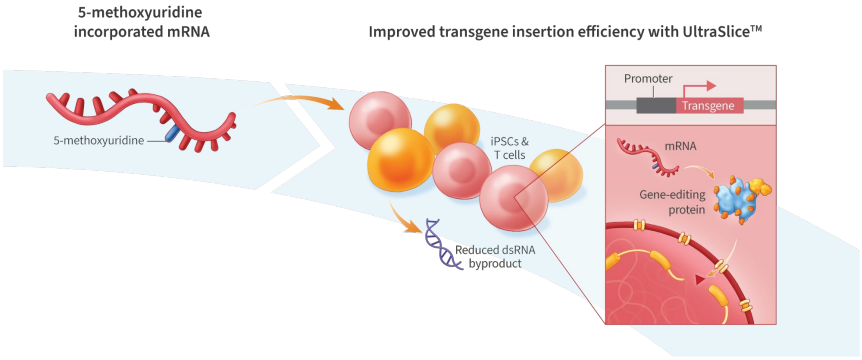
byproducts during iVT and enables efficient targeted insertion of transgene sequences. 5moU-containing mRNA may therefore serve as a useful tool for the development of both *ex vivo* and *in vivo* gene editing therapies.



1174 TREX1 Knockout Does Not Improve Gene-Length Insertions Using Single-Stranded DNA Templates

Reza Nouri[1], Aparna Venugopalan[2], Cosimo Ducani[3], Sriram Vaidyanathan[2]
[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Moligo Technologies, Solna, Sweden

CRISPR/Cas9-based genome editing offers a promising approach for treating genetic disorders by modifying DNA sequences or regulating gene expression. Upon cleavage by Cas9, the homology-directed repair (HDR) pathway could be leveraged to generate precise modifications at a target locus in the presence of an exogenously introduced repair template. While adeno-associated virus (AAV) has been the gold-standard template for gene editing, P53 activation by AAV reduces the regenerative potential of some edited stem cells. There is an interest in non-viral single-stranded DNA (ssDNA) templates because they induce less P53 activation. However, the degradation of ssDNA within the cells by intracellular nucleases limits the efficiency of gene insertion using ssDNA templates.

Previous studies found that a single exonuclease, three prime repair exonuclease 1 (TREX1), reduces HDR efficiency using ssDNA. However, the study only included short ssDNA (<200 nt) and it was unclear if blocking the activity of TREX1 is essential for replacing complete genes using ssDNA templates. While short ssDNAs can correct point mutations, gene-length ssDNAs templates needed for whole gene replacement are >2 kb long. Here, we investigate gene insertion using ssDNA >2 kb in wild-type and TREX1 knock-out primary airway basal stem cells (ABCs), human umbilical vein endothelial cells (HUVECs), and induced pluripotent stem cells (iPSCs).

While editing with ssDNA <200 nt, TREX-KO ABCs, and HUVECs show significantly higher gene insertion (knock-in %) compared to WT cells (Figure 1A). This result confirms the findings of previous studies. To evaluate the effect of TREX1 KO on gene insertion by long ssDNA, we designed a 2297 nt template to insert expressing green fluorescent protein (GFP) to Exon1 of the CFTR gene. We then evaluated gene insertion in WT and TREX1 KO ABCs and HUVECs. Surprisingly, no difference in editing efficiency was observed between wild-type and TREX-KO cells (Figure 1B). These results suggest that while TREX1 degrades ssDNA <200 nt and significantly decreases the editing efficiency, gene-length ssDNA templates are not degraded by TREX1. To further verify the role of TREX1 in reducing gene insertion using gene-length ssDNA, we edited iPSCs, which do not express TREX1 naturally. Surprisingly, GFP insertion in WT iPSCs is significantly higher (~ 26% GFP+ cells) than in ABCs and HUVECs (~ 5% GFP+ cells) (Figure 1C). These findings indicate that a factor distinct from TREX1 (present in ABCs and HUVECs and absent in iPSCs) is likely responsible for restricting gene insertion. Future studies will investigate alternative factors that limit gene insertion by ssDNA >2kb in ABCs and HUVECs. We believe this study would help to improve our understanding of CRISPR-mediated gene editing systems using long ssDNAs to replace whole genes.

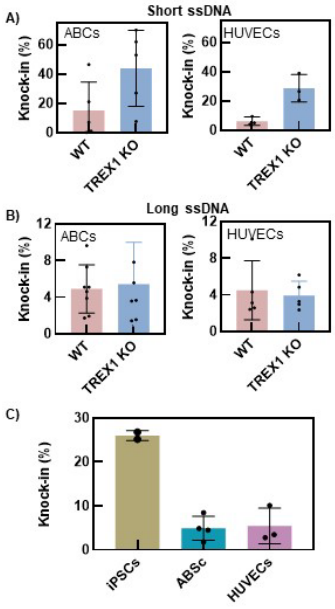


Figure 1. A. Editing wild type and TREX1-KO ABCs and HUVECs using a short ssDNA confirmed the role of TREX1 in degrading the short ssDNAs and decreasing the gene insertion efficiency. B Gene insertion efficiency of wild type versus TREX-KO ABCs and HUVECs using a long ssNDA template. This result showed that TREX1 does not affect gene insertion using a long template. C) Substantial editing efficiency was observed in iPSCs versus ABCs and HUVECs using a long template.

1175 Development of a Novel Full-Length F8 CELiD DNA Vector (ceFVIII) for Hemophilia A Gene Therapy

Lina Li, CELiD Biotechnologies Inc., Rockville, MD

Hemophilia A is an X-linked bleeding disorder caused by mutations in the factor VIII (F8) gene, resulting in factor VIII deficiency. While adeno-associated virus (AAV)-based gene therapies have shown promise for treating Hemophilia A, their utility is limited by AAV's packaging capacity (~4.7 kb). The F8 coding sequence (CDS), exceeding 7 kb, poses significant challenges for delivery using AAV. Truncation strategies may compromise F8 protein folding and functionality, while dual-AAV approaches often suffer from low efficiency. To overcome these limitations, we have developed a novel closed-ended linear duplex (CELiD) DNA vector for Hemophilia A. CELiD DNA has previously demonstrated long-lasting expression and stability in vivo, making it an attractive alternative to viral vectors.

The newly designed CELiD DNA vector, ceFVIII, incorporates a full-length FVIII expression cassette (8.3 kb) driven by a ubiquitous promoter. This study outlines the production of ceFVIII and highlights its potential for therapeutic development. The CELiD DNA-based ceFVIII vector represents a novel, non-viral platform that overcomes the size constraints of AAV-based systems. With its potential for durable in vivo expression and scalable production, ceFVIII holds promise as a next-generation gene therapy for Hemophilia A, addressing critical unmet needs in this patient population.

1176 Unlocking Safe and Scalable Engineering: Non-Viral and Non-Integrating SMAR DNA Vectors with Improved Payload Capacity

Silvia Rizzato[1], Alice De Roia[2], Matthias Bozza[3], Toros Tasgin[4], Annabel Grewenig[5], Richard Harbottle[6]*

The ability to efficiently deliver large DNA sequences is of pivotal importance in the advancement of cell therapies. Conventional methods for cellular engineering face limitations in both safety and payload capacity, associated with the use of viral vectors and gene editing technologies such as the CRISPR/Cas system. These issues are especially problematic for the clinical translation of next-generation cellular therapies employing multiple receptors and complex genetic circuits to enable precise control over gene expression and therapeutic outcomes. To address these challenges, we developed a non-viral non-integrating approach for long-term genetic modification of cells using DNA vectors. At the core of our platform are Scaffold/Matrix Attachment Regions (SMARs), sequences derived from human DNA that allow episomal maintenance and extra-chromosomal vector replication within the host cell nucleus. This means that, unlike integrative technologies, these vectors do not carry the risk of insertional mutagenesis. Additionally, employing DNA vectors has the key advantage of enabling the inclusion of large and/or multiple independent transgenes without size constraints, making this technology highly versatile and simple to use.

We have demonstrated the utility of SMAR vectors across a range of cell types, including primary human T cells: engineered cells exhibit stable and robust expression of transgenes and maintained high cytotoxic activity when equipped with Chimeric Antigen Receptors (CARs) or T Cell Receptors (TCRs). In this study we built on previous work to generate dual-promoter constructs and evaluate the performance of multi-cassette systems in Jurkat T cells. Several iterations of the vectors were assembled, testing various promoter and transgene configurations, with sizes ranging from 5.7kb to 9kb. We successfully expressed multiple proteins in parallel, including fluorescent markers and clinically validated therapeutic receptors such as the anti-CEA CAR and anti-MART-1 TCR, with no adverse effect of larger vectors on cell viability post-delivery. Importantly, the engineered cells were able to successfully initiate intracellular signaling cascades essential for immune responses upon stimulation.

The promising results obtained thus far emphasize how the SMAR vector platform provides a safe, flexible alternative to current cell engineering methods, with the potential to stably deliver larger payloads without compromising genomic stability. Follow-up studies are ongoing and focused on further characterizing vector dynamics in the nucleus, as well as incorporating other molecular designs such as logic-gated CARs. With these advancements, we aim to offer a scalable, safe, clinically compliant solution for the genetic modification of cells used in various applications, including cancer immunotherapy and beyond.

1177 A Next Generation Immune and Stem Cell Engineering Platform to Create Multifunctional Cells, at Clinical Scale, Using a Silicon Membrane

Eleni Rogers[1], Zhihui Song[2], Sophia Hirsch[3], Darby Kreienberg[1], Andrew Larocque[1], Jacquelyn Hanson[1], Alec Barclay[3], Armon Sharei[1]
[1]Portal, Watertown, MA, [2]Arlington, MA, [3]Portal Biotechnologies, Watertown, MA

Despite their unprecedented efficacy in the clinic, cell and gene therapies remain inaccessible to many patients due to their immense cost and complex manufacturing. Currently, delivery of cell modulating materials (e.g. CAR) to cell types of interest is done through viral, lipid, or electroporation technologies which are expensive, can only accommodate specific cargos or cells, and lack scalability - creating a bottleneck. We have developed a cell engineering platform by leveraging mechanoporation, a technique based on rapid mechanical deformation of cell membranes, to achieve universal compatibility across diverse cell types and cargo molecules. This approach enables efficient delivery of a wide range of cargo, including mRNA, CRISPR RNP, circular RNA, siRNAs, and proteins, to various cell types, notably primary immune cells and hematopoietic stem cells, which have traditionally been challenging to modify. For example, we have shown multiplexed delivery of mRNA and CRISPR RNP to naive T cells efficiently engineering more than 85% of total viable cells with both GFP expression and deletion of B2M. In iPSCs, we have used this technique to deliver mRNA encoding the transcription factor Neurogenin 2 (NGN2) to drive the differentiation of iPSCs into neuronal precursors while maintaining a viability of 75% at a RNA expression level of over 70%. The silicon membrane-based delivery system streamlines the cell engineering process, facilitating seamless integration with existing clinical manufacturing equipment and enabling scalable production of cell

therapies. Using our clinical scale integration module, we have the capacity to deliver cargo to more than 1 billion cells per minute. We show high viability and over 80% mRNA expression in activated T cells when integrated into standard GMP manufacturing equipment. This approach is simple, economical, amenable to many cell and cargo types, and scales from research to clinical applications. This technology has the potential to alleviate major bottlenecks enabling broader accessibility of impactful cell therapies.

1178 Computationally Designed Miniproteins Enable Precise And Potent In Vivo Delivery Of Gene Editors To Challenging Tissues

Geoffrey Berguig[1]*, Beeke Wienert[2], Cody Krivacic[3], Benjamin Spangler[4], I-Li Tan[1], Stephanie Maiocco[5], Brian Vash[3], Cody Jackson[3], Josh Park[3], Erin Hsiao[1], Edurne Gonzalez[3], Felicia Ng[3], Ajeeth Adhikari[3], Hui Yin Tan[3], Colleen Matzie[3], Pengcheng Zhang[3], Oghene Efagene[3], Lizet Reyes Rodas[3], Clapton Hernandez[3], Meenu Karson[1]

Gene editing technologies hold extraordinary potential to correct the root causes of genetic diseases by precisely targeting affected tissues in vivo. Despite these exciting prospects, current delivery methods—including lipid nanoparticles (LNPs), viral-like particles (VLPs), and viral vectors—pose significant limitations. Not only do they come with safety concerns, such as the risk of immune responses, but they also lack the characteristics required for diverse tissue accessibility and specificity (i.e. muscle, heart, kidney, etc.).

To overcome these challenges, we have developed an innovative approach centered on protein-based therapeutics. This strategy pairs gene editors with customizable miniprotein targeting moieties that enable precise self-delivery to hard-to-reach tissues through receptor-mediated uptake. Notably, these therapeutics are designed to be modular, potent and transient, offering distinct advantages over traditional delivery methods.

Building on recent breakthroughs in machine learning for protein structure and function, we engineered miniproteins fused to guide gene editors to specific cell surface receptors—targeting muscle cells, neurons, and kidney. By performing self-delivery experiments in cellular models engineered to overexpress the corresponding receptors, we observed that our targeted gene editors achieved a 4,000-fold increase in potency over untargeted editors. When paired with an endosomal escape agent, we achieved potencies between 10 and 100 pM with the targeted gene editors *in vitro*. Furthermore, by chemically engineering both guide RNA and Cas9 protein, we demonstrate enhanced stability of the ribonucleoprotein (RNP) complexes within diverse biological matrices, ensuring greater durability and functionality in complex biological environments.

We use transgenic mouse models to evaluate the translational potential of the targeted gene editors. We perform histological analysis to assess the ability of de novo designed miniproteins to deliver gene editors to muscle and neurons in vivo, focusing on their co-localization with intended receptor targets. Additionally, we utilize localized delivery methods, such as intramuscular and intrastriatal injection, to explore targeted uptake and gene editing, highlighting the platform's modularity and versatility.

These results mark a significant step forward in our ability to precisely and safely deliver gene therapies to difficult-to-drug tissues.

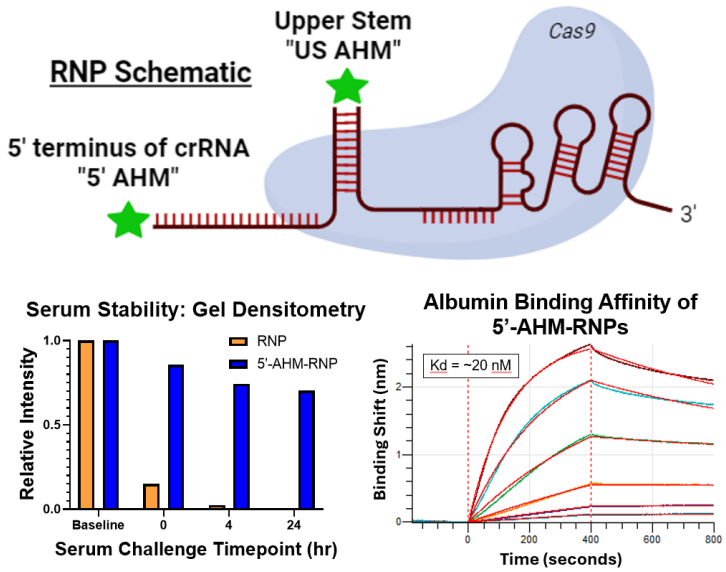
1179 Engineering the CRISPR-Cas9 Ribonucleoprotein Complex for Carrier-Free Gene Editing

Zach Lamantia[1], Nora Francini[1], Larry Stokes[1], Craig Duvall[1]*
[1]Vanderbilt University, Nashville, TN
**Corresponding Author*

Introduction: Despite the rapid development of CRISPR-Cas9 delivery technology for gene editing, translating these technologies for application outside of liver and eye has proven to be a challenge. Systemic delivery of high doses of viral carriers comes with toxicity risks, motivating nonviral approaches, such as lipid or polymeric nanoparticles. However, ionizable carrier systems come with relatively narrow therapeutic indices due to carrier associated toxicities. Our work focuses on increasing the stability and pharmacokinetics (PK) of the RNP to allow its systemic delivery for in vivo carrier-free editing of muscle. To achieve this goal, we are synthesizing RNPs that bind to albumin through a lipid modification placed on the RNA component. *In situ* albumin hitchhiking is known as a promising strategy for cargo stabilization and is validated clinically (e.g., Ozempic) to extend *in vivo* PK. We seek to optimize an albumin-hitchhiking modification (AHM) in combination with other RNA stabilizing modifications to engineer RNPs that are stable against nuclease degradation, have extended PK to enable delivery to sites of tissue inflammation, and maintain targeted DNA cleavage.

Methods: We use solid-phase synthesis to introduce the AHM with varying linker chemistries as well as protecting 2′ and backbone chemical modifications to the dual guide RNA (dgRNA) system. Plasmid cleavage assays (to assay targeted dsDNA cleavage) and *in vitro* gene editing studies in primary mouse cells are used to assess the activity of the modified RNPs, while biolayer interferometry and serum challenge assays determine the albumin-binding potential and serum/nuclease stability, respectively. We put a special emphasis on exploring the differences in activity and stability introduced through varying AHM locations and linker lengths.

Results and Conclusions: Chemically modified dgRNAs can achieve similar plasmid cleavage efficiency as unmodified dgRNAs, but the cleavage kinetics are slower. Similarly, RNPs with heavily or fully modified dgRNA and added AHM have reduced gene editing activity in primary mouse cells as do RNPs without the AHM, likely due to steric hindrance of DNA targeting or RNP formation. However, we demonstrate that varying AHM linker length and location can be used to somewhat restore the gene editing activity, and an optimal length was determined for one of the AHM locations that enables 3.6-fold increase in activity relative to other linker lengths ($p<.0001$). Importantly, AHM-RNPs all demonstrate albumin-binding affinities of approximately 20 nM and ~70% retained product after 24 hours of incubation in serum compared to 0% non-AHM-RNP product. Finally, all AHM-RNPs were shown to have significantly increased carrier-free cellular uptake ($p<.0001$, ~30% more uptake at 24 hours) in mouse muscle cells relative to normal RNPs. Therefore, we have found that the incorporation of the AHM and chemical modifications to the dgRNA comes at a cost of reducing editing activity but that these modifications greatly improve cell uptake and the stability of the complex, while providing high-affinity albumin-binding. These results motivate future work exploring the *in vivo* PK and gene editing activity of lead modified RNPs vs. unmodified RNPs to dissect the contribution of RNP potency vs. stability. We will further explore new, additional AHM linker chemistries and chemical modification patterns for optimization of the stability and activity of the RNPs.



1180 Microglia-specific miRNA gene therapy with homing peptides for amyotrophic lateral sclerosis in mice model

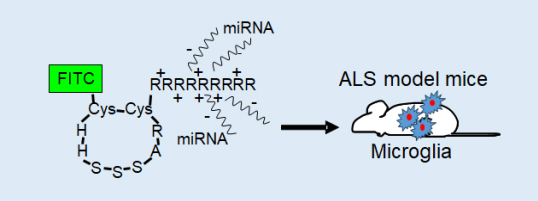
Tomoya Terashima[1], Kazuki Mera[2], Rika Zen[3], Bach Nguyen[2], Makoto Urushitani[4]
[1]Shiga University of Medical Science, Otsu,Shiga, Shiga, Japan, [2]Shiga University of Medical Science, Otsu, Shiga, Japan, [3]Shiga University of Medical Science, Otsu-city, Shiga, Japan, [4]Shiga University of Medical Science, JAPAN

Introduction: Amyotrophic lateral sclerosis (ALS) is an intractable neurodegenerative disease, most of which is sporadic, and no established treatment has yet been developed. Microglia are universally known as immunocompetent cells in the central nervous system and have been related with pathogenesis in ALS, recently. Therefore, microglia is an important target for treatment of ALS, and we decided to develop the selective delivery of therapeutic miRNA to microglia by our previously identified homing peptides for the treatment of ALS. We also screened for the miRNAs to be delivered and developed a novel treatment method using a complex of microglia targeting peptide and therapeutic candidate miRNA.

Material and Methods: (1) Screening the candidates of therapeutic targeting miRNA, miRNA array was performed in spinal cord of SOD1(G93A) transgenic mice (ALS mice) at early, middle, and late stages of the disease. (2) The affinity of the microglia homing peptides with candidate miRNA, and the stability of the complex between microglia homing peptide and miRNA was also evaluated. (3) The gene delivery experiments of miRNA into microglia with homing peptides was performed *in vitro*. Transduction efficiency in the complex including microglia homing peptide was evaluated by comparing with the chemical regents for transfection of genes. (4) miRNA-microglia peptide complexes were administrated into the ALS mice and their therapeutic effects were evaluated by behavioral experiments and survival curve. And mRNA expression levels were analyzed in cytokines and growth factors.

Results: (1) Several miRNAs were identified as therapeutic candidates against microglia in ALS. (2 and 3) The miRNAs with microglia homing peptides specifically targeted to microglia and were successfully delivered into microglia. The complexes showed higher transduction efficiency than lipofection regents. (4) Application of miRNA-microglia peptide complex showed therapeutic effects on motor behavioral tests and survival rate in the ALS mice. And the expression of pro-inflammatory genes was suppressed in treatment group, whereas the expression of neuroprotective genes was increased by miRNA-microglia peptide complex.

Conclusion: A novel gene therapy for ALS with miRNA delivery targeting to microglia was developed, and clinical application will be expected.



1181 Non-Viral Cell Engineering and Gene Delivery Optimization from Discovery to Clinical Applications Across Broad Cell Types

Joseph Wawrzyniak[1], Ranganatha Somasagara[1], Deepak Kumar[1], Olga Cohen[2], Gregory Bonello[1], Shahan Molla[3], Arseny Smirnov[1], Namritha Ravinder[4]
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]Thermo Fisher Scientific - Carlsbad, CA, Carlsbad, CA, [3]Carlsbad, CA, [4]ThermoFisher Scientific, Carlsbad, CA

Cell and gene therapy (CGT) demands workflows that transition seamlessly from research-level optimization to clinical-scale manufacturing. Thermo Fisher Scientific offers a powerful portfolio designed to enable this scalability, including the Neon™ NxT Electroporation System (single- and 8-channel), the CTS™ Xenon™ Electroporation System, and the CTS™ Rotea™ Counterflow Centrifugation System. The Neon NxT system provides a flexible research use platform for rapid, small-scale optimization of electroporation conditions, while the CTS Xenon system allows these optimized protocols to be seamlessly scaled up for high-volume non-viral gene delivery, supporting GMP-compliant cell therapy manufacturing, ensuring consistent performance at all stages. The CTS Rotea system supports efficient upstream preparation, enabling high-quality starting material that enhances the reproducibility of downstream electroporation results. We demonstrate the scalability of this workflow using multiple cell types, showcasing its versatility and reproducibility. In T cells, knock-out (KO) of the TRAC locus and knock-in (KI) of a GFP donor DNA payload yielded comparable editing efficiencies and consistent viability on both the Neon NxT and CTS Xenon system. Similarly, iPSCs edited at the CD38 locus using CTS HiFi Cas9 RNP for KO and a MESO3-V5 dsDNA donor for KI retained their pluripotency markers post-electroporation, confirming their potential for banking or differentiation applications. NK cells, a challenging cell type to engineer, were successfully edited at the B2M locus using CRISPR, achieving equivalent KO efficiencies across both platforms. These results collectively validate the seamless scalability from the Neon NxT to the CTS Xenon system, enabling consistent gene editing outcomes across diverse and demanding cell types. By combining flexibility at the research level with robust performance at manufacturing scale, Thermo Fisher Scientific empowers researchers to efficiently optimize gene editing and delivery workflows for diverse and challenging cell types. This integrated approach accelerates the development of next-generation therapies, driving their successful translation from bench to bedside.

1182 Enhancing CAR NK Cell Production - A Comparative Analysis of Non-Viral Gene Engineering Systems

Beeke Tappe[1], Maximilian Bauser[2], Leonie Binder[1], Luisa Burger[3], Leon Gehrke[2], Hermann Einsele[4], Michael Hudecek[5], Richard Harbottle[6], Jürgen Löffler[2], Michelle Seif[2]
[1]German Cancer Research Center, Heidelberg, Baden-Wuerttemberg, Germany, [2]University Hospital Wuerzburg, Wuerzburg, Bayern, Germany, [3]German Cancer Research Center Heidelberg, Heidelberg, Germany, [4]University Hospital Würzburg, Würzburg, Bayern, Germany, [5]University Hospital Würzburg, Würzburg, Germany, [6]German Cancer Research Center, Heidelberg, Germany

Chimeric antigen receptors (CARs) are artificial fusion proteins comprising an extracellular domain, typically a single-chain variable fragment (scFv) derived from a monoclonal antibody, a transmembrane domain, and an intracellular signaling domain. Expressed in immune cells like T or NK cells, CARs enable antigen recognition and activation, leading to the targeted destruction of cells. Despite their efficacy, CAR T-cell therapies can lead to complications such as graft-versus-host disease (GVHD). In contrast, natural killer (NK) cells offer inherent advantages due to their intrinsic ability to kill without prior antigen-stimulation and reduced risk of inducing GVHD. These properties make allogeneic CAR NK cells viable as ready-to-use treatments, eliminating the need for patient-

specific lymphocyte preparation. Non-viral methods of genetic engineering offer advantages over viral transduction, including a better safety profile, lower immunogenicity, cost-effectiveness, and fewer regulatory challenges. Our aim is to refine the non-viral genetic engineering of CAR NK cells using the NK92 line to enhance the speed, efficiency, and simplicity of the process. To achieve this, we aim to enhance the transfection rates by exploring various non-viral gene engineering systems, including diverse electroporation devices and mechanoporation techniques.

We have successfully transfected the NK92 cell line to express CARs using the non-viral Sleeping Beauty (SB) Transposase system equipped with the SB100x hyperreactive transposase. Performing the transfection through electroporation utilizing a Neon Transfection device initially yielded approximately 3 to 14 % CAR-positive cells. The cells expressing the transgene were subsequently selected and further cultivated to establish cell cultures with an average of 95 % CAR-positive cells. Using digital droplet PCR (ddPCR), we quantified the copy-number variation (CNV) of integrated CAR DNA within the NK92 cell genome. Cells electroporated with two distinct CAR constructs, each incorporating different scFvs, displayed CNVs ranging from 3 to 48. These constructs were further modified to include a gene cassette for continuous IL-15 production, increasing their size. Surprisingly, CNVs were 1.6-fold higher for constructs with the IL-15 cassette than those without it, regardless of the scFv type. Additionally, we assessed the surface density of CARs on NK92 cells using flow cytometry. The analyses revealed a significant 1.7-fold increase of the Antibody-Binding Capacity, aligning closely with the ddPCR results. Engineered CAR NK92 cells have demonstrated reactivity to their specific targets, effectively initiating signal transduction. This activation is evidenced by a significant secretion of IFN-γ (up to 1400 ng/ml) with up to 38 % degranulating cells. These properties are currently compared to NK92 cells engineered on various non-viral gene delivery systems.

Increasing transfection efficiency will not only accelerate the production process but also facilitate the adaptation of these methods to primary NK cells, thereby making CAR NK cell therapies a more viable clinical option.

1183 Making Personalized Possible: A Miniaturized, Automation Integrated Nonviral Delivery Platform for High-Throughput Arrayed CRISPR Screening in Rare Patient-Derived Cells

Alison Hirukawa[1], Brittany Boribong[1], Hugo Sinha[1], Miti Patel[1]
[1]*DropGenie, Cambridge, MA,*

The development of clinically relevant drug discovery workflows requires scalable and efficient tools to interrogate genetic function in preclinical models. Arrayed CRISPR screening offers a powerful approach to systematically evaluate gene perturbations, enabling multi-parametric high-content assays. However, translating arrayed screening to patient-derived cells remains a challenge due to the high cellular inputs required, the cost of reagents, and the need to pool samples from multiple donors, which can obscure inter-patient variability.

To address these limitations, we have developed an automated microfluidic platform that enables miniaturized, nonviral transfection at scale. This platform leverages a novel droplet-based electroporation system that leverages digital microfluidics for precise micro volume liquid handling with a unique electrode geometry that leverages the electric field to transiently porate cells in a manner that optimizes delivery efficiency while preserving cell viability. By reducing the required cell numbers from millions to just a few thousand per perturbation, our approach makes genome-wide arrayed CRISPR screening feasible in primary and patient-derived cells. We have validated robust delivery of diverse payloads—including mRNA, RNP, and DNA—demonstrating high-efficiency editing with no impact on cell function across multiple primary cell types, including immune cells, stem cells, and 3D organoid structures.

Here, we present a fully automated 48-plex editing cartridge designed for seamless integration with standard laboratory automation. We will detail the workflow adaptations that enable compatibility with SBS-format consumables and acoustic liquid handling technologies, allowing precise deposition of 48 independent guide RNAs across the cartridge. Furthermore, we will showcase our automation efforts, which support robotic loading and unloading of reagents, enabling hands-free execution of thousands of edits per day. Finally, we will highlight our

custom user interface, which facilitates real-time monitoring and parameter customization for each electroporation event.

By enabling high-throughput, cost-effective, and patient-specific genetic screening, our platform has the potential to accelerate drug discovery and improve translational relevance, ultimately advancing precision medicine and the development of more effective therapies.

1184 Development of Novel CaptureSelect Affinity Tools for Extracellular Vesicle Purification and Detection; Enabling a New Class of Gene Therapy Products

Sandra Bezemer[1], Frank Detmers[1], Jaco Hazenoot[2], Pim Hermans[1]
[1]Thermo Fisher Scientific, Leiden, Netherlands, [2]Thermo Fisher Scientific, Leiden, Zuid-Holland, Netherlands

Extracellular vesicles (EV) are small vesicles produced by various cell types in the range of 30-100 nm diameter, and are involved in intercellular communication by delivering proteins, metabolites and nucleic acids into recipient cells that effectively alter their biological response. These natural properties of EVs make them a promising platform for new gene therapy products. The manufacturing process of these type of biopharmaceuticals is challenged by their complexity and heterogeneity, and scalable downstream processes are not available. Currently, most of the purification strategies described in literature are based on time consuming and non-scalable options like density gradient ultracentrifugation.

Using the CaptureSelect ligand technology, based on llama single domain antibodies, we have developed a range of affinity ligands that target different tetraspanin membrane proteins that are present on EVs and selectively bind three different proteins being CD81, CD9, and CD63.

Here we report the development of a novel affinity purification tool for EVs by immobilizing the CaptureSelect CD81 affinity ligand on a magnetic bead platform. EVs containing CD81 protein were specifically captured from cell-line derived and human plasma feed streams and eluted from the magnetic beads with arginine-based buffers. Efficient elution was achieved at mild pH which kept the EVs structurally intact. Due to their complexity, orthogonal analytical methods were implemented to characterize and quantify EVs throughout the workflow.

Sandwich ELISA based on affinity ligand conjugates targeting three distinct tetraspanins (CD81, CD9, and CD63), SDS-PAGE, western blot analysis, and SP-IRIS with immunofluorescence (Leprachaun™) were performed for phenotypic characterization, intactness, sizing, and titer determination.

Analysis demonstrated an effective and efficient purification of CD81 bearing EV particles enabled by this magnetic bead platform. The development of this easy purification method together with ligand-based analytical characterization assays can help advance the development and manufacturing of new EV based therapies.

CaptureSelect ligands and resins: For Research Use or Further Manufacturing. Not for diagnostic use or direct administration in humans or animals.

1185 The anti-inflammatory properties of Mescenchymal Stromal Cell derived Extracellular Vesicles on feline neuroinflammation

Nikolia Darzenta[1], Maria Naskou[2]
[1]Auburn University, Auburn, AL, [2]Auburn University, College of Veterinary Medicine, Auburn, AL

Introduction. Extracellular vesicles (EVs) secreted from mesenchymal stromal cells (MSCs-EVs) are lipid nanoparticles with multiple inherent anti-inflammatory and immunomodulatory properties. Their biological action is dependent on the MSCs' culture conditions, and it is still unclear which cell culture condition produces the most immunosuppressive EV isolates. Moreover, EVs are able to diffuse through the blood-brain-barrier and exhibit low

immunogenicity, so they are promising therapeutic candidates for neuroinflammation. Neuroinflammation is triggered by neuronal death and when persists exacerbates the progression of neurodegenerative diseases. Traditional anti-inflammatory drugs have side effects and offer minimal symptomatic relief. Therefore, there is a critical need to develop novel treatments that dampen neuroinflammation and reverse its role in neurodegenerative disease prognosis. Our goal is to evaluate the anti-inflammatory effects of MSC-EVs in Sandhoff Disease (SD), which is a fatal and aggressive inherited neurodegenerative disease. Our objectives was a) to identify the anti-inflammatory effects of different MSCs-EVs on inflammatory mixed glia, b) to assess their immunomodulatory properties in peripheral mononuclear blood cells (PBMCs) from SD cats c) and to determine their *in vivo* anti-inflammatory effects in SD cats.

Methods. Primary mixed glia were isolated from feline brains and were phenotypically characterized via immunofluorescence. MSC-EVs were isolated under different culture conditions including a serum free environment (SF-EVs) or in the presence of FBS (FBS-EVs) or following priming of MSCs with IFN-γ and TNF-α (IF-EVs). Subsequently, EVs were added to naïve and LPS-stimulated cells for 24 and 48 hours. Cell culture supernatants from mixed glia were collected and analyzed for inflammatory factor expression through ELISA and RTq-PCR. Additionally, PBMCs from SD cats were treated with concanavalin-A for 48h and stained against FOXP3/CD4/CD3 markers to evaluate the effect of IF-EVs on T-regulatory cell proportion via flow cytometry. Potential cytotoxicity of the IF-EVs was assessed via XTT assay. Furthermore, 10^{12} UCMSC-EVs were intravenously administered in SD and normal cats at 4 months old. Brain and peripheral tissues were collected three days post injection. Enzymatic activity assays, immunohistochemistry and gene studies via qPCR were performed for main inflammatory mediators.

Results. Isolated brain cells from normal cats were confirmed as a mixed glia population due to the expression of neuronal (anti-NeuN), astrocytic (GFAP), microglial (Iba-1) and pericyte (PDGFR-β) cell markers. The addition of MSC-EVs into inflammatory feline mixed glia suppressed the pro-inflammatory cytokine production and downregulated factors involved in inflammatory signaling pathways. IF-EVs exerted the best immunomodulatory capacity compared to SF- and FBS-EVs. Also, IF-EVs reduced SD systemic inflammation via increasing the proportion of the T-regulatory cells compared to the control and no cytotoxicity effects were observed. Lastly, the IV administration of MSC-EVs suppressed neuroinflammation by decreasing the expression of Iba-1, GFAP and MHCII and CD4 inflammatory markers in the brains of SD cats compared to the untreated controls.

Conclusions. Our findings reveal that MSC-EVs reduce feline neuroinflammation during neurodegeneration.

1186 Engineering Extracellular Vesicles for Neuroprotective Gene Delivery to the Central Nervous System

Megan Keiser[1]*, Krithiga Aruljothi[2], Simon Bouscher-Helbig[3]
[1]Ohio State University, Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]The Ohio State University, Westerville, OH
**Corresponding Author*

Introduction: Acute central nervous system (CNS) injuries, such as traumatic brain injury (TBI) and stroke, initiate a cascade of neuroinflammatory and degenerative processes that contribute to long-term functional deficits. Gene therapy offers a promising strategy to modulate these pathological responses and promote neuroprotection. However, efficient and minimally invasive delivery of therapeutic genes to the CNS remains a significant challenge. Engineered extracellular vesicles (EVs) have emerged as a versatile and non-immunogenic delivery platform capable of transporting genetic cargo across the blood-brain barrier (BBB) to target neural cells. Here, we present our preliminary work on engineering EVs for the delivery of neuroprotective genes to the CNS following acute injury.

Methods: EVs were isolated from genetically modified producer cells engineered to package neuroprotective genes of interest. The efficiency of gene loading into EVs was assessed using quantitative PCR and fluorescence-based reporter assays. In vitro studies were conducted by exposing naïve cell cultures to engineered EVs to evaluate cellular uptake and transgene expression using fluorescence microscopy and qRT-PCR. For in vivo studies, EVs

were administered intranasally or via direct intracranial injection to the striatum or thalamus in Td-Tomato-reporter mice, followed by histological analysis of brain tissues to assess gene transfer efficiency and cellular targeting.

Results: Our data confirm that engineered EVs successfully incorporate neuroprotective genes and deliver their genetic cargo to recipient cells in vitro, leading to detectable transgene expression in naïve cells. Preliminary in vivo experiments demonstrate that intranasally administered EVs can transduce neurons in the cerebellum of murine brain and directed intracranially injection results on regional specificity depending on the mode of administration. Immunohistochemical analysis reveals sustained transgene expression within neuronal populations, suggesting potential for therapeutic CNS intervention.

Conclusions: These findings support the feasibility of engineered EVs as a non-viral vector for gene delivery to the CNS, highlighting their potential to mitigate neuroinflammation and promote neuronal survival after acute injury. Further studies are underway to optimize EV surface engineering for enhanced brain targeting and therapeutic efficacy in mouse models of traumatic brain injury. This approach holds promise for developing next-generation of transient gene therapies for CNS disorders and injury.

1187 Improving and targeting programmable RNAi enriched Extracellular Vesicle for biomedical applications.

Extracellular vesicles (EVs) are emerging as important vehicles in biotherapeutic applications. Small EVs (Exosomes) derived from multivesicular bodies can deliver nucleic acid and protein payloads to recipient cells, representing an engineerable non-viral biological nanoparticle for the delivery of biomedicines. EVs are considered non-immunogenic, biocompatible, and non-toxic. Furthermore, targeting of nanoparticles to specific tissues remains a challenge, and EVs are amenable to surface modification with targeting ligands through modified EV-enriched scaffolds. RNA interference (RNAi) is an established therapeutic approach; however, targeted delivery remains a significant barrier to the wider adoption of RNAi-based treatment. Various methodologies to selectivity load RNAi into EVs have been explored, but suffer from low programmability for new targets, complex loading procedures that use immunogenic architecture, cumbersome post-production loading processes, or questionable effective transfer of potent RNAi. Furthermore, strand selectivity can prevent toxic off-target effects through the 'passenger' strand, making it a beneficial feature of a highly on-target RNAi technology

To this end, we have identified an innovative RNAi scaffold termed the Exo-shRNA system that exploits dicer-independent short hairpin RNAs to enrich RNAi within small EVs to transfer functional cargo to recipient cells. The Exo-shRNA's simple architecture is readily programmable and is strand selective because of the dicer-independent maturation process. However, improving potency is essential to ensure competitive applications of the EV-delivered Exo-shRNAs. Exploring different features of the Exo-shRNA, such as the promoters, sequence features, export motifs, and host factors screened using high-throughput assays, we identified features of Exo-shRNA that can enhance knockdown by 2-fold through alternative promoter and shRNA sequences. Furthermore, a host factor, Cx43, can improve RNAi enrichment in EVs by doubling mature RNAi effectors per particle. Furthermore, building on previous work, we modified the EV-enriched CD63 scaffold to target the GP160 receptor of HIV, which resulted in selective reporter knockdown on GP160 expressing cells versus unmodified cells, demonstrating the Exo-shRNA is amenable to targeted delivery. Finally, Human Papillomavirus (HPV) causes a range of epithelial malignancies, and the viral oncogenes (E6 and E7) are critical for tumor transformation and maintenance of cervical cancer, representing ideal targets for therapeutic intervention. As proof-of-concept application of the Exo-shRNAs to a therapeutically relevant cancer target, Exo-shRNAs were designed to the E6/E7 viral oncogene, which reduced expression in reporter models, and when transferred by EVs to an HPV-associated cancer cell line reduced proliferation. Overall, the Exo-shRNA system represents a generalizable, next-generation biocompatible delivery platform for targeted gene knockdown applications for biomedicine.

1188 *Engineered SIRPα-Enriched Extracellular Vesicles Enable Targeted Clearance of CD47+ Pathological Fibroblasts in Fibrotic Disease*

Minjeong Kwon[1], Seo-hyun Kim[2], Dong-U Shin[3], In-San Kim[4]*, Gi-Hoon Nam[3]*

The persistence of pathological fibroblasts driven by CD47-mediated "don't eat me" immune evasion has shown a critical challenge in addressing fibrotic diseases. Here, we present an innovative therapeutic approach using engineered extracellular vesicles (EVs) enriched with Signal Regulatory Protein Alpha (SIRPα) to block the CD47 signal and promote clearance of diseased fibroblasts through professional phagocytes.

We have stably transduced human bone marrow-derived mesenchymal stem cells (MSCs) using lentiviral vectors to express SIRPα. Furthermore, we have developed a novel three-dimensional large-scale manufacturing process for EV production that achieved over 90% purity and a tenfold increase in yield compared to conventional methods. The therapeutic potential of SIRPα-EVs was evaluated in a bleomycin-induced idiopathic pulmonary fibrosis (IPF) mouse model, supported by single-cell transcriptomic analysis of human IPF samples that confirmed significant CD47 upregulation in disease-associated fibroblasts and macrophages. Biodistribution studies using fluorescently labeled SIRPα-EVs demonstrated preferential accumulation in fibrotic lung tissue. Flow cytometry revealed approximately fivefold higher uptake in pathological fibroblasts compared to normal fibroblasts. In vivo data indicated that SIRPα-EVs exhibited superior therapeutic efficacy compared to conventional treatments (dexamethasone, nintedanib, pirfenidone) at lower doses, evidenced by restored alveolar architecture, reduced fibrotic lesions, and decreased Ashcroft scores. Molecular analyses confirmed the downregulation of key fibrotic markers, including α-SMA, CD47, inflammatory cytokines, and TIMP1.

These findings highlight the transformative potential of SIRPα-EVs as a targeted therapy for fibrotic diseases and establish a foundation for clinical translation in conditions that currently lack effective treatment options.

1189 Development of a Scalable and Reproducible Large-scale Purification Method for Biologically Active Extracellular Vesicles Using Tim4-Phasphatydilserine Affinity Interaction

Mitsuo Watanabe[1], Saki Kado[2], Masayuki Yamane[3], Takamasa Ishidome[4], Shotaro Masuda[2], Ryo Ukekawa[4], Takahiro Nishibu[4]
[1]FUJIFILM Wako Pure Chemical Corporation, Chuo-ku, (None), Japan, [2]FUJIFILM Wako Pure Chemical Corporation, Osaka, Japan, [3]Bio Science & Engineering Laboratories, FUJIFILM Corporation, Osaka, Japan, [4]FUJIFILM Corporatipon, Osaka, Japan

Introduction: Extracellular vesicles (EVs) are lipid bilayer membrane structures secreted by cells and contain various bioactive substances such as lipids, nucleic acids, and proteins. Since EVs derived from mesenchymal stem cells (MSCs) have therapeutic potential on various diseases, the use of EVs as therapeutic agents in medicine has been thought to be promising. Consequently, multiple methods have been developed for a larger scale EV purification. Here, we have sought to develop a scalable and reproducible method for affinity purification of EVs by using Tim4 protein, which specifically binds phosphatidylserine (PS) displayed on the surface of EVs. Because the binding is Ca^{2+}-dependent, intact EVs can be easily released from Tim4 by adding Ca^{2+} chelators. This method is capable of purifying EVs derived from cell culture supernatants with high recovery and purity.

Methods: Recombinant Tim4 protein was covalently immobilized on the surface of agarose resin and the Tim4-resin was packed into a 1 mL column. 200 mL of MSC cell culture supernatant was directly applied into the Tim4 column. After washing the column, 4 mL of EDTA solution was applied to elute the captured EVs. The resulted EVs were analyzed by using NTA, ELISA, BCA methods, and cell-based functional reporter assay. In parallel, EVs were also purified from the 200 mL of the same culture supernatant by using tangential flow filtration (TFF), TFF +

size exclusion chromatography (SEC), or TFF + anion exchange chromatography (AEX), and the resulted EVs were analyzed for comparison.

Results: More than 5 X 10^{11} particles of EVs were purified per 1 mL of the Tim4 resin, and it was confirmed that yield of the purified EVs with the PS affinity method was higher (70 – 90%) than the other commonly used methods, such as TFF combined with SEC or AEX method. We used the same Tim4 column repeatedly for 10 times, and the resulted each EV preparation showed a similar tetraspanin protein expression profile to what observed with the EVs purified with the Tim4-immobilized magnet beads-based small scale purification method, indicating that the Tim4 column is scalable and reusable with an appropriate washing procedure. Furthermore, we observed the EVs purified using the Tim4 column showed higher purity and anti-inflammatory effect than the EVs purified with the other conventional methods.

Conclusions: Our affinity purification method using Tim4-immobilized resin can purify EVs with higher recovery, purity and biological activity in fewer steps than competing methods and is also scalable. The method is also cost-effective because of the multiple-use capability. Therefore, we propose that our affinity purification method has potential for use in manufacturing process of therapeutic EVs.

1190 Designing a Plug-and-Play System to Produce Engineered Extracellular Vesicles

Vijetha Bhat[1]*, Ali Navaei[2], Chien-Ting Li[3], Davide Zocco[4]*

Extracellular vesicles (EVs), including exosomes, are being studied extensively and have emerged as a promising novel technology for the delivery of complex therapeutic payloads such as nucleic acids or proteins. EVs are naturally occurring within the body and have several potential advantages over other delivery vehicles such as LNPs or viral vectors, such as their ability to evade the immune system response and therefore support repeat dosing, as well as their capacity to access biological barriers and deliver a wide range of cargo to specific target tissue types given their tropism profiles. These attributes make EVs favorable candidates to engineer as drug delivery systems.

Here, we discuss a plug-and-play platform approach to express biomolecules using engineered EVs. Therapeutic cargo may be loaded onto or within EVs via identified scaffold proteins using novel plasmid design. This concept was explored in the development of therapeutics such as exoSTING™, exoASO-STAT6™ and exoIL-12™, which have completed Phase 1 clinical studies within oncology applications. Alternatively, small molecules may be linked to EVs using a proprietary linker technology. A dedicated cell line for EV production was also generated, which resulted in a clone capable of high particle titer, integrity, and purity. These technologies will be made available to the wider scientific community under a research license, or via Lonza's CDMO service offerings.

1191 CD47-Targeted Extracellular Vesicles Enable Enhanced Endolysosomal Escape for Oligonucleotide Therapy Delivery

Yoon Kyoung Kim[1], Seok Ho Song[2], Hyemin Joo, Hyeyoon Nam[3], Min Kyoung Jo[4], Gi Beom Kim, In-San Kim[5]*, Gi-Hoon Nam*

Despite significant advances in oligonucleotide therapeutics, translating small interfering RNA (siRNA) and antisense oligonucleotides (ASO) into clinical use remains challenging due to inadequate drug delivery systems (DDS). While these therapeutics hold promise for targeting "undruggable" pathogenic genes such as mutant KRAS in cancer and NLRP3 in inflammatory diseases, their efficacy is often hindered by rapid degradation, poor cellular

uptake, and insufficient endosomal escape. The current lipid nanoparticle (LNP) delivery system has notable limitations, including high immunogenicity, predominant accumulation in the liver, and endosomal entrapment.

To address these issues, we developed a CD47-mediated oligonucleotide delivery platform using engineered extracellular vesicles (EVs) expressing SIRPα membrane protein (SIRPα-EVs). By developing optimized lentiviral transduction and isolation protocols, we generated SIRPα-EVs and incorporated therapeutic oligonucleotides through cholesterol-based conjugation. Mechanistic studies revealed that SIRPα-EVs utilize clathrin-independent endocytosis for cellular uptake, allowing for efficient endolysosomal escape and enhanced therapeutic delivery compared to conventional endocytic pathways.

In vivo imaging and flow cytometry confirmed selective accumulation of SIRPα-EVs in CD47-overexpressing pathological tissues. Therapeutic evaluation in two disease models highlighted the versatility as a DDS platform: KRAS siRNA-loaded SIRPα-EVs achieved 60% complete remission in combination with PD-1 blockade in a KRAS-mutant tumor model, while NLRP3 ASO-loaded SIRPα-EVs demonstrated superior anti-inflammatory effects in an LPS-induced inflammation model. Both applications exhibited significantly improved oligonucleotide delivery compared to naive EVs.

This translational study establishes CD47-targeted EVs as a versatile platform for oligonucleotide delivery, demonstrating efficient endolysosomal escape and superior therapeutic outcomes across multiple disease models. Our findings provide compelling evidence for clinical applications in both cancer and inflammatory conditions characterized by CD47 overexpression.

1192 Extracellular Vesicle Delivery of Oligonucleotide Antiviral Therapy Against Rabies Encephalitis

Y Savanie Fernando[1], Anna Cochran[2], Miguel Sena-Esteves[3], Henry Baker[2], Douglas Martin[4], Maria Naskou[5]
[1]Auburn University, Auburn, AL, [2]Auburn University Scott Ritchey Research Center, Auburn, AL, [3]UMass Chan Medical School, Worcester, MA, [4]Auburn University, Auburn University, AL, [5]Auburn University, College of Veterinary Medicine, Auburn, AL

Introduction: There are many neuropathic viruses that can cause viral encephalitis in humans that are mostly lethal and incurable. Among these viruses, zoonotic rabies virus (RABV) is invariably fatal to humans following the onset of clinical symptoms. Although there are preventable measures for rabies post-exposure prophylaxis, existing interventions are ineffective once the virus reaches the central nervous system and neurologic symptoms become apparent. The primary reason current treatment methods for encephalitis are unsuccessful is the blood brain barrier which limits the delivery of treatments into the brain. Therefore, it is essential to develop novel therapeutic approaches to treat rabies encephalitis. Extracellular vesicles (EVs) derived from plasma membrane presents an innovative platform for developing novel therapeutics with their ability to shuttle molecules between cells and through crossing the blood brain barrier. Moreover, RNA interference (RNAi) using synthetic short double stranded DNA (siRNA) is an innovative approach used to selectively bind targeted viral messenger RNA to induce viral mRNA degradation. In this project our objective is to modify extracellular vesicles to express rabies virus glycoprotein (RVG) derived peptide, which binds to nicotinic acetylcholine receptor, which will target neuronal cells and deliver therapeutic antiviral siRNAs designed to inhibit rabies virus replication into the central nervous system. We hypothesize that engineered extracellular vesicles expressing RVG will increase brain tropism and increase the efficiency of anti-viral siRNA delivery into the central nervous system to rapidly inhibit rabies virus replication. This project aims to implement a novel therapeutic approach and advance the viral suppression therapy for rabies encephalitis.

Methods: We modified EVs derived from HEK293 cells to express RVG by transfecting parent cells with a plasmid encoding Lamp2b-construct fused to the neuron specific RVG. A plasmid consisting of Lamp2b-construct fused to FLAG was used as the control. We used a surrogate siRNA (GAPDH) to evaluate the efficiency of encapsulation into RVG modified EVs and to evaluate the delivery of cargo into neuronal cells. Next, we screened forty-six

antiviral siRNA candidates against rabies N gene for their high binding and gene inhibition *in vitro* using psiCHECK2 luciferase assay system. In addition, we used RT-PCR to evaluate gene expression.

Results: Our preliminary data showed successful modification of EVs with the RVG peptide and loading of a surrogate siRNA (GAPDH). Moreover, we found that RVG modified EVs were able to deliver their load to neuronal cells *in vitro*. In addition, our preliminary data from Luciferase assay shows that six antiviral siRNAs candidates can induce more than 90% N gene interference in HEK293 cells.

Conclusions: We aim to evaluate the therapeutic effect of EVs to deliver antiviral siRNAs in rabies infected neuronal cells and mice via bio distribution and gene expression assays.

1193 Targeted Extrahepatic Gene Delivery and Editing with Non-Viral Fusogenix Proteolipid Vehicles

Genetic medicines hold great promise to treat a wide array of diseases, yet success in the clinic has been hindered by limitations in the tolerability, biodistribution, scalability, and immunogenicity of current delivery platforms. We developed a novel delivery platform that overcomes these limitations by combining aspects from viral and non-viral platforms. The Fusogenix proteolipid vehicle (PLV) incorporates fusion-associated small transmembrane (FAST) proteins isolated from orthoreovirus into a well-tolerated lipid formulation using a scalable microfluidic mixing approach. Incorporation of FAST protein into an optimized lipid formulation was found to significantly increase the expression of DNA/mRNA in vitro and in vivo, without accompanying increases in toxicity. Systemic administration of PLVs encapsulating DNA-GFP or mRNA-GFP in mice and non-human primates efficiently delivered these nucleic acids to numerous extra-hepatic tissues, primarily muscle, lungs, and kidneys. This led to substantial gene expression, confirmed with histology, ELISA, and PCR. Systemic DNA delivery is a major challenge for non-viral platforms; therefore, to establish a suitable benchmark we compared the systemic delivery of DNA-FLuc to a clinically approved lipid nanoparticle (LNP) formulation. PLVs displayed exceptional tolerability, with no liver toxicity or elevated cytokine levels that were observed with the LNP formulation – all without sacrificing DNA expression. Next, we examined the extrahepatic nature of PLVs and compared the delivery of mRNA-FLuc to three clinically approved LNP formulations across multiple administration routes, including intramuscular, intracerebroventricular, and intravitreal injection. Unlike LNPs, which showed significant off-target liver expression regardless of injection route, PLVs achieved robust localized expression in the intended tissues with no off-target expression. The combination of low immunogenicity, sustained efficacy, and precise delivery highlights the PLV platform's potential for diverse gene therapy applications. Building on these findings, we explored the versatility of the PLV platform for extrahepatic gene editing. Using the Ai9 mouse model, systemic delivery of mRNA-Cre via PLVs induced widespread tdTomato expression across multiple tissues, while intrastriatal (IS) injection localized expression to the striatum, hippocampus, cortex, and thalamus. We then optimized PLVs to co-encapsulate mRNA-Cas9 and sgRNA, ensuring effective colocalization of CRISPR components. In vivo validation in Ai9 mice mirrored the Cre results, with IV delivery achieving gene editing in the same tissues and IS injection facilitating extensive neuronal editing. Translating these results into a therapeutic context, we developed a durable, DNA-based leptin gene therapy (DNA-Lep) for the treatment of obesity. IV injection of leptin-deficient mice with DNA-Lep resulted in a sustained increase in circulating leptin levels, extending beyond a six-month duration. This was associated with significant improvements in body weight and metabolic function relative to control animals. These findings were validated in a diet-induced obesity model, where DNA-Lep treatment increased circulating leptin levels, resulting in a corresponding reduction in food intake and body weight while improving markers of metabolic health. The favorable activity and safety of the PLV platform defines a new standard for redosable gene therapies and genetic medicine.

1194 Streamlined Cell Therapy Manufacturing: Highlighting Workflow Flexibility and Functionality with Advanced Processing and Fill Finish Instrumentation

Carl Dargitz[1], Pushpalatha Chaluvappa[2], Young Kim[3], Norbert Hernandez[2], krishna Kundu[2], Arseny Smirnov[2], Gregory Bonello[2], Namritha Ravinder[4], **Ranganatha Somasagara[2]**
[1]Thermo Fisher Scientific, Carlsbad, California, [2]Thermo Fisher Scientific, Carlsbad, CA, [3]Carlsbad, CA, [4]ThermoFisher Scientific, Carlsbad, CA

Background and Aim: Advancing cell therapy manufacturing necessitates robust, flexible, and efficient systems to ensure high-quality outcomes for patients. This study evaluates primary T cell recovery, viability, and phenotype in the concentration, formulation, fill and finish steps of the cell therapy workflow using semi-automated instrumentation. Additionally, we investigated the volume accuracy and cell concentration consistency of a new fill finish instrument capable of producing between 1 and 10 outputs with a volume between 750mL and 0.5mL. Both instruments were analyzed independently to understand their capabilities and potential applications in the field as part of the larger workflow.

Methods, Results & Conclusion: This work was conducted through a series of workflow-based experiments designed to assess the core functionalities of the two instruments. Key performance metrics included primary T cell recovery, viability, and phenotype for washing and concentration as well as volume accuracy, and cell concentration consistency between final output containers. Data were collected from multiple runs to ensure reproducibility and accuracy.

In cell processing step we saw consistent primary T cell recovery exceeding 80% and little to no change in viability before and after the T cell processing steps. Additionally, the phenotype of the primary T cells remained stable throughout the processing. Within the fill-finish steps, high accuracy, recovery, and viability of primary T cells was achieved. Output samples from 200mL to 1mL showed percent errors below 5% from the target volume, and cell concentration was consistently within 10% between all seven outputs using a starting cell concentration of 10e6.

Both instruments exhibit significant strengths in their respective functionalities, offering valuable tools for cell therapy manufacturing. This evaluation highlights their potential to enhance product yield and consistency in manufacturing. The high viability, recovery, and phenotype of T cells during processing, along with the accuracy, precisions, and high recovery rates during fill-finish operations, underscore their effectiveness in supporting cell therapy manufacturing. Additional work is in progress to explore seamless workflow integration of these systems.

1195 Evaluating CAR T-Cell Potency in 2D and 3D Models Using Fluorescent Live-Cell Imaging

Nathalie Opdam – van de Laar[1], Inge Thijssen-van Loosdregt[1], Skylar Dewees[2], Stacie Chvatal[2], Danielle Califano[2], Denise Sullivan[2], **Henry Ordutowski[2]**
[1]Axion BioSystems, Eindhoven, Netherlands, [2]Axion BioSystems, Atlanta, GA

The development of immunotherapies relies on the use of in vitro potency assays—which are key for understanding complex interactions between immune (effector) cells and cancer (target) cells. Immune effector T-cells, specifically CAR T-cells, show great promise due to their innate cytotoxicity. CAR T-cell therapy utilizes genetically engineered T-cells expressing a chimeric antigen receptor (CAR) that binds to a specific antigen on tumor cells. Assessing the efficacy and potency of such CAR T-cell therapies in vitro is vital for preclinical development. In this study, we describe an in vitro potency assay using the Omni live-cell imaging systems to quantify immune cell-mediated cytotoxicity of fluorescent cancer cells by HER2-targeted CAR T-cells in 2D and 3D cancer cell models. First, a GFP fluorescent HER2-expressing lung cancer cell line (A549) was seeded into 96-well plates, and HER2 CAR T-cells were added at various effector-to-target (E:T) ratios (1:10, 1:5, 1:2, 1:1, and 5:1) at 24 hours after target cell seeding. Fluorescent images of target cells were captured every 5 hours using the Omni Pro 12, an automated, high-throughput live-cell analysis platform that continuously images inside an incubator. Automated image analysis quantified attachment, proliferation, and cell death of the A549 target cells, which demonstrated a dose-dependent decrease in green fluorescence confluency, with near-complete cell lysis at a 5:1 E:T ratio by 160 hours. Next, cancer spheroids were formed in a U-bottom 96-well plate from A549-GFP (low expression of HER2) and SKOV3-GFP (overexpression of HER2) cells. After 48 hours of incubation, HER2 CAR T-cells were added at E:T ratios of 1:10, 1:5, 1:2, 1:1, 2:1, 5:1, and 10:1. CAR T-cells showed antigen-specific killing, with higher E:T ratios (2:1, 5:1, and 10:1) resulting in approximately 75% reduction in green fluorescence intensity in SKOV3 spheroids at 72 hours. In contrast, A549 spheroids exhibited similar killing only at the 10:1 ratio. These findings suggest that the efficacy of CAR T-cell therapies may be influenced by the target antigen expression levels on cancer cells, emphasizing the need for optimized dosing and E:T ratios dependent on tumor characteristics. Real-time monitoring with live-cell imaging tools like Omni provides valuable insights into the dynamics of immune cell interactions, helping to refine and improve CAR T-cell therapies.

1196 Assessing *In Vitro* Cytotoxicity of CAR-T Cells Against Cancer Cells Using Three Assay Platforms

Jiu Jiang[1], Lisa Yu[1], Karen Doucette[2], **Rabinarayan Mishra[3]**, Sid Bhoopathy[1]
[1]Pharmaron, Exton, PA, [2]Pharmaron US Labs, Exton, PA, [3]Absorption Systems, a Pharmaron Company, Exton, PA

Introduction. Determining CAR-T cell potency is a critical parameter to measure its efficacy at various stages of development. Comparing different assay platforms is essential in selecting a suitable method based on assay parameters and intended purposes. In this study, the potency of CAR-T cells was evaluated by comparing the cytotoxicity of CAR-T cells against tumor cells using three different assay platforms - Flow cytometry, Maestro Z, and CLARIOstar.

Methods. CAR-T cells recognizing the CD19 molecule were generated by transduction and used as effector cells, and Raji-Luc cells ($CD19^+CD20^+$) were used as target cells. Raji-Luc cells were incubated and re-suspended in complete medium and plated in a 96-well round-bottom plate (25,000 cells/well). In parallel, freshly generated CAR-T cells were washed and re-suspended in a medium supplemented with rhIL-2. The CAR-T cells and un-transduced cells were added to the wells at appropriate dilutions to obtain different effector-to-target (E:T) ratios (1:1 and 5:1). Target and effector cells were co-cultured at 37°C for 24 hours and 48 hours and analyzed by flow cytometry after staining with an antibody cocktail (anti-CD3, -CD20, -CD69, FMC63, and 7-AAD). Raji-Luc cells were tethered to the wells of a CytoView-Z plate using anti-CD40 for 24 hours before co-culture in the Maestro assay for real time monitoring over 48 hours. Luciferase expression of Raji-Luc cells was measured 48 hours post co-culture using CLARIOstar microplate reader.

Results. Flow cytometry data revealed that, compared to un-transduced cells, the percentage of tumor cells ($7\text{-}AAD^-$ $CD20^+$) was significantly lower when co-cultured with CAR-T cells at E:T ratio of 5:1, with 43% and 81% of tumor cells killing observed at 24 hours and 48 hours, respectively. At E:T ratio of 1:1, approximately 25% of tumor cells were killed at both 24-hour and 48-hour time points indicating specificity of effector cells towards tumor targets. CAR-T cells exhibited significant upregulation of CD69, an early activation marker, at both 24-hour and 48-hour time points, while control un-transduced T cells showed lower activation. Real time cytotoxicity determined by Maestro Z showed comparable killing efficiency. At E:T ratio of 5:1, 71% and 85% of Raji-Luc cells were killed at 24 hours and 48 hours post co-culture, respectively. At E:T ratio of 1:1, 33% and 38% were killed at the

corresponding time points. Cytotoxicity assessment using CLARIOstar microplate reader showed 6% and 84% killing at E:T ratios of 1:1 and 5:1, respectively. These results demonstrate comparable cytotoxicity of anti-CD19 CAR-T cells across these three assay platforms, particularly at the high E:T ratio (5:1) within our experiment setup.

Conclusion. Compared to both the Maestro and CLARIOstar assay platforms, flow cytometry provides additional information on the activation and expansion of CAR-T cells, while real-time cytotoxicity can be easily monitored by Maestro Z. Therefore, these assay platforms can be complementary for evaluating the potency of CAR-T cells depending on the purpose.

1197 Real-time, Label-free Assessment of HER2-targeted Antibody-drug Conjugate Therapies

Benjamin Streeter[1], **Danielle Califano[1]**, Skylar Dewees[1], Stacie Chvatal[1], Daniel Millard[2], Henry Ordutowski[1]
[1]Axion BioSystems, Atlanta, GA, [2]Axion BioSystems, Inc., Atlanta, GA

Antibody-drug conjugates (ADCs) consist of monoclonal antibodies covalently linked to small molecule drugs that, together, can improve both components' anti-tumor effects. Several ADCs are targeted towards human epidermal growth factor receptor 2 (HER2), a cell surface receptor that is overexpressed in many cancers. Its increased expression in tumor cells makes HER2 an attractive target for cytotoxic therapies, allowing for the specific killing of cancer cells while minimizing off-target effects. Here, we developed an in vitro assay to assess the cytotoxic capacity of ADCs that use the HER2-targeted monoclonal antibody trastuzumab. This assay was performed in a real-time, label-free manner using the Maestro Z platform. The Maestro Z measures electrical impedance via electrodes embedded in the surface of the well to monitor cell growth and proliferation. To assess the cytotoxic effects of one HER2-targeted ADC, trastuzumab-deruxtecan (DS-8201a, branded as ENHERTU®), 5,000 HER2-positive SKOV3 cells were plated in CytoView Z plates and monitored for 24 hours before being dosed with increasing amounts of DS-8201a. SKOV3 cells were killed in a dose-dependent manner, and higher doses of DS-8201a led to larger decreases in SKOV3 impedance, indicative of greater SKOV3 death. SKOV3 cytolysis at the highest dose reached 90.9% at ~ 5 days post dose, and the EC50 value was calculated to be 30.7 µg/mL. We also tested the effects of DS-8201a against other cell types with varying degrees of HER2 expression, including A549 (low HER2 expression) and MDA-MB-231 (no HER2 expression) cells. As expected, impedance data showed that DS-8201a had enhanced cytotoxic effects on the high HER2-expressing SKOV3 cells compared to the other two cell types with lower HER2 expression. Finally, we compared the cytotoxic effects of DS-8201a to another trastuzumab-based ADC, trastuzumab-emtasine (T-DM1, branded as Kadcyla®) on the Maestro Z. Taken together, these results show that the cytotoxic capacity of ADC therapies toward HER2 positive cell types can be screened using the Maestro Z. The assay presented here can be used to further develop ADC therapies aimed at HER2-positive cancers as well as ADCs toward other cancer-specific targets.

1198 Development of a Faster Potency Assay for Evaluation of Immune Cell-mediated Cytotoxicity In Vitro

Sierra Barnes[1], Benjamin Streeter[1], Skylar Dewees[1], Denise Sullivan[1], Daniel Millard[2], Stacie Chvatal[1], **Danielle Califano[1]**, Henry Ordutowski[1]
[1]Axion BioSystems, Atlanta, GA, [2]Axion BioSystems, Inc., Atlanta, GA

Evaluating the effectiveness of CAR T cell therapy depends on reliable in vitro potency assays that measure the interaction between CAR T cells and cancer cells. Conventional methods typically require target cells to incubate for over 24 hours, which limits assay throughput and efficiency. In this study, we sought to significantly reduce assay duration by employing an impedance-based system to track the cytotoxic activity of CAR T cells against SKOV3 cancer cells. By comparing the standard protocol with an expedited approach that shortens the target cell resting period, we aim to develop a more time-efficient framework for potency testing—one that preserves accuracy while accelerating advancements in CAR T cell therapies. Beyond reducing overall assay time, introducing CAR T cells earlier in the process ensures that actual Effector to Target (E:T) ratios remain accurate by minimizing the opportunity for target cell proliferation. Here, we describe an in vitro potency assay that reduces the assay duration from over 72 hours to just 24 hours for immune cell-mediated cytotoxicity. SKOV3 target cells were seeded at

10,000 cells per well in a 96-well microplate equipped with embedded electrodes to monitor cell attachment and growth. HER-2 CAR T cells were introduced either 4 or 24 hours after SKOV3 cell seeding at various E:T ratios (1:10, 1:5, 1:2, 1:1, and 5:1). Killing kinetics were assessed by calculating Kill Time 50 (KT50), the time required to eliminate 50% of target cells. For target cells treated at 4 hours post-seeding, KT50 values were 92.5 ± 3.6 (1:10), 55.1 ± 21.9 (1:5), 20.6 ± 1.5 (1:2), 17.1 ± 0.7 (1:1), and 9.8 ± 0.7 (5:1) hours. In contrast, target cells treated at 24 hours post-seeding exhibited KT50 values of 154.2 ± 6.1 (1:10), 116.6 ± 7.2 (1:5), 84.5 ± 4.5 (1:2), 50.1 ± 2.8 (1:1), and 29.8 ± 0.7 (5:1) hours. As expected, earlier CAR T cell addition resulted in faster KT50 times due to reduced SKOV3 proliferation and more precise E:T ratios. At 24 hours post-CAR T addition, a dose-response curve was generated, determining EC50 values of an E:T ratio of 1:2.4 for target cells treated 4 hours post-seeding and 1:1 for those treated at 24 hours. Overall, these findings highlight a label-free, in vitro workflow using the Maestro Z impedance assay, providing a faster and more efficient method for assessing CAR T cell potency.

1199 Identification of Pharmacologically Relevant Species for IND-Enabling Toxicology Studies by Deep Comparative Transcriptomic Profiling of PBMCs Treated With Recombinant Human Payloads

Chris Lovejoy[1], Ethan Fenton[1], Tian Lee[1], Akela Kuwahara[1], Nathalie Clement[1], Nicole Paulk[1], Lauren Kelly[1]*
[1]Siren Biotechnology, San Francisco, CA
**Corresponding Author*

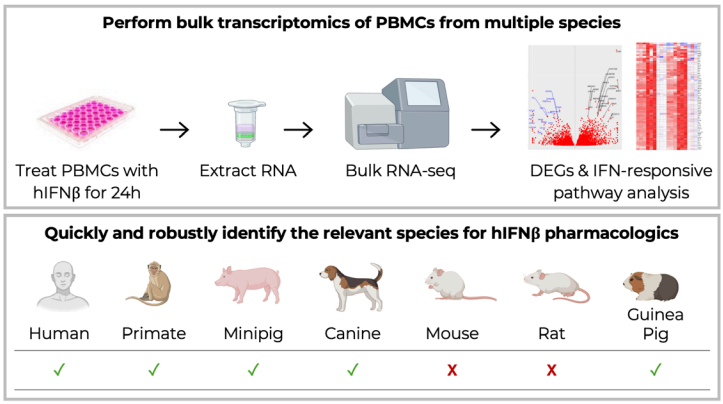
BACKGROUND: Identifying pharmacologically relevant animal species for toxicology assessments ensures study findings translate into safe human clinical trials. Siren Biotechnology has developed AAV vectorized cytokines as a novel modality for the treatment of solid tumors. As our cytokine payloads are predicted to exhibit species specificity, we developed an assay to identify pharmacologically relevant species for IND-enabling toxicology assessments. Here, we describe the methodologies and findings of this assay when implemented for an engineered human interferon beta (hIFNβ) transgene payload.

METHODS: We performed bulk transcriptomics of peripheral blood mononuclear cells (PBMCs) from human, primate, pig, canine, guinea pig, mouse, and rat donors following treatment with recombinant hIFNβ and classified each species as responsive or non-responsive. RNA was purified from PBMCs treated in triplicate with either 1,000 IU/mL (high dose) of hIFNβ, 100 IU/mL (low dose), or media alone, for 24h. Bulk transcriptomic profiling was performed by RNA-sequencing on an Illumina NovaSeq 6000 with 150 bp paired-end reads. Reads were aligned to the host species' genome using STAR v2.7.11b and counted using subread v2.0.6. Differentially expressed genes (DEGs) were identified relative to media alone and were considered significant if pAdj<0.01.

RESULTS: We first defined a target hIFNβ response signature based on the transcriptomic response of human PBMCs to hIFNβ. As expected, the human response was robust and dose-responsive (4,071 and 6,082 DEGs for low and high doses, respectively). Pathway analysis confirmed this response was Type I IFN signaling-specific, with 92% of genes from the 'Hallmark Interferon Alpha response' curated gene list being differentially expressed. The leading genes driving significance included overexpression of 3 key IFN response genes: STAT1, ZBP1, and ISG15. Mouse PBMCs were used as a negative control, as their IFNAR1 receptor (the receptor for IFNβ) is minimally cross-reactive to hIFNβ. Indeed, mouse PBMCs showed no significant treatment response (0 and 13 DEGs for low and high doses, respectively). Primate PBMCs were used to verify the method's sensitivity and accuracy to detect cross-reactivity, as primates are a "gold standard" toxicology species and have been used in nonclinical safety packages for approved hIFNβ drugs. Treated primate PBMCs showed robust and dose-responsive Type I IFN-specific transcriptomic changes, albeit with fewer DEGs than humans (192 and 821 genes for low and high doses, respectively). Excitingly, our screening approach also identified pigs, canines, and guinea pigs as highly cross-reactive alternatives to NHPs based on DEGs, hallmark pathway analysis, and consistent overexpression of STAT1, ZBP1, and ISG15. Like mice, rat PBMCs showed no significant transcriptomic changes in response to hIFNβ treatment.

CONCLUSION: We demonstrated that bulk transcriptomic profiling of cytokine-treated PBMCs can be used to quickly and robustly identify pharmacologically relevant species while bypassing development of costly species-specific reagents, enabling investigators to propose cost-effective and easier to source species alternatives to NHPs

for IND-enabling studies. This approach shows promising applications to guide species selection for other immunotherapeutic modalities or to justify the use of species-specific drug surrogates if a relevant species cannot be found.



1200 Fibroblast Activation Protein (FAP) Directed Bispecific Antibodies Target Pediatric Sarcomas

Julie Tomolonis[1], Elizabeth Garfinkle[1], Pin-Yi Wang[2], Chun-Yu Chen[3], Elaine Mardis[4], Timothy Cripe[5]*
[1]Nationwide Children's Hospital, Columbus, OH, [2]The Research Institute at Nationwide Children's Hospital, Columbus, OH, [3]The Research Institute at Nationwide Children's Hospital, Columbus, OH, [4]Nationwide Children's Hospital, [5]Nationwide Children's Hospital, Columbus, Ohio

Solid tumors contain a diverse tumor microenvironment (TME) that can drive cancer progression by secreting growth factors and signaling molecules that stimulate tumor proliferation, promote angiogenesis, invasion, and metastasis, remodel extracellular matrix, and drive immunosuppression and chemoresistance. Cancer associated fibroblasts (CAFs) are a critical stromal component of the TME that mediate these processes. CAFs have been well studied in adult tumors, but their prevalence and role in pediatric tumors has been largely unelucidated. A previously studied CAF target in adult tumors, fibroblast activation protein or FAP, is highly expressed on the cell surface of activated CAFs but has little to no expression on tissue fibroblasts and other cells throughout the body making it an ideal target for T-cell based cancer immunotherapy. Using bulk RNA sequencing datasets from Treehouse Childhood Cancer Initiative and internal sequencing of patient samples from the Institute for Genomic Medicine at Nationwide Children's Hospital, we screened a panel of pediatric tumors and controls for FAP expression, stromal score by ESTIMATE, and CAF content by EPIC. We identified that pediatric sarcomas showed the highest expression of FAP and had the highest stromal and CAF scores – with osteosarcoma (OS) leading the sarcomas tested. This is not unexpected as these tumors have previously been identified to have fibroblast-like properties and histology. We developed a bispecific antibody construct that combined the anti-FAP scFv from clone BIBH 1 (sibrotuzumab) with that of the anti-CD3 scFV LK2-07 (blinatumomab). To evaluate binding efficacy, we engineered a human fibrosarcoma cell line, HT1080, to overexpress FAP (HT1080-hFAP) compared to control vector (HT1080-Ctrl) to test FAP domain and human PBMCs to assess CD3 domain. We found that our construct specifically bound the overexpressed FAP on the HT1080-FAP line but not HT1080-Ctrl line in a dose-dependent manner. Similarly, our construct bound CD3 on T cells in a dose-dependent manner. Due to the high expression of FAP in OS, we tested a panel of OS cell lines and PDX models for FAP expression and found variable cell line dependent expression (ranging from no expression to high). To evaluate the killing efficacy of our bispecific antibody construct we performed an in vitro killing assay using the Incucyte system and co-cultures of target cells with human PMBCs. We found that our construct had efficient killing of target cells in a manner that was directly proportional to surface expression of FAP. Overall, we have identified that pediatric sarcomas contain a high proportion of CAFs and furthermore the that the tumor cells can express fibroblast surface markers, including FAP. We have developed a bispecific antibody that in combination with human PBMCs, successfully kills FAP-high expressing cells, while sparing those with no or low expression. Coupled with our lab's novel rAAV expression

system, this approach shows promise as a targeted therapy against CAFs and FAP-expressing sarcomas, though further in vivo studies are needed to assess its anti-tumor efficacy.

1201 Dual Costimulatory Receptors enhance antitumor immunity through cell -extrinsic and -intrinsic signals

Simonne Guenette[1]*, Ryma Toumi[2], Josh Veatch[3], Shannon Oda[2]*
[1]University of Washington, Seattle, WA, [2]Seattle Children's Research Institute, Seattle, WA, [3]Fred Hutch, Seattle, WA

Adoptive cell therapy (ACT) utilizing genetically modified T cells has shown clinical efficacy against some hematological cancers; but ACT success against solid tumors is limited by (1) immune suppressive states of innate immune cells, (2) lack of T cell costimulation in the TME, and (3) tumor heterogeneity. Dendritic cells (DCs) are innate immune cells that act as messengers between the innate and adaptive systems. DCs can infiltrate solid tumors, capture, and process tumor antigens, and catalyze an adaptive immune response. Flt-3 Ligand (FLT3L) can increase the number of immature DCs by facilitating their differentiation from precursor cells. After differentiation, DCs are licensed and activated into mature DCs through CD40 signaling, enhancing antigen-specific T cell priming, epitope spreading, inducing a more robust antitumor immune response. Drugs that systemically activate FLT3 and CD40 have shown clinical efficacy but have caused significant toxicity in non-tumor organs. Here, we propose a novel strategy to locally deliver these important signals - we developed novel engineered fusion proteins, Dual Costimulatory Receptors (DCRs), that are expressed on the surface of cytotoxic, tumor-targeted T cells, which localize to the site(s) of tumor. DCRs combine a FLT3L or CD40L ectodomain with different costimulatory endodomains (e.g. CD40, 4-1BB, OX40), to provide both T cell-extrinsic and -intrinsic costimulatory signals, respectively. We hypothesized that the combination of FLT3L and CD40L DCR-T cells would synergize to further enhance antitumor immunity against solid tumors. Through *in vitro* assays, we showed that DCRs provide cell intrinsic costimulatory signals that enhance T cell function. Additionally, FLT3L and CD40L DCRs functionally signal to increase DC frequency and maturation. In a murine pancreatic cancer model (KPC), CD40L and FLT3L DCR-T cell therapy significantly enhanced tumor control ($p<0.001$). DCR-T cells increased dendritic cell populations, induced maturation, and increased endogenous antitumor T cell responses. These results demonstrate innovative approaches to deliver immune-activating signals to an immunosuppressive TME.

1202 Persistent Genetic Modification of NK Cells Using Non-Integrating SMAR DNA Vectors for Cancer Immunotherapy

Enhancing the anti-tumour capability of NK cells via genetic modification remains a complex task. Current clinical studies primarily rely on retroviral and lentiviral transduction, which present significant limitations. NK cells are integral to the immune defense against viral infections and exhibit strong reactions to viral vectors, resulting in low transduction efficiencies. Furthermore, risks such as insertional mutagenesis and constraints on transgene size hinder the overall efficacy of viral transduction methods.

To overcome these obstacles, we have developed a DNA vector platform devoid of viral components, featuring a minimal bacterial backbone. These vectors are non-integrative and replicate extrachromosomally in the nuclei of dividing cells through the incorporation of Scaffold/Matrix Attachment Regions (S/MAR). This design offers a

promising alternative for the long-term, persistent genetic modification of NK cells while preserving genomic integrity.

Recognizing the inherent difficulty in transfecting NK cells, we optimized electroporation protocols and refined our SMAR vectors to enhance their performance. By combining a feeder-based expansion system with electroporation, we achieved transfection efficiencies of up to 70% in peripheral blood-derived NK cells with SMAR vectors expressing chimeric antigen receptors (CARs).

Additionally, we evaluated our vectors in the NK-92 cell line, which is widely employed in preclinical and clinical studies for NK cell-based cancer immunotherapies. We successfully established multiple NK-92 cell lines which stably express reporter genes or CARs targeting common tumor antigens such as CD19 and CEA. Transgene expression remained stable for at least six months and the CAR-NK-92 cells demonstrated enhanced and CAR-specific cell killing against target-expressing cancer cell lines, while their molecular phenotype remained unchanged. We found that our vectors typically establish at a single copy in NK92 cells.

During protocol development for NK-92 genetic modification, we observed significant variability among commercially available NK-92 cells from different manufacturers. The cells differ in their response to transfection with our vectors and to DNA sensing inhibitors, their transcriptomic profiles, and their killing ability against various cancer cell lines.

Our study underscores the potential of our non-viral vector system and refined transfection strategies in overcoming current limitations, paving the way for more effective and stable genetic modification of NK cells for cancer immunotherapy.

1203 NK-like Cells (GAIA-102) Induce Antitumor Adaptive Immunity via the Host NK derived IFN-γ

Situo Zheng[1], Yui Harada[2], Yosuke Morodomi[3], Kenta Ishimoto[4], Noriko Yasuda[4], Yoshikazu Yonemitsu[2]
[1]Kyushu University, Fukuoka, shigashi-ward, Japan, [2]Kyushu University, Fukuoka, Japan, [3]Fukuoka, Japan, [4]Kyushu University, Fukuoka, Fukuoka, Japan

Background: We have developed a novel cell therapeutic agent, GAIA-102, which exhibits an NK cell-like phenotype characterized by $CD3^-$/CD56bright/$CCR5^+$/$CCR6^+$/$CXCR3^+$/integrin-$\alpha1^+\alpha3^+\beta3^-$ expression and demonstrates significant anti-tumor activity in vitro. In previous studies, we evaluated the potential of GAIA-102 against solid tumors in various mouse models. While a marked reduction in tumor mass was observed in immunodeficient mice, the survival remained low at approximately 30%. By contrast, immunocompetent mice treated with GAIA-102 showed markedly improved survival rates (over 80%). In the subsequent second challenge test, mice that were completely cured were inoculated subcutaneously with the original tumor (CT26-GFP) and a third-party tumor (4T1). Specific rejection to CT26-GFP not 4T1, occurred in all cured individuals, indicating the establishment of tumor-specific adaptive immunity. However, the underlying mechanism remained unclear. IFN-γ, a crucial humoral factor known to activate and program the immune infiltrates in cancer vaccines and other immunotherapies, plays an uncertain role in the GAIA-102-induced immune response. Here, we aimed to evaluate whether IFN-γ is essential for the host immune response induced by GAIA-102.

Methods: We used a peritoneal dissemination model of mouse colon cancer (CT26-GFP) with repeated administration of GAIA-102. Since there is no cross-reactivity between human and mouse IFN-γ, we hypothesized that GAIA-102 would upregulate mouse-derived IFN-γ (mIFN-γ). To confirm this, we measured mIFN-γ levels in tumors, spleens, and lymph nodes on day 7 using ELISA. We then performed in vivo neutralization of mIFN-γ with anti-mIFN-γ antibody to assess its functional significance. Peripheral blood samples taken on day 7 and 17 were analyzed by flow cytometry for Ki67 expression in $CD8^+$T cells and for tumor-specific (tetramer-positive) T cells. Additionally, we investigated the role of host NK cells as potential producers of mIFN-γ by flow cytometry and evaluated the effect of NK cell depletion on $CD8^+$T cell response using GM1-asialo treatment.

Conclusion: GAIA-102 treatment led to a significant increase in mIFN-γ secretion in tumors, whereas no substantial level was detected in other immune organs. Notably, the marked rise in $Ki67^{+}CD8^{+}$T cells observed on day 7 was completely abolished following mIFN-γ blockage. By day 17, tumor-specific tetramer-positive $CD8^{+}$ T cells also diminished, emphasizing the crucial role of mIFN-γ in tumor control. Further investigation revealed that host NK cells infiltrating the tumors were the primary source of mIFN-γ. Consistent with this, GAIA–102–treated mice displayed increased NK cell numbers in both tumors and spleens. Depletion of NK cells suppressed the induction of proliferating and tumor-specific CD8+ T cells, highlighting the importance of the NK-derived IFN-γ (NK-IFN-γ axis) in promoting an effective immune response**.** Our findings demonstrate that the host adaptive immunity induced by GAIA-102 is dependent on the NK-IFN-γ axis and suggest that strengthening the interactions between T cells and NK cells may yield improved antitumor response in solid tumors.

1204 CRISPR-Guided Evolution of Oncolytic Virotherapies for Improved Delivery

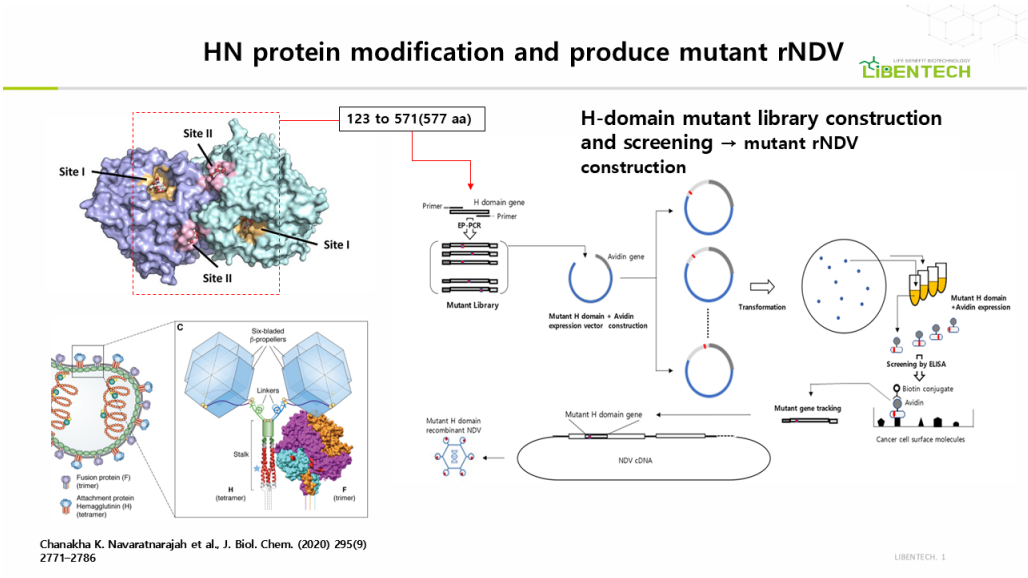
Adam Schieferecke[1], Hyuncheol Lee[2], Vindhya Kilaru[3], Yujung Park[1], Juan Hurtado Koolik[1], Kevin Rose[1], Nadia Kuxhausen Ralph[1], Priyam Baruah[1], John Dueber[1], David Schaffer[4]
[1]University of California, Berkeley, Berkeley, CA, [2]University of California Berkeley, Berkeley, CA, [3]University of California Berkeley, [4]University of California Berkeley, Berkeley, California

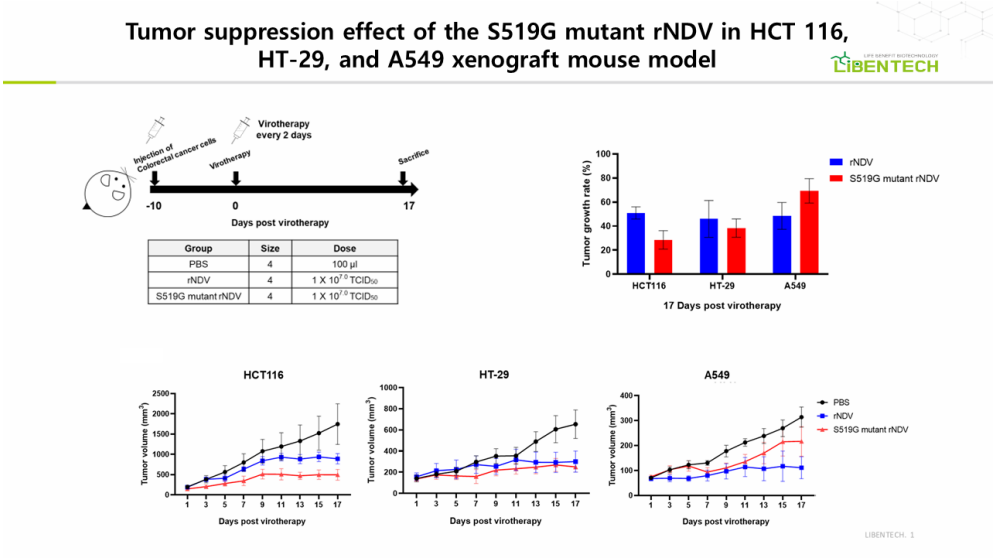
Directed evolution, the iterative process of genetic diversification and selection for genotypes that confer improved function, has been widely used to optimize small genome viral vectors for gene therapy. Nucleocytoplasmic large DNA viruses (NCLDVs) can deliver long genetic payloads, rendering them as promising candidates for vectored vaccines and oncolytic virotherapy. However, technological challenges for targeted diversification of NCLDV's complex genomes limit their amenability to be optimized by directed evolution using conventional DNA synthesis and cloning techniques. To address this challenge, we have developed CytoEvolvR, an RNA-guided, error-prone polymerase that localizes to and continuously diversifies cytoplasmic DNA in cells. Next-generation sequencing and fluorescence conversion assays showed that optimized versions of CytoEvolvR generated tunable, multiplexable, site-specific, and non-PAM-constrained diversification to all four nucleotides within endogenous loci of a double-deleted oncolytic vaccinia vector. CytoEvolvR-mediated diversification of a vaccinia surface protein, A34R, coupled with selections for extracellular enveloped vectors uncovered a novel variant that enabled increased survival and decreased tumor burden in syngeneic mouse models of colorectal cancer. Moreover, CytoEvolvR screening uncovered a previously unknown protein that is expressed from an open reading frame overlapping with the A34R gene and has fitness implications in the viral replication cycle. Accordingly, CytoEvolvR is a powerful tool for rapidly improving the therapeutic properties of oncolytic virotherapies and elucidating new biology.

1205 Molecular modification of viral surface protein enhances targeting ability of oncolytic virus

Hyun Jang[1], Sunn hee Kim[2]
[1]Libentech Co.LTD., Daejon, Korea, [2]Libentech Co. LTD, YUSUNGGU, DAEJON, South Korea

Oncolytic viruses represent a promising therapeutic approach for cancer treatment due to their selective targeting and destruction of cancer cells. However, enhancing their specificity for certain tumor types remains a critical challenge. This study utilized directed evolution to modify the hemagglutinin-neuraminidase (HN) surface protein of Newcastle Disease Virus (NDV), aiming to improve its targeting ability toward colorectal cancer cells. A mutant library of the HN protein was generated using error-prone PCR and screened for affinity to HCT 116 colorectal cancer cell surface proteins. The S519G mutation was identified as significantly increasing specificity and binding affinity for HCT 116 cells. Recombinant NDV (rNDV) incorporating the S519G mutation (S519G rNDV) exhibited enhanced oncolytic effects and higher tumor specificity in vitro and in xenograft mouse models compared to wild-type rNDV. Tumor suppression was most pronounced in HCT 116 xenografts, achieving a 71.6% reduction in tumor volume. Importantly, the mutation did not alter the pathogenicity of NDV, as demonstrated by intracerebral pathogenicity and median death time tests. This research highlights the potential of molecular modification of viral surface proteins to improve the tumor-targeting specificity of oncolytic viruses, paving the way for more effective cancer therapies.





1206 Using primary cell culture models to study adenoviral vectors for virotherapy of head and neck squamous cell carcinoma

Inga M.C. Seute[1], Goar Agabekian[2], Katrin Schröer[3], Lisa-Marie Dawson[4], Julius Knierer[5], Ryan Lampe[6], Markus Ruwe[7], Jonas Park[1], Anja Ehrhardt[8], **Eric Ehrke-Schulz[9]**

Introduction: Adenoviruses (AdVs) are investigated as oncolytic adenoviral vectors (OAdV) and for tumor gene therapy (TGT). Antitumor effects can be enhanced by expression of effectors such as gene editing tools or immune

modulators. Head and neck squamous cell carcinomas (HNSCC) have a poor prognosis, are difficult to treat or resect and common treatments cause severe side effects. Moreover, a portion of HNSCC is HPV positive. As HPV oncogenes can complement OAdV replication, HPV related cancers potentially support and enable OAdV-mediated tumor lysis. Therefore, HNSCC are interesting targets for OAdVs therapy. As HNSCC are heterogeneous with regard to HPV status and other biomarkers and response to treatment, we aimed to address these individual differences between patients by establishing primary patient derived tumor cell cultures to identify characterize novel improved AdV vectors for HNSCC. AdV vectors are mostly based on AdV5, having limited applicability due to high seroprevalence and strong liver tropism. Alternative AdV serotypes might have beneficial features for the treatment of HNSCC such as transduction efficiency and oncolytic potential and can be used as OAdV or for TGT instead of AdV5.

Methods: Following tumor resection we established a pipeline for primary patient derived tumor cell cultures to study their response to AdVs. Using a library of reporter gene expressing AdV serotypes representing the natural diversity of human AdVs, we investigate the potential of alternative AdVs Serotypes for oncotherapy of HNSCC. Transduction of individual primary HNSCC cell cultures with reporter gene expressing AdV library identified AdV candidates with improved transduction and gene expression as well as inhibitory effects on tumor cell viability. Selected serotypes were vectorized by replacing AdVE1 promotor with hTert Promotor and armed with AdV death protein or P19. Subsequently their oncolytic properties in primary HNSCC cells were compared to their AdV5 based counterpart.

Results: Transduction of individual primary cell cultures with different AdV serotypes and comparison of reporter gene expression and the effects on tumor cell viability identified AdV4, 21, 34, and 35 and 37 as superior to AdV5 in HNSCC even though we observed differences from patient to patient and differences in transduction and cell killing efficiency between the different serotypes. AdV4, 14, 21, 34, and 35 were vectorized and armed. Comparison of their oncolytic potential in established and primary HNSCC cultures revealed 10 to 100 fold improved tumor cell killing in vitro.

Discussion: Our primary tumor cell culture pipeline in combination with our reporter gene expressing AdV library allowed identification and vectorization of improved AdV vectors. Newly developed armed OAdV based on alternative serotypes are promising candidates to improve oncolytic therapy or TGT for HNSCC. Investigation of HPV status and AdV receptor expression of primary tumor cells and cells and collection of disease-relevant patient information will allow to correlate these findings with the outcome of AdV transduction experiments. In the future, this will enable us to predict treatment outcomes and to choose the optimal OAdVs for each individual HNSCC patient. The combination of OAdV treatment with radiation and chemotherapy will give insights on the influence of pretreatments on the potential response towards viral tumor therapy.

1207 CF33-hNIS Alone and Combined with Anti-PD-L1 Eliminates Gastric Cancer Peritoneal Metastasis in an Immunocompetent Mouse Model

Annie Yang[1], Zhifang Zhang[2], Anthony Park[3], Shyambabu Chaurasiya[3], Sang-In Kim[4], Jianming Lu[4], Hannah Valencia[4], Courtney Chen[5], Yanghee Woo[6], Yuman Fong[3]
[1]City of Hope Inc, Duarte, CA, [2]City of Hope National Medical Center, Duarte, CA, [3]City of Hope, Duarte, CA, [4]City of Hope National Medical Center, [5]Cedars Sinai, Los Angeles, CA, [6]City of Hope Medical Center, Duarte, CA

INTRODUCTION: Peritoneal metastasis (PM) from gastric cancer (GC) is fatal. Despite improved survival with the addition of anti-PD-L1 therapy to systemic chemotherapy, majority of GCPM patients have tumors with genomic stability, low tumor mutational burden, and anti-tumor immunogenic inactivity, leading to immunotherapeutic failure. To overcome these barriers, we are developing a peritoneal-directed strategy using oncolytic virus (OV) combined with anti-PD-L1.

METHODS: CF33-hNIS, a novel orthopoxviral chimera was used to treat five human (intestinal-type: AGS and MKN-74; diffuse-type: KATO-III, MKN-45 and SNU-16) and 2 murine (ACKPY3944 and ACKPY4113) GC cell lines at various multiplicities of infection (MOI 0.01, 0.1, 1.0 and 10.0). Standard plaque and cell proliferation assays were performed for viral replication and cytotoxicity. Cell surface and intracellular expression of PD-L1 were

evaluated by flow cytometry. ACKPY3944 cells derived from transgenic mice (KRAS G12D mutant/CDH-1 attenuated) were transfected with ffluc (ACKPY3944-ffluc), and 10^6 cells were injected IP (day 0) to establish a reproducible PM model in C57BL/6 mouse. We separately evaluated immunogenicity and anti-tumor efficacy, and overall survival in these mice. First, we compared 4 different cohorts: (A) IP PBS, (B) IV anti-PD-L1, (C) IP CF33-hNIS ($3x10^7$ pfu, days 3, 5, 7), (D) IP CF33-hNIS ($3x10^7$ pfu, days 3, 5, 7) + IV anti-PDL-1. Peritoneal fluid/washings were collected on days 5, 9, and 21 and analyzed by flow cytometry and immunohistochemistry for immune cell changes. Then, we compared 6 cohorts: (A) IP PBS, (B) IP anti-PD-L1, (C) IP CF33-hNIS ($3x10^7$ pfu, day 3, 5, 7), (D) IP CF33-hNIS ($3x10^7$ pfu, day 3, 5, 7) + IP anti-PDL-1, (E) IP CF33-hNIS (10^8 pfu, once), and (F) IP CF33-hNIS (10^8 pfu, once) + IP anti-PD-L1. Survival was observed daily, and peritoneal tumor burden was monitored weekly using bioluminescence.

RESULTS: CF33-hNIS infected, replicated in, and killed both human and mouse GC cell lines in a time and dose-dependent manner. While no differences in oncolytic viral properties were observed between diffuse- versus intestinal-type human GC cell lines, greater antitumor efficacy was seen against human versus mouse GC cells. We confirmed endogenous PD-L1 expression in ACKPY3944 and ACKPY4113 cells. Compared to PBS control, IP CF33-hNIS transiently but significantly increased the total CD45+ leukocytes, CD3+ T cells, and CD8+ T cells in the peritoneal cavity on day 9. All IP CF33-hNIS cohorts (alone or combined with IP anti-PD-L1) prolonged mouse survival. A one-time high dose of IP CF33-hNIS (10^8 pfu) + IP anti-PD-L1 showed the highest efficacy against peritoneal tumors with 6 of 8 survivals for 112 days (Figure 1). In contrast to PBS (0 survival), IP anti-PD-L1 (0 survival), cohorts treated with 3 doses of $3x10^7$ CF33-hNIS had 3 survivals; 3 doses of $3x10^7$ CF33-hNIS + IP anti-PD-L1 had 4 survivals; and one dose of 10^8 CF33-hNIS had 2 survivals.

CONCLUSION: CF33-hNIS exhibits robust anti-tumor activity against GCPM, transiently upregulating PD-L1 with immune activation. Combining a one-time high dose of IP CF33-hNIS with IP anti-PD-L1 eliminated peritoneal tumors and prolonged survival in an immunocompetent mouse model. These results demonstrate the robust potential of CF33-hNIS against GCPM.

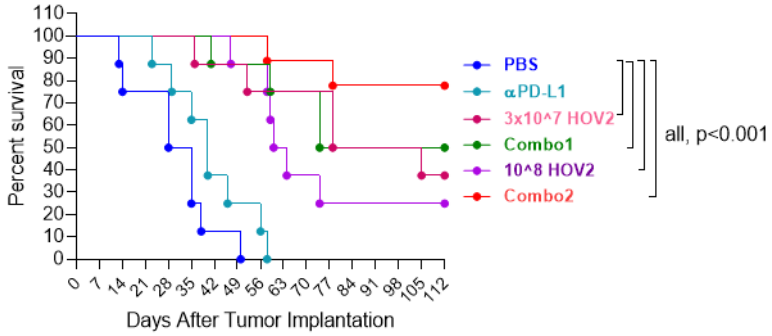

Figure 1. Intraperitoneal (IP) delivery of CF33-hNIS with anti-PD-L1 cure gastric cancer peritoneal metastasis in an immunocompetent mouse model. Kaplan-Meier survival analysis of ACKPY3944 peritoneal tumor-bearing mice following treatment with IP CF33-hNIS with or without IP anti-PD-L1 or PBS control. *** p<0.001. Note: Combo1 = CF33-hNIS ($3x10^7$ pfu, three times) plus anti-PD-L1 antibody, Combo2 = CF33-hNIS (10^8 pfu, one time) plus anti-PD-L1 antibody.

1208 Intraperitoneal Delivery of Chimeric Orthopoxvirus CF17 Improves Survival in a Syngeneic Mouse Model of Gastric Cancer Peritoneal Metastasis.

Zhifang Zhang[1], Annie Yang[2], Anthony Park[3], Shyambabu Chaurasiya[3], Sang-In Kim[4], Jianming Lu[4], Hannah Valencia[4], Courtney Chen[5], Yuman Fong[3], Yanghee Woo[6]
[1]City of Hope National Medical Center, Duarte, CA, [2]City of Hope Inc, Duarte, CA, [3]City of Hope, Duarte, CA, [4]City of Hope National Medical Center, [5]Cedars Sinai, Los Angeles, CA, [6]City of Hope Medical Center, Duarte, CA

INTRODUCTION: Peritoneal metastasis (PM) from gastric cancer (GC) remains lethal despite improved systemic therapies. Peritoneal-directed therapies are under investigation to improve the survival of GCPM patients who have a 2% five-year overall survival. CF17 is a novel chimera with a unique genome created by the random recombination of nine orthopoxvirus species. We investigated the antitumor effects of CF17 on mouse GC cell lines in vitro and in a syngeneic mouse model of GCPM.

METHODS: We infected two mouse GC cell lines (ACKPY3944 and ACKPY4113) with CF17 or CF17-GFP and analyzed infection, replication, and cytotoxicity using immunofluorescence microscopy and standard plaque and cell proliferation assays. We further established an immunocompetent GCPM mouse model in C57BL/6 mice by intraperitoneal (IP) inoculation of ACKPY-3944-ffluc cells ($1x10^6$). These mice were intraperitoneally treated with either PBS (n=11) or $3x10^7$ pfu CF17 (n=11) on days 3, 5, and 7. Peritoneal tumor progression and tumor burden were monitored weekly using bioluminescence imaging. Each group was further divided into two groups: one for analyzing immune cell changes by flow cytometry and immunohistochemistry by collecting peritoneal washings and tumor (day 9; n=3); and another for observing survival (n=8).

RESULTS: CF17 infected and replicated in ACKPY3944 and ACKPY4113 cells with GFP expression of CF17-GFP and more than 4-log increase viral titers of CF17 than control after 72-hour infection. Treatment with CF17 showed anti-tumor activity in a dose and time-dependent manner (91% cell killing on day 5 of MOI=1 *vs.* 95% cell killing on day 3 of MOI=10). In the syngeneic GCPM mouse model, IP CF17 continued to decrease tumor burden between days 7 to 21 ($P<0.05$) and prolonged survival ($P<0.001$), with an average survival of 41.5 days (CF17) *vs.* 18.7 days (PBS). IP CF17 also significantly increased leukocyte infiltration into the tumor microenvironment of the peritoneal cavity, which included CD45+ cells (2.5x), CD3+ cells (5.1x), CD8+ cells (10.1x), and into the solid tumors, which included CD8+ cells and CD4+ cells.

CONCLUSION: IP CF17 shows effective anti-cancer potential in an immunocompetent GCPM mouse model with significant antitumor activity and survival benefit. A significant increase of CD8+ T cells in the tumor microenvironment of the peritoneal cavity and tumors after IP CF17 treatment suggests that CF17 may increase the immunogenicity of the peritoneal tumors.

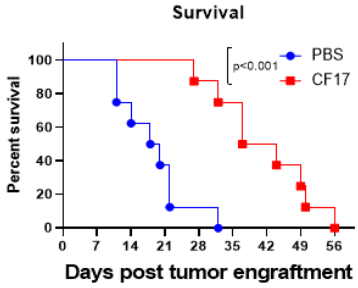

Figure 1. Intraperitoneal (IP) CF17 treatment improves survival. Kaplan-Meier survival analysis of IP ACKPY3944 tumor-bearing mice following treatment with IP CF17 or PBS control. P<0.001

1209 Arming an RNA-Based Oncolytic Picornavirus Platform Using LNPs for Replicon Co-Delivery

Kyla Boyd[1], Rebecca Nace[2], Caitessa Venables[3], Velia Penza[4], Autumn Schulze[4]
[1]Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN, [2]Mayo Clinic in Rochester, [3]Mayo Clinic, Rochester, Minnesota, [4]Mayo Clinic, Rochester, MN

Oncolytic virotherapy is the use of viruses to treat cancer. With their lytic and immunogenic lifecycles, picornaviruses are excellent candidates for oncolytic vector development with several being explored in clinical

settings. However, the strict genome size limitation of these viruses prevents efficient gene insertion for arming. Since picornavirus genomes are inherently infectious, vector constructs can be delivered without a capsid, enabling the use of non-viral carriers like lipid nanoparticles (LNPs) for co-delivery of external RNA expression constructs. One such construct is the replicon, a modified picornavirus genome in which the capsid proteins are replaced with a transgene. Without the structural proteins, they act as self-amplifying expression vectors but cannot spread beyond the initially transfected cell. If the capsid proteins are provided in trans, replicons can be packaged. Thus, co-delivery of virus genome and replicon can facilitate the spread of transgene expression with the virus without directly encoding the gene within the genome. Previous studies, including our own, have demonstrated the feasibility of formulating oncolytic picornaviruses as infectious RNA (iRNA) using Coxsackievirus A21 (CVA21), a clinically developed oncolytic virus. However, preclinical evaluation in immunocompetent models is limited, as mice are not a natural host for CVA21. In contrast, mengovirus can be explored in unmodified immune competent mice. Previously, we showed a significant improvement in overall survival with our optimized mengovirus viral platform, MC_0NC, in an immune competent murine MPC-11 model. Here, we use an attenuated mengovirus construct, MC_0R, optimized for replication as an iRNA platform. MC_0R is attenuated via deletion of the polyC tract, a known virulence factor, and inclusion of microRNA-target sequences corresponding to tissues of pathogenicity. Specific infectivity, translation, and cytotoxicity of the iRNA were evaluated *in vitro*. *In vivo* studies determined the efficacy via disease burden and survival. Mice bearing MPC-11 subcutaneous tumors were treated intratumorally with empty LNPs or LNPs containing MC_0R iRNA or luciferase expressing replicons (MC_0R-fLuc). MC_0R iRNA, *in vitro*, demonstrated specific infectivity, translation, and cytotoxicity similar to unmodified genomes. *In vivo*, the MC_0R-LNP treated groups showed control of tumor growth, improved overall survival and measurable viremia compared to empty and MC_0R-fLuc LNP treated groups. MC_0R-fLuc treatment showed minimal therapeutic efficacy but resulted in consistent intratumoral expression 6hrs following treatment with a small amount of expression maintained out to 24hrs. *In vivo* studies are ongoing to determine the impact of iRNA and replicon co-delivery. Overall, oncolytic picornavirus iRNAs delivered by non-viral vectors can elicit therapeutic efficacy, and self-amplifying RNA alone is not enough to achieve the same effect. Further, replicons can act as short-term expression vectors. This work supports the continued development of mengovirus as an RNA-based oncolytic virus platform and the use of replicons as RNA-based arming factors.

1210 In Vivo Efficacy of a NIS-expressing Oncolytic Adenovirus for Colorectal Cancer Treatment

Stacey Wilber[1], Sacha Robert[2], Margarita Romanenko[2], Julia Davydova[3], **Christopher LaRocca[4]***
[1]University of Minnesota, Minneapolis, [2]University of Minnesota, Minneapolis, MN, [3]UMN, Minneapolis, Minnesota, [4]University of Minnesota, Minneapolis, Minnesota
**Corresponding Author*

Introduction: Colorectal cancer (CRC) remains a leading cause of cancer-related death throughout the world. Many patients develop metastatic disease, but conventional therapies are often not effective at treating these advanced malignancies. Therefore, novel therapeutics are needed, and our group is investigating oncolytic adenoviruses (OAd) as a novel treatment approach.

Methods: Our research group has designed an oncolytic adenovirus which expresses the sodium iodide symporter (NIS) with each cycle of viral replication (OAd-NIS). Using multiple human CRC cell lines, the viral vectors were evaluated for optimal fiber structure, cytocidal effects, and transgene expression. Murine models were also utilized to test the therapeutic effect of the virus in addition to its ability to enable radiotracer (^{124}I) uptake and imaging in human CRC tumors.

Results: As we have previously described, the adenovirus employs the ΔE3 NIS backbone structure. Our *in vitro* studies in multiple human CRC cell lines demonstrated that the Ad 5/3 chimeric fiber is optimal for virus binding and transduction. Crystal violet cell viability assays demonstrated strong cancer-killing effects across all tested cell lines at early time points with low viral doses. Importantly, *in vitro* immunohistochemical staining demonstrated strong NIS expression. Human CRC xenografts (LoVo cell line) were established in the flanks of nude mice and then treated with a single, intratumoral dose of OAd-NIS. After radiotracer (^{124}I) administration via an intraperitoneal route, small animal PET/CT images were acquired with the Sofie G8 system and demonstrated high

levels of signal within the flank tumors. The avid signal in the tumors confirms the ability of the OAd-NIS virus to facilitate *in vivo* NIS expression to enable radioiodine uptake, and this was correlated with viral copy number via PCR analysis. A separate experiment was conducted with LoVo subcutaneous xenografts in nude mice, where they were treated with multiple injections of virus ($1x10^9$ pfu on Days 0 and 3). The OAd-NIS group demonstrated robust and statistically significant tumor growth suppression when compared to the PBS control group.

Conclusion: Our OAd-NIS virus demonstrates excellent transduction efficiency, transgene expression, and cell-killing effects in CRC cell lines. Strong NIS expression in our murine models enables PET/CT imaging with radioactive iodine and highlights the ability of the virus to support radionuclide-based imaging for CRC. The *in vivo* tumor growth suppression demonstrated by our murine model suggests a high potential for clinical translation of the OAd-NIS virus to be used as part of a novel regimen for CRC treatment. Future studies will test the effects of the virus in combination with radioiodine ^{131}I.

1211 Intraperitoneal Administration of The CD133-targeted Oncolytic Adenovirus Suppresses Peritoneal Metastases of Colon Cancer in Mouse Xenograft Model.

Mizuho Sato-Dahlman[1], Praveensingh Hajeri[2], Kari Jacobsen[1], Brandon Hitchcock[1], Masato Yamamoto[3]
[1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Circle Pines, MN, [3]University of Minnesota, Minneapolis, Minnesota

Introduction: Colorectal cancer (CRC) is the third most common cause of cancer-related death in the US, and about 20% of patients with local advancement develop peritoneal metastasis (PM) during follow-up. The 5-year survival for patients with PM is limited to @14%. The patients with PM who had previously been treated with chemotherapy frequently show resistance to chemotherapy regimens, and their prognosis after acquiring resistance is dismal. It is therefore critically important to develop novel therapeutic approaches for targeting treatment-resistant cells toward improved prognosis and quality of life for CRC patients with PM. Cancer stem cells uniquely contribute to establishment of metastases, recurrence, and treatment resistance. It has been demonstrated that a variety of cancer treatments increase expression of CD133, and these CD133-positive ($CD133^+$) cells contribute to the acquisition of treatment resistance. Interestingly, elimination of $CD133^+$ cells restores the sensitivity to chemotherapy in CRC. We therefore hypothesize that the development of a novel approach eliminating $CD133^+$ cells would lead to a more effective treatment of CRC with PM.

Methods: We used CD133-targeted oncolytic adenovirus to eliminate CD133-positive cells. We generated CD133-targeted OAd (CD133-OAd) by using our adenovirus-based library screening system. We evaluated the target specificityof the virus *in vitro* and *in vivo* analysis. For in vitro analysis, we used binding assay and cell killing assay with CD133-positive or CD133-negative CRC cell lines. As a proof of concept, the *in vivo* theraputic potential of the CD33-OAd was investigated in a mouse peritonerally metastatic colon cancer model with 2 CD133-positive CRC cell lines (HCT116 and LoVo). Luciferase-labeled cells were inoculated intraperitoneally into mice, and treatment started 5 days post cell inoculation. On day 6, mice with tumors were divided into 4 groups: PBS intraperitoneal (i.p.) injection (200ul, 3 times), wild-type Adenovirus type 5 (Ad5-WT), CD133-OAd, and integrin-targeted OAd (RGD-OAd) i.p. injection (1×10^{10}vp/200ul, 3 times). All mice were monitored by IVIS imaging once a week to confirm and track tumor growth.

Results: Binding and cell killing assay confirmed that the CD133-OAd selectively infected CD133-positive cells and lysed them efficiently. *In vivo* anti-tumor assay demonstrated that CD133-OAd significantly suppressed the peritoneal metastasis of CD133-positive CRC cells compared to administration of PBS or RGD-OAd. The survival of mice with PM was significantly increased by treatment with CD133-OAd compares with PBS, Ad5-WT, or RGD-OAd treatment. Interestingly, Adenovirus type 5 (Ad5-WT) showed anti-tumor activity, and its level was comparable with CD133-OAd. However, Ad5-WT injected mice started to show severe toxicity. At necropsy of Ad5-WT injected mice, all of the mice showed abdominal adhesion. While the level of IL-6 and TNF-alpha in serum were significantly high in Ad5-WT injected mice, the level in CD133-OAd injected mice were similar to the control mice.

Conclusions: Intraperitoneal administration of CD133-OAd has therapeutic potential to suppress the peritoneal metastasis in mouse model without significant toxicity, resulting in prolonged survival.

1212 ML-Driven Design of Lipid Nanoparticles for In-Vivo T-Cell Delivery

Nir Suissa[1], Lee Danan Goldfryd[2], Guy Rosin[3], Igor Nudelman[2], Amit Benazraf[4], **Alex Lagadinos[5]**, Yogev Debbi[6]
[1]Mana.bio, Tel Aviv, Tel-Aviv, Israel, [2]Mana.bio, Haifa, Haifa, Israel, [3]Mana.bio, Binyamina, HaZafon, Israel, [4]Mana.bio, Tel Aviv-Yafo, Tel-Aviv, Israel, [5]Mana.bio, Boston, MA, [6]Mana.bio, Bat yehoshua, HaZafon, Israel

T-cell-based immunotherapies like CAR-T have revolutionized cancer treatment, offering life-saving treatment for patients with refractory cancers. However, high manufacturing costs, challenging supply chains, labor-intensive ex-vivo manipulation, and prerequisite lymphodepletion limit scalability. In-vivo mRNA delivery to reprogram T-cells directly within the body offers a potentially transformative alternative by streamlining production, reducing costs, and broadening patient access. However, developing efficient delivery systems to target T-cells remains a critical challenge.

To address the complexity of lipid nanoparticle (LNP) development, Mana.bio has created a machine learning-driven platform to optimize LNPs for T-cell transfection in-vivo and ex-vivo. Our platform integrates over 80,000 data points from proprietary experiments and 45,000 from public literature, using advanced ML algorithms to screen ~50 million formulations. The model demonstrates high performance with predicted T-cell transfection accuracy (MAE: 3.72, Pearson correlation: 0.83) and T-cell viability (MAE: 13.71, Pearson correlation: 0.72), effectively predicting lipids and LNP compositions based on key parameters. These algorithms rapidly identify LNP candidates for therapeutic development based on physicochemical properties, toxicity profiles, and the likelihood of successful T-cell transfection. Initial validation using eGFP mRNA showed over 90% transfection efficiency in activated CD3+ T-cells from human peripheral blood mononuclear cells (hPBMCs) within 24 hours, with >80% cell viability, effectively outperforming an industry-standard immune cell-transfection reagent at the same dose. Notably, our LNPs also maintained high transfection efficiency (70%) in non-activated CD3+ hPBMC T cells. Mana's formulations exhibited enhanced transfection efficacy compared to MC3, a clinically validated LNP, as well as toxicity profiles assessed by measuring TNF-α, IL-1β, and IL-6 levels in both activated and non-activated hPBMCs 24 hours post-treatment. In-vivo activity was validated in NSG mice injected with hPBMCs three days before LNP administration, and eGFP expression was evaluated in blood, spleen, lung, and liver after 24 hours. The results demonstrated successful transfection, with lead LNP candidates yielding ~25% transfection in CD3+ T-cells. Lead formulation preferentially transfected subsets of CD4+ and CD8+ T cells with our leading formulation, achieving 18% and 24% transfection, respectively. Spleen analysis exhibited a 10% transfection rate of CD3+ T-cells. Immuno-histological analysis of liver tissues revealed minimal to no eGFP expression, while flow cytometry analysis of lung sections showed only 1% of lung cells transfected with eGFP; thus demonstrating selective T-cell targeting in-vivo.

Our ML-driven optimization model and custom-designed LNPs enable highly specific T-cell targeting with low toxicity. Beyond CAR-T, this technology has therapeutic potential in autoimmune and infectious diseases, where targeted T-cell reprogramming is crucial. By integrating advanced computational modeling and experimental data, Mana.bio is laying the foundation to unlock the potential of RNA delivery, accelerate therapeutic development, and enable next-gen immunotherapies.

1213 A novel polymeric gene delivery platform to precisely target and reprogram cells *in vivo* for haematological malignancies & beyond

Alice COILLARD[1], Julie BERGALET[1], Marion LHUAIRE[1], Eva MAUNICHY[1], Laurence SELLIER[1], Inès Morouche, Céline Jaudoin[2], Alexandre Da Silva, Léa DANDAN[1], Sarra LESCHIUTTA, Elina Rosoy, Justine Hadjerci, Rachel PACHERIE[3], Frederic Mourlane, Renaud VAILLANT[4], Cecile Bauche[4]*
[1]Alaya.bio, PARIS, Paris, France, [2]Alaya.bio, Antony, Paris, France, [3]Alaya.bio, VILLEJUIF, Val-de-Marne, France, [4]Alaya.bio, Paris, Ville de Paris, France
**Corresponding Author*

With seven marketed products and more than 900 ongoing clinical trials, CAR-T cells have revolutionized blood cancer treatment by targeting and eliminating B cells. However, their *ex vivo* manufacturing remains complex, costly and directly impacts the fitness and efficacy of engineered cells. *In situ* CAR-T therapies emerged as promising alternatives but face challenges such as off-targeting, immunogenicity, and viral particle potency.

Alaya.bio is a preclinical-stage biotechnology company developing a scalable gene delivery platform to target and reprogram cells *in situ* using nanoparticles consisting of engineered lentiviral vectors coding for various payloads and coated with cationic and shielding biodegradable polymers. Up to 20 monodispersed nanoparticles were successfully formulated with different surface potentials, excellent batch-to-batch consistency and stable gene delivery in human cell models relevant for gene and cell therapies.

Here we report on nanoparticles consisting of lentiviral vectors lacking the VSV-G immunogenic protein and encoding CD19 CARs or GFP coated with poly(beta-amino ester)s biodegradable polymers with or without a polysarcosine lipid shielding polymer allowing the bioconjugation with CD3-targeting agents. *In vitro*, we achieved long-term, dose-dependent expression and integration after exposure of human cell lines to PBAE-based nanoparticles. Interestingly, cell toxicity was directly linked to the quantity of cationic polymers used in the formulations. In addition, the stability of the polymeric nanoparticles was confirmed biophysically in various cell culture media with or without serum. Importantly, stable delivery of the transgene was achieved in human primary T cells without the need of CD3/CD28 activation addition normally required for transduction with classical lentivectors.

In vivo, the biodistribution of nanoparticles has been investigated in immunocompetent and humanized mice after multiple intravenous administrations or infusions and showed a different profile compared to pseudotyped lentivectors. Long-term expression of GFP or CAR transgenes was detected in blood leukocytes up to 80 days post-treatment. The pronounced tropism for blood cells observed *in vivo* with our polymeric nanoparticles provides an obvious advantage for CAR T-cell therapy of blood malignancies. Repeat administration was safe and well tolerated as no obvious sign of distress, body weight loss, hepatotoxicity, change in blood cell count or cytokine levels were reported. Preliminary efficacy data have shown in healthy Balb/c mice that repeat administration of anti-CD19 CAR encoding nanoparticles induced B cell depletion. In mice with A20-induced lymphoma, repeat treatment cycles showed promising anti-cancer efficacy and reinfusion at relapse was possible.

To conclude, this technology shows great potential for further preclinical and clinical development of *in situ* universal CAR T-cell therapy. In addition, Alaya.bio's versatile platform offers the potential to target and reprogram a broad range of therapeutic cells beyond the immuno-oncology field and treat genetic disorders.

1214 LENTIVIRAL VECTOR ENGINEERING WITH POLYMER SURFACE MODIFICATION FOR CAR-T CELL THERAPY

Céline Jaudoin[1], Justine Hadjerci[2], Alexandre Da Silva[2], Julie BERGALET, Léa DANDAN, Sarra LESCHIUTTA, Elina Rosoy[2], Alice COILLARD, Laurence SELLIER, Marion LHUAIRE, Eva MAUNICHY, Inès Morouche[2], Rachel PACHERIE[3], Frederic Mourlane, Renaud VAILLANT[4], Cecile Bauche[4]*
[1]Alaya.bio, Antony, Paris, France, [2]alaya.bio, Paris, Paris, France, [3]Alaya.bio, VILLEJUIF, Val-de-Marne, France, [4]Alaya.bio, Paris, Ville de Paris, France
**Corresponding Author*

CAR-T cells have revolutionized blood cancer treatment by targeting and eliminating B cells. However, their *ex vivo* production remains complex and costly. *In situ* therapies emerged as promising alternatives but face challenges such as off-targeting, immunogenicity, and viral particle potency. Alaya.bio's technology combines biodegradable polymers with lentivectors (LVs). Our VSV-G-deficient LVs lack cell transduction ability until coated with pH-responsive cationic polymers, while modification with shielding polymers enhances stability and allows bioconjugation with targeting agents.

Alaya.bio's LVs lacking VSV-G immunogenic protein are engineered and manufactured through a scalable and reproducible GMP-compatible bioprocess. In addition, we developed high-throughput biophysical read-outs using

among others DLS and interferometry allowing us to screen 40 families of biocompatible cationic and shielding polymers with various shapes (linear, star, dendrimers), nature (polyamino acids, polysaccharides, poly β-amino esters (PBAE), polyethylenimine-derived polymers), molecular weights, and pK_A values. These polymers were used to formulate monodisperse LV-based nanoparticles with controlled biophysical characteristics (Dh<300 nm and PdI<0.3). Two surface modification strategies were compared: layer-by-layer coating with cationic/anionic polymers and self-assembled coating with shielding lipid/cationic polymers. For layer-by-layer coating, key parameters included mixing process, buffer composition, salt concentration, and polymer molecular weight. Coating optimization involved pH and polymer concentration adjustment to achieve surface saturation while minimizing cytotoxicity. Polysarcosine lipid self-assembled coating resulted in monodispersed particles with shielding properties. Subsequent cationic coating produced stable nanoparticles with positive zeta potential requiring lower polymer concentrations.

So far we have developed over 20 polymeric nanoparticles with different surface potentials and confirmed the excellent batch-to-batch consistency according to biophysical and functional characteristics. Each formulation specific parameters were easily transposed to various lentiviral vector batches coding either for GFP and several CD19-CAR constructs, reflecting the robustness of the selected surface modification strategies.

Taking the example of PBAE coating, dose-dependent GFP and CAR transgene expression and integration were achieved in human cells treated with nanoparticles. While single-layer cationic nanoparticles demonstrated higher transduction efficiency at lower concentrations compared to shielded cationic particles, both formulations were functional *in vitro* over 10 days.

These encouraging results prompted us to engineer T-lymphocytes targeting nanoparticles by conjugating anti-CD3 scFv to shielding polymers. The best binders have been screened for affinity, specificity and activation before being added to shielding polymers by amine coupling. The cell-specific gene delivery of modified targeting nanoparticles is currently investigated.

To conclude, Alaya.bio has developed polymeric nanoparticles with different surface potentials and *in vitro* properties. By combining optimized LV bioproduction and formulation screening, Alaya.bio has now access to next-generation nanoparticles for gene delivery. These will be applied to the rapid and universal manufacturing of CAR T-cells with preserved naive and memory phenotypes.

1215 Introduction of Novel *in vivo* Cell Specific Payload Delivery Platform - CARGO

Chih Hong Lou[1]*, Soo-Mi Kweon[2], Cu Nguyen[2], Atousa Khalatbari[3], Brian Newsom[2]
[1]Carrigent, Inc., Covina, CA, [2]Carrigent Inc, Covina, CA, [3]Carrigent, Covina, CA
**Corresponding Author*

Chimeric Antigen Receptor-mediated (CAR) cell therapy, such as CAR-T cell therapy, represents a groundbreaking advancement in the field of immunotherapy, offering a novel paradigm for cancer treatment. Despite its potential, current CAR cell therapies face significant challenges, including weak cytotoxicity, cytokine release syndrome (CRS), and limited efficacy, primarily in treating blood cancers rather than solid tumors. While CAR cell therapy focuses on destroying target cells, the adeno-associated virus (AAV) platform has emerged as a widely used tool for delivering genetic material, offering a solution for reprogramming malfunctioning target cells. AAV-mediated *in vivo* gene therapy holds promise as an alternative, enabling the delivery of therapeutic genes for sustained protein expression in target tissues. However, several issues still need to be resolved, such as non-specific targeting, unclear in the factors affecting cellular and whole-body disposition, dose-exposure and exposure-response relationships, as well as the impact of product quality and immunogenicity on these properties.

Recognizing the potential of CAR-mediated cells to be engineered for precise cell targeting and addressing the limitation of AAV in lacking target specificity, we have developed a novel concept called CARGO, which leverages CAR-mediated cell-specific targeting as its core principle.

CARGO is a new strategic platform designed to deliver molecules of interest to target cells by facilitating interactions between CAR-mediated cells and their target cells (e.g., CD19CAR to CD19). Thus, CAR-mediated cells can serve as delivery vehicles to transport molecules or drugs to target cells, enabling specific gene editing or cell killing. As proof-of-concept, The CD19CAR module was used as the targeting segment, and HSVTK with in/out cell transporting sequences was used as the payload package in delivery cells. CD19-expressing cell-specific targeting, expression, and migration of HSVTK were observed in vitro and in vivo, demonstrating that the proof-of-concept CARGO system is effective and provides new insight into innovative drug delivery system based on direct binding between delivery and target cells. Utilizing the CARGO platform, the key limitations of current CAR-mediated cell therapy and AAV-mediated cargo delivery can be improved.

1216 Generation of Human iPSC-Derived Hematopoietic Progenitor Cells and Natural Killer Cells with Anti-Tumor Functionality Using a Feeder-Free Differentiation Platform

Abigail Becker[1]*, Marcus Bunn[1], Lindsay Bailey Steinitz[2], Pratima Rayavarapu[1], Jeremy De Leon[1], Chris Yankaskas[1], Vivek Chandra[2], Mark Kennedy[1], Navjot Kaur[2]

Securing a reliable source of high-quality hematopoietic stem and progenitor cells (HSPCs) is critical for the development of many autologous and allogeneic cell and gene therapies. The therapeutic use of primary HSPCs from sources such as bone marrow or cord blood is constrained by the availability of source materials and HLA-matched donors. Induced pluripotent stem cell (iPSC)-derived HSPCs (iHSPCs) offer a consistent source for generating various clinically relevant cell types, including Natural Killer (NK) and T cells. However, these differentiation workflows typically take weeks or months to complete, and labor- and material-intensive testing during development phases can rapidly increase costs. Implementing an efficient differentiation system early in the process is crucial for the effective development and characterization of both the therapeutic product and the production processes.

Here, we describe a fit-for-purpose feeder-free iHSPC differentiation system suitable for disease modeling and the development of cell-based therapies. The system utilizes cell therapy grade and regulation-compliant reagents and can be initiated from either 2D or 3D iPSC culture. This flexible protocol supports testing throughout process development by enabling cost-effective, small-scale testing that can be scaled up using shake flasks. By avoiding steps that can hinder culture scale-up, like spin embryoid body formation and complicated handling procedures, this protocol facilitates the translation of process development insights to scale-up or scale-out manufacturing.

Using CTS™ StemPro-34™ serum-free xeno-free medium in this differentiation system, we generated iHSPCs that were >65% CD34+CD43+ and >90% viable, in both 2D multi-well plate and 3D shake flask culture formats. To demonstrate their functionality, the iHSPCs were differentiated into iNK cells in 100 mL cultures in shake flasks, followed by two weeks of expansion resulting in $>10^9$ CD56+ CD3- iNK cells, with >90% purity and >80% viability. NK cells have significant potential as “off-the-shelf” allogeneic therapeutic products due to their ability to target cancer cells in an antigen- and HLA-independent manner. We therefore tested the functional ability of the expanded iNK cells to mediate anti-tumor activity against the K562 erythroleukemia cell line and cancer organoids (“tumoroids”) derived from human colorectal adenocarcinoma. The iNK cells displayed significant cytotoxic activity, killing >80% of target K562 cells and adenocarcinoma tumoroids in a dose-dependent manner, without requiring enrichment prior to use.

In conclusion, we demonstrate the use of a streamlined, versatile differentiation workflow to generate clinically relevant cell types, including functional iHSPCs and iNK cells. Utilizing a cost-effective differentiation system like this during process development can help to identify and resolve production pain points, ensure product quality, and facilitate a smooth transition from the research stage to clinical trials and ultimately commercialization.

1217 CRISPR-Cas9-induced Double Strand Breaks Cause Chromosome Catastrophe and Eliminate Pancreatic Cancers

Selina Shiqing Teh[1]*, Eitan Halper-Stromberg[2], Akhil Kotwal[2], Alexis Bennett[1], Laura Morsberger[2], Michael Goldstein[2], Ying Zou[2], **James Eshleman[1]***
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]The Johns Hopkins University School of Medicine, Baltimore, MD

Pancreatic cancer (PC) is the third leading cause of cancer-related deaths in the U.S. with a 5-year survival rate of just 13%. Most patients are diagnosed at advanced stages when their cancers are unresectable, and current standard of care has shown limited efficacy with most patients eventually developing resistance. We have previously adapted the CRISPR-Cas9 gene editing technology as a cancer-specific treatment modality targeting somatic mutations in PC. However, the tumoricidal potential of CRISPR-Cas9 remains unclear, especially the cell death mechanism and risk of treatment resistance.

Using multi-target sgRNAs containing 2-16 target sites in the noncoding regions of the human genome, we found that targeting more sgRNA target sites correlated with increased γH2A.X foci and decreased clonogenic survival in both Panc10.05 and TS0111 PC cell lines. Multi-target sgRNAs with >10 target sites exhibited >90% clonogenic inhibition. Using sgRNA tag survival (where lethal sgRNAs are eliminated from the pool of sgRNA "tags" over time), we found that multi-target sgRNAs with higher number of target sites demonstrated a greater degree of sgRNA tag loss. Interestingly, most tag reduction occurred between days 7 and 21 post transduction of sgRNAs instead of the first 7 days. We further demonstrated that scission and repair happened within the first few days and peaked 3-4 days post transduction, indicating that CRISPR-Cas9-induced DSBs did not immediately and directly trigger cell death.

Cytogenetic analyses on PC cells transduced with a 14-cutter sgRNA revealed accumulation of karyotypic abnormalities (e.g. chromatid breaks, dicentrics, ring chromosomes) peaking at day 14, polyploidization peaking at day 10, and decreasing by day 21. Whole genome sequencing (WGS) on surviving colonies from cells treated with multitarget sgRNAs also revealed that CRISPR-Cas9-induced structural variants (SVs) increased as a function of the number of sgRNA target sites. Importantly, 87% of SVs detected were novel SVs arising from endogenous DSBs rather than direct CRISPR-Cas9 scission. Our results demonstrated that CRISPR-Cas9 scissions led to ongoing chromosomal rearrangements which peaked before cell death, indicating that CRISPR-Cas9 induces "chromosome catastrophe" that is incompatible with cell survival.

To investigate whether the surviving/resistant colonies from the clonogenicity experiment increased tumor growth, we injected parental and resistant cells into athymic, nude mice and observed tumor growth over 33 days. We found no significant differences in growth with tumors grown from resistant cells compared to the parental/non-transduced controls. We also harvested tumors and found no significant differences in size and weight between resistant tumors and non-transduced controls, except for 5-cutter-resistant tumors that showed decreased growth. Finally, surviving colonies that were resistant to 5-, 8-, and 16-cutter sgRNAs were re-challenged with their original multitarget sgRNA, 12-, and 14-cutter sgRNAs. Re-treating with original sgRNA showed no growth inhibition, while >95% cytotoxicity was observed by re-challenging them with 12- or 14-cutter sgRNAs. Our results demonstrate that cells resistant to one sgRNA retain sensitivity to other sgRNAs and do not induce significantly more aggressive disease.

1218 Personalized CRISPR/Cas9 Cytokine Gene Therapy to Remodel Solid Tumor Microenvironment and Enhance Adoptive T Cell Therapy

Michael Launspach[1], Julia Macos[2], Shoaib Afzal[3], Janik Hohmann[4], Jonas Kath[5], Angelika Eggert[3], Dimitrios Wagner[6], Annette Kuenkele[7]
[1]Charité - Universitaetsmedizin Berlin, Berlin, Berlin, Germany, [2]Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]Charité - Universitaetsmedizin Berlin, Berlin, Germany, [4]University Hospital Duesseldorf, Duesseldorf, Germany, [5]Charité - University Medicine Berlin, Berlin, Germany, Germany, [6]Baylor College of Medicine, Houston, TX, [7]Charite University Hospital Berlin, Germany

Therapy-resistant solid tumors remain a significant challenge in oncology, requiring innovative therapeutic strategies. Immunotherapy, such as chimeric antigen receptor (CAR) T cell therapy, has demonstrated remarkable

success against hematological malignancies but often fails in solid tumors due to poor T cell infiltration and an immunosuppressive tumor microenvironment. Solid tumors with increased immune cell infiltration and elevated cytokine levels have shown better prognoses and enhanced responses to immunotherapies. To address this challenge, we developed a personalized CRISPR/Cas9-based cytokine gene therapy to remodel the tumor microenvironment and enhance the efficacy of CAR T cell therapy in solid tumors.

Central to this effort is CancerPAM, an automated multi-omics pipeline we developed for identifying tumor-specific CRISPR/Cas9 knock-in target sites. This Python-based tool, analyzes cancer- and healthy tissue genomes to discover novel tumor-specific PAM sites, enabling safe and effective transgene integration. In a cohort of 54 neuroblastoma patients, 8570 potential CRISPR targets were identified in the coding genome, representing 14% of all called single nucleotide variants. The pipeline employs a robust ranking algorithm that integrates factors such as copy number, gene expression, and CRISPR efficiency and specificity scores, ensuring precise target prioritization while minimizing off-target risks. CancerPAM's versatile framework facilitates the discovery of genomic CRISPR targets across various solid tumors, making it a valuable tool for personalized in vivo gene therapy **(Fig.1)**. Our therapeutic strategy employs CRISPR/Cas9 knock-in via homology-directed repair to engineer tumor cells to secrete T cell-attracting chemokines (CXCL10, CXCL11) or the T cell-activating cytokine IFNG. These cytokines enhance CAR T cell infiltration and activation, even in tumors with immune-exclusion signatures. Unlike conventional tumor gene therapy, our augmentative approach does not depend on gene transfer to all tumor cells. Instead, cytokines secreted by the targeted tumor cells modulate the surrounding cells and reshape the tumor microenvironment. Proof-of-concept studies in neuroblastoma cell lines demonstrated precise transgene integration and cytokine expression. Functional validation in vitro revealed significant enhancements in CAR T cell migration in trans well migration assays which was confirmed in a 3D bioprinted tumor model for transgene expressing tumors. Moving in vivo, xenograft-studies with CXCL10-expressing neuroblastoma cells after targeted knock-in, transplanted into immunodeficient mice, revealed early increases in CAR T cell infiltration and an increased remission rate compared to unmodified tumors in a CAR T cell resistant tumor-model. These findings underscore the potential of our approach to overcome the immunosuppressive barriers of solid tumors and enhance the efficacy of adoptive T cell therapies **(Fig. 2)**.

In conclusion, our multi-omics pipeline-based and personalized CRISPR/Cas9 cytokine gene therapy offers a versatile and scalable solution to the challenges of solid tumors. By reprogramming the tumor microenvironment to promote immune cell activation and infiltration, this strategy holds significant promise for improving immunotherapeutic outcomes across diverse solid malignancies, with neuroblastoma serving as a proof-of-concept model.

The *all variants* group includes insertions, deletions, InDels (<300 bp), and single nucleotide variants (SNVs). **(D)** Circos plots showing the chromosomal distribution of SNVs and novel tumor-specific PAM sites and radar plots visualizing annotated feature characteristics for the top three highest- and the lowest-ranked PAM site in two patients (A and B) **(E)** Overlap between novel PAM sites identified via manual screening of five neuroblastoma cell lines and those identified using the CancerPAM pipeline shows a 99% sensitivity of the CancerPAM pipeline. *Data are presented as means ± SD.*

Figure 2

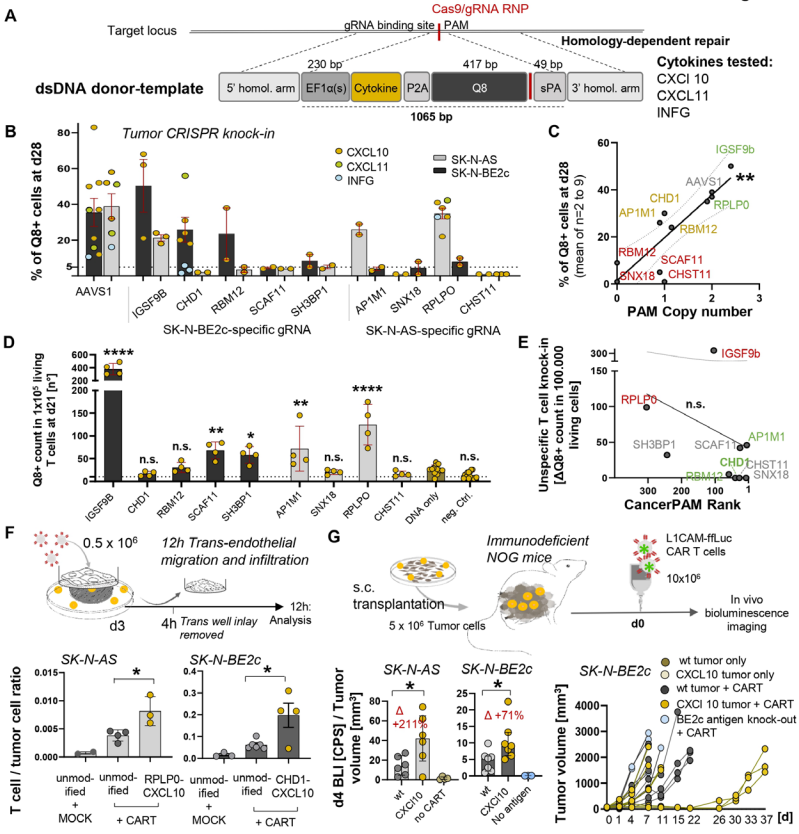

Fig. 2. Gene therapeutic CRISPR knock-in of cytokine transgenes is specific to top-ranked novel PAM targets and enhances CAR T cell infiltration and efficacy in vitro and in vivo. (A) Schematic representation of CRISPR/Cas9-mediated transgene knock-in via homology-directed repair (HDR) following ribonucleoprotein (RNP) electroporation. The linear double-stranded (ds) donor templates consisted of 5' and 3' homologous arms (400bp), a custom-designed EF1a promoter, the cytokine transgene linked via a P2A self-cleaving peptide to Q8 (CD34 epitope and CD8 transmembrane domain), followed by a synthetic poly A (sPA) sequence. **(B)** Knock-in efficiency of three cytokines (CXCL10, CXCL11, IFNG) measured by Q8 antigen expression via flow cytometry at day 28 post-electroporation across different novel PAM sites in two neuroblastoma cell lines. Site-specific knock-in was confirmed by dPCR and Sanger sequencing (data not shown). **(C)** A positive correlation between knock-in efficiency and novel PAM copy number was observed. **(D)** Off-target knock-in in primary T cells from two donors lacking the identified novel PAM sites, assessed by Q8+ expression at day 21 post-RNP electroporation using guide RNAs targeting the novel PAMs identified in (B). **(E)** Correlation of off-target knock-in in T cells with CancerPAM ranking of novel PAM sites showed a good safety profile for highly ranked novel PAM sites (e.g. CHD1 for SK-N-BE2c). **(F)** 3D tumor trans-endothelial migration and infiltration assay using L1CAM-targeting CAR T cells and unmodified or cytokine-expressing neuroblastoma cell lines (SK-N-AS ist L1CAM low, SK-N-BE2c is L1CAM high). T cell infiltration was quantified after 12 hours and represented as the T cell-to-tumor cell ratio. **(G)** Xenograft mouse model using unmodified or cytokine-expressing neuroblastoma cell lines and L1CAM CAR T cells transduced with firefly luciferase (ffLuc). CAR T cell tumor infiltration was assessed by in vivo bioluminescence imaging (BLI), analyzed via the BLI-to-tumor volume ratio at day 4. CXCL10-expressing SK-N-BE2c tumors showed early complete response in 3/7 animals, which was not observed in control groups (0/8). CAR T cells disappeared by d15 followed by relapse in early-response cases (Data not shown). *Data are presented as means ± SD. Statistical analyses: (D, F, G) Kruskal-Wallis with Dunn's post hoc test; (C, E) Spearman correlation. P values: *<0.05, **<0.01, ***<0.001, ****<0.0001; n.s., not significant.*

1219 OUTWIT: An *In Vivo* Approach to Engage Innate Immune Cells with Clinically Approved T Cell Engagers

Kevin Carbajal[1], Warren Anderson[2], Adam Pecoraro[3], Katerina Fagan-Solis[3], Mathew Esquivel[3], Matthias Schroff[3], Maximilian Richter[3]

T cell engagers (TCEs) activate T cells by linking their T-cell receptors (TCRs) to a target antigen on tumor cells. They have achieved remarkable successes both in liquid and solid tumors. However, they are vulnerable to antigen escape and can lead to exhaustion of T cells and loss of tumor control. Because innate cells can be directly anti-tumorigenic and can also promote epitope spreading, a strategy that endows clinically approved TCEs with the ability to engage innate immune cells in addition to engaging T cells presents an opportunity to improve the durability of TCE-based therapies and, ultimately, prevent tumor antigen escape. Here we describe OUTWIT, a receptor for TCEs that can be delivered to innate immune cells *in vivo* to render them engageable by TCEs.

OUTWIT is comprised of an extracellular domain that all TCEs can bind that is linked to intracellular signaling domains to drive innate cell effector function upon TCE-mediated target binding.

CD3ε is the constant subunit of the TCR that is universally bound by the anti-CD3 binding side of TCEs. Equipping OUTWIT with the ectodomain of CD3ε allowed all anti-CD3 antibody clones tested to bind to OUTWIT-expressing monocytes. Linking these cells to antigen via TCE induced NFκB signaling and cytokine expression. Coculture with target-positive tumor cells resulted in TCE-mediated phagocytosis of tumor cells by OUTWIT-expressing monocytes. Furthermore, we demonstrate efficient *in vivo* delivery of mRNA transcripts to >80% of innate immune cells in circulation following IV injection of loaded lipid nanoparticles (LNPs). Taken together, these data lay the groundwork for a promising strategy to endow any TCE in the market with the ability to enlist innate immune cells to home to tumors and be activated therein. As innate cells have potent cytotoxic and epitope-spreading abilities, this approach could be employed in combination with any current or future approved TCEs to orchestrate a broader and more complete immune rejection of tumors.

1220 Preclinical efficacy of a HER2 synNotch/CEA-CAR combinatorial immunotherapy against colorectal cancer with HER2 amplification

HER2 amplification occurs in about 5% of colorectal cancer (CRC) cases and is associated only partially with clinical response to combined human epidermal growth factor receptor 2 (HER2)/epidermal growth factor receptor (EGFR)- targeted treatment. An alternative approach based on adoptive cell therapy (ACT) using T-cells engineered with anti-HER2 chimeric antigen receptor (CAR) proved to be toxic due to "on-target off-tumor" activity. Here we describe a combinatorial strategy to safely target HER2 amplification and CEA expression in CRC using a synNotch-CAR based artificial regulatory network. The natural killer cell line NK-92 was engineered with an anti-HER2 synNotch receptor driving the expression of a CAR against CEA only when engaged. After being transduced and sorted for HER2-driven CAR expression, cells were cloned. The clone (5F) with optimal performances in terms of specificity and amplitude of CAR induction demonstrated significant activity in vitro and in vivo specifically against HER2amp/CEA+ CRC models, with no effects on cells with physiological HER2 levels. To further improve survival, tumor penetration and in vivo efficacy of the NK-92.5F clone, a more complex system was built, in which HER2 synNotch engagement drives expression of both the CEA-CAR and different cytokine (5Fck). 5F-IL cells displayed further increased cytotoxicity in vitro. In vivo, 5Fck cells drastically increased survival of mice carrying HER2amp CRC xenografts with respect to the parental 5F clone. In conclusion the HER2-synNotch/CEA-CAR-NK system provides an innovative, scalable and safe off-the shelf cell therapy approach with potential against HER2amp CRC resistant or partially responsive to HER2/EGFR blockade.

1221 *piggyBac* transposon-mediated EPH family protein-specific CAR-T cells engineered through scalable automated manufacturing with optimized T cell metabolic fitness and sustained stemness

Background: *piggyBac* (PB) transposon-mediated CAR-T cells have emerged as a promising therapeutic platform due to their enhanced T cell stemness, which is associated with long-term antitumor efficacy and sustained clinical responses. This stemness is achieved by directly introducing the PB CAR transgene into resting CD45RA-positive peripheral blood mononuclear cells (PBMCs) and expanding these cells using a feeder cell-based system that preserves physiological T cell activation. Leveraging this platform, we developed dual-targeting PB CAR-T cells which redirected to both EPHB4 and EPHA2 (PB EPH CAR-T cells), two crucial targets in solid tumors.

Methods: A modified Ephrin B2, natural ligand of EPHB4, fused with CD28 and CD3ζ signaling domains, was cloned into a wild-type PB transposon plasmid. Beyond the previously developed manual manufacturing system for PB CAR-T cells, we established a GMP-compliant, semi-automated, and closed manufacturing process for PB EPH CAR-T cells. In this process, autologous PBMCs were collected by leukapheresis and these cells were enriched using the automated centrifugation system, transfected with the PB CAR transgene and transposase plasmid through an optimized electroporation protocol, and expanded over 14 days in a feeder cell-based system within automated cell expansion platform. The system was further optimized by regulating dissolved oxygen levels to enhance cell expansion and functionality. Comprehensive assessments of phenotypic characteristics, metabolic profiles, and antitumor efficacy were performed through in vitro sequential co-culture assays and in vivo xenograft models.

Results: PB EPH CAR-T cells were successfully manufactured with high CAR expression, a dominant population of stem cell-like memory T cells (Tscm), and low PD-1 expression, reflecting a less exhausted phenotype. Compared to manually produced CAR-T cells, the semi-automated process enhanced CAR expression and expansion efficiency while preserving OXPHOS-driven metabolic fitness despite robust proliferation. Functional studies demonstrated that PB EPH CAR-T cells, with its modified ligand-based CAR design, possessed dual specificity for EPHB4 and EPHA2. PB EPH CAR-T cells effectively eliminated EPHB4+ and EPHA2+ solid tumors and exhibited superior, durable antitumor efficacy. Notably, direct comparisons with retrovirally (RV) engineered EPHB4/EPHA2 CAR-T cells revealed the superior performance of PB EPH CAR-T cells, which showed enhanced resistance to immune exhaustion and maintained long-term cytotoxic activity through multiple tumor rechallenges. Specifically, tumor cell lysis rates (%cytolysis) at 100 h after co-culture for PB CAR-T cells surpassed RV CAR-T cells in both the second (92.2 ± 0.63% [PB] vs. 59.7 ± 12.7% [RV]) and third (73.5 ± 3.7 % [PB] vs. 0 ± 11.3 % [RV]) rounds of rechallenge **(Figure 1)**.

Conclusion: PB EPH CAR-T cells demonstrated potent and durable antitumor efficacy by preserving T cell stemness and resisting immune exhaustion, even under chronic antigen stimulation. The semi-automated manufacturing process enhances scalability and ensures optimal metabolic fitness, enabling the production of high-quality CAR-T cells. We have initiated a Phase 1 clinical trial targeting EPHB4-positive Ewing sarcoma and other solid tumors, with plans to expand to global Phase 1/2 trials for colorectal cancer and hepatocellular carcinoma, further extending the therapeutic potential of this platform.

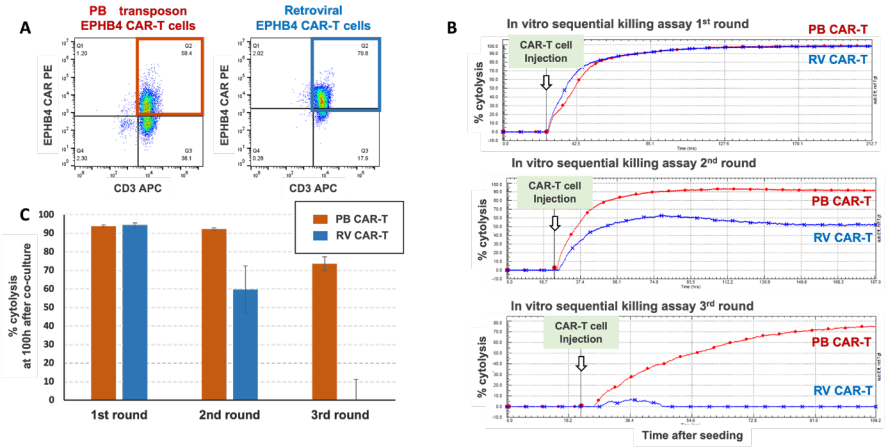

Figure 1 Anti-tumor efficacy of PB- and RV-EPH CAR-T cells
A. CAR positivity of PB- and RV-CAR-T cells. **B.** Anti-tumor efficacy of EPH CAR-T cells during sequential tumor rechallenges. EPH CAR-T cells and Rh30 cells were co-cultured at an E:T ratio of 1:2, and % cytolysis was monitered by real time cell analyser, xCELLigence. **C.** % cytolysis at 100h after co-culture for each tumor rechallenge. Data are presented as mean ± SD.

1222 Induced Pluripotent Stem Cells (iPSCs) Provide an Unlimited, Effective Claudin18.2-targed CAR-NKT cell for Allogeneic and Off-the-Shelf Immunotherapy and gastric and pancreatic cancer

Xiaowen He[1], Yanhong Xu[1], Xuhui Dong[1], Huijiao Li[1], Kehua Li[1]
[1]*Oricell Therapeutics Co.,Ltd., Shanghai, Shanghai, China*

Background: Invariant natural killer T(iNKT) cells exhibit potent anti-tumor activity through direct killing mechanisms and indirectly through triggering the activation of other anti-tumor immune cells, overcoming limitations of CAR-T therapy in solid tumors challenged by immunosuppressive environments. Compared to classic αβT, iNKT cells are not restricted to HLA and bind exclusively to the monomorphic CD1d molecule, avoiding graft versus host disease. To address the scarcity of iNKT cells in PBMC, we aimed to generate clinically competent NKT cells from induced pluripotent stem cells (iPSCs). It would also be possible to activate the iPSC-iNKT cells by their direct recognition of tumor cells upon expression of chimeric antigen receptors (CARs) in the iPSC-iNKT cells.

Methods: We amplified iNKT cells from PBMC and generated iPSCs through episomal reprogramming, combined with the specific medium and induction method. iNKT-iPSC clone was identified by iNKT specific TCR α chain(Vα24) and TCR β chain (V β 11) gene rearrangements. Good pluripotency iPSCs were re-differentiated into iNKT cells through optimized cytokines and transduced with Caludin18.2-targeted CAR using gene editing. Caludin18.2 antigen is widely expressed in many types of solid tumors including gastric and pancreatic cancer. The function of CAR-iNKT cells was assessed by surface markers, cytotoxicity, and cytokine secretion.

Results: We established a robust protocol for reprogramming human Vα24+ iNKT cells, obtaining different iNKT cell-specific TCR types of iPSCs, and re-differentiating them into functional CAR-iNKT cells. These iPSC-derived CAR-iNKT cells expressed >90% TCRα on CD3+ cells. We evaluated the target-mediated CAR-dependent cytokine production of CAR-iNKT by co-culturing the cells with NUGC4 (gastric cancer line) or ASPC1 (pancreatic cancer line) as a stimulator**.** We also found that the iPSC Vα 24+ iNKT cells can be activated by target cells overexpress CD1d and produce a large amount of interferon-γ and tumor necrosis factor upon activation, and exhibit good cytotoxic activity against other tumor cell lines(K562/Huh7/SKOV3) at ratios of 5:1, the cytotoxicity was about 100%.

Conclusions: iPSCs can provide an unlimited source of allogeneic, off-the-shelf CAR-iNKT cells without GVHD risk. Our findings demonstrate the potential of NKT-TCR carrying CAR-T cells as a universal cancer immunotherapy strategy against gastric and pancreatic cancer.

1223 Preclinical Study of Combination therapy of GUCY2C CAR-T with Immune Checkpoint Inhibitors for Metastatic Colorectal Cancer

[1]Beijing Imunopharm Technology Co., Ltd., Beijing, Beijing, China, [2]Beijing Imunopharm Technology, Beijing, China, [3]Beijing Imunopharm Technology, Beijing, Beijing, China, [4]Beijing Imunopharm Technology Co. Ltd., Beijing, China, China
**Corresponding Author*

Background: Chimeric antigen receptors-T (CAR-T) cell therapy has shown demonstrable success against hematologic malignancies, but much lower efficacy against solid tumors. One important reason lies in the immunosuppressive microenvironment of solid tumors, leading to exhaustion and insufficient expansion of CAR-T cells in vivo. Previously, we developed a GUCY2C-targeted CAR-T cell and observed over 30% of overall response rate in the 3rd- or late-line therapy of microsatellite stable (MSS) metastatic colorectal cancer (mCRC) patients. Immune checkpoint inhibitors (ICIs) have shown clinical benefits in microsatellite instable (MSI) mCRC, but limited effects on MSS mCRC which accounts for the majority of metastatic colorectal carcinomas. To further improve the clinical response and durable efficacy of GUCY2C CAR-T, we investigated the potential of combination therapy of GUCY2C CAR-T cells with ICIs for MSS mCRC in vitro and in vivo.

Methods: To construct the mouse GUCY2C CAR-T cells, T cells isolated from BALB/c mice were transduced with lentiviral vectors carrying the GUCY2C CAR gene, and the tumor killing efficiency was examined in vitro. We used the murine MSS colorectal cancer cell line CT26 to establish a metastatic CRC model that exhibited disseminated tumor cells in the lung tissues of female BALB/c mice. CT26 cells were transduced with lentiviral vectors with GUCY2C gene to establish the GUCY2C-positive CRC cell line (GUCY2C-CT26). BALB/c mice were inoculated individually with 0.1 million of GUCY2C-CT26 cells via the tail vain injection. After 5 days, each mouse received 4 Gy irradiation and was then intravenously infused with 1 million GUCY2C CAR-T cells. For the combination therapy group, additional administrations of ICIs (αPD-1 or/and αCTLA-4) were conducted for 4 times within 10 days. Monotherapies of CAR-T cells and ICIs were used as control groups. Peripheral CAR-T cell expansion was monitored along with time. The tumor fluorescence intensity and survival of mice were analyzed statistically.

Results: GUCY2C CAR-T cells derived from BALB/c mouse T cells exhibited high killing efficiency and excellent expansion after multi-round chronic stimulation with GUCY2C-CT26 cells in vitro, and significantly suppressed tumor growth in vivo. Combination therapies of CAR-T cells with ICIs including αPD-1, αCTLA-4, or combined αPD-1 and αCTLA-4 demonstrated superior inhibition of tumor relapse compared with CAR-T monotherapy. Among the ICIs, combination therapy of CAR-T with αPD-1 and αCTLA-4 showed the best antitumor efficacy, exhibiting the lowest tumor burden and the longest overall survival. CAR-T cells combined with αCTLA-4 showed higher benefits for mouse survival than CAR-T cells combined with αPD-1. All the ICIs showed limited effects on the amplification of T cells or CAR-T cells in the peripheral blood.

Conclusions: This study demonstrated that combination therapy of GUCY2C CAR-T cells with ICIs has superior efficacy in MSS mCRC, especially the triple combination of CAR-T, αPD-1, and αCTLA-4.

1224 Glypican-3-Specific CAR-T Cells Co-expressing CD40L Exhibit Antitumor Activity Against Osteosarcoma

Yajun Wang[1], Shi Feng[2], Dongqun Liu[3], Yanping Ding[4], Junhua He[5], Qiaozhen Li[1], Chenyang Wan[5], Tao Yang[6], Chi Zhang[6], Jielong Zhou[5], Guoqing Zhong[6], Haishan Ye[7], Jia Liu[7], Ting He[8], Yu Zhang[6]*, **Xin-an Lu[3]***
[1]Beijing Imunopharm Technology Co., Ltd., Beijing, Beijing, China, [2]Beijing Imunopharm Technology Co., Ltd., Beijing, China, [3]Beijing Imunopharm Technology, Beijing, China, [4]Beijing Imunopharm Technology Co. Ltd., Beijing, China, China, [5]Guangdong Provincial People's Hospital, Guangzhou, Guangdong, China, [6]Guangdong Provincial People's Hospital, Guangzhou, China, [7]South China University of Technology, Guangzhou, China, [8]Beijing Imunopharm Technology, Beijing, Beijing, China
**Corresponding Author*

Background: Chimeric Antigen Receptor T-cell (CAR-T) therapy for solid tumors often demonstrates limited efficacy, primarily due to the complex tumor microenvironment (TME), which is rich in immunosuppressive cells and molecules. These factors hinder CAR-T cell expansion and persistence. CD40L is a co-stimulatory molecule that is inducibly expressed on activated T cells. CD40L interacts with CD40 on antigen-presenting cells (APCs), promoting their differentiation, survival, cytokine production, and antigen-presenting function. CD40L can also interacts with CD40 on tumor cells, leading to tumor cell apoptosis. In this study, we targeted glypican-3 (GPC3), a protein that is overexpressed in various solid tumors, to develop a next-generation CAR-T therapy: GPC3-CAR-T cells armoring CD40L (named IM83), and assessed the antitumor activity against osteosarcoma both in vitro and in vivo.

Methods: The expression profile of GPC3 in osteosarcoma and normal tissues was confirmed using immunohistochemistry. Lentivirus carrying the IM83 CAR construct was transfected into primary T cells to generate IM83 CAR-T cells. These cells were then co-cultured with osteosarcoma organoids to evaluate the cytotoxic effects of IM83 CAR-T cells in vitro. To study the role of CD40L, a control "unarmored CAR" (lacking CD40L) was constructed. Both IM83 and "unarmored" CAR-T cells were co-cultured with GPC3-CD40+ tumor cells, and tumor cell apoptosis was assessed. Furthermore, to investigate the impact of IM83 on APC activation, both CAR-T cell types were co-cultured with monocyte-derived dendritic cells (DCs). The potential for IM83 to activate bystander T cells was also tested by co-culturing the CAR-T cells with monocyte-induced DCs, tumor antigens, and $GPC3^{-}CD40^{-}$ tumor cells. In vivo tumor suppression was evaluated using a patient-derived xenograft (PDX) model of osteosarcoma. Finally, the clinical efficacy of IM83 was assessed in a patient with osteosarcoma.

Results: In the osteosarcoma organoid model, IM83 induced a high tumor cell death rate (62.27%). Mechanistic studies confirmed that IM83 CAR-T cells, when compared to "unarmored" CAR-T cells, induced higher levels of tumor cell apoptosis when co-cultured with $GPC3^{-}CD40^{+}$ tumor cells. Additionally, IM83 CAR-T cells more effectively activated monocyte-derived DCs than the "unarmored" CAR-T cells, leading to enhanced activation and antitumor activity of bystander T cells. In the PDX model of osteosarcoma, IM83 induced tumor suppression at lower doses compared to "unarmored" CAR-T cells (1×10^6 vs. 5×10^6 cells). To assess the clinical potential of IM83, a 58-year-old patient with osteosarcoma, who had undergone three lines of treatment, received an infusion of IM83 CAR-T cells at a dose of 5×10^8. The patient experienced grade 2 cytokine release syndrome (CRS) on day 2 post-infusion. Neurotoxicity was not observed. By day 12, MRI imaging revealed a liquefied necrosis area in the target lesion, measuring 5.5 cm in length.

Conclusions: This study demonstrates that IM83 CAR-T cells possess significant antitumor activity against osteosarcoma. These findings suggest that IM83 holds strong therapeutic potential, warranting further clinical investigation

1225 Identifying genetic determinants of solid tumor infiltration of T cells using a microscopy-based cell isolation approach.

Jihwan Lee[1], Francois St-Pierre[2], Mimi Healy[3], Andries Zijlstra[4]
[1]Imagen Bioworks, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Stimulus Bio, Houston, TX, [4]StimulusBio, Houston, TX

A major challenge in immunotherapy has been engineering CAR-T cells capable of infiltrating and effectively targeting solid tumors. The genetic factors that regulate infiltration, targeting, and the persistence of immune responses remain incompletely understood. Unlike in hematologic malignancies, CAR-T cells face multiple barriers in solid tumors, including a hostile tumor microenvironment, physical exclusion from tumor sites, and T-cell exhaustion. Identifying and manipulating key genetic determinants could enhance CAR-T efficacy, providing a path toward more durable and effective treatments for solid tumors. To achieve this, we developed a microscopy workflow that enables isolating tumor-infiltrating immune cells from *in vitro 3D* solid tumor-immune cell co-culture models. These isolated immune cells can then be subjected to transcriptomic and proteomic profiling to identify differentially expressed genes and proteins, providing insights into the genetic and molecular determinants of immune cell infiltration and function.

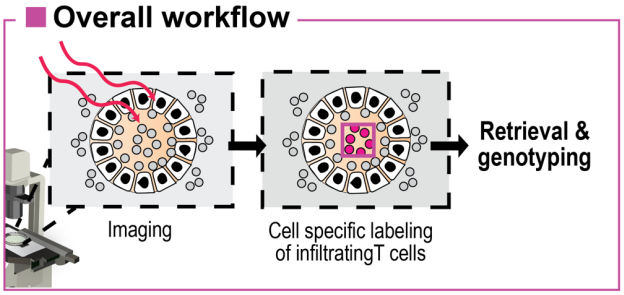

Figure 1. Overall workflow of our method to isolate tumor infiltrating immune cells from spheroid-immune cell co-cultures.

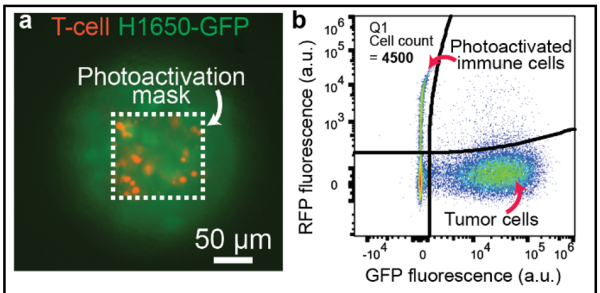

Figure 2. (a) Image of spheroid-T cell co-culture. T-cells expressing PAmCherry1 were optically labeled and isolated (white dashed box). (**b**) 24-wells of co-culture in a 96-well plate were photoactivated, as seen in (a). Cells were dissociated, pooled, and ran under FACS. Around 4500 T-cells were detected.

1226 Expanding the Potential of T-Cell Therapies with the ARTEMIS Cell Receptor Platform

Bryan Zimdahl[1], Pei Wang[1], Hongbing Zhang[2]
[1]Eureka Therapeutics, Emeryville, CA, [2]Eureka Therapeutics, Inc., Emeryville

Conventional chimeric antigen receptor (CAR)-T cells "redirect" T-cell activation by delivering both T-cell receptor (TCR) signals (signal 1) and costimulation (signal 2) through a single chimeric surface receptor. While effective against hematologic malignancies, CAR-T cells can cause unwanted toxicities, have poor persistence, and face efficacy challenges in solid tumors due to limited tumor infiltration in immunosuppressive microenvironments – challenges primarily arising from the inherent design of the CAR construct.

To address these limitations, we developed the ARTEMIS® Cell Receptor Platform, directing the synthesis of two molecules: an antibody-T-cell receptor (AbTCR) and a co-stimulatory molecule. The AbTCR incorporates a target-binding domain fused to an effector domain from human γδ TCR chains, while the co-stimulatory molecule contains a target-binding domain coupled with a co-stimulatory domain from a human co-stimulatory receptor. Both proteins are co-expressed from the same transgene, co-localizing on ARTEMIS T cells, thus mimicking the natural TCR/co-stimulatory receptor system. This arrangement promotes regulated T-cell activation and enhances the destruction of target-positive cancer cells while maintaining a safety feedback mechanism to prevent unwanted toxicity. We also conducted a screening campaign identifying a co-stimulatory domain that significantly enhances solid tumor infiltration by ARTEMIS T cells.

Initially, we compared the AbTCR and CAR constructs by engineering T cells to express CD19-targeting domains. AbTCR-T cells matched CAR-T cell potency while significantly reducing cytokine release during target cell elimination in vitro and in mouse models. To further optimize the anti-tumor immune response, we incorporated a co-expressed, yet separate, co-stimulatory molecule into the platform, designed to bind either the same or a different tumor-specific antigen as the AbTCR. Subsequently, we developed an AFP-targeting ARTEMIS T cell therapy for hepatocellular carcinoma (HCC), where the AbTCR recognizes an AFP peptide/HLA-A2 complex, and the co-stimulatory molecule targets glypican-3 (GPC3). These T cells demonstrated potent anti-tumor activity, significant infiltration, and no adverse reactions in HCC xenografts. These findings suggest that the ARTEMIS Cell Receptor Platform may offer a safer and more effective alternative to conventional CAR-T therapies across various cancers.

To clinically validate the ARTEMIS Cell Receptor Platform, several proof-of-concept studies were conducted. In trial NCT03642496, CD19-targeting ARTEMIS T cells showed efficacy and a favorable safety profile in adults with relapsed/refractory (r/r) B-cell lymphoma. In trial NCT03888859, AFP-targeting ARTEMIS T cells showed significant efficacy in a heavily pre-treated advanced HCC patient, resulting in reduced serum AFP levels and significant shrinkage of both primary hepatic and metastatic lung tumors. Building on these promising results, we initiated U.S. IND trials for both liquid and solid tumors. Current Phase 1/2 trials include STARLIGHT-1

(NCT06343311), evaluating CD19-targeting ARTEMIS T cells in high-risk lymphoma patients, ARYA-2 (NCT04634357) testing AFP-targeting ARTEMIS T cells in pediatric patients with r/r liver cancer, and ARYA-3 (NCT04864054) assessing GPC3-targeting ARTEMIS T cells in adults with advanced HCC.

1227 Antigen-Specific T cells Generated Using Photothermal Nanoparticles Demonstrate Enhanced Function Compared to Alternative Tumor Antigen Release Methods

Sveta Jagannathan[1], Sophie Eisenberg[1], Danielle Schmidt[1], Samantha Chin[1], Grace Olsson[1], William Murphy[1], Conrad Russell Cruz[2], Elizabeth Sweeney[3], Rohan Fernandes[1]*
[1]George Washington University, Washington, DC, [2]Children's National Medical Center, Washington, DC, [3]Washington, DC

Multi-antigen-specific T cells are a promising immunotherapy for solid tumor treatment, offering advantages over current T cell approaches, which target pre-defined subsets of antigens that may lead to tumor antigen escape (PMID: 30135176) and ultimately treatment failure. Our lab has developed a T cell therapy targeting multiple antigens using Prussian blue nanoparticle photothermal therapy (PTT). T cells generated using dendritic cells (DC) primed with PTT-treated tumors display more potent tumor-specific cytotoxicity and function than those generated from tumor lysis alone (PMID: 37278683, 38818122).

We hypothesized that nanoparticle-based antigen capture and immunogenicity of our tumor treatment approach enhances tumor-specific T cell activation at each of the three activation signals—antigen presentation to T cell receptors (TCR), costimulation, and cytokine stimulation—offering an advantage over classical multi-antigen-specific T cell generation methods (heating, freeze-thaw lysis, and oxidation with lysis). Proinflammatory cytokine secretion was higher in PTT compared to other treatments (including IFN-γ, IFN-β, TNF-α, and IL-6) though this difference was not statistically significant across all treatments. Costimulatory marker expression in primed DCs was comparable across treatments. Proteomic analysis revealed unique protein profiles in PTT-treated tumors. MHC-presented peptide analysis identified 55 peptides upregulated in PTT-primed DCs compared to lysate- or un-primed DCs. Of these peptides, 62% overlapped with the tumor peptidome, and two peptides induced an IFN-γ response in PTT-derived T cells but not in heating- or lysate-derived T cells. These findings support our hypothesis that PTT promotes proinflammatory signaling and distinct antigen profiles that amplify tumor-specific T cell activation and proliferation.

We additionally studied whether these differences in proinflammatory signaling, tumor antigens, and TCR-MHC interactions affected tumor-specificity of the T cell product. PTT-derived T cells (PTT-T) had higher tumor-specific cytotoxicity than the other treatments. PTT-T cells also had a higher percentage of CD8 T cells co-expressing markers of activation and degranulation when compared to other treatments, as measured by flow cytometric staining of CD107a and IFN-γ. TCR sequencing revealed an increase in T cell Simpson clonality (from 0.04 to 0.14) and maximum productive frequency (from 2.3% to 9.1%) in the T cell product, suggesting selective expansion of multiple tumor-specific TCR clones. This data further supports our hypothesis that proinflammatory signaling and distinct antigen presentation during PTT-T cell culture stimulates expansion of a more tumor-specific and potent T cell product.

Our findings suggest that differential antigen release, antigen presentation, and proinflammatory cytokine stimulation during PTT-T cell manufacture promote both tumor specificity and T cell activation signaling, yielding a more efficacious product. These findings also highlight the need for further study of the mechanistic differences driving these observations at the antigen release, presentation, cytokine secretion, and T cell recognition stages. Our results demonstrate that PTT expands a multi-targeted yet clonal tumor-specific T cell product, supporting its potential for further development as an adoptive cell therapy for solid tumors alone and in combination with complementary immunotherapeutic modalities.

1228 Metabolic Reprogramming Enhances HER2-CAR T Cell Therapy for HER2-ADC-resistant tumors

Xiaotong Song, Texas A&M University, Houston, TX

Background: HER2-ADC therapy (e.g., T-DXd) has limited success in HER2-positive tumors, with a response rate of just 29.4% in solid tumors. Resistance is driven by HER2 heterodimerization with HER3 or EGFR. Meanwhile, HER2-CAR T cell therapies struggle in clinical settings due to poor survival in the glucose-deprived tumor microenvironment (TME). Building on our findings that inosine can fuel CAR T cells in glucose-deprived conditions (*Nat Metabolism*, 2020), we recently showed that adenosine deaminase 1 (ADA1) enhances CAR T cell persistence by converting adenosine into inosine (*Cell Rep Med*, 2024). This study evaluates ADA1-based metabolic reprogramming to improve HER2-CAR T cell efficacy in HER2-ADC-resistant tumors.

Methods: Human PBMCs were transduced with retroviral vectors encoding HER2-CAR, ADA1, and CD26 (HER2-MRCAR). Functional assays assessed transgene expression, cytotoxicity, and persistence in vitro. Antitumor activity was evaluated in HER2-positive xenograft mouse models resistant to HER2-ADC therapy.

Results: HER2-MRCAR T cells outperformed conventional HER2-CAR T cells in vitro, showing greater proliferation, reduced exhaustion, and superior targeting of HER2-ADC-resistant cells. CD26 further enhanced T cell trafficking and invasion into tumor tissues. In xenograft models, HER2-MRCAR T cells achieved significant tumor regression compared to standard HER2-CAR T cells, with no additional toxicity observed.

Conclusions: Metabolic reprogramming via ADA1 and CD26 transforms HER2-CAR T cells into a potent therapy for HER2-ADC-resistant tumors. This approach enhances metabolic fitness, persistence, and antitumor efficacy, offering a promising strategy to overcome current therapeutic limitations. Further clinical validation is warranted.

1229 FT836, a Novel MICA/B-targeting CAR T-cell Therapy Engineered to Eliminate the Need for Conditioning Chemotherapy with Broad Activity Across Solid Tumor Indications

Spas Markov[1], Shilpi Chandra[1], Samad Ibitokou[1], Soheila Shirinbak[1], Kyla Omilusik[1], Miguel Meza[2], Thomas Dailey[1], Angela Gentile[1], Mochtar Pribadi[1], Lauren Fong[3], Betsy Rezner[1], Tom Lee[1], Ramzey Abujarour[1], Karina Palomares[1], Raedun Clarke[1], Jode Goodridge[1], Kai Wucherpfennig[4], Bob Valamehr[1], Alex Garcia[5], Martin Hosking[1]*

**Corresponding Author*

Several challenges hinder the successful application of chimeric antigen receptor (CAR) T-cell therapies in solid tumor settings, including tumor antigen selection, antigen heterogeneity and escape, and inconsistencies in the manufacture of drug product. Furthermore, autologous and allogeneic CAR T-cell therapies have traditionally required administration to patients of lymphodepleting chemotherapy to eliminate the host immune systems and promote product expansion. However, adverse events following lymphodepletion, especially the susceptibility to opportunistic infections remain a significant and ongoing concern. The limited activity of CAR T-cell therapies within the solid tumor space combined with the toxicity risks of lymphodepletion underscores the need for (i) novel antigen targeting solutions and (ii) reduction or elimination of conditioning chemotherapy.

We have developed FT836, an off-the-shelf CAR T cell engineered to broadly target solid tumors without requiring administration of conditioning chemotherapy to patients. Through a novel CAR (3MICA CAR) that recognizes the conserved α3 domain of the inducible and highly polymorphic NKG2D stress ligands MHC class I related proteins A and B (MICA/B), FT836 targets a wide range of tumor indications across varying antigen density levels, reaching 94.5% $\pm$ 5.0% tumor growth inhibition (TGI) in xenograft models of prostate, ovarian, lung, and cervical cancer, comparable to primary CAR T-cells (Fig. 1). Notably, combination with chemotherapy, radiotherapy, or antibody drug conjugates, such as trastuzumab-deruxtecan, increased MICA/B expression on tumor cells and enhanced FT836 CAR-mediated anti-tumor activity. FT836 is also engineered with a high affinity non-cleavable CD16 (hnCD16) that allows for combination with therapeutic antibodies targeting EGFR, cMET, PDL1, or HER2, promoting antibody-dependent cellular cytotoxicity and enabling the elimination of MICA/B+ and MICA/B- target cells.

FT836 has also been specifically engineered to support functional persistence without the need for conditioning chemotherapy. Resistance to host immune cell-mediated rejection is the direct result of: (i) CD58 deletion to unidirectionally limit immune synapse formation by allogeneic immune cells, and (ii) alloimmune defense receptor (ADR) expression to target and eliminate reactive 4-1BB+ allogeneic immune cells. FT836 demonstrated functional persistence over multiple rounds of tumor challenge even with repeat exposure to allogeneic immune cells primed to specifically target FT836 (Fig. 2).

In summary, FT836 is an off-the-shelf, multiplexed-engineered CAR T cell targeting the α3 domain of MICA/B for pan-tumor applicability that demonstrates robust and durable anti-tumor activity across multiple solid tumor indications, including in the presence of primed and potent allogeneic immune cells. As a result, FT836 is uniquely equipped to eliminate the need for conditioning chemotherapy, facilitating broader clinical application both as monotherapy and in combination with standard-of-care agents such as chemotherapy and therapeutic monoclonal antibodies, overcoming multiple challenges that limit adoptive cell therapies in treating solid tumor.

Fig. 1: ***FT836 demonstrates broad and potent anti-tumor activity in several xenograft settings in vivo, uniquely matching primary CAR-T cell activity.***

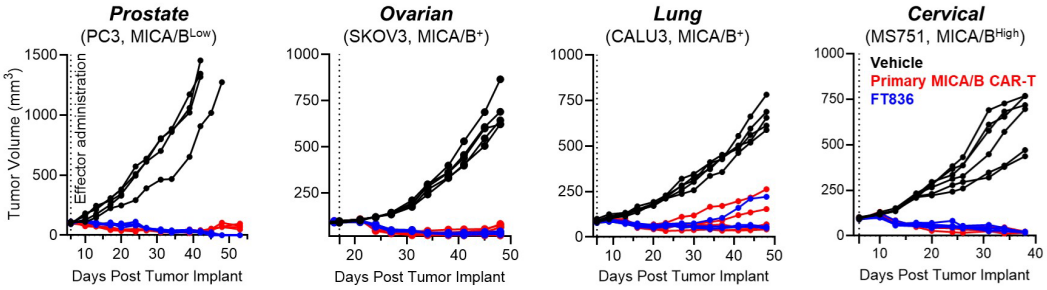

Fig. 2: ***FT836 resists allorejection while maintaining durable anti-tumor activity and persistence.***

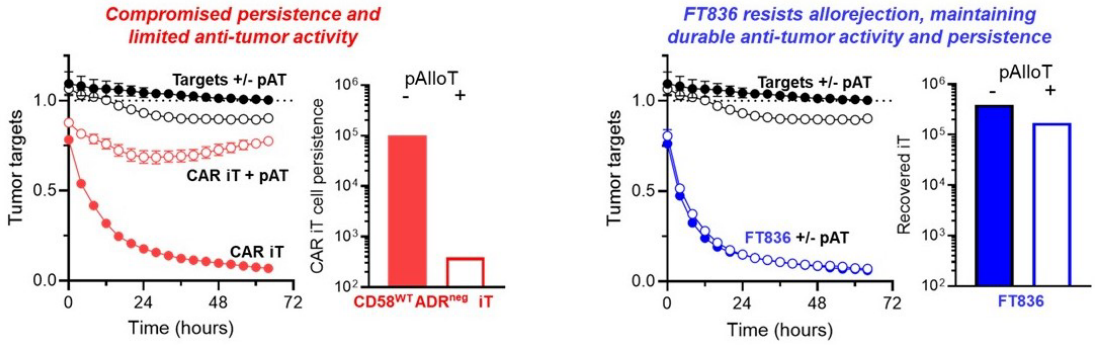

1230 Onboard, Membrane-tethered IL-12 Boosts Potency and Maintains Selectivity of a Tmod NOT Gate

Jingli Zhang[1], Sara Imboden[1], Jushen Liang[1], Sanam Shafaattalab[1], Richele Bruno[2], Alexandre Zampieri, Alexander Kamb[3]

Introduction: Cell therapies for solid tumors are associated with unique challenges compared with liquid tumors, such as antigen tissue-specificity, accessibility to tumor tissues, and problematic tumor microenvironment. Cells engineered with receptors that act as synthetic logic gates promise to address the issue of tumor specificity by

targeting antigen profiles rather than single antigens. Nevertheless, there are limits to the potency benefit that can be achieved at the level of the antigen-targeting receptors. One approach to enhance potency beyond the acute sensitivity of antigen receptor activation is to co-opt a major source of ancillary stimulation in the normal immune response, signal 3 cytokine pathways.

Methods: Enhancing CAR efficacy with engineered onboard cytokines, often referred to as 'armoring', is one such approach to boosting potency. However, such constructs run the risk of overriding tumor selectivity and eroding the therapeutic window. Here we design and test membrane-tethered IL-12 that enhances potency and preserves selectivity of a synthetic NOT logic-gated, dual-receptor CAR-T system called Tmod^{TM}, potentially addressing some of the major challenges in oncology in a single synthetic design[1 2] (Figure 1).

Results: We focused especially on a module that encodes T cell activation-inducible membrane-tethered IL-12 (mem-IL-12) and found that it significantly augments Tmod antigen-dependent cytotoxicity and long-term persistence both *in vitro* and *in vivo*, without compromising the NOT gate tumor selectivity. Notably, 2 substantially different *in vivo* models, including one that employs mouse surrogate antigens[3] (Figure 2), were used to assess preclinical dose-dependent efficacy and safety. In addition, the membrane-tethered format displayed minimal soluble IL-12 release both *in vitro* and *in vivo*, limiting the potential systematic toxicity caused by IL-12.

Conclusions: Together, these studies demonstrated the robustness of the design of membrane-tethered IL-12 as a new module that can be added to the Tmod^{TM} platform and suggested further avenues for improvement of solid tumor cell therapy.

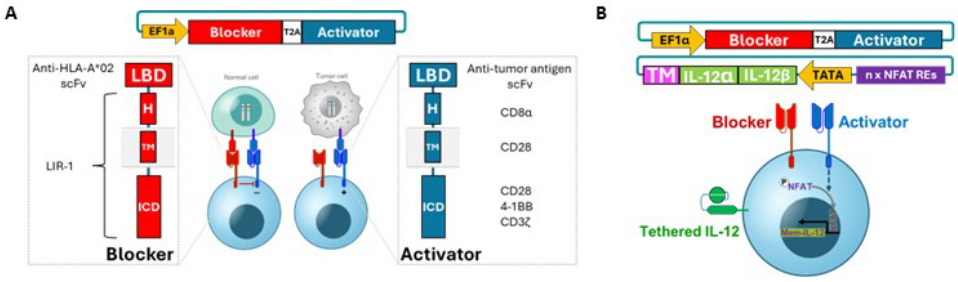

Figure 1 (A) Molecular composition of tumor antigen-targeted Tmod(sh) constructs. Tumor antigen-targeting activator and HLA-A*02-targeting blocker receptors linked by a T2A were co-expressed on a single transcript. The blocker receptor is composed of a LILRB1 (LIR-1) hinge, transmembrane (TM), and intracellular domain (ICD). The activator receptor is a generation 3 (Gen3) CAR composed of a CD8α hinge, CD28 TM, and fused CD28, 4-1BB, and CD3z ICDs. (B) Tmod(sh) and membrane-tethered IL-12 are co-expressed from two separate lentiviral constructs, with one construct encoding HLA-A*02 blocker and activator and the other construct encoding IL-12 heterodimer linked to B7 transmembrane domain (membrane-tethered).

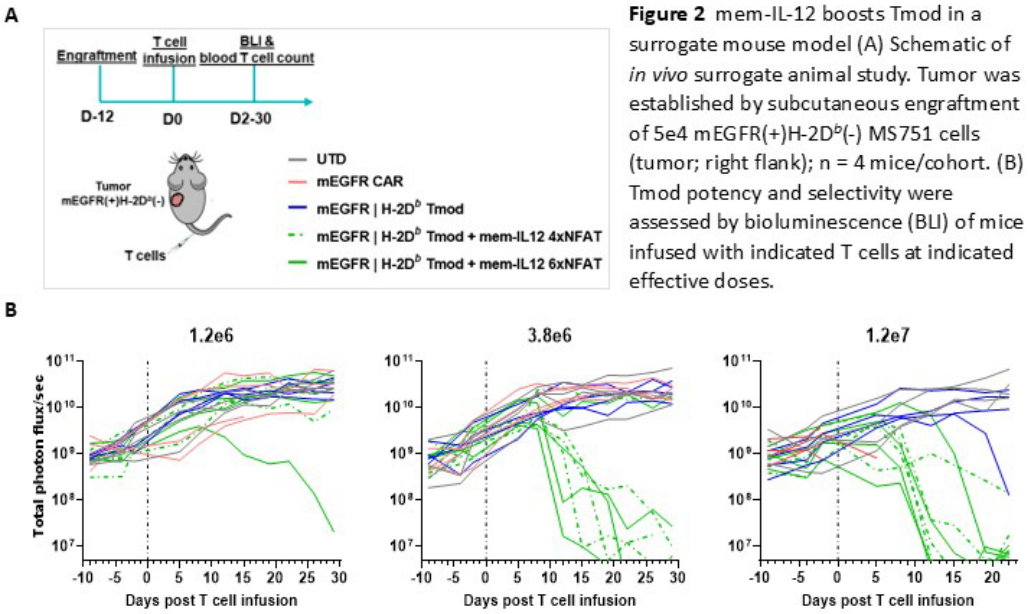

Figure 2 mem-IL-12 boosts Tmod in a surrogate mouse model (A) Schematic of *in vivo* surrogate animal study. Tumor was established by subcutaneous engraftment of 5e4 mEGFR(+)H-2D^b(-) MS751 cells (tumor; right flank); n = 4 mice/cohort. (B) Tmod potency and selectivity were assessed by bioluminescence (BLI) of mice infused with indicated T cells at indicated effective doses.

1231 Enhancing CAR-T Cell Therapy Efficacy Against Solid Tumors Using a Synthetic Pathway Activator (SPA)

Weidong Feng[1], Lan chen[2], Thomas Gardner[2], Beatriz Millare[2], Anzhi Yao[3], Josephine Giles[4], Ashley Cass[2], Suchismita Mohanty[2], Jeremy chen[2], Alma Gomez[2], David DeTomaso[2], Aaron Cooper[5], Levi Gray-Rupp[2], Edward Wherry[6], Nicholas Haining[2]

Chimeric antigen receptor T (CAR-T) cell therapy efficacy against solid tumors is hindered by antigen escape, T cell exhaustion, limited persistence, and adverse events (e.g. CRS, IEC-HS and ICANS). We introduce a novel synthetic biology module termed a Synthetic Pathway Activator (SPA) that is designed to overcome these challenges.

To develop the SPA, we screened a library of synthetic cytokine receptors to identify those that increase the potency, expansion and persistence of autologous T cells. The SPA selected for inclusion in our clinical programs significantly enhanced both the short-term and long-term potency of CAR-T cells, demonstrated through cytotoxicity assays in vitro against diverse target cell lines and in vivo via human xenograft models. Specifically, SPA-expressing CAR-T cells showed improved proliferation in response to TCR ligation and CAR antigen stimulation without exhibiting cytokine independent outgrowth. Additionally, expression of the SPA rendered CAR-T cells more sensitive to activation by tumor antigens, enabling effective targeting of low antigen-expressing cells. Furthermore, SPA-expressing CAR-T cells exhibited increased persistence in vitro and in vivo, alongside notable delay or prevention of exhaustion. Importantly, SPA altered the effector gene expression and cytokine secretion profile of CAR-T cells, showing elevated levels of Perforin, Granzyme B, and IL-10.

Ongoing mechanistic investigations reveal that SPA elevates intracellular pSTAT3 and pSTAT1 levels, thereby upregulating downstream gene expression linked to T cell proliferation. We tested the effect of SPA expression on the development of T cell exhaustion in a 14-day repetitive stimulation assay. Temporal single-cell RNA sequencing (scRNA-seq) and pseudotime analysis of SPA-expressing CAR-T cells indicated distinct differentiation trajectories compared to control CAR-T cells lacking SPA, with enhanced retention of memory markers. Importantly, SPA-expressing CAR-T cells did not develop the transcriptional or epigenetic hallmarks of exhaustion, while control CAR-T cells did.

In our ongoing phase I/II clinical trial for clear cell renal carcinoma (ccRCC) using SPA-expressing CAR-T cells, we aim to clinically validate the enhanced anti-tumor activity achieved through this innovative design. Our work continues to deepen our understanding of the mechanisms driving the next generation of CAR-T cell therapies targeting solid tumors.

1232 Label-free, High-throughput Functional Assays for Evaluating the Potency and Safety of Cell Therapies

Benjamin Streeter[1], Denise Sullivan[1], Austin Passaro[1], Skylar Dewees[1], Stacie Chvatal[1], Daniel Millard[2], Danielle Califano[1], **Henry Ordutowski[1]**

Chimeric antigen receptor (CAR) T cells have emerged as a promising treatment for several cancers. Effective CAR T cell products should have cytotoxic effects that are sufficient to eliminate tumor cells and that are specific to cancerous tissue, thereby avoiding off-tumor adverse events. To that end, we developed in vitro assays to assess on-tumor CAR T cell potency using the Maestro TrayZ and off-tumor CAR T cell cardiotoxicity using the Maestro Pro system. Both assays utilize the high-throughput, label-free capabilities of the Maestro platforms. To assess CAR T cell potency, HER2+ ovarian cancer cells (SKOV3s) were treated with HER2-specific CAR T cells at three effector-to-target (E:T) cell ratios (1:5, 1:2, 2:1). Real-time electrical impedance measurements on the Maestro TrayZ detected SKOV3 proliferation and death in four different plates simultaneously. SKOV3s were killed in a CAR T cell dose-dependent manner; that is, higher CAR T cell doses induced larger decreases in SKOV3 impedance, indicative of increased SKOV3 death. At the highest dose (E:T = 2:1), the KT50 was 10.4 hours, with a coefficient of variation of 9.8% across the four plates. Following this assessment of CAR T cell potency, we used induced pluripotent stem cell-derived cardiomyocytes (iPSC-CMs) to study the same HER2-CAR T cells' possible cardiotoxic side effects. The iPSC-CMs, confirmed to express HER2, were dosed with increasing E:T ratios (1:80 to 1:1) of HER2-CAR T cells. Both MEA viability (resistance) and electrophysiology measurements were taken each day for up to 7 days using the Maestro Pro. We found a dose-dependent decrease in resistance detected from iPSC-CMs dosed with increasing E:T ratios of HER2-CAR T cells and detected significant killing (55.6% decrease in resistance) by the 1:1 CAR T group as early as Day 1 post-dose. By comparison, we observed no difference in resistance between HER2-negative iPSC-derived neuron control wells and those treated with HER2-CAR T cells. Further, we dosed the iPSC-CMs with non-transduced T cells and saw a minimal (5.7%) decrease in iPSC-CM resistance at Day 4 compared to dosing with CAR T cells at the same E:T ratio (71.8% decrease). Finally, we measured the changes in Fridericia-corrected field potential duration (FPDc) of iPSC-CMs dosed with CAR T cells at increasing E:T ratios. Interestingly, large decreases in the FPDc were apparent at 1 hour post-dose in the 1:1 CAR T dose group, illustrating that these electrophysiological changes may signal on-target, off-tumor effects even earlier than cytotoxicity data. In summary, the assays developed here on the Maestro platforms can be used to assess two of the most vital qualities of a given CAR T cell therapy: potency and safety.

1233 High Output, Low-Background Hypoxia Responsive Synthetic Gene Circuits for Improving the Safety and Potency of Solid Tumor CAR T Cell Therapy

Yannick Schreiber[1]*, Joshua Leonard[2]
[1]Northwestern University, Chicago, IL, [2]Northwestern University, Evanston, IL
Corresponding Author

Chimeric antigen receptor (CAR) T cell therapies have demonstrated promise in treating hematological malignancies, but their application in solid tumors remains limited due to challenges including (1) a lack of unique solid tumor antigens, leading to potential off-target effects and safety risks, and (2) the immunosuppressive microenvironment that hinders T cell efficacy. To address these challenges, we engineered synthetic gene circuits that incorporate a hypoxia biosensor (HBS) that enables cells to sense and respond to the hypoxic conditions ubiquitous to solid tumor microenvironments. The biosensor circuit drives expression of CAR along with the native hypoxia-inducible transcription factors HIF1α and HIF2α to enable tumor-specific activation. Expanding on our prior work applying the sensor in an oxygen-degradable CAR expression system, we evaluated biosensor-circuit engineered HEK cells expressing LumiScarlet reporter under normoxic (21% O_2) and hypoxic (5% and 1% O_2)

conditions. This approach identified candidate circuits with high reporter output and low background expression, providing new insights into hypoxia-responsive gene regulation. Additionally, we observed differential CAR transgene expression across HIF1α- and HIF2α-containing circuits, suggesting distinct regulatory mechanisms. We also demonstrated that incorporating synthetic transcription factors and promoters markedly amplifies transgene expression beyond that achievable with HIF1α and HIF2α circuit architectures. Ongoing studies are assessing the function of these constructs in primary T cells, with the goal of enhancing CAR-T cell function in solid tumors. This work establishes a foundation for safer, more effective cell therapies by leveraging synthetic biology to overcome challenges posed by the solid tumor microenvironment.

1234 *In Vivo* Persistence and Clonal Dynamics of Genetically Barcoded IL-15-Armored vs. Unarmored Anti-CD20 CAR-NK Cells in an Autologous Rhesus Macaque Model

Taha Bartu Hayal[1], Chuanfeng Wu[2], David Allan[1], Brynn Duncan[2], Sogun Hong[2], Rafet Basar[3], Katy Rezvani[3], Cynthia Dunbar[2]*
*[1] NHLBI-NIH, Bethesda, MD, [2]National Institutes of Health (NIH), Bethesda, MD, [3]MD Anderson Cancer Center, Houston, TX *Corresponding Author*

Natural killer (NK) cells can recognize and kill virally-infected or malignant cells. Chimeric antigen receptor (CAR) NK cells combine the inherent immunosurveillance of NK cells with the directed precision of CARs, and are associated with efficient targeting, antitumor activity, and low toxicity. Interleukin-15 (IL-15) is a key cytokine supporting NK homeostasis, proliferation, and survival. Murine xenograft studies suggested that inclusion of the IL-15 cDNA in CARs enhances CAR-NK expansion, persistence, and cytotoxicity *in vivo*, with IL-15-armored CAR-NK showing promise in clinical trials for hematologic cancers. However, the long-term safety, persistence, and clonal dynamics of IL-15-armored versus unarmored CAR-NK remains underexplored.

In this study, we utilized barcoded lentiviral vectors expressing anti-CD20 CAR with or without soluble IL-15 to engineer CAR-NKs, which were administered post-cyclophosphamide conditioning in autologous macaque at a concentration of $1x10^7$ CAR-NK cells/kg. Equal proportions of IL-15-armored (CAR-IL15-Lib21) and unarmored (CAR-EGFRt-Lib19) CAR-NK cells were infused, allowing a detailed comparison of their dynamics, trafficking and clonality in peripheral blood (PB), bone marrow (BM), liver, spleen, lymph nodes (LN) and implanted subcutaneous B cells (Fig. A). The transduction efficiency of NK cells was robust, reaching 50% for CAR-EGFRt-Lib19 and 60% for CAR-IL15-Lib21 vectors, with similar phenotypic profiles at the time of infusion. *In vivo*, CAR-NK expansion in PB peaked on day 12, before declining to low levels by day 28, accompanied by a significant reduction in PB CD20+ B cells as early as day 1, persisting through day 28 (Fig. B). Similarly, tissue resident B cell percentages decreased over time, particularly in BM and liver. By day 7, CAR-NKs were more abundant in tissues compared to PB, gradually diminishing by day 17, with better persistence in LNs (Fig C). Additionally, CAR-NKs were enriched at B cell injection sites compared to control sites 7 days after subcutaneous B cell injections (Fig. D). Interestingly, IL-15-armored CAR-NKs did not demonstrate superior *in vivo* expansion or persistence compared to unarmored CAR-NKs, as revealed by barcode analysis. Notably, IL-15-armored cells exhibited similar clonal diversity up to day 17 (Fig. E), with significantly lower number of clones (Fig. F), without overt oligoclonal expansions. No toxicities related to the CAR-NK infusion was noted.

These findings suggest while anti-CD20 CAR-NKs effectively target B cells and traffic into tissues, inclusion of IL-15 does not significantly enhance short-term expansion or persistence of CAR-NK and may not be necessary in an autologous or non-xenogeneic setting. Ongoing studies will explore the long-term impact of IL-15 on CAR-NK cells in additional animals.

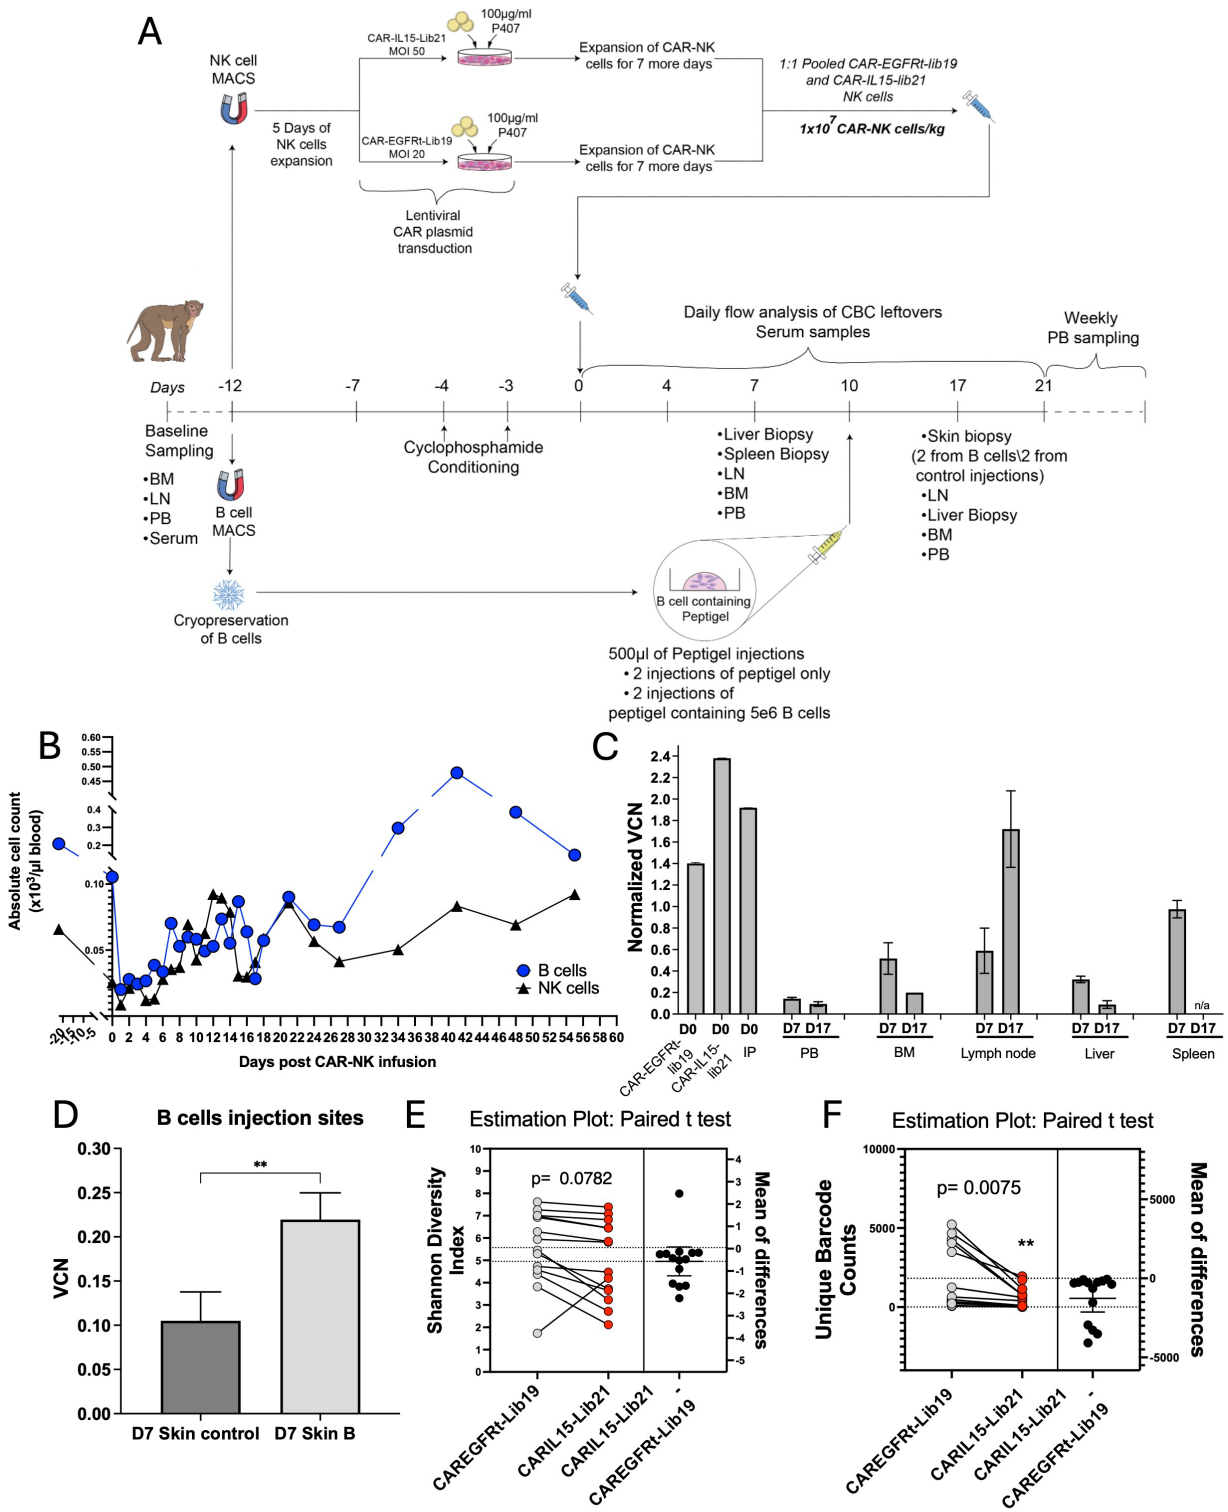

Figure. (A) Experimental design, including the isolation of peripheral blood (PB) NK cells, expansion, transduction of rhesus macaque NK cells using CAR-EGFR-Lib19 and CAR-IL15-Lib21 lentivirus barcode libraries, and the autologous infusion of CAR-NK cells. (B) Absolute counts of B and NK cells over time in PB following CAR-NK infusion. (C) Vector copy number (VCN) of the CAR cassette in NK cells from *in vitro* and *in vivo* samples, detected by ddPCR. "IP" indicates the infusion product. VCN was normalized based on the percentage of NK cells in mononuclear cells isolated from *in vivo* samples. (D) CAR vector copy number (VCN) in cells from skin biopsies at subcutaneous B cell injection sites, collected 7 days after injection, detected by ddPCR. (E) Statistical analysis of barcodes for both the IL-15-armored and unarmored arms in each sample showing that IL-15-armored CAR-NK cells exhibit similar overall diversity to IL-15-unarmored CAR-NK cells in peripheral blood (PB) and tissues *in vivo*. The left panel shows results from a paired t-test for Shannon diversity across all *in vivo* samples, while the right panel displays the mean differences in Shannon diversity indexes. (F) Statistical analysis demonstrating that IL-15-armored CAR-NK cells exhibit fewer clones compared to unarmored CAR-NK cells in both PB and tissues *in vivo*.

1235 Understanding the role of *NEFM* and *UACA* genes in CART cell effector function and dysfunction

Cody Hall[1]*, Ismail Can[1], R. Sakemura[1], Claudia Manriquez-Roman[1], Olivia Sirpilla[1], Carli Stewart[1], Kun Yun[1], Truc Huynh[1], Grace DeFranco[1], Sophia Goldberg[1], Dominic Skeele[1], Ekene Ogbodo[1], Lionel Aurelien Kankeu Fonkoua[1], Jennifer Feigin[2], Long Mai[1], Hong Xia[1], Brooke Kimball[1], Mehrdad Hefazi Torghabeh[1], Michael Ruff[1], Elizabeth Siegler[1], Saad Kenderian[3]

Introduction: Despite the high initial responses to chimeric antigen receptor T (CART) cell therapy, most patients relapse within the first 1-2 years. T cell quality influences the success of CART cell therapies greatly, and T cells from cancer patients are prone to transition into dysfunctional states, such as exhaustion and senescence. Previously, we developed an *in vitro* model for repeated cycles of antigen-specific CART cell activation followed by rest periods, mimicking cancer relapse, to study the development of CART cell dysfunction and identify the mechanisms behind it. We repeatedly activated/rested CART cells generated from three healthy donors. Through RNA-seq analysis of CART cells at different activation/resting stages, we identified Uveal Autoantigen with Coiled-Coil Domains and Ankyrin (*UACA*) and Neurofilament Medium Chain (*NEFM*) genes to be downregulated in recurrently activated/rested CART cells that are costimulated with 4-1BB. To expand on these results, we induced overexpression of *NEFM* and *UACA* in CD19-targeted CART cells with costimulation via 4-1BB (BBζ) or CD28 (28ζ) and examined CART immunophenotype and effector functions.

Methods: Briefly, *UACA* and *NEFM* were ectopically expressed in BBζ or 28ζ CART cells (n=4, healthy donors) through lentiviral integration. *UACA* and *NEFM* gene expression was measured by qPCR. The resulting CART cells were flowed for exhaustion and senescence markers. The amount of cycling CART cells after target cell coculture was measured by 5-Ethylyl-2'-deoxyuridine (EdU) assay. The efficacy of control, *UACA,* and *NEFM* overexpressing BBζ and 28ζ cells was measured by antigen-specific cytotoxicity and proliferation assays.

Results: *UACA* and *NEFM* genes both showed multifold overexpression as compared to controls in both BBζ and 28ζ cells (BBζ: $p=<0.001$; 28ζ: $p=<0.001$). CART cell cycling 24 hours after target cell coculture increased in *UACA*- and *NEFM*-overexpressing BBζ and 28ζ cells as measured by EdU assay (BBζ: $p=<0.001$; 28ζ: $p<0.05$). Cytotoxicity assays after 48 hours of target cell coculture showed increased killing in *UACA*- and *NEFM*-overexpressing BBζ and 28ζ cells as compared to controls across multiple effector-to-target ratios (BBζ: $p<0.01$; 28ζ: $p<0.05$). Finally, when looking at T cell exhaustion markers LAG3 (BBζ: $p<0.001$; 28ζ: $p<0.01$), TIM-3 (BBζ: $p=0.001$; 28ζ: $p<0.01$), and PD1 (BBζ: $p=<0.001$; 28ζ: $p<0.05$) were all significantly downregulated in *UACA*- and *NEFM*- overexpressed CART cells compared to control CART cells.

Conclusion: Our prior RNA-seq analysis indicated downregulation of *UACA* and *NEFM* in recurrently activated/rested BBζ. In the present study, we overexpressed these two genes of interest in CART cells that were costimulated with either 4-1BB or CD28. Ultimately, our study indicates that *UACA* and *NEFM* overexpression appears to confer improved cytotoxicity and proliferative ability in CART cells as compared to control CART cells. The increased expression of these genes also leads to a decreased exhaustive immunophenotype. Further elucidation into the role of these two genes could shed light into important pathways that are key for CART cell dysfunction.

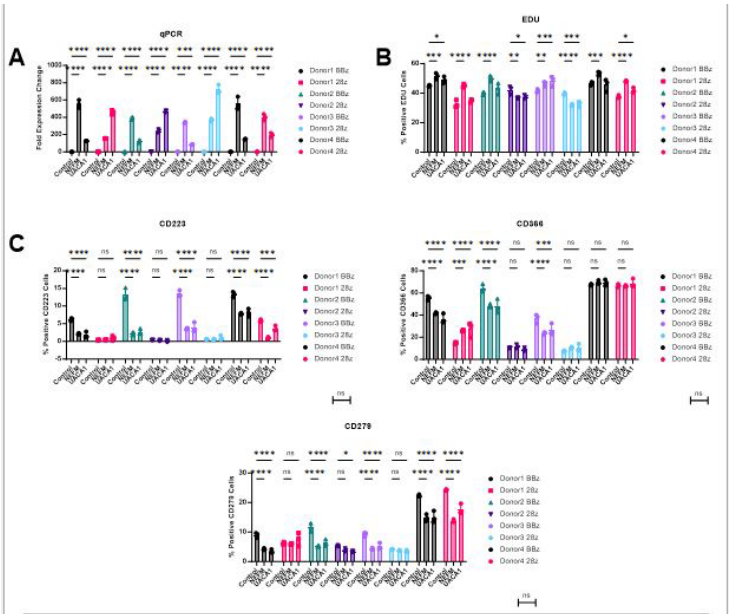

Figure 1: *NEFM* and *UACA* overexpression increases Proliferation and reduces dysfunction. A. UACA and NEFM overexpression was confirmed by qPCR analasys across all 4 healthy donors. **B.** EdU assays displaying percent positive cells after 24 hour of coculture with target cells. **C.** Immunophenotyping across all 4 healthy living donors for LAG3 (CD223), TIM-3 (CD266), and PD1 (CD279)

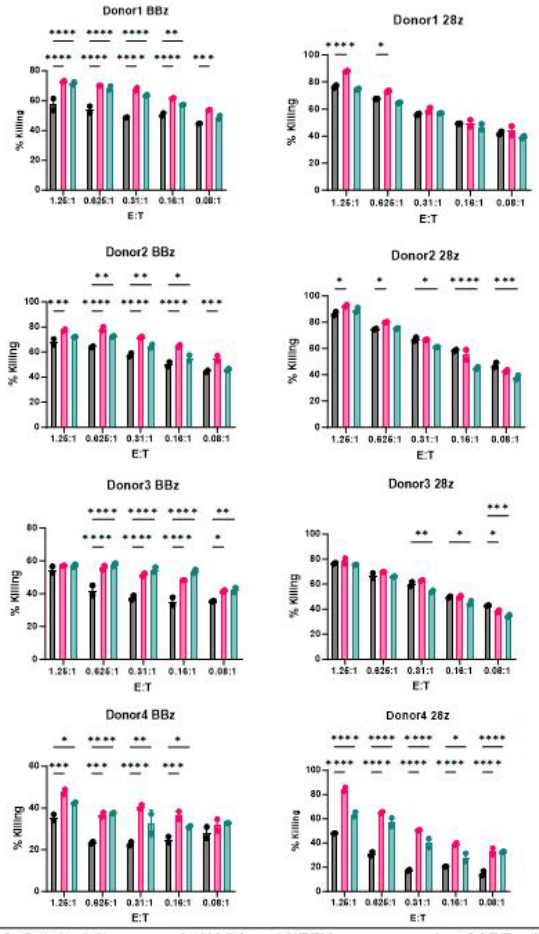

Figure 2: Cytotoxicity assays in UACA and NEFM overexpressing CART cells. Cytotoxicity assay were completed after 48 hours of coculture of CART cells transfected with either a control plasmid, *NEFM*, or *UACA* with luciferase expressing target cells

1236 Gamma Retroviral Vectors Pseudotyped with Either Baboon or RD114 Envelope Achieved High Transduction Efficiency and Improved Cytotoxicity of CAR-CYNK Cells

Minjun Yu[1], John Fitzgerald[1], Alexandra Hariri, Lin Kang[1], Anna Gosiewska[2], Robert Hariri[1], **Rafijul Bari**
[1]Celularity, Florham park, NJ, [2]Celularity Inc., Florham Park, NJ

Introduction: Celularity CYNK cells are allogenic, off-the-shelf, cryopreserved natural killer (NK) cells differentiated from placental CD34$^+$ cells. CYNK cells are shown to have the potential to be good resources for CAR-NK cell therapy. However, low transduction efficiency and the loss of transgenes in the lentiviral vector-based transduction method present a major hurdle in developing CAR-CYNK cells for cell therapy. To address this, in this study, we compared the transduction efficiency and functional activities of CYNK cells with gamma retroviral vector pseudotyped with either baboon or RD114 envelope glycoprotein, and lentiviral vector pseudotyped with VSV-G envelope glycoprotein.

Methods: The differentiation and expansion of CYNK cells from placental CD34$^+$ cells were achieved following a 35-day cell culture protocol developed in Celularity. CD19-CAR was cloned into lentiviral and the gamma retroviral vector backbone. The lentiviral vector was pseudotyped with VSV-G envelope glycoprotein (VSV-G-LV), and the gamma retroviral vector was pseudotyped with either baboon (BaEV-RV) or RD114 (RD114EV-RV) envelope glycoprotein using 293Vec-RD114 and 293Vec-Baev cell lines from BioVec Pharma. Transduction was performed on Day 5 of the cell differentiation process. The transduction efficiency was determined by flow cytometry using

CAR detection reagents. The CAR-CYNK cell purity, phenotype, and functions were assessed after the differentiation was completed.

Results: Compared to the VSV-G-LV, both BaEV-RV and RD114EV-RV mediated transductions demonstrated significantly higher transduction efficiency. The highest transduction efficiency of CYNK cells after differentiation was observed with BAEV-RV (79.1%) followed by RD114EV-RV (68.9%). VSV-G-LV based transduction efficiency of CYNK cells was only 10.3%. Moreover, unlike lentiviral vector transduction, in which transgene expression is significantly reduced during the differentiation process, retroviral vector-based transduction of CYNK cells showed improved transgene persistency. Due to the higher transduction efficiency and stable CAR expression, the cytotoxic function of CAR-CYNK cells against target cells also improved in retroviral-based transduction method. Both lentiviral and retroviral vector-mediated transduction did not significantly impact CYNK cell phenotype and cell expansion compared to non-transduced cells.

Conclusions: Baboon and RD114 envelope pseudotyped gamma retroviral vector-based transduction method could be a potential gene modification tool for placental CD34+ derived CYNK cells.

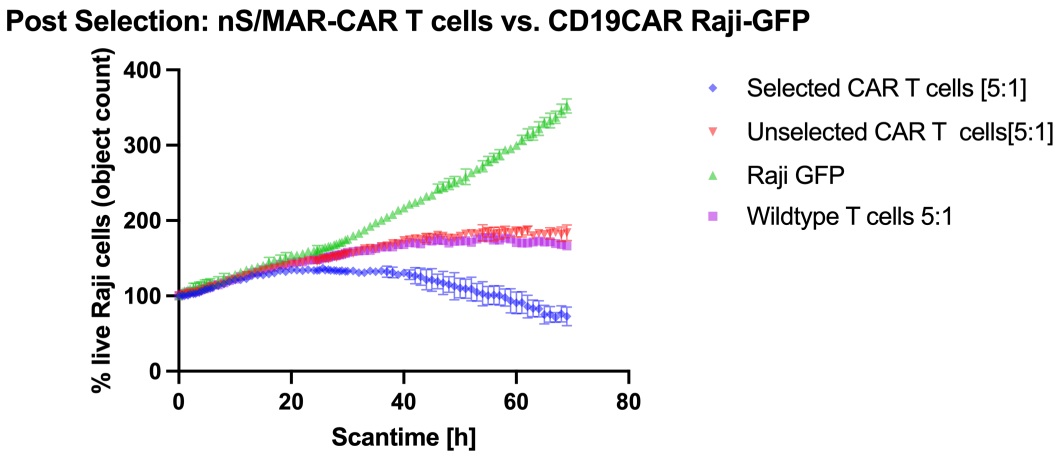
1237 Methotrexate-Based Selection of S/MAR DNA Nanovectors Enhances Cytotoxic Activity of CAR-Modified Blood Cells

Malte Thomas[1], Patrick Derigs[2], Alice De Roia[3], Luisa Burger[4], Carsten Mul¨Ler-Tidow[5], Richard Harbottle[6]
[1]German Cancer Research Center Heidelberg, Heidelberg, Baden-Wuerttemberg, Germany, [2]German Cancer Research Center, Heidelberg, Germany, Heidelberg, Baden-Wuerttemberg, Germany, [3]Heidelberg, B-W, Germany, [4]German Cancer Research Center Heidelberg, Heidelberg, Germany, [5]Universität Heidelberg, GERMANY, [6]German Cancer Research Center, Heidelberg, Germany

Genetic modification of blood cells such as T cells and NK cells holds significant promise in cancer therapy, enabling targeted and potent immunotherapies. While CRISPR/Cas9 and viral vectors are frequently employed for introducing engineered constructs such as chimeric antigen receptors (CARs), these approaches still involve risks like off-target effects and insertional mutagenesis. To address these limitations, we have developed a Scaffold/Matrix-Associated Regions (S/MAR) based non-viral DNA nanovector platform (nS/MAR). S/MAR elements, derived from chromatin-associated regions, confer episomal persistence to the nanovectors, thereby minimizing the risk of mutagenesis. Unlike viral vectors, nS/MAR does not trigger strong immune responses. Additionally, nS/MAR can carry large therapeutic transgenes or complex genetic constructs and has the potential to reduce manufacturing costs for clinical-scale gene modification of primary blood cells.

In this project, we have developed nS/MAR vectors that carry a double-mutant variant of the human dihydrofolate reductase gene (hDHFR), conferring resistance to the clinically established drug methotrexate (MTX). Using the MaxCyte ExPERT GTx™ electroporation system, we transfected K562 cells, NK92 cells, and primary T cells. Transfection efficiency, cell viability, and transgene persistence were assessed by flow cytometry. Cell killing assays were conducted against Raji-GFP cells using the IncuCyte SX5™ system. We demonstrate that MTX serves as an effective selection agent for nS/MAR vectors across multiple blood cell types. This enabled stable genetic modification of K562 cells. Strikingly, MTX-based selection significantly enhanced the cytotoxic activity of CAR-modified T cells, prolonging their tumor cell-killing function in vitro (Figure 1). Similarly, in NK92 cells, MTX selection achieved higher transgene positivity (97.3%) compared to puromycin (28.9%), with comparable viabilities (~50%).

These results underscore the potential of combining nS/MAR vectors with MTX selection to achieve safe, stable, and functionally enhanced genetic modification of T and NK cells. The capability for in vivo selection using a clinically approved drug like MTX offers a promising pathway to more effective and controlled immunotherapies for hematologic malignancies and solid tumors.



1238 Cytokine Release Syndrome and Cardiovascular Outcomes: A Population-Based Comparison Between Patients Infected With Severe Acute Respiratory Syndrome Coronavirus 2 and Those Who Received Chimeric Antigen Receptor T-Cell Therapy

Abdu Mohammed[1], Adamsegd Gebremedhen[2], Mamdouh Souleymane[3], Jowan Al-Nusair[4], Michael Fatuyi[5], Mark Mizikar, Donald Lynch[6]
[1]Trinity Health System, Steubenville, OH, [2]Marshall University School of Medicine, Huntington, WV, [3]Marshall University Joan C. Edwards School of Medicine, Huntington, WV, [4]Marshall University, Huntington, WV, [5]University of Wisconsin, Madison, WI, [6]University of Cincinnati College of Medicine, Cincinnati, OH

Introduction: Cytokine release syndrome (CRS) is common in patients infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and those receiving chimeric antigen receptor (CAR) T-cell therapy, leading to complications such as cardiovascular collapse and death. However, comparative analyses of CRS-associated cardiovascular outcomes between these groups are limited. This study aims to fill this gap in literature.

Methods: We identified patients from the National Inpatient Sample with SARS-CoV-2 infection and those who received CAR T-cell therapy from 2018 to 2021, using the International Classification of Diseases, 10th Revision. We included those with a concurrent diagnosis of CRS. We compared sociodemographic characteristics and comorbidities between SARS-CoV-2 patients with CRS and CAR T-cell therapy patients with CRS. Our primary outcome was all-cause mortality, and we studied various secondary cardiovascular outcomes. We utilized multivariate regression models to evaluate outcome disparities between the groups, with statistical significance set at $p < 0.05$.

Results: We analyzed 20,785 SARS-CoV-2 patients and 2,150 CAR T-cell therapy patients with CRS. The mortality rate was 19.8% for SARS-CoV-2 patients versus 3.5% for CAR T-cell patients. SARS-CoV-2 patients were younger (mean age 59.9 vs 61.5 years, p=0.03) and had a higher proportion of non-white patients (40.5% vs 23.3%, p<0.001). They had higher odds of all-cause mortality, with an adjusted odds ratio (aOR) of 19.75 (95% confidence interval [CI] 10.34-37.72) as well as acute congestive heart failure (aOR 5.16, 95% CI 2.20-12.08), acute coronary syndrome (aOR 44.92, 95% CI 5.92-341.19), cardiogenic shock (aOR 17.60, 95% CI 1.54-200.74) and ischemic stroke (aOR 11.40, 95% CI 2.92-44.61). Conversely, they had lower hospitalization charges ($167,489 vs $1,279,681, p<0.001).

Conclusion: Patients with CRS related to SARS-CoV-2 experienced higher rates of adverse cardiovascular outcomes and mortality than those with CRS from CAR T-cell therapy. These differences may be due to the greater severity of CRS in SARS-CoV-2 cases, underscoring the need for tailored management strategies for patients with CRS.

1239 Exploring the Impact of Chronic Kidney Disease on In-Hospital Outcomes in Patients Receiving Chimeric Antigen Receptor T-Cell Therapy: Insights From a United States Population-Based Study

Adamsegd Gebremedhen[1], Abdu Mohammed[2], Jowan Al-Nusair[3], Sinen Zeleke[1], Subigya Thapa[1], Kemnasom Nwanwene[1], Eva Tackett[1]
[1]Marshall University School of Medicine, Huntington, WV, [2]Trinity Health System, Steubenville, OH, [3]Marshall University, Huntington, WV

Introduction: Since the FDA approved the first Chimeric Antigen Receptor (CAR) T-cell therapy in 2017, it has revolutionized cancer treatment. Currently, six CAR T-cell therapies are approved for relapsed or refractory non-Hodgkin's lymphoma (NHL), B-cell acute lymphoblastic leukemia (ALL), and multiple myeloma (MM). While effective, CAR T-cell therapy can cause cytokine release syndrome and tumor lysis syndrome, which may contribute to kidney injury. Many patients with hematologic malignancies have preexisting kidney disease (CKD); however, data on CAR T-cell therapy outcomes in CKD patients are limited to single-center studies with inconsistent results. This study aims to assess the impact of CKD on outcomes in NHL, ALL, and MM patients receiving CAR T-cell therapy, using national data.

Method: We used the National Inpatient Sample to identify adults with ALL, NHL, and MM who underwent CAR T-cell therapy between 2018 and 2021, based on relevant ICD-10 codes. After excluding those with end-stage renal disease, we stratified the cohort by the presence or absence of CKD and applied complex sampling weights for national representativeness. We compared sociodemographic characteristics and comorbidities between CKD and non-CKD patients. The primary outcome was all-cause mortality, and secondary outcomes included acute kidney injury, renal replacement therapy, respiratory failure, mechanical ventilation, shock, vasopressor use, tumor lysis syndrome, immune effector cell-associated neurotoxicity, disseminated intravascular coagulation, gastrointestinal hemorrhage, intracerebral hemorrhage, length of stay, and total hospitalization charges. Multivariate regression models assessed outcome disparities between the groups, with statistical significance set at $p < 0.05$.

Results: A total of 4,120 adults with NHL, ALL, and MM received CAR T-cell therapy from 2018 to 2021 (82.5% NHL, 12.6% MM, and 4.9% ALL). Among these, 370 patients (9.0%) had a concurrent CKD (1.4% stage I, 14.9% stage II, 29.7% stage III, 4.1% stage IV, and 50.0% with unspecified stages). Patients with CKD were older (mean age, 64.8 vs. 60.2 years; $p<0.05$) and had a higher proportion of males (74.3% vs. 58.3%, $p<0.05$). A higher proportion of CKD patients had Charlson Comorbidity Index >2 (100.0% vs. 38.9%, $p<0.001$), atrial fibrillation (25.7% vs. 10.4%, $p<0.001$), and hypertension (60.8% vs. 37.8%, $p<0.001$). CKD patients had higher odds of developing acute kidney injury (adjusted OR 2.9, 95% CI 1.5–5.6). No significant differences were observed in the odds of all-cause mortality or other secondary outcomes between CKD and non-CKD patients. The mean hospitalization charge for CAR-T patients was $1,196,413, and the mean length of stay was 17.0 days, with no significant differences between the two groups.

Conclusion: Our study suggests CKD patients undergoing CAR T-cell therapy have a higher risk of acute kidney injury compared to non-CKD counterparts. However, these patients do not have an increased risk of all-cause mortality or other complications. Acute kidney injury in CAR T-cell therapy patients is typically mild and reversible with treatment. This evidence should be considered when developing strategies for CKD patients receiving CAR T-cell therapy, ensuring approaches are tailored to this population.

1240 Pooled CAR-T screening in nonhuman primates identifies architectures with enhanced proliferation, trafficking, and persistence

Lucy Maynard[1], Eric Cavanaugh[2], Haiying Zhu[3], Carly Starke[4], Sarah Doherty[2], Teresa Einhaus[2], Ailyn Perez[5], Laurence Stensland[5], Michelle Hoffman[4], Veronica Nelson[2], Sarah Herrin[5], Chad Littlewood[5], Kaycee Camou[5], Erica Wilson[5], Christopher Wessel[5], Keith Jerome[2], Hans-Peter Kiem[6]*, Christopher Peterson[2]*

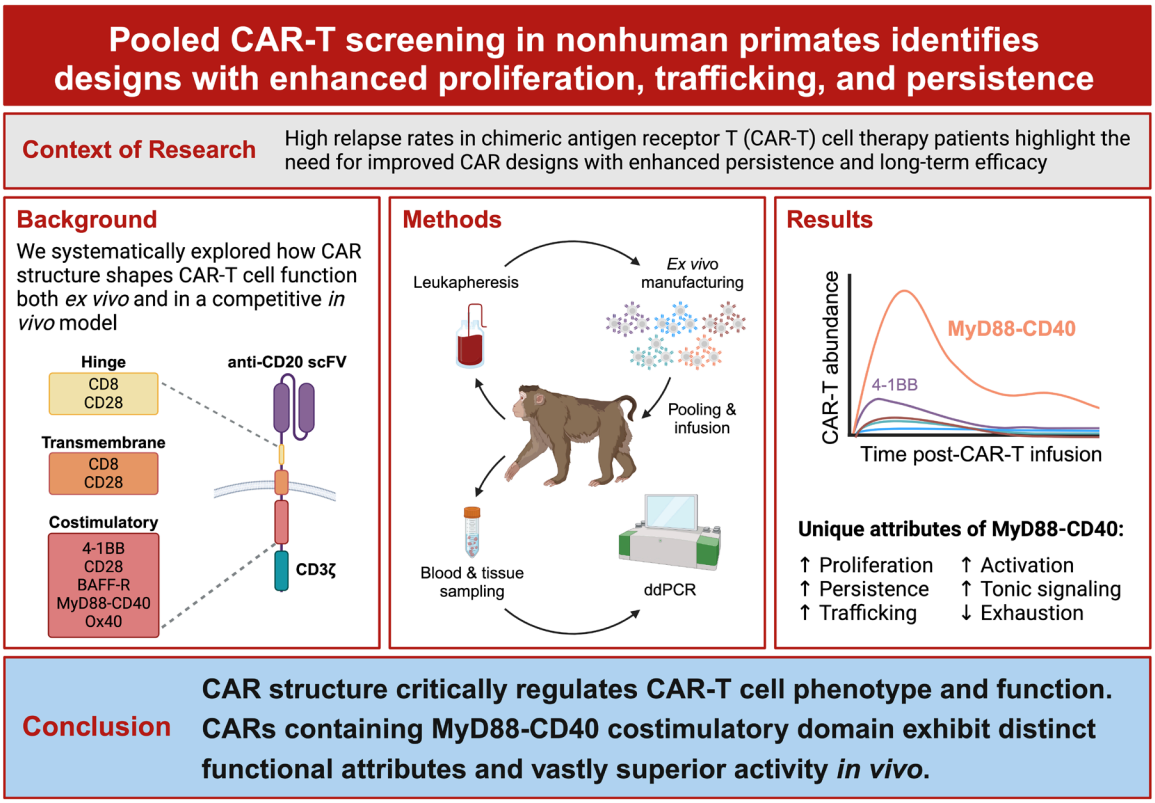
Introduction: Chimeric antigen receptor T (CAR-T) cell therapy has revolutionized treatment for B-cell malignancies, yet over 60% of patients relapse within one year, often due to insufficient CAR-T persistence. While mouse and primary cell models have been instrumental in advancing CAR-T therapy, they frequently fail to predict clinical outcomes, underscoring the need for more translationally relevant models.

Methods: We conducted the first systematic evaluation of CAR structure-function relationships in an immunocompetent nonhuman primate (NHP) model. We engineered an array of 20 CD20-targeted CARs, each containing distinct combinations of hinge, transmembrane, and costimulatory domains. Following rigorous *ex vivo* characterization, we administered pooled autologous CAR-T arrays to three NHPs and tracked CAR abundance longitudinally using a novel digital droplet PCR assay.

Results: *Ex vivo*, CAR-T cells incorporating the MyD88-CD40 costimulatory domain exhibited markedly distinct functional profiles, including increased activation, unique cytokine secretion, tonic signaling, and resistance to exhaustion. *In vivo*, MyD88-CD40 CARs expanded dramatically, comprising up to 100% of peripheral T cells and significantly outperforming canonical CD28- and 4-1BB-based CARs. This expansion was associated with robust B-cell depletion in peripheral blood across all animals. MyD88-CD40 CARs, particularly those with a CD28 hinge and transmembrane domain, demonstrated superior trafficking to secondary lymphoid tissues and persistence through study endpoint, unlike other CARs which waned by day 28.

Conclusions: Our findings highlight the value of immunocompetent NHP models for screening CAR designs and identify MyD88-CD40 CARs as candidates with unmatched potency. The unique functional attributes conferred by this domain, including hyperactivation, tonic signaling and resistance to exhaustion, may provide key insights into features that drive enhanced CAR-T cell activity.



1241 Long-term Dynamics and Integration Site Analysis of CAR-T Cell Therapy in Relapsed/Refractory Lymphoma and Multiple Myeloma: A Retrospective Study

Zhihan Chen[1], yun kang[2], Ni Shuai[3], Ning Wu[4], chenggong li[2], Wenjing Luo[2], Yinqiang Zhang[5], Xindi Wang[2], Jia Xu[2], Qiaolin Liu[2], Heng Mei[6]

Background: CAR-T cell therapy has emerged as a promising treatment modality for relapsed/refractory lymphoma and multiple myeloma, achieving notable clinical success. Despite these advancements, several key questions remain unanswered. Specifically, the relationship between the persistence of CAR-T cells in the body and their therapeutic efficacy is still not well understood. Additionally, the impact of integration sites on T cell persistence and the potential for oncogenesis remains an area of investigation. Studies have shown that integration site at *TET2* gene can enhance the persistence of CAR-T cells in both preclinical and clinical settings. highlighting the potential significance of specific genetic modifications in CAR-T treatment. To address these gaps in knowledge, the current study employs a retrospective analysis of 18 patients with relapsed/refractory lymphoma and multiple myeloma who underwent CAR-T therapy. This investigation aims to elucidate the dynamics of CAR-T cells within the body and it potential associations with patient clinical outcomes. Furthermore, the study compares the persistence of different CAR-T cell products and evaluates the risk of secondary malignancies, providing valuable insights for the optimization of CAR-T therapy and informing clinical decision-making

Methods: This retrospective study included 18 patients who received CAR-T therapy for relapsed/refractory lymphoma (n=8) or multiple myeloma (n=10). CAR-T products used included relma-cel (n=5), axi-cel (n=1), humanized CD19 CAR-T (n=2), BCMA single-target (n=5), BCMA/CS1 dual-target (n=4), and BCMA/CD38 dual-target (n=1). During follow-up, digital droplet PCR (ddPCR) was used to monitor CAR-T cell levels by measuring CAR-T copy numbers. LAM-PCR (S-EPTS/LM-PCR) and high-throughput sequencing were employed to analyze integration sites of CAR lentiviral vectors in the host genome during expansion and low-level phases.

Results: Among the 8 patients with relapsed/refractory lymphoma, all currently remain in complete remission. Of the 10 patients with multiple myeloma, 7 are in complete remission, while 3 have relapsed. Digital droplet PCR (ddPCR) monitoring showed that the levels of CAR-T cells in the body did not significantly differ based on the type of CAR-T product infused. However, the 3 relapsed patients exhibited significantly lower CAR-T cell levels at 6 months compared to the other 7 patients (t-test, $p < 0.05$). We show that integration sites in the T cell genome were not randomly distributed, with the chromosome 11q13 region identified as the top integration site-enriched region. Notably, long-term follow-up (over 24 months) using LAM-PCR (S-EPTS/LM-PCR) identified several persistent integration sites near PACS1 gene and RPTOR gene in the 8 patients with relapsed/refractory lymphoma, suggesting these sites may confer selective advantages for T cell evolution and potential long-term efficacy of CAR-T therapy. Furthermore, no dominant clone was observed at integration sites within the previously identified common integration regions during the Long-term follow-up, the risk of secondary malignancies following CAR-T therapy was therefore found to be low, However, further long-term follow-up studies are warranted.

1242 Development of Humanized VHH-Based Bi-paratopic BCMA CAR-Ts for Multiple Myeloma Treatment via a Streamlined High-Throughput CAR^2-pool Screening Platform

Gregory Sowd[1], Yanping Xie[1], Xiaorong Wu[1], Yang Liu[1], JiHyun Kim[1], Maggie Yates[1], Boro Dropulic[1], Ying Xiong[1], Zhongyu Zhu[2]
[1]Caring Cross, Gaithersburg, MD, [2]Caring Cross, Frederick, MD

Multiple Myeloma (MM) is a malignancy of plasma B cells characterized by high relapse rates and poor prognosis. B cell maturation antigen (BCMA), a plasma B cell-specific marker, has emerged as a promising target for CAR-T cell therapies. Carvykti, an FDA-approved bi-paratopic CAR-T treatment, demonstrates superior clinical efficacy,

highlighting the advantages of targeting BCMA with dual binding domains. Factors such as antigen escape, immunosuppressive tumor microenvironments, and T cell exhaustion further emphasize the need for innovative CAR-T designs and screening to achieve durable responses. Elevated levels of the BCMA ligand APRIL in MM patients contribute to drug resistance by competing for BCMA binding to CAR-T cells, thusly promoting tumor survival.

To address these challenges, we developed a novel high-throughput functional screening strategy to streamline bi-paratopic CAR development. A BCMA-specific humanized VHH binder pool was enriched through panning against a semi-synthetic humanized VHH yeast display library. The 2,124 BCMA binders were cloned in bulk in a tandem repeat format into a lentiviral vector and transduced into primary T cells, generating a bi-paratopic CAR library designated as the CAR^{2} pool. These CAR-T cells underwent cell-on-cell sorting in the presence of APRIL to enrich for CAR-T bound cancer cells. Sequential multi-round co-culture with BCMA^{+} cancer cells was performed to select for CAR-T expression, cytotoxicity, expansion, and persistence. CAR VHH elements amplified from genomic DNA of CAR-T cells collected from each round of co-culture were subjected to Nanopore sequencing. Millions of CAR sequences emanating from each round of culture of CAR-T cells with cancer cells were processed, generating a ranked list of unique CAR sequences from both CD4^{+} and CD8^{+} CAR-T cell populations detailing the dynamics of the 2,046 bi-paratopic CARs relative to the round of CAR-T killing of cancer cells. A panel of 15 CAR candidates with the highest abundance and/or accumulation during the multiple rounds of co-culture of CAR-T cells with cancers cells was selected and characterized as single-clone bi-paratopic CAR-Ts. 14 out of 15 bi-paratopic CARs identified by Nanopore sequencing promoted potent MM1.S cancer cell killing by CAR-T cells with no off-target killing of BCMA-negative RS4;11 cells. The 4 leading candidates, maintained persistent CAR expression during multi-round co-culture with BCMA^{+} cancer cells, demonstrated robust CAR-T functionality even in the presence of APRIL, exhibited BCMA^{+} target cell dependent cytokine secretion, and facilitated killing of MM1.S or U266 cancer cells during 4 or 3 rounds of co-culture, respectively.

Future work focuses on evaluating these novel CARs in preclinical models and advancing the most promising candidates into clinical development. Overall, our streamlined CAR development platform provides a versatile, library size independent, comprehensive strategy for high-throughput CAR-T screening and engineering, with the potential to enhance CAR-T function and persistence in both *in vitro* and *in vivo* settings.

1243 Development of a Universal, Off-the-Shelf CAR-T Cell Immunotherapy for Multiple Myeloma

Xiaowen He[1], Yongqin Li[1]
[1]*Oricell Therapeutics Co.,Ltd., Shanghai, Shanghai, China*

Background: Multiple myeloma (MM) is the second most prevalent hematological malignancy worldwide. It is forecasted that by 2029, the global market of multiple myeloma will reach $28 billion. Chimeric antigen receptor T cells (CAR-T) have shown transformative efficacy for hematologic cancer. However, as an individualized treatment, the huge cost has become the biggest obstacle to the widespread use of autologous CAR-T products. Human pluripotent stem cells (iPSCs) have unlimited expansion potential, are easy to genetically manipulate and can be differentiated into T cells, making them an ideal universal source of immunotherapy. Here we aimed to develop an iPSCs-derived universal CAR-T product for multiple myeloma by targeting BCMA.

Methods: iPSCs were engineered to express tumor specific BCMA CAR from the T cell receptor alpha constant chain (TRAC) locus, controlling the CAR expression timing and eliminating the risk of GvHD. Immunogenecity-related MHC-I, II genes were knocked out as well to avoid HvGD. In serum- and feeder- free cultures, iPSCs were first differentiated into hematopoietic progenitor cells (iHPCs) via the well established embryoid body system and followed by differentiation on the matrix containing immobilized-delta like 4 protein and retronectin to induce the generation of CD8αβ T (iT) cells. Then iT cell maturation was accomplished by BCMA antigen stimulation. Incubation with MM cell line MM1S, H929 and OPM2 cells were used for evaluating the expansion potential, in vitro cytotoxicity capacity and cytokine release level of iT cells upon target-dependent stimulation.

Results: We developed a scalable, serum- and feeder- free differentiation system, which could efficiently induce the engineered iPSCs into iT cells. During the iHPC stage, CD34+ cell percentage could reach more than 90% with high level of CD45 expression. T progenitor stage was predominantly CD7+ (95%) cells, co-expressing CD5 (72%). Late T cells after stimulated with BCMA antigen could reach into 82% CD4-CD8α+, co-expressing 73% CD8β, and showed a low exhaustion profile (0.5% Tim3 and 11% PD-1) and memory T cell type (83% CD45RA–CD45RO+). The iT cells could be activated repeatedly by MM1S cells accompanying on average of 56-fold increase after each stimulation. In vitro killing assay showed that iT cells could efficiently kill target cancer cell line MM1S, H929 and OPM2 cells. In addition, the cytokine IFN-γ, TNF-α and IL-2 were released rapidly in iT cells upon the stimulation

by MM1S cells.

Conclusions: Here we report the development of a highly efficient and scalable method for CAR-T cell generation from engineered human iPSCs in the absence of serum and feeder layers. The resulting iT cells could specifically and efficiently kill the targeted cancer cells for multiple rounds. This system, for the first time, provides a foundation to manufacture universal iPSC-derived CAR-T products for multiple myeloma by targeting BCMA.

1244 BCMA CAR engineering arms T cells with superior functions post-*ex vivo* stimulation by MUC1 peptide-loaded autologous PBMCs

Kun Yun[1], R. Sakemura[1], Ismail Can[1], Omar Gutierrez Ruiz[1], Ekene Ogbodo[1], Truc Huynh[1], Claudia Manriquez-Roman[1], Olivia Sirpilla[1], Carli Stewart[1], Jennifer Feigin[2], Grace DeFranco[1], Sophia Goldberg[1], Dominic Skeele[1], Mariam Stein[1], Dara Missan[3], Latha Pathangey[3], Long Mai[1], Hong Xia[1], Brooke Kimball[1], Lionel Aurelien Kankeu Fonkoua[1], Mehrdad Hefazi Torghabeh[1], Michael Ruff[1], Elizabeth Siegler[1], Leif Bergsagel[3], Michael Gustafson[4], Sandra Gendler[3], Saad Kenderian[1]*

Chimeric antigen receptor T (CART) cell therapy has shown clinical successes in B cell hematological malignancies. Two B cell maturation antigen (BCMA)-directed CART cell therapies treating multiple myeloma (MM) were approved by FDA, but most patients relapse within 1-2 years. *Ex vivo*-expanded antigen-specific T cells as a cancer treatment rely on TCR-mediated tumor killing. We hypothesized that arming *ex vivo*-enriched tumor-specific T cells with CARs targeting a different antigen improves T cell functions.

First, we expanded mucin 1 (MUC1)-activated T cells from patients with MM through *ex vivo* stimulation by MUC1 peptide-loaded autologous PBMCs for 19 days. Then, we engineered MUC1-activated T cells with 4-1BB-co-stimulated BCMA CAR to generate MUC1 TCR^+ BCMA CAR^+ T cells. Baseline T cells without MUC1 stimulation were engineered with BCMA CAR as control.

Baseline T cells, MUC1 T cells, baseline BCMA CART cells, or MUC1 BCMA CART cells were cocultured with $luciferase^+$ RPMI-8226, a $MUC1^+$ $BCMA^+$ MM cell line, for 3 days. MUC1 BCMA CART cells showed stronger tumor killing than BCMA CART or MUC1 T cells in all 3 patient samples ($p<0.0001$). MUC1 BCMA CART showed higher proliferation than BCMA CART or MUC1 T cells ($p=0.0765$, $p<0.0001$, respectively) after a 5-day stimulation by RPMI-8226. To exclude possibility of metabolic alterations by 19-day PBMC incubation leading to better T cell functions in MUC1 BCMA CART, baseline and MUC1-stimulated T cells from 3 healthy donors underwent BCMA CAR transduction and *ex vivo* expansion for 19 days and compared in the same assays. Day 19 BCMA CART cells showed inferior tumor killing compared to baseline BCMA CART in all 3 donors ($p<0.0001$). Lower T cell proliferation was also observed in Day 19 BCMA CART compared to baseline BCMA CART ($p=0.0838$). Our data indicate that improved T cell functions in MUC1 BCMA CART were unlikely due to metabolic changes but rather were likely through the MUC1 TCR.

Additionally, MUC1 T cells, BCMA CART, or MUC1 BCMA CART cells from 3 tested patients were stimulated by RPMI-8226 for 24 hours and then isolated for bulk RNA sequencing. Both BCMA CART and MUC1 T cells had distinct transcriptomic features from MUC1 BCMA CART cells. Differential gene expression analysis showed upregulation of T cell function-associated genes (*RYR2*, *ITGA1*, *GNLY*, *GZMA*, etc.) in MUC1 BCMA CART vs BCMA CART. Enrichment of T cell function-associated pathways was also observed in MUC1 BCMA CART. Analysis between MUC1 T cell and MUC1 BCMA CART showed upregulation of T cell function-associated genes (*SF2, IL2, IFNG, GZMB*, etc.) and enrichment of immune response pathways in MUC1 BCMA CART. Our findings suggest that equipping *ex vivo*-enriched tumor-specific T cells with CARs targeting a different antigen improves T cell functions *in vitro*. Importantly, this provides a rationale for a therapeutic regimen where patients receive *ex vivo*-enriched T cells followed by CAR engineering. Persistence of the engineered T cells is being investigated.

1245 Pre-Existing Immunity to Adeno-Associated Virus: A Global Meta-Analysis of Anti-AAV Neutralizing Antibodies in 9,887 Patients

Brandon Henry[1], Tanya Partridge[2], Melvin Yesid Rincon Acelas[3]
[1]IQVIA, San Antonio, TX, [2]Cell and Gene Therapy Center of Excellence, IQVIA, Durham, NC, NC, [3]Fundación Cardiovascular de Colombia, Floridablanca, Santander, Colombia

Introduction: Adeno-associated virus (AAV)-based gene therapy has emerged as a promising approach for treating a wide range of genetic disorders. However, pre-existing immunity poses a significant challenge to its clinical success. Anti-AAV neutralizing antibodies (NAbs) can inhibit vector transduction, reducing therapeutic efficacy and potentially increasing the risk of adverse reactions. Consequently, the presence of NAbs often leads to the exclusion of patients from clinical trials. Understanding the global seroprevalence of anti-AAV NAbs is essential for optimizing product development, refining clinical trial design, identifying populations at risk of being ineligible for treatment, and ultimately expand global access to AAV-based gene therapy. This meta-analysis comprehensively investigates the worldwide seroprevalence of anti-AAV NAbs across multiple serotypes in diverse patient populations and geographical regions.

Methods: A systematic search of major electronic databases (PubMed, SciELO, and CNKI) was performed to identify articles reporting data on the seroprevalence of anti-AAV NAbs calculated utilizing cell-based methods with a provided titer definition. Data was extracted and classified according to AAV serotype and NAb titer. Data on geographical region, patient age, and disease status was also extracted for subgroup analyses. Data extraction was supported with PlotDigitizer as appropriate. For data pooling, NAb seropositivity titer cutoffs were classified as low (≤1:10), intermediate (1:16–1:20), and high (≥1:50). Pooled seroprevalence estimates (PSE) with 95% confidence intervals (95% CIs) were calculated using MetaXL v5.3. This study was prospectively registered on PROSPERO (CRD42025636026).

Results: A total of 42 studies (9,887 patients) from all major continents and 28 countries were included in the analysis. Among included studies, 22 (52.3%) reported data at an intermediate titer (1:16-1:20). Subsequent analyses in this meta-analysis utilized this cutoff for consistency in reporting. The highest global PSE was observed for AAV2 (39.0%, 95%CI: 30.1-48.3%), followed by AAV1 (32.2%, 95%CI: 26.5-38.2%), AAV9 (28.9%, 95%CI: 20.8.-35.8%), and AAV3B (28.7%, 95%CI: 9.1-52.9%). The lowest global PSE was observed for AAV5 (19.0%, 95%CI: 11.9-27.4%). In adults, the highest PSE was observed for AAV2 (45.6%, 95%CI: 28.3-63.3) and AAVrh74 (35.2%, 95%CI: 31.5-39.1). The PSE in children was generally lower as compared to adults, with the highest PSE observed for AAV2 (25.7%, 95%CI: 13.2-40.5%), followed by AAV8 (23.5%, 95%CI: 13.2-35.7%) and AAV9 (22.0%, 95%CI: 12.6-33.0), with the lowest PSE observed for AAV5 (6.8%, 95%CI: 3.1-11.6%). Overall, a trend towards higher PSEs were observed across most AAV serotypes (AAV1, 2, 8, and 9) in East Asian and European populations as compared to North American populations. As compared to normal donor samples, no significant differences in PSEs for any serotype were observed among patients with hemophilia A, hemophilia B, or cystic fibrosis.

Conclusions: Our analysis reveals significant variability in the seroprevalence of anti-AAV NAbs across different populations and geographical regions. These findings provide valuable insights into the global epidemiology of pre-

existing immunity to AAV. This knowledge can inform the development and selection of more effective AAV vectors and guide clinical trial design, including patient selection and choice of trial locations.

1246 Depletion of AAV8 Antibodies in Seropositive Individuals Treated with the IgG Cleaving Enzyme Imlifidase

A proportion of the patients in need of gene therapy has previously been exposed to wild-type adeno associated virus (AAV) and thus has high prevalence of antibodies against AAV. These pre-existing anti-AAV antibodies are a major challenge in AAV-based gene therapy, as they inhibit transduction and may constitute a safety concern[1]. In the first part of this study, serum samples from 200 healthy individuals were screened for anti-AAV8 seropositivity using a total IgG anti-AAV8 antibody (TAb) assay. In the second part, serum samples from 44 clinical trial subjects treated with the IgG cleaving cysteine protease imlifidase were anonymized and analyzed. Out of the 200 screened samples, 106 (53%) were positive for anti-AAV8 in the TAb assay, and 10 (5%) had anti-AAV8 titer >1:2560. Out of the 106 seropositive samples, the majority (70%) were low positive (RECL<25). Out of the 44 screened imlifidase-treated individuals, 11 (25%) were positive for anti-AAV8 in pre-imlifidase treated samples and further analyzed in the TAb assay for post-imlifidase treated samples at different timepoints (6h, 24h, 48h, 72h, day7, day14 and day64). The highest pre-dose titer was 1:2560. Additionally, the seropositive samples from ten imlifidase-treated individuals were analyzed in a functional neutralizing assay. For all subjects, a dramatic decrease in AAV8 antibody titers was observed as early as 6 hours after dosing with imlifidase. The titers remained low for several days, creating a potential time window for gene therapy dosing. The results from the TAb assay confirmed the ability of imlifidase in depleting anti-AAV IgG antibodies, with a similar pattern to that of total IgG depletion following imlifidase dosing. Taken together, the results indicate an anti-AAV IgG free window of 5-7 days post-imlifidase treatment, during which time gene therapy dosing would be most efficient. The potential of imlifidase to remove AAV antibodies has previously been demonstrated [2-4], both *in vivo* and *in vitro* and is under further evaluation in collaboration with our gene therapy partners. The results with serum from imlifidase treated individuals, support the potential use of imlifidase as pre-treatment to AAV-based gene therapy in patients with elevated pre-existing anti-AAV antibodies.

Disclaimer:
Imlifidase is an investigational product and is not approved in the USA for any use.

1247 Modulation of Adenovirus Vector Immunogenicity by Non-neutralizing Antibodies and Complement C3 Deposition

Svetlana Atasheva[1], Jia Yao[2], Dmitry Shayakhmetov[1]
[1]Emory University, Atlanta, GA, [2]Emory University, Atlanta, Georgia

Adenovirus vectors are an excellent platform for gene therapy. They have a large payload capacity, are cost-effective to manufacture, and can be administered systemically to target disseminated cells throughout the body.

However, one major concern with using adenovirus vectors is the potential activation of a cytokine storm and the unpredictable responses of individual patients to high-dose infusions.

In our study, we examined the cytokine responses of human PBMCs to human adenovirus 5 in the presence of sera from healthy volunteers. Surprisingly, even non-neutralizing sera caused dramatic variations in cytokine responses. Furthermore, these sera deposited complement C3 on the viral particles, suggesting that antibodies from patients with no prior exposure to Ad5 can facilitate complement deposition and thereby alter the way the virus is presented to cytokine-producing myeloid cells. To investigate this phenomenon further, we conducted a mouse experiment in which we could control the adenovirus species to which the mice were exposed and against which they developed antibodies. Groups of mice were immunized with phylogenetically distant adenoviruses including Ad2, Ad3, Ad6, Ad11, Ad28, and Ad5 and, 35 days post-immunization, were injected intravenously with Ad5. We then analyzed vector distribution at 30 minutes and 6 hours post-injection, along with cytokine production and the capacity of antibodies from pre-immunized mice to deposit C3 on Ad5 particles. We designated the non-neutralizing antibodies capable of C3 fixation as Cryptic Opsonizing Non-neutralizing antibodies (CON-Abs). Unlike neutralizing antibodies, CON-Abs did not prevent virus-mediated membrane rupture or the subsequent activation of cytokine responses in spleen macrophages. In fact, cytokine responses were universally stronger in the presence of CON-Abs compared to those in naïve mice or mice with neutralizing antibodies. Interestingly, IL-12 was the only cytokine that remained at consistent levels in mice immunized with Ad5, and we observed a direct correlation between the amount of IL-12 released and the sera's ability to fixate C3 on the viral particle. To further elucidate the mechanism behind adenovirus-induced cytokine production, we sought to identify the responding cells following adenovirus injection. Given the importance of antibody binding and complement fixation in this process, we evaluated cytokine responses in pre-immunized Fcer1g KO, Trim21 KO, C3 KO, C1q KO, and C4 KO mice. We also performed immunofluorescence staining of mouse spleen tissue to pinpoint the cells responsible for cytokine production.

In conclusion, the severity of immunological responses to adenovirus vectors depends on the individual's antibody repertoire and the capacity of these antibodies to mediate C3 fixation on viral particles. Myeloid cells in the spleen phagocytose the adenovirus vectors and produce cytokines in response to the composition of the opsonized viral particles.

1248 Immunobiology of Proteasome-Targeted Strategies to Prevent Anti-AAV T-Cell Responses

Robert Clark[1], Jay Kolls[1]
[1]*Tulane University Health Science Center, New Orleans, LA*

RATIONALE: Early AAV gene therapy failures linked to anti-capsid CD8+ T-cell responses prompted studies revealing proteasome-dependent cross-presentation as the primary driver. Strategies targeting the ubiquitin-proteasome system, such as capsid Y-F mutations or proteasome inhibitors (bortezomib, doxorubicin), reduced MHC-I antigen presentation and enhanced transgene expression, likely via improved AAV nuclear import. Doxorubicin is now being tested in a cystic fibrosis inhaled gene therapy trial (NCT06526923). While these approaches mitigate T-cell-mediated cytotoxicity, their effects on de novo anti-AAV immune priming and their interactions with antigen-presenting cells remain understudied. This work evaluates their potential to suppress CD8+ T-cell activation and amplify transgene expression in lung-directed AAV therapy.

METHODS: Using intubation, we delivered $1x10^{11}$ vector genomes (vg) of lung-tropic Adeno-Associated Virus serotype 6.2 or 6.2FF (AAV6.2-Luc) with or without doxorubicin to the respiratory tract of the BALB/c mice by intubation. At one month, transgene expression was assessed and mice were euthanized to assess the development of anti-vector immunoglobulins (IgG, IgM, IgA) in bronchoalveolar lavage fluid (BALF) and lung by ELISA and the development of AAV capsid-specific T-cells by MHC-I tetramer staining and flow cytometry. To validate our findings, similar experiments were conducted using AAV6.2-GFP and AAV6.2FF-GFP vectors, and the protein content of our AAV preps was assessed by Bicinchoninic Acid (BCA) Assay. We also repeated the AAV6.2-Luc experiment with or without doxorubicin, tracking transgene expression over time by *in vivo* bioluminescent imaging.

Finally, we evaluated the response of mouse bone-marrow derived dendritic cells (BMDC) to doxorubicin treatment *in vitro*.

RESULTS: Surprisingly, delivery of AAV6.2FF-Luc appeared to result in significantly increased antibody responses relative to AAV6.2-Luc and marginally increased T-cell responses. Inclusion of doxorubicin in viral inoculum resulted in significantly increased capsid-specific T-cell responses (Fig 1A). BCA assay revealed that while AAV6.2FF-Luc had greater protein content per vector genome than AAV6.2-Luc, the opposite was true for AAV6.2FF-GFP and AAV6.2-GFP. When comparing the GFP vectors, there were no differences in T-cell responses and a lower amounts BAL IgA in AAV6.2FF-GFP treated mice (Fig 1B). For doxorubicin, tracking of transgene expression over time revealed doxorubicin significantly increased transgene expression at early timepoints (1d, 3d) but differences converged and were no longer statistically significant after 7d. Interestingly, numbers of transgene-specific T-cells were not increased with doxorubicin treatment. *In vitro* treatment of mouse BMDC with 0.25µM of doxorubicin induced greater expression of costimulatory molecules CD80 and CD1d.

CONCLUSIONS: Our results comparing AAV6.2 with AAV6.2FF highlight the importance of characterizing antigen load or empty/full capsid ratios across AAV preps when assessing the immunological impact of capsid mutations. We further found that while doxorubicin promotes increased transgene expression at early timepoints, it may activate capsid-specific T-cells and result in loss of transgene expression. Our *in vitro* data suggest that doxorubicin may activate dendritic cells; studies are ongoing to validate these results *in vivo*.

1249 A Novel NK Inhibitor Provides "Best-in-Class" Protection of HLA Knockout Allogeneic Human Engineered Regulatory T Cells to Effectively Evade Immune Rejection

Tingxi Guo[1]*, Kaya Epstein[1], Tom Wickham[2], Christopher Moore
[1]GentiBio Inc, Cambridge, MA, [2]GentiBio, Cambridge, MA
**Corresponding Author*

Allogeneic regulatory T cell therapies offer substantial advantages over autologous therapies, but are limited by persistence for treating chronic indications due to host immune rejection. Knockout (KO) of human leukocyte antigen (HLA) class I and II combined with natural killer (NK) cell inhibition is a promising approach to evade

immune rejection. While molecules such as HLA-E and CD47 have successfully prevented NK rejection in certain contexts, allogeneic cell therapies need more robust approaches which provide protection of HLA KO cells broadly across a heterogeneous population.

Here, we observed the extent of HLA class I KO cell elimination by peripheral blood mononuclear cells (PBMCs) significantly correlated with the frequency of NK cells expressing a particular inhibitory receptor (Receptor X). HLA class I-negative cell rejection did not associate with other NK or major immune subsets in the donor PBMC, suggesting missing-self rejection is driven by Receptor X+ NK cells in humans. Based on this finding, we assembled a panel of inhibitory molecules that bind to Receptor X. When expressed on HLA KO human engineered regulatory T cells (EngTreg), these NK inhibitors demonstrated varied levels of target cell protection from PBMC killing.

We focused on a top performing inhibitor and demonstrated superior protective function over field-standard NK inhibitors such as CD47 and HLA-E across 10 PBMC donors using a 1-day killing assay. The NK inhibitor specifically protected inhibitor-expressing cells and not bystander HLA KO cells lacking the inhibitor in a three-cell co-culture system, demonstrating cell-intrinsic protective effect of the inhibitor. To highlight the applicability of the Receptor X inhibitor approach to our EngTreg platform, we generated an HLA KO and inhibitor-expressing version of our EngTreg asset specific for a pancreatic islet-specific autoantigen to treat type 1 diabetes. Inhibitor expression protected the EngTreg from PBMC killing compared to HLA KO alone and did not interfere with islet antigen-specific EngTreg responses.

Lastly, we explored molecular variants of the inhibitor to optimize its activity. We also developed an aggressive in vitro rejection system that concurrently captures both T and NK mediated rejection over 7 days. Using this rigorous rejection model, we observed that NK inhibitor optimization enabled higher persistence and expansion of HLA KO EngTreg in the presence of allogeneic PBMCs (12 donors tested) compared to the field-standard NK inhibitors CD47 and HLA-E, as well as an emerging CD300a trans-antigen signaling receptor (TASR) NK inhibitor technology. In summary, we have developed a potent immune evasion molecule, Receptor X Inhibitor, that suppresses an NK subset which may be responsible for missing-self rejection in humans. Importantly, Receptor X inhibitor outperforms competing NK inhibitory technologies for immune evasion, and this technology can be readily incorporated in GentiBio's dual AAV manufacturing process to generate future off-the-shelf allogeneic EngTreg products.

1250 Epigenetic targeting of macrophage polarization

Davide D'Onghia[1], Aidan Engel[2], Garret Haskett[3], Lucrezia Rinaldi[4], Juan Patiño-Mercau[2], Francesca Bose[5], Stelvio Tonello[6], Liliana Intropido[5], Laura Pezzetti[5], Roberto Crocchiolo[5], Pier Paolo Sainaghi[7], Annalisa Di Ruscio[8]*

Macrophages are key players in the innate immune system. The two major polarized states, M1 and M2, exhibit distinct phenotypes and specialized functions in immunity and inflammation. M1 macrophages are characterized by enhanced microbicidal activity and the secretion of pro-inflammatory cytokines, while M2 macrophages promote inflammation resolution, and immune regulation. Dysregulation of M1/M2 polarization has been implicated in autoimmune diseases and cancer. Understanding the molecular mechanisms that govern macrophage polarization is essential for developing targeted therapies aimed at modulating immune responses and restoring tissue homeostasis[1]. Epigenetic modifications, particularly DNA methylation, have emerged as key regulators of macrophage plasticity by modulating gene expression patterns that define M1 and M2 phenotypes. Recent studies suggest that DNA methylation influences macrophage fate by repressing or enhancing specific transcriptional programs; however, its precise contribution remains incompletely understood[2]. Here, we addressed the impact of DNA methylation

perturbation on macrophage-like and primary macrophage polarization. We established protocols to differentiate monocytes into macrophage-like cells using both a cell line model and primary human peripheral blood mononuclear cells (PBMCs). Phenotypical differentiation into M1 or M2 macrophages was confirmed by flow cytometry analysis of both primary cells and the cell line, as well as by morphological assessment using Wright-Giemsa staining. To investigate the impact of DNA methylation in macrophage polarization, we treated cells with the hypomethylating agent 5-azacitidine (5-Aza)[3] at different stages of differentiation. Flow cytometry and neighborhood analyses revealed an enrichment of the M2 phenotype over the M1 phenotype in 5-Aza-treated cells. Cytokine secretion and phagocytosis evaluation further demonstrated that treated U937-derived macrophages exhibited lower cytokine production and reduced phagocytic capacity compared to untreated controls. In primary macrophages, we observed increased presence of M2-like upon 5-Aza treatment in M1 stimulated cells and distinct M1 and M2 polarization upon M2 stimuli unlike untreated cells. Notably, IL-6 expression was absent in M1- but present in M2-stimulated cells following 5-Aza treatment, suggesting a DNA methylation-dependency of IL-6 expression. Lastly, we used a DNMT1 selective inhibitor, recently developed in our laboratory[4] – aptaDiR, to evaluate the effect of targeted DNA demethylation on macrophage polarization. Following assessment of cellular uptake of aptaDiR formulated in APC-labeled lipid nanoparticles (LNPs), we did not observe toxicity in peripheral blood stem cells as compared to 5-Aza. Remarkably, when compared to 5-Aza, aptaDiR treated cells exhibited a skewed toward M2 polarization in the tested culture conditions, supporting a potential DNMT1-mediated role in macrophage polarization. Our findings suggest that perturbations of DNA methylation do affect macrophage polarization. The absence of IL-6 in M1-stimulated, 5-Aza-treated cells and its presence in M2-stimulated cells highlight a potential methylation-dependent regulatory mechanism. Furthermore, DNMT1 inhibition via aptaDiR supports the involvement of DNA methylation in shaping macrophage fate. These results provide new insights into the epigenetic regulation of macrophage plasticity and their implications in inflammatory responses.

1251 *Targeting immune checkpoint receptor ligands to reactivate T-cell function and eliminate persistent hepatitis B virus infection*

Merve Gültan[1], Nico Fischer[2], Till Bunse[3], Anna Kosinska[4], Edanur Ates Öz[4], Swati Singh[4], Jonas Becker[5], Dirk Grimm[6], Ulrike Protzer[7]*

[1]Technical University of Munich, München, germany, Germany, [2]University of Heidelberg, Heidelberg, Baden-Wuerttemberg, Germany, [3]Technical University of Munich, Munich, Bayern, Germany, [4]Technical University of Munich, Munich, Germany, [5]University Hospital Heidelberg, Heidelberg, BW, Germany, [6]Heidelberg University Hospital, Heidelberg, Baden-Wuerttemberg, Germany, [7]Technical University of Munich, München, Germany
**Corresponding Author*

Introduction: Hepatitis B virus (HBV), a member of the Hepadnaviridae family, primarily infects liver hepatocytes and can cause acute or chronic infection. Chronic hepatitis B (CHB) infection is a major global health problem that can lead to liver cirrhosis and hepatocellular carcinoma. Although therapeutic approaches such as pegylated interferon alpha and nucleoside analogs are available for CHB, they rarely eradicate the virus. Therefore, there is an urgent need for novel therapeutic strategies to achieve a complete cure for persistent HBV infection. A robust T-cell response is essential for viral clearance during acute HBV infection. However, in CHB, virus-specific T cells are scarce and dysfunctional with increased expression of inhibitory molecules like PD-1 and TIM-3. These molecules bind to their ligands, suppressing T-cell activation and weakening the immune response. This study aims to knock down the ligands for PD-1 and TIM-3, specifically PD-L1, PD-L2, and Galectin-9 (Gal-9), which are predominantly expressed on non-parenchymal liver cells, in order to restore T-cell function and potentially cure chronic hepatitis B infection.

Methods: Short hairpin RNAs (shRNAs) were designed and screened for mouse PD-L1, PD-L2, and Gal-9. The knockdown efficiency of the shRNAs was evaluated using a dual-luciferase assay. Continuous expression of shRNAs was achieved using adeno-associated viruses (AAV). This project used a capsid with enhanced tropism for non-parenchymal liver cells, specifically liver-resident macrophages. Selected shRNAs targeting immune checkpoint receptor ligands were cloned in a single self-complementary AAV genome (AAV-ICI). As a control, a scrambled shRNA sequence was cloned into the same backbone as AAV-ICI. The toxicity of AAV-ICI and AAV-Ctrl was tested *ex vivo* in primary mouse hepatocytes. An AAV carrying a 1.2-fold overlength HBV genome was used to establish persistent HBV replication. Additionally, HBV transgenic mice were used to evaluate the therapeutic effect of AAV-ICI.

Results: Selected shRNAs targeting Gal-9, PD-L1, and PD-L2 showed up to 85% knockdown efficiencies. The knockdown efficiency of the final construct was verified by a dual luciferase assay. Knockdown levels varied due to the different promoters: Gal-9 at 90%, PD-L1 at 80%, and PD-L2 at 25%. Neither AAV-ICI nor AAV-Ctrl exhibited toxic effects *ex vivo* in primary mouse hepatocytes. However, *in vivo*, high alanine transaminase (ALT) levels, indicating liver damage, were detected, along with a strong innate immune response induced in both the AAV-ICI and AAV-Ctrl groups. Additionally, no persistent HBV replication was established when mice were co-infected with AAV-HBV and either AAV-ICI or AAV-Ctrl.

Conclusion: Targeting liver macrophages with a self-complementary AAV led to significant liver damage with both AAV-ICI and AAV-Ctrl treatments. Thus, suppression of immune checkpoint ligands has to be tackled using small interfering RNAs with diverse modifications to specifically target non-parenchymal cells.

1252 The Intracellular Fc Receptor TRIM21 Promotes Type I Interferon Responses to Antibody-complexed AAV

Nicholas Giovannone, **Julia Provino**, Chun Wai Yip, Arielle Glatman Zaretsky, Sven Moller-Tank, Katherine Cygnar, Andrew Baik*

**Corresponding Author*

Tripartite motif-containing protein 21 (TRIM21) is an intracellular Fc receptor and E3 ubiquitin ligase that facilitates antiviral immunity by sensing virus-antibody complexes, triggering their proteasomal destruction and mediating downstream immune signaling through NF-kB, AP-1, and IRFs. Non-enveloped viruses, such as adenoviruses, picornaviruses, and rhinoviruses, have been shown to be particularly susceptible to TRIM21 activity due to direct cytoplasmic exposure of antibody-bound capsids during cellular infection. However, whether TRIM21 may also impact the immune response to non-enveloped viral vectors used for gene therapy, such as adeno-associated viral vectors (AAV), remains uncertain.

Here, we hypothesized that TRIM21 may contribute to immunogenicity of AAV in the presence of pre-existing anti-AAV IgG. To test this hypothesis, we isolated human PBMCs from whole blood of healthy volunteers, treated with AAV in the presence or absence of an AAV-specific monoclonal human IgG1 (anti-AAV hIgG1), and analyzed IFN-α secretion ~18hr later. We found that in the absence of anti-AAV IgG1 both AAV8 eGFP and AAV9 eGFP

vectors failed to elicit a detectable IFN-α response, even at a relatively high MOI (1e6). However, in the presence of anti-AAV hIgG1, we observed a dramatic boost in IFN-α secretion, consistent with a potential role for TRIM21. To more directly interrogate the contribution of TRIM21, we introduced a mutation to the antibody Fc domain (of the same AAV mAb clone) that ablates TRIM21 binding, but not FcγR binding (hIgG1 H433A). Unexpectedly, compared to unmodified antibody, co-treatment of AAV8 eGFP with anti-AAV hIgG1 H433A resulted in a substantial reduction in IFN-α secretion, in some cases by >90% (Mean [SD]: 77.1% [15.5]; n=8). Importantly, introduction of the H433A mutation had no measurable impact on antibody binding to AAV8 by ELISA. Taken together, our data suggest TRIM21 may be a previously unappreciated innate immune sensor that can exacerbate immune responses to AAV-antibody immune complexes. Future work will be critical to understand whether TRIM21 impacts AAV transduction and immunogenicity *in vivo* in the context of pre-existing antibodies to AAV.

1253 *In vivo* Engineering of HSPCs for HIV Gene Therapy using Helper-Dependent Adenoviral Vectors expressing HIV Fusion Inhibitors

HIV fusion inhibitors, which block the viral fusion process, have shown promise as therapeutic agents. Enfuvirtide, a widely used fusion inhibitor peptide, controls HIV replication when administered via subcutaneous injection. However, it requires bi-daily dosing, increasing the risk of injection site reactions, infections, costs, and reducing bioavailability with limited delivery to the HIV reservoirs. We hypothesize that engineering hematopoietic stem and progenitor cells (HSPCs) in vivo would lead i) to the expression of membrane-localized HIV fusion inhibitors in HIV target cells, thereby protecting them from infection, or ii) to the secretion into the parenchymal space, which would also provide bystander protection of non-transduced cells. To test this, we are evaluating three fusion inhibitors expressed from two promoters (human β-Actin and human ubiquitin-C): i) de-immunized C46-v20, ii) stability-enhanced C34 (Sifuvirtide, C34-SFT), and iii) FDA-approved Enfuvirtide (T20). All of them are under the regulation of miRNA126 to suppress expression in HSPCs. We validated the expression of T20 secreted and membrane-anchored forms using ELISA and Flow Cytometry. We used real-time qRT-PCR to measure the expression of C34 SFT and c46v20. Plasmid transfections in TZM-bl cells showed that secreted forms blocked HIV effectively, while membrane-anchored forms were less effective, likely due to limited membrane density of the fusion inhibitors. We produced HDAd5/35++ vectors and transduced them into PM-1 and TZM-bl cells. A single-round HIV infection assay demonstrated up to 90% resistance to HIV in cells expressing fusion inhibitors as well as 60-90% resistance to replication-competent R5, X4, and SIVmac239 strains, depending on the dose tested. In these studies, we observed that prolonged exposure to the secreted form of T20 induced cytotoxicity in various cell lines. Additionally, we transduced HDAd encoding fusion inhibitors along with a Sleeping Beauty transposase vector (for integration) into CD34+ cells, enriched stably transduced cell with O^6BG/BCNU, and differentiated them into macrophages. In vitro HIV challenge assays in macrophages derived from transduced cells showed HIV resistance. Among the fusion inhibitors tested, the secretory version of C46-V20 was selected for in vivo transduction due to its broad efficacy and low immunogenicity. To assess its safety, we performed in vivo HSPC transduction in G-CSF/AMD3100-mobilized human CD46 transgenic mice. One-week post-transduction, we observed severe toxicity with 50% mortality. The administration of dexamethasone, MMF, and rapamycin rescued the remaining mice, suggesting inflammatory responses by/to C46-v20. We also hypothesized that ubiquitous expression of C46-V20 from the UbC promoter might have contributed to in vivo toxicity. Notably, serum collected from in vivo transduced mice (under immunosuppression) neutralized infectious HIV in TZM-bl cells. To fully harness the capabilities of HDAd vectors (which can accommodate transgenes up to 35kb), we are developing a combination vector for CCR5 base editing and lineage-specific expression of anti-HIV genes. These genes include the secreted decoy receptor eCD4Ig expressed from erythroid cells and HIV fusion inhibitors expressed from macrophages, along with modules that allow for the expansion of transduced cells such as tEPOR, tHMGA2, and $MGMT^{P140K}$. We believe that this strategy will improve the safety and efficacy of HIV therapy.

1254 Toward a Prophylaxis of SIV Infection in Rhesus Macaques by in vivo HSC Transduction with HDAd-S-eCD4Ig

Chang Li[1], Anna Anderson[2], Anne-Sophie Kuhlmann[3], Sucheol Gil[4], Aidan Maynard[5], Donna Palmer[6], Philip Ng[6], Brandon Keele[7], Michael Farzan[8], Stefan Radtke[9], Hans-Peter Kiem[9], John Bui[3], Andre Lieber[5]*
[1]University of Washington, Seattle, Washington, [2]University of Washington, Sandy, UT, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]University of Washington, [5]University of Washington, Seattle, WA, [6]Baylor College of Medicine, Houston, TX, [7]Frederick National Laboratory, Frederick, MD, [8]Boston Childrens Hospital, [9]Fred Hutchinson Cancer Center, Seattle, Washington
**Corresponding Author*

We have developed an *in vivo* HSC transduction approach that requires only intravenous injections and could be provided as outpatient treatment. In this approach, HSCs are mobilized from the bone marrow into the peripheral blood stream and transduced with intravenously injected *in vivo* gene transfer vectors (helper-dependent adenovirus 'HDAd' vectors) that target receptors present on primitive HSCs. HSCs transduced in the periphery return to the bone marrow, persist there long-term, and can be expanded by O^6BG/BCNU treatment to therapeutic levels in mouse models of disease. Here, we used HDAd 6/3+ vectors to transduce HSCs *in vivo* in rhesus macaques to express eCD4-Ig-Emm06, a secreted decoy receptor that targets the primary viral receptors for HIV, CD4 and CCR5. eCD4-Ig-Emm06 expression was driven by the constitutive EF1a-promoter within an integrated cassette that also encoded the sulfation enzyme TPST2, which we demonstrated to sulfate all 7 tyrosine residues in eCD4-Ig-Emm06 for efficient HIV neutralization. Rhesus macaques were assigned to receive either an HDAd vector expressing eCD4-Ig-Emm06 (N=3) or a control HDAd vector (N=3). Animals underwent two rounds of O^6BG/BCNU *in vivo* selection followed by serial escalating-dose challenges of SIVmac239, an HIV-like virus used to assess protection from viral replication and disease progression. Analysis of bone marrow aspirates showed preferential transduction of $CD34^+$ cells with HDAd vector copy numbers in the range of 0.1-1.2 copies per cell. Because of lung toxicity associated with O^6BG/BCNU selection, we were not able to achieve similar VCNs in PBMCs. Nevertheless, in the test animals, stable serum levels of eCD4-Ig-Emm06 were 2.1 µg/mL to 38.3 µg/mL, which is 100-1000-fold higher than the serum IC_{50} concentrations (10.6 to 34.7 ng/mL). One animal exhibited eCD4-Ig-Emm06 levels exceeding therapeutic thresholds, effectively delaying onset to viremia following infection. This was accompanied by lower peak viral loads, lower setpoint viral loads, and protection from $CD4^+CCR5^+$ T-cell depletion, suggesting enhanced protection against viral replication and disease progression. eCD4-Ig-Emm06 was detectable across a broad range of cell subsets and tissues, including T cells, B cells, and monocytes within PBMCs, bone marrow, spleen, lymph nodes, and gut tissues. Tissue viral reservoirs were significantly reduced in tissues with higher VCNs, likely due to greater tissue-specific levels of eCD4-Ig-Emm06. Single-genome sequencing of SIV from serum samples is ongoing to identify routes of viral escape from eCD4-Ig-Emm06, which will inform the development of future therapeutic strategies targeting these escape mechanisms. In summary, this study demonstrates that *in vivo* HDAd transduction efficiently generated long-term levels of eCD4-Ig-Emm06 to protect against HIV/SIV infection. To further enhance the anti-HIV effect, we have developed combinatorial HDAd vectors that express an integrated eCD4-Ig-Emm06 cassette and a transiently expressed base editor to knockout CCR5 ('dual combo') to synergistically target major viral replication mechanisms. To improve safety for otherwise healthy people living with HIV, these new combination vectors incorporate a tHMGA2 auto-expansion approach (PMID: 39282078) to enrich *in vivo* transduced HSCs. These dual combo HDAd vectors are currently being tested in rhesus macaques.

1255 Advancing Precision Immunotherapy for EBV-Associated Malignancies Through HLA-Driven TCR Engineering

Darya Palianina[1]*, Dennis Strobbe[2], Claudia Stühler[2], Nina Khanna[3]*
[1]University Hospital Basel, Basel, Basel-Stadt, Switzerland, [2]University Hospital Basel, Basel, Switzerland, [3]University Hospital Basel, Switzerland
**Corresponding Author*

Epstein-Barr virus (EBV)-associated diseases, including post-transplant lymphoproliferative disorder (PTLD), EBV+ lymphomas, nasopharyngeal carcinoma (NPC), and gastric cancer, pose a significant therapeutic challenge

due to their diverse latency patterns (types I, II, and III) and poor clinical outcomes. While EBV-specific adoptive T cell therapy (ACT) has shown remarkable efficacy against PTLD (latency III), limited success in latency I and II malignancies highlights a critical unmet need for more precise and effective therapies.

To address this, we investigated how HLA alleles influence immune responses against specific EBV antigens. Preliminary experiments using T cells from five healthy donors with diverse HLA alleles revealed distinct differences in their ability to control autologous EBV tumor growth *in vitro*, despite successful expansion of antigen-specific T cells. For example, in case of EBNA-1 specific T cells (median 4.22% IFNγ^+ T cells, range 1.16-7.06%, measured by intracellular cytokine staining 6h after EBNA-1 peptide pool stimulation), only two donors exhibited significant tumor control, making them more suitable for the ACT treatment of Burkitt's Lymphoma (latency type I, presenting only EBNA-1 latent protein). Notably, these donors shared a number of HLA alleles, including B35. We hypothesize that these findings underscore the importance of HLA-driven variability in immune responses and suggest a path forward for selecting optimal donors for allogeneic ACT or designing transgene TCR therapies. We are aiming at testing a substantial number of donors and establishing adequate EBV latency type I and II tumor models and assays to further investigate the relevant HLA alleles.

Our ongoing work involves developing personalized models of EBV latency type I and II tumors and systematically identifying high-performing cytotoxic T lymphocyte (CTL) clones from diverse HLA backgrounds. By establishing a comprehensive library of EBV-specific TCRs optimized for HLA profiles, we aim to enhance therapeutic precision and broaden the applicability of cancer immunotherapy. This project promises transformative advancements in targeting EBV-driven malignancies, improving patient outcomes through personalized, HLA-informed T cell engineering.

1256 STING activation, DNA clearance, and autoimmune disease: Investigating pathogenic mechanisms with DNAse dysfunction and novel therapeutics in SLE and AGS models

Dominique Sims[1], Paul Stabach[2], Sam Lopez[3], Ethan Lester[3], Demetrios Braddock[2]
[1]Yale University School of Medicine, New Haven, CT, [2]Yale University School of Medicine, [3]Yale University, New Haven, CT

Background: DNase1, DNase1L3, and TREX1 enzymes play crucial roles in clearing excess chromatin and DNA in healthy individuals. Mutations or autoantibodies against these enzymes impair DNA clearance, leading to DNA accumulation at inflammatory sites. Systemic lupus erythematosus (SLE) is a leading cause of death among young women and shares features with type I interferonopathies like Aicardi-Goutières syndrome (AGS), a rare autoimmune disorder marked by neuroinflammation, with 30% of AGS cases linked to TREX1 deficiency.

Objective: This study investigates the therapeutic potential of a novel long-acting DNase biologic in autoimmune diseases resulting from TREX1 deficiency, focusing on its effects in AGS.

Methods: We engineered a bioavailable, dual acting DNase1/DNAse1L3 biologic and tested its efficacy in an AGS mouse model (Trex1 knockout, TKO). Survival in treated mice was monitored over 250 days, and a smaller cohort underwent mechanistic analysis of immune biomarkers (cytokines, autoantibodies) and molecular pathways.

Results: DNase biologic-treated mice showed improved survival vs. controls. Treatment also reduced biomarkers, such as anti-dsDNA abs, anti-MYH6 abs, cfDNA, and IFN-γ. Untreated TKO mice experienced significant weight loss and myocarditis, which were alleviated in treated mice.

Conclusions: The dual-acting DNase1/DNAse1L3 biologic significantly improved the survival of TKO mice, demonstrating the role of extracellular free DNA and chromatin in the pathogenesis of AGS. Our observations have important implications for the development of novel therapeutics for autoimmune disorders.

1257 Selective Inhibition of Human Plasmacytoid Dendritic Cells Reduces TLR9-mediated Type I IFN to CpG DNA in AAV Gene Therapy Vectors

Kate Henry[1], Deeptha Gokul[1], Anumeha Shah[2], Alex Pellerin[1], Amos Gutnick[3], John Anderson[1], Pete Clarner[1], Janine Ferrant-Orgettas[1], Linda Burkly[4], Junghae Suh[1], Jinkuk Choi[1]
[1]Biogen, Cambridge, MA, [2]Leal Therapeutics, Newton, MA, [3]PackGene Biotech INC, Brookline, MA, [4]Editas Medicine, Inc., Cambridge, MA

CD8+ T cell immune responses to adeno-associated virus (AAV) capsid protein can contribute to the loss of successfully transduced cells, resulting in toxicity and reducing efficacy. The generation of de novo capsid-specific CD8+ T cells requires Type I interferon (IFN) production from plasmacytoid dendritic cells (pDCs). CpG DNA motifs in AAV gene therapy vectors stimulate pDC production of Type I IFN in a toll-like receptor 9 (TLR9)- and IL-1R associated kinase 4 (IRAK4)-dependent manner. Reduction in CpG DNA content in viral vectors is one proposed approach to reducing pDC Type I IFN in response to AAVs and thus, capsid-specific CD8+ T cells. For internal programs, we tested this hypothesis by establishing a human in vitro assay to measure Type I IFN production in human peripheral blood mononuclear cells (PBMCs) to AAV9, a clinically relevant serotype. Using AAVs with varying CpG amounts, we demonstrate that human Type I IFN induction in PBMCs from various human donors positively correlate with CpG content of the AAV vectors. Furthermore, Type I IFN production in this assay was TLR9 and IL-1R associated kinase 4 (IRAK4) dependent. Given that CpG motif reduction may not be possible for all AAV cargos and current pharmacological modulators of this pathway (e.g. IRAK4 inhibitors) are not specific to pDC-TLR9 signaling, we investigated whether blocking activation of pDCs via a pDC-specific mechanism could reduce TLR9-dependent Type I IFN production against AAV. Previous work established that targeting a pDC-specific receptor blocks TLR9-mediated Type I IFN production to CpG-A, a synthetic TLR9 stimulus, in pDCs. Promisingly, we significantly reduced Type I IFN production in response to an AAV9 vector containing TLR9-stimulatory CpG content in PBMC from multiple donors. Our data suggests we can selectively inhibit pDC mediated Type I IFN following AAV gene therapies while maintaining other immune responses.

1258 Targeting human plasma cells using small molecule regulated BCMA CAR T cells eliminates circulating antibodies in humanized mice

Peter Cook[1], Yuchi Honaker[2], David Gruber[2], Chester Jacobs[3], Rene Cheng[2], Shivani Patel[4], Christopher Galvan[4], Iram Khan[5], Kevin Zhou[4], Karen Sommer[6], Alexander Astrakhan[7], Richard James[4], David Rawlings[8]
[1]Seattle Childrens Research Institute, Seattle, Washington, [2]Seattle Children's Research Institute, [3]Seattle Children's Research Institute, Portland, ME, [4]Seattle Children's Research Institute, Seattle, WA, [5]Seattle Children's Research Institute, Seattle, Washington, [6]Seattle Childrens Research Institute, Seattle, WA, [7]2seventy Bio, Inc., [8]University of Washington, Seattle, WA

Pathogenic long-lived plasma cells (LLPCs) secrete autoreactive antibodies, exacerbating autoimmune diseases and complicating solid organ transplantation. Targeted elimination of the autoreactive B-cell pool represents a promising therapeutic strategy, yet current treatment modalities fall short in depleting mature plasma cells. Here, we demonstrate that chimeric antigen receptor (CAR) T cells, targeting plasma cell marker BCMA utilizing a split-receptor design, offer a controlled and effective therapeutic strategy against LLPCs. Dimerizing agent-regulated immune-receptor complex (DARIC) T cells demonstrated robust rapamycin-dependent targeting of BCMA+ tumor cells in-vitro and in-vivo. Using an in-vitro differentiation platform, DARIC T cells also selectively targeted primary human plasma cells from a mixed B cell population. Notably, in humanized mouse models, DARIC-T cells regulated peripheral human immunoglobulin levels through specific elimination of human LLPCs from the bone marrow. Furthermore, DARIC constructs were efficiently integrated into the T-cell receptor α constant (TRAC) locus while maintaining potent antigen-specific cytotoxicity. These findings underscore the potential of split-receptor CAR T cells in autoimmune and transplant medicine, highlighting their versatility in applications beyond oncology.

1259 Next-Generation Off-the-Shelf CAR T-Cell Therapies for Conditioning-Free Treatment of a Broad Spectrum of Autoimmune Diseases and Hematologic Malignancies

Mark Jelcic[1], Daniel Morales-Mantilla[1], John Reiser[1], Alison O'Connor[1], Rina Mbofung[1], Alan Williams[1], Alma Gutierrez[1], Yijia Pan[1], Brian Groff[1], Angela Macia[1], Sreedevi Raman[1], Ramesh Janani[1], Bryan Hancock[1], Pei-Fang Tsai[1], Betsy Rezner[1], Ramzey Abujarour[1], Tom Lee[1], Karl-Johan Malmberg[2], Maksim Mamonkin[3], Bob Valamehr[1], John Goulding[1], Jodie Goodridge[1]*
[1]Fate Therapeutics, Inc., San Diego, CA, [2]Oslo University Hospital, Oslo, Norway, [3]Baylor College of Medicine, Houston, Texas
**Corresponding Author*

Chimeric antigen receptor (CAR) T-cell therapies have achieved durable remissions in the treatment of hematologic malignancies and continue to present promising clinical outcomes in autoimmune disease (AID) indications, driving the demand to increase patient accessibility and expand applicability to other disease settings. However, approved CAR T-cell therapies face limitations, such as inadequate targeting of disease-causing cells, inconsistencies associated with manufacturing of heterogeneously edited cells, and the need for conditioning chemotherapy (CCT), which mandates hospitalization and treatment at specialized centers to monitor adverse events including the risk of severe infection.

To maximize patient access and expand CAR T-cell therapy to multiple disease indications, we developed a platform that allows for the creation of clonal, multiplexed-engineered induced pluripotent stem cells and their differentiation into next-generation multi-antigen targeting (NxM) CAR T-cell therapies. Off-the-shelf NxM CAR T cells incorporate novel synthetic functional elements designed to effectively eliminate a range of aberrant cells while evading recognition by alloreactive immune cells.

NxM CAR T cells exhibit a CD8αβ T-cell phenotype, lack TCR expression to avoid graft versus host disease, lack CD38 expression for improved fitness and avoidance of fratricide, and express two unique CARs to target pathogenic CD19+ cells and a second antigen to target a broad range of disease-causing cells. NxM CAR T cells targeting cell surface glycoprotein CD38 (NxM 19x38 CAR T cells) specifically eliminated a variety of malignant cell types, including CD19+ lymphoma and CD38+ multiple myeloma cell lines, in several *in vitro* cytotoxicity assays and *in vivo* models. Notably, NxM 19x38 CAR T cells showed enhanced elimination of CD19+CD38+ cells *in vivo* compared to single CAR controls ($p<0.05$) as well as robust eradication of aberrant CD19+ B cells, CD38+ plasma cells, and CD38+ activated T cells from AID patient-derived peripheral blood mononuclear cells (PBMCs). Additional expression of a high-affinity, non-cleavable CD16 supports NxM 19x38 CAR T cell combination with monoclonal antibodies to further enhance antigen targeting and versatility.

To eliminate the need for administration of CCT alongside CAR T-cell therapy, NxM 19x38 CAR T cells also express a novel allo-immune defense receptor (ADR), which promotes CAR T-cell expansion, function, and persistence in an allogeneic setting, and harbor genetic disruption of the immune synapse adhesion ligand CD58 ($CD58^{KO}$) for passive evasion of host immunity. In an *in vitro* allogeneic re-stimulation assay, ADR/$CD58^{KO}$ NxM CAR T cells eliminated target cells upon serial re-challenge in the presence of alloreactive PBMCs, displaying enhanced persistence and cytotoxicity compared to control. Additionally, ADR/$CD58^{KO}$ NxM CAR T cells maintained tumor growth inhibition and persistence *in vivo* in the presence of unmatched alloreactive T cells.

With the potential to specifically target several disease-causing cell types without requiring administration of CCT, NxM 19x38 CAR T cells can be manufactured at scale in a cost-effective manner, administered off-the-shelf to broadly reach patients, and used to target multiple pathogenic cell types for the treatment of autoimmune diseases and hematologic malignancies.

1260 Allogeneic CD19-targeted CAR-T Therapy for refractory Systemic Lupus Erythematosus (SLE)

Biao Zheng[1]*, Chunmei Yang[2], Chuanyin Sun[2], Binghe Tan[3], Chris Wang[4], Bing Du[4], Mingyao Liu[4], Jin Lin[2], Hongyan Tong[2]

BACKGROUND: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with significant morbidity and mortality. It can affect various tissues and organs throughout the body, leading to a broad spectrum of clinical symptoms. The treatment approach for SLE primarily involves immunomodulation and immunosuppression. However, these drugs have considerable toxicity and are not effective in all patients. Conceptually, a deep depletion of $CD19^+$ B cells and plasmablasts could trigger an immune reset in autoimmune diseases. Autologous CD19-targeted CAR-T therapies has been explored in several autoimmune diseases and reported promising efficacy in recent studies. In this study, a healthy donor-derived, multiplex genome-edited allogeneic CD19-targeted CAR-T product (BRL-303) was developed for refractory SLE patients. Here we report effciacy and safety profiles of BRL-303 after treating 3 patients with systemic lupus erythematosus (SLE).

METHODS: This is an investigator-initiated trial evaluated the safety and efficacy of BRL-303 in adult patients with refractory SLE (NCT05988216). Participants were screened and underwent lymphodepletion chemotherapy with cyclophosphamide (300 mg/m², day -5 to -4) and fludarabine (25 mg/m², day -5 to -3), then BRL-303 infusion at day 0 with a dose level of 1×10^6 cells/kg. After BRL-303 infusion, each patient underwent safety and systematic follow-up assessments according to the protocol.

RESULTS: As of June, 13, 2024, 3 patients with refractory systemic lupus erythematosus have been treated. These patients were unable to control disease progression despite treatment with corticosteroids and various immunosuppressants. After BRL-303 infusion, CAR-T cells expanded in vivo in all subjects significantly within 7 days and reached a peak around 14-21 days. Notably, Patient SLE-03 exhibited the most robust CAR-T cell expansion, with peak CAR copy numbers reaching 13,680/μL at day 14 post-infusion. CAR-T cells remained detectable in all patients at 3 months.With expansion of BRL-303, B cells in peripheral blood of patients reached deep and persistent depletion about 1-3 months. After BRL-303 infusion, all patients met the Systemic Lupus International Collaborating Clinics (SLICC) criteria for a sustained response (SRI-4). Moreover, all subjects showed a significant decrease in serum ds-DNA and increase in complements (C3 and C4). Meanwhile, 24-hour proteinuria significantly decreased in 2 subjects with lupus nephritis. Importantly, SLE-01 discontinued all immunomodulatory and immunosuppressive medications, including glucocorticoids, at 3 months, achieving drug-free remission, while other patients require low-dose glucocorticoid maintenance therapy (≤ 5 mg). The most commonly observed grade 3 or 4 adverse events (AEs) within the first few weeks included neutropenia, lymphopenia and fatigue, which were considered relatively to the lymphodepletion conditioning regimen. All of them developed grade 1 CRS for 2 or 3 days, which recovered soon without tocilizumab and steroid usage. No serious infection (Grade 3/4), no ICANS and GvHD observed in all subjects.

CONCLUSIONS: Overall, SLE subjects treated with BRL-303 achieved significant clinical remission, with a controllable safety profile, offering a potential paradigm shift for SLE patients who are refractory to currently available treatments. Further observation of SLE and more autoimmune disorders treated with BRL-303 are ongoing in our studies.

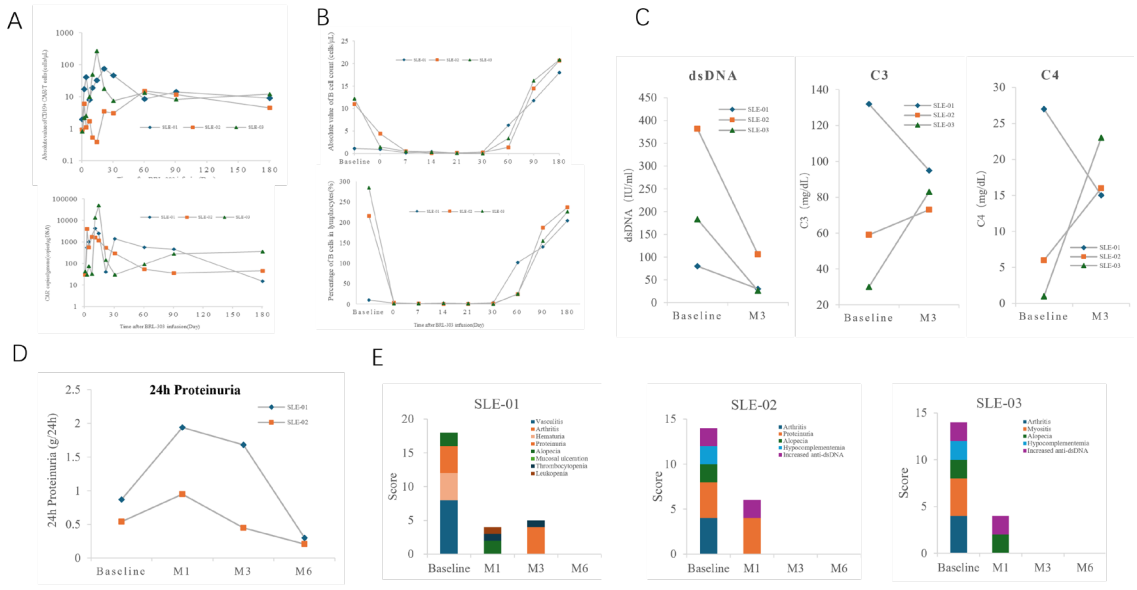

Figure 1 Effects of BRL-303 for SLE patients befor and after BRL-303 treatment (A, BRL-303 detected by flow and qPCR. B, B cell percentage and absolute B cells value. C, ds-DNA, C3 and C4 change. D, 24-hour proteinuira changes. E, SELENA-SLEDAI Score changs);

Repurposing oncology drugs to treat autoimmune disease

Juan Liang[1], Jialu Fan[2], Yinlian Zhang[1]
[1]GemPharmatech Co., Ltd., Nanjing, Jiangsu, China, [2]GemPharmatech Co., Ltd., Nanjing, China

Introduction: Approved drugs have successfully passed costly toxicological studies and their pharmacokinetics and pharmacodynamic properties are well characterized. Drug repurposing can provide new treatment options for patients with unmet medical needs. Rituximab is the first monoclonal antibody approved for treating lymphoma, becoming one of the most popular and versatile drugs in clinical application and revenue. Rituximab is widely used to treat autoimmune diseases mediated by B cells. In 2014, Blincyto was approved by the FDA for treating acute lymphoma, opening the door to developing T cell engagers (TCE). In addition to treating cancer, new indications for TCE are unlocking, especially autoimmune and inflammatory diseases. SLE is an autoimmune disease caused by the loss of B-cell tolerance leading to auto-antibody production and multi-system damage. Gempharmatech developed two humanized SLE models by transferring peripheral blood mononuclear cells (PBMC) from SLE patients to immunodeficient mice or transferring human hematopoietic stem cells (HSC) to immunodeficient mice followed by TLR7/8 agonist treatment to induced lupus. Humanized SLE models can partially reconstruct the human immune system and mimic the human in vivo microenvironment. It will build a bridge for repurposing oncology drugs to treat autoimmune diseases.

Objective: Develop humanized autoimmune mouse model for oncology drug repurposing

Methodology: PBMC-induced SLE model was constructed by intraperitoneal injection of SLE patient-derived PBMC. Blincyto was administered intravenously 7 days after PBMC inoculation, twice a week for three consecutive weeks. The peripheral blood was collected 14 and 28 days after PBMC inoculation for flow cytometry analysis of plasma B cells. The plasma was separated simultaneously for ELISA test of human anti-dsDNA and total IgG. The kidney was collected and freshly embedded for immunofluorescence staining of human IgG. TLR 7/8 agonist Resiquimod was applied on the ear of immunodeficient mice after 14 weeks of HSC reconstitution, 3 times a week, with a modeling period of 6 weeks. Rituximab was administered intravenously 4 weeks after Resiqiumod induction, 3 times a week for 3 consecutive weeks. The peripheral blood will be collected 10 and 26 days after

Rituximab treatment for flow cytometry analysis of human CD19+ B cells. The plasma was collected 3, 10, 17, and 26 days after the dosing for ELISA test of human anti-dsDNA.

Results: In the SLE patient-derived PBMC-induced model, after 1 week and 3 weeks of Blincyto administration, the level of plasma anti-dsDNA and IgG levels, as well as the number of peripheral plasma B cells, were significantly reduced. IgG deposition in the kidneys was also considerably reduced 3 weeks after the drug dosing. In the TLR 7/8 agonist-induced SLE model based on HSC reconstituted mice, Rituximab treatment could significantly increase mice survival and inhibit the production of human anti-dsDNA. Human CD19+ B cells were effectively depleted after Rituximab treatment.

Conclusion: Developing new drugs requires a significant investment of time and economic costs. The research on drug repurposing has significant advantages over developing new drugs. Humanized SLE models exhibit similar pathological features seen in SLE patients such as high levels of auto-antibodies and pathogenic B cells. It will be an excellent tool for research on the repurposing of B cell-directed oncology drugs.

1262 RESET-SLE^{TM}: Clinical Trial Evaluating Rese-cel (Resecabtagene Autoleucel), A Fully Human, Autologous 4-1BB Anti-CD19 CAR T Cell Therapy in Non-Renal SLE and Lupus Nephritis: Correlative Findings

Jason Stadanlick[1], Larissa Ishikawa[1], Thomas Furmanak[3], Mallorie Werner[2], Zachary Vorndran[4], Alexandra Ellis[3], Jazmean Williams[3], Justin Cicarelli[3], Steve Flanagan[2], Danielle Kobulsky[2], Quynh Lam[3], Fatemeh Hadi-Nezhad[3], Yvonne White[2], Carl DiCasoli[2], Rebecca Estremera[2], Saira Sheikh[5], Vimal Derebail[5], Natalie Grover[5], Gaurav Gulati[6], Mehrdad Abedi[7], Meghan Sise[8], Matthew Frigault[8], Christopher Palma[9], Patrick Reagan[9], Cuoghi Edens[10], Satyajit Kosuri[10], Caitlin Elgarten[11], Jon Burnham[11], Jonathan Hogan[2], Raj Tummala[2], David Chang[12], Samik Basu[13], Daniel Nunez[13], Jenell Volkov[2]*
[1]Cabaletta Bio, Philadelphia, PA, [3]Cabaletta Bio, [4]Cabaletta Bio Inc, [5]University of North Carolina, Chapel Hill, NC, [6]University of California Davis, Davis, CA, [7]University of California Medical Center, Sacramento, [8]Massachusetts General Hospital, Boston, MA, [9]University of Rochester Medical Center, Rochester, NY, [10]University of Chicago, Chicago, IL, [11]Children's Hospital of Philadelphia, Philadelphia, PA, [12]Philadelphia, PA, [13]Cabaletta Bio, Philadelphia, Pennsylvania
**Corresponding Author*

Background: Current therapies for systemic lupus erythematosus (SLE) aim to control disease activity, reduce organ damage, and decrease long-term morbidity and mortality. Achieving durable clinical responses without chronic immunosuppressive drugs is desired. CD19-targeting chimeric antigen receptor (CAR) T cells have demonstrated durable, drug-free responses in SLE patients in an academic program. Rese-cel (formerly referred to as CABA-201) is a fully human, autologous 4-1BB anti-CD19-CAR T cell therapy, designed to deeply and transiently deplete CD19 positive B cells following a one-time weight-based infusion of $1x10^6$ CAR T cells/kg. Rese-cel may enable durable responses without chronic immunosuppression. RESET-SLE^{TM} (NCT06121297) is an ongoing Phase 1/2 trial evaluating the safety and efficacy of rese-cel in two cohorts of non-renal SLE and lupus nephritis (LN).

Results: Six patients, 4 in the non-renal SLE cohort (SLE-1, SLE-2, SLE-3, SLE-4) and 2 in the LN cohort (LN-1, LN-2), have been dosed with rese-cel with at least 1 month of follow-up. Rese-cel has been well-tolerated with Grade 1 cytokine release syndrome (CRS) reported in 2 patients, one from each cohort (SLE-2 and LN-1). As reported previously, the LN-1 patient experienced Grade 4 immune effector cell-associated neurotoxicity syndrome (ICANS), linked to a potential occult infection, which resolved rapidly following standard management. No other patient experienced ICANS. Infusion products were predominantly CD4+ CAR T cells and showed *in vitro* cytolytic activity towards a NALM6 target cell line. Leukocyte and lymphocyte counts reduced quickly and transiently after a standard preconditioning regimen of fludarabine ($25mg/m^2$/day x 3) and cyclophosphamide ($1000mg/m^2$) that inversely corresponded with a transient elevation in serum IL-15 levels. Following rese-cel infusion, peak CAR T cell concentration occurred between days 7 and 16 post-infusion (C_{max}), with the LN-1 patient also experiencing a second peak at day 29, followed by contraction. Serum IFNγ levels peak before or in parallel with CAR T C_{max}. In the CAR T population at $C_{max,}$ CD8/CD4 ratios increased in 4 out of 6 subjects (CAR T cells were too low to be

detected by flow cytometry in 2 subjects). Circulating B cells were rapidly reduced within the first 29 days post-infusion. Early-stage transitional B cells (CD19+CD20+CD38++CD24++) were evident in 4 out of 6 patients (SLE-1, SLE-3, SLE-4, LN-2) at 8 weeks post-infusion and at 12 weeks for SLE-2. B cells in LN-1 were detectable but too low to phenotype at 20 and 24 weeks post-infusion. Serum BAFF levels increased during periods of B cell depletion and stabilized in most patients over time. Vaccine related antibodies were stable in most patients, whereas serum levels of lupus-specific and related autoantibodies decreased in 5/6 subjects, as of the most recent follow-up. Clinical improvement has been observed in all 6 patients (follow-up range 1 month to 9 months), with all patients exhibiting substantial reductions in Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scores which have deepened with increasing follow-up.

Conclusions: These emerging data detail the pharmacokinetics and pharmacodynamics of rese-cel in patients with SLE and LN and support the potential for rese-cel to lead to durable, drug-free remissions. Evaluation of safety and efficacy of rese-cel continues in the ongoing Phase 1/2 RESET-SLE™ trial.

1263 RESET-SSc™: Clinical Trial Evaluating Rese-cel (Resecabtagene Autoleucel), A Fully Human, Autologous 4-1BB Anti-CD19 CAR T Cell Therapy in Systemic Sclerosis: Correlative Findings

Zachary Vorndran[1], Mallorie Werner[2], Thomas Furmanak[3], Jason Stadanlick[4], Larissa Ishikawa[2], Alexandra Ellis[3], Justin Cicarelli[3], Jazmean Williams[3], Steve Flanagan[2], Danielle Kobulsky[2], Quynh Lam[3], Domenick Braccia[2], Fatemeh Hadi-Nezhad[3], Courtney Little[2], Carl DiCasoli[2], Mikaela Raymond[2], Dinesh Khanna[5], Monalisa Ghosh[5], Ankoor Shah[6], Eliza Tsou[5], Charles Ross[5], Raj Tummala[2], David Chang[7], Samik Basu[8], Daniel Nunez[8], Jenell Volkov[2]*

[1]Cabaletta Bio Inc, [2]Cabaletta Bio, Philadelphia, PA, [3]Cabaletta Bio, [4]Cabaletta Bio, Jenkintown, PA, [5]University of Michigan, Ann Arbor, MI, [6]Duke University, Durham, NC, [7]Philadelphia, PA, [8]Cabaletta Bio, Philadelphia, Pennsylvania

**Corresponding Author*

Background: Treatments for systemic sclerosis (SSc) aim to control disease activity, limit progression of organ damage, and decrease morbidity and mortality but many fail to provide durable clinical responses without requiring chronic immunosuppression. CD19-targeting chimeric antigen receptor (CAR) T cells produced durable, drug-free responses in SSc patients in an academic program. Rese-cel (formerly referred to as CABA-201) is a fully human, autologous 4-1BB anti-CD19-CAR T cell therapy, designed to deeply and transiently deplete CD19 positive B cells following a one-time weight-based infusion of $1x10^6$ CAR T cells/kg. Rese-cel may enable durable responses in patients without the need for chronic immunosuppression. RESET-SSc™ (NCT06328777) is an ongoing Phase 1/2 trial evaluating rese-cel in two cohorts of adults with SSc and either severe skin or organ involvement.

Results: A total of 3 patients have been enrolled and one patient dosed in the RESET-SSc™ trial. The dosed patient had severe skin involvement (SSc-Skin-1) at baseline prior to rese-cel. The patient has completed 3 months of follow-up. The patient tolerated rese-cel with no dose-limiting toxicity or immune effector cell-associated neurotoxicity syndrome (ICANS). The patient experienced grade 2 cytokine release syndrome (CRS), manifesting as fever and hypotension which resolved following intravenous fluids without requiring tocilizumab. Infusion product from the SSc-Skin-1 consisted of predominantly CD4+ CAR T cells and exhibited in vitro cytolytic activity towards a NALM6 target cell line. Leukocyte and lymphocyte counts dropped quickly and transiently after a standard preconditioning regimen of fludarabine (25 mg/m^2/day x 3) and cyclophosphamide (1000 mg/m^2) which inversely corresponded with an elevation in serum IL-15 levels. Following infusion of rese-cel, the patient exhibited CAR T cell expansion that peaked 2 weeks post-infusion (C_{max}) and was undetectable by day 29. CAR T cells exhibited a mainly CD8+ phenotype at C_{max}. Serum IFN-γ levels peaked prior to rese-cel C_{max} and IL-6 peaked in parallel with C_{max}. Peripheral B cells were rapidly reduced following infusion and were undetectable by 2 weeks post-infusion. The patient also exhibited depletion of B cells in lymphoid tissue obtained from ultrasound guided inguinal lymph node biopsies and immunologic staining performed at the University of Michigan in a separate biorepository study designed to support exploratory analyses. Lymph node sections consisted of a mixture of T cells ($CD3^+$) and B cells ($CD19^+$ and $CD20^+$) at baseline. At 21-days post-infusion, lymph node sections contained T cells and were fully devoid of B cells. Peripheral B cell reconstitution was observed at 8 weeks post-infusion with reemergent B cells

presenting with a transitional naïve phenotype ($CD19^+CD20^+CD38^{++}CD24^{++}$). Antibodies associated with vaccinations remained stable, whereas serum levels of SSc-associated autoantibodies decreased over the first 16-weeks. The patient has maintained a drug-free clinical response through 3 months of follow-up.

Conclusions: These emerging data detail the pharmacokinetics and pharmacodynamics of rese-cel in one SSc patient. Rese-cel deeply and transiently depleted B cells in circulation and in lymphoid tissue and support the potential for rese-cel to induce durable, drug-free remission. Evaluation of the safety and efficacy of rese-cel continues in the ongoing Phase 1/2 RESET-SSc™ trial.

1264 Modeling Innate Immune Cell Loss-of-Function in Nonhuman Primates with Anti-*CD16 and Anti-NKG2A CAR T Cells*

Taylor Oeschger[1], Benjamin Varco-Merth[2], Carly Starke[3], Manuel Medina[2], Nikhita Poole[4], Afam A. Okoye[5], Christopher Peterson[1]*

Introduction. Innate immunity is the first line of defense against foreign pathogens. To better understand the interplay between innate and adaptive immune responses, we have applied our nonhuman primate (NHP) model of chimeric antigen receptor (CAR) T-cell gene therapy to deplete broad (CD16) or narrow subsets of innate immune cells (NKG2A). CD16/FcγRIII is a member of the immunoglobulin superfamily, expressed on numerous innate immune subsets including monocytes, macrophages, granulocytes, and natural killer (NK) cells. NKG2A is a member of the C-type lectin-like receptor family. Although primarily known as an inhibitory receptor on NK cells, it also supports the survival of $CD8^+$ T-cells. Our long-term goal is to apply this model to better understand innate immune mechanisms in the pathogenesis of infectious diseases such as HIV and autoimmune diseases such as rheumatoid arthritis (RA), inflammatory bowel disease (IBD), and systemic lupus erythematosus (SLE).

Methods. We screened an array of NHP-adapted CAR molecules in *ex vivo* primary cell-based assays, then evaluated the most promising anti-CD16 and anti-NKG2A CARs in 6 rhesus macaques. Our pilot study included one animal that received anti-CD16 CAR T-cells, three that received NKG2A targeting CARs, and two controls that received low-dose conditioning but no CAR T-cells (**Figure 1**). In addition to peripheral blood, tissue collections were performed 2 weeks after each infusion to quantify CAR T-cells and target depletion in solid organs. Necropsy was performed 36-65 days after infusion. Total $CD16^+$ cells and NK cells ($CD3^-CD20^-CD8a^+NKG2A^+CD8b^-$) were quantified by flow cytometry and $\%CAR^+$ T cell in PBMCs were quantified by qPCR.

Results. Anti-CD16 CAR T-cells showed limited potency in peripheral blood with a peak of 13% CAR in PBMC at Day 11 with a decrease in %CD16 cells by flow to 0.5% on Day 12, however, the target cells rebounded quickly by Day 17 (**Figure 2A**). Anti-NKG2A CAR T-cells were administered in two doses: the first infusion had limited efficacy whereas the second infusion led to significant and more sustained NK depletion (**Figure 2B, 2C, 2D**). We detected anti-CD16 and anti-NKG2A CAR^+ cells in spleen and PBMCs and at low levels in axillary, mesenteric, and peripheral lymph nodes. All 3 animals displayed decreases in NK cells in the blood around the time of the second transplant that dropped to below 1% total NK. Low levels of NK cells were sustained in animals 32258 and 31530 until necropsy.

Conclusions. Our first NHP anti-CD16 and anti-NKG2A CAR T-cells experiments showed target depletion in blood, with anti-NKG2A CAR activity augmented by a repeat infusion. Modest *in vivo* activity relative to our previously published NHP CD20 CAR T-cell experiments may reflect key roles of $CD16^+$ and $NKG2A^+$ subsets for CAR cytotoxicity. Future work will focus on higher CAR T-cell infusion doses, which may be necessary for potent and sustained ablation. To account for overlap in marker profiles for NK cells, T cells and other innate immune subsets, Boolean-gated CARs could be designed for example to target NKG2A (NK cells) but not CD3 (T-cells). In our NHP model of HIV pathogenesis and cure, optimized anti-CD16 and anti-NKG2A CAR T-cells will be applied to unravel positive and negative impacts of innate immunity on the virus-specific inflammatory response and viral replication both at early and late infection time points.

