a role in AAV infection. MAAPs were found in all currently reported natural serotypes. The structure of MAAP is highly conserved across different serotypes. This study aimed to investigate the role of the conserved protein MAAP in AAV production and assess the impact of targeted mutations to the protein on recombinant AAV titers.

Methods: AAV vector production involves transient co-transfection of human embryonic kidney (HEK) 293 cells with three plasmids: pHelper, pGOI, and pRepCap. The quality and titer of AAV product can be correlated with improved vector design. To improve AAV titer, we developed novel RepCap plasmids with MAAP substitution mutations termed as RepCapExcels. Changes included 15 unique mutations in serotype specific regions as well as conserved areas across serotypes. Specific changes included stop and start codon substitutions, amino acid

substitutions, and combinations thereof. The MAAP mutated RepCapExcel vectors were evaluated for the production of several AAV serotypes, including AAV5, AAV6, AAV8, and AAVrh10, and it was ensured that, while MAAP was mutated, the VP1 protein amino acids remained unchanged.

Results and Conclusions: Compared to the standard pRepCap with WT-MAAP (wildtype MAAP), most of the mutants tested contributed to an improved titer without significant increase in residual packaged hcDNA (host cell DNA) in all tested serotypes. Particularly, we identified an amino acid mutation variant RepCapExcel 5 and a substitution variant RepCapExcel 2 that played a critical role in MAAP function in all the serotypes tested, with up to 3-7-fold increase in rAAV production. Variant RepCapExcel 5 exhibited the highest vector genome titer increase (for example 7-fold increase for AAV5) as well as the highest AAV particle titer increase, compared to other tested mutants in various serotypes tested. These findings demonstrate a critical role of these RapCapExcel vectors in MAAP functionality and highlight potential for optimizing AAV production.

961 Enhancing AAV Production Efficiency through Plasmid Modification and Dual-Plasmid Systems

Tiffany Pan[1], **Irene Song[2]**
[1]PackGene Biotech INC, Houston, TX, [2]Packgene Biotech, Houston, TX

Adeno-associated virus (AAV) vectors are a cornerstone of gene therapy, offering a safe and effective means to deliver therapeutic genes. However, high production costs and lengthy timelines hinder their widespread application. To address these challenges, PackGene has developed an optimized AAV production platform that significantly improves yield, purity, and cost-efficiency. Key innovations include the engineering of a high-efficiency PCS3.0 suspension cell line, the design of a novel high-yield rep-cap (RC) plasmid, and the development of a dual-plasmid production system.

The novel RC plasmid, incorporating a proprietary non-coding regulatory element, increased AAV yield by 3-8 times across multiple serotypes in both adherent and suspension cultures, while reducing plasmid DNA encapsulation to 0.1-0.2%. Additionally, PackGene's dual-plasmid system, which integrates RC and helper functions into a single plasmid (TP011), demonstrated superior AAV production efficiency compared to traditional triple-plasmid methods. The TP011 system achieved over 3x higher AAV9 titers and reduced residual host cell DNA (HCD) by more than 3x, while maintaining comparable plasmid DNA impurity levels.

Further optimization of transfection reagents and process parameters within PackGene's ℝ?-Alpha 293 High-yield AAV Production Platform ensured consistent and scalable production. Case studies confirmed the dual-plasmid system's ability to produce high-quality AAVs with low empty capsid ratios, making it a cost-effective solution for IND to BLA and commercial manufacturing.

These advancements collectively reduce production timelines and costs, paving the way for broader accessibility to AAV-based gene therapies. PackGene's platform represents a significant leap forward in AAV production technology, enabling the efficient and scalable manufacturing of gene therapies for treating genetic disorders.

962 rAAV Manufacturing Solutions: Strategic Designs of Engineered rAAV Two Plasmid Systems for Cost Effective Scaling and Product Safety

Jenna Rodden[1], Lysa-Anne Volpe[1]*
[1]Capsida Biotherapeutics, Inc., Thousand Oaks, CA
Corresponding Author

Recombinant adeno-associated virus (rAAV) is becoming an increasingly common delivery system for a variety of gene therapy applications. Advances in rAAV engineering have led to the development of novel AAV capsids with significantly improved target tissue tropism, higher transduction efficiency, and lower immune toxicity, enabling safer, more effective gene therapies. More than ever, these newly engineered AAV capsids are being investigated as

vehicles to treat a variety of genetic diseases for which there are currently limited or no treatment options available. As the demand for treatments grows, innovative manufacturing solutions are essential to meet scaling needs, boost production, and reduce costs while maintaining efficacy and safety for patients. Currently, transient transfection of mammalian cells with three plasmids containing rAAV components is the most widely used method for manufacturing rAAV vectors. While effective, the three plasmid system has a high cost of raw materials, is complex to optimize, and may introduce variability between runs, making it less ideal for scalable manufacturing.

We initially developed a proof-of-concept two plasmid rAAV transfection system, which displayed improved productivity and packaging efficiency compared to our three plasmid system. Although the system met evaluation criteria, key AAV components appeared in a wild-type-like configuration (ITR-GOI-ITR-Rep-Cap), thereby increasing the risk of producing replication-competent AAV. To mitigate this risk, we designed, constructed, and evaluated various plasmid configurations that separate these components. Additionally, we isolated specific adenovirus helper open reading frames (ORFs) to reduce plasmid DNA size and enhance transfection efficiency. Leveraging an internally developed, high throughput functional screening method with 24-deep well suspension culture transfection, we evaluated these numerous sequence modifications and plasmid configurations to identify the most effective combinations. We simultaneously evaluated our two plasmid system using a diverse range of transgenes to gain further insights into its characteristics and functionality. Preliminary results from these studies demonstrate that the newly configured two plasmid system sustains productivity while minimizing risks of replication competent rAAV. We aim to take our two plasmid system to the next stage of development, which includes upstream optimization and scaling for production in stir-tank bioreactors using our suspension platform.

963 An Engineering Biology Design Approach to Improving Genome Upload into AAV Capsids

Qiantong(Tina) Chen[1], Robert Whitfield[2], Darren Nesbeth[3]*
[1]University College London, London, London, United Kingdom, [2]Cytiva Europe Limited, Portsmouth, Hampshire, United Kingdom, [3]Cytiva Europe Limited, Portsmouth, Hampshire, United Kingdom, UNITED KINGDOM
**Corresponding Author*

Introduction: AAV capsids are understood to be filled with single-stranded DNA genome payloads via a series of molecular encounters between viral proteins within the host cells. The Rep52 and Rep40 proteins encounter and bind ATP molecules. ATP-bound Rep proteins then encounter and bind payloads. The Rep-ATP-DNA complex must then diffuse and collide with an empty capsid. Once everything is correctly positioned, the Rep proteins hydrolyse ATP molecules to power the mechanical process of threading the DNA into the capsid interior. This intricate dance of molecules finding each other through diffusion and maintaining specific binding interactions ensures that the viral genome is properly packaged. While the cellular environment helps bring these components together in a confined space, and specific binding interfaces ensure correct interactions, the process still fundamentally relies on molecules randomly encountering each other through diffusion until they find their correct partners. We sought to test the hypothesis that engineering the capsid Viral Protein 2 (VP2) with the ability to bind payload directly, without the need for diffusion/collision with or among Rep proteins, could increase the level of capsid filling with payload at the time of viral harvest.

Method: We co-transfected standard AAV production plasmids with a selection of novel plasmids encoding the central repeating domain (CRD) of the Transcription Activator-Like Effector (TALE) at the VP2 N-terminus with flexible linkers of varying lengths in a set of VP2-TALE fusion plasmids. Different numbers of TALE CRD target sequences were also inserted into various positions within the self-complementary payloads to facilitate binding to the TALE CRD at the VP2 N terminus and the payload during the rAAV2 assembly and packaging process. The rAAV2 variants were produced using combinations of VP2 fusion variant and payload variant constructs, supplemented with either wild-type Rep-Cap plasmids or VP2-silenced Rep-Cap plasmids. The variants were evaluated for viral genome titres (qPCR), capsid titres (ELISA), infectious titres (Flow cytometry), and full:empty capsid ratios inferred therefrom. Selected variants were characterised by TEM imaging.

Results and conclusions: We first demonstrated that the presence of TALE targets inserted at three different positions within the payload genome was compatible with infectious viral particle production, with no notable

reduction in titres. We used a novel, 4-plasmid transfection procedure consisting of standard Helper and Rep-Cap plasmids, a novel payload plasmid with three TALE target sequence inserts, and a CMV-driven fusion plasmid, encoding VP2-TALECRD. This novel method resulted in an 18% filling, compared to 5% filling with conventional AAV production, as determined by ELISA and qPCR. Viral particles from this novel method have comparable *in vitro* infectious titres and morphology comparable to particles produced using a conventional method. These observations are consistent with our hypothesis that the presence of VP2-TALECRD fusions within the viral particles are increasing the frequency of genome-capsid collision events per unit time. Future work, outside the scope of this current study, will directly characterise viral particles to confirm VP2-TALE fusion incorporation and CRD:DNA binding in this context.

964 Assessing the Impact of AAV Genome Size on Vector Productivity and Quality: A Comprehensive Analysis using Automated Small Scale AAV Production

Kenneth Thompson[1], Huachao Huang[1], Andrew Sanford[1], Collin Rasmussen[2], Emily Jackson-Holmes[3], Chao Yan Liu[4], Jonathan Zmuda[1]
[1]Thermo Fisher Scientific, Frederick, MD, [2]Thermofisher Scientific, Frederick, MD, [3]Thermo Fisher Scientific, Carlsbad, California, [4]Thermo Fisher Scientific, Waltman, Massachusetts

Recombinant Adeno-associated virus (AAV) has emerged as a leading vector in gene therapy, with several approved therapies and numerous clinical trials underway. Enhancing AAV productivity and product quality are critical for gene therapy advancements, as systemic treatments often require high doses (up to 1E14 vector genomes per kg of patient body weight), and the presence of empty capsids poses manufacturing, regulatory, and clinical challenges.

AAV is a small, non-enveloped, single-stranded DNA virus with a packaging capacity of approximately 4.7 kb. The impact of genome size on the critical quality attributes of recombinant AAV vectors remains unclear, with studies showing conflicting results. Some research suggests that extending the transgene length close to the natural virion packaging capacity improves quality attributes, while other studies indicate reduced productivity and capsid packaging efficiency with full-capacity vectors compared to smaller genomes. As the demand for AAV therapies grows, a deeper understanding of how cargo size affects the production and quality of recombinant AAV vectors is essential.

To address this, we automated AAV production using a liquid handler at a 96-well plate scale, facilitating consistent, high-throughput AAV production. We generated a panel of recombinant AAVs with various genes of interest (GOIs) for five different AAV serotypes, with cargo sizes ranging from 3 to 4.8 kb. Additionally, for one construct, we investigated the inclusion of a stuffer sequence to increase the cargo size to the wild-type virion capacity. These small-scale lysates were purified via automated bead-based purification and analyzed for viral genomes per mL, infectivity, percent full capsids, residual host cell DNA, and residual plasmid DNA.

This study illustrates the impact of genome size on AAV productivity and quality and highlights the potential of incorporating automation into the AAV production workflow. Automation enhances experimental design by improving throughput and reducing variability, enabling efficient data generation for screening at sample volumes sufficient for relevant analytical analyses.

965 Removal of Additional P5 and VA RNA II Elements from AAVone Enhances AAV Productivity, Increases Full Particle Ratio, and Reduces Impurities

Jiantao Zhang[1], Yuyan Wang[2], Yuling Dai[3], Huan Hu[2], zhen shi[4], Lemin Wang[2], Danhui Lu[2], Yu Liu[4], Rongze Yang[1], Daozhan Yu[5]*, Qizhao Wang[6]*
[1]AAVnerGene, Rockville, MD, [2]AAVnerGene Inc., Rockville, MD, [3]AAVnerGene INC., Germantown, MD, [4]AAVnerGene Inc, Rockville, [5]AAVnergene Inc, Rockville, MD, [6]AAVnerGene Inc
**Corresponding Author*

Adeno-associated viruses (AAV) are widely used as gene delivery vectors in clinical applications, with several AAV-based treatments already approved. However, high production costs and impurity-related challenges limit

broader use. Our single-plasmid AAV production system, AAVone, streamlines vector generation by integrating adenoviral helper genes (E2A, E4orf6, and VA RNA), AAV helper genes (Rep and Cap), and the AAV vector genome into a compact 13-kb plasmid, pAAVone. Compared to the traditional triple-plasmid system, AAVone achieves 2–4 times higher yields while reducing plasmid-related impurities. The original pAAVone plasmid (pAAVone1.0) features the following structure: F1 ori-KanR-Ori-(L)ITR-GOI-(R)ITR-VARNA-P5-Cap-Rep-P5-E4orf6-E2A, with an additional P5 promoter located between VA RNA II and Cap PolyA. We found that removing the additional P5 and VA RNA II elements in pAAVone1.0 to generate pAAVone1.1 significantly increased AAV2 productivity by 36–50% in HEK 293T and HEK 293 cells. Additionally, this modification improved the AAV2 full particle ratio (increasing from 28.7% to 34.4%), as determined by mass photometry analysis. Most importantly, pAAVone1.1 significantly reduced VA RNA-related impurities located outside R-ITR compared to pAAVone. Further evaluation of the effects of pAAVone1.1 on AAV productivity, full particle ratios, and impurities with AAV6, AAV8, and AAV9 is ongoing. Taken together, optimizing the AAVone design has the potential to further enhance AAV productivity, improve the full/empty capsid ratio, and reduce plasmid-related impurities. These advancements significantly improve overall vector quality, reinforcing AAVone1.1 as a promising platform for large-scale, GMP-compliant AAV production.

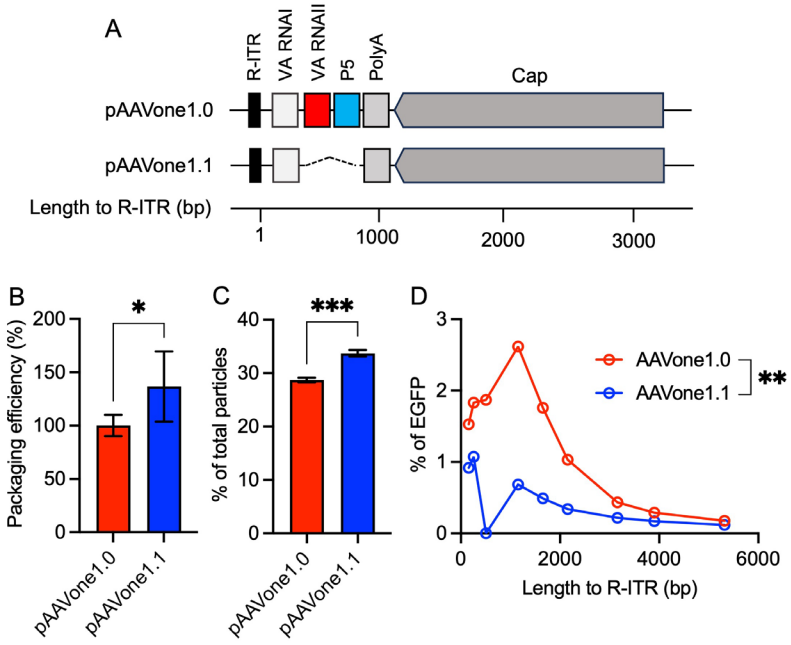

Fig. 1: Removal of the additional P5 and VA RNA II elements from pAAVone1.0 to generate pAAVone1.1 (A) improves AAV packaging efficiency (B), increases the full/empty capsid ratio (C), and reduces VA RNA-related impurities (D).

966 Application of DoE method to improve the rAAV Packaging Titer of Large GOIs

Chunyan He[1]*, Tao Hu[2], Fengpeng Li[2]
[1]Suzhou GenAssist Therapeutics Co., Ltd, Suzhou, Jiangsu, China, [2]Suzhou GenAssist Therapeutics Co., Ltd, suzhou, China
**Corresponding Author*

Recombinant adeno-associated virus (rAAV) has been widely used as an effective vector in gene therapy. However, Due to the limited packaging capacity of rAAV (4.5 kb excluding ITRs), the viral titer drops significantly when the gene of interest (GOI) exceeds this size. Increasing the packaging titer of large GOIs remains a critical challenge in the field.

To improve rAAV packaging titer, we employed a systematic approach using design of experiment (DoE) method to optimize transfection conditions for a therapeutic cytosine base editor (CBE101) with 4.8 kb long. Previously, we conducted single factor experiments to screen suitable cell lines, total mass/proportion, and transfection reagent concentrations. Under optimal conditions, the packaging titer reached to 1E+11 vg/mL. FectoVIR®-AAV, a novel transfection reagent from Polyplus, has been reported to increase transfection efficiency of small GOI AAV vectors. Here, the DoE method was applied to investigate the optimal transfection conditions for CBE101. This DoE study contained two factors and their interaction effects: (1) DNA amount (micrograms per 10^6 cells) ranging from 0.2 to 0.6 µg; and (2) DNA-to-FectoVIR®-AAV ratio (µg:µL) ranging from 0.5 to 1.5. Using response surface methodology, a total of 12 experiments were conducted, including positive controls. The results indicated a significant positive correlation between rAAV titer and DNA amount ($P = 0.031$). Additionally, there was a significant quadratic relationship between the titer and the DNA-to-FectoVIR®-AAV ratio ($P = 0.023$). The highest titer was achieved at a 1:1 ratio, with deviations leading to lower titers. Model predictions suggest a 40% increase in maximum titer compared to single factor optimization, reaching 1.4E+11 vg/mL. Robust testing confirmed these results within the 95% confidence interval, demonstrating a 30%-50% improvement in titer. These findings indicate that the use of FectoVIR®-AAV and DoE method can effectively improve transfection efficiency and rAAV packaging titer for large GOIs, providing valuable insights for future research in this area.

967 Small Scale AAV Bioreactor Optimization Demonstrates Iterative Titer Gains of rAAVrh74 Serotype EPI-321, a CRISPR-mediated Epigenetic Therapy

James Kim[1], Surabhi Godbole[2], Aayushma Gautam[3], Laren Lofchy[3], Yi Ting Lai[2], Dipali Patel[2]
[1]Epic Bio, San Francisco, CA, [2]Epicrispr Biotechnologies, South San Francisco, CA, [3]Epicrispr Biotechnologies, South San Francisco

Although recombinant AAV is a viable option for delivering gene therapies with a high degree of tropism, high cost of goods remains a significant obstacle in the field. At Epicripsr Biotechnologies, we have developed EPI-321, an epigenetic therapy to treat Facioscapulohumeral muscular dystrophy (FSHD), the most common adult muscular dystrophy caused by the misexpression of DUX4 gene in skeletal muscle. It works by encoding an ssDNA sequence of a small transcriptional repressor tethered to a miniaturized Cas molecule and a unique sgRNA sequence within an rAAVrh74 capsid. Our technology can target the hypomethylated D4Z4 locus of DUX4 gene, thereby inhibiting its ability to activate downstream signaling cascades which cause rapid cell death and subsequent muscular wasting. The discovery and engineering of such a medicine is challenging; generating patient-ready rAAV poses further obstacles, including, but not limited to, process flexibility, productivity, and scalability. rAAV production can be triggered through the introduction of essential AAV genes and the gene therapy cassette of interest through a triple transfection system in mammalian HEK293 cells, the most widely executed method today largely due to its process flexibility. However, scalability remains a pain point as HEK293 culture requires thousands of liters to manufacture, thus confounding matters of rAAV titer productivity and reproducibility. To address these reservations, small scale bioreactor production of rAAV offers insight into scaling. Furthermore, increasing productivity from conception is a boon since it tends to drop at each stage of scaling. One way to enhance productivity in the triple transfection system is by selecting the transfection reagent that stably delivers plasmids into host cells; often, commercial versions of a cationic polymer known as polyethylenimine (PEI) are used. For each reagent screened, parameter optimizations including, but not limited to, PEI volume, DNA level (ug/mL), plasmid ratios, PEI to DNA ratios, and transfection complex formation times, are often required. Here, we first screened Reagents A-D at a smaller 125 mL shake-flask scale to identify the best-performing system (Note: Reagent B is our control transfection method). Then, we executed DoE using our top performing Reagent A to evaluate the effects of adjusting the parameters previously described. Furthermore, we evaluated the impact of the addition of a small molecule Enhancer X with both Reagents A and B and after observing comparable results, decided to move forward with Enhancer X alongside Reagent A only. Following our shake flask studies, we scaled the use of Reagents A and B to 2 L and 5 L bioreactors. Next, we screened for the optimal AAV harvest timepoint for Reagent A and assessed that 3-days post transfection with Reagent A works best. With all iterations of testing considered, we conclude that Reagent A mediated transfection with addition of Enhancer X increases titer (vg/mL) by nearly 1 order of magnitude compared to using Reagent B alone. These gains in productivity can lead to significant cost savings when scaled up appropriately. Our current framework provides us with a process to efficiently generate EPI-321 but also leaves room for further growth until full tech transfer to large scale manufacturing is achieved.

968 Scalable Production of an AAV Manufacturing Platform: Transitioning from Adherent to Suspension-Based Triple Transfection

Derek Kichula[1], Eden Fucci[2]
[1]Passage Bio, Newtown, PA, [2]Passage Bio, Pennington, NJ

Adeno-associated virus (AAV) gene therapy holds immense potential for addressing genetic causes of frontotemporal dementia (FTD). Clinical supply of Passage Bio's PBFT02, an AAV1-based gene therapy candidate for treating FTD-GRN and FTD-C9orf72, has been produced to date using a triple transfection adherent process in HEK293 cells. To improve the scalability and efficiency of PBFT02 manufacturing, a high-productivity, suspension-based process has been developed.

This presentation describes the output of development activities that enabled the adaptation of HEK293 cells to a suspension process under serum and animal component-free conditions, and focuses on the optimization of key process parameters to maximize yield; these parameters include cell density at transfection, DNA ratios, transfection reagents, and harvest time.

The suspension process conducted at a 200-liter scale demonstrated a significant increase in vector yield per cell (vg/cell) and more than a 20-fold increase in volumetric productivity (vg/L) relative to the adherent process. Furthermore, key quality attributes were observed to be comparable or improved.

The successful demonstration of this suspension based triple transfection process is a significant milestone in the development of PBFT02, as it enables a commercially viable process that is both robust and efficient. Additionally, this high productivity and adaptable suspension process represents a significant step towards the establishment of a scalable platform for the manufacturing of future AAV products.

969 Capillary Isoelectric Focusing (cIEF) Platform for Characterization of Charge Variants of Adeno-Associated Virus (AAV) Capsids and Impact on Their Transduction Efficiency

Brandon Hoyle, Solid Biosciences, Charlestown, MA

Background: Adeno-associated virus (AAV) vectors comprised of a capsid protein encapsulating a deoxyribonucleic acid (DNA) transgene have been used in the gene therapy field in an effort to treat a range of genetic diseases. Improved methods in the field of gene therapy should be used to deepen understanding of AAVs, particularly regarding charge heterogeneity of capsid species to assess stability from a chemistry, manufacturing, and controls (CMC) perspective. CMC is a crucial aspect of drug development to maintain quality and consistency during manufacturing. Objective: In this study, a versatile approach was used to investigate the charge heterogeneity of a variety of AAV capsid serotypes. Capillary isoelectric focusing (cIEF) coupled with native fluorescence imaging detection were used and underwent exhaustive validation. Methods: Seven different AAV serotypes (AAV1, AAV3, AAV4, AAV5, AAV6, AAV8, and AAV9) from multiple manufacturing platforms were analyzed and demonstrated its platform nature. Vectors contained either enhanced green fluorescent protein (EGFP) or luciferase gene of interest (GOI). The distinctive profiles generated for each AAV serotype served as valuable indicators for both identity confirmation and stability assessment. Results: It was shown that thermal (4 °C, 25 °C, 45 °C, and 100 °C) and oxidative (hydrogen peroxide treatment) stress conditions played a role in increasing acidic charged variants over time, affecting the charge heterogeneity of the tested AAVs. High thermal stress conditions resulted in consistently increasing acidic variants for all AAV serotypes, but total acidic species was serotype specific. Increase in acidic variants for each serotype was statistically significant ($p<0.0001$). Peptide mapping LC-MS was used to qualitatively assess the common post translational modifications (PTMs) following thermal and oxidative stress conditions, which include deamidation, oxidation, phosphorylation, and acetylation. Oxidation was the primary PTM used to quantitatively assess acidic charged variants and effects on in vitro potency using an AAV9 vector. Diminished protein expression levels at high thermal and oxidative stress were statistically significant ($p<0.0001$). Conclusions: The cIEF method developed successfully analyzed a variety of AAV serotypes. Increasing trends of

acidic variants and PTMs (such as oxidation) were associated with a reduced level of in vitro potency. The AAV serotypes showed comparable trends to each other relating to how acidic charge variant totals changed with increased thermal stress at various timepoints. In quantitative evaluations using AAV9, oxidation resulted in an increase of overall acidic variants and both stress conditions demonstrated a correlative trend of decreasing in vitro protein expression levels that were statistically significant ($p<0.0001$). These findings suggest that ensuring AAV manufacturing processes do not inadvertently increase acidic variants during the later stages of purification may be an important factor in generating a more potent AAV final product.

970 AAV9 Process Optimization and Robustness Evaluation in Cloud-native 250mL Bioreactors

Rebecca Du[1], Nicholas Castro[2], Collin Rasmussen[3], Hannah Monroe[1], Sam can Herwaarden[1], Nils Williston[4], Kenneth Thompson[5], **Jean-Marc Guedon[1]**, Kris Tyner[1], Emily Jackson-Holmes[6], Jonathan Zmuda[5]
[1]Culture Biosciences, South San Francisco, CA, [2]Thermofisher Scientific, Frederick, [3]Thermofisher Scientific, Frederick, MD, [4]Frederick, MD, [5]Thermo Fisher Scientific, Frederick, MD, [6]Thermo Fisher Scientific, Carlsbad, California

Gene therapy has significantly advanced the treatment of rare diseases previously deemed incurable. Among the various delivery methods for gene therapy, adeno-associated virus (AAV) vectors are the most utilized due to their safety and efficacy.
While significant strides have been made in the large-scale production of AAV vectors to improve yields and reduce costs, there remain opportunities for further improvement as the demand for AAV therapies increases.

During process development, it is crucial to gain a comprehensive understanding of the process design space. This can be effectively achieved through Design of Experiments (DoE) studies, which systematically investigate the interactions between various process parameters and their impact on desired outcomes. For AAV systems, two key goals are to maximize viral titers and to increase the proportion of fully packaged capsids.

We sought to explore the impact of process parameters on production of AAV9-GFP in a HEK293 suspension-based product system, with the goal of optimizing for viral titers and full capsids. To do this, we leveraged the Gibco™ AAV-MAX Helper-Free AAV Production System and Culture Biosciences' cloud-native proprietary bioreactors. In our initial DoE, we adjusted dissolved oxygen (DO), pH, agitation, and viable cell density (VCD) at the time of transfection while keeping other process parameters constant. Genome titers and percent full analysis of AAV9-GFP particles showed no negative impact on titer across all parameter ranges tested, demonstrating the robustness of the production system. However, statistical analysis suggested that increasing pH and VCD at time of transfection positively influenced AAV9-GFP titers. Consequently, we evaluated pH effects on viral titers and found that higher pH at time of transfection resulted in higher viral genome titer up until around a pH of 7.3. However, we also observed that percent full levels decreased at these higher pH levels, indicating a tradeoff between optimizing production parameters for titer and percent full levels. By employing Design of Experiments (DoEs) methodologies, manufacturers can systematically explore the effects of these critical parameters, leading to higher yields, improved product quality, and more consistent outcomes. This guidance serves as a valuable example for AAV manufacturers aiming to enhance their production strategies and achieve significant improvements in their overall process performance through data-driven optimization.

971 Leveraging High-Throughput Virology and Design of Experiment Expertise for Rapid Transfection Reagent Optimization for AAV/LV Production

GARIMA SINHA[1], Keara Sutherland[2], Nai Brown[3], Sakib Hossain[1], Katelyn Badham[4], Abigail Fernandes[4], Adam Smith[4], Jondavid De Jong[4], Sreejit Menon[5]
[1]Croda Inc., Plainsboro, NJ, [2]Virica Biotech Inc., Ottawa, Ontario, [3]New Castle, DE, [4]Virica Biotech, Ottawa, ON, [5]Croda, Plainsboro, NJ

Background: The Design of Experiments (DoE) methodology is a powerful tool for linearizing testing parameters, significantly enhancing the efficiency of complex workflows. Traditional trial-and-error methods can be time-

consuming and costly, but DoE enables researchers to test multiple variables concurrently, accelerating the experimental process. In our comprehensive study, we used DoE methodology in our high throughput virology experiments to optimize transfection processes. Our objective was to identify and analyze key factors significantly affecting the production of recombinant adeno-associated virus (rAAV/AAV) and lentivirus (LV).

Method and Result: Adhering to DoE methodologies, the key design space was confirmed for the three key drivers of viral production - cell concentration, total DNA, and transfection reagent ratio. This allowed the generated model to be leveraged to specify key factor levels for optimal functional viral production using the cationic polymer polyethyleneimine (PEI). These optimal factor levels were then assessed at a larger scale to validate the optimal functional AAV/LV production. Initially, we adopted a standard set of parameters, widely referenced in existing literature, to establish a baseline for our experiments. This approach enabled us to achieve the anticipated AAV/LV production levels. However, our optimization process revealed that by reducing the amount of DNA while increasing the cell concentration, we obtained yields of functional AAV/LV that were either similar to or exceeded those produced under the standard conditions.

Conclusion: This result challenges long-held assumptions about the amounts of DNA necessary for successful transfection. This finding is especially significant given that DNA is one of the most expensive raw materials in cell and gene therapy. Our DoE studies clearly show that through careful optimization, ideal conditions can be identified that lower DNA consumption and maintain or improve virus production performance. Consequently, these advancements contribute to enhancing the overall efficiency and cost-effectiveness of processes within the field of gene therapy, making treatments more accessible and economically viable to potentially millions of patients.

972 One Size Does NOT Fit All: Impact of AAV Serotype and GOI on Choosing the Optimal Transfection Reagent

James Ludtke[1], Nick Rossi[2], Neha Andhole[2], Yuyuan Wang[3], Oksana Hart[2], Becky Reese[2], Austin Storck[2], Jenni Swanson[4], **Laura Juckem[5]**
[1]Mirus Bio LLC, Madison, Wisconsin, [2]Mirus Bio LLC, Madison, WI, [3]Madison, WI, [4]Waunakee, WI, [5]Mirus Bio, Madison, WI

Adeno-associated virus (AAV) has emerged as a leading platform for gene delivery in the treatment of a variety of human diseases. Transient transfection of suspension 293 cells is the most common method for large scale AAV production. High titer manufacture of AAV is more complicated and unpredictable compared to the delivery of a conventional reporter plasmid DNA construct such as green fluorescent protein (GFP). This is due to the complex regulation of the expressed viral genes, the intricate coordination of AAV capsid protein trafficking, assembly and genome loading, and the variety of therapeutic molecules that are required to treat genetic diseases. Often, GFP is used as a representative gene of interest (GOI) during the manufacture of recombinant AAV. This is due to its ease of detection; the efficiency of transfection can be monitored during AAV production representing one of the plasmids that has been transfected. We have observed that when generating an AAV carrying a GFP genetic payload, high GFP expression was necessary but not sufficient for high titer AAV production.

To investigate the role of the GOI in AAV production, we synthesized a therapeutic GOI encoding retinal pigment epithelium-specific 65 kDa protein (RPE65) and tested it with different capsid serotypes. The transfection reagent is a critical raw material in recombinant AAV production and can have profound effects on the overall titers obtained. When comparing GOIs, such as GFP and RPE65, we found that different transfection reagents can result in > 2-fold different relative AAV production efficiencies using the same experimental parameters. This underscores the need to test different transfection formulations for therapeutic GOIs when maximizing the AAV production conditions. Additional optimization was performed to reduce the amount of plasmid DNA, resulting in equal or higher titers when utilizing 50-75% the amount of input plasmid DNA. Proof-of-principle experiments were done at the 2L scale to demonstrate scalability. Altogether, we demonstrate an enhanced experimental workflow that offers an option to increase AAV titers and reduce pDNA input to generate a lower cost-per-dose AAV therapeutic.

973 Quantifying DNA Point Mutations in Commercial AAV products

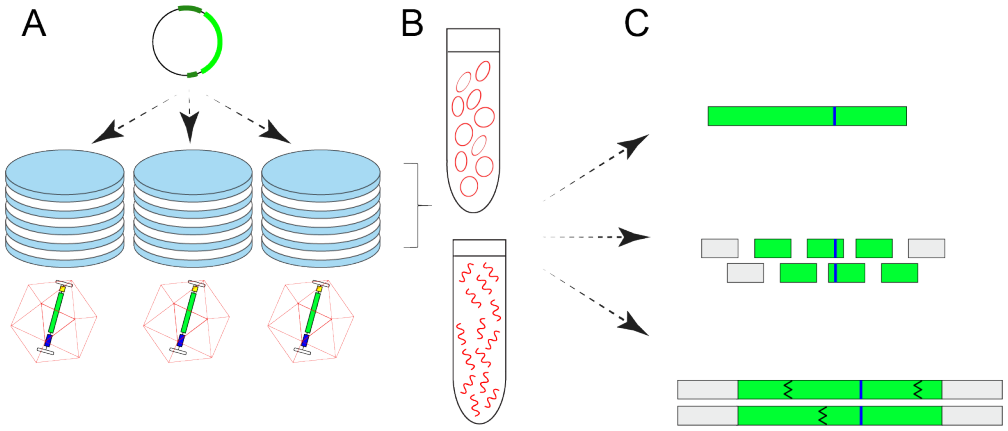
Rebecca Rose[1], **David Nolan[2]**, Jonathan DaRoza[3], Sanford Boye[4], Susanna Lamers
[1]BioInfoExperts, LLC, Thibodaux, LA, [2]Bioinfoexperts LLC, Alachua, FL, [3]Bioinfoexperts LLC, Thibodaux, LA, [4]Powell Gene Therapy Center, University of Florida, Gainesville, FL, Gainesville, Florida

Background: Manufacturing adeno-associated virus (AAV) products may result in a sub-population of capsids with genomes that contain non-target DNA derived from producer cell and/or plasmid DNA, have major genomic rearrangements (e.g., truncations/chimeras), or which harbor single nucleotide point mutations. Although single-point mutations are the most difficult to detect, they can change a codon or binding site, which may reduce transgene expression, resulting in a sub-optimal product. Currently, there is no standardized protocol that identifies point mutations in AAV vector DNA with high accuracy and confidence.

Methods: To compare the accuracy and potential utility of three sequencing methods for quantifying point mutations in AAV products, we sequenced the green fluorescent protein (GFP) transgene from two commercial AAV9 reporter vectors and their respective producer plasmids using single template amplification followed by Sanger sequencing (STA-Sanger), a lower-throughput STA-Sanger method (commonly used in HIV research to study individual viral genomes), as well as two next generation sequencing (NGS) platforms (Illumina and Oxford Nanopore). We purchased three lots of AAV products produced from the same plasmid stock from two different suppliers (Figure 1A), extracted DNA from the AAV virions (Figure 1B), and sequenced the producer plasmid and vector DNA using STA-Sanger and NGS (Figure 1C). After strict filtering, the per-base mutation rates for the GFP gene were calculated for each sample/platform. For the NGS data, the majority variant frequency (MVF) was calculated for each position in the GFP gene.

Results: Significantly more STA-Sanger vector GFP sequences (10.2%) contained ³1 point mutation compared to plasmid GFP sequences (1.3%; $p<0.001$). The average overall vector per-base mutation rate was similar for both STA-Sanger (0.018%) and Illumina (0.013%) GFP sequences, although much higher in Nanopore (2.5%). In addition, the vector per-base mutation rate was higher than the plasmid per-base mutation rate for all platforms. For both NGS platforms, the MVF was strongly correlated among vector lots for Nanopore ($R^2=0.88$) and Illumina ($R^2=0.47$) across GFP positions; although no correlation was found for the same vector lot, or plasmid, between platforms ($R^2<0.05$).

Conclusions: The vector point mutation rate was higher than expected, requiring additional studies to determine the underlying mechanisms. The consistency of the per-base mutation rate between two markedly different sequencing approaches (Illumina and Sanger) was encouraging, as was the strong correlation of positional frequency of variants among different vector lots for each NGS platform. On the other hand, the lack of MVF correlation between the two NGS platforms and the much higher per-base mutation rate for Nanopore, highlight the limitations of NGS applied to AAVs. As the AAV industry is pivoting to genomic sequencing to ensure they manufacture genetically homogeneous and efficacious products at scale, our results demonstrate that systematic studies are needed to validate sequencing approaches before they can be reliably incorporated into cGMP.



974 Leveraging Short- and Long-Read NGS Technologies In-House for Optimal Quality Control in Manufacturing of Gene and Cell Therapies

Ziwei Li[1], Thipa Asvarak[1], David Killen, Marcell Veidner[2], Qiu Ruan[3], Thomas Hartsch[2]
[1]Genedata Inc., Lexington, MA, [2]Genedata AG, Basel, Switzerland, [3]Genedata, Lexington, MA

Biopharmaceutical companies are increasingly adopting next-generation sequencing (NGS)-based assays in the cell and gene (CGT) therapy manufacturing process to assess Critical Quality Attributes (CQAs), such as the integrity and safety of the product. Regulatory agencies, such as the FDA or EMA, can request thorough information from biopharmaceutical companies about the product CQAs during the IND application.

Besides the broad adaptation of short-read technology, long-read sequencing has further advanced the field of NGS by enabling the sequencing of long DNA fragments. Long-read NGS-based assays can be used for CGTs to, for example, detect fusion or truncation events. This ensures product safety and efficacy as well as fully sequenced plasmids and vectors to verify the orientation of gene inserts so that correct and error-free adeno-associated viruses (AAVs) are packaged into capsids.

Here we report on how to automate, validate in-house, and optimally use both short- and long-read sequencing in manufacturing QC assays of CGTs. We show how both techniques complement each other to achieve optimal outcomes. We demonstrate how to simplify and streamline all NGS workflows in-house in a GMP environment, ensuring reliable results, faster turnaround times, and improved ROI. This contributes to safer, more efficient, and more ethical biotherapeutic development.

975 Mapping of common vector genome breakpoints and non-specific DNA fragments in single-stranded and self-complementary AAV vectors by nanopore sequencing

Aaron Hall[1], Jeffery Tan[2], Robert Fusco[1], Joshua Hull[1], Aravind Asokan[3]*

Recombinant adeno-associated viral (rAAV) vectors have become a cornerstone of human gene therapy. A commonly encountered challenge in rAAV preparations is the high degree of vector heterogeneity, not just driven by empty, partial and full particles, but also often characterized by unwanted byproducts such as host genome contaminants and truncated vector genomes. This heterogeneity reduces therapeutic potency and necessitates higher vector doses, which can lead to dose-dependent toxicity and increase the risk of adverse effects. Application of nanopore sequencing to directly interrogate vector genome content and obtain full-length inverted terminal repeat (ITR)-to-ITR resolution of encapsidated genomes has been reported and adapted by several groups. In particular, identification of truncation hotspots in vector genomes similar to SMRT sequencing has been demonstrated. Further bioinformatic pipelines for processing long-read data from AAV directed evolution experiments have also been developed.

Here, we build on these efforts using the Oxford Nanopore Technologies (ONT) MinION platform to enhance the resolution of vector genome profiling. Custom code is implemented to investigate common vector genome breakpoints with the goal of mapping specific nucleotide sequences that are prone to generating truncated vector genomes. We also pair ONT sequencing with Canu sequencing alignment to generate consensus maps de novo. Using an ONT workflow - “What’s in My Pot” (WIMP), we evaluate non-specific packaging of undesirable host DNA content with a particular focus on Adenoviral helper gene and bacterial plasmid fragments within AAV vectors. Together, this workflow introduces rapid and low-cost assessment of AAV vector genomes that can be readily adapted for research validation across GT pipelines and potentially help avoid common pitfalls in AAV vector genome design.

976 Enabling Innovation Through Transition to the FUEL™ Platform: Regulatory Feedback on the Comparability of Ad Helper Plasmid pEMBR™ 1.2 vs. pEMBR™ 2.0

Christopher Shilling[1], Claire Marasco[1], Julianne Bartz[1], Ashley Shay[1]
[1]*Forge Biologics, Grove City, OH*

Forge's FUEL™ platform provides an accelerated foundation for adeno-associated virus (AAV) development and includes innovative technologies to deliver faster, potentially safer, and more efficient AAV manufacturing. As part of the FUEL™ platform, Forge developed the pEMBR™ 2.0 adenovirus (Ad) helper plasmid. pEMBR™ 2.0 is one of the smallest Ad helpers commercially available and has demonstrated an increase in manufacturing efficiency as well as an improved safety profile by reducing the adenoviral components that are unnecessary for AAV production (Adsero et al., 2024). Before the release of pEMBR 2.0™, products manufactured using the Forge platform utilized the predecessor, pEMBR™ 1.2 helper plasmid. For historical clients wanting to adopt the pEMBR™ 2.0 plasmid, Forge developed a risk assessment and comparability strategy to support the change in Ad Helper plasmid and gained regulatory feedback on the approach. Leveraging a Type D meeting with US FDA, Forge submitted a meeting package that presented: 1) proposed AAV critical quality attributes (CQAs), 2) a risk assessment on the impact of the plasmid change to each of the CQAs, and 3) a comparability study outline that evaluates each of the AAV CQAs with a ranking of moderate to high risk of impact from the plasmid change. Importantly, the comparability study plan leverages a surrogate vector (AAV9-GFP) manufactured in Forge's platform process for broad applicability across client programs. This presentation will discuss the details of the submission content as well as FDA feedback received on the approach. Overall, the approach was well-accepted by FDA. Key guidance from the agency included a request for the development of an AAV9-GFP potency assay (abstract submitted to ASGCT by Forge) to support client comparability packages, as well as improvements to the methodology for the selection of the study's sample size and acceptance criteria. FDA accepted the platform study design and the potential to support the change in multiple products. As a result, the innovative FUEL™ Platform has been de-risked and provided a path to be incorporated into existing and historical client manufacturing programs, enabling more efficient manufacturing. Forge is uniquely positioned to support clients through regulatory interactions to gain feedback on new innovative technologies before they reach the production records.

977 Optimizing AAV Production: Accelerating Discovery of Small Molecule Enhancers using High Throughput Virology and Design of Experiments

Keara Sutherland[1], Katelyn Badham[2], Stacia Dolliver[2], Abigail Fernandes[2], **Jondavid De Jong**[2], Andrea Vervoort[2], Oliver Varette[3]
[1]*Virica Biotech Inc., Ottawa, Ontario,* [2]*Virica Biotech, Ottawa, ON,* [3]*Virica Biotech, Ottawa*

Adeno-associated virus (AAV) has become essential in the advancement of cell and gene therapies due to its ability to deliver genetic material safely and efficiently to target cells. However, the production of AAV for gene therapy applications is a complex process where final yields and product quality are often a manufacturing bottleneck. Process optimization is traditionally a time-consuming process, yet necessary to reach robust yields and product quality, and ultimately, commercial viability.

With process optimization playing a large factor in therapeutic success, methods of maximizing yields and quality on expedited timelines are of critical importance. Virica Biotech has developed a panel of proprietary small molecules called Viral Sensitizers (VSE™) which enhance the production yields of viruses by transiently dampening cellular antiviral defenses. These defenses are triggered upon the introduction of foreign particles and nucleic acid into a cell, consequently limiting viral transfection, assembly and replication. We have combined our yield-enhancing VSE technology with our expertise in Design of Experiments (DoE) and high-throughput virology capabilities to achieve rapid process optimization and scale-up validation for increased AAV production.

Our high-throughput, 96-well viral production platform leverages liquid-handling automation and luciferase-based transduction quantification methods to rapidly produce and quantify functional AAV2 yields for process optimization and VSE screening. Coupling this high-throughput approach with DoE statistical modelling methodologies allowed for rapid AAV yield enhancement screening of up to 360 unique conditions. These conditions comprised six novel VSEs at various concentrations in the presence or absence of other transfection kit-associated additives, to understand compound synergy and antagonism while identifying novel small molecule enhancers. The top VSE molecules/combinations from small-scale screening were identified in a single DoE

iteration and then refined in additional iterations to yield up to 3-fold improvement in functional AVV2 titer. This formulation was then successfully scaled up directly to Culture Biosciences 250mL cloud-connected bioreactor, where a consistent enhancement in functional AAV2 titer was achieved.

By combining our proprietary small molecule enhancing technology with high throughput production screening methods and DoE statistical expertise, we identified a robust AAV-enhancing VSE formulation and demonstrated performance at a 250 mL scale. Our novel approach to rapid production optimization has the potential to substantially reduce both timelines and costs for AAV production optimization, addressing a fundamental bottleneck for the cell and gene therapy industry as demands continue to rise.

978 Optimizing AAV Production: Advances in Transfection Agents, Additives, and Clonal Cell Line Development

Giuliana Vallanti[1], **Margherita Neri[2]**, Martina Brunati[3], Luca Crippa[3], Francesca Rossetti[4], Silvia Ungari[5], Angela Testasecca[3], Laura Mosti[3], Francesca Bonfanti[3], Annamaria Cafarella[3], Emanuele Simonetti[3], Veronica Meraviglia[6]
[1]AGC Biologics, Milano, Milano, Italy, [2]AGC Biologics, Milano, Milan Italy, Italy, [3]AGC Biologics, Bresso, Italy, [4]AGC Biologics - Milan, Bresso (Milano), Italy, Italy, [5]AGC Biologics, Bresso, Italia, Italy, [6]AGC Biologics - Milan, Milano, Italy

AGC Biologics is a leading global Contract Development and Manufacturing Organization (CDMO), specializing in the development and production of therapeutic proteins, plasmid DNA, viral vectors, and genetically engineered cells derived from both mammalian and microbial systems. Our expertise on viral vectors originally focused on LVVs and RVVs, has expanded to the production of Adeno-Associated Virus (AAV) vectors via transient transfection in HEK293 cells, utilizing both adherent and suspension cultures for applications in ex vivo and in vivo gene therapies.
AGC Biologics has developed the BravoAAV™ platform, a scalable and adaptable system capable of supporting multiple AAV serotypes. To keep pace with market demands for higher productivity, enhanced purity, and compliance with increasingly stringent regulatory standards, the development of this platform is undergoing continuous optimization. In this study, we present the evaluation of novel transfection agents, specific additives, and optimized packaging plasmid designs, each contributing to improved vector yields. In addition, the continuous optimization of key process parameters—including the amount of DNA used in transfection, cell seeding density, and plasmid ratio—has proven to be a successful strategy for further enhancing overall productivity.
Furthermore, regulatory expectations are progressively shifting toward the use of clonal cell lines for vector production, ensuring greater batch-to-batch consistency and product uniformity. In response to this need, AGC Biologics has developed a proprietary suspension-adapted clonal HEK293 cell line, specifically selected to enhance AAV production. This clonal line has been established in GMP and successfully compared not only to its bulk parental population but also to other cell lines used in AAV manufacturing.
Some of the above mentioned process improvements have been tested at 2L and 50L scales, yielding successful results and demonstrating their readiness for scaling up to higher production volumes (200L-1000L).
This work highlights the advancements we made in AAV production through strategic process optimization and the development of robust cell lines, paving the way for more efficient, reproducible, and scalable manufacturing solutions that AGC can offer for gene therapy applications.

979 Increasing rAAV productivity through selection of a high producing HEK293 transient cell line and addition of an enhancer

Sonal Patel[1], Gregory piscitello, Hiral Gami[2], John Mumira[3], Joe Orlando[4]
[1]MilliporeSigma, Bedford, MA, [2]Bedford, MA, [3]MilliporeSigma, BEDFORD, [4]Milliporesigma, Burlington, MA

Adeno-associated virus (AAV) has emerged as a very popular viral vector for gene therapy due to its low pathogenicity, ability to transduce many cell types, and long-term gene expression. The increase in demand for these vectors to meet dose requirements for clinical trials has created manufacturing challenges. To increase productivity and to reduce cost of production, the industry has shifted to use of suspension based HEK293 cells and 3-plasmid transient production in large scale bioreactors, plasmid engineering, and the use of feeds and enhancers. Here, we

highlight our screening and selection of a high producing HEK293 transient cell line and the use of an enhancer to boost rAAV titers for platform process development.

980 Cell Cycle Modulation as a Strategy to Enhance AAV Production Across Serotypes

Junneng Wen, Johns Hopkins University, Baltimore, MD

Adeno-associated virus (AAV) vector production remains a key bottleneck in the development of gene therapies due to low titers. Here, we examined the relationship between cell cycle status and AAV productivity in suspension HEK293 cells. Further, we identified cell cycle–modulating strategies that substantially enhance vector output. By applying a targeted additive at key points in the production process, we increased AAV titers and specific productivity across multiple serotypes. These findings highlight a biomanufacturing strategy to enhance AAV vector production, providing a scalable and cost-effective solution for both clinical and commercial manufacturing processes.

981 Small samples, big insights: accelerating AAV stability studies with high-quality, low-volume analytics

Astrid Stockinger[1], Bianca Hager[2], Tobias Klötzler[3], Matthias Gora[2], Christine Zach[4], Marie Weidler[2], Stefan Harbich[3], Britta Volland[1], Nicole Spada[3], Alexandra Schoberth[3], **Philipp Beck[5]***, Sonya Schermann[6]

**Corresponding Author*

Adeno-associated virus (AAV) products are at the forefront of gene therapy innovation, yet their inherent complexity poses significant challenges for characterization and regulatory compliance. In response, we have developed an extensive portfolio of in-house analytical capabilities tailored to the needs of gene therapy product developers.

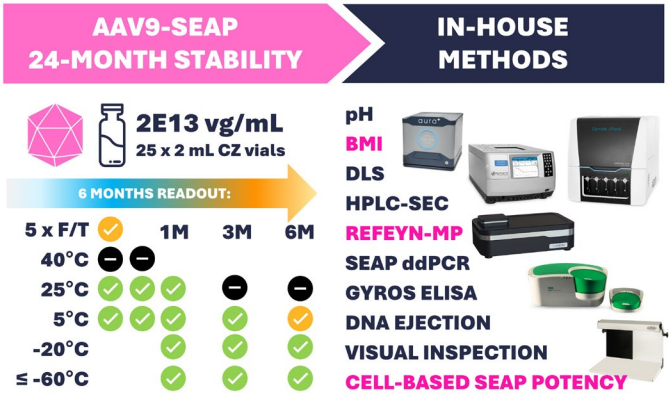
To showcase these capabilities, we conducted a stability study that encompasses a comprehensive set of methods and quality parameters. By employing low-volume techniques such as backgrounded membrane imaging (BMI) and mass photometry, we minimized sample requirements for traditionally resource-intensive assays (e.g., subvisible particles, full-empty characterization). This allowed detailed analysis at earlier time points and extended the study duration to 24 months, using only 25 vials and less than 30 mL of an AAV9-SEAP drug product at 2E13 vg/mL stored in industry-standard 2 mL CZ® vials with a fill volume of 1.1 mL.

At the 6-month interim read out, the study showed that storage at −20°C sufficiently maintains the stability of AAV and that storage and ≤ -60°C is not required. Dynamic light scattering (DLS) results indicated low particle dispersity across all temperature levels, even after six months at room temperature and five freeze-thaw cycles. Visual inspection also demonstrated absence of visible particulates. However, BMI, a high-throughput, low-volume method requiring only 150 µL per measurement, revealed subvisible particle formation particularly after one and five freeze-thaw cycles down to ≤ −60°C. Interestingly, no significant increase in subvisible particles was detected after a single freeze-thaw cycle at −20°C. This finding was confirmed by HPLC-SEC, which detected smaller aggregates, and by increased SYBR-GOLD fluorescence, indicating ejected DNA, after one or repeated freeze-thaw cycles at ≤ −60°C, but not after storage at -20°C.

Despite these observations, no reductions in capsid and genome titers were detected after one or multiple freeze-thaw cycles. Furthermore, our in-house cell-based SEAP reporter gene assay demonstrated that vector efficacy remained unaffected by repeated freeze-thaw stress. Loss of functional transduction during liquid storage was only observed after exposure to stress temperature or after prolonged storage (40°C; 3 months at 25°C, 6 months at 5°C).

Our in-depth analytical expertise enables faster development timelines, a better understanding of the product and

greater confidence in meeting regulatory requirements. We provide AAV developers with the insights and data they need to successfully advance their AAV therapies. Innovative approaches and the provision of cutting-edge analytics ensure that we remain at the forefront of the gene therapy landscape.



982 Characterization of Plant-made AAVs and a Side-by-side Comparison with HEK-derived AAV

Kevin Wong[1], Pranav Mathur[1], Qingqinh Xie[2], Katarina Dumar[3], Finley Burns[3], Matthew Schafer[3], Jake Connors[3], Daniel Gibbs[1]
[1]Cirsium Biosciences, San Diego, CA, [2]Cirsiumbio, San Diego, CA, [3]Cirsium Biosciences, San Diego

Introduction: Gene therapies hold immense promise for treating genetic disorders, however, their widespread adoption is hindered by major manufacturing challenges, high costs, complex production processes, and scalability limitations. Current manufacturing platforms, primarily based on mammalian and insect cell systems, are expensive, slow, and often difficult to scale, contributing to therapy costs that exceed millions of dollars per patient, making these life-saving treatments inaccessible to many. Given the urgency of delivering these therapies efficiently, there is a pressing need for a new, scalable, cost-effective, and reliable manufacturing platform. We have developed an innovative plant-based alternative that reduces costs, shortens production timelines, and ensures consistent vector quality that is crucial for the future of gene therapy. A new platform must integrate seamlessly with existing purification methods while offering flexibility for different vector types and therapeutic applications. By overcoming current limitations, such a system could make gene therapies more accessible, accelerating their potential to transform global healthcare.

Methods: We produced AAV2 and AAV9-CMV-GFP in Nicotiana benthamiana by infiltrating leaves with Agrobacterium carrying the necessary plasmids. After five days, leaves were harvested, homogenized, and purified using tangential flow filtration, affinity capture, and iodixanol gradient purification mirroring HEK293-based methods. Both plant- and HEK-derived AAVs were characterized via qPCR, ELISA, TEM, SDS-PAGE, sterility, endotoxin, and mycoplasma testing. Infectivity was assessed in vitro, ex vivo, and in vivo, and post-translational modifications were analyzed via mass spectrometry.

Results: Agrobacterium carrying recombinant plasmids successfully infiltrated N. benthamiana leaf cells, enabling AAV vector assembly in plants yielding more than 1e14 viral genomes per kilogram of biomass. Using standard AAV purification methods, we obtained comparable recovery rates to mammalian cell-derived AAVs. Quality assessments confirmed ~90% full particles, endotoxin levels well below FDA guidelines, and absence of bacterial, fungal, or mycoplasma contamination similar to HEK293T-derived AAVs. Both Plant and HEK-derived AAVs exhibited proper VP1, VP2, and VP3 ratios on SDS-PAGE, with ~90% full capsids confirmed by TEM and ELISA. We observed better transgene expression and reduced neutralizing antibody profile from plant-produced AAV in Non-human Primates compared to HEK-derived AAVs, despite identical transduction rates. Finally, a thorough post-translational modification analysis showed a very similar profile besides some differences in phosphorylation.

Conclusion: We successfully demonstrated transient AAV production in plants, reducing costs by over tenfold and significantly shortening scale-up time. Since each plant serves as an independent, reproducible production unit, scalability is highly reliable. Additionally, the plant-based platform integrates with existing purification workflows used in AAV production, making it easily adaptable. A head-to-head comparison of the plant produced AAVs with those from the HEK origin showed similar analytical profile, and better activity in the Non-Human Primates, making the plant platform more interesting and worth exploring. We strongly believe this innovation addresses key challenges in the CGT field, offering a cost-effective and scalable solution.

983 Increasing the Susceptibility of Cell Lines to a Broad Range of Adeno-Associated Viral Vectors to Enable in Vitro Potency Assays

Jan Carette[1], James Zengel[2], Emma Esterman[1], Anitha Ponnuswami[3], Andreas Puschnik[1], Nicholas Wall[1]
[1]Stanford University, Stanford, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford, CA

Adeno-associated virus (AAV)-based vectors are promising tools for gene therapy, but robust cell-based assays are needed to quantify their potency in transgene expression for clinical development. However, many clinically relevant AAV serotypes exhibit poor in vitro transduction and often contain cell type-specific promoters that remain inactive in commonly used cell lines. To address these limitations, we employed a multi-faceted approach to enhance *in vitro* AAV transduction by (1) overexpressing the AAV receptor (AAVR/KIAA0319L), (2) preventing transcriptional silencing by the HUSH complex, and (3) using CRISPR activation to drive transgene expression. For the latter, we designed guide RNAs targeting the conserved AAV2 inverted terminal repeat sequence present in most AAV transfer vectors. This strategy led to the development of engineered cell lines with significantly increased transduction efficiency across a wide range of AAV serotypes, including those with cell type-specific promoters. These optimized cell lines enable the robust determination of AAV functional (infectious) titers, and facilitate standardized potency assays across diverse AAV preparations. The enhanced susceptibility of these engineered cell lines to AAV transduction could provide a valuable platform for standardization of *in vitro* quantitative assays in AAV-based gene therapy development.

984 Development of High-performing Stable Producer Cell Lines for Therapeutic AAV Vector Manufacturing

Gang Li[1], Natalie Knowles[2], Chien-Ting Li[1], Fernando Lugo[2], Phi Le[3], Bingnan Gu[4]
[1]Lonza Houston Inc., Houston, TX, [2]Research & Development, Lonza Houston Inc., Houston, TX, [3]Process Development, Lonza Houston Inc., Houston, TX, [4]Lonza Houston Inc., Houston, Texas

Attributed to their safety profiles and transduction efficiencies, recombinant Adeno-associated virus (AAV) vectors are widely used for treatment of human genetic diseases. However, the high cost and low productivity in AAV vector manufacturing process limit the clinical and commercial development of these life-changing therapies for more patients. Recently, we reported the development of high-performing, HEK293 cell based, helper virus-free AAV stable producer cell lines (PCL) that significantly increased the AAV productivity (>1E12 vg/mL at harvest) compared to transient transfection based process. In this new case study, we describe the generation of high-titer stable PCL for AAV vectors using a clinically relevant transgene and an engineered capsid provided by our partner. The beta test results confirmed the robust AAV PCL development process from stable pools to selected single cell clones, which produced significantly higher titers than the transient transfection process. Therefore, our Xcite® AAV stable PCL represents a next-generation technology to enable large-scale AAV manufacturing at markedly reduced cost and complexity.

985 Generation and Characterization of a Novel HEK293 Suspension Cell Line for rAAV Production.

Mélissa Vona[1], Iris Bodenmann[1], Luca Nanni[2], Romain Daveau[1], Pelin Kolcak Yasli[1], Alexandre Felix[1], Marc Antoine Perrenoud[3], Rachel Buchs[3], Steffen Hinz[1], Thierry Schuepbach[4], Igor Fisch[3], **Efrain Guzman**[2], Nicolas Mermod[1]

[1]NewBiologix SA, Epalinges, Switzerland, [2]NewBiologix, Epalinges, Vaud, Switzerland, [3]NewBiologix SA, Epalinges, Vaud, Switzerland, [4]NewBiologix SA, Epalinges, VD, Switzerland

Advanced therapeutic medicinal products (ATMP) have led to an increased focus on biologics produced in mammalian cells. The HEK293 cell line is currently used for the manufacturing of several therapeutic proteins and viral vectors. Several HEK293 derivatives are commercially available for R&D activities and for the GMP-manufacturing of biologics. However, we still have limited knowledge on the genetic composition of these cells and on how to improve their properties.

In this study, we generated a novel HEK293 cell line specifically selected for the efficient transfection of plasmids and for rAAV production. Single-cell clones derived from a polyclonal parental HEK293 cell line were selected based on their high transfection efficiency, growth profile in suspension culture, capacity for efficient single-cell sorting and growth in selected culture media, and ultimately for improved rAAV production efficiency following triple-plasmid transfection. Several clones were characterized both genomically and functionally. A single clone displaying a homogeneous and stable genomic structure was selected and its performance was compared to that of currently available HEK293 cell lines used in pre-clinical and clinical studies. The selected HEK293 clone was fully characterized at the genomic level using PacBio's High-Fidelity long-read sequencing and Bionano's optical genome maping, and at the transcriptomic level using high-throughput Illumina's paired-end short-read sequencing. This analysis revealed fewer genomic rearrangements in the selected clone compared to the parental heterogeneous HEK293 cell line. In addition, the selected clone was genetically stable over 55 generations, making it an ideal choice for long-term and bioreactor cell culture applications.

The novel HEK293 clone produced similar or higher rAAV titers as compared to either the parental polyclonal cell line or currently available leading HEK293 cell lines. This effect was demonstrated using various transgenes or culture volumes, and it was consistently observed over 55 generations of culturing. In addition, the new clonal cell line produced 2-fold higher ratios of DNA-containing vs empty capsids when compared to the materials produced by a leading HEK293 cell line, as well as comparable or higher degree of AAV genome integrity as assessed by high-throughput sequencing.

In conclusion, we have generated and characterized a novel cell line specifically optimized for the production of high quality rAAV gene therapy candidate vectors.

986 Optimization of rAAV Production Using an In-House Suspension HEK293 Cell Line

Chris Brown[1], Yeonji Kim[2], Jing Zhu[1], Xiaojun Liu[1]*
[1]ReciBioPharm, Watertown, MA, [2]Boxborough, MA

Recombinant adeno-associated virus (rAAV) vectors have emerged as a leading platform for gene therapy, necessitating the development of efficient and scalable production methods. One routinely used manufacturing approach for these vectors involves the transient transfection of plasmid DNA into mammalian cell lines such as HEK293. Many HEK293 cell lines are available commercially and have been used to produce rAAV with varying levels of success. These commercial HEK293 cell lines offer advantages such as their adaptability to suspension culture and their availability at GMP-grade, but they are often burdened with challenges such as low productivity, inconsistent quality, and high cost. To address these limitations, we have developed a manufacturing approach using a novel, in-house suspension HEK293 cell line optimized for rAAV production.

Developing this process first involved comprehensive screening of serum-free, chemically defined media formulations to support robust cell growth and high rAAV titers. In addition, transfection conditions were also optimized, including the evaluation of novel transfection reagents and enhancers. To mitigate cell clumping, various anti-clumping strategies and reagents were tested, resulting in a solution that reduced cell aggregation by greater than 75%. Lastly, we were able to increase both vector yield and quality through targeted plasmid engineering. We have also demonstrated the scalability of this cell line and process and have established scaled-up production methods in single-use bioreactors at both the 2L and 10L scales through targeted optimization of key parameters

such as pH, dissolved oxygen, and agitation rate. Through this work, our proprietary HEK293 cell line and optimized process meets or exceeds the bar set by commercially available cell line options, achieving rAAV titers of 1.5E15 genome copies per liter in crude lysate across multiple serotypes. In addition, vector quality was improved, with a proportion of full capsids in crudeupstream lysate greater than 40% in some serotypes. This optimized platform offers a robust, scalable solution for high yield and high quality rAAV production, allowing for reduced costs compared to commercially available HEK293 cell lines and improving the manufacturability of the rAAVs needed as a critical vector for gene therapy.

987 Recombinant Adeno-Associated Virus (rAAV) Production in Spodoptera Frugiperda (Sf9) Cells: Viral Cathepsin Mediated Capsid Cleavage and Mitigation Strategies

Currently, the two most common methods of recombinant adeno-associated virus (rAAV) production are plasmid transfection of human embryonic kidney 293 (HEK293 cells) or infection of Spodoptera frugiperda (Sf9) insect cells with recombinant baculovirus (rBV). Our group focuses on rAAV production in Sf9 cells, and we have used this method to produce naturally occurring and novel rAAV capsids. While many capsids are produced without issue in the Sf9 system (such as AAV2, AAV9, and STAC-BBB), some AAV capsids are prone to additional viral protein (VP) banding observed by SDS-PAGE or Western blotting (such as AAV8 and some novel capsids). Peptide sequencing confirmed that the additional bands are cleavage fragments from the VPs. Viral cathepsin (VCATH*)* is a known cathepsin L-like proteinase expressed by baculovirus as a late viral gene. Galibert et al. demonstrated that some naturally occurring capsids are sensitive to VCATH-mediated VP cleavage during manufacturing in the Sf9 system, and such degradation can be prevented by eliminating or inhibiting VCATH (PMID: 30440025). We tested the addition of a known VCATH proteinase inhibitor (E64) and glycosylation inhibitor (tunicamycin) in Sf9 AAV productions with two affected capsids (capsid A and B).

For capsid A and B, we performed multiple small-scale Sf9 productions with 50µM of E64 (n=7 or 4 respectively) or 10µg/mL of tunicamycin (n=2 or 3 respectively) vs. standard productions (n=10 or 7 respectively). We analyzed the AAV for VP cleavage products, yield, VP ratio, and transgene potency (as an orthogonal measure of capsid integrity). Our results showed that tunicamycin did not eliminate the cleavage products and instead caused additional aberrant capsid protein staining by SDS-PAGE for both capsids. E64 addition successfully reduced or eliminated the VP cleavage products. However, E64 addition negatively impacts AAV yield for capsid A, while capsid B slightly improved (58% and 1.08% of the average absolute yield). Adding E64 improved the VP1 content for both capsids and more closely aligned the VP ratio to the ideal 1:1:10 (1:5:14 to 1:2:11 for capsid A and 1:5:34 to 1:2:14 for capsid B). Finally, we assayed the activity of a zinc finger repressor transgene from productions with E64 or tunicamycin vs. control productions. Adding either inhibitor improved the transgene expression and target repression for both capsids, but most notably for capsid A. For capsid A, average transgene expression improved 4x with tunicamycin vs. 13x with E64, corresponding to 300x vs. 459x repression of the native gene target, respectively. For capsid B, average transgene expression improved 1x with tunicamycin vs. 2x with E64, corresponding to 6x vs. 2x repression. There is no consensus recognition sequence for VCATH, so capsid cleavage cannot be easily predicted before manufacturing or preemptively prevented by capsid engineering. However, our results demonstrate that E64 successfully inhibits VCATH-mediated cleavage of VP proteins with largely beneficial effects on AAV production when VCATH is present in the rBV backbone. Additionally, this work supports the adoption of VCATH null rBV to produce rAAV.

988 Engineering a stable cell line for AAV production through synthetic biology

Virginia Fusco[1], Diego Di Bernardo[2], Giuliano de Carluccio[3]
[1]Tigem, Pozzuoli, Italy, Italy, [2]Telethon Institute of Genetics and Medicine, Naples, Napoli, Italy, [3]MIT, boston, MA

Adeno-Associated virus (AAV) vectors have emerged as highly promising tools for in-vivo gene therapy in clinical applications. However, the large-scale industrial bioproduction of AAV faces challenges in terms of efficiency and scalability, primarily due to its reliance on transient transfection of HEK293 cell lines. Efforts to develop more scalable systems, such as AAV producer cell lines endowed with inducible viral gene expression system to initiate viral vector production "on demand" have been hindered by the toxicity associated with the leaky expression of viral genes. We previously designed the CASwitch, a novel inducible gene expression system with minimal leakiness. It combines the CRISPR-Cas endoribonuclease CasRx with the state-of-the-art Tet-On3G inducible gene system and can act as a switch for gene expression in response to doxycycline administration [https://doi.org/10.1038/s41467-024-47592-y]. Specifically, in the absence of doxycycline, the CasRx cleaves a short sequence (direct repeat - DR) placed in the 3'UTR of the target gene's mRNA thus leading to the loss of its polyA tail and subsequent degradation, thus eliminating leaky gene expression. In the presence of doxycycline, the tet-transcativator fully expresses the target gene while repressing the CasRx, thus enabling the target gene to be maximally expressed.

Here, we developed a stable AAV producer HEK293T cell line by using the CASwitch to regulate the inducible expression of Helper genes (E2A, E4, and VA RNAI) derived from Human Adenovirus 5 (HAdV-5). To this end, we first engineered a minimal Helper gene cassette with a doxycycline inducible promoter driving a minimal Helper gene cassette (pTRE3G-E2A[DBP]-IRES-E4[Orf6]). We then integrated this cassette, together with the VA RNAI and the CASwitch components in the genome of HEK203T cells by PiggyBack and Sleeping Beauty transposases to obtain an AAV producer cell line. Cell viability and growth analyses indicated a higher metabolic burden when the integrated cells were continuously induced with doxycycline compared to both uninduced cells, and to wild type cells grown in doxycyline, suggesting that constant expression of the helper genes for prolonged periods causes a decrease of cell viability.

We then proved the inducer cell line can efficiently be used to produce AAV vectors on demand. To this end, we first expanded cells in a cell stack with medium without doxycycline. Once the desired confluence was reached, only the Transgene and Packaging plasmids were transfected, as opposed to the traditional triple transfection method. We achieved a production efficiency of 80% compared to the triple transfection in the presence of doxycycline.

We demonstrated that integrating the CASwitch control network into a stable HEK293T cell line for AAV production significantly enhances scalability and production efficiency by minimizing the reliance on transient transfection. This stable system offers a more efficient and consistent approach for AAV vectors suitable for clinical applications.

989 Transient vs stable cell lines for AAV manufacturing: a cost modeling approach

EMMANUELLE CAMEAU[1], Federico Saltarin[2], Mischa Schwendy[3]
[1]Cytiva Genomic Medicine, Saint Germain En Laye, Yvelines, France, [2]Cytiva, Fribourg, Fribourg, Switzerland, [3]Cytiva, Frankfurt, Germany

To address the growing demand for industrial-scale adeno-associated vector (AAV) production, we recently launched an innovative solution for stable, helper virus-free AAV production. The ELEVECTA™ producer cell line incorporates all the necessary components for AAV production stably integrated into its genome, enabling high-titer AAV production upon induction with an inducing agent.

Stable cell lines like the ELEVECTA producer cell line hold the potential to reduce the manufacturing costs of AAV-based viral vector therapies. Cost modeling can be a valuable tool in understanding how their use would impact manufacturing costs and, consequently, the cost per dose. Using the BioSolve software from Biopharm Services Limited, we established a cost model for AAV manufacturing with the current ELEVECTA producer cell line.

In this study, we modeled two different processes: a transient process based on our in-house, best-performing data corresponding to average industry standards and a process using the ELEVECTA producer cell line based on the

average process performance achieved thus far. These two processes were compared in terms of manufacturing costs for two different yearly throughputs of viral genomes, based on modeled diseases, including a sensitivity analysis on plasmid DNA cost.

ELEVECTA is a trademark of Global Life Sciences Solutions USA LLC or an affiliate doing business as Cytiva. BioSolve Process is a trademark of Biopharm Services Limited.

990 Generation of a Universal AAV Packaging Cell Line for use in Commercial Gene Therapy Manufacturing

Brian Tomkowicz[1], Margeurite Campbell, Kelly Geosits, Ngan Trinh, Khan Umaer, Srivanya Tummala
[1]SK Pharmteco - US, King of Prussia, PA

The urgency to generate large quantities of high-quality viral vectors while simultaneously reducing costs is critical to support both rare disease indications and broader therapeutic applications. The SKPT-US suite of cell lines includes the validation of a cGMP-ready, clonally derived, universal viral production cell line, SKPT-HEK293-4G9, for plasmid-based transient viral vector production, supporting programs from research to commercial scale. Using a common parental cell, the serum-free, suspension-adapted SKPT-HEK293 cell line, the SKPT-HEK293 AAV packaging cell line has been developed with stable integration of Rep, Capsid, and Ad Helper elements under the control of a doxycycline-inducible promoter system. Transfection with a gene-of-interest (GOI) cis-plasmid enables single-step AAV production upon induction, eliminating the need for inefficient multi-plasmid-based transient transfection. This strategy reduces process complexity, production costs, and batch variability. Here, we present the workflow for generating stable pools and, subsequently, single-cell clones using the Cytena F.Sight platform for cell printing. Our results demonstrate stable expression and comparable production efficiency to transient triple transfection assays. Our off-the-shelf stable AAV capsid product offerings, combined with our robust manufacturing, quality, and regulatory expertise, provide an attractive solution for large-scale commercial manufacturing.