Background: Dendritic cells (DCs) are professional antigen-presenting cells involved in the initiation of both immune defense and immune tolerance. Any dysfunction in the frequency or function of the two DC types can lead to onset and progression of autoimmune disorders (AD), infectious diseases, and cancer, among others. Due to their role in maintaining immune tolerance to harmless antigens, tolerogenic DCs (Tol-DCs) hold significant potential for treating various ADs, making their study of utmost importance. While obtaining primary DCs from blood is feasible, their low frequency limits their use in therapeutic vaccine and basic studies. Induced pluripotent stem cells (iPSCs) offer an attractive alternative for differentiating DCs with high efficiency. Traditional methods to generate Tol-DCs from iPSCs risk shifting the Tol-DC phenotype from tolerogenic to stimulatory upon encountering self-antigens,

pro-inflammatory cytokines, or microbial agents which acts as danger signals. The use of CRISPR/Cas9-engineered iPSCs offers an alternative method to maintain the immunotolerant phenotype of Tol-DCs by genetically modifying the cells to preserve this characteristic. Here, we describe the technical flow to generate either stimulatory DCs from human wild type (WT) iPSCs or TOL-DCs from CD86 knockout (KO) iPSCs.

Methods: In this study, we used a fibroblast-derived human iPSC (hiPSC) line (KOLF2-C1) referred to as WT and CD86 KO-derived clones (CD86-KO) generated by partially deleting exon 3 in the CD86 coding region in the WT using the CRISPR/Cas9 system. We identified and selected suitable KO clones by PCR and Sanger sequencing and confirmed the absence of CD86 protein in iPSC-derived DCs through flow cytometry, as shown in Figure 1. We established the culture conditions for obtaining conventional DCs (cDCs) from human WT or CD86-KO iPSCs and evaluated their ability to induce proliferation and differentiation of human naïve $CD4^+$ T cells.

Results: After approximately 35-40 days of differentiation, iPSC-derived DCs exhibited a switch from CD34+ to $CD45^+$, displayed typical DC morphology, and expressed markers such as HLA-DR, CD11C, and CD1C. The partial deletion of exon 3 of CD86 efficiently led to the disruption of this protein, as shown in Figure 1. Functional analysis of cDC2 (a DC subset) in co-culture with naïve $CD4^+$ T cells confirmed their differential efficiency. CD86-KO iPSC-DCs showed dramatically diminished effects on $CD4^+$ T cell differentiation, with reduced cytokine production, particularly interferon gamma, behaving as expected like Tol-DCs (Figure 2).

Conclusion: Our study established the method to generate Tol-cDCs from iPSCs, with potential clinical applications and a valuable tool for studies focused on AD diseases.

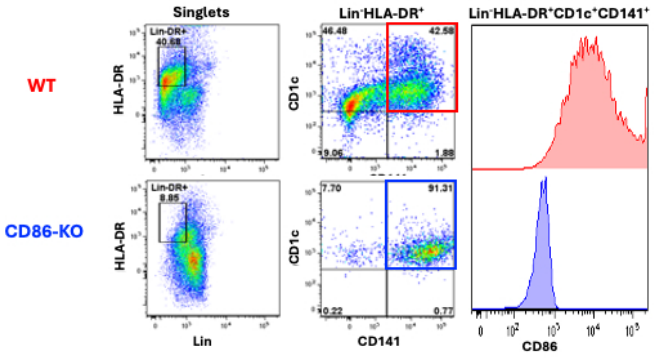

Figure 1: Validation of cDC2 iPSC-derived CD86-KO vs. WT (Day 36 of differentiation). Flow cytometry analysis confirms that CD86-KO cDC2 cells do not express the CD86 protein, as expected, while WT cDC2 cells show normal CD86 expression.

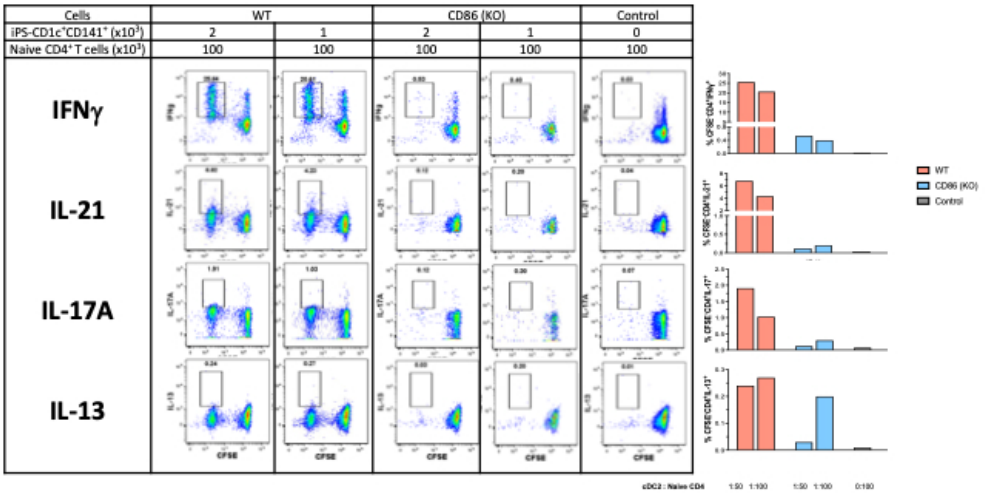

Figure 2.Capacity of cDC2 derived from WT iPSC to induce proliferation and differentiation of naïve CD4$^+$ T cells is abrogated in cDC2 derived from CD86-KO iPSCs.

1266 Neural Induction of Gene-Edited mRNA-Reprogrammed iPSCs Yields Highly Proliferative Neural Stem and Progenitor Cells That Display Persistent Transgene Expression

Claire Aibel[1]*, Ian Hay[1], Christopher Rohde[2], Matthew Angel[2]

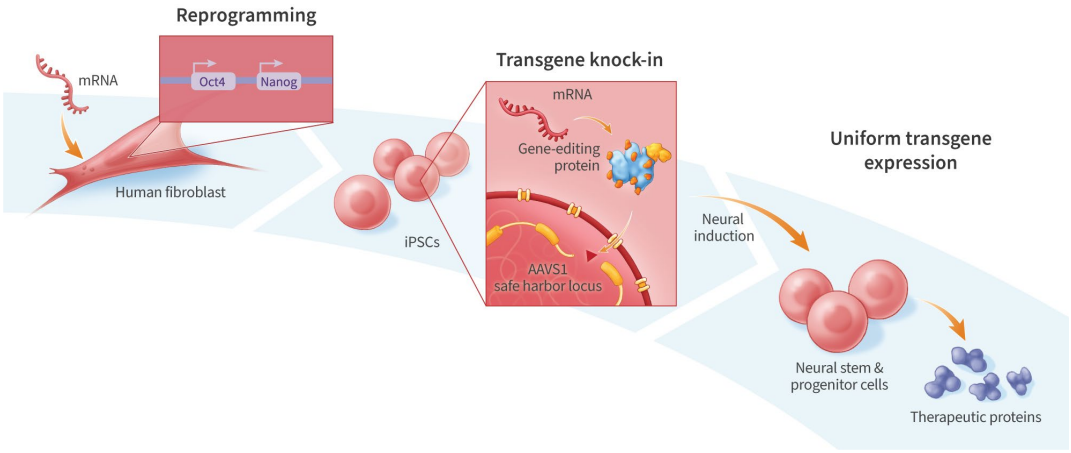
Background. Engineered neural stem and progenitor cells (NSPCs) can provide neuroprotection and modulate inflammation and thus are a promising therapeutic modality for neurodegenerative diseases. However, recent clinical trials for CNS disorders employ virally-transduced cortical-derived NSPCs, introducing risks of insertional mutagenesis and restricted by scarce source material. Here, we detail a virus-free process for scalable neural induction of wildtype or engineered induced pluripotent stem cells (iPSCs) that maintain transgene expression through differentiation.

Methods. mRNA-reprogrammed iPSCs were co-electroporated with single-stranded DNA donors and mRNA encoding gene-editing endonucleases for targeted insertion into the AAVS1 safe harbor locus. Clonal lines were subsequently established via colony selection and Sanger sequencing. iPSCs were then seeded into a 0.1L vertical wheel bioreactor and transitioned to neural induction medium to facilitate embryoid body (EB) formation. EBs were transferred to flasks and developed rosettes, which were selected, replated, and expanded to generate NSPCs. In parallel, a fully static differentiation was performed using microwell plates. Microwell-formed EBs were transferred to flasks and the remainder of induction was carried out identically to the bioreactor differentiation.

Results. Both static- and bioreactor-derived iNSPCs expressed characteristic NSPC markers Sox1, Sox2, Pax6, GAP-43, and Nestin, and did not express pluripotency markers Oct4 and Nanog. After induction, iNSPCs were expanded and harvested every 5-9 days to yield, on average, 3.2 x 10^6 cells/cm^2/harvest (static induction) and 3.8 x 10^6 cells/cm^2/harvest (bioreactor induction). iNSPCs retained characteristic marker expression and morphology for >4 passages and after cryopreservation. We also demonstrated that bioreactor-derived iNSPCs could be engineered to overexpress neurotrophic factors and cytokines, including interleukin-10 (IL-10), an anti-inflammatory protein with therapeutic applications to neurodegenerative disorders. Electroporation of 3.0 x 10^5 iNSPCs with mRNA encoding IL-10 resulted in >3ng/mL of secreted protein, compared to undetectable levels in untransfected iNSPCs. In addition to comparing neural induction of wildtype cells, we evaluated differentiation potential of iPSCs knocked-in with a GFP reporter. Induction efficiency, calculated based on rosette quantity, was 95% in the wildtype cells and 100% in the knock-in cells. Both displayed upregulation of characteristic NSPC markers and

downregulation of pluripotency markers. Notably, transgene expression was retained through differentiation, with >99% of iNSPCs expressing GFP at the end of neural induction.

Conclusions. We demonstrate that neural induction of mRNA-reprogrammed iPSCs can be executed in small bioreactors – with potential for scalability to larger vessels – to generate clinically relevant yields of iNSPCs. Additionally, we show that iNSPCs can be directly engineered to express therapeutic proteins and can be derived from transgenic iPSCs. These results suggest that scalable neural induction of iPSCs engineered to secrete therapeutic proteins could yield iNSPCs with uniform and stable transgene expression in an entirely non-viral process, which could contribute to the development of engineered cell therapies for neurodegenerative diseases.



1267 A Platform for Designing Neuron, Astrocyte and Hepatocyte Specific Promoters for Gene Therapy

Assen Roguev[1], Joseph Draut[2], Myles MacEachern[3], Thant Zaw[2], Magdalena Cichewicz[4], Rebecca Cottman[5], Frances Liu[5], Michelle Hung[4], Nicholas Frankel[2], Brian Kelly[6], Esteban Engel[6], Sean Armour[6], Daniel Cohen[6], Philip Lee, Timothy Lu[2], Russell Gordley[4]
[1]GeneFab, Alameda, CA, [2]Senti Biosciences, South San Francisco, CA, [3]GeneFab, San Francisco, CA, [4]GeneFab, South San Francisco, CA, [5]GeneFab, LLC, South San Francisco, CA, [6]Spark Therapeutics, Philadelphia, PA

In recent years, gene therapy approaches relying on targeted expression of transgene(s) in specific cell types, organs, or systems have become more prevalent and important in the treatment of various diseases. However, limiting the expression of therapeutic transgenes to the intended ON-target cell types remains a challenge. A contributing factor may be promoter leakiness which leads to undesirable transgene expression in OFF-target cell types. Risks associated with OFF-target cell types include immunogenicity and/or inflammatory responses.

In this work we developed highly specific, potent, and compact synthetic promoters for three clinically relevant cell types -- neurons, astrocytes and hepatocytes -- to address the above challenges. Specifically, neuron specific promoters were designed to be inactive in astrocytes and hepatocytes; astrocyte specific promoters were designed to be inactive in neurons and hepatocytes; and hepatocyte specific promoters were designed to be inactive in Kupffer cells and cardiomyocytes.

In all cases, we utilized two design approaches in parallel: (1) pooled screening of short, fully synthetic promoters, and (2) clonal screening of natural sequences from endogenous promoters and putative enhancers. For the first approach, we designed libraries of arrays of binding sites for transcription factors or short fragments of natural sequences that are differentially regulated in the desired ON / OFF target cell combinations which were then screened in a Massively Parallel Reporter Assay (MPRA). For the second approach, differentially regulated

promoters and enhancers in each of the ON / OFF target cells combinations were cloned and screened individually by transient transfection. Promoters and enhancers displaying the desired expression pattern were functionally dissected by targeted mutagenesis to identify core regulatory elements. Both approaches rely heavily on bioinformatics mining of publicly available as well as de novo generated transcriptomics and chromatin accessibility data. Screening was done using primary cells or surrogate cell lines representative of each ON and OFF target cell type. We developed a powerful computational platform for mining and analyzing the experimental results and built machine learning models aiding the generation of new improved promoter designs. Strong hits from the two approaches were then combined in designs that further improved their strength and specificity. The outlined strategy yielded a wide spectrum of highly compact (less than 1kb) promoters for the three ON target cell types. Our neuron specific promoter designs outperform the widely used hSyn1 promoter by several fold both in terms of strength and specificity. Likewise, we designed several compact astrocyte-specific promoters with superior strength and specificity (several fold in both cases) compared to the GFAP promoter. We were also able to design hepatocyte specific promoters vastly outperforming a well-known hepatocyte-specific promoter with many of them being extremely compact (less than 200bp).

These results validate our strategy and workflow for designing highly compact, specific, and potent clinically relevant synthetic promoters, which can be applied across various cell types and diseases of interest.

1268 Investigation of the Long-Term Effects and Post-Disease Onset Impact of Wild-Type Hematopoietic Stem Cell Transplantation in a Mouse Model of Alzheimer's Disease

Jessica K Schenck[1], Henry Basila Rabamad[2], Rola Chen[2], Rafael Badell-Grau[3], Sol Diaz[2], Betul Gunes[4], Stephanie Cherqui[5]*
[1]University of California, San Diego, La Jolla, CA, [2]University of California, San Diego, San Diego, CA, [3]UC San Diego, La Jolla, CA, [4]University of California San Diego, San Diego, CA, [5]University of California, San Diego, La Jolla, California

Alzheimer's Disease (AD) is the most common form of dementia and poses a significant global health burden, yet there is currently no effective treatment for AD. We previously showed compete rescue of memory and neurocognitive impairments, microgliosis, neuroinflammation, and decrease of amyloid plaque burden in the 5xFAD model of familial AD after a single systemic infusion of wild-type (WT) hematopoietic stem and progenitor cells (HSPCs) performed at 2-months of age and analyzed 4-months post-transplantation. When evaluating HSPC-derived therapy for Alzheimer's disease, two key questions emerge: the long-term impact of the treatment and whether HSPC therapy could be effective when administered after disease onset, given that most patients are diagnosed at this stage. To assess the long-term effects of WT HSPC transplantation, 2-month old myeloablated 5xFAD mice were transplanted with $Sca1^+$ HSPCs from either WT (AD/WT_{HSPC}) or 5xFAD (AD/AD_{HSPC}) mice. At 8-months post-transplantation, preliminary data showed that long-term AD/WT_{HSPC} mice exhibited significant improvement in the elevated plus maze (EPM), open field (OF), and novel object recognition (NOR) tests compared to untreated 5xFAD mice, while no recovery was observed in long-term AD/AD_{HSPC} mice. Furthermore, immunostaining of the cortex revealed a reduction in amyloid plaque size and number of $IBA1^+$ microglia in long-term AD/WT_{HSPC} mice compared to their untreated littermates, indicating a sustained decrease in plaque burden and neuroinflammation after a single systemic WT HSPC transplantation. Since amyloid plaque accumulation is detected in 5xFAD brains by 4-months and significant neurocognitive deficits observed by 6-months of age, we are further investigating the effects of WT HSPC transplantation after disease onset in 6-month-old mice. Compared to their untreated littermates and after-onset AD/AD_{HSPC} mice, after-onset AD/WT_{HSPC} mice showed significant improvements in the EPM, OF, and NOR tests at 4-months post-transplantation. Sholl analysis of $IBA1^+$ microglia in the hippocampus of AD/WT_{HSPC} mice revealed increased dendritic complexity compared to untreated 5xFAD mice, indicating a shift towards a less activated microglial state. Neuroinflammation and plaque burden status are being currently analyzed. Taken together, this rescue in cognitive performances and neuropathology of 5xFAD mice transplanted with WT HSPCs both long-term and after disease onset demonstrated the potential of WT HSPCs in treating AD despite the severe accumulation of amyloid aggregates.

1269 Hematopoietic Stem Cell Transplantation with Enhanced Brain Conditioning Corrects Progranulin Deficiency in mouse models

Pasqualina Colella[1], Maria Suarez-Nieto[2], Eduardo Tejeda-Polanco[2], LUISA NATALIA PIMENTEL VERA[3], Edina Poletto[4], Jessica Arozqueta Basurto[5], Kwamina Nyame[5], Jian Xiong[5], Monther Abu-Remaileh[5], Natalia Gomez-Ospina[6]
[1]Stanford University, Atherton, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford University Laboratory for Cell & Gene Medicine, Stanford, CA, [4]Stanford University, Stanford, CA, [5]Stanford University, Palo Alto, [6]Stanford, Palo Alto, CA

Hematopoietic stem cell transplantation (HSCT) is a therapy for neuronopathic diseases, offering benefits through allogeneic and autologous approaches. Allogeneic HSCT (allo-HSCT) uses donor-derived cells and has been the standard treatment for severe neuronopathic diseases. However, its application is limited by donor scarcity and immunological complications like graft-versus-host disease. Autologous HSCT (auto-HSCT) gene therapy is an emerging approach that genetically modifies a patient's own hematopoietic stem and progenitor cells (HSPCs) *ex vivo*, avoiding these issues and enabling disease-specific cell engineering, such as enhanced therapeutic protein expression.

Our work focuses on progranulin (GRN) deficiency, a lysosomal protein defect causing neurological diseases, including neuronal ceroid lipofuscinosis type 11 (CLN11; bi-allelic loss-of-function) and frontotemporal dementia (FTD-GRN; mono-allelic loss-of-function). These conditions are suited to HSCT as wild-type or gene-modified cells can secrete GRN and cross-correct GRN-deficient cells through receptor-mediated endocytosis and lysosomal trafficking. We are investigating allo- and auto-HSCT in preclinical models. We previously showed that wild-type bone marrow transplantation (BMT) in *Grn -/-* mice treated with enhanced conditioning improves microglia replacement, achieves biochemical correction in the brain and eye, and normalizes brain disease biomarkers compared to standard myeloablative conditioning (Colella et al., Nat Commun. 2024, PMID: 38969669).
This enhanced conditioning combines busulfan with PLX3397, a CNS-penetrant inhibitor of the Colony-stimulating factor 1 receptor (CSF1R). Building on this, we tested allo-HSCT using purified mouse HSPCs expanded in culture. Transplantation of these HSPCs into immunocompetent *Grn-/-* mice resulted in rapid microglia replacement (91 ± 2.6% of brain CD45+ cells), GRN protein reconstitution in circulation and brain (40% of wild-type levels), and correction of brain biomarkers.

For auto-HSCT, we engineered mouse and human HSPCs using genome editing to integrate GRN transgenes at safe harbor loci via homology-directed repair (HDR). Optimized editing achieved 70% and 90% edited alleles in mouse and human HSPCs, respectively, with non-viral promoter-driving GRN expression. Transplantation of GRN-edited mouse HSPCs into immunocompetent *Grn-/-* mice showed full hematopoietic reconstitution, high retention of edited alleles (100 ± 17% vs. cultured HSPCs, n=18), and GRN protein restoration in the periphery and CNS. The therapeutic effects of auto-HSCT on disease biomarkers are being evaluated. Initial xenotransplantation of human GRN-edited HSPCs into immunodeficient *Grn-/-* mice demonstrated long-term engraftment and multilineage differentiation. We are currently assessing the long-term stemness and engraftment of human HSPCs using optimized genome editing protocols. Our work highlights the potential of allo- and auto-HSCT coupled with enhanced microglia replacement to tackle diseases caused by progranulin deficiency. These findings lay the foundation for advancing these approaches toward clinical application.

1270 Lentivirus-based Hematopoietic Stem/Progenitor Cell Therapy Provides Safe and Long-term Treatment in Hypophosphatasia Mouse Model

Mayra Carrillo[1], Shallu Tomer[1], Li Wang[2], Wally Wennerberg[3], Ethan Cook[1], Nicholas Tien[3], Hwee Ng[3], Jayashree Alargasamy[1], Valerie Rezek[4], Heather Martin[5], Jose Luis Millan[6], Phillipe Crine[7], Michael Yan[7], Steven Lee[7], Ryan Rodriguez[7], Megan Martinez[7], Ryan Agabani[8], Na Jeong Kim[7], Nicholas Lee[7], Peyton Bishop[7], Virginia Le Verche[9], Irvin Chen[3], Scott Kitchen[10], Louis Breton[7], Jeffrey Bartlett[8], Minh-Ha Do[11], Anjie Zhen[12]

[7]Rampart Bioscience, Monrovia, [8]Rampart Bioscience, Monrovia, CA, [9]Los Angeles, CA, [10]David Geffen School of Medicine at UCLA, LOS ANGELES, CA, [11]Rampart Bioscience, San Diego, CA, [12]UCLA, Los Angeles, California

Hypophosphatasia (HPP) is a multi-system metabolic disorder characterized by skeletal hypomineralization, rickets, muscle weakness, and premature tooth loss in milder forms and perinatal lethality in severe cases. It is caused by loss-of-function mutations in the gene *ALPL* encoding tissue-nonspecific alkaline phosphatase (TNALP). Currently, enzyme replacement therapy with asfotase alfa (STRENSIQ®) is the only FDA-approved treatment for HPP, though it is only approved for individuals with severe forms of the condition. Asfotase alfa enhances survival and improves bone mineralization but is burdensome because patients must undergo frequent injections for the rest of their lives. Here we report the development of a lentiviral vector (LVV), RMP100-LVV, to stably express a secreted form of TNALP from LVV-transduced hematopoietic stem/progenitor cells (HSPCs) and their progeny. This vector encodes a codon-optimized secreted form of TNALP fused to a human IgG1 Fc domain to prolong serum half-life and a targeting peptide to deliver the soluble TNALP protein to the bone. We show high levels of gene transfer to HSPC, as well as engraftment and differentiation of human RMP100-LVV-modified HSPCs in humanized bone marrow-thymus-liver (BLT) mice. Gene modified cells were detected in the peripheral blood, the bone marrow and spleen as assessed by vector copy number (VCN) analysis. Importantly, we detected multilineage reconstitution of marked huCD45+ cells, including CD3+ T cells, CD19+ B cells and CD11c+ dendritic cells, indicating that RMP100-LVV transduction of human HSPCs is feasible and does not affect immune reconstitution. Finally, we demonstrate that treatment with this cell therapy approach leads to a durable correction of plasma alkaline phosphatase activity, rescues early mortality, and skeletal manifestations of the disease in the severe HPP mouse model ($Akp2^{-/-}$). All untreated $Akp2^{-/-}$ mice, including those exhibiting mild bone phenotype, died by PND30 due to complications related to bone deformity or seizure. However, all mice transplanted with RMP100-HSPCs survived until scheduled termination on PND30 and there was a significant improvement in bone development based on radiographic image analysis of bone length and spacing. Additional analysis with micro-CT further demonstrated improved bone development that was indistinguishable from WT ($Akp2^{+/+}$) or HET ($Akp2^{+/-}$) controls. Restoration of musculoskeletal activity was assessed by open-field testing. We observed no significant difference between WT and transplanted $Akp2^{-/-}$ mice in total distance traveled, maximum speed (Vmax), or other parameters, further demonstrating the curative effects of RMP100-HSPC transplantation. Long-term efficacy was assessed by following a group of transplanted $Akp2^{-/-}$ mice for up to 1.5 years. Remarkably, all transplanted $Akp2^{-/-}$ mice survived and remained as healthy as their WT littermates, with maintenance of high plasma ALP activity and normal skeletal phenotype during this period. Our study provides critical insights into treating metabolic bone disorders with an autologous HSPC-based gene therapy and demonstrates that this approach is a potential safe and one-time treatment for HPP.

1271 Amnion mesenchymal stromal cells have the potential to preserve muscle function in a mouse model of Duchenne muscular dystrophy

Yuko Kasahara[1], Soya Nakayama[2], Koichi Kimura[3], Sho Yamaguchi[2], Yuko Aizen[4], Chikako Nito[5], Masahiro Hayashi[6], Tomoyuki Nakaishi[7], Yasuyoshi Ueda[7], Takashi Okada[8]*

**Corresponding Author*

Background: Duchenne muscular dystrophy (DMD) is an incurable genetic disease characterized by degeneration and necrosis of myofibers, chronic inflammation, and progressive muscle weakness resulting in premature mortality. Immunosuppressive multipotent mesenchymal stromal cells (MSCs) therapy is a possible option for DMD patients. We focused on human amnion-derived mesenchymal stromal cells (hAMSCs), a clinically viable cell source owing to their unique characteristics, such as non-invasive isolation, mitotic stability, ethical acceptability, and minimal risk of immune reaction and cancer. We aimed to identify novel immunomodulatory effects after transplantation of hAMSCs for the functional recovery of skeletal and cardiac muscles.

Methods: We analyzed extracellular secretion of cytokines and chemokines in the co-cultured medium of hAMSCs with myocytes. hAMSCs were intravenously injected into DMD model mice (mdx mice) to assess the efficacy of therapeutic interventions. hAMSCs-treated mice were evaluated using myokine expression, histological examinations, spontaneous wheel-running activities, grip strength, and echocardiography.

Results: In vitro co-culture of hAMSCs and dystrophic myocytes showed disease specific activation of hAMSCs through up-regulated cytokine/chemokine expression, indicating the enhanced secretion from hAMSCs in the dystrophic environment of myocytes and the induction of M2 macrophage activation. After repeated systemic hAMSC injections, limited mononuclear cell infiltration and a decreased number of centrally nucleated fibers were indicative of regenerated myofibers following degeneration, revealing an improved histological appearance of the skeletal muscle of hAMSC-treated mdx mice. Upregulated M2 macrophages and altered myokine expressions were observed in the hAMSC-treated muscles. During long-term experiments, a significant decrease in the grip strength in untreated mdx mice significantly improved in the hAMSC-treated mdx mice. hAMSC-treated mdx mice maintained running activity and had an enhanced daily running distance. Notably, the treated mice could run longer distances per minute, indicating high running endurance. Left ventricular function in hAMSC-treated mdx mice improved when compared to untreated DMD mice. In contrast, we did not detect significant differences in the fibrotic area in the diaphragm and cardiac muscle.

Conclusions: Early systemic hAMSCs administration in mdx mice ameliorated progressive phenotypes, including pathological inflammation and motor dysfunction, resulting in the long-term improvement of the skeletal and cardiac muscle function. The therapeutic effects might be associated with the immunosuppressive properties of hAMSCs via M2 macrophage polarization. This treatment strategy could provide therapeutic benefits to DMD patients.

1272 Mesenchymal Cells as a Therapeutic Targets for ex-vivo Gene Writting in MDC1A

Maria Pallarès-Masmitjà[1]*, Oscar Garriga[2], Carles Bayod[3], Núria Rafel[4], David Gomez[5], Laura Costa[5], Francina Munell[5]*, Jordi Barquinero[5]*
[1]Vall D'Hebron Research Institute, SAnt Boi de Llobregat, Barcelona, Spain, [2]VHIR, Barcelona, Barcelona, Spain, [3]Pompeu Fabra University, Barcelona, Barcelona, Spain, [4]Pompeu Fabra University, Barcelona, Spain, [5]VHIR, Barcelona, Spain
**Corresponding Author*

Congenital muscular dystrophy type 1A (MDC1A) is a severe, progressive pediatric disorder caused by recessive mutations in the *LAMA2* gene. The LAMA2 protein trimerizes with LAMB1 and LAMC1 proteins and is fully secreted as laminin 211 into the muscle extracellular matrix, where it interacts with multiple proteins. The absence of LAMA2 or the presence of aberrant forms due to gene mutations results in an unstable extracellular matrix, reduced muscle mass and function, inflammation, and fibrosis. The large size of the *LAMA2* ORF presents a major limitation for gene therapy, and there is currently no effective treatment for MDC1A.

Since laminin 211 can reach the muscle extracellular matrix upon systemic administration, our study aims to use mesenchymal stem cells (MSCs) as laminin 211 protein pumps. Given the immunomodulatory properties of MSCs, we aim to both target the fibrotic component of MDC1A and develop an ex vivo gene editing approach to restore *LAMA2*expression.

MSCs are an optimal target for producing laminin 211 due to their immunomodulatory properties and low immunogenicity. To address their short lifespan in vivo following injection, we propose pre-differentiation into adipose progenitor cells. Although we have found evidence that MSCs naturally produce *LAMA2*, a gene writing strategy is employed to enhance production and ensure therapeutic levels. MSCs are obtained from wild-type mouse adipose tissue.

Our findings confirm the systemic distribution of laminin 211 following recombinant protein injection in the dy2j MDC1A mouse model. A preliminary study assessing *LAMA2*, *LAMB1*, and *LAMC1* production by MSCs and pre-adipocytes provides strong evidence supporting the potential of MSCs as laminin 211 protein pumps. Additionally,

MSCs have been successfully edited to produce laminin 211 and studied in vivo following intramuscular injection. Our approach—targeting MSCs for both fibrosis regulation and ex vivo gene therapy—introduces novel therapeutic opportunities for MDC1A. Given the critical role of fibrosis in MDC1A pathogenesis, we propose that an effective treatment must not only restore *LAMA2* expression but also modulate fibrosis. Our findings represent a step toward addressing the unmet clinical need for effective MDC1A treatments.

1273 Gene Supplementation via *DARS2*-AAV9 Rescues Phenotype in LBSL Patient Cells and *in Vivo* Mouse Model

Bayley Lindsay[1], Ines Garofolo[2], Yajie Liang[3], Miroslaw Janowski[4], Ali Fatemi[5], Christina Nemeth Mertz[5]
[1]Kennedy Krieger Institute, Towson, MD, [2]Kennedy Krieger Institute, Mount Airy, MD, [3]University of Maryland School of Medicine, Baltimore, [4]University of Maryland, Baltimore, Baltimore, MD, [5]Kennedy Krieger Institute, Baltimore, MD

Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL) is a rare, neurological disorder cause by variants in the *DARS2* gene. *DARS2*, an enzyme that catalyzes the attachment of aspartic acid to its corresponding t-RNA in the mitochondria, is ubiquitously expressed and essential. All people with LBSL possess compound heterozygous variants on *DARS2*, the most common of which results in a frameshift, premature termination, and decreased protein abundance. Upon disruption of *DARS2* production, clinical presentation can take a wide phenotypic spectrum, most commonly manifesting in progressive spasticity, ataxia, and dorsal column dysfunction, characterized as primary axonopathy with secondary demyelination. In this study, we aimed to test the efficacy of gene supplementation via *DARS2*-AAV9 in LBSL patient-derived sensory neurons as well as in an LBSL mouse phenolog in which *Dars2* is deleted in Advillin-expressing neurons of the dorsal root ganglia. Patient neurons treated with *DARS2*-AAV9 showed increased gene expression, which correlated with functional improvements measured by increased mitochondrial function, axonal growth, and decreased lactate production. Further, knock-out mice reflected functional improvements *in vivo*, displaying improved survival and gait following a single intrathecal injection of *DARS2*-AAV9. These data suggest that gene supplementation via AAV9 improves both cell survival and function, reducing phenotypic burden. Combined with the success of existing AAV9s in treating loss of function monogenetic disorders, these data demonstrate promise for *DARS2*-AAV9 as a potential therapeutic for LBSL and compel further investigation.

1274 Long-term Tolerance to Leydig Cell Transplantation with Localized Treg Immunomodulation Using the NanoLymph Platform

Nikitha Kota[1], Danilo Settis[2], Corrine Chua[1], Alessandro Grattoni[3]
[1]Houston Methodist Research Institute, Houston, TX, [2]Houston Methodist Research Institute, Houston, [3]Houston Methodist Hospital, Houston, TX

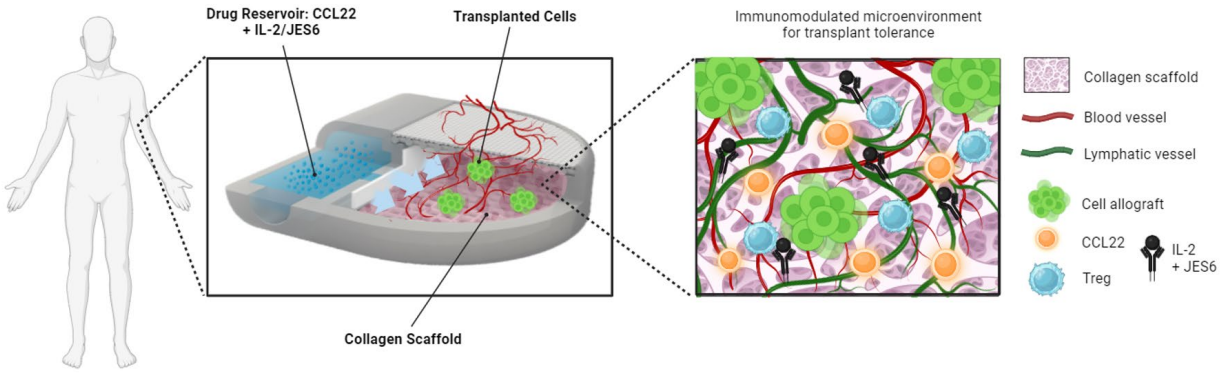
Cellular therapies aim to treat or manage disease by introducing living cells that integrate into the host and restore or eliminate dysfunctional tissues. Despite their clinical success, the host immune response to cellular treatments remains a challenge. Traditional approaches for controlling immune rejection involve systemic immunosuppression, which can result in severe off-target toxicity. An alternative strategy to restrain immune responses involves harnessing the natural immunomodulatory capabilities of Regulatory T-cells (Tregs), a specialized subset of T cells that suppress inflammatory immune responses and promote transplantation tolerance.

To achieve long-term immunological tolerance with fewer systemic side effects, we propose using the NanoLymph platform, an implantable subcutaneous device designed for continuous localized recruitment of Tregs. This device features a dual-reservoir system that supports sustained release of immunomodulatory agents through a nanoporous membrane and a vascularized compartment that facilitates cell homing and allograft integration with the host. The current work presents the development and characterization of the NanoLymph device as a cell transplantation platform supported by Tregs. We show that upon implantation, the NanoLymph platform integrates into the subcutaneous space through vascularization and lymphatic in-growth, creating an environment conducive to long-term allograft integration. We also demonstrate controlled and sustained release of Treg immunomodulatory therapies both in vitro and in vivo. Flow cytometry analysis confirms that these therapies effectively promote Treg

recruitment and expansion at the device site for up to 14 days. Furthermore, using a luc-Treg model, we characterize the kinetics of Treg migration to the device in vivo with high spatial and temporal resolution.

Finally, we assess the long-term efficacy of the NanoLymph platform using a proof-of-concept Akaluc-Leydig cell transplantation model. Longitudinal bioluminescence imaging demonstrates that localized Treg-promoting therapies sustain long-term cell transplant viability compared to systemic immunosuppression controls. Imaging mass cytometry of the local device space reveals interactions between regulatory and effector cells with high spatial accuracy, clarifying the role of these cells in immunomodulation toward tolerogenicity. Additionally, flow cytometry confirms an enriched local ratio of Tregs to CD8+ T cells and cytokine analysis reveals reduced pro-inflammatory cytokine production in the localized Treg-promoting therapy condition, highlighting the platform's capacity to create an immunomodulated environment that supports successful cell transplantation without the need for maintenance immunosuppression.

In summary, the NanoLymph platform supports the sustained release of immunomodulatory agents to create a safe, localized immunosuppressive environment, reducing systemic side effects while maintaining effective immunological tolerance. This innovative strategy holds clinical relevance for advancing cell transplant therapies by minimizing off-target toxicity and promoting long-term success.



1275 CD80/CD86-CD28 Signal Blockade during the Mixed Lymphocyte Reaction Augments the Alloantigen-specific Inhibitory Function of Natural Regulatory T Cells

Kyoko Tsuji-Yogo[1], Kazuyoshi Takeda[2], Ryuichi Murakami[3], Shohei Hori[3], Ko Okumura[4], Koichiro Uchida[2]
[1]Juntendo University, Tokyo, Tokyo, Japan, [2]Juntendo University, Tokyo, Japan, [3]The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [4]Juntendo University, Bunkyo-ku, Tokyo, Japan

Purpose: Antigen-specific Regulatory T cells (Tregs) therapy is promising approach for transplant rejection and autoimmunity. Our group has reported that co-culture of recipient lymphocytes and irradiated donor lymphocytes (mixed lymphocyte reaction (MLR)) under the condition of CD80/86-CD28 co-stimulation blockade with anti-CD80/CD86 mAbs induced anergic T cells that acquired alloantigen-specific immune suppressive function in mice and humans, successfully inducing operational tolerance in seven out of ten liver transplant patients. Tregs have been suggested to be the major population exerting the alloantigen-specific suppressive function. In this study, we investigated the mechanism by which Tregs augmented donor-specific suppressive function during MLR in the presence of anti-CD80/86 mAbs.

Methods: C57BL/6 *Foxp3*^{hCD2} mice were used to evaluate suppressive function and the expression of function-associated molecules in Tregs before/after MLR with or without anti-CD80/86 mAbs. Mice expressing a single TCRβ chain were used to analyze the TCRα repertoire of Tregs.

Results: The proliferation of Tregs was remarkably inhibited by anti-CD80/86 mAbs. Anti-CD80/86 mAbs significantly enhanced the suppressive function in an alloantigen-specific manner (Figure 1). An increase in the concentration of IL-2 restored the proliferation of Tregs but inhibited the enhanced alloantigen-specific suppressive

function. TCR repertoire analysis showed that several Treg clones were expanded after MLR, but anti-CD80/86 mAbs limited the number of expanded Treg clones (Figure2). Treg clones expanded during MLR with anti-CD80/86 mAbs were different between MLR with BALB/c and that with CBA.

Conclusions: These results suggest that MLR with antagonistic anti-CD80/86 mAbs selectively expanded Tregs expressing high-affinity TCRs for alloantigens.

1276 The Therapeutic Effect of Adipose-Derived Stem Cells and Hydrogen Sulfide Donor Sodium Hydrogen Sulfide Combination Treatment on Erectile Dysfunction in a Rat Model Following Radical Prostatectomy

Serap Gur[1]*, Heba Asker[2], Sena F Sezen[3], Didem Yilmaz-Oral[4], Damla Turkcan[5], Mualla Pınar Elci[6], Omer Faruk Kırlangıc[2]
[1]Ankara University, Ankara, Türkiye, Turkey, [2]Ankara University, Ankara, Ankara, Turkey, [3]Karadeniz Technical University, Trabzon, Turkey, [4]Cukurova University, Adana, Turkey, [5]Ankara University, Ankara, Turkey, [6]Sağlık bilimleri üniversitesi, Ankara, Ankara, Turkey
**Corresponding Author*

Introduction: A radical prostatectomy is likely to result in erectile dysfunction (ED) due to cavernous nerve damage. Hydrogen sulfide (H_2S) is an endogenous gasotransmitter produced by cystathionine-β-synthase (CBS),

cystathionine-γ-lyase (CSE) and 3-mercaptopyruvate sulfurtransferase (3-MST) and involved in penile erectile physiology. Adipose-derived stem cells (ADSCs) provide a significant cellular resource for treating degenerative diseases. We aimed to evaluate the potential therapeutic benefits of the H_2S donor, sodium hydrogen sulfide (NaHS), and the intracavernosal injection of ADSCs, both alone and in combination, on ED induced by bilateral cavernous nerve transection (CNT).

Methods: Sprague-Dawley rats were divided into five groups: Sham-operated, CNT (4-wk), intracavernosal injection) and CNT-treated with NaHS and ADSCs groups. ADSCs were intracavernosally injected after the transection. The *in vivo* erectile response and the *in vitro* relaxant and contractile responses of the corpus cavernosum (CC) were assessed. Protein expression and localization of neuronal nitric oxide synthases (NOS), H_2S synthesis enzymes, TGF-β_1, and HIF-1α, as well as the smooth muscle/collagen ratio were analyzed.

Results: Rats with CNT showed considerable reductions in erectile responses, acetylcholine and electrical field stimulation (EFS)-induced relaxation, as well as phenylephrine and EFS-induced contractile responses of the CC, which were moderately enhanced by NaHS and ADSCs treatments alone. The combined treatment significantly enhanced the decrease. There was a significant decrease in the expression of neuronal NOS (nNOS) and endothelial NOS (eNOS) in the CNT group ($p<0.001$). Furthermore, the protein expression of CSE, CBS ($p<0.001$), and 3-MST ($p<0.05$) in rats with CNT were lower than in control rats. TGF-β_1 and HIF-1α expression, as well as collagen in the penile tissue obtained from the transected group were significantly increased compared to controls ($p<0.001$). The combination therapy elicited more effective alterations in all protein expressions and collagen deposition in rats with CNT.

Conclusions: The combined therapy of NaHS and ADSCs is more efficacious than monotherapies in ameliorating CNT-induced ED. H_2S and cell-based therapy are likely to synergistically recover erectile function via the modulation of molecular processes and alterations in penile structure, which can support to improve clinical outcomes in the treatment of ED after radical prostatectomy.

1277 Grafting Strategies for Transplantation of Organoids into Solid Organs

Lola Reid, UNC School of Medicine, Chapel Hill, NC

Zhang W1,a, Lozoya O[1,a,] Oikawa T[1],Wauthier E[1,] Yi X[1] , Hani H[1,] Turner R[1], Allen, A[1.] Lanzoni G[2], Dominguez-Bendala J[2,] Alvaro D[3,] Cardinale V[3], Overi D3, Gaudio E[3], Carpino G[3], Gerber D[1], Sethupathy P[4], Kyle Mathews5[b,] Christopher Adin[5b], Jorge Piedrahita[5b,] Prestwich G[6b,] Wang Y[7b], He Z[8b], and Reid L.M[1b.] [1]UNC School of Medicine (Chapel Hill, NC, USA); [2]University of Miami (Miami, FL, USA); [3]Sapienza University (Rome, Italy); [4]Cornell University (Ithaca, NY, USA); [5]NCSU's School of Veterinary Medicine (Raleigh, NC, USA), [6]University of Utah (Salt Lake City, UT, USA),[7]Tsinghua University (Beijing, China); [8]Tongji University (Shanghai, China); First authors[a]; Senior authors[b].

Transplantation of organoids is blocked by their inability to engraft into solid organs as well as by immunological barriers. We have overcome the barriers with patch grafting . Successful conditions consist of embedding organoids into Glycosil (thiol-modified hyaluronans), prepared in a defined medium and triggered with poly (ethylene glycol) diacrylate (PEGDA) to form soft hydrogels (less than 100 Pa). The defined medium is designed for stem/progenitors: a basal medium with low calcium, no copper, lipids (free fatty acids and lipid carriers such as albumin and high density lipoprotein), plus insulin and transferrin/Fe but with no or as few as possible other signals that might drive differentiation. Graft conditions enable organoids to express the requisite repertoire of secreted and plasma-membrane-associated forms of matrix metalloproteinases (MMPs), enabling engraftment into solid organs within hours to a few days. Grafting biomaterials are absorbed naturally by host processes leaving donor cells to mature fully amidst host environmental and organ-specific conditions. After transplanting the hydrogel, it is covered with a barrier to tether the graft and to provide protection from abrasion. The barrier can be any of commercially available ones used surgically or can be porous silk impregnated with Glycosil and triggered with PEGDA to form a more rigid hydrogel (~ or >500-600 Pa). The barrier's conditions causes organoids at the barrier interface to mature sufficiently to cease expression of secreted MMPs and so be unable to move. By contrast, organoids placed adjacent to the target organ are able to engraft. During surgery, a coating of the more rigid

hydrogel is applied to the exterior surface of the barrier to minimize adhesions. Patch grafting methods have proven successful to permit engraftment of approximately a gram of donor organoids per patch into every solid organ evaluated (liver, pancreas, intestine, kidneys, large bile ducts) and in the two species tested (mice and pigs). Grafts of donor organoids were able to rescue murine hosts from various disease states such as tyrosinemia (liver) or type I diabetes (pancreas). Efforts are ongoing to learn if the strategies are successful also for organoids of mesodermal and ectodermal epithelial cells and in other host species. **Background References**: Lozoya O, et al. 1278 Development of a mode of action-based testing suite for the screening of regenerative macrophage cell therapy candidates for end-stage liver disease and beyond

Kayleigh Thirlwell[1], Moony Su, Niya Aleksieva[1], Mark Cant[1], Alex Armesilla[1], Philip Starkey Lewis[1], **Lara Campana***
[1]Resolution Therapeutics, Edinburgh, Edinburgh, City of, United Kingdom
Corresponding Author

Regenerative macrophages have a well-established role in promoting liver regeneration via control of inflammation and promotion of fibrosis remodelling. Previous data obtained at the University of Edinburgh provided clinical proof of concept of safety and efficacy of autologous regenerative macrophages therapy (RMT) in patients with liver cirrhosis, the final manifestation of chronic liver damage from distinct aetiologies. To transform this academic proof of concept into a cell therapy product with the potential to treat a patient population with decompensated liver disease, Resolution Therapeutics proceeded to engineer the regenerative macrophages with payloads designed to improve its anti-inflammatory and anti-fibrotic potency. To this end, we underwent an extensive screening process to select the most effective payloads. The unique challenge in this context was to design an in vitroscreening suite that could recapitulate the main mechanisms of action (MoA) of the RMT, whilst also allowing benchmarking of the engineered macrophages against the already clinically tested non-engineered cells. Previous in vivo experiments informed us of the key cellular mechanisms underpinning the anti-inflammatory and anti-fibrotic MoA of the regenerative macrophages (Fig.1A). We were able to design a cell-based, research-grade assay for each of the mechanisms. To test the anti-inflammatory MoA, we established assays to measure: phagocytosis, recruitment of monocytes, and polarisation of naïve macrophages to a regenerative phenotype. To test the anti-fibrotic MoA, we set-up assays to measure collagen degradation and de-activation of myofibroblasts, i.e. scar-producing cells. We tested 7payload at 18-24h post-transfection: 5 aimed to improve anti-inflammatory cellular mechanisms, and 2 aimed to improve anti-fibrotic cellular mechanisms. This comprehensive testing suite led to the identification of IL10 and MMP9 as best-in-class candidates for anti-inflammatory and anti-fibrotic MoA, respectively (Fig.1B). Further, we harnessed the same testing suite to compare the combination of IL10+MMP9 payload against IL10-only payload. The combination of IL10+MMP9 offered unique advantages as compared to IL10-only in terms of increased monocyte recruitment (4x enhancement vs non-engineered and 2x enhancement over IL10-only, respectively) and increased suppression of myofibroblasts activity (50% suppression vs 20% suppression, respectively), leading us to select the combination of IL10+MMP9 to engineer our lead asset, RTX001 (Fig.1C). In conclusion, we have established a robust, versatile, research-graded testing suite to benchmark engineered RMTs against the clinically tested, non-engineered RMT. This MoA-based testing suite has allowed the selection of IL10+MMP9 as payloads to increase the anti-inflammatory and anti-fibrotic potency of our lead asset, RTX001, facilitating the treatment of a more severe subset of patients. RTX001 has now progressed to clinical testing in UK and Spain (EMERALD Phase 1/2 study). An important consideration for future applications of the testing suite is that regenerative macrophage phenotype and functions are remarkably conserved amongst distinct organ and tissues. For this reason, we are now investigating the use of RMT in other areas of major unmet medical need, namely lung fibrosis and Graft-versus-Host disease, and it will harness the testing suite presented here to identify the best candidate in these clinical settings.

1279 Development of 3D Printed PLG-Based Liver Tissue Therapeutic for the Treatment of Alcoholic Liver Disease and Liver Failure

Regeant Panday[1], Rafal Witek[1], Caitie Chismarich[1], Andrew Golin[1], Kirstin Kebo[1], Matthew Remy[1], Jon Burke[1], Xin Li[1], Ramille Shah[2]
[1]*Dimension Inx, Chicago, IL,* [2]*Dimension Inx, Oak Brook, IL*

Introduction: Alcoholic liver disease (ALD) is a major cause of liver failure-related deaths globally[CJ1] . Severe forms of ALD, such as alcohol-associated hepatitis (AH) and severe alcohol-associated hepatitis (SAH), have high mortality rates up to 50% at 28 days for AH and up to 70% at six months for SAH. While existing treatment options offer limited benefit, liver transplantation remains the only curative solution. Alternatively, an ectopic implant containing a large number of hepatocytes, capable of providing both immediate and sustained liver function, could be developed. Such an implant could serve as a bridge to liver transplantation or recovery. However, existing strategies that use bioinert hydrogels to deliver therapeutic cells face significant challenges, primarily due to poor tissue integration and inadequate vascularization. In this study, we explore the potential of 3D printed poly lactide-co-glycolide (PLG) scaffolds with an open-pore design as a more effective means of delivering high-density functional hepatocytes through minimally invasive subcutaneous implants, offering a novel solution for liver failure treatment.

Methods: Highly porous PLG scaffolds were 3D-printed in two designs, D1 and D2, with varying porosity. Cryopreserved primary human hepatocytes (PHHs) were first screened for quality via in vitro stability and functionality testing, as well as their ability to assemble into 3D aggregates. PHHs were aggregated into hepatic spheroids and seeded onto 10mm scaffolds at 2×10^6 PHHs per scaffold. In vitro, cell-laden scaffolds were cultured for 2+ weeks and assessed for viability, albumin and urea synthesis, and CYP3A4 activity. In vivo, scaffolds were implanted subcutaneously in NOD SCID mice for one month, with circulating human albumin (hALB) measured and compared to cell-laden hydrogels of similar size and cell density. Explants were analyzed via histology/IHC for tissue integration and vascularization.

Results: In vitro results showed that optimized 3D-printed scaffold designs enabled uniform seeding of hepatic spheroids at densities up to 5×10^6 hepatocytes/ml. Within 24–48 hours, hepatocyte aggregates adhered to the scaffold and organized within the scaffold microporous architecture. Live/dead staining showed high viability after two weeks in culture. In vitro, both D1 and D2 scaffolds maintained stable albumin and urea secretion for over two weeks, with D2 scaffolds exhibiting ~4-fold higher albumin secretion and ~2.8-fold higher CYP3A4 activity than D1, while urea secretion remained comparable. In vivo, steady hALB levels persisted in both scaffold groups for up to four weeks post-implantation. While hydrogel implants initially showed ~2- and ~1.7-fold higher hALB levels than D1 and D2, respectively, levels declined 2 weeks post implantation[RS2] , resulting in ~2- and ~4-fold lower hALB compared to D1 and D2. Histological analysis at one month revealed dense vascular networks in PLG scaffold groups, which weren't observed in[CJ3] the hydrogel conditions.

Conclusions: 3D-printed porous PLG scaffolds provide a promising approach for ectopic liver implants. Our data demonstrates efficient hepatocyte delivery and sustained functional phenotype (synthetic and metabolic), supported by robust vascularization. Future studies will evaluate the efficacy of using PLG scaffolds to deliver hepatocytes for the therapeutic treatment of liver conditions characterized by rapid loss of hepatic function, such as liver

1280 Genome-Orthogonal Gene Circuitry: Improved Synthetic Enhancer-Transcription Factor Systems with Minimal Off-Target Effects

Denny Nguyen[1], Michelle Hung, Russell Gordley, Assen Roguev[2], Philip Lee
[1]*Genefab, South San Francisco, CA,* [2]*GeneFab, Alameda, CA*

Background: Cell therapies, which synthesize therapeutics precisely when and where they are needed, hold promise for addressing numerous challenging diseases. However, to fully realize this potential, synthetic regulators are required that can drive therapeutic gene expression without perturbing endogenous transcriptional programs. Zinc finger-based transcription factors (ZFTFs) are highly programmable, human-derived proteins well suited for therapeutic use, given their specificity, small size, and compatibility with small molecule or SynNotch-based control. Building on the recent publication of genome-orthogonal ZFTFs [1], we have developed novel enhancer-ZFTF pairs with improved orthogonality to human and mouse genomes. This advance expands the toolbox for synthetic biology-enabled gene expression in complex cell therapies, enhancing both safety and efficacy.

Methods: To construct genome-orthogonal expression circuits, we identified binding sequences that do not occur in the human genome. Specifically, we screened all possible 19 nucleotide (19mer) sequences composed of six GNN

trinucleotides plus one final N (N= A, T, C, or G). We then computationally filtered these 19mers to remove: 1) sequences that match or nearly match any region of the human genome and 2) sequences that match mammalian transcription factor binding sites. From the remaining 19mers, synthetic enhancers were assembled by placing four repeats of the 19mer in tandem, separated by 10bp spacers devoid of known transcription factor binding sites. Each enhancer was then inserted upstream of a minimal promoter to drive GFP expression. For each synthetic enhancer, two six-finger ZF arrays were designed and fused to a miniVPR transcriptional activator. These enhancer-ZFTF pairs were transfected into HEK293T cells to evaluate their GFP expression strength. Top pairs were subsequently transduced into multiple cell types and analyzed by bulk RNA-seq to assess potential off-target transcriptional effects.

Results: We identified three ZFTFs that outperformed a previously published genome-orthogonal ZFTF [1] by >1.5-fold in transcriptional strength. Bulk RNAseq revealed that these top three ZFTFs drove higher GFP expression per ZFTF RNA molecule than the published ZFTF, while affecting significantly fewer off-target genes (1, 7, or 9 vs. 80). Further studies showed that our most potent ZFTF also exhibited reduced off-target effects in two additional human cell types (T cells and liver cells) and in mouse melanoma cells.

Conclusions: We have designed novel mammalian genome-orthogonal enhancers and ZFTFs that serve as potent transcriptional activators with minimal impact to endogenous gene networks. These tools form the basis of powerful, highly specific gene circuitry that can be incorporated into small molecule or environmentally responsive transcriptional switches. By enabling precise, dynamically controlled therapeutic payload production, our improved genome-orthogonal ZFTFs advance the promise of next-generation cell therapies.

1281 Toward Treatment with Gene-Modified B Cells Engineered In Vivo Using iGPS Particles

Jeff Wood[1], Samir Mendonça[1], Connor Dobson[1], Denise Wong[1], Joey Chung[1], Tharani Sivanandam[1], Gabby Feig[1], Josue Figueroa[1], Kelly Nichols[1], Jacob Miller[1], Vionnie Yu[1], **Russell McConnell[1]***, Shannon Contrastano[1]

Genetically-engineered B-cells are emerging as a powerful platform to secrete therapeutic proteins as treatment for congenital and infectious diseases. Autologous or donor-derived B cells are genetically modified and used to treat patients with or without preparative lymphodepleting chemotherapy. We hypothesize that in vivo modification of B cells could improve cost, patient access and persistence compared to ex vivo manufactured B cell therapies. The in vivo gene placement system (iGPS™), an advanced lentiviral vector (LVV) particle with specific envelope modifications to improve gene transfer efficiency and cell specificity, has shown potent and T cell-specific genetic modification in vivo using CD3 as an entry receptor in preclinical models. Here we tested the feasibility of adapting the iGPS system to target and modify B cells in vivo. Antibodies specific to a variety of B-cell surface molecules were engineered into the iGPS system and screened for potent and B cell specific transduction of primary and established B cell lines. While standard VSV-g pseudotyped LVV are inefficient at B cell transduction, the lead B cell-targeting iGPS molecule caused activation and transduction of ~50% of resting B cells in vitro, including 40% of CD27+ memory B cells. There was no transduction of a Jurkat T cell line demonstrating the transduction was B cell specific. Finally, we tested the transduction of B cells in a humanized mouse model. NSG-DKO mice were injected with 1e7 human PBMCs; 15 days later (when a detectable B cell population is present in this model) mice were dosed i.v. with B-cell targeting-iGPS particles delivering a GFP reporter transgene. Seven days post-iGPS particle injection, we observed dose-dependent GFP+ transduction of up to 4% of all B-cells (CD19+CD3-) in spleen, bone marrow, and blood. Together, these data demonstrate the feasibility of efficiently engineering B cells in vivo toward applications treating congenital and infectious diseases with a single-treatment of B cell-targeted iGPS particles.

1282 In Vivo CAR-T Therapy Powered by Novel CLAMP Technology for T cell-Targeted mRNA Delivery

Jingwei Sun[1], Xi Zhu[2], Zhongzheng Cao[3], Zhao Xu[3], Dalang Li[4], Hong Chen[4], Jiaming Ren[4], **Pin Wang[5]**, Yarong Liu[3]
[1]Grit Biotechnology, Shanghai, Shanghai, China, [2]Shanghai Vitalgen Biopharma, Shanghai, Shanghai, China, [3]Grit Biotechnology, Shanghai, China, [4]Shanghai Vitalgen Biopharma, Shanghai, China, [5]University of Southern California, Los Angeles, CA

Autologous CAR-T cell therapy has demonstrated clinical efficacy in hematologic malignancies and potential in autoimmune diseases (AID) where B cell played a crucial role. However, challenges such as complicated cell manufacturing, lymphodepletion and high costs hinder its use as personalized medicine. An off-the-shelf, cost-effective product with simplified manufacture process could better meet patient needs and democratize genetic medicine. Inspired by the success of COVID-19 mRNA lipid nanoparticle (LNP) vaccine, we developed a T cell-targeted mRNA-LNP (T-LNP) system capable of delivering anti-CD19 CAR to T cells in vivo for AID treatment. T-LNPs were created using Controllable Ligand Attachment Modification and Purification (CLAMP) technology on the Kailash™ platform. CLAMP streamlines surface conjugation and purification of antibody-conjugated LNPs by optimizing components such as chemical linkers and site-specific residues engineered onto antibodies. This platform simplifies conjugation procedures while remaining compatible with scalable LNP production. We evaluated T-LNPs targeting three T cell-specific surface proteins for CAR transfection and B cell cytotoxicity using human peripheral blood mononuclear cells (hPBMCs). Surface protein B emerged as the optimal choice, achieving over 30% CAR expression in total CD3+ T cell population, favoring CD8 subset, and inducing nearly 100% B cell killing at 24 hours. In vivo, T-LNP carrying anti-CD19 CAR mRNA injected into hPBMC-reconstituted NOG mice showed over 95% B cell killing in spleen at 24 hours with a dose of 0.33mg/kg. The therapeutic effect was further evaluated in an aggressive B cell leukemia model, Nalm-6. NOG mice reconstituted with hPBMC were inoculated with Nalm6-luc cells and treated with a single T-LNP dose carrying anti-CD19 CAR mRNA on day 3. Both 0.2 mg/kg and 1 mg/kg T-LNP dose groups achieved complete tumor control, and 1 mg/kg fully eradicated established large Nalm-6 tumors. These data collectively demonstrate that our novel T-LNP delivery platform enables efficient and specific T cell delivery, resulting in sufficient CAR expression and potent B cell killing, highlighting its potential as a universal drug product for AID treatment.

1283 In vivo mRNA CAR-T Cell Engineering Utilizing a Novel CD3/CD5 Peptide Based Targeted Nanoparticles.

Gilles Divita[1], Audrey Grunenberger[2], Léa Cabrera[2], Julien Vollaire[3], Neil Desai[4], Veronique Josserand[3]
[1]Aanastra Inc., Pacific Palissades, CA, [2]DIVINCELL, Nimes, Hérault, France, [3]Institute for Advanced Biosciences INSERM, Grenoble, France, [4]Aanastra Inc, Pacific Palisades, CA

The Chimeric Antigen Receptor (CAR) T cell therapy has emerged as a ground-breaking immunotherapeutic approach in cancer treatment and demonstrated encouraging clinical results in autoimmune disease indications. However, personalized CAR T cell production is a bottleneck due to challenges in cell manufacturing, scalability, side effects and high production costs. In vivo CAR T cell generation has been proposed to make this treatment immediately accessible to patients and applicable for broader use. However, efficient and highly selective gene delivery to target cells in vivo is challenging. To that end, we are developing a new peptide based (non-lipid) delivery platform (PEP-NP) to enable in vivo delivery of mRNA encoding an anti CD19 CAR to reprogram CD3/CD5 expressing T-cells.

The PEP-NP platform is based on short amphipathic peptides that form stable, scalable nanoparticles capable of efficiently packaging and delivering RNA to the target site. The structure of PEP-NPs have been designed to bypass the liver and enhance mRNA expression in the spleen and T-cells in vivo. PEP-NPs were selected based on their efficiency to deliver functional Fluc-mRNA on Jurkat cells and primary human T cells from different donors. Efficiency of PEP-NP to deliver a mRNA encoding for an anti-CD-19 CAR was evaluated on human primary T cells. The cytotoxicity of CAR-PEP-NPs transfected T cells was evaluated by co-cultured with either Nalm6 CD19+ human acute lymphoblastic leukemia cells or K651 (CD19-) cells. In-vivo efficacy of PEP-NP (0.5 and 1.0 mg/kg)

to deliver mRNA in the spleen and specific immune cells, was evaluated in C57BL/C6 mice using luciferase or eGFP encoding mRNA and analyze by bioluminescence or flow cytometry.

PEP-NPs carrying mRNA encoding luciferase or GFP showed a dose responsive transfection starting at 6 hr post treatment with more than 90% of treated T cells expressing Luciferase or GFP after 48 hr. We validated transfection, translation and surface expression of a functional CD19 CAR protein by transfecting human T cells with PEP-NPs mRNA encoding for an anti-CD19 CAR protein. CAR expression was observed in more than 80% of the transfected T cells from different donors. The cytotoxic potential of CAR-PEP-NPs transfected T cells was evaluated by co-cultured with CD19+ Nalm6 cells. CAR-PEP-NPs transfected T Cells showed a robust dose response specific cytotoxic effect, resulting in 65 % to 92% killing of Nalm6 cells, while in contrast, no cytotoxicity was observed on K561 (CD19-) cells or with T cells transfected with PEP-NP eGFP mRNA . We then demonstrated that IV administration of CD3/CD5 T cell targeted PEP-NPs exhibits high Luc or GFP mRNA expression in the spleen. PEP-NPs carrying GFP mRNA, showed a dose-dependent mRNA delivery to T cells in the blood as well as in splenic T cells with 15-18% of T cells positive for GFP after a single injection. No toxicity of PEP-NP was detected after single or repeat dosing. PEP-NP-CAR have been evaluated on NSG-CD45 mice engrafted with human PBMCs and the B cells frequency was monitored over 24 hr.

Our study provides a proof-of-concept that PEP-NP platform can be applied to directly target T cells for in vivo CAR T cell engineering. PEP-NP is a novel strategy for specific CD3/CD5 T cell reprogramming which provide a redosable, off the shelf T cell gene therapies for patients.

1284 A "Plug-and-Play" Erythrocyte-Mediated mRNA Delivery System Enables *In Vivo* Generation of CAR-Myeloid Cells for Cancer Immunotherapy

Xiaoqian Nie[1], Yuting Song[2], Xiaofei Gao[1]*
[1]*Westlake University, Hangzhou, Zhejiang, China,* [2]*Westlake Therapeutics, Hangzhou, China*
**Corresponding Author*

Background: Despite the success of COVID-19 vaccines, the targeted delivery of mRNA-based therapies to immune cells remains a significant challenge. Current lipid nanoparticles (LNPs) primarily target the liver when administered systemically, limiting the broader applicability of mRNA for targeting immune cells in lymphoid organs. Additionally, LNPs suffer from low endosomal escape rates and may induce off-target immunotoxicity in healthy tissues. Here, we developed a simple and adaptable erythrocyte-mediated delivery system, which enables the covalent conjugation of mRNA-loaded lipid nanoparticles to erythrocyte membrane proteins in a "plug-and-play" manner, termed mRNA-LNP-Ery. Leveraging the natural splenic homing ability of erythrocytes, mRNA-LNP-Ery selectively targets the spleen, facilitating efficient delivery of mRNA to immune cells for cancer immunotherapy.

Method: We evaluated the *in vivo* gene expression profile of mRNA-LNP-Ery using luciferase-LNP-Ery and Cre recombinase-LNP-mEry in C57BL/6 mice and C57BL/6 Cre-reporter mice, respectively. We further investigated the internalization pathway of mRNA-LNP-Ery in immune cells through co-localization studies. Additionally, we delivered anti-HER2 CAR mRNA via erythrocytes and assessed its anti-tumor efficacy in MC38-hHER2 C57BL/6 tumor models.

Result: Unlike mRNA-LNPs alone, which predominantly accumulate in the liver, mRNA-LNP-Ery exhibited a preferential distribution to the spleen. Over 90% of mRNA expression mediated by mRNA-LNP-Ery localized to splenic CD11b+ myeloid cells, where it was efficiently phagocytosed. *In vitro* co-localization studies revealed that erythrocyte-mediated delivery bypassed endosomal trapping, leading to significantly enhanced mRNA expression compared to conventional mRNA-LNPs. Furthermore, we demonstrated the therapeutic potential of this platform by delivering anti-HER2-specific chimeric antigen receptors (CAR) mRNA via erythrocytes to generate CAR-myeloid cells *in vivo*, which can migrate to the tumor sites. These cells not only directly targeted and killed tumor cells but also reprogrammed the tumor microenvironment, promoting enhanced lymphocyte infiltration. This resulted in more effective tumor suppression in immunocompetent tumor models compared to CAR-LNP treatment. Importantly, CAR-LNP-Ery required only one-tenth of the mRNA dose used by CAR-LNP to generate CAR-myeloid cells *in vivo*, further highlighting the efficiency of spleen-targeted delivery. Additionally, CAR-LNP-Ery caused minimal

side effects, in contrast to CAR-LNP treatment, which induced significant body weight loss and splenomegaly in treated mice, indicating that CAR-LNP-Ery offers enhanced safety and reduced systemic exposure.

Conclusion: Erythrocyte-mediated mRNA delivery enables the generation of CAR-myeloid cells *in vivo* by targeting splenic immune compartments for cancer immunotherapy. This study presents the first cellular-based mRNA delivery platform, offering precise immune cell programming and providing new opportunities for improving cancer therapeutic strategies.

1285 Bioproduction of messenger RNA therapeutics in yeast cells: a proof of concept study.

Messenger RNA (mRNA) has emerged as a promising biopharmaceutical for a vast array of therapeutic applications. Currently, in vitro transcription (IVT) is the available technology for mRNA production. However, IVT requires a complex supply chain and costly purification processes. Despite the advantage of being cell-free, questions about the reliability and cost of large-scale IVT production arise as therapeutics enter clinical applications, which require high doses.

Our project groundbreaking nature lies in generating a specific mRNA bioproduction process in yeast, integrating extraction and purification techniques—a complete paradigm shift compared to IVT production. To this aim, we built an interdisciplinary consortium coming from the fields of molecular biology, biophysics, biotechnology, material, computational chemistry and chemical engineering working in mRNA therapeutics, yeast biology, engineering and bioproduction as well as purification processes.

By leveraging yeast's established capabilities in industrial biotechnology, our consortium is producing the desired mRNA within yeast cells, followed by packaging into specific cytoplasmic foci, extraction, and purification. Rigorous quality control analyses ensure the structure and efficacy of the yeast-produced mRNA therapeutics.

Our research has the potential to revolutionize the production of mRNA therapeutics and vaccines, making them more affordable and easier to manufacture, thus expanding access to a wider population quickly, safely, and reliably. Furthermore, the development of a yeast-based mRNA bioproduction platform could significantly impact the global response to emerging viral threats.

1286 Overcoming Challenges in mRNA Plasmid Preparation: Advanced Solutions for Poly(A) Tail Integrity and High-Yield Production

Andrew Tsao[1], Wenlu Zuo[2], Xiang Zhang[2], Xiangnan Chen[2], Yang Wang[3], Meng Wei[4], Kangming Chen[5]
[1]GenScript USA Inc., Piscataway, NJ, [2]GenScript Biotech Corporation, Nanjing, China, [3]GenScript USA Inc, Piscataway, NJ, [4]GenScript USA Inc., Nanjing, China, [5]GenScript Biotech Corporation, Nanjing

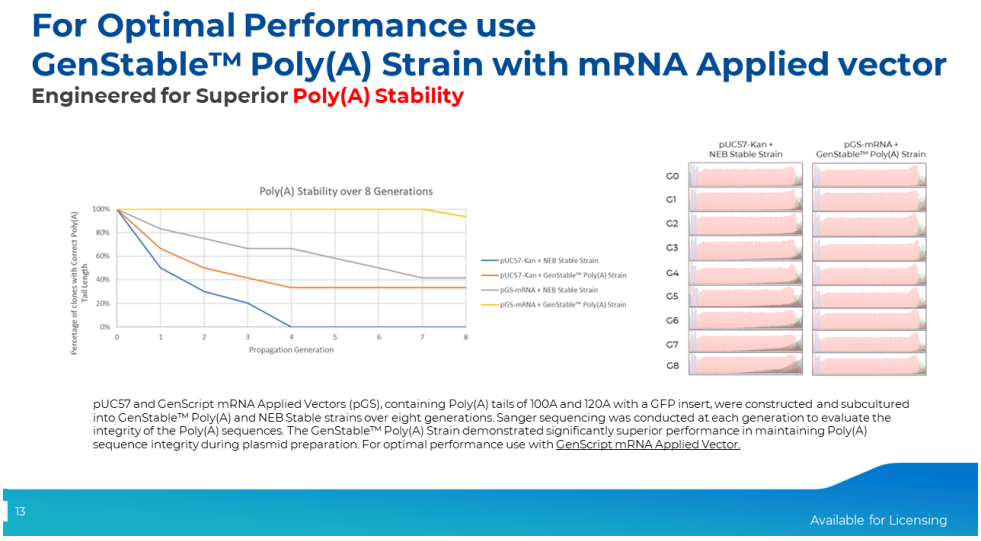
mRNA research has experienced unprecedented growth, driving breakthroughs in fields such as vaccine development, cancer immunotherapy, regenerative medicine, and beyond. As researchers push the boundaries of mRNA-based therapeutics, the demand for efficient, high-quality plasmid DNA templates has surged. These templates are essential for in-vitro transcription (IVT) and play a critical role in ensuring the integrity and effectiveness of mRNA production. However, challenges persist, particularly in propagating plasmids containing Poly(A) tail sequences in *E. coli*. Researchers frequently encounter issues such as low plasmid yields, compromised

Poly(A) tail integrity, and extended development timelines—challenges that significantly hinder therapeutic development and drive-up costs.

The Poly(A) tail is a vital component of plasmid templates for mRNA production, influencing transcription efficiency, mRNA stability, and downstream application success. Recognizing these pain points, GenScript has developed innovative solutions to accelerate mRNA research and streamline plasmid preparation workflows.

GenScript's proprietary mRNA vectors, featuring prebuilt Poly(A) tail sequences, deliver consistent and optimized templates for in vitro transcription (IVT). Paired with our GenStable™ Poly(A) strain—engineered specifically for the propagation of plasmids containing Poly(A) tails—these solutions set a new standard in plasmid stability and productivity. Together, they achieve a remarkable >90% success rate in preparing intact clones with intact Poly(A) tail sequences through 8 generations, representing a 300% improvement over conventional tools, while increasing plasmid yields by over 7-fold, ensuring reliability and efficiency in mRNA production workflows.

GenScript's advanced tools address persistent challenges in mRNA plasmid preparation, dramatically improving yield and intact Poly(A) tail success rates. These enhancements reduce time, resources, and costs, streamlining workflows and accelerating progress in mRNA research and therapeutic development.



1287 A new linear plasmid process platform enabling small scale GMP production with significantly short lead time, high titer, superb polyA stability dedicating to nuclei acid production

Enshi Liu[1], **Jing Zhu[1]***
[1]ReciBioPharm, Watertown, MA
**Corresponding Author*

mRNA vaccines have been demonstrated as a powerful alternative to traditional conventional vaccines because of their high potency, safety and efficacy, and capacity for rapid clinical development. The overall CMC production process of mRNA vaccines can be divided into three modules: pDNA production, mRNA production, and LNP encapsulation. While tremendous efforts have been dedicated into mRNA and subsequent LNP encapsulation process development, plasmid process has not been improved significantly and still heavily relied on the traditional approaches that was developed for viral vector applications. While it deliveries the DNA template for mRNA production, the tradition plasmid production has become the bottleneck for the mRNA vaccine applications due to its long lead time and high cost for both process development and manufacturing in its supercoil isoform and later linearization and difficulty in maintain the integrity of long coded polyA unit. At ReciBioPharm, we have developed

a new plasmid platform dedicating to nucleic acid application. First, a systematic upstream optimization in cell bank, batch strategy, fed-batch strategy was executed to increase plasmid titer up to 1.5g/L fermentation batch size while maintain the desired full length polyA up to 120A. Second, linearization step was integrated as part of downstream process to reduce 30% unit operation and increase total recovery rate to 40% while reaching all required impurity specifications. This new platform has been well demonstrated with various plasmid sizes from 4000 to 9000bp and different polyA tail length from multiple DNA constructs. Such high titer can offer >500mg final linear plasmid from a 3L GMP batch size, which is enough to meet most of Phase I/II needs for mRNA vaccine clinical trials. Comparing to current 30L batch size based plasmid process in the market, it is no doubt that this new linear-dedicated plasmid process will significantly deployment not only of mRNA vaccines for rapid response against future pandemics but also of novel mRNA therapeutics to patients around the world.

1288 Case Study on an Insect Cell-Produced AAV6 Gene Therapy Vector for Neuromuscular Disease

Scott Walker[1], Hannah Collier[1], Joseph Rininger[2], Buel Rodgers[3], **Thera Mulvania[4]**
[1]Expression Sytems, Davis, CA, [2]Latham Biopharm Group, Elkridge, MD, [3]AAVogen Inc., Rockville, MD, [4]Expression Systems, An Advancion Company, Davis, CA

Developing AAV gene therapies for systemic delivery presents unique manufacturing challenges, such as producing commercially viable titers, achieving acceptable full capsid ratios and complying with regulatory requirements. These conditions can be met with the use of the inherently safe and scalable insect cell system. This presentation provides a case study of the production and activity of AVGN7, an AAV6-based gene therapeutic for treating rare neuromuscular diseases. The upstream manufacturing process employs a newly introduced expression platform comprised of a rhabdovirus negative clonal Sf9 RV-Free cell line derived from a single cell printing method, as well as a co-developed chemically defined insect cell medium, ESF AdvanCD™. Additional process improvements include formulation of a lysis reagent specific to the baculovirus and insect cell system. Preliminary studies demonstrate the ability to produce high levels of AAV expression using a high cell density, high MOI (multiplicity of infection) methodology followed by increased recovery utilizing the optimized lysis reagent.

RV-Free Sf9 cells were seeded at a density of 3 million per mL in ESF AdvanCD. Culture volumes ranged from 500-2500 mL. Cells were grown overnight to ensure log phase cultures receptive to recombinant baculovirus infection. Cultures were infected at an MOI of 3 for the rep-cap and the hSmad7 constructs and incubated for approx. 72 hours. Whole cell cultures were treated with a novel reagent that simultaneously lysed the insect cells and baculovirus, treated with DNase to remove non-encapsidated DNA, and clarified by depth filtration. AAV6 yields were determined by capsid ELISA and dPCR using primers directed to the gene of interest demonstrating high yields in excess of 10^{14} vg/L (Figure 1).

Downstream processes for purification include conventional affinity chromatography followed by enrichment of full capsids by anion exchange. Clarified lysate was applied to an affinity chromatography column consisting of Poros GoPure AAVX resin. Following two washes with increasing NaCl, capsids were eluted with 75 mM citric acid, 10 mM $MgCl_2$ directly into a 1M tris neutralization buffer. Eluate was diluted 1:20 into an AEX equilibration buffer of 20mM bis-tris propane, 10 mM $MgCl_2$, pH 8. The AEX binding and elution conditions were modified from standard AAV enrichment conditions to reduce the binding affinity of AAV6. The higher binding affinity of AAV6 to the AAVX as compared to other serotypes was correlated with loss of genetic payload. Elution was performed with 20 mM bis-tris propane, 10 mM $MgCl_2$, 250 mM sodium acetate. Eluate was exchanged into PBS containing 2mM $MgCl_2$ and sterile filtered. Efficacy of enrichment was determined by calculating the ratio of viral genomes to intact capsids in following AAVX purification and AEX enrichment followed by buffer exchange. The final product contained greater than 90% full capsids, enriching from 26% full capsids following affinity purification (Figure 2). Finally, potency will be discussed with assessments of bioactivity (data pending).

Here we have presented the application of a novel insect expression platform for the generation of high titers of an AAV6 gene therapy vector for treatment of neuromuscular disease. The combination of an upstream process capitalizing on high cell densities with enrichment procedures specific to the AAV6 serotype results in a high yield of vector exceptionally enriched for full capsids.

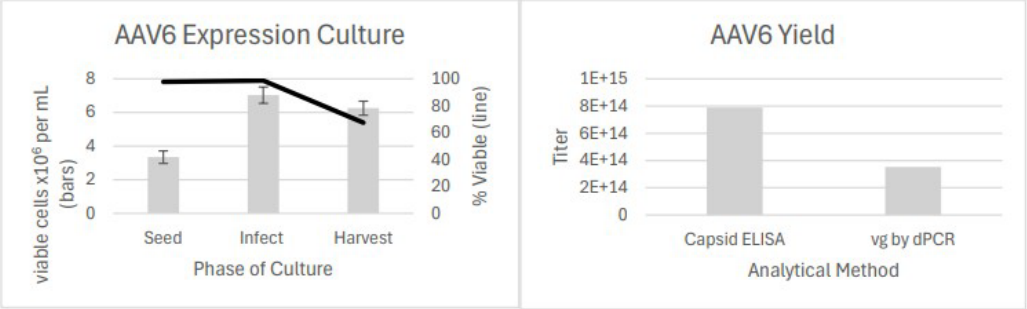


Figure 1. Viable cell density was measured during the course of the production, with harvest at 72 hours post infection and a drop in viability to approximately 65%. Whole culture samples were lysed and assayed for yield as measured by Capsid ELISA and dPCR.

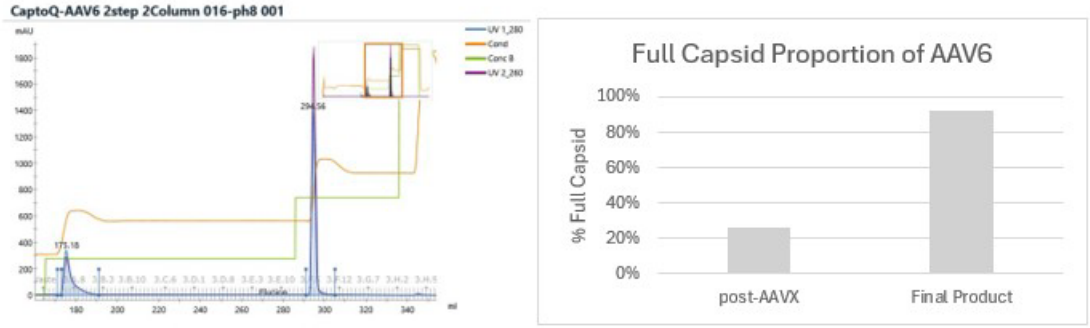

Figure 2. Capto Q AEX enrichment using BTP buffer was set to 15% which favors purity while reducing some yield. Elution was performed using 40% elution buffer which favored capsid stability based on binding strength.

1289 Enhanced Thermostability of a Gorilla-derived Adenoviral (GRAd) vector via E4 region chimerism

Michela Gentile, ReiThera, Rome, Italy

ReiThera has developed a COVID-19 vaccine based on a gorilla adenoviral vector (GRAd-COV2). The vector is replication-defective due to the deletion of the E1 region; two additional deletions have been added in the E3 and E4 regions replacing E4 with human Adenovirus 5's E4 orf6. This backbone is referred to as backbone (c). The GRAd-COV2 (c) vaccine has undergone Phase I and Phase II clinical trials. The GRAd-COV2 (c) vector was initially selected for its high productivity, crucial for rapid vaccine dose production. However, other adenoviral platforms also widely used in clinical settings retain an intact, yet chimeric, E4 region.

Here we show GRAd-COV2 (b2) - that retains GRAd32's E4 orf1, orf2, and orf3, while replacing orfs 4, 6, and 6/7 with those from human Adenovirus 5 - demonstrated superior thermostability, when compared to GRAd-COV2 (c), enabling storage at 2-8°C, which is advantageous for global distribution.

In vitro comparability studies assessed productivity, infectivity, and expression. GRAd-COV2 (b2) exhibited satisfactory productivity, slightly lower than GRAd-COV2 (c) but meeting the necessary criteria for large-scale manufacturing. Infectivity assessments indicated comparable performance between the two vectors, with a marginally better ratio for GRAd-COV2 (b2). Expression analysis via Western blot and FACS showed no significant difference in Spike protein expression levels between the two vectors.

Preclinical studies evaluated immunogenicity in BALB/c mice, with both vectors inducing comparable Spike-binding antibody titers and T cell responses. Toxicology studies in rabbits confirmed that GRAd-COV2 was well-tolerated, with reversible local and systemic effects indicative of an immune response. Biodistribution studies in rats showed that GRAd-COV2 was primarily localized to the injection site and draining lymph nodes, with no significant presence in major organs.

Overall, the GRAd-COV2 (b2) vector demonstrated a good immunogenicity, productivity, and infectivity. In addition, the backbone b2 provide a more thermostable product, a property linked to the possibility of storing formulated vaccine lots at 2-8°C, which is extremely beneficial for transport and storage in different countries worldwide. These important characteristics support the use of this backbone for the Phase I clinical trial for GRAdHIVNE1.

1290 Development of a universal ddPCR based lentivirus infectivity assay

Suddhasil Mookherjee[1], Tanuza Das[2], Bhargavi Kondragunta[3]*
[1]Catalent Pharma Solutions, Gaithersburg, MD, [2]Catalent Pharma Solutions, Baltimore, MD, [3]Catalent, Rockville, MD
**Corresponding Author*

Introduction: Lentiviral vectors, derived from the human immunodeficiency virus, have been extensively used for gene delivery in eukaryotic cells. In multiple clinical trials, third-generation, self-inactivating lentiviral vectors were used to introduce genes into hematopoietic stem cells to correct primary immunodeficiencies and hemoglobinopathies. Determining the infectious titer of the lentiviral vector samples during upstream and downstream processing is critical for assessing dosing quantities to achieve optimal results. However, several challenges complicate accurate determination of infective titers. These include discrepancies between p24-based viral particle titers and actual infective titers, cell line dependency for performing the assay, sensitivity and variability issues with qPCR-based methods, and inconsistencies in titer measurements caused by variations in multiplicity of infection (MOI). To address these issues, this study aimed to develop a robust, universal droplet digital PCR (ddPCR)-based infectivity assay for reliable lentiviral titer determination, with improved consistency and minimized variability.

Methods: A ddPCR-based infectivity assay was designed using primers and probes targeting the LTR and HIV Ψ regions, with a housekeeping gene as a ploidy control. Although a qPCR method for infectivity was initially developed with the same target, owing to lower sensitivity, data inconsistency, higher reagent cost, and complexity of data analysis, we instead developed a ddPCR based assay using an HT1080 cell line. A control lentivirus from a vendor, with known infectivity titer was used as a reference. Sensitivity, linearity, and range were assessed using serial dilution of a commercial control lentivirus vector (LVV) and compared with internal LVV produced using Catalent off-the-shelf (OTS) packaging, and envelope plasmids, along with model transgene plasmids. A dilution-based variability of infectivity was determined by setting target droplet number cut-off and determining dilutions of the LVV sample and extracted DNA amount. Impact of passage number of HT1080 and source of cell banks was also studied as a variable for controlling the background. The assay was used to evaluate infective titer from several internal model LVV CAR transfer plasmids post LVV production.

Results and Conclusion: The assay dilution range and sensitivity were determined with a commercially obtained lentivirus stock with titer >1e7 TU/ml (Transducing units). The assay performed reliably in the selected dilution range for commercial control, with a %CV of ~20% range as determined from this preliminary study. Infective titer by ddPCR based method was evaluated across multiple batches of upstream, as well as purified lentiviral samples and compared using orthogonal assays (flow cytometry, fluorescence imaging). A Master Cell Bank of HT1080 cell is now in process for use with the assay. The ddPCR-based infectivity assay demonstrated improved reliability and consistency, addressing the previously noted challenges in lentiviral titer determination. The assay has now been successfully adopted at Catalent for routine measurement of lentiviral infective titers during production.

1291 How Far Away are we from Global Regulatory Convergence: Analyzing CAR-T Quality Control Standards Across Six Jurisdictions`

Nancy Lunney[1]*, **Hicham El Bariqi[2]**, Jingke Yang[3], Chris Learn[2], Jamie Pierson[4]
[1]Parexel, Doylestown, PA, [2]Parexel, Durham, NC, [3]Parexel, Glendale, CA, [4]Parexel, Prosper, TX
**Corresponding Author*

Chimeric Antigen Receptor T-cell (CAR-T) therapy represents a breakthrough in cancer treatment prompting regulatory bodies worldwide to establish comprehensive quality control standards safeguarding product safety and efficacy. This analysis compares quality control requirements for CAR-T cell therapies across major regulatory jurisdictions, examining their commonalities and variations, and evaluating potential impacts on patient safety and clinical outcomes. A review of CAR T-cell development and manufacturing documents across six jurisdictions: Canada, Japan, Singapore, Australia, USA and EU were conducted to evaluate commonalities and differences.

This analysis encompassed 12 distinct categories related to CAR T-cell therapy development and manufacturing. Results reveal a complex landscape of regulatory consistency: 41.67% of categories demonstrate high uniformity across agencies, 25% show partial alignment and 33.33% exhibit low harmonization or a lack of comprehensive guidance from some agencies. The FDA CAR-T guidance emerges as the most comprehensive, providing guidance across approximately 90-100% of categories reviewed, while other agencies display varying degrees of coverage with specific focus areas.

Key findings include that 66.67% of agencies recommend site validation and 100% of agencies provide guidance on both autologous and allogeneic products. However, significant inconsistencies exist in areas such as fresh versus cryopreserved products management. Notably, three categories - environmental considerations, Transmissible Spongiform Encephalitis (TSE) risk, and in-vivo versus ex-vivo manufacturing are the least consistently addressed, accounting for 25% of the total categories examined.

This analysis highlights strong alignment in core areas of CAR T-cell development and manufacturing among major regulatory guidance documents. However, it also reveals significant gaps and inconsistencies in newer or more specialized aspects of the field. These findings suggest opportunities for standardization and further guidance development, particularly in emerging areas of CAR T-cell therapy as the science develops.

This analysis emphasizes the critical need for ongoing collaboration among regulatory agencies to address disparities and enhance global consistency in CAR T-cell therapy manufacturing and delivery. Collaboration across agencies will lead to diminishing methodological variability that can impact data quality and comparability across studies and ultimately impact patient safety and CAR-T outcomes. As the field of CAR T-cell therapy rapidly evolves, future efforts should focus on addressing the identified areas of inconsistency and exploring strategies for global regulatory harmonization.

1292 Revolutionizing CAR-T Cell Therapy Manufacturing with AI

Geoffrey Stephens[1], Zhexu Li[2]
[1]Aicella, Inc, Escondido, CA, [2]AiCella, Inc, San Diego, CA

CAR T manufacturing is uniquely complex compared to other treatment modalities. Despite significant advancements in the field, much remains unknown about the intricate processes involved in creating these therapies. Currently, 30% to 60% of patients fail to respond to CAR T therapies, and 30% to 40% of manufacturing runs do not produce enough cells for treatment. We hypothesize that AI-based approaches can offer deeper insights into how manufacturing processes influence cell performance in patients. To address the challenge of predicting cell therapy outcomes, we employed our AI/ML platform, Insights™, which utilizes artificial intelligence and machine learning to optimize and automate key aspects of biomanufacturing. This platform integrates 27 commonly used ML/DL algorithms to build customized models for CAR T therapy. By uncovering critical process parameters, we can better understand how manufacturing impacts patient outcomes. Overall, the Insights™ platform demonstrates significant

potential by efficiently processing large volumes of data generated during development and scaling. This enables faster decision-making and helps identify potential bottlenecks, ultimately advancing the manufacturing process.

1293 Optimizing Stem Cell Collections Using a Hematopoietic Progenitor Cell Apheresis (HPC-A) Collection Calculator Application: Web-App Development and Validation

Claire Shao[1], Maxwell Roth[2]*, Maria Chen[3], Amelia Haj[3], Sanjana Shah[4], Jun Liu[5], Patricia Brunker[3], Kristen Ruby[6]

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Mass General Brigham, Boston, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Harvard Medical School, Boston, MA, [5]Brigham and Women's Hospital, Cambridge, MA,

[6]*Mayo Clinic, Rochester, MN*
**Corresponding Author*

Introduction: Hematopoietic progenitor cell apheresis (HPC-A) protocols are designed to minimize the risk of under-collection, resulting in extended collection times, and frequent overcollection. The recent merger of our two academic medical centers (AMCs) presented an opportunity to standardize CD34+ cell collection and potentially address overcollection challenges at both institutions. We developed a HPC-A calculator web-app based on the validated mean collection efficiency (CE2 model), designed to provide patient-specific and standardized estimated blood processing volume recommendations to meet collection goals. In this study, we describe the development of the web-app and validate its performance using simulated data.

Methods: The web-app was developed using the R shiny framework. It is open-access and hosted on the ShinyApps.io platform. Web-app validation was performed using a set of 20 randomly generated simulation patient cases with a range of peripheral CD34+ cell counts (10–200 cells/μL), recipient weights (40–120 kg), target collection doses (2–6 x10^6 cells/recipient kg), and estimated collection efficiency coefficients (0.2, 0.3, or 0.4). To validate the technical accuracy of the web-app, two blinded evaluators calculated estimated processing volumes of the simulated cases using the web-app versus the standard CE2 equation, with >95% concordance set as the passing threshold.

Results: The HPC-A calculator app allows users to input the following parameters: peripheral blood CD34+ cell count (as CD34+ cell percent and WBC count, or direct CD34+ cells/μL), recipient weight (kg), expected CE coefficient, flow rate (mL/min), and y-axis breakpoints for the resultant graphical output. Dynamic input validation ensures adherence to clinical guidelines, such as recipient weight ≥25 kg, CE coefficient between 0 and 1, and flow rates in the expected clinical range, minimizing user errors. The real-time outputs are estimated peripheral blood CD34+ cells per μL, derived from input parameters or provided directly, along with the calculated whole blood volumes (L) required to achieve a specified collection goal under three efficiency scenarios: higher efficiency (HE, +10%), expected efficiency (EE), and lower efficiency (LE, -10%). Additionally, the app generates a plot of CD34+ x10^6 cells collected per recipient kilogram over time given the provided flow rate, plotted across a range of collection durations (0 to 6 hours) and stratified by efficiency scenario. The graphical output features a customizable y-axis (y-axis breakpoints), ensuring that visualization scales are clinically meaningful and adaptable. Simulation validation performed by two blinded evaluators reached 100% concordance, with all web-app predictions matching the manually calculated volumes using the CE2 formula exactly.

Conclusion: We developed and validated a web-based calculator app to standardize CD34+ cell collections at both our AMCs. Our simulation based validation showed perfect concordance between the web-app and the CE2 equations, confirming the technical accuracy of the underlying algorithm. Given the heterogeneity in practice across both AMCs, we hypothesize that strict adherence to the web-app's standardized recommendations will result in decreased over-collection overall, while still meeting collection goals. Future studies will test this hypothesis using both retrospective and prospective cohorts at both AMCs.

1294 Cyclic Olefin Polymer-based Vial Systems for Cell and Gene therapy

Vidya Murthy[1], **Krishnendu Khan[2]**
[1]*West Pharmaceutical Services, Inc., Hokinton, PA,* [2]*West Pharmaceutical Services, Radnor, PA*

As cell and gene therapy (CGT) drug products are becoming more mainstream, primary packaging consideration for these classes of therapies are evolving and increasingly gaining regulatory attention. When selecting a primary packaging solution, it is imperative to understand the critical quality attributes of an ideal containment system, including low particulate levels, container closure integrity (CCI), ice nucleation, drug-material compatibility, and ease of fill-finish.

Particulates come in many forms. Unlike traditional biologics, the active ingredients of CGT products (e.g., viral vectors, cells) are considered particles themselves. On the other hand, particulates other than the intended active ingredient, which can be of visible and subvisible sizes, or be of intrinsic (e.g., cellular debris) or extrinsic origin

(e.g., environmental contaminants, raw materials, consumables), can accumulate in the drug product from manufacturing through cold chain all the way to the point of care. Using light microscopy and flow imaging microscopy, cyclic olefin polymer (COP) vials were found to have similar or fewer subvisible particles, compared to ISO standard glass vials, polypropylene (PP) screw cap vials and ethylene vinyl acetate (EVA) bags, with or without freeze-thaw, upon ultra-cold (-80°C) or cryogenic (≤ -150°C) storage.

Product sterility depends on the primary container being able to maintain CCI. Containers with proper CCI prevent the ingress of low-temperature gasses, over pressurization of the container, and consequent hazard to its handlers. Oxygen headspace analysis and Helium leak test revealed that COP vials can maintain CCI upon proper crimping after short-term (1 week) or long-term (24 month) cryogenic storage.

Ice nucleation is a critical process parameter for the cryopreservation of biological materials composed of sensitive membrane structure. Controlling ice nucleation within a tolerable range of temperatures and time is important to avoid loss of the high-value material and its potency. Our study presented a new method of measuring ice nucleation that captured a greater extent of critical process deviations in a be packaged aqueous system than the conventional method.

Drug-material compatibility is an important aspect to protect the drug product integrity as any interaction could result in its degradation resulting in reduced potency and/or generation of harmful by-products. Here we show the compatibility of COP vials with different cell types which upon cryo-storage for short-term showed optimal functionality in different tested assays.

Additionally, COP based Daikyo Crystal Zenith(R) (CZ) vials are packaged in a nested tub configuration and designed to meet selected exterior dimensions for ISO glass standard 8362-1, are sterile, ready-to-use offer broad compatibility with automated and flexible fill-finish systems for CGT drug products as well as other advanced therapies.

We hereby emphasize the importance of primary packaging for CGT manufacturing and demonstrate the advantage of COP vials as a primary packaging system in the various technical considerations. The compatibility of CZ vials with different cell types along with its availability in different sizes and packaging formats offers a convenient and efficient containment solution for small batch fill-finish operations for CGT applications.

1295 Autofluorescence Imaging Reveals the Impact of Cryopreservation on T Cell Metabolism and Activation Response

Dan Pham[1], Cole Weaver[2], Melissa Skala[3]
[1]University of Wisconsin - Madison, Madison, WI, [2]Department of Biomedical Engineering, University of Wisconsin-Madison, Madison, [3]Morgridge Institute for Research

Introduction: Cryopreservation, which involves using low temperatures (-80°C and -196°C) to slow down cell metabolism and other cellular functions, is central to cell therapies such as Chimeric Antigen Receptor (CAR) T-cell therapy. The complex cell manufacturing process requires specialized facilities and expertise, which necessitates a central manufacturing model that relies on cryopreservation of both the starting materials and final products. However, recovering cell viability and function post-thaw remains challenging. Additionally, the impact of cryopreservation on cell metabolism and function immediately after thawing is not fully understood. Since T cell metabolism is closely linked to function, we used label-free Optical Metabolic Imaging (OMI) of metabolic coenzymes NAD(P)H and FAD to assess the metabolic and functional responses of frozen T cells upon thawing and activation.

Methods: Primary T cells were isolated from three healthy donors and divided into fresh and cryopreserved groups. Fresh T cells were cultured overnight in ImmunoCult XF medium, while frozen T cells were cryopreserved in FBS + 10% DMSO at -80°C for 24 hours before thawing. Donor-matched fresh and frozen T cells were activated with αCD2/αCD3/αCD28 antibodies and imaged with OMI every hour up to 4.5 hours post-activation.

Results and Conclusion: We observed stable metabolism in fresh quiescent T cells throughout 4.5-hour imaging time course (Fig 1A, dashed lines). In contrast, cryopreserved quiescent T cells showed significant increases in NAD(P)H mean lifetime (τm) immediately post-thaw up to 4.5 hours (Fig 1B, dashed lines). Fresh activated T cells demonstrated rapid and significant metabolic changes, characterized by decreased NAD(P)H τm within 30 minutes after activation. However, metabolic differences between cryopreserved quiescent and activated T cells were not observed until 2.5 hours (Fig 1A-B, solid lines). Additionally, Glass's Delta analysis between quiescent and activated groups revealed that frozen T cells exhibited smaller activation responses (D=-0.7 - 0.7) compared to fresh T cells (D=-2.8 - 3.0). UMAP projections based on OMI parameters showed distinct clusters for fresh quiescent and activated T cells, indicating significant metabolic differences post-activation (Fig 1C). Frozen T cells, however, did not cluster by activation status (Fig 1D). We also observed significantly higher levels of IFN-γ secretion by fresh T cells after 4.5 hours of activation compared to donor-matched frozen T cells. Overall, using label-free OMI, we have characterized significant metabolic shifts in T cells immediately post-thaw, along with a delayed and diminished activation response in cryopreserved cells. Our results highlight the need for optimized cryopreservation and thawing protocols to improve T-cell functionality in therapeutic applications.

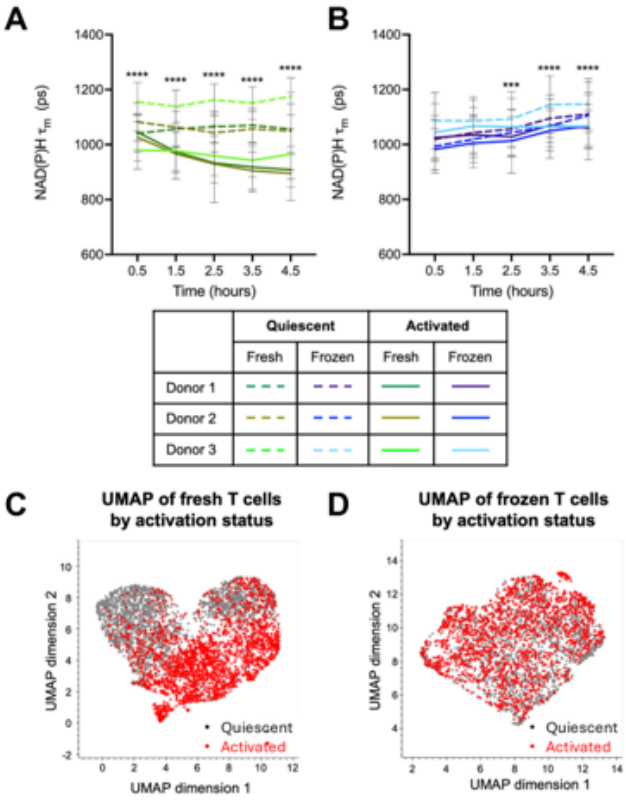

Figure 1. Cryopreservation delayed and diminished activation response in frozen T cells upon thawing. (A-B) Quantification of NAD(P)H τ_m of fresh **(A)** or frozen **(B)** T cells from 3 independent donors. Statistical tests were performed on quiescent versus activated groups. **(C-D)** Uniform Manifold Approximation and Projection (UMAP) of 11 OMI parameters (NAD(P)H and FAD τ_m, τ_1, τ_1, α_1, α_2, and cell size) of **(C)** fresh and **(D)** frozen T cells from 3 donors, color coded by activation status.

1296 Off-the-Shelf GMP-Compliant iPS Cells for Application in Cell Therapy

Björn Hiller[1], Noah Henschel[2], Claudia Traeger[2], Jens Lichte[2], Anna Gamerschlag[2], Melanie Huehne[2], Francois Hafezi[2], Daniel Terheyden-Keighley[3], Soraia Martins[2], Boris Greber[4]*
[1]Catalent Duesseldorf GmbH, Langenfeld, Deutschland, Germany, [2]Catalent Duesseldorf GmbH, Langenfeld, Nordrhein-Westfalen, Germany, [3]Catalent Cell & Gene Therapy, Langenfeld (Rheinland), Germany, Germany, [4]Catalent Cell and Gene Therapy, Düsseldorf, Germany, Rheinland, Rheinland-Pfalz, Germany
**Corresponding Author*

Cell and gene therapy has evolved as an important instrument for the treatment of many life-threatening diseases, including various types of cancer. As a global CDMO, Catalent aims to support cell and gene therapy strategies for the treatment of patients. As such, we enable fully integrated cell therapy services, from manufacturing, banking, and differentiation of induced pluripotent stem cell (iPSC), as well as development and manufacturing expertise, to process and analytical development across various cell types.

To support cell therapy services, we have developed a new process for the banking of GMP-compliant iPSCs that relies on the expansion and cryopreservation of single cells rather than cell clusters, rendering the process significantly more robust and fully controllable. Building on those iPSC lines, we have further developed downstream protocols for the differentiation of iPSCs into multiple cell types, including mesenchymal stem cells (MSCs), retinal pigment epithelium cells (RPEs), cardiomyocytes, and different types of immune cells such as NK cells, T cells and monocytes/macrophages.

Based on our new process we have generated three off-the-shelf iPSC banks of German and American origin, with full compliance with FDA requirements. These iPSC lines are comprehensively tested to ensure their identity, safety, and reliability. Testing protocols included, but were not limited to, comprehensive safety testing involving sterility, mycoplasma, and endotoxin testing according to US Pharmacopoeia, as well as extensive viral screening using various test methods like RNA sequencing and virus-specific PCR. Successful differentiation of our iPSC lines into MSCs, RPEs, cardiomyocytes, and immune cells has demonstrated full pluripotency of the iPSC lines, indicating the great quality and reliability of our innovative iPSC banking process. As a result, these iPSC lines are readily available for use and can be conveniently accessed off-the-shelf, facilitating research and therapeutic applications.

1297 A rapid and cost-effective solution for CAR- T cell manufacturing

Liping Yu[1]*, **Huiyu Wang[2]**, Silin Sa[3]
[1]Applied Cells, Santa Clara, CA, [2]Applied Cells Inc., Shanghai, Shanghai, China, [3]Applied Cells Inc., Santa Clara, CA
**Corresponding Author*

Introduction: The development of rapid and low-cost cell therapy products represents a significant advancement in the field of cell therapy. The rapid CAR- T cell manufacturing process minimizes cell differentiation and exhaustion, thus produces cells with higher potency and higher anti-tumor activity. This innovative process will benefit from streamlined production of therapeutic cells utilizing new technologies and tools, such as automated cell culture systems and efficient cell separation methods and adopting cost-effective materials and scalable production strategies to ensure the economic viability of the cell therapy manufacturing. In this report we demonstrate a novel automated closed cell manufacturing platform, MARS® Atlas, being an end-to-end solution for rapid CAR-T cell manufacturing by completing cell isolation, viral transduction and cell purification/formulation within 72 hours. This solution is intended to revolutionize the traditional CAR-T manufacturing paradigm and enable the delivery of potent, patient-specific therapies at near patient “point-of-care” settings.

Methods and results: Step 1: Fast and economic cell separation. A 1/10 leukopak containing 6E8 cells was incubated with CD4/CD8 magnetic beads at room temperature for 30 minutes. Then, the cell suspension was diluted and pumped through the separation channels on MAG modules for separation. The process resulted in a recovery of 60% T cells with 96% purity. The percentages of CD4 and CD8 cells remained consistent before and after separation. Step 2: Activation and transduction with low-seeding cells. With the advent of the rapid CAR-T process, the clinical dosage for each patient typically ranges from 1E6 to 2E7 CAR-T cells (1.2). Considering the transduction efficiency and QC need, a total of approximately 6E7 cells are needed. In this study, 3E6 T cells were seeded in the "Transduction module," which contained complete T-cell medium supplemented with CD3/CD28 magnetic nanobeads, IL-2, IL-7, and IL-15, and were incubated at 37C with 5% CO2 for 24 hours. The cells were successfully activated, exhibiting high expression of CD25 and CD69. Subsequently, the CD19 CAR lentivirus was added for an additional 24 hours. A phenotype with CCR7 expression reaching 90% is observed. Step 3: Unique Magnetic Harvest. In this method, the final products undergo further purification and formulation through the third MAG module. Notably, our approach demonstrated > 80% cell recovery, >99% virus removal, and completion in 30 minutes.

Function assessment: To assess the functionality of the CAR-T cells produced on MARS Atlas, killing assay and potency assay were performed and results were comparable to CAR T cells manufactured by conventional process. Repeated stimulation experiments demonstrated the long-term proliferation and persistence of rapidly generated CAR-T cells, which effectively exhibited tumor-killing capabilities, evidenced by the progressive reduction in target tumor cells over time. Furthermore, fewer Atlas-harvested cells were required to achieve the same level of tumor cytotoxicity as those produced through the conventional CAR-T process.

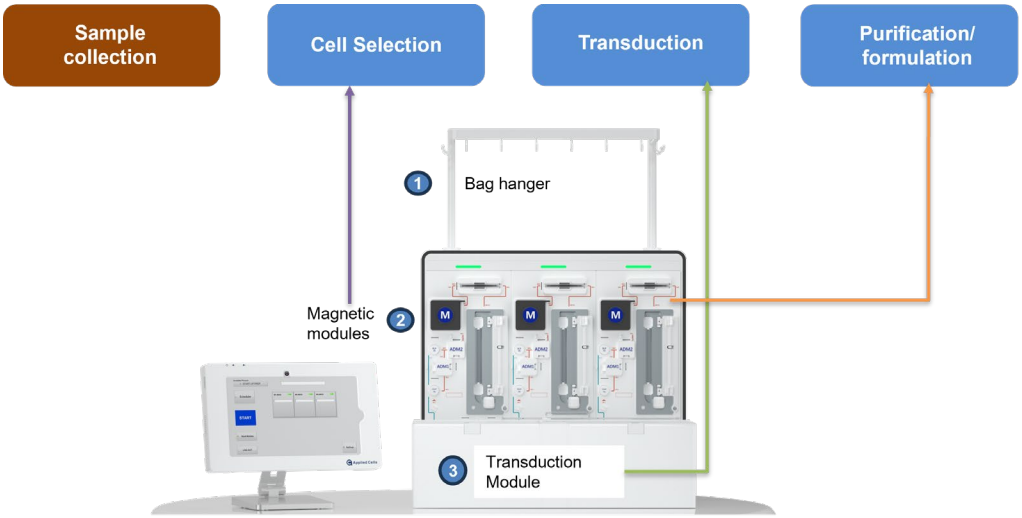

Figure 1: Schematic illustration of the workflow of rapid CAR-T cell manufacturing on Mars® Atlas. The single platform for automated rapid CAR- T manufacturing. Cell selection and purification/formulation are done on the magnetic modules and transduction step is done in the transduction module. All steps are done in closed fluidics and controlled by software.

1298 Development of Low-Cost CAR-T Process Street with Improved Manufacturing Success

Priyadarshini Chatterjee[1]*, Nasreen Valangar[2], Niraj Mishra[2], Parthipan Sivashanmugam[3]
[1]Aurigene Discovery Technologies Ltd., Bengaluru, Karnataka, India, [2]Aurigene Oncology, Bengaluru, Karnataka, India, [3]Aurigene Oncology, Bengaluru, India

Chimeric antigen receptor (CAR) T-cell therapy utilizes the immune response by modifying T cells in a laboratory setting. These engineered T cells are designed to efficiently locate and destroy cancer cells. CAR T-cells have demonstrated remarkable efficacy in treating multiple hematologic malignancies, including B-cell ALL, multiple subtypes of lymphoma (including the two most common types, diffuse large B-cell lymphoma and follicular

lymphoma), and multiple myeloma. However, any therapy is useful only to those who can access them. The patient-tailored nature of autologous CAR T-cell therapy raises two major concerns, the challenges in manufacturing using highly fragile patient cells and the cost of production per batch. Cellular and gene therapies are among the most expensive therapies on the market, typically over $400,000 USD. Manufacturing constraints have also been well documented for many approved CAR-T therapies, with complaints from doctors about the drug's long waiting list and relatively high rate of production failures.

A Phase 1 clinical trial, SWASTH, (CTRI/2023/11/059795 [Registered on: 14/11/2023]) of an anti-BCMA CAR-T in patients with r/r MM has been completed (n = 8) and the results show that a single dose of DRL-1801 (2.0–10.0 × 10^6 CAR+ T cells/Kg) administered by IV infusion in r/r MM patients is effective and safe, with an overall response rate of 100%, indicating that DRL-1801 may provide significant benefit to patients with r/r MM (Upload 01). However, manufacturing failures were encountered during this Phase I trial, accounting to about 20%. Literature also suggests manufacturing failures in similar range (Blood Adv (2024) 8 (2): 337–342; Meeting Abstract: 2024 ASCO Annual Meeting I). Each manufacturing failure entails cost, longer wait time or no treatment for patients, and a reputational damage for the sponsors. For a developing country like India, where the population is large, cancer burden is surging and CGT therapies are inaccessible and/or unaffordable for many, we decided to have a focussed endeavour at developing cost effective, scalable and robust manufacturing processes for CAR based cell therapies.

The modified manufacturing process for CAR-T cells is a semi-automated, modular Process Street design that involves a manufacturing cost that is significantly lower than in the Western world (Upload 02). We have well defined Manufacturing lines involving Automation for Cell Processing and T cell Purification, G-Rex Bioreactors are used for efficient T cell activation and transduction using an indigenously developed procedure (Patent Application No. 202541001697) and CAR-T cell expansion performed within next 3 days (Upload 02). This process involves minimal intervention with less resource need, reduces the chances of compromised sterility and generates CAR-T cells with better stemness. Also, rapid manufacturing for 5 days helps assess CAR protein expression reliably and does not necessitate additional monitoring for toxicities in clinical practice. Initial data using this new Process reveals successful manufacturing from multiple patient material, with well proven Quality standard of the released batches. Our preliminary data indicate that this robust and cost-effective process can also be implemented across multiple CAR-T products in a “plug and play” mechanism.

1299 *Challenge to Develop a GMP-compliant Integrated Manufacturing Process for Novel CAR-T Cells Using a Closed and Single-use Automated Culture System at Academic Gene and Cell Processing Facility*

Toshihiko Okazaki, OSAKA University Hospital, Suita City, Osaka, Japan

The effectiveness of gene-modified cell therapy with chimeric antigen receptor T cells (CAR-T) has been widely recognized as a promising modality in clinical applications. The manufacturing process for CAR-T cells is complex and requires advanced technology. A development of manufacturing process with stable quality for clinical trials and establishing infrastructure of manufacturing platform are becoming increasingly important. Therefore, we attempted to develop a manufacturing process for GMP-compliant CAR-T cells using a closed and single-use automatic cell culture system for clinical trials at academic gene and cell processing facility.

As a result, drawing 150 mL of peripheral blood as a raw material, through the main steps of cell separation, gene transduction to the cells, cell expansion, and concentration and filling (packaging), a final 6.5 to 7.5 x E+8 CAR-T cells (survival rate: >95%, transduction efficiency >18.5%) were stably obtained. We also attempted to optimize the process parameters to aim more long-term persistent CAR-T, and as a result, the T cell subsets analysis of Tn, Tscm, Tcm, Tem of the CAR-T products before and after system process optimization showed 0, 2, 75, 21 v.s. 0.05, 6.9, 55.5, 37.5, respectively.

It was demonstrated that GMP-compliant CAR-T cell manufacturing as qualified investigational drug for gene and cell therapy was demonstrated to work effectively in academic CPC. Our findings also reveal that robust CAR-T subsets of Tscm expansion could be obtained, suggesting even higher quality CAR-T cell production was feasible through optimizing the existing system program.

1300 Automating iPSC Processing and Engineering for Allogenic Cell Therapies: The Role of Closed Modular Systems.

Ranganatha Somasagara[1], Olga Cohen[2], Young Kim[3], Pushpalatha Chaluvappa[1], Lindsay Bailey Steinitz[1], Vivek Chandra[1], Carl Dargitz[4], Gregory Bonello[1], Namritha Ravinder[5]
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]Thermo Fisher Scientific - Carlsbad, CA, Carlsbad, CA, [3]Carlsbad, CA, [4]Thermo Fisher Scientific, Carlsbad, California, [5]ThermoFisher Scientific, Carlsbad, CA

Induced pluripotent stem cell (iPSC)-derived natural killer (iNK) cells have emerged as a promising platform for next-generation immunotherapy, offering a homogeneous, scalable and versatile approach for consistent large-scale manufacturing of off the shelf allogeneic therapies. This approach involves multiple steps including iPSC culturing and banking followed by gene editing and differentiation to tumor specific iNK cells to enhance cytotoxicity, persistence, and tumor-targeting specificity, while minimizing risks of graft-versus-host disease. Building closed modular automated workflows will help minimize risks associated with manual processes associated with these methods. Through this work we built closed automated cell harvest, cell wash and buffer exchange, gene delivery and editing protocols that can enable iNK-based cell therapy manufacturing.

In our current workflow, we cultured and expanded iPSCs up to a billion cells in a 10-layer cell factory system for master cell bank preparation. iPSC manual process and harvest in 10-layer cell factory system is very labor intensive and prone to contamination. Utilizing CTS Rotea counterflow centrifugation system minimized human intervention at multiple stages, including removal of media, washing of cells, addition of cell detachment media, collecting, concentrating iPSCs and delivering cells to collecting bags. Using this protocol, we processed the harvesting of entire iPSC culture in 10-layer cell factory system in a single batch to create a master bank for cell therapy development. The iPSCs prepared using this method retain pluripotency characteristics with good viability and expansion rate. We then successfully used these iPSC banks and carried out CRISPR-based non-viral gene editing using Neon NxT or CTS Xenon closed automated electroporation system for gene delivery, GMP grade CTS™ StemFlex media and high fidelity CRISPR-Cas9 system. Results show successful generation of engineered CAR-iPSC with reproducible KI efficiency of up to 15%. We established the optimal target gene and promoter combination to stabilize transgene expression during the differentiation of iPSCs to iNK cells. With methods developed through this work, we successfully generated potent CAR iNK cells. Together the workflows described here utilizing the clean room compliant closed automated cell processing and gene delivery platforms and the GMP compatibility iPSC and NK media systems enable clinical scale iNK cell therapy manufacturing.

1301 Automated Manufacturing of T cells for Therapy by LNP-Engineering

Caroline Brandes[1], Nihal Kus[1], Lydia Kopplin[1], Mara-Kristin Nuding[1], Jana Ciomperlik[1], Montassar Khalil[1], Felix Heider[1], Stefan Wild[2], Boris Engels[3], **Dominik Lock**[1]

Adoptive T cell therapies such as chimeric-antigen receptor (CAR)- or T cell receptor (TCR)-engineered T cells are powerful medical tools, as shown for the treatment of hematological malignancies. However, giving patients in need a widespread access to these technologies is still limited by the complexity of manufacturing and associated costs. Lipid nanoparticles (LNPs) have the potential to be established as pivotal advancement for gene-delivery for adoptive T cell therapy, with a cost-effective, safer and comparable or even better performance compared to lentiviral vectors or electroporation. This study focusses on the specific requirements for scaling the production of LNP-engineered T cells in an automated, closed and Good Manufacturing Practice (GMP)-compliant process using the CliniMACS Prodigy. Based on small scale studies assessing transfection conditions and kinetics, we optimized the transfection protocol reaching up to 98% gene-modified, highly viable (>90%) engineered T cells with a favourable, early memory phenotype. In a second step, we adapted the procedure for a scaled process. Starting from cryopreserved leukapheresis, 1-2 E8 T cells were enriched, subsequently activated and transfected using LNPs. Using an optimized pre-defined activity matrix defining the chronological order of all process steps, we cultured the T cells for 8 days yielding clinical relevant T cell numbers. Transfection efficiency (up to 93%) and viability (>90%) was comparably high as in small scale controls using the same donor. In conclusion, this platform and process

robustly and reproducibly resulted in clinically relevant doses of high-quality cell products and thus have the potential to greatly expand patient access to T cell therapies.

1302 Toward the Development of an Automated Manufacturing Process for Haematopoietic Stem Cell Gene Therapies

Ana Rubio Gomez[1], **Vassilis Paraskevas[2]**, Chris Holes[3], Swatisha Patel[4], Angela Palo[5], Matthew Turley[5], Carlotta Peticone[5], Emma Chan[6]
[1]Orchard Therapeutics, London, United Kingdom, [2]Orchard Therapeutics, London, United Kingdom, United Kingdom, [3]Orchard Therapeutics (Europe) Limited, London, London, United Kingdom, [4]Orchard Therapeutics (Europe) Limited, London, Greater London, United Kingdom, [5]Orchard Therapeutics (Europe) Limited, London, United Kingdom, [6]Orchard Therapeutics, LONDON, London, United Kingdom

Haematopoietic Stem Cell (HSC) Gene Therapies (HSC-GT) are a powerful technology to address a range of severe genetic diseases. This approach consists of delivering autologous gene-corrected HSCs, following *ex vivo* genetic modification with viral vectors, thus providing potential for long lasting therapeutic benefit with a single administration.

However, challenges in manufacturing could potentially limit the application of HSC-GT to treat more diseases. Manufacture of many cell and gene therapies uses processes that have been established over the last decades, to support investigative treatment in a small number of patients. These historical processes are often highly manual, include multiple open steps, and therefore require highly trained operators and high-grade clean rooms.

Here we aim to address some of these manufacturing limitations by developing a closed and semi-automated manufacturing process for ex vivo HSC-GT. The Miltenyi CliniMACS Prodigy provides an integrated platform for enrichment, viral transduction and culture in a closed system. We have established a flexible process that can reproducibly produce gene-modified HSCs. Most product Critical Quality Attributes were similar to those from a standard manual process, e.g. viability, phenotype and clonogenic potential. Importantly however, measures of potency such as transduction efficiency and vector copy number were improved (by 23% and 86%, respectively), whilst reducing the requirement of vector by 50%.

After transduction, harvested cells are washed, formulated and filled into cryobags. Another cell processing system, the Cue (Fresenius Kabi), has been evaluated to automate these unit operations and again compared to a manual process. The Cue gave similar results to the manual process but with improved operational efficiencies due to automation, such as standardisation, reduced DMSO contact time and electronic records. Furthermore, the Cue was shown to effectively wash cells as demonstrated by the high cell recoveries and viability (>85% and >88%, respectively) and the efficient removal of process residuals, as shown in cytokine spiking studies.

Encouraging results have been obtained with the technologies tested, significantly reducing the hands-on operator and overall processing time, and with comparable or improved product attributes compared to existing processes. Therefore, these cell processing devices could be considered for use in next-generation HSC manufacturing platforms.

1303 Lonza Cocoon® Platform Demonstrate Compatibility with Off-the-shelf Process Analytical Technology (PAT) and Electroporation Systems for Closed and Automated In-process CPP Monitoring and Genetic Modifications.

Peter Szaraz[1], Salvador Flores-Torres[1], Smitha Mathews[1], Ashkan Tabibian[1], Hosna Hadavi[2], Michele Vicentini-Hogan[3], Chad Ibbotson[1], Carlene Petes[1], Nuala Trainor[2]
[1]Lonza Personalized Medicine, Kingston, ON, [2]Lonza Personalized Medicine, Kingston, [3]Lonza, Kingston, ON

Introduction: In-process monitoring of critical process parameters (CPP) is a universal requirement and often cost-driving feature of cell manufacturing. Solutions for closed, automated CPP monitoring are in high demand, yet the

successful integration of analytical capabilities as PATs into the cell production workflow is challenged by the limited versatility of bioreactor platforms. Non-viral genetic modification processes apply external equipment (e.g. Nucleofector® Systems) that requires manual fluid transfers. Ideally a bioreactor platform should provide reliable, closed and automated transfer of target cells.

Methods: 908 Devices MAVEN Systems: Proximal diffusion module and distal sensor/transmitter module were integrated at-line with Cocoon® Platform fluidics. Glucose/lactate readings were obtained from day 1 to day 10 of the Cocoon® Platform cell expansion process. Reference readings were performed by manual sampling and BioProfile® FLEX2 analyzer (NovaBiomedical).

Ovizio at-line prototype system: Quantitative Phase Imaging (QPI), label-free, next gen cell analyzer prototype based on the Ovizio iLine F PRO, connected via reusable connectors to the Cocoon™ platform with a disposable sampling kit containing an optical chamber. Automated cell suspension transfer from bioreactor cultures at day 1, 3, 6 and 9 of the T-cell expansion process. Reference reading were performed by manual sampling and NucleoCounter® NC-200™ (Chemometec).

Lonza Nucleofector® System: Cell suspension transfer of 100 to 500 E6 cells from the Cassette to the proximal LV-reservoir was executed by Cocoon® Platform automated fluidics via reusable sampling connectors. Nucleofector® System closed, controlled fluidics filled LV-cartridge for electroporation and returned the transfected cells to the Cassette. Cell counting was performed by NucleoCounter® NC-200™ (Chemometec). Results: 908 Devices MAVEN systems: At-line glucose readings from culture media were <10% relative error (n=5) compared to reference throughout the entire process. Lactate measurements were <10% relative error (n=5) compared to reference over 1mg/mL media lactate content. Ovizio at-line prototype system: Cell counting relative error was <10% of manual reference when operating in recommended range (≤25x106 cells/ml). Total cell count RE≤8.6%; Viable cell count RE≤6.7% Lonza Nucleofector® System: Viable cell transfer efficiency between Cocoon® Platform and Nucleofector® System unit was 94%+/-3% (n=19)

Conclusions: The presented results demonstrate:
High fidelity, non-invasive in-process sampling of Cocoon® Platform bioreactor and precision delivery of small, representative samples to external devices in a closed and automated manner. Proven compatibility to establish at-line connection with off-the-shelf process ananlytical devices (PTA) to functinally integrate CPP monitoring into the Cocoon® Platform bioreactor process. Precision delivery of cell suspensions formulated in the Cocoon® Platform for genetic modifcation in at-line integrated electroporation unit (Lonza Nucleofector® System).

1304 Perfusion-Powered Production of Over 100 CAR-T Doses in a 2-litre Stirred-Tank Bioreactor With Automation of Downstream Harvest and Concentration Steps

Rukmini Ladi[1], Pierre Springuel[2], Fern Slingsby[3], Nicola Bevan[3], Amanda Frangleton[3], Michal Szelwicki[3], Timo Schmidberger[4], Asma Ahmad[5], Earl Pineda[5], Rachel Legmann[6], Rene Gantier[7], Noushin Dianat[8], Julia Hengst[9], Qasim Rafiq
[1]Sartorius, Ann Arbor, MI, [2]University College London, London, United Kingdom, [3]Sartorius, Cambridge, United Kingdom, [4]Sartorius, Goettingen, Niedersachsen, Germany, [5]Repligen Corporation, Boston, [6]Seahorse Bioscience, Lexington, MA, [7]Repligen, Waltham, MA, [8]Sartorius, Paris, Paris, France, [9]Sartorius Stedim Biotech GmbH, Goettingen, Germany

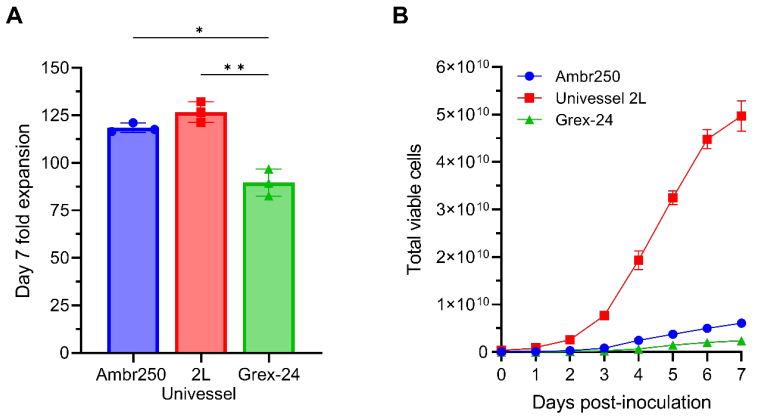
Introduction: Allogeneic CAR-T therapies offers the potential to mass produce "off-the-shelf" doses, addressing the limitations of lengthy manufacturing processes in approved autologous products. To realise this potential, industrially scalable upstream and downstream workflows are required. To this end, we characterised a CAR-T cell perfusion manufacturing process in a 2-litre stirred-tank bioreactor (STR), with a solution to automate the bioreactor harvest, final product wash, and concentration steps.

Methodology: Healthy donor-derived anti-CD19 CAR-T cells were cultured in parallel in the Ambr® 250 High Throughput Perfusion and Univessel® 2-litre single-use STR, the latter coupled with the XCell ATF® 2 cell retention device. CAR-T cells were expanded in 4Cell® Nutri-T serum-free medium in perfusion for seven days,

and performance was benchmarked against a G-Rex® 24 well plate process. The Ksep® 400 was evaluated as a closed, automated solution for the harvesting, concentration, and washing of the final CAR-T product from the 2L STR. Comparability between the 250mL and 2L systems was examined, alongside the impact of automated harvesting on cell yield, viability, activation, maturation, exhaustion, cytotoxicity, and cytokine release.

Results: CAR-T cells were successfully expanded ~125-fold in perfusion in both 250mL and 2L STRs. At the2L scale, final yields of ~50 billion total viable cells were consistently generated, with a CAR transduction efficiency of 34%, corresponding to over 100 representative doses of 150x10 CAR+ T cells. Harvested cells were predominantly in the naive and central memory subset (>95%) and expressed negligible levels of exhaustion markers (<1%). No statistical differences were observed in CAR-T cell yield, viability, surface marker expression, or cytotoxicity between the 250mL and 2L bioreactors. Automated harvesting recovered>90% of the total yields, concentrated cells 8-fold, and had no impact on CAR-T cell phenotype, cytotoxicity, or growth kinetics post-harvest.

Conclusion: These findings demonstrate the feasibility of multi-litre expansion of functional CAR-T cells to generate hundreds of doses in perfusion-based stirred-tank bioreactors. The Ambr® 250 effectively served asa scaled-down model and facilitated seamless scale-up to 2L. Finally, automated harvesting and concentration streamlined the downstream workflow while maintaining CAR-T cell quality. This scalable upstream and downstream workflow is ideally suited for mass production of future allogeneic therapies.



A) CAR-T cell fold expansion in perfusion is comparable between the Ambr® 250 HT Perfusion and Univessel® 2-litre stirred-tank bioreactors, significantly outperforming the G-Rex®24 well plate process. **B)** Perfusion in the 2-litre bioreactor enables final cell yields exceeding 50 billion viable cells. Data represents mean of n=3 replicate runs.

1305 Improving CAR T Cell Production: Comparing Stirred Tank Bioreactors and Static Vessels

Mina Ahmadi[1], Yongchang Ji[2], Max Dotson[3]
[1]Thermofisher Scientific, Carlsbad, CA, [2]Thermofisher, Carlsbad, CA, [3]Thermo Fisher Scientific, Carlsbad, CA

T cell activation and transduction are critical steps in the production of autologous CAR T cells, where primary T cells are genetically modified to express chimeric antigen receptors (CARs) for targeted tumor treatment. Traditionally, these processes have been performed in static culture systems, which require significant manual intervention and are subject to variability in cell expansion and product quality. This has led to challenges in scaling up the production of CAR T cells for clinical applications. Stirred tank bioreactors (STRs) offer a promising solution for automating and streamlining the T cell activation and transduction processes. By integrating both the activation and transduction steps into a single, closed system, STRs minimize the need for manual handling and reduce the risk of contamination. In our study, we compared the simultaneous activation and transduction of primary T cells in STR bioreactors versus G-Rex vessels. Our results demonstrate that activation and transduction levels are similar across both platforms; however, STR bioreactors led to significantly better expansion of CAR-T cells without affecting the

early memory phenotype composition. Our data suggest that, by leveraging STRs in the CAR T cell workflow, the industry can meet the growing demand for personalized immunotherapies while improving efficiency, reducing costs, and advancing automation in cell therapy production.

1306 Scalable and Controlled Expansion of Genetically Engineered CAR-T cells in Stirred-Tank Bioreactors

Max Dotson[1], Mina Ahmadi[2], Yongchang Ji[3]
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]Thermofisher Scientific, Carlsbad, CA, [3]Thermofisher, Carlsbad, CA

Chimeric antigen receptor T cells (CAR T) have emerged as a promising therapy for hematologic malignancies. To achieve successful CAR T manufacturing, automation, closed operation, improved control, and scalability are crucial. Bioreactors provide advantages in cell therapy manufacturing, offering a controlled and optimal environment for cell growth. While rocking motion bioreactors have been widely used for CAR T cell expansion, stirred-tank bioreactors (STRs) have gained attention due to their scalability, precise gassing and agitation control, and smaller footprint. Previous studies have shown enhanced growth of activated T cells in STRs compared to rocking motion or static cultures. However, it remains unclear whether genetically engineered CAR T cells can be cultured in STR platforms and maintain CAR expression and functionality.

In this study, we integrated STR platforms into an end-to-end closed and automated workflow to expand non-virally generated CAR T cells. Our investigation focused on tracking cell growth kinetics and functionality attributes. We observed higher growth and viability of CAR-T cells in STRs compared to static bioreactors; notably, engineered T cells expanded in STRs maintained high expression of the CAR gene and exhibited improved cytolytic function compared to those expanded in static bioreactors.

The findings showcase stirred-tank bioreactors as an improved platform for *ex vivo* culture of engineered T cells, enabling the maintenance of CAR expression and enhanced cytolytic function. This highlights the significance of integrating automation, closed operation, and enhanced control in CAR T cell manufacturing to optimize therapy outcomes and meet the rising demand for effective cell-based immunotherapies.

1307 Scaling CAR-T Manufacturing: Redefining Large Volume Fill-Finish with ARES X20+ Automation

Meredith Safford[1], Joshua Jendusa[2], Minsung Park[3], Terri Staab[4], Despina Pleitez[5], Marcelle Koudji[4], ShaNelle Yelity[4], Alex Sargent[6]
[1]Charles River - Hanover, MD, Hanover, MD, [2]Xiogenix, Waterford, WI, [3]Charles River Laboratory, Hanover, MD, [4]Charles River Laboratories, Hanover, MD, [5]Charles River Labs, Hanover, MD, [6]Charles River, Wilmington, MA

The final fill-finish step of cell and gene therapies (CGT) manufacturing is critical to ensuring drug product (DP) integrity and consistency. Manual fill-finish of DP is time consuming, requires skilled operators, and introduces considerable risk to meeting regulatory requirements of sterility, uniformity, and efficacy. It also limits DP batches to small volumes, preventing the scaling of DP to larger patient populations. Closed automated fill-finish systems address these risks and scaling issues by decreasing manual process steps, improving process control and the precision of formulation and filling, thereby decreasing process time overall and improving cell viability and DP efficacy. This study assessed the capabilities of the ARES X20+ closed automated fill-finish system to fill both vials and bags and maintain T-cell product viability and efficacy using enriched, CAR-T transduced, CD4+ and CD8+ T cells from n=2 donors. The ARES X20+ system was configured to run a process with specific parameters designed to test various features of the equipment while analyzing the impacts on the health of the CAR-T cell product. For this study, to illustrate the range of fill volumes by the ARES X20+, two disposable manifolds were sequentially used for each donor: Manifold 1 contained 15 bags (30 mL fill vol.) and 5 vials (3 mL fill vol.); Manifold 2 contained 20 vials (10 vials with a 5 mL fill vol. and 10 vials with a 1 mL fill vol.). T-cell product was continuously cooled and mixed during the operation, flow rates were adjusted higher for bag filling, lower for vials with filling, and set to be slightly above target volume to ensure its attainment. The ARES X20+ filling duration and filling

accuracy of bags and vials by the ARES X20+ were compared to manual filling. Manual filling used standard cryo vials and cryo bags. Time assessments of filling included the ARES X20+ line purges and air evacuation of bags before filling and removal of air post fill of bags for both ARES X20+ and manual processes. The ARES X20+ filled Manifold 1 bags and vials 8x faster than manual processes and filled Manifold 2 vials 2x faster. Manual bag filling had an 18-fold higher variance compared with bags filled using the ARES X20+. Manual filling of 1 mL and 3 mL vials had 1.2 -fold and 3.5-fold, respectively, higher variance compared to ARES X20+. For 5 mL, the ARES had a 15.3-fold higher variance compared to manual processes, which reflected a median filling at 5.3 compared to 4.95 for the manual process. To test the health of the T-cell product after ARES X20+ fill-finish, ARES X20+-filled bags and vials were cryopreserved using a controlled-rate freezer. After > than 3 months in LN2 storage, bags and vials were thawed and viability, CAR-T expression, and T cell phenotype were assessed. % viability, TIGIT and PD1 expression were evaluated to assess the health of the T-cell products post-thaw. For both donors, across all bags and vials, TIGIT expression was < 23% on average and PD1 expression was < 8.3 on average with STDEVs less than 2.9 and 2.3, respectively. Viability for both donors was > 90%. CAR-T expression and phenotypic populations (TEM, SCM, CM, and EM) were consistent over bags and vials for each donor. These data show that the ARES X20+ exceeds manual filling at speed and filling precision, while maintaining cell health and phenotype and providing the ability to fill large volumes of DP.

1308 The Simple CAR-T Cell Production: RetroNectin can Promote Simultaneous T-cell Activation & Transduction in G-Rex Bioreactor.

Yasunori Amaishi[1], Izumi Maki[1], Seina Inui[1], Thomas Quinn[2], Michael Haugwitz[2], **Sachiko Okamoto[3]**
[1]Takara Bio Inc., Kusatsu, Shiga, Japan, [2]Takara Bio USA, San Jose, CA, [3]Takara Bio Inc., Kusatsu, Shiga, Shiga, Japan

CAR-T cell therapy has demonstrated high efficacy against hematologic malignancies, achieving partial or complete remission in many patients. A variety of approaches are being developed to target various antigens, making it a promising therapy for the various kind of tumors. However, there are still many challenges in the cell manufacturing process, especially when using autologous T cells. The process is complex and carries the risk of manufacturing failures, leading to high production costs and limiting the number of patients who can receive the therapy. Therefore, there is a need for a simple and efficient method to produce high-quality CAR-T cells. In this study, we have established a simple CAR-T manufacturing method by combining RetroNectin and G-Rex.

RetroNectin is a recombinant human fibronectin fragment containing three functional domains: a cell-binding domain (C-Domain), a heparin-binding domain (H-Domain), and a CS-1 sequence. RetroNectin enhances gene transduction via lentivirus and retrovirus by promoting the co-localization of target cells and viral particles. This is achieved through specific interactions between RetroNectin and various cell surface integrin receptors. The H-Domain of RetroNectin binds to viral particles, while target cells primarily bind to RetroNectin through interactions between their integrin receptors VLA-5 and VLA-4 and the C-Domain and CS-1. By promoting the physical proximity of viral particles and target cells, RetroNectin significantly improves the efficiency of virus-mediated gene transduction. RetroNectin is currently considered the gold standard for enhancing viral transduction in various clinical applications involving genetically modified cells, such as T cells and hematopoietic cells. Furthermore, RetroNectin is known as a T cell activator when used in combination with anti-CD3 antibodies (Abs).

G-Rex is a gas-permeable bioreactor developed by Wilson Wolf Corporation, suitable for high-density culture of immune cells like T cells and NK cells, and it is becoming increasingly utilized in various clinical cell manufacturing processes due to its ease of scalability.

In the conventional CAR-T production process, lentiviral transduction is performed mostly 24-48 hours after T cell activation. By coating the membrane of G-Rex with RetroNectin, we were able to perform simultaneous activation and efficient transduction of T cells with lentiviral vectors. This method is expected to significantly reduce the amount of lentiviral vectors used. Additionally, CAR-T cells cultured in this RetroNectin-coated G-Rex showed higher proliferation rates and a more undifferentiated phenotype compared to uncoated conditions. This effect was consistent with both stimulation methods, including CD3/CD28 activation beads and RetroNectin/anti-CD3 Ab stimulation method, indicating a beneficial effect regardless of the T cell stimulation method.

Moreover, by optimizing the each step in this culture process, we were able to establish a simple manufacturing process requiring only three operation days. This simple CAR-T manufacturing method is expected to be applied to various T cell therapies. The combination of RetroNectin and G-Rex not only simplifies the manufacturing process but also enhances the quality of CAR-T cells and efficiency of CAR-T cell production, making it a promising approach for future clinical applications.

1309 Platforming iPSCs: a modular approach for all differentiation modalities

Adam Janvier, EXmoor Pharma, BRISTOL, South Gloucestershire, United Kingdom

Induced pluripotent stem cells (iPSCs) are mature cells that have been reprogrammed to behave like embryonic stem cells, allowing them to differentiate into any desired cell type. In recent years, iPSCs have become the preferred starting material for cell therapy applications due to their differentiation potential and the absence of ethical concerns associated with embryonic stem cells. However, achieving specific cell types from iPSCs requires distinct culture methods, making it difficult to standardise manufacturing platforms and leading to a variety of novel approaches in the field. While these innovative methods produce high-quality cells at a small scale, they often face challenges when scaling up, particularly in Good Manufacturing Practice (GMP) environments for clinical applications. To address this, we have developed a modular iPSC platform covering expansion, differentiation, and harvest. Our approach integrates commercially available, GMP-grade platforms and consumables, ensuring regulatory compliance and scalability. After assessing your manufacturing process, we select the optimal unit operations for your platform. This may include iPSC suspension culture for cell expansion, adherent culture for differentiation, enzymatic digestion and centrifugation for harvest, and encapsulation ahead of cryopreservation. To ensure quality, we use a standardised analytical panel to assess genetic stability, phenotype, and pluripotency, alongside therapy-specific analytics. Since iPSC cell lines respond differently to environmental and biological factors, we conduct small-scale optimization studies to adapt each platform step. We continuously look to implement the latest advancements in iPSC reprogramming and GMP-ready reagents are enhancing standardisation, enabling scalable, compliant processes that accelerate clinical translation.

1310 Platforming iPSCs: a modular approach for all differentiation modalities.

Autologous cell therapies have demonstrated significant clinical success and sparked a medicinal revolution. However, challenges such as limited cell supply, high costs due to manufacturing complexities, extended patient treatment timelines, and constrained manufacturing and administration sites continue to hinder accessibility and affordability. Developing off-the-shelf, scalable, and standardized cell products offers a potential solution. Allogeneic induced pluripotent stem cell (iPSC)-derived therapies present a transformative approach to overcoming these hurdles, leveraging unlimited cell supply, standardized manufacturing, and low-cost production of homogeneously edited cell products.

To fully utilized potential of iPSC-derived therapies, three critical conditions must be met. First, access to well-characterized, GMP-grade iPSC lines free from pathogenic genetic alterations is essential. Current public or commercial iPSC banks often contain uncharacterized clones, with studies showing that up to 20% harbor cancer-related mutations. Therefore, obtaining iPSC clones with confirmed genomic integrity is crucial. Second, variations in donor genetics and epigenetics mean that not all iPSC clones exhibit equal differentiation or expansion efficiencies for specific cell types. Identifying suitable iPSC clones through rigorous screening is necessary. Third, differentiation and expansion protocols must be optimized to the productivity of the selected clones. The synergy of selecting the right iPSC clone and optimizing differentiation processes will unlock the full potential of iPSC-derived therapies, driving the next wave of innovation in cell therapy.

To address these requirements, a stringent donor recruitment process was implemented, ensuring compliance with regulations across multiple regions. Blood cells from eligible donors were reprogrammed into clinical-grade T cell-derived iPSC lines (αβT- and γδT-derived iPSCs). Rigorous characterization of these T-iPSC clones, including assessments of pluripotency, differentiation capacity, karyotype, and comprehensive genome integrity assessments. Ten clinical-grade T-iPSC lines successfully passed all tests and were found to be free of likely-pathogenic variants present in the OncoKB, ClinVar, and COSMIC databases.

Innovative feeder-free differentiation and expansion platforms were then developed to maximize the potential of GMP-grade T-iPSC clones. These protocols achieved unprecedented efficiency, are capable of generating 95% CD8αβ+ mature T cells and over 99% γδ T cells without enrichment steps. Remarkably, both αβ T and γδ T cells could be expanded more than 10 million-fold from a single iPSC. Functional assays demonstrated robust cytotoxic activity for both cell types, confirming their therapeutic potential.

To enable commercial-scale production, the differentiation and expansion processes were reproduced in a closed system, facilitating large-scale manufacturing in a single batch. These advances represent a competitive edge in scalability and efficiency, significantly improving the accessibility and affordability of iPSC-based therapies.

BeiGene Cell Therapy's iPSC-derived platforms offer a breakthrough in allogeneic T cell therapy, paving the way for scalable, cost-effective, and functional cell products that address current limitations in the field. These advancements hold the promise of transforming cell therapy accessibility and driving future innovations.

1312 Scalable and Consistent Manufacturing of Functional Lung Cells from iPSCs: Ncardia's Advanced Differentiation Protocols for Drug Discovery and Tissue Engineering

Mariana Argenziano[1]*, Ilse Veldkamp-Baak, Pieter van Loenen, Jessica Koepke[2], Stefan Braam
[1]Ncardia, Leiden, Zuid-Holland, Netherlands, [2]Ncardia, LEIDEN, Netherlands
Corresponding Author

Induced pluripotent stem cells (iPSCs) offer unparalleled potential for drug discovery, disease modelling, and tissue engineering due to their ability to self-renew indefinitely and differentiate into any cell type. However, the manufacturing of functional cells from iPSCs with consistent quality and at scale remains a significant challenge. Variability in iPSC differentiation, influenced by numerous biological factors, complicates standardization, leading to increased risk, cost, and development time. Leveraging over a decade of innovation, Ncardia has developed robust, scalable procedures for differentiating iPSCs into various cell lineages, including the complex endodermal lineage, thereby enabling the production of functional lung cells for multiple applications.

The development process begins with client collaboration to define the target cell quality profile, including parameters such as identity, purity, potency, and scale. Ncardia's expert team then conducts parallel testing of various protocols using scalable platforms to establish proof of concept. This iterative process identifies critical process parameters (CPP), critical material attributes (CMA), and critical quality attributes (CQA), facilitating the selection of optimal protocols for scale-up development. Throughout this process, robust data collection and analysis enable predictive modelling, ensuring consistent and reproducible outcomes.

Ncardia successfully developed scalable differentiation protocols for four main human lung cell types: distal type II alveolar epithelial cells (AT2), proximal lung basal cells, endothelial cells, and stromal cells. The iPSC-derived AT2 cells exhibited characteristic morphology with secretory granules (lamellar bodies) and expressed specific markers (ABCA3, SPC), essential for pulmonary surfactant production. Proximal lung basal cells, crucial for epithelial repair and maintenance, demonstrated typical morphology and expressed TP63 and KRT5. Endothelial cells displayed elongated shapes, formed vessel-like structures, and expressed CD31 and CD144, with functional capabilities such as LDL uptake. Stromal cells showed expression of PDGFRβ and SMA, with assessed growth and contractility, confirming their role in structural support and immune regulation in lung tissue.

Ncardia's approach addresses the challenges of iPSC manufacturing by minimizing variability and enhancing scalability, quality, and consistency. By integrating deep stem cell biology expertise with scalable platforms and data-driven decision-making, Ncardia accelerates process development while reducing risks. The successful differentiation of lung cell types from iPSCs highlights Ncardia's capability to produce high-quality cells in big volumes for drug discovery and regenerative medicine. This comprehensive work highlights Ncardia as a premier partner for advancing therapeutic development through innovative iPSC technologies, offering customized, large-scale manufacturing solutions that enable significant scientific and clinical breakthroughs.

1313 Development of Highly Sensitive Liquid Chromatography Assays to Ensure Excipient Clearance in AAV Products

Micah Witte, Forge Biologics, Grove City, OH

The development of high-performance liquid chromatography (HPLC) assays for the detection and quantitation of residual process-related impurities is essential for the quality control of adeno-associated viral (AAV) vectors used in gene therapy. This work presents the development of HPLC-based analytical methods to detect and measure key residuals commonly used during AAV vector production: Triton X-100, polyethyleneimine (PEI), Poloxamer 188, and RevIT™. These reagents are critical in optimizing transfection efficiency and viral vector purification, but their

residual presence in final products may pose risks to patient safety and product quality. The assays were developed to ensure high sensitivity, specificity, and reproducibility for the accurate quantitation of these impurities at low concentrations. Optimization of chromatographic conditions, including column selection, mobile phase composition, and detection methods, was essential for achieving reliable separation and detection. The methods were validated for parameters such as linearity, accuracy, precision, and limit of quantitation (LOQ), and were shown to provide reproducible results across multiple batches. The lower limit of quantitation (LLOQ) for TritonX-100, PEI, and RevIT™ was determined to be at or nearing 1ppm when achieving sufficient signal: noise ratios on the chromatograms (>20). Poloxamer 188 is often a target value ranging from 10ppm to 100ppm in finished AAV drug substances/products. Therefore, the assay was developed with an LLOQ of 5ppm, also with acceptable S/N ratio >20. The fully developed assays were robust to allow changes in analyst, instrument, and minor errors in sample preparation. These HPLC assays represent a vital tool for routine monitoring of process residuals, ensuring that AAV-based gene therapies meet stringent safety and regulatory standards while minimizing potential risks associated with these residual impurities.

1314 Percent Fulls – What landscape is your data painting?

Clifford Froelich[1], Praveen Kusumanchi[2], Wei Guo[2], Chistopher Aimable[3], Megan Caten[3], Kevin Vera[3], Pouria Motevalian[2]
[1]ThermoFisher Scientific, Plainville, MA, [2]Thermo Fisher Scientific, Plainville, MA, [3]Thermo Fisher Scientific, Plainville

Gene therapy manufacturing requires robust recombinant Adeno Associated Virus production, where viral strength (capsid and genome titers) and empty:full purity are critical quality attributes. Traditional "gold standard" methods—sedimentation velocity analytical ultracentrifugation (SV-AUC), size-exclusion chromatography with multi-angle light scattering (SEC-MALS), and charge detection mass spectrometry (CDMS)—provide accurate purity assessments. However, newer technologies such as mass photometry and Bio-Rad's Vericheck Empty:Full kits offer potentially faster and simpler analyses. This study compared these orthogonal approaches across multiple serotypes (AAV2, AAV5, AAV8, AAV9) and different genes of interest to identify optimal strategies for both harvest-stage and purified samples.

Harvest Evaluation –
Compared three strategies to measure viral strength (vg/cp titers) and purity:

- Industry-standard vg:cp ratio.
- Small-scale AAVX affinity purifications on Tecan and KingFisher, followed by mass photometry and A_{260}/A_{280} analysis
- Bio-Rad Vericheck kits for direct vg, cp, and empty:full data.

Orthogonal Testing (Purified Samples)
Analyzed rAAV preparations using SV-AUC, SEC-MALS, mass photometry, and Bio-Rad Vericheck to determine empty:full ratios.

All orthogonal methods produced comparable purity profiles across serotypes, with mass photometry offering rapid results using minimal sample. SEC-MALS enabled quick (~20-minute) titer measurements but required more material. At harvest scale, Tecan and KingFisher workflows yielded similar accuracy, though KingFisher proved more cost-effective. Interestingly, the A_{260}/A_{280} demonstrates great linearity with the mass photometry numbers. Bio-Rad Vericheck required less sample manipulation overall and delivered integrated vg, cp, and empty:full data (~7.5 hours). The traditional vg:cp ratio frequently diverged from the refined orthogonal assays. Orthogonal methods each offer reliable rAAV purity and strength data but differ in cost, sample demands, and turnaround time. Mass photometry and Bio-Rad Vericheck are particularly practical for routine analyses, while SEC-MALS provides rapid titer quantification where enough material is available. Given the limitations observed in vg:cp ratios, re-evaluation of this industry-standard approach is warranted to ensure accurate, cost-effective rAAV characterization.

From the perspective of a CDMO that sees all serotypes of AAVs, human and non-human, with Genes of Interests addressing a broad range of indications, we are finding that being able to “paint the story” with the orthogonal data to drive the needs of the intellectual property and regulatory agencies and how they are homing on a refined image of the Quality of the material.

1315 Accelerating Sterility Testing to <3 Days: Rapid, Real-Time Phenotypic Detection of Microbial Contamination with calScreener+

Frida Svanberg-Frisinger, **Wilhelm Paulander**
Symcel, Stockholms, Sweden

**Accelerating sterility testing is critical for cell and gene therapy products (CGTPs), where rapid and reliable microbial detection ensures compliance with regulatory standards and patient safety. Traditional sterility testing requires up to 14 days, delaying batch release and increasing costs. The Symcel calScreener+ utilizes isothermal microcalorimetry for real-time, phenotypic detection of microbial contaminants in a non-destructive, matrix-independent manner. This study evaluates its 3-day sterility testing performance, focusing on Limit of Detection (LOD), specificity, detection times, and robustness in handling small sample volumes and complex matrices with high eukaryotic cell concentrations.

The calScreener+ detects microbial metabolic activity in sample volumes ranging from 0.05 ml to 0.5 ml. Validation studies determined its LOD, detection times, comparability and specificity across 20 microbial strains aligned with regulatory guidelines. Tests were conducted using TSB and FTM media at 25°C and 35°C, targeting key microorganisms such as Staphylococcus aureus, Pseudomonas aeruginosa, Candida albicans, Aspergillus brasiliensis, Cutibacterium acnes, and Micrococcus species. Additional evaluations included temperature screening to assess microbial growth dynamics under different incubation conditions, as well as robustness testing under inhibitory conditions, including the presence of cryopreservants commonly used in CGTP formulations. Statistical analyses confirmed reliability and reproducibility.**

Results demonstrated an LOD of <5 CFU and detection within 3 days, even in complex matrices with high eukaryotic cell concentrations (10^6–10^8 cells/ml). Detection times included S. aureus, P. aeruginosa, and C. albicans within 24 hours, A. brasiliensis within 30 hours, Micrococcus within 36 hours, and C. acnes within 60 hours. The system effectively detected a broad range of sterility-relevant microorganisms, including critical contaminants such as Burkholderia complex and Penicillium species, maintaining robust performance across varied conditions. Temperature screening confirmed consistent detection performance at both 25°C and 35°C, while cryopreservants were evaluated for their inhibitory effects, demonstrating that microbial metabolic activity could still be detected under these conditions.

By reducing sterility testing from weeks to days, the calScreener+ offers a rapid, phenotypic solution tailored for CGTPs. Its ability to analyze small sample volumes minimizes material use, making it ideal for limited batch sizes. Eliminating enrichment steps and accelerating detection enhances operational efficiency, streamlining sterility testing workflows and supporting rapid batch release.

1316 The 3 Rs of Replication-Competent Lentivirus (RCL) Formation Risk: Real, Rare or Artificial?

Samuel Stockdale[1], Jordan Wright[2], Manisha Bapat, Kathryn Perrett, Kyriacos Mitrophanous[2], Georgina Ferrige[2], **Dan Farley**
[1]Oxford BioMedica, Oxford, Oxfordshire, United Kingdom, [2]Oxford Biomedica, Oxford, United Kingdom

The development of retroviral and lentiviral vector systems has culminated in the contemporary 3rd generation platforms, which are now being used in the clinic. The chief driver for development has been to minimise the possibility of generating replication-competent virus through recombination events in retroviral/lentiviral vector (RV/LV) production cells. Replication-competent retrovirus (RCR) has been detected in the earlier generations of

RV systems employing: 1] wild type LTRs; 2] homology between genomic, gagpol and envelope sequences, and 3] certain cell lines or packaging cells. To date, there have been no reports of RCL formation in products generated from 3rd generation LV systems. Despite this, RV/LV products still require testing for RCR/RCL prior to batch release, and this activity remains a significant burden, and is often a gating factor to clinical batch release. Whilst the regulatory agencies have recently adjusted these testing requirements, to our knowledge, a fundamental reassessment of the underlying principles and mechanisms of RCR/RCL formation has not been carried out. Moreover, whilst the adjusted guidance enables a degree of reduced testing of RV/LVs intended for *ex vivo* application, these changes have major implications and challenges for high concentration, low doses-per-batch products intended for *in vivo* applications. As LV production scales and yields increase, and the ability to now target LVs, expanded *in vivo* use of LVs will likely soon become a reality.

OXB has been a leader LV platform engineering over three decades. As part of CMC analytical work, this has necessitated RCL assay development across HIV-1, EIAV and SIV-1 based products. Here we provide a summary review of past RCR formation with the publicly available reports, and suggest the likely mechanisms of how these occurred. We'll present mathematical calculations for the (im)probability of RCL formation from 3rd generation LV systems, and propose a roadmap for reduced testing as a product progresses through to commercialization. Our model infers that the probability of generating a single copy of RCL genome (irrespective of replication fitness) for a typical 4-component LV product at 200L bioreactor scale is no greater than 1 in 10 thousand per bioreactor. We propose that the use of packaging cell lines represents an opportunity to lower this risk substantially further, and therefore is part of the proposed roadmap to reduce the burden of testing. This would depend on the approach taken to stably introduce gagpol/rev/envelope components, and places greater emphasis on deeper, 'one-off' characterisation of packaging cell lines (i.e. full NGS) to ensure the absence of 'pre-RCL' intermediate sequences. This argues for reduced testing of LVs produced from these 'clean' packaging cells, since far fewer template molecules are available for recombination compared to the fully transient method. Finally, we provide insights into RCL assay method development, and consider the key aspects of a given assay with respect to choice of amplification cell line, as well as the basis of positive controls and what they are actually controlling/monitoring within the assay. We propose that whilst the end-point assay is typically a pass/fail threshold, the use of a highly sensitive test, such as those based on reverse-transcriptase activity (a necessary property of any RCR/RCL), potentially provides justification for reducing the cell culture (amplification) phase.

1317 Design of Experiment (DoE) Methodology Effectively Reduces Cost and Time to Completion of Complex Analytical Method Development

Patrick Kellish[1], Danielle Kling[1], Richard Smindak[1], Roger Herr[1], Bruce Thompson[2]
[1]Kincell Bio, Gainesville, FL, [2]Kincell Bio, Wake Forest, NC

Robust assays are a cornerstone of cell therapy program success, inclusive of process development through commercialization and ultimately supportive of product release to the patient population. Thus, assay development underpins a successful cell therapy program as it enables accurate and precise assessment of critical process parameters, ensuring therapeutic product consistency and effectiveness. Assay development, especially for complex cell-based assays, can represent a potentially prohibitive investment of time and money, especially for innovator companies focused on early phase programs. To help address this issue, Kincell Bio has adopted a Design of Experiment (DoE) methodology to optimize complex cell-based assays. This approach accelerates method development by allowing for assessment of more parameters in a single study than traditional one factor at a time experimentation. Moreover, DoEs facilitate a more resource-efficient use of experimental resources and precious raw materials, which ultimately reduces the overall cost of development. Through practical examples using DoE methodology to develop IFN-γ release, target cell killing, and IL-2 independent growth assays, we demonstrate how DoE techniques can lead to significant time savings, cost reductions, and improved decision-making in the development of robust analytical methods for cell therapy programs.

1318 Streamlined Virus Titration Workflow Enables Advancement of Upstream Process Development for AAV Producer Cell Lines

Michael Earle[1], **Darrick Yu[1]**, Jeong Lee
[1]Sanofi, Waltham, MA

Introduction: With recent advancements in high-throughput cell culture process development tools, there is an increased demand for high-throughput analytical assays to support process development (PD) for AAV mediated gene therapy to enable the fast pace of gene therapy programs. One measurement of interest for AAV PD is the vector genome titer in cell culture samples, as the productivity measurement. The manufacture of AAV with Producer Cell Lines (PCL) utilizes adenovirus as a helper virus, and it is necessary to know helper Ad byproduct titer for clearance during purification. Ad5 expression competes for resources with AAV affecting AAV productivity and presents challenges to the Ad5 removal steps during purification process at high levels. The ideal workflow for analytical methods supporting PD should be accurate, repeatable, reliable, high throughput, ergonomically friendly, highly flexible and possess a short turnaround time. We report a workflow established within Sanofi's Genomic Medicine upstream PD that exhibits these qualities, enabling rapid advancement of gene therapy programs utilizing PCL processes.

Methods: Cell culture samples were taken from bioreactors and lysed via Triton X-100 detergent based methods. Manual DNAse and proteinase K (PK) and treatment were performed to digest residual host DNA and release AAV DNA, respectively. Using the Lynx LM1200 liquid handler, the process steps after DNAse/PK were automated for ddPCR analysis. The Lynx was programmed using vendor software in two separate methods, post PK dilution and ddPCR setup. The performance of these automation methods was tested by a side-by-side comparison of manually prepared samples and liquid handled samples (n=11), samples were analyzed with two separate dilutions in triplicate. The multiplexing was performed by performing IDT's oligo analysis to determine compatibility of the two assays followed by comparison of single plex vs multiplex on the same set of samples (n=6), samples were analyzed with two separate dilutions in duplicate.

Results: The automated methods vs manual methods performed with an average of 7% difference in titer with the lowest being 2% and highest being 14% amongst the samples tested. In general, the titer was greater in the automation samples and resulted in a coefficient of variation on average of 7% compared to 5% for manual. Multiplexing the AAV and Ad5 assays when compared to their singleplex counterparts had an observed average % difference of 8% in Ad5 and 3% in AAV. As a result of automation, the throughput of plates analyzed by the BioRad QX200 workflow went from 3 to 6 per day. In terms of time saving, the automation reduced the hands-on time it took to perform the post PK dilutions and ddPCR setup for 6 plates from ~4 hours to just 1 hour. By multiplexing the AAV Ad5 assays, not only is the time of running two separate assays cut in half, but also the cost of reagents and plasticware. In addition, utilization of the liquid handler has reduced pipetting steps, resulting in improved ergonomics and the prevention of work-related injuries.

Conclusion: The workflow described has supported PD work for numerous gene therapy programs, enhancing the efficiency of cell culture operations and enabling rapid advancement of programs.

1319 Lentivirus Infectious titer – Scaling up and scaling out on a budget

Pouria Motevalian[1], Sarah Li[1], Daniel Millard[2], Dan Matuszek[1], Clifford Froelich[3]
[1]Thermo Fisher Scientific, Plainville, MA, [2]Thermo Fisher, Worcester, MA, [3]ThermoFisher Scientific, Plainville, MA

Lentiviral vectors (LVs) are widely used in both in vivo and ex vivo gene therapy applications, from direct patient administration to cell-based therapies such as CAR-T. As demand for high-quality, high-titer LV continues to grow, process optimization must be supported by robust analytical assays to ensure efficient viral production and potency. Among these assays, the Infectious Titer assay plays a critical role in decision-making, as it directly quantifies the number of functional viral particles capable of delivering the therapeutic gene. However, traditional infectious titer methodologies are labor-intensive, low-throughput, and lack scalability, limiting their utility in high-throughput process development. A more efficient, high-throughput approach is necessary to support the increasing complexity

of LV process development, where multiple conditions are evaluated in parallel using Design of Experiments (DOE) and automated bioreactor systems such as the Sartorius Ambr15.

To address this challenge, we adapted and scaled the Universal ddPCR-based Infectious Titer assay published by Kandell J, et al. (2023) to streamline the analytical process. Within our lab, the lack of automation in analytical systems created a bottleneck in testing material generated by the automated Sartorius Ambr15 system. We not only needed to implement the titration assay but also scale it up to: (1) handle 48 samples per week, (2) maintain a manageable material and cell load, (3) generate accurate, precise, and robust data to identify optimal conditions in a fully matrixed DOE system, and (4) streamline sample preparation and readout following the four-day infection period.

Here, we present our strategy for optimizing and scaling the assay, demonstrating how we transitioned from a 12-well to a 96-well format. This shift significantly reduced material requirements, ultimately lowering the cost of goods, while maintaining data quality. Additionally, we simplified the sample preparation process for ddPCR readout, improving workflow efficiency. As a result, what previously required five weeks to determine an infectious titer can now be completed in just one week. These advancements enable more agile and data-driven process development, facilitating the rapid optimization of LV manufacturing for gene therapy applications.

1320 Fit-for-Purpose Analytics for Novel Engineered Capsids: Advancing Precision in AAV Characterization

Jorge Santiago-Ortiz[1]*, Sisi Chen[1], Christopher Davis[1], Von Wiltman[1], Sampada Kalan[1], Ada Zhang[1], Jade Ganter[1], Anthony Stabile[1], Jessica Luo[1], Max Seaman[1], Megan Powell[1], Blake Albright[1], Max Ezekiel[1], Andrew Steinsapir[2]

Introduction: Engineered AAV capsids are designed to enhance tropism, immune evasion, and manufacturability, yet these modifications can introduce unique analytical challenges. Compared to natural serotypes, engineered capsids may exhibit altered physicochemical properties, including reduced thermostability and changes in binding affinity to antibodies used for purification or detection. These differences necessitate the development of fit-for-purpose analytical methods to ensure accurate quantification and characterization of key quality attributes such as genomic titer, capsid titer, and empty/full ratios.

Development of a ddPCR Method Compatible with Both Natural and Engineered Capsids: Engineered capsids may exhibit lower solubility and reduced thermostability compared to natural serotypes, which can introduce challenges in virus dilution and nuclease digestion steps—critical components of ddPCR workflows. To ensure accurate and reproducible genomic titer quantification across both natural and engineered capsids, a refined ddPCR method was developed that accounts for these physicochemical differences. The approach incorporates virus formulation buffer for sample pre-dilution to mitigate aggregation and minimize viral loss while also integrating EDTA treatment to control residual nuclease activity. These optimizations improve assay robustness and reproducibility, enabling precise titer quantification across different capsid variants. The method has been successfully applied to multiple engineered capsids, demonstrating high precision within recommended CV limits and suitability for drug product characterization and release.

Development of a Suitable Capsid Titer Assay: Evaluation of a commercially available AAV9 capsid ELISA kit confirmed its suitability for wild-type AAV9 but showed limitations in detecting certain AAV9-based engineered capsids due to reduced binding efficiency. To address this gap, an assay is being developed using alternative anti-AAV affinity reagents that offer broader applicability and improved binding across a diverse set of engineered capsids. Initial results indicate strong potential for this assay to provide accurate and reproducible capsid quantification.

Mass Photometry for Empty/Full Ratio Analysis: Mass photometry provides an efficient and powerful alternative for measuring empty/full capsid ratios, particularly in cases where full/empty estimations rely on genomic titer in

combination with capsid titer. This single-particle method enables direct measurement of AAV capsid populations without requiring antibodies, making it an effective approach for engineered capsids that may have altered binding properties. Suitability has been confirmed for AAV9, engineered capsids, and capsid libraries, demonstrating high precision and reproducibility across multiple operators and viral lots. Its implementation strengthens analytical workflows by providing a robust, label-free technique for evaluating AAV vector quality and manufacturing consistency.

Conclusion: The development of optimized analytical workflows compatible with both natural serotypes and engineered capsids ensures robust characterization of gene therapy vectors. These refinements align with regulatory expectations and enhance the reliability of engineered AAV drug product characterization, supporting efficient clinical translation and manufacturing scalability.

1321 Development of a ddPCR Assay to Quantify AXV-101 Levels for a Mouse Biodistribution Study

Victor Hernandez[1]*, Natalie Northcott[2], Marian Seda[3], Jeshmi Jeyabalan Srikaran, Rakhi Kesavan Nair Rema
[1]Axovia Therapeutics Inc, London, Greater London, United Kingdom, [2]Axovia Therapeutics Ltd, London, Greater London, United Kingdom, [3]Axovia Therapeutics Ltd, LONDON, London, United Kingdom
**Corresponding Author*

Introduction: As part of the Preclinical pipeline, a cohort of toxicology study mice were culled 30 days post sub-retinal injection and several tissues harvested post-mortem for analysis of AXV-101(an AAV9 BBS1 gene therapy) [VH1] biodistribution. Prior to sample arrival an in-house assay was developed by Axovia Therapeutics to determine baseline levels in naïve tissues, and upper and lower limits of detection for AXV-101. Tissue samples 'spiked' with ssDNA of AXV-101 were analysed to demonstrate that viral detection is possible from tissue samples, and show that there would be a difference in quantified levels between naïve and 'injected' tissue.

Methods: C57BL/6j mice were culled, tissues excised, snap frozen on dry ice, and stored at -80°C until processing. DNA was extracted using Meridian (feces) and Qiagen (all other tissue) kits. Nucleic acid levels were measured using a spectrophotometer. ddPCR assays followed a previously validated in-house protocol. On all plates positive controls, non-template controls (NTC), and dilution buffer blanks were included, and all test wells run in duplicate. AXV-101 virus stocks were used as positive control reference and spiking material. These were processed through DNase I and Proteinase K ddPCR steps to produce ssDNA ready for droplet generation. Five initial dilutions of spiking material were tested on a plate, starting with stock from the vial (dilution factor from DNase I and proteinase K processing steps) and progressing through a 10-fold serial dilution. The concentration was too high to be within the detection range of the assay until the lowest range, which was selected as the starting concentration for the next test plates, and further serially diluted alternating between 5-fold and 2-fold. Simultaneously, tissue sample was evaluated at different concentrations of DNA to test whether it influenced sample readout, and where a matrix effect might be observed. Eye tissue was selected as the test tissue due to its relevance for the study. A range of 130ng/ul to 0.25ng/ul was tested. After confirming appropriate dilutions for tissues and virus spike material, plates were run with both naïve and spiked tissue samples to compare baseline levels against simulated 'injected' tissues. Samples were all diluted to a concentration of 0.5ng/ul.

Results: AXV-101 levels in naïve tissues were comparable to NTC wells whereas spiked wells of the same tissues had copy numbers comparable to the lowest positive controls. (A,B,C) A viral dilution factor (DF) of 1.76E+07 was the upper limit for detection by ddPCR and sat above the top positive control. DF 8.80E+07 was selected for use as spiking concentration. The lower limits had copies per reaction concentrations comparable with NTC wells at a DF of 8.80E+10 and above. (E) We started to see erroneous results at the lower concentrations of virus in sample wells with DNA concentration 35ng/ul and higher. This increased with concentrations of 60ng/ul and above. (D,F)

Conclusions: The study objective was to develop protocols for ddPCR quantification of AXV-101 in mouse tissues. The data obtained have determined baseline levels in naïve tissues comparable to NTC samples and proven the difference in quantified levels between naïve and 'spiked' tissues with ssDNA of the reference material containing the same AXV-101 gene of interest. This supports the use of the assay in measuring biodistribution of AXV-101 in toxicology study samples.

1322 Validation of Real-Time qPCR Method for Vector DNA Quantitation from rAAV2-shmTOR in Rat and Monkey Tissues Samples

Kyoungsik Moon[1], Dong Ho Woo[2], Ye-Ji Kim[3], Sang-Jin Park[1], MI LANG KYUN[4], Yu Bin Lee[3], Myeongjin Choi[4], Keerang Park[5]

[1]Korea Institute of Toxicology, Daejeon, Korea, [2]Korea Institute of Toxicology, Deajeon, Korea, [3]Korea Institute of Toxicology, Daejeon, South Korea, [4]Daejeon, Korea, [5]Institute of New Drug Development Research, CdmoGen Co, KOREA

Recently numerous gene therapies have been already approved and launched for clinical use to treat rare and genetic diseases. Especially, viral vector-based gene therapy such as AAV have emerged as a promising and effective tool for gene transfer in treating neurological, ocular, and hepatic disorders. Preclinical safety evaluation of biodistribution/persistence for novel gene therapies is required for IND application with regulatory authorities. In general, the quantitative analytical method by polymerase chain reaction (qPCR) or droplet digital PCR (ddPCR) is highly suggested to evaluate biodistribution of viral vector gene therapies. In the present study, the objective was to validate a real-time QPCR method for detection of vector DNA from a recombinant AAV2 expressing an mTOR-inhibiting siRNA (rAAV2-shmTOR) in rat and monkey tissue samples. The validation was conducted to evaluate for specificity, linearity, accuracy, and precision. There were no interfering reacts with the targeted sequence between true positive and negative control (no template control) samples. The correlation coefficient of vector DNA were 0.999 and 1.000 ($1/x^2$ weighted) in rat and monkey tissue genomic DNA (gDNA), respectively. The limit of detection for vector DNA was also 50 and 25 copies/500ng of tissue gDNA, respectively. Furthermore, the accuracy and precision were verified < 20% CV in intra- and inter-assay analysis. Therefore, the analytical method was

quantitative with good linearity, accuracy and precision for vector DNA. In conclusion, the highly specific and sensitive qPCR analytical method for vector DNA from rAAV2-shmTOR was well-established in this study and could be also used in biodistribution/persistence studies in animals.

1323 The Fab Four -- Validated GMP QC Assays to More Reliably Assess DNA Impurities for rAAV Batch Release

Sabine Geiger[1]*, Felicia Thoennissen[2], Marina Magerl[2], Paul Zanotti[2], Sophie Beer[2], Renée Kober[2], Sonya Schermann[3]

During recombinant adeno-associated virus (rAAV) production, the majority of capsids efficiently encapsidate the intended full-length transgene cassette flanked by AAV inverted terminal repeats (ITRs). However, a small proportion of the packaged DNA consists of undesirable fragments which mainly originate from residual plasmid DNA or host cell genomic DNA. These impurities are an unavoidable byproduct of vector manufacturing, and regulatory authorities mandate their rigorous characterization and quantification to ensure that they do not compromise the safety profile and overall efficacy of the final therapeutic product.

In response to these regulatory requirements, we present a comprehensive panel of GMP-compliant QC assays specifically designed to assess DNA impurities in rAAV products. Developed in accordance with ICH Q14 and validated following ICH Q2(R2), our QC assay panel ensures reliable and accurate impurity profiling for batch release while reducing sample volume and costs for release testing.

The four GMP QC droplet digital PCR (ddPCR) assays include quantification of host cell-derived DNA (HCD) via the 18S rRNA gene (202 bp and 482 bp, with sizing) and plasmid-derived DNA impurities including Adenovirus E4orf6, AAV cap, and bacterial kanamycin resistance (kanR) gene sequences. The cap and kanR sequences are measured using a duplex ddPCR approach, allowing simultaneous detection of both targets in a single reaction, thereby saving time and sample material.

Unlike currently used qPCR methods for the assessment of host cell-derived impurities which often measure only a small fragment of the DNA to be quantified, our ddPCR sizing assay targets two distinct fragments of the 18S rRNA gene and allows sizing of DNA fragments up to approximately 500 bp in length, thus meeting recent demands of regulators. Additionally, our ddPCR assays do not require a standard curve for accurate quantification. This eliminates the need for generating and bridging GMP-grade standard material, simplifies the assay process and saves costs. Compared to traditional qPCR methods, ddPCR also offers superior resistance to matrix interference, enabling more reliable impurity quantification in complex rAAV product formulations.

We also highlight strategies to overcome key technical challenges in impurity testing, including the establishment of appropriate assay acceptance criteria.

This work underscores the critical importance of robust impurity profiling for rAAV gene therapy products and complements our EpyQ platform, which has been developed to minimize DNA impurities in AAV clinical batches. It provides a practical framework for developers and manufacturers seeking to enhance the quality, safety, and regulatory compliance of their therapeutic candidates, ultimately facilitating their journey toward clinical and commercial success.

1324 Consistent rAAV In-Process Monitoring with PEA-dPCR Technology

Chengjing Liu[1], Noah Elder[2], Kimberly Gomez[2], Cinta Gomez[2]
[1]Thermo Fisher Scientific, El Cerrito, CA, [2]Thermo Fisher Scientific, South San Francisco, CA

Recombinant adeno-associated viruses (rAAV) are widely utilized vectors for gene and cell therapies, requiring precise and consistent characterization of key attributes, including genomic titer, viral particle titer, and full/empty capsid ratio. The field currently lacks a single platform capable of consistently and accurately measuring these three attributes across various stages of rAAV manufacturing. To address these limitations, we developed a robust workflow utilizing Proximity Extension Assay (PEA) technology on the QuantStudio™ Absolute Q™ digital PCR (dPCR) platform, delivering consistent data across various stages of rAAV production.

rAAV6 was systematically tested across the entire production process using PEA-dPCR at the following stages: cell culture, tangential flow filtration, affinity chromatography, anion-exchange chromatography, and the final product. By quantifying three genome targets and viral particles collocated within dPCR microchambers, we calculated the capsid content ratio (Poster: Precise rAAV Capsid Characterization via Digital PCR and Statistical Modeling). This approach leverages the dPCR platform's resistance to inhibition from complex sample matrices, providing stable and reproducible measurements. Compared to other methods in the field, including ELISA, ddPCR, and ultracentrifugation, the PEA-dPCR workflow offers improved consistency and reliability across diverse process stages.

This consistency throughout the process allows for accurate tracking of AAV quality attributes, enabling better control and optimization during manufacturing.

In summary, our PEA-dPCR workflow provides a reliable and consistent method for monitoring rAAV production in less than one work shift, offering a significant advancement in characterizing viral capsid content ratio across diverse process samples. The PEA-dPCR workflow enables precise quantification of %full, %partial, and %empty capsids, offering researchers and manufacturers an advanced tool for rAAV sample characterization. This innovative approach ensures robust and consistent results, addressing critical challenges in AAV analytics and supporting the development of high-quality gene therapy products.

1325 Determination of sgRNA and mRNA Sequence Identity by Ion-Pair Reversed-Phase Chromatography Coupled With High-Resolution Tandem Mass Spectrometry

Tran Pham[1], Roxanna Eggleston-Rangel[2]
[1]Phenomenex, Inc. - Torrance, CA, Fallbrook, CA, [2]Phenomenex, Torrance

RNA vaccines and CRISPR-based gene editing are two breakthroughs used to fight SARS CoV-2 and numerous genetic diseases. The safety and efficacy of RNA vaccines and CRISPR-based gene editing therapeutics highly depend on the stability and purity of the RNA final product. Drug developers are often challenged with accurately characterizing these nucleic acid modalities and finding comprehensive solutions remains a gap. IP-RP chromatography is the current method of choice, but conventional approaches are not often sufficient for longer RNAs such as sgRNA and mRNA. Here, a sgRNA targeting the BRAC1 and Cas9-mRNA were used as model systems and enzymatically digested to be analyzed by IP-RP chromatography coupled with HRMS. This workflow shows full sequence identification and chromatographic resolution of impurities and Phosphorothioate (PS) diastereomers of sgRNA. Similarly, Cas9-mRNA sequence identification was achieved in 5'-UTR / 3'-UTR regions, 5'Cap, and Poly-A tail, all while revealing partially capped species, deletions, and Poly-A heterogeneity.

1326 Dual-Platform NGS for Comprehensive Characterization of Engineered rAAV Vector Integrity

Zach Mason[1], Jesse Granados[1], Leandro Fernandez[1], Hari Acharya[1], Mark Chin[2], Lysa-Anne Volpe[3]*
[1]Capsida Biotherapeutics, Inc., Newbury Park, CA, [2]Capsida Biotherapeutics, Inc, Newbury Park, CA, [3]Capsida Biotherapeutics, Inc., Thousand Oaks, CA

Recombinant adeno-associated virus (rAAV) vectors represent one of the most promising delivery systems for gene therapy. The demand for engineered rAAV capsids with improved target tissue tropism and reduced toxicity is rapidly growing as clinical pipelines expand to treat both rare and common diseases. As such, the need for precise, robust, and reproducible analytical methods is essential for characterizing viral vectors, accurately detecting full-length viral genomes, and identifying residual DNA species in vector drug products. Short-read sequencing delivers high-resolution and high-throughput data, providing accurate quantification of genetic heterogeneity. However, it struggles to resolve structural variations, repetitive elements, and homopolymeric regions, which limits its ability to fully characterize genomic complexity. Long-read sequencing technologies, such as PacBio and Oxford Nanopore, enable comprehensive characterization of viral genome structure and length but lack the throughput and quantitative precision of short-read sequencing.

We have developed a dual-platform sequencing strategy that integrates long-read and short-read technologies for orthogonal analysis of novel engineered rAAV vectors with a focus on packaging efficiency and analytical performance. This integrative approach facilitates robust assessment of vector genome integrity by evaluating ITR states, alignment terminal hotspots, vector-size distributions, structural variants, and residual quantifications, all of which can critically influence potency, purity, and safety of gene therapy products. Evaluation of results is compared with standard analytical methods, including PCR-based quantifications, gel electrophoresis, and analytical ultracentrifugation (AUC). This hybrid sequencing approach, integrated with our data analysis framework, enhances sequence resolution and enables comprehensive viral payload characterization, offering greater detail and higher throughput than single target assays. It delivers precise encapsidated DNA measurements, streamlines quality testing, and enhances efficiency in process development and manufacturing workflows.

1327 Adapting a Replication Competent Lentivirus (rcLVV) Assay for Commercial Manufacturing

Brian Tomkowicz[1], Leann Walsh[1], Alok Upadhyay[2], Oxana Tsygankova[3], Dana Cipriano[4]
[1]SK Pharmteco - US, King of Prussia, PA, [2]SK Pharmteco, Mount Laurel, NJ, [3]CFBM, King of Prussia, PA, [4]SK Pharmteco, King of Prussia, Pennsylvania

A universally applicable assay to monitor the emergence and estimate the frequency of recombination events during commercial manufacturing is required. Herein, we report on the development and application a cGMP-compliant, dual cell-based PCR and p24 antigen ELISA assays to detect the emergence of replication competent lentiviruses (RCLs) in manufactured viral vectors and gene-mediated cell therapy products. Lentiviral vectors, derived from HIV-1, are widely used for gene therapy due to their ability to deliver genetic material efficiently. While these viral vectors are designed to be replication-deficient, there still poses a risk that recombination events during vector production could generate RCLs. Thus, even a trace presence of RCLs can pose significant safety risks when administered to patients including insertional mutagenesis, immune responses, and chronic infections. This assay incorporates a dual detection method using droplet digital PCR (ddPCR) and p24 antigen ELISA to ensure high sensitivity and specificity. The validation process confirmed the absence of RCL in tested samples across multiple amplification and indicator phases, demonstrating the assay's robustness. This comprehensive detection strategy meets regulatory standards and enhances the safety profile of lentiviral vector-based therapies for clinical applications.

1328 Rapid Cell-Specificity and Integration Safety Profiling of AAVs

Alex Hale[1]*, Claire Tebbutt[2], Valerie Ferreira[1]*, Mark Aspinall-O'Dea[3], Caitlin Edwards[4]*, Daniel Rocca[5], Christopher Kirkham[5], Michael Templin[6], Roxana Redis[7]
[1]Charles River Laboratories, Leiden, Zuid-Holland, Netherlands, [2]Charles River Laboratories, HIGH PEAK, Derbyshire, United Kingdom, [3]Charles River Laboratories, High Peak, United Kingdom, [4]Charles River, BOLTON, Greater Manchester, United Kingdom, [5]Charles River Laboratories, Portishead, United Kingdom, [6]Charles River - Reno, Reno, NV, [7]Charles River Laboratories, Leiden, Netherlands

With more than 200 AAV (Adeno-Associated Viruses) vectors in clinical trials (1), AAV gene therapies will soon become the predominant approach for delivery of gene therapies. However, demonstrating specificity and safety, in the form of cell type specific targeting/binding and lack of random genomic integration of the AAV, remains a laborious and complex challenge. Here we describe a novel combinatory process using cell microarray, digital droplet PCR (ddPCR), linear amplification mediated (LAM) PCR technologies to rapidly screen and validate AAV cell specificity and genomic safety, thus facilitating the identification of lead AAV candidate(s) for gene therapy payload.

First, a functional binding screen is performed using Charles River's Retrogenix® Cell Microarray technology, consisting of >6,500 full length human cell surface secreted and heterodimeric proteins over-expressed in HEK293 cells (2), to identify cell surface receptors with which AAV variants bind, thus identifying the on- and off-targets of the AAV variants compared to wild-type. Second, the therapeutic target patient-derived cells are treated with the 5-10 hit AAV variants and the viral vector transduction efficiency and functional transgene expression of each is quantified in a single ddPCR assay by measuring both AAV vector DNA and functional transgene mRNA. Relevant other cell types expressing the off-target cell surface receptors identified from the Retrogenix® Platform are included to compare the levels of viral vector transduction efficiency and transgene expression that occur. In the final step, the lead AAV variant candidate, selected on highest on-target viral vector transduction efficiency, transgene expression, and selectivity, is assessed for potential genomic integration using NGS of LAM-PCR products and integration site analysis (ISA) (3).

This streamlined process helps to de-risk therapeutic candidates by providing a rapid and cost-effective way to produce the key supporting safety data required for investigational new drug submissions. This accelerates the safe development of personalized AAV therapies for n-of-1 rare disease studies and makes them more accessible.

1329 Gene Therapy Studies and Germline Integration Assessment Considerations in Preclinical Research

Kaylyn Koenig[1], Norbert Makori[2], Francesca Barone[3], Karlin Morse[1], Petronella Magunda[1]
[1]Altasciences Preclinical Seattle LLC, Everett, WA, [2]Altasciences, Laval, QC, [3]Altasciences Preclinical & Bioanalysis Services, Sacramento, CA

Introduction: Gene therapies targeting rare genetic conditions and disorders are on the rise. While somatic or tumor cell targets are often the aim of these therapies, risk of germline integration of the vector target sequence in gametic cells is of recent safety and regulatory awareness. With the intent to confirm zero target germline integration, *in vivo* sample collection must be performed with precision and optimal nucleic acid isolations are required.

Methods: Preclinical gene therapy studies are conducted on sexually mature laboratory animals, including nonhuman primates (NHPs), canines, and minipigs. A 6-12 month observation period follows gene therapy administration. Semen is collected at various study timepoints for downstream nucleic acid isolations. Two sperm

cell separation techniques were compared for feasibility and preservation of nucleic acids present: (1) whole cryopreservation method, where whole semen samples were collected, flash frozen, and then thawed prior to washes and nucleic acid isolation; and the (2) swim-up method, where fresh semen was incubated with a 'swim-up' buffer where the sperm cells are separated from the extraneous cells contained in semen; the sperm fraction is then flash frozen and preserved for nucleic acid isolations. For females, ovaries are collected at necropsy and the tissue is manually disrupted under a microscope to isolate individual oocytes; extraneous cellular/tissue debris is removed and 'clean' oocytes are collected and flash frozen for downstream isolation procedures. DNA and RNA are isolated from both frozen sperm and oocytes.

Results: Semen yielded an average of 10^8 purified sperm cells per collection, which yielded between 120 and 4404 ng of DNA. Of the two methods evaluated, the whole cryopreservation method resulted in higher sperm cell isolation and subsequent DNA yields as compared to the swim-up method. Notably fewer gametic cells were obtained from female ovaries; averaging 72 oocytes per ovary. Accordingly, lower DNA yields of 140-892 ng and RNA yields of 72-800 ng were obtained.

Conclusions: Successful and meticulous collection of gametes from *in vivo* test models will be applied to ongoing and future gene therapy studies to assess potential vector target germline integration. These collections and isolations procedures pave the way for and impact preclinical industry standards for sufficient assessments of gene therapies with regard to risk of potential germline integration.

1330 Interlaboratory Assessment of Candidate Reference Materials for Lentiviral Vector Copy Number and Integration Site Measurements

While lentiviral vectors have played a critical role in the emergence of gene-modified cell therapies, safety concerns remain regarding potential insertional mutagenesis. Regulatory authorities strongly recommend risk assessment and management of vector copy numbers (VCN), integration profiles, and integration sites in the lentivirus-based cell and gene therapy products. However, accurately measuring these parameters remains a significant challenge due to the lack of standardized methodologies and VCN reference materials (RMs). Toward this challenge, we conducted an interlaboratory study on NIST candidate RMs for VCN measurements. The candidate RMs comprise of five human genomic DNA samples or fixed cells from clonal Jurkat cell lines with defined VCNs ranging from 0 to 4. All 12 study participants were able to identify the VCN in the five blinded samples using quantitative real-time PCR (qPCR), digital PCR (dPCR) or next generation sequencing (NGS) assays. Consensus value of VCN and integration sites in these candidate RMs were achieved. The fixed clonal VCN cells were also used to evaluate an emerging imaging-based technology called molecular combing. This interlaboratory assessment demonstrated the utility,

commutability, and suitability of the NIST VCN candidate RMs for quality assurance and improved confidence in VCN, integration profile, and integration site measurements.

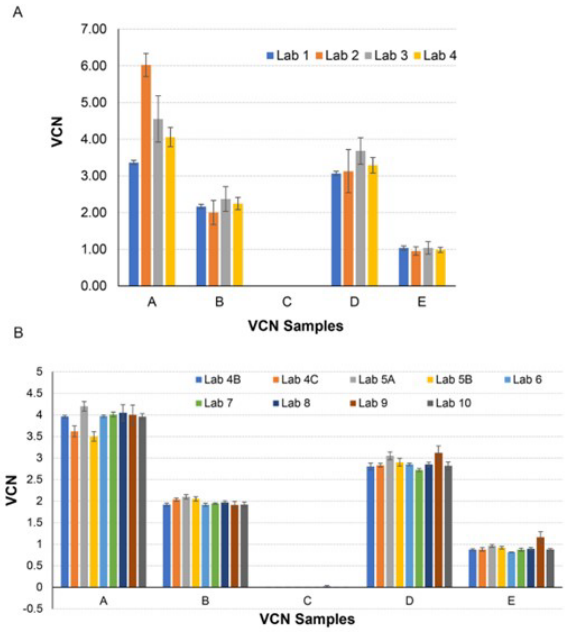

Figure 1. qPCR and dPCR Interlaboratory study results of NIST candidate reference materials.

A) For qPCR, the copy concentration of target and reference genes were analyzed by using individual laboratories' standard curve and raw Cq data. The VCN values were calculated based on the ratio of copy concentration of target and reference genes. The error bar is the standard deviation (N>=6)

B) For dPCR estimates calculated using individual laboratories' protocol, such as provirus targets and reference gene selection. The error bar is the standard deviation (N>=3)

5 samples: A (VCN4), B (VCN2), C (VCN0), D (VCN3), and E (VCN1).

Three laboratories evaluated LV integration sites for candidate materials using NGS based methods following individual laboratories' in-house protocols. Table 1 shows identical integration sites were detected by all three laboratories for 10 integration sites in 5 samples from Sample A (VCN4), B (VCN2), C (VCN0), D (VCN3), to E (VCN1). Surprisingly, the initial results from all three laboratories only reported partially identical integration sites. Strikingly, all three labs reported a site in chr16: 2,259,702 instead of the expected chr4: 5,612,738 for Sample A (or VCN4), that was published previously when these clonal cell lines were established (* Paugh, B. S. et al. Reference standards for accurate validation and optimization of assays that determine integrated lentiviral vector copy number in transduced cells. *Scientific Reports* 11 (2021). https://doi.org/10.1038/s41598-020-79698-w)

1331 Development and Validation of a Replication Competent Virus Safety assay for Adenoviral products

Brynne Pergolini[1], Casey MacArthur[2], Morgan Rogers[2], Katie Kelly[1], Han Thach[1], Leann Walsh[3], Brian Tomkowicz[3], **Alok Upadhyay[4]**, Christopher Larson[2], Dana Cipriano[5]
[1]Testing and Analytical Services, SK Pharmteco, King of Prussia, PA, [2]SK Pharmteco, King of Prussia, PA, [3]SK Pharmteco - US, King of Prussia, PA, [4]SK Pharmteco, Mount Laurel, NJ, [5]SK Pharmteco, King of Prussia, Pennsylvania

Recombinant Adenoviruses are powerful vectors for gene therapy and vaccines, offering efficient gene delivery. However, the generation of replication-competent adenoviruses (RCAs) during vector production poses a significant safety risk. RCAs can replicate autonomously, leading to potential adverse events such as viral infection, unintended replication, and host inflammatory responses in patients. Therefore, sensitive and robust RCA detection assays are crucial for ensuring the safety and efficacy of adenovirus-based therapies. We developed and validated a cell-based RCA assay to detect replication-competent adenoviruses in viral vector preparations. This assay utilizes A549 cells and incorporates two culture formats: roller bottles and flasks. The assay involves infecting cells with the test article, a wild-type Ad5 positive control, and a negative control. During 28-day incubation period, cytopathic effects (CPE) are monitored and confirmed using immunofluorescence. Prior to assay initiation, test articles are assessed for non-toxic Multiplicity of Infection (MOI) to avoid cytotoxicity. The assay demonstrated high sensitivity and specificity in detecting the presence of RCAs. The validation process confirmed the absence of RCA in the tested samples. This validated method is GMP-compliant and meets regulatory requirements for ensuring the safety of adenovirus-based gene therapy products. This robust and reliable assay plays a critical role in the quality control of adenovirus-based therapeutics, minimizing the risk of adverse events and ensuring patient safety.

1332 Automation of AAV Capsid ELISA on Tecan Fluent

Sarah Tong[1], Bisma Ajaz[2], Peter Webster[2]
[1]Solid Biosciences, Charlestown, MA, [2]Solid Biosciences, Cambridge, MA

Utilizing robust analytical methods for product characterization is of paramount importance in AAV gene therapy development. A widely employed analytical method for measuring a recombinant AAV product's capsid titer is an enzyme-linked immunosorbent assay, or ELISA. Capsid titer results, particularly its role in determining empty/full capsid ratios, help to optimize upstream and downstream processes, and may be informative for maintaining consistency in manufacturing lots used for clinical administration.

Due to the nature of the method, capsid ELISA is a difficult assay to perform correctly. Because of its time sensitive incubation periods, precise pipetting to avoid binding disruption, and repetitive wash steps, the method requires long periods of intensive labor to produce accurate data. Furthermore, the assay has a low sample throughput with a high demand for results. It takes a minimum of 4 hours to run one plate of capsid ELISA, with much of this time spent diluting reagents or samples for the next step of the assay. Samples have a failure rate of approximately 30%, either because the capsid ELISA plate fails system suitability criteria, or the sample does not pass acceptance criteria for reporting due to high % CVs. Despite increasing requests for capsid data to aid process development (oftentimes upwards of 48 samples per week), the current throughput is only a maximum of 8 samples per plate at a time, and analysts can rarely run more than one plate at a time. The high failure rate and the expensive reagents make capsid ELISA an extremely costly assay to re-run.

Automation of capsid ELISA on a liquid handler can readily address some of the method's main complications. Automated liquid handlers mitigate human error, allow scientists to redirect their focus and time towards other tasks, and enhance sample throughput efficiency. In this study, an in-house AAV capsid ELISA method was programmed onto a Tecan Fluent automated liquid handler. 24 samples from varying stages in the production process and with a range of expected titers from e10 to e14 capsids/mL were run on the Tecan. Results demonstrated automated AAV

capsid ELISA performed superior to manual AAV capsid ELISA, resulting in an increase in sample throughput and consistency. The Tecan Fluent increased the method's sample throughput by up to 300% because of its capacity to run plates in parallel. Additionally, there was an average capsid titer variability of 4% amongst samples that were re-run on the Tecan to test consistency, and all samples passed acceptance criteria for reporting.

AAV capsid ELISA, along with other types of ELISAs, are highly sensitive and repetitive methods that see extensive usage, thereby making them strong candidates for automation on a liquid handler. The successful transfer of a manual AAV capsid ELISA method to the Tecan Fluent automated liquid handler supports utilizing preexisting workflows and technical concepts to automate other types of ELISAs in a product characterization panel, as well. The automation of ELISAs may lower costs, generate more sample data faster, and increase productivity for scientists, ultimately improving the AAV gene therapy development process.

1333 *Comparative Analysis of Total Antibody Titer and Neutralizing Antibody Titer: Correlation and Implications for AAV-Based Gene Therapies*

Martin März[1], Silja Adam[2], Kirsten Prestel[3], Lea Hupe[3], Iris Queitsch[3], Juan del Rio Martinez[3], Adil Jafarov[3], Zoi Edinger[3], Jeff Nelson[4], Klaus-Ingmar Pfrepper[3], Dana Holzinger[5]
[1]PROGEN, Heidelberg, Baden-Wuerttemberg, Germany, [2]PROGEN Biotechnik GmbH, Heidelberg, Baden-Wuerttemberg, Germany, [3]PROGEN, Heidelberg, Germany, [4]Promega Corporation, Madison, WI, [5]Progen Biotechnik GmbH, Heidelberg, Germany

Today, AAV-based gene therapy still remains one of the most promising and fastest growing branches of modern medicine. However, the prevalence of anti-AAV antibodies in patients limits the efficacy and safety of gene transfer using rAAV vectors. Therefore, it is indispensable to test patients eligible for AAV gene therapy for preexisting AAV antibodies. Two types of assays can be used for this purpose, (1) binding assays that measure total antibodies, including both neutralizing (NAbs) and non-neutralizing antibodies (nNAbs) and (2) neutralization assays that specifically detect neutralizing antibodies.

In this study, AAV antibody responses were analyzed by (i) an AAV serology ELISA for determination of total IgG and (ii) an neutralization assay for the most commonly used AAV serotypes (AAV2, AAV6, AAV8 and AAV9). AAV seroprevalences were calculated and the correlation was compared.

For the seroprevalence study, a cohort of 100 human serum samples from healthy donors were tested for pre-existing anti-AAV antibodies. 18% of the samples were tested IgG seropositive for all tested AAV serotypes 2, 6, 8 and 9. Among all AAV serotypes included in this study, AAV2 was the predominant serotype with 45% seropositive individuals.

Out of this cohort, ten serum samples, including positive, negative and borderline samples, were additionally tested for neutralizing antibodies for AAV2, 6, 8 and 9, using AAV-NanoLuc® viral particles. The EC_{50} value, which indicated the existence of neutralizing antibodies, was then compared to the results gained with the total antibody (TAb) ELISA.

Across all serotypes 92% of TAb positive samples exhibited neutralizing activity. Only two serum samples that tested positive in the total IgG ELISA showed no detectable neutralizing titer for AAV2 and AAV8. This suggests that the antibodies present in these samples are non-neutralizing. Thus, TAb ELISA and the NAb assay showed a strong correlation in this experimental set up. This observation correlates well with percentages reported in the literature, as the prevalence of TAbs is generally considered to be higher since a moderate percentage of TAb positive samples contain low to undetectable NAb titers. However, more research is needed to understand the correlation of TAb levels and their clinical impact in AAV based gene therapies.

1334 *AAV Serology ELISA for Testing Pre-Existing Immunity to AAV*

Martin März[1], Silja Adam[2], Iris Queitsch[3], Juan del Rio Martinez[3], Adil Jafarov[3], Kirsten Prestel[3], Zoi Edinger[3], Lea Hupe[3], Kirsten Coleman[4], Rebecca XICLUNA[5], Alisa Bowen[6], Klaus-Ingmar Pfrepper[3], Dana Holzinger[7]
[1]PROGEN, Heidelberg, Baden-Wuerttemberg, Germany, [2]PROGEN Biotechnik GmbH, Heidelberg, Baden-Wuerttemberg, Germany, [3]PROGEN, Heidelberg, Germany, [4]University of Florida, [5]F.Hoffmann-La Roche Ltd, Basel, Switzerland, [6]4D Molecular Therapeutics, Emeryville, CA, [7]Progen Biotechnik GmbH, Heidelberg, Germany

Recombinant adeno-associated virus (rAAV) vectors are leading tools for *in vivo* gene therapy. Depending on socio-demographic factors and geographic region, a high proportion of the general population has developed antibodies against various AAV capsids as a result of naturally acquired infections. However, presence of these antibodies can directly affect efficacy and safety of gene transfer using rAAV vectors. Furthermore, antibody levels after rAAV mediated gene therapy might differ compared to those after naturally acquired infections. Thus, testing for pre-existing AAV antibodies in sera is of significant importance for ensuring patient safety and evaluating the efficacy of gene therapy. Monitoring antibody levels after gene transfer and comparing with AAV antibody levels in the healthy population will provide comprehensive data on the natural history of AAV infections as well as immunogenicity in patients after gene therapy.

Currently, PROGEN is developing AAV serology ELISAs for the most commonly used AAV serotypes (AAV2, AAV5, AAV6, AAV8 and AAV9). These antigen-capture assays offer a fast, sensitive and reproducible method for the quantification of total IgG antibodies against AAV in human sera. The assays contain recombinant human chimeric antibodies to generate a standard curve, making them reliable and reproducible. As the kits have a quantitative read-out [in units, (U)], they are useful for patient pre-screening, comparing antibody levels between individuals, and determining antibody kinetics during the course of infection or after systemic gene therapy administration. Additionally, commercially available assays may offer a means to harmonize results between clinical trials, and streamline regulatory hurdles associated with development of individual assays for each gene therapy product.

Here, we show assay data on the detection range, linearity, inter-operator variability, and inter-lab variances for our newly developed AAV2, 6, 8 and 9 serology ELISAs.

1335 *Addressing Pre-Existing Immunity in AAV Gene Therapy: Automation of Serology ELISAs*

Joshua Baal[1], Ina Berger[2], Juan del Rio Martinez[3], Klaus-Ingmar Pfrepper[3], Martin März[4], Dana Holzinger[2]
[1]PROGEN Biotechnik GmbH, Heidelberg, Baden-Wuerttemberg, Germany, [2]Progen Biotechnik GmbH, Heidelberg, Germany, [3]PROGEN, Heidelberg, Germany, [4]PROGEN, Heidelberg, Baden-Wuerttemberg, Germany

The increasing prevalence of gene therapies based on adeno-associated virus (AAV) vectors highlights their potential in modern medicine. However, naturally acquired infections have led to the development of AAV-specific antibodies in a significant portion of the population, with variations influenced by socio-demographic factors and geographic regions. The presence of these pre-existing antibodies poses challenges for the efficacy and safety of rAAV-mediated gene transfer, making it essential to assess patient sera for AAV antibodies prior to therapy.

To address this need, PROGEN developed AAV serology ELISAs targeting the most commonly used AAV serotypes, including AAV2, AAV5, AAV6, AAV8, and AAV9. These antigen-capture assays provide a rapid, sensitive, and reproducible platform for quantifying total IgG antibodies against AAV in human serum samples. Given the increasing demand for high-throughput analysis due to the growing number of samples and limited processing time, automation of these assays offers a practical solution. Automated systems can reduce human error, variability, and hands-on time, enabling more efficient large-scale sample characterization.

To demonstrate the suitability of our AAV serology ELISAs for high-throughput applications, we tested the AAV2 and AAV9 assays exemplarily on an automated platform. Key performance parameters such as plate homogeneity, intra- and inter-assay variability, and recovery rates were assessed for the automated method and compared with results from manual processing.

The automation of our AAV serology ELISA has been demonstrated as an effective solution for high-throughput analysis of AAV antibodies in human serum samples. The results confirm that the automated system preserves accuracy and reproducibility while significantly improving analytical efficiency.

1336 Screening for Pre-Existing Immunity Against AAV Vectors: A Multipronged Approach

Shian-Jiun Shih[1]*, David Hsieh[2], Lichun Huang[2]
[1]Cellentia, Inc., Foster City, CA, [2]Cellentia, Inc., Foster City
Corresponding Author

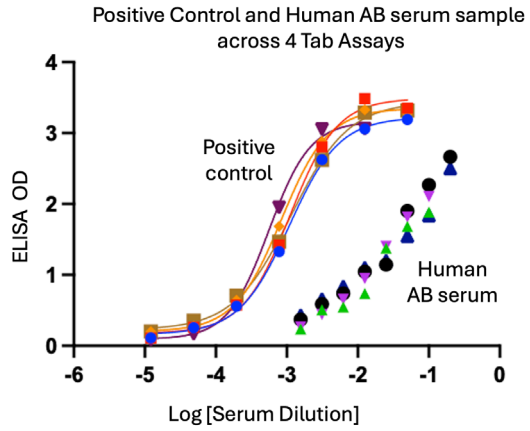
The high prevalence of pre-existing immunity to adeno-associated virus (AAV) in the general population presents a significant challenge for AAV-mediated gene therapy. A robust screening tool is needed to assess neutralizing activity in patients prior to treatment. Cellentia has developed a multi-tiered strategy to evaluate AAV immunity, beginning with the measurement of total antibodies (Tab) against AAV, followed by a neutralizing antibody (Nab) assay that assesses inhibition of 293T cell transduction. An in vivo confirmatory assay is then used to establish an appropriate cutoff for pre-existing immunity.

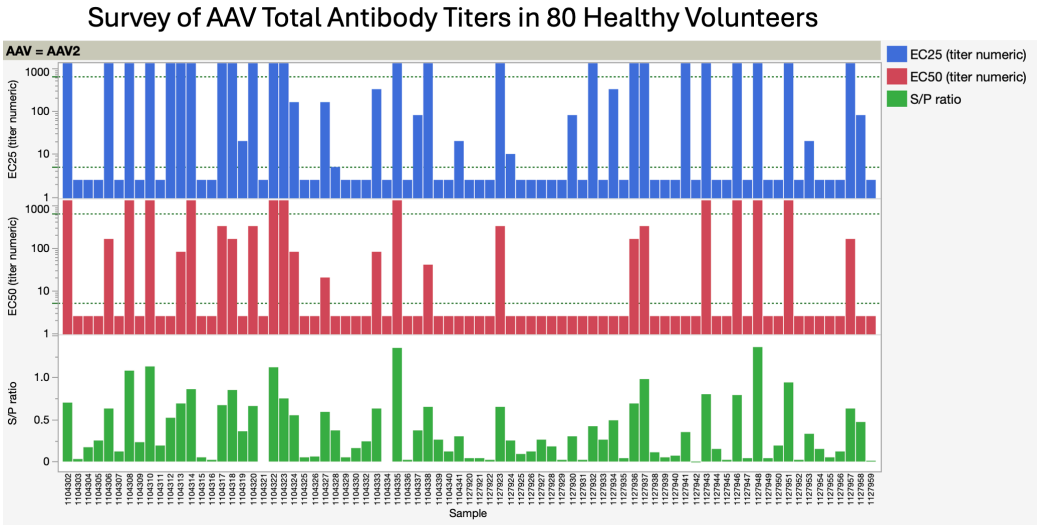
To ensure accurate Tab detection, we developed an in-house ELISA with direct AAV particle immobilization. Specificity, reproducibility, and assay performance were validated, with response curves optimized using a four-parameter model. To enhance data reliability, we implemented algorithms to correct the hook effects at high concentrations and detect statistical outliers in triplicate wells per titration.

We analyzed 80 serum samples from healthy donors for AAV2, AAV9, and other serotypes using our direct sandwich ELISA. Samples that consistently exhibited strong signals across tested serotypes were further evaluated, and one sample was selected as the positive control, while those with negligible or no response were also screened to identify one negative control. The final assay format incorporates both controls in Tab assays for AAV1, 2, 5, 6, 8, and 9, ensuring standardization across assays. Positive control response curves were further utilized to estimate sample titers.

To facilitate comparison, we reported antibody prevalence using three readouts: titers based on two pre-set cutoff values and the sample-to-positive control (S/P) ratio based on the positive control analyzed in the same assay. The prevalence of total antibodies against AAV2 ranged from 30-50%, while AAV9 exhibited a lower prevalence of 20-40% in the tested population, depending on the titer reporting method used. Serum samples with negative or borderline results were further assessed using a 293T cell-based neutralization assay, confirming negativity in most cases, with one sample showing modest inhibition.

These samples are planned for in vivo neutralization testing in mice to evaluate transduction efficiency in the target organ and determine the final acceptance criteria for AAV vector administration. Once a definitive cutoff is established, we aim to refine our ELISA into a streamlined assay tailored for rapid preclinical and clinical screening, facilitating rapid evaluation of pre-existing immunity to novel AAVs in both animal models and target patient populations.





1337 Molecular characterization of acute lymphoblastic leukemia in Tanzania

Jeffer Bhuko[1]*, collin nzunda[2], Erius Tebuka[3]
[1]Muhimbili University of Health and Allied Sciences, Dar Es Salaam, Dar-es-Salaam, Tanzania, [2]Muhimbili University of health and allied sciences, Dar es salaam, Tanzania, [3]Catholic university of health and allied sciences, Mwanza, Dar-es-Salaam, Tanzania
**Corresponding Author*

Introduction: Acute lymphoblastic leukemia (ALL) cancer diagnosis may be improved by using targeted therapies of tyrosine kinase inhibitor (TKI) management for gene translocation for p190 Philadelphia (BCR-ABL) positive and somatic mutations referred to as single nucleotide variants (SNVs). Molecular diagnosis has led to targeted therapies of specific molecular profiles. The frequency of somatic pathogenic mutations related to ALL in adult and pediatric patients, the uniformity of p190 Philadelphia q-PCR methods with Next Generation Sequencing (NGS), and the clinical presentation and behaviour of ALL patients with the noticed mutations.

Methods: A cross-sectional study from Muhimbili National Hospital and Bugando Medical Centre used samples that were initially suspected of being ALL cancers based on cellular morphology. The study was carried out at the Muhimbili University of Health and Allied Sciences. The two-year study conducted from August 2023 until June 2025. Using a panel of monoclonal antibodies conjugated to fluorochromes (FITC, PerCP, and PE) and the proper isotype controls in accordance with the Euroflow panel guidelines, practice flow cytometry. Library preparation

performed using the AmpliSeq for Illumina Myeloid Panel sequencing. To filter out variants with a higher likelihood of being common benign variants, performing exclude variants with an allele frequency greater than 0.1 in the African population from the Genome Aggregation Database (gnomAD) database. This filtering step helps prioritize potentially pathogenic variants for analysis.

Results: Preliminary findings 21(48%) ALL patients currently recruited, 17(39%) ALL samples currently sequenced. Translocations identified in 5(11%) samples BCR - ABL1 rearrangement from the NGS against 3(7%) from q-PCR of the same group patients. Target ID T00653 breakpoint A chr22:23524426, breakpoint B chr9:133729451, patient currently on going with TKI management. 10(22.7%) had pathogenic mutation deletion variant out of 17 sequenced; the somatic variants where JAK2, and CREBBP.

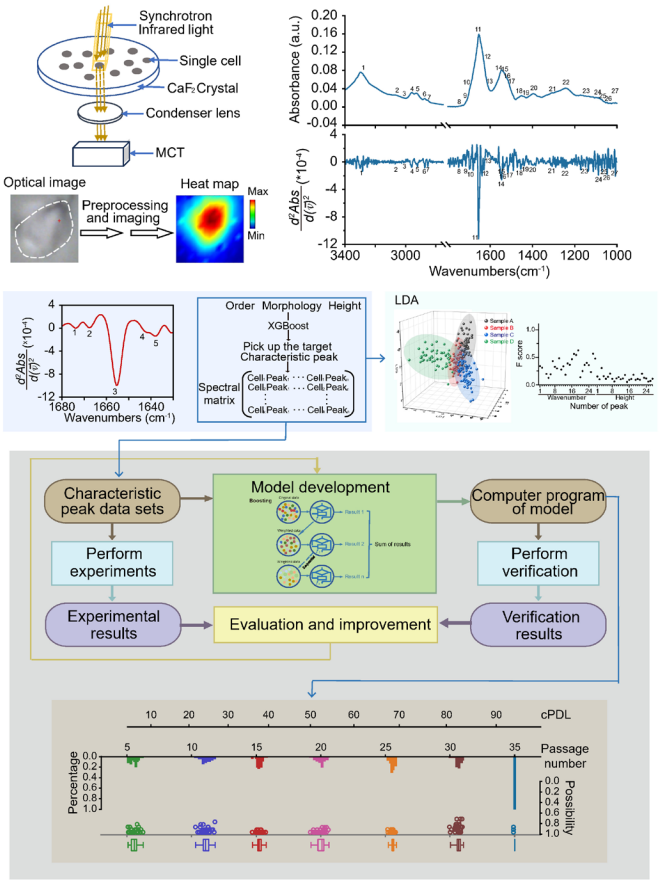
Conclusion: Describe the most common somatic pathogenic mutations in acute lymphoblastic leukemia that are presently unidentified in Tanzania and the molecular profile that determines whether or not these mutations are associated with poor or favourable outcomes for targeted therapy in ALL.

1338 Deploying Fourier-transform infrared spectral signatures and machine learning to standard cell identities and ages (SCIAGE)

Jian Zhao[1]*, Yulei Deng[2], Junwu Tu[3]
[1]Shanghai Clinical Research and Trial Center, Shanghai, Shanghai, China, [2]Ruijin Hospital affiliated with Shanghai Jiao Tong University School of Medicine, Shanghai, China, [3]ShanghaiTech University, Shanghai, China
**Corresponding Author*

Translating cell-based therapies from laboratory to clinic faces significant challenges, particularly in maintaining cellular integrity during the culturing process and large-scale expansion. Current characterization methods lack standardized "snapshot" measurements of cellular biological states, hindering optimization for therapeutic efficacy. Here, we reported SCIAGE (Standard Cell Identities and Ages), a framework integrating transmission Fourier-transform infrared (FTIR) single-cell microspectroscopy and machine-learning techniques. Firstly, an automatic data-capturing program was developed for extracting the intrinsic FTIR spectral variables corresponding to cellular biomolecular components. Linear discriminant analysis revealed distinct segregation among different cell types, cells from different donors, and cells at various culture cycles, indicating FTIR spectra could serve as label-free cellular molecular fingerprints. We then developed SCIAGE using the eXtreme Gradient Boosting algorithm, based on FTIR spectral variables of neural progenitor cells (NPCs) at different population doubling levels (PDLs). SCIAGE demonstrates highly accurate quantitative characterization of NPCs across various PDLs and effectively characterizes aging states of NPCs subjected to obscured senescence-induction or anti-aging treatments. Together, SCIAGE provides a phenotyping technique for robust cell characterization, sensitive and accurate cell aging state detection and comparison, thereby addressing the critical gap in current cell characterization methods, and potentially accelerating the development and optimization of cell-based therapies.

Graphical abstract



1339 Application of Mass Photometry to Characterize Adeno-associated Virus Particle Content

Christopher Gough[1], Nigel Moore[1], Karaiman Feroz[1], Christopher Larson[1], Alok Upadhyay[2]*
[1]*SK Pharmteco, King of Prussia, PA,* [2]*SK Pharmteco, Mount Laurel, NJ*

Mass Photometry (MP) is a label-free bioanalytical technique utilizing interference reflection microscopy and interferometric scattering microscopy to measure single molecules in solution. This study demonstrates the application of MP for the characterization of adeno-associated virus (AAV) vectors, specifically quantifying empty, partially filled, and full capsids. Compared to traditional methods like analytical ultracentrifugation (AUC) and electron microscopy (EM), MP offers a rapid, cost-effective, and high-throughput platform with minimal sample volume requirements, enabling faster process development and product release decisions. We developed and qualified an MP method using Refeyn's Mass Photometer to determine the percentage of empty, partially filled, and full AAV capsids within a GMP environment. Method qualification encompassed the evaluation of precision, accuracy, linearity, limit of quantitation (LOQ), and specificity. The method demonstrated high intra-day precision, with %CV values of 4% and 10% for empty and full capsids, respectively. Further, the inter-day precision, as measured by the %CV, were 12% and 8% for Empty and Full capsids, respectively. Accuracy was assessed by spiking known amounts of empty capsids into AAV samples, with recoveries ranging from 92-105% for empty capsids and 92-111% for full capsids. A strong linear relationship was observed, with R^2 values of 0.9927 and 0.9990 for empty and full capsids, respectively. The LOQ was determined to be 4.00E+11 VP/mL. In conclusion, the qualified MP method provides a GMP-compliant, label-free, rapid, user-friendly, and orthogonal approach for

quantifying AAV particle content. This method is applicable for characterizing both in-process and final drug substance/product AAV viral vectors.

1340 Use of Statistical Analyses for Evaluating Large Historical Datasets of AAV Productions to Assess Process Parameters – A Case Study.

John Ketz[1], Byron Carper[1], Sarah Bergman[1], Samir Acharya[2]*
[1]*Andelyn Biosciences, Columbus, OH,* [2]*Andelyn Biosciences, Dublin, OH*
**Corresponding Author*

Introduction: Andelyn Biosciences, Inc., a CDMO launched out of Nationwide Children's Hospital in 2020, has developed Curator™ Platforms for adherent and suspension AAV productions. Using the Curator™ adherent platform, we have manufactured more than 450 Phase I and II clinical batches over 17 years, covering a variety of serotypes and indications. To assess the strength of the Curator™ adherent platform and identify potential critical process parameters, historical data generated from each process step of GMP productions-including 44 sublots of Serotype A and 74 sublots of Serotype B, were compiled and analyzed.

Methods: Process parameters (e.g., titer, volume, yield, percent recoveries, confluency at cell growth, pressures during processing, BSA levels, etc.) were compared using a matrix correlation to identify positive and negative correlations (Figure 1). Specific parameters (e.g., cell culture times, concentration factor, pressures, BSA levels, etc.), were then analyzed along with the viral yields and percent recoveries at each stage of the process. To simplify the analysis, *p*-values (for significance) corresponding to the Pearson correlation of the matrix were analyzed along with the *r*-values (for correlation). The matrices were used as a tool to compare parameters with strong or weak interactions. If two parameters had a low *p*-value (0 – 0.05) and/or high *r*-value (0.7 – 1.0), linear regression was used to assess the relationship.

Results: Percent recoveries of the viral yield for each serotype were calculated across each step of the process (clarification, TFF, IDX, etc.). IDX had the lowest recovery with minimal variability (Serotype A: 48.6± 12.1%; Serotype B: 51.3% ± 11.0%). Throughout the analysis, few trends showed strong correlation (r = 0.7-1) or weak correlations (r = 0.5-0.7). Most trends had relatively low r values ($r < 0.5$) with strong or weak significance. Overall, the trends identify steps incurring maximum loss, those requiring close monitoring, and potential process improvement strategies. Notably, Trans Membrane Pressure (TMP) during TFF and concentration factor showed significant correlations with certain parameters. TMP correlated with several parameters including large harvest volumes and long processing times. Though the TMP was targeted in these productions, close monitoring of the TMP throughout the TFF is recommended. Additionally, an increase in the concentration factor correlated with recovery losses for both serotypes across IDX, necessitating process improvements to mitigate the losses. The data suggest that the product yield is mostly unaffected by the different parameters throughout processing. This is also reflected in the lack of correlation trends in chromatography. The overall recoveries compared to harvest were 24% for serotype A and 38% for serotype B. The process thus appears largely optimized.

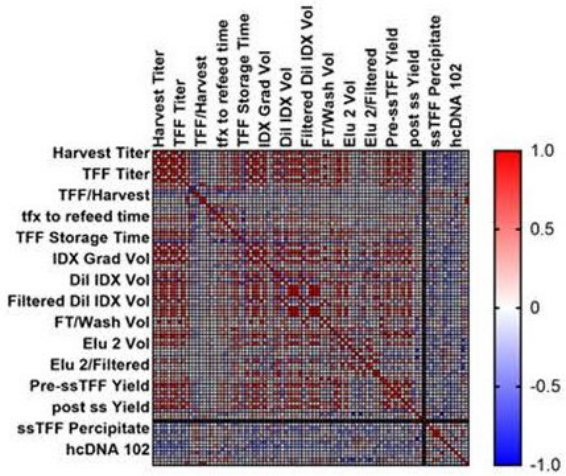

Figure 1. Pearson Correlation Matrix: Initial visual representation of the data. Each square represents a comparison between two parameters; red squares represent positive correlations while blue squares represent negative correlations. Due to the complexity of the figure, only a few parameters can be represented on each axis. For simpler interpretation, individual correlations were analyzed.

1341 As new gene and cell therapies emerge from academia, we must RISE to the opportunity

Nandhitha Uma Naresh[1], Dana Hammill[2], Mark Kessel[3], Roger Hajjar[4], Nathan Yozwiak[5]*
[1]Mass General Brigham GCTI, Newton, MA, [2]Mass General Brigham, Cherry Hill, NJ, [3]Independent consultant, Cambridge, NY, [4]Mass General Brigham GCTI, Cambridge, [5]Mass General Brigham, Boston, MA
**Corresponding Author*

With over 30 FDA approved products in the United States, the cell and gene therapy (CGT) sector has flourished, as evidenced by the surge in clinical trials and the broadening scope of pre-clinical research. Academic medical centers (AMCs) are critical to CGT developments, serving as a wellspring of early-stage innovation and the sites for clinical trials. Yet reaching the clinic is a lengthy development path, and new CGTs must overcome numerous challenges, including navigating the translational 'valley of death' and balancing the interests of various stakeholders. Unlike traditional small molecule or biologics development, CGTs are further complicated by high costs and complex regulatory requirements. Some federal funding initiatives are now focused on late pre-clinical stage CGTs to accelerate their translation from bench to clinic. Fueling these efforts, AMCs must play a crucial role in overcoming CGT development hurdles by establishing institutional frameworks that offer comprehensive support, extending beyond financial assistance. We propose the adoption of RISE, an institutional model currently implemented by Mass General Brigham's Gene and Cell Therapy Institute (MGB - GCTI) to foster development of CGT innovations that originate in academia. The **RISE** model exemplifies the following: – **R**esource sharing to minimize costs and infrastructure required for CGT manufacturing, **I**nterdisciplinary collaboration by accessing key opinion leaders (KOLs) and patients that intersect at AMCs, **S**ustainable funding by investing into pre-clinical research with long-term commercial viability, and **E**ducational efforts that can engage the research, clinical and patient community in discussions on bridging knowledge gaps. We argue that the promising pipeline of CGT innovations may languish without a concerted focus and investment within AMCs, and the RISE model can serve a win-win approach for both innovators and patients by providing a well-supported path to accelerate the development of new CGTs to the patients in need.

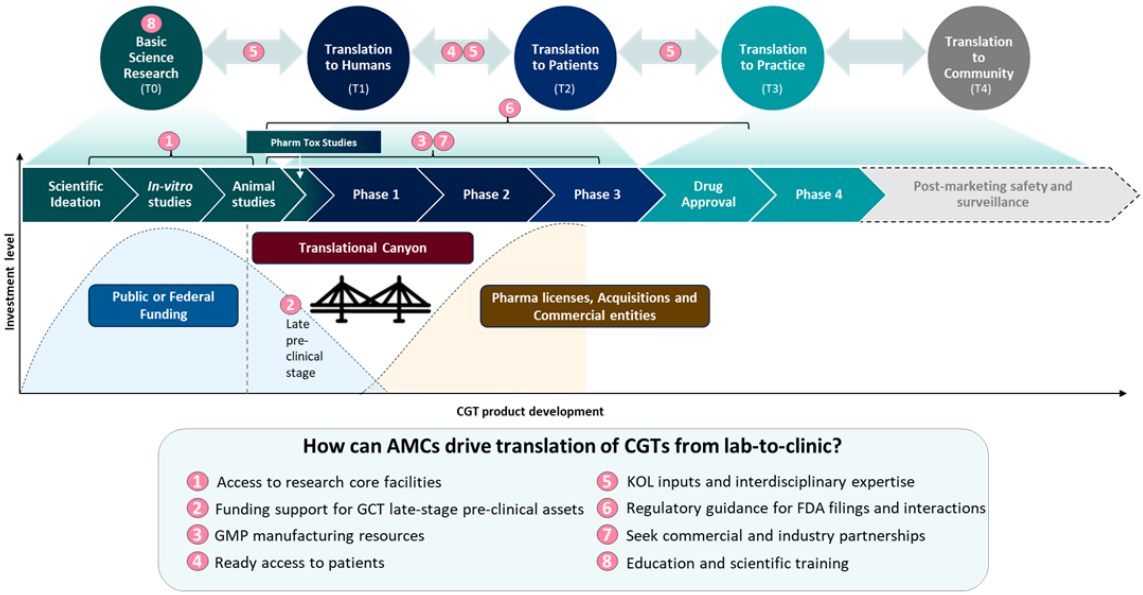

Figure 1: Different ways in which AMCs can drive translation of GCTs. GCTs from lab-to-clinic traverse a long and arduous path which begins with scientific ideation in academic labs. A translational canyon, also called the 'valley of death' develops between late-stage basic science research and clinical applications where the investment needs of GCT product development and type of investors involved shift. AMCs can offer support in multiple ways across all stages of CGT development to bridge existing gaps in clinical translation such as by providing access to shared resources (core facilities, GMP manufacturing, patients), leveraging interdisciplinary expertise, educating scientific community.

1342 *PPQ Ready Risk-Based Identity Testing for Ancillary Raw Materials in Gene Therapy Manufacturing*

Carson Greco[1], Will Fountain[1]
[1]*Andelyn Biosciences, Columbus, OH*

Introduction: Ancillary raw materials play a critical role in gene therapy manufacturing by enabling key processes without becoming part of the final product. Ensuring the identity of these materials is essential to maintain product quality, safety, and compliance. The variety of these materials, their often non-compendial nature, and the complexity of gene therapy workflows present challenges for qualification. A risk-based approach to identity testing provides a balance between compliance and efficiency. This study aims to outline a risk-based framework for identity testing and qualification of ancillary raw materials that focuses on integrating regulatory expectations and widely used analytical techniques to establish robust yet practical strategies for testing.

Methods: Regulatory guidance, including USP <1043> and ICH Q9, were used to develop a framework for assessing risk and determining appropriate identity testing. The risk-based tiers outlined in USP <1043> are critical to assess materials and determine required testing. Per USP <1043> there may be instances where performance testing of materials may serve as identity testing. Ultimately, formal identity testing is required to ensure compliance, but performance testing may bolster material qualification or serve as part of required identity tests. The risk-based framework for test selection incorporates material grade, vendor specified intended use, intended use in manufacturing, critical specifications for performance, vendor qualification, reliance on Certificates of Analysis (CoA's), and risk-based thresholds to guide testing intensity.

Results: A risk-based identity testing approach was designed, prioritizing comprehensive testing for high-risk ancillary materials and reduced testing for lower-risk materials. Purchased custom-prepared solutions proved challenging, as components may be identical at varied concentrations. Critical analytes were identified in the solution through analytical testing (e.g., Fourier Transform Infrared Spectroscopy, Nuclear Magnetic Resonance). Additional characterization tests (e.g., pH, conductivity) were added to distinguish solutions with similar components. The combination of critical analyte detection and characterization tests allowed for solution

identification. Amino acid analysis for complex formulations (e.g., Dulbecco's Modified Eagle Medium) and electrophoretic profiling of materials (e.g., bovine serum) were utilized. For lower-risk materials, simpler techniques or CoA verification testing were deemed sufficient. This approach aligns with regulatory guidance and minimizes redundant testing.

Conclusion: A risk-based approach to identity testing for ancillary raw materials can streamline qualification processes while ensuring regulatory compliance. The framework presented here highlights the importance of integrating robust analytical methods alongside specialized tests to address the unique challenges of gene therapy manufacturing. The outlined approach can lead to substantial cost savings, particularly for prepared solutions where identification of each analyte would be costly. This represents up to 75% savings compared to the total cost in prepared solutions. Other material testing costs were similarly reduced with the risk-based approach. The approach supports consistent product quality, efficient workflows, and a scalable model for managing ancillary raw materials in a cost-efficient manner.

1343 Minimizing Volume Requirements and Turnaround Time for Compendial Testing of Cell and Gene Therapy Products

Steven Henry[1], Alexander Chiappini[2], Stacie Fichthorn[3]*, Marian McKee[1]
[1]Eurofins BioPharma Product Testing, Lancaster, PA, [2]Eurofins BioPharma Product Testing, Lancaster, [3]Lancaster, PA
**Corresponding Author*

Cell and gene therapy (CGT) products have unique needs principally driven by the scarcity of material (i.e. limited volume availability for testing) and the desire for fast turnaround times (TAT), especially for autologous cell therapy products. Compendial methods for critical quality attributes such as Visible Particulates, Color, Clarity, Extractable Volume, Osmolality, and pH often require volumes well above those available for most CGT products, especially when performed in sequence on different samples. We have optimized standard compendial offerings for the specific needs of CGT products. We have developed and a platform method that satisfies these needs. The method is adaptable in terms of manufacturers' preferred testing order and modifiable with respect to total volumes tested by authoring tailored method guidance documents. This process addresses the full range of testing options covering both United States Pharmacopeia (USP) and European Pharmacopoeia (EP) guidelines. Testing offerings include Visible Particulates, Color, Clarity (visual and instrumental), Extractable Volume, Osmolality, and pH. The goal is to highlight the various strategies used to satisfy USP and EP guidelines while minimizing volume and accelerating TAT.

1344 Upstream Process intensification for a Gorilla derived Adenoviral (GRAd) vector by using a Perfusion System

Michela Gentile, ReiThera, Rome, Italy

Recombinant adenovirus vectors are effective gene transfer tools used both in gene therapy, cancer therapy and infectious diseases.

Current processes for manufacturing Adenoviral vectors (AdV) involve the use of serum free media and stirred tank bioreactors by employing HEK293 cells as packaging cell line. Cells are amplified in shake flask, wave and stirred tank bioreactors where viral production is achieved by infecting the cells with the AdV at a specific Multiplicity of Infection.

Developing a process capable of producing large quantities of doses both for clinical and commercial phases has become crucial for the biotech market in recent years.

Viral productivity as well as bioreactors size determine the number of doses that can be produced for each batch. Although large scale stirred tank bioreactors are available for cell cultivation and production phases, huge amount of

cell biomass is needed for the inoculation, thus increasing both the timing for cell amplification and the overall manufacturing costs.

One strategy to boost viral productivity is to increase the concentration of the cells at the infection phase thus improving the total volumetric productivity. However, a challenge with this strategy is the cell density effect, where higher cell densities often lead to lower per cell productivity due to lack of nutrients and toxic cell metabolites accumulation. The perfusion process, which involves continuously replacing exhausted medium with fresh medium, can be a successful solution to achieve higher cell density during the infection phase.

In this study, we present an intensified upstream process based on proprietary HEK293 cell line adapted to suspension growth in a small-scale 2L Stirred Tank Bioreactor for the production of Gorilla-derived Adenoviral vector (GRAd). Through the use of a Perfusion system, we achieved a high cell density culture of approximately 1E+07 cells/mL. Furthermore, infecting the cells at a density of 2E+06 cells/mL after perfusion led to a threefold increase in the total volumetric productivity of the vector compared to standard processes, without affecting vector quality. Cell growth, viability, and metabolite profiles were monitored throughout the process to characterize cell culture, demonstrating that medium exchange can sustain exponential cell growth maintaining high cell viability.

This study establishes that a successful and reproducible intensified process can be applied for the production of GRAd vector in HEK293-derived cell line. This could lead to a reduction in vaccine manufacturing time and an increase in the number of doses produced per batch at the manufacturing scale.

1345 Dissecting the effect of shear during rAAV production using perfusion bioreactors in PCLs

David Diaz-Vera[1], Nipun Goel[2], Olivia Tsang[3], Lois Horton[3], Madhuresh Sumit[4], Jeong Lee
[1]Genzyme, a Sanofi Company, Waltham, MA, [2]Genzyme, a Sanofi Company, Acton, MA, [3]Sanofi, Waltham, MA, [4]Sanofi US Services Inc, Waltham

Recombinant Adeno Associated Virus (rAAV) has recently become one of the most common vectors in gene therapy, with several products already approved by the FDA. While approval is based on therapeutic efficacy, market success in the long term also requires robust quality and cost effectiveness. One way to achieve these goals is through implementation of intensified perfusion-based processes using producer cell lines (PCLs) in combination with a helper virus. While perfusion has proven beneficial in rAAV production, it requires a cell retention device that could lead to unfavorable shear stress on cells. This is relevant especially after virus infection when shear sensitivity increases. This entails a comprehensive understanding of perfusion related process parameters optimization. Using a PCL platform in bench-top bioreactors we examined various operating parameters such as recirculation pump type, recirculation flux, permeate flux, inner diameter of hollow fiber filter (HFF) lumens and total filtration area. The experimental results indicate that shear forces within HFF lumens and the recirculation flow path, influenced by factors like length and inner diameter, can adversely impact cell culture viability and rAAV titers. Additionally, we demonstrate that usage of levitating pumps, that reduce pinch points in the recirculation flow path, can potentially facilitate better productivity and AAV capsid quality. Overall, our studies revealed that shear is an important parameter for rAAV manufacturing that can significantly impact cell physiology and should be carefully examined for perfusion process during process intensification and scale-up.

1346 Establishing a Scalable rAAV Production Platform for Research-Grade Vector Supply within a Pharmaceutical Setting for rAAV Gene Therapy Early Research and Development

Tony Cijsouw[1], Helena Meyer-Berg[2], Fabian Hosp[3], Benedikt Oswald[2], Sabine Linder[2], Iliya Rafiei[4], Denis Phichith[5], Miriam Lopez Ferreiro[6]
[1]Roche, Mannheim, Bayern, Germany, [2]Roche, Penzberg, Germany, [3]Roche Pharma Research & Early

Development, Penzberg, Germany, [4]Roche, Munich, Bayern, Germany, [5]Roche - Basel, Basel, N/A, Switzerland, [6]F. Hoffmann-La Roche Ltd., Basel, Switzerland, Switzerland

Introduction: The increasing demand for research-grade recombinant adeno-associated virus (rAAV) vectors necessitates the establishment of robust, scalable and fast-pace production platforms within pharmaceutical research environments. Here, we describe the evolution and implementation of such a platform, encompassing standardized plasmid design, upstream processing (USP), downstream processing (DSP), analytical characterization, and FAIR data capture to support early-stage rAAV-based gene therapy research and development.

Methods: We formed a dedicated rAAV production team, integrating expertise in molecular biology, cell culture, purification, and analytical development. For plasmid design and production, a standardized workflow was implemented for generating rAAV expression constructs. While initially adherent HEK293 cultures were employed, we early-on transitioned to suspension HEK293 cell cultures for scalable rAAV production using the triple transfection method using different scale formats from deep-well and shake flask up to 1 L scale. Similarly, increased demands required the implementation of additional DSP methods based on affinity and ion-exchange chromatography, which allow for a more scalable, high-yield rAAV purification. Therefore, the adoption of several platforms allows flexibility to cater to various internal programs that require different virus quantities and/or higher construct numbers for screening purposes. A comprehensive analytical panel was established, including assays for titer determination, capsid purity, genome integrity and identity, aggregation, and endotoxin levels. Finally, a standardized IT system for FAIR (Findable, Accessible, Interoperable, Reusable) data storage and management system was implemented to enable data-driven decision making.

Results: The established platform enables the routine production of research-grade recombinant rAAV vectors of various serotypes at scales ranging from milliliters to liters, capable of supporting early-research projects for fast screening in cellular models to supplying rAAV material for NHP studies. We describe here how 1) optimized plasmid designs and 2) improved USP production processes resulted in high-titer AAV production, and 3) the implemented DSP strategy achieved high-quality vector recovery with minimal empty capsid contamination. Furthermore, 4) the implemented rigorous analytical testing suite confirmed the quality and consistency of the produced rAAV batches, meeting pre-defined acceptance criteria. As an example, we present here a research-grade rAAV supply (3 vectors), including extensive analytical panel and CoA criteria, for an ocular NHP study. In addition, we provide comparisons and general learnings–from over a 100 different rAAV batches–on rAAV productivity between vector genome designs, capsid serotypes, and batch-to-batch variability.

Conclusions: This integrated rAAV production platform provides a reliable and scalable source of research-grade rAAV vectors, streamlining early-stage gene therapy research within a pharmaceutical company. The standardized workflows and rigorous quality control measures ensure consistent vector quality and facilitate the rapid progression of promising gene therapy candidates from concept to preclinical development.

1347 ReiCell-AAV: A Fully Documented High-Yield Suspension Cell Line for Scalable AAV Vector Manufacturing

Michela Gentile, ReiThera, Rome, Italy

Adeno-associated virus (AAV) has become a pivotal tool in gene therapy, driving an increasing demand for large-scale production of diverse AAV serotypes, particularly for pre-clinical and clinical applications. Addressing this demand requires enhancing the packaging capacity of producer cells to optimize AAV vector productivity. This study investigates the growth characteristics and AAV packaging efficiency of a high-yield monoclonal cell line derived from HEK293 cells. Starting with a vial of adherent Frank Graham HEK293 cell line frozen at passage 7, the cells were put in culture and successfully adapted to grow at high cell density under animal component-free suspension conditions in shake flasks and bioreactors. To improve AAV productivity, the suspension-adapted cells underwent two rounds of single-cell cloning and screening using the triple-plasmid transfection platform. ReiCell-AAV was further evaluated for production efficiency across multiple AAV serotypes, including AAV DJ, AAV2, AAV8, and AAV9, using shake flasks and 2 L stirred bioreactors. These tests demonstrated stable production capacities, with lysate genome titers ranging from 1E+14 vg/L to 5E+14 vg/L. Host cell DNA (HCD) and empty

capsid ratio in DS were further evaluated. For the AAV8 capsid, preliminary results showed 30–40% full particles at harvest, enabling chromatographic polishing that achieved high enrichment (>90% full capsids) without the need for ultracentrifugation.

In summary, we developed a suspension single-clone cell line, ReiCell-AAV, with fully detailed history starting from the origin of 293 cells and high production capacity, stability, and quality. This platform is well-suited for industrial-scale AAV manufacturing across a range of serotypes, payloads, and production scales, meeting the evolving requirements of gene therapy applications

1348 Demonstrating Key Processes of the T Cell Therapy Workflow in Chemically Defined Media

Anastassia Tselikova[1], Shahram Shahabi[2], Chandana Sharma[2]
[1]FUJIFILM Irvine Scientific, Santa Ana, CA, [2]FUJIFILM Irvine Scientific - Santa Ana, CA, Santa Ana, CA

Although technologies used in the generation of immunotherapies are diverse and rapidly evolving, they share the goal of efficiently generating sufficient cell numbers with high viability and consistent clinical quality. The elimination of undefined media components, such as serum-derived proteins, reduces variability to facilitate safe and efficacious translation for clinical use. Chemically defined media are uniquely amenable to consistent and reproducible scale-up due to the lack of undefined media components, enabling manufacturers to reliably make high-quality products when transitioning from preclinical development to GMP manufacturing of cell-based therapies.

In this study, thawed human PBMCs were activated with αCD3/αCD28 beads, expanded in G-Rex cell culture vessels and Quantum hollow fiber bioreactors in PRIME-XV T Cell CDM with Shenandoah CTGrade GMP rh IL-2_{C126S}, and assessed for functionality. CT Grade GMP IL-2_{C126S}-independent expansion, expansion post-thaw from DMSO-free media without an initial wash step, and lentiviral transduction were likewise performed in G-Rex vessels in chemically defined conditions.

Join us to discover how to:

Achieve scalable expansion, activation, lentiviral transduction of Human PBMC-derived T cells in G-Rex Cell Culture Systems and Quantum hollow fiber bioreactors

Omit the post-thaw wash step to simplify processes and expand cells while maintaining robust functionality in response to antigenic stimulation

Benefit from a powerful toolset for T cell therapy manufacturing with PRIME-XV FreezIS DMSO-Free, PRIME-XV T Cell CDM, and Shenandoah CTGrade GMP Recombinant Proteins working together across a variety of cell sources and culture/activation methods

1349 High-Performing GMP CRISPR Cas9 Nuclease for Cell and Gene Therapy

Sarah Rains, KACTUS, Silver Spring, MD

Introduction: CRISPR/Cas9 technology has been widely used in cell therapy. To address the need for high-quality and high-performing Cas9 nuclease, KACTUS developed a GMP-manufactured Cas9 nuclease and implemented a comprehensive quality control process to make it suitable as an ancillary material for cell therapy applications. The results showed that KACTUS GMP-grade Cas9 enzyme had a good batch-to-batch consistency and long-term

stability. Compared to a leading commercially Cas9 enzyme, KACTUS GMP-grade Cas9 had a comparable gene editing efficiency in both in vitro cleavage assay and in multiple cellular gene editing. Currently, KACTUS GMP-grade Cas9 enzyme has supported multiple cell and gene therapy developments and clinical IND submissions.

Objective: The primary objective focused on achieving stability and high yield, alongside ensuring high activity and consistent quality across batches. This goal was underpinned by the need to minimize risks and align with compliance standards. Achieving these targets was essential for maintaining the reliability and effectiveness of the processes involved, providing a solid foundation for operational excellence.

Methodology: KACTUS addressed these objectives through a multi-faceted approach. They designed the nuclear localization signal (NLS) and optimized the expression and purification process to ensure high yield and activity. The use of animal origin-free materials and the
implementation of a closed process under a Good Manufacturing Practice (GMP) environment were critical steps towards minimizing risks and aligning with compliance. Quality control measures were rigorously applied, including testing for bioburden, endotoxin, residual host nucleic acids, and protein, ensuring the safety and purity of the products. Additionally, both the process and analytical methods underwent thorough validation, further reinforcing the reliability and consistency of the outcomes.

Results: High In Vitro Cleavage Activity
Results: High gene editing efficiency across multiple cell types

Conclusion:
→ High quality and gene editing performance
based on KACTUS GMP manufacturing process
→ Consistent batch-to-batch performance
→ Validated on both T cell and HSC applications
→ Animal origin-free processes and materials

Results: Robust & High-Quality Production

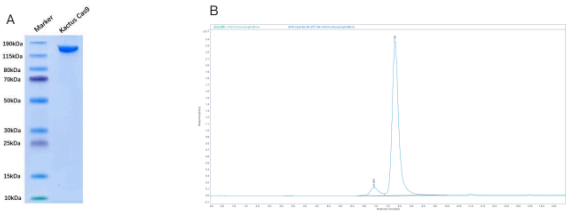

Figure 1. A high purity Cas9 protein was obtained based on the KACTUS GMP production process. (A) detected by Tris-Bis-PAGE.(B)analysis by SEC-HPLC(Agilent). Results show the purity is greater than 95%.

Results: Excellent Long-Term Stability and Batch-to-Batch Consistency

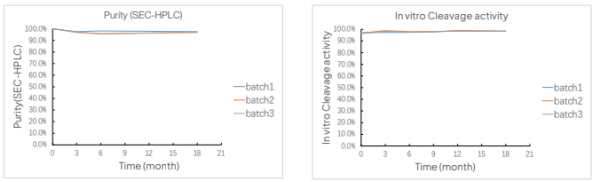

Figure 2. Consistent purity and activity performance observed across three manufacturing batches of KACTUS GMP-grade Cas9. Three batches of KACTUS GMP-grade Cas9 were stored at -20°C for long-term stability test, analyze the purity by SEC-HPLC and in vitro cleavage activity at 3, 6, 9, 12, 15, 18 months, respectively. The results showed KACTUS GMP-grade Cas9 has a good stability and consistent among different manufacturing batches.

Results: High In Vitro Cleavage Activity

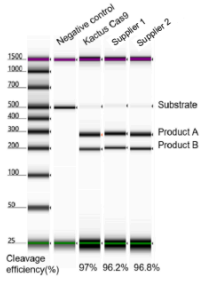

Figure 3. KACTUS GMP-grade Cas9 shows an comparable in vitro cleavage activity with leading suppliers Cas9. 2μL 0.1μg/μL Cas9 protein with 2μL 2μM sgRNA cuts 300ng substrate DNA for 15min at 37°C, then using 4150 TapeStation to analysis the cleavage efficiency. KACTUS GMP-grade Cas9 achieved cleavage efficiency of 97% vs 96.2% of supplier 1 and 96.8% of supplier 2.

Results: High gene editing efficiency across multiple cell types

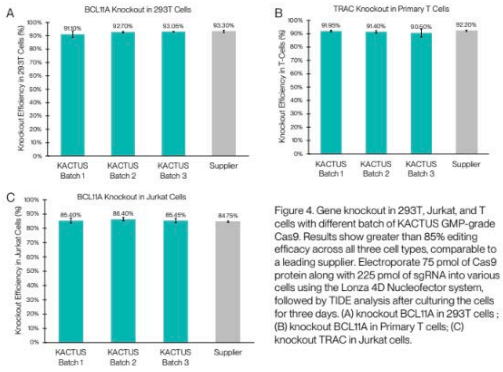

Figure 4. Gene knockout in 293T, Jurkat, and T cells with different batch of KACTUS GMP-grade Cas9. Results show greater than 85% editing efficacy across all three cell types, comparable to a leading supplier. Electroporate 75 pmol of Cas9 protein along with 225 pmol of sgRNA into various cells using the Lonza 4D Nucleofector system, followed by TIDE analysis after culturing the cells for three days. (A) knockout BCL11A in 293T cells ; (B) knockout BCL11A in Primary T cells; (C) knockout TRAC in Jurkat cells.

Case Study 1: Gene editing in primary T cells for UCAR-T

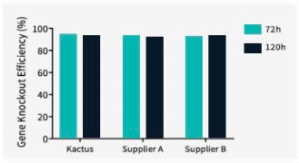

Figure 5. Gene knockout of the HLA gene for UCAR-T application. KACTUS GMP-grade Cas9 demonstrates efficient gene editing activity, comparable to two other suppliers in the market.

Case Study 2: Gene editing in Human Stem Cells (HSCs) for β-thalassemia

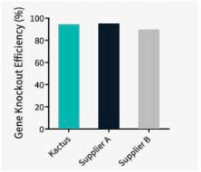

Figure 6. KACTUS GMP-grade Cas9 shows efficient BCL11A knockout activity in gene editing HSCs for the treatment of β-thalassemia, comparable to two other suppliers in the market.

Universal High Sensitivity ELISA Kit for Quantitative Detection of Cas9 Residues

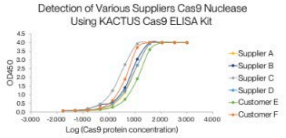

Figure 7. KACTUS has developed a Cas9 residue detection kit (sandwich ELISA method) and tested it with Cas9 products from other commercial suppliers on the market. After testing, the kit has proven to be effective in identifying and quantitatively detecting Cas9 products from various suppliers, demonstrating its potential as a universal Cas9 detection kit.

1350 3-Year Functional Outcomes of Patients With Duchenne Muscular Dystrophy: Pooled Delandistrogene Moxeparvovec Clinical Trial Data vs External Controls

Jerry Mendell[1], Anne Connolly[2], John Day[3], Craig McDonald[4], Crystal Proud[5], Perry Shieh[6], Craig Zaidman[7], Matthew Furgerson[1], **Sravya Ennamuri[1]**, Kai Ding[1], Carol Reid[8], Alex Murphy[9], Jake Elkins[1], Louise Rodino-Klapac[1]

[1]Sarepta Therapeutics, Inc., Cambridge, MA, [2]Nationwide Children's Hospital, Columbus, OH, [3]Stanford University, Palo Alto, [4]UC Davis Health, Sacramento, CA, [5]Children's Hospital of the King's Daughters, Norfolk, VA, [6]UCLA, Los Angeles, CA, [7]Department of Neurology, Washington University in St Louis, St Louis, MO, [8]Roche Products Ltd, Welwyn Garden City, Hertfordshire, United Kingdom, [9]Roche Products Ltd

Delandistrogene moxeparvovec is an rAAVrh74 vector-based gene therapy for Duchenne muscular dystrophy encoding an engineered, functional form of dystrophin shown to stabilize or slow disease progression. It is approved in the US and in other select countries. Here we compare 3-year functional outcomes of ambulatory patients aged 4.0-8.9 y treated with delandistrogene moxeparvovec (treatment group) with those of external controls (ECs), well matched using propensity-score weighting of key baseline prognostic factors.

Delandistrogene moxeparvovec data (n=50) were pooled from studies 101 (NCT03375164, n=4), 102 (NCT03769116, n=26), and ENDEAVOR Cohort 1 (NCT04626674, n=20) and compared with an EC group (n=73) using a propensity-score–weighted median regression model and a mixed-effects model for repeated measures (MMRM). Changes from baseline (CFBLs) to year 3 in the North Star Ambulatory Assessment (NSAA) total score and timed function tests (TFTs) of time to rise (TTR) from floor and 10-meter walk/run (10MWR) were assessed.

At baseline, treatment and EC groups had similar median ages (6.3 y vs 6.5 y), weights (22.0 kg vs 22.6 kg), NSAA total scores (22.0 points vs 21.0 points), TTRs (3.9 s vs 4.3 s), and 10MWR times (4.9 s vs 5.1 s). Median regression analyses showed clinically meaningful stabilization of disease over 3 years in the treatment group vs the EC group. The 3-year CFBL (SE) in NSAA total score for the treatment group vs the ECs was −2.55 (0.76) points vs −5.55 (0.77) points (between-group difference [SE]: 3.00 [0.80] points, *P*=0.0003). MMRM analyses yielded similar results and will also be presented alongside TTR and 10MWR assessments.

Our findings show that treatment with delandistrogene moxeparvovec results in long-term stabilization or slowing of disease progression compared with a rigorously matched EC group, with an increase in between-group divergence over time.

1351 Brogidirsen -The First Dual-Targeting Exon 44 Skipping Drug for Duchenne Muscular Dystrophy Safety, Tolerability, and High Dystrophin Restoration in Long-Term Clinical Studies

Yoshitsugu Aoki[1]*, Eri Takeshita[2], Katsuhiko Kunitake[3], Yuko Shimizu-Motohashi[2], Shinsuke Maruyama[4], Eisuke Hida[5], Rena Miyagi[6], He Zhang[7], Hirofumi Komaki[8]

Corresponding Author

Introduction: Duchenne muscular dystrophy (DMD) is a severe X-linked muscle disorder caused by mutations in the DMD gene, which encodes dystrophin, a crucial protein found at the muscle cell membrane. NS-089/NCNP-02 (Brogidirsen) is the first drug designed for dual-targeting exon 44 skipping and was developed by the National Center of Neurology and Psychiatry (NCNP) in collaboration with Nippon Shinyaku Co., Ltd. Preclinical studies have shown highly effective skipping of exon 44 and restoration of dystrophin in cells derived from DMD patients with mutations suitable for this approach, suggesting the drug's potential to slow disease progression.

Methods: Six participants were assigned into two cohorts in the previous Phase 1/2 study (NCT04129294) for safety and efficacy investigations. Brogidirsen was administered intravenously once weekly at therapeutic doses of 40 mg/kg once a week (low dose, Cohort 1) or 80 mg/kg (high dose, Cohort 2) for 24 weeks in Part 2 of the study. Ongoing extension study (NCT05135663) is evaluating Brogidirsen's safety, tolerability, and efficacy in patients with DMD over 2 years and is ongoing. The study includes molecular and biochemical analyses, pulmonary function tests, and assessments of motor function. In vitro assays conducted with MYOD1-converted urine-derived cells (MYOD1-UDCs), myoblasts, and MYOD1-converted fibroblasts from the same patients demonstrated a dose-dependent efficiency in exon skipping and dystrophin restoration.

Results: No severe adverse events or anaphylaxis related to Brogidirsen were reported, and there were no treatment discontinuations. The efficacy of exon 44 skipping and dystrophin levels in biopsied muscles significantly improved, with the high-dose Brogidirsen achieving 24.47% on average of normal dystrophin levels in 24 weeks. Additionally, plasma biomarkers associated with DMD (such as PADI2, TTN, MYOM2, MYLPF) showed reductions, correlated with improved clinical profiles. After 99 weeks, the high-dose Brogidirsen achieved 18.17% on average of normal dystrophin levels. Four out of six participants maintained or improved their motor function, as measured by the North Star Ambulatory Assessment. In vitro assays showed effective exon skipping and

dystrophin expression in a dose-dependent manner in MYOD1-UDCs, myotubes, and MYOD1-transduced fibroblasts from six patients, supporting the case for human trials.

Conclusion: These findings underscore Brogidirsen's safety and potential to modify the progression of DMD. The extension study is ongoing, and a Phase 2 trial in the USA (NCT05996003), sponsored by NS Pharma, Inc., is also in progress to further evaluate its safety and efficacy.

1352 Design of the Phase 1 ASCEND Study to Investigate the Safety and Biodistribution of INS1201 Gene Therapy in Males With Duchenne Muscular Dystrophy

Mark Stahl[1], Gretchen Thomsen[2], Marissa Kruger[3], Paul Chang[4], Kathleen Church[5], Maite Francois[6], Michelle Fortin[4], Olivier Francillon[4], Sheritha Lee[7], Allan Kaspar[2], Samit Varma[4], Brian Kaspar[2], John Day[8]
[1]Insmed, San Diego, CA, [2]Insmed, Inc., San Diego, CA, [3]Insmed Gene Therapy, San Diego, CA, [4]Insmed Incorporated, San Diego, CA, [5]Insmed Gene Therapy, Naperville, IL, [6]Insmed Inc., San Diego, CA, [7]Insmed Inc, Collegeville, PA, [8]Stanford University, Palo Alto

Background: INS1201 is a recombinant adeno-associated virus serotype 9 carrying a micro-dystrophin gene expression construct currently in development for the treatment of Duchenne muscular dystrophy (DMD). INS1201, designed to express a micro-dystrophin protein in muscle, has demonstrated histopathological improvement and functional efficacy in the *mdx* mouse and high levels of muscle fiber expression in both mouse and nonhuman primates. INS1201 is delivered via a single intrathecal administration, which has been shown in mice and nonhuman primates to efficiently target skeletal and cardiac muscles at relatively low vector doses compared to those required for intravenous administration.

Objective: To present the study design for the phase 1, first-in-human, open-label, 2-part, dose escalation ASCEND study assessing the safety and biodistribution of INS1201 in ambulatory males aged 3 to <5 years (Part 1) and 2 to <3 years (Part 2) with genetically confirmed DMD.

Design/Methods: The study will evaluate up to 12 participants to determine the recommended phase 2 dose (RP2D). Each study part consists of 2 dose cohorts (n=3 each), with a starting dose of 5.0E+14 vector genomes (vg) in the first cohort and a higher dose of 1.0E+15 vg in the second. The study will open with the starting dose in Part 1 only; enrollment into each dose cohort will be staggered with a 30-day safety observation period between each participant. The study will be monitored by an independent safety monitoring committee, which will review cumulative safety data throughout the study and prior to the opening of Part 2 and all dose level increases. The primary endpoint is the incidence and severity of treatment-emergent adverse events (AEs), AEs of special interest, and serious AEs. The RP2D will be identified based on safety, tolerability, and change from baseline to week 16 in quantity of INS1201 micro-dystrophin protein expression from biopsied muscle tissue. Additional exploratory endpoints will evaluate micro-dystrophin transgene levels, multiple measures of motor function, developmental milestones, and caregiver-reported outcomes. Participants will be followed for 96 weeks after INS1201 administration, after which all participants will be enrolled in a 3-year extension study to assess long-term safety.

Conclusion: The ASCEND study will assess the safety and biodistribution of INS1201 to inform RP2D selection.

1353 Assessment of Cardiac Outcomes in Delandistrogene Moxeparvovec Clinical Trials for Duchenne Muscular Dystrophy

[1]Arkansas Children's Hospital, Little Rock, AR, [2]NUTH NHS Hospitals Foundation Trust, Newcastle upon Tyne, United Kingdom, [3]Stanford University, Palo Alto, [4]UC Davis Health, Sacramento, CA, [5]Sarepta Therapeutics, Inc., Cambridge, MA, [6]Vanderbilt University Medical Center, Nashville, TN, [7]Department of Neurology, Washington

University in St Louis, St Louis, MO, [8]Sarepta Therapeutics, Inc., Austin, TX, [9]Sarepta Therapeutics, Inc., Cambridge, Massachusetts, [10]Roche Products Ltd, [11]F. Hoffmann-LaRoche Ltd, Basel, Basel-Stadt, Switzerland

Delandistrogene moxeparvovec, an rAAVrh74 gene therapy, delivers a transgene encoding a functional form of dystrophin shown to stabilize or slow the progression of Duchenne muscular dystrophy (DMD). Here we assess pooled cardiac safety outcomes from delandistrogene moxeparvovec studies with 1-5 years of follow-up.

Data from 156 patients (mean age [range], 6.7 [3.2-20.2] years; baseline left ventricular ejection fraction [LVEF] range, 48.9%-77.0%; ambulatory, 148 [95%]) were collected from 4 studies (101 [NCT03375164; n=4], 102 [NCT03769116; n=41], ENDEAVOR Cohorts 1-5b [NCT04626674; n=48], and EMBARK Part 1 at 52 weeks [NCT05096221; n=63]); all excluded patients with LVEF <40%. Troponin-I (TnI) was assessed regularly in ENDEAVOR and EMBARK.

Two cases of myocarditis were reported within days of delandistrogene moxeparvovec infusion; both resolved within 3 weeks (1 with sequelae). Except in the 2 myocarditis cases, TnI fluctuations were asymptomatic and compatible with fluctuations observed in DMD. In ENDEAVOR Cohorts 1-3 (n=32), there was no apparent relationship between total capsid load and peak TnI levels 1-2 weeks post-infusion. At week 52, cardiac MRI performed in a subset of patients from EMBARK revealed no relevant differences in cardiac function (including LVEF), volume, or mass between patients treated with delandistrogene moxeparvovec or placebo. Overall, LVEF values were stable across all studies.

Results of delandistrogene moxeparvovec studies to date, with 1-5 years of follow-up, indicate a manageable cardiac safety profile in this population of patients with DMD. Therapy is generally well tolerated and safe, with no signs of persistent treatment-related cardiac injury.

1354 Innovative Intrathecal AAV9-mediated Gene Therapy for Spinal Muscular Atrophy: Phase I/II Safety and Efficacy Topline Results

Xiaodong Wang[1]*, Yingying Mao[2], Shuangqing Yu[3], Wenhao Ma[1], Cuijie Wei[4], Hui Xiong[5], Xiuwei Ma[6], Zhichun Feng[6], Dan Sun[7], Xiaoyan Dong[8], Xiaobing Wu[9]*

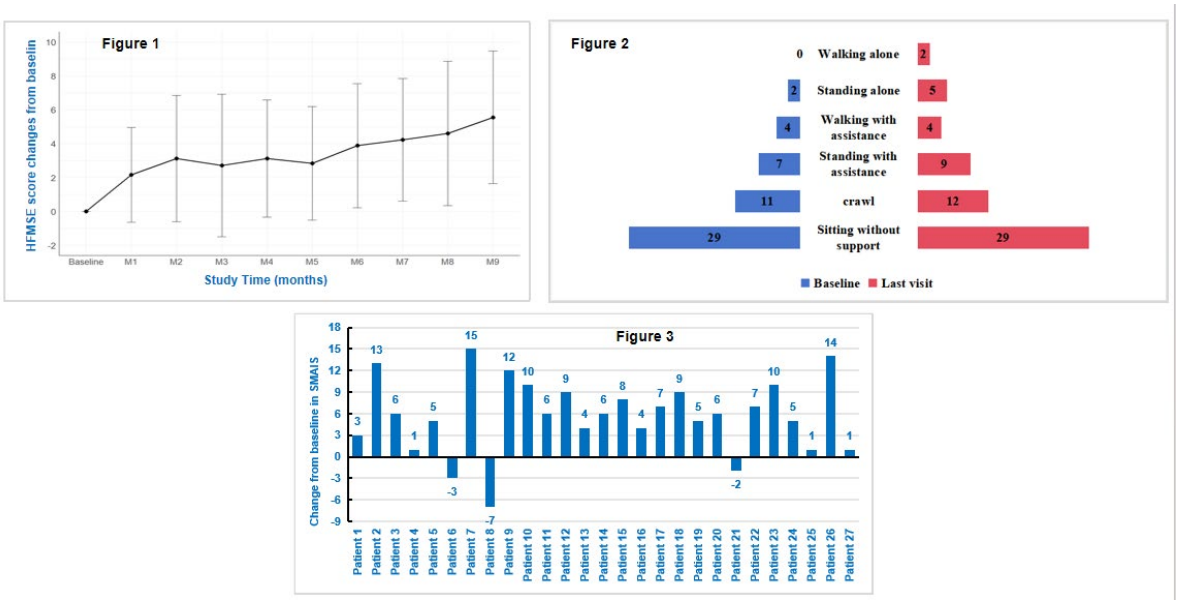
Corresponding Author

Background: Spinal Muscular Atrophy (SMA) is a severe neuromuscular disorder caused by homozygous mutations in the SMN1 gene, leading to motor neuron degeneration and muscle weakness. Intravenous AAV-mediated gene therapy has shown promise in treating Type 1 SMA but raises safety concerns, including immune responses indicated by elevated liver enzymes. This study evaluates an innovative AAV9-mediated gene therapy (GC101) delivered via intrathecal injection in patients with late-onset SMA, focusing on safety, tolerability, and efficacy.

Methods: A Phase I/II single-arm, single-dose, open-label clinical trial assessed GC101's intrathecal administration in pediatric patients aged 2 to 12 years with genetically confirmed Type 2 SMA, capable of sitting independently but unable to walk. Before GC101, patients completed a washout period, discontinuing Nusinersen and/or Risdiplam. Post-administration, all prior treatments were ceased. Safety assessments monitored adverse events, immune responses, and viral shedding. Efficacy was evaluated using the WHO-MGRS, HFMSE, and RULM scales, with measurements at baseline and predefined intervals over 12 months. Quality of life was assessed using the SMAIS.

Results: Twenty-nine patients received GC101, showing good tolerability with no severe therapy-related adverse events. All serious adverse events were respiratory infections resolved with standard care. Mild immune responses in a few patients resolved with standard management. Efficacy data revealed significant motor function improvements. HFMSE scores increased by 3.85 points on average at 6 months, with 58.6% achieving ≥3-point improvement. By 9 months, HFMSE scores rose by 4.89 points, with 69% showing ≥3-point improvement. Among 13 patients completing 12-month follow-up, HFMSE scores improved by 4.77 points, with 61.5% demonstrating ≥3-point improvement. RULM scores showed a similar trend. Treatment led to significant motor milestone improvements, with 24.1% achieving at least one new milestone, including two gaining independent walking ability and five gaining independent standing ability. SMAIS scores increased by 5.65 points on average at 9 months, indicating enhanced daily functioning and quality of life.

Conclusions: GC101, an intrathecal AAV9-mediated gene therapy, is well-tolerated and shows promising efficacy in Type 2 SMA patients. Patients previously treated with Nusinersen and/or Risdiplam can safely benefit from GC101. These results support GC101's ongoing development as a potential Type 2 SMA treatment, with further studies needed to assess long-term safety and efficacy. The study highlights intrathecal AAV9-mediated gene therapy's potential to provide significant clinical benefits for SMA patients.



1355 *Advances in AAV9 Gene Therapy for CLN3 – Update on the Phase I/II Clinical Trial Indicating Lasting Efficacy at 5 Years Post Dosing and Next Steps in Program Development*

Emily De Los Reyes[1], Shawn Aylward[1], Jessica Scherr[1], Charles Albright[1], Cassandra Dennys[2], Shibi Likhite[1], Deep Singh[3], Jill Weimer[4], PJ Anand[5], **Kathrin Meyer[6]***

**Corresponding Author*

Juvenile neuronal ceroid lipofuscinosis (JNCL), also called CLN3 Batten Disease, is a debilitating autosomal recessive neurodegenerative disorder affecting children with onset around 4-10 years of age. The lack of functional CLN3 protein causes accumulation of cellular waste (storage material) due to malfunction of the lysosomes, as well as other intracellular defects including mitochondrial dysfunction. Affected children display rapid vision loss in most cases, followed by decline in motor function, behavior and cognition accompanied by development of seizures. While a few treatments are currently advancing through various stages of clinical trials, there is no cure or effective treatment for CLN3 Batten Disease that could change the course of this degenerative disorder. Thus, current

treatment focuses on symptom management. Natural history studies indicate worsening of individuals by 2.86 points/year as measured by the Unified Batten Disease Rating Scale (UBDRS). Investigators at Nationwide Children's Hospital, Columbus, Ohio developed the first gene replacement therapy for CLN3 Batten Disease and in 2018 initiated an open label, dose escalation phase I/II clinical study using lumbar intrathecal delivery of adeno-associated viral vector serotype 9 (AAV9) allowing expression of a functional CLN3 coding sequence in the central nervous system. Four patients were treated with the initial clinical vector lot. Treatment was well tolerated with only a few adverse events recorded, one involving liver enzyme elevation to more than 3-fold normal levels. Evaluation of disease progression indicates stabilization of the disease as measured by UBDRS (-0.13 points/year). Importantly, long-term efficacy data from over 5 years post-treatment demonstrate that 3 out of 4 patients maintain mobility (measured by the 50 meter walk test). We will also present long-term cognitive and adaptive functioning measures. To prepare for a potential dose escalation in clinic, additional high dose large animal studies were also conducted, further underlining the safety of this treatment. Taken together, the highly promising clinical data demonstrates the safety and suggests long-lasting efficacy of a classic gene replacement strategy for CLN3 Batten's Disease. Additional preclinical efforts have positioned this program optimally for further development to bring this therapy to patients with urgent need.

1356 *Completed Phase 1/2 Trial of Dual-Vector rAAVrh8 Gene Therapy for GM2 Gangliosidosis Administered by Bilateral Intrathalamic, Cisterna Magna and Intrathecal Delivery*

Florian Eichler[1], Oguz Cataltepe[2], Rrita Daci[3], Ajit Puri[3], Toloo Taghian[3], Xuntian Jiang[4], Mohammed Shazeeb[3], Anna Kuhn[5], Asma Hader[5], Hakki Celik[3], Zeynep Vardar[3], Connor Lewis[6], Rebecca Artinian[7], Amanda Nagy[8], Behroz Vachha[3], Robert Thompson[9], Thomas Gallagher[2], Scot Bateman[3], Julia Parzych[3], Spiro Spinakis[3], Toby Vaughn[3], Kirsten Pier[10], Erika De Boever[11], Mary-Alice Abbott[12], Eleonora D'Ambrosio[3], Danielle Kokoski[3], Meghan Blackwood, Elise Drummond[1], Eva-Marie Ratai[1], Elise Townsend[13], Haley McLaughlin[1], Cynthia Tifft[14], Allison Keeler-Klunk[3], Miguel Sena-Esteves[3], Heather Gray-Edwards[15], Terence Flotte[3]
[1]Massachusetts General Hospital, Boston, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]UMass Chan Medical School, Worcester, MA, [4]Washington University, St. Louis, St. Louis, MO, [5]UMass Chan, Worcester, MA, [6]National Human Genome Research Institute, Bethesda, MD, [7]UMass Chan Me, Worcester, MA, [8]Mass General Brigham, Boston, MA, [9]Boston Children's Hospital/Mass General Brigham, Boston, MA, [10]TKD Solutions, [11]EDB Consulting, Haverford, PA, [12]Baystate Medical Center, Springfield, MA, [13]MGH Institute of Health Professions, Charlestown, MA, [14]National Institutes of Health, BETHESDA, Maryland, [15]UMass Chan Medical School, Worcester, Massachusetts

We previously developed a dual rAAVrh8 vector encoding HEXA and HEXB which can restore central nervous system hexosaminidase (Hex) enzyme activity, decrease GM2 levels in cerebrospinal fluid (CSF), and rescue most or all the phenotypic consequences of GM 2 gangliosidosis Tay-Sachs and Sandhoff diseases (TSD and SD) in animal models following simultaneous bilateral injection into the thalami. Following up on a small (N of 2) expanded access (EA) trial, we initiated a Phase 1/2, single-dose, dose-escalation of combined bi-thalamic (BiT), intra-cisterna magna, and intrathecal infusion of rAAVrh8-HexA/HexB in children affected by GM2 gangliosidosis with four cohorts at dosage levels ranging from 1.42E+14 to 3.56E+14 vg per patient (5.87E+12–4.08E+13 vg/kg per patient). The BiT injection volume and vector dose was doubled between each cohort with the lowest dose matching the dose used in the prior EA trial. Six infantile and three juvenile patients were enrolled, and all patients were immune suppressed with rituximab, sirolimus, and corticosteroids prior to being dosed and continued with sirolimus for approximately 7 months and steroids for 3 months post-dosing. CSF HexA enzyme activity, serum total Hex activity, and GM2 levels showed a dose-dependent biochemical correction of the disease [Figure 1]. Importantly, serum Hex activity surpassed 40 nmol/hr/ml, which is 2× the lower limit of normal and neuroimaging demonstrated an increase in the net fiber tract number [Figure 2]. Enzyme activity and fiber tract increases were greatest at 12 weeks, but in decline by 24 weeks post-dosing. Infantile patients experienced global clinical stabilization and prolonged oral feeding without aspiration until 3 to 3.5 years. Adverse events were rare in infantile patients, but worsening dystonia was observed in juvenile patients, and so juveniles were excluded from ongoing enrollment in the study. These data on safety and dose-response effects on GM2 biomarkers and clinical outcomes informs route of delivery and patient selection in the next phase of clinical development for gene therapy treatment of TSD and SD.

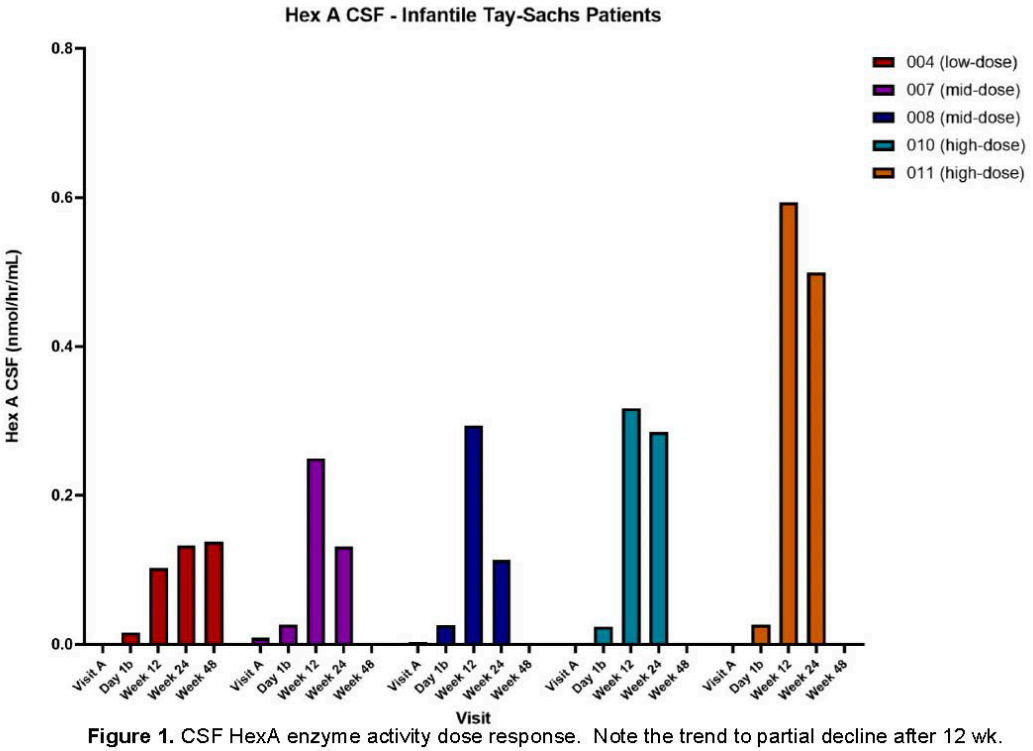

Figure 1. CSF HexA enzyme activity dose response. Note the trend to partial decline after 12 wk.

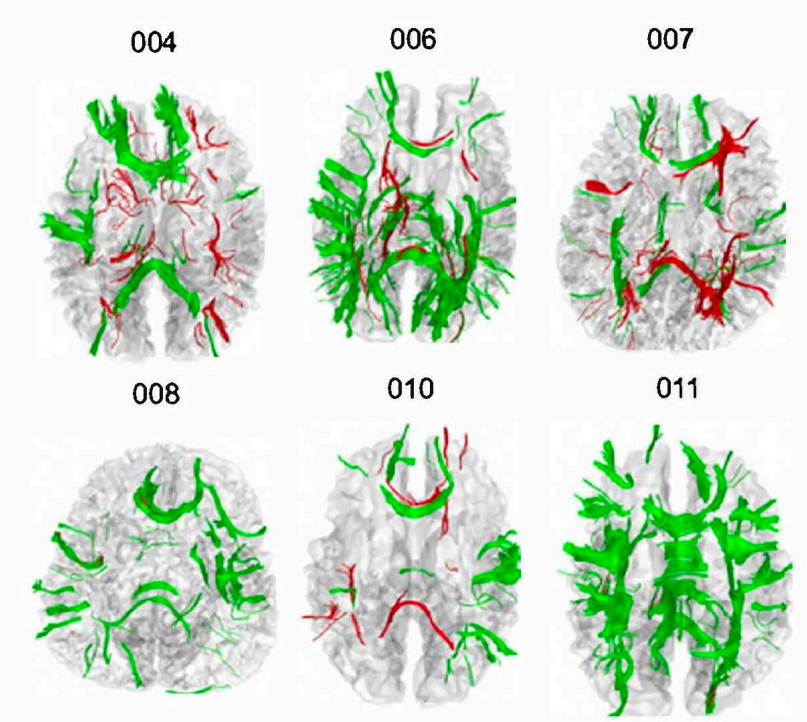

Figure 2. Diffusion Tensor Imaging analysis from scans done prior to vector delivery and at 24 weeks after vector delivery showing areas of increased (green) or decreased (red) fiber track development

1357 Urine NAA Results from the CVN-101 Natural History Study for Canavan Disease: Correlation with Phenotype

Amanda Nagy[1], Florian Eichler[2], Alexander Fay[3], Paul Harmatz[4], Adam Shaywitz[5], Mitra Tavakkoli[5], Rachel Williams[5], Christine Burton[5], Annette Bley[6], Heather Lau[7], Genevieve Laforet[8], Beth Leiro[5]
[1]Mass General Brigham, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]UCSF, San Francisco, CA, [4]UCSF Benioff Childrens Hospital Oakland, Oakland, CA, [5]BridgeBio, Palo Alto, CA, [6]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [7]NYU School of Medicine, [8]AS2 Bio, Middleton, MA

Gene therapies offer an extraordinary promise for rare and ultra-rare diseases. For many reasons, including but not limited to very small sample sizes, placebo-controlled trials are not practical. Therefore, identifying an easily sampled biomarker on the causal disease pathway that is associated with clinical phenotype would be of tremendous value. Here we demonstrate the feasibility of such an approach in Canavan disease (CD), leveraging the power of an independent, prospective longitudinal natural history study.

CD is an autosomal recessive, early-onset fatal spongiform leukoencephalopathy caused by loss- of-function mutations in the ASPA gene. Deficient ASPA enzymatic activity leads to elevated levels of its substrate, N-acetylaspartate (NAA), and profoundly impaired psychomotor development, with typically affected patients failing to gain even the most basic milestones. Currently, there is an actively enrolling trial investigating the impact of restoring ASPA activity via systemically administered AAV gene therapy on CD. Although sampling ASPA activity in the clinic is challenging, urine NAA represents an easily sampled biomarker that directly reflects underlying ASPA activity. Within CD, a subset of patients exhibits a milder phenotype with more milestone acquisition, including the ability to walk independently or with support. The milder phenotype is possibly related to greater residual ASPA activity. As NAA levels reflect residual ASPA activity, we hypothesized that there may be an association between urine NAA levels and clinical phenotype within the CD spectrum.

CANinform (CVN-101; NCT04126005) is an ongoing natural history study evaluating urine NAA levels prospectively and developmental /motor skills assessments, retrospectively and prospectively, in CD patients receiving standard supportive care. To date, 66 participants have been enrolled in this study globally. Prospective urine NAA data were available from 27 participants, 20 with a typical phenotype and 7 with a mild phenotype. These data were leveraged to compare urine NAA levels and associated genotypes in patients classified with mild or typical CD, with the hypothesis that urine NAA levels reflect ASPA activity and therefore can distinguish between the two phenotypes. Urine NAA levels were lower, on average ($p = <0.0001$), in participants with mild (mean 578, range 249.5 – 767.1 mmol/mol Cr) compared to typical CD (mean 1429, range 426.2 – 2440 mmol/mol Cr). In agreement with the literature, mutations R71H, Y288C, and G274R (variants that may harbor residual ASPA activity) were unique to the mild phenotype population (71%, 5/7) and not found in individuals with a typical phenotype in CVN-101 (0%, 0/20). Additionally, collection of prospective assessments of clinical functional tests in this study lends itself to understanding the potential relationship between the course of the psychomotor development impairment and urine NAA levels in CD patients, which is important for determining potential efficacy in gene therapy trials in CD.

Conclusion: In aggregate, the CANinform natural history data suggest urine NAA, by reflecting underlying ASPA activity, is an easily sampled biomarker on the causal pathway of CD and, importantly, can distinguish between mild and typical Canavan disease phenotypes. The Sponsor aims to fully investigate potential correlation between urine NAA and functional status of CD patients in this study.

1358 Volumetric Magnetic Resonance Imaging, Diffusion Tensor Imaging, and Differential Tractography Metrics Correlate with Clinical Outcomes Following Gene Therapy in GM1 Gangliosidosis Patients

Connor Lewis[1], Zeynep Vardar[2], Jean Johnston[3], Precilla D'Souza[4], William Gahl[1], Mohammed Shazeeb[2], Cynthia Tifft, Maria Acosta[5]
[1]National Human Genome Research Institute, Bethesda, MD, [2]UMass Chan Medical School, Worcester, MA, [3]NIH Office of Rare Disease Research, [4]National Institutes of Health, Bethesda, Maryland, [5]NIH - National Human Genome Research Institute, Bethesda, MD

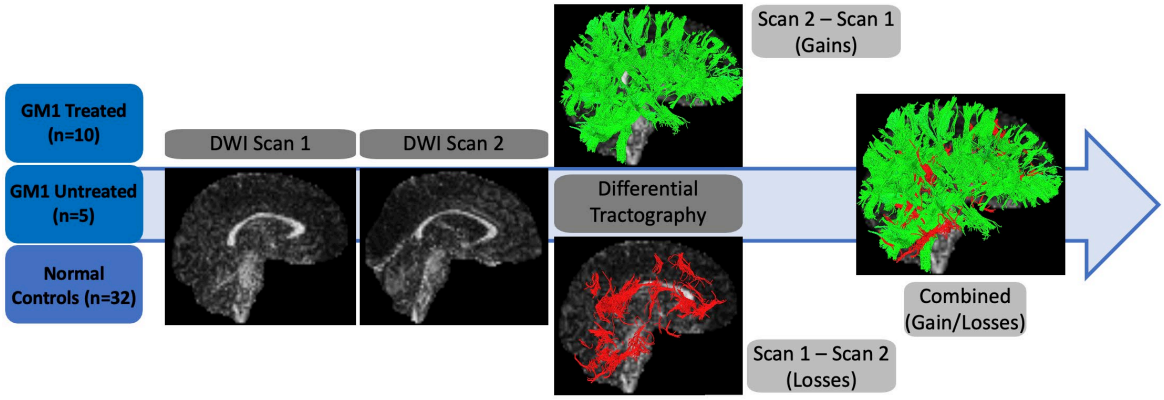
Introduction: GM1 gangliosidosis is a progressive neurodegenerative lysosomal storage disorder caused by biallelic variants in *GLB1*. There are no approved therapies, however AAV9 gene therapy trials are underway. Previous studies have documented imaging findings associated with GM1; however, no study has shown changes associated with an intervention in this cohort.

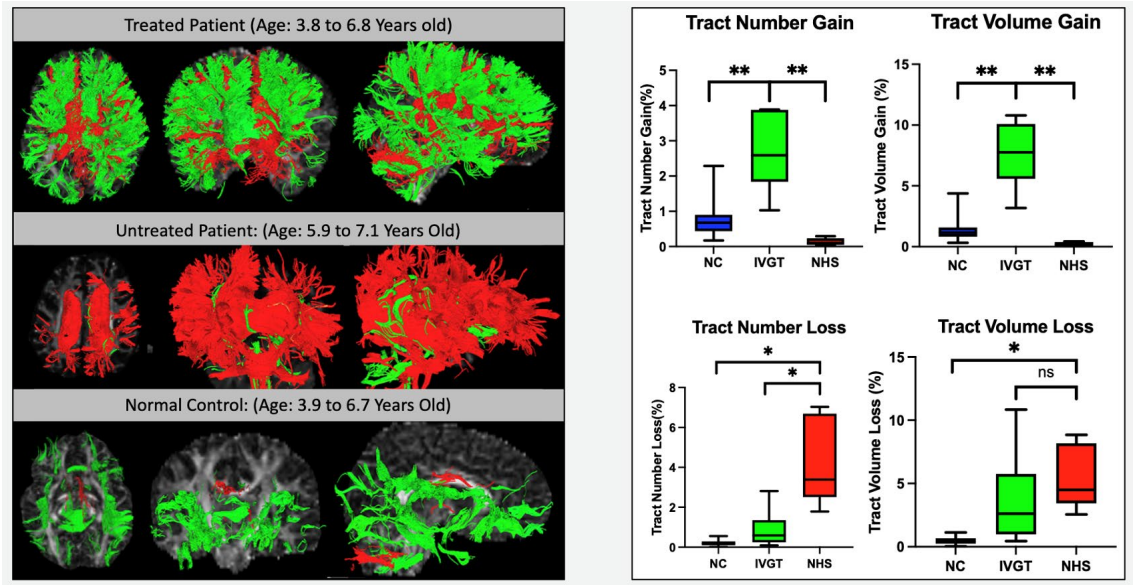
Methods: We compared volumetric magnetic resonance imaging (MRI), diffusion tensor imaging (DTI), and differential tractography between untreated GM1 patients (NHS, n=5, NCT00029965), gene therapy treated patients (IVGT, n=10, NCT03952637), and neurotypical controls (NC, n=32). Gene therapy treated GM1 patients were treated as a part of a Phase 1/2 open-label, dose-ranging, intravenous administration of AAV9-GLB1. GM1 patients from both cohorts underwent sedated MRI using a Phillips Achieva 3T system. Age-matched NC were obtained from open-source data repositories. Volumetric MRI analysis was performed using Freesurfer's *recon-all* pipeline. Atlas-based fiber tractography was performed using DSI Studio to calculate fractional anisotropy (FA) and mean diffusivity (MD) in the whole brain, corpus callosum, cerebellum, cingulum, and corticospinal tracts. Differential tractography (DT) is a subject level DTI analysis technique enabling longitudinal comparisons in white matter fiber tracts within a patient over time. A one-way ANOVA was used to analyze volumetric data, Welch's two sample t-tests to evaluate DTI and DT parameters between NHS and IVGT patients, and linear mixed effects models to correlate DTI and DT metrics with Vineland adaptive behavior scores and CGI-C change in clinical global impressions scores.

Results: Treated patients showed significant reduction in the rate of ventricular enlargement ($p = 0.0297$) compared to NHS patients. Treated patients also showed significantly increased changes in FA in the whole brain ($p = 0.0006$), corpus callosum ($p = 0.0382$), cerebellum ($p = 0.0007$), cingulum ($p = 0.0002$), and corticospinal tracts ($p=0.0411$). Untreated patients showed significantly increased changes in MD in the whole brain ($p=0.0049$), cerebellum ($p < 0.0001$), cingulum ($p=0.0020$), and corticospinal tracts ($p = 0.0424$). Whole brain FA ($\mathbb{R}?^2 = 9.41$, $p = 0.002159$, R^2

= 0.4104) and MD ($\mathbb{R}?^2 = 10.83$, p=0.001001, $R^2 = 0.4434$) correlated with Vineland-3 scores. DT showed increases change in fiber tract density ($p = 0.0047$), and volume ($p = 0.0016$) in the treated cohort compared to untreated GM1 patients. Untreated NHS patients showed decreases in fiber tract density ($p = 0.0116$) compared to treated patients. Net fiber tract density ($p = 0.001373$) and volume were also higher in IVGT than untreated NHS patients. There was no statistical difference in net fiber tract density or net fiber tract volume between IVGT and NC. DT assessed net fiber tract number ($\mathbb{R}?^2 = 31.49$, $p < 0.001$, $R^2 = 0.3764$) and net fiber tract number ($\mathbb{R}?^2 = 36.58$, $p < 0.001$, $R^2 = 0.4176$) both correlated with longitudinal change in patients' clinical presentation as assessed by CGI-C.

Conclusion: This is the first study demonstrating the utility of DTI and DT in evaluating longitudinal changes following therapeutic intervention in GM1 patients. We found improvements resulting from gene therapy as assessed by volumetric MRI, DTI, and DT. We also found our MRI derived metrics correlated with clinical outcomes indicating potential as a robust biomarker.





1359 What is the Formula for Commercial Success of a Gene Therapy? Reflections on Approved GTx

Simone Seiter[1], Christian Hinneburg[1]
[1]*Simon-Kucher, Frankfurt, Hessen, Germany*

Introduction: As of today, fewer than 20 gene therapies (GTx) have been approved in the US and Europe, yet only one has reached blockbuster status, with two more expected to follow. Despite their transformative potential, the majority of gene therapies fail to achieve widespread commercial success. One of the most decisive factors influencing a GTx's market trajectory is the selection of the right indication. This analysis seeks to identify the key characteristics of commercially successful indications and how they drive adoption, pricing potential, and long-term viability.

Methods: A retrospective analysis of approved gene therapies was conducted, focusing on the indications selected by manufacturers. Key variables analyzed include disease severity, prevalence, life expectancy with standard of care (SoC), quality of life (QoL) impairment, the competitive landscape, and clinical development feasibility. Structured expert interviews with industry leaders and real-world case studies were incorporated to validate insights. The session will be presented by Simone Seiter (Senior Partner, Simon-Kucher), leveraging expertise in gene therapy commercialization.

Results: Preliminary findings reveal that the selection of the right indication is one of the most critical determinants of commercial success. The following five key criteria emerged as pivotal:

- Life Expectancy & Disease Severity: Gene therapies targeting life-threatening diseases with limited SoC options tend to achieve higher adoption, as the urgency for a curative treatment is greater.
- Quality of Life (QoL) Impairment: Indications with severe, progressive QoL decline create a stronger value proposition, making them more attractive for both payers and patients.
- Patient Population & Age: The age of the target population plays a critical role—pediatric indications may benefit from longer lifetime value, whereas adult indications often require more established treatment paradigms for adoption.
- Future Treatment Alternatives: The expected evolution of the competitive landscape is a key consideration, as some indications may see disruptive alternative therapies that limit the long-term market opportunity for a GTx.
- Technical & Clinical Feasibility: Indications with clear, clinically validated biomarkers and regulatory precedent for approval tend to have a smoother development and commercialization path.

Conclusions: The success of a gene therapy is highly dependent on indication selection—more than any other commercial factor. An indication that aligns with high unmet medical need, strong patient and provider demand, and regulatory feasibility has a significantly greater chance of commercial success. This session will provide industry leaders with a structured framework for making strategic indication selection decisions, ensuring the long-term viability of their gene therapy assets. The success of a gene therapy is **highly dependent on indication selection**—more than any other commercial factor. An indication that aligns with **high unmet medical need, strong patient and provider demand, and regulatory feasibility** has a significantly greater chance of commercial success. This session will provide industry leaders with a structured framework for making strategic indication selection decisions, ensuring the **long-term viability** of their gene therapy assets.

1360 Characteristics of Long-Term Follow-Up Studies for Gene Therapies registered in ClinicalTrials.gov

Carolyn Chapman[1], Ava Glazier[1], Emina Berbic[2], Barbara Bierer[1]
[1]The Multi-Regional Clinical Trials Center of Brigham and Women's Hospital and Harvard, Boston, MA, [2]MRCT Center, Boston, MA

Guidance from the FDA and other regulatory agencies recommends long-term follow-up (LTFU) studies of gene therapy recipients. The primary objective of LTFU studies is to understand the long-term safety of gene therapy

products; the evaluation of efficacy outcomes may be a secondary goal. To learn more about LTFU study design and conduct, we conducted a descriptive study of key characteristics of LTFU gene therapy study protocols registered in ClinicalTrials.gov, including data about the status and duration of the studies, funding source, enrollment, number of clinical trial sites per study, eligibility criteria, geographic location, and intent to monitor and report adverse events (AE). The characteristics of 103 "stand-alone" LTFU studies, as well as eight other records describing GT interventional clinical trials mentioning or incorporating an LTFU component, are described and analyzed. This analysis of registered LTFU studies enabled a better understanding of how these studies are currently designed and stimulated ideas for improvement, which are discussed. Most notably, our results suggest that there is a lack of harmonization in how safety outcomes are monitored and reported across LTFU studies. Standardization and/or harmonization of adverse event and outcome reporting for LTFU studies of GTs may increase their scientific and social value. The development of better guidance and innovative approaches for LTFU study design and conduct may support best practices and the fulfillment of LTFU commitments to understand the overall long-term benefit-risk profile of GT products.

1361 Safety and efficacy of the therapy with cd4+cd25highcd127- t regulatory cells – 12 years after administration

Piotr Trzonkowski, Medical University of Gdansk, Gdansk, pomorskie, Poland

OBJECTIVE: CD4+CD25highCD127- T regulatory cells (Tregs) remain a drug candidate for immunotherapy of type 1 diabetes (T1DM). We completed three trials testing Tregs in T1DM in recently diagnosed (stage 3) children. Here, we looked for long-term safety and efficacy aspects which is a key to the authorisation of this therapy.

RESEARCH DESIGN AND METHODS: We re-examined 51 T1DM patients tested with Tregs in our previous trials. At the time of assessment, these patients were 7,5 to 12 years after the therapy. They were assigned to the groups treated with Tregs and anti-CD20 antibody (Tregs+antiCD20, N=9), with 1 or 2 doses of Tregs only (Tregs 1 dose, N=10 and Tregs 2 doses, N=8) and standard of care group (SoC control, N=24). The patients underwent diabetes-oriented tests as well as non- to minimal invasive evaluation of the anatomy and function of the eye, micro- and microcirculation, endocrine system, genitourinary tract and fertility, kidney and liver profiles and detailed biochemistry lab tests. Particular attention was paid to any safety issues reported by the patients. Altogether, over 700 variables were analysed.

RESULTS: Tregs+antiCD20 group was superior to SoC control group in terms of C-peptide secretion in mixed-meal tolerance test (MMTT), the time of insulin independence and the time of remission. No clinically relevant between-groups differences were found in other performed examinations. Importantly, no severe adverse effects including tumours or deaths were reported during entire posttreatment time in any of the groups.

CONCLUSIONS: We confirmed long-term safety and efficacy of the therapy with Tregs. Due to superior efficacy profile, the combined treatment with Tregs and antiCD20 antibody should be considered as a routine therapy for recent onset T1DM patients.

1362 Reviving Hearts, Restoring Lives: Long-term Clinical Outcomes of Allogeneic iPSC-derived Cardiomyocytes Transplantation for Advanced Heart Failure Patients

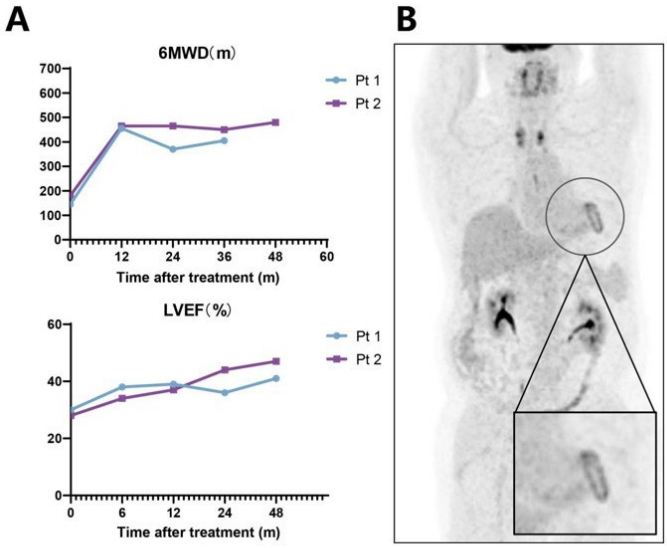
Alex Zhang, OneTwenty Therapeutics, Burlingame, CA

Heart failure is the leading cause of morbidity and mortality worldwide. Standard treatments are often insufficient to reverse heart failure especially in advanced heart failure patients (NYHA III-IV). Heart transplantation is considered the one last choice, limited by the shortage of donor organs. Cell-based therapies emerge as a promising alternative to restore cardiac function. Human induced pluripotent stem cells (hiPSCs) have the capacity for ex vivo differentiation into highly purified cardiomyocytes, thus making them an ideal source for heart regenerative medicine aimed at restoring lost myocardium1,2. However, there are still multiple challenges and technical hurdles

that need to be overcome, such as large-scale differentiation, optimal delivery route, management of the immune response, long-term safety and patient stratification.

Here, we report the First-in-Human study of direct epicardial transplantation of allogeneic iPSC-derived cardiomyocytes concomitant with open-chest coronary artery bypass grafting (CABG) surgery. The study protocol was approved by the Institutional Ethical Committee of Nanjing Drum Tower Hospital (SC2019008). Two patients with advanced heart failure (NYHA Class IV) were enrolled and received intramyocardial injections of allogeneic iPSC-derived cardiomyocytes in May 2019. On completion of the CABG anastomoses, 100 million cardiomyocytes were evenly injected into the peri-infarct tissue at 10 injection sites in the left anterior wall and heart apex. One-month immunosuppressant regimen was used, including methylprednisolone, basiliximab, tacrolimus and mycophenolate mofetil. Both patients successfully recovered from surgery, and completed 12-, 24-, 36-, and 48-month follow-ups.

The current first-in-human study of allogeneic iPSC-CMs transplantation provides the longest safety data in cardiac regenerative therapy and also demonstrates an improvement in heart function. In particular, improvements in exercise capacity, QoL, and NYHA class were observed in both patients by 12-month follow-up. No tumors, off-target effects or severe adverse events were recorded. A striking finding is that the improved cardiac enhancement segment was spatially related to the sites of cell implantation, even at 48-month (Patient 2). While the study design, primarily poised to assess feasibility and safety and which thus entailed a concomitant CABG, prevents to distinguish the effects of cells from those of myocardial revascularization, the clear documentation of safety is a strong incentive to further explore iPSC-derived cardiomyocytes as a new treatment modality for severe heart failure. Further trials, including those under way[5], should more specifically aim at addressing the key clinically-relevant roadblocks that still need to be overcome: the optimal management of immunosuppression; the efficacy of less invasive routes of cell administration and the potential benefits of repetitive dosing.



(A) Exercise capacity assessments by 6MWD and changes in LVEF; (B) 18F-FDG-PET at 48 months after HiCM-188 treatment in Pt 2.

1363 A Scalable Retroviral Vector Production platform for T-cell Therapy

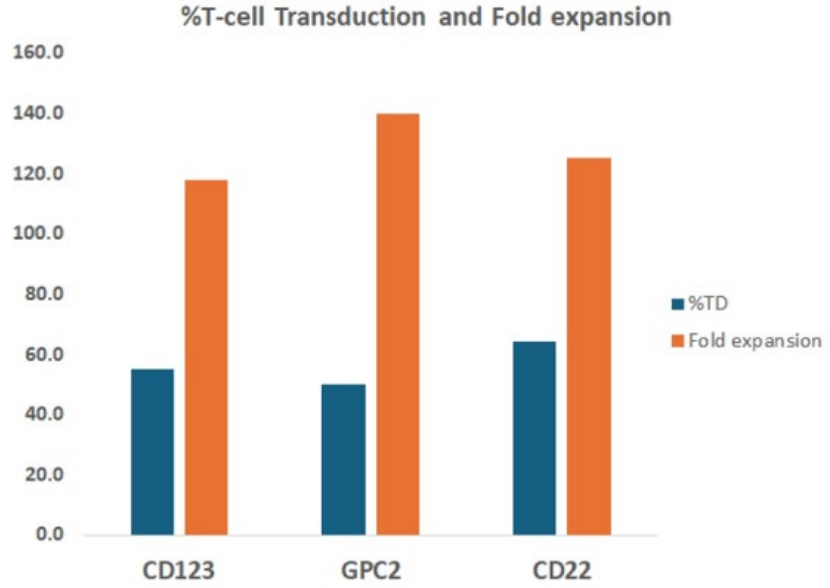
Alokesh Ghosal[1], Cynthia Ng[2], Vinay Vyas[2], Sharada Paudel[1], Raymond Harris[3], Jayne Christen[4]
[1]Leidos Biomedical Research, Frederick, MD, [2]Biopharmaceutical Development program, FNLCR, NIH, Frederick, Maryland, Frederick, MD, [3]Biological Resource Branch, DTP, DCTD, NCI, NIH, Frederick, Maryland, Frederick, MD, [4]NCI, Frederick, MD

Introduction: T-cell based therapy is one of the most promising approaches to treat liquid and solid tumors as evidenced by numerous successful clinical trials. In many cases, T-cell engineering is performed by using gammaretroviral vectors for gene delivery. Significant advancements have been made to viral vector manufacturing processes which have lowered the time and cost to develop and manufacture viral vectors suitable for early clinical evaluation. We developed a gammaretroviral vector production platform that requires only one gene-transfer plasmid. Using our production platform, we successfully manufactured multiple GMP-grade viral vector lots for use in generating T-cell patient products to support planned early-stage clinical trials that include B-cell leukemia (CD22TCR), acute lymphoblastic leukemia (CD123), and neuroblastoma (GPC2).

Methods: Using a multifactor design of experiment strategy, the transfection conditions for the gene transfer plasmid into the producer cell line (293VecRD114 obtained from BioVec Pharma Inc.) to generate RD114 envelope pseudotyped gammaretroviral vector were optimized and translated successfully to a 10L cell-culture process. Subsequently, the post-transfection harvest was concentrated by an optimized Tangential Flow Filtration (TFF) process into a vector stabilizing diafiltration buffer containing trehalose as the stabilizer. The concentration step resulted in a 3-4-fold titer increase. Finally, the TFF concentrate was sterile filtered. This manufacturing process routinely generated approximately 2L of concentrated, filtered retroviral vector. The transduction efficiency of the retroviral vector batches was tested by an optimized process using G-Rex technology.

Results: The 3-day retroviral vector manufacturing process generated a harvest with an infectious titer of 1-2x10^7 TU/mL in Jurkat cells that was concentrated and had a titer of 3-4x10^7 TU/mL post-sterile filtration. Approximately 30-35% of the total post-transfection virus measured by infectious titer was recovered following the manufacturing process. Transduced T-cells were expanded in the G-Rex resulting in a total of 30-40 million transduced cells. Transduction efficiency of CD4/CD8 T-cells was 40-60% across all retroviral vector batches, and no replication-competent retrovirus (RCR) was detected.

Conclusion: We developed a novel GMP-compliant retroviral manufacturing process that requires only one plasmid. This transient transfection process generates high-titer vector (>1x10^7 TU/mL) in the harvest that can be concentrated to 3-4x10^7 TU/mL. Using this manufacturing process, we were able to produce the required quantities of retroviral vector for generating engineered T-cells to treat patients with different clinical indications.



1364 Enhancing titres of therapeutic lentiviral vectors using PKC agonists

Charles Moore-Kelly[1], Thomas Evans[2], Jordan Wright[2], Dan Farley[3], Kyriacos Mitrophanous[2], Nicholas Clarkson[4], **Andre Raposo[5]***
[1]OXB, Oxford, United Kingdom, [2]Oxford Biomedica, Oxford, United Kingdom, [3]Oxford Biomedica, Oxford, Oxfordshire, United Kingdom, [4]Oxford Biomedica, Oxford, Oxon, United Kingdom, [5]OXB, Oxford, Oxfordshire, United Kingdom
**Corresponding Author*

Achieving high upstream lentiviral vector (LV) titres is fundamental to the development and manufacture of a commercially viable gene therapy product. Product titres can vary considerably with different therapeutic transgene sequences despite being produced in the same mammalian cell system. Implementing new technologies able to recover low titres or improve high titres further is invaluable.

Here, we identify protein kinase C (PKC) agonists as robust enhancers of LV production. Activation of PKC rapidly increased transcription of LV genomic RNA and release of vector particles. This enhanced induction method resulted in a ~3-fold improvement in chimeric antigen receptor (CAR)-LV titre, and a ~9-fold improvement was achieved when combined with co-expression of modified U1 snRNA molecule ('256U1') that binds to and stabilises LV genomic RNA. Importantly, LV produced using PKC agonists had comparable or superior particle-to-infectivity ratios and preserved an equivalent T-cell transduction profile. An in-house HPLC assay has demonstrated that PKC agonists effectively cleared from product following anion exchange chromatography.

Our investigation highlighted that PKC treatment during LV production strongly activated AP-1 transcription factors, whereas enhancement of LV titre was found to be independent of NF-κB activation. This enhanced induction method increases upstream productivity and can be easily implemented within GMP manufacturing schema and therefore offers commercial scope to reduce the cost per patient dose of new gene therapies.

1365 Large-Scale, High Titer Lentiviral Production Using Suspension Transient Transfection Platform

Tsai-Yu Chen[1], Khanh Ho[2], Shuo Lu[2], David Chiu[2], Chen Wei Su[1], **Mariya Viskovska[1]**, Kate Shen[2], Michael Haller[1], Bingnan Gu[3], Wenling Dong[4]
[1]Lonza, Houston, TX, [2]Lonza, Houston, [3]Lonza Houston Inc., Houston, Texas, [4]Lonza, Basel, Switzerland

Lentivirus vector (LVV) is a major player in cell and gene therapies. It efficiently transduces both dividing and non-dividing cells and is able to incorporate large transgenes, making it a versatile viral vector for a number of applications where gene delivery is required. Given the growing demand for the LVV-based therapies, Lonza developed an Xcite® LVV suspension transient transfection platform using a proprietary clonal HEK293T cell line. The platform utilizes a transient transfection with a plasmid expressing the gene of interest (GOI) and three packaging plasmids, and can be scaled up to 250L production and transferred to GMP manufacturing.

The platform as tested with two client-specific GOIs at a shake flask and 3L scale, and then successfully scaled up to 50L production. First, the optimal transfection parameters for each GOI were determined via the design of the experiment (DoE) performed in shake flasks. Conditions with varying plasmid ratios, cell densities at transfection, and a total plasmid DNA concentration were evaluated to determine the highest producing condition for each respective GOI. Second, the highest producing conditions were confirmed at a 3L scale, using the platform upstream and downstream processes. At 3L scale an average titer of 4.6E07 TU/mL was achieved for GOI 1 and 6.1E07 TU/mL was achieved for GOI 2 at harvest, as measured by the infectious titer assay (ITA), with the overall recovery of 23-30% for both GOIs.

Production for both GOIs were successfully scaled up to 50L. GOI 1 production resulted in 2.2E07 TU/mL of LVV at harvest and 2.2E08 TU/mL of bulk drug substance (BDS). GOI 2 production resulted in 1.1E08 TU/mL at harvest and 3.1E08 TU/mL BDS. The overall recovery at 50L was 15.3% and 39% for GOI 1 and GOI 2, respectively. BDS generated from the 50L runs was formulated into a formulation buffer and the final drug product (DP) was tested for stability at room temperature and at 2-8°C. DP for both vectors was stable when held at 2-8°C up to 72 hrs (the last time point tested). When held at room temperature GOI 1 DP showed no significant titer reduction up to 48hrs (last

time point tested). GOI 2 DP showed a 30% titer reduction after 12 hrs and 50% titer reduction at 72 hrs (last time point tested). DP for both vectors were stable for 5 freeze/thaw cycles. The long-term -80°C storage stability studies are currently ongoing.

In summary, Lonza developed a robust, scalable suspension transient transfection platform for LVV production. The platform was successfully applied for two client-specific GOIs at shake flask, 3L, and 50L scale.

1366 Lentiviral Vector Production Process Intensification: High-Yield and Cost-Efficient Manufacturing Solutions

Olga Makovich[1], Lauren Torres[2], Nirnath Sah[3], Saya Vijily[4], Elena Prikhodko[1], Carey Connelly[1]
[1]Catalent Cell & Gene Therapy, Baltimore, MD, [2]Repligen, Waltham, MA, [3]Catalent Cell and Gene Therapy, Baltimore, [4]Catalent Cell and Gene Therapy, Baltimore, MD

Introduction: Process intensification for lentiviral vector (LVV) production involves innovative approaches to improve productivity, scalability, robustness, and product quality while reducing overall costs. This study evaluated the impact of two key factors on LVV production in suspension cell culture: (i) transfection at high cell density and (ii) enhancer addition. Tangential flow depth filtration technology (TFDF, Repligen) was used to perform transfections at high cell density, maintain perfusion cell culture, and harvest viral vector material. Sodium butyrate was added as an LVV production booster to enhance the yield.

Methods: Batch and perfusion modes of LVV production were compared in 2-L Univessel™ Single-Use bioreactors (Sartorius) using the Catalent® clonal HEK293 cell line (CAT293), Catalent® Off-the-Shelf (OTS) 3rd-generation lentivirus packaging plasmids, and a transfer plasmid encoding the EGFP transgene. CTS™ Viral Production Medium (Thermo Fisher) was used for cell amplification and LVV production. The concentration of plasmid DNA at transfection was normalized to cell density at the time of transfection. FectoVIR®-AAV (Polyplus) was used as a transfection reagent. Batch mode bioreactors were transfected at 2.0-3.0´10^6 viable cell (vc)/mL density and harvested on day 3 post-transfection by centrifugation. Perfusion mode bioreactors were equipped with 30 cm^2 or 50 cm^2 TFDF filters. Perfusion was performed at 0.75-3´ vessel volumes per day to achieve a 4-7-fold higher cell density at the time of transfection compared to batch mode. The LVV-containing conditioned medium was continuously collected at 2-8°C as a TFDF permeate fraction for 3 days after the transfection.

Results: High cell density transfection in perfusion mode, combined with sodium butyrate addition, significantly increased LVV yields. At 4-fold higher cell density, transgene and capsid production increased by 4.8-7.5-fold and 8.0-9.8-fold, respectively, compared to batch mode. At ~7-fold higher cell density and 4 mM sodium butyrate, a 10-10.5-fold increase in transgene and capsid production was observed. Batch mode processes enhanced by 2-4 mM sodium butyrate achieved only a 1.5-1.9-fold increase in LVV production. The combined effects of the transfection at 4 to 7 times higher cell density and sodium butyrate addition resulted in a 12- and 32-fold increase in transgene production, respectively. Capsid yields were increased by 19 and 22 times under the same conditions. The highest LVV yield was achieved in perfusion culture transfected at 7 times higher cell density with 4 mM sodium butyrate, reaching 1.01´10^{14} transgene/bioreactor and 2.78´10^{14} capsid/bioreactor. In contrast, batch mode production without enhancer yielded 3.15´10^{12} transgene/bioreactor and 1.25´10^{13} capsid/bioreactor.

Conclusion: A comparison of the LVV-intensified and typical batch productions indicated that a single intensified perfusion process could generate viral vector amounts comparable to 32 batch productions. Thus, a single 50-L perfusion run could yield the same quantity of LVV as 1500-L batch production. The perfusion process will require 52% less production medium and 77% less plasmids and transfection reagent.

1367 Exploring the potential of different point-mutated HIV-1 protease variants for continuous lentiviral vector production

Gene therapy has transformed modern medicine by addressing previously untreatable conditions. Lentiviral vectors (LV) play an important role in the gene therapy field, both on clinical trials and market-approved products. Traditionally, LV production relies on transient transfection, a method limited by scalability constraints, high costs of GMP-compliant plasmids, and a narrow production window due to the cytotoxicity of key LV components, namely the viral protease and the vesicular stomatitis virus G glycoprotein (VSV-G). Alternatively, LV production can be performed in stable platforms such as constitutive producer cell lines which offer a more cost-effective, scalable, and standardized alternative to transient systems. However, their development is hindered by the toxicity of the LV components. Strategies to mitigate this toxicity include the use of gamma-retroviral envelope glycoproteins (e.g., Gibbon ape leukemia virus, GaLV, or amphotropic murine leukemia virus, 4070A) or mutated protease variants like the T26S protease. However, T26S has shown limitations, particularly in supporting infectious titers with clinically relevant pseudotypes such as GaLV, highlighting the need for novel protease variants with reduced cytotoxicity.

Here, we assess the potential of a newly engineered protease variant (mutation X) for LV production and compare it to other existing protease variants. Mutation X reduces the autoproteolytic activity of the protease without a major impact on K_{cat}/K_m when compared to the wild-type (WT) protease. However, its effects on LV production and cytotoxicity remain uncharacterized. To investigate this, we introduced mutation X into the LV packaging plasmid and evaluated its performance in transient and semi-stable LV production using VSV-G, 4070A, and GaLV pseudotypes. The WT gag-pro-pol (GPP), GP(D25N)P (inactive protease), and GP(T26S)P (reduced-activity protease) were used for comparison.

Transient LV production revealed that GP(X)P supports total particle (T.P.) and transducing unit (T.U.) titers comparable to WT GPP, regardless of the pseudotype, suggesting that mutation X does not impair LV proteolytic processing or maturation. Most importantly, it rescued the titers lost with GP(T26S)P, in GaLV-pseudotyped LV. To assess its potential for stable production, cells were stably transfected with either GP(X)P or the control GPP variants, followed by REV stable transfection, in 3 biological replicates. Semi-stable LV production, where the transgene and envelopes were delivered transiently, showed that cells expressing GP(X)P supported T.P. and T.U. titers similar to the WT GPP, at least for VSV-G. These cells also exhibited a higher growth rate than WT GPP-expressing cells. Gag gene expression analysis by qPCR showed that, despite variability across replicates, cells expressing GP(T26S)P or GP(X)P generally supported higher gene expression levels than the WT GPP. Overall, these findings suggest that mutation X results in a less cytotoxic GPP variant, making it a promising candidate for stable cell line development. Further characterization, including cell proliferation assays, are currently ongoing to evaluate the impact of these protease variants on cell viability.

In conclusion, this study demonstrates the potential of a novel GPP variant for LV production, contributing with a new strategy to advance the development of continuous LV producer cell lines with clinically relevant pseudotypes.

1368 Chemically Defined BalanCD HEK293 Viral Feed Boosts Viral Vector Production

Shan Gao[1], Hamid Soleymani[1], Shahram Shahabi[1], Chandana Sharma[1], **OMID TAGHAVIAN[2]***
[1]FUJIFILM Irvine Scientific - Santa Ana, CA, Santa Ana, CA, [2]FUJIFILM Irvine Scientific, Santa Ana, CA
**Corresponding Author*

With a range of applications in cell and gene therapy, the most commonly used cells to produce viral vectors for gene modification are HEK293 cells (typically using standard batch mode for viral vector production). Approaches to increase viral genome titers include engineered cell lines, use of transfection reagents and enhancer supplements, and optimization of viral plasmid systems, all of which require costly process optimization. In this study, we describe a simplified approach to enhance viral vector production by utilizing a chemically defined feed medium for fed-batch production of adeno-associated virus (AAV). Developed using Rational Culture Media Design, Design of Experiment (DoE), and Multivariate Analysis methods, the feed medium, BalanCD HEK293 Viral Feed, was shown

to increase AAV titers 3-fold to 10-fold in multiple AAV serotypes (AAV2, AAV5, and AAV9) when applied at 12% (v/v), 24 hours post-transfection. Performance was further demonstrated in shake flask and small-scale bioreactors, in suspension HEK293 and adherent HEK293T cell lines, and compatibility with various basal growth media and different transfection methods. By adapting the use of this viral feed medium in fed-batch HEK293 cultures, we show increased AAV titers and improved VG/capsid ratios can be achieved with minimal process optimization.

In this presentation, you will learn about how HEK293 Viral Feed can:

- Increase AAV titer 3-fold to 10-fold across various AAV serotypes (AAV2, AAV5, and AAV9) and improve LV genome and functional titer by 3-fold
- Easily convert to fed-batch with minimal disruption to the workflow
- Scale-up viral vector production from shake flasks to bioreactors

1369 Increasing Lentivirus Production and T-cell Transduction Efficiency: Discovery and Validation of Next Generation Viral Sensitizer (VSE™) Compounds

Katelyn Badham[1], Keara Sutherland[2], Abigail Fernandes[1], Glib Maznyi[1], Jondavid De Jong[1], Oliver Varette[3], **Andrea Vervoort[1]**
[1]Virica Biotech, Ottawa, ON, [2]Virica Biotech Inc., Ottawa, Ontario, [3]Virica Biotech, Ottawa

Biomanufacturing of cell and gene therapies is a highly intricate process, often challenged by variability in yield, product quality, and scalability of manufacturing platforms. A critical yet frequently overlooked barrier to efficient viral vector and cell therapy production is cellular innate antiviral defenses. When foreign particles or nucleic acids are introduced into living cells, they activate robust antiviral responses, which can inhibit viral transfection/transduction, assembly, and replication. Virica's Viral Sensitizers (VSEs™) offer an innovative solution: a proprietary collection of small molecules which transiently and effectively suppress these cellular antiviral defenses, thereby enhancing viral production and transduction.

Virica leverages our high-throughput virology capabilities to screen and identify small molecule enhancers of viral vector production and transduction to increase the efficiency of cell and gene therapy manufacturing processes. We provide evidence supporting the use of VSEs in lentivirus-based therapeutics manufacturing, targeting 2 distinct and complementary aspects of the manufacturing process:

1. more efficient production of lentiviral vectors across adherent and suspension-based platforms

2. more efficient T-cell lentiviral transduction processes

We utilized our 96-well high-throughput transient transfection-based production assay to screen a library of 15,000 bioactive compounds to identify several new candidate VSE molecules for enhanced production of lentivirus in adherent HEK293T cells. Upon additional screening iterations, ten candidate molecules that met pre-defined screening criteria were then further validated at 96-well scale in both adherent HEK293T/17 and suspension VPC1.0 cells. Increases in functional lentivirus titer, quantified by a luciferase-based transduction assay, ranged between 1.5-3-fold (adherent) and 2-4-fold (suspension) across VSE candidates. Top VSE candidates from small-scale screening in both adherent and suspension-based platforms were then scaled to T-75 flask and 125mL shake-flask format, respectively, where consistent enhancement in functional lentivirus yield previously demonstrated at small scale was achieved.

Additionally, screening of VSEs for increased transduction efficiency revealed several molecules which enhanced the transduction of T-cells with lentiviral vectors. Further validation of candidate molecules demonstrated repeatable multi-fold increases in transduction efficiency across multiple T-cell donors, with little to no impact on cell viability post-transduction.

Together, this data demonstrates the applicability of next-generation small molecule VSEs for enhanced production of lentivirus-based cell and gene therapies.

1370 Novel nanofiber-based microcarriers designed for improved upstream productivity of viral vector biomanufacturing

Geddy Hamblen, Cellevate, College Station, TX

Jessica Giacomoni1, Anki Knutsson1, Henrik Bratt1, Jean-Christophe Bourdon2, John Counsell3, Luke Tappouni3, Mikael Sommarin4, and Linda Dexlin Mellby1

1 Cellevate AB, Lund, Sweden, 2. Cellular Medicine, University of Dundee, Dundee, Scotland, 3. UCL Division of Surgery and Interventional Science, London's Global University, London, UK, 4. Redoxis AB, Lund, Sweden.