991 Enhanced AAV Vectors for Targeted and Efficient Gene Expression in Brain Microglia

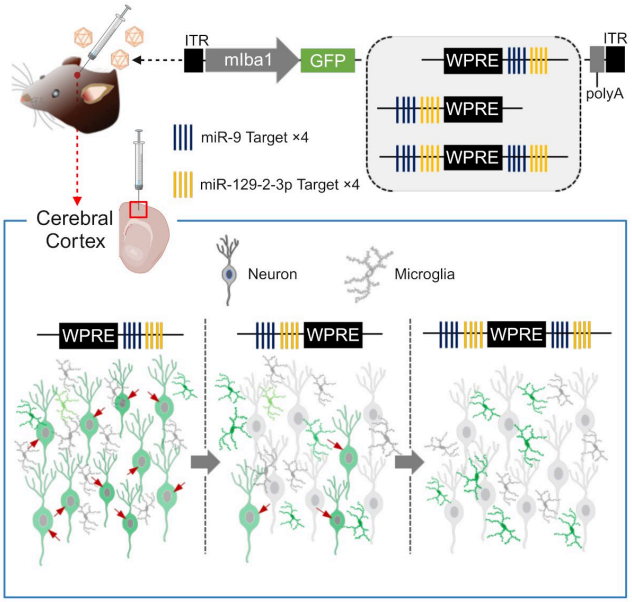
Ryo Aoki[1], Ayumu Konno[2], Nobutake Hosoi, Hayato Kawabata[3], Hirokazu Hirai[4]
[1]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [2]Gunma University, Maebashi, GUNMA, Japan, [3]Gunma University Graduate School of Medicine School of Medicine Faculty of Medicine, JAPAN, [4]Gunma University, Maebashi, Japan

Microglia are immune cells of the central nervous system that originate from yolk sac progenitors during embryonic development. They interact with synapses and axons, monitoring and regulating neuronal function. Upon pathological conditions, microglia become activated, migrating to lesion sites, phagocytosing damaged cells and amyloid-beta (Aβ), and releasing soluble factors. Microglia play a crucial role in the onset and progression of central nervous system disorders such as Alzheimer's disease and multiple sclerosis, making them a promising therapeutic target. However, since microglia function as immune cells that eliminate invading viruses in the brain, efficient gene delivery via viral vectors remains highly challenging.

We previously reported an AAV vector capable of microglia-specific gene expression by combining the microglia-specific mIba1 promoter with microRNA target (miR.T) sequences. While the mIba1 promoter selectively functions in microglia, it also exhibits activity in neurons. To overcome this limitation, we incorporated complementary sequences for miR-9 and miR-129-3p—microRNAs expressed in neurons and astrocytes but absent in microglia—into the vector. In neurons, transcribed mRNA containing complementary sequences binds to endogenous microRNAs and undergoes degradation. In contrast, in microglia, where miR-9 and miR-129-3p are absent, the mRNA remains intact, enabling gene expression. When injected into the brain parenchyma, this AAV vector successfully achieved microglia-specific gene expression in the cerebellum and striatum. However, in the cerebral

cortex, while microglia-specific expression was maintained for up to one week post-injection, neurons exhibited substantial transgene expression by the third week.

In this study, we further optimized microglial targeting by repositioning the miR.T sequences from the 3′ to the 5′ side of WPRE, significantly improving specificity and efficiency in the cortex. Additional enhancement was achieved by placing miR.T sequences on both sides of WPRE, resulting in 90% specificity and 60% efficiency of GFP expression three weeks post-injection. This optimized vector enabled GCaMP expression in cortical microglia, allowing real-time visualization of calcium dynamics and microglial process movement. Furthermore, intravenous administration of an AAV-9P31 capsid mutant led to widespread transgene expression in microglia throughout the brain, although off-target expression in vascular endothelial cells was observed. Our findings demonstrate that this AAV system ensures long-term, specific, and efficient gene expression in cortical microglia, offering new insights into their pathophysiological roles.



992 Identification of common AAV surface residuals responsible for AAV pre-existing antibody recognition

Rui Hao[1], Qingshuo Zhang[2], **Zhongya Wang[3]**
[1]RenoViron Biotechnology, Suzhou, Jiangsu, China, [2]Renoviron (Suzhou) Biotech Co., Limited, Suzhou, Jiangsu, China, [3]RenoViron, Suzhou, Jiangsu, China

AAV has been widely regarded as one of the most promising vectors for in vivo gene therapy. However, 30%–60% of individuals have pre-existing anti-AAV antibodies, which could compromise the therapeutic effect or exclude some patients from AAV treatment. How to solve the pre-existing antibody issues remains one of the biggest challenges for AAV gene therapy.

In our efforts to systemically map all the AAV9 surface functional units, we utilized insertional mutagenesis strategy to disrupt these units and purified the corresponding mutant AAVs. We then injected these mutant AAVs into non-human primates to monitor any functional loss. We also tested these mutant AAVs for their reaction with pre-existing AAV antibodies in a panel of human serums from 48 different individuals. Three key sites on AAV surface showed unique features from these two assays. The corresponding AAV mutants were able to evade the recognition by this panel of AAV pre-existing antibodies. Next, we performed a functional test, in which these selected mutant AAVs and the wild-type AAV9 control virus were incubated with serially diluted human serum, followed by

infection of HEK293 cells. All these mutants, but not wild-type AAV9, were able to infect 293 cells at higher concentration of serums. As a comparison, without human serum incubation, all mutants and wild-type AAV9 could infect 293 cells. To further prove these sites are universal among different AAV serotypes, we mutated similar sites on AAV6. These AAV6 mutants also escaped recognition by this panel of pre-existing antibodies. Similarly, AAV2 variants containing these mutation sites displayed resistance to pre-existing antibodies too.

To further validate these findings and to apply these findings to more AAV variants, we inserted different length of tags from 2 amino acids to 12 amino acids at these sites. All the corresponding mutants display similar resistance to pre-existing antibody binding.

Furthermore, knowing the complex nature of the pre-existing antibody, we tested these mutants in different serums from different backgrounds. In both Asian groups and North American groups, these mutants displayed similar resistance to pre-existing antibody recognition.

These findings will be helpful for understanding the mystery of pre-existing antibody generation, and possibly benefit the patients with a high titer of pre-existing antibody who currently can't receive AAV gene therapy.

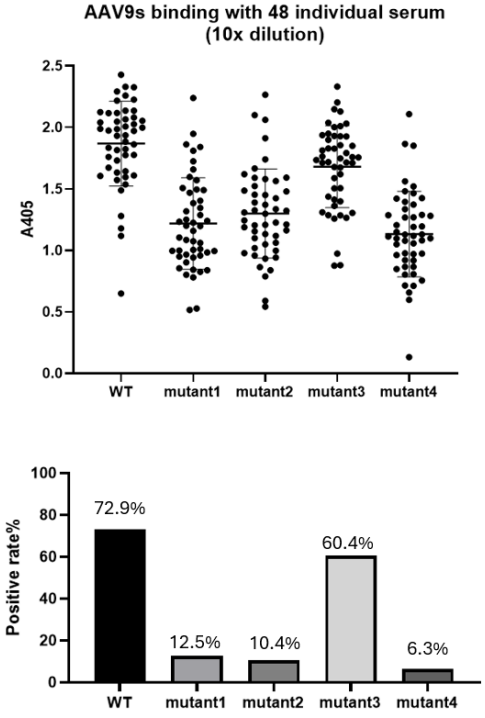


Fig 1 Binding assay of AAV9 and its mutants with individual serum containing pre-existing antibody. AAV9 with mutation in different positions (Mutant 1, mutant 2 and mutant 4) but not AAV9 wild type and other irrelevant mutant (AAV9 and mutant3 can escaping recognition of about 80% pre-existing antibody from 48 individual serums. Interestingly no mutants, can escaping all the pre-existing antibody binding

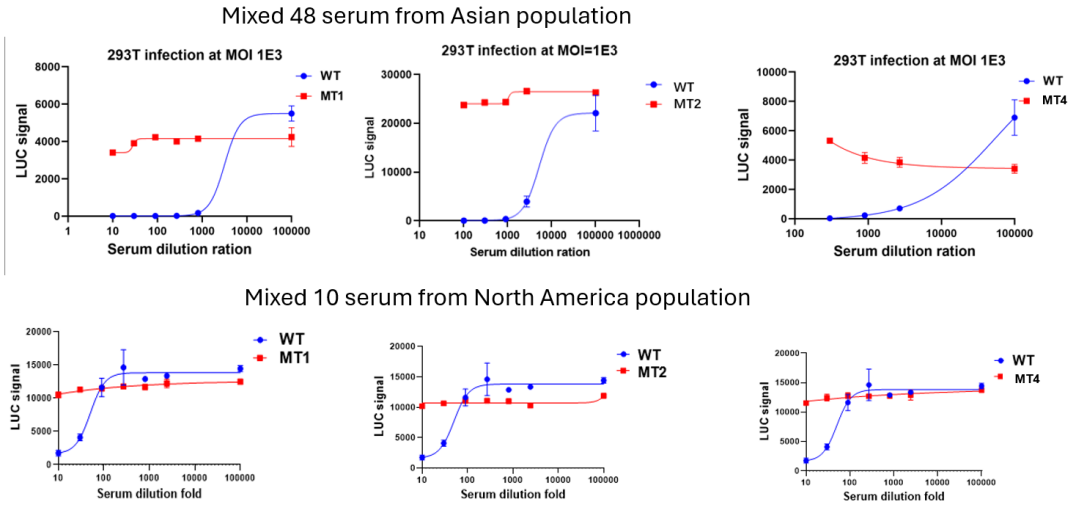

Fig 2 Function test: AAV infect 293 cells with incubation of serial diluted mixed human serums from different populations. AAV9 and three mutants were incubated with serial diluted mixed serums from 48 individuals from Asia and 10 individuals from North America, containing pre-existing AAV antibody. WT: wild type AAV9, MT1, MT2, MT4, three AAV mutants containing disrupted AAV pre-existing antibody recognition sites.

993 Evaluation of Multiple Immunoassay Formats for the Detection of AAV Capsid Specific Antibodies

Ashley Morando[1], Theresa Seitel[1], Josh Holter[2], Brian Long[1], An Song[1], Christian Vettermann[1]
[1]4D Molecular Therapeutics (4DMT), Emeryville, CA, [2]Iris Medicine, Richmond, CA

Background: AAV capsid-specific antibodies may impact clinical efficacy and safety of gene therapies and thus need to be monitored in clinical trials. Monitoring includes both pre-existing antibodies that arose from previous exposure to natural AAVs in the environment and post-treatment immune responses following AAV gene therapy administration.

Methods: We compared several different clinical assay formats to detect capsid antibodies against a proprietary AAV capsid, including an electro-chemiluminescent (ECL) sandwich assay, a colorimetric bridging ELISA, and ECL bridging formats with either sequential or simultaneous addition of capture and detection reagents. Assays were characterized for sensitivity, precision, and other performance parameters, allowing for a comprehensive comparison.

Results: The sandwich ECL assay was the least sensitive of all evaluable methods, as judged by the limits of detection (LOD) for the surrogate positive control (SPC) antibodies across assay formats. Limited sensitivity was largely attributable to increased background signals in negative human serum, likely due to binding of anti-human kappa/lambda detection antibodies to non-specifically captured total human IgG. In sharp contrast, bridging ECL and ELISA methods had much lower background signals, resulting in the ability to detect positive control anti-AAV antibody concentrations below 100 ng/mL, the recommended minimal sensitivity limit per health agency guidance. Furthermore, bridging formats were more advantageous from a practical point of view, since this format does not rely on species-specific antibody detection, allowing for use of a single detector with both clinical samples and non-human positive-controls to monitor performance of the assay over time. Intra- and inter-assay precision of all assay formats was largely comparable.

Conclusion. Bridging immunoassays utilizing either electro-chemiluminescent or colorimetric technology can allow for highly sensitive detection of AAV-specific antibodies, while sandwich immunoassays may be more restricted in achieving sensitivity of sub-100 ng/mL. The ultimate utility of each assay format to detect pre-existing AAV antibodies that may be relevant for gene therapy eligibility needs to be established in clinical trials.

994 Structural Characterization of Antibody Interactions from Infants with AAV2-associated Hepatitis to Guide Rational Capsid Redesign

Mario Mietzsch[1], Jon Zachary[1], Mark Potter[1], Neeta Khandekar[2], Ann-Maree Huang[3], Paul Chipman[4], Juha Huiskonen[5], Ian Alexander[6], Grant Logan[7], Robert McKenna[1]
[1]University of Florida, Gainesville, FL, [2]Children's Medical Research Institute, AUSTRALIA, [3]University of Sydney, Westmead, Australia, [4]University of Florida, [5]University of Helsinki, Helsinki, Uusimaa, Finland, [6]Sydney Children's Hospitals Network, Westmead, NSW, Australia, [7]Children's Medical Research Institute, Westmead, Australia

Pre-existing neutralizing antibodies (NAbs) against the capsids of adeno-associated virus (AAV) vectors pose a significant challenge for AAV-mediated gene therapy, resulting in patients being excluded from receiving these therapeutics. These antibodies originate from prior exposure to naturally circulating AAVs. Recently, a global outbreak of acute pediatric hepatitis concomitant with an AAV2 infection has been reported. For this study, infants who presented with an AAV2-associated hepatitis at the Children's Hospital at Westmead, Australia showed high anti-AAV2 IgG endpoint titers. Subsequently, monoclonal antibodies (mAbs) were reconstituted from these patients enabling the characterization of the natural antibody response towards the AAV capsids.

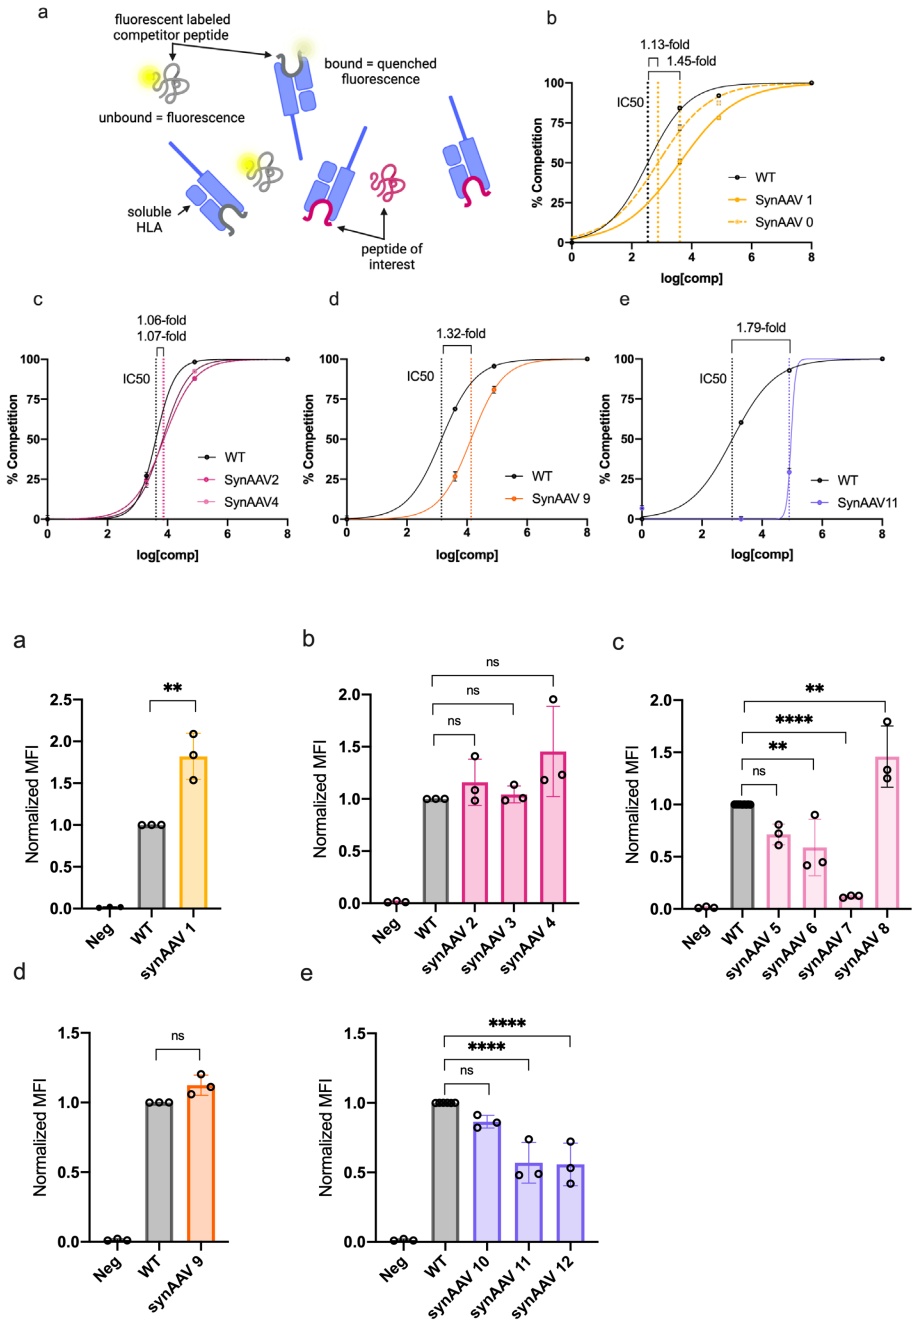
Reported here, are six human derived anti-AAV2 mAbs, that have been confirmed by dot blots to recognize the AAV2 capsid. Additionally, cross-reactivity studies showed that three of the mAbs recognized AAV3 and one recognized several AAV serotypes. For further insights, the binding sites of the fragment antigen binding (Fab) regions of the anti-AAV2 mAbs were determined to the AAV2 capsid using cryo-electron microscopy. To date, two AAV2-Fab complex structures have been reconstructed from 83,248 and 262,343 particles to ~2.2 Å resolution and showed different binding modes. While one of the antibodies bound to the capsid two-fold depression, the other bound at the side of the 3-fold protrusion and 2/5-fold wall towards the 5-fold canyon. Due to its binding position, the 2-fold binding antibody does not conform to the icosahedral symmetry of the capsid and required localized reconstruction to resolve the specific interactions to the capsid. The contact information of these Fabs is being used to guide site-directed mutagenesis efforts to develop a novel AAV2 capsid capable of escaping these pre-existing Nabs, potentially expanding the patient pool eligible to receive AAV2 biologics such as Upstaza®. Furthermore, regions occluded by the Fab provide insights into the mechanism by which these NAbs inhibit transduction.

995 Redesigning Immunogenic AAV Epitopes to Prevent Cell Surface Display by Human Leucocyte Antigens

Ranim Maaieh[1], Michael Garton[1]
[1]University of Toronto, Toronto, ON

AAV's have proven to be feasible and effective gene delivery vehicles, as evidenced by their approval for treating various diseases, such as Leber congenital amaurosis (retinal dystrophy), spinal muscular atrophy, and Hemophilia B. Nevertheless, the field faces a significant challenge in addressing capsid immunogenicity, given that approximately 90% of the adult population has prior exposure to wild-type AAVs. This prior exposure leads to cytotoxic T-lymphocyte (CTL) destruction of transduced cells by memory CTLs, as seen in several clinical trials. To tackle this issue, we aimed to engineer the AAV capsid to evade recognition by memory CTLs by introducing point mutations to decrease binding affinity and presentation of immunogenic epitopes on MHC I. Leveraging previously published mutagenesis data and rational protein design techniques, we identified and tested potential mutations within the AAV capsid for decreased HLA presentation of immunogenic epitopes. Mutant AAV vectors were synthesized in HEK293T cells and tested for capsid assembly and transduction efficiency. Furthermore, mutations at MHC I anchor residues within each peptide were tested for change in molecular binding affinity and CTL recognition using human PBMC samples through ELISpot assays. Mutations exhibiting a similar transduction

efficiency to wild-type AAV and decreased MHC I binding affinity were identified for several immunogenic epitopes. These findings demonstrate a proof of concept for addressing CTL responses towards AAVs in the context of gene therapy.



996 The Seropositivity Dilemma for AAV Gene Therapy

Barbara Sullivan[1], Serap Sankoh[2], Tim Chiu[2], Derek Kennedy[2], Lorraine Sullivan[3], Mitra Azadeh[4], Jack Allen[2], J Lawrence Merritt[2], Jason Cataldo[5], Richard Collis[2], Andrew Grimm[2]
[1]Ultragenyx, Novato, California, [2]Ultragenyx Pharmaceutical Inc., Novato, CA, [3]Novato, CA, [4]Ultragenyx, Novato, CA, [5]Ultragenyx Gene Therapy, Novato, California

Anti-capsid antibodies inhibit transduction and effectiveness of AAV gene therapy, creating a major hurdle in the transformative potential of these therapies, as antibody-positive individuals are often excluded from AAV GT programs. Parameters that may impact transduction include antibody titer, serotype, dose, route of administration, and percentage of full capsids. Each sponsor must create an assay, define the specifications, and test against the individual product for efficacy. In addition, the anti-capsid antibody assays are generally not publicly available for people with these conditions, creating challenges for families to understand and compare between treatment options. Altogether, this has resulted in a real "seropositivity dilemma".

To explore the impact of seropositivity further, we characterized the total binding antibody titers in individuals with Ornithine Transcarbamylase Deficiency (OTC), Glycogen Storage Disease type Ia (GSDIa) and Wilson Disease (WD), as these are the populations that are under investigation for DTX301, DTX401 and UX701 AAV gene therapies, respectively. We also performed an AAV gene therapy study in cynomolgus macaques that were all neutralizing antibody negative, but some animals were total antibody positive.

Six of 31 (19.4%) evaluable individuals with GSDIa had detectable anti-AAV8 titers, with levels ranging from 1:47 to 1:6275. Eight of 17 (47.1%) evaluable individuals with WD had detectable anti-AAV9 titers, with levels ranging from 1:36 to 1:4854. The one individual with OTC did not have detectable anti-AAV8 titers.

A cynomolgus macaque intravenous AAV gene therapy study was conducted to determine the impact of dosing total antibody (TAb)-positive (+) or TAb-negative animals at two doses (1e13 Vector Genome (VG)/kg and 7e13 VG/kg). Animals were pre-screened and neutralizing antibody (NAb)-negative prior to study entry. In the 1e13 VG/kg group, four animals were TAb seronegative, and two had titers of 1:200. In the 7e13 VG/kg group, three animals were TAb seronegative, and three had titers of 1:100, 1:1600, and 1:12,800. Following AAV GT administration, no clinical observations were noted, and there was no apparent change in platelets eight days after dosing. Whole blood vector genome levels were lower in the TAb+ group compared with the TAb-negative group at the 1e13 VG/kg dose; there was no difference in the 7e13 VG/kg dose TAb groups. All animals had detectable VG DNA and mRNA in the liver.

We demonstrated that individuals with GSDIa and WD may have a 3-log range of pre-existing anti-AAV titers. In cynomolgus macaques, we demonstrated that AAV GT can deliver VG to the liver of TAb+ animals. Additional work to assess the safety of dosing TAb+ humans with AAV GT is needed. These data support further investigation into more frequent AAV TAb testing and will inform discussions about the possibility of dosing low TAb+ individuals in future AAV GT trials.

1000 tRNA at the Frontier: Developing Medicines to Treat Stop Codon Disease

Sandra Visser[1], George Lai[1], YounKyoung Lee[1], Katherine Hall[1], **Isabelle Sansal[1]**, Caroline Kohrer
[1]AlltRNA, Cambridge, MA

Alltrna is developing a class of engineered transfer RNA (tRNA) based drugs that read through nonsense mutations, also known as premature termination codons (PTCs), and re-introduce the wildtype (WT) amino acid into the growing protein chain during translation. PTCs within an mRNA prevent synthesis of the full-length WT protein often resulting in severe disease due to complete loss, diminished or altered protein function. Nonsense mutations are the underlying cause of approximately 10% of all genetic diagnoses in humans. The fact that a given nonsense mutation can be found in multiple disease-causing genes opens the possibility of developing a drug to target PTCs across multiple indications. In recent years, tRNAs engineered to read through PTCs and restore continued synthesis of the polypeptide chain have gained attention as an emerging novel therapeutic approach to potentially unify the treatment of thousands of rare and ultrarare PTC diseases, also known as Stop Codon Disease, including liver diseases with high unmet needs.

To develop tRNA therapeutics, Alltrna has built a unique platform based on (i) high-throughput screening of engineered tRNA oligonucleotides combining optimized sequence and chemical modification patterns and (ii) rational and machine learning-guided design principles. In parallel, we have developed clinically relevant disease

mouse models to assess tRNA performance and delivery to the relevant target tissue and characterize pharmacokinetic and pharmacodynamic relationships that can support preliminary human dose predictions.

Preclinical data demonstrated productive restoration of full-length functional protein in vitro and in vivo, confirming preclinical proof of concept. Preclinical data studying Alltrna's drug candidate AP003, a chemically modified, engineered tRNA oligonucleotide (tRNA-3) in a lipid nanoparticle (LNP), showed that a single dose of AP003 tRNA leads to robust *in vivo* restoration of protein production to clinically meaningful levels in two transgenic Stop Codon Disease mouse models, methylmalonic acidemia (MMA) and phenylketonuria (PKU).

In the MMA mouse model, a single dose of the tRNA-3 in a LNP delivery system restored in vivo protein levels of methylmalonyl-CoA mutase (MMUT) over 25% of wild type levels at Day 4, well above the 1-2% protein rescue considered to be clinically meaningful in MMA by key opinion leaders.

In the PKU mouse model, a single dose of AP003 demonstrated phenylalanine hydroxylase (PAH) restoration to 7% of wild type levels within 72 hours, exceeding the clinically relevant 3% protein rescue target defined by key opinion leaders. Further, this PAH protein restoration resulted in a meaningful 76% reduction of phenylalanine (Phe) levels from baseline, as PAH is the enzyme responsible for breaking down Phe. When PAH is mutated or deficient, Phe accumulates to toxic levels, causing the hallmark elevated Phe levels observed in PKU.

Additionally, tRNA levels and dose response data were collected through several preclinical studies that together form the basis of translational PKPD models that are used for preliminary human dose predictions in support of clinical trial design.

Enabled by the development of a tRNA platform, Alltrna's preclinical data with AP003 show the potential of tRNA therapeutics as a novel drug modality for the treatment of Stop Codon Disease patients across multiple rare diseases in liver

1001 AAV-mediated Gene Knock-down and Replacement Therapy for PKU was Effective with High Efficacy and Low Dosage

Yong Wang[1], Zhou Yang[1], Yan Yang[1], Congshi Zhai[1], Jianghong Zhang[1], **Tenghui Yu[2]**
[1]Gritgen Therapeutics, Suzhou, China, [2]Grtigen, BEIJING, BEIJING, Peoples Republic of China

Background: Phenylketonuria (PKU) is an autosomal recessive disorder of amino acid metabolism caused by mutations in the phenylalanine hydroxylase (PAH) gene, causing impaired phenylalanine (Phe) metabolism. The standard care for PKU requires life-long strict dietary restrictions, whose compliance is poor. Attempts to improve the life-quality of PKU patients have met with limited successes. Restoring PAH in 10 to 20% hepatocytes in mice is sufficient to normalize plasma Phe concentration, but clinical trials with gene therapies have not been very successful. Because PAH functions as a tetramer and most of the PAH mutations in PKU patient are missense mutations instead of null mutations, we reasoned that we should reduce endogenous mutant PAH at the same time when we introduce exogenous wild type (WT) PAH for gene therapy. **Results**: We utilized two PKU mouse models, the PAH-KO (PAH null) and ENU2 (PAH F263S mutant) models. When we introduced PAH-expression only vector to these mouse models, the magnitude of Phe decreases in PAH-KO mice was larger than that in ENU2 mice. Instead, when we introduced a vector to simultaneously express WT PAH and silence mutant PAH, the magnitude of Phe decreasing in ENU2 was slightly larger than that in PAH-KO mice. These results support a novel approach for PKU treatment. After rounds of vector optimization, we obtained GS1168 as our candidate. GS1168 uses a single AAV to simultaneously expresses a therapeutic RNAi-resistant PAH protein and a miRNA to knocks down the endogenous mutant gene. In the ENU2 male mouse models, we achieved the therapeutic effects (Phe<360uM) at a dosage as low as 3E11 vg/kg. We also observed a dose and sex dependent effect after a single injection of GS168. Toxicological studies showed GS1168 was safe and well-tolerated in both mice and non-human primates (NHP). **Conclusions**: By reducing the mutant PAH at the same time of introducing a functional PAH, GS1168 provides an effective AAV-based gene therapy for PKU. Our innovative strategy sets GS1168 apart from existing gene therapies, offering new hope to improve the quality of life of PKU patients.

1002 LY-M003, An AAV Gene Therapy Product with Copper Responsive Engineering of ATP7B Expression (CREATE) for Wilson Disease

Yuzhe Peng[1], Xuyang Zhang[1], Guofang Yan[2], **Yixiong Chen[3]**, Qing Lin[4]*
[1]Lingyi Biotech, Shanghai, China, [2]Lingyi Biotech, Shanghai, Shanghai, China, [3]Lingyi Biotech, Shanghai, China, China, [4]Lingyi Biotech, Lutherville, MD
**Corresponding Author*

Wilson disease (WD) is a rare autosomal recessive metabolic disorder primarily caused by mutations in the human *ATP7B* gene, located on chromosome 13 (13q14.3). This genetic aberration results in diminished ATP7B activity, leading to the progressive accumulation of copper in vital organs, including the liver, brain, and kidney. The consequential organ damage underscores the severity of WD, manifests as multi-organ involvement and a deteriorating clinical presentation. The fundamental approach to addressing Wilson's disease involves restoring ATP7B protein function. LY-M003, designed to hepatic-specifically produce a modified ATP7B^{LY} protein in a copper-dependent manner, emerges as an investigational adeno-associated virus (AAV)-based gene therapy for Wilson's disease.

A novel modified ATP7B^{LY} protein was optimized through exhaustive screening from single MBD to maximum four MBD combinations with nucleotide sequence optimization, and validated to remain copper-dependent intracellular translocation and exhibit comparable functionality to the full-length wild-type ATP7B. LY-M003 emerges as an investigational AAV8-based gene therapy intended for Wilson Disease, employing Copper Responsive Engineering of ATP7B Expression (CREATE) scheme to regulate the expression of the ATP7B^{LY} in a copper dependent manner. *In vitro* study demonstrated that LY-M003 could controllably express ATP7B^{LY}, offering a finely tuned response to cellular copper levels, and displayed high level of copper exportation capacity. LY-M003 was further found to efficiently protect hepatocytes from copper mediated toxicity and restore ceruloplasmin synthetical pathway, indicating a successful reversal of abnormal copper metabolism.

Preclinical efficacy studies were conducted in *Atp7b*$^{-/-}$ mice and *Atp7b*$^{M1/M1}$ mice models, both of which were confirmed detrimental copper accumulation in liver, abnormally high urinary copper excretion, and deficient serum ceruloplasmin activity. Comparative analyses demonstrated that LY-M003 with CREATE scheme exhibited more potent therapeutic effect than the corresponding control with regular hepatic-specific promoter in male *Atp7b*$^{-/-}$ mice. In *Atp7b*$^{M1/M1}$ mice, treatment with LY-M003 brought hepatic-specific ATP7B^{LY} expression and restoration of fecal copper excretion pathway. Pharmaceutical study of LY-M003 dose-dependently resulted in decrease of hepatic copper level, reduction of 24-hour urinary copper level and normalization of serum ceruloplasmin activity following a 13-week therapeutic regimen. Moreover, LY-M003 could stably expression ATP7B^{LY} and exhibit efficacy in *Atp7b*$^{M1/M1}$ mice model up to 8 months. Toxicology studies of LY-M003 were conducted in both SD rats and Cynomolgus macaques with dose-ranging investigation, the results of which demonstrated high safety and tolerability of LY-M003. Significantly, copper metabolism in healthy animals remained unchanged after LY-M003 administration.

The comprehensive preclinical data strongly support the safety and long-term therapeutic efficacy of LY-M003, warranting the further study of human clinical trials. An Investigator Initiated Trial (IIT) to evaluate the safety and efficacy of a single intravenous infusion of LY-M003 in patients with WD is ongoing.

1003 Mitochondria Targeted rAAV Gene Therapy for Cytochrome C Oxidate Deficiency

Cytochrome c oxidase 20 (COX20) deficiency is a rare autosomal recessive disorder caused by mutations in the *COX20* gene. The COX20 protein functions as a chaperone, stabilizing the COX2 subunit on the inner mitochondrial membrane, which is critical for assembling mitochondrial complex IV and maintaining respiratory

chain function. To date, over 30 cases have been reported, with patients experiencing symptoms including sensory neuropathy, early onset ataxia, dysarthria, hypotonia, dystonia, and ophthalmoplegia. Despite the growing recognition of this disorder, its underlying pathomechanism remains poorly understood. Additionally, the absence of Cox20 animal models that replicate human disease phenotypes has impeded the establishment of an effective therapeutic intervention. In this study, we developed a recombinant adeno-associated virus (rAAV)-based gene therapy for COX20 deficiency and assessed its efficacy in a newly engineered COX20-deficient mouse model.

Our first-generation rAAV9-hCOX20 vectors utilized the ubiquitously active chicken beta-actin (CB) promoter and expressed one of the two isoforms of the human *COX20* gene (201 and 203). hCox20 expressed from rAAV9.CB-hCOX20 localized to mitochondria and rescued the mitochondrial defects in COX20 deficient HEK293T cells, as demonstrated by Western blot and Seahorse Mito stress tests, suggesting its proper functionality. In a proof-of-concept study, rAAV9.CB-hCOX20 vectors were administered intravenously to neonatal wild-type mice. Mitochondrial localization of the hCOX20 protein in the brain, liver, and heart was confirmed by immunofluorescence analysis. Safety evaluations including complete blood count (CBC), basic metabolic panel (BMP) blood tests, and histological analysis conducted six months post-treatment revealed no pathological findings. rAAV9.CB-hCOX20 treated wild-type mice exhibited a reduction in body weight compared to untreated mice, possibly due to increased complex IV activity and energy consumption associated with hCox20 overexpression driven by the CB promoter. To avoid the risk of unintended side effects resulting from excessive protein expression, we developed second-generation rAAV9-hCOX20 vectors using endogenous COX20 regulatory elements derived from human COX20 promoters, which are currently being evaluated for their expression and toxicity profiles.

Given the embryonic lethality caused by complete COX20 loss, we generated a conditional COX20 knockout mouse model. Induction of ubiquitous *COX20* knockout resulted in rapid body weight loss starting around day 40 post-tamoxifen injection, followed by phenotypes including abnormal hair appearance, kyphosis, and cataract, ultimately leading to death between 80 to 100 days post-induction. To evaluate therapeutic efficacy, both first- and second-generation rAAV9-hCOX20 vectors were delivered at different stages of disease progression, and their ability to prevent or reverse disease phenotypes is currently being studied.

In summary, our ongoing study presents a potential and safe rAAV-based gene therapy approach for COX20 deficiency and suggests that improved specificity with an endogenous promoter might be advantageous. Additionally, this work may contribute to uncovering the mechanisms underlying other mitochondrial-related disorders.

1004 Correction of a Recurrent Pathogenic Variant in Methylmalonic Acidemia Using Adenine Base Editing

Elena Kahn[1], Xiao Wang[2], Rebecca Ahrens-Nicklas[3], Kiran Musunuru[2]
[1]University of Pennsylvania School of Medicine, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA

Methylmalonic acidemia (MMA) is a recessive genetic disease caused by variants in *MMUT* (mitochondrial enzyme methylmalonyl–CoA mutase) or by defects in transport or metabolism of *MMUT* cofactor (5' deoxyadenosylcobalamin), including the *MMAB* gene. MMA is diagnosed by routine newborn screening, and the first metabolic decompensation event typically occurs within the first few days of life, when toxic compounds accumulate in the blood. MMA can result in serious complications, such as an enlarged liver, kidney failure, vision problems, and intellectual and motor disability. The current standard of care is liver transplantation, yet patients typically need to reach at least one year of age to undergo the procedure, and elevated toxic metabolites often remain even after transplantation. Thus, there is a pressing need for improved therapeutic strategies to treat patients with MMA. Previous studies suggest that there is a survival advantage of cells with corrected alleles in the livers of patients with MMA, and that correction in the liver may provide enough functional enzyme to slow or halt disease progression. Here, we show corrective editing of a recurrent pathogenic variant (*MMAB* R186W) using adenine base editing in cell lines containing the pathogenic variant.

First, we developed a cell line using the human hepatoma HuH-7 cell line as a background and containing four pathogenic variants for MMA, all of which are amenable to adenine base editing. These variants were inserted into the HuH-7 cells via lentiviral vector transduction. We tested a variety of adenine base editors (ABEs) in combination with different guide RNAs (gRNAs) and selected the best performing pairs. For one of the recurrent variants, *MMAB* R186W, we achieved substantial corrective editing (≈30%) with minimal bystander editing using standard plasmid transfection. mRNA transfection using the best performing ABE/gRNA pair yielded robust editing at the desired locus (≈76%). The other three variants displayed less corrective editing and more bystander editing upon initial screening, so we prioritized *MMAB* R186W to pursue a therapeutic ABE strategy. In parallel, we have been developing a cell line that incorporates this pathogenic variant into the endogenous *MMAB* locus via prime editing, with a plan to validate our best performing ABE/gRNA pair. To assess off-target editing at other locations in the genome with the ABE/gRNA pair, we used ONE-seq to generate a list of candidate genomic sites and are in the process of verifying/ruling out the list of nominated sites in hepatocytes.

Once the ABE/gRNA pair has been validated *in vitro* using cell lines, we will dose a humanized murine model containing the human pathogenic variant with the ABE/gRNA pair encapsulated in lipid nanoparticles (LNPs). We plan to measure levels of on-target, bystander, and off-target editing in the mouse model via next generation sequencing (NGS), assess for improved survival, and measure biochemical markers of MMA such as serum levels of methylmalonic acid and propionylcarnitine.

While *in vivo* gene editing may provide an elegant solution for the correction of many pathogenic variants associated with metabolic and other genetic diseases, there are currently no approved *in vivo* gene editing therapies in the clinic. If results from our murine studies and off-target analyses are favorable, this study will provide a new approach to treating a rare genetic metabolic disease.

1005 AAV9 -Mediated Gene Therapy of MMAB Deficiency: Preclinical Efficacy in Mouse models of Cobalamin B Type Methylmalonic Acidemia

Eun-Young Choi[1], Karenna Choi[2], John Selser[3], Charles Venditti[4]*

**Corresponding Author*

Introduction: Cobalamin B-type (*cblB*) methylmalonic acidemia (MMA) is a rare and severe autosomal recessive inborn error caused by pathogenic variants in the MMAB gene, which encodes the enzyme ATP:cob(I)alamin adenosyltransferase (ATR). ATR catalyzes the synthesis of 5'- deoxyadenosylcobalamin (AdoCbl), the essential cofactor for methylmalonyl-CoA mutase (MMUT). MMAB deficiency can be clinically severe, characterized by lethality and severe biochemical perturbations, with massively elevated methylmalonic acid levels in the blood. Despite medical and dietary management, some patients require elective liver or liver-kidney transplantation. There are currently no established therapies for MMAB deficiency, which is an indication for the Platform Vector Gene Therapy (PaVe-GT) Program.

Methods: We studied a cohort of 17 patients with MMAB deficiency identified through the natural history study of MMA (NCT00078078). Two severe mutations, the orthologue of a recurrent missense mutation in patients who received LT/LKT (p.Arg186Trp), and a deletion of exons 3-7 to mimic null phenotype, were engineered into the *Mmab* locus. Additionally, a germline rescue transgene was created to restore MMAB expression in the skeletal muscle under the control of the murine muscle creatine kinase (MCK) promoter, knocked into the ROSA26 locus ($Tg^{MCK\text{-}Mmab}$), generating a hypomorphic model ($Mmab^{D3\text{-}7/D3\text{-}7}$; $Tg^{MCK\text{-}Mmab}$). AAV vectors expressing *MMAB* under the EF1L or EF1s promoters in either single-strand (ss) or self-complementary (sc) genome configurations (NCATS-BL2680), respectively, were tested for in vivo efficacy.

Results: $MMAB^{R180W/R180W}$ mice exhibited growth retardation, lethality around weaning, and massively elevated plasma methylmalonic acid (pMMA) levels (1777 +/- 693 uM, 1399 x WT), resembling patients with severe forms of *cblB* MMA. $Mmab^{D3\text{-}7/D3\text{-}7}$;$Tg^{MCK\text{-}Mmab}$ mice survived with near-normal growth but exhibited significant MMAemia (496+/- 91 uM, 203x Het). Neonatal or adolescent treatment of $MMAB^{R180W/R180W}$ mice with AAV

vectors (systemically delivered at a dose of 1E11 GC/pup on DOL1 or 1E13 GC/kg on DOL 21) resulted in complete rescued from lethality (Figure 1), normalized body weight, and reduced pMMA levels.

Young adult Mmab$^{D3\text{-}7/D3\text{-}7}$;Tg$^{MCK\text{-}Mmab}$ mice treated with either vector at a dose of 1E13 GC/kg showed substantial reductions in pMMA levels (27 +/- 6.7 uM for ss, 18 +/- 4.9 for sc at 6 months post treatment) and restoration of ^{13}C propionate oxidation to wild type levels. In contrast, treatment with 1E12 GC/kg revealed different outcomes: sc-treated mice showed similar reductions in pMMA (33 +/- 7.5 uM) as those treated with 1E13 GC/kg ss vectors, while ss treatment at 1E12 GC/kg had a minimal effect (330 +/- 112.5 uM) (Figure 2). Older mice treated with 1E12 GC/kg sc vectors demonstrated marked improvement in hepatic pathology.

Conclusions: We have developed a series of clinically relevant MMAB animal models and demonstrated that AAV9-mediated gene therapy can rescue survival, reduce of pMMA levels, and improve pathological outcomes. Notably, sc AAV vectors provided superior correction compared to ss vectors at low doses. These models provide a platform for neonatal and adult proof-of-concept therapeutic studies and hold promise for advancing AAV gene therapeutics for MMAB deficiency, a severe form of MMA.

1006 The Mouse Peroxisome Research Resource for Testing Gene and Cell-based Therapies

Joseph Hacia[1], Yunus Polat[2], Dr. Nancy Braverman[3], Aamir Zuberi[4]
[1]University of Southern California, Los Angeles, CA, [2]Research Institute of the McGill University Health Centre, Montreal, QC, [3]McGill University, Montréal, QC, [4]The Jackson Laboratory, Bar Harbor, ME

Peroxisomes are metabolic membrane-bound organelles that play essential roles in the development and physiological functions of all mammalian organ systems. This is exemplified by Zellweger spectrum disorder (ZSD), a group of rare multisystemic disorders caused by inherited defects in peroxisome assembly, structure, and replication. ZSD and X-linked adrenoleukodystrophy, the most common inherited peroxisomal disorder, can be detected by newborn screening prior to irreversible organ damage in many patients. This provides therapeutic windows for targeted gene and cell-based therapies to address unmet needs of patients. Nevertheless, the limited number of well-annotated publicly available mouse models and their often-suboptimal genetic backgrounds has slowed the pace of translational peroxisome-related research. Here, we discuss recent progress made by the NIH-funded Mouse Peroxisome Research Resource (MPRR), a central resource for mouse models for basic and translational research relevant to peroxisome biology and disorders caused by peroxisome dysfunction. This community-driven effort leverages expert knowledge of mouse model development, gene editing, and peroxisome biology to accelerate the generation, distribution, and proper use of high-impact mouse models for peroxisome research. All deposited mouse models are on standardized genetic backgrounds and publicly available as well-annotated resources with minimal required legal restrictions. The models produced or in production include strains expressing reporter proteins to visualize peroxisomes in mouse tissues or immunopurify peroxisomes from cell extracts. Furthermore, a host of conditional knockout alleles and single copy CAG-lox-stop-lox (LSL) regulated human cDNA transgenes for the tissue-specific elimination or tissue-specific over-expression of specific peroxisomal genes, respectively, have been generated. Mice with humanized copies of whole genomic regions encompassing peroxisome genes in safe harbor sites are also under development. The MPRR captures baseline data such as measurement of peroxisomal metabolite levels, including those of very long-chain and branched-chain fatty acids in addition to lifespan determinations of these new models. Overall, the MPRR has substantially increased the number of available mouse models for peroxisome research and accelerated preclinical testing of rationally designed therapeutic interventions for disorders caused by peroxisome dysfunction.

1007 Systemic lentiviral and AAV gene therapies correct several metabolic imbalances in the brain of the maple syrup urine disease mouse model

Ala'a Siam[1], Zeinab Asgarian[1], Ellie Chilcott[1], Anna Keegan[2], Julien Baruteau[3], Rajvinder Karda, Simon Waddington[4], John Counsell[5]*
[1]University College London, LONDON, London, United Kingdom, [2]UCL, LONDON, London, United Kingdom, [3]Great Ormond Street Institute of Child Health University College London, London, Kent, United Kingdom, [4]University College London, London, United Kingdom, [5]University College London, LONDON, Greater London, United Kingdom
**Corresponding Author*

Maple syrup urine disease (MSUD) is an inborn error of metabolism that is caused by mutations in any of the constituents of the branched chain ketoacid dehydrogenase complex, thereby impairing the metabolism of branched chain amino acids (BCAAs). It is associated with severe neurologic sequalae, including intellectual disabilities, seizures and ataxia. We have investigated the efficacy of VSVg-pseudotyped lentiviral (LV) and AAV9 vectors in the intermediate MSUD mouse model, which is a knock-out (KO) for the endogenous *Dbt* gene. Both vectors encode a codon-optimised human DBT transgene under the control of a synthetic liver-specific promoter, and were administered intravenously to pups at P1-P2 at doses of 1.4E11 TU/kg (n=9) and 1.0E14 vg/kg (n=9), respectively. The mice were sustained on diets with normal protein content.

Both therapies significantly ameliorated the general phenotype. Untreated and AAV-treated KOs had median survivals at P20 and P73 respectively, whereas seven of the LV-treated KOs survived beyond the study's P120 endpoint. LV-treated animals at P120 demonstrated complete normalisation of speed (15.2±1.2 vs 15.0±0.6 cm/s;

p>0.9999), hind limb swing speed (52.0±1.9 vs 53.6±1.2 mm/s; p=0.9712), stride length (5.0±*0.2* vs 5.5±0.2 cm; p=0.1839) and regularity index (89.3%±0.7% vs 90.0%±1.6%; p>0.9999) compared to wildtypes (WTs), respectively. LV lowered plasma leucine, isoleucine and valine levels in KOs by 54% (p<0.0001), 35% (p=0.0074) and 52% (p<0.0001), and AAV by 37% (p=0.0012), 44% (p=0.0006) and 36% (p=0.0003), respectively. In adult subjects that survived past the study's mid-timepoint of P60, LV and AAV were found to have mean hepatic vector copy numbers of around 0.6±0.1 and 9±2 vector copies per cell, which mediated expression at around 26%±4% and 8±3% of WT *DBT* mRNA levels, respectively.

Metabolomic brain analysis revealed that these therapies corrected many of the MSUD-associated bioenergetic imbalances. Although most glycolytic intermediates remained stable in untreated KOs, levels of around 35% of 17 TCA cycle-related metabolites including pyruvate were significantly altered in P15-P20 subjects. While only one of 66 fatty acids (1.5%) was significantly affected at that timepoint, around 33% of 42 fatty acyl carnitine and CoA ester, 41% of 46 sphingolipid and 14% of 236 phospholipid metabolite reads exhibited significant differences from age-matched WTs. LV- and AAV- treated KOs in contrast exhibited significant differences from adult WTs in around 0% and 12% of TCA cycle, 7% and 12% of fatty acyl carnitine and CoA ester, 6.5% and 2% of sphingolipid, and 7% and 10% of phospholipid metabolite reads, respectively. These results suggest that systemic gene therapies may exert their efficacy via mechanisms beyond correction of plasma BCAA levels.

1008 AAV-Mediated Restoration of Hepatic *CYP27A1* Expression in Chenodeoxycholic Acid-Pretreated Mice with Cerebrotendinous Xanthomatosis

LAIA TRIGUEROS MOTOS[1], Angie Molina Delgado[2], Guiomar Perez[3], Leire Neri[4], Cristina Gazquez[5], Leticia Odriozola[3], Irene Marcilla[6], Manuela Molina[5], Oihana Murillo[3], Anne Douar[7], Jean-Philippe Combal[8], Blanche Tamarit[9], Céline Bouquet[9], Gaetan Despres[10], Pranvera Krasniqi[10], Antonin Lamaziere[11], Ruben Hernandez-Alcoceba[12], **Gloria Gonzalez-Aseguinolaza[13]***

**Corresponding Author*

Cerebrotendinous xanthomatosis (CTX) is an autosomal recessive disease resulting from mutations in the *CYP27A1* gene, which encodes the mitochondrial enzyme sterol 27-hydroxylase. This enzyme plays a critical role in the conversion of cholesterol into bile acids. Loss-of-function mutations in *CYP27A1* disrupt bile acid synthesis, leading to the accumulation of toxic intermediates such as cholestanol and 7α-hydroxy-4-cholesten-3-one (7αC4) in blood, eyes, tendons and brain. These deposits result in clinical manifestations such as infantile-onset diarrhea, juvenile cataracts, adolescent-onset xanthomas, and adult-onset neurological impairments like ataxia, dementia, and peripheral neuropathy. The standard treatment for CTX is oral administration of chenodeoxycholic acid (CDCA), which works by downregulating hepatic *CYP7A1* enzyme and the synthesis of bile acids. It effectively reduces toxic metabolite levels and alleviates symptoms but may not fully prevent neurodegeneration, highlighting an unmet medical need for improved therapeutic strategies. In this sense, liver-directed gene therapy becomes a valuable treatment alternative to improve patient outcomes. We first developed an adeno-associated virus (AAV) vector serotype 8, VTX-806(8), with high potency and low immunogenicity carrying a codon-optimized CpG-depleted *CYP27A1* sequence under the control of a liver-specific promoter. Treatment of CTX mice with 5E12 VG/kg of VTX-806(8) achieved a full correction of disease biomarkers, including circulating 7αC4 levels, expression of hepatic bile acid synthesis-related genes and hepatomegaly, as well as the levels of 7αC4 in the brain, tendons and liver. We then determined that the therapeutic dose of chenodeoxycholic acid (CDCA) able to reduce hepatomegaly, expression levels of *Cyp3a11* in the liver and 7αC4 levels in blood in CTX mice, without any associated toxicity, was 0.25% admixed in the diet (0.375-0.75 µg/g/day). After diagnosis is confirmed, CTX patients are immediately placed under treatment with the standard of care CDCA. Therefore, to mimic the conditions in which a CTX patient under CDCA could potentially be treated with VTX-806(8), an efficacy study of VTX-806(8) in mice pre-treated

with CDCA was performed and the interaction and comparison of these two therapeutic approaches were assessed. Four-week-old CTX mice were fed with 0.25% CDCA admixed in the diet for 4 weeks and then received a single intravenous administration of VTX-806(8) at 5E12 VG/kg. Four weeks later, CDCA was removed in a group of mice and maintained in another group. Healthy animals and untreated CTX animals, as well as groups treated with each of the therapies alone were included as controls. The levels of serum disease biomarkers were followed over time in all the groups of mice to assess and compare the efficacy of the different therapeutic regimens. Moreover, hepatomegaly, expression of *Cyp7a1* and *Cyp3a11* and the levels of 7αC4, cholestanol and 27-hydroxycholesterol in the brain were quantified after sacrificed at 16 weeks of age. In conclusion, our study determined the therapeutic dose of CDCA for CTX mice to be 0.25% admixed in the diet and evaluated the efficacy of VTX-806(8) in combination with CDCA treatment. This comprehensive approach allowed for a thorough comparison of different therapeutic regimens, providing valuable insights into the interaction of CDCA and gene therapy treatments, mimicking potential clinical scenarios for CTX patients.

1009 Improvement of Progressive Familial Intrahepatic Cholestasis Type 2 Via AAV-Mediated Hepatic BSEP Expression in Mice

Angie Molina Delgado[1], LAIA TRIGUEROS MOTOS[2], Manuela Molina[3], Guiomar Perez[4], Cristina Gazquez[3], Leticia Odriozola[4], Blanche Tamarit[5], Céline Bouquet[5], Jean-Philippe Combal[6], **Gloria Gonzalez-Aseguinolaza[7]***, Cristian Smerdou[8]*

**Corresponding Author*

Progressive familial intrahepatic cholestasis type 2 (PFIC2) is an uncommon genetic condition inherited in an autosomal recessive manner, resulting from alterations in the *ABCB11* gene. This gene encodes the hepatic bile salt export pump (BSEP), which transports bile salts (BS) from hepatocytes to the bile canalicular lumen. BSEP deficiency or dysfunction leads to impaired BS excretion and their buildup in the liver, causing severe hepatic damage. PFIC2 patients typically exhibit symptoms in early childhood, including cholestasis, growth retardation, jaundice, hepatomegaly, and pruritus. Many develop early-onset fibrosis and end-stage hepatic disease, with an elevated risk of developing hepatocellular carcinoma. Treatment options include symptom management, surgical bile diversion, or liver transplantation, which is currently the only curative option. We demonstrated the safety and therapeutic benefits of adeno associated virus (AAV)-mediated liver directed gene therapy for the treatment of PFIC2 in an *Abcb11*$^{-/-}$ mouse model of PFIC2. After developing VTX-802(8), an AAV8 vector containing a codon-optimized human *ABCB11* sequence controlled by a liver-specific promoter, a dose range finding study of the therapeutic vector was performed. Five-week-old female PFIC2 mice received a single intravenous injection of VTX-802(8) at three different doses and the therapeutic efficacy was monitored up to five months of age. Treated mice showed a dose-dependent improvement in serum transaminase levels maintained over time. These mice also exhibited partial but significant correction of hepatomegaly, and increased BS transport from the liver to bile and small intestine at 15 weeks post-injection, indicating partial restoration of normal bile secretion. These findings suggest that VTX-802(8) may have therapeutic potential for PFIC2 patients. Current treatment with IBAT inhibitors limit treatment to certain patient profile and specific mutations, therefore combination with gene therapy could improve treatment efficacy to expand population. Developing a long-lasting cure for PFIC2 by restoring long-term hepatic BSEP expression and physiological bile secretion would provide a transformative option for these pediatric patients with significant unmet medical needs.

1010 New murine models of propionic acidemia caused by PCCB deficiency allow for the testing of genomic therapies in both severe and mild disease phenotypes

Randy Chandler[1], Christian Kim[2], Charles Venditti[3]
[1]National Institutes of Health, Bethesda, Maryland, [2]National Institutes of Health, Bethesda, MD, [3]NIH, Bethesda, MD

Propionic acidemia (PA) is rare autosomal recessive metabolic disease caused by defects in the mitochondrial localized enzyme propionyl-CoA carboxylase (PCC). This enzyme is composed of six α- and six β-subunits with causative variants occurring at equal frequencies in either the nuclear encoded *PCCA* or *PCCB* genes. PA patients can suffer from stunted growth, potentially lethal metabolic crises, cardiomyopathy, and chronic kidney disease. The poor prognosis for PA patients has led to the exploration of gene therapy as a new treatment option. To explore the etiology and to test new therapies for PA, we have developed and characterized 5 new murine models of PCCB deficiency. Gene editing of the 7th and 14th exon of the murine *Pccb* gene was used to create loss of function alleles: an 8 bp deletion in the 7th exon, and a 4 bp deletion in the 14th exon. Both alleles result in a frameshift and premature stop codon in the *Pccb* gene and no detectable PCCB protein. $Pccb^{E7del/E7del}$ and $Pccb^{E14del/E14del}$ homozygotes manifest an immediate neonatal lethal phenotype accompanied by elevations of disease related metabolites, 2-methycitrate (2-MC) and 3-hydroxypropionate (3-OHP). Because of the severe lethality displayed by the homozygous *Pccb* frameshift stop mutations, we designed a germline transgene to express the murine *Pccb* cDNA under the control of a muscle specific promoter ($Tg^{Mck\text{-}Pccb}$) and bred to rescue the $Pccb^{E14del/E14del}$ mice. The resultant $Pccb^{E14del/E14del}$;$Tg^{Mck\text{-}Pccb}$ animals are rescued from neonatal lethality but perish by 2 months of age. These mice express low levels of PCCB only in the skeletal and cardiac muscle, and have milder biochemical perturbations of 2-MC and 3-OHP in comparison to the $Pccb^{E14del/E14del}$ mice but are severely growth retarded, very much like patients with PA. To generate a murine model with a late onset form of PA, we used gene editing to insert the c.C689T (p.P230L) mutation into the murine *Pccb* gene. PA patients who are homozygous for the orthologous missense mutation in the human *PCCB* c.C683T (p.P228L) are mildly affected, but symptomatic when stressed. Subsequently, $Pccb^{P230L/P230L}$ homozygous were bred to $Pccb^{WT/E7del}$ mice to create compound heterozygous $Pccb^{P230L/E7del}$ mice. Both $Pccb^{P230L/P230L}$ and $Pccb^{P230L/E7del}$ mice express a dysfunctional PCCB protein, display attenuated metabolic changes and less impaired growth in comparison to $Pccb^{E14del/E14del}$;$Tg^{Mck\text{-}Pccb}$ mice. However, a lethal metabolic crisis can be induced when the $Pccb^{P230L/P230L}$ or $Pccb^{P230L/E7del}$ mice ingest an increased protein diet. To demonstrate the utility of these models to test new therapies, $Pccb^{E14del/E14del}$ were treated with AAV-PCCB at a dose of 1e11 vg/pup at birth, which resulted in a significant increase in survival in comparison to untreated mutant controls ($p<0.01$). Similarly, when $Pccb^{E14del/E14del}$;$Tg^{Mck\text{-}Pccb}$ mice were treated at weaning with a dose of 1e14 vg/kg of AAV-PCCB , there was a significant increase in survival and growth in comparison to untreated controls. These new murine models replicate the clinical and biochemical spectrum of PA, and can be used to test the effects of new genomic and small molecule therapies targeting both mild and severe forms PA caused by PCCB deficiency.

1011 AAV capsid prioritization in normal and steatotic human livers maintained by machine perfusion

Adeno-associated virus (AAV) vectors have revitalized gene therapy. In the liver, AAV vectors proved to be effective and safe for hepatocyte-targeted gene therapy of hemophilia A and B, with vectors produced with the AAV5 capsid being the first to receive FDA approval. However, whether the reach of AAV gene therapy can be extended to other liver diseases is uncertain because most require a higher fraction of hepatocytes to be transduced than hemophilias, which cannot be safely achieved by vector dose escalation. Using clinical trial data to predict the hepatocyte transduction efficiency of AAV capsids in the human liver is challenging because of variability in vector dose and design, and lack of liver biopsies. Similarly, even advanced preclinical models, such as mice repopulated

with human hepatocytes or non-human primates, produce contradictory results. Moreover, it is unknown whether AAV capsids target functionally distinct hepatocyte zones or other cell types in the human liver, which has implications for efficacy and safety of liver gene therapy. It is also unknown how the tropism of AAV capsids is impacted by hepatic steatosis, which affects more than a third of the global population and is a common comorbidity in gene therapy patients. To address these uncertainties, we established side-by-side comparison of AAV vectors produced with different capsids in normal and steatotic human livers maintained under physiological conditions by normothermic machine perfusion. We analyzed transduction of hepatocytes and other liver cell types at the DNA, RNA and protein level, including by single-cell RNA sequencing. Focusing on the capsids most commonly used in clinical trials, we found that AAV-LK03 transduces hepatocytes much more efficiently than AAV5, AAV8 and AAV6; AAV-LK03 is also better than AAV-NP59, which is more efficient at transducing human hepatocytes engrafted in immune-deficient mice. In normal human liver, AAV-LK03, and to a lesser extent AAV8, preferentially transduces periportal hepatocytes, a tropism lost in steatotic liver. Conversely, AAV5 preferentially transduces pericentral hepatocytes only in steatotic human liver. While AAV-LK03 is specific for hepatocytes, AAV5 and AAV8 also efficiently transduce liver sinusoidal endothelial cells. In addition, we discovered that the AAV capsid influences vector episome formation, which determines the durability of gene therapy, with AAV5 delaying concatemerization. We also found that steatosis impairs vector episome formation. Our findings inform capsid choice in clinical trials of hepatocyte-targeted AAV gene therapy, enabling advanced strategies that consider disease-specific zonation and steatosis. Moreover, our findings establish an opportunity for physiological gene therapy of hemophilia A targeting liver sinusoidal endothelial cells. Our approach facilitates the development of AAV capsids that transduce hepatocytes or other therapeutically relevant cell types in the human liver with maximum efficiency and specificity.

1012 Impact of liver fibrosis on AAV-mediated gene transfer to hepatocytes

Liver fibrosis, characterized by the accumulation of scar tissue in response to various insults, poses a significant challenge for liver-directed gene therapy. Patients with liver fibrosis are currently excluded from clinical trials and fibrotic liver diseases are hindered to enter the clinical pipeline because intact liver architecture is postulated to be required for safe and efficient gene transfer to hepatocytes by adeno-associated viral vectors (AAV), the platform of choice for vivo gene therapy.

In this study, we investigated the biodistribution and hepatocyte transduction of AAV8-based vectors in the context of liver fibrosis. Studies in three mouse models, with induced or genetic liver fibrosis and different fibrotic patterns, revealed that AAV8 vectors transduce fibrotic livers with reduced efficiency. This reduction primarily arises from diminished vector uptake by the liver rather than vector genome loss due to hepatocyte proliferation. Additionally, liver fibrosis led to changes in blood vector clearance and biodistribution in extra-hepatic organs, with a model-specific impact on increased viral particle uptake by spleen, lung, and kidney. At the cell-type level, fibrosis resulted in decreased vector genome content in hepatocytes and increased content in non-parenchymal liver cells, as well as in splenic macrophages and dendritic cells. Finally, we demonstrated that the impact of liver fibrosis on AAV-

mediated transduction is capsid-dependent, with the AAV-KP1 variant maintaining efficient transduction in fibrotic livers comparable to non-fibrotic ones.

Overall, this work emphasizes the need for careful evaluation of AAV administration in patients with liver fibrosis and underscores the importance of more extensive safety assessments, while highlighting the potential of AAV as a platform to broaden gene therapy applications to include fibrotic diseases.

1013 Determination of the Minimum Effective Dose of AAV9-LSP-hPYGL in a Glycogen Storage Disease Type VI Mouse Model

Jeong-A Lim[1]*, Su Jin Choi[1], Rebecca Koch[1], Priya Kishnani[2]*

Glycogen Storage Disease Type VI (GSD VI), also known as Hers disease, is a rare inherited metabolic disorder caused by a deficiency or dysfunction of hepatic glycogen phosphorylase (PYGL), a key enzyme in glycogen breakdown in the liver. PYGL is activated via phosphorylation by phosphorylase kinase, converting the inactive phosphorylase b into the active phosphorylase a, which catalyzes glycogen degradation to glucose 1-phosphate (G1P). PYGL deficiency results in impaired glycogenolysis and hepatic glycogen accumulation, leading to hepatomegaly, ketotic hypoglycemia, growth retardation, elevated hepatic transaminases, hypertriglyceridemia, and hypercholesterolemia. While GSD VI is often considered a mild disorder, severe cases may progress to liver cirrhosis. Current treatment is limited to dietary management, including uncooked cornstarch and high-protein diets. The recently characterized Pygl knockout (KO) mouse model recapitulates key symptoms and pathophysiological features of the disease. Over time, hepatic glycogen accumulation in these mice leads to liver damage, inflammation, elevated hepatic transaminases, and collagen deposition, increasing the risk of liver fibrosis. In this study, we aimed to determine the minimum effective dose of an adeno-associated virus (AAV) vector carrying the human PYGL gene (hPYGL) under the control of a liver-specific promoter (LSP) and packaged into an AAV9 capsid (AAV9-LSP-hPYGL) in Pygl KO mice. Both male and female Pygl KO mice were administered AAV9-LSP-hPYGL intravenously at three doses (1E+12, 3.16E+12, and 1E+13 vg/kg), with outcomes assessed after two weeks. Results revealed a dose-dependent response with sex-specific differences. At 1E+12 vg/kg, male mice showed minor improvements, while female mice showed no noticeable effects. At 3.16E+12 vg/kg, disease phenotypes improved in males, although the effects on females were minimal. In contrast, at 1E+13 vg/kg, both male and female mice exhibited significant improvements across various disease indicators. These improvements included decreased liver size, normalized expression of PYGL, increased enzyme activity, reduced hepatic glycogen accumulation, and normalized serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels. Overall, our findings suggest that the minimum effective dose of AAV9-LSP-hPYGL that produces positive effects in both male and female Pygl KO mice is 1E+13 vg/kg. This study provides critical insights for optimizing AAV-based gene therapy strategies for patients with GSD VI.

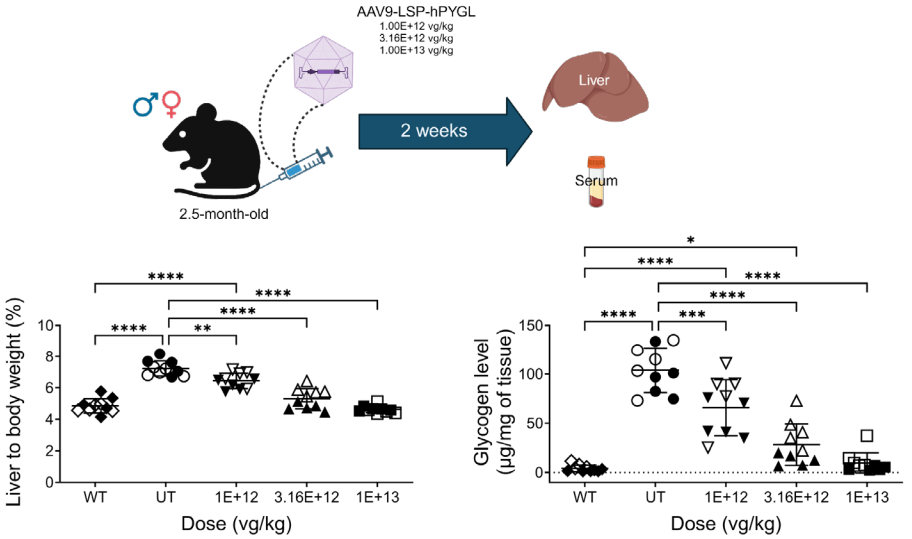

Figure Legend

2.5-month-old male (n=5, closed symbols) and female (n=5, open symbols) Pygl KO mice were intravenously administered AAV9-LSP-hPYGL via tail vein injection at three doses (1E+12, 3.6E+12, and 1E+13 vg/kg). After two weeks, liver and serum samples were collected to evaluate disease phenotypes. Age- and sex-matched untreated Pygl KO (UT) and wild-type (WT) mice served as controls. Liver size and hepatic glycogen levels decreased in a dose-dependent manner, with observed sex-specific differences.

1014 *Ass1* Targeted Gene Insertion in Newborn Mice Provides Effective, Long Term Disease Correction in a Lethal Mouse Model of Citrullinemia Type I

Citrullinemia Type I (CTLN1) is a life-threatening urea cycle disorder impacting approximately 1 in every 57,000 live births. It is a monogenic condition arising from deficiency of argininosuccinate synthetase (*ASS1*). Left untreated, CTLN1 can lead to life threatening ammonia elevation and metabolic decompensation. Today CTLN1 is included in the newborn screening panels of all 50 states in the US, and several additional countries worldwide. These screening programs have helped support rapid diagnosis of CTLN1, enabling prompt initiation of dietary protein restriction and nitrogen scavenger therapy. However, lifelong dietary protein restriction and frequent administration of nitrogen scavenger medication pose significant adherence challenges, leaving patients at risk for periodic bouts of hyperammonemic crises and metabolic decompensation. These events lead to progressive accumulation of irreversible neurological, behavioral, and cognitive sequelae. A gene therapy approach that can be administered early in life to provide durable protection is critical to prevent the irreversible neurological manifestations associated with CTLN1.

To address known durability challenges of AAV episome-based liver gene therapies in pediatric settings, we have developed an alternative, CRISPR-based platform for hepatic gene replacement that can be administered early in life, even as the liver is undergoing rapid growth. We aimed to apply this technology to develop a durable and effective liver-directed, native locus gene insertion treatment for CTLN1 that can be administered during childhood. Our approach transiently delivers Cas9 mRNA and a guide RNA via a lipid nanoparticle, which is co-administered with an AAV that contains a promoterless human ASS1 partial cDNA. Together these components mediate targeted insertion of the ASS1 partial cDNA into the native Ass1 gene locus to restore expression of wild type ASS1 protein. Gene insertion treatment of *Ass1*^{fold} citrullinemic mice, dosed either as juveniles (P28) or as newborns (P7) resulted

in rapid, durable, and complete normalization of blood ammonia levels throughout a 20-week study period. Blood citrulline was reduced to levels seen in CTLN1 patients that have received a human liver transplant. Histological and molecular analyses of the liver revealed robust targeting and correction of the *Ass1* gene. In contrast, episomal AAV delivery of *ASS1* in newborn *Ass1*^{fold} pups failed to durably reduce blood ammonia levels. Importantly, *Ass1* native locus gene insertion led to preferential expression of ASS1 protein in peri-portal hepatocytes with high urea cycle activity, reflecting the natural *Ass1* zonation pattern of expression. Collectively, these results demonstrate that *ASS1*gene insertion may provide an effective and durable treatment that can be administered early in life to promptly halt the progression of irreversible damage caused by high ammonia levels in CTLN1.

1015 Long-term Efficacy of VTX-806(8) for the Treatment of Cerebrotendinous Xanthomatosis: Sustained Correction of Metabolic Abnormalities in Mice

**Corresponding Author*

Cerebrotendinous xanthomatosis (CTX) is a rare recessively inherited metabolic disorder caused by mutations in the *CYP27A1* gene, which encodes the sterol 27-hydroxylase enzyme. This deficiency leads to impaired bile acid synthesis that results in a dramatic decrease in 27-hydroxycholesterol and to the accumulation of toxic metabolites like 7 alpha-hydroxy-4-cholesten-3-one (7αC4) and cholestanol in blood, eyes, tendons and brain resulting in a diverse array of clinical manifestations. CTX is characterized by the presence of xanthomas in multiple tissues, particularly in the brain and tendons and the early symptoms include chronic diarrhea, bilateral juvenile cataracts, and progressive neurological dysfunction. Chenodeoxycholic acid (CDCA) is the standard treatment for CTX and has shown efficacy in halting disease progression but its effectiveness in improving or stabilizing neurological symptoms varies between patients, with some individuals still experiencing neurodegeneration despite CDCA treatment. This highlights the potential need for alternative approaches such as gene therapy. We have previously shown that adeno-associated virus (AAV)-mediated gene supplementation of *CYP27A1* in the liver corrects disease biomarkers in a mouse model of CTX. VTX-806(8) is an AAV8 vector carrying an optimized expression cassette including a liver-specific promoter and a codon-optimized *CYP27A1* sequence depleted of CpG motifs to avoid the potential activation of an innate immune response. VTX-806(8) demonstrated the ability to correct hepatomegaly, normalize the expression of *Cyp7a1* and *Cyp3a11* genes and the levels of 7αC4 in blood, brain, liver and tendons of CTX mice one month after the administration of the vector. In order to evaluate the capacity of VTX-806(8) to maintain a sustained therapeutic effect, CTX male and female adult mice were treated with a single intravenous administration of the vector at the therapeutic dose of 5E12 VG/kg and the levels of serum disease biomarkers were followed over a period of 9 months, showing at 4 months a sustained normalization of 7αC4 levels. Mice were sacrificed 9 months after treatment and hepatic transduction, transgene expression, hepatomegaly, expression of hepatic genes and the levels of 27-hydroxycholesterol and toxic metabolites in tissues were evaluated.

To summarize, this study demonstrates the long-term efficacy of VTX-806(8) in a mouse model of CTX. A single administration of VTX-806(8) at 5E12 VG/kg resulted in sustained correction of serum and tissue biomarkers, reduced hepatomegaly, and restored proper expression of hepatic bile acid synthesis-related genes. These findings suggest that VTX-806(8) holds promise as a potential long-term therapeutic option for CTX, addressing the underlying genetic defect and correcting associated metabolic abnormalities.

1016 Exploring Cell-Free DNA Signatures as Biomarkers for Disease Progression in Metachromatic Leukodystrophy

Carlo Cipriani[1]*, Laura Rudilosso[2], Francesca Fumagalli[3], Valeria Calbi[4], Sara Mazza[5], Marco Masseroli[6], Alessandro Aiuti[7], Daniela Cesana[8]

Metachromatic leukodystrophy (MLD) is a rare, inherited lysosomal storage disorder characterized by progressive demyelination and neurodegeneration. Hematopoietic stem cells gene therapy (GT) has shown remarkable success in early-onset pre-and early symptomatic patients. Unfortunately, nowadays it is difficult to predict disease progression in presymptomatic MLD patients because the clinical course cannot be followed by validated biochemical assays, challenging the clinical decision-making for treatment. Therefore, there is a strong need for the identification of novel, reliable and non-invasive biomarkers for the diagnosis and assessment of MLD disease severity.

Here we explore the role of cell-free DNA (cfDNA) as biomarker for MLD. We recently showed that cfDNA levels were at a pathological level in MLD patients compared to healthy donors (HDs) before GT ($p=0.01$, 5-fold), and these values decreased progressively to normal levels after GT, only in those patients with a positive therapeutic outcome[1]. Elevated cfDNA levels have been described in disease conditions associated with inflammation and increase in cell death rate. Therefore, the high cfDNA concentration observed in these patients may reflect the number of dying cells due to the toxic accumulation of lysosomal compounds at the different stages of disease progression. Identifying the specific cells contributing to cfDNA production could provide deeper insights into the biological mechanisms underlying tissue degeneration during disease progression. Methylation-based approaches have been utilized to determine the cellular origin of cfDNA, as cell-specific epigenetic signatures are preserved within cfDNA fragments. To determine the cellular origins of cfDNA, we applied enzymatic approaches to profile CpG methylation, followed by high-throughput sequencing. For tissue deconvolution, we refined an existing non-negative least squares model to enhance performance on low-coverage sequencing data based on cell type-specific methylation atlas. Studies performed on cfDNA samples collected from HDs demonstrate that we can reproduce published data showing that cfDNA mainly originates from leukocytes (80%)- particularly granulocytes, monocytes/macrophages, and megakaryocytes. To demonstrate the accuracy and specificity of our approach, we analyze cfDNA profiles from patients with hematological malignancies, revealing a clear shift in cellular contributions compared to HDs. Indeed, patients with T-cell leukemia or B-cell tumors showed a marked increase in fragments derived from T (50% T-frag vs. 2% in HD) and B-cell (30% B-frag. vs. 0.5% in HDs), respectively. Our preliminary analysis of 4 untreated MLD patients showed a significantly different pattern compared to HDs, with neuronal and oligodendrocyte derived-fragments present at higher relative ($p=0.03$, 4-fold) and absolute levels ($p=0.01$, 25-fold), reflecting damage in these cell types associated to disease pathology. Further studies in larger cohorts of pre- and symptomatic patients associated with different disease variants and monitored overtime will be required to validate these findings and establish cfDNA as a predictive biomarker in MLD. If validated, this approach may provide a non-invasive tool that can be used to monitor disease progression, guide clinical intervention to improve patient care.

Cesana et al, Nat Medicine 2021

1017 Development of a Durable Gene Therapy for Targeting CNS and Visceral Pathologies in Acid Sphingomyelinase Deficiency

Daniel Virga, Maria Praggastis, Katherine Cygnar, Yuxin Zhu
Regeneron Pharmaceuticals Inc., Tarrytown, NY

Acid Sphingomyelinase Deficiency (ASMD) is a lysosomal storage disorder caused by mutations in the sphingomyelin phosphodiesterase (*SMPD1*) gene. The resulting deficiency of ASM activity leads to an accumulation of sphingomyelin in both visceral and central nervous system (CNS) tissues. ASMD patients exhibit visceral manifestations in the liver, spleen, lung, and heart, as well as severe, progressive neurodegeneration. The current enzyme replacement therapy (ERT), Olipudase alfa, is limited to treating non-CNS pathologies due to its inability to cross the blood-brain barrier (BBB). We have developed a novel BBB-crossing antibody-targeted therapeutic by fusing the ASM enzyme with a single chain variable fragment (scFv) that binds to transferrin receptor 1 (TfR1). Hepatocyte-specific gene insertion of this anti-TfR1scFv fusion results in the expression and secretion of the fusion enzyme into the bloodstream, facilitating transcytosis and uptake into both visceral and CNS tissues. Our results demonstrate that liver insertion of anti-TfR1:ASM significantly reduces sphingomyelin accumulation in the brains of ASMD mice, an effect not observed with untargeted ASM. Additionally, anti-TfR1:ASM gene therapy reduces sphingomyelin accumulation in the heart, spleen, and lungs. Anti-TfR:ASM expression also results in robust improvements in behavioral performance as measured by rotarod and balance beam, in addition to preventing cerebellar neurodegeneration. This innovative gene therapy approach not only reduces the need for frequent ERT infusions required by the current standard-of-care but also effectively targets and mitigates CNS deficits in ASMD, making it a potential therapeutic to address unmet need in neurovisceral ASMD.

1018 Engineering T Lymphocytes for Enzyme Replacement Therapy

Evan Kleinboehl[1], Kanut Laoharawee[2], Jacob Jensen[3], Joseph Peterson[3], Nicholas Slipek[4], Matthew Johnson[5], Beau Webber[6], Branden Moriarity[5]
[1]University of Minnesota - Moriarity Lab, Minneapolis, Minnesota, [2]Prime Medicine, Cambridge, MA, [3]University of Minnesota Twin Cities, [4]Saint Paul, MN, [5]University of Minnesota, Minneapolis, Minnesota, [6]University of Minnesota, Minneapolis, MN

Background: Enzymopathies are metabolic disorders caused by enzyme deficiencies or dysfunctions, leading to toxic substrate accumulation and metabolic imbalances. Among these, lysosomal storage diseases (LSDs) result from defective lysosomal enzymes, causing progressive, multi-system pathology. Mucopolysaccharidosis type I (MPS I) is a severe LSD caused by a deficiency in alpha-L-iduronidase (IDUA), an enzyme essential for degrading glycosaminoglycans (GAGs). Without functional IDUA, GAG accumulation leads to widespread tissue damage, including skeletal abnormalities, organ dysfunction, neurological decline and early mortality. Current treatments, including hematopoietic stem cell transplantation (HSCT) and enzyme replacement therapy (ERT), provide limited efficacy, particularly for neurological symptoms, due to poor blood-brain barrier (BBB) penetration. T cells are a promising platform for enzyme delivery due to their longevity, high protein secretion, and ability to migrate into tissues, including across the BBB. These properties make them ideal for sustained in vivo enzyme replacement, enabling targeted IDUA delivery to affected organs.

Objective: To develop a novel cell-based therapy using autologous, engineered T cells for sustained and systemic IDUA delivery, addressing the limitations of current therapies and improving outcomes for MPS I patients.

Methods: As a proof-of-concept, human T cells were engineered to express IDUA using homology-directed repair with AAV-mediated delivery for targeted knock-in at the AAVS1 safe harbor locus and successfully evaluated in an MPS I NSG mouse model. To improve clinical scalability, we recently developed a non-viral, transposon-based engineering approach for IDUA expression. Preclinical studies utilizing MPS I T cells assessed transgene integration, enzyme secretion, cell viability, and cross-correction of IDUA-deficient cells in vivo/in vitro.

Results: In a pilot study, engineered human T cells expressing IDUA were evaluated in an MPS I NSG mouse model. A single dose led to sustained IDUA activity above heterozygous levels, significantly reducing GAG accumulation and improving MPS I-associated pathology. By 10 weeks post-treatment, peripheral GAG levels matched heterozygous controls, and histological analysis showed improved liver and brain morphology, supporting the therapeutic potential of T cell-based enzyme delivery. Building on these findings, we developed a non-viral

transposon system to generate IDUA-expressing T cells using patient-derived MPS I T cells, achieving >95% engineering efficiency with an average of four transposon copies per cell. These cells exhibited a >300-fold increase in IDUA secretion compared to healthy, non-MPS I T cells. Engineered cells remained viable and expanded 30-fold over seven days ex vivo. In vitro studies confirmed that secreted IDUA effectively cross-corrected IDUA-deficient cells, further supporting the feasibility of T cell-based enzyme delivery for addressing manifestations of MPS I.

Conclusion: These findings highlight the potential of engineered T cells as a transformative, durable, and effective therapy for MPS I. By providing sustained enzyme replacement, this platform could significantly improve patient outcomes. Future studies will focus on evaluating long-term persistence, immune response, and BBB penetration in additional MPS I models, further advancing this approach toward clinical application.

1019 Penetrating the blood-brain barrier: Utilization of the PS Gene-editing System to encode a novel fusion β-galactosidase for the treatment of GM1 gangliosidosis

Michael Przybilla[1], Li Ou[2], Chester Whitley[1]
[1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota Twin Cities

GM1 gangliosidosis is a lysosomal disorder caused by β-galactosidase (β-gal) deficiency, leading to the accumulation of GM1 and GA1 gangliosides, particularly in the central nervous system (CNS). Currently, there are no effective therapies available due to the inability of therapeutic enzymes to cross the blood-brain barrier (BBB). The PS Gene-editing (PSG) system has previously demonstrated efficacy in producing sustained therapeutic levels of enzyme that prevent the onset of cognitive decline in a murine model of GM1 gangliosidosis. However, there is still room for improvement in CNS uptake of the enzyme. This study explores the use of a novel β-gal-ApoE fusion enzyme to enhance BBB penetration and improve CNS pathology in the murine model of GM1 gangliosidosis.

In this study, the PSG system was employed to integrate the β-gal-ApoE fusion cDNA into intron 1 of the albumin gene of hepatocytes via two adeno-associated viruses (AAVs), administered intravenously into β-gal$^{-/-}$ mice at P0-P2. Over the course of the study, plasma was collected to measure and monitor β-gal enzyme activity. At six months of age, motor and cognitive function were assessed using the Barnes maze, balance beam, accelerating rotarod, and pole test. At 10-12 months of age, tissue β-gal enzyme activity was measured, and ganglioside levels were quantified in the hippocampus, cerebellum, and cerebral cortex. Plasma β-gal enzyme activity was sustained for up to 7 months post-dosing, averaging 1284- and 692-fold higher than heterozygous levels in female and male PSG-β-gal-ApoE-treated β-gal$^{-/-}$ mice over the 7 months. This significant elevation of plasma enzyme activity resulted in significant increase in β-gal enzyme activity in the liver, heart, spleen, kidney, muscle, bone marrow, spinal cord and brain of β-gal$^{-/-}$ mice who received treatment. Importantly, this elevation of brain β-gal enzyme activity was 12-fold higher than previous experiments using the non-fusion enzyme. Normalization of GM1 and GA1 gangliosides in the brain was observed. In behavior testing, mice that received PSG-β-gal-ApoE maintained normal cognitive and motor function.

In conclusion, the use of the PSG system encoding the novel β-gal-ApoE results in permanent, high levels of circulating β-gal enzyme, which is effectively taken up throughout the body. Additionally, these results demonstrate that the β-gal-ApoE fusion enzyme effectively crosses the BBB, restoring enzymatic function in the CNS and reducing the pathogenic gangliosides, resulting in improved neurological outcomes. These findings further demonstrate the power of the PSG system as a platform technology for treating not only lysosomal disorders, but any disorder that could benefit from circulating proteins.

1020 Biological Pacemaker Activity Induced by AAV-TBX18

Rodrigo Miguel Dos Santos[1], James Dawkins[1], Thassio Mesquita[1], Lizbeth Sanchez[1], Liang Li[1], Eduardo Marban[2], Eugenio Cingolani[2]
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Cedars-Sinai Heart Institute, Los Angeles, CA

Background: Bradycardia is a clinical disorder characterized by an abnormally slow heart rate and a common cause of fatigue and fainting. Patients with this condition often need an electronic pacemaker. Although it is the current standard of care, these devices can have complications. A biological pacemaker has been created by adenovirus expressing the transcription factor T-box 18 (TBX18) as an alternative to electronic pacemakers. However, adenoviruses are immunogenic, limiting the duration of expression.

Objective: We investigated whether expressing TBX18 in the less inflammatory adeno-associated virus (AAV-TBX18) represents a viable alternative to induce somatic reprogramming and sustained pacemaker activity.

Methods: AAV9 containing GFP or TBX18 was directly injected into the myocardium of eight-week-old male Sprague Dawley rats (n=70) at low ($1x10^9$ GC), mid ($1x10^{10}$ GC) and high ($1x10^{11}$ GC) doses. Transient AV block was induced by tail vein injection of adenosine. A permanent complete AV block was induced by ablation of the his bundle. Hearts were harvested for optical mapping, mRNA analysis and immunofluorescence. Yorkshire-SPF farm pigs were subjected to a surgery to induce AV block by ablation of the his bundle, and a backup electronic pacemaker was implanted (VVI: 50 beats/min). Viral vectors were injected into the ventricular septum using a minimally invasive percutaneous approach.

Results: Six weeks after injection, all doses of AAV9-TBX18 had increased heart rate compared to AAV9-GFP when we induced AV block using adenosine. AAV9-GFP and -TBX18 mid dose injected rats underwent surgery to induce complete AV block. TBX18 group presented superior heart rate over the 24 hours monitored. 6-lead EKG analysis of the QRS axis in the frontal plane revealed that the ventricular ectopic beats from the AAV9-TBX18-injected group originated from the injection site. Activation maps further confirmed that the injection site originated those beats in TBX18-injected rats only. Successful reprogramming of adult ventricular myocytes into SAN-like cells was confirmed by transcriptional profiles, resembling the native SAN. A nonlinear analysis of the heart rate variability reavealed a reduction in the sympathetic overstimulation in the AAV9-TBX18-injected rats. In a clinically relevant porcine model of AV block, the TBX18 group presented a superior heart rate, and reduced dependency on the backup pacemaker. AAV-TBX18 injection also induced transcriptomic changes consistent with cellular reprogramming in the pigs' heart.

Conclusion: Collectively, these data indicate that the AAV-based somatic reprogramming induced by TBX18 leads to sustained biological pacemaker activity in different AV block models. Long-term studies are needed to characterize the long-term effects of sustained TBX18 expression.

1021 Gene Therapy Targeting the Hippo Pathway for In Vivo Cardiac Regeneration in Ischemic Heart Failure

John Leach[1], Tyler Kibbee[1], Melanie Hartsough[2], Abdelmotagaly Elgalad[3], Ross Durland[4], Suzanne Bull[1], Emerson Perin[5], James Martin[6]
[1]YAP Therapeutics, Houston, TX, [2]Hartsough Nonclinical Consulting, LLC, Derwood, MD, [3]The Texas Heart Institute, Houston, TX, [4]YAP Therapeutics, Laguna Hills, CA, [5]Texas Heart Institute, Houston, TX, [6]Baylor College of Medicine, Houston, TX

This preclinical study evaluates a first-in-class gene therapy designed to stimulate cardiomyocyte cell division and coordinate cardiac regeneration to treat ischemic heart failure with reduced ejection fraction (HFrEF). Current treatments, including pharmacotherapy and mechanical interventions, fail to reverse ischemia-induced myocardial damage. Consequently, there is an urgent unmet need for novel therapies that promote cardiac regeneration involving cardiomyocyte proliferation, vascular recruitment, and a reduction in fibrosis.

We developed YAP101, a non-replicating recombinant adeno-associated virus serotype 9 (AAV9) vector encoding a cardiac-specific troponin T promoter to drive the expression of three short hairpin RNAs (shRNAs) that suppress Salvador-1 (*SAV1*), a core Hippo pathway component. By reducing *SAV1* expression, YAP101 increases nuclear localization of YAP, activating multiple endogenous cardiomyocyte-directed repair pathways that promote cardiac regeneration.

To assess efficacy, safety, and biodistribution, we conducted preclinical studies in mouse and pig models using a clinical-grade YAP101 formulation. We evaluated efficacy in a pig model of myocardial infarction (MI)-induced heart failure using a catheter-based delivery system to administer 15 transendocardial injections of YAP101 directly into the myocardium surrounding an infarct. We also conducted pharmacology and, biodistribution, and toxicology studies over 3 and 6 months in healthy pigs, 3 months in MI pigs, and 3 months in healthy mice to gather essential preclinical safety data.

Results demonstrated robust pharmacological activity across species. Mechanistic and efficacy studies revealed that YAP101 effectively suppressed Hippo pathway activity, leading to functional cardiac improvement. In MI pig models, YAP101 administration enhanced ejection fraction, reduced infarct fibrotic scar size, stimulated cardiomyocyte cell division, and activated revascularization of the myocardium. Notably, YAP101 did not induce cardiac hypertrophy or arrhythmias at any tested clinically relevant doses.

Pharmacokinetic and biodistribution studies demonstrated sustained cardiac expression of YAP101. Biodistribution studies in mice and pigs confirmed that YAP101 localizes to the heart, and we detected transgene DNA in the myocardium up to six months post-administration. We also detected transgene RNA localized to the heart, which demonstrates the specificity of the cardiac-specific troponin T promoter. Importantly, YAP101 did not induce adverse immune responses beyond transient antibody formation, which did not impact efficacy. Toxicology studies across species confirmed that YAP101 is well tolerated, and we observed no organ toxicity or long-term adverse effects.

These findings support advancing YAP101 into clinical development as a first-in-class gene therapy targeting the Hippo pathway for cardiac regeneration. By coordinating in vivo cardiomyocyte cell division, vascular recruitment, and fibrosis reduction, YAP101 activates cardiac regeneration, leading to improved cardiac function and offering a potential breakthrough treatment for ischemic heart failure.

1022 TN-501 Gene Editing Therapy for PLN-R14del-Associated Cardiomyopathy

Emma Xu[1], Lynn Yamamoto[1], Uma Lakshmanan[2], Max Levine[3], Farshad Farshidfar[1], Chayse Jones[1], Melissa Van Pell[4], Cristina Dee-Hoskins[4], Xiaomei Song[4], Jianmin Lin[5], Gretchen Argast[1], Amara Greer-Short[5], Laura Lombardi[1], Rudolf de Boer[6], Herman Silljé[7], Tim Hoey[1], Kathy Ivey[1], **Huanyu Zhou[8]***

Corresponding Author

PLN-R14del-associated cardiomyopathy, caused by a pathogenic mutation in the *Phospholamban (PLN)* gene, disrupts calcium handling in cardiomyocytes, leading to life-threatening arrhythmias, progressive heart failure, and high mortality rates. Current treatment options, limited to standard heart failure and arrhythmia management, fail to address the underlying genetic defect. TN-501 is an in vivo gene editing therapy designed to specifically inactivate the mutant *PLN-R14del* allele, eliminating the "poison peptide" effects of the mutant protein while preserving wild-type allele function.

TN-501 employs an adeno-associated virus 9 (AAV9) vector to deliver a cardiac-specific Cas9-sgRNA system. This vector ensures precise editing and transient Cas9 expression through tissue-specific promoters, self-inactivation elements, and liver-detargeting mechanisms. Preclinical studies in patient induced pluripotent stem cell derived cardiomyocytes (iPSC-CMs) and murine models demonstrate that TN-501 effectively prevents mutant PLN protein aggregation, reduces cardiac fibrosis, improves cardiac function, and significantly enhances survival. These findings highlight its potential to prevent sudden cardiac death, halt heart failure progression, and reduce the need for advanced interventions such as heart transplantation.

With its targeted approach, TN-501 represents a significant advancement in the treatment of PLN-R14del-associated cardiomyopathy. By addressing the genetic root cause of the disease, this therapy offers a promising, durable, one-

time intervention for a condition with high unmet medical need. TN-501 is currently in preclinical development, with further studies planned to refine its safety and efficacy and inform future clinical trials.

1023 AAV-Based Gene Therapy Targeting p53 Signaling as a Therapeutic Strategy for Arrhythmogenic Right Ventricular Cardiomyopathy Type 5

Laura Lalaguna[1], Marina Lopez-Olañeta[2], Pablo Garcia-Pavia[2], Enrique Lara-Pezzi[2]*
[1]CNIC, Madrid, Madrid, Spain, [2]CNIC, Madrid, Spain
**Corresponding Author*

Introduction: Arrhythmogenic right ventricular cardiomyopathy type 5 (ARVC5) is the most aggressive form of ARVC, caused by a fully penetrant missense mutation (p.S358L) in TMEM43. The disease is characterized by progressive dilation of the cardiac chambers and fibro-fatty replacement of the myocardium, leading to heart failure and sudden cardiac death. The function of TMEM43 and its role in ARVC5 pathogenesis remain largely unknown, hindering the development of effective therapeutic options.

Methods: We performed single-nucleus RNA sequencing (snRNA-seq) on cardiac tissue from TMEM43-S358L transgenic mice (TMEM43mut mice) at three different disease stages (early, mild and severe disease) to investigate the molecular drivers of ARVC5 progression. Based on these findings, we developed an adeno-associated virus (AAV)-based gene therapy to selectively deliver GSE56 (AAV-GSE56), a dominant-negative p53 mutant, to cardiomyocytes. Eight-week-old TMEM43mut mice were treated systemically via femoral vein with either AAV-GSE56 or AAV-Luciferase (control). Cardiac function was assessed through electrocardiography (ECG) and echocardiography until 16 weeks of age.

Results: snRNA-seq analysis revealed a marked depletion of cardiomyocytes and an expansion of fibroblasts and inflammatory myeloid cells in TMEM43mut mice. A subset of mutant cardiomyocytes displayed upregulation of genes linked to the DNA damage response (DDR) and p53 signaling activation in 5-week-old mouse hearts, preceding overt functional impairment. Western blot analysis confirmed these findings, showing increased levels of γH2AX, ATM/ATR, and phosphorylated p53 in TMEM43mut hearts. Therapeutic inhibition of p53 signaling via AAV-GSE56 significantly improved cardiac function compared to AAV-Luciferase controls, as evidenced by increased left ventricular ejection fraction, reduced left ventricular volume, and enhanced right ventricular performance. Additionally, treated mice exhibited shortened QRS duration and increased QRS amplitude, indicative of improved electrical conduction.

Conclusion: Our findings establish DDR activation and p53 signaling as key contributors to ARVC5 pathogenesis. AAV-mediated inhibition of p53 signaling in cardiomyocytes effectively slows disease progression, preserving cardiac structure and function. These results provide novel mechanistic insights into ARVC5 and highlight p53 inhibition as a promising gene therapy strategy for this highly lethal disease.

1024 A Novel Investigational AAV Gene Therapy for Treatment of BAG3 Dilated Cardiomyopathy

Lisa Stanek[1], **Matt Edwards**[2], Bryan Mastis[2], Charles Gualtieri[2], Tyler Ironside[2], Jennifer Joubert[2], Cynthia Pryce[2], Elizabeth Scott[2], Nick Robinson[2], Emily Grandell[2], Mayara Ribeiro[2], Giridhar Murlidharan[2], John Reece-Hoyes[2], Sherry Cao[2], Roberto Calcedo[2], Charles Albright[2], Laura Richman[2]
[1]Life Biosciences, Waltham, MA, [2]Affinia Therapeutics, Waltham, MA,

Gene therapy with adeno-associated virus (AAV) vectors is emerging as a promising therapeutic platform for the treatment of cardiovascular disease. Unfortunately, effective gene delivery to the heart and safety concerns have been major limitations to clinical translation. Achieving therapeutically relevant levels of cardiomyocyte transduction with intravenous-delivered AAV vectors at doses that are well tolerated has been the field's most pressing challenge. We have identified novel AAV capsids by a machine learning-guided rational design approach that demonstrates significantly improved cardiac transduction at lower doses compared to wild-type AAV9. Dilated

cardiomyopathy (DCM) is defined as dilation and systolic impairment of the left ventricle and is the most common cause of heart failure (HF) in the young and most frequent indication for heart transplantation. More than 50% of patients with DCM have a genetic predisposition. B-cell lymphoma 2 (Bcl-2) associated anthanogene-3 (BAG3), a cochaperone that interacts with members of the heat shock protein (HSP) family, has been identified as a DCM-causing gene. BAG3-DCM represents a significant unmet medical need in patients with rapidly progressive cardiac dysfunction, for whom no treatments targeting the disease mechanism exist. We are developing AFTX-201, an AAV-mediated gene replacement therapy to treat BAG3-associated DCM using a novel cardiotropic capsid with an improved safety profile. Here we report therapeutic benefit in a genetically relevant mouse model and achieve safe, therapeutic levels of BAG3 in nonhuman primates at low doses.

To evaluate therapeutic efficacy in a disease-relevant context, we employed a conditional *BAG3* KO mouse with cardiac-specific haploinsufficiency (*BAG3* cKO$^{+/-}$). Cardiac-specific heterozygous (+/-) deletion in BAG3 provides a model that mirrors the biology (reduced BAG3 protein in heart) and phenotype (decreased ejection fraction and a dilated heart) seen in the presentation and natural history of BAG3 Dilated Cardiomyopathy (DCM) patients. Mice received a single IV injection of AAV containing full length human BAG3, similar to the proposed first-in-human Ph1/2 trial, under the control of a cardiac promoter at a timepoint in which mice exhibit significant cardiac dysfunction as measured by echocardiography. We demonstrate that *BAG3* cKO$^{+/-}$ mice show significant improvement in cardiac function following systemic administration of our vector with no safety findings. A dose range finding study performed in NHPs demonstrated levels of BAG3 protein comparable to efficacious *BAG3* cKO$^{+/-}$ mouse protein measurements in the heart at very low dose levels of AFTX-201. Histological analysis showed no evidence of test article-related changes in any tissue analyzed. Immunohistochemistry confirmed BAG3 expression in >70% of the NHP cardiomyocytes and expression throughout the heart with little to no expression in other tissues.

In summary, we propose AFTX-201 as an investigational gene therapy to safely achieve broad, therapeutic levels of BAG3 in the heart, while effectively detargeting other tissues. The proposed First-in-Human Phase 1/2 trial will be a multicenter, open-label, dose-escalation study with an expansion cohort. This trial aims to evaluate the safety, tolerability, and pharmacodynamics of AFTX-201, administered as a single intravenous dose to adult patients with symptomatic BAG3 mutation-associated dilated cardiomyopathy (DCM).

1025 Gene Replacement Therapy for Barth Syndrome Using a Novel Cardiotropic Capsid

Juliette Hordeaux[1], Nicholas Roberts, Yingxian Chen[2], Swapnil Shewale[3], Ali Ramezani, Clarissa Shoffler[3], Dina Abbasian[3], Christopher Petucci[3], James Wilson[3]
[1]Gemma Biotherapeutics, Philadelphia, PA, [2]Gemma Bio, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

Barth syndrome is a pediatric onset, X-linked mitochondrial cardiomyopathy caused by loss of function of tafazzin (TAZ), a protein highly expressed in cardiac and skeletal muscles. TAZ is critical to maintaining the mitochondrial inner membrane structure, and thus cellular energy levels, through its role in cardiolipin metabolism. Heterozygous females are generally asymptomatic, but affected boys develop cardiomyopathy during infancy, a mild proximal myopathy, and neutropenia. Many patients do not respond to conventional heart failure treatments and 12% require heart transplantation at a median age of 1.7 years. The severity and rate of deterioration means that Barth syndrome represents a severe unmet medical need that may be suitable for AAV-mediated gene replacement therapy. By varying the position of an RGD motif within the 7 amino-acid peptide capsid insert, our group recently developed novel AAV variants that exhibit a spectrum of cardiotropic and myotropic properties in mice and NHPs, thereby providing new translational opportunities for targeting either heart or heart and skeletal muscle. Our lead cardiotropic capsid for Barth syndrome demonstrates a 30-fold increase in cardiac transduction (mRNA levels) compared to a clade F benchmark in nonhuman primates, with >50% of cardiomyocytes positive for TAZ transcript by *in situ* hybridization 90 days after intravenous (IV) dosing at 2E13 GC/kg. Upon assessing the efficacy of the candidate in a TAZ knock-down mouse model, IV vector administration at 1E13 GC/kg led to improvements in heart-to-body-weight ratio, echocardiography-based measures of cardiac function, and disease-specific biomarkers, namely GDF-15 in serum (a mitochondrial stress biomarker) and monolysocardiolipin-to-cardiolipin ratio in cardiac

tissue. We evaluated the pharmacology and safety of our lead candidate in a good-laboratory-practice compliant toxicology study in cynomolgus macaques to test three dose levels (2E12, 6E12, 2E13 GC/kg; 2 animals per group) at Day 90 or 180 timepoints. Robust cardiac transduction was observed at 6E12 and 2E13 GC/kg, and no dose-limiting toxicity was detected. These data suggest our candidate exhibits a promising risk-benefit profile that warrants further clinical development for the treatment of Barth syndrome.

1026 Human iPSC-Derived Cardiomyocyte Disease Modeling of Friedreich's Ataxia and Duchenne Muscular Dystrophy for Therapeutic Assessment

Jessica Koepke[1], **Mariana Argenziano[2]**, Shushant Jain[3]*
[1]Ncardia, LEIDEN, Netherlands, [2]Ncardia, Leiden, Zuid-Holland, Netherlands, [3]Ncardia, Leiden, Netherlands, Netherlands

The reprogramming of patient-derived fibroblasts into human induced pluripotent stem cells (hiPSCs) and their subsequent differentiation into cardiomyocytes (hiPSC-CMs) has enabled the development of physiologically relevant in vitro models for human cardiac diseases. Here, we present data from models of Friedreich's ataxia (FRDA) and Duchenne muscular dystrophy (DMD), demonstrating a drug-screening platform with closer fidelity to human pathophysiology. These models recapitulate key cellular disease phenotypes, offering advantages over murine and other animal models.

Control and disease-specific (FRDA and DMD) hiPSC-CMs were differentiated using controlled stirred-tank bioreactors, facilitating large-scale production under tightly regulated conditions (e.g., pH and gas exchange). This approach minimized batch-to-batch variation and yielded consistently pure hiPSC-CMs in sufficient quantities for high-throughput drug screening.

FRDA is characterized by reduced frataxin levels, while DMD results from the absence of dystrophin. To assess these deficiencies, we quantified frataxin and dystrophin levels using ELISA and immunocytochemistry (ICC), respectively. As expected, FRDA patient-derived hiPSC-CMs exhibited significantly lower frataxin expression compared to controls, whereas DMD hiPSC-CMs showed an absence of endogenous dystrophin.

A key pathological feature of FRDA is elevated reactive oxygen species (ROS) levels. Using flow cytometry with a CellROX probe, we detected a significant increase in ROS levels in FRDA hiPSC-CMs relative to controls. Additionally, both FRDA and DMD hiPSC-CMs exhibited aberrant calcium handling. Calcium transients recorded via the FDSS/μCell kinetic reader (Hamamatsu) revealed prolonged calcium transient duration and decay in FRDA hiPSC-CMs. In DMD hiPSC-CMs, impedance-based contractility measurements and calcium transient recordings showed significantly reduced calcium transient amplitude and duration compared to controls.

To mitigate the functional deficits observed in FRDA and DMD hiPSC-CMs, cells were transduced with adeno-associated virus (AAV) vectors encoding Frataxin or Dystrophin. ELISA and ICC confirmed successful overexpression of frataxin and dystrophin, respectively. Functionally, FRDA hiPSC-CMs exhibited a significant reduction in calcium transient duration and ROS levels following frataxin overexpression, while DMD hiPSC-CMs showed significant recovery of calcium transient amplitude upon dystrophin restoration.

In conclusion, patient-derived hiPSCs differentiated into cardiomyocytes provide a robust platform for in vitro modeling FRDA and DMD. By leveraging controlled stirred-tank bioreactors, we achieved high-yield, high-purity hiPSC-CM production suitable for large-scale screening of new therapeutics. Our findings confirmed expected molecular deficiencies in FRDA and DMD models and highlighted disease-specific phenotypic abnormalities. Importantly, we demonstrated the potential of this platform for therapeutic assessment by successfully rescuing key disease phenotypes through AAV-mediated gene delivery of Frataxin or Dystrophin.

1027 A gene regulatory element modulates myosin expression and alters cellular stress response

Taylor Anglen[1], Irene Kaplow[1], Baekgyu Choi[2], Enya Dewars[1], Robin Perelli[3], Kevin Hagy[1], Duc Tran[1], Megan Ramaker[1], Svati Shah[1], Inkyung Jung[2], Andrew Landstrom[3], Ravi Karra[1], Yarui Diao[1], Charles Gersbach[1]
[1]Duke University, Durham, NC, [2]Korea Advanced Institute of Science and Technology, Daejeon, South Korea, [3]Duke University School of Medicine, Durham, NC

A hallmark of heart disease is gene dysregulation. Reactivation of fetal programs has compensatory effects during heart failure, depending on the type and stage of the underlying cardiomyopathy. We identified and characterized a potentially therapeutically relevant gene regulatory element essential for regulating cardiac fetal myosin, *MYH6*, a gene silenced during stress and heart failure. We identified the myosin enhancer through ATAC sequencing and RNA sequencing. The intergenic enhancer increases in accessibility and transcription with increased *MYH6* expression. CRISPR-mediated enhancer activation increases *MYH6* expression (238%, P_{adj} <0.0001) and repression reduces expression (49% of control, P_{adj} =0.0003). The enhancer interacts with the *MYH6* promoter based on human cardiac Hi-C data. Repression or activation of the enhancer invitro can reproduce the various chromatin conformations in the human heart. Activation of the enhancer attenuates the functional declines and alterations in iPSC-derived cardiomyocytes following stress generated by the hypertrophy-inducing and disease-related peptide endothelin-1. Endothelin-1 treatment reduced *MYH6* expression to 30% of control, and enhancer activation significantly increased expression to 59% of control under stress (P_{adj} =0.0003). Increased *MYH6* expression led to higher expression of other factors essential for cardiac function under basal and stressed conditions: NPPA (P_{adj} <0.0001), NPPB (P_{adj} =0.007), TNNT2 (P_{adj} =0.0001), and ATP2A2 (SERCA2A, P_{adj} <0.0001). Stress reduced the expression of function factor ATP2A2 to 71% of the control (Padj =0.0006), while stressed enhancer-activated cells maintained higher expression than the unstressed control (119%, P_{adj} <0.0001). The enhancer's function and pleiotropic effects are conserved in the mouse's endogenous context, tested in the mouse cardiomyocyte cell line HL-1. The alteration in gene expression resulted in functional differences in the iPSC-derived cardiomyocytes and reduced functional alterations in polyploidization and calcium dynamics induced by endothelin-1. Enhancer activation reduced stress-induced polyploidization (P_{adj} =0.0026) and reduced the resulting stress-related cellular hypertrophy. Stressing control iPSC-derived cardiomyocytes significantly decreased calcium amplitude (P_{adj} =0.0057), necessary for generating contractile force, while enhancer-activated cells saw no such decline with stress (P_{adj} =0.96). Finally, enhancer activation prevented stress-induced declines in sarcomere protein density (P_{adj} = 0.019*)*. Using chromatin conformation assays combined with epigenome editing, activating this key enhancer reduces stress-driven alterations in chromatin looping (Padj = 0.023) and maintains higher expression of *MYH6* (P_{adj} =0.0003). These results identify regulatory mechanisms of cardiac gene expression programs that modulate the cellular stress response, providing insights for developing future therapeutics to maintain or improve cardiac function during failure.

1028 Developing *In Vivo* Prime Editing as a Potential Treatment Option for Heart Disease

Lindsey Rollosson[1], Wenjing Liang[2], Emilee Easter[1], Amara Greer-Short[3], Laura Lombardi[4], Tim Hoey[4], Kathy Ivey[4], Ze Cheng[5]*

**Corresponding Author*

Heart disease is the leading cause of death in the world, and the unmet need for curative therapies that target the underlying causes of heart disease is high. Heart disease comes in many forms, affects individuals at many ages, and can be a result of many factors, including cardiomyocyte malfunction caused by genetic mutations. Gene editing technologies have the potential to correct the underlying genetic causes of cardiac conditions, and prime editing (PE) approaches are particularly attractive for its versatility and precision. However, the large size of standard PE machinery exceeds the packaging capacity of a single AAV, posing challenges to cardiac delivery.

To enable *in vivo* cardiomyocyte PE, we employed our proprietary, small, strong, cardiomyocyte-specific promoters, optimized dual-AAV cassette arrangement, and novel cardiomyocyte-targeting AAV capsids. When tested in mice targeting a reference genome locus, *Dnmt1*, our prototype corrected 22% of all genome copies in the heart at a high dose, providing proof of concept for dual AAV vector-based PE in the heart. The percentage correction of cardiomyocyte genome copies is likely higher than the measured value, as our PE machinery expresses specifically in cardiomyocytes, but genome copies from all cell types were collected and contributed to the denominator. Further optimization of the PE machinery resulted in enhanced *in vivo* editing efficiency, potentially benefiting hard-to-edit loci within the genome and/or allowing clinically meaningful editing at a lower dose. To demonstrate the therapeutic potential of *in vivo* PE, we developed PE cassettes targeting a mouse *Rbm20* region corresponding to the mutation hotspot identified in human *RBM20* dilated cardiomyopathy (DCM) patients and dosed the heterozygous *Rbm20* R636Q (corresponding to human *RBM20* R634Q mutation) DCM mouse model. Our *Rbm20* PE treatment drove *in vivo* correction of the mutated *Rbm20* allele, correction of the resulting transcripts, and successful improvement of cardiac function. The results of our *in vivo* studies suggest that our PE strategy may be a potential treatment option for heart disease caused by genetic mutations. We plan to focus future efforts on improving PE efficiency and tailoring our PE strategy for specific human genetic mutations known to cause heart disease. (WL and LR contributed equally to this work.)

1029 Comparison of New and Existing Promoters for Cardiac Gene Expression and Specificity

Timo Jonker[1], Ruud Visser[2], Guillem Buesa Maes[2], Arie Boender[2], Mischa Klerk[3], Yuting Yang[2], Osne Kirzner[4], Hanno Tan[4], Phil Barnett[2], Vincent Christoffels[4], Gerard Boink[5]*

Gene delivery has offered new treatment options for cardiovascular diseases. When using DNA carrying vectors such as AAV for gene delivery, an appropriate choice of promoter is an important aspect in designing gene therapy vectors, as this determines both expression level and off-target expression.

To compare and improve promoters used in cardiac gene therapy, we have tested benchmark promoters. This included several promoters used in cardiac gene therapy trials such as the muscle promoter SPC5-12 and the cardiac-specific promoter TNNT2, as well as novel promoter iterations and promoter-enhancer combinations designed based on sequence and epigenetic state analysis (cell type-specific accessibility, level of H3K27ac). We used neonatal-rat ventricular myocytes to compare cardiomyocyte gene expression, while using C2C12 mouse myoblasts, HEPG2 human hepatocytes and HEK293T producer cells for off-target expression quantification. Cells were transfected with plasmids containing the nano-luciferase reporter driven by the selected promoter-enhancer sequences. The read-out was performed using a nano-luciferase assay. In neonatal rat ventricular myocytes, CMV, SPC5-12 and derivatives/combinations thereof were 5 fold more active compared to TNNT2. SPC5-12 also showed high activity in C2C12 and HEK293T cells compared to TNNT2, while maintaining low activity in HEPG2, indicating partial specificity. Using deletion assays based on chromatin state, we identified a 200bp shorter version of TNNT2 that retained cardiac activity as well as specificity, being inactive in C2C12, HEPG2 and HEK293T. Additionally, we identified a 294bp promoter-enhancer combination with significantly higher cardiac and HEK293T activity when compared to TNNT2, while showing similar activity in C2C12 and HEPG2 cells.

In conclusion, we have identified several promoter candidates which provide useful expression profiles for specific cardiac gene therapy applications where vector length is highly limiting or where transgene expression in producer cells is unwanted, for example, due to transgene toxicity.

1030 Gene Expression Alterations in HIV-Associated Chronic Obstructive Pulmonary Disease: Insights into Molecular Pathways and Inflammation

Md. Sohanur Rahman[1], Kingshuk Panda[2], Irfan Rahman[3], Srinivasan Chinnapaiyan[4], Hoshang Unwalla[2]*
[1]Florida International University Herbert Wertheim College of Medicine, Miami, FL, [2]Florida International University, Miami, FL, [3]University of Rochester Medical Center, Rochester, NY, [4]Florida International University, Herbert Wertheim College of Medicine
**Corresponding Author*

Background: Chronic obstructive pulmonary disease (COPD) poses a significant health challenge for individuals living with HIV, with the prevalence of COPD among this population emerging as a serious concern. HIV-infected individuals exhibit a higher susceptibility to COPD, potentially due to immunological and genetic factors. This study aims to conduct preliminary screenings of genes that may contribute to the pathogenesis of HIV-associated COPD, seeking to identify molecular pathways that could inform future therapeutic interventions.

Methods: We conducted experiments *in vitro* and *in vivo* using primary human bronchial epithelial (NHBE) cells re-differentiated at an air-liquid interface (ALI) and tissue samples from HIV-infected human lungs and SP-C Tat Transgenic mice model, respectively. NHBE ALI cultures were grown on a trans-well infected with the R5-tropic viral strain (HIV BaL) at a concentration equivalent to 5 ng/mL of p24. In addition, NHBE ALI cultures were also treated with HIV-Tat. Total RNA was extracted, and the expression of POFUT1, ZNF451, and RUNX1 were assessed using quantitative reverse transcription polymerase chain reaction (qRT-PCR), and Western blotting was employed to quantify protein levels. Additionally, various pro-inflammatory cytokines were measured using an enzyme-linked immunosorbent assay (ELISA).

Results: The expression levels of POFUT1, ZNF451and RUNX1 were significantly reduced in HIV-infected lung tissue and SP-C Tat mice lung tissue samples, indicating these genes' involvement in recurrent lung inflammation. The mRNA expression levels of Pofut1, ZNF451and RUNX1 were significantly reduced in HIV-infected lung tissue and SP-C Tat mice lung tissue samples, indicating these genes' involvement in recurrent lung inflammation. Similar downregulation of mRNA levels is also observed in HIV-infected NHBE cells, and HIV-Tat treated NHBE cells. In addition, Pofut1 expression is markedly reduced in smoker and human COPD lung tissue samples.

Conclusion: Downregulation of POFUT1 destabilizes the Notch signaling that affects lung development and maintenance and can lead to developmental defects and various lung pathologies. In addition, altered expression of the ZNF451 and RUNX1 genes can significantly impair lung function and exacerbate pulmonary inflammation. Reduced expression of ZNF451 leads to increased fibroblast activation and fibrosis, while RUNX1 dysfunction can disrupt immune responses and promote chronic inflammation, resulting in severe respiratory complications.

1031 Single-Cell RNA Sequencing Reveals Lung T and B Cell Dysregulation in SP-C Tat Transgenic Mice Models and Cigarette Smoke Exposure

Kingshuk Panda[1], Md. Sohanur Rahman[2], Irfan Rahman[3], Srinivasan Chinnapaiyan[4], Hoshang Unwalla[1]
[1]Florida International University, Miami, FL, [2]Florida International University Herbert Wertheim College of Medicine, Miami, FL, [3]University of Rochester Medical Center, Rochester, NY, [4]Florida International University, Herbert Wertheim College of Medicine

Background: Chronic obstructive pulmonary disease (COPD) is marked by chronic lung inflammation and immune dysregulation, with T and B cells playing central roles in shaping the immune microenvironment. T cells persist in COPD lungs, exhibiting cytotoxicity and promoting inflammation, while B cells produce autoantibodies that contribute to lung injury through immune complex formation and complement activation. The interplay between HIV Tat protein and cigarette smoke (CS) exposure may exacerbate immune dysregulation, leading to accelerated lung damage. This study aims to explore gene expression changes in T and B cells in the lungs of COPD mouse models using single-cell RNA sequencing (scRNA-seq).

Methods: Four experimental groups of mice were analyzed: control mice, SPC-TAT mice, wild-type (WT) mice exposed to cigarette smoke, and SPC-TAT mice exposed to cigarette smoke. Single-cell suspensions were prepared from mouse lungs using the gentleMACS™ Octo Dissociator with Heaters and the Miltenyi Biotec mouse lung dissociation kit. 10,000 cells per lung sample were processed for library preparation using the Chromium platform

(10X Genomics). Libraries were sequenced on a NovaSeq 6000 system (Illumina) at a mean sequencing depth of 30,000 reads per cell. Differential gene expression analysis was performed to identify dysregulated genes in T and B cell populations across experimental groups.

Results: scRNA-seq analysis revealed significant dysregulation of genes in both T and B cell populations. T cells in SPC-TAT mice showed increased expression of genes associated with cytotoxicity and inflammatory responses. SPC-TAT mice exposed to cigarette smoke exhibited an exacerbated dysregulation of both CD4+ and CD8+ T cell-related genes compared to control mice. Similarly, B cells demonstrated enhanced gene expression in maturation, activation, and autoantibody production. Notable changes were observed in mediators linked to immune complex formation and complement activation in COPD lungs. These findings were most pronounced in the SPC-TAT with cigarette smoke group, indicating a synergistic effect of HIV Tat protein and cigarette smoke in driving immune dysregulation.

Conclusions: This study highlights the molecular mechanisms by which HIV Tat protein and cigarette smoke contribute to immune dysregulation in COPD. Dysregulated gene expression in T and B cell populations provides insights into their roles in chronic lung inflammation and injury, with implications for therapeutic targeting in COPD patients with HIV. Future research will focus on validating these findings and identifying specific pathways that mediate the combined effects of Tat and smoke exposure.

1032 CRISPR-Cas9-Mediated *ATXN3* Gene Inactivation as a Promising Gene Therapy for Machado-Joseph Disease

Sara Lopes[1], Miguel Lopes[2], Magda Santana[3], Daniela Oliveira[4], Rita Fernandes[3], Maria Casquinha[4], Ana Vasconcelos-Ferreira[4], Dina Pereira[3], Clévio Nóbrega[4], Carlos Matos[5], Rui Nobre[6], **Luis Pereira de Almeida[4]***

**Corresponding Author*

Machado-Joseph disease (MJD) is an autosomal dominantly-inherited neurodegenerative disorder, caused by an over-repetition of the polyglutamine-codifying region in the ataxin-3 (*ATXN3*) gene. The resulting mutant ATXN3 protein is prone to aggregation, leading to cellular dysfunction and death. Currently, no treatment able to reverse or stall MJD progression has been developed. Gene suppression strategies have shown promise in preclinical models. However, these strategies do not directly target the underlying genetic cause of the disease, resulting in incomplete and/or transient therapeutic effects. CRISPR-Cas9 has emerged as a powerful tool to permanently inactivate disease-associated genes, offering the potential for the development of definitive treatments for a wide range of diseases.

In order to prevent the downstream toxic pathways, we developed a CRISPR-Cas9-based approach to efficiently inactivate the human *ATXN3* gene. A panel of single guide RNA sequences targeting an early exon of the human *ATXN3* gene was designed. Functional characterization was performed in a human cell line and the top-ranked sequence was selected for further *in vivo* experiments.

Recombinant adeno-associated viruses (rAAV1/2) encoding CRISPR-Cas9 sequences were delivered into the striatum of a lentiviral-based mouse model of MJD by intracranial injection. This resulted in a marked reduction of aggregates and the preservation of neuronal function. Further validation in a transgenic mouse model of MJD, through the cerebellar administration of rAAVs encoding the CRISPR-Cas9 system, demonstrated a 75% reduction in the number of cells with intranuclear ATXN3 accumulation in deep cerebellar nuclei. However, this was insufficient to rescue motor deficits of treated animals in the open-field test. To achieve a broader brain transduction and early intervention, we administered CRISPR-Cas9-encoding rAAVs into the cerebrospinal fluid of neonatal transgenic mice. This approach successfully preserved locomotor function, in contrast to untreated mice, which showed a deterioration of their motor performance over time.

Our findings demonstrate the efficacy of CRISPR-Cas9-mediated *ATXN3* inactivation in two MJD mouse models, supporting its potential as a novel therapeutic strategy for this incurable disorder.

1033 CRISPR-hfCas12Max-Mediated DNA Editing Restores Motor Function in Spinocerebellar Ataxia Type 3

Dong Yang[1], Zhuoying Huang[2], Alvin Luk[3], Linyu Shi[1], Hui Yang[4]
[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China, Shanghai, Shanghai, China, [2]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China, [3]Huidagene Therapeutics Inc, Clinton, NJ, [4]HuidaGene Therapeutics Co., Ltd., Shanghai, China; Shanghai Institute of Meteria Medica, Chinese Academy of Sciences, Shanghai, China, Shanghai, Shanghai, China

Background: Spinocerebellar ataxia type 3 (SCA3), a rare autosomal dominant neurological disorder that significantly impairs motor functions and quality of life and typically manifesting symptoms between 30 and 40 years of age. The progressive nature of the disease imposes substantial psychological and economic burdens on patients and their families. Increasingly, early disease onset is being observed, driven by genetic factors. SCA3 is caused by a CAG repeat expansion of the poly Q tract in exon 10 of the *ATXN3* gene, producing toxic ataxin-3 protein that aggregates and triggers neuronal death in the cerebellum, brainstem, spinal cord, and other neural tissues. Despite advances in understanding molecular pathogenesis, effective therapeutic options remain unavailable, with current treatments limited to clinical symptom management. Therefore, there is an urgent need to develop disease-modifying therapies for SCA3.

Methods: Here, we developed a potential therapeutic strategy using a high-fidelity Cas12Max (hfCas12Max) system to target exon 10 of the *ATXN3* gene using an engineered CRISPR-Cas12i variant that we show has increased activity and specificity. A panel of guide RNAs (gRNA) targeting *ATXN3* exon 10 was screened in HEK293T cells for editing efficiency and specificity. The potential off-target sites were nominated using Cas-OFFinder and assayed in treated HEK293T cells. The optimal *ATXN3*-targeting gRNAs (g*ATXN3*) were packaged with hfCas12Max into a single AAV vector (AAVhfCas12Max-g*ATXN3*). Neonatal humanized SCA3 (84Q) transgenic mice received intracisterna magna (ICM) injection of AAVhfCas12Max-g*ATXN3* to evaluate editing efficacy in the forebrain (FB), cerebellum (CB), and brain stem (BS). The motor function in these mice was evaluated monthly in the rotarod test after ICM injection.

Results: Eighteen gRNAs targeting human *ATXN3* were designed and cloned into the hfCas12Max plasmid and transfected into HEK293T cells. *ATXN3* gRNA4 exhibited the highest editing efficiency (41.12±2.54%) in HEK293T cells. No detectable off-target editing was detected when sequencing DNA from the treated cells at the 23 nominated sites, highlighting the specificity of *ATXN3* gRNA4. In SCA3 (84Q) transgenic mice, the AAVhfCas12Max-g*ATXN3* achieved robust editing efficiencies of 74.17±3.49%, 48.33±15.17%, and 40.20±12.37% in FB, CB, and BS, respectively, at 4 weeks post ICM injection (**Fig. 1b**). Correspondingly, the mutant human Ataxin-3 protein levels were reduced to 57.5±1.1%, 62.0±15%, and 51.2±10.4% in the FB, CB, and BS, respectively, compared to PBS-treated controls (**Fig. 1c** and **1d**). Importantly, rotarod performance, a measure of motor coordination, showed significant improvement in 3-month-old and 4-month-old AAVhfCas12Max-g*ATXN3* treated SCA3 (84Q) transgenic mice compared to PBS-treated controls (**Fig. 1e**).

Conclusions: AAV-mediated delivery of hfCas12Max-g*ATXN3* demonstrates high on-target editing efficiency and specificity, effectively reducing toxic ataxin-3 protein levels and improving motor function in a preclinical model of SCA3. Our findings position hfCas12Max-based gene editing as a promising therapeutic approach for SCA3 and warrant further investigation.

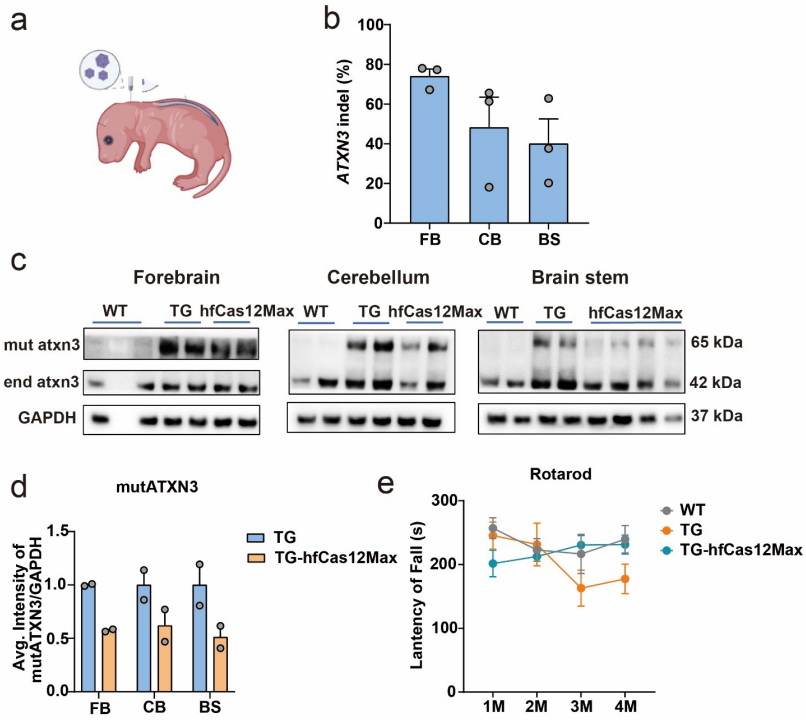

Figure 1 The edit efficiency of *ATXN3* and the motor function of the SCA3 (84Q) mice after AAV dosing.

1034 The Use of AAV2.retro to Deliver Transgenes to Both Upper and Lower Motor Neurons in the Rat for the Treatment of Amyotrophic Lateral Sclerosis

Anthony Donsante[1]*, Kelly Poth[2], Yvonne Milligan[3], Caitlin Fix[3], Ehsaas Madan[4], Nicholas Boulis[2]

Amyotrophic lateral sclerosis (ALS) is fatal disorder affecting both upper and lower motor neurons. The onset of this disease is generally between 40 and 60 years of age, and median survival from diagnosis is approximately three years. The pathophysiology of the disease is poorly understood, but it likely includes mitochondrial defects, inflammation, changes in pro- and anti-apoptotic signals, and defects in axonal transport. Experimental therapies, including gene therapy, have been evaluated for this disease. Most treatments either support motor neuron health and function or target one of the dozens of genes associated with this disease for degradation. However, efficiently treating both upper and lower motor neurons in these patients remains a challenge.

We have begun to investigate the use of an adeno-associated viral vector, AAV2.retro. This adeno-associated viral capsid was previously identified by Tervo *et al*. using an *in vivo* evolution strategy, selecting for the ability to achieve retrograde transduction in GABAertic and glutamatergic neurons when injected into the central nervous system. Since upper motor neurons are glutamatergic, injections of AAV2.retro vectors in the spinal cord should transduce both the lower motor neurons at the site of injection and the upper motor neurons projecting to that level. In healthy adult male rats, injection of an AAV2.retro vector expressing GFP into the lumbar spinal cord provided robust transduction at the site of injection. Transduced cells were also found in the cervical spinal cord. The location of these neurons suggested that they are propriospinal neurons. These neurons are involved in coordinating forelimb and hindlimb movement and project axons long distances up and down the spinal cord. In addition, GFP-positive axons were observed in the dorsal columns, particularly the gracile fasciculus, and in the pyramidal tracts, consistent with retrograde transport from the lumbar spinal cord. In the brain, substantial transduction was observed in the red nucleus and primary motor cortex, as well as in pontine nuclei.

Both ALS patients and animal models of this disease exhibit axonal transport defects that could negatively affect therapeutics based on the AAV2.retro capsid. We are currently assessing the potency of AAV2.retro vectors in the $SOD1^{G93A}$ rat model of ALS, both before and after disease onset. Spinal cord transduction in animals treated presymptomatically yielded a distribution similar to that of wild type animals. Quantitation of transduction in the brain and spinal cord for both wild type and SOD1 animals is currently ongoing. The current results suggest that AAV2.retro is a promising vector for ALS therapeutics.

1035 Exploring the Role of Inverted Terminal Repeats in AAV Vector Performance for CNS Gene Therapy

Crystal Richardson[1], Prassanna Rao[2], Andrea O'Hara[1], **Michael Karney[3]**, Sumit Kumar[3]
[1]Azenta, Burlington, MA, [2]Azenta, Burlington, [3]Genewiz From Azenta Life Sciences, South Plainfield, NJ

Diseases of the central nervous system (CNS) are difficult to treat due to the blood-brain barrier preventing many therapeutic drugs from crossing. Gene therapy using adeno-associated viruses (AAVs) offers a promising solution with the advancement of new capsids including AAV-DJ, which has been demonstrated to cross the blood-brain barrier and achieve targeted and effective expression in CNS tissues. AAVs are well suited for CNS treatments because they can achieve long-term gene expression with minimal immune response, and are ideal for conditions such as Alzheimer's, Huntington's, and Parkinson's diseases. The AAV genome consists of a transgene construct flanked by 145bp inverted terminal repeat (ITR) sequence. Previous studies have demonstrated that inverted terminal repeats (ITRs) are essential for AAV packaging; however, they are prone to mutations and deletions during bacterial propagation, leading to inconsistent experimental results. While advances in capsid engineering have led to enhanced ability for AAVs to cross the blood-brain barrier, the instability of the ITRs remains a major concern.

The impact of five common ITR mutations, which exhibited varying degrees of integrity and insert length, were evaluated. HEK293T cells were co-transfected with the transfer, Rep/Cap (serotype AAV-DJ), and helper plasmids for viral packaging. AAV-ITR Sanger sequencing verified the ITR mutations in the transfer plasmid sequence in comparison to the wild-type. Following iodixanol purification, viral titers were assessed using quantitative PCR (qPCR), and transduction efficiency was evaluated through fluorescence microscopy of a GFP marker. To further investigate the effects of these mutations, each mutation was repaired to the wild-type sequence, and the titer and fluorescence were re-evaluated. To assess brain-wide transgene expression and the impact of ITR mutations, AAVs targeting the CNS tissues were performed and evaluated using a triple-labeling immunofluorescence technique with DAPI, NeuN, and GFP to analyze AAV-mediated gene expression in the mouse brain.

The results show recombinant AAV genomes with partial or significant deletion of the 5’-ITR had reduced titers compared to wild-type; even a single base pair deletion resulted in decreased titer. This drop in viral titer was more pronounced in constructs with significant ITR deletions and larger transgene cassette cargo. A marked decrease was also noted in GFP fluorescence, which correlated to the severity of the ITR deletion and transgene size. AAV mutant constructs retained the capability to cross the blood-brain barrier, with wild-type vectors achieving the highest efficiency.

In conclusion, this study demonstrates the critical role of the 5’-ITR in the efficacy of recombinant AAV vectors. Even minor alterations, such as single base pair deletions, can significantly affect viral titers and transduction efficiency. These findings provide valuable insights into the design of AAV vectors for gene therapy applications, emphasizing the need to carefully consider ITR integrity at all stages of design and development, and transgene size to maximize therapeutic potential.

1036 Novel Noninvasive Gene Therapy for Parkinson's Disease Using Viral Encoded Single-Chain Antibody Treatment

Anne-Marie Castonguay[1], Béatrice Morin[2], Claude Gravel[2], Martin Levesque[1]
[1]Laval University, Québec, QC, [2]Université Laval, Québec

Parkinson's disease is primarily characterized by the degeneration of dopaminergic neurons from the substantia nigra of the brain. Intracellular inclusions composed mainly of phosphorylated alpha-synuclein (aSyn) are present in affected neurons and play a key role in driving cellular dysfunction and neurodegeneration. Evidence in various animal and cell models suggest that pathological aSyn can be transmitted from cell-to-cell in a prion-like manner. Blocking either the aggregation of pathological proteins or their transmission across the brain could represent effective therapeutic strategies. We generated small antibodies in the form of secreted single-chain variable fragments (scFv) that bind to aSyn. We validated the specificity of our antibodies with dot blots and ELISA and identified one scFv specific for phosphorylated aSyn, and one recognizing both phosphorylated and non-phosphorylated aSyn. We then encoded the single-chain antibodies in an AAVCap-B10 viral vector, a serotype that can cross the blood-brain barrier when injected intravenously (IV) in mice. After IV injection, we verified the expression of the antibodies in the brain with immunohistochemistry for the Myc tag expressed by the antibody fragments. To model Parkinson's disease and the spreading of aSyn pathology, we injected human pre-formed fibrils (PFF) of aSyn into the dorsal striatum of transgenic mice overexpressing human mutated aSyn (M83 mouse line). Seven days later, we administered an AAV encoding the aSyn scFvs or a control scFv. Control groups were also injected with PBS instead of PFF. We closely monitored the motor impairments arising after the injections with a clinical scoring system. Results show a strong protective function of the scFvs against motor impairments. Moreover, aSyn brain pathology was significantly reduced in mice who received the AAV-scFvs against aSyn compared to the mice who receive the control scFv. We also show that our secreted scFvs can penetrate brain cells and possibly act on intracellular aSyn. Finally, we did not observe signs of immune reaction and inflammation following the administration of our AAV-scFvs in mice. In conclusion, we developed scFvs targeting pathological aSyn and proved that, when administered as a gene therapy through a viral vector, they can modulate aSyn pathology in a mouse model of PD. Our future steps toward clinical development include the humanization of the antibodies, and the development of a brain penetrating AAV vector for efficient biodistribution in the human brain.

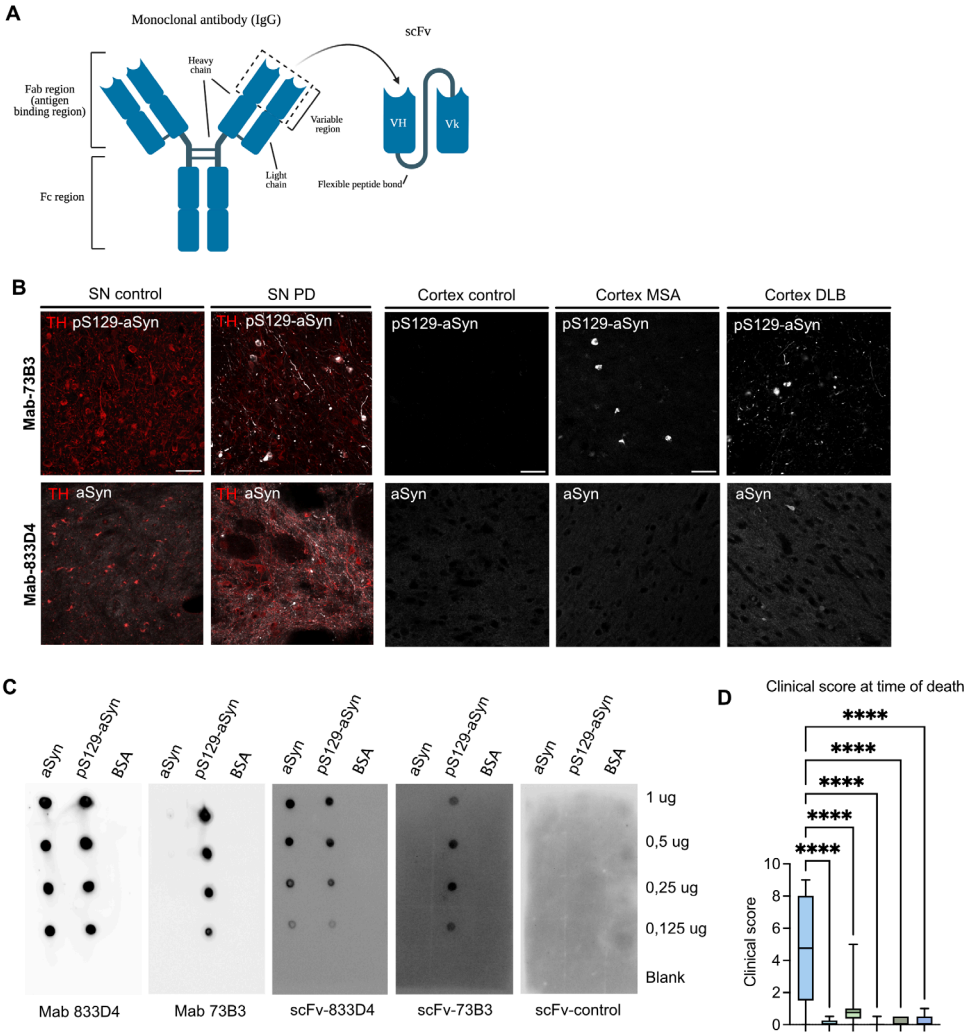

Figure 1: Single-chain variable fragments (scFvs) against alpha-synuclein were generated from murine monoclonal antibodies and show neuroprotective potential in a PD mouse model. **A)** Schematic representation of an IgG and its scFvs derivative containing the variable regions. **B)** Confocal images showing the binding of IgG 73B3 and 833D4 to pathological aSyn aggregates in PD, MSA and DLB human brain sections, in comparison to control brains. **C)** Dot blot performed on aSyn WT or pS129-aSyn monomers showing the preservation of the binding specificity of scFv 833D4 and 73B3. **D)** Clinical score at the time of sacrifice in mice that received aSyn preformed fibrils 12 weeks prior, and were treated with anti-aSyn scFvs compared to a control scFv.

1037 RSwitch Enabled Gene Therapy to Fine Tune Frataxin Expression for the Treatment of Friedrich's Ataxia

Samuel Hasson[1], Simon Xi[2], Jon Dempersmier[3], Mariam Elhawary[1], Travis Wager[1], Chris Yates[1], Ian McLachlan[1], Diane Hamann[1]

[1]Rgenta Therapeutics, Woburn, MA, [2]Rgenta Therapeutics, Inc, Woburn, MA, [3]Rgenta, Woburn, MA

Improvements in engineered AAV capsids are enabling the development of next-generation therapeutics for unmet medical needs. However, there remains a pressing need for transgene control features to improve the safety and tractability of gene therapy. Amongst advancements in transgene engineering, exogenous tunability of transgene expression has long been a sought-after technology. While methods exist, they typically rely on engineered transcription factors and repurposed pharmacology, not specific to the switching system. Rgenta has developed a

platform for imparting gene therapy vectors with regulation by orally bioavailable small molecules. These DNA-encoded elements, called RSwitches, can be selectively modulated by synthetic small molecules, called RDrugs, in a dose-dependent manner. Tailored to interact with each RSwitch, the RDrugs direct specific pre-mRNA splicing events needed for therapeutic payload production. Our collection of synthetic small molecule RDrugs is built to meet the needs of each indication with a range of pharmacokinetic properties. We have generated a variety of RSwitches and demonstrated their ability to functionally regulate transgene expression in vitro and in vivo. Gene therapy for Friedrich's Ataxia (FA) is a prime use case for exogenous regulation of transgenes. FA is an autosomal recessive disorder where expansion of GAA repeats in intron 1 of the Frataxin gene (FXN) result in loss of expression. Frataxin loss inhibits iron-sulfur (Fe-S) cluster biogenesis, leading to mitochondrial dysfunction and cell death. FA patients experience debilitating symptoms brought on by neurodegeneration and cardiomyopathy. While constitutive replacement of FXN by AAV vectors has shown promise in animal models, multiple studies have demonstrated the cardiotoxic effects of Frataxin overexpression. We, therefore, hypothesized that AAV-RSwitch control of an FXN transgene could facilitate safe and efficacious levels of gene rescue while maximizing tissue transduction coverage in the heart. Given the need for titratable Frataxin expression, we have optimized RSwitch DNA elements fused to human FXN cDNAs. This process has been aided by massively parallel sequence library screening and deep learning-driven design. Successive rounds of in vitro engineering yielded a system that displays a highly dynamic Frataxin expression, dose-responsive to a brain-penetrant RDrug molecule (Cp7). Complementation of Frataxin loss to WT levels occurs at single-digit nanomolar levels of Cp7 in cultured cells. When part of an AAV vector, the RSwitch performs similarly, providing functional Frataxin protein to transduced cells in response to Cp7. Dose-range finding studies in MCK Cre cardiac models of FA demonstrate the relationship between AAV-RSwitch-FXN vector dose, Cp7 daily oral dose, and steady-state levels of Frataxin in mouse tissues. We are now pursuing an efficacy study in MCK Cre mice to demonstrate how sustained RDrug Cp7 dosing after systemic AAV administration: 1) maintains non-toxic levels of exogenous Frataxin expressed in the mouse heart and 2) rescues the morbidity that the mice develop at ~10 weeks of age. Overall, we foresee RSwitch, with the highly drug-like RDrug molecules, will improve the safety and clinical success of gene replacement therapies for diseases such as FA. The technology could create therapeutic opportunities for a variety of gene therapy applications needing temporal control of transgene expression levels.

1038 Muscle-Mediated Klotho Secretion Outperforms Spinal Overexpression in Mitigating ALS Progression

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by the progressive degeneration of motoneurons (MNs), leading to muscle weakness, paralysis, and ultimately respiratory failure. In the $SOD1^{G93A}$ mouse model, we targeted the secreted form of α-Klotho (sKL) to skeletal muscles or the spinal cord at an early disease stage. Skeletal muscle overexpression was achieved using systemic MyoAAV delivery and the desmin promoter, while spinal cord targeting used intrathecal AAV9 delivery with the CMV promoter.

Muscle-targeted sKL therapy significantly improved motor function, delayed disease onset, and preserved muscle mass. Treated mice showed enhanced neuromuscular function, with increased compound muscle action potential (CMAP) amplitudes, larger hindlimb motor units, and preserved motor endplate innervation. Connectivity between corticospinal and spinal MNs was improved, as evidenced by preserved motor-evoked potentials (MEPs), and lifespan was extended. In contrast, spinal cord overexpression of sKL produced milder benefits, primarily in

females, where CMAPs, MEPs, and muscle mass were partially preserved. Functional improvements were observed in both sexes, but other parameters showed limited benefit in males.

To uncover the mechanisms of action in our muscle-targeted strategy, we employed RNA sequencing and proteomics on the lumbar spinal cord and gastrocnemius muscles. In muscles, sKL therapy restored pathways associated with muscle contraction and development while reducing fibrosis and atrophy. In the spinal cord, sKL enhanced synaptic activity, reduced neuroinflammation, alleviated mitochondrial dysfunction, and modulated RNA processing, proteostasis, and apoptosis, offering key insights into its protective effects.

Our results demonstrate that muscle-driven sKL delivery is more effective than spinal cord overexpression in preserving neuromuscular function and delaying ALS progression, supporting the dying-back hypothesis in this model. These findings highlight sKL's therapeutic potential and uncover mechanisms relevant to ALS and related disorders.

1039 Supraphysiological expression of SMN1 protein leads to compromised heart function improvement and cardiac thrombosis in mice

G.Gao, J.Xie. are co-corresponding authors.

Spinal muscular atrophy (SMA) is an autosomal recessive disease, which compromises the α-motor neurons located in the spinal cord, progressively leading to symmetrical muscle atrophy and weakness. SMA affects approximately 1 in 11,000 newborns and remains the leading genetic cause of infant deaths. Onasemnogene abeparvovec (Zolgensma®), a self-complementary adeno-associated virus serotype 9 (scAAV9) vector that expresses the native *SMN1* transgene is an intravenously administered gene therapy. The heart and liver had also been found to be the main target organs of Zolgensma® toxicity in pre-clinical studies. Except the liver damage, signs of cardiac damage also emerged among the most frequently adverse events reported, such as the increase in troponin I.

We previously developed a 2nd-generation SMA gene therapy expressing a codon-optimized *hSMN1* transgene driven by a promoter derived from the native *hSMN1* gene. This vector restored SMN expressions close to physiological levels in the central nervous system and other major tissues of a severe SMA mouse model. Here, we investigated the 2nd-generation vector and a benchmark vector with a design identical to Zolgensma on the heart toxicity in SMA and FVB mice.

We assessed the heart function of SMA mice received these two vectors at the dose of 3.3xE14 vg/kg at P1 by facial vein by echocardiography on day 30. Compared to healthy carriers, the benchmark vector group showed compromised ejection fraction, fractional shortening, and stroke volume, whereas mice that received the 2nd-generation vector did not show any heart function abnormalities. Premature ventricular contractions were observed in the benchmark vector-treated animals but were not observed in the 2nd-generation vector group. This data demonstrated that the benchmark vector was unable to rescue heart function in SMA mice. In contrast, the 2nd-generation vector-treated mice normalized heart function to the level comparable to healthy carriers. Notably, we detected more SMN expressions in the heart from benchmark vector-treated mice than in the 2nd-generation vector treatment on day 30. At day 90, the SMN expression in the benchmark group is ~5-fold higher than the healthy carriers, but the 2nd-generation vector treatment showed indistinguishable SMN expression to the healthy carriers in the heart. By ICV administration, the benchmark vector significantly extended the survival of SMA mice but was still less effective than the 2nd-generation vector. In the seven surviving animals (total of 16) from the benchmark group, we observed cardiac thrombosis in 3 of them but not in all eight surviving mice (total of 12) from the 2nd-generation vector group. To further illustrate the need to maintain physiological expression, we replaced the coding sequence of SMN1 with the codon-optimized sequence in the benchmark vector genome to maximize SMN1 expression. In the ICV-treated SMA and wildtype mice, the codon-optimized vector group developed left atrial

thrombosis more rapidly at a higher frequency than the benchmark group. By facial vein at P1, strikingly, all the FVB mice manifested atrial thrombosis and died in two weeks after receiving the codon-optimized vector at 1.0E+14 vg/kg, also increased with SMN protein in left atrium. These data suggest that supraphysiological SMN expressions in the heart are detrimental to cardiac function and safety.

1040 Preclinical Efficacy and Potency Assay Development of An Optimized AAV-hUPF1 Gene Therapy for Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal Dementia (FTD)

Jeroen Bastiaans[1], Ann Lettko[1], Patricia Gordon[2], Josefa Sullivan[1], Ce Feng Liu[1], T.D. Barbara Nguyen-Vu[3], Alexandria Forbes[1]
[1]MeiraGTx, New York, NY, [2]MeiraGTx, London, United Kingdom, [3]Menlo Park, CA

Amyotrophic lateral sclerosis (ALS) is a devastating progressive neurodegenerative disease that damages motor neurons in the brain and spinal cord. While the pathogenesis of ALS can result from either sporadic or familial inherited mutations, the underlying pathology in over 95% of cases is associated with dysregulation of TAR DNA-binding protein 43 (TDP-43). Here, we present the optimization and preclinical efficacy of AAV-hUPF1, a central regulator in nonsense-mediated RNA decay (NMD), in multiple ALS models. Our data and the mechanism of Up-frameshift 1 (hUPF1) action suggest that the efficacy of this therapy would be agnostic to patients' genetic background.