Viral vector manufacturing needs to ensure scalability while upholding high product yield, quality, and process robustness. Adherent cell cultures systems known for their ability to produce high yields of viral vectors are associated with scalability challenges. Nanofiber-based microcarriers, a novel microcarrier format, providing three-dimensional (3D) cell culturing of adherent cells readily scalable in stirred tank (suspension) bioreactor systems, offers promising avenues for scale up of adherent cell cultures. Data showed that HEK293T cells adhering to Cellevat3d® nanofiber microcarriers formed homogeneous 3D cultures, generating cell-dense spheroids with high cell viability. The scalability of the microcarrier cultures was demonstrated by successful scale-up from spinner flasks up to a 10L SU stirred bioreactor using an enzyme-free passing process and maintaining consistent cell growth curves and viability above 95% throughout the culture. Transient plasmid transfection of HEK293T cells on Cellevat3d® nanofiber microcarriers showed high transfection efficiency (88–94%) for both adeno-associated virus serotype 2 (AAV2) and 9 (AAV9). Importantly, AAV2 vectors yielded high volumetric productivity (1014 vg/L) with higher titers compared to parallel 2D. Benchmarking results conducted by UCL in London demonstrated a 3.1-fold significant increase in AAV9 vector titer using Cellevat3d® nanofiber microcarriers compared to current standard microcarriers. These findings demonstrate the potential of the nanofiber-based microcarriers as a scalable platform for adherent cell cultures in gene therapy applications, advancing bioprocessing strategies for enhanced yield, reduced time and costs leading to improved upstream bioprocessing productivity.

1371 Using High-Throughput Genetic Screening to Improve Stable AAV Producer Cell Lines and to enhance viral vector production

Michelle Hussong[1], Julia Mahlberg[1], Tobias Bonifert[1], Rina Mahmuti[1], Thu Bauer[1], Vibha Simha[1]
[1]Cytiva, Köln, Nordrhein-Westfalen, Germany

Adeno-associated virus (AAV) vectors are key materials in many gene therapies, yet how recombinant AAV production is regulated within producer cells—including vector genome packaging efficiency and yield—still isn't well understood. To address this challenge, we developed a high-content, modular genetic screening platform that can evaluate hundreds of plasmid designs in a few weeks.

Our approach pairs combinatorial design with advanced analytics to evaluate how diverse genetic elements influence AAV production. Using this platform, we identified several design combinations that enhance vector genome titer and packaging efficiency, leading to marked increases in vector titers and fullness. These findings provide helpful insights into the molecular determinants of how AAV vectors are regulated and offer a useful tool to optimize AAV production processes to meet the growing demands of gene therapy candidates in the clinic.

1372 Optimising Production of 4th Generation Lentiviral Vectors (LV) of the TetraVecta™ System: Towards Plug-and-Play LV Manufacturing

Ben Alberts[1], Thomas Evans[2], Jordan Wright[2], Charles Moore-Kelly[3], Byrne Donna[2], Dogan Gur, Kyriacos Mitrophanous[2], Andre Raposo[4], **Dan Farley**
[1]Oxford Biomedica, OXFORD, Oxfordshire, United Kingdom, [2]Oxford Biomedica, Oxford, United Kingdom, [3]OXB, Oxford, United Kingdom, [4]OXB, Oxford, Oxfordshire, United Kingdom

HIV-1 based lentiviral vectors (LVs) are a popular choice for the delivery of gene therapies. LV architecture has not markedly changed over the past 20 years, with most therapies utilising 3rd-generation vectors. As the complexities of therapies increase, the LV platform will need to evolve accordingly. LV attributes such as purity and *in vivo* efficacy can be improved, for example, through elimination of transgene expression during production, reducing contamination of the final product and increasing batch consistency.

OXB have previously described a 4th-generation LV platform – called TetraVecta™ - with several improvements over the current 3rd-generation. Firstly, promiscuous splicing from the HIV-1 Major Splice Donor (MSD) during LV production has been ablated through inactivation of the donor sequence (2KO), leading to an increased pool of unspliced, intact vector genome RNA. 2KO-LVs exhibit improved repression of transgene expression during production when employed with the TRiP System™, further reducing contamination of the final drug product. Third-generation LVs utilise the native HIV-1 polyadenylation site for both genomic and transgene RNAs. However, the SIN-LTR safety modification has weakened this polyadenylation activity. We have therefore developed novel SIN LTRs – termed supA-LTR™ - with improved polyadenylation activity of the transgene mRNA in target cells. SupA-LTR™ reduces both transcriptional read-in/out of the integrated LV and generally improves transcriptional insulation without affecting the integration site profile. Rev-dependent LVs of the TetraVecta™ system are called SupA2KO-LVs.

Here we compare the production of LVs encoding a Chimeric Antigen Receptor (CAR) using 3rd-generation or Tetravecta™ vector platforms. LVs were made at 5L bioreactor scale in both 293T and 293T-TRiP cells before purification by anion exchange chromatography and hollow fibre filtration. Purified vectors were then used to transduce primary T cells and CAR-T cell activity was measured by killing assay. SupA2KO-LVs made in both 293T and 293T-TRiP cells attained comparable titres to the 3rd-generation control but displayed a greatly improved vector RNA profile due to the 2KO feature, with reduced levels of aberrantly-spliced transcripts detected in both production cells and LV particles. Furthermore, we observed reduced CAR expression in 293T-TRiP production cells when SupA2KO-LVs were used. Additionally, we demonstrate optimised implementation of the TRiP System™ during use of plasmid-encoded TRAP (the translational repressor) in standard 293T cells. SupA2KO-LVs display altered kinetics of production compared to 3rd-generation LVs. We will discuss our efforts to explore and further improve the production of TetraVecta™ LVs through optimisation of various parameters, including the use of the small-molecule enhancer Ingenol-3-Angelate (I3A).

We show that SupA2KO-LVs transduced primary T-cells with similar efficiency to the 3rd-generation control. Modestly improved expression of the CAR was detected on the target cells, most likely due to improved expression from the transgene cassette as a function of the supA-LTR™. The killing activity of CAR T-cells was comparable between both platforms, confirming that TetraVecta™ modifications do not adversely affect therapeutic LV function. Taken together, these data emphasise the potential of TetraVecta™ technology to improve overall LV quality without affecting function.

1373 A HTPD Approach for Rapid AAV Process Optimisation & Scale-Up

Shandel Pariag[1], Gareth Berry[2], Amy Hawksworth[3], Nicholas Pearman[2], Damon Ho[2], Ben Johnson[2]
[1]Pharmaron Biologics, Liverpool, LIVERPOOL, Merseyside, United Kingdom, [2]Pharmaron Biologics, Liverpool, Merseyside, United Kingdom, [3]Pharmaron UK Ltd, LIVERPOOL, United Kingdom

Pharmaron have successfully designed a platform process which can be tailored to a specific AAV gene therapy product. Through a manufacturing feasibility assessment, a rapid small-scale evaluation of a new product's 'fit' to the multi-serotype platform can be performed in as little as 6 weeks. This provides information on a product's performance using HEK293 cells in Ambr250® mini-bioreactors, before small scale chromatography-based

downstream purification. Targeted areas for process optimisation are rapidly identified, rather than a requirement for full process development.

Cost effective high-throughput development (HTPD) automated robotics platforms, alongside Design of Experiment (DoE), allows multiple conditions to be assessed at micro-scale determining the optimal parameters to meet the product's critical quality attributes (CQA's). HTPD, alongside a tiered approach to analytical testing, gives rapid, targeted results and allows data-driven decisions to be made on the next steps. Once, optimisation is complete, results are confirmed via lab-scale studies and exemplified at pilot scale. This demonstrates consistency across scales and confidence in the process before transferring it from development laboratories into 'at-scale' GMP production.

Pharmaron's reproducible platform process at increasing scales alongside their world-class analytics, provides fast confirmation that a product is ready for GMP manufacture. From a novel transgene plasmid to full GMP production, Pharmaron can accelerate from lab to full product release in as little as 6 months.

1374 A Novel Lentiviral Vector Cargo Gene Silencing System to Benefit Manufacturing of Cell Therapies

Sherin Johny[1], Maria Ababi[2], Harry Jenkins[3], Lorna McCall[4], Keith Meaney[5], Qian Liu[6], **Maria Patricio[5]**, Matthew Tridgett
[1]Oxford Genetics Limited, UNITED KINGDOM, [2]Oxford Genetics Limited, Oxford, Oxfordshire, United Kingdom, [3]OXGENE, Oxford, Oxfordshire, United Kingdom, [4]OXGENE, United Kingdom, [5]OXGENE, Oxford, United Kingdom, [6]OXGENE (Oxford Genetics), Oxford, Oxfordshire, United Kingdom

Lentiviral vector (LVV) is the most used delivery tool for genetic modification in ex vivo cell therapies and has also been used recently in in vivo therapy clinical trials. However, cargo gene expression during lentiviral vector (LVV) production can reduce titres and disrupt production cell growth and viability. In addition, the consequent byproducts of production cell death can complicate downstream processing. Ideally, cargo gene expression would be controlled. However, because the cargo gene is nested within the LVV genome, cargo gene knockdown also impairs LVV production, creating a significant challenge to the control of manufacturing processes. To address this issue, we engineered the vector RNA and the cargo gene mRNA to be distinct, enabling cargo gene silencing by an shRNA, the target of which remains unchanged regardless of the cargo gene. For optimal production, we also included an shRNA against an antiviral gene. We tested this system using XOFLX™ Packaging and Producer cell line platforms with anti-CD19 chimeric antigen receptor and pro-apoptotic *BAX* driven by a human promoter. This resulted in up to 95% gene silencing during manufacturing, and up to a four-fold increase in LVV production yield. Importantly, this system enabled the recovery of otherwise unrecoverable producer cell lines. We anticipate that the use of this system will de-risk development of novel LVV-based therapeutics and reduce the requirement to customise downstream processes with novel cargo genes. Process standardisation and timeline reduction is likely to result in decreased costs, therefore improving patient access to LVV-based therapies.

1375 Accelerating the AAV Path to Clinic through Targeted CMC Development

Shandel Pariag[1], Amy Hawksworth[2], Paul Young[2], Gareth Berry[3], Louise Winstanley[3]
[1]Pharmaron Biologics, Liverpool, LIVERPOOL, Merseyside, United Kingdom, [2]Pharmaron UK Ltd, LIVERPOOL, United Kingdom, [3]Pharmaron Biologics, Liverpool, Merseyside, United Kingdom

Pharmaron have successfully developed a manufacturing feasibility assessment as a fast, small-scale method of evaluating their platform's suitability of fit for any new product. This assessment can be completed in as little as 6 weeks from obtaining a novel transgene. The short study provides valuable product quality insight and allows rapid diagnosis of areas for process optimisation.

A triple transfection approach using Pharmaron's suspension HEK293 cell line, AAV Rep/Cap and Helper plasmids and either supplied gene of interest (GOI) plasmid or GOI plasmid produced by Pharmaron, can be used to produce

different AAV serotypes/products in Sartorius Ambr®250 bioreactor vessels. Consistent viral titres, genome titres and transfection efficiencies are observed across all 8 Ambr®250 vessels. Material from the Ambr®250 vessels are processed through a small-scale downstream version of the large-scale manufacturing process. Purification focuses on chromatography, including the challenging separation of empty capsids from full capsids, as a highly scalable solution and a toolbox approach based on the specific AAV serotype. Product performance over clarification, affinity and polishing steps are benchmarked against Pharmaron platform data where they consistently observe greater than 70% recovery for different AAV serotypes. Ion Exchange Chromatography (IEX) is used for removal of 'empty' AAV capsids from 'full' product containing capsids. Data analysis and benchmarking against the Pharmaron platform database facilitates a targeted development pathway.

Manufacturing feasibility, in combination with world-class analytical solutions, gives an early indication of product performance including yield and quality. Once complete, the manufacturing feasibility assessment provides an invaluable data set identifying any areas requiring targeted process optimisation rather than full process development, fast-tracking the product into scale-up and GMP manufacture.

1376 Unveiling the Secrets: Pathway Analysis Provides Molecular Insights into Stable Lentiviral Packaging and Producer Cell Lines (GPRTG)

Jona Röscheise[1], Holger Laux[2], Kerstin Otte[3]
[1]University of Applied Sciences Biberach, Ulm, Baden-Wuerttemberg, Germany, [2]CSL Behring Innovation GmbH, Marburg, Hessen, Germany, [3]University of applied sciences Biberach, Ulm, Germany

Lentiviral vectors (LVVs) are widely used in gene therapy due to their ability to infect both dividing and non-dividing cells, permanently transform target cell genome and allow stable transgene expression. For LVV production, the creation of stable packaging cell lines with integrated genes necessary for viral replication offer a more consistent and scalable alternative to transient plasmid transfection approach.

Although the development of such stable LVV packaging cell lines has been reported[1], the molecular changes induced by stable and inducible viral gene expression and the impact of genome integrated viral genes on cellular pathways remain poorly characterized. For better insight, we investigated the molecular characteristics of a stable LVV packaging cell line and its host cell line (HEK293T/17) by comparing differential expressed genes.

The performed pathway analysis revealed significant changes in pathway usage between packaging and host cell lines, influenced by different viral transgenes. Gag-pol expression was found to suppress host translational processes and nonsense mediated decay, with the majority of ribosomal assembly genes being downregulated. Rev and VSV-G expression modulated mitochondrial pathways, including oxidative phosphorylation and mitochondrial dysfunction, while HIV-1 tat expression activated histone-related genes. These regulatory shifts suggested a strategic reprogramming of host cellular states to favour viral replication, curbing protein synthesis and energy production to levels that support viral assembly, but impair the host's immune defence and the production of immune-related proteins.

Our findings provide a deeper understanding of the molecular changes associated with stable viral gene expression, which can inform the optimization of LVV production in gene therapy applications.

Miniaturized plasmids have been developed to resolve safety issues with gene therapy production, however these typically rely on alternative methods, e.g. supplement-based selection. These plasmids have significant disadvantages including compounding variables and associated cost. We've designed a novel miniaturized plasmid which bypasses the need for either antibiotic or supplement-based selection, providing improved efficacy, safety, and manufacturability for cell and gene therapies. Compared to traditional plasmids, we show that our miniVec plasmid has higher plasmid manufacturing and virus packaging yields, improved transgene expression, and an enhanced safety profile. The miniVec backbone supports a novel combination of antibiotic-free and supplement-free selection and can be applied across diverse viral and non-viral expression systems offering enhanced flexibility and ease of production from development through GMP manufacturing.

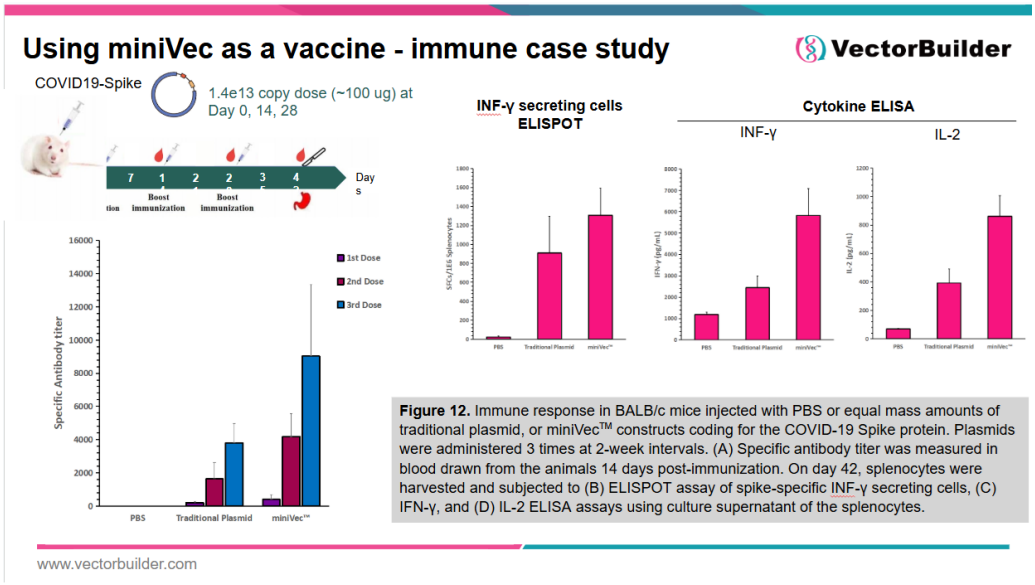

Figure 12. Immune response in BALB/c mice injected with PBS or equal mass amounts of traditional plasmid, or miniVec™ constructs coding for the COVID-19 Spike protein. Plasmids were administered 3 times at 2-week intervals. (A) Specific antibody titer was measured in blood drawn from the animals 14 days post-immunization. On day 42, splenocytes were harvested and subjected to (B) ELISPOT assay of spike-specific INF-γ secreting cells, (C) IFN-γ, and (D) IL-2 ELISA assays using culture supernatant of the splenocytes.

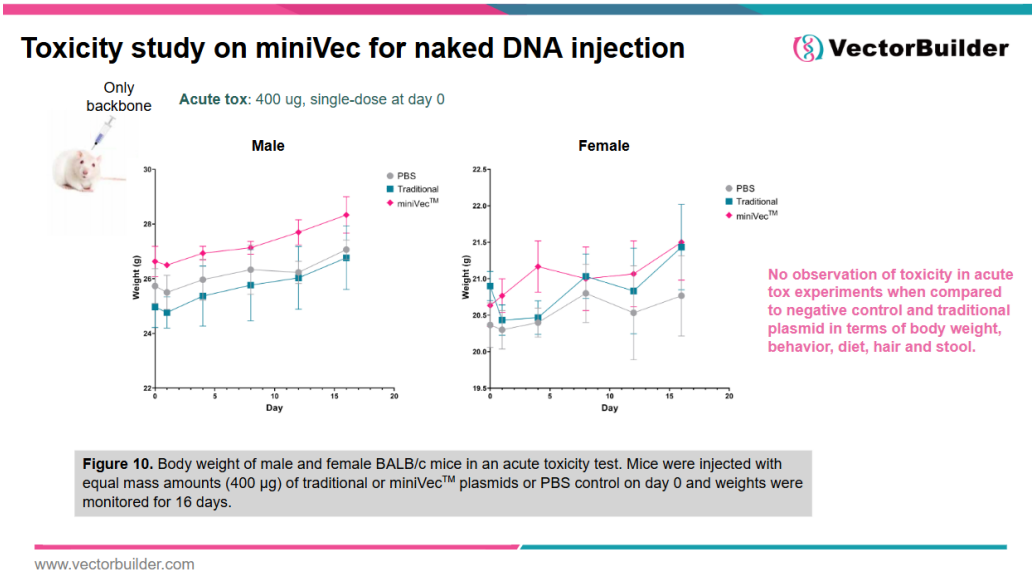

Figure 10. Body weight of male and female BALB/c mice in an acute toxicity test. Mice were injected with equal mass amounts (400 μg) of traditional or miniVec™ plasmids or PBS control on day 0 and weights were monitored for 16 days.

1378 Accelerating and Advancing the Pinnacle PCL™ Platform

Alix Eastham[1], **William Weir[2]**
[1]Ultragenyx Pharmaceutical Inc., Novato, CA, [2]Ultragenyx Pharmaceutical Inc., Cambridge, MA

Ultragenyx has developed the Pinnacle producer cell line (PCL) manufacturing platform for production of recombinant AAV (rAAV) gene therapy products, which has demonstrated scalable 2000L production in an industrial setting to support ongoing clinical trials. The process of stably transfecting a large Triple Play plasmid (pTP), containing the therapeutic vector construct and the AAV Rep and Cap genes, into HeLa S3 cells, to isolating a number of high rAAV-producing monoclonal cell lines, involves a series of screening steps and quality assessments. By employing specialized instrumentation, optimized methodology and capitalizing on PCL tractability in culture, the path to banked polyclonal PCLs was reduced by 4 weeks. First, we improved stable transfection efficiency of the pTP plasmid yielding a larger number of potential polyclonal candidates for screening, thereby increasing the probability of isolating high producing, high quality monoclonal PCLs. To support evaluation of the higher numbers of polyclonal candidates we added additional microbioreactor systems to more than double our screening capabilities, which affords us the capability to improve clone screening throughput in an optimized scaled-down process. The implementation of multiple automated and quantitative instruments, such as CE-SDS to evaluate capsid ratios, replaced legacy qualitative assays, further facilitating faster and more comprehensive generation of PCL quality profiles. Finally, next-generation sequencing tools, such as TLA integration analysis and Nanopore sequencing, offer deeper insights into the PCL's genomic landscape and the viral vector produced from the PCL. The cumulation of all these improvements not only decreases the timeline to a monoclonal lineage but allows us to make more informed candidate selection based on desired quality attributes.

1379 A Comprehensive Approach to Adeno-Associated Virus Upstream Process Development

Hugh Murray[1], Mitchell Simmonds[2], Frank Fabian[2], Jaime Garcia Escalante[3], Mikkal Blick[4], Ayan Dey[5], Samit Dutta[4], Eva Fong[6], Michael Shen[7]
[1]MilliporeSigma, Vista, CA, [2]MilliporeSigma, Carlsbad, CA, [3]MilliporeSigma, Oceanside, CA, [4]MilliporeSigma - Carlsbad, CA, Carlsbad, CA, [5]MilliporeSigma - Carlsbad, Carlsbad, CA, [6]Milliporesigma, Burlington, MA, [7]Carlsbad, CA

The development of an efficient and scalable manufacturing platform for adeno-associated virus (AAV) production is critical to meet the growing demand for gene therapies. Our process workflow leverages a robust design of experiments (DoE) framework, utilizing both mixture designs to optimize plasmid DNA ratios, as well as A-optimal designs to optimize other transfection and bioreactor parameters. High-throughput batch purification of upstream samples enables quantitation of a critical quality attribute that requires a purified sample matrix, such as empty, full and partial capsid quantitation using mass photometry. Dynamic Light Scattering (DLS) technology is used to characterize the transfection complexation process, which is a valuable tool for both optimizing the transfection parameters as well as ensuring consistent performance at scale. This process workflow demonstrates seamless scalability from bench-scale production to the 200L single-use bioreactor (SUB) scale and is conducive to a Quality by Design (QbD) approach to process design.

1380 Forced Degradation Studies of Multi-Characteristic Opsin Gene Therapy Drug Product

AMIR SINGH[1], SUBRATA BATABYAL[2], Samarendra Mohanty[3], Najam Sharif[4], Brett Kiedaisch[5], Sabrina Macias[5], Saurav Mohanty[4]
[1]Nanoscope Therapeutics, Arlington, TX, [2]Nanoscope Technologies LLC, Bedford, TX, [3]Nanoscope Therapeutics Inc, Bedford, TX, [4]Nanoscope Therapeutics, Dallas, TX, [5]Nanoscope Therapeutics Inc, Dallas

Multi-characteristic Opsin (MCO) gene therapy has demonstrated durable efficacy in treating advanced retinitis pigmentosa (RP) patients with severe vision loss. MCO-010 is a trimeric fusion protein with high sensitivity and fast

kinetics to light across the visible spectrum. Since MCO-010 is delivered via adeno-associated virus serotype-2, it is susceptible to environmental conditions such as temperature excursions and freeze-thaw during storage, shipment, and use in analytical labs as well as clinical settings. Hence, we conducted forced degradation studies, along with imposed freeze-thaw cycles, on MCO-010 to evaluate its possible degradation and to gain insights into the formation of impurities that may reduce its potency. In addition, the sensitivity of various analytic methods and stability-indicating critical quality attributes were identified using the force-degraded MCO-010 samples.

Specifically, we examined the impact of temperature excursion at 40°C for up to 4 weeks and 10 freeze-thaw cycles on the integrity and functionality of the MCO-010 drug product. The study tested the detection limits and performance of analytical assays, including ELISA for capsid integrity assessment, SDS-PAGE silver staining for detecting degradation-induced structural changes, qPCR for genomic titer quantification, and flow-based transgene expression for relative potency measurements. The incubation of MCO-010 drug product at 40°C for 1 week resulted in significant decreases in capsid titter (50%), genomic titter (35%), and relative potency (31%). These effects became more prominent in week 2 and week 4, indicating a time-dependent degradation. Additionally, the 10 freeze-thaw cycles caused a moderate decrease in capsid titter (15%), genomic titter (17 %), and relative potency (6%).

The study confirmed the sensitivity of the analytical methods, demonstrating their ability to detect subtle changes in MCO-010 drug product quality under forced degradation conditions. These findings support the use of these validated assays for quality control and stability monitoring during MCO-010 drug product storage and handling for future clinical use.

1381 In Vivo Selection of Randomly Integrated rAAV Does Not Cause an Increased Risk of Tumorigenesis

Amita Tiyaboonchai[1], Anne Vonada[1], Markus Grompe[2]
[1]Oregon Health and Science University, Portland, OR, [2]Oregon Health & Science University, Tualatin, OR

Liver-targeted recombinant adeno associated viruses (rAAVs) typically have only a short therapeutic benefit when administered to pediatric patients due to loss of episomes during liver growth. While rAAVs can persist through multiple rounds of cell division by rare random integration into the genome, these integration events are too infrequent to reach a therapeutic threshold. In vivo selection and expansion of targeted hepatocytes results in therapeutic levels of these integration events. However, it remains unknown whether multiple rounds of cell division and selection will increase the likelihood of rAAV mediated tumorigenesis and oncogenesis in the liver.

We have previously developed a pharmacologically selectable shRNA that can allow expansion of a small population of gene edited hepatocytes in vivo. This shRNA functions by blocking expression of Cytochrome p450 reductase (Cypor), which is required for the metabolism of the drug acetaminophen (APAP) to a hepatotoxic byproduct. Accumulation of this hepatotoxic byproduct leads to cell death in hepatocytes. By creating a loss of Cypor linked to the desired gene edits, therapeutic cells can no longer metabolize acetaminophen and are protected from its toxicity.

rAAVs containing a U6-driven shRNA targeting Cypor in cis with a CAG promoter driving a human Factor IX (hFIX) transgene were delivered into wild-type neonatal mice. APAP was then administered to select for hepatocytes with integrated rAAV vectors. Blood serum hFIX levels and immunofluorescence staining of the liver confirmed the >20x expansion of Cypor negative, hFIX positive hepatocytes to a highly therapeutic level. To assess increased oncogenic risk, mice with expanded rAAV integrations were then placed on either a Western diet or regular mouse diet for 6 months. The Western diet, consisting of high fructose and high cholesterol, has been shown to induce tumorigenesis in mice even in the absence of rAAV or APAP treatment. At termination of the experiment, mice on the Western diet did have increased tumor frequency compared to mice on a regular diet as expected. However, there were no significant differences in the frequency of tumor occurrence, tumor size or tumor volume of the tumors between rAAV-treated mice that had been acetaminophen selected as compared to mice that were unselected. These results demonstrate that APAP selection in the liver does not lead to an increased risk of

oncogenesis in the liver. We conclude that APAP selection can be safely used to expand hepatocytes with therapeutic rAAV transgene integrations.

1382 Integration Frequency of Full and Truncated AAV Genomes in Cas9-Induced DSB Sites Is Determined by DNA Repair Pathways

Martin Bilbao-Arribas[1], Laura Torella[2], Julen Torrens-Baile[3], Nerea Santana-Gonzalez[3], Nerea Zabaleta[4], Gloria Gonzalez-Aseguinolaza[5]*

The unintended integration of adeno-associated virus (AAV) vector sequences at CRISPR-induced double-strand breaks (DSBs) poses significant concerns for AAV-mediated gene editing. Despite reports describing AAV integrations in various *in vivo* settings, the DNA repair mechanisms involved are not fully understood. In a prior study, we delivered CRISPR-Cas9 systems into the mouse liver using recombinant AAVs to disrupt the *Hao1* gene. Using short-read amplicon sequencing, we observed that paired Cas9 nickase editing resulted in fewer AAV sequence insertions on target compared to Cas9 nucleases, despite demonstrating comparable editing efficiencies. Paired nicks were preferentially repaired by microhomology (MH)-dependent pathways. Nevertheless, the widely used amplicon sequencing approach limits the full characterization of inserted AAV sequences. In this work, we further characterize the full range of AAV insertions after paired Cas9 nickase and Cas9 nuclease editing with targeted long-read sequencing and we explore the relationship between AAV integration frequency and DSB repair pathway choice.

We used long-read nanopore Cas9-targeted sequencing (nCATS). This PCR-free method was critical in overcoming the limits of short-read sequencing. Overall, paired nickase editing produced much fewer AAV integrations than paired nuclease editing, consistent with our earlier findings. In both cases, insertion breakpoints were predominantly located on the inverted terminal repeats (ITRs.) We categorized AAV insertions into three types: short insertions (<200 nucleotides) of ITR sequences, full-length AAV genome insertions, and truncated AAV genome insertions. Short ITR insertion frequency was 1.15% with paired nickases compared to 11% with paired nucleases (similar to amplicon sequencing data). Full and truncated AAV insertion frequency was 3.95% with paired nickases compared to 12.5% with paired nucleases. This meant that not only AAV insertion frequencies changed between both approaches, but also the structure of inserted sequences.

To investigate the factors underlying the reduced AAV insertions observed with paired nickase editing, we reanalyzed short-read amplicon sequencing data from multiple studies that used various CRISPR-Cas systems delivered by AAVs. We identified a correlation between increased MH-mediated repair and decreased AAV insertions. Remarkably, the greatest MH scores and the lowest AAV insertion rates were produced by nucleases that generate staggered ends, like Cas12 family nucleases. Since the reanalyzed samples originated from very heterogeneous experiments in terms of AAV dose, tissue, animal age etc., we designed and tested four gRNAs *in vivo* with the same experimental conditions. Using amplicon sequencing, the two gRNAs with the highest MH-mediated repair showed lower editing efficiency-normalized AAV insertions (4% and 9%) compared with the other two (12% and 16%).

These results suggest that the nature of the DSB and the involved repair mechanism significantly impact the extent and type of AAV insertions into CRISPR-induced DSBs. This implies that rational CRISPR system design and target site selection may improve the safety profile of AAV-delivered gene editing treatments by intentionally directing DSB repair toward MH-dependent pathways.

1383 mRNA-loaded AAV Vectors Enable Safer CRISPR Gene Editing for Neurological Diseases

Weiya Bai[1], Dong Yang[1], Yaqing Zhao[2], Haifeng Quan[2], Panzhi Xiong[2], Peng Chen[2], TJ Cradick[3], Alvin Luk[4], Linyu Shi[1], Hui Yang[5]
[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China, Shanghai, Shanghai, China, [2]HuidaGene (Shanghai) Therapeutics Co. Ltd., Shanghai, China, Shanghai, China, [3]HuidaGene Therapeutics, Clinton, NJ, USA; Cholgene Therapeutics, Middletown, DE, USA, Clinton, NJ; Middletown, DE, MA, [4]Huidagene Therapeutics Inc, Clinton, NJ, [5]HuidaGene Therapeutics Co., Ltd., Shanghai, China; Shanghai Institute of Meteria Medica, Chinese Academy of Sciences, Shanghai, China, Shanghai, Shanghai, China

Background: We developed a novel mRNA-loaded AAV (RAAV) system by incorporating RNA-packaging components into the AAV production process and engineering Rep proteins. This RAAV vector combines the transient mRNA expression with the broad tissue tropism of AAV capsids, addressing critical *in vivo* gene editing safety concerns such as nuclease immunogenicity, possible off-target effects, and genomic integrity. Unlike existing liver-targeted mRNA delivery methods, RAAV enables mRNA-based therapies in non-hepatic tissues, including the brain. We applied RAAV with AAV for a dual-virus delivery system, enabling gene editing in neurological diseases.
Methods: We used RAAV for Cas12Max expression and AAV for gRNA delivery to deliver the CRISPR system. Gene editing efficiency and safety were assessed in HEK293T cells and mouse brains. For therapeutic evaluation in an ALS model, TDP-43 transgenic mice received intracerebroventricular (ICV) injections of RAAV-hfCas12Max and AAV-ATXN2-gRNA on postnatal day 0, P0 (**Fig. 2A**). On-target/off-target editing, ATXN2 protein levels, and toxic TDP-43 aggregation were analyzed 3 weeks post-injection (**Fig. 2B**). To explore broader applications, RAAV was used to deliver ZFcharm, an epigenetic editor targeting Prnp transcription for prion disease treatment. RAAV-ZFcharm was applied to cultured cells and injected into mouse brains, and DNA methylation, Prnp transcription and Prp expression were analyzed.

Results: Co-infection with RAAV-hfCas12Max and AAV-gRNA efficiently edited the hTTR locus in HEK293T cells and ATXN2 locus in mouse hippocampus (**Fig. 1A, 1C**). Off-target editing was measured in the cells/tissues treated with AAV delivery (**Fig. 1B, 1C**), but cells/tissues receiving RAAV had background low levels comparible to mock-treated cells (**Fig. 1B, 1C**).
In the ALS model, RAAV-hfCas12Max with AAV-ATXN2-gRNA achieved 3.8% on-target gene editing of *ATXN2* in the cortex with no significant off-target effects (**Fig. 2C**). Off-target editing rates with RAAV-Cas12Max-infected cells and brains were comparable to those of uninfected controls (Mock) and significantly lower than those observed with conventional AAV-Cas12Max (**Fig. 2C**), highlighting that RAAV-mediated mRNA delivery provides a safer approach for gene editing. Western blot showed a 47.4% reduction in cortical ATXN2 protein levels of treated TDP-43 mice compared to controls (**Fig. 2D**). Toxic TDP-43 aggregates were reduced by 25.3% (**Fig. 2E**). While untreated TDP-43 mice had a median lifespan of ~25 days, RAAV-hfCas12Max-treated mice showed a significant extension of medical lifespan (**Fig. 2F**). The RAAV-ZFcharm treatment effectively induced targeted DNA methylation at the Prnp promoter for prion disease. This led to a significant reduction in Prnp RNA and protein levels in cultured cells and mouse brains, confirming the potential of RAAV for epigenetic editing(Not Shown).

Conclusions: We developed a dual-virus delivery system utilizing RAAV for Cas12Max mRNA expression and AAV for gRNA delivery. This system demonstrated effective gene editing with significantly reduced off-target effects compared to conventional AAV vectors *in vitro* and *in vivo.* RAAV-mediated gene editing showed therapeutic efficacy in ALS mouse model and was successfully adapted for epigenetic editing to treat prion disease. These findings establish RAAV as a versatile platform for safe and effective mRNA-based gene therapies with broad applications in neurodegenerative and other genetic disorders.

Recombinant adeno-associated virus (rAAV) vectors have emerged as a promising delivery vehicle for gene therapy, but their efficacy can be significantly influenced by the size of the packaged genome. Presented at ASGCT 2024 were results showing that different AAV serotypes exhibit varying packaging limits (1). This variability underscores the critical role of stuffer sequences in rAAV vectors, particularly when the transgene is small and fails to meet the optimal packaging limit. Stuffer sequences offer a versatile solution to this challenge, allowing researchers to fine-tune vector size, potentially enhancing transgene expression and vector performance. However, the design and implementation of these sequences requires careful consideration to avoid unintended biological effects and ensure optimal vector functionality, especially when rAAV vectors are developed for clinical purposes.

Here, we evaluated multiple stuffer sequences in silico using FORMsightAI, a proprietary artificial intelligence (AI) technology engineered to optimize nucleic acid therapeutics for safety and manufacturability using rational design and AI-Augmented CDS optimization. In silico modeling revealed that the truncation risk associated with a 4340bp sequence from the 3'UTR of human bone morphogenic protein 10 (BMP10) transcript stuffer was low, with few predicted secondary and tertiary structures, no significant CpG islands and nominal %GC content. Supported by these data, different portions of the BMP10 stuffer sequence were strategically selected (lack of start codon & splice sites etc) for synthesis and leveraged for two different gene therapy applications, gene augmentation and gene silencing. This approach allowed for tailoring the stuffer length to meet specific packaging requirements for each application, while maintaining optimal vector performance. The resulting vectors were packaged into AAV8 capsids. Vector genome integrity was evaluated using alkaline gel electrophoresis and empty/full capsid ratio using analytical ultracentrifugation (AUC). For both applications, alkaline gel electrophoresis showed homogenous product at the expected vector size, with AUC demonstrating >75% full capsids, indicating high-quality vector preparation with promising packaging efficiency and genome integrity. Taken together, this study supports the use of in silico tools to identify viable stuffer sequences prior to in vitro and in vivo testing. This approach leads to vector designs with significantly higher manufacturability (>E14vg/L; ~80% full) and improved safety while reducing the time and costs associated with empirical methods and trial-and-error testing for gene therapy applications.

Introduction: Given the size of select transgenes being pursued for therapeutic development, oversized AAV vector cassettes are used widely in clinical AAV programs. This includes all hemophilia A vectors with either regulatory approval or in late-stage clinical development. During manufacturing, the 5' end of the cassette is inserted last with

resultant cleavage of unpackaged DNA. In turn, this may lead to incomplete virion packaging, virion heterogeneity and reduced expression of AAV vectors manufactured from oversized cassettes. Following gene transfer, species lacking complete ITRs will be preferentially degraded. We hypothesized that even modestly oversized cassettes may impact AAV manufacturing yields, virion heterogeneity and transgene expression.

Methods: Two separate 4.65 kb cassettes between the ITRs (*F8*-1 or *F8*-2) were generated. Each cassette was codon optimized, CpG reduced, to encode *F8* and express coagulation factor VIII (FVIII) under a liver specific promoter. Cassettes were then modified to include an intronic sequence, increasing the cassette size to 4.78 kb between the ITRs. The 4.65 kb or short *F8*-1 and *F8*-2 cassettes were compared to the corresponding 4.78 kb or long cassettes. AAV8 vectors (AAV-*F8*-1short, AAV-*F8*-1long, AAV-*F8*-2short and AAV-*F8*-2long) were manufactured from each of the four cassettes and evaluated for manufacturing yield, virion heterogeneity as well as in vitro and in vivo expression.

Results: Preliminary analysis of manufactured AAV vectors by alkaline gel and TapeStation DNA electrophoresis demonstrated greater virion heterogeneity of AAV-*F8*-1long and AAV-*F8*-2 long relative to AAV-*F8*-1short and AAV-*F8*-2short, respectively; long-read sequencing analysis of packaged virion DNA is ongoing. As expected, cassette size did not impact FVIII expression from plasmid DNA *in vitro*. Specifically, transient transfection of Huh7 cells of plasmid DNA of the long versus short cassettes demonstrated no significant difference in FVIII expression measured by one-stage FVIII activity assay. In contrast, transduction of Huh7 cells by AAV vectors demonstrated significantly greater FVIII expression measured by one-stage FVIII activity assay of AAV-*F8*1short relative to AAV-*F8*-1long at all MOIs evaluated. Analogous trends were observed with AAV-*F8*-2short versus AAV-*F8*-2long. Next, 8–12-week-old male hemophilia A CD4 knockout mice (HA/CD4KO) mice were treated with equal AAV vector doses and plasma FVIII antigen was determined by ELISA. Preliminarily, 4- and 6-week expression data demonstrated significantly greater FVIII expression from AAV vectors generated from short versus long cassettes (Fig. 1).

Conclusion: Preliminary data support that even modestly oversized AAV expression cassettes markedly impact virion heterogeneity and diminish transgene expression relative to cassettes under 4.7 kb. Studies are ongoing to investigate the impact on manufacturing yields and further interrogate preliminary expression observations.

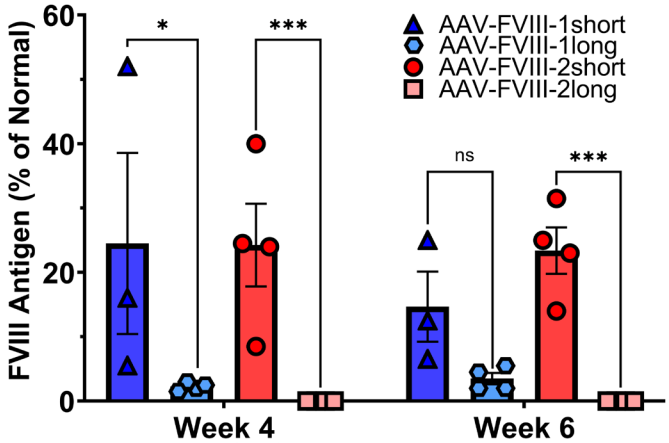

Figure 1. *In vivo* factor VIII (FVIII) expression was significantly greater for FVIII-short constructs relative to FVIII-long. Data are mean ± SEM (n = 4 mice) with 2-way ANOVA, 0.1234 (ns), 0.0332 (*), 0.0021 (**), 0.0002 (***).

1386 MAR Sequences Enhance AAV Transduction and Promote Weight Gain in a Lethal Mouse Model of Methylmalonic Acidemia

Zhong-Dong Shi[1]*, Jiayun Liu[2], Amy Jiang[3], Therese Salameh[3], Xinyan Li[4]*
[1]Frontera Therapeutics, Belmont, MA, [2]Wellesley, MA, [3]Frontera Therapeutics, Bedford, MA, [4]Frontera

Therapeutics, Shanghai, China

Methylmalonic acidemia (MMA) is a severe and potentially life-threatening autosomal recessive metabolic disorder, primarily caused by mutations in the methylmalonyl-CoA mutase (MUT) gene. MUT deficiency leads to the failure of converting methylmalonyl-CoA to succinyl-CoA in the propionate pathway, resulting in the accumulation of toxic metabolites such as methylmalonic acid in tissues and circulation. Patients with a complete loss of MUT enzyme activity face high morbidity and mortality at an early age. Restoration of MUT activity by AAV gene therapy is a promising approach. However, rapid hepatic growth during the neonatal/pediatric period results in dilution of the episomal DNA (such as AAV genome), consequently leading to loss of therapeutic efficacy. Scaffold/matrix-attachment region (MAR) sequences have been shown to increase plasmid DNA maintenance in the extrachromosomal space and duplicate when cell divides, which could potentially be used to enhance long-term transgene expression for cell and gene therapies. Here we evaluated whether MAR could improve AAV gene therapy in a lethal MMA mouse model.

Two MAR sequences (MAR-A: INFB1 MAR and MAR-B: APOB3'MAR) were tested in AAV GFP vectors and MUT vectors. We found that MARs could improve GFP+ cell percentage (~4X) in 293T cells after 2-3 months of long-term culture. After intravenously injecting these GFP vectors in WT mice on postnatal day 0 (P0), MAR-A vector gave higher GFP expression (~1.5X) in the liver than the control vector (no MAR) at 6 weeks post injection of 1E11 vg/g dose, and MAR-B gave higher GFP expression (~2X) than the control vector in the liver at 18 weeks post injection at 5E9 vg/g dose. When injecting MUT vector with or without a MAR sequence into the MMA mice at 1E10 vg/g dose on P0, all vectors had similar rescue rates for survival (~70%), while all the MMA mice injected with vehicle died within 2-3 days after birth. However, MMA mice injected with MAR vectors had higher body weight than MMA mice injected with the control vector when normalized to their corresponding littermate WT animals (10-20% higher from day 30 through day 160). Liver vector genome copy analysis of 4 mice per group at day 150 showed that MAR vectors gave a trend of higher vector genome copies than the control vector. Episomal over total vector genome quantification using exonuclease V digestion followed by qPCR showed that AAV genome copies in the episomal form were less than 5% of total vector genome for all three vectors, and MAR vectors did not give higher episomal copy ratio.

The data showed that MARs could improve vector copies and body weight gain when injected into neonatal mice with lethal MMA, but did not enhance long-term episomal vector genome maintenance based on the method of episomal and linear genome quantification used. We speculate that MARs did improve AAV genome episomal maintenance early after transduction, and higher vector copies promoted higher body weight gain in the beginning. During liver expansion, the hepatocytes having integrated functional AAV genome were quickly enriched due to growth advantage conferred by the MUT protein, resulting in enrichment of integrated AAV genomes and loss of episomal AAV genomes. The role of MARs could be model-specific and context-dependent. The exact underlying mechanisms of MAR in regulating AAV vector episomal maintenance and integration and protein expression remain to be carefully explored.

1387 *In Vitro* and *In Vivo* Characterization of Oversized AAV Vectors With High Genome Integrity That Encode Microdystrophins With Extended C Terminal Sequences

Randolph Qian[1], Steven Foltz[2], Ting Chen[1], Benjamin Heithoff[2], Samantha Yost[3], Hannah Jasick[2], Olivier Danos[2], Ye Liu
[1]REGENXBIO, Rockville, MD, [2]REGENXBIO Inc., Rockville, MD, [3]REGENXBIO, Inc., Rockville, MD

Gene replacement strategies utilizing adeno-associated virus (AAV) to deliver truncated versions of the full-length dystrophin gene have emerged as a therapeutic option for DMD patients. Several "microdystrophins" with AAV genome-compatible sequence lengths have been designed and shown to retain many, though not all, functional features of the full-length protein. Incorporation of an extended, but incomplete, fragment of the highly conserved dystrophin C-Terminal domain (CT) into microdystrophin (μDysCT194) provides functional and histopathological benefits in dystrophin deficient mice. However, it is unclear whether incorporation of the remaining portion of the

CT into a microdystrophin could provide additional functional benefits, as it typically pushes the genome size beyond the 4.7kb packaging limit of AAV, leading to genome integrity and potency issues.

To study this, we compared three oversized AAV8 vectors which encode the same base microdystrophin with increasing amounts of the CT domain for productivity, genome integrity, and functionality. The vectors, termed µDysCT243 (4834bp), µDysCT278 (4939bp), and µDysCT325 (5080bp), utilize a newly designed compact muscle promoter. All three vectors had similarly high harvest titers comparable with µDysCT194 (4676bp). Surprisingly, the genome integrity of the oversized vectors was remarkably good with a vast majority of reads (82-88%) corresponding to full-length AAV genomes, as analyzed by long read NGS. However, we observed a slight reduction for *in vitro* potency of the vectors in both differentiated mouse and human myoblasts when compared to µDysCT194, indicating something other than genome integrity was impacting transgene expression. This was not explained by construct design or protein stability as all tested microdystrophins accumulate at similar levels following plasmid transfection. Visualizing AAV particles with negative stain electron microscopy (nsEM) revealed an increased presence of "collapsed" AAV particles when comparing µDysCT194 (3%) to µDysCT243 (23%) and µDysCT325 (29%). This suggests that the integrity of the AAV capsid is diminished when packaging a genome larger than 4.7kb and could additionally explain why the potency of the vector is reduced *in vitro* even when genome integrity is excellent. Interestingly, dystrophin-deficient mice injected with µDysCT243, µDysCT278, and µDysCT325 all showed improvements in eccentric contraction, maximal force, and treadmill assays over untreated controls, suggesting the loss of potency observed *in vitro* may not hamper the functionality of these vectors *in vivo*. This data will provide insights into our understanding of how AAV transgene size affects genome/capsid integrity and potency, and enable the development of functional and manufacturable oversized vectors.

1388 Cell-line and Antibody Epitope-dependent Expression Models Inform Selection of AAV-GNE Epimerase/Kinase Transgenes to Treat GNE Myopathy

Rachana Patil[1], Bradley Hamilton[2], John Day[3]
[1]Stanford University Dept. of Pediatrics, Palo Alto, CA, [2]Stanford, Palo Alto, CA, [3]Stanford University, Palo Alto

Background/ Rationale: FDA approved AAV gene therapies and promising new AAV investigational products offer new hope to families enduring neuromuscular diseases. Due to AAV packaging limitations, groups developing new therapeutics must often modify endogenous genes. Further, the reduction of CpG dinucleotides in AAV expression cassettes is proposed to increase safety, but must be balanced with transgene expression. As a result, antibodies against etiologic genes do not always recognize transgene protein products, and methods to evaluate novel transgene expression must be carefully considered. Here, we interrogated three open reading frames, with synonymous codon substitutions that varied their CpG content, encoding identical glucosamine (UDP-N-acetyl)-2-epimerase/N-acetylmannosamine kinase (GNE) protein products. GNE1 contained moderate CpG density near wildtype levels, GNE2 had high CpG content due to traditional codon optimization for human expression, and GNE4 had significantly reduced CpGs. Five GNE splice variants are found ubiquitously in human tissue, potentially confounding cell line-based strategies to measure relative transgene expression. We therefore evaluated novel transgene driven protein expression in human embryonic kidney (HEK293T), cervical cancer (HeLa), and chronic myeloid leukemia (K562) cell lines, using three monoclonal and polyclonal antibodies.

Methods: We transfected cells with 0.5ug to 2.5ug of AAV2-GNE plasmids or GFP control plasmids and incubated under standard conditions. Four days later we observed GFP transgene expression by fluorescence microscopy. Protein was harvested, quantified, and subjected to western blot analyses using 1) rabbit polyclonal (Invitrogen Cat# PA5-55559), 2) mouse monoclonal 2A11E10 (Proteintech Cat# 67649-1-Ig), or 3) rabbit polyclonal (Proteintech Cat# 25079-1-AP) anti-GNE antibody probes.

Results: Consistent with expectations, we recovered the highest protein concentrations from HEK293T, followed by HeLa and then K562. The first polyclonal showed variable GNE expression between cell lines and was excluded from further analyses. The K562 cell banding pattern was non-specific and could not be distinguished from controls. Surprisingly, monoclonal antibodies raised against immunogen Ag18702 and recognizing an epitope between amino acids 376 and 722 bound non-specifically to lysate from all tested cells, and banding patterns from experimental conditions could not be distinguished from controls. The second rabbit polyclonal, raised against immunogen

Ag18689 also bound non-specifically in HeLa cell lysate, but band intensity at the molecular weight for GNE trended with DNA input levels below 2.0ug, suggesting these cell lines do not tolerate higher plasmid concentrations. Importantly, the second polyclonal bound specifically to exogenous GNE expressed in HEK293T cells, and far less to endogenous GNE, suggesting pooled antibodies recognizing variable epitopes may be a valuable tool for verifying expression in the early stages of novel transgene characterization.

Conclusions: We found K562 cells were not a viable method for evaluation GNE transgene expression, HeLa did not tolerate high levels of protein expression, and HEK293T cells consistently showed increasing band intensity corresponding to higher plasmid inputs, likely due to efficient interactions between plasmid SV40 origin of replication and cellular SV40 large T antigen. Future studies will evaluate transgene product function.

1389 AAV-SLB101, a Novel Muscle-Tropic Capsid, Increases Gene Delivery and Expression Versus AAV9 and AAVrh74, in Mouse Models of DMD and FSHD Muscle Disease

Prushti Bhavsar[1], Jessica Boehler[1], Jamie Marshall[2], Marie Ralff[1], Meghan Soustek[3], Jennifer Gifford[1], Brian Price[4], Lindsay Wallace[5], Scott Harper[6], Sharon McGonigle[1]
[1]Solid Biosciences, Charlestown, MA, [2]Solid Biosciences, Cambridge, MA, [3]Solid Biosciences, Inc, Cambridge, MA, [4]ArmatusBio, Columbus, OH, [5]Nationwide Children's Research Institute, Columbus, OH, [6]The Ohio State University, Columbus, OH

AAV-SLB101, a rationally designed capsid with the goal of increasing muscle tropism, is used in Solid Biosciences' next generation gene therapy SGT-003, which is currently in a clinical study for the treatment of Duchenne muscular dystrophy (DMD) (NCT06138639). To explore its potential for broader indications, we demonstrated markedly increased AAV-SLB101 transduction and expression of multiple reporter and therapeutic transgenes, when compared with first generation vectors, *in vivo* in wild type (WT) mice and mouse models of muscle disease.

In WT mice administered AAV-SLB101, AAV9 or AAVrh74, luciferase expression as measured by whole body IVIS was detected as early as 2 days post-dose for AAV-SLB101. On Day 7, expression for AAV-SLB101 remained substantially higher than for AAV9 and AAVrh74. In a 30-day study, whole body luciferase expression plateaued for all 3 capsids by Day 15, with significantly higher expression levels maintained at Day 30 in AAV-SLB101- versus AAV9- and AAVrh74-treated mice. Increased AAV-SLB101-driven expression was also reflected in *ex vivo* luciferase assays in heart and quad tissues.

Studies comparing AAV-SLB101 versus AAVrh74 delivery of a microdystrophin transgene in the *mdx* mouse model of DMD revealed higher biodistribution of vector genomes in disease-relevant quadriceps, gastrocnemius, diaphragm, and heart of mice treated with AAV-SLB101 versus AAVrh74. Increased AAV-SLB101 biodistribution translated into increased expression of microdystrophin in quadricep tissue as measured by immunofluorescence across all dose levels. Higher microdystrophin expression from AAV-SLB101 versus AAVrh74 resulted in a greater impact on serum biomarkers of muscle health; more reduction was observed in the AAV-SLB101-treated *mdx* mice, reflecting a more profound impact on the disease than in mice treated with AAVrh74.

In wild type mice, AAV-SLB101 and second-generation capsid MyoAAV3a achieved similar levels of muscle biodistribution of mi405, the therapeutic microRNA developed for treatment of Facioscapulohumeral muscular dystrophy (FSHD). Comparable levels of mi405 expression achieved by AAV-SLB101 and MyoAAV3a were also observed in the TIC-DUX4 mouse model of FSHD disease, which expresses elevated levels of the toxic *DUX4* gene. AAV-SLB101-mediated delivery of mi405 also resulted in significantly more muscle expression than for AAV9 in the disease model. Higher mi405 expression translated into protection from DUX4-induced histological damage and substantially lower levels of expression of the DUX4-activated biomarker *Wfdc3*, at low dose levels.

Together, these data highlight that AAV-SLB101 provided enhanced muscle delivery and expression of reporter and therapeutic transgenes versus first generation capsids and comparable levels compared to a second-generation capsid. In mouse models of DMD and FSHD muscle diseases, increased muscle expression of therapeutic transgenes

enabled disease modulating intervention at lower doses, highlighting the superiority of AAV-SLB101 over AAV9 and AAVrh74.

1390 Enhancing AAV gene therapy targeting retinal diseases with AI-guided rational design

Alessandro Barberis[1], Bryan Dafniet[2], Timothée Van Meter[3], Ulisse Ferrari[4], Perla EL DARAZI, Dylan SERILLON[5], Deniz Dalkara, Julien Cottineau
[1]WHITELAB GENOMICS, PARIS, Paris, France, [2]WhiteLab Genomics, Paris, Essonne, France, [3]Institut de la vision, PARIS, Paris, France, [4]Institut de la vision, PARIS, France, [5]WhiteLab Genomics, Paris, Paris

Gene therapy using adeno-associated viral vectors (AAVs) has been proven to be clinically effective for the treatment of retinal dystrophies, with most mutations residing in the outermost retinal cells. To target these cells, viral vectors need to cross the inner limiting membrane, and inner retinal neurons making them more difficult to target via this injection route. Current viral vectors are mostly injected into the subretinal space to target these cells, albeit with the efficacy being limited to the bleb region.

To address these challenges, we developed AI-guided, rationally designed approaches to engineer AAV2-derived vectors for ocular gene therapy, enabling low dose wider spread human retinal transduction via subretinal injection. We applied machine learning approaches to single-cell RNA-sequencing data and protein databases to identify receptors of interest for AAV targeting into human photoreceptors.

We started with the identification of human photoreceptor-specific markers using our proprietary single-cell Atlas and analytical platform. To quantify their specificity to retina, we computed the average expression levels of these markers as well as their percentage of expression at the photoreceptors surface compared to other retinal cell types grouped together. We also computed key metrics such as localization information about associated proteins. Additionally, we evaluated their involvement in both immune and endocytosis pathways. To ensure cross-species relevance in experimental models for pre-clinical studies, we curated single-cell RNA-seq data from pig, performing quality control and cell annotation using automated and manual approaches to identify cell-specific markers in the pig retina. We then explored the conservation of these markers with human.

Once markers expressed at the surface membrane were identified, computational structural biology approaches were performed for target validation. We assessed both the presence of already existing 3D structures and the capabilities of prediction tools to accurately reconstruct them in 3D when none was available. The presence of an interactor in the resolved structure was of importance to consider a marker as a potential candidate using our rational-guided approach. For the final step of our target validation approach, we performed analysis of structural conservation of the interacting site, when known, between human and pig. This allowed for a more effective cross-species AAV design and led us to the selection of one promising target, maximizing all our criteria for the design of novel viral vectors against retinal diseases. The next step will be the creation of optimized AAV libraries by inserting peptides targeting the receptor in the AAV2 vector sequence.

Efficient delivery remains a major challenge in the development of gene therapies for retinal diseases. Our comprehensive approach integrating AI-driven rational design, cross-species marker validation, and computational structural biology helps to overcome this current limitation. By identifying conserved, surface-exposed targets, we have laid the foundation for the development of optimized AAV vectors with enhanced retinal transduction capabilities. These advancements bring us closer to addressing a critical unmet need for more effective and targeted treatments for hereditary retinal diseases.

1391 A Single Suppressor-tRNA Restores Clinically Meaningful Protein Levels in Multiple Disease Models with Premature Termination Codons *In Vivo*

Lingjie Kong[1], Kangyun Dong[2], Jianguo Zhu[3], Rong Huang[4], Jianfeng Dong[5], Dong Wei[1]
[1]Codone Biotechnology Co., Ltd, Guangdong, China, [2]Codone Biotechnology Co., Ltd, Guangdong, Guangdong,

China, [3]Codone Biotechnology Co., Ltd, Zhuhai, Guangdong, China, [4]Codone Biotechnology Co., Ltd, 珠海, Guangdong, China, [5]Codone Biotechnology Co., Ltd, Guangdong, Shanghai, China

Premature stop codon (PTC) diseases encompass thousands of genetic disorders caused by PTC, where a single base pair mutation converts an amino acid codon into a stop codon, leading to mRNA degradation and the production of truncated polypeptides with null, reduced or detrimental biological activity. Approximately 11% of all genetic diseases, affecting around 30 million people worldwide, are due to PTCs, of which 40% is the UGA mutation. Over half of these are CGA to UGA mutations, converting an arginine codon to a stop codon (Arg-UGA). We have engineered a series of Suppressor-tRNAs targeting Arg-UGA mutations and tested one of them, CDN001, in various cellular and animal models, delivered through adeno-associated viruses (AAV).

Mucopolysaccharidosis type II (MPS II) is a genetic disease caused by mutations in the iduronate 2-sulfatase (IDS) gene, leading to glycosaminoglycan (GAG) accumulation. In a transgenic mouse model with a PTC in the IDS gene, CDN001 packaged in AAV9 was administered through tail vein and through intracerebral ventricular injection. At Week four, IDS enzyme activity was restored to up to 90% in peripheral organs and 17% in the brain, significantly above clinically meaningful levels. Concurrently, glycosaminoglycan levels were significantly reduced in clinically relevant tissues.

Rett Syndrome is a genetic disease caused by mutations in the methyl-CpG binding protein 2 (MECP2) gene, leading to neurodevelopmental deficits. In a transgenic mouse model with a PTC in the MECP2 gene, CDN001 packaged in AAV9 was administered through intracerebral ventricular injection. At Week four, Full-length MECP2 protein level in brain tissue was restored up to 14% of the levels seen in wild-type mice. Together with the results of the MPSII model, these demonstrated the potential to treat multiple genetic disorders in the same organ with the same suppressor tRNA and the same AAV delivery system.

Stargardt Disease is a genetic disease caused by mutations in the ATP Binding Cassette Subfamily A Member 4 (ABCA4) gene, leading to progressive loss of central vision. In a transgenic mouse model with a PTC in the ABCA4 gene, CDN001 packaged in AAV2-7m8 virus was administered through subretinal injection. Full-length ABCA4 protein level was restored to 10-35% of wild-type levels, which are believed to be clinically meaningful for Stargardt Disease treatment.

Altogether, our data support the hypothesis that a single Suppressor-tRNA product could treat multiple diseases caused by the same premature stop codon mutations across different genes and organs.

1392 Expanding AAV vector delivery capacity: improving efficiency and vector genome cargo size

Mariana Ferreira[1], Marina Curto[2], Júlia Guerra[2], Mafalda Ventura[3], André Nascimento[3], Cristina Peixoto[4], Sofia Fernandes[5], Gabriela Silva[3], **Ana Coroadinha**
[1]IBET, 2781-901 Oeiras, Portugal, [2]iBET, Oeiras, Lisboa, Portugal, [3]iBET, Oeiras, Portugal, [4]Oeiras, PORTUGAL, [5]IBET, 2781-901 Oeiras, SA, Portugal

Background and novelty: Advanced therapy medicinal products are transforming medicine. Gene therapies are providing treatments to previously unmet medical needs. To be effective, gene therapy requires vectors that deliver the therapeutic material to the affected cells efficiently and safely. Adeno-associated virus (AAV) vectors represent one of the most versatile clinical platforms for either localized or body-wide gene delivery. However, AAV vectors have a small packaging capacity, delivering small therapeutic genes up to 3.5 kb. This limits their use in treating numerous genetic diseases. Additionally, AAV vectors transduce cells fairly poorly, resulting in the administration of exceedingly high doses in the clinic, increasing the risk of adverse events. Herein, we describe vector engineering strategies, at the level of AAV vector transgene cassette and capsid, to enable extended and improved cargo delivery.

Experimental approach: To address the vector limitations in delivering large genes we are using dual AAV vectors enabling the delivery of therapeutic transgenes that exceed their natural packaging capacity. Dual AAV vectors have their cargo split in two AAV vectors. Current state-of-the-art strategies provide low efficiency of full-therapeutic protein reconstitution. To overcome this, we are developing novel molecular technologies for reconstituting the therapeutic full protein in the target cell through DNA recombination or protein trans-splicing. Furthermore, we are exploring rational capsid engineering strategies. Through peptide and protein insertion in specific VP proteins and locations of the capsid we aim to deliver more cargo at lower vector doses. The impact of genome and capsid engineering is being evaluated both at vector production yields and quality of AAV vector particles (i.e. particle stability, percentage of full genome particles, transduction efficiency).

Results and discussion: Naturally discovered split-intein sequence from Nostoc Punctiforme (Npu DnaE) has been extensively studied. In the AAV dual vectors we are assessing several novel split-inteins systems, such as engineered-consensus (Cfa) and cyanophage-like (Gp41-1). Using a split-GFP we observed consistently higher efficiencies of protein reconstitution provided by GP41-1 followed by Cfa. GP41-1 reconstitution rates were over two-fold higher than Npu DnaE and 100% of cells presented protein reconstitution after AAV vector dual co-infection. Targeting the treatment of Duchenne Muscular Dystrophies we developed novel therapeutic mini-dystrophins of about 220 KDa. The superior performance of GP41-1 was again observed for the reconstitution of this bigger therapeutic protein. In parallel we are developing methodologies based on DNA recombination. DNA-level reconstitution approach relies on occasional DNA recombination events occurring between AAV genomes after internalization. We are developing enzyme assisted DNA recombination which shows to have higher reconstitution efficiencies.

To improve vector cargo delivery capacity and transduction efficiency, we are rationally designing novel capsids. We assessed and identified different sites for capsid engineering without impacting vector yields. Studies performing peptide insertion are ongoing showing transduction efficiencies improvements of about 2-fold. This work demonstrates how AAV vector engineering drives the development of higher-performing vectors, ultimately reducing vector doses and costs.

1393 A System for Distinguishing Protein and Gene Delivery Elucidates Mechanisms of EV-AAV Vehicles

Jonathan Boucher[1], Devin Stranford[2], Hailey Edelstein[3], Neha Kamat[4], Danielle Tullman-Ercek[4], Joshua Leonard[4]
[1]Northwestern University, Chicago, IL, [2]Syenex, Inc., Evanston, IL, [3]Syenex, Evanston, IL, [4]Northwestern University, Evanston, IL

The clinical success of adeno-associated virus (AAV)-based therapies has established a new paradigm in disease treatment. However, challenges such as preexisting humoral immunity and off-target tissue transduction necessitate higher vector doses, which are associated with adverse effects. Encapsulation of AAV within engineered extracellular vesicles (EVs) is a promising strategy to address these barriers by shielding the capsid from antibody neutralization and enabling tissue-specific targeting. A key challenge in evaluating engineered EV-AAVs is differentiating protein delivery, originating from transgene expression in producer cells, from true transgene expression in recipient cells. This challenge is analogous to the phenomenon of pseudotransduction with lentiviral vectors, but the scale of the challenge is heightened for EV-AAV since greater particle (vesicle) numbers are generally required to achieve a given rate of transduction. Developing methods to better separate signal from noise could facilitate characterization and improvement of EV-AAV vectors.

We first investigated whether choice of EV purification method (i.e., size exclusion chromatography, density gradient centrifugation) impacts the separation between gene and protein delivery. We found that no rigorous EV purification method substantially reduced protein delivery to a degree that mock delivery (e.g., EV-AAV produced without the Rep and Cap genes) could be distinguished from true EV-AAV transduction.

Thus, we next developed a new reporter system to rigorously distinguish true transduction from protein delivery by EV-AAVs. We designed a Cre-responsive AAV “stoplight” reporter vector that initially encodes for expression of an mCherry fluorescent protein, but upon Cre-mediated recombination, mCherry is excised such that the vector

drives mNeonGreen expression. By delivering such an EV-AAV vector to Cre-expressing cells, observation of mNeonGreen+ cells unambiguously confirms transduction, while allowing for simultaneous quantification of protein (mCherry) delivery. This validated assay provides a new, sensitive, and specific reporter of EV-AAV transduction.

Using this tool, we investigated surface functionalization strategies to probe how the mechanism of EV-AAV uptake impacts the rate of functional delivery on several target cell types. Interestingly, we found that enhancing EV-AAV uptake by HEK293FT recipient cells increased protein delivery, as expected, but not gene delivery; this was also observed when EVs were functionalized with VSVG to increase fusion as well as uptake. In contrast, when targeting Jurkat T cells, increasing uptake and membrane fusion via VSVG functionalization increased both protein and gene delivery. These results provide a basis for new mechanistic investigations. These insights were uniquely enabled by the discrimination between false and true delivery conferred by this novel EV-AAV characterization tool.

1394 Development of heart tropism AAV capsid by directed evolution

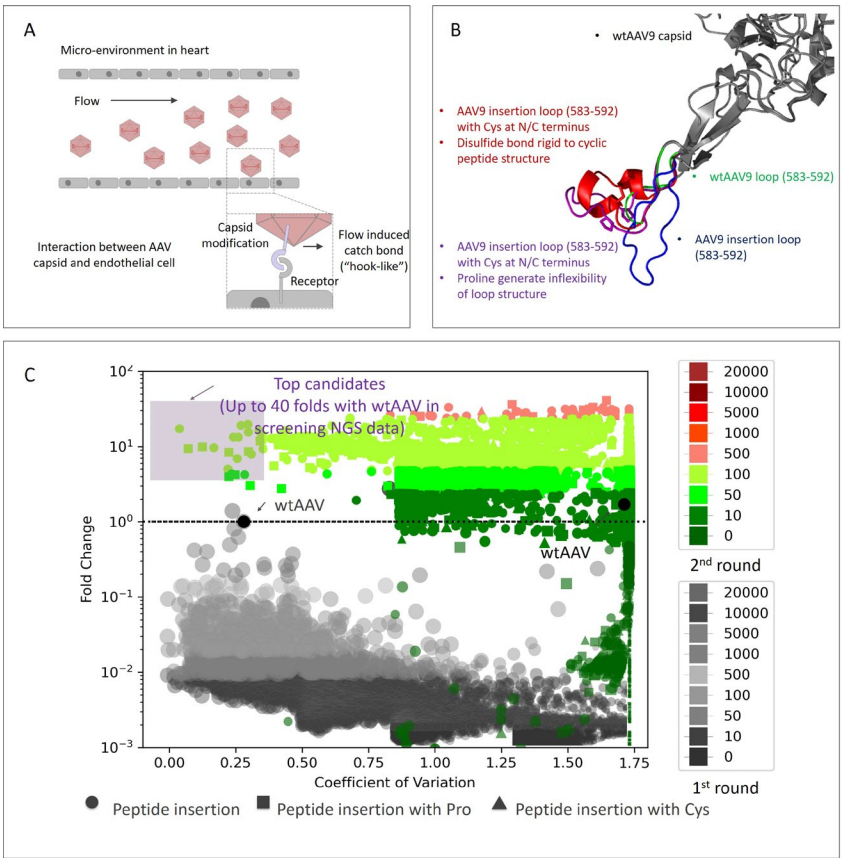
Lei Zhao[1], Tongxin Liu[2]
[1]Cure Genetics, SuZhou, Select State, China, [2]Cure Genetics Co. Ltd., Su Zhou, China

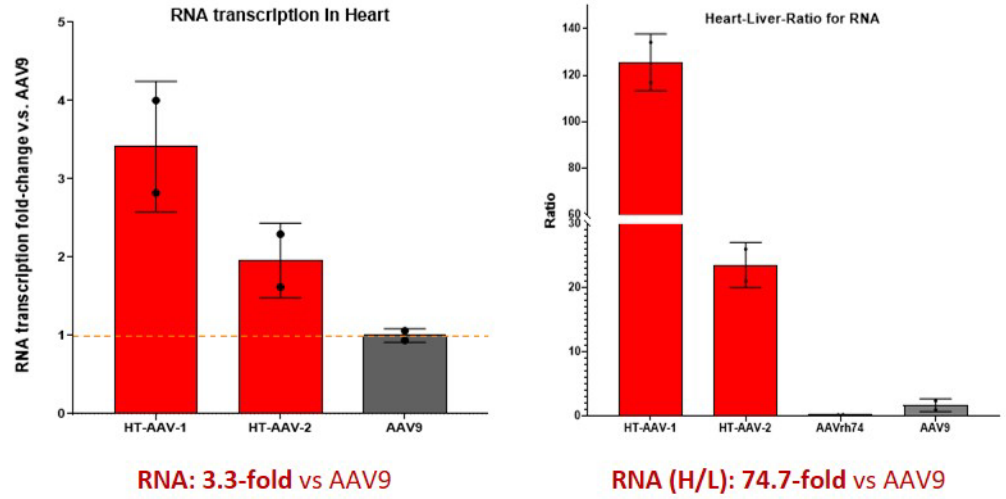
Adeno-associated virus (AAV) is one of the best viral-vector in gene therapies due to the long-last expression and the relatively low immunogenicity. However, the side effects from innate immune response by high dosed AAV vector and the toxicity of liver still remains the limitation for AAV based therapy. Thus, novel AAV capsid with specific organ tropism, which represents not only higher GOI expression in non-liver organs but also low liver target effects, plays important roles in development of innovated AAV gene therapies which would be potentially required by common diseases. Herein, we developed a novel AAV capsid for cardiac tropism with superior liver de-targeting effect.

To obtain the heart specific AAV capsid, directed evolution is the way to generate the heart-directed property. The challenge of cardio tropism screening would be 1) how to maintain the relatively high concentration of AAV in the microenvironment of cardio vascular in a long time period with higher shear force of blood flow by systematic administration and 2) how to increase the transduction efficiency in cardiomyocytes. Those problems may cause the failure of the evolution since the beginning of library design. Therefore, we designed our cardio tropism AAV library with 1) the special peptide insertion sequence, which including the peptide loops located within 2 prolines or 2 cysteines of the N-/C- terminus, to generate rigid loop or cyclic loop respectively which forms “catch-bond” under particular force dependent manner; and 2) the unique DNA shuffling library with wtAAVs especially AAV9, AAVrh74 and AAVrh10 which are the high cardio tropism AAVs so far to increase the transduction potency.

After screening in NHP for 2 rounds. We observed an obvious enrichment of AAV capsid with rigid “catch-bond” design, especially with the insertion loop modified by prolines in N-/C- terminus. The probable reason could be the expectation of di-sulfate bond formed by cysteines modification generate a low yield during the AAV packaging step. Moreover, the top candidates from DNA shuffling library represented better enrichment as well in compare with wtAAV after 2 rounds screening. Therefore, the top capsid candidates were then move forward to single serotype validation in NHPs.

During the single serotype validation, we identified the top cardio tropism AAV capsid named HT-AAV-1 and HT-AAV-2. The HT-AAV-1 represents high heart mRNA transduction efficiency which is 3.3-fold over AAV9 (8-fold over AAVrh74), indicating that the HT-AAV-1 shows better potential GOI expression in heart compared with wtAAVs. Moreover, HT-AAV-1 represents superior liver de-targeting effect than AAV9 and AAVrh74. It represented 74.7-fold heart-liver ratio of mRNA transduction vs. AAV9. The high cardio tropism and super low liver target properties may generate an ideal viral vector in the future of gene therapies for heart diseases.





1395 In vivo evolution of heart-derived AAV capsids: Development of novel vectors with enhanced cardiac tropism

Anna Schrattel[1], Andreas Jungmann[1], Stephanie Molter[1], Marie Plechinger[1], Dorothea Kehr[1], Mai Vo[1], Franziska Beedgen[1], Patrick Most[1], Julia Ritterhoff[1]
[1]*University Hospital Heidelberg, Germany*

Heart failure (HF) continues to be a leading global cause of mortality, highlighting the critical need for innovative therapeutic strategies. Gene therapy has the potential to revolutionize HF treatment by targeting its molecular underpinnings, but its success relies on efficient and selective delivery of therapeutic genes to the heart. The commonly utilized AAV9 serotype shows a strong affinity for the liver, often resulting in severe hepatotoxicity and limiting its clinical applicability. To address these challenges, this study focuses on developing novel cardiac-specific AAV capsids through an innovative combination of experimental and computational approaches.

Novel heart-derived AAVs (HDVs) isolated from failing human myocardium were used alongside AAV6 and AAV9 to construct highly diverse libraries through DNA shuffling and peptide display techniques. The libraries underwent two rounds of in vivo evolution after systemic injection into small (mice) and large (pigs) animal models, followed by recovery of AAV capsids efficiently transducing cardiac tissues. Advanced bioinformatic analyses using both short- and long-read sequencing were employed to evaluate biodistribution and transduction efficiencies across cardiac and non-cardiac tissues. Starting with a library of 1E8 variants in the first round, the selection process narrowed this down to 1.5E5 variants in the second library, achieving a 1E6-fold enrichment of cardiac-targeting AAV variants. Across the two screening rounds, the newly created variants exhibited a 9E-2 reduction in liver tropism and demonstrated a twofold increase in the heart-to-liver targeting ratio. After the selection process, 50 capsids demonstrating enhanced cardiac tropism were identified.

Parental sequence analysis of the top 10 capsids variants revealed high shuffling diversity and a predominant contribution from our novel HDV vectors compared to AAV6 and AAV9. In addition, they exhibit distinct transduction profiles and superior cardiac transduction efficiency, with heart-to-organ ratios exceeding 1. Several of our novel capsids demonstrated specificity for different cardiac regions. One left ventricle (LV)-targeted variant achieved 71% transduction in the LV, compared to 5% in the right ventricle (RV), 10% in the atria, and 14% in other organs. A right ventricle (RV)-directed variant demonstrated 30% transduction in the RV, 24% in the atria, and lower levels in the LV (6%) and other tissues (40%). Similarly, an atrial-specific variant achieved 24% transduction in the atria, with minimal transduction in the RV (7%) and LV (4%). Notably, one candidate exhibited a balanced distribution between the heart (36%) and brain (35%), with the remaining 29% in other organs, offering potential utility for treating conditions affecting both the cardiovascular and central nervous systems.

In summary, this study establishes a versatile platform for engineering cardiac-specific AAV capsids tailored for cardiac gene therapy. When paired with optimized promoters and therapeutic transgenes, these novel vectors hold great potential to address both rare and common cardiac disorders, paving the way for transformative advancements in HF treatment.

1396 Engineering Novel AAV Capsids for Cardiac Gene Delivery

Ze Cheng[1]*, Emilee Easter[2], Lindsey Rollosson[2], Karl Doerner[3], Jianmin Lin[4], Tim Hoey[3], Kathy Ivey[3], Laura Lombardi[3]

Gene therapy is an emerging treatment option for both acquired and inherited cardiac disorders. Targeting cardiomyocytes following systemic delivery is critical to enable gene therapy treatments for many cardiac conditions. While several natural adeno-associated virus (AAV) serotypes, including AAV9, AAVrh.10, and AAVrh.74, can transduce cardiomyocytes *in vivo* and are being advanced in cardiac gene therapy programs, the requirement of high doses and the substantial viral load to the liver or off-target cell types raise the critical need for novel AAV capsids with enhanced cardiomyocyte targeting efficiency. Our previous work demonstrates that AAV9 more efficiently expresses transgene in cardiomyocytes following systemic administration compared to AAVrh.10 and AAVrh.74 in murine and non-human primate models. Starting from wildtype AAV9, we introduced various modifications to the capsid protein and collected *in vivo* cardiomyocyte transgene expression data for thousands of capsid variants. With these datasets as input, we developed multiple *in silico* methods, including human-directed design approaches and machine-learning based approaches, to extract sequence-to-fitness information, model the functional landscape, and design thousands of new variants that may outperform wildtype, as well as the best-

performing input variant. Next, we screened these *in silico* designed variants in mice and observed >60 newly designed variants showing higher cardiomyocyte transgene expression than the best-performing input variant. Individual validation of selected variants confirmed the library-based screen results. We further characterized a subset of *in silico* designed variants in cynomolgus monkeys and identified multiple candidates with greater cardiomyocyte transgene expression than AAV9, the best-performing input variant, and an industrial benchmark muscle-tropic capsid. Finally, our novel capsid candidates mediate significantly higher *in vivo* cardiac gene editing efficiency compared to AAV9, highlighting their potential therapeutics advantage. Our state-of-the-art capsid engineering platform that combines high throughput *in vivo* experimental screening and various *in silico* design methods has led to the identification of multiple novel capsid candidates with enhanced cardiomyocyte targeting efficiency following systemic delivery in both murine and non-human primate models, which may enable more efficacious and safer next generation gene therapies for cardiac disorders.

1397 An Improved Approach Enables Efficient and Cost-effective Directed Evolution of AAV Capsids in Non-human Primates via Different Delivery Routes

Introduction: Non-human primates (NHPs) are ideal and valuable models for the directed evolution of Adeno-associated virus (AAV) capsids. It is attractive to use fewer NHPs to obtain more experimental data. Here, we developed a modified platform called DynEvoLib (Dynamic Evolution Library) for simultaneous directed evolution of capsids targeted at multiple tissues via different delivery routes in NHPs.

Methods: DynEvoLib contained three types of libraries and pools (Fig. 1A). The first-round screening was conducted using high-throughput capsid mutation libraries, in which random peptides or peptides derived from known proteins were inserted into the AAV9 capsid. Degenerate code mutations were introduced to flank the insertion site and used as degenerate barcodes (dBCs) to distinguish different libraries. Degenerate oligonucleotides generated peptide inserts (peptide-derived degenerate barcodes, pdBCs) for capsid libraries of subsequent screening rounds. mRNA expression of variants was then quantified by deep sequencing of barcoded AAV pools. Finally, AAVs containing multiple peptide tags were used to characterize variants at DNA, RNA, and protein levels. Libraries containing different dBCs/pdBCs, barcoded pools, and/or pools of peptide tags were administered to a single animal simultaneously via multiple delivery routes (Fig. 1A). Specific oligo-based magnetic beads were used for the enrichment of viral mRNA from total RNA to improve the acquisition of viral transcripts (Fig. 1A).

Results: DynEvoLib was optimized in a mouse model. It showed that dBCs/pdBCs combinations not only facilitated distinguishing between libraries used for multiple delivery routes but also improved the accuracy of peptide transcription analysis based on unique barcode counts compared with the analysis based on mRNA expression levels alone. Up to 576 variants showed more efficiency in brain transduction compared to AAV-F (Fig. 1B). There was good consistency between capsid libraries, barcoded pools, and peptide tags, including enhanced brain transduction and liver de-targeting (Fig. 1B, C, D). DynEvoLib was applied to rhesus macaques via multiple delivery routes. It showed that the mRNA enrichment strategy processed up to 10g of single tissue sample, resulting in a 151-fold increase in the collection of viral transcripts over the regular single-tube RT-PCR strategy. Enrichments of variants were first seen in the heart, muscle, kidney, and bone by intravenous administration, and in the central nervous system (CNS) by intrathecal administration. Characterizations using peptide tags identified several myotropic variants in rhesus macaques via intravenous injection (Fig. 1E). The optimal variant BY087 transduced skeletal muscle 21-fold and cardiac muscle 13-fold more effectively than AAV9 and performed cross-species muscle tropisms in NHPs, mice and rats (Fig. 1F). CNS tropic variants were characterized using the barcoded pool in rhesus macaques via intrathecal injection. BY253 showed 30-fold higher transduction in the spinal cord than AAV9 and transported more efficiently than AAV-DJ in the spinal cord, brainstem, cortex, and cerebellum (Fig. 1G).

Conclusions: DynEvoLib enables efficient and cost-effective simultaneous directed evolution of AAV capsids, simultaneously targeting multiple tissues through different delivery routes in NHPs.

Introduction: We have recently developed a new AAV9 derived capsid called AAV-PR, displaying the 7-mer peptide, PRPPSTH. AAV-PR mediates unprecedented transduction of brain vascular smooth muscle cells (SMCs) and pericytes as well as SMC in the aorta in mice after systemic delivery. We set out to investigate the translational potential of this new capsid using a variety of methods.

Methods: Database searches were performed to identify potential peptide motifs which could indicate the mechanism of action of the capsid's binding partners. *In silico* modeling was performed to predict peptide confirmations in the VR-VIII loop of the capsid, as well as to predict interactions with AAV-R and T-cell epitopes. We assessed whether AAV-PR could transduce primary human adult aortic SMCs in culture. Cells were transduced with $2x10^5$ vg/cell of either AAV-PR or AAV9 (two independent batches tested for each capsid), both delivering an AAV-CBA-GFP cassette. Seventy-two hours later, cells were imaged for GFP fluorescence (vector transduction), followed by quantitation of GFP concentrations by ELISA. We also assessed the ability of AAV-PR to retain AAV9's galactose binding by comparing binding and transduction on Pro5 and Lec2 cells.

Results: A database search revealed that the AAV-PR peptide had a 100% match to rat FERM domain-containing protein 4A (FRMD4A). Interestingly this motif was conserved in 5-6 out of 7 residues in mice, old world monkeys, and humans. *In silico* modeling of the PR peptide in the VR-VIII loop of the AAV9 capsid revealed that the insertion of PR does not alter the overall structure of the VP3 domain as expected given the insertion position and the short length of the peptide. Interaction energy for the capsid with the AAV receptor's (AAVR) PKD1 and PKD2 domains were performed. Neither AAV-PR or AAV9 interact with AAVR's domain PKD1, (AAV5 is the only natural serotype known to bind PKD1). Strikingly, the calculation predicts that AAV-PR binds stronger to AAVR's domain PKD2 than AAV9, in all three analyzed species (mouse, human, orangutan), with a strength of interaction similar to AAV2. T cell epitopes were predicted to be comparable to AAV9, which may indicate a similar immunological profile. AAV-PR showed a remarkable 16-fold increase ($p<0.012$) in GFP concentration in primary human VSMCs compared to AAV9. Galactose binding was increased with AAV-PR compared to AAV9 when comparing transduction increases on N-terminal galactose deficient Lec2 cells compared to galactose expressing Pro5 cells.

Conclusions: The identify of the multi-species conserved, putative FRMD4A motif may provide directions towards a mechanism of action of AAV-PR's robust transduction of SMCs. Future studies validating the predictions of AAV-R binding affinity as well as the increased binding to galactose may also provide insight into its transduction properties. These findings, combined with the transduction of human VSMCs suggest AAV-PR has potential as a clinically relevant gene delivery vehicle to treat diseases of the vasculature.

1399 Artifical Modification of Adeno-Associated Virus Type 2 for Direction to Vascular Smooth Muscle Cells

Yoshihide Sehara[1]*, Ayumu Konno[2], RYOTA WATANO[3], Kenji Ohba[4], Masashi Urabe[5], Hiroaki Mizukami[6]

Introduction: Adeno-associated virus (AAV) vectors are widely used to transduce genes of interest safely and effectively. AAV is a small non-enveloped virus with a diameter of 25 nm. The transduction efficiency, called tropism, is known to be determined by amino acid sequence of the protruded region of capsid protein. Especially, variable region VIII (VR VIII) has been focused on to change tropism. In this study, we inserted random sequences of 7 amino acids into VR VIII of AAV2 to develop suitable AAV vectors for smooth muscle cells.

Methods: We cloned a reporter and capsid protein-expressing plasmid which contains two main elements flanked by AAV2 inverted terminal repeats (ITRs), including (a) the mCherry cDNA driven by human UBC promoter and followed by a synthetic polyadenylation sequence, and (b) the AAV5 p41 promoter sequence and splicing sequences taken from the AAV2 *rep* gene followed by AAV2 *cap* gene which contains insertion of 21-mer randomized nucleotide sequence in frame after amino acid 587 of VP1. Recombinant AAVs were generated by triple transfection of 293T cells with the above-mentioned plasmid, adenoviral helper plasmid pHelper (Agilent Technologies), and assembly-activating protein helper plasmid, shown in the previous study by Deverman et al. (Nat Biotech, 2016). Seventy-two hrs after transfection, viral particles were harvested from both the cells and media, and AAVs were purified using chloroform technique (Negrini et al., Curr Protocol Neurosci, 2020). Purified AAVs were transduced into cultured smooth muscle cells of human or mouse, which were sorted using fluorescence activated cell sorter (FACS). The viral DNA of mCherry-expressing cells was extracted and amplified by PCR using primers interposing randomized nucleotide sequence. The PCR-generated sequence was cloned back into the above-mentioned reporter and capsid protein-expressing plasmid. Using this plasmid, recombinant AAVs were again generated and transduced to smooth muscle cells. Seventy-two hrs after transfection, the viral DNA of mCherry-expressing cells was again extracted in the same way as the first round. The nucleotide sequences of *cap* gene in the first and second rounds were identified and the frequency was quantified using the next generation sequencer.

Results: Analysis by the next generation sequencer showed that NRPETNP and SHDPSKE identified in the human brain vascular smooth muscle cells and RENKLGE and KDTVPRE identified in the mouse aorta smooth muscle cells were the two of the most frequent amino acids sequences in frame after amino acid 587 of AAV2 VP1, which showed more than half of the recovered library sequences.

Conclusions: Using the *in vitro* assay system, we have identified smooth muscle cell-directed variant of AAV2. In the next step, we're going to inject above-mentioned variants of AAVs into nonhuman primates and mice to confirm that their tropism is directed to smooth muscle cells *in vivo*.

1400 Development of muscle tropism AAV capsid by directed evolution

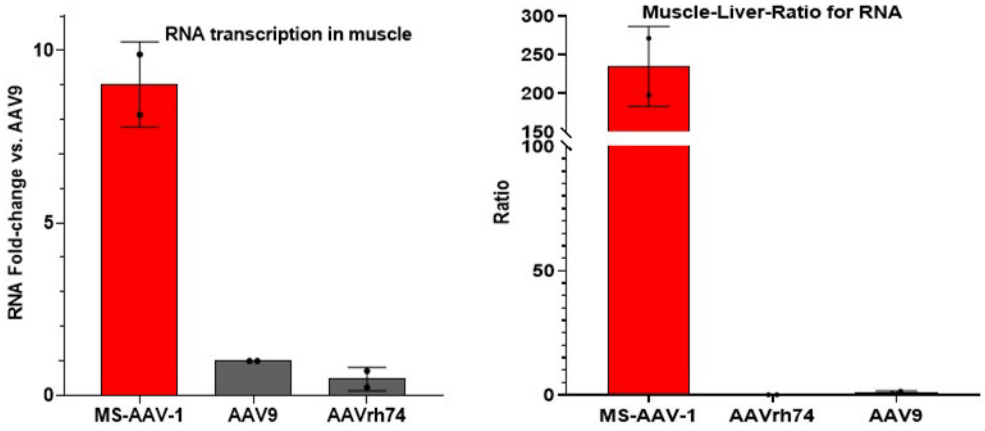
Lei Zhao[1], Tongxin Liu[2]
[1]*Cure Genetics, SuZhou, Select State, China,* [2]*Cure Genetics Co. Ltd., Su Zhou, China*

Single gene disorders related to the muscular tissue plays important role in development of gene therapies for rare diseases such as Duchenne muscular dystrophy (DMD) and Becker muscular dystrophy (BMD). Adeno-associated virus (AAV) gene therapy is one of the ideal therapy for single gene disorders such as FDA proved Elevidys for DMD. However, the side effects from innate immune response by high dosed AAV vector and the toxicity of liver still remains the limitation for AAV gene therapy. Thus, novel AAV capsid with specific muscle tropism such as myo-AAV, an AAV9 based peptide insertion AAV capsid showed 6-fold increasing of mRNA transduction and around 0.5-fold liver targeting effect than AAV9 in NHP, plays important role in development of innovated AAV gene therapies. Herein, we developed a novel AAV capsid for muscle tropism with high muscular mRNA transduction efficiency and superior liver de-targeting effect.

To obtain the muscular specific AAV capsid, directed evolution is the way to generate the muscle-directed property. The challenge of muscle tropism screening would be how to increase the transduction efficiency in myocytes. Thus, we designed our muscle tropism AAV library with the unique DNA shuffling library with wtAAVs especially AAV9, AAVrh74 and AAVrh10 which are the high muscle tropism AAVs so far to increase the transduction potency.

After screening in NHP for 2 rounds. We observed an obvious enrichment of AAV capsid with in muscle, we then validated the top capsid candidates with single serotype validation in NHPs. We identified the top muscle tropism AAV capsid named MS-AAV-1. The MS-AAV-1 represents high muscle mRNA transduction efficiency which is 9-fold over AAV9 (19-fold over AAVrh74), indicating that the MS-AAV-1 shows better potential GOI expression in muscle compared with wtAAVs. Moreover, MS-AAV-1 represents superior liver de-targeting effect than AAV9 and AAVrh74. It represented 204-fold muscle-liver ratio of mRNA transduction vs. AAV9 (1416-fold muscle-liver ratio

over AAVrh74). The high muscle tropism and super low liver target properties may generate an ideal viral vector in the future of gene therapies for muscular single gene disordered diseases.



1401 Identifying Muscle Stem Cell Tropic AAV Variants Through Directed Evolution

Harry Chen[1], Michael Emami[2], Courtney Young[2], Kevin Liu[3], Emily Skuratovsky[4], Braeden Freitas[4], Thomas Rando[5], OLUWATAYO Ikotun[6], April Pyle[4], Melissa Spencer[4]

Duchenne Muscular Dystrophy (DMD) is a rare genetic disease caused by frameshifting mutations in *DMD*, resulting in lack of dystrophin protein. CRISPR-based gene editing can restore the *DMD* reading frame and restore an internally deleted dystrophin; however, studies suggest that the restored dystrophin protein diminishes over time. Loss of dystrophin is likely due to the dilution and replacement of edited nuclei by unedited nuclei that derive from muscle stem cells that fuse to muscle fibers. One strategy to retain durable dystrophin is to target Muscle Stem Cells (MuSCs) with CRISPR/Cas9 to correct genomic DNA in the proliferating cell population. We previously conducted an in vivo screen of an AAV capsid library that contains a random 7 amino acid sequences inserted between amino acids 589A and 590Q in the surface region VIII (VR-VIII) of AAV9. Five variants isolated from either muscle stem cells (MuSCs) and five from skeletal muscle fibers (SkMu) were identified and validated in vitro against both mouse and human myoblasts and myotubes. Several variants performed nearly 40x better than wtAAV9 and 15x better than MyoAAV1A in transducing MuSC, while retaining their tropism for myotubes. In addition, in vivo studies in mice have demonstrated a similar enhanced tropism compared to wtAAV9. These data have been confirmed through flow cytometry, luciferase, and qPCR of viral genomes. While further characterization must be done, these new variants provide a potential new platform for achieving long-term dystrophin restoration and durability when AAV is used to deliver CRISPR components in DMD and other myogenic diseases that involve muscle degeneration and regeneration.

1402 Rational Design of AAV9 Capsids for Targeted Delivery to Muscle and Heart and Detargeting of the Liver

Huachun Liu[1], Mateusz Durbacz[2], Fangtao Chi[3], Julio Sanmiguel[4], Reynette Estelien[5], Sumant Brahmankar[6], Yu-Chung Pien[2], Omer Yilmaz[3], Ning Liu[7], Eric Olson[8], Luk Vandenberghe[9], Nerea Zabaleta[10]
[1]Mass Eye & Ear, Somerville, MA, [2]UT Southwestern, Dallas, TX, [3]MIT, Cambridge, MA, [4]Harvard Medical School, [5]SERI@MEEI, Boston, MA, [6]Mass Eye & Ear, Boston, MA, [7]UT Southwestern Medical Center, TX, [8]UT Southwestern Medical Center at Dallas, Dallas, TX, [9]Harvard Medical School, Boston, MA, [10]Schepens Eye Research Institute, Pamplona, MA, Spain

Adeno-associated viruses (AAVs) are widely recognized as efficient vectors for in vivo therapeutic gene transfer. However, a key challenge in using AAVs as gene therapy vectors is to achieve high transduction efficiency while maintaining tissue and cell type specificity. Extensive research has focused on engineering the AAV protein capsid to fine-tune its in vivo tropism and biodistribution. These efforts have yielded numerous functional motifs that target or detarget diverse tissues and cells. Some functional motifs exhibit modularity, retaining functionality when transferred across AAV serotypes or incorporated into different surface-exposed variable regions. In contrast, others may depend on surrounding amino acid sequences. Harnessing these motifs collectively could enable the design of synthetic AAV capsids with versatile functions. In this study, we combined two functional motifs to create a synthetic AAV9 capsid, termed AAV9-GAST-MyoAAV. The first motif mediates liver detargeting, which is achieved by substituting GGSS (residues 266-269) in AAV9 with GAST residues. The second motif mediates muscle targeting, by MyoAAV peptides introduced as 7-10 amino acid insertions or replacements at variable region (VR) VIII of AAV9. Both motifs have demonstrated efficacy in non-human primates. The resulting synthetic capsid exhibited desirable properties. Compared to AAV9, AAV9-GAST-MyoAAV4E demonstrated a 61-fold increase in mRNA expression in the heart, a 34-fold increase in the quadriceps, and a 25-fold decrease in liver expression at a dose of 1E13 vg/kg in adult mice. Superior transduction efficiency was observed in the heart and diaphragm across most doses and in the quadriceps at doses exceeding 1E12 vg/kg. These observations were the same in both sexes. In neonatal mice, the synthetic capsid outperformed AAV9 in transducing the quadriceps and diaphragm but exhibited limited heart transduction, likely due to differential receptor expression levels in neonatal tissues. This study demonstrates the feasibility of combining functional motifs on a single AAV capsid to achieve tailored transduction profiles. If extended to other motifs, this rational "plug-and-play" approach to synthetic AAV capsid design could streamline the development of novel capsids with multifunctional capabilities.

1403 AI-guided Vector Engineering for Enhanced ALS Therapy

Gene therapy has significant potential for treating a broad range of genetic and non-genetic diseases, but one of the major hurdles is achieving efficient and targeted delivery. Recombinant adeno-associated viruses (rAAVs) are commonly used as vectors for gene therapy, yet their ability to effectively target specific cells or tissues is often limited. This challenge underscores the urgent need for more efficient and safer rAAV vectors. Recent advances have focused on developing next-generation AAV vectors that offer improved specificity and delivery capabilities. One of the approaches is the use of machine learning to enhance rAAV transduction. In this study, we developed InsightMiner^{TM}, an AI that learns the characteristics of viruses that infect humans and suggests the sequence of coat proteins to improve the properties of virus vectors such as AAV. By analyzing a variety of human-targeting virus species and applying machine learning algorithms, we identified 7-mer amino acids that improve BBB penetration and central nervous system (CNS) delivery. Consequently, these 7-mer amino acids were inserted into rAAV9, generating GCAPs that show enhanced delivery both in vitro and in vivo compared to wild-type AAV9. GCAPs were then applied to neurodegenerative disease, amyotrophic lateral sclerosis (ALS). The GCAP001 and GCAP002 efficiently delivered the hSTMN2 gene into cultured motor neurons of STMN2 knockout mice, promoting axon regeneration more effectively than wild-type AAV9. Furthermore, intrathecal delivery of hSTMN2 via the GCAP002 significantly improved motor function at 3 months post-injection. In summary, this study demonstrates the power of combining capsid engineering, human virus data, and machine learning to enhance the effectiveness of gene therapy, especially for ALS.

1404 AAVrh32.33: A Promising Gene Delivery Vector for Skin Disorders

Skin disorders, affecting millions worldwide, include over 3,000 conditions, with 700 having a genetic basis. These disorders can severely impact physical and mental health, often leading to long-term symptoms. Gene therapy for skin disorders is promising due to the skin's accessibility and ease of monitoring treatment outcomes. However, gene delivery remains challenging, with both viral and non-viral methods having limitations. Adeno-associated viruses (AAVs) are considered a promising option due to their low immunogenicity and non-pathogenic nature, but past studies have struggled to show their effectiveness in targeting skin cells, prompting further exploration of less common AAV serotypes for improved results.

In our study, we evaluated the efficiency of five AAV serotypes—AAVrh32.33, AAV1, AAV2, AAV5, and AAV6—in C57BL/6 mice, all expressing GFP. While AAV2 and AAV5 failed to express GFP, the other three vectors effectively targeted similar cell types, with transgene expression predominantly observed in the dermis. Interestingly, AAVrh32.33 demonstrated the highest transduction efficiency compared to AAV1 and AAV6, despite its known immunogenicity in mice. Flow cytometry analysis revealed that dermal fibroblasts were the majority of transduced cells, followed by bulge and isthmus cells. Some immune cells, including monocytes and macrophages, were also labeled with GFP. Histological and intravital microscopy confirmed that dermal fibroblasts were the predominant transduced cell type. Importantly, GFP-labeled cells exhibited sustained expression for up to two years, despite previous studies reporting CD8 T cell responses and transgene loss with rh32.33. Vector genome analysis showed no significant reduction in the skin over the course of one year. However, flow cytometry data revealed a decrease in GFP-labeled cells among bulge cells, monocytes, and macrophages after one year. Additionally, intradermal injections into human skin biopsies confirmed that AAVrh32.33 is capable of targeting human dermal cells in addition to mouse cells.

To address immunogenicity of AAVrh32.33, we modified the capsid by replacing the previously reported immunodominant peptide with one from AAV6. This modification preserved transduction efficiency similar to the wild-type AAVrh32.33, but notably, there was a statistically significant increase in transduction of dermal fibroblasts compared to the unmodified version. Additionally, fewer monocytes were labeled with GFP using the modified vector. Flow cytometry analysis indicated no significant T-cell response specific to the immunodominant peptide. These findings suggest that modifying the AAVrh32.33 capsid reduces its immunogenicity without compromising transduction efficiency.

In conclusion, our study highlights the potential of AAVrh32.33 as a highly efficient gene delivery vector for skin gene therapy. Its ability to target dermal fibroblasts and hair follicle cells makes it a promising candidate for treating a variety of skin disorders, including hair-related diseases. Furthermore, the modified capsid version enhances its safety profile by reducing immunogenicity, making it an even more attractive option for clinical applications in skin and hair gene therapies.

1405 Engineering the AAV capsid to evade neutralizing antibody-mediated immune responses

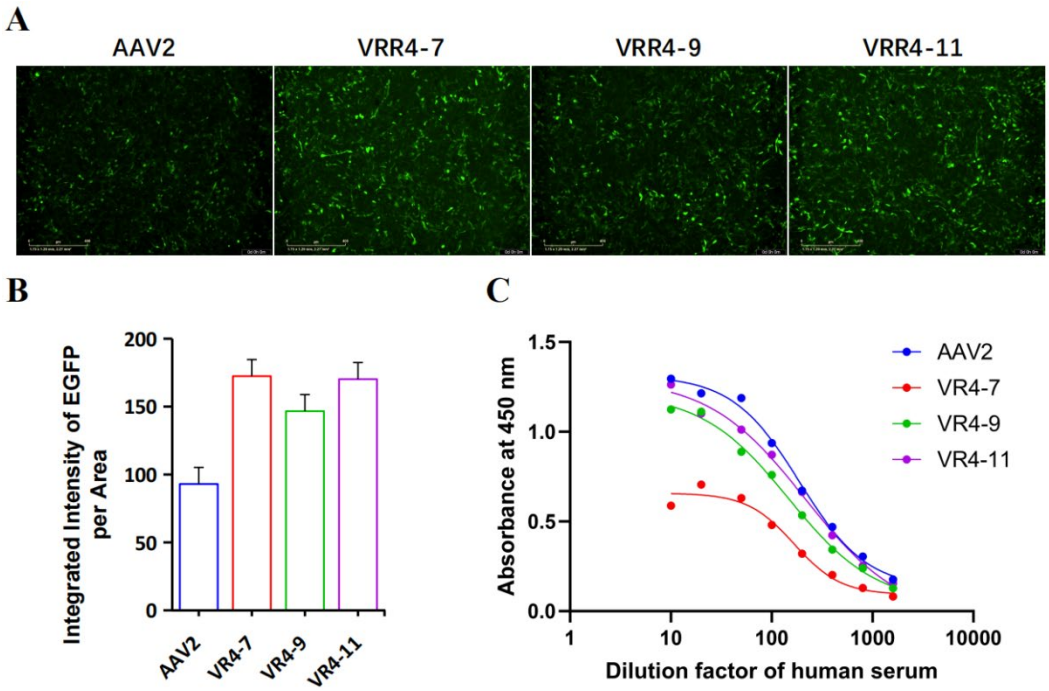
Purpose: AAV2 is one of the most used vector in ocular gene therapy. However, following intravitreal injection, AAV2 frequently elicits an immune response, posing a risk of retinal inflammation, which may restrict its clinical application. Part of the reason for this phenomenon is the presence of pre-existing antibodies (Nabs) within the host. Therefore, modifying viral capsids to evade immune recognition is crucial for safe and effective vector delivery. The current study reported strategies for developing AAV capsids to evade Nabs.

Methods: We employed a domain-swapping strategy, involving the exchange of VRs among different AAV serotypes. Specifically, we substituted the variable region IV (VR IV) of AAV2 with the corresponding VR IV from AAV7, AAV9, and AAV11, generated a series of chimeric capsids include VR4-7, VR4-9, and VR4-11.

Results: The VRR4-7, VRR4-9 and VRR4-11 recombinants AAV variants exhibited significantly improved transduction efficiency in HEK293 cells compared to the wild-type AAV2. Notably, the AAV2-7 variant demonstrated reduced binding affinity to human serum AAV2 NAbs, achieving superior immune evasion ability compared to the parental wild-type AAV2.

Conclusions: Our findings underscore the potential of rational capsid engineering to enhance AAV-mediated gene delivery by improving transduction efficiency and mitigating susceptibility to pre-existing Nabs, thereby presenting a promising strategy for the development of safer and more effective gene therapy vectors.

Fig.1 (A) EGFP reporter gene was packaged into different AAV2 variants. Fluorescent microscopy images showing GFP expression in HEK293 cells transduced with different AAV variants. Transduction efficiencies were assessed at 48h post infection. Scale bar = 400μm. (**B**) Quantitative data of transduction efficiencies for each AAV variant relative to the wild-type AAV2 capsid from (A). (**C**) The binding affinity of different chimeric AAV variants for AAV2 neutralizing antibodies was tested using the ELISA method. Briefly, AAV2, VR4-7, VR4-9 and VR4-11 capsids were coated at an equal concentration in a PVDF membrane. The membrane was incubated with serial dilutions of AAV2-positive human serum, followed by detection of Nabs using an anti-IgG Fc antibody.



1406 Neo-antigen tumor vaccination depends on CD4-licensing conveyed by adeno-associated virus like particles.

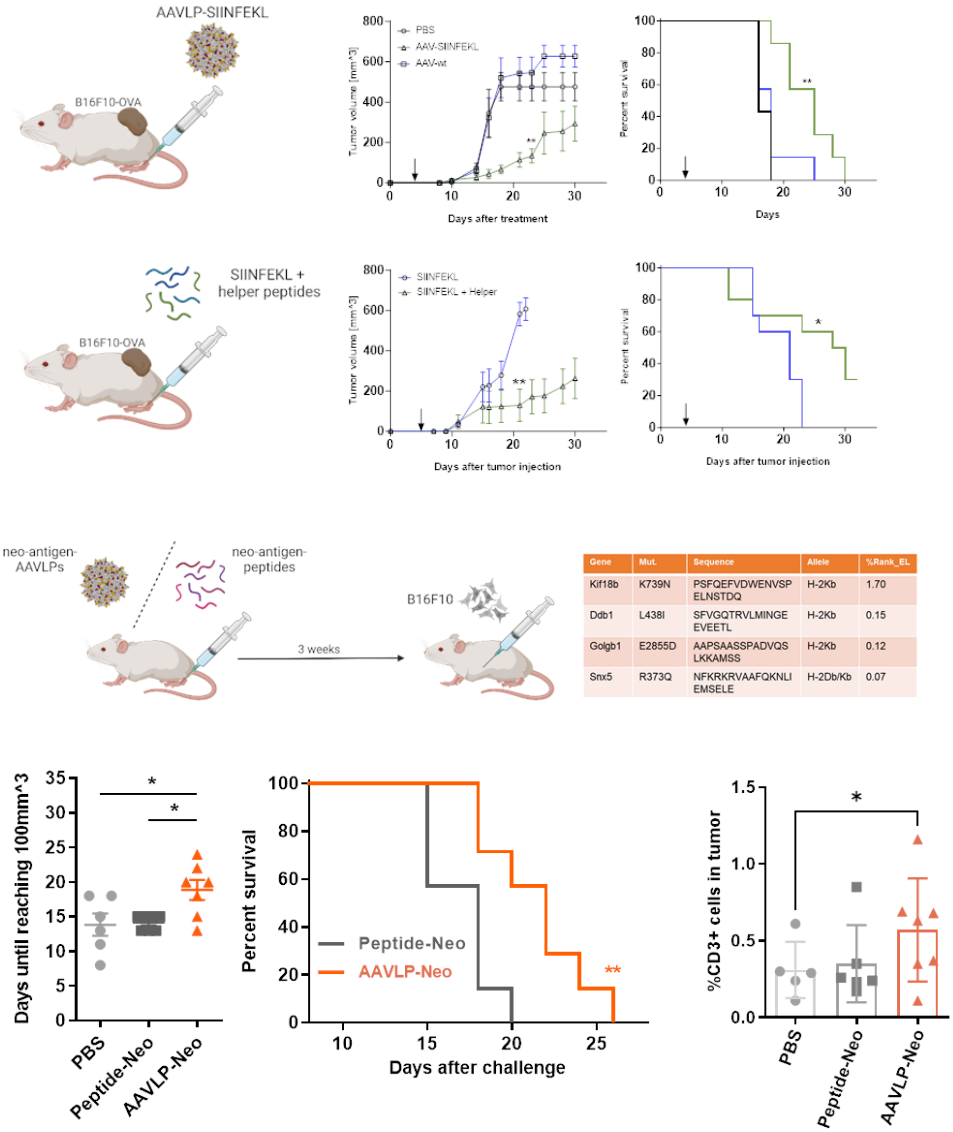
[1]National Center for Tumor Diseases, Heidelberg, Baden-Wuerttemberg, Germany, [2]German Cancer Research Center (DKFZ), Heidelberg, BW, Germany, [3]National Center for Tumor Diseases, Heidelberg, Germany, [4]NCT Heidelberg, Heidelberg, Baden-Wuerttemberg, Germany, [5]NCT Heidelberg, Heidelberg, Germany, [6]University Hospital Heidelberg, Heidelberg, Germany, [7]German Cancer Research Center, Heidelberg, Baden-Wuerttemberg, Germany, [8]German Cancer Research Center, Heidelberg, Germany

Personalized treatment has become a realistic option for tumor patients, accelerated by significantly reduced sequencing costs of tumor genomes and advances in vaccine formulations. The druggability of cancer neo-antigens caused by individual mutations is centered in this effort. We here use an AAV-based VLP platform to compose a neo-antigen specific protein vaccine that is effective in a murine prevention and treatment setting. Furthermore, we show that CD4+ T cell responses that are provided by the AAV capsid are crucial for an effective murine melanoma treatment. To uncover the optimal composition of a peptide vaccine we de-linked MHC-II helper peptides from the capsid and formulated an efficient neo-antigen specific vaccine, which showed the independence of CD4+ T cell response from tumor sequences. The findings are supported by clinical data of neo-antigen vaccinated tumor patients. Our results punctuate on the significance of MHC-II epitopes for CD8+ T cell responses and suggest a future use of AAVLPs as neo-epitope vaccines in personalized cancer treatments.



1407 Common AAV Gene Therapy Vectors Show Indiscriminate Transduction of Living Human Brain Cell Types

Maria Guevara[1], JP McGinnis[1], Joshua Ortiz[2], Sai Mallannagari[1], Daniel Curry[3], Jeffrey Lange[4], Benjamin Arenkiel[1]

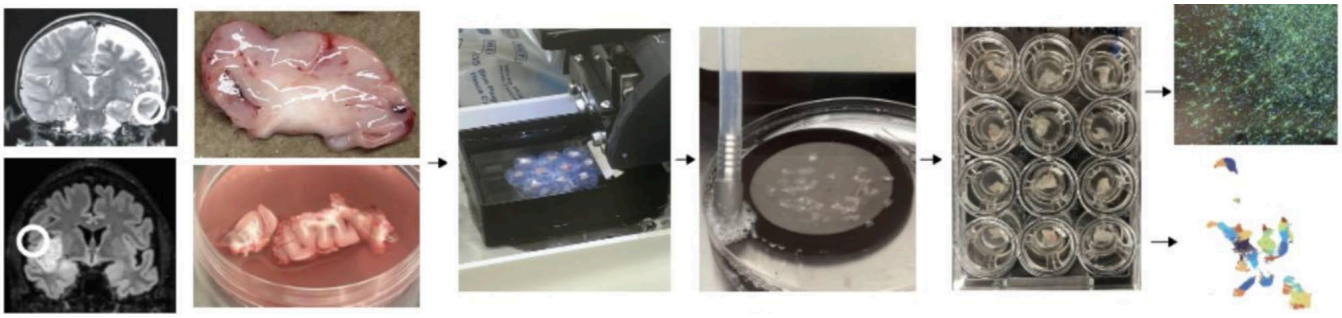
[1]Baylor College of Medicine, Houston, TX, [2]RioGrande Urology, El Paso, TX, [3]Houston, TX, [4]Stowers Institute fir Medical Research, Kansas city, MO

Introduction: The development of cell-type-specific gene therapy vectors for treating neurological diseases holds great promise, and there is growing recognition that the field of medicine will soon see widespread use of molecular tools, including CRISPR-based gene editing, optogenetics and other DNA- and RNA-based therapies. However, in many cases, the safety and efficacy of these tools will depend on our ability to deliver these therapeutics precisely to target cell types while avoiding neighboring but uninvolved cells. Viral vectors, including adeno-associated viruses (AAVs)—the most common vectors in ongoing clinical trials for neurological diseases, rely on their surface proteins' recognition of cellular membrane components to gain entry to a cell. For this reason, modifying AAV capsids to target specific cell types has been an area of broad interest. To date, AAV tropism has been tested mainly in animal models, primarily mice with some non-human primates, and it has been shown that AAV tropism does not usefully translate across species and sometimes even across strains of mice.

Materials and methods: For this study, we have adapted a human brain organotypic slice model using resected neurosurgical specimens not needed for pathologic diagnosis and maintained them in a living state for two weeks in vitro. We determined the tropism profiles of fourteen common AAV vectors via a combination of immunofluorescence and single-nucleus RNA sequencing using eight natural AAV variants (AAV1, 2, 5, 6, 7, 8, 9, rh10), and six engineered AAV variants (DJ8, DJ, AAV2-retro, PHP.S, PHP.eB, Sch9). All serotypes carried eGFP constructs driven by the ubiquitous CAG promoter (ITR-CAG-eGFP-WPRE-hGH polyA signal-ITR). We used brain tissue from eight patients that included temporal lobe cortex and other lobectomy specimens resected due to intractable epilepsies, as well as normal cortex resected en route to deeper tumors.

Results: Of the fourteen variants tested by immunofluorescence, both PHP.eB (60%) and PHP.S (55%)showed the most significant overall transduction rates, whereas AAV5, DJ, and rh10 demonstrated the lowest transduction rates, with all three averaging less than 25% of the total cells in the quantified area. In comparison, AAV2 and AAV9—the most common AAV variants used in neurological trials—both exhibited moderate transduction rates, infecting approximately 30-40% of cells within the analyzed area. Regarding general neuronal transduction, PHP.eB and PHP.S again demonstrated the highest transduction rates (~55%), while AAV9 and AAV2 transduced approximately 40% and 30% of NeuN+ neurons, respectively. Notably, astrocytes (GFAP+ cells) emerged as the most highly transduced cell type for the majority of capsid variants tested. Specifically, AAV6, AAV7, PHP.S, and PHP.eB all transduced ~75% or more of astrocytes within the analyzed areas. In contrast, microglia (Iba1+ cells) showed variable transduction levels, ranging from as low as ~3-15% with AAV5, AAV8, and DJ, to as high as 45% with PHP.S and PHP.eB.

Conclusions: Using immunostaining and single-nucleus RNA sequencing, we found that common AAV vectors show astrocyte preferences but have generally indiscriminate transduction of normal cell types.



1408 Determinants of AAV9 capsid mediated transgene suppression in the rat CNS

Sara Powell[1], Thomas McCown[2]
[1]UNC Chapel Hill, Chapel Hill, NC, [2]University of North Carolina, Chapel Hill, NC

We recently reported that AAV exhibits a capsid-promoter interaction that alters *in vivo* cellular tropism/transduction within the rat and NHP Central Nervous System (CNS). This interaction is seen in AAV9 with an insertion of six glutamates (EU) at aa 139 of the capsid (VP1 numbering) which results in significantly reduced rat striatal transduction that is limited to mostly oligodendrocytes, not neurons. We sought to determine the transduction phenotypes of other CNS relevant AAV capsids (AAV1, AAV2, and rh10) with six glutamate insertions (AAV1EU, AAV2EU, and rh10EU) in both the rat striatum and hippocampus. Transduction is reduced with AAV1EU and AAV2EU like AAV9EU relative to their parental serotype. However, rh10EU retains robust transduction in cells morphologically resembling neurons and colocalizes with rh10 transduction in 76% of cells in both the striatum and hippocampus. Further analysis revealed that AAV9EU has a reduction in both nuclear transgene copies (~ 10- fold less) and relative transgene mRNA levels (~2000-fold less) compared to AAV9, while rh10EU exhibits values comparable to rh10. To identify determinants of the AAV9EU phenotype, thirteen vectors containing different regions of AAV9EU and rh10EU were cloned and assessed for transduction within the rat striatum. Preliminary studies revealed that two mutants mut8 and mut11 exhibited robust transduction similar to rh10EU. Further, sequence analysis identified VP1 capsid residues within rh10EU that contribute to its robust neuronal transgene expression over AAV9EU. Together, these results suggest that capsid-promoter interactions arise from VP1 residues that appear to underly alterations in AAV transduction within the CNS.

1409 Bioconjugated AAV vectors with enhanced functionality and tropism

Paul Heppenstall[1], Daniela Hainberger[1], Elena Groppa[2], Irene Schiavo[3], Denise Ferrarini, SARA TRIFARI[4], Niccolo Bacchi[5]
[1]SISSA, Trieste, Trieste, Italy, [2]SISSA, Trieste, Gorizia, Italy, [3]SISSA, TRIESTE, Italy, [4]Borea Therapeutics, MILANO, Italy, [5]Borea Therapeutics, Kobenhavn SV, Denmark

Enhancing AAV functionality through capsid engineering has become an area of enormous growth for gene therapy. The most common method to achieve this is to use genetic engineering, whereby sequences encoding short peptides are inserted into exposed loops of the capsid proteins. While many new AAV genetic variants have been described with potential for clinical applications, this approach brings certain shortcomings, most notably the necessity to operate within the constraints of preserving the capsid integrity and vector yield, and the lack of knowledge of the underlying biological mechanism that endowed the selected new capsid variant with the new desired tropism.

Here we describe an alternative approach to capsid engineering based upon bioconjugation of targeting ligands onto exposed residues of an AAV capsid using biorthogonal chemistry. By implementing a post-manufacturing functionalization step, we can make virtually any AAV vector amenable to accept a ligand that will re-direct, modify or enhance its tropism. We show that our approach can accommodate multiple classes of ligands, from active peptides to full-length protein domains, allowing pre-determined human validated targets to be used as binding receptors, and resulting in enhanced AAV vector potency with no impact on yield. Our approach does not require extensive screening of capsids or targeting ligands, since it works from knowledge of the receptor-ligand expression profile and function to the desired tissue tropism. Depending on the ligand chosen we can add new functionalities to AAV, such as improving transduction across a variety of cell types, achieving cell-specific targeting, or increasing transport into the CNS.

By applying optimized chemistry to clinically relevant AAV capsids, performance and specificity of AAV mediated gene therapy can be enhanced across highly coveted target tissues.

1410 Direct Comparison of the Engineered Capsid AAV-DB-3 and Wildtype AAV5 in Nonhuman Primate Basal Ganglia and Cerebral Cortex

David Leib[1], Luis Tecedor[2], Elena Lysenko[2], Paul Ranum[3], Noah Smith[4], Christopher Fluta[1], Beverly Davidson[2], Jang-Ho Cha[5]
[1]Latus Bio, Inc, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA [3]Latus Bio, Philadelphia, PA, [4]Latus Bio, Boston, MA

Introduction: Latus Bio is developing an adeno associated virus (AAV) gene therapy as a potential treatment for Huntington's Disease (HD). A major challenge for HD gene therapy is delivery of gene therapies to the most severely affected cell type in HD, medium spiny neurons of the caudate nucleus and putamen. The current state of the art requires multiple intraparenchymal injections per hemisphere under convection enhanced delivery, with surgery times in excess of 10 hours. We previously identified an engineered AAV capsid, AAV-DB-3, in an in vivo screen in nonhuman primates (NHPs), that broadly transduced medium spiny neurons following a single injection per hemisphere in the globus pallidus (GP). Here we compared AAV-DB-3 to AAV5 in a head-to-head experiment in NHPs and evaluated caudate nucleus and thalamus delivery of AAV-DB-3 as alternatives to the GP.

Results: AAV-DB-3 and AAV5 vectors with fluorophore transgenes were delivered to the left and right GP, respectively, at the same dose and volume in two adult rhesus macaques. In a third rhesus macaque, AAV-DB-3 was delivered to the caudate nucleus and thalamus. Following necropsy, tissue was processed for histology and digital droplet PCR (ddPCR) analysis of AAV biodistribution and transgene expression. Following GP delivery, AAV-DB-3 expression was dramatically higher than AAV5 in caudate nucleus, putamen, and motor cortex: 92X in globus pallidus, 531X in caudate nucleus, 184X in putamen and 271X in motor cortex. AAV-DB-3 viral genome biodistribution was also higher than AAV5, but to a lesser degree: 1.2X in the GP, 1.5X in the caudate nucleus, 4.6X in the putamen, and 2.5X in the motor cortex. Fluorescent microscopy in the AAV-DB-3-injected hemisphere revealed broad transgene expression in the GP, caudate nucleus, putamen, and motor cortex. In contrast, AAV5 transgene expression was much lower and largely limited to the injection site in the GP. Neither caudate nucleus nor thalamus delivery resulted in the same broad distribution of AAV-DB-3 in the caudate nucleus, putamen, and motor cortex as revealed by microscopy and ddPCR.

Conclusion: AAV-DB-3 dramatically outperformed AAV5 for transgene expression in key brain areas and cell types for HD gene therapy. In addition, GP delivery led to broader AAV-DB-3 biodistribution in the caudate nucleus, putamen, and motor cortex than caudate nucleus or thalamus delivery. Together, the data support GP delivery of the engineered capsid AAV-DB-3 as a promising approach for the delivery of therapeutic payloads for HD and other disorders of the basal ganglia.

1411 Next Generation Whole Capsid Engineering Yields Translational AAV Capsids for Neurological, Neuromuscular. and Muscular Gene Delivery

Irvin Garza[1], Vijayashree Ramesh[1], Yuhui Hu[2], Matthew Rioux[3], Harrison Higgs[2], Hye Ri Kang[4], Erik Lykken[5], Mehmet Takar[1], Peter Kunach, Ashwani Kumar, Daniel Kieffer, Ruhar Singh, Cynthia Trygg[6], Nicholas Slimmon[1], Chao Xing, Lukasz Joachimiak, Rachel Bailey, Stephen Braun[7], Steven Gray[8]
[1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Dallas, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]The University of Texas Southwestern Medical Center, [5]Dyno Therapeutics, Watertown, MA, [6]Tulane National Primate Research Institute, Covington, LA, [7]Tulane University, New Orleans, LA, [8]University of Texas Southwestern Medical Center, Dallas, Texas

Adeno-associated viral (AAV) vectors show great promise as gene delivery vehicles. In recent years, laboratory engineered capsids have emerged with promising results, but AAV9 continues to be the vector of choice in clinical applications aiming to ameliorate neurological, neuromuscular, and muscular diseases. While clinical trials continue to show success with AAV mediated gene therapies, efficiency and specificity remain as a major bottleneck. Furthermore, AAV mediated gene therapies are among the most expensive treatment options for genetic diseases. Many of these issues can be addressed with improved AAV capsid technology. Previously, we presented work on a novel AAV9-based library generated through controlled randomization to multiple specific regions across the entire capsid gene. To identify species cross-compatible capsids amenable for translational studies, parallel screens were performed in mice and non-human primates (NHPs) using intrathecal (IT) or intravenous (IV) administration of AAV libraries. To overcome previous technological limitations of capsid identification strategies, we employed PacBio's SMRT sequencing of capsid amplicons derived out of isolated nuclei from several tissues of the CNS and peripheral organs. We developed and used a custom bioinformatics pipeline to analyze our datasets and coupled our hit identification with computational protein design tools, Rosetta and AlphaFold. Our lead candidate, "AAV9fyhr," harbors two amino acid alterations across two distinct variable regions with respect to AAV9's CAP gene. These two mutations result in AAV9fyhr's 4-fold higher production yields compared to AAV9 and enhances transduction.

Additional mutations from our screens are currently under assessment for our second generation AAV9fyhr variants. To validate our transduction hits, we developed a multiplexed reporter system to evaluate up to 4 novel AAV capsids compared to AAV9 within the same animal. DNA biodistribution to CNS tissues within NHPs demonstrates 2- to 4- fold higher vector genome delivery of AAV9fyhr. RNA expression in tissue sections via RNA in situ hybridization reveals comparable increased expression levels in the CNS to that of the DNA vector genome biodistribution (i.e. a higher number of transduced cells). In mice, comparable DNA biodistribution is observed to that of the NHP, validating species cross-compatability from small rodent models to larger NHP models. Likewise, we observe comparable RNA expression compared to that of the DNA biodistribution. Capsid systemic circulation in mice reveals that AAV9fyhr has decreased systemic circulation compared to AAV9 up to 72 hours post injection, suggesting that vector is binding more cells compared to AAV9. The additional advantage of our novel multiplexed reporter system is the unique vector design to implement single cell spatial transcriptomics at nanometer resolutions. Assessments of the highest single cell spatial resolution of AAV9's, as well as our engineered capsids, tropism using Vizgen's MERFISH technology are ongoing. Lastly, we shed light on structural rearrangements of AAV9fyhr using Cryo-EM with the highest resolution of an AAV9 derived capsid currently available (~1.86 A). Our findings support translational use of AAV9fyhr in platform gene therapy programs and pave the way towards the generation of novel AAV variants through whole capsid engineering.

1412 Common AAV Capsid Serotypes Better Transduce Resected Glial-type Tumor Tissue, with Feasibility for Engineering Tumor-targeted Gene Therapy Vectors

Sai Likhith Mallannagari[1], JP McGinnis[1], Maria Guevara[1], Joshua Ortiz[2], Jeffrey Lange[3], Akdes Serin Harmanci[1], Daniel Curry[4], Benjamin Arenkiel[1]
[1]Baylor College of Medicine, Houston, TX, [2]RioGrande Urology, El Paso, TX, [3]Stowers Institute fir Medical Research, Kansas city, MO, [4]Houston, TX

Glial-type tumors originate from glial cells within the central nervous system and represent a diverse group of primary brain tumors ranging from low-grade gliomas to one of the most aggressive and malignant brain cancers, glioblastoma multiforme. These tumors account for a significant proportion of brain cancers and current treatment approaches include a combination of surgical resection, radiation therapy, and chemotherapy. However, despite these interventions, the prognosis for glial-type tumors remains poor, particularly for glioblastoma, due to the tumors' infiltrative growth and resistance to standard therapies, highlighting the urgent need for novel therapeutic strategies. The emerging field of gene therapy holds promise as a viable treatment with adeno-associated viruses (AAVs) being the most promising vector candidate. AAVs offer a safe and efficient platform with minimal immunogenicity while having the potential capacity for cell-type-specific targeted delivery of therapeutic genes. However, we still lack the ability to target specific cell types in the human brain, including pathogenic tumor cells. To develop viable AAV gene therapy vectors that efficiently yet selectively target human brain tumor cells, we have adapted a human organotypic tissue culture model to culture resected human brain tumor tissues for two weeks. During this time, we transduce the tissue with 14 common AAV capsid serotypes (AAV1, AAV2, AAV5, AAV6, AAV7, AAV8, AAV9, DJ8, DJ, AAV2-retro, PHP.s, PHP.eB, sch9, and rh10) and allow time for transgene expression to occur. The in vivo transduction profile of these serotypes has been well established within various animal models (including mice, rats, dogs, and non-human primates) but it has been noted that these transduction profiles often poorly correlate between species. Using our model, we can generate the transduction profiles using the cells we care most about for therapeutics: human brain tumor cells. We use immunostaining methods alongside single nuclei RNA sequencing to establish the cell types each AAV capsid serotype is able to transduce. Our findings indicate that most of the 14 common AAV capsid serotypes are able to transduce glial-type tumor tissue (including ependymomas, oligodendrogliomas, astrocytomas, low-grade gliomas, and glioblastomas) better than non-glial-type tumors like medulloblastomas and atypical teratoid rhabdoid tumors (ATRTs), as well as normal-like resected brain tissue. In glioblastoma tissues, using immunofluorescence, capsid serotypes PHP.s (49%), AAV2-retro (37.6%), and PHP.eB (37%) show the highest transduction rates on average, though this varies by patient sample. Single-nucleus RNA sequencing of a patient glioblastoma sample transduced with a combined equimolar AAV library shows the greatest number of cells with identified transcripts from DJ, AAV6, AAV2-retro, and PHP.s. Having shown that the organotypic tissue culture model is a viable assay of AAV transduction of tumor tissue, we will assess the transduction of novel AAV capsid variants in order to identify highly efficient and tumor-targeted variants.

1413 Shuffling of HVR in AAV capsid reveals a context-dependent role for HVR5 in peripheral tissue detargeting while ensuring CNS targeting

Adeno-associated virus (AAV) vectors have revolutionized gene therapy, providing an effective platform to treat a wide range of genetic disorders. Their versatility stems from the high capsid diversity of wild type (wt) AAVs and engineered variants. Their ability to transduce non-dividing cells, along with a favorable safety profile, has led to the approval of seven AAV-based drugs. However, challenges remain in optimizing AAV gene therapy, particularly vector distribution, safety, and efficacy. A major challenge of AAV use is the broad vector biodistribution with preferential liver and heart targeting. Achieving therapeutic effects in other organs, such as muscle or central nervous system (CNS), often requires high vector doses increasing the risk of tissue overload. Capsid engineering is key to overcoming such a challenge by improving target specificity and enhancing therapeutic outcomes. In this study, we developed a novel capsid engineering method which uses regions derived from wtAAVs (La Bella et al, 2020) to modify the tropism of an acceptor capsid yielding advantageous biodistribution profile, while maintaining low seroprevalence and high production yield. Acceptor capsids were modified in the hypervariable regions (HVR) corresponding to the looped-out domains of the capsid and thus interacting with host-cell receptors (Gao et al, 2003). The biodistribution analysis of 31 wtAAV2-13 variants in mice revealed a strong muscle and CNS tropism with liver detargeting. However, their high seroprevalence in humans (~70%) limits their use. We hypothesized that transferring AAV2-13 HVRs to a low-seroprevalent capsid, such as AAV8, might enable the transfer of AAV2-13 biodistribution properties while preserving the low acceptor capsid seroprevalence. A structural analysis was performed to compare the VP3 of AAV2-13 variants to AAV8 and the local structural similarity of the HVRs. Despite sequence diversity, all HVRs of AAV2-13 showed high structural homology to AAV8, except for HVR5, which displayed a different loop orientation. Interestingly, HVR5 also emerged as the most variable region among AAV2-13 variants, suggesting a key role for this domain. We generated a collection of 49 shuffled AAV8 mutants confirming that the transfer of selected AAV2-13 HVRs on AAV8 led to increased muscle and CNS transduction with reduced liver targeting. Notably, no impact on AAV8 seroprevalence and production was observed in the mutants. The rational shuffling method was also validated using AAV9 as acceptor capsid showing similar results. Four rationally shuffled capsids were then tested in non-human primates (NHPs) using a novel barcoding method. We identified one HVR5-mutated AAV9 being able to target the NHP brain with efficiency comparable to AAV9, the gold standard for CNS delivery, while significantly reducing the off-target of liver (15x), heart (10x), dorsal root ganglion (3x) and muscles (11x). Notably, transferring the same HVR into AAV8 capsid had no effect on the engineered capsid biodistribution. The promising primate data demonstrated that shuffling of wtAAV2-13 HVRs is an effective approach to engineer capsids with high translational potential, unveiling the role of the AAV9 HVR5 in peripheral organ detargeting and CNS targeting. These advancements offer the potential to accelerate the development of more effective and safer AAV-based gene therapies, particularly for treating severe neurological disorders through systemic administration.

1414 A Rationally Designed AAV9 Capsid with Minimal Liver Tropism

Zoe Nabakowski[1], **Geoffrey Keeler**[1]
[1]University of Florida, Gainesville, FL

Recombinant adeno-associated virus (AAV) vectors are small, non-enveloped viruses that are unable to replicate in vivo due to the removal of the rep and cap genes. In place of rep and cap, therapeutic transgene sequences can be

loaded into the vector. Thus, AAV vectors represent an ideal gene delivery platform. Further, AAV vectors are generally considered to be safe and minimally immunogenic while providing stable, long-term transgene expression. For these reasons, amongst others, AAV vectors are amongst the most popular gene therapy platforms worldwide. Several AAV serotypes have shown clinical efficacy and are being utilized in over 300 clinical trials that are either recruiting, underway, soon to start recruiting, or completed (ClinicalTrials.gov). This has led to several AAV therapies gaining Food and Drug Administration (FDA) approval. One caveat to systemically administered AAV is that the liver often acts as a 'sponge' for AAV, resulting in high levels of liver transduction. When treating diseases such as Hemophilia, this characteristic is highly desirable as the liver is the target tissue. When treating diseases where extrahepatic tissue is targeted, high levels of liver transduction can result in low therapeutic indices in the target tissues. To combat this, high doses of AAVs are delivered. However, the use of high doses of AAV has resulted in severe adverse side-effects and has even been implicated as playing a possible role in the death of twelve patients in clinical trials (*Hum Gene Ther*. Jul 2020;31, *Hum Gene Ther*. Aug 2020;31, *Hum Gene Ther*. Jul 2020;31, *Human Gene Therapy*. 2022;33). We have argued that a better approach would be to develop AAV capsids with reduced liver tropism. In this work, we have developed a novel AAV9 capsid that shows significant reduction in liver expression as compared to wild-type AAV9 (Fig 1). Further, our new capsid presents lower liver transduction as compared to AAV9-16 or AAV9-HR, the two 'parent' capsids off which our double mutant was designed (Fig 1). Importantly, we show that the reduced liver tropism is mainteined for 5 weeks post vector administration (Fig1). We believe this new capsid will result in delivery of transgene products to extrahepatic tissue, at reduced doses, resulting in improved therapeutic indices.

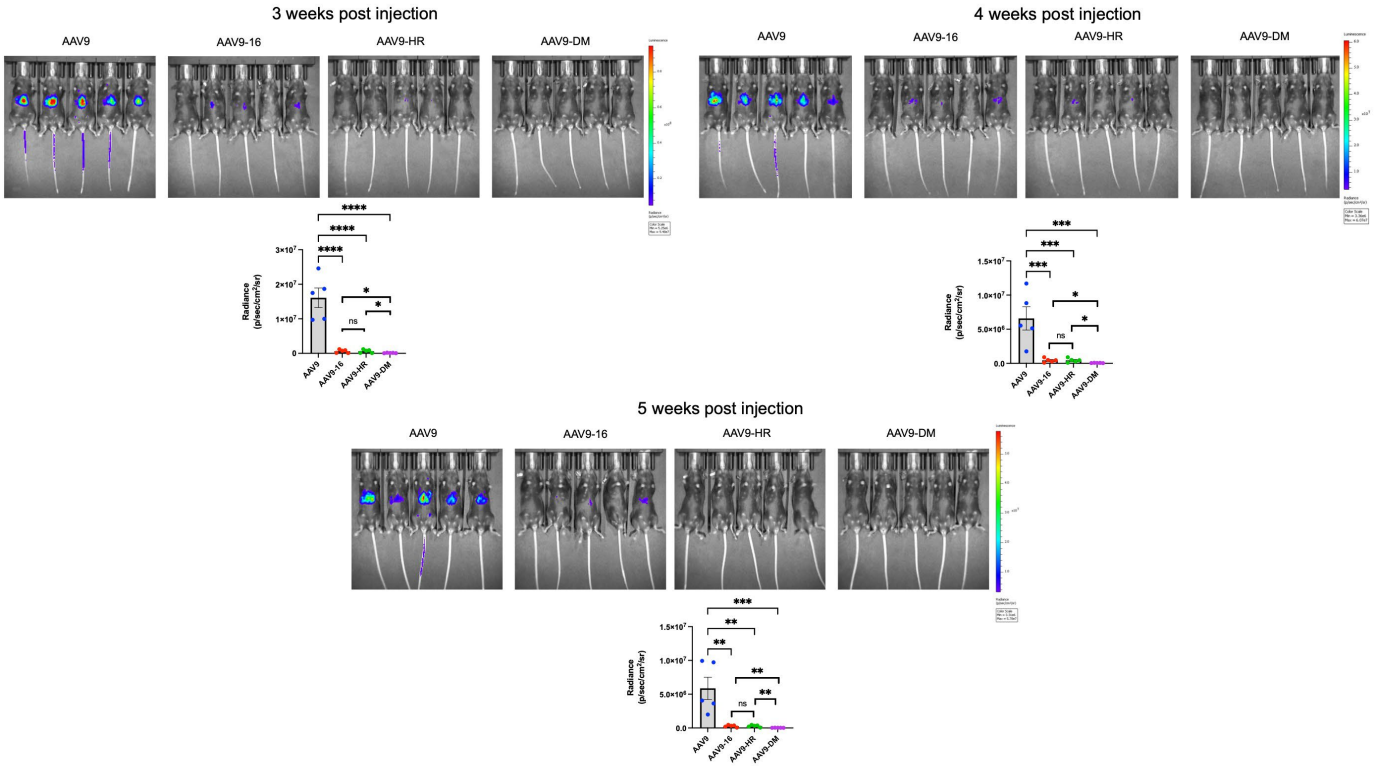

Figure 1: Whole body imaging of AAV capsids. Animals received 1E11vg of either AAV9, AAV9-16, AAV9 HR, or AAV9 DM with firefly luciferase under the control of a CBA promoter. Luciferin was injected subcutaneously, images taken, and bioluminescence quantified at 3, 4, and 5 weeks post AAV administration. The AAV9 DM shows significantly less liver tropism than any of the other capsids tested at all three timepoints.

1415 A single amino acid variant in the variable region I of AAV capsid confers liver detargeting

AAV capsid serotypes isolated from nature have been widely used in gene delivery and gene therapy. Recently, more than 1,000 distinct AAV capsids were identified from human clinical samples by high-throughput, long-read sequencing (Hsu HL et al. *Nature Communications* 2020). In this study, we tap into this broad natural biodiversity of AAV capsids to develop liver-tropic AAV capsids. We initially screened a subset of variants derived from AAV8 (n=159) for packaging efficiency. The top 30% of these variants were individually used to generate vectors carrying a barcoded transgene. These vectors were then pooled according to their titers to ensure comparable representation in the final vector library. This approach minimized gene delivery bias caused by drastic differences in vector abundance. Following systemic delivery of the vector library to wildtype mice, we evaluated vector DNA abundance and transgene expression in the liver, heart, and tibialis anterior (TA) muscle using next-generation sequencing (NGS). Although no variant surpassed AAV8 for liver targeting, several exhibited a liver detargeting phenotype. Among these, we focused on the N271D variant (AAV8 VP1 numbering), located in the variable region I (VR-1), which has been previously implicated in influencing liver tropism (Cabanes-Creus M et al. *Molecular Therapy Methods & Clinical Development* 2021; Zinn E et al. *Cell Reports Medicine* 2022). To further validate capsid tropism, we generated AAV8 and AAV8.N271D vectors, both packaging the same *EGFP* transgene, and compared their gene delivery and transduction in mice side-by-side. This experiment confirmed that the N271D variant confers liver detargeting: vector DNA and mRNA levels in the liver were reduced by 33-fold and 108-fold, respectively. In contrast, vector DNA and mRNA in the heart were moderately reduced by approximately 3-fold, with no significant changes observed in the TA muscle. We also grafted the N271D variant onto AAV9 and MyoAAV capsids (N270D by AAV9 VP1 numbering), which showed a similar liver-detargeting phenotype, although muscle targeting was moderately reduced. This study reinforces the important role of VR-1 in determining liver tropism and highlights the potential of AAV capsid amino acid variants in modulating tissue-specific delivery for gene therapy. **Corresponding Author*

X-linked myotubular myopathy (XLMTM) is a congenital disease caused by mutations in the *MTM1* gene that presents with muscle weakness, hypotonia, feeding and breathing difficulties, and in some instances, death. ASP2957 is an investigational gene therapy for the treatment of XLMTM, which has the coding sequence of the *MTM1* gene contained in an engineered muscle-trophic MyoAAV3.8 capsid (Tabebordbar et al., 2021). In this construct, myotubularin is under the control of the muscle-specific promoter MHCK7 and has a transcription enhancing synthetic intron.

ASP2957 was evaluated in a mouse model of XLMTM (*Mtm1* knock-out [KO]) following a single injection at doses of 0 (vehicle), 1E11, 3E11, 2E12, 6E12 and 1.3E13 vg/kg. The observation period was 5 or 10 weeks post-dosing, and experimental endpoints included vector transduction, protein expression, functional efficacy, and safety. There was a dose dependent increase in muscle tissue VCN and myotubularin protein between the 2E12 and 1.3E13 vg/kg doses. Off-target tissue (liver, spleen) protein expression was not observed, suggesting muscle specific expression

via the MHCK7 promoter. After 5 or 10 weeks, 95% (40 of 42) *Mtm1* KO mice treated with vehicle or low doses of ASP2957 (1E11 or 3E11 vg/kg) were found dead or euthanized, likely because of the severe XLMTM-like phenotype, including inability to move, that develops in these mice. Survival rate increased in a dose-dependent manner of ASP2957, as 88% (37 of 42) *Mtm1* KO mice that received ASP2957 at doses of 2E12, 6E12, or 1.3E13 vg/kg survived until their scheduled euthanasia. Consistent with the survival results, *Mtm1* KO mice treated with ASP2957 had body weight gain improvements in a dose-dependent manner, with statistically significant improvements at ≥2E12 vg/kg. The motor function assessment (rotarod test) also showed a significant increase in latency to falling in *Mtm1* KO mice that received 2E12, 6E12 and 1.3E13 vg/kg ASP2957 compared with the few surviving vehicle-treated KO mice. In the open-field test, ASP2957-dosed *Mtm1* KO mice showed a trend towards increased overall activity at doses of 2E12, 6E12 and 1.3E13 vg/kg. Histopathological evaluation of skeletal muscles in vehicle or ASP2957-treated *Mtm1* KO mice revealed various degrees of myofiber hypotrophy, vacuolation and nuclear displacement associated with adipose infiltration, which are hallmarks of myotubular myopathy. The incidence and/or severity of these microscopic findings were generally inversely correlated with ASP2957 dose increases, suggesting improvements or reversal of the *Mtm1* KO phenotype. There were no adverse findings in clinical pathology or histopathology associated with ASP2957, however, mononuclear cell infiltrations in the heart and skeletal muscle were observed, which suggest an immune response to ASP2957.

A dose-response analysis of the rotarod data from *Mtm1* KO mice that received ASP2957, enabled an estimation of a 50% maximal response (ED50) of 2.06E12 vg/kg. This dose range in which robust efficacy was achieved, is several-fold lower compared to previously published reports that utilized AAV vectors to transfer the *MTM1* gene in the same *Mtm1* KO mouse strain (Buj-Bello et al., 2008; Childers et al., 2014). These results demonstrating high potency of ASP2957 in *Mtm1* KO mice are promising in the context of potentially treating XLMTM patients with ASP2957 at a relatively low dose that could achieve efficacy while also reducing safety risks.

1417 Lowering CpG content in rAAV genomes reduces DRG toxicity without compromising therapeutic benefits in mice

Xiupeng Chen[1], Hong Ma[2], Mojiao Tang, Mengtian Cui, Mengyao Xu[1], Ailing Du, Tapan Sharma[1], Wassamon Boonying[1], Sandhiya Ravi[3], Hao Liu[1], Jinghua Liu[1], Veena Kumanan[1], Phillip Tai[4], Guangping Gao[1]*, Jun Xie[1]*

**Corresponding Author*

For CNS gene therapy, one major toxicity observed is DRG degeneration in preclinical models. DRG toxicity has been documented for many rAAV platforms, irrespective of the AAV serotype, the therapeutic cassette, or the vector manufacturing method. The root cause of DRG toxicity is not entirely understood. An accumulation of transgene protein causing endoplasmic reticulum stress in rAAV-transduced cells has been suggested as a mechanism. A strong immune response is likely a key driver of DRG toxicity but is regarded as a secondary response to cell damage. CpG depletion or incorporation of TLR-9 inhibitors in the AAV genome can obviate the immune response in animals and enable sustainable transgene expression. Spinal muscular atrophy (SMA) is an autosomal recessive disease characterized by progressive degeneration of α-motor neurons, resulting in muscle weakness and atrophy. We previously developed a 2nd-generation AAV9 (2nd-gen) gene therapy expressing a codon-optimized hSMN1 transgene, driven by a native hSMN1 promoter outperforms a benchmark vector that is identical in design to Zolgensma. The 2nd-gen vector utilized the SMN1 promoter, which enables exogenous SMN expression at levels similar to those of the endogenous SMN gene throughout the body. A head-to-head comparison between this 2nd-gen vector and the benchmark vector in SMA mice showed that the 2nd-gen vector had a better safety profile (no increase in liver transaminase levels) and significantly improved efficacy (e.g., lower effective dose, broader therapeutic window, longer life span, and increases in cardiac and motor functions). However, we found hindlimb clasping phenotypes in the wildtype C57/B6 mice injected with the 2nd-generation vector by facial vein at a high dose 3.3E14 vg/kg at P0, but not in the benchmark vector-treated mice. However, H&E staining revealed increased satellite glia cells in DRGs in the 2nd-gen vector-treated mice compared to the PBS-treated animal. Based on the 2nd-gen vector genome, we re-optimized the SMN1 coding sequence to make it CpG-free or depleted of CpGs (CpG-low). Strikingly, no mice (C57/B6 or FVB) that received the CpG-modified vectors showed the hindlimb clasping phenotype after one month of treatment. After 5 months, 10-50% of the animals from these two groups started to show hindlimb clasping phenotype but with less severity. In contrast to the difference in

phenotype from the original 2nd-gen vector and CpG-modified vectors, SMN expression in DRG is abundant and comparable among these three groups, indicating that CpG modification is beneficial for ameliorating toxicity. We injected these vectors into SMA mice at P1 by ICV injection at 3.3E13 or 1.1E13 vg/kg. The CpG-low vector treatment improved the lifespan of SMA mice as effectively as the 2nd-gen vectors at both doses and more efficiently than the benchmark group. The CpG-low vector performed the best in gaining body weight at the 3.3E13 vg/kg dose and was like the 2nd-gen vector at 1.1E13 vg/kg. The CpG-low vector group also performed the best in the grid test among all the groups, including the 2nd-gen vector. In a 90-day study period, no hindlimb clasping phenotype was observed in the treated SMA mice. Taking together, we conclude that the reduction of CpGs ameliorates DRG toxicity without compromising its therapeutic benefits in SMA gene therapy, holding potential for overcoming DRG toxicity in other AAV-mediated CNS gene therapies. **G.Gao, J.Xie.** Co-corresponding authors.

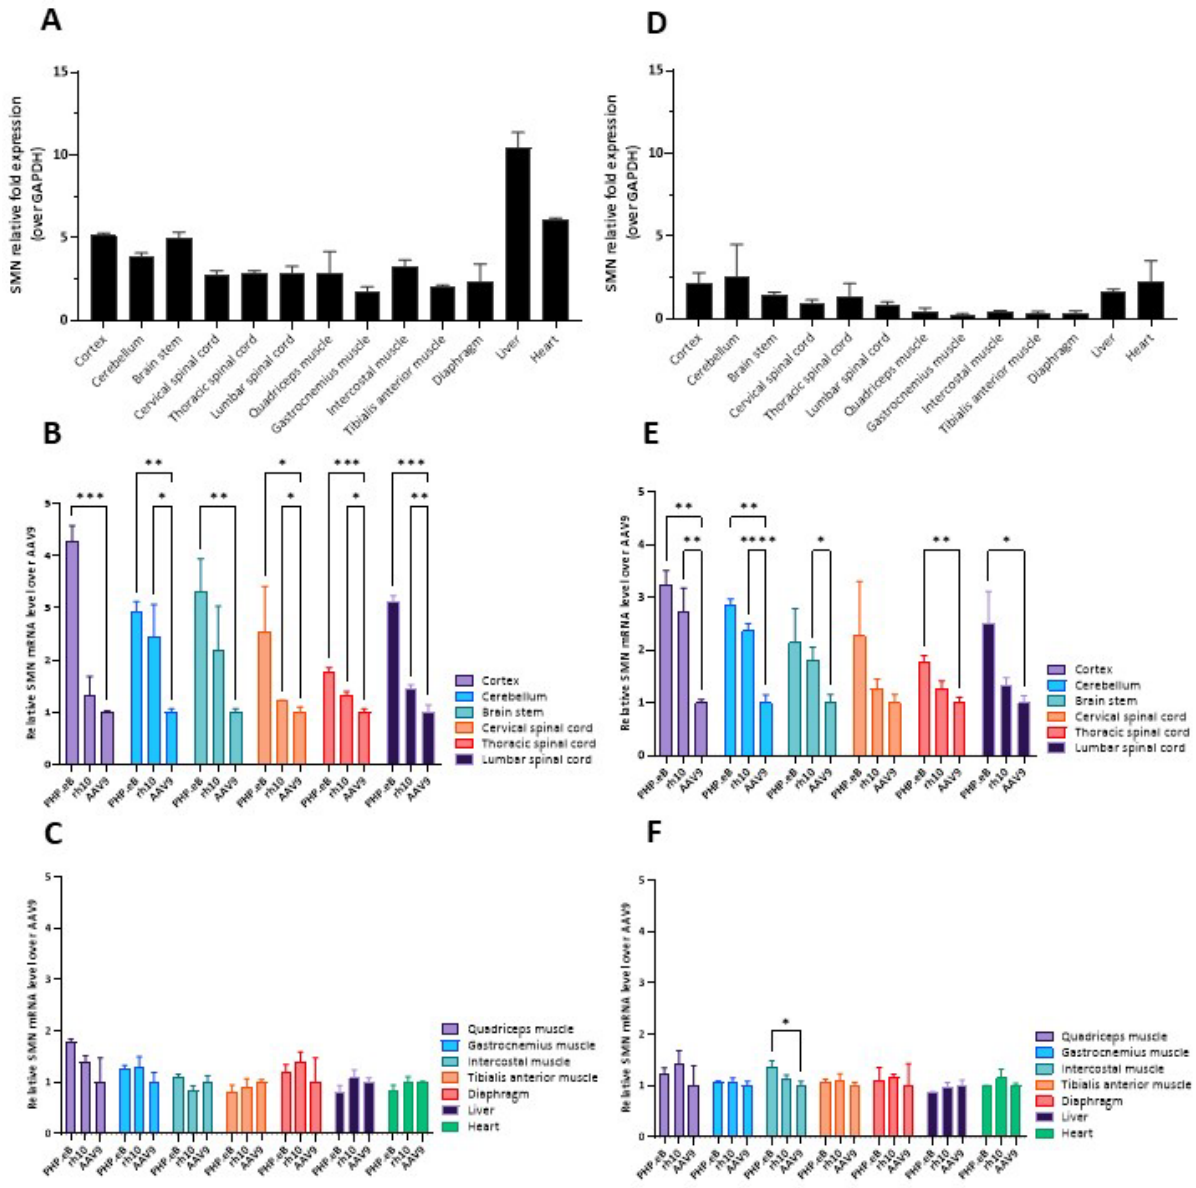
1418 Comparative Analysis of Transgene Expression of Neurotropic AAV Serotypes and Their Potential in Combination Treatments

Maryam Bemanalizadeh[1], Vahid Mansouri[1]*
[1]*Tehran University of Medical Sciences, Tehran, Tehran, Iran*
**Corresponding Author*

SMN protein have been shown to have a vital role in several cellular pathways. Accordingly, therapeutic approaches should restore the SMN expression not only in central nervous system (CNS) tissues but also in peripheral tissues. Adeno-associated virus (AAV) vectors have revolutionized gene therapy due to their ability to efficiently transduce cells in both the CNS and peripheral tissues. Among the diverse AAV serotypes, AAV9, AAVrh10, and AAV-PHP.eB exhibit considerable tropism toward CNS tissues, making them promising for treating neuromuscular diseases such as spinal muscular atrophy (SMA), however, nonspecific off-target transduction of these vectors results in their side effects. Combinitional therapies using multiple AAV serotypes through different administration routes, while reducing their doses might be an innovative strategy to mitigate their toxicities meanwhile improving the specific on-target therapeutic effects. A comparative analysis of these serotypes can guide the AAV combinational therapy for SMA.

Newborn C57BL/6J mice received intravenous injections of self-complementary AAV (scAAV) vectors (AAV9, AAVrh10, and AAV-PHP.eB) encoding codon-optimized survival motor neuron (coSMN) gene at a dose of 5×10^{11} vector genomes per mouse at P1 (n= 8 per group). Tissue-specific transgene expression was assessed at both 4 and 24 weeks post-injection across various organs, including the brain, spinal cord, skeletal muscles, liver, and heart. SMN mRNA levels were analyzed using qPCR. At 4 weeks post-injection, mice treated with scAAV9-hcoSMN showed the highest SMN mRNA expression in the liver and heart, followed by CNS tissues and muscles (Figure 1A). RT-PCR analysis revealed significantly higher SMN mRNA levels in the cortex, cerebellum, and spinal cord of mice treated with scAAV-PHP.eB and scAAVrh10 compared to scAAV9 (Figure 1B). Results showed no significant differences in peripheral tissues across groups (Figure 1C). At 24 weeks post-injection, SMN mRNA expression remained high in the CNS, liver, and heart (Figure 1D). However, some aforementioned differences diminished over time (Figure 1E). AAV PHP.eB-treated mice exhibited higher SMN mRNA levels in the intercostal muscle compared to AAV9-treated mice, while no significant differences were found in other peripheral tissues (Figure 1F). AAV-PHP.eB demonstrated superior transduction efficiency within CNS tissues, achieving significantly higher SMN expression in the brain and spinal cord compared to AAV9 and AAVrh10. This serotype achieved widespread neuronal transduction, highlighting its potential for CNS-specific applications. AAV9 and AAVrh10 displayed an intermediate transduction pattern, with moderate efficiency across both CNS and peripheral tissues.

AAV-PHP.eB is the most promising vector for CNS-targeted gene therapy due to its robust and sustained transgene expression in the brain and spinal cord. Given the inability of PHP.eB for passing BBB in NHPs (and possibly in humans), using this serotype (with lower doses) through intrathecal or intracerebroventricular routes, would provide the adequate expression in CNS tissues. In combination, lower doses of other serotypes can be used for necessary systemic gene expression, as needed in SMA. This combinational approach helps minimize the toxicity of viral gene therapies in comparison with the intravenous injection that needs administration of high doses of vectors to achieve sufficient CNS expression.



1419 Short-Term Hurdles, Long-Term Promise: AAV9-SMN1 Gene Therapy for SMA

Maryam Bemanalizadeh[1], Vahid Mansouri[1]*
[1]*Tehran University of Medical Sciences, Tehran, Tehran, Iran*
**Corresponding Author*

Introduction: Spinal muscular atrophy (SMA) is a severe neuromuscular disorder caused by mutations in the SMN1 gene, leading to motor neuron degeneration and progressive muscle atrophy. Gene therapy using adeno-associated virus serotype 9 (AAV9) has shown promise in restoring SMN protein expression and improving clinical outcomes. However, concerns about hepatotoxicity and cardiotoxicity following vector administration necessitate comprehensive long-term safety and efficacy evaluations. We hypothesize that overcoming the acute toxicity phase is critical and that, post-recovery, the long-term safety and sustained therapeutic effects of AAV9-based therapies

warrants thorough assessment. This study investigates the safety and efficacy of an AAV9 vector expressing codon-optimized human SMN1 (AAV9-coSMN) in neonatal mice to 24 weeks.

Methods: Neonatal mice were randomly assigned to treatment (n=10) and control (n=10) groups. The treatment group received a single intravenous injection of AAV9-coSMN at 5×10^{11} vector genomes (vg) per mouse at P1, while controls received phosphate-buffered saline (PBS). Clinical parameters, including body weight, well-being (general appearance, skin and fur, eyes, nose, mouth, respiration, urine, feces, and locomotor symptoms), and survival were monitored. Safety assessments included hematological and biochemical analyses, necropsy, and histopathological examination of major organs. Efficacy was evaluated via western blotting to measure SMN expression in key tissues, including the central nervous system (CNS), skeletal muscles, heart, and liver.

Results: AAV9-hcoSMN treatment resulted in a 100% survival rate with no observable adverse clinical signs to 24 weeks. Treated mice exhibited normal growth trajectories, with no significant differences in weight gain compared to controls (Figure 1A). Hematological and biochemical findings remained within normal ranges. In particular, platelet count, ALT, AST, and CK-MB showed no significant differences with the control group (Figure 1B). Necropsy and histopathological examination of the brain, spinal cord, liver, heart, lungs, and skeletal muscles showed no signs of inflammation, fibrosis, or pathological changes. Efficacy analysis demonstrated robust sustained SMN expression, with the highest levels observed in CNS tissues, followed by the heart, liver, and skeletal muscles. (Figure 1C).

Conclusion: This study provides strong preclinical evidence supporting the long-term safety and efficacy of AAV9-coSMN gene therapy for SMA. This 6-month period in mice lifespan is equivalent to approximately 30 years in humans, which could be consider a long-term evaluation. The absence of adverse clinical and pathological findings, combined with sustained transgene expression in target tissues, highlights the potential of AAV9-mediated SMN1 delivery as a viable treatment option.

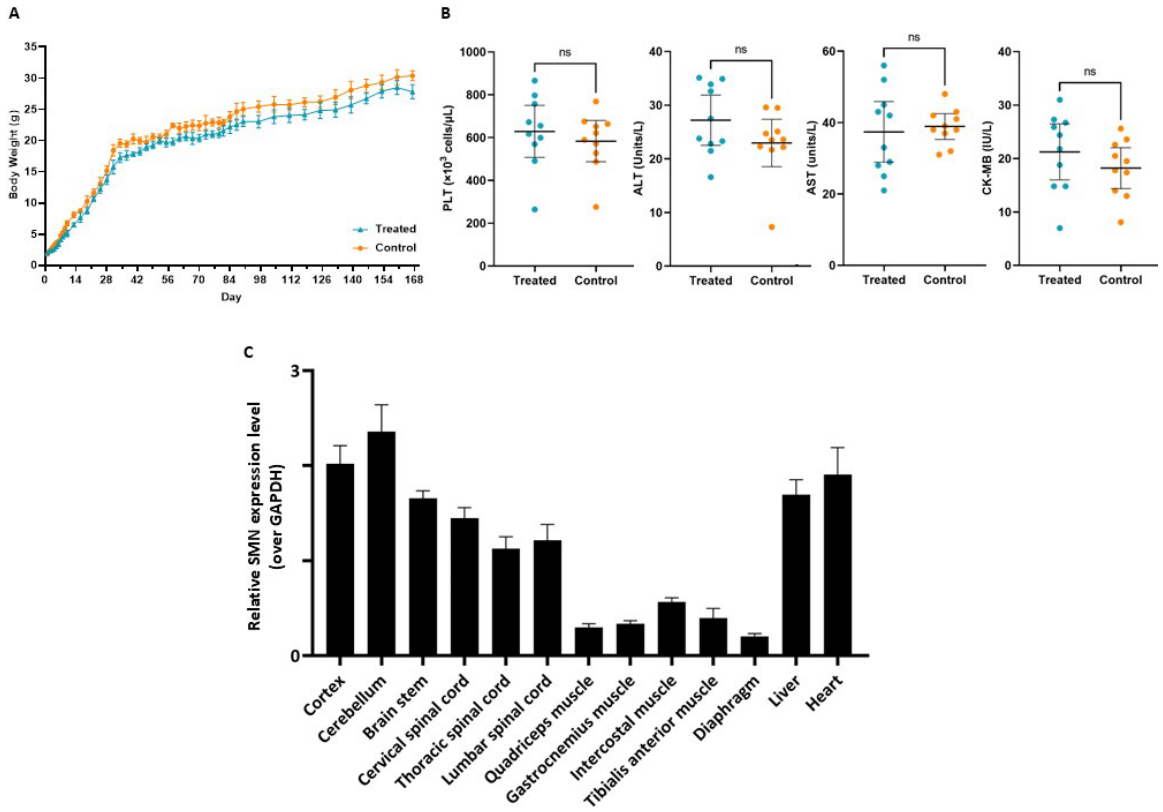


Figure 1- Long-term safety and efficacy of AAV9-coSMN (A) Trend of weight changes over a 24-week follow-up period in two groups. (B) Comparison of laboratory findings between two groups at 24 weeks post-injection. (C) Relative SMN expression (over GAPDH) in various tissues at 24 weeks post-injection.

1420 Evaluating a "silence and replace" approach for development of an AAV gene therapy for Spastic Paraplegia type 4

Ananya Uppalapati[1], Simon Wentworth[2], Monique Otero[3], Heather Gray-Edwards[4], Miguel Sena-Esteves[1], Ana Rita Batista[1]
[1]UMass Chan Medical School, Worcester, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]UMass Chan Medial School, Worcester, MA, [4]UMass Chan Medical School, Worcester, Massachusetts

Hereditary spastic paraplegia (HSP) is an umbrella of neurodegenerative disorders characterized by weakness and stiffness of muscles in the lower extremities along with other central nervous system impairments. There are more than 80 types of HSPs each caused by mutations in different genes. Spastic Paraplegia type 4 (SPG4) is the most common form of HSP and it is caused by mutations in the *SPAST* gene encoding for spastin. Spastin is a microtubule severing enzyme that is crucial in cytoskeletal regulation, its loss of function can lead to the degeneration of axons and dysfunction in neuronal maintenance throughout the corticospinal tract. This leads to a spectrum of disease phenotypes, termed pure and complex SPG4. Pure SPG4 is more common and presents with lower limb weakness and minimal neurological impairments. Complex SPG4 affects the overall central nervous system more severely, presenting with ataxia, spasticity, epilepsy and other neurological phenotypes. Onset of SPG4 varies by age, childhood onset symptoms can be seen early, progressing to a more severe form of the disease, or late adulthood presenting with slower progression and milder symptoms. Updated prevalence and incidence data remains largely incomplete as HSP is considered a rare condition, affecting around 3.6 per 100,000 cases worldwide. While SPG4 is not considered a fatal diagnosis, its gradual advancement significantly impacts patients' quality of life.

Currently, there is no available treatment for SPG4. Our lab has designed a variety of dual function AAV vectors to silence the endogenous Spastin alleles using an artificial microRNA, while simultaneously expressing normal Spastin from a cDNA where codons in the seed sequence of the miRNA target are modified to make it resistant to silencing. To ensure that expression levels of Spastin remain close to standard physiological levels, we are testing numerous promoters to drive transgene expression. We have achieved successful knockdown of endogenous Spastin and expression of our transgene at both transcript and protein levels. AAV vectors are currently being validated in patient fibroblasts prior to initiating efficacy studies in SPG4 animal models.

1421 Validation of a Göttingen Minipig Gene Therapy Biodistribution Assay for AVGN7 Using Droplet Digital Polymerase Chain Reaction

Agostinho Gomes Rocha[1]*, Tony Yu[2], Magdalena Loveland[2], Dhrumi Patel[2], Buel Rodgers[3]

Göttingen Minipigs are rapidly gaining popularity as a large animal non-rodent model in preclinical gene therapy studies. Regulatory agencies require biodistribution and pharmacokinetic studies to support IND enabling studies. Molecular biology techniques are utilized to quantitate gene therapy products where traditionally "real-time" qPCR platforms have been used. To increase sensitivity and accuracy, we developed and validated a droplet digital PCR (ddPCR) duplex assay to quantify AVGN7, an AAV gene therapeutic featuring a codon-optimized human *Smad7* gene, and *RPP30*, a reference gene, in Göttingen minipig tissues and blood. The validation parameters included precision and accuracy, limit of detection (LOD), ruggedness/robustness, dilutional linearity, stability, selectivity and recovery. Accuracy and precision were demonstrated across the dynamic range of 5-25,000 cp/µL, producing an inter-assay total error of ≤35.5% for *Smad7* and ≤2.6% for *RPP30*. The assay was sensitive to 10 cp/µg DNA with an LOD of 0.125 cp/µl. Ruggedness was assessed over time using multiple analysts, instruments and reagent lots, demonstrating high reliability and reproducibility. Linearity was established across 1,000-fold dilutions and stability was demonstrated up to 6 freeze-thaw cycles at -20°C and 24 hours at room temperature. Selectivity and recovery were demonstrated by spiking samples after or before nucleic acid extraction, respectively, using multiple lots of different tissue matrices and whole blood. These data not only validate the assay for tracking and quantifying AVGN7 in preclinical studies with Göttingen minipigs, but additionally address challenges of using pig models in general while providing a procedural road map for developing other AAV biodistribution assays.

1422 In Situ Biodistribution and Localization of Bidridistrogene Xeboparvovec (SRP-9003) in LGMD2E/R4 Mice After 1 Year of Follow-up

Stephen Baine[1], Young-Eun Seo[2], **Stephen Fasul[3]**, Jenna Greve[4], Chrissy Hopkins[4], Akansha Pradhan[4], Jasmine Wu[4], Alex Haile[5], Rachael Potter[1], Sarah Lewis[5], Louise Rodino-Klapac[4]
[1]Sarepta Therapeutics, Cambridge, MA, [2]Sarepta Therapeutics Inc, Columbus, OH, [3]Sarepta Therapeutics, Inc., Durham, NC, [4]Sarepta Therapeutics, Inc., Cambridge, MA, [5]Sarepta Therapeutics Inc

Introduction: Limb-girdle muscular dystrophy type 2E/R4 (LGMD2E/R4) is caused by mutations in the β-sarcoglycan (*SGCB*) gene, resulting in loss of functional SGCB protein, progressive muscle degeneration, and shortened lifespan. Bidridistrogene xeboparvovec (SRP-9003, rAAVrh74.MHCK7.hSGCB) is an investigational adeno-associated virus (AAV)-based gene therapy designed to restore functional SGCB expression in muscle and improve clinical outcomes in patients with LGMD2E/R4. RNAscope™ has emerged as a technology capable of determining tropism, transduction efficiency, and in situ localization of targeted gene therapies. We report the use of RNAscope™ to elucidate the in situ spatial biodistribution, cellular tropism, transgene expression, and durability of SRP-9003 following intravenous (IV) administration in LGMD2E/R4 mice.

Methods: Mouse tissues were assessed on necropsy at day (D) 1, 14, 28, 60, 120, 240, and 365 after single IV administration of SRP-9003 (7.41 × 1013 vg per kilogram [vg/kg]). Two RNAscope™ in situ hybridization probes were designed to detect either the AAVrh74-vector DNA or hSGCB transgene messenger RNA (mRNA). Digital droplet polymerase chain reaction (ddPCR) (copies per nucleus) was used to quantify vector DNA, and hSGCB

mRNA was measured using reverse transcription (RT)-ddPCR. Immunofluorescence (IF) was used to assess hSGCB protein expression (as percent beta-sarcoglycan–positive fibers [%PβPF] quantified with HALO® Muscle Fiber FL algorithm).

Results: We previously demonstrated maintenance of SRP-9003 vector DNA and transgene mRNA up to 120 days following systemic administration in LGMD2E mice. Here, we determine SRP-9003 vector durability up to 1 year. Following IV administration, SRP-9003 vector DNA levels (ddPCR) and mRNA expression (RT-ddPCR) were maintained through D365 in the heart and skeletal muscle, indicating vector durability over extended periods in the LGMD2E/R4 mice. In off-target organs such as liver and kidney, detectable SRP-9003 vector DNA and RNA were also present up to D365. In skeletal muscle (tibialis anterior [TA]), vector DNA signal (RNAscope™) gradually declined from D1 to D240, but transgene mRNA signal was stable between D14 and D240. In the heart, vector DNA signal gradually declined from D1 to D120 but stabilized at D240 and D365. A durable transgene mRNA signal was achieved in the heart by D14 and was maintained to D365 post injection. No RNAscope™ mRNA signal was detected in the kidney over the course of the study. In congruence with durable transgene mRNA signal, SGCB protein expression (%PβPF by IF) was maximized at D240 and remained elevated up to D365 in the TA. These data demonstrate targeted SGCB protein restitution via SRP-9003 is maintained up to 1 year to provide long-term efficacy in LGMD2E/R4 mice.

Conclusions: This study demonstrates the applicability of RNAscope™ to determine spatial, cellular organization, and molecular trafficking of SRP-9003. The results indicate the durability of SRP-9003 to generate stable *SGCB* mRNA and protein expression over extended periods of up to 1 year in a mouse model of LGMD2E/R4. These data may be useful to inform future application of RNAscope™ for biodistribution evaluation of AAVrh74 gene therapy.

1423 CSF Delivery of AAV9/SLC52A2 is Effective for the Treatment of RTD2 in a Novel Mouse Model

Maximiliano Presa[1], Stephen Kneeland[1], Jennifer Ryan[1], Dweet Chhaya[1], Pierre-Alexandre Piec[1], Holly Savage[1], Keith Massey[2], Steven Gray[3], Cathleen Lutz[1]
[1]The Jackson Laboratory, Bar Harbor, ME, [2]Cure RTD Foundation, Calgary, AB, [3]University of Texas Southwestern Medical Center, Dallas, Texas

Riboflavin transporter deficiency type 2 (RTD2, OMIM 614707) is a rare neurodegenerative disorder, caused by biallelic pathogenic variants in the *SLC52A2* gene, which encodes the riboflavin transporter RFVT2. It is characterized by muscle weakness, vision loss, deafness, sensory impairments, and respiratory failure. High-dose riboflavin supplementation slows the progression of functional disability and stabilizes or improves function in certain domains. Since 2011, more than 200 patients have been reported.

We have developed new mouse models for RTD2, carrying the p.Leu317Pro and p.Leu344Pro alleles (corresponding to human clinical variants p.Leu312Pro and p.Leu339Pro, respectively). Among reported RTD2 patients, 32% have at least one of these corresponding mutations. Compound heterozygous ($Slc52a^{(L317P/L344P)}$) mice are late embryonic lethal under standard husbandry breeding conditions. Water supplementation with high dose flavin mononucleotide during gestation allows $Slc52a^{(L317P/L344P)}$ pups to be born and survive into adulthood. $Slc52a^{(L317P/L344P)}$ adults exhibit growth impairment, progressive muscle weakness, motor coordination deficits, and 40-50% mortality by 8 weeks of age, thus providing a good time window for intervention.

To assess whether gene augmentation therapy is a potential treatment for RTD2, we developed a rAAV9 vector carrying a codon-optimized human SLC52A2 cDNA. Neonatal administration via intrathecal injection of rAAV9/SLC52A resulted in improved survival, with 100 % of $Slc52a^{(L317P/L344P)}$ mice alive more than 26 weeks post-injection. Additionally, the treatment rescued the growth defects. The $Slc52a^{(L317P/L344P)}$ mice receiving the gene therapy performed indistinguishable from wild type mice on motor and muscle strength tests. The preliminary data

from this proof-of-concept study supports the use of gene augmentation therapy for the treatment of RTD2 and sets the base for further preclinical studies.

1424 AAV-Delivered Anti-PC-OxPL Antibody Fragments as a Novel Therapeutic Approach to Target ALS

Andreia Duarte[1], Jamie Wong[2], Svetlana Pasteuning-Vuhman[3], Wouter Pos[4], Rob Haselberg[1], Marina Sogorb-Gonzalez[5], Sofia Pascoal[3], Roland van Dijk[1], Farangis Sharifi[6], Martin Giera[7], Pavlina Konstantinova[3], Sotirios Tsimikas[8], Saud Sadiq[9], Sander Van Deventer[10]
[1]VectorY Therapeutics, Amsterdam, Noord-Holland, Netherlands, [2]Tisch Multiple Sclerosis Research Center of New York, New York, NY, [3]VectorY Therapeutics, Amsterdam, Netherlands, [4]VectorY Therapeutics, Amsterdam, The Netherlands, Netherlands, [5]VectorY, Amsterdam, Noord-Holland, Netherlands, [6]VectorY Therapeutics, Ams, Netherlands, [7]Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands, [8]Division of Cardiovascular Medicine, Sulpizio Cardiovascular Center, University of California San Diego, San Diego, [9]Tisch Multiple Sclerosis Research Center of New York, New York, [10]Amsterdam, Netherlands

Amyotrophic lateral sclerosis (ALS) is characterized by the progressive loss of motor neurons and premature death. The limited understanding of the mechanisms underlying selective motor neuron death has significantly hindered the development of disease-modifying treatments. Ferroptosis, a form of cell death dependent on iron accumulation, has been implicated in the selective degeneration of motor neurons in ALS. Oxidized phosphatidylcholines (PC-OxPL) have been identified as key effectors in the pathophysiological processes associated with this pathway. Preclinical observations revealed a distinct PC-OxPL profile in the cerebrospinal fluid (CSF) of sporadic ALS (sALS) patients and identified apolipoprotein E (APOE) particles as the primary carriers of PC-OxPL in the CSF. Furthermore, in ALS brain and spinal cord tissue sections, PC-OxPL was found to be predominantly associated with motor neurons. Exposure of iPSC-derived motor neurons to PC-OxPL led to transcriptomic changes in genes known to be linked to ALS, as well as the induction of significant TDP-43 pathology and motor neuron death. To counter this, we developed a single-chain antibody fragment (scFv) encoded by an AAV-delivered DNA construct that specifically targets PC-OxPL neoepitopes (PC-OxPL-VecTab). PC-OxPL-VecTab effectively neutralized PC-OxPL-induced neurotoxicity and TDP-43 aggregation in motor neurons, while preventing motor neuron death and deficits in a sALS CSF mouse model. When administered intrathecally to minipigs, PC-OxPL-VecTab was distributed to both upper and lower motor neurons and expressed at levels predicted to be therapeutically effective. Our work identifies PC-OxPL as a critical pathological factor and a key inducer of TDP-43 pathology in ALS, providing the foundation for a novel therapeutic intervention modality for patients with sALS. Furthermore, it offers the exciting potential to be expanded to diseases characterized by PC-OxPL neurotoxicity.

1425 Immunomodulation Approaches to Improve Safety and Efficiency of Gene Therapy in Friedreich's Ataxia

Kayla Mandolini[1], Denise Cloutier[1], Kirsten Coleman[2], Shelby Sexton[1], Barry Byrne[1], Manuela Corti[3]
[1]University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, [3]University of Florida, Gainesville, Florida

Friedreich's Ataxia (FA) is the most common form of hereditary ataxia. It is caused by an autosomal recessive inheritance of GAA (acidalpha-glucosidase) repeat expansions in the first intron of the Frataxin (FXN) gene, resulting in reduced levels of mitochondrial protein. This mutation leads to accumulated iron and decreased activity of iron-sulfur cluster enzymes necessary for energy production. Deficient Frataxin causes cell dysfunction, leading to eventual cell death in cardiac cells and the central nervous system. FA is a systemic disorder with hallmark features including cardiomyopathy (the primary cause of mortality), gait ataxia and other central nervous system manifestations. FXN gene replacement is a promising therapeutic strategy across disease-relevant tissues, preventing progression or reversing the course of the disease. However, host immune response to the viral vector remains a critical challenge. The goal of this study is to evaluate the safest and most effective immunomodulation (IM) strategies in animals with pre-existing immunity to AAV to enable safe and effective dosing with AAV. In this study, six-week-old C57BL6 mice were pre-immunized with a 25 µg systemic dose of AAV9 empty capsid to induce a 5,000U/mL response. Four weeks after eliciting an immune response, different IM regimens were

administered to reduce humoral and cellular responses to AAV9. Six groups receiving different IM regimens were compared to a no-IM control. The groups comprised of 1) rituximab + rapamycin, 2) rituximab + bortezomib, 3) bortezomib, 4) rituximab + daratumumab, 5) daratumumab and 6) Vyvgart. Rituximab was administered biweekly at an 8mg/kg dose through intraperitoneal (IP) injection, rapamycin daily at 4mg/kg orally, bortezomib twice weekly at a 0.75mg/kg IP dose and daratumumab weekly at a 16mg/kg IP dose. Serum and plasma was collected from bleeds performed before AAV9 empty capsid administration (day 0) and before immunomodulation (day 28). Sera was used to quantify circulating anti-AAV9 Tab through ELISA, and plasma was used for flow cytometry analysis using a panel consisting of anti-CD3, CD19 and CD45 antibodies to quantify B and T cells. At day 70, mice were euthanized and the serum and spleen were collected for quantification of circulating anti-AAV9 TAb through ELISA, and quantification of B and T cells through flow cytometry, respectively. ELISA data shows a significant decrease in circulating anti-AAV9 Tab in groups 1 ($p = 0.0111$), 2 ($p = 0.0006$), and 6 ($p = 0.0260$). These groups had a decrease of at least 60% between IM and endpoint compared to the no-IM group, which showed an average decrease of 20%. Flow cytometry data shows a complete depletion of CD19+ cells in groups receiving rituximab, a B-cell depletor, compared to groups receiving bortezomib, daratumumab or Vyvgart alone and the no-IM control, which showed no change in CD19+ cells between days 28 and 70. This study achieves the reversal of AAV pre-immunity using different IM regimens including the anti-CD20 antibody, rituximab, as seen by a decrease in circulating AAV9 Tab and B cells. This could expand AAV-based gene therapy clinical trial inclusion to FA patients currently non-eligible due to pre-existing immunity. Future efforts will aim to identify the most effective IM regimen that leads to higher FXN expression after a systemic dose of AAV. This phase will follow the same layout as described above, receiving a selected dose of AAV9-Des-Endo7-FXN at day 70.

1426 Intracisternal AAV9-MAG-hABCD1 Vector Reverses Motor Deficits in Adult Adrenomyeloneuropathy Mice.

Yasemin ÖZGÜR GÜNES[1], CATHERINE LE STUNFF[2], Romina Aron-Badin[3], Pierre Bougnères[4]
[1]UMass Chan Medical School, Worcester, MA, [2]INSERM, LE KREMLIN-BICETRE, ILE DE FRANCE, France, [3]Molecular Imaging Research Center, Fontenay Aux Roses, Hauts de Seine, France, [4]THERAPY DESIGN CONSULTING, Paris, Hauts-de-Seine, France

Thousands of male patients who carry *ABCD1* mutations develop adrenomyeloneuropathy (AMN) in mid adulthood, a debilitating axonopathy affecting ascending and descending tracts of the spinal cord. *Abcd1-/-* mice mimic human AMN. In gene therapy experiments using AAV vectors, the choice of the promoter determines which cells will express the therapeutic transgene. Our strategy against AMN was to use the MAG promoter to target oligodendrocytes (OL) in spinal cord, brainstem and cerebellum. We selected OL as target cells because they provide myelin and energetic fuels to the long axons of the ascending and descending tracts. We previously showed that an AAV9-MAG-*hABCD1* vector injected iv to p10 *ABCD1-/-* mice was able to prevent the disease up to 24 mo of age. In the current study, the same vector was injected intracisternally to *Abcd1-/-* mice at 18 mos of age, when about half of these mice start showing motor deficits. As soon as 1-3 mo after vector injection, motor tests evolved differently in treated and untreated mice, so that at 24 mo of age, motor performances deteriorated in 34 untreated mice were near normal in 24 matched treated mice ($p \leq 0.001$). In the white matter of the cervical spinal cord, expression of hALDP coded by the *hABCD1* transgene at 24 mo of age was still present in 22% (18-27) of OL and 22% of astrocytes (A). hALDP expression was also abundant in OL and A in brainstem or cerebellum, less abundant in lower spinal cord, absent from microglia or neurons in DRG or motor cortex. The fact that motor deficits were rapidly stabilized or reversed despite a long course of the disease suggests that the expression of MAG-driven h*ALDP* in OL peroxisomes could durably improve metabolic exchanges with long spinal cord axons. The current results pave a novel OL-targeting way for the AAV gene therapy of AMN myelopathy in its early clinical stages.

1427 Leveraging host cell modulators of adeno-associated vectors transduction across serotypes to detarget liver

Eloise Hudry[1], Katie Kubek-Luck[1], Jason Velazquez[2], Xiaorui Yao[1], Chien-Hsiang (Charles) Hsu[1], Sanjay Arora[3], Lara Bontadelli[4], Yoann Gilbart[5], Joseph Gabriels[1], Jairo Nunes[1], Frederic Sigoillot[1], Jan Weiler[6], Emily Meseck[7], Keith Mansfield[8]
[1]Novartis, Cambridge, MA, [2]Novartis BioMedical Research, Cambridge, [3]Novartis, [4]Novartis Biomedical Research,

Basel, Basel-Stadt, Switzerland, [5]Novartis, Basel, Basel-Stadt, Switzerland, [6]Novartis, Basel, Switzerland, [7]Novartis, East Hanover, New Jersey, [8]Novartis Institutes for BioMedical Research Inc

Recent clinical successes in gene therapy using adeno-associated vectors (AAV) are offering a hopeful path towards the correction of several monogenic disorders. Those achievements fundamentally depend on the efficient delivery of the vector genome and expression of a therapeutic gene into target cells, a complex process that remains incompletely understood. At its core, AAV gene delivery relies on multiple interactions between the capsid and host cell factors, from the initial docking of viral particles onto the cell membrane to the uncoating and viral genome stabilization within the nucleus. Whether different serotypes necessarily hijack the intracellular machinery in a similar manner to transduce a specific cell type and whether those processes are conserved across species for a specific serotype is not known. To identify key host factors either enabling or preventing transduction, whole-genome CRISPR/Cas9 screens were undertaken in mouse (AML12) and human (Huh-7) cell lines using either AAV serotype 2 or 9. While those results certainly confirmed previous reports in identifying key common entry factors such as AAVR or GPR108, our dataset also highlights the potential role of other host cell modulators. Interestingly, while serotype-specific differences were observed for the host cell factors mediating AAV2 or AAV9 transduction in a specific cell line, species-specific divergence was even more striking for each serotype. Leveraging those data, we developed a novel approach to detarget liver transduction by transiently downregulating the expression of key entry factor in this tissue using GalNac-siRNAs prior AAV9 administration. Such manipulation not only blunted hepatic transduction but also re-directed the vector to other transduction-permissive tissues.

1428 Immunocompetent Liver-on-a-Chip Model for Preclinical Evaluation of AAV-Based Gene Therapies

Flavio Bonanini[1], Roelof Dinkelberg[2], Manuel Torregrosa[2], Rumaisha Annida[2], Paul Vulto[2], **Remko van Vught[2]***, Kristin Bircsak[2], Vincent van Duinen[2], Dorota Kurek[2]
[1]MIMETAS B.V, Oegstgeest, Zuid-Holland, Netherlands, [2]MIMETAS B.V, Oegstgeest, Netherlands
Corresponding Author

Gene therapies using recombinant adeno-associated virus (rAAV) vectors require comprehensive preclinical models to assess safety, efficacy, and immunogenicity. Current in vitro systems often lack the complexity to replicate the liver's microenvironment, including vascular structures and innate immune components, critical for accurate toxicological evaluation. The purpose of this study was to develop a scalable, immunocompetent 3D liver sinusoid model in the OrganoPlate(r) Graft platform that enables detailed analyses of rAAV transduction, tropism, and immune response. The OrganoPlate Graft, a 64-chip microfluidic platform in a 384-well plate format, was used to develop a liver-on-a-chip model. The culture chamber was seeded with liver endothelial cells, hepatic stellate cells, and iPSC-derived or primary hepatocytes in a fibrin hydrogel. Gravity-driven perfusion supported vascular bed formation, while monocyte-derived macrophages enabled Kupffer-like cell differentiation. To test AAV tropism, rAAV serotypes with fluorescent reporters were applied at 400K GC/cell for 72 hours, with observations over 8 days. The impact of rAAV9-mCherry was assessed for toxicity (LDH release) and inflammation (IL8 release). Embedding of liver bulk non-parenchymal cells (NPCs) in the hydrogel inside of the OrganoPlate yielded extensive vascular networks visible by VE-Cadherin staining after 10 days. Confocal microscopy confirmed the presence of lumenized microvasculature supported by stellate cells. Tricultures involving hepatocytes, LDECs, and HSCs formed organized liver microstructures after 7 days, with CD31 and LYVE-1 staining indicating vascular development. Proximity between hepatocytes and vascular structures was validated through live Calcein-AM imaging, and hepatocyte polarization was confirmed by MRP-2 staining. Kupffer-like cells were successfully incorporated, maintaining a macrophage phenotype across 11 days, aligning with liver endothelium and distributing uniformly through the Z plane of the culture. TThe vascular networks allowed perfusion, enabling rAAV introduction via simulated bloodstream and assessment of transduction. Differential reporter expression was noted between vascular and direct application. This dual delivery method offers insights into delivery route effects. Serotype screening revealed specific transduction efficiencies, with rAAV9-mCherry showing dose-dependent responses quantified using an ImageJ workflow. Toxicity assays revealed transient LDH release at 72 hours post-exposure to rAAV, which normalized after removal of rAAVs. Notably, IL8 release increased significantly in cultures containing Kupffer-like cells, indicating an immune response enhanced by the presence of immune cells. The data underscored the relevance of including macrophage components to capture immune-mediated effects accurately. The immunocompetent liver-on-a-chip offers a scalable platform for rAAV gene therapy studies,

replicating liver architecture and enabling evaluation of tropism, transduction, and immunogenicity. Macrophage-like cells enhance its ability to simulate immune responses, supporting toxicology and preclinical optimization, thus improving the translation of gene therapies to clinical use.

1429 AAV Gene Therapy for LMNA Associated Laminopathies

Monique Otero[1], Simon Wentworth[2], Olivia Morales[3], McKenna Watson[4], Tyler Mola[5], William Callahan[3], Ananya Uppalapati[3], Ana Rita Batista[3], Miguel Sena-Esteves[3]
[1]UMass Chan Medial School, Worcester, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]UMass Chan Medical School, Worcester, MA, [4]University of Massachusetts Chan Medical School, Worcester, MA, [5]UMass Chan Medical School, Leominster, MA

Background: Laminopathies are a phenotypically diverse group of diseases caused by dominantly inherited mutations in the *LMNA* gene. *LMNA* encodes Lamin A and C, two intermediate filament proteins of the nuclear lamina formed through alternative splicing. Laminopathies are a broad group of 13 identified diseases that present with a range of clinical phenotypes, severity, and age of onset. Our focus is a severe *LMNA*-associated congenital muscular dystrophy (L-CMD). The challenges in developing an effective AAV gene therapy for L-CMD are the need to silence the dominant negative endogenous alleles and the need for balanced expression of both Lamin A/C isoforms from a single vector. To achieve this, we used a "silence and replace" approach with a dual-function AAV that encodes an artificial microRNA (miRNA) to target endogenous *LMNA* for silencing, and a miRNA-resistant *LMNA* transgene that mimics the natural alternative splicing mechanism to generate both Lamin A/C.

Methods: The miRNAs were designed to target homologous sequences in the mouse and human *LMNA* gene and screened in human HEK293T and mouse Neuro2A cells for silencing efficiency. The transgene was made miRNA-resistant through alternative codon usage in the miRNA target seed sequence. The AAV-LMNA-miR^{LMNA} vector is driven by a muscle specific promoter (MCK7), given that skeletal and cardiac muscle are the target tissues for L-CMD. We tested different vector designs, where the miRNA position within the vector genome (intron or 3'UTR) and the scaffold used was varied, as these factors can impact silencing efficacy and transgene splicing. The goal is to identify an AAV vector design with the most potent silencing of endogenous *LMNA* mRNA, and balanced expression of both Lamin A and C.

Results: We identified a top miRNA that silenced *LMNA* by ~50% in both human and mouse cells. We cloned this miRNA into the AAV-LMNA-miR^{LMNA} in different locations in the vector genome and within the context of different miRNA scaffolds. We tested the plasmids in human and mouse cells to measure silencing of the endogenous *LMNA* allele, and expression of Lamin A/C. We identified AAV candidates that overexpressed both Lamin A/C isoforms compared to naïve and silenced the endogenous allele by ~50% in human cells.

Conclusions: We have identified 4 top vector designs that will be packaged into a muscle specific capsid (Myo4A) for testing in the LMNA$^{R249W/R249W}$ mouse model of L-CMD. This model has a severe phenotype with a shortened lifespan (~6 weeks), reduced body weight and muscle weakness allowing for rapid testing of therapeutic efficacy. The top vector will be chosen based on the most potent silencing of endogenous mouse *Lmna* mRNA and expression of Lamin A/C in skeletal and cardiac muscle. Successful outcomes will be significant extension of lifespan and improved phenotype.

1430 Micro-utrophin Redesign Improves Physiological and Metabolomic Outcomes in Dystrophic *mdx^{4cv}* Mice.

Introduction: As the most common lethal genetic muscular disorder of children, Duchenne muscular dystrophy (DMD), is caused by mutations in the 2.2 MB DMD gene. Absence of the dystrophin protein from the dystrophin-glycoprotein complex, leads to myofibers being highly susceptible to contraction injury, leading to progressive rounds of degeneration and regeneration. There is no cure, and DMD patients ultimately succumb to the disease via cardiorespiratory failure. Utrophin (Utr), a dystrophin paralog, has long been suggested to be a potential therapeutic for DMD. We previously demonstrated morphological and functional deficits of a 1st generation μUtr (ΔR4-R21/ΔCT, here defined (μUtr1) to protect from contractile injury and resultant degeneration in the *mdx*^{4cv} mouse model of DMD. The μUtr redesigns included spectrin-like repeat (R) variation, a utrophin-syntrophin binding domain, plus endowing unique dystrophin functionality via neuronal nitric oxide synthase sarcolemma localization.

Method: We evaluated 4 novel micro-utrophins, with the original μUtr1, and micro-dystrophin (μDys5) as controls. Two-week-old *mdx*^{4cv} mice were intravenously administered 5x10^{11} vector genomes of recombinant adeno-associated viral vector (rAAV2/9myo1) harboring human codon-optimized micro-transgene(s), driven by the creatine kinase regulatory cassette (CK8e). At ~8 months of age, lower limb muscles were assayed *in situ* and *in vivo* for protection from contraction-induced injury. After functional testing, animals were sacrificed, and tissues were processed for histology, molecular assays, and metabolomics.

Results: Following rAAV2/9myo1 vector delivery, body-wide striated muscle transduction was revealed by immunofluorescence microscopy. A leading 6-R μUtr variant emerged (μUtr2) based on physiological improvements in resistance to contraction-induced injury and various pathological indices. As evidence, following an *in situ* lengthening-contraction protocol for tibialis anterior, net-injury recovery force yielded 83.34% in wt, 25.94% in *mdx*^{4cv}, and 63.91% in μUtr2 treated *mdx*^{4cv} mice while μUtr1 and μDys5 were 43.39% and 59.87%, respectively. In the contralateral limb we performed *in vivo* (foot pedal) experiments to monitor contractile performance with fatigue, outcomes were similar with μUtr2 showing the most significant improvement. We also performed univariate and pathway analysis of ~200 targeted metabolites. Interestingly, relative to wt, the *mdx*^{4cv} demonstrated 156.97 and 221.14 fold change increase(s) in hippuric acid, for heart and gastrocnemius respectively, which were significantly reversed with either μDys5 or μUtr2 treatment. Tricarboxylic acid (TCA) cycle intermediates were also significantly decreased in *mdx*^{4cv} hearts compared to wt, which were increased in μUtr2 and μDys5 treated *mdx*^{4cv} along with several genes controlling glucose metabolism. Lastly, volcano analysis showed no significant differences in metabolites for μDys5-vs-μUtr2 treated cohorts.

Conclusion: The μUtr2 variant resulted in metabolic and physiological gains towards alleviating symptoms associated with disease progression in the *mdx*^{4cv} mouse model, and may hold promise as a treatment for DMD. Gene delivery of functional utrophin-centric proteins could avoid adverse events that recently occurred in human clinical trials against dystrophin sequences, potentially providing an alternative therapy for some patients not meeting exclusion criteria due to these risks.

1431 Hepatic-Restricted Microdystrophin Expression Induces Immune Tolerance and Enhances Transgene Expression in Dystrophin-Deficient *Mdx* Mice

Objective: This study evaluates the efficacy and immunological response of hepatic-restricted AAV9-LSP-μDys9.2 and non-hepatic AAV9-Des-μDys9.2 microdystrophin vectors in *mdx* mice under immunosuppressive treatment.

Background: Duchenne muscular dystrophy (DMD) is a rare X-linked disorder caused by DMD gene mutations, leading to dystrophin deficiency, muscle damage, weakness, and eventual cardiac and respiratory failure. Gene therapy involving AAV-mediated delivery of microdystrophin shows promise, but is hindered by adverse immune responses to the vector and/or transgene. This study evaluates whether hepatic-restricted microdystrophin expression (AAV-LSP-μDys9.2), combined with immunosuppression (IMS), enhances immune tolerance and therapeutic outcomes in mdx mice. μDys9.2 differs from PF-06939926 and SRP-9001 by including the nNOS binding domain, and from SGT-001 by including R3 and excluding R23.

Materials and Methods: We synthesized a novel microdystrophin construct (µDys9.2) harboring the desmin (Des) promoter and incorporated it into a single-stranded AAV9 plasmid. µDys9.2 is a 3.7-kb transgene containing key domains from full-length dystrophin, including the actin-binding domain 1 (ABD1), hinge 1, and spectrin repeats R1, R3, R16, and R17, with R16 and R17 forming the nNOS binding domain, critical for muscle physiology. We utilized two vectors: LSP-driven (AAV-LSP-µDys9.2) and desmin-driven (AAV-Des-µDys9.2) microdystrophin. To assess the efficacy and immunological response of these vectors, we used five-week-old male *mdx* mice (C57BL/10ScSn-Dmdmdx/J), divided into four groups of five mice each. The IMS regimen involved three weekly pre-doses of anti-CD20 antibody at 10 mg/kg and oral gavaging with sirolimus at 4 mg/kg three days per week, until week 12. Group 1 received the anti-CD20 regimen, followed by AAV-Des-µDys9.2 i.v. administration (1×10^{14} vg/kg) at eight weeks of age, along with continuous sirolimus dosing until week 12. Group 2 received anti-CD20 before administration of the hepatic-restricted vector AAV-LSP-µDys9.2 (2×10^{13} vg/kg) at eight weeks, followed by AAV-Des-µDys9.2 (1×10^{14} vg/kg) at twelve weeks, with ongoing sirolimus dosing. Group 3 received AAV-Des-µDys9.2 (1×10^{14} vg/kg) at eight weeks without IMS. Group 4 served as a control, receiving no vectors or IMS. We assessed microdystrophin protein expression in the heart, skeletal muscles, brain and liver. Immune responses were evaluated through anti-AAV9 ELISA to measure total antibodies in the serum, and flow cytometry was performed to quantify B cells and T cells across the different groups.

Results: Hepatic-restricted µDys9.2 combined with desmin-driven µDys9.2 delivery under IMS (Group 2) showed superior outcomes compared to AAV-Des-µDys9 alone (Group 3) or with IMS (Group 1). Group 2 exhibited a three-fold increase in µDys9.2 expression in the heart, and a two-fold increase in skeletal muscle compared to Group 3. Additionally, it showed a significant decrease in T and B cell populations at day 22, and an increase in Treg activation as measured by FoxP3+CD25+ cells in the spleen and lymphocytes (Figure 1). Cytotoxic and helper T cells were also reduced in this group. IgG antibody formation against AAV9 was reduced by half at day 22 in Group 2 compared to Group 3.

Conclusions: Hepatic-restricted and nonhepatic µDys9.2 delivery, combined with IMS, enhances transgene expression and immune tolerance in *mdx* mice, improving efficacy and safety.

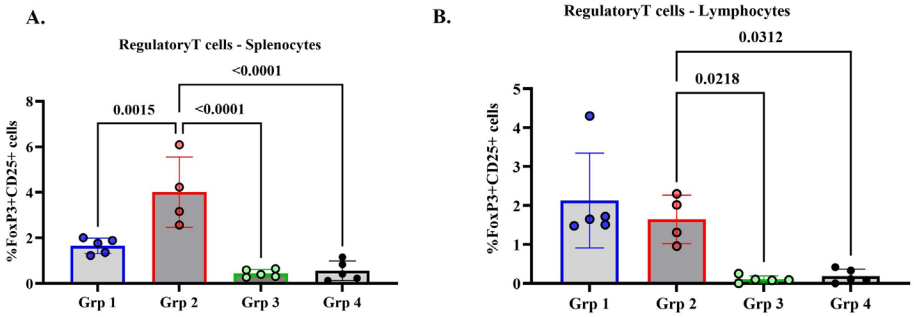

Figure 1: AAV-LSP-µDys9.2 induces systemic tolerance via increased FoxP3+ Tregs. Splenocytes and lymphocytes were stained with anti-CD25–BV421, permeabilized, fixed, and then stained with anti-FoxP3–PE. (A) Percentage of FoxP3+ CD25+ T cells in total splenocytes. (B) Percentage of FoxP3+ CD25+ T cells among lymphocytes isolated from blood. Means and standard error are shown after one-way ANOVA and Tukey's multiple comparison test. p values are shown.

1432 Evaluation of a Novel AAV Capsid with Widespread CNS Biodistribution Following Intra-CSF Dosing in Nonhuman Primates

Adeno-associated viruses (AAV) have emerged as the preferred delivery vector for neurological gene therapy due to their favorable safety profile and longevity of transgene expression in post-mitotic cells. However, clinical translation of AAV-based gene therapies for neurologic disease has been limited due to the inability of naturally occurring AAVs to broadly transduce the central nervous system (CNS). AAV capsid engineering has enabled the generation of AAV variants with enhanced CNS tropism, transduction efficiency and safety versus naturally occurring AAVs. In this study we report the evaluation of novel capsids administered by minimally invasive intra-CSF infusion in non-human primates (NHPs). In a pooled capsid screen, we identified three capsids, AAV.GMU05, AAV.GMU06, and AAV.GMU09, that demonstrated 1-3 log increases in biodistribution across brain regions compared to benchmark capsid AAV9. Notably, this improvement was CNS-specific, as peripheral tissues including liver and spleen did not show increased vector biodistribution compared to AAV9. In an unpooled validation study, AAV.GMU05 showed superior CNS biodistribution and transgene expression compared to AAV.GMU06 and AAV.GMU09. Of note, AAV.GMU05 showed comparatively low vector genomes in circulating blood immediately post-dosing, suggesting that the increased CNS tropism of AAV.GMU05 may arise from reduced peripheral leakage from the CSF. We further evaluated the spatial distribution and identity of AAV.GMU05-transduced cells across cortical and subcortical brain regions. Transgene expression was observed to follow a largely homogenous distribution pattern, and was detected in neurons, astrocytes, oligodendrocytes, and microglia. Collectively, these data support the continued development of novel capsid AAV.GMU05 for neurological indications. The superior CNS targeting of AAV.GMU05 compared to first- and second-generation capsids can enable efficacious therapeutic delivery to affected regions in neurologic diseases with high unmet need.

1433 Intrathecal delivery of INS1202 AAV9-SOD1-shRNA rescues hallmarks of neurodegeneration in a disease model of ALS and targets glia and neurons in the spinal cord and brain of non-human primates

Laura Ferraiuolo[1]*, Gretchen Thomsen[2], Erin Hurley[1], Hana Julazadeh[2], Jannigje Kok[2], Cleide Dos Santos Souza[3], Ashley Fox[4], Ryan Weiss[2], Melissa McAlonis-Downes[5], Robert Cano[2], Binh Chu[2], Angelique Braen[6], Junguo Zhou[7], David Arnold[8], Stephen Kolb[4], Allan Kaspar[2], Brian Kaspar[2]

**Corresponding Author*

INS1202 is an AAV9 shRNA construct targeting human SOD1 that is being evaluated for the potential treatment of amyotrophic lateral sclerosis (ALS). The nonclinical program for INS1202 comprises proof of concept intrathecal route of administration and AAV9 biodistribution in mice and nonhuman primates (NHPs), in-life assessment of muscle function, translational biomarkers and histological evaluation of motor neuron survival and gliosis in the $SOD1^{G93A}$ mouse model of ALS, as well as an ongoing 3-month GLP-toxicology study in NHPs.

Pharmacology: $SOD1^{G93A}$ mice were treated with INS1202 or vehicle via intracerebroventricular (ICV) delivery at postnatal day (p)1 and assessed for disease onset and survival, motor skills and muscle force. Plasma neurofilament levels, a validated predictive biomarker of efficacy, were evaluated at pre-symptomatic and end-stage time points; SOD1 levels, motor neuron numbers and glial activation were analyzed in spinal cords collected at disease end-stage. Treatment with INS1202 in $SOD1^{G93A}$ mice significantly delayed disease onset, as seen by consistent gain and maintenance of body weight throughout the study, compared to the early weight loss seen in mice treated with vehicle control. INS1202 treatment resulted in a significant increase in muscle function in both the rotarod test, which measures motor coordination and endurance, and hind-limb muscle force testing by the *in vivo* Aurora Scientific system. Additionally, $SOD1^{G93A}$ mice treated with INS1202 as compared to those treated with vehicle exhibited significantly reduced levels of plasma neurofilaments, which were similar to levels detected in wildtype mice at both pre-symptomatic (p50) and end stage (p120±10). When vehicle-treated $SOD1^{G93A}$ mice were euthanized at humane end-stage, mice treated with INS1202 were also sacrificed, despite lack of disease symptoms, for histological and protein analyses. INS1202 treatment reduced the levels of both total human SOD1 and misfolded SOD1 by 50-60% in the spinal cord, which resulted in significant rescue of motor neuron numbers, choline acetyltransferase (ChAT) protein expression, ionized calcium-binding adaptor molecule 1 (Iba1) and glial fibrillary acidic protein (GFAP) staining intensity to levels observed in wildtype mice, indicating a complete rescue

of neurodegeneration and glial activation. Taken together, treatment with INS1202 resulted in delayed disease onset, improved muscle function, and amelioration of hallmarks of neurodegeneration in $SOD1^{G93A}$ mice, thus supporting the functional efficacy of INS1202 in a mouse model of ALS.

Pharmacokinetics: Biodistribution studies using ddPCR in both mice and NHPs demonstrated significant vector genome delivery to all segments of the spinal cord, brainstem and motor cortex with limited distribution to other peripheral organs.

Toxicology: A one-month non-GLP toxicology study evaluating in-life parameters, as well as histopathological findings, indicated that INS1202 was generally well tolerated at all doses when administered via intrathecal delivery in NHPs. A 3-month GLP NHP toxicology study is nearing completion to evaluate safety in a larger number of animals, which will provide additional safety and tolerability data.

1434 Assessing the impact of age on AAV9 biodistribution and safety following intravenous administration in infant and juvenile cynomolgus macaques

Pete Clarner[1], Ana Claudia Silva Amaral[1], Ingrid D Pardo[2], Sijia Wu[1], Tom Magee[1], Melanie Abongwa[3], Ting Jiang[1], Samneet Kashyap[1], Xiaodong Lu[1], Jennifer Zoll[1], Misha Chittoda[1], Harini Sampath[1], Shawn Bourque[4], Aditya Utturkar[1], Samantha Desmarais[1], Edward Guilmette[5], Kate Henry[1], Nicholas Gallo[1], Davide Gianni[5], Mukesh Lulla[1], Kelly Bales[1], Samir Koirala[1], Dale Morris[1], Jinkuk Choi[1], Junghae Suh[1]
[1]Biogen, Cambridge, MA, [2]Peabody, MA, [3]Johnson & Johnson, Spring House, Pennsylvania, [4]Cambridge, MA, [5]Biogen, Cambridge, Massachusetts

AAV9 is used for a number of clinical and commercial stage AAV-based gene therapy products, as well as extensively for preclinical research. Previous studies have shown that AAV9 administrated intravenously can cross the blood brain barrier (BBB) and transduce cells in the brain of non-human primates (Bevan, Mol Ther. 2011). Other studies have also indicated there may be an age-related difference in BBB permeability to AAV9 vectors as well as cell tropism differences, with younger age at dosing associated with a higher degree of neuronal transduction (Foust, Nat Biotechnol. 2009). For an internal program, we tested the hypothesis that the BBB is more permissive to AAV9 at infant age. We performed a direct age comparison by administering 1.1E+14 VG/kg of the AAV9 vector intravenously to approximately 3-month-old (N=3, infant) and 10-month-old (N=2, juvenile) cynomolgus macaques. Animals were selected for dosing based on negative or low seropositivity for anti-AAV9 neutralizing antibodies (NAbs). NAbs analysis was also performed on serum from blood collected just before dosing and at necropsy. After a 6-week in-life period, tissues from multiple brain regions of interest, spinal cord, liver, and muscle were harvested for DNA biodistribution and mRNA expression analysis. Brain, spinal cord, dorsal root ganglia (DRGs), and liver tissue sections were processed for histopathology. *In situ* hybridization (ISH) analysis was also performed to determine % neuronal transduction in various brain regions. DNA biodistribution analysis shows no significant differences between the two age groups for any of the tissues analyzed. Liver shows the highest level of exposure, followed by muscle and spinal cord. The lowest levels of DNA biodistribution were observed in the brain regions tested. Similarly, liver shows the highest transgene mRNA expression levels followed by spinal cord. The lowest levels are observed in the brain. Transgene mRNA expression is nominally higher in CNS and muscle tissues of the infant animals compared to the juvenile animals but is not statistically significant. The ISH analysis shows an overall low neuronal transduction in the brain for all animals, with cortical and subcortical regions of interest showing only 1-6% neuronal transduction. Highest % neuronal transduction are seen in the thalamus. No associations were found between % neuronal transduction and age at dosing. These data do not support the hypothesis that the BBB is more permissive to AAV9 in the 3-month-old infant cynomolgus monkeys compared to 10-month-old juvenile animals tested. This suggests that any changes in AAV9 cell tropism, vector biodistribution, and transduction are minimal during the age range tested. Histopathology analysis shows findings in the liver and DRGs in some animals. The liver histopathology findings consist of single hepatocyte necrosis, bile duct hyperplasia/hypertrophy, mononuclear cell infiltrate within portal areas, and increased cellularity within sinusoids. Interestingly, juveniles were more prone to develop liver lesions, compared to infants, based on severity and incidence of liver findings. In the sacral DRG, there is minimal and focal neuronal necrosis and focal to multifocal mononuclear cell infiltrate in one juvenile and one infant. The incidence and severity of liver findings are higher in

juvenile NHPs compared to those observed in infants. There are no AAV9-related histopathology findings in the brain or spinal cord.

1435 CAP-003, a CNS-Targeted IV-delivered AAV Gene Therapy, Safely Increases Brain GCase in NHPs to Level Supporting Potential Normalization of Activity in PD-GBA Patients

Kimberly McDowell[1], Reed Ressler[1], Brandon Wheeler[2], Lubov Grigoryeva[1], Alexander Armendariz[1], Maeve Flynn[1], Hari Acharya[1], Paul Denis[1], Jesse Granados[1], Pavel Tchourilov[3], Carrie Pedeferri[1], Melanie Brandabur[4], Swati Tole[2], Nicholas Goeden[5], Nicholas Flytzanis[1]*

Parkinson's disease (PD) is the second most common neurodegenerative disorder in the United States with no approved disease modifying treatments to date. *GBA1* gene mutations are the most significant risk factor for PD, with current evidence suggesting up to 15% of PD patients may carry mutations. *GBA1* encodes a lysosomal hydrolase enzyme, glucocerebrosidase (GCase), the reduced levels or aberrant function of which is associated with accumulation of alpha synuclein, loss of nigrostriatal dopaminergic neurons and development and spread of aggregated protein inclusions known as Lewy bodies, the pathological hallmarks of PD. CAP-003 is a next-generation gene therapy candidate, comprised of a novel capsid engineered through use of directed evolution and *hGBA1* cargo, that was developed for administration as a single intravenous (IV) infusion to Parkinson's disease patients with *GBA1* mutations (PD-GBA). The CNS-targeting and liver/DRG de-targeting profile of CAP-003 offers the potential to safely and stably supplement wild-type GCase protein throughout the brain, enabling long-term disease modification that could slow or stop the progression of PD-GBA with limited treatment burden.

In a mouse model that exhibits both reduced GCase activity and overexpression of alpha-synuclein in the brain, systemic AAV administration with *hGBA1* cargo resulted in significant and dose-dependent increases in brain GCase protein and activity. This restoration of GCase activity also resulted in significant and dose-dependent decreases in glucosylsphingosine (GluSph), a key GCase substrate shown to contribute to alpha-synuclein pathology. In non-human primates (NHPs), systemic administration of CAP-003 resulted in widespread neuronal transduction of disease relevant brain regions, including the substantia nigra, caudate, and putamen. These levels of transduction show marked improvement over wildtype AAV serotypes and resulted in significantly increased GCase activity that is expected to normalize GCase activity in the PD-GBA patient population. Analysis of clinically relevant biomarkers in treated NHPs showed increases in GCase protein and activity and reductions in GluSph levels. CAP-003 was found to be well tolerated, de-targeted from the liver and DRGs, and lacking adverse clinical pathology, immunogenicity or histopathology findings associated with higher-dose systemic gene therapies. In addition, a novel human receptor for CAP-003 was identified with complete homology between humans and macaques in the predicted binding pocket, thus supporting clinical translatability of CAP-003 performance from NHP to humans. Targeting a 1H 2025 IND filing, CAP-003 is being advanced with the goal of achieving disease modifying clinical benefit for patients with PD-GBA through a convenient single dose intravenous administration.

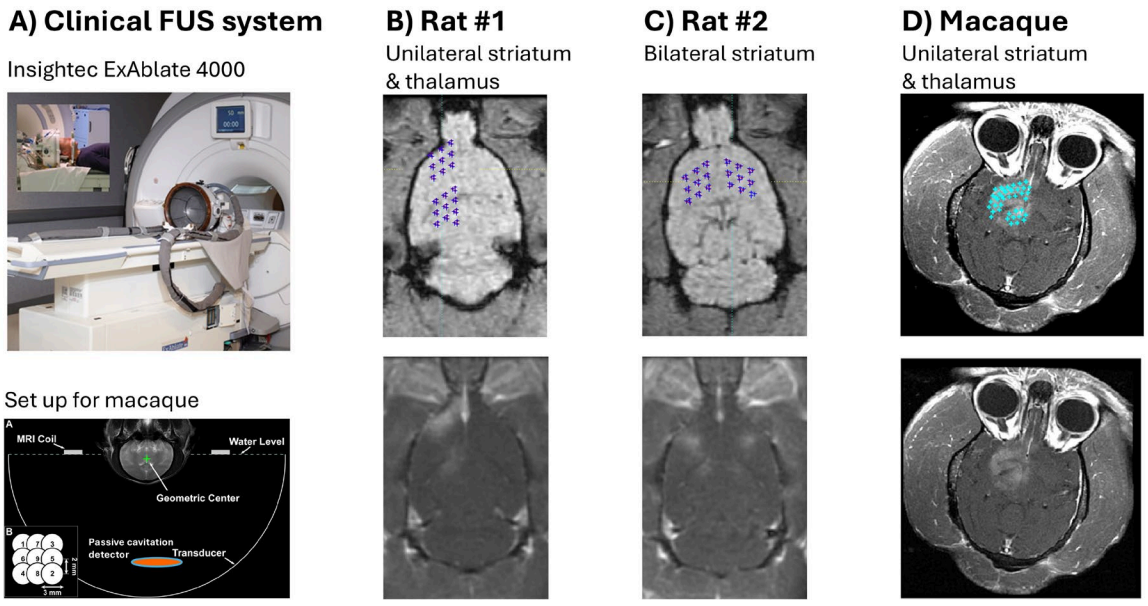
1436 Focused ultrasound-mediated delivery of a novel engineered AAV capsid to the rat and non-human primate brain using a human clinical FUS system

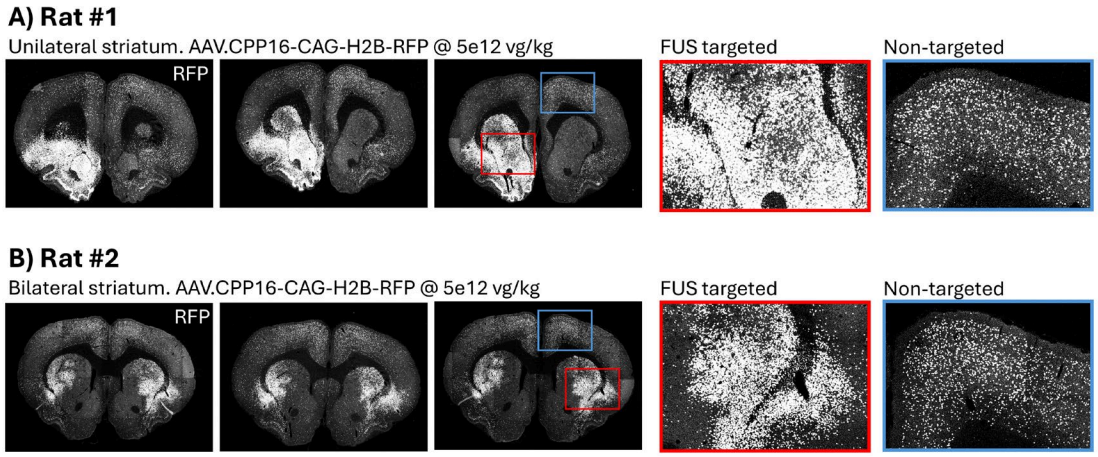
Nick Todd[1], Paige Nowlin[2], Zhenghui Li[1], Yongzhi Zhang[3], Stecia-Marie Fletcher[1], Bernie Owusu-Yaw[3], Margaret Livingstone[4], Nathan McDannold[1], Fengfeng Bei[5]
[1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital & Harvard Medical School, Boston, MA, [4]Harvard Medical School, Boston, MA, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background: We have previously presented our work at ASGCT showing significantly improved gene therapy delivery to the mouse brain using a genetically engineered adeno-associated virus (AAV) combined with the technology of focused ultrasound (FUS)-mediated disruption of the blood-brain barrier (BBB). The AAV capsid, AAV.CPP16, was engineered for BBB penetrance by inserting a cell penetrating peptide into the receptor-binding domain of the AAV9 capsid. FUS is applied in combination with systemically injected microbubbles to exert mechanical forces on vessel walls that act to increase BBB permeability. Under this approach, we achieved >70% neuronal transduction in FUS-targeted brain regions at a systemic AAV dose of 2e12 vg/kg in mice, 55x lower than the dose for the FDA-approved AAV9 based Zolgensma. The goal now is to validate this FUS + AAV.CPP16 approach in larger animals under a clinically feasible treatment paradigm. Translation challenges include focusing through a thicker skull, electronic beam steering to open the BBB over a larger volume, real-time feedback control based on passive cavitation detection, and regulatory limits on microbubble dose. Here we use a human clinical FUS system for BBB disruption and delivery of AAV.CPP16 in two rats and one macaque non-human primate.

Methods: Two Sprague-Dawley rats (280 g, 258 g) and one macaque non-human primate (10.9 kg) were treated on the Insightec ExAblate 220 kHz FUS system. FUS targeting was done based on MRI imaging and designed to target unilateral or bilateral deep brain structures. 10 ms FUS sonication bursts were applied at 1 Hz repetition frequency over 120 seconds. The FUS focus was electronically steered over up to 32 target locations per sonication set. The FUS intensity was adjusted for each target separately under real-time feedback control based on the strength of the first harmonic signal and an empirically determined goal. After FUS treatment, susceptibility-weighted MRI images were acquired to look for signs of hemorrhage and T1-FSE images were acquired pre- and post-injection of gadolinium to assess BBB opening. AAV.CPP16 with a CAG promoter and H2B for nuclear localization of an RFP reporter gene was injected IV at a dose of 5e12 vg/kg. Rats were sacrificed at three weeks post-treatment for histology; the macaque was just treated and will be sacrificed at three weeks post-treatment for histology.

Results: Figure 1A shows the MRI-compatible clinical FUS system used in this study. Figures 1B – D show the sonication targets and the post-treatment contrast MRI images for the two rats and one macaque. In Rat #1, the right striatum and thalamus were targeted; in Rat #2, bilateral striatum was targeted; in the macaque, the right striatum and thalamus were targeted. BBB opening based on contrast MRI was observed in all three cases, without signs of hemorrhage (not shown). The BBB opening in the rats was more anterior than intended. Figure 2 shows fluorescent imaging of three brain sections for Rat #1 and Rat #2. The nuclear-targeted RFP signal is shown in white. Zoomed in regions show examples of the FUS-targeted striatum and non-targeted cortex. At this low dose, the AAV.CPP16 capsid still shows strong transduction in non FUS-targeted regions. In FUS-targeted areas, the transduction is particularly strong. Next immediate steps will be to perform histology on the recently treated macaque and quantify transduction efficiency in terms of percent neurons transdu





1437 Parkin Gene Therapy for Parkinson's Disease

Marshall Goodwin[1], Elizabeth Higgins[2], Jennifer Johnston, Christina Gamba-Vitalo[3], Ronald Mandel[4], Amy Poirier[5]
[1]Nysnobio, Gainesville, FL, [2]Nysnobio, Mill Valley, CA, [3]ClearPoint Neuro, Inc., Solana Beach, CA, [4]University of Florida College of Medicine, Gainesville, FL, [5]University of Florida, Gainesville, FL

Disease-modifying therapies for Parkinson's Disease (PD) are desperately needed. PD patients with a validated genetic cause offer promise for application of precision medicine therapeutics directly targeting the genetic defect. Autosomal recessive PD caused by biallelic loss of the Parkin gene (Parkin-PD) is 100% penetrant and strikes patients as early as the teenage years, yielding life-long disability impacting employment and family-life. NysnoBio is advancing NB001, a recombinant adeno-associated virus (rAAV) gene therapy designed to deliver a functional Parkin gene directly to the substantia nigra of Parkin-PD patients, restoring the missing protein that caused the disease. We have completed nonclinical studies assessing NB001 in human patient fibroblasts, Parkin knock-out (pKO) rats, and non-human primates (NHP). Human patient fibroblasts were used to determine the level of NB001-mediated Parkin expression required to restore Parkin enzymatic activity in cells obtained from Parkin-PD patients. Intra-nigral injection of NB001 in pKO rats revealed the minimum dose required to restore Parkin expression in the substantia nigra to wild-type levels and significantly increase Parkin enzymatic activity. We have also completed non-GLP studies in NHPs to assess biodistribution, target area coverage, and safety following MRI-guided, convection-enhanced delivery of NB001 directly into the substantia nigra. Intra-parenchymal injection of an allometrically scaled dose resulted in NB001 biodistribution that was largely confined to the brain with minimal peripheral exposure. The dose levels tested achieved supraphysiological Parkin expression in the primate substantia nigra that was safe and well tolerated for the entire length of both the 6-week and 12-week studies. The completed nonclinical studies successfully identified the doses, drug delivery devices, and methods for the upcoming GLP-compliant toxicology study. Taken together, these results provide strong rationale for the future clinical translation of NB001 to treat Parkin-PD patients.

1438 Direct Administration of AAV2-Derived Vector Library to the Putamen of Non-Human Primates Identifies Capsid Variants with Enhanced Retrograde Transport Properties

Yulia Dzhashiashvili[1], Jodi McBride[1], Emily Fabyanic[1], Xin Huang[1], Brian Kelly[1], Greglynn Gibbs[2], Zhenming Yu[1], Pichai Raman[3], Elizabeth Ramsburg[1], Marcus Davidsson[4], Tomas Björklund[5], Esteban Engel[1]
[1]Spark Therapeutics, Philadelphia, PA, [2]Spark Therapepeutics, Reading, PA, [3]Bryn Mawr, PA, [4]Lund University, SWEDEN, [5]Lund University, Lund, Sweden

Adeno-associated virus (AAV) has become a leading vector for gene therapy in the central nervous system due to its ability to transduce brain cells, including mature differentiated neurons, efficiently, durably, and safely. Direct AAV

injection into the brain parenchyma bypasses the blood brain barrier, minimizes transgene expression and immune response in the periphery and results in high neuronal transduction rates at doses that are substantially lower than those required for an intravenous injection. Previous studies reported that AAV2-derived capsids developed using the BRAVE (Barcoded Rational AAV Vector Evolution) approach have enhanced retrograde transport properties in the rodent brain, compared to the parental AAV2 capsid. Retrograde transport enables coverage of connected brain regions after a single focal injection and is therefore a powerful tool for delivery of vectors to distant sites with potentially higher specificity, transduction efficacy and safety. Because transport properties can vary among species, we further characterized a barcoded library of 25 BRAVE-derived AAV2 capsid variants in brains of adult cynomolgus monkeys after intra-putaminal dosing to determine whether these novel capsids retained their properties. Based on RNA and DNA amplicon sequencing, single-nucleus RNA sequencing, and histological assessment, we report here capsid variants with enhanced retrograde transport and biodistribution in the non-human primate brain, which makes them potentially relevant for indications that warrant broader brain coverage beyond the injection site.

1439 Translational Considerations When Comparing Brain Structures in Humans, Cynomolgus Macaques and Adolescent Baboons: Implications for Anatomical Targeting and Drug Delivery

Geary Smith[1], Stephanie Korszen[1], Cassandra Tang-Wing[2], Rachel Lortz[3], Zachary Carr[1], Jeremy Stigall[4], Ernesto Salegio, Vincenzo Roncace[3]
[1]ClearPoint Neuro, Inc., Solana Beach, CA, [2]ClearPoint Neuro, Solana Beach, CA, [3]ClearPoint Neuro, Inc., San Diego, CA, [4]ClearPoint Neuro, Inc., Solana Beach, California

When developing novel therapeutics for the treatment of neurological disorders, *in vivo* animal studies are essential to assess safety and efficacy before advancing to human clinical trials. Nonhuman primates (NHPs) are the primary models for such studies, with cynomolgus macaques and rhesus macaques being the most commonly used species. However, limitations on the importation and availability of rhesus macaques have led to increased use of cynomolgus macaques, including those as small as 2 kilograms in body weight. These smaller cynomolgus macaques have considerably smaller brains than those of humans, which poses challenges for dose scaling studies and estimations of drug volumes deliverable into brain structures. Using magnetic resonance imaging (MRI), the work herein provides data on the volumetric differences between the brains of cynomolgus macaques and humans. Additionally, it explores the potential of adolescent baboons as an alternative NHP model that addresses the availability issues affecting rhesus and cynomolgus macaques. Several anatomical brain regions were examined including the putamen, thalamus, caudate, substantia nigra, dentate nucleus, and the lateral ventricles. Our findings demonstrate that adolescent baboons offer a closer weight-to-brain size match to humans compared to macaques. This similarity enhances the translatability of surgical and therapeutic interventions, while volumetric data show that the brain structures of adolescent baboons are more comparable to those of humans, which is crucial for accurate dose scaling and effective drug delivery. While cynomolgus macaques remain valuable for neurological research, adolescent baboons present significant advantages in anatomical comparability and practical application for clinical translation of novel therapeutics delivered to the brain. This study supports the consideration of adolescent baboons as a viable alternative model for preclinical neurological studies, which could lead to more accurate and effective therapeutic development.

1440 Potent and Specific AAV9-miRNA Candidates Demonstrate Robust Reduction of Microtubule-associated Protein Tau (*MAPT*) in Non-Human Primates

Veda Tatavarty[1], Chao Tai[1], Szu-Ying Chen[2], Ron Chen[1], Alex Diaz de Arce[2], Peter Bove[1], Kristen Valentine[1], Rangoli Aeran[1], Pingping Jia[1], Sawyer Randles[2], Katarina Maier[2], Jason Le[1], Keith Place[2], Ben Zhao[2], Puja Dhanota[1], Serena Liu[1], Sammy Liang[1], Keiko Takahashi[3], Mark Elegue[2], Elizabeth Hallam[1], Saki Shimizu, Nathan Moerke[1], Myat Soe[1], Warren Macdonald[2], Ricky Thu[2], Juan Reza[1], Sirika Pillay[1], Winnie Lin[3], Annie Tanenhaus[1], Raghavendra Hosur[1], Archana Belle[3], Suresh Poda[2], Stephanie Tagliatela[2]
[1]Encoded Therapeutics, South San Francisco, CA, [2]Encoded Therapeutics, South San Francisco, [3]Encoded Therapeutics, South San Francisco, California

Tauopathies, including Alzheimer's disease (AD) and frontotemporal dementia (FTD), are characterized by abnormal Tau protein accumulation, which disrupts neuronal function and contributes to disease progression. Variants in microtubule-associated protein Tau (*MAPT*), the gene encoding Tau, are directly implicated in tauopathies. Tau reduction has emerged as a promising therapeutic strategy for slowing the progression of cognitive decline and is in clinical trials for AD and other Tauopathies. Leveraging Encoded's vector engineering platform, we explored the use of adeno-associated virus 9 (AAV9)-mediated microRNA (miRNA) delivery to knock down *MAPT* expression with a durable, potential one-time therapy. Here, we present the optimization and validation of miRNA candidates to reduce Tau in non-human primates (NHPs). We computationally designed over 7,000 miRNA candidates targeting *MAPT*. Top candidates were selected for further evaluation based on cross-species homology, predicted specificity, and stability. Top miRNAs were evaluated in vitro using human iPSC-derived neurons and in vivo in mice and NHPs. NHPs received a single intracerebroventricular (ICV) injection of AAV9-vectorized miRNA candidates, and *MAPT* knockdown was evaluated via transcript and protein quantification across multiple brain regions. In vitro miRNA screening identified various candidates that achieved up to 96% *MAPT* knockdown in human iPSC-derived GABAergic neurons. The top 4 candidates in vitro were administered to wild-type (WT) mice at postnatal day 1 (PND1) and demonstrated significant, dose-dependent *MAPT* knockdown —achieving over 50% reduction in both transcript and protein levels —with minimal off-target effects, as confirmed by RNA sequencing (RNAseq). In NHPs, a single ICV administration of 3 lead AAV9-miRNA candidates achieved robust *MAPT* reduction across multiple disease-relevant brain regions, with transcript levels decreasing by up to 34% in the cortex and 32% in the hippocampus. These findings provide the first evidence of AAV9-mediated Tau knockdown across large regions of the NHP brain. This study highlights the potential of Encoded's vector engineering platform to develop potent, specific, and durable miRNA-based therapies for central nervous system (CNS) disorders. Robust *MAPT* knockdown achieved broadly in the NHP brain underscores the translational promise of this approach for treating tauopathies such as AD and FTD.

1441 Alternate Reporter Genes for Safe & Durable CNS Delivery of AAV Vectors in Non-Human Primates

Fluorescent reporter genes are a valuable tool for analyzing adeno-associated virus (AAV) capsid transduction *in vivo*; however, they can result in toxicities that lead to undesired in-life takedown timepoints and potentially underrepresent capsid capabilities. Toxicities are most notable when fluorescent reporter genes, such as green fluorescence protein (GFP), are delivered to the central nervous system (CNS). A head-to-head comparison of a fluorescent reporter gene to novel, less toxic reporter genes is a clear gap within the field. Identification of less toxic reporter genes for the evaluation of AAV and other modalities in CNS would allow full characterization of emerging therapies *in vivo* while maximizing animal use.

This study compares three reporter genes, enhanced green fluorescent protein (EGFP), cynomolgus macaque sodium iodide symporter (CynoNIS), and human alpha galactosidase (hAGA) delivered by a proprietary AAV capsid to cynomolgus monkeys via the intracisternal magna (ICM) route of administration at a single dose. An empty capsid and vehicle arm were included as controls. Animals (n=3 per treatment group) were monitored for 56 days, followed by necropsy and tissue harvesting and processing. Toxicity was measured by clinical observations, clinical and histopathology, anti-drug antibody responses, and cerebrospinal fluid cytokine and biomarker profiling. DNA and RNA were assessed by digital droplet PCR and *in situ* hybridization, and protein was assayed by ELISA and immunofluorescence.

All animals in the EGFP cohort showed neurological toxicities on day 11, were found moribund on day 12 and euthanized. Animals in the other cohorts, CynoNIS, hAGA, and controls exhibited no lasting clinical observations of note, and survived to the scheduled end point of 56 days. This study identifies NIS and AGA as safe and durable reporter gene options to use in the CNS to assess transduction of AAV and support product development.

1442 Rationally designed chimeric AAV capsids demonstrate reduced liver tropism and enhanced muscle transduction in both rodents and non-human primates

Tiffany Pan[1], Irene Song[2], **Amos Gutnick[3]**
[1]PackGene Biotech INC, Houston, TX, [2]Packgene Biotech, Houston, TX, [3]PackGene Biotech INC, Brookline, MA

Recombinant adeno-associated viral (rAAV) vectors have emerged as essential tools for gene delivery in therapeutic applications. However, their clinical efficacy is often hindered by insufficient tissue-specific transduction and undesirable off-target effects, particularly liver toxicity. To address these issues, we developed a two-step AAV capsid engineering strategy aimed at reducing liver tropism and enhancing target-specific transduction.

Initially, we engineered AAV2 by loop swapping with AAV9, yielding three novel capsid variants: AAV.Zero1, AAV.Zero2, and AAV.Zero3. Among them, AAV.Zero1 and AAV.Zero3 exhibited a significant reduction in liver transduction while maintaining a low transduction background in various rodent tissues. Building on AAV.Zero3, we further optimized muscle tropism by inserting an RGD-containing peptide, creating PG007, a capsid with enhanced muscle-specific targeting in both rodents and non-human primates.

To evaluate PG007's therapeutic potential, we compared its performance to AAV9, which is under clinical investigation for Duchenne muscular dystrophy (DMD). Systemic administration of a micro-dystrophin gene (2E+13 vg/kg) in dystrophin-deficient (DMD-KO) mice showed that PG007 significantly improved muscle strength, reduced CK and AST levels, and lowered liver and muscle damage compared to AAV9. PG007-treated mice also exhibited broader micro-dystrophin expression in muscles and lower off-target transduction in the liver and kidney.

Immunofluorescence confirmed enhanced dystrophin restoration in skeletal and cardiac muscles of PG007-treated mice. Over a 10-month period, PG007 increased survival rates significantly compared to both AAV9 and vehicle-treated controls.

Our study underscores PG007's therapeutic efficacy and its potential as a next-generation capsid for muscle-targeted gene therapy. Additionally, AAV.Zero1 and AAV.Zero3 serve as versatile backbones for tissue-specific targeting. The π-Icosa serotype screening platform provides a robust pipeline for the rapid development of optimized AAV vectors across various tissues and species, accelerating human gene therapy advancements.

1443 A Comparative Study of Full Adeno-Associated Virus 8 (AAV) Capsid Enrichment Platforms

Shaofeng Wang[1], Jack Ren[2], Mukesh Mayani[3], Patrick Hossler[1], James Warren[4]
[1]Ultragenyx Pharmaceutical Inc., Woburn, MA, [2]Ultragenyx Inc, Woburn, MA, [3]Ultragenyx Pharmaceuticals, Woburn, MA, [4]Ultragenyx, Novato, CA

Introduction: The production of therapeutic AAV vectors typically results in a mixture of full, partially full (partial), and empty capsids, with the latter two forms potentially reducing product efficacy and posing safety risks to patients. Minimizing these unwanted species remains a key challenge in AAV-based gene therapy production. Ultragenyx is a gene therapy company with both early- and late-stage assets, spanning various serotypes, administration routes, and target tissues/organs. With over a decade of research in AAV purification, we have evaluated the strengths and limitations of various capsid enrichment technologies including Anion Exchange Chromatography (AEX), iodixanol-based step density gradient ultracentrifugation (IDXUC), and CsCl-based density gradient equilibration (DGEUC). This work will further explore these insights using AAV8 vectors designed for the treatment of a rare genetic disorder.

Methods: The AAV8 affinity pool material was generated in-house and processed through AEX chromatography, IDXUC, and DGEUC, respectively (**Figure 1**). Buffer exchange was performed four times against formulation buffer using a spin column with a 100 kDa cutoff for the AEX eluate, IDXUC harvest, and CsCl DGEUC harvest. Genomic copies (GC) of the gene of interest (GOI) in the load and the three processed harvests were quantified

using quantitative PCR. Full, partial, and empty AAV species were assessed by analytical ultracentrifugation (AUC). The relative potency of the AAV vectors was determined through a cell-based assay by measuring the expression of the protein encoded by GOI using a fluorescence-labeled specific antibody.

Results: Quantitative PCR analysis in this study revealed comparable GC recovery across all three platforms, with recovery rates ranging from 40% to 50%. DGEUC achieved the highest percentage of full AAV in the harvest (96 - 99%), followed by IDXUC (55 - 65%), and AEX Chromatography (25-32%). The relative potency of harvests from the three platforms were normalized to a reference standard sample by comparing protein expression levels in cells. DGEUC showed a relative potency of 175%, IDXUC exhibited 160%, and AEX demonstrated 87%, respectively (**Figure 2**).

Conclusions: In this study, AEX, IDXUC, and DGEUC demonstrated comparable GC recoveries. The IDXUC and DGEUC showed a better capability in separating empty, partial, and full AAV8 capsids. The observed differences in relative potency are likely attributed to the distinct empty-partial-full profiles of AAV vectors produced by each separation method. Since these platforms rely on different principles for AAV species separation, they may recover varying populations of AAV vectors, which in turn impacts the relative potency of the final harvests.

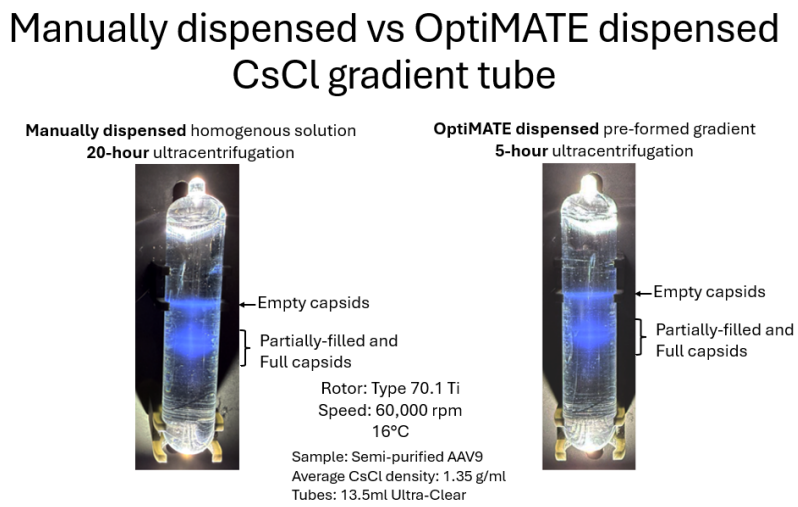
1444 Ensure Accurate Density Gradients Through a Novel Automation Platform – the OptiMATE Gradient Maker

Balasubramanian Venkatakrishnan[1], Aparna Jasti[1], Amy Henrickson[2], Shawn Sternisha[3]
[1]Beckman Coulter Life Sciences, Bengaluru, Karnataka, India, [2]Beckman Coulter Life Sciences, Indianapolis, IN, [3]Beckman Coulter Life Sciences, Miami, FL

Density gradient ultracentrifugation (DGUC) allows for high-quality separation of empty, partial, and filled Adeno-Associated Virus (AAV) capsids. While DGUC protocols are effective across serotypes and engineered variants of AAV, filling the tubes can be labor-intensive and user-dependent, while the centrifuge run time can be lengthy (>16 hours for self-forming cesium chloride (CsCl) density gradients). The OptiMATE Gradient Maker* from Beckman Coulter Life Sciences allows for automated dispensing of easy-to-program density gradients (step, linear, or a combination of both). It is compatible with a variety of gradient forming materials, rotors and tube types. The OptiMATE Gradient Maker also provides automated sealing of Quick-Seal tubes. This significantly minimizes labor and variability without compromising purification efficiency. Furthermore, the OptiMATE Gradient Maker can dispense accurate linear gradients with AAV sample incorporation. By dispensing a pre-formed gradient with AAV, CsCl separations can now be completed in 5 hours or less (a run-time reduction of 70% or more compared to current protocols). Overall, the OptiMATE Gradient Maker provides plug-and-play operation to generate ultracentrifuge-ready tubes, making high purity AAV purification simpler and more accessible.

*Product in development. Performance characteristics have not been validated.



1445 Large-scale purification of highly effective recombinant adeno-associated virus with a zonal ultracentrifugation

**Corresponding Author*

Background: Recombinant adeno-associated viruses (rAAV) are powerful tools for gene therapy. However, systemic high-dose injections of rAAV have caused severe adverse events (SAEs), including acute liver and kidney injury, cardiopulmonary insufficiency, and death. To decrease these risk, empty and incomplete genome rAAV should be removed as much as possible by purification, and input samples should include as many full capsids as possible. We developed a method to purify rAAV in a short time (4 hours), on a large scale (900 mL), and with high purity (>90% full capsids) by using zonal ultracentrifugation with cesium chloride (CsCl). To increase the ratio of full/empty capsids and decrease the capsids containing, only incomplete genomes or plasmid backbones (including drug resistant gene), we also developed a gene of interest (GOI) plasmid for rAAV that includes a stuffer sequence. The size of the backbone including stuffer sequence is over the limit size for packaging of rAAV (4.7 kb).

Methods: The rAAV-ZsGreen1 was harvested from culture supernatant without cell lysis 3 to 10 days after plasmid transfection. Large-volume rAAV-containing culture media (up to 900 mL) and escalating densities (2 or 4 steps) of CsCl solutions were sequentially added to the zonal rotor. Following large-scale density-gradient ultracentrifugation, the samples were automatically fractionated. The samples were then evaluated for rAAV genome copies by quantitative PCR, for rAAV capsid protein amounts by western blotting, and for ZsGreen1 transduction efficiency by flow cytometry. The ratio of full/empty capsids was measured by mass photometry, analytical ultracentrifugation (AUC), and transmission electron microscopy (TEM) with phosphotungstic acid stain. The genomic DNA regions packaged in rAAV particles were detected by digital PCR (dPCR) using primers and probes targeting the whole vector genome.

Results: We improved 2-step CsCl density-gradient ultracentrifugation with a zonal rotor, allowing for a large volume (900 mL) of rAAV purification as well as a shorter (4 hours) ultracentrifugation with a steeper density-gradient in the range of the rAAV fractions, as compared to the conventional method of 4-step density-gradient (300 mL) for 10 hours. High-purity separation of full and empty fractions was demonstrated with genome, capsids, and biological titrations. These full and empty fractions were also analyzed by mass photometry, AUC, and TEM, demonstrating a high rate (>90%) of full capsids that could be separated with our upgraded method. The full rAAV ratio produced by transfection with plasmids including stuffer sequences increased compared to the one with conventional plasmids. In rAAV produced with stuffer plasmids, the mispackaging ratio of the backbone sequence of plasmid, including the drug-resistant gene, decreased, indicating that the risk of rAAV toxicity was reduced.

Conclusion: We upgraded a 2-step density-gradient ultracentrifugation method with a zonal rotor to 4 hours, allowing for the large-scale purification of functional full-genome rAAV. We also improved the plasmids, including stuffer sequences to increase the ratio of full capsids. Our large-scale rAAV purification method would apply to in vivo experimentation and clinical investigation. Furthermore, we designed a safety cabinet for zonal ultracentrifugation, a seamless multiple-closed bag to produce viral vectors, and plan to prepare cleaning validation and documentation.

1446 Development of a Full Capsid Enrichment Polishing Step in AAV8 Purification Process With CIMmultus® PrimaT® Monolithic Column

Franck Gaston[1], Ricardo Rojas Gonzalez[1], Duncan Dulac[1], Cyril Luc[1], Gabriel Livet[1], Laurence Lerondeau[1], Romain Fragnoud[1], GREGORY ROUBY[2], Patrick Santambien[3], ESTHER ATTEBI[4]
[1]GENETHON, Evry, Essonne, France, [2]GENETHON - EVRY, EVRY, France, [3]Généthon, Evry, France, [4]GENETHON, EVRY COURCOURONNES, FRANCE, France

Gene therapies treatments based on AAV vectors are promising for rare diseases. However, while producing AAV vectors for these gene therapies, empty capsids are also produced in a certain amount. Clinical effect of empty capsids is unclear. Empty capsids are not the intended therapeutic product and could include a toxicological effect. Thus, process development teams need to reduce their presence. This objective could be achieved by designing new capsids and transgenes, by changing cell culture conditions or by implementing a polishing step on current purification process. The latter approach is evaluated using the CIMmultus® PrimaT® monolithic column developed by Sartorius. Parameters including viral loading, residence time, conductivity of loading and elution are investigated. Based on the generated data, optimal conditions are determined to enrich the product in full capsids while maintained an acceptable viral genome yield. These conditions are subsequently applied up to 200 L scale. Results obtained confirm the performance, repeatability, and scalability of CIMmultus® PrimaT® monolithic column to remove empty capsids and some product-related impurities.

GENETHON CURE THROUGH INNOVATION

Background and Objectives

Gene therapy treatments are promising for treating rare genetic diseases, particularly at Genethon, with a focus on muscular dystrophies and metabolic disorders. However, during the production of AAV vectors for these therapies, a certain amount of empty capsids is also generated, and their clinical impact remains unclear. CIMmultus® PrimaT monolithic column was evaluated for its ability to enrich the product in full capsids. Key parameters such as viral loading, residence time, and loading/elution conductivity were tested on an AAV8 product. Optimal conditions for full capsid enrichment and viral genome recovery were identified and successfully scaled up to 200L.

1. Introduction - CIMmultus® PrimaT monolithic column technology

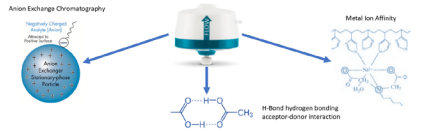

Fig. 1: CIMmultus® PrimaT technology overview.

CIMmultus® PrimaT is a mixed-mode monolithic column based on anion exchange, hydrogen bonding interactions, and metal ion affinity. It uses the physical differences between full and empty capsids to separate the two populations.

2. Method

The AAV8 polishing step was developed using a 1 mL PrimaT column on an AKTA pure 150 system. The product, previously clarified and purified by an affinity chromatography, was diluted X-fold before achieving low conductivity to ensure optimal capsid binding. Elution was performed using a conductivity gradient with a divalent salt. The resulting profile is as follows:

A first peak is obtained, containing primarily full capsids, followed by a second peak with mainly empty capsids and other contaminants. To optimize this separation, various elution volumes, residence times, dilutions, and loadings were tested.

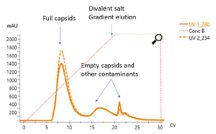

Fig. 2: Chromatogram profile of the PrimaT monolith

The viral genome yield is measured by qPCR and HPLC, while the ratio of full capsids is determined using HPLC (SEC-MALS) and AUC.

3.1 Results - Impact of viral loading

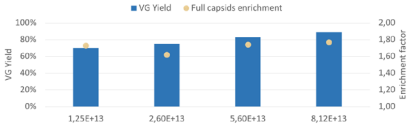

Fig. 3: Viral loading (VG/mL of monolith) evaluated on a 1 mL PrimaT

All viral loadings resulted in similar viral genome (VG) yields, ranging from 70% to 89%, and full capsid enrichment, ranging from 1.62 to 1.77. The selected loading corresponds to a 400L AAV8 production on an 80mL PrimaT monolith.

3.2 Impact of elution volume

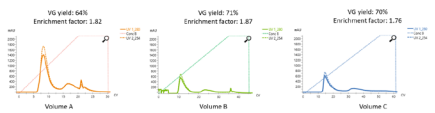

Fig. 4: Chromatography profiles obtained on a 1 mL PrimaT with different elution volumes

Increasing the elution volume further separates the different populations; however, there is no improvement in either the viral genome yield or the enrichment factor.

3.3 Impact of residence time and product dilution

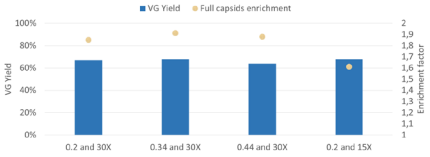

Fig.5: Residence time (min) and dilution impact on a 1mL PrimaT

There is no impact of residence time on the values tested. However, dilution appears to slightly affect the full capsid enrichment. Nevertheless, a 1.6 enrichment factor is still considered as correct.

3.4 Inter and intra batch repeatability

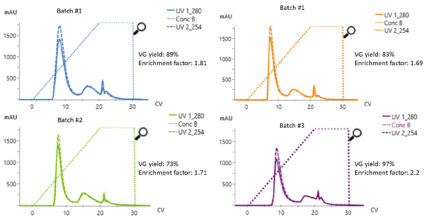

Fig.6: Chromatography profiles obtained on PrimaT 1 mL for the inter and intra batch repeatability

On the 1 mL PrimaT, similar chromatography profiles were obtained across four tests. The viral genome (VG) yield is approximately 80%, with a full capsid enrichment of around 1.8.

3.5 Scale up: 50L and 200L

Conditions developed at a scale of 1 mL were tested on 8 mL and 40 mL monolith scales.

Prima T volume	VG yield[1]	Full capsides enrichment[2]
1mL	80%	1.8
8mL	81%	1.7
40mL	110%	1.8

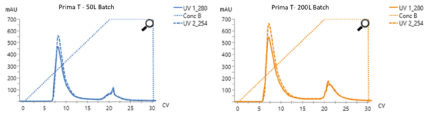

Fig.7: Scale-up results on PrimaT and chromatogram profiles

Conditions developed at a small scale are scalable to 50L and 200L production scales, achieving similar viral genome (VG) yield and full capsid enrichment.

Conclusion

Based on the data generated at multiple scales, conditions were established on the CIMmultus® PrimaT monolith for the industrial purification of a AAV8 product. The process achieves a full capsid enrichment of approximately 1.8 and a viral genome (VG) yield of 80%. Additionally, the PrimaT column effectively removes impurities, including some residual DNA and mainly host cell proteins, thereby improving the overall quality of the final product. These findings underscore the potential of the PrimaT monolith for large-scale AAV production in gene therapy applications.

1447 Development of a Novel Flow-Through Polishing Approach for Simplified Full/Empty Separation of Adeno-associated Viruses

Benjamin Graf[1], Frederik Meierrieks[2], Karl Pflanz[3], Michael Wolff[4], Alisa Weltken[1], Andreas Pickl[5]
[1]Sartorius Lab Instruments GmbH & Co KG, Göttingen, Niedersachsen, Germany, [2]Sartorius Lab Instruments GmbH & Co. KG, Göttingen, Outside USA, GERMANY, [3]Sartorius Stedim Biotech GmbH, GERMANY, [4]University of Applied Sciences Mittelhessen, GERMANY, [5]Sartorius Lab Instruments GmbH & Co. KG, GERMANY

Adeno-associated viruses (AAVs) are extensively utilized as viral vectors for in vivo gene therapy. Purifying AAVs, particularly separating genome-containing capsids from empty ones, poses major challenges. Traditional chromatographic methods for this separation typically depend on linear salt gradients, leading to high buffer consumption and demanding high resolution from chromatographic columns. In this study, we introduce an innovative anion exchange flow-through polishing method that separates full and empty AAV particles using a single isocratic elution step (**Figure 1 A**).

Our experimental investigations revealed that using the divalent salt $MgCl_2$ as an eluent provides good separtion performance between empty and filled AAV particles (**Figure 1 B**). This method was successfully applied to three different AAV serotypes (AAV8, AAV5, and AAV2) across two types of stationary phases: an anion-exchange membrane adsorber and a multimodal monolithic column. This approach resulted in a 4 to 7.5-fold enrichment of full AAV particles. Importantly, the enriched filled AAV particles maintained their functional potency and structural integrity.

The flow-through polishing method offers several advantages for the AAV purification process. The use of convective matrices, such as monolithic columns and chromatographic membranes, enables higher flow rates compared to traditional chromatographic resins. Additionally, this method allows users to avoid buffer-intensive linear elution gradients and mitigates the risk of overlapping elution peaks, which can lead to poor enrichment of filled AAV particles. A further benefit of this method is that the binding capacity of a column can be increased since empty particles that appear in the flow-through fraction are not competing for binding sites on the column with filled particles.

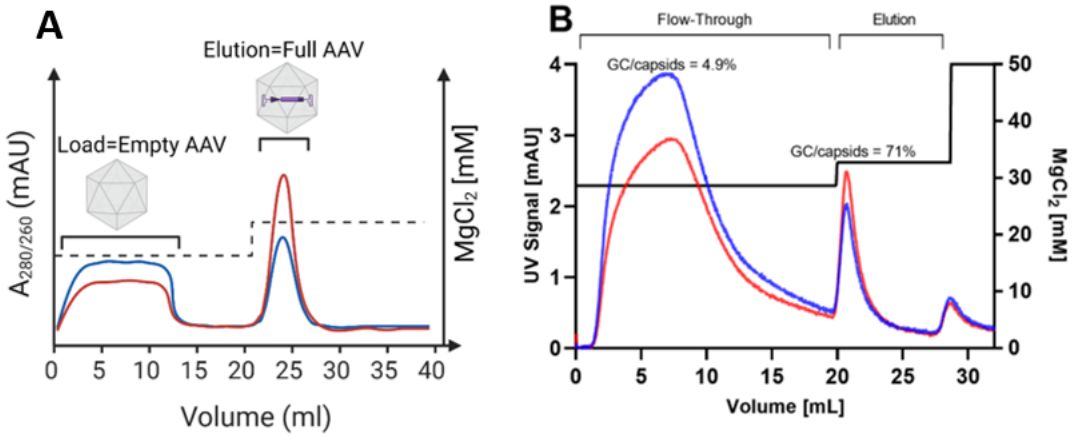

Figure 1: **A**) Exemplary illustration of flow-through chromatogram for empty/full AAV separation. During the sample loading empty AAV particles do not bind to the stationary phase. An increase of the ionic strength with a single isocratic step leads to elution of filled AAV particles. **B**) Flow-through chromatogram of a AAV5 empty/full separation. Using $MgCl_2$ the ionic strength of the AAV solution is adjusted in a way that empty particles appear in the flow-through fraction (4.9% filled particles) whereas the filled particles elute after a single isocratic elution step (71% filled particles).

1448 Purification Process Toolbox Development for Gene Therapy Vector AAV

Lihua Yang[1], Xue Mi[1]
[1]*AbbVie, Worcester, MA*

Gene therapy viral vector, adeno-associated virus (AAV) is becoming a viable and popular option for gene modification. Different serotypes have different tissue tropisms, enabling a broad application for these vectors. However, the current AAV packing technique at genome level is very inefficient, up to 80% of the formed AAV capsids may not contain the gene of interest (GOI), resulting in a mixture of significant amount of empty AAV capsids. In addition, the cell culture process is typically required to lyse the cells to maximize harvest of viral particles, but also release tremendous host cell impurities such as host cell proteins (HCP) and host DNAs. Moreover, AAV engineering is becoming popular to improve their therapeutic efficacy, but engineered AAVs can be more unstable. All these challenges create more complications for downstream purification. In our study, new filtration technologies, resins, chromatography, and operation modes are being explored to improve purification processes with high throughput, yield, full/empty capsid ratio and impurity removal for AAV vectors. We aim to develop a toolbox that can be suitable for different AAV vectors to streamline and speed up the purification process development.

Herein, a downstream purification process for several serotypes of AAV viral vectors are being explored for harvest clarification, tangential flow filtration (TFF), affinity chromatography and anion exchange (AEX) chromatography unit operations. An integrated AEX-based depth filter and filter train of several traditional polypropylene, cellulose, and diatomaceous earth-based, as well as synthetic depth filter with minimal leachable were screened to reduce cells, cellular debris, cell host and process impurities. The traditional depth filter train showed better throughput and a higher degree of reduction of host cell impurities and turbidity than the integrated filter. A large molecular weight cut-off (30, 100 and 300 kD MWCO) tangential flow filtration (TFF) cassette (mPES) and TFF capsule (regenerated cellulose) were compared to reduce the affinity load volume, reduce small-sized impurities and buffer exchange into the desired affinity column load buffer.

In addition to filtration steps, two chromatography downstream unit operations are being developed. A large pore-sized affinity POROS AAVX resin was selected to capture the AAV to reduce the majority of impurity burden, while lowering the mass transfer diffusion hindrance caused by the large viral particles. A high virus recovery rate of over 90% was achieved for each serotype with optimized low pH step elution. A new modality monolith AEX was compared with traditional resin based AEX for evaluation of full/empty capsid separation and further impurity clearance. As high as over 40% increase of full capsids were achieved using the optimal column and operating conditions. With these two steps of chromatography, impurities were greatly reduced to either below assay detection limit or significant low levels.

In conclusion, several purification unit operations were developed for different AAV serotypes to establish purification toolbox, including filtration and chromatography separation, and optimized process parameters for effective manufacture of best quality AAV products. Our next step would include model construction to continuously develop a platform process with high efficiency and performance.

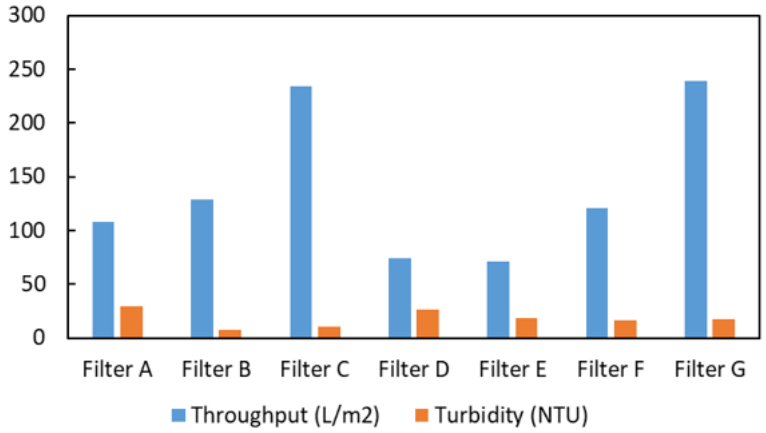

Figure 1. Clarification depth filter performance. Filters C and G show better throughput.

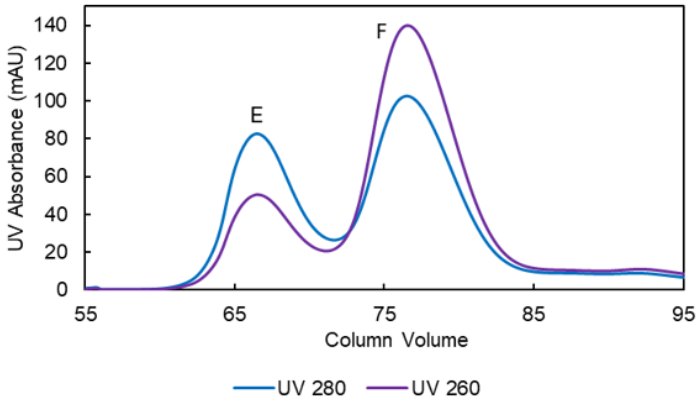

Figure 2. AEX chromatogram. Full (F) & empty (E) capsid ratio increased by over 40%.

1449 Critical Considerations For Full/Empty AAV Separation

Cecile Toussaint[1]*, David Catalan- Tatjer[2], Barbara Martins Fernandes Paes[1], Eugne Sun[3], Stairs Robert[4], Alina Venereo Sanchez[5]
[1]VVector Bio, Montréal, QC, [2]Novo Nordisk Foundation Center for Biosustainability, Lygby, Denmark, [3]Thermo Fisher Scientific, Bedford, MA, [4]Thermo Fisher Scientific, Waltham, MA, [5]VVector Bio, Beaconsfield, QC
**Corresponding Author*

The inefficiency of AAV to package therapeutic genes leads to the production of a substantial amount of empty or partially filled capsids, which can impact the efficacy and safety of AAV-based therapies. Developing a robust and scalable purification method to separate full and empty AAV particles at large scale remains challenging due to the similar physicochemical properties of these two populations.

In this study, we developed a streamline downstream process including, capture and full capsid enrichment. Capture using POROS™ CaptureSelect™ AAVX resulted in 95% recovery of AAV2-GFP functional particles. For the polishing step, we introduce a conductivity-based strategy that combines linear and step gradient elution using

POROS™ XQ resin to enhance the separation of full and empty capsids. This approach demonstrated a 5-fold enrichment of full AAV2-GFP particles, while empty capsids were reduced by 4-fold.

Thus, the removal of empty capsid offers the possibility to further concentrate full capsids carrying the therapeutic gene while minimizing the risk of aggregation. Furthermore, as total capsid dose appears to be responsible of immune-mediated toxicities, eliminating empty capsid with no therapeutic benefit is crucial. These developments offer a scalable and robust solution for AAV manufacturing, which is essential for producing high-quality gene therapies.

1450 Utilization of Real-time Multi-angle Light Scattering (RT-MALS) for Accelearted AAV Chromatography Development

Samit Dutta[1], Eva Fong[2]
[1]MilliporeSigma - Carlsbad, CA, Carlsbad, CA, [2]Milliporesigma, Burlington, MA

The use of process analytical technology (PAT) to measure product quality attributes during process development can reduce the analytical workload and enable faster development timelines. Real-time multi-angle light scattering (RT-MALS) is an example of PAT that can be utilized in downstream process development for the measurement of titer, aggregation, and full capsid ratio. The work summarized describes our use of RT-MALS for accelerated AAV chromatography development.

1451 A Novel Harvest-Capture Process for Rapid Clarification and Recovery of rAAV9 from Cell Lysate Using a Macroporous Filtration Device and AVIPure AAV9 Affinity Resin

Philip Yuen[1], Mike Bransby[2], **Westley Blacklock**[3], Marlon Tannous[2]
[1]Repligen, Long Beach, CA, [2]Repligen, Waltham, MA, [3]Repligen, Rancho Dominguez, CA

Recombinant adeno-associated virus (rAAV) vectors are a leading platform for gene delivery for a variety of human diseases and have been the focus of hundreds of clinical trials over the past several decades. The manufacturing of rAAV therapies at the industrial scale involves a number of labor intensive and expensive steps, such as clarification by depth filters or centrifugation, UF/DF by tangential flow filtration, and chromatography. To optimize the manufacturing of rAAV, Repligen has developed a novel process combining the clarification of rAAV9 from cell lysate and affinity chromatography using a macroporous filtration device and AVIPure affinity resin in a single step. In roughly 3 hours, up to 90% of affinity purified rAAV9 capsids were recovered directly from 1-L of cell lysate. Scale down experiments have also been shown to reduce volumes by >50x from initial cell lysate to final product recovery. The benefits of this process include elimination of depth filters or centrifugation for clarification, removal of the initial TFF concentration step and high clearance of host cell proteins and host cell DNA. The process has been designed to be fully scalable so that a single filter in the 3-hour timeframe can be used for manufacturing runs of up to 2000-L, requiring ~10-L of AVIPure AAV9 affinity resin. The novel harvest-capture methodology will provide value to the rAAV vector space by reducing the number of unit operations, time, and cost of the manufacturing process without negatively impacting product yield and purity to ultimately help bring down the price of these transformative therapies.

1452 Optimization of AAV6 Production at Benchtop Scale: The Role of Affinity Chromatography in Overcoming Aggregation

Ruud Visser[1], Timo Jonker[2], Mischa Klerk[3], Emiel Kramer[4], Hanno Tan[5], Osne Kirzner[5], Oliver Mueller[6], Vincent Christoffels[5], Gerard Boink[7]
[1]Amsterdam UMC, Amsterdam, Noord-Holland, Netherlands, [2]Amsterdam UMC, Utrecht, Utrecht, Netherlands, [3]AmsterdamUMC, Amsterdam, Noord Holland, Netherlands, [4]PacingCure BV, Amsterdam, Netherlands, [5]Amsterdam UMC, Amsterdam, Netherlands, [6]University of Kiel, Kiel, Germany, [7]Amsterdam, Netherlands

Adeno-Associated Virus (AAV) serotypes exhibit distinct characteristics, including tissue tropism and production efficiency. We found that, among AAV serotypes with cardiovascular tropism, AAV6 yields higher transduction efficiency than others when delivered via direct intramyocardial injection. However, standard lab-scale purification methods, comprising of collection and concentration of production media, cell lysis by repeated freeze-thaw cycles, clarification by centrifugation, purification and enrichment by iodixanol density gradient ultracentrifugation, and buffer exchange, are ineffective for purifying AAV6, as anecdotally reported. In contrast, larger batches of AAV6 can be sourced from contract manufacturers, indicating that purification at a larger scale is possible. Interestingly, AAV1, whose capsid protein differs from that of AAV6 by only six amino acids, does not present these purification issues.

To investigate the critical step where AAV6 purification fails, we produced AAV1, AAV6, and AAV9 at a benchtop scale (30×15 cm plates, 0.435 m^2). Quantitative PCR (qPCR) analysis of the clarified lysate confirmed similar yields for AAV1 (1.43×10^{13} vg) and AAV6 (0.99×10^{13} vg), with AAV9 (6.25×10^{13} vg) outperforming both. This suggested that the issue lies in downstream processing. We then performed iodixanol gradient ultracentrifugation and analyzed DNA isolated from all fractions using agarose gel electrophoresis. The full AAV particles of AAV1 and AAV9 were present in the expected fraction, while AAV6 genomes were only detected in fractions corresponding to the protein disc, a finding further confirmed by qPCR.

In large-scale AAV production, affinity chromatography is often employed before iodixanol gradient ultracentrifugation to purify vectors and prevent overloading of the gradient. We hypothesized that this additional step, which is not typically necessary for other serotypes at benchtop scale, might be required for AAV6. Furthermore, it has been reported that human serum protein galectin-3 binding protein, which is also secreted by the production cells, can bind to AAV6, leading to µm scale aggregates. Importantly, this interaction relies on the E531K substitution between AAV1 and AAV6. To test this, we used the AAVx affinity chromatography resin to purify AAV1 and AAV6 from both cell lysates and production media, all clarified using a 0.22 µm filter, following the manufacturer's protocol. Both AAV1 and AAV6 were successfully purified from the cell lysates, whereas only AAV1 was purified from the production medium, pointing to an aggregation problem with AAV6 in the production medium.

To further explore purification strategies for AAV6, we compared iodixanol gradient ultracentrifugation with or without prior affinity chromatography. We found that successful purification and enrichment of AAV6 only occurred when affinity chromatography was included in the protocol.

In conclusion, our study reveals that AAV6 presents unique purification challenges at the benchtop scale despite similar yields to AAV1. These issues likely stem from aggregation, mediated by interactions with galectin-3 binding protein, and are not overcome by conventional purification methods alone. Affinity chromatography is essential for the successful purification of AAV6, providing critical insights into improving its production efficiency and utility for gene therapy applications.

1453 Affinity purification analysis: a comparison of AAV2 and AAV5 serotypes

Smriti Mishra[1]*, Matthew Kuc[2], Sana Afzal[1], Paul Turiano[1], Lori Mullin[3], Joe Orlando[2]

Viral vector-mediated gene therapies are among the most efficient approaches for correcting genetic disorders. Adeno-associated viruses (AAV) are acknowledged as potent vectors for in vivo gene delivery. The production of AAV viral vector necessitates a downstream process that encompasses the capture of viral vectors and a full-capsid polishing enrichment step. Antibody-based affinity resins selectively capture vectors while effectively removing most host cell proteins and DNA contaminants. The study evaluates capture chromatography, including elution and wash buffers for AAV2 and AAV5, with the objective of establishing a manufacturing friendly AAV affinity purification process.
In the work, we used Tris-based equilibration and wash buffers for AAV2 and AAV5 maintained at a mildly alkaline pH (approximately 7.5) and a salt concentration 250-500 mM to eliminate non-specifically bound proteins.

In contrast, we utilized low pH elution buffers (approximately 2.5) to effectively elute the bound AAV capsids from the affinity resin. A capture chromatography method was developed specifically for the AAV2 serotype using a low pH glycine elution buffer. The method was subsequently utilized for the AAV5 serotype; however, the lack of AAV5 in the elution pool necessitated a change in the salt used for AAV5 elution. Citric acid which corresponds to different proton state at low pH, resulted in effective elution of AAV5. We evaluated multiple concentrations of citric acid and determined the optimal concentration for the elution. The optimal concentration not only enhanced the effectiveness of AAV5 elution but also reduced the elution volume. We illustrate the similarities of alkaline pH in wash buffers, differences of salts in elution buffers, and efficiencies associated in capturing AAV2 and AAV5 serotypes in downstream vector processing. Our work highlights the significance of tailored elution salts for each serotype. Additionally, it underscores the relatively minor role of the buffers employed during the equilibration and washing processes. The study develops a method that can effectively capture both serotypes by merely adjusting the elution buffer.

1454 Performance of Alkali-Tolerant Affinity Chromatography Resins Immobilized with AAV Receptor and Full/Empty Separation of AAV1

Yuriko Makino Manabe[1], Kouhei Yoshida[2], Keita Omura[3], Kiyoshige Iwabuchi[3], Toru Tanaka[4], Teruhiko Ide[3]*, Yuji Tsunekawa[5], Takashi Okada[6]

Adeno-associated virus (AAV) is the most popular vector for in vivo gene therapy. To purify AAV more specifically, we focused on the AAV receptor AAVR (KIAA0319L), which is important for the intracellular entry of various AAV serotypes. So far, we have developed an affinity chromatography resin with immobilized modified AAVR and have reported on its alkali resistance and the purification of AAV8.

Concretely, first, we developed alkaline-tolerant AAVR. The stability in alkaline condition is desired for alkaline cleaning-in-place (CIP), which is conducted to wash out strongly bound host-cell proteins and AAV remaining in resin after use of column. Our AAVR mutant exhibited high stability in acidic and alkalic buffer. Next, we developed the resin immobilized by the AAVR mutant (AAVR resin). And the affinity column packed with this resin have been able to purify AAV8 vector from culture with a recovery yield of more than 90%.

In this presentation, we report on the performance of the AAVR resin for serotypes other than AAV8. Since there are various serotypes of AAV, we confirmed the ability to purify representative serotypes. First, AAV1, AAV2, and AAV9 were cultured and we confirmed that these AAV serotypes can purify with AAVR resin at least.

On the other hand, Tosoh bioscience LLC has presented in papers1) and conferences that the Full rate of AAV2, AAV5, AAV6, and AAV8 can be analyzed using anion exchange chromatography.

By using TSKgel Q-STAT for analysis and TOYOPEARL GigaCap Q-650S for preparative chromatography, and adding choline chloride to the buffer, the Full rate can be analyzed and AAV solutions with high Full rates have been obtained.

We therefore investigated the possibility of purifying AAV1 after purified by AAVR resin in a similar manner, using a GigaCap Q-650S 5-mL column with 20 mM Tris pH 9.0 and 20 mM Tris, 300mM choline chloride, pH 9.0

as the buffers. Although it should vary depending on the specifications of the equipment and the purity of the choline chloride, the results we examined with AKTA showed that a gradient to 66% was performed, washed to remove empty AAV, and then eluted stepwise to 100% to obtain the full AAV fraction. Full AAV fraction was analyzed using the "Refeyn" equipment. Analysis showed that the full AAV fraction, which was 53% after affinity purification, was enriched to 87%.

In summary, we have developed affinity chromatography resin with high durability in both acidic and basic conditions and process of purification of high quality Full AAV. It is founded that AAVR resin can AAV1, AAV2, AAV8 and AAV9. Additionally, we confirmed that AEX can remove the empty capsids from the mixture of full and empty particles not only AAV8 but also AAV1. We believe that the two-step purification process with affinity purification and anion exchange chromatography purification provides AAV with high purity in a simple manner.

1455 Enabling Large Scale Implementation of Anion Exchange Chromatography for Full Capsid Enrichment of a Novel Adeno-Associated Viral Vector

Tom Elich[1], Roberto Facendola[2], Kavitha Bodige[3], Jacob Guzman[3], Patrick Carroll[4], Kevin Nguyen[3], Andrew Joyce[3], Russell Udani[2], Shamik Sharma[2], Kumar Dhanasekharan[1]
[1]Voyager Therapeutics, Inc., Lexington, MA, [2]Voyager Therapeutics, Cambridge, MA, [3]Voyager Therapeutics, Lexington, MA, [4]Voyager Therapeutics, Inc., Cambridge, MA

During the production of adeno-associated virus (AAV) gene therapies, a significant percentage of the viral capsids generated do not contain the packaged transgene of interest. These empty capsids are considered product-related impurities and must be reduced to the extent possible during downstream purification. Anion exchange (AEX) chromatography has emerged as a viable approach for separating empty and full capsids by exploiting slight differences in surface charge properties. Compared to alternative full capsid enrichment methods such as preparative ultracentrifugation, AEX chromatography is attractive for its linear scalability and ability to automate product collection using standard manufacturing equipment. However, while AEX is amenable to implementation at large scale, a development team must account for operational differences between laboratory-scale and manufacturing-scale equipment to ensure smooth tech transfer. System and scale dependent factors such as pump capacity, peak collection strategy, column sizing, and product stability during processing should be carefully considered for successful scale-up. Here, we share case study data which supports more than 100-fold scale-up of an AEX monolith chromatography operation to enrich full capsid content for a novel AAV feed. An analysis of development scale AEX trends is presented to inform strategies for large-scale implementation.

1456 Efficient Separation of Empty and Full AAV Capsids with Choline Chloride in Preparative Anion Exchange Chromatography

Yuliya McAnany[1], Leila Bonakdar[1], Alan Bouskila[1], Danielle Baun[1], Tianyu Li[1], Ryuichi Sato[1], Romain Dabre[2], Egbert Müller[3], Jukka Kervinen[1], Yuriko Makino Manabe[4]

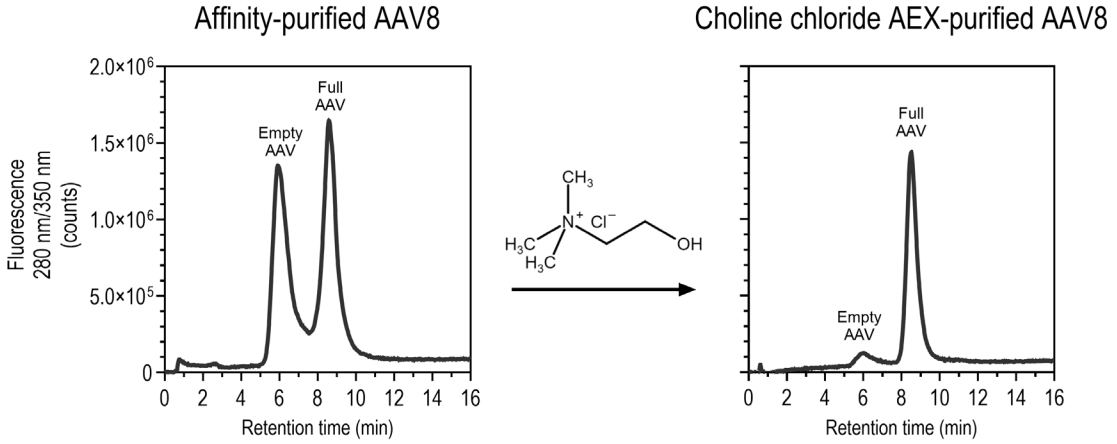
Adeno-associated virus (AAV) vectors are a widely pursued platform to deliver genetic medicine via *in vivo* direct administration. However, in upstream manufacturing, AAV genome packaging is an inefficient process, resulting in a heterogenous population of empty capsids, capsids with partial genomic material, and functional viral vectors containing the full genomic payload. Empty AAV capsids are considered a product-related impurity and may increase the risk of immunogenic adverse events. Empty capsids also may compete with full capsids for AAV receptors, thereby reducing the transduction potential of the full virion. Therefore, there is a strong motivation to

pursue the highest possible full AAV content in a finished drug product to ensure acceptable drug potency and safety.

The small net charge difference between empty (pI ≈6.2) and full (pI ≈5.9) AAV particles due to the encapsidated DNA payload can be exploited as a means of separating empty and full capsids in anion exchange (AEX) chromatography. However, conventional AEX purification schemes often do not result in sufficient empty and full capsid separation. Here, we describe a novel polishing AEX purification method using choline-Cl as the gradient salt on columns prepacked with TOYOPEARL GigaCap Q-650S, a resin functionalized with quaternary amines (Q-type resin ligand). Choline-Cl is a quaternary ammonium salt with a chemical structure similar to that of Q-type resin ligands. Elution with a choline-Cl linear gradient more than doubled the resolution between empty and full AAV8 capsid peaks as compared to ordinary monovalent salts such as sodium chloride. During further optimization, the linear gradient was modified and the method fully optimized using a series of elution steps specific to a particular AAV serotype. Starting from 40-50% full AAV8 content in an affinity-purified fraction, we were able to achieve ≈95% full AAV8 content in a single AEX polishing run. This level of full content is comparable to that of commercially sourced AAV samples purified with preparative ultracentrifugation.

This rapid, scalable, customizable, and adaptable choline-based process for Q-type AEX resins is an efficient chromatographic polishing method to remove empty particles and to enrich full AAV content. This leads to greater cost savings to produce AAV gene therapies by reducing the number of chromatography steps, avoiding loss of full AAV capsids contaminated with empty capsids, and fully eliminating the need for preparative ultracentrifugation. Implementing this choline-based AEX process supports the unmet need for potent, safe, and cost-effective AAV products.



1457 High Yield and Full-Empty Ratios Achieved with a Scalable GMP-Ready AEX Chromatography

Eleni Tsiaousi[1], Julia Trommer[2], Christos Mantzoros[2], Matthias Boscher[2], Johanna Wagner[3], Jared Babic[2], Beatriz Carnio[2], Christine Zach[2], Sebastian Ritter[2], Matthias Gora[4], Tobias Klötzler[5], Alexandra Schoberth[5], Ahmed Youssef[6], **Melanie Langhauser[7]**
[1]Ascend Advanced Therapies, Planegg, Germany, Germany, [2]Ascend Advanced Therapies GmbH, Planegg, Germany, [3]Ascend Advanced Therapies GmbH, Planegg, Bayern, Germany, [4]Ascend Advanced Therapies GmbH, Munich, Bayern, Germany, [5]Ascend Advanced Therapies GmbH, Munich, Germany, [6]Ascend Advanced Therapies GmbH, Planegg-Martinsried, Bayern, Germany, [7]Ascend Advanced Therapies, Planegg, Bayern, Germany

A minimum of 70% full particles is typically recommended for the majority of clinical AAV applications since an excess of non-functional or empty capsids can impact both, therapeutic efficacy and safety. The design of plasmids and overall AAV upstream manufacturing platform significantly impacts the level of full-length AAV packaging.

Technologies such as our EpyQTM can make further enrichment of full particles dispensable, resulting in higher AAV vector titers and overall process recoveries. When a full capsid enrichment step is required in downstream processing, it is very challenging to develop a robust and scalable step to significantly reduce empty capsids. Here we describe a systematic process development strategy to optimize full/empty separation using anion exchange chromatography (AEX), with a focus on methodical screening and stepwise refinement.

Development began with a screening phase to identify a suitable AEX resin to separate full and empty AAV9 capsids. Three commercially available AEX resins were evaluated under linear gradient elution conditions. Following resin selection, the buffer system was optimized by testing various salt compositions and dual salt combinations to ensure operational simplicity and compatibility with previous and following downstream processing steps. Linear gradient experiments with different salt types provided insights into the optimal elution profiles for full capsid enrichment.

Based on these findings, the chosen resin and buffer system were further evaluated to develop a step gradient protocol, replacing the linear gradient for enhanced process reproducibility and scalability. The step gradient resulted in an enrichment to ≥70% full of the already high % full starting material (~50% full for AAV9 & 3kb GOI) with a step recovery of more than 60 %, sufficient to include it in the purification process. Mass photometry was employed as a reliable analytical tool to determine the enrichment factor for full capsids. Concurrently, droplet digital PCR (ddPCR) was applied to quantify vector genome (vg) titers, enabling accurate calculation of step recovery. These two analytical approaches ensured a comprehensive evaluation of process performance.

This study highlights the critical role of robust and qualified analytical tools and a stepwise, well-structured process development for establishing an efficient method to separate full and empty capsids. A scalable, GMP-ready AEX step was developed first for AAV9, and is now available for the serotypes AAV2 and 8 as well. These studies offer a good basis for future projects with different serotypes and gene-of interests.

1458 Maintaining Superior Viral Vector Recovery in Cell and Gene Therapy Applications by using Daikyo Crystal Zenith® Vials

Vidya Murthy[1], Eric Kurtz[2]
[1]West Pharmaceutical Services, Inc., Hokinton, PA, [2]West Pharmaceutical Services, Inc., Exton, PA

This study aims to evaluate the impact of vial material of construction on the stability of two adeno-associated virus (AAV) serotypes under varying stress and storage conditions. AAV8 and AAV9 were chosen as representative AAV serotypes, with respective titers in a common buffer formulation, and evaluated in different 2mL vial types: Daikyo Crystal Zenith® (CZ) vial, and two commercially available borosilicate vials. To simulate viral vector recovery in cell and gene therapy applications, the vial combinations were tested across five challenge conditions:

- 3 months at -80°C, recommended condition for long term storage
- 2 months at 5°C, recommended condition for temporary refrigerated storage
- 3 weeks at 25°C, simulating room temp clinical ambient conditions
- 72 hours of 250 RPM agitation, to mimic stress environment during shipping and handling
- 5 cycles of Freeze/Thaw, to mimic handling during manufacturing and the potential for structural damage to proteins or DNA

In all conditions, the Daikyo CZ vial demonstrated improved viral vector recovery compared to borosilicate glass vials. The data shows that there were no significant changes in product quality due to container storage in the Daikyo CZ vials, and that the CZ vials may comparatively improve viral vector recovery across common storage and handling conditions.

1459 Benefits of High-Throughput Sequencing-Based Methods for In-Depth Characterization of Recombinant AAV Products

Sonia Stinus[1], Sheila Maestro[2], Achille François[3], Emilie Lecomte[4], Cesar Trigueros[5], Aitor Navarro Nieto[6], Adrian Perez[7]
[1]Viralgen Vector Core, San Sebastián, Guipúzcoa, Spain, [2]Viralgen, San Sebastián, Guipúzcoa, Spain, [3]Viralgen Vector Core S.L., DONOSTIA/SAN SEBASTIÁN, Guipúzcoa, Spain, [4]Inserm UMR1089, Nantes, Pays de Loire, France, [5]Viralgen, San Sebastian, Spain, [6]Viralgen Vector Core, San Sebastian, Spain, [7]Viralgen Vector Core, San Sebastian, Guipúzcoa, Spain

With the success of clinical trials, gene therapy today may represent hope for patients suffering from genetic diseases. Recombinant Adeno-associated virus (rAAV) products are extensively characterized prior to release. Among the Critical Quality Attributes (CQAs) used for release testing, those related to the identity and purity of rAAV products are scrutinized to ensure patient safety and treatment efficacy. Although quantitative polymerase chain reaction (qPCR) PCR and Sanger sequencing are currently among the gold standard techniques, the rapid development of high-throughput sequencing (HTS) technologies has paved the way for a much more exhaustive characterization of rAAV product's DNA content.

It has been just over ten years since rAAV products began to be closely studied by high-throughput sequencing, initially using Next Generation Sequencing (NGS) with short-reads (e.g., Illumina) and then using Third-generation sequencing, also known as long-read sequencing (e.g., Pacific Biosciences and Oxford Nanopore Technologies). Studies carried out so far show that both short-read and long-read sequencing technologies are of importance for the characterization of DNA, each with its own strengths. Next-generation sequencing offers HTS depth and a low sequencing error rate, enabling exhaustive identification and quantification of contaminating DNA, and detection of mutations at unprecedented levels. On the other hand, long-read sequencing technologies offer the opportunity to sequence DNA at single-molecule level, allowing the identification and quantification of truncation events in rAAV genomes as well as determining the size of contaminating DNA. There is currently no consensus on the method of choice, and a combination of different HTS technologies is needed to obtain the most exhaustive view of the DNA present in rAAV products.

In this study, both Illumina and Oxford Nanopore Technologies were used to characterize AAV preparations. All the experiments were carried out using laboratory methods established internally, from sample and library preparation, to sequencing and bioinformatics analyses, to guarantee the quality of the results in particular with the sequencing of controls, the introduction of acceptance criteria and determining the limit of quantification of each method. The results provide information on 3 CQAs: (1) payload sequence identity, (2) payload sequence integrity, and (3) residual DNA sequence quantification. The presence of Single Nucleotide Polymorphisms, indels and truncation hotspots were assessed; and DNA contaminants were identified and quantified.

We believe our HTS-based methods can be applied to the exhaustive characterization of both DNA starting materials (e.g. plasmids) and rAAV gene therapy products and could be validated in the near future.

1460 Determination and Characterization of Capsid Full Ratio of the Clincal Grade rAAV Product by Transmission Electron Microscopy, Analytical Ultracentrifugation, Digital Droplet PCR, and Capsid ELISA

Shengjiang Liu[1], Jin Zhong Li[1], Xiangchun Chen[2], Derrick Huynh[3]
[1]Avirmax Inc., Hayward, CA, [2]Avirmax CMC Inc., Hayward, CA, [3]Avirmax, 22710 Zaballos Ct., CA

Adeno-associated (AAV) vector is the main *in vivo* gene delivery method, widely used in over 250 clinical trials for various indications. Empty and partial capsids that do not contain full-length genome sequences are by-products of AAV production and significantly affect the clinical safety and efficacy of AAV gene therapy. Therefore, determining the full capsid ratio of AAV products is essential before clinical application. Thus, three orthogonal methods, transmission electron microscopy (TEM), ELISA coupled with ddPCR, and analytic ultracentrifugation (AUC) were comparatively studied. TEM showed homogenous AAV morphology in spherical structure and identified 98.0% full, 0.7% partial, and 1.3% empty capsids. Then, ELISA coupled with ddPCR was performed to measure total capsid concentration and AAV genome copy, respectively. ELISA coupled with ddPCR identified 64.6% full capsids without distinguishing empty and partial capsids. Finally, AUC was performed based on

estimated AAV molecular weight and sedimental velocity analysis. The results showed 60.4% full capsids (101S peak), 37.0% partial (81 and 91S), and 1.1% empty (72S), with a good correlation with ELISA/ddPCR results. In summary, AUC is the most reliable test for determining full, partial, and empty capsids, while ELISA coupled with ddPCR could be a fast, convenient, and cost-effective alternative for in-process measurement.

1462 Methods to Improve the Clarification Process of AAV Therapy Manufacturing

Philip Szymanski[1], Dana Kinzlmaier[2], Taylor Goldstone[1], Akshat Gupta[1]
[1]MilliporeSigma, Burlington, MA, [2]MilliporeSigma, Burlington

The high cost of manufacturing for therapeutic grade AAV is a significant barrier to these life-saving therapies. To this end, focus was placed on designing an efficient AAV purification process. This work explores opportunities to optimize the clarification process for an AAV5 vector produced in HEK-293 cells.

Two different approaches to clarification (flocculation and precipitation) were explored together with a screen of depth filtration media. An optimal process was identified based on product recovery, depth filter capacity as determined by differential pressure and filtrate turbidity, sterilizing grade membrane filter capacity, and residual levels of common impurities like host cell DNA and host cell proteins in the filtrate. Maximal particulate retention and impurity clearance were achieved by implementing lysate pretreatment coupled with an appropriately selected depth filtration media. The filter capacity exceeded 250 L/m^2, filtrate turbidity stayed below 5 NTU, and sterilizing grade membrane area was significantly reduced. Residual hcDNA, a key impurity, was reduced by >3 logs and vector recovery was >90%. The superior filtrate quality from this optimized clarification process results in less purification burden for the costlier subsequent affinity chromatographic separation technique.

1463 Optimizing AAV8 Capsid Purification with Oversized GOI: Efficient Separation of Empty, Partial, and Full Capsids Using Anion Exchange Chromatography

Yeonji Kim[1], Chris Brown[2], Jing Zhu[2], Xiaojun Liu[2]*
[1]Boxborough, MA, [2]ReciBioPharm, Watertown, MA
**Corresponding Author*

Adeno-associated virus (AAV) vectors are widely used in gene therapy, but the production process often yields heterogeneous populations of viral particles, including empty capsids (lacking a genome), partially filled capsids (containing fragmented DNA), and full capsids (encapsulating an intact genome). Empty capsids, classified as product-related impurities, lack the therapeutic gene of interest and are devoid of functional relevance. While their precise role remains unclear, studies suggest they may influence therapeutic efficacy and safety profiles or act as decoys for neutralizing antibodies. Consequently, effective separation of empty capsids is critical to ensure a high-quality AAV product (Zhu et al., 2025)

Anion exchange chromatography (AEX) has emerged as the preferred method for large-scale separation of AAV capsids due to its scalability, reproducibility, and ability to maintain vector integrity. ReciBioPharm's platform AEX process demonstrated high-resolution separation, achieving greater than 90% full capsid purity with minimal loss of vector potency. In this study, we aim to achieve the same with large sized GOI (>4.9 kb) by systematically evaluating AEX as a platform for oversized AAV8 capsid separation.

Critical factors, including buffer composition, were systematically investigated to achieve optimal separation. Trivalent sodium phosphate (PO_4^{3-}) was selected over monovalent and divalent salts, such as sodium chloride and sodium sulfate, due to its superior resolution power. This advantage is likely attributed to its higher ionic and displacement strength, enabling more precise differentiation between empty, partial, and full AAV8 capsids (Joshi et al., 2021). Analytical methods such as mass photometry, Analytical ultracentrifugation (AUC), and droplet digital PCR (ddPCR) were employed to assess capsid content and DNA encapsulation efficiency. The study also compared partial capsid separation across different conditions to ensure accurate quantification and removal of intermediates.

These findings provide a robust framework for refining AAV manufacturing processes, ensuring improved therapeutic efficacy and compliance with regulatory standards. By leveraging AEX for AAV8 capsid purification, this work contributes to advancing the production of high-quality AAV-based gene therapies.

Adeno-associated virus (AAV) is a highly promising gene therapy vector, widely used in clinical applications due to its ability to deliver genetic material to target cells. A challenge in AAV manufacturing is the occurrence of empty capsids in the final product, which can reduce the efficacy and/or impact the safety profile of AAV-based therapies. These empty particles, which lack the therapeutic transgene, can accumulate during the production process, leading to lower viral vector purity and reduced yield of full, functional virions. Additionally, the presence of empty capsids complicates downstream processing, demanding more extensive purification steps, and increases the risk of immunogenic responses upon administration. Overcoming this challenge is crucial to improving the quality, consistency, and scalability of AAV production. In this study, we examine the impact and implications of varying levels of empty capsids on AAV vector production during manufacturing of Sangamo's novel blood-brain barrier penetrant AAV capsid (STAC-BBB) and present strategies for improving yield and purity. Additionally, a stabile formulation is required in order to administer these AAV treatments. We developed a stable formulation buffer for STAC-BBB by evaluating aggregation and capsid stability profiles. With optimized process parameters, we have established a robust, scalable manufacturing process and formulation that ensures critical product quality attributes meet requirements, advancing the development of novel viral vectors and genomic medicines for the treatment of neurological disorders.

1465 Accelerating AAV Processing: Scalable, Serotype-Agnostic Process Eliminating 2-steps (DNase and TFF) and Optimized for Physiological-Like Conditions

Adeno-associated virus (AAV) production for gene therapy applications has become increasingly important, yet the downstream processing of AAV remains a complex and cumbersome series of steps, each contributing to reduced overall yield and extended processing time. Current methodologies generally consist of seven or more individual steps: DNase treatment>Clarification>TFF1>Capture step>TFF2>Polishing step>Formulation and filtration. The resulting low yields and prolonged timelines hinder the scalability and efficiency of AAV production, posing significant challenges to manufacturing.

This study proposes a streamlined alternative to traditional AAV downstream processing, focusing on reducing the number of steps while simultaneously improving both recovery and process efficiency. We demonstrate a novel approach comprising just five integrated steps shown to work on various serotypes (AAV8, AAV9, AAV2).

The first step involves a direct lysate treatment using CIMasphere, media designed to effectively reduce both host cell DNA and host cell protein levels, thus eliminating the need for an additional DNase digestion step. Next, the lysate undergoes clarification through depth filtration, a well-established method that aids in the removal of large debris and clarifies the sample. The third step incorporates a capture process using novel CIMmultus IEX based column, that operates under near-physiological conditions for both binding and elution steps, specifically with pH and salt concentrations optimized for AAV stability. The capture step eluate seamlessly transitions without the need of TFF into the final polishing phase, which ensures high enrichment of the therapeutic AAV species. Finaly a formulation step using TFF is performed.

The innovative process presented in this study significantly reduces the number of individual steps required for AAV downstream processing. By optimizing the treatment conditions and eliminating redundant steps such as DNase digestion, we achieve higher viral yields and reduce the overall time for processing. This approach not only improves the scalability of AAV production but also offers a more efficient and cost-effective pathway for the production of AAV-based gene therapies, potentially accelerating the development of clinical applications.

1466 Next-Generation Sequencing for AAV Characterization

Ltd., A subsidiary of Merck KGaA, Darmstadt, Germany), Bangalore, India., Bangalore, Karnataka, India, [6]Sigma Aldrich Co, [7]Carlsbad, CA

Viral vectors are valuable vehicles for the delivery of gene therapies. Adeno-associated viruses (AAVs) are among the most promising and versatile viral vectors, as AAVs are non-pathogenic and lowly immunogenic, and may deliver targets to a range of tissue types. Moreover, several AAV-based therapies have already received regulatory approvals, demonstrating their safety and efficacy. For gene therapies, AAV contains a modified genome that consists of viral inverted terminal repeat (ITR) sequences flanking the target therapeutic gene. An important characterization assay of AAV products is the confirmation of the sequence of the gene being delivered, also known as identity testing. Identity testing of AAV products is critical to verify that the encapsidated genome is accurate, and that no unwanted genetic variants are present which could lead to nonfunctional gene products or detrimental effects in patients. We have applied complementary next-generation sequencing (NGS) technologies, to confirm the sequence identity of the viral encapsidated genome from several AAV serotypes. We have also been able to identify process-related impurities in AAV preparations, including residual host cell genomic DNA, residual plasmid DNA, and genome truncations or partial genomes. Finally, because plasmids are critical raw materials in the production and manufacturing of AAVs, we have used long-read sequencing for the confirmation of plasmid sequence identity. NGS is an important approach for the characterization of viral vectors, thus we have integrated short-read and long-read sequencing platforms as routine steps in our AAV process development and characterization workflow.

1467 Multiplex ddPCR Approach as Proof-of-Principle for Accurate AAV Genome Integrity Assessment and Enhanced Vector Production

Ricardo Correa[1], Tabitha Hernandez[2], Wen Chen[3], Ayan Dey[4], Michael Shen[5]
[1]BioReliance Corporation (MilliporeSigma/Merk KGaA), Carlsbad, CA, [2]MilliporeSigma - Carlsbad, CA, Carlsbad, CA, [3]Millipore Sigma, [4]MilliporeSigma - Carlsbad, Carlsbad, CA, [5]Carlsbad, CA

Adeno-associated viruses (AAVs) are widely used in gene therapy due to their ability to achieve targeted expression with minimal immunogenicity. While their small genome size (4–5 kB) limits gene transfer capacity, they provide long-term therapeutic expression, making them valuable for clinical applications. Recombinant AAVs (rAAVs)

replace viral genes with therapeutic transgenes while retaining inverted terminal repeats (ITRs) for efficient gene delivery.

A key challenge in large-scale rAAV production is genome heterogeneity, where capsids may contain truncated or incomplete genomes, affecting efficacy and safety. To address this, we developed a multiplex droplet digital PCR (ddPCR) assay to assess genome integrity, utilizing hydrolysis probes targeting regions near the 5' and 3' ITRs for precise genome quantification.

Our feasibility study designed primers targeting the CMV promoter (FAM-labeled) near the 5' ITR and the TK promoter (HEX-labeled) near the 3' ITR. The assay demonstrated high specificity, accurate quantification across multiple runs, and no off-target amplification. Comparative analysis with mass photometry confirmed strong alignment in detecting full and partial AAV genomes.

This approach offers strong linearity and reproducibility, making it a reliable tool for genome quantification across AAV production stages. By integrating ddPCR with complementary biophysical techniques, we enhance quality control, supporting the production of safe and effective gene therapy vectors.

1468 Evaluating the Performance of Nanoneedle Assays for Robust Quantification and Determination of AAV Genome species packaged and Capsid Titers during Manufacturing Process

Suvana Lin[1], Yongmei Pei, Sylvain Cecchini[2]
[1]Umass Chan Medical School, Worcester, MA, [2]University of Massachusetts Chan Medical School, Worcester, MA

Adeno-associated virus (AAV) vectors are a leading platform for gene therapy, but robust quality control (QC) measures are critical for their safe and effective clinical application. A major challenge in AAV production is ensuring complete viral genome packaging, as incomplete genomes can significantly impact therapeutic potency and increase the risk of immunogenicity. While next-generation sequencing (NGS) provides valuable information regarding sequence quality and can identify sequence alterations within the AAV preparation, it is not quantitative and offers only a general overview of the DNA fragments present. Current methods for quantifying full-length genomes are limited. Some lack resolution on the completeness of the packaged genome (e.g., AUC, mass photometry), while others, like qPCR and dPCR, only quantify a short fragment, providing limited information on the quantity of intact genomes. Therefore, a fast, accurate, and quantitative method for assessing full-length transgene packaging is crucial for quality control (QC) of the manufacturing process.

Here, we evaluate a novel suite of nanoneedle assays (Tessie nanoneedle technology) designed to quantify various aspects of AAV samples, including full-length AAV genomes, shorter viral-DNA fragments, and capsid titer. To assess the accuracy of the viral-genome assays, we measured a defined mixture of plasmid DNA fragments using three distinct assays targeting: 1) the full-length transgene, 2) a long-truncated fragment, and 3) a short-truncated fragment (see Figure). We further evaluated the repeatability and reproducibility of both the full-length viral genome assay and the capsid titer assay. Finally, we applied these assays to comprehensively characterize AAV samples across various manufacturing stages, from crude material to ultracentrifugation-purified fractions, and compared the results to those obtained using ddPCR.

Our findings demonstrate that the nanoneedle assays are robust, with measurements ranging between 96% and 124% of the known DNA titers. Furthermore, both the capsid and viral-genome quantification assays exhibit high repeatability (intra-plate) and reproducibility (inter-plate), with coefficient of variation (CV) of 6% (intra-CV) and 14% (inter-CV) for the capsid assay and 3% (intra-CV) and 7% (inter-CV) for the viral-genome assay, respectively. This novel suite of assays offers a robust and reliable approach for AAV QC by providing a more accurate and comprehensive assessment of genome packaging, ultimately enhancing the safety and efficacy of AAV-based gene therapies. In addition, the rapid and precise quantification enables efficient evaluation at the early stages of vector design toward the development of more potent and targeted gene therapies.

1469 AAV Genome Integrity: Full and Partial Genome Characterization Utilizing Digital PCR and Long Read Sequencing

Ryan Massopust[1], Annabelle Phillips[2], Jordan Smith[3], Swetha Devi Velivela[3], Sarang Brahma[3], Maria Belousova[4], Andrea Moore[3]
[1]Asklepios Biopharmacuetical, Durham, NC, [2]AskBio, Durham, NC, [3]AskBio Inc., Research Triangle Park, NC, [4]AskBio, Durham, North Carolina

The rapid growth of the cell and gene therapy field presents a need for improved product-specific analytics. Critical quality attributes, such as viral genome (VG) or viral particle (VP) titer, do not consistently correlate with drug potency or safety, demonstrating a lack of genome-specific analyses. It is hypothesized that the heterogeneity of packaged genomes is a potential cause for this inconsistency. Therefore, there is a pressing need to improve characterization of packaged genomes for their heterogeneity and integrity. Our approach employs quadplex digital Polymerase Chain Reaction (dPCR), utilizing four primer probe sets that span the critical elements of the AAV cassette. Powerful genome integrity analysis calculates both the absolute number and distribution (heterogeneity) of the target based AAV genome variants. These results are compared and contrasted with Long Read Sequencing

results of the same drug product lots. The results presented here demonstrate correlation of genome integrity measurements across dPCR and NGS for multiple serotypes. These methods have complementary strengths and may provide impactful insights into variable potencies and packaging efficiencies of gene therapy products. dPCR provides absolute quantification, has low sample requirements and samples can be analyzed quickly. NGS provides a platform approach with deeper characterization and is better suited to detect insertions and deletions. Thus, results from these genome integrity analyses may be utilized throughout the drug development pipeline, informing research and development all the way through patient dosing.

1470 Characterization of High and Low rAAV Producer Cell Populations in Pinnacle PCL using Single Cell RNA Sequencing

Alix Eastham[1], **Emily Phillips[1]**
[1]Ultragenyx Pharmaceutical Inc., Novato, CA

Over the last two decades, single cell sequencing techniques have allowed researchers to capture the heterogeneity of their cell populations by revealing gene expression differences on an individual level. Utilizing 10X Genomics single cell RNA sequencing (scRNA-seq) technology, full length mRNA from individual cells was isolated and then barcoded, which was then converted into cDNA and processed through Illumina-based workflows to achieve gene expression profiling at a single cell level. The Pinnacle Producer Cell Line (PCL) system is capable of supporting scalable 2000L clinical grade rAAV production and has been used to generate material for the ongoing UX701 clinical trial for Wilson Disease. By applying scRNA-seq methodology to our cells, we are gaining critical insights into sub-populations that may be influencing productivity and quality within the population and how each producer cell is interacting with helper and production viruses. Here, we present the potential of this technology to identify significant gene expression differences within our polyclonal and monoclonal cell lines during viral production. Experiments were designed to simultaneously examine the profiles of the PCL host cells, the Adenovirus 5 helper virus, and rAAV. Time course experiments enabled us to interrogate the infectious cycle of the helper Adenovirus and determine key events required to provide optimal helper function. Finally, vector constructs with engineered secondary structure have been analyzed to understand key differences between our high and low producing PCL clones.

1471 Quantification of Adeno-Associated Viral Genomes Using a Newly Developed qPCR Assay

Mao Fu[1], Brian Park, Dezhong Yin[2], Laily Jaghori, Julian Heller[3], Ha Thai[4], Xuan Liu[4], Wei Fu
[1]Origene, Rockville, MD, [2]OriGene Technologies, Inc., Rockville, MD, [3]OriGene Technologies, Inc., Germantown, MD, [4]OriGene Technologies Inc., Rockville, MD

Recombinant adeno-associated viruses (AAV) are widely used as gene therapy vectors in emerging field of *in vivo* gene therapies. Measuring the vector genome copy (GC) titer is crucial for the development of AAV-mediated gene delivery research and AAV gene therapy products. Reliable, accurate, and rapid quantification of the AAV genome titer is essential for precise dosing, which is critical for patient safety. In this context, we introduce the AAV qPCR Fast Titer Kit, a newly developed assay for quantifying AAV genomes in purified vector samples. The core component of the Universal SYBR qPCR master mix is Taq Pro DNA Polymerase, a new generation hot-start polymerase modified through an antibody method. This polymerase offers several advantages, including improved specificity, increased detection sensitivity, and higher amplification yield. Additionally, we have incorporated a specific enhancer and optimized the qPCR buffer to further enhance specificity and sensitivity during the qPCR

reaction. This kit also includes a Specific ROX Reference Dye, which is compatible with all qPCR instruments, eliminating the need to adjust the ROX concentration on different devices. To simplify sample processing, we developed an accelerator buffer that can lyse AAV capsids in just 5 minutes at room temperature. With the AAV qPCR Fast Titer Kit, it is possible to quantitate AAV genome titer in under 2 hours. In summary, our AAV qPCR Fast Titer Kit provides a reliable, accurate, and efficient assay for quantifying AAV genome titer, making it widely applicable in AAV manufacturing and beneficial for AAV gene therapy and AAV-mediated gene delivery research.

1472 Precise rAAV Capsid Characterization via Digital PCR and Statistical Modeling

Conor Cox[1], Noah Elder[2], Stefan Bengston[3], Christopher Thomas[4], Kimberly Gomez[2]
[1]Thermo Fisher Scientific, Oceanside, CA, [2]Thermo Fisher Scientific, South San Francisco, CA, [3]ThermoFisher Scientific, Carlsbad, [4]ThermoFisher Scientific, South San Francisco

Precise quantification of recombinant adeno-associated virus (rAAV) subpopulations—particularly distinguishing capsids containing whole genomes, partially fragmented genomes, or fully fragmented sequences—is critical for advancing gene therapy development and manufacturing for research purposes. Traditional methods often fail to resolve these subpopulations accurately, especially when accounting for linkage between genomic fragments.

To address these challenges, we developed a novel PEA-dPCR workflow leveraging the QuantStudio™ Absolute Q™ digital PCR (dPCR) platform, Poisson-based statistical modeling, linkage analysis, and multiplexed-multiomic detection within dPCR partitions. The dPCR partitions samples into thousands of independent reactions, enabling simultaneous detection of multiple target sequences in each partition. By statistically unwinding the multiplexed results with Poisson-based modeling, we precisely determine the presence and proportions of all genomic subpopulations, including discrete fragments, partially linked genomes, and fully intact genomes. This approach not only resolves the capsid content but also calculates confidence intervals for each measurement, a robust assessment of accuracy and reliability.

Initial validation was conducted using synthetic wet-lab constructs with predefined linkage patterns, simulated datasets spanning a range of packaging profiles, and select rAAV samples. The workflow demonstrated high precision and reproducibility, accurately identifying and quantifying even complex subpopulations while offering statistical confidence in the results.

In summary, this PEA-Absolute Q™–based workflow integrates digital PCR, multiplexed-multiomic detection, statistical modeling, and linkage analysis to precisely characterize rAAV capsid subpopulations. By providing exact quantification of capsid species, their linkage states, and associated confidence intervals, this approach offers a powerful research tool for optimizing rAAV production and the quality of gene therapy vectors.

1473 GeneSwift: a PCR-Free, Hybydization Method to Determine Gene Therapy Vector Titer

Wai Choi[1], Pu Li[2], Hongshan Li[1], Robert Zuk[2]
[1]Gator Bio, Palo Alto, CA, [2]Gator Bio, Palo Alto

Background: Adeno-Associated Virus (AAV) is one of the most widely used viral vectors for gene therapy. Standard methods for determining AAV titers, such as qPCR and dPCR/ddPCR, are time-consuming, labor-intensive, and require multiple serial dilutions. These methods are also prone to interference from PCR inhibitors. Additionally, mRNA-based gene therapy presents challenges that PCR cannot adequately address, particularly in distinguishing between single-stranded (ss) and double-stranded (ds) RNA, the latter of which can trigger cytotoxic responses. To overcome these limitations, we developed GeneSwift, a PCR-free assay that integrates DNA hybridization, immunochemistry, and biolayer interferometry (BLI) for rapid and accurate gene titer quantification.

Methods: Figure 1A shows the GeneSwift workflow. AAV samples are mixed with two gene-specific DNA oligos (fluorescein-labeled F*Oligo and biotin-labeled B*Oligo) and lysed by heating in Hybridization Buffer. Upon

cooling, the oligos hybridize to the gene of interest (GoI) to form the hybridized complexes. Adding an anti-Fluorescien coated BLI Biosensor captures the hybridized complexes, followed by a Biotin Detection Solution to generate BLI signals. Use of a calibration curve with known GoI levels enables precise titer measurement. Total assay time is 30 minutes, and the oligos can be formatted to hybridize with either ssRNA or dsRNA. To evaluate GeneSwift's performance, we tested AAV8-GFP, ssRNA-GFP, and dsRNA-GFP as model analytes.

Results: The GeneSwift data (Figure 1B) indicated that BLI signals increased correspondingly with the titers of AAV standards. Based on the data testing AAV8-GFP, the assay showed a dynamic range from 4E+9 up to 1E+12 vg/ml, covering typical AAV production levels. Similar results were observed with AAV2 and other serotypes. We tested the performance of GeneSwift in various upstream (cell growing medium or cell crude lysate) and downstream AAV media (anion exchange or in-process buffers). The results (Figure 1C) showed robust signals and dose response curves in all tested AAV manufacturing media, demonstrating a broad compatibility of the assay with various matrices. A comparison using AAV8-GFP spiked into crude insect cell lysates showed excellent correlation with ddPCR ($R^2 = 0.99$, slope = 1.05) (Figure 2A). Both GeneSwift and ddPCR assays exhibited comparable precision with ~10% of CV in crude cell lysate samples (Figure 2B). However, GeneSwift delivered results in just 30 minutes with undiluted samples, whereas ddPCR required ~5 hours and a 10,000-fold dilution, making GeneSwift a much more efficient method for titer determination. To extend GeneSwift's applications to genome integrity assessment, we designed an oligo pair targeting widely separated regions (CMV enhancer and SV40 polyA). The results (Figure 2C) produced a robust dose-response curve, confirming the assay's potential to evaluate genome integrity. Finally, we tested GeneSwift's ability to detect ssRNA and dsRNA. Detection of dsRNA entailed selection of the oligo pair to hybridize to the opposite strands. The results (Figure 2D) still showed very good dose response curves, demonstrating the assay's versatility in measuring both ssRNA and dsRNA titers.

Conclusion: GeneSwift is a rapid, PCR-free assay for quantifying AAV and mRNA vectors. Its speed, accuracy, and broad applicability make it a powerful tool for advancing gene therapy research and bioprocessing.

**Corresponding Author*

Adeno-associated virus (AAV) gene therapies hold great promise for curing genetic disorders, but their high cost—often exceeding $2 million per treatment—limits patient access. Lowering production expenses is essential to increase affordability and expand the footprint of this modality. During production, AAV particles accumulate inside the cytoplasm of producer cells. Extracting these particles via cell lysis is a key step before purification. Conventional lysis methods, such as polysorbate 20-based surfactant lysis, indiscriminately break down cell membranes, releasing both AAV and unwanted host-cell contaminants. A significant challenge in downstream processing (DSP) is the loss of up to 70% of viral vectors, with host-cell impurities like residual DNA being an important cause of reduced yield. PCI Biotech's objective is to develop a more selective lysis approach that simplifies DSP, enhances overall AAV recovery, and lowers the manufacturing cost per dose.

Photochemical lysis (PCL) is a novel, light-activated technology that selectively targets the plasma membrane, releasing AAV with minimal host-cell-derived contaminations, especially DNA. PCL uses a GMP-grade amphiphilic photosensitiser that anchors in the plasma membrane. When added at the end of AAV production, it is activated by blue or red light, initiating a localised photochemical cascade that disrupts the plasma membrane while leaving cellular structures like the nucleus intact. This selective action reduces host-cell impurities by over 50% compared to surfactant-based lysis. Here we report the scale-up from HEK293 AAV production in shake-flasks to a benchtop bioreactor using red light illumination, representing a 500x scale-up from initial proof of concept with

adherent HEK293 cells. In this model, photosensitiser removal during DSP and preservation of AAV potency after photosensitiser exposure have been validated. Despite assumptions that some AAV serotypes (e.g., AAV8) are predominantly secreted, we show that PCL improves yield across multiple serotypes, with AAV8 showing close to 100% increase in USP yield in benchtop bioreactor following PCL, strongly outperforming Tween 20. Current efforts focus on optimising PCL for improved net yield in benchtop bioreactors. Success at this scale will pave the way for deploying PCL for research and development purposes. Moreover, we present a compelling case for further scaling PCL to commercial manufacturing using off-the-shelf LED bioreactors, enabling its use to boost AAV yields and reduce manufacturing costs per dose.

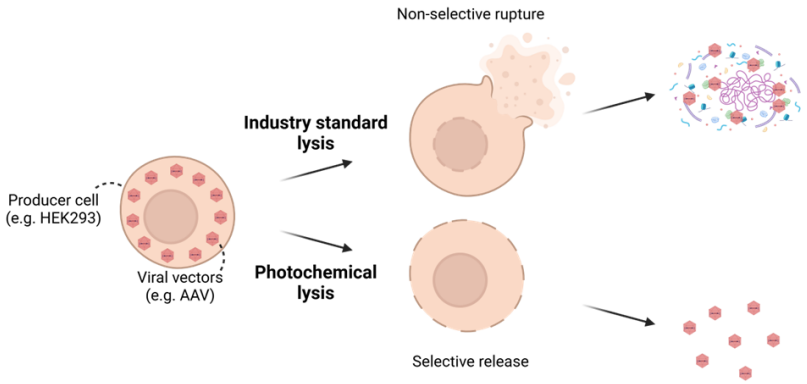

Figure: Cell lysis is an essential step in extracting AAV from producer cells before purification. The industry standard for cell lysis involves the use of chemicals (e.g., polysorbate 20), which non-selectively break open producer cells, releasing AAV alongside host-cell impurities that complicate downstream processing (DSP) — a significant cause of viral vector loss. Photochemical lysis (PCL) is a novel technology that selectively disrupts the plasma membrane of producer cells. The purpose of PCL is to enhance viral vector yield by more targeted and efficient AAV extraction, while simultaneously reducing host-cell impurities and, hence, manufacturing costs per dose.

1475 Strategies for residual DNA Clearance in Adeno associated Virus (AAV) purification process.

Akshat Gupta[1], Philip Szymanski[1], Dana Kinzlmaier[2], Taylor Goldstone[1], Melissa Deschamps[2], santosh Rahane, Jella Ujwal
[1]MilliporeSigma, Burlington, MA, [2]MilliporeSigma, Burlington

Host cell Deoxyribonucleic acid (DNA) is a critical process impurity which requires removal during an Adeno-associated purification to mitigate potential oncogenicity and infectivity concerns. In an AAV purification process multiple unit operations can be leveraged either independently or in combination to achieve desired DNA clearance. These unit operations typically include enzymatic digestion, clarification using depth filters and affinity capture chromatography. In addition, pretreatment technologies can also be leveraged as a method to achieve clearance on residual DNA.

In this work, we demonstrated clearance of host DNA using three approaches. In the first approach, we leverage enzymatic digestion as single step for DNA clearance. In second approach clearance levels using an absorptive depth media were established with reduced endonuclease and in third approach we demonstrate leveraging two pretreatment methods to establish achievable DNA clearance.

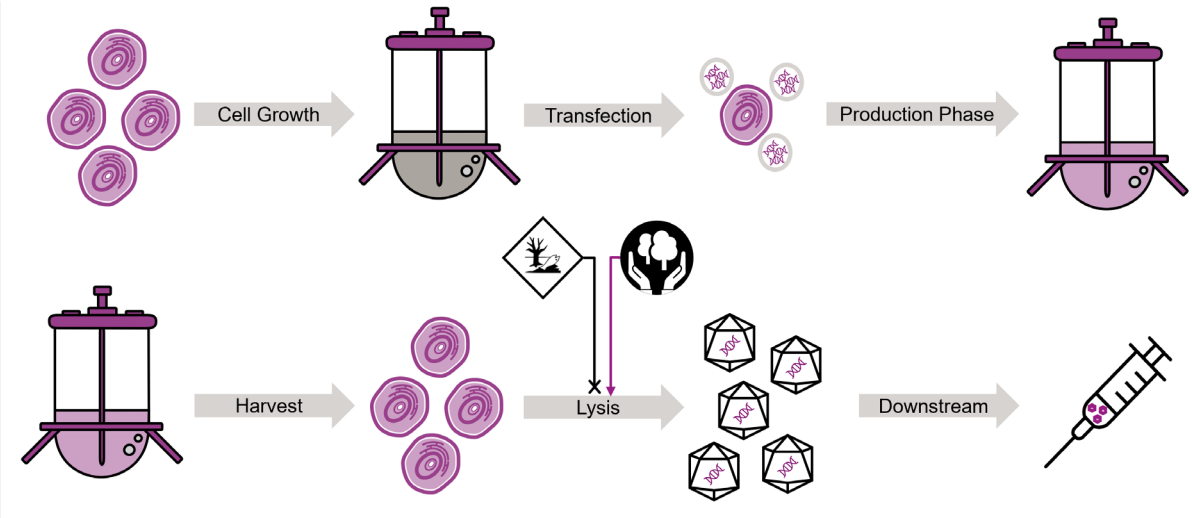
Impact on process, development considerations and Cost of Goods will be provided for the three approaches.