To improve AAV packaging and thus convey manufacturing benefits, we reduced the size of the original hUPF1 construct by 1.5kb while improving therapeutic efficacy in both in vitro and in vivo models. Using an efficient capsid for CNS delivery and a highly potent expression cassette, our therapeutic strategy is to minimize AAV dosage while maintaining a high level of expression and subsequent efficacy. The optimized AAV-hUPF1 effectively mitigated toxicity in TDP-43 and C9orf72 iNeuron models and restored the normal function of neurons derived from C9orf72 patient cell lines at a lower multiplicity of infection (MOI) than used for the original. Mechanistically, UPF1 target engagement was confirmed in transduced C9orf72 patient-derived neurons by the downregulation of known NMD targets. In a Fused in Sarcoma (FUS) mouse model of ALS, optimized AAV-hUPF1 significantly improved motor neuron survival to levels comparable to wild-type controls at approximately 36% transduction.

To further develop the AAV-hUPF1 program, we piloted different TDP-43 induced toxicity models as in vitro potency assays for manufacturing release. To induce cell death, TDP-43 was overexpressed in primary mouse neurons using AAV9 transduction, and in human SH-SY5Y cells using the doxycycline-inducible TET-ON system. While toxicity was reliably and robustly induced in the primary neuronal model, UPF1 co-expression did not result in a measurable global effect and thus did not meet the requirements for our assay development. In contrast, repeated experimentation in the stably transduced and differentiated SH-SY5Y cells showed that TET- inducible overexpression of TDP-43 caused significant toxicity in only about 50% of the cases, demonstrating that the TET-inducible system is too variable to be implemented as a reliable potency assay. After exploring gross neuronal toxicity as a strategy to establish a validated potency assay, we now aim to explore other approaches that are based on the proposed underlying mechanism of action for UPF1, including RNA homeostasis. Developing a robust potency assay is a major component in the manufacturing of clinical therapeutics and our goal towards treating ALS patients safely and effectively with AAV-hUPF1.

Collectively, the data from in vitro and in vivo studies using FUS, TDP-43, and C9orf72 models demonstrate that hUPF1 holds significant potential for treating the majority of patients with ALS and other degenerative diseases caused by TDP43 pathology such as Frontotemporal Dementia, as we continue the development of this program.

1041 AAV-mediated delivery of an intrabody targeting TDP-43 for Amyotrophic Lateral Sclerosis therapy

Paula Miranda[1], Svetlana Pasteuning-Vuhman[2], Linda Borst[3], Marina Sogorb-Gonzalez[1], Rob Haselberg[4], Roland van Dijk[4], Pavlina Konstantinova[2], Wouter Pos[5], Giulia De Sabbata[6], Sander Van Deventer[7]
[1]VectorY, Amsterdam, Noord-Holland, Netherlands, [2]VectorY Therapeutics, Amsterdam, Netherlands, [3]VectorY, Amsterdam, Zuid-Holland, Netherlands, [4]VectorY Therapeutics, Amsterdam, Noord-Holland, Netherlands, [5]VectorY Therapeutics, Amsterdam, The Netherlands, Netherlands, [6]ICGEB, Amsterdam, Netherlands, [7]Amsterdam, Netherlands

Amyotrophic lateral sclerosis (ALS) is a devastating neurodegenerative disorder characterized by progressive motor neuron degeneration, leading to muscle atrophy, and ultimately death. The vast majority of ALS cases involves the pathological mislocalization and aggregation of TAR DNA binding protein 43 (TDP-43), a key player in RNA metabolism. Loss of motor neuron nuclear TDP-43 disrupts its role splicing regulation, further disrupting the neuronal transcriptome, all contributing to ALS pathology. Therefore, targeting TDP-43 pathophysiology presents a promising avenue for therapeutic intervention. Here, we present an AAV vector encoding a novel intrabody designed to selectively target and neutralize TDP-43 aggregates while preserving TDP-43 nuclear function. We demonstrated the therapeutic efficacy of the vectorized intrabody in iPSC-derived ALS models, by showing target engagement with a reduction in TDP-43 aggregates, correction of loss-of-function of TDP-43 and ALS transcriptome, and restoring motor neuron survival. In addition, we showed that the therapeutic intrabody has preferential binding to cytoplasmatic TDP-43 in disease-relevant specimens. To enable widespread motor neuron targeting, we developed an AAV-mediated delivery ensuring efficient transduction in central nervous system regions implicated in ALS pathology. Collectively, our findings suggest that AAV-mediated intrabody delivery targeting TDP-43 is a viable therapeutic strategy for ALS and paves the way for clinical development in ALS and other TDP-43-related disorders.

1042 Preclinical Evaluation of LY-N001 in an innovative GBA1-Associated Parkinson's Disease Model

Guofang Yan[1], Xiaojing Sheng[2], Chenming Lu[2], Ruifang Liu[1], **Yixiong Chen**[3], Qing Lin[4]*

Parkinson's disease (PD), a globally prevalent neurodegenerative disease characterized by striatal dopamine (DA) deficiency and intracellular inclusions containing aggregated α-synuclein, leading to motor and cognitive impairments. Increasing evidence indicates that loss of function mutations in GCase are a significant risk factor for Parkinson's disease. GBA1 related PD (GBA1-PD) typically presents at an earlier age than idiopathic PD, with clinical symptoms progressing more rapidly, including motor dysfunction and cognitive decline. This highlights the urgent need for therapeutic interventions aimed at restoring GCase levels in the brain to slow or even halt the progression of GBA1-PD. Numerous transgenic GBA1 related mouse models have been employed to study GBA1-PD, however, these models have notable limitations in replicating human clinical symptoms. Most models exhibited GCase deficiency, substrate accumulation, some with slightly a-synuclein deposition, while absence of neurodegeneration and behavior abnormalities.

Acknowledging the complexity and heterogeneous characteristics of PD, we developed an innovative compound rat model that combines both GBA1 genetic deficiency and a low-dose 6-hydroxydopamine (6-OHDA)-induced chemical lesion. This model exhibited diminished GCase activity in the striatum and substantia nigra, along with a more pronounced degree of degeneration of tyrosine hydroxylase (TH)-positive neurons compared to the 6-OHDA model in wild type (WT) rats, closely mirroring the progression and severity of GBA1-PD. LY-N001, an innovative adeno-associated virus (AAV9)-based gene therapy, was designed to constitutively express a codon-optimized GBA1 gene, aiming to rectify the intrinsic genetic defect causing lysosomal dysfunction and potentially altering the disease's trajectory. Administration of LY-N001 in 6-OHDA *GBA1*$^{M1/M1}$ rat model resulted in widespread distribution of GCase enzyme activity throughout cerebral regions, including cortex, striatum, hippocampus and

substantia nigra. Immunohistochemistry results further affirmed the distribution of GCase in CNS. Notably, LY-N001 effectively mitigated the degeneration of tyrosine hydroxylase (TH)-positive neurons in the striatum and substantia nigra, accompanied by functional and behavioral improvement. Additionally, an 8-week Non-GLP toxicology study in Cynomolgus monkeys was conducted via intra cisterna magna (ICM) injection and preliminary results indicated the dose-dependent GCase biodistribution in CNS and endorsed LY-N001's safety profile, exhibiting exceptional tolerability and absence of toxicity. In summary, the extensive preclinical data in both rodent model and NHPs demonstrate the therapeutic potential of LY-N001 for GBA-PD, potentially ushering in a new era in the treatment of this complicated neurodegenerative disease.

1043 Characterisation of a dnajc6^{R857G} Knock-in Mouse Model of PARK19 Towards Gene Therapy Development

Parkinson's disease (PD) is the second most common neurodegenerative disorder with up to 10% of PD with genetic aetiology, including PARK19/ *DNAJC6.* The DNAJC6 gene encodes auxilin, a neuronal cochaperone required for uncoating clathrin-coated vesicles during clathrin-mediated endocytosis (CME). It is crucial for synaptic vesicle recycling and neurotransmission, and bi-allelic loss of function mutations in the *gene* result in juvenile Parkinsonism or early onset PD. We previously reported a paediatric cohort of individuals with *DNAJC6* related juvenile parkinsonism with rapidly progressive parkinsonism, and broader neurological symptoms including cognitive decline and epilepsy. There is a major clinical need to develop novel therapies for this disorder, as no disease-modifying treatments exist. Our collaborators recently reported generation of *DNAJC6* patient derived induced pluripotent stem cell (hiPSC)-derived midbrain dopaminergic (mDA) neuronal model and demonstrated proof of principle of *in vitro* lentiviral gene therapy for this disorder (Abela et al. Brain 2024).

To progress gene therapy approach for this disease we have characterised the dnajc6^{R857G} knock-in mouse model, performing a comprehensive behavioural battery, including open field locomotor activity, vertical pole descent, rotarod, and neuroscore assessments. At six months of age, these mice displayed significant motor coordination deficits, impaired balance, and seizures recapitulating human disease phenotype. Additionally, brain immunohistochemistry showed dopaminergic neuronal degeneration in the *substantia nigra*. These findings pave the way for *in vivo* preclinical studies aimed at developing novel genetic therapeutic strategies to address synaptic dysfunction in juvenile and early-onset PD.

1044 Targeted Delivery to Putamen via MRI-Guided Surgery: Nonhuman Primate versus Göttingen minipig®

Erin Slosarek[1], James Nelson[2], Rick Haas[1], Sarah Newman[1], Jay Herman[3], Brian McIntosh[3]
[1]Labcorp Drug Development, Madison, WI, [2]Labcorp, Madison, WI, [3]Labcorp Drug Development - Madison, WI, Madison, WI

Introduction: Recent advances in clinical approaches to delivering targeted gene or cell therapies to the brain using MRI-guidance have necessitated in vivo safety studies applying the similar procedures used in the clinical studies. While the standard preclinical animal model, to date, has been the nonhuman primate (NHP), the Göttingen minipig® has emerged as an important human-relevant preclinical model for brain and central nervous system (CNS) targeted gene or cell therapies. The minipig is a more human-relevant model than rodents while balancing the monetary cost and debate sometimes associated with using NHPs. The NHP and minipig brain are similar to the human brain developmentally, anatomically, and neurochemically and represent valuable models for therapies intended to target the CNS. Neurodegeneration in the putamen as indicated in Parkinson's and Huntington's disease requires precise treatment for gene replacement or disease reversibility. By targeting current surgical approaches to disease-specific parenchymal structures, one can minimize broader distribution and focus the therapy to the intended area.

Methods: In this work, we used magnetic resonance imaging (MRI)-guided Clearpoint catheter-based infusion to directly target parenchymal structures, including the putamen, in NHPs and Göttingen minipigs®. A 1.5T MRI scanner in conjunction with ClearPoint® Navigation software was used to scan the brain and plan the bilateral trajectories to the putamen. Clearpoint® catheter based infusion of 2% Gadoteridol and MRI scanning during infusion confirmed the correct trajectory and dosing of the targeted structure. After surgery, animals were taken to necropsy where 4 mm coronal sections of the brain were examined for correct target and dose placement.

Conclusions: The surgical procedures were well tolerated with no neurological or clinical impairments during the surgical procedures. Together, these data offer a path forward when testing the delivery of cells or cell specific gene therapies directly to the putamen and can provide a clinically relevant method for targeted brain delivery with accuracy in NHPs and Göttingen minipig®.

1045 Next-Generation AAV-Based Gene Therapy for Spinal Muscular Atrophy: Safety and Efficacy of EXG001-307 in Clinical Trials

Zhenhua Wu[1], Chunjuan Song[2], Wenhui Li[3], Xiaojing Li[4], Xiaomei Zhu[3], Hui Li[3], Meijia Yang[2], Wenshu Yang[4], Rui Ji[2], Kuan Lu[2], Yanna Zhang[2], Lijun Wang[5], Guo-Jie Ye[6], Yi Wang[3]
[1]Exegenesis Bio Inc., Lansdale, PA, [2]Exegenesis Bio Inc., Wayne, PA, [3]Children's Hospital of Fudan University, Shanghai, China, [4]Exegenesis Bio, Wayne, PA, [5]CoJourney, Lower Gwynedd, PA, [6]Exegenesis Bio Inc, Gainesville, FL

***Introduction*:** Gene therapy has transformed the treatment landscape for spinal muscular atrophy (SMA). Onasemnogene abeparvovec (Zolgensma), approved by the FDA in 2019, offers significant clinical benefits but is associated with off-target toxicities, including liver failure, as highlighted in its black box warning. This underscores the need for next-generation therapies with improved tissue-specific transgene expression and reduced toxicity.

***Methods*:** We developed EXG001-307, an AAV-based gene therapy engineered to enhance neuronal transgene expression. A Phase 1/2 open-label, multicenter, single-arm, dose-escalation clinical trial was initiated to evaluate its safety and efficacy in Type 1 SMA patients.

***Results*:** Thirteen patients were enrolled across two dose cohorts (3 patients in Low-dose Cohort [1.1×10^{14} vg/kg] and 10 patients in High-dose Cohort [1.5×10^{14} vg/kg]. Clinical efficacy was compelling, with all patients demonstrating rapid and sustained improvements in motor function: (1) CHOP-INTEND scores exceeded 40 in 100% of patients in the High-dose cohort within 5 months post-dosage; (2) 44% of patients in the High-dose cohort with over two months of follow-up were able to sit independently, achieving the primary endpoint; (3) one patient also demonstrated the ability to stand with assistance at 16.6 months of age. Notably, only one patient in the High-dose cohort has reached 18 months of age so far, and we anticipate additional developmental milestones as more patients reach this age. Two patients in High-dose Cohort experienced thrombotic microangiopathy (TMA), which resolved following treatment with *eculizumab* (anti-C5 antibody). Notably, both patients presented with concurrent infections within three days of AAV administration, involving either encapsulated bacteria or coronavirus. These infections have been recognized as potential triggers for TMA, suggesting a plausible association between the timing of the infections and the onset of TMA in the context of AAV administration. Most of other treatment-related adverse events (AEs) were mild, transient, and resolved without intervention.

***Conclusions*:** EXG001-307 demonstrated remarkable efficacy, enabling Type 1 SMA patients to achieve critical motor milestones, such as sitting and standing, which are unattainable in the natural history of the disease. This novel therapy offers a promising, targeted approach to SMA treatment, advancing the standard of care for patients with this devastating condition.

1046 Nonclinical Evaluation of AAV Gene Therapy EXG001-307 for Spinal Muscular Atrophy

Chunjuan Song[1], Qingzeng Wang[1], Xin Xin[2], Wei Hu[3], Zhongwan Li[1], Jiayi Xu[1], Zhucheng Lin[1], Ying Zhou[1], Shuyuan Chen[4], Ye Zhang[1], Junhui Li[5], Lijun Wang[6], Zhenhua Wu[7], Guo-Jie Ye[8]
[1]Exegenesis Bio Inc., Wayne, PA, [2]Exegenesis Bio Inc., Lower Gwynedd, PA, [3]Hangzhou, Zhejiang Province, China, [4]Exegenesis Bio Inc, Hangzhou, Zhejiang, China, [5]Cojourney, Wayne, PA, [6]CoJourney, Lower Gwynedd, PA, [7]Exegenesis Bio Inc., Lansdale, PA, [8]Exegenesis Bio Inc, Gainesville, FL

***Introduction*:** Spinal muscular atrophy (SMA) is a rare genetic disorder and the leading inherited cause of mortality in children under two years old. While the current gene therapy has demonstrated significant benefits, safety concerns related to off-target effects highlight the need for advanced, tissue-specific therapies. EXG001-307 is being developed to address these challenges by providing enhanced precision, efficacy, and safety.

Methods: EXG001-307, an AAV-based gene therapy, was administered directly into the cerebrospinal fluid (CSF) in preclinical animals. Efficacy and dose range-finding studies in SMA mice (SMNΔ7) were conducted to establish therapeutic potential. A pilot safety study was performed in wild-type rats, followed by a 6-month GLP-compliant toxicology study in nonhuman primates (cynomolgus macaques) to evaluate safety, toxicokinetics, biodistribution, shedding, and immunogenicity.

***Results*:** Preclinical studies demonstrated exceptional efficacy and a favorable safety profile for EXG001-307. SMA mice treated with the highest dose (2×10^{11} vg/animal) exhibited a median survival of 373 days, with a maximum survival of 501 days, compared to a maximum survival of 17 days in vehicle-treated controls. Biodistribution studies revealed robust AAV genome presence and transgene expression in the central nervous system (CNS) while minimizing expression in the liver and heart, resulting in an improved therapeutic profile. GLP toxicology studies in cynomolgus macaques confirmed safety and tolerability at all tested doses (1×10^{13} vg and 3×10^{13} vg/animal).

***Conclusion*:** These findings strongly support the clinical development of EXG001-307 for intrathecal administration in SMA patients. This approach has the potential to treat all SMA subtypes across various ages while addressing critical limitations of existing therapies. Regulatory communication with the FDA has been initiated, and IND submission is targeted for June 2025.

1047 Development of Tissue Engineered Tregs for the Treatment of Ischemic Stroke and Neurodegenerative Diseases

**Corresponding Author*

Stroke represents a significant global health burden, ranking a leading cause of disability and death with a staggering prevalence of nearly a million individuals affected annually in the United States alone. Current reperfusion therapies used for stroke treatment, provide life-saving treatment but fail to address neuro-repair, therefore offering little promise for reducing the burden of long-term disability often associated with stroke patients. Regulatory T cells (Tregs) play a central role in establishing and maintaining immune tolerance, with more recent discoveries suggesting a subset of these cells, dubbed “Tissue Tregs”, are additionally involved in orchestrating tissue homeostasis, repair and regeneration. Tissue Tregs, enriched in tissues following injury but rare in circulation, have been shown to play a critical role for controlling neuroinflammation and promoting neurogenesis following injury. We report the generation of engineered Tissue Tregs (Tissue EngTregs) using a gene editing approach from bulk CD4+ T cells resulting in the stable expression of FOXP3, a chemically inducible signaling complex providing tunable IL-2 signaling in the edited cells, and an alarmin responsive transgene imparting tissue Treg-like phenotype.

The resulting engineered cells displayed a robust Treg phenotype as measured by the expression of key Treg-associated proteins including FoxP3, CD25, CD39, HLA-DR, TNFRII, and increased suppressive ability relative to control mock-engineered cells. Tissue EngTregs also upregulated key chemokine receptors required for homing and anchoring to inflamed tissue (including CCR4, CCR5, and CCR8). When exposed to an acute inflammatory cytokine milieu, tissue EngTregs facilitated sequestration of inflammatory cytokines (e.g. TNFα, IL-2, IL-4, IL-33) in vitro. Finally, Tissue EngTregs can uniquely express neuro-repair associated growth factors such as Osteopontin, an important biomarker of stroke known to improve BBB function and promote microglia mediated white matter repair in models of ischemic stroke. To validate the off-the-shelf efficacy of this approach, we used surrogate allogeneic polyclonal murine Engineered Tregs (mEngTreg) in the transient middle cerebral artery occlusion (tMCAO) mouse model of ischemic stroke. Briefly, mEngTregs were generated by Cas-9 mediated editing of MND in the Foxp3 locus of C57BL/6 (autologous) or CB6F1 (allogeneic) CD4 splenocytes and administered IV to tMCAO mice. tMCAO mice treated with autologous or allogeneic mEngTregs but not disease controls, showed enhanced motor skills and sensory function as assessed by multiple readouts including accelerated rotarod, foot fault and adhesive removal tests. Impressively, allogeneic Tissue mEngTreg treated mice showed improvements in key learning and memory readouts at four to five weeks after administration of allogeneic cells and injury onset as assessed by activity in the Morris Water Maze and passive avoidance tests. Finally, Tissue mEngTregs showed injury specific engraftment as they were enriched only in the injured segment of the brain but not in the contralateral hemisphere or other uninjured tissue. Altogether, the ability of mEngTregs to ameliorate disease as measured by key translatable biomarkers supports the potential for developing a potent off-the-shelf allogeneic engineered Treg cellular therapy for ischemic stroke with potential efficacy in additional neuroinflammatory and neurodegenerative indications.

1048 Development of deficits in attention and cognitive functions in Spinal Muscular Atrophy mouse model with non-physiological restoration of SMN1 transgene expression

Luis Labrador[1], Zhenting Zhang[1], Xiaohong Wang[1], Erin Rath[1], Junping Zhang[2], Weidong Xiao[3], Dao Pan[1]*
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Indiana University, Indianapolis, IN
**Corresponding Author*

Spinal muscular atrophy (SMA) is a genetic neuromuscular disorder characterized by the degeneration of alpha-motor neurons, primarily caused by the loss of functional survival motor neuron gene 1 (SMN1) and retention of SMN2. While the FDA-approved gene therapy using adeno-associated virus vector (AAV) has marked a significant advancement in SMA treatment, concerns persist regarding potential toxicities and phenotype alternations with long-term benefits still to be seen. This study investigates the therapeutic potentials of neuromuscular, cognitive, and mental functions of a novel AAV vector (cceAAV) in a humanized SMA mouse model. We tested various doses and vector designs for profiles on hSMN1 expression, survival, and body weight, as well as behavioral assessments for motor function, coordination, locomotor activity, gait patterns, and cognitive and attention-/anxiety-like behaviors. A dose-dependent increase of therapeutic benefits was observed, reaching the highest at 1x1011 vg/g for cceAAV9 with a lifespan of 2.5-fold of untreated SMA, a level comparable to parallel controls treated with conventional self-complimentary vector (scAAV9) at A the same dose. Interestingly, when separating treated SMA mice into short ($/_S$, lifespan<6 weeks) and long-survivor groups ($/_L$), all AAV-treated SMA groups, except for SMA SC$/_S$, exhibited normalized motor functions like heterozygous littermates (Δ7Het) at Day 14 of age in behavioral tests for surface righting reflex, negative geotaxis test and hind-limb posture. However, only the SMA CCE$/_L$ group showed horizontal activities comparable to normal controls on Day 16 of age in the open-field test. Such normalized locomotor activities were also observed in the SMA CCE$/_L$ group but not in SMA SC$/_L$ mice at 2 months, with significantly fewer rearing activities. Markedly, all SMA mice treated with either vector displayed a complete loss of marble burying reflex at 4 weeks of age when normal or significantly higher horizontal mobilities were detected compared to Het controls. Such abnormal behaviors indicated the possible involvement of attention and anxiety deficits in AAV-treated SMA. Moreover, unlike normal controls exhibiting habituation to the environment with a 50% reduction of horizontal activities in the 3rd trial during the repeated open-field tests, the AAV9-treated SMA mice failed to habituate with only a 7% reduction, suggesting cognitive abnormalities in treated mice. Notably, such abnormalities in non-motor functions were not detected in age-matched normal littermates injected with the same dose of AAV vectors. Investigations are underway to determine potential disfunctions/dysregulations in the cerebrum of AAV-treated SMA mice. The data not only presents defects of neuropsychiatric and cognitive

functions in outlived SMA mice after AAV gene therapy but also reveals novel neurological phenotypes with undefined pathogenesis that might uniquely affect the outcomes and quality of life for treated SMA patients.

1049 Chemogenetic silencing of hyperexcitable neurons demonstrates sustained pain relief in a preclinical model of lumbosacral radiculopathy

Rachel Eclov[1], Andrea Pappas[2], Gregory Stewart[3], Michele Stone[4]
[1]Kriya Therapeutics, Morrisville, NC, [2]Kriya Therapeutics, Redwood City, CA, [3]Alchemy Neuroscience, Chanhassen, MN, [4]NA, Morrisville, North Carolina

Lumbosacral Radiculopathy (LSR) is a chronic pain condition that affects 3-5% of the US population and results from compression or irritation of lumbar nerve roots leading to neuropathic back pain along with sensory and motor dysfunction. Treatments, including anti-inflammatory drugs, physical therapy, and epidural steroid injections typically fail to provide pain relief, leading to invasive surgical intervention or nerve ablation as final options which often yield variable and transient results.

A novel therapeutic approach to address the unmet medical need in LSR and potentially other chronic pain indications is through the application of chemogenetics. Using AAV, a chimeric receptor/ion channel can be introduced into target sensory neurons designed to alter membrane potential and reduce overactive firing associated with pain following treatment with a high affinity receptor ligand. The efficacy of AAV carrying a modified nicotinic α7 receptor coupled to a glycine receptor (AAV.m-α7-GlyR) was evaluated in a rat peripheral neuropathic pain model of LSR. AAV.m-α7-GlyR is designed to drive expression of a glycine channel that is activated by the FDA approved, high affinity, nicotinic agonist drug varenicline (VT). AAV.m-α7-GlyR + VT is expected to decrease lumbar nerve root hyperexcitability following focal administration to dorsal root ganglia (DRGs) representing a potential new and durable treatment option for chronic pain.

The preclinical efficacy of AAV.m-α7-GlyR + VT was evaluated in the chronic constriction injury (CCI) rat model of neuropathic pain. Nerve ligation surgeries resulted in mechanical allodynia as measured by a reduction in Paw Withdrawal Threshold (PWT). Three to four weeks prior to ligation surgery, AAV.m-α7-GlyR was administered using a transforaminal epidural (TFE) administration at doses ranging from 1E9 to 1E10 vg/animal. Efficacy was measured using von Frey filament assays to determine PWT between 2 and 8 weeks after model induction. Animals were divided into three treatment groups: AAV + VT (active gene therapy); AAV without VT (inactive gene therapy); and vehicle + VT (control). PWT was measured at baseline and 1 to 24 hours post VT treatment (0.05 to 0.1 mg/kg, PO).

Animals treated with AAV.m-α7-GlyR + VT demonstrated significant improvement in mechanical hypersensitivity. PWT at baseline were between 2 and 4 g, which increased to 6 to 10 g between 1 to 6 hours post-VT ($P < 0.01$); PWT returned to near baseline levels within 24 hours. This efficacious effect of AAV.m-α7-GlyR + VT was sustained throughout the study duration. Neither AAV.m-α7-GlyR alone nor VT alone demonstrated significant changes in PWT. There were no surgery or treatment related changes in PWT measured on the contralateral side. Analysis of DRGs showed dose-dependent vector DNA and transgene mRNA expression, with the highest expression observed in targeted DRG neurons that correlated with efficacy. These results support further development of AAV.m-α7-GlyR + VT as a novel therapeutic approach for LSR and other chronic pain conditions.

1050 AAV9-h*PLA2G6* Gene Therapy Improves Survival in a Preclinical Mouse Model of Infantile Neuroaxonal Dystrophy

Jennifer SanMiguel[1], Ashley Paris[1], **Neil Hackett**[2], Julia Glassman[1], Leena Panwala[3], Amanda Hope[4], Cathleen Lutz[1]
[1]The Jackson Laboratory, Bar Harbor, ME, [2]Neil Hackett Consulting, New York, NY, [3]Fairfield, NJ, [4]INADcure Foundation, Fairfield, NJ

Infantile neuroaxonal dystrophy (INAD) is a rare neurodegenerative disorder affecting approximately 5,000 children globally. Pathology arises from autosomal recessive loss-of-function variants in the *PLA2G6* gene, leading to a rapid loss of vision, motor, and cognitive function. The disease is severe, with children not surviving beyond ten years of age. Currently, no approved treatment exists, highlighting the urgent need for effective therapies. As such, the primary goal of this work is to develop a gene therapy intervention for INAD using adeno-associated virus serotype 9 (AAV9) mediated delivery into cerebrospinal fluid. Our preclinical studies use the B6.C3-Pla2g6^{m1J}/CxRwb mouse model (mutant *Pla2g6* mouse) of INAD, which exhibits a severe loss-of-function allele of *Pla2g6*. Like INAD patients, mutant mice develop phenotypes that progressively worsen including tremor, body weight loss, unstable gait, loss of righting ability, histopathological findings in the central nervous system, and most notably, a significantly shortened lifespan. We compared neonatal intracerebroventricular delivery of an AAV9 vector expressing the full-length human isoform of *PLA2G6* driven by either the ubiquitously expressed EF1α- or the neuronal-specific SYN1 promoter. mRNA expression levels were measured by qRT-PCR in both spinal cord and brain of mice receiving either vector. In the brain, homozygous *Pla2g6* mutant mice had approximately 2% *Pla2g6* mRNA compared to wild-type controls. Human *PLA2G6* expression ranged from 4 - 38 fold higher than endogenous wild-type mouse expression, whereas spinal cord expression ranged from 0.07 - 1.24 fold of wild-type expression. There was a strong sex-dependent difference in median survival between male (17 weeks) and female mice (28 weeks) in the vehicle-treated homozygous mice cohorts ($p < 0.01$). AAV9-EF1α-hPLA2G6 treatment extended median survival to 23 weeks for homozygous males and 30 weeks for homozygous females ($p > 0.05$ in males and $p < 0.05$ compared to vehicle-treated homozygotes). However, expression from the SYN1 promoter further extended survival to a median of 25 weeks in male mice and 35 weeks in female mice (both $p < 0.05$ compared to EF1α promoter). Nevertheless, SYN1-mediated expression of membrane-bound PLA2G6 was not sufficient to completely restore survival or motor defects in homozygous *Pla2g6* mice. We conclude that the central nervous system delivery of AAV9 vectors expressing the membrane-bound isoform of PLA2G6, from either a neuron-specific or a ubiquitous promoter, provides a credible candidate for preclinical development and have commenced dose dependency and toxicology studies towards this goal.

1051 Human patient-specific FOXG1 syndrome mouse model reveals roles of protein homeostasis and neuroinflammation in neurodevelopmental disorder

Neurodevelopmental disorders (NDDs) are characterized by disrupted brain development, leading to cognitive, behavioral, and neurological impairments. FOXG1 syndrome (FS), caused by heterozygous mutations in the *FOXG1* gene, exemplifies a severe monogenic NDD. To investigate FS pathogenesis, we generated a patient-specific W300X mouse model carrying a truncation mutation. Our findings reveal that the truncated FOXG1 protein is more stable and almost exclusively nuclear-localized relative to the full-length protein, suggesting potential underlying mechanisms for its pathogenic effects. W300X-heterozygous (W300X-Het) mice exhibited profound dentate gyrus (DG) abnormalities, including disrupted neurogenesis, impaired granule cell migration, and altered dendritic morphology. Transcriptomic analyses identified widespread dysregulation in synaptic and protein homeostasis pathways, highlighting impaired ribosomal biogenesis, translational machinery, and proteostasis. The disruption of the FOXG1-MYCN pathway, critical for robust protein synthesis required in neural stem cell (NSC) division, synaptogenesis, and synaptic plasticity, emerged as a key mechanism underlying these defects. Furthermore, microglial activation and inflammation were markedly increased in the DG, contributing to a pro-inflammatory environment that exacerbates neurogenic and structural deficits. Mirroring hippocampal dysfunction in FS patients,

W300X-Het mice exhibited significant spatial learning and memory impairments. This study highlights disrupted protein homeostasis and neuroinflammation as central mediators of FS pathogenesis, providing a framework for developing therapeutic strategies targeting these pathways.

1052 Amsterdam Oncology and Neuroscience Research: ADORE is breaking barriers in therapy and diagnostics research in the Netherlands

Mark Mizee, Amsterdam UMC, Amsterdam, Noord-Holland, Netherlands

ADORE is a revolutionary initiative embedded in the Netherlands' largest academic hospital, Amsterdam UMC. Our unique approach has a clear mission: by fostering collaboration between oncology and neurology researchers, we aim to accelerate progress in the fight against cancer and neurological diseases. This requires us to think and act beyond conventional boundaries. Our leading clinicians, cancer researchers and neuroscientists, both from the Netherlands and abroad, collaborate in this research center to unravel the most pressing questions in cancer and neurological diseases. The goal is to enable earlier diagnoses, develop better and more effective personalized treatments, and reduce the risk of cancer and neurological diseases.

To enable our more than 2000 scientists to reach this goal, ADORE utilizes both public and private funding and has realized a state-of-the-art research center in Amsterdam, housing shared labs, infrastructure, and workspaces. Combining existing and new infrastructure and established expertise, 7 core focus areas are currently in development, with a focus on next generation modalities like cell and gene therapy:

Bioanking
Proteomics and Genomics
Total Body PET-CT
Clinical Trial Unit
Immuno- and cellular therapy
AI and Biocomputation
Target and Drug discovery

Within these core focus areas, an ever-evolving group of investigators will determine allocation of project and infrastructure funds, initiate interdisciplinary research initiatives, and utilize their network for public-private partnerships. Besides enabling our researchers to develop novel therapies and diagnostics, a dedicated team of business developers is actively pursuing worldwide research collaborations with biotech and pharma. Our aim is to drive breakthroughs needed to improve patient care, both now and in the future, at an accelerated pace.

1053 Characterization of a SOD1 Rat Model of ALS using Behavior, Electrophysiology, and Biomarkers: An Ideal Model to Test Novel Gene and Cell Therapies

Alexis Zajicek[1], Brian Haner[1], Melville Osborne[1], Moriah Jacobson[2]*, Laura Griffin[2], Daniel Havas[3], Afshin Ghavami[1], Michael Carr[2], **Taleen Hanania***
[1]Psychogenics, Paramus, NJ, [2]Taconic Biosciences, Rensselaer, NY, [3]Psychogenics, St. Radegund, Steiermark, Austria
**Corresponding Author*

Amyotrophic lateral sclerosis (ALS) is a fatal neurological disorder characterized by progressive motor neuron degeneration resulting in muscle weakness, paralysis, and eventually death. Superoxide dismutase 1 (SOD1) gene mutations are associated with familial and sporadic forms of ALS. In collaboration with Taconic Biosciences, PsychoGenics characterized a SOD1 G93A overexpressing (NTac:SD-Tg(SOD1G93A)L26H) transgenic rat model of ALS. A total of 30 wildtype (WT) and 30 transgenic SOD1 mixed-sex rats (15 per sex in each group) were obtained at 12 weeks of age, and survival was measured up to 38 weeks of age. Body weight (BW) was measured weekly, and phenotypical characterization began at 14 weeks of age. Locomotor activity was assessed by open field,

grip strength, rotarod, and gait was assessed using PsychoGenic's automated platform, NeuroCube®. Neuromuscular responses were assessed by EMG. Additional biomarker analysis was performed at necropsy.

SOD1 rats exhibited a progressive decrease in BW and hindlimb grip strength starting at 20-22 weeks of age in both males and females, whereas decreased locomotor and rearing activities occurred at 29 weeks of age, only in males. Deficits in rotarod performance were also seen in the SOD1 rats starting at 22 weeks of age, clearly manifesting by 25 weeks. In general, behavioral deficits were more robust in male SOD1 rats compared to female rats, and female rats survived longer than male rats. NeuroCube® analysis showed a clear age-dependent discrimination of gait features between WT and SOD1 rats. Some of the gait changes seen in SOD1 rats were step length, stance and stride duration, and average speed. Assessment of compound muscle action potential (CMAP) found that starting at 24 weeks of age, onset latency, which corresponds to the time from initiation of nerve stimulus to response, was increased in SOD1 rats. Peak amplitude and neuromuscular conduction velocity were reduced in SOD1 rats compared to WT rats starting at 24 weeks of age.

Analysis of cerebrospinal fluid (CSF) and plasma showed an increase of Neurofilament light (NFL) and the inflammatory marker IL-6, in the plasma and CSF of SOD1 rats. Immunohistochemistry analysis showed significant astrocyte (GFAP+)- and microgliosis (Iba1+) accompanying pFTAA positive SOD1 aggregate load in the spinal cord and brain stem. Additional histological marker analysis of brain and spinal cord are ongoing (ChAT, SOD1, NeuN markers). Together, these results suggest that the SOD1G93A transgenic rat model can be used for screening novel therapeutics, such as gene and cell therapies, for ALS treatment.

1054 Morc2a Variants Cause Hydroxyl Radical-Mediated Neuropathy and Are Rescued by Restoring GHKL ATPase

Hye Yoon Chung[1], **Geon Seong Lee[2]**, Soo Hyun Nam[3], Jeong Hyeon Lee[4], Jeong Pil Han[5], Sumin Song[6], Gap-Don Kim[6], Choonkyun Jung[6], Do Young Hyeon[7], Daehee Hwang[7], Byung-Ok Choi[3]*, Su Cheong Yeom[8]*

**Corresponding Author*

Mutations in the Microrchidia CW-type zinc finger 2 (MORC2) GHKL ATPase module cause a various of neuropathies, however, the aetiology and therapeutic strategy are not understood. Previously, we reported that the Morc2a p.S87L mouse exhibited neuropathy through DNA damage accumulation. In this study, we investigated the pathological pathway using Morc2a p.S87L mouse embryonic fibroblasts and human fibroblasts in MORC2 p.R252W. We revealed that Morc2a p.S87L causes a protein synthesis defect, resulting in the loss of function of Morc2a and high hydroxyl radical levels. We considered the Morc2a GHKL ATPase domain as a therapeutic target because it complements hydroxyl radical level. We used the adeno-associated virus (AAV)-PHP.eB, to express Morc2a or Morc2a GHKL ATPase domain protein *in vivo*. Notably, AAV gene therapy ameliorated neuropathy in Morc2a p.S87L mouse. Loss of function in Morc2a p.S87L were also noted in human MORC2 p.S87L or p.R252W variants, indicating the correlation between mouse and human pathogenesis. In summary, this study demonstrates that the Morc2a p.S87L variant causes hydroxyl radical-mediated neuropathy, which can be rescued through AAV-based gene therapy.

1055 A humanized *Atl1* mouse model for Spastic Paraplegia 3A exhibits accelerated clinical phenotypes in a *Reep1* KO background.

Matthew Simon[1], **Ana Paula Segantine Dornellas[1]**, Xue-Jun Li[2], Stephen Murray[1], Craig Blackstone[3], Cathleen Lutz[1]

Introduction: Hereditary spastic paraplegias (HSPs) encompass a diverse group of rare diseases hallmarked by a progressive spasticity and weakness in the lower limbs. These disorders can arise from genetic mutations in a variety of different genes and cellular pathways. Mutations in the gene Atlastin-1 (Atl1) gives rise to spastic paraplegia 3A (SPG3A), an autosomal dominantly inherited disease accounting for about 10% of hereditary spastic paraplegia cases. *Atl1* functions in the fusion of smooth endoplasmic reticulum (ER) tubules at three-way junctions, which plays a vital role in cellular trafficking and communication. Mutations in *Atl1* fail to properly distribute the tubular ER, which severely impacts larger cell types. In the case of SPG3A, the long corticospinal axons of the central nervous system are unable to operate effectively due to a disrupted ER network failing to support the full length of the axons.

Methods: Mouse models for human diseases have played a pivotal role in the development of new treatments. A major hurdle for developing new mouse models is phenocopying the human disease in a nonhuman organism. In the case of *Atl1*, mutant mice develop a progressive loss of hindlimb function, albeit at a much slower rate compared to the developmental timeline of the disease in humans. One way to overcome delayed onsets in mouse models is to compound the defective pathway with a sensitizing genetic background or mutation. Zhu, *et al* demonstrated this approach by crossing a mouse pathogenic *Atl1* mutation into a *Reep1* KO background, resulting in paraplegia onset occurring within a few weeks compared to several months in the single mutant. Reep1 binds Atl1 and also functions in shaping the tubular ER network, and its dysfunction similarly produces a human HSP, SPG31. By generating a mouse model that contains the human exon harboring the offending SPG3A mutation, insights gained from mouse studies are much more translatable to the clinic. Here, we employ a humanization strategy to introduce the human genetic sequence, along with a severe pathogenic p.M408T mutation, into a mouse model. We then use the mutational load of *Reep1* KO to accelerate the disease onset. Using the human mutation to establish and then correct the disease state offers fewer regulatory hurdles when moving treatments into the clinic.

Results: Here, we demonstrate that a humanized *Atl1* mouse model harboring the p.M408T patient mutation produces the SPG3A phenotypes previously seen in the mouse *Atl1* mutant in a *Reep1 KO* background (B6.Cg-Reep1$^{Gt(OST398247)Tigm}$; Atl1^{em4Lutzy}, referred to as Reep1 KO; Atl1 hM408T). Significant decline in several phenotypes, including progressive loss of rotarod performance, hindlimb grip strength, and limb clasping, recapitulate the disease presentation in humans. Characterization of this mouse has also revealed an additional clinical phenotype, in the form of prominently reduced compound muscle action potentials (CMAPs).

Conclusions: Taken together, these readouts validate the Reep1 KO; Atl1 hM408T model as a functional platform for SPG3A study and therapeutic testing.

1056 A PURA Knock-out mouse model for PURA syndrome exhibits fatal seizures

Vincent Pons[1], **Matthew Simon[1]**, Katelyn Tracey[1], Stephen Murray[1], Cathleen Lutz[1]
[1]*The Jackson Laboratory, Bar Harbor, ME*

Introduction: The Pur-alpha protein (Purα) is a DNA-RNA-binding protein involved in various cellular processes such as DNA replication and the regulation and control of transcription and translation. This 322 aa protein is highly conserved from bacteria to humans. *PURA* is ubiquitously expressed throughout the body, with highest found in the prefrontal cortex, and immune system. *PURA* plays a crucial role for brain development, supporting growth and division of neurons. A microdeletion in *Pura* leads to PURA syndrome. This rare disease is caused by *de novo* mutations leading to a wide range of symptoms, including but not limited to neonatal hypotonia, developmental delay, and seizures. The mechanism is believed to be haploinsufficiency with no direct treatment available. Physical, occupational speech and language therapies are currently the only options. To date, few mouse studies have investigated PURA deficiency. Here, we describe a new model for PURA that produces phenotypes making it ideal for therapeutic investigations.

Methods: Mouse models for human diseases have played a pivotal role in the development of new treatments. A major hurdle for developing new models is phenocopying human disease into a nonhuman organism. We generated a new mouse knockout model to study PURA syndrome using CRISPR/Cas9. RNA expression was utilized to establish the mechanistic underpinnings of any physiological or behavioral phenotypes. To interrogate the mouse model, we established phenotyping cohorts of heterozygous (Het) and homozygous (Hom) animals. Body weight and survival were monitored weekly. Additionally, home cage monitoring was utilized to record mouse activity in cages that tracked the animals 24/7 to capture seizure events.

Results: In this study, we identified several patient-relevant phenotypes in our PURA mouse model. After confirming Het animals had reduced mRNA expression in whole brain tissue, animals were assessed for body

weight, survival. We observed that Hom mice were leaner at birth compared to Het and wild-type counterparts. Hom mice experienced early attrition and died prematurely by 20 day of age. Het mice also exhibited a reduction in survival, with an increased death rate between 8 and 13 weeks of age. By 13 weeks, 90% of mice had died. To better understand the nature of this early attrition, Het and wildtype littermates were housed in camera-equipped DIVA cages, allowing for 24/7 recording of the animals. We found that all Het animals that succumbed to early death experienced a massive, terminal seizure event.

Conclusion: These results indicate that the PURA mouse model exhibits phenotypes consistent with human disease. Our initial findings show that PURA KO mice exhibit reduced PURA mRNA expression compared to controls. Additionally, we see that the terminal event for the mice demonstrates a massive seizure event, indicating abnormal neuronal activity in this model and resulting in shortened lifespan. It is worth noting, previous Het PURA models did not exhibit this attrition, nor reduced survival, making this new model an attractive platform for therapeutic interventions. Future investigations using VEEG/EMG to establish neuronal activity are currently underway. This platform will provide support for the scientific community in further understanding the role of PURA and exploring potential therapeutic strategies such as gene therapies.

1057 Gene Therapy Development for DDX3X Syndrome

Andrea Boitnott[1], Anjala Jiji[2], Xin Chen[2], Steven Gray[3]*
[1]UT Southwestern Medical Center, Dallas, Texas, [2]UT Southwestern Medical Center, Dallas, TX, [3]University of Texas Southwestern Medical Center, Dallas, Texas
**Corresponding Author*

Background: DDX3X syndrome is a neurodevelopmental disorder first described in 2015 and today is thought to be one of the leading known genetic causes of intellectual disability in females. The syndrome is caused by mutations in the Dead-Box Helicase 3 X-Linked gene (*DDX3X*), which encodes an abundant and ubiquitously expressed RNA helicase. Despite the clinical burden of DDX3X syndrome and the known genetic cause, there is no effective treatment for these patients. We have previously shown that intracerebroventricular administration of an AAV9-mediated gene therapy delivering a functional human optimized *DDX3X* transgene in mice at postnatal day 1 is safe but results in minimal efficacy, warranting further studies to understand if the loss of DDX3X during embryonic development results in permanently altered postnatal behavior.

Methods: To determine if gene reinstatement after birth can ameliorate postnatal phenotypes, we generated a Ddx3x reinstatement mouse using the flip excision (FLEx) genetic technology. With this model reactivation of *Ddx3x* under endogenous conditions occurs after two steps: 1. Cre mediated inversion of a stop cassette by homologous recombination to turn *Ddx3x* off after conception, and 2. tamoxifen inducible FLPO excision of the stop cassette postnatally at a user defined timepoint to turn *Ddx3x* back on. The stop cassette used in this mouse models heterozygous *DDX3X* variants resulting in haploinsufficiency, which accounts for at least half of the patient population who have known loss-of-function mutations. *Ddx3x* was reinstated at postnatal day (P) 1 via a subcutaneous injection or P21 via an intraperitoneal injection of tamoxifen to assess if there is a time window necessary for treatment. A battery of behavioral tests at 3 months of age assessing motor function, anxiety, and other disease relevant behaviors was conducted.

Results and Conclusions: The mice treated with tamoxifen had varying degrees of *Ddx3x* reinstatement dependent on tissue type as measured by digital PCR. *Ddx3x* in the liver, ear, and brain showed about 90%, 60%, and 35% reinstatement (respectively), 4 months after a P1 injection of tamoxifen. Four months after a P21 injection of tamoxifen, *Ddx3x* in the liver, ear, and brain showed about 90%, 60%, and 15% reinstatement, respectively. At both reinstatement timepoints phenotypes were not rescued or ameliorated. These phenotypes included anxiety as measured by both duration in the center and frequency to enter the center of an open field, repetitive behavior as measured by number of marbles buried during a marble burying paradigm, and weight. Tamoxifen related toxicity was observed in relation to motor readouts, making it difficult to understand the effect of gene reinstatement on motor coordination and function. While it is possible that higher reinstatement in the brain could ameliorate phenotypes, the data suggests that mutations in *Ddx3x* cause phenotypes that will be difficult to treat postnatally with current vector technology such as AAV9. A caveat to these experiments is the relatively low degree of brain-

specific reinstatement that was achieved, and it remains possible that a higher proportion of rescued cells could alter the course of the disease.

1058 AAV Gene Therapy for a Newly Identified Inherited Disorder of Copper Transport

Sangeetha Hareendran[1], Tarun Kaniganti[2], Denise Lanza[3], Haonan Zhouyao[3], Lindsay Burrage[3], Jason Heaney[3], Stephen Kaler[2]
[1]Columbia University, New York, USA, [2]Columbia University Irving Medical Center, New York, NY, [3]Baylor College of Medicine, Houston, TX

CTR1 (*SLC31A1*) is a high-affinity importer of the trace metal copper that is required for proper infant brain development and that enhances the metastatic potential of certain copper-dependent cancers. Our report of twin males homozygous for a novel *SLC31A1* missense variant, R95H, provided the first detailed description of human CTR1 disease (Batzios et al., 2022). These patients manifested a distinctive clinical phenotype: profound infantile-onset neurodegeneration characterized by seizures, developmental delays, hypotonia, and brain atrophy. To futher characterize this disorder, we are conducting detailed clinical, biochemical and molecular studies, and experimental therapeutics in a CRISPR/Cas9-generated *SLC31A1*^{R95H} mouse model, as well as in cerebral organoids derived from iPSCs generated from cultured fibroblasts of affected individuals. Initial data reveal that R95H homozygous affected mice have shortened lifespans, drastically reduced brain copper levels, impaired growth, and neurological abnormalities, including seizures, features that recapitulate findings in affected human subjects. We are assessing the clinical and biochemical impacts of systemic AAV9-*SLC31A1*(dose ranging from 2.6 x 10^{12} vg/kg to 2.6 x 10^{13}vg/kg). In addition, we are performing transcriptomic and proteomic profiling of cerebral organoids derived from patient fibroblasts harboring CTR1^{R95H} or other variants (CTR1^{L79P}, CTR1^{Q125K}) from other recently identified subjects. These studies include CRISPR-corrected isogenic controls as well as complete CTR1 knockout brain organoids. The evaluation of the impact of AAV6-*SLC31A1* gene transfer on cerebral organoid phenotypes is also in progress, since the AAV6 serotype has high tropism for cerebral organoids. Considering the absence of CTR1 deficiency models, our combined studies provide valuable insight concerning 1) brain-associated functions of CTR1, 2) disease mechanisms related to CTR1 deficiency, and 3) proof of principle for AAV-mediated gene therapy in affected patients.

1059 Dissecting Molecular Mechanisms Underlying Blood-Brain Barrier Deficits in Tuberous Sclerosis Complex

Gongbo Guo[1], Morgan Moser[1], Alecia Biel[2], Tianli Ding[1], Mark Hester[3]

Tuberous sclerosis complex (TSC) is a multisystem rare genetic disorder. It is caused by mutations in either *TSC1* or *TSC2*, encoding for Tuberin and Hamartin, respectively. Tuberin and Hamartin interact to form a complex that negatively regulates cell growth by inhibiting signal transduction mediated by the mammalian target of rapamycin (mTOR). TSC patients not only develop benign growths in multiple organs such as skin, lungs, and brain, but also show a high incidence of refractory epilepsy, which adversely impairs cognitive abilities. Current treatment options include the use of mTOR inhibitors, although they have multiple limitations such as suppressing the immune system and show variable efficacies in patients. Perivascular inflammation and dysfunction of the blood-brain barrier (BBB) have been reported in TSC patients. Specifically, several studies have reported focal perivascular leakage of serum proteins in cortical tubers, which elicit neuronal hyperexcitability and may trigger the onset of seizures. Brain pericytes play an important role in the establishment and maintenance of the BBB. They control key physiological functions such as regulating BBB permeability and relaying inflammatory responses. In addition, pericyte dysfunction has been implicated in several neurological disorders including epilepsy, although their role in TSC pathogenesis has been understudied.

To investigate BBB dysfunction in TSC, we adopted a method to differentiate pericytes from patient-specific human induced pluripotent stem cell (iPSC) lines and have characterized their function in an in vitro BBB model. We have also generated *TSC2* KO pericytes and show they exhibit an increased propensity towards a calcified phenotype,

suggesting hyperactive mTOR signaling may contribute to tuber calcification in vivo. Moreover, we generated isogenic iPSC cell lines from the TSC patients with CRISPR-Cas9 techniques, thereby providing rigorous controls for our studies. In summary, this study will broaden our understanding of molecular mechanisms underlying BBB deficits in TSC and will reveal novel mechanistic insights into the role of pericyte-mediated calcification during disease pathogenesis, thus providing new strategies for therapeutic development for TSC.

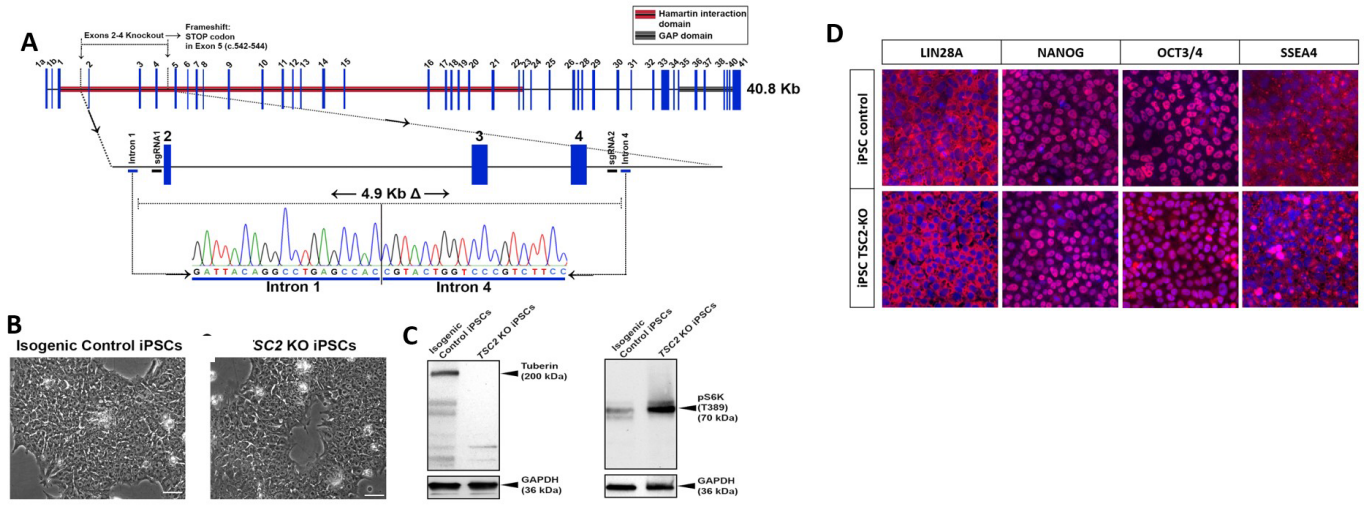

Figure 1| *TSC2* CRISPR Cas9 KO strategy and characterization of iPSCs. Briefly, peripheral blood mononuclear cells (PBMCs) were isolated from patient and control blood samples and underwent Sendai virus transduction with Yamanaka factors (OCT3/4, SOX2, KLF4, c-MYC) to produce induced-pluripotent stem cells (iPSCs). **(A)** *TSC2* genome locus, CRISPR Cas9 knock-out strategy and Sanger's sequencing results showing the 4.9kb deletion. **(B)** Phase contrast image of control and *TSC2* KO hiPSCs. **(C)** Western blot analysis showing TSC2 (Tuberin) and pS6 kinase expression in control and *TSC2* KO iPSCs. **(D)** Immunofluorescence staining of pluripotency markers in control and *TSC2* KO iPSCs showing LIN28a, NANOG, OCT3/4, and SSEA4.

Introduction: Tuberous sclerosis complex (TSC) is a haploinsufficiency disorder affecting approximately 42,000 individuals in the United States, with ~70% of cases caused by *TSC2* mutations. These mutations lead to hyperactive mTOR signaling, contributing to a range of disease manifestations, including epilepsy and neurodevelopmental symptoms. TSC2 mutations are highly heterogeneous, making a single gene-editing approach impractical; instead, gene supplementation is the most viable therapeutic strategy. Importantly, overexpression of *TSC2* has not been associated with toxicity, meaning that restoration of *TSC2* protein levels does not carry the risk of a "goldilocks effect" requiring strict dose control. However, gene therapy for *TSC2* presents two major challenges: (1) its coding sequence (5.4 kb) exceeds AAV packaging limits, and (2) its delivery requires widespread distribution across the brain, as no single brain region or cell type is uniquely responsible for seizure generation. While minigene-based approaches have been explored to overcome the size limitation, they have failed to restore mTOR regulation in preclinical studies. To evaluate therapeutic potential preclinically, we developed a cell-based potency assay to assess *TSC2* payload function in vitro. This assay revealed that a previously published *TSC2* minigene was unable to restore mTOR regulation. Notably, this same minigene failed to demonstrate a therapeutic effect in an established *in vivo* disease model, underscoring the need for alternative strategies. In parallel studies with *TSC1*, payloads that restored function in the potency assay also demonstrated therapeutic effects in vivo, reinforcing the potential translational utility of this approach. Here, we present a novel split intein-based *TSC2* payload that enables full-length protein reconstitution, alongside a cell-based potency assay and a clinically relevant delivery strategy using an intravenously administered, BBB-penetrant capsid.

Methods: A phospho/total p70S6K-based potency assay was developed to assess therapeutic potential and guide payload optimization. Five split intein *TSC2* payloads were designed to splice within key domains, preserving critical folding and functional regions. *In vitro* studies were conducted in *TSC2* knockout (KO) HEK293 cells via co-transfection and viral co-transduction to assess protein expression and mTOR regulation. Comparative studies included 21 novel minigene constructs, as well as one previously published minigene.

Results: Despite efficient protein expression in *TSC2* KO cells, none of the 21 novel minigenes nor the previously published minigene restored mTOR regulation. Likewise, the previously published minigene failed to demonstrate a therapeutic effect in an established animal model. The split-intein payloads tested demonstrated expression and function in vitro, paving the way for future in vivo studies.

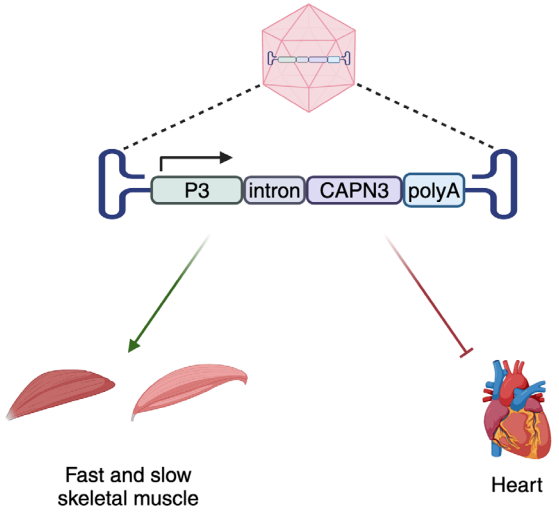
Conclusion: We report the successful development of a functional *TSC2* payload using split inteins, supported by a cell-based potency assay with clear preclinical and regulatory applications. The potential predictive value of this potency assay has been reinforced by successful in vivo studies in *TSC1*, supporting its utility for gene therapy development. These findings establish a viable path forward for *TSC2* gene therapy, with next steps including in vivo validation.

1061 Design of Synthetic Promoters for AAV-Driven Treatment of Limb-Girdle Muscle Dystrophy Type R1

Ruby Goldstein de Salazar[1], Irina Kramerova[2], Jesus Perez[3], Stephen Hauschka[4], Jeffrey Chamberlain[4], Melissa Spencer[1]

[1]UCLA, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, CA, [3]UCLA, Los Angeles, [4]University of Washington, Seattle, WA

Limb-girdle muscle dystrophy type R1 (LGMDR1) is an autosomal recessive, progressive muscle-wasting condition caused by mutations in the *CAPN3* gene. *CAPN3* encodes for Capn3, a muscle-specific member of the calpain family of calcium-dependent cysteine proteases. Patients with LGMDR1 typically begin to exhibit clinical symptoms in their second decade of life. The muscle wasting is progressive and often leads to wheelchair dependence within 10 to 20 years after diagnosis. Since LGMDR1 is a loss-of-function disease, AAV-delivery of a healthy *CAPN3* gene should represent a promising therapeutic strategy for affected individuals. However, due to the absence of Capn3 expression in cardiac tissue, it was necessary to develop an artificial promoter that avoids expressing Capn3 in the heart while promoting high expression in both fast and slow skeletal muscle tissue. Currently, no existing promoters meet this specific expression pattern. To address this challenge, synthetic promoters were designed using various approaches, including machine learning, which was trained on known skeletal muscle enhancers. We packaged each engineered promoter that drives the mouse Capn3 gene into the myotropic vector AAVMyo and then assessed Capn3 expression across a wide range of muscle types as well as in the heart using capillary western analysis. Any promoters that resulted in Capn3 expression in the heart were excluded from further studies. This process identified promoter #3 (P3), which showed the strongest expression of Capn3 across both fast and slow muscle types, with no detectable expression in the heart. At the highest in vivo dose of 2e14 vg/kg, P3 achieved over 100% restoration of Capn3 across all tested muscle tissues, including the soleus. Additionally, Capn3 was not detected in either the heart or liver at this highest dose, and no signs of toxicity were observed in muscle and heart tissues expressing this elevated level of Capn3. A preliminary dose-response assessment using dosages of 1e13 vg/kg, 5e13 vg/kg, and 2e14 vg/kg indicated that even at the lowest dose of 1e13 vg/kg, at least 75% restoration of Capn3 occurred across various muscle types. Future studies will focus on establishing the relationship between Capn3 levels and the functional restoration of the LGMDR1 phenotype.



1062 Novel Muscle-Targeted Gene Therapy Vectors with Increased Potency based on Combinatorial Assembly of Evolutionary Conserved Human Transcriptional C*is*-Regulatory Elements (CRE) Identified by Comprehensive Transcriptome-Wide Data-Mining

Hong Pham Quang[1], Bheemsetty Anudeep[2], Phuong Anh Nguyen[1], Warut Tulalamba[1], Gao Fangye[1], Emira Samara-Kuko[1], Marinee Chuah[3]*, **Thierry Vandendriessche[4]***

**Corresponding Author*

In vivo gene therapy based on adeno-associated viral vectors (AAV) is a promising modality to treat hereditary muscle disorders by directly tackling the root cause of the disease. Nevertheless, current AAV vectors are characterized by a relatively narrow therapeutic window and often result in low expression, toxicity and even mortality in clinical trials, especially with higher vector doses. To overcome these limitations of muscle-directed AAV gene therapy, we aimed to maximize transcription of the therapeutic genes in the afflicted target tissues. To achieve this, we have validated novel combinations of transcriptional cis-regulatory elements (CREs) that serve as "molecular turbo-chargers" to specifically boost expression of the therapeutic genes in the diseased target cells including skeletal muscle, heart and diaphragm. These CREs were identified by transcriptome-wide data-mining of genes that are highly expressed in human muscle, heart and/or diaphragm, providing a selected short-list of evolutionary conserved transcriptional elements. The potency and specificity of these CREs was validated based on in vivo AAV9 gene delivery in various murine disease models of severe genetic muscle disorders, including Duchenne muscular dystrophy (DMD), limb girdle muscular dystrophy (LGMD) and Pompe disease. Notably, incorporation of these CREs led to a significant increase in transcription of luciferase gene expression when combined with desmin and Spc5-12 promoters and outperforming potent muscle-targeted promoters such as MHCK7. These CREs also boosted expression of therapeutically relevant genes including micro-dystrophin or myostatin in the case of DMD, beta-sarcoglycan for LGMD or a-glucosidase (GAA) for Pompe. The extent of the increased transcription varied depending on the gene and/or target tissues attaining a significant 10- to 100-fold increase in transcriptional activity. The increased transcription correlated with a concomitant increase in protein expression levels of the respective therapeutic genes. The increased expression of the therapeutic protein was consistent with the normalization of nuclear localisation. Most importantly, systemic administration of the CRE-containing AAV9 vectors expressing the respective therapeutic genes resulted in sustained phenotypic correction in the DMD, LGMD or Pompe mouse models. In particular, Pompe mice treated with the CRE-containing vectors exhibited a normalisation of glycogen accumulation in skeletal muscle, diaphragm and heart resulting in complete functional correction of skeletal muscle, diaphragm and cardiac (S-T interval) function using comprehensive functional assays (i.e. hanging assay, grip tests, diaphragm force assay, electrocardiogram). In contrast, control vectors without CRE only yielded partial phenotypic correction, consistent with the lower GAA expression levels. Finally, the elevation of gene expression by these CREs was not confined to these murine models but was also confirmed in transfected human primary cardiomyocytes. Taken together, these preclinical results underscore the potential broad therapeutic implications of using CRE-containing vectors for the treatment of severe hereditary muscle disorders by improving the therapeutic window and overcome some of the manufacturing constraints.

1063 RNA-guided Transcriptional Upregulation of Neuromuscular Disease Modifiers Using CRISPR-DREAM

Daniel Maxenberger[1]*, Christopher Nelson[2], Ian Popp[2], Ryan Rouse[2]
[1]University of Arkansas, Fayetteville, Fayetteville, AR, [2]University of Arkansas, Fayetteville, AR
**Corresponding Author*

Duchenne Muscular Dystrophy (DMD) is an X-linked neuromuscular genetic disease caused by mutations in the gene that codes for dystrophin which results in no expression or the expression of nonfunctional protein. This disease affects 1 in 5,000 male births and results in muscle degradation leading to weakness, cardiac and respiratory complications, loss of ambulation, and premature death with a median life expectancy of 28 years of age (1). The CRISPR-dCas9 recruited enhanced activation model (CRISPR-DREAM) can potently increase transcription of

target genes. CRISPR-DREAM is a CRISPR-dCas9 system that makes use of human derived transcriptional activation domain plasmids (TADs) which may elicit lesser immune responses in humans than those derived from viruses (2). To demonstrate broad utility in skeletal muscle, we examined the following target genes. *UTRN* is a paralog of dystrophin and has been shown to alleviate the impact of dystrophin protein deficiency, and increased *UTRN* RNA expression causes increased protein production to alleviate the effects of dysfunctional dystrophin protein (3). IL-10 is of interest due to its inhibition of immune response, thus working to reduce inflammation when upregulated (4). Klotho is of interest due to its role in metabolism and aging (5). This study aims to determine optimal use of CRISPR-DREAM in skeletal muscle tissue for guide sequences of the gene targets to treat DMD in mouse skeletal muscle myoblast cells (C2C12). Target sequences in the mouse genes Utrophin (*Utrn)*, *IL-10*, and *Klotho* have been transformed into CRISPR-DREAM plasmids for transcriptional regulation. Multiple guide sequences were designed for each genetic target and transformed into CRISPR-DREAM plasmids for genetic regulation. Protospacer sequences in the respective DREAM plasmids were confirmed through sanger sequencing with whole plasmid nanopore sequencing also confirming the identity of all cloned plasmids. The C2C12 cells were then transfected with lipofectamine to deliver the therapy. Afterwards, RNA transcriptional efficacy was observed through quantitative real-time polymerase chain reaction (qRT-PCR) of the media of the treated cells, showing increased *UTRN* expression for both TADs with higher performance from guide sequences upstream of the gene's promoter region rather than downstream showing potential as a tool in DMD applications. Due to successful epigenetic regulation of the C2C12 cell line using CRISPR DREAM, a constitutively expressed CRISPR-DREAM C2C12 model cell line is being developed through lentiviral transduction to allow for rapid testing of several new targets. Through this design, optimal combinations of genetic targets for holistic gene therapy approaches to treating DMD will be tested in conjunction with each other to test for the most efficient combination.

1064 RNA Polymerase II Transcription of RNAi Sequences for Myotonic Dystrophy Gene Therapy

Stephanie Lee-Diaz[1], **Joel Chamberlain[2]**
[1]University of Washington School of Medicine, Seattle, WA, [2]University of Washington School of Medicine, Seattle, Washington

INTRODUCTION: We are developing a gene therapy approach for the dominant genetic disease myotonic dystrophy (DM), a rare genetic disease affecting ~1 in 9000 adults. Individuals with DM experience progressive muscle weakness and myotonia (delays in muscle relaxation) and other multisystem effects such as sleep disturbances, executive function deficits, gastrointestinal discomfort, and heart conduction failure that can lead to sudden death. DM type I is caused by a CTG repeat expansion, with larger generational expansions (anticipation) that lead to accumulation of the repeat-expanded myotonic dystrophy protein kinase gene (*DMPK*) mRNA in the nuclei of cells and subsequent mis-regulation of splicing of hundreds of different mRNAs.

BACKGROUND: Previous proof of principal studies have demonstrated the potential for systemic AAV6-RNAi for reduction of the *DMPK* expanded repeat mRNA. We have pioneered delivery of the key splicing factor MBNL1 to mice for additional phenotypic correction, while preventing damaging over expression in heart. We have shown 2.5-fold upregulation in the quadriceps muscle of the HSALR mouse model of DM1.

CURRENT WORK: Our current focus is development of RNA polymerase II expression of DMPK RNAi sequences and we are currently testing *β*-actin promoter driven RNAi hairpin expression in the HSALR mouse model. Intramuscular injection of modified cassettes was performed and comparison with RNA polymerase III U6 expression of RNAi will be presented. Our goal is to combine RNA polymerase II limited expression of RNAi with supplemental MBNL1 protein as a dual therapeutic approach for DM1.

1065 Developing Suppressor-tRNAs to Treat Duchenne Muscular Dystrophy

Warisha Faiz[1], Mengyao Xu[1], Jialing Liang[1], Dan Wang[1]*
[1]*UMass Chan Medical School, Worcester, MA*
**Corresponding Author*

Nonsense mutations are point mutations that convert a sense codon into a premature termination codon (PTC) in the mRNA. One promising strategy to address these mutations is the use of suppressor transfer RNAs (sup-tRNAs) that can induce PTC readthrough during translation, thereby restoring full-length protein production. This approach has long been considered a viable gene therapy for approximately 11% of human pathogenic mutations caused by nonsense mutations. Recently, we reported the *in vivo* safety and therapeutic efficacy of AAV-NoSTOP, an adeno-associated virus (AAV)-delivered sup-tRNA targeting the TAG nonsense mutation, in the Hurler syndrome's mouse model (Wang J. et al. *Nature* 2022). Building on this work, the current study aims to expand the AAV-NoSTOP toolbox to target the TAA nonsense mutation, the most prevalent type of nonsense mutation in patients living with Duchenne muscular dystrophy (DMD) (Torella A. et al. *PLOS One* 2020). We hypothesized that AAV-NoSTOP could be an effective treatment for nonsense-mediated DMD because 10-15% of *DMD* mutations are nonsense in nature, and this strategy circumvents the challenge of delivering the full-length *DMD* cDNA, which exceeds the packaging capacity of AAV. The mdx mouse model, carrying a TAA nonsense mutation in the *Dmd* gene resulting from a glutamine codon (Gln)-to-TAA change, provides an ideal system for testing dystrophin restoration through AAV-NoSTOP, as this mutation represents a significant proportion of nonsense mutations in DMD patients. (Torella A. et al. *PLOS One* 2020). Therefore, we focused on developing UAA-sup-tRNA^{Gln}. Using a dual reporter plasmid with a Gaussia luciferase (*Gluc*) gene and a mutant *EGFP* gene disrupted by the TAA premature stop codon, we were able to assess the UAA-sup-tRNA's ability to readthrough the PTC by measuring the reporter protein levels. In HEK293 cells, we found that 11 out of 18 UAA-sup-tRNA^{Gln} designs achieved ≥30% readthrough. To assess whether the top UAA-sup-tRNA^{Gln} candidates could induce UAA readthrough *in vivo*, we co-delivered the reporter and sup-tRNA plasmids into wild-type mice via hydrodynamic injection. Interestingly, we observed a significant discrepancy between the readthrough activity in HEK293 cells and the mouse liver, suggesting that readthrough capacity in HEK293 cells is not a reliable predictor of sup-tRNA functionality *in vivo*. This may be due to the altered tRNA and aminoacyl-tRNA synthetase regulation in cancerous cell lines like HEK293, which may create a cellular environment more permissive to sup-tRNA biogenesis and function. Importantly, we identified one UAA-sup-tRNA^{Gln} candidate that exhibited ~9% UAA readthrough *in vivo*. We are now proceeding with the generation of AAV.NoSTOP reagents and will test their ability to restore dystrophin expression in *mdx* mice. (WF and MX: co-first authors)

1066 Long-term Follow-up and Evaluation of Multi-Exon Skipping by CRISPR/Cas9-based Genome Editing in a Canine Model of Duchenne Muscular Dystrophy

Hidenori Moriyama[1], Rika Maruyama[1], Harry Wilton-Clark[2], Yuki Ashida[3], Mutsuki Kuraoka[4], Koichi Kimura[5], Katsura Minegishi[6], Yoshitsugu Aoki[7], Toshifumi Yokota[1]
[1]*University of Alberta, Edmonton, AB,* [2]*University of Alberta,* [3]*National Center of Neurology and Psychiatry, Kodaira, Japan,* [4]*Nippon Veterinary and Life Science University, Tokyo, Japan,* [5]*Department of Laboratory Medicine, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [6]*National Center of Neurology and Psychiatry (NCNP), Kodaira, Tokyo, Japan,* [7]*National Center of Neurology and Psychiatry, Tokyo, Japan, Japan*

Duchenne muscular dystrophy (DMD) is a severe and progressive genetic disorder caused by mutations in the DMD gene, leading to the absence of dystrophin protein. Genome editing has emerged as a promising therapeutic approach for DMD, with ongoing validation in animal models. However, long-term studies assessing genome editing in large animal models of DMD are still lacking. In this study, we performed CRISPR/SaCas9-mediated multi-exon skipping genome editing in beagle-based Canine X-linked Muscular Dystrophy (CXMD). This model carries a point mutation at the splice acceptor site of exon 7, located in a hotspot N-terminal region of the DMD gene. We followed up for one year to evaluate the efficacy and safety of the treatment.

We developed an all-in-one recombinant adeno-associated virus 9 vector-based CRISPR/SaCas9 system, which included a spc 5.12 muscle-specific promoter and dual guide RNAs designed to excise exons 6-8 of the DMD gene. After validating the vector in immortalized DMD canine muscle cells, we intravenously administered the vector (2.0×10^{14} GC/kg) to 4-week-old DMD dogs (n=3). Age-matched DMD dogs (n=3) received saline as a control group.

Molecular analysis conducted one year post-treatment showed sustained exon skipping and dystrophin expression in various skeletal muscles and the heart. In the treated skeletal muscle tissues, in-frame exon skipping ranged from 1-22%, as detected by RT-PCR, with varying levels between muscle regions or individuals. Western blot analysis revealed 1-6% restoration of dystrophin protein of healthy levels. In the heart, in-frame exon skipping ranged from 5-33%, and dystrophin expression was restored by 2-17%. No significant changes in dystrophin expression were observed in temporalis muscle biopsy samples taken at 8 weeks and one year post-treatment. Histopathological analysis showed improved conditions in the treated skeletal muscles, including larger fiber size, fewer centrally nucleated fibers, and reduced fibrosis compared to untreated controls. Functional assessments at 1, 2 and 4 months post-treatment, including the 15-meter running test and standing test, showed promising trends in motor function. At one year, the treated group demonstrated improved isometric dorsiflexion torque, an indicator of hind limb muscle strength. Mild elevations in liver enzymes were observed in the treated group, but no other adverse events were noted. Over the one-year follow-up, there were no significant changes in serum creatine kinase levels between the treated and untreated groups.

These results demonstrate that our CRISPR/Cas9-based multi-exon skipping strategy induces long-term dystrophin expression in skeletal muscle and the heart, leading to improvements in muscle function. Our findings provide valuable insights for the future clinical application of gene editing therapies for DMD.

1067 Advancing the Novel CasX-Editor for Precise Genome Editing to Address Muscular Dystrophies

Cécile Fortuny[1], Lola Takirov[1], Jennifer Saraya[1], Nicholas Aguirre[1], Sean Higgins[1], Isabel Colin[1], Christie Sze[1], Sarah Denny[2], Maroof Adil[1], Benjamin Oakes[2]

Duchenne Muscular Dystrophy (DMD) is a severe, progressive neuromuscular disease caused by loss-of-function mutations in the DMD gene, leading to life-threatening respiratory and cardiac failure. Recent advances in AAV-mediated gene therapy, including the FDA-approved micro-dystrophin, offer promise for alleviating disease severity. However, challenges remain, as the micro-dystrophin encodes for a truncated, partially functional form of dystrophin that may also elicit immune responses, diminishing long-term efficacy. This underscores the urgent need for genome-editing strategies to directly address DMD mutations. Most notably, over 70% of DMD mutations are amenable to exon skipping or reframing to restore the expression of a nearly functional protein product, and advances in these approaches could provide mechanisms towards more effective and safe genetic solutions.

This study presents novel genome-editing strategies using a highly engineered CRISPR-CasX paired with a guide RNA molecule called the X-Editor (XE) to target mutations in DMD. We demonstrate that XE has a unique deletion pattern allowing for highly effective exon skipping by perturbing key splicing elements to produce a functional, near-full-length, truncated dystrophin protein. We first demonstrate highly efficient targeting of the 5' intron-exon boundary of DMD exon 53. In myoblasts derived from patients with a deletion of exon 52, we achieved ~90% editing efficiency, resulting in near-complete exon 53 skipping and robust dystrophin restoration in myotubes. Next, we set out to identify additional mechanisms of exon skipping other than canonical 5' exon boundary targeting. We predicted enhancer splicing elements in exon 53 in an engineered DMD exon 53 reporter line to demonstrate that XE-based genetic modification at these sites can induce exon skipping at levels comparable to or higher than those achieved via the canonical splice acceptor targeting strategy. Building on these in vitro findings, we evaluated AAV-mediated delivery of XE into muscle tissue in vivo. XE's compact size enabled efficient packaging into a single all-in-one AAV vector with different muscle-specific regulatory elements. Systemic delivery of these AAVs encoding the XE transgene into wild-type mice resulted in saturated editing in both cardiac and skeletal muscle at

exceptionally low viral genome levels (1-2 copies per diploid cell). To our knowledge, this is the first demonstration of saturated editing in muscle tissue at very low AAV doses.

Our findings establish XE as a powerful and versatile genome-editing technology for neuromuscular diseases like DMD, with the ability to target various splicing elements to enable therapeutic levels of exon skipping or reframing. By enabling precise and efficient AAV-mediated genome-editing in vivo, XE addresses critical challenges in neuromuscular gene therapy, offering a promising path toward scalable, durable treatments that could redefine the standard of care for DMD and other inherited muscle disorders.

1068 Development of Self-Delivering Gene Editors for Enhanced Non-Viral Delivery in Duchenne Muscular Dystrophy

Shilpi Agrawal[1], Christopher Nelson[1]*
[1]*University of Arkansas, Fayetteville, AR*
**Corresponding Author*

Duchenne muscular dystrophy (DMD) is a severe genetic disorder characterized by progressive muscle degeneration, leading to loss of mobility and premature death due to cardiac and respiratory failure. Despite advances in gene therapy and exon-skipping treatments, there is still no curative therapy. AAV-based gene therapy has shown potential in delivering microdystrophin, but challenges remain regarding long-term efficacy, immune responses, and restricted access due to pre-existing immunity. Non-viral gene delivery offers a promising alternative but currently lacks the efficiency needed for effective skeletal muscle targeting.

This study presents a novel approach to overcoming these challenges by developing a "self-delivering" gene-editing platform. We designed a CRISPR-Cas9 delivery system modified with cell-penetrating peptides (CPPs) using cysteine-disulfide chemistry, improving tissue-specific delivery and enhancing cellular uptake while preserving Cas9's gene-editing functionality. Solvent-accessible surface area (SASA) analysis identified key residues (V743, S204, R1078, and L551) as ideal modification sites for conjugation with CPPs *via* reversible thiol-maleimide chemistry. Protein purification results using Ni-Sepharose affinity chromatography show that the Cys modified Cas9 proteins were successfully expressed and purified. Western blot analysis confirmed the successful modification of Cas9, with the mutants displaying a band at 160 kDa. In vitro DNA cleavage assays demonstrated that the cysteine-modified Cas9 variants retained full gene-editing functionality, comparable to commercial Cas9, with efficient DNA cleavage activity.

This strategy provides an efficient, non-immunogenic alternative to viral-based delivery systems, ensuring that Cas9 retains its activity post-delivery, making it suitable for gene therapy applications in muscle tissues. This platform holds potential not only for DMD but also for a wide range of genetic diseases requiring precise gene-editing tools. Future work will focus on preparing the Cas9 library with CPPs and testing them on transwell and microphysiological systems (MPS). The developed MPS will have broader applications in studying the biology of biomacromolecular drug delivery through the vascular endothelium. This study aims to establish a versatile toolbox of self-delivering gene editors optimized for muscle tissue delivery, addressing key barriers in non-viral gene therapy and paving the way for restoring muscle function in DMD and other genetic muscle disorders.

1069 MM201-Mediated Gene Activation Therapy Enhances Utrophin Expression and Improves Muscle Function in Duchenne Muscular Dystrophy

Guoling Li[1], Jiajia Lin[2], Tong Li[3], Hainan Zhang[3], Yiqun Yuan[1], Xin Zhang[4], Linyu Shi[1], Alvin Luk[5], **Hui Yang**[6]

Background: Duchenne Muscular Dystrophy (DMD) is a severe neuromuscular disorder primarily affecting young males, that leads to progressive muscle degeneration, loss of ambulation, and premature mortality. Given the devastating impact of DMD on individuals and their families, there is an urgent need for effective therapeutic strategies. Utrophin is a protein that shares structural and functional similarities with dystrophin, partially compensating for dystrophin loss. Increasing utrophin expression levels may improve muscle function, enhance quality of life, and potentially alter the disease's progression. We investigated a novel therapeutic approach using MM201-miniVPR, a Cas protein-mediated gene activation tool delivered via a single AAV vector to upregulate utrophin expression. This approach is mutation-independent, potentially benefiting a wide range of DMD patients.

Methods: Two DMD mouse models were generated: one with exon50 deletion ($DMD^{\Delta E50E51,hE50KI}$), and the other with nonsense mutation in exon23 ($DMD^{\Delta E23,hE23KI}$) (Fig. 1A). Muscle pathology in the tibialis anterior (TA), diaphragm (DI), and heart was assessed as dystrophin expression using immunofluorescence and H&E staining (Fig. 1B and C). MM201-miniVPR-mediated utrophin activation was evaluated in human HEK293T cells, mouse N2a cells, and porcine PK15 cells. Based on these in vitro results, AAV vectors encoding MM201-miniVPR were injected intramuscularly into two DMD mouse models. Utrophin expression and therapeutic outcomes were analyzed 7 weeks post-injection.

Results: Both DMD mouse models exhibited a complete loss of dystrophin expression compared to wild-type mice (Fig. 1B). Hematoxylin-eosin (H&E) staining revealed disorganized muscle fibers and severe fibrosis in the muscle tissues (Fig. 1C), displaying phenotypes closely resembling those of human patients. In vitro studies demonstrated MM201-miniVPR increased utrophin expression ~10-fold in N2a cells, ~6-fold in HEK293T cells, and ~4-fold in PK15 cells (Fig. 1D). Intramuscular administration of MM201-miniVPR-containing AAV vectors significantly increased utrophin expression in TA muscle, with over 4-fold and 6-fold increases in the $DMD^{\Delta E50E51,hE50KI}$ and $DMD^{\Delta E23,hE23KI}$ mouse models, respectively (Fig. 1E–G). Studies with a newly developed DMD pig model are ongoing to validate the effectiveness of MM201-miniVPR-mediated utrophin upregulation in a larger organism.

Conclusions: MM201-miniVPR-mediated utrophin activation offers a novel therapeutic strategy for DMD. By leveraging a mutation-independent mechanism, MM201-miniVPR could address the needs of a broad patient population. This study highlights MM201-miniVPR as a promising intervention to improve muscle function and mitigate the progression of DMD.

1070 Design and Evaluation of FKRP Dimer Expression for Restoration of Functional Matriglycan in a LGMD 2I/R9 Mouse Model

Jason Tucker[1], Pei Lu[2], Molly Holbrook[3], Anthony Blaeser[3], Qi Lu[4]
[1]Atrium Health, Charlotte, NC, [2]Carolinas Medical Center, Charlotte, NC, [3]Atrium Health, [4]Carolinas HealthCare System, Charlotte, NC

Defects in the glycosylation of the membrane protein α-Dystroglycan result in numerous muscular dystrophies termed dystroglycanopathies. Of these, Limb Girdle Muscular Dystrophy 2I/R9 results from mutation-bearing Fukutin-related protein (FKRP) having little or no functional capacity as ribitol-phosphate (RboP) transferase to elongate the core M3 glycan (matriglycan) which is required to bind laminin and other proteins, securing the muscle membrane and extracellular matrix. The reduced or absent matriglycan expression results in destabilized cardiac and skeletal muscle with fiber damage followed by degeneration, inflammatory response, and regeneration. Decreased regenerative capacity coupled with ongoing inflammatory response results in fibrosis and intramuscular fat infiltration which reduce muscles' function. A number of AAV-mediated hFKRP transgene replacement constructs have been developed and demonstrated in LGMD mouse models to be effective at restoring matriglycan expression to levels comparable to that of unaffected wild-type mice, but at high AAV doses elevating risks of severe to lethal side effects. Recently, Kuwabara et al characterized the crystal structures of FKRP in monomeric, and dimeric form, with the FKRP dimer being most efficient in enzymatic activity.

We have designed an AAV9 vector encoding an FKRP dimer to replicate the naturally occurring dimer conformation. Systemic administration at $1x10^{13}$ VG/Kg of this FKRP dimer expression vector resulted in dramatic levels of matriglycan restoration detectable in skeletal, cardiac, and diaphragm muscles after four weeks and amelioration of the early stages of disease progression, as compared to the untreated LGMD 2I/R9 animals. Remarkably, the effect of this dimer-FKRP expression does result in an increased efficiency (~1.5 x) compared to monomer-FKRP at the same dose, as observed through immunofluorescence and western blot. This observed improvement in the functional matriglycan expression is also correlated with improved muscle histology including reductions in centrally nucleated fibers as well as monocyte infiltration and improvement in fiber size distributions. This novel approach to FKRP gene replacement has the potential to restore greater levels of matriglycan expression at lower doses of AAV thereby reducing dose related toxicity.

1071 In vivo overexpression of muscleblind-like 1 leads to cardiac toxicity in mice

Anna Kuperman[1], Lucy Marie, Jaunetta Hill[2], Anton Pritchard, Shiliang Hu[3], Emilie Legue[4], Corrinne Grant[4], Michele Peruzzi[5], Nelson Chau[6], Ricardos Tabet[7], **Claudia Huichalaf[8]**

Myotonic Dystrophy Type 1 (DM1) is the most common adult-onset muscular dystrophy, caused by an autosomal dominant CTG repeat expansion in the 3' noncoding region of the *DMPK* (DM1 protein kinase) gene. This expansion leads to the formation of secondary RNA structures that sequester splicing regulators, such as the muscleblind-like protein family (MBNL), resulting in widespread splicing defects. DM1 is a multisystemic disorder primarily affecting skeletal muscle, with hallmark symptoms including myotonia and muscle weakness.

Preclinical studies in mice have shown that MBNL1 overexpression is either partially effective (Yadava et al) or insufficient (Kanadia et al) to reverse the phenotypes caused by CUG RNA toxicity. To evaluate gene therapy potential, we tested an AAV-based MBNL1 approach in vitro and in vivo, utilizing a muscle-specific promoter and a surrogate muscle tropic MYO-AAV capsid (Tabebordbar et al). In vitro, MBNL1 expression in myocytes from DM1 patients successfully restored splicing defects in patient derived myotubes. However systemic administration of MYO-AAV-MBNL1 to C57BL/6 mice caused significant toxicity, including weight loss and euthanasia by day 17 post injection. Postmortem heart analysis revealed necrosis, inflammation, and cell infiltration, indicating toxicity from MBNL1 overexpression. While partial restoration of splicing defects was observed in vitro, the in vivo results demonstrated unbalanced splicing likely due to supra-physiological expression levels.

These findings suggest that achieving therapeutic benefits of MBNL-1 based gene therapy will require precise regulation of gene expression levels to avoid toxicity and ensure safety, highlighting the need for controlled approaches in future studies.

1072 Editing of Satellite Cells and Postmitotic Muscle for Continuous Correction of Dystrophin Expression in Duchenne Muscular Dystrophy

Nuoying Ma[1]*, Quynh Nguyen[2], Bianca Druta[2], Stephen Hauschka[1], Jeffrey Chamberlain[1], Niclas Bengtsson[3]*

Duchenne Muscular Dystrophy (DMD) is a fatal X-linked muscle wasting disease caused by mutations in the *dystrophin* gene, characterized by progressive muscle weakness, loss of ambulation, cardiorespiratory insufficiency, and premature death. Several DMD gene therapy clinical trials deliver functional miniaturized dystrophin using systemic adeno-associated virus (AAV) delivery. However, the lifelong workloads of skeletal muscles may cause therapeutic efficacy to decrease over time due to muscle remodeling in response to growth, maintenance, exercise, or trauma. An alternative strategy is to use genome editing to correct DMD-causing mutations in both postmitotic muscle and satellite cells (SCs), restoring long-term capacity of muscle to endogenously express functional

dystrophin. Our approach leverages base editors delivered by myotropic AAV vectors. So far, we have screened five myotropic AAV capsid variants to identify the most potent capsids for achieving optimal muscle transduction and editing of both muscle fiber nuclei and stem cells. To achieve specific editing in SCs we have designed miniaturized AAV-size-compatible gene regulatory cassettes (RCs) comprised of highly conserved regulatory regions from the human *PAX7* and *MYOD1* genes. These SC-RCs exhibit a range of activities in primary SC-derived myoblasts *in vitro* and in FACS-isolated SCs from wild-type and dystrophic mice. *In vivo*, prime SC-RC candidates display multifarious myogenic transcriptional patterns, ranging from preferential activity in SCs to more widespread activity in both SCs, myoblasts and postmitotic striated muscle. Encouragingly, our synergistic dystrophin gene editing approach is showing great promise, resulting in restoration of near normal dystrophin expression levels (>90%) in certain muscle groups, and with SC-RC-mediated editing boosting dystrophin gene correction in SCs over 100-fold compared to postmitotic muscle-specific editing alone using our CK8e RC.

Importantly, we believe achieving efficient SC gene correction to be crucial for addressing current DMD gene therapy longevity concerns, and that effective SC-editing methods could prove highly beneficial for the treatment of many muscle wasting disorders.

1073 Novel Circular RNA Scaffolds Enable Efficient Circularization and Expression of Full-Length Dystrophin as an Advanced Therapeutic Approach for Duchenne Muscular Dystrophy

Siqi Li[1], Xiaoliang Shi[1], Fei Lin[1], Xiyu Huang[2], Xuzhi Wang[1], Xiaowen Zou[2], Jian Ye[1], Yang He[1], Yunni Lei[1], Guiping Zhang[2], Roi Mashiach[3], **Edo Kon[4]**, Weiyi Zhang[1]
[1]RiboX Therapeutics, Shanghai, China, [2]RiboX Therapeutics, Shanghai, Shanghai, China, [3]RiboX Therapeutics, Ness Ziona, Israel, [4]RiboX Therapeutics, Cambridge, MA

Duchenne Muscular Dystrophy (DMD) is a severe, progressive genetic disorder caused by mutations in the DMD gene, resulting in the absence of functional dystrophin protein and premature death. Due to the large size of the dystrophin coding region (11 kilobase, 11kb), current therapies can only partially restore the dystrophin protein function.

Circular RNA (circRNA), known for its high intracellular stability and low immunogenicity, is emerging as a promising novel modality for protein replacement therapy. However, conventional scaffolds for RNA circularization are optimized for sequences up to 3 kb and are unsuitable for longer RNAs which limit the therapeutic applications of circRNA. We developed a novel scaffold specifically designed for the circularization of long RNA fragments. This advanced scaffold successfully circularized full-length DMD (circDMD) and enhanced the circularization efficiency of various lengths of circDMD (6.6, 10 and 11.7 kb). Transfection of full-length circDMD into cells resulted in robust expression of functional full-length dystrophin protein. The circDMD payloads were encapsulated in lipid nanoparticles (LNPs) to efficiently deliver and express the full-length dystrophin protein in the muscles of DMD *Del52/mdx* mice.

This breakthrough paves the way for more effective and comprehensive therapeutic strategies for DMD, offering a significant advancement over current treatments by enabling the expression of full-length dystrophin protein.

1074 AAV-Delivered U7snRNA Restores Full-Length Dystrophin in Patient Cell Lines with *DMD* Intronic Pseudoexon Mutations

Joseph Beljan[1], Liubov Gushchina[2], Stefan Nicolau[1], Robert Weiss[3], Kevin Flanigan[4]
[1]Nationwide Children's Hospital, Columbus, OH, [2]The Ohio State University and Nationwide Children's Hospital RI, Columbus, OH, [3]The University of Utah Department of Human Genetics, [4]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH

X-linked Duchenne muscular dystrophy (DMD) is caused by a null allele of the *DMD* gene, resulting in absent or altered dystrophin expression. Deep intronic mutations within the *DMD* locus represent an under recognized class

of pathogenic variants, accounting for 1-7% of all DMD patients. These are typically point mutations that create splice acceptor or donor sites, resulting in the inclusion of an intronic fragment as a pseudoexon within the *DMD* mRNA. Because such patients possess all of the canonical *DMD* coding exons, efficient exclusion of the pseudoexon from the mature mRNA restores a full-length transcript. To induce such skipping in patient-derived cells, we employed a modified U7 small nuclear ribonucleotide (U7snRNA) that targets either a splice acceptor (SA), splice donor (SD), or exon splice enhancer (ESE) sequence of the frame-shifting pseudoexons. Human MyoD-transformed cells with the pathogenic variants c.2292+1024 G>T (intron 18), c.2949+909 C>T (intron 22), c.5448+67 A>G (intron 38), or c.9163+2510 G>A (intron 61) were treated with increasing doses of AAV1 vectors containing a U7snRNA antisense sequence targeting the respective pseudoexon. Treatment resulted in dose-dependent pseudoexon skipping. In cells carrying the c.2292+1024 G>T variant, skipping efficiency reached 93%, resulting in 34% of wild-type dystrophin protein levels. Our preliminary data confirm that the pseudoexon class of *DMD* mutations is amenable to U7snRNA treatment and studies in additional cell lines are underway. This approach addresses an orphan class of *DMD* mutations, and demonstrates the potential of bespoke gene therapies to restore full-length dystrophin in individual patients.

1075 Optimized triple-vector gene therapy system enhances full-length dystrophin restoration in DMD mice

Chen Zhang[1], Shuang Li[2], Renzhi Han[2]
[1]*Indiana University, Indianapolis, IN,* [2]*Indiana University School of Medicine, Indianapolis, IN*

Gene therapy for Duchenne muscular dystrophy (DMD) has traditionally relied on adeno-associated virus (AAV) to deliver micro-dystrophin (μDys). However, μDys lacks critical functional domains of full-length (FL) dystrophin, providing only partial protection for striated muscles. To overcome this limitation, we recently developed a triple-vector system capable of delivering FL-dystrophin to skeletal and cardiac muscles, achieving efficient protein assembly and functional restoration. Building on this foundation, we optimized the system to further enhance FL-dystrophin expression and improve therapeutic outcomes. FL-dystrophin was divided into three fragments linked by two orthogonal pairs of split inteins and subjected to a series of rational engineering to improve the expression and assembly. Western Blot analyses showed that these modifications resulted in the shift of an optimal ratio of the three fragments from 4:2:1 to a more desirable 1:1:2, as well as a 3- to 5-fold increase in FL-dystrophin expression levels *in vitro*. The optimized transgenes were packaged into a myotropic AAV (MyoAAV4A) and delivered to male *mdx*^{4cv} mice. The optimized system improved gastrocnemius muscle force and wire hanging time and further reduced serum creatine kinase (CK) levels, reflecting enhanced muscle integrity. These results demonstrate that the optimized triple-vector system significantly enhances FL-dystrophin expression and functional outcomes in DMD mice. This mutation-independent approach represents a promising direction for further clinical development.

1076 Administration of AAV9-Midlength-Dystrophin Gene Therapy Demonstrates Functional Efficacy in a Mouse Model of DMD

Gretchen Thomsen[1], Allan Kaspar[1], Lukas Bachmann[2], Kathryn Hilde[1], Laura Ferraiuolo[3], Binh Chu[1], Robert Cano[1], Veronica Garcia[4], Nuria Casanova[1], Theresa Slaiwa[1], Ryan Weiss[1], Haunani Bautista[1], Maiya Lee[5], Jaedyn Rollins[6], Ashley Renteria[1], Melissa McAlonis-Downes[7], W. David Arnold[8], Brian Kaspar[1]
[1]*Insmed, Inc., San Diego, CA,* [2]*Insmed Gene Therapy LLC, San Diego, CA,* [3]*Insmed Inc, San Diego, CA,* [4]*Insmed Gene Therapy, LLC., San Diego, CA,* [5]*Insmed, San Diego, CA,* [6]*San Jose, CA,* [7]*UCSD, Encinitas, CA,* [8]*University of Missouri, Columbia, MO*

An AAV9-midlength-dystrophin construct in development creates a 248 kilodalton (kDA) dystrophin for the treatment of DMD versus the more common ~140 kDA micro-dystrophin by utilizing RNA end-joining (REJ) technology to piece together two RNA fragments within a cell. This work opens the possibility of developing potential improved dystrophin constructs that may have therapeutic benefit in muscles affected by the dystrophic pathology experienced in patients with DMD.

When dosed systemically at postnatal day (p)1, *mdx* mice treated with AAV9-midlength-dystrophin demonstrated significant dose-response improvement in hindlimb strength when assessed at ~p115 as well as a later time point of

~p275, relative to *mdx* (-) controls. Using the Aurora Scientific Whole Animal System for Mice, physiology measurements were performed to assess contractile torque of the plantar flexion muscles, which includes the gastrocnemius muscle. Peak plantar flexion twitch torque and peak tetanic torque measurements were both improved by ~100%, relative to *mdx* controls following administration of the higher dose in the study. This magnitude of improvement was observed at both ~p115 and ~p275 timepoints, indicative of durable biological activity and functional benefit following early administration of midlength-dystrophin. Significant impairment of muscle strength in *mdx* (-) control mice was evident, relative to WT mice, as early as ~p28 and declined over time. When AAV9-midlength-dystrophin was administered to *mdx* mice via the cerebrospinal fluid at ~p28, muscle strength was maintained when tested at ~p115 showing improvement of over 90% in both peak plantar flexion twitch torque and peak tetanic torque measurements, relative to *mdx* (-) controls.

In accordance with functional improvements, successful RNA end-joining within skeletal and cardiac muscle tissue from *mdx* mice dosed with AAV9-midlength-dystrophin was confirmed using ddPCR to detect joined RNA and by immunostaining to demonstrate robust expression of midlength-dystrophin protein. Ongoing studies are designed to test the optimal timing of administration, route of administration and length of dystrophin construct.

1077 Evaluate DWORF Gene Therapy in the Diaphragm of Dystrophin-deficient mdx Mice

Duchenne muscular dystrophy (DMD) is the most common form of muscular dystrophy and is caused by an absence of the protein dystrophin in muscle. Without dystrophin, patients experience severe muscle weakness and degeneration. One cause for rapid muscle degeneration is high calcium concentrations within the cytosol of DMD muscle fibers that activate cellular proteases and phospholipases. Dwarf open reading frame (DWORF) is a positive regulator of the sarco-endoplasmic reticulum calcium ATPase (SERCA), a pump responsible for moving cytosolic calcium into the sarcoplasmic reticulum (SR) of muscle cells. SERCA function is reduced in DMD. Increasing SERCA activity by DWORF is one avenue for clearing aberrant cytosolic calcium in DMD. We recently demonstrated that adeno-associated virus (AAV)-mediated DWORF overexpression significantly attenuated dilated cardiomyopathy in aged mdx mice, a symptomatic DMD mouse model. Diaphragm is the most severely affected muscle in mdx mice. Here we examined whether AAV DWORF therapy can attenuate dystrophic pathology and force loss in the mdx diaphragm. We delivered 6 x 10^{12} vg/mouse of the AAV9.DWORF vector to 6-week-old male mdx mice via the tail vein. We examined DWORF expression, diaphragm histology (fibrotic area, myofiber size, and % of centrally nucleated myofibers), and diaphragm function (twitch force, tetanic force and resistance of eccentric contraction-induced muscle force loss) when mice reached 6 months of age. Surprisingly, we did not detect significant improvements in the parameters we analyzed. Future studies are needed to understand the discrepancy in the therapeutic outcomes between the diaphragm and the heart.

1078 Characterization of New Dystrophic Mouse Models of Duchenne Muscular Dystrophy as a Tool for Therapeutic Development

Liubov Gushchina[1], Atiya Khan[2], Gabrielle Dufresne[3], Adrienne Bradley[4], Kayla Stevens[2], Natalie Rohan[5], Emma Frair[4], Tatyana Vetter[2], Kevin Flanigan[6]
[1]The Ohio State University and Nationwide Children's Hospital RI, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Nationwide Children's Hospital, [4]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [5]Abigail Wexner Research Institute at Nationwide Children's Hospital, [6]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH

Objective: Duchenne muscular dystrophy (DMD) is a severe, X-linked muscle wasting disorder affecting newborn males. DMD is characterized by progressive muscle degeneration caused by mutations in the dystrophin gene. Gene

therapies targeting exon skipping have shown promise, but developing personalized treatments for unique mutations has been hindered by the lack of specific mouse models. This study aimed to comprehensively characterize multiple DMD mouse models to elucidate the disease's underlying mechanisms, paving the way for tailored gene therapies.

Methods: We examined three dystrophic mouse models in comparison with wild-type C57Bl/6 mice. The models consisted of the previously characterized Dup2 mouse and two novel models: Del18-41, featuring a large exon 18-41 deletion, and Dup2Del18-41, combining both mutations. Our analysis consisted of survival studies, electrophysiological assessments, including measurements of absolute and specific forces, eccentric contraction fatigue in the tibialis anterior muscle, and morphological and histopathological examinations of muscles and organs collected after euthanasia. This comprehensive approach enabled a thorough evaluation of the dystrophic mouse models.

Results: Our study revealed significant reductions in longevity among all dystrophic mouse models compared to C57Bl/6 mice. *In situ* physiology assessments demonstrated substantial declines in muscle function, including in specific force and force retention during eccentric contractions (ECC). These declines were statistically significant across various time points (3-12 months) and consistent among all three dystrophic models. In addition, muscle histopathology showed progressive dystrophy, characterized by increased central nucleated fibers. Ongoing studies include behavioral testing and additional histopathological analyses to further elucidate the disease phenotype.

Conclusion: Our study provides preliminary characterization of two novel dystrophic mouse models (Del18-41 and Dup2Del18-41), revealing significantly reduced lifespans and impaired muscle function in all DMD mice. Electrophysiological analysis of the tibialis anterior muscle showed decreased resistance and endurance in response to tetanic and eccentric contractions, correlating with negligible or low dystrophin levels. These findings set the stage for future behavioral studies to further elucidate the disease phenotype in these models.

1079 AAV-expressed Microdystrophin Containing Extended C-terminus Improves Muscle Function and Protects Against Injury in a Mouse Model of Duchenne Muscular Dystrophy

Benjamin Heithoff[1], Steven Foltz[1], Randolph Qian[2], Hannah Jasick[1], Kirk Elliott, Jason Yang[1], Jared Smith[1], Olivier Danos[1]
[1]REGENXBIO Inc., Rockville, MD, [2]REGENXBIO, Rockville, MD

Duchenne Muscular Dystrophy (DMD) is a fatal, X-linked disease resulting from mutations in the *DMD* gene, leading to progressive loss of skeletal and cardiac muscles. Muscle weakness in DMD initially affects proximal muscles, presenting as difficulties in walking and running. As the disease progresses, patients lose the ability to walk and eventually face respiratory or cardiac failure. In developing dystrophin replacement or restorative gene therapies, preserving muscle function that resists injury in early stages is essential to slowing the degenerative progression of the disease. Specifically, gene replacement therapy via viral vectors has demonstrated restoration of muscle strength in rodent models using shortened “microdystrophins” (µDys), which are accommodated by the 4.7kb packaging limit of AAV vectors. Yet debate exists regarding the selection of which dystrophin domains to include that optimize muscle function improvement. Inclusion of an extended portion of the C-terminus (CT) of dystrophin in the µDys has been shown to improve resistance to force loss from repeated eccentric injury compared to µDys lacking the CT domain.

To further characterize the CT domain’s role in improving µDys efficacy via rescuing muscle function, we tested two AAV vectors expressing µDys with and without the extended CT domain (µDysCT194 and µDysCT48 respectively). Vectors were administered i.v. via tail vein at 5 weeks of age in male *mdx* mice, which lack dystrophin. At 6- and 12- weeks post-dosing, mice expressing µDysCT194 showed significantly improved forelimb grip strength, exhaustion treadmill performance, and distance traveled in the open field compared to mice expressing µDysCT48.

To determine whether these effects were mediated through direct protection of myofibers expressing µDysCT194, we used Evans blue dye to visualize damaged muscle following an *in vivo* plantar flexion eccentric injury assay. We

found that µDysCT194-treated mice showed significantly less force loss from repeated eccentric injuries compared to the µDysCT48 group, concomitant with significantly fewer number of Evans Blue positive (i.e. damaged) myofibers in the µDysCT194 animals. To address natural motions experienced by muscles, we developed the downhill treadmill running assay, a physiologically relevant eccentric injury model based on movement that is discouraged for DMD patients. This assay produced a severe phenotype in mdx mice, indicating its utility for preclinical studies of µDys gene therapies, opening an important future direction of REGENXBIO's research.

In summary, across numerous behavioral and physiological assays, we observe that animals treated with the extended CT domain of dystrophin (µDysCT194) demonstrate superiority in motor function, muscle force, and resilience to eccentric injury compared to animals treated with µDys lacking the extended CT domain. These findings suggest a critical function of the dystrophin CT domain in improving the therapeutic benefit of µDys gene therapies.

1080 CSF Delivery of INS1201 AAV9-Micro-Dystrophin Demonstrates Long-Term Durability of Efficacy in a Mouse Model of DMD

Gretchen Thomsen[1], Allan Kaspar[1], Laura Ferraiuolo[2], Binh Chu[1], Veronica Garcia[3], Nuria Casanova[1], Theresa Slaiwa[1], Ryan Weiss[1], Robert Cano[1], Hana Julazadeh[1], Haunani Bautista[1], Erin Hurley[2], Ashley Renteria[1], Jaedyn Rollins[4], Maiya Lee[5], Melissa McAlonis-Downes[6], W. David Arnold[7], Brian Kaspar[1]
[1]Insmed, Inc., San Diego, CA, [2]Insmed Inc, San Diego, CA, [3]Insmed Gene Therapy, LLC., San Diego, CA, [4]San Jose, CA, [5]Insmed, San Diego, CA, [6]UCSD, Encinitas, CA, [7]University of Missouri, Columbia, MO

INS1201 is an AAV9-based micro-dystrophin gene therapy construct being evaluated as a potential treatment for Duchenne muscular dystrophy (DMD). This vector expresses a truncated form of dystrophin, which has demonstrated therapeutic efficacy in the *mdx* mouse model of DMD and is delivered via a single intrathecal (IT) injection. INS1201 was administered to *mdx* mice via the cerebrospinal fluid (CSF) at postnatal day (p) 28 with subsequent evaluation of its effects on functional efficacy, histopathology, vector genome biodistribution, and micro-dystrophin expression at approximately one-year post-administration.

Following intracerebroventricular (ICV) administration of INS1201 in *mdx* mice at p28, significant long-term functional improvements were observed in hindlimb muscle strength. Using the Aurora Scientific Whole Animal System for Mice, physiology measurements were performed to assess contractile torque of the plantar flexion muscles, which includes the gastrocnemius muscle. At approximately 400 days of age, INS1201-treated mice exhibited substantial enhancements in peak plantar flexion twitch torque, with improvements of 87%, 67%, and 104% at doses of 4.0E+11, 8.0E+11, and 1.6E+12 vector genomes (vg), respectively, compared to *mdx* (-) controls. Furthermore, when assessed at stimulation frequencies of 80-160 Hz, INS1201-treated mice showed notable improvements in plantar flexion peak torque across these doses relative to controls.

Histopathological analysis of gastrocnemius muscle at p400 revealed significant reductions in dystrophic pathology, including improved structural organization, fewer inflammatory cells, and reduced fibrosis in INS1201-treated mice. These findings were consistent across all doses evaluated, with the highest dose demonstrating the most pronounced effects. Importantly, micro-dystrophin expression was sustained in the gastrocnemius muscle of treated mice at this late time point at all doses, confirmed by immunostaining and Western blotting. Quantitative Jess Western analysis revealed a significant increase in micro-dystrophin expression at the 1.6E+12 vg dose relative to controls. Vector genome analysis using ddPCR showed a positive correlation between vector genome presence and micro-dystrophin expression. Sustained micro-dystrophin expression was also observed in cardiac muscle tissue at p400, as confirmed by immunostaining and Western blotting, with a significant dose-dependent increase in protein expression at all doses evaluated. Biodistribution analysis of INS1201 vector genomes in the heart correlated with protein expression levels, with mean values of 0.758, 1.509, and 3.225 vg/diploid genome at the respective doses.

In conclusion, these results demonstrate that CSF delivery of INS1201 in *mdx* mice leads to long-term (at least one year) durability of micro-dystrophin expression and vector genome biodistribution in both skeletal and cardiac muscle, along with sustained functional benefits. These findings support ongoing studies to evaluate the potential of INS1201 as a therapeutic option for DMD.

1081 Comprehensive analysis of longitudinal SV95C measurements, an e-digital mobility assessment in a real-life Duchenne population in the GNT-014-MDYF natural history study

Silvana De Lucia[1], Jean Davion[2], Tristan Montier[3], Caroline Espil[4], Michaela Guglieri[5], Laure Le Goff[6], Brigitte Chabrol[7], Andreea Seferian[8], Laurent Thibaut[9], Eric Guemas[10], **Arnaud Valent[11]**, Gerald Perret[12], Fei Ghoul, Vincent Laugel[13], Francesco Muntoni[14]

Duchenne muscular dystrophy (DMD) is characterized by a wide range of clinical manifestations, and its progression can vary greatly. Hospital-based, physiotherapist-assisted functional assessments, including the North Star Ambulatory Assessment (NSAA), the Six Minute Walk Test (6MWT), the 10 Meter Walk Test (10MWT), and the Time to Raise from Floor (RFF), are widely utilized for monitoring disease progression in both clinical and research settings. Stride Velocity at the 95th Centile (SV95C), captured via a wearable device, provides a continuous measure of daily mobility in real-life environments. This method reduces dependence on patient cooperation (e.g., young patients) and minimizes inter-evaluator variability. Recently, the European Medicines Agency (EMA) has qualified SV95C as a primary endpoint for clinical trials in DMD. The current analysis aims to evaluate the validity and establish normative data for SV95C within the context of a natural history (NH) study.

Seventy-seven boys with DMD, aged 5-9 years, receiving steroids and achieving a NSAA score of ≥18, were enrolled in the prospective NH study GNT-014-MDYF. Both SV95C and other clinical functional outcomes (e.g., NSAA, RFF, 10MWT) were measured biannually. Data were described by age subgroups (5-8 years and >8 years). The accuracy of SV95C was evaluated and compared to both age-matched healthy controls (n=66) and DMD populations (n=107) from the EMA SV95C Qualification Dossier. Reliability was assessed using the intra-class correlation coefficient (ICC), with SV95C data separated into two half-recording periods. Spearman's correlation was employed to assess the consistency between different functional outcomes.

From baseline to 2 years, SV95C demonstrated high reliability, with ICC ranging from 0.96 to 0.98. The mean SV95C values in DMD patients were distinctly separated from those of healthy controls and were consistent with the data reported in the EMA SV95C Qualification Dossier. At the 1-year follow-up, the mean changes in SV95C were -0.097 m/s and -0.162 m/s for the 5-8 years and >8 years age groups in GNT-014-MDYF, respectively, compared to -0.263 m/s and -0.226 m/s for the corresponding age groups in the DMD population from the EMA Dossier.

While the overall trend in SV95C change was consistent, the changes observed in GNT-014-MDYF were numerically lower, which may be attributed to differences in baseline characteristics. Strong correlations were observed between SV95C and other clinical outcomes, with correlation coefficients of 0.70, 0.56, -0.73, and 0.83 for NSAA, 6MWT, RFF, and 10MWT, respectively. Notably, these correlations appeared to improve over time. The minimal clinically important difference (MCID) for NSAA, defined as a 3-point change, anchored the SV95C change in this natural history population to -0.140 m/s, with values of -0.125 m/s and -0.221 m/s for the 5-8 years and >8 years age groups, respectively.

This analysis demonstrated the validity of SV95C in a NH study with standardized follow-up, confirming its consistency with previously published data. It further suggested that SV95C is a sensitive measure for detecting clinical changes and showed strong correlations with other clinical assessments, supporting its potential application in the clinical development of innovative treatments. The predictive value of SV95C is currently being explored, and additional analyses will be conducted to better understand its MCID.

1082 Patient-Specific 3D Myofiber Cultures as Model for Therapeutic Development

Hui Lin[1], Nizar Saad[2], Kayla Stevens[1], Sarah Atkins[3], Tatyana Vetter[1], Stefan Nicolau[1], Emma Frair[4], Nicolas Wein[5], Liubov Gushchina[6], Kevin Flanigan[7]*

Understanding the functional impact of patient-specific disease-related mutations in muscle often requires functional assessments, particularly regarding contractility. However, culture of patient myoblasts and differentiation into myotubes is typically performed in two-dimensional (2D) monolayer cultures that preclude contractility assessments. In vivo studies are limited as most private mutations are not found in animal models, and the cost of repeatedly creating patient-specific models is prohibitive. As an alternative, 3D cultures offer the possibility to better represent myofiber organization in muscle and to model diseases in vitro. 3D cultures include cell-cell and cell-extracellular interactions which may be important in the formation of myofibers. In addition, 3D cultures methods that allow assessment of contractility provide the opportunity to measure the responses of pathological skeletal muscle to different therapies.
We have used the Mantarray platform (CuriBio) to generate preliminary studies of patient-derived cells from our large Wellstone P50-funded Cell Line bank, which includes 37 primary myoblast lines and 149 transdifferentiatable FibroMyoD (FM) lines. Mantarry integrates 3D myofiber cultures with a magnetic sensing system to measure contractile forces in response to spontaneous contraction or electrical stimulation as well as small chemical treatments. Specifically, 3D myofiber cultures of iPSC-derived myoblasts, primary myoblasts and MyoD induced FM lines under tension to generate aligned myofibers. By comparing their morphology, gene expression, and contraction to those of wild type myofibers, we are able to assess the pathological and functional characteristics associated with a range of mutations responsible for Duchenne and Becker muscular dystrophy, facioscapulohumeral muscular dystrophy, and congenital myopathies. Our preliminary data suggest that 3D myofiber culture is a promising model for both characterizing functional impact of mutations and assessing treatment effects with AAV vectors.

1083 Targeting of ribitol metabolic pathway using AAV to enhance glycosylation and therapeutic efficacy of metabolites in the FKRP-P448L mutant mouse.

Anthony Blaeser[1], Molly Holbrook[2], Qi Lu[3]
[1]Atrium Health, Huntersville, NC, [2]Atrium Health, [3]Carolinas HealthCare System, Charlotte, NC

The glycosylation of alpha-dystroglycan is crucial in binding extracellular matrix proteins to provide structure and stability to the muscle membrane. There are currently 18 known genes involved in the glycosylation of alpha-dystroglycan and mutations in any of these can result in the loss or reduction of glycosylation causing a subset of muscular dystrophy known as dystroglycanopathies. Mutations in Fukutin-related protein (FKRP) are the primary cause of limb-girdle muscular dystrophy 2I/R9. FKRP functions as a ribitol-5-phosphate transferase working in tandem with fukutin to add ribitol-5-phosphate to the core M3 glycan chain, a necessary step for completing an elongated glycan chain of repeating units of glucuronic acid and xylose referred to as matriglycan.

The full biosynthetic pathway of ribitol-5-phosphate is unknown but advancements have been made to identify several different proteins involved. FGGY has been shown to convert ribitol to ribitol-5-phosphate but other reductases have also been identified to have this activity. The aldo-keto reductases AKR1A1 and AKR1B1 have also been shown to be involved in the conversion of ribose to ribitol and/or ribose-5-phosphate to ribitol-5-phosphate with varying degrees of efficiency. Our lab has shown that administration of ribitol to the FKRP-P448L mutant mouse increases levels of ribitol-5-phosphate and subsequently ameliorates the disease phenotype. Similarly, it has been shown that administration of ribose can have beneficial effects to FKRP-related muscular dystrophies.

However, the recovery of glycosylation is incomplete, and attempts are being made to improve the effectiveness of metabolite administration. Here we use AAV9 delivery of 1E13vg/kg and 5E13vg/kg of FGGY, AKR1A1 and AKR1B1, with and without exogenous metabolite administration, to examine their potential of improving alpha-dystroglycan glycosylation and metabolite effectiveness. Analysis of heart, TA and diaphragm tissues 1 month post administration shows increased levels of alpha-dystroglycan glycosylation in the FKRP-P448L mutant mouse. By targeting the biosynthetic pathway of ribitol-5-phosphate the effectiveness of ribitol treatment can potentially be improved for treating FKRP-related muscular dystrophies.

1084 Development of dosing protocol to reduce the required dose of rAAV using adult stem cells

Hiromi Hayashita-Kinoh[1], Akiko Ishii[2], Ken Sugo[3], Guillermo Posadas-Herrera[4], Masahiro Hayashi[5], Tomoyuki Nakaishi[6], Takashi Okada[7]*

Background: AAV vectors are safe and allow long-term expression of therapeutic genes. rAAV-based gene therapy is being tested for genetic disorders such as SMA, XLMTM, and Duchenne muscular dystrophy (DMD). In clinical trials, the typical intravenous rAAV dose is $3x10^{13}$~$1x10^{14}$ vg/kg body weight.
DMD is a congenital disease in which skeletal and cardiac muscles are gradually lost due to mutations in the dystrophin gene. We previously reported a therapeutic effect of bone marrow-derived MSC (BM-MSC) pretreatment followed by a low-dose ($2x10^{12}$ vg/kg BW) rAAV-μDys administration in DMD dogs ($CXMD_J$), and a clinical trial is planned to use this administration method. In this presentation, we investigated the safety of AAV-μDys in combination with adult mesenchymal stromal cells (MSCs), which are used for cell therapy in children with DMD, using non-human primates.
Methods: Normal cynomolgus monkeys were intravenously injected with MSCs and rAAV8-LacZ ($2x10^{12}$ vg/kg BW). Seven days after injection, MSCs were administered systemically again. Eight days after the first injection, the same monkeys were injected intramuscularly with rAAV8-LacZ. Blood samples were collected over time for biochemical analysis and neutralizing antibody titers against rAAV8. Muscle biopsies were performed at 8, 16, and 24 weeks after rAAV injection.
Results: When rAAV was administered to non-human primates according to the above protocol, no weight loss was observed, and no blood biochemical abnormalities were detected with AAV vector and/or MSCs administration.
Conclusion: These results indicate that the combination of MSCs and rAAV is safe in nonhuman primates. This dosing protocol appears to be a practical approach for analyzing transgene expression and function *in vivo*. These findings support the future potential of rAAV-mediated protein replacement strategies in the treatment of DMD and various genetic disorders.

1085 Base Editing Screen For Endogenous Activation of Zeta Globin Expression As A Treatment For Alpha Thalassemia Major

Marco Carpenter[1], Rosa Choi[2], Philip Zoltick[2], Mohamad-Gabriel Alameh[3], William Peranteau[2]
[1]Childrens Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania, Children Hospital of Philadelphia, Philadelphia, PA

Alpha Thalassemia is an inherited blood disorder caused by mutations or deletions in the alpha-globin locus. The most severe form, Alpha Thalassemia Major (ATM) occurs when all four alpha globin genes (HBA1 and HBA2) are absent. In some cases, deletion of HBA1 and HBA2 results in upregulation of the nearby alpha like zeta globin gene (HBZ), which may compensate for the loss of HBA and rescue the lethal phenotype. In normal erythropoiesis, transcriptional control of HBZ, HBA1, and HBA2 is mediated by common enhancer elements. The embryonic HBZ globin is expressed almost exclusively in primitive erythroid cells and silenced in definitive erythroid cells. Known regulators of HBZ expression include leukemia/lymphoma-related factor (LRF) and B-cell lymphoma/leukemia 11A

(BCL11A), which coordinate HBZ repression via binding in enhancer and promotor regions of the HBZ gene. To uncover activator elements that can be leveraged to induce HBZ expression in definitive erythroid cells, we designed a sgRNA library that encompassed the entire alpha globin locus. The library included sgRNAs targeting the alpha globin locus (HBZ, HBA2 and HBA1; ~7500), positive control sgRNAs targeting the LRF (ZBTB7A) and BCL11A gene (100), and non-targeting sgRNAs controls (500). We constitutively expressed an adenine base editor (ABE 8.20) and a single sgRNA in HUDEP-2 cells, an erythroid test cell line and isolated high expressing HBZ cells. sgRNA enrichment was quantified and top individual sgRNA targets were validated in HUDEP-2, primary CD34+ human cord blood and adult hematopoietic stem cells. Positive control sgRNAs targeting the LRF and BCL11A gene induced HBZ expression. sgRNAs targeting HBA2 and HBA1 gene induced HBZ expression, suggesting reciprocal control between these genes. Overall, this approach identified numerous sgRNAs with varying degrees of HBZ induction in normal models of erythropoiesis. Future studies test the functional significance of endogenous HBZ induction on the accumulation of toxic beta-globin dimers observed in ATM cell models.

1086 Identification of Genetic Variants Associated with T-Cell Lymphoma: A Case-Control SNP Analysis

SOHAIB Al-KHATIB[1], **Jowan Al-Nusair[2]**, Nour Abdo[3], Laith AL-Eitan[3]
[1]Jordan University of Science and Technology, Irbid, Amman, Jordan, [2]Marshall University, Huntington, WV, [3]Jordan University of Science and Technology, Irbid, Jordan

Introduction: T-cell lymphoma (TCL) is a rare and heterogeneous group of malignancies characterized by poor prognosis and limited therapeutic options. While the role of genetic predisposition in TCL remains poorly understood, recent advances in genomic studies suggest that specific single nucleotide polymorphisms (SNPs) may contribute to disease susceptibility. This study aims to identify SNPs associated with TCL by comparing genetic variants between patients diagnosed with TCL and healthy controls.

Methods: This retrospective case-control study was conducted at a single institution, analyzing genetic data from 31 TCL patients and 301 healthy controls. A targeted SNP analysis was performed to assess differences in allele and genotype distributions. Pearson's Chi-square and likelihood ratio tests were utilized to determine statistical significance. The SNPs included in the analysis were selected based on prior associations with immune regulation, inflammation, and tumorigenesis.

Results: A total of 10 SNPs demonstrated statistically significant differences between TCL patients and controls. Among these, rs308395 (FGF2, $p<0.001$) and rs3025039 (VEGFA, $p<0.001$) exhibited the most significant associations, suggesting their potential role in TCL susceptibility through pathways related to angiogenesis and tumor progression. Additionally, rs2228001 (XPC, $p=0.028$), a variant linked to DNA damage repair, and rs2167270 (LEP, $p=0.029$), associated with immune regulation and metabolism, showed significant differences between cases and controls. Variants in key inflammatory and immune-related genes were also identified, including rs1800890 (IL10, $p=0.050$), rs1800629 (TNF, $p=0.029$), and rs1790192 (CXCR5, $p=0.041$), all of which have been implicated in cytokine regulation and immune surveillance. Moreover, rs17757541 (BCL2, $p=0.034$), a critical regulator of apoptosis, and rs1800683 (LTA, $p=0.140$), involved in lymphotoxin signaling, showed trends toward significance, warranting further investigation into their roles in TCL pathogenesis.

Conclusions: Certain SNPs exhibit varying frequencies between TCL patients and controls. These findings highlight potential genetic markers for TCL risk, which could inform future gene-targeted therapies and precision oncology approaches.

1087 Gene Editing Primary T Cells to Enable CRISPR-On-Demand Therapy in an "Every Patient Brings Their Own Mutation" Setting: the Use Case Scenario of Hemophagocytic Lymphohistiocytosis

Dror Assa[1]*, Allison Bien[1], Elise Wolf[1], Kevin Briseno[2], Taylor Hudson[3], Aysel Ogul[1], Petros Giannikopoulos[4], Fyodor Urnov[3], David Nguyen[5]

**Corresponding Author*

The toolbox of CRISPR gene editing enables targeted repair of disease-causing mutations, but particular genetic disorders where every patient has a private mutation pose a profound challenge for nonclinical development. We are developing a platformized gene editing approach to treat hemophagocytic lymphohistiocytosis (HLH) - a rare and life-threatening immunological disorder marked by persistent hyperinflammation stemming from consequences of defective cytotoxic function in immune cells, particularly T and NK cells, with inability to terminate the immune response. Ca 40% of newly diagnosed patients fail to survive under standard care, with only a few months available to develop an on-demand therapy for each patient's unique mutations. In the case of fHLH caused by mutations in the PRF1 gene, most patients are compound-heterozygous for loss-of-function mutations of different severity, and de novo mutations are initially classified variants of uncertain significance (VUS). Before therapeutic editing can occur, a viable platform requires the ability to rapidly determine mutation pathogenicity and which allele(s) to target for repair.

Here we describe such an approach: we used gene editing to introduce PRF1 variants of uncertain significance (VUS) found in a patient with HLH at UCSF [c.112G>A (p.Val38Met, VUS1) and c.133G>A (p.Gly45Arg, VUS2)]. To assess the functional consequence of these VUSs and enable VUS derisking in < 1 week, VUS1 and VUS2 were individually introduced into the endogenous PRF1 locus using CRISPR targeted HDR integration of a partial cDNA bearing one or the other VUS translationally linked to a reporter gene that allows rapid isolation of mutation-bearing cells. Functional assays demonstrated significant reductions in perforin expression (60% for VUS1 and 90% for VUS2) and corresponding defects in CTL cytotoxic function. This demonstrated clear pathogenicity of these variants and sets a methodology for studying other PRF1 VUSs. Given the exceptionally narrow window of time available for clinically impactful mutation repair, we developed a gene-editing approach to correct PRF1 mutations that relies on the same gene editor - nuclease Cas9 (rather than mutation-bespoke isoforms of other editors - such as base or prime - each of which would need additional derisking pre-dosing). We combine Cas9 RNPs with ssODN HDR templates to attain locally efficient mutation repair in PRF1 in primary T cells at numerous different gRNA targets; a non-exhaustive tiling approach across the PRF1 locus identified multiple optimal gRNAs to attain therapeutically-relevant repair within a given window.

Taken together our work establishes, for the first time, an end-to-end platform of rapid derisking a VUS to nominate it for clinical repair and then repairing it using a set of genome editing tools that are clinic-grade and where the transition from mutation 1 to mutation 2 would not require changing the protein subunit of the genome editor, potentially accelerating the path of such a CRISPR-on-demand approach through regulatory review.

1088 A base editing platform optimised for efficient editing retains stemness and differentiation potential of hematopoietic stem cells

Hematopoietic stem and progenitor cells (HSPCs) are a foundational cell type for the development of engineered therapies. Since engineered HSPCs are meant to persist throughout a patient's lifetime and are sensitive to DNA damage, it is important to utilize a technology which minimizes genotoxicity and safeguards engineered cell

functionality. Nuclease-induced double strand breaks (DSBs) trigger a DNA damage response which may lead to chromosomal aberrations, decreased viability and cell function, and ultimately reduce the efficacy and safety of engineered therapies. Base editors are not reliant on DSBs and represent an effective mitigation strategy but must be optimised for efficient delivery into HSPCs. Our proprietary Pin-point^{TM} platform is a flexible modular base editor typically comprising a DNA binding Cas, a DNA modifying deaminase, and a sequence-targeting guide RNA which assembles at the target locus, and demonstrates an advanced safety profile compared to nuclease-based technologies. This makes it well suited to the development of cell and gene therapies in sensitive cell types such as HSPCs. In this study we used a Pin-point base editing system composed of Rat APOBEC1 mRNA, SpCas9 nickase mRNA and a synthetic aptamer-containing gRNA to edit CD34+ HSPCs with 80% efficiency. Flow cytometry of edited cells revealed an unaltered frequency of hematopoietic stem cells (HSCs) compared to the control and high levels of gene knock out in both the bulk and HSC population which was retained over 5 weeks. Moreover, primitive hematopoietic cells edited with the Pin-point platform retain their stemness capacity as validated in a Long-Term Culture-Initiating Cell (LTC-IC) assay. Additionally, no significant DNA damage response was detected, further supporting the gentler activity on cells. Next, we validated the technology on two separate loci known to reactivate γ-globin expression and achieved high levels of base editing that corresponded with an increase in γ-globin mRNA and protein expression as a relevant therapeutic outcome. The ability to base edit HSPCs efficiently and safely, while maintaining their stemness and differentiation potential, demonstrates the strength of the Pin-point platform as a tool for the generation of advanced cell therapies using sensitive multipotent cell types.

The Pin-point™ base editing platform technology is available for clinical or diagnostic study and commercialization under a commercial license from Revvity.

1089 A new model using humanized mice to explore the fate of HIV DNA in secondary lymphoid and hematopoietic organs during the early phase of acute infection

Jean-Sébastien DIANA[1], Yevgeniy Tatirovsky[2], Selen Ay[2], Celine Cuche[2], Chiara Tomasini[2], Marina Cavazzana[3], Viviana Scoca[2], James Di Santo[2], Francesca Di Nunzio[2]
[1]APHP, Paris, Paris, France, [2]Institut Pasteur, Paris, Paris, France, [3]Necker Hospital, Paris, France

The HIV-1 replication cycle has been extensively studied through biochemical analysis, yielding valuable insights into the replication cycle. However, unveiling the potential of viral reservoirs for elimination necessitates more efficient techniques to identify these cells *in vivo*. Traditional methods restrict the assessment of new therapeutic strategies for the HIV cure.

Recent advances in imaging technologies have provided new tools for studying the HIV-1 life cycle and reservoir formation. We have developed a combination of imaging microscopy with fluorescently labeled viral genomes that enable the investigation of HIV-1 biology at the single-cell level. Here, we present a unique approach by fluorescence microscopy-based method, using a humanized (HIS) mouse model sensitive to HIV-1 to live-track the final products of the reverse transcription. Our technology employed a bacterial-derived fluorescence technique (OR-GFP) to tag the replication-competent virus. The genetically modified mice expressing the OR-GFP protein in CD4+ T-cells can reveal, by confocal or in live, individual double-stranded full-length HIV DNA forming bright nuclear puncta in the nucleus. Combined with the RNA-FISH, this method distinguished between non-transcribing and actively transcribing viral DNA from lymph nodes, spleen, and bone marrow extracted from infected mice. Our results were consistent with the notion that viral reservoirs are established during the early stages of viral infection. Of paramount significance, our innovative *in vivo* system not only provides a sensitive and fresh approach for live tracking the full-length viral DNA genome in infected cells without relying on cell culture but also holds the potential for mapping the trajectories of infected cells throughout various phases of HIV infection. This aspect of our research is promising, as it opens up new possibilities for understanding the dynamics of HIV infection and developing new treatments targeting early reservoir cells and potential latent viral forms.

1090 Induction of Immune Tolerance in a Food Allergy Model Utilizing Platelet-Targeted Therapy

Saurabh Kumar[1], Jocelyn Schroeder[2], Yu Hongyin[3], Qizhen Shi[4]*
[1]Versiti Blood Research Institute Wisconsin, Milwaukee, WI, [2]Medical College of Wisconsin and Versiti Blood Research Institute, Milwaukee, WI, [3]Versiti, Milwaukee, WI, [4]MCW/Pediatric Hematology, BRI, Milwaukee, WI

Background: Food allergy is a significant public health concern driven by a failure in oral immune tolerance, with no definitive cure. Our previous studies demonstrated that platelet-specific gene therapy induces antigen-specific IgG-mediated immune tolerance in hemophilia models. Additionally, we found that desialylated platelets suppress immune responses. This study aims to develop a novel strategy to induce immune tolerance to allergens and mitigate allergic reactions. *Methods*: Using ovalbumin (OVA) as a model allergen, we investigated two mouse models: the OVA-specific OT-II model (98% OVA-specific CD4 T cells) and IL4ra^{F709} mutant mice (prone to allergic responses). For preventive therapy, we transduced hematopoietic stem cells (HSCs) with a 2bOVA lentivirus, followed by transplantation. Platelet-OVA expression was confirmed via ELISA. Mice were sensitized weekly with OVA (10 mg/kg) and staphylococcal enterotoxin B (SEB, 0.4 mg/kg) for eight weeks before a high-dose OVA challenge (6 g/kg). For treatment studies, OVA-containing platelets from 2bOVA transgenic mice were transfused into pre-sensitized mice before rechallenge. Anaphylaxis was assessed via body temperature changes, and immune tolerance was evaluated using tissue analysis. *Results*: Platelet-OVA expression levels were 11.49 ± 7.49 ng/10^8 platelets in 2bOVA-transduced OT-II recipients and 6.82 ± 6.89 ng/10^8 platelets in IL4ra^{F709} recipients. Following OVA challenge, body temperature dropped significantly in control mice (1.89 ± 1.29ºC in OT-II; 2.05 ± 0.59ºC in IL4ra^{F709}) but remained stable in 2bOVA-transduced animals. Anti-OVA IgE titers increased in controls but remained unchanged in the 2bOVA group. Flow cytometry revealed significantly lower Th2 cell percentages in 2bOVA mice (0.87 ± 0.60% OT-II; 0.40 ± 0.33% IL4ra^{F709}) compared to controls (3.18 ± 2.11% OT-II; 2.89 ± 1.39% IL4ra^{F709}), while Treg and Tr1 cells were markedly increased. Importantly, mast cell protease-1 levels were significantly reduced in 2bOVA-transduced recipients compared to control (2bGFP or untransduced) groups under the same immune challenge protocol. Notably, transfusion of desialylated 2bOVA platelets effectively suppressed anaphylaxis via IgE regulation. *Conclusion:* Our findings demonstrate that platelet-targeted gene therapy induces immune tolerance by modulating the Th2/IgE pathway and preventing anaphylaxis. Furthermore, transfusion of allergen-expressing platelets mitigates anaphylactic responses, with suppression of mast cell activation, highlighting a novel therapeutic approach for food allergy treatment.

1091 An iPSC-derived 3D liver model for safety assessment of AAV-based gene therapies

Estelle Berreur[1], Rebecca XICLUNA[2], Ramona Matheis[3], Adrian B. Roth[4]
[1]Hoffmann-La Roche, Basel, Basel-Stadt, Switzerland, [2]F.Hoffmann-La Roche Ltd, Basel, Switzerland, [3]Basel, Switzerland, [4]Hoffmann-La Roche, Baserl, Basel-Stadt, Switzerland

Adeno-associated viral (AAV) vectors have evolved as one of the key delivery methods in the growing field of gene therapy. However, systemic administration of AAVs can lead to accumulation not only in the desired target tissue, but also in other organs such as the liver. Due to its particular anatomy, the liver is prone to take up AAVs and it has been observed in several clinical studies that AAVs may lead to severe liver toxicity and even fatalities. This raises significant concerns for AAV programs as the mechanism of AAV-driven liver toxicity is not understood and there are currently no good biomarkers to predict who is at risk. Furthermore, conventional preclinical in vitro liver models that do not encompass the complexity and individual variability in humans have failed to recapitulate AAV-mediated liver toxicity. To tackle this issue, the aim of this study was to develop a patient-specific, iPSC-derived, multi-cell type liver-immune organoid model that is able to predict liver cells transduction and AAV-mediated liver toxicity. We made use of peripheral blood mononuclear cells (PBMC)-derived induced pluripotent stem cells (iPSC) that were differentiated into hepatocytes, stellate cells, endothelial cells and monocytes - the four main cell types of the liver. We co-cultured these cells as organoids and characterized the model by immunohistochemistry and qRT-PCR for liver-specific markers. We then exposed the organoids to GFP-labeled wild type AAVs and could show that they can be transduced by different AAV serotypes. Our model is able to recapitulate the transduction of the

different cell types by various rAAVs. However, AAV-mediated hepatotoxicity could not be observed following AAV transduction in this configuration. We therefore established a co-culture of the organoids with PBMCs from the same donor to reflect the immune component. Using such a multicellular, immunocompetent liver organoid model we sought to perform T Cell priming experiments in combination with multi-omics assessment of the liver-immune system. While still in an exploratory stage, the results from this innovative approach are encouraging and provide deeper insights into the mechanisms and individual patient-factors that contribute to rAAV transduction and AAV-driven liver toxicity, eventually leading to the development of more effective and safer gene therapies.

1092 Generation of Functional Liver Organoids Using CD34+ Cord Blood-Derived GMP Friendly iPSCs

RANRAN ZHANG[1], Xuan Guo[2], Junxia Wang[3]
[1]Catalent Cell & Gene Therapy, Princeton, NJ, [2]Catalent Cell and Gene Therapy, Princeton, USA, Princeton, NJ, [3]Premier Biosciences, Princeton, NJ

Background & Aim: Liver transplantation is the standard treatment for patients suffering from acute and chronic liver disease caused by congenital diseases, infectious agents, and environmental factors. Recent progress in liver organoid technology has opened a new opportunity for organ transplantation and cell therapy to treat liver diseases. However, current methods relying on stochastic self-organizing potential produce mixed cell populations of differentiated cell types, raising concerns about ectopic tissue formation. Induced pluripotent stem cells (iPSCs), which can differentiate into three-dimensional (3D) liver organoids, present a promising alternative. Moreover, the application of homozygous human leukocyte antigen (HLA) donor-derived iPSCs minimizes the risk of immune reaction post-transplantation. This study aims to develop reproducible GMP-compliant liver organoids from HLA-homo iPSCs and assess their potential for clinical cell therapy applications.

Methods: Human HLA-homo GMP iPSCs were used to generate gut endoderm cells (GECs) via a reproducible, scalable protocol. GECs were further differentiated into two-dimensional (2D) hepatocytes and 3D liver organoids using stepwise differentiation media. The generated cells were analyzed for hepatic functionality, including gene expression of alpha-1 antitrypsin (AAT), transthyretin (TTR), albumin (ALB), and secretion of human albumin. Functional comparisons were performed between 2D hepatocytes and 3D liver organoids to evaluate their maturation and suitability for clinical applications.

Results: The differentiation protocol successfully produced 2D hepatocytes and 3D liver organoids from HLA-homo GMP iPSCs. Hepatic genes, including AAT, TTR, and ALB, are highly induced in generated liver organoids. Human albumin reached as high as 3 µg/ml/24hr per million cells in 3D liver organoids, which is 10-fold higher than induced 2D monolayer hepatocytes.

Conclusion: This study demonstrates that liver organoids derived from HLA-homo GMP iPSCs offer scalable, reproducible, and functionally enhanced alternatives for clinical cell therapies targeting end-stage liver disease. These findings highlight the feasibility of using GMP-compliant iPSCs to strengthen organogenesis and advance next-generation liver regenerative medicine.

1093 An Optimized Protocol to Transduce Photoreceptors in Human Retinal Organoids Using AAV

Sophie Tran[1], Céline Nanteau[2], Guillaume Labernede[3], Stã©Phane Fouquet[4], Olivier Goureau, Deniz Dalkara[3]
[1]Institut de La Vision, Paris, France, France, [2]Institut de La Vision, Paris, France, [3]Institut de La Vision, Paris, Paris, France, [4]Institut de La Vision, FRANCE

In vitro models, such as retinal organoids, are increasingly used to evaluate novel gene therapy strategies. While we have demonstrated the feasibility of infecting retinal organoids with AAV vectors, outcomes vary significantly depending on factors such as organoid age and infection medium, both of which influence infection efficiency and

organoid development. Therefore, optimizing these parameters is crucial to achieving high expression levels without compromising organoid integrity.

Using RT-ddPCR quantification and RNA sequencing, we monitored gene expression and organoid development post-infection. The infection process was notably affected by the presence of serum in the medium, which competes with AAV receptors. Additionally, organoid age played a key role: infecting immature organoids risked impairing post-infection development, whereas mature organoids with segment structures exhibited lower infection efficiency due to the presence of a mechanical barrier.

Our results underscore the importance of considering seemingly minor factors, such as age and infection medium, to ensure successful AAV transduction in retinal organoids.

1094 Advanced Base and Prime Editing Strategies to Correct Common ALS-causing *SOD1* Mutations

Katharina Meijboom[1], Nathan Bamidele[2], AdityaValji Ansodaria[2], Jacob Eisenberg[2], Erik Sontheimer[2], Robert Brown[2]
[1]UMASS Medical School, Worcester, Massachusetts, [2]UMass Chan Medical School, Worcester, MA

Objective: Develop innovative base and prime editing therapies to achieve precise somatic gene correction for common missense mutations in *SOD1*.

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease with no effective treatment, leading to death within five years of diagnosis. Approximately 10% of ALS cases are familial, with mutations in *SOD1* being the second most common genetic cause. These mutations drive toxic gain-of-function properties in SOD1 protein, accelerating motor neuron degeneration. Our goal is to develop cutting-edge base and prime editing approaches to correct prevalent *SOD1* mutations. We will test and optimize next-generation domain-inlaid base editor strategies with enhanced efficiency, compact size to facilitate AAV delivery, and minimized bystander editing. We will also optimize different prime editor systems with optimal editing efficiencies and low off-target editing. Additionally, we will optimize adeno-associated virus (AAV)-mediated delivery of these gene editing tools for *in vivo* application.

Design/Methods: We generated *SOD1* mutant HEK293T cells via prime editing and will systematically screen base and prime editor strategies in these mutation-carrying cells. Optimized editors will then be evaluated in patient-derived fibroblasts and *in vivo* mouse models. The therapeutic impact of gene correction will be assessed by analyzing molecular, cellular, and motor phenotypes linked to both gain- and loss-of-function consequences of *SOD1* mutations.

Results: Preliminary data show 30% correction of the A5V mutation in patient fibroblasts and A5V-HEK293T cells using unoptimized base editing, with minimal bystander editing. Additionally, prime editing without nicking guides achieved 15% correction of the A5V mutation in patient fibroblasts.

Conclusions: We propose that AAV-mediated somatic gene correction using base or prime editing to target *SOD1* mutations (A5V and G94A) will mitigate toxic gain-of-function pathology, restore wild-type SOD1 protein levels, and rescue motor deficits. This strategy offers a promising therapeutic avenue for SOD1-ALS.

1095 Restoration of MeCP2 Function by converting the R270X Nonsense STOP Mutation to Tryptophan Through A-to-I RNA Editing

Zili Qiu[1], Chenjie Shen[2], Steven Colvin[1], Stephen Yu[1], Feng Guoping[1]*
[1]MIT McGovern Institute for Brain Research, Cambridge, MA, [2]MIT, Chelsea, MA
**Corresponding Author*

Rett syndrome (RTT) is a severe neurodevelopmental disorder primarily caused by single-nucleotide variants in the *MECP2* gene, with approximately 70% involving C-to-T mutations. Among the most severe forms are nonsense mutations, where a CGA codon is mutated to TGA, creating a premature stop codon (e.g., R168X, R255X, and R270X). This truncates the MeCP2 protein, leading to severe RTT phenotypes due to the loss of MECP2 function. To address this, we plan to utilize REPAIR, a programmable RNA editing tool that fuses the ADAR2 deaminase domain with a catalytically inactive Cas13b domain to achieve adenosine-to-inosine RNA editing with high specificity. Our goal is to convert the UGA stop codon into UGG using REPAIR, effectively substituting the stop codon with tryptophan. We hypothesize that this approach could restore MeCP2 function and alleviate the RTT phenotype associated with MECP2 nonsense mutations.

To evaluate the potential of this approach, we used R270X as a test case and generated R270W knock-in mice, where the R270 residue was replaced with tryptophan. This allowed us to assess whether the tryptophan substitution affects MeCP2 function. Behavioral analysis revealed that MeCP2 R270W mice exhibit no significant differences compared to their wild-type littermates. At the cellular level, a pathological hallmark of MeCP2 loss is the disruption of its interaction with alpha-thalassemia/mental retardation X-linked (ATRX) at heterochromatic foci. Immunohistochemistry analysis demonstrated that MeCP2 R270W retains normal interactions with ATRX. Together, these findings suggest that tryptophan substitution at R270 maintains MeCP2 function. To further develop a therapeutic approach for in vivo STOP-to-Trp conversion using the Cas13-based REPAIR system, we developed an in vitro reporter system and identified the most optimal guide RNA for subsequent in vivo testing. Altogether, these findings indicate that STOP-to-Trp conversion through RNA editing holds significant potential as a viable therapeutic strategy for MeCP2-R270X, offering a reversible, precise, and potentially safer alternative to DNA editing.

1096 Development of a Humanized Mouse Model for PACS1 Syndrome and Evaluation of Base Editing as a Therapeutic Approach

Caryl Young[1], Caleb Heffner[1], Stephen Kneeland[1], Cathleen Lutz[1], Stephen Murray[1]
[1]*The Jackson Laboratory, Bar Harbor, ME*

PACS1 Syndrome is a rare neurodevelopmental disorder caused by a de novo mutation (c.607C>T) in the *PACS1* gene, resulting in a gain-of-function arginine to tryptophan substitution. PACS1 is involved in trans-Golgi membrane trafficking, but the pathogenic mechanism remains unclear, and there is currently no cure for the disorder.

We developed a humanized mouse model with the R201W amino acid substitution to study PACS1 Syndrome and investigate base editing as a potential therapy. Due to embryonic lethality in constitutive R201W knock-in mice, we generated a conditional knock-in model carrying a humanized exon 4 with the R201W substitution and an upstream lox-STOP-lox cassette. We used a Nes-Cre driver to express the mutation specifically in neurons. Phenotyping assays revealed hyperactivity, anxiety-like behavior, and increased seizure susceptibility in Nes-cre;$Pacs1^{PACS1(R201W)}$ mice. Female mice were more prone to seizures, and both sexes showed reduced survival starting at 18 weeks, but no changes in learning and memory were observed.

We tested seven base editing strategies *in vitro* using $Pacs1^{PACS1(R201W)}$ mouse embryonic stem cells (mESCs), including both correction using A-base editors (ABE) and gene disruption via stop codon conversion using C-base editors (CBE). We identified a lead CBE design that resulted in robust and specific stop codon installation in our in vitro assay. To support proof-of-concept in vivo experiments, we developed split-intein dual AAV vectors. We achieved up to 80% base editing in transfected ES cells. We have produced AAV particles and are testing editing efficiency and therapeutic efficacy in postnatal $Pacs1^{PACS1(R201W)}$ pups via intracerebroventricular injection. In summary, our model highlights behavioral phenotypes and a promising base editing strategy for potential therapeutic intervention for PACS1 syndrome.