1476 A Functional Alternative to Triton™ X-100 for Cell Lysis in Therapeutic Virus Harvesting

Ewan Stephenson[1], Hwee Sze Ng[2], Abirramee E[1], Xavier Tan[1], Palanivel Balaji[1], Shubham Purwar[1], Johanna Peters[1], Eva Loo[1]
[1]Evonik, Singapore, Singapore, [2]Evonik (SEA) Pte Ltd, Singapore, Singapore

A lysis step is often necessary in the manufacture of cell and gene therapies. Notably for AAV-based therapeutics this is very commonly required, due to the propensity of AAVs to remain intracellular (Figure 1). At the scales necessitated by biopharmaceutical production, the only practical method for this lysis is chemical cell membrane disruption. The most common detergent for this purpose is octyl phenol ethoxylate, known more commonly as Triton™ X-100. Triton™ X-100 is near perfect for this purpose as it is efficient at disrupting membranes to release intracellular contents and yet is mild to proteins and therefore does not disrupt the viral capsid. However, it has become clear that Triton™ X-100 has a significant negative environmental impact due to its degradation products having endocrine disrupting properties which are a danger to aquatic life and potentially humans. Due to this, the EU opted to phase out the use of Triton™ X-100 in large scale, non-exempt, pharmaceutical production.

Due to these concerns, we screened a catalogue of potential alternative surfactants for efficacy along three main performance indicators: cell lysis, viral harvest and foaming. For cell lysis we targeted ~100% cell integrity disruption at 30-60 minutes, for viral harvest we targeted an agent with as good or better post-lysis viral titre compared to Triton™ X-100, for foaming our target was equal—or preferably less—foaming in a bioreactor environment compared to Triton™ X-100. We have identified a candidate in the form of a bio-based surfactant which can be produced by fermentation processes, is biodegradable, and demonstrates low aqua toxicity. We have found that this surfactant is capable of lysing mammalian cells, disrupting membranes almost entirely as early as early as 20 minutes post-exposure. In viral production processes we found this biosurfactant is capable of harvesting an AAV titre equal or exceeding Triton™ X-100 and demonstrates a lower amount of foaming in a bioreactor setup. Evaluation of compatibility with AAV downstream processes (e.g. affinity chromatography) are ongoing.



Graphical Abstract. Lysis agents are added during viral harvest, which is a key step for all intracellular viruses. The current gold standard is aqua toxic, but we demonstrate environmentally friendly alternatives can be equally functional.

1477 An Alternative to Detergent Lysis: Promoting rAAV Release to Media by Optimizing pH, osmolality and harvest timing

Christian Gagnon[1], Zeynep Guillemin[1], Shamik Sharma[2]
[1]Voyager Therapeutics, Inc., Cambridge, MA, [2]Voyager Therapeutics, Cambridge, MA

rAAV technology for gene therapy is rapidly improving, increasing the demand for high yield manufacturing techniques. The most widely used process for rAAV production - HEK293 triple transfection - utilizes a detergent lysis step at culture harvest to release rAAV particles from inside the cells. Detergent lysis improves rAAV yield,

but also generates cell debris and releases impurities such as host cell proteins, which, in combination with the detergent itself, can also impact performance of downstream purification steps such as clarification and affinity chromatography. While a majority of the rAAV resides within the cell, some percentage of rAAV is also naturally released into the cell culture media post transfection and prior to harvest. In order to eliminate the need for cell lysis, manipulations to the cell culture, such as increasing the osmolality or pH post transfection, can be used to increase rAAV released to the media. In this study we examined different high osmolality conditions and pH strategies to maximize the release of rAAV into the media. The most favorable method was able to release 95%- 100 % of the rAAV to media with yields similar to conventional detergent lysis. This material could be directly utilized for column purification without the need for a buffer exchange step. Final column purified material from both processes were compared and found to be comparable for important product quality attributes such as empty/ full capsids, residual host cell protein and DNA. This “lysis free” harvest method can be a viable alternative to traditional detergent lysis, and help decrease time and costs of rAAV manufacturing.

1478 Characterisation with Relative Quantification of AAV Capsid Particle Population Heterogeneity Using Charge Detection Mass Spectrometry in Comparison with Orthogonal Technologies

Anisha Haris[1], Kevin Giles[2], David Bruton[3], Keith Richardson[4], **Kate Yu[5]**, Michael Walker[6], Paul Getty[6]
[1]Waters Corporation, Cheshire, Cheshire, United Kingdom, [2]Waters Corporation, [3]Waters Corporation, Manchester, United Kingdom, [4]Waters Corporation, UNITED KINGDOM, [5]Waters Corporation, Milford, MA, [6]PHarmaron Biologics (KU) Ltd, Liverpool, United Kingdom

Recombinant adeno-associated viruses (rAAVs) are key vehicles for gene therapy, delivering therapeutic genes to target cells. During manufacturing, viral particles may lack the full intended insert, instead containing partial sequences or multiple small transgenes, known as partially full and overfull capsids. Assessing analytical tools to enhance characterisation of AAVs is crucial, as impurities can impact clinical efficacy, safety, and immunogenicity. We used charge detection mass spectrometry (CDMS), mass photometry, and analytical ultracentrifugation (AUC) to identify and quantify different AAV capsid populations, addressing the need for improved characterization methods to support development.

Mass analysis of AAV2 and AAV5 with different transgenes (CMV-GFP and CMV-LacZ), including their mixtures was performed on a Waters prototype CDMS instrument, with data processed and visualized using Waters’ in-house software. Ions trapped for 100 ms were recorded, and frequency information was converted to the mass domain. Only ions trapped for the full 100 ms were compiled and binned to generate histograms. The m/z, mass, and charge were binned to obtain the average, sigma, and area of each peak. Mass photometry samples were diluted appropriately before data acquisition on a Samux^{MP} system and analysed using Discover^{MP} software. Capsid populations were identified based on theoretical masses. AUC was performed using a Beckman Optima AUC instrument, and data were analysed with Sedfit software to assign capsid population identity based on measured S-values.

An assessment of the method resolution for both CDMS and mass photometry using commercially sourced model AAV material with known masses were carried out. For both serotypes with the different transgenes, identification and resolution of the varying capsid payload status, (empty, partially full, full, and overfull) was achieved using CDMS, with average mass distributions for each capsid type in good agreement with the expected capsid masses. Empty, full and overfull capsids were detected for the AAV-CMV-GFP samples whereas empty, partially filled, and full capsids were observed for the AAV samples with the LacZ insert. The relative capsid ratios were determined based on the individual capsid ion counts to the total capsid count in the AAV mass range and compared to the results from mass photometry and AUC analysis. Additionally, CDMS revealed distinct charge distributions between the two different AAV serotypes. Specifically, charge populations around 163 and 181, were detected for AAV2 and AAV5, respectively. This charge difference is likely due to a structural change, attributed to variations in the amino acid sequences of the capsid proteins. These variations can affect the surface charge, hydrophobicity, and the presence of specific motifs, ultimately influencing the virus's ability to bind to cellular receptors. Overall, the data herein demonstrates that CDMS can support extended characterisation of capsid population profiles including relative quantification of individual capsid types.

1479 Comparison of Mass Photometry (MP) and Charge Detection Mass Spectrometry (CD-MS) in AAV Characterization

Yuyan Wang[1], Benjamin Draper[2], Jiantao Zhang[1], Qizhao Wang[3], Martin Jarrold[4], Cuiping Chen[1]
[1]AAVnerGene, Rockville, MD, [2]Megadalton Solutions, BLOOMINGTON, IN, [3]AAVnerGene Inc, [4]Bloomington, IN

Adeno-associated virus (AAV), a key vector in gene therapy, requires precise characterization to ensure production quality control and successful clinical applications. Quantification of empty, partial, full capsids is an important critical quality attribute. This work leverages Mass photometry (MP) and charge detection mass spectrometry (CD-MS), two advanced techniques, to characterize 16 different serotypes manufactured by the same process containing the same AAV-CAG-EGFP genome. Overall, AAV with high productivity, such as AAV9 and AAV8, have high full particle ratios and less impurities. MP, an optical scattering-based technique, stands out for its label-free, rapid, low-sample-consumption, and highly efficient analysis. It can quickly differentiate between empty capsids, partially filled capsids, and full capsids based on mass differences. As an optical technique the mass is inferred from the scattered light of capsids with different masses scattering more light. MP has been positioned as the standard for rapid in-process monitoring of AAV capsids, but is limited in resolution, detection of large aggregates and correlating size dispersity to mass. CD-MS is a mass spectrometry technique that determines the mass of particles by directly measuring the *m/z* and charge of ions. CD-MS offers high resolution, high sensitivity, and single-particle analysis capabilities, enabling simultaneous measurement of mass and charge of AAV particles but commercial instruments are not yet widely available. Moreover, CD-MS is able to assess the heterogeneity of the packaging based on the measured peak widths as well as extracting the genomes and measuring them directly, which has not been shown by MP. The serotypes each have different viral protein masses which can be measured by CD-MS and this work shows a valuable comparison to the response of small mass changes to mass photometry. There is tremendous value in comparing CD-MS and MP, not only for profiling E/P/F capsids but also for correlating low molecular weight and aggregate measurements from both techniques. This comparison can help inform best practices for addressing the differences between the methods. Throughout the development and formulation of AAV, both techniques can be used in combination. By leveraging the availability, low sample consumption and in-process monitoring of MP alongside the high-resolution data attained from CD-MS, the combed strengths of these methods offer a more efficient and accurate approach to comprehensive AAV vector characterization.

1480 Rapid and Accurate AAV Capsid Quantification Using Multi-Angle Dynamic Light Scattering (MADLS) for In-Process Gene Therapy Manufacturing

Tiffany Pan[1], Venkata Kuppireddy[1], **Irene Song**[2], JIn Qiu[3]
[1]PackGene Biotech INC, Houston, TX, [2]Packgene Biotech, Houston, TX, [3]PackGene Biotech INC, Houston, MA

Adeno-associated viruses (AAVs) are widely utilized as vectors for gene delivery in therapeutic applications. Precise quantification of AAV capsid titers is crucial for ensuring consistent product quality and safety during manufacturing. Current methods such as ELISA, while effective, are time-consuming and involve multiple steps, including incubation and washing, which may limit their suitability for quick paced in-process sample testing.

We conducted a study to evaluate Multi-Angle Dynamic Light Scattering (MADLS) as a rapid and reliable alternative method for measuring AAV capsid titer, particle size, and aggregation. Unlike ELISA, the MADLS assay is a one-step process that requires no sample manipulation and yields results in under 10 minutes. This feature makes MADLS particularly suitable for real-time, in-process testing, enabling faster decision-making during AAV manufacturing.

Our findings show that MADLS provides results comparable to ELISA in terms of accuracy, while significantly reducing the time required for analysis. The method's capability to perform repeated measurements without time constraints further enhances its utility in ensuring consistent product quality across multiple stages of the production workflow. Additionally, MADLS eliminates the need for complex sample preparation, thereby reducing the potential for operator-induced variability.

The adoption of MADLS in AAV manufacturing reflects the growing need for fast, precise, and simple nanoparticle characterization in gene therapy, pharmaceuticals, and medical applications. By streamlining key analytical processes, MADLS enhances manufacturing efficiency, accelerates production timelines, improves process control, and ensures consistent product quality, ultimately enabling the faster delivery of high-quality gene therapy products to meet patient needs.

1481 Highly Accurate Direct Mass Measurement of Extracted AAV Genomes Coupled with Intact Capsid Analysis to Assess Sequence Integrity and Viral Protein Ratio by Charge Detection Mass Spectrometry

Benjamin Draper[1], Lohra Miller, Junping Zhang[2], Weidong Xiao[3], Martin Jarrold[4]
[1]Megadalton Solutions, BLOOMINGTON, IN, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Indiana University, Indianapolis, IN, [4]Bloomington, IN

Recombinant adeno-associated virus (rAAV) is a non-pathogenic virus that has shown continued success as a gene therapy vector. Previous studies have shown charge detection mass spectrometry (CD-MS) can resolve and quantify empty, partial, and full capsids. More recently, CD-MS characterized an AAV8 construct with multiple vector packaging and found that, due to the heterogeneity caused by the stochastic nature of viral protein incorporation, intact mass measurements cannot resolve peaks with less than a 700 nt difference between two packaged sequences. Through a combination of throughput and resolution advances we present a new assay for the accurate mass measurement of packaged DNA. Previously, mass measurements by both CD-MS and Mass Photometry have determined the mass of the packaged contents by calculating the mass difference between DNA containing peaks and the empty capsid peak. This measurement relies on the assumption that the protein mass of the DNA containing capsids and the empty capsid are equal, which recent data suggest is not the case. This new assay allows for a more complete understanding of the nature of packaging and confirmation that expected gene of interest is packaging in capsids centered around the correct viral protein ratio.

In addition to a more complete understanding of the packaging of AAV the direct mass measurement of the DNA is highly accurate and can be correlated to a sequence length with a <1% uncertainty. The high resolution measurement of the DNA has also shown peak widths far narrower than the protein heterogeneity intrinsic to intact capsids. As a consequence multiple vector packaging can now be quantified below the previous 700 nt limit.

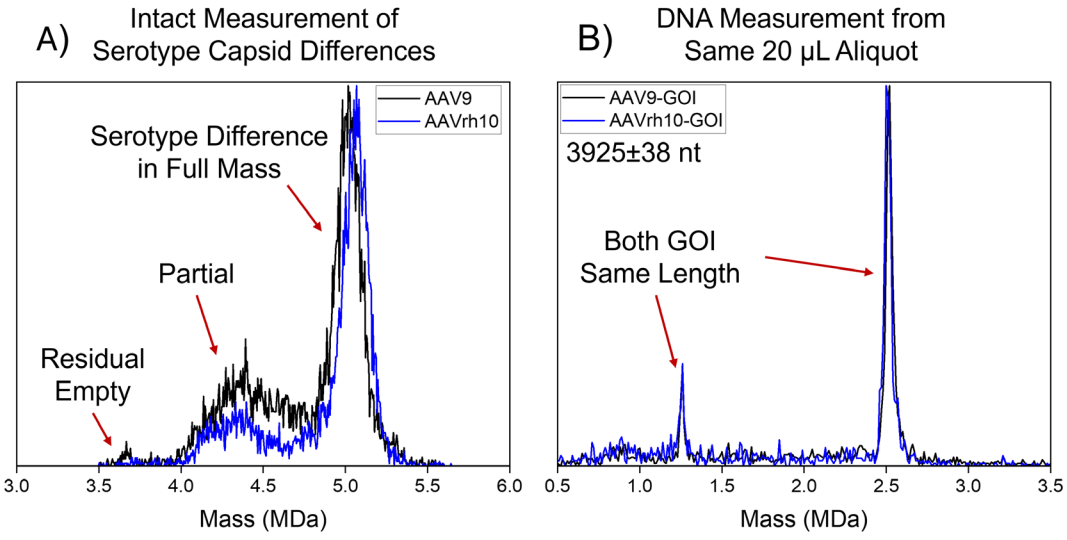


Figure 1. CD-MS Mass measurements of a) two AAV serotypes AAV9 (black) and AAVrh10 (blue) with the corresponding CD-MS mass measurements of the extracted DNA of the two serotypes intact GOI, AAV9 (black) and AAVrh10 (blue) in b).

1482 Direct Monitoring of rAAVs in Crude Cell Lysate and Conditioned Medium

Yuki Yamaguchi[1], Saki Shimojo[2], Risa Shibuya[2], Karin Bandoh[3], Aoba Matsushita[4], Mitsuko Fukuhara[4], Yasuo Tsunaka[2], Tetsuo Torisu[5], Susumu Uchiyama[6]*
[1]Osaka University, Suita-shi, Osaka, Japan, [2]Osaka University, Suita, Osaka, Japan, [3]Osaka University, JAPAN, [4]U-Medico, Inc., Suita, Osaka, Japan, [5]Osaka University School of Engineering Graduate School of Engineering, JAPAN, [6]Osaka University, Osaka, Japan, Japan
**Corresponding Author*

Recombinant adeno-associated virus (rAAV) has been attracted as a gene therapy vector. rAAVs are mostly produced by the transfection of three plasmids with human or insect cells. The rAAVs produced by these processes usually contain both full particles (FP) that encapsidate a designed full-length genome and empty particles (EP) that have no encapsidated genome, and sometimes contain partial particles that encapsidate an incomplete genome or over-packaged particles which encapsidate the genome more than FP. The particle besides FP are considered as product-related impurities and must be removed; however, it is difficult to completely remove these impurity particles because their outer shell, the capsid, is almost identical to FP. Thus, several researchers have studied to improve the percentage of FP to the total particles at the production stage by optimizing plasmid ratio, the transfection pH, production pH, complexation time, viable cell density at transfection, and transfection reagent to DNA. To promote these upstream optimizations, it is required for the method which can immediately analyze genomic titer and FP ratio of rAAV without performing subsequent purification steps.

Here, we established the direct analysis method for identifying FP and EP and quantifying the F/E ratio and genomic titer of unpurified rAAV in crude cell lysate and conditioned medium. Our established method can quantify the F/E ratio of rAAV in cell lysate, with a good correlation by linear fitting, with a slope of 0.892 and an R^2 value of 0.993, which is almost same accuracy for purified sample with a good correlation with linear fit (Slope = 0.914, R^2 = 0.993). The rAAV particle counts in the cell lysate which were obtained also showed an excellent linearity, with a range of 3.91×10^9 to 7.00×10^{11} vg/mL, the R^2 value of 0.998, and the %CV within 25%, indicating that our established method can estimate the genomic titer. Then, we analyzed the crude cell lysate which is a culture medium containing post-transfected cells producing rAAV to which lysis buffer containing a surfactant is added. For crude cell lysates that produced rAAV2, rAAV8, and rAAV9, the F/E ratios of rAAV2, rAAV8, and rAAV9 were determined to be 9.8%, 20.3%, and 24.8%, respectively, and genomic titers were 2.10×10^{11}vg/mL, 3.21×10^{11}vg/mL, and 2.10×10^{11}vg/mL, respectively. Finally, the analysis of conditioned media producing rAAV8 at 24, 48, and 72 hours post-transfection (hpt) showed an increase in the FP count was observed in a time-dependent manner, whereas the F/E ratio was higher at 72 hpt compared to that at 48 hpt. For the conditioned medium of rAAV8 at 72 hpt, genomic titer estimation resulted in 2.30×10^{11} vg/mL. Compared with the cell lysate collected at 72 hpt, the genomic titer in the conditioned medium was 71.7% of that in the cell lysate. In previous studies, the proportion of rAAV8 present in the conditioned medium relative to the cell lysate was reported to be 70-85% of rAAV8, which is consistent with our obtained values. These results demonstrates that our established method can quantify unpurified rAAV and have potential to facilitate the optimization of rAAV production process, including screening of production conditions.

1483 Real-Time Monitoring of AAV Empty:Full Capsid Separations using Near Infrared High-Precision Tunable Laser Spectroscopy

Bryan Hassell, Nirrin Technologies, Billerica, MA

Adeno-associated virus (AAV) vectors are a cornerstone of gene therapy, but their efficacy and safety depend heavily on the ratio of empty-to-full capsids. Traditional analytical methods for monitoring this critical quality attribute (CQA) during purification processes, such as ultracentrifugation and mass photometry, can be time-intensive and laborious, while rapid methods such as AEX-HPLC and SEC-MALS can typically not resolve partial from full capsids. Here, we present a novel approach utilizing Near Infrared (NIR) High-Precision Tunable Laser Spectroscopy (HPTLS) for real-time monitoring of AAV empty-to-full capsid ratios using chromatography. Nirrin Technologies' proprietary HPTLS technology enables high-resolution spectral separation of capsid species, providing quantification of full and empty capsids in real-time. This method eliminates the need for extensive

sample preparation while maintaining accuracy comparable to traditional methods. The integration of HPTLS into downstream bioprocessing workflows enhances process control, enabling rapid decision-making and reducing production timelines. This work demonstrates the potential of HPTLS to transform AAV purification through non-invasive, real-time analytics.

1484 Leveraging TruTiter™ Technology to Overcome Thermal Stability Challenges in Engineered AAV Quantitation

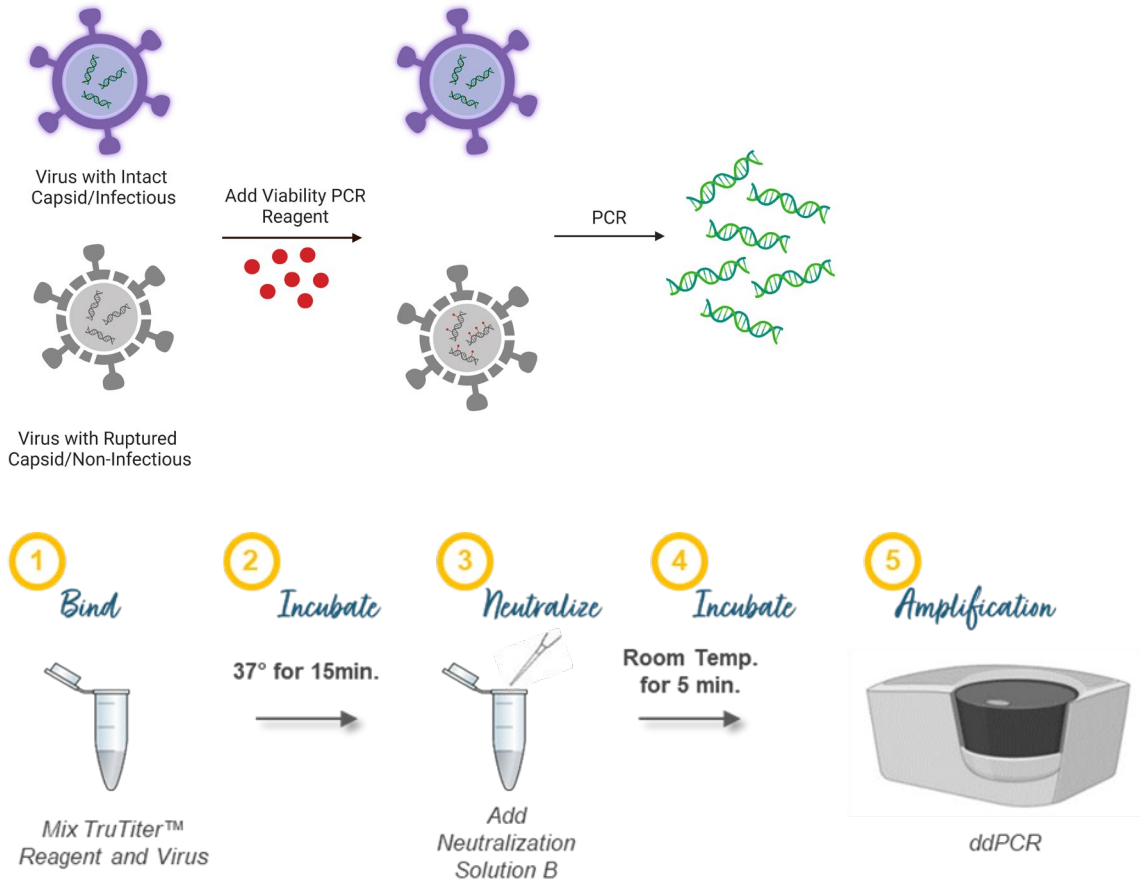
Nathan Feirer[1], Chris DJamoos[2], Jeff Nelson[3], Subhanjan Mondal[4]
[1]Promega Corporation, Fitchburg, WI, [2]Promega Corporation - Madison, WI, Brighton, MI, [3]Promega Corporation, Madison, WI, [4]Promega Corp, Fitchburg, WI

Adeno-associated virus (AAV) is one of the most commonly used vectors for gene therapy delivery. One of the main challenges for AAV gene therapy is the development of effective quality control and quality assurance protocols, as accurate quantification and characterization of AAV production batches is essential for proper clinical dosing. Current protocols are often inadequate, leading to a high degree of lot-to-lot variability, often resulting in non-optimal trial outcomes due to inaccurate determination of functional gene dosage.

Present methods of AAV characterization rely on a combination of mammalian infectivity assays and digital PCR coupled with DNase pre-treatment. These approaches are often cumbersome and lack the precision needed for accurate determination of viral titer. The workflow described below uses a novel small molecule (Viability PCR Reagent) pre-treatment approach to estimate the functional AAV titer in a viral preparation. The Viability PCR Reagent, owing to its small size, has enhanced accessibility to exposed nucleic acids from damaged viral or non-viral sources. Furthermore, use of this reagent suppresses the PCR signal more consistently from such exposed nucleic acids, allowing for a more precise determination of functional AAV titer. This new platform, called TruTiter™, enables users to quantify AAV preparations in a more robust and accurate manner.

Engineered AAV capsid variants are often used in gene therapy approaches to escape immune system detection and degradation, an effect commonly seen with WT AAV variants. In this study, we used TruTiter™ technology to quantitatively titer four AAV2 engineered capsid variants. For all four variants, the TruTiter™ workflow resulted in higher titers compared to a traditional DNase-pretreatment workflow. Using digital PCR, TruTiter™ treated samples exhibited two to four-fold higher gene titers compared to the same variant treated with DNase, resulting in a quantitative measure that was closer to the expected value. We hypothesized that the decreased titer observed with DNase-treated samples was due to the potential reduced thermal stability of the engineered AAV2 capsid variants. To test this, SYPRO Orange dye was used to perform differential scanning fluorimetry (DSF), which can differentiate general capsid stability between AAV variants. Using DSF, clear differences were observed between WT and engineered AAV2 capsids.

Overall, this data suggests that the TruTiter™ workflow can better address the challenges associated with the accurate titering of AAV capsid variants compared to traditional workflows.



1485 Quantification of Full, Empty, and Partial Particles of AAV8 Reference Standards From Multi-Lab Study

Anthony Blaszczyk[1], Amy Liu[1], Li Ma[1], Benjamin Clarke[2], Jerome Jacques[1]
[1]*United States Pharmacopeia, Rockville, MD,* [2]*US Pharmacopeia, Germantown, MD*

Background: Gene therapy is rapidly emerging as a leading field in the biopharmaceutical industry, with Adeno-associated virus (AAV) at the forefront due largely to its safety and efficacy. These factors have spurred an increase in new technologies and new applications for existing technologies used for biophysical analysis of AAV, specifically for analysis of empty, full, and partial capsids. However, the lack of well-characterized standards has hindered the adaptation of many of these new technologies. Because limitations exist for every well-established AAV empty/full characterization methods, all the commercially available AAV materials, which are typically only analyzed using one method, lack characterization data representative of these innovative methods. By not having this benchmark material, development and adoption of new methods has been hampered.

Results: In this study, AAV8 (Empty Capsids) and AAV8 (Full Capsids) standards, which will be made available to the public, were analyzed using six different methods, Analytical Ultra Centrifugation (AUC), Size-Exclusion Chromatography with Multi-Angle Light Scattering (SEC-MALS), Charged Detection Mass Spectroscopy (CD-MS), Cryogenic Electron Microscopy (cryo-EM), Mass Photometry, and UV-vis. The samples were analyzed in a collaborative study with five participating laboratories. Herein, we present and compare data from these studies. Data from each method show that the AA8 (Empty Capsids) and AAV8 (Full Capsids) do indeed contain

predominantly empty and full capsids, respectively. In addition to empty/full capsid analysis, AUC, CD-MS, and Mass Photometry were able to successfully quantify partially filled capsids. The AAV samples were also analyzed by other biophysical methods, including Peptide Mapping, Next Generation Sequencing (NGS), Digital PCR (dPCR), and Capillary Gel Electrophoresis (CGE), to further characterize these particles. Results from these analyses provided quantitative data on the following attributes: capsid titer, genomic titer, capsid purity, aggregation, capsid identity, genome integrity, and genome identity. The totality of data collected from these various tests, which measure various critical quality attributes, will be presented.

Conclusion: Thorough characterization of AAV reference standards was completed in this study. The data gathered in this study, in conjunction with the public availability of this material, has the potential to greatly help advance the adaption of new AAV technology, by providing material that can be used for accurate assessment of new or existing methods. These data can be useful to early-stage researchers and commercial manufacturers alike, as these standards can be used from early development to validation and through commercialization. We hope that these studies can be used to leverage the advancement of additional new technologies to further support AAV development. Furthermore, many of the methods assessed in this study are commonly used for characterizing other gene therapy products, such as Lentivirus, which further expands the application of this study.

1486 Comprehensive Analytic Tools Comparison for Empty, Full, and Partial Genome Characterization of Adeno-associated Viruses Show Need for Parallel Assay Verification

Linda Chio[1], Chase Bowman[2], Carmen Le[3], Chris Towne[1], Francisco LePort[2], Martin Borch Jensen[4]
[1]Gordian Biotechnology, San Francisco, CA, [2]Gordian Biotechnology, South San Francisco, CA, [3]Gordian Biotechnology, South San Francisco, [4]Gordian Biotechnology, San Francisco, California

Recombinant adeno-associated virus (rAAV) gene therapies are most commonly produced in mammalian HEK cell lines using transient triple transfection methods leading to nonhomogeneity in the final drug product. Empty and partially-filled viral capsids have been identified as major contaminants in the production method and could have adverse effects upon administration. It is important to characterize these contaminants in a fast and robust manner to accelerate the manufacturing process. We characterized AAV produced by three common methods: adherent HEK cells with iodixanol ultracentrifugation, adherent HEK cells with affinity chromatography, and suspension HEK cells with affinity chromatography. We subsequently tested AAV enrichment through cesium chloride (CsCl) ultracentrifugation and anion exchange chromatography (AEX). Herein we compare different analytical and long-read sequencing assays to identify full-empty capsid ratios and confirm genomic integrity of our AAV gene therapy products. We highlight differences between the methods and the need for parallel verification to characterize AAVs.

Several analytical methods were compared to assay empty-to-full capsid ratios as compared to the current gold standard method of analytical ultracentrifugation (AUC): mass photometry (MP), vector genome and capsid titers, and transmission electron microscopy (TEM). We show that MP had the highest qualitative correlation, genome/capsid titers gave high qualitative correlation but suffered from poor quantification, and TEM had low concordance as compared with AUC. Notably, we show that the transfection system and purification methods contribute to varying levels of empty capsids in the rAAV gene therapy. The quantitative disagreement between the methods show the need to pre-qualify the assay with suitable AAV controls when determining empty-full ratios, and supports the use of MP as a faster and cheaper method of characterization.

We also showed the utility of long-read sequencing to assay empty-full capsid enrichment of vectors. Empty AAV capsids were removed from our gene therapy product using either CsCl ultracentrifugation and fractionation or AEX. Individual fractions as well as the final pooled sample were analyzed using PacBio Single Molecule Real Time (SMRT) sequencing. Long-read sequencing methodologies have a tendency to overrepresent shorter genomic fragments, and we needed an orthogonal assay of alkaline agarose gels to confirm genomic integrity of the our AAV samples. Additionally, these data offered the ability to improve the empty removal process and highlighted the difficulty of enrichment of full length AAV genomes from partial AAV genome containing capsids.

Characterization remains challenging for rAAV for gene therapy due to the high nonhomogeneity of the final drug product. We comprehensively compared different AAV upstream, downstream, and analytical methods. Our data supports the need to add suitable controls, prequalify assays, and run orthogonal or parallel methods to characterize the rAAV drug product.

1487 Development of a High Throughput Flow Cytometry *in vitro* Relative Potency Assay as an Analytical Tool to Support rAAV Process Characterization

Julia Zalewski[1], Samantha Powers[1], Ryan Pasquino[1], Adam Studebaker[1], Adam Davis[1], David Dismuke[1]
[1]*Forge Biologics, Grove City, OH*

In an ever-changing landscape of manufacturing optimization for recombinant adeno-associated virus (rAAV) vectors, a high throughput, quantitative process characterization method is required for efficient confirmation of control over the manufacturing process. Specifically, confirmation of similar potency is necessary to support comparability of processes for drug product use in the clinic. Relative *in vitro* potency assays can directly compare vectors prepared from two processes. However, *in vitro* potency assays are often product specific and necessarily slow to develop and implement. Here, we present the development of a high throughput flow cytometry based *in vitro* potency assay to detect vector derived eGFP expression, and successful implementation of the assay to quantify relative potency between two different manufacturing processes.

Forge Biologics has previously discovered that decreasing the size of the pEMBR™ Ad Helper plasmid increased rAAV yield. In order to assess the biological activity of vectors produced from pEMBR™ 1.2 and pEMBR™ 2.0 Ad helper plasmids we successfully developed an AAV9.eGFP *in vitro* relative potency assay. The assay determines the potency of AAV9.eGFP through quantification of eGFP expressed by cells after viral transduction. Briefly, Lec2 cells were transduced with AAV9.eGFP vector in serum-free media then harvested 48 hours post-transduction for a flow cytometry fluorescein isothiocyanate (FITC) channel fluorescent readout denoting eGFP positive or negative cells and median fluorescence intensity. Relative potency determination was calculated from four-parameter logistic (4PL) log(dose)-eGFP percent positive response curves using PLA 3.0 software.

Assay development evaluated multiple parameters including (i) dose levels, (ii) harvest conditions, (iii) plate coating, (iv) transduction conditions, and (v) cell line screening. System and sample suitability acceptance criteria were confirmed for (i) linearity across nine dose levels, resulting in an $R^2 \geq 0.90$, (ii) accuracy, confirmed by quality control fluorescent microspheres, (iii) precision, demonstrated by percent eGFP positive coefficient of variation across three biological replicates, (iv) specificity, demonstrated by the non-transduced percent eGFP positive $\leq$ 0.05%. The samples evaluated had a similar biological response, thus demonstrating equivalent potency estimation using PLA 3.0 software. The confirmation of similar potency supports the transition from pEMBR™ 1.2 to pEMBR™ 2.0 Ad helper plasmid to increase rAAV yield.

In conclusion, the herein presented potency assay can support future process characterization with AAV9.eGFP and would only require minor modification to translate to other AAV serotypes. This robust platform assay data can be leveraged as a surrogate process characterization for clients' who switch to the FUEL™ platform, Forge's new AAV manufacturing platform that incorporates pEMBR 2.0, our modified rep/caps, and foundation Ignition cells™ for more efficient manufacturing at various stages. In a fast-paced field with constant research breakthroughs, an actionable, rapid system in place to confirm similarity will save time and money when there are process changes, design changes, and molecular breakthroughs in the future.

1488 Smartphone-based Titration of AAV Vector Preparations

Thomas Quinn[1], Lily Lee[1], Mei Fong[1], Andre Dharmawan[1], Yi Zhao[1], MD Myn Uddin[1], Michael Haugwitz[1], Andrew Farmer[1]
[1]*Takara Bio USA, San Jose, CA*

Adeno-associated virus (AAV)-based vectors have gained widespread recognition for their potential in gene therapy, thanks to their exceptional safety profile and ability to sustain long-term gene expression. With over 130 clinical trials and eight approved gene therapy products, AAV has emerged as one of the most reliable and versatile tools for delivering therapeutic DNA directly into living organisms. The AAV expression system offers several advantages, including efficient transduction, broad tropism, stable high yields, and compatibility with gene-editing components. Recombinant AAV is typically produced through the co-transfection of 293 cells with vectors containing an ITR-flanked expression cassette, adenoviral helper sequences, and AAV Rep/Cap genes. Successful application of a recombinant AAV vector relies on knowing the titer of the AAV preparation, as it permits calculation of the multiplicity of infection, which can influence the final expression level of the recombinant protein in transduced cells. Quantitative real-time polymerase chain reaction (ddPCR or qPCR), ELISA, cell-based infectious unit assays, and transmission electron microscopy (TEM) have all been used to determine AAV titers. However, these methods are time-consuming and labor-intensive, with time-to-results ranging anywhere from two hours to multiple days. In this work, we present an iOS and Android-compatible smartphone application that analyzes a serotype-specific lateral flow assay and can deliver particle number values in 10 minutes. The two-step assay consists of adding a small amount (20 µl) of AAV-containing supernatant to the lateral flow device, followed by imaging of the device and analysis of the resulting signal intensity using a smartphone. Densitometric analysis of the observed bands is performed by the intuitive GoStix Plus software, which compares the results to an automatically downloaded, lot-specific standard curve (R2 greater than 0.990). The result is a GoStix Value that, like an IFU or qPCR assay, can be used to normalize virus stocks before being used for transduction. To demonstrate the utility of GoStix Plus assays as compared to ELISA, qPCR, and infectious unit assays, we used a ZsGreen1-expressing AAV2 vector. The tests demonstrated that GoStix titer values fall within three-fold of current titration methods with coefficients of variation of less than 15%, indicating comparable precision to ELISA-based approaches. In addition, we were able to quantify AAV in both crude and purified preparations, with detection ranging from 5 × 10^8 to 1 × 10^10 particles/ml. The simplicity of the assay facilitates easy monitoring and optimization of AAV production processes to ensure consistency and confidence in downstream applications. In summary, this highly convenient, lateral flow-based titration technology can quantify AAV vector preparations in approximately 10 minutes, saving time, reducing expenses related to labor and materials, and accelerate AAV vector production and application.

1489 Quality analysis and biological evaluation of AAV particle derived from AAV stable Producer cell line

Satomu Ishii[1], Yusuke Mori[2], Yuki Uchida[3], Taichi Muraguchi[4]*, Takaaki Kurinomaru[5], Mitsuko Fukuhara[6], Susumu Uchiyama[5]
[1]FUJIFILM, Ashigarakamigun, Kanagawa, Japan, Japan, [2]Kaisei-machi, Ashigarakami-gun, KANAGAWA, JAPAN, Japan, [3]FUJIFILM, Kaisei-machi, Kanagawa, Japan, [4]FUJIFILM Corporation, Ashigarakami-gun, Kanagawa, Japan, [5]U-Medico Inc., Suita-city, Osaka, Japan, [6]U-Medico, Inc., Suita, Osaka, Japan
**Corresponding Author*

Introduction: Plasmid-polymer complex transfection (Triple Transfection) method is widely used for the production of recombinant adeno-associated virus (AAV). On the other hand, we are developing a cell line in which the genes necessary for AAV production is integrated into the chromosome of human cell line, AAV stable Producer Cell Line (PCL), which does not require huge number of plasmids and transfection reagents for the AAV production. Because AAV production using the developed PCL is novel method, in this study, we attempted to confirm the equivalence of the quality of the particles and their biological titer based on the comparison of AAV produced by the Triple Transfection (TT) method and PCL.

Methods: PCL or TT derived full particle of AAV5 (GOI is GFP) purified by ultracentrifugation were used. The size distribution of the AAV particles were determined by analytical ultracentrifugation (AUC). The viral protein (VP) stoichiometry was analyzed using capillary gel electrophoresis. The biological titer was evaluated by exposing the same number of particles to HeLa cells and measuring the positive rate of GFP.

Results and Discussion: The sedimentation coefficients of AAV produced by TT and PCL obtained from AUC were the same, that means the encapsuled DNA length and shape of AAV were equivalent to each other. The value was consistent with the theoretical one based on the designed GOI length, suggesting that PCL could package GOI

into AAV correctly. The results from the capillary gel electrophoresis of AAV produced by TT and PCL showed that VP stoichiometry were similar to each other, indicating PCL produced the three VPs, assembled them in the same ratio as in TT method. In addition, GFP positive rate showed transgene expression was equivalent.

Conclusion: This study suggests that AAV particles produced by PCL have the same biological function and quality as AAV produced using TT method. PCL based AAV production is expected to be an alternative to TT method.

1490 Tailored AAV Solutions: AAV ELISA Kits and Customized Variant Kit Development

Hannah Flaherty, KACTUS, Waltham, MA

Adeno-associated viruses (AAVs) are indispensable tools for gene delivery, with diverse serotypes and engineered variants targeting various therapeutic applications. Accurate AAV capsid titer determination is critical for clinical use, yet the weak immunogenicity of AAVs poses challenges in generating high-quality monoclonal antibodies (MAbs). To address this, KACTUS Bio has developed a proprietary immunization scheme, significantly enhancing anti-AAV serum titers across multiple serotypes, including the notoriously low-immunogenicity AAV2. This breakthrough enables the production of premium monoclonal antibodies, forming the foundation of KACTUS's robust AAV ELISA kits.

These kits exhibit exceptional precision, broad quantification linear ranges, and superior signal-to-noise ratios compared to leading competitors. Stability testing confirms their reliability under varied conditions, and their intra- and inter-assay precision consistently meet stringent CV thresholds below 10%. Additionally, the kits maintain high recovery rates, ensuring minimal interference from assay matrices. KACTUS's expertise extends to customized AAV ELISA kits tailored to specific variants, providing gene therapy companies with reliable solutions for precise AAV quantification.

1491 Development of *in vitro* methods for the analysis of TLR9 stimulation by AAV vector genomes.

Justin Glenn[1], Metewo Enuameh[2], Olivier Danos[2], Ye Liu
[1]Regenxbio, Rockville, MD, [2]REGENXBIO Inc., Rockville, MD

Pro-inflammatory innate immune responses to the AAV genome are significant obstacles to successful, long-term transgene expression and re-dosing efforts. Engagement of particular AAV genomic components and Toll-like receptor-9 (TLR9) leads to the production of Type-I interferons and inflammatory cytokines that enhance dendritic cell-mediated T cell activation. Activated cytotoxic T cells ultimately promote loss of transgene-expressing cells. Given the imperativeness of assessing AAV genomic immunogenicity prior to patient administration, rapid and reliable *in vitro* methods to achieve this goal are needed. In this study, we utilized a modified AAV receptor-expressing, murine macrophage cell line (RAW264.7-AAVR) and primary human peripheral blood mononuclear cells (hPBMCs) to measure TLR9 activation via flow cytometry following stimulation by AAVs harboring different amounts of known TLR9 agonists in their genome using three separate approaches.

In the first approach, we sought to determine whether reduction of Ik-B-alpha protein, a negative regulator of NF-kB that is rapidly degraded following TLR9 stimulation, in RAW264.7-AAVR cells could be used as an indicator of TLR9 stimulation. Following kinetic addition with AAV9 genomes at MOI of $1x10^7$, IkB-alpha protein was reduced

by 60% as early as 1 hour following vector genome stimulation, and the extent of reduction was dependent on the amount of TLR9 agonists present within the genomes.

We also discovered that the upregulation of inducible nitric oxide synthase (iNOS) could be used as a readout of AAV genome-mediated TLR9 stimulation. Vector DNA with higher agonist concentrations significantly increased both the percentage and expression levels of iNOS in the RAW264.7-AAVR cell line compared to vectors with lower agonist amounts. iNOS expression was upregulated downstream of TLR9 engagement since pre-incubation with the TLR9 antagonist ODN2088 prevented iNOS induction. Extending experimental assessment to human cells, we found that AAV addition to hPBMCs led to production of IFN-alpha and IL-6 in CD11c+ DCs. Similar to the murine macrophage cell line, cytokine expression was directly proportional to the amount of TLR9 agonist in the AAV genome.

Our studies demonstrate that multiple *in vitro* assays can be developed to detect and measure TLR9 stimulation and predict the innate immunogenicity of AAV vector genomes.

1492 Elucidating the Mechanisms of Hepatic induced Tolerance Following Liver-Directed AAV Gene Therapy

Cristina Gaddie[1], Christopher Chan[2], **Geoffrey Keeler[2]**
[1]University of Florida, [2]University of Florida, Gainesville, FL

The use of hepatic AAV gene transfer has been shown to result in tolerance induction to the transgene. This tolerance is attributed to the formation of Ag-specific $CD4^+Foxp3^+$ Tregs, and, anergy/deletion of transgene-specific effector $CD4^+$ T cells. We have seen this in our own work where we showed that liver directed AAV gene therapy results in a significant increase in Ag-specific $CD4^+Foxp3^+$ Tregs capable of reversing EAE (*Mol Ther*. Sep 19 2017;doi:10.1016) However, it is currently unknown if $CD4^+Foxp3^+$ Tregs are solely responsible for the induction and maintenance of immune tolerance following liver-directed AAV gene therapy. Interestingly, in other work we showed that liver-directed AAV gene therapy also resulted in a significant up-regulation of CD8 regulatory cells suggesting other regulatory cells may play a role in the induction and maintenance of tolernce.

In this work we investigated whether $CD4^+Foxp3^+$ Tregs are needed to induce and maintain tolerance. We utilized the experimental autoimmune encephalomyelitis model of multiple sclerosis due to previous findings showing $CD4^+Foxp3^+$ Tregs played a role in tolerance induction (*Mol Ther*. Sep 19 2017;doi:10.1016). We also utilized the $Foxp3^{DTR}$ mouse strain to allow $Foxp3^+$ cells to be rapidly depleted upon administration of Diphtheria toxin. Using this model, we were able to determine that $CD4^+Foxp3^+$ Tregs are required to induce/establish immune tolerance via liver-directed AAV gene therapy (Fig 1). However, within 3 days these cells are no longer needed to maintain tolerance and their ablation does not result disease re-establishment (Fig 1). Interestingly, ablation of Foxp3 cells results in a significant increase in CD8 regulatory cells (Fig 1). Elucidating the mechanisms of tolerance induction following hepatic AAV gene transfer will result in the development of improved therapies.

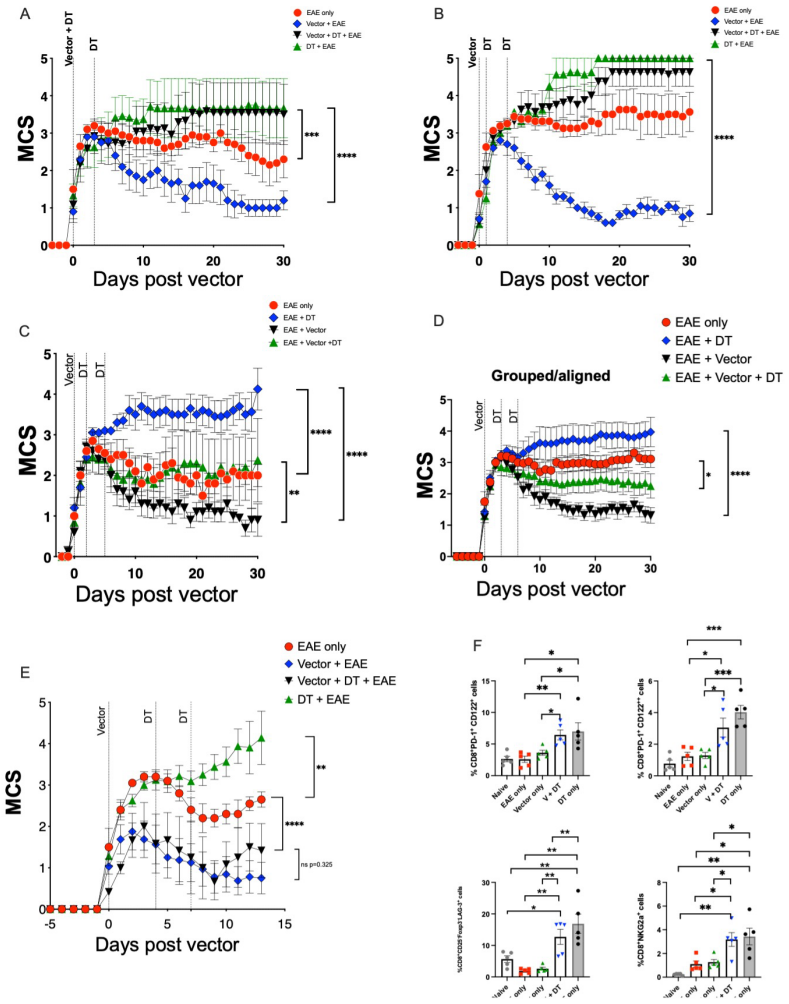


Fig 1: Defining the role of regulatory cells in tolerance induced following hepatic AAV gene transfer. A-E) EAE was induced and Foxp3 Tregs were ablated at various timepoints in relation to vector administration. Tregs are necessary for tolerance onset but not for maintenance. **F)** Treg ablation results in significant up-regulation of multiple CD8 regulatory cell subsets.

1493 Evaluating Immune Responses to AAV Transgenes in THP-1 Cells

Blake Williams[1], Robert Jimenez[2], Melissa Spencer[2]
[1]UCLA, Foster City, CA, [2]UCLA, Los Angeles, CA

The host immune response poses a significant challenge to safe and efficient systemically delivered adeno-associated virus (AAV)-mediated gene therapies. The immune system recognizes all components of the AAV vector including capsid, transgene, and the protein product of the transgene through many different cellular and molecular sensors. Plasmacytoid dendritic cells (pDCs) recognize unmethylated CpG motifs in the AAV genome via Toll-like receptor 9 (TLR9), exacerbating innate immune responses and priming adaptive immunity for a stronger and more deleterious response. A common approach to mitigate this response is to reduce CpGs in the AAV genome. However, CpG depletion may not guarantee reduced downstream immunity, as nucleotides adjacent to these motifs may influence their binding and activation of TLR9. Wright et al. (2020) proposed formulae to calculate the risk factor (RF) of a DNA sequence that considers the %CpG, the tetranucleotide motifs 5'-NCGN-3', and CpG

methylation, potentially providing a more physiologically relevant measure of the immunogenicity of AAV transgenes. However, this formula is theoretical and has not been validated *in vitro* or *in vivo*. To test the validity of RF scores and provide a biological readout of AAV transgene immunogenicity, we developed an assay using THP-1 cells to compare a number of AAV vectors with varying RF scores.

THP-1 cells express TLR9 and certain pDC markers in their undifferentiated state, supporting their use as an *in vitro* model of pDCs. THP-1 cells exhibit a minimal inflammatory response to AAV alone. However, when AAV is opsonized with IgG to form immune complexes, these enter THP-1 cells at higher rates in an FcγR-dependent manner, subsequently increasing pro-inflammatory cytokine expression. Notably, *CXCL10* expression is triggered by AAV packaged with a transgene as well as by CpG DNA but fails to increase with AAV capsid alone. *CXCL10* expression is abrogated by treatment with E6446, a TLR9 small molecule inhibitor, suggesting this cytokine is transcribed downstream of TLR9 activation. By testing THP-1 cells with AAV vectors containing promoter sequences with a range of %CpG content and RF scores, our data show that *CXCL10* expression is a scalable biological readout of TLR9 activation and most strongly correlates with predicted transgene immunogenicity as calculated by the RF_3 score as compared to %CpG (RF_1) and RF_2.

Future work will use this THP-1 cell-based assay to test the immunogenicity of AAV vectors for limb girdle muscular dystrophy type 2A (LGMD2A) containing codon optimized transgene sequences. The process of codon optimization tends to increase %CpG content and RF scores, therefore codon optimized sequences were also modified to decrease the RF_3 score. Both the codon-optimized vectors and their RF_3-lowered counterparts will be tested with this THP-1 cell-based assay to determine if this strategy can diminish the inflammatory response to the AAV genome. To further validate of this assay, the top candidates will be tested in mouse models of LGMD2A to measure the extent of the immune response, levels of transgene expression, and the therapeutic effect on the phenotype of these mice.

1494 Immunosuppression with αCD20 and Rapamycin Limits Adaptive Immune Responses to AAV6.2 and Permits Unimpeded Redelivery to the Mouse Respiratory Tract

Robert Clark[1], Jay Kolls[1]
[1]*Tulane University Health Science Center, New Orleans, LA*

RATIONALE: Host immune responses to adeno-associated viruses (AAV) have emerged as a primary impediment to effective gene therapy. These immune responses include anti-AAV neutralizing antibodies and CD8+ T-cell responses which have been observed to block repeated vector transduction and reduce the duration of transgene expression, respectively. Accordingly, there has been extensive work published on the nature of immune responses to systemically delivered gene therapy vectors and the development of strategies to mitigate the risk of immunological rejection. However, our understanding of immune responses to inhaled AAV gene therapy is less well developed. The lung is a unique mucosal niche and site of frequent pathogen encounter that has evolved mechanisms such as resident memory B (B_{RM})- and T (T_{RM})- cells which may present unique challenges for gene therapy vector delivery as compared to systemic administration. We therefore sought to describe the lung-resident immune response to respiratory administration of AAV in mice and to evaluate immunomodulatory for their ability to prevent priming of anti-AAV immune responses in the lung and permit redosing with sustained transgene expression.

METHODS: Using BALB/c mice, we first evaluated the immune response to intubation-mediated delivery of $1x10^{11}$ vg of lung-tropic Adeno-Associated Virus serotype 6.2 (AAV6.2-GFP). Using intravascular staining of lymphocytes and flow cytometry with MHC-I tetramer staining, we evaluated the formation of antigen-specific (capsid and transgene) lung T-resident CD8+ memory T cells (T_{RM}), total CD4 T_{RM}, and total B-resident memory cells (B_{RM}). We also evaluated the formation of anti-AAV antibodies (IgM, IgG, IgA) in serum and bronchoalveolar lavage fluid (BALF) by ELISA. Using the same assays, we next evaluated several promising immunomodulatory strategies to suppress primary immune responses to AAV6.2 and permit re-dosing, including αCD20, αCD20/tacrolimus, αCD20/rapamycin, αCD40L, CTLA4-Ig, αIL1α/αIL1β, αIFNαR, and IRAK4 inhibition. To validate the efficacy of immunomodulation, untreated or αCD20/rapamycin treated mice were dosed with AAV6.2-GFP, then one month later dosed with AAV6.2-luciferase (repeat dose groups). An additional control group received only AAV6.2-

luciferase (single dose group). Secondary gene transfer efficiency and duration of expression was measured using *in vivo* bioluminescent imaging.

RESULTS: AAV6.2 delivery elicited vector- and transgene- specific lung T-resident CD8+ T_{RM}. Airway delivery also induced anti-AAV humoral responses in serum (IgG, IgM) and BALF (IgG, IgA, IgM). Among the immunomodulatory strategies tested, αCD20/rapamycin performed best in suppressing primary immune responses (Figure 1A). Repeat dosing without immunomodulation resulted in a near-complete block to second-round gene transfer. In contrast, treatment with αCD20/rapamycin completely rescued second-round gene transfer, yielding luciferase expression equivalent to that of the single dose group (Figure 1B). Luciferase expression was equivalent and stable for at least 8 weeks in single dose and αCD20/rapamycin repeat dose groups (Figure 1B).

CONCLUSIONS: Combination immunotherapy with αCD20/rapamycin effectively prevents priming of anti-AAV immune responses after delivery to the airway, rescuing secondary gene transfer and facilitating prolonged stable transgene expression.

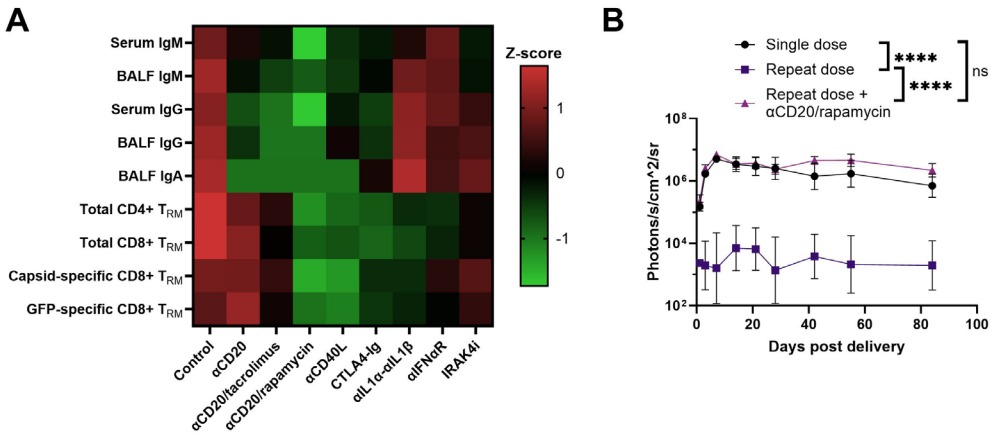

Figure 1. Immunomodulation permits effective redelivery of AAV6.2 to the respiratory tract. **(A)** Heatmap of immunological parameters measured 2 weeks after delivery of $1x10^{11}$ vector genomes (vg) of AAV6.2 via intubation to mice treated with immunomodulatory agents listed on the x-axis. A lower z-score (green) corresponds with a lower immunological response, n=3-5 mice per treatment group. **(B)** Luciferase signal over time after delivery of $1x10^{11}$ vg of AAV6.2-Luciferase to untreated or αCD20/rapamycin treated mice dosed with AAV6.2-GFP one month prior, as compared to single dose controls. ****p<0.0001 by one-way ANOVA after area-under-the curve analysis, n=5 mice per group.

1495 Extracellular Vesicles Reduce Type I Interferon Responses to AAV Gene Therapy in a Human Model of Innate Immunity

Bradley Hamilton[1], Ming Cheng[2], Rachana Patil[3], Fraser Wright[4], Adam Crain[5], John Day[6], Casey Maguire[7]
[1]Stanford, Palo Alto, CA, [2]Harvard Medical School, [3]Stanford University Dept. of Pediatrics, Palo Alto, CA, [4]Kriya Therapeutics - Redwood City, CA, Redwood City, CA, [5]MASSACHUSETTS GENERAL HOSPITAL, Charlestown, MA, [6]Stanford University, Palo Alto, [7]The Massachusetts General Hospital, Charlestown, MA

Background/ Rationale: Innate immune responses to adeno-associated virus (AAV) gene therapy vectors have been implicated as potentiators of serious adverse events and are a significant safety concern. The advancement of novel immunomodulatory strategies to avoid immunotoxicity after systemic dosing is critical to expand the therapeutic index of AAV-based treatments. The cytokine interferon-α (IFNα) is a hallmark inducer of innate Type I IFN responses and subsequent adaptive immune responses. We recently reported that extracellular vesicle associated AAV (EV-AAV), a subpopulation generated during conventional vector production, stimulates less IFNα release than standard AAV counterparts. Interestingly, EV-AAV and standard AAV were equivalently taken up by immune cells, suggesting an inhibitory rather than an avoidant mechanism of immune suppression. Phosphatidyl serine

phospholipids can be employed by enveloped viruses to inhibit Type I IFN responses and are displayed on the exterior of extracellular vesicles (EVs), which are commonly produced by diverse cell-types. We therefore hypothesized that highly purified EVs co-formulated with standard AAV vectors would dampen Type I IFN responses in our human peripheral blood mononuclear cell (PBMC) model of innate immunity.

Methods: Using our previously described novel assay to measure IFNα and other cytokines released from human PBMCs in response to antibody-complexed AAV, we compared antibody-complexed AAV2-CAG>GFP (AAV+Ab) to AAV+Ab co-formulated with serial dilutions of EVs. We purified 293T cell-derived EVs by size exclusion chromatography and verified endotoxin concentrations of <5 EU/mL. Next, we isolated human PBMCs from six random healthy donors and exposed them to AAV+Ab preincubated with 2-fold dilutions of purified EVs ranging from 1.2e7 to 6.4e9 EVs/well, or controls.

Results: Concentrations of IFNα released from PBMCs exposed to AAV without antibody-complexation were equivalent to those from untreated PBMCs at baseline, and nearly undetectable. However, AAV+Ab vectors induced significant donor dependent increases in IFNα release above baseline to 4, 10, 70, 275, 374, and 415 pg/mL ($p<0.05$ – $p<0.0001$, N=6). For all donors, IFNα release dramatically decreased in a dose dependent manner with the addition of EVs and reached up to 25-fold decreases at 1.6e9 EVs/well, approaching baseline. We next subjected the three most responsive donor's cell supernatants to Luminex assay of 80 human cytokines. AAV+Ab stimulation increased release of commonly queried IL-6, TNFα, MCP-1, IP-10, and MIP-1α, but EVs did not modulate this effect. AAV+Ab elicited no change from baseline for 18 cytokines, including commonly queried RANTES, IL-8, IL-18, MIP-1β, and MIP-5. Importantly, for 29 cytokines, robust AAV+Ab elicited effects were restored toward baseline by EVs in a dose dependent manner. The largest 11 effect sizes were observed in IFNα1 and IFNα2, which validated our ELISA data, followed by MCP-2, Eotaxin-2, IL-10, IL-3, TNFSF10, IL1-ra, IL-1b, IL-7, and IL-12p40.

Conclusions: This preliminary study begins to reveal an elusive human cytokine signature elicited by AAV and suggests uncommonly queried cytokines for analyte panel refinement. Further, these data suggest a potentially substantial immunomodulatory role for EVs co-formulated and administered with AAV. Ongoing investigations are interrogating the putative role of phosphatidyl serine and other EV components in the observed immunomodulations.

1500 An RNA switch-regulated AAV gene therapy for obesity, insulin resistance, and MASH

Xiaojuan Tang[1], Chengzhi Du[1], Haimin Wang[1], Guocai Zhong[1]*
[1]*UMass Chan Medical School, Worcester, MA*
**Corresponding Author*

Obesity, insulin resistance, and particularly metabolic dysfunction-associated steatohepatitis (MASH) are major global health challenges with limited effective treatment options. Fibroblast growth factor 21 (FGF21)-based biologics are emerging as promising therapeutics for treating these metabolic disorders, particularly MASH. However, native FGF21 has a short half-life (30 minutes to 2 hours); therefore, its clinical application would require frequent injections (e.g., daily), which may lead to poor patient adherence. Meanwhile, FGF21 analogues with improved PK profiles have been found to elicit the development of anti-drug antibodies (ADAs) at an incidence of 70–90%.

In this study, we developed a regulatable FGF21 gene therapy in which AAV-mediated native FGF21 expression is tightly regulated by an RNA ON-switch system, termed Z^{on}. Z^{on} is an ultra-efficient, protein-independent RNA switch that we developed recently. It has minimal leakiness and enables switch-inducer-dose-dependent tight regulation of transgene expression by over five orders of magnitude. Furthermore, monthly repeated administration of the inducer can consistently induce AAV transgene expression with near-flat kinetics for over one year in mice. Here we applied Z^{on} to control AAV-delivered FGF21 gene therapy in a genetic obesity mouse model (ob/ob). Compared to native FGF21-based biologic which may require daily administration, AAV-mediated FGF21 expression induced every three weeks led to significant improvements in multiple metabolic markers. Z^{on}-regulated

expression of FGF21 at ~100 ng/mL (35-212 ng/mL) for eleven weeks resulted in up to 25.6% reduction in body weight. It resulted in a 39.1% to 64.8% decrease in blood glucose levels as early as one week after induction. Serum insulin was also restored to 2.6 ng/mL, a level comparable to that of wild-type C57BL/6J mice (2.3 ng/mL), three weeks after induced expression of FGF21. Furthermore, multiple liver-related parameters were also significantly improved: (i) the liver-to-body weight ratio was reduced by 52.8%, from 78.9 mg/g to 39.8 mg/g, comparable to that of wild-type C57BL/6J mice (43.4 mg/g); (ii) serum levels of hepatic injury markers ALT and AST decreased by 80.9% and 60.8%, respectively. Serum ALT levels, a liver-specific injury marker, were reduced from 35.0 U/L to 6.7 U/L, approaching the levels in wild-type C57BL/6J mice (4.1 U/L).

These findings demonstrate the potential of this RNA switch-regulated FGF21 gene therapy for the treatment of obesity, insulin resistance, and MASH. In addition, they highlight the potential of the Z^{on} RNA switch as an effective tool for enabling the development of controllable gene therapy for various common metabolic disorders and beyond, expanding the scope of gene therapy applications.

1501 Gene therapy rescues adrenocortical cells from lipid cytotoxicity in mice and humans with adrenoleukodystrophy

Yi Gong[1], Yedda LI[2], Ashley Glover[3], Natalie Golovanov[2], Casey Maguire[4], Florian Eichler[5]
[1]MGH, Boston, MA, [2]Massachusetts general hospital, Boston, [3]Mass General Hospital, Boston, MA, [4]The Massachusetts General Hospital, Charlestown, MA, [5]Massachusetts General Hospital, Boston, MA

X-linked adrenoleukodystrophy (X-ALD) results from pathogenic variants in the ATP binding cassette subfamily D member 1 (*ABCD1*) gene and impairs transport of very long chain fatty acids (VLCFAs) into the peroxisome for β-oxidation. Affected patients have abnormally high VLCFA buildup in the nervous system, adrenal glands, and testes. An estimated 80% of X-ALD patients develop primary adrenal insufficiency (PAI), but the related pathophysiology remains poorly understood. In this study, we showed that the development of PAI in X-ALD patients directly correlates with significantly higher levels of C26:0-lysophosphatidylcholine (C26:0-LPC), a complex lipid containing C26:0 VLCFA. We demonstrated that exposure of HAC15 human adrenocortical cells to C24:0-LPC and C26:0-LPC significantly reduced HAC15 cell viability. Transient knock-down of *ABCD1* expression in HAC15 cells resulted in a biochemically faithful cellular model of X-ALD-related PAI characterized by VLCFA accumulation and diminished cortisol production. A compensatory increase in expression of cytochrome P450 side-chain cleavage enzyme, which catalyzes the rate-limiting step in the cortisol synthesis pathway, could not overcome the cortisol deficiency potentially caused by reduced expression of CYP17A1 and HSD3B2, key enzymes in cortisol synthesis. Finally, we showed that adeno-associated virus (AAV)9 vector-mediated gene replacement therapy reduces VLCFA accumulation in *ABCD1*-knockout HAC15 cells and therapeutically corrects histopathologic abnormalities in the adrenal glands of *ABCD1*-deficient mice delivered intrathecally. These results significantly advance our understanding of the mechanisms and pathways affected in X-ALD-related PAI and equally importantly, demonstrate that the deficits can be corrected, at least in the murine X-ALD model, by an AAV9-mediated gene replacement therapy that is already in human clinical trial (NCT05394064).

1502 Partial Deficiency Mouse Model of Cobalamin B Class MMA: Systemic AAV9 Gene Therapy Confers Resistance to Metabolic Crisis

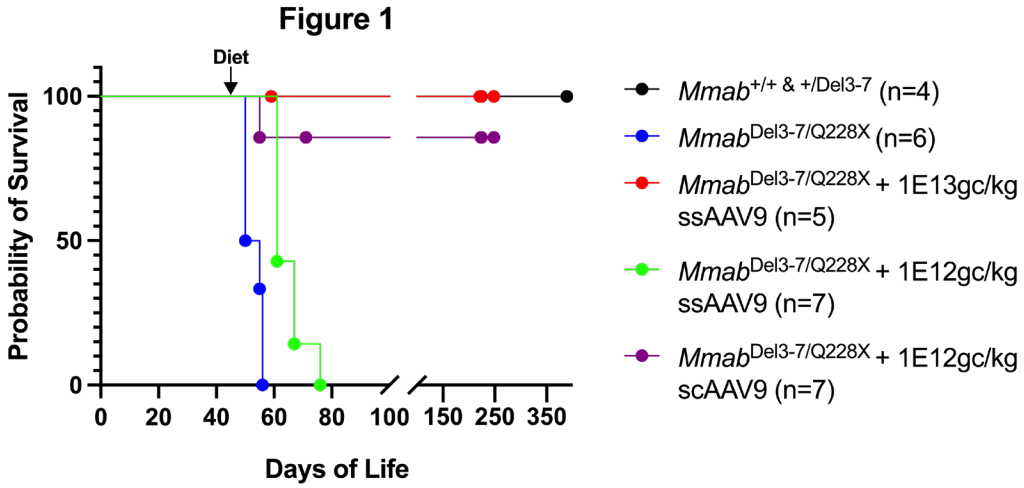
John Selser[1], Eun-Young Choi[2], Charles Venditti[3]*
[1]National Human Genome Research Institute, Bethesda, MD, [2]NHGRI/NIH, Bethesda, MD, [3]NIH, Bethesda, MD
**Corresponding Author*

Background: Cobalamin B-type (cblB) methylmalonic acidemia (MMA) is a severe ultra-rare autosomal recessive inborn error of metabolism caused by pathogenic variants in the MMAB gene that encodes the ATP:cob(I)alamin adenosyltransferase (ATR) enzyme. ATR generates 5'-deoxyadenosyl-cobalamin (AdoCbl), the obligate cofactor for the methylmalonyl-CoA mutase (MMUT) reaction. Current treatment relies on supportive care, including dietary management, carnitine supplementation, and intermittent antibiotics. Elective liver (LT) or combined liver-kidney (LKT) transplantation has been offered to severely affected patients as an experimental surgical therapy for the treatment of MMAB.

Methods: Compound heterozygous mice (Mmab$^{Del3\text{-}7/Q228X}$) carrying one nonsense mutation, frequently found in patients (Q234X, Q228X in mouse) and one null allele, deletion of exon 3-7, were characterized and challenged with a diet consisting of a 10-fold increase in isoleucine and valine (Ile/Val) amino acids. These mice were then used in proof-of-concept AAV gene therapy studies. These mice were treated with either a single-stranded (SS) or self-complimentary (SC) AAV9-MMAB vector (NCATS BL2680) systemically at DOL 30 and then exposed to Ile/Val enriched diet 2 weeks post-treatment to assess the efficacy of gene therapy.

Results: Mmab$^{Del3\text{-}7/Q228X}$ displayed normal survival, weight gain, and 1-C^{13} propionate oxidation compared to wild type or heterozygous littermate. Mmab$^{Del3\text{-}7/Q228X}$ mice displayed mild methylmalonic acidemia [MMA](80 +/- 77 uM, ~100x WT), much like patients with attenuated forms of MMAB. When fed the Ile/Val diet, Mmab$^{Del3\text{-}7/Q228X}$ mice demonstrated significant weight loss (-6.2±.8g n=6 over 4 days) and 100% lethality within 5 days, while controls fed the same diet thrived and gained weight. Plasma MMA (pMMA) levels were drastically increased with the Ile/Val diet (1223 +/- 738 uM, ~1500x WT), reflective of severe clinical disease. In a proof-of-concept study, Mmab$^{Del3\text{-}7/Q228X}$ mice were treated with AAV9-MMAB gene therapy at a dose of 1E13gc/kg systemically on DOL 30. 1E13gc/kg SS was sufficient to rescue survival, normal weight gain, and reduced pMMA level on the challenge diet. In a follow-up trial, mice were treated with either an SS or SC vector at a dose of 1E12gc/kg. SC treated animals showed fully rescued lethality with normal weight gain, but SS could not protect lethality (Fig.1). Neither dose conferred any change in oxidation relative to WT controls. Analysis by ddPCR of the 1E12gc/kg treated mice showed no significant difference in vector genome copies between SS and SC AAV treatments (P>.05) in tested tissues except in kidney, where a slight but statistically significant difference (.011±.005 [SS] vs .056±.007 [SC], P=.0029) was noted. Protein expression after 1E12gc/kg showed that both SS and SC AAVs produce MMAB in MMAB$^{Del3\text{-}7/Q228X}$ hypomorphic mice, exceeding WT levels in the liver, heart, kidney, and muscle. Mean MMAB tissue expression values were higher in SC treated animals than in SS treated animals but were only statistically significant in heart (P=.0019) and muscle (P=.0405).

Conclusions: The Mmab$^{Del3\text{-}7/Q228X}$ mouse model can be used in conjunction with an Ile/Val diet to induce a lethal metabolic crisis and is fully rescued from lethality by systemic AAV9 gene therapy. We have also shown that an SC vector can protect against the lethality and growth inhibition of an Ile/Val diet at a 10-fold lower dose than using an SS vector.



1503 STX-Arg1: exosome-based enzyme replacement therapy restores Arg1 activity in vivo and improves lifespan of Arg1-/- mouse model.

Mafalda Cacciottolo[1], Li-En Hsieh[1], Micheal J Leclaire[1], William Morrison[1], Bailey Murphy[1], Christy Lau[1], Kristi Elliott[1], Minghao Sun[1]
[1]*Capricor Therapeutics, San Diego, CA*

Arginase 1 (Arg1) deficiency (ARG1-D) is a rare genetic disorder caused by the loss of Arg1, the final enzyme in the urea cycle. Current treatment approaches primarily aim to control plasma arginine and ammonia levels. Among novel therapies under development, long-term resolution was only observed in AAV-based gene therapy in preclinical settings. Currently, no approved treatment specific for ARG1-D is available in the United States.

Lately, extracellular vesicles (EVs) have been gaining recognition as a potent therapeutic tool. By using Capricor's StealthX™ platform, EVs were engineered to express human Arg1. In vitro, nanograms of Arg1 carried by EVs were biologically active and able to convert arginine into urea as potent as micrograms of human recombinant Arg1 (rHuArg1). STX-Arg1-in EVs further demonstrated advantage in intracellular delivery of the active enzyme which was not achievable by the rHuArg1. In vivo, STX-Arg1-in EVs were non-toxic and able to restore the arginase activities in the liver of the Arg1-/- mice, which leads to a lowered plasma arginine concentration similar to wildtype mice. Most importantly, STX-Arg1-in EVs expanded the life span of the lethal neonatal Arg1 deficiency mouse model. Taken together, our data suggested StealthX™-engineered STX-Arg1-in EVs have a better safety profile due to extreme low dosage and had great potential to serve as a novel enzyme replacement strategy for patients suffering from ARG1-D.

1504 A Novel *Mmachc* c.80A>G Mouse Model: Insights of Mitochondrial Dysfunction in Skeletal Muscle and Potential AAV-mediated gene therapy for cblC

Wenhao Ma[1]*, Yingying Mao[2], Hongze Niu[2], Zhijie Wu[2], Ping Zheng[3], Tianyi Zhao, Cengceng Zhanng, Shuangqing Yu[4], Jianfang Zhou[2], Zipei Ren, Peidi Cheng[3], Lina Zhang[2], Lina Xie[3], ZheYue Dong, Yan Xia[5], Wang Sheng[6]*, Zhichun Feng[7], Xiaoyan Dong[8], Qian Chen[3], Xiaobing Wu[5]*

**Corresponding Author*

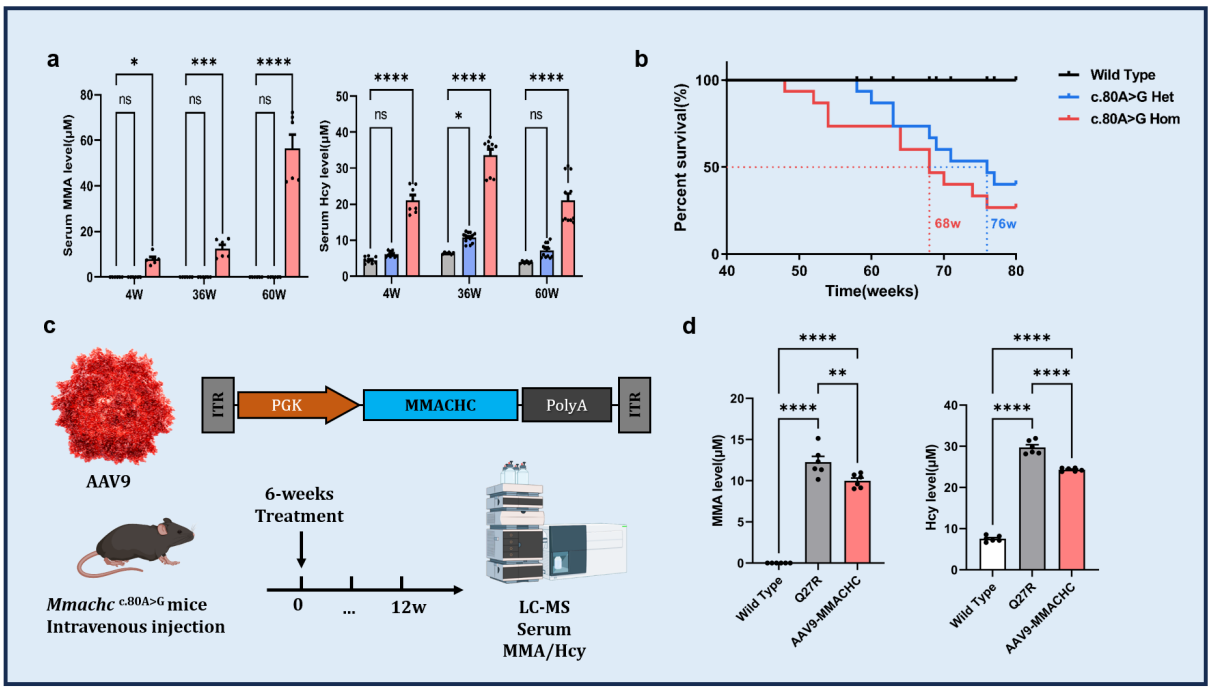
Combined methylmalonic acidemia and homocystinemia (cblC) is an autosomal recessive disorder characterized by aberrant organic acid metabolism. The c.80A>G mutation in the MMACHC gene has been widely documented and linked to cblC phenotypes, but its pathogenic mechanisms remain elusive, as it has not yet been fully validated through functional studies. To explore the underlying mechanisms of this disorder, a murine model carrying the Mmachc c.80A>G mutation was developed. These model animals exhibited markedly compromised survival rates (Figure b), altered blood biomarkers (Figure a), and imaging abnormalities that mirror the clinical manifestations of cblC.

Our current investigation delves deeper into the cblC mouse model, revealing persistently elevated levels of methylmalonic acid (MMA) and homocysteine (Hcy) in blood, urine, and tissues. This phenomenon is attributed to diminished expression of Mmachc. Surprisingly, the c.80A>G mutation leads to the p.Q27R change, yet research indicates that this mutation actually enhances B12 processing capacity. Therefore, the overall deficiency in functional B12 processing emerges as a key factor in the pathogenesis of cblC.

Further analysis revealed that the accumulation of MMA and Hcy in tissues not only results from impaired B12-processing but also contributes to mitochondrial dysfunction, which is particularly pronounced in skeletal muscle. The c.80A>G mouse model exhibited disruption of mitochondrial autophagy, leading to mitochondrial proliferation and impaired ATP metabolism. Notably, MMA was found to be a critical factor in cellular energy stress, causing damage to the mitochondrial respiratory chain and ATPase activity.

To investigate whether MMACHC expression could correct the severe cblC phenotypes in these model animals, we achieved MMACHC expression through intravenous (IV) administration of an adeno-associated virus (AAV) carrying the MMACHC expression cassette. This resulted in a reduction of MMA and Hcy levels (Figure c and d).

Collectively, our findings indicate that the c.80A>G mutation plays a significant role in the mitochondrial pathogenesis of cblC by inducing intron retention, providing novel insights into the underlying disease mechanisms. Additionally, AAV-mediated gene replacement emerges as a potential therapeutic strategy for cblC.



1505 Long Term PK/PD and Preliminary Safety Study of FGF21 Following Intramuscular Administration of KRIYA-497 (AAV1.hFGF21) in Healthy NHPs

Andrea Pappas[1], Ira Liolis[1], Nancy Bordelon[2], Peter Ross[3], William Quinn[2], Michele Stone[4], Xavier Leon[5], Veronica Jimenez[5], Fatima Bosch[5]
[1]Kriya Therapeutics, Redwood City, CA, [2]Kriya Therapeutics, Morrisville, NC, [3]Kriya Therapeutics, Durham, NC, [4]NA, Morrisville, North Carolina, [5]Center of Animal Biotechnology and Gene Therapy (CBATEG), Universitat Autònoma de Barcelona

Fibroblast growth factor (FGF) 21 is a 181-amino acid hormone that plays a key role in lipid metabolism, glucose homeostasis, energy expenditure, and thermogenesis. Its effects are mediated by binding to fibroblast growth factor receptors (FGFRs) and the coreceptor β-klotho, activating multiple intracellular signaling pathways.

Several FGF21 analogues are currently in late-stage clinical development and have been designed to improve the pharmacokinetic profile of native FGF21 given its short half-life. These analogues have been studied in numerous metabolic diseases including metabolic dysfunction-associated steatohepatitis (MASH) (Harrison et al. 2024). MASH is an advanced form of liver disease associated with liver steatosis, inflammation, and hepatocyte injury. Progression of MASH can lead to fibrosis and potentially to hepatocellular carcinoma and death. MASH afflicts approximately 40 million people in the United States and European Union, (O'Hara et al., 2020).

KRIYA-497 is comprised of an AAV1 capsid and an expression cassette encoding native human FGF21. It is designed to be administered via intramuscular (IM) injection to provide consistent circulating levels of native FGF21 in MASH patients.

Previous studies in mouse models of MASH indicated that AAV1.mFGF21 treatment resulted in sustained increased circulating levels of FGF21, reversing hepatic fibrosis, halting liver tumor development and counteracting obesity and insulin resistance (Jimenez.et al, 2024).

Healthy cynomolgus macaques received AAV1.hFGF21 at three dose levels with or without immunosuppression (IS). The vector was administered as a single dose on Day 1, with IS on Day -1. Dose groups received varying numbers of injections in the quadriceps, hamstrings, biceps, maintaining consistent vector concentrations within dosing cohorts.

Results:

- AAV1.hFGF21 was generally well tolerated with no adverse changes in body weight, food consumption, clinical observations, hematology, or clinical chemistry
- Robust increases in human-FGF21 protein serum levels were observed in all dose groups and maintained for the duration of the 6-month study.
- Greater than 100% increases in adiponectin were observed across all dose groups, consistent with the role of FGF21 in stimulating adiponectin secretion. These changes align with findings from nonclinical and clinical studies of FGF21 analogues.
- Biodistribution analysis revealed a widespread presence of vector genomes and RNA expression in the treated muscles with low off target expression in the liver.
- Correlation between vector genome levels, vector mRNA expression and circulating protein levels was observed.
- All animals developed expected humoral immunity against AAV1 capsid and transgene with no overt impact on FGF21 expression or detection.
- Low T cell responses restricted to AAV1 capsid, were detected and did not appear related to dose.

The demonstrated pharmacodynamic activity, sustained FGF21 expression, and observed favorable safety profile in NHPs support further development of KRIYA-497 for the treatment of MASH.

1506 A GLP-compliant Toxicology Study of Intravenously Administrated EXG110 for Treating Fabry Disease

Shaoyong Li[1], Chunjuan Song[2], Hong Wang[3], Pengfei Yu[3], Mingwen Liu[3], Xin Xin[4], Wei Hu[5], Guo-Jie Ye[6], **Zhenhua Wu[7]**
[1]Exegenesis Bio, Lexington, MA, [2]Exegenesis Bio Inc., Wayne, PA, [3]Exegenesis Bio Inc., Lower Gwynedd, [4]Exegenesis Bio Inc., Lower Gwynedd, PA, [5]Hangzhou, Zhejiang Province, China, [6]Exegenesis Bio Inc, Gainesville, FL, [7]Exegenesis Bio Inc., Lansdale, PA

Fabry disease is a X-linked metabolic disorder resulting from deleterious mutations of *GLA* gene which encoding a-galactosidase A (α-Gal A). Due to deficient or reduced a-Gal A activity, the accumulation of its substrates within lysosomes results in cellular dysfunction and systematic organ damages. We developed an AAV-based gene therapy product EXG110 for treating Fabry disease. It comprises an engineered liver-muscle targeting AAV9 variant capsid packaged with an optimized human *GLA* transgene expression cassette. The efficacy of EXG110 has been demonstrated in Fabry mice (*Gla* KO) after a single intravenous administration. Here we presented the GLP-complaint toxicology study of EXG110 in non-human primates (NHP). Adult cynomolgus monkeys with low or no pre-existing neutralizing antibodies against the AAV9 variant capsid were enrolled in the study before the administration of EXG110. One group of vehicle control and 3 groups of animals treated with low, medium and high dose of EXG110 with equal numbers of gender were used. The routine clinical observations, food consumption, body weight, body temperature, ophthalmological examination, hematology profiles, clinical chemistry, coagulation, urinalyses, ECG, blood pressure, respiration, functional observational battery (FOB), immunotoxicity (T cell subpopulation, cytokines, complements, capsid or transgene product specific T and B cell responses), vector clearance in the blood, vector shedding were monitored before and after administration. The plasma was also collected at different time points to determine EXG110-mediated α-Gal A activities in the circulation. Four weeks and 13 weeks after administration, animals were necropsied for gross observation, organ weight, tissue collections and histopathological examinations. The biodistribution of EXG110 in the animals treated

with high dose was studied. The transgene expression at mRNA level in the key tissues were analyzed for all the 3 dose groups. The results revealed general safe profiles with no adverse clinical signs and no histopathological findings in all animals through the 13-week duration. Compared to vehicle control, only transient ALT elevations were observed in the high dose group at Day 8. All EXG110-treated animals generated anti-capsid binding and neutralizing antibodies. No animal had capsid or transgene product specific IFN-γ producing T cells from PBMCs. EXG110 mediated robust and sustained α-Gal A enzyme activities in the plasma of NHP from all 3 dose groups with dose-dependent effect. The biodistribution results showed that liver and heart are the major target organs. The transgene mRNA levels correlated with vector genome DNA in the liver and heart. These safety profiles and superior transgene expression data from NHPs support the clinical development of EXG110 for treating Fabry disease.

1507 Long-Term Efficacy of Genome Editing in Infant Mice With Glycogen Storage Disease Type Ia

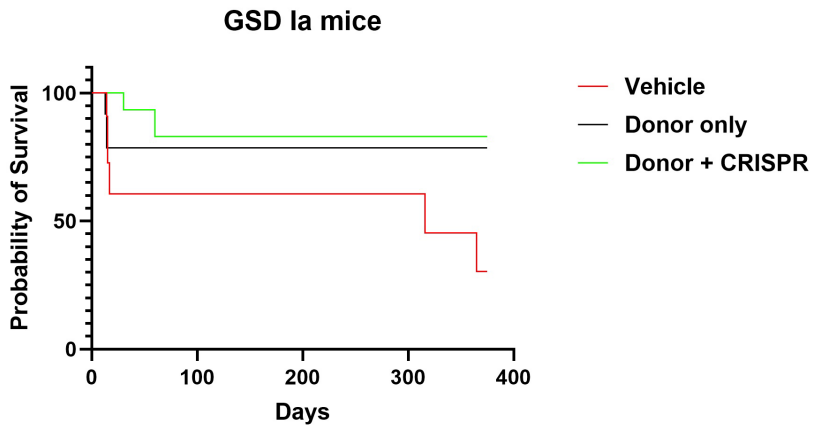
Elizabeth Brooks[1], Dwight Koeberl[1]*, Beatrice Bissig-Choisat[2], Ekaterina Ilich[3], Karl-Dimiter Bissig[2], Yuxin Wang[2], Rachel Weng[2], Songtao Li[2]
[1]Duke University Medical Center, Durham, NC, [2]Duke University, Durham, NC, [3]Duke University
**Corresponding Author*

Background: Glycogen storage disease type Ia (GSD Ia) is caused by the deficiency of glucose-6-phosphatase (G6Pase), which causes life-threatening hypoglycemia, hyperlipidemia, and a long-term risk for hepatocellular adenoma and carcinoma formation. Although gene replacement therapy with adeno-associated virus (AAV) vectors has been established, its benefits gradually wain. We developed a genome editing approach to integrate a therapeutic transgene expressing G6Pase, which is flanked by two homology regions of the *G6pc* locus such that it is integrated at a double-stranded break created by CRISPR/Cas9. One AAV vector delivers the transgene expressing G6Pase and a single guide RNA (Donor vector), and the second the *S. pyogenes* Cas9 (CRISPR vector).

Methods: Vectors were administered to 12 day old liver-specific *G6pc* -/- mice with GSD Ia: either Donor + CRISPR vector to achieve genome editing, or Donor-only treatment that was equivalent to gene replacement therapy. The vectors were administered at a relative low dose (Donor, 2E+13 vector genomes/kg; CRISPR 4E+12 vector genomes/kg). Mice were fed a high fat/high sucrose diet, and the efficacy of these treatments was evaluated at Week 52.

Results: Treatment with genome editing (Donor + CRISPR vectors) achieved the highest rate of survival (81%), followed by gene replacement therapy (Donor only; 78%), while vehicle administration achieved the lowest survival (38%; Figure). An interim analysis of 3 mice per group revealed the benefits of genome editing at 52 weeks. Blood chemistry testing revealed the following improvements for treatment with genome editing, in comparison with gene replacement therapy: alanine aminotransferase and low-density lipoprotein cholesterol were significantly decreased, and triglycerides trended lower in the genome editing group. Blood glucose trended higher in the genome editing group. Blood chemistry was not available for two of 3 vehicle-treated mice due to poor health. However, one healthy vehicle-treated mouse had hypoglycemia during a 13 hour fasting test, whereas vector-treated mice maintained normal blood glucose. Analysis of the liver revealed lower liver weight in genome editing mice (4.0 +/- 0.9 g), in comparison with vehicle treated mice (9.8 +/- 1.4 g), demonstrating improvement in hepatomegaly associated with GSD Ia. Donor-only, gene replacement therapy failed to decrease hepatomegaly (liver weight 7.7 +/- 4.2 g). The appearance of vehicle-treated livers was grossly abnormal with multiple very large tumors, whereas the genome editing- and gene therapy-treated livers appeared much more normal (histology is pending). Furthermore, liver glycogen content was decreased by >50% for the genome editing and gene therapy groups, in comparison with the vehicle-treated control group.

Conclusions: This interim analysis demonstrated improved efficacy from genome editing with CRISPR/Cas9 that integrates a therapeutic transgene at a double-strand break in the mutant *G6pc* gene, in comparison with gene replacement therapy with the same transgene, following a 52 week study. Infant GSD Ia mice treated with genome editing had improved blood chemistries, in comparison with gene replacement therapy, and uniquely decreased hepatomegaly in comparison with vehicle-treated control mice. These data support the further development of genome editing to stably treat GSD Ia early in life.



Vehicle: n = 7
Donor only: n = 5
Donor + CRISPR: n = 6

1508 Lipid Nanoparticle Delivered Circular RNA Encoding Ornithine Transcarbamylase (OTC) for the Treatment of OTC Deficiency: A Novel and Sustainable Therapeutic Approach

Siqi Li[1], Fei Lin[1], Xiyu Huang[2], Xiaoyu Pan[3], Xiaowen Zou[2], Jian Ye[1], Yang He[1], Yunni Lei[1], Roi Mashiach[4], **Edo Kon[5]**, Weiyi Zhang[1]

Ornithine Transcarbamylase Deficiency (OTCD) is a rare genetic disorder caused by a complete or partial lack of the OTC enzyme, leading to hyperammonemia, severe neurological issues, and potentially lethal outcomes. Liver transplantation remains the only viable therapeutic option, yet it involves considerable surgical risks and potential post-operative complications.

Circular RNA (circRNA), known for its high intracellular stability and low immunogenicity, offers a novel modality for protein replacement therapy. We have developed circOTC-encapsulating lipid nanoparticles (circOTC-LNPs) to drive OTC expression in the liver, as a potential therapeutic approach for OTCD.

We demonstrate that LNPs delivering circOTC with optimized Internal Ribosome Entry Site (IRES) and potent liver-targeting capabilities exhibit robust and sustained expression both in vitro and in vivo. In a conditional OTC knockout mouse model, administration of circOTC-LNPs effectively prevented weight loss and maintained normal blood ammonia levels for over two weeks, whether used preventively or therapeutically. Compared to linear mRNA, circOTC showed significantly extended pharmacological efficacy and superior hepatic safety.

Our findings highlight the potential of LNP-delivered circOTC as a promising therapeutic strategy for treating OTCD, offering a safer and more sustainable alternative to current treatments.

1509 ATP7B mRNA therapy for the treatment of Wilson's disease (WD)

Celine Pang[1], Liu Yang[1], Tingting Niu[1], Zach Zhu[2], Linxian Li[3], **Jingsong Cao[4]**
[1]Innorna, Nanjing, China, [2]Innorna USA, Inc, Cambridge, MA, [3]Innorna, Hong Kong, China, [4]Innorna USA, Inc, Lexington, MA

Wilson's disease (WD) is a rare inherited disorder caused by genetic mutations in the ATP7B gene, which encodes a P-type copper transporter primarily expressed in hepatocytes. ATP7B is responsible for transporting copper from intracellular chaperone proteins into the secretory pathway, facilitating both excretion into bile and incorporation into apo-ceruloplasmin for the synthesis of functional ceruloplasmin. A deficiency in ATP7B leads to copper overload in the liver and other critical organs such as the brain and eyes, resulting in hepatic, neurological, and ophthalmologic symptoms.

Current treatment options for WD, including copper-chelating agents like D-penicillamine and Trientine, have limited efficacy and are associated with numerous adverse effects. Traditional protein replacement therapy is not viable for WD patients due to drug delivery challenges, and viral-based gene therapies have yet to succeed due to the limited packaging capacity of adeno-associated viruses (AAV), neutralizing antibodies, and potential genotoxicity.

We aimed at developing a new treatment for WD using mRNA/lipid nanoparticle (LNP) technology. By screening the proprietary Diversity-oriented Lipid Library (DOLL), we identified liver-targeted LNP formulations that exhibit high efficiency and favorable safety profiles. The top LNP was subsequently used to encapsulate nucleoside-modified and codon-optimized mRNA encoding human ATP7B (hATP7B-mRNA-LNP). Our study demonstrates the therapeutic efficacy of hATP7B-mRNA-LNP in cultured human cells and in a mouse model of WD (Atp7b-/-) that resembles human conditions. Robust protein expression of hATP7B was observed in transfected cells, along with a significant increase in copper-transporting activity. Intravenous administration of hATP7B-mRNA-LNP resulted in robust and sustained expression of the hATP7B protein in livers of mice.

Furthermore, in Atp7b-/- mice, treatment with hATP7B-mRNA-LNP restored the deficient copper transporting function, reducing copper accumulation in the liver by enhancing copper loading onto ceruloplasmin (as evidenced by increased serum ceruloplasmin activity) and promoting copper excretion via feces. Collectively, our findings provide strong preclinical proof-of-concept for systemic mRNA-LNP as a potential disease-modifying therapy for patients with WD.

1510 Rescue of glutaric aciduria type I mice by liver directed gene editing

Karl-Dimiter Bissig[1]*, Beatrice Bissig-Choisat[1], Jean-Francois Rivest[2], Eli Kaufman[3], Haoyue Zhang[4], Mercedes Barzi[1], Claudia Goupil[5], Yunhan Ma[1], Maiya Fujiwara[6], Ashlee Stiles[6], Sarah Young[6], Paul Valdmanis[3], Yannick Doyon[7]

**Corresponding Author*

Glutaric Aciduria Type I (GA-1) is an inborn error of metabolism with a severe neurological phenotype caused by the deficiency of Glutaryl-CoA dehydrogenase (*GCDH*), the last enzyme of lysine catabolism. Currently, the only treatment option available for patients with GA-1 is lysine restriction, carnitine supplementation and emergency care during acute crisis. Nevertheless, complex movement disorders are still encountered in one-third of patients.

We previously showed that restoring a normal lysine catabolism in the liver of adult *Gcdh-/-* mice via Adeno-Associated Viral (AAV) gene therapy is sufficient to rescue the lethality and the neurological phenotype (Barzi et al. *Sci Transl Med* 2023). However, the therapeutic success was markedly reduced in neonatal mice, most likely due to the dilution of the AAV vector.

Here, we explored a more permanent gene editing solution, integrating a wildtype copy of *Gcdh* into the albumin locus. We injected neonatal *Gcdh-/-* mice with two AAV vectors, one expressing the *S. thermophilus* Cas9 and sgRNA targeting the albumin locus under a liver specific promoter, the other one a homology directed repair template carrying a wildtype copy of the *Gcdh* gene. Applying this treatment, we observed a rescue of the lethality phenotype when putting the *Gcdh-/-* mice on high protein diet (52 weeks, n=9), while all mice in both control groups (individual AAV vectors) succumbed only after a few days (n=2x9). More importantly, the treated mice had

a normal neurological phenotype and were not distinguishable from wildtype mice even after one year on high protein diet. Our results demonstrate that the neurological and metabolic phenotype of *Gcdh-/-* mice can be rescued by gene editing and restoring normal lysine catabolism in the liver.

1511 Alpha-1 antitrypsin correction by in vivo gene editing

June Baik[1], Cathleen Cornell[2], Tadeh Derstepanian[3], Saikat Manna[3], John Bladon[4], Hong Wang[4], Patricia Berthelette[5], Mahmud Hossain[4], Laura Blaha[3], Behnaz Lahooti[3], Rong Luo[3], Cao James[6], Renee Bodinizzo[7], Nathan Westcott[4], Robert Jackson[6], Martin Goulet[4], Ashish Sarode[3], Bailin Zhang[7], Christopher Borges[4], Christian Mueller[8], Tongyao Liu[9], Christophe LECHAUVE[4]
[1]Genzyme, a Sanofi Company, Waltham, MA, [2]Sanofi, Framingham, MA, [3]Sanofi, Waltham, [4]Sanofi, Waltham, MA, [5]Genzyme, a Sanofi Company, Cambridge, MA, [6]Sanofi, Cambridge, MA, [7]Sanofi, Cambridge, [8]Sanofi Genzyme, Waltham, MA, [9]Sanofi, Waltham, Massachusetts

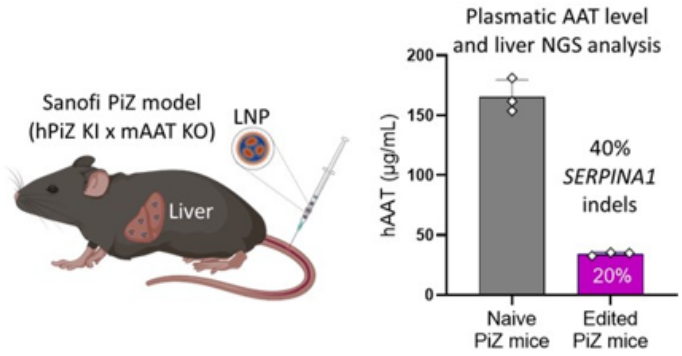
Alpha-1 antitrypsin deficiency (AATD) is an inherited disorder caused by mutations in *SERPINA1*, with >95% of severe clinical cases homozygous for the PiZ mutation (G>A point mutation). The PiZ mutation leads to the accumulation of misfolded AAT within hepatocytes (gain of toxicity) associated with low blood circulating levels of AAT as well as the destruction of alveoli in the lungs over time (loss of function). Considering this genetic condition, AATD is an ideal candidate for in vivo gene correction therapy to restore the normal expression and function of AAT.

To develop gene editing of the PiZ allele, we generated mouse models by introducing one copy of a human *SERPINA1* transgene with the Z allele, comprising coding exons and some non-coding sequences associated with various regulatory elements. PiZ mouse models were further backcrossed with AAT knockout mice resulting in the generation of a model with the exclusive expression of the human mutant AAT protein. We next evaluated lung function of PiZ mice using Flexivent plethysmography upon lipopolysaccharide induced inflammation and observed a distinct pathological phenotype based on lung compliance and inspiratory capacity compared to control mice.

A liver tropic LNP was engineered (LNP1), that resulted in high transfection of liver cells and low off-tissue transfection in vivo. As a proof of concept, we further evaluated in vivo gene editing by treating PiZ mice with LNP1 encapsulating Cas9 mRNA along with a guide targeting human *SERPINA1*. We measured ~40% indels as well as ~80% loss of protein expression by NGS and ELISA respectively (Figure 1). These results demonstrate that the Sanofi PiZ mice can be used to assess *SERPINA1* editing using in vivo non-viral gene therapy.

Our findings identify a platform to treat AATD by gene correction and we are currently evaluating technologies to correct the PiZ point mutation. These approaches may lead to an effective gene therapy to tackle the lung and liver phenotypes of AATD patients.

Figure 1:



Legend: **In vivo *SERPINA1* editing using liver tropic LNP**. Sanofi PiZ models: single copy *SERPINA1* transgene with the Z allele crossed with AAT knockout strain (Jackson Laboratory; 035015). Sanofi PiZ mice were i.v. infused with liver tropic LNP1 encapsulated Cas9 mRNA and gRNA targeting *SERPINA1*. Naïve and treated animals were euthanized 10d post-treatment. Plasma and liver tissues were analyzed by ELISA and NGS respectively to measure indels percentage and protein levels.

1512 A Potential Gene Editing Approach for AATD-Associated Liver and Lung Diseases Intended to Correct the PiZ Allele

Zsanett Jancso[1], Xiaolong Dong[1], Alan Mendoza[1], Erin Spofford[1], Sarah Ducat[1], Kenneth Ganley[1], Meghna Tupal[1], Gulen Tonga[1], Michael Hahn[1], Thomas Colace[1], Gang Sun[1], Jeff An[1], James Rottman[1], Luciano Apponi[1], Anne Bothmer[4], Jane Wang[1], Bill Querbes[1], Cecilia Cotta-Ramusino[1], Michael Holmes[1]
[1]*Tessera Therapeutics, Inc., Somerville, MA,*

Mutations in the *SERPINA1* gene (Serine Protease Inhibitor, group A, member 1) cause Alpha-1 antitrypsin deficiency (AATD), an inherited disorder that is associated with an increased risk of liver disease in adults and children, and with lung disease in adults. There are approximately 250,000 people in developed countries living with AATD including 1 in every 1,500 to 3,500 people of European ancestry. One of the clinically most relevant variants is the PiZ mutation, which results in lysine substitution for glutamic acid at amino acid position 366 (E366K). Individuals who are homozygous for the PiZ allele (PiZZ genotype) develop liver phenotype caused by retained toxic aggregates of misfolded protein within the endoplasmic reticulum of hepatocytes, whereas reduced circulating AAT levels promote development and progression of lung phenotype due to impaired neutrophil elastase inhibition.

We developed an RNA Gene Writer designed to correct the E366K mutation (PiZ allele) to wild type in the *SERPINA1* gene. LNP-RNA delivery of our RNA Gene Writer corrected this mutation in a commonly used transgenic mouse model with high copy numbers of the mutation (NSG-PiZ), where we precisely edited more than 90% of the hepatocytes at very low doses, based on the assumption that 60% of liver cells are comprised of hepatocytes, and observed a corresponding >90% of corrected mRNA transcripts after a single intravenous administration. We also observed significant increases in serum AAT levels with no detectable circulating Z-AAT protein, restored neutrophil elastase inhibition, and reductions in protein aggregates in the liver. Durable mutation correction and phenotypic rescue was demonstrated for up to 10 weeks post-treatment. Separately, we generated a humanized mouse model with only two PiZ alleles to better approximate the efficacy of our product in patients with the homozygous PiZZ genotype. LNP-RNA delivery of our RNA Gene Writer achieved an estimated 89% correction of hepatocytes after a single low dose (0.25 mpk) treatment in this mouse model. A study in non-human primates (NHP) demonstrated RNA Gene Writer achieved an estimated 79% editing efficiency of the *SERPINA1* gene in hepatocytes, which corresponded to 84% of mRNA transcripts containing the edited sequence, with editing levels remaining stable for up to 6 months.

In summary, we demonstrated that our LNP formulated RNA Gene Writer efficiently edited the *SERPINA1* gene responsible for AATD in the liver of mice and NHP with a single administration at therapeutically relevant doses.

1513 Anti-SGSH antibodies following Hematopoietic Stem Cell (HSC) Gene Therapy in Patients with MPSIIIA Neither Impact Engraftment of Genetically Modified HSC nor Interfere with Multi-compartment Substrate Reduction

Stuart Ellison[1], Rachel Searle[2], Poppy Osman[3], Jane Kinsella[4], Nathan Jeffreys[5], Rebecca Holley[6], Adrian Thrasher[7], Claire Booth[8], Simon Jones[9], Robert Wynn[10], **Brian Bigger[11]**
[1]University of Manchester, Manchester, Greater Manchester, United Kingdom, [2]University of Edinburgh, Ecinburgh, United Kingdom, [3]University of Manchester, Manchester, United Kingdom, [4]Manchester University NHS Foundation trust, Manchester, United Kingdom, [5]Royal Manchester Children's Hospital, Manchester, Greater Manchester, United Kingdom, [6]The University of Manchester, MANCHESTER, Greater Manchester, United Kingdom, [7]University College London, United Kingdom, [8]Great Ormond Street Hospital for Children NHS Foundation Trust, UNITED KINGDOM, [9]Manchester University NHS Foundation Trust, UNITED KINGDOM, [10]MANCHESTER, G Man, United Kingdom, [11]University of Edinburgh, Edinburgh, East Lothian, United Kingdom

Mucopolysaccharidosis IIIA (MPSIIIA, Sanfilippo A syndrome) is a neurodegenerative lysosomal storage disease caused by a deficiency in the glycosaminoglycan (GAG) degrading enzyme N-sulphoglucosamine sulphohydrolase (SGSH). SGSH deficiency results in the accumulation of heparan sulphate in cells, leading to cellular dysfunction which is particularly apparent in the brain. Symptom onset begins within the first 2 to 4 years of life and is characterised by a plateau in development, speech delay, and worsening behavioural problems, with progression to death in the mid-teenage years.

Anti-enzyme antibodies have previously been reported following ERT in other metabolic conditions. In Hurler syndrome, anti-IDUA antibodies are present in all whom receive ERT prior to hematopoietic stem cell therapy (HSCT) and resolve with the immune suppression of HSCT. However, during periods of anti-IDUA antibody production, patients with uptake inhibition of >30% and IgG titres of >1/4000 demonstrate increases in GAG levels commensurate with reduced disease correction. In primate studies of genetically modified-autologous HSCT, immune responses against genetically modified cells and the protein product, if that product is both “foreign” and secreted, have significantly attenuated therapeutic efficacy with loss of genetically modified cells or neutralisation of secreted protein, unless there is significant pre-transplant immune suppression of the recipient.

Our group has developed a gene-modified autologous haematopoietic stem cell gene therapy (HSCGT) that is currently being evaluated in 5 patients with severe MPSIIIA in a phase I/II clinical trial (NCT04201405). Here we sought to understand if anti-SGSH antibodies were produced following HSCGT, and if they had any negative impact on engraftment of genetically-modified HSC, or multi-compartment substrate reduction by the transgene enzyme product, SGSH.

An anti-SGSH ELISA was developed to detect antibodies in the serum of MPS-IIIA patients following HSCGT. We assessed anti-SGSH antibody levels at set time points before and after treatment of these patients. An uptake inhibition assay was developed to assess if anti-SGSH antibodies of even low titres inhibit SGSH uptake into MPSIIIA fibroblasts and therefore potentially impact clinical outcomes.

Anti-SGSH IgG antibodies were detected in the serum of all 5 patients, peaking at 1-3-months post-treatment at titres of 1/512-1/65,536, followed by a large reduction from 9-months post-treatment, and continued reduction over time. None of the patients had uptake inhibition >30%. All patients showed sustained HSCGT engraftment and stable vector copy number (VCN). Leukocyte, plasma and bone marrow SGSH levels were well above normal from 1-3-months post-treatment and were unchanged with either the onset or resolution of anti-SGSH antibodies. CSF SGSH levels were within or above the normal reference range by 3-6 months and remained unchanged by presence of anti-SGSH antibodies. CSF, plasma and urinary GAG levels showed continued and sustained reduction of >80% post-treatment, regardless of the anti-SGSH IgG titre, and were consistent with full biochemical correction of disease.

Transient elevations of anti-SGSH IgG antibodies do not appear to be associated with any impact on the therapeutic efficacy of the HSCGT treatment, affecting neither cell engraftment nor transgene enzyme levels, or the biological action of that enzyme in catabolising accumulated substrate

1514 Correction of Glycogen Accumulation in Muscle, Heart and CNS in a Pre-Clinical Model of Hematopoietic Stem Cell Gene Therapy for Pompe Disease

Slawomir Wantuch[1], Steven Tuske[2], Sara Benedetti[3], Chiara Recchi[4], Paul Heal[4], Piv Sagoo, Tyler Johnson[2], Nickita Mehta[2], Jon Brudvig[5], Fulvio Mavilio[4], Jill Weimer[5], Hubert Gaspar[6]
[1]Orchard Therapeutics, London, United Kingdom, United Kingdom, [2]Amicus Therapeutics, Princeton, NJ, [3]University College London, London, London, United Kingdom, [4]Orchard Therapeutics, London, United Kingdom, [5]Amicus Therapeutics, Philadelphia, [6]University College London, United Kingdom

Pompe disease (PD) is a severe and life-threatening lysosomal storage disorder caused by mutations in the acid alpha-glucosidase (*GAA*) gene. Deficiency of the lysosomal enzyme encoded by *GAA* results in toxic glycogen accumulation, primarily in skeletal and cardiac muscles, as well as the central nervous system (CNS), leading to profound neuromuscular dysfunction and progressive degeneration. While enzyme replacement therapy (ERT) is the current standard of care, its efficacy is hindered by several limitations, including the development of neutralising antibodies in cross-reactive immunological material (CRIM)-negative patients, partial correction of skeletal muscle pathology, and inadequate penetration of the blood-brain barrier.

Autologous transplantation of haematopoietic stem cells (HSCs) genetically modified *ex vivo* using lentiviral (LV) vectors presents a promising therapeutic approach for systemic enzyme delivery, with demonstrated success in achieving phenotypic correction in neurometabolic disorders such as metachromatic leukodystrophy and mucopolysaccharidosis type I. In this study, we explored the potential of HSC gene therapy to correct GAA deficiency and restore functionality in affected tissues, including the CNS, using a murine model of Pompe disease.

To enhance GAA uptake and cross-correction within target tissues, we developed a modified GAA enzyme tagged with a variant Insulin-like Growth Factor-2 binding domain (vIGF2-GAA) under the control of a mammalian PGK promoter. This modification permits GAA uptake through glycan-independent interactions with the Cation-Independent Mannose-6-Phosphate Receptor (CIMPR). The vIGF2 tag was engineered to minimise binding to insulin or IGF1 receptors while maximising cellular uptake of GAA mediated through the CIMPR receptor. Transplantation of *Gaa-/-* haematopoietic stem/progenitor cells transduced with an LV vector encoding vIGF2-GAA into conditioned *Gaa-/-* mice resulted in robust and stable engraftment and sustained systemic GAA levels. Alongside the vIGF2-GAA transgene, a wild-type (WT) GAA transgene was included as a baseline comparator.

Quantitative assessment of glycogen storage in the gastrocnemius muscles, tibialis anterior, diaphragm, heart, and brain revealed that vIGF2-GAA exhibited superior efficacy in reducing glycogen accumulation to normal levels compared to the wild-type GAA enzyme. This glycogen reduction was accompanied by histopathological correction in affected tissues and significant phenotypic improvement, as evidenced by enhanced rotarod performance three months after transplantation. Both the vIGF2-GAA and WT-GAA groups demonstrated comparable GAA enzymatic activity levels in plasma. These findings indicate that the improved correction observed in the vIGF2-GAA group is exclusively due to the enhanced functionality conferred by the vIGF2 tag only. This tag facilitates increased interactions with the IGF2 binding domain of the CIMPR, a mechanism that is not achievable with the unmodified WT-GAA enzyme. Additionally, treated mice showed complete normalisation of the surrogate Pompe clinical biomarker, urine glucose tetrasaccharide.

These findings underscore the therapeutic potential of delivering the vIGF2-GAA enzyme via genetically corrected HSCs for effective correction of skeletal muscle, cardiac tissue, and CNS pathologies. The results strongly support the clinical translation of HSC gene therapy as a transformative treatment for Pompe disease.

1515 Improving blood-brain barrier penetration in Hurler syndrome using an IDUA-ApoE fusion enzyme delivered via the PS Gene-editing System

Michael Przybilla[1], Li Ou[2], Chester Whitley[1]
[1]*University of Minnesota, Minneapolis, MN,* [2]*University of Minnesota Twin Cities*

Mucopolysaccharidosis type I (MPS I) is a lysosomal disorder caused by mutations in the IDUA gene, which encodes α-L-iduronidase (IDUA). This deficiency results in the accumulation of glycosaminoglycans (GAGs), primarily heparan and dermatan sulfate, leading to multi-organ dysfunction and neurodegeneration. Current treatments, including hematopoietic stem cell transplantation and enzyme replacement therapy, have shown limited efficacy in addressing central nervous system (CNS) symptoms due to poor blood-brain barrier (BBB) penetration. This highlights the need for therapies capable of crossing the BBB to address CNS pathology in MPS I.

To enhance CNS enzyme delivery, we developed a novel IDUA-ApoE fusion enzyme designed to bind to low-density lipoprotein receptors (LDLR) on the BBB, facilitating CNS uptake. Using the PS Gene-editing (PSG) system, IDUA-ApoE cDNA was integrated into intron 1 of the albumin gene in neonatal MPS I mice. MPS I mice (n>10 per sex, per group) received low, middle, or high doses of the PSG-IDUA-ApoE therapeutic via intravenous administration at P0-P2. Plasma IDUA activity was monitored for 6 months and urine was collected to assess secreted GAG, which serves as an in-life biomarker of therapeutic efficacy in MPS I. Beginning at 8 months of age, cognitive and motor function was assessed using the Barnes maze, delayed fear conditioning and the pole test. At 8-10 months of age, endpoint analysis was conducted, measuring the levels of IDUA enzyme activity in the tissues and GAG accumulation. In the plasma, there was dose-dependent response in plasma IDUA enzyme activity, with all reaching supraphysiological levels that were sustained for at least 6 months. For the duration of the study, urinary GAGs were normalized. Cognitive assessment at 8 months of age showed that mice receiving PSG-IDUA-ApoE performed the Barnes maze and delayed fear conditioning test similar to untreated, normal mice. Similarly, the pole test revealed that mice receiving the mid and high dose of PSG-IDUA-ApoE maintained their motor function compared to untreated MPS I mice. In all tissues assayed, including the liver, spleen, kidney, heart, bone marrow, spinal cord, and brain, enzyme activity was significantly elevated above normal, heterozygous levels. Additionally, this increase in IDUA enzyme activity resulted in reduction and normalization of the GAGs within these tissues.

In summary, the IDUA-ApoE fusion enzyme, delivered via the PSG system, achieved supraphysiologic IDUA levels in plasma and tissues throughout the body, including the CNS, resulting in cognitive preservation and brain GAG normalization. These results support the PSG system as a promising platform for CNS-targeted gene therapy in lysosomal disorders.

1516 Evaluation of Clinical Safety and Efficacy of LY-M001: A Phase I/II Trial of AAV8-Mediated Gene Therapy for Gaucher Disease Type I

Fengkui Zhang[1]*, Yixiong Chen[2], Liping Jing[3], Ruijuan Zhang[4], Tianqi Jiang[5], Rihong He[6], Chenming Lu[6], Xiaojing Sheng[6], Guofang Yan[7], Jian Wang[7], Juan Chen[6], Qing Lin[8]*
[1]*Institute of Hematology & Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, Tianjing, China,* [2]*Lingyi Biotech, Shanghai, China, China,* [3]*Institute of Hematology & Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjing, China,* [4]*Department of Hematology, Third Hospital of Shanxi Medical University, Shanxi Bethune Hospital, Shanxi Academy of Medical Sciences, Tongji Shanxi Hospital, Taiyuan, China,* [5]*Lingyi, Shanghai, China,* [6]*Lingyi Biotech, Shanghai, China,* [7]*Lingyi Biotech, Shanghai, Shanghai, China,* [8]*Lingyi Biotech, Lutherville, MD*
**Corresponding Author*

Background: Gaucher disease (GD), a prevalent lysosomal storage disorder, arises from mutations in the GBA1 gene. LY-M001, a novel rAAV serotype 8 vector-based therapy, aims to rectify this deficiency by delivering a codon-optimized *GBA1* gene, driven by a hybrid hepatic-specific promoter, and expressing a modified glucocerebrosidase ($GCase^{LY}$). Several clinical trials is being conducted across multiple centers in China including a pilot study (NCT06162338), a Phase I/II dose-escalation trial (CTR20241092) and the first administration for an adolescent patient (NCT06528080). In this Phase I/II dose-escalation trial (CTR20241092), both naive and pre-treated patients with GD1 are eligible for inclusion. Pre-treated patients are required to discontinue standard of care (SoC) therapy at least two weeks prior to receiving the LY-M001 infusion. The primary objectives of the study are

to assess the safety and efficacy of escalating doses of LY-M001. Participants will be monitored for 38 to 52 weeks post-treatment, after which they will be enrolled in a long-term follow-up.

Results: Since August 2024, four participants have been enrolled in a phase I/II clinical trial (CTR20241092) and administered LY-M001 injection. Overall, the treatment was well tolerated across two dosage groups. A mild elevation in liver enzymes was observed in some of participants, which was promptly managed and resolved with immune modulation therapy. No serious adverse events (SAEs) related to the subjects occurred. Rapid normalization of GCase activity in peripheral blood within the 1st week after LY-M001 infusion was noted, and the GCase activity continued to increase to peak in the following 8 – 16 weeks before reaching a plateau, accompanied by reduction in Lyso-GL1 levels. Notably, despite the exceptionally elevated GCase secretion in circulation, no anti-drug antibodies (ADA) targeting GCase were detected in any patient, indicating no immunogenicity of the modified GCase^{LY} *in vivo*. Up to date, the clearance of harmful substrate led to clinical improvements in Gaucher disease symptoms in all participants, including increases in hemoglobin (by 9 to 41 g/L) and platelet levels (by 10 to 41 × 10^9/L), as well as reductions in spleen volume (by 18 to 19.5%) and liver volumes (by 5.6 to 18.8%), compared to the corresponding screening period levels. Rapid clinical responses were observed following LY-M001 administration. For instance, a participant in the high-dose cohort, who initially exhibited hemoglobin levels near the lower limit of the normal range and platelet levels below the normal range, demonstrated significant improvements of hemoglobin and normalization of platelet levels accompanied by a marked elevation in circulating GCase activity. Additionally, significant improvements in quality of life were reported by most subjects. Notable improvements in abdominal distension and fatigue were reported by all participants, with most resuming work or social activities following the LY-M001 infusion.

Conclusion: LY-M001 is a novel AAV8-based therapeutic approach for Gaucher disease currently under investigation. Preliminary clinical data from various dosage groups demonstrate a favorable safety profile and promising efficacy outcomes. Enhanced GCase expression facilitates substrate clearance, leading to improvements in both Gaucher disease symptoms and patients' quality of life.

1517 Pharmacokinetic, Pharmacodynamic, and Toxicokinetic Analysis of an rAAV8 Gene Therapy for Friedreich Ataxia-Associated Cardiomyopathy

Introduction: Friedreich ataxia (FA) is a monogenic disease caused by frataxin protein deficiency leading to progressive neurodegeneration and, in most patients, severe cardiomyopathy.

Methods: ASP2016 is a rAAV8-based vector containing the human *FXN* gene under the control of a human PGK promoter (rAAV8-hPGK-hFXN) designed to increase the expression of frataxin. After a single intravenous dose of ASP2016, the preclinical pharmacokinetics, pharmacodynamics, toxicokinetics, or safety of ASP2016 were evaluated in a mouse model of FA (FA-MCK) and healthy non-human primates (NHPs). The overall objectives of these studies were to understand the cross-species translation and estimate the therapeutic window for treating FA-associated cardiomyopathy.

Results: Pharmacokinetic analysis of FA-MCK mice tissues demonstrated linear dose-proportional increases in vector copy number (VCN), mRNA, and frataxin protein. The highest correlation between VCN and frataxin expression was observed in the heart, followed by the liver and quadriceps. In NHPs, there were non-linear dose-dependent increases of VCN, mRNA, and frataxin expression in the heart, with similar transduction levels across both species. A significant dose-dependent improvement in survival was observed starting at the lowest dose of

1E12 vector genomes per kilogram (vg/kg) relative to vehicle-treated FA-MCK mice. Pharmacodynamic assessment in FA-MCK mice demonstrated dose-dependent rescue of ejection fraction (EF) starting at 1E12 vg/kg and plateauing at 1E13 vg/kg, with a predicted normal 50% EF at a dose of 5E12 vg/kg. Interestingly, this 5E12 vg/kg dose was predicted to yield 30% of normal wild-type frataxin expression, corresponding to the lowest level of expression in healthy human heterozygous carriers. These results demonstrate the efficacy of ASP2016 and supports the hypothesis that the increase in frataxin expression leads to improved cardiac function and survival in this mouse model. Toxicokinetic analysis identified a dose-dependent reduction in nerve conduction velocity in certain NHPs administered ASP2016, which progressed over time. Related dorsal root ganglion histological findings in NHPs were observed at doses ≥ 2E13 vg/kg and were more pronounced at the highest dose, but there were no adverse clinical or neurological examination correlates.

Conclusions: A 20-fold therapeutic window for ASP2016 was established based on the observed efficacy at the lowest dose of 1E12 vg/kg in FA-MCK mice, and the lowest observed adverse effect level without unacceptable toxicities at 2E13 vg/kg in NHPs. These results identify ASP2016 as a promising clinical candidate for treating cardiac manifestations in Friedreich ataxia patients.

1518 Slow Retrograde Renal Pelvis Injection of Centrifugally Ultrafiltered AAV Miniprep Vectors Enables Rapid Capsid Screening For Kidney Gene Delivery

Pratheppa Rajagopal[1], Hideyuki Hakui[2], **Anusha Sairavi[2]**, Ranjan Das[1], Taisuke Furusho[3], Hiroyuki Nakai[4]*
[1]Oregon Health and Science University, Portland, OR, [2]Oregon Health & Science University, Portland, OR, [3]Morgridge Institute for Research, Madison, WI, [4]Oregon Health & Science University School of Medicine, Portland, OR

Developing novel AAV capsid variants with desired phenotypes is a key research focus in gene therapy. However, generating variants and testing their transduction profiles is often expensive and time-consuming. Generally, AAV vectors are purified using cesium chloride (CsCl), iodoxinol gradients, or chromatography and then tested in vitro or in vivo. This conventional process is lengthy, requires expensive reagents, sophisticated equipment, and skilled technicians, ultimately extending the timeline for evaluation. The use of centrifugally ultrafiltered (CU) AAV miniprep vectors is a cost and time-effective approach that eliminates these expensive, time-consuming, and labor-intensive requirements. Prior studies have shown that CU AAV miniprep vectors have been shown to be as effective as AAV vectors obtained through conventional purification (e.g., CsCl AAV vectors) in various experimental settings, but not in the field of renal gene delivery following local administration. Here, we demonstrate that CU AAV miniprep vectors can be effectively utilized for a rapid transduction profiling of AAV capsids in gene delivery to the kidney via renal pelvis (RP) injection. In this study, we evaluated the CU AAV minipreps using two capsids, AAV9 and KP3, packaged with the CAG-Tdtomato (tdT) transgene. To prepare CU AAV vectors, HEK293 cells were transfected in a single flask with the necessary plasmids and harvested together with the media five days post-transfection. The collected cells and media were freeze-thawed once, and the lysate was treated with Benzonase to eliminate free-floating DNA. The lysate was filtered with a 0.45 μm PVDF syringe filter to remove particulate matter before being concentrated by centrifugation in a molecular weight cutoff column centrifuge until the desired volume (approximately 500 μL) was achieved. The vectors were quantified using a dot blot assay. C57BL/6J male mice were then injected with CU KP3 or CU AAV9 vector at 3.0 x 10^{11} vg/mouse using the slow retrograde RP injection technique and vector transduction in the livers and injected kidneys were assessed two weeks post-injection. The harvested kidneys underwent molecular and immunofluorescence analysis. Fluorescence analysis indicated that the CU KP3 vector transduced the proximal tubules in the kidney, while the CU AAV9 vector primarily transduced mesangial cells in the glomeruli, with minimal renal tubular transduction observed. The Tdt expression in proximal tubules was 12.9% for CU KP3 and 0.3% for CU AAV9, with no significant difference between these two AAV vector preparations (CU AAV and CsCl AAV). DNA isolated from the AAV-injected kidneys was analyzed using qPCR to quantify vector genome copy numbers. CU KP3 showed 73 times more vector genomes than AAV9-injected kidneys. The off-target effects in these injected mice were examined by imaging the liver, revealing that KP3 exhibited significantly lower liver transduction compared to the AAV9 vector. All these findings are consistent with those observed in the control animals injected with CsCl AAV vectors. Therefore, RP injection of CU AAV miniprep vectors not only demonstrate safety and efficacy but replicate renal transduction profiles that would be obtained with fully purified AAV vectors. This technique offers a rapid profiling of AAV

vector transduction in the kidney, eliminating the time-consuming, complicated purification process while obtaining insightful results for further investigation.

1519 Adeno-Associated Viral Mediated Genome Editing as a Curative Therapy for Polycystic Kidney Disease

Fernando Gomez Garcia[1], Lily Thompson[1], Miriam Rivera Moreno[1], Shashank Chetty[2], Jing Wang[2], Miguel Garcia-Gonzalez[3], George Church[4], Vivek Bhalla[2], Avnesh Thakor[5], Demetri Maxim[6]*
[1]Nephrogen Inc., New York, NY, [2]Stanford University, Stanford, CA, [3]NEPHROCHUS, Santiago de Compostela, La Coruña, Spain, [4]Harvard Medical School, Boston, [5]Stanford University, Palo Alto, CA, [6]Nephrogen, New York, NY
**Corresponding Author*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease, with a prevalence of approximately 1 in 1000 live births. It is characterized by the progressive formation of cysts in kidney and extrarenal tissues, leading to kidney enlargement and ultimately, end-stage renal disease. ADPKD accounts for ~10% of chronic kidney failure cases and is a significant public health problem. ADPKD is primarily caused by mutations in the *PKD1* or *PKD2* genes. Previously, we conducted a computational analysis of the ADPKD mutation landscape and showed that ~40% of *PKD1* and *PKD2* mutations can be corrected with CRISPR-Cas base editing. Base editing to correcting these mutations could restore the normal function of *PKD1* and *PKD2* and offer a potentially curative therapeutic approach. Furthermore, studies suggest that ADPKD kidneys exhibit plasticity, which suggests that re-expression of *PKD1* or *PKD2* in cystic kidneys could rapidly reverse the disease.

Methods: A missense mutation in *PKD1*, p.R3277C, is present in the homologous Pkd1 RC/RC mouse model, which carries the homozygous p.R3269C mutation. To investigate the potential of base editing to correct this mutation, we isolated and cultured kidney epithelial cells from these mice. Pkd1 RC/RC cells were used in vitro to test the efficacy of various CRISPR-Cas guide RNAs and identify the guide RNA with the highest editing efficiency. After selecting the most efficient guide RNA via lipid-based transfection in HEK293T cells, the optimal guide RNA and the ABE8e base editor were packaged into a novel adeno-associated virus capsid (AAV-S1) using a split-intein dual-AAV system. Edited cells were analyzed to assess Pkd1 expression via Western Blot and qPCR as well as various downstream markers associated with ADPKD progression.

Results: Our initial guide RNA screening studies showed that the most efficient guide RNA (RC_gRNA1) achieved 85% editing efficiency at the target nucleotide, without bystander editing when delivered via AAV-S1. RC_gRNA1 edited cells showed a two-fold increase in the RNA and protein expression of *PKD1* and improved mitochondrial function via an established MitoTracker assay. We also demonstrated efficient *in vivo* delivery with a modified AAV-S1 capsid using an mCherry reporter, showing transduction in ~40% of kidney cells via flow cytometry and 50% of renal tubules via automated image analysis.

Conclusions: This is the first study to show, at the cellular level, that CRISPR-Cas base editing can correct a pathogenic variant in *PKD1* to increase *PKD1* protein levels and improve downstream functional readouts. We demonstrate that a single dose of AAV-S1 achieves high editing efficiency (85%) and, crucially, without bystander editing. We also offer a comprehensive quantitative analysis of in vivo AAV-S1 delivery efficiency that is among the greatest efficiency reported to date for in vivo renal gene delivery. Taken together, these data provide strong evidence to support CRISPR-Cas base editing as a promising strategy to correct pathogenic variants of ADPKD as a potentially curative therapy.

1520 Enhancing Delivery Methods for Kidney-targeted Gene Therapy

Asmaa Mekawy[1], Brian Parrett[1], Jeffrey Rubin[2], Michael Barry[1]
[1]*Mayo Clinic, Rochester, MN,* [2]*Regel Therapeutics, Berkeley, CA*

Many gene therapies are delivered by the intravenous (IV) route. While this route can be useful for various diseases, it is generally ineffective for kidney diseases since the kidney's own filter excludes molecules above 50 kDa and vectors are megaDaltons in mass. To circumvent the kidney filter and deliver molecular therapies into the kidney, we and others have tested direct kidney injection methods in mouse models using subcapsular (SC- through the capsule of the kidney), retro-ureter (RU), and injections into the renal pelvis (RP). In most cases, these methods require surgery to expose the kidney and its structures for injection, so are time-consuming and invasive. Vectors can also be injected percutaneously through the skin if the kidney is visualized by ultrasound or is isolated manually. While these direct injection methods can mediate gene delivery inside the kidney, cells are generally not saturated with transgene products and most vectors leak into the blood to transduce the kidney and other tissues. To explore how different vectors perform under these conditions, we compared lipid nanoparticles (LNPs), different adenovirus serotypes (Ad), and different adeno-associated virus (AAV) serotype vectors, and peptide-modified Ad and AAVs by non-invasive percutaneous injection or by microsurgery with or without renal vasculature clamping into reporter mice of different ages. Detection of the vectors in the kidney, as well as in other organs such as the liver, was achieved using *in vivo* and *ex vivo* imaging, along with tissue sectioning and confocal microscopy. Our data demonstrate that direct kidney injections can bypass the kidney's size-exclusion barrier, leading to greater vector deposition in the kidney. We are currently comparing different serotypes and mouse ages to determine the most efficient serotype for kidney targeting, as well as identifying off-target effects associated with different delivery methods. This work lays the foundation for the development of vector platforms for gene therapy targeting diverse kidney diseases.

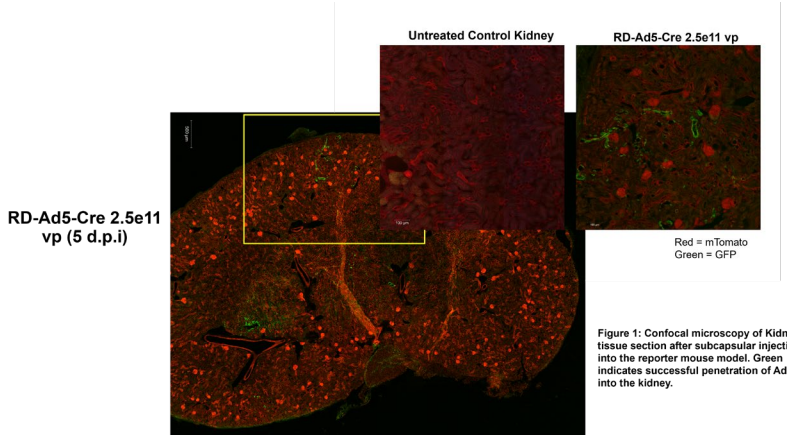

Figure 1: Confocal microscopy of Kidney tissue section after subcapsular injection into the reporter mouse model. Green indicates successful penetration of Ad5 into the kidney.

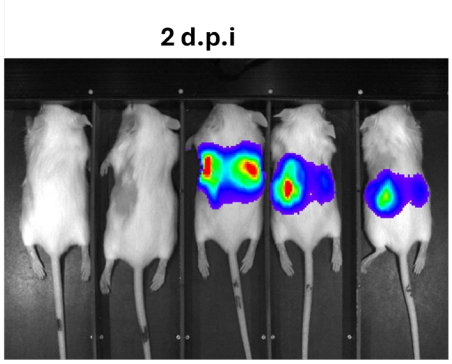

Figure 2: In-vivo imaging of the reporter mouse model showing a signal that potentially comes from the kidney as well as the liver. Adenovirus was injected using the direct non-invasive subcapsular method into the left kidney of the mice.

1521 Lentiviral complementation restores phenotypic defects of ABCA3 pathogenic variants

ABCA3 deficiency is caused by pathogenic variations in the ATP-binding cassette A3 (*ABCA3*) gene and results in reduced or loss of surfactant production from pulmonary alveolar type 2 cells (AT2s). Lack of surfactant leads to neonatal respiratory distress and can be lethal at birth or cause later onset childhood interstitial lung disease (ChILD). Supportive care or lung transplantation are the only current treatments for severe neonatal onset forms of ABCA3 deficiency. A genetic therapy that stably complements defective ABCA3 production offers promise. Previous studies show that repairing or complementing ABCA3 in induced pluripotent stem cell (iPSC)-derived AT2s restores defining phenotypes (e.g., lamellar body morphology and surfactant production). All ABCA3 pathogenic variants are rare or private; however, they can be categorized into class 1 (mistrafficking) or class 2 (impaired phospholipid transport activity) based on the impact of the genetic mutation on protein processing and activity. Little is known about the cellular responses to complementing class 1 or 2 variants. A limitation for advancing a gene therapy for ABCA3 deficiency is lack of a high throughput cell model that recapitulates phenotypes of iPSC-derived AT2 cells. Here we show that ABCA3 complementation using a lentiviral vector in A549 cells stably expressing *ABCA3* missense variant cDNAs restores multiple phenotypic features of 3 different variants: L101P (type 1), E292V (type 2), and E690K (type 2). Parental and ABCA3 knockout cells serve as controls. We observed restoration of lamellar body-like structure morphology and cell proliferation in ABCA3 complemented cells. Interestingly, results from bulk RNA sequencing indicate that lentiviral complementation of ABCA3 ameliorates aberrant TNFa signaling via NF-KB in E292V and E690K cells, but not in knockout or L101P cells. These studies help address important questions for understanding complementation of ABCA3 on various mutation backgrounds and provide relevant endpoints for efficacy to advance a gene therapy for ABCA3 deficiency.

1522 Leveraging ML to Improve Potency and Safety of Lung-Targeted Lipid Nanoparticles

Lee Danan Goldfryd[1], Guy Rosin[2], Igor Nudelman[1], Eilam Yeini[2], Nir Suissa[3], Galoz Kaneti[1], Amit Benazraf[4], **Alex Lagadinos[5]**, Yogev Debbi[6]
[1]Mana.bio, Haifa, Haifa, Israel, [2]Mana.bio, Binyamina, HaZafon, Israel, [3]Mana.bio, Tel Aviv, Tel-Aviv, Israel, [4]Mana.bio, Tel Aviv-Yafo, Tel-Aviv, Israel, [5]Mana.bio, Boston, MA, [6]Mana.bio, Bat yehoshua, HaZafon, Israel

Lipid nanoparticles (LNPs) have revolutionized RNA-based therapeutics. However, ensuring safe and effective delivery of mRNA to extra-hepatic tissues, such as the lungs, remains a significant hurdle largely due to challenges with cell-specific targeting and systemic toxicity. To address these challenges, Mana.bio has developed a machine learning (ML) platform capable of predicting critical LNP features required for specific and tolerable systemic mRNA delivery. The power and utility of this platform are demonstrated through Mana's lung delivery program, which leverages ML to model physicochemical properties, in-vivo targeting, and systemic safety toward unlocking the potential mRNA therapeutics for lung diseases.
Mana.bio's platform integrates over 80,000 proprietary data points and 45,000 publicly available data points, including results from in-vitro, ex-vivo, and in-vivo models. Leveraging advanced ML capabilities, we can accurately predict physicochemical properties—such as size, charge, and encapsulation efficiency, in-vivo lung targeting, and key toxicity parameters—such as cytokine secretion, liver enzyme elevations, and coagulation risks—while screening, in-silico, tens of millions of potential LNP formulations. The model ranks LNP candidates based on physicochemical properties, activity probabiility, and safety profile, enabling rapid identification of optimized formulations for specific therapeutic applications. The platform initially identified MB-LNP-01, an intravenously administered LNP candidate with highly specific lung delivery. Subsequent optimization efforts, incorporating only in-silico and in-vitro data, led to MB-LNP-02, a second-generation candidate with 100-fold increased potency. These findings highlight the platform's ability to rapidly enhance therapeutic performance while reducing development timelines. Towards improving the potential therapeutic index of MB-LNP-02, Mana.bio's safety prediction model identified subsequent novel LNP candidates by optimizing for critical toxicity assessments such as direct toxicity, immunotoxicity, hepatotoxicity, and coagulation. Through iterative refinement, MB-LNP-05 was engineered and validated in C57bl/6 mice, demonstrating above 100-fold reduction in cytokine elevation and a 100% improvement in tolerable dose with no off-target effects in key organs. Importantly, MB-LNP-05 exhibited enhanced lung-specific mRNA expression compared to MB-LNP-02, measured 6 hours after an IV dose of 0.65 mg/kg and 1.2 mg/kg fluc mRNA. Non-Human Primate (NHP) studies further confirmed these improvements, showing a 30-fold reduction in inflammatory cytokines, including IL-6, TNF-α, and IP-10, even at double the dose of MB-LNP-02. ALT and AST levels remained normal, with no acute liver damage observed at the maximum tested dose. This work underscores the transformative potential of integrating ML-driven modeling with experimental validation to accelerate drug development and unlock the potential of RNA medicines.

1523 Peptide insertions enhance AAV capsid tropism for airway epithelia

Ashley Cooney[1]*, Yonghong Chen[2], Brian Lewandowski[2], Shakayla Lamer[1], Priyanka Newase[1], Katarina Kulhankova[3], Beverly Davidson[2], Paul McCray[1]

Recent progress in therapies for genetic diseases, including both gene addition and gene editing, has achieved impressive results in immunodeficiencies, hemoglobinopathies, and neuromuscular disorders. A key limitation to applying these and other emerging technologies to cystic fibrosis (CF) is efficient delivery to target airway cell types. Adeno-associated virus (AAV) is a broadly useful vector for delivery to many cell types and is safe unless delivered at very high doses. Because of its persistence as an episome, expression lasts for months or years in slowly dividing cells. Here a peptide modified AAV capsid library approach was leveraged to identify highly performant capsid variants targeting human airway epithelia. Each parental AAV serotype was modified by insertion of a library of 7-mer amino acid sequence into a variable region loop. Beginning with a pool of ~6.8 million peptide sequences, we performed 3 passage rounds of capsid libraries from multiple serotypes in primary cultures of human airway epithelia (HAE) isolated from CF and non-CF individuals. Following each passage, genomic DNA and RNA were isolated and amplicon sequences enriched in HAE were selected for the following round. We selected 20 new AAV capsids with remarkable expression in HAE. These AAV capsid variants transduced target human cell types, including basal, secretory, and ciliated cells, at doses 1 to 2 logs lower than currently available capsids. We also observed enhanced transduction in primary human airway basal cells, pig airway epithelia, and mouse airways (**Figure 1**). Benchmarked to an airway tropic AAV (AAV2.5T), we identified several capsids with increased GFP reporter gene transfer. Importantly, we identified capsids that transduce HAE without the proteasome modulator,

doxorubicin (Dox). These newly identified capsids could be broadly utilized for the delivery of diverse genetic therapy reagent cargoes to the respiratory tract.

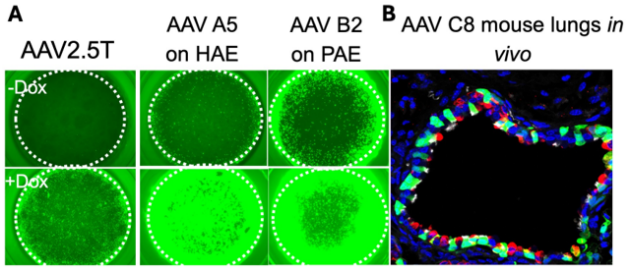

Figure legend: A) AAV2.5T, A5 and B2 capsids were applied to the apical surface (MOI=50,000) of human airway epithelia (HAE) or pig airway epithelia (PAE) overnight. Doxorubicin (1 μM) was applied overnight 48 hours later. Airway cultures were imaged by fluorescence microscopy 2 weeks later. Dotted white line indicates edge of Transwell filter. B) Mice received $1x10^{11}$ vg of AAV C8 expressing GFP intratracheally. Two weeks later, lungs were collected, embedded and sectioned for visualization. Immunofluorescence staining: red= CCSP (club cells), white= tubulin (ciliated cells), blue= DAPI.

1524 Optimising Magnetic-Guidance of Lentiviral Vectors for Improved Airway Gene Therapy Efficacy

Madison Davis[1], Alexandra McCarron[2], Ronan Smith[1], Nathan Rout-Pitt[1], Nicole Reyne[3], Lucy Costello[4], Kaye Morgan[4], David Parsons[5], **Martin Donnelley[6]**
[1]University of Adelaide, North Adelaide, South Australia, Australia, [2]The University of Adelaide, Adelaide, SA, Australia, [3]Cystic Fibrosis Airway Research Group, NORTH ADELAIDE, SA, Australia, [4]Monash University, Clayton, Victoria, Australia, [5]Women's & Children's Hospital, Adelaide, SA, Australia, [6]University of Adelaide, North Adelaide, SA, Australia

Introduction: For gene therapy to be effective for treating cystic fibrosis airway disease, higher efficacy is needed. Proposed enhancements include better targeting to disease-contributing conducting airways and increasing vector residence time. These could be achieved by magnetic guidance, where conjugation of iron-oxide magnetic nanoparticles (MNP) to gene vectors allows particles to be guided to and held within specific regions of the airway using external magnetic fields. This study aimed to optimise parameters for translation to an in-vivo study assessing the efficacy of magnet-guided gene therapy.

Methods: Wildtype rat basal epithelial cells were cultured in-vitro, and cells were transduced with lentiviral (LV)-GFP conjugated with MNPs with and without magnet exposure. Parameters such as nanoparticle choice (CombiMag vs. ViroMag), ratio of magnetic particle to functional LV vector (MNP:LV) (1:1, 1:10, 1:50, 10:1, 50:1, 200:1, 500:1 and 1000:1) and time spent co-incubating (5, 10, 15 and 20 min) were tested. GFP expression was measured with flow cytometry. In-vivo synchrotron phase contrast X-ray imaging was employed to understand how MNP behaviour can be manipulated on the rat tracheal airway surface under exposure to external dynamic magnetic fields.

Results: Without a magnetic field, increased volumes of MNPs improved efficacy. Magnetic field exposure led to significantly higher GFP expression regardless of factors such as co-incubation time and MNP:LV ratio (except for the lower MNP ratios, 1:1 and 1:50). Co-incubation time had no significant effect on GFP expression. Without magnet exposure, increasing the ratio of MNP:LV significantly increased GFP expression by 2.3, 4.4 and 3.6 fold respectively. With magnet exposure, each higher ratio significantly increased GFP expression until it plateaued at 200:1. In-vivo synchrotron studies identified a rotating wheel of magnets alternating between north and south poles (arranged into a Halbach array to enhance magnetic field strength) as the optimal setup for testing with gene therapy.

Conclusions: Magnetic field exposure consistently improved GFP expression. Higher ratios of MNP:LV significantly improved GFP expression under magnetic field exposure up to 200:1 after which increasing the ratio provides no further benefit. Co-incubation times tested did not influence efficacy. Optimised parameters will be adapted to an in-vivo gene therapy study in wildtype rats.

1525 Development of Lung-tropic Lipid Nanoparticles for Endothelial Cell Nucleic Acid Delivery

Autumn Greco[1], Jinghan Lin[2], Leonardo Cheng[1], Xiaoya (Julia) Lu[2], Karthik Suresh[3], Hai-Quan Mao[2]*
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore, MD
**Corresponding Author*

Introduction: Endothelial cell injury and dysfunction are largely implicated in the progression and development of various pediatric and adult pulmonary diseases, yet they remain under-addressed therapeutic targets [1]. While inhaling nanoparticles has proven to be highly effective in targeting epithelial cell populations [2], this method encounters physiological barriers before nanoparticles can reach the pulmonary vascular endothelium. Moreover, in disease contexts where ventilatory inefficiency can complicate nanoparticle dispersion and deposition, an intravenous and physiochemical-selective approach can help minimize these barriers to transfection while still allowing for organ-specific activity and a reduction of systemic adverse effects. We hypothesize that lipid nanoparticles (LNPs) trafficking to the pulmonary endothelium can be effectively directed without needing additional targeting ligands or lipid components. Since endothelial cell dysfunction linked with pulmonary diseases can lead to the dynamic acquisition and loss of cell surface markers, the significance of a compositional-based LNP screening approach for this target is highlighted.

Methods: We pursued a multi-step screening approach to identify optimized formulations for delivering mRNA and pDNA to endothelial cells. Utilizing a library of 649 formulations featuring SM-102 as the ionizable lipid, with helper lipids comprising cationic (DDAB, DOTAP), zwitterionic (DSPC, DOPE), and anionic (18BMP, 18PG) charge, along with cholesterol and the pegylated lipid DMG-PEG-2000, we assessed the transfection efficiency of Luciferase (Luc) mRNA-LNPs in Human Umbilical Vein Endothelial Cells (HUVEC) [3,4]. To evaluate these formulations *in vivo*, we stratified formulations by percentage of helper lipid content and examined the top four formulations for both DDAB and DOTAP using a cluster-mode screen in C57BL/6J mice. Transfection efficiency was quantified through whole-body and ex vivo imaging of major organs via IVIS at 24 h following intravenous injection of Luc-mRNA-LNPs. We also investigated the effectiveness of these formulations in delivering pDNA by evaluating Luc-pDNA transfection using the DDAB cluster.

Results: Benchmarking our library against the formulation used in the SARS-CoV-2 mRNA LNP vaccine, we observe that over 44% of formulations across all helper lipids surpassed the Moderna formulation in HUVEC transfection efficiency alone (Figure 1a). All DDAB and DOTAP formulations evaluated *in vivo* demonstrated extrahepatic tropism and nearly exclusive lung transfection (Figure 1b, c). Lung transfection in the DDAB mRNA cluster showed over four-fold higher transfection compared to the DOTAP cluster (n=3, p=0.0171). pDNA-DDAB-LNPs exhibit the same tropism pattern, though with lower luminescence overall. Individual formulations within these clusters will be further evaluated.

Conclusions: Lung-tropic nanoparticle formulations derived from this screening approach can direct specific therapeutic cargo of various sizes to the pulmonary endothelium.

1526 Pulmonary delivery of circular RNA therapeutics for cystic fibrosis

Ri Tang, University of Michigan, Ann Arbor, MI

Cystic fibrosis (CF) is a life-threatening autosomal recessive disease with > 30,000 cases of all races and ethnicities in the US. The disease arises from mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene, which encodes the cystic fibrosis transmembrane conductance regulator protein, leading to dysfunctional chloride ion transport and multi-organ damage, particularly in the lungs. The development of gene therapies for CF is hampered by the limitations of current CFTR modulator therapies, which fail to benefit approximately 10% of CF patients due to specific genetic mutations. Here, we disclose pulmonary delivery of circular RNA (circRNA) encoding wildtype functional CFTR protein (circRNA-CFTR), for the CFTR-mutant-agnostic treatment of CF patients. circRNA-CFTR is featured with high biostability, long-lasting expression of CFTR protein in lung epithelial cells. For the pulmonary delivery of circRNA-CFTR, we used a Design of Experiment (DOE) approach and identified lead lipid nanoparticles (LNPs) that enabled efficient protein expression in mouse lung, upon intratracheal administration of LNP-circRNA-CFTR. Further, upon intratracheal administration in mice, these LNPs enabled circRNA delivery to mouse upper tracheal epithelial subtypes, such as ciliated cells and ionocytes, of which the normalization of CFTR physiological function is pivotal for CF-associated lung diseases. The resulting LNP-circRNA-CFTR showed efficient CFTR protein production in CF patient-derived bronchial epithelial cells without invoking strong immune responses, resulting in the restoration of the physiological function of CFTR to pump Cl^- across the cell membrane in these cells. Furthermore, in a genetically engineered CF mouse model and CF rabbit model with CFTR loss-of-function mutation, LNP-circRNA-CFTR resulted in efficient CFTR expression in mouse and rabbit tracheal epithelia, as shown by ex vivo tissue flow cytometry, immunofluorescence imaging and western blot, and hence restored the CFTR function of a chloride channel, as shown by a Ussing chamber experiment in tracheal epithelia.

1527 A hybrid gene correction strategy for Cystic Fibrosis

Anais Amaya[1], Yehui Sun[2], Sumanta Chatterjee[3], Zexiang Chen[3], Daniel Siegwart[4], Matthew Porteus[5]
[1]Stanford University, Stanford, CA, [2]UT Southwestern Medical Center, Dallas, TX, [3]The University of Texas

Southwestern Medical Center, Dallas, TX, [4]UT Southwestern Medical Center, Dallas, [5]Stanford University School of Medicine, Stanford, CA

While treatments based on the use of CFTR modulators have significantly improved the quality of life of people with Cystic Fibrosis (CF), there is still the need for the development of durable therapies that could correct the disease at the genetic level. Using highly efficient genome editing systems such as CRISPR/Cas9, mutations in the *CFTR* gene can be corrected to produce a functional protein in lung cells. Our group has developed Cas9 ribonucleoprotein (RNP) and AAV reagents for highly efficient *ex vivo* editing of airway basal cells in two different approaches: a mutation specific approach and a universal strategy. However, the methods employed were designed to edit cells *ex vivo* that would later need to be transplanted. Transplantation of airway cells into the lower airways is still a work in progress in the field though interesting proof of concept work has been done in the trachea. Therefore, we developed a novel strategy that combines non-viral (lipid nanoparticles, LNPs) and viral vectors (adeno associated viral vectors, AAV) for the delivery of the editing reagents that could be used *in vivo*. Selective organ targeting (SORT) LNPs delivered TdTomato mRNA to nearly all primary Human Bronchial Epithelial Cells (HBECs) *in vitro* (>99%). Moreover, SORT LNPs carrying 5moU or N1MePsU Cas9 mRNA and a previously validated sgRNA targeting exon 11 of the *CFTR* gene resulted in 86% editing in wild type HBECs and 78% editing in HBECS homozygous for the most common CF mutation, dF508. We then combined the editing SORT LNPs with an AAV donor template for homologous recombination (HR) packaged in the natural capsid AAV6 or AAV2.5T, a synthetic capsid designed for airway tropism. We found that using this hybrid approach we were able to correct up to 73% of alleles in CF HBECs. The correction efficiency could be further enhanced by using AZD7648, an inhibitor of DNA-PK, achieving up to 81% corrected alleles. We are now validating this therapeutic approach in more advanced models such as precision-cut human lung slices.

1528 Allogeneic Engineered T Regulatory Cells Improve Disease Outcome in Preclinical Models of Acute Lung Injury

Maegan Hoover[1], Priya Saikumar Lakshmi[2], Yash Agarwal[3], Madison Milaszewski[4], Nicole Reed[5], Carlos Frias[6], Kassandra Baron[7], Abigail Doherty[6], Nathan Zammit[6], Hēth Turnquist[8], Tom Wickham[1], Tiffany Chen, Payam Zarin[9]
[1]GentiBio, Cambridge, MA, [2]Genti Bio, Boston, MA, [3]GentiBio, Somerville, MA, [4]GentiBio, Boston, MA, [5]GentiBio, Boston, [6]GentiBio, Cambridge, [7]University of Pittsburgh, Pittsburgh, [8]University of Pittsburgh, Pittsburgh, PA, [9]GentiBio, Brighton, MA

Acute Respiratory Distress Syndrome (ARDS) is a life-threatening condition characterized by run-away inflammation and maladaptive tissue-repair processes. Specifically, symptoms include diffuse alveolar tissue damage, pulmonary edema, severe hypoxemia, and increased local inflammatory cytokine response and immune cell infiltration. Causes of ARDS are numerous, ranging from direct tissue insult or drug-induced etiologies to pulmonary infections of bacterial or viral origin. Despite recent advancements in standard of care, ARDS remains largely associated with poor prognosis.

Foxp3+ T regulatory cells can play a key role in lung homeostasis and tolerance, controlling inflammation and promoting tissue repair processes. Our platform creates stable, tissue targeted, and selectively activated Tregs from abundantly available T cell populations. Specifically, we utilize CRISPR-Cas9 mediated gene editing of bulk CD4+ T cells to engineer Tregs (EngTregs) for stable expression of Foxp3, and a rapamycin-activated chemically inducible signaling complex that provides tunable, targeted, IL-2 signaling as well as the expression of the tissue damage alarmin receptor ST2. These “Tissue EngTregs”, recapitulate the gene signature observed in naturally occurring Tissue Tregs based on bulk RNAseq analysis compared to PBMC isolated natural Tregs and conventional Engineered Tregs. Flow cytometric comparison of Tissue EngTregs to EngTregs without ST2 revealed a cell product with higher expression of activation markers (e.g. Ki67 and HLA-DR), lung specific repair cytokines (e.g. IL-13), and tolerogenic markers (e.g. CD39, TIGIT, CD25). When cultured with inflammatory cytokines and alarmins, Tissue EngTregs were better able to sequester pro-inflammatory cytokines including IL-2, IL-33, TNF-a and IL-4, further suggesting an enhanced ability to respond to acute injury. Importantly, Tissue EngTregs expressed

high levels of lung inflammation homing chemokine receptor CCR4 as well as enhanced expression of tissue anchoring receptor CCR8.

A murine engineered Treg (mEngTreg) surrogate was used for preclinical *in vivo* evaluation of this approach in mouse models of pulmonary inflammation and acute tissue injury. We utilized the lipopolysaccharide (LPS) induced acute lung injury (ALI) model for studying severe lung injury and an extended bleomycin induced lung injury model to examine the later fibrotic phase of disease. Cell generation from CB6F1 (C57BL/6 x BALB/c F1 cross) donor mice allowed for allogeneic cell assessment.

Both allogeneic CB6F1 and autologous C57BL/6 derived mEngTregs improved disease outcome in the LPS and bleomycin induced ALI models. ALI mice in both models treated with mEngTregs showed restored blood oxygen saturation, reduced immune infiltrates as assessed by flow cytometry, lower levels of inflammatory cytokines in the bronchoalveolar lavage fluid, and reduced tissue damage by H&E. mEngTreg treated ALI animals also showed attenuated interstitial lung fibrosis as measured by Masson's Trichrome compared to ALI controls. Critically, mEngTregs preferentially engrafted at the site of injury, supporting an inflammation tuned homing mechanism. Overall, the ability of mEngTregs to not only ameliorate disease as measured by key, translatable biomarkers but also improve downstream tissue repair mechanisms supports the potential for developing a potent off-the-shelf allogeneic engineered Treg cellular therapy for human ARDS.

1529 Ultrasound-Guided Nano-Enhanced Optical Delivery of Optogenes in the Central Nervous System for Modulating Pain

Darryl Narcisse[1], Bob Benkowski[2], Samarendra Mohanty[3]
[1]Opsin Biotherapeutics, Bedford, TX, [2]Bedford, TX, [3]Nanoscope Therapeutics Inc, Bedford, TX

Purpose: Pain represents a significant health concern, leading to substantial psychological and physiological impairments in patients globally. Previous studies have shown that pain can be inhibited through optogenetic modulation of specific neurons within the Anterior Cingulate Cortex (ACC) and spinal cord via AAV-based gene delivery. Achieving localized gene expression in targeted cells is critical for efficacy, while minimizing off-target effects and adverse outcomes. The research outlined here compares viral and far-red laser-based spatially targeted nano-enhanced delivery (NOD) of genes encoding for multi-characteristic opsin (MCO) in the CNS.

Method: MCO is a sensitive optogenetic actuator activated by red light, which can penetrate deeper tissue with reduced absorption and scattering loss. NOD is a non-viral delivery technique that uses nano-enhancers to amplify light intensity, creating hot spots near targeted cells to perforate membranes and facilitate gene uptake. Gold Nanorods (GNRs) were used as nano-enhancers along with a 650 nm laser to deliver GAD-MCO genes into the dorsal regions of the ACC and lumbar spine. The mixture of GNRs and GAD-MCO plasmids was injected into the target tissue (intracranial for ACC and intrathecal for the spinal cord at the L5-L6 junction) before laser irradiation. Optogenetic stimulation of MCO-sensitized ACC and spinal cord was performed using a wirelessly controlled low-power red LED. Both acute inflammatory (via formalin injection) and chronic neuropathic hyperalgesia (by sciatic nerve constriction) pain models were used to assess the therapeutic efficacy of laser-delivered and optically-stimulated MCO in ACC and spinal cord.

Results: The qPCR-based analysis of MCO-transgene biodistribution indicated localized presence in the targeted tissues. Immunohistochemistry of the targeted tissue demonstrated expression of mCherry (reporter for MCO) in the inhibitory GABAergic neurons of the ACC and spinal cord regions treated with laser irradiation. Red light stimulation (via LED) of MCO-expressing GABAergic neurons in localized areas of the ACC and spinal cord resulted in inhibition of inflammatory pain (measured by formalin test of licking/lifting) and reduction of chronic

pain (assessed via paw withdrawal threshold using Von Frey assay). Efficacy results were comparable between the two gene delivery methods.

Conclusion: Non-viral laser delivery of MCO to neurons in the ascending/descending pain pathway may enhance the effectiveness of optogenetic modulation by targeting gene expression to the specific site(s) of interest. The NOD method is expected to allow control over the duration of gene expression and potential for redosing while minimizing immunogenicity associated with virally delivered gene therapies.

1530 Evaluating Behavioral Outcomes of Whole-Brain AAV9 Gene Therapy for Fragile X Syndrome via Focused Ultrasound and BBB Opening

Thomas ADOR[1], Sébastien Rigollet[2], Vasile Stupar[3], Anthony Laugeray[4], Emmanuel Barbier[2], Chantal PICHON[5], Arnaud Menuet[6], **Anthony Delalande[7]***
[1]University of Orléans, Orléans, France, [2]Université Grenoble Alpes, Grenoble, France, [3]INSERM, Grenoble, Isère, France, [4]NBPharmaTox, Orléans, France, [5]INSERM, Orléans, Loiret, France, [6]University of Orleans, Orléans, France, [7]University of Orléans, Orléans, France, France
**Corresponding Author*

Fragile X syndrome (FXS) is the leading inherited cause of intellectual disability and currently lacks effective treatments. This monogenic disorder results from a CGG triplet expansion that silences the *Fmr1* gene. Gene therapy holds promise for restoring *Fmr1* expression but requires efficient delivery across the blood-brain barrier (BBB). In this study, we employed focused ultrasound combined with microbubbles (FUS-BBBo) to achieve whole-brain BBB opening and facilitate AAV-mediated gene delivery in *Fmr1*-KO mice.

Whole brain BBB opening was conducted using 1.5 MHz ultrasound at 450 kPa peak negative pressure in raster scan mode during 92s at a speed of 10mm/s (Image-guided Therapy, Pessac, France) combined with the intravenous bolus injection of 10^8 microbubbles (Harmonix, France). Two AAV9 viral vectors encoding Luciferase and Fmr1 were produced and injected at a dose of 10^{11} viral genomes following FUS-BBBo on 8-12 weeks old Fmr*1*-KO mice. We then conducted imaging, qPCR, immunochemistry and behavioural analyses following the treatment (fig 1).

First, The T1 MRI contrast ratio following Gd/DOTA injection demonstrated an average of >60% successful BBB opening of the total brain volume was achieved with system. The use of AAV9-Luciferase vector confirmed by bioluminescence imaging the widespread and stable transgene expression in treated brains. Subsequent delivery of an AAV9-*Fmr1* vector resulted in variable but efficient rescue of *Fmr1* expression (15.2 +/- 7.6% of expression wild type control mice), assessed via RT-qPCR 8 weeks after transduction (fig 2). We observed by immunohistochemistry the protein FMRP in neurons in several brain regions, including the cortex and hypothalamus in all examined mice, and in the hippocampus less frequently. The combination of FUS-BBBo and AAV9-*Fmr1* gene therapy further enhanced behavioural outcomes on *Fmr1*-KO mice, particularly in reducing hyperactivity and anxiety-like behaviours with a significant diminution of the distance travelled in the open field in treated mice compared to sham control and a significant lower number of marbles buried over time in treated mice over sham control. It has to be noted that interestingly, whole-brain BBB opening without AAV led also to some improvements in hyperactivity phenotype.

These findings highlight the potential of FUS-BBBo as a non-invasive strategy for whole-brain gene delivery and its therapeutic benefits beyond transgene expression. This approach could pave the way for novel treatments for FXS and other neurodevelopmental disorders.

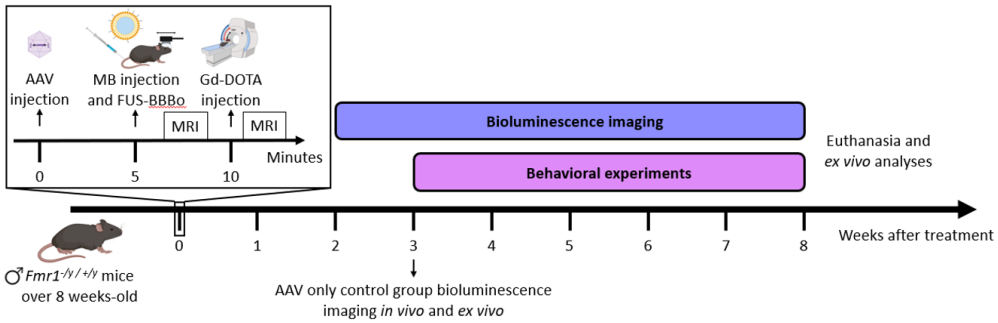

Figure 1: Timeline of FUS-BBBo procedure and following experiments.

1531 Intravenous Delivery of a CNS-Penetrant AAV Gene Therapy Provides Survival Benefit in a TSC1 Disease Model

Christopher Davis[1], Sisi Chen[2], Ellen Horste[2], Tina Hu-Seliger[2], Von Wiltman[2], Jorge Santiago-Ortiz[2], Andrew Steinsapir[3]
[1]Apertura Gene Therapy, Somerville, MA, [2]Apertura Gene Therapy, New York, NY, [3]Deerfield Management, New York, NY

Introduction: Tuberous sclerosis complex (TSC) is a neurodevelopmental disorder caused by loss of function mutations in the genes *TSC1* or *TSC2*, which regulate mTOR activity. Mutations in TSC1 or TSC2 lead to hyperactivation of the mTOR pathway, resulting in abnormal cell growth, gliosis, and epileptogenesis. While options exist for the treatment of TSC-associated epilepsy, ~60% of TSC patients develop recalcitrant epilepsy resistant to multiple anti-seizure medications, underscoring the need for improved treatments for TSC. Given the neurological impact of TSC, an effective therapeutic would require widespread distribution throughout the central nervous system (CNS).

Approach: Apertura has developed AGTX-1111, an AAV-based therapeutic designed to deliver a functional copy of the human *TSC1* (*hTSC1*) gene to the CNS after intravenous delivery using TfR1 CapX, a capsid engineered to cross the blood-brain barrier (BBB) via the human transferrin receptor (hTfR1). Preclinical studies for AGTX-1111 make use of a surrogate approach wherein a mouse-specific BBB-crossing capsid, PHP.B, is used in place of TfR1 CapX for mouse disease models lacking expression of hTfR1. We applied this approach to a previously described

loss of function mouse model in which *Tsc1* is conditionally disrupted in GFAP-expressing cells (*Tsc1 fl/fl GFAP-Cre*; "CKO"), leading to loss of function in astrocytes and some neurons. These mice show a severe disease phenotype, wherein loss of Tsc1 function results in reduced lifespan, seizures, and aberrant brain morphology (Uhlmann, et al. 2002).

Results: In pilot studies, we confirmed the ability of PHP.B to deliver a previously described hTSC1 transgene (Prabhakar, et al. 2015) to the CNS after intravenous dosing and provide a survival benefit in CKO mice relative to untreated controls. Development of an hTSC1 transgene made use of hTSC1 knockout cell lines wherein loss of TSC1 function leads to elevated mTOR activity, evidenced by increased phosphorylation of the mTOR target p70S6 Kinase (p70S6K). We developed an ELISA-based potency assay to measure the ability of hTSC1 transgene expression to rescue TSC1 function, restoring normal levels of phosphorylated p70S6K in hTSC1 knockout cells. This potency assay was used to nominate AGTX-1111, which uses an EFS promoter to drive expression of an hTSC1 transgene. While we observe lower overall levels of hTSC1 expression in vitro using the AGTX-1111 transgene cassette compared to the published transgene, we observe similar reduction of phosphorylated p70S6K to wild-type levels.

Conclusions: These preliminary efficacy data of the nominated development candidate AGTX-1111 motivate its advancement to proof-of-concept in vivo efficacy evaluations for the developed TSC1 gene therapy. These data will fit within a broader regulatory strategy to identify TfR1 CapX dose levels that achieve similar levels of CNS distribution as an efficacious dose of the surrogate capsid PHP.B. We anticipate that this strategy will help enable identification of AGTX-1111 dose levels appropriate for treatment of TSC patients.

1532 Identification of AAV engineered capsids that allows efficient CNS transduction through comparative biodistribution studies.

Background: The efficacy of a gene therapy mediated by an adenoviral-associated virus (AAV) vector is partly determined by the tropism of the viral capsid used. For genetic conditions affecting the CNS, gene therapies would optimally be delivered using an intracerebroventricular (ICV) route of administration. There is currently lack of understanding around the ideal AAV capsid to be used for such treatments .

Aims: To enable the translational development of AAV mediated gene therapies for CNS related disorders, we strove to examine the efficacy of delivery to the CNS of various AAV capsids by assessing biodistribution through use of a packaged bioreporter expression cassette.

Methods/Materials: AAV vectors carrying a SSFV-Luc-2TA-eGFP expression cassette were packaged in AAV-9, AAV-F and AAV-B1 capsids. These were administered through an ICV route into adult mice at 3.7e9 vp. At four weeks post-administration, various body wide tissues were harvested and divided up for RNA harvest for eGFP expression and for protein for luciferase assay assessment. Tissue was also embedded for subsequent cryo-sectioning for fluorescent histochemical analysis.

Results: On the basis of eGFP expression at the mRNA level (in liver kidney, brain, blood, lung, heart, spleen, muscle), intensity of fluorescence on sectioned tissues (brain cortex, optic nerve, and sciatic nerve) and luciferase enzymatic activity (in liver kidney, brain, blood, lung, heart, spleen, muscle), we establish that AAV-B1 and AAV-F are far superior to AAV-9 for the transduction of and the delivery of cargoes to the CNS by ICV routes of administration. For example, at the brain transcript level AAV-F is 715 fold and AAV-B1 81 fold greater than

AAV-9; and at the protein level AAV-F is 104 fold and AAV-B1 is 69 fold greater than AAV-9. Consideration of the readouts as a whole suggest that AAV-F is the most efficient of the three capsids for delivery/transduction efficacy to target tissues.

Conclusions: With the identification of AAV serotypes that allow efficient transduction and delivery of transgenes to the CNS, we provide validated opportunity for gene therapies for CNS-related genetic disorders to their reach maximal potential.

1533 Multivariate Analysis of Routes of Administration and AAV Capsid Selection for Efficient Brain Transduction in the FVB Strain of Mice

David Cameron[1], Kyle Fink[2], Julian Halmai[3], Jennifer Waldo[4]
[1]University of California Davis Department of Neurology, Sacramento, CA, [2]UC Davis, Sacramento, CA, [3]UC Davis, Sacramento, California, [4]Scribe Therapeutics, West Sacramento, CA

Effective delivery of biologics to the brain remains as one of the leading challenges in the field of neurogenetic therapeutic intervention. Adeno-associated viruses (AAVs) have long been the delivery vehicle of choice for CNS gene therapies due to their safety, CNS tropism, and long-term durability of associated therapeutic effect. However, there are several limitations that limit the broad use across many indications including: transduction efficiency, including restriction of transfer through the blood brain barrier (BBB), immune response and generation of neutralizing antibodies due to the delivery of high vector genome, peripheral effects involved with liver accumulation and toxicity, and limited genome size. To address these shortcomings, many in the field have developed new and evolved capsids that have enhanced BBB crossing ability along with de-enrichment of liver transduction. However, there are limited reports directly comparing this new class of evolved capsids with the naturally occurring AAV9, that is preferentially used for delivery to the brain, across multiple routes of administration. In this study, an optimized, hypercompact CRISPR protein construct was fused nanoluc and GFP to

allow for non-invasive imaging and co-localization studies and was packed using three publicly available evolved capsids that have been developed to specifically target neurons, capB10, PhP.eB, and DJ8 and compared against AAV9. All vectors were packaged following our lab's established protocols and where injected via three translationally relevant routes of administration: intrastriatal, intracerebral ventricular, and intravenous (tail vein) in mice (FVB/NJ). Evaluation and analysis of efficiency of distribution was performed using longitudinal bioluminescence imaging (IVIS) for up to 6 months post-delivery. Immunohistochemistry was also performed to quantify transduction efficiency, neuronal co-localization, and pilot studies to assess neuroinflammation. Based on our analysis we found that the AAV9 capsid delivered through CSF routes resulted in the highest expression, distribution, and transduction efficiency.

1534 A Minimally Invasive Enzyme Replacement Therapy for Angelman Syndrome

Delihla Correa[1], Rachel Stoub[1], Tyler Johnson[2], Linna Han[2], Yara Al Mashriki[1], Moses Lee[1], Albert Keung[2], Lisa Ellerby[2], **Barbara Bailus[1]**

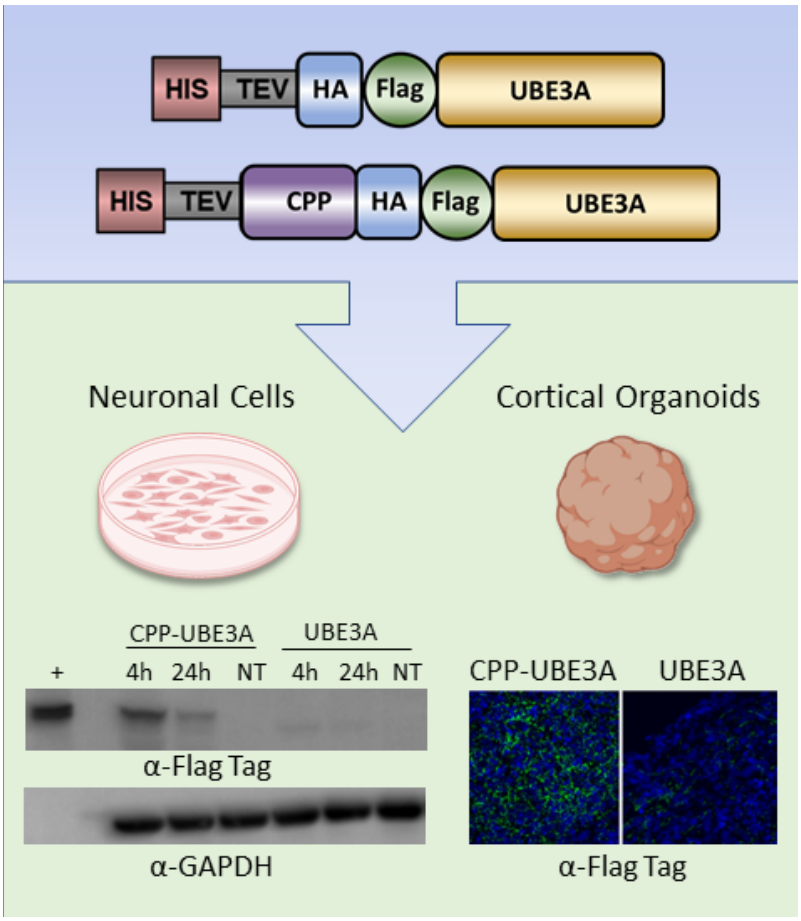
Angelman syndrome is a rare neurodevelopmental disorder caused by a loss of function of ubiquitin-protein ligase E3A (UBE3A) protein in the brain. Individuals with Angelman syndrome are generally non-verbal and experience debilitating seizures, gait abnormalities, sleep disturbances, and intellectual developmental delays. Despite decades of research characterizing Angelman syndrome and developing relevant model systems, there remains a continuing unmet need for treating this disease. Several potential and promising treatments are currently in clinical trials, including two ASOs. However, delivery of ASOs remain a challenge as they are delivered by regular injections into the cerebral spinal fluid. The injections are invasive and must be done at a hospital by specially trained physicians. Our work aims to create a minimally invasive enzyme replacement therapy, by delivering UBE3A to the brain through a simple intravenous injection that could potentially be done at home or at an outpatient clinic. The delivery of the UBE3A to the brain is made possible by the use of novel cell-penetrating peptides (CPPs), that can cross the blood-brain barrier. One of these cell penetrating peptides called "ZIP" is derived from the Zika virus. Our work has demonstrated that "ZIP-UBE3A" can enter human and mouse neuronal cells lines and human cortical organoids at a significantly higher rate than UBE3A without ZIP. We have also shown that ZIP-UBE3A retains enzymatic activity, adding ubiquitin to one of its targets TP53. We are currently evaluating the efficacy of ZIP-UBE3A in crossing the murine blood brain barrier from an intravenous injection. This presentation will highlight our progress towards developing "ZIP-UBE3A" as a minimally invasive enzyme replacement therapy for Angelman syndrome.



1535 A MyoAAV Capsid Variant Revealed Schwann Cell Specific Colocalization in AAV Serotype Screening Studies for Peripheral Nervous System Gene Therapies

Charcot-Marie-Tooth disease (CMT) is a heterogeneous group of disorders caused by mutations in over 100 genes. Clinically, patients can be divided into two major groups, demyelinating and axonal neuropathies. Demyelinating CMTs including CMT1, CMT4, and CMTX are caused by gene mutations affecting Schwann cells and disrupting normal myelination in peripheral nerves. While various adeno-associated virus (AAV)-based gene therapies are under investigation for these genetic disorders and have shown great promises preclinically, targeting Schwann cells has remained a significant challenge. Recently, capsid engineering has laid the ground for introducing novel AAV serotypes and capsid variants with improved specificity toward cells and tissues of interest. In this study, we aimed to compare widely used AAV serotypes to screen their Schwann cell-specific targeting properties.

To elucidate the Schwann cell targeting ability of different AAV serotypes including AAV1, AAV4, AAV5, AAV6, AAV9, AAVrh10, AAVv66, AAVPHP.EB, MyoAAV3A, AAVF, and AAVrh74, we studied the AAV transduction efficiency along with Schwann cell-specific markers' colocalizations at in vitro, ex vivo, and in vivo levels. Immortalized human and isolated primary mouse Schwann cells were transduced with AAV vectors at a multiplicity of infection (MOI) of 5E+3 and the transduction efficiency was evaluated seven days post-treatment. Furthermore, an ex vivo model of dorsal root ganglion (DRG) was applied to study the lead serotype (5E+5 vector genomes (vg)

per DRG), and immunostained with a Schwann cell-specific biomarker, Sox10, for colocalization observations. Finally, wild type FVB mice were injected intrathecally at six weeks old with 5E+11 VG of different serotypes to express enhanced green fluorescent protein (EGFP) under a cytomegalovirus (CMV) enhancer/chicken beta-actin (CAG) promoter and sacrificed eight weeks post-injection. Sciatic nerves were collected and sectioned, and the sections were processed for immunofluorescence staining.

AAV1, AAV4, and AAV6 successfully transduced immortalized human and primary mouse Schwann cells in vitro, with AAV6 showing greater efficiency compared to AAV1. Interestingly, we observed highly efficient Schwann cell transduction with MyoAAV3A, which was greater than other serotypes. Immunofluorescence staining of MyoAAV3A-treated mouse DRGs revealed about 70% colocalization of EGFP with Sox10 at four days post-treatment, demonstrating its remarkable efficiency in targeting Schwann cells ex vivo. The Schwann cell-specific transduction of MyoAAV3A was investigated in vivo along with AAV6, AAV9, AAVF, and AAVrh10 vectors. While AAV9 and AAVrh10 exhibited Schwann cell transduction, AAVrh10 showed higher GFP expression in Schwann cells compared to AAV9. Surprisingly, in sciatic nerve sections, we observed colocalization of EGFP expression with a Schwann cell-specific marker when using MyoAAV3A vectors. While we used the ubiquitous CAG promoter, GFP expression was exclusively observed in Schwann cells and was absent in axons, a distinction not seen with other studied serotypes. Further in vivo studies on MyoAAV3A alongside quantification of Schwann cell transduction in different parts of peripheral nerves and liver by qRT-PCR are underway.

The novel muscle-tropic AAV serotype, MyoAAV3A, demonstrated highly Schwann cell-specific tropism in vitro, ex vivo, and in vivo, highlighting its potential for Schwann cell targeting in different disease models.

1536 Development of an antibody-conjugated AAV platform for non-invasive and targeted delivery of therapeutics to the peripheral nervous system.

Carolina Serrano Garcia, Emily Lo, Ammar Tareen, Adina Buxbaum, Garima Thakur, Zhe Zhang, Iryna Labinskyy, Dennis Marlowe, Poulami Samai, Samvitha Cherravuru, Jennie Jaswal, Sheldon Mink, Richard Copin, Andrew Tustian, Lynn MacDonald, Nicole Alessandri-Haber, Christos Kyratsous, Sven Moller-Tank, **Mathieu Desclaux**
Regeneron Pharmaceuticals Inc.

Chronic pain is a prevalent condition that affects more than 20% of the adult population and for which the current standard of care still focuses mostly on opioid use, often associated with heavy side effects or subsequent life-threatening disorders. Therefore, there is a real unmet need for the development of safer and efficient pain treatments with reduced side effects. In that context, gene therapy emerges as a promising modality to deliver new pain therapeutics to neurons of the peripheral nervous system (PNS). One major obstacle remains in the generation of appropriate vectors for delivery to the PNS. Adeno-Associated Viruses (AAV) have taken a leading place as viral vectors for the treatment of various acute and chronic neurological disorders in the central nervous system (CNS). However, in comparison to the CNS, controlled delivery of AAV to the PNS for therapeutic purposes has proven to be more challenging and less successful. So far, few examples of engineered capsids have led to specific delivery to PNS neurons with translatability across species.

To address this gap, we applied our modular and antibody-driven AAV retargeting platform to generate novel AAV that can be efficiently redirected to the PNS in rodents and NHPs. We employed rational capsid engineering and covalent conjugation of antibodies to variable loops of the viral capsid through a protein tagging system, an approach that has been already successfully validated for redirecting AAV to brain and muscle tissues with cross-species translatability. Through cross functional in-house efforts combining *in vivo* antibody internalization and biodistribution studies, we previously identified the neurotrophin receptor p75 (p75NTR) as an ideal target to redirect AAV to the PNS. In particular, we validated the capacity of anti-p75NTR-conjugated AAV to efficiently transduce dorsal root ganglion (DRG) and trigeminal ganglion (TG) neurons in wild type mice after systemic administration, while being de-targeted from the CNS and peripheral organs.

With the aim to optimize this p75-retargeted AAV platform for delivery of pain therapeutics in the clinic, we screened a larger pool of twenty anti-human p75 monoclonal antibodies (mAb) and Fab conjugated to barcoded AAVs for their ability to mediate transduction of DRG and TG neurons after systemic delivery in mice expressing

human p75NTR. To demonstrate the translatability of our approach in a large animal model, we are now evaluating the anti-human p75 AAVs in cynomolgus macaques, particularly focusing on evaluating the tropism and potency of those antibodies across species. Once validated, we aim to apply this technology for the development of novel treatments for chronic pain and PNS disorders.

1537 Gene drive viral vector suppress recurrences of herpes simplex virus 1 and 2 in mice

**Corresponding Author*

Herpes simplex viruses (HSV) 1 and 2 cause lifelong recurrent infections that can have severe medical and psychosocial consequences. HSV travels through nerves and remains latent for life in the peripheral nervous system, with periodic reactivations causing oral or genital ulcerations. HSV infection lacks vaccines or cures. Here, we report a new type of viral vector as a preventive or therapeutic treatment for HSV infection. We recently developed a viral gene drive in herpesviruses that relies on the co-infection of neurons by wild-type and engineered gene drive viruses. After CRISPR-mediated recombination between viral genomes, wild-type viruses are converted into new gene drive viruses. Here, we describe a gene drive against HSV-1 and 2 that inactivates the transport of virions from the nervous system to the mucosal periphery. We hypothesize that gene drive vectors could reach the site of HSV latency in ganglionic neurons and prevent wild-type HSV from traveling to the periphery and causing disease. We show that gene drive vectors act as live-attenuated HSV vaccines that induce a protective immune response in addition to CRISPR-based protection. We report that prophylactic treatment with gene drive vectors prevents latency establishment and viral shedding after vaginal infection of mice with HSV-1 and HSV-2. Furthermore, therapeutic treatment reduces vaginal shedding in mice latently infected with HSV-2. Overall, our results suggest that gene drive vectors could combine immune and CRIPSR-based protection to durably prevent or suppress HSV disease.

1538 Gene Therapy for Tuberous Sclerosis Complex 1: AAV-Mediated Hamartin Delivery Enhanced via Extracellular Vesicles in a Mouse Model of TSC1.

Tomeh Tomeh[1], Edwina Abou Haidar[2], Shilpa Prabhakar[3], Roberta Beauchamp[2], Koen Breyne[4], Vijaya Ramesh[2], Xandra Breakefield[3]
[1]Mass General Brigham, Charlestown, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital, Charlestown, MA, [4]Massachusetts General Hospital and Harvard Medical School, Charleston, MA

Tuberous sclerosis complex (TSC) is a dominantly inherited disease affecting multiple organs with an incidence of about 1 in 5500. TSC is caused by mutations in either the *TSC1* gene encoding hamartin or the *TSC2* gene encoding tuberin, which normally form a complex that inhibits mammalian target of rapamycin (mTOR). The loss of either of these proteins due to genetic mutations results in growth and proliferation in susceptible cells causing abnormal development and tumors. Neurodevelopmental manifestations, which are responsible for the greatest morbidity, include refractory epilepsy, hydrocephalus, and cognitive impairment. In our stochastic, cerebral mouse model of Tsc1, mice (Tsc1 flox/flox) are injected into the cerebral ventricles with a Cre recombinase encoding an adeno-associated virus (AAV) vector on the day of birth (P0; **Prabhakar et al., 2013**). The resulting loss of function leads to hypertrophy and proliferation of cells lining the ventricles, enlarged neurons and elevated phosphorylation of ribosomal protein S6 in hamartin-null cells, as well as dysmyelination, and early death with a mean of 50 days. AAV vectors have been used widely in clinical trials for many hereditary diseases with little-to-no toxicity, long-term action in nondividing cells, and benefits seen after a single injection. We used AAV9, a serotype that can efficiently cross the blood-brain barrier to deliver hamartin to cells in Tsc1 lesions, which would make them shrink and stop dividing. It could then be delivered to other cells in the brain via extracellular vesicles (EVs), increasing the range of delivery over time. We have been able to normalize the neuropathological disturbances in our mouse model of TSC1 via the intravascular administration of an AAV9 vector encoding hamartin at postnatal day 21, extending the average lifespan from 50 to over 120 days in 85% of animals (**Prabhakar et al., 2019; Abou Haidar et al.,**

under review). Our current work aims to improve gene therapy by enhancing hamartin delivery using AAV vectors combined with EVs. We have generated different modified forms of hamartin plasmid expression constructs to identify modifications that can increase hamartin uptake into EVs. We have transfected these constructs into HEKT cells and showed via western blot that we can increase incorporation of modified hamartin cargo into EVs. A version of hamartin tagged with a palmitoylation signal at the N-terminal was most effective at EV incorporation. The palmitoylation signal anchors the protein to the plasma membrane, facilitating its inclusion in EVs. Furthermore, we have used a 1.0- µm-pore Transwell system seeding stably transfected HEKT cells in the upper chambers and TSC1-null HEK cells in the bottom chambers. We confirmed successful hamartin production, packaging, and transfer to recipient cells through EVs by immunohistochemistry, as we detected a robust signal of the in-frame V5 epitope tag used in our constructs. We are currently evaluating the effects of the hamartin-loaded EVs on inhibiting mTOR activity using immunohistochemistry and flowcytometry to measure its impact on the levels of phosphor-S6 protein expression in cultured TSC1 null HEK cells and neuroprecursor cells. We have packaged these constructs into AAV vectors for *in vivo* studies on our stochastic cerebral mouse knock-out model of TSC1. We will evaluate the enhanced delivery of hamartin by combining AAV gene therapy and EV spread of the protein/mRNA in the brain.

1539 Human Secreted Klotho Expression Improves Cognition and CNS Status in Aged Non-Human Primates

**Corresponding Author*

Aging is the primary risk factor for numerous diseases that significantly impact people's health. New therapeutic strategies for achieving healthy aging must be developed to mitigate the rising social and economic costs of senescence in modern societies. In this context, the protein Klotho exhibits pleiotropic beneficial functions, slowing down the progression of aging. While its therapeutic potential has been well established in murine models, limited data exist regarding its translatability to animal models that are closely evolutionarily related to humans.

Here, aged individuals of the non-human primate species *Microcebus murinus* were treated with AAV9 vectors expressing the alternatively spliced secreted isoform of the human *Klotho* gene (s-KL). Nine months post-administration, we confirmed s-KL expression in both the hippocampus and liver. Notably, s-KL-treated animals showed improved performance in the novel object recognition test over time, demonstrating enhanced cognitive preservation compared to Null-treated animals. The observed cognitive improvements in s-KL-treated aged individuals correlated with changes at the cellular level in the central nervous system (CNS). Specifically, we detected an increase in the thickness of the CA1 neuronal layer in the hippocampus. Additionally, the treatment modulated glial cell populations, leading to a significant reduction in astrocytes and an increase in microglia, as measured by GFAP and ferritin markers, respectively. Furthermore, the effect of s-KL on CNS white matter was also assessed, measuring lipid oxidation levels using synchrotron-Fourier transform infrared microspectroscopy.

In this study, we demonstrate that the secreted isoform of *Klotho* enhances cognitive performance in aged non-human primates and, for the first time, link this effect to cellular and molecular changes in the CNS of treated animals.

1540 A new, patient-derived *SYNGAP1* mouse model demonstrates multipledisease-relevant phenotypes.

[1]*The Jackson Laboratory, Bar Harbor, ME*

Introduction: SynGAP is a Ras-GTPase activating protein, enriched at excitatory synapses in the brain. It is critical for neuronal development and synaptic plasticity, as well as a negative regulator of excitatory neurotransmission. At sub-homeostatic levels, SynGAP deficiency results in excessive AMPA receptors on the cell membrane, which impacts neuronal development, integrity, signaling and other aspects critical for cognition and excitability. Not surprisingly, SYGNAP1 is one of the most frequently mutated genes in Neurodevelopmental Disorders (NDD). SYNGAP1-Related Disorders (SRD) describe a spectrum of pathologies that arise from clinical alleles of the *SYNGAP1* gene, impacting 1 in 16,000 live births. Patients typically harbor a loss-of-function *de novo* nonsense or missense mutations resulting in an autosomal dominant haploinsufficiency with symptoms that can include: epilepsy, intellectual disability, developmental delays, behavioral problems, high pain threshold, hypotonia, eating problems, sleep disorders, autism spectrum disorder and ataxia/gait abnormalities. In fact, large exome sequencing in the UK found *SYNGAP1* to be the 5th most prevalent NDD-related gene in and accounts for ~1% of the NDD population. Currently, treatments are limited to symptom management, as no treatments can address the underlying genetic condition or SynGAP protein deficiency.

Methods: Previously, heterozygous Syngap1 knockout mice have demonstrated several disease-relevant phenotypes, including learning and memory deficits, abnormal social behavior, seizures and hyperactivity. However, most patients do not possess deletion alleles, as most clinical alleles are nonsense mutations. Here, we describe a new mouse model with a patient derived mutation, Q503X. By employing data from previous models, we assessed behavioral, physiological, and molecular metrics in this newly developed mouse model.

Results: Q503X mice demonstrated multiple phenotypes consistent with other *SYNGAP1* -deficient models, including reduced working memory and sleep disturbance. Open field metrics identified a robust hyperactivity and vertical rearing, in addition to perturbed center-margin dwell time. We noted several previously undescribed sex-specific differences, such as acoustic startle, body weight, and 3-Chamber social discrimination index. Notably, these phenotypes track with symptoms reported in SRD patients

Conclusions and Future Directions: Upcoming assessments into pain perception and EEG telemetry. SRD is often inclusive of seizures and many caregivers report unusually high pain tolerances in patients. While we anticipate EEG to reveal spike train events and other previously identified phenotypes in other *SYNGAP1* models, Von Frey and Hot Plate assessments have been widely unexplored in mouse models for SRD. Currently, the assessed data validate this new, patient derived model platform for further study and therapeutic development addressing SRD, with a direct connection a human pathogenic variant. Combined with the upcoming assessments, the Q503X model is poised to become a robust and effective tool in the efforts to understand and treat SRD.

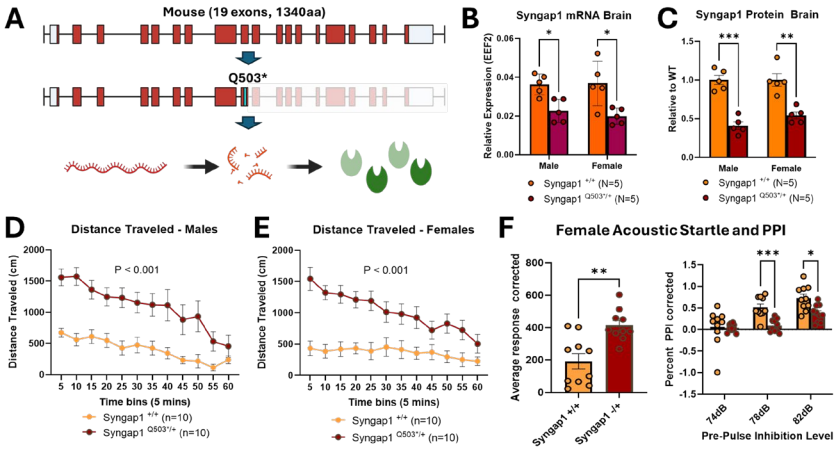

Figure 1: Key Phenotypes in the Patient-Derived Syngap1Q503 mouse*

*(**A**) The Q503* mutation is predicted to result in nonsense mediated decay, effectively reducing the amount of SYNGAP protein. Syngap1 mRNA **(B)** and SYNGAP protein **(C)** is reduced in brain tissues of both males and female Syngap1 Q503* heterozygous mice. **(D,E)** Open field analysis demonstrates hyperactivity of Syngap1 Q503* heterozygotes compared to WT littermates. **(F)** Female Syngap1 Q503* heterozygotes show enhanced freezing in acoustic startle tests, as well as reduced pre-pulse inhibition. Males were unaffected. Data presented as mean ± SD. Asterisks indicate P≤0.05(*), 0.01(**), 0.001(***), two-tailed unpaired t-tests with Welch correction.*

1541 Enhancing Chemotherapeutic Efficacy by Combining Efflux Transporter Inhibition with CED Using a Novel sEEG-based Drug Delivery System

Liang Zhang[1], David Daniels[1], Maria Porto Cruz[2], Guadalupe Zepeda[3], Su-youne Chang[1], Jiwon Kim[1], Inyong Kim[1], Filip Milvat[1], Alfonso Chavez[3], Mary McNeil[3], Paul Kullmann[4], Maria Vomero[5], Camilo Diaz-Botia[3], Dave Rosa[6], Gregory Worrell[1], **Aura Kullmann[2]**
[1]Mayo Clinic Rochester, Rochester, MN, [2]NeuroOne, Eden Prairie, MN, [3]NeuroOne Medical Technologies Corporation, Los Gatos, CA, [4]University of Pittsburgh, Pittsburgh, PA, [5]NeuroOne Medical Technologies Corporation, Los Gatos, [6]NeuroOne Medical Technologies Corporation, Eden Prairie, MN

Chemotherapeutic efficacy in brain tumors is primarily challenged by inadequate drug penetration into the tumor due to the blood-brain barrier (BBB) and short drug-tumor residence time due to drug efflux. To address these limitations, we explored the use of convection-enhanced delivery (CED) to bypass the BBB, combined with pharmacological inhibition of efflux transporters to enhance drug retention following CED infusion, using small and large animal models.

Topotecan has shown promise for treating diffuse midline gliomas (DMG). In mouse models of DMG, topotecan concentrations in the midbrain were significantly higher after CED infusion (20 µL of 100 µM topotecan) when mice were pre-treated with either everolimus (5 mg/kg/day) or elacridar (100 mg/kg/day) for 5 days prior to topotecan infusion. A single CED infusion of a large drug volume may not provide adequate tumor coverage and can lead to local toxicity. To improve coverage and reduce local drug concentration, multiple infusion trajectories can be used. In clinical settings, this approach is often limited by the size of the available CED devices, which are bulky (e.g. take up a large area on the scalp) and restrict the number of trajectories. To address this limitation, we employ a new, slenderer device. This device is an adaptation of a stereoelectroencephalography (sEEG) electrode, which has been modified to enable drug delivery (DD-sEEG). The DD-sEEG device, with a diameter of 0.8 mm and an anchor bolt of less than 2.5 mm in diameter, allows the implantation of multiple probes in close proximity. Additionally, this device can record real-time neural activity, which can be used as a surrogate measure to evaluate drug toxicity. The DD-sEEG device was evaluated both in bench studies and in vivo in a porcine brain model. Bench tests, using a 0.6% agarose gel and 1% Methylene Blue dye, demonstrated effective CED for infusion rates ranging from 0.5 to 5 µL/min. In vivo testing in porcine brain confirmed that multiple DD-sEEG electrodes per animal could be stereotactically implanted using a clinical workflow, including structural MRI for trajectory planning, followed by device implantation and drug delivery. CED of gadolinium was successfully visualized via

post-infusion MRI, and localized infusions were observed in the putamen and hippocampus. Furthermore, real-time neural recordings were obtained before, during, and after drug delivery using penicillin (60 µL/site), a drug known to modulate neural activity.

These results demonstrate the feasibility of enhancing chemotherapeutic efficacy in the brain by combining efflux transporter inhibition with CED using a slender infusion device. Moreover, the ability to record real-time neural activity provides an innovative method for assessing local toxicity and long-term effects of chemotherapeutic drugs on neurons. Since in diffuse glioma the tissue consists of both tumor cells and neurons, the ability to monitor neural activity could greatly impact therapy development and evaluation. Future studies will focus on testing CED with topotecan and oral everolimus in a large animal model.

1542 Comparative Gene Therapy Efficacy for KO and KI Models of SLC13A5 Citrate Transporter Disorder

SLC13A5 Citrate Transporter Disorder is an ultra-rare pediatric neurodevelopmental disorder characterized by intractable neonatal seizures, cognitive delay, and motor impairment. This disorder is caused by pathogenic loss of function variants in the SLC13A5 gene, which encodes for the plasma membrane sodium citrate co-transporter (NaCT). Pathogenic mutations cause a deficiency of citrate transport, which results in both increased extracellular citrate and decreased citrate import. Increased circulating citrate is a consistent feature of the disorder in both patients and rodent models. NaCT functions as a homodimer that is folded and assembled in the endoplasmic reticulum before being translocated to the plasma membrane. There are at least forty known mutations that fall within two major classes, affecting either transporting capabilities at the plasma membrane or protein folding/complexing. The most common patient mutation, G219R, is predicted to affect protein folding, causing protein retention within the endoplasmic reticulum.

Currently, while most patients are on several anti-seizure medications with varying amounts of control, there are no therapeutic options that target the underlying cause of the disorder. Because the disorder is monogenic, gene therapy offers a promising therapeutic option for patients. Our group has developed an adeno-associated virus (AAV) vector encoding a codon optimized human SLC13A5 gene (scAAV9/SLC13A5). In previous studies, we showed scAAV9/SLC13A5 is efficacious in Slc13a5 KO mice, decreasing citrate concentration in the plasma and cerebral spinal fluid, and ameliorating epileptic phenotypes as assessed through EEG recordings and seizure induction paradigms. Currently, it is unknown whether this gene therapy approach would be efficacious within a model that produces misfolded protein, as there could be issues with complexing between endogenous mutant copies and gene therapy introduced copies of Slc13a5.

To assess this, we used a recently created knock-in mouse (KI) that contains the human-equivalent G219R mutation in mouse Slc13a5. This model, like the KO model, displays increased citrate in the CSF as a result of nonfunctional NaCT in the brain. Slc13a5 KI and KO mouse models were treated with scAAV9/SLC13A5 at post-natal day 10 via intrathecal lumbar puncture injection along with vehicle treated WT, KI, and KO littermate control mice. Weight and survival were monitored throughout the study to monitor treatment tolerability. At approximately 4 months of age, seizure susceptibility was assessed via a kindling pentylenetetrazol (PTZ) seizure induction paradigm. Plasma and cerebral spinal fluid were collected and are being quantified for citrate concentration using GC-MS analysis to assess NaCT function. Up to 4 months following virus treatment, scAAV9/SLC13A5 appears to be well tolerated in life, as evidenced by normal weight gain and survival in both mouse models of SLC13A5 Citrate Transporter Disorder. In a small pilot study that used a low dose of PTZ, seizure severity was not worsened in virus treated KI mice. Follow-up studies are ongoing using a higher dosage of PTZ and will be reported. Results from these studies will inform on the efficacy of AAV-mediated SLC13A5 gene restoration in a patient relevant context and could be applicable to other disorders where protein misassembling is a component of disfunction.

1543 Gene therapy for mouse models of 6-pyruvoyl-tetrahydropterin synthase deficiency

Wuh-Liang Hwu[1], Ju-Chen Yen[2], Ya-Ting Lee[2], Hao-Chun Wang[3], Yu-Han Liu[4], Karine Chang[3], Ni-Chung Lee[4], Yin-Hsiu Chien[4]
[1]China Medical University Hospital and National Taiwan University Hospital, Taipei, Taipei, Taiwan, [2]China Medical University Hospital, Taichung, Taiwan, [3]National Taiwan University Hospital, Taipei, Taiwan, [4]National Taiwan University Hospital, Taipei, Taipei, Taiwan

6-pyruvoyl-tetrahydropterin synthase (PTPS) is an enzyme responsible for the synthesis of tetrahydrobiopterin (BH4), and BH4 in turn is a cofactor for the synthesis of monoamine neurotransmitters and nitric oxide (NO). PTPS deficiency causes severe motor dysfunction and neurodegeneration. Although this disease can be treated by oral levodopa (L-DOPA), the treatment is life-long, and symptoms appear shortly after dose missing. In view of the heavy burden of the disease and the improvement in the safety of gene therapy, we plan to develop a gene therapy for PTPS deficiency. The gene therapy expression cassette includes a CMV promoter and three cDNAs (PTS + GCH1 + SPR) separated by IRES and 2A peptide. In 293T cells transfected with this tricistronic plasmid, pcDNA3.1-BH4, western blot analysis detected the expression of the three proteins. AAV9-CMV- BH4 was successfully packaged. Injection of AAV9-CMV- BH4 to the putamen of adult wild-type mice elected the levels of BH4 and dopamine in the brain. Currently, a toxicity study of intracisternal injection of AAV9-CMV- BH4 in adult wild-type mice is ongoing. Several approaches are employed to obtain a suitable mouse model of PTPS deficiency. A knock in (KI) mouse model with a Chinese founder PTS mutation c.259C>T (P87S) have been created. However, neither BH4 nor dopamine levels in the brain of P86S KI mice decreased. We are currently working on a conditional (inducible) knockout (cKO) mice created by flanking a PTS exon with loxP, and after mating the cKO mice with mice expressing tamoxifen inducible Cre (Cre recombinase), symptoms can be induced by tamoxifen in adult mice. A rescued PTS KO mouse model previously created by Dr. Ichinose can be another choice. We hope a safe and effective gene therapy will be available for PTPS deficiency in the future.

1544 Utilizing Cytosine Base Editors to Generate *MECP2*-R270X Knock-in Models of Rett Syndrome

Jordan Dattero[1], Chenjie Shen[2], Stephen Yu[3], Qiangge Zhang[4], Feng Guoping[4]

Rodent models have played a crucial role in advancing our understanding of many biological processes and diseases. However, to fully capture the complexity of human neurological disorders, additional model organisms are needed. Non-human primate (NHP) disease models offer a valuable complement, given their similarities to humans. Recent advancements in genome-editing technologies, such as cytosine base editors (CBEs), have made it possible to generate primate models. CBEs, with their ability to target C-to-T conversions at the single base-pair level without inducing double-strand breaks, offer a powerful and efficient tool to edit the genome at the embryonic stage. Here we used YE1 BE4 Max, an evolved CBE, to introduce targeted mutations in the MeCP2 genes in marmoset embryos. In this study, we conducted preimplantation genetic testing (PGT) to genetically analyze each individual embryo and selectively transfer those carrying the mutation. In combination with this approach, we have successfully generated MeCP2 R270X founders for Rett Syndrome studies, and trio deep sequencing analysis shows minimal off-target effects in these founders.

1545 AAV-Mediated Gene Supplementation in Combination with Microglial Replacement for Vanishing White Matter Disease Using Circulation-Derived Myeloid Cells (CDMCs)

Institute at Nationwide Children's Hospital, Columbus, OH, [4]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH, [5]Nationwide Children's Hospital, Columbus, Ohio

Leukoencephalopathy with Vanishing White Matter (VWM) is a rare, untreatable neurodegenerative leukodystrophy that presents with ataxia, seizures, and progression to death. Our ultimate goal is the development of a therapy. VWM is caused by autosomal recessive mutations in the five subunit genes of the Eukaryotic Initiation Factor 2B (EIF2B) complex, which is necessary for the regulation of the integrated stress response (ISR). VWM has abnormal activation of the ISR. Current dogma in the field has suggested that astrocytes are responsible for VWM pathophysiology. We developed adeno-associated virus (AAV)-mediated *EIF2B5* gene (the most commonly mutated subunit) replacement therapy for VWM with targeted astrocyte expression. Using iterations of the GFAP promoter we found astrocyte targeting throughout the neuroaxis. In the classic R191H mouse model and a more severe I98M mouse model, we showed that the astrocyte-targeted gene therapy delays disease progression, partially rescues body weight and motor function, and attenuates myelin loss (Herstine et al., 2024). However, our current data demonstrates waning efficacy in treated mice who developed phenotypes similar to untreated mutants including recrudescent ISR activation. To explore this, we tested the role of microglia on astrocytes- activated microglia secrete cytokines which induce reactive astrocytes. In R191H VWM mutants, as well as once AAV-treatment had waned, we found extensive infiltration of Iba1+/CD68+ microglia into the CNS, and increased formation of stress granules that mirrored the presence of activated microglia. Our hypothesis is that activated microglia contribute to VWM pathophysiology, and that transplant of wild-type microglia is necessary for full gene therapy rescue of VWM by interrupting the cycle of microglia-driven reactive astrocyte activation. Currently, AAV transduction in microglia is poor, necessitating transplant. To test our hypothesis, we are characterizing the timing and extent of activated microglia involvement in R191H mice at multiple ages; in comparison to wt and AAV9-treated VWM affected mice. Histological, molecular, and biochemical targets are for activated and stable microglia; and CNS cell type markers; and quantification of ISR activation. We found extensive infiltration of activated microglia in the CNS of mutants, especially in the cervical spinal cord. The activated microglia also expressed high levels of stress granules. Since dysregulated microglia may interfere with gene therapy rescue, we are testing microglia replacement using circulation-derived myeloid cells (CDMCs). Through an established protocol, including busulfan ablation of endogenous hematopoietic cells, followed by transplant with donor CDMCs and microglia depletion through PLX5622 treatment, we have shown GFP-labeled donor CDMCs cross the blood-brain barrier and replace endogenous microglia in the CNS of wt mice. We are comparing efficacy between three groups: untreated VWM mice; VWM mice receiving microglia replacement and AAV9-EIF2B5 gene therapy; and VWM mice with microglia replacement only. In the VWM mutants, busulfan and PLX5622 treatment with CDMC transplant does not worsen disease progression. We have however observed low rates of donor cell engraftment in mutants and are currently optimizing our protocols in order to assess the response on VWM disease rescue. Gene therapy in combination with microglia transplant may provide a route towards rescue of VWM.

1546 Selective reactivation of *Scn1a* gene in GABAergic interneurons to explore symptomatic reversibility in Dravet Syndrome

Gaia Colasante[1], Martina Mainardi[2], Claudia Di Berardino[3], Maria Tammaro[1], Vania Broccoli[4]
[1]San Raffaele Scientific Institute, Milan, Milano, Italy, [2]Università Vita-Salute San Raffaele, Milan, 20132, Italy, Milan, Milano, Italy, [3]San Raffaele Scientific Institute, Milan, Italy, [4]Ospedale San Raffaele, Milan, Milano, Italy

Dravet Syndrome (DS) is a developmental and epileptic encephalopathy characterized by drug resistant tonic-clonic seizures, psychomotor delay, cognitive impairment, and a high risk of mortality by sudden unexpected death (SUDEP). It results from haploinsufficiency of the *SCN1A* gene, encoding the alpha subunit of the voltage-gated sodium channel Nav1.1, predominantly expressed in GABAergic interneurons (IN). DS is triggered by IN hypoexcitability, but secondary circuit modifications contribute to disease progression. Significant efforts in gene therapy aim to provide a cure, with most of the strategies directed restoring *SCN1A* gene expression specifically in INs. We provided evidence that ubiquitous restoration of physiological levels of *Scn1a* after symptom onset is sufficient to revert seizures and behavioral alterations in a mouse model of the disease. However, information on the optimal neuronal populations to target at different disease stages is lacking. Therefore, this study investigates whether IN correction alone is sufficient to treat the disease at various stages.

We utilized a DS mouse model carrying a conditionally removable STOP cassette in the *Scn1a* locus (Scn1a$^{Stop/+)}$ crossed with the constitutive (Gad2-Cre) or inducible (Gad2-CreERT2) GABAergic Cre drivers to restore *Scn1a* gene expression selectively in INs.

Phenotypic evaluations of *Scn1a*$^{Stop/+}$;Gad2Cre mice were conducted through survival monitoring until post-natal day P60, video-EEG recordings to detect spontaneous seizures, thermal induction to assess seizure susceptibility and whole-cell patch-clamp recordings in hippocampal circuit. to evaluate neuronal excitability and synaptic transmission *Scn1a*$^{Stop/+}$;Gad2Cre mice were fully protected from SUDEP and thermal induced seizures, and exhibited a substantial reduction in spontaneous seizure frequency and severity compared to *Scn1a*$^{Stop/+}$mice. Intriguingly, fast-spiking IN firing properties and inhibitory postsynaptic currents in Scn1a$^{Stop/+}$;Gad2Cre mice were not completely normalized, suggesting the existence of non-cell autonomous defects that cannot be corrected by a specific therapeutic intervention in INs. To mimic the effect of an IN specific gene therapy administered in the chronic phase of the disease, we restored *Scn1a*gene expression in INs of *Scn1a*$^{Stop/+}$; Gad2CreERT2 adult mice. After seizure baseline video-EEG recordings from P45 to P60, mice were randomized and injected with vehicle or tamoxifen, that activates Cre recombinase and restores physiological Nav1.1 expression. Mice are being recorded for 30 days after Nav1.1 re-expression and the effect on seizure frequency and severity will be evaluated.

This study will enhance our understanding of the impact of GABAergic IN dysfunction at different stages of DS and will inform ongoing gene therapy efforts regarding the sufficiency of correcting only GABAergic INs at various phases of the disease.

1547 The Importance of High-Density Microelectrode Arrays for Recording Multi-Scale Extracellular Potential and Label-Free Characterization of Network Dynamics in iPSC-Derived Neurons

Karin Morandell[1], Francesco Modena[2], Zhuoliang Li[3], Elvira Guella[2], Laura D'Ignazio[3], Silvia Oldani[3], Praveena Manogaran[3], Marie Engelene Obien[3]
[1]Maxwell Biosystems, Zurich, Switzerland, Switzerland, [2]MaxWell Biosystems, Zurich, Switzerland, Zurich, Switzerland, [3]MaxWell Biosystems, Zurich, Switzerland

Advances in microelectrode array (MEA) technology for in-vitro electrophysiological recordings have made it possible to study neuronal networks across multiple scales, from subcellular properties to network-level dynamics. These devices are essential for exploring the phenotypes of neurological disorders and accelerating drug discovery, offering unique insights into the behaviour of neuronal networks. Key factors such as electrode density, spacing, and size significantly impact signal quality, noise, and sensitivity. To exhaustively characterize neuronal networks, MEAs must combine single-cell and subcellular resolution with high-throughput capabilities, maintaining sensitivity to small extracellular action potentials to capture the full range of network activity. In this study, the MaxOne and MaxTwo high-density (HD) MEA systems (MaxWell Biosystems, Switzerland) were utilized to record activity from induced pluripotent stem cell-derived neurons. These systems, with 26,400 electrodes per well, demonstrated the benefits of increased statistical power in longitudinal data collection. HD-MEA recordings were compared to simulated low-density recordings, where adjacent electrodes on HD-MEAs were clustered to mimic larger, lower-density electrodes. Additionally, the AxonTracking Assay, an automated tool for analysing individual axonal arbours from multiple neurons simultaneously, was used to evaluate axonal structures and network functionality in the recorded cultures. Results showed that higher electrode density and smaller electrode size enhanced sensitivity, allowing for the detection of smaller spikes and capturing the complete spectrum of network dynamics. The high-resolution analysis of network activity, combined with subcellular insights from the AxonTracking Assay, offers a robust platform for drug screening and disease modelling.

1548 Novel Stem Cell Model for CASK-Related Disorders and Evaluation of a CRISPR/dCas9 Based Rescue

Casiana Gonzalez[1], Julian Halmai[2], Aashka Jhaveri[3], Charynna Pe Benito[4], Kyle Fink[1]
[1]UC Davis, Sacramento, CA, [2]UC Davis, Sacramento, California, [3]UC Davis, Davis, CA, [4]UC Davis, Sacramento

CASK-related disorders are an ultra-rare neurodevelopmental disorder with under 300 patients described. The severe form, CASK-related microcephaly with pontine and cerebellar hypoplasia (MICPCH), results from loss of function mutations within the X-linked *CASK* gene, which then contributes to aberrant neuronal activity and development. Additionally, there is no current treatment to address the underlying issue of a lack of functional CASK protein. In this study, we created a human female neuronal model system to understand the cellular deficits caused by a lack of CASK. Similarly, this model provides an epigenetically relevant system to test reactivation approaches using CRISPR/dCas9 epigenetic editors. Utilizing CRISPR-based NHEJ, we generated two distinct cell lines, one with a heterozygous 4 base pair deletion within the CASK PDZ domain and the other, homozygous for the same mutation. Pluripotency was maintained and checked through immunocytochemistry at both the iPSC and NSC stage. Edits were confirmed via amplicon sequencing of gDNA and RNA for *CASK* expression at each stage. Interestingly, the heterozygous iPSC showed low levels of escape from X chromosome inactivation (XCI), around 18% of WT *CASK* expression, while other XCI subject genes tested did not. Further, upon differentiation to neural stem cells (NSCs), *CASK* expression was seen only from a single allele, where it expressed mutant CASK on the active allele and WT was silenced via X chromosome inactivation. These results suggest low levels of *CASK* escape at an iPSC stage that can be epigenetically stabilized upon lineage commitment to an NSC. To test if WT *CASK* expression can be rescued from the inactive allele, we utilized CRISPR/dCas9 paired with an epigenetic modifier and a transcriptional activator. Guide RNA screens in this system, transfected into the heterozygous NSCs, identified lead combinations that reactivated WT expression to approximately 10% as compared to the active allele. Western blot of CASK was performed to test if this increase in mRNA is sufficient to rescue CASK protein. In summary, this project generated novel female human stem cell lines to model CASK-related disorders and demonstrated the reversal of a low level escape gene following defined lineage commitment. Further, we show increased expression of *CASK* with CRISPR/dCas9 paired with an epigenetic modifier and transcriptional activator. This project demonstrates the first therapeutic avenue for CASK-related MICPCH, as well as highlighting the potential to utilize targeted X-reactivation as a platform approach for X-linked disorders.

1549 Disruption of UBE3A-ATS by Gene Editing with a Type V CRISPR-Cas Enzyme as a treatment for Angelman Syndrome

Adele Bubnys[1], Raphael Bendriem[1]*, Andrew Park[1], Troy Panico[2], John Murphy[1], Chee Yeun Chung[3]*
[1]Arbor Biotechnologies, Cambridge, MA, [2]Oxford Biomedica Solutions LLC, [3]Brookline, MA
**Corresponding Author*

Angelman Syndrome is caused by the loss of maternal UBE3A. Reactivation of the paternal UBE3A allele, normally silenced by the expression of the UBE3A antisense transcript (UBE3A-ATS) in mature neurons, has been extensively pursued as a therapeutic treatment for Angelman syndrome. Here, we describe a gene editing strategy using a Type V CRISPR-Cas enzyme to potently disrupt UBE3A-ATS and restore UBE3A mRNA and protein levels in in vitro Angelman patient neurons.

We first screened multiple type V CRISPR nucleases and guides, spanning a 60,000 base pair region from the SNORD115 clusters to the 3' end of the UBE3A coding region, in HEK293 cells. Approximately 100 nuclease/guide pairs with efficient indel formations from the initial HEK293 screen were then tested in wild-type human iPSC-derived cortical neurons using a lentivirus-based delivery for the nuclease and lipofectamine-based delivery for the associated guides to identify pairs that were capable of robustly disrupting UBE3A-ATS and recovering UBE3A mRNA and protein levels. Several regions were identified within the UBE3A-ATS locus where editing led to more efficient protein recovery. Finally, 8 guides paired with two nucleases (ABR-001 and ABR-004) demonstrated UBE3A recovery equal to or greater than that of a benchmark ASO (GTX-102) in Angelman patient neurons, including 5 guides that reached UBE3A levels equivalent to neurotypical controls.

To demonstrate the functional impact of the UBE3A-ATS locus disruption, we developed an assay for measuring neuronal network activity of human iPSC-derived cortical neurons on a multi-electrode array (MEA). We identified a network hyperexcitability phenotype in Angelman patient-derived neurons. Our nuclease/guide pairs that robustly restored UBE3A expression were able to reverse this hyperexcitability phenotype and this degree of rescue was correlated with guide potency. Taken together, these results demonstrate the feasibility of using a Type V CRISPR-Cas enzyme to durably treat Angelman Syndrome.

1550 AI-Guided Gene Therapy Strategy for Treating Patients with Tuberous Sclerosis Complex Type 2

Morgan Moser[1], Gongbo Guo[1], Alecia Biel[2], Subhodip Adhicary[3], Sergiy Chornyy[4], Allison Bradbury[5], Craig McElroy[6], Mark Hester[7]
[1]Nationwide Children's Hospital, Columbus, OH, [2]Texas Children's Hospital, Houston, TX, [3]The Ohio State University, Columbus, OH, [4]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [5]Nationwide Children's Hospital, Columbus, Ohio, [6]InfinixBio, Columbus, OH, [7]The Research Institute at Nationwide Childrens Hospital, Columbus, OH

Tuberous sclerosis complex (TSC) is an autosomal dominant disorder caused by mutations in either the *TSC1* or *TSC2* genes, which affects nearly 1 in every 5,500 newborns, ~80,000 people in the U.S., and 2 million people worldwide. There is currently no cure. *TSC1* and *TSC2* encode for Hamartin and Tuberin, respectively, and together with TBC1D7, form a protein complex which negatively regulates mammalian target of rapamycin complex 1 (mTORC1) signaling. While TSC affects multiple organ systems, the most frequent causes of mortality and morbidity are due to neurologic complications, including refractory epilepsy, autism, neuropsychiatric issues, and uncontrolled ependymal growth lesions resulting in life-threatening hydrocephalus. As epilepsy occurs in approximately 85 percent of patients, the inability to control seizures is one of the most debilitating aspects of the disease as most existing medications show loss of efficacy within 1-2 years of treatment. Everolimus is a potent mTOR inhibitor that has been shown to reduce tumor lesions and treat intractable epilepsy in TSC. However, only 50% of patients show a clinically relevant reduction in seizure frequency and no evidence supports a positive impact for reducing cognitive and neuropsychiatric deficits in patients. Based on all these challenges and limitations, there is a desperate and unmet clinical need to develop long-lasting and highly efficacious treatment options for TSC.

We have developed a novel gene replacement strategy using an adeno-associated viral (AAV) vector to treat TSC type 2. Since the coding region of *TSC2* (~5.4 kb) far exceeds the packaging capacity of current AAV vectors, we leveraged principles based on rational protein design and artificial-intelligence (AI)-based protein structure prediction to develop micro-Tuberin (MT) candidates with the same key structural motifs and functional components as encoded in full-length Tuberin (Figure 1A). Our strategy to miniaturize full-length Tuberin was based on excising unstructured regions and replacing them with short flexible linkers (consisting of glycine and serine residues). Based on these principles, we generated seven novel MT candidates, which were validated by homology modeling using Swiss model and the AI-guided folding prediction tool, AlphaFold 2 (Figure 1B-I). Recently, a condensed form of Tuberin (cTuberin) was designed and evaluated as a potential gene therapy candidate for TSC type 2. However, our analysis has shown it lacks a dimerization interfacial region and overall structural homology to that of full-length Tuberin (Figure 1J-K). We rigorously characterized our MT candidates using multiple independent functional in vitro assays based on their ability to inhibit mTOR signaling in astrocytes and neural progenitor cells (Figure 2). Strikingly, our preliminary data show that several of our MT candidates show superior functional activity in comparison to cTuberin and at similar levels to that of full-length Tuberin, thereby providing a strong rationale for further preclinical development (Figure 2). Current studies include down-selecting top-performing candidates using patient-specific 3D cerebral organoid models, followed by subsequent *in vivo* efficacy testing using a *Tsc2* conditional knockout mouse model. Successful completion of these goals will be critical elements in the path towards clinical translatability for micro-Tuberin gene therapy for patients with TSC type 2.

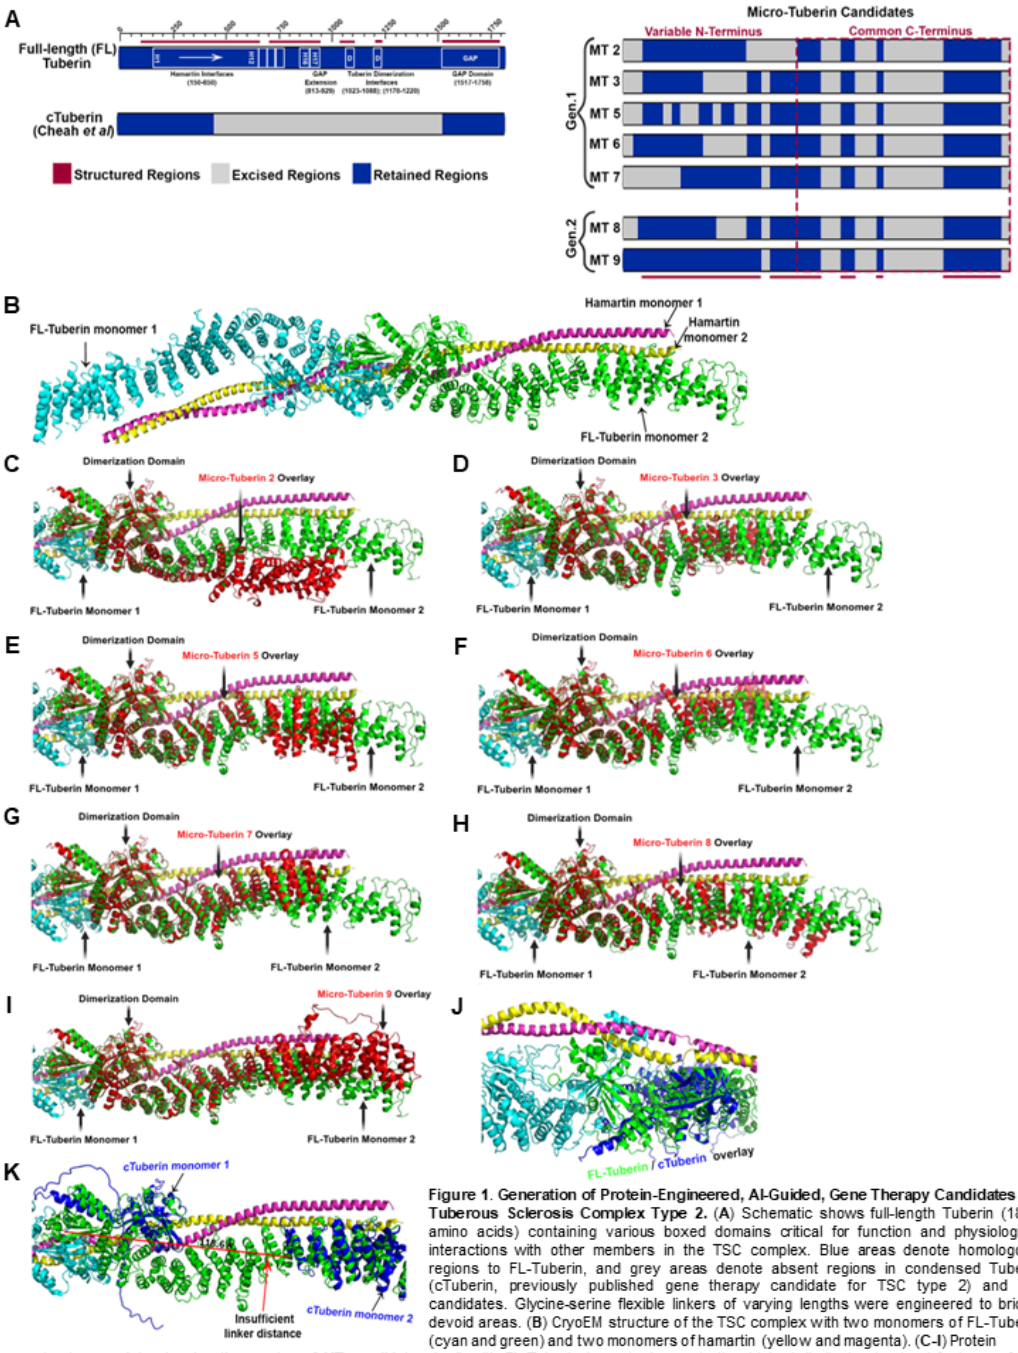

Figure 1. Generation of Protein-Engineered, AI-Guided, Gene Therapy Candidates for Tuberous Sclerosis Complex Type 2. (**A**) Schematic shows full-length Tuberin (1807 amino acids) containing various boxed domains critical for function and physiological interactions with other members in the TSC complex. Blue areas denote homologous regions to FL-Tuberin, and grey areas denote absent regions in condensed Tuberin (cTuberin, previously published gene therapy candidate for TSC type 2) and MT candidates. Glycine-serine flexible linkers of varying lengths were engineered to bridge devoid areas. (**B**) CryoEM structure of the TSC complex with two monomers of FL-Tuberin (cyan and green) and two monomers of hamartin (yellow and magenta). (**C-I**) Protein structure models showing the overlay of MT candidates (red) with FL-Tuberin (green), demonstrating high similarity in structural features of FL-Tuberin. (**J**) Overlay of one monomer of FL-Tuberin (green) with the AlphaFold2 predicted structure of cTuberin (blue), demonstrating that cTuberin lacks the Tuberin dimerization interfacial region. (**K**) Overlay of the amino terminal region of one molecule of cTuberin (blue, far right) and the carboxy terminal region of another molecule of cTuberin (left) with the corresponding regions in FL-Tuberin (green), demonstrating that the flexible linker of cTuberin is insufficient to traverse the distance between the conserved regions (118.6 Å, red line).

**Corresponding Author*

Friedreich ataxia (FA) is a neurogenerative disorder caused by homozygous GAA expansion mutation in the first intron of frataxin (*FXN*) gene. FXN is a mitochondrial protein, and its deficiency leads to mitochondrial iron overload, defective energy production, and oxidative stress. We previously showed complete rescue of neurologic complications of FRDA in YG8R mice with a single, systemic infusion of wild-type hematopoietic stem and progenitor cells (HSPC), and this rescue was mediated by FXN transfer from engrafted HSPC-derived microglia to diseased neurons. We next developed an autologous stem cell transplantation approach using CRISPR/Cas9-mediated excision of GAA repeats in FRDA patients' $CD34^+$ HSPCs that increased FXN expression and improved mitochondrial functions. The current study aims to understand tissue degeneration in FRDA, focusing on complex interactions between HSPC-derived cells and FRDA-affected tissues. To achieve this, we utilized: a) two HSPC-lineage cell models - patient iPSC-derived microglia (iMGs) and lymphoblast cells, both uncorrected or CRISPR/Cas9 gene corrected , and b) two FRDA affected cell models - iPSC-derived neurons and fibroblasts. We previously validated the FRDA phenotype in these iPSC-derived neurons which exhibited characteristic disease phenotypes including non-homogenous microtubule staining in neurites, increased caspase-3 expression, elevated mitochondrial superoxide levels, mitochondrial fragmentation, partial cristae degradation and loss in endoplasmic reticulum-mitochondria contacts compared to healthy controls. Similarly, FRDA-iMGs displayed an activated, amoeboid morphology with compromised phagocytosis and mitochondrial dysfunction. Notably, our CRISPR/Cas9 approach achieved complete phenotype rescue in both cell types, reinforcing its potential as a good therapeutic strategy for FRDA. In this study, we performed *in vitro* co-culture experiments to study both direct physical interactions between neurons and microglia, as well as transwell-diffusion interaction between lymphoblasts and fibroblasts. Immunostaining for Caspase-3 and beta-III tubulin showed that healthy control neurons cocultured with FA-iMGs exhibited increased non-homogenous microtubule staining of neurites and apoptosis compared to those cultured with gene-corrected iMGs. Similarly, FRDA fibroblasts exposed to FRDA lymphoblasts in transwell cultures showed a significant increase in Annexin-V positive, apoptotic fibroblasts compared to those cultured with gene-edited lymphoblasts. These findings highlight the cytotoxic effects of FRDA hematopoietic lineage cells on both healthy and FRDA-affected cells and the therapeutic benefits of excision of GAA repeats in these cells.

1552 AAV9-based gene therapy for PDHA1 deficiency.

Siyuan Hao[1], Xin Chen[1], Thomas Dong[2], Rachel Adams[1], Harrison Higgs[3], Yuhui Hu[3], Steven Gray[4]
[1]UT Southwestern Medical Center, Dallas, TX, [2]20000, Dallas, TX, [3]UT Southwestern, Dallas, [4]University of Texas Southwestern Medical Center, Dallas, Texas

Pyruvate Dehydrogenase Complex Deficiency (PDCD) is a genetic mitochondrial disorder primarily featured by progressive neurological and neuromuscular deterioration, typically leading to childhood mortality. Approximately 80% of PDCD cases are caused by mutations in the X-linked pyruvate dehydrogenase E1 subunit alpha 1 (PDHA1) gene. PDHA1 deficiency lacks adequate disease-modifying treatments. Adeno-associated virus (AAV)-based gene therapy provides a highly targeted and minimally invasive method for delivering therapeutic genes, offering promise for treating a broad spectrum of genetic disorders.

Our research aims to develop PDHA1 deficiency disease models and utilize AAV-based gene therapy to specifically target and deliver the PDHA1 gene, assessing the therapeutic efficacy. Initial *in vitro* studies utilized patient-derived fibroblasts treated with the AAV2/PDHA1 vector, chosen because AAV2 exhibits better tropism for fibroblasts. the treatment resulted in a significant increase in PDHA1 protein expression, proper localization of the protein to mitochondria, restoration of PDC enzymatic activity, and dose-dependent normalization of mitochondrial

respiration. *In vivo* efficacy experiments employed a tamoxifen-induced Cre-Lox knockout (KO) strategy to create conditional knockouts, since constitutive KO of PDHA1 results in prenatal lethality. After administering tamoxifen, we established a hemizygous male model, representing a severe disease phenotype, and a heterozygous female model, representing a milder disease phenotype. Following AAV9/PDHA1 intrathecal injection, in these models at postnatal day 7, we observed a small but significant extension in survival and improved PDC enzyme activity in major organs of male mice. Long-term survival studies in the female mice are ongoing, and preliminary results indicate a small improvement in body weight and a partially normalized PDC enzyme activity in major organs. The in-life part of an *in vivo* experiment to evaluate the safety of the treatment was recently completed in WT C57BL/6J mice. No obvious side effects or animal death were observed over the 12-month, long-term study, indicating no toxicity concern from the treatment.

In summary, we have developed both cell and mouse models for PDHA1 deficiency disease and tested AAV-based gene therapy on these models to assess treatment efficacy and safety. Our results demonstrate that AAV gene therapy significantly improves cellular function and animal survival with no obvious safety concern, supporting further development of this AAV9/PDHA1 approach to treat PDHA1 deficiency.

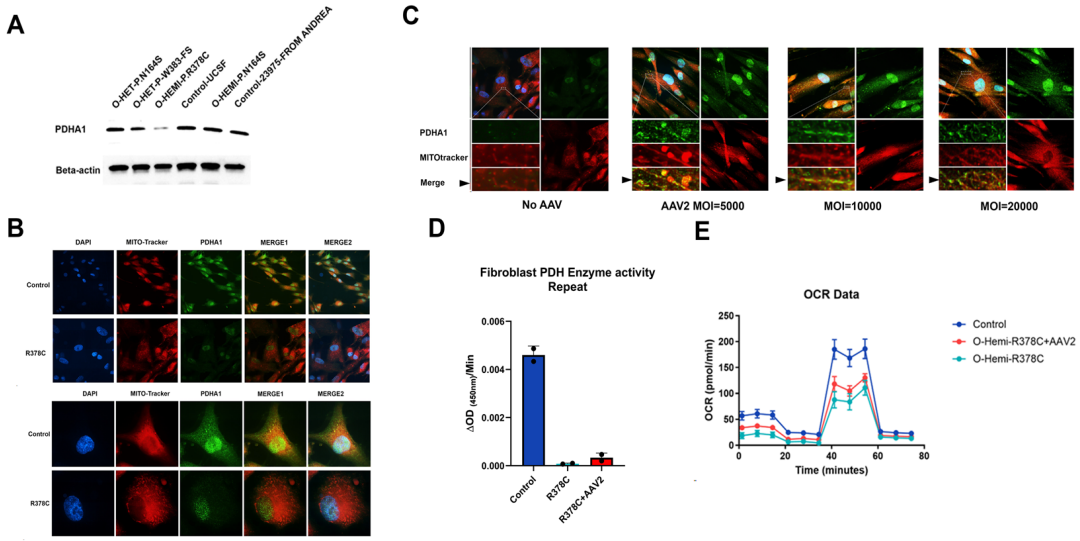

Figure.1 preliminary result of AAV gene therapy efficiency on Human patient fibroblast cells.
(A) Western blot assays were conducted on four distinct PDHA1 deficiency patient-derived fibroblast cell lines and two normal fibroblast cell lines, cultured to the same confluence in 100 mm flasks. Beta-actin was used as the loading control.**(B)** Confocal immunofluorescent staining visualized PDHA1 protein expression in both normal and patient-derived fibroblasts, cultured in 4-well slide chambers. Green fluorescence indicates PDHA1 protein tagged with Alexa488, while red fluorescence shows mitochondria stained with Deep Red MitoTracker. Images were captured at magnifications of 60x and 100x. **(C)** AAV2 was transfected into patient-derived fibroblasts at multiplicities of infection (MOI) of 5000, 10000, and 20000. These cells were also cultured in 4-well slide chambers. Three days post-infection (DPI), cells were fixed and stained with a PDHA1-specific antibody and MitoTracker. The lower left panel highlights an enlarged view of mitochondria with PDHA1 proteins labeled, where green fluorescence indicates PDHA1 protein tagged with Alexa488, and red shows mitochondria stained with Deep Red MitoTracker. **(D)** PDHA1 enzyme activity assays were performed on patient-derived fibroblasts both with and without AAV treatment, measured at three DPI. A protein concentration of 22.5 mg/ml was collected from each group, and 200 µl of this protein was used in the assays. Asterisks in the figures indicate different p-values. **(E)** A Seahorse assay measured the oxygen consumption rate (OCR) in fibroblasts, seeded into a Seahorse 96-well plate. Oligomycin, FCCP, and Antimycin-A were added to stimulate OCR.

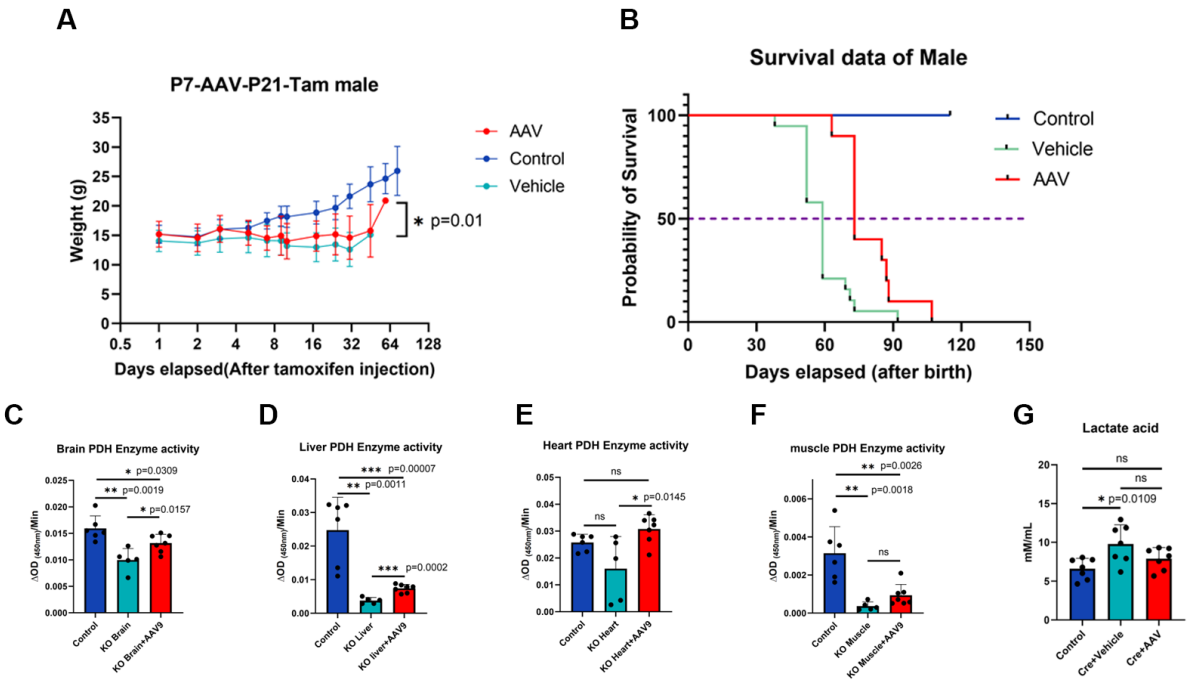

Figure 2: Effects of AAV9 Treatment on Male Mouse Disease Model
(A) Weight of male mice in the disease model after treatment with either AAV9 or vehicle.
(B) Survival curve of male mice following treatment with AAV9 or vehicle. The median survival time for vehicle treatment is 59 days, compared to 73 days for AAV9 treatment. (C-F) PDHA1 enzyme activity in major organs of male mice in the disease model after treatment with AAV9 or vehicle.
(G) Serum lactate acid concentration in the male mouse model following treatment with AAV9 or vehicle.

1553 Investigating allotopic expression and mitochondria-targeted base editors as therapeutic strategies to alleviate *MTATP6* associated Leigh Syndrome

Sarah Holbrook[1], Prahant Mishra[3], Steven Gray[2], Qinglan Ling[1]
[1]UMass Chan Medical School, Worcester, MA, [2]University of Texas Southwestern Medical Center, Dallas, Texas, [3]Children's Research Institute, UT Southwestern Medical Center, Dallas, TX

Introduction: Leigh Syndrome (LS) is the most common mitochondrial disease with about 1 in every 40,000 people affected with no approved treatment yet. Though it can be caused by mutations in over 100 genes, deleterious mutations in *MTATP6* (mitochondrially encoded ATP synthase membrane subunit 6) result in 10% of LS cases with most being caused by the mutation, m.8993T>G. *MTATP6* is a mitochondrial gene that translates into a mitochondrial transmembrane protein associated with ATP synthase. Here, we explored the feasibility of developing a gene therapy for patients with the m.8993T>G mutation in *MTATP6*. Since *MTATP6* is encoded in the mitochondrial DNA (mtDNA), there are several existing challenges: 1) The mtDNA resides in the mitochondria rather than the nucleus meaning there are different membrane transportation processes for nucleic acids and proteins; 2) Mitochondria have different DNA repair mechanisms than those within the nuclei; 3) There are between 100 to 100,000 copies of mtDNA within a cell vs one copy of nuclear DNA (nDNA). To achieve our goal, we explored two approaches. First, we tested allotopic expression of human ATP6. Allotopic expression is the expression of genes derived from the mtDNA within the nucleus. Through allotopic expression, the MTATP6 RNA exits the nucleus and is translated into a protein in the cytosol and transported into the mitochondria via a mitochondrial targeting sequence (MTS). This method would work for any loss of function MTATP6 mutations that can be alleviated by increased WT expression. We also tested DddA-derived cytosine base editors (DdCBEs) as a potential therapeutic strategy to alter *MTATP6* directly. DdCBEs are composed of a pair of mitochondrial base editors (mitoBEs) which each contain half of a deaminase. When these pairs align along a sequence, the deaminase is then able to edit cytosines.

Results: Our first step for preclinical evaluation was the in vitro transfection of HeLa cells via a plasmid expressing WT *MTATP6* and an MTS. To evaluate efficacy, we determined that ATP6 was being significantly translated via Western Blot. We then conducted fluorescent imaging and determined the ATP6 protein had successfully translocated to the mitochondria. Seeing that ATP6 was being translocated to the mitochondria, we wanted to determine if the ATP6 was able to translocate to the correct region, the inner mitochondrial membrane (IMM). Unfortunately, we discovered that the MTATP6 protein was embedded in the outer membrane and thus did not restore mitochondrial function. With the advent of new base editing technology and the inefficiency of allotopic expression to restore mitochondrial function, we decided to test DdCBEs to alter the mtDNA. We created 18 pairs of DdCBEs and transfected A375 cells homoplasmic for the m.8993T>G mutation to find the pairs with the best editing potential. Our results indicated that 2 of the 18 DdCBEs had ~5% desired editing.

Conclusions: In our study, we were unsuccessful with restoring MTAP6 function via allotopic expression. However, we found promising DdCBEs that were able to edit the mtDNA.

Future directions: We hypothesize that the highly hydrophobic nature of human MTATP6 prevented the successful translocation of the protein into the IMM. Future studies will include testing the less hydrophobic algal form of ATP6 and determining if the mitoBEs are able to alleviate the cellular defects caused by the m.8993T>G mutation.

1554 Two Years of Efficacy: Astrocyte-Targeted Gene Replacement for Vanishing White Matter Disease Exposes Uncorrected Disease Mechanisms

Jessica Herstine[1], Tamara Stevenson[2], Sergiy Chornyy[3], Julia Wentz[2], Nettie Pyne[1], Abigail Biddle[1], Tatyana Vetter[1], Kevin Flanigan[4], Joshua Bonkowsky[2], Allison Bradbury[5]
[1]Nationwide Children's Hospital, Columbus, OH, [2]University of Utah, Salt Lake City, UT, [3]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [4]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH, [5]Nationwide Children's Hospital, Columbus, Ohio

As a rare, progressive, childhood leukodystrophy, Vanishing White Matter Disease (VWM) presents with white matter loss, ataxia, spasticity, seizures, and neurological decline which lead to premature death. VWM is caused by loss of function mutations in the subunits of Eukaryotic Initiation Factor 2B (eIF2B) with the most common pathologic variants found in subunit 5 (*EIF2B5)*. Previous in vitro and in vivo studies have indicated *astrocytic dysfunction* leads to VWM pathophysiology and are therefore a critical therapeutic target. Currently, there are no FDA-approved treatments. Thus, we aimed to develop adeno-associated virus (AAV)-mediated gene replacement therapy for VWM. Baseline measurements of disease pathology in the VWM *Eif2b5* I98M murine model indicates significant mobility loss, ataxic gait, and demyelination with a shortened lifespan of 5 months. Important for assessing therapeutic impact, this is the only VWM model that experiences epileptic seizures. To ensure astrocytic targeting of our AAV9 vectors, we employed two shortened iterations of the endogenous glial fibrillary acidic protein (GFAP) promoter, including gfaABC(1)D, and one ***novel*** intermediate—gfaABCD1405 (gfa1405). Expression profiling of the reporter AAV9-gfa1405-*eGFP* indicates we were able to achieve significantly increased expression throughout the central nervous system while maintaining comparable astrocyte specificity to gfaABC(1)D. Currently, we are monitoring disease progression after neonatal intracerebroventricular administration with one of our two astrocyte-specific, or one ubiquitous AAV-*EIF2B5* vectors in two murine VWM models: the patient orthologous *Eif2b5*^{R191H} model, and the severe *Eif2b5*^{I98M} model. In both models, gene therapy delays disease progression, partially rescues body weight and motor function, and attenuates myelin loss. The life spans of the *Eif2b5*^{I98M} animals treated with AAV9-CAG-*EIF2B5* ($p<0.0001$; 207 days), AAV9-gfa1405-*EIF2B5* ($p<0.0001$; 222 days), and AAV9-gfaABC(1)D-*EIF2B5* ($p<0.0001$; 298 days) were significantly increased. In fact, our longest extension in life expectancy **exceeds 2 years of age** in both astrocyte-specific, gfaABC(1)D and gfa1405-treated cohorts. Dose escalation studies with our most efficacious vectors—gfaABC(1)D-*EIF2B5* and gfa1405-*EIF2B5*—support that our high dose has more robust therapeutic rescue than a 5-fold lower dose. However, even our high dose astrocyte-targeted gene therapy does not fully rescue all disease, as the I98M mice are still experiencing severe and life-limiting seizures. To achieve total rescue, we are investigating uncorrected VWM pathophysiology after astrocyte-targeted gene replacement through single-cell RNA sequencing and spatial proteomics. We anticipate the

resolution of respective disease contributions and genetic pathways of other cell types (microglia, oligodendrocytes, neurons, etc.) that can be addressed for a more comprehensive and durable therapy. Through our multimodal molecular, cellular, and clinically relevant measures in two VWM models of varying disease manifestations, we anticipate the development of a lead gene therapy candidate allowing for expeditious translation to the clinic.

1555 Exploring Enzymatic Restoration and Sphingolipid Modulation through AAV-Mediated Gene Addition of a Subunit of Serine Palmitoyltransferase

Robert Thompson[1], Ashley Glover[2], Natalie Golovanov[3], Julie Tassinari[4], Kenneth Gable[5], Casey Maguire[6], Yi Gong[7], Teresa Dunn[5], Florian Eichler[4]
[1]Boston Children's Hospital/Mass General Brigham, Boston, MA, [2]Mass General Hospital, Boston, MA, [3]Massachusetts general hospital, Boston, [4]Massachusetts General Hospital, Boston, MA, [5]Uniformed Services University of the Health Sciences, Bethesda, MD, [6]The Massachusetts General Hospital, Charlestown, MA, [7]MGH, Boston, MA

The enzyme serine palmitoyltransferase (SPT) catalyzes the initial and rate-limiting reaction in de novo sphingolipid synthesis which involves the condensation of an acyl-CoA with L-serine to form a sphingoid or long-chain base. SPT is comprised of multiple subunits: a heterodimer comprised of SPTLC1 (SPT long chain base subunit-1) and either SPTLC2 or SPTLC3 which forms the active site, and a smaller third subunit, either SPTSSA or SPTSSB, which increases the enzyme's catalytic activity by more than 25-fold. ORMDL proteins regulate sphingolipid synthesis by interacting with SPT and providing feedback inhibition. We care for a 7 year old girl with a de novo pathogenic variant (c.152 C>T, p.Thr51Ile) in *SPTSSA* which causes loss of ORMDL-mediated feedback inhibition and therefore excessive de novo synthesis of sphingolipids which are neurotoxic and cause a Complex Hereditary Spastic Paraplegia (HSP). Based on SPT inhibition with myriocin in a *Sptssa*$^{T51I/+}$ mouse model we treated our patient with the known SPT inhibitor D-Cycloserine under an IRB approved investigational protocol. We have observed an improvement in the patient's appendicular spasticity which, after 20 weeks of treatment, has led to a 71% reduction in the patient's daily dose of Baclofen, as well as a modest decrease in serum sphingolipid levels. This provided the framework to study *SPTSSA* gene addition using AAV9 and AAVF (a new variant of AAV9) in the *Sptssa* $^{T51I/+}$ mouse which we present here.

AAVF and AAV9 carrying CMV enhancer/chicken beta-actin hybrid promoter and *SPTSSA* cDNA carrying HA tag were cloned and produced in 293 cells. In vitro and in vivo studies were carried out. Retro-orbital injections of rAAV vectors were performed in a *Sptssa*$^{T51I/+}$ knock-in mouse model. Mouse tissue was processed for immunofluorescence and immunohistochemistry using HA tag, NeuN, GFAP, Olig2 and IBA1 antibodies. Tissue lysates were prepared for western blot with GADPH as loading control. SL level in mouse plasma and tissues were analyzed using LCMS. Statistical analysis was performed using $p<0.05$ to determine significance.

Mixed glial cells treated with AAV9-SPTSSA demonstrated successful transduction as well as a dose dependent SL reduction. CNS transduction (brain and spinal cord) was 6-fold higher with AAVF compared to AAV9 by retroorbital injection, whereas AAV9 was overall more efficient in peripheral tissues. Delivery of AAVF-SPTSSA mainly transduced astrocytes and neurons in CNS. AAV9-SPTSSA treatment at 3e11 gc/mouse significantly reduced SL accumulation in lung tissue but not plasma or CNS.

Overall our studies demonstrate the feasibility of adding a single unit of a multi-subunit enzyme complex to confer functional benefit in *Sptssa* $^{T51I/+}$ mice. The dose dependent reduction in SL levels seen in mixed glial cells treated with AAV9-SPTSSA demonstrates functional correction of SPT activity. A significant reduction in SL levels in lung tissue but not plasma or CNS was observed after treatment with AAV9-SPTSSA. Importantly, AAVF showed better CNS transduction compared to AAV9, mainly by targeting astrocytes and neurons. Further studies are needed to optimize the dose of AAVF-SPTSSA to demonstrate SL level reduction in the CNS and meaningful improvement in neurological phenotypes in *Sptssa* $^{T51I/+}$ mice.

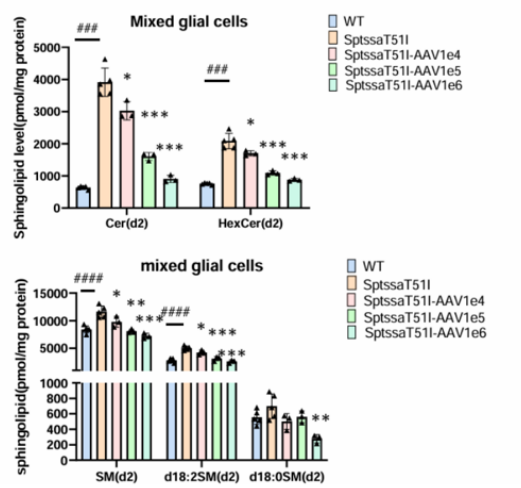

Figure 1: AAV9-SPTSSA treatment in mixed glial cells from *Sptssa*$^{T51I/+}$mice leads to a dose dependent SL reduction. Statistically significant differences in SL levels are labeled with "#" (WT vs. *Sptssa*$^{T51I/+}$) and "*" (*Sptssa*$^{T51I/+}$ vs. AAV treated groups).

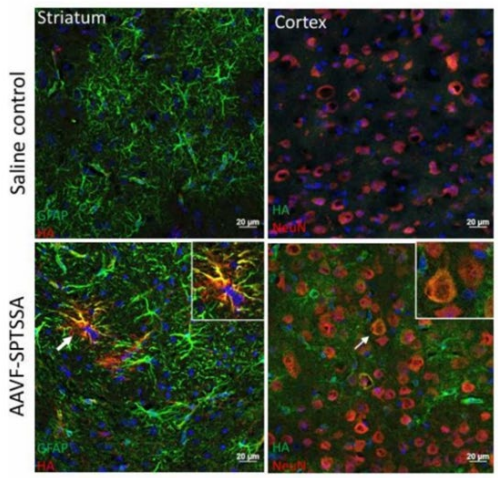

Figure 2: AAVF-SPTSSA IV delivery at 7e11gc/mouse transduce astrocytes and neurons in CNS. (GFAP=Astrocytes, NeuN=Neurons)

1556 Safety and efficacy of GJB2-GT, an adeno associated vector-based gene therapy treatment candidate for the autosomal recessive non-syndromic deafness 1A (DFNB1A)

**Corresponding Author*

In the world, the estimated prevalence of severe or profound deafness in human is 1 out of 1000 neonates, and genetic factors account for half of the cases. Pathogenic variants of GJB2, the gene encoding for Connexin 26 (Cx26), are involved in 50% of congenital deafness and are mostly associated with an autosomal recessive non-syndromic DFNB1A. In the cochlea, *GJB2* is largely expressed in the supporting cells (SCs) of the sensory neuroepithelium, fibrocytes, basal and intermediate cells of stria vascularis but not in sensory hair cells. It is hypothesized that Cx26 is essential for the recycling of potassium, which is essential for the proper functioning of sensory hair cells, but *in vivo* studies also suggest that Cx26 deficiency leads to cochlear developmental disorders. Gene therapy is a promising therapeutic strategy for autosomal recessive forms of deafness, and Adeno-Associated Vectors (AAVs) are being developed to this aim.

Here, we have developed GJB2-GT, an Adeno-Associated Virus (AAV) vector for DNFB1A with proprietary cis-regulatory elements for a safe and targeted expression of the transgene *in vivo*. GJB2-GT efficiently transduces human cell lines to produce Cx26 protein that is adequately addressed to the plasma membrane. Using an adapted dye transfer assay, we show that the transgenic Cx26 protein is functional and permits the passage of a gap -junction permeable fluorescent tracer to neighboring cells.

Early tolerability and biodistribution of GJB2-GT, or GJB2-FLAG-GT studies were conducted in mice and Non-Human Primates (NHP) species after injections through the round window (RW). Intracochlear injection in both species results in transgene expression in most cells that naturally express *Gjb2* along the tonotopic axis of the cochlea, with good local and systemic tolerability. In all analyzed cochleae, no sensory hair cell express the transgene, confirming the specificity of the expression cassette. Importantly, GJB2-GT administration in NHP were performed using the surgical procedure and injection device intended for clinical use. Long-term safety studies conducted in wild-type mice demonstrate persistence of transgene expression with no impact on auditory function and maintenance of the cochlear cytoarchitecture. Additionally, high dose intravenous injection of GJB2-GT in mice does not induce any adverse events or changes in behavior, vital functions, increase in hepatic damage or inflammatory biomarkers.

To circumvent embryonic mouse lethality caused by complete loss of *Gjb2* expression, a conditional model was generated, resulting in a biallelic *Gjb2* inactivation mimicking the most common forms of DFNB1A and severe/profound hearing loss. Intracochlear injections of GJB2-GT lead to improvement of hearing thresholds as early as 3 weeks post-injection in a dose dependent manner which was statistically significant across multiple frequencies. Microscopic examination of injected cochlea confirmed that GJB2-GT efficiently restores Cx26 expression in the sensory epithelium. Current dose-response experiments confirm that intracochlear GJB2-GT injection is safe over a wide range of doses administered and provide a significant therapeutic benefit in our DFNB1A mouse model.

Altogether, these data support GJB2-GT development to restore physiological hearing in DFNB1A patients.

1557 Novel Gene Therapy Shows Cell Specific Transduction in Non-Human Primate Cochlea and Provides A Robust and Durable Rescue of Hearing in Mouse Models of GJB2 Related Deafness

Domenica Karavitaki[1], Andre Landin-Malt[2], Felicia Gilels[3], Jason Farnsworth[3], Alexander Flynn[4], May Wang[2], William Neidermyer[2], Anjil Giri[3], Marc Johnson[2], Casey Maguire[5], David Corey[6], Shawn Harriman[7], Jodi Cook[2]
[1]Skylark Bio, Boston, MA, [2]Skylark Bio, Cambridge, MA, [3]Skylark Bio, Cambridge, [4]Skylark Bio, Southborough, MA, [5]Harvard Medical School, Charlestown, MA, [6]Harvard Medical School, Boston, MA, [7]Skylark bio, Charlestown, RI

Introduction. The most common human hereditary deafness, DFNB1, is caused by mutations in the *GJB2* gene. Currently, there is no cure for *GJB2*-related hearing loss. *GJB2* encodes the gap junction protein connexin 26, which mediates transport of potassium and metabolites between cells. The *GJB2* coding sequence easily fits in an AAV viral vector, making gene addition an attractive therapeutic approach. Here, we optimize the vector design to achieve robust expression of human GJB2 protein in the appropriate cells of mouse and nonhuman primate cochlea, and greatly improving hearing in GJB2 deficient mouse models.

Methods & Results. Human *GJB2* coding sequence was packaged in the AAV-S capsid, which shows high transduction of *GJB2*-expressing cells in neonatal mouse and monkey cochleae. This vector showed strong transduction and gap junction activity *in vitro*. Vectors were injected into mouse inner ears via the round window membrane (RWM) at age P1. To understand the transduction efficiency and expression specificity of the vector, wild-type mice were injected with an HA-tagged vector. After 30 days, cochleae were removed and processed for histological analysis. Cochlear cells natively expressing *Gjb2* produced the HA-tagged GJB2 protein, but the sensory hair cells did not, demonstrating targeted, cell-specific expression by the vector. To test the efficacy of the vector, a *Sox10-Cre*, $Gjb2^{flox}$ conditional knock-out (cKO) mouse was injected at different doses. Notably, the *Gjb2* cKO model has been notoriously difficult to obtain hearing rescue with prior AAV gene therapy strategies. Animals were tested by auditory brainstem response (ABR) 30 days after injection. Cochleae were subsequently removed and stained with markers to assess hair cell survival. Functional rescue was dose-dependent, with an increasing response rate and magnitude as the doses increased. Similarly, dose dependence was observed in hair cell survival, with 100% survival at the highest dose. We also assessed the efficacy of AAVS-GJB2 in the *Gjb6* KO model, which has hearing loss caused by a 90% GJB2 reduction. We and others observed that this model has substantial hearing loss but lacks the severe histological phenotype of the *Gjb2* cKO model. The *Gjb6* KO showed even greater incidence, magnitude, and potency at efficacy than the *Gjb2* cKO model, with wild-type thresholds of hearing at the highest dose, and nearly complete hair cell preservation. This response was shown to be durable over 3-months. Finally, to assess potential for efficacy in human, the vector was injected through the RWM of cochleae of cynomolgus monkeys (*Macaca fascicularis*), using allometrically scaled mouse doses. As in mouse, we demonstrated targeted transduction and cell-specific expression.

Conclusions. Our vector demonstrated cell-specific expression of human *GJB2* in mice and nonhuman primates. Auditory sensitivity testing demonstrated significant rescue of hearing thus far reported in both a mouse *Gjb2* deletion model of DFNB1, and a milder *Gjb2* downregulation model, improving auditory sensitivity to wild-type levels.

1558 Cell-Specific Delivery of GJB2 Restores Auditory Function in Mouse Models of DFNB1 Deafness and Mediates Appropriate Expression in NHP Cochlea

Maryna Ivanchenko[1], Kevi Booth[1], Domenica Karavitaki[1], Larisa Antonellis[1], Aurel Nagy[1], Cole Peters[2], Spencer Price[2], Yaqiao Li[2], Anton Lytvyn[1], Eric Griffith[1], Sinisa Hrvatin, Michael Greenberg[1], **David Corey[1]**
[1]Harvard Medical School, Boston, MA, [2]Harvard Medical School

Mutations in the *GJB2* gene cause the most common form of human hereditary hearing loss, known as DFNB1. *GJB2* is expressed in two cell types of the cochlea—epithelial cells of the organ of Corti and fibrocytes of the inner sulcus and lateral wall—but not by sensory hair cells or neurons. In constitutive knockout mice, absence of *Gjb2* expression is lethal. In conditional mouse models of DFNB1, absence of *Gjb2* results in progressive degeneration of the sensory epithelium of the cochlea, with hearing sensitivity being almost completely abolished as measured by auditory brainstem recording (ABR). Attempts to treat mouse models of DFNB1 with AAV vectors mediating nonspecific *Gjb2* expression have not substantially restored function, perhaps because inappropriate expression in hair cells and neurons could compromise their electrical activity.

To target AAV-encoded *Gjb2* expression to the appropriate cells in the mouse cochlea, we used ATAC-seq on mouse and NHP cochleas, and identified gene regulatory elements (GREs) that could mediate specific expression in epithelial cells and fibrocytes. Using an AAV9-PHP.B vector, HA-tagged GJB2 was delivered under GRE control to the cochleas of wild-type mice at P1. Assessed at P30 by anti-HA labeling, GJB2.HA was localized to the appropriate cell types. When delivered to a conditional knockout model ($Gjb2^{fl/fl}$, *Sox10-Cre*), GJB2.HA largely prevented the cochlear degeneration observed in untreated knockout mice, but only slightly rescued hearing sensitivity.

We then turned to a milder model of DFNB1 deafness. As previously reported, deletion of the nearby *Gjb6* gene is thought to delete a *Gjb2* regulatory element, as *Gjb2* expression is reduced by up to 90%. In this $Gjb6^{-/-}$ model, mice are severely hearing-impaired but not completely deaf. Again, we used an AAV9-PHP.B vector to deliver GJB2.HA with GREs to P1 cochleas, but hearing was not rescued.

Concerned that the HA tag might interfere with GJB2 function, we injected the same vector encoding GJB2 without the HA tag. Assessed at P30, the vector prevented degeneration, and it preserved hearing nearly at wild-type levels. Thus GJB2-related GREs are able to direct expression of GJB2 to the correct cell types, and GJB2 lacking a HA tag can preserve normal morphology and hearing.

Finally, we tested control of expression by GREs in nonhuman primate cochleas. In three NHP cochleas , AAV9-PHP.B-delivered human GJB2.HA was located in all the appropriate cell types. Assessed with ABR recording, the vector caused little or no reduction in hearing sensitivity. Together, these results suggest that GRE-mediated expression of *GJB2* could prevent hearing loss in DFNB1 patients.

1559 *GJB2* gene therapy-response of two pre-clinical mouse models of the most frequent form of human deafness, DFNB1A.

Anne-Valérie Héritier[1], Andrea Lelli[2], Amrit Singh-Estivalet[1], Nawel Mekdad[2], Solene Roux[2], Muriel Sudres[2], Nicolas Michalski[2], **Rafik Boudra[3]**, Arnaud Giese[4], Laurent Desire[5], Christine Petit[2]
[1]Institut de l'Audition, MONTPELLIER, Hérault, France, [2]Institut de l'Audition, Paris, Paris, France, [3]Sensorion, Montpellier, Hérault, France, [4]Sensorion, Montpellier, France, [5]Sensorion, Paris, Paris, France

More than 1.5 billion people worldwide live with hearing loss (HL). Sensorineural HL affects one new-born in 700-1000 and approximately one child or young adult in 500 before the age of 20. Approximately 70% of congenital severe to profound deafness cases are hereditary due to monogenic defects, thus potentially treatable by gene therapy (GT).

GJB2-related autosomal recessive non syndromic HL (also referred as DFNB1A) is the most common genetic cause of congenital sensorineural HL in many world populations, frequently accounting up to half cases. In addition, it is also responsible for deafness occurring later, even after 40 years of age. *GJB2* encodes connexin-26 (Cx26) gap-junction channel protein that plays a key role in metabolites and ions homeostasis necessary to cochlear development and sensory hair cell function and survival. Hundreds of pathogenic *GJB2* variants including large deletions, loss-of-function and missense variants have been reported which outcome spans from mild to profound deafness.

To assess GT approaches for HL caused by *GJB2* defects, we developed several experimental mouse models: the *Gjb2* cKO/cKO model resulting in a biallelic *Gjb2* inactivation mimics the most common form of congenital DFNB1, and the *Gjb2* cKO2/Hmut, a compound heterozygote, expressing a human missense pathogenic variant (Hmut), corresponds to a frequent human *GJB2* genotype. To circumvent embryonic mouse lethality caused by *Gjb2* inactivation, conditional knockouts were generated using the same Cre-recombinant mice which displays a large cochlear spatial expression, i.e. in a vast majority of *Gjb2*-positive cells.

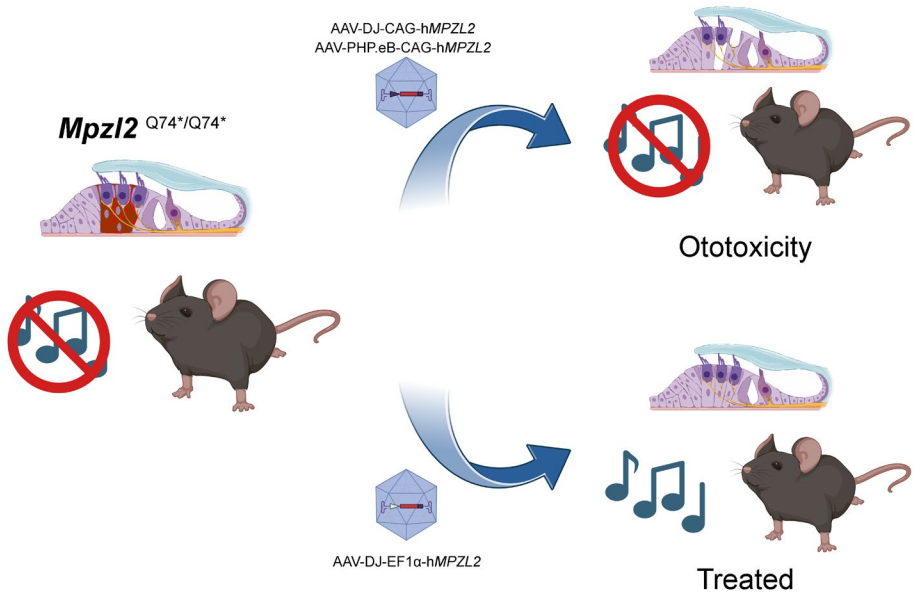
Gjb2 cKO/cKO and *Gjb2* cKO/Hmut mice showed cochlear structure disruption (neurosensory epithelium loss and collapsed organ of Corti, respectively) and congenital HL (profound and severe deafness, respectively, measured at P16). In both models, intracochlear injections of GJB2-GT lead to hearing improvement 4 weeks post-injection. Best responding mice show up to 40-50dB ABR threshold shifts and wave 1 amplification comparable to CTRL littermates for mid-range frequencies. Histological analysis showed cochlear structure preservation in almost all GJB2-GT injected mice. Especially, in treated *Gjb2* cKO2/cKO2 mice, GJB2-GT fully prevent hair cells and supporting cells (SCs) loss. In those mice, Cx26 expression was broadly detected along the tonotopic axis in SCs. No transduction was observed in inner nor outer hair cells.

These data support that GJB2-GT improves audition in two preclinical models of human pathogenic *GJB2* variants.

1560 Gene Replacement Therapy Ameliorates Hearing Loss in a Mouse Model with an Mpzl2 East Asian Founder Variant.

Heon Yung Gee[1], Seung Hyun Jang[2], Hyeong Gi Song[3]
[1]Yonsei University College of Medicine, Seoul, Korea, [2]Yonsei University College of Medicine, Seoul, Seoul Teugbyeolsi, South Korea, [3]Yonsei University College of Medicine, Seoul, South Korea

Hearing loss is the most common sensory organ disorder, with genetic factors substantially contributing to the disease. Among the 87 genes responsible for autosomal recessive nonsyndromic hearing loss, mutations in MPZL2 have been frequently linked to mild-to-moderate autosomal recessive hearing loss (DFNB111). Here, we present multiple families whose hearing loss arose from biallelic mutations in the MPZL2 gene and found that the MPZL2 p.Q74* mutation may be a founder allele among East Asians. Furthermore, we generated an Mpzl2 p.Q74* knock-in mouse model that exhibited autosomal recessive, progressive, ski-sloping hearing loss with disorganized Deiter's cells. Gene replacement using AAV-DJ or AAV-PHP.eB to deliver human MPZL2 (hMPZL2) under control of the CAG promoter induced ototoxicity, whereas employing an alternative EF1α *promoter with AAV-DJ (DJ-EF1α-hMPZL2) circumvented this issue, restoring long-term auditory function and Deiter's cell organization in Mpzl2$^{Q74*/Q74*}$ mice for up to 24 weeks. Overall, this study provides the foundational steps for developing a safe and effective biological treatment for DFNB111 and underscores the importance of precise regulation of target cells and transgene expression in AAV-based treatments.*



1561 Large animal model for human inner ear gene therapy: Transgene expression of viral vectors in pigs

Erdem Yildiz[1], Katrin Niisuke[2], Till Buschhorn[2], Caroline Sesztak[2], Matthias Gerlitz[2], Anselm Gadenstaetter[3], Clemens Honeder[2], Christoph Arnoldner[3], Lukas Landegger[4]*
[1]Medical University of Vienna, Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Wien, Austria, [3]Medical University of Vienna, Vienna, Austria, [4]Stanford University, Palo Alto, CA
**Corresponding Author*

Objective: The recently published data on the clinical application of viral vectors to prevent the natural course of hearing loss in human patients with OTOF variants show the potential of inner ear gene therapy. For the first time, children affected by autosomal recessive otoferlin mutations were treated by delivering adeno-associated viruses (AAVs) into the inner ear. An in-depth investigation of the respective efficacy of the applied viruses has so far only been carried out in a limited number of large animal models. In this study, AAVs were injected into the cochleae of pigs to investigate transduction patterns of the inner ear tissue.

Methods: In three pigs, AAV2-eGFP with a CAG or CMV promoter was injected via the round window membrane using an established surgical procedure under general anesthesia. Pre- and postoperative brainstem audiometry was performed. After a follow-up of one week, inner ears and other organs relevant for systemic biodistribution were extracted and analyzed by means of immunofluorescence and confocal microscopy.

Results: Successful transduction was identified in the cochlear hair cells leading to a decreasing gradient from base to apex in the outer hair cells, but increasing transduction rate from base to apex in the inner hair cells. A unilateral injection showed no transduction in the contralateral ear. In addition, no threshold changes were observed in the injected ears when measuring auditory brainstem click responses. In our preliminary results, no peripheral organs were transduced with AAV2.

Conclusions: Due to the large dimensions of the inner ear (most comparable volume to the human cochlea), the pig represents a suitable alternative large animal model for hearing research and in particular inner ear gene therapy. The above-mentioned findings confirm that AAV2 is a reliable vector for targeting sensory hair cells and that future gene therapies can be investigated preclinically in pigs to optimize vector delivery, distribution, and corresponding transduction patterns, all of which could result in translational benefits by developing more effective human therapies.

1562 Supporting the Informed Consent Process in Clinical Trials of Induced Pluripotent Stem Cell–Derived Corneal Epithelium Transplantation

Kayo Takashima[1]*, Takeshi Soma[2], Kohji Nishida[2], Jusaku Minari[3]*
[1]Kyoto University, Kyoto, Kyoto, Japan, [2]Osaka University, Suita, Osaka, Japan, [3]Kyoto University, Center for iPS Research and Application, Kyoto, Japan
**Corresponding Author*

Background: In clinical trials involving induced pluripotent stem cells (iPSCs), one of the most significant areas of progress is in ophthalmology, especially in relation to diseases that affect the retina and cornea. However, the details of such advanced trials are often complex and difficult for participants to understand; thus, we need to consider how to ensure genuine informed consent from patients with eye diseases. In particular, for patients with visual impairments, does providing the details of cutting-edge clinical trials solely through conventional, written information sheets truly respect their autonomy in decision-making? To address this question, we collaborated with individuals with visual impairments and professionals supporting the visually impaired to create audio support materials. These were specifically designed to improve accessibility and comprehension for visually impaired participants in clinical trials on iPSC-derived corneal epithelium transplantation. This presentation outlines our attempt to assess the initiative through interviews with trial participants. These interviews, conducted after the completion of the clinical study, focused on the participants' perspectives on their trial participation.

Methods: Semi-structured interviews were conducted with four patients who participated in a clinical trial on iPSC-derived corneal epithelium transplantation. All had given their informed consent before participating. The interviews were audio-recorded, transcribed, and coded using qualitative data analysis software. We extracted and analyzed the portions of the interview dataset where the participants mentioned the audio support materials.

Results: From the feedback participants provided on their comprehension of the research and the impact of audio assistance, we identified four distinct experiences: (1) understanding without difficulty, (2) achieving comprehension after repeated listening, (3) experiencing challenges in understanding the information, and (4) comprehending the information with the help of family members. The audio material was also considered helpful for

sharing information and facilitating discussions with family members regarding trial participation.

Discussion and Conclusion: Three key insights emerged from the dataset. Using audio support materials tailored to patients with low vision had the potential to enhance accessibility and contribute to respecting patient autonomy. Next, while it has been noted that evaluating the usefulness of patient and public involvement and engagement is challenging, discussions with research participants after their participation may be useful for assessing such initiatives. Finally, this approach could help advance the discussion on reasonable accommodations in clinical research for patients with visual impairments. In our view, the findings from the participants' experiences provide a valuable reference for further consideration and improvement.

1563 IMPROVING ACCESSIBILITY TO CELL AND GENE THERAPY FOR RARE DISEASES

Cecilia Marinova[1], Miriam Kolnikova[2], Eva Vlkova[3], Monika Horackova[4], Magdalena Netukova[5], Cecilia Skalicka[6], Veronika Sladkova[7]
[1]Medasol, Prague, Praha, hlavní město, Czech Republic, [2]National Institute of Children's Diseases, Bratislava, Slovakia, Bratislava, Bratislavský kraj, Slovakia, [3]Faculty Hospital Brno,, Brno, Praha, hlavní město, Czech Republic, [4]Faculty of Medicine, Masaryk University Brno, Brno, Praha, hlavní město, Czech Republic, [5]Faculty Hospital Kralovske Vinohrady, Praha, Czech Republic, Praha, Praha, hlavní město, Czech Republic, [6]General University Hospital in Prague, Praha, Czech Republi, Praha, Praha, hlavní město, Czech Republic, [7]Medasol sro, Praha, Praha, hlavní město, Czech Republic

Objective: Despite growing awareness of rare diseases, knowledge of approved cell & gene treatment (CGT) treatments and their accessibility remains limited. The administrative and logistical challenges involved in managing patient eligibility and treatment initiation also hinder CGT's broader application. Complexity of CGT, and its case-by-case individual character is another limiting factor for its wider use. We evaluated the role of processes in accelerating the access to CGT in practice, including autologous CGT, which are among the most complex treatments.

Methods: The administrative processes for 6 different cell&gene therapies in 20 diagnostic and treatment centers in Europe, from diagnosis to treatment, were mapped and evaluated with 2 years follow up. A total of 52 different processes were required from diagnosis to local treatment or cross-border treatment.

Results: 133 patients were evaluated, of whom 29 were eligible for and received approved CGT, which is subject to strict eligibility criteria. Between 6 and 18 months elapsed between diagnosis and initiation of therapy, due to limited experience with CGT and de novo, intense interactions among all stakeholders. Of the 52 processes identified, 29 were specific to CGT, with 21 processes (40%) requiring more than 100 additional hours of effort to establish treatment centers. Additionally, 31 processes (60%) related to the cross-border treatment (diagnosis assessment, treatment proposal, review, and implementation). The allocated CGT team helped clarify responsibilities and coordinated all interactions to speed up processes.

Conclusions: The administrative and logistical burden associated with CGT significantly impacts the scalability of treatment. The complexity of the process, requiring coordination across multiple stakeholders (including diagnostic centers, treatment centers, and payers), increases the time and resources needed to initiate therapy. Therefore, standardization of documentation and the establishment of CGT team can improve access to CGT, since effective management of these processes is essential. Where treatment centers lack dedicated CGT teams, external coordination, such as those provided by Medasol, can help streamline these tasks. Ensuring proper process management from diagnosis to treatment initiation will facilitate broader access to CGT and support timely, effective treatment for rare disease patients.

1564 Generation of induced Pluripotent Stem Cell (iPSC)-derived Retinal Pigment Epithelium (iRPE) from a patient with Retinitis Pigmentosa associated with a mutation in *PROM1*

Ivan Fernandez-Bueno[1]*, Kevin Puertas-Neyra[2], Leticia Hernández-Rodríguez[3], Miguel De la Fuente[4], Rosa Coco-Martín[5]
[1]Universidad de Valladolid, Valladolid, Castilla y León, Spain, [2]Grupo de Retina, Unidad de Excelencia Instituto Universitario de Oftalmobiología Aplicada (IOBA), Universidad de Valladolid; Departamento de Cirugía, Oftalmología, Otorrinolaringología y Fisioterapia, Facultad de Medicina, Universidad de Valladolid, Valladolid, Valladolid, Spain, [3]IOBA, Universidad de Valladolid, Valladolid, Valladolid, Spain, [4]Grupo de Modificación Genética Dirigida, Unidad de Excelencia Instituto de Biología y Genética Molecular (IBGM), Universidad de Valladolid, Valladolid, Valladolid, Spain, [5]IOBA, UVa, Valladolid, Valladolid, Spain
**Corresponding Author*

Introduction: *PROM1* encodes the protein Prominin-1, which plays a critical role in regulating key processes in the Retinal Pigment Epithelium (RPE), including waste removal through autophagy and the stabilization of lysosomal activity. In the retina, Prominin-1 is also present in photoreceptors, where it contributes to the structure and morphology of their membranes. Mutations in *PROM1* have been associated with all major phenotypes of Inherited Retinal Diseases (IRD). Specifically, the c.1354dupT (p.Tyr452Leufs*13) mutation located in exon 13 of *PROM1* has been linked to various IRD phenotypes, including Retinitis Pigmentosa (RP). The aim of this study was to generate induced Pluripotent Stem Cell (iPSC)-derived RPE (iRPE) from a patient with RP and the c.1354dupT mutation in *PROM1*, for future molecular and functional characterization of the effects of this mutation.

Methods: A dermal biopsy was obtained from a patient previously diagnosed with RP and carrying the homozygous c.1354dupT mutation in *PROM1* to establish a primary culture of fibroblasts. The patient's fibroblasts were reprogrammed via non-integrative nucleofection using the Epi5 Episomal iPSC Reprogramming Kit (OCT4, SOX2, KLF4, L-MYC, and LIN28) and the Neon Transfection System under the following pulse conditions: 1,400 V; 20 ms; two pulses. After 21 days of culture, iPSC colonies were manually selected. Subsequently, iPSC characterization was conducted through immunocytochemistry using pluripotency markers (SOX2, TRA-1-60, and SSEA-4) and *in vitro*differentiation of embryoid bodies (EB) into the three germinal layers, assessed by the expression of β-III Tubulin, α-SMA, and α-1 Fetoprotein markers. To generate iRPE, EBs were cultured in Neural Induction Medium (DMEM/F12 supplemented with 1% N-2, 0.1% Heparin, and 1% MEM NEAA) until day 16. The culture was then continued in Retinal Differentiation Medium (DMEM/F-12 supplemented with 2% B27 and 1% MEM NEAA). Between days 28 and 35, iRPE was manually harvested from the optic vesicles. The generation of iRPE was subsequently confirmed through immunocytochemistry utilizing antibodies against key retinal pigment epithelium (RPE) proteins, including retinal pigment epithelium-specific 65 kDa (RPE65), cellular retinaldehyde-binding protein (CRALBP), and bestrophin 1 (BEST1).

Results: The generated iPSC line (designated [RP]-FiPSC1-Ep5F-10) tested positive for membrane (TRA-1-60 and SSEA-4) and nuclear (SOX2) pluripotency markers, demonstrating the ability to differentiate *in vitro* into the three germinal layers. The resulting iRPE demonstrated a homogeneous and polygonal morphology, along with distinct pigmentation. Furthermore, iRPE cells expressed the markers RPE65, CRALBP and BEST1.

Conclusions: Reprogrammed iPSCs derived from a patient with RP and the c.1354dupT mutation in *PROM1* can be successfully differentiated into iRPE cells. While further functional characterization of iRPE cells and elucidation of the role of the *PROM1* mutation are necessary, patient-derived iPSCs provide a promising avenue for the design and development of future precision medicine and disease modeling strategies.

1565 A Novel AAV2 Capsid Variant-based Dual-Acting Ocular Gene Therapy Targeting VEGF and Inflammatory factors for Neovascular Age-related Macular Degeneration

Xiaoming Gong, Akron Children's Hospital, Akron, OH

Background: Anti-vascular endothelial growth factor (VEGF) therapies have revolutionized treatment and visual outcomes for patients with neovascular age-related macular degeneration (nAMD), yet up to 30% of patients fail to achieve significant visual improvements and remain at risk of severe, irreversible vision loss. Furthermore, anti-VEGF agents have been associated with adverse ocular events, including occlusive retinal vasculitis, intraocular inflammation, and geographic atrophy development, highlighting the need for improved therapeutic strategies. Chronic inflammation, including aberrant complement activation, has emerged as a critical contributor to AMD pathogenesis, presenting an opportunity for a dual-targeting approach to enhance the efficacy of anti-VEGF monotherapy and mitigate adverse ocular outcomes.

Methods: We developed a novel dual-acting gene therapy leveraging an engineered AAV2 capsid variant (AAV2.NG) identified through rational design and directed evolution in non-human primates (NHPs). This platform enables intravitreal delivery of both anti-VEGF agents (*e.g.,* anti-VEGF single-chain variable fragments [scFv], aflibercept) and anti-inflammatory factors (*e.g.,* anti-TNFα_scFv, complement component 3 inhibitory protein/peptide [C3IP]). Several transgene constructs were vectorized and assessed for their expression and functionality.

Results: AAV2.NG demonstrated an enhanced transduction efficiency for central retina in NHP eye compared to AAV2. Transgene expression in HEK293 or ARPE19 cells confirmed robust secretion of bioactive anti-VEGF_scFv, anti-VEGF_aflibercept, anti-TNFα_scFv and C3IP proteins, as determined by Western blot and ELISA. Functional assays demonstrated potent VEGF inhibition in HUVEC proliferation models, TNFα inhibition in HEK-Blue TNF-alpha cells and effective complement blockade in Raji cell-based assays. These results validate the feasibility and activity of this dual-acting gene therapeutic approach.

Conclusions: This innovative AAV-mediated gene therapy represents a promising strategy to address the unmet clinical needs in nAMD. By targeting both VEGF and inflammation signaling pathways, it offers the potential for improved efficacy and safety profiles compared to current treatments. Ongoing in vivo studies will evaluate its therapeutic potential in preclinical models, paving the way for future clinical translation.

1566 NT-501 Capsule Stability and Encapsulated Cell Technology Platform Capabilities

Lovisa Selander[1], Preston Lanier[2], Kayla Springhetti[2], Konrad Kauper[3]
[1]Neurotech Pharmaceuticals, Inc., Cumberland, RI, [2]Neurotech Pharmaceuticals, Inc., Cumberland, [3]Neurotech, Cumberland, RI

Purpose: The NT-501 implant uses Neurotech's novel encapsulated cell technology (ECT) to provide long-term intraocular drug delivery of ciliary neurotrophic factor (CNTF) to the retina for treatment of Macular Telangiectasia type II. The ECT is a combination product that contains cells encapsulated within a capsule. The capsule's main components are the semi-permeable hollow fiber membrane, the polyethylene terephthalate scaffold, and the UV-cured adhesive. Due to the expected long-term duration in which the NT-501 implant will be exposed to an aqueous environment in vivo, the capsule materials, as well as the sealed capsules' stability, needed to be evaluated over a two-year duration. Additionally, the ECT platform's configuration capabilities to deliver different levels of therapeutics was evaluated.

Methods: To evaluate material stability, real time and accelerated aging in a simulated in vivo condition (0.9% Saline Solution) was performed on the capsule, the UV-cured adhesive, and the PES/PVP HFM. The integrity of the capsules was evaluated quantitatively using both pressure-decay leak testing and an HPLC-MS method for detecting the adhesive degradant molecule 4-4'-methylenebis(cyclohexylamine) (HMDA), and morphologically by H&E staining. The materials were evaluated for either chemical, functional, or physical properties. To evaluate the ECT

platform capabilities, modifications were made to the capsule to increase the delivery of therapeutic protein compared to the NT-501 implant. NT-501 (control) and modified ECT capsules were tested in vitro and conditioned media samples from both groups were tested using ELISA. Samples were tested and evaluated by ELISA to determine the level of protein delivered.

Results: The NT-501 capsule remained integral throughout the entire two-year simulated in vivo study and no substantial decrease in material properties were detected. By modifying the ECT capsule, increased levels of secreted therapeutic protein were detected compared to the control group in vitro.

Conclusions: The simulated in vivo stability study supports that the NT-501 capsule remains integral and the capsule materials are stable for at least two years. Additionally, modifications can be made to the ECT capsule to alter the delivery levels or targets of therapeutics making it a versatile long term delivery platform for intraocular diseases.

1567 Analysis of Spatial Transcriptomic Data in a Non-Human Primate Ophthalmology Model

Sasha Makohon-George[1], Russell Buchanan[1], Jennifer Israel[2]
[1]Kriya Therapeutics, Durham, NC, [2]Kriya Therapeutics, Redwood City, CA

In this study, we demonstrate what is, to our knowledge, the first the successful application a high-resolution spatial transcriptomics platform for gene expression analysis in a non-human primate retina using a human probe set. Through cross-species in silico analysis, we identified high probe compatibility between human and cynomolgus transcripts, with 61% of genes showing perfect probe matches and an additional 36% exhibiting minor sequence variations predicted to maintain hybridization efficiency. We validated these computational predictions using retinal samples from cynomolgus macaques alongside human control tissue.

Our results show robust cross-species performance, with over 15,000 genes detected across all samples, enabling the identification of major retinal cell types and retinal layers based on distinct transcriptional signatures. These include retinal pigment epithelial cells, photoreceptors (rods and cones), and interneurons located in the inner nuclear layer, as well as the distinct retinal layers such as the photoreceptor layer, outer nuclear layer, and ganglion cell layer. The platform's high spatial resolution further revealed transcriptional domains corresponding to known anatomical structures and functional regions of the retina.

These findings lay the foundation for studying AAV transgene delivery in primate retinal tissue, offering critical insights into cellular and regional effects of gene therapies. By enabling high-resolution, cross-species spatial transcriptomics, this study highlights the potential of advanced transcriptomics platforms to advance preclinical research and inform the development of targeted therapies for retinal diseases, bridging preclinical findings with clinical applications.

1568 Encapsulated Cell Technology Enables Steady State Delivery of a Wide Range of Therapeutic Targets

Ian McHugh[1], Eugene Gonzalez-Lopez[2], Matthew Fera[1], Konrad Kauper[1], Arne Nystuen[1], Lovisa Selander[3]
[1]Neurotech, Cumberland, RI, [2]Neurotech Pharmaceuticals, Inc, Cumberland, RI, [3]Neurotech Pharmaceuticals, Inc., Cumberland, RI

Purpose: Encapsulated Cell Technology (ECT) is a novel cell delivery platform that provides continuous, steady-state release of therapeutics. Neurotech's ECT is a validated therapeutic platform that overcomes many of the barriers of intraocular drug delivery and eliminates the need for repeated intraocular treatments. Implanted in the vitreous humor, human retinal pigment epithelial cells are encapsulated in a semi-permeable membrane. The membrane allows for the inward diffusion of nutrients to support cell survival while cell-secreted therapeutics

diffuse out of the implant simultaneously. Here, we demonstrate that the human cell line is fully customizable and can be genetically engineered to produce a wide class of therapeutics that can be delivered by ECT.

Methods: The parental cell line was derived from human retinal pigment epithelium (RPE) cells. These parental cells have been genetically engineered to express select therapeutic proteins at stable delivery rates. Proteins were designed to be secreted from the cell by adding a signal peptide vector element. Expression of therapeutic proteins was detected by immunoassays of both implant and cell-conditioned media samples. Cell line characteristics were monitored by evaluating phenotypic morphology and immunofluorescence using RPE-specific markers.

Results: The implant is tunable to allow for the optimal release of secreted therapeutics. Various proteins have been successfully expressed, including trophic factors, fusion proteins, Fab fragments, small peptides, and large inhibitory monoclonal antibodies ranging from molecular weights of 20kDA to 185kDA. Clones that produce stable levels of functional protein over time were identified and evaluated. Additionally, genetic manipulation was shown to not change the phenotype of the parental cell line. Cells secreting ciliary neurotrophic factor (CNTF) have been encapsulated in the validated implant and successfully undergone phase 3 clinical trials.

Conclusions: Encapsulated cell technology (ECT) is a versatile platform capable of secreting a wide variety of intraocular therapeutic proteins. ECT has been recently evaluated in two Phase 3 clinical trials and the long-term, safe, and effective delivery of CNTF has been established.

1569 Intra-Articular Re-administration of High-Capacity Adenovirus (HCAd) for Gene Therapy in Post-traumatic Osteoarthritis

Jiansen Yan[1], Camilla Majano[1], Racel Cela[1], Zelong Dou[1], Syed Mehdi[1], Ming-ming Jiang[2], Amanda Shaw[2], Oscar Ruiz[2], Philip Ng[1], Masataka Suzuki[1], Yangjin Bae[1], Brendan Lee[1]
[1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, Houston

High-Capacity Adenovirus (HCAd) vector-based intra-articular (IA) gene therapy expressing an NFkB-responsive interleukin-1 receptor antagonist (IL-1Ra) has completed phase I clinical trial for osteoarthritis (NCT04119687) without significant toxicity and significant improvement of pain and functional endpoints after two years. Preliminary results demonstrated that baseline neutralizing antibodies (NAbs) did not correlate with the efficacy of WOMAC-A pain score reduction, suggesting the feasibility of repeated vector administrations. Therefore, we investigated the impact of pre-existing anti-vector immunity on HCAd vector transduction and transgene expression in the joint, as well as explored the potential for enhancing therapeutic efficacy of IL-1Ra gene therapy in osteoarthritis through repeated HCAd vector injections.

To model maximal pre-existing NAbs, FVB/NJ mice were first immunized intramuscularly with serotype 5 first-generation adenovirus (Ad5) and subsequently treated with IA administration of HCAd5 expressing β-galactosidase. Vector genome copy number and X-gal staining showed that pre-existing anti-Ad5 immunity reduced HCAd5 transduction and transgene expression in joint tissues. Furthermore, single IA immunization of HCAd vectors induced production of NAbs against the viral capsid five weeks post-injection. Repeated IA injections of the same serotype HCAd resulted in a reduction of transduction and transgene expression in joint tissues, supporting that in the murine model, intramuscular immunization can induce sufficient NAbs to reduce subsequent transduction.

To increase transduction with pre-existing NAbs, we evaluated serotype switching strategies. Alternative HCAd serotypes (HCAd1, HCAd2, and HCAd6) displayed joint tropism and long-term expression of luciferase comparable to HCAd5 in healthy joints and osteoarthritic joints induced via anterior cruciate ligament transection (ACLT). Importantly, prior HCAd5 exposure did not generate cross-NAbs against these serotypes. Serotype switching markedly improved transduction efficiency and transgene expression in mice with pre-existing anti-Ad5 immunity or prior IA HCAd exposure, as demonstrated by vector genome quantification, β-galactosidase mRNA levels, and X-gal staining.

Therapeutic studies in an ACLT-induced OA mouse model revealed that a single IA injection of HCAd5-NFkB-IL1Ra significantly preserved cartilage volume at 5 weeks post-injection, as assessed by phase-contrast μCT. However, continued OA progression was evidenced by reduced cartilage thickness at 9 weeks post-injection. Interestingly, a second injection with both HCAd2-IL1Ra or HCAd5-IL1Ra at 5 weeks post-initial injection effectively preserved cartilage and delayed OA progression at this second later timepoint compared with singly-injected mice, irrespective of serotype. These data suggest that while serotype switching can indeed overcome potential pre-existing NAbs, at least for the IL-1Ra vector, sufficient transduction even with the same serotype reinjection may be sufficient to mediate improved efficacy with readministration.

These findings provide critical insights into the potential impact of adenoviral immunity and highlight the feasibility of repeated HCAd vector-based IA gene therapy to achieve sustained therapeutic benefits for knee joint diseases such as post-traumatic osteoarthritis.

1570 Treatment of Rheumatoid Arthritis in a Collagen-Induced Arthritis Mouse Model Using Intra-Articular Injection of AAV6-Delivered sIL17RA

Susi Feng[1], Wenjun Li[2], Chengwen Li[3]*
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]UNC Gene Therapy Center - Chapel Hill, NC, Chapel Hill, NC, [3]UNC at Chapel Hill, Chapel Hill, NC
**Corresponding Author*

Rheumatoid Arthritis (RA) is a chronic autoimmune disorder characterized by joint inflammation. Modern therapies, such as biologic DMARDs, disrupt dysfunctional immune signaling in RA by targeting pro-inflammatory cytokines. However, less than 50% of patients treated with biologics achieve sustained remission, largely due to rapid drug clearance in the joints. Recently, Interleukin-17A (IL17A) has emerged as a key target due to its direct involvement in RA pathophysiology, such as bone destruction and synovitis, with several studies indicating the efficacy of the extracellular domain of Interleukin-17 Receptor A (sIL17RA) as a soluble inhibitor. Adeno-associated virus (AAV) is an ideal vector due to its ability to maintain robust, long-term expression of packaged transgenes, with our prior data identifying AAV6 as the optimal serotype for joint transduction. Here, we investigated the therapeutic potential of local IL17A inhibition via AAV6-delivered sIL17RA in a collagen-induced arthritis (CIA) mouse model. Our ITR2-flanked expression cassette encoded the extracellular domain of human IL17RA (Met1-Trp320), with a 3' His-tag at the C-terminus and a constitutive CBh promoter to drive expression. Secretion ability of the construct was confirmed *in vitro* by transfecting HEK293 cells and verifying the presence of sIL17RA in the supernatants through western blot. Next, the ability of sIL17RA produced from our construct to inhibit human IL17A activity was confirmed by measuring its ability to lower IL17A-induced CXCL1 production in HT-29 cells. Although the positive control IL17RA ECD (-0.239±0.007) had greater purity due to commercial production, compared to sIL17RA produced from our construct (purified in-house), we found that sIL17RA still significantly dampened IL17A activity (0.049±0.086) relative to cells incubated with IL17A only (0.393±0.060) ($p<0.05$). Finally, to assess the therapeutic efficacy of sIL17RA in vivo, 10-week-old DBA/1J mice were immunized on day 0 with an emulsion of Complete Freund's adjuvant and Bovine Type II Collagen (CII), and on day 21 with a booster of Incomplete Freund's adjuvant and CII to induce CIA. On day 42, treatment group mice received intraarticular injections of 1E10 vg AAV6-sIL17RA in the left knee joint and PBS in the right (n=8), while vehicle controls received AAV6-Luc in the left and PBS in the right (n=4). Two naive mice were kept for comparison. On day 70, arthritis severity was evaluated post-sacrifice with a 12-point H&E scoring system. Several mice experienced distinct improvement in the AAV6-sIL17RA-treated left joint, with an average score of 5.047±2.923, relative to the PBS right joint (7.104±2.174). While not statistically significant, this result showed a promising trend towards improvement. Lastly, we found that locally expressed sIL17RA showed minimal systemic leakage, as His-tagged sIL17RA was undetected in sera. ELISA also showed no significant difference in anti-CII antibody titers between vehicle and treatment groups, suggesting that local injections did not affect the systemic immune response (1.58E5±3.80E4 vs 5.88E4±1.23E5, $p>0.05$). To conclude, we developed an sIL17RA expression construct with the ability to inhibit IL17A activity *in vitro* and demonstrated the promise of AAV6-sIL17RA as a localized RA treatment *in vivo*. Future studies will optimize constructs for higher transduction, modify injection timing for prophylactic use, and increase replicates to mitigate variability.

1571 High Capacity Adenoviral Intra-articular NFkB-responsive IL1RA gene therapy on a genetic osteochondrodysplasia model

Yangjin Bae[1], Zelong Dou[1], Jiansen Yan[1], Lisa Yuva[1], Camilla Majano[1], Carolina Leynes[1], Racel Cela[1], Surabi Veeraragavan[1], Nele Haelterman[1], Brendan Lee[1]
[1]*Baylor College of Medicine, Houston, TX*

Osteogenesis Imperfecta (OI), or brittle bone disease, is a rare genetic disorder caused by either mutations in type 1 collagen encoding genes *COL1A1* or *COL1A2*, qualitative post-translational over-modification defects of type 1 collagen, or dysregulated signaling factors in bone cells and matrix. Patients with OI primarily manifest musculoskeletal phenotypes including bone fragility, recurrent fractures, and skeletal deformities and pain. Moreover, more than 30% of children and adolescents with OI experience chronic pain which disrupts functionality and quality of life. There are no FDA approved intervention for the pain management. Moreover, natural history studies have also demonstrated a broader growth and joint defect which is especially prominent in forms of OI that impact both cartilage and bone collagens. Thus, there is significant unmet need for treating chronic pain in OI patients. One contributor joint-related osteoarthritis (OA) pain, which was reported by a nationwide register-based cohort study from Danish group. In our previous published studies, we showed that *Crtap* $^{-/-}$ mice, a preclinical mouse model of moderate to severe OI type, have severe musculoskeletal phenotypes including joint disease including tendinopathy and osteoarthritis. Here, we focused on accessing the pain behavior of *Crtap* $^{-/-}$. We found that *Crtap* $^{-/-}$ mice showed a motor deficit associated with a significant reduction of vertical activity (VACTV) and rearing time (RTIME) based on the Open Field Assay (OFA). In addition, several parameters of CatWalk assay (Print-Area, Contact Intensity, Swing speed, Stride Length and Duty cycle) indicated that *Crtap* $^{-/-}$ mice manifest OA associated pain behavior. Consistent with OA like behaviors, we also confirmed histological changes in the knee joint of *Crtap* $^{-/-}$ early as 3 months of age which showed decreased proteoglycan in articular cartilage, ectopic chondrocytes in menisci, and hyperplasia in synovium. More interestingly, consistent with an elevated inflammation shown in tendons of *Crtap* $^{-/-}$ in the previous study, we identified infiltration of macrophages in the joint space of *Crtap* $^{-/-}$. To target OA pain in *Crtap* $^{-/-}$ mice, we performed the intra-articular High-Capacity Adenovirus expressing NFkB responsive IL1RA (HCAd-IL1RA) into the knee. This vector has been shown encouraging results in treatment of OA in a phase I clinical trial two years after a single injection (NCT04119687). We found an improvement of overall activity based on OPF and CatWalk assays after post 8wks IL1RA injection compared to Ad0 control. Overall, our study shows that *Crtap* $^{-/-}$ mice manifest osteochondrodysplasia related joint disease phenotype characterized by pain-associated behavioral changes and OA. Treating the inflammatory component of this disease with a current vector in clinical trial appears to impact pain measures in this rare disease model of OI.

1572 Antibody-Based AAV Retargeting to CACNG1 Mediates Enhanced Skeletal Muscle Transduction and Reduced Hepatotoxicity in Non-Human Primates

The use of adeno-associated virus (AAV) for gene therapy delivery shows significant potential for treating various muscle diseases. However, the high doses of AAV required to effectively transduce extrahepatic tissues, such as muscle, have led to severe adverse events in patients, including liver toxicity and death. To address this issue, we have employed a rational engineering approach to design AAVs specifically targeted to skeletal muscle, via conjugation of antibodies against a skeletal muscle-specific protein, CACNG1. These antibody conjugated AAVs are also detargeted from the liver using an AAV9 capsid with mutated galactose binding domains.

We have generated a panel of monoclonal anti-CACNG1 antibodies and previously demonstrated that AAV particles can be retargeted to skeletal muscle in an antibody-dependent manner in both human myotubes and humanized mice genetically modified to express the human CACNG1 protein. Here, we evaluated the safety and efficacy of CACNG1-retargeted AAVs in cynomolgus macaques to demonstrate the translation of CACNG1-mediated skeletal muscle transduction in a large animal model.

Following intravenous delivery, CACNG1-retargeted AAVs, packaged with a muscle-specific promoter driving expression of a therapeutic transgene, enhanced therapeutic transgene expression more than 10-100 fold in multiple skeletal muscle tissues, compared to wild-type (WT) AAV9. The efficiency of CACNG1 retargeted AAV was similar between rodents and cynomolgous monkeys, demonstrating the cross-species translatability of our delivery platform. Additionally, CACNG1-retargeted AAVs were markedly detargeted from the liver (>200 fold) and heart (>20 fold) at DNA level. At a dose of 2E14vg/kg, NHPs treated with WT AAV9 exhibited transient ALT elevation, platelet loss, and complement activation post-dosing. In contrast, NHPs injected with CACNG1 retargeted AAV had no significant differences to control animals in these parameters, indicating a superior safety profile compared to WT AAV9.

In summary, these data demonstrated that CACNG1-retargeted AAV vectors significantly outperform WT AAV9 in both the efficiency and specificity of muscle transduction. These muscle -targeted vectors could enhance the therapeutic efficacy and reduce off-target toxicity of gene therapies for multiple muscle diseases.

1573 AAV Gene Therapy for Digit Regeneration Informed by Spatial Transcriptomics

Madeleine Landau[1], Thomas Dvergsten[2], Erin Brush[2], Alyssa Ehrhardt[2], Colleen Milligan[2], Melissa Tran[2], Timothy Curtis[3], Jianhong Ou[2], Grant Darner[2], Katja Koll[2], Kendall Reitz[2], Rochelle Bitolas[2], David Salven[2], Aravind Asokan[4], Kenneth Poss[5], David Brown[2]

Introduction: Limb loss presents a significant clinical challenge that stands to benefit from fields such as gene therapy. Mouse digit tip (MDT) regeneration serves as a mammalian model of complex tissue regeneration that can provide insight into strategies for enhancing tissue repair and bone lengthening after limb amputation. However, little is known about optimal gene therapy methods for manipulating this process. This study employed spatial transcriptomics to identify gene promoters active in key anatomic regions of the regenerating MDT. Subsequently, promoter sequence fragments were tested in adeno-associated viral vector (AAV) assays for their ability to enhance bone regeneration by driving overexpression of a potent osteogenic effector gene (BMP2).

Methods: Hindpaw digits of 8-week-old BALB/cJ mice were amputated at the level of the middle (P2) or distal (P3) phalanx. Fourteen days post-amputation (dpa), samples were processed through the STOmics Stereo-seq platform to delineate gene expression in anatomic sub-regions of the regenerating digit. Proximal promoter fragments (2 kb) were cloned from the *Krt16*, *Postn*, or *Col1A2* genes and placed upstream of the BMP2-3xFLAG coding sequence, followed by plasmid synthesis and packaging into AAV8 vectors. AAV8 CMV:GFP vectors were used as controls. At 10 dpa, vectors were systemically delivered by retro-orbital injection. At 14 dpa, digits were harvested for histological analysis or Stereo-seq. P3- and P2- amputated digits were collected at 21 dpa and 28 dpa timepoints, respectively, for micro-CT analysis. Scans were reconstructed and scaled in ImageJ. Whole and segmental measurements of length, thickness, and volume were obtained for regenerating bone, then normalized by comparison with corresponding original amputated digit tips.

Results: Stereo-seq analysis revealed a rich architecture of genetically distinct regions of the digit tip. Differential gene expression in keratinocyte populations allowed for segregation of epidermal cells into computationally defined clusters, localized to the regeneration epidermis (RE). Osteogenic genes, such as *Ibsp*, *Sparc*, *Spp1*, *Postn*, *Bglap*, and *Alpl,* were induced in both P3 and P2 amputations compared to uninjured P3 digits. Spatially localized GFP expression in areas of the MDT suggested successful transduction of injected AAV constructs, whereas anti-FLAG immunofluorescence revealed promoter-specific patterning of viral construct expression. Mice injected with AAV8 POSTN:BMP2-3xFLAG demonstrated increased P3 regenerated volume when normalized and compared to the GFP control mice (mean 550% ± 250% vs 190% ± 60%, p=0.0036), and increased P2 regenerated volume relative to GFP control mice (mean 180% ± 86% vs 98% ± 47%, p=0.0085). AAV8 KRT16:BMP2-3xFLAG showed increased thickness (mean 72% ± 10% vs 49% ± 3.7%, p=0.0086) and volume (190% ± 81% vs 98% ± 47%, p=0.0467) in P2 regenerated digits. Trabecular structural properties appeared similar between mice injected with AAV8 COL1a2:BMP2-3xFLAG and those injected with control virus.

Conclusion: This study presents a novel methodology for identifying AAV control sequences in the MDT and suggests that bony digit regeneration can be enhanced by spatially directed overexpression of BMP2. Ongoing work seeks to probe cell type-specific dynamics and associated signaling pathways modulated by these vectors. This work may lead to new approaches for treating complications of limb loss through AAV gene therapy.

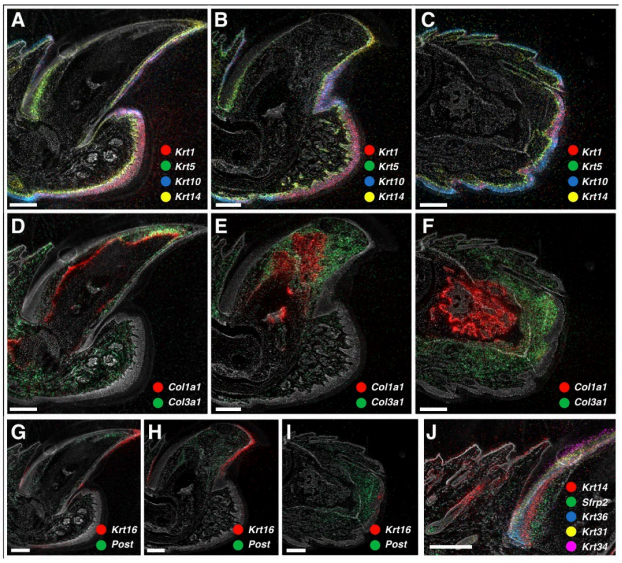

Figure 1. STOmics Stereo-seq gene expression profiles of an uninjured P3 mouse digit tip (A,D,G,J), a mouse digit tip 14 days post-amputation at P3 (B,E,H), and a mouse digit 14 days post-amputation at P2 (C,F,I).

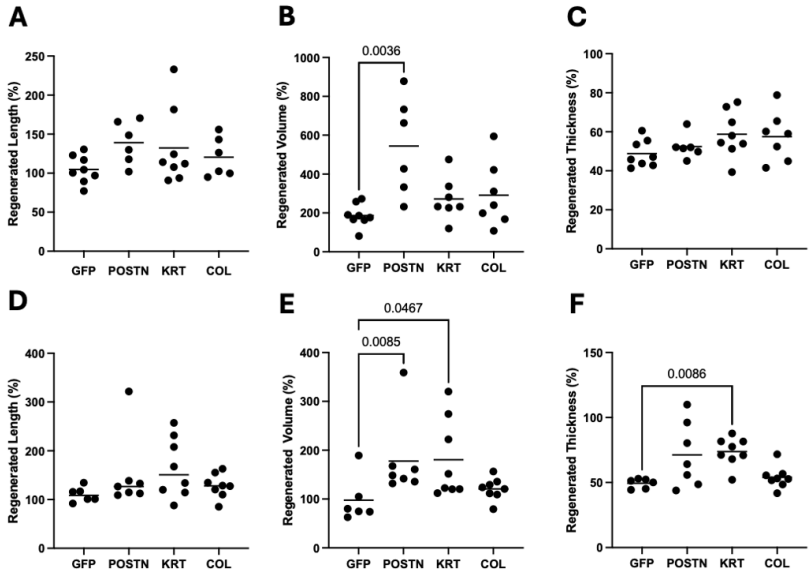

Figure 2. Measurements from 3D-rendered mouse digit tips generated from micro-computed tomography imaging. (A-C) Length, volume, and thickness of mouse digit tips amputated along P3 and harvested at 21 days post amputation, normalized to the corresponding value for original amputated digit tip counterparts. (D-F) Length, volume, and thickness of mouse digit tips amputated along P2 and harvested at 28 days post amputation, normalized to the corresponding value for original amputated digit tip counterparts.

1574 Secreted microRNAs are implicated in the reversal of myogenesis defects in ALS-derived myocytes.

[1]University of Padova, Padova, Italy, Italy, [2]University of Padova, Padova, Italy, [3]University of Padova, Padova, Padova, Italy, [4]Istituto Zooprofilattico Sperimentale delle Venezie, Padova, Italy, [5]University of Padova Department of Biology, Padova, ITALY, [6]CNR - Neuroscience Institute, Padova, Padova, Italy

Amyotrophic lateral sclerosis (ALS) is the most prevalent adult-onset paralytic disorder, characterized primarily by a progressive loss of motor neurons (MNs). Skeletal muscle, a plastic tissue that responds to insults through proliferation and differentiation of satellite cells, is affected by MN degeneration. The process of skeletal muscle degeneration and regeneration is meticulously regulated by signals that govern satellite cell proliferation and differentiation. While it is known that satellite cell differentiation is impaired in ALS, the role of microRNAs (miRNAs) and their involvement in intercellular communication within skeletal muscle in ALS remain poorly understood.

In this study, we demonstrated impaired differentiation of satellite cells derived from ALS mice, which is associated with the impairment of myogenic p38MAPK and PKA/pCREB signaling pathways. These signaling pathways can be regulated by miR-882 and -134-5p. These miRNAs participate in autocrine signaling in conjunction with miR-26a-5p, which is secreted from wild-type (WT) and captured by ALS myoblasts. This secreted miR-26a-5p enhances ALS-related myoblast differentiation by repressing Smad4-related signals.

These findings underscore the paramount importance of elucidating the role of intercellular communication and the molecular mechanisms underlying ALS pathogenesis and progression. They also suggest that miRNAs could be targeted or utilized as potential therapeutic agents to promote myofiber regeneration.

1575 A Highly Potent MyoAAV4A Vector Achieved Long-Term Correction of Muscle Disease in Young Adult GSD IIIa Mice and Reversed Muscle Dysfunction in Aged Mice

Background: Glycogen storage disease type III (GSD III) is caused by glycogen debranching enzyme deficiency, which leads to pathological accumulation of cytoplasmic glycogen in muscle and liver. We recently reported an innovative gene therapy approach using an AAV9 vector expressing a bacterial debranching enzyme (pullulanase) from an immunotolerizing dual promoter, which consists of a liver-specific promoter (LSP) and a ubiquitous CMV enhancer/chicken β-actin (CB) promoter. We showed that the LSP-CB dual promoter effectively suppressed pullulanase-specific cytotoxic T lymphocyte responses in GSD IIIa mice while allowing sustained pullulanase expression and glycogen reduction in liver, heart, and skeletal muscles. We have further demonstrated that two high potency MyoAAV capsids (MyoAAV4A and MyoAAV4E) remarkably enhanced transduction efficiencies in the cardiac and skeletal muscles of GSD IIIa mice, in comparison with AAV9 at 6 weeks following AAV injection. In this study, we evaluated the long-term efficiency and therapeutic efficacy of the lead MyoAAV4A capsid in young adult and aged GSD IIIa mice. **Methods:** An AAV vector carrying the LSP-CB dual promoter and a codon optimized CpG-free pullulanase cDNA was packaged in MyoAAV4A capsid and the resulting viral vector (MyoAAV4A-Dual-Pull) was intravenously injected into 3-month-old (young adult mice) or 13-month-old (aged mice) male and female GSD IIIa mice at a dose of $5x10^{12}$ vg/kg. Untreated (UT) age- and gender-matched GSD IIIa mice were used as controls. After 9 (young adult mice experiment) or 3 (aged mice experiment) months, the improvement of muscle function was evaluated by the wire-hang and treadmill tests. Tissues were harvested to assess the pullulanase expression and glycogen content. Plasma samples were collected to measure the levels of plasma creatine kinase (CK). **Results:** In young adult mice, AAV treatment led to slightly increased pullulanase activities in the heart (10.38 ± 4.08 vs UT: 4.22 ± 0.28 mU/mg of protein) and skeletal muscle (1.29 ± 0.55 vs UT:

0.58 ± 0.25), but not in the liver. AAV treatment significantly decreased glycogen contents in the heart (-53%) and skeletal muscle (-53%), accompanied by improved muscle function (as determined by the wire-hang and treadmill performances) and reduced plasma CK level (**Table 1**). In aged mice, AAV treatment resulted in significantly increased pullulanase activities in the liver (4.53 ± 2.93 vs UT: 2.19 ± 0.22), heart (143.44 ± 19.62 vs UT: 6.00 ± 0.58), and skeletal muscle (46.18 ± 26.82 vs UT: 0.27 ± 0.24), and significantly decreased glycogen contents in these tissues (-47% in liver, -88% in heart, and -87% in skeletal muscle). AAV treatment also significantly improved muscle function and reduced the plasma CK level, in comparison with UT (**Table 1**). Furthermore, the MyoAAV4A-Dual-Pull vector showed similar therapeutic outcomes in male and female mice in both experiments (**Table 1**). **Conclusions:** Our data demonstrated the long-term efficacy of MyoAAV4A-Dual-Pull-mediated gene therapy in a mouse model of GSD IIIa and its ability to reverse muscle dysfunction in aged GSD IIIa mice. Follow-up experiments to test the therapeutic efficacy in GSD IIIa dogs are being conducted. This novel muscle-tropic capsid can also be broadly used for treating other inherited disorders that affect cardiac and skeletal muscles as well as diseases with late-onset muscle manifestations.

1576 In vitro models and viral vectors and for targeted gene replacement therapy in Calpainopathy (LGMD2A/R1)

Julienne Dietz[1], Lampros Mavrommatis[2], Wenli Zhang[3], Dirk Grimm[4], Mathias Vorgerd[2], Anja Ehrhardt[5], **Eric Ehrke-Schulz[1]***

[1]Witten/Herdecke University, Witten, Nordrhein-Westfalen, Germany, [2]University Hospital Bergmannsheil, Heimer Institute for Muscle Research, Ruhr University Bochum, Germany, Bochum, Nordrhein-Westfalen, Germany, [3]University Witten/Herdeck, Witten, Germany, [4]Heidelberg University Hospital, Heidelberg, Baden-Wuerttemberg, Germany, [5]Private University Witten/Herdecke, Witten, Nordrhein-Westfalen, Germany

**Corresponding Author*

Introduction: Calpainopathy, (Limb Girdle Muscular dystrophies 2ALGMD2A/R1) is caused by mutations in the calpain 3 gene (CAPN3), is characterized by progressive, symmetrical weakness of the proximal limb and girdle muscles. Although physical therapy and orthopedic surgery can address symptoms, no disease modifying or curing treatment available. To support the development of targeted gene addition approaches we aimed to develop differentiated human CAPN3 deficient cell culture disease models and explore different muscle specific Adeno associated virus (AAV) derived vectors for CAPN3 gene delivery.