1097 Base Editing Strategies for Restoring Functional Collagen VII Expression in Recessive Dystrophic Epidermolysis Bullosa

Julia Benincasa[1], Lucas Rossetti[1], Aldilene Munhoz[1], Davi Torres[2], Priscila Keiko Matsumoto Martin[3], **Ricardo Weinlich[1]***
[1]Hospital Israelita Albert Einstein, Sao Paulo, Sao Paulo, Brazil, [2]Hospital Israelita Albert Einstein, [3]Hospital Israelita Albert Einstein, São Paulo, Sao Paulo, Brazil
**Corresponding Author*

Recessive Dystrophic Epidermolysis Bullosa (RDEB) is a devastating genetic disorder marked by extreme skin and mucosal fragility, resulting in chronic blistering, slow-healing wounds, and premature mortality. This condition is caused by mutations in the *COL7A1* gene, which encodes collagen VII (C7), a critical structural protein for dermal-epidermal cohesion. In Brazil, exon 54 mutations, particularly c.5047C>T, are predominant and result in reduced or absent C7 expression.

Our study focuses on developing a gene-editing strategies to restore functional C7 expression in cells derived from individuals with RDEB harboring exon 54 mutations. Two complementary approaches are being investigated: (i) exon 54 skipping to bypass the pathogenic mutation and (ii) precise correction of the c.5047C>T mutation. Both strategies leverage advanced adenine base editors (ABEs), which offer enhanced specificity and safety compared to conventional CRISPR/Cas9 systems.

Preliminary experiments using the BJ-hTERT cell line harboring the c.5047C>T mutation demonstrated successful optimization of the gene-editing protocol. Nucleofection of ABE8e-mRNA and guide RNAs (gRNAs) yielded high transfection efficiency while maintaining cell viability. Targeted editing at the c.5047 locus achieved A-to-G conversion efficiencies of 80–90% with gRNA-04 and gRNA-05. Additionally, exon skipping was induced with approximately 80% efficiency using gRNA-02. In these approaches all bystander mutations are silent and the induced indel levels were quite low.

The optimized gene-editing protocols are being currently tested in primary fibroblast from patient's skin biopsies and the edited cells will be used to generate three-dimensional skin equivalents comprising dermal and epidermal layers. These bioengineered skin fragments, expressing functional C7, will serve as prototypes for autologous skin grafts aimed at accelerating wound healing in RDEB patients and improving their quality of life. By the conclusion of this project, we aim to deliver a validated, safe, and efficient protocol for restoring C7 expression in fibroblasts and keratinocytes, laying the groundwork for future clinical applications in gene therapy for RDEB.

1098 Prime Edited T-regulatory Cells for Immune Therapy

Mark Osborn[1], Sophia Hani[1], Amber McElroy[1], Alvin Hsu[2], David R. Liu[3], Sandro Vivona[4], Paul-Joseph Aspuria[4], Martin Oft[4], Keli Hippen[1], Bruce Blazar[1]
[1]University of Minnesota, Minneapolis, MN, [2]Harvard and MIT, Boston, MA, [3]Eli and Edythe L Broad Institute of Harvard and MIT, [4]Synthekine, Menlo Park, CA

T-regulatory cells (Treg), CD4+25hi127neg T-cells, are immune suppressive and as such useful as cellular therapy to control adverse immune responses including graft-versus-host disease (GVHD). Since Tregs do not produce interleukin-2 (IL-2), systemic infusion of recombinant IL-2 (rIL-2) is required to maintain cell viability and function. However, exogenous IL-2 can promiscuously activate and expand T-cells resulting in toxicity. To minimize rIL-2 side-effects, previous work generated an orthogonal IL-2 system and showed that a two amino acid conversion (H134D Y135F) in the interleukin-2 receptor beta (IL-2Rβ) gene enabled selective responses to an orthogonal IL-2 ligand (orthoIL-2)[1].

Initial studies employed lentiviral ortho-IL-2Rβ delivery[2], and here we pursued a DNA prime editing (PE) strategy. PE uses a programmable nickase fused to a reverse transcriptase and a user-specified sequence encoded by an engineered prime editor guide RNA (epegRNA)[3] to install all base substitutions, insertions, deletions, and

combinations thereof. PE operates without inducing significant double-stranded DNA breaks (DSB) thereby minimizing the cellular/genotoxicity associated with gene editing nucleases and lentiviral vectors[4,5].

We designed an epegRNA to mediate the PE conversion of H134D Y135F at the endogenous IL-2Rβ locus (Fig. 1A). Using FACS-purified peripheral blood Tregs (n=2 donors) we electroporated a synthetic epegRNA, complementary-strand nicking guide RNA, PE6c[6] mRNA, and mRNA of a dominant negative version of the cellular mismatch repair protein MLH1[7]. Following gene transfer, Tregs were cultured in orthoIL2 (STK009; labeled "PE S100", 100 nM) or native IL-2 (Proleukin, 300 IU/ml; labeled "PE P300"). Genomic analysis showed H134D Y135F prime edit installation, demonstrated by Sanger (Fig. 1B) and Illumina sequencing with a low frequency of insertions and deletions (indels) (Fig. 1C), consistent with the high allelic purity expected of a PE strategy.

PE Tregs maintained their characteristic FOXP3^{+} CD127neg phenotype (Fig. 1D) and suppressed, to a similar degree, the proliferation of activated T-cells in an *in vitro* co-culture assay (Fig. 1E) in the presence of PE orthoIL2 (PE S100) or native IL-2 (Proleukin (PE P300)).

Sub-lethally irradiated, immune-deficient NSG-SGM3 mice (n=5) were given HLA-A2^{+} PE Treg alone or with STK009 (20 µg/dose, 3 doses/week) along with HLA-A2^{-} peripheral blood mononuclear cells (PBMC) (Fig. 2A). We observed superior in vivo PE Treg *in vivo* Treg expansion in the presence vs absence of STK009 orthoIL2 (Fig. 2B; p=0.004). Preliminary studies showed improved GVHD prevention, evidenced by less pronounced weight loss (Fig. 2C), and improved survival in PE Treg STK009-treated mice over the PBMC treated or unedited Treg only control mice (Fig. 2D; p=0.021).

PE mediated the conversion of the endogenous IL-2Rβ locus to an orthogonal version with minimized formation of DSBs and indels than are generated using nuclease-based strategies. PE Tregs expanded in vitro and in vivo with STK009 orthoIL2 ligand injection. PE Treg also retained the ability to respond to Proleukin, consistent with intact IL2Rb signaling and PE Treg capacity to respond to activated donor T-cell derived IL-2.

In conclusion, our data shows that PE is a promising approach for Treg engineering that should facilitate immune therapy without employing lentiviral vectors or generating DSBs.

1099 Paired Prime Editors to excise GAA repeats in the Friedreich's Ataxia gene

Xuntao Sheena Zhou[1], Scot Wolfe[2], Erik Sontheimer[1], Jonathan Watts[1], Wen Xue[3]*
[1]UMass Chan Medical School, Worcester, MA, [2]UMass Chan Medical School, Worcester, Massachusetts, [3]UMass Medical School, Worcester, MA
**Corresponding Author*

Background: Friedreich's ataxia (FRDA), a rare autosomal recessive neurodegenerative disorder, belongs to the group of genetic disorders known as Repeat Expansion Diseases (REDs), in which repeats of three nucleotides beyond a critical threshold lead to developmental, neurological, or neuromuscular disorders. In the case of FRDA, the repeat unit is the triplet GAA•TTC, located in the first intron of the frataxin (FXN) gene. The GAA repeats can form an R-loop, which potentially affects histone modification and leads to a reduction in the transcription of FXN. FXN protein plays a pivotal role in maintaining mitochondrial function, facilitating the conversion of iron into heme and iron-sulfur clusters. Disruption of this process results in oxidative stress, thus contributing to damage in the nervous system and muscle weakness with scoliosis. Patients with severe FRDA typically do not live past the age of 40 due to cardiomyopathy or arrhythmia. The prevailing therapeutic approach aims to increase FXN protein levels, but it does not address the underlying causes of FRDA. Thus, the optimal therapeutic solution to treat FRDA would be to correct the genetic cause at its root by removing the triplet repeat. Prime editing (PE), a Cas9 nickase paired with a polymerase and a guide RNA, could install any substitution, small insertion or deletion without inducing double-stranded breaks (DSBs). Previous data from our lab show that Prime Editors-Cas9-based deletion and repair (PEDAR) could produce precise and efficient 10kb deletion. Here, we utilized paired prime editors to precisely contract GAA repeats in cells.

Methods and Results: We designed two engineered pegRNAs (epegRNAs) that target distinct regions flanking the GAA repeats. The reverse transcription template (RTT) sequence with AttB facilitates a 1.2 kb deletion and precise integration of the AttB sequence in HEK293T cells. Editing rate measured by ddPCR is around 27%. We also showed different lengths of RTT, 6xGAA repeats or 6xGAA repeats flanking with 20nt 3' end hangover, can efficiently contract GAA repeats. Illumina sequencing (NGS) showed perfect editing can achieve around 92.79% and the indel is 7.21%. We also electroplated GM03816 FXN patient-derived fibroblasts with two synthetic pegRNAs (38bp AttB as RTT) and PE nickase mRNA. Our paired PE system for 2.2kb GAA repeats contraction has around 12.85% editing efficiency in patient fibroblasts and the perfect editing rate is around 91.41%.

Conclusions: These results demonstrate paired PE system can contract 1.2kb and 2.2kb GAA repeats both in HEK293T cells and patient-derived fibroblasts with highly precise editing at FXN locus. This work provides a foundation to explore PE-mediated deletion as a strategy of FRDA treatment.

1100 A compact RT editor built from the metagenome

**Corresponding Author*

To grow the list of treatable genetic diseases beyond the liver, it is essential to develop compact genome editors deliverable by size-constrained approaches like adeno-associated viruses (AAVs). AAVs allow for efficient targeting of many tissues, including heart, muscle and brain, but impose a strict size limit that precludes delivery of many highly active, large Cas enzymes. The size limitation is particularly limiting for the delivery of reverse transcriptase (RT) genome editors, which show exceptional therapeutic promise for introducing highly specific genomic edits without creating double stranded breaks, as the addition of the RT enzyme consumes valuable real estate in the AAV vector.

To build an RT editor capable of fitting in a single AAV vector, we searched through our metagenomic sequence database to identify deep branching examples of nucleases containing both RuvC and HNH domains (RHNs) and a diverse set of RTs. Through biochemical and *in vitro* screening, we found RHNs <800aa that were active in human cells, and RTs as small as 300 aa supporting high levels of RT editing. After multiple rounds of mutagenesis of each enzyme, we combined the most active candidate enzymes into new RT editors and observed significant precise editing in both mouse and human primary cells following AAV delivery.

Our small RT editor enables a path toward unlocking potential new treatments for genetic diseases in tissue types beyond the liver without the need for manufacturing or delivering multiple viral vectors.

1101 Cas13-Mediated RNA Base Editing Using mxABE Restores Heart Function in a Humanized Hypertrophic Cardiomyopathy Model

Guoling Li[1], Qun Hu[2], Jiajia Lin[3], Tong Li[4], **Hui Yang**[5]

Background: Hypertrophic Cardiomyopathy (HCM) is the most common inherited heart disease, affecting 0.2% to 0.5% of the population (15-20 million people worldwide). About half of the cases are linked to gene mutations, with 25-40% caused by mutations in the *MYH7* gene (5-8 million people), including the c.1208G>A (p.R403Q) variant. These mutations disrupt normal heart function and energy consumption, increasing the risk of arrhythmias, heart failure, and premature death. Current treatments, such as Aficamten and Mavacamten, do not address the underlying genetic cause and have significant side effects. Base editing techniques can correct disease-causing mutations in vivo and in vitro, potentially rescuing disease phenotypes. RNA base editing offers a safer, reversible alternative to correct disease-causing mutations without altering the DNA. This study investigates the potential of a mini CRISPR-Cas13X-mediated adenosine base editor (mxABE) to treat HCM by correcting the MYH7 mutation in a preclinical humanized mouse model.

Methods: To create a genetically humanized HCM mouse model carrying the human *MYH7* c.1208G>A (p.R403Q) pathogenic mutation, we replaced part of the mouse *Myh6* exon 13 sequence with the corresponding sequence from human *MYH7* exon 13, which contains the c.1208G>A (p.R403Q) missense variant (Figure 1A). In the in vitro studies, gRNAs targeting the mutant allele were screened in HEK293T cells co-expressing the *MYH7* mutation, identifying g8 as the most efficient gRNA. An all-in-one adeno-associated virus (AAV) vector encoding mxABE

base editor and g8 was injected into 2-week-old *Myh6*$^{hR403Q/+}$ mice. Heart function and histology were analyzed 6 months post-treatment.

Results: The homozygous *Myh6*$^{hR403Q/hR403Q}$ mice exhibited high mortality within two weeks of birth (Figure 1B). The heterozygous *Myh6*$^{hR403Q/+}$ mice developed severe ventricular hypertrophy and fibrosis by 6 and 9 months of age, closely mimicking human HCM (Figure 1C). We co-transfected the *MYH7* gene carrying the mutant allele and the candidate gRNAs in HEK293T cells. In the in vitro studies, g8 gRNA achieved an average RNA editing efficiency of 63.69% for the c.1208G>A mutation (Figure 1D). We injected into 2-week-old *Myh6*$^{hR403Q/+}$ mice with either saline or mxABE and then monitored their development for over 6 months (Figure 1E). The results demonstrated that mxABE achieved high A-to-I editing rate in cardiac tissues (Figure 1F). Furthermore, AAV-mxABE-treated mice exhibited significantly improved cardiac function, including restored ejection fraction, fractional shortening, and reduced ventricular wall thickness, effectively reversing disease progression (Figure 1G).

Conclusions: This study demonstrates the successful application of mxABE, a CRISPR-Cas13-based RNA base editor being developed for HCM treatment by correcting the *MYH7* mutation. The AAV-mxABE therapy effectively prevented heart remodeling and restored heart function in a humanized *Myh6*$^{hR403Q/+}$ mouse model, highlighting its potential as a safe and targeted therapeutic strategy for hereditary cardiomyopathies.

1102 A prime editing approach to rapidly model rare neurological disease variants in wild type animals

Colin Robertson[1], Patrick Davis[2], Ryan Richardson[3], Phillip Iffland[1], Daiana Vieira[1], Marilyn Steyert[1], Paige McKeon[1], Andrea Romanowski[1], Garrett Crutcher[1], Eldin Jašarević[4], Steffen Wolff[1], Brian Mathur[1], Peter Crino[1], Tracy Bale[5], Ivy Dick[1], Alexandros Poulopoulos[1]
[1]University of Maryland School of Medicine, Baltimore, MD, [2]Boston Children's Hospital, Harvard Medical School, Boston, MA, [3]NIH, Rockville, Maryland, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Colorado School of Medicine, Denver, CO

Genetic diseases have traditionally been difficult to treat owing largely to heterogeneous genetic underpinnings. These disorders are a collection of common symptoms with highly varied etiology, a phenomenon well represented by genetic epilepsies. More than 30% of epilepsies are caused by genetic perturbations in one or more of 977 distinct genes, any one of which may harbor up to hundreds of unique pathogenic loci. Standard preclinical animal modeling methods are not well suited to handle this level of diversity due to the cost and time required to produce a single strain. With the goal of expediting timelines for rare disease variant modeling, we have developed a toolset and pipeline for precise in vivo genome manipulations using prime editing. We begin with a webtool, PegAssist.app, that expedites the design of pegRNAs with cloning compatibility for a publicly available plasmid set. To confirm in vivo prime editing functionality in the target cells and provide a visual assessment of editing efficiency, we designed a deliverable reporter for prime editing. This reporter makes use of an externally expressed, editing-dependent fluorophore, providing compatibility with various downstream assays for cell/tissue function or assessment of editing outcomes. We then use this validated editing approach to introduce rare epilepsy variants in wild type mice. We show precise integration of the target variants via Next-Generation Sequencing and functionally confirm gene activity. The low error rate makes this approach amenable to direct use in vivo, eliminating lengthy and costly screening steps. Most strikingly, a subset of mice with these introduced variants displays frequent spontaneous seizures, a result that is upheld across multiple genetic targets. Utilizing this feature, we demonstrate a proof-of-concept experiment for drug screening in a personalized mouse model of genetic epilepsy. The results of this work demonstrate an alternative modeling strategy for genetic diseases that could serve as patient surrogates for n-of-one trials of candidate drugs. Demonstrable efficacy could justify off-label use for approved therapeutics and greatly benefit an underserved patient population.

1103 Base Editing Premature Stop Codons Within the *ATXN2* Repeat Reduces Pathogenic Polyglutamine Proteins.

Spinocerebellar Ataxia Type 2 (SCA2) has an incidence of 1 in every 50,000 individuals, and causes ataxia, dementia, and premature death. SCA2 is caused by greater than 33 CAG trinucleotide repeats in exon 1 of the *ATXN2* gene (*mATXN2*). Previous work from our lab has shown that targeting *mATXN2* with a nuclease via AAV delivery can result in genomic integration of AAV DNA following repair of the induced double stranded break. To advance therapies that avoid genomic integration events, cytosine base editing using a Cas9 nickase and cytosine deaminase to alter CAGs into premature termination codons (PTCs) via C:T conversion was tested. Unlike Cas9 nuclease editing, base editing modifies DNA without a double stranded break, thereby reducing insertions, deletions, translocations, and integrations. Here, we exploited the ability of cytosine base editors to make C: T substitutions within a broad window of nucleotides, increasing the likelihood for multiple PTCs. Screening base editors in human cells identified guides that inserted PTCs at multiple sites along the repeat at greater than 50% efficiency at any one repeat, and up to 6 repeats consecutive repeats. In a model N2A reporter line containing m*ATXN2* exon 1 at various repeat lengths the C:T conversion reduced target protein levels by 35% and 17% for 58 and 114 CAG repeats, respectively. For in vivo work, base editor mRNA and guides packaged in lipid nanoparticles (LNPs) resulted in similarly edited consecutive repeats. Ongoing work is focused on testing of LNP and AAV delivery modalities in two distinct SCA2 mouse models for impact on disease phenotypes.

1104 Regulation of the *ABCD2* uORFs as a Therapeutic Approach to Adrenoleukodystrophy

Yousif Almehza[1], Sylvia Thomas[2], Ali Fatemi[1], Gregory Newby[3], Christina Nemeth Mertz[1]
[1]Kennedy Krieger Institute, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University

Adrenoleukodystrophy (ALD) is an X-linked disorder with a wide phenotypic spectrum, ranging from adrenal insufficiency to a highly fatal childhood or adult presentation of rapid demyelination – known as cerebral ALD (cALD). The disease is caused by mutations in the *ABCD1* gene encoding the peroxisome ALD associated transporter. As a result, the peroxisome is less able to transport and oxidize very long chain fatty acids (VLCFAs), which accumulate in tissue. To date, there are no cures for ALD. Treatment options, including hematopoietic stem cell transplantation, are limited by early detection and associated morbidities. Upstream Open Reading Frames (uORFs) have been identified as gene suppressors in various loci, preventing the translation of their associated downstream ORFs. The *ABCD2* gene and protein is homologous to the *ABCD1* gene and has been shown in prior studies to offer some rescue of function when expressed in mutated Abcd1 cells and mice. Therefore, in this study, we have designed and optimized adenine base editors of *ABCD2* uORFs to disrupt their recognition by the translation machinery, thus allowing the translation of the *ABCD2* region to compensate for loss of *ABCD1*. This novel therapeutic strategy has the potential to be applied to any of the thousands of *ABCD1*-associated pathogenic variants. The efficiency of different base editing packages was tested by Next Generation Sequencing 72 hours after electroporation. *In vitro* analysis and validation of gene edited human ALD derived fibroblasts was conducted to determine expression of *ABCD2* via Western blot, qPCR, and immunohistochemistry, as well as accumulation of VLCFA (C26:0 lysophosphatidylcholine) measured by liquid chromatography-tandem mass spectrometry – the gold standard ALD diagnostic test. Reductions in VLCFA accumulation, as well as increases in *ABCD2* expression have been observed. Additional guides will be designed to target the homologous region in mouse, and tested in N2a cells prior to AAV9 packaging and delivery to the *Abcd1* knock-out mouse model of ALD. The mouse ALD model exhibits a robust behavioural and biochemical phenotype, and will offer a platform to determine the viability of *Abcd2* uORF modulation as a treatment to ALD. Further studies are required to determine the potential of this therapy to mitigate demyelination and slow the progression of cALD. In absence of a reliable cALD mouse model, patient derived iPSCs and organoids may offer translational relevance.

1105 Design and Assembly of Modular Pin-point™ Base Editors for Precise Correction of Pathogenic SNVs

Paul Russell[1], Rodrigo Osorno[1], Amanda Haupt[2], **Immacolata Porreca**[3], Pablo Pérez-Durán, Robert Blassberg[4]

Single nucleotide variants (SNVs) account for the majority of pathogenic mutations associated with monogenic diseases. These single-base changes can disrupt protein function, alter gene regulation, or interfere with splicing, leading to severe and often life-threatening conditions. The ability to correct such mutations at the DNA level has long been a goal of precision genome engineering. However, due to the diversity of rare disease causing SNVs, this remains an ongoing challenge. Targeted genome editing technologies, such as CRISPR-Cas9 nucleases, enable the programmable editing of diverse DNA sequences required to tackle this challenge but rely on double-strand breaks (DSBs) and homology-directed repair (HDR) which can be error-prone, and lead to genomic instability.

Base editors have emerged as next-generation genome editing tools that precisely and efficiently correct SNVs in post-mitotic cells with undetectable levels of DSBs and without requiring donor DNA templates. However, a major challenge faced by base editors is their potential to introduce unintended 'bystander' edits adjacent to target DNA bases. As a solution to this challenge we have developed the Pin-point™ base editing platform, which enables the modular assembly of DNA binding Cas and DNA modifying deaminase components via an aptamer encoded in the sequence-targeting guide RNA (gRNA). This modularity allows the flexible design and assembly of diverse base editor configurations with defined base conversion activities, protospacer-adjacent motif (PAM) specificities, and

target sequence editing preferences. These characteristics make the Pin-point platform a powerful tool for assembling bespoke base editors tailored to correct SNVs with high efficiency and specificity.

Here we present our pipeline for the design and development of bespoke modular Pin-point base editors with defined editing activities across therapeutic DNA target sequence space. We have established an arrayed screening platform and optimised gRNA libraries to characterise the editing activities of diverse combinations of Cas and deaminase modules at scale. Knowledge obtained from arrayed screens is used to guide the design of massively parallel screens to empirically determine the efficiency and specificity of favourable base editor assemblies across pooled libraries covering all targetable pathogenic SNVs, with promising candidates validated and further optimised in cellular models harbouring SNV target sequences. In addition to generating an inventory of validated base editor assemblies with strong potential for further preclinical development the knowledge obtained from our screening activities is synthesised in predictive models of base editor activity. These predictive capabilities enable both the identification of additional candidate targets not empirically analysed through screening and inform the strategy of future screening campaigns with novel modular base editor assemblies.

Disclaimer: The Pin-point base editing platform technology is available for clinical or diagnostic study and commercialization under a commercial license from Revvity

1106 Optimized RESTORE+ oligonucleotides for an efficacious and safe RNA base editing treatment for Alpha-1 antitrypsin deficiency

Tobias Merkle[1], Daniella de Moraes Mizurini[1], Konstantin Licht[2], Inga Jarmoskaite[3], Kaiko Kunii[4], Namita Bisaria[4], Anindya Sen[5], Sriram Sathy[6], Victor De Jesus[7], Veronica Giachin[8], Christopher Volkert[8], Manvi Upadhyay[4], Elisangela Bressan[8], Juri Eyberg[8], Li-Hao Chang[8], Peter Borsos[9], Angelika Oswald[9], Lange Saleh[8], Piotr Putaj[9]
[1]AIRNA, Tübingen, Baden-Wuerttemberg, Germany, [2]AIRNA, Tübingen, Germany, [3]AIRNA, Arlington, MA, [4]AIRNA, Cambridge, MA, [5]AIRNA, Revere, MA, [6]AIRNA, Henderson, NV, [7]AIRNA Corporation, Cambridge, MA, [8]AIRNA, Tubingen, Baden-Wuerttemberg, Germany, [9]AIRNA, Tubingen, Germany

Endogenous ADAR-mediated RNA editing is a transformative technology enabling precise A-to-I editing of mRNA. Unlike DNA editing, RNA editing is transient, reversible, and redosable, ensuring safety and flexibility. Using the RESTORE+ platform, we developed fully chemically modified oligonucleotides to optimally recruit endogenous ADAR and enhance RNA editing therapeutics through improved potency and delivery.

Our optimized GalNAc delivery system, combined with advanced chemical modifications, significantly enhances RNA editing efficiency and durability while minimizing potential safety risks. Specifically, we designed oligonucleotides targeting the SERPINA1 mRNA to treat Alpha-1 Antitrypsin Deficiency (AATD). By catalyzing precise A-to-I conversion, the platform corrects the PiZZ mutation (E342K), a G-to-A substitution responsible for misfolding and aggregation of the Z-AAT protein, leading to liver and lung pathology in AATD. In primary mouse hepatocytes, we achieved >90% editing efficiency in vitro, and >40% editing in vivo in the NSG-PiZ mouse model 7 days post-dose. This restored wild-type (M-AAT) and total AAT levels above therapeutically meaningful thresholds (>14 μM and >17 μM, respectively). Long-term studies demonstrated sustained M-AAT levels (>14 μM) with multiple doses over 8 weeks, alongside improvements in liver health and pathology.

Pharmacokinetics (PK) and safety profiling in non-human primates (NHPs) showed 3-4x extended oligonucleotide half-life compared to mice, with no observable toxicity. This PK enhancement aligns with the durability and potency improvements observed in siRNA therapeutics across species. We have established a robust and competitive disease modifying RNA-based therapeutic for AATD with the RESTORE+ platform enabling rapid development of RNA editing therapies for other diseases with high unmet needs.

1107 Correction of Multiple Dominant-Negative Mutations in Collagen VI-Related Muscular Dystrophy via ADAR-Mediated RNA Editing

Russell Butterfield[1]*, Manshu Tang[1]
[1]University of Utah, Salt Lake City, UT
**Corresponding Author*

Introduction: Collagen VI-related muscular dystrophies (COL6-RD) are a group of muscle disorders characterized by progressive muscle weakness, distal joint laxity, and proximal joint contracture. COL6-RD is caused by mutations in any of the three genes encoding collagen VI, with inheritance patterns either dominant or recessive, depending on the mutation and its location. The most common mutations are missense variants that result in the substitution of glycine within the conserved Gly-x-y repeat sequences of the triple helical (TH) domain. These mutations impair collagen VI assembly by incorporating aberrant chains into the secreted tetramer. Allele-specific gene silencing has emerged as a potential therapeutic approach for COL6-RD, with early-stage developments focusing on antisense oligonucleotides (ASOs) and small interfering RNA (siRNA) technologies. In this context, we present an alternative therapeutic strategy for COL6-RD involving ADAR-mediated RNA editing. ADAR is a site-specific RNA editing enzyme that converts adenosine (A) to inosine (I) in RNA transcripts. Since I is recognized by the translation machinery as guanine (G), A-to-I editing of G-to-A transition mutations effectively corrects the mutation at the transcript level. Unlike ASO and siRNA approaches, which are limited to specific mutations, ADAR editing offers the potential to target multiple adjacent mutations using a single guide RNA. This is particularly advantageous in COL6-RD, where dominant-negative mutations are clustered in the N-terminal end of the TH domain. We hypothesize that a single guide RNA could be designed to target several nearby mutations, thereby expanding the applicability of ADAR-based therapies to a larger cohort of patients.

Methods: Two fibroblast lines derived from patients with COL6-RD harboring commonly observed missense mutations in the TH domain, c.850G>A (p.G284A) in exon 9 and c.868G>A (p.G290A) in exon 10, were utilized in this study. Our previous work using circularized guide RNAs achieved approximately 20% editing efficiency at the c.850G>A mutation site; however, no significant editing was observed at the c.868G>A site. In this study, we introduced multiple mismatches and structural loops, along with different configurations of ADAR-recruiting domains, into the guide RNAs to enhance editing efficiency. Candidate guide RNA sequences were cloned and delivered into fibroblasts using an AAV-based system. RNA editing efficiency was assessed using RNA-seq by comparing read counts of wild-type and mutant transcripts.

Results: Several guide RNAs capable of inducing A-to-I editing at both mutation sites were identified. Both the guide RNA sequence and secondary structure affect recruitment of ADAR and editing efficiency. The most effective guide RNA achieved an editing efficiency of 35% at the c.850G>A site and approximately 20% at the c.868G>A site. The introduction of a mismatch 35 bp upstream of the target site and the inclusion of ADAR-recruiting domains were found to be the key to editing efficiency.

Conclusions: We demonstrate feasibility of using a single guide-RNA to target A-to-I editing of multiple adjacent mutations in COL6A1. Our next experiments will next determine editing efficiency of our most effective guide RNAs on other nearby mutations with goal to identify a single guide RNA to treat most of these mutations. These experiments support development of ADAR editing as a therapy for COL6-RD.

1108 MM201-miniVPR: A Novel Single AAV-Delivered Multiplexed Gene Activation System for Therapeutic and Research Applications

Hainan Zhang[1], Lin Yang[2], Yuling Liu[3], Dingyi Han[4], Yingnan Li[4], Guoling Li[5], Jiaxu Hu[6], Jinhai Huang[7], Yingsi Zhou[6], **Hui Yang[8]***

Background: CRISPR-based activators (CRISPRa) have expanded the potential of CRISPR technology by enabling precise control over gene regulation. These systems use catalytically inactive Cas proteins fused to transcriptional activators, such as VPR, miniVPR, SunTag, or SAM, to upregulate target genes. In many therapeutic and research contexts, such as somatic cell reprogramming into iPSCs or regenerative therapies, multiplexed gene activation targeting multiple promoter sites, such as *Oct4, Sox2, Klf4, and c-Myc*, is essential. However, the large size of traditional Cas proteins (e.g., Cas9 and Cas12a) and their associated guide RNA scaffolds limits packaging into a single adeno-associated virus (AAV) vector. Cas12f, though smaller, lacks efficient self-processing of sgRNAs, further complicating multiplexed activation. Here, we develop MM201-miniVPR, a novel compact CRISPRa tool capable of multiplexed gene activation using a single AAV delivery system.

Methods: We used a computational pipeline to analyze bacterial genomes and identify novel, compact Cas proteins (<630 aa), leading to the discovery of wtMM201, a protein with self-processing crRNA capabilities. Using a dual-fluorescence reporter system, we optimized the activation efficacy of wtMM201 through mutagenesis and combinatorial modifications of its key domains, generating MM201-miniVPR. We evaluate MM201-miniVPR's single and multiplex gene activation efficiency against dhyperCas12a-miniVPR, dCasMINI-miniVPR, and wtMM201-miniVPR at 28 endogenous sites in HEK293T cells. Additionally, we compared MM201-miniVPR with dhyperCas12a-miniVPR for multiplexed activation using pooled or crRNA arrays.

Results: We identified and engineered wtMM201, a previously undocumented compact Cas protein with binding activity and self-processing crRNA abilities in mammalian cells. Through multiple rounds of protein engineering, we generated MM201-miniVPR with higher efficiency of single and multiplexed gene activation based on the dual-fluorescence reporter genes and endogenous genes in HEK293T cells (Fig. 1b and c). MM201-miniVPR exhibited significantly improved gene activation efficiency (Fig. 1d) compared to dCasMINI-miniVPR and wtMM201-miniVPR. It achieved comparable activation efficiency to dhyperCas12a-miniVPR at endogenous sites with 5'-NTTN PAMs (Fig. 1d). Additionally, MM201-miniVPR enabled efficient simultaneous activation of three genes using a multiplex crRNA array, comparable to the activity of dhyperCas12a-miniVPR (Fig. 1e). Importantly, MM201-miniVPR's compact size allows packaging into a single AAV vector with up to 10 crRNAs, addressing a major limitation of existing CRISPRa tools (Fig. 1a).

Conclusions: MM201-miniVPR is a powerful and versatile CRISPRa platform capable of robust single and multiplexed gene activation. Its compact size, high efficiency, and compatibility with a single AAV delivery make it a promising tool for basic research and therapeutic applications.

1109 A Miniature CRISPR Editor for Epigenetic Rescue in Human Models of ZC4H2-associated rare disorders

Yomira Palacios[1], Kyle Fink[2], Julian Halmai[3]
[1]UC Davis Health, Sacramento, CA, [2]UC Davis, Sacramento, CA, [3]UC Davis, Sacramento, California

Females undergo random X chromosome inactivation to regulate gene dosage. In X-linked intellectual disability, this process creates a mosaic pattern in affected tissues, such as the brain, where cells express either the wild-type or mutant allele. ZC4H2 Associated Rare Disorders (ZARD) is an ultra-rare X-linked intellectual disability caused by a spectrum of inherited and *de novo* mutations in the *ZC4H2* gene. This gene encodes a zinc finger protein that is highly expressed in the brain during early neurodevelopment, yet its direct role in regulating neurodevelopment remains unclear. Current understanding of ZARD pathophysiology is predominantly based on non-human models, with limited insights from human models. Identifying the molecular and cellular mechanisms underlying ZARD is essential for elucidating its neuropathology and potential therapeutic interventions. In our study, we have established female patient iPSC-derived neural stem cells to explore the cellular and molecular perturbations underlying ZARD pathology and to assess the feasibility of reactivating wildtype *ZC4H2* using epigenetic tools. To determine whether ZARD NSCs are primarily self-renewing or differentiating into neurons, we performed RNA sequencing and immunocytochemistry (ICC). RNA sequencing data from ZARD neural stem cells revealed >2000 differentially expressed genes. Notably, Gene Ontology enrichment analysis identified significant enrichment of pathways related to neuron differentiation, neuron generation, and stem cell differentiation, suggesting a pro-neural fate at the transcriptomic level. Protein-level analysis showed elevated expression of both immature and mature neuronal markers, including TUJ1, PAX6, and MAP2, in ZARD NSCs compared to controls. Orthogonal shRNA-mediated knockdown of *ZC4H2* in a wildtype NSC line recapitulated the significant increase in MAP2 mRNA expression ($p<0.05$), reinforcing the critical role of *ZC4H2* in maintaining the balance between NSC self-renewal and differentiation. Conversely, pathways regulating BMP-signaling, cellular responses to BMP signaling, and SMAD

protein phosphorylation were downregulated, providing a potential molecular mechanism underlying ZARD pathogenesis. We then sought to investigate a newly engineered miniature CRISPR-Cas system to demonstrate the feasibility of reactivating *ZC4H2* in this clinically relevant cell type. Here we demonstrate that single guide RNA (sgRNA) paired with dCasMINI-VPR transfections of NSC successfully reactivated using two independent sgRNAs ($p<0.05$). Multiplexing sgRNAs did not result in increased mRNA levels. In conclusion, our study reveals that ZARD NSCs are proliferating faster and maturing more rapidly than sex-matched control cell lines, likely driven by aberrant BMP-signaling. We also demonstrate the potential of smaller Cas systems for reactivating X-linked genes, expanding therapeutic options.

1110 Compact DNA Demethylase-Activator combination Modulators for CRISPR-Mediated Epigenetic Gene Activation

Xiao Yang[1], Courtney Klappenbach[1], Robin Yeo[2], Zaki Jawaid[1], **Dan Hart[3]**
[1]Epicrispr Biotechnologies, South San Francisco, CA, [2]Epic Bio, San Francisco, CA, [3]Epic Bio, South San Francisco, CA

Epigenetic silencing of gene expression is a well-characterized mechanism that has been successfully harnessed for therapeutic applications, particularly in CRISPR-based approaches. In contrast, the development of epigenetic tools for robust and sustained gene activation has lagged, representing a significant barrier to advancing transformative therapies for human disease. While DNA demethylation, mediated by enzymes such as TET family members, has shown promise in de-repressing silenced genes, two major challenges remain: (1) the large size of current DNA demethylation editors, which limits their delivery via adeno-associated viruses (AAVs), and (2) the variability in gene activation across distinct chromatin states and transcriptional contexts. To address these limitations, we developed a new class of compact, AAV-compatible DNA demethylating enzymes, termed "miniTETs," which are 33% smaller than conventional catalytic domains. These miniTETs can be co-packaged with guide RNAs and tissue-specific promoters into a single AAV vector, facilitating efficient in vivo delivery. We demonstrate that dCas9-miniTET variants are capable of stable reactivation of silenced loci in vitro, with sustained target gene expression observed for up to 100 days in HEK293T cells following transient transfection. Additionally, we engineered an ultra-compact dCas variant, dCasONYX (<500 amino acids), and showed that a fusion to miniTET domains is highly active in human cells, and capable of epigenetically reactivating a silenced locus. Remarkably, dCas-miniTET fusions with transcriptional activators yielded synergistic reactivation of a silenced synthetic reporter gene, with stable expression maintained for 30 days post-transfection. These findings provide a foundation for the next generation of CRISPR-based tools for epigenetic gene activation, tailored for therapeutic applications. Our work establishes a robust platform for precise, durable, and tissue-specific control of gene expression in vivo.

1111 CRISPR Epigenetic Reprogramming of Neuroprotective Factors as Therapy for Alzheimer's Disease

Thyago Calvo[1], Viviana Salinas-Rios[2], Ilana Burg[1], James Hahn[1], Katie Vostrejs[1], Fernanda De Felice[3], Fyodor Urnov[4]
[1]UC Berkeley, Berkeley, CA, [2]University of California Berkeley, [3]University of Rio de Janeiro, [4]University of California, Berkeley, Berkeley, CA

Background. Alzheimer's disease (AD) is a neurodegenerative condition imposing a significant burden on healthcare systems globally. Despite extensive efforts, it remains incurable, with only moderately effective treatments available for some patients. Gene therapy, particularly using CRISPR-Cas, holds promise as an advanced alternative. The ability to reprogram cell phenotypes by regulating gene expression via epigenetic reprogramming using the CRISPR-dCas9 variant has widened our options for complex disease therapies, like AD. It's known that exercising modulates genes encoding for neuroprotective factors that can induce neurogenesis, reduce neuropathology, and lead to fewer cognitive deficits in AD. We hypothesized that using CRISPR-dCas9 epigenetic reprogramming to upregulate exercise-responsive (*FNDC5, BDNF*) and other neuroprotective genes (*NGF, GDNF, KL, GRN, NTF3,* and *NTF4)* could mimic the beneficial effects of exercise in the brain, potentially slowing AD progression. As CRISPR delivery methods advance, there's optimism that this strategy could not only delay the onset of AD and its progression but also reduce cognitive decline in patients.

Methods. We used a variety of CRISPR-dCas9 activation domains known to recruit epigenetic effector proteins or directly modifying CpG methylation and histone residues. We evaluated four to six single-guide RNAs (sgRNAs) designed around 200 bases upstream of the top neuroprotective genes' transcription start sites. The cells used were iPS-derived neural progenitor cells (NPCs). sgRNAs and mRNAs were transfected with cationic lipids. The readouts were mRNA expression measured by TaqMan RT-qPCR and ELISA for the secreted proteins. The specificity of the leading sgRNAs was assessed by mRNA sequencing. We also tested different effector domains known to upregulate gene expression in different configurations (SunTag or fusioned to dCas9) either at N- or C-terminus of dCas9.

Results. For the tested sgRNAs, we obtained 3× to 487×-fold increase in mRNA expression of the target genes compared to controls (Fig. 2AB). The leading sgRNAs for the upregulated neuroprotective factors were assessed for specificity using mRNA sequencing. The results showed specific upregulation of *FNDC5* using the dCas9-VPR system for at least one of the leading sgRNAs (Fig. 2C). ELISA from the supernatants showed parallel upregulation for most of the neuroprotective factors tested (Fig. 2D). The gene and protein expression were upregulated for at least seven days for some of the targets (Fig. 2D).

Conclusions. In summary, the sgRNAs located upstream of the transcription start sites showed upregulation of the target transcripts and protein levels for most of the neuroprotective factors chosen. The leading sgRNAs showed good specificity, and different effector domains and their configurations lead to different upregulation of the neuroprotective factors. Next experiments will evaluate if the upregulation of these factors can avoid or dampen neuronal cytotoxicity in vitro. In the future, in vivo experiments on Alzheimer's disease mouse models will measure the effect of this approach on disease progression, memory, and neuropathology.

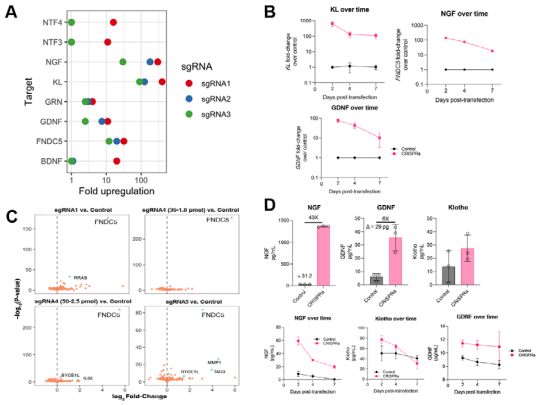

Figure 2 – Upregulation of gene expression of different neuroprotective factors (A). Longitudinal assessment of gene expression for selected neuroprotective factors (B). Volcano plots showing the differentially expressed genes from RNA-sequencing after activation with CRISPR-dCas9-VPR plus FNDC5's leading sgRNAs (C). ELISA protein quantification of neuroprotective factors from neural progenitor cells' supernatants after transfection with CRISPR-dCas9-VPR and lead sgRNAs.

1112 Epigenetic CRISPR Editors Encoded as mRNA for Engineering Primary Human T Cells

Rachel Conover[1], Sean McCutcheon[1], Charles Gersbach[1]*
[1]*Duke University, Durham, NC*
**Corresponding Author*

Autologous T cell therapies for cancer, including CAR-T and TILs, have transformed cancer care by engineering the endogenous immune system. However, these therapies are limited by the heterogenous subpopulations of the cell product, with high prevalence of an exhaustion phenotype which limits efficacy and durability. We have developed CRISPR screening platforms to interrogate perturbations in a high-throughput manner. Previous screens using stable lentiviral expression of CRISPR activators and repressors have focused on identifying genes which modulate IL7R expression in primary human T cells, as IL7R is an important marker of a more stem-cell like memory phenotype. Here, we designed CRISPR epigenetic editors as messenger RNA (mRNA) and delivered the mRNA to healthy T cells to screen for transcription factors which can improve T cell phenotype after transient perturbation. mRNA-based delivery may offer a better safety profile for clinical translation due to the lack of genomic integration and transient expression of epigenome editing machinery. We validated our mRNA constructs against IL7R and saw a decrease in expression for 7 days using ZIM3-KRAB-dCas9 (CRISPR inhibition) and an increase in expression for 3 days using 2xVP64-dCas9 (CRISPR activation). We performed screens using gRNAs against all human transcription factors and delivered either CRISPRi or CRISPRa as mRNA, and sorted cells based on IL7R expression at both 2 and 10 days post-delivery. Sequencing of cells which had low or high IL7R expression revealed many significant transcription factor hits on day 2, but this effect was lost by day 10. Future work will investigate using CRISPR constructs which aim to cause a permanent epigenetic change using targeted DNA methylation or demethylation. These constructs, delivered as mRNA, may be more robust for generating stable, durable changes to cell phenotype without genomic integration or continuous transgene expression – and improve the phenotype of cells used in adoptive T cell therapies.

1113 Programmable Epigenome Editing by Transient Delivery of CRISPR Epigenome Editor Ribonucleoproteins

Da Xu[1], Swen Besselink[2], Gokul Ramadoss[3], Philip Dierks[4], Justin Lubin[1], Rithu Pattali[5], Jinna Brim[2], Anna Christenson[1], Peter Colias[1], Izaiah Ornelas[1], Carolyn Nguyen[1], Sarah Chasins[1], Bruce Conklin[4], James Nuñez[6]*

Programmable epigenome editors offer a powerful approach to precisely modulate gene expression by altering the local chromatin environment at target loci without introducing DNA breaks. These tools hold great promise for advancing both fundamental research and therapeutic applications. However, their large size poses a challenge for delivery, limiting their broad use in gene and cell therapy applications. To address this limitation, we developed Robust ENveloped Delivery of Epigenome-editor Ribonucleoproteins (RENDER), a platform for delivering CRISPR-based epigenetic repressors (CRISPRi, DNMT3A-3L-dCas9, CRISPRoff) and activators (TET1-dCas9) as ribonucleoprotein complexes into human cells.

Through rational engineering, RENDER achieves durable epigenetic silencing of endogenous genes in a wide range of human cell types. Importantly, our results show that RENDER enables target gene silencing in primary human T cells with significantly lower cytotoxicity compared to conventional mRNA electroporation methods, highlighting its suitability for therapeutic applications. Furthermore, we demonstrate the therapeutic potential of RENDER by reducing the level of neurodegeneration-associated V337M-mutated Tau protein in human stem cell-derived neurons. Our findings establish RENDER as a transformative platform for precise and robust modulation of gene expression without altering DNA sequences. By overcoming key delivery challenges, RENDER broadens the accessibility of CRISPR-based epigenome editing technologies, paving the way for their use in fundamental research, immunotherapy, and the development of novel gene and cell therapies.

1114 Programmable RNA Editing Enables Precise Protein Modulation in the Central Nervous System

Alison VanSchoiack[1], Leah Helton[2], Lucia Shumaker[2], Lina Bagepalli[3], Kayleigh Marsh[2], Jana Henry[2], Rachael Fastnacht[2], Jennifer Moon[2], Eric Chadwick[2], Robyn Laing[2], Alexis Blokker[2], Jonathan Wang[2], Brian Johnson[2], Evan Kania[2], Chelsea Fortin[4], Turnee Malik[2], Katherine Stewart[5], Yue Jiang[6], Yingxin Cao[2], Aditya Radhakrishnan[2], Lynsey Kovar[2], Joanne Boysen[2], Robert Lloyd[2], Ted Gniffke[2], Palmer Fliss[2], Stephen Burleigh[1], Yiannis Savva[7], Melissa Works[2], Brian Booth[6], Thomas Long[2], Ronald Hause[6], Adrian Briggs[1], David Huss[1]
[1]Shape Therapeutics, Inc., Seattle, WA, [2]Shape Therapeutics, Seattle, WA, [3]ShapeTx, Seattle, WA, [4]Shoreline, WA, [5]Shape Therapeutics, Inc., Bothell, WA, [6]Shape Therapeutics Inc., Seattle, WA, [7]Shape Therapeutics, Inc.

Therapeutic RNA editing enables programmable, genomically-scarless genetic manipulation to treat complex human disease. To realize the full therapeutic potential, precise nucleotide-level manipulation must be combined with targeted delivery to reach organs beyond the liver. ShapeTX's RNAfix® platform uses generative machine learning to design efficient and precise gRNAs that recruit Endogenous Adenosine Deaminase Acting on RNA (ADAR) to virtually any target sequence, resulting in functional A-to-G base substitutions. RNAfix gRNAs are delivered via AAV for sustained, high-level expression that maximizes the durability and therapeutic impact of a single administration and harnesses the tissue targeting potential of AAV. ADAR is highly active in the central nervous system (CNS) and thus, can be harnessed to treat a wide range of neurological diseases due to the diversity of ways that editing transcripts can modulate protein expression and function. Here we present preclinical data highlighting the potential of RNAfix to both restore protein function and reduce pathogenic proteins implicated in neurological diseases. We also demonstrate robust RNA editing activity in the CNS of both mice and non-human primates (NHPs).

Rett syndrome is a devastating neurodevelopmental disease caused by loss-of-function mutations of the X-linked *MECP2* gene, with over 30 percent of causal mutations being nonsense mutations that generate premature termination codons (PTCs). In heterozygous female Rett patients, ADAR-mediated editing could restore functional MECP2 protein by converting the PTC into a tryptophan and allowing full-length protein translation. Using RNAfix gRNAs, we demonstrate mutant allele-specific editing of *MECP2* in human Rett patient iPSC derived neurons of up to 43% and associated full-length MECP2 protein restoration in 38% of cells. MECP2 gRNAs delivered via a single systemic injection of AAV achieve broad distribution throughout the mouse brain (average of 66% gRNA-positive cells) and mutant allele-specific editing of 52-69%, restoring full-length protein in an average of 39% of cells.

Beyond genetic diseases, RNA editing can regulate protein levels in patients with more diverse and complex etiology by targeting transcripts encoding pathogenic proteins. For example, we applied RNAfix to knockdown two genes implicated in serious neurodegenerative diseases. By designing gRNAs targeting a canonical translation

initiation site (**A**UG>**G**UG) or a splicing signal, we found that target editing led to dose-dependent protein knockdown by both mechanisms. We achieved >50% editing/splicing and >70% protein knockdown in iPSC-derived glutamatergic neurons and >30% editing/splicing and >50% protein knockdown in the mouse brain following a single systemic AAV dose.

Delivery is critical to maximize translatability from rodent to NHP and ultimately, to human patients. We previously demonstrated high efficiency editing in the NHP brain using direct intraparenchymal delivery of gRNAs packaged in AAV9. Building on this data, we developed novel brain-penetrating capsids and achieved up to 88% RNA editing in focal brain regions following systemic delivery. Collectively, the data presented here demonstrate the broad applicability and enormous therapeutic potential of the RNAfix platform for CNS diseases.

1115 Direct Reprogramming of Primary Human Astrocytes to Functional Neurons with CRISPR-Based Epigenome Editing

Samuel Reisman[1], Dahlia Halabi[2], Samantha Miller[1], Grayson Rice[1], Nicholas Sangvai[1], Charles Gersbach[1]
[1]Duke University, Durham, NC, [2]Duke University, Durham

Neurodegenerative disorders and brain injuries impact millions and are steadily increasing in prevalence. Thus, there is a dire need for regenerative therapies able to restore the neuronal loss resulting from these conditions. Direct reprogramming of endogenous astrocytes into neurons has emerged as a promising approach for replenishing these lost neurons. However, current approaches are limited in efficacy and efficiency, preventing clinical utility. Here, we establish a CRISPR activation (CRISPRa)-based epigenome engineering strategy to reprogram primary human astrocytes to neurons and conduct high-throughput CRISPRa screens of all human genes encoding transcription factors (TFs) to identify novel and efficient astrocyte-to-neuron reprogramming factors.

To establish a CRISPRa-based epigenome editing system for astrocyte-to-neuron reprogramming, we first activated known neurogenic TFs ASCL1, NeuroG2, and NeuroD1 in primary human astrocytes. These perturbations resulted in widespread transcriptome remodeling and outperformed cDNA overexpression of the same factors in a direct comparison, leading to higher expression of downstream neuron marker genes. However, reprogramming efficiency (percent of cells converted) remained limited. Therefore, we next devised a strategy for pooled CRISPRa screening in primary cells without requiring cell-line engineering and utilized it to functionally interrogate the reprogramming capability of all TF genes in the human genome in astrocytes from multiple donors. In total, we screened 1,627 TF genes and identified >60 novel hit TFs, with top hits performing vastly more efficiently than previously established reprogramming factors (58% vs. 5%). To map the fidelity and determine the subtype of induced neurons resulting from activation of each TF, we next performed a single cell RNA-sequencing CRISPR (perturb-seq) screen and mapped the resulting transcriptomes to multiple atlases of the human neurodevelopment. This screen revealed that single novel factors reprogram primary human astrocytes into multiple neuronal subtypes with distinct cell type-specific gene signatures. We functionally characterized the electrophysiology of the resulting neurons using multi-electrode-arrays and found that they display subtype-specific firing patterns. Further, we investigated the robustness of hit TFs, demonstrating that they successfully reprogram astrocytes to neurons via orthogonal systems, including CRISPRa and ORF overexpression, and across multiple contexts, including both human and mouse primary astrocytes as well as directed differentiation of iPSCs to neuron. Finally, we conducted combinatorial CRISPRa screens to identify co-factors that cooperate to enhance reprogramming efficiency and neuronal subtype-specificity. ATAC- and RNA-sequencing of induced neurons generated by identified TF combinations elucidated modes of neurogenic TF interaction and resulted in chromatin remodeling and increased expression of key synaptic genes. In sum, here we demonstrate a modular platform for primary cell reprogramming screens and apply it to discovery of factors capable of reprogramming primary astrocytes to neurons, widely expanding the list of potential targets for neuroregenerative therapies.

1116 In silico prediction of domain insertion sites for the engineering of inducible CRISPR gene editors

Jan Mathony[1]*, Benedict Wolf[2], Ann-Sophie Kroell[2], Pegi Shehu[2], Luca Brenker[3], Anna von Bachmann[2], Nicholas Southern[2], Stefan Holderbach[2], Joshua Eigenmann[2], Sabine Aschenbrenner[2], Dominik Niopek[2]*

Domain insertion engineering is a powerful approach to juxtapose otherwise separate biological functions and is frequently used to engineer switchable proteins including inducible CRISPR effectors. For instance, insertion of a photoreceptor or ligand-binding domain (LBD) into a CRISPR-Cas nuclease can yield gene editors whose activity is regulated by light or small molecules. In these cases, a trigger-mediated conformational change of the receptor domain is transmitted to the acceptor protein, thereby activating or deactivating it. However, identifying suitable allosteric sites for domain insertion typically requires extensive screening and optimization, explaining the small number of potently switchable Cas variants. We present ProDomino, a novel machine learning pipeline to rationalize domain recombination and showcase its application to the efficient engineering of potent inducible CRISPR genome editors and modulators.

Our approach builds on a novel curated protein dataset based on naturally occurring intradomain insertion events fetched from public protein databases, exceeding the size and complexity of existing experimentally derived datasets by orders of magnitude. Using this diverse dataset, we leveraged ESM-2-derived protein sequence representations and a novel masking strategy to train ProDomino (protein domain insertion optimizer), a powerful model for accurately predicting domain insertion sites in proteins (Fig. 1a-b). We extensively validated ProDomino *in silico* and *in vitro* as showcased by a comparison with experimental insertion tolerance data for the protein AraC (Fig. 1c). As expected, the model correctly distinguished insertion-permissive from non-permissive sites as indicated by an AUROC of 0.84. To test whether ProDomino would facilitate low-N engineering of switchable genome editors, we predicted the domain insertion tolerance for all amino acid positions of the widely employed *S. pyogenes* Cas9 and *M. bovoculi* Cas12a orthologs (Fig. 2a, c). Next, we inserted the blue light-responsive *As*LOV2 photoreceptor domain at four high-ranking positions of a dCas9-VPR transactivator fusion and tested the resulting hybrids in a luciferase CRISPR activation assay in HEK293T cells (Fig. 2b). Consistent with our predictions, all four dCas9-LOV2 hybrids were still active in the dark and strongly induced luciferase expression. Excitingly, three of the four variants were highly photosensitive, resulting in strongly decreased luciferase activity when incubated under blue light (Fig. 4c).

Finally, we sought to apply ProDomino to engineer Cas12a variant responsive to a clinically relevant drug via insertion of a glucocorticoid receptor 2 (GR2) LBD. We introduced the receptor at two promising ProDomino-inferred insertion sites, K487 and N1153, followed by experimental validation of the resulting protein hybrids by targeting several endogenous loci in HEK293T. Remarkably, we observed potent, cortisol-induced gene editing for both hybrid proteins in the presence of the ligand, while editing efficiencies in the absence of cortisol were close to the detection limit (Fig. 2d). Our Cas12a receptor hybrids represent the first single-chain switches of a Cas12a ortholog and their robust response to cortisol was achieved without any further optimization. Taken together, we believe that ProDomino will enable scientists to more effectively engineer allosteric proteins including novel on-demand inducible CRISPR genome editors with tailored function

Background: Ornithine transcarbamylase (OTC) deficiency is the X-linked hereditary urea cycle disorder, often presenting with severe neonatal phenotypes and hyperammonemia. Genome editing to insert the target gene offers potential long-term solutions. However, the size limitation of adeno-associated virus (AAV) vectors makes it challenging to simultaneously package both a donor sequence and a genome-editing tool. To address these limitations, we previously developed an engineered AsCas12f (enAsCas12f), enabling all necessary knock-in components to fit into a single vector (Cell 2023; 186: 4920-4935).

Aim: To develop a gene knock-in genome editing strategy using a single AAV vector for OTC deficiency.

Methods: We constructed an AAV8 vector harboring enAsCas12f, a guide RNA, its target sequence, and a segment of the murine albumin (Alb) intron conjugated with a 2A-fused cDNA. The vector was administrated into mice. Genome editing efficiency was assessed by immunohistochemistry or next-generation sequencing. Phenotypic correction was evaluated in male $Otc^{spf\text{-}ash}$ (low expression) mice on a high-protein diet, and in heterozygous female OTC-knockout mice generated by genome editing. Body weight and blood ammonia levels were monitored following vector injection.

Results: Compared with homology-directed repair (HDR) targeting Alb intron 14, non-homologous end joining (NHEJ)-mediated knock-in targeting Alb intron 13 significantly enhanced the knock-in efficiency in mice treated with a single AAV vector harboring enAsCas12f and the donor sequence (HDR: 2.4 ± 0.4% in neonates, <1% in adult mice; NHEJ: 5.8 ± 0.6% in neonates, 29.6 ± 3.4% in adult mice). Administration of a single AAV vector harboring enAsCas12f and OTC cDNA in adult $Otc^{spf\text{-}ash}$ mice significantly prevented body weight loss and hyperammonemia induced by a high-protein diet. Enzymatic activity, mRNA expression, and protein expression of OTC in liver tissue increased in a dose-dependent manner. Female heterozygous OTC-knockout mice showed growth retardation and mild hyperammonemia even on a normal diet. *In vivo* genome editing using a single AAV vector harboring enAsCas12f and OTC cDNA improved body weight and reduced blood ammonia levels.

Conclusion: A single AAV vector harboring enAsCas12f with the donor sequence successfully inserted the target sequence in liver cells *in vivo* and restored the phenotype of OTC deficiency in mice.

1118 A novel and empowered TARGETED Gene Addition Approach at a Relevant Microglia Locus for the Treatment of X-linked Adrenoleukodystrophy – Mechanistic Insights

Pietro Rigoni[1], Anna Tognon[2], Davide Mattioli[3], Giulia Santinon[3], Annita Montepeloso[4], Alessandro Mongera[5], Alessandra Biffi[6]
[1]University of Padova, Asiago, Veneto/Italy, Italy, [2]University of Padova, Padova, Padova, Italy, [3]University of Padova, Padova, Italy, [4]Gene-thing, Milano, Milano, Italy, [5]University College of London, London, United Kingdom, [6]University of Padua Department of Women's and Children's Health, Padova, Padova, Italy

Adrenoleukodystrophy (X-ALD, OMIM: 300100) is an X-linked genetic disorder caused by mutations in the ABCD1 gene, which disrupt peroxisomal beta-oxidation and result in the accumulation of saturated very long-chain fatty acids (VLCFAs) in body tissues. This pathological accumulation primarily affects the Central Nervous System (CNS). The pediatric form, Childhood Cerebral ALD, remains a major cause of severe neuropathology and early mortality during infancy. While allogeneic Hematopoietic Stem and Progenitor Cell (HSPC) transplantation and lentiviral gene therapy (GT) are valuable therapeutic options for childhood cerebral X-ALD, their effectiveness is constrained by the slow engraftment of transplanted cells in the CNS, which is outpaced by the rapid progression of neurodegeneration. Moreover, side effects are associated to the use of either a specific lentiviral design in gene therapy, with recent FDA reports identifying cases of hematological malignancies likely associated with clonal expansion events following vector integration, or of an allogeneic stem cell source, i.e. graft-versus-host disease. We have identified CX3CR1, a chemokine receptor expressed on microglia that binds fractalkine (CX3CL1), as a key

target for enhancing the ability of hematopoietic stem and progenitor cells (HSPCs) to generate microglia-like cells (MLCs) following transplantation. CX3CR1 plays a critical role in regulating microglial recruitment to sites of neuroinflammation and microglial ontogeny. Our studies demonstrated that transplantation of CX3CR1-haploinsufficient HSPCs leads to faster and more robust engraftment, improved generation of MLCs, and more efficient acquisition of a mature microglia-like phenotype compared to wild-type cells. Building on these findings, we developed a CRISPR/Cas9 gene editing strategy to precisely insert the human ABCD1 cDNA at the CX3CR1 locus. This approach simultaneously creates haploinsufficiency at the CX3CR1 locus and drives therapeutic cassette expression under its control. By leveraging this strategy, we aim to achieve accelerated microglia replacement by gene-corrected cells while ensuring microglia-specific, regulated expression of the therapeutic gene. Additionally, this method mitigates safety concerns associated with the use of integrating vectors. We developed a promoterless splice-trapping cassette encoding hABCD1 cDNA, targeting the CX3CR1 intron to achieve highly efficient targeted insertion and regulated transgene expression in microglial cell lines and human HSPCs. Our results demonstrated successful transgene integration in up to 60% of targeted alleles in human HSPCs. Furthermore, we observed robust, CX3CR1-promoter-regulated hABCD1 expression in HSPC progeny cells upon myeloid differentiation, alongside the establishment of CX3CR1 haploinsufficiency, which retained a functional copy of the gene. We are currently assessing the efficacy of CX3CR1-edited human HSPCs in relevant immunodeficient models to generate proof-of-concept data for correcting disease-associated biochemical abnormalities, specifically using the NSG-SGM3 ABCD1-KO (Δ897) disease model, as well as testing protocols compatible with large scale manipulation. Moreover, to investigate the hyper-functional phenotype of the HSPCs edited at the CX3CR1 locus, we are generating CX3CR1 mutant iPSC lines (WT, haploinsufficient, KO). As single-cell RNA sequencing (scRNA-seq) data from our lab suggest migratory pathways as key drivers of this

1119 Optimizing gene editing for erythroid-specific therapeutic protein expression using HSPCs

Marine Laurent[1], Laurie Lacombe[2], Margaux Mombled[3], Julie Oustelandt[3], Christine Jenny[4], Giorgia Falco[5], Giulia Scalisi[6], Mario Amendola[7]
[1]UMRS_951 Genethon, Evry, France, France, [2]Genethon, Evry, France, [3]UMRS_951 Genethon, Evry, Essonne, France, [4]UMRS_951 Genethon, Evry, France, [5]University of Foggia, Foggia, Italy, [6]GENETHON, EVRY, SA, France, [7]Genethon, Evry, Essonne, France

We previously described an *ex vivo* editing approach to achieve efficient gene targeting in human hematopoietic stem/progenitor cells (HSPCs) and robust expression of clinically relevant proteins in the erythroid lineage. Using CRISPR-Cas9, we integrated various transgenes under the transcriptional control of the endogenous α-globin promoter, recapitulating its high erythroid-specific expression. Erythroblasts derived from targeted HSPCs secreted therapeutic proteins that retained enzymatic activity and cross-corrected patient cells.

To validate the erythroid-specific expression platform in vivo, we obtained a humanized mouse model, where the mouse α-globin locus was replaced with the human α-globin locus (~120 kb), and we optimised editing of murine HSPCs. First, we confirmed that the sequence of the human HBA locus was correct, using nanopore DNA sequencing, and functional, confirming human alpha globin expression by HPLC analysis. We then nucleofected murine HSPCs with CRISPR-Cas9 and human gRNA (RNP) and confirmed the efficient generation of indels at the expected target site.

To perform DNA-targeted integration, we combined RNP nucleofection with the transduction of an AAV6 coding for a promoterless ΔNGFR reporter gene, expressed by the endogenous HBA promoter, and a PGK.GFP cassette flanked by homology arms to the genomic locus. Combination of RNP and AAV6 resulted in good DNA integration and transgene expression, but it was associated with some cellular toxicity. Therefore, we first compared different RNP nucleofection protocols in terms of indel efficiency and cellular toxicity. Then, we tested the addition of a caspase inhibitor, Z-VAD, and observed a 1.5-fold increase in targeted integration. We are now exploring Cas9/gRNA delivery using different lipid nanoparticles (LNPs).

Concerning donor DNA delivery, we screened a library of AAVs with or without polyvinyl alcohol (PVA) as enhancer of transduction, including AAV6 mutants previously shown to enhance transduction of human HSPCs, and

identified one mutant that outperformed natural AAV6 of about 3- fold. To improve DNA integration and reduce toxicity, we are currently comparing AAV with novel integration-deficient lentiviral vectors (IDLVs) and naked DNA delivery methods. In addition, we demonstrated that chemical modulation of cellular DNA repair resulted in a 1.5-fold improvement in DNA integration.

Finally, we aim to perform targeted integration of a therapeutic gene in HSPCs and transplant edited cells into a $Lal^{-/-}$ mouse model that recapitulates the severe lipid accumulation seen in lysosomal acid lipase (LAL) deficiency. This will allow us to evaluate the therapeutic benefit of erythroid-derived LAL transgene expression. Currently, we are evaluating different conditioning regimens, including busulfan and irradiation, to improve the engraftment of edited HSPCs in recipient mice. This analysis will include evaluating mouse survival, body weight, and normalization of lipid accumulation in liver and spleen.

Overall, we have optimised DNA targeted integration in murine HSPCs in terms of efficacy and toxicity of CRISPR/Cas9 editing and DNA template delivery to be able to perform the in vivo experiment required to move our universal HSC-based gene therapy platform to the clinics, thus paving the way for in vivo testing of other HSC based treatments.

1120 In vivo therapeutic gene knock-in for hemophilia A and B using LNP and AAV

Jeong Pil Han[1], Yeji Lee[2], Jeong Hyeon Lee[3], Hyukjin Lee[2]*, Su Cheong Yeom[4]*
[1]Seoul National University, Pyeong Chang-gun, Korea, [2]Ewha Womans University, KOREA, [3]Pyeongchang, Gangwon, Korea, [4]Seoul National University, PyeongChang, Gang'weondo, South Korea
**Corresponding Author*

Hemophilia treatment has advanced through therapeutic gene expression and rebalancing therapies, yet challenges such as immune responses, temporary efficacy, and inadequate control of acute bleeding remain. To address these limitations, we developed a combined strategy of rebalancing and therapeutic gene knock-in (KI) using lipid nanoparticles (LNPs) and adeno-associated viruses (AAVs) for hemophilia A and B. Targeting the anticoagulation pathway at the SerpinC1 locus, we achieved sustained downregulation of antithrombin (AT) and integration of human Factor 9 (hF9) and Factor 8 (hF8) coding sequences. In hemophilia B models, LNP-CRISPR and AAV-donor achieved 20% indel efficiency in SerpinC1, reducing AT levels by 67%, with hF9 KI restoring coagulation activity and producing hFIX at therapeutic levels for up to 63 weeks. Similarly, in hemophilia A models, low-dose AAV and 244-cis LNPs enabled safe and effective hF8 KI, improving coagulation and survival for 40 weeks without adverse effects. The proliferation of genetically edited hepatocytes ensured sustained therapeutic benefits, even following partial hepatectomy. These results highlight a promising, safe, and long-term genome editing approach for treating hemophilia and protein-deficient genetic disorders.

1121 Autologous MPO Knock-out HematopoieticStem and Progenitor Cells for Pulmonary Arterial Hypertension

Aurelien Colamartino[1], Karen Li[1], Jenny Shapiro[2], Anat Kahana[3], Zulema Romero Garcia[1], Donald Kohn[1]
[1] University of California, Los Angeles, CA, [2]Bar-Ilan University, Ramat-Gan, Israel, [3]Lempo Therapeutics Ltd., Binyamina, Israel

Pulmonary Arterial Hypertension (PAH) is a progressive condition for which there is no cure. Even with substantial pharmacologic advances in the modern treatment era, existing treatments provide only symptomatic relief and survival remains unacceptably poor. Patients who fail to respond to medications usually have the worst prognosis and patients with persistently elevated pulmonary pressure and right heart failure usually die within 5 years. PAH may be a severe complication of Systemic Sclerosis (SSc) affecting approximately 8-12% of patients. SSc affects 13.5–44.3 per 100,000 individuals and is complex and diverse, with limited treatment options. SSc-associated PAH is the second largest group of patients with PAH. Once diagnosed, PAH becomes the leading cause of mortality among this patient population. Although the exact cause of PAH is not known, there is extensive evidence for a pathogenic role for neutrophil myeloperoxidase (MPO) in PAH disease. PAH patients with higher levels of MPO have a poorer outcome. Studies in murine models of PAH demonstrate significant disease amelioration by

elimination of neutrophil MPO by hematopoietic stem and progenitor cells (HSPC) transplantation with HSPC lacking *MPO* from germline *MPO* gene knock-out.

Based on this evidence, we developed a gene therapy approach to PAH in which HSPC undergo gene editing using CRISPR/Cas9 to achieve bi-allelic disruption of the *MPO* gene followed by auto-transplantation. Autologous transplantation has been shown to limit SSc progression by interfering with inflammation. Transplantation of autologous HSPC in which the *MPO* gene is disrupted is expected to further prevent progression of PAH, due to the essential role of neutrophil MPO activity in disease development. We identified a sgRNA that leads to high frequency disruption of *MPO* in human CD34+ HSPC, leading to efficient elimination of MPO protein in the resultant neutrophils. That sgRNA was assessed for genome-wide off-target and showed no detectable off-target sites, validating it as a lead candidate for safe gene editing. In an *in vitro* neutrophil differentiation model, neutrophils produced from *MPO* KO CD34+ HSPC exhibited reduced neutrophil extracellular trap formation (NETosis) and absence of MPO protein. Outside of the MPO-related function, the differentiated neutrophils retained normal functions such as phagocytosis and degranulation. A clinically-compatible HSPC gene editing protocol was optimized and showed consistent ≥80% MPO allelic disruption. The edited cells retained hematopoietic potential and showed no skewing in the generated lineages in both *in vitro* colony-forming assay and *in vivo* humanized mouse model. We developed a surrogate gene editing protocol for murine cells and optimized electroporation to achieve high allelic disruption of the murine *Mpo* gene in lineage-negative murine HSPC. In a murine model, transplant of these cells showed reduction of MPO plasma level over the control group. An *Mpo* KO rat line was generated to confirm the results in a second *in vivo* model. Both models are currently being tested for the effect of MPO reduction on SSc-PAH.

The limited therapeutic options and severity of PAH, and specifically SSc-PAH compels developing new approaches. Based on clinical evidence implicating MPO in the pathogenesis of PAH, the gene therapy protocol developed shows promising results. This approach would help to understand the development of PAH but also bring a new therapeutic option.

1122 Highly Efficient Gene-editing with SaCas9 and AsCas12a in Patient Hematopoietic Stem and Progenitor Cells for Treating Sickle Cell Disease

ByoungYong Yoo[1], So Hyun Park[1], Vivien Sheehan[2]*, Gang Bao[1]*

**Corresponding Author*

Introduction: Sickle cell disease (SCD) is caused by a single nucleotide mutation (A>T) in β-globin gene (*HBB*). CRISPR/Cas9 mediated gene-editing has emerged as a promising approach to cure SCD by either correcting the sickle mutation or reactivating fetal hemoglobin (HbF) in hematopoietic stem and progenitor cells (HSPCs). Most advances in gene-editing therapies including the FDA-approved Casgevy have utilized *S. pyogenes* Cas9 (SpCas9). However, for *in vivo* gene editing therapy of SCD, it is important to evaluate smaller Cas orthologs, such as *S. aureus* Cas9 (SaCas9) and *Acidaminococcus sp*. Cas12a (AsCas12a). We investigated the editing efficiency of SaCas9 and AsCas12a in targeting three critical loci for SCD therapy, *HBB*, the *HBG* promoter, and the *BCL11A* erythroid enhancer, and compared their performance to SpCas9.

Methods: HSPCs derived from peripheral blood of five SCD donors were gene-edited. For correcting the sickle mutation, SpCas9 or SaCas9 ribonucleoprotein (RNP) complexes with single guide RNA (sgRNA) and single-stranded oligodeoxynucleotide (ssODN) donor templates were delivered via electroporation. To reactivate HbF, RNPs of SpCas9 and AsCas12a were used to disrupt the *HBG* promoter, while RNPs of all three orthologs were used to target the *BCL11A* erythroid enhancer. Editing efficiency was measured using next-generation sequencing (NGS) and edited HSPCs were differentiated into erythroid cells over 14 days. The percentage of F-cells (cells expressing HbF) was analyzed by intracellular staining and flow cytometry, while HbS, HbA, and HbF levels were quantified by high-performance liquid chromatography (HPLC). Unintended editing outcomes, including off-target editing, large deletion, and chromosomal rearrangements, were evaluated using GUIDE-seq, ddPCR, LongAmp-seq, and CAST-seq, respectively.

Results: We found that SaCas9 showed a higher rate of sickle mutation correction (53%) than SpCas9 (49%), resulting in increased adult hemoglobin (HbA) levels (81% vs. 75%) and fewer chromosomal rearrangements (5 vs. 11 sites detected by CAST-seq). At the *HBG* promoter loci, AsCas12a outperformed SpCas9 in cutting efficiency (37% vs. 34% at *HBG1* and 60% vs. 44% at *HBG2*), and generated more F-cells (80% vs. 72%) and higher HbF levels (69% vs. 59%) than SpCas9. However, it induced a higher frequency of 4.9 kb intergenic deletions (54% vs. 25%) measured by ddPCR. Neither SpCas9 nor AsCas12a showed detectable chromosomal rearrangements by CAST-seq. At the *BCL11A* erythroid enhancer loci, SaCas9 had the highest editing rate (92%), followed by AsCas12a (84%) and SpCas9 (79%). F-cell percentages were similar across the orthologs (51% for SpCas9, 50% for SaCas9, and 53% for AsCas12a), with HbF levels being comparable (47% for SpCas9, 44% for SaCas9, and 50% for AsCas12a). SaCas9 showed no rearrangements by CAST-seq, whereas SpCas9 and AsCas12a showed rearrangements at three and five sites, respectively.

Discussions: This study demonstrates that SaCas9 and AsCas12a offer high efficiency and reduced off-target effects compared to SpCas9 when editing *HBB*, *HBG*, and *BCL11A* erythroid enhancer for treating SCD, and their smaller size provides a distinct advantage for *in vivo* delivery using adeno-associated virus (AAV) or lipid nanoparticle (LNP) vectors. These findings highlight the therapeutic potential of SaCas9 and AsCas12a as viable alternatives to SpCas9 for the development of efficient and safe gene-editing therapies for SCD.

1123 *In Vivo* CRISPR Editing of Genetic Regulatory Regions Results in Functional Upregulation of Target Protein and Meaningful Reduction of Disease-Associated Biomarker in Mice

Benjamin Diner[1], Vikram Soman[1], Tushare Jinadasa[2], Ameya Apte[3], Meng Wu[3], Atti English[3], Steve Bottega[3], Mansi Thakkar[4], Deep Majithia[3], Luis Agosto[3], Shreya Jambard[5], Emily Kaye[3], Briana Steward[4], Jim Bochicchio[3], Eugenio Marco[3], Tanya Teslovich[3], Linda Burkly[3], Jenny Xie[3], Paul Wrighton[6]*

CRISPR-Cas is a transformative gene editing technology with the potential to enable durable genetic medicines for diseases with severe unmet needs. CRISPR-Cas-based gene editing can be used to knock down expression of disease-causing proteins. However, knockdown can also be achieved with established modalities, such as RNA interference. Editas' differentiated strategy aims to edit regulatory regions of genes to induce functional upregulation of disease-mitigating target proteins. Our strategy for this specific target is genetically validated in humans by a naturally occurring variant of the gene that results in upregulation of the target protein expression and reduction of a disease-causing pathway biomarker.

Here, we demonstrate proof of concept for upregulation of a liver target using *in vivo* CRISPR editing with both AsCas12a and SpCas9 nucleases. *In vitro* guide RNA (gRNA) screens were conducted in primary human hepatocytes to delineate critical regulatory regions and demonstrated up to 9-fold upregulation of target protein expression. Proof of upregulation *in vivo* was achieved by lipid nanoparticle (LNP) delivery of RNA-encoded gene editing cargo in mice, which resulted in up to 3.5-fold target protein upregulation in the liver and clinically relevant reduction (up to 56%) of a disease-associated biomarker.

Our data provide proof of concept for *in vivo* gene editing–based upregulation therapeutic strategies resulting in meaningful reduction of a disease biomarker. These results support advancing this approach to non-human primates for further validation.

1124 Targeting MSH3 for Triplet Repeat Diseases Treatment using CasPlus

**These authors contributed equally to this work.*

Huntington's disease (HD) and myotonic dystrophy type 1 (DM1) are progressive disorders caused by DNA triplet repeat expansions in the *HTT* and *DMPK* genes, respectively. Human genome-wide association studies have identified MSH3, a DNA mismatch repair gene, as a modifier of disease onset/severity in both HD and DM1. Moreover, studies in preclinical disease models have established that MSH3 is a driver of somatic triplet repeat expansion, which in turn is increasingly regarded as underlying disease pathology. Therefore, modulation of MSH3 function has been drawing attention as an attractive therapeutic strategy for treatment of multiple neurodegenerative diseases, and indeed several approaches are currently under evaluation. These include gene therapy approaches, although a key bottleneck remains the ability to deliver such therapeutic agents to the CNS.

At Script Biosciences, we are developing a one-and-done therapeutic agent that combines the CNS tropism of our proprietary lipid nanoparticle delivery platform with our unique CasPlus gene-editing technology to knock out MSH3 in the brain. Herein, we show that CasPlus enables high knockout efficiency of MSH3 (70 - 90%) in HEK293 cells, and unlike Cas9-based approaches, CasPlus displayed virtually no on-target deletions flanking the editing site. We also show that CasPlus knockout of MSH3 in HEK293 results in robust attenuation of MSH3 protein levels as judged by immunoblot assay (Fig. 1A), in-house developed Meso Scale Diagnostics (MSD) assay (Fig. 1B), and by immunofluorescence microscopy (Fig. 1C). Likewise, we have also been able to achieve ~70% knockout of MSH3 in mouse NIH3T3 cells.

In order to deliver MSH3-targeting CasPlus components to the brain, we have used Script's proprietary CNS-specific lipid nanoparticle (LNP) platform that has been validated for delivery of reporter mRNAs and CRISPR components directly to the mammalian CNS, with minimal accumulation in the liver, spleen or other peripheral organs. With these CNS-tropic LNPs, we have succeeded delivering Cas-Plus targeting hMSH3 to HEK293 cells, achieving >60% MSH3 knockout at the genomic level, paving the way for validation of LNP-mediated delivery of MSH3-targeted CasPlus in HD and DM1 pre-clinical mouse models. Script's innovative Cas-Plus platform and CNS-specific LNP technology offer a promising strategy to address unmet medical needs in triplet repeat diseases like HD and DM1 that could complement therapeutic currently developed by other biopharmaceutical companies.

Familial hypercholesterolemia (FH) is an autosomal dominant inherited disease characterized by high circulating low-density lipoprotein (LDL) cholesterol. Affected patients quickly develop atherosclerosis, leading to peripheral and coronary artery disease often followed by heart attack, stroke, or other cardiovascular complications. Transthyretin amyloidosis (ATTR) is a progressive life-threatening disease characterized by the accumulation of misfolded transthyretin (TTR) protein in nerves and heart tissue leading to neurodegeneration and cardiomyopathy. While significant progress has been made to demonstrate the utility of Class 2 Type II Cas9 for *in vivo* genetic intervention, the *in vivo* potential of Class 2 Type V Cas12a has not fully been realized. In these proof-of-concept studies, three clinically validated gene targets for FH and ATTR, proprotein convertase subtilisin/kexin type 9 (*Pcsk9*), angiopoietin-like 3 (*Angptl3*), and transthyretin (*Ttr*), were targeted using Cas12a chRDNA genome-editing technology. It has been previously shown that CRISPR hybrid RNA-DNA guides (chRDNAs), designed with a combination of RNA and DNA nucleotides, can be leveraged with either Cas9 or Cas12a to enhance nuclease specificity and significantly reduce off-target genome editing. Upon identification of high-activity gene targeting Cas12a chRDNA guides, optimization of the Cas12a mRNA sequence, and refinement of our lipid nanoparticle (LNP) formulation, we sought to demonstrate functional gene disruptions in wild-type Balb/c mice. A single intravenous dose of Cas12a mRNA and chRDNA guides optimized to target *Pcsk9* resulted in nearly 60% hepatic editing, followed by a 50% reduction in circulating PCSK9 protein and a 30% reduction of plasma cholesterol in wild-type mice. Similarly, targeting *Angptl3*, we demonstrated >70% hepatic editing efficiency followed by a >70% reduction of plasma ANGPTL3 protein, accompanied by a 30% reduction in plasma cholesterol. Surprisingly, dual knockout of *Pcsk9* and *Angptl3* did not further reduce circulating LDL cholesterol compared to single gene disruptions. Lastly, we observed 70% gene disruption targeting *Ttr* in liver with a single administration, leading to a 98% reduction in circulating TTR protein levels. Notably, gene editing of *Ttr* demonstrated long-term durability, with effects persisting over one year following single low-dose administration. With all three targets, we did not detect significant liver toxicity or chronic cytokine release. Moreover, analysis of *in silico* predicted off-target sites by nextgeneration sequencing (NGS) did not identify off-target genome editing. In addition, no significant peripheral organ on-target genome editing was detected following tissue isolation and NGS analysis in mice. Early preclinical rat tolerability studies suggest that the chRDNA guides may offer improved tolerability compared to all-RNA guide designs, supporting their potential for clinical use. Furthermore, we observed highly efficient editing across multiple clinically relevant targets, highlighting the broad therapeutic potential of this platform. Our studies demonstrate that LNP delivery of Class 2 Type V Cas12a mRNA in conjunction with an optimized chRDNA guide is a powerful tool for efficient and functional genome editing in hepatocytes.

1126 Generation of a *de novo* intronic junction in the *DMD* gene through CRISPR/Cas genome editing as a potential therapy for a high proportion of Duchenne muscular dystrophy patients.

Monica Gil-Garzon[1], Linda Popplewell[2], Alberto Malerba[3]
[1]University College London, LONDON, London, United Kingdom, [2]Teesside University, Darlington, County Durham, United Kingdom, [3]Egham, UNITED KINGDOM

Background: Duchenne Muscular Dystrophy (DMD) is caused by mutations across the *DMD* gene. The subsequent absence of dystrophin protein compromises muscle stability and contractility and gives rise to progressive muscle wasting. Different gene therapies are being investigated, such as AAV micro-dystrophin delivery, premature termination codon read-through, exon-skipping and utrophin upregulation. Nevertheless, these therapies require repeated administration, could carry an adverse immunological risk and some are restricted by mutation specificity. Such problems may be circumvented with genome editing.

Aims: We aim to create a *de novo* junction between introns 18 and 55 (deleting exons 19-55), using CRISPR/Cas, to express an internally truncated functional dystrophin from the endogenous *DMD* locus. The gRNAs are designed to target introns and produce a ~800 kbp deletion. It is estimated that this strategy would eliminate ~81% of total DMD mutations.

Methods/Materials: To produce the deletion of exons 19-55, gRNAs for *Staphylococcus aureus* (*Sa*)Cas9 were designed and screened individually *in-vitro* for cleavage efficacy using TIDE analysis. The optimal gRNAs for each intronic site in murine *Dmd* were multiplexed into an *Sa*Cas9 construct. Top multiplexed candidate gRNAs were

tested in Neuro2A and C2C12 cells to confirm edited deletion by PCR and Sanger Sequencing. Gene editing constructs were packaged into AAV9 vectors, locally injected into 2-months old *mdx* mice and functional efficacy assessed by muscle electrophysiology. As a positive control, a cDNA construct expressing D19-55 dystrophin was generated and tested in *mdx* mice for protein expression.

Results: The positive control plasmid significantly increased dystrophin positive fibres *in vivo* by plasmid intramuscular injection, indicating that D19-55 dystrophin is expressable and has the potential for beneficial effects when expressed in sufficient levels. Deletion of exons 19-55 was confirmed at DNA level *in vitro*. Multiplex construct and co-delivery of gRNAs packaged into AAV9 were assessed *in vivo* but no beneficial effects on muscle physiology was seen likely as a result of inability to detect a deletion in treated muscle samples using the techniques employed.

Conclusion: This study shows the development of a universal genome editing strategy from theory to *in-vivo* testing, exploring limitations of achieving a large deletion *in-vivo* and highlighting potential functionality of a new truncated dystrophin.

1127 Genome Editing with Fast Degrading Cas9 Restores Dystrophin Expression in mdx Mice

Bryan Hu[1], Yongping Yue[1], Xiufang Pan[1], Keqing Zhang[2], Roland Herzog[3], Dongsheng Duan[4]

Adeno-associated virus (AAV)-mediated CRISPR-Cas9 gene editing holds great promise in treating Duchenne Muscular Dystrophy (DMD). This technology can be adapted to precisely edit the DMD gene and restore dystrophin expression. However, previous studies have revealed that Cas9-specific immune responses can eliminate edited fibers, impeding successful treatment. Thus, there is an urgent need to address Cas9-specific immune responses for AAV CRISPR therapy. One such approach is through employing immune-evasive variants of Cas9. Fast degrading Cas9 (fdCas9) is a variant of SpCas9 that contains a pentapeptide motif that directs its degradation towards the lysosomal pathway. This motif, otherwise known as a KFERQ-like motif, is recognized by the HSC70 chaperone and trafficked to lysosome associated membrane protein 2A (LAMP2A) for chaperone-mediated autophagy (CMA). Importantly, proteins degraded under the CMA pathway produce peptide fragments that are loaded onto MHC class II complexes instead of MHC class I. By avoiding MHC-I, fdCas9 can remain less detectable by cytotoxic CD8+ T cells, which are largely responsible for the Cas9-specific immune response in AAV CRISPR therapy. Here, we assess the application of fdCas9 and its potential for DMD gene therapy by evaluating its characteristics *in vitro* and *in vivo*. First, we transfected HEK293 cells with plasmid constructs encoding for CK8.fdCas9 or CK8.SpCas9. RNA and protein extracts were harvested at 24h, 48h, and 72h. We detected ample RNA transcripts for both constructs, but low to no protein expression for fdCas9 compared to SpCas9. For the *in vivo* murine study, we utilized gRNAs that target exon 23 of the mdx mouse model as reported by Long et al. (Science 351:400-403, 2016). We packaged the mdx gRNA vector, CK8.fdCas9 vector, and CK8.SpCas9 vector in AAVMYO. As a pilot study, we co-injected 1×10^{11} vg/muscle/vector of the mdx gRNA vector with CK8.fdCas9 vector into the left and right tibialis anterior (TA) of mdx mice. Immunostaining revealed robust dystrophin restoration in injected tissues. Contrary to *in vitro* data, we also detected high fdCas9 protein expression in muscle injected with CK8.fdCas9 vector. We hypothesized that the amount of fdCas9 delivered may be too high in expression for basal CMA activity to efficiently degrade. Subsequently, we tested 4 different doses of CK8.fdCas9 vector: 1×10^{10}, 1×10^{9}, 1×10^{8}, and 1×10^{7} vg/muscle. We detected dystrophin restoration at 1×10^{10} and 1×10^{9} vg/muscle doses, but not at the lower doses. Futheremore, we detected some fdCas9 protein expression at the 1×10^{10} dose, but no fdCas9 protein expression at the 1×10^{9} dose. For a direct side-by-side comparison, we co-injected 1×10^{11} vg/muscle of the mdx gRNA vector with 5×10^{9} vg/muscle of CK8.fdCas9 vector or CK8.SpCas9 vector into the left and right TA of mdx mice. We are currently processing and evaluating the tissues collected from the study. We will report our findings at the annual conference (Supported by University of Missouri Life Science Fellowship and NIH grants NS131416 and AI177600).

1128 Sequencing analysis of *in vivo* editing of the DMD gene using homology-independent targeted integration

Stefan Nicolau[1], Breanna Trecha[1], Arden Santa[2], Jessica Sarff[3], Aryan Tyagi[2], Gabrielle Dufresne[3], Emma Frair[4], Tatyana Vetter[1], Anthony Stephenson[3], Kevin Flanigan[5]
[1]Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, [3]Nationwide Children's Hospital, [4]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [5]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH

Background: We developed a gene editing system using homology-independent targeted integration (HITI) to correct N-terminal mutations causing Duchenne muscular dystrophy. The system is based on insertion into the native intron 19 of a new promoter and superexon composed of the coding sequence of exons 1-19, effectively bypassing transcription from the 5' end of the gene. The system is delivered using a pair of adeno-associated virus (AAV) vectors. Cas9 is expressed from the first vector, then cleaves the genomic DNA and the second vector, which contains the donor construct. The donor construct is integrated into the genome through non-homologous end joining.

Methods: The editing system was evaluated *in vivo* in a mouse model of exon 2 duplication. Molecular analyses were performed in the heart, skeletal muscles, and liver at 1 month and 3 months post-treatment. Editing outcomes were evaluated by ddPCR and by targeted long-read sequencing. This was accomplished using a custom panel of oligonucleotides to capture integrated and episomal AAV vectors, followed by Nanopore sequencing.

Results: The highest therapeutic editing efficiency was seen in the heart, reaching 3%. In skeletal muscles, efficiency was lower and further declined between 1 and 3 months post-treatment. Breakpoints between the donor vector and genomic DNA at the target site primarily coincided with the expected cleavage sites on the vector, but integration occurred in either the forward or reverse orientation. Integration of Cas9 vectors was also observed, though at a lower frequency. Episomal concatenation occurred both between identical (Cas9-Cas9 or donor-donor) and different (Cas9-donor) vectors. Partial or complete loss of the inverted terminal repeats were common in both integrated and episomal vectors.

Conclusions: Therapeutic editing can be achieved using HITI with AAV-based delivery, but its reliance on non-homologous end joining can lead to unintended editing outcomes, including reverse integration and integration of the Cas9 vector.

1129 ARCUS-Mediated Gene Editing Excision of Exons 45-55 of the Human Dystrophin Gene using PBGENE-DMD Leads to Functional Dystrophin Protein and Durable Restoration of Skeletal Muscle-Function In Vivo for the Treatment of Duchenne Muscular Dystrophy

Adam Mischler[1], Gary Owens[1], Whitney Lewis[1], Nicole Heard, Ben Morris[2], Haley Grimason, Krsna Rangarajan[2], Chengwei WANG[1], Kalpana Kodi, Dominique Burgess[2], Katie Poe[2], Traci Reddick, Wendy Shoop, Cassie Gorsuch, Jeff Smith[3]
[1]Precision BioSciences, Durham, NC, [2]Precision Biosciences, Durham, [3]Precision BioSciences, Inc., Durham, NC

Duchenne muscular dystrophy (DMD) is a genetic disorder associated with mutations in the dystrophin gene that prevent expression of functional dystrophin protein in skeletal, smooth, and cardiac muscle tissues. Dystrophin protein is essential for stabilizing muscle cells by connecting cytoskeletal actin to the cell membrane-bound dystrophin-associated protein complex. The absence of functional dystrophin protein leads to inflammation and fibrosis, resulting in progressive loss of muscle function, and eventual death in the second or third decade of life due to worsening cardiomyopathy and respiratory insufficiency. DMD occurs in 1 in 3,500-5,000 male births, and current treatments, such as gene therapies which express a synthetic, miniature dystrophin protein missing many important dystrophin protein domains, have shown limited improvement to disease prognosis and have not met primary clinical endpoints. Further, all gene therapies have potentially limited durability, particularly in pediatric patients due to cell turnover, immunological responses, and silencing over time. By contrast, the permanence of a gene editing approach could allow for lifelong benefits of muscle retention and function. We have previously described an approach to restore native dystrophin function by utilizing two ARCUS nucleases, delivered using a single AAV, to excise exons 45-55 of the dystrophin gene, resulting in a natural form of the dystrophin protein

(del45-55 dystrophin) that is functionally competent and found in a subset of Becker Muscular Dystrophy patients who are often asymptomatic. Up to 60% of DMD patients exhibit pathogenic mutations in the 45-55 exon region, potentially allowing for broad applicability of this therapeutic approach. Here, we demonstrate functional improvement using PBGENE-DMD, clinical candidate ARCUS nucleases packaged together in a single AAV, in a humanized DMD mouse model. Following AAV delivery, we observed dystrophin protein in target tissue types such as heart and skeletal muscle. Importantly, in skeletal muscle the ARCUS-edited dystrophin transcript was observed in $PAX7^+$ cells, a marker for muscle satellite stem cells, supporting the potential for long-term durability. The maximum force output (MFO), a key functional readout, was significantly improved in vivo 3 months after ARCUS treatment. Additionally, PBGENE-DMD-treated DMD mice displayed significant resistance to eccentric injury, reaching 66% improvement compared to untreated DMD mice. Over the course of a full 6-month time interval, the disease progression of untreated DMD mice caused the MFO to drop from 72% to 58% of levels observed in healthy mice. In contrast, PBGENE-DMD-treated DMD mice sustained functional improvement over the 6 months, maintaining 88-93% of the MFO observed in healthy mice, demonstrating strong durability of the ARCUS gene editing approach. Moreover, between 3 and 6 months, we observed similar improvements in MFO between ARCUS-treated DMD mice and healthy mice, in stark contrast to continued disease progression in untreated DMD mice. This in vivo durability and efficacy study further supports the therapeutic potential of PBGENE-DMD for the treatment of DMD and ongoing development toward clinical trials.

1130 Targeted Integration of Large DNA Cassettes in the *B2M* locus of induced Pluripotent Stem Cells

Benjamin Persily, CJ Willett, Paul Gadue, Giulia Pavani
Children's Hospital of Philadelphia, Philadelphia, PA

Targeted integration of large DNA fragments using CRISPR/Cas9 and other nucleases remains challenging in induced pluripotent stem cells (iPSCs). Serine site-specific recombinases like Bxb1 can integrate large DNA fragments in a specific locus when short sequences (*attB* and *attP* sites) are present in the genome and in the donor. This reaction is irreversible and unidirectional, making this ideal for stably integrating expression cassettes into the genome. Several safe harbor loci have been used to integrate and express transgenes in iPSCs, including *AAVS1* and *CLYBL*. However, many targeted constructs have shown heterogenous expression and promoter silencing when iPSCs are differentiated in specific cell lineages. The *B2M* gene is expressed in most cell types (including iPSCs) as it encodes the β-2 microglobulin protein, which is a component of MHC class I molecules. Moreover, B2M knockout doesn't impact cell fitness or pluripotency, and it has been widely used to generate hypoimmune iPSC for off-the-shelf cell therapy.

Here, we hypothesize that inserting a Bxb1 landing pad in the *B2M* locus in iPSCs will result in stable transgene expression in different lineages upon site-specific recombination. This approach will allow the targeted integration of large DNA payloads and the rapid generation of monoallelic or biallelic transgenic lines, without the introduction of DNA double-stranded breaks.

We first tested and validated our approach in immortalized cell lines (HEK293 and K562). We used prime editing to introduce a 38 bp *attB* sequence downstream of the *B2M* promoter, and then used Bxb1 recombinase to integrate the cassette. We designed a reporter plasmid containing the *attP* site followed by a promoterless GFP and a constitutively expressed puromycin resistance-TagBFP reporter. This donor allowed us to easily recognize on-target vs. off-target integration, as GFP is expressed only upon integration at the *B2M* locus.

After transfection of prime editing components, Bxb1, and DNA donor followed by puromycin selection we were able to detect co-expression of GFP and TagBFP in HEK293 and K562 by flow cytometry. We confirmed on-target integration in GFP expressing clones by PCR amplification of the 5' and 3' ends of the cassette. Importantly, we detected *attL* and *attR* sites flanking the integration by Sanger sequencing, indicating successful site-specific recombination.

Following the functional validation of our approach, we used the same prime editor components to create iPSC lines with monoallelic and biallelic *attB* insertion at the *B2M* locus. We confirmed the presence of *attB* sites in individual

iPSC clones and verified genome integrity and pluripotency. We then targeted our GFP-TagBFP reporter to the *B2M* locus using Bxb1. After puromycin selection and clone isolation, we verified on-target recombination with functional assays and DNA analysis. We are currently performing tri-lineage differentiations with a targeted iPSC clone to monitor GFP/TagBFP expression from the *B2M* locus in neuronal, pancreatic, and blood progenitors.

In summary, we have generated iPSC lines with monoallelic and bi-allelic *attB* sites in the *B2M* locus using prime editing. We successfully integrated a large DNA cassette (5.6 kb) in the *attB* landing pad using Bxb1 and confirmed functional expression of the cassette. Future plans include the targeted integration of other relevant DNA donors, including a Dox-inducible *NGN2* construct to generate iPSC-derived neurons.

1131 Enhanced human NK cell function by CLICK, an efficient non-viral CAR integration on *CISH* locus with a mini-circular single stranded DNA

Howard Wu[1]*, Jiao Wang[1], Yao Sun[2], Guozhu Xie[2]
[1]Full Circles Therapeutics, Cambridge, MA, [2]Southern Medical University, Guangzhou, China
Corresponding Author

Natural killer (NK) cells are promising for adoptive cell therapy due to their potent innate cytotoxic abilities. Early clinical trials have shown their safety and efficacy in treating cancer and autoimmune diseases. Enhancing NK cells with chimeric antigen receptors (CARs) improves their target specificity, positioning them as viable off-the-shelf allogeneic cell therapy products. However, engineering NK cells, whether through viral or non-viral methods, poses significant challenges. Here, we present a novel non-viral approach for CAR NK cell engineering using a mini-circular single-stranded DNA-based target genome editing system. This system led to the development of our CAR-NK engineering platform, named CLICK (*CISH* Locus Integrated CAR Killer), which efficiently integrates CD19CAR sequences into a metabolic checkpoint *CISH* locus. NK cells derived from peripheral blood and engineered with CLICK exhibited high and stable CAR expression throughout NK cell expansion, with specific cellular enrichment at the CISH locus. CLICK-engineered CAR NK cells showed potent cytotoxicity compared to *CISH*knockout NK cells and demonstrated strong anti-leukemic activity *in vitro* and *in vivo* using a xenograft leukemia mouse model. Importantly, CLICK engineered CAR-NK cells exhibited extended lifespans and reduced exhaustion *in vivo*, maintaining durable anti-tumor functions. Our findings indicate that the CLICK NK cell engineering platform is a highly efficient, safe, flexible, and cost-effective method for non-viral engineering of functional CAR NK cells, making it a compelling approach for scalable allogeneic immune cell therapy against cancer and autoimmune diseases.

1132 Developing a Gene Insertion Strategy for Homozygous Familial Hypercholesterolemia

Usosa Too-Chiobi[1], Marco De Giorgi[2], William Lagor[3]
[1]Baylor College of Medicine, Pearland, TX, [2]Baylor College of Medicine, Houston, TX, [3]Baylor College of Medicine, Houston, Texas

Homozygous Familial Hypercholesterolemia (HoFH) is a severe genetic disorder characterized by excessively high levels of low-density lipoprotein (LDL) cholesterol and premature atherosclerotic vascular disease. HoFH is caused by loss-of-function mutations in the LDL receptor (*LDLR*), a critical gene that removes excess cholesterol from circulation by the liver. A recent attempt at human gene therapy for HoFH using an Adeno-Associated Virus (AAV) was unsuccessful, likely due to immune responses to the vector or transgene silencing. The goal of this project is to develop a gene insertion strategy for *LDLR* in the liver in which correctly edited hepatocytes can be selectively expanded overtime through transient inhibition of an essential gene. To accomplish this, we generated AAV8 vectors to express *Ldlr* driven by the hybrid-liver promoter (HLP) to test the optimal configuration for integration into the genome. Specifically, we tested AAV8 co-expressing tdTomato and LDLR in *Ldlr* knockout mice to determine whether LDLR would tolerate a P2A skipping peptide on its N- or C-terminus. We injected four groups of

mice (n=3) with one of four AAV8 vectors: HLP-tdTomato-2A-*Ldlr*, HLP-*Ldlr*-2A-tdTomato, HLP-tdTomato, or HLP-*Ldlr*, and collected plasma prior to initial injection (t=0) and once weekly for four weeks. We measured cholesterol levels in plasma and analyzed protein expression in the liver by western blotting. We found that LDLR protein expression is independent of P2A position, however LDLR with P2A peptide on the N-terminus failed to lower plasma cholesterol. Based on these studies we conclude that LDLR best tolerates a P2A skipping peptide at its C-terminus, as this vector configuration lowered plasma cholesterol on par with overexpression of the native LDLR protein. This data will be used to further develop a permanent cure for HoFH through targeted integration of the *LDLR* gene into the genome and selective expansion of *LDLR*-corrected cells.

1133 Precise and Efficient Immune Cell Engineering via Pin-pointTM Base Editing Platform: Insights from TotalSeq Single-Cell Multiomic Analysis

Amanda Haupt[1], Anastasia Kaufman[2], Josh Croteau[3], Alexandra Corella[4], Andre Fernandes[5], Anna Sheydina[5], Shannon Hinsdale[6], Immacolata Porreca[7], Kevin Taylor[5], Kevin Hemphill[8]
[1]Revvity, Superior, CO, [2]Lafayette, CO, [3]Revvity, Waltham, MA, [4]Revvity, San Diego, CA, [5]Revvity, San Diego, [6]Revvity, Lafayette, CO, [7]Revvity, CAMBRIDGE, Cambridgeshire, United Kingdom, [8]Revvity, UNITED KINGDOM

Many gene editing platforms, such as CRISPR-Cas9, rely on nuclease activity to introduce a targeted protein knockout through the introduction of DNA double-strand breaks (DSBs). While this revolutionary platform has been used in a wide array of cell and gene therapy applications and at varying stages of pre-clinical research up through recent FDA approvals, the technology does not come without risks. DSBs introduced by nucleases can lead to unwanted genomic alterations and cytotoxicity. These effects are magnified when more complex genomic perturbations, such as editing at multiple genomic sites, are introduced. Here, we demonstrate efficient multiplex gene editing using the Pin-point base editing platform as a safe and suitable technology for the creation of CAR-T cell therapies. The Pin-point platform can efficiently knockout four or more protein targets simultaneously with limited impact on cell viability in T cells and can also be utilized for a number of iPSC and HSPC therapeutic engineering applications. Through single-cell multiomic approaches, we can characterize the effect of editing with the Pin-point platform at the RNA and protein level. We see that the platform can efficiently edit multiple subpopulations of cells, for example, CD4, CD8, and dual CD4/CD8 positive T-cells, with high on-target efficacy and with no detectable off-target phenotypic impacts identified via interrogation of the whole transcriptome and a highly-multiplexed protein panel. From discovery to pre-clinical development, the Pin-point and TotalSeq platforms are well suited for engineering and characterizing next generation cell and gene therapies.

1134 Signature of base editor RNA edits in the transcriptome and reduction of RNA editing

Allie Crawley[1], Lisle Mose[1], Isaiah Taylor[1], Megan Williamson[1], Adrian Oliver[1], Joel Parker[1]
[1]Life Edit Therapeutics, Durham, NC

As base editor therapeutics progress through the clinic, better metrics are needed to understand the guide-independent mutational burden they place on the transcriptome. CRISPR-derived base editors are used to alter specific bases in the target DNA sequence in order to introduce a stop codon, alter expression of a gene through splice site disruption, or repair a disease-causing mutation. However, the deaminases used for A-base editors are widely evolved from proteins that recognize and deaminate tRNAs. Activity at the DNA level is a feature that must be engineered into these proteins. As deaminases increase their ability to recognize DNA, it is thought their activity on RNA should decrease inversely. Quantification of RNA deamination by evolved deaminases remains difficult due to high rates of naturally occurring, endogenous RNA editing. Here we present a method that can separate the signature of RNA edits made by base editors from endogenous RNA editing. Using mammalian cell systems including primary cells, we demonstrate that RNA editing from base editors is dose-dependent and transient. Further, we show that targeted engineering of the deaminase enables a significant reduction in RNA editing. We believe this approach enables the design and engineering of improved base editor systems, which in turn supports

the advancement of improved genomic medicines with higher on-target efficacy while minimizing off-target RNA editing.

1135 Improving Precision and Specificity of CRISPR Gene Editing with RGEN-seq and RGEN-mod

Alexander Kuzin[1], Haiwang Yang[2], Pradeep Bhaskar[2], Alexei Slesarev[3]
[1]BioReliance Corporation (MilliporeSigma/Merk KGaA), Rockville, MD, [2]MilliporeSigma, Rockville, MD, [3]MelliporeSigma, Rockville, MD

CRISPR nuclease-based genome editing (GE), along with zinc finger nucleases (ZFNs) and transcription activator-like effector nucleases (TALENs), has emerged as a powerful molecular tool across various biological disciplines, including gene therapy. However, off-target effects pose a significant challenge, highlighting the need for sensitive genome-wide detection methods to establish reliable gene therapy platforms. Since its inception, considerable efforts have been made to enhance the specificity of CRISPR nuclease GE and minimize off-target activity to ensure its safety for therapeutic applications. While no single method currently fully eliminates off-target effects, ongoing advancements continue to improve precision.

Here, we present RGEN-seq [1], a sensitive, amplification-free next-generation sequencing method designed for unbiased detection of double-stranded breaks induced by RNA-guided CRISPR endonucleases and other nucleases. Originally developed on the Illumina platform, this amplification-free digital method is now compatible with all major sequencing platforms, including Illumina, DNBSEQ, Nanopore, and PacBio, enhancing its versatility and applicability across various laboratory settings. RGEN-seq optimizes workflows by eliminating genomic coverage bias and gaps typically associated with PCR and enrichment procedures, providing a robust foundation for correlating DNA cleavage scores with the likelihood of off-target mutations in cells. We also introduce the RGEN-seq-based RGEN-mod method, a novel approach that combinatorially functionalizes guide RNA libraries to select CRISPR-sgRNA complexes with minimal off-target activity. RGEN-mod utilizes phosphoramidite chemistry to incorporate succinimido moieties during RNA synthesis, enabling the creation of diverse RNA primer libraries. These libraries can then be screened using RGEN-seq in high-throughput, automated environments.

Together, the combination of RGEN-seq and RGEN-mod offers a comprehensive and platform-agnostic strategy for identifying and validating the most efficient and specific CRISPR nuclease complexes, thereby advancing the development of safer and more effective gene therapy applications.

Kuzin et al. RGEN-seq for highly sensitive amplification-free screen of off-target sites of gene editors. Sci. Rep. 11, 23600 (2021).

1136 Preclinical Safety Assessment of Anti-Viral Gene Editing in Chronic Hepatitis B Models

Sam Slattery[1], Wenwen Huo[1], Amena Arif[1], Jennifer Gordon[2]*, **Ryo Takeuchi**[1]*
[1]Excision BioTherapeutics, Watertown, MA, [2]Excision Biotherapeutics, Inc., Watertown, MA
**Corresponding Author*

Chronic hepatitis B (CHB) is estimated to affect more than 250 million people globally and there are no FDA-approved curative therapies. Nucleos(t)ide analogues are the standards of care and reduce hepatitis B virus (HBV) load however these therapies do not block low level viral replication which allows for HBV persistence in infected hepatocytes. Multiplex gene editing has been demonstrated to remove viral DNA from chronically infected cells and is being developed as a therapy to cure infectious diseases, including CHB. While nuclease-induced double strand breaks lead to rapid clearance of viral DNA, they could potentially cause genome instability in the forms of HBV DNA integration or chromosomal translocations.

To assess these safety concerns, we performed a series of deep sequencing assays with HBV-infected primary human hepatocytes (PHHs) and two CHB mouse models edited by CRISPR-Cas9 targeting HBV. In animal models, viral replication stems from two distinct sources: episomal and chromosomally integrated constructs carrying the viral genome. We characterized DNA repair outcomes following cleavage of the intended target sites within the two structurally different forms of HBV DNA. To achieve this, we first confirmed that multiplex gene editing with a pair of HBV-targeting guide RNAs substantially reduced the viral DNA in hepatocytes and blocked secretion of viral antigens in vitro and in vivo. Small insertions and deletions (indels) and structural variants such as excisions and inversions were detected on the residual HBV DNA recovered from the edited samples, indicating that our HBV-targeting nuclease efficiently cleaves the viral DNA in vitro and in vivo. Consistent with this finding, the level of HBV DNA integration was suppressed in cells receiving our anti-HBV CRISPR-Cas9, suggesting that nuclease-mediated fragmentation of episomal HBV DNA copies does not promote viral DNA integration. To verify sequence specificity of our editing approach, we analyzed the flanking sequences of the HBV integration sites and found that very few sites shared high sequence identity with the HBV on-target sites. Collectively, these results suggest that HBV-targeting multiplex gene editing inhibits viral replication and integration with minimal risk of chromosomal aberrations. The potential for HBV-associated translocations will be discussed as well.

1137 INDUCE-seq®: Ensuring the Safe Development of Cell and Gene Therapies by Gene Editing

Simon Reed, Broken String Biosciences Ltd, Cambridge, Cambridgeshire, United Kingdom

Advances in genome editing are making it increasingly possible to develop new cell and gene therapies. Synthetic genes and modifications to existing ones can be made in a site-specific manner, while immune-compatible cells created for use in allogeneic patients enable production of ‘off-the-shelf’ cellular therapies.

However, gene editing is a new way of treating disease, requiring new tools to ensure their safe and efficacious use in patients. Genome editing comes with risk, including malignant transformation of target cells caused by culturing cells outside the body. This can introduce mutations that confer growth advantages to cells. Furthermore, gene editing can directly cause genomic instability. In cells harboring pre-existing DNA repair defects, the selection for outgrowth of clones with oncogenic mutations may result.

Finally, the gene editing tools themselves can cause DNA breaks in the genome at sites other than the intended target. Such off-target editing could activate proto-oncogenes, or disrupt tumor suppressors thus driving carcinogenesis. Off-target mutagenesis may also generate neoantigens, triggering autoimmunity, or other types of cellular dysfunction. Furthermore, rare penetrant mutations are now known to confer severe risk of common disease, underscoring the importance of identifying off-target gene editing.

More precise methods are needed for testing off-target editing during all phases of therapeutic development, including treatment follow-up. At present standardised assays to assess the safety of gene editing-based therapies are lacking. Here, we describe the development and characterization of INDUCE-seq to address this. CRISPR-Cas9-based gene editing of five well-studied genetic targets was conducted by two independent industry partners, using two different cells types. On and off-target gene editing was assessed by measuring breaks in the genome using INDUCE-seq. The genetic changes at these locations were subsequently measured using Duplex Sequencing, which allows for sensitive detection of exceptionally rare mutations. The results of the study will be presented.

1138 Evolving Solutions for Effective Genotoxicity Assessment in CRISPR-Cas Gene Editing

Kyle Kinney[1], Kun Jia[2], **Gavin Kurgan[3]***, Morgan Sturgeon[1], He Zhang[4], Ellen Schmaljohn[1], Thomas Osborne[4], Bernice Thommandru[1], Karthik Murugan[1], Ashley Jacobi, Kyle Cromer[5], Garrett Rettig
[1]Integrated DNA Technologies, Coralville, IA, [2]University of California - San Francisco, San Francisco, [3]Integrated DNA Technologies Inc, Coralville, IA, [4]Integrated DNA Technologies, Coralville, [5]University of California, San

Francisco, San Francisco, CA

Next-generation CRISPR-based editing systems continue to be developed, bringing more diverse editing capabilities to the 'toolbox'. Sensitive nomination of off-target sites in diverse editing systems (e.g. blunt double-stranded break (DSB), staggered DSB, nicked SSB) is a challenge that needs to be addressed in pre-clinical studies during genotoxicity safety assessments. To this end, we present an improved off-target nomination workflow using a proxy system to sensitively nominate off-target sites across different cell types and editors spanning a variable range of gRNA specificity levels. Using clinically relevant cell types (e.g. iPSCs, Primary T-cells) it is demonstrated that the workflow serves as a sensitive (<0.01% indel editing nominated) and effective (>99% event nomination) method across a range of relevant cell types and gRNAs. By quantifying down to 0.01% indel editing frequencies and 0.5% base editing frequencies in the nominated targets, it is demonstrated that editing with diverse editor types (e.g. ABE, CBE), correlates well to frequencies observed using DSB based editors in HSPCs using mRNA delivery. Furthermore, the method shows evidence of nominating sites uniquely undergoing indel editing only with SSB editing modalities in HSPCs. This set of experiments across a broad range of gRNA specificities demonstrates an end-to-end to process for nominating and confirming bona fide off-target sites using both current and next-generation editors.

1139 Evaluating Optimal Volume and Dose of AAV9-mCherry in Stereotaxic targeting of Putamen in C57BL/6 mice

Mayuri Prasad[1], Sarah Newman[2], Vaithinathan Selvaraju[3], Jamie Jamie Farr[4], Alok Sharma[5], Brian McIntosh[6]
[1]Labcorp Drug Development, Madison, WI, Madison, WI, [2]Labcorp Drug Development, Madison, WI, [3]Labcorp Drug Development - Madison, WI, Madison, [4]Labcorp, Madison, [5]Madison, [6]Labcorp Drug Development - Madison, WI, Madison, WI

Introduction: It is estimated that approximately 3% of the population is affected with some form of monogenic neurological disorder. Adeno-associated virus (AAV) gene therapy has the potential to treat these central nervous system indications, however delivering the viral vector carrying the correct genetic information to the specific neural tissue is a significantly challenging process. Systemic administration of the viral vector results in a greater dose requirement to achieve clinically relevant levels due to difficulty navigating the blood brain barrier. This in turn increases exposure in non-target tissues and the risk of immunotoxicity associated with a broader biodistribution and can result in increased off target expression. A direct, stereotaxic administration of AAV gene therapy can safely and effectively deliver genetic payload into defined structures in the brain, alleviating concerns associated with systemic administration and requires a lower vector dose for clinically relevant transgene expression, poses a lower risk of full immune response and limits unwanted expression in non-target tissues.

Method: In this 4-week study we evaluated the biodistribution and transduction efficiency of AAV9-mCherry via qPCR when administered as a single, bilateral stereotaxic dose in 3 different volumes and dosages to the putamen of female C57BL/6J mice. We used mouse as a model for this study to leverage the availability of a wide variety of established genetic murine models for CNS disease. We assessed the spatial mCherry gene expression within individual cells in neural target tissue sections by RNA In-situ hybridization. The mCherry protein level expression was assessed by immunohistochemistry. In addition, we evaluated for procedure-related traumatic brain injury by immunolabeling for biomarkers of neuro inflammation and trauma using markers for microglia activation (Iba-1), astrogliosis (GFAP) and inflammation (MMP9). We evaluated tissue specific transduction efficiency in the putamen, thoracic dorsal root ganglion, cervical, lumbar and thoracic spinal cord and liver tissues.

Result: A volume/dose dependent increase in the transduction efficiency was noted across all the tissues and the highest biodistribution of AAV9-mCherry was noted in the putamen dosed with 7 µl/7.42 x 10^{10} GC/site, with the liver having approximately 50-fold lower expression. Similar trends in the mCherry expression were noted via the mCherry immunohistochemistry and mCherry RNA in situ hybridization. Minimal expression of Iba-1 and GFAP in control group animals and minimal to moderate expression of Iba-1 and GFAP in animals dosed with 7 µl /7.42 x 10^{10} AAV9-mCherry GC/site indicated the presence of some procedure or volume related neural inflammation. Expression of MMP9 was not observed in either the control or AAV9-mCherry dosed animals.

Conclusion: Taken together, this data demonstrates that efficient neural tissue biodistribution of AAV9 vector can be achieved with limited/minor post-surgery related tissue inflammation in stereotaxic dosed murine models. The volumes and dosages used in this study are a reliable starting point for developing refined genetic murine models for CNS diseases targeting putamen or other neural structures to obtain high transduction with minimal off target expression and lowered risks of neural inflammation. This information can also serve as a guidance for precision targeted CNS dosing in large animal species and humans as well.

1140 Precise Gene Writing System for CAR-T cell therapy generation.

Avencia Sanchez-Mejias[1], Ivan Fernandez Muñoz[1], Alejnadro Ragel Lopez[1], Paolo Petazzi[2]
[1]Integra Therapeutics, Barcelona, Barcelona, Spain, [2]Integra Therapeutics, Barcelona, Spain

The development of effective, precise, and safe gene-editing technologies for ex vivo therapies, particularly in hematopoietic stem cells (HSCs) and chimeric antigen receptor T cells (CAR-Ts), posesa critical challenge. Current platforms face technical limitations and safety concerns, impeding the realization of their full therapeutic potential. To address these challenges, FiCAT emerges as a groundbreaking gene-writing platform with the aim of providing a flexible and universal solution for safe editing of small regions and efficient, programmable editing of large genes in clinically relevantprimary cells.

FiCAT is composed of a CRISPR-Cas nuclease and propietary engineered transposase, with outstanding efficiency reached through rational protein engineering and an unsupervised variability generation approach. Over 400,000 variants are tested using a proprietary high-throughput screening system grounded in synthetic biology principles. In practical application, FiCAT RNPs had been produced and validated in T cells and HSCs using nucleofection for targeted integration of a minimal reporter. Our system compared favourably against existing systems like homology-directed repair (HDR) or homology-independent targeted insertion (HITI) using CRISPR-Cas9 alone. To enhance both efficiency and viability, electroporation is coupled with inhibitors targeting toxicity associated with double-stranded exogenous DNA. In addition, FiCAT therapeutic potential has been shown with the successful integration of CAR19 in a relevant locus (TRAC) for T cells . In vitro Functional validation of FiCAT generated CAR-T cells revealed comparable cytotoxicity with LV-generated CAR-T cells.

These results open up new possibilities with enhanced cargo size integration in HSCs and T cells, surpassing current gene editing techniques . This is of critical importance for both HSCs (i.e. correction of monogenic blood diseases) and T cells, since new generation of immunotherapies relies on targeting more than one epitope (Dual CAR) but also benefits from the inclusion of immunomodulators to enhance CAR-T cells efficiency and persistence.

FiCAT is designed to overcome precision and safety limitations in gene editing, streamlining the cell engineering process into a single step. Its potential to reduce costs and eliminate the need for viral vectors promises expanded accessibility to treatment. In summary, FiCAT represents a significant advance in gene editing, poised to enhance precision, safety, and cost-effectiveness in clinical applications.

1141 Development of viral-free FiCAT gene writing platform for liver-directed in vivo application

Francesco Starinieri[1], Natalia Artigas[2], Jon Martínez de Lagos[3], Jessica Jaraba Wallace[2], Marc Güell[4], Avencia Sanchez-Mejias[2]
[1]Integra Therapeutics, Esplugues de Llobregat, Barcelona, Spain, [2]Integra Therapeutics, Barcelona, Barcelona, Spain, [3]Barcelona, Barcelona, Spain, [4]Pompeu Fabra University Department of Medicine and Life Sciences, Barcelona, Catalonia, SPAIN

FiCAT is a novel genome writing platform developed to achieve on-target integration by coupling DNA scanning and cutting activity of Cas9 with donor DNA processing and transfer activity of piggyBac transposase (Pallares et al., Nat. Comm 2021). In our platform, we use a triple-mutant version of the hyperactive piggyBac transposase (hyPB-t) in which random integration activity is lost while the excision capacity of the transposon is increased,

therefore integration can occur only when hyPB-t is coupled with Cas9. We have previously described that FiCAT allows efficient and precise transposon or donor DNA integration, achieved also with long non-viral donor DNA (>4kb), and we have shown up to 20% on-target integration of therapeutically relevant cargos such as CAR19 in primary human T cells. Here, we aim to further develop our platform to target hepatocytes in vivo, by delivering the integration machinery in mRNA format exploiting lipid nanoparticles (LNP). We are able to efficiently co-encapsulate FiCAT mRNA and gRNA in LNP, and obtain up to 40% of editing in mouse liver, at a level similar to Cas9+gRNA only. As an initial proof of concept, we used AAV8 to deliver donor transposon DNA. Although AAV vectors are known to efficiently target hepatocytes, episomal AAV genome is lost upon cell proliferation leading to reduced expression in the long term, undermining its use in particular into pediatric patients. Co-delivery with FiCAT mediates on-target integration of the AAV genome, overcoming these limitations. We initially tested co-delivery of AAV vector and LNP by random integration of donor DNA carrying luciferase gene mediated by hyPB. We observed up to 20% of hepatocytes expressing luciferase upon liver growth when treating newborn, and >2-log higher luciferase expression when hyPB is co-delivered compared to AAV-only condition, showing that integration leads to higher expression levels, in both adult and newborn-treated mice. In this context, we then validated FiCAT-mediated programmable integration in vivo in newborn and adult mice. AAV vectors present some further important restrictions, such as the limited cargo capacity, reduced but widely described random integration activity and pre-existing immunity in the population that can impair clinical application. Therefore, our aim is to develop a viral-free system, by delivering also the donor DNA with LNP. We optimized LNP formulation conditions to encapsulate DNA with >90% efficiency. In vivo delivery of viral-free DNA is impaired by inefficient nuclear translocation. We observed that hyPB-t can increase 2-fold the nuclear translocation of donor DNA in vitro by binding the transposon in the cytosol before moving into the nucleus. Overall, our results show the potential of FiCAT platform to achieve viral-free on-target integration in vivo.

1142 A Versatile Anti-CRISPR Platform for Opto- and Chemogenetic Control of CRISPR-Cas9 and Cas12a across a Wide Range of Orthologs

Luca Brenker[1], Sabine Aschenbrenner[2], Felix Bubeck[3], Kaloyan Staykov[2], Carolin Gebhardt[4], Benedict Wolf[2], Michael Jendrusch[5], Ann-Sophie Kroell[2], Jan Mathony[6], Dominik Niopek[2]*
[1]University of Heidelberg, Heidelberg, Baden-Württemberg, Germany, [2]Heidelberg University, Heidelberg, Germany, [3]BioQuant Heidelberg University, Heidelberg, Germany, [4]Technical University Darmstadt, Darmstadt, Germany, [5]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, [6]Heidelberg University, Heidelberg, Baden-Wuerttemberg, Germany
**Corresponding Author*

CRISPR-Cas technologies have revolutionized the life sciences by enabling programmable genome editing across diverse organisms. Achieving dynamic and precise control over CRISPR-Cas activity with exogenous triggers, such as light or chemical ligands, remains an important need. Existing tools for CRISPR-Cas control are often limited to specific Cas orthologs or selected applications, restricting their versatility.

Anti-CRISPR (Acr) proteins, natural inhibitors of CRISPR-Cas systems originating from bacteriophages, offer a highly flexible regulatory layer for CRISPR control. A wide range of Acrs have been discovered, targeting class II, type II, V and VI CRISPR effectors. While most Acrs are ortholog-specific, some have been found to exhibit broad-spectrum activity and effectively block various Cas orthologs. Prominent examples include AcrIIA5 and AcrVA1, broad-spectrum inhibitors targeting Cas9 orthologs from the II-A, -B and -C subtypes or CRISPR-Cas12a, a type V effector, respectively.

In this study, we built on our previously reported concept for optogenetic activation of CRISPR-Cas effectors with engineered, light-switchable Acrs and expanded it from ortholog-specific Acrs towards AcrIIA5 and AcrVA1 and thereby towards broad spectrum control. First, hybrids between AcrIIA5/-VA1 and the *Avena sativa* light-oxygen-voltage 2 (LOV2) domain were engineered by inserting the photosensor into allosteric surface sites of these Acrs. The resulting Acr-LOV2 chimeras release Cas9 or Cas12a activity upon stimulation with blue light, thereby activating genome editing in human cells. Beyond employing conventional, strong Polymerase II promoters to drive the CRISPR-Cas effectors, we were able to co-express all required components, i.e. the Acr-LOV2 chimera, Cas effector and RNA guide, from a single H1 promoter (Polymerase III), resulting in a particularly compact transgene

conformation. Next, we investigated whether the system could be modularized in terms of input and mode of action (stimulus activated vs stimulus inactivated). To this end, we generated a set of circularly permuted ligand receptor domains derived from the human estradiol receptor β, thyroid receptor β and glucocorticoid receptor 2 (GR2). Replacing the LOV2 domain with these novel ligand binding domains gave rise to a chemogenetic Acr platform that facilitates ligand-dependent suppression of genome editing with six different, clinically relevant drugs in various human cell lines. Finally, we demonstrated that the circularly permuted GR2 domain can be plug-and-play integrated into other Acrs, CRISPR-Cas effectors, and even unrelated protein species, highlighting the potential for a broad application in synthetic biology.

In sum, this work establishes a versatile platform for opto- and chemogenetic control of CRISPR-Cas systems, with immediate applications in basic research and biotechnology and potential for therapeutic use in the future.

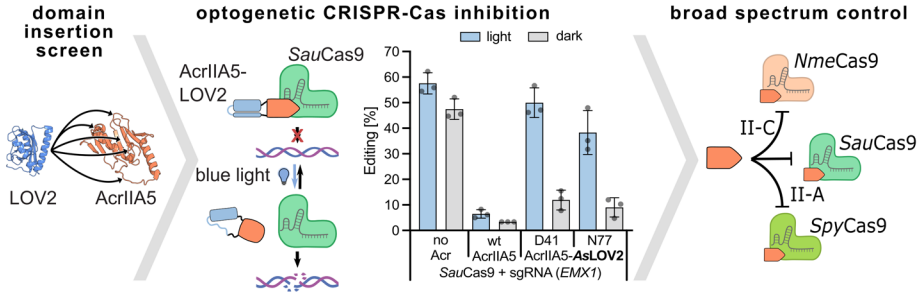

Figure 1: Design of AcrIIA5-LOV2 chimeras for broad spectrum optogenetic CRISPR-Cas9 control. Insertion of LOV2 into surface-exposed loops of AcrIIA5 results in AcrIIA5-LOV2 hybrids (left). These were co-expressed with *S. aureus* Cas9 and an EMX1-targeting sgRNA in HEK293T. Cells were exposed to blue light pulses or kept in the dark for 72 h, followed by assessment of InDels via NGS (center). The resulting AcrIIA5-LOV2 chimeras enable broad-spectrum optogenetic control of type II CRISPR effectors (right).

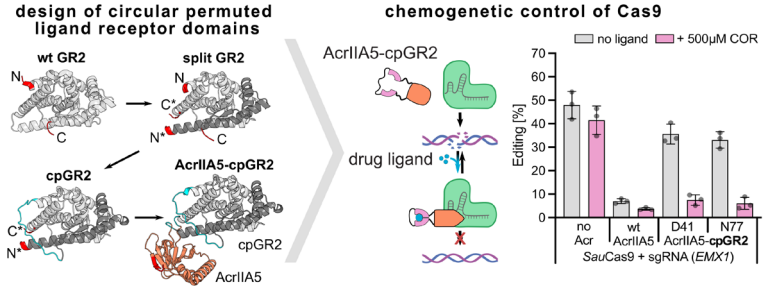

Figure 2: Generation of circularly permuted receptor domains for ligand-mediated suppression of genome editing. The concept for engineering circularly permuted (cp) receptors for allosteric Acr control is illustrated using GR2 as example. Receptor domains were opened at previously identified split-sites (Rithar et al. (2023) *Nat Chem Biol.*), thereby creating new N- and C-termini that are in direct proximity (C*, N*). Former N- and C-termini were connected by fusion via a long GS-linker indicated in blue (left). Schematic of ligand-dependent CasOFF switch.The cpReceptors take on a compact conformation in presence of the ligand, due to proximate N- and C-termini, but are relaxed in absence of the ligand. This results in ligand-dependent disorder of the fused Acr structure (center). Cortisol-dependent genome editing in HEK293T cells using an AcrIIA5-cpGR2 hybrid for CRISPR-Cas9 control (right).

1143 Engineering miniature SpaCas12f genome editing potential

**Corresponding Author*

The miniature (497 a.a.) CRISPR-Cas12f1 nuclease from Syntrophomonas palmitatica (Spa) is triggered by a 5' G(G>W>C)TTC protospacer adjacent motif (PAM) to cleave double-stranded (ds) DNA targets and prefers elevated temperatures, 44-58°C. To broaden its utility as a genome editor, we have simplified its PAM recognition and performed protein and guide RNA (gRNA) engineering to enhance cellular activity and enable robust dsDNA substrate cleavage at temperatures as low as 30°C without measurably impacting its intrinsically high fidelity gRNA target recognition. Our advancements have more than doubled the number of sites that can be targeted and provide around a 10-fold improvement in editing efficiency in human cells at 37°C. Altogether, we have improved SpaCas12f1 cellular activity, shifted its thermal preferences, and expanded its targeting range, paving the way for its use as a compact RNA-guided genome editing tool.

1144 Engineering a potent CRISPR-Cas12l genome editor with C-rich PAM recognition

Here, we solved the structure of a compact (~850 aa) type V CRISPR effector, Cas12l, at 2.9 Å using cryo-electron microscopy (cryo-EM) and used it to engineer variants capable of editing the human genome. Structural analyses revealed similarities to type V CRISPR nucleases as well as new previously unobserved features. These included: 1) an H-type RNA pseudoknot forming guide RNA (gRNA) scaffold; 2) a unique N-terminal domain that stretches from the beginning to the end of the ribonucleoprotein (RNP) bound DNA target site effectively locking the ternary complex in place. Next, using structure-guided engineering, we improved Cas12l DNA target editing in human cells by approximately 10-fold by fine-tuning its electrostatic binding potential at DNA and gRNA interfaces mapped in our structure. To maximize potency, amino acid substitutions predicted with large language protein models to improve folding and stability were next introduced and evaluated for additional enhancements. In combination with the structure-guided modifications, two of the AI-predicted substitutions enabled efficient Cas12l editing when delivered transiently as mRNA or RNP in human cells. Collectively, this work expands the RNA guided genome editing repertoire to one that is compact, recognizes a simple C-rich PAM, and displays a distinctive DNA target lock and catch mechanism.

1145 A Panel of Novel Engineered Nucleases Unlocks the Full Potential of Genome Editing

[1]Emendo Biotherapeutics, New York, New York, [2]Emendo Biotherapeutics, Rehovot, HaMerkaz, Israel, [3]EmendoBio, Rehovot, Israel

A successful CRISPR based gene editing strategy requires developing an optimized composition of nuclease and gRNA per target gene per organ. Different editing strategies require specific nuclease characteristics, such as nuclease size, diverse PAM recognition, compatibility with delivery systems and high activity and specificity to the target site. A panel of nucleases, the OMNI nuclease series, was developed by EmendoBio to overcome such key challenges in the field. The OMNI nucleases recognize different PAM sequences that cover approx. 80% of the human genome; they vary in size; and they are compatible with all common delivery modalities, including AAV. These nucleases are engineered to be as active as industry gold standard while portraying enhanced

specificity, thus eliminating off-target effects and enabling allele specific editing. EmendoBio's technology enabling the development of tailor-made nucleases by combining a discovery pipeline and cutting-edge protein-engineering capabilities, which is supported by extensive computational tools, including proprietary AI.

While EmendoBio has developed more than 300 OMNI nucleases, this abstract focuses on three OMNI nucleases exceeding promise. OMNI-A1 is an allele specific editor, capable of full discrimination between two alleles that differ even by a single nucleotide. OMNI-A2 is a small nuclease that fits into an AAV; using EmendoBio's engineering technology, the activity of OMNI-A2 was increased by 4-fold. OMNI-A4 is a novel nuclease capable of recognizing a non-NGG PAM sequence. Using a non-NGG PAM enables an extended freedom-to-operate beyond that of SpCas9 and expanded genome coverage. OMNI-A4 is highly active, can achieve high editing efficiency and knock-out of multiple gene targets commonly used for cellular therapy.

EmendoBio's panel of novel nucleases, and its proprietary techniques to customize such nucleases, enables expansion of the existing CRISPR toolbox and overcomes major gene editing challenges, offering solutions for a wide range of diseases.

1146 Systematic Analysis of Oligonucleotide Approvals in the EU and US: Identifying the reasons for Non-Approval Decisions

Limin Wang[1], Josh Norris[2]
[1]*Cytiva, Marlborough, MA,* [2]*Cytiva, Amersham, United Kingdom*

Background Oligonucleotides therapeutics show their potential for treating a wide range of conditions, especially previously untreatable rare diseases. Continue efforts for oligo development are on-going to expedite patient access to life-changing therapies. To date, a total of 20 oligo drugs have been approved in the US and EU. However, an analysis of these approvals reveals inconsistencies in market authorization for certain types of oligo therapies between the two regions. Furthermore, some approved oligo therapies have gone through multiple review cycles from the FDA before receiving approval. Analyzing approval and non-approval data can provide valuable insights for future oligo therapy development, offering a unique perspective to both drug developers and regulators on how to accelerate these often-complex therapeutics to market.

Methods Data were gathered from the regulatory filings publicly disclosed by the FDA and EMA, specifically from the Drugs@FDA database and the EU EPAR reports, respectively. Complete Response Letters (CRLs) are confidential and can only be made public once the drug has been approved by the FDA. Information on CRLs for approved drugs can be found in the drug-specific FDA application review files under "Other Action Letters." Plot and chart were generated with Excel.

Results Of the 20 approved oligonucleotide drugs (Fig.1), 14 (70%) were submitted to both the EU and US agencies for market authorization. These submissions covered various types of oligonucleotides, including aptamers, antisense oligonucleotides (ASOs), ASO vaccine adjuvants, siRNAs, and single-stranded/double-stranded DNA (ss/ds DNA). Among these, 7 out of 14 (50%) submissions were for ASO therapies. Notably, 3 out of these 7 ASO submissions (43%) received inconsistent decisions between the EU and US regulators (approval vs. non-approval). This inconsistency has only been observed in ASO therapies so far. Additionally, among the oligonucleotide drugs approved by the FDA, 3 out of 20 (15%) required more than one review cycle, with deficiencies addressed through FDA-issued Complete Response Letters.

Conclusions It was observed that the three inconsistent decisions between EU and US regulators were centered around the ASO type of oligonucleotide products. In the two non-approval cases from the EU agency, it was concluded that the efficacy and safety of the products were not sufficiently demonstrated. The major reasons included a limited clinical dataset for analysis, such as high withdrawal rates in patients, limited participation of EU patients, or a small number of patients per study arm. In the non-approval case from the FDA, the specifics were not clearly described as the Complete Response Letter (CRL) for a non-approved drug is not disclosed to the public. This non-approval may be due to safety concerns associated with the drug. The discrepancies between EU and US regulators underscore the importance of robust clinical datasets and safety profile in the regulatory approval for

ASO type oligonucleotide products. Among all the approval cases from the FDA, three products underwent more than one review cycle and received CRL before approval. The deficiencies addressed in the CRL covered issues related to clinical benefits, serious safety concerns, inspection issues, and CMC issues. Notably, inspection issues were mentioned in two out of three CRLs, serving as a reminder to the industry to ensure facility readiness for commercial production.

1147 Targeted Delivery of siRNA to Activated Hepatic Stellate Cells Using Aptamers: A Novel Approach for Fibrotic Liver Treatment

Ridhima Lal[1], Tom Ward[1], Jamie Withers[1], Hrishi Varayathu[1], Daniel Kidd, **David Bunka[1]**
[1]*Aptamer Group, York, North Yorkshire, United Kingdom*

A lack of effective strategies for targeted delivery of gene therapies to different cell types (beyond hepatocytes) is hindering the development of therapeutic modalities such as RNAi for many diseases. Aptamers offer the potential to selectively deliver RNAi therapies to new biomarkers and cell types.

Activated hepatic stellate cells (HSCs) are a key driver of fibrosis within the liver; thus, targeting this cell type and the fibrotic differentiation process may offer new potential treatments for liver fibrosis. Applying cell-based aptamer selection methods to human primary activated HSCs, with negative selection against hepatocytes, an aptamer was developed that selectivity binds and internalises to activated human HSCs. Targeting of the aptamer to activated HSCs is ideal for targeting the cells actively involved in fibrotic disease without affecting the remaining hepatic cell

population. Further screening with alternative cell types showed the aptamer does not interact with T lymphocytes, renal tubule epithelial cells, prostate, breast, or lung epithelial cells, or other hepatic cell populations, including hepatocytes and Kupffer cells. Multiple cleavable and non-cleavable Optimer-siRNA linker types have been tested for functionality, with the greatest siRNA silencing effect seen with a cathepsin-cleavable linker. siRNA conjugation to the aptamer delivery vehicle did not interfere with aptamer binding or selectivity. Four different siRNA molecules have been conjugated to the aptamer delivery vehicle, including those targeting ColA1 and PDGFR as critical molecular mediators of fibrosis. Each of the tested aptamer-siRNA conjugates resulted in significant silencing of the respective genes in HSCs by flow cytometry and qPCR ($p < 0.0001$), with no observable off-target gene silencing in hepatocyte cultures, indicating that the developed aptamer is selective and can deliver diverse siRNA payloads with sufficient endosomal escape to enable effective gene silencing.

Taken together, these data demonstrate for the first time the development of a delivery vehicle selective for activated HSCs, with the potential to deliver diverse therapeutic cargo to this cell type. Advancing this delivery vehicle into the clinic with a relevant siRNA conjugate opens the potential for new treatment approaches in liver fibrosis.

1148 Multi-Targeted Organ Specific MicroRNA Intervention for Cancer (MOSAIC)

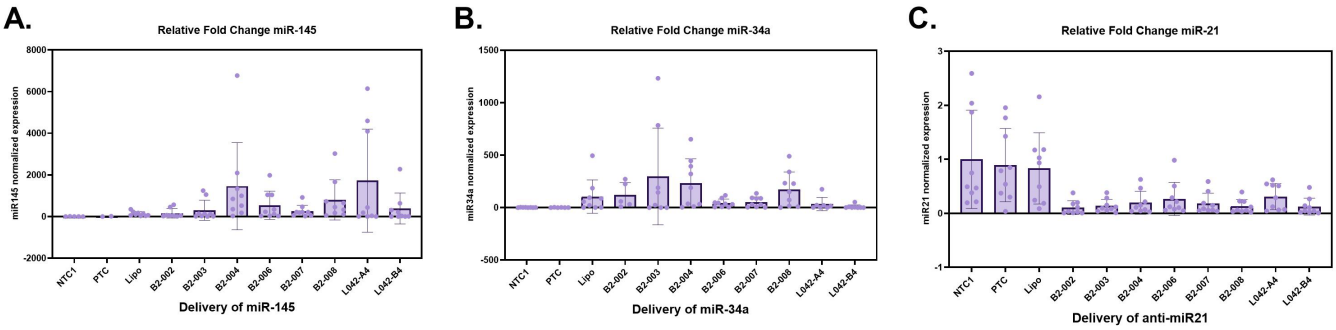
Ashlee Colbert[1], Kenneth Sims[2], Molly Kaufman[3], Allison Secard[3], Emma Schmitz[2]
[1]Battelle Healthcare Products, Blacklick, OH, [2]Battelle Memorial Institute, Columbus, OH, [3]Battelle, Columbus, OH

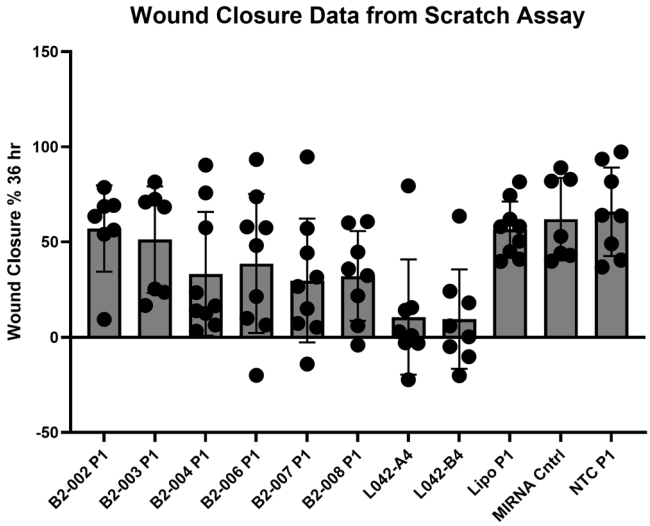
Introduction: Lung cancer is one of the most common and deadly forms of cancer worldwide. Traditional therapies for lung cancer include surgery, radiation therapy, and chemotherapy. However, these methods often come with severe side effects and limited efficacy, particularly in advanced stages of the disease. MicroRNAs (miRNAs) are emerging as a novel approach in lung cancer therapy due to their ability to regulate gene expression. These small, non-coding RNA molecules can inhibit the translation of specific messenger RNAs (mRNAs), thereby controlling the production of proteins that are involved in cell growth, differentiation, and death. In the context of lung cancer, specific miRNAs have been found to be dysregulated, leading to uncontrolled cell proliferation and tumor growth. By introducing or inhibiting these specific miRNAs, researchers can potentially alter the behavior of cancer cells. For instance, miRNAs that act as tumor suppressors can be introduced to inhibit tumor growth, while those that promote cancer can be inhibited. The challenge lies in the delivery of these miRNAs to the target cells. Recent advancements in nanoparticle technology have shown promise in addressing this issue, allowing for targeted delivery of miRNAs to lung cancer cells, thereby enhancing the efficacy of the therapy and minimizing side effects. Nanoparticles have been shown to help shield molecules and offer the ability of targeted delivery with minimal toxicity. In this work we identified two lung cancer tumor suppressors miRNA-34a and miRNA-145 and one oncogenic target, miRNA 21 from literature. A combination of the two mimics was co-delivered with the anti-miRNA oligo (AMO) using polymeric nanoparticles (PNPs). Delivery of miRNAs using these PNPs has demonstrated the ability to increase and decrease the targeted miRNAs and markedly reduce growth in A549 lung cancer cells.

Methods: Six PNPs were designed based on results from previous *in vivo* work and literature to increase lung cell targeting. Polymers were synthesized using reversible addition fragmentation chain transfer (RAFT) polymerization. A549 lung cancer cells were cultured and plated on 48 well plates to analyze the efficiency of PNP delivery. PNPs were loaded with a miRNA cocktail of miRNA-34a, miRNA-145 and AMO-21 at a final concentration of 0.13 µmol/L. Cells were dosed with each loaded PNP in triplicate 24 hours after plating at a PNP concentration of 0.05 mg/mL. The cells were processed and analyzed 48hrs post dose via imaging, flow cytometry and RT-qPCR.

Results and Conclusions: Relative fold change from RT-qPCR data showed an upregulated expression for miRNA 145 and 34a (Fig1A,B), compared to the negative control and a downregulated expression in miRNA 21(Fig1C). These results are consistent with the hypothesis that PNPs successfully delivered the cocktail of miRNAs to lung cancer cells *in vitro*. Moreover, analysis by flow cytometry indicated an increase in apoptotic cells upon delivery with PNPs compared to controls. The wound healing assay (Fig2) also showed decreased cell migration in cells treated with loaded PNPs. The selected polymers prove to be promising vehicles for co-delivery of miRNA mimics

and inhibitors. This data supports a potential for a novel miRNA combinatorial therapeutic for not only lung cancer but any disease with dysfunctional miRNA targets.





1149 Aptamer-Based Discovery of Annexin A2 as a Novel Plasma Biomarker for Early Detection of Hepatocellular Carcinoma

Hongyu Wang[1]*, Usha Menon[2], Ahmed Abdel Aal,[3], Ananya Surabhi[4], Anil Pillai[5]
[1]UTHealth Houston, Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]The University of Texas Health Science Center at Houston, Houston, TX, [4]University of Texas MD Anderson Cancer Center, Houston, TX, [5]The University of Texas Southwestern Medical Center, Dallas, TX
**Corresponding Author*

Introduction: Hepatocellular carcinoma (HCC) is a major global health challenge, with its incidence in the United States having tripled over recent decades. Early detection through effective surveillance and the use of reliable diagnostic biomarkers is critical for improving patient outcomes. Alpha-fetoprotein (AFP), the most commonly utilized serum biomarker, has limited specificity and reliability, particularly in early-stage HCC when tumor sizes are less than 3 cm. Alternative biomarkers, such as Glypican-3 (GPC3), AFP-L3, and Des-γ-carboxyprothrombin (DCP), have been explored but have shown mixed results. Aptamer-based protein biomarker discovery has emerged as an attractive solution due to its rapid selection, target-specific, and versatile modification approaches. Aptamer-based protein biomarker discovery has become a promising approach due to its rapid selection process, target

specificity, and versatile modification capabilities. Notably, modified aptamers achieve enhanced binding specificity and affinity, ranging from nanomolar to picomolar levels, by conjugating drug-like ligands to the aptamer backbone.

Methods: We developed a bead-based modified aptamer (XA) library to identify novel proteomic biomarkers and their corresponding affinity reagents. Pooled plasma samples from HCC patients (n=10) and healthy controls (n=10) were immunodepleted of abundant proteins, labeled with distinct fluorescent dyes, and incubated with the bead-based XA library. Proteins bound to XA beads were sorted via flow cytometry, followed by next-generation sequencing (NGS) to identify high-frequency aptamer sequences. Top XAs were synthesized and incubated with plasma samples to pull down target proteins for mass spectrometry (MS) analysis, with subsequent validation by ELISA and western blot. Functional analysis was conducted using DAVID Bioinformatics Resources and the Human Protein Atlas.

Results: Annexin A2 (ANXA2) was identified as the top target protein in the HCC group, showing significantly elevated levels compared to healthy controls. Validation using ELISA and western blot assays confirmed increased Annexin A2 levels in an independent cohort (HCC: n=39, controls: n=20). Functional analysis revealed Annexin A2 overexpression in HCC and its association with tumor aggressiveness.

Conclusion: Our aptamer-based platform enabled the rapid and specific identification of annexin A2 as a novel plasma biomarker for HCC. Elevated ANXA2 levels, correlated with tumor aggressiveness, may complement AFP, particularly in AFP-negative cases. A diagnostic model integrating ANXA2 and AFP could improve early detection and disease stratification. Future studies incorporating machine learning or statistical modeling may further enhance diagnostic accuracy and clinical utility.