Methods: We established two genetically different patient derived cell culture disease models with defined CAPN3 mutations. We used immortalized myocytes as well as induced pluripotent stem cells (iPSCs) derived myocytes and applied advanced protocols using electrical pulse stimulation (EPS) to evoke differentiation into Myotubes and sarcomere formation in 2D cell culture. Both models were characterized with regard to differences compared healthy controls. To analyze viral vector mediated CAPN3 gene replacement in the differentiated myotubes, we designed vectors based on muscle specific capsids of AAV9 and AAVmyo encoding the full length CAPN3 cDNA fused to a GFP gene via a 2A peptide signal under control of the muscle specific MHCK7 promotor. Vector genomes were assembled and vectors were generated and produced to high titers. Subsequently both vectors were utilized to transduce differentiated CAPN3 deficient myotubes and healthy control myotubes. CAPN3 gene transfer and expression was analyzed by RT-qPCR, Western blot and fluorescent microscopy. Systemic *in vivo* delivery of both vectors was performed for biodistribution- and gene expression analysis in mice.

Results: Both CAPN3 deficient cell culture models were suitable for in vitro differentiation into mature contractile Myotubes and displayed morphological as well as physiological differences compared to healthy controls. AAV mediated gene transfer of the human CAPN3 cDNA resulted in enhanced CAPN3 gene expression *in vitro* and had compensatory effects on mRNA and protein levels in the two different Capn3-disease models. Preliminary *in vivo* experiments showed that systemic delivery resulted in robust CAPN3 gene expression in muscular tissue for both vectors, with AAVmyo showing reduced gene expression in non-target organs.

Discussion: This study provides novel preclinical *in vitro* disease models that help studying potential treatment options for Calpainopathy and provides insights helping to choose ideal gene transfer vehicle and or transgene expression setup for future translation into *in vivo* studies regarding tissue specificity and expression strength.

1577 Non-Viral Genetic Medicine for Targeted Delivery of Full-Length Dystrophin to Skeletal, Cardiac, and Diaphragm Muscles in DMD Mouse Models and Non-Human Primates.

Ivan Krivega[1], Charles Levine[1], Bert Frederich, Jon Chan[1], Margarita Krivega[1], Julia Poniatowski[1], Katie Benthall[1], David Kim[1], Nana Ingram[1], Shubhangi Singh[1], Elizabeth Del Greco[1], Julia Suffoleta[1], Gwendolyn Austin[1], Surabhi Rao[1], Victor Foster[1], Divia Mehra[1], Glenda Arauz[1], Celia Ortiz[1], Oliver Chen[1], Tanaya Ghosh[1], David Satyadi[1], Jessica Canzolino[1], Matt Lindeblad[1], Sherry Bullens[1], Steven Feinstein[1], Ken Greenberg[1]
[1]*SonoThera, South San Francisco, CA*

Duchenne muscular dystrophy (DMD) is a life-threatening genetic condition caused by mutations in the DMD gene, which result in the complete loss of functional dystrophin protein. To effectively treat DMD, therapies must aim to restore dystrophin production in the skeletal, diaphragm, and heart muscles, as these are the primary tissues affected by the disorder. Current gene therapy strategies utilizing truncated micro-dystrophin transgenes have faced challenges in achieving effective outcomes. These challenges stem in part from the limitations of viral delivery systems, including immune responses, inability to re-dose, restricted payload capacity, and limited organ biodistribution. Epidemiological studies of DMD patients indicate that even minimal expression levels of the full-length dystrophin gene (>0.5% of wild-type levels) may significantly alleviate the disease burden. This underscores the necessity to develop advanced non-viral genetic medicines capable of delivering full-length dystrophin (DMD) transgenes to achieve robust therapeutic efficacy. Transcutaneous ultrasound-mediated gene delivery (UMGD) represents a noninvasive and precision-targeted approach to address current challenges in genetic medicine delivery. SonoThera is advancing a proprietary UMGD-based non-viral genetic medicine platform designed to enable highly selective and efficient targeting of muscle tissues, offering a safe, extremely durable, and redosable therapeutic solution.

To evaluate the potential of UMGD for safe and effective gene delivery to muscle tissues, a nonviral DNA construct incorporating full-length human DMD transgene driven by a muscle-specific promoter was developed. Under optimized UMGD conditions, efficient delivery of the full-length DMD transgene was achieved in the skeletal, cardiac, and diaphragm muscles of the DMD disease (mdx) mouse model. Further analysis confirmed robust transgene expression across the targeted muscle tissues in the mdx mice.

To assess the feasibility of UMGD for delivering therapeutic payloads in large preclinical models, the full-length DMD nonviral DNA construct was delivered to muscle tissues in non-human primates (NHPs). Molecular analyses confirmed efficient transgene delivery to the NHP target tissues, resulting in high levels of transgenic DMD protein expression in the treated tissues.

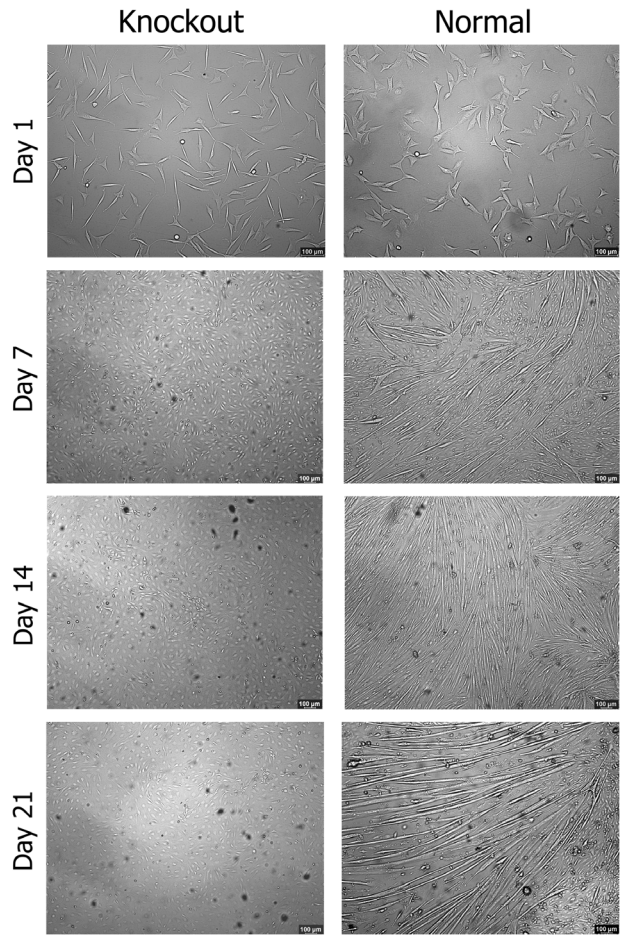
These findings position UMGD as an efficient and scalable platform for delivering genetic medicines to key muscle groups impacted in DMD patients, facilitating robust expression of functional full-length dystrophin protein. This innovative approach lays a foundation for the development of next-generation therapeutic strategies with broad potential applications across various muscular dystrophies.

1578 Development and Characterization of a Mouse Model, Cell Model, and AAV-Based Gene Therapies for TNNT1 Nemaline Rod Myopathy

Sarah Nath[1], Erin Hall[2], Hannah Villeneuve[3], Alisha Gruntman[4], Debora Pires Ferreira[5], Phillip Tai[4], Miguel Sena-Esteves[2], Dongsheng Guo[2], Charles Emerson[1], Yvette LOPEZ[2], Jillian Gallagher[4], Toloo Taghian[2], Hector Ribeiro Benatti[2], Jey Koehler[6], Heather Gray-Edwards[4]
[1]University of Massachusetts Chan Medical School, Worcester, MA, [2]UMass Chan Medical School, Worcester, MA, [3]Worcester, MA, [4]UMass Chan Medical School, Worcester, Massachusetts, [5]University of Massachusetts Chan Medical School, Worcester,, MA, [6]Auburn University, Auburn, AL

TNNT1 nemaline rod myopathy is a genetic disorder caused by a c.505G>T nonsense mutation in the TNNT1 gene, which encodes for the T subunit of the troponin complex in slow twitch skeletal muscles. Initial clinical signs develop around 3-4 months of age and include axial hypotonia, limb stiffness, and tremors. As the disease progresses, diffuse muscle weakness, atrophy, and contracture occurs. The median survival time is 18 months with the cause of death being due to thoracic contracture resulting in restrictive lung disease. There is currently no treatment, and so only palliative care can be offered to patients. We created and characterized a TNNT1 gene knockout mouse and cell model to utilize in the development of AAV-based gene therapy. There was no difference between knockout and normal mice in rotarod, inverted screen, treadmill, and grip strength. Plethysmography was performed in 5 knockout and 5 normal mice at 2 ages, 4-5 and 15-16 months. There were no differences observed at the younger timepoint. At the older timepoint, the knockout mice had reduced tidal volume, reduced peak inspiratory flow, increased enhanced pause, and reduced mid-tidal expiratory flow, changes consistent with restrictive lung disease. In electromyography, 22 of the 37 knockout mice had fibrillation potentials. On histology of the knockout mice, the appearance of the biceps, triceps, quadriceps, semimembranosus/tendinosus, and cranialis tibialis was unremarkable, but there was reduced quantity and size of type 1 muscle fibers in the soleus and diaphragm. The lifespan of the knockout mice was normal. To create a cell model, we used CRISPR-Cas9 with 2 guide RNA's targeting coding sequences of the TNNT1 gene, one in exon 8, the other in exon 10, in C2C12 cells. On sequencing there were multiple edits at both guide locations, which were expected to result in either nonsense-mediated decay or a truncated, non-functional protein. In the myoblast stage, there was no phenotypic difference between the knockout and normal cells. When stimulated to differentiate, the knockout cells initially developed a more spindled appearance. Within 7 days, a majority of the normal cells formed myotubes. No myotubes were formed by the knockout cells within the 28-day evaluation period, but we did observe loss of defined cell margins, suggestive of cell fusion without organization, indicating a role of TNNT1 in myotube formation. In developing an AAV gene therapy, we designed and tested 8 vectors in the mouse model with combinations of AAV9 and AAV8 capsids, muscle specific promoters, human and murine TNNT1, and intravenous and intramuscular delivery. In skeletal muscles, mRNA was measurable, but no troponin T was detected. We hypothesize that this may be due to the need for all 3 troponin subunits to be co-translated given their complex interactions. As such, we built and packaged 2 vectors which contained all 3 genes. One vector has a single cassette comprised of the MHCK promoter, TNNC1, P2A, TNNI1, P2A, TNNT1, and an SV40 polyA. The other vector has two cassettes with opposing read

directions, the first cassette consists of the MHCK promoter, TNNC1, P2A, TNNI1, and an RBG polyA, and the second cassette consists of the Desmin promoter, TNNT1, and an SV40 polyA. These vectors are in the process of being tested in the mouse and cell models. If proven to be efficient, these vectors will not only benefit TNNT1 myopathy but could be used in treatment of TNNC1 and TNNI1 deficiencies.



Comparison of knockout and normal C2C12 cells at various timepoints after the initiation of differentiation. The knockout cells do form a more spindle-shaped appearance and appear to fuse but do not form myotubes.

1579 Therapeutic Screening of Dual AAV-Split Intein MIDI Dystrophins by Analysis of Mechanical Properties in Vivo and in Human Muscle Organoids

Laura PALMIERI[1], Matteo Marcello[2], Maxime Ferrand[2], Isabelle Richard[3], **Sonia Albini[4]***
[1]GENETHON, EVRY, Paris, France, [2]genethon, evry, France, [3]GENETHON, EVRY, Essonne, France, [4]GENETHON, EVRY, france, France
**Corresponding Author*

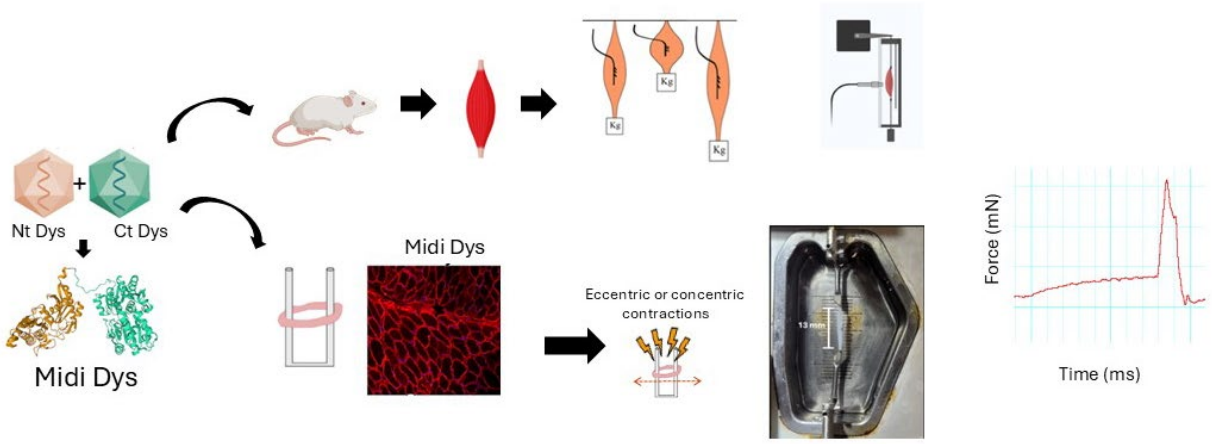
Duchenne Muscular Dystrophy (DMD) is a yet incurable muscle disorder affecting children and causing premature death. DMD is caused by genetic mutations leading to the absence of Dystrophin, a protein essential to preserve muscle integrity during contraction. In the last few years, AAVs have proved to be a promising tool for DMD gene therapy. However, due to the limited packaging capacity of AAVs, only shorter versions of dystrophin (microdystrophin) can be accommodated. Several microdystrophin products currently under investigation in clinical trials have shown promise but demonstrated limited and below-expected efficacy compared to results observed in animal models. This evidence raises questions about the reliability of current disease models or therapeutic readouts

and how microdystrophins can truly replicate the full-length dystrophin function in human patients, given that the shortened version lacks critical structural and signalling domains essential for optimal dystrophin performance.

We have recently generated two larger versions of dystrophin (MIDI dystrophin) (MIDI-DYS1 and MIDI-DYS2-EP23306256.1) using a Dual AAV system with trans-splicing intein approach, showing high protein reconstitution efficacy and therapeutic benefits in severe the DMD mouse model (D2-mdx). Because our constructs differ in key structural domain combinations, favoring dystrophin anchoring either to the sarcolemma or the cytoskeleton, we employed a more physiologically relevant muscle force assay to evaluate muscle performance based on distinct mechanical properties of the muscle when subjected to concentric (shortening) and eccentric (lengthening) contractions. Preliminary data from in situ muscle force assays indicate that MIDI-DYS1 outperforms both MIDI-DYS2 and microdystrophin, under these conditions.

To address the translational gap, we developed a human disease model that recapitulates critical hallmarks of DMD severity, such as fibrosis and muscle dysfunction, providing a more predictive framework for therapeutic investigation. By employing a muscle engineering approach, we generated MYOrganoids from iPSC-derived muscle cells co-cultured with fibroblasts, which enables functional maturation for muscle force analysis during contractions. Testing our candidates in MYOrganoids demonstrated the superiority of MIDI-DYS1, using eccentric contractions and fatigue assays—outcomes that were not revealed by isometric contractions alone, similar to in vivo data.

Overall, these findings underscore the importance of further exploring the changes in muscle mechanical properties following gene replacement, which could lead to improvements in current strategies. They also highlight the utility and translatability of dynamic muscle function assay, similar to real-world muscle movements, for therapeutic screening in human DMD muscles.



1580 3D Bioprinted Platform as a High-Throughput Model for Drug Screening and Discovery for Myopathies and Neuromuscular Diseases

Cristina Antich Acedo, NIH, Thurmont, MD

Myopathies and neuromuscular illnesses encompass several conditions that lead to a progressive decline in motor function due to faulty motoneurons (MN), muscle tissue, or a mix of both. Although there are several treatments to relieve symptoms, a cure has not yet been found. Our lab has developed an innovative platform that enables rapid and high-throughput biofabrication of human muscle tissue equivalents for therapeutics screening and discovery. The 3D muscle tissue assay system consists of a bioprinted muscle structure composed of human iPSCs-derived myoblasts and fibroblasts embedded in a hydrogel wrapped around a pillar-based multi-well culture plate to enable

the functional measurement of muscle contractility. Our work is focused on recreating various disorders included in Congenital Myasthenic Syndromes (CMS) to evaluate the efficacy of novel therapeutic gene therapies being developed by NCATS and NINDS, as part of PaVe-GT program. We used genetically modified iPSCs-derived myoblasts with deletion in the genes DOK7 or COLQ, using CRISPR technology and a doxycycline-inducible transcription factor system for iPSC differentiation. Mutations in those two genes account for about 20% of CMS cases, leading to alterations in the development and maturation of the postsynaptic domain. Our results showed that we were able to replicate the clinical features of both deficiencies in the biofabricated muscle tissues. This was evidenced by impaired contractility, with a significant drop in contractile force and noticeable fatigue after chemical (acetylcholine) and electrical stimulation, respectively. Currently, we are testing the safety and effectiveness of gene therapy using adeno-associated virus (AAV) delivery. This new 3D functional muscle tissue platform has the potential to improve understanding of muscle and neuromuscular pathologies while also providing a predictive tool for new therapeutic approaches.

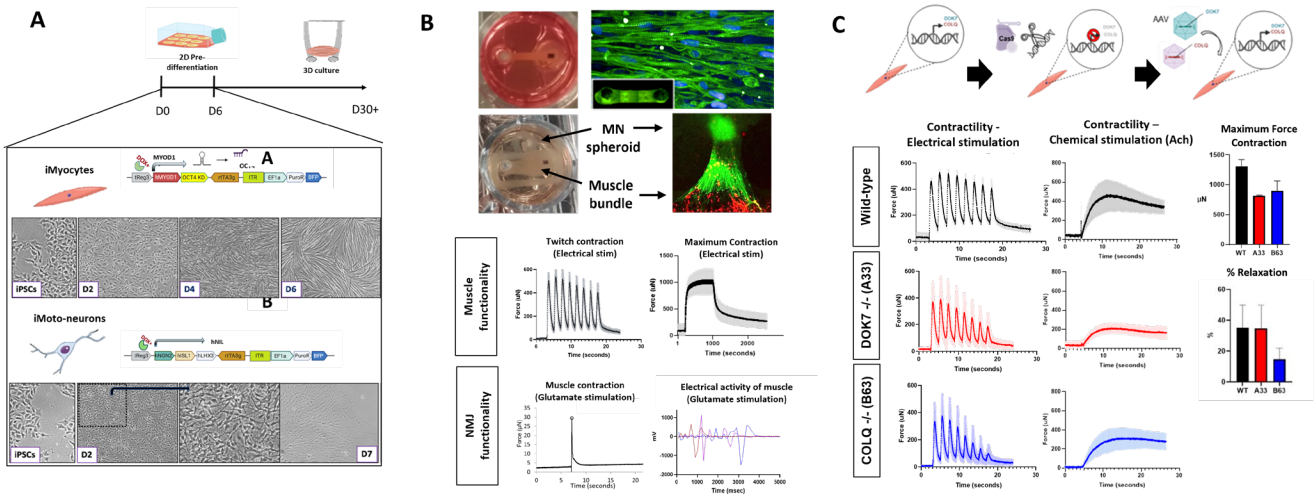


Figure 1. A. To produce the 3D muscle and NMJ models, we used hiPSCs-derived myocytes and MNs embedded in an ECM hydrogel, and then promote the muscle and neuro-muscular formation in a 3D culture system. B. Anatomical and functional studies of 3D skeletal muscle and NMJ model. Microscopic images from muscle and NMJ tissue after formation and maduration in vitro. Functional studies of contractibility and electrophysiological activity of muscle and NMJ after stimulating electrically, or chemically (glutamate), respectively. C. CMS modeling and evaluation of impaired functionality. Contractibility assays of muscle by electrical and chemical (ACh) stimulation proved the ability to recapitulate the clinical features of both CMS deficiencies.

1581 Optimizing CRISPR/Cas9 and AAV6-Based Gene Therapy for Sickle Cell Disease: The Dual Impact of Polyvinyl Alcohol on HDR Efficiency and HSC Viability.

Mariana Benício[1], Barbara Moraschi[2], Camila Hernandes[3], Lucas Pereira[3], Mariana Morato Marques[1], Flavia Albuquerque[3], Gracielle Lima[3], Paulo Schuroff[3], Ariane Diniz[3], Danielle Carvalho[3], Angelica Costa[3], Carla Melo[3], Luiz Rizzo[3], Karina Tozatto Maio[1], Karina Oliveira[3], Davi Torres[1], Priscila Keiko Matsumoto Martin[4], **Ricardo Weinlich[3]***

**Corresponding Author*

Sickle cell disease (SCD) is a severe monogenic disorder caused by a single-point mutation in the *HBB* gene, leading to abnormal hemoglobin (HbS) production and associated pathophysiology. Gene therapy strategies targeting the HBB locus offer the potential for permanent therapeutic correction by replacing or repairing the defective gene in patient-derived hematopoietic stem and progenitor cells (HSPCs). CRISPR/Cas9-mediated editing has emerged as a promising approach, with homology-directed repair (HDR) being a critical mechanism for precise gene correction. However, efficient delivery of CRISPR-Cas9 machinery and HDR templates via adeno-associated virus (AAV) vectors remains a challenge due to limited transduction efficiency in primary HSPCs and potential toxicity associated with high viral doses. Polyvinyl alcohol (PVA) has been reported to enhance AAV6 transduction efficiency, potentially by improving viral stability and/or facilitating its binding to cell surface receptors. We hypothesized that incorporating PVA into the transduction protocol could enhance HDR rates while reducing the viral dose required, thereby mitigating AAV6-associated toxicity and improving gene therapy efficacy and safety for

SCD. To test this, we evaluated the impact of PVA on AAV6-mediated gene correction in HSPCs at different multiplicities of infection (MOI: 312, 625, and 1250). PVA addition significantly increased targeted gene editing across all MOIs tested (MOI 312: 25% ± 9.7 vs. 13.4% ± 11.2, $p = 0.001$; MOI 625: 29.3% ± 10 vs. 12.4% ± 8, $p = 0.004$; MOI 1250: 42.5% ± 5.6 vs. 34.1% ± 8.0, $p = 0.02$). In primary transplants, all groups showed significant bone marrow engraftment 16 weeks post-infusion. HDR analysis demonstrated increased *HBB* targeting with PVA, particularly at higher MOIs (1250 + PVA: 23.88% ± 2.39; 625 + PVA: 12.83% ± 8.53; 312 + PVA: 10.78% ± 6.99). Notably, reducing AAV6 MOI was associated with improved human cell engraftment in the bone marrow of transplanted mice. As an example, frequency of $hCD45^{+}HLA\text{-}ABC^{+}$ cells was 1.8-fold higher for MOIs 312 and 625 compared to 1250. Our findings indicate that lowering AAV6 MOI while incorporating PVA enhances the clonogenic potential and engraftment of gene-edited HSPCs. The 312 + PVA group demonstrated particularly favorable outcomes in terms of myeloid lineage commitment and peripheral hematopoietic reconstitution. However, variability in HDR efficiency across treatment groups, particularly in secondary transplants, underscores the challenge of achieving consistent and robust gene correction in HSPCs. While PVA-mediated enhancement of transduction efficiency improves HDR rates at lower MOIs, its associated cytotoxicity at higher MOIs highlights the delicate balance between maximizing gene editing efficiency and preserving HSPC viability. This study underscores the need for fine-tuning HDR optimization while maintaining HSC fitness and provides a framework for refining ex vivo gene editing strategies for SCD and other hematologic disorders.

1582 Introduction of the Human Sickle Cell Mutation in Sheep Beta-globin by CRISPR/Cas9 Models Human SCD in Cloned Sheep

Iuri Viotti Perisse[1], Caroline Kuczynski[2], Ying Liu[1], Elmira Alipour[3], Cecily LaPradd[4], Misha Regouski[5], Stephen Baker[3], Laxman Poudel[3], Carmen Lau[5], Alexis Sweat[5], Michael Beaty[4], Daniel Kim-Shapiro[6], Anthony Atala[2], Christopher Porada[7], Irina Polejaeva[1], **M Graça Almeida-Porada[8]**
[1]Utah State University, Logan, UT, [2]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, [3]Wake Forest University, Winston Salem, [4]Wake Forest School of Medicine, Winston Salem, [5]Utah State University, Logan, [6]Wake Forest University, Winston Salem, NC, [7]Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, [8]Wake Forest School of Medicine, Winston-Salem, North Carolina

Sickle Cell Disease (SCD) is the most common inherited blood disorder in the US, affecting ~100,000 people in the US and millions more worldwide, and the World Health Organization has forecast that SCD incidence will rise to >400,000 births/year by 2050. While early diagnosis and current therapies have improved, to some extent, the survival and quality of life of people with SCD, disease burden continues to be high, as treatment options are limited, they do not always permit the disease to be well-controlled, and many of the current therapies have significant side effects contributing to long-term morbidity and lack of patient compliance. Since SCD hemolytic anemia and associated chronic organ damage, as well as other clinical complications such as stroke, splenic crisis, pain episodes, life-threatening infections, and episodes of acute chest syndrome, can begin as early as 6 months of age, it is imperative to find novel therapies for infants and children affected by this disease and/or ensure the safety of the current ones for this age group. There is thus an urgent need for highly translational model systems to provide better insights into the pathobiology of the disease and to test novel therapeutic approaches. The sheep β-globin gene shares ~87.5% identity with the human gene. In addition, sheep, like human, undergo a g- to b-globin switch near birth, thereafter silencing HbF. The presence of this switch has led to the extensive use of sheep to understand this critical developmental process and makes sheep an ideal model in which to study hemoglobinopathies. After performing molecular dynamics simulations to ascertain that insertion of the human SCD-causing mutation into the sheep β-globin gene *in silico* induced conformational changes consistent with Hb polymerization driving RBC sickling, CRISPR/Cas9 editing was used to introduce the single A-to-T substitution present in human SCD into the β-globin locus of sheep fibroblasts, and somatic cell nuclear transfer generated animals harboring the human SCD mutation. SCD lambs, and the offspring of SCD animals bred with normal ewes (sickle cell trait - SCT - animals), exhibit multiple clinical and laboratory parameters that recapitulate human SCD or SCT, respectively, including sickled erythrocytes and polychromasia, positive SICKLEDEX®, and the presence of Hb with the same migration pattern as human HbS. Moreover, ektacytometry demonstrated a leftward shift of the elongation index–osmolality curves mirroring that seen in people with SCD. Importantly, in contrast to the transgenic SCD pig, sheep express HbF at birth, which gradually decreased and was almost completely replaced by HbS by the first month of age (~1 yr in humans). A deep convolutional neural network was developed and trained that enabled highly accurate identification and quantitation of various abnormal RBC shapes in blood smears of the SCD and SCT sheep. The

percentage of sickled RBCs increased with age in these sheep paralleling what is seen in people with SCD. Circular shape factor and elliptical shape factor scattergraphs of RBCs demonstrated that both SCD and SCT sheep exhibited elongated, deformed RBCs, at levels mirroring the human phenotypes. Collectively, data to-date support the high translational relevance of the SCD sheep model and suggest that this new large animal model will be a valuable and highly clinically relevant resource for the SCD community for its future use in the development of novel SCD therapies.

1583 Robust Gene Editing of CD34+ Hematopoietic Stem Cells Using a Microfluidics-Based Gene Delivery Technology

Seyeon Bae[1], Sewoon Han[1], Alla Zamarayeva[1], Todd Sulchek[1], Leonid Fomin[1], Chih-Wen Ni[2]
[1]CellFE, Alameda, CA, [2]NVI Therapeutics, Inc, Hayward, CA

Introduction: Hematopoietic stem cell (HSC)-based gene therapy represents a promising approach for treating inherited hematopoietic disorders and facilitating allogeneic cell therapies. However, HSCs present unique challenges due to their limited manipulation window and manufacturing constraints, which affect long-term cell therapy efficacy. Traditional gene delivery methods, such as viral vectors and electroporation, often induce cytotoxicity, inhibit cell proliferation, and limit therapeutic yield. Here, we present an optimized workflow utilizing microfluidics-based gene delivery technology as a gentler yet highly effective alternative for gene editing in HSCs. This approach ensures high efficiency, minimal toxicity, and robust therapeutic yield, while offering flexibility in processing time. It represents a promising solution for improving manufacturing processes and enhancing clinical outcomes.

Methods: We optimized a workflow using a microfluidic mechanoporation technology for efficient gene delivery into HSCs. EGFP-mRNA was initially used for optimization. We then evaluated the performance of this workflow in delivering CRISPR/Cas9 ribonucleoprotein complexes targeting the Beta-2-microglobulin (B2M) gene into human CD34+ hematopoietic stem and progenitor cells (HSPCs) across various ex-vivo culture time points. Key metrics, including cell viability and recovery, gene-editing efficiency and yield, and differentiation potential, were assessed and compared to electroporation, a conventional transfection method.

Results: The optimized workflow using a microfluidic-based mechanoporation technology efficiently delivered mRNA into HSPCs, achieving over 90% cell viability and 70% recovery the following day, along with greater than 95% transfection efficiency. Gene editing of HSPCs using this microfluidic system was successful, preserving cell viability, proliferation, and differentiation potential across transfection timepoints. The workflow achieved dose-dependent B2M gene knockouts, with a maximum editing efficiency of over 80%. Notably, this microfluidic technology required significantly lower RNP concentrations to achieve peak editing efficiency—up to four times less than electroporation. Additionally, the system supported same-day transfection post-thaw, with gene-edited HSPCs retaining their stem cell phenotype with high recovery and editing efficiency.

Conclusion: The microfluidic-based gene editing technology provides a highly efficient, low-toxicity platform for gene editing in HSCs. It is compatible with shorter editing workflows and offers a robust approach that preserves the stem cell phenotype while reducing payload requirements. This workflow has the potential to significantly enhance the clinical application of HSC-based gene therapies, improving both manufacturing processes and therapeutic outcomes.

1584 Impact of novel mobilizers and disease modifying agents in the sickle mouse

Justin Yoo[1], Ashwin Patel[1], Kennedy Goldsborough[1], Britney Hernandez[1], Mary Aliche[1], Jedidah Titus[1], Larry Wilson[1], Dennis Liotta[1], **Vivien Sheehan**[2]
[1]Emory University School of Medicine, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, Georgia

Background: Ex vivo gene therapy (GT) can transform the lives of people with sickle cell disease (SCD). However, collecting sufficient hematopoietic stem cells (HSCs) is challenging; granulocyte colony-stimulating factor (GCF)

cannot be safely used, and inflammation and a disordered bone marrow (BM) stroma and vasculature impair mobilization. In a sickle mouse model, we showed that BM abnormalities can be reversed with osivelotor, a drug that covalently binds to the alpha globin chain, keeping the hemoglobin (Hb) in a high oxygen affinity conformation, reducing polymerization and sickling, increasing Hb to normal levels. We now ask if osivelotor can improve plerixafor mobilization in the sickle mouse, and test the ability of a novel CXCR4 inhibitor, EMU116, to mobilize HSCs.

Methods: 8-week-old Townes sickle mice (SS) were fed 8 weeks of control chow (6M, 6F) or osivelotor chow (6M, 6F). Half were mobilized with plerixafor at 5 mg/kg given subcutaneous (SC), half received PBS. Two hours later, peripheral blood (PB) was collected for a complete blood count (CBC), flow cytometry (flow), and colony forming unit (CFU) assessments. 12-week-old animals were treated with EMU116 via gavage at 30 mg/kg (3M, 3F), or SC at 4 mg/kg (3M, 3F). PB was collected and analyzed 6 hours after EMU administration. HbAA mice were also treated with plerixafor (3M, 3F), EMU116 SC (3M, 3F) and EMU116 (3M, 3F) orally. Median values were compared across groups using non-parametric tests.

Results: WBC was higher in HbSS+PBS animals compared to HbAA+PBS; plerixafor and EMU116 increased WBC. The %lineage negative Sca-1cKit+ as a percentage of all Lin- (%LSKLin-) cells in the PB were significantly higher with EMU116 than PBS control in HbAA and HbSS mice (Fig 1). Compared to plerixafor, EMU116 SC mobilized a higher %LSK in HbAA (0.004 vs 0.03%, p=0.02) and HbSS mice (0.005 vs 0.08%, p=0.01). Further, EMU116 SC mobilized more Flt3-CD34- cells in HbSS compared to plerixafor (0.3 vs 0.05%, p=0.006) but comparable to HbSS+plerixafor when pretreated with osivelotor. There was a trend toward higher CFUs in all mobilized HbSS groups (Fig 2). WBC and flow were comparable for EMU116 oral and SC.

Conclusions: The novel mobilizing agent EMU116 increases stem cells with long term potential (LSKLin-) and primitive HSCs able to rapidly reconstitute (%Flt3-CD34-) in the PB of HbSS and HbAA mice significantly more than plerixafor. CFU are also higher with mobilization indicating stem cells able to proliferate and differentiate, although not statistically significant likely due to sample size. SCD modification with anti-sickling drug osivelotor increased plerixafor mobilization of %Flt3-CD34- HSCs. Future studies include treating HbSS mice with osivelotor prior to EMU116 mobilization. We conclude that EMU116 is a promising mobilizer for individuals with SCD and may replace plerixafor in combination with GCSF for healthy individuals. Treatment with osivelotor may be an effective pretreatment strategy in individuals with SCD seeking GT to improve mobilization efficiency and quality of HSCs.

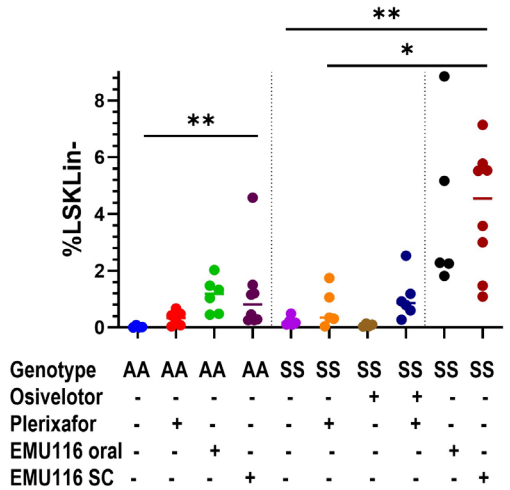

Figure 1: Mobilizer and disease modifier effects on %LSKLin- cells in the peripheral blood of wild-type (HbAA) and sickle mice (HbSS). HbSS were mobilized with plerixafor with and without a SCD disease modifier (osivelotor), or with EMU116. *p<0.01; **p<0.001.

1585 Heterozygous SCD Sheep Produced by Breeding Exhibit Sickle Cell Traits

Carson Stoker[1], Iuri Viotti Perisse[1], Caroline Kuczynski[2], Cheyenne Marriott[1], Jada Jacobson[1], Rusty Stott[1], Christopher Porada[3], M Graça Almeida-Porada[4], Irina Polejaeva[1]
[1]Utah State University, Logan, UT, [2]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, [3]Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, [4]Wake Forest School of Medicine, Winston-Salem, North Carolina

Sickle cell disease (SCD) is the most common inherited hemoglobinopathy, affecting more than 100,000 people in the United States and millions more worldwide. SCD is caused by a single 'A to T' nucleotide replacement at the sixth codon of the β-globin gene (*HBB*) that results in the substitution of a glutamate for valine triggering abnormal polymerization of hemoglobin (HbS) and erythrocyte sickling. These changes decrease the ability of erythrocytes to carry and deliver oxygen to the tissues, leading to SCD pathology.

Sheep and humans exhibit a high degree of homology at the β-globin (*HBB*) gene and have similar anatomy, organ physiology, immune system development, and transitions from fetal to adult hemoglobin isoforms. Previously, we generated an SCD sheep model via CRISPR/Cas9 and Somatic Cell Nuclear Transfer (SCNT) and characterized their phenotype. We produced two rams that closely resembled the SCD phenotype in human patients. These animals exhibited sickled erythrocytes and abnormal hemoglobin with the same migration pattern as human hemoglobin S (HbS). They also displayed positive SICKLEDEX® test and RBCs with decreased membrane deformability. We hypothesized that breeding of these SCD rams would pass the *HBB* gene sickle mutation to the offspring and lead to Sickle Cell Traits (SCT) in heterozygous sheep. Here we describe the production of heterozygous SCT sheep by the breeding of SCD ram to wild-type (WT) ewes, and their phenotypic characterization.

The homozygous SCD2239 ram was placed with 20 WT Romney ewes for breeding. Twelve ewes became pregnant (12/20 (60%)). Two of the 12 pregnancies were lost spontaneously, and one ewe gave birth to a stillborn fetus. The remaining nine ewes delivered 12 healthy lambs (9 females and 3 males, three sets of twins and six singletons). DNA was extracted from blood samples of the lambs for genotyping by PCR and Sanger sequencing. We confirmed that all lambs carried heterozygous SCT and SM (silent mutation) in the *HBB* and *HBG* genes, respectively. Four animals were identified with the haplotype A allele in the WT sequence of *HBB* with a SNP upstream of the SCD mutation site and the rest contain the haplotype B allele. The overall pregnancy rate was lower than anticipated for the WT Romney breed. Sickle cell tests confirmed that these heterozygous animals have hematological parameters consistent with human SCT. The SCT sheep (currently around 2-years of age) have improved survival to adulthood compared to the original SCD rams that died prior to 12-months of age. Additionally, we observed impaired spermatogenesis with abnormal sperm morphology in both SCD and SCT rams. This parallels observations in men with SCD who are at risk for impaired fertility (e.g., abnormal sperm concertation and quality at baseline). These findings support the translational relevance of the SCD and SCT sheep and highlight their potential use in the development of novel SCD treatments for this devastating disease.

1586 Human Engineered Heart Tissues to Model Genetic Dilated, Hypertrophic, and Arrhythmogenic Cardiomyopathies.

Viet Dau[1], Alex Mora Pagán[2], Benjamin Archer[1], William Dorion[1], Xia Li[2], Stuart Campbell[2], **Cassady Rupert**[1]
[1]Propria LLC, Branford, CT, [2]Yale University, New Haven, CT

CRISPR modification of human induced pluripotent stem cells (hiPSCs) enables the study of genetic cardiomyopathies, which affect at least 1 in 500 American adults[1]. However, the contractile changes expected in cardiomyocytes derived from hiPSC disease lines are often impossible to detect in traditional 2D cell culture formats, making it difficult to mimic the clinical phenotypes of genetic cardiomyopathies in vitro. The development of 3D engineered heart tissue (EHT) models that recapitulate key aspects of contractile dysfunction of cardiomyopathies are critical for studying disease progression and evaluating the efficacy of therapeutics. We

propose that in vitro models of arrhythmogenic (ACM), dilated (DCM), and hypertrophic (HCM) cardiomyopathy can be developed by generating EHTs from hiPSC-cardiomyocytes and measuring isometric force.

HiPSC lines heterozygous for clinically identified mutations were either generated with CRISPR engineering (DCM: TTN P22582fs, ACM: DSP R451G, HCM: MYH7 R403Q) or were derived from a patient sample (HCM: MYBPC3 1800delA) and isogenic control hiPSC lines were generated in parallel. MyoPod® EHTs were generated from each pair of isogenic control/disease lines and cultured for 3 weeks to maturity. The contractile phenotype of EHTs was assessed by measuring tissue isometric twitch contractions in the MyoLab® tissue analyzer to obtain baseline contractility, the force-frequency response, and the length-dependent activation response in each genotype compared to isogenic control.

HCM EHTs exhibited hypercontractility, prolonged relaxation, and a blunted response to increasing frequency as well as both shortening and stretch whereas ACM and DCM EHTs exhibited hypocontractile behavior and a blunted response to stretch. Contractile assessments of EHTs formed using cardiomyocytes differentiated from engineered hiPSC disease and isogenic control lines revealed distinguishable properties characteristic of each type of cardiomyopathy. In the future, these models can be used to assess the functional efficacy of novel therapies across a range of cardiomyopathies.

Neurodevelopmental disorders (NDD) pose significant diagnostic and therapeutic challenges despite advances in genomics. Critical pathways in neurodevelopment have been linked to syndromic NDD with phenotypes including autism and intellectual disability (Patterson, V. et al., 2023). Recently, haploinsufficiency of several key components of the JNK pathway, including MAP4K4 and MAP2K4, were linked to syndromic NDD with phenotypes including autism and intellectual disability. Our study aims to identify additional novel JNK-associated genes linked to NDD using a genotype-first approach. In our study, we plan to conduct phenome-wide association studies (PheWAS) using biobanks to identify other potentially NDD-associated genes in the JNK pathway and to clarify the molecular mechanisms behind JNK-associated NDD using induced pluripotent stem cell (iPSC) models. Using Sanger sequencing, Next-generation sequencing, and other quantitative methods, we have selected biallelic and heterozygous mutated clones that cause frameshift mutation effects (See Figure 1). Through the differentiation of these iPSCs into neurons expressing Neurogenin 2 (NGN2) and regular NPC differentiation, we can evaluate the different mechanisms these mutations use to affect neuronal differentiation (See Figure 2). By using an integrative approach, it is possible to identify potential therapeutic targets and gain new insights into the genetic landscape of NDD.

1588 Leveraging automation and AI to streamline and scale iPSC-based drug screening

Daniel Paull[1], Dorota Moroziewicz[2], Tomasz Rusielewicz[2], Josephine Wesely[3], Stefan Semrau[1], Bianca Milgliori[1], Jordan Goldberg[2], Geoff Buckley-Herd[2], Neeloy Bose[2], Maria Sapar[2], The NYSCF Global Stem Cell Array Team[2]
[1]The New York Stem Cell Foundation, New York, NY, [2]The New York Stem Cell Foundation, New York, [3]The New York Stem Cell Foundation Research Institute, New York, NY

The lack of screenable phenotypes in scalable cell models and platforms has hindered progress in drug discovery and early diagnostics for complex diseases. As the value of iPSCs for drug discovery has become ever more recognized, numerous technical factors, including intrinsic line-to-line variability and batch variation, make it challenging to define phenotypes in large-scale studies. Likewise, as biobanks have grown, technical opportunities have arisen that have allowed the development of sophisticated systems that can conduct cell biology at scale. We have leveraged advancements in robotic technology to develop the NYSCF Global Stem Cell Array®, our fully automated cell culture platform for parallelized iPSC reprogramming, gene editing, and differentiation into a range of downstream cell types, including astrocytes, glutamatergic/GABAergic neurons, hepatocytes, and cardiomyocytes, along with 3D neural and pancreatic organoids. Through this platform, we have created large biobanks of iPSCs, available to the community, spanning diseases including Alzheimer's, Age-Related Macular Degeneration, MS, and Parkinson's disease, as well as several rare diseases.

Building on this platform, we have recently developed a fully automated pipeline that integrates high-content imaging and machine learning to identify novel morphological disease phenotypes and enable drug discovery systematically. Importantly, this pipeline controls for inter- and intra-batch variation while accommodating large numbers of donor samples that allow us to capture subtle yet complex disease phenotypes across genetically diverse patients and clinically relevant subsets. In combining experiments containing upward of 96 donors, with multiple experiments running in parallel, we have used this platform to predict Parkinson's disease in patient-derived fibroblasts accurately. We are now performing phenotypic screens using multiple iPSC-derived cell types across various diseases.

We have identified novel phenotypes in a rare neurological disorder, Infantile Neuroaxonal Dystrophy, and used high-throughput compound screening to uncover novel drug candidates that display dose-responsive effects in shifting the cells to a healthier state. By combining biology with AI and software development, we have created tools such as ScaleFEx℠, enabling meaningful insights into these morphological disease phenotypes and drug-induced changes. Our phenotyping platform can be readily applied to various complex and rare diseases to advance precision drug discovery.

1589 Ethical and Social Considerations of Heritable Genome Editing in Human Embryos: A Focus on UNESCO Initiatives

Hristina Gaydarska[1], Jusaku Minari[2]
[1]Kyoto University, Center for IPS Research and Application, Kyoto, Kyoto, Japan, [2]Kyoto University, Center for iPS Research and Application, Kyoto, Japan

Recently, genome technologies have emerged as one of the fastest-growing fields, attracting significant attention from scientists and raising important ethical and social implications. Among these technologies, one of the most critical issues to address is whether the human genome should be modified through genome editing approaches. Many researchers have already discussed the nature of heritable gene editing, as reflected in the reports and guidelines issued by WHO and the US National Academy of Sciences. In the European context, UNESCO has actively considered the nature of the genome. The first UNESCO Universal Declaration on the Human Genome and Human Rights (1997) recognizes the human genome as *the heritage of humanity*, a symbol that should be protected, while also prohibiting human cloning. The latest UNESCO International Bioethics Committee report (2015) reflects the relationship between human rights and the human genome, building on the earlier declaration that heritable genetic changes should be prohibited (Universal Declaration on the Human Genome and Human Rights, 1997,

Article 24). This study examines the relationship between genome editing technologies, their clinical application in a heritable manner, and those ethical and social initiatives by UNESCO. Given that clinical trials involving CRISPR/Cas9 are increasingly underway, the ethics, values, and prospects of genome editing should be revisited.

1590 Deep CRISPR Nuclease Portfolio and Multiple Editing Modalities Accelerates Identification of Viable Clinical Candidates

Vasu Kommireddy[1], Anastasya Birger[1], Bikash Shakya[2], Allie Crawley[2], Matthew Nethery[3], Chuck Pepe-Ranney[1], Hui-Chia Yu-Kemp[1], Andy Chan[1], Tim Schwochert[1], Drew Kelso[1], Logan Brown[2], Julia Portocarrero[1], Lucas Ribeiro[1], Victor Bartsevich[1], Salem Faham[1], David Wiley[1], John Russell[1], Sarah Compton[2], Joel Parker[2], Philip Borden[1], Michael Coyle[1], Ron Chong[2], Tedd Elich[4]
[1]LifeEDIT Therapeutics, Durham, NC, [2]Life Edit Therapeutics, Durham, NC, [3]LifeEDIT Therapeutics, Durham, [4]LifeEdit Therapeutics, Research Triangle, NC

CRISPR associated RNA guided nucleases are widely applied in genome editing applications such as cell therapies, treatments for genetic diseases, and crop engineering. These nucleases enable programmable targeting of specific genomic DNA sequences encoded in their cognate guide RNAs (gRNA) and can be coupled to deaminases, reverse transcriptases (RT) or other genome modifiers for precise correction of disease mutations. However, challenges remain in the field such as developing disease-specific editors with maximal on-target potency and minimal off-target and bystander editing.

In order to address this gap, we have developed one of the largest collections of CRISPR Type II and Type V genome editors through categorizing 10B+ natural proteins and are leveraging AI-driven search, engineering and design methods to further expand this library. Leveraging such a large *in silico* catalogue, systems can be prioritized for characterization targeting desirable features for *in vivo* therapeutics, such as protein size, guide size, and PAM diversity. We characterized Type II and Type V nuclease systems with diverse PAM recognition sites enabling vast coverage of the genome, which expands the range of genomic targets for editing. We have implemented automated high throughput screening to characterize the activity of our novel CRISPRs in mammalian cells and found that 34% of Type II and 15% of Type V novel proteins with biochemically identifiable PAMs retained therapeutically relevant nuclease activity, which we have demonstrated can be significantly improved by enzyme engineering and guide modifications, in mammalian cells. We believe these novel proteins represent a significant expansion in the known library of CRISPR genome editors. Altogether, our deep portfolio of nucleases, diversity of natural and engineered PAM recognition, base and RT editing modalities, allow rapid identification of multiple editors with high potency and specificity for a large spectrum of disease-relevant human genomic targets, thus increasing success rates for developing these initial hits into viable clinical candidates.

1591 A single-step process for non-viral engineering of hypoimmunogenic pluripotent stem cells with the Pin-point™ base editing platform

Leigh-Anne Thomas[1], Olga Mielczarek[2], Jesse Stombaugh[2], Robin Loesch[3], Alexis Duringer[4], Amanda Haupt[5], Kevin Hemphill[2], **Immacolata Porreca**, Robert Blassberg[2]
[1]Horizon Discovery Ltd, Cambridgeshire, United Kingdom, [2]Revvity, UNITED KINGDOM, [3]Revvity, Cambridge, United Kingdom, [4]Revvity, Cambridge, Cambridgeshire, United Kingdom, [5]Revvity, Superior, CO

Pluripotent stem cells (PSCs) hold great promise for manufacturing advanced cell therapies. Off-the-shelf allogeneic products derived from PSCs, engineered to be compatible with large patient cohorts, can broaden access to these therapies. However, their sensitivity to DNA damage presents challenges for complex genome editing. Base editors offer a solution due to their reduced genotoxicity compared to nuclease-based technologies. We developed the Pin-point platform, which enables the modular assembly of base editors composed of DNA binding Cas and DNA modifying deaminase components associated via an aptamer encoded in the sequence-targeting guide RNA (gRNA). Owing to the aptamer-dependent recruitment of the deaminase component to target DNA sequences, the Pin-point platform uniquely allows multi-purposing of a single Cas nickase component for simultaneous multiplexed base editing and targeted transgene knock-in. To demonstrate the platform's utility for engineering allogeneic PSCs, transient delivery of mRNAs encoding a Pin-point base editor (Rat APOBEC1 and SpCas9 nickase) with synthetic

aptamer-encoding and aptamer-less gRNAs was used to generate clonal hypoimmunogenic iPSC lines with various genotypes, including targeted large cargo transgene integration, using an automated clone tracking and picking workflow. Durable target protein knockout, substantially improved cell viability, editing efficiency, and genome integrity following multiplexed base editing compared to CRISPR-Cas9 with no adverse impacts on pluripotency were achieved. Hypoimmunogenic iPSC lines, generated via both multiplexed base editing and simultaneous base editing with targeted transgene integration, retained pluripotency, exhibited the expected reduced immune responses associated with their modified human leukocyte antigen (HLA) phenotypes and evaded both innate and adaptive immune responses when differentiated into therapeutic cell products. The Pin-point platform therefore represents a safe and efficient solution for multiple simultaneous genome engineering operations via a novel single step process compatible with downstream automation, dramatically streamlining the development of allogeneic iPSC-derived cell therapies.

The Pin-point™ base editing platform technology is available for clinical or diagnostic study and commercialization under a commercial license from Revvity.

1593 Expanding Base Editor Scope with Embedding Strategy

yunfei Ma[1], Qian Feng[2], Tiangang Yuan[2], **Chunyan He[3]***

Base editors can achieve base replacement without DNA double-strand breaks and have shown substantial potential in scientific research and gene therapy. Nevertheless, a variety of applications necessitate a range of unique features for base editors. For site-specific mutations, the base editor with narrow editing window is favored due to possible bystander mutations. In comparison, modifying the activity of regulatory elements on genome (e.g transcription enhancer), which is difficult to determine the exact regulatory sequences, requires a large editing window. To date, the editing windows of the majority base editors are +4 to +13 positions (+1 position at the far PAM end), which makes it difficult for effectively mutate these sites. Therefore, expanding the editing window will be another evolutionary direction. In this study, we evolve the Targeted AID-mediated Mutagenesis (TAM) cytosine base editor to expand its editing window using transposon technology. TAM CBE is a pioneer developed cytosine base editor that uniquely deaminate the ssDNA substrate, with an editing window of +1 to +12. First, we randomly inserted an activation-induced cytidine deaminase (AID) into the nSaCas9-KKH by MuA transposase to obtain a chimeric cytosine base editor (EB-TAM). We then introduced the EB-TAM library into E. coli along with a screening vector with inactivated kanamycin resistance. After IPTG induction, clones grown on kanamycin plates indicated that functionally EB-TAM restored the antibiotic resistance. The insertion sites of AID were mapped by Sanger sequencing. We successfully obtained 11 EB-TAMs in the prokaryotic screening. Then, the editing efficiency and their editing windows of 11 EB-TAMs were identified by five C-rich endogenous sites in HEK293T cells. Among the 6 functional EB-TAMs identified in HEK293T, EB-TAM-007 showed modest to higher editing efficiency from +1 to +17 compared to the other 5 EB-TAMs. Since nSaCas9 (D10A)-KKH cleave the middle of the +17 and +18 nucleotides of the sgRNA targeting strand, it is theoretically difficult to develop a base editor to edit the +18, +19 and +20 nucleotide of the non-targeting strand. Therefore, we assume that EB-TAM-007 harbor the largest window among the reported cytosine base editors based on the nSaCas9 (D10A) KKH. To further improve the editing efficiency, the linkers between AID and SaCas9 in EB-TAM-007 were optimized with three different linkers (L1, L2, L3). The EB-TAM-007-L1 exhibited an enhanced editing efficiency, showing a 1.51-fold to 1.82-fold increase compared to EB-TAM-007-L3 and 1.75-fold to 3.75-fold increase compared to prototype TAM CBE. Finally, we employed EB-TAM-007-L1 to edit the DMD E53 splicing site. As expected, 20% editing efficiency and 50% E53 exon skipping were obtained in DMD iPSC-derived myotubes. In summary, we developed a novel CBE with high editing efficiency and large editing windows enable for effective editing, especially for regulatory elements.

1594 Tricking Protein Translation: A Novel Base Editing Strategy to treat Dravet Syndrome

Elena Benvenuto[1]*, Angela Avella[2], Mirko Luoni[3], Serena Giannelli[4], Lucas Kissling[5], Gerald Schwank[6], Vania Broccoli[4], Gaia Colasante[7]
[1]Vita-Salute San Raffaele University, Milan, Italia, Italy, [2]San Raffaele Scientific Institute, Milan, Italy, [3]San Raffaele Scientific Institute, Busto Arsizio, Varese, Italy, [4]Ospedale San Raffaele, Milan, Milano, Italy, [5]University of Zurich, Zurich, Zurich, Switzerland, [6]Zurich, Zurich, Switzerland, [7]San Raffaele Scientific Institute, Milan, Milano, Italy
**Corresponding Author*

Dravet syndrome (DS) is a severe developmental and epileptic encephalopathy caused by haploinsufficiency (HA) of *SCN1A* gene, encoding NaV1.1 sodium channel. Several novel therapeutic strategies are being developed at the preclinical stage, with some already entering clinical trials, but they necessitate lifelong administration of therapeutic agents. Here we describe a one-time permanent base editing of 5' untranslated (UTR) regulatory sequences to boost NaV1.1 protein translation.

To assess 5'UTR regulatory sequences effect on NaV1.1 protein translation and verify the possibility to interfere with this regulation to enhance protein expression, we set a reporter system screening platform to quantify fluorescence increase. Starting from the wild-type (wt) sequence, we cloned in a GFP/mCherry reporter vector 23 variants of *Scn1a* 5'UTR sequence harboring distinct combinations of nucleotide transitions reproducible with base editing. Flow cytometry analysis highlighted some variants able to significantly increase GFP fluorescence intensity over wt sequence. In particular, enhanced GFP levels were associated with specific A>G mutations in two ATG triplets upstream (uATG) to the main ATG (mATG), converting them into GTGs. By integrating available data of Ribo-sequencing performed in brain tissues, we learned that those two ATGs are candidate starting codons of upstream open reading frames (uORF) partially overlapping to the *Scn1a* mORF. uORFs have been described for 50% of human genes and are known to inhibit translation by sequestering ribosomes from the CDS; hence uATGs disruption is expected to enhance *Scn1a* translation, mirroring the results obtained in the GFP reporter. To verify this, we installed uATG>GTG mutations in the endogenous *Scn1a* locus using SpRY- and Sp-Cas9 adenine base editors. After setting up the base editing strategy in HEK-293T cells, we delivered the editor and the sgRNA in either lentiviral vectors or dual-adeno-associate viral vectors in cortical mouse primary neurons. Deep sequencing of the amplicon spanning the targeted region revealed that 60% of *Scn1a* reads carried at least one edited uATG and 13% exhibiting concomitant edits of both uATGs. Remarkably, this editing rate was sufficient to increase by 40% NaV1.1 levels without affecting mRNA levels, reinforcing the idea that these uORFs primarily regulate translation. Of note, in DS mouse model-derived neurons, uORF editing restored NaV1.1 levels back to wild-type. In addition, analysis of predicted off-target sites revealed neglectable editing activity, and the impact of bystander edits, evaluated in the reporter screening, showed minimal or no effect on the previously observed GFP fluorescence increase. This further confirms the specificity and safety of the approach. Next, to bring our therapeutic approach closer to clinical translation, we tested our system in human neurons, differentiated from pluripotent stem cells, and confirmed similar editing efficiency as in murine neurons. Finally, to further assess the therapeutic potential of our strategy, we are delivering the system *in vivo* in DS mice. Overall, we identified *SCN1A* uORFs as an inhibitory control of protein translation and showed that disrupting this via uATG editing increases NaV1.1 protein, providing a novel avenue for treating DS. Lastly, we found this mechanism to be shared across other *SCN1A* paralogs, which may further broaden the applicability of the approach to other haploinsufficiency diseases.

1595 The Second-Generation High-Fidelity Cytosine Base Editor AccuBase™ Can Proficiently Modify Multiple Genes Within A Human Primary T cell While Minimizing Off-target Effects

Sarah Rains, KACTUS, Silver Spring, MD

Introduction: In the realm of gene editing tools, one of the most prominent challenges is mitigating off-target mutations, chromosomal rearrangements, and insertion-deletions (indels). We utilized synthetic biology strategies to create a

novel cytosine base editor (CBE), AccuBaseTM , that has the highest editing efficiency in the industry, with zero off-target events. This was achieved by strategically inserting deaminases into Cas9 at specific, tolerance-verified sites, a process guided by an extensive transposon-based genetic screening, protein engineering, and direct evolution approach. AccuBaseTM forms a complex with the sgRNA, but at this step, the inserted deaminase is not yet engaged with the target DNA and is not in contact with any non-targeting dsDNA because it is hidden inside the protein. This mechanism avoids guide RNA-independent indiscriminate off-target mutations that were a common problem of first-generation base editing tools. When guided by sgRNA, AccuBaseTM associates with the target double-stranded DNA, triggering structural alterations within the AccuBaseTM. This results in the outward exposure of the deaminase domain, facilitating the editing of the target base. AccuBaseTM substantially reduces off-target effects while maintaining on-target editing when compared to BE4max. This improvement has been confirmed in multiple human cell lines, mouse cell lines, human primary T and NK cells, human embryonic stem cells, and in animal embryos and liver. In this study, we apply AccuBaseTM to multiplex gene modifications in primary human T cells, demonstrating its capacity for highly efficient multiplex gene disruption without inducing off-target effects. Importantly, the multiplex base-edited T cells exhibit enhanced ex-vivo cell expansion and do not exhibit the double-strand break-induced translocations observed in T cells edited with Cas9 nuclease. Therefore, we strongly believe that AccuBaseTM represents a solution to unmet demands within the gene editing field. It offers the highest on-target editing efficiency while minimizing off-target effects, setting a new standard for precision and effectiveness.

AccuBaseTM was made by inserting deaminases into Cas9 at specific, tolerance-verified sites, a process guided by an extensive transposon-based genetic engineering. AccuBaseTM forms a complex with the sgRNA (depicted as a purple double helix). Within this synthetic CBE, the deaminase domain (colored in red) is intricately integrated and is not in contact with any non-targeting dsDNA.

Summary: In this study, we harnessed AccuBaseTM to perform multiplex gene modifications in primary human T cells. Specifically, we targeted PDCD1, B2M, and TRAC using AccuBaseTM through the Lonza 4D nucleofector system. The knockout efficiencies for individual genes were as follows: 89% for PDCD1, 81% for B2M, and an impressive 96% for TRAC. When applied to create a triple knockout, the editing efficiency reached 60%, and this was confirmed through flow cytometry analysis. Remarkably, the edited T cells exhibited normal expansion characteristics and did not display the double-strand break-induced translocations typically observed in T cells edited with Cas9 nuclease. Equally significant, our analysis revealed the absence of any off-target effects in the AccuBaseTM -edited T cells.

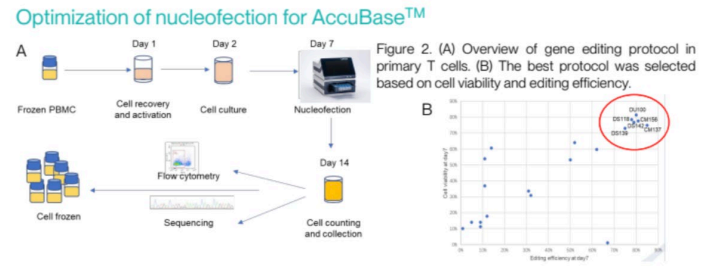

Figure 2. (A) Overview of gene editing protocol in primary T cells. (B) The best protocol was selected based on cell viability and editing efficiency.

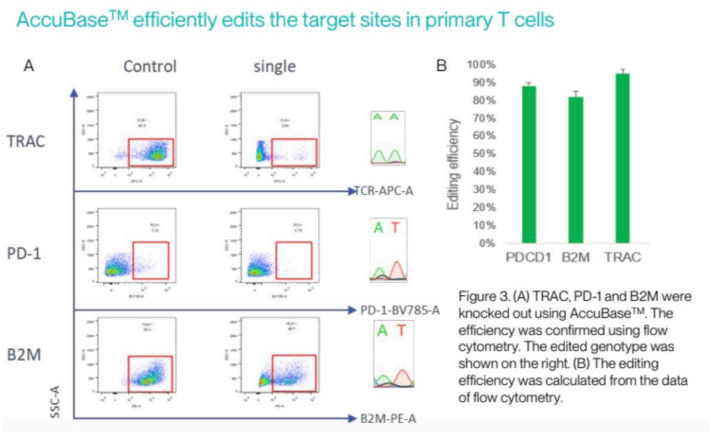

Figure 3. (A) TRAC, PD-1 and B2M were knocked out using AccuBase™. The efficiency was confirmed using flow cytometry. The edited genotype was shown on the right. (B) The editing efficiency was calculated from the data of flow cytometry.

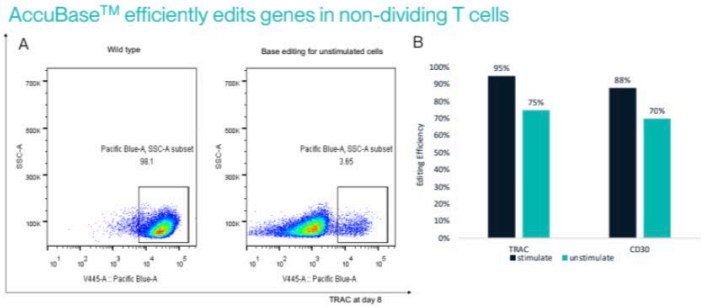

Figure 4. (A) The unstimulated T cells were edited, and the flow cytometry was used to confirm the knockout at day 8 after nucleofection. (B) The editing efficiency was calculated based on Sanger sequencing on day 4 after nucleofection.

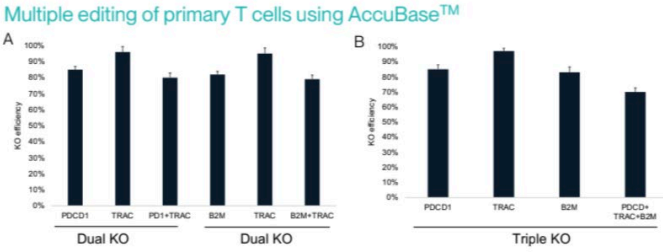

Figure 5. (A) Two genes were simultaneously edited using AccuBase™. The editing efficiency was calculated based on the flow cytometry. (B) Three genes were simultaneously edited using AccuBase™. The editing efficiency was calculated based on the flow cytometry.

1596 Minimal activation of the p53 DNA damage response by a modular cytosine base editor enables effective multiplexed gene knockout in induced pluripotent stem cells.

Robert Blassberg[1], Olga Mielczarek[1], Jesse Stombaugh[1], **Immacolata Porreca[2]**
[1]Revvity, UNITED KINGDOM, [2]Revvity, CAMBRIDGE, Cambridgeshire, United Kingdom

Precise genome editing of induced pluripotent stem cells (iPSC) holds great promise for engineering advanced cell therapies. CRISPR-Cas systems have been widely adopted in genome engineering applications, however their dependence on genotoxic DNA double strand breaks (DSBs) presents challenges in hypersensitive iPSCs, including the selection for defective DNA DSB responses. Base editors are capable of both modifying and ablating gene function without generating DSBs making them an attractive solution in iPSC engineering applications. Here we report efficient and durable target knockout and substantially improved cell viability and expansion with a cytosine base editor assembled using the Pin-point™ platform compared to SpCas9. The cytosine base editor minimally activated p53-mediated DNA damage signalling independently of the number of simultaneous edits installed. By contrast, multiplexed editing with SpCas9 lead to high levels of p53 signalling and an associated reduction in editing efficiency. While transient inhibition of the p53 DNA DSB response enhanced SpCas9 multiplexed gene editing efficiency this was not required to achieve maximal base editing efficiency. Multiplexed editing of iPSCs with Pin-point base editors therefore both enhances the efficiency of genome engineering processes and substantially reduces the risk of selection for defective DNA damage responses inherent to DSB-dependent CRISPR-Cas systems.

1597 One-step engineering of allogeneic CAR-T cells by simultaneous multiplex knockout and site-specific transgene integration with the Pin-point™ base editing platform configured with OpenCRISPR-1, an AI-engineered CRISPR-Cas enzyme

Olga Mielczarek[1], Bronwyn Joubert[2], Robert Blassberg[1], Anastasia Kaufman[3], Jesse Stombaugh[1], Amanda Haupt[4], Kevin Hemphill[1], Pablo Pérez-Durán[5], **Immacolata Porreca**
[1]Revvity, UNITED KINGDOM, [2]CAMBRIDGE, United Kingdom, [3]Lafayette, CO, [4]Revvity, Superior, CO, [5]Revvity, Cambridge, Cambridgeshire, United Kingdom

As our understanding of the effects of the tumor microenvironment on immune cells function improves, increasingly more complex cell engineering is needed to improve the efficacy and durability of cellular immunotherapies. First-generation genome engineering approaches utilizing CRISPR/Cas9 rely on double-strand DNA breaks (DSBs), which bring an increased risk of genomic rearrangements and cytotoxicity, particularly when multiple edits are required.

We have developed the RNA aptamer-mediated Pin-point base editing platform to facilitate complex cell engineering in a safer manner than conventional DSB-based technologies. The platform consists of either a nickase or a catalytically inactive RNA-guided nuclease, an extended guide RNA with an aptamer, and an aptamer binding protein fused to an effector (e.g a deaminase). By using a combination of aptamer-containing and aptamer-less guide RNAs, along with mRNAs encoding Rat APOBEC1 and SpCas9 nickase, the platform enables efficient multiple knockouts by base editing and simultaneous targeted insertion of a CD19-CAR at the TRAC locus in primary human T cells. Multigene edited, allogeneic CAR-T cells are therefore generated in a single intervention with a single nickase while overcoming the deleterious effects of DSBs and reducing significantly manufacturing timelines.

To broaden the applicability of the Pin-point platform, we demonstrate robust complex T cell editing using the nickase OpenCRISPR-1, an AI-generated enzyme from Profluent. A screen to identify optimal gRNA designs for base editing knockout revealed distinct editing features of the Pin-point platform employing OpenCRISPR-1 compared to SpCas9. Additionally, this novel nuclease supports both viral and non-viral targeted transgene knockin. The successful integration of the open-access OpenCRISPR-1 with the Pin-point base editing platform demonstrates versatility of our platform and provides further choices for advanced gene editing applications.

The Pin-point™ base editing platform technology is available for clinical or diagnostic study and commercialization under a commercial license from Revvity

1598 Customizing the versatile Pin-point™ platform: Modular components for tailored base editing in genomic applications

Paul Russell[1], Robert Blassberg[2], Robin Loesch[1], Alexis Duringer[3], Shannon Hinsdale[4], Ryan Prestil[1], Jesse Stombaugh[2], Terry Cleary[5], Amanda Haupt[6], **Immacolata Porreca**, Kevin Hemphill[2], Pablo Pérez-Durán[3]
[1]Revvity, Cambridge, United Kingdom, [2]Revvity, UNITED KINGDOM, [3]Revvity, Cambridge, Cambridgeshire, United Kingdom, [4]Revvity, Lafayette, CO, [5]Revvity, Lafaiette, [6]Revvity, Superior, CO

CRISPR based gene editing technologies are extensively used for both functional genomic screening and adoptive cellular therapeutics. Among these, base editors represent a promising class of next-generation genome editing tools with the potential to precisely correct disease-causing genetic variants and safely knock out multiple gene targets simultaneously. The Pin-point base editing platform is a modular assembly of DNA binding Cas and DNA modifying deaminase components associated via an aptamer encoded in the sequence-targeting guide RNA (gRNA). This modular design allows for the creation of diverse Pin-point architectures, each with distinct base editing characteristics. This flexibility enables a “plug-and-play” approach, facilitating the use of optimal DNA-binding and modifying enzymes for specific applications.

We have developed an arrayed screening platform for high-throughput characterization of these configurations, demonstrating specific editing characteristics achieved with the Pin-point platform when employing different

cytosine deaminases. Furthermore, we show that the Pin-point platform can be configured with adenine deaminases to mediate adenine-to-guanine transitions in induced pluripotent stem cells (iPSCs) and T cells. We also use distinct aptamers fused to sgRNAs to achieve recruitment of both adenine and cytosine deaminases, enabling simultaneous editing of multiple genetic targets. By employing specific aptamer-deaminase combinations, we were able to target multiple genes independently, showcasing the potential to design sophisticated gene editing strategies for complex therapeutic interventions or functional genomic studies.

Additionally, we performed a massive parallel cell-based screen analyzing the editing activity of two different Pin-point base editor configurations with gRNAs targeting thousands of sequences. The resulting data enabled us to construct predictive models of editing outcomes for each configuration. Using these models, we ranked gRNAs designed to achieve functional knockouts of clinically relevant gene targets, including CIITA and PCSK9. Validation of the models revealed a strong correlation between in silico predictions and observed cell-based editing performance, paving the way to leverage the modularity of the Pin-point platform to design tailored configurations for specific edits. These results highlight the flexibility, precision, and scalability of the Pin-point platform, establishing it as a next-generation solution for advancing genome editing technologies.

Disclaimer: The Pin-point base editing platform technology is available for clinical or diagnostic study and commercialization under a commercial license from Revvity.

1599 Engineering TadA-Derived Base Editors with Enhanced Potency and Safety for non-viral In Vivo Gene Editing

Feifei Duan[1], Songyuan Li[2], Huanle Liu[1], Fuxin Shi[3], Ke Qin[1], Jialin Tao[4], **Yongzhong Wang[5]**
[1]Accuredit Therapeutics Limited, suzhou, Jiangsu, China, [2]Accuredit, Suzhou, Jiangsu, China, [3]Cambridge, MA, [4]AccurEdit Therapeutics, Suzhou, Jiangsu, China, [5]Accuredit Therapeutics US, suzhou, Jiangsu, China

Base editors (BEs) have emerged as powerful tools for precise, single-nucleotide modifications without inducing double-stranded DNA breaks. Despite their potential, the therapeutic application of next-generation adenine (ABE) and cytosine (CBE) base editors in non-viral, in vivo settings has been constrained by suboptimal potency and safety concerns.

In this study, we present the discovery and engineering of novel TadA-derived BEs, identified through a metagenomic pipeline screening for new deaminases and Cas enzymes, followed by iterative rounds of rational protein engineering and directed evolution. This systematic approach resulted in a suite of ABE/CBE variants with significantly improved on-target editing efficiency, reduced sequence-context biases, and enhanced purity profile.

To further enhance potency, our lead ABE underwent linker engineering, Cas protein refinement, and mRNA sequence optimization, collectively leading to improved stability, catalytic activity, and expression. Unlike conventional studies that rely on plasmid delivery and a limited number of gRNAs to assess editor potency—an approach prone to bias— we evaluated the activity of our enhanced editors in mRNA form using a gRNA library comprising over 1,000 endogenous sites. This strategy provides a reliable and unbiased assessment of the general potency of editors under transient expression conditions.

To evaluate in vivo efficacy, the optimized ABE mRNA was encapsulated in lipid nanoparticles (LNPs) and co-delivered with a clinically validated gRNA targeting human PCSK9 in hPCSK9 mice. Our engineered ABE achieved >90% knockdown of PCSK9 at a dose of 0.6 mpk, outperforming the clinical benchmark ABE8.8, which required 1 mpk to achieve similar efficiency, highlighting the improved potency of our variant. Comprehensive whole-genome sequencing (WGS) and transcriptomic analyses further confirmed its excellent safety profile, supporting readiness for clinical translation.

In a preclinical program focused on a particularly challenging liver target, our lead ABE exhibited significantly enhanced editing efficiency, achieving over 75% ex vivo and 48% in vivo in clinically relevant models. In comparison, ABE8.8 reached only 65% editing ex vivo and 38% in vivo at the same target, underscoring the

enhanced performance and therapeutic potential of our engineered variant. Furthermore, to expand the potential therapeutic window, we developed a next-generation LNP formulation incorporating a novel cationic lipid with enhanced safety features. This novel formulation demonstrated a clear toxicity advantage over the industry-standard benchmark ALC-0315 in preclinical models, significantly enhancing the clinical viability and therapeutic potential of our platform for addressing complex liver targets.

In summary, these engineered base editors—offering enhanced potency, improved safety, and robust in vivo efficacy—represent a versatile and scalable platform for therapeutic gene editing. Our innovations pave the way for transformative drug development in liver diseases and beyond.

1600 High fidelity C-to-T editing with TALE base editors

Louisa Mayer[1], Alexandre Juillerat[2], Alex Boyne[2], Maria Feola[3], Diane Tkach[2], Aminah Lawal[2], Sylvain Pulicani[4], Robert Hong[3], Julienne Lomibao[3], Aymeric Duclert[5], Julien Valton[6], Frederic Paques[7]
[1]Cellectis, New York, NY, [2]Cellectis, Inc., [3]Cellectis, New York, [4]Cellectis, Inc., Paris, Paris, France, [5]Cellectis, Paris, France, [6]Cellectis, Inc., New York, NY, [7]Cellectis SA, Paris, Paris, France

TALE base editors (TALEB) are fusions of a transcription activator-like effector domain (TALE), split-DddA deaminase halves, and a uracil glycosylase inhibitor (UGI). The C-to-T class of TALEB edits double strand DNA by converting a cytosine (C) to a thymine (T) via the formation of a uracil intermediate.

We recently developed and applied a strategy that allowed the comprehensive characterization of C-to-T conversion efficiencies within the target editing window. This method also takes advantage of a highly precise and efficient TALEN®-mediated knock-in of ssODN in primary T cells to assess how the composition and spacer variations of target sequences affect TALEB activity/efficiency.

Additionally, we highlighted that the composition of bases surrounding the target bases (TC) may strongly influence the editing efficiencies. We also demonstrated that different TALEB scaffolds could be used to relax target sequence limitations (to increase the targetable sequence) or be used to decrease or eliminate bystander editing within the editing window (to increase specificity). Overall, these findings allow for the fine-tuning of TALEB for a desired gene editing outcome.

We then applied a range of different techniques to assess characteristics of nuclear genome editing. First, we focused on on-target editing and then explored the possibility and risk associated with genome-wide TALE-dependent/independent binding and editing. By using an experimental model relevant for therapeutic application with TALEB mRNA vectorization in primary cells (e.g. PBMCs and HSCs), we demonstrated that targeted binding of a single TALEB arm does not lead to detectable editing (detection limit: 0.1-0.2%).

Finally, we further applied hybrid capture assays to test for off-target editing, in particular, within regions of the genome that were previously highlighted in cell lines. We demonstrated, in our relevant experimental setup with primary T cells, that editing at these sites was not detectable (detection limit: 0.2%).

Altogether, the results of this study have enhanced our control and use of TALEB and allow for the design of extremely efficient (high editing frequencies and edit purity) and specific (absence of TALE-independent off sites and very limited, if not absent, DSB generation) TALEB, compatible with the development of future therapeutic applications.

1601 Optimization of the modular Pin-pointTM base editing platform for an engineered Type V CRISPR-Cas effector

Amanda Haupt[1], Ryan Prestil[2], Natalia Gurule[3], Kevin Hemphill[4], Pablo Pérez-Durán[5]
[1]Revvity, Superior, CO, [2]Revvity, Cambridge, United Kingdom, [3]Revvity, Lafayette, [4]Revvity, UNITED KINGDOM, [5]Revvity, Cambridge, Cambridgeshire, United Kingdom

The recent appreciation of the variable function of the natural diversity of CRISPR-associated nucleases has led to an interest in expanding the gene editing toolbox. The type V CRISPR-Cas system is particularly attractive for clinical development due to its smaller size than SpCas9 and its unique PAM specificities, permitting a greater variety of delivery vehicles and allowing for enhanced accessibility of editing sites not always attainable with type II CRISPR-Cas enzymes, such as Cas9.
Revvity's modular Pin-point™ base editing platform employs the delivery of either a nickase or deactivated Cas enzyme, a deaminase fused to an aptamer binding protein, and an aptameric guide RNA (gRNA) that assemble in vivo and act in conjunction to facilitate precise single nucleotide conversions. While originally developed using Cas9 nickase, the modularity inherent to the Pin-point platform permits swapping of components to achieve optimal editing results. Here, we demonstrate robust site-specific editing at different target loci using a deactivated CasONYX (dCasONYX) version of the Pin-point base editing platform. dCasONYX is an engineered version of dCasMINI developed by Epic Bio. It has an improved off-target profile compared to SpCas9, exhibits very low immunogenicity compared to Cas9 and is less than 1.5 Kb in size. Further utilizing the modularity of the Pin-point base editing platform, we show that additional components of the system such as different deaminases and aptameric gRNA scaffold configurations can be leveraged in combination with alternative Cas enzymes to adjust the base editing window; this is of particular advantage for applications including SNP correction and gene knockout at sites that are not usually accessible with the nCas9 configuration. Finally, we have significantly improved the design and optimized the delivery parameters of the dCasONYX version of the Pin-point platform through generation of IVT mRNA and achieving robust chemical synthesis of gRNA over 150nt in length, making this configuration suitable for application to therapeutically relevant cell types such as T cells and induced pluripotent stem cells (iPSCs).

1602 EPIREG®: A Novel Epigenetic Platform for Safe and Efficient Multi-Gene Silencing in Universal CAR-T Cell Therapies

Shutan Jiang, Epigenic Therapeutics, Shanghai, Shanghai, China

Introduction: Universal allogeneic CAR-T cells have broad applications, particularly in autoimmune diseases, providing a scalable, off-the-shelf solution for immunotherapy. Efficient silencing of immune targets, such as TCR and HLA class I/II, is essential to prevent immune rejection (GVHD and HVG) and enhance therapeutic efficacy. TCR editing is critical for eliminating T cell receptor recognition of host tissues, while HLA class I/II silencing prevents immune rejection of the infused CAR-T cells. Traditional gene-editing tools face safety risks, particularly with multiplexed editing of multiple genes, including off-target effects and chromosomal abnormalities associated with CRISPR/Cas9 and ABE. EPIREG® provides a safer, more efficient alternative, enabling precise, durable, and nuclease-free silencing of multiple genes in T cells.

Methods: EPIREG® utilizes epigenetic modifications via DNA-binding domains and DNA methylation/histone-modifying effectors. sgRNAs targeting genes involved in immune recognition, such as TCR, HLA class I, HLA class II , and immune checkpoint genes, were optimized using a deep-learning model. Multi-omics analyses, including RNA-seq, WGBS, PEM-seq, and CUT&TAG, were performed to evaluate on-target editing efficiency and potential off-target effects. A lipid nanoparticle (LNP)-based delivery system was developed for ex vivo editing of human primary T cells, achieving >90% editing efficiency while maintaining cell viability and proliferation.

Results: EPIREG® demonstrated excellent safety with no detectable off-target effects or chromosomal abnormalities, even when multiplexing up to seven target genes. TCR silencing was highly efficient, achieving >99.8% suppression of TCR expression through *CD3D* and *CD3E* editing, which remained fully suppressed after 60 days of continuous antigen stimulation. HLA class I silencing was achieved with >75% suppression through targeting B2M and TAP1, providing broad suppression of all HLA class I types. *HLA-A* and *HLA-B* were specifically targeted for combined editing to preserve the positive role of *HLA-C* in T cell functionality. HLA class II silencing exceeded 95% through *CIITA* editing, which regulates transcription of class II genes, providing efficient and durable suppression. Immune checkpoint genes (*PDCD1, TGFBR2, LAG3*) were effectively silenced, with editing efficiencies exceeding 95%, enhancing the immune modulation properties of the edited T cells. The LNP delivery system enabled efficient editing of primary human T cells, achieving >90% editing efficiency without compromising cell viability or proliferation. This streamlined the CAR-T cell manufacturing process, significantly

enhancing efficiency. Functional assessments of EPIREG-edited CD19-CAR-T cells demonstrated improved stemness, cytokine secretion, and cytotoxicity compared to conventional universal CAR-T cells.

Conclusions: EPIREG® provides a transformative platform for multiplexed gene silencing in universal CAR-T cells, overcoming safety challenges associated with traditional gene-editing tools. Its highly efficient LNP delivery system enables scalable and safe engineering of CAR-T cells, offering a robust solution for universal CAR-T therapies. This platform has significant potential for clinical applications in autoimmune diseases, providing a promising strategy to enhance the safety, efficacy, and manufacturability of universal CAR-T cell.

1603 Epigenetic Suppression of HBF Modifiers, Efficiently Reactivates Gamma Globin Expression in Primary Cells

INTRODUCTION: Advances in genome editing have enabled new gene therapy strategies, such as in situ gene correction or introduction of disease-modulatory mutations. In β-hemoglobinopathies, targeted genome editing to modify fetal hemoglobin (HbF) transcription modulators has enabled the therapeutic reactivation of gamma globin, offering the ability to compensate for the dysfunctional or deficient adult hemoglobin. However, the DNA double strand breaks induced by the genome editing machinery remain a limitation. Recently, the development of custom-designed epigenome editors has allowed the introduction of specific epigenetic alterations to tightly regulate gene expression, without affecting genome integrity. The aim of the study is to assess the safety and efficacy of HbF reactivation in human primary cells, mediated by novel epigenome editing tools.

METHODS: Initially, we investigated dCas9-KRAB mediated epigenetic suppression of three HbF major suppressors, namely LRF promoter, BCL11A enhancer and promoter, and ZNF410 promoter in combination with various gRNAs, in HUDEP-2 cells. Proliferation and HbF levels of the HUDEP-2-dCas9-KRAB cells were assessed at different time points. Epigenomic suppression of the transcription factors was assessed using quantitative Q-PCR. To confirm the safety and efficacy of the approach in human primary cells, composite erythroid-specific lentiviral vectors were generated that incorporated both the dCas9-KRAB domain and the most effective gRNAs. The erythroid expression of the dCas9-KRAB was achieved using a compact erythroid-specific enhancer in combination with a minimal beta-globin promoter. Normal and thalassemic donor CD34+ cells were transduced with the composite vectors and the clonogenic capacity and multilineage differentiation were assessed ex vivo. The oxidative stress and HbF levels were evaluated during erythroid differentiation.

RESULTS: The epigenomic suppression of ZNF410, LRF and BCL11A was translated into significantly increased gamma globin levels in transduced HUDEP-2 cells ($p=0.009$, $p=0.05$, $p=0.003$, respectively). Among the three suppressors, the epigenomic silencing of ZNF410 promoter or BCL11A enhancer induced the highest increase in HbF+ cell ($p=0.009$, $p=0.0002$, respectively) with no observed adverse effects in proliferation and cell maturation. In contrast, targeting the LRF or BCL11A promoters resulted in evident cell toxicity. In subsequent experiments in primary cells, we employed the composite erythroid specific vectors, carrying both the dCas9-KRAB effector and the most effective gRNA targeting the ZNF410 promoter or the erythroid enhancer of BCL11A. Epigenomic

suppression of ZNF410 and BCL11A in both normal and thalassemic CD34+ cells had no effect on cell proliferation, clonogenic capacity or the differentiation/maturation process. Importantly, the ZNF410 and BCL11A epigenetic silencing significantly increased the percentage of HbF+ cells at the end of erythroid differentiation in the edited over unedited cells, in both normal (p=0.02) and thalassemic (p=0.004) cells. The HbF reactivation in the thalassemic cell group resulted in increased expansion rates and reduced oxidative stress over the control group.

CONCLUSIONS: Overall, our findings establish the feasibility and efficacy of epigenetically mediated suppression of gamma globin regulators leading to efficient HbF induction both in normal donor- and beta-thalassemia patient-derived cells, without apparent cell toxic

1604 Development of a Novel Chimeric Suppressor tRNA Successfully Rescues Functional Protein in Nonsense Harboring *TP53* Mutants

Alejandro Tapia[1], Roland Herzog[2], Jeffery Tharp[1]
[1]Indiana University School of Medicine, Indianapolis, IN, [2]IU School of Medicine, Indianapolis, IN

Over 10% of genetic diseases are caused by mutations that introduce stop codons, known as premature termination codons (PTCs), into protein-coding genes. mRNA transcripts harboring PTCs result in premature polypeptide cleavage, leading to loss of protein function. One promising approach promote PTC-readthrough utilizes engineered suppressor transfer RNAs (sup-tRNAs), which are modified to recognize one of the 3 stop codons. Sup-tRNAs can outcompete release factors that terminate translation and incorporate amino acids (AAs) at PTCs-encoded positions, rescuing full-length protein synthesis. Previous success with sup-tRNA-mediated protein rescue has been demonstrated in cystic fibrosis (CF) and Duchenne muscular dystrophy (DMD) models; however, the application of sup-tRNAs as a cancer therapeutic has not been explored. Tumor suppressor protein p53 (encoded by *TP53*) is one of the most frequently mutated proteins in cancer—11% of cancer-associated mutations in *TP53* are PTCs. We hypothesize that sup-tRNAs can induce translational readthrough of PTCs in the *TP53* gene to restore p53 protein levels and rescue p53 activity. Further, we hypothesize that PTC-readthrough facilitated by sup-tRNAs will induce p53-mediated apoptosis and cell senescence. As a result, we hypothesize that this sup-tRNA delivery will inhibit tumorigenesis and cancer cell proliferation. In addition to assessing sup-tRNAs for tumor suppressor rescue, there is also a need to optimize these sup-tRNAs to increase their readthrough efficiency. The archaeal species *Methanomethylophilus alvus* expresses an endogenous sup-tRNA that installs pyrrolysine in conserved PTC-containing transcripts. With this naturally occurring nonsense suppression capability, we developed a novel chimeric sup-tRNA (PASS-tRNA) using the archaeal tRNA as a scaffold. This chimeric PASS-tRNA can be recognized by the human alanine aminoacyl-tRNA synthetase. PTC-readthrough analysis shows significant efficiency improvement when comparing the PASS-tRNA against two sup-tRNA variants. Using a human epithelial lung cancer cell line, NCI-H1299, we assessed the recovery of full length p53 protein using plasmid transfection encoding for the various *TP53* mutants harboring PTCs. Cells transfected with our PASS-tRNA rescued synthesis full-length p53 protein; additionally, the PASS-tRNA was able to rescue p53 activity in a luciferase-based transactivation assay. qRT-PCR results further demonstrate an upregulation of p53 downstream target genes such as *CDKN1A*, and *MDM2*. In a similar fashion, we transfected PASS-tRNAs in human cancer cell lines SK-MES-1, C2bbe1, and Calu6. These cell lines contain homozygous PTC mutations in the genomic *TP53* gene. The PASS-tRNA successfully recovered full-length p53 and its transactivation activity from these endogenous mutations; additional qRT-PCR results also solidify an upregulation in p53 downstream gene targets. These results indicate that sup-tRNAs can induce PTC-readthrough in *TP53* to rescue functional p53 protein. These sup-tRNAs are applicable to a variety of PTC-mediated disorders; our findings shed light on a useful approach for cancer therapeutics.

1605 CRISPR-hfCas13Y RNA-targeting Therapy Restores Cognitive Function by Reducing *BACE1* or *MAPT* in Alzheimer's Disease Model

Background: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by the accumulation of amyloid-beta (Aβ) plaques and tau neurofibrillary tangles, leading to progressive neuronal loss and memory deficits. Current therapies focus on symptom management and often have limited efficacy and side effects. Targeting key contributors to AD pathology, such as BACE1, which drives Aβ production, and MAPT, which encodes tau protein, offers a promising therapeutic approach. CRISPR-Cas13Y RNA-targeting therapy provides a precise and reversible method for reducing harmful protein levels by degrading *BACE1* or *MAPT* mRNA without permanently altering DNA.

Methods: The CRISPR-high-fidelity Cas13Y(hfCas13Y) RNA editing system was used to screen gRNAs targeting the *BACE1* and *MAPT* mRNAs, promoters and functional elements, in HEK293T cells and N2a cells using fluorescence-activated cell sorting (FACS). To evaluate the therapeutic potential of BACE1 knockdown, we administrated AAV-hfCas13Y-g*BACE1* via retro-orbital injection into 3-month-old 5xFAD mice, a classic AD mouse model. Behavior tests, including fear conditioning and the Morris water maze, were conducted 3 months post-treatment to assess memory function. For MAPT knockdown, we injected AAV-hfCas13Y-g*MAPT* into the hippocampus of 3-month-old PS19 mice, another widely used AD mouse model, via intracranial injection. *MAPT* mRNA and protein expression levels were analyzed 4 weeks post-injection using qPCR, western blot, and immunostaining. To investigate whether AAV-hfCas13Y-g*MAPT* treatment could improve cognitive deficits, hippocampal injections were performed in 7-month-old PS19 mice, followed by cued and contextual fear conditioning tests 2 months post-treatment to evaluate learning and memory.

Results: This comprehensive approach evaluated CRISPR-hfCas13Y-mediated RNA editing in two key AD mouse models, targeting distinct pathological mechanisms of Aβ and tau protein accumulation. The CRISPR-hfCas13Y-g*BACE1* system efficiently targeted *BACE1* mRNA in HEK293T cells, achieving a 99% reduction ($P<0.001$, Fig. 1A). Administration of AAV-CRISPR-hfCas13Y-g*BACE1* into the hippocampus of 5xFAD mice significantly reduced in BACE1 protein levels (Fig. 1B). Moreover, fear conditioning and Morris water maze results revealed that retro-orbital injection of AAV- hfCas13Y-g*BACE1* significantly alleviated cognitive deficits in 5xFAD mice (Fig. 1C–G). For the CRISPR-hfCas13Y-g*MAPT* system, we screened 33 gRNAs and identified two (g31 and g7) that significantly reduced *MAPT* mRNA levels in HEK293T cells by 90.8% and 77.2%, respectively ($P<0.001$, Fig. 2A). Delivery of AAV-hfCas13Y-g*MAPT* via hippocampal injection in PS19 mice led to a significant reduction in *MAPT* mRNA and protein levels of MAPT in the hippocampus (Fig. 2B and C). Furthermore, fear conditioning tests demonstrated improved learning and memory in PS19 mice 2 months post-treatment with AAV-hfCas13Y-g*MAPT* (Fig. 2D). Development of a dual-target AAV-hfCas13Y system that simultaneously targets both *BACE1* and *MAPT* is underway, with the potential to address multiple pathological mechanisms of AD.

Conclusions: This study demonstrates that CRISPR-hfCas13Y RNA editing can precisely and efficiently reduce *BACE1* or *MAPT* mRNA levels, significantly improving cognitive function in AD mouse models. These findings support the potential of RNA-targeting therapies for AD and pave the way for a dual-target treatment strategy.

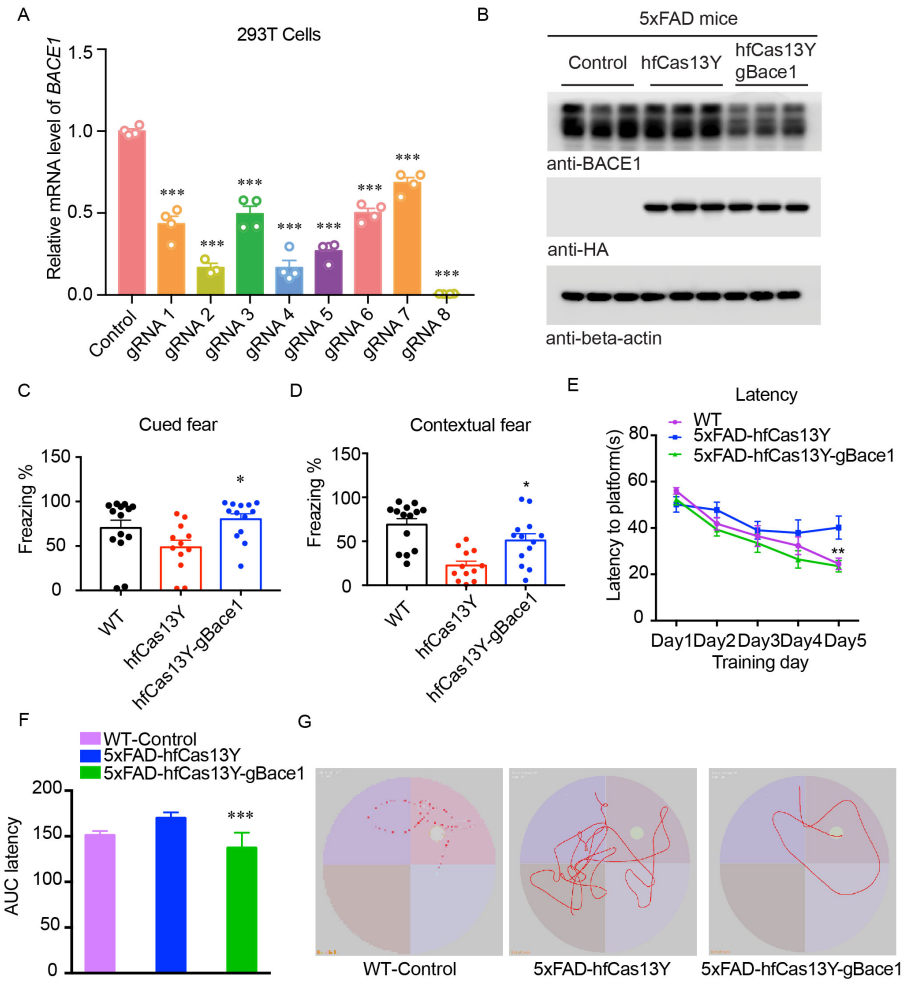

Figure 1. hfCas13Y-g*Bace1* improved the cognitive function of 5xFAD mice 3 months after retro-orbital injection. (A) gRNA2 and gRNA8 showed> 90% knockdown efficiency of BACE1 in HEK293T cells. **(B)** Injection of AAV-hfCas13Y-*BACE1*-gRNA2 into the hippocampus of 5xFAD mice resulted in the reduction of BACE1 levels. **(C-D)** Fear conditioning results show that hfCas13Y-*BACE1*-gRNA2 treated 5xFAD mice via retro-oral injection enhanced the learning and memory capabilities 3 months after treatment compared to hfCas13Y-treated 5xFAD mice, *P<0.05. **(E-G)** Water maze analysis revealed that hfCas13Y-*BACE1*-gRNA2 treatment rescued learning and memory deficits of 5xFAD mice. WT-Control (n=14), 5xFAD-hfCas13Y (n=12), 5xFAD-hfCas13Y-g*Bace1* (n=13), ***P<0.001.

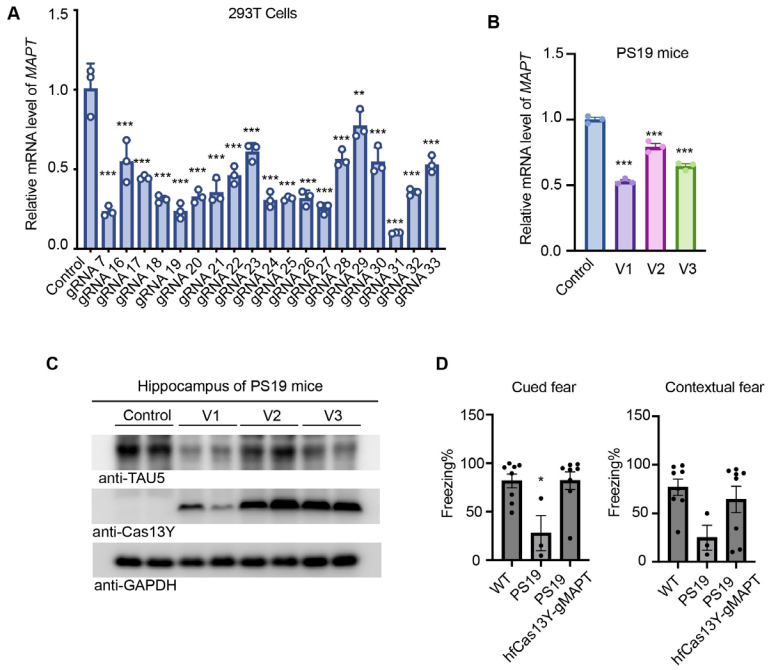

Figure 2. Administration of AAV-hfCas13Y-g*MAPT* significantly decreased MAPT and improved the cognitive functions of PS19 mice. (A) qPCR analysis of MAPT mRNA level in 293T cells transfected with different versions of hfCas13Y-g*MAPT*, **P<0.01, ***P<0.001. **(B-C)** qPCR and western analysis of MAPT in the hippocampus of PS19 mice 1 month after administering AAV-hfCas13Y-g*MAPT* via hippocampal injection. Three versions of AAV-hfCas13Y-g*MAPT* were desinged by combining different gRNAs. **(D)** Cued and contextual fear conditioning of 9-month-old PS19 mice 2 months after treatment with AAV-hfCas13Y-g*MAPT* via hippocampal injection. WT (n=8), PS19 (n=3), hfCas13Y-gMAPT(n=8), * P<0.05 .

1606 Engineering CRISPR/dCas9-based modalities in primary neurons for gene modulation of *ΔFosb* in the context of cocaine substance use disorders (SUD)

Daniel Reed[1], Mark Krimmer[1], Sarah Reid[1], Elizabeth Heller[2], Laura Lavery[1], Isaac Hilton[1]
[1]Rice University, Houston, TX, [2]University of Pennsylvania, Philadelphia, PA

Cocaine substance use disorder (SUD), one of an array of mental health disorders in the United States, is devastating for individuals and society in terms of health and economic consequences. While there are some common approaches for treating cocaine SUD, such as counseling, support groups, and off-label use of medication for withdrawal symptoms, there is no guarantee that any of these strategies may work or even be readily available to patients, and unfortunately, there are no curative FDA-approved treatments for this class of mental health disorders. Therefore, therapies that enable a shift from treating the symptoms of SUDs to instead targeting the pathological drivers of SUD, could both enhance the understanding of SUDs and revolutionize the ability to cure this devastating class of disorders.

Drugs of abuse lead to increased levels of the ΔFosB transcription factor, a splice variant produced from the *FOSB* gene, within the nucleus accumbens (NAc) brain region known for regulating the reward system. Specifically in cocaine SUD, ΔFosB is induced in dopamine receptor 1 expressing medium spiny neurons (D1-MSNs) within the NAc. Additionally, ΔFosB persists in the NAc substantially longer than full length FosB and plays a substantial role in the maladaptations that occur at the cellular and tissue level, which consequently creates and sustains cocaine SUD. Despite the therapeutic importance of ΔFosB in cocaine SUD and many other SUDs, the factors that control ΔFosB expression and splicing remain incompletely understood.

DNA methylation is a stable, yet reversible epigenetic mark, that typically leads to gene repression when present at promoter regions. We have analyzed publicly available sequencing data sets that suggest a strong possible link between repeated cocaine exposure and increased levels of DNA methylation at the *Fosb* splice site in mice and post-mortem human brains. This data *drives our hypothesis* that engineering DNA methylation states can be used to control and mechanistically dissect endogenous Fosb/ ΔFosB expression. To test this hypothesis, we have leveraged CRISPR/dCas9-based epigenome editing technologies to functionally interrogate the epigenetic control of *Fosb* isoforms levels (including ΔFosB), as well as uncover new therapeutic opportunities to effect sustained improvement of the neuropathology involved in cocaine SUD.

Recently, two epigenome editing platforms known as CRISPRoff and CRISPRcharm have been developed for programmable DNA methylation and potent gene repression. We have tested these systems in a murine primary neuron culture system that we have established using MSNs sourced from within the NAc of newborn mice. This system serves as a powerful *in vitro* proxy to study cocaine SUD. Here we quantified gene expression levels of both *Fosb* and *ΔFosb* and coincident changes in DNA methylation levels at these loci and tested how the targeting of either CRISPRoff or CRISPRcharm modulate these chromatin and gene-regulatory effects.

Our results demonstrate a proof-of-concept for the use of programmable DNA methylation to understand gene regulation in primary neurons *in vitro* and opens new routes for potential therapeutic approaches aimed at controlling *Fosb* isoforms and reducing cocaine driving reward behaviors in the mammalian brain.

1607 Efficacy and Safety of a CasRm-Based Therapy for Parkinson's disease in Non-Human Primates

Wang Shimin[1], Huabao Liao[2], Hui Xu[3], Zhendong Xiao[4], Junjiu Huang, Junbin Liang[3]*

**Corresponding Author*

Background: Parkinson's disease (PD) is one of the most prevalent neurodegenerative disorders in the world, characterized by the progressive loss of dopaminergic neurons in the substantia nigra and a resultant decrease in striatal dopamine levels, leading to a spectrum of motor abnormalities. To date, there remains a significant unfulfilled demand for effective and safe treatment that can provide long-term benefits for patients with Parkinson's disease. Recent years, the in situ conversion of glial cells to neurons either by overexpressing transcription factors, such as NeuroD1, or by inhibiting repressors of neuronal differentiation, such as Polypyrimidine tract-binding protein 1 (PTBP1) and RE1-silencing transcription factor (REST), has emerged as a potent therapeutic strategy. Here we present the initial preclinical results of RM-201, an innovative adeno-associated virus (AAV) gene therapy that harnesses a state-of-the-art CasRm system to specifically knock down PTBP1 and high-effiently induce glial-to-neuron transdifferentiation.

Methods: The therapeutic potential of RM-201 in PD was evaluated through injection in the midbrain of non-human primate (NHP) model induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Control groups received an AAV expressing CasRm along with a non-targeting guide RNA. The levels of plasma membrane dopamine transporter (DAT) within the striatal dopaminergic terminals were monitored using positron emission tomography-computed tomography (PET-CT) with 11C-2β-Carbomethoxy-3β-(4-fluorophenyl) tropane (11C-CFT) monthly, consistent with the schedule for behavioral evaluations following the administration of RM-201. Immunogenicity and safety profiles were evaluated by the level of anti-CasRm antibodies in peripheral blood and the systemic distribution of AAV DNA.

Results: Compared to the control, the NHPs treated with RM-201 exhibited a restoration of the striatal dopamine transporter by over 10% as early as three months following the administration of RM-201, and persisting for at least ten months. These imaging outcomes were supported by durable and significant enhancements in behavioral assessments, with a substantial reduction in dyskinesia scores observed in the RM-201-treated NHPs, particularly in the improvement of tremor and defensive motor responses. These data imply that RM-201 could promote the

regeneration of functional dopaminergic neurons and enhance motor function. Moreover, immunogenicity analyses revealed that there is no adverse immune reactions to the CasRm system in the RM-201-treated primates. What's more, the viral genomes of RM-201 were predominantly confined to the nigral tissue, with minimal diffusion to other brain regions and negligible systemic circulation.

Conclusions: Our study affirms RM-201 as an efficacious agent for promoting neuronal regeneration and restoring motor abilities in PD NHPs, while maintaining an acceptable safety profile at therapeutic doses. This research provides robust evidence in support of RM-201 as a promising gene editing therapeutic candidate for the treatment of PD patients.

1608 A Skeletal Muscle-Specific dCas9-KRAB Mouse Model for Precision Gene Silencing

Abbey Stokes[1], Ronald Jones[2], Pieter Koopmans[2], Kevin Murach[3], Christopher Nelson[4]
[1]University of Arkansas, Springdale, AR, [2]University of Arkansas, Fayetteville, [3]University of Arkansas, [4]University of Arkansas, Fayetteville, AR

Genetic screens are pivotal in uncovering gene function, shedding light on their roles in both healthy and diseased states across specific organs or throughout the entire body. Current mouse models to perform genetic screens involve gene editing mouse embryos with the desired gene mutation and breeding the model. However, one model is limited to a single gene, is expensive, and labor- and time-intensive. When studying a new gene a new model is required. Therefore, a new model is essential that enables the screening of any gene of choice. The groundbreaking gene editing technology, CRISPR-Cas9, alongside a gene-specific sgRNA, has the ability to target any gene in the genome. Recently, a lab incorporated CRISPR-Cas9 into mouse skeletal muscle to allow organ-specific gene knockout. However, gene-based therapies for diseases typically achieve partial knockdown instead of full knockout. Therefore, examining genetic knockdown would be more beneficial in the context of studying treatment effects on an organ in a healthy or diseased state. The catalytically deactivated CRISPR-Cas9 (dCas9) connected to transcription factor, Krüppel Associated Box (KRAB), is able to transcriptionally downregulate gene expression. *Therefore, we established a mouse model that expresses dCas9-KRAB exclusively in skeletal muscle.*

Currently, we crossbred mice containing tamoxifen inducible Cre recombinase under the control of the human skeletal muscle α-actin promoter (HSA-Cre) and mice containing dCas9-KRAB controlled by a loxP-flanked STOP cassette (LSL-KRAB). Upon breeding, Cre recombinase will remove the STOP cassette allowing expression of dCas9-KRAB under the control of the HSA promoter (HSA-KRAB), creating organ-specificity in skeletal muscle. dCas9-KRAB expression was verified to be >100x in somatic skeletal muscle (tibialis anterior, plantaris, soleus) when compared to non-tamoxifen induced HSA-KRAB mice using RT-qPCR. Negligible amounts of dCas9-KRAB were found in the liver or heart using Western Blot. Current models are able to achieve muscle specificity, but are challenging and time-intensive, unlike ours which only involves breeding and tamoxifen injections.

To determine the functionality of our model, we targeted the myostatin pathway, an inhibitor of muscle hypertrophy, that would allow the physical readout of muscle weight alongside gene and expression analysis. We selected 5 sgRNAs to target each of the following: myostatin (Mstn), activin A receptor 2A (Acvr2A), and activin A receptor 2B (Acvr2B). Each array of 5 sgRNAs was cloned into an AAV transfer plasmid produced at a high hiter in the highly myotropic myoAAV1C capsid. Each set of sgRNAs is paired with the reporter tdTomato. Currently, myoAAV was injected intramuscularly into the tibialis anterior muscle at a dose of 5×10^{11} vg. Muscle will be isolated and analyzed via RT-qPCR, western blot, histology, and RNA-seq to verify the functionality of our model. Future experiments include investigating systemic delivery and simultaneous silencing of multiple genes.

1609 A Multi-Omic Deep Learning Approach to Predict CRISPR Activation and Interference Efficacy

Renee Napoliello[1], Hongru Hu[1], Gerald Quon[1]
[1]*University of California, Davis, Davis, CA*

CRISPRi (interference) and CRISPRa (activation) systems are powerful molecular tools for modulating gene expression. CRISPRa/i relies on a guide RNA (gRNA) to target the gene of interest and recruit epigenetic modifiers. CRISPRa/i efficacy varies widely due to complex factors influencing gene expression and efficient CRISPR intervention. Such factors include promoter epigenetics, local genomic DNA, and gRNA features. We propose a convolutional-based machine learning approach to integrate these factors and predict the efficacy of CRISPRa/i interventions based on gRNA design. We hypothesize that full integration of all modalities in our model will enhance predictions and reveal determinants of CRISPR-based transcriptional perturbations.

Using two genome-wide CRISPRi screens (a single gRNA and a dual gRNA screen) and one genome-wide CRISPRa screen, we identified several principles for effective CRISPRa/i activity. Using only the guide and transcript location, the model exhibited moderate predictive power for the single CRISPRa/i datasets (~0.3-0.4 Spearman correlation) and weak predictive power for the dual CRISPRi dataset (~0.2 Spearman). This is unsurprising, as the dual library was designed with a small search space per promoter. Results from the single-guide datasets indicate a strong influence of guide location on outcomes. Surprisingly, the model using only gRNA features (sequence, structure, energetics) also had moderate predictive power (Spearman correlation ~0.2-0.4). This suggests that guide efficacy may have some independence from target context. Further, integrating the RNA and transcript modalities boosted model performance across all datasets, indicating that both modalities influence CRISPRa/i interventions.

Interrogation of model predictions revealed critical rulesets governing epigenetic perturbations. The model trained on the single-guide CRISPRi data, using only transcript/guide location, significantly preferred placement immediately downstream of the TSS. Interestingly, the model trained on the paired CRISPRi data exhibited a similar preference for placing both guides within the gene body. The model trained on the CRISPRa screen revealed more relaxed rulesets, with ideal locations distributed between the (slightly preferred) promoter and gene body. In addition, the model utilizing gRNA features indicated the importance of scaffold secondary structure for gRNA efficacy. Input ablation studies showed that removing the scaffold features worsened model performance. This is particularly novel, as the chosen scaffold is a guide design parameter that has not been extensively explored previously.

We have also performed initial experiments to integrate epigenetic inputs into our model. A screen of epigenetic features relevant to gene expression (e.g., chromatin accessibility or transcription factor binding) revealed some markers that significantly improve the prediction of CRISPRa efficacy. Future directions involve refining the integration of epigenetic features to interrogate the CRISPRi and CRISPRa datasets. Overall, the findings from our model demonstrate the utility of machine learning approaches in predicting CRISPR epigenetic perturbations.

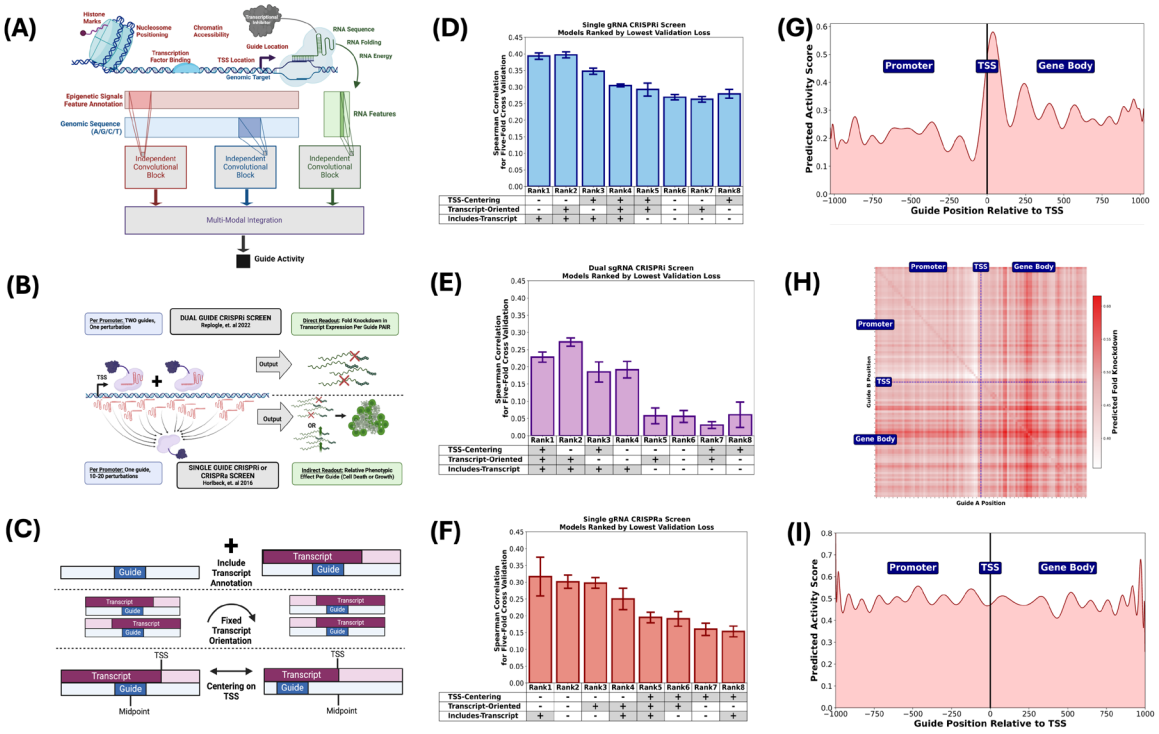

Figure 1: Appropriate representation of gRNA with respect to transcript location improves model predictions for CRISPRi and CRISPRa screens. (A) Schematic for the proposed convolutional-based model with multi-modal fusion**. (B)** Depiction of experiment design for the CRISPRi/CRISPRa screens chosen to assess the model. **(C)** Diagram of all tested representations for transcript and gRNA location. Explicit representation of transcript improved model predictions for the single CRISPRi screen **(D)**, dual CRISPRi screen **(E)**, and single CRISPRa screen **(F)** according to Spearman correlation between true and predicted guide activity. Interrogation of model predictions revealed strong model preference for placement of sgRNAs within gene bodies for the single CRISPRi **(F)** and dual CRISPRi **(G)** screens, whereas only moderate preference for upstream of the TSS in the single CRISPRa screen **(H).**

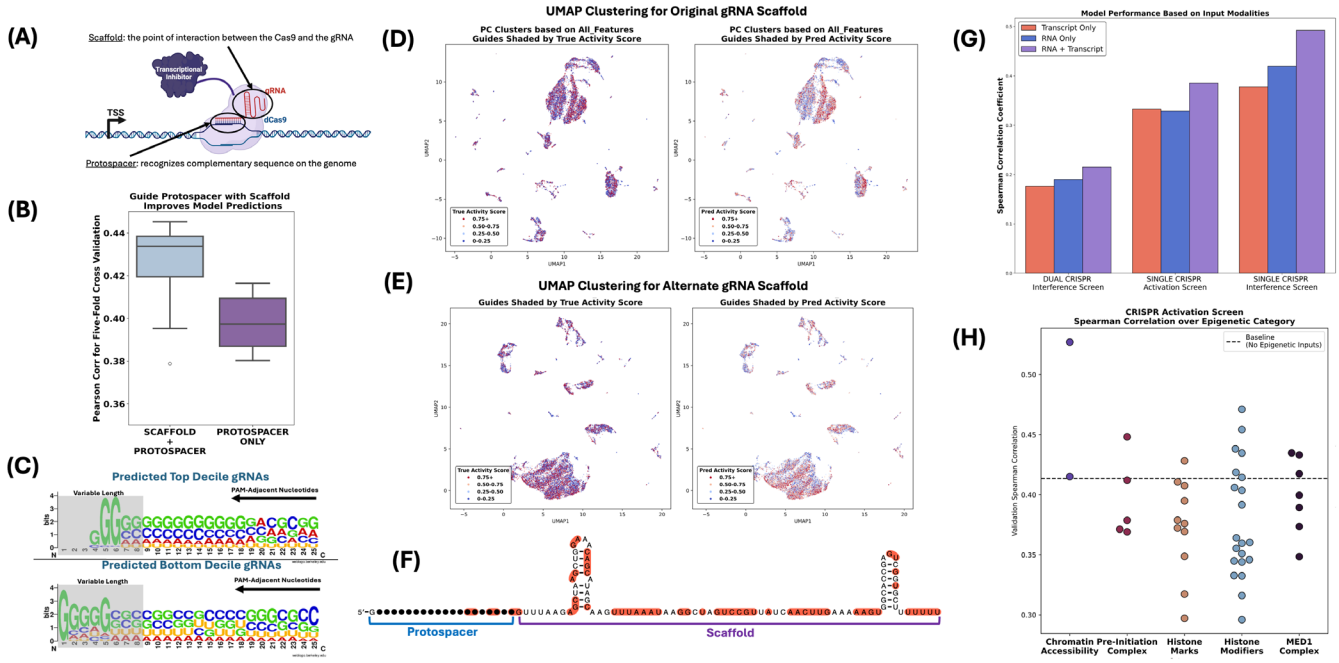

Figure 1: Model integration of RNA and epigenetic modalities reveals principles of CRISPR epigenetic interventions. (A) Depiction of gRNA scaffold and protospacer. **(B)** Input ablation indicates signifigance of gRNA scaffold features for predictions for single CRISPRi screen. **(C)** Motif enrichment of the top and bottom predicted gRNAs for the single CRISPRi screen indicate GC-richness in high performing gRNAs. **(D)** Cluster analysis of single CRISPRi screen guides based on RNA structure shows segregation of gRNAs based on true and predicted activity. **(E)** Clustering of gRNA protospacers with alternate (i.e.not utilized in the original screen) scaffold indicates loss of this segregation.**(F)** Nucleotides with the greatest model gradients were shaded along the gRNA structure, indicating model attention to nucleotides relevant to scaffold structure. **(G)** Integration of RNA with transcript annotation improves model performance for all screens **(H)** Multiple epigenetic features relevant to gene expression regulation are predictive of CRISPRa interventions.

1610 AI-Driven Engineering of RNA Control Systems for Precise Regulation of Gene Therapy Activity

Matthew Dale[1]*, Jessica Birt
[1]*Concinnity Genetics, GLASGOW, Glasgow City, United Kingdom*
**Corresponding Author*

The inability to regulate gene therapy activity after administration limits the ability to manage adverse effects, restricting both safety and therapeutic potential. One method for preventing these side effects is the use of gene control systems – sequences that are placed within the gene therapy cassette and allow transgene expression to be controlled in a defined manner. Such systems hold huge promise, with the potential to allow gene therapies to respond to disease state, tissue location, or clinically administered drugs. Achieving such precise control over gene therapies will be essential in overcoming their current limitations and enabling their broader application across diverse therapeutic areas.

RNA-based control systems in particular have significant advantages. They are compatible with a broad range of therapeutics from gene therapies through to mRNA therapeutics and gene editing, where conventional DNA-based control systems (e.g. synthetic promoters) cannot be used; their small size (< 150 bp) makes them highly compatible with space-constrained vectors such as AAVs; and they can be engineered to respond to a wide variety of molecules, making them applicable to a range of disease areas.

However, these types of control system are heavily underutilised in the gene therapy sector. The key reason for this is their difficulty to engineer, with high time and resource costs and low success rates, which has greatly limited their utility in the gene therapy sector to date. To address this issue, we have developed a high-throughput and AI-guided methodology that allows 10,000s of control system sequence variants to be rapidly screened in cell lines. Our AI algorithm uses this data to predict improved variants for further rounds of testing, and by iterating through this process highly effective control systems can be developed. Using this method, we have shown significant

improvements over existing control systems and demonstrated the functionality of new-to-human control systems in cell lines.

Our approach represents a transformative step forward in the development of RNA-based gene control systems, offering a scalable and efficient strategy to overcome key engineering challenges. By expanding the toolbox available for precise and fine-tuned gene regulation, gene control systems have the potential to enable the next generation of safer and more effective gene therapies.

1611 Engineering Synthetic Epigenetic Regulation to Enable State-Switching Genetic Programs in Mammalian Cells

Gauri Bora[1], Joshua Leonard[2]*
[1]Northwestern University, Chicago, IL, [2]Northwestern University, Evanston, IL
**Corresponding Author*

Engineered cell therapies are a promising frontier, with early successes in cancer treatment demonstrating the transformative potential of this approach. Most cell therapies today are programmed to express outputs at a steady-state; however, cells programmed with dynamic control of gene expression, such as state-switching, could enable implementation of novel therapeutic functionalities, such as autonomous stem cell differentiation or pulsating therapeutic delivery. In nature, eukaryotic systems have evolved epigenetic control as a solution for inducing, maintaining, and switching states, but these behaviors are challenging to implement in a synthetic, orthogonal context when building novel genetic programs. A reason this challenge arises is the lack of understanding as to how specific biological mechanisms interact; it remains unknown how the use of synthetic epigenetic- or chromatin-modifying domains can be composed into genetic programs to modulate the behavior of a cell. While previous work has generated quantitative insights for mapping biological understanding into these mechanisms, many fundamental design principles relating to implementation of epigenetic regulation remain unexplored. This leaves biologists with little intuition on how to construct genetic programs to encode cells with dynamic behaviors.

To address this need, we characterized and employed synthetic transcription factors (synTFs) that incorporate a library of repressing chromatin regulatory domains (CRD) fused to a panel of DNA binding domains that can be implemented with precise local composition using cognate promoters. These constructs were tested in HEK293FTs and primary T-cells. We explored key design criteria that will guide usage of these domains in genetic programs, including: (1) effect on gene expression and memory when recruiting both activating and repressing synTFs to a promoter; (2) synTF dominance due to temporal and spatial organizations; (3) variation in promoter binding site composition to modulate cooperative interactions. Though previous literature suggests synTFs with CRDs will silence most activated genes, we find varied levels of repression across different promoter types. Moreover, when recruited with an activating synTF, the spatial orientation of the synTFs and stoichiometry of each part greatly impacts the level of conferred silencing, revealing previously unknown rules of dominance of competing biological mechanisms. For example, KRAB, a well-known, potent repressor, was found to increase gene expression at certain stoichiometries when repressing VP64, an activating domain. Lastly, we hypothesized and assessed how multiplexing CRDs will improve or dampen gene expression. Using our unique testbed that allows for intricate promoter architecture, we discovered unique combinations of CRDs that can be leveraged to make versatile gene expression profiles with distinct memory and potency. This type of deep characterization will enable us to build more complex programs that require multiple handles to tune dynamic gene expression. Overall, these exhaustive design principles will guide the next phase of the project, in which we construct a small panel of state-switching programs with therapeutic utility. Achieving these important and sophisticated functionalities will be a crucial step towards building safer and more effective cell-based therapies.

1612 The Long and Short of It: Comparing Next Generation Sequencing Methods for Quality Control in AAV Development

Carrie Ziemniak[1], Andrea O'Hara[2], Elizabeth Louie[3], Haythem Latif[4], Ginger Zhou[5]
[1]Azenta Life Sciences, Burlington, MA, [2]Azenta, Burlington, MA, [3]Azenta Life Sciences, South Plainfield, NJ, [4]GENEWIZ from Azenta Life Sciences, South Plainfield, NJ, [5]Azenta Life Sciences

Interest in gene therapy-based disease prevention and treatment has grown rapidly over the last decade, with adeno-associated viral vectors (AAV) emerging at the forefront with widespread application due to the non-integrating ability. With safety as the top priority in all therapies, extensive quality control (QC) throughout the entire development and manufacturing process is essential. A robust QC process expedites safe and effective commercialization of the final product. While Sanger sequencing can be ideal to verify and validate plasmid sequences pre-packaging, next generation sequencing (NGS) combined with post-viral production methodologies such as CE analysis and transmission electron microscopy offer an effective high-throughput approach for monitoring AAV quality, from initial construct assembly to analysis of the encapsulated product. Illumina® short-read, Oxford Nanopore® long-read and PacBio® long-read sequencing technologies each offer distinct advantages including sequencing of the entire viral genome, with detection of potential mutations, truncations, and contaminants. Here we compare each of these applications as a means to assess the purity, clonality and fidelity of the packaged AAV product. When evaluating the same sample with Illumina, PacBio and ONT, we show how these methods compare with detection of contaminating alternatively packaged products, detection of point mutations and indels in the ITRs and region of interest, and detection of full-length vs partially packaged genomes. Based off these results, we also evaluate how sample quality and library preparation can influence the conclusions generated and describe when each method can be ideally used within the therapeutic development workflow, starting from early research to late-stage pre-clinical work. Additionally, we consider regulatory assays, with Good Laboratory Practices (GLP) methods being ideal for late-stage development products. Ultimately, a combined NGS approach post-packaging enables a comprehensive solution and enhances the overall QC process, ideal for sequence confirmation of both transfer plasmid and final packaged product for improved viral vector gene therapy manufacturing in advance of FDA or EMA filings.

1613 B-GEn is an Innovative Bayer Proprietary Genome Editor Suitable for CRISPR Applications and Therapeutic Developments

Sören Turan[1], Andreas Neerincx[2], Florian Richter[3], Saskia Markert[1], Timsi Rao[4], Philipp Knyphausen[5], Christien Bednarski[1], Jaishree Chittoor[6], Adnan Nurani[7], Sebastian Oliver[8], Xinyang Bing[9], Aastha Ravat[8], Kuei-Ling Tung[8], Benjamin Burnett[10], Tatiana Gelaf-Romer[10], David Sparfeld[11], Florian Mann[11], Corinna Stetzer[1], Sabine Tippelt[1], Corinna Saalwaechter[1], Maximilian Koch[1], Prabhakar Bastola[12], Jacqueline Frost[13], James Krantz[14], Holly Schroeder[15], Sophie Fahlenbock[16], Angela Mote[15], Alea Powell[13], Kelsey Higgins[14], Heidrun Ellinger-Ziegelbauer[1], Marian Raschke[1], Mark Tomishima[17], Scott Munzer[10], Marco Weinberg[18], Andre Cohnen[1]*

RNA-programmable nucleases from bacterial CRISPR systems, have helped revolutionize life sciences and offer enormous potential for therapeutic genome editing. Bayer has built a proprietary collection of >170,000 microbial assemblies and metagenomes, many of which are not represented in public databases.

We bioinformatically mined this collection for CRISPR loci and identified approximately 8000 systems, containing both previously known and new CRISPR effectors. We experimentally characterized ~100 nuclease candidates, ranging in size from 450 to 1100 amino acids (aa). A proprietary Bayer Gene Editing nuclease (B-GEn), a medium sized nuclease of 1091 aa with a 5'-ATTN-3' PAM, featured robust activity in mammalian cell lines, primary human cells, and mice. Engineered B-GEn, showed several folds higher indel activity on several disease targets without compromising its specificity.

We used B-GEn to edit a safe harbor locus in mice liver and find almost complete editing, at doses for which benchmark SpCas9 reagents yielded significantly lower editing. At the same time, we did not identify any detectable off-targets.

Next, we performed AAV-mediated insertion of a nano-luciferase reporter into this safe harbor in primary human cells and humanized transgenic mice. We found levels of transgene expressed that are consistent with therapeutic levels, on par with benchmark SpCas9 reagents. Furthermore, we packaged therapeutic payload in a well-established liver-tropic capsid to show robust insertional editing *in vivo* establishing a path forward for liver-targeted stable expression of therapeutic transgenes from this safe harbor.

In summary, B-GEn constitutes a valuable addition to the portfolio of CRISPR nucleases that may achieve therapeutic levels of insertional gene editing, potentially lending itself to development of therapeutic approaches.

1614 Engineering a Compact Gene Switch for Temporal Control of AAV-CRISPR Gene Editing

Yifan Ding[1], Zhenghui Li[1], Jenna Liang[2], Fengfeng Bei[3]*

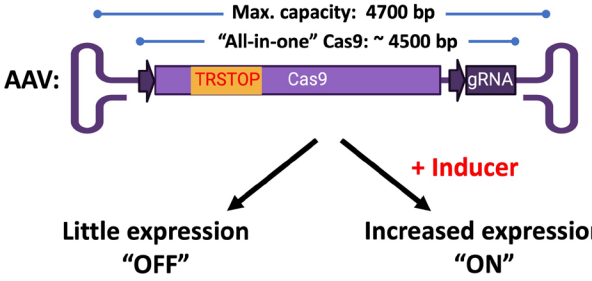
Gene therapy holds significant promise for treating human genetic disorders. To enhance the safety and effectiveness of gene therapy, there is an increasing need for gene switches that can provide “on-demand” control over gene therapy products. In this study, we aimed to engineer a gene switch by exploring the mechanism of stop codon readthrough. We began by investigating the efficiency of the three stop codons (UAA, UAG, UGA) in terminating protein translation using an in vitro cell culture assay. Consistent with previous research, we observed that all three stop codons exhibited low-level “leakiness,” allowing for termination readthrough under certain conditions. Notably, the stop codon UGA (TGA in DNA), when flanked by six virus-derived downstream nucleotides, demonstrated increased susceptibility to chemical modulation of its readthrough propensity. Building on these findings, we designed a novel two-component gene switch, termed "TREAD". TREAD consists of a nine-nucleotide DNA effector sequence containing the TGA stop codon, designed to be inserted into the gene of interest, and a chemical inducer (such as gentamicin or PTC124) that enhances TGA readthrough, effectively "switching on" gene expression. We tested the functionality of this gene switch by incorporating it into a CRISPR-Cas9 gene editing system. In experiments using Ai14 reporter mice, we demonstrated that the administration of AAV vectors expressing the switchable Cas9 and dual guide RNAs resulted in minimal background gene editing. However, when the chemical inducer PTC124 was administered over two weeks, we observed significant gene editing activity in tissues including the liver, heart, and skeletal muscles with edited cells persisting for at least five months. TREAD gene switch has several advantages, including its small DNA footprint, low immunogenicity risk, and the availability of safe chemical inducers. These attributes make it a promising tool for developing inducible gene therapies. Our ongoing research is focused on creating an inducible AAV-CRISPR gene editing therapy for cardiomyopathy associated with Friedreich ataxia, leveraging TREAD in conjunction with our newly engineered cardiotropic vector AAV.CPP.16.

Components of "TREAD", an AAV-CRISPR-compatible gene switch:
1) A DNA effector TRSTOP (9 base-pair long)
2) A clinically approved chemical "inducer" (e.g., PTC124)



TREAD-applicable AAV-CRISPR editing:
- Indel (e.g., saCas9, Nme2Cas9)
- Base editing (e.g., Nme2ABE8e, SaKKHABE8e, CjABE8e, SauriABE8e)

1615 hfCas12Max: Engineered CRISPR Nuclease for Safer and Effective CGT

Michael Molnar[1], Hainan Zhang[2], Hui Yang[3], Kevin Holden[4], Alvin Luk[5], TJ Cradick[6], Yingsi Zhou[7], Dong Yang[8]
[1]Synthego Corporation, Redwood City, CA, [2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China, Shanghai, Shanghai, China, [3]HuidaGene Therapeutics Co., Ltd., Shanghai, China; Shanghai Institute of Meteria Medica, Chinese Academy of Sciences, Shanghai, China, Shanghai, Shanghai, China, [4]Synthego, Redwood City, CA, [5]Huidagene Therapeutics Inc, Clinton, NJ, [6]HuidaGene Therapeutics, Clinton, NJ, USA; Cholgene Therapeutics, Middletown, DE, USA, Clinton, NJ; Middletown, DE, MA, [7]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China, Shanghai, China, [8]HuidaGene Therapeutics Co., Ltd., Shanghai, China, Shanghai, Shanghai, China

Background: In recent years, the continued exploration of new Class 2 CRISPR-Cas systems has resulted in the identification of Cas12i. Though Cas12i holds promise as for genome editing, enhancements in its efficiency and specificity are necessary for effective utilization.

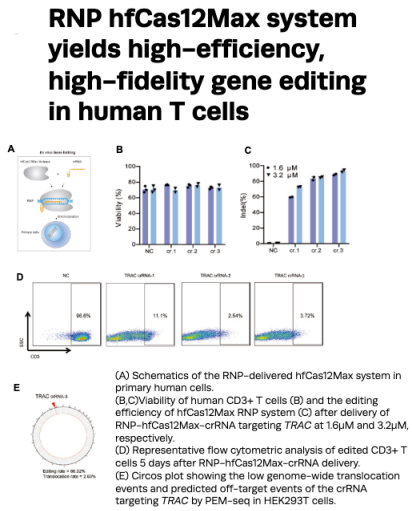
Methods: Leveraging HuidaGene's AI-driven, CRISPR-based – Platform for Rational Engineering of CRISPR-Cas Identification by Synergic Expertise (HG-PRECISE), a potent directed evolution system for both protein and guide RNAs (gRNAs), we developed hfCas12Max CRISPR nuclease, an engineered Cas12i, which recognizes 5'-TN-3' or 5'-TTN-3 PAMs with high editing activity and specificity in mammalian cells. Compared to Cas9 and Cas12a, hfCas12Max CRISPR nuclease is more compact, making it an ideal candidate for single adeno-associated viral (AAV)-based delivery. Here, we assessed the applicability of hfCas12Max CRISPR nuclease in creating gene editing therapies and cell therapies, incorporating multiple delivery methods such as AAV, lipid nanoparticle (LNP), and ribonucleoprotein (RNP). AAV is a commonly used gene-therapy delivery vehicle due to its proven efficacy, safety, and broad tissue targeting, including brain, skeletal, and cardiac muscle.

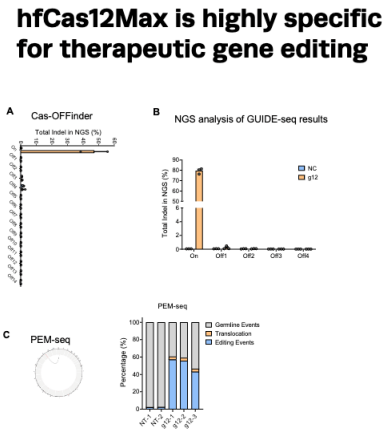
Results: After systemic delivery of a single all-in-one AAV vector that contained hfCas12Max CRISPR nuclease along with a gRNA targeting the splice donor (SD) site of the human *DMD* exon 51 in the Duchenne Muscular Dystrophy (DMD) mouse model, we observed efficient restoration of dystrophin expression. Histopathology and grip strength also showed significant improvement. Therapeutically acceptable editing efficiency in exon 51 SD was induced in a healthy wild-type non-human primate with a low dosage of AAV-hfCas12Max-gRNA without any observed hfCas12Max-related toxicity, indicating the relative safety of the AAV-hfCas12Max therapy.

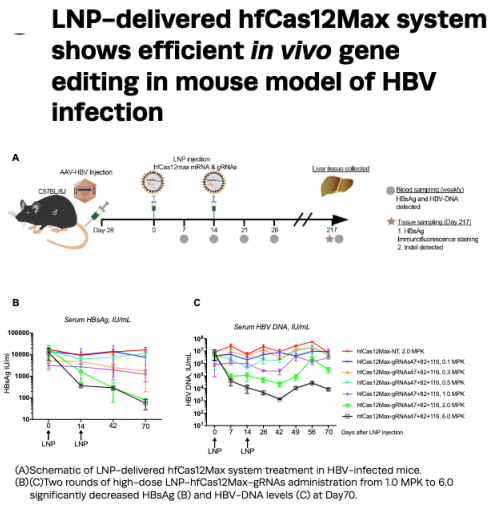
Safety and efficacy using hfCas12Max was also demonstrated in amyotrophic lateral sclerosis (ALS) studies. AAV containing hfCas12Max CRISPR nuclease and gRNA targeting the *ATXN2* gene considerably reduced toxic pTDP-43 protein aggregation to near-normal levels in the humanized *TDP-43*$^{Tg/Tg}$ mice, a widely used ALS mouse model. hfCas12Max CRISPR nuclease notably alleviated astroglial and microglial inflammation in the motor cortex, restored motor function, and significantly extended the lifespan of the humanized *TDP-43*$^{Tg/Tg}$ mice.

hfCas12Max safety and efficacy was also demonstrated targeting HBV using LNP-mediated delivery of hfCas12Max mRNA and gRNAs. Treatment led to a significant reduction in cDNA, HBV-DNA, and hepatitis B surface antigen (HBsAg) levels in HBV-infected primary human hepatocytes (PHH). Two rounds of LNP-hfCas12Max system administration resulted in a sustained reduction of serum HBsAg and HBV DNA levels in the AAV-HBV mouse model. In addition, by administering hfCas12Max RNP targeting the *TRAC* gene in primary human T cells, we detected approximately 90% editing efficiency in CD3+ T cells, with cell viability remaining around 80%. *In silico* and genome-wide off-target analyses, we have indicated the high specificity of hfCas12Max.

Conclusions: Our findings suggest that hfCas12Max CRISPR nuclease, with its robust editing activity and high specificity, is a promising tool for safer and more effective gene and cell therapy treatments. Synthetic guide RNAs and purified nuclease for hfCas12Max CRISPR nuclease are now readily available for CRISPR medicine developers through Synthego as







1616 Automated CRISPR/Cas9-based genome editing of human pluripotent stem cells using the StemCellFactory

Introduction: The CRISPR/Cas9 technology has become a leading method for efficient gene editing, allowing the creation of isogenic pairs of mutant and control human induced pluripotent stem cells (hiPSCs). While hiPSCs offer valuable opportunities for disease modeling and personalized medicine, challenges remain in distinguishing the effects of specific mutations from genetic backgrounds. Manual genome editing processes often face scalability, efficiency, and standardization limitations. StemCellFactory, a modular robotic system, has been developed to automate the reprogramming, expansion, and differentiation of hiPSCs, enhancing the application of CRISPR/Cas9 technology in research.

Methods: HiPSCs were cultured in StemMACS iPS-Brew XF medium on Geltrex or Matrigel-coated plates, with daily medium changes and mycoplasma testing. For CRISPR/Cas9 genome editing, target gene-specific CRISPR-RNA and tracrRNA were prepared to form ribonucleoprotein (RNP) complexes using an optimized nucleofection protocol. HiPSCs were dissociated with Accutase, counted, and subjected to manual and automated nucleofection. In manual editing, hiPSCs were nucleofected with the RNP complex using a Lonza 4D-Nucleofector, followed by cell seeding into tissue culture plates for culturing monoclonal single cell colonies. The automated process on the StemCellFactory involved three subprocesses: cell preparation, nucleofection, and cell seeding, utilizing a robotic arm for material transport. The control software COPE managed the integrated hardware, enabling the execution of commands and data visualization and facilitating the automated genome editing process. Post-editing and genotyping of polyclonal hiPSCs were performed via Sanger sequencing to assess editing efficiency. Automated isolation of monoclonal colonies was conducted using the StemCellFactory-integrated CellCelector, which identified and isolated colonies meeting the specified criteria.

Results: The StemCellFactory successfully integrated a 4D-Nucleofector with a 96-well shuttle device to enable automated CRISPR/Cas9 genome editing. Adjustments were made to replace manual consumables with scalable formats, enhancing efficiency. Optimal conditions for automated editing were determined, showing that the CM150 electroporation program yielded high cell viability (83.5%) and indel rates (81.7%). The best culture conditions combined Laminin 521 with CloneR-supplemented iPS-Brew medium, supporting single hiPSC survival and colony formation. The automated workflow system allowed for the parallel processing of up to 24 independent conditions. Validation of the automated process using various hiPSC lines and target genes demonstrated high editing efficiencies, with indel rates exceeding 80% across all tested cell lines, comparable to manual methods. Monoclonal colonies were monitored using the CellCelector, allowing for the isolation of colonies derived from single cells.

Conclusions: These findings indicate the successful establishment of an automated CRISPR/Cas9 genome editing process on the StemCellFactory platform. The editing efficiency assessed across different hiPSC lines and numerous target genes was consistent with manual methods. Developing such a standardized and scalable automated system represents an exciting new tool in genome editing, enhancing the ability to address a wide range of scientific questions in disease modeling, drug development, and personalized medicine.

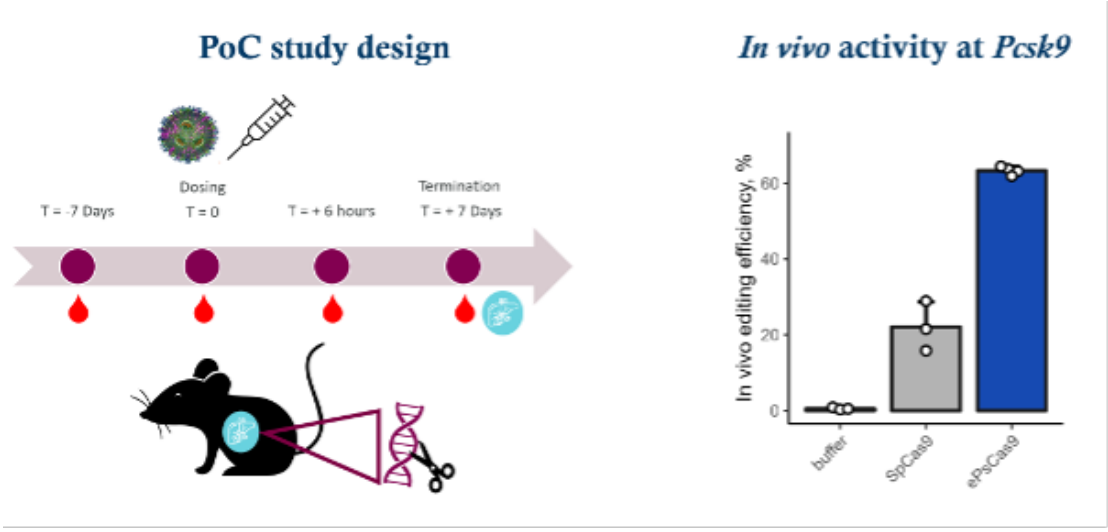
1617 PsCas9 (eSpOT-ON): An Engineered High-Fidelity CRISPR Nuclease for Therapeutic Applications.

Pinar Akcakaya[1], Kevin Holden[2], **Catherine Morffy Smith[3]**, Marcello Maresca[4], Grzegorz Sienski[5]
[1]AstraZeneca, Gothenburg, Sweden, [2]Synthego, Redwood City, CA, [3]Synthego Corporation, Chicago, IL, [4]AstraZeneca-Gothenburg, Moelndal, Sweden, [5]AstraZeneca, MoIndal, Sweden

CRISPR-Cas technologies offer great potential for therapeutic genome editing. However, most Cas enzymes have not achieved sufficient in vivo activity for clinical applications. Our previous work introduced PsCas9 (SpOT-ON), a Type II-B Cas9 from *Parasutterella secunda*, as a high-fidelity enzyme. PsCas9 delivered via adenoviral vectors achieved editing levels comparable to SpCas9, with minimal off-target events and reduced chromosomal translocations.

In this study, we sought to understand why PsCas9 delivery methods beyond adenoviral vectors showed reduced efficacy. Cellular studies revealed that PsCas9 editing activity was limited under conditions of low intracellular concentration. Biochemical assays showed that PsCas9 has a lower DNA-binding affinity compared to SpCas9. We hypothesized that improving DNA interaction could enhance PsCas9 activity. To address this, we leveraged structural information to fuel the rational engineering of the enzyme. Optimizing the sgRNA scaffold modestly increased PsCas9 activity. In contrast, targeted mutagenesis resulted in up to a 20-fold enhancement across multiple genomic targets. These improvements correlated with stronger DNA binding in vitro. Importantly, the engineered PsCas9 retained its high fidelity, including low off-target effects and minimal chromosomal translocations. Finally, we tested the optimized PsCas9 (also referred to as ePsCas9 or eSpOT-ON) for therapeutic genome editing in vivo. Using lipid nanoparticles (LNPs), we delivered ePsCas9 to mouse liver to target the Pcsk9 gene, a model for hypercholesterolemia treatment. ePsCas9 achieved efficient liver editing and significantly reduced Pcsk9 protein levels in plasma, outperforming SpCas9 in this setting.

This work establishes ePsCas9 as a precise and efficient genome editor. Its enhanced activity and intrinsic fidelity make it highly suitable for therapeutic applications. Synthetic guide RNAs and purified nuclease for eSpOT-ON / ePsCas9 are now readily available for CRISPR medicine developers through Synthego as part of a strategic partnership with Astrazeneca to enhance the accessibility of these CRISPR tools.

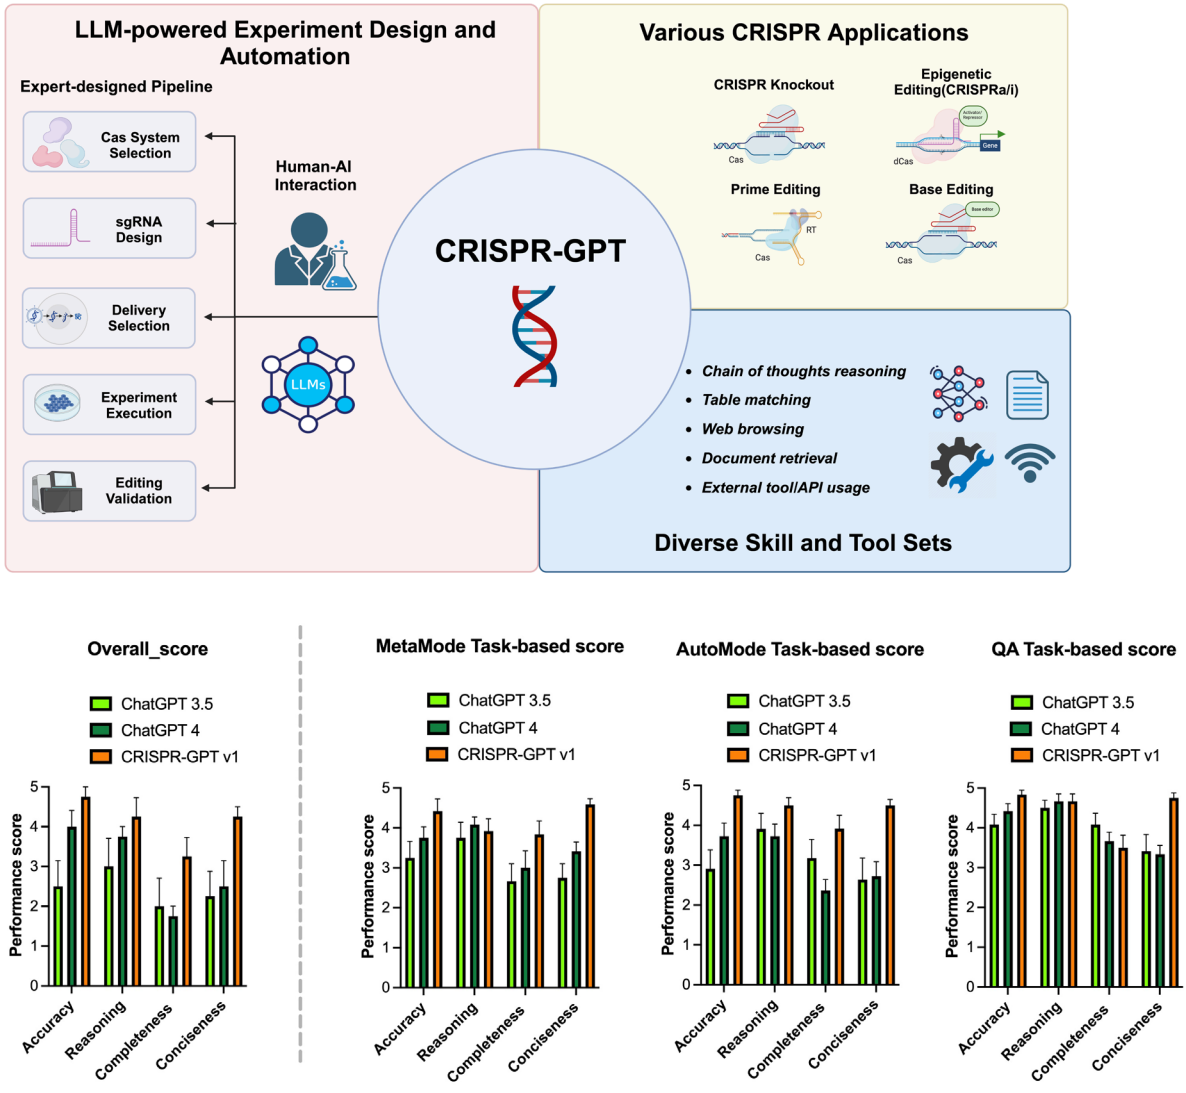


1618 CRISPR-GPT: LLM Agents for Automated Design of Gene-Editing Experiments

Yuanhao Qu[1], Kaixuan Huang[2], Ming Yin[2], Kanghong Zhan[3], Dyllan Liu[3], Di Yin[1], Henry Cousins[1], William Johnson[4], Xiaotong Wang[5], Russ Altman[1], Denny Zhou[6], Mengdi Wang[2]*, Le Cong[7]*
[1]Stanford University, Stanford, CA, [2]Princeton University, Princeton, [3]UC Berkeley, Berkeley, [4]Stanford University Laboratory for Cell & Gene Medicine - Palo Alto, CA, Stanford, CA, [5]Stanford University, Palo Alto, CA, [6]Google, Mountain View, [7]Stanford University Stanford, California
**Corresponding Author*

Genome engineering has revolutionized biomedical research by enabling precise genetic modifications, yet designing effective CRISPR experiments remains complex, requiring deep expertise in both gene-editing technology and biological systems. While Large Language Models (LLMs) offer broad capabilities, they often lack the domain-specific knowledge needed for complex biological design tasks. To address this gap, we introduce CRISPR-GPT, an AI-driven system that automates and enhances CRISPR-based gene-editing design and data analysis (Figure 1). CRISPR-GPT leverages the reasoning power of LLMs for task decomposition, decision-making, and interactive human-AI collaboration. It employs a multi-agent framework incorporating domain expertise, retrieval techniques,

external tools, and a specialized LLM fine-tuned with a decade of gene-editing discussions. This system assists in CRISPR selection, experiment planning, gRNA design, delivery optimization, protocol drafting, assay development, and data analysis. Compared to general LLMs like GPT-4o, CRISPR-GPT's agentic framework significantly improves accuracy, completeness, reasoning, and conciseness, as evaluated by gene-editing experts (Figure 2). To validate its effectiveness, beginner researchers successfully knocked out four genes in A549 cells using CRISPR-Cas12a, achieving 80–100% efficiency, and epigenetically activated two genes in A375 cells with CRISPR-dCas9, reaching 56.5% and 90.2% efficiency—on their first attempt. These results demonstrate the feasibility of AI-guided genome engineering, positioning CRISPR-GPT as a powerful AI co-pilot for CRISPR research, even for users with minimal prior experience.



1619 Standardized methods in iPSC for CRISPR-based editing and Homology-Directed Repair (HDR)

Karthik Murugan[1], Bernice Thommandru[1], Steve Glenn, Jessica Woodley[1], Garrett Rettig
[1]*Integrated DNA Technologies, Coralville, IA*

CRISPR-based gene editing and homology-directed repair (HDR) are used in several drug-discovery, pre-clinical, and clinical investigations to modify the genomes of stem-cell-based models. However, there is a critical need for standardized CRISPR reagents and protocols for making precise changes with high efficiencies in therapeutically relevant cell types. Here, we report the use of Alt-R™ CRISPR reagents such as Cas nucleases, synthetic guide RNAs, chemically modified HDR templates and HDR enhancers with optimized methods in various cell types including iPSC. We also showcase the application of rhAmpSeq™ CRISPR analysis system that provides a streamlined workflow for high throughput, targeted NGS-based screening of editing outcomes and HDR rates in any cell type of interest. Our optimized methods for iPSCs were also used for functional testing of Cas9 guide RNAs synthesized at IDT's therapeutic oligonucleotide manufacturing facility.

1620 *Tales from the R-loops*: how RNA/DNA hybrids may influence CRISPR/Cas9-mediated homologous recombination gene editing outcomes

Francesco Puzzo[1], Hagoon Jang[2], Feijie Zhang[3], Mark Kay[4]
[1]Stanford University, Stanford, California, [2]Stanford University, Stanford, CA, [3]Stanford University School of Medicine, [4]Stanford University School of Medicine, Stanford, CA

R-loops have been implicated in influencing genomic integration of recombinant adeno-associated viral (rAAV) vectors (*Puzzo et al., Mol. Ther., 2024*). Using DNA-RNA immunoprecipitation sequencing (DRIP-seq), we have mapped the R-loop formation in murine hepatoma cells (HEPA1-6) and mouse liver tissue *in vivo*. Our findings revealed that elevated R-loop levels enhance AAV-mediated nuclease-free homologous recombination (AAV-HR), particularly in R-loop-enriched regions such as the 3' end of the *Albumin* gene. Additionally, we demonstrated that HEPA1-6 cells exhibited significantly higher R-loop levels compared to murine liver.

To extend this work, we investigated the impact of R-loop formation on CRISPR/Cas9-mediated gene editing. Using HEPA1-6 cells and transgenic mice constitutively expressing *Streptococcus pyogenes* Cas9 (SpCas9), we designed guide RNAs (gRNAs) targeting two distinct regions of the murine *Albumin* gene: the mid-region (Mid Alb, exons 8–9) and the 3' region (3' Alb, exons 13–14), characterized by low and high R-loop levels, respectively (*Puzzo et al., Mol. Ther., 2024*).

Self-complementary AAV vectors expressing the gRNAs were utilized to assess the influence of R-loops on SpCas9-induced double-strand breaks (DSBs). Both *in vitro* and *in vivo* experiments revealed no significant differences in indel formation between the Mid Alb and 3' Alb regions.

To further evaluate the effect of R-loops on homology-directed repair (HDR)-mediated gene editing, donor DNA cassettes were designed for each target region. *In vivo* AAV-mediated delivery of gRNAs and donor DNA did not show significant differences in gene targeting efficiency between the two regions. However, in HEPA1-6 cells, integration rates were significantly higher in the Mid Alb compared to the 3' Alb region. Notably, overexpression of RNaseH1, which degrades genome-wide R-loop structures, enhanced gene editing efficiency at the 3' Alb without affecting the Mid Alb region. These results were in stark contrast to non-nuclease mediated AAV-HR, which was substantially higher in 3' Alb region (*Puzzo et al., Mol. Ther., 2024).*

Our current hypothesis is that high levels of R-loops at the 3'Alb in the HEPA1-6 could potentially inhibit the HDR mediated by SpCas9 and have studies in progress to address this question. Given the overall higher R-loop levels and active replication in HEPA1-6 cells compared to murine liver, we investigated the relationship between R-loop levels and cell cycle progression. Rapamycin treatment showed cell cycle arrest primarily at the G1/S phase and significantly reduced R-loop levels in HEPA1-6 cells. Our ongoing experiments are designed to determine whether the combination of cell cycle arrest and reduction in R-loop levels might influence the gene editing efficiencies at the Mid Alb and 3' Alb regions. Our new preliminary results highlight the potential interplay between R-loop formation, cell cycle status, and the efficacy of gene editing outcomes. Our findings provide novel mechanistic insights that could help design more effective gene editing strategies.

1621 Chemically Modified and Ligated Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Guide RNAs (LgRNA) and Their Anti-HBV Activities

Minghong Zhong[1], Qiong Zhao[2], Yueyang Jin[3], Xiaoyun Lin[1], Ju-Tao Guo[4]
[1]GeneLancet Biosciences, Inc., Doylestown, PA, [2]Baruch S Blumberg Institute, Doylestown, PA, [3]University of North Carolina, Chapel Hill, Chapel Hill, NC, [4]Baruch S. Blumberg Institute, Doylestown, PA

Cure of chronic hepatitis B requires elimination or inactivation of both HBV cccDNA and integrated HBV DNA. Several CRISPR/Cas DNA editing-based therapeutics are currently under preclinical development in hope to achieve this therapeutic goal. To improve the gene editing efficiency and accuracy, we optimize guide RNAs through chemical ligation of short RNA segments via non-phosphoramidite chemistry, i.e., ligated guide RNA (LgRNA), and chemical modifications. Compared to the classical single guide RNA (sgRNA), our proprietary LgRNA technology provides high-quality products (>99% purity by HPLC) containing a single spacer sequence and enables cost-effective scaleup productions (potentially multiple kilograms), diverse chemical modifications, targeted delivery by conjugations and various formulation technologies. We have reported the exceptional anti-HBV activity of LgRNA-33 by multiple mechanisms of action (MOA). LgRNA-33 used in our previous report was terminally modified only. In order to further improve LgRNA's drug properties, we have modified LgRNAs at sugar moieties, nucleotide bases, and by conjugations with peptides such as nuclear localization sequences (NLS).

We have firstly designed and evaluated full modifications at the sugar moieties of 11 nucleotides of the PAM-distal region. We have observed LgRNA with most of modified sugar moieties (Fig. 1) maintained the activity despite heavy modifications, which can be beneficial for improving guide's in vivo stability and decreasing the host immune responses.

Based on the crystal structures of substrate-Cas9-sgRNA tertiary complexes showing the major groove of RNA/DNA duplex is accessible for additional molecular interactions (Fig. 2), we incorporated both G-clamps (cytosine analogues of 9-(2-aminoethoxy) phenoxazine and 9-(2-guanidinoethoxy) phenoxazine) and locked 5-methyl-cytidine (LA-5mC) modifications at various positions. G-clamp modifications showed significant increase in the guide's targeting specificity, while LA-5mC modifications introduced additional off-targets in at least one example. LgRNAs with G-clamp modifications in general showed better activities than with LA-5mC modifications. No cytotoxicity was observed.

Syntheses and evaluations of LgRNA-peptide (NLS) conjugates in an in vitro cleavage assay and their anti-HBV activities in hepatocytes will also be reported.

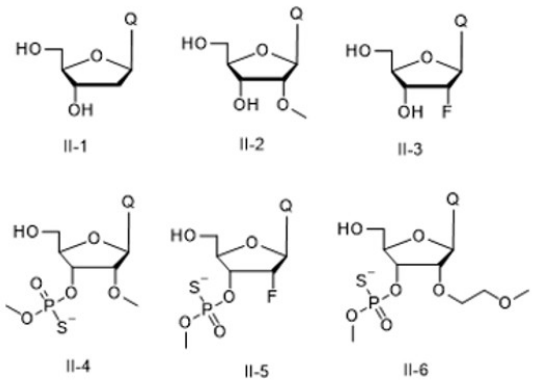


Fig. 1 Modified nucleotides. II-1 is a DNA nucleotide. II-2 has 2'-methoxy modification. II-3 has 2'-F substitution. II-4 has 2'-methoxy phosphorothioate modification (MS). II-5 has 2'-F phosphorothioate modification (FS). II-6 has 2'-ethoxymethoxy phosphorothioate modification (MoeS).

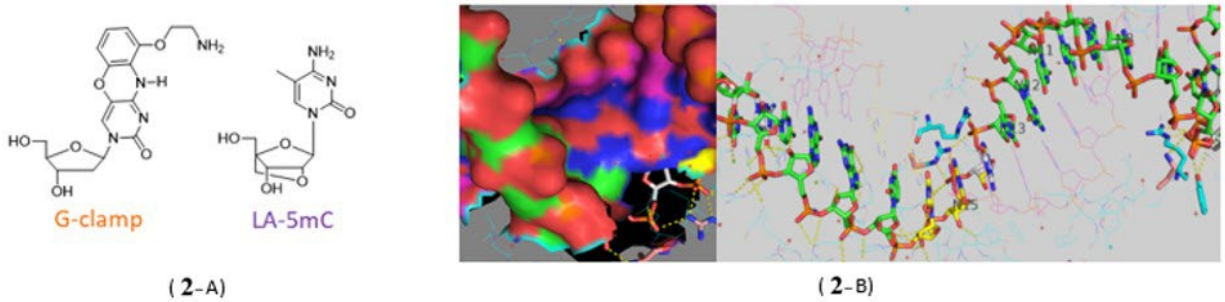

Fig. 2 Base modifications of spacer region. Structure of G-clamp and LA-5mC(2-A) and binding of RNA/DNA duplex to Cas9 protein (2-B). The major groove shows accessible space for base modifications to enhance base recognitions (20-B).

1622 Constructs of Chemically Ligated Guide RNAs (LgRNA) for Precise Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Gene Editing

Yueyang Jin[1], Hongsheng Zhao[2], Xiaoyun Lin[3], Minghong Zhong[3]*
[1]University of North Carolina, Chapel Hill, Chapel Hill, NC, [2]University of Southern California, Los Angeles, CA, [3]GeneLancet Biosciences, Inc., Doylestown, PA
**Corresponding Author*

The clustered, regularly interspaced short palindromic repeats (CRISPR) gene editing has the potential to cure many diseases of unmet needs, as indicated by the first approval of CRISPR-edited medicine (Casgevy). CRISPR-Cas9 is directed by a guide RNA (sgRNA) to its targeting site, and the sgRNA is a vital drug substance of in vivo CRISPR therapeutics. However, sgRNA (~100 nt) presents unprecedented chemistry, manufacturing and control (CMC) challenges. The available commercial scales are at grams with overall isolated yields of single digits (< 6%), and the best purity available in the industry is below 50% by LC-MS in spite of reported above 80% purity by High-Performance Liquid Chromatography (HPLC) methods, which do not resolve impurities even with lengths of 5 nt shorter (i.e., 95mer). Importantly, many truncated products and products of invalid sequences (97-101mer) are biologically fully active leading to guide-dependent catastrophic off-targets. Lately developed CRISPR editors such

as Prime editor requires guide RNAs significantly longer (>160 nt for epegRNAs), while there are rarely vendors capable of providing chemically modified RNAs longer than 160 nt. Chemically ligated guide RNA (LgRNA) is our distinct proprietary intellectual property to enable state-of-the-art precise CRISPR gene editing. LgRNA is a single molecule guide RNA comprising short oligonucleotide segments joined by one or more non-nucleotide Linkers (nNt-Linker). One example is an LgRNA incorporated with a single nNt-Linker between a crRNA and a tracrRNA (both shortened) or at another site by a chemical ligation. Others have observed the structures (e.g., tetrazine-derived linkers) and locations of an nNt-Linker (e.g., between the spacer and the guide scaffold, G21U22) can decrease the activities of resulting guides, though the decrease in activity was reported to be recoverable by further modifications.

Herein we report our efforts in optimizations of nNt-Linkers (Fig. 1). We have observed an nNt-Linker can enhance guide's activity at different locations including the spacer region, and multiple nNt-Linkers can substitute nucleic acid components of guide RNAs with no loss of guide's activity. The crRNA segment of an often-used LgRNA is 32 nt long, while tracrRNA (68 nt) is still long. We showed tracrRNA can be further divided into shorter segments (e.g., 36 nt and 22 nt), and such short RNA segments of high quality with refined chemical modifications are routinely manufactured in kilograms in industry. This segmented nucleic acid strategy of multiple nNt-Linkers has been applied to productions of high-purity long guide RNAs in prime editing (epegRNA of >160 nt, Fig. 2) and of chimeric guides (RNA-DNA conjugates) in STAR editing (STAR editing guide nucleic acids (segNA) of >180 nt) by this team. The chemically ligated epegRNA (lg-epegRNA) showed similar activity to an all-RNA guide, while STAR editor guided by a segNA showed ~20% precise editing in hepatocytes with further optimizations in progress.

In summary, we have demonstrated LgRNA having nNt-Linkers at various positions is superior to sgRNA and LgRNA technology provides scalable and efficient access to long guide RNAs (epegRNA and segNA) with minimal off-target-causing impurities, which are critical for their clinical applications. We expected LgRNA to be a critical component of CRISPR therapeutics, including prime editors and STAR editors.

1623 Engineering the sgRNA Scaffold to Enhance Editing Efficiency in CRISPR/Cas9-Based Gene Therapy

Max Levine[1], Ze Cheng[2], Tim Hoey[3], Kathy Ivey[3], Huanyu Zhou[2]
[1]Tenaya Therapeutics, San Francisco, CA, [2]Tenaya Therapeutics, South San Francisco, California, [3]Tenaya Therapeutics, South San Francisco, CA

Gene therapy has emerged as a promising approach for the treatment of genetic disorders, offering potential cures for conditions previously thought untreatable. Recent advances in gene editing technologies, particularly CRISPR-based systems, have made significant strides in improving the precision and efficacy of therapeutic interventions. Despite these advances, however, challenges remain in achieving consistently high editing efficiencies, particularly for certain diseases that require precise and large-scale genetic modifications. Low editing efficiencies, especially within specific targets, can limit the clinical applicability of gene therapies for a wide range of conditions, preventing the development of this potentially curative approach.

To address this challenge, our work focuses on engineering the single guide RNA (sgRNA) portion of the CRISPR/Cas system to increase editing efficiency within the *Staphylococcus aureus* derived CRIPSR/Cas9, SaCas9. Specifically, we explore the potential of synthesizing a library of sgRNA mutants that have an altered scaffold region to enhance the system's performance. The scaffold region of the gRNA, though relatively small in terms of base pairs, plays a critical role in the stability, specificity, and efficiency of the CRISPR/Cas9 via its distinct tertiary structure. Because of its compact size, the scaffold region presents a unique opportunity for targeted mutagenesis; subtle changes within this small region can significantly impact the Cas9-sgRNA interaction, leading to improved performance without affecting the overall structure of the sgRNA or its ability to guide Cas9 to the target sequence.

By generating a library of scaffold mutants, we aim to systematically explore a wide array of sgRNA variants to identify those that enhance the overall editing efficiency of the CRISPR/SaCas9 system. The mutational library approach leverages the small, 76 base pair size of the scaffold region to rapidly identify sequences that may outperform the wildtype scaffold. This approach allows us to focus on a region that directly influences Cas9 binding without needing to redesign the entire sgRNA, alter the target sequence, or engineer the Cas9 enzyme, offering a more efficient and targeted strategy for improving gene editing.

We hypothesize that modifying the sequence, and thus the structure of the sgRNA scaffold will enhance the specificity and overall editing efficiency of SaCas9, providing a valuable tool for fine-tuning CRISPR systems for different therapeutic contexts. Preliminary results from two mutational screens have identified ~300 mutants that display enriched editing scores above wildtype based on next generation sequencing data. Moreover, we have performed quantitative and functional assays to confirm the viability of mutants identified from our screen.

1624 Engineering SpCas9 to be Compatible with sgRNAs with Shorter Constant Regions

Steve Glenn[1], Christopher Vakulskas[2]
[1]Integrated Dna Technologies, Coralville, IA, [2]Integrated DNA Technologies Inc

Despite the constantly growing CRISPR-Cas toolset, Cas9 from *Streptococcus pyogenes* remains one of the most commonly used enzymes for genome editing. SpCas9 is guided to a 23-nt DNA target sequence by a two-part guide RNA (gRNA) complex consisting of a 42-nt CRISPR RNA (crRNA) containing a target site-specific 20-nt complementary RNA region (spacer region) and a universal ~89-nt trans-activating CRISPR RNA (tracrRNA). It was found that the 20 nt spacer plus 12 nt of the crRNA constant region could be joined to a 60 nt segment of the tracrRNA using a 4 nt linker to form a functional single-guide RNA (sgRNA). Expression of sgRNAs in mammalian cells is typically done using a U6 promoter and a poly-T terminator resulting in the addition of on average 4 U's to the end of the guide resulting in a ~100 nucleotide sgRNA. Chemical synthesis of sgRNAs provides the advantage of being able to incorporate chemical modifications to improve guide stability and enhance editing rates however it also comes with a tradeoff between guide length and yield of full-length product. This becomes particularly problematic for production of the 125+ nucleotide guides regularly used for prime editing or of gram scale amounts of high purity guides for applications like *in vivo* editing. Reducing the length of the guide constant region needed to

facilitate Cas9 activity would help ameliorate this issue. To generate a Cas9 variant with strong nuclease activity when paired with guides with a reduced length constant region we generated a Cas9 mutant library and used a bacterial screen where Cas9 nuclease activity with short constant region guides was linked to bacterial survival. We identified multiple beneficial mutations that we subsequently validated as improving the activity of Cas9 in human cells using guides with constant regions shorter than 55 nucleotides. Combining these mutations resulted in the identification of a variant that retains high levels of editing activity when paired with short constant regions guides and delivered as a ribonucleoprotein complex into human cells.

1625 Infusion of Sso7d DNA-Binding Protein Boosts Gene Editing Efficiency of the Engineered Hypercompact OsCas12f (enOsCas12f) in Mammalian Cells

Dabbu Jaijyan[1], Xinxu Yuan[1], Jian Xu[1], Abdul Rasheed[1], Danmeng Zhang[2], Yuekun Li[1], Abdul Baloch[1], Fang Li[1], Binhua Ling[3], Wenhui Hu[1]*

Compact CRISPR/Cas editors offer significant advantages in viral packaging and targeting efficiency. The hypercompact Type V-F CRISPR-Cas12f is emerging as a promising genome editor for gene therapy, especially with small-capacity viral delivery vectors like adeno-associated virus (AAV). Initially, Un1Cas12f (529 aa) from an *uncultured archaeon* cleaved ssDNA exclusively, with later studies showing nuclease activity (dsDNA) in prokaryotic but not eukaryotic cells. Protein engineering and sgRNA scaffold modifications have since enhanced Un1Cas12f's editing efficiency in mammalian cells. Similar improvements were seen in AsCas12f from *Acidibacillus sulfuroxidans* (422 aa) and OsCas12f from *Oscillibacter sp.* (433 aa). Our previous study using the LoxP-STOP-LoxP-tdTomato (LSL-tdT) reporter system validated high editing efficiency (>85%) of enhanced OsCas12f (enOsCas12f) in mammalian cells with transient transfection of the LSL-tdT reporter. A non-specific dsDNA binding protein, Sso7d, when fused with Cas nucleases, has been shown to improve gene editing efficiency of spCas9, cjCas9 and nme2Cas9(Yin et al. 2023) or the transcriptional activation of dUn1Cas12f(Hu et al. 2024) and dspCas9(Yin et al. 2023). To improve enOsCas12f's editing efficiency on endogenous integrated target genes (10-15%), we fused to the C-terminus of enOsCas12f, creating SosCas12f. This modification significantly increased genome editing efficacy to 50-60%, as determined by quantitative confocal imaging and PCR fragmental genotyping in mouse microglia cell line SIM-9A stably expressing the LSL-tdT reporter and primary neural stem cells from LSL-tdT Ai14 mice. Additionally, we constructed an all-in-one AAV vector encoding SosCas12f and quadruple sgRNAs targeting LTRa, LTRc, Gag, and Pol of the SIV genome. Using the SIVmac-239-eLuc reporter assay, we found that SosCas12f robustly increased SIV genome eradication efficiency compared to enOsCas12f alone. These findings suggest that the enOsCas12f-Sso7d fusion exhibits superior genome editing activity and therapeutic potential. This innovative SosCas12f construct can be efficiently packaged into AAV, advancing CRISPR/Cas gene therapy applications. **Acknowledgements:** This study is supported by NIH R01MH130193 and R01DA056876 funding.

1626 Optimizing knock-in efficiency of therapeutic transgenes using novel Cas9 fusion proteins

Federica Esposito[1], Roberto Di Cunto[2], Stefano Auricchio[3], Arjun Padmanabhan[4], Fabio Dell'Aquila[5], Alberto Auricchio[6]
[1]TIGEM, Naples, Campania, Italy, [2]TIGEM, Naples, Roma, Italy, [3]Tigem, Pozzuoli, Napoli, Italy, [4]Fondazione Telethon, Napoli, Campania, Italy, [5]TIGEM, Portici, Campania, Italy, [6]TIGEM, Telethon Institute of Genetics and Medicine, Roma, Roma, Italy

Homology-independent targeted integration (HITI) is a powerful genome-editing system enabling precise DNA integration without relying on homology-directed repair. We have demonstrated the potential of adeno-associated viral vector-mediated HITI (AAV-HITI) to target effectively gain-of-function mutations in a mouse model of autosomal dominant retinitis pigmentosa. Additionally, we have shown that AAV-HITI results in sustained lysosomal enzyme expression under conditions of hepatocyte proliferation in a mouse model of lysosomal storage

disease. Despite its potential, HITI efficiency may be insufficient for applications that require high transgene expression.

To overcome this challenge, we have engineered the *Sp*.Cas9 nuclease by fusing it to critical components of the non-homologous end joining (NHEJ) and microhomology-mediated end joining (MMEJ) pathways. These innovative fusion proteins are engineered to promote the targeted recruitment of a specific repair pathway at Cas9-induced double-strand breaks (DSBs), with the intent to enhance knock-in of a desired donor DNA.

In vitro data suggest a mild improvement in donor DNA integration when the *Sp*Cas9 fusion leverages the MMEJ pathway. Building on this, we will design and evaluate a panel of fusion proteins incorporating additional key repair factors from the same pathway whichwill be then tested in relevant mouse models of inherited retinal and liver diseases.

This study seeks to expand the scope of current knock-in approaches by developing more efficient, mutation-independent strategies for the treatment of genetic disorders.

1627 Engineering an Improved Inhibitor of 53BP1 to Enhance HDR Efficiency

Joe OBrien[1], Steve Glenn*, Adam Brainard[1], Vaughn Thada[2], Michael Collingwood, Bernice Thommandru[1], Karthik Murugan[1], Christopher Vakulskas[3]

One of the most common methods for achieving precise genome editing is by creating a double-strand break using a targeted nuclease that is then repaired by endogenous cellular double-strand break repair machinery using a supplied template with the desired edits. The cell has two primary methods of repair of double-strand breaks, non-homologous end joining (NHEJ) in which broken DNA ends are directly joined together and homology directed repair (HDR), which encompasses a number a of different pathways that use a DNA template to facilitate repair. The rate of HDR varies by cell type and target site within the genome and limits the efficiency of some genome editing strategies. The protein p53-binding protein 1 (53BP1) plays a critical role in determining if a break is repaired by HDR or NHEJ. 53BP1 is recruited to sites of double-strand breaks and inhibits end resection, a key initial step in HDR. A modified variant of ubiquitin (i53) was shown to block 53BP1 recruitment to the broken DNA ends and to enhance the rate of HDR when delivered as mRNA or plasmid. We tested i53 and found that it did not function as well when delivered as purified protein. To improve the efficiency of 53BP1 inhibition, we performed a two-hybrid screen to identify ubiquitin variants with improved affinity for binding to 53BP1. Based on this screen, we developed ubiquitin variants with improved efficacy for enhancing HDR when delivered as protein during nucleofection. We found that our improved ubiquitin variant (Ubv-A) was able to improve rates of HDR in multiple cell types and using multiple types of donor template. We also did not observe the cytotoxicity or off target effects we observed with a small molecule inhibitor of NHEJ. We envision that our ubiquitin variants targeting 53BP1 can be a valuable tool for *ex vivo* genome editing, where both high efficiency and cell viability are needed and the effects of blocking NHEJ are a potential concern.

1628 Optimizing phenotype and function of non-viral CRISPR-Cas9 *TRAC*-replaced CAR T cells by pharmacological tyrosine kinase inhibition during ex vivo expansion

Laura Hartmann[1], Jonas Kath[2], Maik Stein[3], Alice Vitali[4], Annette Kuenkele[5], Dimitrios Wagner[6]
[1]Baylor College of Medicine, Berlin, Berlin, Germany, [2]Charité - University Medicine Berlin, Berlin, Germany, Germany, [3]Berlin Institute of Health at Charite, Berlin, Berlin, GERMANY, [4]Charité - University Medicine Berlin, Berlin, Berlin, Germany, [5]Charite University Hospital Berlin, Germany, [6]Baylor College of Medicine, Houston, TX

CAR-T cell therapy has revolutionized the treatment of B cell malignancies, however it has been less effective in solid tumors. Tonic signaling describes antigen-independent signaling of CAR molecules, which promotes premature differentiation ex vivo, that has been associated with reduced in vivo efficacy of certain CAR constructs. Previous studies demonstrated that tyrosine kinase inhibitors, such as Dasatinib, can prevent CAR signaling and temporary "resting" of CAR T cells enhances their in vivo efficacy. Thus, we hypothesized that suppressing tonic signaling during ex vivo culture should help maintain an optimal CAR T phenotype and retain their potential for improved in vivo function and long-term efficacy.

Here, we investigated the effects of Dasatinib on non-viral CRISPR-Cas9 edited CAR-T cells expressing CAR targeting CD19, L1CAM or GD2 from the endogenous *TRAC* locus. Culturing *TRAC*-replaced CAR-T cells with Dasatinib for 9 days after CAR knock-in significantly reduced the differentiation, without affecting their expansion rates. Retaining higher frequencies of less-differentiated CCR7+ central memory and naïve-like T cells was more prominent in CAR constructs that tend to induce tonic signaling. Culturing with Dasatinib (100 nM) increased the percentage of CCR7+ cells by 1.7-fold for L1CAM-CAR (39.95% to 66.81%) and 1.2-fold for GD2-CAR (57.85% to 70.53%). We also detected decreased expression of inhibitory receptors associated with exhaustion (TIM-3, LAG-3, PD-1) in Dasatinib-treated cells, but similar cytotoxic capacity 16 hours upon drug removal. In co-cultures with antigen-positive tumor cells, Dasatinib-treated CAR-T cells exhibited enhanced proliferation capacity, with 12.1-fold and 2.7-fold increases in proliferation for GD2- and L1CAM-specific *TRAC*-CAR T cells, respectively, over their untreated counterparts. Intriguingly, antigen-dependent proliferation of CD19-CAR T cells was also improved (Dasatinib-treated: 9.38-fold vs untreated: 5.49-fold), even though this construct was less prone to tonic signaling.

Our results suggest that Dasatinib can modulate the phenotype and expansion capacity of non-viral generated *TRAC*-replaced CAR-T cells by mitigating tonic signaling during ex vivo culture. These insights may contribute to the development of more potent and durable CAR-T cell therapies.

1629 Therapeutic transgenes need optimization – lessons from Cystic Fibrosis

Kezhi Yan[1], Alisa Bell[1], Caitlin Macadino[1], Katherine Gierer[1], Joshua Conte[1], Cheng Yi[1], Barbara Tabak[1], Kevin Coote[1], Normand Allaire[1], Andrey Sivachenko[1], Martin Mense[2], John Carulli[1], Hillary Valley[1]
[1]Cystic Fibrosis Foundation, Lexington, MA, [2]Cystic Fibrosis Foundation Therapeutics, Lexington, MA

Introduction: More than 2,000 mutations in the *CFTR* gene cause Cystic Fibrosis (CF); therefore, genetic editing approaches that can provide benefit for many or all mutations are promising strategies. Targeted insertion of a partial cDNA (aka "super exon" (SE)) coding for wild type *CFTR* exons (E) 2-27 into *CFTR* intron 1 can restore all mutations downstream of the insertion site and provide therapeutic benefit for almost all people with CF (>99%). In contrast to safe harbor approaches, insertion into the native genomic locus likely maintains native gene regulation, which is important since *CFTR* is not expressed in all cell and tissue types. Our previous work demonstrated a strong effect of sequence components (such as splice acceptor, 3' UTR/polyA, insertion site, and intron) on SE performance and the need to optimize the SE transgene sequence. Our first-generation E2-27 SE provided full CFTR functional rescue in clonally isolated CF cells. However, mRNA stability was notably reduced compared to wild type *CFTR*, so we then sought to optimize the SE transgene.

Methods: To enable more extensive and facile optimization, we developed a robust, medium-throughput NanoLuc SE reporter system to evaluate the sequence components. The NanoLuc SE reporter was constructed with a splice acceptor, non-cleavable peptide linker, promoter-less NanoLuc cDNA (named NanoLuc SE), 3' UTR/polyA, and homology arms for targeting *CFTR* intron 1. Genomic integration of this reporter results in a *CFTR* exon 1-NanoLuc SE fusion protein. We then applied the best combinations to the context of the *CFTR* SE. *CFTR* SE insertion editing was achieved in 16HBEge *CFTR* G542X (CFTR null) cells by pre-treating with an Adenovirus containing a *CFTR* E2-27 SE construct for 24 hours, followed by nucleofection with RNP targeting *CFTR* intron 1. CFTR rescue was evaluated in a bulk population of edited cells by Western blot. Subsequently, cells were sub-cloned and clonal cell lines with the SE inserted were identified and fully characterized for *CFTR* mRNA abundance, protein expression, electrophysiology function, and NGS analysis of *CFTR* isoforms.

Results: We tested over 110 NanoLuc SEs with combinations of insertion sites, mini-introns, splice acceptors, and 3' UTR/polyA sequences identified from human genes with a 3' UTR length of <400 bp and highly expressed in airway cells. NanoLuc SEs with different components resulted in a wide range of NanoLuc expression, further demonstrating that sequence components dramatically influence transgene expression. The best combinations were then applied to *CFTR* SE constructs with therapeutic potential. Full CFTR rescue was observed with a viral polyA element, and 35.1% CFTR rescue was achieved with a human gene 3' UTR. Additional NanoLuc-SE screening of 3' UTR elements was recently completed, which identified human 3' UTRs from *NDUFB86* and *SOD1* as promising candidates, which are currently being applied to the next generation of *CFTR* SEs.

Conclusion: We demonstrated robust rescue of CFTR using the SE insertion approach and show that optimizing SE sequence elements is critical for efficient expression, splicing, stability, and function of the SE. Our on-going work is focused on understanding SE expression and optimizing constructs for *CFTR.* This approach could provide benefit for almost all people with CF and provides a paradigm for many genetic diseases.

1630 DNA repair precision after gene editing, unveiled

Giandomenico Turchiano[1], Nathan White[2], Alex Chalk[3], Yi-Ting Hu[4], Samuel Pins[4], Panagiotis Antoniou[5], Sandra Wimberger[6], Stina Svensson[7], Soraia Silva[8], Anne Mudde[4], Rajeev Rai[9], Sridhar Selvaraj[10], William Feist[11], Marianna Romito[12], Chinnu Rose Joseph[13], Grzegorz Sienski[14], Roberto Nitsch[15], Giorgia Santilli[16], Alessia Cavazza[16], Matthew Porteus[17], Marcello Maresca[18], Adrian Thrasher[8]

As the therapeutic applications for CRISPR/Cas or TALEN are expanding at rapid pace, we embarked in the mission of describing their effect on the treated cells genomes. Numerous techniques have emerged to detect or anticipate genotoxic events, reflecting the need for thorough characterization of these editing tools' activities. Nevertheless, these approaches face limitations such as high costs, time-consuming procedures, extensive bioinformatics requirements, and biased evaluations of genetic aberrations. Additionally, the temporal dynamics of DNA editing and subsequent repairs are poorly understood, leading to potential misinterpretations and observational biases.

To address these challenges, we introduce "Multipurpose Editing and Genotoxicity Assessment" (MEGA), a novel diagnostic toolkit that employs multiplexed digital PCR (dPCR) assays for comprehensive characterization of mutations at both on- and off-target sites induced by gene editing tools. This technique allowed us to reveal previously unreported significant biological information with unprecedented precision, including:

1. Precise (error-free) DNA repair mediated by NHEJ
2. Recurrent designer nuclease cleavage events
3. Kinetics of DNA repair mechanisms in primary cells
4. Timing of DSB resolution
5. Designer Nuclease activity

Furthermore, we demonstrated how to rapidly track and quantify various mutations in a temporal fashion.

MEGA addresses critical gaps in the genetic engineering analysis toolkit by providing a rapid, accessible, and specific overview of genome integrity post-gene editing, applicable to clinically relevant samples. Furthermore, by leveraging this novel technique, we elucidated fundamental biological concepts underlying DNA repair, paving the way for extensive mechanistic studies aimed at improving designer editor activity and gene therapy safety.

1631 The missing link: Kromatid's Next-Gen Cytogenetic Platform, KROMASURE™, Provides Critical Insight for Evaluating Cell and Gene Therapy Products for Chromosome Structural Variation, including Edit Integrity and Genomic Stability.

Erin Cross[1], Matthew McGowan[2], Greg Husar[2], Christopher Tompkins[3], Michael Vernich[2]
[1]Kromatid Inc, Fort Collins, CO, [2]Kromatid Inc, Longmont, CO, [3]KromaTiD, Longmont, CO

When cells are edited, differentiated, modified, or engineered for therapeutic applications such as CAR-T, accurately measuring chromosomal stability and mutation is critical. Comprehensive, accurate analysis of the genome for potentially deleterious and cancer-inducing changes requires a panel of assays. The most robust characterization of genomic and target integrity is provided by combining cytogenetic cell-based analysis (to profile the starting material and monitor the product for chromosomal stability and integrity), which detects chromosome structural variation and aneuploidy, with targeted sequencing approaches such as NGS and dPCR. Cytogenetic assays provide critical data for structural variant discovery/validation and algorithm tuning, enabling robust breakpoint identification at the base pair level. These direct visualization assays supply characterization of low frequency, heterogenous, and complex events. Because they do not utilize pooled DNA from a heterogeneous cell population or a bioinformatic reconstruction of the genome, cytogenetic assays can characterize events with low prevalence or complex presentations, or events that involve breakpoints nested in repetitive sequence. Conventional cytogenetic methods can be burdensome and require extensive manual analysis for a relatively small number of cells (normally 20). These legacy methods (G-banding, FISH, SKY and M-FISH) are utilized on a limited basis, and often only when chromosomal aberration measurements are expected to be present in most/all cells in a sample, or they are required for assessing the risk of a gene editing or cellular engineering process.

Kromatid's KROMASURE platform of advanced cytogenetic tools enriches the dataset available beyond classic cytogenetic techniques and offers a custom suite of solutions for in-depth single cell analysis of genomic targets of interest. Targets as small as 2kb (inSite and PPF), up to the entire genome, can be characterized with KROMASURE for chromosome structural variation (K-Band and Screen). The platform leverages proprietary probe design and hybridization methods, as well as automation and advanced imaging solutions to increase the number of cells analyzed. All platform methods can be paired with custom analytical packages to support a wide variety of study designs, including therapeutic product release testing and comparative analysis. Individual structural variants, as well as structural variation phenotypes (clones with a signature structural variant profile) can be tracked, even at low prevalence, via the analysis of hundreds of individual cells per sample.

Improving and automating these direct visualization methods, along with streamlining the integration of this data with sequencing and/or array-based approaches for measuring variation is an active area of development, showcased here using the GIAB HG008-T Tumor cell line. The KROMASURE platform provides the next generation of cytogenetic assays for the characterization of cell and gene therapy products, from research and development phase all the way through drug product validation.

1632 Diji: The First Integrated Method to Analyze Single and Double-strand Breaks in GUIDE-seq and Digenome-seq Data for Unbiased Assessment of Editing Outcomes

Ayaan Hossain[1], **David Kuo**[1], Sudeepa Syamala[1], Lavanya Venkatesan[1], Ian Lin[1], Maria Muraca[1], Miles Duncan[1], Suravi Pramanik[1], Pradeep Ramesh[1], Michael Holmes[2], Cecilia Cotta-Ramusino[3], Anne Bothmer[2], Sumanprava Giri[4], Gregory McAllister[1], Andrea Calabria[1]*
[1]Tessera Therapeutics, Somerville, MA, [2]Tessera Therapeutics, Cambridge, MA, [3]Tessera Therapeutics, Inc., [4]Tessera Therapeutics, Boxborough, MA

Genome editing technologies hold great promise for developing genomic medicines to correct monogenic disorders and restore functional cellular activity. Our RNA Gene Writers leverage the mechanism of target-primed reverse transcription and have shown in vivo efficacy in mouse and non-human primate models for diseases such as phenylketonuria (PKU), alpha-1 antitrypsin deficiency (AATD), and sickle cell disease (SCD).

A critical step before advancing these technologies to the clinic is assessing their genotoxic potential through rigorous evaluation of on-target and putative off-target effects, including any unintended mutations at the on-target site. Existing in vitro and in cellula methods, such as Digenome-seq and GUIDE-seq, can quantify editing outcomes. However, these methods lack an integrated, robust, scalable, and standardized framework to analyze both assays simultaneously. Furthermore, current tools cannot infer single-strand breaks (SSBs) alongside double-strand breaks (DSBs), a key limitation for emerging technologies that aim to minimize reliance on DSB repair mechanisms.

To address this gap, we present Diji, a novel computational method designed to analyze both GUIDE-seq and Digenome-seq datasets, accommodating experimental designs that include single or double-strand genomic breaks. Diji features read-level analysis combined with spacer-matching logic to identify putative off-target mutations. Additionally, it introduces a normalized cleavage score (NCS), which quantifies editing outcomes based on sequencing depth relative to a control, enabling unbiased comparisons across samples and conditions.

We evaluated Diji using simulated datasets encompassing diverse editing outcomes, sequencing quality (generated via ART and wgsim simulators), and sequencing depths (ranging from 1× to 100×). Diji demonstrated superior performance, achieving average precision and recall scores of 0.92 and 0.97, respectively, compared to digenome-toolkit2 (the state-of-the-art Digenome-seq analysis tool), which achieved 0.69 precision and 0.59 recall at 20× coverage and Illumina HiSeq error rates. Furthermore, benchmarking the NCS revealed its high accuracy ($r^2 = 0.97$) compared to the standard cleavage score ($r^2 = 0.48$) when correlated with the rank order of synthetic sites. By analyzing simulated data containing known off-target sites, we determined the optimal sequencing depth and number of replicates needed to maximize the discovery of off-target sites using Diji in real-world conditions.

In summary, we believe Diji provides a significant advancement in the standardization and scalability of genome editing analysis. It offered superior precision and recall, a more accurate quantification score, and supported experimental design optimization. Diji is a potentially valuable tool for assessing the precision and safety of genome editing technologies, paving the way for accelerated preclinical and clinical applications.

1633 Fast Quantification of Genome-Editing Outcomes using CRISPR-based detection

Charles Blanluet[1], Henrik Sperber[1], Sridhar Selvaraj[2], Matthew Porteus[3]
[1]QUiCKR Bio, New York, NY, [2]Stanford University, Stanford, CA, [3]Stanford University School of Medicine, Stanford, CA

Introduction: Genome editing is rapidly gaining traction in many clinical applications. However, the evaluation of editing outcomes remains time consuming and impedes R&D timelines, especially when multiple iterations are needed to optimize workflows. Amplicon sequencing (amp-seq) is considered the gold standard for quantification of editing efficiency. However, amp-seq is time consuming (~1 week turnaround time), and can be costly. Faster methods have been developed, but these often pose a trade-off of accuracy. The introduction of new workflows into research pipelines also requires additional equipment and/or extensive assay optimization. Hence, there is a critical need for fast, accurate, and cost-effective quantification of gene editing efficiency. To address this need, we have developed an assay which can be easily run on standard lab equipment for quantification of indels, knock-ins, and off-target activity. The assay is called QUiCKR (Quantification Using initial CRISPR Kinetic Rates) and offers results in 20 min with minimal steps. The assay protocol consists of generating a DNA sample dilution series, which is added to a pre-plated reagent mix containing Cas12, crRNA and fluorescent reporters, followed by fluorescence read-out (Fig 1a). The editing efficiency is then quantified using a machine-learning trained software. Current CRISPR based detection assays typically have a binary output, and are ill-suited for precise quantification. In contrast, the QUiCKR assay quantifies the kinetic rates of Cas12 trans-cleavage to quantify gene editing efficiency, with amp-seq level accuracy. Pre-plated reagents remain stable during long-term storage, which provides users with ready-to-use reagents, a quick workflow, and accurate results.

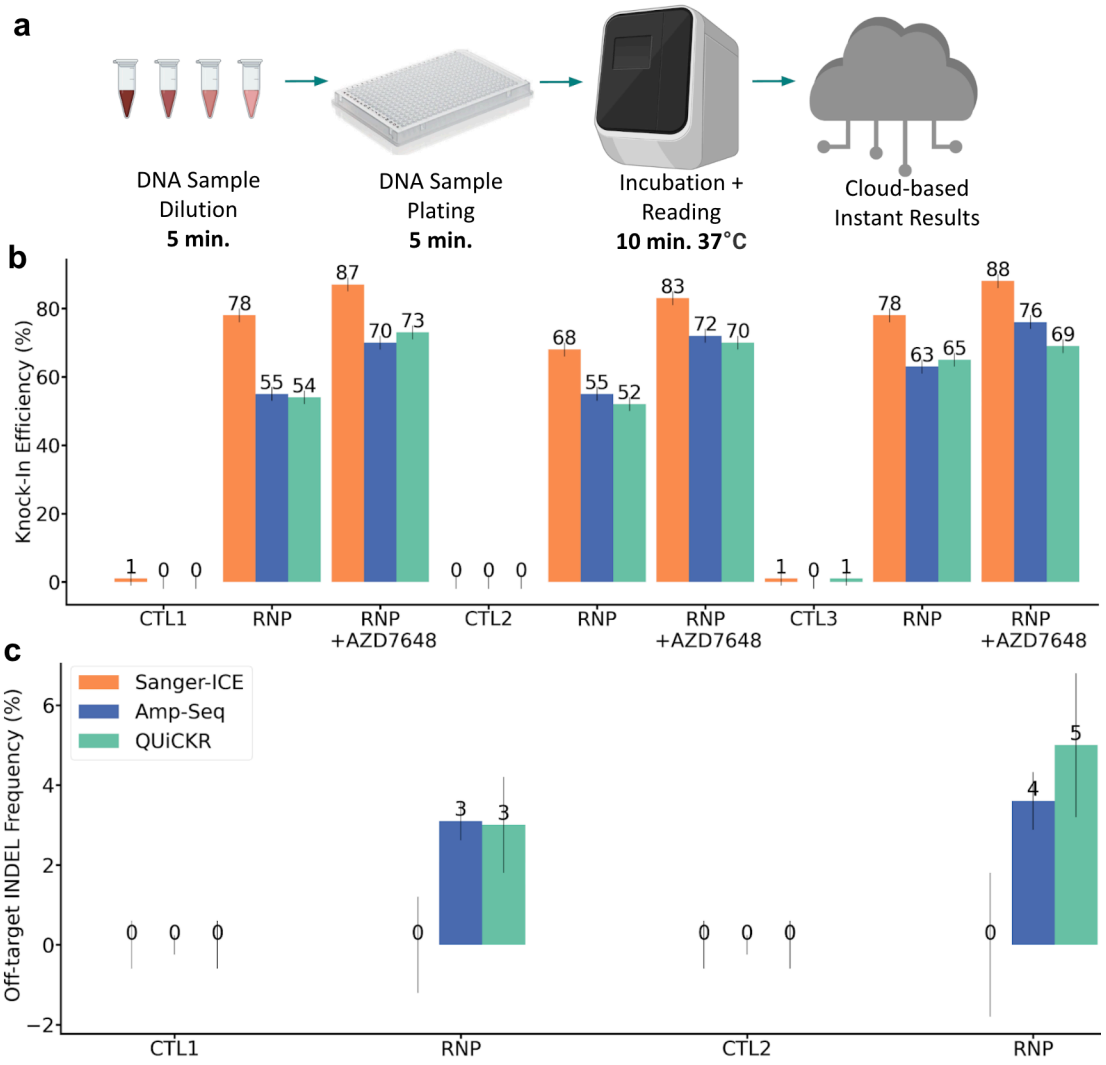
Experiments and Results: Edits quantification with QUiCKR, amp-seq and Sanger-ICE HSPCs were separately edited at HBB, and STING1 loci with Cas9 ribonucleoprotein (RNP) with or without a knock-in AAV6 donor template, followed by amplification of the on-target sites and an off-target site. On- and off-target INDEL frequency, knock-in efficiency, and wild-type ratios were quantified by Sanger sequencing with ICE analysis, amp-

seq, and the QUiCKR assay (Fig 1b). QUiCKR demonstrated 99.1% R-square fit with amp-seq data over 35 data points. In contrast, ICE showed 91.9% R-square fit with amp-seq data and did not capture low levels of off-targets (~3%, Fig 1c).

LOD study on CCR5 single-base deletion iPSCs were edited at CCR5 locus with RNP, quantified at 98% with Sanger-ICE. Edited CCR5 amplicons were diluted with unedited CCR5 amplicons to form 9 mixes (editing frequencies from 90% to 0%). Editing frequencies were quantified with QUiCKR, which yielded a 98.2% R-square fit with Sanger-ICE data.

Dynamic-Range study on BCL11A 15-base substitution Mixes of wild type and mutated DNA amplicons were prepared at ratios from 0%-90%, and quantified by QUiCKR. The R-square fit with mutant ratios was 98.4% and the standard error of the assay was 0.7%.

Conclusion: The QUiCKR assay accurately quantified INDEL edits, 15bp knock-ins with 99% R-square fit with amp-seq (versus 91% for Sanger-ICE). The QUiCKR assay also demonstrated a sensitivity below 3% for a single nucleotide edit and INDEL edits at off-site, modifications that Sanger-ICE was not able to capture. To conclude, QUiCKR offers a 20-min and accurate alternative to amp-seq, which has the potential to significantly increase the speed of gene editing research.



1634 Comprehensive On- and Off-target Validation Using Integrated rhAmpSeq and Targeted DNA Resequencing Single-Cell Technology for Gene Editing Applications

Indira Krishnan[1], Ellen Schmaljohn[2], Gavin Kurgan[3], Rolf Turk[2], Alex Li[4], Saurabh Gulati[5], Benjamin Schroeder[6], Daniel Mendoza[7], **SHU WANG[1]***
[1]Mission Bio, South San Francisco, CA, [2]Integrated DNA Technologies, Coralville, IA, [3]Integrated DNA Technologies Inc, Coralville, IA, [4]Genomic Insights Consulting, Rowland Heights, CA, [5]Mission Bio, South San Francisco, California, [6]Mission Bio, San Francisco, CA, [7]Mission Bio, South San Francisco

Advances in genome editing technologies have facilitated precise correction of adverse mutations and the engineering of cells with novel therapeutic functions. Among the critical determinants of robust genome editing outcomes is assay specificity, particularly in CRISPR-based systems where guide RNAs (gRNAs) enable precise on-target edits with minimal off-target activity. To address off-target effects, both in-silico and empirical methods have been widely utilized to predict and characterize potential off-target sites. Amplicon-based targeted resequencing has emerged as the leading methodology for validating on- and off-target edits due to its multiplexing flexibility, high sensitivity, and cost efficiency.

Indeed, recent innovations, such as rhAmpSeq, which leverage novel reaction primer design and chemistry to improve performance in bulk validation by reducing background noise in multiplexed PCR, have gained prominence. Concurrently, innovations in droplet-based single-cell DNA resequencing technologies provide critical insights into single-cell context, including editing zygosity, co-occurrence of edits, and clonality across thousands of individual cells. These attributes are particularly valuable for gene and cell therapy applications.

In this study, we integrated rhAmpSeq chemistry with droplet-based single-cell assays to develop a comprehensive and flexible workflow for on- and off-target validation with single-cell resolution. To validate this approach, we used two well-characterized cell lines, GM24385 (son, HG002) and GM24149 (father, HG003), targeting loci that are homozygous in HG003 and heterozygous in HG002, with indel sizes ranging from 1 bp to >2,000 bp. These cell lines and targets were chosen because of the abundance of orthogonally validated bulk sequencing data which would be useful for benchmarking the performance of the overall workflow. Targeted amplicons were designed using rhAmpSeq design pipeline incorporating unique parameters that are compatible with droplet-based single-cell DNA resequencing platform. The resulting multiplex panel was compatible with both bulk rhAmpSeq and single-cell workflows.

With this targeted panel, we assessed the droplet-based single-cell rhAmpSeq chemistry, evaluating assay performance at critical enzymatic steps. For sequencing data analysis, we employed an automated single-cell genome editing analytical pipeline to quantitatively evaluate on- and off-target editing efficiency, co-occurrence, and zygosity of the experiments. We also compared the single-cell assay performance with available orthogonal bulk assay, rhAmpSeq assay in detecting indels. The integration of the panel design pipeline, chemistry and analytical software from both rhAmpSeq and the single-cell workflow enables a highly customizable, comprehensive, yet cost efficient approach to evaluate on- and off-target with single-cell context which is highly valuable to genome editing applications in the CGT field.

1635 RGENtool - a CRISPR/Cas double-strand cleavage evaluator

Haiwang Yang[1], Alexander Kuzin[2]
[1]MilliporeSigma, Rockville, MD, [2]BioReliance Corporation (MilliporeSigma/Merk KGaA), Rockville, MD

Haiwang Yang, Alexander Kuzin, Pradeep Bhaskar, Alexei Slesarev

CRISPR/Cas is a powerful gene-editing tool that allows precise genome modifications. However, unintended off-target effects can lead to unwanted genetic changes at unintended sites. Evaluating off-target effects is crucial in research, therapeutic development, and regulatory assessments to ensure the safe application of CRISPR/Cas technologies in clinical settings. Next-generation sequencing (NGS) offers a high-throughput method for DNA sequencing, enabling comprehensive genome analysis to detect both intended and unintended edits. Various assays, such as RGEN-seq, INDUCE-seq, AID-seq, and SITE-seq are designed to identify double-strand cleavage by CRISPR/Cas and may show similarities in analyses, allowing for a universal pipeline to assess off-target effects.

From the large volumes of NGS data generated in CRISPR/Cas experiments, we can extract two key aspects: read coverage around cut sites and sequential homology around those sites. These indicators are cruicial for identifying authentic CRISPR/Cas cleavage. We use Convolutional Neural Networks (CNNs) for pattern recognition of both indicators. Given the interconnection between coverage signatures and homology, our RGENTool's initial coverage-CNN automatically generates training data for the downstream homology-CNN. Additionally, we have developed a customized pipeline for efficient and specialized CRISPR/Cas alignment. This pipeline includes trimming to narrow the alignable region and automatic extension at the flanks of the Smith-Waterman alignment, along with a text-based visualization system for human analysis. Ultimately, we predict CRISPR/Cas cut sites with varying confidence levels based on the combined results of coverage and homology. We have also designed a robust reporting folder system to summarize and visualize these results.

1636 Enhancing Precision and Safety in CRISPR/Cas Gene Editing: A Combined Off-Target Detection Strategy

Kejia Kan[1], Ni Shuai[2], Fengjiao Zhu[3], Wei Wang[3], Ning Wu[3]
[1]Shanghai Waker Bioscience Co., Ltd, Shanghai, Shanghai, China, [2]Waker Bioscience Co., Shanghai, Shanghai, China, [3]Shanghai Waker Bioscience Co., Ltd. , Shanghai, China

The advent of CRISPR/Cas systems has revolutionized gene editing, providing unprecedented precision for modifying genomes to treat genetic disorders and advance biological research. However, the potential for unintended genetic alterations, or off-target effects, poses significant safety concerns. Current detection methods lack systematic approaches, underscoring the need for an integrated strategy that enhances safety protocols in gene editing applications. Here, we introduce a combined off-target detection approach to enhance the reliability of CRISPR applications, making it an essential tool for advancing precision medicine.
We utilized a diverse range of computational tools to predict potential off-target sites based on the sgRNA sequences. These tools incorporate various algorithms and machine learning techniques to assess the likelihood of unintended genetic alterations.
Based on the predictions, we identified a range of potential off-target sites and designed probes for hybrid capture to target these regions. The captured DNA fragments from biological samples were then sequenced and analyzed to assess off-target risks. This method efficiently enriched and detected off-target events, confirming and quantifying the predicted sites with high precision, thus enhancing the accuracy and safety of our CRISPR/Cas system.
These computational predictions provided a foundational list of potential off-target sites, which were then combined with experimental prediction in later stages of the study. By combining multiple predictive models, we ensured a comprehensive assessment of off-target risks.

1637 Type V CRISPR nuclease edit patterns enable highly sensitive off-target detection

Ivan Kristanto[1], Gabrielle Munoz[1], Anthony Garrity[1], Gal Lumbroso[1], Yalda Amidi[1], Malini Varadarajan[1], Quinton Wessells[1], Jesse Tordoff[2], Noah Jakimo[3], Gregory Hoffman[1], Tia DiTommaso[1], John Murphy[1], David Cheng[1], Yurong Xin[1]*

The CRISPR Cas12i nuclease family represents a promising therapeutic tool, but the off-target effects remained to be understood. This study characterizes the off-target activity of Cas12i2, an engineered type V nuclease, to ensure the safety of therapeutic applications. We have previously demonstrated that Cas12i2 generates predominantly 5-20

nucleotide deletions at the target site with a reproducible and target-dependent pattern. To characterize off-target editing outcomes, we designed a library of guide RNAs and corresponding potential off-target sites, a total of 60,000 on- and off-target sequences. For those active off-target sites verified in the library, deletions are observed in much greater frequency than insertions, similar to the on-target pattern. Enabled by the large deletion pattern, we further demonstrated that we could detect editing activity in off-targets at approximately 10-fold higher sensitivity than reported by using other CRISPR nucleases in the field. This high sensitivity allows for the rigorous identification and selection of safe and effective Cas12i2 guide RNAs. This work significantly enables our assessment of Cas12i2's safety profile and advances its potential for therapeutic applications.

1638 Sensitive Rearrangement Detection at CRISPR On- and Off-target Editing Loci Using SAFER Detection

Hongyao Yu[1], FNU Shankaracharya[1], Ricardo Petroni[2], Vijetha Vemulapalli[3], **Douglas Smith[4]**
[1]SeQure Dx, Waltham, [2]SeQure Dx, Inc., Waltham, MA, [3]SeQure DX, Holliston, MA, [4]SeQure DX, Waltham, MA

Gene editing strategies that target multiple loci using engineered CRISPR Cas systems or other sequence-specific gene editing nucleases run a high risk of generating chromosomal rearrangements. Here, we applied Selective Amplification for Efficient Rearrangement Detection (SAFER detection) to detect intrachromosomal deletions and inversions as well as inter-chromosomal translocations involving loci for several therapeutic guide RNAs targeting *CCR5, FXN, TRAC, TRBC1, TRBC2, B2M, and PDCD1*. The assay uses transposome-based tagmentation of genomic DNA, followed by selective amplification of rearranged molecules using a target-specific primer and locked nucleic acid blocker. The target specific primer is typically anchored near the on-target locus where double strand breaks are intended to occur, but it can also be designed to bind near any known off-target locus. The assay can be performed in less than 1 week; it requires less genomic DNA than competitive methods, and sensitively detects rearrangements involving the target locus, in a genome-wide, unbiased way. Our analysis pipeline quantifies independent rearrangement events involving split reads with UMIs across multiple sample replicates, providing tabular and graphical summaries. Rearrangements with breakpoints in close proximity to regions of homologous sequence or off-target editing sites are classified as homology-mediated, or off-target mediated, respectively.

For the *CCR5* guide, we detected off-target and homology-mediated events at the *CCR2* locus and off-target mediated translocations involving loci in chr13, 19, and 20 that had been characterized previously by others using the same guide. A novel chromosomal translocation, mediated by off-target editing near oncogene *PTP4A2* on chr1, was detected at an off-target site with 3 mismatches and 1 indel when aligned to the target. These sites were validated by PCR and dPCR. Editing with guides in the homologous regions of TRBC1 and TRBC2 exon 1 results in frequent deletions and inversions of the intervening region on chromosome 7. We also investigated a model system for treatment for Friedreich's ataxia in which two guides at adjacent loci on chromosome 9 were used to edit a lymphoblastoid cell line from a patient with Friedreich's ataxia carrying an expanded GAA repeat cluster at the Frataxin locus (Rocca *et al*, 2020). SAFER detection identified frequent deletions, as described in the initial study, but it also detected inversions of the GAA repeats between the two target loci.

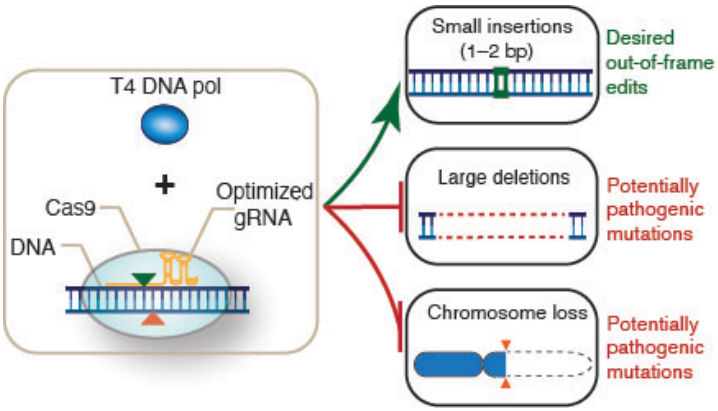
The SAFER detection assay is complementary to nomination methods such as GUIDE-seq and ONE-seq, as it provides a cost-effective approach to assess the risk of chromosomal rearrangements in therapeutic genome editing, and is especially valuable where multiplex editing strategies are employed. The method can also be adapted to identify viral or transposon integration sites.

1639 Preventing large deletions and chromosome loss in engineered human primary T cells by CasPlus with optimized guide RNAs

Qiaoyan Yang[1], Jonathan Abebe[2], Michelle Mai[2], Colin Konishi[1], Orrin Devinsky[3], **Chengzu Long[4]**
[1]NYU Langone Health, [2]NYU Langone Health, New York, [3]New York, NY, [4]NYU School of Medicine, New York, NY

Genetically engineered T-cell therapies rely heavily on genome editing tools, such as the CRISPR/Cas9 system. However, unintended on-target chromosomal alterations, including large deletions and chromosome loss can occur

and pose significant risks including tumorigenesis. Here we combined CasPlus and optimized guide RNAs to reduce these issues in CRISPR/Cas9 engineering human primary T cells. CasPlus, which integrates an engineered T4 DNA polymerase with Cas9 nuclease and guide RNA, promotes favorable small insertions (1-2 bp) while reducing large deletions and chromosome loss in T cells. Our optimized guide RNAs favoring small insertions reduced large deletions and chromosome loss by two- to five-fold versus those favoring small deletions. Moreover, combining optimized guide RNA with T4 DNA polymerase further synergistically reduced large deletions and chromosome loss by additional two-fold. Notably, replacing currently used guide RNA pairs in clinically applications with optimized pairs biased towards small insertions, along with CasPlus instead of Cas9, for editing greatly reduced large deletions and chromosome loss in gene-edited human primary T cells. These findings demonstrated that pre-selecting target sites favoring small insertions via guide RNA optimization coupled with CasPlus editing is a safer and more effective strategy to improve genome stability in T-cell engineering and other gene-editing applications.



1640 Potent and specific activation of fetal hemoglobin expression by cis-regulatory interference

Control of gene expression is mediated by sequence-specific binding of transcription factors (TFs) in regulatory DNA, and genetic variants that modulate TF binding underlie many disease phenotypes. Several naturally-occurring genetic variants within the γ-globin promoter have been identified that attenuate the binding of transcriptional repressor proteins, resulting in hereditary persistence of fetal hemoglobin (HPFH) and clinical silencing of co-inherited sickle cell disease or β-thalassemia. Currently it is not possible to phenocopy the effects of such genetic variants without introducing alterations to DNA, which may carry unknown downstream risks. To phenocopy the effects of genetic regulatory variants using a non-invasive approach, we developed highly specific, single chain cis-regulatory interfering proteins (cRIPs) capable of precisely displacing a transcriptional repressor or activator from a single site in the human genome. We show that delivery of a cRIP targeting the -200 region of the γ-globin promoter via either mRNA or lentivirus potently and specifically reactivates fetal hemoglobin expression and reverses hemoglobin switching in both human primary erythroid cells and humanized mice. We show further that cRIPs can be deployed combinatorially to enable complex control of gene expression including quantitative gene silencing or activation via the displacement of activating or repressing transcriptional factors in either promoters or enhancers, and are capable of phenocopying the effects of diverse genetic regulatory variants. Cis-regulatory interfering proteins present a new modality for precisely and non-destructively controlling endogenous gene expression with direct therapeutic application to hemoglobinopathies.

1641 Robust Genome Editing with Reduced Cytotoxicity and Enhanced Engraftment Using Protein-Assisted Delivery of Cas12a-RNP into Human HSPCs

Genome editing technologies, such as CRISPR-Cas, offer transformative potential for treating sickle cell disease (SCD). SCD is caused by a heritable mutation in the β-globin gene, impairing oxygen transport and resulting in anemia, acute pain crises, ischemic tissue damage, and early mortality. Emerging therapies for SCD focus on autologous hematopoietic stem and progenitor cell (HSPC) transplantation after *ex vivo* genome editing. Given that patients with SCD often have reduced stem cell numbers and compromised cell quality, maintaining the viability and functionality of edited HSPCs is essential for successful therapeutic outcomes. Electroporation (EP) is a widely used method for delivering ribonucleoprotein (RNP) editors into HSPCs, but it presents significant challenges, including cytotoxicity and disruptions to global RNA expression, which negatively impact stem cell function. Protein-assisted genome editing, utilizing cationic endosomal-escape peptides (APs), offers a promising alternative by enhancing RNP delivery and minimizing cellular stress, potentially improving editing efficiency and HSPC recovery.

In this study, we utilized an AP for the transfer of Cas12a-containing RNPs to induce BCL11A editing in healthy human CD34+ HSPCs to boost fetal hemoglobin expression. Cell recovery in AP-treated groups (50-200 μM AP) was significantly higher (70-86%) compared to the EP group (53.6%). Higher concentrations of AP (150-200 μM) achieved editing levels comparable to EP (83.5-87.7% vs. 86.7%, respectively). Furthermore, significant γ-globin expression was achieved in both the EP and high-AP groups (125-200 μM) compared to non-edited controls (21.5-23.3% vs. 6.2%). Similar improvements in cell recovery and editing efficiency were observed in SCD CD34+ HSPCs, with 52.3% cell recovery and 80.5% editing in the EP group and 72.4-91.3% cell recovery and 77-78% editing in the AP groups, further demonstrating the potential of AP-based delivery for improving HSPC editing in both healthy and SCD samples.

Next, we transplanted non-edited, AP-edited, and EP-edited SCD CD34+ HSPCs into NBSGW mice, along with two 1:1 mixed groups of EP- and AP-edited cells (marked with GFP or YFP) in a competitive transplantation assay. After 16 weeks, human cell engraftment in peripheral blood (~35%) and bone marrow (~96%) was comparable across all groups. F-cell and γ-globin levels were significantly elevated in both the AP- and EP-edited groups compared to the non-edited control group (46.8-48.1% vs. 15.4% for F-cells and 23.2-29.1% vs. 6.0% for γ-globin), with no significant difference between the two edited groups. Importantly, the competitive assays revealed that AP-edited cells exhibited significantly higher engraftment frequencies than EP-edited cells, demonstrating a survival advantage to AP-edited cells despite similar initial editing efficiency. Secondary transplants have now been performed and will provide further insights into long-term outcomes, with updates to follow.

In conclusion, AP-based RNP delivery offers a gentler alternative to traditional electroporation for editing HSPCs. Despite comparable editing efficiencies, AP-based delivery resulted in improved cell recovery, better engraftment, and enhanced survival in a humanized NBSGW mouse model. These findings highlight the potential of AP-assisted genome editing to optimize *ex vivo* gene therapies for SCD, offering a more efficient and safer approach to clinical translation.

1642 Engineered Extrachromosomal Technologies for Tunable and Persistent Control of Therapeutic Gene Expression in Human Cells

Daniel Brenner[1], Selvalakshmi Selvaraj Anand[1], Jacob Goell[1], Hailey Szadowski[1], Sofi Aguilera[1], Ana Naqvi[1], Isaac Hilton[1]*
[1]*Rice University, Houston, TX*

Though retroviral vectors have seen clinical success with respect to delivering transgenes to primary human cells, they are prone to random genomic integration of payloads, which poses clinical drawbacks, such as the disruption of endogenous genes, epigenetic silencing of integrated transgenes over time, and oncogene activation. These drawbacks converge to make the use of programmable non-integrating methods of transgene expression attractive. Current non-integrating viral systems used in therapeutic contexts, such as adeno-associated virus (AAV), are limited by small payload capacities or extensive modifications designed to reduce virulence and immunogenicity. These modifications often lead to transient transgene expression. Additionally, both integrating and non-integrating approaches lack the ability to fine-tune transgene expression levels.

To overcome these limitations, we developed a novel technology that recapitulates the long-term gene expression strategies of latent non-integrating viruses using a synthetic biology toolset. This approach enables the creation of persistent and programmable extrachromosomal expression systems that provide user-defined tunability of transgene expression and maintenance of genetic components. Specifically, we designed and optimized a class of modular, non-integrating DNA systems that are stably maintained through mitotic stability and host-mediated replication. We hypothesized that this system would allow episomal DNA to persist in dividing human cells without requiring genomic integration.

We first constructed and tested an engineered tethering system to site-specifically control the targeting and engagement frequency between extrachromosomal DNA and the human genome in live cells. Using ChIP-qPCR, we confirmed that the tethering modules effectively bind both the human genome and synthetic extrachromosomal DNA. Fluorescence in situ hybridization (FISH) and high-resolution microscopy further verified co-localization. We then transfected human cells with episomes containing EGFP, our tethering system, and an engineered replication module. By optimizing the number of tether binding sites in the host genome, we demonstrated long-term persistence of EGFP expression for over 3 months post-transfection. qPCR analysis of isolated genomic DNA confirmed that persistence was not due to off-target genomic integration of the payload.

To enhance versatility for both viral and non-viral delivery methods, we developed truncated versions of the tethering and replication modules. These compact designs enable us to successfully deliver our system to primary human T cells. Our goal is to deliver therapeutic payloads, such as anti-CD19 CAR, for targeted killing of B cell lymphomas, without any genomic integration. Importantly, this platform allows for modulation of CAR expression levels, and this tunability, combined with the absence of genomic integration, offers an alternative approach for CAR T cell therapy. In summary, we created a novel approach for maintaining extrachromosomal DNA payloads in human cells, demonstrating the ability to sustain therapeutic gene expression in dividing primary cells without genomic integration. This extrachromosomal genetic technology offers new possibilities for transgene-based treatments, mitigating the risks associated with altering the endogenous human genome.

1643 Self-Targeting CRISPR-CasX-Editor AAV Vectors Enable Potent and Controllable On-target Editing in the Murine CNS

Kathleen Christie[1], Ming Yang[2], Sarah Denny[3], Zikun Wang[2], Garrett Daniels[4], Sitharthan Kamalakaran[2], Ryan Leenay[5], Brett Staahl[1], Benjamin Oakes[3]
[1]*Scribe Therapeutics, Alameda, CA,* [2]*Eli Lilly and Company, New York, NY,* [3]*Scribe Therapeutics, Alameda,* [4]*Eli Lilly and Company, Indianapolis, Indiana,* [5]*Eli Lilly and Company*

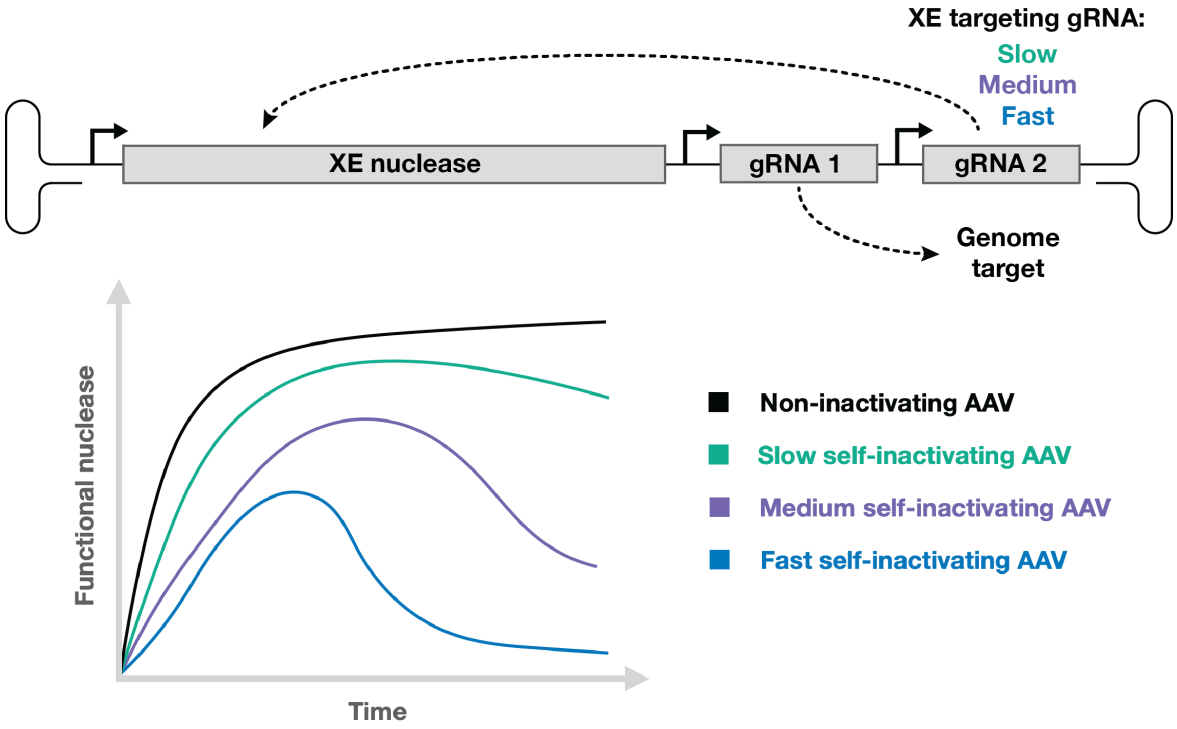
Adeno-associated viral (AAV) vectors are among the most promising vehicles for delivering genetic cargo, including CRISPR-based editing technologies, to the CNS. However, long-term expression of CRISPR from AAV

raises concerns about undesired off-target effects. To mitigate this, we have engineered self-inactivating AAV (siXAAV) vectors that self-target and cleave their CRISPR components, thereby limiting constitutive nuclease expression once the desired edit is achieved.

Our siXAAV system features a potent, highly engineered, compact CasX-Editor (XE) in a single AAV vector with multiple guide RNAs (gRNAs), including one on-target gRNA and a second, lower-activity gRNA that targets the XE coding sequence for self-cleavage and inactivation.

To develop siXAAV, we systematically screened dozens of XE-targeting gRNAs—varying guide-target mismatch designs—to identify distinct self-cleavage potencies and kinetics capable of maximizing on-target genomic editing before self-inactivation. We employed a tagged XE plasmid system to quantify XE expression, self-targeting, and on-target editing, ultimately selecting three prototype gRNAs for *in vivo* validation. We then packaged the siXAAV: XE, a safe harbor-targeting gRNA, and a self-targeting gRNA into a single AAV vector. Assessment of packaged AAV genome integrity revealed high quality genomes with no measurable indels at the self-targeting sites. We administered siXAAV and non-inactivating control AAV vectors via intracerebroventricular injection into adult C57BL/6 mice. Tissues were analyzed at 1 and 2 months post-injection for vector biodistribution, on-target genome editing, and self-targeting events.

Both siXAAV and control AAVs achieved robust on-target editing. Crucially, siXAAV-treated mice showed editing within the target sites in the XE coding sequence, confirming self-cleavage. Despite high self-editing rates, vector distribution remained stable, indicating potential episome repair rather than degradation. Notably, while controls exhibited small increases in on-target editing over time, siXAAV-treated animals did not, indicating effective nuclease self-inactivation. This work demonstrates the feasibility of developing self-inactivating AAVs for transient but potent *in vivo* genome editing, offering a promising avenue for safer therapeutic applications by avoiding long-term nuclease expression.



1644 CRISPR/Cas9 enables efficient knockout of CD52 without CD3/CD28 in expanded CMV-specific T cells

Naseem Maghzian[1], Cecilia Motta[2], Susan Conway[2], Daisy Ayala-Gomez[3], Pamela Chansky[2], Nethaji Muniraj[2], Gloria Pezzella[4], Samantha Murphy[5], Joshree Shrestha[2], Haili Lang[6], Catherine Bollard[7], Wei Li[2], Conrad Russell Cruz[8], Allistair Abraham[9], Michael Keller[2]

[1]Children's National Hospital, Washington D.C., DC, [2]Children's National Hospital, Washington, DC, [3]Children's National Hospital, Arlington, VA, [4]Childrens National, Washington, DC, [5]Children's National Hospital, Alexandria, VA, [6]Children's National Medical Center, Washington, DC, [7]The George Washington University, Washington, DC, [8]Children's National Medical Center, Washington, DC, [9]Children's National Hospital, Vienna, VA

Adoptive immunotherapy using virus-specific T-cells (VSTs) has been successfully used in clinical trials to prevent and treat viral infections in immunocompromised patients post-hematopoietic stem cell transplantation (HSCT). Alemtuzumab, a lymphodepleting monoclonal antibody that targets the surface antigen CD52, is commonly used as a conditioning regimen to prevent the development of graft versus host disease (GVHD). However, it increases time for lymphocyte recovery post-HSCT and the potential risk for viral infections and reactivations. CD52 has no known critical impact on the immune system, and there have been no reported toxicity by knocking out CD52 per prior phase I chimeric antigen receptor (CAR) T-cell cancer immunotherapy trials. Therefore, we predicted that using CRISPR-Cas9 mediated knockdown (KO) of CD52 in VSTs provides a potential novel preventative therapy early post-HSCT. We compared two methods of generating KO VSTs to determine the most effective way to remove CD52 while maintaining antiviral activity.

CRISPR single-guide RNA (sgRNA) were designed using CRISPick and CRISPR-DO. Resulting guides were chosen based upon predicted high efficiency and off-target sites. CD52 KO was performed in a Lonza Nucleofector System. Cas9 protein and sgRNA were used to electroporate PBMCs using the program for stimulated Human T cells. For method one, cryopreserved VSTs were thawed and activated for 72 hours using anti-CD3/anti-CD28 in RPMI media supplemented with GlutaMAX™, fetal bovine serum, and IL-2 (CTL media) and cultured for 5 days prior to RNP-CRISPR electroporation. In method two, we optimized our existing rapid ex vivo expansion of cytomegalovirus (CMV)-specific VSTs protocol to include gene editing on day 7 of VST expansion, followed culture in CTL media supplemented with IL-4 and IL-7 for an additional 5-7 days.

To confirm and assess the percentage of CD52KO on a protein level, VSTs were surface stained with CD52 antibodies and acquired on a CytoFLEX Cytometer. For indel evaluation, PCR products of isolated DNA were Sanger sequenced and KO rate was determined using ICE CRISPR Analysis Tool.

Six CRISPR sgRNA that targeted the CD52 gene were tested using method one with KO frequencies ranging from 18% to 85% seen on flow cytometry. The two sgRNAs with higher efficiency (sgRNA1 - 83%, and sgRNA2 - 85%) were further investigated. In silico analysis identified 88 and 168 off-target sites requiring additional analysis for sgRNA1 and sgRNA2, respectively, but none involved known oncogenes. Rhampseq performed on CMV-VSTs for sgRNA1 showed no significant off-target editing at any site of interest in the edited population compared to non-edited control. Furthermore, sgRNA1 (UUACCUGUACCAUAACCAGG) had a 70% ICE-d score via ICE analysis.

After comparing both stimulation methods, we were able to successfully optimize and generate CD52 KO CMV-VSTs without the use of anti-CD3/anti-CD28 (Figure 1) which is thought to maximize CRISPR-Cas9 editing efficiency. We instead did electroporation during ex vivo expansion of VSTs in the presence of growth-enhancing cytokines and viral peptides and achieved comparable KO of CD52,73.2% (method two) compared to 82.5% (method one), N = 3 (Figure 2).

This demonstrates the feasibility of CD52 KO with peptide stimulated T cells in absence of CD3/CD28 and could facilitate production of “next generation” gene-edited VST product to restore antiviral immunity early post HSCT alongside prevention of GVHD.

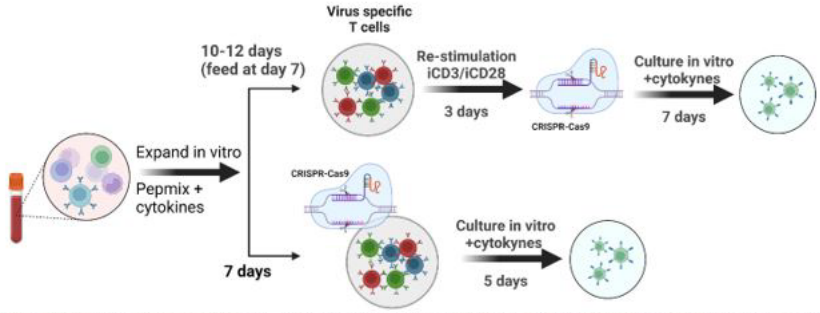


Figure 1CRISPR/Cas9 mediated knockout (KO) of CD52 in CMV-specific VSTs. (A) Schematic summary of the protocol for CRISPR-Cas9-mediated KO of CD52 in primary human VSTs. PBMCs were stimulated with a CMV pepmix in the presence of IL-4 and IL-7. On day 7 of in vitro expansion, primary human VSTs were nucleofected with control Cas9 alone or Cas9 preloaded with gRNAs targeting the CD52 gene. KO efficiency and functional assays were performed at day +12 post-initial PBMC isolation.

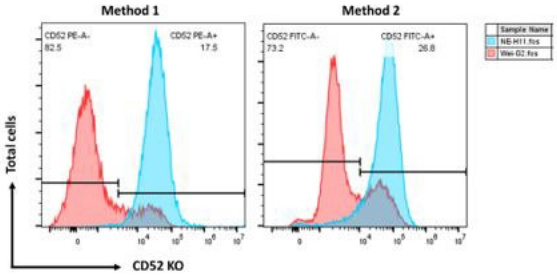

Figure 2 KO efficiency for two different stimulation methods to generate CD52 KO CMV-VSTs.

1645 ADAR-Mediated RNA Editing of Premature Termination Codon Results in Functional Correction in *MECP2* for Rett Syndrome

Marko Potman[1], Sherissa Wirabuana[2], Maaike van Berkel[1], Christopher Langeveld[3], van de Giessen Jeroen[1], Seda Yilmaz-Elis[4], **Gerard Platenburg[5]**
[1]ProQR Therapeutics, Leiden, Netherlands, [2]ProQR Therapeutics, Leiden, Zuid-Holland, Netherlands, [3]ProQR Therapeutics, Sassenheim, Zuid-Holland, Netherlands, [4]ProQR Therapeutics, Leiden, Noord-Holland, Netherlands, [5]ProQR Therapeutics B.V., Leiden, Zuid-Holland, Netherlands

Rett Syndrome is a severe neurodevelopmental disorder affecting approximately 350,000 people worldwide. It mainly occurs in females and is caused by mutations on the methyl CpG binding protein 2 (*MECP2*) gene on the X-chromosome. This gene codes for the MECP2 protein which is a key regulator of gene expression and is vital for maintaining normal brain function and development. The severity of the disease is determined by the location, mutation type and level of X-chromosome inactivation. The premature termination codon gives rise to p.R270X which is one of the most commonly occurring pathogenic variants of MECP2. Axiomer, an RNA editing platform, uses chemically modified editing oligonucleotides (EONs) to recruit and guide endogenous Adenosine Deaminase Acting on RNA (ADAR) to perform adenosine to inosine (A-to-I) editing on double stranded RNA, which can restore the precise regulatory function of the MECP2 protein.

ADAR-mediated RNA editing edits the stop codon (X) to a Tryptophan (W) coding codon, leading to a functional MECP2 protein. EONs were designed and screened in vitro in patient primary fibroblasts to assess editing efficiency, impact on RNA and protein levels. Three EON optimisation rounds resulted in highly efficient A-to-I editors. R270X MECP2 patient fibroblasts were transfected with EON, and editing efficiencies were measured. Top performing EONs demonstrated mean editing efficiencies between 50-60%. Additionally, a time course experiment was performed where editing was measured for 5 days after a single dose treatment. Sustained editing was measured from days 1-5.

Premature termination codons often lead to nonsense-mediated decay (NMD) which reduces RNA levels. Total RNA copies of MECP2 were measured in patient fibroblasts treated with EONs vs. non treated, to assess differences in copy number. An approximately 4-fold increase in total RNA copies was measured for top performing EONs when compared to the non-treated sample, indicating inhibition of NMD.

Furthermore, upon EON transfection of HeLa MECP2 KO cells, R270W MECP2 protein levels were approximately 8-fold higher than R270X MECP2 protein levels in the untreated sample. This shows transcriptional read through and translation into a functional MECP2 protein.

ADAR-mediated RNA editing of the mutated p.R270X MECP2 shows great potential as a disease modifying therapy for Rett syndrome. The dual action - recoding the premature termination codon and stabilizing the mRNA - obtained with EONs, could ensure that the corrected RNA is not only functional but also restored to physiological levels, maximizing therapeutic impact. Lead EONs are currently being optimized for further development.

1646 Novel U7 Small RNA mediated modulation of TCF4 Promoter activity as a therapeutic strategy for Pitt-Hopkins syndrome

ARUN PARIPATI[1], Shibi Likhite[1], Yanina Tkachenko[1], Abuzar Kaleem[2], Babatunde Ogunlade[3], Kathrin Meyer[4]*, Jingting Zhu[5], Afrooz Rashnonejad[6]*

Introduction: Pitt-Hopkins syndrome (PTHS) is an autosomal dominant disorder with an estimated prevalence of 1 in 41,000 individuals. It results from mutations in the TCF4 gene and is marked by intellectual disability, significant delays in motor development, absence of functional speech, and breathing difficulties. TCF4 is a basic helix-loop-helix (bHLH) protein that is broadly expressed, especially in the nervous system, and regulates gene expression by interacting with other bHLH proteins to either promote or inhibit transcription. Due to its large size and multiple known protein isoforms, TCF4 poses a challenge for traditional gene replacement approaches. However, since patients still have one functional copy of the gene, enhancing TCF4 expression presents a promising alternative. In this study, for the first time, we modified U7 small nuclear RNAs (U7-snRNAs) to modulate TCF4 promoter activity and enhance its expression, proposing a novel gene therapy approach for PTHS.

Methods: We designed 3 U7 small RNA cassettes targeting different regions of the TCF4 promoter that we predicted could modulate the promoter activity. We assessed the efficiency of U7 cassettes through transient transfection in HEK293 cells to evaluate their ability to enhance TCF4 expression. Next, we generated AAV9 viral particles and validated their effectiveness in an in vitro model with human PTHS patient cell lines, employing RT-PCR and immunofluorescent imaging to measure TCF4 expression. Functional assays were used to determine the effect of the treatment on cellular health as well. In addition, we used mouse embryonic fibroblasts (MEFs) from a mouse model that expresses the green fluorescent protein under the human TCF4 promoter as an additional model system to further validate our approach. We also evaluated the efficiency of AAV9.U7-TCF4 in enhancing TCF4 expression in a transgenic mouse model that carries the human TCF4 promoter with GFP downstream of TCF4 gene.

Results: In vitro studies in HEK293 cells and a PTHS patient induced astrocytes demonstrated elevated expression of TCF4 following transient transfection of U7 cassette, as confirmed by qRT-PCR and immunofluorescence staining after 72hrs of transfection. The enhanced expression of TCF4 improved the survival of co-cultured mouse motor neurons interacting with patient-derived induced astrocytes, providing functional evidence of the treatment's efficacy. Moreover, using mouse embryonic fibroblasts expressing GFP under the control of the human TCF4 promoter, we showed upregulation of GFP expression 72 hrs after treatment with AAV9.U7-TCF4. Interestingly, stereomicroscopic imaging of brain tissues showed increased GFP fluorescence in the injected animals compared to the uninjected controls after 6 months post-injection, which confirms the TCF4 protein expression. The qRT-PCR

analysis of Intracerebroventricular injection of 4.4´1010 dose of AAV9.U7-TCF4 into a transgenic mouse model showed a 1.4-fold increase in TCF4 transcript levels at 1- and 6-months post-injection.

Conclusion: We developed a novel U7-snRNA-based technology that enables modulation of TCF4 promoter activity. Altogether, our in vitro results in HEK293 cells, PTHS patient-induced astrocyte cell lines, and mouse embryonic fibroblasts expressing GFP under the human TCF4 promoter, along with in vivo studies in a transgenic mouse model, demonstrate the effectiveness of this approach. Our novel therapeutic strategy holds great p

1647 Combined Targeting of *HTT*, *HTT1a* and Somatic Instability in Huntington's Disease using LinQURE®: a Feasibility Study in Multiple HD Mouse Models

M. Leontien Van Der Bent[1]*, Christian Landles[2], Roberto Morais[3], Georgina Osborne[2], Izaskun Pueyo Mendoza[4], Javier Villamil-Ortiz[4], Lisa Spronck[5], Morgane Wartel[6], Sarah Tabrizi[7], David Howland[8], Gillian Bates[9], Astrid Valles-Sanchez[10]

Huntington's disease (HD) is an autosomal dominant disorder caused by an expanded CAG repeat in the huntingtin (*HTT*) gene. The unstable CAG repeat expansion leads to toxic gain-of-function of *HTT* mRNA and protein species, causing cellular dysfunction and neurodegeneration. There are currently no disease modifying therapies for HD. Many therapies that are under development, including uniQure's clinical-stage candidate AMT-130, are designed to lower HTT levels, with the goal of slowing neurodegeneration.

Recent studies indicate that somatic expansion of the CAG repeat in mutant *HTT* through aberrant mismatch repair is a pivotal disease contributor, with MutS homolog 3 (*MSH3*) as a promising therapeutic target. Furthermore, there is increasing evidence for a repeat-length dependent increase in expression of a truncated isoform called HTT1a, which is considered to be the most toxic HTT protein species. Here, we have explored the feasibility of simultaneous dual or triple targeting of *HTT*, *HTT1a* and *MSH3*, using uniQure's LinQURE® AAV platform, as a potential next-generation therapeutic approach for HD.

Therapeutic miRNAs targeting *HTT1a* or *MSH3* were screened *in vitro*, and several lead candidates were selected for *in vivo* evaluation in relevant HD mouse models. We tested the individual *HTT1a*-targeting candidates in YAC128 mice, showing preferential lowering of the HTT1a protein and more modest reductions of full-length HTT. Individual *Msh3*-targeting candidates were tested in $Hdh^{Q111/+}$ mice, showing potent reduction of *Msh3* mRNA and a concomitant reduction in somatic repeat instability. We then proceeded to test multi-target approaches using LinQURE® in two different HD mouse models: R6/1 and BAC-CAG. Dual *Msh3* and *HTT* targeting led to a potent, dose-dependent reduction of *Msh3* mRNA and was associated with reduced somatic instability in R6/1 mice. Finally, dual and triple *Msh3*-, *HTT*- and *HTT1a*-targeting LinQURE® candidates all showed potent target engagement and rescue of the molecular phenotype in BAC-CAG mice. Importantly, we could recapitulate both the allele-preferential effect of *HTT1a*-targeting, as well as the inhibition of somatic instability by reducing *Msh3* expression, in multiple HD mouse models.

These data support the feasibility of concurrently targeting *HTT* and *MSH3* using LinQURE®, as well as the option to preferentially lower mutant *HTT1a* using a miQURE® or LinQURE® approach. Such approaches hold major promise as potential next-generation gene therapies for HD.

1648 PYC-002, a Novel Antisense Oligonucleotide Targeting SHANK3 Haploinsufficiency in Phelan-McDermid Syndrome

Phelan-McDermid Syndrome (PMS) is a rare neurodevelopmental disorder generally diagnosed between 3 and 6 years of age. It is caused by deletions or mutations resulting in haploinsufficiency of the SH3 and multiple ankyrin repeat domain 3 (SHANK3) gene, which is critical for synaptic structure and function. These genetic alterations result in various behavioural and physical symptoms, that can include speech impairment, intellectual disability, seizures, and autism, which permanently affect the quality of life for patients. Currently, there is no effective treatment available for PMS patients, which highlights the significant unmet medical need for this disorder.

This study aims to develop a therapeutic approach for PMS by upregulating SHANK3 expression levels using antisense oligonucleotides (ASOs). ASOs are short synthetic nucleic acids that modulate gene expression through ASO-mRNA interactions and provide a precise and reversible method to address this deficiency.

ASOs were designed to target regulatory regions of the *SHANK3* transcript, to enhance the expression of functional SHANK3 protein isoforms. Initial ASO screening in SH-SY5Y neuroblastoma cells identified a hotspot region within the *SHANK3* gene that could be targeted to increase SHANK3 protein levels by 1.3-1.5-fold ($p<0.01$). Subsequent screening was conducted in healthy induced pluripotent stem cell (iPSC)-derived glutamatergic neurons and ASO candidates that induced a 1.4-2.3-fold uplift in SHANK3 protein expression were selected for further assessment. The pharmacodynamic profile of two ASOs was then assessed in iPSC-derived glutamatergic neurons differentiated from four PMS patients, with both candidates demonstrating robust patient-agnostic efficacy. The lead ASO, 'PYC-002', was evaluated *in-vivo* to determine safety and efficacy in wild-type Sprague-Dawley rats following intrathecal injection. PYC-002 was well-tolerated and a 1.2-1.5-fold upregulation of SHANK3 protein was observed in brain regions that are affected by disease in PMS patients.

Our data highlights that PYC-002 is a promising clinical candidate to treat PMS by restoring SHANK3 expression. This novel approach addresses an urgent unmet need and extends ASO application to a broader spectrum of neurodevelopmental disorders. Future research will investigate the effect of optimized PYC-002 delivery on neuronal function, with an Investigational New Drug submission projected for 2026.

1649 First in Class ASO Targeting *A53T* Allele: Preclinical Efficacy

Christina Tyner[1], Sandra Smieszek[2], Bartlomiej Przychodzen[3], Christos Polymeropoulos[3], Gunther Birznieks[3], Mihael Polymeropoulos[3]
[1]Vanda Pharmaceuticals Inc., Washington, DC, [2]Sandra Paulina Smieszek, Bethesda, MD, [3]Vanda Pharmaceuticals Inc, Washington, DC

Introduction: First delineated by Dr. Polymeropoulos et al. in 1997, the Ala53Thr (A53T) missense mutation in *SNCA* has been identified as one of the most significant risk factors in early-onset Parkinson's disease (PD) (Polymeropoulos et al., 1997). We propose an antisense oligonucleotide (ASO)-based allele-specific strategy to target the mutant A53T *SNCA* allele and reduce resulting aberrant α-syn production, without downregulating the wild-type (WT) allele. This strategy is unique compared to existing ASOs under development for the treatment of PD, as these target the general knockdown of SNCA via recruitment of RNase H activity despite mutation status. α-syn is critical for neuronal function and survival; depletion in the functional pool of α-syn by RNAi-mediated silencing induces neurodegeneration (Gorbatyuk et al., 2010). An allele-specific therapeutic that targets just the mutant A53T allele ensures that healthy levels of α-syn are maintained by the WT allele. Given the high prevalence of this disease, a treatment that works by directly targeting an underlying molecular cause of PD holds significant potential to significantly improve PD patients' disease manifestation and quality of life.

Methods: We designed an 18-mer gapmer phosphorothioate (PS) methoxyethyl (MOE) ASO that selectively targets the *A53T* mutant allele. This ASO was designed to have a higher affinity for the mutant allele, as predicted *in silico,* as opposed to the same sequence from WT of the same length. HEL cells were incubated for 72-hours with the A53T-specific ASO (at 1μM) using gymnotic uptake. The HEL cell line was chosen due to its abundant SNCA expression.

Results: ASO treatment resulted in a 40% reduction of SNCA expression. This knockdown with qPCR is consistent with RNAseq data. Positive control gapmers as well as siRNA were used as controls. Limited off-target effects of this ASO were demonstrated *in silico*. Furthermore, fibroblasts from a patient with confirmed A53T mutation status were obtained and iPSCs were generated. Currently, further molecular characterization in a human iPSC-derived PD model is planned to assess the effects of A53T-specific ASO silencing in rescuing PD phenotype. This model contains dopaminergic, GABAergic, and glutamergic neurons, which display disease-relevant phenotypes at basal conditions which correlate with the brains of A53T PD patients.

Conclusions: It has been previously demonstrated that using a CRISPR-Cas9 system to delete the A53T *SNCA* mutation improved PD-related conditions, including α-syn overproduction, reactive microgliosis, dopaminergic neurodegeneration, and motor symptoms (Yoon et al., 2022). Achieving a ratio in favor of mutant allele downregulation is desirable as it does not knockdown the WT allele while targeting the aberrant gain-of-function allele, a phenomenon that is not possible with other proposed lines of treatment. We present a novel ASO that achieves this goal *in vitro*. An iPSC-based system containing a mixed neuronal population is a more comprehensive model for A53T synucleinopathy and for assessing therapeutic agents. We plan to utilize this model to examine the efficacy of our ASO in reducing numerous parameters, including the presence of Lewy neurites, Lewy bodies, extracellular Lewy body-like formations, varicosities, bulbous endings, and degenerating neurons.

1650 Exon 45 Skipping, Dystrophin Production, and Functional Improvement with ENTR-601-45 in Preclinical Models of Duchenne Muscular Dystrophy

Xiang Li[1], Nelsa Estrella[2], Ajay Kumar[3], Amy Hicks[4], Jia Qi Cheng Zhang[4], Maureen Fredricks[4], Mary Lou Beerman[4], Chris Brennan[5], Sara Blake[2], Mah Kheirabadi[6], Patrick Dougherty[2], Matthew Streeter[4], Mahasweta Girgenrath[7], Ziqing Qian[8]
[1]Entrada Therapeutics, Belmont, MA, [2]Entrada Therapeutics Inc, [3]Entrada Therapeutics, Sharon, MA, [4]Entrada Therapeutics, Boston, MA, [5]Entrada Therapeutics, Canton, MA, [6]Boston, MA, [7]Entrada Therapeutics Inc, Boston, MA, [8]Entrada Therapeutics, Boston, Massachusetts

Currently approved exon skipping phosphorodiamidate morpholino oligomer (PMO) therapies for Duchenne muscular dystrophy (DMD) produce modest amounts of dystrophin due to poor cell entry and limited escape from the endosome. In order to overcome these limitations, we developed a family of therapeutics consisting of Endosomal Escape Vehicle (EEV™) cyclic cell penetrating peptides conjugated to exon skipping PMOs.

ENTR-601-45 is an exon 45 skipping PMO conjugated to the EEV platform and is in development for the treatment of exon 45 skip-amenable DMD. Here, we examined the efficacy of ENTR-601-45 in cell and animal models. Treatment of exon 45 skip-amenable, DMD patient-derived skeletal and cardiac muscle cells with ENTR-601-45 demonstrated robust, dose-dependent exon 45 skipping and dystrophin production. To assess the therapeutic potential of ENTR-601-45 in vivo, we utilized del44hDMD.*mdx* mice containing a human dystrophin-expressing transgene (hDMD) with *DMD* exon 44 deleted on an *mdx* background. These mice are amenable to human exon 45 skipping allowing for quantification of both exon 45 skipping and dystrophin production *in vivo*. Three doses of ENTR-601-45 administered every six weeks (Q6W) to del44hDMD.*mdx* mice produced robust, dose-dependent exon 45 skipping, dystrophin expression, and proper localization to the sarcolemma in skeletal muscle 6 weeks after the third dose. In addition, three Q6W doses of ENTR-601-45 produced a dose-dependent reduction to damage after repeated eccentric contractions in the gastrocnemius skeletal muscle which was maintained in all dose groups 5 weeks after the third dose.

These findings demonstrate the efficacy of ENTR-601-45 in both cell and animal models of exon 45 skip-amenable DMD. Improved skeletal muscle function in an exon 45 skip–amenable DMD mouse model suggests that ENTR-

601-45 can produce functional dystrophin protein *in vivo*. Together, these results show the therapeutic potential of ENTR-601-45 and support further study in DMD patients amenable to exon 45 skipping.

1651 Translating *IGHMBP2* Variants with a CMT2S Patient-Specific Model: Personalized Medicine Rescue

Caroline Johnson[1], Sandra Smieszek[2], Bartlomiej Przychodzen[3], Christina Tyner[1], Christos Polymeropoulos[3], Gunther Birznieks[3], Walker Hagan[4], Caitlyn Niccum[4], Rocky Brighton[4], Kenneth Hawkins[5], Romy Aiken[6], Ahmad Nawaz[5], Xiufang Guo[5], James Hickman[7], Mihael Polymeropoulos[3]
[1]Vanda Pharmaceuticals Inc., Washington, DC, [2]Sandra Paulina Smieszek, Bethesda, MD, [3]Vanda Pharmaceuticals Inc, Washington, DC, [4]Hesperos, Orlando, FL, [5]University of Central Florida, Orlando, FL, [6]Nanoscience Technology Center, University of Central Florida, Orlando, FL, [7]Hesperos Inc, Orlando, FL

Introduction: Charcot-Marie-Tooth disease Type 2S (CMT2S) is a rare Charcot-Marie-Tooth disease subtype caused by pathogenic immunoglobulin mu-binding protein 2 (*IGHMBP2*) variants that result in abnormal RNA processing leading to alpha-motor neuron degeneration. A patient was reported with variants in *IGHMBP2*: a pathogenic missense variant acting in trans with a confirmed intronic cryptic splice site variant (c.1235+894 C>A) deep in intron 8. This non-coding *IGHMBP2* variant was shown to result in the creation of a new splice acceptor site, loss of reading frame and nonsense-mediated decay, ultimately reducing levels of IGHMBP2. We developed an antisense oligonucleotide (ASO) that targets this cryptic intronic variant to restore canonical splicing, rescuing levels of IGHMBP2. A microphysiological system (MPS) of the neuromuscular junction (NMJ) was utilized to characterize the CMT2S phenotype. Our objective was to rescue neuromuscular defects caused by this variant with our novel ASO.

Methods: We designed a 19-mer ASO targeting this cryptic intronic variant. To develop an *in vitro* model for this CMT2S patient, patient cells were transformed into induced pluripotent stem cells (iPSCs) and differentiated into motor neurons (MNs). The NMJ was analyzed using a patient-derived 'human-on-a-chip' NMJ system created by Hesperos Inc. CMT2S-MNs were integrated into a dual-chamber NMJ system. NMJs underwent ASO treatment and were assessed. To evaluate axonal defects, CMT2S-MNs were integrated on microelectrode arrays with wild-type (WT) Schwann cells. Conduction velocity (CV) effects were assessed before and after ASO treatment.

Results: In patient fibroblasts, ASO treatment significantly increased the ratio of restored WT transcript to cryptic exon containing transcript and resulted in over a 50% increase in IGHMBP2 protein levels. CMT2S-MNs displayed an overall functional decay at later stages of development, aligning with the motor function decay observed in CMT2S patients. CMT2S-NMJ analyses revealed a higher fatigue index (FI) than WT-NMJs and showed high levels of decay and chaotic tetanus. Following treatment with VCA-894A, we demonstrate rescue of NMJ functioning, captured by a decrease in FI and decay and chaotic responses. CMT2S-MN CV was evaluated by assessing average velocities of all conductions and the number of conductions over 28 days. CMT2S-MNs exhibited consistently fewer conductions at all testing time points and a reduced average conduction velocity, with the exception of Day 14. Following ASO treatment, CMT2S-MNs experienced a significant dose-dependent rescue of CV and number of conductions, as compared to WT control MNs and vehicle treated CMT2S-MNs.

Conclusions: We show rescue of NMJ functioning post-ASO treatment, captured by FI decrease and reduction in decay and sporadic responses. Furthermore, ASO treatment resulted in a dose-dependent increase in CV and number of conductions. This provides translational evidence that this ASO may improve fatigue and restore clinical motor control. We are further analyzing this patient-specific model to continue phenotyping CMT2S caused by *IGHMBP2* variants. N-of-1 ASO-based therapeutics may prove instrumental in the design of treatments for this diverse genetic disorder.

1652 Functionalized Nonsense Suppressor tRNA Picovectors Represent a Novel Therapeutic Cargo for the Treatment of PTC-associated Diseases

Joseph Porter[1]*, David Dean[2], **John Lueck[1]**
[1]University of Rochester, Rochester, NY, [2]University of Rochester, Rochester, New York
**Corresponding Author*

Background: Nonsense mutations or premature termination codons (PTCs) occur when a canonical triplet nucleotide codon is converted into one of three stop codons (TGA, TAG and TAA). These mutations make up 10-15% of all genetic lesions that cause disease including Cystic Fibrosis (CF), Duchenne muscular dystrophy, spinal muscular atrophy, and choroideremia, among others. We have recently demonstrated the function of a series of nonsense suppressor anticodon edited tRNAs (ACE-tRNAs) to suppress CF-causing PTCs in the cystic fibrosis transmembrane regulator (*CFTR*) gene in gene-edited immortalized human bronchial epithelial (16HBE14ge) cells. A major advantage of ACE-tRNAs as a therapeutic cargo is the small (~125 bp) size of the ACE-tRNA gene including promoter and transcriptional terminator. Taking advantage of this property, we have previously encoded ACE-tRNAs in non-viral DNA minivectors, which impart several favorable characteristics to the vectors including increased cell transfection efficiency and higher molar equivalents of the cargo sequence per vector delivered. Through these efforts, we now understand that linear covalently closed DNA vectors with sizes as small as 200 bp can serve to produce a robust PTC suppression response. However, this approach towards a therapeutic cargo for treatment of PTCs had a poor outlook due to technical challengers related to minivector production methods, which exhibited poor scalability, adaptability, and GMP adherence.

Methods: With this in mind, we developed a novel assembly method for production of synthetic linear ACE-tRNA picovectors (sLPV; 'picovectors' owing to their small size) using substrates produced by solid-phase oligonucleotide synthesis, with DNA hairpins serving to covalently close the sLPV ends. Further, these hairpins were synthesized to contain internal DBCO functionalized nucleotides for labeling with azide functionalized moieties in copper-free click reactions. Introduction of this chemical functionality allows for dual labeling of the sLPVs with any combination of azide functionalized fluorophores, peptides, proteins, or other DNAs to improve either cellular delivery, intracellular trafficking, or intracellular imaging of the sLPVs. Using this approach we labeled ACE-tRNA picovectors with peptides comprising several different nuclear localization signals (NLS) for active transport to the nucleus. To test the NLS-functionalized sLPV in a manner consistent with delivery to post-mitotic cells, aphidicolin was utilized to arrest cell division in 16HBEge cells.

Results and Conclusions: We tested previously characterized but disparate NLS sequences, with a scrambled peptide serving as a control. All NLSs improved PTC suppression in aphidicolin treated 16HBEge cells, with the best sequence outperforming other NLSs (3.5-fold over scrambled and 17.5-fold over unlabeled plasmid DNA). While the presence of dsDNA in the cytoplasm of human cells can trigger the cGAS-STING innate immune pathway, sLPV labeled with the best performing NLS produces ~80% less cGAMP as compared to plasmid DNA. This novel modular sLPV assembly procedure allows for production of minimal ACE-tRNA therapeutic vectors with properties that can be engineered for optimal cellular delivery and intracellular trafficking.

1653 Micro RNAs in the core arsenal of Molecular Paradigms in Papillary Thyroid Cancer Modalities

Rashida Khan, Institute of Biomedical & Genetic Engineering Islamabad Pakistan, Rawalpindi, Islamabad Capital Territory, Pakistan

Introduction: To improve the diagnosis of thyroid cancer miRNAs are one of the novel classes of molecular markers that are being used now a day. The pattern of expression of miRNAs can be the rich source of biological information. miRNAs are endogenous, noncoding RNAs with lengths ranging from 19 to 25 nucleotides. They play major roles in the posttranscriptional regulation of gene expression. In general, miRNAs down modulate the

expression of a target gene by diminishing the stability of its transcript and/or inhibiting its translation. variations in the expression patterns can provide clues as to how different cellular processes are modulated under both physiological and pathological conditions.

Research on microRNA expression in thyroid tumors provides a new insight for the development of novel biomarkers that can be used to diagnose thyroid cancer and optimize its management. Specific patterns of miRNA expression have been identified in many studies and several miRNAs were found overexpressed or downregulated in major types of thyroid tumors.

Objectives: The study aimed to speculate the overexpression of miRNA-146b and miRNA-181b in thyroid cancer, as compared with levels in normal thyroid tissues & MNGs, Moreover, mutations in the same miRNAs may alter the pathways and correlated with the aggressiveness of cancer proving these miRNAs as tangible biomarkers for diagnosis of the disease.

Methodology: QRT-PCR is probably the most popular method currently used for detection of miRNAs expression. miRNA profiling begins with the isolation of total RNA which entails reverse transcription of miRNA to cDNA, followed by real-time monitoring of the accumulation of polymerase reaction products. An internal control was used for relative quantification of the expression. Sanger sequencing was used for the mutational analysis as compared to normal specimen and correlated the mutations with thyroid cancer specimen.

Results: 5 to 20 folds and 4-60 folds' overexpression of miRNA-146b & miRNA-181b was observed in thyroid cancer tissue specimen compared to controls and MNGs which was statistically significant expression. Similarly, rare genotypes and alleles were observed significantly in PTC tissue samples compared to controls and MNGs.

Conclusion: This forged maladaptation of the miRNA-146b and miRNA-181b in the cancer microenvironment may warrant analytically, therapeutically and genetically and this upregulation is positively correlated with tumor aggressiveness.

Figure.1: Relative Expression of miRNA-146b & -181b in PTC specimen, controls & MNG samples.

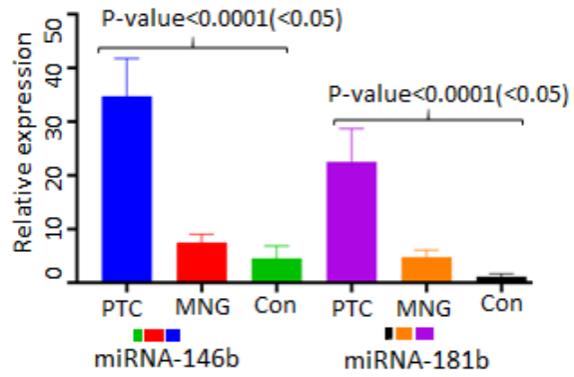

Figure.2: Heterozygous mutation of miRNA-146b (A/G) observed in PTC specimen.

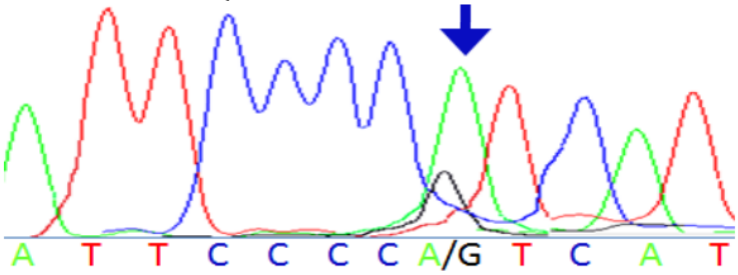

1654 ADAR-Mediated RNA Editing-Based Correction of PNPLA3 I148M Functionality to Address Hepatic Steatosis

Werner Helvensteijn[1], Petra de Bruijn[2], Lieke Herbschleb[3], Nadia Keijzer[3], Marguerite Toros[4], Tsinatkeab Hailu[3], Zhana Karneva[1], Marjon Mourik[1], Francesco De Chiara[1], Seda Yilmaz-Elis[4], **Gerard Platenburg[5]**
[1]ProQR Therapeutics, Leiden, Netherlands, [2]ProQR Therapeutics NV, NETHERLANDS, [3]ProQR Therapeutics, Leiden, Zuid-Holland, Netherlands, [4]ProQR Therapeutics, Leiden, Noord-Holland, Netherlands, [5]ProQR Therapeutics B.V., Leiden, Zuid-Holland, Netherlands

Metabolic dysfunction–associated steatotic liver disease and steatohepatitis (MASLD/MASH) and subsequent stages of liver disease are very prevalent and still on the rise worldwide. MASH individuals have a high unmet medical need due to the progressive nature of the disease (hepatic steatosis, cirrhosis, and hepatocellular carcinoma) and the limited therapeutic options available making it the second cause of liver transplantation in the US. Patatin-like phospholipase domain-containing protein 3 (*PNPLA3*), a lipase expressed in hepatocytes and liver stellate cells, is involved in lipid homeostasis and metabolism. PNPLA3 I148M (rs738409) is a variant commonly reported in the MASH population worldwide (20-60% of the patients) and is known as an associated risk factor for hepatic steatosis and an increased risk of developing MASH. Approximately 8 million individuals in US and EU are homozygous for the 148M variant. PNPLA3 I148M variant induces triglyceride accumulation in hepatocytes, leading to increased lipid droplet size and number, which in turn promotes cellular stress, fibrosis, and disease progression to cirrhosis.

Axiomer, an RNA editing platform, uses chemically modified and complementary editing oligonucleotides (EONs) to recruit and guide endogenous Adenosine Deaminase Acting on RNA (ADAR) to perform targeted A-to-I editing on double stranded RNA. Editing oligonucleotides convert the PNPLA3 148 Methionine into a Valine, restoring wild-type like function of the PNPLA3 and alleviating the induction of hepatic steatosis. Here we present preclinical proof-of-concept data to support the approach.

In-silico 3D structural modelling analysis revealed that the PNPLA3 148M (ATG) shows a non-conservative substitution with predicted functional consequences, leading to a change in binding cavity volume limiting access of substrate to the active site, impairing its metabolic function. On the contrary, PNPLA3 148V (GTG) variant showed similar structure to wild-type (WT) PNPLA3 (148I, ATC), with Valine expected to exhibit similar properties and behave like isoleucine leading to minimal impact on the activity/functionality of the protein. To investigate experimentally if PNPLA3 148V variant can function as WT, PNPLA3 148V, 148M and WT variants were expressed in HeLa cells loaded with linoleic acid. Confocal imaging revealed that PNPLA3 148V (Bodipy, mean area per cell of 3.65 μm^2) showed similar levels of triglycerides and lipid droplet sizes inside the cell compared to PNPLA3 WT (1.33 μm^2 per cell, $P<0.0001$, one-way ANOVA) versus PNPLA3 148M (34.00μm^2 per cell).

Following this proof of concept, EON induced *PNPLA3* editing was observed up to 53% in primary human hepatocytes. Subsequently, in a homozygous 148M HepG2 cell model exposed to linoleic acid, Axiomer editing resulted in a significant decrease in lipid droplet size, ranging from -17% to -26% compared to control.

Axiomer ADAR RNA editing technology has the potential to convert PNPLA3 148M into a WT-like functional PNPLA3 148V protein. This approach could become a promising therapeutic opportunity for homozygous and heterozygous MASLD/MASH individuals, limiting changes only to affected allele(s).

1655 Developing suppressor tRNAs to target the most common type of pathogenic nonsense mutation

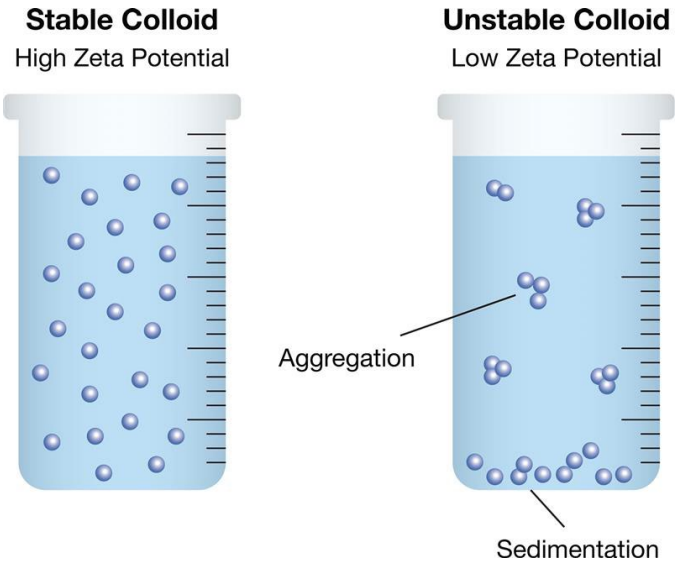
Nonsense mutations are point mutations that convert a sense codon into a premature termination codon (PTC) - UAA, UAG or UGA - resulting in the premature cessation of protein synthesis. These mutations account for 11% of human pathogenic mutations. In a proof-of-concept study, we demonstrated that **AAV**-delivered **no**nsense **s**uppressor **t**RNA **o**perating on **P**TC (AAV.NoSTOP) can efficiently and safely overcome a TAG nonsense mutation in a disease mouse model, suggesting its therapeutic potential for a broad spectrum of disorders caused by a common genetic defect, namely the TAG nonsense mutation (Wang J et al. *Nature* 2022). This therapeutic approach is especially advantageous for restoring the endogenous expression of large or dose-sensitive proteins, such as dystrophin in Duchene muscular dystrophy or MECP2 in Rett syndrome, where traditional rAAV gene replacement therapies face significant challenges. Notably, nonsense mutations that convert arginine codons to UGA (ArgàUGA) are the most prevalent, representing 22% of all disease-causing nonsense mutations. In this study, we expand the AAV.NoSTOP platform by developing sup-tRNAs that target UGA and install arginine. We first screened 25 arginine tRNA-derived, UGA-targeting sup-tRNAs driven by the U6 promoter (U6.UGA-sup-tRNA^{Arg}) for their ability to induce PTC readthrough in HEK293 cells by plasmid co-transfection, with one plasmid expressing a readthrough reporter and another carrying a U6.UGA-sup-tRNA^{Arg} candidate. This assay revealed a broad range of readthrough capabilities from barely detectable to 17%. The top three candidates were further evaluated in mice by hydrodynamic co-injection of the two plasmids, a delivery method that predominantly targets the liver. We observed up to 13% of reporter PTC readthrough in mouse liver. As an alternative sup-tRNA cassette design, we placed the best-performing sup-tRNA candidate in its natural flanking sequence (NFS) context, omitting the U6 promoter to exploit the intrinsic Pol III promoter activity of tRNA genes. Compared to U6.UGA-sup-tRNA^{Arg}, NFS.UGA-sup-tRNA^{Arg} improved PTC readthrough efficiency by 4-fold in mouse liver, reaching above 50%. To assess its function in suppressing a genomic nonsense mutation in human cells, we used lentiviral vectors to deliver NFS.UGA-sup-tRNA^{Arg} to fibroblasts from a Batten disease patient harboring ArgàUGA nonsense mutations in the *TPP1* gene (*TPP1*$^{R127X/R208X}$). Lenti.NFS.UGA-sup-tRNA^{Arg} treatment restored TPP1 protein from undetectable levels to above 10% of the normal level, as determined by western blotting. To further evaluate therapeutic efficacy *in vivo*, we generated and characterized a new Hurler syndrome mouse model carrying a TGA nonsense mutation in the *Idua* gene (*Idua-TGA*). This mouse model enables us to quantify readthrough efficacy across multiple tissues using a sensitive iduronidase activity assay, and it provides logistical convenience in terms of colony maintenance. In contrast, other existing ArgàUGA mouse models are limited to testing efficacy in specific tissues (e.g., *Mecp2-R168X* mice for Rett syndrome) or present breeding challenges (e.g., *Tpp1-R207X* mice for Batten disease). Currently, we are generating AAV.NoSTOP reagents and evaluating their efficacy in the new *Idua-TGA* mouse model. (MX and HL: co-first authors)

1656 Optimizing LNP-RNA Formulations: Key Insights into Size, Zeta Potential, and Stability

Adam Brooks[1], Udayabagya (Bud) Halim[1]
[1]Wyatt Technology, Goleta, CA

The microfluidic formulation of RNA-containing lipid nanoparticles (LNP-RNA) is a widely utilized approach for developing and producing non-viral gene delivery systems. A critical challenge in this process is optimizing lipid

selection and formulation conditions to achieve targeted particle sizes and surface potential. This study highlights the application of the DLS/SLS/ELS instrument for rapid characterization of LNP-RNA therapeutics, focusing on size, polydispersity, and zeta potential. Results demonstrate the impact of production methods on LNP formulations, colloidal stability across various buffer conditions, and structural changes following freeze-thaw cycles. These findings underscore the importance of precise characterization for optimizing LNP-RNA formulations and ensuring their stability and efficacy.



1657 Large-scale Transfection of T cells in a Xuri™ Cell Expansion System W25 Bioreactor Using LNPs

Paula Marcus[1], **Danylo Sirskyj[2]**, Vlada Sadetckaia[3], Dana Arab[2], Sadegh Davoudi[3], Mana Novin[4], Aruna Balgi[5], Natalie Orr[6], Reka Geczy[7], Darryl Knight[2], Azher Razvi[2], Samuel Clarke[5]
[1]Cytiva, Toronto, ON, [2]Cytiva, Toronto, [3]CCRM, Toronto, [4]Cytiva, Vancouver, BC, [5]Cytiva, Vancouver, [6]Cytiva, Marlborough, MA, [7]Precision NanoSystems Inc, Vancouver, BC

Current methods for gene modification of immune cells can impact cell viability and total yield, and are time-consuming, complex processes. Lipid nanoparticles (LNPs) are an emerging technology for T cell transfection. LNPs efficiently encapsulate and transport payloads, such as mRNA, to target tissues and cells, and have the potential to improve cell transfection, reduce cell damage, and simplify cell culture workflows. The Xuri™ cell expansion system W25 bioreactor has a reputation for its ability to generate T cells required for a broad spectrum of immunotherapies. Here, we compare the difference between electroporation and a commercially available Cytiva LNP cell therapy kit for CRISPR-Cas9-mediated gene knockout of the T-cell receptor (TCR) within the Xuri™ Cell Expansion System W25 — an established system for generating T cells for a broad spectrum of immunotherapies.

Using NxGen™ mixers on the NanoAssemblr™ Ignite™ instrument, we manufactured LNPs encapsulating Cas9 mRNA and TCR-targeted guide RNA (sgRNA).. T cells were isolated from fresh Leukopaks using positive selection for CD4/8. T cells were seeded and activated directly in the Xuri™ cell expansion system W25 bioreactor for LNP transfection and after 3 d, cells were transfected using the TCR LNPs. Cells were activated in a G-Rex for EP and after 3 d, cells were resuspended in EP buffer and electroporated. Cells were then placed back into the G-Rex for 24 h, prior to seeding into the Xuri™ cell expansion system W25 bioreactor. Both sets of cells were batch-fed to 1 L and then perfusion was initiated. Cells were monitored daily for counts and viability. Transfection efficiency was determined at multiple time points throughout the culture.

In situ activation was comparable to G-Rex controls, although cell proliferation was reduced when compared to G-Rex activation. The hands-on time required for LNP transfection and scale-up was significantly reduced compared

to EP due to the one-step nature of the process. EP resulted in a significant decrease in cell viability 24 h post EP, which also resulted in a reduction in total cells at harvest, when compared to LNP transfection. The was no difference observed in transfection efficiency between the two groups.

In conclusion, we have developed a highly efficient, end-to-end, large-scale one-step T cell transfection workflow. LNPs manufactured using the NanoAssemblr™ Ignite™ nanoparticle formulation system can be scaled to the requirements for cell-based therapies manufactured in a Xuri™ cell expansion system W25 bioreactor. In addition, by activating and adding LNP directly within the Xuri™ cell expansion system W25 bioreactor, manual manipulation and process steps are reduced when compared to EP. LNP transfection also doesn't have any impact on cell health and proliferation, with similar transfection efficiency observed. This simplified and efficient process for gene modification of T cells has the potential to reduce manufacturing costs accelerating the development of next generation T cell-based immunotherapies, including gene-edited allogeneic CAR T cell therapies.

1658 Insights of CMC, Quality & regulatory for mRNA-based gene editing program – A case study and lessons learned from early phase development to final GMP manufacturing for IND application

Jing Zhu[1]*, Melanie Cerullo[1], Jovanka Bogojeski[1]
[1]ReciBioPharm, Watertown, MA
**Corresponding Author*

In the rapidly evolving field of mRNA-based gene editing, developing and manufacturing such innovative therapies demand a comprehensive understanding of CMC processes. ReciBioPharm has successfully delivered multiple GMP programs in this field, from early-phase prototype, process, and analytical development to final GMP manufacturing. Leveraging this unique experience, this abstract introduces a case study that delves into the CMC best practices and invaluable lessons learned in the journey from sequence to IND for a Gene Editing Program.

The presentation will provide an in-depth exploration of the following key aspects:

- Development and Manufacturing Considerations: We will spotlight the critical points along the road in plasmid DNA, drug substance, and drug product process and analytical development and GMP manufacturing.
- Regulatory and Quality Assurance: We will address the regulatory hurdles and how to navigate in the early phase landscape while still ensuring patient safety and successful IND submission.
- Lessons Learned and Future Perspectives: This case study reflects on the challenges faced, setbacks encountered, and strategies adapted during the entire development and manufacturing process. Insights gained from real-world experiences will offer valuable guidance to sponsor companies.

It serves as a vital resource for CMC stakeholders, offering a roadmap for success in bringing mRNA-based gene editing therapies from sequence to IND.

1659 Comprehensive evaluation of T7 polymerase for enhanced yield and quality in mRNA production

Jing Zhu[1]*, Caining Jin[1], Kithmie MalagodaPathiranage[1], Jiayue Zhang[1], Aaron Cowley[1]
[1]ReciBioPharm, Watertown, MA
**Corresponding Author*

messenger RNA (mRNA) drug modalities are a revolutionary breakthrough in medicine, offering the potential to treat various rare and infectious diseases. ReciBioPharm, contract with MIT, follows the largest award from FDA's Center for Biologics Evaluation and Research office (CBER) to MIT, enabling next generation mRNA manufacturing capacity and providing faster readiness and reaction to new pandemic threats. One major effort of the

ground-breaking initiatives is to systematically identify critical raw materials during mRNA production and scientifically understand their impact on the final quality of these drug products. In vitro transcription (IVT) is an enzymatic process used in the synthesis of mRNA products. In a typical IVT process, a RNA polymerase is responsible for the transcription of RNA from a DNA template. While T7 polymerase is the most common used in both research and commercial purposes and there are multiple offerings of both wild type and engineered T7 polymerases in the market, so far there is no systematic studies to understand the performance of these commercially available T7 polymerases. Herein, we conducted a comprehensive study to characterize total 19 of T7 polymerases including 4 wild types and 15 modified ones. Briefly, a high throughput screening (HTS) workflow was established to enable >1500 IVT runs with subsequent critical analytics including yield, purity, dsRNA and potency; these DOE based optimizations were followed by subsequently lot-to-lot variations, and scalability studies; the desired process range for each T7 was defined and some high potential process parameters was proposed to offer >15g/L mRNA yield with >95% purity and minimum dsRNA (below dsRNA ELISA LOD). The outcomes as a T7 knowledge library with deep profiling their performance & cost analysis was well established, which will accelerate the deployment not only of mRNA vaccines for rapid response against future pandemics but also of novel mRNA therapeutics.

1660 Developing a Cost-Effective and Reproducible Protocol for Lipid Nanoparticle Synthesis and Characterization to Advance Preclinical Research and Education

Shilpi Agrawal[1], Abbey Stokes[2], Christopher Nelson[1]*
[1]University of Arkansas, Fayetteville, AR, [2]University of Arkansas, Springdale, AR
**Corresponding Author*

Nanotechnology has transformed clinical applications, with its impact extending into gene therapy, targeted drug delivery, and diagnostic tools. Among its most notable advancements are lipid nanoparticles (LNPs), which have gained prominence as an efficient vehicle for nucleic acid delivery. In recent years, LNPs played a critical role in the development of mRNA vaccines, contributing to the swift global response to the COVID-19 pandemic. The success of LNP-based vaccines demonstrated the potential of these nanoparticles for broader therapeutic applications, but their adoption in research and clinical settings remains limited by challenges such as high production costs and difficulties in achieving effective delivery beyond hepatic tissues.

As more research institutions look to harness the potential of LNPs for various disease therapies, there is a growing demand for affordable, standardized manufacturing protocols that can be easily implemented across diverse labs. Traditional methods for LNP synthesis, such as pipette mixing and vortexing, often yield inconsistent results, while microfluidic mixing offers better control over LNP properties but requires expensive equipment. This financial barrier prevents many laboratories from accessing cutting-edge LNP technology, slowing down the pace of preclinical research and limiting the exploration of its full therapeutic potential.

To address this, we developed a standardized protocol for microfluidic mixing using a syringe pump and commercially available microfluidic chips. This approach provides a cost-effective, reproducible method for LNP synthesis. The protocol details the synthesis of LNPs, physical characterization via dynamic light scattering (DLS), encapsulation efficiency using the RiboGreen assay, and evaluation of in vitro transfection efficiency using OneGlo assay and flow sorter.

Various experimental parameters were explored, including different mRNA concentrations, syringe and tubing reusability, stability profiles, dialysis conditions, and total flow rates. Using the ionizable lipid DLin-MC3-DMA as a baseline, we formulated LNPs with three different ionizable lipids—LP01, DLin-MC3-DMA, and SM102—alongside Cholesterol: DSPC: DMG-PEG: DOTAP. We found that syringes and tubing remained functional for up to six continuous runs. Encapsulation efficiency remained high (96-100%) across mRNA concentrations ranging from 10 µg to 2.5 µg, though particle size increased from 82 nm to 100 nm at the lower concentration. Luciferase luminescence assays revealed a marked decrease in intensity as mRNA concentration decreased. Validation with

GFP mRNA and flow cytometry demonstrated that both 7.5 µg and 10 µg formulations produced adequate fluorescence, leading us to select 7.5 µg for subsequent studies.

Dialysis experiments showed minimal variation in encapsulation efficiency across 1-hour, 2-hour, and overnight conditions, but LNP size increased significantly after 12 hours of dialysis. Notably, longer dialysis times correlated with decreased luminescence intensity. The polydispersity index (PDI) for most samples remained below 0.2, indicating a narrow size distribution.

The next phase of this research will focus on evaluating the LNPs in in-vivo mouse models, with an emphasis on non-viral gene delivery. By applying this streamlined and cost-effective protocol, we aim to accelerate preclinical studies and broaden the therapeutic applications of LNPs.

1661 Key learnings during mRNA-LNP drug product process development

Huu Thuy Trang Duong[1], Pinaki Ranadive[1], Jay Kang[1], Haresh More[1], Bindhu Rayaprolu[2], Amardeep Bhalla[1], Mohammed Shameem[1]
[1]Regeneron Pharmaceuticals Inc., Tarrytown, NY, [2]White Plains, NY

In recent years, lipid nanoparticle-based delivery of mRNA therapeutics in infectious diseases has shown great clinical and commercial success. However, in contrast to protein therapeutics, mRNA-LNP drug products manufacturing involves complex steps that pose number of challenges in building a robust process. Hence, it is critical to develop a good understanding of mRNA-LNP drug product unit operations to ensure a successful manufacturing scale up and tech transfer. The purpose of this talk is to inform on process considerations to develop high-quality mRNA-LNP drug products.

1662 Enzymatic Linearized DNA – A Novel, Cell-Free Platform for Accelerated mRNA Therapeutic Development

Pawan Bhatt[1], **Alvin Jogasuria[2]***
[1]GenScript ProBio, Pennington, NJ, [2]ProBio Inc USA, Pennington, NJ
**Corresponding Author*

The production of high-quality DNA templates remains a critical bottleneck in mRNA therapeutic development, often constrained by the inefficiencies of traditional plasmid DNA (pDNA) workflows. We introduce a **novel, cell-free enzymatic linearization platform** that streamlines DNA template production, eliminating the need for plasmid cloning, bacterial fermentation, and enzymatic purification. This innovative approach delivers **backbone-free, high-purity linearized DNA** in just weeks, significantly reducing development timelines and enhancing mRNA production efficiency.

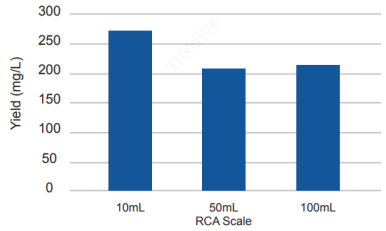
Key advantages of this platform include:

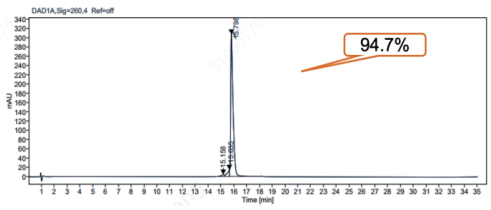
- **Rapid turnaround**: By bypassing months-long pDNA processes, the platform accelerates progression from research to clinical applications.
- **Superior purity**: The technology generates clean, consistent DNA templates, minimizing dsRNA impurities and poly-A tail instability, which are known to compromise mRNA performance.
- **Scalability**: Designed for seamless scale-up, the platform ensures a reliable supply of DNA templates for both preclinical and commercial mRNA manufacturing.

This enzymatic linearization technology addresses the limitations of traditional pDNA methods, enabling researchers to achieve **higher mRNA yields, improved stability, and reduced immunogenicity**. By advancing the efficiency and quality of DNA template production, this platform represents a transformative step forward in mRNA therapeutic development, empowering researchers to accelerate the delivery of life-changing therapies.

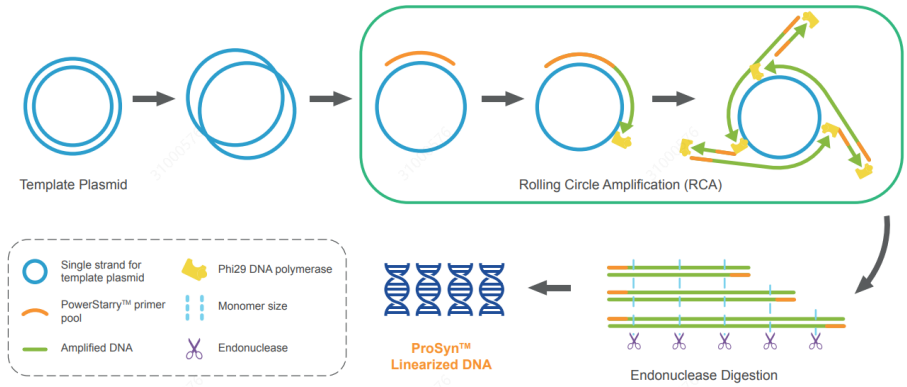
☐ **2~3 mg per 10 ml with 4000~5000x amplification rate**

☐ **Purity (IEC-HPLC): ~95%**





Cell-free technology is a breakthrough in plasmid and linearized DNA manufacturing with its short turnaround time. ProSyn™ Linearized DNA is using enzymatic DNA synthesis through rolling circle amplification (RCA). Under the action of proprietary PowerStarry™ Primer Pool, GenScript ProBio is able to accelerate different projects by reducing time and manpower.



1663 Effective Quality Control is Crucial Throughout mRNA Product Development

Andrea O'Hara[1], Crystal Richardson[1], Sumit Kumar[2], Haythem Latif
[1]Azenta, Burlington, MA, [2]Genewiz From Azenta Life Sciences, South Plainfield, NJ

At the forefront of therapeutic delivery is an array of vectors and targeting methods that hold immense promise for precision medicine in cell and gene therapies. Lipid nanoparticle (LNP) encapsulated RNA and circular RNA (circRNA) are emerging as a preferred method for new therapies, offering faster development and production with high specificity, transient expression and reduced long-term risk, as it does not integrate in the host genome. As a result, mRNA therapeutics have the potential to quickly and effectively treat a wide range of diseases.

Here we present an end-to-end RNA production workflow engineered for quality and scalability through novel methods for minimizing synthetic risks and validation by sequencing. Critical to successful production is maintaining the integrity of complex polyA regions. Using proprietary methods for synthesis and plasmid preparation, monodispersity of polyA tails are conserved within DNA templates. Examination of the final mRNA transcript is performed utilizing a new library generation method for PacBio long-read Single-Molecule, Real-Time (SMRT) technology, capable of full-length sequencing of products up to and beyond 10kb without limitations or bias due to repetitive sequence or C/G content. Crucially, this method preserves the entire length of the polyA tail enabling sensitive and specific counting of the polyA tail length -- an important parameter when confirming overall sample purity, including intermediate and alternative products present within the sample.

Both circRNA and linear mRNA products are amenable to the above workflow, providing a robust solution for any RNA research program. The workflow results in an accelerated mRNA development program with higher quality templates and rigorous qualification post transcription.

1664 mRNA Manufacturing: from Template DNA to Lipid Nanoparticles – an Integrated Platform Approach

Linda Gombos[1]*, Edina Csaszar[2], Bernhard Maderegger[3], Kathrin Seyrl[3], Martina Hauer[3], Florian Haider[3], Hauke Hüttmann[3], Ernst Böhm[3], Angela Neubauer[3], Hans Huber[3]
[1]Biomay, Vienna, Österreich, Austria, [2]Biomay AG, Vienna, Austria, [3]Biomay, Vienna, Austria
**Corresponding Author*

The manufacturing of messenger RNA (mRNA) has emerged as a pivotal technology in the development of novel therapeutics and vaccines. For mRNA production, Good Manufacturing Practice (GMP) is the essential quality standard to ensure product safety, consistency, and regulatory compliance. The complex nature of mRNA requires precise in-vitro synthesis, base modification, purification, and quality control and demands highly controlled and standardized manufacturing processes.

This abstract provides a case study for the establishment of a GMP-compliant mRNA manufacturing platform integrating the whole process chain from template DNA, mRNA production, and lipid nanoparticle (LNP) formulation until final aseptic filling of drug product. The essential elements of GMP mRNA production will be highlighted, emphasizing the key challenges to ensure the scalable, reproducible, compliant and economic manufacturing of mRNA-based therapeutics.

The investigated target products were mRNA transcripts encoding a CRISPR/Cas9 nuclease featuring a 5´-cap analog, a 3´-poly(A) tail, and N1-methyl-pseudouridine base modifications. The GMP manufacturing process was carried out at full scale in certified clean rooms. Manufacturing of the linear DNA template consisted of cloning of a circular plasmid, preparation of an *E. coli* master cell bank, fed-batch fermentation, alkaline cell lysis, chromatographic purification, and enzymatic linearization steps. The mRNA was synthesized by enzymatic in-vitro transcription (IVT) using T7 RNA polymerase and co-transcriptional addition of a 5´-cap analog. Subsequent mRNA purification was achieved by oligo dT affinity chromatography. The mRNA was encapsulated in lipid nanoparticles (LNP) by impingement jets mixing. The drug product was formulated by tangential-flow filtration (TFF) and finally aseptically filled.

A comprehensive analytical platform conforming to GMP regulations has been set up, including raw material testing, in-process controls, Quality Control release and stability testing, as well as extended characterization of the mRNA. It was confirmed that all quality parameters (content, identity, purity, safety) were within pre-defined specifications at all stages. Bulk mRNA was highly homogenous (≥ 90 % by CE). 5´-capping efficiency was ≥ 95 %, and 3´-poly(A) tail length was confirmed by LC/MS. The LNPs showed a high encapsulation efficiency (> 90 %) and a low polydispersity index (PDI). Satisfying stability was confirmed from both the bulk mRNA as well as from the formulated LNPs by performing stability studies at several conditions.

Functionality of the CRISPR/Cas9 mRNA was shown in a cellular assay by measuring Cas9-mediated recombination in HEK293 cells. As a conclusion, with the established mRNA platform, the parameters and requirements of yield, throughput time, GMP compliance and quality were successfully achieved.

1665 Versatile Lipid Nanoparticle Platform for Efficient CRISPR-Cas9 Gene Editing in Primary T Cells and CD34+ Hematopoietic Stem Cells

Reka Geczy[1], Aruna Balgi[2], Stella Park[3], Meenakshi Swaminathan[4], Mana Novin[5], Hannah Ly[5], Rita Zhao[2], Angela Zhang[6], Anitha Thomas[6], Samuel Clarke[2]
[1]Precision NanoSystems Inc, Vancouver, BC, [2]Cytiva, Vancouver, [3]Precision NanoSystems Inc, [4]Vancouver, BC, [5]Cytiva, Vancouver, BC, [6]Cytiva, Marlborough, MA

Background and Aims: Lipid nanoparticles (LNPs) have emerged as a promising nonviral alternative for delivering CRISPR-Cas9 components to difficult-to-transfect cell types such as human primary T cells and CD34+ hematopoietic stem cells (HSCs).We have developed a library of novel ionizable lipids and lipid nanoparticle compositions designed for *ex vivo* applications. In this work, we show the results of screening and optimization of Cas9 mRNA and sgRNA delivery to achieve multiplex gene knockouts across both T cells and HSCs. Further, we investigate the interplay between cell culture media and vessels to develop protocols suitable for scale-up and clinical translation.

Methods: A range of novel LNPs were formulated using the NxGen™ mixing platform and evaluated by adding LNPs directly to activated human primary T cells and CD34+ HSCs obtained from mobilized peripheral blood (**Fig 1A**). LNPs were encapsulating various RNAs, such as GFP or αCD19-CAR mRNA, or Cas9 mRNA and sgRNAs targeting TCR/CD52 in T cells and CD33/CD45 in HSCs. Culture media, supplements, and transfection kinetics were systematically varied and optimized for high gene delivery efficiency (**Fig 1B**). Viability, proliferation, and colony-forming potential (in the case of HSCs) were used to measure functional outcomes for LNP post-editing.

Results: Up to 90% TCR–/CD52– double knockout was achieved in T cells, with > 90% viability maintained. Similarly, LNP addition to HSCs showed 80% and 90% knockouts (CD45 and CD33, respectively), preserved > 95% viability, and showed strong proliferative capacity relative to untreated controls. Colony-forming unit (CFU) assays indicated no significant changes in multi-lineage differentiation. Media optimization proved essential, with some commercial T cell and HSC media producing higher editing efficiencies. In addition, treatment kinetics, media supplements, and small molecules showed a significant impact on editing efficiency in long-term HSC (LT-HSCs). Lastly, LNPs and the optimized cell culture conditions were successfully scaled from well-plates to G-Rex bioreactors for both cell types.

Conclusions: This work highlights a versatile, nonviral LNP platform for efficient gene delivery and editing in difficult-to-transfect cell types. LNP scalability, combined with minimal cytotoxicity and high efficiency, supports its potential as a rapidly translatable and gentle platform for gene delivery in both T cells and HSCs.

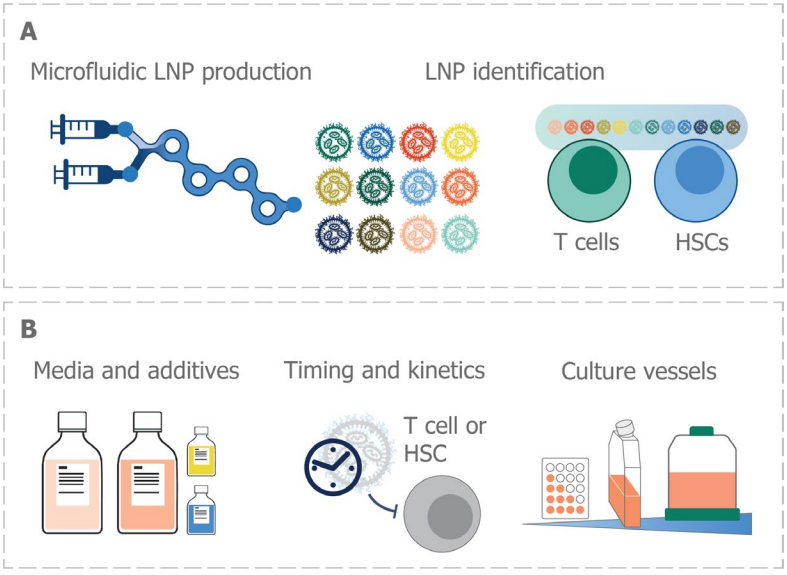


Figure 1. Optimization of lipid nanoparticles and culture conditions for LNP-mediated gene editing. (A) Various LNPs were produced and tested on both T cells and HSCs. (B) Media composition, timing and kinetics were optimized. LNPs and cell culture were scaled up from plates to small bioreactors.

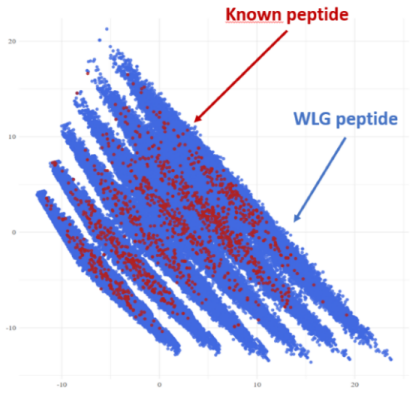
1666 Novel In Silico Generation of a Synthetic Peptide Library Derived from Biological Complexes for Protein and Vector Engineering

Camille Alliot[1], **Bryan Dafniet[2]**, Yanis Habtoun[3], Claire COLAS[1], Juliette MAES[1], David Del Bourgo[4], Julien Cottineau, Dylan SERILLON[5]
[1]WhiteLab Genomics, Paris, Paris, France, [2]WhiteLab Genomics, Paris, Essonne, France, [3]WhiteLab Genomics, Viry-chatillon, France, France, [4]WhiteLab Genomics, Paris, France, [5]WhiteLab Genomics, Paris, Paris

The generation of chemical libraries, specifically peptide libraries, has been an ongoing topic for the past decades. Peptide design is actively being researched due to their specific properties (stability, binding...) both as a therapeutic agent and, in the cell and gene therapy field (C&G), for their targeting properties. They can be combined with various viral or non-viral vectors (e.g., adeno-associated viruses, nanoparticles...) as they have a diverse set of association possible ranging from, but not limited to, peptide conjugation as well as insertion in both linear and cyclized conformations. A common strategy for designing peptide libraries involves using a random approach, which typically leads to a large volume of candidates, with a high proportion of structurally and biologically irrelevant sequences, driving up both cost and time in identifying relevant binders. Despite the rapidly evolving field, the concept of in silico peptide library, especially based on rational biological complexes, represents an important breakthrough, yet remains largely unexplored due to its complex nature.

WhiteLab Genomics is presenting a novel in silico approach, stemming from structurally resolved experimental data from protein-peptide complexes. The objective is to create a peptide library specifically tailored in a vector engineering context for gene therapy that can also be used in the discovery of pertinent motifs for new therapeutic peptides. It is based on biologically active motifs that, when combined with WhiteLab Genomics' rational-guided approach, can enhance both in silico discovery and evaluation of new hits against a receptor of interest reducing the risk of having biologically irrelevant peptides. It led to the generation of more than 300 thousand unique sequences, ranging from 5 to 12-mer peptides, reconstructed in 3D, in four initial conformations, namely helix, linear, cyclized and beta-sheet, forming a total library of more than 1.2 million unique structures. This allows expanding synthetically the chemical space of available peptides by exploring a highly diverse conformational space. Every newly generated structure is mapped and characterized with sequence and structural descriptors.

To significantly improve the success rate of our approach, we also developed a subset called the Diversity library composed of peptides representative of key properties. It enhances both the search for efficient therapeutic screening and improves the engineering of a vector of choice by allowing us to explore a large chemical space while extracting a minimal number of peptides sharing similar properties. Finally, the generated properties in both these libraries will also be useful in the development of tailored machine-learning or artificial intelligence models, paving the way for new and better solutions in the C&G therapy field.



Principal Component Analysis (PCA) illustrating the expansion of the chemical space, based on 1D & 2D physico-chemical descriptors, with the WhiteLab Genomics peptide library (in blue) compared to already known peptides (in red).

1667 Revolutionizing Peptide Discovery: AI-Driven Drug Design Paving the Way for the Future of Cell & Gene Therapy

Camille Alliot[1], Claire COLAS[1], Bryan Dafniet[2], Juliette MAES[1], Jean-Philippe Buffet[3], Patrice Vidal[1], Alexandre MURZA[4], David Del Bourgo[5], Julien Cottineau, Pierre-Luc Boudreault[4], **Dylan SERILLON[6]**
[1]WhiteLab Genomics, Paris, Paris, France, [2]WhiteLab Genomics, Paris, Essonne, France, [3]WhiteLab Genomics, Paris, France, France, [4]University of Sherbrooke, Sherbrooke, [5]WhiteLab Genomics, Paris, France, [6]WhiteLab Genomics, Paris, Paris

Over the past decade, rational peptide design has gained significant momentum as a promising approach in drug discovery. Peptides are emerging as highly versatile therapeutic agents, offering unique advantages in targeting complex biological pathways. However, their design and development still represent a significant challenge due to their intrinsic structural flexibility and potential for unintended biological interactions, which can complicate therapeutic applications. Beyond their therapeutic potential, peptides may enhance gene delivery through various vector types and modifications. For Adeno-Associated Virus (AAVs) vectors, peptides can be inserted into their sequences to trigger better targeting. Peptides can also be conjugated as linear or cyclic forms to improve stability and binding of AAV vector or non-viral vector (e.g. Lipid Nanoparticles, LNP). Optimization opportunities include incorporating non-canonical amino acids to improve pharmacological properties.

In this context, we apply a drug design protocol for the discovery of novel peptides towards a pivotal therapeutic target in oncology and immunotherapy. Despite extensive data availability, this receptor remains challenging for peptide-based drug design due to the atypical nature of the binding site: non-buried, without any specific pocket to be used as a basis for docking. However, the existing crystallized receptor structures provide a solid foundation for structure-based computational approaches, in addition to the availability of a reference peptide (Kd = 4.2nM), enabling competitive binding assays.

WhiteLab Genomics' AI-powered platform pre-screened tens of thousands of unique peptides extracted from our proprietary peptide library, employing a rational workflow: (i) Analysis of known binders to identify critical interaction motifs, (ii) Customization of computational tools tailored to receptor binding, (iii) Virtual screening of high-potential candidates, (iv) Structural optimization using SAR (Structure Activity Relationship) analysis, and (v) Peptides refinement through macrocyclization, sampling, and dynamic modeling.

During the virtual screening phase, over 1,000 peptides were modeled in complex to predict binding affinity and assess virtual structure-activity relationships. Approximately 200 peptides were shortlisted based on predicted binding strength and compatibility with macrocyclization strategies. Using Surface Plasmon Resonance (SPR) assays, we evaluated the binding affinity of our peptides library and achieved hit rates of 6.3%. Notably, every hit demonstrated a higher binding affinity than the reference, underscoring the efficiency of our computational and

experimental pipeline. Although no gold standard exists for both hit rate and hit definition, we considered the WhiteLab Genomics platform to have surpassed established field methodologies by defining hits as superior to the reference while still achieving an impressive hit rate. We are presenting an automated AI-driven platform for the discovery and optimization of peptide binders. This platform demonstrated exceptional performance, culminating in experimental validation of high-affinity binders (Kd) for a clinically relevant oncology target. These findings highlight the potential of AI-enhanced peptide design to drive the next generation of cell and gene therapy innovations.

1668 A Novel Technology for Sequence-Specific Determination of Lipid Nanoparticle Encapsulation Efficiency

Chris DJamoos[1], Nathan Feirer[2], Subhanjan Mondal[3], Laura Alexander[4]
[1]Promega Corporation - Madison, WI, Brighton, MI, [2]Promega Corporation, Fitchburg, WI, [3]Promega Corp, Fitchburg, WI, [4]Promega corporation, Madison, WI

Lipid nanoparticles (LNPs) are an established non-viral delivery platform for nucleic acids and other biomolecules, offering significant promise for gene and cell therapy applications. As the utilization of LNPs expands to diverse cargo types and complex formulations, there is a growing need for robust tools to characterize encapsulation efficiency and ensure the integrity of therapeutic payloads.

This study introduces the TruTiter™ Reagent, a novel small molecule that facilitates the assessment of LNP encapsulation efficiency. TruTiter™ selectively reacts with exposed nucleic acids but is excluded from encapsulated or compartmentalized cargo, thus preserving nucleic acids within intact LNPs. By covalently modifying unprotected nucleic acids, TruTiter™ prevents their amplification by PCR or digital PCR (dPCR). This enables accurate quantification of encapsulated nucleic acids and supports optimization of lipid composition, cargo properties, and storage conditions.

Quantitative analysis using RT-qPCR or dPCR with TruTiter™ was employed to measure encapsulation efficiency (%EE). Encapsulation efficiency was calculated using the formula: $\%EE = (1/2^{dCq}) \times 100$, where dCq = Cq [with TruTiter™] - Cq [without TruTiter™]. Nucleic acid purification was performed prior to amplification to mitigate the inhibitory effects of certain lipid components on reverse transcriptase and DNA polymerase activities. The Maxwell RSC simplyRNA Cells Kit was validated as an effective method for isolating nucleic acids from LNPs.

To demonstrate the utility of TruTiter™, in vitro-transcribed RNA (Firefly luciferase, 1.5 kb) was encapsulated within pre-formulated LNPs. Samples were analyzed with and without TruTiter™ treatment, followed by neutralization, nucleic acid extraction, and quantification using RT-qPCR and dPCR. Additionally, GFP mRNA encapsulated in LNPs was subjected to thermal stress (22°C, 42°C, and 55°C) to assess the impact of temperature on encapsulation integrity. TruTiter™ detected significant reductions in encapsulation efficiency with increasing temperature, aligning with the loss of LNP structural integrity. In contrast, the RiboGreen assay failed to detect similar losses, underscoring its limitation in assessing structural changes and providing sequence-specific information.

These results highlight TruTiter™ as a valuable tool for characterizing LNP encapsulation efficiency, offering sequence-specific insights that complement existing techniques. This method advances the characterization of LNP formulations, contributing to the development of more effective delivery systems for gene and cell therapy applications.

1669 Comprehensive Imaging Methods to Quantify mRNA Lipid Nanoparticle Trafficking and Expression

Teresa Einhaus[1], Carly Starke[2], Christopher Peterson[1]
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]Fred Hutch Cancer Center, Seattle, WA

Introduction: Messenger RNA lipid nanoparticles (mRNA-LNPs) have excelled as vaccines for infectious diseases including COVID-19. We are interested in applying our expertise in nonhuman primate (NHP) models of gene therapy to broaden the therapeutic applications of mRNA-LNPs. For example, Human Immunodeficiency Virus (HIV) and simian/human immunodeficiency virus (SHIV) establish infection in distinct tissues, which can be identified via viral RNA (vRNA)-specific *in situ* hybridization (ISH). We have developed a highly sensitive and specific RNAscope ISH technique to identify both vRNA and LNP-delivered mRNAs. To simultaneously quantify virally infected cells and therapeutic mRNA/protein trafficking, we couple RNAscope ISH with immunohistochemistry (IHC) assays specific for mRNA-LNP-encoded proteins. Here, we applied our dual RNAscope-IHC assay to identify reporter mRNA-LNP formulations and dose routes that efficiently traffic to systemic sites of SHIV latency in NHPs.

Methods: Reporter mRNA-LNPs encoded enhanced green fluorescent protein (eGFP). Nine SHIV-infected rhesus macaques received eGFP mRNA encapsulated in one of two LNP formulations ("LNP-A" or "LNP-B"), administered via intravenous or intranodal injection. Twenty-four hours later, tissues were collected from a broad array of anatomical sites that harbor latent SHIV-infected cells. The tissues were paraformaldehyde-fixed, paraffin-embedded, sectioned and mounted on slides. After paraffin removal, hydrogen peroxide and target retrieval, the slides were incubated with an eGFP RNA probe or SHIV RNA probe followed by the use of the RNAscope kit as directed. Slides were then analyzed for the presence of positively stained cells. Established IHC methods were applied to compare eGFP mRNA to eGFP protein.

Results: Localization of LNP-delivered eGFP mRNA varied based on LNP formulation and dose route. When injected intranodally, eGFP mRNA was highly enriched in lymph nodes relative to intravenous injection. In particular, eGFP mRNA localized predominantly to draining lymph nodes near the injection site. When given intravenously, LNP- B more efficiently delivered eGFP mRNA to the marginal zones and red pulp of the spleen while LNP-A delivered mRNA in clustered regions near the marginal zones. Additionally, LNP-B enhanced delivery to the lung and gastrointestinal tissues. The localization of eGFP protein was often distinct from eGFP mRNA and associated with areas antigen presenting cells are known to reside.

Conclusions: These data demonstrate that RNAscope ISH coupled with transgene-specific IHC is a useful tool to trace each step in mRNA-LNP therapies, from LNP-dependent delivery of mRNA within tissues to the biodistribution of mRNA-encoded proteins. In our NHP model of HIV, we are particularly interested in targeting therapeutic mRNA-LNPs to sites of virus persistence, as well as to HIV-specific immune effectors. We predict that efficient, on-target mRNA-LNP delivery will be associated with more effective therapeutic endpoints in our NHP model, validating analogous clinical approaches for people living with HIV. Our future goals are to broaden our suite of disease-specific multiplex assays, namely for degenerative diseases of the central nervous system (CNS).

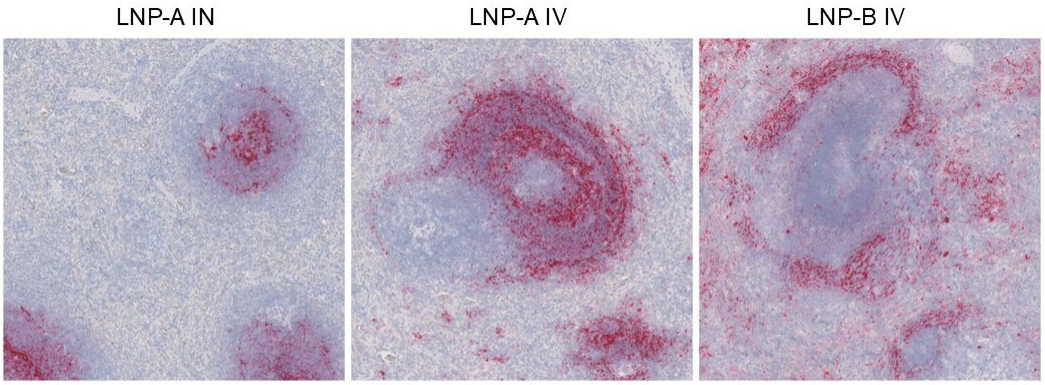


Figure 1: Lipid nanoparticles (LNP) delivery of mRNA to various locations differs by formulation and route of administration. Representative images of eGFP RNAscope (red) in the spleen of rhesus macaques administered with LNP-A or LNP-B. IN=intranodal injection, IV= intravenous injection.

1670 Total Holographic Characterization: A New Tool for Empty/Full Ratio Determination

Laura Philips[1]*, Juliana Lumer[1], Tiffany Markus[1]
[1]*Spheryx, Inc., New York, NY*
**Corresponding Author*

Total Holographic Characterization (THC) has the unique capability of distinguishing sub-visible particles by size and composition in complex heterogeneous mixtures of colloidal particles. THC shows promise as an analytical tool to distinguish filled versus empty AAV capsids or lipid nanoparticles (LNP).

THC is currently used to distinguish individual sub-visible contaminants in biologic pharmaceuticals, ranging in size from 0.5 µm – 10 µm. In biologic formulations different contaminants are distinguished by their different indexes of refraction. THC uses Lorenz-Mie Theory to analyze holograms of individual sub-visible particles. The analysis yields the size distribution of particles present and simultaneously determines the composition from the index of refraction of the particles. Particle symmetry provides additional information about the morphology of the particles. Spherical particles, such as those of emulsion droplets or air bubbles are distinguished from more irregularly shaped particles, by the symmetry of their holograms. Particles that are identical in shape, such as innocuous silicone oil emulsion droplets and dangerous degradation products of surfactant degradation, can be easily distinguished by their indexes of refraction. Protein aggregates are another application of THC in biologic pharmaceuticals. While protein aggregates are irregular in shape, their holograms can be analyzed using Lorenz-Mie theory, approximating the aggregates using an effective sphere model.

Filled or empty capsids or lipid nanoparticles have different indexes of refraction and therefore will have their own unique and distinguishable THC signatures. While individual capsids or LNPs are below the detection threshold of THC, their aggregates are easily detected. The dramatic difference in index of refraction can be used to determine the Empty/Full ratio in these aggregates.

THC measurements are performed in 10-15 min with minimal sample preparation and no labeling required. Characterization requires 25-35 mL of sample per measurement. Samples flow down a channel in a disposable microfluidic sample chip, and is crossed with a laser. The scattered light from the particles interferes with the incident laser beam thereby creating the hologram of the particle which encodes all of the structural information about the particle.

1671 High throughput process development for column-free purification of mRNA via BioRMB™ platform

Thiago Millen[1], **Alex Schaffer[2]**, Dalton Kinnard, Oleg Shinkazh, Sreeja Edara, Dwayne Kenney
[1]ChromaTan, Ambler, PA, [2]ChromaTan Inc., Ambler, PA

The BioRMB™ Kascade™ is a column-free and steady-state purification platform that is specifically tailored for sensitive modalities such as gene therapies, vaccines, mRNA, and complex antibodies. By moving resin as a slurry through the system, rather than utilizing packed resin beds, on-column contact time can be reduced, improving product quality. Because the resin within the system is cycled continuously, this results in significantly lower resin usage than a typical packed column, or even that of column-switching devices.

In this work we will present the protocol for a linear scale-up development onto the BioRMB™ System. An eGFP mRNA molecule was bound to off-the-shelf (OTS) Poros Oligo(dT)-25 resin. The first step of the scale-up development was to perform binding kinetics in 96-well plates to create binding kinetics curves for multiple binding conditions. From this study, it was determined that an optimal load challenge of 1.25 g of eGFP per L of resin achieved a binding efficiency of 95% after 18 minutes in two-stage binding. As a secondary condition, a load challenge of 0.75 g of eGFP per L of resin achieved a binding efficiency of 96% after 18 minutes in two-stage binding. It was also determined that a higher feed concentration of eGFP (0.4 g/L vs. 0.2 g/L) could achieve similar binding efficiencies at upwards of 2.0 g of eGFP per L of resin. This condition was not explored for scale up due to material constraints.

Wash and Elution screenings were also performed in 96-well plates. eGFP mRNA was bound to the OTS Poros Oligo(dT)-25 resin at 1.25 g of eGFP per L of resin. After removing the supernatant, the resin was resuspended in buffers of various conductivities from 0 mS/cm (elution), and 50 mS/cm (binding) to assess a suitable working range for development of a wash buffer and to determine the critical value for complete elution of the mRNA from the resin. This determined that a conductivity no lower than 20 mS/cm could be used to wash the resin without incurring more than 5% product loss.

To validate the filter plate binding kinetics model, slightly larger volumes were prepared for static mixing in syringes. At various time points, a syringe filter was used to sample the supernatant while retaining the resin. These curves demonstrated a slightly lower binding efficiency of 93% for the condition at 1.25 g of eGFP per L of resin, but similar binding efficiency of 97% for the condition at 0.75 g of eGFP per L of resin.

By applying ChromaTan's recipe maker and buffer model to design a recipe within these set parameters, a BioRMB™ run was performed. This run resulted in 92% binding efficiency for the condition at 1.25 g of eGFP per L of resin, and 97% binding efficiency for the condition at 0.75 g of eGFP per L of resin, within 2% of the modeled binding efficiency. Wash losses aligned closely with the model, losing 3.4% of product compared to the modeled 4.8%. Elution also aligned closely, recovering 97% of the bound product compared to the predicted 98%.

1672 Heterogeneous RNA Loading and Size Correlations in Lipid Nanoparticles Revealed by Single-Particle Spectroscopic Chromatography

Yizong Hu[1], Sixuan Li[2], Tza-Huei Wang[2]*, Hai-Quan Mao[2]*
[1]Massachusetts Institute of Technology, Cambridge, MA, [2]Johns Hopkins University, Baltimore, MD

Introduction. Lipid nanoparticles (LNPs) have emerged as essential delivery vehicles for RNA therapeutics. Previous research and development typically assumed that LNPs are homogeneous in population, loading density, and composition. Such perspectives are challenging to evaluate due to the absence of appropriate tools to characterize these physicochemical properties. Here, we introduce an integrated spectroscopy−chromatography approach as a generalizable strategy to unravel the complexities of multicomponent LNP assembly. Our platform combines cylindrical illumination confocal spectroscopy (CICS)[1] with single-nanoparticle free solution hydrodynamic separation (SN-FSHS) to simultaneously profile population identity, hydrodynamic size, RNA loading levels, and distributions of helper lipids and PEGylated lipids of LNPs at the single-particle level in a high-throughput manner.

Methods. The laminar flow generated by SN-FSHS produced a parabolic velocity profile in the tube due to the nonslip boundary condition (Figure 1). Larger particles sample the central flow streams more due to size exclusion from the channel wall, resulting in a higher average velocity and faster elution than smaller particles. This method allows for differential separation of any LNP formulation based on its size distribution. The CICS platform was coupled immediately downstream SN-FSHS. It features one-dimensional beam shaping, which enables accurate measurement of payloads by quantifying fluorescence with single-fluorophore sensitivity, assisted by a fluorescence deconvolution technique. To label LNPs, Cy3-siRNA served as the cargo, while a specific ratio of the DSPC helper lipid and PEG lipid was substituted with TopFluor-PC and DSPE-PEG-Cy5, respectively.

Results. Utilizing a benchmark siRNA LNP formulation, we analyzed the 4-dimensional parameter output from SN-FSHS-CICS. When examining the siRNA loading level (Cy3), the PEG loading level (Cy5), and the size of each LNP in a 3D space, a power regression for all formulations was observed, particularly for the 0.5% PEG formulation, where R^2 reached 0.90 (Figure 2a). Notably, a significant degree of heterogeneity in loading density (in terms of either siRNA or PEG) was observed for each formulation. In other words, the same LNP size can accommodate different amounts of siRNA or PEG lipid within each LNP.

By combining data points from all three formulations with a size distribution ranging from 30 to 200 nm, we can better visualize the spread of the data points between the maximum and minimum loading boundaries (Figure 2b). The size-dependent convergence of these boundaries clarifies the super-volumetric scaling observed in each formulation and suggests potential changes in the packing structure or density as the particle size varies. We attribute this observation to siRNA packaging in LNPs, which shifts from surface packing to heterogeneous volumetric packing, and ultimately to uniform volumetric packing as the size of the LNP increases.

Conclusions. This SN-FSHS-CICS analysis offers insights into a significant degree of heterogeneity in the packing density of RNA in LNPs. We anticipate that this technical framework will guide development efforts to refine manufacturing processes to achieve greater compositional homogeneity.

1673 Orthogonal chromatography analytics to allow for faster AAV or LNP process development and better in-process control

Ales Strancar, Sartorius BIAA Separations, Ajdovscina, Ajdovscina, Slovenia

- In-process analytics supports process engineers who want to visualize process related execution data and to have a clear representation of the process flow and/or to monitor and improve process execution.
- Biomolecules production is very complex process and analytical data may be misleading and lead to erroneous conclusions. Orthogonal analytical methods are therefore required to diminish the mistakes and enable faster and cheaper biomanufacturing processes.

- Chromatography is orthogonal method of choice to molecular biology methods. Examples of two-dimensional liquid chromatography in-process methods, for AAV and LNP production will be presented in this paper.

1674 An End-to-End High-Throughput LNP Formulation Device Platform for mRNA & LNP Screening

Rui Zhang, XGen Bio, Winchester, MA

Lipid Nanoparticles (LNPs) have been widely utilized in prophylactic vaccines and liver directed therapies; however, their applications in other areas remain limited due to challenges in payload design, LNP chemistry, composition, and formulation process optimization. To address these challenges and facilitate clinical translation, large-scale screenings are essential to establish robust design rules for LNPs. Promising methodologies, such as barcoded *in vivo* screening and plate-based *in vitro* assays, have been adopted but often require labor-intensive, one-by-one formulation of LNPs. Therefore, high-throughput formulation platforms are crucial to accelerating the development of genetic medicines.

At XGen Bio, we developed a high-throughput screening instrument, "INano^{TM} HT-Smart," which integrates three key modules for LNP preparation within a 96-well plate: (1) an automated lipid preparation module that mix lipid components in defined ratios, (2) a mixing module that facilitates the rapid mixing of lipids and payloads using either a T-mixer or a microfluidic mixer, and (3) an automated buffer exchange module for removing ethanol and acidic buffers. The device also features a temperature control system to maintain payload and mRNA stability throughout the process.

To validate the HT-Smart platform, several experiments were conducted:

- Mixing Regime Validation: T-mixers and microfluidic mixers were compared directly, demonstrating that both mixers could produce LNPs with consistent physical properties (size and PDI) when the optimal flow rate was identified.
- Reproducibility Testing: A single LNP formulation was independently prepared 96 times within a plate. The resulting LNPs showed high reproducibility with sizes <80 nm and PDI <0.1 across wells.
- Process Optimization: By varying mixing flow rates, LNP sizes were tuned from 70 to 100 nm.
- Large-Scale DOE Experiments: A Design of Experiment (DOE) approach was applied to formulate 96 unique LNPs encapsulating luciferase mRNA. Parameters such as lipid ratios, N/P ratios, and flow rates were systematically varied, resulting in LNPs with diverse size, PDI, encapsulation efficiency, and charge. From these, 30 formulations with >90% encapsulation efficiency and size <80 nm were selected for in vivo testing. Intramuscular injection into mice revealed a lead LNP formulation with over 5-fold higher mRNA expression compared to other candidates.

These findings demonstrate that HT-Smart is a robust platform for high-throughput screening of payloads, LNP formulations, and process parameters. This capability is expected to significantly accelerate the discovery and development of genetic medicines.

1675 Advanced mRNA Lipid Nanoparticle Analysis by Flow Cytometry

Jerilyn Izac[1], Sumeet Poudel[1], Thomas Cleveland[2], Haley Pugsley-Jessup[3], Maria Gracia Garcia Mendoza[3], Megan Cleveland[2], Lili Wang[4]
[1]NIST: National Institute of Standards and Technology, Gaithersburg, MD, [2]National Institute of Standards and Technology, Gaithersburg, MD, [3]Cytek Biosciences, Seattle, WA, [4]National Institute of Standards and Technology, Gaithersburg, Maryland

Lipid nanoparticles (LNPs) have emerged as a widely used delivery system for vaccines and therapeutics since the successful deployment of mRNA LNP vaccines against COVID-19. Recognized as a platform technology, LNPs can facilitate the rapid production and widespread availability of new medicines for various complex diseases upon FDA approval. The increasing demand for new mRNA LNPs underscores the need for high throughput methods to analyze their dosage and quality accurately.

Current techniques for measuring mRNA LNPs have limitations. Dynamic light scattering estimates diameter based on time correlations of the scattered light intensity but is biased towards larger particles, making it problematic for

heterogeneous samples. Nanoparticle tracking analysis suffers from variable detection limits due to sample polydispersity. Cryo-electron microscopy, recognized as the gold standard, is impractical for routine use due to its high cost and time requirements. RNA loading and encapsulation efficiency are often measured by ribogreen assay but this bulk measurement technology also has limitations. In contrast, flow cytometry offers significant advantages, enabling high-throughput analysis at the single nanoparticle level. In this study, we utilized a flow cytometry assay with various lipophilic, lipid-impermeable, and RNA dyes to detect empty LNPs and those with poor encapsulation efficiency. Several LNP preparations and fluorophores were examined on the Amnis Imagestream Flow Cytometer and other orthogonal methods. We have identified LNP and nucleic acid dyes that can be optimized for LNP analysis in flow cytometer platforms. Different subpopulations of LNP particles, including those with LNP membrane-bound RNAs and LNPs containing multiple mRNAs, were characterized with flow cytometry to provide great insights into LNP quality. This study has significant implications for LNP manufacturing and the analytics of nanoparticles, providing a fast and accurate assessment method with a high-throughput flow cytometry platform.

1676 A Novel HPLC-ELSD Method for Lipid Identification and Quantification in mRNA-LNP Complexes

Xiulian Sun[1], Zhong Ming[1], Hu Liu[2], Xiaohong Huang[2], Xiulan Zhu[2]
[1]Richmond, BC, [2]uBriGene Biosciences International Co., Suzhou, China

Objective: A typical Lipid Nanoparticle (LNP) delivery system for mRNA vaccines consists of four types of lipids: cationic lipids with amine functional groups that bind to mRNA via ionic interactions, lipid-polyethylene glycol conjugates, cholesterol, and zwitterionic phospholipids. However, LNPs are prone to aggregation and degradation during storage and transportation, which can compromise the efficiency and safety of mRNA vaccines. Qualitative and quantitative testing of individual lipids is essential for process and formulation development and serves as a critical QC item during the release stage

Methods: This method utilizes an Agilent 1260 Infinity II HPLC system equipped with an Agilent Poroshell 120 EC-C18 column (inner diameter: 4.6 mm, length: 150 mm, particle size: 4.0 μm) and an Agilent 1260 Infinity II Evaporative Light Scattering Detector (ELSD). The mobile phase consists of methanol and water (98:2) with 7.5 mM ammonium formate. The flow rate is set at 1.2 mL/min. The column, evaporation, and nebulizer temperatures are maintained at 65°C, 50°C, and 40°C, respectively.

Result: The chromatogram in Figure 1 below demonstrates the baseline separation of all four lipids, with each lipid component identified by its unique retention time. Furthermore, each of the four lipid components exhibits linear quantitation within the following detection dynamic ranges: PEG2000-DMG, 0.004 mg/mL to 0.12 mg/mL; Cholesterol, 0.0006 mg/mL to 0.50 mg/mL; SM102, 0.002 mg/mL to 1.25 mg/mL; and DSPC, 0.003 mg/mL to 0.30 mg/mL.

Conclusion: A method for determining lipids extracted from mRNA-LNP vaccines, featuring high detection sensitivity and a wide dynamic range, has been developed using the cost-effective Evaporative Light Scattering Detector (ELSD) compared to the more expensive Charged Aerosol Detector (CAD). A comprehensive methodology verification was performed, and the results confirmed that the method is reliable, accurate, and free from interference, making it suitable for ensuring the safety and efficacy of lipids in mRNA complexes.

1677 Optimized CRISPR-Cas9 Editing of Primary Human Immune and CD34+ Hematopoietic Stem and Progenitor Cells using a Mechanoporation Platform

Eric Ouellet[1], Ulrike Lambertz[2], Quan Nguyen[3], Tina Liao[2], Phillip Chau[2], Gil Paik[2], Elinor Binson[2], Colin Hammond[3], Marta Walasek[3], Nooshin Tabatabaei-Zavareh[1], Allen Eaves[4], Sharon Louis[3], Andy Kokaji[1]
[1]STEMCELL Technologies, Inc., Vancouver, BC, [2]STEMCELL Technologies, Vancouver, BC, [3]STEMCELL Technologies, Vancouver, [4]STEMCELL Technologies Inc, Vancouver, BC

Genetic engineering of human immune cells and hematopoietic stem and progenitor cells (HSPCs) is critical for advancing immunology and regenerative medicine research. However, traditional intracellular delivery methods, such as viral transduction or electroporation, can pose significant challenges to cell engineering due to increased cytotoxicity, inefficient delivery to non-dividing cells, and altered cellular physiology.

Mechanoporation is a non-viral intracellular delivery approach that relies on controlled mechanical deformation of cells within microfluidic channels. This creates transient pores in the cell membrane for cytosolic cargo delivery. Unlike conventional methods, mechanoporation minimizes unwanted cellular perturbations and safeguards physiological function. These features are advantageous for applications that require manipulation of sensitive cell types that are prone to loss or need to be studied in their resting states, such as unactivated immune cells or primitive HSPC populations. The CellPore™ Transfection System is a mechanoporation platform that efficiently delivers diverse biomolecules while preserving cell quality attributes, such as viability, phenotype, and function. Here, we demonstrate the efficiency of CellPore™ in delivering CRISPR/Cas9 ribonucleoproteins (RNPs) for achieving robust gene knockout in unactivated T cells, natural killer (NK) cells, and CD34+ HSPCs.

In unactivated T cells, CRISPR-mediated knockout (KO) of surface markers MHC-I and TCRαβ achieved efficiencies of 74% (mean; n = 12) and 94% (n = 3), respectively, while maintaining high viability (> 80%; n = 15) and preventing unwanted activation (indicated by low CD69 activation marker expression and minimal pro-inflammatory cytokine secretion, comparable to untreated control). Importantly, we also demonstrated that gene-edited unactivated T cells retained their downstream activation/expansion potential. Similarly, in primary human NK cells, KO efficiencies of 85% for TIGIT and 87% for NKp46 were obtained (n = 3), and cells retained their downstream cytotoxic and expansion capabilities.

In CD34+ HSPCs, CellPore™ mechanoporation achieved KO efficiencies of 92% (n = 4) for MHC-I and 84% (n = 3) for CD45, with a shortened pre-transfection culture timeline. Reliable RNP transfection and subsequent gene knockout was achieved as early as 4 hours post-thaw, and optimally after 24 hours in culture, contrary to electroporation, which required 48 hours in culture to achieve similar gene editing performance. The shortened workflow resulted in higher retention of CD34+CD90+CD45RA- hematopoietic stem cells, with minimal impacts to differentiation, expansion, and clonogenic potential, for edited HSPCs relative to the untreated control.

This study highlights the power of mechanoporation-based intracellular delivery to meet the evolving demands of modern generic engineering. The CellPore™ Transfection System achieves high editing efficiencies with minimal cellular perturbations, and offers a streamlined and practical solution for ex vivo engineering of immune cells and

HSPCs. It enables the study of novel immune functions, disease mechanisms, and cell-based therapies that would be otherwise challenging to perform using conventional methods. This platform provides researchers with reliable tools and avenues for accelerating innovations in cell therapy and regenerative medicine research.

1678 Exploring Mechanoporation for Efficient Genetic Modification Across Diverse Cell Types Using SMAR Vectors

Leonie Binder[1], Anna Hartley[2], Silvia Rizzato[3], Beeke Tappe[4], Krishna Vallabhaneni[5], Paul Carman[6], Todd Sulchek[5], Richard Harbottle[7]*

Gene and cell therapies rely on stable and safe genetic modification of cells for various applications such as cancer immunotherapy and the generation of stable cell lines. Our research focuses on leveraging non-viral, Scaffold/Matrix Attachment Region (S/MAR)-based vectors that provide sustained gene expression without genomic integration. These vectors have shown effectiveness across multiple cell types, including T and NK cells, Jurkat cells, HEK cells, induced pluripotent stem cells (iPSCs), and hematopoietic stem cells (HSCs). However, efficient DNA delivery and cell viability remain key challenges. Mechanoporation offers a promising solution for efficient DNA delivery with the potential to improve cell recovery and viability. The CellFE technology employs a microfluidic system to achieve rapid cell deformation, generating mechanical forces to porate cells and enhance transport through convective forces. DNA delivered by CellFE mechanoporation results in a more evenly distributed DNA payload, with a lower concentration of DNA leading to effective uniform delivery. Consequently, this technique reduces toxicity and improves cell recovery following gene transfer. Data from our lab demonstrates that mechanoporation with SMAR vectors can be used for the efficient transfection of cell lines such as HEK293T and Jurkat cells. This study illustrates the use of mechanoporation for the transfection of these cell types with SMAR vectors carrying fluorescent reporter genes and chimeric antigen receptors (CARs). We measure key metrics such as transgene expression efficiency and cell viability, along with functional assays measuring tumor-killing efficiency in CAR-transfected immune cells. Additionally, we show that mechanoporation can be used to efficiently generate stable cell lines. We show that CellFE mechanoporation is applicable as an advanced transfection technique compatible with SMAR vectors. The results contribute to understanding the versatility and robustness of SMAR vectors for diverse use cases including immune cell engineering, the generation of stable cell lines, and applications in regenerative medicine.

1679 Improving Workflow Efficiency of CAR T Cell Gene Editing Using Microfluidic Delivery Technology

Christie Ciarlo[1], Ailin Goff[1], Sewoon Han[1], Alla Zamarayeva[1], Todd Sulchek[1], Leonid Fomin[1], Chih-Wen Ni[2]
[1]CellFE, Alameda, CA, [2]NVI Therapeutics, Inc, Hayward, CA

Genetic editing of CAR T cells beyond introduction of the CAR transgene holds great promise for expanding the applicability of CAR T cell therapies. Editing is essential for mitigating allogeneic interactions in donor-derived T cell therapies and can be applied to increase T cell fitness in immunosuppressive microenvironments. However, the introduction of additional editing steps increases the complexity of manufacturing processes and results in substantial toxicity to cells using currently available methodologies.

To address these challenges, we have developed a transformative system for microfluidics-based mechanoporation that can be used to introduce gene editing reagents such as CRISPR/Cas9 into T cells. We found that microfluidic mechanical compression can seamlessly integrate T cell transfection and viral transduction without increasing the total editing time compared to viral transduction alone. In the new workflow, T cells are edited by mechanical transfection of Cas9 RNP on the same day as lentiviral transduction of a CAR transgene. Using TCR knockout as a

test case, we show that the workflow routinely produced T cells edited with greater than 80% efficiency. Cells recovered viability within 2 days of transfection and proliferated at the same rate as non-transfected controls. Transfected cells exhibited superior CAR transduction efficiency compared to non-transfected controls. Gene editing preserved CAR T cell immunophenotype, particularly stem cell memory prevalence. Edited CAR T cells retained high cytotoxicity and cytokine production in response to CD19-expressing target cells.

The workflow provides multiple benefits compared to conventional gene editing protocols. First, cells recover quickly from transfection and can be immediately handled for purposes of viral transduction, simplifying the production process. Second, viral transduction immediately following transfection increases gene transfer compared to transduction alone.

Importantly, the microfluidics-based gene editing process can also be applied to non-activated T cells. Comparable rates of gene editing and CAR T cell yield were achieved by transfecting T cells maintained in a quiescent state. These cells differentiate less than activated T cells and retain their stem cell memory phenotype, offering a platform for production of CAR T cell products with exceptional potency and durability.

1680 Non-viral, high throughput genetic engineering of diverse human primary immune cells using nanostraw-mediated transfection

Andy Tay, National University of Singapore, Singapore, Singapore, Singapore

Transfection of proteins, mRNA, and chimeric antigen receptor (CAR) transgenes into immune cells remains a critical bottleneck in cell manufacturing. Current methods, such as viruses and bulk electroporation, are hampered by low transfection efficiency, unintended transgene integration, and significant cell perturbation. The Nanostraw Electro-actuated Transfection (NExT) technology offers a solution by using high aspect-ratio nanostraws and localized electric fields to precisely deliver biomolecules into cells with minimal disruption. We demonstrate that NExT can deliver proteins, polysaccharides, and mRNA into primary human CD8+ and CD4+ T cells, and achieve CRISPR/Cas9 gene knockout of *CXCR4* and *TRAC* in CD8+ T cells. We showcase NExT's versatility across a range of primary human immune cells, including CD4+ T cells, γδ-T cells, dendritic cells, NK cells, T_{reg} cells, macrophages, and neutrophils which are being developed for a variety of immune cell-based therapies. Finally, we developed a scalable, high-throughput multiwell NExT system capable of transfecting over 14 million cells and delivering diverse cargoes into multiple cell types from various donors simultaneously. This technology holds promise for streamlining high-throughput screening of allogeneic donors and reducing optimization costs for large-scale CAR-immune cell transfection.

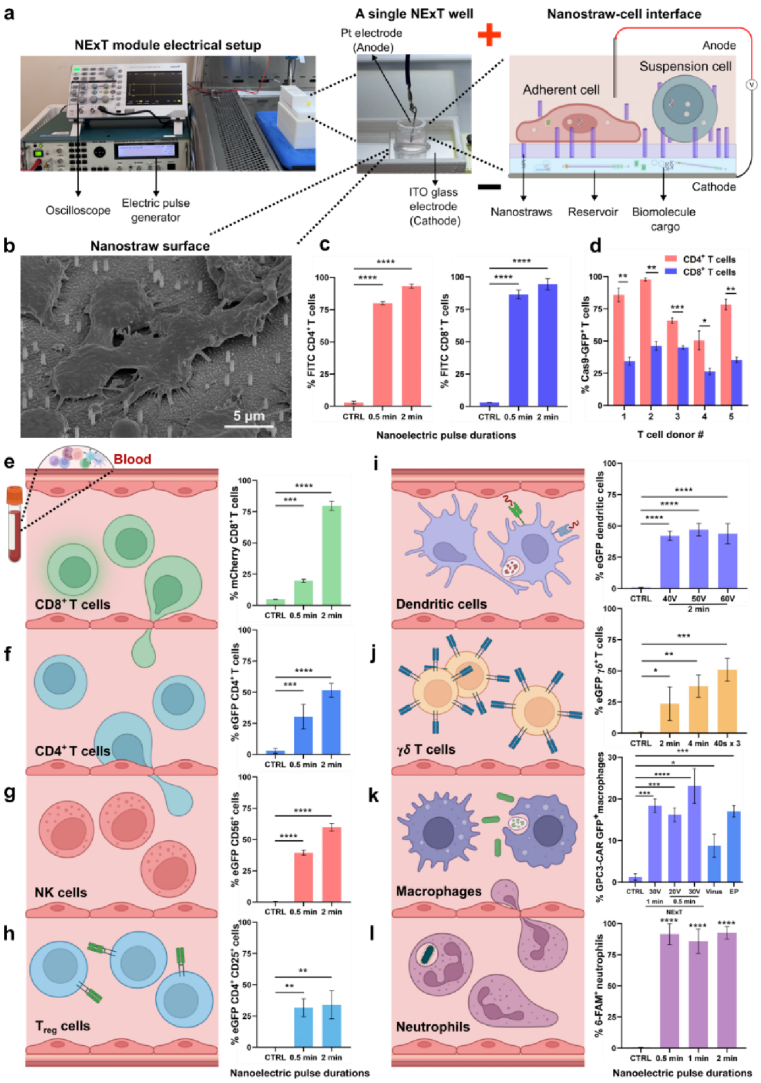

Figure 1. NExT transfection system enables intracellular delivery to diverse primary human immune cell types. (a) Schematic of NExT transfection system illustrating the different components including an electrical pulse generator and oscilloscope on the left image. The magnified image exhibits a single NExT well, comprising a plastic cylinder with nanostraw membrane adhered at the bottom, facilitating the channel between the biomolecule cargoes at the bottom and cells overlaid on the top. The circuit is closed by placing the Pt electrode anode dipped into the media and the bottom ITO glass electrode serving as the cathode. **(b)** FE-SEM image showing close adherence of CD8+ T cells around high aspect-ratio nanostraws after centrifugation and incubation for 2 hours. **(c)** Transfection efficiency of FICT-Bovine Serum Albumin (BSA) showing more than 80% delivery in CD4+ and CD8+ T cells respectively after 24 hours (n = 3 donors). **(d)** Transfection efficiencies of, GFP-Cas9 into CD4+ and CD8+ T cells demonstrate donor-to-donor differences (n = 5 donors). **(e)** Transfection efficiency of mCherry mRNA with > 80% in CD8+ T cells after 24 hours. **(f)** eGFP mRNA delivery with > 50% is observed in CD4+ T cells after 24 hours (n = 3). **(g)** Transfection efficiency of eGFP mRNA of up to 60% efficiency in NK cells (cell selection with CD56+ marker) after 24 hours (n = 4). **(h)** Delivery of eGFP mRNA in CD4+CD25+ T_{reg} cells was observed in over 30% cells with 2 min electric pulse after 24 hours. (n = 3). **(i)** Transfection of eGFP mRNA into human dendritic cells was observed up to 45% efficiency with 2 min electric pulse delivered at 50V (n = 3). **(j)** The transfection efficiency of eGFP mRNA resulted in delivery efficiency of up to 50% in γδ-T cells within 24 hours. (n = 3 donors). **(k)** Transfection efficiency of THP-1-derived M1 macrophages with GPC3 CAR constructs evaluated 24 hours after transfection by measuring the GFP expression. NExT delivered GPC3-CAR constructs with up to 23.08 ± 4.15% efficiency, surpassing viral vectors transfect (Virus: 8.75 ± 2.26%) and bulk electroporation (EP: 17 ± 1.09%) (n = 3 biological repetition) Expression efficiency was evaluated by measuring the GFP tag in CAR expressing macrophages. **(l)** NExT could achieve up to 90% delivery efficiency of 6-FAM-labelled siRNA into primary bone marrow derived mouse neutrophils (n = 3). Statistical significance was determined by one-way ANOVA test with post-tests performed with Tukey's multiple comparisons test * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; **** $p < 0.0001$.

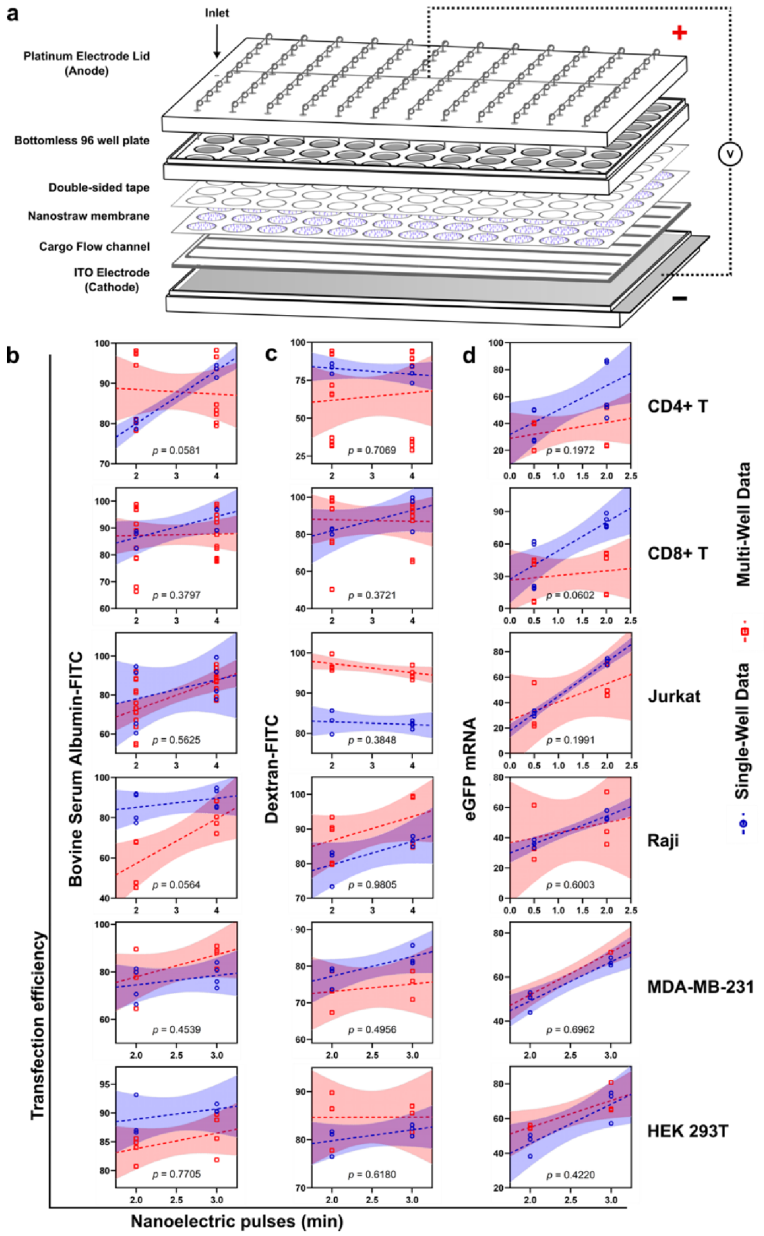

Figure 2. High throughput multiwell NExT platform enhances transfection throughput and exhibits comparable efficiencies to single well NExT system. (a) Schematic of high-throughput 96-multiwell NExT system. **(b)** Diverse cell types were seeded into the 96-well NExT system and transfected with BSA-FITC protein throughout the well plate. The transfection efficiency was evaluated 24 hours after transfection using flow cytometry. There was no significance observed between the multi-well system and single-well system with transfection of BSA-FITC and an overall increasing trend of transfection efficiency with increasing nano-electric pulse durations (min) **(c)** Diverse cell types were seeded into the 96-well NExT system and transfected with Dextran-FITC throughout the well plate. The transfection efficiency was evaluated 24 hours after transfection using flow cytometry. There was no significance observed between the multi-well and single-well system with transfection of Dextran-FITC and an overall increasing trend of transfection efficiency with increasing nano-electric pulse durations (min) except for Jurkat cells. **(d)** Diverse cell types were seeded into the 96-well NExT system and transfected with eGFP mRNA throughout the well plate. The transfection efficiency was evaluated 24 hours after transfection using flow cytometry. There was no significance observed between the multi-well and single-well system with transfection of eGFP mRNA and an overall increasing trend of transfection efficiency with nano-electric pulse durations (min) can be observed.

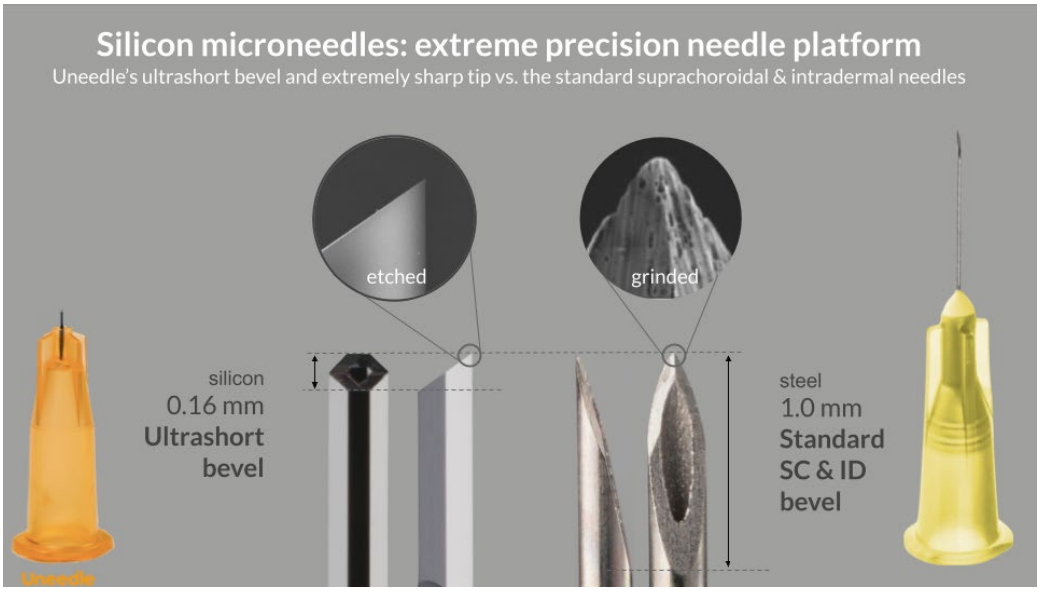
1681 Precise intradermal and suprachoroidal delivery of gene and cell therapeutics using a silicon microneedle

Sven Mentink[1]*, Jeffrey Stolwijk[2]*, Chang Luo[3], Shuaizhou Bai[3], Yuxin Wei[3]
[1]Uneedle, Enschede, Netherlands, Netherlands, [2]Uneedle, Enschede, Overijssel, Netherlands, [3]PharmaLegacy Laboratories (Shanghai) Co., Ltd., China., Shanghai, Shanghai, China
**Corresponding Author*

Introduction: The precise delivery of novel gene and cell therapeutics into superficial tissues is critical for maximizing their efficacy. Treatments such as cell-based cancer vaccines targeting the skin or adeno-associated viral (AAV) vectors administered to the suprachoroidal space rely on accurate depth-specific administration. However, traditional delivery methods, such as steel needles, lack precision and present challenges in achieving the targeted depth. Inaccurate administration of gene and cell therapies leads to unreliable dosing limiting therapeutic effectiveness and hampering translatability in larger clinical trials or real-world situations. Using silicon, a crystalline material, provides a promising solution to enable precise depth delivery in the dermis and suprachoroidal space, advancing the potential of gene and cell therapeutics.

Methods: Uneedle has developed a silicon microneedle platform that can precisely deliver therapeutics at depths anywhere between 200 and 1400 µm. This innovative delivery technology is simple to use in combination with any Luer lock syringe to administer therapeutics in superficial layers of the skin or eye. Clinical evaluations were conducted using cell-based and DNA-based cancer vaccines, as well as mRNA vaccines. The effectiveness, usability and dose sparing effects were assessed. Preclinical ophthalmological proof-of-concept evaluations were conducted using Non-human primates and New Zealand rabbits to assess the feasibility of microneedle delivery for suprachoroidal applications.

Results & conclusions: Here, we present data from (pre)clinical studies demonstrating the successful administration of gene and cell therapeutics using Uneedle's silicon microneedle technology. These studies establish proof of concept for the precise and efficient delivery of therapeutics into the dermal layers of the skin and the suprachoroidal space of the eye, highlighting the versatility and potential of this innovative platform. By enabling precise targeting and delivery, silicon microneedles offer a significant advancement in the field of gene and cell therapy, enhancing therapeutic efficacy and broadening clinical applications of current and novel therapeutics.



1682 ThecaFlex DRx™: Implantable Intrathecal Catheter and Subcutaneous Port System for Repeated Intrathecal Delivery of Nusinersen

Kathrin Meyer[1], Cassandra Dennys[2], JOHN MCGUIRE[3], Rachael Coughlin[4], Burt Raymond[4], Megan Holmes[5], Todd Washburn[4], Catalina Troche[6], Natalia De Souza[1], DJ Johnson[4], Melissa Breedlove[3], Deep Singh[3], Chris Coletta[4], Andrew East[4], PJ Anand[7]
[1]Alcyone Therapeutics, Lowell, MA, [2]Alcyone Therapeutics, Columbus, OH, [3]Alcyone Therapeutics Inc., Lowell, MA, [4]Alcyone Therapeutics, Lowell, [5]Alcyone Therapeutics, Nashua, NH, [6]Gainesville, FL, [7]Alcyone Therapeutics, Lowell, Massachusetts

Many genetic therapies, including antisense oligonucleotides, RNA-based therapies, and biologics for treatment of neurological disorders require repeated intrathecal (IT) dosing via lumbar puncture (LP). Repeated LP can be challenging for younger children, individuals with complex spinal anatomy and those who require repeat anesthesia and radiation exposures for therapeutic administration. Additional obstacles may also include complications from therapy administration such as post-LP headache. Consequently, patients who fall in these categories may benefit from an alternative delivery method.

Currently, there are no US Federal Drug Administration (FDA) approved IT catheter and subcutaneous port systems for therapeutic delivery. The ThecaFlex DRx™ System, part of Alcyone's Falcon™ Intra-CSF Delivery Platform, is designed to address this significant unmet need. ThecaFlex DRx™ has undergone extensive pre-clinical testing including design verification, in vitro functional testing, biocompatibility and extractables, drug-device compatibility, ovine in vivo safety and functionality studies, and extensive human factors usability evaluations. The design allows for both aspiration of CSF and infusion of therapeutics and is intended to reduce rate of infusion failures due to kinking, breakage, occlusion, migration or catheter-port disconnection, when compared to available off-label implanted systems.

Following development, the investigational device, ThecaFlex DRx™, received CE Mark Approval in Europe and Breakthrough Device Designation from the FDA. The safety and performance of ThecaFlex DRx™ is currently under evaluation in a two-stage IDE clinical trial (PIERRE, NCT05866419) delivering nusinersen to individuals with spinal muscular atrophy (SMA). In stage 1, 10 participants were enrolled, implanted, infused with nusinersen and followed for 30 days. During stage 1, ThecaFlex DRx™ performed as intended, and no device-related infections or device-related adverse events were observed. After reviewing these data, FDA approved stage 2, which is currently enrolling the balance of 80 individuals across the U.S. and Europe. Concurrently, an additional study (PIERRE-PK, NCT06555419) comparing nusinersen pharmacokinetics between LP and ThecaFlex delivery routes is also being conducted.

Potential clinical benefits of the ThecaFlex DRx™ system may include:

- Mitigating the challenges associated with repeat LP dosing, including potential reduction in the need for anesthesia and/or radiation for therapy, infusion, and monitoring, especially for patients with complex spinal anatomy.
- Enabling routine subcutaneous administration of therapies historically delivered intrathecally to the cerebrospinal fluid with the goal of improving the patient treatment experience.
- May allow more reliable intrathecal dosing, due to the potential variability of needle placement with manual injections

Combined, these benefits may improve the patient treatment experience of repeat drug administration to the CNS and may provide an easier approach to CSF sampling and therapeutic delivery. Importantly, ThecaFlex DRx™ IT catheter and port system may be applicable to broad populations with neurological disorders.

1683 MRI-Guided Focused Ultrasound: A New Drug Delivery Modality Addressing the Blood Brain Barrier

Zeinab Noroozian[1], **Michael Templin[2]**, Catherine Spickler[3], Kathryn McCabe[4], Rafi de Picciotto[4], Itay Rachmilevitch[4], Yeruham Shapira[4], Michael Plaksin[5], Sang Won Choi[4], Arjun Desai[4], Julius Haruna[3], Madhu Ravi[3], Simon Authier[6]
[1]Charles River Laboratories, Laval, [2]Charles River - Reno, Reno, NV, [3]Charles River Laboratories, Laval, QC, [4]Insightec Ltd, Miami, FL, [5]MichaelP@insightec.com, Miami, FL, [6]Charles River, Wilmington, Massachusetts

The use of gene therapy and vector delivery as potential treatment methods for neurodegenerative diseases is of peak interest to the scientific and clinical communities. Delivery mechanisms to the brain that can overcome the blood-brain barrier (BBB) are critical to ensure effective non-invasive drug delivery to the target region. MRI-Guided Focused Ultrasound (FUS) has been used as an effective tool in delivering antibodies, RNA and small molecules to specific target areas of the brain. Results from the current study provided insight on the neuroanatomical region to treat and on acceptable acoustic dose levels to be used in cynomolgus monkeys to allow delivery through the BBB. The technology used in the current study was the same as used clinically (Insightec Exablate Type 2 Low Frequency device). An AAV9 gene therapy vector with mCherry as reporter gene was used. Specifically, during these assessments (n= 12), sensitivity and tolerance to the acoustic dose (A.D) was confirmed in all animals using MR with contrast agent (i.e. gadolinium). The acoustic dose ranges for several brain targets were also assessed (A.D = 0.7 (caudate nucleus and putamen); A.D = 0.5 (thalamus and hippocampus)).The blood-brain barrier was noted to close approximately 4 hours postdose, with complete closure by 48 hours postdose. T2* imaging confirmed changes in the vascularization of tissue with fluid mobility through the BBB. High resolution diffusion tensor imaging (DTI) was used to map neuronal tracks to help predict drug diffusion patterns following FUS in cynomolgus monkeys. In conclusion, the use of FUS has provided great insight into the capability of locally surpassing the BBB and will serve as an effective method of therapeutic delivery of gene therapy to the brain.

1684 Scalable Softporation™ platform for intracellular delivery to primary natural killer (NK) cells

Kourtney Kostecki[1], Mohammad Albuhssin[2], Levent Degertekin[1], Andrei Fedorov[1], Behzad Mahdavi[1], Mark Meacham[1], Michael Binkley[1]*

Introduction: Transfection of primary immune cells, including natural killer (NK) cells, is essential for next-generation immunotherapies. However, current methods suffer from low viability and high cell loss. This study evaluates Softporation™, a novel transfection platform, for modifying primary NK cells and delivering intracellular payloads. The system uses fluid pressure generated by acoustic amplification to eject cells through a nozzle array and reversibly porate cell membranes, enabling the efficient introduction of large molecules while preserving native cell conditions. This method of payload delivery retains high cell viability and enables continuous processing of 1-300M cells/min, representing a critical step in the realization of an end-to-end NK cell manufacturing platform. Leveraging the Softporation™ platform's ability to increase throughput while preventing significant cell loss, we have established that the platform can be used for delivery of large fluorophore conjugates to primary NK cells. Effective operation with cell concentrations ranging from 1E6 cells/mL to 2E7 cells/mL were used to demonstrate the capacity of the system to support large-scale cell engineering and production pipelines.

Methods: Primary human NK cells from multiple donors were treated with the Softporation™ platform for delivery of three payloads - fluorophore-conjugated dextran molecules (70kDa, 500kDa, 2MDa) - using a range of device parameters. Following Softporation™ treatment, delivery efficiency was evaluated relative to untreated cell cultures incubated with equivalent concentrations of payload. Flow cytometry was used to quantify the delivery efficiency of the treatment. Cell viability and total cell yield were also evaluated. Cell concentrations of 1E6, 3E6, 1E7, and 2E7 cells/mL were tested. Payload concentration was kept constant at 0.5 mg/mL for fluorophore conjugates.

Results: The Softporation™ platform was successfully delivered large payloads to primary NK cells while retaining high viability (>99% of initially viable cells remained viable post-treatment). Cell viability following passage through the Softporation™ platform was not statistically different from starting viability ($p=0.86$). System throughput (flow rate over modified-cell production rate) was associated with applied acoustic field strength ($p<0.001$) under constant cell concentration. It was also observed that increasing cell concentration resulted in increased delivery ($p<0.001$).

Conclusion: The OpenCell Technologies Softporation™ platform enables efficient, high-viability delivery of large molecules (fluorophore-conjugated dextran) to primary NK. This platform addresses outstanding issues in the engineered NK cell manufacturing workflow and enables the possibility of repeated exposure to increase cumulative delivery.

1685 Swine Reporter Model for *In Vivo* Vector Characterization

Jarryd Campbell[1], Daniel Carlson[2], Jonathan Watts[3], Niren Murthy[4], Derek Korpela[5], Hesong Han[6], Sheng Zhao[6], Dennis Webster[1], Yen Anh Nguyen[3], Robyn Aune[1], Hinsoukpo Dagan[1]
[1]Recombinetics, Eagan, MN, [2]Recombinetics, Eagan, Minnesota, [3]UMass Chan Medical School, Worcester, MA, [4]Berkeley, CA, [5]Recombinetics Inc, Saint Paul, MN, [6]University of California Berkeley, Berkeley, CA

Delivery of nucleic acids to the appropriate tissues and cells at an effective dose is a significant challenge for *in vivo* gene therapies. Rodent reporter models activated by recombinases or gene editing reagents have been indispensable for characterization of new gene delivery vector modalities. However, their small size and anatomy do not always accurately translate to delivery in large mammals. To address this concern, we are developing a series of swine reporter models designed to track *in vivo* vector delivery to any tissue or cell in the body. The first Swine Reporter Model (SRM-1) harbors a modified Ai9 allele to allow for Cre mediated recombination as well as single-guide SpCas9 or AsCas12a CRISPR-based activation. This reporter is driven by a highly active and ubiquitous CAG promoter and is positioned at the *Rosa26* safe harbor locus. After removal of a strong transcriptional stop domain by CRISPR or Cre, the transfected cells will begin producing a fluorescent gene (tdTomato) that can be tracked by flow cytometry or direct imaging of the tissue. Additionally, a sodium iodide symporter (NIS) gene is expressed to also allow for non-invasive imaging of cell activation.

To assess the effectiveness of SRM-1 for tracking vector transfection *in vivo,* we intravenously injected AAV9-Cre into a male SRM-1 piglet and collected tissues for analysis of reporter activation. The injected animal was found to have widespread viral tropism with the highest reporter activation in muscle, adrenal glands, testicular tissue, and liver. These tissues were analyzed by IHC to visualize the reporter activation, which showed clear and robust reporter activation at the tissue and cellular level. We next systemically delivered LNPs carrying Cre mRNA and analyzed tissues from three piglets using fluorescent imaging of tdTomato. We observed the highest rates of reporter activation in the swine liver, as previously observed in mice, NHP, and humans. In addition, we saw substantial uptake in the spleen, testicular tissue, and adrenal gland, with lower levels of transfection in lung and gastrointestinal tissues. To broaden the utility of a swine reporter models, a second reporter pig model has also been created that can be activated by adenine base editor and by prime editing. We anticipate these pig models will be impactful for studying novel nucleic acid delivery vectors, as well as for establishing clinically relevant routes of administration in large animals for viral or nonviral gene therapies.

1686 Charge Detection Mass Spectrometry of Large Biomolecular Assemblies: A Novel Tool for the Characterization of Gene Therapy Vectors

Introduction: *Mycobacterium tuberculosis* (*Mtb*) encodes a rare prokaryotic proteasome system essential for evading the human immune system. Substrate access to the active sites of the 20S core particle (CP) is tightly controlled via proteasome activators to avoid spurious degradation. Proteasome activators recruit substrates and induce proteasome gate opening to facilitate substrate degradation. In *Mtb*, this is partly handled by Bpa (bacterial proteasome activator - 228 kDa homododecameric ring). Functional assays have established that Bpa can bind its native substrate, HspR, and translocate it to the 20S CP for degradation. The stoichiometry, oligomeric heterogeneity, and high-resolution structures of Bpa:HspR complexes remain elusive. Here we use charge detection mass spectrometry and electron cryomicroscopy (cryo-EM) to address these questions.

Methods: *Mtb* Bpa and its well-established substrate HspR were recombinantly co-expressed in *E. coli*. Proteins were purified using immobilized metal affinity chromatography (IMAC), followed by size exclusion chromatography (SEC). We performed native MS on a prototype Waters CDMS instrument to study the previously unknown Bpa:HspR complex stoichiometry. Additional CDMS experiments where the ion sampling inlet was heated to induce complex dissociation were also performed. Single-particle cryo-EM data was collected on either a 200 kV Glacios or a 300 kV Titan Krios microscope to generate a high-resolution reconstruction of the Bpa:HspR complex. Data processing was done using CryoSPARC 4.6.2 to generate 2D and 3D classifications. The resulting density maps will then be used to structurally model the Bpa-HspR complex.

Preliminary data: SDS-PAGE and intact protein mass spectrometry showed that His-SUMO-tagged HspR could pull down untagged Bpa during IMAC and co-eluted with Bpa during SEC, indicative of tight binding between Bpa and HspR. Reconstitution of a functional Bpa-20S CP degradation system *in vitro* was tested using discontinuous SDS-PAGE based degradation assays. CDMS was performed on a Waters prototype CDMS instrument equipped with an electrostatic linear ion trap and a nanoelectrospray source. The resulting spectra established dodecameric Bpa bound to two copies of HspR, with minimal heterogeneity in the number of HspR subunits bound (Fig 1). CDMS experiments where the ion sampling inlet was heated to induce complex dissociation showed charge-reduced Bpa dodecamers, consistent with asymmetric charge partitioning of the Bpa:HspR complex due to HspR ejection (Fig 2). We used single-particle cryo-EM to generate a high-resolution reconstruction of the Bpa:HspR complex. Substrate-bound samples analyzed using a 200 kV Glacios microscope yielded 2D classes with clear density within the central pore of Bpa. The preferred orientation of Bpa dodecamers yielded limited orientations and therefore made 3D classification difficult. An experiment in which Bpa-HspR is mixed with 0.25% IGEPAL and subsequently frozen appeared to drastically broaden the distribution of orientations. These samples will be subjected to 300 kV Krios analysis, and the resulting data will be processed to generate high-resolution maps suitable for structural modeling, thereby enabling the elucidation of the interaction sites between Bpa and HspR at atomic resolution. The implications of these findings for the gene therapy manufacturing pipeline will be discussed.

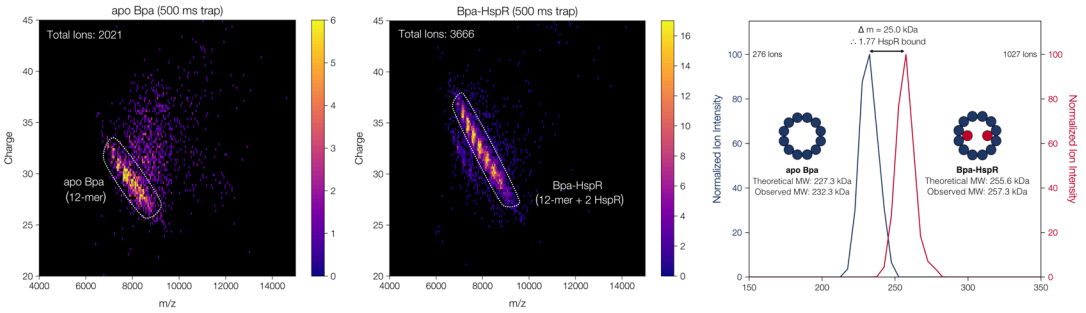

Fig 1. CDMS data represented as 2D and mass histograms of apo Bpa and Bpa-HspR complex. White hatched lines indicate points included after data filtering for m/z, z, and m analysis. (A) 2D histogram of apo Bpa created using in house Python scripts. (B) 2D histogram of Bpa-HspR created using in house Python scripts. Bin size and number for z and m/z is (0.5,100) and (50, 220), respectively (C) Mass histograms comparing filtered apo and substrate bound Bpa data. Bin size and number for m is (5000,1000), respectively. All experiments were conducted at 1 uM Bpa (Bpa monomer) in 10 mM ammonium acetate, pH 7.0. Both data sets were collected utilizing nano electrospray ionization via pulled borosilicate capillaries (5 um tip diamater) and 500 ms ion trapping time on a prototype Waters charge detection mass spectrometer.

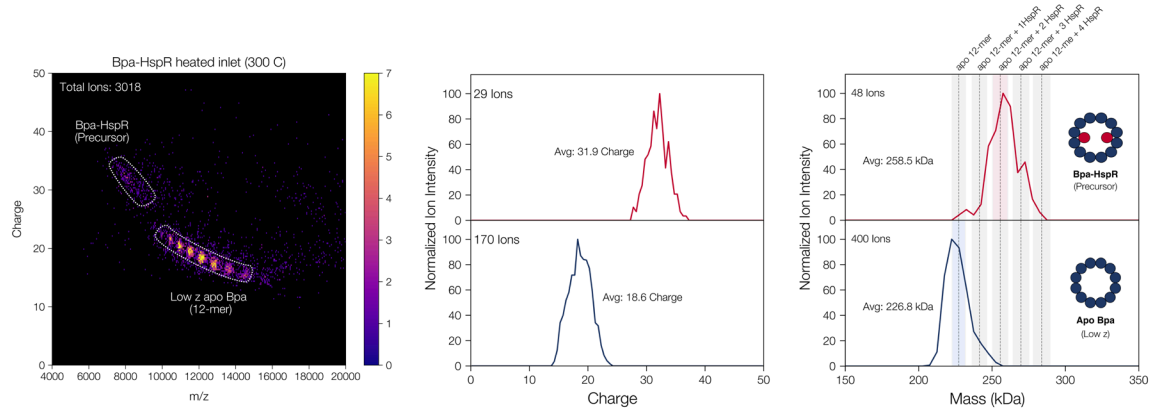

Fig 2. CDMS data represented as 2D and mass histograms of Bpa-HspR after dissociation via inlet heating (300 °C). (A) 2D histogram of Bpa-HspR created using in house Python scripts. White hatched lines indicate points included after data filtering for m/z, z, and m analysis. (B) Charge histogram of Bpa-HspR created using in house Python scripts. Bin size and number for z is (0.5,100). (C) Mass histograms comparing filtered Bpa-HspR precursor and low z apo Bpa data. Bin size and number for m is (5000,1000), respectively. Grey hatched area represents ± 2% of the theoretical weight for each respective species. All experiments were conducted at 1 uM Bpa (Bpa monomer) in 10 mM ammonium acetate, pH 7.0. Both data sets were collected utilizing nano electrospray ionization via pulled borosilicate capillaries (5 um tip diameter) and 500 ms ion trapping time on a prototype Waters charge detection mass spectrometer.

1687 Advancements in Charge Detection Mass Spectrometry for Characterizing Large, Intact mRNA Structures and Optimizing mRNA Therapeutic Analytics.

Lohra Miller[1], Benjamin Draper, Mark Chipley[2], Lauren Barnes[2], Thomas Powers[3], Martin Jarrold[3]
[1]Megadalton Solutions, Bloomington, IN, [2]Pfizer, Chesterfield, [3]Pfizer Global Research and Development

Rapid advances in biotechnology have accelerated the use of messenger RNA (mRNA) to combat a wide range of incurable diseases. Since the release of the mRNA-based COVID-19 vaccines, the potential of mRNA technology has only begun to be fully realized. mRNA utilizes host cell machinery to produce proteins that aid the immune

system in fighting infection and disease. The process of mRNA translation is tightly regulated, with a delicate balance between the decay of its structure, especially in the 5' cap and the poly(A) tail. The 5' cap protects the mRNA from 5' to 3' exoribonucleases, while the length of the poly(A) tail determines the 3' to 5' exonucleolytic decay. Numerous studies have focused on optimizing these features to develop the most effective mRNA designs. As mRNA is modified, techniques to characterize these structures are required at every stage of their development. As the use of mRNA therapeutics expands analytical techniques to confirm identity and stability need to be explored. Mass spectrometry is a robust technique to confirm identity of small molecules, but therapeutic mRNA's fall beyond the mass limit of conventional mass spectrometers. Methods have been developed to enzymatically cleave mRNA to sizes that can be measured by conventional mass spectrometry; however, information on truncations and/or partial sequences can be lost. Charge detection mass spectrometry (CD-MS) is an emerging technique that has shown significant utility in the high-resolution mass measurement of large heterogenous biomolecules. Herein, we developed a CD-MS method for intact mRNA analysis, featuring optimized sample preparations for high resolution analysis of large mRNA sequences. Using this high-resolution technique, we measured the mRNA construct for hemagglutinin (HA) protein of the influenza virus and were able to differentiate constructs with variable poly(A) tail length.

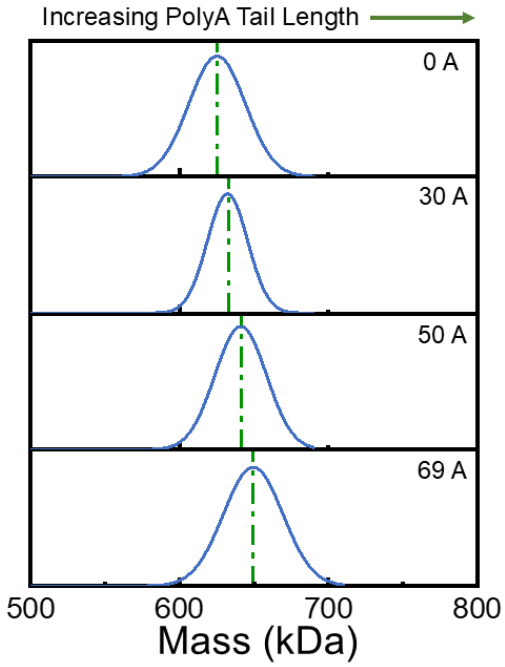

Figure 1. CD-MS Mass distributions for HA mRNA Constructs with increasing PolyA tail lengths.

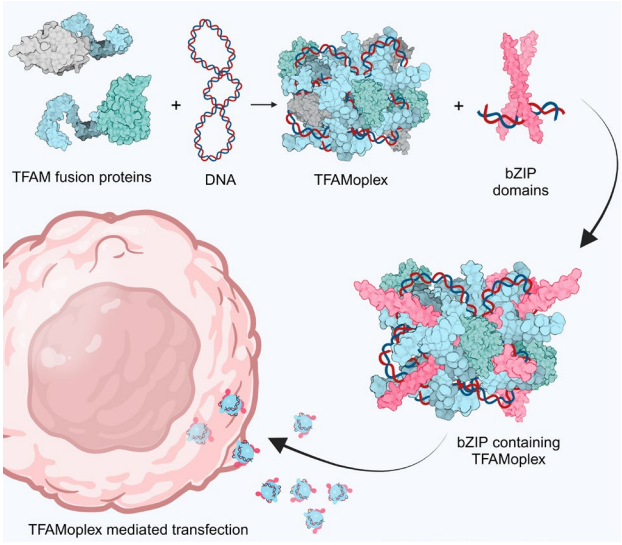
1688 Closing the Gap: Boosting the *TFAMoplex* Transfection System with bZIP Domains allows Comparison with AAVs

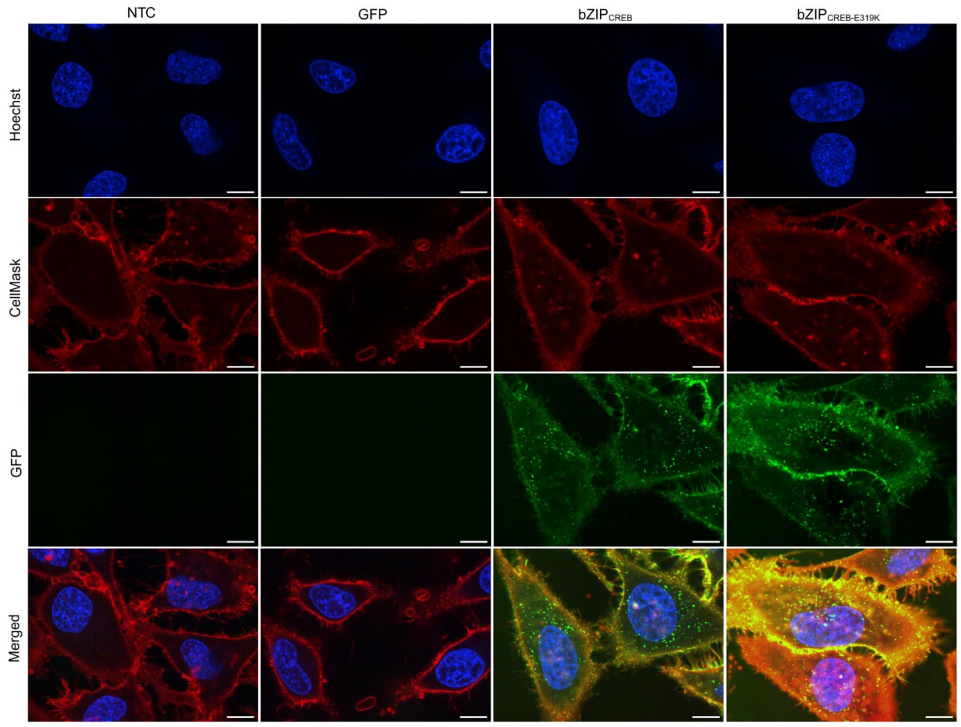
Steffen Honrath[1], Michael Burger[1], Jean-Christophe Leroux[2]
[1]ETH Zurich, Zurich, Zurich, Switzerland, [2]ETH Zurich, Zurich, Switzerland

Gene therapy offers promising treatments for a wide range of diseases, but efficient delivery of DNA into target cells remains challenging due to its large size and negative charge. While viral vectors are highly effective, nonviral systems are often preferred for their safety and ease of production, though they typically suffer from limited efficiency and stability in biological fluids. Our group previously developed a nanoparticulate gene delivery system called **TFAMoplex**, which leverages the mitochondrial transcription factor A (**TFAM**) protein that binds and

condenses DNA into **nanoparticles**. This system can be customized with functional domains by protein engineering to enable efficient **plasmid DNA transfection**.

In this study, we redesigned the TFAMoplex system by integrating basic leucine zipper (**bZIP**) **domains**, particularly from the cAMP response element-binding protein (CREB), which binds DNA through dimerization. We also evaluated bZIP domains from other proteins, including BACH1, ATF-3, and BATF, under challenging *in vitro* transfection conditions like **pure serum and only 10 min incubation time**. Among these, the bZIP domain of BACH1 ($bZIP_{BACH1}$) was identified as the most effective one, significantly enhancing TFAMoplex performance by reducing the half-maximal effective concentration (EC_{50}) by more than 2-fold. Additionally, we show that bZIP domains increase the interaction of TFAMoplexes with cell membranes, thereby enhancing cellular DNA association, which could partially explains the enhanced transfection. Finally, we **compared the optimized $bZIP_{BACH1}$-TFAMoplex to adeno-associated viruses (AAVs)** in terms of transfection efficiency and transgene expression. Although AAVs demonstrated superior transfection efficiency based on the number of transfected cells, both the original and optimized TFAMoplex constructs significantly outperformed AAVs in terms of transgene expression per cell.

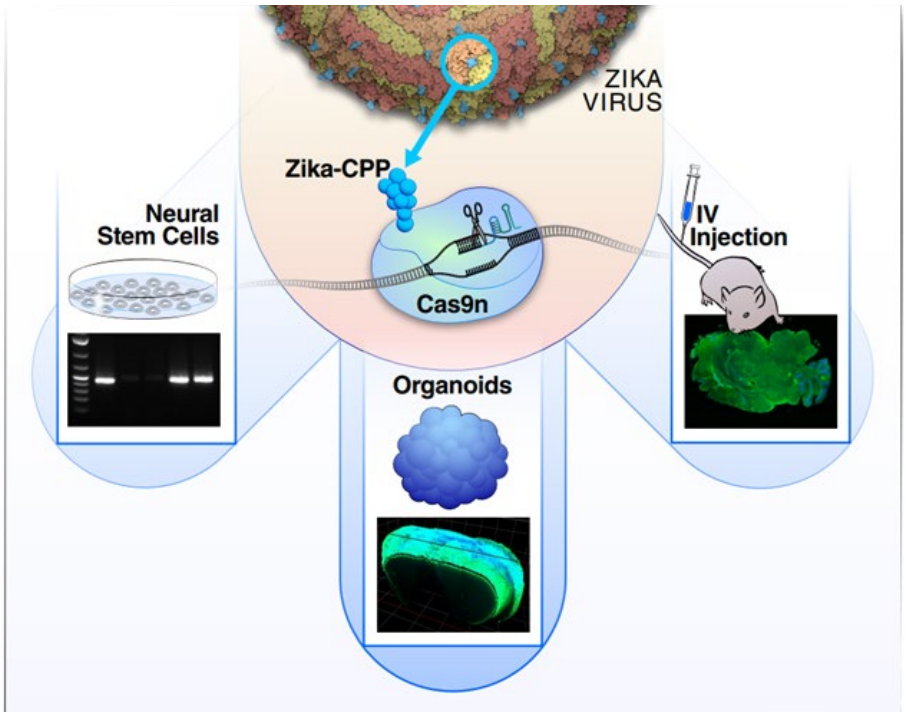




1689 Title ZIP Delivery: A Versatile Delivery Platform for the Central Nervous System

Barbara Bailus[1], Stephen Scheeler[2], Kizito Tshitoko-Tshilenge[2], Ningzhe Zhang[2], Swati Naphade[2], Sally Mak[2], Kenneth Wilson[2], Robert O'Brien[2], Mahru An[2], Brian Rossmiller[2], Stanislav Moroz[2], Jennifer Suoja[2], Maria Sanchez[2], Tyne McHugh[2], Anja Sandholm[2], Delihla Correa[1], Akos Gerencser[2], Lisa Ellerby[2]
[1]Keck Graduate Institute, Claremont, CA, [2]The Buck Institute for Research on Aging, Novato, CA

One of the major challenges in developing therapeutics for neurological disorders remains the widespread delivery of therapeutics to the brain. To address this challenge, we designed a novel cell-penetrating peptide based on the Zika virus, called "ZIP". We tested this technology in neuronal stem cells, striatal organoids, and murine models. We have fused ZIP to both Cas9 and to EGFP to evaluate its ability to transport cargo both into neuronal cells and past the blood-brain barrier. Our initial experiments focused on using Huntington's disease (HD) models to explore a potentially therapeutic mechanism for decreasing the number of CAG repeats in the exon 1 CAG expansion. HD is a rare, devastating, neurodegenerative disorder with no disease progression modifying treatments. It has been previously shown that a reduction in the expanded CAG repeat in exon 1 in HD mice leads to amelioration of symptoms. Using our ZIP-Cas9 delivery system we genetically corrected the exon 1 CAG expansion in both neuronal stem cells and striatal organoids. Impressively, we have been able to show that the "ZIP" transports Cas9 past the adult murine BBB and into neurons and astrocytes with extremely high efficiency, including into the hippocampal and striatal regions using a single intravenous injection. Further, we tested the ability of the ZIP to transport different cargos such as EGFP, again showing transport into human striatal organoids and past the adult murine brain. We have also tested the versatility of ZIP when attached to different versions of Cas9 including dCas9VP64 and dCas9KRAB. To move this technology toward potential human use, we have explored the ability to have the ZIP-Cas9 commercially synthesized, and we are testing this new construct to evaluate recombination efficiency at therapeutically relevant levels. Our presentation will highlight the advances ZIP technology continues to make as a potential therapeutic delivery platform for neurological diseases and disorders.



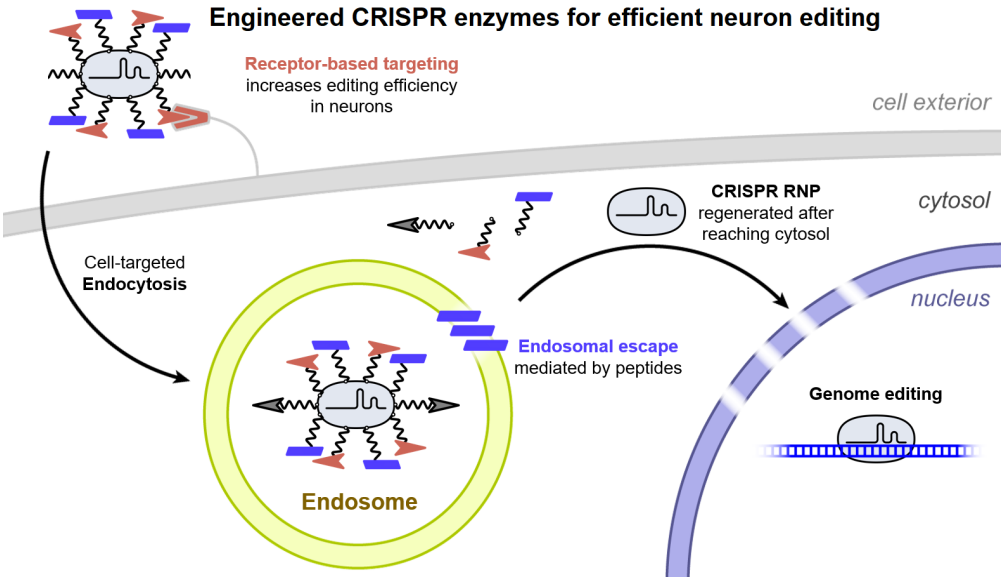
1690 Engineered CRISPR enzymes mediate highly efficient editing of neurons in mice and pigs

Ross Wilson[1], Christopher Baehr[2], Brigette Manohar[3], Lily Rahnama[4], Min Kang[1], Rania Materum[3], Vikas Munjal[5], Addison Byrne[6], Jonathan Green[6], Allison Clark[7], Meika Travis[7], Rohit Sharma[1], Sheng Zhao[1], Lluis Samaranch[7], Kevin Wells[6], Krystof Bankiewicz[7], Niren Murthy[8], Victor Van Laar[7], Russell Lonser[9]
[1]University of California Berkeley, Berkeley, CA, [2]UC Berkeley, Berkeley, CA, [3]Innovative Genomics Institute, Berkeley, CA, [4]University of California, Berkeley, Hayward, CA, [5]Ohio State University, Columbus, OH, [6]University of Missouri, Columbia, MO, [7]The Ohio State University, Columbus, OH, [8]Berkeley, CA, [9]OSU Wexner Medical Center, Columbus, OH

CRISPR-driven genome editing of the central nervous system (CNS) has the potential to revolutionize the treatment of neurological disorders such as Huntington's and Parkinson's diseases. However, developing CRISPR therapeutics for the CNS has been challenging, due in large part to delivery. Two key obstacles need to be overcome before gene editing in the human brain is feasible: (1) safe and effective intracellular delivery of editing machinery into neurons, and (2) establishment of strategies that enable targeted brain regions to be efficiently edited.

Our team has advanced an approach for highly efficient editing of neurons in the brain. This approach relies on the intersection of three technologies: NLS-rich CRISPR ribonucleoprotein (RNP) enzymes that possess some capacity for self-delivery into cells, amphiphilic peptides that substantially enhance efficiency of intracellular RNP delivery, and convection-enhanced delivery (CED), a means of administration that promotes optimal distribution after local injection. Furthermore, the CRISPR and peptide components are reversibly tethered using a PEG linker, enabling improved tissue distribution as well as neuron-specific targeting. This approach results in widespread, high-efficiency genome editing of neurons in the mouse brain following administration into striatum, thalamus, or hippocampus. Following extensive optimization using reporter mice, this approach is being used to edit neurons in the brain of a large mammal (pig) and has conferred phenotypic correction in a murine model of Huntington's disease. Our experiments to date demonstrate favorable host responses: negligible toxicity and only moderate immune responses to the reagents. Our approach relies on components – CRISPR protein, guide RNA, PEG-based

linker, and synthetic peptide – that are all straightforward to manufacture at scale. The transient nature of our reagents provides the benefits associated with non-viral delivery: minimal risks of off-target genome editing or immune responses to the CRISPR cargo. In contrast to CRISPR mRNA cargo delivery using lipid nanoparticles, which are typically at least 100 nm in diameter, our particles are an exceptionally small ~20 nm in diameter, faciliating diffusion through the brain parenchyma (~50 nm pore size). Together, these properties suggest our approach for CRISPR enzyme delivery has substantial potential for clinical translation in addressing neurological diseases.



1691 Peptide-Based Nanoplatform for Improved Cas9 RNP Delivery and Editing

Joseph Lavalla[1], Alyson Schwartz[1], Audrey Wessinger[1], Jennifer Singleton[1], Santiago Rivero[1], Jessica Larsen[1], Angela Alexander-Bryant[1]
[1]*Clemson University, Clemson, SC*

Introduction: Clustered regularly interspaced short palindromic repeats (CRISPR) technology has transformed the field of genetic engineering over the last decade by enabling precise and permanent changes to the genome. Despite its immense potential to correct and cure human genetic diseases, CRISPR technology has been limited in its clinical translation. The Cas9/gRNA system can be delivered to cells in multiple ways, including plasmids, messenger RNA (mRNA), or ribonucleoproteins (RNPs). Delivering Cas9 via RNPs has led to higher editing efficiencies and lower off-target effects than either plasmids or mRNA. However, due to their large size, net negative charge, and endosomal entrapment, RNPs require a delivery vehicle for efficient cellular internalization to achieve therapeutic efficacy. Currently, no therapeutic systems on the market enable the delivery of Cas9 RNP. Peptides have emerged as a promising non-viral delivery vector for transporting bioactive nucleic acids into cells due to their high tunability, stability, and biocompatibility. Our lab has previously demonstrated that a novel fusogenic peptide, DIV3W, can electrostatically complex with and protect RNA, is cytocompatible, and mediates efficient endosomal escape of bioactive RNAs. This study aims to evaluate the DIV3W peptide for delivery of RNPs to induce efficient green fluorescent protein (GFP) knockout in healthy HEK293 cells.

Methods: RNP:DIV3W complexes were synthesized by combining gRNA and Cas9 at equimolar ratios, followed by complexation with various molar concentrations of DIV3W peptide. The complexation of RNP with DIV3W was analyzed using agarose gel electrophoresis and was further characterized by dynamic light scattering. MTS assays determined a maximal RNP/DIV3W concentration that will not significantly kill healthy cells. gRNA was replaced with Cy5-fluorescently-tagged siRNA to visualize and quantify 4-hour cellular internalization using fluorescent imaging and flow cytometry. RNP:DIV3W and RNP:Lipofectamine complexes were also delivered to HEK293-

GFP cells to knockout GFP expression, and changes in fluorescence after 96 hours were analyzed using flow cytometry.

Results and Discussion: RNP:DIV3W molar ratios greater than 1:20 resulted in complete complexation of RNPs and, therefore, a successful delivery vehicle capable of protecting the RNP from premature degradation. MTS results confirmed that 50 nM RNP:DIV3W complexes were not cytotoxic to HEK293 cells up to 1:40 molar ratios (Figure 1A). 50 nM RNP/1:40 DIV3W molar ratio complexes were measured at 169 nm with a PDI<0.3, confirming monodisperse nanoparticle formation (Figure 1B). Preliminary uptake studies show ~50-60% cellular internalization after 4 hours. Knockout studies have demonstrated significant GFP knockout using the 50 nM/1:40 concentration compared to Lipofectamine CRISPRMax, highlighting comparable editing efficiencies as a commercially available system (Figure 2).

Conclusion: The DIV3W peptide can self-assemble with and completely complex free RNPs and is cytocompatible with HEK293 cells. The RNP:DIV3W nanocomplexes can escape the endosome prior to lysosomal degradation and traverse the nuclear membrane, as shown through successful gene editions. This peptide system has achieved significant GFP knockout comparable to that of Lipofectamine. These results demonstrate the potential of peptide-based delivery systems for Cas9 RNPs and warrant further investigation.

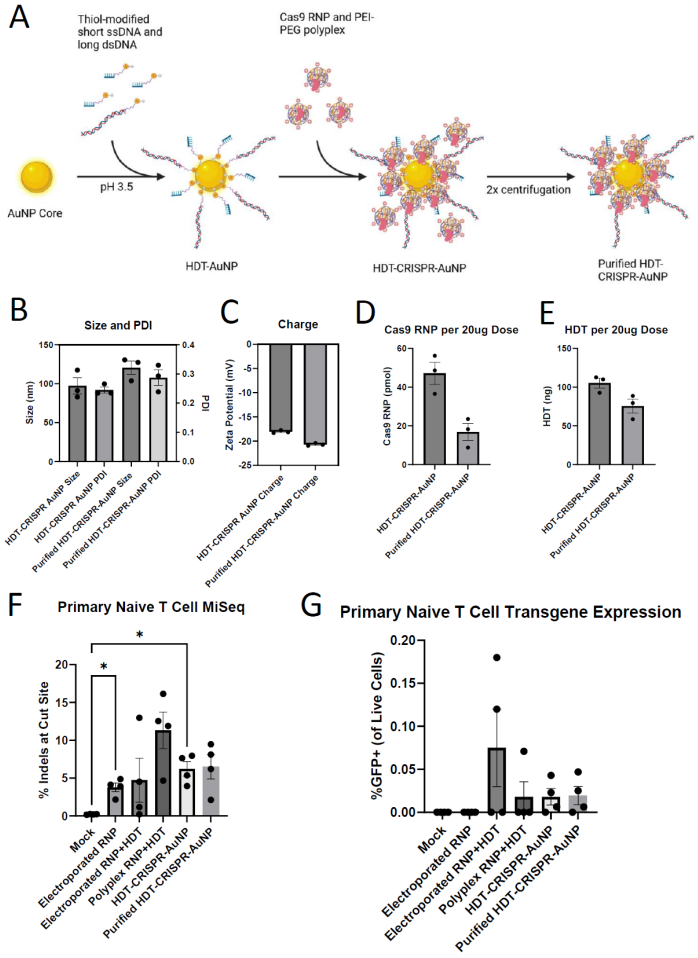
1692 Non-viral Co-delivery of Long DNA Template and Cas9 Ribonucleoprotein into Primary Blood Cells

Rachel Cunningham[1], Karthikeya Gottimukkala[1], Daniel Lane[1], Katrina Poljakov[2], Jennifer Adair[3]
[1]Fred Hutchinson Cancer Center, Seattle, Washington, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]University of Massachusetts Chan Medical School, Worcester, MA

CRISPR systems can direct mutations to specific loci and have been engineered to introduce small segments of DNA into the genome through direct write-in approaches. However, the delivery of large, transgene-encoding DNA cassettes with CRISPR systems remains limited. Current state of the art relies on viral vectors such as AAV to deliver double-stranded DNA (dsDNA) templates encoding the desired transgene(s) flanked by regions of homology to the target CRISPR site in the genome. These viral vectors are costly to manufacture and immunogenic, which limits repeat dosing. We developed a nonviral, synthetic gold-based nanoparticle (AuNP) that can deliver fully assembled Cas9 ribonucleoprotein (RNP) and long dsDNA homology directed repair template (HDT). This HDT-CRISPR-AuNP can be stably formulated with dsDNA as long as 2.5kb. In brief, thiol-modified HDT is conjugated to the gold core surface, then purified by centrifugation. The HDT-modified gold cores are then concentrated and added to a polyplex solution consisting of Cas9 RNP and PEGylated-polyethylenimine to allow binding to the gold surface (**Figure 1A**). If necessary, further purification by centrifugation can be performed. Characterization by dynamic light scattering showed that HDT-CRISPR-AuNP is stable with a hydrodynamic diameter and polydispersity index (PDI) of 97.2±18nm and 0.245±0.018 for unpurified and 120.5±14.72nm and 0.287±0.046 for purified formulations respectively (**Figure 1B**), with average charge (zeta potential) of –18.1±0.31mV and –20.71±0.29mV (**Figure 1C**). Analysis by SDS-PAGE and agarose gel electrophoresis showed that HDT-CRISPR-AuNP carried an average of 47.12±9.93pmol RNP and 105.1±10.86ng HDT per 20ug of 15-20nm gold core solution (determined by transmission electron microscopy), for unpurified and 16.84±7.48pmol RNP with 75.58±15.46ng HDT for purified samples (**Figure 1D, E**). HDT-CRISPR-AuNP synthesis required a maximum of 6.5 hours, with up to 2 hours of hands-on time and is scalable to the calculated available surface area of the gold cores. Nanoparticle treatment of unstimulated primary human naïve T cells resulted in statistically significant editing at the *β2-microglobulin* locus with unpurified formulations yielding 6.23±1.9% and purified with 6.49±3.2% insertion/deletion mutations (indels) at the target site. Additionally, T cells demonstrated expression of an enhanced green fluorescent protein (GFP) reporter transgene encoded in the HDT confirming delivery of DNA cargo into these cells (**Figure 1F, G**). While overall levels of GFP-expressing cells were low, for primary T cells engineered to

express a CAR transgene, these levels are sufficient to elicit an immune response (i.e. activation and proliferation) in the presence of target antigen [PMID: 29849141]. Future studies will confirm the efficacy of HDT-CRISPR-AuNP at clinically relevant loci such as *TRAC* and *CCR5*, as well as efficacy for editing primary blood cells in murine models. Given the low cost of AuNP core synthesis ($179 for 1g), and the reduced total and hands-on time required for assembly, HDT-CRISPR-AuNP are a simple alternative to viral vectors or electroporation for evaluating CRISPR-mediated transgene cassette delivery into primary T cells and possibly other hematopoietic cells of interest.



1693 E4/K4 Coiled-coils Improve Cargo Loading in Engineered Virus-Like Particles

Dylan Dautel[1], Karol Budzik[1], Pauline Schmit[1], Liana Behmoiras, Melissa Bonner[1], Claudia Pereira[1], Mahmudul Hasan, Yi Yu[1], Tatiana Ketova
[1]*nChroma Bio, Boston, MA*

An urgent need exists for novel delivery modalities to fully realize the therapeutic potential of gene editing technologies, including CRISPR-Cas-based gene editors. Recently, engineered virus-like particles (eVLPs) have emerged as a promising approach for *in vivo* delivery of gene editing therapies, offering transient delivery of ribonucleoproteins (RNP) and targeted payload delivery. Fluorescent imaging analysis revealed the majority of eVLPs do not contain detectable amounts of RNP. As a result, the editing activities of eVLPs containing less efficient cargoes, such as ABE7.10 and prime editors, were lower than direct plasmid transfection in HEK293T cells. David Liu *et al.* have demonstrated enhanced prime editor loading in eVLPs by utilizing P3/P4 coiled-coil (CC) peptides. In this study, we further optimized the CC loading strategy in our eVLP-derived DLVR-X system to enhance cargo loading efficiency and broaden cargo compatibility.

Heterodimeric coiled-coils consist of two short alpha-helical peptides that tightly wrap around each other to shield hydrophobic amino acids along the peptide backbones. These interactions can be strengthened by complementary electrostatic interactions and adapted to have different binding affinities, specificities, and orientations. We constructed DLVR-X particles by inserting one CC peptide between MMLV-Gag and Pol (Gag-CC-Pol) and the other to the N or C terminus of gene editing cargoes. To identify CCs with optimal properties for loading cargoes into eVLPs, we screened different configurations and types of CC domains. DLVR-X particles loaded with the E4/K4 CC pair outperformed the canonical v4-BE-eVLP design and P3/P4 CCs when loading ABE7.10, OpenCRISPR-1, prime editors, CBE, enAsCas12f, and enAsCas12a, highlighting that this E4/K4 CC cargo loading method is a modular and generalizable approach to deliver a wide variety of gene editors via DLVR-X. E4/K4 CCs resulted in an up to 6–fold increase in editing efficiency in HEK293T cells. In addition, we demonstrated potent editing in primary human cortical neurons and NHP hepatocytes with E4/K4 DLVR-X particles. Using a particle staining protocol developed on the Leprechaun particle imaging system, we showed that the increase in editing efficiency was linked to a 3-fold improvement in RNP loading efficiency compared to v4-BE-eVLP. These novel DLVR-X™ particles are anticipated to be highly versatile, addressing some of the constraints of existing delivery methods in both research and therapeutic contexts.

1694 Engineered Virus-like Particles with Minimal Viral Components for Improved Base Editing Efficiency in vivo

Karol Budzik[1], Dylan Dautel[1], Liana Behmoiras, Chen Wang[1], Geoffrey Burns, Stephen Pyon, Melissa Leitner, Matteo Gentili[1], Anne Richard, Angela Dao[1], Mahmudul Hasan, Claudia Pereira[1], Luca Biasco, Melissa Bonner[1], Yi Yu[1]
[1]*nChroma Bio, Boston, MA*

Novel delivery methods are essential to fully realize the therapeutic applications of CRISPR and related gene-editing technologies. Engineered virus-like particles (eVLPs) derived from Moloney Murine Leukemia Virus (MMLV) have recently emerged as a promising approach for in vivo delivery of gene-editor cargoes, providing flexibility in targeting specific cell types and reduction of off-target effects through transient ribonucleoprotein (RNP) delivery. However, the assembly efficiency of these eVLP particles is lower than wild-type MMLV virions, representing a manufacturing challenge. In addition, cargo loading and release require substantial improvement to unlock the full potential of this delivery platform. The presence of nonessential viral-derived components in the particle, the viral reverse transcriptase (RT) and integrase (IN) within the Gag-Pol scaffold, also poses potential safety concerns.

Here, we report the successful generation of RT- and IN-free DLVR-X particles, which exhibited significantly improved production efficiency and cargo release compared to the original v4-BE-eVLP design. The standard Gag-Pol scaffold was modified by truncating Pol to only the protease function and split into two constructs: (i) Gag and (ii) Gag-Protease (Gag-Pro). The optimal Gag-Pro/Gag plasmid ratio in ABE8e-carrying DLVR-X particles was determined as 1:20, which was in line with the reported 1:20 protease/Gag ratio in wild-type MMLV virions. This Gag-Pro particle design resulted in a ~10-fold improvement in titer, measured via p30 ELISA. Interestingly, the Cas9 content in the particles and editing efficiency of HEK293T cells significantly decreased with increasing Gag-Pro/Gag ratios. This indicated that cargo may be prematurely released in producer cells due to the increased cytoplasmic concentration of the MMLV protease, hindering cargo loading into DLVR-X particles. An automated Western blot assay confirmed the association of premature cargo release with high Gag-Pro/Gag ratios. The introduction of Amprenavir, an HIV protease inhibitor, during Gag-Pro particle production resulted in up to a 5-fold increase in particle Cas9 content relative to untreated Gag-Pro controls and a dramatic increase in editing efficiency of HEK293T cells. Surprisingly, Amprenavir treatment also increased cargo cleavage within the assembled Gag-Pro DLVR-X particles and significantly improved cargo release. Next, we replaced the native MMLV protease in the Gag-Pro construct with the HIV protease and observed further improvement in cargo processing and editing efficiency of different cell types. Finally, RT- and IN-free DLVR-X particles are under evaluation in mice for in vivo potency improvements. This is the first retroviral eVLP design for protein delivery that is completely free of RT and IN, to our knowledge. The increased production efficiency and cargo loading/release resulting from the design and process changes described above, in addition to the improved safety profile, enable exploration of the full potential of DLVR-X as a therapeutic protein delivery platform.

1695 Regulation of rAAV transgene expression using nanoparticle-delivered Cre-recombinase protein

Natalie Correa[1], Matthew Gardner[2]
[1]Emory University School of Medicine, Decatur, GA, [2]Emory University, Atlanta, GA

Introduction: Recombinant adeno-associated virus (rAAV) is a common gene therapy vector engineered to deliver a transgene cassette into the nucleus of a cell that persists as an episome resulting in durable transgene expression. However, no strategy currently exists to permanently terminate rAAV transgene expression in an event where an adverse reaction occurs. Unregulated expression of rAAV-delivered transgenes, like broadly neutralizing antibodies (bNAbs), can have several potential consequences that can include immune responses to high levels of transgene expression, off-target effects that could lead to toxicity, and development of anti-drug antibodies against the bNAbs reducing their efficacy. With the potential to utilize rAAV as an HIV-1 therapy, we can mitigate these risks through deployment of a strategy to regulate gene expression. Our approach encompasses a rAAV cassette engineered with LoxP sites flanking the transgene and leverages the use of engineered virus-like particles (eVLPs) or nanoparticles to deliver Cre recombinase (Cre) proteins to irreversibly terminate expression.

Methods: We engineered six different rAAV cassette designs, each with varying LoxP site locations that flank the transgene and evaluated the impact on transgene expression after AAV transduction by a luciferase reporter assay in HEK293T cells. All nanoparticles were assessed by ELISA, flow cytometry, and western blot to determine the amount of Cre recombinase packaged into the particle. Next, we evaluated different nanoparticle delivery systems (eVLPs and gesicles) that contain the recombinant Cre protein (Cre-eVLPs or Cre-gesicles), which were assessed on their ability to decrease rAAV transgene expression in vitro. Lastly, we evaluated our rAAV transgene cassette designs expressing the HIV-1 bNAb 10-1074 in mice that were treated with nanoparticles delivering Cre.

Results: Four out of six transgene cassettes containing LoxP sites resulted in equal or better luciferase expression compared to the cassette without LoxP sites after rAAV transduction of HEK293T cells. We observed a considerable decrease in luciferase signal of up to 99% in rAAV-transduced cells treated with Cre-gesicles. In contrast, rAAV-transduced cells treated with Cre-eVLPs only resulted in a decrease of luciferase signal of up to 90%. The two LoxP cassettes tested in vivo (LoxP-5 and LoxP-6) yielded concentrations of 10-1074 higher than the control rAAV vector harboring no LoxP sites. Current experiments are ongoing to assess Cre-eVLP and Cre-gesicle knockdown of in vivo transgene expression.

Conclusion: Our study demonstrates that nanoparticles provide an efficient system to deliver functional Cre-recombinase protein into cells transduced with rAAV cassettes engineered with LoxP sites resulting in a substantial decrease of transgene expression in vitro. Additionally, we conclude that rAAV cassettes containing strategically placed LoxP sites do not interfere with transgene expression in vitro or in vivo.

1696 A versatile platform for the manufacturing of lentiviral vectors-based nanoparticles for *in situ* gene delivery - an integrated solution to accelerate advanced therapies into the clinics

Léa DANDAN[1], Céline Jaudoin[2], Sarra LESCHIUTTA, Elina Rosoy, Alexandre Da Silva, Justine Hadjerci, Julie BERGALET[1], Alice COILLARD[1], Laurence SELLIER[1], Marion LHUAIRE[1], Eva MAUNICHY[1], Inès Morouche, Rachel PACHERIE[3], Frederic Mourlane, Renaud VAILLANT[4], Cecile Bauche[4]*
[1]Alaya.bio, PARIS, Paris, France, [2]Alaya.bio, Antony, Paris, France, [3]Alaya.bio, VILLEJUIF, Val-de-Marne, France, [4]Alaya.bio, Paris, Ville de Paris, France
**Corresponding Author*

Recent market approval of CAR-T cell therapies, their development beyond oncology and the continuously growing number of *ex vivo* and *in vivo* gene therapies evaluated in the clinics has created a huge constraint on the supply of high-quality grade lentiviral vectors (LVs). This results in higher manufacturing costs and longer timelines that are

not sustainable for early-stage development programs. Bioproduction remains a bottleneck for most biotech companies and established biotech players have invested in their own bioproduction capabilities.

Alaya.bio has built up a versatile manufacturing platform for the production of high-quality grade LV material to cover internal and customers' needs for R&D *in vitro* and *in vivo* evaluation. Our 350 m2 facility and team of 17 scientists based in Paris is operating a scalable and GMP-compatible bioprocess based on mammalian cell suspensions from 30 mL (for screening and feasibility tests) to 2 L of bulks produced in synthetic medium with no antibiotic or serum needed. The facility complies with the European regulations on the handling and use of genetically modified organisms. We have shown an excellent reproducibility of the production yields in bulks from the 30-mL to the 2 L-scale in shake flasks (>1e6 TU/mL or 1e9 vp/mL). We are now operating at the 30 mL scale for feasibility studies to test the combination of new transgenes, ubiquitous or tissue-specific promoters with LV variants. From the 2 L scale, bulks are endonuclease-treated, clarified, purified and concentrated (by chromatography and TFF). LVs are sterile-filtered and stored at -80 °C. 20 to 40 mL of sterile purified drug product are obtained within 4 days (>2e6 TU/mL or 1e9 vp/mL).

Product quality, process performance and repeatability are systematically verified through the integrity and functionality of viral particles (DLS, interferometry, ELISAs, RT-qPCR, flow cytometry and qPCR). The robustness of this bioprocess has been applied to second (106 batches) and third generation LVs (50 batches), integrating or non-integrative lentiviral vectors (NILV), mainly pseudotyped with the VSV-G envelope protein.

We engineered VSV-G-deficient LVs that lack cell transduction ability until coated with pH-responsive cationic polymers. Further modification with shielding polymers enhances stability and allows bioconjugation with targeting agents. A portfolio of 40 families of cationic or shielding polymers (with diversified shape, MW and pKa) has been assembled and screened to formulate homogeneously sized LV-based nanoparticles (Dh<300 nm and PdI<0.3) that efficiently deliver *in vitro* transgenes to different types of human cells that are relevant for the development of gene and cell therapies. We are currently implementing microfluidics-based formulation and TFF-polishing to render these nanoparticles compatible with industrial manufacturing. Further developments include the engineering of T-lymphocytes targeting nanoparticles by conjugating anti-CD3 scFv to shielding polymers by amine coupling. Targeted gene delivery to other cells or tissues can easily be redirected by switching binder specificity. By combining optimized bioproduction of lentiviral vector payload and high throughput screening of formulations with superior biophysical and functional properties, Alaya.bio provides an integrated solution to support biotech companies and academic laboratories throughout the development of their disruptive gene therapy programs.

1697 Efficient, Large-Scale Virus-Like Particle Manufacturing for Gene Editing by a GMP-Compliant Flow Electroporation Platform

Isabel Daher[1], Peter Gee[2], Tien Nguyen[3], Sean Menarguez[4], Andrew Mancini[5], Marianna Romito[2], Ashley Strickland-Dietz[6], Lauren Unsworth[7], James Brady
[1]MaxCyte, Inc., Washington, DC, [2]MaxCyte, Gaithersburg, Maryland, [3]MaxCyte, Inc., Rockville, [4]MaxCyte, Rockville, MD, [5]MaxCyte Inc., Rockville, MD, [6]Na, Montgomery Village, MD, [7]MaxCyte, Inc., Rockville, MD

Virus-like particles (VLPs) are non-infectious, virally-derived nanoparticles that lack a viral genome. Upon packaging a CRISPR ribonucleoprotein complex (RNP), VLPs can target and transiently deliver cargo for genome editing *in vivo* to specific cell and tissue types. They are safer than traditional viral vectors as they are incapable of genomic integration. Scaling up VLP production can be cumbersome and time-consuming, requiring several rounds of optimization to transition from research to clinical scale. Additionally, consistency and reproducibility between batches is a major concern when relying on chemical methods of VLP production. Here, we utilized the MaxCyte

ExPERT GTx®, a GMP-compliant electroporation instrument, to manufacture clinical-scale VLPs, in adherent and suspension HEK cells, packaged with CRISPR Cas9 or adenine base editor RNPs for genome editing in primary human cells. We found that electroporation consistently produced high yields of functional VLPs with an optimized electroporation workflow. We also demonstrated effective gene editing at several therapeutically relevant loci in primary hematopoietic cells, such as B2M and PD-1. Furthermore, the production of VLPs using electroporation exhibited favorable production kinetics compared to other transfection methods, enabling a one-day manufacturing process. Finally, we highlight the scalability of VLP production across a 400-fold volume range with minimal re-optimization, transfecting over one billion cells per production. In summary, our results show that MaxCyte's Flow Electroporation® technology is a viable means for consistent, efficient, and scalable manufacturing of VLPs for gene editing applications and has high promise to address the needs of future clinical and commercial manufacturing.

1698 Capsid and Virus-Like Particle Biophysical Characterization by High Sensitivity, High Resolution SEC-MALS: Case Studies on QBeta, Hepatitis B, and Recombinant Protein VLP Control

Lavelay Kizekai[1], Bala Addepalli[1], Michelle Chen[2], Matthew Lauber[3]
[1]Waters Corporation, Milford, MA, [2]Wyatt Technology, [3]Waters Corporation, Miford, MA

Virus-like particles (VLPs) can serve as novel antigen-presenting vaccine modalities. Moreover, critical insights into their capsid morphologies can be translated into the creation and optimization of delivery vectors for genetic medicine. Their compositions must be well characterized and documented to determine if they are to be used as components in a therapeutic or vaccine. VLPs are manufactured by controlled self-assembling viral structural proteins to mimic the size and shape of viruses without infectious genetic materials. Monitoring the size, shape, structural integrity, and stability under various conditions and formulations is essential to ensure the drug substances' safety and efficacy and uncover key insights about structure-function relationships. VLPs can range from 20 nm upwards of 200 nm in diameter or larger. Integrity analysis is essential for validating product quality in advanced therapeutics and vaccines. Size exclusion chromatography (SEC) combined with multiangle light scattering (MALS) provides a platform analytical approach for these investigations. Success of SEC technology for intact analysis of Megadalton VLP complexes require appropriate pore size of stationary phase and low adsorption hardware to facilitate maximum recovery of molecules to achieve high-throughput, multi-attribute, intact biophysical measurements of VLPs. VLPs can be complex and, at times, heterogeneous in composition; developing robust SEC methods can aid in the speed of formulation measurement and monitoring at each stage of the process. There is promise in improving SEC column technology through the development and implementation of low-adsorption flow paths. In addition, there is an opportunity to enhance separation efficiency and throughput on miniaturized particles with average pore diameters approaching 1000 and 2000Å. Using low adsorption 1000Å and 2000Å 3 µm SEC columns, we investigated VLPs as large as 300 nm, smaller 28 nm QBeta VLP, and 42 nm Hepatitis B VLP as well as 100 – 300 nm VLP prepared from HEK293 for use as an immunology isotope control. As these VLPs increase in hydrodynamic size, there is a significant risk to stability and self-induced aggregation. For instance, for a small VLP like QBeta, we observed recoveries for higher order aggregates and resolution of T=1 form to T=3 forms with the GTx Resolve 1000 Å 3 µm column that was about 30 to 50% better than another commercially available SEC 1000 Å column. Furthermore, the low adsorption GTxResolve 1000 Å 3 µm column technology exhibited lower MALS noise to facilitate more sensitive and accurate biophysical measurements. These observations were also corroborated by SEC-MALS, as displayed in Figure 1. Through additional mobile phase optimization, we obtained improved recovery of greater than 85% and have measured the radii of VLPs as large as 120 – 160 nm in diameter upon applying a prototype SEC 2000 Å 3 µm column. The hydrodynamic size of this proteinaceous VLP was confirmed by DLS measurement. While DLS measures the size distribution and polydispersity, SEC-MALS quantifies the heterogeneity, size, shape, and average molar mass of the VLPs and their impurities. In summary, we have shown that with new column technologies and method considerations, SEC-MALS can become an even more powerful tool for biophysical measurements of VLPs. These measurements are essential to maintaining drug and product stability for efficacy, controlling immunogenic responses, and unlocking k

1699 Virus-Like Particles: Advanced Insights through Charge Detection Mass Spectrometry (CDMS)

Anisha Haris[1], Kevin Giles[2], David Bruton[3], Keith Richardson[4], Jakub Ujma[5], **Erin McAllister[6]**, Kate Yu[6], Lars Thiede[7], Ronja Pogan[8], Jocky Kung[8], Charlotte Uetrecht[8]
[1]Waters Corporation, Cheshire, Cheshire, United Kingdom, [2]Waters Corporation, [3]Waters Corporation, Manchester, United Kingdom, [4]Waters Corporation, UNITED KINGDOM, [5]Waters Corporation, Wilmslow, United Kingdom, [6]Waters Corporation, Milford, MA, [7]CSSB Center for Structural Systems Biology, University Lubeck, Lubeck, Germany, [8]CSSB Center for Structural Systems Biology, Hamburg, Germany

Over the past few decades, virus-like particles (VLPs) have shown immense potential in vaccine-based therapeutics, addressing the limitations of traditional vaccines. A major advantage of VLPs is their high immunogenicity combined with non-infectiousness, as they lack the core genetic material of the virus. However, characterizing intact native VLPs remains a significant challenge due to their structural complexity and large size, in which the masses of VLPs often exceed 1 MDa. Charge detection mass spectrometry (CDMS), utilizing an electrostatic linear ion trap (ELIT), is an ultra-high mass technique that enables direct mass measurement of individual ions by simultaneously determining their mass-to-charge ratio (m/z) and charge (z). CDMS can overcome the limitations of conventional mass spectrometry in analysing large and heterogeneous analytes, where overlapping and unresolved charge states hinder mass determination. We demonstrate the potential of CDMS in characterizing the structural integrity and stability of various VLPs, including those of dengue, chikungunya, and different strains of human norovirus (hNoV). All samples were buffer exchanged into ammonium acetate solution using Micro Bio-Spin columns (Bio-Rad) or 100 kDa molecular weight cut-off filters (Amicon). Ions were generated in positive ion mode using nanoelectrospray ionisation (nESI) and mass analysis was performed using a prototype CDMS instrument. Signal processing and data visualization were performed using software developed in-house. Ions were trapped for 100 ms and the frequency and amplitude information were converted to m/z and z values respectively, and ultimately mass (m/z x z). These data are subsequently binned to generate the corresponding spectra (histograms). The m/z, mass, and charge data were binned to obtain the average, sigma, and area of each peak. CDMS capabilities in the structural characterisation of different MDa-sized VLP ions are highlighted. The VLPs mentioned can vary in heterogeneity and range in size from 20 – 60 nanometres. Icosahedral capsids are defined by their triangulation number (T), which is related to the number of monomers (T x 60) in the structure. Dengue virus serotype 1 VLP was studied, where a significant mass distribution was observed around 7 MDa with 155 charges, corresponding to the dimer of the VLP. Low level aggregation was also detected, with the presence of an additional peak at 14 MDa, at approximately less than 2 % of the dimer peak of the dengue VLP. The mosquito-borne Chikungunya virus-like particle (CHIKV VLP) was observed at a higher mass, with the presence of a distinct peak in the mass spectrum around 50 MDa. Aggregation of the CHIKV VLP was also observed with ion populations observed up to 200 MDa. It is important to monitor the stability of VLPs, which are often used in vaccine therapeutics, as aggregation may have potential implications for clinical safety and efficacy. Finally, hNoVLPs[TL1] [UC2] derived from three different strains were also analysed including GI.1 Norwalk and GII. 17 Kawasaki[TL3] [UC4] . T=3 particles were observed for Norwalk and Kawasaki strains around ~ 11 MDa[UC5] [TL6] . Overall, the measured masses agree well with

expected masses for the geometrically allowed capsids, while accounting for the presence of counterions observed with CDMS. The results presented here demonstrate the potential of CDMS to provide valuable mass information about the different capsid geometries of VLPs

1700 A Novel Non-Viral DNA Delivery Platform for Durable and Potent Expression of Bispecific T-cell Engagers

Mayra Salgado-Flores[1], **William Hallows[2]***, Virginia Le Verche[3], Chi-Lin (Steven) Lee[1], Brian Truong[4], Ryan Agabani[1], Annika Holquist[4], Anthony Pham[4], Vahid Raessi[1], Martha Velasco[1], Minh-Ha Do[4]*, Jeffrey Bartlett[1]
[1]Rampart Bioscience, Monrovia, CA, [2]Rampart Biosciences, Monrovia, CA, [3]Los Angeles, CA, [4]Rampart Bioscience, San Diego, CA
**Corresponding Author*

Bispecific T-cell engagers (BTE) are immunotherapies engineered to drive apoptosis by linking activated T cells to target cells. These molecules are approved for the treatment of CD19-positive B-cell precursor acute lymphoblastic leukemia (BCP-ALL) and hold promise for treating autoimmune disorders by depleting autoreactive B cells. However, their clinical application is constrained by their short half-life, requiring continuous intravenous infusions over 4-week cycles. To overcome this limitation, we evaluated our novel DNA gene therapy platform, HALO™, for providing efficient and durable BTE therapy. HALO is a circular DNA vector with unique structural DNA elements designed to favor nuclear uptake, nuclear retention, and immunomodulation, which greatly increases the efficiency, durability and redosability of gene delivery *in vivo*.

Here, we describe the design and evaluation of HALO DNA encoding CD3 x CD19 BTE fused to a peptide secretion tag (HALO BTE). HALO BTE was first transfected into HEK293 and HEPG2 cells, resulting in efficient BTE secretion. The secreted BTE potently activated T cells. Then, we showed that HALO BTE, delivered as lipid nanoparticles (HALO BTE-LNP), enabled durable BTE expression for up to 14 days in iPSC-derived hepatocytes. Using a CD19-positive Raji B cellular model, HALO-derived CD3 x CD19 BTE effectively activated primary human T cells and induced Raji B cell lysis in an effector-to-target ratio dependent manner. Finally, to evaluate *in vivo* potency and durability, HALO BTE-LNP was intravenously administered as a single ascending dose to wild-type mice. Expression of BTE in plasma was detected by ELISA and shown to be functional through *in vitro* T-cell activation assays. The expression was dose dependent and activated T-cells *in vitro* is a similar dose dependent manner. BTE expression persisted for at least 3 weeks *in vivo*, with ongoing evaluation for more than one month.

Altogether, these findings demonstrate that the HALO™ DNA platform enables safe, robust, and durable BTE expression *in vivo*. This innovative non-viral approach offers an attractive alternative to current BTE-based therapies, particularly if co-expressed with key oncogenic or immunogenic regulators, and holds significant potential for advancing other antibody-based therapies as well.

1701 Development of a Stable Lyophilized Formulation of a Quadrivalent Frame-Shift Peptide Vaccine for Cancer Prevention in Lynch Syndrome

Tim Fouts[1], Shanker Gupta[2], Bijay Misra[3], Indu Javeri[3], Kaliappanadar Nellaiappan[3], Robert Shoemaker[2]
[1]ABL Inc., Rockville, MD, [2]National Cancer Institute, Bethesda, MD, [3]CuriRx, Wilmington, MA

Some cancers are deficient in their ability to repair mismatched DNA which results in the accumulation of frameshift mutations in genes that contain microsatellite sequences, repeated sequences of DNA. Translation of these genes generates proteins with frameshift peptides induced by the mutations. These neoantigen peptides can provide a means for the immune system to target these microsatellite-unstable (MSI) cancers. Such frameshift peptides have been identified in four proteins, TAFB(-1), AIM2(-1), HT001(-1) and TGFBR2(-1) are being developed as vaccines to prevent/treat colorectal cancer, endometrial cancer, gastric cancer or small bowel cancer. A stable lyophilized formulation containing quadrivalent frameshift peptides (FSP) AIM2(-1), HT001(-1),

and TAFB (-1), TGFBR2(-1), was obtained through an iterative screening process. The screening included evaluation of pH, stabilizers, bulking agents, and surfactants. The screening resulted in a scalable formulation and lyophilization process with 100 µg/ml each peptide,10 mM Histidine at pH 5.5, 260 mM trehalose, and 0.02% polysorbate 20 as a clinical formulation. Based on peptide content and peptide purity from a three-month stability study, the lyophilized formulation is estimated to be stable at ambient temperatures for 18 months. Asymptomatic carriers of DNA mis-match repair mutations (Lynch Syndrome carriers) will be the target population to be vaccinated and monitored for safety and immunogenicity in a Phase 1 clinical study.

1702 Evaluation of Immunomodulatory Effects of Oncolytic Adenovirus Therapy in Immunocompetent Hamster Models of Metastatic Breast Cancer.

Sacha Robert[1], Natasha Roman[1], Kazuho Inoko[2], Margarita Romanenko[1], J. Michael Mathis[3], Daniel Lyadov[1], Julie Ostrander[1], Julia Davydova[4]
[1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Saint Anthony, MN, [3]University of North Texas Health Science Center, Stephenville, TX, [4]UMN, Minneapolis, Minnesota

Breast cancer remains a significant clinical challenge, particularly due to recurrence and progression to metastatic disease driven by therapy-resistant breast cancer stem cells (BCSCs). Despite effective initial therapies, estrogen receptor-positive (ER+) breast cancer patients frequently experience relapses, with up to 41% developing resistance to endocrine and chemotherapy. Current immunosuppressive tumor microenvironments further complicate therapeutic intervention. This highlights the urgent need for innovative therapies capable of targeting BCSCs while addressing immune evasion.

We previously developed OAd5/3-Cox2-NIS, a tumor-selective, infectivity-enhanced oncolytic adenovirus (OAd) encoding the sodium iodide symporter (NIS), which facilitates radioiodine imaging and therapy. Our studies demonstrated the superior ability of OAd5/3-Cox2-NIS to induce oncolysis and enhance NIS expression in paclitaxel-resistant ER+ BCSCs, including chemoresistant tumorsphere models. The vector selectivity was further validated in therapy-sensitive and -resistant human breast cancer cell lines, with low viral titers effectively eliminating cancer cells while sparing normal human mammary epithelial cells. However, the lack of a relevant immunocompetent and adenovirus-permissive preclinical model has hindered the evaluation of OAd-driven immune responses in breast cancer.

To address this limitation, we established a novel “Mammary INtra Ductal” (MIND) model in immunocompetent, adenovirus-permissive hamsters using the luminal-B HMAM5 cell line. This orthotopic model closely recapitulates key features of human ER+ breast cancer, including tumor formation within mammary ducts, estrogen receptors expression, epithelial markers retention (e.g. CK-18, pancytokeratin), and consistent metastatic spread to lymphatic nodes. Importantly, OAd replication in this model was confirmed via bioluminescence imaging (using luciferase-expressing Ad) and qPCR detection of viral E4 transcripts in tumors, overcoming the limitations of non-permissive rodent models.

Therapeutic study of OAd5/3-Cox2-NIS in this model demonstrated a significant ten-fold tumor volume reduction accompanied by robust viral replication in tumors and minimal off-target presence in non-tumor tissues (e.g. liver, lung, spleen).

Building on this newly developed model, we are currently conducting comprehensive studies to assess OAd-driven immunomodulation. This includes the abscopal effect studies in a bilateral tumor model to determine whether OAd-mediated immune activation can suppress distant, untreated tumor sites. Additionally, we are performing immune profiling using flow cytometry to analyze tumor-infiltrating immune cells (T-cell subsets and NK cells), alongside assessments of cytokine secretion and immune checkpoint expression to characterize OAd-induced immune activation. Furthermore, single-cell RNA sequencing will provide insights into gene expression changes induced by OAd infection, particularly in pathways related to innate and adaptive immune responses, tumor antigen presentation, and immune evasion mechanisms.

In conclusion, our MIND model offers a robust, immunocompetent system for evaluating OAd-based viroimmunotherapy in ER+ breast cancer, overcoming limitations of other models. By elucidating immune modulation and establishing proof-of-concept for multimodal therapies, this work supports the clinical translation of OAd for breast cancer patients, including metastatic disease.

1703 Development and Validation of a Six-Plex Quantitative PCR Potency Assay for an Anti-Breast Cancer DNA Plasmid Vaccine

Tiffany Edwards[1], Nitya Sharma[1], Carolyn Mammen[1], Tamara Cash[1], Katherine Smith[1], Michelle Kennedy[1], Neal Green[2], Shanker Gupta[2], Brian Cholewa[2], Shizuko Sei[3], Brian Necela[4], Keith Knutson[4], **Rachel Ginther[1]***

**Corresponding Author*

Breast cancer represents a major health burden, with over 40,000 deaths annually in the United States alone. This disease encompasses several subtypes, each with distinct genetic profiles and treatment needs. Prevention strategies for breast cancer remain limited, with most interventions either by surgery (e.g., prophylactic mastectomy for BRCA mutation carriers) or targeting only specific subtypes (e.g., tamoxifen for hormone receptor positive breast cancer prevention). Options such as chemotherapy and radiation have serious risk of adverse side effects and are not suitable in the prevention setting. Vaccination offers a promising alternative, leveraging the immune system's ability to mount immune responses specifically to overexpressed tumor-associated antigens (TAAs) without inducing harmful immune responses against normal tissues. Recent studies have demonstrated the potential for vaccines targeting overexpressed self-antigens to safely elicit an immune response, particularly in the context of cancer prevention. The Artemis Project, a collaboration among leaders in breast cancer and immunology, aims to develop a multi-antigen prophylactic vaccine targeting six TAAs: MUC1, HER2, hTERT, Survivin, MAGEA3, and Mammaglobin A, which are overexpressed across all major subtypes of breast cancer, including triple-negative, estrogen/progesterone receptor-positive, and HER2-positive cancers.

Two DNA plasmids were designed to co-express six human antigens in separate constructs (2 and 4 antigens in each construct) using 2A peptide technology. Multiantigen gene cassettes were inserted into pUMVC4a vaccine plasmid to create, pBC.1 (pUMVC4a-Her2ECD_Muc1_Her2ICD) and pBC.2 (pUMVC4a-Mamma_Survivin_MAGEA3_hTERT). Expression was validated by transient transfection in HEK293T cells. To support the analysis of these complex plasmids, we have developed a robust pipeline of assays to evaluate potency of the DNA plasmid vaccine during ongoing formulation and stability studies.

The mRNA expression of each TAA was quantified using our custom developed six-plex qPCR assay with a standard curve generated from gBlocks of each antigen, details of which will be described. Total protein expression was quantified using a commercially available ELISA kit for each antigen. During development and optimization of the 6-plex qPCR assay we consistently observed <10% CV for each standard curve and contrived samples. Contrived samples were consistently found to have <20% relative error during development. We observed an 84 to 26,000-fold overexpression of mRNA transcripts for each antigen relative to the vector control and mock transfection controls, indicating suitable transfection efficiencies for both plasmids. Similarly, we observed up to 56-fold overexpression of each TAA protein via ELISA. These data indicate that both DNA plasmids are transfected with high efficiencies and all six antigens are overexpressed relative to the mock and vector controls. In conclusion, we developed and validated a novel potency assay workflow to evaluate potency of two DNA plasmid vaccine candidates. These potency assays are integral to evaluating the expression of multi-antigen vaccines for breast cancer prevention and contribute to the ongoing development of safe and effective prophylactic strategies. Our assays provide robust measurements of TAA expression and serve as a key tool for vaccine development.

1704 Phase 2 Study Using Talimogene Laherparepvec, Nivolumab, and Trabectedin for Advanced Leiomyosarcoma and Liposarcoma (NCT03886311)

Jason Ballon[1], Samantha Jeffrey[1], Anmol Agarwal[1], Lauren Woolsey[1], Angela Savage[1], Vanessa Xayasak[1], Sarosh Syed[1], Ania Moradkhani[1], Victoria Chua[1], Neal Chawla[2], Erlinda Gordon[3], Sant Chawla[4]

[1]Sarcoma Oncology Center, Santa Monica, CA, [2]City of Hope, Duarte, CA, [3]Cancer Center of Southern California/Sarcoma Oncology Research Center, Santa Monica, CA, [4]Sarcoma Oncology Center, Santa Monica, California

Background: Advances in cell therapy/immunotherapy present the opportunity to further improve established chemotherapy regimens for soft tissue sarcoma. Here, we present the results of a phase 2 study for patients with advanced leiomyosarcoma (LMS) or liposarcoma (LPS), combining intravenous anti-neoplastic agent Trabectedin (T) with PD-L1 inhibitor Nivolumab (N) and intratumoral cell-therapy product Talimogene Laherparepvec (TVEC), a genetically modified Herpes simplex Type 1 oncolytic virus expressing GM-CSF which evokes a cytotoxic immune response.

Objectives: Primary: To assess progression-free survival (PFS); Secondary: (1) To evaluate the best overall response (BOR) by RECIST v1.1, disease control rate (DCR), 6 month PFS rate, 6 month overall survival (OS) rate, and Incidence of treatment-related adverse events (TRAEs). **Key eligibility criteria:** ≥ 18 years, locally advanced unresectable or metastatic LMS/LPS, measurable disease by RECIST v1.1, at least one accessible tumor for TVEC intratumoral injection; adequate hematologic and organ function; no concurrent clinical trial; no known hypersensitivity to study drugs; no known autoimmune disorder. **Study Design:** This is an open label single center phase 2 study. Treatment schedule: N (240 mg i.v. q 2 weeks), T (1.2 mg/m2 i.v. q 3 weeks), and TVEC (1x10e8 PFU intratumorally q 2 weeks depending on tumor size) were administered. A starting dose of TVEC (1x10e 6 PFU) was initially given, followed by a dose of 1x10e8 PFU q 2 weeks (according to tumor size) three weeks after the test dose.

Efficacy: The modified-intention-to-treat population (n=24), which includes patients who completed at least one treatment cycle and had a follow-up CT/MRI was used to determine the following: Median PFS = 8.0 (95% CI: 4.1-17.8) months; BOR = 2 PR, 18 SD, 4 PD; DCR = 83.3%; 6 month PFS rate = 62.5%; 6-month OS rate = 87.5%. The intention-to-treat population (n=35), which includes patients who received at least one dose of T, N, and TVEC, was used to determine the following: Median OS = 19.2 (95% CI: 10.2- 37.9) months. **Safety:** The intention-to-treat population (n=35), which includes patients who received at least one dose of T, N, and TVEC, was used to evaluate safety. Eighteen of 35 patients (51%) experienced Grade 3 TRAEs that included anemia (n=4), fatigue (n=3), ALT increased (n=3), AST increased (n=3), thrombocytopenia (n=3), abdominal pain (n=2), myalgia (n=2), localized edema (n=2), injection site pain (n=2), alkaline phosphatase increased (n=1), LVEF decreased (n=1), pain in extremity (n=1), neutropenia (n=1), colitis (n=1), headache (n=1), flu-like symptoms (n=1). There were no ≥ Grade 4 or unexpected adverse events.

Conclusions: Taken together, the results indicate that the combination regimen of Talimogene laherparepvec, Nivolumab, and Trabectedin may be more effective than Trabectedin alone (Median PFS 4.1 months) as treatment for previously treated patients with advanced leiomyosarcoma and liposarcoma with manageable toxicity. A randomized phase 2 clinical trial is warranted to confirm these promising results.

1705 Targeting Adenosine Immunosuppression in Glioblastoma with Oncolytic Virotherapy

Judit Sanchez Gil[1], Shanawaz Ghouse[2], Louise Leparc[2], Samuel Rabkin, Robert Martuza
[1]MASSACHUSETTS GENERAL HOSPITAL, Boston, MA, [2]Massachusetts General Hospital - Boston, MA, Boston, MA

Background: Glioblastoma (GBM) is highly immunosuppressive, with the adenosine (ADO) pathway playing a central role in disrupting immune responses within the tumor microenvironment (TME). To overcome this, we have developed new oncolytic herpes simplex virus (oHSV) G47Δ vectors armed with enzymes able to reduce extracellular (e)ADO and/or signaling and decrease immunosuppression and enhance immunovirotherapy. This novel combination of ADO degrading enzymes (ADEs) and the immune-stimulatory properties of oHSVs should improve clinical outcomes for GBM patients.

Methods: To construct novel oHSVs expressing ADEs, adenosine deaminase isoform 1 (ADA1) and adenosine kinase short isoform (ADK-S) were chosen to arm G47Δ. ADA1 can be intra- and extra-cellular and converts ADO to inosine. ADK-S catalyzes ATP-dependent phosphorylation of ADO to AMP and is appealing due to its higher affinity for ADO. Both enzymes are engineered to be secreted. To our knowledge, ADK has never been expressed in the TME, adding to the uniqueness of this strategy. Codon-optimized mouse mADA1 or mADKS with a secretory sequence (IL-2 signal peptide) upstream were inserted into G47Δ-using the CRISPR/Cas9 technique. G47Δ has been conditionally approved to treat recurrent GBM in Japan**.** Expression of ADO pathway proteins was determined using western blots, and immunohistochemistry and FACS of orthotopic mGSC-derived tumors.

Results: The lab has established unique panels of murine GBM stem-like cells (mGSCs) tumorigenic in C57BL/6 mice and primary and recurrent human GSCs (hGSCs). The expression of key ADO pathway proteins (CD39, CD73, and A2aR) in GSCs *in vitro* and in their derived tumors *in vivo* was characterized. *In vitro* analysis found large variability between GCSs. *In vivo* expression varied greatly in tumor cells and different immune cells in 005 mGSC-derived tumors (high CD39 and CD73 in T cells, low in macrophages, and high A2aR in microglia). This variability in the ADO pathway in both human and murine GSCs and tumors provides representative models to evaluate the effects of G47ΔmADA1 and G47ΔmADKS *in vitro* and *in vivo*. *In vitro*, mADA1 and mADKS were detected in infected 005 mGSCs, and their supernatants. mADA1 enzymatic activity, increased inosine, was only detected in the supernatants from G47ΔmADA1 infected mGSCs. mADK activity will be measured using highly sensitive liquid chromatography-mass spectrometry (LC-MS/MS) for adenosine, inosine, and AMP/ATP levels. Because eADO has its largest impact on immunotherapy, we will evaluate the activity of G47ΔmADA1 and G47ΔmADKS in immunocompetent mouse models *in vivo*. We will also examine the combination of G47ΔmADA1 and G47ΔmADKS. In a separate cohort of treated mice, immune cell subtypes will be determined by FACS and immunohistochemistry to observe a shift in the TME. Our hypothesis is that one or both viruses will improve survival vs. G47Δ and that improvement will be related to changes in tumor-infiltrating lymphocytes and polarized macrophages.

Conclusion: Infection with the novel oHSV-ADEs described here of our unique collection of mGSC-derived tumor models, with variable expression of ADO pathway components in tumor and TME cells, should lower eADO levels in the TME, reduce immunosuppression, and induce anti-tumor immunity. This innovative strategy can be translated to the clinic and potentially impact GBM patients.

1706 Evaluating IL27-expressing Oncolytic Adenovirus for Treating Advanced Prostate Cancer

Ying Cheng Chen[1], Marxa Figueiredo[1]
[1]*Purdue University, West Lafayette, IN*

The mortality of prostate cancer mainly consists of patients experiencing recurrence after androgen deprivation therapy (ADT) and those with distant metastasis, especially in bone, for which the five-year survival rate is only ~30%. The lack of effective therapeutics drives our objective to develop systemic treatments. Oncolytic viruses, such as adenoviruses (oAd), have shown success over decades, as evidenced by their entering clinical trials in several countries. However, limitations such as restricted delivery routes (intratumoral) to reach effective doses, and rapid neutralization by the host immune system remain key challenges to their broader therapeutic application. In this study, we engineered an oAd with a chimeric fiber to express genes of interleukin 27 (IL27) and green fluorescent protein (GFP), using adipose-derived mesenchymal stromal cells (ASCs) as carriers due to their distinct tumor-homing and immune-modulatory properties. We hypothesized that ASC carriers for oAd-IL27 would be *more effective than oAd or ASCs alone.*

Characterization confirmed selective viral replication in cancer cells (through an E1A deletion design), IL27/GFP expression, and cytotoxicity in the prostate cancer cell line, PC3. Cell cycle analyses indicated a significant increase in the subG1 phage in PC3 cells following treatment with oAd-IL27-loaded ASCs, as suggested by reduced confluency after five days of incubation. Further, in a 3D spheroid model, by coculturing NucLight-transfected PC3 spheroids with control oAd- or oAd-IL27-carrying ASCs, we observed promising effects for the IL27 treatment in reducing viable cancer cell number, as indicated by Nuclight intensity. Significant viral replication was detected as an increase in GFP integrated intensity, in both oAd- and oAd-IL27-loaded ASCs treatment groups. A PC3 xenograft mouse model was used to evaluate the therapeutic efficacy *in vivo*. Athymic male mice bearing subcutaneous PC3 tumors received a single treatment of phosphate-buffered saline (PBS), ASCs, oAd-carrying ASCs, or oAd-IL27-carrying ASCs when the tumor volume reached 50 mm^3. From the preliminary results, a prolonged survival time was observed in the treatment groups versus PBS control. Additionally, decreases in tumor volumes and tumor growth rate were also detected in groups given either of the oAd-carrying ASCs, and tumor reductions tended to be greater in PC3 tumors treated with oAd-IL27-carrying ASCs.

We will focus on optimizing the administrations toward multiple treatments to maximize therapeutic efficacy. Using ASCs to disguise oAd can reduce rapid neutralization and inflammatory responses from the host, enhancing the potential for repeated treatments. Ongoing and future studies may include immunohistochemistry and bulk RNA sequencing of tumors to validate and characterize the mechanisms of treatment efficacy. Additionally, immune cell profiling will be conducted to understand better the interactions between these oncolytic viruses, cancer cells, and the host immune system.

1707 Intranasal Delivery of IR-780-Conjugated Oncolytic Adenovirus: A Non-Invasive Approach Combining Virotherapy and Photothermal Therapy for Glioblastoma Treatment

A-Rum Yoon[1], Yuebin Zhao[2], Dayananda Kasala[1], Ao Jiao[2], JinWoo Hong[3], Chae-Ok Yun[4]
[1]Hanyang University, Seoul, Korea, [2]Hanyang University, Seoul, South Korea, [3]GeneMedicine, Seoul, South Korea, [4]Gene-Medicine, Seoul, Korea

Intranasal delivery has recently gained attention as a promising and highly safe method of drug administration. This non-invasive approach involves direct application of drugs to the nasal mucosa, allowing for direct delivery to the brain via olfactory and trigeminal neural pathways that originate in the olfactory neuroepithelium of the nasal cavity and terminate in the brain. Here, for efficient delivery of intranasal delivery of oncolytic adenovirus (oAd), we have developed a novel nanohybrid vector comprising an oAd complexed with a photosensitive carrier (INP-IR780). The intranasal administration of this oAd-INP-IR780 complex uniquely bypasses the blood-brain barrier, a major obstacle in conventional GBM therapies, enabling direct and efficient delivery to the brain. This nose-to-brain route significantly enhances the accumulation of both the oncolytic virus and the IR780 photosensitizer in glioma tissues, overcoming the limitations of systemic delivery. The pH-sensitive nature of the carrier allows for targeted release in the acidic tumor microenvironment, while IR780 enables localized photothermal therapy upon near-infrared laser irradiation. In vivo studies demonstrated synergistic antitumor effects with reduced systemic toxicity, highlighting the potential of this non-invasive, targeted approach to revolutionize GBM treatment strategies. Taken together, this multifunctional nanohybrid vector offers a promising, minimally invasive approach for targeted GBM treatment, potentially transforming therapeutic strategies for this challenging malignancy.

1708 Overcoming Recombination in Semi-Replicating Retroviral Vectors: A Novel Double Suicide Gene Therapy for Glioblastoma

Soojin Kim[1], Moonkyung Kang[2], Yeon-Soo Kim[3]*
[1]Articure Inc., Daejeon-si, Korea, [2]Chungnam National University, Daejeon, Korea, [3]Chungnam National University, Daejon, Korea
**Corresponding Author*

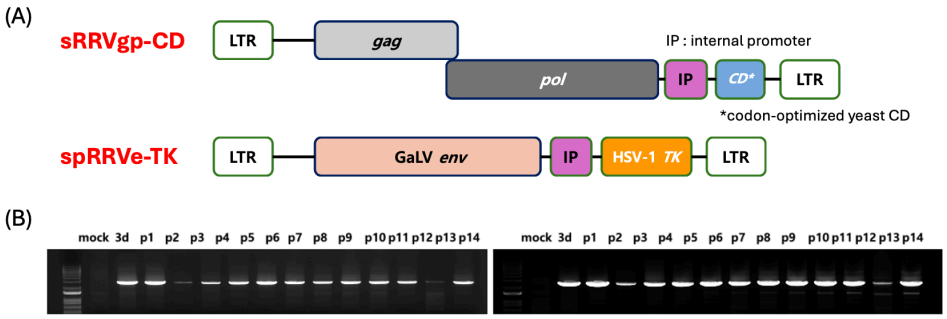
One of the major challenges in developing semi-replicating retroviral vector (sRRV) systems has been the loss of therapeutic genes due to non-homologous recombination during the reverse transcription in tumor cells. Despite prolonged efforts, previous studies have failed to prevent such recombination events. However, after years of optimization, we have successfully developed a recombination-resistant sRRV system that maintains the integrity of both therapeutic genes while efficiently replicating and spreading within tumor cells.

In this study, we utilized a gibbon ape leukemia virus (GaLV) envelope-pseudotyped semi-replicating retroviral vector system (spRRVs), consisting of two trans-complementing replication-defective retroviral vectors, MuLV-Gag-Pol and GaLV-Env, each encoding a therapeutic suicide gene. After confirming the antitumor efficacy of the spRRVs-mediated double suicide gene therapy in glioblastoma multiforme (GBM), we conducted survival and tumor burden analyses in six experimental groups (n=8 per group) stratified by viral dose and prodrug treatment in a rat glioma model.

Glioma models were established by intracranial injection of C6 cells into Wistar rats. The spRRV vectors expressing yeast cytosine deaminase (CD) and herpes simplex virus type 1 thymidine kinase (HSV1-TK) (sRRVgp-CD and spRRVe-TK, respectively) were intratumorally injected, followed by administration of the prodrugs 5-fluorocytosine (5-FC) and/or ganciclovir (GCV). On day 98 post-tumor induction, animals were sacrificed for histological analysis, revealing a dose-dependent reduction in tumor size. Notably, complete tumor eradication was observed in the cohort receiving the highest dose of therapeutic vectors in combination with both prodrugs. These histopathological findings correlated well with the survival data, demonstrating a significant therapeutic benefit.

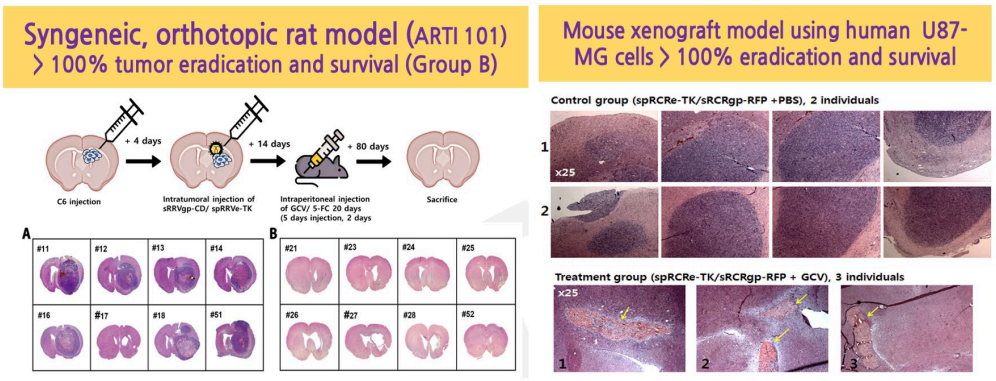
Furthermore, we performed statistical analyses to compare survival rates across control and treatment groups, establishing the efficacy of our spRRV system. Importantly, our results demonstrate that despite encoding two separate therapeutic genes, our novel spRRV design effectively prevents non-homologous recombination, ensuring stable replication and therapeutic function. This breakthrough overcomes a long-standing limitation of split-replication retroviral vectors, paving the way for more robust and clinically viable gene therapies for GBM and other malignancies.

Structure and Stability of the sRRV System Encoding Dual Suicide Genes



(A) Schematic representation of the two-component semi-replicating retroviral vector (sRRV) system used in this study. (B) PCR analysis demonstrating the genetic stability of the sRRV system in tumor cells over multiple passages. Genomic DNA was extracted from glioma cells infected with sRRVgp-CD and spRRVe-TK, and PCR was performed to detect the presence of both therapeutic transgenes across different passages (p1–p14).

Efficacy of the sRRV Vector System in Syngeneic and Xenograft Glioblastoma Models: 100% Tumor Eradication and Long-term Survival



This study confirms that the sRRV vector system effectively eliminates glioblastoma in both syngeneic and xenograft models, achieving 100% tumor eradication and long-term survival.

1709 Stem Cell Delivered Viro-immunotherapy Advancements for Ovarian Cancer Treatment

Jacqueline Lara[1], Hoi Wa Ngai[2], Yunyi Kang[3], Duong Nguyen[4], Ivelina Minev[3], Linda Flores[5], Marisa McDonald[5], Michael Laidlaw[5], Yate-Ching Yuan[6], Rachael Mooney[6], Thanh Dellinger[5], Antonio Santidrian[7], Karen Aboody[8]

[1]City of Hope, Santa Fe Springs, CA, [2]City of Hope & Beckman Research Institute, Duarte, CA, [3]Calidi Biotherapeutics, San Diego, [4]Calidi Therapeutics, La Jolla, CA, [5]City of Hope, Duarte, [6]City of Hope, Duarte, CA, [7]Calidi Biotherapeutics, San Diego, CA, [8]Beckman Research Institute of the City of Hope, Duarte, CA

Oncolytic viro-immunotherapy is a highly promising cancer treatment which uses replicating oncolytic viruses (OVs) to induce tumor cell lysis and stimulate an anti-tumor immune response. Currently, clinical trials administering free virus have demonstrated safety but limited efficacy due to rapid inactivation by the host immune system. To address this barrier, tumor-tropic stem cells can be used as an OV delivery vehicle, providing protection from immune neutralization, allowing for viral amplification which increases the payload, and enabling enhanced targeting and viral distribution at metastatic tumor sites. Once tumor cells are infected with the OV, viral replication ensues until lysis occurs – releasing more virus to infect neighboring tumor cells in a self-amplifying fashion until normal tissue is reached and replication ceases. Resulting changes to the tumor microenvironment and exposure of new tumor antigens attract immune cells and can ultimately stimulate an anti-tumor immune response.

We are using a stable, allogeneic, immortalized, human neural stem cell line, (HB1.F3.CD21 NSCs), that has demonstrated clinical safety and tumor localized delivery of therapeutic payloads in brain tumor trials. We have loaded these NSCs with a conditionally replication-competent adenovirus (CRAd-S-pk7) that has been genetically modified 1) with a pk7 poly-lysine fiber knob to increase tumor infectivity, and 2) the insertion of a *survivin* promoter to drive E1A transcription, making it selective to tumor cells with high *survivin* expression, including glioma and cisplatin resistant ovarian cancer. A phase I trial with a single dose intracerebral administration of NSC.CRAd-S-pk7 (CLD-101) as an adjuvant to temozolomide and radiation in newly diagnosed glioma patients yielded promising results (Lancet Oncol, 2021). A multi-dose study in recurrent glioma patients is ongoing at COH (NCT05139056).

We have now optimized the manufacturing protocols to generate a NSC.CRAd-S-pk7 product with increased efficacy for application to intraperitoneal (i.p.) ovarian metastases. Effects of the process optimization on RNAseq, protein expression, and critical quality attributes of the therapeutic product have been characterized. Comparative persistence and distribution studies were conducted in both immunodeficient and immunocompetent preclinical models of i.p. ovarian metastases, demonstrating significant benefit. Translational biodistribution, efficacy, and

safety/tox IND-enabling studies are ongoing with our goal of initiating a phase I clinical trial of NSC.CRAd-S-pk7 for patients with platinum resistant Stage III ovarian cancer in 2026.

1710 A Novel Oncolytic Adenovirus-based Therapy for Pediatric Neuroblastoma

Margarita Romanenko[1], Sacha Robert[1], Kazuho Inoko[2], David Largaespada[1], Julia Davydova[3]
[1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Saint Anthony, MN, [3]UMN, Minneapolis, Minnesota

Neuroblastoma, the most common and lethal extracranial pediatric tumor, originates from sympathetic neuroblast precursors that fail to differentiate properly, remaining in a pro-proliferative developmental state. This tumor accounts for 12%–15% of childhood cancer-related deaths. Current treatments for high-risk neuroblastoma, which typically involve intensive multimodal approaches, including radiation and immunotherapy, often result in severe adverse effects. To mitigate these effects and enhance treatment efficacy, novel therapeutic strategies are needed. One promising approach is the use of Sodium-Iodide-Symporter (NIS) delivered by a replication-competent adenoviral vector. This strategy combines the oncolytic and immunomodulatory potentials of adenoviruses with the ability of NIS to facilitate the uptake of radioactive iodine by tumor cells, which may not only improve detection of neuroblastoma, but also facilitate radiotherapy with 131-I.

This project aims to develop a novel oncolytic adenoviral vector specifically targeting neuroblastoma. To identify the vector with the best binding to neuroblastoma cells, we tested a panel of adenoviruses with various fiber proteins targeting different cellular receptors: the coxsackie and adenovirus receptor (CAR)-targeted Ad5, CD46- and human desmoglein 2-targeted Ad5/3, and integrin-targeted AdRGD. Our results indicate that while Ad5/3-based vectors typically exhibit superior binding across most cancer cell lines, AdRGD-based vectors show the highest efficacy in the SK-N-SH neuroblastoma cells, as well as in the Ewing sarcoma EW-8 cell line. To further restrict viral replication to neuroblastoma cells, we incorporated the 796-bp Achaete-scute homolog 1 (ASCL1) promoter upstream of the adenoviral early gene E1A. ASCL1, a proneural transcriptional master regulator, plays a crucial role in the proliferation and differentiation of sympathetic neuroblast precursor cells and is essential for maintaining the oncogenic program in MYCN-amplified neuroblastomas. We are currently evaluating the new vector in a variety of neuroblastoma cell lines, including MYCN-amplified and non-amplified strains, as well as functional and non-functional p53 variants.

To incorporate the NIS transgene into the adenoviral backbone, we are replacing the Adenovirus Death Protein (ADP) gene in the E3 region as our previous studies have shown that ADP expression interferes with NIS membrane localization and inhibits radiotracer uptake. Importantly, we will keep other E3 genes, including E3-6.7K, E3-gp19KID, RID, E3-14.7K, as they are known to reduce vector clearance and promote prolonged circulation. Following these modifications, we will conduct in vivo evaluations to assess the imaging and therapeutic potential of the RGD-ASCL1-NIS vector in combination with radioactive iodine.

We believe this adenoviral platform has the potential to improve treatment outcomes for pediatric neuroblastoma, a devastating disease with limited therapeutic options.

1711 A Highly Tumor-Specific Oncolytic Virus in Combination with a Viral Protein-Targeted T Cell Engager for the Treatment of Triple-Negative Breast Cancer

Yoya Vashi[1], Paul Yazaki[2], Yuman Fong[1], Shyambabu Chaurasiya[1]
[1]City of Hope, Duarte, CA, [2]City of Hope National Medical Center, Duarte, CA

Triple negative breast cancer (TNBC), a subtype comprising 15-20% of all breast cancers, is known to be the most aggressive and carries the bleakest prognosis. The ineffectiveness of targeted therapies due to a lack of targets in TNBC underscores the urgent need for alternative therapies against a larger demographic of TNBC patients. We propose that combining oncolytic herpes simplex virus type 1 (HSV-1) with a bispecific T cell engager (BiTE) specific for glycoprotein D (gD), a viral protein expressed on the surface of infected cells, will result in better

therapeutic efficacy against TNBC. Furthermore, the HSV-1 used in this study has a *UL40* gene deletion and deletions in both copies of the *γ34.5* gene, which are intended to enhance its cancer specificity and reduce neurovirulence. We compared the replication and cytotoxic properties of the *UL40*-deleted virus (SY134ΔUL40) with its parental virus (SY134) in both normal and cancer cells. The UL40-deleted HSV-1 showed significantly reduced activity in normal cells and cancer cells. We also evaluated the impact of RRM2 (the catalytic subunit of ribonucleotide reductase) on the replication of the SY134ΔUL40 virus. Our results showed that virus growth was significantly attenuated when RRM2 was knocked down. Additionally, we assessed the tumor specificity of SY134ΔUL40 compared to SY134 in a TNBC model using athymic mice. We observed that the SY134ΔUL40 virus remained confined to the tumors, with limited presence in the lungs, while the parental virus spread to other normal organs. This finding suggests that the deletion of *UL40* reduces the virus' ability to replicate in normal tissues, thus enhancing the safety profile of the oncolytic virus. Next, we have constructed a full-length BiTE against gD and CD3 and confirmed binding of the BiTE to $CD3^+$ cells and TNBC cells expressing gD protein. In addition, we have verified the efficacy of this combined approach in killing TNBC cells *in-vitro*. Further confirmatory *in-vivo* studies are ongoing.

1712 Neural Stem Cell Delivered CRAd-S-pk7 Dose Interval Optimization for Ovarian Cancer in an Immunocompetent Mouse Model

Gurmeet Kaur[1], Rachael Mooney[1], Linda Flores[2], Hoi Wa Ngai[3], Marcin Kortylewski[4], Thanh Dellinger[2], Karen Aboody[5]*

**Corresponding Author*

Background. Ovarian cancer (OC) is a high mortality gynecologic malignancy with more than 19,000 new cases and an estimated 13,000 deaths occuring annually in the U.S. This highlights an urgent need for novel therapeutic strategies to improve clinical outcomes. Oncolytic viro-immunotherapy has emerged as a promising strategy due to the ability of oncolytic viruses (OVs) to selectively target tumor cells while sparing healthy tissue. We are using tumor-tropic neural stem cells (NSCs) to deliver a conditionally replicating adenovirus, CRAd-S-pk7, genetically modified with a poly-lysine fiber knob to enhance tumor cell infectivity, and the insertion of a survivin promoter that drives viral replication. Survivin overexpressed in >85% chemoresistant OC patients. The use of NSCs to deliver this OV (NSC.CRAd-S-pk7), shields the virus from immune inactivation, allows for viral amplification, and enhances tumor-specific targeting and distribution- resulting in increased efficacy as compared to free virus. However, the optimal dosing interval for maximizing this NSC-OV therapy remains to be determined.

Objective. This study aimed to determine the optimal dosing interval for a multi-dose regimen of NSC.CRAd-S-pk7 in a syngeneic immunocompetent mouse model of intraperitoneal (i.p.) ovarian metastases to achieve maximal survival efficacy. We hypothesize that i.p. NSC.CRAd-S-pk7 will effectively infect and lyse OC cells, inducing a dynamic immune response within the tumor microenvironment (TME), characterized by early activation of innate immune cells followed by progressive engagement of adaptive immunity. We postulate that optimizing the dosing interval will enhance the anti-tumor immune response while mitigating immune exhaustion, thereby improving long-term survival outcomes.

Methods. NSC.CRAd-S-pk7 was produced by transduction of an immortalized, allogeneic NSC line (HB1.F3.CD21) with CRAd-S-pk7 and frozen down as the therapeutic product. ID8.eGFP.ffluc murine OC cells were used to induce i.p. tumors in C57BL/6 mice on Day 0. Mice were divided into five groups: A) tumor-only control, B) single dose, C) 3 weekly doses, D) 3 doses every other week, and E) 3 doses every two weeks. Each dose consisted of 2 x 10^6 NSC.CRAd-S-pk7 cells. Disease burden was monitored using BLI, ascites onset, CA-125 and HMGB1 expression in the blood, daily scoring of clinical observations and long-term survival. Endpoint gross distribution of tumor nodules was assessed and scored. Ascites fluid was analyzed for innate natural killer cells, dendritic cells macrophages, and neutrophils, and adaptive CD4 and CD8 immune cell profiles to characterize the immune response in the TME over time.

Results. NSC.CRAd-S-pk7 significantly improved survival in when comparing treated groups vs. control ($p < 0.0001$), and multiple doses vs. single dose ($p < 0.0001$) (**Fig. 1)**. Furthermore, the efficacy of every other week dosing was significantly more efficacious than other dosing schedules (Group D vs. Group C; $p=0.010$) and also delayed ascites onset. Immunophenotyping showed a peak adaptive response on Day 7. Ongoing studies are investigating the add-value of repeat interval cycles, as well as adjuvant treatments.

Conclusion: These findings suggest that administration of NSC.CRAd-S-pk7 treatment every other week optimizes therapeutic outcomes in OC models by balancing sustained immune activation and viral replication.

1713 Somatic Cell Gene Editing for Translational Preclinical Cancer Modeling in Swine

Derek Korpela[1], Jarryd Campbell[2], Nicholas Koes[3], Daniel Carlson[4]
[1]Recombinetics Inc, Saint Paul, MN, [2]Recombinetics, Eagan, MN, [3]Recombinetics Inc, Eagan, Minnesota, MN, [4]Recombinetics, Eagan, Minnesota

Cancer, as a disease, encompasses a diverse taxonomy of malignancies that impart a high degree of burden on the global healthcare system. With incidence of morbidity and mortality expected to rise in the coming decades, novel approaches to treating cancer are needed. To drive innovative therapeutic development, comparative preclinical animal models that recapitulate the disease, genetically and phenotypically, are essential to the process. While *in vitro* cell work and rodent models have been the historical standard for developing and testing cancer therapies, their deficiencies in complexity, shared anatomy and physiology, have contributed to high failure rates in late preclinical and early clinical trial phase testing. This equates to significant losses of fiscal resources and valuable time. ***To provide the necessary tools to reverse this trend, we are using somatic cell gene editing to create genetically and phenotypically accurate cancer models in swine for preclinical therapy development.*** Using CRISPR/Cas9 to knock-out tumor suppressor genes and transposons to knock-in oncogenes, Recombinetics has focused on modeling two types of deadly cancer, glioblastoma (GBM) and hepatocellular carcinoma (HCC). These cancers are of high priority as the former is the most prevalent and aggressive primary brain tumor, with a 3% survival beyond 5-years, and the latter is the fourth most common and second deadliest cancer worldwide. To create the GBM model, we use stereotactic lateral-ventricular delivery of gene editing reagents in piglets and monitor tumor growth through development with a simple blood-based test. Results consistently demonstrate tumor formation that mimics the pathological characteristic of human GBM within 115 days post-induction. To create the HCC model, we exploit on the phenomena of hydrodynamic cellular delivery to distribute gene editing reagents to the liver of neonate piglets. Tumor growth is monitored in these animals by ultrasound imaging. Notably, the cancer models created replicate the anatomy, physiology, and intact-immune system of human patients. With robust numbers and molecularly accurate swine model platform, we anticipate that the resources spent on cancer therapy will yield greater progress and drive development of targeted small molecules, immunotherapies, surgical and biopsy techniques, biomarker identification, and imaging technologies.

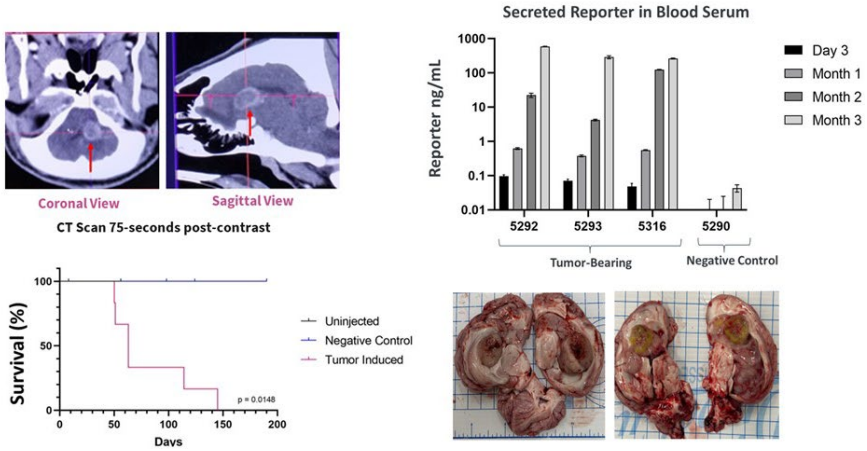

Figure: An *in vivo* model of GBM in swine. A. CT imaging of a GBM tumor in swine, a potential method for monitoring tumor status. B. Monthly secreted reporter used to monitor tumor growth in models. C. Kaplan-Meier plot showing the rate at which swine succumb to tumors. D. Swine mesenchymal GBM tumors harvested at necropsy.

1714 Cost-Effectiveness of Gene Therapy for Sickle Cell Disease in Uganda: Tailoring High-Income Evidence to Uganda's Context

Felipe Montano-Campos[1], Ryan Hansen[1], Jennifer Adair[2], Anirban Basu[1], Rachel Kyeyune[3], Lois Bayigga[3], Cissy Kityo[4]
[1]University of Washington, Seattle, WA, [2]University of Massachusetts Chan Medical School, Worcester, MA, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]JOINT CLINICAL RESEARCH CENTRE, Kampala, Uganda

In high-income countries, cost effectiveness analysis (CEA) models are used to support policy regulating access to transformative treatments such as gene and cell therapies. However, translating cost-effectiveness models for gene and cell therapies to low resource settings is hampered by lack of local clinical trial data. Here we describe a novel CEA model to assess gene therapy for sickle cell disease (SCD) in Uganda. While two gene therapies to treat SCD are authorized in the U.S. and Europe, neither has been evaluated clinically in sub-Saharan African countries. Uganda carries a high burden of SCD, with 13.3% of its population carrying sickle cell trait and 0.7% having SCD. To estimate lifetime SoC costs in Uganda, we employed a Markov model designed to simulate the progression of patients across three health states: (1) standard of care (SoC) without hydroxyurea, (2) SoC with fixed dose hydroxyurea, and (3) death. Scaling factors were calculated using Basu et al.'s methodology and two different CEA models (UW-MEASURE (UWM) and FH-HISCORE (FHH)) to adjust U.S.-based gene therapy costs to Uganda's context. Application of lovo-cel (bluebird bio) or exa-cel (Vertex Therapeutics) gene therapy for SCD was targeted to the same patient populations for authorized use in the U.S. and Europe: eligible individuals with SCD aged 12 years and older who meet specific trial inclusion criteria. Clinical benefits of gene therapy treatment, including life-years, quality-adjusted life-years (QALYs), and health years in total (HYT), were assumed to be the same across settings and gene therapy drug products, aligning with global expectation of biological consistency for gene therapy across populations. Incremental cost-effectiveness ratios (ICERs) were calculated under healthcare and societal perspectives, with sensitivity analyses using Uganda's gross domestic product per capita-based thresholds recommended by the World Health Organization. All values were represented in US dollars (USD) and Ugandan Schillings (UGX) based on currency conversion in January 2025 ($1 = 3,680.18 UGX). Lifetime SoC costs in Uganda were calculated to be $21,877 (80,511,250.39 UGX). Scaling factors of 0.018 (UWM) and 0.033 (FHH) contextualized U.S.-based gene therapy costs for Uganda. For **lovo-cel**, healthcare ICERs were $5,219 (19,206,848.09 UGX) and $20,023 (73,688,200.69 UGX) per QALY (UWM and FHH, respectively), while societal ICERs were $3,992 (14,691,269.90 UGX) and $16,091 (59,217,741.46 UGX) per QALY (UWM and FHH). For **exa-cel**, healthcare ICERs were $3,837 (14,120,842.33 UGX) and $20,023 (73,688,200.69 UGX) per QALY (UWM and FHH), with societal ICERs at $2,610 (9,605,264.14 UGX) and $16,091 (59,217,741.46 UGX) per QALY

(UWM and FHH). Reflecting broader economic benefits like improved productivity and reduced caregiver burden, the societal ICER for **exa-cel** under the UWM model is cost-effective at a per drug product cost of $40,205 (147,961,549.66 UGX). Using this CEA framework, a gene therapy for SCD which costs $2.2M in the U.S. offers a cost-effective intervention in Uganda when societal benefits are considered. Importantly, per product local manufacturing cost of CAR T cell gene therapy drug products in India ($35,107 or 129,200,003.08 UGX) (Palani, H. *et al.* 2023) is lower than the scaled cost of a SCD gene therapy product in this model, suggesting a profit margin is possible for a locally manufactured gene therapy product for the treatment of SCD in Uganda.

Table 1. Incremental Effectiveness and Costs of exa-cel Gene Therapy Compared to Standard of Care in the U.S. and Uganda

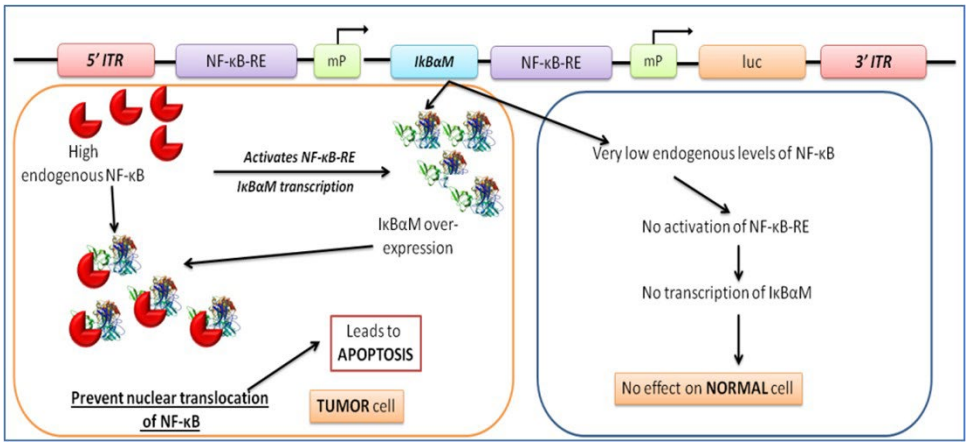
1715 Therapeutic Potential Of NF-κB Inhibition In Glioblastoma: Gene Therapy Approach Using rAAV-5 Mediated IκBαM Overexpression

Ceera Manikandan[1], Amit Jaiswal[2]*
[1]*Vellore Institute of Technology, Vellore, India, India,* [2]*Vellore Institute of Technology, Vellore, Tamil Nadu, India*
**Corresponding Author*

Current treatment strategies for glioblastoma, including resection followed by concurrent chemotherapy/radiotherapy are not curative. Angiogenesis and hypoxia are two major factors responsible for GBM growth and resistance to existing therapies, leading to poor clinical outcomes. The transcription factor NF-κB induces tumor progression by activating genes associated with cell proliferation and angiogenesis. It is expressed constitutively in gliomas and is known to regulate the expression of HIF-1α and VEGF in GBM. Activation of NF-κB is a significant contributor to the cancerous characteristics associated with GBM, indicating a poor prognosis for patients. Non-specific anti-inflammatory drugs have been the main means of targeting NF-κB, but their short-lived action and numerous side effects prevent them from producing persistent results. Novel techniques must be developed to attenuate NF-κB activity selectively within certain cell types and mitigate any adverse consequences in clinical settings. One such approach is overexpressing IκBαM (a dominant negative mutant of IκBα) to inhibit NF-κB expression in the glioma cells. This will inhibit the nuclear translocation of NF-κB, thereby facilitating a decrease in the expression of downstream targets. AAVs have emerged as one of the most widely used methods for delivering genes into the central nervous system because of their broad range of infectivity, ability to induce long-term transgenic expression, and lack of toxicity. In this study, we aim to investigate the potential of IκBαM, resistant to IKK phosphorylation and known to block NF-κB, as a therapeutic agent to treat GBM. U87-MG cells were transduced in 2D and 3D spheroids using recombinant adeno-associated virus-5 (rAAV-5) to induce IκBαM over-expression. Employing this rAAV 5 prevented the nuclear translocation of NF-κB in LPS-stimulated U87-MG cells. This result supports our hypothesis that over-expression of IκBαM inhibits NF-κB nuclear translocation by remaining sequestered to NF-κB and preventing it from entering the nucleus. The cues from this study could aid in developing a gene therapy approach to target crucial pathways in GBM tumor progression.



1716 AK2, COL1A1, and PLG protein signatures: targeted therapeutics for meningioma

Rashmi Rana, Sharma, Swati, Shamjetsabam, Nandibala Devi, Kirti Chauhan, M.H. Yashavarddhan, Satnam S Chhabra, Rajesh Acharya, Samir K Kalra, Anshul Gupta, Sunila Jain, Nirmal K. Ganguly

Institute of Liver and Biliary Sciences, Delhi, India
Sir Ganga Ram Hospital, Delhi, India

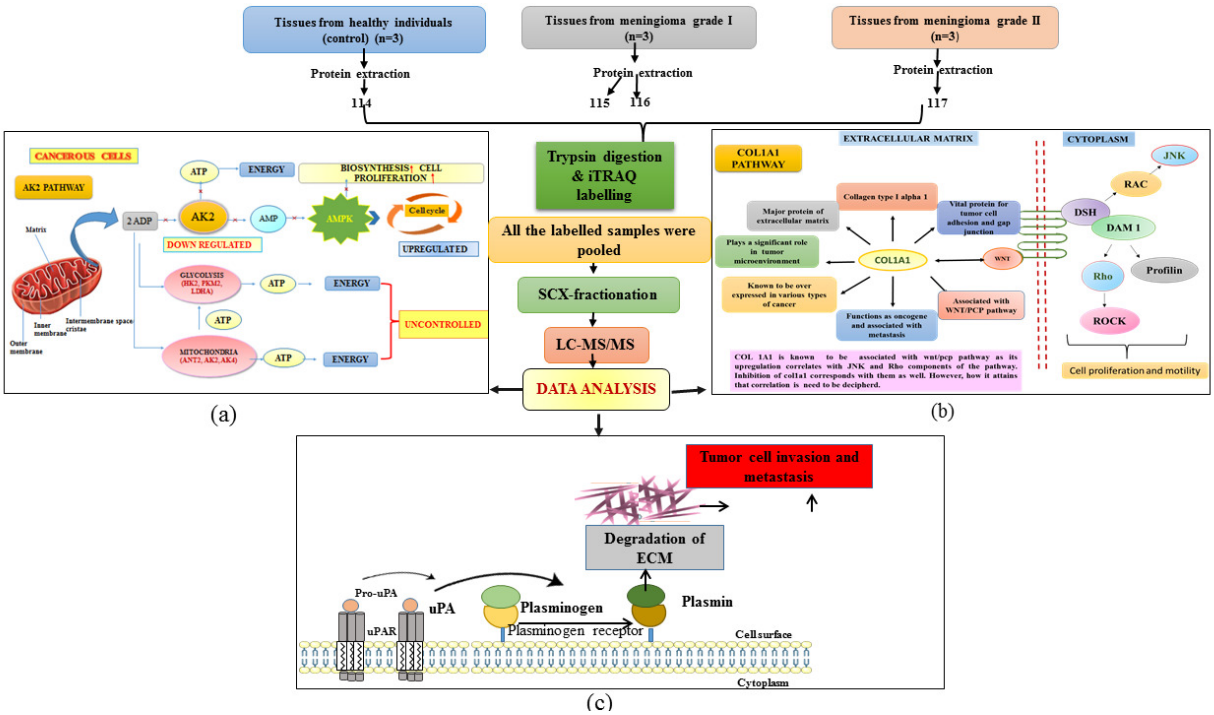
Background: Meningioma is the most prevalent primary intracranial brain tumor and accounts for one-third of all CNS tumors. Meningioma is known to be the most common yet life-threatening brain tumor with a higher recurrence rate. Globally, there is an increase in the healthcare burden due to meningioma and hence in its research. The present clinical approach includes surgical resection, chemotherapy, and radiation therapies to which the malignancy does not seem to respond efficiently. Targeted therapies and molecular markers provide elite patient treatment and care for individuals suffering from meningiomas as compared to conventional measures. Although

there is proteomic data on meningioma the knowledge of potential biomarkers differentiating the grades is scarce. To identify the best set of biomarkers, validation of reported markers in large and independent sample cohorts in the future is necessary.

Methods: A total of 12 samples, 3 each of control (which made pool 1) meningioma grade I (which made 2 sets: pool 2 and pool 3), and meningioma grade II (which made pool 4) were taken for LC-MS/MS. After this, the expression of three proteins was checked by immunocytochemistry, flow cytometry, and western blotting.

Results: Protein expression was analysed using various techniques like mass spectrometry, immunocytochemistry, flow cytometry, and western blotting. Mass spectrometry is the most commonly used standard and reliable technique for identifying and quantifying protein expression. We got three highly upregulated proteins namely AK2, COL1A1, and PLG using this technique. The biomarker potential of these proteins was further checked by ICC, western blotting, and flow cytometry. Three important proteins were found to be upregulated namely, AK2 (Adenylate kinase 2), COL1A1 (collagen 1A1), and PLG (plasminogen). The order of increased protein expression was control < MG grade I < MG grade II according to mass spectrometry and western blotting. In immunocytochemistry, we found that COL1A1 expression increases significantly with grades in comparison to control. Similarly, AK2 and PLG also showed little increase but not as much as COL1A1. In flow cytometry, PLG showed higher upregulation in grades than control. While AK2 and COL1A1 showed little increase in expression in grades than control. All techniques, especially mass spectrometry and western blotting, presented higher expression of these proteins in grades as compared to control.

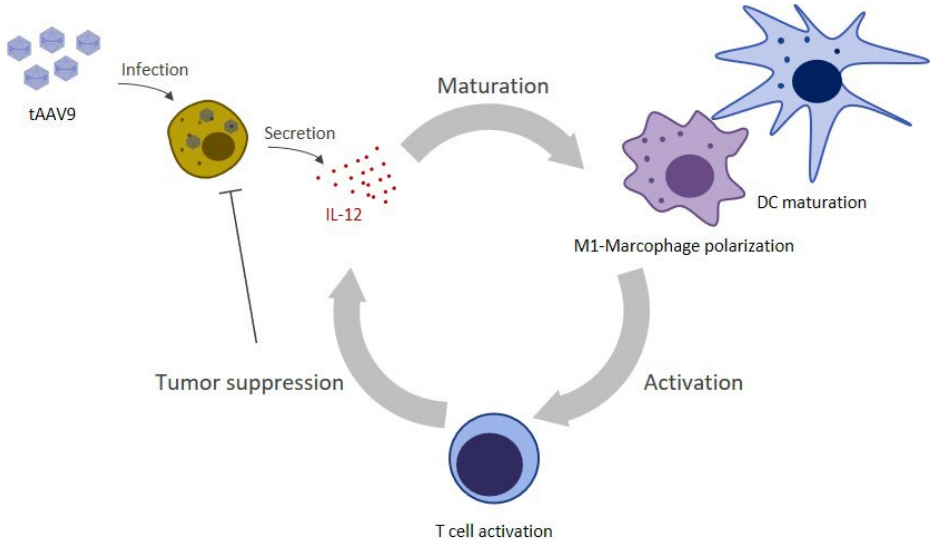
Conclusion: In the quest to find a suitable therapeutic marker, this study incorporates quantitative labelling and detection followed by flow cytometry, immunocytochemistry, and western blotting for early diagnosis and treatment of meningioma. The article further explores the efficacy of some proteins namely AK2, COL1A1, and PLG to be the targeted molecules.

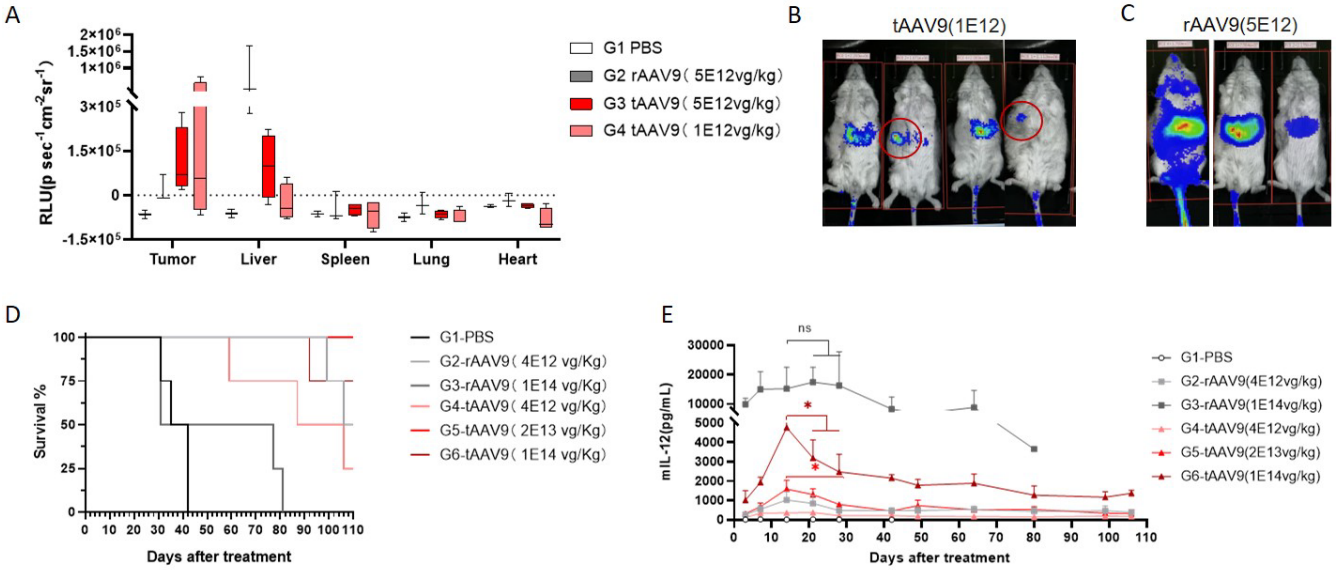


1717 Tumor-specific AAV Delivery of Interleukin-12 Enhances Antitumor Immunity and Safety in Ovarian Cancer

Lei Zhao[1], Yongji Jiang[2]
[1]*Cure Genetics, SuZhou, Select State, China,* [2]*Cure Genetics Co. Ltd., Su Zhou, Jiangsu, China*

Interleukin-12 (IL-12) is a promising pro-inflammatory cytokine for cancer immunotherapy, but its toxicity and short half-life in serum limit its clinical application. Tumor targeted delivery of IL-12 either by fusion with antibody or secretion by CAR-T cells showed reduced systematic toxicity; however, the poor TME response or the lack of systematic IL-12 regulation still remains risk of low efficacy or high toxicity. Here, we developed TME specific delivery of IL-12 by a tumor targeted AAV (tAAV9). The tAAV9 was formed by an anti-FOLR1 antibody fragment conjugated with AAV9 via highly efficient Spy-ligation. With targeted infection of FOLR1+ cells *in vivo*, intravenous (IV) administration of tAAV9 specifically delivered IL-12 (tAAV9-IL-12) to TME and significantly suppressed tumor progression with favorable safety profile compared with rAAV9 (recombinant wild-type AAV9) delivery. Moreover, the IL-12 level in the serum was decreased significantly with the suppression of tAAV9-IL-12 infected tumor cell so that generates promising negative feedback to ensure the safety profile.





1718 Programmable iPSC-derived monocytes for the treatment of solid tumours

Vishal Menon[1], Jade Edey[2], Yu Jin Chung[2], Yamuna Raghvani[2], Alina Letzel[2], Angelos Petropoulos[2], Lauren Overend[2], Anusha Thapa[2], Robert Atkinson[2], Anna Klucnika[2], Kevin Gillinder[2], Verena Brucklacher-Waldert[2], Tom Payne[3], Timothy Allsopp[4], **Vlad Seitan[3]***
[1]Laverock Therapeutics, London, Hertfordshire, United Kingdom, [2]Laverock Therapeutics, London, United Kingdom, [3]Laverock Therapeutics, STEVENAGE, Hertfordshire, United Kingdom, [4]Laverock Therapeutics LTD, STEVENAGE, Hertfordshire, United Kingdom

The development of effective immunotherapies for solid tumours has been challenging due to several barriers, including antigen heterogeneity, reduced infiltration, and the presence of an immunosuppressive tumour microenvironment (TME). Faced with these challenges, CAR-T cell therapies – which have been transformative in haematological cancers - have mostly produced disappointing results in trials for solid tumours, calling for new modalities to be developed.

The majority of solid tumours recruit and subvert myeloid cells to support tumour growth, angiogenesis and to inhibit an effective immune response. Indeed, tumour associated macrophages (TAMs) orchestrate the establishment and maintenance of the immunosuppressive environment through the secretion of cytokines and immunomodulatory ligands, and are known to supress immunotherapies as well as conventional cancer treatments such as chemotherapy.

The ability of macrophages to infiltrate and establish long term residence within the tumour, makes these cells extremely valuable as therapeutic agents. If macrophages can be programmed to maintain their tumour-homing abilities, but resist polarisation into immunosuppressive TAMs and instead trigger potent inflammatory responses, they can be used as ‘trojan horses’ to effectively remodel the TME, facilitating the direct killing of tumour cells, the anti-tumour response of infiltrating lymphocytes, and enhancing the efficacy of immuno- and chemotherapies.

Here we show proof of concept data for an allogeneic cell therapy based on iPSC-derived monocytes programmed to preferentially differentiate into pro-inflammatory macrophages within the tumour, and to resist anti-inflammatory polarisation. To engineer the therapeutic cells, we deploy a novel programmable gene silencing technology based on repurposing endogenous microRNAs (miRNA) to silence desired target genes. Gene edits are introduced in myeloid-specific miRNA genes to redirect their silencing activity towards critical macrophage polarisation factors, thus programming the myeloid-specific silencing of these factors. iPSCs engineered in this manner maintained the ability to differentiate into monocytes (iMonocytes) and macrophages (iMACs), and the differentiated cells showed effective cell type-specific silencing of the target genes. Remarkably, when cultured under strong anti-inflammatory conditions, the engineered iMACs were resistant to these stimuli, and instead spontaneously activated a pro-inflammatory programme characterised by the upregulation of STAT1. *In vivo* administration of iMonocytes to animals bearing ovarian cancer xenografts showed the therapeutic cells were able to persist and differentiate within the tumour. The engineered iMACs delayed tumour growth and showed reduced expression of TAM markers compared to control wild type iMACs. Our data demonstrates the power of our gene silencing approach in an *in vivo* model, and the feasibility of applying this technology to the development of macrophage-based cell therapies for solid tumours.

1719 Identifying a target for CAR therapy in tumor-initiating cells

Lloryn Cylin[1], **Ilana Chefetz Menaker[1]**
Department of Biomedical Sciences, Mercer University School of Medicine

Eliminating cancer stem cells (CSCs) has the potential to significantly improve patient prognosis, as studies in mice demonstrate that CSC eradication can enhance cure rates and reverse chemotherapy resistance. However, ovarian CSCs present a unique challenge, as they develop chemoresistance to standard therapeutics, such as cisplatin and paclitaxel. While nearly 70% of ovarian cancer patients initially respond to chemotherapy, recurrence occurs within weeks or months. Thus, to effectively cure ovarian cancer, there is an urgent need to specifically target ovarian CSCs to block their tumor initiation and propagation capabilities.

To identify ovarian CSCs, both we and others have utilized aldehyde dehydrogenase (ALDH) activity and CD133 expression as biomarkers. ALDH consists of a group of 20 enzymes responsible for converting toxic aldehydes into corresponding carboxylic acids. However, the commonly used ALDEFLOUR FACS-based assay does not distinguish between different ALDH enzymes. Additionally, many ovarian cancer cell lines express high levels of CD133 (up to 50%), indicating the necessity to identify more specific markers for CSCs. These CSCs are defined by their resistance to chemotherapy and their capacity to initiate tumors. Tumor initiation capacity in vitro is assessed through clonogenic assays, where serial dilutions of cell numbers are evaluated. We have previously shown that as few as 10 CSCs are capable of forming viable clones.

Our objective is to identify surface biomarkers of ovarian CSCs using proteomic analysis that correlate strongly with their tumor initiation capacity. Based on the identified tumor antigens, we aim to develop genetically engineered T cells with chimeric antigen receptors (CARs) to specifically target ovarian CSCs, thereby preventing recurrent disease.

In our approach, we utilized serial dilution clonogenicity assays to evaluate tumor initiation. Proteomic analysis of five biological replicates from two ovarian cancer cell lines revealed 11 upregulated proteins located on the cell surface that are common across both lines. Current validation studies are underway to identify the most promising candidates for CAR therapy development.

1720 Programmed evolution: Delivery of asexual gene drives to sculpt tumor populations and combat genetic diversity

Scott Leighow[1]*, Farnaz Naeemikia[1], Justin Pritchard[1]
[1]Penn State University, University Park, PA
**Corresponding Author*

In oncology, therapeutic opportunity is fundamentally constrained by the genetic similarities between malignant and off-target, healthy cells. Even in cases where actionable drug targets have been identified (e.g. EGFR in lung cancer), resistance to targeted agents inevitably develops in patients with late-stage disease. Suicide gene therapy seeks to artificially create therapeutic opportunity by directly introducing genetic vulnerabilities into cancer cells. Suicide gene systems generally leverage bystander killing, such that both modified and nearby, unmodified tumor cells are susceptible to the therapeutic effect. However, current gene delivery technologies are insufficient to eliminate all malignant cells in a tumor, even with bystander function. As a result, efforts to translate suicide gene therapy have been unsuccessful. Here, we describe a novel gene therapy platform that bridges the gap between existing gene delivery capabilities and the requirements for effective suicide gene therapy. In reprogramming tumors with additional genetic vulnerabilities, the resulting potential for combination therapies makes durable remission possible.

Our modular platform employs a tumor-directed lentiviral vector that stably modifies cancer cells in situ (Figure 1a). The delivered cargo is a genetic circuit that couples a therapeutic payload (suicide gene) with an inducible marker that amplifies the frequency of the engineered cancer cell population. After gene delivery, engagement of the inducible marker reprograms the tumor to be majority-engineered cells (Figure 1b). Then, activation of the suicide gene targets modified and – through bystander activity – low-frequency, unmodified cells.

To develop a tumor-selective vector that can safely deliver our genetic circuits, we pseudotyped lentiviral vectors with a mutant, receptor-blinded VSVG and tumor-targeting scFv molecules. We designed and evaluated targeted vectors in vivo by administering tumor-directed lentiviral particles in NSCLC-xenografted mice via tail vein injection. Across diverse targets, our approach demonstrated remarkable specificity in transducing tumor cells, suggesting a generalizable platform for modifying cancer cells in vivo (Figure 2a). Additionally, the compatibility of this approach with systemic administration indicates the potential to target metastatic sites in disseminated disease, where unmet need is the greatest.

After delivery, the next phase of treatment involves leveraging approved targeted inhibitors to amplify the frequency of genetically modified cells and reprogram the bulk tumor. To develop a genetic circuit capable of “hijacking”

cancer evolution, we designed a drug target analog capable of transiently rescuing modified cancer cells from targeted therapy function. We coupled this selection marker with cytosine deaminase, a suicide gene that locally activates an otherwise inert prodrug. We found that in coupling an inducible fitness benefit with a shared fitness cost, we could effectively reprogram cancer cell populations, even at low levels of genetic modification. In vivo, these genetic circuits durably eliminated tumors that otherwise develop resistance under standard-of-care monotherapy (Figure 2b).

Together, our tumor-directed vectors and evolutionary-guided genetic circuits demonstrate the potential to reprogram tumors with more therapeutic opportunity to pave the way for durable remission.

1721 DEC205-Targeting mRNA Cancer Vaccines for Enhanced Antigen Presentation in Dendritic and Tumor Cells

Wonbeom Park[1], Yelee Kim[2], Minkyeom Kim[3], Yoosoo Yang[4]*, Dae-Hyuk Kweon[4]*
[1]Sungkyunkwan University, Suwon, Kroea, Republic of, Korea, [2]Korea Institute of Science and Technology (KIST), Seoul, Seoul Teugbyeolsi, South Korea, [3]Sungkyunkwan University, Suwon-si, Gyeonggido, Korea, [4]Sungkyunkwan University, Suwon, Gyeonggido, South Korea
**Corresponding Author*

Introduction: Genetic alterations in cancer produce neoantigens that can elicit robust anticancer immune responses when effectively presented to T cells. However, the immunosuppressive tumor microenvironment often hampers antigen presentation, contributing to immune evasion. Although lipid nanoparticle (LNP)-based mRNA cancer vaccines have shown promise in delivering neoantigen-encoded mRNA, their tendency to accumulate in the liver diminishes tumor-specific antigen presentation and antitumor efficacy. To overcome this limitation, the current study employs a novel "Grab Antibody" (GrAb) approach, where apolipoprotein A1 is fused to the Fc domain of a DEC-205 antibody (NLDC145). DEC-205, known to be highly expressed on both dendritic cells (DCs) and various cancers, facilitates receptor-mediated delivery of mRNA to these crucial cell populations. By simply mixing GrAb and LNPs, the apolipoprotein moiety anchors the antibody on the LNP surface, enabling dual targeting while circumventing conventional chemical conjugation pitfalls.

Results: DEC-205-functionalized LNPs (dLNPs) retained a spherical morphology similar to control LNPs (cLNPs) (Fig. 1B). In DEC-205-expressing MutuDC1940 DCs, dLNPs prompted receptor-mediated endocytosis, evidenced by a dose-dependent reduction in surface DEC-205 (Fig. 1C). Flow cytometry and confocal microscopy confirmed that dLNPs significantly enhanced mRNA (FLuc) uptake and translation in both DCs and MC38 colorectal cancer cells, effects abrogated by DEC-205 pre-blocking (Fig. 1D–F). *In vivo*, dLNPs administered to MC38 tumor-bearing mice exhibited stronger tumor and tumor-draining lymph node localization compared to cLNPs or isotype-control LNPs (iLNPs), while reducing liver accumulation (Fig. 1G–I). Using CpG plus ovalbumin (OVA) mRNA as a model vaccine, dLNP-treated cells displayed increased MHC class I presentation of OVA peptides (Fig. 1J), leading to robust antitumor effects in MC38 tumor-bearing mice (Fig. 1K). Immune profiling revealed elevated DC maturation, effector memory $CD8^+$ T cell expansion, and higher infiltration of DCs, macrophages, and cytotoxic T cells in tumors (Fig. 1L–N). Notably, IFNγ production was also enhanced, indicating a potent T cell response (Fig. 1O). Although cLNPs induced liver toxicity (Fig. 1Q), dLNPs demonstrated no significant toxicity, as confirmed by normal blood chemistry (Fig. 1P). These findings highlight the potential of DEC-205-targeting GrAb LNPs for dual delivery of mRNA to DCs and tumor cells, resulting in improved antigen presentation, enhanced immune activation, and reduced off-target effects.

Introduction: T-cell receptor (TCR) therapy is a promising immunotherapy approach with demonstrated efficacy and durability in the treatment of solid tumors. Emerging base-editing technology exploits CRISPR mechanisms with adenine/cytidine deaminase enzyme to introduce single nucleotide changes at specific chromosomal sites in the genome without creating detrimental double-stranded DNA breaks. We have leveraged this novel targeted base-editing technology to perform multiplexed gene knockouts in human T cells to improve safety and effector function of a TCR product.

Methods: We have successfully developed a novel process which combines lentiviral transduction for TCR expression, and base editing technology for ablating expression of up to 3 genes, including endogenous TCRs, in primary T cells. This process can be translated into a large-scale GMP compliant process. The electroporation process was optimized to base edit up to 1E+09 cells effectively to ablate 3 different genes using gene-specific sgRNA's and a base-editor encoding-mRNA. The base editing process was optimized with two different electroporation systems (Maxcyte GTx and Prodigy ELPO) separately. Different cell densities, buffer systems and different sgRNA's and mRNA concentrations and time intervals were tested for the optimum editing efficiencies during electroporation for both Maxcyte GTx and Prodigy ELPO. The gene edited TCR-T was produced using a 13-day process. The developed small-scale model was successfully scaled up to a large-scale production process using the Miltenyi Prodigy platform for transduction, cell growth & expansion while using Maxcyte GTx. This TCR-T cell process, developed using GMP compatible reagents and equipment, is ready for manufacturing a cellular product for clinical applications.

Results: The 13-day TCR-T production process resulted in approximately ~20-30-fold expansion in small scale studies with greater than 90% viability during harvesting. Multiplexed base editing quantification assays showed >90% knock out of 3 genes using either Prodigy or Maxcyte instruments for electroporation. The TCR transduction efficiency was found to be ~32-53%. This small-scale process model was successfully scaled-up to produce a minimum of ~1E+09 transduced and edited TCR-T cells using the Prodigy cell culture expansion and Maxcyte electroporation systems.

Conclusion: A novel scalable GMP-compliant process to produce TCR T cells was developed by combining lentiviral transduction and multiplexed ablation of 3 genes by base editing technology. New strategies to optimize the base editing protocols with two different GMP-compatible electroporation instruments were developed. To our knowledge this scalable and GMP - compatible protocol represents an innovative manufacturing process that combines lentiviral transduction and base-editing for generation of clinical-grade TCR T cell products. This pioneering approach will benefit the production of both TCR-T, and CART cell products thereby providing new opportunities for the treatment of cancer.

Results of 13-day process for the production of highly effective and potent TCR T cell therapy products which combines lentiviral transduction and base editing

Donor	% of Transduction efficiency	% of Cell Viability during harvest (Day 13)	Fold expansion	Electroporator used

Chimeric antigen receptor (CAR) T cells have proven to be effective cancer therapies. However, it is widely accepted that T cell receptors (TCRs) are superior in reacting to antigens with lower surface density compared to CARs. To address this, we developed a novel receptor architecture called COMET (constitutively operational multiplexable endogenous T-cell receptor). COMET combines antibody-based (surface or intracellular) antigen targeting with the signaling proficiency and inherent sensitivity of native T-cell receptors. COMET consists of two polypeptides (organized N to C-term): the first is a CH3-derived heterodimerization domain fused to full-length CD3ε, and the second is an antigen targeting modality linked to the counterpart CH3-derived heterodimerization domain followed by a CD4-derived hinge and transmembrane domain. This design enables integration and efficient redirection of the TCR complex to antigen targets of interest.

Here, we demonstrate that COMET-T cells outperformed CAR-T cells in vitro and in vivo across a variety of target antigens and solid tumor models. COMET-T cells exhibited lower tonic signaling, were less differentiated, and had increased antigen-driven IL-2 production and cytotoxicity. They also displayed higher sensitivity to low-density antigens compared to CAR-T cells. Transcriptomic analysis indicated that COMET-T cells show hallmarks of TCR activation, suggesting improved fidelity to native T cell responses over that of CAR-T cells. Additionally, we show

that COMET-T cells armed with peptide-in-groove (PiG) scFvs recognizing a peptide-HLA complex were functional, enabling recognition of intracellular targets with in vitro sensitivity to low-density antigen approaching that of control TCR counterparts. Importantly, in a xenograft model, PiG COMETs achieved greater anti-tumor activity and clearance at multiple doses compared to TCR and CAR counterparts.

In conclusion, our data demonstrate that the COMET architecture enables COMET-T cells to target either surface or intracellular antigens with significantly enhanced in vitro and in vivo potency compared to 2nd Generation CAR-T cells, which may lead to more successful solid-tumor immunotherapies in the clinic.

1724 DLL3-targeting CAR co-deletion of PD1 results in enhanced T cell cytotoxicity and persistence in a pre-clinical model for small cell lung cancer.

Purpose: Small cell lung cancer (SCLC) is an aggressive and high-grade neuroendocrine disease with few treatment options. Delta-like ligand 3 (DLL3) is highly expressed on SCLC and several other types of neuroendocrine cancers with minimal or absent expression in normal adult tissues, making it a promising CAR-T target for SCLC and other solid tumor indications.

Methods: A VHH antibody for human DLL3 was selected and generated from a humanized Camelid synthetic library. Subsequently, it was made into a second-generation CAR format and the one with additional PD1 intracellular retention (a non-gene editing technique to remove membrane proteins), both of which were compared for *in vitro* activities and an *in vivo* subcutaneous SHP77 tumor animal model for target-dependent T cell cytotoxicity and persistence.

Results: The CAR with PD1 intracellular retention demonstrated a much better long-term cytotoxicity against SHP77 tumor cells than the unmodified CAR *in vitro* by repeatedly adding two more rounds of the tumor cells in an Incucyte's real-time killing assay at an E:T ratio of 1:2. To further evaluate the activities of both DLL3 CAR T cells *in vivo*, $5x10^6$/mouse of SHP77 cells were implanted subcutaneously in nonobese diabetic SCIDg (NSG) mice and allowed to engraft for 7 days, reaching a mean size of approximately 40-60mm^3 before treatment with a single tail vein injection of $2x10^6$ CAR+ T cells/mouse. For this well-established *in vivo* solid tumor model, we found that PD1-deleted CAR-T group started to show the tumor growth slowing down D13, soon reaching the peak volume D20 at a mean size of 1500mm^3, and then steadily declining close to the baseline D30. But the unmodified CAR-T group was observed to have a much delayed and gradual decline of the tumor volume starting D20 instead at a mean size of 2500mm^3, with shrinkage down to a mean tumor volume of 600mm^3 D30 and further down to the 300mm^3 D34. In addition, both groups showed the CAR-T cell expansion during the tumor shrinkage and no signs of GVHD in the study.

Conclusions: Although both CAR-T groups exhibited good tumor suppression capabilities, PD1-deleted DLL3 CAR-T showed a quicker and stronger response in this adoptive T cell therapy against solid tumors in a pre-clinical animal model. The findings of improved preclinical efficacy and persistence warrant further evaluation of PD1-deleted DLL3 CAR-T cells as a potential clinical candidate for the treatment of SCLC.

1725 A Novel Approach To Preclinical Safety Assessment Of TCRs, Pairing Quantitative Immunopeptidomics With Cell-Based Functional Assays, Identified a Development-Limiting Risk Of Cardiotoxicity for a PRAME TCR

Background: T cell receptor (TCR)-engineered T cells (TCR-T) are a promising modality for the treatment of solid tumors. However, cross-reactivity of TCRs to other antigens has the potential to drive off-target (OT) reactivity to normal tissues and must be evaluated preclinically, despite the absence of *in vivo* models. Given this challenge, holistic approaches integrating computational modeling with empirical *in vitro* data are needed to comprehensively assess the potential risks of OT reactivity. Here, we present data showcasing an innovative approach combining mass spectrometry (MS)-enabled quantitative immunopeptidomics, to determine copy numbers of peptides presented on the cell surface, with cell-based functional assays that identified a development-limiting risk of cardiotoxicity for a TCR targeting an HLA-A*02:01-restricted PRAME $_{(425\text{-}433)}$ epitope.

Methods: A bioinformatic analysis of the human peptidome was used in conjunction with an X-scan assay to identify potential OTs. TCR sensitivity to these OTs was determined using a T2 peptide-pulse assay. *In vitro* cell models that either endogenously expressed or were engineered to overexpress the OT peptides were leveraged to determine OT reactivity. Quantitative immunopeptidomics was performed on these cells and primary tissues samples to evaluate OT peptide copy numbers on the cell surface and compare it to the levels of the OT peptides observed in healthy and diseased tissues.

Results: 119 cross-reactive peptides were predicted as potential off-targets via the X-scan assay. 4 out of 191 predicted peptides were confirmed as OTs using the T2 peptide-pulse assay. 3 of these potential OTs were derisked since the peptides were not detected in essential normal tissues by MS. The remaining OT, the LRP1 peptide $_{(408\text{-}416)}$ (*LRP1*), was therefore prioritized for further de-risking. Initial *in vitro* functional assays using primary normal cells and tumor cell lines endogenously expressing *LRP1* (<250 copies/cell) did not induce TCR-T cell reactivity. However, overexpression of *LRP1* in HLA-A*02:01^{+} tumor cells at supraphysiological levels (>12,000 copies/cell) elicited robust TCR-T cell reactivity as measured by IFNγ release and cytotoxicity. By pairing the functional and quantitative immunopeptidomic readouts of the T2 peptide-pulse assay, a threshold of reactivity of ~1,000 copies/cell of *LRP1* was determined. Immunopeptidomic analysis of essential normal tissues predicted to express LRP1 quantified copy numbers ranging from 200-7,000 copies/cell, which was higher than observed in cell lines and normal cells initially tested (<250 copies/cell). Notably, multiple samples derived from aorta and diseased coronary arteries presented *LRP1* at copy numbers exceeding the 1,000 copies/cell threshold of reactivity, thus uncovering a risk of cardiotoxicity in patients.

Conclusions: By pairing *in vitro* co-culture data with quantitative immunopeptidomics, we elucidated the threshold of reactivity to *LRP1* peptide for a PRAME TCR. Comparing the threshold of reactivity with the observed peptide copy number in normal and diseased tissues identified a potential high risk of cardiotoxicity presented by this OT reactivity. Standard *in vitro* models did not reveal this risk because they did not present physiologically relevant *LRP1* copy numbers. These data demonstrate the importance of leveraging peptide copy number analysis in normal tissues in conjunction with *in vitro* assays when evaluating the safety of TCRs.

1726 CARD11-PIK3R3 Potency Enhanced p53R175H-HLA-A*02:01 TCR T Cell Therapy: Overcoming Barriers in Solid Tumor Treatment

Julie Garcia[1], Jane Mundorff[1], Mandy Iniguez, Jordan Jarjour[2]
[1]*Moonlight Bio, Seattle, WA,* [2]*Pregenen Inc., Seattle, WA*

Engineered T Cell Receptor (TCR) T cell therapies hold significant promise for targeting tumor specific antigens[1], with the first TCR T cell therapy receiving FDA approval in 2024[2]. TP53 is the most frequently mutated tumor suppressor gene in cancer. The hotspot missense mutation p53R175H, found in approximately 5% of all cancers[3], stabilizes the neoepitope's presentation on HLA-A*02:01, resulting in robust and selective presentation of the mutant peptide[4]. This selective tumor expression, combined with the role of p53R175H as an oncogenic driver and key dependency in tumor survival, makes it a highly attractive target for TCR T cell therapy development[5,6]. While ongoing efforts to develop therapies targeting p53 mutant neoepitopes are encouraging[7,8], several challenges remain that limit the broader clinical potential and impact of TCR therapies. TCR therapies commonly require high T cell doses to achieve adequate engraftment and proliferation, and often experience progressive T cell dysfunction and exhaustion, limited persistence, and impaired T cell memory formation[9]. Strategies to address some of these limitations, such as the co-administration of high-dose IL-2 to enhance T cell engraftment and expansion[10], have improved clinical efficacy but add significant cost, complexity, and toxicity[11]. More recently, a CARD11-PIK3R3 fusion protein (C11P3) was discovered and shown to enhance T cell cytokine secretion and proliferation, and dramatically amplify the *in vivo* potency of engineered CAR and TCR T cells[12]. Importantly, C11P3 was demonstrated to substantially reduce the T cell dosing required for anti-tumor efficacy in various mouse tumor models, including in syngeneic systems where lymphodepletion was not required for anti-tumor activity. Expression of C11P3 alongside engineered TCRs may solve for many of the mechanistic, manufacturing, and clinical limitations currently confronting the development of TCR T cell therapies.

Here, we present the preclinical development of a novel HLA-A*02:01 restricted p53R175H TCR T cell therapy that co-expresses the C11P3 fusion protein. We describe three patient-derived p53R175H TCRs[13] that demonstrate high specificity, robust antigen-dependent activation of both CD4+ and CD8+ T cells, and superior *in vivo* anti-tumor efficacy compared to a clinically tested HLA-A*02:01 restricted p53R175H TCR[14] (Figure 1A). Co-expression of C11P3 markedly enhanced *in vitro* antigen-dependent T cell cytokine secretion and cytotoxicity. Notably, antigen-driven IL-2 secretion increased by as much as 260-fold over TCR T cells alone (Figure 1B). *In vivo* studies using a tumor model endogenously expressing p53R175H demonstrated potent efficacy of C11P3 enhanced TCRs (Figure 1C). Specifically, TCR T cells alone achieved tumor clearance in 2/6 mice, while TCR T cells co-expressing C11P3 achieved full tumor clearance in 6/6 mice without requiring IL-2 co-administration (Figure 1C). Importantly, co-expression of C11P3 did not increase the off-target risk profile of the TCR T cells, preserving specificity and safety. These findings highlight the potential of C11P3 to address key limitations in TCR T cell therapies by enhancing cytokine secretion, cytotoxicity, and *in vivo* efficacy. Furthermore, this study demonstrates the promise of a C11P3-enhanced p53R175H TCR therapy, offering a novel approach with the potential to treat a wide range of solid tumors harboring the p53R175H mutation.

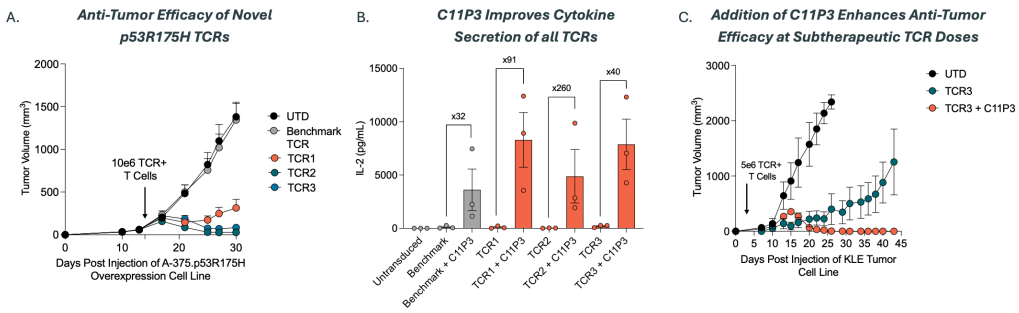

Figure 1. CARD11-PIK3R3 Enhances the Potency of p53R175H-HLA-A*02:01 TCRs

Tumor growth curves of NCG (NOD-Prkdcem26Cd52Il2rgem26Cd22/NjuCrl) mice bearing A-375 tumor xenografts that overexpress p53R175H. Animals were treated with 10e6 TCR+ T cells 14 days after tumor inoculation and tumor volumes were measured twice weekly using calipers. Untransduced (UTD) cells were used as a negative control (A). IL-2 cytokine secretion levels of TCRs with or without co-expression of CARD11-PIK3R3 (C11P3), measured 24 hours post co-culture with a p53R175H positive tumor cell line (B). Tumor growth curves of NCG mice bearing KLE tumor xenografts that endogenously express p53R175H. Animals were treated with 5e6 TCR+ T cells 14 days post tumor inoculation and tumor volumes were measured twice weekly via calipers (C). Error bars depict mean ± SEM.

1727 Novel Innate Immune Receptor-Based Chimeric Antigen Receptors For In Vivo Programming Of Myeloid Cells Show Potent Anti-Tumor Activity In Preclinical Solid Tumor Models

Yuxiao Wang[1], Neha Diwanji[2], Shannon Argueta[2], Ewa Grudzien-Nogalska[3], Junming Tong[4], Michael Gorgievski[3], Josephine D'Alessandro[3], Edward Cochran[3], Philip Darcy[5], Jian Ding[3], Daniel Getts[3], Robert Hofmeister[3]
[1]MyeloidTx, Cambridge, MA, [2]Myeloid Therapeutics, Cambridge, MA, [3]Myeloid Therapeutics, Cambridge, [4]Peter MacCallum Cancer Centre, Melbourne, Australia, [5]Melbourne, AUSTRALIA

Background: Chimeric antigen receptor (CAR) T cell therapy faces significant challenges in solid tumors due to the immunosuppressive tumor microenvironment (TME). Given their tumor-infiltrating capability, phagocytic activity, and ability to promote adaptive immune responses, CAR-engineered myeloid cells represent a promising therapeutic approach. Here we introduce a novel class of CARs designed for programming myeloid cells in vivo. These CARs comprise antibody binders against tumor antigens fused with truncated innate immune receptors CD89 or NKp44. Like the natural receptors, activation of CD89 and NKp44-based CARs require association with their cognate signal adapters FcRγ or DAP12, which are only expressed in myeloid/NK cells. Such segregation of antigen binding from cellular activation ensures immune cell-restricted CAR activity, minimizing off-target effects during in vivo administration.

Methods: The CAR constructs comprise a single-chain variable fragments (scFv) against HER2 or gp75, fused to truncated CD89 or NKp44. CAR mRNA was encapsulated in lipid nanoparticles (LNPs) to achieve in vivo programming. Coding sequences and 3' UTR of the mRNA were optimized for prolonged expression. In vitro, CAR expression and function were evaluated in a THP1 reporter cell line and primary monocytes. Anti-tumor efficacy of the CARs was assessed in a human HER2 (hHER2) transgenic mouse model and a syngeneic B16/F10 melanoma model, in which CAR mRNA/LNPs were administered intravenously.

Results: The CD89 or NKp44-based CARs were highly expressed in primary CD14+ monocytes for more than 7 days post electroporation. Transfection of human PBMCs with mRNA/LNP showed preferential CAR expression in myeloid cells. NKp44-based CAR specifically associated with DAP12, whereas the CD89-based CAR associated with and FcRγ. Upon antigen binding, CAR-expressing monocytes expressed genes associated with a proinflammatory phenotype, and NKp44-based CAR induced more durable pro-inflammatory response than CD89. In the hHER2 transgenic mouse model bearing hHER2-MC38 tumors, intravenous administration of mRNA/LNPs encoding HER2-targeting CARs showed potent anti-tumor activity and prolonged survival. Likewise, gp75-targeting CAR mRNA/LNP inhibited tumor growth and increased $CD8^+$ T cell infiltration into tumors demonstrating that CAR-programmed myeloid cells remodel the TME towards an immunostimulatory state.

Conclusions: In vivo programmed CAR myeloid cells elicit potent anti-tumor activity and promote an increase in T cells in tumors in syngeneic mouse models. The functional dependence of the CARs on endogenous signaling adaptors, combined with the preferential mRNA/LNP uptake by myeloid cells, ensures immune cell-specific activity and provides an enhanced safety profile for in vivo myeloid cell engineering.

1728 ACTallo: Developing an Allogeneic T Cell Therapy Platform Using Engineered γδ T Cells

Thomas Treiber[1], Inbar Azoulay-Alfaguter[2], Franziska Heckel[1], Mamta Kalra[3], Norbert Hilf[1], Madhu Katepalli[4], Fabian von Landenberg[1], Duy Le[4], Pooja Mehta[4], Nina Moeker[1], Divya Nandakumar[1], Martina Ott[1], Oliver Schoor[1], Gayatri Vyas[5], Claudia Wagner[1], Steffen Walter[4], Dominik Maurer[1]*

In the last decade, cell therapies have shown promising success in the treatment of hematological malignancies and tremendous progress has been made to expand their utility to more difficult to treat solid tumors. In addition to chimeric antigen receptors (CARs), T cell receptor (TCR)-based immunotherapies hold a great potential for the treatment of solid tumors by targeting extra- and intracellular tumor-associated peptide antigens on the cell surface with high sensitivity. Autologous TCR-T therapies like ACTengine IMA203 targeting PRAME have demonstrated deep and durable objective responses in heavily pretreated patients with solid tumors in clinical trials.

We have developed an allogeneic, off-the-shelf adoptive T cell therapy platform, ACTallo, with the intent to lower costs, expedite the supply of cell therapy products to patients and at the same time incorporate more extensive cell engineering to enhance functionality and durability in different indications. ACTallo is based on *ex vivo* feeder cell-free expansion and multiplexed genetic engineering of healthy donor-derived γ9δ2 T cells, which by themselves possess remarkable innate anti-tumor functionality. This T cell subset is not alloreactive, thus avoiding the risk of graft-versus-host activity. The known degree of donor-to-donor variability of γδ T cell expandability and functionality is addressed by a donor selection program, including extensive pre-screening, thereby ensuring optimal quality of starting material and process performance.
Efficient multiplex targeted gene engineering using CRISPR/Cas enables us to introduce 1) targeted cytotoxic capabilities by expressing a highly functional TCR or CAR, 2) cloaking technology to avoid fast graft rejection and 3) armoring to counteract the suppressive tumor microenvironment and supporting γδ T cell expansion and persistence.

Using the ACTallo platform, we have developed a multi-edited product candidate targeting a proprietary peptide target. The product candidate shows specific cytotoxic activity against target-positive tumor cell lines *in vitro*; incorporation of CD8 in the product design enables recognition of low target expressing lines. A single dose of cell product candidate was sufficient to induce complete tumor remission in a cell line derived xenograft model in immunodeficient mice with γδ T cells persisting for several weeks. *In vitro* coculture experiments have shown reduced rejection responses to the engineered product by cytotoxic HLA-mismatched T cells and natural killer cells, validating the functionality of the cloaking approach.

This data indicates that the ACTallo platform could be a promising pathway to enhance future TCR-T and CAR-T approaches for the benefit of cancer patients.

1729 Engineering Inducible Signal3 Chimeric Cytokine and Antigen Receptors for T Cell Therapy in Solid Tumors

Clinical efficacy of CAR-T cells in patients with solid tumors has been lower than expected, mainly due to the lack of expansion and survival of CAR-T cells. Providing the signal 3 to CAR-T cells has been proposed as a strategy to overcome this limitation. Most of the CAR constructs studied in the clinic include only the first and second signals, while strategies to provide signal 3 are typically focused on constitutive interleukin signaling, which can generate toxicities. Here, we hypothesized that inducing signal 3 in CAR-T cells upon antigen recognition through cytokine receptor activation motifs from the IL-7Rα will increase T cell activation and persistence.

First, we designed chimeric cytokine receptors (CCR) by coupling a scFv to the IL-7Rα intracellular domain, including either the IL-7Rα or CD8α transmembrane domain. Signaling was compared to a constitutively signaling IL-7Rα chain able to phosphorylate STAT5 autonomously, due to the homodimerization via a disulfide bridge within the transmembrane domain. All IL-7-based CCRs were efficiently expressed, and further characterized in single transduction or co-transduction with a first-generation CAR. In single transduction, CCRs were unable to induce STAT5 signaling after antigen recognition. In co-transduction, the CCRs did not provide a cytotoxic nor a proliferative advantage.

Next, we explored the addition of specific IL-7Rα signaling motifs within ICOS or CD28-based second-generation CAR constructs. We generated a panel of constructs including different configurations of the box 1, interbox and box 2 motifs that lead to JAK/STAT5 signaling. Once expressed in T cells, we observed differences in terms of expression and cytotoxicity *in vitro* among the different constructs. We could not detect a clear upregulation in phosphorylation of STAT5 after antigen recognition, probably due to background STAT5 signaling from the CD3ζ domain. Using an *in vitro* model of continuous antigen exposure, some IL-7R-based CAR-T cells revealed enhanced cytotoxicity compared to the second-generation CAR-T cells. *In vivo*, IL-7-based HER2-CAR-T cells behaved similarly to the control group, showing no clear advantage in antitumor activity.

We next hypothesized that the impaired STAT5 signaling was due to insufficient dimerization with the endogenous common gamma chain, known as CD132. To test this, we evaluated CD132 bioavailability in T lymphocytes. Our observations indicate that the surface lifetime of CD132 is relatively short, as it undergoes constant endocytosis and recycling. Despite this, CD132 mRNA was highly expressed and the protein could heterodimerize with other cytokine receptors, suggesting that the bioavailability of this molecule is not the main hurdle behind the lack of CCR signaling.

As previously published, diverse IL-7R conformations may signal constitutively once expressed in T cells. However, we have demonstrated that, if these signaling domains are expressed in an inducible conformation, they lack STAT5 signaling. Further analysis of CCR 3D-structure and molecule dimerization is being performed to decipher whether they can form homo- or heterodimers to activate downstream signaling. We believe that these results could shed light on the dynamics of cytokine signaling and allow the design of an inducible CCR.

1730 A Novel T Cell Receptor Targeting Cancer Testis Antigen NY-ESO-1

Sebastian Snedal[1], Miguel Gomez-Fontela[2], Aileen Alontaga[1], Theresa Boyle[1], Biao Liu[3], Birgit Schultes[3], John Mullinax[1], Shari Pilon-Thomas[2], Daniel Abate-Daga[4]*
[1]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [2]Moffitt Cancer Center, Tampa, FL, [3]Intellia Therapeutics, Cambridge, MA, [4]H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida
**Corresponding Author*

BACKGROUND: New York esophageal squamous cell carcinoma 1 (NY-ESO-1, encoded by the CTAG1A gene) is a well-characterized cancer testis antigen (CTA) with documented potential as a target for immunotherapy [1, 2]. We hereby report the isolation of a novel HLA-A*02:01-restricted T cell receptor (TCR) that recognizes NY-ESO-1, and the functional characterization of TCR-transgenic T cells for their use in adoptive immunotherapy of cancer. In addition, we provide CTAG1A RNA expression data across cancer types, using a CLIA-certified assay that may serve as a patient-selection tool.

METHODS: Tumor-infiltrating lymphocytes (TIL) were expanded as previously described [3] from a sarcoma patient. NY-ESO-1-reactive TIL clones were identified and FACS-sorted using an HLA-A*02:01 dextramer

(epitope: SLLMWITQV). TCR rearrangements (VDJ) were identified by single cell RNA sequencing and the resulting sequences were cloned in a gamma-retroviral vector (MSGV1) for expression in peripheral blood T cells. TCR expression and dextramer binding were assessed via flow cytometry. Co-cultures were performed for IFN-gamma ELISA and RTCA experiments to evaluate reactivity and cytotoxic efficacy, respectively, of TCR-transduced T cells against myeloma, melanoma, and sarcoma cell lines. Finally, we tested the *in vivo* antitumor effect of TCR-transgenic T cells using a xenograft of A375 melanoma cells in NSG mice. For the analysis of NY-ESO-1 expression in clinical specimens, we compiled RNA expression data from 809 tumor samples analyzed at Moffitt Cancer Center using the CLIA-certified RNA Salah Targeted Expression Panel (RNA STEP) [4]. Tumors displaying expression values that were 4-fold ($\log2 \geq 2$) greater than the normal tissue controls were considered positive for CTAG1A/NY-ESO-1.

RESULTS: We identified a T cell clone with specificity for a 9-mer NY-ESO-1 peptide within a TIL culture expanded from synovial sarcoma. VDJ sequencing of these TIL yielded a highly enriched TCR clonotype (>50%), and a retroviral vector was generated to express the TCR variable regions fused to murine TCR constant regions. Upon retroviral transduction, both CD4+ and CD8+ T cells expressed the TCR and bound NY-ESO-1 dextramers. Using co-culture experiments, we demonstrated specific IFN-gamma secretion by transduced T cells against HLA-A2+/NY-ESO-1+ U266 (myeloma), A375 (melanoma), and STB024 (sarcoma) cell lines ($p<0.0001$). Cytotoxicity assays showed significant dose-dependent cytolysis of A375 cells by TCR-transduced T cells after 72-hours ($p<0.0001$). Utilizing an NSG mouse model, we found that injection of TCR-transduced T cells resulted in a significant delay in A375 melanoma xenograft growth, in comparison to untransduced T cells ($p=0.0003$), and untreated mice ($p<0.0001$). Using an institutional database of RNA expression data, we found that 9.9% of samples analyzed showed positive expression of CTAG1A/NY-ESO-1. Among these, 10.7% of lung tumor, 14.8% of adrenal tumor, and 27.3% of thyroid tumor samples expressed high levels of CTAG1A/NY-ESO-1 compared to normal tissues.

CONCLUSION: We generated a retroviral vector for expression of a novel TCR that recognizes NY-ESO-1. Functional validation of TCR-T cells generated using this retroviral vector indicate that the TCR is specific, and that the resulting transgenic lymphocytes can lyse tumor cells *in vitro* and *in vivo*. Altogether, our results support the future clinical translation of a novel NY-ESO-1-targeted TCR-T cell product.

1731 Multiplexed Engineering for Generation of HLA-Class I Restricted CD4 T Cells

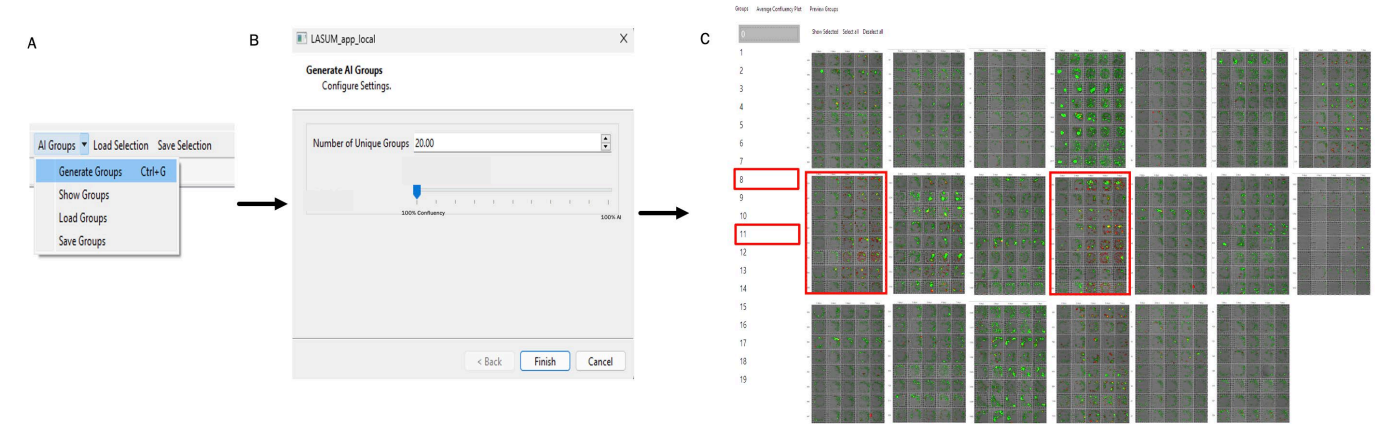
Mayra Cruz Tleugabulova[1], Sascha Rutz[2], Christine Huang[3], Patrick Holder[4]
[1]Genentech, Inc, San Francisco, CA, [2]Genentech, Inc, South San Francisco, CA, [3]Genentech, South San Francisco, [4]Genentech, South San Francisco, CA

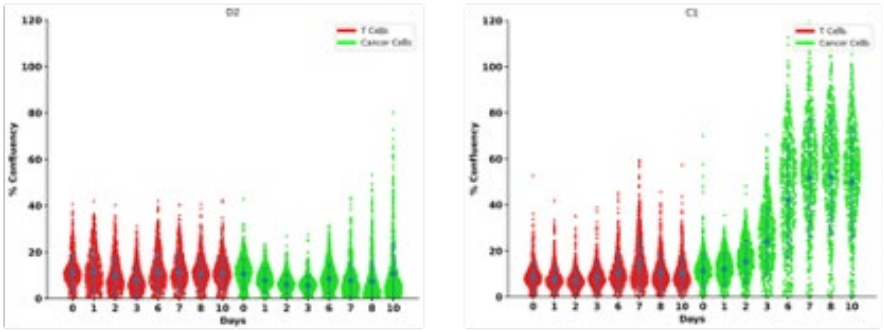
TCR-based T cell therapies have a remarkable potential for the treatment of solid tumors. The success of such therapies relies on the use of a TCR that can recognize tumor specific antigens presented on HLA-Class I. Although CD8 T cells were long thought to be the main effectors in this process through their direct killing of tumor cells, it has recently become evident that CD4 T cells play a crucial role. Thus, in order to harness the full potential of T cell therapies it is vital to generate CD4 T cells that can target tumor cells. HLA-Class I restricted TCRs can be expressed on CD4 T cells, but tumor antigens often have low affinity for TCRs and full activation of a T cell requires the CD8 co-receptor to stabilize the TCR-peptide-HLA complex. To this aim, we engineer HLA-Class I restricted CD4 T cells through CRISPR Cas9 mediated knockin of an HLA-Class I restricted TCR accompanied by a CD8 co-receptor. Through multiplex engineering approach that optimized for order of expression, promoter use and proteolytic sites, we engineer a single knockin construct with optimal expression of all four genes: TCRa, TCRb, CD8a and CD8b. To reduce cargo load and simplify our construct design, we also explore engineering a single chain CD8 co-receptor. We find that HLA-Class I restricted CD4 T cells engineered to express the CD8 co-receptor effectively recognize the respective tumor antigens with kinetics similar to CD8 T cells. The approach here shows the successful engineering of HLA-I restricted CD4 T cells using a single CRISPR Cas9 knockin construct. These findings improve T cell therapies in the quest to transform for the treatment of solid tumors.

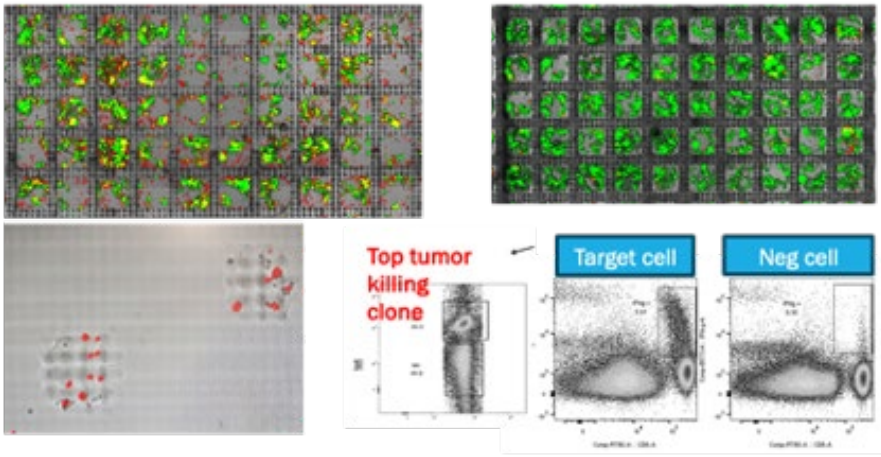
1732 AI guided tumor reactive cell isolation using immune cell tumor microcultures

Qi Zhao, Enrich Biosystems Inc., Branford, CT

Robust determination of single-cell kinetics, including killing rate, proliferation rate, and engaging time… are the basis for comparing and predicting in-vivo performances among different cell clones, especially in CAR-T development or TCR-T identification. To suppress single cell noise, different strategies to increase sample size are used on Enrich TroVo platform. We here use hydrogel-based microwell systems and deep-learning based cell behaviour movie grouping to analyze, rank and isolate optimal Tumor killing T cell clones for downstream studies i.e. Rapid expansion, single cell multiomics.







1733 Development of Novel TCR Based Cell Therapies Targeting Tumor Specific Mutation in AML.

**Corresponding Author*

Treatment of acute myeloid leukemia (AML) remains an unmet medical need due to the mortality arising from the complexity of the disease. Patient responses to current treatment regimens compound the challenge of finding effective AML treatments. One of the most common and clinically significant AML mutations occurs in the nucleophosmin 1 (NPM1) gene. The main objective of this program is to identify clinically viable therapeutic TCRs targeting mutated NPM1 (NPM1c+). Here we described the discovery, selection and characterization of therapeutic TCR candidates.

Anti-NPM1c+ TCRs were identified through tetramer-based screening, single cell sorting and NGS sequencing of potential candidates. In total, 15 TCRs were found to bind NPM1c+ target peptide. Jurkat reporter assays, as well as OCI-AML2 and OCI-AML3 cytotoxicity assays were used to further characterize TCR candidates. TCRs that showed activity at an effector-to-target (E:T) ratio of <1:1 in OCI-AML3 cytotoxicity assays were investigated further. Three candidates showed reproducible potency using multiple donors to generate TCR-Ts. Additional cytotoxicity assays utilizing cysteinylated target NPM1c+ peptides demonstrated the ability of TCRs to target post translationally modified peptides. We further examined TCR epitope specificity by performing alanine scanning on two NPM1c+ TCRs. Both TCRs showed an overlap in critical peptide residues and had very similar initial cytotoxicity profiles. However, each TCR recognized a distinct single amino acid target and had different tetramer binding characteristics. The initial cytotoxicity profiles for the two TCRs are similar. Nevertheless, additional studies indicated differences in binding characteristics using tetramer-based binding assays.

In summary, we demonstrate the selection and characterization of viable AML anti- NPM1c+ TCRs. While several TCRs demonstrated similar cytotoxicity profiles, there were clear differences in target peptide binding which are under investigation. The data demonstrates the development of TCR based therapies for addressing an unmet need in AML patients.

Summary of anti-NPM1c+ lead candidate TCR endogenous cytotoxicity assays.

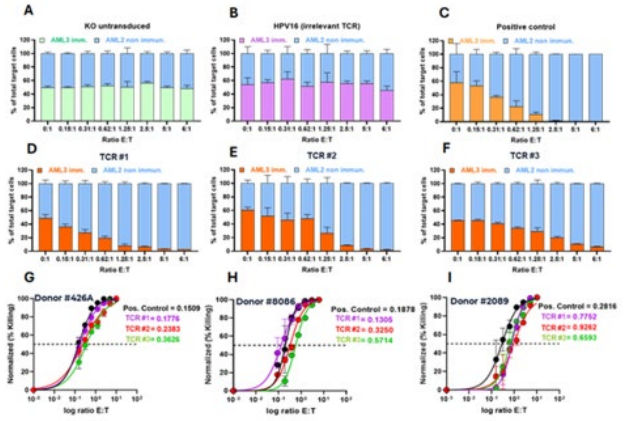

Figure summary. Bar graphs **A, B, and C** represent OCI-AML3 and OCI-AML2 cytotoxicity percentages at a 1:1 E:T ratio for the positive control, untransduced negative control, and HPV irrelevant TCR negative control, respectively. Bar graphs **D, E, and F** represent cytotoxicity against OCI-AML3 (immunogenic) and OCI-AML2 (non-immunogenic) at varying E:T ratios for anti-NPM1c+ TCR 1, 2, and 3 respectively. Summary of EC50 cytotoxicity for lead and positive control is summarized for Donor #426A **G**, #8086 **H** and # 2089 **I**, respectively. For control conditions green, pink, and yellow are used for immunogenic cells for the untransduced , irrelevant, and positive controls, respectively. The proportional killing of non-immunogenic (blue) and immunogenic (orange) cells is also shown. Graphs represent the percentage of killing (%) of target cells as determined by flow cytometry. Data points represent the mean average value for 3 technical replicates, and the error bars represent the standard deviation.

1734 Deep Learning Algorithm-Guided Optimization of a Natural Ligand-based CAR-T against CD70 in Acute Myeloid Leukemia

Amrik Kang[1], Radhika Dalal[1], Mingcheng Li[1], Sujata Walunj[1], Trishna Patel[1], Tanja Kortemme[1], Justin Eyquem[2]*, Arun Wiita[2]*
[1]*University of California San Francisco, San Francisco, CA,* [2]*UCSF, San Francisco, CA*
**Corresponding Author*

Introduction: Acute myeloid leukemia (AML) has a 5-year survival rate under 30% and has a great clinical need for new therapies. CD70 is a promising AML target antigen due to its high expression on AML tumor cells and absence on healthy hematopoietic stem and progenitor cells (HSPCs). One of the most potent CD70-targeting strategies is a "natural ligand" (NL) binder derived from the extracellular domain of CD27, the receptor for CD70. Our group has shown that NL binder CAR-Ts display improved proliferation and tumor control compared to scFv-based CD70 binders (Kasap et al, *Biorxiv* 2024). However, there are currently no described strategies for the optimization of NL CAR-T binders, which may follow different "rules" compared to scFv-based CAR-Ts. Here, we utilize deep learning-based algorithms to address this gap, generating an NL variant CAR that outperforms the wildtype (WT) CD27-based CAR-T in preclinical AML models.

Methods: CD27-based variants were generated and evaluated using proteinMPNN and Rosetta based on the 7KX0 PDB structure. CAR constructs were delivered into primary T-cells using AAV and integrated at the *TRAC* locus via CRISPR knock-in. *In vitro* cytotoxicity was measured by luminescence after co-culturing CAR-Ts with luciferase-expressing target cell lines for 24 hours. Intracellular cytokine staining was performed on CAR-Ts following stimulation, brefeldin A treatment, fixation, and permeabilization. Ligand-receptor affinity was measured on an Octet RED384 biolayer interferometry instrument. *In vivo* evaluation of CAR-Ts was performed in NSG mice, with tumor burden measured using bioluminescence imaging and CAR-T expansion by flow cytometry.

Results: We first utilized deep learning and physics-based algorithms to model substitutions on the CD27 surface that would stabilize binding to CD70. We identified 8 single mutations and 4 combinations of mutations, with ΔΔG values ranging from +11.2 to -33.0 Rosetta energy units relative to the WT CD27-CD70 interaction (Fig. 1). We expressed these CD27-variant CARs in T-cells and evaluated their cytotoxicity against the AML cell lines MOLM-14 and NOMO-1. We observed that a subset of our CD27 variant CARs outperformed the WT CAR, particularly at

lower effector-to-target ratios, and that the best-performing variants expressed higher levels of TNF-α, IFN-γ, and IL-2 in a cytokine stimulation assay. We compared the best-performing CD27-variant CARs in a "stress test" *in vivo* model using the MOLM-14 cell line. We observed initial tumor control in the WT CD27-based CAR group, followed by tumor relapse and death. In comparison, several CD27-variant CARs had improved tumor control, with the best performing variant, named "N88A", showing complete tumor control in all surviving mice for the duration of the study (Fig. 2). We also observed improved peripheral blood expansion for this CAR compared to the WT CAR. Finally, we measured the binding affinity of the N88A CAR to CD70 using biolayer interferometry and measured a Kd value of 110 ± 35 nM, about a 3-fold improvement over the WT CD27 CAR, which has a Kd measured at 350 ± 110 nM.

Conclusion: We report here the development of a novel deep-learning based approach to develop improved natural ligand-based CAR binders, identifying a CAR variant with improved binding to CD70 and improved anti-tumor efficacy *in vitro* and *in vivo*. These results highlight this methodology's potential to improve natural ligand CAR-Ts in several tumor indications.

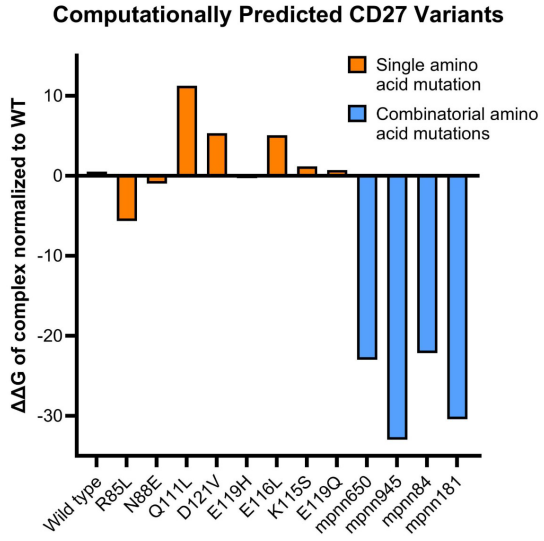

Figure 1: Predicted target binding stability for CD27-based variants, normalized to the WT CD27-CD70 interaction. Units given are arbitrary Rosetta energy units, with variants consisting of a single amino acid substitution colored in orange and variants with multiple amino acid substitutions colored in blue.

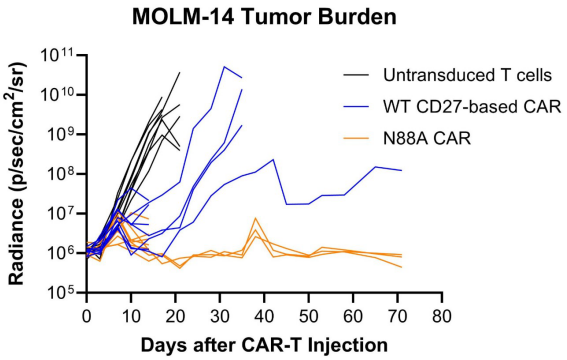

Figure 2: The N88A NL variant CAR-T outperforms the WT CD27-based CAR-T in a stress-test MOLM-14 AML murine xenograft model. Curves represent quantified bioluminescence imaging values for each mouse. Increased radiance indicates higher tumor burden.

1735 Super Immunodeficient NOG-EXL Mice Have Enhanced Patient-Derived Xenotransplantation of Acute Myeloid Leukemia: An Ideal Model to Test Novel Therapies

Tanmoy Sarkar[1], Sarah Skuli[1], Nicolas Skuli[1], Martin Keough[1], Anthony Secreto[1], **Laura Griffin[2]**, Moriah Jacobson[2]*, Martin Carroll[1]*
[1]University of Pennsylvania, Philadelphia, PA, [2]Taconic Biosciences, Rensselaer, NY
**Corresponding Author*

Xenotransplantation of human acute myeloid leukemia (AML) cells into immunodeficient mice is an established model for preclinical development and increasing our understanding of translational AML biology. AML xenotransplantation has been well characterized in highly immunocompromised NSG mice, but with variable results, including overall poor engraftment or a prolonged time to engraft. Previously we have found that TP53 mutant AML and splicing factor mutant AML engraft poorly in NSG mice. Alternative mouse models that may improve engraftment efficacy include the NSG-SGM3 (SGM3) and NOG-EXL mice, which combine severe

immunodeficiency with transgenic expression of human myeloid stimulatory cytokines. However, we have found that the SGM3 strain is also prone to high variability in regard to time to engraft and level of engraftment, as well as spontaneous animal death.

To address these concerns, we collaborated with Taconic Biosciences to compare AML primary sample engraftment in the NSG, SGM3, and NOG-EXL mice. We first studied overall survival in SGM3 and NOG-EXL mice engrafted with four separate AMLs (n=5 per cohort). Consistent with previous results, 5/20 of SGM3 mice engrafted with AML became ill and required sacrifice approximately 5 weeks after injection. SGM3 health and survivability did not correlate with the level of AML engraftment, and over time additional SGM3 mice required sacrifice. In contrast, AML successfully engrafted in all NOG-EXL mice and only 1/20 NOG-EXL mice became ill during 12 weeks of observation.

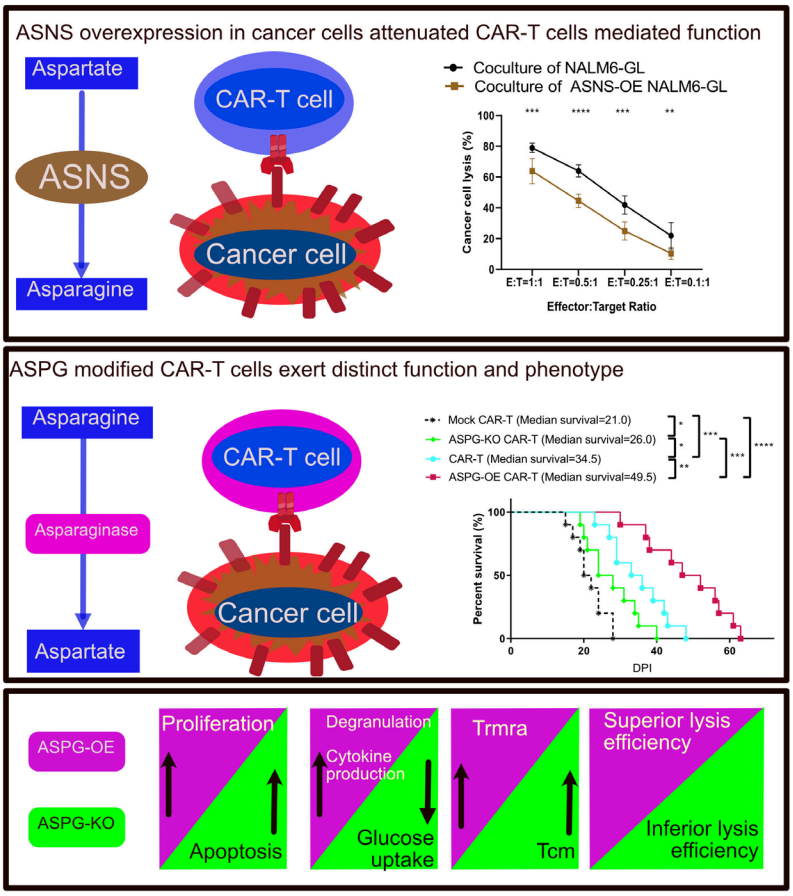
We next studied relative engraftment in all three mouse strains of five TP53 mutant AML samples that had either previously not engrafted or engrafted poorly in NSG mice. We aspirated bone marrow on all mice five weeks after injection. Level of engraftment across strains varied from not detectable in NSG mice to over 80% in NOG-EXL and SGM3 mice. Mice were observed until symptoms of leukemia engraftment developed (42 to 77 days) at which time mice were sacrificed and analyzed for leukemic burden by measuring huCD45+huCD33+ cells in the bone marrow and spleen. Interestingly, bone marrow burden increased in NSG mice over time although total mouse leukemic burden in NSG mice was consistently lower than in the SGM3 and NOG-EXL mice. Comparing leukemic burden in NOG-EXL to SGM3 mice showed a modestly higher leukemic burden and lower variability in NOG-EXL mice at time of sacrifice. Human CD45+ and human CD33+ cell expression, as assessed by flow cytometry, were higher in SGM3 and NOG-EXL compared to NSG mice. We also found that splicing factor mutant AML engrafted poorly in NSG mice, with shorter time to engraftment and higher levels of engraftment in both NOG-EXL and SGM3 mice. Again, no early deaths were seen in the NOG-EXL strain but were observed in the SGM3 mice.

Overall, these results support the hypothesis that the NOG-EXL strain is an improved mouse model for use in AML xenotransplantation compared to NSG and NSG-SGM3, with enhanced levels of engraftment without spontaneous mortality. Currently, response to cytotoxic, venetoclax, and novel therapies in the NOG-EXL mice is ongoing.

1736 Asparaginase Coupled CAR-T Cells Overcome ASNS Mediated Resistance to CAR T Cell Therapy in Leukemia

Quanjun Yang, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, Shanghai, China

Asparagine is a conditionally essential amino acid that plays a crucial role in certain types of hematologic malignancies. In this study, we found that asparagine synthetase (ASNS) overexpression (OE) attenuated CAR-T cell-mediated cancer cell lysis efficiency in the co-culture of anti-CD19 CAR-T cells and NALM6 cancer cells. Asparaginase (ASPG) is a medication that breaks down circulating asparagine in the leukemia and lymphomas, thereby depriving cancer cells of asparagine and inhibiting cancer growth. We thus generated ASPG-modified engineered CAR-T cells for the killing against ASNS-overexpressing cancer cells. ASPG-OE CAR-T cells exhibited enhanced killing efficiency, while ASPG-KO CAR-T cells attenuated killing efficiency. Phenotypic analysis showed that ASPG-OE CAR-T cells exhibited distinct differentiation states, including central memory T cells and effector memory cells re-expressing CD45RA. This distinct phenotypic switch and functional enhancement of ASPG-OE CAR-T cells also confirmed from the in vitro co-culture experiments and in vivo xenogeneic mouse models. The ASPG-OE CAR-T cells showed an increased survival and a differentiation trend towards effector memory cells re-expressing CD45RA. Taken together, ASPG-OE CAR-T cells overcome ASNS-mediated resistance to CAR T cell therapy in leukemia. Further research is warranted to investigate the safety and efficacy of ASPG-modified CAR-T cells in clinical trials.



1737 Advancing AML CAR-T: Transposon Based CAR-T Cells

Rachel Bito[1], Shawn Barman[2], Babak Moghimi[3]
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]USC/CHLA, Valencia, CA, [3]Children's Hospital Los Angeles (CHLA), Los Angeles, CA

Survival outcomes for pediatric acute myeloid leukemia (AML) lag significantly behind other pediatric leukemia and lymphomas. Given the unprecedented success of Chimeric Antigen Receptor T cells (CAR-T) for lymphoblastic leukemias, there is a dire need to develop AML-targeted CAR-T cells. However, its success has been limited due to the need for tumor-specific antigen targets in AML and the risk of off-tumor toxicities in the absence of such antigens. Strategies to overcome the AML clonal heterogeneity has lead to the design of very complex and large CAR constructs. The traditional approach to CAR- T cell engineering utilizes the lentiviral vector to deliver DNA into the T cell in a process that is both time and money consuming on the clinical scale. To address this issue, we have engineered CAR-T cells using a non-viral PiggyBac transposon-based method aiming to facilitate the manufacturing of these novel treatments for AML. We demonstrate that ERM2 CAR, CD123 CAR, and CD33 CAR engineered using the PiggyBac system was effective against multiple in AML cell lines invitro. Furthermore, we have successfully demonstrated that more complex dual gated structures, such as a synthetic notch CD33>CD123 CAR can also be generated into a single frame of the transposon cassette. This non-viral platform demonstrates that more complex structures can be constructed amount of time and materials as simpler CAR constructs and have similar efficacy against AML cell lines. The implementation of non-viral methods to create complex CAR-T modules is novel and could significantly contribute to advancing future clinical trials more rapidly and at a lower cost. This approach could translate into improved access and equity of these life-changing treatments for all patients.

1738 Development of ARI-007: CD7negative Anti-CD7 CAR-T Cells for the Treatment of T-Cell Malignancies

**Corresponding Author*

CAR-T cell therapy has demonstrated remarkable efficacy in B-cell malignancies. However, treating T-cell acute lymphoblastic leukemias and lymphomas (T-ALL/LBL) remains challenging. A major obstacle to therapeutic success is the shared expression of the target antigen between CAR-T cells and malignant T cells, leading to self-killing, known as fratricide. Additionally, there is a risk of contamination of the infusion product with circulating malignant blasts, which could be transduced with the lentiviral vector. We hypothesized that selecting the CD7negative (CD7neg) population may reduce T cell fratricide while ensuring a safer infusion product in comparison to other expansion strategies.

Our center developed three scFvs targeting CD7 from in-house hybridomas (124.1D1, 142.9 and 142.24), and incorporated them into second-generation 4-1BB-based CAR constructs. To compare the three anti-CD7 CAR candidates in the absence of T-cell fratricide, we first used the CRISPR/Cas9 system to knockout CD7. CAR avidity against Jurkat T-ALL cell line was similar for all candidates, consistent with antibody affinity results. *In vitro*, CAR-mediated activation was confirmed in cytotoxicity, cytokine secretion and proliferation assays using Jurkat, CCRF-CEM and MOLT4 cell lines. Although all scFvs eradicated the tumor cells and had similar cytokine secretion, 124.1D1 and 142.24 groups showed greater *in vitro* proliferation than 142.9 group. Accordingly, in a Jurkat xenograft mouse model, 124.1D1 and 142.24 groups significantly reduced tumor burden and prolonged animal survival compared to 142.9. Based on these findings, the 142.24 CAR was selected as our final candidate construct.

To avoid gene-editing, CD7 protein expression blockers (PEBLs) were designed by fusing the scFvs to an endoplasmic reticulum intracellular retention domain. The final PEBL construct combined the 124.1D1 scFv, which showed the highest retention capacity, with the 142.24 CAR sequence in a bicistronic construct. This strategy generated CAR-T cells with robust *in vitro* performance, including cytotoxicity, cytokine production and proliferation. *In vivo*, the PEBL strategy achieved animal survival rates comparable to those of the CD7KO approach.

Additionally, other expansion strategies to prevent fratricide were explored, including pharmacological inhibition of CAR signaling using dasatinib (tyrosine kinase inhibitor) in a 10-day expansion (D10) and in a shortened 3-day protocol (D3). Both approaches successfully generated anti-CD7 CAR-T cells, but D3 cells showed superior IL-2 production and proliferation *in vitro* and significantly extended animal survival *in vivo* compared to the CD7KO, PEBL and long-term pharmacologically inhibited CAR-T cells.

Finally, to enhance safety during manufacturing, we generated CD7neg anti-CD7 CAR-T cells using a custom magnetic depletion process. The obtained CAR-T cells significantly enhanced survival rates compared to untreated mice, similarly to D3 CAR-T cells. The feasibility of producing CD7neg 142.24 CAR-T cells was further evaluated in a GMP-grade bioreactor using apheresis samples.

Overall, we developed and compared five approaches to mitigate fratricide and ensure safety in anti-CD7 CAR-T cells. Based on these results, and due to the reduced risk of contamination of the infusion product with malignant blasts, CD7neg 142.24 CAR-T cells (ARI-007) were selected as our final candidate to be evaluated in clinical trials in patients with T-ALL/LBL.

1739 In Vivo CAR-T Cell Therapy Using Modified AAV Capsids Targeting Human T Cells

Haifeng Chen[1]*, Tsvetelina Hoang[1], Ching Yi Ho[1], Anastasiya Smith[1], Tara Shahim[1], Platon Selemenakis[1], Stone Xia[1], Moeed Ahmad[1], Gwendolyn Vu[1], Min Chen[1]

Adeno-associated virus (AAV)-mediated generation of chimeric antigen receptor T (CAR-T) cells in vivo represents a transformative approach to cancer immunotherapy and autoimmune diseases. Unlike traditional ex vivo CAR-T cell therapy, which requires complex procedures including T cell isolation, genetic engineering using lentivirus or retrovirus, expansion and reinfusion, in vivo CAR-T cell therapy enables direct genetic modification of T cells within a patient. Leveraging AAV vectors for efficient gene delivery, this method eliminates the need for labor-intensive and costly manufacturing processes, offering a scalable, fast and affordable treatment paradigm.

However, the progress of in vivo CAR-T cell therapy using AAV vectors has been significantly hindered by their low transduction efficiency of unactivated T cells. To overcome this, we genetically engineered the AAV capsid proteins VP1, VP2, and VP3 by introducing pre-designed polypeptides at various positions in the proteins. Through extensive testing using our Bac-to-AAV system in Sf9 cells, we developed the Precision AAV Capsid Engineering (PACE) platform technology. We also applied this platform technology to the mammalian system mediated by triple-plasmid transfections. This technology allows for the insertion of pre-designed DNA fragments at specific VP sites, thereby altering the capsid affinity for various cellular targets. Utilizing this approach, we engineered a modified AAV capsid, dubbed AAV^{TceT}, which demonstrated an increased affinity for human T cells. Unlike other modifications that often compromise AAV packaging efficiency, the AAV^{TceT} capsid maintained normal production yields.

AAV^{TceT} vectors carrying CMV-GFP and CD19-specific CAR were produced using the Bac-to-AAV system in Sf9 cells. These vectors were then used to transduce peripheral blood mononuclear cells (PBMCs) from various donors in vitro. The results were striking, showing a transduction efficiency increase of over 70 folds compared to their wild-type counterparts (FIG. 1). When these transduced PBMCs were co-cultured with CD19-positive Raji tumor cells, the modified T cells demonstrated efficient killing capabilities, rivalling those of lentivirus-transduced CAR-T cells.

An in vivo mouse study is currently underway, where we aim to observe the cancer-killing effects by directly administering AAV^{TceT}-CD19-specific CAR to NSG mice bearing Raji tumors. Preliminary results have already indicated that animals treated by a single injection of AAV^{TceT}-CD19-specific CAR have significantly smaller tumors than the control group (FIG. 2). This enhanced T cell targeting of the modified capsids could pave the way for an affordable, off-the-shelf in vivo CAR-T cell therapy using AAV vectors.

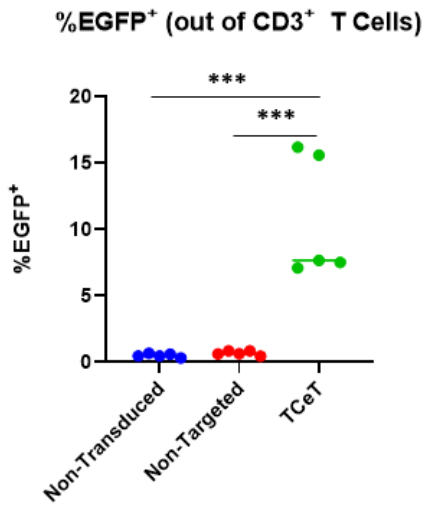

Figure 1. rAAV containing TCeT capsids transduce T cells with up to 70-fold higher efficiency than non-targeted (wt) rAAV. Each dot represent a healthy human donor. Statistical significance was evaluated using One-way ANOVA and Tukey's multiple comparisons test in Graphpad Prism.

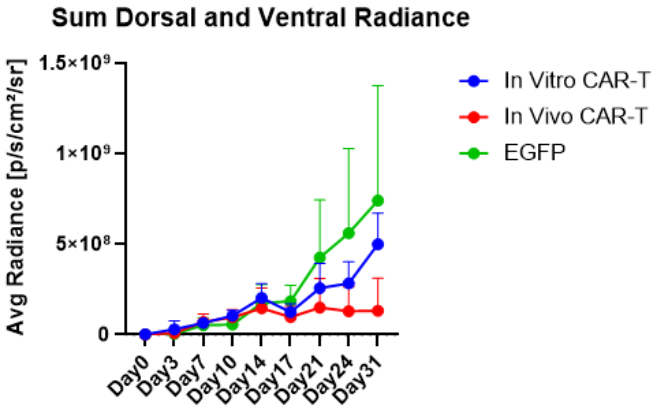

Figure 2. In vivo generated CD19-specific CAR-T cells effectively control Raji tumor cell growth.

1740 Low Dose Methotrexate as a Combinatorial Therapy with mDHFR+ Allogeneic CAR-T Cells

Michael Coffey[1]*, Aimee Loyola[2], Jasmine Kwong[2], Arturo Barcenas[2], Danny Mendoza[2], Garrett Arauz[2], Nicholas DeMarco[2], Mona Connerney[1], Nina Timberlake[1], Julia Coronella[1], Devon Shedlock[3]

Allogeneic (allo) CAR-T cells, derived from healthy donor material, are susceptible to rejection by the recipient's immune system as demonstrated by reduced clinical persistence compared historically to autologous CAR-T products. This has prompted exploration of various shielding strategies to reduce, delay, or prevent rejection. Poseida's allo CAR-T cells are manufactured using a DNA transposon-based delivery system and the Cas-CLOVER™ Gene Editing System (Madison, 2022). Gene editing to eliminate the endogenous T-cell receptor and partially delete beta-2-microglobulin minimizes the likelihood of graft-versus-host disease and host-versus-graft CD8+ T cell-mediated rejection. The CAR transgene encodes a mutant dihydrofolate reductase (mDHFR) gene, enabling the ex vivo selection of transgene-positive cells during manufacture using the antimetabolite methotrexate (MTX). MTX targets rapidly dividing cells and is commonly used in oncology and, at lower doses, to reduce inflammation in autoimmune diseases such as rheumatoid arthritis (RA) and psoriasis.

We hypothesized that administering low-dose MTX to patients after mDHFR+ allo CAR-T infusion could reduce host allorejection while sparing mDHFR+ CAR-T cells, thus enhancing their therapeutic window for antitumor

activity. To test this, mDHFR$^+$ allo CAR-T resistance to MTX was assayed in vitro by incubating antigen-stimulated CAR-T and either unstimulated or antigen-stimulated pan-T cells with increasing concentrations of MTX. These studies demonstrated that exposure to clinically relevant concentrations of MTX (~250-500 nM) (Bannwarth, 1996) was sufficient to kill >80% of activated pan-T cells within 48 hours, while unstimulated pan-T and antigen-activated mDHFR$^+$ allo CAR-T were largely resistant at these concentrations with 85-100% of CAR-T cells surviving on average across multiple donors. Further, abrogation of alloreactivity by 250 nM MTX was assessed in 7-day mixed lymphocyte reactions. MTX completely eliminated HLA-mismatched pan-T cell alloreactivity, as measured by a >95% reduction in proliferating T cells, while mDHFR$^+$ allo CAR-T proliferation was unchanged compared to controls not treated with MTX.

We further investigated whether mDHFR$^+$ CAR-T retain in vivo potency in the presence of low dose MTX. NSG mice engrafted with Raji tumors were administered either mDHFR$^+$ or mDHFR$^-$ anti-CD20 CAR-T, followed 24 hours later by insertion of subcutaneous pumps set to release MTX over the subsequent 5 days (Figure 1A). This method of administration resulted in stable MTX serum levels that were comparable to those observed clinically in RA patients receiving low dose MTX treatment (Figure 1B) (Bannwarth, 1996). Importantly, the in vivo expansion and potency of mDHFR$^+$ CAR-T were unaffected by MTX. Conversely, MTX delayed the expansion of mDHFR$^-$ CAR-T resulting in impaired tumor control (Figure 1C-D). As MTX is rapidly metabolized in mice, mDHFR$^-$ CAR-T were able to expand and regain tumor control after MTX release from the subcutaneous pumps ended on Day 5.

Our results show how MTX effectively reduces alloreactive T cell activity in vitro without affecting the proliferation and cytotoxicity of mDHFR$^+$ CAR-T. Furthermore, in vivo in the presence of clinically relevant serum MTX concentrations the potency of mDHFR+ CAR-T was unchanged. This strategy holds potential for improving allo CAR-T persistence and expanding their therapeutic window by inhibition of alloreactive host T cells.

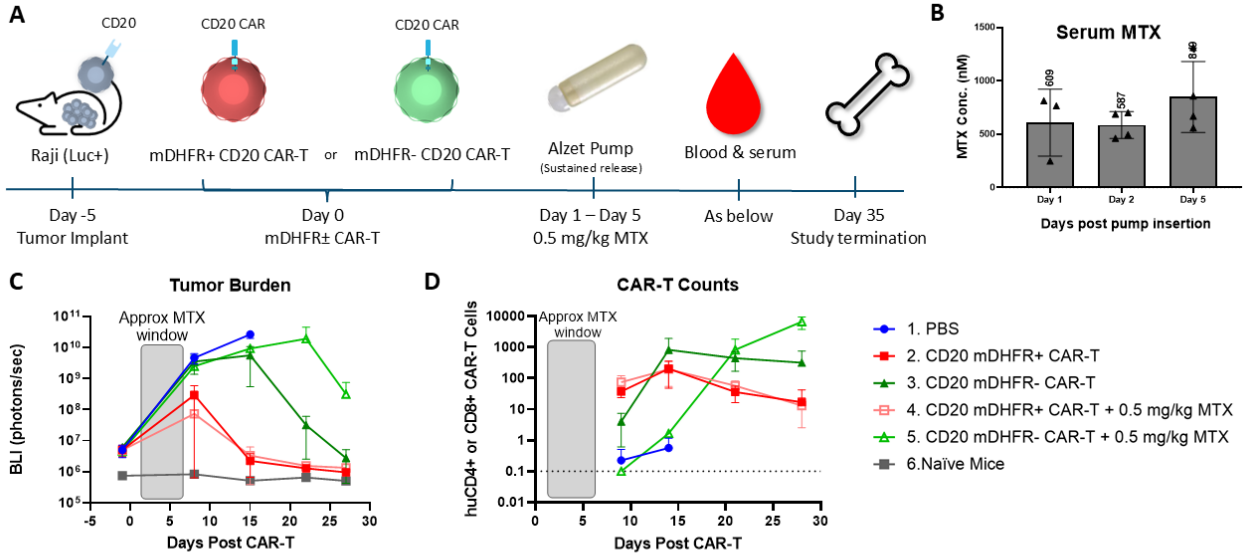

Figure 1: mDHFR+ CAR-T are resistant to clinically-relevant MTX doses in vivo: (A) Schematic for assessing the effect of MTX on mDHFR+ and mDHFR- CAR-T using Alzet pump-mediated delivery (B) Concentration of methotrexate detected in serum samples collected 1, 2 and 5 days after pump implant. Introduction: Anti-CD19 CAR-T cell therapies are effective for treatment of relapsed /refractory B-cell lymphomas (r/r B-NHL). However, loss or down-regulation of CD19 poses a challenge, contributing to 60% relapses. CAR-T therapies targeting alternative antigens could mitigate this risk. The efficacy of anti-CD20 therapies like Glofitamab post-CAR-T failure is well-established; however, high costs and limited availability restrict access to these therapies in India. We aimed to develop a CD20-directed CAR-T therapy to complement our approved CD19-directed CAR-T therapy (Tali-cel) to improve the durability of responses in r/r B-NHL.

Methods: Two humanized anti-CD20 CAR constructs (h1CAR20 and h2CAR20) were designed and synthesized from parent murine anti-CD20 scFv (mCAR20). CAR-T cells were generated using lentiviral transduction of healthy donor T cells and extensively characterized for functionality in vitro (antigen dependent cytotoxicity and cytokine release, repeat antigen stimulation assay). In vivo studies were performed in NOD/SCID mice, wherein luciferase-tagged CD20+ Raji cells were injected intravenously, followed by CAR-T cells. Tumor progression in the animals was monitored by bioluminescent imaging (BLI).

Results: CAR-T cell manufacturing feasibility demonstrated comparable transduction efficiency (~50%) and ex vivo expansion (40-60-fold) in all anti-CD20 CAR constructs. In co-culture assays, CAR-T cells were tested for anti-tumor activity against tumor cells expressing CD20 at variable levels (low CD20+: Wild type Nalm-6; mid CD20+: Raji cells; high CD20+: transgenic Nalm-6 CD20+, K562 CD20+). Humanized anti-CD20 h2CAR-T cells showed robust antigen dependent efficacy comparable to murine CAR-T cells even at low CD20 expression (Figure 1A). Optimal cytokine release (IFN-y, IL-2 and TNF-α) was seen from humanized CAR-T cells on antigen stimulation, comparable to mCAR20-T cells (Figure 1B). Further, h2CAR20-T cells retained their functional capabilities after multiple antigen exposures. We further evaluated the in vivo efficacy of h2CAR20-T cells in NOD/SCID animal models implanted with Raji cells. Rapid and durable tumor suppression was observed with h2CAR20-T cells compared to mCAR20-T cells and h1CAR20-T cells ($p = 0.0399$ and 0.0352, respectively). h2CAR20-T cells were also associated with low toxicity, with no adverse events, whereas treatment with mCAR20-T cells and h1CAR20-T cells resulted in instances of lethal toxicity in mice. The mice treated with h2CAR20-T cells showed improved survival; with a median survival of 14 days for mCAR20-T cells, while the median survival for h2CAR20-T cells was not reached after 60 days, further supporting the robust anti-tumor activity.

Conclusion: The novel h2CAR20-T cells exhibit robust efficacy, and safety in preclinical models. This indigenous CD20 CAR-T product holds promise for use in combinational CAR-T therapy for r/r B-NHL.

1742 The human natural killer (NK) cell line YTS as a novel platform for cellular therapy

Hanan Jaber[1], Anas Abu khalaf[1], Itay Cohen[2], Lola Weiss[1], Yarden Engel[1], Michael Berger[3], Ofer Mandelboim[3], **Shlomo Elias[2]***

**Corresponding Author*

The introduction of CAR T cells has revolutionized the treatment of lymphoma and myeloma. However, this approach has notable limitations, including severe adverse events, complex and costly production processes, dependence on the patient's own T cells, and variability in the final product. In contrast, natural killer (NK) cells are not MHC-restricted, making them suitable for allogeneic use, and they do not trigger cytokine release syndrome. Despite these advantages, NK cell manufacturing remains complex and expensive.

YTS is a human NK cell line characterized by a limited number of activating receptors and can be easily cultured and transfected. In this study, we demonstrate that YTS cells transfected with a CD19-targeted CAR can serve as a novel immunotherapy against CD19-expressing cells. We demonstrate that YTS cells transfected with CAR against CD19 efficiently kill both the B-cell line Raji and primary chronic lymphocytic leukemia (CLL) cells. We show that CAR activity relies on intracellular signalling and, in certain tumors, on co-stimulation through the 2B4-CD48 pathway.

To use YTS cells therapeutically, they must be irradiated before injection to prevent proliferation while maintaining cytotoxic activity. We evaluated irradiation effects using multiple methods. In vitro, a 1000 rad dose effectively inhibited proliferation, as shown by reduced viable cell numbers, lower metabolic activity in an MTT assay, and cell trace labeling (data not shown and Figure 1A). In vivo, NSG mice injected with YTS-CAR-CD19 cells irradiated at 2000 rad or higher showed no tumor growth (data not shown). Based on these findings, a 2500 rad dose is optimal

for safely preventing proliferation. Next, we evaluated whether the cytotoxic activity of YTS cells expressing CAR was retained after irradiation at 2500 rad. Additionally, we froze the cells post-irradiation to simulate how these engineered YTS cells could be administered to patients. A cytotoxicity assay was performed, in which irradiated YTS cells, both with and without CAR targeting CD19, were incubated with Raji cells. The assay showed that YTS-CAR CD19 cells maintained their cytotoxic activity after irradiation and freezing (Figure 1B). To assess the therapeutic function of YTS cells expressing CAR CD19 in vivo, we used a tumor model in which Raji cells were injected subcutaneously into NSG mice. Once tumors became palpable, we injected irradiated YTS CAR CD19 cells twice a week. As controls, we used non-transduced YTS cells or PBS. Tumor size was evaluated, and injection of YTS CAR CD19 cells resulted in a significant reduction in tumor size (~50%) (Figure 1C).

We also transduced the cells with the Fc receptor CD16 and demonstrated that the transduced YTS cells can induce antibody-dependent cytotoxicity (ADCC) mediated by rituximab when targeting B cells. More importantly, these cells were also capable of inducing ADCC against solid tumor cells.

We propose that genetically engineered YTS cells can serve as a novel, cost-effective, and accessible "off-the-shelf" immunotherapy, which can be tailored to target different antigens. These modified cells have potential applications in treating resistant lymphoma, autoimmune diseases, and solid tumors.

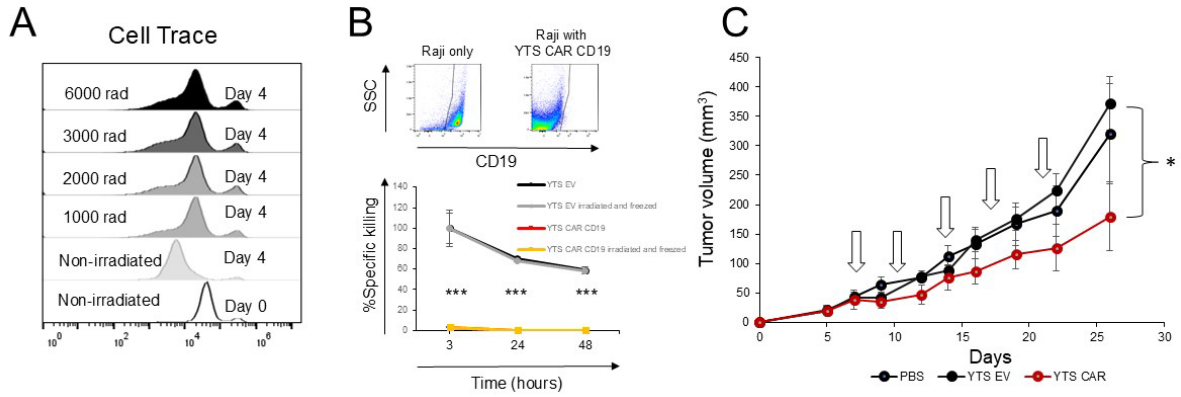

Figure 1. Safety and efficiency of irradiated YTS-CAR CD19 cells. (A) YTS cells expressing CAR against CD19 were non-irradiated or irradiated at different levels and then subjected for proliferation assay using CellTrace. (B) YTS cells expressing either a CAR against CD19 or an empty vector were irradiated with 2500 rad or left non-irradiated, then frozen and later used in a killing assay against Raji cells. The degree of killing was assessed at multiple time points over 48 hours. E:T 20:1. (C) Effect of YTS cells expressing CAR against CD19 *in vivo*. 15x10^6 Raji cells were injected subcutaneously into immunodeficient mice. Once tumors became palpable, mice were injected with 10x10^6 YTS cells expressing CAR against CD19, which were irradiated with 1000 rad (marked with arrows). *, P<0.05, ***, P<0.001, ANOVA test with multiple comparisons or Student's t-test.

1743 DesignCell® Platform for Optimal CAR Discovery

Atsushi Okuma[1]*, Yoshihito Ishida[2], Daisuke Ito[3], Taketo Kawara[3], Takuya Yamashita[3], Kei Yoshida[3], Shoji Hisada[2], Tomohiko Okuda[3], Hiroko Hanzawa[2], Shizu Takeda[3]

Introduction: Chimeric antigen receptor (CAR) T cell therapy has demonstrated promising outcomes in B cell leukemia and multiple myeloma. However, its efficacy against other tumor types remains suboptimal. Most CAR-T studies employ a limited range of CAR designs, similar to the approved CD19 CARs, differing mainly in the binder domain. these conventional designs may not be optimal for CARs targeting other tumors or even for CD19 CAR-T therapies. To maximize CAR efficacy, we have developed the DesignCell® platform, which can rapidly design CAR

sequences, build CAR T cells, test their functionality, and learn the relationship between CAR sequence and cell function for subsequent design-build-test-learn (DBTL) cycles. Our platform integrates original AI capable of generating CAR designs with predicted functionality, a pooled screening system specialized in evaluating CAR T cells on a single-cell level, and an automated high-throughput arrayed screening system for CAR T cell phenotyping.

Results: We started a CD19 CAR screening from a theoretical diversity of 10^8 designs generated by our AI. To handle CAR libraries with such enormous diversity, we developed a pooled screening system utilizing an optofluidic system to verify the single-cell cytotoxicity of each CAR T cell. Our pooled screening system provides up to 14,000 single-cell data per run, capturing cytotoxicity and stimulation-dependent cell growth. Our in-house long-read sequencing setup links each CAR sequence to its phenotypes. Following the enrichment of active CAR designs through pooled screening, we performed arrayed screening to obtain bulk data for hundreds to thousands of cells per CAR. Our arrayed screening system, compatible with high throughput and automated via robotic handling, covers the entire process from production to evaluation of CAR T cells. This system can evaluate short-term cytotoxicity and serial killing activity of over 500 CARs in one cycle. Upon completion of the screening flow, we identified CAR designs with superior activity compared to commonly used designs from the huge CAR library.

Conclusion: Our DesignCell® platform facilitates rapid CAR T cell screening based on cytotoxic activity from a vast CAR library. Using the platform, we selected several enhanced CD19 CAR designs. This strategy holds potential for optimizing CARs targeting other antigens.

1744 SynKIR-310 Provides a Novel Split-Signal CAR T Platform (KIR-CAR) Based upon Natural Killer Cell Signaling to Prolong Anti-Tumor Treatment in B-NHL

Single-chain CD3-based chimeric antigen receptors (CARs) utilize FMC63 single-chain variable fragments (scFv) to target CD19 and demonstrate robust clinical responses in patients with B cell non-Hodgkin lymphomas (B-NHL). Despite initial response rates of 60-80%, about 40% of responders experience relapse within 1 year[1]. Therapies that improve upon CAR T cell functional durability remain an unmet medical need. Previously, we developed a multi-chain specific killer immunoglobulin-like receptor (KIR)-derived CAR T cell therapy, SynKIR-110, targeting mesothelin on solid tumors with enhanced anti-tumor function in a murine xenograft model of a CAR-resistant patient-derived mesothelioma, compared to 2nd generation (gen) CD3-based CAR T[2].

Using our newly developed anti-human CD19-specific canine scFv, DS191, with 84% heavy chain homology to humans as opposed to murine FMC63 with only 64% homology, we designed a novel KIR-CAR (SynKIR-310) with separated antigen binding and T cell activation in attempts to confer the prolonged functional durability observed in SynKIR-110 with solid tumors, to address patients with refractory/relapsed CD19-targeted B-NHL. Expressed on the same KIR-CAR T backbone, DS191 binder showed comparable sensitivity and specificity to FMC63 *in vitro* in antigen density assays, equivalent anti-tumor activity *in vivo* as FMC63, and no off-target cross-reactivity as measured by membrane proteome array and co-culture with primary cells from different organs[3].

To evaluate whether the differing signaling components in single chain benchmark FMC63 CD19-CAR T vs multi-chain SynKIR-310 had any impact on transduced T cells' antigen sensitivity and activation, we compared the two *in vitro* both qualitatively and quantitatively. Results demonstrated comparable T cell activation of CD107a, TNF-α, IL-2 and IFN-γ, to the extent that not only the types of cytokines produced matched, even the concentration of each cytokine produced in response to targets matched between SynKIR-310 and FMC63 CD19-CAR. These data suggest that although they are comprised of different scFv binders and different signaling mechanisms, SynKIR-310 and benchmark FMC63 CD19-CAR are comparable in their specificity, sensitivity, and potency *in vitro* in the presence of various levels of CD19 antigen.

Previous work on SynKIR-110 demonstrated that although there was no apparent difference between 2nd gen CAR and KIR-CAR *in vitro*, once applied in *in vivo* tumor models, a different profile emerged, with KIR-CAR reducing or eliminating solid tumors that were resistant to single-chain CD3-based CAR T treatment[2]. This work supports further *in vivo* evaluation and translation into clinical studies, as we have shown that DS191 binder can recognize CD19 targets with equivalent sensitivity and specificity as the globally approved FMC63.

Our next steps include conducting SynKIR-310 *in vivo* tumor-killing studies compared to benchmark CD19-CAR in CD19-positive heme tumor models. These results should provide insights into the correlation between *in vitro* and *in vivo* potency of SynKIR-310, building upon the mechanism for prolonged anti-tumor response observed in SynKIR-110, and supporting clinical development of SynKIR-310 for patients with relapsed/refractory B-NHL in a Phase 1 clinical trial (NCT06544265).

1745 Immunobiology of Adeno-Associated Virus (AAV) in Murine Liver: A Cross-Sectional Comparison of AAV8, AAV6, and a Chimeric Liver-Tropic Capsid in a Preclinical Model

Alan Curtis[1], **Rachel Hedinger[2]**, Kelsey Higgins[3], Joshua Hatfield[4], Rachel Reynolds[5], Youjun Chen[6], Abbie Svancarek[2], Layth Awartani[7], Cody Evans[2], Yash Shah[1], Erik Wielechowski[5], Audry Fernandez[2], Amaury PupoMerino[1], Angela Mote[7], Scott Hammond[8], Simon Lacey[9], Sherif Gabriel[1], Anna Tretiakova[10], Shari Gordon[11]
[1]AskBio, Durham, NC, [2]AskBio, Morrisville, NC, [3]AskBio Inc., Morrisville, NC, [4]AskBio, Morr, NC, [5]AskBio, Philadelphia, PA, [6]Asklepios Biopharmaceutical, Morrisville, NC, [7]Askbio, Research Triangle Park, NC, [8]Asklepios Biopharmaceutical, Research Triangle Park, NC, [9]AskBio, Milton, DE, [10]Stealth, Chapel Hill, NC, [11]Ask Bio, Morrisville, NC

Adeno-associated virus (AAV) vectors are leading candidates for gene therapy product delivery. However, capsid-specific immune responses reduce therapeutic benefit by driving transgene loss and have been linked to adverse events. AAV8 is a well-described liver-tropic capsid, yet clinical trials in hemophilia have varied in measures of safety and efficacy (Nathwani 2014, Konkle, 2021). In rare cases, liver toxicity, including liver failure, has been observed after high-dose AAV8 administration in patients with X-linked myotubular myopathy (Shieh, 2023; Wilson & Flotte, 2020). Conversely, AAV6 was generally well tolerated in a hemophilia A study even at high doses (Leavitt, 2024). Additionally, a recently described chimeric liver-tropic capsid demonstrated minimal liver inflammation and sustained transgene expression in a hemophilia B clinical trial (Xue, 2022). Thus, a better understanding of AAV-induced immune pathways in the liver has the potential to inform capsid design, immunomodulatory regimens, and enhance clinical trial outcomes.

The current study directly compared the biology of AAV8, AAV6, and the chimeric liver-tropic capsid in a murine model. Adult female B6(Cg)-Tyrc-2J/J albino mice (n=4/group) received $1E^{11}$ vg (~$5E^{12}$ vg/kg) of AAV8, AAV6, or the chimeric liver-tropic capsid carrying a luciferase reporter or formulation buffer by tail vein injection at day 0. Mice were sequentially culled at 2, 5, 8, 16, 24, 72 hours (h) or 7, 30, or 90 days (d) post-dose.

Whole body and ex-vivo liver IVIS imaging showed significantly higher transgene expression from AAV8 (~1.0 log) compared to AAV6 and chimeric liver-tropic capsid at all timepoints. Interestingly, the chimeric liver-tropic capsid exhibited higher (~0.5 log) viral DNA copies in liver compared to AAV6 and AAV8. In situ hybridization of luciferase DNA/RNA in liver 2h post-dose revealed distinct vector distribution patterns. AAV8 nucleic acids were uniformly distributed, with small, punctate foci whereas AAV6 was less uniform with larger foci. The chimeric liver-tropic capsid was organized into large areas of intense staining, and AI-assisted image analysis demonstrated an increased number of membrane-associated aggregates whose staining co-localized with F4/80, a marker of murine macrophages and Kupffer cells. Gene expression analysis demonstrated that the chimeric liver-tropic capsid transiently elicited an upregulation of select innate genes including interferon alpha (~10 fold) and flow cytometry revealed increased plasmacytoid dendritic cell frequency and natural killer cell activation relative to AAV8, AAV6, and mock controls. Despite aggregation of the chimeric liver-tropic capsid and immune involvement observed at

early timepoints, AST and ALT remained at background levels across all groups/ timepoints, and apoptotic hepatocytes were not observed by TUNEL staining, suggesting normal liver function after capsid delivery. At later timepoints we observed similar levels of T cell activation in the liver and spleen and circulating AAV binding antibodies induced by all three capsids. Overall, this study suggests capsid-specific differences in the early host response may impact transgene expression and potentially therapeutic efficacy.

1746 A Multitherapeutic Approach Combining *Ex vivo* and *In vivo* Cell Engineering to Treat HIV in Nonhuman Primates

Anne-Sophie Kuhlmann[1], Edward Kreider[2], Wenli Mu[3], Daniel Stone[1], Andrew Riker[1], Jasmin Martinez-Reyes[1], Shruti Shankar[1], Laurence Stensland[4], Richard Wilson[5], Richard Wyatt[6], Keith Jerome[1], Veronica Nelson[1], Nadja Meumann[7], Scott Kitchen[8], Drew Weissman[9], Hans-Peter Kiem[10], Hildegard Büning[11]
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]University of Pennsylvania, Philadelphia, PA, [3]UCLA, Los Angeles, CA, [4]University of Washington, Seattle, WA, [5]Scripps Institute, La Jolla, CA, [6]Department of Immunology and Microbiology, Scripps Consortium for HIV/AIDS Vaccine Development (CHAVD) Scripps Research, La Jolla, CA, [7]Hannover Medical School, Hannover, Germany, [8]David Geffen School of Medicine at UCLA, LOS ANGELES, CA, [9]University of Pennsylvania Perelman School of Medicine, [10]Fred Hutchinson Cancer Center, Seattle, Washington, [11]Hannover Medical School, Hannover, Niedersachsen, Germany

The recent advances in *in vivo* cell engineering will contribute to a great acceleration in the application of therapies in oncology and infectious diseases. However, few studies have explored these approaches in immunocompetent large animal models such as nonhuman primates (NHP), which most closely model and predict therapeutic potential in patients. Here we focused on HIV-1, a virus responsible for acquired immunodeficiency syndrome (AIDS). Since its identification in the 80's, a very limited number of people living with HIV have been cured following transplant of hematopoietic stem cells to treat hematologic malignancies. However, these treatments remain burdensome, restricting this approach. Additionally, HIV-1 has shown unprecedented ability to adapt to the host immune response and treatment attempts, complicating its eradication and suggesting that combining therapeutics might be key. In this study we evaluated a combination of *ex vivo* and *in vivo* cell engineering with the goal to deliver several therapeutics as a treatment against SHIV (Simian-human immunodeficiency virus) in pigtail macaques.

Nine pigtail macaques were enrolled. Three control animals were SHIV-infected, suppressed with antiretroviral therapy (ART-suppressed) and left untreated. The remaining 6 animals were SHIV-infected and ART-suppressed before being transplanted with autologous *ex vivo* chimeric antigen receptors (CAR)-modified hematopoietic stem cells. Following a 6-month recovery period, the animals were divided in two groups and received *in vivo* injections of $CD4^+$ T cells- and hepatocytes-directed lipid nanoparticles (LNPs; n=3) or Adeno-associated virus vectors (AAVs; n=3) encoding broadly neutralizing antibodies (bNAbs) and Brec1-recombinase. In total the treated animals received a combination of two CARs, two bNAbs directed against the HIV-1 Envelope and a Brec-1 recombinase (Brec).

Throughout the study, viral load, $CD4^+$ T cells, bNAb concentrations and CAR expression were monitored in peripheral blood and tissues. Limited but detectable CAR expression was observed despite low to no viral antigen expression for the duration of antiretroviral therapy administration. Preliminary results indicate that LNP-receiving animals had detectable bNAbs with concentrations ranging from 1.3 to 9 µg/ml in the first two weeks following injections. bNAb expression from the AAVs-receiving animals is still being investigated. Among these animals receiving LNPs, bNAbs could be detected for several weeks and one animal presented a delayed viral rebound at 5 weeks post ART withdrawal correlating with the most sustained and highest bNAb expression. The other animals from the treatment or control groups had a shorter bNAb half-life and the virus rebounded between 1 to 3 weeks after ART withdrawal. More experiments are being performed to analyze bNAb concentrations and persistence in the LNP- and AAV-receiving animals.

While more investigations are required to unravel the efficiency and contribution of each therapeutic approach employed in this study, our data show that a combination of *ex vivo* and *in vivo* cell engineering can be delivered and potentially impact the viral rebound. Although this study focused on *ex vivo* and *in vivo* cell engineering, future

developments will be geared toward an all–*in vivo* approach to facilitate a one shot multitherapeutic approach as standard of care.

1747 Cross-reactive Immunologic Material (CRIM) Analyses for AAV Gene Therapy

Leah Cardwell[1], Michael Parfenov[2], Richard Collis[2], Julien Couthouis[2], Sean Daugherty[2], Deniz Erturk-Hasdemir[3], Andrew Grimm[2], J Lawrence Merritt[2], Heather Richbourg[2], Lorelei Stoica[4], Barbara Sullivan[4]
[1]Ultragenyx, Somerville, MA, [2]Ultragenyx Pharmaceutical Inc., Novato, CA, [3]Ultragenyx, Novato, CA, [4]Ultragenyx, Novato, California

The absence of Cross-Reactive Immunologic Material (CRIM) may potentially impact the long-term efficacy of AAV gene therapy, by eliciting strong immune responses against the transgene protein. Parameters that may impact the immune response to the transgene protein can include gene therapy dose, route of administration, genotype of the individual, and immunomodulatory history.

AAV gene therapies are predominantly designed for monogenic rare diseases where a single defective gene is responsible for driving disease pathology. At the individual level, genotypes can be analyzed for the degree of homology between the pre-existing protein, the transgene protein, and other proteins in the genome. Individuals with significant lack of protein homology may be predicted to be "CRIM-high risk"; *eg* these people may be more likely to generate a stronger immune response to the transgene protein than others. The immune response to the transgene protein may be driven by CD8+ T cells or both CD4+ T cell and B cells (antibodies). Just as an antibody response may limit biodistribution of soluble protein therapies, antibodies and CD8+ T cell responses may kill transduced cells. To address the potentially strong immune response, stronger immunomodulation regimens may be introduced, or CRIM-high risk individuals may be excluded from studies.

To understand the potential impact of CRIM risk in people with OTC and GSDIa, we created an *in silico* CRIM-analysis workflow utilizing IEDB tools, AlphaFold, and custom programs. This workflow includes 1) individual genotype impact on protein product, 2) homology to other genome proteins, 3) predicted B cell epitopes, 4) antibody accessibility based on protein secondary structure, and 5) interaction score with most common HLA-A, HLA-B, and HLA-C haplotypes in North America and Europe; these HLA predictions were compared with published Duchenne clinical cases where CRIM-high risk individuals were identified.

For individuals with OTC enrolled in the DTX301 Phase 1/2 study (ClinicalTrials.gov Identifier: NCT02991144), 1 of 8 participants with available data was characterized as CRIM-medium risk due to a hemizygous splicing mutation predicted to cause absence of a portion of ornithine transcarbamylase protein. For individuals with GSDIa enrolled in the DTX401 Phase 1/2 study (ClinicalTrials.gov Identifier: NCT03517085), two of 12 participants were characterized as CRIM-high risk and three of 12 were characterized as CRIM-medium risk due to homozygous or compound heterozygous mutations predicted to result in truncation or absence of glucose-6-phosphatase protein.

The relationship between *in silico* CRIM-analysis workflow predictions and clinical outcomes will be important for refining these tools as clinical results become available. As more people consider taking AAV gene therapy, understanding the impact of CRIM more comprehensively will help guide discussions to optimize these potentially transformative treatments.

1748 Genetically Engineered Organs for Early Reporting of Transplant Rejection

Raphaela Bento[1], Irina Filz von Reiterdank[2], Antonia Dinicu[2], Christopher Taveras[3], Madeeha Hassan[4], Bradley Ellis[4], Gregory Wojtkiewicz[4], Ralph Weissleder[2], Basak Uygun[4], Curtis Cetrulo Jr[4], J. Coert[5], Aebele van der Molen[5], Biju Parekkadan[6], Korkut Uygun[7]
[1]Massachusetts General Hospital - Harvard Medical School, Cambridge, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospitalsetts, Boston, MA, [4]Massachusetts General Hospital, Boston, [5]University Medical Center Utrecht, Utrecht, Netherlands, [6]Rutgers University, Piscataway, NJ, [7]Harvard Medical School, Boston, MA

The diagnosis of organ transplant rejection remains a major clinical challenge due to the limited sensitivity and specificity of blood tests and the invasive nature of biopsies. This study presents a novel approach for rejection monitoring by genetically modifying transplant organs to serve as immunosensors. Using viral gene delivery during ex vivo machine perfusion, we successfully incorporated transgenes into vascularized composite allografts (VCAs), enabling real-time, in situ detection of rejection through the release of a sensitive, blood-based biomarker (**Fig. 1A**).

We demonstrate, for the first time, that genetically modified VCAs maintain stable expression of Gaussia Luciferase (GLuc) for over 300 days—equivalent to approximately 30 years in humans—highlighting the durability of this approach (**Fig. 1B**). Given the high immunogenicity of skin, VCA recipients, such as face or arm transplant patients, experience acute rejection episodes in 89% of cases within the first year post-transplant, despite intensive immunosuppression. Additionally, the short preservation window of six hours and the complex tissue architecture of VCAs pose significant challenges for efficient transduction.

To address this, we designed an inflammation-responsive construct using a synthetic NF-κB promoter to drive GLuc expression, enabling early, non-invasive detection of rejection. This system allowed for biomarker detection up to *six days* before any detectable histological signs of rejection, providing a crucial diagnostic advantage (**Fig. 1C, D, E**). Our findings establish that integrating gene therapy with ex vivo machine perfusion can significantly enhance the diagnostic capabilities of transplantable organs, offering a groundbreaking strategy to improve long-term graft survival and patient outcomes.

Beyond transplantation, this proof-of-concept study sets the stage for broader applications in transplantation and regenerative medicine, such as localized inflammation and infection monitoring in burn injuries and wound healing. By defining key parameters for effective tissue transduction, this approach paves the way for innovative, real-time diagnostic and therapeutic strategies in transplant and wound care medicine.

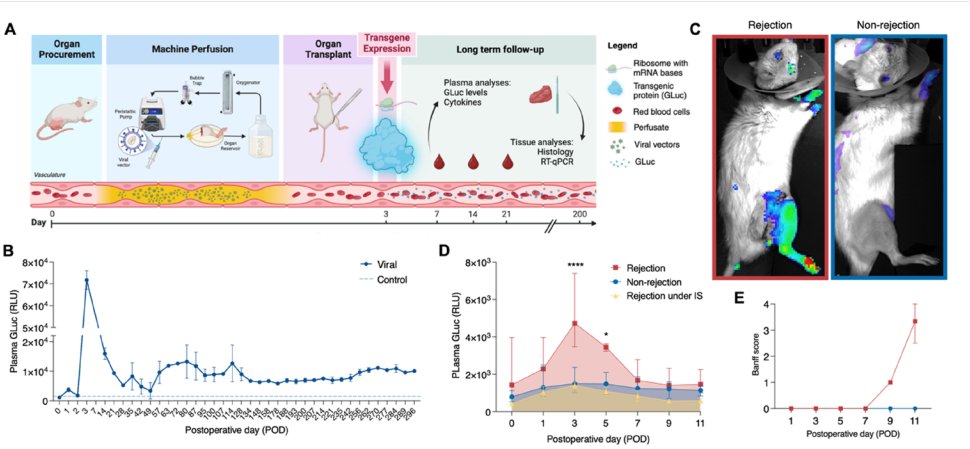

Figure 1. Genetically Engineered *'Smart Grafts'* Detect Rejection *In Vivo* Earlier Than Biopsies. (**A**) Experimental design describing the study timeline. (**B**) Plasma GLuc levels of constitutive animals stabilize after postoperative day (POD) 14 and remain consistent for near 300 days. (**C**) *In vivo* bioluminescence imaging shows significant luminescence in rejected hindlimb. (**D**) Plasma GLuc levels in rejection animals are significantly elevated at PODs 3 and 5 compared to non-rejection or rejection group that received immunosuppression (IS). (**E**) Blinded histopathological assessment shows rejection on POD 9 in rejection group. Two-way ANOVA (* $p \leq 0.0332$; **** $p \leq 0.0001$).

1749 Towards a Universal Cell Replacement Therapy: Engineering Human Pluripotent Stem Cell Lines to Evade Xenogeneic Transplantation Barriers

Hannah Pizzato[1], Paula Alonso-Guallart[2], James Woods[2], Bjarki Johannesson[2], Jon Connelly[3], Todd Fehniger[4], John Atkinson[5], Shondra Pruett-Miller[6], Frederick Monsma[2], Deepta Bhattacharya[7]
[1]University of Arizona, Phoenix, AZ, [2]The New York Stem Cell Foundation Research Institute, New York, NY, [3]St. Jude Children's Research Hospital, Memphis, TN, [4]Washington University School of Medicine In St. Louis, Saint Louis, MO, [5]Washington University School of Medicine, St. Louis, MO, [6]St. Jude Children's Research Hospital, Memphis, TN, [7]University of Arizona, Tucson, AZ

Human pluripotent stem cell (hPSC)-based therapies for regenerative medicine are beginning to fulfill their promise, with several exciting treatments for degenerative and autoimmune diseases having reached clinical testing. However, immunological rejection of hPSC-based therapies remains a limitation to their widespread adoption. To circumvent rejection, these therapies can be combined with systemic immunosuppression, but this increases the risk of infections and cancer. Alternatively, induced PSCs (iPSCs) can be used autologously, but this has the practical limitation of scalability. A third option is genetic modification of the starting hPSCs to evade immunological rejection, which can enable scalable production of cell replacement therapies without the need for systemic immunosuppression. To create cells capable of evading immune rejection for preclinical testing, we used CRISPR-Cas9 to genetically ablate expression of HLA-I, HLA-II, and natural killer (NK) cell activating ligands in hPSCs (HM-KO hPSCs). Additional combinations of immune evasion factors were expressed on HM-KO hPSCs to inhibit NK cells, complement deposition, and/or phagocytes. To define the immunological barriers causing immune rejection, we performed teratoma assays in fully immunocompetent mouse models using these modified lines. Immunocompetent mouse models present the extremely high immune barrier of xenogeneic transplantation and, unlike 'humanized' mice, have a fully intact and functional immune system. Transplantation of HM-KO hPSCs expressing additional inhibitors for NK cells and complement deposition led to persistent teratomas in fully immunocompetent wild-type mice. Expression of additional inhibitory factors such as CD24, CD47, and/or PD-L1 had no discernible impact on teratoma growth or persistence. Transplantation of HM-KO hPSCs into mice genetically deficient in complement and depleted of NK cells also led to persistent teratomas. Thus, T cell, NK cell, and complement evasion are necessary to prevent immunological rejection of hPSCs and their progeny. These hPSCs and versions expressing human orthologs provide a template for regenerative therapies and could eventually serve as a universal hPSC bank for cell replacement therapies that circumvent the need for systemic immunosuppression.

1750 The Effects of Antigen-Specific CD8$^+$ T Cells on Successful Engraftment in Platelet-Targeted Gene Therapy

Jocelyn Schroeder[1], Calvin Williams[2], Qizhen Shi[3]*

Background: Immune responses, particularly CD8$^+$ T cell-mediated rejection, remain a major obstacle in gene therapy, leading to the elimination of genetically engineered cells and therapy failure. Our platelet-targeted gene therapy, driven by the αIIb promoter, has demonstrated therapeutic potential and immune tolerance in F8^{null} mice. However, pre-existing immunity can impair engraftment by targeting transgene-expressing cells. Identifying the threshold of antigen-specific CD8$^+$ T cells that can be tolerized is crucial for optimizing platelet gene therapy in primed recipients.

Objective: To determine the threshold of antigen-specific CD8$^+$ T cells that allows successful engraftment of engineered bone marrow (BM) cells and sustained transgene expression in platelet-targeted gene therapy, overcoming immune barriers to improve therapeutic outcomes.

Methods: We used ovalbumin (OVA) as a surrogate protein for platelet-specific gene expression (2bOVA) and generated a transgenic model, 2bOVA^{Tg}, with OVA expressed explicitly in platelets. CD8 T cells from OT-I mice [OVA-specific T cell receptor (TCR) transgenic mice] were used to explore the effects of antigen-specific CD8 T cells on the genetically manipulated engraftment.

Results: In a mixed BM transplantation (BMT) setting, OVA-specific CD8$^+$ cells appear to have killed the 2bOVA^{tg} BM cells in all mixed BMT groups when OT-I BM cells were 10% or greater, demonstrating too many OVA-specific CD8$^+$ cells for successful engraftment of 2bOVA^{tg} BM under 660R total body irradiation (TBI). The 1% and 0.1% OT-I groups exhibited < 10% peripheral blood donor-derived leukocyte chimerism by week 7, with nearly 100% of donor-derived CD8$^+$ being Vα2$^+$Vβ5$^+$ OT-I-specific T cells. There were undetectable 2bOVA transgene by week 8 post-BMT and undetectable platelet-OVA protein expression at all time points. Similarly to the 0% control, the 0.001% group exhibited ~ 90% peripheral blood donor-derived chimerism, with only ~ 1-2% Vα2$^+$Vβ5$^+$CD8$^+$ T

cells and stable OVA expression over the study course. In the 0.01% group, 4 of 7 mixed BMT recipients exhibited parameters similar to the 0% control and 3 of 7 to those of the 1% and 0.1% groups. In the second model we examined, we transplanted OVA-specific OT-I CD8 T cells alongside 2bOVA^{Tg} BM cells to mimic the gene therapy scenario where engineered cells encounter primed CD8 T cells. We found that OVA-specific CD8^{+} T cells could be tolerized when the proportion of these cells was 0.5% or less in the presence of engineered 2bOVA^{Tg} BM mononuclear cells, and successful engraftment of 2bOVA^{Tg} BM cells was achieved. Flow cytometry analysis revealed that granzyme B (GrzmB) expression changed over time as OVA-specific CD8 T cells were tolerized. In

Conclusion, the findings indicate that a threshold of 0.5% antigen-specific CD8+ cells can be tolerated in platelet gene therapy. This level is conducive to achieving successful engineered engraftment in the primed model under conditions of 660 TBI. This insight is crucial for optimizing therapeutic strategies and ensuring effective outcomes in platelet gene therapy applications.

1751 A localizing nanocarrier formulation enables anti-enterovirus antibody responses from multivalent replicon RNA by limiting systemic interferon responses

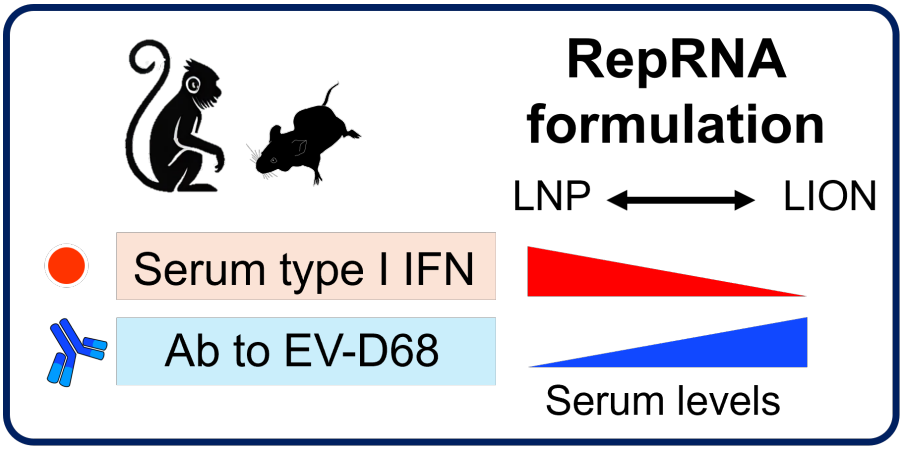
Replicon RNA (repRNA) vaccines are a promising platform for inducing robust immune responses at reduced doses. However, systemic inflammatory responses triggered by lipid nanoparticle (LNP)-formulated RNA vaccines may compromise both safety and immunogenicity. Cationic nanocarriers such as LION™ offer an alternative delivery approach by facilitating localized repRNA retention at the injection site. Here, we evaluated a multivalent repRNA vaccine encoding three distinct virus-like particles (VLPs) from different enterovirus D68 (EV-D68) subclades and two respiratory syncytial virus (RSV) antigens (F and G) in pigtail macaques. LION-formulated repRNA elicited robust antigen-specific antibody (Ab) responses while mitigating the systemic type I interferon (IFN) response observed with LNP formulations. Notably, elevated systemic type I IFN levels negatively correlate with EV-D68-specific binding and neutralizing Ab titers but not with RSV-F and G-specific binding Ab titers, suggesting antigen-specific sensitivity to IFN-mediated suppression. These findings underscore the importance of modulating innate immune activation to optimize the immunogenicity of multivalent repRNA vaccines. LION-based delivery may provide a safer and more effective platform for RNA vaccines targeting IFN-sensitive pathogens, with broader implications for refining RNA vaccine design in inflammatory settings.



1752 Alphaviral Genetic Background of Self-Amplifying RNA Influences Protein Expression and Immunogenicity Against SARS-CoV-2 Antigen

Irafasha Casmil[1], Nuthan Bathula[2], Cynthia Huang[2], Christopher Wayne[2], Evan Cairns[2], Josh Friesen[2], Shekinah Soriano[2], Suiyang Liao[2], Chia Ho[2], Kristen Kong[2], Anna Blakney[3]
[1]The University of British Columbia, Vancouver, BC, [2]The University of British Columbia, [3]University of British Columbia - Vancouver, Vancouver, BC

Introduction: Self-amplifying RNA (saRNA) vectors are a next-generation RNA technology that extends the expression of heterologous genes. Structurally similar to conventional messenger RNA, saRNA are designed to contain viral replicases and conserved sequence elements derived from alphaviruses. Clinical trials have shown the dose-sparing capacity of saRNA vectors as evidenced by 6-33 lower dosages of the approved ARCT-154 vaccine compared to Spikevax and Comirnaty messenger RNA vaccines against SARS-Cov-2. Historically, saRNA vectors have been based on a limited number of alphaviruses, and only the Venezuelan equine encephalitis virus-based saRNA vaccines have been used clinically. Blanketed application of the VEEV saRNA vector as a vaccine or protein replacement therapy is potentially problematic. The efficacy of a saRNA-based therapy will be affected by the expression profile, toxicity, translational efficiency, and cellular tropism, which are determined by the genotype of the alphaviral source and its interaction with the host cell. Therefore, this work sought to determine the suitability of unique alphaviruses as saRNA vectors and their utility as a vaccine platform.

Methods: Twelve unique alphaviruses were adapted into saRNA vectors encoding a green fluorescent protein or firefly luciferase. Expression kinetics of the saRNA vectors were assessed in mammalian cells, human skin explants and female Balb/c mice. Furthermore, competent saRNA vectors were re-configured into SARS-CoV-2 vaccine platforms and evaluated for their level of immunogenicity in C57Bl/6 mice.

Results: Five of the 12 saRNA vectors were replication-competent, resulting in higher protein production than the control saRNA by a 2 to 5-fold difference in fluorescent cells. Lipid nanoparticle delivery of saRNA vectors encoding the firefly luciferase (Fluc) into mice resulted in variable pharmacokinetics, enabling modulation of the magnitude and duration of protein expression. saRNA-Fluc vectors based on the VEEV TC83 variant, Tonate (TONV), Chikungunya (CHIKV) and O'nyong-nyong (ONNV) viruses resulted in 7.8-, 6.7-, 8.4- and 1.5-fold total expression as determined by the area under the curve of the total flux compared to the control saRNA vector derived from VEEV Trinidad Donkey variant. Additionally, standard homologous prime-boost vaccination of the saRNA vectors encoding the SARS-CoV-2 antigen resulted in differential humoral immunity before and after booster immunization. Two weeks after booster vaccination, the concentration of spike-specific IgG antibodies was 5- to 14-fold higher than the control saRNA. Except for the ONNV-saRNA vector, similar levels of antigen-specific splenocytes were observed after vaccination as determined by an interferon-gamma ELISpot assay. ONNV saRNA vaccination resulted in 2.7 higher anti-spike splenocytes. Interestingly, a heterologous vaccination regimen using distinct genotypes of saRNA resulted in differential immunity depending on the sequence of administration. Heterologous vaccination using CHIKV-VEEV (prime-boost) saRNA vectors resulted in a 7 times higher anti-spike IgG boost than the 1.4-times boost in the VEEV-CHIKV regimen.

Conclusion: Unique alphaviruses can be adapted into saRNA vectors. The genotype of the saRNA vectors influenced the magnitude and duration of expression as well as cellular and humoral immunity against an infectious disease antigen.

1753 T Cell Targeted mRNA tLNPs Drive Fast, Selective and Highly Effective in *situ* CAR T Cell Programming

Manfred Kraus[1], Ryan Landis[1], Amy Wang[1], Cafer Ozdemir[1], Joseph Parrella[2], BURAK YILMAZ[3], Balkrishen Bhat[1], Yusuf Erkul[1]
[1]*Kernal Biologics, Cambridge, MA,* [2]*Kernal Biologics, Cambrdige,* [3]*Cambridge, MA*

Chimeric Antigen Receptor (CAR) T Cell therapies have shown impressive clinical benefit in patients with hematologic malignancies. More recently, they have also shown encouraging signs of clinical efficacy in autoimmune diseases. However, all six of the CAR T therapies currently approved by the FDA and EMA have costly and time-consuming *ex vivo* T cell manufacturing protocols. In addition, these therapies are based on viral transduction resulting in permanent CAR expression that is associated with some safety concerns. On-target off-tumor activity of persistent CD19 CAR T cells kill healthy B cells leading to hypogammaglobulinemia with an increased risk of infections. Approved therapies now come with boxed warnings from regulatory agencies because viral transduction may be associated with secondary T cell leukemia and lymphoma. Recent developments in our mRNA LNP technology allow the design of a novel *in situ* CAR therapy benefitting from transitory CAR expression circumventing numerous potential risks of viral constructs while offering tremendous cost advantages over autologous cell-based therapies with *ex vivo* manufacturing protocols (Figure 1).

Materials & Methods: We developed T cell targeted LNP formulations (tLNP) via surface functionalization that achieve highly effective (>90%) uptake not only in activated but also in resting T cells. T cell targeting is achieved through surface functionalization of our LNPs via direct conjugation of targeting ligands onto the surface, enabling our tLNPs to bind to desired T cell-specific antigens and heighten delivery of our mRNAs into the cells *in vivo*. T cell-selective delivery is further enhanced with Kernal's peripheral LNP formulation that is optimized to redirect biodistribution away from the hepatic system and into secondary lymphoid organs, including the spleen, thymus, lymph nodes. Importantly, in addition to LNP targeting, we sequence engineer the mRNA payload for T cell selective CAR expression to limit the potential off-target CAR expression in different cell types.

Results: We developed T cell targeted tLNPs that exhibit reporter protein expression in nearly all $CD4^+$ and $CD8^+$ T cells (90%). The selectivity of mRNA-encoded receptor protein expression in T cells is >20-fold over myeloid cells and >60-fold over B cells. In addition to our *in vivo* data, we demonstrated similar selectivity in human peripheral blood mononuclear cells (PBMCs). Next, we delivered human CAR mRNAs into human primary T cells with targeted tLNPs and observed CAR-mediated T cell activation within 24 hrs. Furthermore, functional B cell depletion was achieved in mice with *in situ* CAR T cell programming. tLNPs encapsulating murine CAR mRNAs were intravenously administered to C57BL/6J mice. Within days, peripheral B cells in the blood were depleted, demonstrating the efficient CAR mRNA delivery into T cells, their quick activation and *in vivo* cytolytic capacity of *in situ* programmed CAR T cells.

Conclusion: Our goal is to advance our novel state-of-the-art in situ CAR T cell therapy, making a transformative difference in the way the therapy is administered, manufactured and tolerated. If successful, patients with B cell malignancies and with autoimmune diseases will benefit from these CAR mRNA tLNPs that induce effective B cell depletion *in vivo* with reduced side effects, owing to the highly cell-selective, and tolerable transient nature of targeted mRNA tLNP therapeutics.

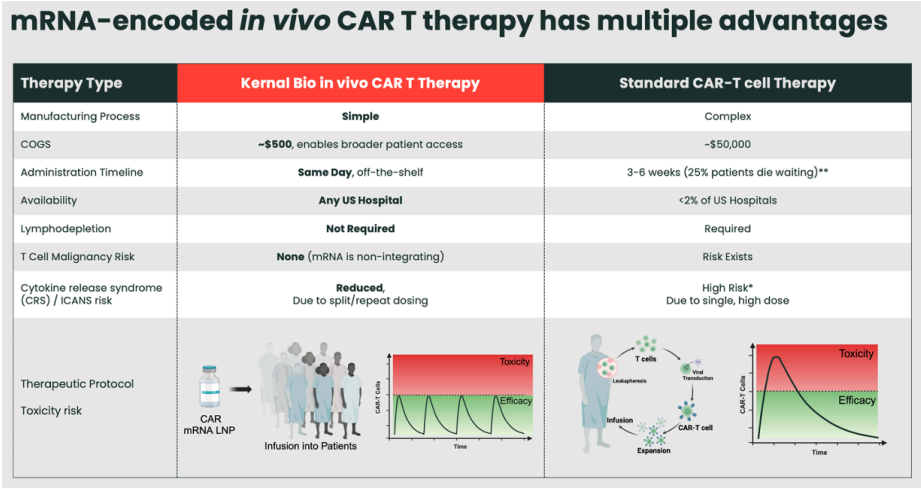

Figure 1. Comparison of standard with *in situ* mRNA tLNP CAR-T cell therapies.

1754 CD19-CAR and IL-10 Reprogramming of $CD4^+$ T Cells Generates Type 1 Regulatory CAR-T Cells for the Treatment of Autoimmune Disease

Autologous CAR-T cells have been remarkably successful in treating B-cell lineage malignancies. Building on this success, autologous CAR-T cell targeting of B cells in various autoimmune conditions has yielded promising early clinical data. However, broad implementation and delivery of autologous cell therapy to large numbers of patients still faces significant challenges, such as inflammatory toxicities (e.g., cytokine release syndrome (CRS) and ICANS), scaling manufacturing to reach all eligible patients, and high cost. Moreover, specifically targeting B cells by conventional CAR-T cells may be sub-optimal in T-cell and B-cell driven autoimmune diseases.

Type 1 regulatory T (Tr1) cells are a subset of peripherally derived FOXP3$^-$ CD4$^+$ T cells known to limit pathogenic T-cell responses across many inflammatory and autoimmune diseases. Tr1 cells suppress inflammation largely through secretion of the anti-inflammatory cytokines, IL-10 and TGF-b, in addition to contact-mediated T-cell suppression. To target autoimmune diseases driven by both B and T cells, we are developing TRX319, a CD19-CAR targeted, type 1 regulatory T (CAR-Tr1) cell product intended for allogeneic use and off-the-shelf availability. TRX319 combines both Tr1 immunoregulatory properties and B-cell depleting functionality to broadly target inflammatory and autoimmune pathways. TRX319 is generated by transducing isolated CD4$^+$ T cells with a lentiviral vector encoding both CD19-CAR and IL-10 through a production process that yields up to 1.6 x 10^{10} cells per manufacturing run.

TRX319 cells were highly pure, reaching 95.4 ± 2.5% CAR$^+$ at the end of manufacturing. TRX319 exhibited hallmark Tr1 characteristics, including a secreted cytokine profile of high IL-10, high IL-22, and low IL-2 relative to control CAR-T cells. The immunoregulatory capacity of TRX319 was demonstrated by suppression of effector T-cell proliferation and suppression of TNF-a and IL-1b secretion by activated monocytes. TRX319 cells demonstrated robust CAR-driven cytotoxicity against the CD19$^+$ NALM6 cell line and primary B cells from autoimmune disease patients in vitro. TRX319 also exhibited significant B-cell depletion in vivo and performed comparably to conventional CAR-T cells in the disseminated NALM6 B-cell leukemia model.

IL-10 reprogramming of CD4$^+$ T cells during TRX319 production resulted in reduced immunogenicity as demonstrated by reduced T cell activation and outgrowth in mixed lymphocyte reactions with multiple donors. This IL-10-dependent reprogramming was further associated with reduced proliferation of TRX319 in response to allogeneic HLA, suggesting that TRX319 presents a reduced risk of GvHD when administered in patients. Further, in an in vitro CRS model, TRX319 exhibited reduced potential to induce IL-6 secretion by monocytes compared to conventional CAR-T cells.

Overall, TRX319 is a promising allogeneic cell therapy for a broad range of autoimmune diseases by coupling Tr1-mediated regulatory function with CAR-T cytotoxicity against B cells.

1755 Role of CD4$^+$ T cell and NK cell subpopulations in CMV IFN-γ production in CMV-specific T-cell products

Sachie Ikegami[1]*, Parash Prasad[2], Ramesh Nayak[1], Daria Heyenbruch[1], Thomas Leemhuis[1], Caroline Alquist[1], Jeremey Rubinstein[1], Stella Davies[1], Michael Grimley[3], Carolyn Lutzko[2], Jose Cancelas[2]

Background: Third-party virus-specific T cell (VST) products represent a safe, effective therapy for cytomegalovirus (CMV) infections in post-transplantation, immunodeficient patients. However, understanding the mechanisms that transform donor anti-CMV immunity into clinically relevant anti-CMV activity in VST remains limited, hindering the optimization and standardization of potent, off-the-shelf VSTs. Current protocols use interferon-γ (IFN-γ) production as a surrogate for VST cytotoxicity. Donor CMV humoral immunity does not reliably predict the presence of cells responsive to CMV IFN-γ upon *in vitro* CMV peptide stimulation. There is a need to quantify factors such as HLA restriction of CMV immunodominant peptides, donor-specific cytotoxic activity, and manufacturing variations to evaluate their impact on clinical outcomes. We investigated the HLA and cellular factors influencing CMV IFN-γ production in CMV-seropositive donor-derived VST products.

Methods & Results: We analyzed 533 individual tetravalent VST products (generated following exposure to peptide libraries from CMV, EBV, adenovirus and BK viruses) derived from 281 CMV-seropositive and 252 CMV-seronegative donors of predominantly white Caucasian descent. We confirmed that the percentage of CMV IFN-γ-expressing T-cells in VSTs from CMV-seropositive donors was increased over 50 times [mean: 3.43 ± 4.9% vs. 0.06 ± 0.1%, $p<0.01$] compared to seronegative donors. HLA class I genotypes HLA-A*02:01, B*07:02, and C*08:01 were more frequently observed in CMV-seropositive donors ($p<0.05$). In contrast, the HLA class II genotype DRB1*04:01 was less frequently observed in CMV-seropositive donors compared to seronegative donors [24/281(8.5%) vs 40/252(15.9%), $p<0.01$]. However, these HLA alleles did not correlate with the frequency of CMV IFN-γ-producing cells in VST products. Phenotypic analysis of donor-derived mononuclear cells (MNCs) showed increased fractions of $CD8^+$ and $CD56^+$ cells in CMV-seropositive donors compared to CMV-seronegative donors ($p < 0.01$). Phenotypic analysis of VSTs revealed higher fractions of $CD8^+$ cells, lower fractions of $CD4^+$ cells ($p < 0.01$), and a reduced $CD4^+/CD8^+$ cell ratio ($p<0.05$) in CMV-seropositive donors. However, these differences showed only weak correlation with CMV IFN-γ production (r_s=0.12-0.37, $p<0.05$). In a representative subgroup of VST products with a wide range of CMV IFN-γ production capability (0.06-14.89%) from 8 CMV-seropositive and 6 CMV-seronegative donors, we found lower frequencies of naïve NKG2C-/NKG2A- $CD4^+$ T cells in VST products from CMV-seropositive donors compared to CMV-seronegative donors (55.5 ± 23.3% vs. 85.1 ± 7.3%; $p<0.01$, 95% CI: -49.6 to -9.5). These naïve $CD4^+$ T cells expressed lower levels of PD-1, a marker of T-cell exhaustion. We also found a strong correlation between CMV IFN-γ production and the content of NKG2A+ $CD4^+$ T cells (r=0.65-0.82, $p<0.01$), and both double-positive and double-negative NKG2C/NKG2A fractions in $CD16^+/CD56^{dim}$ mature NK cells (r=0.83 and -0.71, respectively, $p<0.01$).

Conclusion: The enumeration and typing of specific $CD4^+$ T cell and NK cell subpopulations of VST products may help in the selection of products with clinically-relevant adoptive immune activity against CMV infections. Our data suggests that IFN-γ plays a complex role in coordinating immune responses involving both adaptive and innate immune responses.

1756 *Overcoming Barriers for T-cell Therapy of Chronic Hepatitis B Virus Infection*

Lisa Schiller[1], Eva Loffredo-Verde[2], Sophia Schreiber[3], Anna Fürst[2], Percy Knolle[3], Ulrike Protzer[4]*
[1]Technical University of Munich, München, Bayern, Germany, [2]Technical University of Munich, Munich, Bayern, Germany, [3]Technical University of Munich, Munich, Germany, [4]Technical University of Munich, München, Germany

Hepatitis B virus (HBV) infection is a significant global health problem, with 254 million individuals with chronic infection and a death toll of 1.1 million/year. Current treatment options require lifelong therapy and only rarely achieve viral clearance. In cases of resolved infection, viral eradication is closely linked to a robust T-cell response, while chronically infected patients typically have few and partially dysfunctional T-cells. Adoptive T-cell transfer and therapeutic vaccination have emerged as promising alternative therapeutic strategies for restoring HBV-specific T-cell responses.

Michler et al. have previously shown that a therapeutic vaccination's effectiveness in mice strongly depends on the replication level of HBV, and the vaccine was less effective in high-level HBV-carrier mice. The first clinical studies demonstrated the efficacy of HBV T-cell receptor (TCR) T-cell therapy in patients with HBV-related hepatocellular carcinoma, achieving significant and sustained hepatitis B surface antigen HBsAg (HBsAg) reduction or clearance in 4 out of 6 patients. One patient with initially high HBsAg levels experienced recurring titers post-treatment. These results suggest that high viral antigen levels could prevent the induction of an effective immune response against HBV. Therefore, this study aims to clarify whether high HBV infection levels influence the efficacy of T-cell therapy. We infected immunocompetent C57BL/6 mice with an adeno-associated virus vector carrying a replication-competent hepatitis B virus genome at increasing titers to establish low- and high-titer HBV carrier mice. These mice received two doses of Cor93-TCR^+ $CD8^+$ T cells directed against the immunodominant epitope in the HBV core protein and were monitored over ten weeks. Blood and liver samples were obtained to analyze viral parameters, HBV-specific immune responses, and liver damage.

In low-titer HBV carriers, transferring $1x10^6$ TCR^+ T cells achieved viral clearance associated with transient liver damage. However, when the lower dose with $0.1x10^6$ TCR^+ T cells was administered, 4 out of 5 animals eliminated the virus. In contrast, animals with high infection levels did not achieve HBV clearance at all, regardless of the number of T cells transferred. When examining the transferred Cor93-TCR^+ $CD8^+$ T cells ex vivo by flow cytometry, we observed signs of exhaustion and dysfunction. T-cells showed an increased PD-1, Lag-3, TOX, and 41BB expression in the high-titer HBV-carrier mice, and ex vivo restimulation resulted in decreased cytokine secretion.

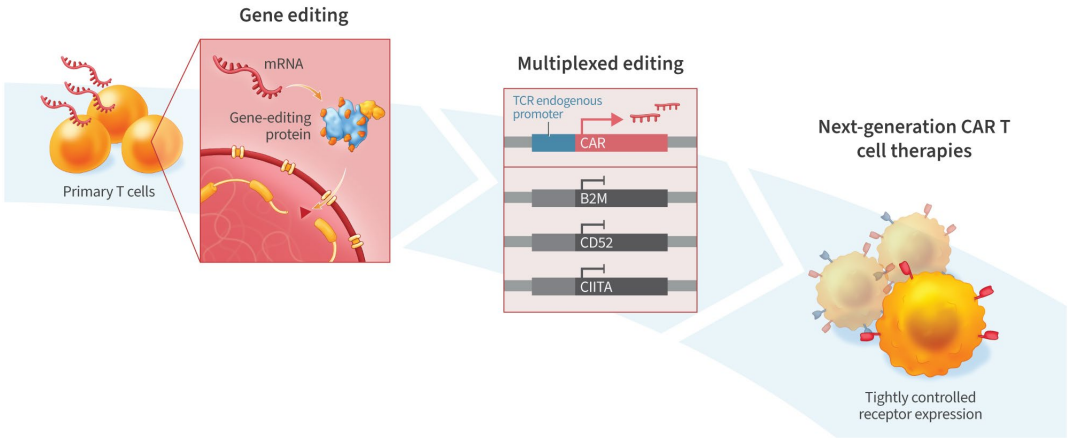
Our data indicates that viral titers significantly impact the effector function of TCR^+ T cells. Single-cell RNA sequencing analyses have been initiated to better understand the dysfunction of the TCR^+ T cells. This will provide deeper insights into the molecular patterns of the T cells, potentially revealing strategies to overcome the limitations of T-cell therapy for chronic HBV infection.

1757 UltraSlice Gene-Editing mRNA Enables Efficient Transgene Insertion into *TRAC* Locus in Primary Human T Cells

Ian Hay[1], Matthew Angel[2]*, Christopher Rohde[2], Ismet Tanrikulu[2]
[1]*Factor Bioscience, Cambridge, MA,* [2]*Factor Bioscience Inc., Cambridge, MA*
**Corresponding Author*

Chimeric antigen receptor (CAR) T cell therapies can successfully treat B cell malignancies and have shown promising results for autoimmune conditions such as systemic lupus erythematosus (SLE). However, manufacturing complexities of autologous CAR T cell therapies have limited their widespread use. Allogenic CAR T cell therapies are being developed to address these limitations, yet CAR insertion with lentiviral and retroviral vectors present their own manufacturing challenges at scale, and allogenic CD19 CAR T cells generated using these vectors have shown lower persistence and expansion *in vivo* than their autologous counterparts. Placing CAR expression under the control of the endogenous T cell receptor promoter by targeted insertion of the CAR transgene to the *TRAC* locus has demonstrated lower levels of T cell exhaustion and enhanced persistence in animal models. Efficient gene editing strategies to precisely engineer CAR T cell therapy products may therefore overcome the manufacturing, persistence, and expansion challenges of existing technologies.

Here, we show that novel mRNA-encoded gene-editing nucleases enable efficient targeted insertion of a CD19 CAR transgene into the *TRAC* locus in primary human T cells. Electroporation of mRNA encoding UltraSlice™ sequence-specific endonucleases results in on-target editing of *TRAC*, *B2M*, *CD52*, and *CIITA* with up to 80% knock-out efficiency as assessed via flow cytometry of TCRαβ, HLA-ABC, CD52, and HLA-DR, respectively. Co-delivery of a transgene sequence resulted in insertion into the *TRAC* locus with 42% efficiency, as assessed by flow cytometry and PCR (n=3 PBMC donors). Simultaneous delivery of mRNA encoding UltraSlice™ targeting *TRAC* and *B2M* enabled multiplexed gene knockout, with 23% of cells demonstrating lack of both TCRαβ and HLA-ABC surface receptors, as assessed by flow cytometry. Co-delivery of *TRAC*- and *B2M*-targeting UltraSlice™ mRNA and a *TRAC*-targeted CD19 CAR transgene sequence yielded CD19 CAR T cells lacking both TCRαβ and HLA-ABC. Up to 6% of T cells expressed the CD19 CAR 72 hours after electroporation, comparable to lentiviral transduction. *TRAC*-replaced CD19 CAR T cells lysed 65% of RAJI B cells, significantly more than wildtype T cells (15%, $p<1e-5$). The efficient generation of potent allogeneic CAR T cells using UltraSlice™ gene editing mRNA may prove useful for the development of more affordable and reliable cell therapies.



1758 Second Generation CD4^{+} CAR T Cells Incorporating a 2B4 Cosignaling Domain Exhibit Enhanced Proliferation and CD8^{+} CAR Help

Reyes Acosta[1], Daniel Claiborne[2], Dalia Bercow[3], Tyler Yang[4]
[1]University of Pennsylvania School of Medicine, Philadelphia, PA, [2]Wistar Institute, [3]Wistar Institute, Philadelphia, [4]Wistar Institute, Philadelphia, PA

Background: Despite early studies on redirected cytotoxic T lymphocytes to specifically recognize HIV envelope-expressing cells, and the success of chimeric antigen receptor (CAR) T cell therapy for treatment of B cell malignancies, successful CAR T cell therapy for HIV has remained elusive. Particularly, the lack of persistence and long-term efficacy in patients is a central hurdle for current CAR T therapies. Expanding the intracellular cosignaling domain (ICD) repertoire to include receptors found on early responding/innate cells may expand the knowledge of how signaling domains from other cell types modulate T cell function. This may in turn inform immunotherapies tuned to optimize distinct aspects of T cell function.

Methods: CD4 and CD8 T cells were separated prior to manufacture and redirected with lentiviral vectors expressing CARs comprised of an HIV-envelope targeting CD4 receptor and one of ten unique costimulatory domains from receptors differentially expressed on αβ T cells, B cells, and NK cells. CAR T cells were assessed for antigen-induced proliferation, HIV suppression, and targeted lysis *in vitro* at baseline and during chronic antigen stimulation.

Results: While CD244 (2B4) is considered an activation receptor on natural killer cells, signaling through adaptor molecules SH2D1A (SAP) or SH2D1B (EAT-2), it is often considered an inhibitory receptor on T cells. Therefore, we sought to engineer and further interrogate CD4-ectodomain (CD4E) CAR T cells with an intracellular 2B4 cosignaling domain to determine the functional impact of 2B4 signaling on CD4 and CD8 T cells. When tested in a panel of 10 distinct cosignaling domains, 2B4^{CAR4} exhibited superlative antigen-driven proliferation over several weeks of stimulation, which was not the case for 2B4^{CAR8}. Further, in an *in vitro* co-culture assay, 2B4^{CAR4} improved expansion of CD28^{CAR8} as compared to CD3z^{CAR4}, CD28^{CAR4}, or 41BB^{CAR4}. In a comparison between co-culture and transwell assays, the fold expansion was significantly higher in cell-cell contact conditions as compared to transwell separation, suggesting that CD4 T cell help to CD8s is contact-dependent. To better understand the effect of 2B4 cosignaling domain on CD8 T cell expansion and survival, we cultured CD4 and CD8 T cells separately *in vitro* and redirected them with CAR vectors containing CD28 or 2B4 ICDs. Immunodeficient mice were reconstituted with human donor CD4 T cells followed by singular injection of CD28^{CAR8} cells or co-injection of CD28^{CAR8} with CD28^{CAR4} or 2B4^{CAR4}. Co-injection of CD8 CAR T cells with 2B4^{CAR4} exhibited the highest expansion levels. Finally, we show that SAP and SHP-2 transcripts are upregulated to similar levels after antigen-driven stimulation;

but, in contrast, at both baseline and post-stimulation, CAR T cells show little to no EAT-2 transcript expression. Importantly, EAT-2 is thought to play a role in the inhibitory nature of CD244 signaling.

Conclusions: 2B4 contains four cytoplasmic immunotyrosine-based switch motifs (ITSMs), which can either be costimulatory or inhibitory depending on which ITSM is phosphorylated, the overall expression level of the receptor itself, and the level of signaling adaptor molecules SAP (SH2D1A) or EAT-2 (SH2D1B). This data suggests that in the context of CD4+ CAR T cells, the 2B4 signaling domain is capable of being co-opted as a costimulatory domain, enhancing persistence of CD4+ CAR T cells and improving the initial expansion of CD8 CARs.

1759 Synergizing Broadly Neutralizing Antibody-Secreting T Cells and CAR-T Cells Against HIV-1 Infection

Hang Su[1], Jianhua Zheng, Agnes Sydenstricker[1], Scott Garforth, Ying Xiong[2], Gregory Sowd[2], Zhongyu Zhu[2], Boro Dropulic[2], Steven Almo, Harris Goldstein
[1]Albert Einstein College of Medicine, Bronx, NY, [2]Caring Cross, Gaithersburg, MD

Introduction: A functional cure of HIV-1 is precluded by latent HIV-1 reservoirs that cause viral rebound when antiretroviral therapy (ART) is interrupted. Broadly neutralizing antibodies (bNAbs) that target highly conserved HIV gp120 epitopes can maintain HIV-1 suppression in people living with HIV (PLWH) in the absence of ART, providing an approach to achieve ART-free HIV-1 remission. However, monthly or bi-monthly administration may be required to maintain therapeutic levels of bNAbs, which can reduce adherence. Genomically engineered T cells, such as CAR-T cells, have shown decade-long persistence with therapeutic function and can migrate to areas of infection where free bNAb may have limited access to. We hypothesize that T cells can be engineered to sustainably secret bNAbs. As a proof-of-concept, we engineered a lentiviral vector (LV) encoding 3BNC117 bNAb (3BNC) to transduce T cells. We further evaluated the synergistic effects of 3BNC-expressing T (3BNC-T) cells and anti-HIV CAR-T cells against HIV-1 infection.