1150 Selective ASO-based JAK2 Inhibitor for the Treatment of Polycythemia Vera

Bartlomiej Przychodzen[1], Sandra Smieszek[2], Christina Tyner[3], Caroline Johnson[3], Christos Polymeropoulos[1], Gunther Birznieks[1], Mihael Polymeropoulos[1]
[1]Vanda Pharmaceuticals Inc, Washington, DC, [2]Sandra Paulina Smieszek, Bethesda, MD, [3]Vanda Pharmaceuticals Inc., Washington, DC

Introduction: Myeloproliferative disorders (MPD) are clonal hematopoietic stem cell malignancies with cytokine independency or hypersensitivity. Due to dysregulation of the JAK-STAT signaling pathway, MPDs display excessive proliferation of megakaryocytic, erythroid, and granulocytic progenitors, causing patients to develop splenomegaly, thrombosis, and bleeding as an overproduction of blood cells occur. Polycythemia vera (PV) is a chronic MPN characterized by aberrant hematopoiesis of myeloid lineage with exuberant red cell production and increased release of pro-inflammatory cytokines. The increased kinase activity of JAK2 is present in several hematologic malignancies, and the somatic *JAK2* V617F mutation can be found in at least 98% of PV patients. Inhibiting JAK2 acts to suppress hematopoiesis, consequently reducing red blood cell, neutrophil, platelet, and lymphocyte production. We hypothesize that preventing *JAK2* transcription by antisense oligonucleotide (ASO)-mediated exon masking of the *JAK2* intron-exon junction will selectively reduce *JAK2* mRNA and protein by providing nonsense mediated decay (NMD) in the reading frame. This approach aims to mitigate the clinical manifestations of hematologic malignancies, such as PV, by curtailing downstream signaling and $JAK2^{V617F}$-driven autonomous cell proliferation.

Methods: We designed a series of 19mer ASOs targeting *JAK2* exon-intron junctions (providing NMD in the reading frame, steric, non-RNAse H1) and tested these at a range of concentrations. ASOs were designed with a phosphorothioate 2'-O-methoxyethyl (MOE) backbone and were prioritized based on *in silico* binding affinity and limited off-target binding. A human HEL cell line harboring the V617F *JAK2* mutation underwent ASO treatment (1μM) and 72-hour incubation, followed by qPCR and Western blot analyses. Peripheral blood mononuclear cells (PBMCs) obtained from PV patients carrying the V617F *JAK2* mutation were plated in methylcellulose, containing erythropoietin, in the presence or absence of ASO (1 μM, 48-hour incubation).

Results: Following ASO treatment of HEL cells, *JAK2* qPCR results show a ~50% reduction of the target *JAK2* transcript, with a dose-response reduction in mRNA observed. Western blot results reveal a significant JAK2 protein

decrease (~70%) in ASO-treated HEL cells compared to untreated samples. STAT5 phosphorylation status further confirmed this effect, and we report a 35% pSTAT5 reduction. The ASO was shown to be a selective inhibitor of JAK2 with no significant JAK1, JAK3, or TYK2 inhibition. Additional *in silico* analyses demonstrated no off-target effects of the ASO. Evaluation of endogenous erythroid colony (EEC) formation following ASO treatment to PV PBMCs revealed a significant reduction of erythroid colonies. Other non-erythroid colonies were produced in this treatment condition.

Conclusions: Our preclinical data supports this ASO as a highly selective JAK2 agent, affecting direct levels of JAK2 as well as downstream STAT signaling. ASOs have the potential to target *JAK2* mutations with high specificity, effectively decreasing JAK2 protein levels without off-target effects on other kinases. Currently, there is no available therapeutic that selectively inhibits JAK2. We propose that the application of our ASO to selectively reduce JAK2 protein may alleviate the disease burden for PV patients with a decrease in unwanted side effects, ultimately improving both the quality and longevity of their lives.

1151 Targeting Local Inflammation in Human Coronary Arteries *Ex Vivo*

Sebastian Arbelaez[1], Isabella Hetherington[2], Hana Totary-Jain[3]*
[1]*University of South Florida, Land O Lakes, FL,* [2]*University of South Florida, Bradenton, FL,* [3]*University of South Florida, Tampa, FL*
**Corresponding Author*

Atherosclerosis, the leading cause of heart disease worldwide, is driven by chronic inflammation triggered by endothelial damage, which fosters plaque growth. The Canakinumab Anti-inflammatory Thrombosis Outcome Study (CANTOS) demonstrated that systemic delivery of anti-IL1β monoclonal antibodies reduced adverse cardiac event risks by 15%. However, this approach increased susceptibility to infections and sepsis, highlighting the need for targeted therapies that suppress inflammation exclusively at plaque sites.

Our study aims to identify key inflammatory markers in human atherosclerotic coronary arteries and develop self-assembling peptide-based plaque-targeting nanoparticles for delivering IL1B siRNA therapy. Coronary arteries from male (65.6%, n=21) and female (34.4%, n=11) donor hearts provided by the LifeLink organization were screened for TNF and IL1B by RT-qPCR. Additional arteries were balloon-injured and perfused with pro-inflammatory cytokines for 4 hours, followed by administration of the plaque-targeting nanoparticle, (previously developed by the Totary-Jain lab DOI: 10.1016/j.ymthe.2021.01.032), containing IL1B siRNA for another 4 hours.

Patient histories revealed that 53.1% of cases (n=17) were cardiovascular (CV)- or stroke-related deaths, with 47% of these occurring in individuals aged 40–59 and another 47% in those 60 and older. In male patients with CV-related deaths (n=4), TNF and IL1B expression were significantly elevated compared to controls ($P<0.001$ and $P<0.01$, in figures 1 and 2, respectively). In all patients (male and female) with CV deaths, TNF was significantly elevated ($P<0.01$), while IL1B was not. Statistical significance was determined by one-way ANOVA, no significant elevations in inflammatory markers were observed in other causes of death (e.g., stroke, blunt injury).

Notably, arteries perfused with IL1B siRNA nanoparticles exhibited a 70-fold decrease in IL1B expression compared to the scramble control siRNA. Our findings build on the success of the CANTOS trial, and demonstrates the potential of this plaque-targeting siRNA nano therapy to combat atherosclerosis and potentially mitigate the risks of systemic IL1B inhibition.

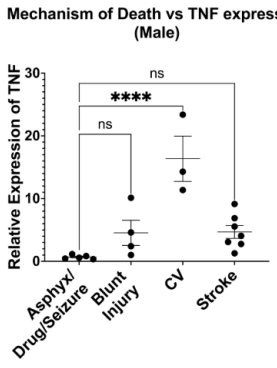


Figure 1. Mechanism of Death vs TNF Expression in Males

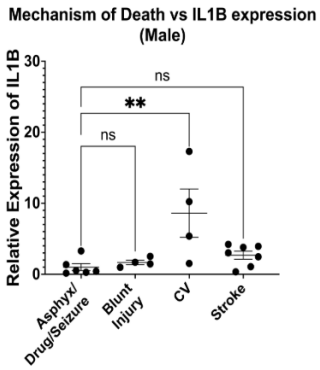

Figure 2. Mechanism of Death vs IL1B Expression in Males

1152 COATSOME® SS Series: Highly Versatile Ionizable Lipid as Vital Component of Lipid Nanoparticle for Gene Vaccine Application

Yuhei Onizuka[1], Shinya Tamagwa[2], Yuta Nakai[2], Hiroki Tanaka[3], Hidetaka Akita[4]
[1]NOF Corporation, Kawasaki, Kanagawa, Japan, [2]NOF Corporation, Kasawaki, Japan, [3]Tohoku University, JAPAN, [4]Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan, Japan

BACKGROUND: Nucleic acid vaccines, DNA and messenger RNA (mRNA), have emerged as promising modalities for infectious disease and for cancer immunotherapy due, in part, to shortened producting cycles and high potency. Lipid nanoparticles (LNP) composed of ionizable lipids are important components of such vaccines as they can convey and present the nucleic acid effectively to the immune system. However, toxicity of ionizable lipids and the challenges of cold chain logistics of LNP have limited their clinical use. Further development of LNP requires 1) reduced systemic toxicity, 2) improved endosomal escape, 3) potent and cytotoxic T-cell specific adjuvating function, 4) reduced adverse reactions, 5) improved storage stability of LNP.

RESULTS: We have previously demonstrated that LNP composed of our biodegradable ionizable lipids (COATSOME® SS series), can deliver plasmid DNA or mRNA in mice to the liver or the solid tumor via intravenous injection and achieve high levels of expression with less toxicity. We also evaluated the safety of the lipids in mice where total lipid doses of up to 175 mg/kg were well tolerated. Here, we describe their potential applications for mRNA-based vaccines. We finely tuned the LNP formulation for infectious disease. First, subcutaneous administration of hemagglutinin (HA)-encoding mRNA encapsulating LNP composed of ssPalm O-Phe (COATSOME® SS-OP) (HA-LNP$_{SS\text{-}OP}$) and neuraminidase (NA)-encoding mRNA encapsulating LNP composed of SS-OP (NA-LNP$_{SS\text{-}OP}$) induced equal amount of anti-HA antibody production compared with the globally-marketed LNP vaccine. This result implies high vaccination effects for infectious disease. On the other hand, subcutaneous administration of HA-LNP$_{SS\text{-}OP}$ induced no significant differences in the levels of inflammatory cytokines in the plasma compared with PBS. This result suggest that HA-LNP$_{SS\text{-}OP}$ attenuates severe inflammatory responses and adverse reactions. Furthermore, the addition of ssPalm E-P4C2 (COATSOME® SS-EC), another type of our ionizable lipids, significantly improved cytotoxic T-cell (CTL) activity as a cancer vaccine. Next, we demonstrated that LNP containing SS-OP and SS-EC clearly suppressed the tumor growth in a mouse model of disseminated malignant diseases. Thus, SS-EC would be used as a promising material for cancer vaccines.

CONCLUSION: We here demonstrate that LNP containing SS-OP stimulate cellular immune responses, in particular, remarkably high antigen-specific antibody responses and low adverse reactions. Moreover, the addition of SS-EC improved CTL activity and suppressed the tumor growth. Finally, we achieved the development of freezing LNP which can improve storage stability.

1153 Translational Potency of Double Stranded and Single Stranded mRNA In Vitro

Kristopher Lukas[1], Kevin Rice[2]
[1]University of Iowa, Iowa City, IA, [2]University of Iowa College of Pharmacy, Iowa City, IA

We have previously reported a novel form of double-stranded (ds) mRNA, possessing one million-fold greater metabolic stability compared to single-stranded (ss) mRNA (1). Importantly, ds mRNA was found to be translationally equipotent to ss mRNA in mouse liver when dosed hydrodynamically (1). However, other reports strongly suggest ds mRNA is lower in potency compared to ss mRNA (2,3). To reconcile these differences, we developed an in vitro transfection assay to compare the potency of ds and ss mRNA delivered by Lipofectamine LTX, Lipofectamine MessengerMAX, TransIT-mRNA, jetMessenger, and lipid nanoparticles (LNPs). Transfection of HEK 293T and HepG2 cells with ss and ds mRNA encoding luciferase established that ss mRNA was consistently 1000-100-fold more potent than ds mRNA regardless of transfection agent. The reason for this large discrepancy in transfection potency in vitro versus in vivo was investigated further to rule-out ds mRNA toxicity and ds mRNA self-knockdown by a siRNA mechanism. Since most in vitro transfections rely upon rapidly dividing cells, we investigated the cell seeding density and percent confluency which appears to play an important role in ss versus ds mRNA potency. When cells were seeded and allowed to achieve confluency, ss mRNA transfection potency decreased 1000-100-fold whereas ds mRNA was not affected. The results demonstrate that ds and ss mRNA LNPs are equipotent in non-dividing quiescent cells, which most closely reflects the in vivo environment. The finding that only ss mRNA potency is highly dependent on rapid cell division suggests two different classes of ribosomes may be involved in ss versus ds mRNA translation.

1154 Mannose-functionalized PEG-free LNPs targeting antigen-presenting cells for effective RNA delivery

Gui Zhao[1], Chuan Yang[2], Yi Yan Yang[2]*
*[1]A*STAR - Agency for Science, Technology and Research, Singapore, Singapore, [2]A*STAR - Agency for Science, Technology and Research Singapore, Singapore, Singapore*
**Corresponding Author*

Lipid nanoparticles (LNPs) have emerged as a promising platform for nucleic acid delivery, particularly for messenger RNA (mRNA). LNPs are composed of ionizable lipids, helper lipids, cholesterol, and polyethylene glycol (PEG)-lipids in specific molar ratios. While PEG-lipids improve LNP stability and reduce immunogenicity, they may also provoke immune responses or hypersensitivity due to the presence of anti-PEG antibodies, highlighting the need for careful evaluation in clinical applications. Antigen-presenting cells (APCs) play a pivotal role in vaccines by processing and presenting antigens to T cells, thereby orchestrating adaptive immune responses. LNPs targeting APCs can significantly enhance vaccine efficacy by efficiently delivering mRNA to these cells. The mannose receptor on APCs is crucial for recognizing and internalizing antigens and thus serves as a target for LNP-based delivery systems. In this study, we introduce mannose-functionalized biodegradable polycarbonate-lipids, where the lipid component is either DTD (two-tailed alkyl group) (DTD-PTMCPMan) or cholesterol (Chol-PMan), as alternatives to PEG-lipids, and offer enhanced targeting capabilities. We synthesized a series of mannose-functionalized polycarbonate-lipids, and after in vitro screening, identified promising candidates, DTD-PTMC6PMan9 and Chol-PMan12. LNPs formulated with DTD-PTMC6PMan9 exhibited hydrodynamic sizes of approximately 170 nm with near-neutral zeta potentials, comparable to those containing ALC-0159 (a commercial PEG-lipid used in Comirnaty). For Chol-PMan12 LNPs, a lipid molar ratio adjustment to 1.0% (from 1.6% in ALC-0159 LNPs and DTD-PTMC6PMan9 LNPs) yielded particles with an average size of about 250 nm and neutral zeta potential. To evaluate their delivery performance, firefly luciferase (Fluc) mRNA was encapsulated in the LNPs and transfected into HEK293T and DC2.4 cells. After 48 hours, DTD-PTMC6PMan9 LNPs demonstrated transfection efficiencies that were 3-fold higher in HEK293T cells and 23-fold higher in DC2.4 cells compared to ALC-0159 LNPs. Similarly, Chol-PMan12 LNPs exhibited 2-fold and 9-fold higher transfection efficiencies in the respective cell lines. Notably, both DTD-PTMC6PMan9 and Chol-PMan12 LNPs showed negligible cytotoxicity, maintaining

cell viability above 80% relative to PBS-treated controls. In summary, we successfully replaced PEG-lipids with mannose-functionalized polycarbonate-lipids in LNP formulations. DTD-PTMC6PMan9 and Chol-PMan12 LNPs exhibited comparable physicochemical properties, significantly enhanced mRNA delivery efficiency, and excellent biocompatibility compared to ALC-0159 LNPs. These mannose-functionalized LNPs represent a promising approach for APC-targeted mRNA delivery in vaccine applications, addressing PEG-associated side effects while improving delivery specificity and efficiency.

1155 Oligo(EG)-functionalized biodegradable polycarbonate-lipids for efficient mRNA delivery with alleviated anti-PEG immunity

Yue Zhang[1], Chuan Yang[2], Yi Yan Yang[2]*
*[1]A*STAR - Agency for Science, Technology and Research, Singapore, Singapore, [2]A*STAR - Agency for Science, Technology and Research Singapore, Singapore, Singapore*
**Corresponding Author*

Lipid nanoparticles (LNPs) are highly versatile non-viral delivery systems that can be utilized for encapsulation of messenger RNA (mRNA), with remarkable applications in both pre- and clinical research. Conventional LNP formulations comprise four components: ionizable lipids, helper lipids, cholesterol, and polyethylene glycol (PEG)-lipids. PEG-lipids are amphiphilic lipids, and largely determine the stability of LNPs and prevent aggregation. However, PEG-specific antibodies can be induced or boosted by repeated administration of PEGylated LNPs, leading to hypersensitivity reactions and diminished mRNA delivery efficacy. To mitigate this issue, we have synthesized a series of biodegradable and amphiphilic polycarbonates consisting of polycarbonate functionalized with oligo(ethylene glycol) (EG) and hydrophobic lipids to replace PEG-lipids in LNP formulations. The compositions of hydrophilic polycarbonates were screened, and DTD-P(MTC-MPEG3)$_{13}$, DTD-P(MTC-MPEG3)$_{23}$, DTD-P(MTC-MPEG9)$_4$, and DTD-P(MTC-MPEG9)$_7$, which had similar total EG units and molecular weights to the commercial PEG-lipid ALC-0159, were selected for LNP formulation at various molar ratios. Notably, DTD-P(MTC-MPEG9)$_4$ and DTD-P(MTC-MPEG9)$_7$ LNPs exhibited hydrodynamic diameters between 100 and 150 nm, neutral surface charge, and up to 8-fold improvement in transfection efficiency compared to ALC-0159 LNPs. When reduced the EG units in the side chains from 9 to 3, the hydrodynamic diameters of DTD-P(MTC-MPEG3)$_{13}$ and DTD-P(MTC-MPEG3)$_{23}$ LNPs exceeded 500 nm, accompanied by a sharp decline in encapsulation and transfection efficiency, despite their total EG units being comparable to those of DTD-P(MTC-MPEG9)$_4$ and DTD-P(MTC-MPEG9)$_7$. Further investigation demonstrated that DTD-P(MTC-MPEG9)$_4$ and DTD-P(MTC-MPEG9)$_7$, which exhibited superior performance, could be applied in combination with different ionizable lipids. These include the commercial lipids ALC-0315 and SM-102, as well as the in-house lipid APDEA, to formulate LNPs for mRNA delivery. In vivo studies revealed that DTD-P(MTC-MPEG9)$_7$ LNPs elicited lower levels of anti-PEG antibodies compared to ALC-0159 LNPs. Moreover, LNPs formulated with DTD-P(MTC-MPEG9)$_4$ which had a shorter polycarbonate chain showed even greater reduction in anti-PEG responses. In summary, the polycarbonate lipids functionalized with short EG units display exceptional potential, offering high transfection efficiency coupled with an improved safety profile. These attributes establish them as promising alternatives to the commercial PEG-lipids, with significant potential for efficient mRNA delivery across a range of therapeutic applications and clinical translation.

1156 Synthetic DNA for IVT mRNA production and delivery with Hermes™ lipopolyplex nanoparticles

Patrick Thiaville[1], Emily Young[2], Ashish Dhir[3], Gözde Tezcan[2], Aiswarya Thulasi[2], Amy Walker[4]
[1]4basebio, Saint Johns, FL, [2]4basebio, Cambridge, Cambridgeshire, United Kingdom, [3]4basebio, cambridge, United Kingdom, [4]CAMBRIDGE, United Kingdom

The large-scale manufacture of plasmid DNA using traditional fermentation methods has become a major bottleneck in the RNA therapeutics and vaccine industry with a worldwide lack or capacity and long lead times for GMP grade DNA. 4Basebio has developed a novel DNA IVT template, termed opDNA™, a linear molecule, covalently closed at the 5' end with a single-stranded hairpin, but open at the 3' end, allowing for use directly in an IVT reaction without prior linearisation or de-ending. Synthesis of opDNA™ is fully enzymatic, facilitating large-scale

production of linear DNA devoid of bacterial backbone with improved yields over traditional plasmid fermentation processes. The process is optimised to handle complex sequences, such as ITRs or long, continuous polyA tails >120 bp.

Here, IVT synthesis of mRNA using opDNA™ was compared to linearised plasmid across several constructs ranging from 1.5-12kb. mRNA delivery was assessed with Hermes™ nanoparticles, which exploit a cationic scaffold component, combined with traditional lipids, to drive payload condensation and provides the option to include a targeting moiety. The system was validated in a cancer vaccine setting, using mRNA encoding 20 neoantigens in the MC38 tumour model.

Maintaining polyA tail length in conventional plasmid DNA templates poses a major challenge due to instability in bacterial hosts. To confirm polyA tail length was maintained in opDNA™ during enzymatic synthesis, capillary gel electrophoresis and LC-MS were performed. In all constructs, a single polyA tail population of the expected length was identified with both methods. Next, IVT synthesis of mRNA was compared for opDNA™ and plasmid DNA templates. opDNA™ was found to achieve significantly higher yields than linearised plasmid, with plasmid requiring greater mass to achieve the same yield. At equimolar ratios, the kinetics of the IVT reaction were faster with an opDNA™ template compared to plasmid DNA. Capping efficiency, dsRNA impurities and RNA integrity were comparable between opDNA™ and plasmid for all constructs. Finally, when encapsulated in Hermes™ nanoparticles, mRNA encoding firefly luciferase from an opDNA™ template achieved comparable bioluminescence to linearised plasmid in HEK293T cells and in mice following intramuscular delivery.

Next, mRNA synthesized from opDNA™ was tested in a cancer vaccine setting. The rapid manufacturing timescale of synthetic DNA is particularly advantageous in this setting, considering that needle to needle time is paramount to clinical outcome. In a prophylactic protocol, mice were vaccinated intramuscularly at days 0, 14 and 28 with Hermes™ nanoparticles encapsulating mRNA encoding 20 neoantigens, and an MC38 tumour challenge was induced on day 52. The vaccine correlated with a significant reduction in tumour growth with 6/7 animals protected from the challenge and, a significant increase in CD8+IFNγ+ and CD8+TNFα+ T cells was observed. Similarly, in an early tumour treatment model where treatment began 2 days following tumour inoculation, mice treated with the Hermes-mRNA vaccine in combination with the αPD-L1 immune checkpoint inhibitor demonstrated a significant reduction in tumour growth compared to untreated animals or either Hermes-mRNA or αPD-L1 alone.

Therefore, IVT synthesis of mRNA from an opDNA™ template is both efficient and efficacious, lending itself to large-scale gene therapy or vaccine applications.

1157 Optimized prime: a transformative LNP composition for scalable RNA vaccines

Natalie Orr[1], Mikayla Walsh[1], Cayden Yu[1], Victoria Hartman[2], Ariel Zhang[1], Pierrot Harvie[3], Leanna Yee[1], Suraj Abraham[3], Nikita Jain[3], Anitha Thomas[1], Deo Tiwari[1], Samuel Clarke[3]

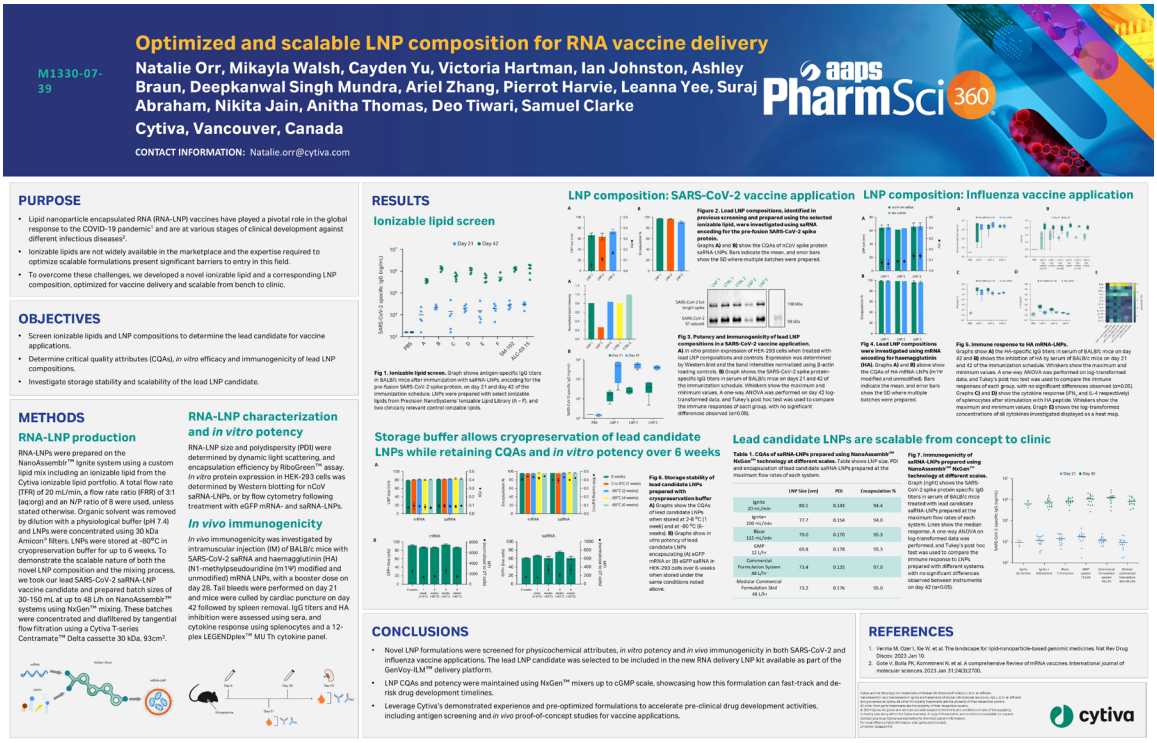
Purpose: Lipid nanoparticle-encapsulated RNA (RNA-LNP) vaccines have played a pivotal role in the global response to the COVID-19 pandemic (1). With proven safety and efficacy, RNA-LNPs are now at various stages of development against a variety of other infectious diseases (2). However, limited access to potent ionizable lipids, a key component in LNPs, and the expertise required to formulate and scale LNPs present real barriers to entry in this field. To overcome these challenges, we developed and optimized a novel ionizable lipid and a corresponding LNP composition for the delivery of RNA in vaccine applications. Using a scalable mixing platform, we formulated vaccine-candidate LNPs with both mRNA and self-amplifying RNA and investigated their physicochemical attributes and *in vivo* immunogenicity.

Methods: RNA-LNPs were prepared on the NanoAssemblr™ Ignite™ system, using a custom lipid mix including an ionizable lipid from our lipid portfolio, at a total flow rate of 20 mL/min. LNPs were diluted with a physiological buffer (pH 7.4), concentrated using 30 kDa Amicon® filters, and stored at -80°C in a cryopreservation buffer. RNA-LNP size and polydispersity were determined by dynamic light scattering and encapsulation efficiency by RiboGreen™ RNA assay. We determined *in vitro* protein expression in HEK293 cells by flow cytometry and we

investigated *in vivo* immunogenicity by intramuscular injection of BALB/c mice with RNA-LNPs, with a booster dose on day 28. Tail bleeds were performed on day 21 and mice were culled by cardiac puncture on day 42 followed by spleen harvesting. To demonstrate the scalable nature of both the novel LNP composition and the mixing process, we took our lead SARS-CoV-2 self- amplifying RNA-LNP vaccine candidate and prepared batch sizes of 100 mL at 48 L/h using the NanoAssemblr™ commercial formulation system.

Results: The novel LNP composition, combined with a scalable mixing process, resulted in high-quality RNA-LNPs with reproducible particle sizes of 60 to 90 nm, polydispersity indices < 0.2, and RNA encapsulation of > 80%. When stored in cryopreservation buffer at -80°C for 6 weeks (wk), we observed no detrimental effects on physicochemical attributes and *in vitro* potency. We completed *in vivo* immunogenicity studies using SARS-CoV-2 self-amplifying RNA and haemagglutinin mRNA-LNPs. A strong immune response was mounted against both antigens, where we observed antigen-specific IgG titers of 10^6 ng/mL, and IFNγ responses > 100-fold higher than naïve mice. Finally, we found that RNA-LNPs prepared on a commercially relevant scale were comparable to those prepared at the benchtop scale with respect to physicochemical attributes and immunogenicity.



1158 Using *in vitro* screening and *in vivo* biodistribution studies to determine endogenous tissue preference of LNP formulations to predict therapeutic potential

Anna Potenski[1], Gabriel Gamber[1], Nicole DeCampo[1], Maya Kitaoka[1], Daniel Basta[2], Elizabeth Cullins[1], Diana Manning[2], Lakshmi Raj[1], Hon-Ren Huang[2]

Lipid nanoparticles (LNPs) have emerged as a promising non-viral delivery modality for cell and gene therapies due to their adaptability and chemical customizability. While there have been commercially successful uses of LNPs for vaccines and liver-targeted siRNA drugs, targeted delivery to extrahepatic tissues remains a challenge to expanding the development of this modality, and there is significant interest in understanding the inherent targeting capabilities of different LNP formulations. We screened different LNP formulations *in vitro* on several different cell lines and primary cell types and through iterative rounds of optimization we were able to identify multiple formulations sharing a common cationic lipid that are able to transfect primary T cells *in vitro*. We then performed an *in vivo* pilot

biodistribution study using four different LNP formulations with this cationic lipid and demonstrated that by changing one element in the LNP, in this case the PEG lipid, we can achieve vastly different biodistribution patterns illustrated through IVIS imaging. qRT-PCR analysis revealed that one formulation specifically enabled delivery of luciferase mRNA to the spleen and lymph nodes efficiently while keeping the expression in the liver about 20,000 fold lower, indicating the potential for extrahepatic delivery. Continued profiling of LNP formulations in this manner could lead to discovery of endogenous tissue selection without the necessity of an additional targeting ligand component and could aid in the selection of the most appropriate formulations for specific therapeutic strategies based on the organ or cell type of interest.

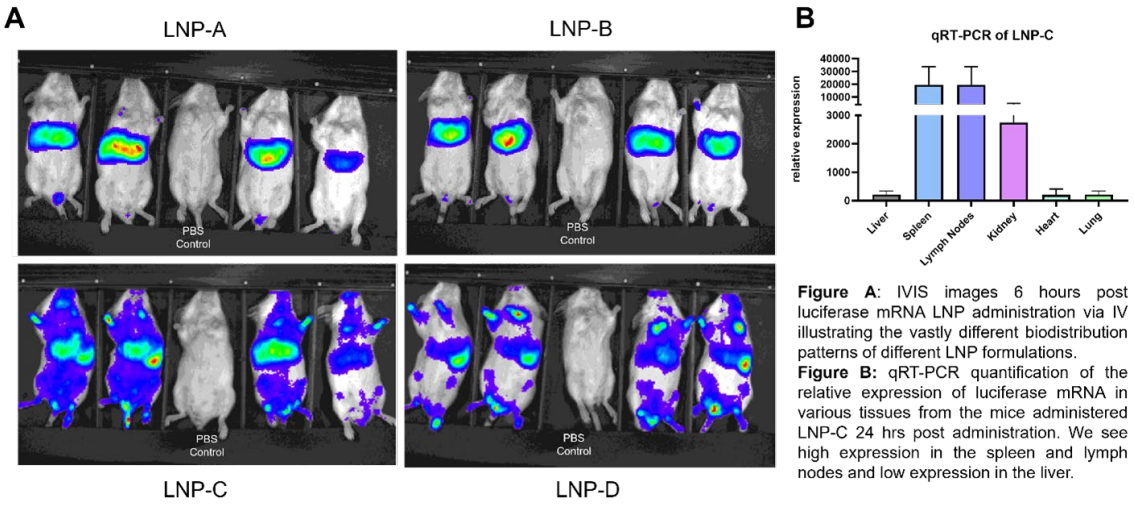

Figure A: IVIS images 6 hours post luciferase mRNA LNP administration via IV illustrating the vastly different biodistribution patterns of different LNP formulations.
Figure B: qRT-PCR quantification of the relative expression of luciferase mRNA in various tissues from the mice administered LNP-C 24 hrs post administration. We see high expression in the spleen and lymph nodes and low expression in the liver.

1159 High-Throughput Screening of Lipid Nanoparticles for Efficient CRISPR RNA Delivery *In Vitro* and *In Vivo*

Balqees Khader[1], Wei Nie[2], Rongyuan Xie[2], Pin Lyu[2], Kyung Whan Yoo[3], Anthony Atala[3], Baisong Lu[4]
[1]Wake Forest University School of Medicine, Winston Salem, NC, [2]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, [3]Wake Forest University School of Medicine, [4]Wake Forest Medical School, Winston Salem, North Carolina

Introduction: Efficient and precise delivery of CRISPR/Cas9 components remains one of the critical challenges toward the advancement of gene-editing therapies. Here, we have developed a high-throughput Barcode-Integration Nanoparticle Screen (BINS) method to evaluate a library of 96 lipid nanoparticles (LNPs) for their delivery efficiency across *in vitro* and *in vivo* models.

Methods: For proof of concept, we designed a library of 96 LNPs made from 24 distinct ionizable lipids, without and with one of three different SORT (Selective Organ Targeting) lipids: cationic-SORT, anionic-SORT, and brain-targeting SORT. Each LNP encapsulated CRISPR/Cas9 mRNA, sgRNA, and a unique double-stranded oligonucleotide barcode. The pooled LNPs were delivered to retinal pigment epithelial (RPE) Cells and human skeletal muscle precursor cells (SkMPCs), and mice through *in vivo* systemic intravenous injections. Integrated barcode DNA was analyzed via PCR and Next-Generation Sequencing (NGS) to quantify integrated barcode, which reflects the delivery efficiency of the barcoded LNP.

Results: We observed different barcode integration profiles in different cells and tissues. Negative control LNPs without sgRNA showed no barcode integration in all cell/organs detected. Whereas many LNPs showed low or no barcode integration in all cell/tissues analyzed, LNPs with high barcode integration frequencies were found for RPEs, SkMPCs and different organs. These LNPs will be validated for their delivery efficiency to their respective target cells.

Conclusions: This work highlights the potential of the BINS method in screening for candidate LNPS for targeted RNA delivery. The screening of multiple ionizable lipids and SORT lipids together with barcoding-based tracking offers an opportunity to optimize LNP formulations for specific organ systems. The LNPs found this way will have translational values in precision medicine.

1160 Learn-Design-Make-Generate: ML Platform for Developing Novel LNP Delivery Systems

Guy Rosin[1], Igor Nudelman[2], Lee Danan Goldfryd[2], Nir Suissa[3], Amit Benazraf[4], **Alex Lagadinos[5]**, Yogev Debbi[6]
[1]Mana.bio, Binyamina, HaZafon, Israel, [2]Mana.bio, Haifa, Haifa, Israel, [3]Mana.bio, Tel Aviv, Tel-Aviv, Israel, [4]Mana.bio, Tel Aviv-Yafo, Tel-Aviv, Israel, [5]Mana.bio, Boston, MA, [6]Mana.bio, Bat yehoshua, HaZafon, Israel

Lipid nanoparticles (LNPs) are a preferred delivery vehicle for RNA therapeutics but face challenges in extrahepatic delivery. Companies often under-utilize data and rely on empirical trial-and-error. Machine learning (ML) can analyze these datasets, predict optimal formulations, and accelerate development.

To address these challenges, Mana.bio has developed an ML platform that predicts key LNP features to optimize particle composition and formulation. The platform leverages proprietary ML algorithms to predict key LNP characteristics, including physicochemical properties, cell/tissue targeting, and toxicity. It operates in an iterative Learn-Design-Make-Generate cycle, continuously improving LNP design through data-driven insights.
In the "Learn" phase, Mana.bio collects relevant data from public literature using proprietary software tools to automate data extraction. This dataset forms the foundation for initial prediction models. During the "Design" phase, the platform defines and generates a theoretical LNP space encompassing up to 100s of millions of in-silico compositions. A two-step screening process filters out LNPs that fail predefined criteria (e.g., size below 90 nm, PDI below 0.2, and positive zeta potential), and a multi-objective optimization process, where we optimize LNP predicted performance (e.g., low transfection efficiency in target cell lines, low cytokine levels, or reduced liver toxicity). Mana.bio's Freedom-to-Operate (FTO) tool integrates data from all relevant patents to ensure the selection of novel LNP components. Top-ranked candidates are selected for empirical tests in the lab based on component diversity. In the "Make" phase, LNPs are synthesized and encapsulated. During the "Generate" phase, physicochemical parameters and in-vitro activities are tested. Experimental results are stored in Mana.bio's database to continuously retrain the models, improving performance in each iteration.

A recently developed capability enhances the "Design" phase by enabling autonomous iteration of lipid design. Inspired by evolutionary methods, the model systematically mutates lipid structures, ranks the generated mutants, and advances the most promising candidates to subsequent cycles. This innovation accelerates the discovery of high-performance LNPs tailored for specific therapeutic applications. So far, across 120 cycles and more than 4,300 LNP formulations tested, Mana.bio has collected over 45,000 experimental data points and generated over 80,000 total data points. To evaluate our models, we apply 5-fold cross-validation. As for evaluation metrics, we use MAE and RMSE for regression models and ROC AUC for classification models. Notable examples include 1) PDI (polydispersity index), which achieved a 0.79 ROC AUC with a threshold of 0.2 for "good" LNPs, 2) particle size, where a regression model achieved an MAE of 27.95 and RMSE of 43.79, 3) transfection in non-activated primary T cells, where the model achieved an MAE of 4.32 and RMSE of 6.54, and 4) ALT and AST toxicity models, which achieved 0.8 and 0.82 ROC AUC, respectively with classification thresholds tailored by mouse strain and sex. These results underscore the platform's capacity to generate accurate, data-driven predictions, accelerating the discovery of safe and effective LNPs for diverse therapeutic applications.

1161 LNP-mRNA-Based Therapeutics for Genetic Mitochondrial Hepato-Encephalopathies

Elisa Pagliari[1], Sabrina Salani[2], Letizia Bertolasi[2], Francesca Sironi[3], Linda Ottoboni[4], Stefania Corti[3], Dario Ronchi[5], Giacomo Comi[1]

[1]University of Milan, Milan, Milano, Italy, [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Milano, Italy, [3]University of Milan, Milan, Italy, [4]University of Milan, [5]University of Milan, Milan, Italy, ITALY

Mitochondrial disorders represent a heterogeneous group of genetic conditions with a broad clinical involvement caused by mutations in mitochondrial DNA or nuclear genes encoding for mitochondrial protein. Among them, MPV17 mutations cause an early onset pathology classified in the subgroup of Mitochondrial DNA Depletion Syndromes, characterized by a significant decrease of the copy number of mitochondrial DNA in the affected tissues, mainly the liver and brain. Current treatments are mainly focused on symptom management. The objective of this study is to develop an mRNA-based therapy with the aid of novel LNP targeting mitochondrial disorders, specifically MPV17-related hepato-cerebral syndrome. This project aims to mitigate liver and central nervous system dysfunction stemming from oxidative phosphorylation assembly disruptions and mitochondrial DNA depletion in in vitro and in vivo models of the disease. Characterization of primary derived MPV17-mutated cell lines confirmed the typical features of the pathology prompting the possibility of testing the delivery of mRNA in vitro, alongside optimization of mRNA strategies through plasmid generation and transfection, evaluating efficiency and viability. In vivo experiments demonstrate the potentiality of lipid-encapsulated mRNA as an effective delivery system, with promising results indicating robust mRNA uptake in both liver and brain tissues of wild-type mice. Different routes of administration and dosage were tested to enhance distribution and expression in the target organs with the aim of shifting the more promising approach to the MPV17-KO mouse model. Overall, this data will offer new insight into the efficacy of a mRNA-LNP non-viral gene therapy, specifically focusing on its application in addressing multisystemic disorders, as the one caused by MPV17 mutations, holding significant promise for advancing therapeutic strategies for mitochondrial disorders.

1162 Conformation-adaptive Lipids for mRNA-Based Gene Editor Delivery via Lipid Nanoparticles (LNPs) in Non-Human Primates: Achieving a Wide Therapeutic Window

Pengbo Guo[1], Bo Chen[2], He Wu[3], Han Qiu[4], Huize Jing[4], Jialin Tao[5], Jing Zhang[6], Zhefan Yuan[3]
[1]CybernaX Bio, Northvale, NJ, [2]CybernaX Biotechnologies, Hangzhou, Zhejiang, China, [3]CybernaX Biotechnologies, Hangzhou, China, [4]AccurEdit Therapeutics, Suzhou, China, [5]AccurEdit Therapeutics, Suzhou, Jiangsu, China, [6]Zhejiang University of Technology, Hangzhou, China

Lipid nanoparticle (LNP)-mRNA therapies have demonstrated proven track record in infectious disease vaccines and are now advancing as a transformative platform for genetic medicine. However, gene editing via intravenous delivery demands substantially higher doses than vaccines, thereby requiring a delivery system with high efficiency, low toxicity, and minimal immunogenicity. Here, we introduce a series of "conformation-adaptive" ionizable lipids designed to enhance endosomal escape through pH-triggered changes in hydrogen bonding and molecular hydration. LNPs formulated with these lipids achieved significant editing of the transthyretin (TTR) gene in the liver of non-human primates following a single intravenous dose, leading to near-complete reduction in serum TTR protein at well-tolerated levels. To optimize tissue specificity, biodegradability, and high transfection efficiency, we screened over 200 preselected ionizable lipids formulated with luciferase mRNA, identifying multiple candidates displaying notably high luminescence intensity both in vitro cell tests and in vivo mice screening. Further in vivo studies in mice and rats confirmed favorable biodistribution and toxicity profiles, with top candidates—CX-322, CX-571, CX-108, and CX-601—showing >99% liver-specific distribution and no significant impact on body weight and liver panel parameters. When co-formulated with Cas9 mRNA and highly modified sgRNA, these LNPs resulted in >65% hepatic TTR gene editing at 0.6 mg/kg in mice, exceeding commercial benchmarks by over fourfold. In cynomolgus macaques, editing efficiencies of liver TTR gene surpassed 75% at 1.5 mg/kg for the CX-108 and CX-601 formulation, with the 3 mg/kg dose being well tolerated and a no-observed-adverse-effect level (NOAEL) established at 1 mg/kg. Stability assessments indicated consistent in vitro characteristics after six months at both –80°C and 4°C. Overall, these conformation-adaptive ionizable LNPs offer a potent, safe approach for in vivo CRISPR/Cas9-based genome editing, underscoring their potential as a clinical platform with a broad therapeutic window.

1163 Evaluation of lipid nanoparticles and polymersomes for gene editing in a mouse model.

Introduction: Inherited monogenic diseases pose a significant clinical burden, many of which cause irreversible pathology in-utero or perinatally, which is a motivation for development of fetal gene editing therapy. Lipid nanoparticles (LNPs) and polymersomes are advanced nanocarriers that have gained significant attention in the fields of drug delivery and biomedical applications. LNPs are composed of lipid materials that form a spherical structure capable of encapsulating both hydrophilic and hydrophobic drugs, enabling controlled release and enhanced bioavailability. On the other hand, polymersomes are amphiphilic block copolymer-based vesicles that mimic the structure of natural lipid vesicles, offering improved stability and versatility in drug delivery as well as low immunogenicity compared to LNPs. In this study, we are evaluating a number of LNPs and polymersomes for the delivery of eGFP mRNA to hepatocytes after intravenous delivery into adult mice and mouse fetuses.

Methods: LNP were formulated using proprietary lipids, such as MC3 and KC2, as well as non-proprietary lipids, such as DOTAP. LNPs contained eGFP mRNA. Briefly, an ethanol phase (containing the LNP components) and an aqueous phase (containing that mRNA to be packaged) are combined via channels in a microfluidic device and subsequently dialysed and purified against PBS and passage through a 0.2µm filter. Polymersomes were also prepared by solvent dispersion method, followed by extrusion to obtain uniform size distribution. After eGFP mRNA encapsulation, the non-encapsulated mRNA was removed by dialysis. Following formulation, the LNP (n=4) and polymersomes were characterised and encapsulation efficiencies determined prior to use in *in vitro with mouse AML cell lines* and *in vivo* studies with both adult NSG mice and C57BL/6 mouse fetuses. six-weeks old NSG mice were injected intravenously (0.5mg/kg,) via the tail vein with the various nanoparticles. Fetal (E15-16) C57BL/6 mouse were also injected via the intravitelline vein (0.15-1.5mg/kg). After 24h, liver cells were isolated from the animals using collagenase digestion, spleen and bone marrow were analysed for the expression of GFP via flow cytometry. Percentage GFP and MFI in the various tissues were determined and compared.

Results: Four different LNP were compared (LNPA, LNPB, LNPC, LNPD), along with polymersomes. In mouse AML cells, the nanoparticles that were found to be able to transfect more than 50% of the cells (100ng/ml) were selected for further in vivo studies. In adult mice, the highest rate of transduction with GFP was with LNPA (80%, MFI 80k) and the lowest with LNPD (25%, MFI 34k). For comparison, polymersomes achieved 43% transduction, MFI 42k. The GFP transduction is quite specific to hepatocytes as there was <10% transduction in the bone marrow or spleenic CD45+ cells. The results are also similar in the mouse fetus with LNPA (60%, MFI 150k) producing the highest transduction rate in liver cells, and LNPD the lowest (20%, MFI 20k). The polymersomes also managed to transduce of the liver cells in both the adult (40%, MFI 40k) and fetal mice (40%, MFI 175k) with much more specificity to liver cells compared with LNP A (<5%).

Conclusion and future work: We identified two nanoparticles LNP A and polymersome that have the potential to conduct further studies with gene editing in utero. These nanoparticles will be packaged with base editors for future liver gene editing work.

1164 Delivery, Potency and Tolerability of Lipid Nanoparticle Formulations of mRNA in PXB-Mice

Hilda Au[1], Kyle Stephenson[1], Sean Semple[2]*
[1]*Acuitas Therapeutics, Vancouver, BC,* [2]*Acuitas Therapeutics, Inc., Vancouver, BC*

Lipid nanoparticles (LNP) enable effective delivery of RNA-based therapeutics and have been clinically validated in approved intravenous products, including ONPATTRO®. Upon entry into the systemic circulation, LNP bind circulating apolipoprotein E (apoE) and interact with low-density lipoprotein receptors to facilitate their uptake into hepatocytes. Given their efficacy, low immunogenicity relative to other delivery vectors, and versatility in encapsulating a wide range of therapeutic modalities, there has been extensive adoption of LNP technology in the development of nucleic acid-based therapeutics, with increasing application in the areas of gene editing and gene modulation. A major challenge in evaluating the efficacy and tolerability of LNP-based therapeutics is the availability of suitable preclinical models. Notable limitations of traditional mouse models include species-specific differences in physiology, drug metabolism and excretion, and limited utility for therapeutics with human-specific targets or diseases with restricted tropism. More human-relevant preclinical models have emerged, which may help bridge the translational gap. Humanized liver chimeric mice, such as PXB-mice, have livers that are repopulated with functional human hepatocytes. Their livers express key transporters and metabolic enzymes, and unlike conventional mouse models, they have human-like lipoprotein profiles. These, along with other features, better represent key aspects of human liver physiology and function. Here, we evaluated the delivery, distribution, potency and tolerability of three different LNP in PXB-mice to characterize these mice as a model for LNP-mediated delivery and activity. Mice were injected intravenously with different LNP (identified as LNP07, LNP09 and LNP13) encapsulating IgG mRNA, and their relative potency was assessed by serum IgG expression. LNP13 exhibited the greatest activity of the three LNP and an expanded dose titration was performed, with doses up to 5.0 mg/kg being tolerated with no observed clinical signs. Interestingly, immunohistochemistry staining of liver sections from LNP-treated mice revealed earlier IgG protein translation in mouse hepatocytes; however, this differential in expression relative to human hepatocytes was reduced at later time points. To further investigate this, we performed pharmacokinetic analyses and MALDI mass spectrometry imaging (MSI) to visualize and quantify the distribution of LNP-derived ionizable lipid in LNP-treated mouse livers. MSI revealed extensive LNP distribution throughout the liver across both mouse and human compartments. This was corroborated by RNA in situ hybridization, which similarly showed widespread mRNA distribution at early time points post-dose. Altogether, these data suggest a potential delay in the uptake and/or expression of mRNA-LNP in human hepatocytes. Despite this, PXB-mice (and other liver-humanized mice) represent a promising preclinical model for mRNA-LNP testing and may be particularly useful in characterizing the biology of human-specific payloads when using highly active LNP.

1165 *In Vivo* Gene Editing and Disease-Associated Biomarker Reduction for Multiple Liver Targets in Non-human Primate Using AsCas12a Nuclease Delivered by LNP

CRISPR-Cas gene editing is a transformative technology with the potential to enable durable treatments for many diseases with unmet medical need. Clinical success of this technology has been demonstrated with *ex vivo* and *in vivo* gene therapies. E*x vivo* gene therapies are costly and can have a long and burdensome patient journey and manufacturability challenges, which have hindered their widespread adoption for treating genetic diseases. In recent years, *in vivo* delivery of CRISPR-Cas using lipid nanoparticles (LNPs) has shown promising preclinical and clinical data, but most studies utilize the Cas9 nuclease. AsCas12a is a highly efficient and specific nuclease that targets a different protospacer adjacent motif sequence (TTTN) which could be advantageous for some targets. To date, *in vivo* gene editing for liver targets using AsCas12a has not been demonstrated. Here, we report the proof-of-concept results from the first *in vivo* mouse and non-human primate (NHP) studies showing high levels of target gene editing in the liver and corresponding biomarker response following intravenous administration of AsCas12a

mRNA and chemically modified guide RNAs delivered using LNPs. Using two different LNPs from a highly potent LNP platform, we demonstrate efficient target editing in the liver and corresponding reduction of target biomarker in the serum. Additionally, biodistribution properties of these novel LNPs were assessed using a GFP reporter mRNA. We observed high levels of GFP mRNA and corresponding GFP protein in the liver with minimal to no GFP mRNA and corresponding protein detected in other non-target tissues. Specifically, we detected minimal to no signal for both mRNA and corresponding protein in the ovary. Furthermore, we demonstrate the translatability of *in vivo* gene editing and biomarker knockdown across *in vitro* and *in vivo* preclinical models, including primary human hepatocytes, humanized mice, and NHPs. Our data highlights the ability to achieve high levels of *in vivo* gene editing and disease-associated biomarker knockdown using a 'plug-n-play' strategy that permits cargo components to be easily interchanged when delivered with this proprietary LNP platform. This strategy enables the rapid identification of efficacious combinations to build a preclinical pipeline and advance novel, *in vivo* genetic medicines to address serious genetic diseases.

1166 CRISPR/Cas9 Genome Editing Using Lipid Nanoparticles for Hepatocellular Carcinoma Therapy

Hepatocellular Carcinoma (HCC) is the 6th most common cancer and one of the most lethal worldwide. The number of cases keep increasing yearly, and current predictions are that HCC mortality will reach 1 million annual deaths by 2030. As of today, HCC remains resistant to most therapies, including new immunotherapy regimens, which often achieve only a few months of progression-free survival. Therefore, new therapeutic approaches are necessary, with gene editing being a promising direction. Gene editing is a method in which engineered nucleases are utilized to induce double-stranded breaks at specific loci to introduce genomic modifications. One of the most common nucleases currently used in gene editing is the CRISPR/Cas9 system. In the case of cancer, CRISPR/Cas9 can be used to knock out a critical gene and lead to cancerous cells` death. In this work, multiple genes were tested as potential targets, with all sgRNAs leading to high levels of editing. The screening process highlighted that PLK1 is the best candidate as it showed ~65% reduction in viability following the editing process. Next, various lipid nanoparticle formulations were tested to determine the best one at delivering mRNA to the tumor cells via GFP measurements. The chosen formulation was then used to co-encapsulate Cas9 mRNA with PLK1-targeting sgRNA, showing above 90% editing and above 90% reduction in viability in HCC cells, highlighting the system's potential. Next, when testing LNPs' biodistribution in an orthotopic xenograft model, the LNPs showed ~12% penetration into the tumor. Finally, we are set to start a final efficacy experiment in an animal model to test both editing of the tumor and the effects on tumor development. It is our belief that this work may open up a new avenue of treatment for HCC, and potentially one day make the leap from the bench to the bedside.

1167 Apolipoprotein Fusion Enables Spontaneous Functionalization of mRNA Lipid Nanoparticles with Antibody for Targeted Cancer Therapy

Wonbeom Park[1], Jiwoong Choi[2], Minkyeom Kim[3], Yoosoo Yang[4]*, Dae-Hyuk Kweon[4]*

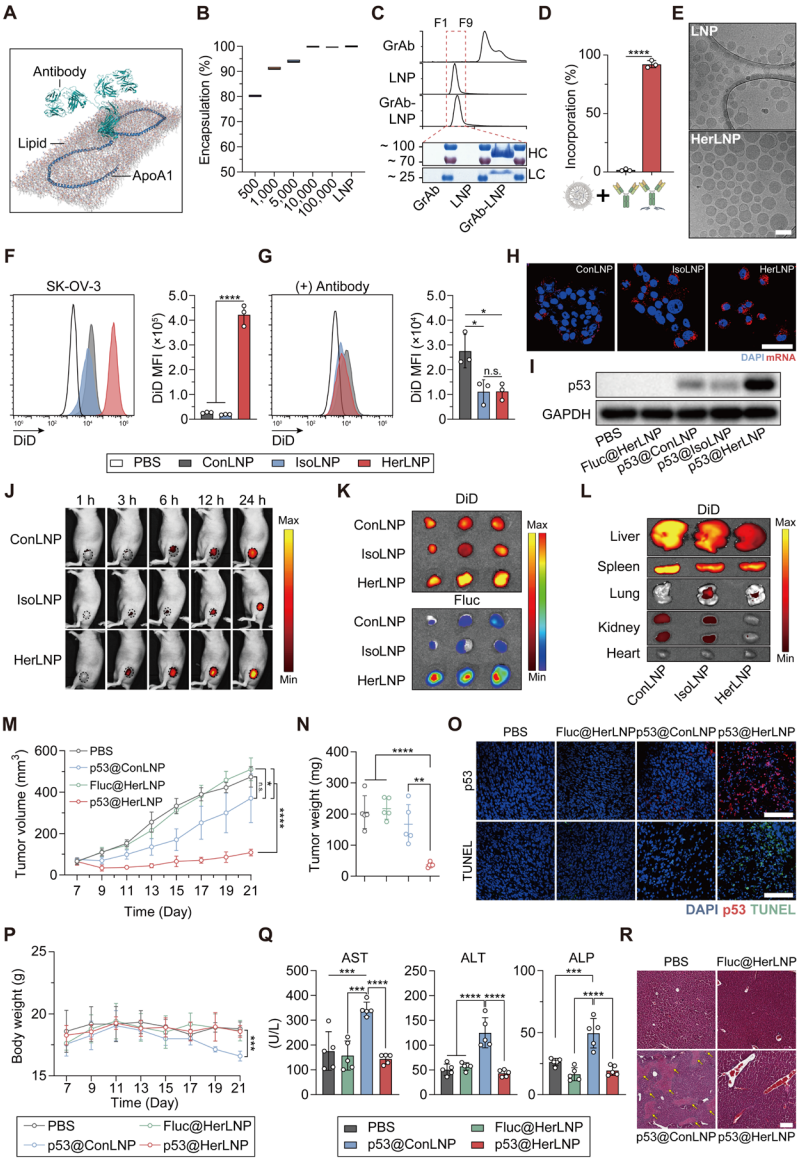
Introduction: The clinical success of mRNA@lipid nanoparticle (LNP) vaccines, especially during the COVID-19 pandemic, has highlighted the broad therapeutic potential of mRNA for various diseases. While LNPs provide effective protection against enzymatic degradation and facilitate cellular uptake of mRNA, limitations such as non-specific tissue distribution and unintended liver accumulation have constrained their clinical utility. Passive targeting approaches often rely on the enhanced permeability and retention (EPR) effect and can fall short in achieving precise cell specificity. Although antibody-mediated active targeting can address this issue, existing

chemical conjugation strategies typically involve multi-step reactions, toxic reagents, and PEG detachment problems, prompting the need for simpler, more stable alternatives. In response, we developed a chemical-free platform by fusing an apolipoprotein (ApoA1) directly to an antibody—termed "Grab Antibody" (GrAb). Owing to the strong lipid-binding affinity of ApoA1, GrAb spontaneously assembles into a stable protein corona on the LNP surface, maintaining appropriate antibody orientation. Using trastuzumab as a model antibody, we demonstrate that HER2-targeted GrAb-LNPs can efficiently deliver p53 mRNA to HER2-overexpressing tumors, yielding significant antitumor effects with minimal off-target toxicity.

Results: A 30-minute incubation at 37°C allowed GrAb to form a robust protein corona on the LNP surface (Fig. 1A). Modulating the lipid-to-protein (LP) molar ratio from 500:1 to 100,000:1 revealed a drop in mRNA encapsulation efficiency at higher GrAb levels, but negligible leakage once the ratio exceeded 10,000:1 (Fig. 1B). Size-exclusion chromatography (SEC) showed that GrAb strictly co-eluted with LNP fractions (Fig. 1C), and fluorescence measurements confirmed high incorporation of Cy5-labeled antibody (Fig. 1D). Cryo-TEM images of nude LNPs and trastuzumab GrAb-conjugated LNPs (HerLNPs) appeared similarly spherical (Fig. 1E). In HER2-overexpressing SK-OV-3 cells, HerLNPs exhibited selective binding and increased DiD fluorescence signals (Fig. 1F), which were abolished when HER2 receptors were pre-blocked (Fig. 1G). Intracellular uptake of Cy5-labeled mRNA was notably higher with HerLNPs (Fig. 1H), leading to greater p53 protein expression *in vitro* (Fig. 1I). *In vivo*, intravenous injection of DiD-labeled Fluc mRNA@HerLNPs led to superior tumor accumulation and reduced liver uptake, as shown by near-infrared fluorescence imaging (Fig. 1J, 1K, 1L). Repeated dosing with p53@HerLNPs significantly suppressed tumor growth (Fig. 1M, 1N) and induced marked apoptosis (Fig. 1O) in an SK-OV-3 xenograft model. Importantly, treated mice maintained stable body weights (Fig. 1P) and showed normal levels of liver enzymes (Fig. 1Q), indicating minimal systemic toxicity. Histological examination confirmed the absence of hepatic damage in HerLNP-treated animals, whereas mice receiving p53@ConLNPs displayed evident liver injury (Fig. 1R). Together, these findings validate GrAb-LNPs as an effective, targeted mRNA delivery platform offering enhanced therapeutic efficacy and reduced off-target effects in cancer treatment.



1168 Innovative Cationic Lipids Fuel Next-Gen LNPs for Targeted Oncology and Advanced Cell Therapies

Pauline Urquia[1], Quentin Huaulmé[2], Mélodie Seiler[1], Marine Fenat[1], Margaux Briand[1], Kassandra Renaud[1], Thibaut Ben Chimol[1], Claire Gueguen[1], Patrick Erbacher[3]

Lipid nanoparticles (LNPs) have shown promising potential in organ selective targeted -Oncology and Gene Modified Cell Therapies; however, the critical challenge lies in fine-tuning their formulation to enhance specificity, efficiency, and safety, to maximize therapeutic outcomes.

Here, we present a novel approach through the development of lipid nanoparticles (LNPs) derived from our library of Innovative cationic lipids. These LNPs demonstrate expanded extrahepatic biodistribution, improving drug delivery and cellular targeting. This addresses major challenges in cancer treatment for the development of therapeutic vaccines via targeting antigen presenting cells (APCs) and T cells in the spleen, and organ selective

oncology treatments via local injection. Optimization of LNP formulations around our cationic lipids leads to localized expression without off-target effects unlike commonly used ionizable lipid-based LNPs.

In addition, we investigate ex vivo cell engineering, employing LNPs. We highlight the efficacy and versatility of LNPs based on our library of lipids, which enable the transfection of mRNA in different types of immune cells, leading to transient engineering of CAR-T and NK cells. This data suggests that LNP formulations based on our cationic lipids, with the addition of targeting ligands, could also prove effective for the generation of CAR-Ts and NKs in vivo. The data underpinning these applications were collected through a blend of proof-of-concept studies conducted both in vitro and in vivo, aimed at evaluating the efficacy and safety of imidazolium lipid-based LNP systems. Molecular assays were employed to monitor biodistribution and cellular uptake, offering real-world insights with an emphasis on safety and dosage optimization.

1169 Delivery of synthetic DNA using Lipopolyplex nanoparticles: a thermostable alternative to mRNA-LNPs

Milena Pavlickova[1], Emily Young, Gözde Tezcan, Hassan Idris, Carmen Manas Torres[2], Zoe Whiffen[3]

mRNA lipid nanoparticles (LNPs) have been hugely successful, but issues remain with mRNA stability and cold chain storage requirements, as well as bottlenecks in the GMP manufacture of DNA IVT templates. 4basebio has developed a fully enzymatic, GMP-compliant synthesis process of linear DNA via our Trueprime™ amplification technology. DNA yields are >1g/L, several orders of magnitude higher than plasmid fermentation, allowing a small footprint using benchtop equipment. The process utilizes isothermal multiple displacement amplification of circular templates. Uniquely, 4basebio's circular templates do not contain typical plasmid backbone features, including antibiotic resistance genes. Combination of sequence-agnostic proprietary primase and engineered, high-fidelity Phi29 DNA polymerase can amplify DNA with high accuracy ($3.75x10^9$), accommodating construct size up to 60kb. The platform is optimized to handle high complexity sequences including high GC regions (up to 80% GC content across 2kb regions), homopolymer regions including poly-Adenine and poly-Guanosine regions and, palindromic sequences such as ITR and recombinase sites. Unique modifications, including fluorescent tags or functional polymer conjugates, can be incorporated. Here, Hermes™ nanoparticles comprising a cationic ligand, as well as traditional lipids, driving payload encapsulation and formulation stability, were optimised for delivery of 4Basebio's hairpin (hp)DNA™. Interestingly, lipid compositions optimal for mRNA delivery demonstrated poor formulation stability with DNA payloads. Using a DOE approach, hpDNA™ formulations with favourable biophysical characteristics, encapsulation efficiency and in vitro transfection rates were identified. In mice, intramuscular delivery of luciferase hpDNA™ demonstrated >1-log improvement in bioluminescence with the optimised formulation over a conventional LNP formulation. Moreover, expression was greater in the hpDNA™ group, compared to plasmid DNA groups at equimass and equimolar dosing, demonstrating the merit of combining both 4basebio's DNA and Hermes™ platforms. The storage stability of DNA in liquid buffers offers a huge advantage over mRNA. To investigate hpDNA™ thermostability, Hermes™ formulations encapsulating an eGFP hpDNA™ were stored at 4°C or -80°C for 3 months. Biophysical characteristics were maintained for Hermes™ formulations over the duration, which was driven by inclusion of the Hermes™ ligand, and a consistent transfection efficiency of >85% was observed in HEK293T cells. Further, no difference in hpDNA™ integrity was noted between 0 and 3 months, or between 4 or -80°C, as determined by capillary electrophoresis. Finally, to evaluate therapeutic potential, hpDNA™ encoding 20 neoantigens was delivered intramuscularly with the optimised Hermes™ formulation, or with electroporation, in the MC38 tumour model. Three doses of Hermes™ 28-days apart prevented development of tumours in 2/7 mice following a tumour challenge at day 52, which was comparable to the electroporated hpDNA™. Furthermore, survival rate was significantly greater in Hermes™ treated mice compared to untreated mice; 71% of Hermes™ or electroporated hpDNA™ treated mice compared to 0% in the untreated group. Therefore, combining the fast, scalable manufacture of 4Basebio's synthetic DNA with the DNA delivery capabilities of Hermes™ lipopolyplex nanoparticles, can offer an effective, thermostable alternative to mRNA-LNP for gene therapy and vaccines.

Efficient and safe delivery of genetic material into cells is critical for translating gene therapy into clinical practice. Recent advancements in molecular biology and nanotechnology have significantly contributed to the development of non-viral vector systems and DNA delivery technologies, which serve as promising alternatives to virus-based gene delivery. While non-viral vectors have several advantages, there are critical issues currently limiting their translation into clinical success. Here we describe a novel circular DNA molecule (HALO™ DNA) with unique structural DNA elements designed to favor nuclear uptake, nuclear retention, and immunomodulation, which greatly increases the efficiency, durability and redosability of gene delivery in vivo. Following intravenous delivery to a mouse of lipid nanoparticle (LNP)-formulated HALO DNA encoding cynomolgus macaque tissue non-specific alkaline phosphatase (cmTNALP), a surrogate of a therapeutic transgene for the treatment of hypophosphatasia, we demonstrate greater than 100-fold supraphysiological levels of plasma ALP activity that remains remarkably stable for more than a year. Potency, at least in part, is mediated by increased nuclear uptake as evidenced by quantitative confocal imaging of HALO DNA in primary human hepatocytes. HALO DNA integration site analysis (ISA) performed by target enrichment sequencing (TES) failed to detect evidence of integrated HALO DNA in liver cells even at very high vector copy numbers and over a year following in vivo DNA administration. Surprisingly, the structural elements present within HALO DNA are also able to modulate immune responses to the transgene product and allow redosing. Indeed, expression of cmTNALP in a mouse using a DNA construct lacking these structural elements was limited and highly inflammatory which prevented re-administration. However, repeat administration of LNP-formulated HALO DNA was non-hepatotoxic, as assessed by evaluation of ALT/AST levels, and non-inflammatory, as assessed by evaluation of a panel of pro-inflammatory cytokines, and led to stable gene expression. Importantly, this immunomodulatory effect is irrespective of the presence of pathogen-associated molecular patterns (PAMPs) such as CpG elements, or selection markers, within the DNA. Using an RNA-Seq based transcriptomics approach following delivery of DNA to mouse liver in vivo, we show that standard mini-circle DNA induces changes in the expression of many genes involved in immune responses, cytokine production pathways, and DNA repair. However, HALO DNA is largely silent, impacting only a small number of genes and to a significantly lesser extent. The primary determinant of this immunomodulatory phenotype appears to be the presence of the unique structural elements within HALO DNA. Finally, HALO DNA is easily produced in a scalable, low-cost manner, providing additional promise for the continued development of this differentiated non-viral DNA vector system.

1171 Simplifying Multigene Vector Design and Construction for Streamlined Development of Complex Therapeutics

Zoe Hermsen[1], Joshua Lee[1], Aaron Clausen[1], Sam Glickstein[2], Thomas Reed[3]
[1]Zymo Research Corp., Tustin, CA, [2]BSD Biosolution Designs, Frederick, MD, [3]BioSolution Designs, Boynton Beach, FL

Molecular therapeutics have revolutionized personalized medicine by offering long-lasting, low-risk alternatives to traditional treatments. Many fatal diseases, including heart disease, neurodegeneration, and cancer involve multiple, complex regulatory pathways that necessitate multigenic therapeutic approaches rather than conventional monogenic solutions for molecular therapy. However, the development of multigenic vectors is often hindered by high costs, lack of precision, off-target effects, and tedious troubleshooting of vector design and construction. Furthermore, the complexity and size of multigenic vectors is challenging for modern DNA synthesis techniques, so traditional time-consuming and cumbersome cloning techniques are necessary for creating recombinant multigenic vectors. To address these challenges, Osprey Bio's Bird of Prey complex vector system provides a standardized, cost-effective method for tunable multigenic vector assembly using modular genetic units, making multigenic vector design as simple as traditional single gene vector design. In this study, we leveraged the Bird of Prey vector construction system in conjunction with Zymo Research's highly efficient cloning technology to construct a quadgene vector incorporating four distinct reporter genes: *rLUC, fLUC, GFP,* and *RFP*. To optimize vector assembly, a DNA gel extraction system with micro-elution spin columns was employed to easily recover highly concentrated, ultra-pure restriction digested DNA inserts suitable for cloning. The ligated vectors were then transformed into specially prepared competent DH10B *E. coli* cells that do not require heat shock, enabling efficient propagation of the recombinant plasmids. Highly concentrated, endotoxin-free plasmid was quickly purified from the transformed *E. coli* using a novel high plasmid binding spin-column purification chemistry to ensure all recombinant plasmids were suitable for transfection. Finally, to assess vector functionality and subcloning success, individual monogenic, bigenic, and final quadgenic vectors were transfected into HEK293T cells and reporter gene expression was quantified using fluorometric and luciferase assays. Results confirmed successful subcloning of all genes of interest, with no observable decrease in gene expression or transfection efficiency as the number of genes per vector increased. These findings demonstrate the adaptability and efficiency of the Bird of Prey subcloning system for creating multigenes when combined with Zymo Research's robust cloning technologies. By significantly streamlining multigenic vector construction, this approach enables efficient testing and development of multigenic therapeutic solutions, facilitating advancements in gene and cell therapy.

1172 Enhanced Yield and Structural Integrity in Plasmid Biomanufacturing Employing the PowerS-ITR E. coli Platform

Rui Tang[1]*, Philemon Asfeha[2], Delicia Henriques[3], Ryan Rubino[4], Sneha Vilayur[4], Ssempa Kisaalita[4], Aparna Nandakumar[4], Murali Jujjavarapu[4], Aneri Maniar[5], Shrey Amin[4]

Introduction: As gene therapy and synthetic biology continue to advance, the need for effective plasmid production systems has grown significantly. These systems must address challenges like maintaining high yields and ensuring molecular stability. The PowerS-ITR E. coli cell line emerges as a transformative platform, purpose-engineered to support the propagation of low-copy plasmids with structurally intricate elements such as Inverted Terminal Repeats (ITRs) and some PolyA tails. This investigation delineates the capabilities of PowerS-ITR in optimizing production workflows and achieving consistency in plasmid biogenesis.

Methods:
1. **Cell Line Engineering**: The PowerS-ITR strain was cultivated under rigorously optimized parameters to enhance replication fidelity and expression capacity.
2. **Plasmid Construct**: A prototypical low-copy plasmid harboring a PolyA tail and ITR sequences was synthesized to serve as a benchmark for experimental validation.

3. **Optimization Screening**: High-throughput methodologies were employed to scrutinize plasmid yield variations across a spectrum of growth media and environmental conditions.
4. **Quantitative Metrics**:o Plasmid yield quantified through spectrophotometric analysis and agarose gel electrophoresis. o Structural integrity evaluated via restriction endonuclease profiling and next-generation sequencing.5. **Benchmarking**: Comparative analyses were performed against the widely utilized E. coli Stable and JM108 strains, facilitating a comprehensive assessment of relative performance indices.

Results: Initial findings underscore the PowerS-ITR cell line's superior performance, as evidenced by:

- A statistically significant 2-fold increase in plasmid yield relative to standard strains.
- Exceptional maintenance of plasmid structural fidelity, with negligible recombination or degradation artifacts which may be present in the comparative strains.
- Demonstrated scalability in bioreactor systems, ensuring reproducibility across production batches.

Conclusion: The PowerS-ITR platform offers meaningful improvements in plasmid production, addressing key limitations of traditional methods. By delivering amplified yields and ensuring sequence stability, it meets the stringent demands of modern biopharmaceutical applications. Ongoing research will prioritize refining production conditions, scaling to high-capacity bioreactors, and extending the evaluation to encompass diverse plasmid architectures with therapeutic relevance.

1173 Incorporation of 5-methoxyuridine Enables Efficient Targeted Transgene Insertion in iPSCs and T Cells

Cassandra Ng[1], Kyle Garland[1], Ian Hay[2], Claire Aibel[2], Christopher Rohde[1], Matthew Angel[1]
[1]Factor Bioscience Inc., Cambridge, MA, [2]Factor Bioscience, Cambridge, MA

mRNA-based gene editing allows transient expression of editing proteins, enabling efficient on-target editing while minimizing off-target effects. mRNA synthesized by *in vitro* transcription (iVT) can contain immunogenic double-stranded RNA (dsRNA) byproducts, which can trigger a potent innate immune response. Mutant T7 RNA polymerases (mT7) and modified nucleotides (NTs) are being explored as strategies to mitigate dsRNA production during iVT. Since mRNA-mediated gene-editing relies on the cell's DNA-repair machinery to complete the edit, we hypothesized that dsRNA-derived immune responses could limit gene-editing efficiency. We synthesized UltraSlice™ gene-editing mRNA with combinations of mT7s and modified NTs and measured targeted insertion efficiency and immunogenicity in T cells and induced pluripotent stem cells (iPSCs).

We first analyzed dsRNA byproduct, immunogenicity, and protein expression of GFP-encoding mRNA. RT-PCR of innate immune markers (OAS1, OAS2, MDA5) in electroporated iPSCs and iPSC-derived mesenchymal stem cells (iMSCs) showed that the mRNA synthesized with standard conditions (standard T7 and canonical (AUGC) NTs) resulted in the greatest immune response ($p<0.01$ for all markers) compared to samples synthesized with mT7 and/or 5-methoxyuridine (5moU/mT7+5moU). dsRNA dot blot confirmed that the standard synthesis condition also resulted in approximately 10x more dsRNA compared to mT7. When iPSCs and iMSCs were electroporated with GFP mRNA, all synthesis conditions resulted in similar percentages of GFP-expressing cells. However, twice the median fluorescence intensity (MFI) was observed in both cell types for mRNA synthesized using mT7 or 5moU.

To assess the effect of dsRNA on targeted insertion efficiency, UltraSlice™ mRNA targeting the AAVS1 safe harbor and T Cell Receptor Alpha Constant (TRAC) loci were synthesized using standard conditions, mT7, 5moU, and mT7+5moU. PBMC-derived T cells were co-electroporated with TRAC UltraSlice™ mRNA and a linear GFP transgene. 5moU mRNA more than doubled the number of GFP-expressing cells compared to mRNA made with standard conditions (17.6% vs 6.71%), while mT7 and mT7+5moU had less of an effect (12.7% and 8.93%, respectively). These results suggest that incorporation of 5moU into iVT mRNA reduces immunogenic dsRNA