Methods: CD3+ T cells were purified from both healthy donors and PLWH, transduced with 3BNC LV and evaluated *in vitro* for anti-HIV activity and 3BNC production by co-culturing with autologous HIV-1-infected PBMCs. 3BNC-T cells were intrasplenically injected into NSG mice and maintained for 2 months to monitor long-term 3BNC secretion. *In vivo* synergistic antiviral function was determined by intrasplenical co-injection of autologous HIV-1-infected PBMCs and effector cells (3BNC-T or CAR-T cells alone or both) into NSG mice. Viral suppression and 3BNC serum levels were measured after 2 weeks.

Results: The transduction efficiency of 3BNC LV was comparable between healthy donors and PLWH. 3BNC was produced at comparable levels between healthy donors and PLWH. At an E:T ratio of 5:1, 3BNC-T cells suppressed HIV-1 infection by an average of 53 ± 1 % *in vitro* as compared to untransduced T cells, with a mean 3BNC concentration of 232 ± 48 ng/ml. In addition, the combination of 3BNC-T and CAR-T cells elicited significant enhancement of HIV-1 killing as compared to CAR-T cells alone ($p < 0.01$). To determine the *in vivo* production of 3BNC, 30 x 10^6 T cells (59% were 3BNC+) were intrasplenically injected into NSG mice. Plasma 3BNC concentration measured weekly were above 1.5 µg/ml throughout the 8-week experiment. In HIV-1-infected NSG mice, plasma 3BNC levels were detected in 3BNC-T cell only (323 ± 46 ng/ml) and combination therapy (414 ± 60 ng/ml) treated animals. Plasma HIV-1 RNA (copies/ml) was most suppressed in combination therapy treated mice (6.0 ± 2.1 x 10^4), followed by CAR-T cell only treated mice (2.5 ± 1.1 x 10^5), compared to control mice (7.2 ± 1.5 x 10^5). Consistently, spleen HIV-1 DNA (copies/ul) was most suppressed in combination therapy treated mice (24.3 ± 5.0), followed by CAR-T cell only treated mice (51.0 ± 5.5), compared to control mice (114.5 ± 40.5). There was no HIV-1 suppression in 3BNC-T cell only treated mice.

Conclusions: We successfully engineered T cells that secrete bNAb, and exhibit *in vitro* anti-HIV function and sustained *in vivo* bNAb production. BNAb-secreting T cells can synergize with CAR-T cells both *in vitro* and in mice to enhance HIV-1 killing as compared to CAR-T cells alone. This novel therapy combining cellular and humoral anti-HIV approach provides a new strategy to generate more potent immunotherapeutics, which may contribute to a functional cure of HIV-1 infection.

1760 Enhancing Engineered B Cells through Expression of B Cell Activating Molecules

Atishay Mathur[1], Geoffrey Rogers[2], Chun Huang[2], Hsu-Yu Chen[2], Catherine Diadhiou[2], Chan-Hua Chang[2], Paula Cannon[3]
[1]USC, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]University of Southern California, Los Angeles, CA

We use CRISPR/Cas9-mediated gene editing to engineer B cells to express custom heavy-chain only antibodies (HCAbs) against hard-to-vaccinate targets such as HIV[1]. The edited B cells express both B cell receptor (BCR) and secreted antibody isoforms and retain important natural features of B cell biology, such as the ability to respond to antigen in tonsil organoid models of immunization. However, in addition to the signals resulting from the interaction of a BCR and its target antigen, B cells also require co-stimulatory signals. These are primarily provided by helper T cells, and allow the B cells to enter germinal centers, expand, generate memory cells, and differentiate into long-lived plasma cells. However, helper T cell functions are frequently impaired in people living with HIV, even when the disease is well-controlled by antiretroviral drugs[2]. Therefore, we are interested in developing a strategy that enhances the ability of HCAb-engineered B cells to respond to antigens *in vivo*, even after ex vivo culture and in immunocompromised hosts.

Toward that goal, we screened a panel of synthetic molecules, designed to mimic the co-stimulatory signals received by B cells and to induce a range of B cell activation states. Among these B cell activating molecules (BAMs), we identified constitutively active, drug-inducible, and chimeric antigen receptor-based BAMs that activated B cells *in vitro*. BAM-expressing B cells had higher fitness in the tonsil organoid model and expanded even in the absence of antigen. Finally, bulk RNA-sequencing revealed a candidate BAM that specifically induced pathways associated with T cell help, B cell-T cell interactions and class II antigen presentation. Finally, because HIV infection perturbs the ability of T cells to provide help to B cells, we are currently evaluating whether dual-engineered HCAb/BAM cells are better able to control HIV infection in tonsil organoids.

In sum, we propose a novel approach to enhancing the functionality of engineered B cells under conditions where T cell help may be suboptimal, such as HIV infection, oncology or autoimmune diseases.

1761 Enhanced CART Function by Arming CAR-T Cells with Cytokines

Luhan Yang[1], Lina Zhou[2], Jiapan Hu[2], Wancheng Yang[2], Yixuan Zhou[2], Yinghao Zhu[3], Fei Yang[2], Nian Chen[2], George Church[4]
[1]Qihan Biotech, Hangzhou, China, Peoples Republic of China, [2]Qihan Biotech, Hangzhou, China, [3]Qihan Biotech, Hangzhou, Zhejiang, China, [4]Harvard Medical School, Boston

Despite the remarkable success of Chimeric Antigen Receptor T-cell (CAR-T) therapy in treating hematologic malignancies, its efficacy in solid tumors and long-term response is often hindered by T-cell dysfunction and poor persistence. Cytokines are essential regulators of immune responses, and their optimization could enhance CAR-T cell function. Many pro-inflammatory cytokines such as IL15, IL12 and IL7 have been utilized in the adoptive cell transfers and their clinical applications are hindered by toxicity associated with systematic expression of cytokines.

On the contrary, some unconventional cytokine such as IL10 and IL4 are reported to enhance CART function while does not trigger systematic toxicity.

In this study, we systematically screened 20 cytokines that does not seem to be pro-inflammatory and belong to the common beta chain family, IL6 family and common gamma chain family, and IL10 families. Using tumor-bearing mice model, we found 12 novel cytokines that can potentially enhance CART functions in vivo without incurring apparent toxicity in the mice model. Interestingly, we found dosage dependent feature for different cytokines, some of them are beneficial with both MOI transduction and some of them only work for low or high concentration. We quantified the increased of efficiency by titrating the amount of CART-cytokine infusion cell number and found some of them will enhance the efficacy with < 1% of the wt CART without cytokine infusion. To further explore the therapeutic potential of this finding and minimize the systematic impact of this cytokine, we attempted to engineer the cytokine receptor pathway of the identified factors. We successfully recapitulate the results of cytokine-X effect by having the constitutive activation receptor. Such construct increases the cart efficacy in vivo and seems to not tumorigenesis based on cytokine independent growth assay and PK in the tumor bearing mice model.

Taken together, tur results highlighted specific cytokines that not only enhanced CAR-T cell expansion and persistence but also improved their anti-tumor activity. Moreover, certain cytokines demonstrated a synergistic effect, further potentiating CAR-T cell function. These findings present new avenues for cytokine-based strategies to optimize CAR-T cell therapies and provide a foundation for future clinical trials aimed at enhancing the therapeutic potential of CAR-T cells in cancer treatment.

1762 In Vivo Generation of anti-CD19 CAR T Cells Utilizing Circular RNA Encapsulated in Targeted Lipid Nanoparticles

Xiaoyu Pan[1], Xiaoning Wang[2], Zhihao Chen[3], Xiaowen Zou[3], Siqi Li[2], Jian Ye[2], Fei Lin[2], Yang He[2], **Edo Kon[4]**, Weiyi Zhang[2]
[1]RiboX Therapeutics, Shanghai, China., Shanghai, China, [2]RiboX Therapeutics, Shanghai, China, [3]RiboX Therapeutics, Shanghai, Shanghai, China, [4]RiboX Therapeutics, Cambridge, MA

Background: Chimeric Antigen Receptor (CAR) T-cell therapy has revolutionized cancer treatment and shown promise in addressing autoimmune diseases. However, current *ex vivo* CAR T-cell therapies encounter challenges such as complex manufacturing processes, scalability issues, reliance on viral vectors, and the necessity for lymphodepleting chemotherapy, which limit broader clinical applications. To address these limitations, there is a critical need for an off-the-shelf *in vivo* CAR technology that can simplify delivery and expand therapeutic potential. We have developed tLNP-circCAR, a novel in vivo anti-CD19-CAR circular RNA product delivered via targeted lipid nanoparticles (tLNPs). Preclinical studies in animal models demonstrate its efficacy in B cell depletion, marking a significant advancement towards overcoming existing barriers in CAR T-cell therapy and expanding its applicability to a broader range of diseases.

Methods: tLNP-circCAR encapsulates a circular RNA encoding an anti-CD19-CAR within a tLNP containing a novel ionizable lipid and a T cell targeting domain, enabling efficient transfection of primary human T cells. The functional activity of tLNP-circCAR-mediated CAR T cells was evaluated using multiple *in vitro* and *in vivo* systems.

Result: In activated primary human T cells, circCAR mediated CAR expression lasted up to 9 days. Notably, tLNP-circCAR efficiently engineered non-activated primary human T cells into functional CAR T cells. *In vitro*, these engineered CAR T cells exhibited robust cytotoxicity against autologous B cells and the $CD19^+$ Raji cell line. *In vivo*, utilizing a humanized NOG-PBMC mouse model, a single intravenous dose of tLNP-circCAR resulted in efficient CAR engineering of T cells, leading to significant B cell depletion in the spleen. Additionally, in humanized NOG-PBMC mice bearing CD19+ Raji lymphoma xenografts, tLNP-circCAR treatment induced tumor remission.

Conclusion: tLNP-circCAR represents a novel *in vivo* CAR therapy that delivers therapeutic anti-CD19 CAR circular RNA efficiently to human T cells, generating highly functional CAR T cells both *in vitro* and *in vivo*. These

results support the further development of tLNP-circCAR for treating B cell disorders, including B cell lymphoma and autoimmune diseases. This innovative approach promises to enhance the accessibility and efficacy of CAR T-cell therapy.

1763 INB-600: A Novel T Cell Engager Platform Specific for gamma-delta (γδ) T cells

Lei Ding[1], Sadhak Sengupta[2], Yanjie Li[3], Mariska Ter Haak, Kate Rochlin[4], **Lawrence Lamb***
[1]In8BIO, New York, NY, [2]IN8Bio, Inc., Birmingham, AL, [3]IN8bio, Birmingham, AL, [4]IN8bio
**Corresponding Author*

Introduction: Although autoreactive B cells comprise only 0.1-0.5% of total B cells, current long-term depletion strategies remain inadequate, exposing patients to severe treatment-related side effects, potential mortality, and impaired quality of life. Clinical data with alpha-beta (αβ) T cell-based chimeric antigen receptor T cell (CAR-T) and T cell engagers (TCE) have demonstrated risks of cytokine release syndrome (CRS) or neurotoxicity (ICANs) and in the case of CAR-T, may require lymphodepletion protocols that can result in ovarian damage and infertility. In patients across three trials (NCT03533816, NCT04165941, and NCT05664243) in two indications and at multiple centers, neither CRS nor ICANs have been observed in patients treated with gamma-delta (γδ) T cells to date. γδ T cell engagers (γδ TCEs) represent a new frontier in immunotherapy, leveraging the unique properties of γδ T cells to provide MHC-independent target recognition, strong immune activation, and improved treatment safety. We now present a novel bi-specific γδ TCE that enables binding and robust expansion of both major γδ T cell subsets and the elimination of target cells. Although IN8bio is developing this CD19-γδ TCE (INB-619) for potential applications in both autoimmune disease and hematologic malignancies, autoimmune indications are presented here.

Methods: INB-619 is added to the culture of γδ T and target cells, and the TCE binding specificity, T cell activation, TCE-induced target cell cytotoxicity, and cytokine release were analyzed by flow cytometry. To determine B cell depletion, γδ T cell expansion, and optimal dosing, incremental concentrations of the INB-619, along with a no-treatment (NT) control and zoledronate treatment (Zol), were cultured with peripheral blood mononuclear cells (PBMC) for up to 10 days from two healthy donors.

Results: INB-619 exhibited concentration-dependent cytotoxicity at an effector-to-target (E:T) ratio of 1:1 against the CD19+ Nalm6 cell line but did not bind nor kill the CD19- myeloid cell line, MOLM-13, at any concentration. Early observations suggest partial competitive binding with Zoledronic acid-derived isoprenyl pyrophosphate, potentially indicating non-exclusive Vd2 receptor binding. Treatment with γδ TCE in a co-culture of γδ T cells and CD19+ Nalm6 target cells (E:T = 1) induced concentration-dependent γδ T cell degranulation, upregulation of activation markers, and the release of inflammatory cytokines such as TNF-α, IFN-γ, IL-4, minor concentrations of IL-17 and IL-6, and cytotoxic molecules including perforin, granzymes, and granulysin. The culture of INB-619 with PBMC revealed a concentration-dependent expansion of both Vd1+ and Vδ2+ γδ T cells up to 450-fold over 10 days, which was sustained through the complete elimination of B cells.

Conclusion: In addition to its specific target binding and robust cytotoxicity, this novel γδ TCE promotes the expansion of both Vδ1+ and Vδ2+ γδ T cells, thereby sustaining its killing effect over time. This approach harnesses the advantages of Vδ2-mediated antigen processing and the long-term durability of Vδ1+ T cells. Should this approach be confirmed in autoimmune disease models, INB-619 could represent a promising off-the-shelf therapy for autoimmune diseases, potentially with fewer side-effects, mobilizing both circulating and tissue-resident γδ T cells to eliminate autoreactive B cells and reset B cell hematop

1764 Treg Specific Synthetic Promoters (TRSP) for Antigen Specific Treg Therapy

Jia Wei[1], Elizabeth Ni[2], Aditi Makhija[1], Zhang Cheng[3], Joshua Beilke[2]
[1]Sonoma Biotherapeutics, Seattle, WA, [2]Sonoma Biotherapeutics, South San Francisco, CA, [3]Sonoma Biotheraputics, San Diego, CA

Antigen-specific regulatory T (Treg) cell therapy holds promise for treating autoimmune disorders, preventing organ transplant rejection, and managing inflammation-associated diseases. However, several challenges arise from the intrinsic properties of Treg cells, including the difficulty of generating pure antigen-specific Treg cells without effector T (Teff) cells contamination, maintaining Treg stability under inflammatory conditions, and ensuring in vivo persistence (1,2).

We developed **Tr**eg **s**pecific **S**ynthetic **P**romoters (TRSP) as a robust solution for addressing key challenges in Treg-based therapy through a high throughput library screening. With a remarkably small footprint, TRSP demonstrated Treg-specific expression and minimal activity in Teff cells, outperforming the published CNS123p promoter derived from endogenous human *FOXP3* regulatory elements (3). More importantly, TRSP transcriptional activity was absent in destabilized Treg cells, whether caused by internal tonic CAR signaling or by exposure to proinflammatory cytokines. Furthermore, TRSP-CAR Treg cells exhibited superior suppressive cytokine profile and functional suppressive effects compared to Treg cells expressing the same CAR under the MND promoter. To assess safety, we engineered Tregs and Teffs with a constitutive IL2 signal for persistence. MND-based constructs promoted Teff expansion, whereas TRSP constructs did not, confirming their safety in the presence of Teff contamination in the cell product. Lastly, to accommodate diverse therapeutic needs, we developed a toolbox of TRSP variants with various transcriptional strengths, all maintaining Treg specificity.

Overall, our TRSP solution enables precise, Treg-specific payload expression, which significantly enhances the safety and efficacy of antigen-specific Treg therapies and ensures the promise of Treg cell therapy.

1765 AlloNK: A Scalable and Consistent NK Cell Therapy in Development for Treatment of Oncology and Autoimmune Diseases

Stephanie Moreno[1], Luis Solchaga[1], Seungryel Han[2], Sanghyun Lee[2], Jaeger Davis[1], Meghan Eberhardt[1], Yu-Jung Chang[1], Claudia Palomino La Torre[1], Gina Chu[3], Lisa Guerrettaz[1]*, **Amanda Conerty[1]***
[1]Artiva Biotherapeutics, San Diego, CA, [2]GC Cell Corporation, Yongin-si, South Korea, [3]Artiva Biotherapeutics, San Diego
**Corresponding Author*

Background: AlloNK® (AB-101) is a non-genetically modified, allogeneic, off the-shelf, cryopreserved natural killer (NK) cell therapy candidate in development for the treatment of cancer and autoimmune diseases. A highly scaled manufacturing process enables production of thousands of 1 billion cell doses from a single donor cord blood

unit (CBU). AlloNK in combination with B-cell depleting monoclonal antibodies (mAbs) has the potential to enhance the antibody-dependent cellular cytotoxicity (ADCC) response thereby leading to deeper B-cell depletion without the safety challenges associated with T-cell approaches, including high rates of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Initial clinical data with rituximab and AlloNK in subjects with advanced B-cell malignancies showed that this treatment approach is well tolerated, and preliminary efficacy of the combination treatment is encouraging (Khanal R 2023). AlloNK is currently in multiple clinical trials as a cellular therapeutic for cancer and autoimmune disease. Here we report on AlloNK manufacturing scale, consistency of viability and cytotoxic activity across multiple drug product (DP) lots.

Methods and Results: CBUs are pre-selected for killer-cell immunoglobulin-like receptor (KIR)-B haplotype and the natural high-affinity variant of CD16 (158V/V polymorphism), which is associated with ADCC enhancement, resulting in a highly active NK cell product without the requirement for additional engineering. Following isolation, the NK cells are expanded utilizing a proprietary engineered feeder cell (eFeeder) to derive a master cell bank (MCB). One CBU yields ≥50 cryopreserved vials of MCB. MCB production is followed by a bioreactor-based (50L) industrial scale NK cell expansion and activation process to produce the DP. At this scale, a DP manufacturing run can produce ≥110-115 billion NK cells from a single vial of MCB with over ~98% CD3-/CD56+ purity and high CD16 expression. With at least a 4-year shelf life, AlloNK demonstrates robust viability pre and post cryopreservation, with ~95% viability pre-cryopreservation and ~94% viability post-thaw. A consistent AlloNK-mediated dose-dependent potency is observed in both short-term and long-term cytotoxicity assays, with minimal variability between lots. Long-term ADCC assays also demonstrate prolonged killing activity in combination with anti-CD20 mAbs against ARH-77, a B lymphoblast cell line.

Conclusions: The current scale of AlloNK production from CBU to DP equates to ≥ 4,000 net vials of 1 billion NK cells per CBU, which is enough to potentially treat >1,000 patients (assuming administration of 3 billion cells per patient). The drug product generated is uniformly high in CD16 expression and has consistent potency across lots. The current scale can support both clinical trial demand as well as potential commercial launch. The manufacturing platform will allow for scaling the process to support full commercial production, without significant process modifications. Developing scalable manufacturing solutions with AlloNK is essential to meet the growing demand for cell therapies across various disease areas.

**Corresponding Author*

Autologous CAR-T cell therapy has demonstrated substantial efficacy in hematologic malignancies, and preliminary data suggest promising results in B cell-mediated autoimmune diseases such as systemic lupus erythematosus (SLE) and systemic sclerosis. However, challenges such as limited accessibility, manufacturing complexities, and the potential for immune-mediated side effects remain. Allogeneic CAR-γδT cells, derived from healthy donors, offer several advantages, including off-the-shelf availability, lower manufacturing costs, and a reduced risk of immune escape. These characteristics make allogeneic CAR-γδT cells a promising alternative for the treatment of B-cell malignancies and autoimmune diseases.
We used lentiviral vectors to deliver a CD19 CAR with a 4-1BB co-stimulatory domain to Vδ2 T cells. *In vitro* experiments demonstrated that CD19 CAR-γδT cells efficiently eliminated CD19-positive Raji and Nalm-6 tumor cell lines and released significant amounts of IFN-γ. Serial killing assays showed that CD19 CAR-γδT cells exhibited sustained anti-tumor activity. To reduce the risk of Host versus Graft (HvG) rejection, we utilized the GDance® platform to reduce the immunogenicity of the CD19 CAR-γδT cells. *In vitro* experiments revealed that

this genetic modification significantly decreased allo-reactive T cell rejection but did not induce killing by allogeneic NK cells, and it did not impair the anti-tumor activity of the CAR-γδT cells. In mouse xenograft models, CD19 CAR-γδT cells effectively inhibited the progression of B-cell leukemia and lymphoma and significantly prolonged the survival of the mice. Additionally, CD19 CAR-γδT cells demonstrated the ability to rapidly eliminate B cells *in vitro*. In humanized mouse models reconstituted with CD34+ hematopoietic stem cells, infusion of CD19 CAR-γδT cells resulted in complete clearance of peripheral blood B cells.
Our preclinical study demonstrates that allogeneic CD19 CAR-γδT cells exhibit robust anti-tumor activity against CD19-positive B cell and malignancies *in vitro* and *in vivo*. These findings support the potential of allogeneic CD19 CAR-γδT cells in treating B-cell malignancies and autoimmune diseases such as SLE and systemic sclerosis, with clinical trials already underway.

1767 Advancing Non-Opioid Pain Management for Osteoarthritis: SN101 Nociceptor Cell Therapy Approach

Tea Soon Park[1], Zhoulun Poppy Wang[2], Weixin Zhang[3], Daniel Saragnese[1], Xinzhong Dong[2], Gabsang Lee[2]
[1]SereNeuro Therapeutics, Baltimore, MD, [2]SereNeuro Therapeutics and Johns Hopkins School of Medicine, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore

Osteoarthritis (OA) is a prevalent condition affecting 250 million people worldwide, with knee OA (KOA) representing the most common form. Chronic pain from KOA, including nociceptive and neuropathic pain, severely impacts quality of life, mobility, and increases reliance on opioids for pain management. Despite promising advances in non-opioid analgesic development, challenges persist due to species-specific differences in pain signaling molecules. Recent breakthroughs in stem cell therapies, particularly human pluripotent stem cells (hPSCs) and human induced pluripotent stem cells (hiPSCs), offer innovative alternatives for chronic pain management by providing an off-the-shelf solution for targeted pain control.

In this study, we explored the potential of hiPSC-derived nociceptor cells and gene therapy approaches to address chronic pain in OA. First, we generated purifiable populations of human sensory neurons, including transient receptor potential cation channel subfamily V member 1 (TRPV1)+, sodium voltage-gated channel alpha subunit 9 (SCN9A)+, and Mas-related G protein-coupled receptor X1 (MRGPRX1)+ neurons from hPSCs. These subsets demonstrated distinct functional polymodalities, with a transcriptomic continuum revealing that mature hPSC-derived sensory neurons (hPSC-SNs) accurately recapitulate the key molecular profiles of human dorsal root ganglia (DRG) neurons.

We tested the therapeutic potential of SN101 hiPSC-derived nociceptor cells in a mouse model of KOA. These SN101 cells, characterized by the expression of pain-related markers SCN9A and TRPV1, exhibited pain-sensing properties *in vitro*, exhibited by calcium influx to noxious stimuli such as capsaicin, mustard oil, and menthol as well as synovial fluid from patients with OA. When transplanted *in vivo*, SN101 cells act as decoys to competitively bind to inflammatory ligands. This mechanism intercepts pain signals typically transmitted by endogenous nociceptors, effectively reducing pain behaviors and alleviating mechanical hypersensitivity. Histological analysis revealed reduced expression of injury markers (ATF3) and pain markers (CGRP) in the DRGs innervating knee joints.

Together, these findings demonstrate that SN101 hiPSC-derived nociceptor cells offer a promising strategy for managing chronic pain in OA. By exploiting the hypoimmunogenic properties of iPSCs and the distinct functional profiles of nociceptor subtypes, SN101 is a novel, non-opioid-based solution for managing pain while also modulating pain transmission at the peripheral level.

1768 *ex vivo* Gene therapy for Artemis-SCID and leaky-SCID patients: results of the French ARTEGENE phase I/II clinical trial

Jean-Sébastien DIANA[1], Despina Moshous[1], Martin Castelle[1], Boris Bessot[2], Elisa Magrin[1], Marwa Chbihi[1], Paul Bastard[1], Alice Girardot[1], Chloe Mollet[1], Cecile Roudaut[1], Axelle Maulet[1], Aurelie Gabrion[1], Clotilde Aussel[1], Eden Schwartz[1], Caroline Tuchmann[1], Olaf Neth[3], Peter Olbrich[3], Irene d'Alba[4], Jacques Riviere[5], Mehdi Oualha[1], Laure Joseph[1], Aurore Touzart[1], Benedicte Neven[1], Jean-pierre de Villartay[2], Anne Galy[6], Chantal Lagresle-Peyrou[7], Marina Cavazzana[8]
[1]APHP, Paris, Paris, France, [2]Institut Imagine, Paris, Paris, France, [3]Hospital Infantil Universitario Virgen del Rocio, Sevilla, Sevilla, Spain, [4]Azienda Ospedaliero Universitaria Delle Marche, Ancona, Ancona, Italy, [5]Hospital Universitari Vall d'Hebron, Barcelona, Barcelona, Spain, [6]Inserm, Corbeil-Essonnes, France, France, [7]Inserm, Paris, Paris, France, [8]Necker Hospital, Paris, France

Genetic deficiency of the endonuclease DCLRE1C/Artemis, a key factor for the Non-Homologous End-Joining (NHEJ) mechanism, causes Severe Combined Immunodeficiency (SCID) characterized by a complete lack of T and B-cells associated with hypersensitivity to ionizing radiations. Allogeneic Hematopoietic Stem and progenitor Cells (HSPCs) transplantation is the gold standard for treating Artemis-SCID. However, graft-versus-host disease and graft rejection, which can lead to post-transplant complications and mortality, are increased in case of HLA incompatibility between the donor and recipient. In this context, the first US clinical trial of lentiviral ex vivo corrected HSPCs in patients with Artemis-Deficient SCID was conducted by Cowan et al. (NEJM 2022). This study utilized pharmacologically targeted low-exposure busulfan, which resulted in the generation of corrected and functional T and B cells after injecting genetically corrected hematopoietic progenitors. While this trial offers valuable insights into the treatment, it is essential to highlight that autoimmune hemolytic anemia occurred in four out of ten patients. A more thorough analysis of post-transplant immune reconstitution is necessary in this case.

We are excited to announce the launch of a European-supported phase I/II clinical trial (NCT05071222) at Necker Hospital in Paris, France. This innovative trial features utilizes a more intense conditioning regimen and a different lentiviral vector (LV) with a more potent promoter (short intron-less EF1α promoter) to regulate the expression of the human DCLRE1C cDNA. We have enrolled two patients with SCID phenotypes (P1 and P3) and one leaky SCID form (P2), with follow-up periods ranging from 6 to 24 months. In two different experimental approaches, we demonstrated that corrected HSPCs derived from the ATMPs initiated productive T-cell rearrangements *in vitro* and recapitulated T-cell differentiation in an *in vivo* xenotransplantation model. For the three patients, the engraftment of gene-corrected HSPCs was quantified in the whole peripheral blood mononuclear cells (PBMCs) and purified CD15+ circulating cells. P1 and P3 experienced a progressive increase in vector copy number (VCN) in PBMCs. Functional T-cell and B-cell compartments were progressively restored as the patients could control viral infections caused by rotavirus and adenovirus without any other specific treatment. Moreover, the severe maternal graft-versus-host disease (GVHD) present in P1 before gene therapy was managed without any post-transplant treatment. In addition, we used a mathematical algorithm to model the CD4+ T-cell reconstitution following the engraftment of gene-corrected cells and compared it with alternative haplo-selected CD34+ cells. We also evaluated the T and B-cell repertoires by sequencing to follow the Immune reconstitution compared to alternative transplantation from our cohort. Our data unequivocally confirm that gene transfer is a valuable strategy to restore a functional T- and B-cell compartment in Artemis patients presenting an SCID phenotype. These results also underlined that the corrected HSPCs restored a functional immune system that efficiently fought against infections or maternal GVHD.

1769 A stable Engineered Regulatory T cell therapy platform with modular targeting for autoimmune and inflammatory diseases

Payam Zarin[1], Maegan Hoover[2], Priya Saikumar Lakshmi[3], Gene Uenishi[4], Victoria DeVault-Nelson[5], Jennifer Mellen[2], Yash Agarwal[6], Jennifer Yam[7], Tingxi Guo[8], Ashley Landuyt[2], Martina Sassone Corsi, Nathan Zammit[7], Nicole Reed[9], Madison Milaszewski[10], Abigail Doherty[7], Marko Repic[11], Dalia Gaddis, Alberto Del Rio-Espinola[5], Tiffany Chen, Tom Wickham[2]
[1]GentiBio, Brighton, MA, [2]GentiBio, Cambridge, MA, [3]Genti Bio, Boston, MA, [4]GentiBio, [5]Gentibio, Inc., Cambridge, MA, [6]GentiBio, Somerville, MA, [7]GentiBio, Cambridge, [8]GentiBio Inc, Cambridge, MA, [9]GentiBio, Boston, [10]GentiBio, Boston, MA, [11]GentiBio, Vienna, Austria

Regulatory T cells (Tregs) play a central role in establishing and maintaining immune tolerance, tissue homeostasis and preventing fatal autoimmunity. Current Treg therapies face challenges of unstable phenotype in an inflammatory microenvironment, a lack of IL-2 support due to IL-2 scarcity in multiple diseased states, and lack of tissue specificity. Our strategy to address these challenges harnesses a gene editing platform with dual AAV to engineer human regulatory T cells (EngTregs) from bulk CD4+ T cells resulting in the stable expression of FOXP3 and a chemically inducible signaling complex split across both vectors to enrich only the engineered population by selectively providing IL-2 signaling with rapamycin in the edited cells. This modular engineering allows for indication specific, interchangeable tissue specific targeting including TCRs, CARs, or inflammation tuned alarmin receptors. Using transcriptomic analysis, we evaluated the stability of cultured sorted Tregs (cTregs) compared to EngTregs. We found EngTregs expressed higher levels of key "Core Treg" and "FOXP3 Synergy" genes based on bulk and single cell RNA-seq analysis as confirmed by flow cytometry. Additionally, favorable expression pattern of key Treg stability markers, CD27, CD70 and IKZF4 was observed in EngTregs compared to cTregs. Finally, we observed that these correlations have a functional implication as demonstrated by higher expression of key tolerogenic markers in EngTregs compared to cTregs. Utilizing different targeting moieties, we have developed therapeutics for Type 1 Diabetes, B-cell driven autoimmune diseases, and acute inflammatory and ischemic diseases. GNTI-122 is an EngTreg with a TCR specific for IGRP, intended for the treatment of patients with recently diagnosed T1D. GNTI-122 demonstrates strong bystander suppression of islet specific T cells against multiple antigens isolated from T1D patients. In a mouse model of T1D, an islet antigen specific autologous mEngTreg surrogate trafficked to the pancreas, decreased the severity of insulitis, and prevented progression to diabetes. CD19 specific CAR (CAR19) EngTregs were developed to address both B and T cell components involved in B cell driven autoimmune diseases. CAR19 EngTreg demonstrate B cell killing and T cell suppression in vitro, while maintaining lower inflammatory cytokine production compared to CD19 CAR-T effectors. Allogeneic CAR19 EngTregs tested in humanized models of inflammatory disease also resulted in B cell depletion and immune reset with low levels of serum inflammatory cytokines compared to CAR T. Finally, we have developed a novel allogeneic EngTreg demonstrating a Tissue Treg phenotype (Tissue EngTreg) by expression of ST2, an alarmin receptor sensitive to injury induced inflammation, aimed to restore tissue homeostasis, repair and regeneration. Tissue EngTregs demonstrate high expression of tolerogenic markers (e.g. CD25, CD39), homing receptors (e.g. CCR5, CCR8), and repair cytokines (e.g. IL-13, Osteopontin) allowing them to serve as "repair ready" for acute inflammatory conditions. Tissue EngTregs have broad applicability to indications of acute inflammation as demonstrated by allogeneic efficacy achieved in various in vivo models of acute lung injury, stroke and acute kidney injury. Taken together, these data are supportive of Engineered Tregs as a potent and stable Treg cellular therapy approach that can be targeted to a broad range of indications.

1770 A Novel *Staphylococcus epidermidis* Compound for the Topical Treatment Epidermal Growth Factor Receptor (EGFR) Inhibitor-Induced Dermal Toxicity

Mary Spellman[1], Travis Whitfill[2]
[1]*Panclarity LLC, San Francisco, CA,* [2]*Azitra Inc., Branford, CT*

Systemic therapeutic agents targeting the EGFR-mediated signaling pathway are used for the treatment of advanced cancers, including of the lung, pancreatic, colorectal, and head and neck. Significant dermal toxicities occur in up to 90% of patients treated with EGFR inhibitors (EGFRIs) and other medications inhibiting downstream signaling pathways. These toxicities may be disruptive to a patient's quality of life and adherence to therapy. Inhibition of the EGFR pathway may suppress host defenses and lead to opportunistic pathogenic colonization or infection. Dermal toxicity is associated with elevated levels of *Staphylococcus aureus* and IL-36g. ATR04-484 is a novel *S. epidermidis* strain isolated from a healthy human volunteer, selected for its ability to reduce *S. aureus* colonization and inhibit IL-36g when applied topically.

ATR04-484 has a promising profile of activities for the treatment of EGFRI-induced dermal toxicity by significantly reducing *S. aureus* growth and completely ameliorating IL-36g levels. Reconstructed human epidermis (RHE) and *ex vivo* pig skin were utilized to measure the effect of ATR04-484 on *S. aureus* in therapeutic and prophylactic settings with *S. aureus* added prior to or after topical ATR04-484 application, respectively. ATR04-484 inhibited growth of both methicillin-resistant (MRSA) and methicillin-sensitive (MSSA) *S. aureus* in both therapeutic and prophylactic settings. In a therapeutic setting, ATR04-484 inhibited MRSA growth by 1 log (90%) compared to untreated MRSA in both RHE and pig skin. In a prophylactic setting, ATR04-484 inhibited MRSA growth by

approximately 5 logs on RHE and 2 logs on pig skin. IL-36g levels were measured on RHE treated with erlotinib alone or in combination with ATR04-484. Application of ATR04-484 reduced erlotinib-induced IL-36g to a level comparable to non-erlotinib treated RHE ($p<0.001$). The effect was dose-dependent; application of 10^9CFU/cm^2 of ATR04-484 trended towards more potent IL-36g reduction compared to 10^8 CFU/cm^2.

An ongoing multicenter, randomized, double-blind, vehicle-controlled Phase 1/2 clinical study is designed to evaluate the safety and tolerability of topical ATR04-484 (10^9 CFU/g) for the treatment of EGFRI-induced dermal toxicity affecting the face of adult patients. ATR04-484 or its vehicle (3:1 randomization) will be applied in a stable volume to all patients, including the face, with application to prioritize affected areas of the neck, chest, back, and paronychial areas (using remaining product on unaffected skin in the same areas). The key objectives of the study are to assess the safety and tolerability of topical ATR04-484 and to evaluate efficacy signals including severity of disease, pruritus, and pain. The bioavailability of ATR04-484 and pharmacodynamic parameters (including IL-36g) are also studied. This clinical study will establish the basis for continued clinical development of ATR04-484.

1771 Reaching Remission: Harnessing Master Regulator Transcription Factor *Zbtb20* for the Development of a Cellular Therapy against IBD

Steven Montecinos[1], Derek Sant'Angelo[2]
[1]NJ Child Health Institute, Middlesex, NJ, [2]Child Health Institute of NJ, New Brunswick, NJ

Inflammatory bowel disease (IBD) poses significant health challenges that diminish the quality of life for patients; its increasing prevalence necessitates the generation of innovative therapeutic approaches. Published data from Dr. Derek Sant'Angelo's lab revealed that the expression of the master regulator transcription factor, Zbtb20, in endogenous T cells, effectively protects mice against this disease. These data led us to hypothesize that genetically engineered Zbtb20-expressing CD4 T-cells could serve as a novel therapy to treat and prevent IBD, thus improving outcomes of afflicted patients. To begin investigating this question, we constructed and optimized the generation of recombinant retrovirus containing Zbtb20, cloned into the retrovirus-producing vector, pMSCV-IRES-GFP. Conventional mouse CD4 T cells were transduced by either Zbtb20-containing or empty vector (EV) retrovirus. We studied the functional and genetic changes induced by ectopic Zbtb20 expression by FACS and RT-qPCR, indicating the significant upregulation of IL-10, a 3-fold increase compared to EV control, and Treg markers in the Zbtb20-expressing cells. To determine the therapeutic potential of these transduced cells, we adoptively transferred 500k T cells, either Zbtb20 or EV control transduced, into the Dextran Sulfate Sodium-induced colitis model and monitored weight over 11 days. Our studies into the induced DSS model indicated a minor rescuing effect with the Zbtb20-expressing cells and homing of the transferred cells to inflammation in the colon. These data indicate that Zbtb20-expressing CD4 T cells produced in-vitro have the potential to serve as a cellular therapy for IBD, though more optimization of cell engineering is needed. Ongoing experiments in the RAG1KO mouse model aim to determine therapeutic function in a T cell-driven IBD model. Future studies will characterize genes controlled by Zbtb20 through bulk RNA-seq of transduced cells and elucidate its role in FoxP3 expression, a key transcription factor in regulatory T-cell differentiation. Our results have the potential to allow patients who have failed other treatment options another shot at remission or even a cure for an otherwise challenging lifelong condition.

1772 STASH-Select: a platform for multi-vector engineering and single-step selection of cell therapies bearing multiple enhancements

Louai Labanieh[1], Kaithlen Pacheco[2], Maria Arenas[3], Chris Fisher[3], Justin Arredondo-Guerrero[4], Sean Yamada-Hunter[3], Peng Xu, Jeremy Bjelajac[3], Elena Sotillo[5], Robbie Majzner[5], Jennifer Cochran, Crystal Mackall[5]*
[1]Mount Sinai School of Medicine, New York, NY, [2]Stanford university, Stanford, [3]Stanford University School of Medicine, Stanford, [4]Baylor College of Medicine, Houston, TX, [5]Stanford University, Stanford, CA
**Corresponding Author*

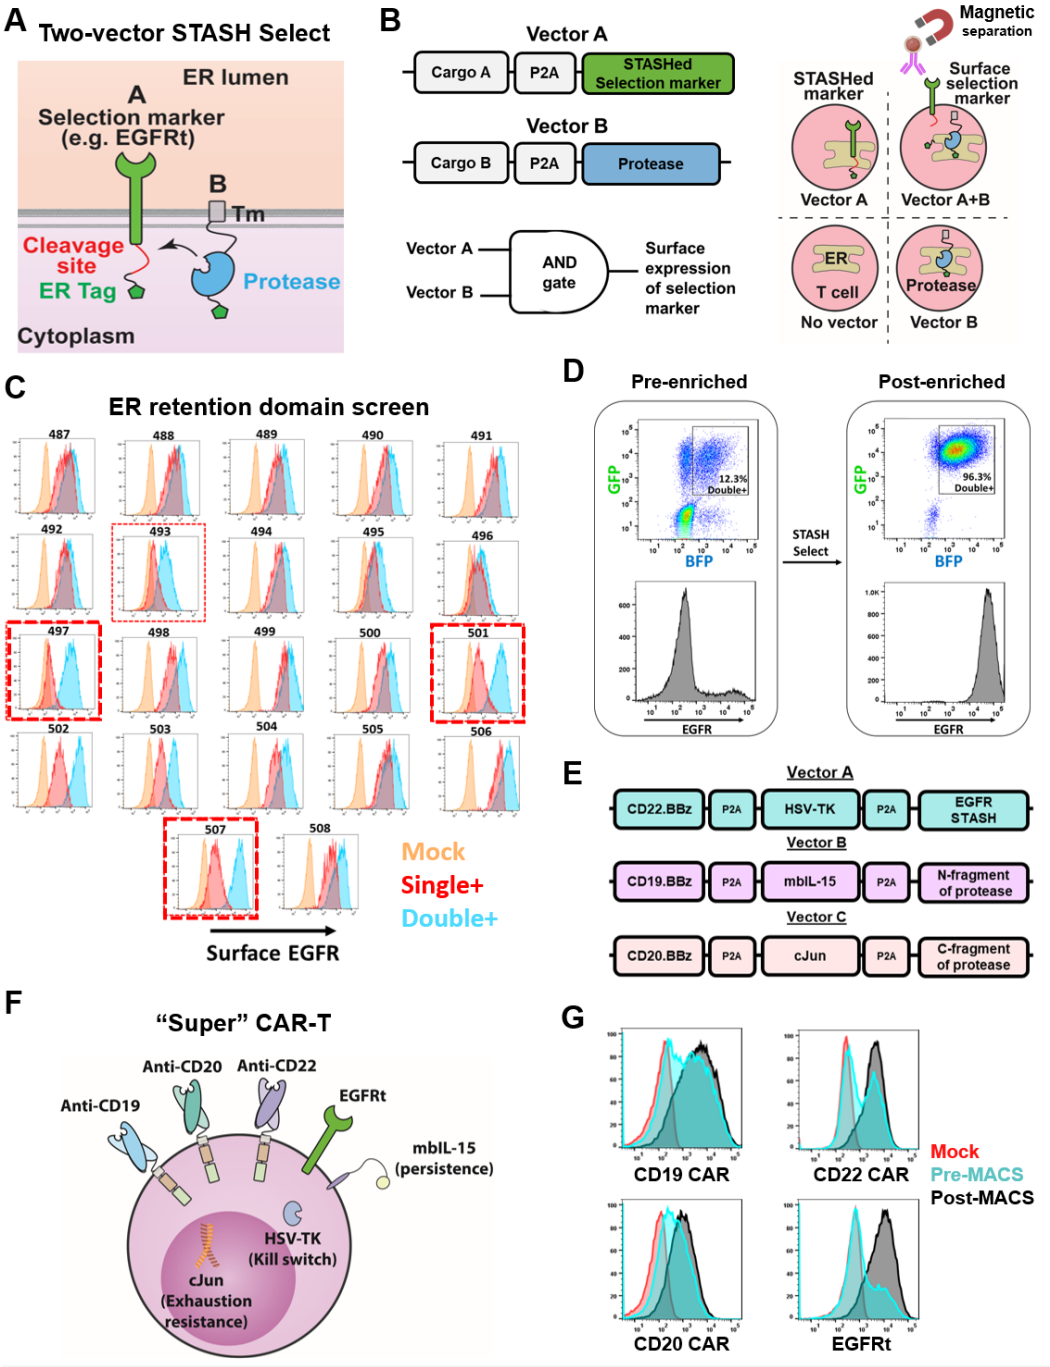
Background: Chimeric antigen receptor T-cells have demonstrated impressive clinical benefit, particularly in hematologic malignancies, but formidable obstacles such as tumor heterogeneity, T cell exhaustion, limited persistence, and a hostile tumor microenvironment limit their broad efficacy. Next-generation CAR-T cells endowed with multiple enhancements could overcome these distinct axes of resistance and expand this class of therapeutics to

solid tumors but will require the introduction of multiple genetic modules that often exceed the cargo capacity of a single vector. Multi-vector engineering results in a heterogeneous, poorly defined cell product. Here we report on STASH-Select, a simple platform technology for purifying cell products containing multiple genetic modifications using a single-step selection that is compatible with current GMP workflows.

Methods: The core principle of STASH-Select is the conditional cellular localization of a selection marker (e.g. tEGFR). We fused a protease-cleavable endoplasmic reticulum (ER) retention tag to the C-terminus of tEGFR, "STASHing" it inside the cell. Co-expression of TEV protease cleaves off the ER tag, allowing tEGFR to translocate to the cell surface, where it serves as a MACS selection handle (**Fig.1A**). Expressing the STASHed tEGFR on a first vector and the TEV protease on a second vector creates an AND gate where only cells transduced by both vectors display tEGFR at the cell surface (**Fig. 1B**). We engineered primary human T cells from healthy donors using retroviral transduction and purified them by MACS. T cells were characterized by flow cytometry and functionality was tested in tumor killing assays, proliferation experiments, and murine models.

Results: We screened 22 ER retention domains and identified several novel human ER tags that efficiently trapped tEGFR in the ER (**Fig. 1C-1D**). We built a 3-vector STASH-Select, which allowed for selection of CAR-T products exceeding 90% purity at high yield. We utilized STASH-Select to generate a uniform product of trispecific CAR-T cells expressing cJun, membrane bound IL-15, a safety switch, and tEGFR (**Fig. 1E-1G**). These "Super" CAR-T exhibited improved efficacy in murine stress test models of cancer and superior safety in toxicity models. We developed further iterations of STASH-Select that allowed for single-step purification of cells engineered with up to six vectors in primary T cells and up to nine vectors in cell lines.

Conclusion: STASH-Select is a broadly applicable platform that enables the deployment of sophisticated next-generation cell therapies bearing multiple enhancements into the clinic, towards addressing multifaceted resistance mechanisms and safety concerns that limit efficacy in solid tumors.



1773 Cell therapy biodistribution and efficacy assessment using a highly sensitive spatial multiomics assay

Anushka Dikshit[1], Maithreyan Srinivasan[2]*, Debia Wakhloo[3], Nancy George[1], Ge-Ah Kim[1], Laetitia Chatelain[1], Julia Yu[1]

Cell therapies such as CAR-T therapies and TCR T cell therapies have proven to be highly effective in treating hematologic malignancies, and major efforts are being made to achieve similar efficacy in solid tumors as well as for autoimmune disorders. To achieve this, it is essential to study the biodistribution of these therapeutics and assess their efficacy, toxicity and response. The RNAscope *in situ* hybridization (ISH) technology can detect any engineered RNA sequence and identify the CAR-T cells *in vivo*. But, to successfully detect very specific immune response associated with the therapeutics, it is essential to localize targeted immune cells with the therapeutic in a spatial context. The new RNAscope™ Multiomic LS assay can combine immune-cell specific protein markers with activation marker RNAs for cytokines and chemokines to determine therapeutic efficacy.

Here, we demonstrate the use of the multiomic assay on the BOND Rx that can detect up to 6 RNA and protein targets on the same slide. The TSA-based amplification strategy offers signal boost for both RNA and protein targets. To optimize protein detection, the workflow is completely protease-free there by preserving antigen integrity and tissue morphology. The assay can be customized to include any target RNA and proteins of interest. Here, we demonstrate the use of our pre-conjugated antibody panel which includes CD8, CD4, FoxP3 and PanCK with *IFNG* and *GZMB* RNA to visualize tumor infiltrating lymphocytes(TILs) in human cancer tissues. We also detected an mRNA-based in vivo CAR-T therapeutic and associated immune cells using a custom panel with CD3, CD45, CD8, CD4, CD20 and a target probe against the CAR sequence in NHP spleen tissue.

Infiltrating Cytotoxic T cell lymphocytes were detected using CD8, *GZMB* and *IFNG* co-expression in human cervical, breast and colon cancer tissues. In the same tissues, regulatory T cells were detected using CD4, FOXP3 co-expression. PanCK was used as a tumor marker to delineate tumor from stroma. In the NHP model, the distribution of the mRNA in tissues was able to be differentiated as on-target (in hematopoietic or T cells) or off target (tissue parenchyma).

The protease-free RNAscope Multiomic LS assay was successfully able to interrogate different subpopulation of immune cells with high fidelity RNA and protein signal while maintaining tissue morphology. The higher plex capability provides detection of more markers simultaneously, in turn enabling immune phenotype profiling while maintaining the sensitivity and specificity . Finally, the assay affords a very high throughput on the Bond Rx allowing large-scale pre-clinical and patient sample analysis.

1774 Allogeneic CAR-γδT cells armored with ‘super-mbIL15’ demonstrates enhanced efficacy towards both liquid and solid tumors

WEIWEI MA[1]*, yinqiang sui[1], Hui Zhao[2], Lina Zhao[2], Lina Yang[2]
[1]Unicet Biotech, Beijing, Beijing, China, [2]Unicet Biotech, Beijing, China
**Corresponding Author*

CAR-T cell therapy has demonstrated remarkable efficacy in hematologic malignancies. However, its application in solid tumors remains limited due to challenges such as the immunosuppressive tumor microenvironment and limited T-cell persistence. γδT cells, a distinct subset of T cells, have shown potent anti-tumor properties with the ability to recognize a wide range of tumor-associated antigens, making them a promising alternative to conventional αβT cells for CAR-based therapies. Additionally, IL-15, a cytokine crucial for T-cell survival and expansion, has been shown to enhance the efficacy of immune cells, particularly CAR-T cells, by promoting their persistence and cytotoxic activity. The constitutive co-expression of IL-15, especially membrane-bound IL-15 (mbIL15), has been demonstrated to significantly enhance the anti-tumor efficacy of CAR-T, CAR-NK, and other immune cells, further potentiating their therapeutic potential.

In this study, we co-expressed mbIL-15 with either CD19 CAR or B7-H3 CAR in γδT cells and observed that it enhanced downstream STAT5 phosphorylation, leading to increased cytokine-independent proliferation and anti-tumor activity *in vitro*. However, mbIL-15 expression significantly reduced CAR transduction efficiency and expression intensity. To overcome these issues, we performed in-depth optimization of the mbIL-15 structure and identified a modified version that induced a significantly higher level of STAT5 phosphorylation compared to mbIL-15, without compromising CAR transduction or expression intensity. This optimized structure was named "super-mbIL15". *In vitro* experiments demonstrated that super-mbIL15 more effectively maintainied CAR-γδT cell

proliferation and viability under cytokine-free conditions. Furthermore, through serial-killing assay, CAR-γδT cells armored with super-mbIL15 exhibited more durable anti-tumor activity and higher level of IFN-γ release compared to mbIL-15 *in vitro*. To evaluate *in vivo* anti-tumor efficacy, we utilized multiple xenograft models, including B-cell acute lymphoblastic leukemia (B-ALL), acute myeloid leukemia (AML), and ovarian cancer. In all of these models, CAR-γδT cells armored with super-mbIL15 demonstrated significantly enhanced anti-tumor activity, peripheral blood expansion, and tissue infiltration levels, outperforming other IL-15 constructs.
Our study demonstrates that CAR-γδT cells armored with super-mbIL15 exhibit enhanced anti-tumor efficacy in both liquid and solid tumor models. The optimized version of membrane-bound IL-15 improves CAR-γδT cell expansion, persistence, and anti-tumor activity, providing a promising strategy for γδT cell-based immunotherapies. Additionally, super-mbIL15 has the potential to enhance the efficacy of other immune cells, such as CAR-T and CAR-NK cells, suggesting broad applicability for engineered immune cell therapies in cancer treatment.

1775 Development of A Feeder-Free Process for IL-2-Independent TIL Expansion

Chen Huang[1], Zhou He[2], Xingming Ma[2], Man Zhang[2], Lie Ma[1], Wenjia Zhuang[2], Huajun Jin[2]
[1]Shanghai Juncell Therapeutics, Shanghai, Shanghai, China, [2]Shanghai Juncell Therapeutics, Shanghai, China

Background: Tumor-infiltrating lymphocyte (TIL) therapy demonstrates significant promise in treating various solid tumors, recently gaining FDA approval for advanced melanoma. The conventional TIL expansion process relies heavily on high-concentration interleukin-2 (IL-2) and feeder cells (irradiated peripheral blood mononuclear cells from healthy donors), rendering TILs dependent on these factors for survival and function. Consequently, high-dose IL-2 is required post-infusion to maintain TIL potency and persistence. This high-dose IL-2, coupled with the need for high-intensity lymphodepletion to reduce pro-tumor regulatory T cells (Tregs), which are also sensitive to IL-2, is associated with significant toxicity, including high mortality rates and frequent intensive care unit (ICU) admissions. Additionally, the use of feeder cells carries inherent risks such as infection transmission, variability in cultivation and supply chain, and high associated costs.

Method: We developed a robust TIL culture process utilizing a chemically defined medium that eliminates the requirement for high-concentration IL-2 and feeder cells. This innovative approach successfully expanded TILs from multiple solid tumors, including melanoma, cervical, ovarian, endometrial, and several other cancers. Flow cytometry was employed to characterize TILs, while potency assays were assessed using a real-time cell analyzer and ELISA against syngeneic primary cells and patient-derived xenograft (PDX) models.

Results: The feeder-free TIL manufacturing process exhibited high robustness across tumors, exceeding a 95% success rate (within specifications). Average viabilities consistently surpassed 90% across tumor types, with cell numbers ranging from 5x109 to 45x109 after a 24-day expansion. Within the CD45+CD3+ T cell population, CD8+ T cells constituted more than 50% on average. Notably, central memory T cells (TCM) and effector memory T cells (TEM) comprised over 95% of the T cell population. Importantly, the proportions of Treg and PD-1+ T cells were both below 0.5%. Remarkably, the TILs exhibited dose-dependent cytotoxic effects against syngeneic primary cancer cells and demonstrated antitumor activity in PDX models without exogenous IL-2 supplementation.

Conclusion: This feeder-free process enables the expansion of abundant and potent IL-2-independent TILs. The TILs exhibit low levels of exhaustion markers like PD-1 and demonstrate robust in vitro and in vivo functions without the need for IL-2 supplementation. This innovative approach has the potential to significantly improve the safety profile and reduce the manufacturing costs of TIL therapy.

1776 Enhancing Production and Functional Potential of Tumor-Infiltrating Lymphocytes via Lipid Nanoparticle-Mediated CRISPR/Cas9 Gene Editing

Jingwei Sun[1], Yao Sheng[2], Fei Li[2], Ke Liu[2], Xi Zhu[3], Hong Chen[4], **Pin Wang**[5], Yarong Liu[2]
[1]Grit Biotechnology, Shanghai, Shanghai, China, [2]Grit Biotechnology, Shanghai, China, [3]Shanghai Vitalgen Biopharma, Shanghai, Shanghai, China, [4]Shanghai Vitalgen Biopharma, Shanghai, China, [5]University of Southern California, Los Angeles, CA

Tumor-infiltrating lymphocyte (TIL) therapy has shown promise in treating solid tumors, but its clinical efficacy remains limited to certain indications. Genetic engineering offers a powerful method to enhance the anti-tumor function and persistence of TILs, potentially broadening their application to a wider range of solid tumor types. Electroporation (EP), a traditional T cell engineering technique using electrical pulses to introduce genetic material into cells, typically achieves high knockout (KO) rates but compromises cell viability, proliferation, and large-scale expansion. In contrast, lipid nanoparticles (LNPs) have emerged as an innovative delivery modality for CRISPR/Cas9 editing tools. Recent studies have demonstrated that LNPs can efficiently edit human peripheral blood mononuclear cells (hPBMCs) efficiently with less cellular stress compared to EP. In this study, we utilized a novel ionizable lipid, which exhibited high delivery efficiency and a favorable safety profile across multiple species. Notably, the ionizable lipid was rapidly metabolized within cells via a cytochrome enzyme-independent pathway, reducing potential adverse effects during T cell transfection. We optimized the transfection process with hPBMC T cells, refining culture conditions, activation methods, and serum concentration. The protocol was subsequently adjusted to the manufacturing process of TILs, achieving KO efficiency similar to EP but with higher cell viability and recovery at 24hr or 48hr post transfection in both hPBMCs and TILs. The LNP-mediated CRISPR/Cas9 KO efficiency was dose-dependent, and LNP-edited cells showed at least a two-fold increase in cell numbers after large-scale expansion. Functional assessments revealed that LNP-edited TILs maintained comparable cytotoxicity and cytokines release in vitro to EP-edited cells in response to tumor cells. Further characterization showed improved memory phenotype, enhanced stemness, and reduced exhaustion and apoptosis. RNA-seq analysis indicated minimal transcriptomic changes with LNP, unlike the significant gene expression disruption seen with EP, especially in exhaustion and metabolism pathways. Taken together, LNP-edited TIL products achieved high KO efficiency with minimal genetic disruption, showing enhanced cell fitness and expansion potential. These findings indicated LNP as a superior CRISPR/Cas9 delivery system for ex vivo TIL editing, warranting further clinical evaluation of LNP-engineered next-generation TIL therapies.

1777 Metabolic Alterations in Highly Activated NK-like Cells (GAIA-102) Through Cryopreservation

Kenta Ishimoto[1], Yui Harada[2], Yosuke Morodomi[2], Situo Zheng[3], Noriko Yasuda[1], Yoshikazu Yonemitsu[2]
[1]Kyushu University, Fukuoka, Fukuoka, Japan, [2]Kyushu University, Fukuoka, Japan, [3]Kyushu University, Fukuoka, shigashi-ward, Japan

Background: We have developed an innovative approach to generate highly activated NK (Natural Killer)-like cells (development code: GAIA-102) with potent antitumor activity against solid tumors. While highly activated NK cells are generally known to be vulnerable to cryopreservation, leading to a decline in post-thaw viability and cytotoxic function, GAIA-102 has been optimized to overcome this challenge and is currently being utilized in clinical trials as a cryopreserved, off-the-shelf product (NCT05207371, NCT05438459, NCT05608148). Our efforts have included refining the pre-freezing culture conditions and modifying the composition of the thawing diluent, significantly improving post-thaw viability and cytotoxic activity. These advancements have led to promising clinical outcomes, supporting the potential efficacy of GAIA-102. However, further optimization of the freeze-thaw process remains necessary to fully preserve its intrinsic antitumor activity and maximize therapeutic efficacy.

Purpose: Recent studies have highlighted the critical role of cellular metabolism, particularly mitochondrial respiration and glycolysis, in regulating NK cell cytotoxicity. Cryopreservation has been shown to induce progressive mitochondrial dysfunction and promote a metabolic shift toward glycolysis in peripheral blood mononuclear cells; however, its specific impact on the metabolism of NK cells remains insufficiently explored. Given the pivotal role of mitochondrial function in NK cell activity, this study aims to elucidate the metabolic changes underlying the decline in GAIA-102 cytotoxicity post-thaw and to develop metabolism-based strategies for further optimizing its cryopreservation process.

Methods: After producing GAIA-102, the cells were cryopreserved at -80℃ for more than two days. Immediately after thawing, GAIA-102 were incubated with the injection solution, and the cytotoxicity and metabolism were assessed. Particularly, the oxygen consumption rate (OCR) and the extracellular acidification rate (ECAR) were measured using an extracellular flux analyzer to evaluate the metabolism (mitochondrial respiration and glycolysis).

Results: Compared to primary NK cells, GAIA-102 demonstrated significantly higher basal respiration and glycolysis, along with enhanced spare respiratory capacity and glycolytic reserve, which are critical indicators of metabolic flexibility and reserves. After thawing, the basal respiration, ATP-linked respiration and spare respiratory capacity, and glycolytic reserve of GAIA-102 decreased significantly, while glycolysis remained roughly equivalent.

Conclusion: GAIA-102 exhibits high metabolic flexibility and reserves at harvest, with respiratory capacity of mitochondria and compensatory function of glycolysis notably impaired through cryopreservation. Further investigation is warranted, specifically targeting mitochondrial respiration and glycolysis mechanisms.

1778 Nonclinical Safety Evaluation of a KRAS G12D Neoantigen-Targeting TCR

Liz Mutter-Rottmayer[1], John Davies[1], Andrew Wallace[1], Andrew McKay[1], Mark Klinger[2], Josefa Chuh[1], Kathy Kozak[1], Amy Gilbert[2], Gabby Cole[1], Somayeh Tarighat[1], Zhilan Hu[1], Ilseyar Akhmetzyanova[1], Soyoung Oh[1], Peter Ebert[2]
[1]Genentech, South San Francisco, CA, [2]Adaptive Biotechnologies, South San Francisco, CA

Engineered TCR T-cell therapies are an emerging class of adoptive cell therapies delivering recombinant cancer antigen-targeting TCR-Ts to kill tumor cells. We developed an autologous CD8+ T-cell product using non-viral gene editing to knock out the endogenous TCR and knock in an engineered TCR targeting the VVVGADGVGK epitope of KRAS G12D, a prevalent tumor-specific somatic mutation important for neoplastic growth, in the context of HLA-A11:01. KRAS G12D TCR T cells were found to effectively recognize and kill tumor cells expressing the target peptide:MHC complex and demonstrated tumor regression in a mouse xenograft model. Due to inter-species variance of MHCs and proteomes, in vivo models are not relevant for toxicity evaluation, necessitating comprehensive in vitro characterization. In vitro studies confirmed a lack of reactivity to wildtype KRAS peptide, though did identify off-target (OT) reactivity to two peptides belonging to ERAS and RASL11b at potencies 1000- and 100-fold lower than cognate peptide, respectively when evaluated using HLA-A11:01 engineered cell lines. No OT reactivity was observed against endogenously expressed epitopes in primary and iPSC-derived human cells covering multiple organ systems, or to a majority of HLA-A11:01+ tumor cell lines that do not express KRAS G12D. Further no alloreactivity was detected in a cell panel covering 90% HLA diversity. Gene editing fidelity was confirmed through multiple orthogonal approaches, showing no OT editing in regions of concern, no gross chromosomal abnormalities, and a lack of cytokine-independent or unregulated cell growth. The cumulative nonclinical data support further clinical evaluation of this autologous TCR-T product in cancer patients expressing KRAS G12D in the context of HLA-A11:01.

1779 Acute safety and biodistribution profile of hematopoietic stem cell (HSC) targeting virus-like particles based on helper-dependent adenovirus serotype 5/35++ in non-human primates

Patrick Au[1], Tiffany Vo[1], Robert Peters[1]
[1]Ensoma, Boston, MA

Ensoma has developed a novel in vivo gene therapy platform that uses virus-like particles (VLP) based on helper-dependent adenovirus serotype 5/35++ for in vivo hematopoietic stem cell (HSC) gene therapy. VLPs are produced in a scalable, suspension-based manufacturing process that can support large patient populations at low cost. VLPs are devoid of viral genes to minimize immunogenicity and allow up to a 35 kb payload capacity to enable large gene insertions. Following systemic delivery, VLPs preferentially transduce HSCs due to the use of CD46 receptor for cell entry. CD46 receptor is expressed at higher density in primitive long-term HSCs compared to other hematopoietic cell lineages. The platform has the potential to significantly improve accessibility for patients with a variety of diseases that affect blood and immune cells.

We evaluated the acute safety, biodistribution and transgene expression profile of VLPs (at doses up to 9.25E12 gc/kg) following intravenous administration in cynomolgus macaques. Cynomolgus macaques were mobilized with granulocyte colony-stimulating factor (G-CSF) and plerixafor and given an immune prophylaxis regimen consisting of dexamethasone, tocilizumab and anakinra. Following dosing, VLPs exhibited a favorable tolerability profile

without any clinical observations and all animals survived to scheduled terminal euthanasia on Day 8. No VLPs-related increase in alanine transaminase (ALT) and aspartate aminotransferase (AST) was observed. VLPs were associated with a transient elevation in IL-6 that peaked at 6 hours and returned to baseline at 72 hours. Gross and histopathology examination was performed on collected tissues from all animals at scheduled necropsy. There were no VLP-related microscopic or gross changes.

Biodistribution and gene expression analysis were performed on whole blood and tissues collected at necropsy. The highest vector copy number (VCN) was detected in whole blood, followed by the lung, liver, and spleen. VCN in gonads (testes and ovaries) was approximately 2 to 3-log lower than the lung, liver and spleen. Gene expression analysis showed no transgene expression in the gonads. The biodistribution and transduction profile supports a low probability of germline transmission with VLPs following systemic administration.

This work demonstrates VLPs to be well tolerated following systemic delivery in cynomolgus macaques and support the further development of Ensoma's VLPs as a platform for in vivo HSC gene therapy.

1780 Novel *In Vivo* Gene Therapy Approach to Hematopoietic Stem Cell (HSC) Engineering Creates Durable HSC-Derived Neutrophils to Treat X-Linked Chronic Granulomatous Disease

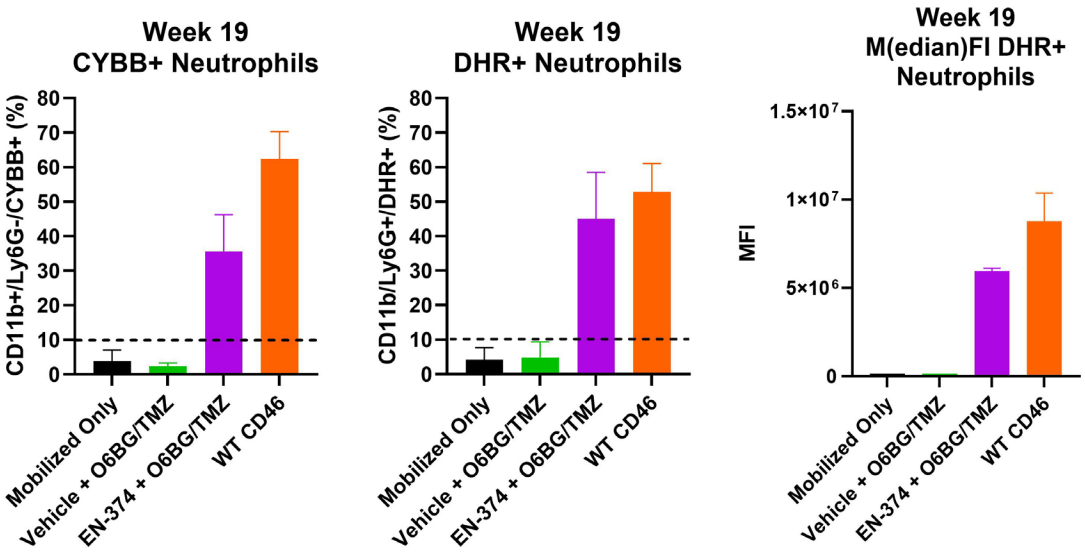
Sravya Kattula[1], Gaurav Rajani[1], Vemika Chandra[1], Mike Martinez[1], Patrick Au[1], Robert Peters[1], Joe Salas[1]
[1]*Ensoma, Boston, MA*

Allogeneic hematopoietic stem cell (HSC) transplant is standard treatment for many diseases involving blood cells, but it carries risks of graft rejection and graft-vs-host disease. Although *ex vivo* autologous HSC gene therapy can bypass donor related issues, it carries risks and burden of conditioning and limited access due to complex N-of-1 manufacturing. Ensoma has developed a novel *in vivo* gene therapy with virus-like particles (VLP) based on helper-dependent adenovirus 5/35++ for *in vivo* HSC genome modification. Our VLPs are devoid of viral genes, minimizing immunogenicity, and allow for up to 35 kB payload capacity for large gene insertions. We show that our VLPs preferentially transduce HSCs by binding to the CD46 receptor, which is highly expressed on primitive long-term HSCs. Ensoma has applied this novel HSC engineering technology for the treatment of X-linked chronic granulomatous disease (X-CGD).

X-CGD is caused by a defect in the NADPH oxidase complex, which inhibits phagocytic cells from eliminating bacterial and fungal pathogens. Ensoma's candidate, EN-374, consists of two independent VLPs; one encodes for Sleeping Beauty 100X transposase and Flp recombinase, and the other contains a transposon with a myeloid specific promoter expressing wild-type CYBB and a ubiquitous promoter expressing a selectable methylguanine methyltransferase (MGMT) marker containing the P140K mutation. In cells co-transduced by the two VLPs, the transposon is excised and integrated into the genome to drive stable expression of CYBB and restore NADPH oxidase activity in neutrophils. Unmodified HSCs are then depleted by O6-benzylguanine (O6BG) and single dose temozolomide (TMZ), at less than conventional regimens, while gene-modified HSCs are protected from the toxic effects of TMZ and enriched to achieve therapeutic levels of gene marking.

In a 19-week *in vivo* study, EN-374 was administered to transgenic human CD46 and CYBB knockout mice. At end of the study, in EN-374 treated mice, CYBB vector copy number was 0.51 ± 0.14 copies/bone marrow cells and gene marking, based on MGMT-P140K expression, in bone marrow HSCs and progenitor cells was 51.0 ± 17.0%. The HSCs demonstrated normal hematopoietic function by CFU assay. CYBB protein expression and NADPH activity in circulating neutrophils was evaluated by flow cytometry and dihydrorhodamine (DHR) assay, respectively. EN-374 mice demonstrated an average CYBB protein expression and DHR activity in neutrophils of 35.6 ± 10.6% and 45.0 ± 13.5% (mean ± SEM), respectively. DHR activity in restored neutrophils, measured by median fluorescence intensity, was 68% of the activity in wild-type controls. Restoring ≥10% of neutrophils with NADPH oxidase activity has been shown to confer clinically meaningful improvements in infection outcomes in X-CGD patients.

Our data demonstrate compelling proof-of-concept for efficient *in vivo* HSC engineering that leads to the expression of functional CYBB in neutrophils at therapeutic levels in X-CGD disease model mice. Additionally, with a scalable, suspension-based manufacturing process, our VLPs can support large patient populations at low cost, and this study sets the foundation for the first VLP-based, off-the-shelf *in vivo* HSC gene therapy to be studied in a X-CGD clinical trial. Our technology has the potential to be applied to a wide range of genetic disorders which thus far have only been addressed with allogeneic-HSC transplants and *ex vivo* gene therapies

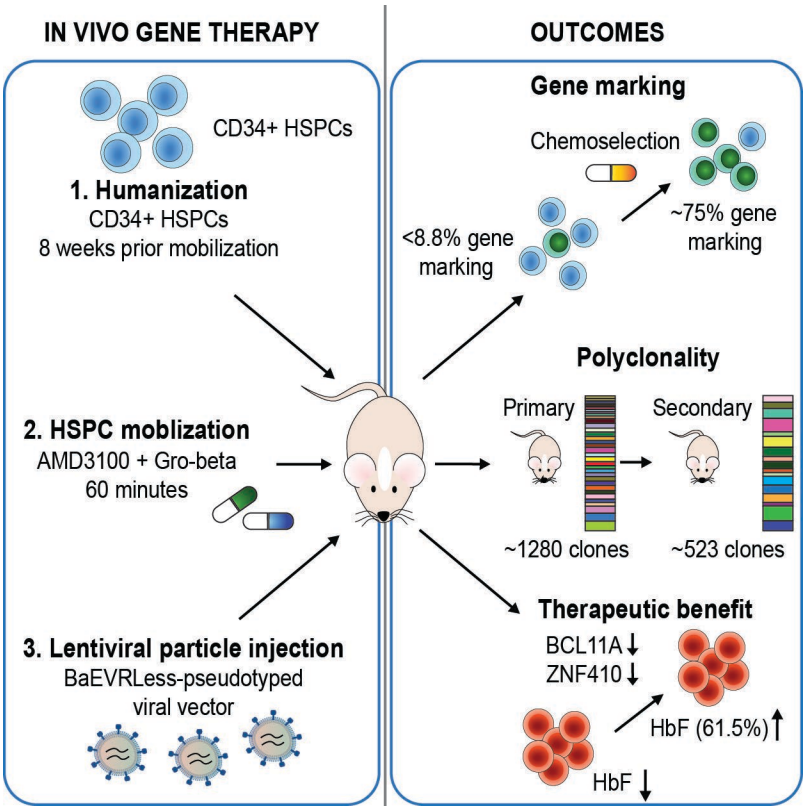


1781 *In Vivo* Hematopoietic Stem Cell Gene Therapy for Sickle Cell Disease Using BaEVRLess-pseudotyped Viral Vectors

Denise Klatt[1], Boya Liu[1], Adele Mucci[2], Marie Peschers[1], Giulia Schiroli[3], Axel Schambach[4], Danilo Pellin[2], John Manis[1], MYRIAM ARMANT[1], David Scadden[5], Els Verhoeyen[6], David Williams[7], Christian Brendel[8]
[1]Boston Children's Hospital, Boston, MA, [2]MASSACHUSETTS GENERAL HOSPITAL, Charlestown, MA, [3]Tessera Therapeutics, Cambridge, MA, [4]Hannover Medical School, Hannover, Germany, [5]Harvard Stem Cell Institute, MGH Center for Regenerative Medicine, Boston, MA, [6]INSERM/CIRI/EVIR, Lyon, France,7[8]Boston Children's Hospital, Boston, Massachusetts, [8]Boston Children's Hospital/Dana-Farber Cancer Institute, Boston, MA

Traditional *ex vivo* hematopoietic stem cell (HSC) gene therapy has effectively cured severe inherited blood disorders, such as sickle cell disease (SCD), but more widespread implementation is limited by high costs, scalability issues, and significant risks associated with myeloablative chemotherapy. *In vivo* HSC gene therapy, which aims to directly modify the cells *in situ*, has the potential to overcome these limitations. Here, we explore the use of viral vectors pseudotyped with the baboon endogenous retrovirus (BaEV) glycoprotein, and its derivative BaEVRLess, for stable gene transfer into HSCs *in vivo*. Although BaEVRLess-pseudotyped retroviral vectors very efficiently transduce quiescent HSCs and are serum-resistant, their production in HEK293T cells is severely hampered by toxicities related to the high fusogenic activity of BaEVRLess. To overcome this problem, we generated a stable BaEVRLess-packaging cell line carrying knockout of the viral entry receptor ASCT2 and stably expressing Gag/Pol and BaEVRLess envelope. This resulted in a 10-fold increase in titers up to 10^9 viral particles/mL ($p<0.001$) and a 3-fold reduction of viral vector-induced cytotoxic apoptosis ($p<0.001$). Additional modifications to the packaging cells include the overexpression of CD47 and knockout of *B2M*, which aims to reduce phagocytosis and immune responses *in vivo*, respectively. To increase *in vivo* HSC gene transfer, we mobilized humanized NBSGW mice with AMD3100 and Gro-beta, prior to injection of ~$3x10^7$ viral particles achieving up to 8.8% gene marking in peripheral blood hCD45+ cells within one week. To enrich gene-marked cells, we overexpressed MGMT-P140K in transduced cells, which mediates resistance to the alkylating agent

BCNU. After three cycles of BCNU treatment, we observed a 33-fold enrichment of gene marked cells in peripheral blood ($p<0.001$). In bone marrow, gene marking reached on average 73.7% in hCD45+ cells 16 weeks after vector injection and averaged 78.4% in hCD34+ cells. Barcode analysis showed the presence of 200-4600 unique barcodes and a polyclonal distribution in >93% of treated mice. Transduction and selection of *bona fide* HSCs was confirmed in secondary transplantations, where gene marking and clonality remained stable at 58.5% transduced hCD45+ cells in bone marrow. As a proof of concept for a therapeutically relevant approach to treat SCD, we used a double shmiR containing vector to downregulate *BCL11A* and *ZNF410* in erythroid cells, which results in reactivation of gamma-globin and induction of fetal hemoglobin, which largely attenuates the hematologic effects of SCD. Following *in vivo* gene transfer and BCNU selection in humanized mice, we observed a significant upregulation of gamma-globin to 61.5% in transduced erythroid cells at week 16 ($p<0.001$). In summary, we demonstrate that BaEVRLess-pseudotyped viral vectors could be applied for *in vivo* gene therapy to treat SCD.



1782 *In Vivo* Truncation of the EpoR Gene Allows for Expansion of Therapeutically Edited Erythroid Cells after HSC Gene Therapy with HDAd Vectors

Karthik Karuppusamy[1], Akshara Velmurugan[1], Hongjie Wang[2], Chang Li[2], Aphrodite Georgakopoulou[1], David R. Liu[3], Audrey Germond[4], Andre Lieber[1]*
[1]University of Washington, Seattle, WA, [2]University of Washington, Seattle, Washington, [3]Eli and Edythe L Broad Institute of Harvard and MIT, [4]University of Washington
**Corresponding Author*

Ex vivo HSC gene therapies for hemoglobinopathies are costly and complex. We have developed a simpler *in vivo* method where HSCs are mobilized and edited *in vivo* using intravenously injected HDAd vectors. A fraction of edited HSCs returns to the bone marrow. The goal of this study is to expand this fraction without using chemotherapy. We used naturally occurring erythropoietin receptor variants (tEpoR) that are associated with benign red blood cell overproduction. We aim to generate tEpoR through *in vivo* EpoR gene editing using HDAd vectors with cytosine base or prime editors. Our screening with base editors identified two EpoR variants that exhibited a

100-fold increase in proliferation in HUDEP-2 cells, even under conditions with 600-fold lower Epo levels. We incorporated optimal tEpoR editors together with an integrating therapeutic g-globin cassette into an HDAd vector. After transduction of $CD34^+$ cells from healthy donors with integrating HDAd-tEpoR-g-globin, we observed 5-10% EpoR gene editing on day 4 post transduction. Importantly, upon erythroid differentiation, the editing rate increased to 40%, indicating selective expansion of edited erythroid cells. Flow cytometric analysis of differentiated erythroid cells showed increased g-globin expression. For *in vivo* studies, integrating HDAd-tEpoR-g-globin was injected into mobilized humanized mice (engrafted with human $CD34^+$ cells from healthy donors). 11 weeks post HDAd transduction, we observed EpoR target site editing in bone marrow $CD34^+$ cells in the range of 0.4 to 4%. Ex-vivo erythroid differentiation of explanted human cells in the presence of human Epo showed an increase in editing from 4% to 16%. This indicates that humanized mice are not efficiently supporting human erythropoiesis. Therefore, we have recently started testing the *in vivo* approach in rhesus macaques. We generated an HDAd vector with rhesus specific guide RNA to edit tEpoR and injected it at the peak of G-CSF/ADM3100 mobilization. Seven days post transduction, we observed >4% of tEpoR target site editing in bone marrow $CD34^+$ cells. The first data on the expansion of edited erythroid cells and g-globin -positive erythrocyte look promising and a 4-month follow-up will be presented. Integration of HDAd-tEpoR-g-globin by a Sleeping Beauty transposase is relatively inefficient which limits the potential of our approach. To address this, we developed dual base editing vectors to truncate EpoR and disrupt sites that bind g-globin repressors (BCL11a and LRF1 sites). To implement this as hit-and-run strategy, we incorporated a pomalidomide-based degron system for precise control of the gene editing machinery. Transduction of the dual base editing vectors in HUDEP-2 and $CD34^+$ cells resulted in preferential expansion with g-globin reactivation. As an alternative approach, we utilized prime editing to truncate EpoR by introducing a 9 bp substitution originally described by Harvey Lodish. Our screening identified an optimal guide RNA that achieved 30% of complete 9bp substitution in HUDEP-2 cells, which resulted in a 5-fold increase in proliferation under low Epo conditions. We then developed a dual prime editing HDAd vector to introduce the EpoR mutation and correct the sickle cell disease mutation. Testing in HUDEP-2 cells showed efficient editing, achieving nearly 30% EpoR site editing and nearly complete correction of the sickle cell disease mutation. The new vectors will be tested in humanized mice and NHPs.

1783 In Vivo Engineering of Hematopoietic Stem Cells with Virus-Like Particles to Generate Multi-Lineage CAR Immune Cell Therapy for Cancer

Chirayu Chokshi[1], Cristina Santoriello[1], Yiwen Zhao[1], Ying Lin[1], Alvin Pratama[1], Richard Davidson[1], Yao Wei[2], Jessica Kohler[1], Charles Fox[3], Victoria Blake[1], Adam Fisher[3], Adam Golding[1], Chapman Wright[4], Corinne Decker[1], Robert Peters[1], Yinghua Wang[1]*

Background: Chimeric antigen receptor-engineered T (CAR-T) cell therapy has achieved remarkable clinical success, particularly in hematologic malignancies. However, its broader application remains limited due to complex manufacturing, limited persistence and functional exhaustion, and high costs associated with personalized approaches. CAR-T cell therapy has shown limited efficacy in solid tumors, owing to an immunosuppressive tumor microenvironment and inefficient trafficking of CAR-Ts to tumor. To overcome limitations of autologous CAR-T therapy, we are pursuing an off-the-shelf, multicellular approach that leverages synergy between myeloid and lymphoid immune cells to establish a new benchmark for durable therapeutic outcomes in solid tumors.

Methods: We developed a helper-dependent adenovirus platform of virus-like particles (VLPs) to enable in vivo engineering of hematopoietic stem cells (HSCs). This vector selectively targets human CD46, a receptor highly expressed on primitive HSCs. Co-transduction with a hyperactive Sleeping Beauty transposase (SB100x) facilitates efficient transgene integration, ensuring sustained development of engineered immune cells. These VLPs have a large cargo capacity of up to 35 kilobases, enabling construction of single- or multi-cellular CAR sequences under distinct lineage-specific promoters for precise immune cell engineering. CAR gene expression, specificity, and function were evaluated in vitro and in vivo.

Results: To achieve selective therapeutic payload expression, we identified and validated lineage-restricted promoters with myeloid- or T/NK-cell-specific activity in primary human and murine immune cells. CAR constructs

driven by monocyte- or T/NK-restricted promoters successfully generated functional CAR macrophages, T and NK cells, respectively, with all CAR effector cell types exhibiting potent antigen-dependent tumor cell cytotoxicity. To assess activity in vivo, hCD46 hematopoietic stem and progenitor cells (HSPCs) were transduced with VLPs encoding CAR driven by a ubiquitous promoter (CAG) or lineage restricted regulatory elements and transplanted into irradiated recipient mice to assess HSPC-derived CAR+ immune cell generation. While the ubiquitous CAG promoter drove CAR expression across all immune cell lineages, myeloid- and T/NK-restricted promoters confined CAR expression to their respective lineages. These lineage-specific CAR immune cells exhibited on-target tumor cytotoxicity comparable to CAG-driven CAR while minimizing off-target expression. Tumor-infiltrating CAR+ effector cells displayed a proinflammatory phenotype compared to their CAR- counterparts. Furthermore, concatenation of myeloid- and T/NK-restricted promoters enabled generation of multi-lineage CAR immune cells from a single VLP.

Conclusions: This study establishes a robust proof of concept for in vivo multicellular CAR immune cell therapy via HSC engineering with lineage-restricted control. Our platform provides a versatile and scalable strategy for delivering CAR and other immunomodulatory payloads to specific immune cell types while preventing expression in HSPCs and off-target lineages. By leveraging a self-renewing reservoir of engineered HSCs and the large cargo capacity of VLPs, this approach offers an off-the-shelf solution that enables a durable and synergistic anti-tumor response.

1784 Effective Gene Editing in Hematopoietic Stem and Progenitor Cells (HSPCs) through a Novel Targeted Lipid Nanoparticle

Esther Chen[1], Xianghong Li[1], Ferran Soldevila-Casals[1], Theresa Hunter[1], Aaron Beams[1], Diti Desai[1], Duy Nguyen[1], Donald Jhung[1], Stuart Sievers[1], Daiki Matsuda[2], Yanjie Bao[1], John Li[1], David Chu[1], Michelle Nguyen[1], Michael Pica[1], Jack Lee[1], Duncan Ugland[1], Claudia Fernandez[1], James Vestal[1], Jeffrey Chen[1], Josephine Nguyen[1], Michael Rosenzweig[1], Gregor Adams[1], Priya Karmali[1], Adrian Bot[1], Haig Aghajanian[1]
[1]Capstan Therapeutics, San Diego, CA, [2]Arcturus Therapeutics, San Diego, California

Background: Ex vivo Hematopoietic stem cell (HSC) gene therapy has achieved substantial progress over the past decade, advancing as a feasible therapeutic strategy for various blood and immune disorders, including sickle cell anemia, beta-thalassemia, and other immunodeficiencies. However, the complexities and challenges of ex vivo HSC gene therapy such as manufacturing, scalability, cost, and accessibility, highlight the need for an in vivo solution that could simplify the process and address many of the current limitations. This study describes a novel lipid nanoparticle (LNP) system designed to selectively deliver gene editing payloads to hematopoietic stem and progenitor cells (HSPCs) in vivo. The targeted lipid nanoparticles (tLNPs) are a product of the CellSeeker™ platform technology and comprise a proprietary LNP formulation, conjugated to a recombinant antibody that binds to a specific surface marker on HSPCs, enabling efficient delivery of CRISPR-Cas components to genetically edit HSPCs in vivo.

Methods: To generate proof-of-concept, a tLNP was designed to deliver Cas9 mRNA and single guide RNA (sgRNA) targeting beta-2 microglobulin (B2M) to human CD34+ HSPCs. This tLNP was formulated with a novel, highly biodegradable ionizable lipid and an antibody targeting the stem cell factor receptor, CD117, which is expressed on the surface of HSPCs. We evaluated the efficiency of tLNP-mediated B2M knock-out (KO) both in vitro and in vivo using a CD34+ hematopoietic stem cell engrafted NCG mouse model.

Results: To evaluate the specificity and efficiency of delivery, we first examined the ability of CD117-targeting tLNPs to deliver a GFP reporter mRNA to human CD34+ HSPCs. tLNP administration resulted in robust GFP expression in plerixafor-mobilized peripheral blood CD34+ human HSPCs in vitro (up to 75% GFP+) and in CD34+CD38- HSPCs in humanized NCG mice upon intravenous dosing. To assess the ability to deliver gene editing payloads, Cas9 mRNA and a sgRNA designed to knock out B2M expression were co-encapsulated in these HSPC-targeting tLNPs. Bone marrow and mobilized peripheral blood CD34+ human HSPCs treated with these gene editing tLNPs displayed a significant loss of B2M expression (up to 80%) as measured by flow cytometry and genome editing by sequencing. The gene editing ability of these CD117-targeting tLNPs translated in vivo in humanized NCG mice, demonstrated by high efficiency B2M-KO in CD34+CD38- HSPCs.

Conclusions: The findings in this study provide compelling evidence of CellSeeker™ platform in general and CD117-targeting tLNPs in particular, as a promising strategy to genomically edit HSPC. The distinctive targeting moiety of these tLNPs facilitated efficient delivery of both reporter mRNA and gene-editing payloads to CD34+ human HSPCs. The successful in vivo gene editing in the NCG mouse model supports the potential of the tLNP system for clinal applications. Ultimately, the study highlights CD117-targeting tLNPs as a powerful strategy for advancing in vivo HSC gene therapy.

1785 Chromatographic purification of linear DNA from supercoiled plasmid DNA

Ming Zhu[1], Siddarth Chandrasekaran[2]*, Wai Hung[1], Peyman Mokarami[1], Hossein Khoshravesh[1], Jamie Lam, Olga Zaslaver[1], Roderick Slavcev[3], **Nafiseh Nafissi[4]***

The demand for high-quality DNA vectors and scalable and cost-effective manufacturing platforms for DNA products continue to grow. Ministring DNA (msDNA™) is a linear, covalently closed double-stranded DNA vector devoid of bacterial sequences, such as antibiotic resistance genes and origins of replication. It contains only the therapeutic gene expression cassette flanked by proprietary supersequences that enhance efficacy and safety (Figure 1A). msDNA™ offers numerous advantages, including lack of immunogenicity, absence of insertional mutagenesis risks , and enhanced stability. Its in-vivo manufacturing process in E. coli ensures high fidelity, scalability, and cost efficiency. These characteristics position msDNA™ as a next-generation efficient and safe DNA-based platform for applications such as gene therapy, gene editing, DNA vaccine, and as starting material for production of viral and RNA-based biologics. To meet the stringent purity requirements of gene therapy products, msDNA™ undergoes a sequential downstream purification process, including chromatography and filtration, to yield pure, endotoxin free, high-quality DNA. We applied a DOE-driven process development approach to optimize purification of linear msDNA™ by removing contaminating episomal DNA species (like supercoiled or relaxed plasmids) and other cellular impurities (such as genomic DNA, RNA, proteins, lipids, and small molecules).

Our investigation compared two scalable chromatographic modalities: anion exchange chromatography (AEX) and hydrophobic interaction chromatography (HIC), using various supports including resins, monoliths, and membranes. Due to the large size and slow diffusion of DNA, supports based on convective mass transport, such as monoliths and membranes, demonstrated superior performance for large scale bioprocessing. Our data showed that monoliths were more effective than membranes in separating linear msDNA™ from other DNA forms (Figure 1B). Additionally, HIC chromatography with selected resines and optimized conditions provided enhanced resolution compared to AEX in resolving the two DNA species.These findings underscore the importance of DOE-driven optimization in downstream process development to achieve high-purity msDNA™ at industrial scale, paving the way for safer and more effective DNA-based therapeutics.

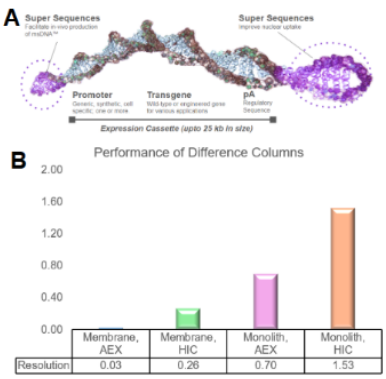

Figure 1: (A) msDNA™ is a linear covalently-closed double-stranded DNA vector free of bacterial backbone DNA carrying a minimal expression cassette composed of the eukaryotic promoter, transgene and regulatory sequences. (B) The relative performance of various columns in separating linear msDNA from its precursor parent plasmid.

1786 Enhancing Lentivirus Depth Filtration Purification: Strategies for Improved Recovery and Quality for Downstream

Yeonji Kim[1], Chris Brown[2], Heather Mallory[2], Hui Wu[2], Jing Zhu[2], Xiaojun Liu[2]*
[1]Boxborough, MA, [2]ReciBioPharm, Watertown, MA

In gene therapy manufacturing, the filtration of lentiviral material from transfected cell culture media during upstream processing is pivotal for ensuring downstream success. Challenges in lentiviral manufacturing include limited titer production and difficulties in achieving high recovery due to the virus's environmental sensitivity. This study focuses on optimizing the initial stages of the lentivirus downstream process through the application of diverse analytical methods.

High-quality lentivirus purification is essential to establish robust preliminary standards for downstream processing prior to chromatography. Filtration steps are critical for removing residual host cell proteins (HCPs) and DNA while preserving viral particles. In this study, a comparative analysis of three vendors' depth filters was performed, with each vendor supplying their top three high-performing filters.

Multiple analytical methods, including physical and functional titer assays, were employed to assess filtration performance. Among these methods, droplet digital PCR (ddPCR) was utilized to quantify DNA and viral particles, complemented by an in-house functional titer assay. Filtrate samples were compared against pre-filtered materials to evaluate turbidity reduction, HCP and DNA removal, viral particle recovery, and aggregation. Considerations such as filtration time and throughput were also assessed.

The optimized filtration methodology developed through this study, supported by advanced analytics, demonstrated greater than 95% viral recovery and enabled the production of lentivirus materials ready for chromatography. The total calculated throughput exceeded 230 L/m². Data on titer recovery using ddPCR, along with assays measuring residual HCPs and DNA, provide valuable insights for enhancing lentivirus purification processes. These findings contribute to improving the efficiency and quality of lentivirus production, supporting advancements in gene therapy applications.

1787 Advancing Purification Strategies for Large Viral Modalities Using Nanofiber Adsorbent Technology

Sujeong Yang[1], Hanna Dreja[2], Beatriz Sant Mora[2], Caroline Daye[2], Joseph Fletcher[2], Graham Clifton[2], Marc Hummersone[2], Ian Scanlon[3]
[1]Astrea Bioseparations Ltd, CAMBRIDGE, Cambridgeshire, United Kingdom, [2]Astrea Bioseparations, Cambridge, United Kingdom, [3]CAMBRIDGE, United Kingdom

The demand for efficient purification strategies in cell and gene therapy is increasing as large viral modalities such as exosomes, Herpes Simplex Virus (HSV), Vaccinia Virus (VACV), and pseudo typed lentiviral vectors gain prominence since they play critical roles in regenerative medicine, cancer immunotherapy, and gene delivery. However, these vectors present significant downstream purification challenges, including low recovery, high host cell protein (HCP) contamination, and scalability limitations in traditional chromatography-based methods. This study evaluates the purification characteristics of an innovative nanofiber adsorbent, focusing on its capacity, impurity clearance, and process efficiency. The nanofiber-based approach demonstrated high binding capacities, improved recovery, and superior removal of host cell proteins compared to conventional chromatography. Additionally, it showed scalability potential, making it attractive for industrial applications.

Nanofiber-based purification presents a promising alternative to conventional chromatography, offering improved performance for large viral vectors. By enhancing impurity removal, binding efficiency, and scalability, this technology supports the advancement of next-generation cell and gene therapy manufacturing. Beyond purification, the therapeutic applications of these viruses highlight the urgency of improved manufacturing strategies. Oncolytic

viruses such as HSV and VACV are increasingly recognized for their potential in cancer therapy, where they selectively replicate in tumor cells, induce cell lysis, and stimulate anti-tumor immune responses. The ability to efficiently purify and scale up these viruses is critical to their clinical success. Furthermore, pseudotyped lentiviral vectors, such as GalV and VSV-G, expand the scope of gene therapy by enabling targeted transduction of specific cell types. The development of robust purification methods, such as nanofiber-based technology, is essential to support the growing demand for these advanced therapeutics, ensuring their efficacy, scalability, and translational success.

1788 Lenti Viral Vectors Displaying Ligands for Enhanced Capture, Purification, Concentration and Targeted Infection of Specifically Selected Cells

Glenda Dickson[1], David Darling[2], Farzin Farzaneh[3]
[1]ViroCell Biologics, 12-18 Theobalds Road, London, WC1X 8SL, UK, LONDON, London, United Kingdom, [2]ViroCell Biologics, London, Greater London, United Kingdom, [3]King's College London, London, United Kingdom

Generation of lenti and g-retroviral vectors displaying specific markers on their outer surface will facilitate vector purification, concentration and the targeted infection of selected cell subsets both *in vitro* and *in vivo*. We have previously demonstrated that expression of specific ligands on the surface of producer cells results in the presence of these ligands on the surface of the virus (Lenti and g-Retro)[1-6]. This can be achieved with the transient or stable modification of cells producing these vectors, without the genetic modification of either the vector or indeed the helpers.[1-6] As a result, liganded vectors can be generated that are suitable for better affinity purification, concentration and targeted delivery of the vector payload, but without genetic modification of the vector.

The range of ligands successfully attached to the surface of the virus include poly-histidine for immobilised metal affinity chromatography (IMAC) columns[1], biotin or StrepTag for avidin/streptavidin mediated capture[2-4], including the use of paramagnetic particles (PMPs)[2,3,5,7]. In addition, proteins and other ligands can be attached to the surface of the vector producing cells by direct chemical modification[2,7], or the metabolic modification of proteins that are displayed on the surface of producer cells and hence the vector[3,5]. These latter modifications can facilitate other forms of affinity capture and targeting of selected receptors on specific cell subsets[6].

The outlined strategies have been used to achieve enhanced capture and recovery of vectors (substantially greater than 100% recovery of the starting infectious titre)[2,7-8]. Such liganded vectors can also promote the more efficient infection of specifically targeted cells. For instance, lenti vectors displaying SCF can be used for the enhanced infection of c-kit positive haematopoietic stem cells[6].

Improved capture, purification and concentration of lentiviral vectors, combined with enhanced target cell infection, can facilitate more efficient *in vitro* applications with the potential for *in vivo* infection of specific human cell subsets. The combination of better vector recovery and enhanced infection of specifically targeted cells, enables the reduction of costs and a potentially safer vector profile. The real challenge will be to minimise the “off-target” infection[9] by applying technologies to increase the efficiency of targeting with the aid of defective/non-infectious vectors that incorporate cell specific ligands.

[1]ABL Inc., Rockville, MD, [2]Advanced Biological Laboratories (ABL) Inc., Rockville, MD, [3]ABL Inc, Rockville, MD

Introduction. ABL has been engaged in Human Immunodeficiency Virus (HIV) research since the 1980s when the virus was first described. Through this work, ABL pioneered one of the first p24 ELISA kits (**ABL® kit**, Catalog #**5421** & #**5447**) for the reliable quantification of HIV capsid protein (p24). Today, ABL provides manufacturing and analytical services for oncolytic, cell and gene therapies, and vaccines. Recently, ABL developed a proprietary platform for the industrial production and purification of Lentivirus (LVV). As LVV shares structural and biological similarities with HIV, we evaluated ABL's HIV p24 kit for the quantification of LVV in-process samples generated during industrial production and purification. One challenge in quantifying such samples is the poor correlation between genomic titer (viral particle titer derived from RNA content) and p24 results (viral particle titer derived from LVV capsid marker-p24), particularly in early-stage and low-concentration samples. However, the **ABL® kit** exhibited remarkable reliability with such samples. To further address this observation, we compared the performance of the ABL® kit to those offered by other vendors.

Note: ABL is a member company and legal affiliate of Ascend Advanced Therapies Group, Inc.

Method. LVV in-process samples were tested for p24 concentration (ng/mL) using the **ABL® kit** and kits from four other vendors (B, C, D, E). Genomic titer (vg/mL) was measured via RNA extraction and qRT-PCR.

Viral particle concentrations (VP/mL) Calculations:

- VP/mL from p24 (**VP-p24**) = p24 conc. (ng/mL) x 1.0E+07.
- VP/mL from Genomic titer (**VP-GC**) = virus genomic copy conc. (**vg/mL**) ÷ 2.

Sample Subgroups:

- All Samples
- Lower Titer: Genomic Titer < 4.0E+09 vg/mL
- Higher Titer: Genomic Titer ≥ 4.0E+09 vg/mL

1. Early Steps: Harvest, AEX Load.
2. Later Steps: AEX eluate, TFF retentate & Sterile filtered product.

Correlation Assessment

- **R^2** (Coefficient of determination): a bigger R^2 indicates stronger correlation and higher reliability
- **VP-p24/VP-GC Ratio** and **CV%** (coefficient of variation).
    - An average ratio ≈ 1.0 indicates that the p24 concentration aligns with the reported standard (1 ng p24 = 1.0E+07 VP).

- To reduce R^2 bias from high-titer samples, CV% of individual sample ratios was used to assess correlation strength within subgroups.

Results.

1. **Ease & Cost Efficiency**: the **ABL® kit** offers a cost advantage, with a simple and fast workflow.

2. **Correlation Strength:** the **ABL® kit** demonstrated higher R^2 values than Kits B, C, D and E particularly in low-titer and early-step samples (**Table 1**).
3. **Ratio & Variability**: The **ABL® kit** average VP-p24/VP-GC ratio is 1.03, consistent with the reported standard 1 ng p24 = 1.0E+07 VP, while Kit-C and Kit-E produced significantly lower ratios (**Fig. 1**). The ABL® Kit also exhibited the lowest CV% (as compared to Kit-B, C and D), particularly in lower titer and early-step samples, confirming superior reliability.

Conclusions. The **ABL® kit** is a reliable, robust and accurate tool for LVV lentivirus quantification in cell & gene therapy applications. The assay is adaptable for cGMP compliance, ensureing suitability for commercial, industrial, and research use.

Correlation of p24 with GC (R^2 value)

	ABL	Kit-B	Kit-C	Kit-D	Kit-E
All Samples	0.984	0.976	0.839	0.981	0.989
Low Titer	0.919	0.890	0.712	0.877	0.887
High Titer	0.981	0.971	0.825	0.980	0.990
Early Step	0.961	0.816	0.836	0.845	0.852
Later Step	0.992	0.981	0.990	0.988	0.998

Table 1. List of R^2 values representing the correlations of viral particle concentration derived from p24 with those derived from genomic titer for each kit across different sample subcategories. Darker green indicates stronger correlations, while darker red indicates weaker correlations.

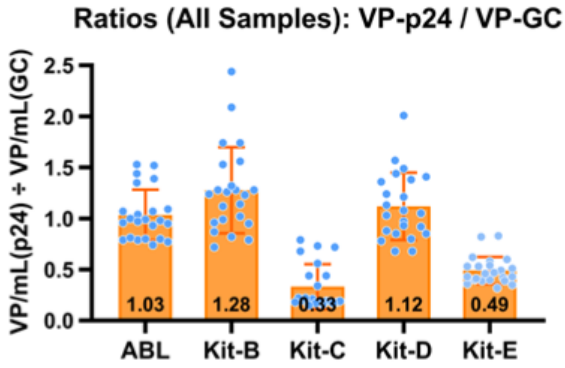

Figure 1. A bar graph displaying average ratios of VP-p24 / VP-GC and sample distributions of each kit in "All sample" subcategory.
- The average ratio of each kit is indicated at the bottom of each bar.
- Each blue dot represents a ratio of an individual sample.

1790 A Lentiviral Vector Downstream Processing Analytic Tool Powered by Knowledge Graph and LLM Technology

Yanis Habtoun[1], Ajanthan Nesarajah[2], David Del Bourgo[3], Julien Cottineau[4], Oscar de Felice[4], Anne Galy[5]
[1]WhiteLab Genomics, Viry-chatillon, France, France, [2]Inserm, CORBEIL-ESSONNES, Essonne, France, [3]WhiteLab Genomics, Paris, France, [4]WhiteLab Genomics, PARIS, Paris, France, [5]Inserm, Corbeil-Essonnes, France, France (*) presenting author

The industrial bioproduction of lentiviral gene therapy vectors (LV) remains a complex and costly operation. Regardless of the production systems used, the harvested LV particles undergo Downstream Processing (DSP), a serial workflow which includes several steps to concentrate and purify the LV. The challenge of DSP is in achieving high biological potency, high quality and high yields of finished product with little batch-to-batch variability. Repeated runs are costly, but necessary: they establish the production workflow and optimize the protocol steps. There is a wealth of information in private and public databases which should be used to assess and establish quality benchmarks for these steps efficiently. However, the heterogenous, high-dimensional and manuscript nature of this available data remains a bottleneck in characterizing runs effectively for inclusion in benchmarks, inference pipelines & analysis algorithms.

Existing computational tools cannot be used effectively because of this lack of structured tools to make sense of the disparate but important corpus of data. Current approaches for streamlining production to facilitate data gathering are centered around reviews or description of protocols without referring to the intricate relationships implied or the results to be expected. Each of these otherwise rich datasets end up representing a finite set which is a strong limitation to scale these approaches.

All the reasons exposed above prompted us to develop a rationally guided approach by providing a solution for structuring data from the literature along with internal data from producers as well as providing statistical solutions upon the structured data. Using a rationally guided approach, we developed OLIVIA, a novel platform leveraging Large Language Models (LLMs) integrated with Retrieval-Augmented Generation (RAG) and a knowledge graph approach to dynamically process and organize bioproduction data. Using our in-house expertise in bioproduction to generate relevant experimental data, we generated a framework for LV bioproduction automated analysis. We have also identified key articles and patents in the field in which production protocols have been documented and which include experimental approaches, assessment of yields and description of relevant materials. OLIVIA employs a comprehensive approach integrating biological context, material, scale, steps and parameters to generate a global outlook on processes, apply analytical methods and even facilitate user interactions. A prototype has been established and will be presented.

This tool is useful not only to track production performance across batches or in comparison with similar process steps, but it also lays the foundation for a potentially more powerful machine learning approach for the enhancement of bioproduction performance and quality. Ultimately OLIVIA is expected to accelerate the development of vector production for novel genomic and cell therapies.

1791 Quality by Design in Plasmid DNA and Gene Therapy: ProBio CDMO's Digital QMS for Risk-Based Manufacturing Excellence

Julie Erwin[1]*, Ben Chen[2]*, Sham Lasker[2], Taruj Patel[2]
[1]ProBio Inc USA, Pennington, NJ, [2]ProBio Inc, Pennington, NJ
**Corresponding Author*

In the high-stakes world of gene therapy and plasmid DNA manufacturing, quality is non-negotiable. ProBio is setting a new benchmark for quality excellence through implementation of its cutting-edge digital Quality Management System (QMS), powered by Veeva's Quality Risk Management (QRM) solutions.

By integrating a risk-based, data-driven approach, ProBio ensures end-to-end quality oversight, regulatory compliance, and operational efficiency across every stage of production. This enables real-time risk identification, proactive mitigation, and streamlined change control, minimizing deviations and accelerating the delivery of life-saving therapies.

ProBio has built a knowledge-centric ecosystem that centralizes critical data, fostering continuous improvement and enabling faster, more informed decision-making. The results are clear: reduced manufacturing cycle times, enhanced audit readiness, and unparalleled customer satisfaction.

This abstract highlights how ProBio's implementation of its first digital QMS and how it redefines ensures highest quality standards in our Hopewell manufacturing site in ensuring product safety.

1792 A Novel Pipeline for the Genomic Characterization of Cell Lines.

Romain Daveau[1], Marc Antoine Perrenoud[2], Rachel Buchs[2], **Luca Nanni[3]**, Mélissa Vona[1], Iris Bodenmann[1], Pelin Kolcak Yasli[1], Thierry Schuepbach[4], Igor Fisch[2], Efrain Guzman[3], Nicolas Mermod[1]
[1]NewBiologix SA, Epalinges, Switzerland, [2]NewBiologix SA, Epalinges, Vaud, Switzerland, [3]NewBiologix, Epalinges, Vaud, Switzerland, [4]NewBiologix SA, Epalinges, VD, Switzerland

Cell line characterization is critical to the control of biological product manufacturing. Confirming the identity, purity, and genomic stability of a cell line is of upmost importance for both viral vector manufacturing and cell therapy. The specific strategy for the characterization of a cell bank varies depending on several factors including the source of the cell line itself, cultivation history, genetic manipulation, clonality and growth requirements, amongst others.

We have developed a novel pipeline specifically designed for the genomic and transcriptomic characterization of cell lines used in gene and cell therapies and for the production of biologics, based on three specific technologies: 1) Optical genome mapping, 2) long-read high-fidelity DNA sequencing and 3) short-read, high-throughput RNA sequencing. The data obtained are integrated and analyzed using a custom-built bioinformatics pipeline. Macro-molecular optical genomic maps (OGM) using Bionano was used to assess clonality and genomic stability over many culture passages. OGM can reliably estimate cell ploidy and detect complex genomic rearrangements in a single, genome-wide workflow, providing a 10,000-fold higher resolution when compared to standard karyotyping. Whole genome sequencing using PacBio's high-fidelity (HiFi) long-read technology was used to simplify the complex processes of whole genome assembly, yielding highly accurate ultra-long reassembled DNA sequences (QV>60, N50=150Mb) including difficult to resolve low complexity regions. HiFi reads also provided simultaneous 5mC detection in CpG contexts without additional library preparation, allowing the analysis of the epigenetic methylation status of the genome from a cell population single sequencing analysis. Whole-transcriptome analysis based on total cDNA sequencing (RNA-Seq) using Illumina short-read sequencing can accurately measure gene and transcript abundance, giving information on the transcriptional capacity of the cell line.

This novel pipeline was applied to fully characterize a new HEK293 cell line specifically developed for the manufacturing of AAV products. The genomic analysis revealed fewer genomic rearrangements the new cell line compared to the parental heterogeneous HEK293 cell line and demonstrated its genetic stable over many cell culture generations. This new pipeline allows for the rapid and accurate characterization of cell lines used for cell and gene therapy applications and for the production of biologics.

1793 Harnessing the Power of Next Generation Sequencing and Bioinformatics to Propel Viral Safety of Cell Therapies

Victor Muthu[1], Luke Karpathios[1], Haydes Rau[1], Parker Blevins[2], Rohita Sinha[3], Jalal Siddiqui[3], **Marian L. McKee[1]**
[1]Eurofins BioPharma Product Testing, [2]Eurofins BPT, [3]Eurofins Viracor

Adventitious viral agents (AVAs) pose significant risks in biopharmaceutical manufacturing, particularly in vaccines, therapeutic proteins, and cell and gene therapies. Traditional animal- and cell- based detection methods often fall short in sensitivity and specificity in the identification of viruses -- especially unknown viruses, leading to potential contamination risks. For short shelf-life products or those requiring rapid turnaround time for testing, such as Cell Therapy products, time to result is critical. Next Generation Sequencing (NGS) is a powerful tool for comprehensive adventitious agent detection, especially viruses in biologics. We have developed an NGS method to detect AVAs leveraging whole transcriptomic sequencing followed by bioinformatic analysis against an internally-developed comprehensive viral database. This method rapidly detects and identifies contaminating viruses in cell therapy products.

1794 Optimization and Comparative Analysis of Host Cell DNA Quantification and Plasmid Supercoiled Percentage: Cost-Effective Agarose Gel Electrophoresis vs. High-Sensitivity qPCR and IEC-HPLC

Delicia Henriques[1], **Philemon Asfeha[2]**, Ryan Rubino[3], Murali Jujjavarapu[3], Aparna Nandakumar[3], Aneri Maniar[4]
[1]GenScript ProBio, Pennington, NJ, [2]ProBio Inc USA, Pennington, NJ, [3]ProBio Inc, Pennington, NJ, [4]ProBio Inc, Pennington, OH

The detection and quantification of host cell DNA (hcDNA) and plasmid supercoiled percentage are essential for biopharmaceutical manufacturing to ensure product safety, purity, quality and regulatory compliance. While

quantitative PCR (qPCR) and IEC-HPLC is widely used for its high sensitivity and accuracy, its cost and complexity can be prohibitive for routine screening in resource-limited settings. This study explores the optimization of agarose gel electrophoresis as an alternative for hcDNA quantification and DNA homogeneity, comparing its performance to qPCR and IEC-HPLC in terms of sensitivity and cost efficiency. By refining parameters such as sample loading, imaging techniques, we demonstrate that agarose gel electrophoresis can reliably detect hcDNA at levels suitable for initial screening, significantly reducing operational costs. Similarly, agarose gel electrophoresis, alongside densitometry, can be utilized to determine plasmid supercoiled percentages comparatively to IEC-HPLC analysis. Our findings provide a practical framework for selecting the appropriate method based on analytical needs and budget constraints, offering valuable insights for optimizing hcDNA quantification and DNA homogeneity processes in biopharmaceutical production. This comparative study highlights the trade-offs between cost and sensitivity, enabling informed decision-making for quality control in biomanufacturing.

1795 Genomic Integrity Analysis of Starting Material using Advanced Cytogenetic Analysis for Donor, Cell Line, and/or Clone Screening and Qualification

Erin Cross[1], Christopher Tompkins[2], Greg Husar[3], Gretchen Pratt[3], Matthew McGowan[3]
[1]Kromatid Inc, Fort Collins, CO, [2]KromaTiD, Longmont, CO, [3]Kromatid Inc, Longmont, CO

Cell and Gene therapies are transforming the treatment landscape for a growing number of medical conditions. In oncology, chimeric antigen receptor (CAR) T-cell therapies are beginning to have significant impacts in several forms of blood cancer, including leukemia, lymphoma, and multiple myeloma. While challenges still exist, treatment solutions for solid tumors are on the horizon, and genetic conditions such as sickle cell disease and spinal muscular atrophy now have multiple disease-modifying therapeutic options approved by the FDA. Additionally, many other therapies are in development for a variety of congenital and/or rare diseases.

When producing a biologics-based therapy from any starting material, donor cells, engineered cells, cell lines, or clones, maintaining the integrity of the genome throughout engineering, editing, and expansion processes is critical. Minimizing new risks to the patients receiving these treatments requires the cellular drug products and the patients receiving these treatments to be monitored for induced chromosomal mutations, clonal outgrowth, and genomic instability. Karyotyping is a classic cytogenetic method for imaging the structure of metaphase chromosomes, typically applied to measure the high frequency structural variation associated with congenital genetic diseases or characteristic of blood cancers.

Here we show how Kromatid's KROMASURE™ whole genome karyotyping assays provide unbiased chromosomal rearrangement and aneuploidy detection with low frequency measurement of events that occur during editing and expansion. These technologies provide advanced cytogenetic studies beyond classical 20-cell analysis with up to 10x the number of cells analyzed and can be used to compliment other methods, providing orthogonal validation. Analysis is performed on a matched sample pair: the pre-editing donor or wild-type cells and the final therapeutic product after editing and any required expansion. The structural variant report provides a "before" and "after" comparison, measuring the differences between edit-associated, engineering-associated, or expansion-associated structural variants and shows the karyotypic variation from baseline levels present in the cellular starting material. Importantly, the risk associated with instability, or a specific variant is only related to the identity of the variant, not the cause or the source. KROMASURE Genomic Integrity K-Banding and KROMASURE Screen provide measurements of structural variation in populations of engineered cells, whether the source of the chromosomal aberration is an edit, the result of impaired DNA damage repair capacity, or is simply present in the donor cell genome.

1796 End-to-End Production of T Cells on the Cocoon® Platform, Using Buoyancy-Activated Cell Sorting™ for T Cell Isolation from Leukopaks

Michele Vicentini-Hogan[1], Ashkan Tabibian[2], Salvador Flores-Torres[2], Chad Ibbotson[2], Peter Szaraz[2], Matteo Da Ros[3], Nuala Trainor[4], Carlene Petes[2]
[1]Lonza, Kingston, ON, [2]Lonza Personalized Medicine, Kingston, ON, [3]Lonza - Personalized Medicine, Kingston, ON, [4]Lonza Personalized Medicine, Kingston

Summary: Using the Lonza Cocoon® Platform, an automated upstream process for isolation and manufacturing of T cells directly from leukopaks was developed using Akadeum Life Sciences' Buoyancy-Activated Cell Sorting (BACS™) technology. Introduction: T cell isolation is a crucial upstream process in chimeric antigen receptor-modified T (CAR-T) cell manufacturing, as it selects an enriched population of T cells from the patient's blood starting material. Two common methods for isolating T cells are positive selection and negative selection. Negative selection is used in therapeutic applications to avoid the potential activation or exhaustion of T cells that can occur with positive selection methodologies. Additionally, negative selection helps minimize impurities from non-T cells, improving the overall efficiency of CAR-T cell expansion and therapy effectiveness.

Methods: CD3+ cells were enriched using the Akadeum Human T Cell Leukopak Isolation Kit – GMP Grade (antibodies and buoyant microbubbles). Antibodies were added directly to the leukopak material, followed by automation using the Cocoon® Platform for mixing, transfer of the microbubbles for binding, buoyant separation using gravitational forces and collection of the negatively selected T cells. Post upstream processing, 1×10^8 enriched T cells were seeded into the Cocoon® Cassette for automated activation and expansion using the standard 9-day CAR-T Cocoon® Platform process.

Results: Upstream processing on the Cocoon® Platform using BACS™ technology recovered 68.7±14.9% of CD3+ cells with purities of 91.3±3.0% and viability of 97.1±2.3%. The 1×10^8 cells seeded in the Cocoon® Cassette expanded to $2.67\pm0.53\times10^9$ cells with 96.1±3.5% viability at the end of the automated 9-day CAR-T Cocoon® Platform process.

Conclusion: The Cocoon® Platform in combination with BACS™ negative selection technology can automate isolation, activation, and expansion of T cells with high purity and recovery, as well as final product viability and yields. Donor leukapheresis materials are processed directly from the leukopak, without need for washes to minimize material and handling steps. This process significantly reduces hands-on time involved in manual T cell isolation and expansion, through reliable automation of end-to-end CAR-T therapy manufacturing.

1797 Healthier Cells with Akadeum's Alerion Microbubble Separation System: A Novel Approach to Gentle and Efficient Cell Isolation

Crisha Barrett[1], Brittany Macintyre[1], Jesse Chen[2], Jordan RoseFigura[1], William Lloyd[1]
[1]Akadeum Life Sciences, Ann Arbor, MI, [2]Akadeum Life Sciences, Ann Arbor

A high-quality cell isolation that preserves cell health and functionality is a critical step in the evolution of chimeric antigen receptor T (CAR T) cell therapy workflows. Isolated T cells undergo significant stress during genetic modification processes, making it crucial for therapeutic efficacy and manufacturing success that the cells are in optimal health prior to modification and their viability and functionality are not compromised during the isolation process. The combination of Akadeum's Alerion™ Microbubble Separation System, BioRise™ consumable, and negative selection Human T Cell Leukopak Isolation Kit provides a novel approach to cell isolation that prioritizes preserved cell health and efficiency.

In this study, the Alerion™ based Human T Cell Leukopak Isolation was evaluated in a head-to-head comparison against magnetic-based method for its ability to gently isolate T cells while also delivering a high yield of pure T cells. Akadeum's unique silica microbubble technology leverages gravity for separation, allowing the T cells to remain untouched throughout the separation workflow, which is proposed to minimize cellular stress. Results demonstrated that the T cell isolation workflow on the Alerion™ consistently outperformed traditional magnetic isolation methods in preserving T cell health and maintaining highly functional cells.

The Alerion™ is a scalable semi-automated instrument that provides a closed system capable of isolating billions of T cells in less than one hour. This allows more cells to be processed in less time, leading to potential cost savings and higher productivity. By preserving the natural state of T cells, the Alerion™ Microbubble System, BioRise consumable, and Akadeum's negative selection Human T Cell Leukopak Isolation Kit demonstrates advantages in cellular survival that could have major impacts on the efficacy of CAR T cell manufacturing, providing the potential for better therapies.

1798 Peripheral Blood Mononuclear Cell (PBMC) Isolation Using Cell Fractionation Filters

Supriya Prakash[1]*, Sharlene Amador[1], Jeff Cram[1]*
[1]ElevateBio, Waltham, MA
**Corresponding Author*

Leukapheresis collections, the standard starting material for CAR-T cell therapies, provide sufficient cell numbers but require specialized equipment and long collection times, increasing the overall manufacturing costs and timelines. In contrast, isolating T cells from whole blood offers a safer and more cost-effective cell procurement alternative, enhancing the overall patient experience. However, whole blood contains 10 to 100 times more red blood cells (RBCs) and platelets than leukapheresis material. These cell impurities interfere with standard T cell labeling and enrichment operations and should be removed via a peripheral blood mononuclear cell (PBMC) isolation step prior to processing. Traditional PBMC isolation methods, such as manual or automated Ficoll gradient separation, often result in low recovery, highlighting the need for improved techniques to make whole blood a viable starting material for CAR-T manufacturing.

In this study, we explored the use of cell fractionation filters with pore sizes ranging from 5 to 9 µm, as a novel method for PBMC isolation. These filters separate the larger white blood cells (WBCs) from smaller RBCs and platelets via size exclusion. Using whole blood from two healthy donors, we identified the optimal filter pore size for RBC and WBC separation, achieving 80% CD3+ T cell recovery—a 2-fold improvement over Ficoll gradient separation. We also demonstrated >99% RBC and platelet depletion, 20% granulocyte depletion, and maintained high cell viability (>94%) in the enriched PBMCs. Additionally, we assessed T cell purity and recovery after magnetic enrichment, both with and without prior PBMC enrichment. Finally, we proposed a closed-system T cell enrichment workflow incorporating cell fractionation filters. This workflow facilitates the rapid and scalable production of CAR-T therapies directly from whole blood, improving their accessibility and affordability.

1799 Rapid Isolation of Immune Cells for Cellular Therapeutics Using Multiple Antigen Criteria

Bob Snyder[1], Alessio Ligabue[2], Shanqiao Wei[3], Anjala Bulathge[3], Ian Mount[3], Cherry Leung[3]
[1]Proteios Technology, Inc., Issaquah, WA, [2]Proteios Technology, Inc, Seattle, WA, [3]Proteios Technology, Inc., Seattle, WA

Introduction. Cell therapies have emerged as highly promising treatments for blood-borne cancers, solid tumors and diseases resulting from viral infection. However, CAR-T cell generation is a labor-intensive, rigorous, and costly procedure, and progress towards optimizing cell selection and manufacturing has been slow. The process requires highly trained personnel and/or equipment with a large footprint and exhibits minimal flexibility to suit patient needs and facility scheduling. Moreover, current methods are based on antibodies - which are expensive and time-consuming to produce, exhibit batch-to-batch variability, can have a stability of less than three months in cGMP settings, and may come with a risk of immunogenicity. Centrifugation is often used in this preparatory step, and it has been shown to be associated with cellular stress and cell damage. Finally, the most common cell isolation strategies are based on magnetic nanobeads, which can cause DNA damage through reactive oxygen species generation. We wish to report the development of a closed and automated cell isolation device and cell therapy manufacturing device that significantly decreases the time and cost of cell isolation from both Leukopak and peripheral blood. The technology does not use centrifugation, magnetic beads, or antibodies, and produces intact immune cells isolated using one or more surface marker criteria (double- or triple-positive isolation). Enrichment/depletion can be performed in parallel, minimizing cellular stress during the process of cellular isolation.

Methods. We compared CD8+ CAR-T cell manufacturing performed using the platform against the current leading platform for cell therapy manufacturing. We have demonstrated the flexibility of this approach to isolate double-positive CD8+/CD62L+ T Cell Helper cells.

Results. Cell therapy manufacturing runs performed on the device resulted in a CD8+ CAR-T product with better cell viability, better transduction efficiency, better expansion rate, reduced exhaustion markers, and comparable purity and yield when compared with the leading cell therapy manufacturing device. In addition, the device does not require platelet washing prior to the manufacturing process - reducing the cell isolation process to less than one hour. In the case of frozen starting material, a simple dilution of the cryopreservant agent is all that is required. Small-scale, double-positive isolation of CD8+/CD62L+ T Cell Helper cells (**Figure 1**) provided about 70 million target cells with a purity greater than 95%, viability greater than 99% and a recovery rate greater than 70% in less than 90 minutes. Further developments are undergoing to increase the cell yield to 1 billion target cells.

Conclusion. The cell isolation device provides research centers and manufacturing facilities with a closed, scalable and automated system that provides intact target cells with high viability based on multiple surface antigen selection criteria.

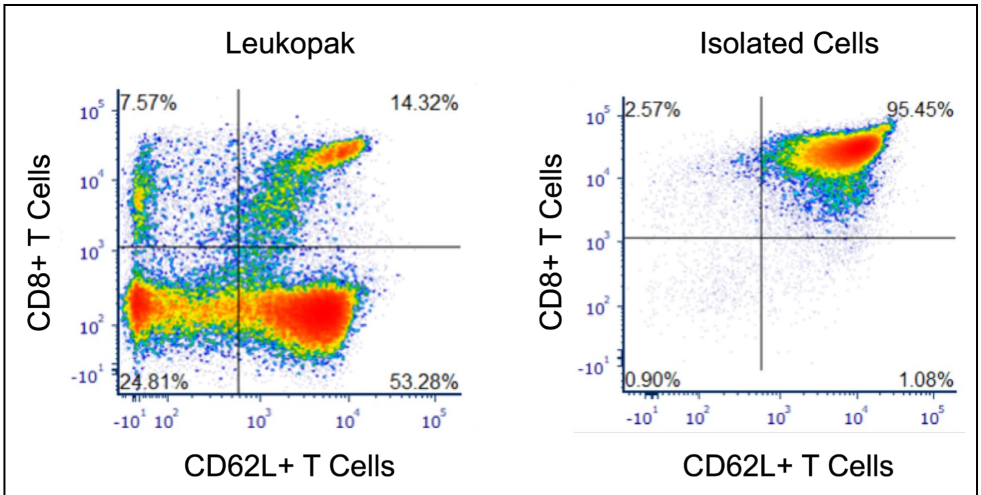

Figure 1: Double-positive isolation of T Cell Helper cells from Leukopak with high purity and yield. Two cell isolation modules were daisy-chained together, with the first module enriching for CD8+ T cells and the second module performing the second selection criteria based on the CD62L surface antigen.

1800 Comparison of Isolation Methods of CD3+ T Cells from Leukapheresis

Ping Wei[1], Tejashree Redij[2], Xuan Guo[3], Junxia Wang[4]
[1]Catalent Pharma Solution, Princeton, NJ, [2]Catalent Pharma Solutions, Princeton, NJ, [3]Catalent Cell and Gene Therapy, Princeton, USA, Princeton, NJ, [4]Premier Biosciences, Princeton, NJ

Method: Healthy donor leukapheresis and whole blood samples were used as starting materials for T cell isolation. Three methods were compared: two rapid isolation processes and a conventional GMP-compliant isolation method. The rapid isolation methods were tested in both open and closed systems. Following isolation, T cells were cultured and transduced with a lentiviral vector encoding a CAR. CD3+ cell recovery, viability, phenotype, purity, transduction efficiency, and expansion capacity were analyzed. Process efficiency, material cost reduction, and isolation time were also assessed for all methods.

Results: The rapid T cell isolation methods demonstrated notable efficiencies. Post-selection, CD3+ frequencies increased from 56% to 83% (open system) and from 58% to 96% (closed system). CD4/CD8 ratios remained stable across all methods, though donor variability was observed with average viability consistently measured at 98%.

Unwanted cell populations, including CD14+, CD56+, and CD19+ cells, were significantly reduced. CD14+ cells decreased from 24% to 4% (open system) and from 27% to 0% (closed system). Similar reductions were observed for CD56+ and CD19+ populations. T cells isolated using the rapid methods exhibited proliferation comparable to cells isolated via the conventional 5-hour process. The transduction efficiency is equivalent to the conventional GMP compliance process. The closed-system rapid isolation method, which is fully GMP-compliant, achieved similar or superior cell quality while reducing material costs by 52% and processing time to 2.5 hours.

Conclusion: This study highlights a new rapid T cell isolation process suitable for GMP-compliant CAR-T manufacturing. Compared to the conventional GMP-compliant isolation process, the rapid method offered significant advantages, including a 50% reduction in labor, over 50% reduction in total isolation time, material cost savings of up to 52%. Most importantly, the rapid process ensured the delivery of CAR transgenes to target cell types such as T cells, thereby mitigating the risk of transducing malignant cells from starting materials. These findings support the use of new rapid cell isolation process as a viable alternative for automated, closed-system CAR-T cell manufacturing, offering enhanced efficiency, cost savings, and scalability for clinical applications.

1801 Novel Automatic Application for Enrichment of CD34$^+$ Hematopoietic Stem and Progenitor Cells from Apheresis Products

Eleni Papanikolaou[1], Julia Dzionek[2], Stephanie Soltenborn[2], Svenja Oberbörsch[2], Valeriya Olevska, Christin Bosbach, Felix Hebbeker, Burgund Kauling, Juliane Raasch, Carina Wenzel[1], Katharina Kraemer[3], Heike Lahnor[3], Rene Meissner[3], Andreas Bosio[4], Rimas Orentas[5]
[1]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Nordrhein-Westfalen, Germany, [2]Miltenyi Biotec B.V. & Co. KG, BERGISCH GLADBACH, Germany, [3]Miltenyi Biomedicine GmbH, Bergisch Gladbach, Germany, [4]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, (None), Germany, [5]Miltenyi Biotec, Gaithersburg, MD

Enrichment of CD34$^+$ cells from leukaphereses samples has been employed for decades as a part of curative treatments for hematologic malignancies in the context of allogeneic hematopoietic stem cell transplantation (HSCT) to mitigate graft vs host disease (GVHD). Accordingly, CD34$^+$ enrichment represents the first and essential process step for the eventual genetic modification in the HSC gene therapy field. In addition, interventions termed as a “stem cell boost” for both HSCT and CAR-T cell therapy, have been introduced as a measure to manage cytopenia. Therefore, the need to advance the CD34 enrichment process still constitutes a major contributing step in manufacturing and constant improvements are mandatory to further advance cell and gene therapies. To this end, we developed two new, highly efficient streamlined processes to facilitate administration of HSCs in differing therapeutic scenarios without compromising the number and purity of transplantable CD34 cells.

Based on MACS Technology the CliniMACS Prodigy HSC Enrichment System (GMP) and the LP-34-(320) (CE) System, enable automatic production of an injectable CD34-enriched cell population which is also T cell depleted by virtue of the processing procedure. Central components of the new application, which utilizes tubing set TS 320, include a newly developed platelet removal step, a white blood cell (WBC)-adjusted separation and the possibility of product release at a requested time point because the process allows storage of the labeled cells for up to 16h. The process is sufficient for the enrichment of $1.2x10^9$ CD34$^+$ cells from up to $120x10^9$ total WBCs. To facilitate analysis during manufacturing, a new fluorescent flow analysis protocol suitable for analysis of the very low percentage of remaining T cells in the purified product and a low percentage of CD34 cells in the starting material was additionally developed.

In house evaluation runs (n=24) using mobilized leukapheresis products resulted in a mean depletion of 4.7 log (range 4.2 – 5.4) for T cells, a mean platelet depletion of 2.8 log (range 2.0 – 3.7), a mean B cell depletion of 3.2 log (range 2.0 –3.8), and a mean purity of 90.9% (range 82.7 – 97) in the CD34-enriched product. Viability of CD34 cells in the target product was above 99%, mean yield was 65.2% and mean WBC recovery was 85.4%. The process duration is approximately within 3.0 – 5.5 hours, depending on the cell numbers, excluding the device set up and the optional in-process storage. The comparability to the existing CliniMACS Plus System was also addressed and will be presented.

Conclusively, the novel application is an automated process in a closed fluidic system with minimal user interaction and flexible time control that supports the need for individual cell manufacturing. The highly purified $CD34^+$ stem cells can be used either as an injectable stem cell graft or as a starting product for subsequent stem cell engineering approaches.

1802 From Fresh to Frozen and Everything in Between: Revolutionizing WBC Isolation from Leukopak and Whole Blood with the Rotea Counterflow Centrifugation System

Pushpalatha Chaluvappa[1], Young Kim[2]*, Carl Dargitz[3], Norbert Hernandez[1], Namritha Ravinder[4], Ranganatha Somasagara[1], krishna Kundu[1]

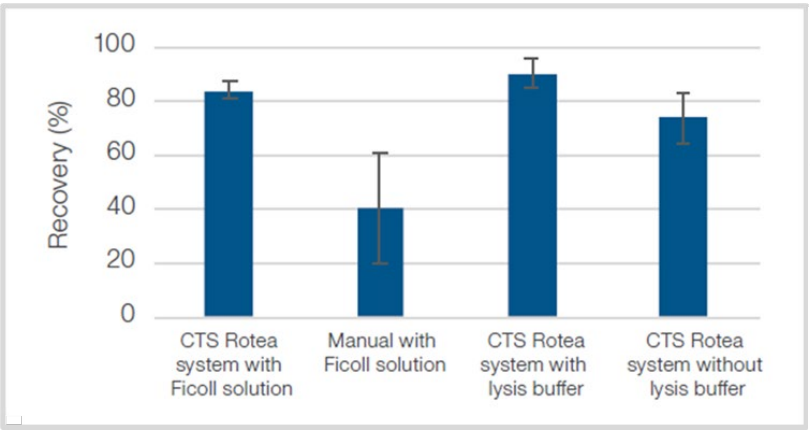
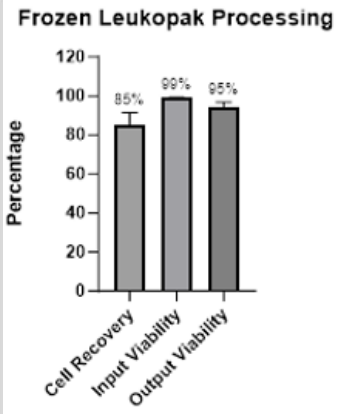
**Corresponding Author*

Aim and background: The cell therapy market today comprises numerous companies and academic institutions utilizing various starting materials to produce final cell therapy products. As the cell therapy market continues to grow rapidly, the demand for flexible and efficient processing instruments is increasingly critical. The Rotea Counterflow Centrifugation System is a versatile cell processing instrument capable of isolating white blood cells (WBCs) from multiple sources, including whole blood, fresh leukopak, and frozen leukopak, with minimal viability loss and exceptional cell recovery.

Methods & Results: The counterflow centrifugation system was used to isolate the WBCs using the 3 different source material with multiple donors to account for the donor to donor variation. The cell recovery and viability pre and post processing was analyzed using an automated counting instrument and the phenotype pre and post processing was measured using flow cytometry. Cells post isolation were also cultured to make sure of no adverse effect in the expansion process. For fresh leukopak, the system offers three distinct methods to isolate WBCs, employing different reagents. These methods cater to customers using legacy reagents like Ficoll and introduce new approaches with ACK lysis buffer for RBC lysis and WBC isolation, achieving a cell recovery rate of 91%. Phenotypic analysis before and after processing indicates no significant differences. For users preferring frozen leukopaks due to their convenience, the system provides an efficient option for WBC isolation, achieving an 85% cell recovery rate without significantly impacting viability. The system also supports whole blood processing, appealing to those seeking time, cost, and resource efficiency. This method yields a 70% cell recovery rate with minimal RBC carryover and no significant viability impact. Phenotypic data confirm no notable differences pre- and post-processing. The process can also be customized to enrich a specific set of cell type as well.

Conclusion: The adaptable and modular design of the Rotea Counterflow Centrifugation System makes it an invaluable tool for laboratories aiming to optimize WBC isolation processes. As demand for advanced cell therapy solutions increases, the need for such versatile and efficient instruments will become even more pronounced, ensuring high-quality outcomes in the evolving cell therapy landscape.





1803 Novel Detection Method for Residual Beads in CAR T-Cell Manufacturing Using Imaging Flow Cytometry

Maetja Verbarendse[1], Kyle Sylakowski[1], Panos Theofilas[1], Jennifer Kandell[1], Shreya Shukla[2], Chad MacArthur[1], Mindy Sadik[3], Uma Lakshmipathy[1]
[1]Thermo Fisher Scientific, San Diego, CA, [2]Thermo Fisher Scientific, San Francisco, CA, [3]Thermo Fisher Scientific, San Francisco

Gene-modified cell therapies, such as Chimeric Antigen Receptor T-cell (CAR-T) therapy, have revolutionized cancer treatment and show potential for treating genetic disorders and autoimmune diseases. The manufacturing process involves isolating, activating, and expanding human T cells, for which CD3/CD28 Dynabeads offer a streamlined solution. These beads have been used in over 200 clinical trials; however, since they are non-biodegradable, their removal from the final product is crucial. Newer systems with detachable beads still consider residual beads as contaminants, with the FDA requiring fewer than 100 beads per 3 million cells in the final product. Consequently, a precise and accurate assay for detecting and quantifying residual beads is essential for product release testing. Current methods are either labor-intensive, have low throughput, or require specialized equipment. This study introduces a novel imaging flow cytometry-based assay designed to improve quality control and reliability in product release testing. The study employed the Attune CytPix flow cytometer, which combines traditional cytometry with high-content imaging, making it ideal for detecting rare events like residual beads in cell products. Over 300,000 images per sample were captured and analyzed using the instrument's software to assess object and pixel attributes. Twenty-six image analysis parameters were explored in various combinations to determine the optimal gating and analysis strategy for distinguishing cells and beads. The analytical procedure was validated according to ICHQ2R2 guidelines to ensure consistency, accuracy, and reproducibility. The method proved reproducible across different users, instruments, and labs, with a lower detection limit of 20 beads and a lower quantification limit of 20 beads per million cells. This novel assay offers a reliable alternative to existing residual bead detection methods and can be implemented on a platform commonly available in cell therapy manufacturing facilities.

1804 Method Development and Scale Prediction for Separation Systems to Solve Challenges in Allogeneic Scale-up

Donald Beers, Entegris Inc., Lakeville, MN

There are many challenges to scalability and continuous processing for allogeneic therapies that will need to be addressed to reduce production costs and ensure stable supply. One such consideration for both the production of viral vectors and for large scale cell therapies is the high weight % of solids in concentrated and process intensified bioreactors. As the titers increase, it is critical to reduce hold-up and utilize smaller surface area devices, achieving high flux and throughput to keep processing times short and eliminate loss. This work presents the application of established filtration methods to predictively model the throughput and hold-up per surface area on different nominal porosity separation systems and compares them to other methods. This also presents a process for establishing surrogate material to establish boundary conditions for the devices ahead of approaching cell separation by trial and error.

1805 Streamlined Ex-Vivo Engineering of Human T Cells: A Single-Step Approach to Activation and Lentiviral Transduction

Thomas Quinn[1], Mei Fong[1], Lily Lee[1], Andre Dharmawan[1], Michael Haugwitz[1], Andrew Farmer[1]
[1]Takara Bio USA, San Jose, CA

Efficient T cell engineering is essential for the success of CAR T cell therapy. Conventional methods—encompassing T cell isolation, activation, and transduction—are often intricate and time-consuming. They typically require materials from multiple suppliers and involve separate activation steps using antibody-coated beads or soluble antibody complexes, followed by transduction processes that frequently depend on spinoculation with

enhancers such as Polybrene or LentiBOOST. These traditional approaches demand considerable time and labor while often exhibiting variability and inefficiencies that can negatively affect cell yield and therapeutic effectiveness. We present an innovative approach to enhance the ex-vivo engineering of human T cells by integrating cell activation and efficient lentiviral transduction into a single step, reducing time and resource requirements while maintaining high performance. Our approach leverages a lyophilized, GMP-grade alginate-based microfluidic sponge embedded with anti-CD3 and anti-CD28 antibodies and interleukin-2 for efficient activation of T cells. The one-step transduction is performed by simply applying a mixture of recombinant virus and unstimulated T cells or PBMCs to the Sponge, followed by incubation at 37°C. The hygroscopic nature and 20-300 nm pore size of the sponge help to spatially colocalize cells and virus within an exceedingly small space, facilitating efficient transduction as well as ensuring uniform exposure to activation signals. The release of activated and transduced cells is facilitated by a chelating release buffer that quickly depolymerizes the sponge, ensuring the rapid recovery of high-quality transduced cells with minimal handling. This design simplifies the workflow compared to spinoculation with Polybrene, reducing the process by 9 steps compared to traditional methods, while enhancing transduction efficiency via a centrifugation and enhancer-free microfluidics approach. The reduced number of handling steps also minimize contamination risks and variability between batches. Our data across multiple donors and operators consistently indicate strong activation and transduction efficiencies (%CV <15%; n=54), with no adverse effects on growth rates, cell phenotypes, or exhaustion marker expression compared to standard protocols. The reproducibility of this new method underscores the robustness of our approach. Furthermore, our ex-vivo lentiviral T cell transduction sponge is user-friendly and scalable, accommodating cell numbers ranging from 2e6 to 1e7 per sponge, making it suitable for both research and preclinical applications. By providing a streamlined and user-friendly system for T cell engineering, we strive to drive progress in T cell therapies and expand their availability to a wider range of patients.

1806 Maximizing Safety and Efficacy in Hematopoietic Stem Cell Gene Therapy

Eleni Papanikolaou[1], Aurora Giommetti[1], Valeriya Olevska[2], Stephanie Soltenborn, Christin Bosbach[2], Julia Dzionek, Felix Hebbeker[2], Svenja Oberbörsch, Lilian Martinez Carrera[2], Nojan Jelveh[3], Kevin Bisdorf[3], Svetlana Khorkova[3], Christian Woehle, Stefan Tomiuk[2], Rimas Orentas[4]
[1]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Nordrhein-Westfalen, Germany, [2]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany, [3]Miltenyi Biotec BV & Co KG, GERMANY, [4]Miltenyi Biotec, Gaithersburg, MD

Although new treatments for hematopoietic stem cell (HSC) gene therapy have been recently approved for several diseases such as beta-thalassemia (Zynteglo), sickle cell disease (Lyfgenia and Casgevy), and adrenoleukodystrophy (Skysona), a certain number of challenges still remain such as the high costs and scalability associated with these therapies, as well as the increased safety concerns regarding the related leukemic events. These indicate a need for improved and standardized manufacturing steps allowing for large scale implementation of gene therapy interventions to a degree that addresses the population suffering from the long-term sequalae of these diseases. Automation is the key to achieve these goals and, to this end, the CliniMACS Prodigy as an automated, closed, GMP-compliant platform for HSC transduction, is an ideal candidate to streamline cell processing. We had previously shown (https://doi.org/10.1182/blood-2019-128780) that lentiviral transduction (LV) is facilitated on the CliniMACS Prodigy compared to manual steps when a VSVG pseudotyped LV expressing GFP was utilized. In the current study, we extended the same rationale by employing LVs expressing CAR constructs, VSVG- or BaEV (Baboon Endogenous retrovirus)- pseudotyped, to compare transductions performed on the CliniMACS Prodigy vs the open manual steps. We also made a slight modification to our original transduction medium which now contains only the “basic” necessary cytokines such as SCT, FLT3 and TPO. With the new modifications we overall observed comparable cell recovery and viability between the manual and automated conditions, but still superior performance of the automated platform in terms of transduction efficiency. Flow cytometric analysis for transgene expression using the VSVG pseudotyped LVs with an MOI of 30 showed 39% vs 20% expression on the Prodigy vs the manual process without a significant difference in vector copies per genome. Interestingly, our analysis for the BaEV pseudotyped vectors demonstrated superior transduction efficiency with a very low MOI (0-5) in the presence of vectofusin. More specifically, by using the open manual process and an MOI of 2 and an MOI of 0.75, we saw 40% and 20% transgene expression, respectively, which is unprecedent for HSC transductions under these minimal MOIs. Even under these conditions of minimal MOI, the automated platform exhibited higher transduction efficiency vs the manual steps. *In vivo* experiments using NSG mice also demonstrated better engraftment for the $CD34^+$ cells processed on the CliniMACS Prodigy under the “basic” transduction conditions compared to the

manually cultivated $CD34^+$ cells and also compared vs the "gold standard" i.e. uncultivated and unmanipulated $CD34^+$ cells directly after enrichment. Better engraftment was also corroborated by the stable number of CFUs generated by the cells processed on the CliniMACS Prodigy vs cells processed manually which showed a clear trend towards decreasing numbers of CFUs. Based on these results, we propose a combined strategy of transduction enhancers and the use of Baboon envelope pseudotyped LV on the automated platform to achieve significantly higher transduction efficiencies and enhanced engraftment. Experiments to investigate the mechanisms involved in better performance of LV transduction on the automated platform, including detailed molecular analysis of gene expression pathways by Next Generation Sequencing (NGS), are ongoing.

1807 Optimizing CRISPR/Cas-mediated CAR Knock-in in Primary Human T Cells Using MaxCyte® Electroporation

Ashley Strickland-Dietz[1], Diwash Acharya[2], Lauren Unsworth[3], James Brady
[1]Na, Montgomery Village, MD, [2]MaxCyte, Rockville, MD, [3]MaxCyte, Inc., Rockville, MD

In recent years, chimeric antigen receptor (CAR) T cells have emerged as a leading treatment for various hematological cancers. Despite demonstrating great promise, there are several challenges that limit CAR T cell therapies including concerns regarding efficacy, safety and manufacturability. To address these, groups have turned to non-viral engineering of CAR T cells using CRISPR gene editing. In addition to reduced immunogenicity and manufacturing costs, this technology enables precise knock-in of tumor-targeting receptors and knockout of genes responsible for rejection, toxicity and immunosuppression. To CRISPR engineer CAR T cells, Cas nucleases, guide RNA (gRNA) and homology-directed repair (HDR) template DNA must be efficiently delivered into T cells without jeopardizing their viability or functionality. With this in mind, we sought to generate optimized workflows that enable CRISPR-mediated gene editing in primary human T cells using MaxCyte® electroporation. To this end, we first identified optimal electroporation protocols and concentrations of sgRNA, Cas9 and HDR template required to knock-in *GFP* at the *TRAC* locus. Next, we compared different repair template designs, including the addition of Cas9 targeting sequences (CTS). We also investigated multiple HDR template DNA formats, including linear double-stranded DNA, single-stranded DNA, conventional plasmids and Nanoplasmids™. In addition, we explored the use of small molecule enhancers and identified several that further improved editing efficiencies. These findings were then used to engineer CD19-targeting CAR T cells. With activated T cells from healthy donors, we could achieve CAR expression levels of greater than 70%. In addition to efficient and reproducible CAR knock-in in T cells from multiple donors, cells engineered using this workflow were viable and retained the ability to expand and eradicate CD19-expressing target cells. Together, these demonstrate the capability of MaxCyte's clinically-validated ExPERT™ electroporation technology to enable non-viral engineering of CAR T cells using the CRISPR/Cas system.

1808 A Versatile Platform for Cell Therapy Cytotoxicity Assays Using mRNA Transfection

Brock Binkowski[1]*, Julia Gilden[2], Nicholas Hess[2], Aileen Paguio[2], Mei Cong[1], Marjeta Urh[2]

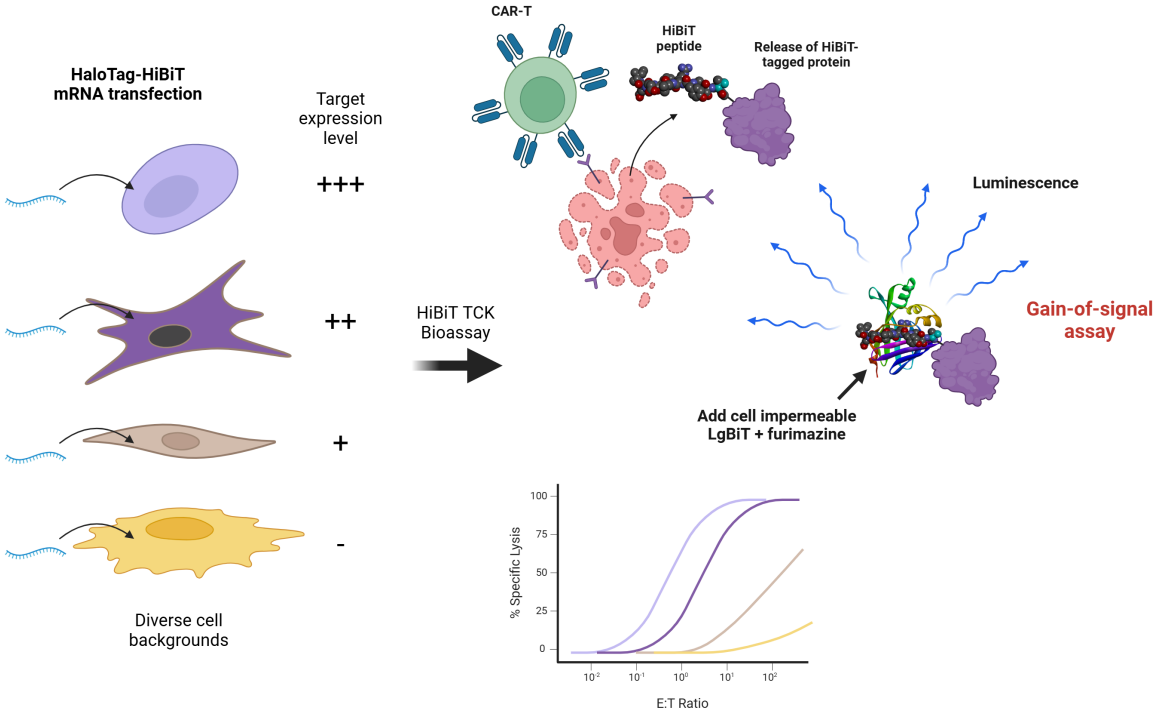
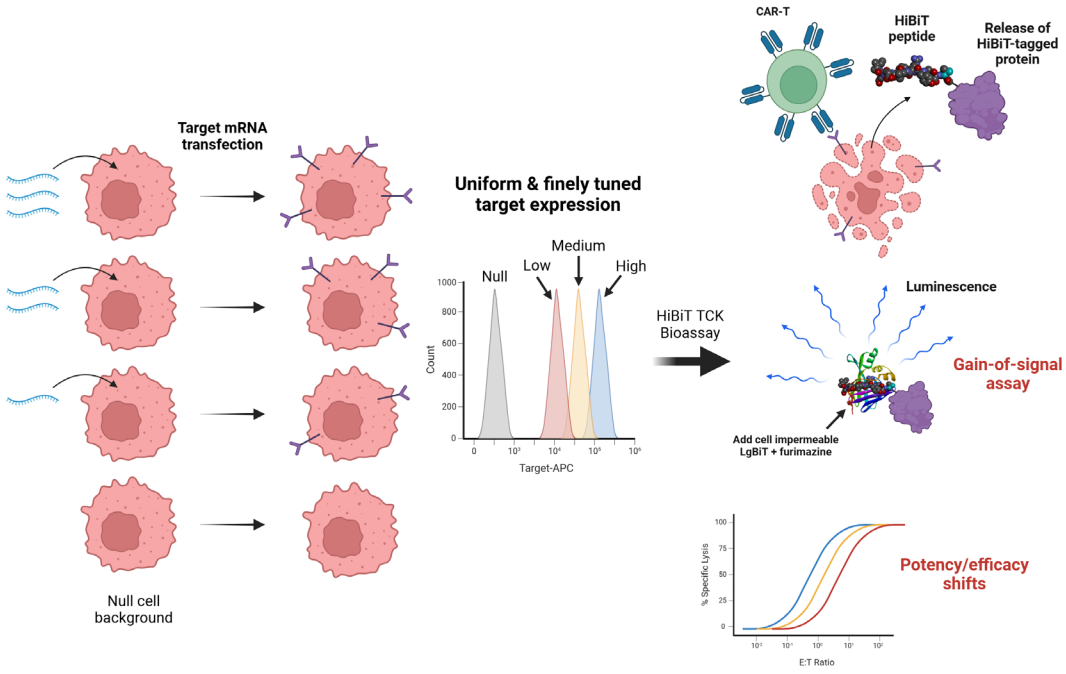
The HiBiT Target Cell Killing Bioassay (HiBiT TCK Bioassay) is a sensitive and selective method for quantifying target cell lysis in coculture experiments with effector cells. In this assay, target cells engineered to express a HiBiT-tagged protein are cocultured with effector cells, where target cell death promotes release of the HiBiT-tagged protein into the extracellular medium. Once there, HiBiT can bind to cell-impermeable LgBiT to generate a bright, luminescent enzyme in the presence of furimazine substrate. In this manner, a non-lytic detection reagent containing LgBiT and furimazine substrate can be used to quantify target cell death in a gain-of-signal assay format with a cumulative readout. To date, this approach has been used exclusively with stable expression of the HiBiT-tagged protein, requiring time and effort to make stable clones.

To expand beyond the use of stable clones, we developed a novel mRNA transfection reagent that enables rapid and uniform expression of HaloTag-HiBiT in a wide range of target cell types. This approach dramatically reduces the

workload for creating HiBiT target cells, allowing users to readily label target cell type(s) of interest. We demonstrate labeling of a variety of target cell types and their use in the HiBiT TCK Bioassay. Additionally, we demonstrate the use of mRNA transfection to achieve uniform and highly tunable expression of target receptors in cells stably expressing a HiBiT-tagged protein, allowing drug potency/efficacy testing across a broad range of receptor expression levels in a single cell type.





1809 Establishment of The Inducible AAV Production Cell Line 293RSS2.0

Tianqi Jiang[1], Xiaojing Sheng[2], Bingbing Wang[2], Xiaoxia Li[2], Yixiong Chen[3], Qing Lin[4]*
[1]Lingyi, Shanghai, China, [2]Lingyi Biotech, Shanghai, China, [3]Lingyi Biotech, Shanghai, China, China, [4]Lingyi Biotech, Lutherville, MD
**Corresponding Author*

The production of adeno-associated virus (AAV) in mammalian cells predominantly relies on the transient triple-plasmids transfection into HEK293-based cells. Four of seven EMA/FDA-approved AAV gene therapy products employ this production approach, capitalizing on its inherent assurance of product quality. Nevertheless, owing to the expenses associated with the transfection reagent and the production of three plasmids, the overall cost of transfection-based manufacturing proves to be high. Conversely, the constrained stability exhibited by the transfection complex during operational durations, coupled with the challenges associated with achieving prompt yet gentle mixing in a bioreactor, poses impediments to the scaling-up of production volumes beyond 500 liters for transfection-based AAV production. The cumulative drawbacks underscore the pressing necessity for the development of a production cell line that can seamlessly integrate all essential elements for AAV production. In our previous work, we have constructed a prototype production cell line, 293RSS1.0, characterized by inducible expression of AAV Rep and Cap proteins, which demonstrated promising potential for inducible AAV vector packaging. A new generation of stable production cell line, 293RSS2.0, was successfully developed with the stable integration of inducible Rep, Cap, and Helper expression cassettes, which only need the GOI plasmid transfection for AAV production.

In 293RSS2.0, further refining the expression ratio between Rep78 and Rep52 was achieved by engineering the inducible Rep expression cassette, which exhibited over a >10-fold enhancement in AAV production yield compared to 293RSS1.0. Lingyi-patented inducible Cap expression cassette and inducible Helper expression cassette were both incorporated in 293RSS2.0 cell line. This 293RSS2.0 production cell line consolidates all essential components necessary for AAV vector packaging, except for the gene of interest (GOI). Efficient AAV vector packaging was achieved via transfection with a single GOI plasmid in conjunction with a small-molecule inducer. In the absence of the inducer, the AAV packaging rate remains exceedingly low, consistent with Western blot results indicating minimal leakage of the essential components required for AAV packaging. The bioactivity of the vector generated through this innovative system was evaluated, demonstrating comparable bioactivity to that of the vector produced via the conventional triple-transfection method.

In conclusion, the 293RSS2.0 cell line facilitates the inducible expression of various components necessary for AAV vector packaging. The comparable yield and quality of AAV production suggest that this stable cell line-based system has the potential to serve as a transformative platform for future AAV vector manufacturing.

1810 The First Coacervate-Based Delivery System for CAR-T Cell Engineering and Manufacturing

Xiaofei Gao[1]*, Peipei Zhu[1], Manman Lu[2], Qing Zhang[2], Xiaoqian Nie[1]
[1]Westlake University, Hangzhou, Zhejiang, China, [2]Nanoportal Biotech, Hangzhou, China
**Corresponding Author*

Chimeric antigen receptor (CAR) T cells have revolutionized the treatment of hematological malignancies, but efficient and scalable engineering of primary cells remains a significant challenge in CAR-T cell manufacturing. Coacervates are condensed droplets containing proteins or nucleic acids formed via liquid-liquid phase separation. Here, we report the identification of a mammalian endogenous protein capable of forming coacervates with nucleic acids. These coacervates exhibit an RNA encapsulation capacity 1000-fold greater than lipid nanoparticles (LNPs), efficient cellular uptake, robust cytoplasmic release of nucleic acids, and broad compatibility with diverse primary immune cell types, including T cells, NK cells, and hematopoietic stem cells (HSCs). Building on these properties, we developed the first coacervate-based system for gene delivery (EASY) engineered using human and mouse proteins (PCT/CN2024/124967). EASY supports a wide range of genetic cargoes for gene overexpression, knockout, and targeted integration.

Using EASY, we achieved >90% transfection efficiency of mRNA encoding GFP in primary human T lymphocytes while maintaining 95% cell viability. GFP expression was sustained in 64% of cells for up to 12 days post-transfection, underscoring the platform's capacity for prolonged expression. Using EASY, we successfully generated mRNA-based anti-CD19 CAR-T cells that eliminated tumor growth in NSG mice xenografted with CD19+ Raji cells after a single dose (5×10^6 CAR-T cells). Furthermore, EASY facilitates efficient gene knockout by co-delivering Cas9 mRNA and sgRNAs. For instance, >80% knockout efficiency was achieved in the TRAC gene in primary T cells, enabling precise CAR-T engineering.

To enable gene-specific integration for CAR-T manufacturing, EASY was employed to co-deliver Cas9 mRNA, sgRNA, and single-stranded DNA (ssDNA) templates for homology-directed repair (HDR). This approach achieved >30% knock-in efficiency of an anti-CD19 CAR cassette at the PD locus, generating CAR-T cells with sustained CAR expression and disrupted PD1 function. These integrated CAR-T cells demonstrated potent anti-tumor activity in NSG mice xenografted with CD19+ Raji cells, highlighting their therapeutic potential.

EASY's simplicity, adaptability, and scalability make it ideally suited for clinical applications. The system has been successfully scaled up to deliver mRNA into over 10^9 primary T cells with >90% efficiency, demonstrating its feasibility for large-scale CAR-T manufacturing. Its straightforward preparation and high-throughput transfection capability further distinguish it as a transformative tool for advancing CAR-T engineering. In conclusion, EASY offers an innovative, non-viral, LNP-free, and electroporation-free platform for efficient and scalable CAR-T cell engineering. Its high efficiency, minimal toxicity, and compatibility with diverse genetic modifications position EASY as a next-generation solution for CAR-T manufacturing, unlocking new possibilities for cell therapy development.

1811 Development of a Quantitative Screen to Assess AAV On/Off-Target Binding and Transduction

Caitlin Edwards[1], Lucy Collins[2], Lucy Coverley[2], Michalis Vasiliou[2], Beth Walker[2], Lucy Hanley[2], Clare Halliday[3], Claire Tebbutt[4], Mark Aspinall-O'Dea[2]
[1]Charles River, BOLTON, Greater Manchester, United Kingdom, [2]Charles River Laboratories, High Peak, United Kingdom, [3]HIGH PEAK, Derbyshire, United Kingdom, [4]Charles River Laboratories, HIGH PEAK, Derbyshire, United Kingdom

Adeno-Associated Viruses (AAV) are a leading vector in gene therapy, with three FDA therapies approved over the last 5 years (1). Continued interest in AAV's shows the promise of this field, however issues including immunogenicity and large-scale manufacturing costs remain limiting factors for advancing AAV-based gene therapies (2,3). Here we describe a novel flow cytometry based dual screening capability for AAV's as a downstream assessment of targets identified using the Charles River Retrogenix® Cell Microarray platform.

Data from the Retrogenix® Cell Microarray technology, consisting of >6,500 full length human cell surface, secreted, tethered secreted, and heterodimeric vectors, and more recently non-human (Cynomolgus) protein targets, each over-expressed in HEK293 cells, is already used extensively in regulatory BLA and IND submissions. To provide further understanding for AAV profiling (4), flow cytometry testing has been developed. This sensitive, multiparametric and quantitative method provides a powerful tool for gene therapy by enabling detection of AAV receptor binding, transduction efficiency, and expression of encapsulated reporter genes in live cells.

Wild Type AAV9 controls were used to develop a flow cytometry binding assay to the known KIAA0319L AAV receptor, along with off targets previously identified using the Retrogenix® platform. In addition, AAV internalization (transduction) methodology was developed by measuring reporter gene expression. To avoid underestimating functional effects of low-level transgene expression, this was recorded as % positive cells, a method typically used in gene therapy (5,6).

Complimenting Retrogenix® Cell Microarray data using an orthologous platform provides a comprehensive insight into primary receptors and potential adverse event liabilities of AAV's. With the recent addition of non-human plasma membrane proteins with 90% human homology in the extracellular domain, our approach of assessing AAV

activity and specificity at these overexpressed proteins can help de-risk therapeutic candidates, aid in-vivo model selection, and provide data to support regulatory submissions.

1812 A Kinetic Perfusion Assay to Measure Gene Switch Responses *in vitro*

Isabel Brandtjen[1], Raphaela Bento[2], Piyushram Sravanam[1], Biju Parekkadan[1]*
[1]Rutgers University, Piscataway, NJ, [2]Massachusetts General Hospital - Harvard Medical School, Cambridge, MA
**Corresponding Author*

Introduction: Synthetic biology has made great strides toward approaching user-controlled gene expression by designing complex signaling systems within one genetic structure. These "gene switches" include the use of inducible promoters, synthetic receptors, and feedback loops to improve the specificity and sensitivity of transgene expression. Yet, these gene switches have transgene dynamics that have short timescales (~ minutes – hours) making them difficult to monitor using conventional cell culture approaches. Here, we present a flow assay system (Fig. 1A) to study the kinetics of gene switches with automated supernatant sample collection by integrated fractionation. Specifically, we tested a small library of inducible promoters that are switched on by cytokines to drive the release of a secreted biomarker (Fig. 1B) and characterized kinetic parameters by curve-fitting experimental data to math models of gene expression.

Methods: A continuous flow system was assembled to perfuse an in vitro cell culture and collect fractionated media over 24 hours. HEK cell reporter lines were stably engineered with different inducible promoter systems that encoded for specific transcription factor response elements (NFkB, STAT3, and AP-1). The inducible gene switches were upstream of a secreted biomarker, Gaussia Luciferase (GLuc), which was measured in fractionated supernatants using a bioluminescence assay. An in vitro stimulation study was performed by pulsing a cytokine-supplemented media followed by 24-hours of continuous flow of cell media to measure GLuc secretion dynamics. Complex media studies were also conducted using combinations of cytokines as well as supernatants harvested from a mixed lymphocyte reaction (MLR) assay to model an immune response. GLuc data was plotted against time to extract gene switch parameters by fitting data to mathematical expressions that model switching phenomena.

Results: Transgene induction and decay of a representative gene switch is shown to exemplify the type of kinetic data gathered using this perfusion system (Fig. 1C). In this example, a short pulse of TNF-α activated the reporter line resulting in a transient increase of GLuc followed by non-linear reduction in GLuc over time. The dose-response curve for the NFkB cell line was normalized to a non-engineered control and an activation curve was plotted (Fig. 1C). From the data provided by this dynamic system, we can extract several parameters (AUC, $t_{1/2}$, C_{max}, k_{on}, and k_{off} rates) of the gene sensors. Results using different inducible promoters, stimulated by single, combinations, or immune cell-derived cytokines were parametrically compared to learn about gene switch response dynamics under more complex conditions.

Conclusions: This flow-based assay system is designed for ease of use to enable kinetic sample collection in a relevant time scale for the study of gene switches. Parametric analysis of this kinetic data becomes useful in comparing responses for different genetic designs to see which is suitable for a given application. The characterization of dose-response relationships, on/off rates for a gene switch, and how complex media conditions can activate a given gene switch can add important insight for translating these technologies for cell and gene therapy.

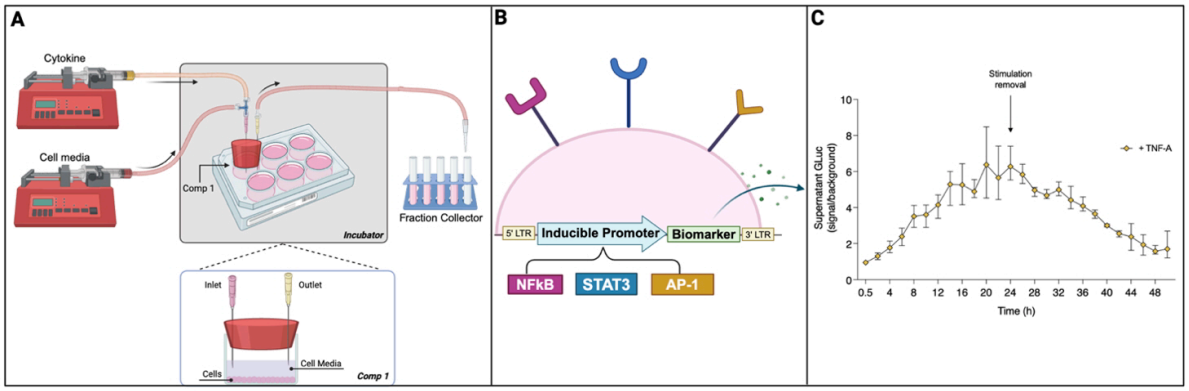


Figure 1. Perfusion assay system to study temporal activity of gene switches. (A) Perfusion bioreactor system with automated supernatant collection for cell secretion dynamic studies. (B) Schematic of inducible immunosensor designs where gene switches are activated to improve specificity and sensitivity of transgene expression. (C) Study of inducible response element (NFkB) activation dynamics upon continuous stimulation with cytokine supplemented media for 24 hours. Stimulation was stopped in the last 24 hours. Biomarker secretion (GLuc) was measured via bioluminescence assay in all fractions collected throughout the study.

1813 Rapid Mycoplasma Detection Techniques for Facilitating Quality in Low-Volume T Cell Therapies

Despina Lymperopoulou[1], Maya Dubey[1]
[1]*Thermo Fisher Scientific, Pleasanton, CA*

The increase in demand for CAR T-based immunotherapies has necessitated improvements in the analytical workflow to enhance patient access while maintaining safety and efficacy. Particularly relevant for cell therapy manufacturers is the potential challenge of limited sample availability. To address this challenge this study delves into the sensitivity and effectiveness of a qPCR-based assay for detecting mycoplasma contamination in T-cell cultures, which are pivotal for the development of cell-based therapies. The research specifically targets the assay's performance in low-volume T-cell samples, typically ranging from 1 to 3 mL.

Methods: The method used in this study involved the preparation and analysis of low-volume T-cell samples to detect mycoplasma contamination using the Applied Biosystems™ MycoSEQ™ Plus Mycoplasma Detection assay, which is PCR-based. Initial sample volumes of 1, 2, and 3 mL were processed. The procedure included spiking DNA templates into the samples, followed by cell lysis, DNA binding, washing, and elution with either Applied Biosystems™ PrepSEQ™ Manual or Automated Express extraction workflow followed by alcohol precipitation steps to concentrate the final eluate. The DNA was then subjected to qPCR analysis using specific reagents and conditions to determine the presence of mycoplasma. Both automated and manual extraction workflows were evaluated to optimize the detection sensitivity and enable reliable results across various sample volumes.

Results: The study demonstrated the high sensitivity of the MycoSEQ Plus assay in detecting mycoplasma contamination in low-volume T-cell samples across various matrices. The detection rates for key mycoplasma species (M. arginini, M. salivarium, M. fermentans, M. orale, and M. pneumoniae) spiked into different media were consistent and reliable, with all tested species detected at a 100% rate at the specified LOD. The comprehensive workflow combining the Applied Biosystems™ PrepSEQ™ Manual or Automated Express extraction, followed by alcohol precipitation, proved effective in concentrating the DNA for accurate qPCR analysis. Both manual and automated workflows seamlessly integrated with the Applied Biosystems™ AccuSEQ™ analytical software, helping to ensure robust and reproducible results while helping to achieve 21 CFR Part 11 compliance.

Conclusions: The MycoSEQ Plus Mycoplasma Detection Kit provides an effective and sensitive solution for the detection of mycoplasma in low-volume T-cell samples. Its successful application in different sample matrices underscores its utility in quality assurance, quality control, and process development for cell therapy manufacturing. By offering reliable detection in lower sample volumes, it expands the usability of the MycoSEQ Plus assay, particularly for cell and gene therapy applications where sample volume is often limited.

For Research Use Only. Not for use in diagnostic procedures.

1814 Assessment of Adeno-Associated Virus (AAV) Purity by Capillary Electrophoresis-Based Western

Julyana Acevedo[1], Yiling Bi[2], Santoshkumar Khatwani[3]
[1]Sangamo Therapeutics Inc, Brisbane, CA, [2]Sangamo Therapeutics, Brisbane, CA, [3]Sangamo Therapeutics, San Ramon, CA

In the development of AAV-based gene therapies, it is important to obtain a drug product with high purity and minimal levels of impurities. In this study, we present two CE-Western assays for the analytical assessment of AAV, focusing on quantifying the relative stoichiometry of viral proteins (VP) and measuring residual baculovirus protein impurities, specifically GP64. Various purified samples from diverse AAV serotypes were analyzed to determine their VP ratio or GP64 levels. The ratio of VP3/VP1 in rAAV samples was correlated with biological activity, and the clearance of GP64 from the manufacturing process was demonstrated. The results were further supported by LC-MS analyses. We demonstrated that CE-Western can be used as a high-throughput platform to assess the identity, composition, and purity of rAAV drug products.

1815 Seroprevalence, Correlation, and Clinical Relevance of Total and Neutralizing Anti-AAV Antibodies and Assay Formats

Stephen Bradley[1], **Gregory Preston**[2], Jihua Chen[3], Jennifer Bond[4]
[1]Alexion, Marlborough, MA, [2]Alexion Pharmaceuticals Inc., Cambridge, MA, [3]Alexion Pharmaceuticals, New Haven, CT, [4]Alexion Pharmaceuticals Inc., Durham, NC

AAV based gene therapies provide great promise for curative treatment of many genetics-based diseases but are limited in practice due to existing anti-AAV antibodies, for which seroprevalence is high and is also dependent on age, race, and disease populations. These pre-existing antibodies can inhibit the transduction of AAVs carrying therapeutic transgenes, and subjects who have them are typically excluded from participating in clinical trials due to safety and efficacy concerns. Therefore, a robust and translatable bioanalytical method that measures and characterizes these antibodies must be employed during screening periods as an exclusion/inclusion criterion. There is currently no formal guidance on what method to use, and therefore, different assay formats have been applied, including cell-based transduction inhibition assays (neutralizing antibody assays; NAb) and total antibody-based ligand binding assays (TAb). We investigated the seroprevalence of anti-AAV antibodies in healthy donors for two different capsids, AAV9 and a variant of AAV9, using TAb and NAb assays to help facilitate the decision for which assay format would be the most appropriate for clinical trial inclusion and exclusion. Among 200 serum samples tested in the TAb assays, 45% and 39% were positive respectively, for anti-AAV9 and the AAV9 variant. TAbs with titers ranging 50 (the MRD or minimum required dilution) to 51,200-fold. 100 samples were tested in the NAb assays resulting in 55% and 50% being NAb positive, respectively, for AAV9 and the AAV9 variant with titers ranging from 5 (the MRD) to >40-fold. We observed a strong correlation between AAV9 and the AAV9 variant TAb positive samples (R^2=0.62). The seroprevalence of AAV9 antibodies that we observed aligns with relevant literature using robust qualified assays and cut-points. We also observed a strong correlation between positive and negative TAb samples with their characterized NAb responses for both capsids with an overall 10% discordance seen between TAb and NAb. We performed isotyping for IgG and IgM to explore the contribution of antibody-related affinity or avidity binding differences between the bridging and cell-based formats and did not observe an IgM related contribution to the discordance. TAb seroprevalence being 10% lower than NAb seroprevalence for both capsids is most likely due to non-antibody related factors and other assay format differences that requires

further investigation. For clinical trial enrollment expectations, a seroprevalence rate of 45% for AAV9 TAbs with a goal to enroll 50 subjects would require recruiting at least 111 subjects for screening.

In summary, the overall concordance data and assessment supports using the TAb assay format for patient screening and future companion diagnostic development for AAV gene therapy programs using AAV9 and closely related capsids.

1816 Novel Bioluminescent Assays for Detecting Anti-AAV Neutralizing and Total Antibodies in Serum Samples

Jeff Nelson[1], Brock Binkowski[1], Morten Seirup[2], Marjeta Urh[2]
[1]Promega Corporation, Madison, WI, [2]Promega Corporation, Fitchburg, WI

Adeno-associated virus (AAV)-based gene therapies have shown great promise for treating a range of genetic disorders. However, pre-existing or therapy-induced anti-AAV antibodies pose significant challenges, impacting therapy efficacy and patient eligibility. Existing methods for detecting anti-AAV antibodies often require extensive hands-on time and specialized instrumentation, limiting their utility in clinical and preclinical settings.

This study aimed to develop and validate multiple novel assays capable of detecting anti-AAV Neutralizing Antibodies (NAbs) and Total Antibodies (TAbs) in serum samples, while offering enhanced sensitivity, specificity, and ease of use.

The first approach, a cell-based AAV transduction inhibition (TI) assay, leverages the superior brightness of NanoLuc Luciferase to detect NAbs or other factors influencing AAV transduction. These assays were optimized for AAV serotypes AAV2, AAV8, and AAV9, with low multiplicity of infection (MOI ≥ 100) and low minimum required dilution (MRD 1:3), maximizing the detection of low-titer samples. At higher MOIs (1,000–10,000), total assay runtimes can be reduced to as little as six hours, enabling completion of TI experiments in a single day. Compared head-to-head with firefly luciferase as the reporter, NanoLuc was found to be >700-fold brighter, significantly enhancing assay sensitivity. Furthermore, the use of thaw-and-use cells was validated to increase assay robustness, further streamlining the workflow.

The second approach focuses on the detection of TAbs through proof-of-concept immunoassays using various forms of split NanoLuc. These include both solid and solution phase approaches. The solution phase method employs a completely homogeneous, no-wash protocol that can be completed in as little as two hours. Further characterization and validation are ongoing to establish assay performance and utility.

Together, these assays provide novel approaches for detecting anti-AAV NAbs and TAbs in serum samples. Their robust performance and user-friendly formats address key limitations of existing methods, facilitating improved patient screening and monitoring in gene therapy programs. Future studies will focus on expanding the assays to additional AAV serotypes and validating their utility in diverse settings.

1817 Anti-Pan AAV – New Versatile Antibody for the Detection of Various AAV Serotypes Including Novel Capsids

Joshua Baal[1], Christina Querfurth, Lea Hupe[2], Rita Lacher[3], Klaus-Ingmar Pfrepper[2], Martin März[4], Maik Lander[5], Dana Holzinger[6]
[1]PROGEN Biotechnik GmbH, Heidelberg, Baden-Wuerttemberg, Germany, [2]PROGEN, Heidelberg, Germany, [3]PROGEN, Heidelberg, 69123 Heidelberg, Germany, [4]PROGEN, Heidelberg, Baden-Wuerttemberg, Germany, [5]PROGEN, 69123 Heidelberg, Germany, [6]Progen Biotechnik GmbH, Heidelberg, Germany

Recombinant adeno-associated virus (AAV) vectors have become leading tools for viral gene therapy. However, some biological mechanisms are still not completely understood. Different AAV serotypes are employed in gene therapy development, each offering unique tissue tropism depending on the specific serotype. Additionally, the field is witnessing a surge in the development of novel, engineered AAV serotypes with optimized properties to address diverse therapeutic needs. In this context, antibodies capable of specifically detecting conformational epitopes on AAV capsids—thereby recognizing only intact and fully assembled particles—are indispensable for the accurate quantification of AAV titers. These specialized antibodies are essential for establishing stringent quality control standards, ensuring robust and precise evaluation of AAV gene therapy products. By enabling accurate titer determination, these antibodies contribute significantly to the therapeutic efficacy and safety of AAV-based gene therapies.

PROGEN offers an extensive portfolio of AAV antibodies tailored to bind the specific serotypes. However, certain research applications can benefit from using a single antibody that recognizes a broad spectrum of serotypes. Additionally, with the increasing use of novel capsid variants and shuffled vectors, commercially available antibodies often fall short. To address this need, we have developed a new recombinant antibody that exhibits robust binding reactivity to intact particles of various AAV serotypes.

Here we present comprehensive characterization data for the new anti-pan AAV antibody. We introduce several variants of this antibody and demonstrate its cross-reactivity and high sensitivity against multiple AAV serotypes, including new variants and shuffled vectors. We provide data supporting its applicability across a range of research needs. Specifically, we illustrate its effectiveness as a neutralizing antibody, its compatibility with ELISA test

systems, and its utility in fluorescence-based applications requiring labelled antibodies. Due to this multifaceted usability, the anti-pan AAV antibody displays a valuable tool in AAV research and therapeutic development.

1818 Developing a methodology for seropositivity assessment through sensitive anti-AAV total antibodies ELISA

Selvi Celik[1], Camilla Nilsson[2], Klaudia Kulak[3], Viktoria Kozma[2], Cecilia Klint[3], Samuel Butler[2], **Jordi Rodo[4]***
[1]Svar Life Science, Malmo, Sweden, [2]Svar Life Science, Malmö, Skane lan, Sweden, [3]Svar Life Science, Malmö, Sweden, [4]Svar Life Science, Cambridge, MA

Adeno-associated virus (AAV) vectors are at the forefront of gene therapy, offering a safe and effective means of delivering therapeutic genes. However, the prevalence of pre-existing anti-AAV antibodies in the human population poses a significant challenge to the widespread application of this technology. These antibodies, particularly total binding antibodies (TAbs), can impact both the efficacy and safety of AAV-based therapies. Therefore, accurate and sensitive methods for detecting and quantifying anti-AAV TAbs are crucial for patient selection, dose optimization, and risk assessment in clinical trials.

This study evaluated the seroprevalence of anti-AAV TAbs in a cohort of 100+ human serum samples from healthy donors, focusing on AAV2 and AAV9 as examples of commonly used serotypes, using a highly sensitive, standardized ELISA platform. Our findings reveal a significant proportion of individuals with detectable TAbs against both AAV2 and AAV9, aligning with seroprevalence data reported in the literature and confirming the widespread pre-existing immunity to these serotypes. Our findings reveal a significant proportion of individuals with detectable TAbs against both AAV2 and AAV9, aligning with seroprevalence data reported in the literature and confirming the widespread pre-existing immunity to these serotypes.

The developed ELISA demonstrates excellent sensitivity and specificity, enabling the reliable quantification of anti-AAV TAbs even at low levels. The assay's performance characteristics, including intraassay precision of <5%, ensure robust and reproducible results. Data analysis revealed a broad range of TAb titers across the cohort, highlighting the variability in individual immune responses to AAV.

These findings underscore the importance of comprehensive TAb assessment in the context of AAV gene therapy. The high prevalence of anti-AAV antibodies, coupled with the observed serotype cross-reactivity, necessitates careful consideration during patient screening and treatment planning. The evaluated ELISA platform provides a valuable tool for characterizing the humoral immune response to AAV, and it is adaptable for the evaluation of other AAV serotypes, contributing to the development of safer and more effective gene therapies. This assay has the potential to guide clinical decision-making and improve outcomes for patients receiving AAV-based treatments.

1819 A Novel Tool for Complement Activation Profiling in AAV Gene Therapy

Klaudia Kulak[1], Viktoria Kozma[2], Cecilia Klint[1], Camilla Nilsson[2], Selvi Celik[3], Samuel Butler[2], **Jordi Rodo[4]***
[1]Svar Life Science, Malmö, Sweden, [2]Svar Life Science, Malmö, Skane lan, Sweden, [3]Svar Life Science, Malmo, Sweden, [4]Svar Life Science, Cambridge, MA

Gene therapy utilizing adeno-associated virus (AAV) vectors demonstrates excellent safety profiles and remarkable clinical efficacy in treating diverse diseases. Despite its relative safety, evidence from clinical trials has shown that AAV can trigger severe life-threatening inflammatory responses, especially when administered intravenously at high doses. Many of these adverse reactions are associated with the secondary activation of the complement system, leading to complications such as acute kidney injury due to atypical hemolytic uremic syndrome–like (aHUS-like) complement activation, thrombotic microangiopathy (TMA), thrombocytopenia, and immune-mediated myocardial inflammation. Though AAV-mediated complement activation is a significant safety concern, we still lack understanding of the activation mechanism and a predictive method to prevent or mitigate activation in administered

patients. In this context, our research has been focused on the development and evaluation of an ELISA-based AAV-mediated Complement Activation assay. The technique combines a serotype specific AAV-coated plate with a tailored buffer composition, selectively allowing evaluation of the distinct classical, lectin, or alternative complement system pathways. The assay detects de novo-generated terminal complement complex (TCC) deposition, making it a robust tool for testing and predicting complement reactions to AAV in analyzed sera.

Utilizing this assay, we demonstrated a clear dose-response relationship between complement activation and different anti-AAV antibody sources, including both IgG and IgM. Experiments using C3- and Factor H-depleted sera confirmed the specificity of complement responses and highlighted a potential role for the alternative pathway in AAV-mediated complement activation. Moreover, the assay effectively captured individual complement system characteristics in response to AAV, independent of baseline complement activity within the sample, demonstrating that it measures the formation of newly generated complement components specifically induced by AAV. Human sera from 100 healthy donors were screened for complement activation in response to AAV2 and AAV9, revealing variability in individual responses. Importantly, the AAV-COMPL assay demonstrated high intra-assay and inter-assay precision for both AAV2 and AAV9.

Given the complexity of serum interactions with anti-AAV antibodies and the complement system, our assay holds promise in shedding light on pivotal immune interactions and offers valuable insights to enhance the safety and efficacy of AAV-based gene therapies.

1820 Development of a Novel Luminescent Assay for Sensitive and Specific Quantitation of Double-stranded RNA

Kara Machleidt[1], Jeff Nelson[1], Rich Moravec[1], Jun Wang[1], Jim Hartnett[1], Mei Cong[1], Jamison Grailer[1]
[1]*Promega Corporation, Madison, WI*

mRNA-based therapeutics have demonstrated clinical efficacy, as evidenced by the success of mRNA vaccines for SARS-CoV-2. Typically, mRNA drug substances are produced via in vitro transcription (IVT). A common byproduct and contaminant of IVT is double-stranded RNA (dsRNA), which is highly immunogenic and can induce inflammation, cell death, and inhibition of protein translation, including the therapeutic mRNA's encoded protein. Consequently, accurate measurement of dsRNA in IVT products is critical to ensuring their safety and efficacy. Current methods, such as dot blot and ELISA, for detecting dsRNA are limited in sensitivity and lack quantitative capability. To address these challenges, we have developed a novel luminescent assay for the sensitive and specific quantitation of dsRNA in IVT products. Unlike traditional assays, this method does not rely on dsRNA-binding antibodies. Instead, it utilizes the two components of the NanoBiT® split luciferase system, which are genetically fused to dsRNA-binding domains. In the presence of dsRNA, these constructs bind via the dsRNA-binding domains, enabling dimerization and reconstitution of functional NanoBiT® luciferase. The resulting luminescence is directly proportional to the amount of dsRNA in the sample. This assay detects dsRNA fragments ≥30 base pairs in length and is independent of their size and sequence. It does not cross-react with single-stranded RNA or DNA and is highly sensitive, with a limit of quantitation of 1 pg/ml. The assay is designed in a convenient "add-mix-read" format, requiring no wash steps or media transfers. It exhibits robust, sensitive, and reproducible performance, making it a groundbreaking tool for the specific detection of dsRNA contaminants in complex mixtures.

1821 A Novel Next-Gen Sequencing Library Preparation Method To Sequence Low-Quality (Fragmented/ Degraded) With Low (*Pico*-Grams) Quantity Of DNA/RNA Templates For Better Diagnostics, Biomarker Discovery, And Research.

Praveensingh Hajeri[1]*, Masato Yamamoto[2]*, Adam Herman[3], Nuri Temiz[3]
[1]*University of Minnesota, Circle Pines, MN,* [2]*University of Minnesota, Minneapolis, Minnesota,* [3]*Unviersity of Minneosta, Minneapolis, MN*
**Corresponding Author*

***Background and limitations of current technologies*:** Next-generation sequencing (NGS) of RNA and DNA is a method of high-throughput sequencing of biological samples. There are several well-established methods in published literature and also commercially available in the form of products/kits dedicated to sequencing total RNA, DNA, exome, small RNAs, and selected panels of gene/ loci to address specific issues. However, it has been a great challenge to sequence highly fragmented and degraded DNA/RNA due to the limitations of library preparation methods. This affects the sequencing of clinical samples, biological research materials, liquid biopsy, FFPE tissue, exosomes, forensics, cell-free RNA/DNA, and archeology, among several other types of materials. A large fraction of archived and even fresh samples do not generate high-quality data, which cripples basic research, biomarker discovery, and diagnostics. Currently, it is also impossible to sequence small RNAs alone or small and long RNAs together with pico-gram quantities of total RNA template.

Methods and results: We have addressed these limitations by developing a novel method to prepare NGS libraries from pico-gram quantities of total RNA templates. Our methods could efficiently capture RNA of all sizes (20bp and above, including small and long RNAs) simultaneously and detect 2-10 times more unique transcripts at a similar sequencing depth than the current state-of-the-art methods. We could capture 20,000 to 100,000 more transcripts than an established method in a proof-of-concept study. We could capture small (as small as 20 bases and above) and long RNAs in the same library using very low (pico-grams) quantities of total RNA.

Applications and broader impacts: Our method is applicable to highly fragmented and degraded samples like Clinical samples, FFPE tissue, cell-free RNA/DNA, liquid biopsies, archeological samples, and also normal biological samples. The variations and errors observed in NGS data due to differential degradation between samples are negligible in our method. This helps generate consistent and high-quality sequencing data. We could generate 2-10 times more high-quality data with as little as 500pg of total RNA, which is close to the total RNA obtained by a single cell and hence applies to single-cell sequencing. The method is compatible with automation as well. Due to its high efficiency and sensitivity, we think our method will enable better diagnostics, biomarker discovery, and research.

1822 Development of a Novel High-Throughput Determination of Infectious Virus Titers by Kinetic Measurement of Infection-Induced Changes in Cell Morphology

Johannes Solzin[1], Dominik Hotter[2], Marco Kunzelmann[3]
[1]Boehringer Ingelheim Pharma GmbH & Co KG, Ochsenhausen, BW, Germany, [2]Boehringer Ingelheim Pharma GmbH & Co KG Biberach, Biberach an der Riss, Baden-Wuerttemberg, GERMANY, [3]Global Development CMCM Biologicals, Biberach an der Riss, Baden-Wuerttemberg, Germany

Infectivity assays are the key analytical technology for development and manufacturing of virus-based therapeutics. We have recently developed a novel assay format that utilizes label-free bright field images to determine the kinetics of infection-dependent changes in cell morphology. This so-called kinetic infectious virus titer (KIT) assay is, provides results within ~24 hours post-infection due to its sensitive readout method. Compared to traditional infectivity assays like TCID50 or plaque assay our cumulated analysis of kinetic data by a fit model results allows a precision of CV < 20% based on only six wells per sample on a 96-well plate. The KIT assay allows for a high throughput with ~400 samples processed by a single operator per week. This assay format is a potent solution to overcome the analytical bottleneck in infectivity assays limiting significance of e.g. process-optimizations within the pharmaceutical industry or routine analytics in academic research.

Here we provide insights into the assay optimization via our functional Design of Experiment approach and the introduction of ready-to-assay cells both contributing to increase the precision of the KIT assay even further.

1823 Enhancing Robustness in rAAV Characterization with Optimized Workflows and PEA Technology

Noah Elder[1], Kimberly Gomez[1], Cinta Gomez[1], Brendan Deal[1], Priscilla Yim[1], **Chengjing Liu**[2]
[1]Thermo Fisher Scientific, South San Francisco, CA, [2]Thermo Fisher Scientific, El Cerrito, CA

Recombinant adeno-associated viruses (rAAV) are essential vectors in researching solutions for gene and cell therapies due to their low immunogenicity, broad tissue tropism, and durable gene transfer capabilities. Precise dosing of these vectors requires rigorous quantification of viral titers throughout development, scale-up, and product release phases. The genomic titer (GC/mL), viral particle titer (vp/mL), and content capsid ratio are critical attributes for characterizing rAAV products. Achieving robust and reproducible results is critical, particularly in workflows susceptible to variability due to viral aggregation and capsid instability during the process.

We've optimized our reagents and workflow, improving capsid stability and minimizing aggregation, while increasing workflow robustness by transitioning from Proximity Ligation Assay (PLA) to Proximity Extension Assay (PEA) technology. While PLA relies on temperature sensitive enzyme, ligase, to generate a DNA template from viral capsids, PEA uses a direct oligo extension mechanism by a temperature stable polymerase, reducing variability in the workflow.

Different rAAV serotypes were tested using PEA vs PLA workflow on the QuantStudio™ Absolute Q™ digital PCR system. Results demonstrated significant improvements of the PEA workflow, increasing replicability and robustness. Capsid content ratios measured using PEA-dPCR aligned closely with results obtained from orthogonal methods and exhibited lower inter-assay variability.

In summary, we present an enhanced workflow that addresses critical bottlenecks in rAAV characterization. By mitigating aggregation and capsid instability and leveraging the stability advantages of PEA technology, we have developed a more robust and reliable process for measuring rAAV genomic titer, viral particle titer, and capsid content ratio. This improved approach has been validated across diverse rAAV samples, including different serotypes, vendors, and in-process materials, supporting the production of high-quality rAAV vectors in researching solutions for therapeutic applications, facilitating precise and consistent results.

For Research Use only. Not for use in diagnostic procedures.

1824 Automated co-detection of small RNAs, mRNAs and proteins with a new RNAscope™ assay on the Roche DISCOVERY™ ULTRA using translucent chromogens

Renzo Adilardi[1], Manvir Sambhi[1], Emerald Doolittle[1], Sonali Deshpande[2], Anushka Dikshit[3], Henry Lamparski[1], Maithreyan Srinivasan[4]
[1]Advanced Cell Diagnostics, Inc., Newark, CA, [2]Newark, CA, [3]Advanced Cell Diagnostics, Inc. - Newark, CA, Newark, CA, [4]Bio-Techne, Newark, CA

Advances in precision medicine utilizing antisense oligonucleotides (ASOs) and small interfering RNAs (siRNAs) as therapeutic platforms have brought promising solutions for various neurodegenerative/neuromuscular disorders and rare diseases. Currently, 20 oligonucleotide drug products have been commercially approved by the FDA and EMA, and many more are in clinical phase I-III trials. The FDA has issued recommendations to generate nonclinical biodistribution (BD) data for gene therapy products to evaluate and interpret nonclinical pharmacology and toxicology findings before initiating human clinical trials. *In situ* hybridization (ISH) and immunohistochemistry (IHC) are increasingly used to spatially visualize the delivered therapeutic, target gene, transgene, and/or cell markers and complement information gathered from molecular technologies such as quantitative polymerase chain reaction (qPCR) and digital PCR. Direct visualization of oligonucleotides can also monitor the risk of off-target events by studying BD of potential therapies in various organs.
To expand our current RNAscope™ capabilities on the Roche DISCOVERY™ ULTRA System, we developed a new ISH assay enabling the detection of ASOs, siRNAs, microRNAs (miRNAs), and other small RNAs that are 17-50 bases. This fully automated assay allows the co-detection of small RNAs and mRNAs and can be combined with IHC to detect protein targets on the same formalin-fixed paraffin-embedded tissue section. This workflow includes harmonized cell conditioning for an efficient combined RNA and antigen retrieval and the new protease-free pretreatment reagent VS PretreatPro, allowing for RNA detection without disrupting protease-sensitive epitopes. Visualization of multiple RNA species and protein targets at the single-cell level is achieved by combining different HRP and AP-based detection, leveraging Roche's translucent chromogens.
For proof-of-concept, we used this new automated assay to investigate the expression profile of miRNAs in the

mouse brain and combine them with RNA and protein markers of specific neural cell populations for spatial and morphological context. Detection of *RNU6* and *Snord85* miRNAs was combined with *Tmem119* mRNA for the identification of microglial cells by ISH, while sequentially detecting NeuN for mature neurons, GFAP for astrocytes, and Olig2 for oligodendrocytes by IHC. This new automated ISH assay showed high sensitivity and specificity for the detection of small RNAs with different expression profiles, and subcellular resolution in intact tissue context. This novel assay will be particularly valuable for the study of ASO/siRNAs delivery, biodistribution, stability, and expression profile of their associated RNA targets for the development of new oligonucleotide therapeutics.

1825 Strategies for Overcoming Analytical Challenges in Complex Upstream AAV Samples

Aparajita Chatterjee[1], Michelle Stracqualursi[1], ELMY XAVIER[1], Kara Levine[1]
[1]*MilliporeSigma, Bedford, MA*

Robust high-throughput analytics that accurately measure viral vector product quality in complex matrices are essential for the development of well characterized upstream processes. Upstream AAV material, particularly from HEK293 cells prior to clarification, often contains a complex mixture of cell debris, DNA, and other process impurities that can interfere with standard analytics. Technologies that facilitate early and precise product characterization in these upstream matrices are critical for making informed decisions about process performance. In this study, we evaluate analytical technologies with a goal of enhancing throughput, improving operational efficiencies, and accelerating process characterization in upstream unit operations. To compare technology performance and usability we leveraged upstream samples from various AAV serotypes produced in HEK293 and insect cells to assess Digital PCR for genomic titer and Mass Photometry for determining empty/full (E/F) capsid ratio. Finally, we present data demonstrating how rapid, cost-effective, process-agnostic analytical methods can be implemented to define, monitor, and control upstream AAV processes effectively.

1826 Massively parallel sequencing-based method to detect misuse of gene transfer technologies in sport

Anna Baoutina[1], Lina Partis[2], Somanath Bhat[2], Denis Bauer[3], Laurence Wilson[3]
[1]*National Measurement Institute, LINDFIELD, NSW, Australia,* [2]*National Measurement Institute, Lindfield, New South Wales, Australia,* [3]*Commonwealth Scientific and Industrial Research Organisation, AUSTRALIA*

With gene and cell therapies continuing their rapid evolution into the clinic, there is a growing danger that the developed technologies might be misused. Gene doping has the potential to unfairly improve athletic performance in sport and the anti-doping community has been focusing efforts on developing tests for its detection. Polymerase chain reaction (PCR)-based methods have already been developed by us and others to detect several doping genes in athletes blood samples. Each PCR assay targets a unique sequence which correspond to exon-exon junction in the intronless cDNA of the doping gene and not present in a natural gene. Nonetheless, a quest for methods that utilise advanced molecular technologies continues.

In this project we designed, evaluated and tested the protocol for a targeted massively parallel sequencing (MPS)-based method for simultaneous detection of erythropoietin, follistatin, growth hormone 1, growth hormone releasing hormone and insulin-like growth factor 1. These genes are likely candidates for gene doping due to their potential to increase athletes' endurance or muscle size and strength. Kits, reagents and protocols for each step were evaluated and optimised with the aim of achieving high reliability and sensitivity, operational ease and reduced cost and turn-around time of a future test.

To mimic DNA extracts from athletes' blood samples we used solutions of doping genes and genomic DNA. Target enrichment was achieved by simplex PCR designed to amplify a large portion of each transgene covering several exon-exon junctions. Enriched materials were purified, mixed and subjected to library preparation and sequencing. We also designed, produced and tested a Control material that is suitable for use in positive controls in the test. Its

unique design enables sequence discrimination from the transgenes and minimises a chance of false positive test results in case it inadvertently contaminates samples during the test. A tailored bioinformatics pipeline with stepwise analysis was developed that reliably distinguishes doping genes from the corresponding endogenous genes and from the Control. Using simulated DNA extracts from blood samples, we showed that MPS-based approach can detect down to five copies of doping genes in a background of genomic DNA similar in quantity to that in one milliliter of blood.

The developed MPS method for detecting gene doping was shown to be reliable and sensitive. Compared to PCR, the MPS approach potentially has higher likelihood of transgene detection as it targets multiple splice sites simultaneously and allows greater flexibility in choosing regions used in target enrichment. The MPS multiplexing capability will allow simultaneous analysis of many samples and genes, potentially reducing test's cost and turnaround time.

The developed approach could also be considered in legitimate applications of gene transfer technologies, for example, in vector biodistribution, persistence and shedding analyses or transgene integration studies.

1827 Confirmation of Lentiviral Vector Identity Using Short-Read Next-Generation Sequencing

Amanda Oran[1], Ying Chen[2], Allyssa Staboleski[3], Robert Hills[4], Alexei Saveliev[5]
[1]SKPT, King of Prussia, PA, [2]King of Prussia, PA, [3]The Discovery Labs, King of Prussia, PA, [4]SK Pharmteco - US, King of Prussia, PA, [5]Center for Breakthrough Medicines, King of Prussia, PA

Lentiviral vectors (LVVs) are valuable tools in gene therapy and biomedical research, enabling efficient and stable delivery of genetic material to target cells. Ensuring the identity and integrity of these vectors is critical for regulatory compliance, therapeutic safety, and experimental reproducibility. In addition, prior confirmation of the genetic fidelity of the lentiviral drug substance is crucial for downstream applications such as integration site analysis in transduced cells. Traditional methods for viral vector characterization and quality control, such as restriction enzyme mapping and Sanger sequencing, often fall short in providing comprehensive sequence verification and detecting low-frequency or compound variants. Here, we present a robust and scalable approach using short-read next-generation sequencing (NGS) to confirm the identity of LVVs.

In this study, we developed and verified an NGS-based workflow for the analysis of LVV genomes. The workflow includes optimized protocols for extraction and purification of encapsidated RNA, cDNA synthesis, library preparation with optional polymerase chain reaction (PCR) amplification, and bioinformatics pipelines for alignment, variant calling, and quality control. We successfully applied this method to lentiviral preparations encoding therapeutic cargo, achieving high coverage and accurate mapping of vector sequences. Key findings include the complete and unambiguous characterization of LVV identity through full-genome sequence analysis. We detected single-nucleotide variants (SNVs) and indels occurring at frequencies as low as 5%, providing insights into the fidelity of vector productions.

Our NGS-based approach demonstrates significant advantages over traditional techniques, offering superior sensitivity, specificity, and throughput. The assay provides a powerful tool for vector quality control as well as support for research applications, aligning with the increasing demands for gene and cell therapy development. This methodology establishes a new standard for lentiviral vector identity confirmation.

1828 Optimizing AAV Sample Preparation Workflow for Short and Long Read NGS for AAV Characterization.

Swetha Devi Velivela[1], Sarang Brahma[2], Jordan Smith[2], Ryan Massopust[3], Annabelle Phillips[4], Maria Belousova[5], Andrea Moore[2]
[1]AskBio, Chapel Hill, NC, [2]AskBio Inc., Research Triangle Park, NC, [3]Asklepios Biopharmacuetical, Durham, NC, [4]AskBio, Durham, NC, [5]AskBio, Durham, North Carolina

The potential safety, efficacy, and quality of gene therapy products such as recombinant adeno-associated virus (rAAV) vectors are ensured by their thorough characterization using well-developed analytical techniques. The next-generation sequencing (NGS) has become a preferred analytical tool for this purpose. NGS plays a crucial role in the design and clinical development of rAAV vectors by enabling the evaluation of key quality attributes, including genome heterogeneity, purity, and identity. Short-read (e.g., Illumina) and long-read (e.g., Oxford Nanopore, PacBio SMRT) sequencing technologies are applied to meet specific characterization requirements.

A critical step for reliable NGS results is optimizing rAAV vector DNA sample preparation. However, this process is often hindered by challenges such as vector type (e.g., single-stranded vs. double-stranded), impurities, and low vector genome titers. To address these issues, we developed an optimized rAAV vector sample preparation method that can be used for both short-read and long-read sequencing partly based on a previously established method (Lecomte E et al., Methods Mol Biol. 2019;1950:85-106.).

These improvements facilitate precise characterization of critical vector attributes, such as determining the percentage of complete versus partial capsids, classifying different rAAV genome configurations, and detecting residual contaminants using Oxford Nanopore sequencing. The method also confirms vector identity and detects INDELs and SNPs through Illumina short-read sequencing. Furthermore, genome heterogeneity results obtained via Oxford Nanopore sequencing are validated against an orthogonal method, ensuring robustness and reliability.

1829 Development of a Novel Scale-Down Model for High-Throughput Clone Selection for Adeno-Associated Virus (AAV) Production

Kevin Chen[1], Ying Liu[2], Gioranah Abellard, Rachel Martineau, Jeong Lee
[1]Genzyme, a Sanofi Company, Waltham, MA, [2]Sanofi, Waltham, MA

Producing Adeno-Associated Virus (AAV) in stable producer cell lines has advanced significantly, with high cell density cultures and perfusion systems becoming more prevalent for large-scale production. However, high cell density culture and perfusion at the early stage of cell line development presents unique challenges due to the difference in scale and operational requirements. Traditional high throughput clone screening method relies on batch or fed batch culture where relative performance of clones being screened is not representative of the relative performance of clones in a perfusion process. To effectively select cell clones with optimal performances for intensified perfusion systems, suitable scale-down models are required. These models should enable high-throughput experiments with minimal raw material requirements. Herein we report the progress that has been made to enable high throughput selection of clones in a much more representative procedure which enable cell culture performance much more similar to a perfusion process as compared to the traditional cone screening method.

AAV production for various clones was evaluated using the automated microbioreactor system (AMBR15), which involves utilizing a scale-down mock perfusion system with cell sedimentation as the method for cell retention. To establish a baseline for the AMBR15 model, we conducted experiments to examine the impact of multiple critical factors, including sedimentation time, cell density, and various strategies for mimicking perfusion conditions. As a result, the mock perfusion process in Ambr15 performed well compared to actual perfusion process in AMBR250. Notably, under high cell density culture condition, mock perfusion process in AMBR15 maintained the AAV productivity and product quality in terms of ratio of full/empty/partial particles. Whereas batch processes exhibited a significant reduction in AAV production with high seeding density. This suggests perfusion strongly supports AAV production under these conditions. Next, we validated the mock perfusion process as a tool for clone screening with multiple programs and clones. Studies demonstrated mock process in AMBR15 showed stronger correlation with actual perfusion in AMBR250 compared to batch process.

Overall, our process in AMBR15 system with mock perfusion provides a more representative high-throughput model for clone selection for AAV production than the previously used batch process. This approach not only streamlines the cell line development process but also enhances its accuracy by closely mimicking the conditions of perfusion at the production scale.

1830 Automated solutions for characterization and release of ATMPs

Francesca Rossetti[1], Marco Rausa[2], Chiara Portugalli[3], Davide Medici[3], Lucrezia Ceretti[3], Chiara Boroni[3], Grazia Frizzale[3], Veronica Meraviglia[3], Fabio Celestini[4], Giuliana Vallanti[2]
[1]AGC Biologics - Milan, Bresso (Milano), Italy, Italy, [2]AGC Biologics, Milano, Milano, Italy, [3]AGC Biologics - Milan, Milano, Italy, [4]Hamilton, Milano, Italy

In the field of gene therapy, an efficient delivery of the therapeutic gene and a proper gene expression are crucial for achieving clinically relevant effects. Lentiviral vectors (LVV) are effective transfer system for the introduction of transgenes into target human primary cells, such as CD34+ cells. AGC Biologics has developed and optimized a manufacturing process for LVV transduction of primary cell lines, that includes a comprehensive set of in-house developed tests for the characterization of the Drug Substance (DS) and the release of the final Drug Product (DP). Some of these tests have been automated based on Hamilton automation solutions.

For the release of the DP, two methods are in place at AGC Biologics to assess the efficacy of the transfer of the vector: the quantification of the mean number of the provirus integrated into the host genome (VCN) and the transduction efficiency (TE). Both methods have a Real Time PCR assay readout and have been automated to increase the throughput, consistently reduce timelines, operator effort and volume dedicate to testing.

The Hamilton's automated liquid handler for qPCR execution is integrated with a variety of devices, including a Real Time qPCR thermal cycler and a plate sealer. This integrated system allows a complete automatic flow from reagents and sample preparation to assay execution and obtaining of raw data. For VCN determination, the lysate of transduced cells is directly processed by qPCR, while the TE includes the harvest and lysis of colonies derived from transduced CD34+ cells, previously seeded on a methylcellulose substrate. A fixed number of picked colonies are analysed and the TE is determined as the percentage of transduced colonies.

Both methods were validated before being transferred to automation, and the automated performance has been optimized to be aligned to the manual execution, as demonstrated by a repeatability ≤ 14% and inter-assay variability ≤ 19%. A maximum percent difference of 4% between automation and manual results for TE was observed, while for VCN the qPCR positive control results were monitored over 2 years showing no significant difference between automation and manual, confirming the consistency of the automated system performance.

Moreover, at AGC Biologics different ELISA assays are executed for the verification of the removal of impurities during the transduction process (e.g. cytokines, Host Cell Proteins (HCP)). Among them, the ELISA for 293T HCP has already been transferred to automation. In this case, the automated system was designed with all devices needed to perform each step of ELISA assay and was conceived with a different requirement, to allow for the flexibility to add other assays to be run together to share the same sample aliquot, always having a complete traceable flow of the tested samples up to the final result. The automated method assures a comparable performance with the manual method ($p \geq 0.26$) and has been qualified according to guidelines with both repeatability and intermediate precision ≤ 20%.

These automated systems are CFR21 compliant that enable a two-fold increase in throughput, reducing timelines, and significantly enhance laboratory capacity during process characterization or DP release.

1831 A Solid-state Nanopore Mesh Device for Quantification and Quality Control of Carrier Particles Used in Gene Therapy

Ali Fallahi[1]*, Yifang Liu[1], Amr Makhamreh[1], Yuchen Qiu[1], Wentao Liang[1], Jacob Potts[1], Hirohito Yamazaki[2], Sara Rouhanifard[1], Meni Wanunu[1]*

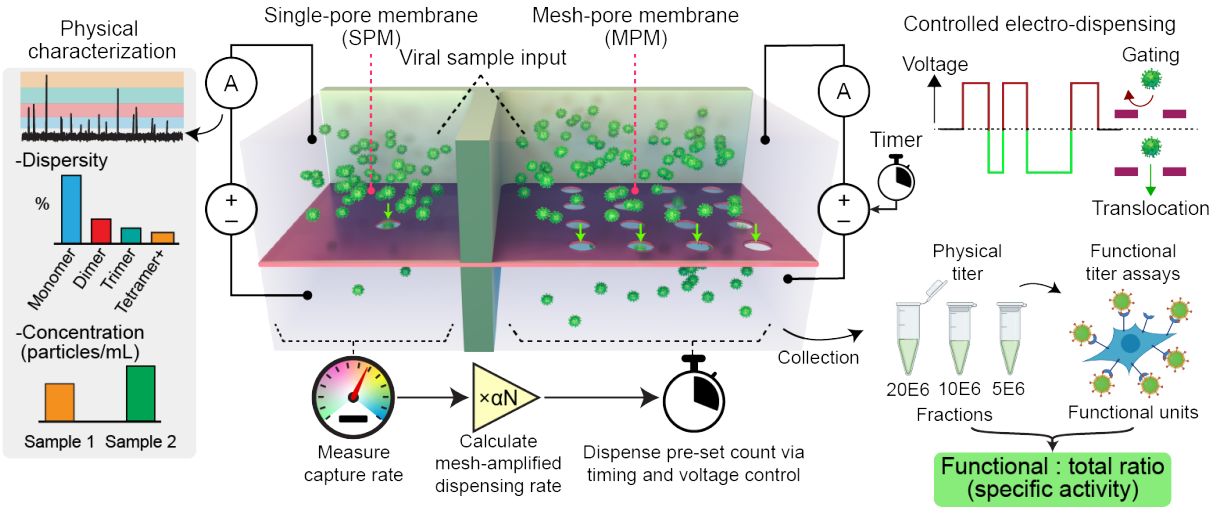
Corresponding Author

Viral vectors for gene therapy remain challenging to measure and control for quality. Comprehensive assessment of concentration, aggregation, and functional activity often relies on separate, uncoordinated methods, and there is no consensus on how to unite these factors in a single quality measure. Here, we present a quantification pipeline that integrates functional assays with physical particle properties, providing a more complete measure of specific activity. Our approach uses solid-state nanopore sensors—a tiny hole in a thin membrane separating two electrolyte baths. As carrier particles pass through the pore, they disrupt the ionic current, creating blockade events. The amplitude of these events indicates particle size, while their frequency reflects particle concentration and charge. This setup lets us measure concentration, size distribution, and aggregation at single-particle resolution. Next, through robotic and electronic automation, we electro-dispense and collect pre-programmed quantities of particles through a nanopore mesh built into the same device, then use these fractions in a functional titering assay (e.g., qPCR or tissue culture transduction). By combining the physical data from the nanopore sensor with the functional data from the assay, we obtain robust and translatable measures of specific activity. We verified this pipeline using protein-coated fluorescent nanoparticles and validated it with AAV vector samples, where the dispensed AAV particles were further characterized with qPCR for genome counts. Given the tunability of nanopore sensor dimensions and surface properties, this system can be used to characterize a broad range of viral and non-viral carrier particles. Our method provides a unified alternative to multiple, fragmented titration assays, improving measurement consistency in gene therapy process development and manufacturing quality control.

Figure 1. Solid-state nanopore pipeline for characterization of gene therapy carrier particles (viral or non-viral vectors). First, physical properties and concentration of particles are measured with single-particle resolution using single-pore membranes. Then, a pre-programmed quantity of particles is electro-dispensed through mesh-pore membranes. These fractions are collected and further analyzed in functional assays (tranduction, genome count, integrity), and the combined analysis provides standardized metric of quality for the particles.



1832 Methodological validation of sedimentation velocity analytical ultracentrifugation method for Adeno-Associated Virus and collaborative calibration of system suitability substance

Xi Qin, National Institutes for Food and Drug Control of China, Beijing, Beijing, China

In recent years, the development of in vivo gene therapy has been in full swing. Currently, there are 9 AAV drugs on the market worldwide. The field of gene therapy is undergoing tremendous development! According to statistics, there are about 350 million patients with rare diseases in the world and 20 million in China, of which 80% are related to genetics. The rapid launch of gene therapy drugs has brought great benefits to the treatment of patients with rare diseases in the world! The AUC-SV method used to detect the empty shell rate of AAV products is known as the gold standard for product impurity detection. 1. For the first time in this study, the AUC-SV method is

systematically used for systematic methodological verification of AAV samples. 2. This study provides the basis for follow-up work, establishes the world's first System Suitability Substance, and provides a new weapon to solve the key attribute problems of gene therapy drugs. 3. Our work can provide valuable reference for AAV methodology validation of gene therapy enterprises, solve the pain points of product impurity detection, and promote the vigorous development of gene therapy industry. We performed the systematic methodological validation of quantifying the AAV empty and full capsid ratio. This includes specificity, accuracy, precision, linearity, and parameter variables involving the sedimentation velocity analytical ultracentrifugation (SV-AUC) method. Specifically, SV-AUC differentiated among the empty, partial, full, and High Sedimentation Coefficient Substance (HSCS) AAV particles while evaluating their sedimentation heterogeneity. The intermediate precision analysis of HE (high percentage of empty capsid) and HF(high percentage of full capsid) samples revealed that the specific species percentage, such as empty or full, was more significant than 50%. Moreover, the RSD (relative standard deviation) could be within 5%. Even for empty or partial less than 15%, the RSD could be within 10%. The accuracy recovery rates of empty capsid were between 103.9% and 108.7% across three different mixtures. When the measured percentage of specific species was more significant than 14%, the recovery rate was between 77.9% and 106.6%. Linearity analysis revealed an excellent linear correlation between the empty, partial, and full in the HE samples. The AAV samples with as low as 7.4×1011 cp/mL AAV could be accurately quantified with SV-AUC. The parameter variable analyses revealed that variations in cell alignment significantly affected the overall results. Still, the detection wavelength of 235nm slightly influenced the empty, partial, and full percentages. Minor detection wavelength changes showed no impact on the sedimentation coefficient of these species. However, the temperature affected the measured sedimentation coefficient. These results validated the SV-AUC method to quantify AAV. Based on the above results, collaborate study was performed to calibrate the prepared empty capsid AAV, precision analysis of 24 replicates recorded a sedimentation coefficient of 61.3S ± 0.3S, with an RSD of 0.6%, and a percentage of empty capsid AAV content of 95.0% ± 2.6%, with an RSD of 2.7%. The empty capsid system suitability substance could be used as an external reference to measure the performance of the instrument（published on Human Gene Therapy). Next, we will expand the application of this standard to AEX, CE and SEC-MALS. In addition, we also established AAV particle count sta

1833 Development of a Novel Automated Loading Approach Which Significantly Reduces Processing Time for Enriching Full AAV Capsids Using Ultracentrifugation.

Varun Gejji[1]*, Akash Bhattacharya[2], Garrett Garrido[3], Abraham Wilson[4], Hari Acharya[3]
[1]Capsida Biotherapeutics Inc, Newbury Park, CA, [2]Beckman Coulter Diagnostics, Loveland, CO, [3]Capsida Biotherapeutics, Inc., Newbury Park, CA, [4]Beckman Coulter Life Sciences, Indianapolis, IN

The use of recombinant AAV (rAAV) as a targeted delivery vehicle is increasingly showing promising results for treating rare and common genetic disorders. As the need to manufacture more material at larger scales grows, several challenges for scaling the full enrichment step (enriching for capsids containing the therapeutic gene) persist. Currently, the most widely practiced unit operation for full capsid enrichment is ultracentrifugation using a cesium chloride (CsCl) density gradient. An ultracentrifuge compatible tube is filled with a high concentration of cesium chloride and bulk AAV material containing empty, partial, and full capsids. The tubes are spun at a high speed for an extended duration forming a density gradient with the cesium chloride. The different populations of capsids migrate to specific locations in the tube based on their buoyant densities. Due to the long processing times, scaling ultracentrifugation to larger production trains (>1000L) is not feasible. In this work, we explore using an automated gradient formation tool, OptiMATE Gradient Maker$ (Beckman Coulter®), which establishes a linear CsCl density gradient prior to spinning. The tool varies the amount of bulk rAAV material and concentrated CsCl stock solution added to the tube during the filling process. We explore several process parameters including density gradient profile, centrifuge run duration, g-force, and spin temperature to identify the optimal conditions for enriching full capsids. As a result of the gradient loading (pre-formed gradient) and optimization studies, the spin time was reduced considerably. Based on product recovery measured by ddPCR, aggregation by HPLC-SEC, purity by CE-SDS, and purity by analytical ultracentrifugation (AUC), we were able to reduce the processing time 10-fold while maintaining the same product attribute profile when compared to typical run conditions.

$ Product in development. Performance characteristics have not been validated.

1834 Purifying AAV Free of Endonuclease Treatment & Pre-Capture TFF

Xiaoling Chen, Wuxi Extpure Solutions Co., Ltd., WUXI, China

Long residence time is necessary when using bead based resin in the purification process due to its low pressure resistance and diffusion effect of the flow within the mesh pore of the matrix. Constrained by the slow flow rate, low culture titer and large culture volume, purification of Adeno-associated virus(AAV) using bead based affinity resin normally require a significantly long time to process. To shorten the loading time, most company pack a super larger columns, resulting not only an oversized column volume, but also a compromised utility of binding capacity of the resin.

Here we present an alternative solution by introducing ACC(affinity convective chromatography). The performance of ACC is independent of flow rate and feed concentration due to its large pore size(2μm-5μm) which eliminates diffusion in the mass transfer mechanism. The large pore size guarantees that the target molecule will flow through the matrix and be captured by the affinity ligand without entrapment, resulting in a high yield(>90%).

Rather than employing endonuclease to cleavage host cell DNA prior to depth filtration, Wuxi Extpure have developed a novel AAV purification process PAEFT which is free of endonuclease treatment and Pre-Capture TFF by utilizing ACC . The process details are as below:

Step 1: depth filtration
Step 2: affinity capture
Step 3: AEX1
Step 4: AEX2

This novel process deviates from conventional bead based chromatography in two distinct aspects: firstly, the absence of endonuclease treatment leads to a substantial reduction in expenses. For instance, in a 500-liter bioreactor AAV production process, the cost of endonuclease is approximately $100,000. The elimination of endonuclease introduction in the process renders the necessity for nuclease residue detection, thus simplifying the QC process and reducing operational expenses. Secondly, a pre-capture TFF free process leads to cost reduction by eliminating the use of membrane and yield enhancement through the reduction of processing steps.

1835 Size Exclusion Chromatography of messenger Ribonucleic acid, Adeno-Associated Virus and Virus-Like Particle Analysis using Newly Developed Wide Pore Size Exclusion Chromatography Columns

Charu Kumar[1], Andrew Coffey[2], John Davies[2], Ace Galermo[1], Andrei Bordunov[1], Ta-Chen Wei[3], Sonja Schneider[4], Chae-Young Ryu[5], **Anne Blackwell[3]**
[1]Agilent Technologies, Santa Clara, CA, [2]Agilent Technologies, Church Stretton, United Kingdom, [3]Agilent Technologies, Wilmington, DE, [4]Agilent Technologies, Waldbronn, Germany, [5]Agilent Technologies, Seoul, Seoul Teugbyeolsi, South Korea

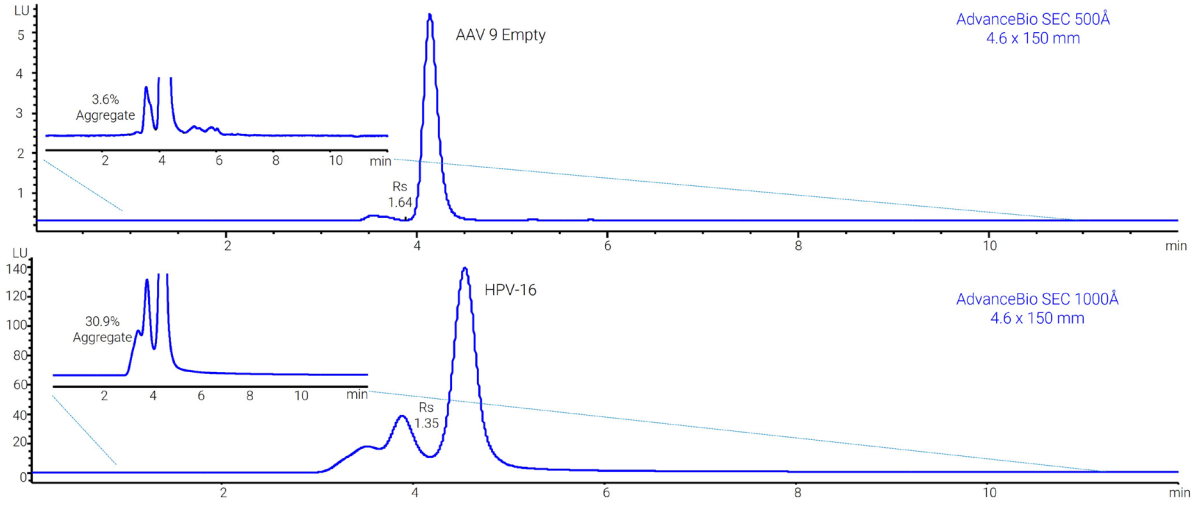
High-resolution SEC HPLC is essential for aggregate analysis of large biotherapeutic molecules like mRNA and viral vectors to ensure their quality and safety. Aggregates are product-related impurities, and their identification and quantification are considered as critical quality attributes. It is vital to choose a SEC column with an appropriate pore size, higher pore volume and consistent pore size distribution to provide a baseline separation between the analyte monomer and its sub-micron size aggregates.

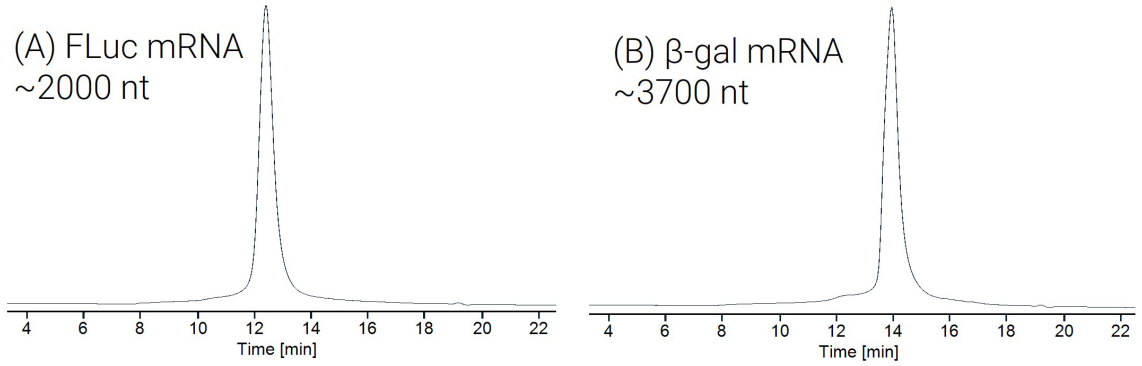
Here, we demonstrate the performance of two novel 2.7 μm SEC columns with 500Å and 1000Å pores that were designed specifically for robust, high-performance analysis of adeno-associated viruses (AAV), messenger Ribonucleic acid (mRNA), single and double stranded oligonucleotides, LNP and virus-like particles (VLP) such as HPV-16. Different molecular weight standards of polyethylene glycol (PEG) and polyethylene oxide (PEO) were

also studied on various columns to understand the effects of column pore size and pore size distribution on separation of variously sized analytes.

Both newly developed SEC columns exhibit excellent baseline resolution between monomer species and their aggregates with a short runtime (< 6 min) for all tested AAV serotypes and VLP test samples (Fig-1). The column also demonstrates excellent performance when tested at different flow rates ranging from 0.1 mL/min to 0.7 mL/min and capturing similar amount of aggregate and monomer species while maintaining the baseline resolution between them. The column showed good compatibility with MALS detector and demonstrated that the biophysical characterization of larger biomolecules like mRNA sample with >4,000 nucleotide in length is easily achievable. The columns demonstrated superior resolution and recovery when compared to columns from other vendors. While SEC is used to estimate analyte molecular weight, a series of double stranded and single stranded oligonucleotide standards, as well as study of a variety of mRNA samples, illustrates the complexity of single stranded oligonucleotide samples. Under ambient or slightly elevated temperatures double stranded oligonucleotides are much more elongated than single strand, requiring large pore sizes for similar length strands. Additionally, mRNA folding in solution may be such that longer mRNA sequences are more compact and elute later, such as the 3700 nt β-gal mRNA eluting later than ~2000 nt FLuc mRNA (Fig-2). Light scattering data confirms relative size in solution of different samples.

In conclusion, the newly developed SEC columns offer fast separation with ultra-high resolution for aggregate analysis & biophysical characterization of larger biotherapeutic molecules.





Despite its shorter sequence, Fluc mRNA (A) elutes earlier than β-gal mRNA (B), indicating it is more elongated in solution

1836 High Throughput Analysis of CRISPR sgRNA using Ultrashort Ion Pairing Reversed Phase Column Chromatography and High Resolution Mass Spectrometry

Kyle Scheel[1], Matthew Lauber[2], **Rachel Ginther[1]***
[1]MRIGlobal, Kansas City, MO, [2]Waters Corporation, Miford, MA

With the first FDA approved CRISPR based therapeutics, high throughput (HT) and reliable analytical methods are more important than ever. Given the inherent cost and time associated with therapeutic development, analytical methods that are faster while providing a wealth of information are desirable. CRISPR gene editing requires two components, a CRISPR Associated Protein (Cas) and a single guide RNA (sgRNA), which together form an ribonucleoprotein (RNP) complex. These RNPs are used to edit genomes by targeting sequences of DNA, making a single strand cut, and inserting a new sequence. Single guide RNA molecules consist of two separate regions. The first ~ 20 nt segment is specific to the gene of interest, designated as crispr-RNA (crRNA). The remainder of the sgRNA sequence is associated with binding the sgRNA to the Cas protein (tracrRNA). It is imperative that sgRNA is pure and that the sequence accurately targets the gene of interest to avoid off-target effects such as DNA mutations or undesired immune response. In addition to purity and sequence confirmation, the ability to investigate the native conformers and charge heterogeneity of sgRNA provides another layer of knowledge about how sgRNA behaves in native conditions.

Methods for analyzing RNA by ion-pairing reversed-phase liquid chromatography (IP-RPLC) with high-resolution mass spectrometry (HRMS) exist but tend to use analytical columns that are ≥ 100 mm and require ≥ 30 min run times. To improve throughput, we developed an IP-RPLC-HRMS method by scaling a published 30-min method to a HT 5-min method. We utilized hexafluoroisopropanol (HFIP) and N,N-diisopropylethylamine (DIPEA) as ion-pairing agents and aimed to reduce analysis time while maintaining an effective chromatographic separation. The method was directly scaled from a 100 mm column to the 20 mm column, followed by scaling equilibration times, and finally optimizing the retention window and focused gradient programming of the method.

Additionally, this method was utilized to analyze sgRNA fractions collected via our published method utilizing directly coupled strong anion / strong cation exchange chromatography (IEX). Single guide RNAs produced with different purification techniques (such as desalting or RPLC) were injected onto the coupled IEX columns where substantial charge heterogeneity was observed. Fractions of these IEX-separated peaks were analyzed by the 5-min IP-RPLC-MS method to investigate differences in charge heterogeneity.

Utilizing ultrashort 20-mm columns, we achieved HT separations with a run time of 5 min per sample. This reduced analysis time not only aids in faster decision making in production and drug development, but also provides a 6X reduction in reagents used. We analyzed sgRNA of differing purity, obtaining accurate mass data for the samples with mass errors ranging from 0.1 to 2 Da (~2 to 50 ppm). Samples were stressed under thermal and acidic degradation conditions prior to analysis to demonstrate method suitability for rapid purity determination. These techniques are viable options for precise stability indicating assays.

Fractions of the heterogeneous sgRNA collected by IEX and analyzed using this 5-min IP-RPLC/HRMS method, revealed that heterogeneous peaks observed in sgRNA samples by IEX were identical in IP-RPLC-HRMS. Our results show the feasibility of this novel application for HT IP-RPLC-HRMS analysis of sgRNA and give insight into sgRNA conformational heterogeneity.

1837 Dual Cation Exchange coupled with Multi-Modal Chromatography Allows the Production of High-Purity and Low residuals cGMP-Grade Cas9 Nuclease for Cell Therapy Applications

Brittany Sangiovanni[1], Virginia Nash[1], Eva Geygan[1], Dylan Vasconcelles[1], Dennis Concepcion[1], Carson White[1], Destiny Jones[1], Ned Drey[1], Mahajoub Bello Roufai[2]*, Telles Telles[1]

[1]*Akron BioManufacturing, Sarasota, FL,* [2]*Akron Biotech, FL, Sarasota, FL*

RNA-guided CRISPR-Cas9 genome editing that exploits the bacterial CRISPR-Cas system to target and edit genome at specific double strand sequence with high precision has opened endless possibilities for cell therapy. The use of CRIPSR-Cas9 system allows specific permanent correction of deleterious base mutations or modifying genes responsible for diseases. The applications of such gene editing tools nucleases are ever-expanding and were recently validated with the US FDA approval of Casgevy, the first gene editing therapy for the treatment of sickle cell disease. This milestone, along with the growing number of gene-editing programs, accentuates the need for scalable, cost-effective enzyme production and purification processes. Previously, we reported the purification of our Histidine Tag-less 160KDa Cas9 employing an optimized homogenization matrix coupled with a size-exclusion chromatography (SEC) polishing step.
In this report, we present a second-generation purification process that significantly improves production efficiency and product quality. This process replaces the labor-intensive and scale-limited SEC-based process with a sequential dual cation exchange chromatography (CEX) followed by multimodal and anion exchange polishing columns, achieving higher product purity and yield, at a fraction of the time and cost. Limitations of the SEC-based first-generation process is presented side-by-side with this second-generation process. The final product consistently showed a purity greater than 95%, less than 20 ng/mg residual host cell protein, less than 1% (w/w) residual host cell DNA, less tha 20 EU/mg endotoxin and low level of residual RNase and DNase. The second-generation process using cGMP compatible resins, chemicals, and supplies supports gram-scale production of cGMP-grade Cas9. In addition, this purification approach could be applied to similar nucleases or other proteins with comparable physicochemical properties.

1838 High-Throughput Developability Assessment of AAV Drug Products: A Predictive Approach

Jacob Cardinal[1], Kaushal Jerajani[2], Andrew Voronin[3], Lori Karpes[2]
[1]*Alexion Pharmaceuticals Inc., Natick, MA,* [2]*Alexion, Cambridge, MA,* [3]*Alexion Pharmaceuticals Inc., Brighton, MA*

Adeno-associated virus (AAV) vectors have demonstrated immense promise for the treatment of genetic diseases, but their successful translation to the clinic requires a robust, developable vector candidate. Here we demonstrate a high-throughput approach to rapidly evaluate and differentiate AAV vector candidates and formulations based on their physical and chemical stability. A suite of predictive techniques was assessed including forced precipitation, forced denaturation, and temperature ramping, to assess colloidal, conformational, and thermal stability, respectively.

We demonstrate the feasibility of predictive approaches for AAV vectors under various conditions in a low-volume, high-throughput manner. Such workflows can be used to prioritize promising candidates for further development. This approach has the potential to significantly accelerate the development of stable and efficacious AAV-based gene therapies.

1839 Upgrading Our Toolbox: New Analytical Tools to Support rAAV Vector Bioprocess Development and Product Understanding

Marco Thomann, Roche, Penzberg, Bayern, Germany

The presentation will give an overview of the current standard analytical panel used during development of rAAV vectors. The main focus will be on new analytical tools for rAAV. Analytical techniques like mass spectrometry, mass photometry, fragment analyzer and next-generation sequencing will be discussed in more detail including opportunities and challenges. Using multiple case study data, the new methods will be compared to current standard methods (e.g. AUC, PCR, SDS-PAGE) and their benefit for using them during process development will be explained. In detail, comparison of full-empty levels across four different methods will be presented (Linearity, Accuracy, Repeatability,…). Furthermore, characterization of rAAV vectors using NGS, fragment analyzer, dPCR

and mass photometry will be presented as an example. The new methods add value to the existing analytical tool box, but also expectations need to be managed, e.g. limitations / complex interpretation of data and potential validation of such methods as well as use for GMP release of rAAV.

1840 Next Generation digital PCR Technology for Sterility Testing of Cell and Gene Therapy Products

Alexandra Müller-Scholz[1], **Benjamin Graf[2]**, Robert Hertel[3]
[1]Sartorius, Goettingen, Niedersachsen, Germany, [2]Sartorius Lab Instruments GmbH & Co KG, Göttingen, Niedersachsen, Germany, [3]Sartorius, Goettingen, Germany

The bio-pharmaceutical world has moved drastically towards short-lived personalized cell and gene therapy products in recent years. With the new quality control requirements, several new rapid microbial detection methods have been developed. USP <1071> states, “The ability to detect contamination, in real-time, prior to the administration of the short life product may be considered more important than detection of a single colony-forming unit (CFU) in the product.” However, the new methods strive to detect the holy grail of 1 CFU. Will this ever be possible, or is it even necessary? In this poster, we will present the first digital (droplet) PCR based approach for sterility testing which is intended for testing of cell and gene therapy products, elucidate the critical steps, and highlight the many benefits of this approach. We will address the handling of background signals of a bacteria digital (droplet) PCR experiment and explain how to clearly differentiate between the background and real positive signals. We will demonstrate how the groundbreaking digital (droplet) PCR technology allows a new level of precision in rapid sterility testing. We propose an open discussion on this advanced method and its potential for QC testing and release.

1841 Using Next Generation Sequencing to Test Raw Materials used in Biologics Manufacturing

Brianna McManus[1], Rebecca Bova[2], Bradley Hasson[2]
[1]MilliporeSigma, Rockville, MD, [2]BioReliance Corporation (MilliporeSigma/Merk KGaA), Rockville, MD

When using raw materials in the manufacturing of biological products and vaccines, there is a risk associated with introducing exogenous sequences attributed to these materials into the test system. Next Generation Sequencing (NGS) testing is recommended at multiple steps in the cell-culture process to look for adventitious viruses but can also be performed on raw materials introduced into the manufacturing process. A popular raw material associated with cell culture is Fetal Bovine Serum (FBS). This serum is an animal derived material which provides additional proteins and growth factors to support cell growth. By using NGS for adventitious virus detection in raw materials, this can help ensure a more comprehensive profile of exogeneous sequences being introduced into the process. The profiles of these sequences can also be used to identify any source of downstream contamination if it were to occur.

In this study, we tested FBS for the presence of contaminating influenza sequences specifically H5N1, due to the increased detection in US herds. Due to the nature of FBS, the serum is full of various components that are extremely beneficial to cell-culture but have the potential to cloud NGS based assays. To reduce the background noise contributed from FBS (i.e. cell-based nucleic acids), an endonuclease treatment such as Benzonase® endonuclease has been proven to remove extraneous nucleic acids. Benzonase® endonuclease removes these residual nucleic acids while leaving intact viruses undisturbed, which enriches the test sample for detection of encapsidated viral sequences.

The study was designed to detect contamination of raw materials and determine if a Benzonase® endonuclease pre-extraction treatment would be beneficial in the detection of influenza contaminants alone. To assess the feasibility of this, FBS lots were processed through our GMP-validated NGS workflow. Prior to extraction, an aliquot of FBS was spiked in with the Center for Biologics Evaluation and Research (CBER) Next Generation Sequencing Virus Reagents virus panel. The representative panel includes five viruses selected for different sizes, genomic characteristics, and chemical resistance and are representative of potential contaminating viruses. One spiked and

one unspiked sample would undergo the Benzonase® endonuclease pre-extraction treatment to look while another set would not undergo the pre-extraction pre-treatment. After the optional treatment, all samples underwent a total nucleic extraction, cDNA conversion and sequence compatible DNA libraries were generated. Sequencing was performed using the Illumina NextSeq2000 and data analysis was performed using proprietary bioinformatics software. A significant reduction in the background sequences was observed when the FBS was treated with Benzonase® endonuclease prior to extraction. For the spiked samples, the Benzonase® endonuclease showed a significant improvement in the detection of the viruses. All five viruses were identified in the treated sample, while in the untreated sample, only two of the five viruses were detected at high concentrations. The detection of the two viruses across the board improved by at least 100X using Benzonase® endonuclease pretreatment. This study demonstrated that the use of our validated NGS method is amenable to adventitious virus detection for raw materials and that the use of a Benzonase® endonuclease could improve the sensitivity of the assay.

1842 Extraction-free ddPCR quantification of host-cell derived E1A impurities in rAAV samples

Sophie Beer[1], Paul Zanotti[1], Felicia Thoennissen[1], Renée Kober[1], **Sabine Geiger[2]**, Sonya Schermann[3]
[1]Ascend Advanced Therapies, Planegg, Germany, [2]Ascend Advanced Therapies, Planegg, Bayern, Germany, [3]Ascend Andvanced Therapies, Martinsried, Germany, Germany

Packaged residual DNA impurities in recombinant adeno-associated virus (rAAV) products arise during manufacturing and pose a risk to the patient safety, product efficacy and persistence of gene therapy. In production processes using HEK293 cells, the integrated adenoviral E1A gene is a potential contaminant from host cell DNA with cell-transforming potential. Therefore, the level of contaminating E1A is a critical quality attribute for AAV produced in HEK293.

Ascend has developed and qualified a ddPCR for the absolute quantification of E1A copy numbers in rAAV batches using sequence-specific primers and probe. While most currently used release methods require DNA extraction to achieve the required sensitivity, the ddPCR method developed and presented here enables analysis without any sample treatment or DNA extraction. Thus, our E1A ddPCR method avoids experimental errors due to insufficient or poor DNA extraction and saves sample volume and time while maintaining high sensitivity. It was developed for purified rAAV samples such as drug substance and drug products, allowing very low sample dilutions without matrix interference.

Method qualification demonstrated high precision, accuracy and sensitivity, enabling product-specific validation with very limited effort and application as a robust and accurate drug substance and drug product release assay in accordance with regulatory expectations.

1843 Rapid and Versatile Analysis of AAV Samples Using Lateral Flow Assays: Applications in Gene Therapy Development

Jesse Kay[1], Martin März[2], Silja Adam[3], Ina Berger[1], Christina Querfurth, Caroline Odenwald[4], Dana Holzinger[1]
[1]Progen Biotechnik GmbH, Heidelberg, Germany, [2]PROGEN, Heidelberg, Baden-Wuerttemberg, Germany, [3]PROGEN Biotechnik GmbH, Heidelberg, Baden-Wuerttemberg, Germany, [4]PROGEN, Heidelberg, Germany

Adeno-associated viruses (AAV) represent the most commonly used viral vector for the delivery of therapeutic transgenes in academia and industry. However, the gene therapy community is facing major challenges like the high demand for effective and reliable analytical AAV tools for gene therapy manufacturing and development.

Though the use of orthogonal methods is recommended for comprehensive characterization, rapid testing of individual and crude AAV samples during the development and manufacturing process is often difficult. Most precise analytical AAV tools are not convenient for single sample measurements and/or require highly purified samples.

Our new AAV lateral flow assays can easily be used for a broad range of applications, helping to facilitate and accelerate AAV-based gene therapy.

Here, we show potential applications of the AAV lateral flow assay for serotypes AAV1, AAV2, AAV5, AAV6, AAV8 and AAV9, i.e. (1.) comparing the capsid titer of two unknown samples, (2.) estimating the titer using a reference standard, (3.) spot landing in the optimal dynamic range and (4.) testing antibody binding to variant AAV serotypes.

1844 A Novel AAV TCID50 Testing Method Using Replication-Deficient Helper Adenovirus and Inducible 293 Cell

Xiulian Sun[1], Zhong Ming[1], Hui Jiang[2], Xin Li[2]
[1]Richmond, BC, [2]uBriGene Biosciences International Co, Suzhou, China

Background: The TCID50 value of adeno-associated virus (AAV) is commonly used to evaluate the infectivity of AAV products in vitro. It serves as a critical testing parameter in the research, production, and quality control of AAV. However, the traditional TCID50 assay involves the addition of wild-type adenovirus, which presents significant challenges to the stability and safety of the test. To address this, we have developed a novel YM-TCID50 testing method. This method incorporates a replication-defective adenoviral vector with E2 mutation to prevent virus replication and cell lysis during the assay and employs a Cre-inducible AAV Rep expression 293 cell line to mitigate the cytotoxic effects of Rep.

Methods:
(1) Constructing a replication-deficient adenoviral vector that can only amplify in specially engineered 293 cells.
(2) Establishing a 293 cell line, 293RC24, with Cre-induced AAV Rep expression to evaluate AAV replication using a luciferase assay.
(3) AAV TCID50 testing was performed using 293RC24 and the replication-deficient AdV, with the traditional HeLaRC32 serving as a control.

Results:
(1) The replication-defective adenovirus was efficiently amplified in our specially engineered 293 cells, achieving a titer of 2.43×10^9 PFU/mL.
(2) AAV replication in 293RC24 cells is 24.6 times and 35.9 times higher than that in 293A cells, respectively.
(3) The AAV TCID50 assay using the 293RC24 cell line is more stable than the traditional HeLaRC32 method due to the non-lytic nature of the replication-deficient AdV.

Conclusion: We have developed a more stable and safer AAV TCID50 analytical method that integrates an inducible Rep 293 cell line (293RC24) and a replication-deficient adenoviral helper virus.

1845 Phase 1 Study of GEN2, A Personalizing Gene Therapy Vector, in Adult Patients with Locally Advanced or Metastatic Solid Tumor Malignancies

Anthony El Khouiery[1], Alexander Spira[2], Dianna Hanna[3], Jacob Thomas[4], Gagandeep Brar[5], Neel Belani[2], Tara Quang[2], Allen Wang[6], Robert Johnson[7], **Alison Hannah**[8], Daneng Li[5]
[1]University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA, [2]NEXT Virginia, Virginia, VI, [3]USC Norris Comprehensive Cancer Center, Los Angeles, [4]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA, [5]City of Hope, Duarte, CA, [6]GenVivo, Pasadena, CA, [7]GenVivo Inc, San Marino, CA, [8]Consultant, Sebastopol, CA

Drug candidates based on oncolytic viruses containing viral thymidine kinase (vTK) or GM-CSF encoding payloads and replication-deficient adenovectors containing a vTK payload have demonstrated encouraging results in skin, bladder, prostate, pancreatic, and lung cancers when administered intratumorally (IT) or intralesionally (IL). However, there are practical limitations to IT or IL administration, including the number of lesions that can be

injected and the invasive nature of injections into non-cutaneous lesions. Therefore, we are investigating GEN2, an intravenously (IV) administered non-replicating gene transfer vector that encodes for both an optimized prodrug activated enzyme (enhanced viral thymidine kinase; HSV-eTK) and the immunostimulatory cytokine GM-CSF. When transduced into a tumor cell and in the presence of the oral prodrug ganciclovir (VGCV), HSV-eTK triggers cancer cell death by DNA chain termination and subsequent release of the full complement of unique tumor antigens including neoantigens (NA). The local secretion of hGM-CSF augments and facilitates an immunotherapeutic effect by enhancing NA presentation to local immune effector cells. IV infusion of GEN2 to forty-eight (48) late-stage cancer patients with hepatocellular cancer (HCC) or cancers metastatic to the liver was well-tolerated with minimal toxicity, with 10 of 48 patients on study > 6 months in an Asian phase 1 clinical trial. A Recommended Phase 2 Dose (RP2D) was not identified. This is an open label, US Phase 1 study in adult patients with locally advanced or metastatic solid tumors to determine the recommended Phase 2 dose (RP2D) for GEN2 by intravenous (IV) infusion. Secondary objectives include immunogenicity, PK and preliminary anti-tumor activity. Exploratory endpoints include assessment of replications competent retrovirus (RCR) in peripheral blood, changes in cytokines and circulating immune cells, and tissue changes in paired biopsies. Dose escalations were initially in semi-log increments in single patient cohorts; after the third dose increase, the maximal additional dose increases are 100%. As of January 20, 2024, 8 patients have been treated at 4 dose levels starting at 3.4E+6TU/kg and reaching 1E +8 TU/kg. Treatment duration ranges from 1 to 9+ weeks. Median age was 60, 4 patients were females; patients had a median of 3 prior lines of therapy (range 3-5). Treatment related adverse events (TRAEs) were all grade 1-2, and included diarrhea (n = 2), nausea (n = 1), vomiting (n = 1), chills (n = 1), and hyperhidrosis (n = 1). Dose Limiting Toxicity has not yet been observed. No patient discontinued treatment due to a related AE. PK data demonstrate an elimination half-life between 0.28 to 3.04 hours; mean clearance 2010-3780 mL/hr/kg and mean Vss 986 - 2030 mL/kg. Safety review for Dose Level 4 is ongoing. RCR/vector persistence has not been observed over this dose range. No objective responses have been observed to date. Batched analysis of correlative data is in progress. GEN2 has been well tolerated early in dose escalation without occurrence of DLTs; further clinical activity including PK results, response assessment, and pharmacodynamic data will clarify determination of a RP2D. A parallel cohort for intratumoral injection is on-going in cutaneous malignancies. Once the IV RP2D is identified, the protocol will open three expansion arms: hepatocellular carcinoma, HR+ breast and cutaneous malignancies (NCT06391918).

1846 Analysis of Clinical Benefit for a Phase 2 Basket Study Using DNG64 Cyclin G1 Inhibitor Gene Vector + Immunotherapy for CCNG1 Oncogene Expressing Tumors Predicts Successful Efficacy Endpoints (NCT04091295)

Sant Chawla[1], Anmol Agarwal[2], Samantha Jeffrey[2], Grace Haroun[2], Angela Savage[2], Ishrat Buhyian[3], Edward Mena[4], Bradley Jabour[5], Rheanna Carter[6], Charles Simone[7], Kambiz Nael[8], Howard Bruckner[9], Anna Gattani[10], Neal Chawla[11], Robin Jones[12], Rebecca Reed[13], William Isacoff[3], Paul Song[14], Frederick Hall[15], Erlinda Gordon[16]

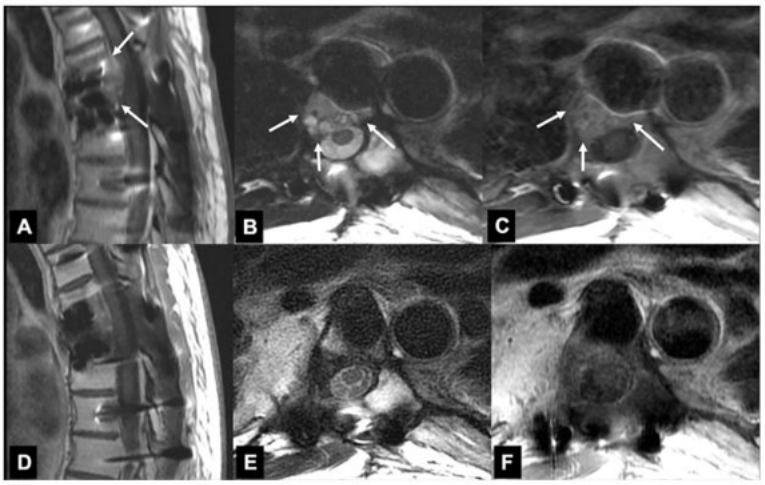
Background: DNG64, a tumor targeted retroviral vector encoding a Cyclin G1 inhibitor construct, not only induces apoptosis in cancer cells and tumor vasculature but also primes the tumor microenvironment for enhanced immune cell and/or drug entry by killing tumor associated fibroblasts, thus, reducing stroma production. Expanded access for DNG64 is currently open for advanced sarcoma, pancreatic cancer, and breast cancer (NCT04091295). In this patient population, the Simon 2-Stage design criteria was implemented to determine the potential of DNG64 + immunotherapy treatment to meet efficacy endpoints in a planned phase 2 basket study for CCNG1 expressing tumors.

Methods: Endpoints: (1) Clinical benefit rate or CBR (CR, PR, SD]) at month 4 by CT/MRI by RECIST v1.1 (2) Overall response (ORR); (3) Correlation between CCNG1 expression and CBR. Up to 40 patients with advanced sarcoma, pancreatic cancer or breast cancer will be treated with DNG64 IV (1.7 x 10e10 RV copies 3x a week x 3

weeks/month) plus FDA approved drug (DNG64+ regimen). Archived tumor specimens from all patients will be analyzed for CCNG1 expression level using RNA sequencing. CCNG1 levels will be stratified as: Low = <17%, Medium-Low = 17- 49%, Medium-High = 50-83%, or High = >83%. A Simon 2-stage design with Type I error rate = 0.1 and power = 0.8 will be used, accordingly, a CBR ≥ 30% would warrant continuing the planned Phase 2 basket study.

Results: All patients had previously failed standard chemotherapy. Eight patients with advanced sarcoma (n=5), pancreatic cancer (n=2), and breast cancer (n=1), were treated with the DNGG64+ regimen. Three patients received DNG64, SNK01 (autologous enhanced natural killer cells) and a PD1 inhibitor. All tumors showed enhanced CCNG1 expression. Four of 8 (50%) patients had PR; 6/8 (75%) patients had PR or SD at month 4; 2/3 (66%) patients treated with DNG64, SNK01 and a PD1 inhibitor had PR. In an analysis of patient tumors by CCNG1 expression level, High CCNG1 expressors (n=3) had a 33% (1/3) CBR, Medium-High expressors (n=3) had a 100% (3/3) CBR, and Medium-Low expressors (n=2) had a 100% (2/2) CBR. By tumor type, sarcoma patients had 60% (3/5) CBR, pancreatic cancer patients had 100% (2/2) CBR, and breast cancer patients had 100% (1/1) CBR. One subject with recurrent osteosarcoma of T4-T5 spine and High (89%) CCNG1 tumor expression had a 65% decrease in tumor volume when DNG64 was given with proton therapy.

Conclusions: Taken together, the data analyses indicate that: (1) All tested tumors show enhanced CCNG1 oncogene expression, reinforcing the use of intravenous DNG64 Cyclin G1 inhibitor therapy for advanced sarcoma, pancreatic and breast cancer; (2) An Overall Response Rate of 50% for all groups, a 66% ORR for DNG64, SNK01 and PD1 inhibitor group, and a clinical benefit rate of 75% for all groups, when categorized by both tumor CCNG1 expression level and cancer type, meet the Simon's 2-stage design threshold clinical benefit rate of 30%, thereby qualifying all groups for further studies of efficacy and safety in a randomized Phase 2 basket study using combination regimens of DNG64 + immunotherapy.



Description of MRI Image:

Sagittal T1-postcontrast, axial T2 and axial T1 postcontrast MR images of thoracic spine are shown before (A, B, C) and after (D, E, F) treatment with proton therapy and concurrently with DNG64, a tumor targeted gene therapy bearing a cytocidal *CCNG1* inhibitor gene. There is a 16 x 14 x 25 mm mass in the ventral epidural space at T5-T6 level with heterogenous T2 hyperintense signal (arrows on B) and postcontrast enhancement (arrows on A and C). MR images obtained 2 months after proton therapy and DNG64 show significant decrease in the size (10 x 14 x 14 mm) and degree of T2 signal and postcontrast enhancement suggestive of treatment response. Note: Mechanistically, intravenously administered DNG64 nanoparticles seek out and accumulate in injured tissues (i.e., irradiated tissues in this case) favoring enhanced efficacy of tumor kill with proton therapy in a subject with osteosarcoma, a notoriously radioresistant type of sarcoma. Phase 2 studies are planned using concurrent administration of DNG64 with proton therapy.

1847 Interim Analysis of a Phase 1/2a Study of ICM-203 AAV Gene Therapy for Osteoarthritis

Alison Heald[1], Lucian Solomon[2], Richard Page[3], Young Na Yum[4], Minsun Park[5], Jayhyuk Myung[6], Jamie Collins[7], Ali Guermazi[8], **Dae-Won Kim[9]***

Introduction: An unblinded interim analysis of the low dose cohort of the first-in-human phase 1/2a study of ICM-203, a recombinant adeno-associated viral (AAV) vector designed to express a truncated form of human Nkx3.2, a transcription factor which plays an important role in both chondrocyte and synoviocyte activity, was conducted to obtain a preliminary assessment of the safety, immunogenicity, and biological activity of ICM-203.

Methods: In the low dose cohort of this phase 1/2a, double-blind, placebo-controlled, dose escalation study (NCT04875754), 8 subjects with Kellgren-Lawrence grade 3 osteoarthritis (OA) of the knee were randomized to receive a single intra-articular injection of ICM-203 or placebo in a 3:1 ratio. The primary safety endpoint was safety and tolerability of ICM-203 through assessment of treatment-emergent adverse events (TEAEs). Immunogenicity endpoints included measuring serum neutralizing antibody (NAb) titers and T-cell responses to ICM-203's AAV capsid. As efficacy endpoints, changes in knee pain and function were assessed using the Knee Injury and Osteoarthritis Outcome Score (KOOS) pain subscale and KOOS activities of daily living (ADL) subscale, respectively; these KOOS scores were then used to calculate Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores. Imaging endpoints included Magnetic Resonance Imaging (MRI) Osteoarthritis Knee Scores (MOAKS), focusing on bone marrow lesions (BML), synovitis, articular cartilage damage, and osteophytes, as well as minimum joint space width (mJSW) as measured by knee radiograph.

Results: Of 11 screened subjects, 8 qualified and received a single intra-articular injection of ICM-203 (N=6) or placebo (N=2); all subjects completed 52 weeks of follow-up. Subject age ranged from 56 to 73 years; body mass index (BMI) ranged from 24.6 to 38.6 kg/m^2. No significant concerns about safety or tolerability arose. The most common treatment-related TEAE was mild to moderate arthralgia, which occurred in 3 of 6 ICM-203 subjects and 1 of 2 placebo subjects. At baseline, 3 ICM-203 subjects had positive NAb responses to AAV capsid; no subjects had significant T-cell responses. All 6 ICM-203 subjects developed both a humoral and cellular response against AAV capsid, whereas neither placebo subject did. ICM-203 subjects with negative NAb at baseline (N=3) demonstrated greater improvement over placebo subjects (N=2) in KOOS pain (1.3-fold), KOOS ADL (2.3-fold), WOMAC (2.7-fold), as well as in imaging endpoints, including MOAKS BML (2.7-fold) and mJSW (2.0-fold). In contrast, ICM-203 subjects with positive NAb at baseline (N=3) showed no sign of efficacy in these endpoints. Improvement in synovitis was observed in 2 of 6 ICM-203 subjects (1 with positive NAb and 1 with negative NAb), whereas no improvement was observed in either placebo subject. For articular cartilage and osteophytes, no significant changes were observed in any subject between baseline and week 52.

Conclusions: Intra-articular injections of ICM-203 were safe and well tolerated. ICM-203 appeared to show greater therapeutic activity over placebo in subjects with negative NAb at baseline. Current findings indicate ICM-203 may demonstrate potential as a disease-modifying osteoarthritis drug (DMOAD), between reducing osteoarthritis symptoms, ameliorating structural joint damage, and alleviating synovial inflammation. Investigation of higher doses of ICM-203 is in progress.

1848 Design of the First Clinical Trial of AAV Gene Therapy in Immuno-Oncology (SENTRY-ALL): A Single Dose CD3/CD19 Bi-Specific T-Cell Engager for the Treatment of CD19+ B-Cell Acute Lymphoblastic Leukemia

Allen Reha[1], Timothy Cripe[2], Allan Kaspar[3], Samit Varma[3], Brian Kaspar[3], Nicholas Short[4]
[1]Vironexis Biotherapeutics, Millstone Township, NJ, [2]Nationwide Children's Hospital, Columbus, Ohio, [3]Vironexis Biotherapeutics, Inc., San Diego, CA, [4]MD Anderson Cancer Center, Houston, TX

VNX-101 is an investigational adeno-associated virus (AAV) gene therapy developed to express a secreted anti-CD19/anti-CD3 scFv diabody (termed GP101). GP101 binds both cluster of differentiation (CD)19 and CD3, inducing T-cells to kill both benign and malignant B-cells. Following a single dose intravenous (IV) infusion, the vector induces the liver and key tissues to continuously secrete GP101 into the bloodstream, resulting in long-term, continuous and consistent serum levels of GP101. Potential advantages of VNX-101 over autologous CAR-T therapy include it is off-the-shelf, provides a gentle onset of action, does not require lymphodepletion chemotherapy, engages all T-cells continuously (including those freshly produced from the bone marrow), and utilizes highly efficient signaling through the native T-cell receptor. Reduction in CD19+ leukemia or lymphoma cells and prolonged survival were observed in NSG mice following VNX-101 administration. Safety, PK, and biodistribution were further established in toxicology and larger species (baboon) studies. Based on these findings, FDA IND clearance was received to conduct a Phase 1/2 clinical trial of VNX-101 in patients with relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL), representing the first FDA approval of an AAV cancer clinical trial.

SENTRY-ALL is a phase 1/2, multicenter, open-label trial in patients with relapsed or refractory CD19+ B-cell ALL (NCT06533579). The key inclusion criterium is CD19+ bone marrow blasts via flow cytometry <50% (baseline or after cytoreductive therapy). Prior blinatumomab and/or CD19 CAR T-cell treatment is allowed. AAVrh74 total antibody titer is required to be <1:400.

In this 2-part study, dose-finding data from Part 1 of the study (n~12 patients) will be used to determine the dose for Part 2. Part 1 is a dose-finding PK study in adults ≥18 years old designed to determine the minimal dose that achieves target PK serum levels of GP101 at steady state (8-week timepoint) without dose-limited toxicities, defined as the recommended Part 2 dose. Part 2 (n~14) will be opened following data safety monitoring board review of Part 1 data and is designed to determine the safety and pharmacokinetics (PK) of VNX-101 at the recommended dose in a broader array of subjects including those of a lower age, ≥13 years old. Patients will be followed for safety and efficacy up to 5 years post VNX-101 dosing. Long-term follow-up assessments for safety will be conducted for 6 to 15 years post VNX-101 dosing. Primary endpoints are safety and to determine the RP2D. Secondary endpoints include change in B-cell counts, immunoglobulin levels, MRD/hematologic response, progression free survival, and disease-free survival. Exploratory endpoints include GP101 PK and vector shedding. The first patient is anticipated to be dosed in Q1 2025. Up to 26 patients will be enrolled across centers in the United States.

VNX-101 has the potential for improved safety, efficacy, and accessibility over current CD19-directed therapies. This trial aims to provide the first clinical experience in the use of AAV gene therapy as a new paradigm for cancer immunotherapy.

1849 A Randomized, Double-Blind, Placebo-Controlled Dose-Ranging Phase 1b Study Evaluating Safety, Tolerability, and Pharmacodynamics of a Local AAV-Mediated Anti-Interluekin-1 Gene Therapy in Subjects With Knee Osteoarthritis: 6-Month Interim Results

Philip Conaghan[1], Jeyanesh Tambiah[2], Shanna Jackson[2], Marianne Concepcion[2], Sharmila Vijay[3], Laurie Halligan[2], Thomas Chalberg[2], **Annahita Keravala[2]***
[1]University of Leeds, Leeds, United Kingdom, [2]Genascence Corporation, Palo Alto, CA, [3]Genascence Corp, Palo Alto, CA

Knee osteoarthritis (OA) is a chronic, painful, and degenerative disease causing disability. It affects millions of people but has no treatment to safely reduce pain and reverse joint damage. Interleukin-1 (IL-1) is an inflammatory and catabolic cytokine that is a major contributor to the pathophysiology of OA, including pain and tissue erosion. Previous attempts with small molecule drugs and biologics targeting IL-1 have failed to show sustained efficacy in affected joints due to inadequate delivery and rapid clearance. Genascence is developing a gene therapy, GNSC-001 to confer local, long-term IL-1 inhibition after a single intra-articular (IA) injection to the affected knee. GNSC-001 is a recombinant adeno-associated virus (rAAV) that encodes human interleukin-1 receptor antagonist (IL-1Ra), a potent inhibitor of IL-1. Following a small open-label, dose-escalation Phase I study, a larger randomized, double-blind, placebo-controlled, dose-ranging Phase 1b trial of GNSC-001 in knee OA subjects was initiated. The primary objective was to evaluate the safety and tolerability of GNSC-001 administered as a single IA injection. A key secondary objective was to evaluate long-term expression of transgenic IL-1Ra in synovial fluid (SF). Another secondary objective was to understand the role of transient immune conditioning (IC) regimens on effectiveness of the gene therapy. Six-month interim results are reported.

Consented subjects (n=53) aged 40-75 years with moderate to severe knee OA, Kellgren Lawrence (KL) Grade 2-3, and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) target knee pain ≥ 20/50 were randomized into 5 groups in 1:1:1:1:1 ratio and received an ultrasound-guided IA injection of: Group 1) GNSC-001 1×10^{12} vg; Group 2) GNSC-001 1×10^{12} vg + IC- oral; Group 3) GNSC-001 1×10^{13} vg; Group 4) GNSC-001 1×10^{13} vg + IC- oral; or Group 5) Placebo (formulation buffer) on Day 1. IC in Groups 2 and 4 was a short course of 60 mg oral prednisone for 7 days, starting Day -1 and tapering for 6 weeks. The trial was expanded to include a non-randomized open-label arm- Group 6 (n=14) that received GNSC-001 1×10^{13} vg with a local steroid injection plus an abbreviated course of oral steroids (IC- IA+oral); specifically, 80 mg IA methylprednisolone, and 60 mg oral prednisone on Day -1 for 3 days. Study visits included Months 1, 3, 6, & 12 (+ 48 months safety follow up).

Follow-up though 6 months showed that there were no deaths or safety-related study withdrawals. Two treatment-unrelated serious adverse events (SAEs) were reported. Treatment-Emergent Adverse Events (TEAEs) were balanced in Groups 1-5, trending higher in Group 6. Target knee AEs (TKAEs) across Groups 1-6 were mostly Grade 1-2 (mild to moderate), with one Grade 3 (severe), which was a recurrent knee effusion in Group 6. TKAEs were generally arthralgia, swelling, effusion, and stiffness. All GNSC-001-treated groups resulted in elevated SF IL-1Ra levels compared to baseline and Placebo. Higher IL-1Ra in SF was associated with IC and a dose-reponse was observed between the 1×10^{12} vg and 1×10^{13} vg groups with IC through the 6-month visit.

The 6-month interim results suggest that this novel treatment is safe, well-tolerated, and capable of yielding and sustaining mean expression of IL-1Ra to target levels in multiple groups of the study. GNSC-001 is thus of potential therapeutic benefit in knee OA, a previously undruggable disease, and warrants further development.

1850 Patients perspective on their cross-border personalized treatment experience

Cecilia Marinova[1]*, Miriam Kolnikova[2], Klara Brozova[3], Veronika Sladkova[4]
[1]Medasol, Prague, Praha, hlavní město, Czech Republic, [2]National Institute of Children's Diseases, Bratislava, Slovakia, Bratislava, Bratislavský kraj, Slovakia, [3]Pediatric Neurology, Thomayer University Hospital, Prague, Czechia, Praha, Praha, hlavní město, Czech Republic, [4]Medasol sro, Praha, Praha, hlavní město, Czech Republic
**Corresponding Author*

Background: Personalised medicine is often only accessible through specialized centres, which for patients with rare diseases are often established in different countries than the patient's country of residence. Attending specialists and affected families can seek effective treatment solutions including Advanced Therapy Medicinal Products (ATMPs) and cross-border options, which can be accessed through various routes (S2 in EU, individual requests, clinical studies, compassionate use etc). This phenomenon is a subgroup of medical tourism, which is not driven by convenience, but only by efficacy.

Methods: We used a questionnaire to interview 12 parents of minor patients who applied for cross-border treatment for specific, personalized treatments that were not available in the country of origin. A total of 5 families from Slovakia and 2 from the Czech Republic were interviewed and provided feedback, who planned treatment in

Germany, Netherlands and Italy. Some families stayed more than 3 months abroad. We have focused on the challenges of travelling abroad for treatment.

Results: All families recommended cross-border treatment. Parents decided to pursue the cross-border treatment of their children based on its efficacy, even though three families also considered less effective treatment available in the country of residence. The health insurance (HI) coverage of treatment was an important aspect, as well as coverage for travel and stay. While speaking at least one foreign language, language limitations in communication with healthcare professionals (HCP) was one of the main concerns, followed by concerns about organization and financial aspects of treatment. The main source of information about treatment options was provided by an attending specialist, closely followed by Internet search and recommendations from families facing similar challenges. Communication with foreign HCP was evaluated as effective, but it was not perceived as effective with administrative personnel nor HI. All considered it important to accompany the child as a whole family.

Conclusions: Although the ATMP treatment option was highly recommended by all, the communication was the main concern and challenge. Attending physicians have a critical role in initiation of cross-border treatment. The Internet search, networking with families with similar experiences and learning the language are highly recommended by the respondents to facilitate treatment.

1851 The Kids Advanced Therapeutics Program – Responding to the Need for Systems Readiness in the Gene Therapy Translation Pathway

Michelle Lorentzos[1]*, Michelle A. Farrar[2], Michelle Ko[3], Paula Bray[4], Lani Attwood[4], Kristi Jones[4], Ian Alexander
[1]Sydney Children's Hospitals Network, WESTMEAD, NSW, Australia, [2]Randwick, AUSTRALIA, [3]Sydney Children's Hospitals Network, WESTMEAD, NSW, Australia, [4]The Sydney Children's Hospitals Network, Sydney, New South Wales, Australia
**Corresponding Author*

Health systems readiness is an imperative aspect of gene therapy clinical trials and translation. The Sydney Children's Hospitals Network (SCHN), Australia's largest paediatric health service, was the first site in Australia to become approved for therapeutic delivery of onasemnogene abeparvovec in spinal muscular atrophy and the first site in the world to deliver gene therapy for Duchenne muscular dystrophy to boys under 4 years. SCHN has responded to this rapidly evolving pipeline by pioneering an innovative enabling platform, the Kids Advanced Therapeutics (KAT) Program, to provide multidisciplinary and disease agnostic frameworks that embed gene therapy trials in existing health systems.

The KAT Program prioritises governance, safety and equity through multiple initiatives that aim to embed gene therapy, as well as CAR-T cell, phage therapy and other advanced therapeutics and in sustainable models of care. A Trial Evaluation Flying Squad (TEFS) enabled investigators, clinicians and administrators to access broad expertise in selecting and preparing for gene therapy trials amid a rapidly changing landscape. A Gene Therapy Multi-Disciplinary Team (MDT) was established to provide consultative services to patients admitted for gene therapy delivery and support optimal management of adverse events including thrombotic microangiopathy, immune mediated myositis and complications from iatrogenic immunosuppression. An AAV Gene Therapy Multi-Disciplinary Education Program provided fit for purpose education modules that responded to areas of need across clinical care and safety, as well as ethics and responsibility.

An ethical model of patient selection for competitive recruitment was devised and piloted following input from clinicians and clinical ethicists. Patient facing materials that provide plain language explanations of gene therapy have been co-designed and disseminated to consumers.

During the last 5 years, systems readiness activities facilitated by the KAT Program have supported expansion of gene therapy activity at SCHN and significantly improved workforce confidence, with the number of clinical staff who felt 'not at all confident' caring for patients with AAV falling 68% to 14% after accessing KAT education resources. SCHN has now expanded its gene therapy clinical trial portfolio to include Rett syndrome, inherited deafness and haemophilia. The KAT Program is supporting capacity building at other Australian tertiary hospitals

and leading interstate advocacy for nationwide systems and infrastructure. There is now a national system for interstate referrals for neuromuscular gene therapy clinical trials in Australia. (1)

Australia's vast geographic landscape position it to be an exemplar for delivering specialised therapies despite physical distance, with an emphasis on agile clinical systems and equity of access. Learnings from the KAT program remain relevant beyond Australia and discussion of these experiences and insights may provide opportunities for partnership and planning across broader jurisdictions and sectors.

1852 Over a Decade of Gene Therapy Trials: Evolution from 2010 to 2025

Maryam Bemanalizadeh[1], Vahid Mansouri[1]*
[1]*Tehran University of Medical Sciences, Tehran, Tehran, Iran*
**Corresponding Author*

The field of gene therapy is evolving rapidly, offering transformative treatment opportunities for various conditions, from inherited genetic disorders to complex malignancies. Since the first successful gene therapy in 1990, significant strides have been made, leading to the regulatory approval of multiple therapies in recent years. As an update to our previous review [1], this abstract reflects the remarkable growth of clinical trials and the expanding therapeutic landscape.

We reviewed clinical trials information on Clinicaltrials.gov from 2010 to January 2025. The search results were initially screened based on their titles, and any unrelated entries were excluded. Data extraction was then conducted on the remaining clinical trials. The final dataset included the following key parameters: study registration details (start year and country), study timelines (start and end dates), type of vectors used, engineered cells or targeted tissues, approach to gene therapy (ex-vivo or in-vivo), clinical trial phase, disease category (cancer, genetic disorders, infectious diseases, and others) along with their respective subcategories, and the specific condition for which gene therapy was applied.

Among 2,987 clinical trials, lentiviral vectors accounted for the largest share (29%), followed by adenoviral vectors (15%), retroviral vectors (10%), and AAV (9%). Among non-viral vectors, RNA-based approaches accounted for the largest share (14%), followed by plasmids (7%), DNA (3%), and gene-editing tools (1%) (Figure 2A). In recent years, gene editing technologies, such as CRISPR, have entered clinical trials. Lentiviral vectors exhibited a marked increase post-2019, peaking from 2021 to 2024, while adenoviral and AAV vectors showed relatively consistent usage. The rise of lentiviral vectors has coincided with the advancement of CAR T cell therapies. We have witnessed an increasing number of CAR T cell clinical trials for autoimmune diseases in recent years (Figure 2B). Over the past decade, in-vivo approaches were initially dominant, but ex-vivo methods have steadily risen, surpassing in-vivo trials in recent years. Ex-vivo trials increased from 33 (36.7% of 2010 trials) in 2010 to 194 (68.1% of 2022 trials) in 2022, while in-vivo trials peaked at 134 (52.1% of 2021 trials) in 2021 before declining (Figure 2C). Among ex-vivo therapies, T cell-based therapies dominate (85%), followed by HSC (6%). In in-vivo therapies, tumors represent the largest target (mainly in trials using oncolytic viruses), followed by the immune system (mainly in vaccine trials), eye, and CNS (Figure 2D). While, cancer trials have the highest number of studies in phases 1 and 2, significantly outnumbering other disease categories, they did not considerably proceed to later stages. On the other hand, genetic disease trials are relatively low in phase 1 but show notable advancement in phases 2 and 3. Infection-related trials also exhibit a similar pattern, with a moderate progression in phases 2 and 3 (Figure 2E).

Analyzing strategic trends in successful clinical trials provides valuable insights for future research, study optimization, and policy development. Understanding these trends can help improve therapeutic approaches, regulatory frameworks, and the translation of gene therapies into clinical practice.

1853 Ethical, legal, and social issues (ELSI) in human somatic gene therapy clinical research: A Scoping Review

Carolyn Chapman[1], Mena Shaikh[2], Ava Glazier[1], Andrew Creamer[3], Barbara Bierer[1]
[1]The Multi-Regional Clinical Trials Center of Brigham and Women's Hospital and Harvard, Boston, MA, [2]MRCT Center, Allston, MA, [3]Brown University Library, Providence, RI

Dozens of gene therapies (GTs) have received marketing authorization, and hundreds more are in various research phases. Still, there are many ethical, legal, and social implications (ELSI) involved with the clinical development of this relatively new therapeutic class. To characterize ELSI arising in the context of human somatic GT clinical research, we conducted a systematic scoping review of the literature. Articles were eligible if they were written in English and discussed ELSI in the context of human somatic GT clinical research.179 articles, including empirical research papers, reviews, commentaries, news articles, and blog posts published from 2019-2024, met eligibility criteria. Relevant text was extracted from these articles and thematic analysis was employed to organize and synthesize findings. 24 themes were identified, leading to the generation of 5 high-level themes: 1) assessment of risks and benefits is scientifically and ethically challenging, 2) communication with and engagement of the patient community is crucial, 3) access and justice issues are heightened, 4) ethical GT trial design requires thoughtful consideration, and 5) resource allocation in GT research has ethical implications and is impacted by financial and regulatory considerations. Potential approaches to these challenges and gaps in the literature are explored and discussed.

1854 Safety and efficacy results from a phase I/II open label gene therapy trial for Spastic Paraplegia 50 (NCT05518188).

Andrea Boitnott[1], Sydney Cooper[1], Kristy Riddle[2], Kaitlin Batley[2], Veronica Bordes Edgar[2], Leslie Nelson[2], Kalayarasan Srinivasan[2], Alagar Muthukumar[2], Souad Messahel[3], Terry PIrovolakis[4], Xin Chen[2], Steven Gray[5], James Dowling[6], Darius Ebrahimi-Fakhari[7], Susan Iannaccone[2]
[1]UT Southwestern Medical Center, Dallas, Texas,2[3]UT Southwestern Medical Center, Dallas, TX, [3]Elpida Therapeutics SPC, Coppell, TX, [4]Elpida Therapeutics SPC, East York, ON, [5]University of Texas Southwestern Medical Center, Dallas, Texas, [6]University of Pennsylvania, Philadelphia, PA, [7]Boston Children's Hospital, Boston, MA

Background: Spastic Paraplegia 50 (SPG50) is an ultra-rare, childhood-onset neurological disorder caused by bi-allelic loss-of-function variants in *AP4M1*. Affected individuals present with global developmental delay, intellectual disability, and progressive motor impairment due to spasticity. Currently, no therapies exist to halt disease progression. To address this unmet need, an AAV9-mediated *AP4M1* gene replacement therapy was developed and evaluated in preclinical models. Efficacy studies showed functional improvement in both *in vitro* and *in vivo* models, while safety assessments in rats and non-human primates indicated minimal toxicity concerns. These findings support the translational potential of AAV9/*AP4M1* as a therapeutic approach for SPG50. The first patient was treated in a phase I open label trial in Canada in 2022.

Methods: In 2023, a phase I/II open label trial was initiated at UT Southwestern Medical Center enrolling 4 patients with SPG50 to determine the safety and tolerability of AAV9/*AP4M1* (primary outcome) and explore efficacy (secondary outcome). The trial utilizes a lumbar intrathecal route of administration to deliver AAV9/*AP4M1* at 1E15 vg per patient. All participants were <10 years of age at treatment, one of which being the youngest we are aware of to receive a lumbar intrathecal gene therapy (treated at 5.5 months of age). An immunomodulatory regimen with corticosteroids, sirolimus, and optional tacrolimus (for CRIM- patients) was implemented to allow inclusion of both CRIM- and CRIM+ patients. The trial will follow participants for 5 years post dosing. We present data through the 2nd year follow-up visit of the first participant.

Results and Conclusions: Safety was assessed by physical and neurological exams, laboratory studies, cerebrospinal fluid analysis, contrast-enhanced brain/spinal cord imaging, and nerve conduction studies. Adverse events were reported in all participants, with expected treatment emergent adverse events in 2 participants that included fever, vomiting, and weight loss soon after dosing which resolved quickly. Neutropenia and

thrombocytopenia were observed in 2 participants at 7 days post dosing but resolved by day 14. No concerns regarding liver function were observed and cerebrospinal fluid tests did not indicate any inflammation. Additionally, nerve conduction studies did not show any evidence to suggest dorsal root ganglion toxicity. Together, AAV9/*AP4M1* was well tolerated among all participants. Efficacy was explored via spasticity, motor function, cognition, and quality of life assessments. The developmental quotient improved for 2 and declined for 1 participant on the cognitive domain, remained stable for 2 and declined for 1 on the receptive communication domain, improved for 1 and remained stable for 2 on the expressive communication domain, and remained stable for 2 and declined for 1 on the fine motor domain of the Bayley Scales of Infant and Toddler Development III. Tardieu scale scores for two muscle groups in 1 participant increased, otherwise scores were stable. Modified Ashworth scale scores were stable for 1 and showed mixed results for 2 participants. SPRS and SPATAX-EUROSPA scores were stable for all participants. In 4/5 domains of the GMFM, scores all trended upwards. The 5th domain, walking/running/jumping, remained stable for all participants. Follow-up visits and comparison to disease natural history will be critical to determine the efficacy of AAV9/*AP4M1*.

1855 Deconstructing FDA's Expedited Program Determinations: Analyzing how the Agency may Set the Bar for RMAT Designation

Steve Winitsky, Parexel International, Durham, NC

Regenerative Medicine Advanced Therapy (RMAT) is an expedited program designation intended to accelerate development of cell and gene therapies (CGTs) that provides similar benefits for drug developers compared to those associated with Breakthrough Therapy (BT) designation.[i] FDA's Office of Therapeutic Products (OTP) publishes annual statistics on the number of RMAT designations.[ii] However, FDA doesn't make public the data that were provided to support an RMAT request and how FDA weighed the evidence in making their decision, often leaving developers to wonder how high FDA sets the efficacy bar for granting RMAT designation. Parexel explored the relationship between the early-phase data from press releases around the time of RMAT designation and pivotal data from FDA review memos for marketing applications for two cases of RMAT-designated gene therapies, VYJUVEK (beremagene geperpavec) and BEQVEZ (fidanacogene elaparvovec-dzkt), that were approved in 2023 and 2024.

For VYJUVEK, a topical gene therapy indicated to treat dystrophic epidermolysis bullosa, the endpoint of interest is wound healing. The data around the time of RMAT were: 7 of 8 (87.5%) treated wounds in the Phase 1 and 2 studies healed completely versus zero (0%) of the placebo-treated wounds;[iii] the pivotal study showed that 20 of 31 (64.5%) treated wounds achieved complete healing versus 8 of 31 (25.8%) placebo-treated wounds.[iv] For BEQVEZ, a gene therapy indicated to treat Hemophilia B, the endpoint of interest is reduced bleeding. In the study supporting RMAT designation, the mean ABR (annual bleed rate) data showed 0.2 bleeds/year post-product administration, compared to 8.9 bleeds/year before product administration.[v] In the pivotal study, the ABR was 2.5 bleeds/year post-treatment, compared to 4.5 bleeds/year before product administration.[vi]

Our analysis found that the point estimates for the treatment effect were larger in the RMAT-supporting studies than in the pivotal studies that supported licensure. No definitive conclusions can be made about FDA evidentiary thresholds for RMAT, due to inherent limitations of this two-product evaluation. However, Parexel's analysis identified factors such as small sample size and short follow-up times, which are common limitations of early-phase CGT studies that can reduce precision in estimating the true treatment effect size. Our analysis suggests that in situations similar to the two presented above, FDA's bar for RMAT can be at least as high, or higher, than that for approval. Conducting analyses, such as the one listed above, that contextualize the RMAT-designation supporting data within the totality of publicly disclosed information for that development program, can help inform developers in making decisions about the amount of evidence and timing for submission of RMAT designation requests.

1856 Accelerated Regulatory Approvals in Cell and Gene Therapy

Ananta Ayyagari[1], Khandan Baradaran[2], Samarendra Mohanty[3]
[1]Nanoscope Therapeutics, Dallas, TX, [2]Nanoscope Therapeutics, Brookline, MA, [3]Nanoscope Therapeuitcs, Dallas, TX

Although there is an increasing number of cell and gene therapy (CGT) products entering the clinical development stage, the rate of regulatory approvals has to increase substantially to enable adequate access to patients suffering from thousands of diseases without any treatment option available today, and the approval timelines need to be significantly shortened. The average time from drug development to final approval takes 8 yrs or more. [1] Further, in slowly progressing diseases, it takes multiple years to observe treatment effects as compared to natural history. According to the FDA website, there has been 188 new Investigational New Drug (IND's) and Investigational Device Exemption (IDE) and 22 biological license application (BLA) in the year 2024. [2] Therefore, there is heightened interest in pursuing accelerated approval pathways using biomarkers/endpoints at an earlier point than what would be needed for final approval.

As emphasized by CBER Director, Dr. Peter Marks, accelerated approvals will be a new norm in the CGT space, enabling this regulatory pathway to bring life-altering therapies to the market sooner. FDA has recently issued a draft guidance in December 2024[3] to further guide the industry on accelerated approval

Sponsors working in the CGT space have leveraged FDA's accelerated pathways to expedite the development and review of therapies targeting serious conditions. The accelerated approval, in appropriate cases, provides a pathway for the approval of drugs for serious conditions to fill unmet medical needs based on a surrogate endpoint or an intermediate clinical endpoint that is reasonably likely to predict an effect on irreversible morbidity or mortality or other clinical benefit.[4]

Over the past few years, several CGT products have gained accelerated approvals based on biomarkers or surrogate endpoints that demonstrated clinical benefit. This presentation will spotlight these products, focusing on each of the disease-specific biomarkers /surrogate endpoint analyses that supported their approval. Additionally, the presentation will detail insights into the clinical designs and evidence of the clinical benefits of these CGT products. All the data will be extracted from the information available publicly from the FDA and the sponsors' websites.

1857 Trade Secret Protections in Early Stage Gene Therapy Research: Patient Harm Through Limited Transparency?

Rafael Escandon[1], Aimee Donald[2], Simon Jones[3], Liza-Marie Johnson[4], Arthur Caplan[5]
[1]DGBI Consulting, BAINBRIDGE IS, WA, [2]University Of Manchester, MANCHESTER, United Kingdom, [3]Manchester University NHS Foundation Trust, UNITED KINGDOM, [4]St. Jude Children's Research Hospital, Memphis, TN, [5]Nyu Langone Health, New York, NY

Early Gene Therapy (GT) trials generally proceed following a rubric established decades ago for small molecule development which includes privileges for protection of trade secrets. While largely methodologically sound, several facets of that traditional early development rubric are problematic in the context of GTs. Unlike small molecules, GTs cannot be re-dosed, they require immunosuppression, and cannot be turned up, turned down, or turned off, each of which can influence proper scientific and ethical trial design. Similarly, because most GTs rely on a viral vector-based delivery system, they are far more related to each other, creating greater cross-trial relevance than the myriad of small molecules in development across thousands of disparate diseases. This similarity intensifies the need for more transparency in early GT development for clinical investigators, ethics committees, and data safety monitoring committees. Any GT investigations using the same or similar vector serotypes, routes of administration, vector genome doses, immunosuppression, and rescue methods for acute reactions should they occur, have relationships to each other, regardless of target indication. Strict trade secrecy protections established during an era dominated by small molecule development which prohibit regulatory agencies from sharing potentially relevant safety or other details are obsolete and dangerous in the context of these greater between-program similarities. A precedent for rapid and wholesale adjustment of first-in-human trials exists, as the requirement for sentinel patient dosing emerged from the Northwick Park/Theralizumab incident in 2006. Although rare, similar acute systemic and fatal reactions have occurred in early-phase GT clinical trials as recently as 2024. It is prudent to re-examine these outdated restrictions on data sharing to allow regulators the latitude to disclose more information about adverse events across relevant GT trials so that untoward outcomes may be reduced or avoided. Several suggestions for achieving greater data sharing, transparency, and reduction of barriers to safety information for early GT clinical investigators and key stakeholders will be presented.

1858 Efficacy and Safety of BRL-101, CRISPR-Cas9-mediated Gene Editing of The BCL11A Enhancer in Transfusion-dependent β-thalassemia and Severe Sickle Cell Disease

Biao Zheng[1]*, Rongrong Liu[2], Xinhua Zhang[3], Bin Fu[4], Yajing Xu[4], Jun Shi[5], Xiaoqin Feng[6], Chris Wang[7], Dali Li[7], Yuxuan Wu[7], Mingyao Liu[7], Yongrong Lai[8]

**Corresponding Author*

BACKGROUND: BRL-101 is a nonviral cell therapy designed to reactivate fetal hemoglobin synthesis by means of editing of autologous $CD34^+$ hematopoietic stem and progenitor cells (HSPCs) to disrupt the GATA1-binding site at the +58 BCL11A erythroid enhancer.

METHODS: In 3 single-arm, open-label, single-dose clinical trials (NCT05577312, NCT04211480 and NCT04205435) for transfusion dependent Thalassemia (TDT) and 1 trial (NCT06300723) for sickle cell disease (SCD), 15 TDT patients who received transfusions of >100 ml/kg of pRBC per year and 1 SCD patient who had a history of 3 vaso-occlusive episodes per year were enrolled respectively (Tab.1). Mobilized autologous $CD34^+$ cells from the 16 patients were edited with CRISPR-Cas9 RNP at the +58 erythroid specific enhancer region of the BCL11A gene. Before BRL-101 infusion, all patients underwent myeloablative conditioning with busulfan. Subsequently, we monitored adverse events (AEs), neutrophil and platelet engraftment, transfusion independence (TI, defined as 60-Day washout period after last red-cell transfusion, no routine transfusions, total Hb continued ≥ 9.0 g/dL) for TDT patients and hemoglobin response (defined as having met the following criteria for at least 6 months: no transfusion and no hydroxyurea use, HbF ≥ 30% Hb with a concurrent Hb increase from baseline ≥ 3.0 g/dL or Hb ≥ 10.0 g/dL without transfusion) for SCD patient.

RESULTS: As of January 16, 2025, the median follow-up was 23.3 (range: 16.8-56.6) months for TDT patients and the SCD patient was followed for 83 days. All 15 TDT patients were transfusion-free and achieved TI. The median time to last pRBC transfusion was 29 (range: 12-116) days and to transfusion-independent was 89 (range: 55-202) days respectively after BRL-101 infusion. The median duration of TI and transfusion-free were 20.6 (range: 10.1-54.0) months and 22.6 (range:14.2-56.0) months respectively (Fig.1). Mean (SD) of total Hb and HbF levels

increased as early as month 2 after BRL-101 infusion and continued to increase to 12.4 (2.2) g/dL and 11.7 (2.4) g/dL respectively at month 6, then maintained thereafter (Fig.2). The proportion of HbF-expressing red blood cells in peripheral blood had reached 96.3% at month 5 and then continued to rise and remained around 98.0-99.0% (Fig.3). The baseline hemoglobin level of the SCD patient was 7.3 g/dL, which increased to 12.8 g/dL at month 2 and 12.2 g/dL at month 3 without transfusion. At baseline, the fetal hemoglobin level was 4.6% and the sickle hemoglobin level was 39.5%. At month 3, the fetal hemoglobin level rose to 64.1% and the sickle hemoglobin level was 32.9% (Fig. 4). As data cut-off, 15 TDT patients occurred 925 adverse events. Among them, 88.4% were ≤ grade 2. 4 patients experienced 5 serious AEs, including decreased platelet count, shock, febrile infection, soft tissue infection, and veno-occlusive liver disease. Only decreased platelet counts related to BRL-101, the others were due to busulfan treatment. All these serious AEs were resolved (Tab.2 and Tab.3). The SCD patient experienced 73 AEs, of which 91.7% were ≤ grade 2 and no serious AEs occurred (Fig. 5).No study withdrawals or deaths occurred in all studies.

CONCLUSIONS: Whether TDT patients or SCD patient, one-time infusion of BRL-101 provided clinically meaningful increases in total Hb and HbF, the safety profile of BRL-101 was manageable, resulted in durable efficacy and improved quality of life for patients with TDT.

**Corresponding Author*

Gemtuzumab ozogamicin (GO), a CD33-targeting antibody–drug conjugate, has demonstrated clinical efficacy in acute myeloid leukemia (AML). However, its broader application is hampered by on-target, off-tumor toxicity against CD33-positive hematopoietic stem and progenitor cells (HSPCs), leading to severe hematologic side effects. To overcome this limitation, we are advancing toward a Phase I clinical trial (GALAXY-33, NCT05662904) that assesses the safety and efficacy of donor-derived, CRISPR/Cas9-edited HSPCs with a targeted disruption of the CD33 gene in patients with AML relapse after allogeneic stem cell transplantation. This approach aims to allow high-dose GO administration without compromising the normal hematopoiesis.

In our preclinical studies, we designed CRISPR/Cas9 ribonucleoprotein (RNP) complexes targeting exon 3 of CD33. RNPs were electroporated into primary human HSPCs using the MaxCyte ExPERT® platform to maximize transfection efficiency and preserve cell viability. Post-editing analyses via Inference of CRISPR Edits (ICE) and flow cytometry revealed editing rates of up to 87%. To ensure the highest level of genomic integrity, off-target effects were evaluated using CAST-Seq and Amp-Seq, revealing only non-relevant off-target edits. Functionally, CD33-null HSPCs remained robustly resistant to clinically relevant GO doses while retaining normal growth and viability (Liu et al., Int J Cancer 2021).

Ongoing investigations include a comprehensive evaluation of safety, incorporating genotoxicity profiling, immune function assays, and long-term engraftment studies *in vivo*. Additionally, preclinical proof-of-concept studies will further validate the protective effect of CD33-null HSPC transplantation against GO-induced toxicity.

By employing a CRISPR/Cas9-based gene editing strategy in the setting of allogeneic stem cell transplantation, the GALAXY-33 trial seeks to harness CD33-directed immunotherapy while mitigating its hematologic toxicity. This strategy holds promise for enhancing the therapeutic index of CD33-directed immunotherapy, ultimately improving survival and quality of life in patients with AML.

1860 Safety and Efficacy of Umbilical Cord-Derived Mesenchymal Stem Cells (TH-SC01) in Patients with Perianal Fistula in Crohn's Disease: Phase 1 and 2 Clinical Trials

Guangdong, China, [16]Nanfang Hospital of Southern Medical University, Guangzhou City, Shandong, China, [17]Tianjin Union Medical Center, Tianjin, Tianjin, China

Objectives: TH-SC01 is an umbilical mesenchymal stem cell product manufactured in a GMP facility. We evaluated the safety and efficacy of intralesional administration of TH-SC01 allogeneic umbilical cord-derived mesenchymal stem cells (TH-SC01) in patients with perianal fistula in Crohn's disease (CD).

Methods: The phase 1 trial was an open-label, single-arm study (from 2022, through 2024). The phase 2 trial was an randomized placebo-controlled, double-blinded study (from 2023, through 2025). Adult patients with treatment-refractory CD perianal fistulas (pfCD) were enrolled.

Main Outcomes and Measures: The primary objectives of phase 1 were to evaluate dose-limiting toxic effects and establish RP2D. The primary objective of phase 2 was to assess combined remission and safety at 24 weeks. Patients received a single intralesional injection of TH-SC01 cells. Combined remission (CM) was defined as an absence of suppuration through an external orifice, complete re-epithelization, and closure of external orifice and absence of collections larger than 2 cm measured by magnetic resonance imaging (MRI) at 24 weeks after cell administration.

Results: Nine in phase 1 (median age, 27 years [range, 18-47 years]) and 40 patients in phase 2 (median age, 26.5 years [range, 18-54 years]) were enrolled. The recommended RP2D was 120 million cells. In the phase 2 population, CM at 24 weeks was 50% (95% CI, 14.2%-65.8%) in the TH-SC01 group and 10% in the placebo group. Significant improvement in Perianal Crohn Disease Activity Index, Pelvic MRI-Based Score, Crohn Disease Activity Index, and quality of life score were observed at 24 weeks in patients who received TH-SC01 cells. No serious adverse events occurred in both phases 1 and 2 trials.

Conclusion: Intralesional administration of 120 million TH-SC01 cells might be safe and effective for treatment-refractory pfCD. These findings warrant further investigation in an ongoing randomised phase 3 trial.

1861 Evaluation of Salt-Tolerant Endonucleases for Lentiviral Vector Purification

Alice Aguiar[1], Thomas Thiers[2], Luke Mustich[3], Guang Yang[4], ASHISH SHARMA[1]
[1]OXB, Oxford, MA, United Kingdom, [2]OXB, Bedford, MA, [3]Oxford Biomedica Solutions, [4]Oxford Biomedica US LLC, Bedford, MA

Lentiviral vectors (LV) are among the most widely used vehicles for delivering genetic material in cell and gene therapy. The success of LVs in clinical trials and the market approval of several LV-based products has driven an increase in both LV manufacturing demand and the need for higher-quality LV products. The downstream purification of LV suspension culture typically starts with an endonuclease treatment, followed by a clarification step. The endonuclease treatment, carried out in the bioreactor, is designed to digest both free and chromatin-associated DNA. Residual DNA poses several challenges to the clarification step by increasing solution viscosity, causing potential filter fouling, prolonging processing time and elevating overall filter pressure differential. Moreover, residual DNA can form hydrodynamically large complexes with viral particles, which are difficult to remove downstream. These complexes may lead to aggregation and potential product recovery losses during the purification process. Despite its importance, traditional endonuclease treatment in LV cultures often exhibits low efficiency and a second endonuclease step is required to achieve higher log reduction values of residuals and host cell DNA levels that meet regulatory requirements. This low process efficiency is primarily due to the low activity of endonucleases under the physiological conditions present in LV cultures. Recently, commercially available salt-tolerant endonucleases, such as M-SAN® HQ and Denarase® High Salt, have shown promise in overcoming these challenges.

In this study, we compared the performance of two salt-tolerant endonucleases (M-SAN® HQ and Denarase® High Salt) at three different concentrations in the digestion of DNA from LV suspension cultures, against a non-salt tolerant enzyme. The effect of sodium chloride (NaCl) and magnesium chloride ($MgCl_2$) to optimize conditions for each endonuclease was also evaluated. Additionally, two design of experiments (DoE) were performed with M-SAN® HQ to investigate the effects of endonuclease concentrations and its co-factor $MgCl_2$ on DNA digestion. All

experiments utilized freshly generated material from a 7L bioreactor. The LV culture was sampled in 250mL shake flasks and incubated with the endonuclease at 37°C for 1-, 2.5-, and 4-hours. The stability of the lentiviral vector in the presence of the different endonuclease and $MgCl_2$ concentrations was accessed by functional titer. All endonucleases tested decrease the DNA content of the LV culture as measured by PicoGreen™ and hcDNA 18s-S (qPCR). Both salt-tolerant endonucleases outperformed the industry-standard endonuclease, even at lower endonuclease concentrations, with M-SAN® HQ showing the best overall host cell DNA digestion. Furthermore, DNA digestion with M-SAN® HQ improved with increased $MgCl_2$ concentration. The combined DoE model predicts Log10 reduction values of at least 1.0 for plasmid DNA, 0.8 for hcDNA18s-S, and 0.5 for total DNA after 1 hour of incubation at 37°C, demonstrating the potential of M-SAN HQ to enhance the efficiency of DNA digestion in LV manufacturing.

1862 High Salt, High Impact: An Endonuclease Engineered for High-Efficiency DNA Removal in Viral Vector Manufacturing

Melissa Rangel, C-LEcta GmbH, Leipzig, Germany

In the manufacturing of viral vectors for cell and gene therapy and vaccine applications, ensuring the safety and efficacy of the final therapeutic product is of utmost importance. DNA contaminants resulting from lysis of genetically transformed cells used for virus production pose the potential threat of being immuno- or oncogenic.[1,2] Therefore, the FDA has set acceptable limits for the concentration (>10 ng/dose) and size (>200 base pairs) of residual host cell and plasmid DNA in the final drug product.[3,4] Endonucleases, which can break down all forms of nucleic acids into smaller fragments without affecting viral particle integrity, are used to meet this regulatory requirements. Currently, endonucleases from *Serratia marcescens*, are the industry standard for enzymatic nucleic acid removal. The use of these enzymes not only enhances the safety profile of the viral vector-based therapeutics but also improves overall process efficiency by preventing the formation of aggregates and viscosity caused by presence of extracellular DNA. This work presents the performance a novel salt-tolerant enzyme, an engineered variant of the wild-type *Serratia marcescens* endonuclease specifically designed for efficient DNA removal at elevated salt concentrations and process-relevant pH conditions offering flexibility in viral vector purification processes.

1863 Characterization of 27 Primate and Non-Primate rAAV/BoV Vectors *in vitro*

Emma Gerstmann[1], Georg Feichtinger[2], Olena Maiakovska[3], Sergio Moreno Velasquez[4], Hans Peter Rottensteiner[5], Friedrich Scheiflinger[6], Dirk Grimm[7]
[1]University Hospital Heidelberg, Heidelberg, Baden-Wuerttemberg, Germany, [2]Evotec GT GmbH, Orth An Der Donau, Austria, [3]University of Heidelberg, Heidelberg, Germany, Germany, [4]University Hospital Heidelberg, GERMANY, [5]Evotec GT GmbH, Orth a.D. Donau, Niederösterreic, Austria, [6]Evotec GT GmbH, Orth An Der Donau, Lower Austria, Austria, [7]Heidelberg University Hospital, Heidelberg, Baden-Wuerttemberg, Germany

Over the last decades, adeno-associated virus (AAV) has become a predominant vector for therapeutic gene transfer in humans. Still, an ever wider use of AAV is often hampered by its restricted cargo capacity of ~5 kb of DNA. Notably, Bocaparvovirus (BoV), another member of the family *Parvoviridae,* has the potential to overcome this problem by enabling the cross-packaging of AAV vector DNA with a size of up to 6 kb. This, in turn, permits the

encapsidation of larger transgenes or regulatory elements, while concurrently allowing to benefit from other unique features of BoV such as their distinct tropism and immunogenicity.

To date, we and others have shown that the human (H)BoV1 capsid efficiently transduces not only primary human airway epithelial (pHAE) cells *in vitro* but also ferret lung *in vivo*. Moreover, our group reported that HBoV1-4 as well as GBoV (gorilla variant) transduce various other primary cells and cell lines efficiently. Together, the extended packaging capacity and the robust transduction by the five previously characterized isolates makes BoV highly interesting and relevant for use in gene therapy, and it therefore motivates continued research into this unique vector system, especially the study of other naturally occurring BoV variants.

To this end, we systematically compared the homology of published BoV sequences before selecting the phylogenetically most distant 27 representative candidates covering the full diversity of known bocaviruses among more than 600 sequences analyzed for experimental investigation. Following the synthesis and cloning of all respective BoV capsid genes into helper plasmids, we discovered marked differences in viral vector production efficiency depending on the viral isolate. In most cases, the primate candidates yielded higher vector titers than the non-primate variants. Curious exceptions were three human BoV variants that yielded only ~1×10^{-2} vector genomes (vg) per cell, which is comparable to the upper titer range of the non-primate candidates. Vice versa, one non-primate isolate was distinguished by its higher titer compared to the other non-primate variants, namely, BoV from bats, which yielded ~3×10^{1} vg/cell similar to most primate isolates.

For further characterization, we studied the *in vitro* transduction profile of the new BoV vector variants expressing a *Gaussia* luciferase in the presence of a proteasome inhibitor in Huh7 cells. Also here, we noted striking differences depending on the viral isolate that ranged over two orders of magnitude for the primate candidates (from 2.4×10^{2} to 2.0×10^{4} relative luminescence units (RLU)). Interestingly, the bat variant outperformed the benchmark GBoV as well as all other primate variants with 6.8×10^{4} RLU, even though ten times less viral particles were used, making it particularly relevant for continued development as a gene therapy vector.

In current work, we are pursuing the hypothesis that vector titers can be further improved by harnessing the cognate non-structural proteins for genome packaging, rather than the HBoV1 counterpart that is routinely employed in present helper plasmids. Concurrently, we study the tropism, as well as the role of specific amino acids and domains of the different viral capsids, that may explain the distinct transduction properties, including cell attachment and post-entry steps, and whose understandings in turn will foster the rational engineering of these promising vectors.

1864 The Challenge of Comparability: The benefit of common release standards for *Serratia marcescens* endonucleases.

Tim McClain, C-LEcta GmbH, Leipzig, Germany

In the manufacturing of viral vectors for cell and gene therapies and vaccines, the removal of residual DNA and RNA from host cells and plasmids is critical to meet regulatory requirements[1] and streamline vector purification. For this purpose, endonucleases are commonly added to enzymatically cleave polynucleotide chains into smaller fragments of around 3-5 base pairs. Endonucleases derived from *Serratia marcescens* are the current industry standards due to their efficient activity on diverse DNA/RNA substrates. Endonucleases from different suppliers are identical in protein sequence and could be applied interchangeably, with the enzyme activity being a key parameter in this context. However, variations in the release testing of enzyme activity in units (U) between vendors make direct comparison of Certificates of Analysis (CoAs) challenging. Despite their widespread use in GMP manufacturing for clinical trials and licensed drugs, there is no pharmacopoeia monograph outlining specifications, release tests and reference standards for *S. marcescens* endonucleases.[2] However, comparability of endonucleases is essential to secure supply chains, including dual sourcing strategies. This study uses the endonuclease activity release test developed by c-LEcta to compare activities two *S. marcescens* nucleases from different suppliers. Applying the same activity release assay test protocol to both enzymes, it is evaluated how these results correspond to the respective product's CoA values.

1865 A New Approach to Designing Synthetic Affinity Ligands for Enhanced Viral Vector Purification

Abdullah Sufan[1], Antonio Guerreiro[2], David Broomhead[2], Francesco Canfarotta[2], Joanna Czulak[2], Emma Daniels[2], Antonio Peon[1], Alan Thomson[2]
[1]Tozaro Limited, Sharnbrook, Bedfordshire, United Kingdom, [2]Tozaro Limited, Sharnbrook, United Kingdom

Introduction: Patient access to cell and gene therapy products is hindered by low recovery, high-cost processes, that limit the commercial viability of these therapies. Development of novel capture reagents is key to addressing these challenges in viral vector purification and analytics. We introduce innovative chromatography solutions utilising rationally designed synthetic polymers as pseudo-affinity ligands for gentle capture and release of viral particles and analytical application. We demonstrate how our approach to reagent design, coupled with the optimisation of bind and elute conditions, ensures high recovery of functional particles.

Methods: We present our rational approach to ligand design targeting chosen surface epitopes of the VSVG envelope protein of lentiviral vectors, aided by in-silico predictive molecular modelling to determine optimum synthetic ligand composition to achieve the desired affinity. After confirmation of monomeric ligand components through in-vitro HPLC testing, synthetic affinity ligands were polymerised using molecular imprinting for synthesising high affinity nanoparticles, suited for analytical applications, or tuned affinity smart polymers, suited for purification application. Polymer characterisation was performed across several manufacturing scales, using tailored analytical techniques, to demonstrate repeatability and reproducibility. The performance of molecularly imprinted polymers was assessed using SPR (Surface Plasmon Resonance) and BLI (Bio-Layer Interferometry). Smart polymer performance and optimisation was performed through immobilisation on filters, resins and monoliths commonly used for purification of viral vector. Optimisation of smart polymer composition was focused on ensuring high recovery of functional particles, by utilising gentle elution conditions. Binding and elution events on these solid supports was visualised using fluorescence and assessed off-line using FIDA (Flow Induced Dispersion Analysis). Toxicity of smart polymers was also assessed using a cell-based assay, to understand the potential impact of leached ligands on patient safety.

Results: Our results demonstrate that the rational ligand design approach resulted in a 38% hit rate out of 50 molecularly imprinted polymers designed against 5 target surface epitopes. Molecularly imprinted polymers showed a dose dependent response to lentiviral vector in the range of 10^5 – 10^8 TU/mL on the BLI platform. Our results also demonstrate our ability to tune smart polymer composition to control affinity, resulting in elution events in physiological buffer conditions. Scale up experiments demonstrated our ability to maintain consistent polymer composition and size at larger scale, with percentage coefficients of variation as low as 5%. Toxicity assessment showed no detrimental impact on cell viability after prolonged incubation in presence of smart polymer, at concentrations greater than expected in application.

Conclusions: Our innovative approach to affinity ligand production, utilising rationally designed synthetic polymers, offers a transformative solution for improving the efficiency and recovery and quantification of functional viral particles.

1866 State-of-the-Art Mass Spectrometry Characterisation of Adeno-associated Virus (AAV) by Intact Mass, Peptide Mapping, Host Cell Protein and Metabolomics Analysis

Shandel Pariag[1], Lauren Tomlinson[2], Kirsty McManus[2], Paul Getty[3], Charlotte Hands[2], Michael Walker[3]
[1]Pharmaron Biologics, Liverpool, LIVERPOOL, Merseyside, United Kingdom, [2]Pharmaron Biologics, Liverpool, Merseyside, United Kingdom, [3]PHarmaron Biologics (KU) Ltd, Liverpool, United Kingdom

Characterisation strategies for AAV gene therapy products have significant challenges due to their large molecular size, structural complexity, heterogeneity, and relative novelty but are essential to support CMC requirements. As with other therapeutic modalities, there is an increasing expectation in terms of the depth of analytical data as methodologies and technologies deepen our understanding of the molecules of interest. A natural starting point is to deploy, and assess, currently available analytical techniques whilst mitigating for the complexity and nuance inherent in the viral vector modalities. To this end, Pharmaron have deployed advanced mass spectrometric techniques to provide deep insights into both product and process – characterising viral capsid critical quality attributes (CQAs) using an intact mass and peptide mapping approach, assessing manufacturing efficiency through LC-MS metabolite analysis, and interrogating the host cell protein profile through application of proteomic analysis. Combined, these state-of-the-art techniques help support AAV product development and data packages for their customers' regulatory submissions.

In the following work two separate AAV serotypes, manufactured on site at Pharmaron Liverpool, were tested. Analysis of the viral proteins was attained by first denaturing the capsid into its constituent VP1, VP2, and VP3 subunits follow by column concentration and subsequent gradient elution/MS analysis. Identities for VP1 to 3 proteins were confirmed with a mass accuracy ranging from 1-35ppm. VP1 and VP2 were identified as predominantly acetylated, whereas VP2 did not show any significant level of acetylation. A clipped variant of VP3 was also identified.

Peptide mapping was performed, digesting the sample material using orthogonal proteases prior to LC-MS analysis. Sequence coverage ≥98% was obtained across all viral proteins, and robust relative quantification of post translational modifications including acetylation, oxidation, and deamidation was achieved (<20% RSD observed for majority of modification sites). Peptide mapping data was then interrogated, leading to the identification of a clipped site of the truncated VP3 protein observed during the intact mass analysis.

Host cell proteins (HCPs) are a major class of process impurities, which require monitoring and reporting to ensure product safety and quality. Early indications of immunogenicity linked with AAV infection/ treatment in human patients may have been exacerbated by the presence of these process related impurities. Compared to an ELISA approach, mass spectrometric analysis can provide a much deeper understanding of the HCP profile of a material and help identify specific proteins of immunological significance, allowing for better monitoring and process related control/removal strategies. Pharmaron demonstrate their expertise on how a mass spectrometric approach, enhanced through the use of cutting-edge instrumentation and nano-LC separation – can provide extensive information on AAV related HCP profiles, with sensitivity to detect proteins down to low ng/mg (HCP:AAV) levels.

1867 Streamlining Downstream Lentiviral Vector Production: A Novel IEX Platform for Improved Recovery, Infectivity, and Purity

Jae Hwang[1], Trey Hanshew[2], Andrew Detzel[1], Michael Faiella[1], Evan Schlaich[1], Annie Daniels[1], Christopher Cultrara[1], Kenneth Kirby[1], Matthew Tomaneng[1], Kieran White[1], Sheik Salma[1], Christopher Nieder[1], Tatiana Nanda[1]
[1]SK Pharmteco - US, King of Prussia, PA, [2]SK Pharmteco, King of Prussia, PA

Lentiviral vectors (LVs) hold immense promise for gene therapy applications; however, current LV production and purification are limited by low process recovery of infectious units (10-15%) after downstream processes. Contributing factors include high concentrations of residual impurities, such as host cell protein (HCP), and lengthy processing times and poor LV stability. Traditional IEX bead-based resins often lack the optimized bead porosity for large viral vectors like LV. This can lead to both optimization challenges and the need for large bed volumes resulting in longer processing times. Despite extensive optimization, current methods (bead-based resins and membrane adsorbers) yield suboptimal infectious LV recoveries (10-30%) and further downstream processing often result in an overall recovery of 10-15%, highlighting the need for improved purification strategies.

To address this challenge, SK Pharmteco Cell and Gene Therapy North America (SKPT CGT NA) has developed and optimized an innovative IEX membrane adsorber capture step. Compared to traditional methods, our optimized process achieves a more than a 2-fold increase in infectious unit titer recovery compared, while reducing processing

time to approximately 1 hour while maintaining a greater than 98% HCP clearance. The reduced processing time enables a 1-day purification process, particularly beneficial for ex vivo applications.

We showcase the development and scale-up of this IEX capture step from benchtop to 50 L production. This streamlined approach simplifies LV capture, enabling rapid and cost-effective production of LV while maintaining high product quality.

1868 Advancements in Lentiviral Purification: From High Throughput Screening to Scalable Solutions

Luka Bevc[1], Ana Pavšič Rijavec[2], Valentina Novak[2], Sandra Potušek[2], Ivana Petrovic Koshmak[3], Maja Leskovec[4], Hana Jug[2], Ales Strancar[5]
[1]Sartorius BIA Separations, Ajdovščina, Slovenia, Slovenia, [2]Sartorius BIA Separations, Ajdovščina, Slovenia, [3]Ajdovščina, Slovenia, [4]Sartorius BIA Separations, Ajdovščina, Slovenia, [5]Sartorius BIAA Separations, Ajdovscina, Ajdovscina, Slovenia

Lentiviruses are commonly used in cell and gene therapy due to large insert capacity and capability to integrate in both dividing and non-dividing cells. The use of LVs, and number of gene therapies involving them, have steadily increased over the years, with focus being mostly on ex vivo therapies. Recently, however, there has also been a surge of interest for in vivo lentiviral treatments, leading to several planned human clinical trials. With in vivo applications, requirements for purity are much higher than ex vivo. As such, the need for better downstream processes, with increased impurity clearance and infective LV recovery, has become evident. With chromatographic step being essential for scalable and cost-effective downstream process, we decided to test monolithic columns for purification of lentivirus.

Good initial results have been achieved on CIMmultus QA. To further improve the recovery of the downstream process, we decided to determine the factors and conditions, which contribute the most to downstream recovery, by using Design of Experiments (DoE) approach. To increase throughput of the DoE studies, we used CIM QA 0.05 mL Monolithic 96-well Plates (6 µm), which significantly speed up the testing process, as well as decrease variables which occur from day-to-day work. From the factors tested in the DoE, results indicated starting NaCl concentration in lentiviral load has the most profound effect on lentiviral recovery, with increased NaCl concentration leading to better downstream recovery. Using DoE and high throughput testing with plates, we could improve the infective lentiviral recovery from 20% up to 90%. The process was then successfully transferred to 1mL QA (6 µm) column, using conditions, which can be scaled up to manufacturing columns. On 1mL column, 70% average infectious recovery was achieved, with over 2000-fold decrease in host-cell protein (HCP) content. Final average HCP and hcDNA contents were calculated to be 490 ng of HCP and 230ng of hcDNA per dose of 10^9TU. Additionally, particle composition analysis demonstrated removal of incomplete particles during chromatography and enrichment of complete lentiviral particles, from 34% in clarified harvest, to 51%, thus increasing potency (ratio infective : non-infective particles) by 51%. When tested for capacity it was determined to be 3E+12 vp/mL of QA monolith (6 µm).

1869 Hedge Your Bets in Genetic Roulette with cliniVec: Accelerating Cell and Gene Therapy Development Through Optimized Vector Design and Characterization

Alan Griffith[1]*, Constance Rich[2], Grace Yu[2], Ting Song[1], Andrew Alcock[3], Hoi Lok Cheng[4], Bruce Lahn[2]*

As the cell and gene therapy (CGT) field expands, the number of therapeutic candidates entering preclinical and clinical pipelines is increasing rapidly. This surge has brought unique challenges related to manufacturing, characterization, and regulatory requirements for vectors used in gene delivery. Key complications include bottlenecks in production scalability, variability in therapeutic efficacy, and the need for enhanced safety and quality

characterization of vectors. It is now understood that a large portion of Chemistry, Manufacturing, and Controls (CMC) issues come from poor manufacturability challenges as a result of inferiorly designed vectors obtained from a variety of sources. These are often legacy constructs that have never been stress-tested or have been redesigned with cloning speed and not manufacturing quality in mind.

This presentation explores developer feedback and how we can facilitate innovative approaches to addressing these challenges by focusing on expanding candidate selection with emphasis on vector design optimization, starting at the candidate selection stage which is way upstream of the clinical construct selection.

By examining how specific intrinsic design elements influence efficacy, manufacturability, and safety, researchers can streamline the transition from early research to clinical application. Furthermore, the importance of deeper vector characterization, even when not explicitly required by regulatory agencies, is emphasized as a strategy to improve outcomes in CGT development and reduce the valley of death.

Drawing from insights in vector construction and characterization (>1 million vectors designed) over the past decade, VectorBuilder highlights key considerations for designing vectors that meet the complex requirements of preclinical and clinical studies. The cliniVec approach aims to provide a comprehensive framework for advancing CGT development through enhanced design and characterisation strategies that prioritize safety, performance, and scalability throughout the entire lifecycle of any CGT viral vector.

1870 Host and viral (non-viral genomic) DNA/RNA contamination in viral particles produced for clinical applications under GLP/GMP and profiling of RNA/DNA packaged inside viral particles.

Praveensingh Hajeri[1]*, Masato Yamamoto[2]*, Adam Herman[3]
[1]University of Minnesota, Circle Pines, MN, [2]University of Minnesota, Minneapolis, Minnesota, [3]Unviersity of Minneosta, Minneapolis, MN
**Corresponding Author*

Background: Viruses are increasingly being used as vectors for delivering therapeutic cargo. Often, viruses themselves are used as therapeutic agents for, e.g., oncolytic viruses. In all such cases, efficient amplification and purification of viral particles is an essential step. It includes designing, producing, testing, and validating viral particles that meet the standards of GLP, GMP, and standards of impurities. Viral particle assembly and packaging in cells is an organized process. The process differs between different viruses based on whether they are enveloped, the type of genome, the structure of the protein capsids, etc. There are several reports that mention host and viral RNAs (non-genomic) get packaged in mature and empty virus particles, which may have functional importance to the virus infection cycle in general. It is not completely clear if all the host and viral non-genomic RNAs found in viruses are of functional importance or if they get packaged randomly. Most importantly, the experiments used in several such reports were not stringent enough to rule out the possibility of such RNAs bound outside the viral particles rather than getting packaged inside. So, at least in some viruses, it still remains to be investigated if host and viral RNAs get packaged inside viral particles at all using very stringent and efficient methods. For clinical applications, such impurities may affect the quality of the viruses (prepared under GLP and GMP) and may lead to many unwanted and untargeted effects on patients. Several reports suggest that some host/viral RNA contamination is unavoidable in adenoviruses and AAVs. The standards for testing such contaminants and how much contamination is acceptable are not very clear and are still being debated.

Material and methods: We tested viruses (AdV and AAVs) prepared with current state-of-the-art methods and standards and observed significant host and viral DNA/RNA contamination. Viruses were prepared using ultracentrifugation. We deployed robust DNA/RNA extraction methods and next-gen sequencing methods to identify if there are RNAs and to determine the sequences, if any, are present. We used current state-of-the-art methods available through our genomics core facilities and also our novel NGS library prep methods, which are more sensitive than others.

Results: We could identify most of such contamination is only from outside of the viral particles rather than inside. We could not detect any of the transcripts (host / viral) reported earlier to be packaged inside viral particles, and also, no new transcripts were detected. This is contradictory to several earlier reports. We also devised novel methods to remove DNA/RNA contaminants from AdV particles, which seem to be mostly from outside. We hope our study and recommendations can be implemented to prepare better-quality viral particles with no contamination of nucleic acids from hosts. This will help in meeting zero contamination levels for clinical applications and manufacturing.

1871 Enhanced Lentiviral Vector Characterization Using Digital PCR: Genome Titer, VCN, and RCL Detection

Miroslav Vranes[1], Anne Schieren[1], Philipp Rink[1], Corinna Hochstein[1], Julius Albers[1], Andreas Hecker[1], Domenica Martorana[1], Anida Mesihovic Karamitsos[2], Francesca Di Pasquale[2]
[1]QIAGEN, Hilden, Nordrhein-Westfalen, Germany, [2]QIAGEN GmbH, Hilden, Germany

The advancement of cell and gene therapies is essential for treating a variety of diseases. Lentiviral vectors (LVVs) have become a key technology for delivering therapeutic genes into cells. Ensuring the safety, efficacy, and consistency of LVs requires thorough characterization. One important aspect is accurately quantifying viral vector genome titers and vector copy number (VCN), which indicates the number of transgene copies in the target cell genome. The effectiveness of viral transduction depends on factors such as viral dose and target cell type, making precise VCN measurement crucial for optimizing viral doses in therapy applications.

After extracting genomic DNA from transduced cells, the number of lentiviral gene copies is compared to a reference gene. Traditional methods often use qPCR, which requires external standard curves. Digital PCR (dPCR) offers absolute quantification with high precision and tolerance for inhibitors, eliminating the need for standards. We propose a rapid dPCR method to determine VCNs, providing insights into transgene stability and expression. Consistent VCNs are vital for maintaining uniform product quality in biopharmaceutical production.

Lentiviral quantitation is another critical quality attribute in viral vector manufacturing for cell therapy development. Digital PCR is a powerful tool for absolute quantification of LVVs, addressing the limitations of qPCR with its precision, accuracy, specificity, and reproducibility.

A significant safety concern with lentiviral systems is preventing the creation of replication-competent lentivirus (RCL) through recombination. Regulatory bodies like the FDA and EMA require comprehensive RCL testing in retroviral vector products. We demonstrate a streamlined dPCR workflow for quantifying lentiviral genome titers, VCN, and RCL detection, enhancing characterization with greater precision, accuracy, and robustness.

1872 Importance of AAV sample preparation for gc/ml titer determination using PCR.

Agnieszka Lass-Napiorkowska[1], Henry George[2], David Razafsky[3]
[1]MilliporeSigma, Saint Louis, MO, [2]MilliporeSigma, Bedford, MA, [3]MilliporeSigma, St. Louis, MO

Determining the gc/ml titer of an AAV sample is not only important for process development but is even more critical for the administration of a therapeutic AAV dose to a patient's body. AAV is known to be a challenging sample for PCR amplification due to several factors, including the template being hidden inside the capsid, the ITR hairpin regions surrounding the packed genome, and small DNA fragments that may be bound to the capsid and potentially amplified. This poster focuses on a comprehensive comparison of gc/ml titers obtained from PCR amplifications with and without sample pre-treatments.

1873 A new approach for high-resolution full and empty AAV capsid analysis using a high throughput method for comprehensive AAV evaluation on a single CE platform

Henry Kang[1], Tingting Li[2], Sahana Mollah[3], Elliott Jones[3]
[1]SCIEX, Framingham, MA, [2]Sciex, Brea, CA, [3]SCIEX, Redwood City, CA

Before regulatory submission, key critical quality attributes (CQAs) for gene treatments delivered by adeno associated virus (AAV) vectors must be thoroughly evaluated to verify their safety and efficacy. Multiple CQAs are currently being characterized using various analytical systems. Without significant improvement, these techniques have drawbacks or cannot be utilized to examine all serotypes. This poster outlines a method for performing multiple CQA analyses of AAVs at high throughput on the multi capillary BioPhase 8800 system. A comprehensive analysis of all key CQAs such as nucleic acid loading and titer, viral capsid protein profile and ratio, capsid titer and full and empty ratio can be done on a single platform, the BioPhase 8800 system, within a single day. Platform methods on the BioPhase 8800 system with fast process times can shorten development timelines, save costs, streamline the QC process and accelerate time to market.

1874 Enhancing rAAV genome integrity through process development optimization

Tomas Andreani-Faborni, Sarepta Therapeutics, Inc., Cambridge, MA

Conventional PCR-based methodologies lack the resolution to characterize integrity of rAAV genomes, which can play a role in rAAV potency. To overcome this, we employed long-read sequencing methods and investigated rAAV samples from two early-stage programs. We found that process changes impacted rAAV genome properties. Thus, long read sequencing technologies overcome the limitations of traditional methods to characterize rAAV genome heterogeneity and can be routinely applied to optimize process development and vector properties.

1875 Counting, Sizing, Imaging, and Identifying Viral Vector Product Aggregates at Ultra Low Volume

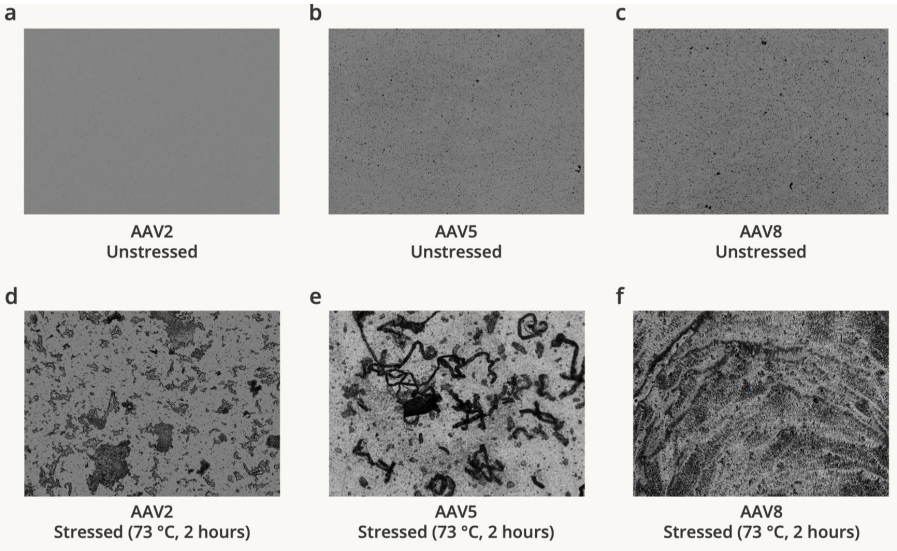
Steven Le, Halo Labs, Burlingame, CA

In all biological products, distinguishing aggregated API from other particle types matters for understanding the root cause of product instability. Until now, subvisible particle (SVP) characterization methods have been unreliable, slow, and difficult to use across many workflows. Subvisible particles are critical quality attributes for parenteral therapies. Recent experience with protein biomanufacturing and formulation has provided insights into the challenges of formulating stable biotherapeutics. The inherent complexity of advanced therapy medicinal products (ATMP) highlights new challenges and opportunities, in the formulation and manufacture of cell and gene therapies.

As the field moves towards biomanufacturing ever more complex APIs, novel formulation strategies must keep pace. More traditional formulation strategies may not be applicable to the complex drug formulations associated with the advancement of cell and gene therapies (CGT), as they present unique stability challenges as multi-component systems. A novel ultra-low volume, high-throughput approach with positive particle identification is needed for rapid sub-visible particle and aggregate assessment.

The Aura+ utilises three imaging approaches: backgrounded membrane imaging (BMI), side illumination membrane imaging (SIMI) and fluorescence membrane microscopy (FMM) to provide a full spectrum of particle analysis. The ability to specifically detect, count, and characterize subvisible particles for product quality measurements is applicable across the whole range of therapeutic products, from small molecule to protein, cell, and gene therapy applications.

Here, we show how the combination of BMI, SIMI, and FMM can be used for total particle analysis providing counts, images, sizes, and positive identification of subvisible API aggregates and extrinsic particles in a rapid and low-volume format. We present case studies highlighting the value of a high throughput approach for SVP analysis across the whole spectrum of bio-manufactured products, from protein therapeutic stability to cell line development through manufacturing, viral vector stability, and cell therapy aggregation and product purity.



1876 Tangential Flow Filtration membranes for robust ultrafiltration and diafiltration in Lentiviral vectors downstream processing

Sara Cardoso[1], Jana Engelhardt[2], Alexander Tappe[2], **Martine Barros[3]**
[1]Sartorius, Göttingen, Niedersachsen, Germany, [2]Sartorius, Göttingen, Germany, [3]Sartorius, Aubagne, France

As the lentiviral vectors (LV)-based therapeutics market grows, their applications are moving from localized to systemic disorders, and their use is now commonplace in academic laboratories and industry for both research and clinical gene therapy applications. As such, manufacturing processes must be optimized to ensure scalability, reproducibility, and cost-effectiveness. One crucial aspect of LV production lies in the downstream purification steps, with ultrafiltration and diafiltration (UF|DF) playing central roles in achieving high product concentration (volume reduction) and buffer exchange in addition to the removal of low molecular weight impurities while retaining vector particles.

Hydrosart® high-performance UF|DF membranes have been optimized for biopharmaceutical process applications, which features a broad pH and temperature range. This cellulose-based membrane is extremely hydrophilic, making it non-protein binding and virtually non-fouling. As a result, it has extremely high fluxes. Furthermore, Sartorius offers two different cassette geometries for ultrafiltration and diafiltration operation, the E-screen and ECO format. Compared to the E-screen geometry, the ECO cassette features 26% more surface area per standard cassette width, making it possible to install more area in the cassette holder as well as decreasing feed pump power demand. Consequently, the need for larger systems at scaled-up processing is reduced when operating with the ECO cassette format.

In this study, Hydrosart® 100 and 300 kDa TFF membranes in two different cassette formats were evaluated for their performance in the UF|DF of LV. The identified optimal processing parameters resulted in high LV recoveries, both in particle and infective titer (95 – 100%), while achieving significant removal of DNA (51 – 63%) and proteins (10 – 47%). Higher pumping rates for the E-screen cassette generally resulted in higher permeate flux and shorter process times. The ECO cassettes still allowed LV concentration in a reasonable time and with gentler processing conditions, as well as reduced pump capacity, which is important when operating at larger scales. Overall, excellent reproducibility of the LV UF|DF process was demonstrated, ensuring reliable process performance.

1877 Development of a Fully Closed and Sterile Manufacturing Process for Lentiviral Vectors: Eliminating the Need for Sterile Filtration

Giuliana Vallanti[1], Margherita Neri[2], Martina Brunati[3], Samuele Corbetta[3], Emanuele Simonetti[3], Luca Allievi[3], Luca Crippa[3]
[1]AGC Biologics, Milano, Milano, Italy, [2]AGC Biologics, Milano, Milan Italy, Italy, [3]AGC Biologics, Bresso, Italy

AGC biologics is a leading global CDMO, providing world-class development and manufacture of mammalian and microbial-based therapeutic proteins, plasmid DNA, viral vectors and genetically engineered cells.
Lentiviral vectors (LVV), produced with transient transfection in HEK293 and HEK293T cells are extensively used for genetic modification in gene therapy for ex-vivo and in-vivo treatments. AGC Biologics developed the ProntoLVV platform for the manufacturing of LVV at different scales in adhesion and suspension, flexible to be adapted to different GOI (Gene Of Interest). The demand for LVV is constantly rising to support advanced clinical phases and commercial applications. In this regard suspension cells-based systems offer a great advantage in scalability vs. traditional adherent systems widely used so far, allowing to design very large scale processes.
While suspension processes significantly boost productivity, optimization of each process step remains essential for both suspension- and adherent-cell based processes. Upstream phases are fine-tuned to maximize vector production, and downstream steps are continuously developed to enhance recovery without compromising vector quality.
Among all downstream steps, the final sterilising filtration has the most significant impact on overall process recovery. Sterilizing-grade membranes pore size is close to that of lentiviral vectors, resulting in low yields and frequent clogging, posing a major challenge to process efficiency. Filtration step recoveries can range from 50% to 30% and – for some particularly difficult LVVs – can get as low as 10%. This represents a major loss of LVVs in the economy of the process.We recently investigated the possibility to remove the final sterilising filtration in our LVV manufacturing platform, by designing a completely closed and sterile process.
To make this strategy viable, every step of the process must be executed in aseptic conditions within a fully closed system. This requires single-use equipment and gamma-irradiated sterile kits that can be connected using sterile connectors. While clarification filters compatible with gamma irradiation are readily available, the DSP chromatographic steps represent a major hurdle for sterile process. Standard IEX and SEC resin-packed column are not supplied as sterile products. Due to these considerations, we present our results on Cytiva Mustang Q membranes, a known chromatographic membrane used for the purification of LV vectors, that are available in a format that can be autoclaved. Development work was conducted to optimize the binding and elution conditions of LVVs to the Q-membrane, and dedicated single-use, sterile flowkits have been designed to aseptically connect and operate the Mustang Q membrane to standard single use Chromatographic skids (AKTA Ready).
Ultrafiltration/Diafiltration steps can easily be designed to be operated in fully closed and sterile conditions, and TFF media such as hollow fibers are already available as sterile units. The results showed recoveries of the new implemented process similar to standard AGC Pronto platform up to the pre-sterilising filtration step.
Thanks to the fully enclosed, sterile nature of the whole process, the final sterilising filtration can be avoided, resulting in a net increase in the overall process recovery ranging from 30% and up to 70% compared to standard processes.

1878 High-Throughput Flow Cytometry Assay for Quantifying Infectivity of AAV, Adenovirus, and Lentivirus Vectors in Gene Therapy Applications

Tahsin Jahan[1], Pouya Mehrkesh[2], Michael Shen[3]
[1]MilliporeSigma - Carlsbad,CA, Carlsbad, CA, [2]MilliporeSigma, Carlsbad, CA, [3]Carlsbad, CA

The efficient delivery of genetic material to target cells is critical in gene therapy, with viral vectors such as Adeno-associated virus (AAV), Adenovirus (Ad), and Lentivirus (LV) being essential to this process. Assessing the infectivity of these vectors is vital for optimizing gene delivery strategies. Traditional methods for evaluating vector infectivity are often time-consuming, qualitative, or lack the sensitivity required for precise and quantitative measurements. Flow cytometry provides a rapid, high-throughput platform that can quantify infectivity titers and percentage transduction with high sensitivity and specificity.

In the present study design, flow cytometry was used to assess the infectivity of in-process and final drug products produced using AAV, Adenovirus, and Lentivirus vector platforms, by utilizing reporter genes or surface markers to quantify transduction efficiency in target cells. The flow cytometry assay demonstrated high sensitivity and reproducibility over traditional cell-based assays such as FFU, PFU, and transduction unit assay, enabling the analysis of large sample sizes and the precise determination of infectious titers. Selected HEK293 suspension cells, Jurkat cells, or HeLa cells were transduced with samples containing AAV, Adenovirus, or Lentivirus vectors, respectively, and a time-course analysis was conducted up to 48 hours. Infectivity was measured by quantifying the number of transduced cells expressing the gene of interest (GOI), and dose-response curves were generated to evaluate the functional efficiency.

The future aspect for this method development involves exploring different cell lines for infectivity-based analyses, therefore assessing how viral vectors interact with and transduce distinct cell types and thereby providing insights into tropism, efficacy, and cytotoxicity. By overcoming the constraints of traditional assays and providing superior specificity, accuracy, and precision, flow cytometry holds the promise of delivering a robust and time-saving approach to measure the functional titer of viral vector samples.

1879 STRATEGY FOR IMPROVING THE RESCUE, REPLICATION, AND PACKAGING OF GENERATION Z (GenZ) SINGLE-STRANDED AAV VECTORS

Jakob Shoti[1], Keyun Qing[1], Dhruv Champaneri[2], Yamika Ramesh[2], Geoffrey Keeler[2], Arun Srivastava[2]
[1]University of Florida, Gainesville, Florida, [2]University of Florida, Gainesville, FL

We have previously reported the development of a generation Z (GenZ) ssAAV DNA genome in which the D-sequences in the AAV inverted terminal repeats (ITRs) were replaced with a sequence obtained from a random nucleotide library (*Mol. Ther*., 31: 234-235, 2023). The GenZ ssAAV genome overcomes the rate-limiting step of the viral second-strand DNA synthesis, and mediates significantly higher levels of transgene expression. Thus, it behaves more like a scAAV genome, but without the size-limitation. However, we observed that the efficiency of rescue and replication and packaging of the GenZ AAV genome from recombinant plasmids were significantly reduced, and depending on the AAV serotype capsid, ranged between ~10% to ~60% that of the AAV genome containing the D-sequence (*Mol. Ther*., 32: 141-142, 2024). This was not entirely unexpected, given the absolute requirement of the D-sequence for the optimal rescue, replication, and packaging of the AAV genome (*J. Virol.*, 71: 3077-3082, 1997; *Mol. Ther.*, 9: 2628-2630, 2021). We have previously reported that the proximal 10 nucleotides (D10), but not the proximal 5 nucleotides (D5), in the D-sequence are necessary and sufficient to mediate each of these functions (*J. Virol.*, 71: 3077-3082, 1997). In our current studies, we revisited the role of D5, D6, D7, and D8 nucleotides (D8, D9, and D10 nucleotides are identical in the D-sequence) in rescue, replication, and packaging of the AAV genome. Four different recombinant AAV genomes expressing a firefly luciferase-enhanced yellow fluorescence (FLuc-EYFP) fusion reporter gene flanked by D5, D6, D7, and D8 sequences. AAV genome rescue and replication analyses (**Figure 1A**) revealed that, consistent with our previously published data, whereas the D5 sequences were insufficient for successful rescue and replication, addition of 1 nucleotide (D6) also failed to mediate successful rescue and replication. Interestingly, addition of 1 additional nucleotide (D7) restored successful rescue and replication, similar to the wild-type D-sequence (D8). Furthermore, the D7 sequences also allowed successful packaging, followed by transduction to nearly the same extent as that by the conventional AAV vectors (**Figure 1B**). Restoration of the D7-sequence in the GenZ genome is likely to overcome the major limitation of the low-titers of GenZ vectors, which has important implications in achieving high-efficiency transgene expression from ssAAV vectors, such as for human clotting factor VIII (hFVIII) for gene therapy of hemophilia A.

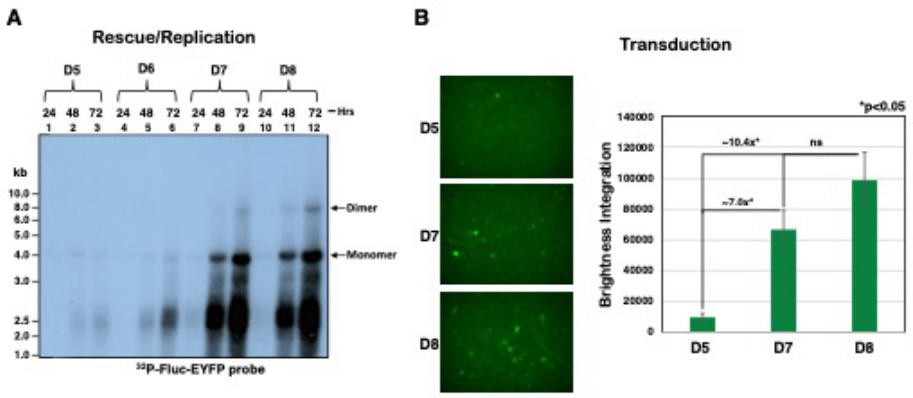


Figure 1: (A) Southern blot analysis for rescue and replication of the AAV genomes containing D5, D6, D7, and D8-sequences. **(B)** Transduction efficiencies of recombinant ssAAV2-FLuc-EYFP vectors containing D5, D7, or D8 sequences that were used to transduce HeLa cells in triplicates at $3x10^3$ vgs/cell. Transgene expression was visualized 72 hrs post-transduction and quantitated using a Keyence microscope. ns=not significant.

1880 A Novel AAV Vector Design for Reducing Cross-Packaged ITR Promoter Activity

yunfei Ma[1], Fengpeng Li[2], **Chunyan He[3]***
[1]Suzhou Genassist Therapeutic Co., Ltd, suzhou, Jiangsu, China, [2]Suzhou GenAssist Therapeutics Co., Ltd, suzhou, China, [3]Suzhou GenAssist Therapeutics Co., Ltd, Suzhou, Jiangsu, China

Adeno-associated virus (AAV) vectors are viable tools for delivering therapeutic drugs to treat various diseases. Nevertheless, during their clinical development, it is essential to address impurities present in even highly purified AAV preparations. Impurities in the AAV packaging production include DNA, proteins, and empty capsids. Most of the DNA impurities, consist of viral plasmids and host cell genomes, can be digested by subsequent purification steps. But non-GOI DNA components encapsulated within the AAV cannot be efficiently eliminated. Non-GOI DNA contain bacterial elements in the plasmid backbone, involving antibiotic genes, bacterial replicons, and potentially open reading frame (ORF) sequences. These ITR guided mis-packaging contaminants are commonly referred to as cross-packaging. ITR is an essential component for viral packaging and replication and possess promoter activity. Adjacent plasmid backbone sequence can be driven for transcription and potential expression of unknown toxic proteins by ITR, which may both incite immune responses and bring safety risk for AAV products. The polyA signal is a DNA sequence that exerts a transcriptional termination effect and guides the polyA tail to attach to the post transcriptional mRNA. To mitigate the ITR-driven transcripts of cross-packaged AAV, we introduced polyA signal sequences (PolyA SS) proximate to ITR and developed a novel viral plasmid for AAV production. In addition, 3x overlapped stop codons (corresponding to +1/+2/+3 reading frames) was incorporated prior to the polyA SS to restrict possible translation from the unexpected transcripts, and these modifications are termed translation and transcription termination elements (TTTE). We evaluated the effects of TTTE on the transcription of the plasmid backbone *in vitro*. HEK293T were transduced with viral plasmids with the additional TTTE at upstream of the 5' ITR or downstream of the 3' ITR or both. Compared to parental plasmid, the insertion of TTTE at upstream of the 5' ITR or downstream of the 3' ITR reduced the backbone transcription products by 38% or 18%, and by about 87% when both insertions were applied. To confirm the TTTE effects *in vivo*, AAV were packaged through triple transfection system and administered into the tibialis anterior muscle of B6 mice. The modified and unmodified products were injected in the left and right legs respectively. Two weeks post injection, muscles were collected and analyzed for backbone expression. In vivo experiments demonstrated that TTTE modifications significantly reduced backbone transcription by more than 99%. These findings indicated that the introduction of TTTE into the upstream of 5'ITR and 3'ITR of AAV packaging plasmid can effectively inhibit the ITR-driven backbone transcription, which facilitates to increase the safety of AAV products.

1881 Adeno-Associated Virus characterization using Nanopore long read sequencing and analysis

Tam Duong[1], Chien-Ting Li[1], Peng Wang[2], Bingnan Gu[3]
[1]Lonza Houston Inc., Houston, TX, [2]Lonza Cell and Gene Therapy, Wayne, PA, [3]Lonza Houston Inc., Houston, Texas

Recombinant adeno-associated virus (rAAV) has become a leading vector for *in vivo* gene delivery, with numerous clinical trials exploring its use for treating a range of human diseases. The quality of the AAV product is crucial for the success of gene therapy, and thorough understanding of the viral genome sequence is becoming essential for effective quality control. During AAV production, non-targeted sequences may be inadvertently packaged alongside the gene of interest (GOI). To ensure the safety of the final product, it is also critical to evaluate and characterize these non-GOI sequences.

In this study, we evaluate and develop optimized Nanopore long-read sequencing workflow to analyze our AAV viral genome produced from our triple transfection platform. This method confirms the correct gene of interest (GOI) sequence for identity, its integrity and provides insights into the impurity profile of the AAV product. Specifically, we assess the presence of mis-packaged sequences from the host cell genome or vector backbone used in a triple transfection platform. Nanopore sequencing offers a comprehensive view of the AAV genome and delivers robust, informative analysis of both in-process and purified products.

Our Nanopore sequencing results demonstrate a strong correlation with our recently developed 3D digital PCR (dPCR) assay, including 3D linkage analysis, further validating its utility in assessing genome integrity. This fast, cost-effective sequencing approach can complement high-dimensional quantitative digital PCR methods, offering a powerful tool to advance rAAV-based gene therapies for treating human diseases.

1882 Evaluating Plasmid Architectures for Improved rAAV Production in HEK293s

Taylor Gunnels[1], Vedud Purde[2], Wendy Walton[3], JOSHUA HORWITZ[4]*
[1]Eli Lilly and Company, Evanston, IL, [2]Eli Lilly and Company, Indianapolis, IN, [3]Eli Lilly & Company, Indianapolis, IN, [4]Lilly, Indianapolis, IN

Gene therapies employing recombinant adeno-associated virus (rAAV) are a leading approach to treat, and even cure, otherwise intractable genetic diseases. A key technical challenge for rAAV-based therapies is the high cost of production, which is partially driven by inherent limitations of any chosen production platform. For example, suspension HEK293-based processes generate rAAV by transiently transfecting HEK293s with three plasmids that encode: 1) the AAV *rep* and *cap* genes (Rep/Cap), 2) the adenoviral "helper" genes necessary for rAAV production, and 3) the gene of interest (GOI), which may be a model or therapeutic cargo. Key advantages of this process are fast prototyping speeds and high potency of the manufactured rAAV. Compared to other processes however, HEK293 systems historically demonstrate low viral production (i.e., titers), have poor loading of genomes into capsids (i.e., low percentages of genome-containing capsids), and require multiple expensive GMP-grade plasmids for large scale rAAV production. Upstream process improvement is needed.

Here, we explored two avenues for improving rAAV yield, product quality, and cost using a commercially-available suspension HEK293 cell line and a model NanoLuciferase GOI. First, we removed extraneous components from a commonly used adenoviral helper plasmid to reduce the plasmid's size by up to 35%. Our modifications enhanced rAAV production by up to 68% as determined by vector genome count via nanoplate digital PCR (ndPCR) and up to 55% by *in vitro* cell-based transduction assays. Additionally, we evaluated three Rep/Cap plasmid architectures head-to-head and identified designs that improved rAAV production by greater than 3-fold for two different serotypes tested via *in vitro* transduction assays. While we are currently evaluating additional designs, these two strategies to date have boosted vector genome yield in excess of 10^{11} copies / mL using a routine shake flask culture process. Next steps include product quality assessments and extension of these studies to additional serotypes. In sum, our studies show that plasmid architecture remains a fruitful area for improving rAAV manufacturing methods,

and we anticipate that the improvements we have identified will be applicable broadly across rAAV serotypes and functional cargos.

1883 Differential Effects of AAV GOI Plasmid Input on the Yield and Impurity Profiles of Single-Stranded Versus Self-Complementary AAV

**Corresponding Author*

Recombinant adeno-associated viral vectors (rAAV) show great promise as gene delivery vectors to treat various diseases. The most commonly used method of rAAV production is triple plasmid transfection which produces rAAV drug products that contain antibiotic-resistance and bacterial DNA impurities from packaged plasmid backbones. Reports indicate residual plasmid DNA levels can exceed 8% of the rAAV product, raising patient safety concerns and highlighting the importance of monitoring and understanding the parameters that can influence these residual values[1,2]. Liu et al. (2024) have reported successfully decreasing plasmid backbone impurity packaging via a low-cis triple transfection method in both single-stranded (ssAAV) and self-complimentary rAAV (scAAV); however, this method is production system dependent and not tested at bioreactor scale[3]. Our study extended this work by testing whether reducing the relative ratio of GOI plasmid in triple transfection rAAV preparations could decrease backbone packaging across three scAAV and two ssAAV constructs produced in HEK293 cells using shake flask and AMBR250 bioreactors. Vector titer and backbone impurity levels of affinity-purified intermediates were measured using ddPCR against GOI and kanamycin resistance sequences, respectively. Our data demonstrate that reducing GOI plasmid input affects residual plasmid DNA impurities and the yield of ssAAV and scAAV differently. Reducing the GOI plasmid content by 50% significantly lowered the backbone impurity levels without affecting the titer in ssAAV production. Conversely, reducing the GOI plasmid content by 50% in scAAV production did not decrease the backbone impurity and, in some cases, reduced the yield of the scAAV vector. Reducing the GOI plasmid content by 90% decreased the titer for both ss and scAAV and had inconsistent effects on backbone impurities. The results of this study offer process development tools to produce safer and more efficient recombinant single-stranded AAV vectors for clinical applications. Our study also highlights the need to monitor residual plasmid DNA impurities during process optimization, noting that the configuration of GOI plasmids (sc vs ssAAV) affects these values.

1884 Long-Read Sequencing Identifies Novel Class of Contaminants in Adeno-associated Viruses

Kelly Fagan[1], Alex Araki[1], Martin Borch Jensen[2], Chase Bowman[1], Jingshu Chen[3], Linda Chio[4], Ian Driver[1], Daniel Fuentes[1], Carmen Le[3], Francisco LePort[1], Hikaru Miyazaki[1], Wyatt Morgan[5], Jesi Nonora[3], Chris Towne[4]
[1]Gordian Biotechnology, South San Francisco, CA, [2]Gordian Biotechnology, San Francisco, California, [3]Gordian Biotechnology, South San Francisco, [4]Gordian Biotechnology, San Francisco, CA, [5]Gordian Biotechnology, Menlo Park, CA

Efficacious and safe adeno-associated virus (AAV) gene therapies require stringent control of vector genome composition. Long-read sequencing, in which continuous kilobases of DNA can be assessed, has been applied to read out the entire genomic composition of AAV particles. It is known that AAVs with secondary structures and high homology as conferred by microRNA or guide RNA constructs can lead to truncations and contaminating species called snapback genomes. Additionally, previous work has shown that an undersized backbone can lead to increased levels of reverse packaging, wherein the backbone region is encapsidated and included in the final AAV product. With long-read sequencing we were able to discover and identify contaminating genomic species in our AAV preps. Surprisingly, the identity of this species demonstrates a unique mechanism of replication with the plasmid backbone outside of the ITRs.

AAV vectors were produced in adherent HEK293T cultures using PEI mediated triple transfection and purified with either iodixanol ultracentrifugation or affinity chromatography. During the quality control of AAV vectors, alkaline gels were run to assess vector packaging and genome integrity. From these gels, the presence of an unexpected band at ~1900 bp was observed in multiple AAV constructs. Due to the consistent appearance of this band in constructs with different transgenes, we further investigated the origin of this conserved band. To identify the contamination band, we assayed our AAV constructs with PacBio Single Molecule Real Time (SMRT) sequencing. We observed that ~12% of reads aligned to the correct length of the aberrant band. De novo assembly of these reads identified a snapback genome, a self-complementary AAV (scAAV) containing a polyA sequence and our AAV genome between the SV40 and the ITR. The formation of this snapback genome is facilitated by the presence of identical SV40 polyA sequences within the transgene to terminate transcription and another SV40 sequence in the backbone. The homology of these regions is sufficient to induce recombination resulting in a significant level of the SV40-snapback genome present in the purified AAV prep. To determine the impact of the external SV40 sequence element, parallel constructs were produced including or removing the backbone polyA. These vectors were analyzed by SMRT sequencing and alkaline gel and confirmed that removal of the external SV40 sequence prevents the snapback genome contaminant. The transduction efficiency of these constructs was tested both in vitro and in vivo. In HEK293 cells, there was no difference in transduction between constructs with or without the external SV40. Mice injected retro-orbitally (n=3) with vectors excluding the external SV40 resulted in decreased liver transduction by 34%.

Here we described the identification through long-read sequencing and analysis of a novel contaminant in AAV vectors that compose a significant sub-species in our final AAV product; however, the mechanism by which SV40-snapback genomes improve transduction in vivo remains unclear. These findings provide further evidence that the composition of the backbone region plays a critical role in packaging and efficiency. Optimization of these features is a crucial step along the path to clinical readiness as a homogenous final clinical product is essential for the safe and effective treatment of patients.

1885 Characterization of the AAV production kinetics from a recombinant baculovirus and insect cell platform

Yuanmei Ma[1], Clarissa Tjoanda[2], Andrew Pla[3], Elliot Jersild[2], Sarah Kudman[2], Stanley Ng[2], Mary Ng[2], John Chan[2], Isabella Gagen[2], Hsuan-Ni Lin[2], Sadie Alperson[3], Jorge Haller[2], Garrett Daniels[4], Zhaohui Yang[2], KENNETH CUNNINGHAM[2]
[1]Eli Lilly and Company, Boston, MA, [2]Eli Lilly and Company, New York, NY, [3]Eli Lilly and Company, New York, [4]Eli Lilly and Company, Indianapolis, Indiana

Recombinant adeno-associated virus (rAAV) has emerged as a leading viral vector for gene therapy due to its strong safety profile and the ability to support long-term gene expression. To meet the growing demand of pre-clinical and clinical-grade rAAV vectors, many studies have been conducted to overcome the bottleneck of high manufacturing cost and low production yields for rAAV-based gene therapy. Recombinant baculovirus (rBV) and Sf9 insect cell system is one of the main rAAV production platforms exploited by academia and industry. Here, we study the production kinetics of two AAV serotypes carrying GFP gene (AAV9-GFP and AAVPVL-GFP) in crude lysate, cell pellet fraction, and supernatant fraction from the rBV/Sf9 platform over a prolonged 6-day process. AAVs were collected from each fraction throughout the 6 days and were titered by ddPCR. For both serotypes, the cell pellet sample collected on day 3 exhibited the highest titer among all the six cell pellet samples, while the supernatant sample obtained on day 6 displayed the highest titer among all six supernatant samples. Total AAV yields from crude lysate (cell pellet + supernatant) maintained at the same level from day 3 to day 6. Western blot was performed to detect the production level of AAV Cap and Rep proteins in Sf9 cells, as these proteins directly affect the yields and quality of rAAV. A high-throughput affinity purification process was utilized to purify rAAVs from both the day 3 cell pellet and day 6 supernatant samples. The purified rAAVs were titered by ddPCR and the capsid purity was assessed by CE-SDS. To evaluate the potency of the purified rAAVs, we performed in vitro transduction in HEK293 cells followed by flow cytometry analysis of the GFP signal. Our results revealed that rAAVs from the day 3 cell pellet had higher VP1 contents and higher GFP expression levels compared to the rAAVs from day 6 supernatant. Based on our historical data, a suboptimal viral capsid protein VP ratio is associated with poor rAAV quality. Our current process of harvesting at day 3 predominantly produces intracellular rAAVs that exhibit higher quality. A 6-day process may be operationally easier since most rAAVs are released into the supernatant, simplifying the harvesting step by only requiring the concentration of rAAVs from supernatant. This helps avoid contamination of host cell DNA and protein during the cell lysis step. However, it results in lower rAAV quality. Taken together, this work highlights the importance of process control, as it significantly impacts the quality of final rAAV product. When comparing AAV production platforms, it is crucial to optimize the process for each platform before conducting the study.

1886 Balance is Key: Optimization of Rep Protein Levels for Superior rAAV Production.

Sven Mathias[1], Yi-hsuan Huang[2], Martina Raasholm[2], Monika Zauner[2], Niklas Kraemer[3], Sadfer Ali[1], Stefano Boi[1], Kristin Thiele[4], Ulrike Jung[1]
[1]Sartorius Stedim Cellca GmbH, Ulm, Baden-Wuerttemberg, Germany, [2]Sartorius Stedim Cellca GmbH, Ulm, Germany, [3]Sartorius Xell GmbH, Bielefeld, Nordrhein-Westfalen, Germany, [4]Sartorius Stedim Cellca GmbH, Ulm, Bayern, Germany

Recombinant adeno-associated viruses (rAAV) are the leading viral vectors in clinical trials, typically manufactured with transiently transfected HEK293 cells. A critical part of the optimization process is to establish genetic constructs and methods which are optimal for the cell line to produce high yield functional titers. As shown by us last year, the interplay between the specific HEK cell line and AAV plasmids is greatly impacting the titer. Hence, it is mandatory to understand the effect of rep expression on a mechanistic level. Accordingly, we dissected the rep wildtype system to better understand baseline levels, the interplay of rep ratios, and split of rep from cap. We performed Western Blot and detailed mRNA ddPCR analysis to characterize the expression of the four rep proteins in various expression setups from wildtype, split construct ribosome skipping to co-transfection and correlated them with vg, cp and TU yields to develop a hypothesis for optimal rep expression strategies. Luciferase experiments complemented the expression analysis as well as tests with a wide range of transcriptional activity from established and novel promoters and very diverse rep ratios.

This allowed us to develop a working model about an optimal long Rep (lRep) : short Rep (sRep) ratio. Combinations which showed poor rAAV titer could be rescued accordingly. Impact of accessory AAV proteins was tested as well as 3’ UTR modifications. In summary, simplification of the rep expression/regulatory feedback loops was possible with identification of optimal baseline levels for specific lRep and sRep protein isoforms facilitating highly efficient rAAV production processes. Interestingly, wildtype results and rAAV data displayed very different pictures, further elucidating the complexity of the rAAV replication process.

1887 Encapsulation of Adeno-Associated Virus-2.5 in Extracellular Vesicles Improves Transduction Efficiency to Human Chondrocytes *in vitro*

Aysegul Atasoy Zeybek[1], Joseph Panos[2], Rodolfo de La Vega[3], Christopher Evans[3]
[1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, ROCHESTER, MN, [3]Mayo Clinic, Rochester, Minnesota

INTRODUCTION: Extracellular vesicles (EVs) are small, lipid-bound vesicles ranging in size from 30 nm to 1 µm, released by cells into the extracellular space.[1] They play a significant role in intercellular communication via paracrine signaling. Beyond their natural biological functions, EVs have emerged as promising vehicles for delivery of therapeutic agents, including adeno-associated viruses (AAVs).[2] EVs possess a highly complex bilayer structure that incorporates numerous proteins, lipids, carbohydrates, and surface-bound molecules, in addition to their internal cargo. This intricate composition protects internal loads from degradation and immune recognition as well as extending systemic retention, thereby addressing key barriers to clinical translation, such as short-lived delivery, neutralization by the immune system, and undesirable side effects. Due to their nanoscale size, EVs are capable of penetrating deep into tissues. Extracellular vesicle-associated AAV (EV-AAV) has several advantageous properties, including high transduction efficacy, reduced immunogenicity, prolonged transgene expression, and the ability to evade neutralizing antibodies.[3,4,5] This study explores the use of EV-AAV2.5 for green fluorescent protein (GFP) gene delivery to human chondrocytes, with a focus on their characterization and efficacy *in vitro*.

METHODS: Naked AAV2.5-GFP and EV-AAV2.5-GFP were prepared following the method described previously.[3] The titers of both vectors were quantified using quantitative real-time PCR. Naked AAV2.5-GFP and EV-AAV2.5-GFP complexes were characterized via nanoparticle tracking analysis (NTA) and transmission electron microscopy (TEM). TEM was employed to confirm the structural integrity of EVs and the encapsulation of AAV within EVs. To evaluate transduction efficiency, HEK293 cells, and human chondrocytes were cultured in monolayers and transduced with either naked AAV2.5-GFP or EV-AAV2.5-GFP of 5,000, 10,000, and 20,000 viral genomes (vg) per cell. GFP expression was visualized using fluorescence microscopy and quantified using a fluorescence reader.

RESULTS: TEM analysis confirmed the proper EV structure and successful encapsulation of AAV2.5 within EVs (Figure 1A). NTA revealed a size distribution of 152.6 nm for EV-AAV2.5, indicating successful complex formation (Figure 1B). HEK293 cells were transduced with both naked AAV2.5-GFP and EV-AAV2.5-GFP (Figure 1C). EV-AAV2.5 demonstrated a higher transduction efficiency compared to naked AAV2.5-GFP (Figure 1D). Similarly, human chondrocytes were transduced with naked AAV2.5-GFP and EV-AAV2.5-GFP (Figure 2A). GFP expression from naked AAV2.5 and EV-AAV2.5 was quantified, revealing comparable GFP expression levels for EV-AAV2.5 relative to naked AAV2.5-GFP (Figure 2B).

DISCUSSION: TEM and NTA characterization confirmed the successful formation of EV-AAV complexes. EV-AAV2.5 demonstrated enhanced transduction efficiency in HEK293 cells. Furthermore, human chondrocytes exhibited robust transduction with EV-AAV2.5. Future studies will focus on evaluating the impact of neutralizing antibodies in knee joints *in vivo*.

1888 Serotype-Dependent Optimization of Formulation for AAV Vectors Based on Stability against Aggregation

Risa Shibuya[1], Kosei Shibata[2], Amane Yamaguchi[1], Kazuto Chino[1], Mitsuko Fukuhara[3], Yasuo Tsunaka[1], Tetsuo Torisu[4], Susumu Uchiyama[5]
[1]Osaka University, Suita, Osaka, Japan, [2]U-medico Inc., Suita, Japan, [3]U-Medico, Inc., Suita, Osaka, Japan, [4]Osaka University School of Engineering Graduate School of Engineering, JAPAN, [5]Osaka University, Osaka, Japan, Japan

Adeno-associated virus (AAV) vectors are a major platform of *in vivo* gene therapy due to their safety and long-term gene expression capabilities. AAV vectors can efficiently target specific tissues or organs depending on the serotype. Considering the practical use of AAV vectors as a pharmaceutical drug, the optimization of formulation for different serotypes of AAV vectors could be one of the keys to the successful development of AAV therapeutics. However, the stability of AAV vectors against aggregation has been considered to be limited. For example, AAV2 vectors tend to form aggregates especially at low salt concentration like 50 mM NaCl [1]. Requirement of high NaCl addition exceeding 200 mM limits the range of feasible formulation screenings. In addition, the low stability against aggregation results in a decrease in vector transduction efficiency. Moreover, aggregation of AAV vectors may trigger immunogenic responses, further limiting their clinical application.
As introduced above, previous studies have reported that high ionic strength in AAV2 vector formulations is important for maintaining the stability against aggregation. However, these findings were mainly based on a limited number of serotypes and formulation conditions, and the applicability to other serotypes has not been sufficiently investigated. Moreover, factors such as pH and buffer composition, which may also play a role in maintaining stability against aggregation, have not been comprehensively studied. Therefore, it is essential to design formulations that consider the characteristics of each AAV serotype when developing AAV-based therapeutics.
In this study, we investigated and compared the effects of pH, ionic strength, and buffer types on stability against aggregation across three serotypes of AAV vectors (AAV2, AAV5, and AAV8) to identify optimal formulations. Consistent with the previous report, our results of AAV2 confirmed that high ionic strength is necessary to maintain the stability. In contrast, for AAV5 and AAV8, high ionic strength did not necessarily improve stability against aggregation, and the optimal ionic strength was crucial for stability against aggregation. The responses to pH and buffer composition also varied among serotypes. Furthermore, the 5 cycles freeze-thaw (5xF/T) stability and storage stability at 4ºC of AAV2, AAV5, and AAV8 were evaluated. AAV2 exhibited lower 5xF/T stability compared to the other serotypes. Subsequently, the potential of additives to enhance the stability of AAV2 was investigated, and it was proposed that the addition of sugar could improve its stability. These findings contribute to the serotype-dependent optimization of AAV vector formulations and provide valuable insights for the development of gene therapy products.

1889 The Impact of Individual Helper Genes on AAV Productivity

Katrina Costa-Grant[1], Laura van Liehout[2], Stacy Ota[3], Diane Golebiowski[4], Ifeyinwa Iwuchukwu[4]
[1]Oxford Biomedica Solutions LLC, Bedford, MA, [2]OXB, Oxford, MA, United Kingdom, [3]Oxford Biomedica Solutions LLC, [4]Oxford Biomedica Solutions, Bedford, MA

The typical helper plasmid used for adeno-associated virus (AAV) manufacturing contains Adenovirus genes essential for AAV replication and gene expression: VA RNA, E2a and E4. The E2a gene produces DNA-binding protein (DBP), however it has recently become clear that a fourth gene, L4 22/33k, encoded on the opposite strand of the E2a gene, plays a critical role in AAV production. Furthermore, VA RNA encodes two individual RNA species, VA RNAI and VA RNAII, and the E4 gene contains a number of unique open reading frames (orfs). In the pursuit to optimize the helper sequence, each helper gene was split into four individual plasmids: VA RNA, DBP, E4 and L4 22/33k.

It was determined that E4orf6 alone was sufficient, but the addition of E4orf6/7 was optimal for AAV productivity. Similarly, L4 22k expression alone was sufficient but addition of L4 33k was beneficial. Lastly, VA RNAI was the major contributor to VA RNA function and VA RNAII plays a minor role.

Removal of each of the four helper gene plasmids had a unique impact on vector genome (VG) and capsid productivity. A lack of DBP was the most impactful at decreasing genome productivity (86x) while VA RNA was the least impactful (5x). 22K was the most effective at decreasing capsid productivity (30x) while Orf6/7 showed minimal impact on capsid productivity. The absence of DBP and Orf6/7 independently resulted in stronger 22K expression shown by western blot. Furthermore, the input of each helper plasmid was varied to identify the optimal level of each component.

These studies led to a better understanding of how the individual helper genes impact AAV production. This allows for the elimination of unnecessary portions of the helper sequence and provides insight to enable an engineered helper plasmid that produces the desirable expression of each component to facilitate optimal AAV production.

1890 Expedited Quantification of AAV Titers Using a Single-Wash ELISA Assay

Yi Zhao[1], Boris Levitan[2], Thomas Quinn[1], Michael Haugwitz[1], Andrew Farmer[1]
[1]Takara Bio USA, San Jose, CA, [2]Takara Bio USA - San Jose, CA, San Jose, CA

Adeno-associated viruses (AAVs) serve as essential vectors in gene therapy and biomedical research, requiring precise and efficient titer quantification methods to ensure experimental consistency and therapeutic success. This study presents optimized single-wash Enzyme-Linked Immunosorbent Assay (ELISA) assays for rapid, reproducible quantitation of AAV titers, for serotypes 2, 8, and 9, respectively.

The single-wash protocol is a key attribute of these assays, which minimizes hands-on time and procedural complexity while preserving analytical rigor. The streamlined workflow is completed within 90 minutes, delivering significant time savings compared to conventional methods, enabling compatibility with high-throughput automation systems. Validation studies demonstrated a high degree of concordance with quantitative PCR (qPCR) titer data, underscoring its reliability.

The assays employ highly specific antibodies detecting AAV capsid proteins for accurate viral particle-capture. A horseradish peroxidase (HRP)-conjugated AAV detection antibody allows for signal generation through enzymatic activity. Empty AAV particles of the respective serotypes with known titers are used to create the standard curve to be used for quantitation. This approach achieves a linear detection range of 10^7 to 10^9 vp/ml and allows for a limit of detection (LOD) of 1.10×10^7 vp/ml and a limit of quantitation (LOQ) of 3.63×10^7 vp/ml. The assays provide a high level of consistency, with inter-assay and intra-assay coefficients of variation (CV) below 20% and 10%, respectively.

These single-wash assays offer a rapid, sensitive, and reproducible method for AAV titer quantification. Its optimized protocol and validated accuracy make it a valuable tool for advancing AAV-based gene therapy research and production, addressing the field's growing demand for efficient and reliable methodologies.

1891 Correlation between Deamidation and Structure of Adeno-Associated Virus Vectors

As one of the most used platforms for gene therapy, recombinant adeno-associated virus (rAAV) vector has been developed and several critical quality attributes (CQAs) of rAAV are directly or indirectly related to the therapeutic product. Recently, chemical modifications of rAAV, one of the potential CQAs, have been studied to reveal the

relation to the safety and efficacy of the vector. Among the chemical modifications, previous studies reported that the deamidation of certain amino acids was related to the reduced transgene expression or potential cause of immunogenicity.
In this study, a workflow of analytical anion exchange chromatography (AEX) was established to monitor the deamidation level of rAAV, which was confirmed by peptide mapping using liquid chromatography tandem mass spectrometry (LC-MS/MS). As a result, we identified at least 2 groups of empty particle (EP) with different behaviors in AEX from the same batch of in-house produced rAAV.
Accelerating storage test was also carried out, with multiple biophysical methods applied to characterize the peaks in AEX of accelerated samples, and led to further identification of the correlation between deamidation and structure of rAAV particles. This study will provide important information that can be used for analytical development of rAAV characterizations by AEX as well as for the process development using preparative AEX.

1892 Advancing Gene Therapy: Stabilization of Viral Formulations with Recombumin® Human Albumin

Chloé Henry[1], Sofia Dente[2], **Daniel Koback[3]**, Peter Davis[4], Phil Morton[5]
[1]Sartorius, Illkirch, Bas-Rhin, France, [2]Sartorius Albumedix, Nottingham, United Kingdom, [3]Sartorius, Seekonk, MA, [4]Sartorius Albumedix Ltd., Nottingham, Nottinghamshire, United Kingdom, [5]Albumedix

Viral Vaccines, and Viral Vector preparations, such as Adeno-associated viruses (AAVs), in gene therapy face a major challenge: maintaining stability in clinical settings because degradation above -80°C compromises biological activity. Our high-quality recombinant human albumin (rHA) Recombumin® effectively addresses this issue by stabilizing AAVs, preserving their integrity during storage, transport, and administration.

As a multifunctional excipient, albumin offers benefits such as preventing surface adsorption, minimizing aggregation, protecting against mechanical stress, and acting as a potent antioxidant. Recombumin® distinguishes itself from serum-derived albumin and other commercially available rHA's with its high purity and low aggregation profile, ensuring reliable viral stabilization by maintaining structural integrity and preventing degradation. This enables more flexible storage options, extends product shelf life, and reduces waste.

The use of high-quality Recombumin® in combination with specific anions and excipients in an AAV formulation, yields enhanced AAV stability, which should lead to more effective gene therapy treatments. Furthermore, we expect the enhanced stability to result in higher intact viral titers and reduced dosing requirements, thereby significantly lowering the costs of developing and delivering viral-based therapies and increasing their accessibility.

Insights into the role of Recombumin® in AAV formulations will be showcased, highlighting its potential to transform the field of gene therapy.

1893 Human iPSC-derived Cells as a Platform to Determine AAV Transduction Efficiency

Kirk Twaroski[1], Ravi Vaidyanathan[2], Scott Schachtele[3], Rebecca Fiene[4], Coby Carlson[4], Simon Hilcove[5]
[1]FUJIFILM Cellular Dynamics, Madison, WI, [2]FUJIFILM Cellular Dynamics Inc. - Madison WI, Madison, WI, [3]FCDI, Madison, WI, [4]FUJIFILM Cellular Dynamics, Inc, Madison, WI, [5]Madison, WI

Introduction: In vitro cellular models are a centerpiece for understanding, modifying, and quantifying the complexity of gene delivery. Induced pluripotent stem cells (iPSC) provide the ability to interrogate biologically relevant cell types *in vitro*. These cell types are compatible with various gene targeting approaches, particularly adeno-associated viral (AAV) vectors. Defining AAV transduction permissibility across different iPSC-derived cell types is a necessity. Quantifying the effects of viral vector serotype, multiplicity of infection (MOI), promoter, media, and assay timing in a human-focused model system is possible with iPSC-derived cells. These specialized cell types offer a major advancement for AAV studies of gene delivery.

Methods: Commercially available cryopreserved human iPSC-derived cell types from FUJIFILM Cellular Dynamics, Inc. (FCDI), culture media and supplements were used according to manufacturer's recommendations. Cells used in this study included: iCell Cardiomyocytes[2], 01434, iCell Hepatocytes 2.0, 01434, iCell Retinal Pigment Epithelial Cells, 01279, iCell Astrocytes, 01434, iCell Astrocytes 2.0, 01279, iCell Pericytes, 01279, iCell Brain Microvascular Endothelial Cells, 01279, iCell Motor Neurons, 01279, and iCell Sensory Neurons, 01279. With Promega, a NanoLuc®-HaloTag® Dual Reporter System for AAV vectors was generated. AAV viruses were manufactured by VectorBuilder. Serotypes examined were AAV1, 2, 3, 4, 5, 6, 7, 8, 9, rh10, and PHP.eB, built with a CMV or SYN1 promoter to drive gene expression. The panel of AAV reagents was used to transduce cells at MOI ranging from 10 to 10^6. If transduction was successful, the expressed NanoLuc® luciferase produced a luminescent signal in the presence of substrate with signal intensity proportional to AAV transduction efficiency. AAV-positive cells could be quantified by imaging or flow cytometry when cells were labeled with Janelia Fluor® HaloTag® 646 Ligand post-transduction. Kinetic assays were performed over 48-72 hours on a BMG Labtech CLARIOstar. In collaboration with FUJIFILM Diosynth Biotechnologies (FDBT), the transfection efficiency of AAV serotypes 1, 2, 4, 5, 6, 8, and 9 was evaluated and CAG and CMV promoters driving GFP was compared. AAV viruses for this part of the study were manufactured at Vector BioLabs. Cells were cultured in 96-well plates with empty AAV vector viruses as negative controls and BacMam GFP as positive transduction control where appropriate. MOI of 100K was the maximum concentration of virus tested. The Celigo S Image Cytometer from Nexcelom and a CytoFLEX flow cytometer from Beckman Coulter were used to quantify GFP expression in different cell types.

Conclusions: As a model to evaluate AAV serotype transduction efficiency, iCell products are a great preclinical system. Cost effective and systematic evaluation of recombinant AAV efficiency variables for any given cell type is recommended. Commercially sourced cryopreserved cells are an ideal reagent for use in these studies because of their scale of manufacture and functional consistency. AAV material handling and storage is critically important and can significantly affect transduction efficiency. Lastly, combining iPSC-derived cells and AAV technology to dissect cellular diseases *in vitro* has the potential to offer a robust method for potency or material release.

1894 Enhanced Gene Transfer to Brain Parenchyma via Next-Generation AAV5 Capsids

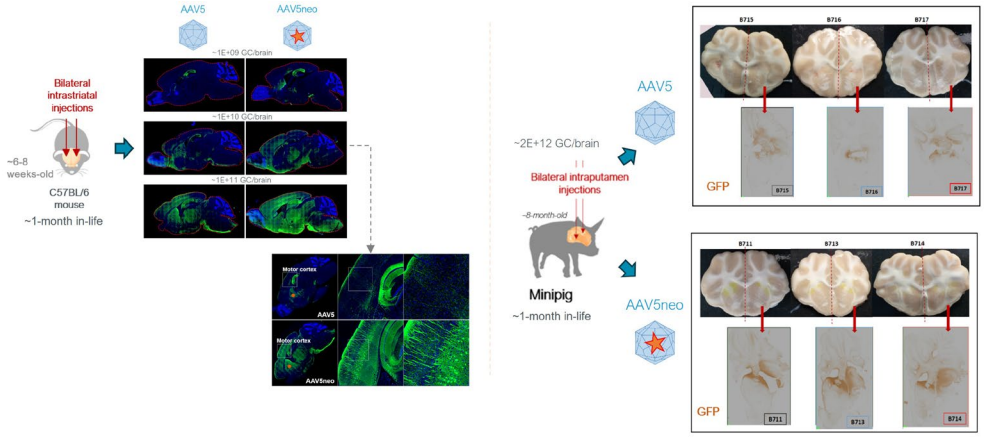
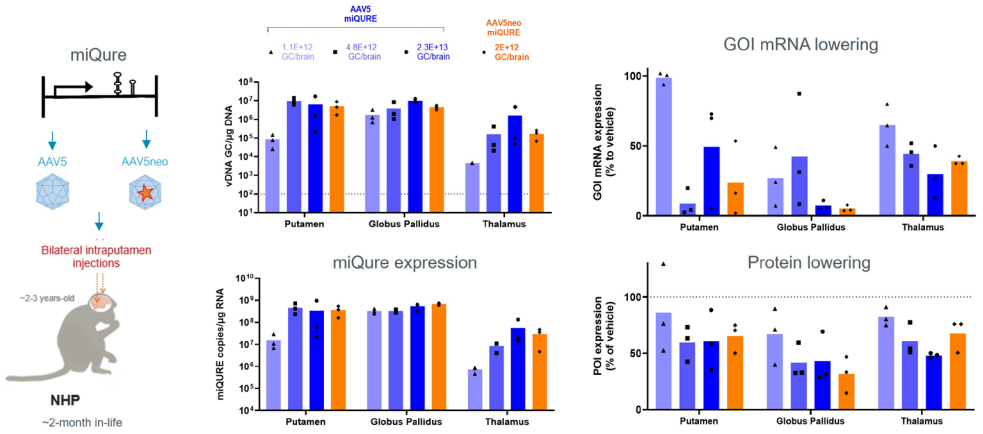
Gene therapies for brain disorders hold great promise but face significant challenges in efficiently accessing the brain parenchyma due to inherent physiological barriers. To overcome these obstacles, intracranial delivery has emerged as a preferred approach to enable precise targeting of brain regions while minimizing therapeutic material loss.

Adeno-associated virus (AAV) vectors are pivotal in intracranial gene delivery, offering safe and long-lasting transgene expression after a single administration. Among natural AAV capsid serotypes, AAV5 stands out for its strong safety profile, low immunogenicity, and proven efficacy in clinical trials, establishing it as a leading choice for therapeutic gene delivery in brain disorders.

Building on AAV5's strengths, a novel AAV5-based capsid variant has been developed and thoroughly characterized. This next-generation capsid, designed to overcome innate physiological barriers, demonstrates enhanced transduction efficiency and broader spread in rodent, minipig, and non-human primate (NHP) models. In NHP studies, it achieves potent therapeutic transgene delivery at significantly lower doses than the original AAV5.

These findings underscore the transformative potential of this advanced capsid for central nervous system gene therapy, paving the way for safer, more effective treatments for brain disorders.





1895 Rewriting Tropism: Engineered AAV-Kingfisher Capsids show Superior Oligodendrocyte Targeting and Spread

Yuriy Pomeshchik[1], Marcus Davidsson[2]*, **Patrick Aldrin-Kirk[3]**
[1]RAAVen Therapeutics, Lund, Skane lan, Sweden, [2]RAAVen Therapeutics, Lund, ., Sweden, [3]RAAVen Therapeutics, Lund, Sweden
**Corresponding Author*

Gene therapy for oligodendrocytes shows great promise in treating demyelinating disorders such as multiple sclerosis and leukodystrophies. However, efficient and targeted delivery of therapeutic genes to these specialized glial cells remains a significant challenge due to the complexity of the central nervous system (CNS) and the need for precision in targeting specific cell types. rAAVen Therapeutics has developed an innovative solution with the rAAptr (rational AAV peptide research) platform, which utilizes the rational design of adeno-associated virus (AAV) capsids to create tailored gene delivery vectors for cell-specific applications. The rAAptr platform employs a rationally designed library of peptide inserts within the AAV capsid, generating a vast array of AAV variants. This approach enables the identification of highly efficient AAV variants in a single round of screening, significantly reducing the number of animals required compared to traditional directed evolution methods. These variants are subsequently screened for cell type-specific transduction by sequencing expressed DNA barcodes from the viral transgene, enabling the identification of AAV capsids that are optimally suited for targeting specific cell types within the brain.
In this study, we applied the rAAptr platform to develop AAV capsids specifically targeting oligodendrocytes. By

designing a library enriched for oligodendrocyte-targeting peptides, we observed a significant shift in transduction profiles, favoring the white matter regions of the brain where oligodendrocytes are predominantly located. Additionally, we identified capsid variants capable of dispersing from the ventricular system to adjacent brain areas, which is crucial for widespread gene delivery within the CNS. To pinpoint variants with a high affinity for oligodendrocytes, we utilized fluorescence-activated cell sorting (FACS) to separate oligodendrocytes from non-oligodendrocytes, followed by sequencing of the viral barcodes. With this approach, we could identify and validate AAV capsids with robust oligodendrocyte specificity. Among these, novel Kingfisher variants 10/28/193/249/D2 demonstrated superior performance compared to parental AAV2 and Olig001, the current best-in-class oligodendrocyte-targeting AAV. Kingfisher variants demonstrated enhanced tropism for oligodendrocytes, along with the ability to spread and effectively transduce cells in white matter regions of the brain, both after direct brain injection and following intracerebroventricular (ICV) delivery.
Our findings underscore the efficacy of the rAAptr platform in designing AAV vectors with precise cell type specificity. The identification of AAV-Kingfisher variants represents a significant advancement in the development of more effective and targeted gene therapies for oligodendrocyte-associated disorders. This research not only provides a pathway for treating demyelinating diseases but also highlights the potential of rational design approaches in creating next-generation gene therapy vectors tailored for specific therapeutic needs, all while minimizing the use of animal models.

1896 Characterization of Receptor-Targeted Blood-Brain Barrier Penetrant AAV Capsids

Ankitha Nanjaraj[1], Stephanye Frias[2], Lori Andrews[3], Esmeralda Ponce[4], Satria Sajuthi[5], Russell Darst[2], Yuri Bendana[4], Hung Tran[6], Yolanda Santiago[2], Andrew Olin[4], Jennifer Hodges[4], Sarah Mueller[2], Matthew Tiffany[4], **David Ojala[7]**
[1]Sangamo Therapeutics, Inc., Richmond, California, [2]Sangamo Therapeutics, Inc., Richmond, [3]Sangamo Therapeutics, San Rafael, CA, [4]Sangamo Therapeutics, Richmond, CA, [5]Sangamo Therapeutics Inc., Richmond, [6]Sangamo Therapeutics, Brisbane, CA, [7]Sangamo Therapeutics, Inc., Richmond, CA

Blood-brain barrier penetrant adeno-associated virus (AAV) capsids have the potential to transform the treatment of neurological disorders by enabling efficient intravenous delivery of genomic medicines to the central nervous system. We have previously described SIFTER, an *in vivo* library screening platform for the identification of AAV capsids that mediate widespread central nervous system (CNS) delivery. We have conducted SIFTER screening campaigns in non-human primates to identify engineered capsids that target the CNS after intravascular (STAC-BBB) or cerebrospinal fluid (STAC-102 and STAC-103) administration. A complementary strategy for engineering AAV capsids is to conduct *in vitro* screens for capsids that interact with receptors on the human blood-brain barrier. Here, we report the characterization of three receptor-targeted AAV capsid families. Each of these capsid families targets a distinct human blood-brain barrier receptor. These receptor-targeted capsid families are unrelated to STAC-BBB, but likewise have the potential to mediate widespread CNS delivery. Multiple lead capsids were selected from each of the three families for further characterization as individual capsids. The capsids were additionally tested in a barcoded pool format with dual ranking of expression from the neuron specific human synapsin 1 and ubiquitous human U6 snRNA promoters. Lead capsids targeting one of the receptors exhibited enhanced transduction in cells expressing the human, macaque, or mouse receptor orthologs. A subset of capsids targeting the other two receptors exhibited cross-species enhancement of transduction in cells expressing the human or macaque receptor orthologs. In the progression from preclinical to clinical testing, cross-reactive receptor engagement in primates is a critical translational consideration. In addition to evaluating capsid potency, capsid manufacturing yield in suspension HEK293 cells was benchmarked against the parental AAV serotype. These receptor-targeted capsids are being evaluated in vivo to assess BBB crossing efficiency and tropism for CNS cell types.

1897 Harnessing Human Brain-Specific Carbonic Anhydrase IV for Targeted AAV Gene Delivery

Changfan Lin[1], Xinhong Chen[1], Jonathan Hoang[1], Fiona Ristic[1], Yujie Fan[2], Jin Hyung (Alex) Chung[3], Erin Sullivan[4], Tomasz Gawda[1], Seongmin Jang[1], Bill Kavvathas[2], Irene Tran[5], Yitong Li[2], Andrew Steele[5], Timothy Shay[6], Viviana Gradinaru[7]

[1]Caltech, Pasadena, CA, [2]Caltech, Pasadena, [3]Caltech, Monterey Park, CA, [4]Pasadena, California, [5]California State Polytechnic University Pomona, Pomona, [6]CLOVER Center, Caltech, Pasadena, CA, [7]California Institute of Technology, Pasadena, CA

Gene therapy delivery to the brain faces significant challenges, particularly penetration of the blood-brain barrier (BBB). While clinically approved adeno-associated virus (AAV) therapies using natural serotypes show promise, their applications remain limited due to poor targeting specificity, high dosing requirements, and associated safety concerns. Although directed evolution has produced enhanced AAV capsids in animal models, inter-species differences complicate translation to human therapies.

Recent in-vitro efforts have engineered AAVs to target specific BBB transcytosis receptors, including murine-specific LY6A (Huang et al., PLOS Biology, 2023) and the widely-expressed TfR1 for human brain gene therapy (Huang et al., Science, 2024). Our work advances this paradigm by targeting the human BBB receptor carbonic anhydrase IV (CA4), which exhibits a more central nervous system (CNS)-focused expression pattern than previously established BBB receptors.

Through in vitro pulldown and cell transduction screening, we identified a pool of human CA4-targeting AAVs. While some AAV variants demonstrated strong CA4 affinity in SPR assays and CA4-enhanced cell infectivity, they did not show significantly improved BBB crossing, as evaluated in transwell models and human CA4-expressing mice.

To overcome this challenge, we further developed a "humanized" mouse model for final candidate selection. This approach uses mouse brain endothelial cell-specific AAVs to introduce human BBB receptors—a more flexible and rapid approach than developing transgenic mice. By utilizing AAV2-based vectors for model development, we enabled subsequent AAV9-based library screening with minimal neutralizing antibody cross-reactivity. Importantly, our approach preserves normal immune competency, unlike immune-deficient mouse models which cannot properly replicate AAV-immune system interactions during brain transduction. Using this workflow, we successfully identified AAV variants with efficient BBB transcytosis and robust brain transduction from our pool of human CA4 binders.

Overall, our work advances our understanding of the complex relationship between BBB receptor binding and efficient barrier crossing. By employing a mechanism-driven approach to engineering that combines selections in receptor binding assays and “humanized” mouse models, we identified AAVs that effectively engage a human BBB transcytosis system. This strategy offers a clear path toward developing more effective and clinically relevant gene therapies targeting the human brain.

1898 Engineering AAV vectors with TfR1-targeting domains for CNS gene delivery in cynomolgus macaques and humanized mice

Richard Martino[1], **Xiaodong Lu[1]**, Caitlin Meeks[1], Mark Julian[1], Pete Clarner[1], Mengying Zhang[1], Nadia D’Lima[2], Samantha Desmarais[1], Aditya Utturkar[1], Shawn Bourque[3], Misha Chittoda[1], Harini Sampath[1], Ankur Thomas[2], Bin Wang[2], Arnold Muccini[2], Gregory Dodge[2], Samneet Kashyap[1], Yuting Liu[2], Jinkuk Choi[1], Adem Koksal[1], Benjamin Smith[2], Thomas Cameron[1], Paul Weinreb[2], Junghae Suh[1], Joe Arndt[2], Yuan Yuan[1]*
[1]Biogen, Cambridge, MA, [2]Biogen, Cambridge, [3]Cambridge, MA
**Corresponding Author*

The development of adeno-associated virus (AAV) vectors capable of efficiently crossing the blood-brain barrier (BBB) and delivering genes to the central nervous system (CNS) would expand therapies for neurological diseases. AAV vectors that can cross the BBB in non-human primate (NHP) and relevant humanized mouse models have been reported. However, it remains challenging to identify capsids with comparable CNS transduction in multiple animal models due to cross-species differences in cognate BBB receptors mediating transcytosis of AAVs across the brain endothelium. To de-risk CNS-targeted gene therapies using engineered novel capsids, one of our current strategies requires that vector candidates demonstrate adequate CNS transduction and safety profiles in both NHPs and humanized mice.

To engineer CNS vectors with species cross-reactivity, we designed AAV capsids displaying targeting domains able to bind to both human and cyno orthologs of transferrin receptor 1 (TfR1), a clinically validated receptor that mediates transcytosis across the BBB. We previously reported that several AAV capsids engineered using this strategy demonstrate enhanced CNS transduction over AAV9 in humanized TfR1 knock-in (hTfR1 KI) mouse screening and NHP screening. In addition, lead capsids were individually evaluated in hTfR1 KI mice, with one top candidate showing robust BBB penetration and neuronal transduction.

Analysis of the first-generation results revealed an inverse relationship between TfR1 binding affinity and neuronal transduction, informing the design of our second-generation library. This library incorporated targeting domains with diverse TfR1 binding affinities and epitopes, alongside modified first-generation leads informed by cryo-EM structures. Following barcoded capsid library screening in hTfR1 KI mice, lead capsids from first- and second-generation libraries were individually evaluated with a therapeutic transgene in NHPs and hTfR1 KI mice. These vectors show widespread and enhanced CNS transduction compared to AAV9 in both models.

This work establishes a platform for developing TfR1-targeted AAV vectors with cross-species BBB penetration and CNS transduction capabilities. Our current leads show enhanced performance relative to AAV9 in both NHPs and hTfR1 KI mice. We will continue to characterize these capsids in future work, leveraging our initial success, the modular nature of this targeting approach, and our increasing knowledge of capsid design parameters.

1899 Blood-Brain Barrier Crossing AAV Vectors Targeting the Transferrin Receptor Engineered Using Two Different Approaches

Elad Firnberg[1], Sigmund Tejada[1], Benjamin Heithoff[1], Johannes Schilling[2], Patrik Forrer[3], Dominik Herbst[2], Ewelina Kurpisz[2], Nora Guidotti[3], Jared Smith[1], Ye Liu, Olivier Danos[1]
[1]REGENXBIO Inc., Rockville, MD, [2]Athebio AG, Schlieren, Switzerland, [3]Athebio AG, Schlieren, Zurich, Switzerland

Naturally occurring AAV serotypes have very low brain penetration when administered intravenously due to the blood-brain barrier (BBB). In this work we employed either designed ankyrin repeat proteins (DARPins) or short peptides to engineer AAV vectors that bind human transferrin receptor 1 (hTfR1). TfR1 is expressed at high levels in the brain vasculature and has been shown to effectively shuttle macromolecules bound to it across the BBB and into the brain parenchyma.

In the first approach, we undertook a ribosome display selection campaign to identify Athebody® platform DARPins that bind to hTfR1 with a wide range of affinities. We optimized the DARPin insertion site in AAV9 VR-IV and generated vectors displaying up to 12 DARPin copies per capsid. In the second approach, we used the REGENXBIO NAVIGATE directed evolution platform to identify a capsid with an hTfR1-binding peptide insertion. Capsid binding to hTfR1 was confirmed via an Octet BLI binding assay and transduction of HEK293-hTfR1 cells. Both methods produced AAV titers similar to the control capsid.

We then intravenously administered the DARPin and peptide insertion vectors to transgenic mice expressing hTfR1. Both vector types robustly transduced the brain and spinal cord resulting in greater than 28-fold higher vector genome copies (vg) per cell and greater than 44-fold higher mRNA transcripts in the brain vs control. In the liver, there was greater than 3-fold reduced vg/cell vs control for the DARPin and peptide insertion vectors. Histological analysis revealed that both vectors efficiently transduced regions throughout the entire brain, with the highest transgene expression observed in the thalamus and striatum. In areas of cortex, the two vectors showed prominent differences in cell type transduction, with the DARPin vector exhibiting neuronal tropism and the peptide vector exhibiting tropism for astrocytes in this humanized mouse model.

Both hTfR1 targeting strategies are effective for crossing the BBB and show promise for CNS gene therapy applications. Further work is needed to characterize BBB crossing and cell-type tropism in a large animal model and manufacturability at a larger scale.

1900 Expanding Access to Gene Therapies for Neurometabolic Disorders: A Platform Approach Using TfR1 CapX

Andrew Steinsapir[1], Christopher Davis[2], Sisi Chen[3], Jorge Santiago-Ortiz[3], Ellen Horste[3], Tina Hu-Seliger[3], Von Wiltman[3]
[1]Deerfield Management, New York, NY, [2]Apertura Gene Therapy, Somerville, MA, [3]Apertura Gene Therapy, New York, NY

Introduction:
Neurometabolic disorders represent a diverse group of conditions with severe CNS manifestations, many of which are amenable to gene therapy. However, effective AAV-based CNS delivery remains a major translational challenge, particularly for large or systemically progressive disorders requiring broad brain distribution. TfR1 CapX, an engineered transferrin receptor-targeting AAV capsid, has demonstrated high-efficiency BBB penetration and robust CNS transduction after intravenous administration, positioning it as a versatile platform for neurometabolic gene therapies.

Finalized and draft FDA guidance as well as INTERACT feedback that Apertura Gene Therapy has recently received support the use of alternative models when scientifically justified, particularly in cases where non-human primate (NHP) studies lack pharmacological relevance. Based on our regulatory experience in genetic epilepsies, preclinical data, and direct FDA engagement, we outline a streamlined pathway for developing neurometabolic gene therapies with TfR1 CapX—one that does not require NHP studies.

Methods:
We leveraged preclinical biodistribution, transduction, and therapeutic efficacy data to assess TfR1 CapX's suitability for neurometabolic disorders. Key regulatory precedents and direct INTERACT feedback were analyzed to define a translationally viable, NHP-free approach.

Results:
TfR1 CapX achieves widespread CNS transduction following intravenous administration in human transferrin receptor knock-in (B-hTfR1) mice, a commercially available model that provides robust pharmacokinetic and safety data. INTERACT feedback confirmed the pharmacological irrelevance of NHPs, as TfR1 CapX does not efficiently bind NHP transferrin receptors. These findings, aligned with prior regulatory decisions, eliminate the need for large-scale NHP toxicology studies and significantly reduce costs and timelines.

Conclusion:
TfR1 CapX represents a scalable and regulatory-aligned platform for neurometabolic gene therapies, allowing for efficient clinical translation without reliance on NHP models. With a clear FDA-supported preclinical pathway, robust CNS delivery, and established translational feasibility, TfR1 CapX is well-positioned to advance next-generation gene therapies for neurometabolic disorders.

1901 Novel AAV capsids that bind human transferrin receptor (TFRC) demonstrate widespread and preferential CNS tropism in TFRC-KI mice after low dose systemic dosing

Adeno-associated viral (AAV) vectors capable of delivering genetic cargo across the blood-brain barrier (BBB) can enable drug development for diseases of the central nervous system (CNS). An approach to potentially de-risk translatability of potential CNS AAVs is to identify capsids that engage receptors with known ability for enabling human BBB penetration, such as the transferrin receptor (TFRC). We developed a high throughput screening platform to identify capsids that can bind human TFRC protein in vitro and penetrate the BBB via TFRC in vivo. We first screened a library of AAV9 capsids with random 7mer peptide insertions for binding the human TFRC extracellular domain immobilized on beads. Clustering these binding hits identified multiple conserved sequence motifs. A deep learning generative AI framework was applied to the binding data to predict additional TFRC hit capsids. A library that combined the observed binding hits with the AI-predicted TFRC hits was used to dose transgenic mice harboring TFRC receptor on the BBB (TFRC-KI) intravenously. Brain samples from these mice revealed a large number of hit motif groups with in vivo activity. Interestingly, the best performing capsids were AI-predicted hits. While multiple capsids demonstrated >100-fold higher RNA expression in the CNS vs AAV9, three capsids with favorable tropism and manufacturability attributes were individually packaged with reporter cargo for dosing TFRC-KI mice at 2.5e13 vg/kg. We observed 20- to 70-fold higher vector genomes and 140- to 270-fold higher mRNA expression, compared to AAV9. These expression levels translated to 90% neuronal transduction across cortical and deep brain regions. In addition to enhanced CNS tropism, one of our TFRC-capsids demonstrated 10-fold lower vector genome levels in the liver. Based on these data, we set out to determine the dose-to-biodistribution relationship for our lead capsids across a 100-fold dose-range within TFRC-KI mouse CNS and non-CNS compartments. Comparison of in vivo potency between our first generation TFRC-capsids vs published comparators is being analyzed and will be shared. Mechanistic characterization of our lead capsids, as well as functional data in a human BBB model system, will also be presented. In summary, we will present our strategy to identify and validate AAVs that engage human TFRC and thus have higher potential for translatability to neurological applications in the clinic.

1902 Second Generation Human Transferrin Receptor Targeted AAV Capsids With Enhanced CNS Tropisms and Liver Detargeting In Vivo

Numerous genetic diseases that affect the central nervous system (CNS) require gene therapies that are efficiently delivered to cells throughout the CNS. Adeno-associated viruses (AAV) have been engineered to deliver genes CNS-wide after systemic injection. However, several engineered AAVs use mechanisms of action that are unknown or not well validated for transcytosis across the BBB. Therefore, we engineered AAV9 to bind human Transferrin Receptor (TfR1), a protein that is highly expressed on the blood-brain barrier (BBB) and well validated for receptor-mediated transcytosis of biologics in humans. The first generation capsid, BI-hTFR1, is actively transported across the BBB and provides CNS-wide transduction in humanized TFRC knock-in mice (Huang & Chan et al., Science, 2024). We developed BI-hTFR1v2, a next generation capsid with improved CNS tropism and reduced liver transduction. When intravenously injected at 2e12 vg/kg into TFRC KI mice, BI-hTFR1v2 demonstrated 2-fold and 175-fold increased AAV genome biodistribution to the brain, alongside 4.5-fold and 3-fold reduced biodistribution to the liver compared to BI-hTFR1 and AAV9, respectively. Remarkably, the enhanced distribution to the CNS resulted in 8-fold and 1300-fold increases in luciferase reporter signal in whole brain homogenates as compared to BI-hTFR1 or AAV9, respectively. Despite the low dose, BI-hTFR1v2 transduced 80% and 55% of neurons in the cortex and striatum, respectively. In parallel studies, we have generated a version of BI-hTFR1v2, BI-hTFR1v2 NAbE, that is capable of evading neutralization by more than 40% of the individual human donor sera that neutralized AAV9 and AAV5 while maintaining the enhanced CNS tropism of BI-hTFR1v2. These capsids can be produced at yields comparable to AAV9 and purified using commonly used affinity resins. They are currently being advanced toward the clinic as part of an SCGE-funded epigenetic editing therapy for prion disease (Neumann et al., Science 2024). Our work establishes these human TfR1-targeting capsids as promising vectors for human CNS gene therapy.

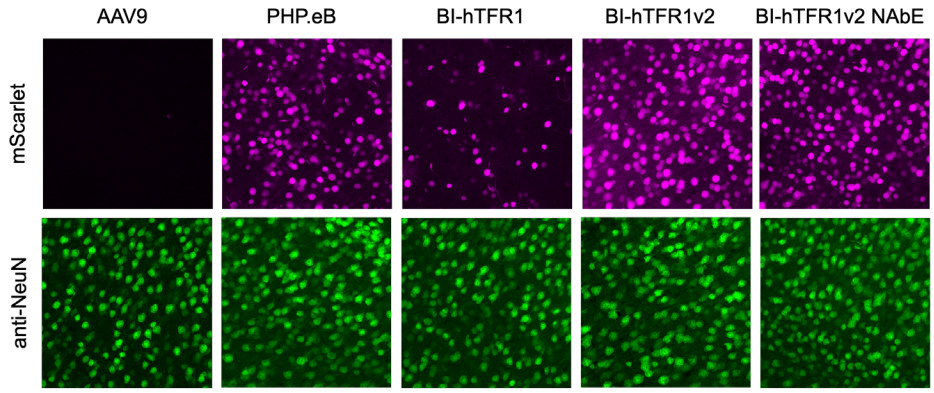

Figure 1. TfR1-targeted AAV capsids achieve efficient CNS-wide transgene expression in human *TFRC* knock-in mice. AAV9, PHP.eB, BI-hTFR1, BI-hTFR1.2 or BI-hTFR1v2 NAbE were intravenously injected into adult *TFRC* knock-in mice at 2.0e12 vg/kg. Representative image of the native mScarlet fluorescence in brain sections stained with anti-NeuN in cortex.

1903 Combining In Vivo and In Vitro Screening Approaches for Identification of BBB-Crossing Capsids Across Species

In recent years, recombinant adeno-associated virus (AAV) vectors have become a pivotal delivery vehicle for in vivo gene therapies. Despite emerging clinical success across multiple therapeutic areas with vectors with increased efficiency and / or specificity for various tissues, targeting the central nervous system (CNS) remains a challenge. The blood-brain-barrier (BBB) has been found to significantly hinder efficient gene transfer into the CNS. Overcoming delivery hurdles like the BBB, will require a combination of identifying novel AAV capsid variants, determining optimal routes of administration (RoA) and understanding the mechanisms underlying cross-species differences.

Here we describe the implementation of a BBB crossing AAV capsid variant screening pipeline, in which specific capsids are uniquely barcoded for the detection and quantification of physical and functional transduction in a high throughput manner. Applying a capsid pool enables us to accurately screen multiple variants in a single experiment more rapidly compared to traditional directed evolution approaches. This approach allows us to generate a quantitative biodistribution for the different AAV capsid variants based on association with their respective barcode. This pooling approach is cost and time efficient, with the additional benefit of a reduction in the number of animals required to generate reliable datasets. Utilizing this pipeline, we have directly compared the performance of natural serotypes and benchmarks in a single pool, in mouse versus non-human primate (NHP) and using two routes of administration: systemic intravenous delivery (IV) and intra-cisterna magna (ICM) injections.

Further, to evaluate the translatability between in vitro and in vivo for crossing the BBB, we utilized the two-channel Emulate chip platform. Here, we have established a comprehensive, microfluidic model of the neurovascular unit comprising four neural cell types in the top channel and brain microvascular endothelial cells in the bottom channel to mimic the human BBB. Analyses of different parameters for characterization of the BBB model, including barrier function and immunofluorescence staining, have been implemented. After application of

our AAV pool to the BBB chip model, we observed robust transduction with variants known for animal CNS-tropism and their ability to cross the BBB.

In summary, the integration of in vivo and in vitro screenings across different species may facilitate the identification of capsids that can cross the BBB and enhances the potential for translation to human studies.

1904 Engineered AAV capsids that target a novel human brain endothelial receptor achieve robust transduction in non-human primate central nervous system after intravenous dosing

Engineered adeno-associated viruses (AAV) can deliver genetic cargo to central nervous system (CNS) by crossing the blood-brain barrier (BBB) after intravenous dosing in preclinical animal models. However, the therapeutic utility of these engineered capsids has been complicated by a lack of cross-species tropism. To address this risk, we identified engineered capsids that bind both the human and non-human primate (NHP) orthologs of a novel protein (referred to as Receptor-Y) that is highly expressed in brain endothelium of the mouse, NHP, and human. We first screened a library of AAV9 capsids with random 7mer peptide insertions for binding the extracellular domain of human or NHP Receptor-Y immobilized on beads. Clustering these binding hits identified many conserved sequence motifs. A library of ~13K Gen1 binding hits was screened in NHPs using intravenous dosing and revealed that a minority of binding hits were detectable in the CNS. A Gen2 library of ~50K capsids was generated using SAR of the Gen1 in vivo active sequence motif families and then used for a second round of screening in NHPs. In comparison to parental AAV9, several Gen2 capsids achieved >1000-fold mRNA expression across NHP cortical and deep-brain regions. Mechanistic characterization of our lead Gen2 capsids will be presented. In summary, we will present a capsid development strategy with a higher potential for translatability to neurological diseases in the clinic due to cross-species binding of a novel brain endothelial receptor.

1905 Optimized CNS-targeting AAV Capsids with NHP and Human Cross-reactivity

Overcoming the blood-brain barrier (BBB) represents the most promising approach for achieving widespread therapeutic gene delivery to the central nervous system (CNS). Directed evolution of peptide insertion AAV libraries has produced a variety of novel capsids capable of crossing the BBB and transducing CNS cells in mice and non-human primates (NHPs). Using this method, we previously developed our Generation A (GenA) CNS-targeting AAV capsids, which demonstrated safe and enhanced CNS gene delivery compared to AAV9 following systemic delivery in NHP.

Here, we focus on establishing human translatability as well as cross-species activity optimization of this capsid family. The key to unraveling the uncertainty around human-translatability lies in identifying cognate BBB receptors

followed by functional comparison of capsid activities against receptor homologs. To this end, we identified 'Receptor X', a membrane protein expressed in brain endothelial cells, as the key receptor mediating transcytosis of GenA capsids. The lead GenA capsid binds to both human and cynomolgus Receptor X homologs.

To identify additional CNS targeting capsids that specifically bind to Receptor X, we designed a unique targeted optimization library based on binding to Receptor X. We then screened this library and identified several Generation B (GenB) capsids that transduce CNS in both NHP and humanized mice. These GenB capsids demonstrate widespread and enhanced CNS transduction compared to AAV9.

In summary, our work highlights the potential of directed evolution and targeted optimization to develop AAV capsids with improved human translatability and cross-species activity. The identified GenB capsids represent another group of promising candidates for CNS-targeted gene therapy, with significant implications for future clinical applications.

1906 AAV-ShDs: Liver-detargeted AAV Capsids with Strong Cross-species Lung Tropism and High BBB Activity in Non-human Primate and In Vitro Human Models

Bing Wang[1], Dabbu Jaijyan[2], Cheng Xu[3], Abdul Rasheed[2], Yu Liu[4], Wenhui Hu[2], Qizhao Wang[5], Daozhan Yu, Danmeng Zhang[6], Xinxu Yuan[2], zhen shi[4], Yuyan Wang[7], Yuling Dai[8], Lemin Wang[7], Haniya Zaidi[4]

The safety and efficacy of gene therapies rely on targeted transgene expression while minimizing off-target effects. The adeno-associated virus-9 (AAV9) serotype is widely used for its strong gene expression across multiple organs, including liver, brain, lung, heart, muscle, and kidney. Utilizing our ATHENA capsid engineering platforms, we selected and evolved AAV capsids, and discovered novel variants with high DNA enrichment in lung, termed AAV-ShDs, which also significantly detargeted liver and other major organs in C57BL/6J and B6C3 mice. The lead capsid, AAV-ShD, showed approximately 500-fold higher DNA levels in lung of C57BL/6J mice compared to AAV9. AAV-ShDs also demonstrated markedly higher RNA enrichment in the lung of B6C3 mice compared to AAV9. The AAV-ShD family specifically targets alveolar type II (AT-II) cells in lung, with VR-IV and VR-VIII regions contributing to lung tropism. To assess translational potential, we conducted similar screenings in non-human primates (Cynomolgus macaques) and identified the same AAV-ShD capsids with high lung enrichment. These capsids showed over 100-fold DNA enrichment and about 22-fold RNA enrichment in lung of macaques compared to AAV9. Additionally, AAV-ShDs efficiently traverse the blood-brain barrier (BBB) in macaque, and AAV-ShDs achieved 385-fold higher DNA level and 8-fold higher RNA level compared to AAV9, based on barcoded next-generation sequencing analysis. In the spinal cord, DNA level was 25-fold higher, and RNA level was 28-fold higher with AAV-ShDs compared to AAV9. In a cellular transwell model, AAV-ShD exhibited enhanced BBB penetration, leading to efficient transduction of human microglia, astrocytes, and neurons. Furthermore, AAV-ShDs successfully delivered transgenes to cultured primary human brain microvascular endothelial cells, pericytes, hippocampal astrocytes, and cortex microglia. Notably, in microglia-containing cerebral organoids derived from human iPSCs, AAV-ShDs demonstrated higher transduction activity than AAV9 in various neural cell types. In conclusion, we identified a novel set of AAV-ShD capsids capable of cross-species lung targeting. Moreover, AAV-ShDs crossed the BBB and efficiently transduced neural cells in both non-human primates and in vitro human cell models. The high DNA levels observed in AAV-ShD-transduced tissues/cells suggest potential for long-term transgene expression at lower dosages, making these capsids promising templates for further engineering and clinical applications.

1907 Cross-species Compatibility of Novel AAV-R2e-MAC to Cross Blood-brain Barrier and Transduce Myeloid Cells in the Central Nervous System

Xinxu Yuan[1], Danmeng Zhang[2], Ruotong Zhao[3], Grey Torre[4], Dabbu Jaijyan[1], Abdul Rasheed[1], Jian Xu[1], Yuekun Li[1], Xufeng Qu[1], Bing Wang[5], Fang Li[1], Hong Wang[3], Qizhao Wang[6], Jinze Liu[7], Binhua Ling[4], Wenhui Hu[1]*

Myeloid cells, including resident microglia and central nervous system (CNS)-associated macrophages, play crucial roles in both healthy and diseased conditions within the CNS. Gene therapy targeting myeloid cells holds significant promise for treating CNS diseases and injuries. Extensive research has identified AAV9, AAV8, and AAVrh10, along with their derivatives, as capable of crossing the blood-brain barrier (BBB) in both neonatal and adult animals. These serotypes, classified as AAV-B, are known for their high efficiency in transducing neurons, astrocytes, oligodendrocytes, and blood vessels. However, these serotypes exhibit limited or no ability to transduce brain myeloid cells in vivo. Conversely, several AAV serotypes, such as AAV1, AAV2, AAV5, and AAV6, have demonstrated potent tropism for myeloid cells (AAV-M). To develop novel AAV serotypes (AAV-BM) that combine the BBB-crossing ability of AAV-B with the myeloid cell transduction capability of AAV-M, we performed epitope insertional hybrid screening. This involved transferring a BBB-crossing epitope from AAV-B to the variable region VIII of the AAV-M capsid. Among the eight AAV-M serotypes validated in our preliminary studies, we selected AAV2 for initial screening due to its high transduction efficiency in human, monkey, and mouse primary microglia, well-documented study history, and natural binding to heparan sulfate proteoglycans (HSPGs) on many cell types. AAV-CAP-MAC, AAV-9P31, AAV-PhP.eB, AAV-cc47, AAV-CPP16, AAV-CPP21, AAV-Pal1, and AAV-MDV1A were chosen for the first trial due to their efficiency in crossing the BBB at relatively low dosages in multiple species. This trial identified R2-MAC as the primary AAV-BM, derived from AAV-CAP-MAC and natural AAV2. By introducing quadruple tyrosine-mutants (Y272F, Y444F, Y500F and Y737F) and one threonine mutant (T491V) to the R2-MAC capsid, we created an enhanced version, R2e-MAC, which showed higher transduction efficiency in cultured microglia. To test R2e-MAC, we packaged CMV-EGFP using the AAVone system and administered doses ranging from 1×10^{10} to 5×10^{12} genome copies (GC) per mouse intravenously (IV). R2e-MAC demonstrated dose-dependent BBB crossing and neural cell transduction across various mouse strains, including C57BL/6, BALB/c, and FVB/N. The capsid also proved effective in rhesus macaques (3×10^{13} GC/kg, IV) and human organoid BBB models. Both male and female C57BL/6 mice showed comparable transduction efficiency, while lipopolysaccharide (LPS) treatment robustly enhanced neural cell transduction. Bioinformatics analysis of single-cell RNA sequencing from fluorescence-activated cell sorting (FACS)-sorted EGFP-positive cells of the C57BL/6 mouse brains ($5x10^{12}$ GC, IV) revealed 30% myeloid cells, 64% endothelial cells, 3.9% astrocytes, 0.6% mature neurons, and 1.4% oligodendrocytes. Hybridization Chain Reaction RNA Fluorescence In Situ Hybridization (HCR-RNA-FISH) validated the transduction in TMEM119 and HexB-positive microglia. In conclusion, the hybrid AAV-R2e-MAC capsid outperforms the parent AAV-CAP-MAC in BBB crossing and AAV2 in myeloid cell transduction across different species, offering a potential gene therapy approach for CNS diseases and injuries.

1908 Efficient Neuronal Transduction of AAV2-derived CereAAV.YN Vector in Cynomolgus Macaque Brain without Liver Transduction by Systemic Injection.

Yoshinori Tanaka[1], Hiroaki Nariki[2], Nozomi Okuda[1], Ibuki Ueoka[3], **Sachiko Okamoto**[4], Tatsuji Enoki[1]
[1]Takara Bio Inc., Kusatsu, Shiga, Japan, [2]Takara Bio Inc., KUSATSU, SIGA, Japan, [3]Takara Bio Inc, Shiga, Japan, [4]Takara Bio Inc., Kusatsu, Shiga, Shiga, Japan

Recombinant adeno-associated virus vectors (AAVs) have been widely used as vehicles to deliver gene of interest for both research and therapeutic purposes. Zolgensma a treatment for spinal muscular atrophy, was approved by the US Food and Drug Administration and numerous pre-clinical and clinical studies have been conducted using AAV2 and AAV9 serotypes to target brain diseases via local and systemic administration. In particular, AAV9 have been frequently used for gene delivery into the brain including central nervous system (CNS), and several AAV9 derivatives such as AAV-PHP.eB, have been identified to transduce CNS efficiently. On the other hand, it has been reported that an AAV2 variant, designated AAV-BR1 efficiently transduced the Blood Brain Barrier (BBB) - associated endothelial cells by systemic administration. However, there is still no AAV2 variant reported to

transduce CNS across the BBB efficiently. To overcome the limitations of AAV2, we addressed to develop a novel brain-targeting AAV vectors based on AAV2 serotype. To date, we have developed AAV2 capsid mutant CereAAV.O, which has shown efficient gene transfer to the brain by intravenous administration in mice and non-human primate models. Furthermore, we have identified a novel CereAAV mutant (designated as CereAAV.YN) that significantly increases the transduction efficiency to the mouse brain compared to CereAAV.O and AAV9.

In this study, we have evaluated the gene transduction capability of CereAAV.YN vector in non-human primate model (Cynomolgus macaque). The CereAAV.YN vector carrying AcGFP gene as a reporter under the CAG promoter control was injected systemically into two male Cynomologus macaques at a dose of 1e13 vg/kg. After 28 days, various tissues were collected and the gene transduction was evaluated by immunofluorescence assay. As a result, significant AcGFP expression was observed in the brain, spinal cord and heart, but not in the liver. Furthermore, immunostaining analysis showed that CereAAV.YN vector was highly transduced into neurons in the monkey brain, but not into astrocyte, oligodendrocyte, or microglia, similar to previous study in a rodent model. The neuronal transduction of the CereAAV.YN vector in the cerebral cortex occurred in more than 70%-90% of neurons in the various region of the brain. Moreover, the AcGFP expression in the cerebral cortex was higher than in internal brain regions, such as the thalamus and putamen. We also evaluated the toxicity of the CereAAV.YN vector systemic injection. To this end, serum alanine aminotransferase (ALT) activity was measured as a marker of liver injury in this study. The ALT activity was transiently increased in response to AAV injection in both macaques on day 3 after injection, but decreased to normal level on day 7. In addition, the ALT activity was transiently elevated again on day 14 in only one macaque and then decreased to normal level on day 21. Finally, the serum ALT activity showed normal level on day28 in both macaques and liver abnormalities were not observed in necropsy samples. These results indicated that CereAAV.YN vector is a promising tool for both research and clinical studies targeting brain diseases without any liver failure. Currently, further studies are underway to reveal the mechanism of gene delivery across the blood brain barrier by CereAAV vectors.

1909 Fitness Maturation of STAC-BBB Yields Second-Generation Capsid Variants with Enhanced Delivery to the Central Nervous System

Engineered Adeno-associated virus (AAV) capsids that cross the blood-brain barrier (BBB) have the potential to enable transformative genomic medicines for a variety of neurological disorders. We previously described the identification and characterization of STAC-BBB, a blood-brain barrier penetrant AAV capsid that exhibits widespread neuronal transduction throughout the central nervous system (CNS) and is de-targeted from the liver following intravenous (IV) injection. Here we describe the fitness maturation of STAC-BBB and the identification of second-generation capsid variants with enhanced CNS delivery relative to STAC-BBB. We first generated barcoded capsid libraries that systematically explore the STAC-BBB sequence landscape. These libraries were administered intravenously to non-human primates and next-generation sequencing analysis was conducted to assess the relative level of neuronal and ubiquitous mRNA expression mediated by each capsid variant. Expression levels were analyzed in whole brain slices, punches from key CNS regions, spinal cord, dorsal root ganglia, and peripheral tissues. We additionally compared the level of barcoded mRNA expression versus DNA vector genome delivery within these tissues. Second-generation STAC-BBB variants were identified that exhibit enhanced delivery to CNS tissues, reduced off-target tissue biodistribution, and demonstrated the ability to engage both the non-human primate and human orthologs of the putative STAC-BBB receptor in vitro. In addition to second-generation capsids that exhibit higher neuronal expression compared to STAC-BBB, we also identified variants that exhibit an apparent shift in cellular tropism. These capsids exhibit much higher ubiquitous expression compared to neuronal expression throughout the CNS. The production yield in suspension HEK293 cells was also assessed in preparation for evaluation of individual capsids in vivo. These second-generation STAC-BBB variants have the potential to further improve CNS delivery after intravenous administration of genomic medicines for neurological disorders.

1910 Machine Learning-Driven Engineering of AAV Capsids for Enhanced Blood-Brain Barrier Penetration and Optimized Tissue Specificity

Adeno-associated viruses (AAVs) are widely utilized as gene therapy vectors due to their safety and long-term gene expression capabilities. However, optimizing AAV capsids for targeted tissue specificity while maintaining high manufacturability remains a key challenge. In this study, we applied machine learning-driven AAV engineering to develop novel AAV capsid variants with enhanced blood-brain barrier (BBB) penetration and improved off-target minimization.

The machine learning approach enabled us to collect high-quality data on packaging efficiency, which was then incorporated into the engineering process. The newly designed AAV variants demonstrated a remarkable increase in BBB penetration efficiency compared to AAV9, as confirmed through in vivo mouse experiments. Moreover, these optimized vectors exhibited excellent tissue specificity, with minimal to undetectable presence in non-target tissues, including the liver, heart, and peripheral nervous system. This specificity ensures a significantly reduced risk of off-target effects, making these AAVs highly suitable for neurological applications.By integrating machine learning-driven design with experimental validation, this study presents a scalable framework for developing next-generation AAV vectors with unparalleled BBB penetration, optimized tissue targeting, and high manufacturability. Our findings highlight the potential of ML-guided AAV capsid engineering to revolutionize gene therapy by overcoming existing delivery limitations and enhancing therapeutic efficacy.

1911 Machine-Learning for AAV9 Mutant-Capsid Screening for both Production and ALPL-Mediated Transduction Efficiency

Daniel Cox[1], Damien Maura[2], Jeron Chen[3], Mathieu Nonnenmacher[2]
[1]Voyager Therapeutics, Inc., Lexington, MA, [2]Voyager Therapeutics, Lexington, MA, [3]Voyager Therapeutics, Inc., Cambridge, MA

We recently identified AAV-capsid variants that show high CNS transduction in rodents and primates, relying on ALPL as their primary surface receptor for transport across the blood-brain barrier. These gene delivery vectors hold significant potential to treat a broad range of CNS disorders. However, their widespread application is constrained by the prevalence of anti-AAV antibodies in a fraction of the human population. This prompted us to further engineer our vectors by removing major antigenic sites on the capsid surface. In so doing, however, two potential problems arose. Data generated from random mutations in a highly constrained AAV9 antigenic area showed that less than 10% of variants assembled into capsids, and of these only a small fraction retained the capacity to infect ALPL-expressing cells in vitro. To mitigate these problems, we took a machine-learning-based (ML) approach. We developed ML models to discriminate between helpful and harmful mutations in terms of both capsid stability ($r = 0.95$) and ALPL-receptor engagement (AUC=0.99), and we then used these models to build a focused AAV capsid library pre-optimized for both capsid stability and ALPL-mediated transduction. Also, to spread the library as evenly as possible across the search space, a minimum hamming distance constraint was applied. The resulting library was then used in an in vivo screen to identify variants with increased antibody evasion. The ML-optimized capsid library, when tested in mice in the absence and presence of human intravenous immunoglobulin, yielded capsids with substantially improved both brain transduction and antibody evasion properties. Our data demonstrate that ML can be successfully used to pre-optimize capsid libraries to perform directed evolution of highly constrained capsid regions.

1912 Rapid Discovery of Novel AAV Capsids Using the BRAIN-X Insect Cell Library and Q-CAST

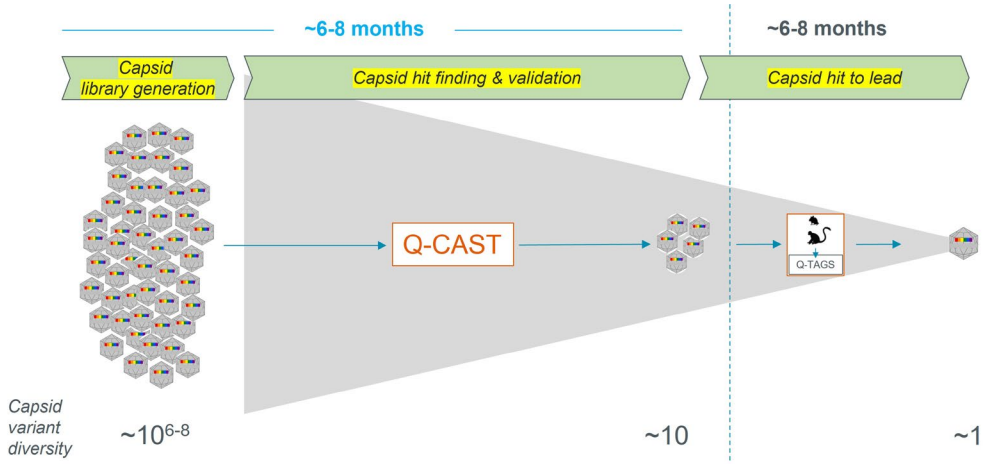
Capsid engineering is critical for advancing the efficacy of gene therapies by developing novel adeno-associated virus (AAV) capsids. Traditional capsid engineering methods, which rely on mammalian cells, face limitations such as cross-packaging artifacts and the high DNA input required per cell. Additionally, mammalian-derived AAV capsids often need further adaptation for efficient expression in insect cell-based production platforms.

To address these challenges, we present the *BRAIN-X capsid library*, a novel methodology leveraging insect cells. This approach significantly reduces the DNA requirement per cell while maintaining high AAV capsid library titers. Libraries generated with the proprietary BRAIN-X technology are deep, diverse, and exhibit minimal cross-packaging artifacts, enhancing the robustness and efficiency of capsid engineering efforts.

To accelerate the discovery of novel capsids, the BRAIN-X capsid library has been integrated with the *Q-CAST (Quick Capsid-library Assessment and Screening in Targeted-evolution)* platform. This combination facilitates the rapid identification of AAV capsids with the potential to cross the blood-brain barrier (BBB). In a short timeframe, multiple discovery campaigns utilizing this integrated platform have yielded several promising BBB-crossing capsid hits with putative consensus sequences.

This study underscores the transformative potential of the combined BRAIN-X and Q-CAST methodologies for rapid and cost-effective AAV capsid development. By significantly reducing costs and timelines, these innovative tools offer valuable advancements for gene therapy research and therapeutic applications.



1913 Enhancing AAV2 Capsid Engineering Through Co-Evolutionary Coupling and Predictive Modelling

Sirimar Laosinwattana[1], Paul Dalby*
[1]*University College London, LONDON, London, United Kingdom*
**Corresponding Author*

Adeno-associated virus (AAV) has emerged as a promising tool in gene therapy due to its safety, long-lasting transgene expression, ability to infect both dividing and non-dividing cells, and wide tissue targeting. Its success is reflected in the growing number of approved therapies and ongoing clinical trials. However, challenges including efficacy, stability and low yield still need to be addressed to improve AAV-based therapies.

Current methods for AAV engineering rely on directed evolution and rational design. Directed evolution involves creating a library and screening capsids for better traits. While effective, it is often inefficient because most single amino acid changes have no effect or are harmful, with only a small percentage showing improvements. Rational design aims to predict useful mutations based on protein structure and function, but it is limited by gaps in our understanding of how these changes affect AAV.

To tackle these issues, we are using a combined approach of co-evolutionary coupling and consensus-based design. Co-evolutionary coupling helps identify groups of amino acids that evolve together and are important for capsid properties. Replacing these residues with their most common natural versions (consensus residues) can reduce the risk of harmful changes. This method has been successfully used to improve enzyme stability and function, like in phytases and transketolase.

Two batches of AAV2 mutants were designed by identifying co-evolutionary coupling amino acids based on the VP1 and VP3. Those sites are substituted by their consensus and second consensus amino acids. We are applying this strategy to create and analyse 105 AAV2 mutants, aiming to design capsids with better infectivity, stability, and yield. The first screening was done using the crude lysate. The stability assay was carried out using heat shock at 60 degrees Celsius for 20 minutes. Based on the performance of the mutants compared to the wildtype AAV2, 21 mutants were selected for further analysis. These selected mutants were purified and placed in a formulation buffer for AAV2 for further testing. Consistency of their performance in the crude lysate compared to in the formulation buffer was tested.

The results were grouped into clusters to identify shared features that may contribute to their viability. Additional mutants will be designed and produced to validate these findings. Ultimately, the overall results will be used to train a model capable of predicting mutations that enhance capsid properties, facilitating the development of safer and more efficient gene therapy vectors.

1914 A Novel Conjugation Technology for Enhanced Specificity and Potency in AAV Gene Therapy

Adeno-associated virus (AAV)-based gene therapy has emerged as a powerful therapeutic modality for treating a range of genetic disorders. However, key challenges, including limited tissue specificity and suboptimal therapeutic potency, have led to toxicity and hinder its broad clinical application. To address these limitations, we have developed a novel technology that enables precise targeting of AAV vectors. By leveraging sortase enzyme-mediated conjugation, we can attach targeting moieties directly to the AAV capsid, enhancing its ability to engage specific human cellular receptors.

This modular AAV retargeting platform has shown compatibility with several serotypes and diverse targeting ligands. *In vitro* studies demonstrated that this approach significantly improves transduction specificity. Furthermore, *in vivo* evaluation leveraging receptor-mediated transcytosis with human transferrin receptor targeting groups revealed enhanced delivery to the central nervous system (CNS). Our platform achieved widespread distribution within the CNS, including deep brain structures, increased neurotropism, and effective liver detargeting.

Our findings suggest that this versatile and potent platform has strong potential to advance the development of AAV-based gene therapies, offering improved targeting specificity and therapeutic outcomes.

1915 The generation of a versatile AAV engineering platform via the separated capsid protein expression

Tristan Cai[1]*, Peng Zhang[2], Senle Rao[2]
[1]Changenic Biotech, Shanghai, China, China, [2]AAVAB Laboratory, Changenic.Biotechnology, Shanghai, SH, Shanghai, Shanghai, China

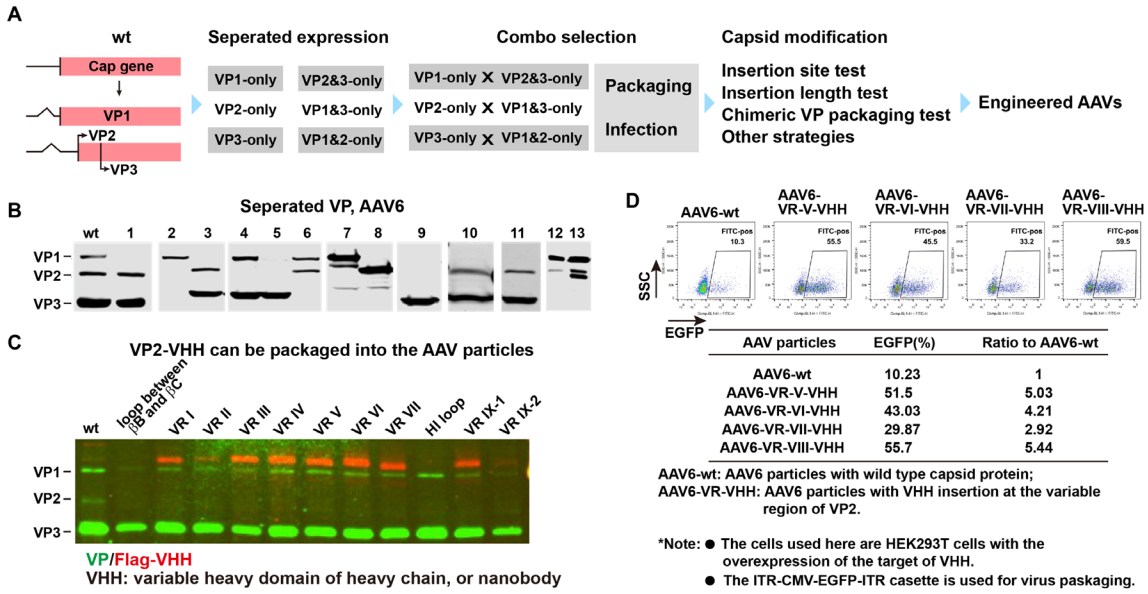
Adeno-associated virus (AAV)-based gene therapy offers great potential for treating genetic diseases by transferring the therapeutic genes toward proper organs or cells. However, the widely used AAV serotypes in AAV-based therapies face several drawbacks: the off-targeting effect and the pre-existing neutralizing AAV antibodies in patients. As a result, higher doses of AAV vectors are required to ensure efficient delivery of therapeutic genes, which not only raises safety concerns but also increases the cost of AAV-based therapies. The targeting efficacy and immunogenicity of AAVs are mediated by capsids, which are composed of three types of capsid proteins: VP1, VP2, and VP3. The three capsid proteins share a common C-terminus, and VP2 and VP3 can be regarded as the truncated forms of VP1 and VP2 respectively. The N- terminus of VP1 and VP2 offers them additional functions such as the infectivity. VP engineering is the promising approach to overcome the off-targeting and naturalization challenges of AAV vectors. However, the conventional engineering strategy changes all the capsids simultaneously for all three capsid proteins are coded by the same genes, which reduces the packaging or transduction efficacy. We hypothesize that selective engineering of specific capsid proteins—where only the necessary capsid protein(s) are modified, rather than all—might provide a viable solution to these problems. We designed the separated capsid protein expression plasmids to express individual or specific combinations of capsid proteins (VP1-only, VP2-only, VP3-only, VP1&2-only, VP2&3-only and VP1&3-only protein) for AAV2, AAV5, AAV6, AAV8, and AAV9 by combining start codon mutation, missense mutation, nonsense mutation, and independent expression with truncated coding sequences. By comparing the packaging and transfection efficacy of all combinations of plasmids, the combos with little reduced packaging and transfection efficacy were selected. Further, we tested the effect of protein (such as peptide, antibody or large binders) insertion on the AAV packaging in all the flexible loops located on the surface of AAV of each VP. Our data demonstrate that different VP tolerated distinct types of insertions in their flexible loops, which can be used for the rational design of AAVs with specific functions. The transfection efficacy was tested by inserting a variable heavy domain of heavy chain (VHH or nanobody) in the flexible loops of AAV6. All variable regions (VRs) are tolerant for VHH insertion, while VHH inserted into the loop between βB and βC or the H1 loop cannot be packaged into the AAV virion. The transfection efficacy of AAV6 with VHH inserted at the VR-V, VR-VI, VR-VII and VR-VIII in VP2 were tested, and VHH-coated AAV6 showed 2.9 to 5.5-fold enhanced transfection efficacy in antigen-expressed HEK293T cells than wild-type AAV6. In summary, we generated the versatile AAV engineering platform via the separated capsid expression for AAV2, AAV5, AAV6, AAV8, and AAV9 with the following advantages: 1, the possibility for the engineering of desired VP(s) without affecting other capsid proteins; 2, the capacity for packaging chimeric AAV particles with the VPs that have different modifications; 3, reduced packaging loss for AAVs using capsids with large protein insertions. This platform is expected to promote AAV engineering and facilitate the development of AAV-based therapies with enhanced safety and reduced costs.



AAV particles	EGFP(%)	Ratio to AAV6-wt
AAV6-wt	10.23	1
AAV6-VR-V-VHH	51.5	5.03
AAV6-VR-VI-VHH	43.03	4.21
AAV6-VR-VII-VHH	29.87	2.92
AAV6-VR-VIII-VHH	55.7	5.44

AAV6-wt: AAV6 particles with wild type capsid protein;
AAV6-VR-VHH: AAV6 particles with VHH insertion at the variable region of VP2.

*Note: ● The cells used here are HEK293T cells with the overexpression of the target of VHH.
● The ITR-CMV-EGFP-ITR casette is used for virus paskaging.

Figure legend:
A, the schematic diagram of the AAV engineering platform via the separated capsid expression. B, western blot analysis of VP expression in each plasmid. The AAV6 were used as an example. The number above each lane indicates the different format of seperated VPs. C, western blot analysis of the incorporation of VP2-VHH into the AAV particles. The sites in which the VHH inserted into VP2 are shown above each lane. D, flow cytometry analysis shows the enhanced infection of AAV6-VHH to HEK293T cells overexpressed with the target of VHH.

1916 Functional, Electrophysiological, and Histopathological Improvements in a Mouse model of CMT2A Following AAVrh74.tMCK.NT-3 Surrogate Gene Therapy

Introduction and Aim: Charcot–Marie–Tooth disease (CMT) is a group of heterogeneous inherited polyneuropathies. Mutations in Mitofusin 2 (MFN2) gene are associated with the most common axonal CMT subtype, CMT2A. Neurotrophin 3 (NT-3) is an autocrine factor supporting Schwann cell survival and differentiation and stimulates axon regeneration and myelination. NT-3 also has a role in the maintenance of neuromuscular junction (NMJ) integrity and mitochondria biogenesis. Previously, we showed the efficacy of AAV1.tMCK.NT-3 gene therapy via intramuscular (IM) delivery in mouse models for CMT1A, CMTX1, CMT2D and CMT4C. In this study, we assessed the efficacy of NT-3 gene therapy using the AAVrh74 serotype in the Mfn2+/− mouse model for CMT2A.

Methods: Eight-month-old Mfn2+/− mice received 3x1011 vg dose of AAVrh74.tMCK.NT-3 via IM injection (NT-3 cohort). Age- and sex-matched Mfn2+/− mice received Ringer's lactate as untreated (UT) controls (n=12 for both cohorts with equal sex distribution). Mice were sacrificed six months post gene delivery. Rotarod and grip strength functional tests and electrophysiological measurements were performed at baseline, four months post-treatment and endpoint. Peripheral nerves, skeletal muscles, and innervation status of NMJs were also assessed with quantitative histological experiments (NT-3, n=7; and UT, n=6 have reached endpoint).

Results: Rotarod and grip strength functional assays showed that NT-3 treated mice performed significantly better than the UT mice by 63.7% and 26.3%, respectively at endpoint (rotarod, NT-3: 27.29 ± 1.6 s vs UT: 16.67 ± 1.0 s, p=0.0002; grip strength, NT-3: 0.111 ± 0.01 vs UT: 0.088 ± 0.01, p=0.027). Compound muscle action potential (CMAP) tests indicated significantly higher values by 13.6% for the treated group at the endpoint (NT-3: 49.07 ± 4.35 vs UT: 43.20 ± 4.31 mV, p=0.033). Serum NT-3 levels detected by ELISA reached therapeutic levels in the

treated cohort (5.39 ± 0.37 ng/ml). We observed a significant increase in the percent of innervated NMJs in the treated mice compared to UT counterparts in the lumbrical muscles (NT-3: 57.58 ± 5.77% vs UT: 22.81 ± 5.76%, p=0.020). Quantitative histological analysis on gastrocnemius (GAS) and tibialis anterior (TA) muscles showed that fiber size distribution shifted significantly towards larger diameter subgroups following NT-3 gene therapy in both muscles analyzed. On the SDH-stained muscle sections of Mfn2+/− mice, we observed an increase in the fibers with abnormal mitochondria content and distribution. Our measurements in GAS and TA muscles showed that number of abnormal fibers significantly reduced in the NT-3 mice compared to UT counterparts, in both muscles (GAS, NT-3: 6.79 ± 1.04 number/mm2 vs UT: 21.41 ± 3.80 number/mm2, p=0.004; TA, NT-3: 5.57 ± 0.58 number/mm2 vs UT: 12.53 ± 1.68 number/mm2, p=0.003). We also observed a significant increase in the fiber size diameter of slow-twitch oxidative fibers in TA muscle from the NT-3 cohort (NT-3: 34.65 ± 1.80 μm vs UT: 28.73 ± 1.70 μm, p=0.038).

Conclusion: IM delivery of AAVrh74.tMCK.NT-3 to the Mfn2+/- mouse model for CMT2A resulted in therapeutic serum NT-3 levels and functional, electrophysiological, and histological improvements. With this study, we show that the AAV.NT-3 gene therapy is efficacious in a mouse model for another CMT subtype, providing further support for the translational application of this surrogate gene therapy approach to large groups of CMT patients.

1917 Targeting Oligodendrocytes in Neonatal Wildtype C57BL/6 Mice

Kristina Zhelcheska[1], Monica Gil-Garzon[1], Hester Wing Sum Chu[2], Viorica Chelban[3], Henry Houlden[3], Joanne Ng[4]
[1]University College London, LONDON, London, United Kingdom, [2]University College London, LONDON, Greater London, United Kingdom, [3]University College London, London, United Kingdom, [4]UCL Queen Square Institute of Neurology, London, Greater London, United Kingdom

Leukodystrophies are a heterogeneous group of rare, progressive genetic disorders primarily affecting the white matter of the central nervous system, with gene therapy emerging as a potential treatment avenue. To assess oligodendrocyte-specific transduction, we conducted a capsid comparison study testing two clinically applicable adeno-associated viral (AAV) capsids, AAV9 and Olig001. We expressed GFP under transcriptional control of CAG, a ubiquitous promoter. AAV9.CAG.GFP and Olig001.CAG.GFP were delivered at 1×10^{11} vg/ pup by intracerebroventricular (ICV) injection into neonatal P1 wildtype C57BL/6 mice. After 4 weeks, five brain regions of interest were collected- cortex, forebrain, midbrain, hindbrain and cerebellum- and were analysed for GFP expression by western blot, quantitative PCR (qPCR), and immunohistochemistry. Western blotting confirmed expression throughout the brain with both capsids with regional differences. AAV9 expressed significantly higher in the cortex, whilst Olig001 expression was highest in the hindbrain and cerebellum. The GFP immunohistochemistry of sagittal brain sections showed widespread brain transduction achieved by both capsids with mixed cell type transduction. The morphology of GFP+ cells revealed that AAV9 is predominantly neuronal, whereas Olig001 exhibits a more mixed neuronal and glial morphology. The % GFP+ cells that were Olig2+ in the corpus callosum was higher in Olig001 (71.43%) compared to AAV9 (59.46%), reflecting increased oligodendrocyte targeting. Future studies to increase oligodendrocyte targeting include using a selective promoter and Olig001 capsid towards leukodystrophy gene therapy application.

1918 Human Frataxin Gene Transfer to the Cerebellar Dentate Nucleus Improves Motor Coordination in a Mouse Model of Friedreich Ataxia

Raj Putatunda[1], Joshua C. Chang[2], Tyler Holt[2], Reca Caballero[2], Kathy Lam[2], Hunter Alves[2], Whitney Blankenberger[2], Joan Bunyi[3], Pooja Bhardwaj[2], Norimasa Jinno[2], Vincent Leonard[2], Eiji Yoshimi[2], Megumi Adachi[2], Carlos Fonck[4]
[1]Astellas Gene Therapies, Redwood City, CA, [2]Astellas Gene Therapies, South San Francisco, CA, [3]Astellas Gene Therapies, South San Francisco, [4]Astellas Gene Therapies

Friedreich ataxia (FA) is a multisystemic genetic disorder that stems from a trinucleotide GAA repeat expansion in the first intron of the frataxin (*FXN*) gene, which results in transcriptional silencing and subsequent loss of function of the frataxin protein. This decreased frataxin expression results in a wide array of clinical symptoms that includes,

but it is not limited to, peripheral neuropathy, proprioceptive abnormalities, dysarthria, diabetes, hypertrophic cardiomyopathy, and most notably ataxia. Specifically, the ataxia that manifests in FA patients is thought to, at least in part, stem from the degeneration and loss of large principal excitatory neurons in the cerebellar dentate nucleus (DN). As such, we hypothesized that restoring frataxin expression in the DN by direct intraparenchymal injection can slow/reverse disease progression in a mouse model of FA neuropathology. Specifically, the PV-Cre::$FXN^{flox/null}$ (FA-PV) mouse model was utilized for these studies. These mice were genetically engineered to fully knock out *FXN* in parvalbumin-expressing neurons, while all other neuronal subsets express heterozygous levels of *FXN*. While these mice genotypically differ from patients with FA, which suffer from a global *FXN* knockdown in all cells, they recapitulate some aspects of the ataxic phenotype that is observed in patients. Our therapeutic approach consisted of designing an AAVrh10-serotyped vector that expresses the human *FXN* gene (*hFXN*) under the control of the SYN1 promoter, which would preferentially restrict vector expression to neurons (AAVrh10-SYN1-hFXN). A concentration-dependent increase in frataxin protein expression was confirmed in SK-N-SH cells. To assess the functional efficacy of our vector after cerebellar intraparenchymal injections, rotarod testing, parallel bar floor grid tests, beam walk assessments, and automated gait evaluations were performed at 11-12 weeks post-dosing. At 12-weeks post-dosing, FA-PV mice treated with 3.0E+8 and 1.0E+9 vector genomes (vg)/brain showed a significant improvement in rotarod performance over mice that were only treated with vehicle ($p = 0.015$ and $p = 0.037$). Additionally, at 11-weeks of age, FA-PV mice treated with 1.0E+9 vg/brain had decreased ataxia ratios compared to vehicle-treated FA-PV mice ($p = 0.011$). Altogether, for the first time, we demonstrated that direct targeting of the DN slows disease progression in FA-PV mice. This study highlights the importance of the DN in FA disease progression, and how restoration of *FXN* expression in that brain region can potentially modify the disease.

1919 Comparative analysis of cell-specific promoters in AAV9-mediated gene therapy targeting the central nervous system.

Sergiy Chornyy[1], Jessica Herstine[2], Caleb Holaway[3], Abigail Biddle[2], Tatyana Vetter[2], Shibi Likhite[2], Nettie Pyne[2], Allison Bradbury[4]
[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Abigail Wexner Research Institute at Nationwide Children's Hospital, [4]Nationwide Children's Hospital, Columbus, Ohio

Advancements in adeno-associated virus (AAV)-mediated gene therapy have highlighted the need for precise transgene expression to maximize therapeutic efficacy while minimizing off-target effects. In this study, we systematically evaluated a panel of ubiquitous and cell-specific promoters delivered via single-stranded AAV9 (ssAAV9) vectors to achieve targeted enhanced green fluorescent protein (eGFP) expression across the mouse central nervous system (CNS). Our findings provide critical insights into promoter-driven gene expression patterns, aiding the development of refined strategies for neurological gene therapy applications. Ubiquitous promoters, such as the full-length cytomegalovirus major immediate-early enhancer combined with the chicken beta-actin promoter (CAG), demonstrated extensive eGFP expression across multiple brain regions and various neural cell types, reinforcing their suitability for applications requiring widespread transgene distribution. However, the use of cell-specific promoters allowed for more precise targeting, which is essential for reducing potential off-target effects and optimizing therapeutic impact. Astrocyte-specific promoters, particularly variants of Glial Fibrillary Acidic Protein (GFAP), exhibited distinct expression patterns. The novel gfaABCD1405 (gfa1405) promoter and the gfaABC(1)D variant both yielded robust astrocyte-selective expression, with notable localization in the neocortex and hippocampus. Our comparative analysis suggests that gfa1405 provides superior transduction efficiency while maintaining stringent astrocyte specificity, offering an improved tool for astrocyte-targeted therapies. Neuronal targeting was achieved using a truncated Mecp2 promoter (p546), which demonstrated high specificity for neuronal populations within the neocortex and hippocampus. The distinct spatial expression pattern of p546, with strong neuronal soma labeling and detectable signals in neuronal projections, underscores its potential for therapeutic strategies addressing neuronal dysfunction in CNS disorders. Oligodendrocyte-specific promoters, including myelin-associated glycoprotein (MAG) and 2',3'-cyclic nucleotide 3'-phosphodiesterase (CNP), produced unique distribution profiles. While MAG-driven eGFP expression was largely restricted to the corpus callosum, CNP-mediated expression extended across a broader range, suggesting differential utility for targeting oligodendrocyte-related pathologies. These findings emphasize the need for precise promoter selection based on disease-specific targeting requirements. Our study provides a comprehensive evaluation of AAV9-delivered promoters and highlights their potential for achieving targeted gene expression in distinct CNS cell populations. These insights

pave the way for more refined gene therapy approaches aimed at treating neurodevelopmental and neurodegenerative disorders. By reducing off-target expression and enhancing therapeutic specificity, promoter optimization plays a crucial role in advancing clinical translation of gene therapy strategies. Future research will focus on refining these promoter-driven vectors, expanding their applicability across various CNS disease models, and integrating them into preclinical and translational pipelines.

1920 Targeting misfolded mutant HTT protein with vectorized antibodies for the treatment of Huntington Disease

Marina Sogorb-Gonzalez[1], Wouter Pos[2], Florence Wavreil[3], Yuanyun Xie[4], Ines Brás[4], **Andreia Duarte[5]**, Sabine Schipper-Krom[3], Eric Reits[3], AMBER SOUTHWELL[4], Sander Van Deventer[6]
[1]VectorY, Amsterdam, Noord-Holland, Netherlands, [2]VectorY Therapeutics, Amsterdam, The Netherlands, Netherlands, [3]Amsterdam UMC, Amsterdam, Netherlands, [4]University of Central Florida, Orlando, FL, [5]VectorY Therapeutics, Amsterdam, Noord-Holland, Netherlands, [6]Amsterdam, Netherlands

Protein misfolding is a pathogenic feature of multiple neurodegenerative diseases, including Huntington Disease (HD). As the pathogenic mechanisms usually include both a loss of function and a gain of toxicity by misfolded and aggregated proteins, strategies are required to specifically target the toxic protein species whilst preserving the function of the native monomers.

In HD, the CAG repeat expansion in the Huntingtin (HTT) gene results in the translation of a mutant protein with an expansion of glutamines (polyQ). In neuronal cells, the mutant HTT protein forms soluble oligomers and insoluble inclusions which induce toxicity and ultimately cell death.

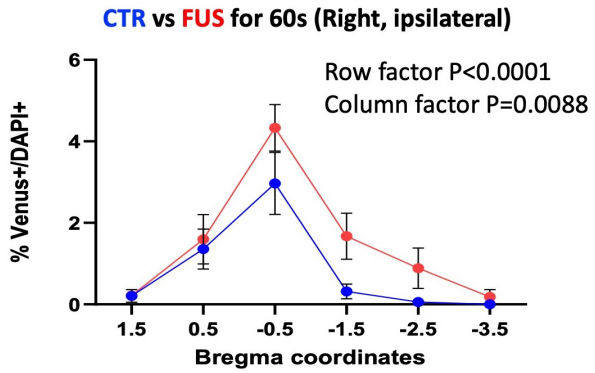
VectorY has developed vectorized antibodies, called VecTabs®, to target and reduce mutant HTT protein species. We screened and identified intracellularly expressed VecTab candidates that reduce mutant HTT protein aggregates in different in *vitro* models. Moreover, VecTabs delivered by adeno-associated virus (AAV), were also tested in a mouse model of HD, resulting in the reduction of mutant HTT protein aggregates in the striatum.

Our data support the further development of a gene therapy for the treatment of HD. In addition, this concept forms the basis of similar approaches in other neurodegenerative diseases caused by the formation of misfolded protein aggregates that cause cellular toxicity.

1921 Focused ultrasounds enhance efficacy of AAV transduction via intracerebroventricular administration in mice

Ken Inoue[1]*, Alessandro Zappala[1], Heng Li[2]
[1]National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan, [2]National Institute of Neuroscience, Kodaira, Tokyo, Japan
**Corresponding Author*

Systemic delivery of AAV vectors targeting the central nervous system has the potential to solve many neurodevelopmental disorders, yet it is made difficult by the filtering effect of the blood-brain barrier and systemic complications. To overcome this limitation, we attempted to inject a Venus-expressing, oligodendrocyte-targeting AAV9 viral vector in the ventricles together with lipid microbubbles and subjected them to focused ultrasound; the resulting mechanical stimulation on the brain ventricles presumably opens small, temporary gaps from which vector particles can leak and spread. Our findings indicate that focused ultrasound can increase viral vector diffusion across both the anteroposterior and left-right axes without influencing cell tropism; significant effects were found with 60 and 90 seconds exposure time, but no effects were observed with longer intervals. Taken together, these results highlight a new strategy for the safe and effective delivery of viral vectors, and offer new perspectives for the development and application of gene therapies for central nervous system diseases.



1922 Comparative Evaluation of Intranasal and Intravenous AAV Delivery for Safe and Targeted CNS Gene Therapy

Chinwendu Chukwu[1]*, Jinyun Yuan[2], Hong Chen[3]*
[1]*Washington University in St. Louis, Saint Louis, MO,* [2]*Washington University School of Medicine, Saint Louis, MO,* [3]*Washington University in St.Louis, Saint Louis, MO*

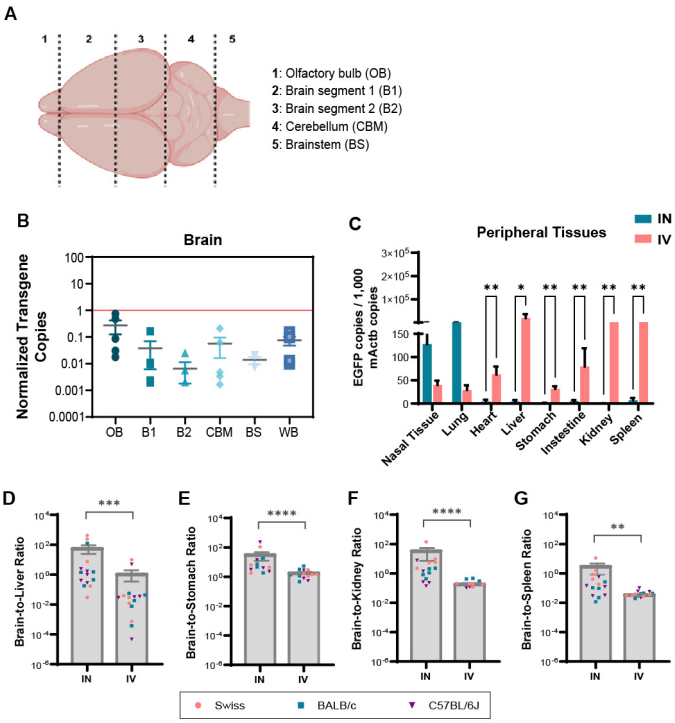
Introduction: Adeno-associated viruses (AAVs) hold significant promise for gene therapy targeting the central nervous system (CNS). However, current delivery methods are limited by their associated procedural risks and off-target effects. Intranasal (IN) delivery offers a transformative, noninvasive alternative by bypassing the blood-brain barrier (BBB) while minimizing systemic exposure. This study systematically evaluates the delivery efficiency and biodistribution of AAV in the brain and peripheral organs following IN administration, assessing its potential for safe and targeted delivery to the CNS compared to the conventional intravenous (IV) route.

Methods: AAV encoding the enhanced green fluorescence protein (EGFP) reporter gene was administered intranasally or intravenously to Swiss, BALB/c, and C57BL/6J mice, enabling evaluation across diverse genetic backgrounds to account for biological variability. Brain and peripheral tissues were collected four weeks post-delivery, and quantification of transgene copies and protein expression levels was performed using droplet digital PCR (ddPCR) and ELISA, respectively.

Results: IN delivery resulted in localized brain transduction, predominantly in the olfactory bulb, while IV injection led to widespread transduction across the brain. Although IN delivery achieved lower overall transgene expression and EGFP protein levels in the brain—approximately 15% and 9% of levels observed with IV injection, respectively—IN delivery significantly reduced systemic exposure, up to 1.3×10^4-fold, in peripheral organs compared to IV injection. Furthermore, IN delivery demonstrated superior brain-to-peripheral transduction ratios for major peripheral organs, including the liver, kidney, spleen, and stomach, highlighting its potential to reduce systemic impact.

Conclusion: These findings suggest that IN delivery offers a viable, noninvasive approach for brain-targeted gene delivery, offering minimized off-target exposure—a critical factor for improving the safety of CNS-targeted therapies.



(A) Schematic illustrating the mouse brain dissection method used to evaluate AAV biodistribution. **(B)** Brain-targeting efficiency of intranasal (IN) AAV delivery relative to intravenous (IV) delivery (red horizontal line) in Swiss mouse brain segments. **(C)** EGFP transgene levels in peripheral tissues of Swiss mice following IN (blue) and IV (red) AAV delivery. **(D-G)** Brain-to-peripheral transgene ratios for the liver (D), stomach (E), kidney (F), and spleen (G), pooled across all tested mouse strains.

1923 Preclinical development of AAV mediated gene editing for SOD1-ALS using a Type V CRISPR-Cas enzyme

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease leading to paralysis and death typically 3-5 years post disease onset. Missense mutations in superoxide dismutase 1 (SOD1) gene cause ALS via a toxic gain of function of SOD1 protein. QALSODY, a clinically validated antisense oligonucleotide dosed once a month via intrathecal injections, is approved for use in SOD1-ALS patients in the US and EU. By lowering SOD1 mRNA, QALSODY reduces protein levels leading to a ~55% decrease in neurofilament-light chain, a marker for neurodegeneration in ALS patients. These results validate the lowering of SOD1 as an attractive target for ALS treatment. In this study, we describe the preclinical development of a one-time treatment for SOD1-ALS by using an AAV vector to carry our proprietary Type V CRISPR enzyme to target the SOD1 gene and efficiently lower SOD1 protein levels.

Large indels (~10bp) generated by Type V enzymes (nucleases) favor targeting across the entire gene to destabilize the protein compared with Type II enzymes that generate small indels and may not lower protein abundance. Using bioinformatics and HEK293T cells, we initially screened ~250 different combinations of guides and nucleases to identify a stratified pool that provides substantial editing. Top nuclease-guide combinations were packaged into AAV and tested in human motor neurons, the primary disease affected cell type. Here, we observed up to 95% indels and subsequently up to a 90% reduction of SOD1 protein with various guides along with a longitudinal

increase in indel formation and subsequent protein reduction. Based on these data, we built our AAV construct comprised of 1) a Pol II promoter driving expression of the Type V nuclease in both neurons and astrocytes, cell types with SOD1 aggregates in patients; 2) a Pol III promoter driving expression of the guide RNA and 3) regulatory elements for spatial control of nuclease expression. Our top five constructs were tested in the high-copy hG93A-BAC mouse model (the gold standard for SOD1-ALS *in vivo* pharmacology) and demonstrated indel formation and subsequent significant lowering of SOD1 protein. In addition, we also evaluated the efficacy of the guides in rescuing survival and grip strength in the transgenic mice and selected our lead guides. Based on preclinical efficacy of the guides lowering SOD1 protein, we also performed rhAMP Seq analysis to assay any off-targets predicted in silico. Three guides demonstrated low off-target liability. Overall, these findings strongly support the continued development of Type V CRISPR-Cas enzymes for the potential treatment of CNS diseases.

1924 Preclinical Mouse Pharmacology Studies Evaluating the Biodistribution and Pharmacodynamics of LTS-101, a Novel Gene Therapy Candidate for CLN2 Batten Disease

Katherine Villa[1], Luis Tecedor[2], David Leib[3], Paul Ranum[3], Yonghong Chen[2], George Yohrling[5], Beverly Davidson[2], Jang-Ho Cha[6]
[1]Latus Bio, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Latus Bio, Inc, Philadelphia, PA [5]Latus Bio, Princeton, NJ, [6]Latus Biosciences, Arlington, MA

Introduction: Latus Bio, Inc. is developing LTS-101, a gene therapy for the treatment of neuronal ceroid lipofuscinosis Type 2 (CLN2), a form of Batten disease caused by deficiency in the tripeptidyl peptidase 1 (TPP1) protein, which causes lysosomal dysfunction and neurodegeneration. LTS-101 is an intracerebroventricular (ICV)-delivered gene therapy utilizing a novel capsid, AAV-Ep+, engineered to express the *hTPP1* transgene. AAV-Ep+ transduces ependymal cells lining the cerebral ventricles, resulting in secretion of human TPP1 into the CSF. AAV-Ep+ was identified by a capsid screening campaign in multiple non-human primate (NHP) species as a potent transducer of ependymal cells and neurons. Studies were conducted wherein LTS-101 was introduced ICV to a mouse model of CLN2 disease to evaluate vector biodistribution, TPP1 production and biodistribution, and efficacy in alleviating well-characterized phenotypes such as tremor, reduced survival, and the accumulation of the pharmacodynamic marker of lysosomal dysfunction, lipofuscin. This work identified doses whereby transgene expression was robust within target CNS regions, with resultant decreased lipofuscin accumulation, increased survival, and decreased tremor. Notably, there was minimal biodistribution in peripheral tissues.

Results: LTS-101 was administered ICV at four doses to $CLN2^{-/-}$ mice to identify a minimally efficacious dose. Bilateral ICV administration of LTS-101 demonstrated high transduction in the brain, therapeutic expression levels of TPP1, and pharmacodynamic activity of the transgene. LTS-101 was distributed broadly throughout the brain, with 1-10 vg/dg at the high dose, and low levels in peripheral tissues such as the heart and liver, with <0.01 vg/dg. The hTPP1 protein produced by LTS-101 was catalytically active in brain tissues and reduced lipofuscin accumulation by approximately 50% in hippocampus and somatosensory cortex. LTS-101 treatment also decreased tremor amplitudes by 68% and prolonged average lifespan by 20%.

Conclusion: Preclinical studies in $CLN2^{-/-}$ mice dosed with LTS-101 provide proof-of-concept data in support of a potential therapeutic candidate for CLN2 disease. Definitive mouse pharmacology and NHP GLP toxicology studies are ongoing. LTS-101 is a promising gene therapy candidate with the potential to treat CLN2 Batten disease patients with a one-time ICV administration providing stable, long-term expression of TPP1 for broad distribution throughout the CNS.

1925 Developing an AAV-based Gene Therapy for Chronic Pain Through Identification of Potent and Selective Artificial miRNA Candidates to Knockdown *SCN9A*

Chao Tai[1]*, Szu-Ying Chen[2], Yosr Bouhlal[2], John McLaughlin[2], Rangoli Aeran[1], Pingping Jia[1], Sheila Sears[1], Peter Bove[1], Veda Tatavarty[1], Nehemiya Feleke[2], Ming Chen[1], Dixon Hoffelt[1], Jason Le[1], Keith Place[2], Sammy Liang[1], Keiko Takahashi[3], Mark Elegue[2], Kristen Valentine[1], Myat Soe[1], Ricky Thu[2], Warren Macdonald[2], Juan Reza[1], Greg

Lucey[1], Camille Artur[2], Elizabeth Hallam[1], Winnie Lin[3], Puja Dhanota[1], Serena Liu[1], Alex Diaz de Arce[2], Sirika Pillay[1], Annie Tanenhaus[1], Raghavendra Hosur[1], Archana Belle[3], Suresh Poda[2], Stephanie Tagliatela[3]

Chronic pain impacts millions of people globally, with many types resulting from the aberrant firing of nociceptive sensory neurons. *SCN9A* encodes the voltage-gated sodium channel $Na_V1.7$, a critical mediator of pain signaling within the peripheral nervous system. Variants in *SCN9A*—resulting in either loss-of-function (LOF) or gain-of-function (GOF)—are directly linked to pain insensitivity or hypersensitivity in known genetic disorders. However, small molecule inhibitors targeting $Na_V1.7$ have faced clinical setbacks due to issues with selectivity (especially the potential for off-target effects on other Na_V channels, such as $Na_V1.5$), inadequate target engagement, and dose-limiting adverse events. To overcome these challenges, we hypothesized that blocking $Na_V1.7$ signaling via a robust and selective AAV-mediated mRNA knockdown approach would result in long-term reduction in pain following a single intrathecal (IT) administration. Using Encoded's vector engineering platform, we developed vectorized miRNA candidates with optimized potency and selectivity. In vitro screening in HEK293 cells and iPSC-derived neurons identified several miRNA candidates capable of potently and selectively knocking down *SCN9A* without affecting other Na_V channels. Whole transcriptomic RNA sequencing further demonstrated a minimal off-target profile for these candidates. Top candidates were validated in rodent models. IT delivery of lead candidates to post-natal day 1 (P1) mouse pups resulted in potent (up to 95%) and dose-dependent knockdown of *Scn9a* mRNA and $Na_V1.7$ protein in the dorsal root ganglia (DRG). Furthermore, when delivered IT to adult rats, the top candidates successfully rescued mechanical and thermal allodynia induced by spared nerve injury (SNI), with the rescue sustained for over 8 weeks post-dosing. Taken together, these results highlight the potential of a vectorized miRNA-based approach as a highly selective and durable strategy for knocking down *SCN9A*. By addressing the limitations of small molecule, this gene therapy approach represents a promising non-opioid strategy for treating chronic pain conditions.

1926 Gene Therapy for ZNF526 Deficiency Using Endogenous Regulatory Elements

Yasemin ÖZGÜR GÜNES[1], Peiyi Guo[1], Anoushka Lotun[1], Morgan Mooney[1], Dominic Gessler[1]*, Guangping Gao[1]*

Neurodevelopmental disorders (NDDs), including autism, attention-deficit/hyperactivity disorder (ADHD), and intellectual disabilities (IDs), are lifelong conditions that disrupt brain development and function. One of the key mechanisms involved in the control of developmental processes is transcriptional regulation of gene expression. Through the activation and repression of target genes, transcription factors (TFs) determine cell fate and orchestrate development at the tissue, organ, and organismal levels. Among the numerous TF families, zinc finger proteins (ZNFs) are particularly notable. Over the past few years, numerous pathogenic variants in zinc finger proteins have been identified in individuals with intellectual disability (ID). The current lack of understanding the disease pathomechanism, coupled with the absence of animal models that accurately recapitulate human disease phenotypes, presents a significant challenge.

ZNF526 deficiency (OMIM: 614387), a severe NDD caused by autosomal recessive frameshift variants in the ZNF526 gene, which encodes a ubiquitous C_2H_2-ZNF protein. This condition is characterized by prenatal-onset microcephaly, developmental delay, bilateral cataracts, hypertonic-dystonic movements, profound psychomotor delay, severe intellectual disability, epilepsy, simplified gyration, and thinning of the corpus callosum. Currently, there is no cure for ZNF526 deficiency. However, rAAV-directed gene therapy holds promise as a potential treatment option Here, ZNF526 deficiency will serve as a powerful tool to evaluate potential therapeutic strategies and unravel the cellular and molecular mechanisms underlying ZNF-related NDDs. One of the key hurdles in developing rAAV-based gene therapies for central nervous system (CNS) disorders is minimizing off-target effects and their associated toxicity. To address this, our goal is to develop a rAAV9-mediated ZNF526 gene replacement therapy regulated by the endogenous ZNF526 gene regulatory elements to precisely control transcription, ensuring physiologically relevant gene expression and regulation for therapeutic applications. We designed four distinct

regulatory cassettes, each containing specific ZNF526 promoter-derived elements driving green fluorescent protein (GFP) expression and evaluated their functionality *in vitro* using human embryonic kidney cells (HEK293), alongside the well-known ubiquitous CB6 promoter as a reference for comparison. We determined that each regulatory cassette expressed varying degrees of GFP. Our results indicate that regulatory elements within the ZNF526 promoter play a critical role in modulating gene expression. These constructs are currently under *in vivo* evaluation using rAAV9 at postnatal day (P)1 and P10.

The use of these regulatory cassettes and dual-injection timepoints will enable the evaluation of spatiotemporal gene expression. Furthermore, this approach will allow for a comparative analysis of ubiquitous versus targeted gene expression, providing valuable insights for optimizing ZNF526 gene therapy.

1927 A codon-optimised human sequence of human *MC4R* regulates cAMP levels and normalise weight in *Mc4r* mutant obese males and females when delivered with as a self-complementary AAV9 (scAAV9) with an intracerebroventricular delivery.

Victor Hernandez[1], Rakhi Kesavan Nair Rema[2], Elisa Cuevas[3], Gabriela Carreno[3], Marian Seda, Phil Beales[4], Jeshmi Jeyabalan Srikaran[2], Natalie Northcott[5]
[1]Axovia Therapeutics Inc, London, Greater London, United Kingdom, [2]Axovia Therapeutics Ltd, London, London, United Kingdom, [3]Axovia Therapeutics Inc, London, United Kingdom, [4]Axovia Therapeutics Ltd, London, United Kingdom, [5]Axovia Therapeutics Ltd, London, Greater London, United Kingdom

Melanocortin 4 receptor (*MC4R*) mutations are the most common cause of human monogenic obesity. Patients with MC4R mutations suffer from hyperphagia, severe obesity and hyperinsulinemia. Impact of the different type of MC4R mutation depends on how they reduce MC4R expression and the impact they have on the production of cyclic AMP (cAMP). Mutations in heterozygosity, with partial MC4R functionality are the most frequent, but homozygous mutations and double heterozygous account for 25% of MC4R mutations. There are approximately 50,000 patients with complete *MC4R* loss of function (LoF) and BMI>40 in the United States, European Union and Middle East. Mouse Mc4r have a slightly different sensitivity than the human MC4R, but all null-Mc4r mouse lines recapitulate the most severe human phenotype.

Here we developed a series of new codon-optimised constructs of the human MC4R. We aimed to develop new Adeno-associated vectors (AAV) vectors, therefore we cloned our new constructs to express the transgene as a single strand (ssDNA) or a self-complementary (scDNA) DNAs once packaged into the AAVs. All constructs were under the regulation of the CAG promoter. We tested expression after transfection in human derived HEK293T cells and saw that the codon-optimised self-complementary sequences were able to express the *MC4R* transgene activity more than 5 times more than the wild-type sequences. After packaging the expression ability of the codon-optimised MC4R construct, HEK293 transductions, the AAV9-CAG-hCOMC4R vectors resulted in the high stable upregulation of hMC4R transgene at mRNA and protein levels compared with the AAV9-CAG-hWTMC4R wild-type and single-strand sequences, from the relative 1644 fold change to AAV9-CAG-hCOMC4R to $1.8x10^8$ fold change of the codon optimised AAV9-CAG-hCOMC4RGA. MC4R protein levels were also increased in the all our constructs . We then tested the ability the transgene to regulate levels of cAMP levels after *in vitro* transduction. We observed a clear dose response of the cAMP activation with all constructs indicating a functional MC4R.

To test *in vivo* efficacy, we prepared AAV2 and AAV9 vectors with our the best scAAV MC4R sequence, with better expression and cAMP activity. We dosed *Mc4r*^{tm1Lowl} mutant mice (Jax lab strain B6.129S4-*Mc4r*$^{tm1Lowl/J}$, Strain #032518) and wild-type, males and females, at P7 after birth with a single intracerebroventricular dose of $1x10^{13}$ viral genomes and followed their weight gain. *Mc4r* mutant treated mice followed normal weight gain pattern till week 7 when then, instead to become obese as their littermates, they followed the same weight gain pattern than the WT untreated mice and never become obese. *Mc4r* mutant female treated with AAV9.COMC4R also followed the same WT trend but with a higher variability. WT treated with AAV9.COMC4R or all vehicle (PBS) treated controls (WT or *Mc4r*) had the same pattern than untreated controls. Surprisingly when the same dosing was repeated with an AAV2 capsid no recue of the phenotype was observed (Figure 1).

In summary, we describe here a new human sequence and AAV9 vector (we called AXV-201) that can rescue the weight gain phenotype and could prove to be a powerful treatment for MC4R patients with severe obesity and very high BMIs.

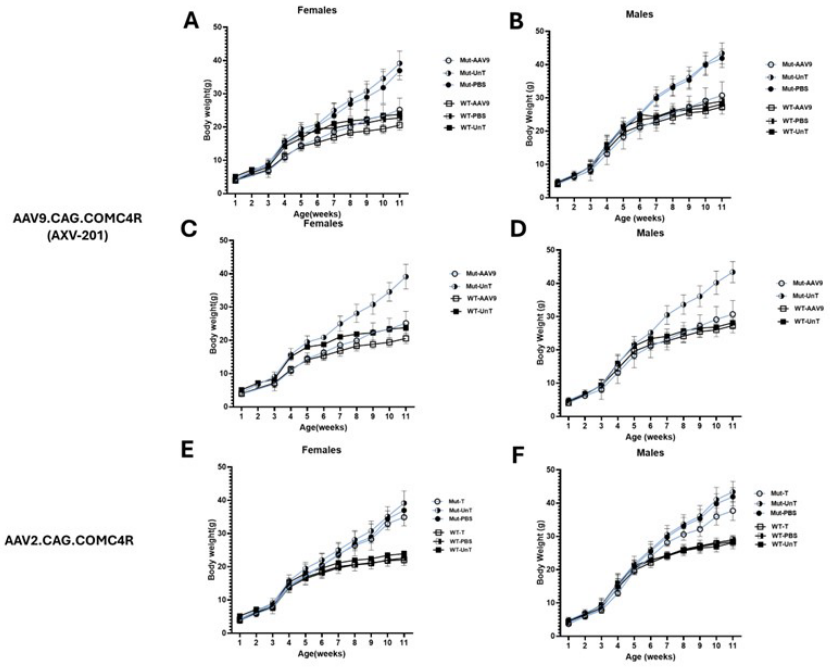

Figure 2. Dosing of Mc4R mutant mice **A-D** AAV9.CAG.COMC4R (AXV-201) completely normalise the weight gain in male and females **E-F**. The same self complementary codon optimised construct (CAG.COMC4R) failed to rescue the mc4r phenotype when delivered in AAV2 capsid.

1928 Ongoing Preclinical Study of an AAV vaccine in Spontaneous Canine Model of Oral Melanoma: Safety and Efficacy Evaluation

Federica Ghersa[1], Ester Molina[2], Caitlin Yung[3], Colin Caine[4], Hisae Kuoch[5], Karina Krotova[6], Antonella Borgatti[7], George Aslanidi[8]

[1]University of Minnesota Twin Cities, Austin, MN, [2]The Hormel Institute, [3]University of Minnesota Collage of Veterinary Medicine, Minneapolis, MN, [4]Austin, MN, [5]Hormel Institute University of Minnesota, Austin, MN, [6]Regents of the University of Minnesota, [7]University of Minnesota Twin Cities, [8]University of Minnesota, Austin, MN

Companion dogs can spontaneously develop oral melanoma (OM), an aggressive cancer that begins in the mouth's mucosal tissue coursing with metastasis in distant organs. OM is treated through surgical removal of tumor followed by intense radiotherapy mirroring human melanoma onset and treatments. This makes OM diagnosed dogs a great preclinical model to test our multivalent optimized AAV6 anti-melanoma vaccine. This vaccine is composed by a mutated AAV6-S663V to prolong the vectors lifespan by avoiding proteolytic degradation in target cells, ensuring delivery of optimized expression cassette and eliciting the corresponding immune response. Briefly, our AAV6 vaccine is obtained through a step gradient protocol using anion exchange chromatography (HiTrap Q HP column) after iodixanol gradient centrifugation of virus from HEK293 triple transfected cells. Chromatography fractions corresponding to UV detection peak are analyzed by qPCR to evaluate vg titers. After, $1x10^{12}$vg or $3x10^{12}$vg of each antigen are used to create a triple-valent vaccine of low or high dose respectively, that delivers 3 known melanoma antigens, glycoprotein 100 (Gp100), tyrosinase (Tyr) and tyrosinase related protein 1 (TRP-1). Previous work has proven the vaccines effectiveness in melanoma mouse models, effectively promoting protection against lung metastasis. The ongoing preclinical trial for this multivalent AAV vaccine against oral melanoma is reaching 3.5

years. To date, 9 dogs with I-III stage OM have been administered the vaccine, 5 males and 4 females ranging between 6.5 and 14.3 years of age. 6 animals received a $3x10^{12}$ vg/ dog dose while 3 animals received $9x10^{12}$ vg/ dog dose. These animals are followed for up to 9 months to evaluate blood, liver and renal function parameters to determine safety and efficacy of vaccine. Prior to vaccine administration, preexisting neutralizing antibodies (NAb) against AAV6 capsid were determined to meet eligibility criteria of 1:2-1:8 titers for enrolment. After vaccine administration, NAb titers increased 1 to 4 weeks in most dogs, and at later time points started to decline, opening the possibility of vaccine boosting. With blood PBMCs, specific immune reaction against vaccine antigens (gp100, TYR and TRP-1) were analyzed through IFN-γ ELISPOT assay determining $CD8^+$ T-cell activation at different time points, revealing three groups of patients, the early, the late responders, and the non-responders (only one dog). Animals were also monitored through blood biochemistry, and chest radiography to track metastasis in the lungs. Globulins and white blood cell (WBC) count were tracked for a sign of inflammatory responses. Alanine transaminase (ALT), alkaline phosphatase (ALP) and aspartate aminotransferase (ALS) were evaluated for liver function, as were creatinine and blood-urea-nitrogen (BUN) evaluated for renal function. The values of these parameters suggested no evidence of liver or renal problems related to the vaccine administration. To date 2 dogs are currently disease-free, and 2 dogs lived 738 and 896 days post-vaccination disease-free before being euthanized due to age related problems. This is the first study that attempts the use of an optimized AAV cancer vaccine in a large spontaneous cancer animal model. The preliminary conclusions resulting from our study indicates that our AAV vaccine based on off-shelf tumor antigens is safe in dogs. These results encourage the possibility of expanding AAV based treated diseases.

1929 Cardiac catheter delivery of AAV5 to Goettingen Minipig hearts

Glen Banks[1]*, Mengping Liu[2], Erica Cook[3], Yanshan Dai[4], Brian Carpenter[5], Daniel Cohen[5], Divakar Rajeswaran[5], Paul Morin[6], Bogdan Sleczka[5], Petia Shipkova[7], Zhuyin Li[7], David Gordon[8], Leonard Adam[9], Paul Levesque[10], Glen Banks[4]

Safely achieving therapeutic expression levels with adeno-associated virus (AAV) gene therapy is a significant challenge for treating the heart. Goettingen minipigs provide a more accurate assessment of the feasibility of achieving an effective and safe dose than rodents due to the significantly larger hearts. Here we developed methods for delivering 3×10^{14} vg AAV5 (~2.3×10^{13} vg/kg in ~13 kg pigs) to Goettingen minipig hearts by retro-coronary sinus infusion (RCSI). We found that optimal placement of the delivery catheter and the delivery flow rate significantly improved the biodistribution of AAV5 in the left ventricle and septum, leading to mRNA expression in ~70% cardiac myocytes. The optimized delivery protocol coincided with minimal changes to blood pressure, ST elevation, and transient serum troponin I levels. In a sperate study, we systemically delivered 6×10^{13} vg/kg AAV5 to n = 2 NHPs that led to mRNA expression in ~26% of cardiac myocytes. We conclude that the optimized RCSI is a safe method to deliver significantly more therapeutic to the left ventricle and septum than systemic delivery, and the methods may be broadly applicable to RCSI delivery.

1930 CGT-003: A novel recombinant parvovirus gene therapy for the treatment of hypertrophic cardiomyopathy resulting from genetic variants of myosin binding protein C3 (MYBPC3)

Samantha Smith[1], Michael Rak[1], Melvys Valledor[1], Yoshifumi Hashimoto[1], Carolyn Pelletier[1], Shu-hao Liou[1], Ryan Farrell[1], Po-Yi Ho[1], Brooke DeSimone[1], Derek Liberti[1], Alfred Tamayo[1], Brian Collins[1], Jeff Moffit[1], Joel Schneider[1], Sebastian Aguirre Kozlouski[1]
[1]Carbon Biosciences, Waltham, MA

Hypertrophic cardiomyopathy (HCM) is the most common form of heart disease, affecting as many as 1 in 200 individuals globally. HCM is characterized by left ventricular (LV) hypertrophy, diastolic dysfunction, heart failure,

and sudden cardiac death. Up to 30% of HCM patients develop atrial fibrillation (AF), which increases risk of death even further. Genetic mutations affecting sarcomeric filaments are the leading cause of HCM because they disrupt contractility and beating of cardiomyocytes. Genetic HCM is inherited in an autosomal dominant pattern and juvenile patients are at a 4-fold greater risk of mortality than adults. Pathogenic mutations in the gene encoding cardiac myosin binding protein C3 (MYBPC3) are the most common cause of HCM and the vast majority of these pathogenic variants result in haploinsufficiency. While medications like beta-blockers and calcium channel inhibitors are available to manage symptoms, there are no approved therapies for genetic forms of HCM. A gene therapy for MYBPC3 is currently in the clinic; however, the utility of this and other rAAVs is hampered by high seroprevalence in the human population, limited cargo capacity, safety and efficacy concerns related to high liver transduction. AAV therapies are limited to only one minor genus (dependoviridae) within the parvovirus family, leaving many potentially better suited vectors unexplored. To overcome these limitations, Carbon Biosciences has developed hybrid parvovirus vectors containing capsids from non-primate-derived autonomous parvoviruses and genomes packaged with AAV2 inverted terminal repeats (ITRs). CGT-003 is a hybrid viral vector featuring a novel recombinant non-AAV parvoviral capsid carrying a 5.5kb genome containing a strong promoter, regulatory elements, and a full-length human MYBPC3 transgene capable of robust and specific protein expression in cardiomyocytes. The vector displays exquisite cardiomyocyte tropism while completely avoiding liver transduction, and still leverages the established regulatory and CMC profiles of AAV. CGT-003 represents a best-in-class treatment for genetic forms of symptomatic hypertrophic cardiomyopathy (HCM), specifically engineered to de-target the liver, thereby enhancing safety. The capsid powering CGT-003 is derived from a virus that has not co-evolved with humans, resulting in an absence of pre-existing neutralizing antibodies. This unique characteristic is expected to streamline patient enrollment and accelerate clinical development by expanding the eligible patient population and minimizing the need for extensive prescreening. In this study, we demonstrate CGT-003-driven expression of human MYBPC3 with appropriate sarcomeric localization in human iPSC-derived cardiomyocytes. Preclinical evaluation shows vector genome deposition in critical regions of the heart for both mice and non-human primates. hMYBPC3 protein was readily detected in murine hearts, while no protein was detected in the liver, highlighting the potential for safe and efficacious MYBPC3 gene replacement.

1931 LTS-101: An Intracerebroventricular Delivered AAV Gene Therapy Using a Novel Capsid Variant for the Treatment of CLN2 Batten Disease

Jang-Ho Cha[1], Jenna Soper[2], George Yohrling[3], John Connelly[2], Katherine Villa[4], David Leib[5], Luis Tecedor[6], Beverly Davidson[6]
[1]Latus Biosciences, Arlington, MA, [2]Latus Bio, Boston, MA, [3]Latus Bio, Princeton, NJ, [4]Latus Bio, Philadelphia, PA, [5]Latus Bio, Inc, Philadelphia, PA, [6]Children's Hospital of Philadelphia, Philadelphia, PA

Introduction: CLN2 disease is a rare, fatal, pediatric neurogenetic disorder resulting from deficiencies in the tripeptidyl peptidase 1 (TPP1) protein, which causes lysosomal dysfunction and progressive neurodegeneration. While bi-monthly infusions of recombinant human TPP1 (cerliponase alfa) to the brain have provided benefit to patients, significant disease burden remains and the therapy requires families relocate to infusion centers for the frequent, hours long, infusions. While ERT slows disease progression, it is not curative and a global survey of patients and caregivers indicated that >90% believe there is a need for alternative treatments such as gene therapies, with greater efficacy and without the need for biweekly administration. Latus Bio, Inc. has developed an AAV-based gene therapy using a novel capsid variant, AAV-Ep+, delivering the hTPP1 transgene. AAV-Ep+ robustly transduces ependymal cells lining CNS ventricular spaces as well as intraparenchymal neurons, allowing for production and secretion of TPP1 protein into the CSF and brain parenchyma. Additionally, AAV-Ep+ exhibits limited transduction of peripheral tissues in mice and multiple non-human primate (NHP) species. Preclinical studies with ICV administration of the AAV-based construct have established proof-of-concept in $CLN2^{-/-}$ mice and identified tolerable doses that provide potentially therapeutically relevant levels of TPP1 in CSF of cynomolgus macaques.

Results: In $CLN2^{-/-}$ mice, bilateral ICV administration of LTS-101 demonstrates high transduction, expression, and engagement. LTS-101 produces TPP1 protein throughout the brain and reduces lysosomal protein accumulation (lipofuscin) up to 58%. In a dose range finding (DRF) study in NHPs, bilateral ICV administration of LTS-101 produces brain-wide TPP1 activity, up to 140 ng/mL TPP1 in the CSF, a favorable safety profile, and low systemic exposure at a total dose of 1.00e12 vg which is a logs-fold lower dose than that of conventional capsids used in

similar clinical gene therapy programs using ICV delivery. LTS-101 is manufacturable reproducibly at 250L scale, producing high quality drug product at suitable concentrations for clinical testing.

Conclusion: Preclinical studies in CLN2$^{-/-}$ mice and NHPs have established proof of concept for LTS-101 as a treatment for CLN2 disease. A definitive mouse pharmacology study and NHP GLP toxicology study are on-going. Clinical development planning is progressing in collaboration with world-leaders in CLN2 disease. LTS-101 is a promising gene therapy candidate with the potential to treat CLN2 Batten disease patients with a one-time ICV administration providing stable, long-term expression of TPP1 while eliminating the caregiver and patient burden of repeated ERT treatments.

1932 AAV Gene Therapy with a Bacterial Glycogen Debranching Enzyme in a Dog Model of GSD IIIa

Elizabeth Brooks[1], Baodong Sun[2]*, Priya Kishnani[3], Haiqing Yi[4], Jeong-A Lim[5], Kuo-An Liao[5], William Eisner[6], Aravind Asokan[7]
[1]Duke University Medical Center, Durham, NC, [2]Duke University School of Medicine, Durham, North Carolina, [3]Duke University Medical Center, Durham, North Carolina, [4]Durham, NC, [5]Duke University, Durham, NC, [6]Duke University, Durham, [7]Duke University, Durham, North Carolina
**Corresponding Author*

Background: Deficiency of glycogen debranching enzyme causes glycogen storage disease type III (GSD III), resulting in pathological glycogen accumulation in both liver and muscle (GSD IIIa) or in only the liver (GSD IIIb). We recently reported an innovative gene therapy approach for GSD III using an AAV9 vector expressing a bacterial debranching enzyme (pullulanase) driven by a unique dual promoter, which consists of an immunotolerizing liver-specific promoter (LSP) and the ubiquitous CMV enhancer/chicken β-actin (CB) promoter. We demonstrated that the LSP-CB dual promoter effectively suppressed transgene-related cytotoxic T lymphocyte responses in adult GSD IIIa mice while allowing persistent pullulanase expression and glycogen reduction in liver, heart, and skeletal muscles. We have expanded this treatment strategy to a dog model for GSD IIIa, which we have characterized previously.

Methods: An AAV vector carrying a codon-optimized CpG-free pullulanase cDNA under the control of the LSP alone (AAV-LSP-Pull) or the LSP-CB dual promoter (AAV-Dual-Pull) was packaged into AAV9. For liver-targeted gene therapy, two 10-month-old GSD IIIa dogs were intravenously injected with AAV9-LSP-Pull. One was treated at a high dose (2.5E+13 vg/kg) and the other at a low dose (5E+12 vg/kg). Dogs received 1 mg/kg prednisone once daily starting 3 days before vector administration, The dose was increased as necessary for liver enzyme elevations which were monitored at least weekly for 12 weeks. Liver and muscle biopsies were performed prior to vector administration and 2, 6 and 12 weeks post-treatment. For neonatal treatment, AAV9-Dual-Pull was intravenously injected into two wild-type dogs on the 2nd day of life (1.4E+14 and 1E+14 vg/kg). They did not receive an immunosuppressive therapy. Skeletal muscle biopsies were performed at 1, 3, 6, and 9 months of age, with final tissue collection at 12 months of age. Blood chemistries were performed throughout the study.

Results: Adult GSD IIIa dogs treated with AAV9-LSP-Pull demonstrated a dose-responsive increase in pullulanase activity and vector genomes in the liver with a subsequent decrease in liver glycogen 2 weeks after treatment. However, loss of this treatment effect was noted 6 weeks after administration. There was also an increase in liver transaminases (ALT and AST) beginning at 24 and 42 days post-treatment in the high-dose and low-dose treated dogs, respectively. Neonatal dogs treated with AAV9-Dual-Pull demonstrated persistent pullulanase activity in skeletal muscle (quadriceps and biceps femoris) over time at biopsies and pullulanase activity was present 12 months after treatment in diaphragm, quadriceps, gastrocnemius, biceps femoris and minimally in heart. Blood chemistries did not show elevations of liver or muscle enzymes demonstrating safe expression of pullulanase throughout the study.

Conclusion: Our data demonstrate the efficacy of AAV9-LSP-Pull-mediated gene therapy in a canine model of GSD IIIa. However, the benefits do not last, likely due to an immune-mediated T-cell response that led to the loss of transgene. When treating dogs as neonates with AAV9-Dual-Pull, pullulanase activity persists within the muscle

throughout the 12 month experiment, demonstrating immune tolerance. Studies are currently being initiated in adult GSD IIIa dogs with the dual promoter that utilizes a high potency MyoAAV capsid, to determine whether pullulanase activity can persist in both liver and muscle.

1933 Optimizing Vector Administration of an AAV Gene Therapy for Surfactant Protein B Deficiency in a Neonatal Pig Model

Nicole Zielinska[1], Erin Howard[2], Cici Yang[2], Brenna Stevens[2], Melanie Goens[3], Yanlong Pei[3], Jeff Caswell[2], Bernard Thebaud[4], Douglas Wey[2], Alexander Valverde[2], Luis Arroyo[2], Sarah Wootton[1]
[1]University of Guelph, Guelph, ON, [2]University of Guelph, Guelph, [3]University of Guelph, [4]Ottawa Hospital Research Institute

Surfactant protein B (SP-B) deficiency is an inherited disorder that leads to respiratory failure shortly after birth due to alveolar collapse. Despite its severity, treatment options remain limited, offering only transient relief without addressing the root cause. Given that SP-B deficiency exclusively affects the lungs and is monogenic in nature, targeted gene therapy to the respiratory tract is a promising treatment option. The novel triple mutant AAV6 capsid, AAV6.2FF, exhibits preferential tropism for the lungs. Earlier preclinical studies in mouse models have demonstrated the corrective potential of AAV6.2FF-SPB; however, clinical translation of this therapy remains a significant challenge. To bridge this gap, we have concentrated our efforts on optimizing lung gene delivery in a neonatal pig model whose lung physiology closely resembles that of human infants. Our optimization protocol involved using two AAV6.2FF vectors, one expressing human placental alkaline phosphatase (hPLAP) and a second expressing secreted alkaline phosphatase (SEAP) to assess vector biodistribution in the lungs across different doses and delivery techniques.

In both studies, AAV vectors were endotracheally delivered to 2-week-old York/Landrace/Duroc mixed piglets using the MADgic laryngo-tracheal mucosal atomization device from Teleflex. In Study 1, piglet #1 and #2 received 5×10^{12} vg/kg of AAV6.2FF-hPLAP and AAV6.2FF-SEAP respectively, and piglet #3 was administered PBS in an inoculum volume of 0.5 mL/kg. In Study 2, piglet #4 was given 1.62×10^{13} vg/kg of AAV6.2FF-hPLAP, piglets #5 and #6 each received 1.73×10^{13} vg/kg of AAV6.2FF-SEAP, and piglet #7 received PBS in an inoculum volume of 0.5mL/kg. Serum samples were collected on days 0, 7, 14, 21, and 28 post-AAV. Piglets were euthanized 28 days post-AAV, and their lungs were harvested and divided into 16 sections, labeled A through P. Additional tissues, including the heart, kidneys, liver, spleen, and trachea, were also collected. Tissue samples were fixed, heat inactivated and stained to detect alkaline phosphatase (AP) reporter gene expression. After AP staining, tissues were imaged, embedded in paraffin, and sectioned for histological analysis to identify transduced cell phenotypes. Serum samples were analyzed with the Phospha-Light™ SEAP Reporter Gene Assay to quantify the levels of AP in the blood over time.

Our findings showed that endotracheal delivery via a laryngo-tracheal mucosal atomization device, especially at a higher AAV dose, efficiently transduces the lungs with no obvious off-target expression in auxiliary tissues.Gross imaging, SEAP expression, and histology collectively demonstrated that increasing the dose in Study 2 significantly enhanced both transgene expression and vector distribution in the lungs. Between the two reporter genes, SEAP was selected for future studies due to our ability to track transgene expression in the blood while retaining the benefit of visually staining tissues to evaluate transgene distribution. Future studies will utilize the higher AAV dose in combination with surfactant to maximize transduction efficiency. These findings demonstrate the ability of AAV6.2FF to transduce the lungs in a large animal model, providing a critical foundation for optimizing dosage and delivery methods, and representing a pivotal step toward advancing the clinical translation of this therapy.

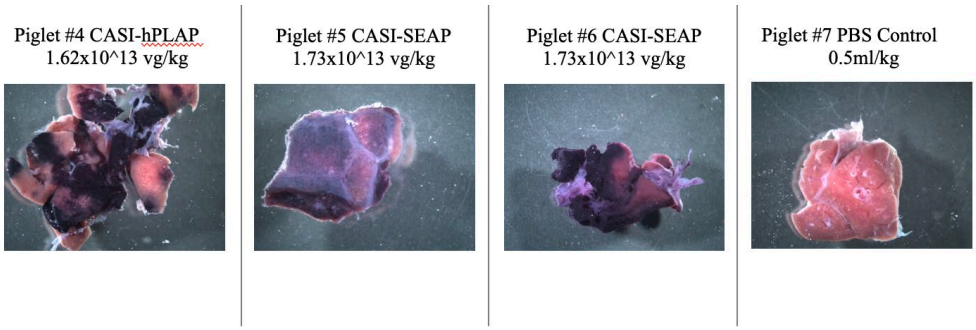

Figure 1: Gross images depicting human placental alkaline phosphatase (hPLAP) or secreted alkaline phosphatase (SEAP) expression in lung section E of piglets 28 days post-AAV administration from Study 2 with elevated doses.

1934 Extending Biolayer Interferometry (BLI) Principles to Develop a Simple Non – Cell Lysis Method for the Detection of Empty vs Full AAV Capsids

David Apiyo, Sartorius Stedim Biotech GmbH, Carver, MN

Adeno Associated Virus (AAV) vectors are the leading platform for gene delivery for the treatment of a variety of human diseases. During development, AAV in-process samples often yield mixed populations of particles that include full capsids, partially full capsids and empty capsids amongst others. This heterogeneity during production necessitates that product characterization be efficiently done to establish the empty to full capsid ratios. While there are many techniques that have been deployed to detect these ratios, they are often either expensive or time consuming in addition to many other challenges hence making it difficult for developers to identify an ideal cost-effective technique. Sartorius's AAVX biosensor was developed to enable rapid, real time and high-throughput measurement of AAV capsid titer in samples across the AAV bioprocess workflow enabling quick process optimization, quality checks and increased productivity. In this talk, we propose a method that extends the use of the AAVX biosensors for use in determining empty to full capsid ratios; a method that does not require the lengthy and often inefficient capsid lysis to expose the ssDNA targeted for binding and subsequent detection by some comparative methods.

The principles of the BLI technology is such that binding on the tip of the biosensor results into a molecular layer which increases in thickness as more analyte molecules bind to the surface. The spectral pattern changes as a function of the optical thickness of the molecular layer is what is monitored at the detector. While the AAVX biosensor utilizes an anti-AAV antibody to bind to capsid proteins, the principles of detection of empty Capsids relative to full capsids on BLI capitalizes on the fact that although both bind to the antibody via the proteins on the surface of the capsids, the genomic insert in the full capsid imparts a density difference (Figure 1) between the two that leads to a difference in the binding saturation level when bound to the antibody on the biosensor surface

1935 Characterization and Optimization of AAV Transgene Cassettes Expressing HIV-1 Broadly Neutralizing Antibody 10-1074 for AAV9-Mediated expression in Non-Human Primates

Isai Leguizamo[1], Michael Kuipa[2], Abubakarr Koroma[2], Matthew Gardner[2]
[1]Emory University School of Medicine, Atlanta, GA, [2]Emory University, Atlanta, GA

Background: Successful AAV-expressed antibody therapy for HIV-1 requires high antibody concentrations and reduced immune responses to sustain viral suppression without ART. In an ongoing study, co-administration of AAV9 expressing 10-1074 and PD-L1 led to high plasma concentrations of 10-1074 and low anti-drug antibody (ADA) responses. Based on previous findings that the WPRE enhances transgene expression, we aimed to increase 10-1074 expression to therapeutic concentrations (>50 µg/mL) with PD-L1 co-expression and evaluate the WPRE's impact. Six constructs with varying promoters and introns were packaged into AAV9 for in vitro and in vivo

assessment. The top four cassettes were selected for NHP studies to evaluate expression, ADA responses, and potency.

Methods: Six promoter and intron combinations (CMV, CMV/R, CBA, CASI, CB7, EF1a) expressing 10-1074 were cloned into AAV9 transfer plasmids. Recombinant 10-1074 proteins were expressed from each cassette and purified after transient transfection of HEK293T cells. In-vitro potency was assessed using the TZM-bl neutralization assay. Six groups of NSG mice (N=4) received $2.5x10^{12}$ vg/kg of AAV9 vectors and expression was assessed by gp120 ELISA for eight weeks. Following transgene selection, rhesus macaques were inoculated intramuscularly with AAV9 constructs (CB7, CMV/R, EF1α at $1.5x10^{12}$ vg/kg; CBA w/ WPRE, CBA w/o WPRE at $2.5x10^{12}$ vg/kg) and AAV9 expressing PD-L1 ($2.5x10^{12}$ vg/kg). Serum samples were analyzed over 20 weeks for 10-1074 expression (gp120 ELISA), ADA responses (Fab ELISA), and potency (TZM-bl assay).

Results: In-vitro expressed 10-1074 from transgene variants demonstrated similar potency to the expressed 10-1074 from the unmodified expression plasmid, indicating the retention of its functional neutralizing activity. Expression in mice showed the CMV promoter yielding the lowest average concentration (21 mg/mL) and the CB7 promoter achieving the highest (231 mg/mL). Other constructs from 94 to 109 mg/mL^{-1}. After week 12 in NHPs, 4 out of 5 groups neared or exceeded the therapeutic target (>50 mg/mL). Group 1 (CB7) had the lowest expression (13 mg/mL), while group 4 (CBA w/ WPRE) showed the highest (198 mg/mL), followed by Group 2 (CMV/R, 64 µg/mL), Group 3 (EF1α, 48 µg/mL), and Group 4 (CBA, 82 µg/mL). ADA responses across all groups remained low with group 1 and 2 having the lowest response. Lastly, ex-vivo neutralization assays from isolated sera demonstrated similar neutralizing activity (IC_{50} < 1 µg/mL) across all groups.

Conclusion: Our study demonstrates that AAV9 delivery of 10-1074, combined with PD-L1 expression, effectively achieves sustained antibody expression and potency while minimizing ADA responses, key requirements for successful HIV-1 therapy. The incorporation of WPRE significantly enhanced transgene expression, with the CBA + WPRE construct achieving the highest expression levels in NHPs. These findings highlight the importance of promoter and enhancer selection in optimizing therapeutic antibody expression and support further development of AAV-based strategies for HIV-1 treatment.

1936 A Cis-Regulatory Element Discovery Platform: Machine Guided Design and NHP Validation

Mat Falkowski[1], Kendrick Goss[2], Aurelija Grigonyte[1], Rory Kirchner[1], LeAnn Lindsay[1], Alyssa Morrow[1], **Adam Scheidegger[1]**, Matthew Youngblut[1], Christen Yuen[1], Siqi Zhao[1]
[1]Ginkgo Bioworks, Boston, MA, [2]Ginkgo Bioworks, Lexington, MA

AAV gene therapies hold great potential to treat rare and complex genetic disorders, but are limited by potency and specificity. Promoters can provide control over tissue specificity and transgene expression strength, but most gene therapies utilize only a limited set of promoters, leaving a vast genetic design space for therapeutic optimization. To address this gap, Ginkgo has developed a comprehensive promoter optimization platform by leveraging machine learning and high-throughput screening. Here, we present measurements from ~40,000 short (258bp) core promoters across 18 cell models in vitro using Massively Parallel Reporter Assays (MPRA). This data set identifies subsets of promoter sequences specific to different tissue types and some showing comparable strength to commonly used constitutive promoters. While we have collected a wide consortium of MPRA measurements in several tissue types, it is also of interest to design promoters in tissues that we have not collected data for. To address this, we developed two machine learning approaches to model promoter activity based on availability of MPRA data in target tissues. In data-rich scenarios, we employ a supervised machine learning strategy that directly learns from experimental measurements. We demonstrate its use by training models on more than 330,000 regulatory sequences collected in vivo from mouse liver and skeletal muscle to design tissue-specific promoters. As a proof of concept, we leveraged this pipeline to design strong, fast-onset muscle-specific promoters. For tissues with limited promoter characterization, we propose a machine learning framework that trains on transcriptomic and epigenetic datasets in a wide range of tissue models, enabling computational design of tissue specific promoters when MPRA data is scarce. To validate experimentally and computationally determined promoter hits, an NHP study was initiated with an AAV library of 500 promoters introduced via two different routes of administration. Tissues were harvested and

sequenced to determine promoter specificity and strength across therapeutically relevant targets. We anticipate that this combined MPRA and machine learning based approach will enable identification of novel promoter sequences that translate to therapeutically relevant applications.

1937 Optimizing Plasmid Design to Enhance Safety and Efficiency in rAAV Production

Azadeh Sarfallah[1], Ahmet Ozdemir[1], Mustafa Yazicioglu[1], Pedro Moura[2]
[1]*Spark Therapeutics, Philadelphia, PA,* [2]*Formerly Spark Employee, Philadelphia*

The AAV2 P5 promoter is commonly employed in the HEK293 cell-based production of recombinant adeno-associated viruses (rAAV) to express Rep78 and Rep68 proteins. While this promoter is known to operate in its original position relative to the Rep gene or downstream of the capsid gene, it sometimes causes the unintended incorporation of plasmid sequences into rAAV virions.

To resolve this, we developed constructs that removed the downstream P5 promoter and upstream backbone elements from the Rep-Cap plasmid. Our results revealed that removing only the downstream P5 promoter did not affect Rep78 expression but prevented the formation of replication-competent AAV (rcAAV). Additionally, removing the upstream backbone elements abolished Rep78 expression, indicating that residual backbone elements, rather than the full P5 promoter downstream of the Cap gene, were driving the non-specific expression of Rep78. Acknowledging the non-specific transcriptional activity of bacterial elements in eukaryotic cells, we redesigned the plasmid to eliminate these backbone elements and the truncated P5 promoter, replacing them with alternative promoters. Among ten tested promoters, one achieved good Rep expression and comparable genome titers to the control.

This study highlights the critical need to optimize plasmid architecture to eliminate non-specific transcriptional activity. By refining plasmid designs, we can ensure the efficacy and safety of gene therapies, mitigating unintended transcriptional consequences.

1938 Fueling Technological and Process Advancements for Increased rAAV Productivity to Meet the Industry's Growing Demand

Corben Davis[1], Smita Menon[1], Keerthana Subramanian[1], Nicole Hoefer[1], Ganesh Krishnamoorthy[1], Frank Agbogbo[1], David Dismuke[1]
[1]*Forge Biologics, Grove City, OH*

The growing demand for large-scale production of gene therapies utilizing recombinant adeno-associated virus (rAAV) vectors is driven by rapid advancement in technology, positive clinical trial results, and the growing number of commercially approved products. A major challenge in rAAV manufacturing lies in developing an optimized, cost-efficient, and scalable process for all rAAV serotypes, including novel capsid designs, to supply both the growing number of programs and large patient populations for these therapies. Forge Biologics has launched a new manufacturing platform called "FUEL™" for AAV gene therapy production, designed to improve process efficiency, productivity and safety by combining its proprietary pEMBR 2.0™ Ad helper plasmid, the Ignition™ cell line, and optimized rep/cap plasmids, all working together for an optimized, efficient and a scalable production process. The synergy between the FUEL™ platform and Forge's tailored upstream and downstream process results in increased rAAV productivity, and therefore reduced manufacturing costs of goods sold (COGS).

Forge's tailored downstream process is designed to support expedited therapeutic rAAV pipeline programs, delivering high yield and high product quality. In our downstream process, crude lysate from the optimized upstream process is clarified using systematically tested depth filters. Following clarification, the rAAV vector is captured using a predetermined resin-buffer combination, based upon our experience with multiple serotypes. Depending on the outcomes, a more customized affinity resin process with specific buffer conditions is incorporated into the process for high recovery and product quality. Subsequent enrichment of the vector material involves

separating full capsids from empty capsids through either cesium chloride ultracentrifugation or anion exchange chromatography. The method of enrichment is determined by program needs and timeline. The final step involves taking the full rAAV capsids through the final formulation process and filling the drug product utilizing state-of-the-art fill/finish processes. This process yields a highly pure rAAV suitable for early preclinical applications, toxicological studies, or clinical use.

The advancements made possible through the development of the FUEL™ platform and optimized process have shown 13x-22x increase in vector productivity compared to a standard process. Forge has systematically tested the rAAV products generated through these advancements on multiple serotypes across multiple scales. This comprehensive approach enables efficient progression through process development and facilitates cGMP manufacturing to achieve optimal yield and reduce process variability. The success of each purification step is verified through stage-appropriate analytical testing, including GOI titer by ddPCR, residual plasmid DNA by ddPCR, product purity by SDS-PAGE or capillary electrophoresis, genome integrity through next-generation sequencing, empty:full particle ratio by analytical ultracentrifugation, potency through qualified cell-based assays, residual host cell DNA, residual host cell protein, endotoxin, and other relevant tests. This presentation will cover key data generated with the FUEL™ platform on rAAV productivity and the product quality attributes of the final drug product.

1939 EPI-321 Development: Strategies to Establish a Scalable and Robust rAAVrh74 Upstream Manufacturing Process from 0.5 L to 1000 L Scale

Surabhi Godbole[1], Dipali Patel[1], Aayushma Gautam[2]
[1]Epicrispr Biotechnologies, South San Francisco, CA, [2]Epicrispr Biotechnologies, South San Francisco

EPI-321 is a therapeutic designed to treat facioscapulohumeral muscular dystrophy (FSHD), leveraging the proprietary “GEMS” platform developed by Epicrispr Biotechnologies, that consists of a guide RNA, dead Cas protein, and modulator proteins. These components allow for regulation at the epigenetic level to address the root cause of diseases, without permanently altering DNA. While traditional gene editing therapies are known to cause unwanted cell growth and/or immune responses, EPI-321 provides this embedded layer of safety. Gene therapies for muscular dystrophy have commonly utilized AAVrh74 as their delivery vehicle due to its tropism to muscle cells and demonstrated safety in the muscular dystrophy space. Meeting pre-clinical and commercial demands is challenging when considering the high dosage requirements for systemic administration in adult patients. To minimize the cost of goods, it is imperative to maximize product yield and demonstrate robustness to scaling. Here, we will discuss strategies that aid in creating a commercially viable, scalable, and robust upstream manufacturing process. Improving yield often involves optimizing the transfection step. Two common strategies are to implement engineered plasmids and/or an optimized transfection reagent. By removing non-essential adenoviral components in the Helper plasmid, we observed a 2-fold increase in clarified lysate titer. Next, an engineered RepCap plasmid was evaluated across three transfection reagents. By integrating Helper 2.0, RepCap 2.0 and Transfection Reagent #2 into the EPI-321 manufacturing process, we improved clarified lysate titer by 20-fold at 0.5 L scale. To ensure process scalability, it is advantageous to define strategies early on. The remaining experiments we discuss here characterize critical process parameters for enhanced control of critical quality attributes. Understanding how volume-dependent and volume-independent parameters affect cell culture is necessary to ensure batch-to-batch consistency. Volume-dependent parameters such as agitation and aeration rate are difficult to keep constant with changing vessel geometries. To better characterize agitation rate, we assessed the impact of tip speed on productivity at 5 L scale. While newer cell lines are more resilient to hydrodynamic stress, it is recommended to keep tip speeds as low as possible. In our study, as tip speed approached 1.5 m/s, clarified lysate titer decreased by 25%, suggesting the presence of shear stress. Lastly, a large challenge for process developers is to scale the transfection unit operation. As batch volumes increase, so do transfection complex volumes; however, chemically defined limitations, such as complexation time, remain unchanged. By characterizing complexation time, we can define acceptable ranges to allow flexibility in transfer flow rate(s). To understand how transfer flow rate impacts titer, we assessed different flow regimes (laminar, transitional, turbulent) using Reynolds number. At 5 L scale, a transitional flow rate decreased titer by 35% when compared to laminar flow. To complement this data, a complexation time-course from 15 to 75 minutes was conducted to help define operational limits. The data from these studies informed a robust transfection strategy that helped scale the EPI-321 manufacturing process from bench-scale to 50 L, 200 L and 1000 L scale.

1940 Leveraging Historical Data and Percentile based Modeling for Improved AAV Production Scaling

Itsasne Arangoa[1], Maria Gonzalez[2], Ainara Apezteguia[3], Jens Keune[4], Cesar Trigueros[5]
[1]Viralgen Vector Core - San Sebastian, San Sebastian, Guipúzcoa, Spain, [2]Viralgen Vector Core - San Sebastian, San Sebastian, Spain, [3]Viralgen Vector Core, San Sebastián, Guipúzcoa, Spain, [4]Viralgen Vector Core, San sebastian, Spain, [5]Viralgen, San Sebastian, Spain

Viralgen is a Contract Development and Manufacturing Organization (CDMO) dedicated to the production of adeno-associated viruses (AAVs). The organization employs an innovative and standardized manufacturing platform utilizing Pro10™ cells, which facilitates the production of diverse AAVs and allows scaling from 2L Erlenmeyer flasks to 2000L bioreactors. This universal platform for different AAV products has enabled the generation of data from over 1000 batches produced under the same process across various scales and serotypes, providing a wealth of valuable knowledge based on prior experience.

Scaling from smaller to larger volumes represents a critical factor impacting both CDMOs and their clients, as inaccurate estimations of required capacities to meet product demands can lead to significant and unwanted costs for both parties involved. Historical data from Viralgen over recent years indicates that productivity is scale-dependent, likely due to differences in bioreactor dynamics, geometry, and other operational parameters, which complicate the ideal scaling process. Contrary to the industry's conventional belief in linear scaling, this variability can be manageable if a suitable method is identified to describe the scaling pattern, enabling more accurate productivity predictions.

Currently, the approach for estimating or projecting productivity assumes a linear relationship between scales, applying a 1:1 factor for productivity predictions. However, the data science department at Viralgen has developed a percentile-based model that has successfully reduced prediction errors by 40-50%, depending on the scales for the projection. In this model, productivity between scales is not treated as constant; instead, it is determined based on historical performance metrics, specifically mean values derived from past production data.

The model calculates the percentile of each product relative to already produced scales, providing insights into the product's performance on the platform. This information aids in decision-making regarding whether to optimize the product or process before initiating the scaling process. Once the performance is established, productivity estimates for the next scale are made using a linear regression model that incorporates historical data.

Furthermore, this model will be semi-automatically readjusted with new platform data as it becomes available, with the expectation of further reducing prediction errors by more than 50% compared to the current linear approach. By leveraging historical data and advanced modeling techniques, Viralgen aims to enhance the accuracy of its productivity projections, ultimately improving the efficiency and reliability of AAV production for its clients.

1941 Gaining control of rAAV production: real-time monitoring with Raman Spectroscopy

Beatriz Carnio[1], Johanna Wagner[2], Matthias Boscher[1], Jared Babic[1], Dila Bitnel[3], Tatjana Fischer[4], Sirri Ndonwi[4], Hadi El Radi[5], Lenaig Savary[5], Christine Zach[1], Bianca Hager[6], Sebastian Ritter[1], Matthias Gora[6], Tobias Klötzler[7], Marie Weidler[6], Alexandra Schoberth[7], **Melanie Langhauser**[8], Markus Hoerer[9], Karl Heller[4], Ahmed Youssef[3]*
[1]Ascend Advanced Therapies GmbH, Planegg, Germany, [2]Ascend Advanced Therapies GmbH, Planegg, Bayern, Germany, [3]Ascend Advanced Therapies GmbH, München, Bayern, Germany, [4]Ascend Advanced Therapies GmbH, München, Germany, [5]Merck KGaA, Strassbourg, France, [6]Ascend Advanced Therapies GmbH, Munich, Bayern, Germany, [7]Ascend Advanced Therapies GmbH, Munich, Germany, [8]Ascend Advanced Therapies, Planegg, Bayern, Germany, [9]Ascend Advanced Therapies GmbH, Planegg-Martinsried, Germany, Germany

During the production of recombinant adeno-associated viruses (rAAVs), slight variations in cell metabolism can affect overall production process in terms of AAV yield and quality. Therefore, close monitoring of offline parameters such as metabolites (Glucose, Lactate, Ammonia and Glutamine) as well as cell density is essential for rAAV vector manufacturing. The application of Raman spectroscopy can help optimize the sampling procedure by providing real-time monitoring of cell growth, nutrient consumption and metabolite accumulation, and may even be able to quantify the rAAV production online. This continuous monitoring will enable faster process optimization, improved error detection and pave the way for process automation via on-demand feeding strategies. To drive innovation in rAAV vector production, this study investigated the use of the ProCellics™ Raman Analyzer to monitor key parameters in real time. The results are used to further optimize our manufacturing platform and integrate emerging market trends.

Raman spectroscopy probes were integrated into four stirred-tank bioreactors (2L and 5L) to collect data for model development. All bioreactor runs leveraged our proprietary EpyQ® two-plasmid system, combined with PEI transfection, to produce AAV2 vectors carrying a 3kb transgene. Different feeding strategies were the only distinguishing feature to create a more representative model. Offline data, including metabolic profiles (BioProfile® FLEX2) and cell density (Vi-CELL BLU analyzer), were collected simultaneously. Capsid titers were determined during lysis using Gyros Immunoassay. These comprehensive data were then used to develop a process-specific analysis model based on the Raman spectral data. The prediction accuracy of this model was subsequently validated in a second round of independent bioreactor runs using the same setup and also adding an AAV9 Capsid serotype to check the generated model robustness.

This successful collaboration between Ascend and Merck has generated a wealth of online data provided by ProCellics™ Raman technology, eventually eliminating the need to generate an excessive number of offline datasets. By enabling online capsid quantification, we can directly proceed with DSP using the appropriate affinity column size, avoiding the time-consuming wait for analytical assay results.

While our current platform has proven to be highly robust and reliable, consistently delivering excellent results, we are constantly seeking to improve our process. This proactive approach ensures that we maintain a competitive advantage, consistently apply best practices, and uphold the highest quality and compliance standards in our AAV gene therapy manufacturing processes.

1942 Optimizing Harvest Time for AAV Full Capsids through Analysis of Production Kinetics in an Industrial System

Lucia Fernandez[1], **Daniel Brownell[2]**, Alexander Lam[2], Jonathan Morgan[3], Zihao Wang[4], Jade Bose[3], James Huynh[4], Yanjian Wang[4], Lauren Kabel[5], Yifeng Chen[3]
[1]VintaBio, Jenkintown, PA, [2]Vinta Bio, Inc., Philadelphia, PA, [3]VintaBio, Philadelphia, PA, [4]VintaBio, Philadelphia, [5]VintaBio Inc, Philadelphia, PA

The current state of industrial viral vector manufacturing is failing to meet the demands required to deliver life-saving gene therapies to patients. Many existing manufacturing workflows, adapted from suspension-based monoclonal antibody (Mab) processes, result in suboptimal AAV productivity. While the industry has largely focused on suspension systems, adherent processes that harness the natural adaptability and efficiency of HEK293 cells for viral vector production have remained underdeveloped. Today, new process intensification methods allow for a reassessment of the optimal model for AAV manufacturing, with the goal of reducing financial barriers for patients, expanding treatment availability, and alleviating healthcare burdens associated with rare genetic disorders.

VintaProcess is an advanced, intensified adherent manufacturing platform designed to eliminate unnecessary complexity, reduce costs, shorten timelines, minimize operator error, and expedite regulatory approval for early and late-stage clinical assets. The platform uses a fixed-bed bioreactor, ideal for analyzing AAV production kinetics to determine the optimal harvest time and efficient implementation into an industrial process—a challenge for suspension systems. Theoretical evidence suggests that viral DNA replication initiates later than capsid synthesis resulting in empty capsids secreted into the cytosol leading to a high empty-to-full capsid ratio. Inherent to VintaProcess™ is a native barrier that allows effective separation of AAV supernatant from the adherent cells, thus

enabling one to determine the optimal temporal window for full-to-empty capsid enrichment at harvest.

To investigate AAV production kinetics, we conducted experiments analyzing genomic titer and AAV8 capsid production over time. Empty and full capsid production was quantified at specific time intervals, with sampling beginning one-hour post-transfection to 116 hours post-transfection. Additional media exchanges were executed post-transfection to replenish cells with fresh media. Impurity profiles were evaluated to ensure clinical and commercial suitability, including residual plasmid analysis to assess plasmid cellular uptake over time.

Unlike suspension processes, VintaProcess offers a scalable, efficient AAV manufacturing platform that inherently enriches full capsids at harvest. This approach enhances AAV efficacy, reduces run times, and lowers downstream processing burdens by minimizing empty capsids. To advance gene therapy, a paradigm shift is required – one that simplifies AAV manufacturing and fulfills the promise of delivering life-saving treatments to patients.

1943 Enhancing the Upstream Performance of Adeno-Associated Virus (AAV) Vector Manufacturing via Multivariate Data Analysis

Ainara Apezteguia[1], Itsasne Arangoa[2], Maria Gonzalez[3]
[1]Viralgen Vector Core, San Sebastián, Guipúzcoa, Spain, [2]Viralgen Vector Core - San Sebastian, San Sebastian, Guipúzcoa, Spain, [3]Viralgen Vector Core - San Sebastian, San Sebastian, Spain

Viralgen as a leading AAV Contract Development and Manufacturing Organization (CDMO) has built a large proprietary data set based on the production of more than 1000 batches produced across multiple scales and constructs using the Pro10 production platform. The goal of our work is to improve the AAV upstream process by identifying with our proprietary data set which parameters exert the most significant impact on titer.

Process variability and high number of process variables create hurdles for the optimization of the manufacturing process. The first results mainly from the nature of biological processes, accuracy of measurements, and manually operated processes; whereas the latter is implied by the hundreds of simultaneous measurements collected for each sample. Traditional univariate or bivariate techniques fail to simultaneously catch the relationships between many variables.

To address the optimization goal with the associated challenges mentioned, dimensionality reduction approaches were applied, and a multivariate data model was developed using data retrieved from over 100 historical batches. The model estimates the relationship between the important process parameters (e.g., pH, metabolite concentration) and product characteristics, with titer as response variable.

Our findings suggest that transfection efficiency decreases as a result of the cell density effect. Specifically, there is a significant negative correlation between vector titer and viable cell density (VCD). Dissolved oxygen levels on the day of the bioreactor inoculation, as well as pH and glucose levels before transfection, along with the transgene size, have also been shown to play crucial roles in batch performance. An experiment was conducted to explore different VCD levels beyond the current process's operational range, confirming the high impact of VCD and aiding to identify its optimal level regarding titer. In addition, it shows that lower viable cell density results in lower pH and higher glucose remnants right before transfection.

To integrate the multivariate analysis in daily operations in Viralgen and to bridge the gap between Data Scientists and process experts, we developed an application which identifies contributing factors to the titer of a historical batch in comparison to others in an automated way. This tool will be utilized by the Manufacturing Sciences & Technology (MSAT), Manufacturing and R&D scientists to review the performance and identify potential process improvements in a continuous fashion.

Future enhancement of the model will include the addition of transfection process information as well as full/empty ratio estimation. In addition, we plan to extend the model to explore mechanistic modeling, incorporating information on metabolic pathways and the virus production process. This will provide a more comprehensive understanding of the interactions and dynamics involved in cell expansion, transfection and virus production.

1944 Streamlining Advanced Therapy Medicinal Product Manufacturing: A Platform Approach for Accelerating Gene Therapy Commercialization at Viralgen

Silvia Gómez[1], Ane Quesada[2], Isabel Guerrero[2], Cesar Trigueros
[1]Viralgen, San sebastian, Spain, [2]Viralgen Vector Core - San Sebastian, San sebastian, Spain

Viralgen Vector Core, S.L.U. specializes in the manufacturing of Advanced Therapy Medicinal Products (ATMP), specifically adeno-associated viruses (AAVs) for gene therapy applications. Their manufacturing process utilizes a state-of-the-art triple transfection method with a HEK-293-derived suspension cell line (Pro10^{TM} cell line), enabling the production of various AAV serotypes while maintaining consistent quality attributes. The unique nature of gene therapy presents challenges in establishing a cost-effective manufacturing process. Viralgen proposes a platform approach that leverages shared characteristics across different AAV serotypes to streamline operations and reduce variability. This strategy unfolds in three stages: Establishing a platform control strategy; generating experimental data to refine this strategy; and verifying it through specific studies. By adopting this approach, Viralgen aims to enhance the robustness, reliability, and predictability of its manufacturing process, from pilot to clinical to commercial scale, by leveraging process knowledge between different AAV serotypes and various drug products ensures consistency, robustness, process, and provide high-quality output with limited data. Ultimately, this methodology has the potential to address unmet medical needs, shorten development timelines, and improve accessibility and affordability of gene therapies.

1945 Accelerating AAV manufacturing timelines via a novel Rolling Seed Approach

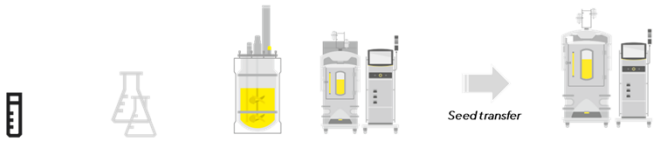
Nazgul Wagner[1], Dennis Carpentier[1], Moritz Speckenbach[1], Julia Niemann[2]
[1]Sartorius, Göttingen, Niedersachsen, Germany, [2]Sartorius Stedim Biotech GmbH, Goettingen, Niedersachsen, Germany

The seed expansion stage is a pivotal phase in AAV production, significantly impacting the overall process duration and efficiency. This study explores three seed expansion strategies: Traditional, Rolling Seed, and a combination of Frozen Seed and Rolling Seed, each offering distinct advantages and challenges. In a 500 L AAV production scenario, the Traditional approach, which takes 22 days, is compared to alternative strategies that can potentially reduce the seed expansion stage to as few as 8 days. These alternative approaches not only shorten the timeline but also enhance process flexibility and enable continuous seed production, facilitating rapid initiation of subsequent AAV batches.

As a proof of concept, multiple AAV batches were produced using the novel Rolling Seed approach. To demonstrate its broad applicability, the novel Rolling Seed method was tested with various suspension HEK293 cells, transfection protocols and bioreactor types, such as stirred tank and rocking motion. Scalability was further demonstrated by expanding the concept from a multiparallel scale-down 250 ml bioreactor system to a 2 L scale. These experiments highlight the Rolling Seed approach's operational flexibility, enabling seamless transitions between production cycles and adaptability to different bioreactor scales and types.

The study was paired with advanced semi-automated analytical techniques, such as the biolayer interferometry (BLI)-based Octet® platform and the Incucyte® Live-Cell Analysis system. As with any emerging process strategy, this study identifies potential bottlenecks that require further characterization and optimization to enhance process efficiencies even further.

Traditional approach



Vessel type	Cryovial	Shaker flasks	Seed bioreactors: 10 L → 50 L STR → 500L	Production bioreactor: 500 L STR
Process volume	Cryoculture	→ up to 0.3 L	→ 1-500 L	→ 500 L
Duration	0 day	~ 7 days	~ 22 days	~ 2-3 days

Viral vector rolling seed

Vessel type	Cryovial	Shaker flasks	Seed bioreactor: 50 L STR	Production bioreactor: 500 L
Process volume	Cryoculture	→ up to 1.2 L	→ 12.5-50 L	→ 500 L
Duration	0 day	~ 10 days	~ 19 days ∞	~ 2-3 days

Frozen seed & Rolling seed

Vessel type	Celsius Pak	Seed bioreactor: 50 L STR	Production bioreactor: 500 L
Process volume	100 ml (5E7 cells/ml)	→ 12.5-50 L	→ 500 L
Duration	0 day	~ 8 days ∞	~ 2-3 days

1946 Optimizing Recombinant AAV Vector Production: Ehnacing Upstream and Downstream Processes for Improved Yield and Quality

Ana Mena Amores[1], Saurav Datta[1], Gargi Ghosh[1], Amita Goel[2], Nikhil Goel[2]
[1]Keck Graduate Institute, Claremont, CA, [2]Celltheon Corporation, Union City, CA

Recombinant adeno-associated virus (rAAV) vectors are one of the most widely used gene therapy delivery vehicles due to their ability to achieve stable and long-term gene expression with minimal immunogenicity and pathogenicity. Since the first FDA approval of Luxturna in 2017, the demand for AAV-based therapeutics has increased significantly. However, existing manufacturing technologies still face challenges in meeting current demands. These challenges are present in both the upstream cell culture process and downstream purification steps. In this study, we aim to bridge the gap between vector manufacturing and demand by identifying key bottlenecks in the HEK293-based rAAV platform and implementing process optimizations to enhance productivity, increase purification yields and product quality.

In the upstream production, we used HEK293 cells for their transfectability and ability to grow in suspension in serum-free media, both crucial for scalable production. However, HEK293 cells show inherent biological variability and transient transfection poses challenges, including cytotoxicity in post-transfected cells due to transfection reagents such as polyethyleneimine (PEI), which leads to batch-to-batch variability. To address these issues, we developed a novel suspension serum-free HEK293 cell population with characteristics comparable to commercial cell lines and additionally improved scalability attributes. Prior to optimization, our cell line achieved a productivity

of 2.5 × 10^{11} vg/mL with a 50% viability and viable cell density of 2.5x10^6 cells/mL at harvest. Through our development, we achieved a 10-fold full capsid titer increase, with 80% viability and a viable cell density of 7x10^6 cells/mL at harvest at shake flask scale. Also, we successfully scaled up transfections to 2 L glass bioreactors, demonstrating the feasibility of large-scale production.

In the downstream process, we focused on improving yields in affinity chromatography, minimizing aggregation, and optimizing ion-exchange chromatography for better full/empty capsid separation. While the affinity step is crucial, low yields often limit efficiency. To address this, we investigated the impact of AAV sample preparation with ultrafiltration and diafiltration (UF/DF), prior to injection into the affinity column. Our results demonstrated that protein clearance with UF/DF process significantly improves AAV yields post-affinity chromatography, with 50% protein clearance leading to a 10% yield increase. Further increasing protein clearance to 90% resulted in an additional 15% AAV recovery, highlighting the critical role of impurity removal. After the affinity process, we optimized buffer composition by testing various excipient and surfactant combinations to enhance monomer stability before ion-exchange chromatography. Finally, we fine-tuned the salt gradients to further optimize the anion-exchange chromatography (AEX) step.

Our study highlights critical processes improvements that enhance AAV vector manufacturing by addressing key challenges in both upstream and downstream workflows. The development of a robust, scalable HEK293 suspension cell line, combined with refined purification strategies, offers a pathway toward more efficient, reproducible, and high-yield AAV production. These optimizations are essential to meet the growing demand for AAV-based gene therapy vectors while maintaining high-quality standards for clinical and commercial applications.

1947 Combining Fixed Bed Bioreactor and Liquid-Phase Affinity Purification Technologies for Next-Generation, Low-Cost Lentiviral Manufacturing

Nicole Votaw[1]*, **Sydney Bear**, Mauri Belasko, Thomas Robert[2], Sheldon Doxilly[3]
[1]Isolere Bio By Donaldson, Durham, NC, [2]Univercells Technologies, Nivelles, Brabant Wallon, Belgium, [3]Univercells Technologies, Gainesville, FL
**Corresponding Author*

Manufacturing lentiviral vectors (LVVs) presents significant challenges due to their complex production process and stringent safety requirements. The delicate nature of these viral vectors demands precise conditions for cultivation and multiple, low-efficiency purification steps, often leading to low yields and high costs. Additionally, ensuring consistent quality and functionality while adhering to rigorous regulatory standards adds further complexity to the LVV manufacturing pipeline. Despite these difficulties, LVVs are invaluable tools in gene therapy and biomedical research, as evidenced by the approval of several lentiviral-based therapeutics with significant clinical benefits, albeit with high drug costs impairing broad adoption. Here, we combine flagship technologies from Isolere Bio and Univercells Technologies to remedy the inefficiencies found throughout LVV manufacturing and drive down costs significantly.

Univercells Technologies scale-X™ fixed-bed bioreactor technology has demonstrated high yields of infectious LVV production in batch and perfusion mode from R&D to commercial scale. The structured fixed-bed within the scale-X bioreactor enables high-density cell culture within a small footprint. LVV production with the scale-X bioreactor achieves upstream titers comparable or up to 3-fold higher than standard flask process and up to 10-fold higher than competing bioreactor technologies. Viral molecules produced in scale-X have also shown to contain up to 10x lower host cell protein and DNA levels compared with traditional methods, potentially simplifying clarification and downstream steps.

Isolere Bio's IsoTag™ LV affinity reagent enables non-chromatographic purification of lentiviral vectors with high recoveries and purity, minimal unit operations, and total processing time under 8 hours. Traditional downstream processing requires multiple steps – typically a TFF, AEX, and SEC, with LVV losses seen at each stage. With IsoTag LV that is reduced to a single TFF operation due to the on-command droplet forming technology. LVVs are sequestered into highly pure, reversable droplets and quickly purified using microfiltration via TFF. With this process, LVV is concentrated 100X with 30% functional recovery and > 2 LRV of host cell proteins and DNA.

In this study, for the first time, we combined the two complementary technologies to both produce and purify high quality LVV at half the cost of traditional processes, while decreasing total manufacturing time by one week, and halving the required amount of consumables. Only two pieces of equipment (scale-X bioreactor and TFF) were required to manufacture LVV from start to finish in a proof-of-concept study. We were able to blend these upstream and downstream technologies and add IsoTag LV directly into the scale-X bioreactor, streamlining processing. Importantly, due to minimal purity requirements for the IsoTag process, we were able to remove the nuclease treatment and clarification steps. This did not impact purification performance nor the purity profiles in the final product.

In conclusion, by pairing disruptive upstream and downstream technologies, we demonstrate the possibility of redefining lentiviral vector manufacturing in a simplified, low-cost workflow. We expect this novel approach to facilitate the production of more accessible cell and gene therapies worldwide.

1948 Optimization of AAV Upstream Production for a Low Producing Vector

Vedud Purde[1], Katherine Gribble[2], Stephanie Sandefur[3], Marshall Poirier[4], Robert Ng[4], Danielle Lenz[5], JOSHUA HORWITZ[6], Beverly Heinz
[1]Eli Lilly and Company, Indianapolis, IN, [2]Eli Lilly and Company, Boston, MA, [3]Eli Lilly and Company, Indianapolis, [4]Akouos, Boston, MA, [5]Eli Lilly and Company, Boston, Massachusetts, [6]Lilly, Indianapolis, IN

Adeno-associated viral vector production is a complex biological and technical process that often involves triple transfection of plasmids into human embryonic kidney (HEK) cells which deliver copies of RepCap, Adenovirus helper genes, and the Gene of Interest (GOI) to generate and package therapeutic AAVs. When the GOI is expressed via a ubiquitous promoter, the protein product of the GOI will be expressed in the HEK cell line following triple transfection, which, depending on the GOI, can lead to cytotoxicity or inhibition of vector production, giving lower-than-expected overall vector yields.

In this study, we present our findings on production optimization of AAV-GOI-1, which originally showed lower-than-expected vector yields in HEK cells. We demonstrate that the lower yields were caused by the function of the GOI-1 protein product. To address this issue, we developed several strategies to improve production yields. These strategies included using biochemical tools to reduce the expression and/or function of GOI-1 during HEK production and employing the Sf9/Baculovirus production platform to avoid GOI-1's expression during vector production. The results from these studies have enabled a potential path forward for vector production of GOI-1 using either the HEK or Sf9 platforms and showcase the strengths of each platform for production of therapeutic AAVs.

1949 Adeno-Associated Viral Vector Production Process Intensification

Arthur Rostovtsev[1], Olga Makovich[2], C. Scott Payne[2], Matthew Powel[3], Lauren Torres[4], Prakash Parajuli[3], Kavita Sapru[1], Elena Prikhodko[2], Carey Connelly[2]
[1]Catalent Cell & Gene Therapy, Somerset, NJ, [2]Catalent Cell & Gene Therapy, Baltimore, MD, [3]Catalent Cell and Gene Therapy, Baltimore, [4]Repligen, Waltham, MA

Introduction: Intensification of recombinant AAV (rAAV) vector production offers significant potential for manufacturing improvements, including increased product yield and quality and decreased cost of goods. This study reports the results of rAAV process intensification, focusing on high cell density transfection and the application of a production enhancer. Tangential flow depth filtration technology (TFDF, Repligen) was used to enable high cell density transfection, cell culture perfusion, and clarification of bulk harvest. An AAV enhancer (RevIT™, Mirus Bio) was added to improve the rAAV yield.

Methods: The effect of RevIT™ on rAAV production was evaluated with Catalent's® clonal cell line (CAT293) propagated in CTS™ Viral Production Medium (Thermo Fisher). Catalent® Off-the-Shelf (OTS) plasmids for serotypes 1, 2, 5, 6, 8, and rh10 were tested with various transfection reagents. For transfection at high cell density, batch and perfusion modes were compared for rAAV5 and rAAV8 productions in 2-L single-use bioreactors

(Sartorius) using Catalent® OTS plasmids. The concentration of plasmid DNA was normalized to cell density at the time of transfection. Batch mode bioreactors were transfected at viable cell densities of 2.0-3.0´10^6 vc/mL and harvested 3 days post-transfection by centrifugation. Perfusion mode bioreactors, equipped with 30 cm^2 or 50 cm^2 TFDF filters, were operated at 1-1.5´ vessel volume per day (VVD) to achieve 2.5-fold to 3.5-fold higher cell density at transfection compared to batch mode. During production, an AAV-containing conditioned medium was continuously collected as a TFDF permeate fraction. At harvest, cells were lysed in the presence of nuclease using a buffered surfactant. Lysates were clarified by TFDF and/or centrifugation. While a 30 cm^2 TFDF filter size with a surfactant concentration of 0.5% resulted in filter clogging, successful clarification was achieved using a 50 cm^2 TFDF filter and 1% Polysorbate 20.

Results: The addition of RevIT™ in shake flask experiments increased the vector genome and vector particle titers by 2-4 times without affecting vector packaging capacity. In 2-L bioreactors, the assessment of the transfection at a 2.5-3.5-fold higher cell density in perfusion culture demonstrated a 2.5-3.1´ increase in rAAV vector genome and particle yields compared to the traditional batch approach, both with and without the addition of the RevIT™ enhancer. The addition of RevIT™ enhanced vector genome yields more than 2.5 times for AAV5 and 1.7 times for AAV8. The combined effect of high cell density transfection and RevIT™ application on vector genomes was calculated at 8.8 times for AAV5 and 4.4 times for AAV8. The AAV5 vector yield in a 2-L perfusion process achieved 6.45´10^{15} vector genomes per bioreactor. For AAV8, the perfusion process yielded 4.65´10^{15} vector genomes per 2-L bioreactor.

Conclusion: A comparison indicated that a single intensified perfusion process could replace nine batch runs for AAV5 and four for AAV8. This study demonstrates the potential of high cell density transfection combined with RevIT™ application to significantly enhance rAAV production efficiency and scalability.

1950 Comprehensive Evaluation of TruStable™ vs Transient Production Systems for AAV Vector Manufacturing

Ken Prentice[1], Ramsey Saleem[2], Blake Engelbert[3], Lauriel Earley[3], Sandhya Pande[4], Zheting Bi[5], Chris Abels[5], Bridget Fisher[6]
[1]Shape Therapeutics, Inc. - Seattle, WA, Seattle, WA, [2]ShapeTx, Seattle, WA, [3]Shape Therapeutics, Inc., Seattle, WA, [4]Shape Tx, Seattle, WA, [5]Shape Tx, Inc, Seattle, WA, [6]Shape Tx, Inc, Seattle

While adeno-associated virus (AAV) vectors are predominantly manufactured using transient transfection systems, stable producer cell lines offer significant advantages in consistency, scalability, and process economics through elimination of plasmid-related costs. In this study, we conducted a systematic comparison of AAV vectors produced via the TruStable™ producer platform versus traditional transient transfection using identical constructs. Vector quality attributes including full-to-empty capsid ratios, VP1/2/3 ratios, in-vitro potency, and impurity profiles were evaluated across multiple production runs. The TruStable™ system demonstrated superior process yield, percent full capsids, and batch-to-batch consistency in viral titers while eliminating plasmid-related impurities. Analysis of genome packaging revealed higher percentages of full capsids in the TruStable™ platform (up to ~60% full in cell lysate), while capsid protein composition (VP1/2/3 ratio) remained consistent between systems. Vector potency of terminally purified materials was comparable between platforms, with both systems producing functional particles capable of efficient transgene delivery. This comprehensive characterization demonstrates the clear advantages of the TruStable™ platform for AAV manufacturing, particularly in achieving high quality vectors with improved process yield and consistency, resulting in reduced costs.

1951 Recent Advancements in Enhanced Starting Materials and Process Optimization for Manufacturing High Yield rAAV in Suspension HEK293 Cells in Single-Use Bioreactors

Jessie Chua[1], Danielle Sexton[1], Mason Bonitz[1], Steven Wesel[1], Frank Agbogbo[1], David Dismuke[1]
[1]Forge Biologics, Grove City, OH

Recombinant adeno-associated virus (rAAV) is the leading platform for in vivo gene therapy delivery due to its low pathogenicity, ability to target a wide range of tissues (broad tissue tropism), and high efficiency in delivering genetic material to cells. The commonly used platforms to manufacture rAAV are transient plasmid transfection of HEK293 cells, infection of HEK293 (or BHK-21) cells with recombinant herpes simplex virus (rHSV), infection of *Spodoptera frugiperda* (Sf9) with baculovirus expression vectors, and stable producer cell lines with induction of gene expression with doxycycline or Adenovirus infection. A major obstacle in producing rAAV using HEK293 cells in the triple transfection method is the relatively low yield of viral vectors compared to the other production methods. To address this problem, Forge Biologics has recently launched FUEL™ (Foundation for Unleashing Excellence in Life-Changing Therapies) AAV manufacturing platform, which leverages enhanced starting materials (optimized Ad helper and rep/cap) and product-specific process optimization, and this has resulted in remarkable improvements in rAAV vector yields. Upstream process optimization is achieved through transfection design of experiments (DoE) studies by evaluating plasmid ratios, DNA/cell, PEI/DNA ratios, and transfection reagents.

Our platform process utilizes our Ignition™ HEK293 suspension cells that are well-documented for robust transient transfection. The process begins with thawing a cell bank (RCB, WCB, or MCB) and passaging it through seed expansion before going into the production vessels, typically at the 50, 500, or 1000L scale. Once the cells reach the required density for transfection, they are transfected with three plasmids (GOI, rep/cap, pEMBR™ Ad helper) with the help of a transfection reagent. The culture is then monitored for a few days and at harvest, cells are lysed with detergent and nuclease treated prior to clarification. The clarified lysate is loaded on the appropriate affinity column and the eluted product is further polished through CsCl ultracentrifugation or AEX purification, depending on the client's preference. The full capsid product from the polishing step is buffer exchanged into the final formulation and taken through sterile filtration steps for the drug product. This process has been used in over 300+ runs over the last 3 years to produce rAAV gene therapies. Improvements have also been made in plasmid ratio optimizations, addition of transfection enhancers, and affinity optimizations leading to improved titers and improved recovery.

This poster presentation will show data that demonstrate how the FUEL™ platform can improve the manufacturability of rAAV through optimization of the rep/cap and Ad helper (pEMBR 2.0™) design, highlighting its transformative impact on AAV manufacturing efficiency, scalability, and cost of goods sold (COGS). These improvements are often additive and when coupled with the FUEL™ platform, 3-22-fold yield improvements have been achieved.

1952 Optimizing Upstream Process Inputs to Enhance Viral Yields and Ensure Product Quality in Adeno-Associated Virus (AAV) Manufacturing

Megan Del Greco[1], Kara Levine[1], Monei Walker[1]
[1]*MilliporeSigma, Bedford, MA*

Adeno-associated viruses (AAVs) have emerged as a prominent therapeutic treatment for life-threatening genetic diseases due to its tissue specificity, low pathogenicity, and long-term efficacy. Bioprocessing for AAV gene therapies is complex, making development of robust, cost-effective, streamlined processes for large-scale manufacturing challenging. An optimized upstream workflow, that maximizes viral yields and ensures consistent product quality, is a crucial step towards addressing this bottleneck. In this case study, we present our design of experiments (DOE)-based approach to optimizing key upstream process inputs for AAV production, with a focus on HEK lineage, cell culture media, and transfection reagents. Additionally, we will share data that characterizes how the predictive models generated from small-scale DOE optimization studies translate to bench and pilot-scale production systems, with a focus on viral titer and product quality.

1953 Scalable Bioprocessing Strategies for Intensified Viral Vector Production in HEK293 Cell Culture

Jose Romero Sanchez[1]*, Shan Gao[2], Hamid Soleymani[2], Francisco Franco[2], Chandana Sharma[2], Katsuko Sato[2], Masafumi Nishino[3], Nozomu Tonoike[4], OMID TAGHAVIAN[1]

Maintaining key culture conditions, such as nutrient supply, mass transfer, and mixing, is essential for achieving consistent cell growth, metabolic behavior, and viral vector production. This presentation explores how intensified cell perfusion systems can work hand in hand with cell culture media development to address these challenges. Our focus for this work is on scale-up strategies that ensure reproducible cell growth and viral vector production across different scales in HEK293 cell cultures.

Join us to discover how to:

- **Enable optimization of nutrient balance**, execute efficient waste management, and achieve consistent and scalable HEK293 cell growth via a specialized HEK293 media perfusion process
- **Intensify viral vector production** by transiently transfecting cells across various perfusion processes and bioreactors
- **Achieve consistent HEK293 cell metabolic profiles** in different cell densities, demonstrating a robust and versatile bioprocess with precise control of bioprocess parameters
- **Reduce operational costs** while enhancing titer yield with the combination of automated control systems and advanced perfusion techniques

1954 Assessment of two HEK293 Cell Line Cloning strategies to improve AAV yield

Hung-Lun Hsu[1], Amanda Ibe-Enwo[1], Nancy Liu[1]
[1]*Voyager Therapeutics, Inc., Lexington, MA*

Adeno-associated virus (AAV) has proven clinical efficacy in delivering therapeutic payloads, potentially curing diseases with a single dose. However, the low volumetric yield of AAV during manufacturing contributes to the high cost of AAV-based therapies. Currently, most AAV production relies on transient transfection in HEK cells. To increase AAV yield, it is essential to develop more productive cell lines for AAV expression.

We implemented two strategies to identify high producing clones for Voyager's engineered AAV capsids, using different parental HEK cell lines. In the first approach, we started with an internal clonal cell line, which produces $>1 \times 10^{10}$ vg/mL of various novel capsid and transgene combinations. We isolated greater than 700 single-cell clones from VYGR-293, which were seeded into 96-well plates using a single cell sorter device. Of these, more than 200 colonies were grown, transferred to 24-well plates, and cultured in suspension for productivity screening through transient transfection. After several rounds of screening, the top 10 clones were identified, with a lead clone that met our productivity criteria, including improved clumpiness and doubling time. In the second approach, we used an alternate HEK293 non-clonal cell line. A limiting dilution method seeded more than 700 cell groups in 96-well plates. After 14 days, more than 200 cell pools were expanded to 24-well plates, cultured in suspension, and screened for productivity. Following two rounds of screening, the top cell pools were expanded into shake flasks. After additional rounds of screening, a lead cell pool was identified and further adapted to five different media conditions, showing comparable titers to the lead clone from the prior approach. When combined we believe these approaches have the potential to yield a clone that could significantly further enhance AAV production.

1955 High cell density AAV production

Takanori Ieki, Astellas Gene Therapies, South San Francisco, CA

The production process of adeno-associated viruses (AAV) is notably expensive, and reducing production costs has consistently been a challenge for companies involved in AAV manufacturing. One effective strategy for improving productivity in pharmaceutical manufacturing processes that include cell culture is to increase the cell density during cultivation. In the case of antibody production using Chinese hamster ovary (CHO) cells, numerous methods for high-density culture exceeding 10^7 cells/mL have been reported. However, when it comes to AAV production using HEK293 cells, most methods do not surpass the 10^6 order range. This limitation arises because increasing cell density often leads to a decrease in AAV production per cell, resulting in little to no increase, or even a decrease, in overall AAV yield. To address this issue, we have developed a novel approach that combines high cell

density culture with a unique media exchange process which enhances AAV productivity more than threefold. This method is applicable to any transfection reagent or AAV serotype. Therefore, the same materials as in the original process can be used for the high cell density process, and no labor is required for either new residual impurity evaluation or new material management, and related processes. This innovative culture method, which is currently under patent application, will be presented.

1956 Increased AAV Yield: From Screen to Scale Up to Cost Savings Using Viral Sensitizer (VSE™) Technology

Oliver Varette[1], Andrea Vervoort[2], Michela Gentile[3], Angelo Raggioli[4], Jessica Mercolino, Keara Sutherland[5], Zeeshan Shaikh[2], Jondavid De Jong[2], Jean-Simon Diallo[2]
[1]Virica Biotech, Ottawa, [2]Virica Biotech, Ottawa, ON, [3]ReiThera, Rome, Italy, [4]ReiThera, Rome, Roma, Italy, [5]Virica Biotech Inc., Ottawa, Ontario

Manufacturing cell and gene therapies (CGTs) is complex and expensive, often resulting in insufficient yields to satisfy commercial demand and high costs that may limit patient access. With an anticipated rise in demand for CGTs in the coming years due to ongoing successful development for new and broader therapeutic applications, it is increasingly crucial to understand the key production cost drivers and explore novel technologies for creating more accessible and affordable therapeutics.

An often underappreciated bottleneck in producing viral vectors, including adeno-associated virus (AAV), are the highly conserved innate cellular defenses present in manufacturing cell platforms. These defenses, triggered during infection, induction or transfection-based manufacturing strategies, can negatively impact both viral vector yield and product quality. Virica's Viral Sensitizers (VSE™) platform offers a novel solution: proprietary small molecule cell enhancers that transiently dampen innate cellular defenses and increase the production of viral vectors across a broad range of cell platforms. VSEs are simple upstream additives, rapidly metabolized by cells with non-detectable residual levels, and can be combined to drive additive enhancements in viral vector yield and significant reductions in manufacturing costs.

Here, we detail the identification and validation of expanded portfolio VSEs specifically for AAV production, using Virica's high-throughput virology platform. We then demonstrate how these novel molecules can be combined with our existing panel of VSEs to drive over a 4-fold enhancement of AAV in the ReiCell-AAV platform developed by our collaborators at ReiThera Srl. This tailored formulation was then validated at a 2L bioreactor scale. Additionally, we highlight a case study in which a third-party client was able to achieve a nearly 4-fold enhancement in AAV yield and a concurrent 2-fold enhancement of full capsids at 5L bioreactor scale, with undetectable residuals, as confirmed by HPLC assay.

Using bioprocess modelling software, we demonstrate the impact of enhanced yield and quality on key metrics such as the cost per patient dose and cost of manufacturing for a hypothetical AAV-based gene therapy. Ultimately, this data underscores the broad applicability of Virica's VSEs as an innovative, economically feasible solution for improved, scalable viral vector production.

1957 Production of large 1e14-1e15 NHP-grade batches of Adeno-associated viruses via fast intensification and parallelized manufacturing

Thomas Cummings[1], Gábor Pap[2], Adam Hiles[2], Richard Mate[2], Gaurav Venkataraman
[1]Trisk Bio Ltd, STEVENAGE, Hertfordshire, United Kingdom, [2]Trisk Bio, Stevenage, Hertfordshire, United Kingdom

Adeno-associated viruses (AAV) hold considerable promise as vectors for gene therapy, but large-scale production remains a significant technical hurdle. Conventional strategies predominantly rely on 'platform processes' necessitated by logistical constraints at high volumes and the prolonged cycle times associated with experimentation at large batch size. Here, we demonstrate that large batches of high-quality AAV can be manufactured without

resorting to a traditional scale-up platform. We have developed a rapid process development pipeline that yields robust, high-quality, and high-yield processes tailored to specific capsid–transgene combinations. This is enabled by a combination of high-throughput cell culture screening techniques with innovations in hardware and software tooling and integration. Individual high-efficiency processes can be effectively scaled out, enabling fast transition from process development to manufacturing. Our approach employs standard HEK293 suspension cell culture, triple transfection, scalable downstream chromatography and filtration operations, and available GMP-grade reagents. By leveraging the collective advances in AAV manufacturing over the past decade, we present an integrated, manufacturing-ready methodology with broad applicability across multiple AAV serotypes.

1958 Scalable Production of Recombinant AAV (rAAV) in HEK293 Suspension Cells: From Shake Flask to 10L Bioreactor Scale-Up

Chunling Xuan[1], Xiangyu Zang[1], Jane Liu[1], Andy Tran[1], Haibo Zhang[1], Davis Xie[1], **Eric Lin[1]**, Moco Wang[1]
[1]ProBio Inc, Pennington, NJ

The production of recombinant adeno-associated virus (rAAV) for gene therapy applications requires robust, scalable processes to meet clinical trial drug supply demands. Here, we present the successful scale-up of rAAV production from shake flask to 10L bioreactor using our proprietary HEK293 (PowerSTM-293) suspension. The platform process, developed by ProBio, employs triple plasmids transient transfection with optimized plasmid ratios and DNA/cell parameters to achieve high yields and consistent product quality.

Methods: HEK293 suspension cells were cultured in chemically defined media and transfected at a target viable cell density (VCD) using a combination of helper, serotype-specific, and gene of interest (GOI) plasmids. The process was scaled from small-scale shake flasks to larger-scale bioreactor, with critical process parameters (CPPs) such as pH, dissolved oxygen (DO), temperature, and metabolite levels (e.g., glucose, lactate, pCO2) closely monitored and controlled. Harvested lysates were clarified through depth filtration and purified using affinity and anion exchange chromatography. Product quality was assessed using a in-house developed analytical methods.

Results: The scale-up process demonstrated consistent performance across scales. Process optimizations, including adjustments to plasmid ratios and DNA/cell parameters, contributed to improved yields and reduced cost of goods (COGS). The larger-scale production runs were successfully executed in a GMP-like environment, underscoring the robustness and scalability of ProBio CDMO's platform process.

Conclusion: This study validates the scalability of ProBio CDMO's platform process for rAAV production, achieving consistent product quality and yield across scales. The results highlight the potential for further scale-up to support the development of commercial-ready gene therapies.

1959 Optimized cell culture media for scalable rAAV bioreactor production

Tala Calvi, Cytiva, Westborough, MA

Viral vector manufacturing is an ever-evolving environment often faced with significant challenges. Along with process conditions, cell culture medium selection impacts cell growth culture characteristics such as cell viability and growth rates. Additionally, media selection can play a role in recombinant adeno-associated virus (rAAV) production and overall process scalability. Scalability and process robustness are critical parameters for success in the diverse gene therapy landscape. To address this demand, HyClone™ prime expression medium was developed to support large-scale GMP production of clinically relevant rAAV titers at high cell densities.

Here, we demonstrate the success of HyClone™ prime expression medium in a few well-adopted, commercially available HEK293 cell lines for cell growth and rAAV production (rAAV serotypes 5 and 8). At shake-flask scale, rAAV titers for both serotypes were at or above 6×10^{10} viral genomes per milliliter. The rAAV8 process was scaled up to a 10 L bench-top bioreactor, which showcased the media performance and scalability across several

viral vector production formats. For these results, an unoptimized process was used, which may suggest the media ha even higher potential with other processes.

1960 Optimizing Serum-Free Conditions for Scalable AAV Production in Fixed-Bed Bioreactors

Thomas Robert[1], Jean-Christophe Drugmand[2], Corey Jacklin[3]
[1]Univercells Technologies, Nivelles, Brabant Wallon, Belgium, [2]Univercells Technologies, Nivelles, Belgium, [3]Univercells Technologies, Bloomington

The clinical and commercial success of gene therapies depends on s**calable, efficient, and cost-effective viral vector manufacturing** platforms capable of meeting the growing demand for high-prevalence indications with substantial dose requirements. A critical enabler of such platforms is the use of **serum-free media** (SFM), which ensures process consistency, eliminates risks associated with animal-derived components, and aligns with regulatory guidance. SFM process should aim to support **high-yield viral vector production** while reducing these **variability and safety concerns**.

In this study, fixed-bed bioreactors were evaluated as a versatile and scalable solution for serum-free AAV-2 production using HEK293 cells. The scale-X™ **fixed-bed bioreactor platform offers a compact, high-productivity design** with demonstrated success in supporting both serum-containing and serum-free processes, making it a promising alternative for scalable viral vector production. Crucially, these fixed-bed systems can help address challenges posed by traditional stirred-tank reactors, such as large operating footprints, limited scalability and the need for suspension-adapted cells.

In the present study, two experimental setups were explored:

- Suspension-adapted HEK293F cells were successfully transitioned to fixed-bed bioreactors under SFM conditions, achieving robust growth and AAV-2 production.
- Adherent HEK293T cells, initially cultured in serum-containing media, were adapted to SFM and maintained efficient growth and AAV-2 production in fixed-bed bioreactors.

These experiments, conducted at small scale, highlighted the system's flexibility and scalability while achieving consistent, high yields comparable to serum-based processes. This study underscores the potential of scale-X fixed-bed bioreactors to overcome key challenges in viral vector manufacturing, offering a **scalable, efficient, and serum-free solution** to meet the growing demands of gene therapy.

1961 Scale-up of an ELEVECTA™ Transient rAAV Production Process in the Xcellerex™ X-platform Single-use Bioreactor

Kelly Cybulski[1], Ben Hudjetz[2]
[1]Cytiva, Marlborough, MA, [2]Cytiva, Cologne, Nordrhein-Westfalen, Germany

The delivery of therapeutic genes using recombinant adeno-associated viruses (rAAV) has emerged as a viable treatment option for various diseases, as shown by the approval of multiple rAAV-based *in vivo* gene therapies in recent years. However, the development of scalable, high-titer GMP-compatible production processes remains a significant challenge for the industry.

Previous work has shown that the ELEVECTA™ transient cell line grows in a single-cell suspension, reaches high cell density, and supports high-titer rAAV production for multiple serotypes with significantly reduced levels of hcDNA (including encapsidated) compared to another commercially available HEK293 cell line. To further this work, the previously established process has been scaled to 50 L in the Xcellerex™ X-platform single-use bioreactor. Scalability is shown across 15 mL, 3 L, 10 L, and 50 L scales with comparable cell culture performance, titer, and product quality.

The next-generation Xcellerex X-platform single-use bioreactor, in tandem with the ELEVECTA transient cell line and optimized, GMP-grade HyClone™ prime expression medium, effectively addresses the market demands for scalable, high-titer manufacturing of high-quality rAAV products from R&D through to commercial manufacturing.

1962 Pseudo-Continuous Manufacturing of Adeno-Associated Virus (AAV) Using a Dual-Bioreactor System with Inertial Microfluidic Cell Retention Device

Do Hyun Park[1], Anna Ucher[2], Suvana Lin, Sylvain Cecchini[2], Robert Kotin[2], Jongyoon Han[1]
[1]Massachusetts Institute of Technology, Cambridge, MA, [2]UMass Chan Medical School, Worcester, MA

Adeno-associated virus (AAV)-based gene therapies have enabled transformative treatments for rare genetic disorders by delivering therapeutic genes that correct underlying defects. Since the first FDA approval of AAV therapy (Luxturna) in 2017, substantial efforts have been made to enhance its production. However, low productivity limits accessibility and increases costs. Traditional batch culture-based manufacturing is constrained by a maximum cell density of ~2×10^6 cells/mL, leading to suboptimal yields. Additionally, batch processes require frequent vessel cleaning and sterilization, increasing operational costs. While single-use setups reduce some of these costs, they remain expensive and pose scalability challenges. To address these limitations, we developed a pseudo-continuous AAV production system utilizing two interconnected bioreactors: a culture bioreactor (CB) for high-density cell cultivation and a production bioreactor (PB) for AAV production. The core innovation is an inertial microfluidic cell retention device that facilitates the removal of spent media while maintaining viable cells. Perfusion of fresh media enables high cell densities in CB, from which cells are periodically transferred to PB for triple transfection using PEI-DNA complexes. The cell retention device at PB supports perfusion culture by removing residual PEI-DNA and toxic byproducts while sustaining high-density cell populations. As AAV production occurs in PB, the remaining cells in CB, diluted to 1×10^6 cells/mL after transfer, regrow to ~8×10^6 cells/mL, preparing for the next cycle. After AAV-producing cell harvest from PB, freshly expanded cells from CB are transferred to PB, enabling continuous operation. We demonstrated this system using HEK 293.sus cells cultured in 500 mL mini bioreactors (300 mL working volume). Cells were inoculated in CB at 0.6×10^6 cells/mL and expanded to 10.8×10^6 cells/mL by day 4, at which point 270 mL was transferred to PB, and CB was replenished with fresh media. This process was repeated every four days for 12 days. Transfection in PB was performed using PEI-DNA complexes at a 2:1 ratio, with 2 pg PEI/cell. PB operated without perfusion for 6 hours post-transfection, after which perfusion was initiated to sustain high cell density during AAV production. After four days of production, cells were removed from PB, and newly expanded cells from CB were transferred for the next cycle. AAV titers quantified via ddPCR demonstrated a >2-fold increase compared to standard batch cultures (inoculated at 0.5×10^6 cells/mL and transfected at 2×10^6 cells/mL on Day 2). Since high-density cell culture, transfection efficiency, and sustained cell viability during production are key engineering factors, we anticipate that further optimization of this pseudo-continuous system will significantly enhance AAV yields. Moreover, our microfluidic cell retention device minimizes product loss compared to membrane-based systems, highlighting its potential for broader bioprocessing applications, including monoclonal antibody and lentivirus production.

1963 Downsizing Process for a Large Amount of rAAV Vector Manufacturing by Combination of Perfusion Culture and Transfection to High Densified Cells

Masafumi Nishino[1], Michiko Edo[2], Risa Kitazaki[2], Junichi Kori[2], Atsushi Inada[2], Taichi Muraguchi[2], Kenji Hayashi[2]*
[1]FUJIFILM Corporation, Ashigarakami-gun, Kanagawa, Kanagawa, Japan, [2]FUJIFILM Corporation, Ashigarakami-gun, Kanagawa, Japan
**Corresponding Author*

Recently, gene therapies using recombinant AAV (rAAV) vectors have gained regulatory approval and the number of rAAV development pipelines is increasing. Since these include whole-body administered therapeutic targets that require high doses, the need for large supplies of rAAV is expected to expand. Conventional rAAV production process using human embryonic kidney 293 (HEK293) cells in suspension culture and the triple-plasmids transfection with cationic polymer represented by polyethyleneimine (PEI) have been widely employed. However, this method has low productivity and requires a huge bioreactor of thousand liters to obtain a large amount of AAV.

In addition, the further decline in productivity associated with large facilities is also an issue.

Here, we introduce the improvement of rAAV production process fitted to the actual manufacturing. We show a very high AAV titer reaching 2E12 vector genome per milliliter (vg/mL) by combination of high densification of HEK cells in perfusion culture and original gene transfer method into high density cells based on PEI method. This corresponds to approximately 10-fold higher productivity (on a Vg basis) per transfection batch compared to the conventional AAV production method using low-density HEK cells. In this case, the full capsid rate of AAV5 at the completion of the USP process was also improved more than 2-fold from the conventional method. Furthermore, the amount of plasmid was successfully reduced by 20~30% per cell, which is considered to account for the majority of production costs, by optimizing transfection conditions.

We further demonstrated that a stable and continuous supply of HEK293 cells at concentrations of 2-2.5E7 cells/ml for one month can be achieved by repeating approximately 50% volume of cell bleedings and refillings of fresh media once a day and concentration recovery in next 24 hours at the perfusion culture process. In fact, transfection to cells obtained by cell bleeding at Day 1, 8, 15, and 22 after reaching 2E7 cells/mL showed that rAAV productivity could be maintained at about 10-fold higher than that of the conventional PEI triple-transfection method in each experiment. This indicates that this method can provide a stable supply of rAAV equivalent to thousand L scale even in a relatively small-scale culture facility.

1964 N-1 Perfusion Process for Intensification of AAV Production

Kyle Burrell[1], Johanna Viiliäinen[2], Christine Sund-Lundström[3], Ann-Christin Magnusson[2], Thomas Falkman[4]
[1]Cytiva, Marlborough, MA, [2]Cytiva, Uppsala, Sweden, [3]Cytiva Sweden AB, Uppsala, Uppsala lan, Sweden, [4]Cytiva, Uppsala, Uppsala lan, Sweden

Traditionally, production of viral vectors is done by transient transfection where cells are grown in batch mode and transfected with plasmid DNA together with a suitable transfection agent to insert the gene of interest. However, the upstream process is still one of the bottlenecks of adeno-associated virus (AAV) manufacturing usually because of the long and tedious cell expansion steps. These steps are often carried out in multiple shake flasks and seed train bioreactors. To increase the efficacy of viral vector production, perfusion is introduced in the N-1 step to intensify the seed train by means of reducing or even eliminating some of the cell expansion steps.

In this work, we summarize several studies performed to develop a N-1 perfusion process of HEK293 cells to intensify the manufacturing of AAV. Initially, a set of 10 mL-scale tube bioreactor perfusion cultures were conducted to understand the growth characteristics and metabolic rates of HEK293 cells in perfusion mode and to set the foundation for a bench-scale (1.5 L working volume) scale-down model. The process was finally scaled up to 50 L using an Xcellerex™ automated perfusion system (APS). The process was based on our ready-to-use HyClone™ peak expression medium supplemented with glucose and glutamine.

Consistent performance across scales with respect to cell growth and viability was demonstrated with viable cell concentrations of up to 35×10^6 cells/mL at both 1.5 L and 50 L scales. Furthermore, a cell specific perfusion rate (CSPR) value of 80 pL media/cell/day was sufficient for a 7-day perfusion culture, enabling inoculum preparation (N-1) of HEK293 cells for production in bioreactors up to 2000 L. AAV production was showcased by seeding an Xcellerex XDR 10 bioreactor with perfused HEK293 cells and transfecting cells with triple plasmid transfection approach by using PEI MAX transfection reagent.

In conclusion, a N-1 perfusion process was developed for a 10 mL proof-of-concept scale-down model; a bench-scale (1.5 L working volume) scale-down model, and a 50 L scale. Each scale had comparable cell growth, metabolic profiles, and volumetric productivity.

1965 Development of a Perfusion Process for AAV Production Using High-Throughput Bioreactor Systems

Yelena Ilin[1], **Adam Osborne**[1], David Diaz-Vera[2], Ningning Xu[1], Paetrice Jones[1], Jeong Lee
[1]Sanofi, Waltham, MA, [2]Genzyme, a Sanofi Company, Waltham, MA

Reduction of cost of goods (COGs) is essential for AAV gene therapy due to low process yield. For recombinant protein therapeutics, cell culture process intensification is widely implemented to increase titer and reduce COGs. However, intensification of AAV production processes is a challenge due to reduced cell-specific productivities observed at high cell densities. To address this challenge, the Sanofi Genomic Medicine Unit (GMU) CMC process development group has developed a perfusion process to produce AAV at high volumetric and cell-specific titers using a producer cell line. Proof-of-concept was first demonstrated in TubeSpin bioreactors by manually exchanging production media at specific intervals after infection with a helper virus. The process was then successfully transferred to benchtop bioreactors with perfusion enabled using tangential flow filtration through a hollow fiber filter. Further development work was conducted in ambr250 perfusion bioreactors, where process parameters such as pH, perfusion rate, and media composition were explored using a DoE approach. Notably, the ambr250 model yielded consistently higher AAV titers and enhanced quality compared to larger scale. This was partially addressed by adjusting gassing and agitation strategy, however some limitations remain in the use of this model to predict process performance. Through this development work, the volumetric AAV titers were increased three-fold at pilot scale, relative to the legacy batch process.

1966 Enhanced AAV-Vector Production Using a Novel Stable Producer Cell Line and Optimized Perfusion Processes

Stefan Seeber[1], Hendrik Knoetgen[2], Nicole Schueler, Alina Schneider[3], Helena Meyer-Berg[4], Sven Markert[5], Josef Gabelsberger[6], Sarah Wuttig[7], Julia Hoelper[8], Michael Muehle[8], Ines Do Carmo Gil Goncalves[9], Michelle Hussong[10]
[1]Roche PRED, Penzberg, Bayern, Germany, [2]Hoffmann La Roche, Basel, Switzerland, [3]Penzberg, Germany, [4]Roche, Penzberg, Germany, [5]Roche Diagnostics GmbH, Penzberg, Bavaria, Germany, [6]Roche Diagnostics GmbH, Penzberg, Germany, [7]Roche Diagnostics GmbH, Penzberg, Bayern, Germany, [8]Cytiva, Cologne, Nordrhein-Westfalen, Germany, [9]CEVEC Pharmaceuticals GmbH, Now Part of Cytiva, Cologne, Germany, [10]Cytiva, Köln, Nordrhein-Westfalen, Germany

The demand for adeno-associated virus (AAV) vectors in gene therapy is rapidly increasing, necessitating scalable and cost-effective production methods. Stable producer cell lines offer significant advantages over traditional triple-transfection methods, including enhanced scalability, reproducibility, and reduced production costs. At the last ASGCT conference, we developed a high-titer HEK293-based producer cell line for AAV vectors with the GAA transgene and an engineered capsid. We now build on that work to introduce a novel producer cell line for a different transgene. This study focuses on process optimization to achieve a six-fold increase in vector titers through the implementation of perfusion processes in ambr15 and 1.5 L bioreactors. Our results demonstrate not only the substantial increase in production yields but also the long-term stability and high quality of the AAV vectors produced. These findings underscore the potential of stable producer cell lines combined with advanced bioprocessing techniques to meet the growing demands of gene therapy applications, offering a robust platform for the production of high-quality AAV vectors.

1967 Process and Quality Considerations for Recombinant Adeno-Associated Virus (rAAV) Manufacturing Platforms

Pouria Motevalian[1], Mintae Park[1], Amrisha Verma[2], Brittany Montaverde[1], Rama Ramaka[1], Abhay Thakur[1], Clifford Froelich[3]
[1]Thermo Fisher Scientific, Plainville, MA, [2]ThermoFisher Scientific, Gainesville, FL, [3]ThermoFisher Scientific, Plainville, MA

Recombinant adeno-associated virus (rAAV) is emerging as a key vector for gene therapy, recognized for its favorable safety profile and capacity for long-term gene expression. Despite major strides in the field, current manufacturing practices face persistent challenges related to scalability, product purity, and full/empty capsid separation. In this presentation, we explore three primary rAAV production platforms—transfection, infection, and stable producer cell lines—to provide insights into optimizing yield, reducing costs, and meeting regulatory expectations for clinical and commercial applications.

A comprehensive literature review and comparative analysis were conducted across each platform, encompassing

upstream processes (e.g., seed-train expansion, cell density management, bioreactor design) and downstream operations (e.g., cell lysis, clarification, chromatography, tangential flow filtration, and virus reduction). Emphasis was placed on identifying critical parameters that influence overall productivity and quality, as well as outlining advanced analytical tools for evaluating potency, purity, and safety. Key considerations for media selection, cell-line engineering, and process-control strategies were also discussed.

Our findings underscore the trade-offs inherent in each manufacturing platform. Transfection-based systems offer rapid development but incur high plasmid costs, infection-based systems excel at large-scale production but require careful baculovirus management, and stable producer cell lines deliver consistent yields yet demand considerable effort in cell-line development. Across all platforms, advances in upstream processing (improved culture media and scale-up approaches) and downstream purification (enhanced chromatography resins and filtration technologies) have led to meaningful gains in product purity, higher titers, and a more favorable full-to-empty capsid ratio. Range for all critical quality attributes based on historical batches will be presented.

The accumulated evidence highlights the critical importance of integrated process design and rigorous analytical testing for successful rAAV manufacturing. By selecting the appropriate platform and refining both upstream and downstream operations, researchers and manufacturers can better balance scalability, cost, and regulatory requirements. Ultimately, these improvements will accelerate the transition of rAAV-based therapies from proof-of-concept to patient-ready treatments, expanding the potential impact of gene therapy across diverse clinical indications.

1968 Development of a Serotype-Agnostic AAV Platform for Suspension Cell Culture

Andrew Detzel, SK Pharmteco - US, King of Prussia, PA

Manufacture of adeno-associated virus (AAV)-based gene therapies requires use of either an adherent or a suspension-based process. Both modalities offer their own unique challenges and advantages, however suspension-based processes have been gaining momentum for large-scale manufacturing due to its scalability and increased upstream process yields. We compared our suspension process to an adherent iCellis (200m^2) process and evaluated process yields, recovery from upstream to downstream, and a full analytical panel using our AAV testing platform, including potency, titer, Empty:Full, aggregation, and process-related impurities. We demonstrate that our serotype agnostic suspension platform for AAV production has increased upstream productivity, comparable downstream recoveries, and equivalent critical quality attributes relative to a well-established adherent production platform.

1969 An Optimized Baculovirus Generation Process and Novel ITR-Transgene Design for High Quality AAV Production Using the Insect Cell Production Platform.

Femke Hoeksema[1], Adriaan de Wilde[2], Jelmer Willems[3], Carmen Gallego[3], Giulia De Sabbata[4], Marina Sogorb-Gonzalez[5], Sander Van Deventer[6], Barbara Sanders[7]
[1]VectorY Therapeutics, Duivendrecht, Netherlands, Netherlands, [2]VectorY Therapeutics, Amsterdam, Zuid-Holland, Netherlands, [3]VectorY Therapeutics, Amsterdam, Noord-Holland, Netherlands, [4]ICGEB, Amsterdam, Netherlands, [5]VectorY, Amsterdam, Noord-Holland, Netherlands, [6]Amsterdam, Netherlands, [7]VectorY, AMSTERDAM, NH, Netherlands

Development of a stable, robust and large scale AAV manufacturing process at low cost of goods is a major hurdle in the Gene Therapy field. The baculovirus/insect cell production system has the potential to overcome these challenges but relies on efficient generation and scale up of intrinsically genetically unstable recombinant baculoviruses. Here, we developed a highly efficient recombinant baculovirus generation process with high rescue efficiency during plaque purification. Furthermore, we engineered a novel molecular ITR-Transgene design to improve baculovirus genetic stability and we identified a small human promoter sequence with desirable sequence characteristics. When incorporated into a recombinant baculovirus, the VectorY ITR-Transgene design provides high genetic transgene stability whilst retaining high AAV production yields, essential for manufacturing scale up. Furthermore, we utilized next-generation sequencing techniques to characterize the AAVs, showing high genome integrity and low contaminating DNA content. Lastly, we show that the AAV batches produced on this production

system exhibit high transduction and transgene expression in human iPSC-derived CNS cell types and *in vivo* in mice and NHP. Process intensification technologies were developed for efficient production and scale-up of these optimized baculoviruses. In conclusion, we present efficient production of stable recombinant baculovirus for high quality AAV production in insect cells.

1970 Development of a Robust and Scalable AAV8 Production Platform: Enhancing Vector Yield and Purity through Optimized Bioprocessing Techniques

Franziska Bollmann[1], Magda Tomala[2], Aishwarya Nair[3], Alexander Wood[4], Vincent Lam[5], Denis Odokonyero[6], Laura Chau[7], Paul Marks[4], Pavitra Talapureddy[4], Brian Windle[8]
[1]Sartorius Stedim Biotech GmbH, Göttingen, Niedersachsen, Germany, [2]Sartorius Stedim Biotech, Goettingen, Niedersachsen, Germany, [3]Matica Biotechnology, College Station, TX, [4]Sartorius Stedim North America, Bohemia, [5]Sartorius, Bohemia, NY, [6]Matica Biotechnologies, College Station, [7]Matica Biotechnologies, College Station, TX, [8]Sartorius Stedim Biotech GmbH, Bohemia, NY

Introduction: Adeno-associated virus (AAV) vectors are pivotal in gene therapy, yet their production faces significant challenges, including scalability, low recovery rates and the need for effective separation of empty and full capsids. This study presents a comprehensive AAV8 production platform developed together with CDMO Matica Biotechnology, addressing these industry pain points through innovative upstream and downstream processes.

Methods: The upstream process was meticulously designed using scalable bioreactor systems up to 50L STR®, specifically optimized for the production of AAV8 vectors. HEK293 cells were cultured under precisely controlled conditions, including temperature, pH, and dissolved oxygen levels, and the transfection protocol was optimized to enhance vector yield, utilizing specific plasmid DNA ratios and FectoVIR-AAV, tailored for AAV8 production. This approach ensured robust vector generation, addressing the critical need for high-efficiency upstream processes in the gene therapy field. The downstream process incorporated advanced filtration and chromatography techniques, including Sartoclear® DL75 depth filter, Sartopore® 2 XLG membrane filter, Hydrosart® TFF cassettes, and CIMmultus® SO3 and PrimaS® monoliths, to enhance virus recovery and purity. The combination of data analytics and screening tools allowed for optimization of process parameters in small scale, and results could be translated to the 50L scale.

Results: The process demonstrated scalability and robustness, with the 50L bioreactor yielding comparable titers to traditional shake flask methods. The downstream platform achieved a good overall process recovery, with a significant reduction in host cell DNA and protein contaminants. Notably, the CIMmultus PrimaS® chromatography step resulted in a three-fold enrichment of full capsids, achieving over 70% full AAV8 particles.

Conclusions: This study successfully addresses key challenges in AAV production, offering a scalable, flexible and efficient platform that ensures high-quality product. The integration of data analytics and innovative screening tools further optimizes process parameters, setting a new standard for AAV manufacturing. This platform not only meets current industry demands but also provides a foundation for future advancements in gene therapy vector production.

1971 Platform Development for Production and Purification of AAV9

Arjun Kumar Mishra[1]*, Chao-Kuei Wang[1], Zachary Liu[1], Nirmala Saptharishi[1], Richa Lomash[2], Rodica Stan[3], Raymond Harris[4], Jason Yovandich[4], Venkata Mangalampalli[5], John Roach[6], Vinay Vyas[6]*
[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]NCATS, Rockville, MD, [3]NIH, Rockville, MD, [4]Biological Resource Branch, DTP, DCTD, NCI, NIH, Frederick, Maryland, Frederick, MD, [5]NIH - National Center for Advancing Translational Science (NCATS), Rockville, MD, [6]Biopharmaceutical Development program, FNLCR, NIH, Frederick, Maryland, Frederick, MD
**Corresponding Author*

Introduction: Adeno-associated virus (AAV) vectors are widely utilized in gene therapy due to their ability to target specific organs and tissues with high efficiency. Among various AAV serotypes, AAV9 holds significant therapeutic potential, driving the need for scalable manufacturing processes. This study outlines the development of a robust and scalable method for producing AAV9 using a triple transfection approach with HEK293 suspension cells cultured in serum-free medium. Production and purification parameters were optimized, and the quality of the final product was characterized using advanced analytical techniques.

Methods: AAV9 production was achieved using a chemical based triple transfection strategy with HEK293 cells grown in suspension cultures. The upstream process included transfection, cell lysis, clarification, tangential flow filtration (TFF) for concentration and diafiltration. Purification was performed using affinity and ion-exchange chromatography. Quantification was conducted via qPCR, and characterization was performed using Cryo-TEM (transmission electron microscopy), size-exclusion chromatography with multi-angle light scattering (SEC-MALS), charge detection mass spectrometry (CDMS), and mass photometry.

Results: Optimization of culture media, transfection reagents, plasmid concentrations, and cell density resulted in AAV9 yields ranging from 1E+15 to 1.5E+15 vg/L. Downstream purification was refined through multiple runs, achieving recovery rates of ~80% using two different affinity resins. To address the challenges of separating empty and full capsids, anion-exchange chromatography was employed as a scalable alternative to ultracentrifugation (UC), which requires density-gradient media and presents scalability challenges. The optimized chromatography process yielded ~20% overall recovery with effective enrichment of full capsids. SDS-PAGE/Silver stain analysis confirmed the presence of capsid viral proteins VP1, VP2, and VP3. Mass photometry analysis of in-process samples showed ~22% full capsids, while final samples following Capto Q purification were enriched to ~85% full capsids. Cryo-TEM indicated ~81.6% full capsid content, SEC-MALS measured ~72% full capsids, and CDMS results aligned with these findings. The process was successfully scaled up to 10 liters, consistently demonstrating robust recovery and high-quality AAV9 vector production.

Conclusion: This study presents an optimized, scalable, process for the production and purification of AAV9. The approach achieves high yields and efficient separation of full and empty capsids, offering a viable solution for large-scale AAV manufacturing in pre-clinical and clinical applications.

1972 Development of a Novel High-Yielding Scalable Sf9-Baculovirus Platform to Produce Quality AAV at 200L Scale

Eric Lin[1], Noah Miller-Medzon[1], Christina Pelella[1], Elena Bianchetti[1], Aileen Rottinger[1], Tim Fenn[2], Marina Goldfeld[1]*
[1]LEXEO Therapeutics, New York, NY, [2]Lexeo Therapeutics, Inc., New York, NY
**Corresponding Author*

Significant costs, timeline difficulties, and scalability concerns pose challenges to the manufacturing of recombinant AAV (rAAV) with mammalian cell culture utilizing transient plasmid transfection. Alternatively, the Sf9-baculovirus system can address these manufacturing challenges and produce rAAV of comparable yield and quality. We herein present the ability of our Sf9-baculovirus process to produce high titers of high quality AAVrh.10 at the 200L stirred tank bioreactor scale. Extensive process development (PD) allowed for the creation of a low cell density process using an asynchronous infection facilitated by baculovirus-infected insect cells (BIICs). Shake flask experiments were conducted to select for improvements in crude lysate yields and cell productivity, followed by bioreactor optimizations at the 250mL scale and confirmation at 10L. Scalability was then verified up to 200L across multiple programs and subsequently into GMP. Notably, cell culture trends such as viable cell density (VCD) and cell diameter were highly comparable during the scale up from 250mL to 200L (Figure 1). We achieved upstream lysate yields and cell productivities surpassing 2.0E+12 vg/mL and 1.0E+06 vg/cell respectively (Figure 2).

In parallel, we designed a downstream purification platform consisting of depth filtration, tangential flow filtration 1 (TFF1), affinity chromatography, anion exchange chromatography (AEX), TFF2 and sterile filtration. Each step of the downstream process was optimized individually for vector genome recovery and full viral capsid enrichment as

characterized by ddPCR, Mass Photometry, Capsid ELISA, Analytical Ultracentrifugation (AUC) and Waters' Charge Detection Mass Spectrometry. This process reliably produces >1E+15 vg/L of purified AAV with overall vector genome recovery from harvest lysate to bulk drug substance (BDS) >60% and >70% full capsids. Our optimized Sf9-baculovirus process provides a solution to the challenges of HEK293 plasmid-transfection AAV manufacturing by substantially reducing the cost of goods and increasing yield of high quality rAAV at the 200L scale.

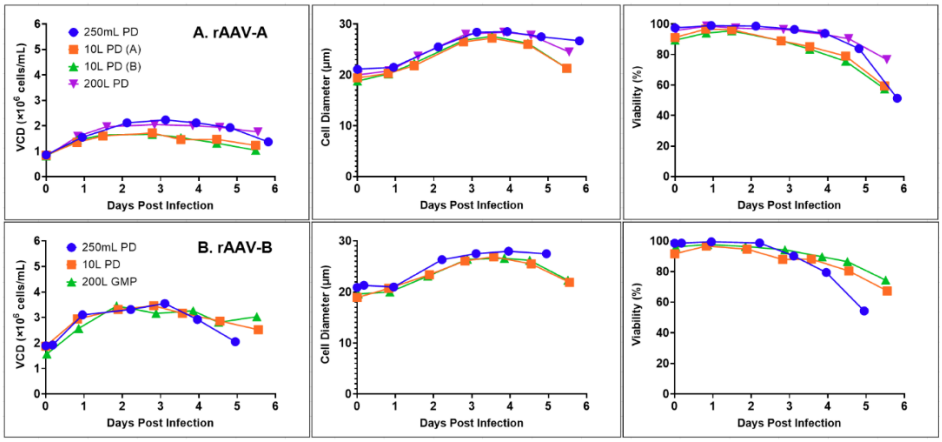

Figure 1: Cell culture behavior following infection by BIICs in 250mL, 10L, and 200L bioreactors.

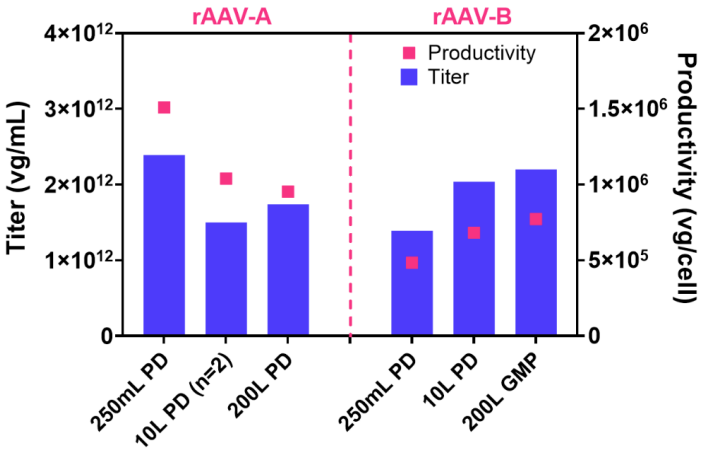

Figure 2: Upstream lysate yields and cell productivities in 250mL, 10L, and 200L bioreactors.

1973 Novel Cell Engineering Platform for High-Yield AAV Production and Improved Manufacturability via Engineered HEK-293 Cells.

Kathy Ngo[1], Anson Shai[1], **Larry Forman[2]***
[1]CHO Plus, Inc., South San Francisco, CA, [2]CHO Plus, South San Francisco, CA

AAV has emerged as a significant therapeutic modality in gene therapy. Challenges such as poor yield and variable product quality persist in the viral vector manufacturing space and we have addressed these problems using our cell engineering technology.

Our cell engineering platform for improved adeno-associated virus (AAV) manufacturing addresses the critical challenges in gene therapy manufacturing, and presents an innovative modality for improving cells for production of viral vector therapeutics. Our platform, yielding cells with improved AAV production and

CQAs, can significantly bolster the efficiency and cost-effectiveness of gene therapy manufacturing, and can accelerate current development timelines.

We used a directed-evolution approach based on repeated cell fusions to shuffle the cell genome, and amplify chromosomes of HEK-293 host cells. Engineered clones enriched for mitochondria phenotypes were isolated, then used as transient-transfection hosts, and for creating stable packaging and producer cell lines. For generation of stable packaging and producer cell lines, we developed a novel inducible system that maximizes the capabilities of the inherent viral production machinery.

Engineered HEK-293 clones grown in suspension culture exhibited up to 15-fold productivity improvement via triple transient transfection for AAV1, AAV2, AAV5, and AAV9 serotypes with capsid titers as high as 10^{17} viral particles/L (vp/L)—at least 10-fold higher than current industrial manufacturing processes. Selection for certain mitochondria phenotypes resulted in a 2-fold improvement in full-to-empty ratio—up to 55% full in crude supernatants. Finally, our engineered stable packaging and producer cell lines achieved capsid titers of up to 10^{16} vp/L.

We demonstrated a multi-modal cell-engineering platform that has significantly improved yield and manufacturability for transient transfection and for stable packaging and producer cell line methods. We further propose a model regarding the role of mitochondria for enhancing capsid percent-full. Taken together, our platform technologies provide solutions for meeting current and future gene therapy manufacturing challenges.

1974 AAVone System Generates over 5E15 VG/L AAV9 Vectors in Suspension HEK 293 Cells

The high cost of adeno-associated virus (AAV) production is a significant hurdle for its widespread use as therapeutics, despite its relative safety and high efficiency in gene delivery to specific tissues. We previously reported a single-plasmid AAV production system, named AAVone, in which all necessary components for AAV packaging are consolidated into a single plasmid with an approximately 13-kb backbone, achieves two-to-four-fold higher productivity and equal or better AAV quality compared to the traditional triple plasmid transfection. The system requires significantly less total plasmid DNA (pDNA) amount for AAV production compared to triple plasmid transfection. To further optimize the AAVone production system, we here report that by selection of cell culture medium, transfection reagents, transfection enhancers and boosters, productivity of the AAVone system can be further increased more than 5E+15 vg/L of culture using one specific medium combined with a specific transfection reagent and two booster reagents in suspension mammalian cells like VPC2.0. For example, using a pAAVone-AAV9-CMV-EGFP construct (transgene size around 2.8 kb), a titer of 5.8E15 vg/L of culture in the crude cell lysate was achieved. Further productivity evaluation with other AAV serotypes and transgenes, as well as scale-up production and characterization of the AAV vectors produced by this protocol, is ongoing. Taken together, process optimization is crucial for new AAV production systems, including AAVone system. The high productivity of AAVone system with less plasmid amount requirement could significantly reduce the cost of high-quality AAV production, especially for large-scale manufacturing, potentially increase patient accessibility to AAV gene therapy drugs.

1975 Process Optimization of a Baculovirus-Insect Cell Expression System for Scalable rAAV Production

Megan Del Greco[1], Kara Levine[1], ELMY XAVIER[1]
[1]MilliporeSigma, Bedford, MA

Large-scale manufacturing of viral vectors can be labor-intensive and costly, particularly when producing materials for therapeutic trials. The baculovirus-insect cell expression system, a well-established platform for vaccine manufacturing, serves as a recognized alternative to HEK-293 platforms for recombinant adeno-associated virus (rAAV) production. This system offers several advantages, including enhanced safety—since baculovirus cannot replicate in mammalian cells—scalability, the use of baculovirus-infected insect cells (BIICs) for streamlined processing, and reduced cost of goods (COGs) at scale. To produce rAAV, the insect cell culture is co-infected with two BIIC banks: one expressing the rep and cap genes (RepCap) and the other expressing the gene of interest. In this study, we present a strategy for development of a scalable and robust upstream process for large-scale AAV production in an insect cell platform. We will also explore how factors such as BIIC ratio, agitation rate, gassing, and cell density at the time of infection can significantly impact process robustness in bioreactors. Finally, we will share data on mid-stream processing methods, including detergent evaluation and endonuclease treatment.

1976 Development of a Robust AAV Upstream Platform Using next generation Raw material, a Comprehensive Design-of-Experiment (DoE) approach & High-Throughput Automated Bioreactors

David Ede[1], Érica Schulze[2], Hakima Flice[3], Christophe Cheve[4], Thomas Jeffrey[5], Paul Giroud[6], Maina Kerbrat[7], Frederique Marme-galloo[7], Timo Schmidberger[8], Noushin Dianat[9], Véronique Blouin[10], Emilie Aubran[11], Oumeya Adjali[12], Laurence Guianvarc'h[13]
[1]Bohemia, NY, [2]Sartorius, Göttingen, Lower Saxony, Germany, [3]Sartorius, Illkirch, France, [4]UMR1089, [5]Sartorius, Royston, United Kingdom, [6]Oxford Biomedica, ILLKIRCH-GRAFFENSTADEN, Bas-Rhin, France, [7]Sartorius, Aubagne, France, [8]Sartorius, Goettingen, Niedersachsen, Germany, [9]Sartorius, Paris, Paris, France, [10]Nantes, FRANCE, [11]Capacites, Nantes, France, [12]TaRGeT Laboratory, Nantes, France, [13]Orchard Therapeutics, London, London, United Kingdom

To date, 7 recombinant adeno-associated virus (rAAV)-based gene therapies have received FDA approval, 215 are in clinical trial phase and over 1,000 are currently underway development worldwide. Despite these advances, vector manufacturing remains challenging for therapeutic applications requiring high systemic doses, highlighting the need for new methods to efficiently scale up rAAV production. This will increase rAAV yields and reduce costs, paving the way for more straightforward commercialization. Past efforts to improve rAAV production have focused on optimizing a single variable at a time in non-automated systems (shake flasks), but this approach does not account for the interactions of multiple factors that contribute to vector generation, nor the environment in which the virus is produced.

To address these limitations, we employed a design-of-experiment (DOE) methodology to optimize rAAV2 production in HEK-293 cells cultivated in an automated bioreactor. In the first round of DOE we chose to focus on optimizing bioreactor operating parameters and cell culture media selection. In the second round of DOE, we further fine-tuned cell culture parameters (feeding and booster strategy). In the third and final round of DOE we focused on optimizing the transfection conditions (VCD, DNA amount, plasmid ratio and transfection reagent volume). Using the optimized process derived from these DoE models, we have increased by 73-fold rAAV2 productivity compared to initial conditions in shake flask, reaching above 8.8 ×1011 vg/mL, along with achieving a full particle count above 20 % for rAAV2, which is known to be challenging to produce. These findings underscore the pivotal role in the choice of raw materials, in the use of DoE and in optimizing production processes in automated bioreactors.

1977 Fast-Tracking AAV Process Development Using Innovative and Universal Approaches – The Platform of the Future

DAVID VINCENT[1], Daphne Bocciarelli[2]
[1]EXmoor Pharma Concepts Ltd, BRISTOL, South Gloucestershire, United Kingdom, [2]eXmoor pharma, Bristol, Bristol, City of, United Kingdom

The gene therapy industry is advancing rapidly, with growing emphasis on milestone-driven investment. In this high-pressure environment, companies no longer have the luxury of time or budgets to undertake extensive, product-specific process development from the outset. As such, the future lies in platform approaches that facilitate IND submission within the first year and enable rapid product launch. This presentation will focus on three key AAV production process steps that are notoriously challenging and time-consuming to optimise: transfection, cell culture, and polishing chromatography. We will explore novel strategies and technologies that may offer solutions to streamline these complex processes.

Traditionally, small-scale experiments and Design of Experiments (DoE) approaches are employed to optimise the transfection step. But what if there were a universal solution that could boost AAV productivity and purity? In this talk, we will investigate innovative additives that can be seamlessly integrated into the upstream process, working independently of major industry suppliers. These additives offer a cost-effective alternative to commonly used reagents. We will present promising results from a small-scale screening study of commercially available additives that are suitable for GMP manufacturing and expand on future hopes from the technology.

Increasing upstream yields can also be achieved through alternative strategies. Rather than spending months developing a process from scratch and incrementally improving it by targeting a range of culture parameters, what if perfusion and high-density cultures could bypass the need for such extensive development? We will evaluate the true impact of perfusion on both development timelines and cost of goods considerations, demonstrating how they can accelerate AAV development.

Lastly, we will delve into the intricacies of downstream AAV development, focusing on the challenges of anion exchange chromatography during the polishing step, which is critical for achieving high particle enrichment. This step is widely recognised as both complex and time-consuming to optimise, often requiring numerous studies that, even with Design of Experiment (DoE) approaches, still fail to yield a streamlined process. What if the use of Choline Chloride as an elution salt could dramatically enhance product separation from the outset, in comparison to the commonly used Sodium Chloride, thereby accelerating the entire development process? We will present a data set that has the potential to transform our approach to the polishing step.

We will conclude by introducing our innovative platform of the future, and showcasing our latest partnerships that will help revolutionise AAV process development.

1978 Scaling Up AAV Manufacturing: Expanding AAV-based Therapies Beyond Rare Diseases with Genevoyager Bac/Sf9 System

Xiaobin He[1], Xing Pan[1], He Xiao[2], Yicheng Zhou[2], Liang Du[2], Mengdie Wang[2], Guangmeng Liu[2], Huanhuan Zuo[2]
[1]Genevoyager, Philadelphia, PA, [2]Genevoyager, Wuhan, China

Adeno-associated viral (AAV) vectors hold immense promises for gene therapy, yet challenges in production yield, scalability, and stability have limited their broader application. To address these challenges, Genevoyager has developed a proprietary Bac/Sf9 system, offering a scalable and efficient platform capable of producing high-quality AAVs with reduced costs.

The Genevoyager Bac/Sf9 system achieves high yields of 1E+15 to 5E+15 vg/L during scale-up manufacturing. With a consistent recovery rate of ≥30% from 5L to 200L and minimal product loss during each purification step, the platform demonstrates good scalability and efficiency for large-scale production.

In this system, the Baculovirus Expression Vector (BEV) has been optimized to maintain stability over multiple passages and during long-term storage at ≤-80°C for over 24 months. This modification ensures consistent high yields and robust expression levels of AAV batches at commercial scales.

AAVs produced with the Genevoyager Bac/Sf9 system exhibit low aggregation even at high concentration (3E+14 vg/mL). Stability assessments, including ddPCR-GOI and main peak SEC-HPLC, demonstrate that product quality remains stable under 4°C and withstands multiple freeze-thaw cycles.

Moreover, the Bac/Sf9-derived AAVs are free of residual replication-competent AAVs (rcAAVs), exhibit high purity and deliver high expression levels, addressing critical safety and efficacy concerns for gene therapy.

The scalability, robustness, and reliability of the Genevoyager Bac/Sf9 system make it an efficient platform for developing AAV-based therapies not only for rare diseases but also for common conditions such as cardiovascular diseases, cancers, and autoimmune disorders. This system represents a significant advancement in overcoming the production and stability challenges of AAVs, thereby enabling broader access to treatments for a larger patient population.

1979 Strategies to Remove Pre-Existing AAV Antibodies: IgG Enzymatic Degradation vs FcRn inhibition.

Yash Shah[1], Rohini Sheth[1], Layth Awartani[2], Deanna Sedlak[3], Cara Richardson[4], Audry Fernandez[3], Lisa Aimone[3], Dan Kemp[3], Canwen Jiang[5], Simon Lacey[6], Shari Gordon[7]
[1]AskBio, Durham, NC, [2]Askbio, Research Triangle Park, NC, [3]AskBio, Morrisville, NC, [4]AskBio, Durham, [5]AskBio, Durham, North Carolina, [6]AskBio, Philadelphia, PA, [7]Ask Bio, Morrisville, NC

Pre-existing Adeno-associated virus (AAV) antibodies may reduce efficacy of gene therapy by preventing transduction of systemically administered AAV vectors. Moreover, high doses of systemically administered AAV vectors may lead to antibody-mediated complement activation and contribute to immune-related adverse events. Thus, individuals with pre-existing circulating AAV antibodies are often excluded from enrollment in gene therapy trials. To address this issue, there has been significant work in the field to evaluate strategies to reduce the levels of circulating immunoglobulins (IgG) in sera such as plasmapheresis, antibody cleaving enzymes, and more recently FcRN inhibitors. In this study we directly compared an FcRn inhibitor to an IgG cleavage enzyme for their ability to reduce circulating IgG antibodies and enable AAV transduction.

This study utilized a transgenic mouse model (scid FcRn-/- hFcRn (32) Tg mice) wherein immunodeficient mice expressed the human alpha chain FCGRT molecule. To model varying titers of pre-existing antibodies, human intravenous immunoglobulin (IVIG) was given to simulate low level NAb titers and a recombinant, anti-AAV antibody was used to model high NAb titers on day 1. Twenty-four hours later, mice were given either saline, IgG cleavage enzyme, or an FcRn inhibitor via tail vein injection. On day 6 mice were administered 5e10 vg/mouse of an AAV-luciferase vector. Circulating levels of human Ig and AAV specific antibodies were measured weekly and transgene expression monitored by luciferase in-vivo imaging. IVIG and antibody infusion inhibited AAV transduction as seen by reducing luciferase expression in the liver. Mice treated with either IgG cleavage enzymes or the FcRn inhibitor had significantly reduced levels of circulating antibodies. IgG cleavage enzyme treatment fully restored transgene expression comparable to animals without pre-existing AAV antibodies. However, mice treated with the FcRn inhibitor showed a partial restoration with the average luciferase expression significantly less than both the IgG enzyme treated group and the AAV control animals without pre-existing antibodies. These preliminary studies directly compare various strategies to remove pre-existing AAV antibodies and confirm the utility of IgG cleavage enzymes as an approach to potentially expand the pool of patients eligible for systemically administered AAV gene therapy.

1980 Short-Term Repeat Dosing of KJ103 (Ricefidase) Enables Sustained IgG Reduction for Enhanced AAV Gene Therapy

Clara Chang[1], **Yunxia (Erica) Xu[2]**
[1]Baopharma, Taiepi, Taipei, Taiwan, [2]Bao Pharma, Shanghai, Shanghai, China

KJ103 (ricefidase) is a recombinant IgG-degrading enzyme designed to transiently reduce circulating IgG levels, thereby enhancing the efficacy and safety of AAV-based gene therapies. While previous studies have demonstrated its ability to lower IgG and neutralizing antibody (NAb) titers, the feasibility of short-term repeat dosing remains uncertain.

In an on-going Phase 2 study conducted by Bao pharma in China, we present clinical evidence confirming that a second administration of KJ103 within one week of the initial dose is both safe and effective in further reducing IgG levels. We had observed the antibody concentration reduction in 2 consecutive doses within 10 days. This dosing strategy will expand the therapeutic window for different types of AAV vector administration, potentially increasing patient eligibility and improving gene transduction efficiency.

Theoretically, our findings support the incorporation of a repeat-dosing regimen into future protocols of AAV-based gene therapies, providing a novel insight to overcome both pre-existing and treatment-induced anti-AAV immunity.

1981 Clinical Validation of Short-Term Triple Dosing of KJ103 (Ricefidase) for Sustained IgG Reduction in AAV Gene Therapy

Clara Chang[1], **Yunxia (Erica) Xu[2]**
[1]Baopharma, Taiepi, Taipei, Taiwan, [2]Bao Pharma, Shanghai, Shanghai, China

KJ103 (ricefidase) is a recombinant IgG-degrading enzyme designed to transiently lower circulating IgG levels, enhancing efficacy of AAV-based gene therapy. While both single and repeat dosing regimens have shown effectiveness, the impact of more intensive IgG depletion remains unexplored.

In a clinical study conducted by Bao Pharma, we evaluated the safety and efficacy of a short-term triple-dosing regimen of KJ103. Our findings confirm that three consecutive doses within 14 days maintain a favorable safety profile while achieving a deeper and more sustained IgG reduction. This intensified approach may further expand the therapeutic window for AAV vector delivery, mitigating both preexisting and treatment-induced immunity.

These results establish KJ103 as a versatile tool for optimizing AAV-based gene therapy strategies, with potential implications for broader clinical applications.

1982 Rapid Transient Antibody Depletion using Genetically Engineered IgG-Degrading Enzyme allows efficient rAAV9 Gene Delivery in an α-AAV9-Ab$^+$ rabbit model

Surendra Sharma[1], Genevieve Abd[2], Allen Zheng[3], Tierra Bobo[4], Haiyan Fu[5]
[1]UNC Gene Therapy Vector Core, Chapel Hill, NC, [2]NeuroGT, Inc., Chapel Hill, NC, [3]NeuroGT Inc, Durham, NC, [4]University of North Carolina, Chapel Hill, North Carolina, [5]The University of North Carolina at Chapel Hill, Gene Therapy Center, Chapel Hill, NC

The widespread presence of pre-existing anti-AAV antibodies (αAAV-Abs) in humans poses a critical barrier to the translation of rAAV gene therapy, and only individuals negative for αAAV-Abs are currently eligible for treatment. The IgG degrading enzyme of Streptococci (IdeS) has been demonstrated to specifically cleave IgG of humans, primates, sheep, and rabbit (but not mouse) origin, with the demonstrated potential of depleting pre-existing αAAV-Abs for AAV gene delivery. Using site-directed mutagenesis, we engineered a new recombinant IdeS protein, Ab-cleaver 9.2 (Ab-C9.2), to address the unmet need, enhancing thermal stability and IgG-depleting function. For

testing Ab-C9.2 in vivo, we generated a αAAV9-Abs+ rabbit model by immunizing the animals with an IV injection of rAAV9 vector at 2-5x109vg/kg, resulting in serum levels of αAAV9 neutralizing Abs (αAAV9-NAbs) at 1:200-1:6,400 and αAAV9-IgG at 1:400-1:6,400. 3 months post-immunization, an IV injection of Ab-C9.2 (0.5mg/kg) in animals with αAAV-nAbs ranging from 1:200-1:1,600 led to the rapid reduction of total IgG to undetectable levels and αAAV-nAbs to ≤1:80 within 24hr. Importantly, an IV injection of AAV9-hSGSH vector administered 24hr post Ab-C9.2 treatment led to effective transduction in rabbits with serum αAAV9-nAbs reduced to ≤1:20, comparable to that in rabbits negative for αAAV9-nAbs. However, the clearance of the IV-injected AAV9 vectors were observed in animals with serum αAAV9-nAbs reduced to 1:80. These results indicate that IV Ab-C offers a great tool to overcome the pre-existing αAAV-Abs for the translation of rAAV gene therapy to treat diseases in humans, though it may have limits in depleting pre-existing αAAV9-nAbs under acute Ab conditions. We believe that Ab depletion with Ab-C9.2 may make rAAV gene therapy available to all patients needing administration and re-administration.

1983 Low Pre-existing AAV-Neutralizing Titers Detected Using a Cell-Based Assay Did Not Impact 4D-310 Safety or Efficacy in Fabry Cardiomyopathy Patients

Brian Long[1], Josh Holter[2], Alan Cohen[1], Zachary Sellers[1], Christian Vettermann[1], David Kirn[1], An Song[1]
[1]4D Molecular Therapeutics (4DMT), Emeryville, CA [2]Iris Medicine, Richmond, CA

Introduction: 4D-310 is an investigational genetic medicine for Fabry disease cardiomyopathy that employs a novel cardiotropic AAV capsid (C102) to deliver a human *GLA* transgene to cardiomyocytes for cell-autonomous alpha-galactosidase (AGA) production. The INGLAXA Phase 1/2 study previously enrolled 6 participants who are followed for up to five years following systemic 4D-310 dose administration.

Methods: Participants were tested for neutralizing antibodies (NAb) specific for the C102 capsid using both a cell-based transduction inhibition assay and an electro-chemiluminescent ligand-binding total anti-drug antibody (ADA) assay.

Results: A retrospective assessment of screening samples revealed that 3 of 6 participants dosed with 4D-310 showed measurable titers of C102 neutralizing factors using the cell-based transduction inhibition assay at baseline, prior to gene therapy dose administration. However, all 6 study participants were negative at baseline for C102 capsid-binding total antibodies as measured in the ligand-binding assay. Participants who were retrospectively found to be positive for pre-existing neutralizing factors, in the absence of clear evidence of capsid-specific antibodies, showed similar or better efficacy outcomes and comparable safety outcomes at Week 52 compared to those who tested negative for neutralizing factors.

Conclusion: Our data underscore that cell-based assays to detect AAV capsid neutralizing factors, in particular assays without a confirmatory Protein A/G/L depletion step, may over-estimate the prevalence of pre-existing AAV neutralizing antibodies. Implementation of ligand-binding total ADA assays for patient screening can help minimize the risk of excluding patients who may otherwise benefit from AAV gene therapy.

1984 Evaluating Neutralizing Antibodies Against AAVs Using a High-Sensitivity LacZ Reporter Assay

Tiffany Pan[1], Venkata Kuppireddy[1], **Irene Song**[2]
[1]PackGene Biotech INC, Houston, TX, [2]Packgene Biotech, Houston, TX

Adeno-associated viruses (AAVs) have become a critical tool for delivering therapeutic genes in gene therapy applications. However, the presence of pre-existing AAV neutralizing antibodies (nAbs) in patients poses a significant risk by reducing the efficacy and safety of AAV-based therapies. Furthermore, the immune response following administration of AAV gene therapy products (DTP) can generate new neutralizing antibodies, complicating long-term treatment outcomes. Therefore, robust methods to measure the levels of nAbs in patients before and after therapy are essential for clinical success.

We have developed a novel LacZ reporter system tailored for multiple AAV serotypes, which enables sensitive and efficient detection of AAV neutralizing antibodies using a cell-based assay. Unlike traditional approaches requiring multi-step protocols and DNA extraction, this single-step method directly quantifies AAV-driven LacZ activity in cell lysates, offering a streamlined workflow with minimal handling and broad dynamic range. The signal remains stable for over one hour, ensuring consistent and reproducible readouts.

This innovative assay offers a powerful and reliable platform for assessing the immunogenicity of AAV-based gene therapies, providing a rapid and streamlined method for detecting neutralizing antibodies. Continued development of such advanced assay platforms is crucial for addressing key challenges in the field, supporting therapeutic research, and ensuring safer and more effective outcomes for patients undergoing AAV-based gene therapy.

3000 Isolation, Quantification, and Cryopreservation of CD34+ Cells from Newborn Cord Blood in Tanzania: Preparing for Gene and Cell Therapy Research

Mohamed Alimohamed[1], Aisha Fikirini[1], Salmaan Karim, Florence Urio[1], Zacharia Mtulo[1], Grace Moshi[1,2], Fadhlun Al-Beity[1], SIANA NKYA[1], Julie Makani[1]
[1]*Muhimbili University of Health and Allied Sciences, Tanzania* [2]*KKH, Singapore*

Introduction
CD34+ cells in cord blood are progenitor stem cells that give rise to all lymphohematopoietic lineages and are crucial for cell-based therapies. The dose and quality of CD34+ cells are vital for successful engraftment in hematopoietic stem cell therapies. This study aimed to validate the efficiency of density gradient centrifugation and magnetic-activated cell sorting (MACS) methods for isolating, purifying, and quantifying CD34+ cells from fresh and frozen cord blood samples in a Tanzanian setting, contributing to the limited knowledge on CD34+ cells from African population.

Materials and Methods
This experimental study included 44 cord blood samples from randomly selected, pregnant women at Muhimbili National Hospital (MNH) and Aga Khan Hospital (AKH). The pregnant women were requested to consent for the cord blood to be collected after they gave birth. Cord blood was collected by qualified nurses and doctors. Sickle cell status of the newborns was determined from the cord blood using a rapid, competitive lateral flow assay (HemoTypeSC TM, Silver Lake Research, USA). Mononuclear cells were isolated by density gradient centrifugation (Ficoll-Paque TM PLUS media, Cytiva, Sweden). A single-platform flow cytometry (BD FACSCanto™ II Clinical Flow Cytometry System - BD Biosciences, USA) assay was used to obtain the absolute count of enriched CD34+ cells with the CD34 MicroBead Kit human 2x2 mL (Order no.: 130-046-702, Miltenyi Biotec, Germany). Both fresh and frozen enriched CD34+ samples were stained with nuclear dye (7AAD) and CD34/CD45 antibodies for enumeration and viability assessment.

Results
Screening for sickle cell status showed that 85.71% of the newborns were AA (homozygous hemoglobin A) and 14.29% were AS (heterozygous hemoglobin S, sickle-cell trait). MACS purification yielded fractions with the maximum purity of 66.3% CD34+ cells for fresh samples and 33.7% for the frozen samples. The median percentage of CD34+ cells in non-enriched samples was 1.17% (IQR, 0.775 – 1.245 %) whereas in enriched samples was 66.65% (IQR, 49.8 – 68.5%). Majority of the enriched cells expressed CD34 antigen alone (66.3%), a small proportion expressed both CD34 and CD45 markers (1.51%), and CD45 was expressed by 32.0%.

Conclusion
The methods for isolating, purifying, and quantifying CD34+ cells were successfully validated in a Tanzania setting, enhancing knowledge of CD34+ cells from African population. This validation of the feasibility of using MACS for CD34+ cell enrichment from
cord blood samples, paves the way for further research and potential clinical applications in the region.

3001 Metabolic Reprogramming with ADA1 and CD26 Overexpression Enhances IL15-GPC3-CAR T Cell Therapy for Hepatocellular Carcinoma and Reduces Cytokine Release Syndrome Risk

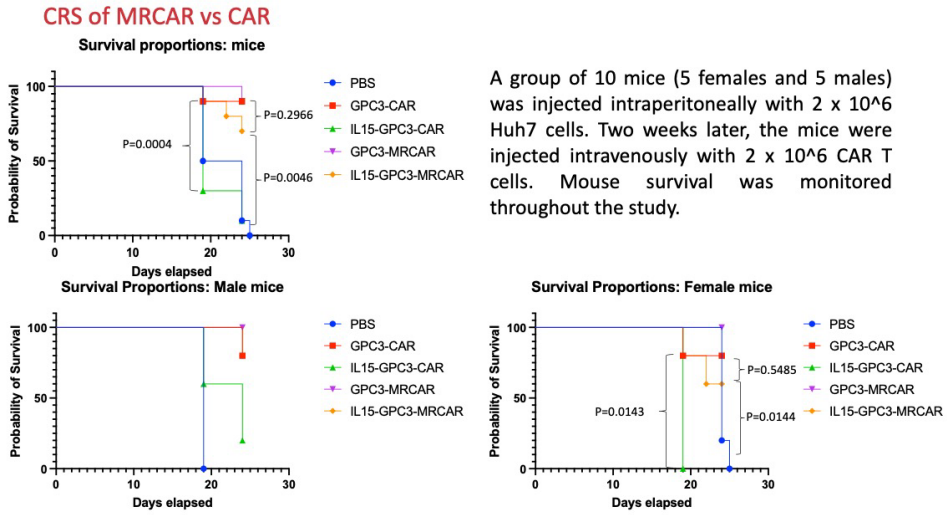
Xiaotong Song[1]
[1]*Texas A&M University, Houston, Texas*

Background:
CAR T cell therapy targeting glypican-3 (GPC3) has shown potential in treating hepatocellular carcinoma (HCC). IL15-GPC3-CAR T cells demonstrated a 33% partial response rate in clinical trials but were associated with severe cytokine release syndrome (CRS) in 75% of patients compared to 8% with GPC3-CAR T cells. Strategies to mitigate CRS while improving therapeutic efficacy are urgently needed, especially for bulky tumors. Previous research established inosine as an alternative energy source for CAR T cells in glucose-deprived tumor microenvironments (TME) (Nat Metab, 2020) and demonstrated that adenosine deaminase 1 (ADA1) enhances T cell survival by converting adenosine to inosine while reducing pro-inflammatory cytokine production (Cell Rep Med, 2024). Additionally, CD26 has been shown to promote T cell trafficking and invasion into solid tumors. This study explores ADA1-driven metabolic reprogramming and CD26 overexpression to optimize IL15-armed GPC3-CAR T cell therapy for HCC by enhancing persistence, invasion capacity, and mitigating inflammatory toxicity.

Methods:
Peripheral blood mononuclear cells (PBMCs) were transduced with retroviral vectors encoding IL15-GPC3-CAR, ADA1, and CD26 (designated IL15-GPC3-MRCAR). Therapeutic efficacy, tumor infiltration, and toxicity were assessed using a Huh7 xenograft mouse model. Cytokine profiles and survival outcomes were evaluated to gauge immune activation, invasion into bulky tumors, and CRS risk.

Results:
IL15-GPC3-MRCAR T cells exhibited enhanced proliferation, reduced exhaustion, and significantly improved invasion into bulky tumors after repeated HCC stimulation in vitro. These cells showed greater cytotoxic activity and deeper tumor penetration compared to IL15-GPC3-CAR or GPC3-MRCAR T cells in vitro and in vivo. While IL15-GPC3-CAR T cells induced severe CRS and high mortality rates, IL15-GPC3-MRCAR T cells significantly prolonged survival with outcomes comparable to GPC3-CAR and GPC3-MRCAR T cells. Tumor infiltration studies confirmed superior invasion of IL15-GPC3-MRCAR T cells due to CD26 overexpression.

Conclusions:
Integrating ADA1 and CD26 overexpression into IL15-GPC3-CAR T cells enhances metabolic fitness, antitumor activity, tumor invasion, and safety by reducing CRS risk. This strategy represents a significant advancement in CAR T cell therapy for HCC, warranting further clinical validation.



3002 Engraftment and HIV Resistance of Gene Modified Peripheral Blood Cells in a Phase I Trial of an HIV Stem Cell Gene Therapy: AIDS Malignancy Consortium 097

Joseph Anderson[1], Julie Beegle[2], Deborah Stewart[1], Christina Dyer[1], Amanda Buck[3], Joanna Donatelli[3], Gunjun Shah[4], David Asmuth[1], Richard Pollard[1], Ariela Noy[4], Mehrdad Abedi[1],

[1]*University of California Medical Center*, [2]*UC Davis*, [3]*University of California San Francisco*; [4]*Memorial Sloan Kettering Cancer Center*

Currently there is no effective cure for HIV infected individuals. Stem cell and gene therapy-based approaches aimed to mimic the result of the Berlin Patient and others, who received a delta-32 CCR5 allograft for leukemia and a functional cure of their HIV, have been developed including ongoing human clinical trials. There is an urgent need, however, for strategies that expand gene therapy beyond CCR5 modification to target multiple stages of HIV replication. Thus, we completed a Phase I clinical trial, AMC097, enrolling HIV-related lymphoma patients requiring an autologous transplant using such a multi-target strategy. Following BEAM conditioning, participants received autologous peripheral blood CD34+ cells transduced with a lentiviral vector containing three HIV-resistance genes including a CCR5 shRNA, a chimeric TRIM5alpha gene, and a TAR decoy. A fourth gene was also included in the vector and used as a selectable marker to purify the gene modified cells prior to transplant. Three cohorts of participants (total N=11) each receiving the gene modified cells in a dose dependent ratio along with unmodified cells: 1:1, 2:1, 1:0 of gene modified to unmodified cells were enrolled. This was to initially evaluate the engraftment of the gene modified while reducing the risk to patients who required immune system reconstitution.

Safety of the vector transduced cells was determined by (1) predetermined engraftment timelines and (2) by average vector copy number in the peripheral blood post-transplant by quantitative PCR using a vector-specific primer and probe set. Flow cytometry of immune cell reconstitution in the peripheral blood was also evaluated. In all participants, including the third cohort which only received the vector transduced cells, successful and steady engraftment was observed over the course of one to two years depending on the continued enrollment of each patient.

One participant underwent an optional analytical treatment interruption (ATI) 42 months post-transplant. Criteria for ATI included CD4 >300 and undetectable plasma viral load. Upon analysis of vector copy number in the peripheral blood, an 8-fold increase in gene marking was observed at seven weeks post-ATI. An in-house single-cell droplet PCR method to evaluate HIV infection in this patient's cells during the ATI estimated that approximately 75% of the gene modified cells were protected from de novo infection compared to cells without detectable lentiviral vector DNA. This protection of infection was similar at both early and late ATI timepoints. ATI was suspended on week 8, after the CD4 and plasma viral load safety thresholds were met. CD4 rose to >300 one week post-treatment resumption and viral load became undetectable by week 8. Our results highlight both the safety and efficacy of our approach and warrants further assessment.

3003 Hematopoietic stem cell gene therapy as a novel therapeutic approach for Angelman syndrome

Joseph Anderson[1], Julie Beegle[2], Anna Adhikari[3], Nycole Copping[3], Jill Silverman[4]
[1]*University of California Medical Center,* [2]*UC Davis,* [3]*University of California Davis MIND Institute,* [4]*University of California Davis SOM*

Angelman Syndrome (AS) is a rare genetic neurodevelopmental disorder characterized by developmental delays, impaired communication, impaired motor skills, including coordination, gait and balance. Cognitive dysfunction is illustrated by traits of poor attention, and moderate to profound intellectual disabilities. Novel strategies to treat Angelman Syndrome are critical as there is no proven efficacious cure nor corrective therapy approved by the FDA. A stem cell gene therapy approach has the potential to deliver therapeutic levels of the missing enzyme, ubiquitin ligase E3A (UBE3A) to affected neurons by cross-correction, a successful form of gene replacement therapy, currently utilized with broad successes in various lysosomal storage diseases and leukodystrophies. Transplantation of autologous blood stem cells that are genetically engineered to express

UBE3A/Ube3a could alleviate, restore, and potentially halt the development of AS phenotypes. Our current work illustrates the effectiveness of transplanted human CD34+ hematopoietic stem and progenitor cells that were transduced using a lentiviral vector that expressed a modified mouse isoform 3 of Ube3a using an immunodeficient Ube3a-deficient mouse model. Transplanted mice were assayed using various indices of behavior including motor and cognitive assays, neurophysiology, and power spectral density, in order for us to quantify efficacy of the cell transplants in newborn and adult mice. Assays included open field exploration, beam walking, gait analysis via treadmill walking, novel object recognition, seizure thresholds and numerous indices using EEG. Significant improvements in AS-related clinical phenotypes in all behavioral and neurophysiological domains tested were observed in the mice transplanted with the Ube3a vector transduced cells compared to empty vector control cell transplanted mice. A significant increase in Ube3a protein expression was observed in the brain tissue of these mice. These results highlight this HSCGT strategy as a novel therapeutic approach for the treatment for AS patients.

3004 Significant improvement of clinical phenotypes for Syngap1 and Rett syndrome upon transplantation of lentivector transduced human CD34+ cells into disease-specific mouse models

Joseph Anderson[1], Jill Silverman[2], Camilla Barbaduomo[1], Alyse Lodigiani[1], Julie Beegle[3],
[1]*University of California Medical Center,* [2]*University of California Davis SOM*, [3]*UC Davis*

Neurodevelopmental disorders (NDDs), including autism spectrum disorder (ASD) and intellectual disabilities (IDs) are prevalent and pervasive lifelong disorders for which no symptomatic targeted pharmaceuticals nor precision curative interventions are readily available. Single gene disorders are among the most well understood NDDs given their straightforward inheritance patterns and genetic etiology. With the demonstrated success of cross-correction stem cell gene therapy for a variety of lysosomal storage disorders, leukodystrophies, and in our recent work for Angelman syndrome, we attempted to utilize hematopoietic stem cell gene therapy for other NDDs, including Syngap1, Rett syndrome. Lentiviral vectors were developed to express modified forms of SYNGAP1 and MECP2, respectively. Upon transduction of human CD34+ hematopoietic stem and progenitor cells(HSPC) and transplantation into immunodeficient versions of the Syngap1+/- and Mecp2+/- deficient mouse models, significant improvement in disease-related phenotypes were observed. These included reductions in elevated activity and improved fine motor grasping ability reported previously, in Syngap1+/-- mice. We observed restoration of movement and improved grasping ability in female Mecp2+/- mice. A significant increase in the expression of Syngap1 and Mecp2 were observed in brain tissues of the respective mouse models upon transplantation of vector transduced HSPC. These results highlight the ability of gene modified human CD34+ cells as a novel therapeutic approach for genetic NDDs, broadly, even in cases of highly differing mechanistic etiologies. Future directions include identifying the underlying mechanism of action and comparing and contrasting how a single therapeutic strategy can provide broad efficacy.

3005 Optimization of *CNGA3* Gene Therapy For Achromatopsia Using Stochastic Modeling and Sensitivity Analysis

Niranjana Sendil Kumar
The Charter School of Wilmington

Achromatopsia is a bilateral inherited retinal degeneration disorder caused by a mutation in the CNGA3 (Cyclic Nucleotide Gated Channel Subunit Alpha 3) protein-coding gene, affecting every 1 in 30,000 people. Mutations in the CNGA3 cause myopia, nystagmus, and loss of photopic vision. Achromatopsia gene therapy treats patients by delivering a functional copy of the CNGA3 gene to the affected cone cells. The treatment uses adeno-associated viruses (AAVs) or other viral vectors. A statistical analysis of stochastic models can be used to analyze the randomness in achromatopsia gene therapy, ensuring the ability to configure efficacy by modeling the sensitivities of the delivery efficiency and immune rejection. The variability in the therapeutic outcome requires an understanding of the factors influencing the efficacy.

A stochastic model was developed to assess the variability of the CNGA3 gene therapy in photopic and scotopic vision. Pycharm, a Python programming software was used to study the stochastic models and sensitivity models from the data provided by the NIH's clinical trials. The analysis and visualizations were conducted using Python and Matplotlib. Based on this variability, a sensitivity analysis was used to evaluate the impact of delivery efficiency and immune rejection probabilities on the sensitivity of scotopic and photopic vision.

From the stochastic modeling, it was concluded that photopic vision has higher variability than scotopic vision. The data revealed that poor delivery efficiency was caused by the immune rejection of the delivery vectors rather than the biological component. Delivery efficiency and immune rejection presented an inverse relationship; for example, delivery efficiency increased only when immune rejection decreased.

The efficiency of CNGA3 gene therapy can be enhanced by utilizing immunosuppressive delivery vectors to mitigate vector-related immune responses. Stochastic modeling is valuable in pinpointing critical variables responsible for CNGA3 therapy's success. Stochastic modeling in medicine can help more than 200,000 individuals worldwide benefit from therapeutic CNGA3 gene therapy, enlisting them for absolute freedom.

3006 Impact of Source Material Refrigerated Shipping and Storage on Isolated B-cell Gene Expression — An Artificial Intelligence and Machine Learning Enhanced Study

Ethan Deitcher[1], Kirk Trisler[1], Hannah Adams[1,2], Steven Deitcher[1]
[1]*Bespoke Biotherapeutics,* [2]*Williams College*

INTRODUCTION:
Apheresis (AP) collection of peripheral blood mononuclear cell (PBMC) products typically requires one- or two-day refrigerated shipping to a central facility for target cell isolation and cellular immunotherapy manufacture. Some have assumed that immune cell populations isolated from shipped PBMC or whole blood (WB) products are unaffected by the delayed processing. We used bioinformatics, artificial intelligence (AI), and machine learning (ML) to compare gene expression profiles of B-cells isolated at 3, 24, and 48 hours after matched healthy PBMC and WB source material collection.

METHODS: WB was collected via venipuncture prior to AP in 3 healthy adult donors. Source materials were transported and stored at 4°C. B-cells were positively isolated using anti-CD19 immunomagnetic MACS® MicroBeads, without prior density gradient centrifugation or red cell lysis, at 3, 24, and 48 hours post-collection. After RNA extraction from the B-cell isolates, individual samples underwent bulk RNA sequencing. Relative proportions of immune cell subtypes were quantified using the iSort™ Fractions v1.4 (CIBERSORT) AI/ML-based digital cytometry deconvolution algorithm applied to bulk RNAseq gene expression data, and by flow cytometry. iSort HiRes v1.1 (CIBERSORT) was run and sequencing reads mapped and quantified by Salmon v1.9 with Gencode v31 annotation. Significant inferred, differentially expressed genes were defined as having log2foldchange >0.5 or <−0.5 and false discovery rate adjusted p-value <0.05. Significance vs. magnitude of expression change was visualized via volcano plots.

RESULTS: Digital cytometry results (mean±SE) for WB and AP-derived PBMC are presented in uploaded Table 1. Immune cell ratios were confirmed by flow cytometry. The number of significantly, differentially expressed genes in B-cells from PBMC and WB are presented in uploaded Table 2. Of 30 evaluated B-cell-specific genes, 24 (80%) were expressed at higher levels in WB- than PBMC-derived B-cells after both 24 and 48 hours simulated shipping. Specifically, CXCR4 expression (i.e., chemotaxis, motility, and survival) decreased and PMAIP1 expression (i.e., pro-apoptosis) increased linearly over time in B-cells from both PBMC and WB.

DISCUSSION: The gene expression profiles of human B-cells isolated from AP-derived PBMC products and WB following 24 hours and 48 hours of simulated shipping at 4°C are not identical to those isolated within 3 hours of collection. We used AI/ML-based digital cytometry and inferred B-cell specific gene expression to eliminate misleading gene expression noise from non-B-cells, mostly monocytes and NK cells, found primarily in the B-cell isolates from PBMC. The differential gene expression profiles suggest that, regardless of source material, but more so in AP-derived PBMC, the longer the period of refrigerated “shipping” the more mitochondrially stressed and likely dysfunctional the isolated B-cells. The interval between source material collection and isolation of B-cells, and probably other immune cells, for the manufacture of adoptive cell therapies should be minimized to optimize infused product performance.

Table 1

	AP-DERIVED PBMC (%)			VENOUS WB (%)

3007 Enhancer AAVs for the Treatment of Motor Deficits in Parkinson's Disease.

Ananya Chowdhury[1], Alex Fraser[1], Max Departee[1], John Mich[1], Emily Kussick[1], Naz Taskin[1], Victoria Omstead[1], Nathaly Munoz[1], Ximena Opitz-Araya[1], Refugio Martinez[1], Kathryn Gudsnuk[1], Boaz Levi[1], Ed Lein[1], Jonathan Ting[1], Tanya Daigle[1]

[1]*Allen Institute for Brain Science*

Impairment of the nigrostriatal system and decreased levels of dopamine release in the striatum has been recognized as the principal neuropathology underlying Parkinson's disease (PD). However, there is still no cure or therapeutics to slow disease progression. The most widely used treatment is levodopa (L-DOPA), and while effective in the short-term, prolonged usage of this drug has been known to cause dyskinesias (i.e., impairments in regular movements), collectively called LIDs (L-DOPA-induced-dyskinesias). Gene therapy has the potential to provide long-term clinical benefits for debilitating human disorders, including Parkinson's disease. One of these trials showed promising results using AAV2 to drive the expression of human aromatic l-amino acid decarboxylase (hAADC)—a rate-limiting enzyme in dopamine synthesis—under the control of a ubiquitous promoter (CMV). This required a bilateral, intraoperative MRI-guided putaminal infusion, which is expensive, highly invasive, and prone to technical issues. The ability to deliver the therapeutic cargo non-invasively while retaining selectivity would be a huge advancement in the field of gene therapy.

To determine if cell type specificity in delivering hAADC may improve the efficacy of L-Dopa treatment and reduced LIDs, we developed an enhancer-based AAV toolkit to systemically target relevant cell populations (striatal medium spiny neurons (pan-MSNs), striatal cholinergic neurons, and midbrain dopamine neurons) with low off-target expression. We tested the efficacy of our lead pan-MSN vector in a 6-OHDA toxin model and MCI genetic PD model in mice, using multiple behavioral paradigms. Our work showed that when directly injected into the

dorsal striatum of mice, the cell-type specific intervention had more robust rescue than ubiquitous expression, which is currently the benchmark in clinical trials. Furthermore, intravenous delivery of pan-MSN-specific hAADC ameliorated specific motor-related deficits in these models while exhibiting fewer adverse side effects than ubiquitous CMV-promoter AAV. Our enhancer-based strategy needed a lower dose of L-DOPA to restore their motor behaviors, which could improve the quality of life by delaying the onset and possibly diminishing the detrimental side effects of L-Dopa in the patients. A higher dose of L-Dopa over two weeks showed a significantly lower frequency of dyskinesia (LIDs) with MSN-specific enhancer AAV compared to no virus and ubiquitous groups. Intravenous delivery of striatal cholinergic- and midbrain dopaminergic-specific hAADC also showed strong behavioral rescue in the unilateral toxin model at the lower L-Dopa dose but not in the genetic model where the loss of dopaminergic projections to the striatum is more pronounced and developmental. The lead pan-MSN vector was further evaluated in non-human primates (NHP) following intraparenchymal and intracerebroventricular delivery, demonstrating cross-species expression and translational capability.

In summary, our work provides strong proof-of-concept data supporting enhancer-AAVs as potential circuit-selective therapies for PD. Cell-type-specific expression of hAADC via a noninvasive route of administration can improve motor functions in PD patients with a lower dose of L-DOPA. This enables us to bypass invasive brain surgery to achieve a similar or better therapeutic effect while simultaneously reducing the disruptive side effects of the drug treatment.

3008 Establishing Chemistry, Manufacturing, and Controls (CMC) and Its Impact on Critical Components of Clinical Trials

Mo Heidaran
CHCF Brain Foundation, Potomac, MD

There are two broad categories of assays used in cell and gene therapy products from my perspective: **Category 1:** These assays are used to characterize and/or release the drug product. Given the higher risk to the product if a release assay is not qualified and validated, it is important for sponsors to demonstrate that these assays are appropriately qualified and validated for each phase. For instance, prior to the initiation of pivotal studies, assays for safety, identity, purity, and potency should be fully qualified and, in some cases, validated. **Category 2:** These assays are used to test patient materials in clinical trials. Examples include genetic tests for determining patient inclusion or exclusion, assays to measure anti-drug antibodies, and assays used to measure potential surrogate endpoints. Because these assays pose a higher risk to the patient if not controlled, there have been recent changes in the formal expectations for how sponsors should demonstrate their fit-for-purpose and robustness during the clinical trial. Assays in the clinical space may be regulated as companion diagnostics (IVD), laboratory-developed tests (LDTs), or may be performed by CLIA-certified labs. I will discuss different requirements for different assays used to support safety and effectiveness of cell and gene therapy products. Is it LDT, IVD and/or companion diagnostics in view of recent changes to the FDA's final rule on LDTs?

3009 VTX-PID Mediated Optimal Depletion of Anti-AAV3B Neutralizing Antibodies in Human Subjects allows to Expand Patient Eligibility for future AAV-Based Gene Therapies

Jean-Philippe Combal[1], Vernadal Elodie[1], Blanche Tamarit[1], Sonia Valero[1], Veronica Ferrer[1], Anne Douar[1], Céline Bouquet[1], Laia Trigueros Motos[2], Gloria Gonzalez-Aseguinolaza[2], Bernard Benichou[1]
[1]*Vivet Therapeutics,* [2]*Center for Applied Medical Research (CIMA) of the University of Navarra*

Preexisting circulating anti-AAV neutralizing antibodies (NAb) prevent AAVs from effectively delivering the therapeutic gene to target cells, reducing the efficacy of gene therapy in a significant proportion of patients ranging from 20 to 65% depending on patient's age and AAV serotype. VTX-PID (imlifidase) is a streptococcal protease that specifically and rapidly cleaves IgG antibodies into F(ab')2 and Fc fragments. Here we report results from a first in man, double blinded and randomized study with single ascending doses (0.075 to 0.6 mg/kg) of VTX-PID in healthy, male subjects, stratified according to their anti-AAV3B NAb levels (intermediate or high) . As of today, twenty-nine subjects have been dosed with VTX-PID or placebo. Within hours, all undigested IgG had disappeared

from plasma at all 4 doses tested and then progressively recovered; similarly, anti-AAV3B NAb levels dropped quickly, with a complete and durable reduction observed at all doses in subjects with intermediate NAb levels. However the effect was more prolonged at the highest dose of 0.6 mg/kg VTX-PID. Three out of 29 currently treated subjects developed transient and self resolving mild or moderate IARs (infusion associated reactions), consisting of hot flushes, facial discomfort, exanthema, and/or abdominal discomfort at the highest dose; 13 experienced mild to moderate reversible AEs consisting of musculoskeletal complaints (arthralgia and/or myalgia) accompanied with hs-CRP elevations and leukocytosis, with or without fever. 2 of these subjects also experienced a transient LFT elevation, which triggered the addition of prophylactic prednisone in the 6 next subjects treated at the highest dose. Based on these data, a PK/PD model has been built including variables from patient-specific factors (e.g. ADA, PK, NAbs level…) to define the most suitable dosing schedule to achieve the optimal window for AAV3B-based treatment. Therefore, VTX-PID-mediated anti AAV NAb removal provides an opportunity to expand the patient population that may benefit from AAV-based systemic gene therapies.

3010 Generation of High Purity Allogeneic CAR-T Cells from CD34+ Cord Blood HSPCs Through the Efficient Delivery of Large Genetic Cargos

Sean Allen[1], Samantha Bremner[1], Nanda Sasi[1], Lanny Gov[1], Jiaji Yu[1], Maha Qubain[1], Jeff Wiezorek[1], JJ Kang[1], Jason Damiano[1]
[1]*Appia Bio*

The development of next-generation allogeneic cell therapies from primary cells requires the efficient delivery of numerous transgenes to maximize product purity and functionality in vivo, necessitating the development of techniques to increase the capacity of genetic cargo delivery. Here we describe an approach that utilizes dual LVV with a “Split TCR” architecture to deliver 5+ transgenes and create stem cell-derived γδT or NKT cells with optimal purity and functional properties. Off-the-shelf chimeric antigen receptor (CAR) expressing T cells derived from hematopoietic stem and progenitor cells (HSPCs) require the stable integration of the CAR transgene (typically >1 kb), a TCR (~1.8 kb), as well as other payloads to provide armoring of the product to improve its potency or persistence. As all viral delivery methods have limitations on the size of DNA that can be packaged and delivered per virion, we have developed a method of transducing cells with two lentiviral constructs simultaneously, where each construct contains one TCR chain. Appia’s ACUA (Appia Cells Utilized for Allogeneic) platform applies selective pressure during cell differentiation and expansion throughout CAR-T manufacturing for cells expressing a complete TCR complex. This allows for cells with the stable integration of both TCR chains to outperform cells with only one chain, resulting in >80% of end-product cells expressing all transgenes. Beyond the CAR and TCR, this "Split TCR" LVV design approach allows for the inclusion of armoring payloads, shRNA expression cassettes, and multiple promoters to provide desirable pharmacological features to drug candidates. “Split TCR” CD19-CAR γδT and NKT cells potently killed target cells in vitro in both short- and long-term cytotoxicity assays, demonstrated robust target-specific expansion in vitro, and displayed high levels of in vivo efficacy in a tumor model. This work demonstrates the ability to efficiently deliver >10 kb of integrated DNA to HSPCs, resulting in robust expression of 5+ transgenes to generate highly efficacious allogeneic CAR-T cells. Furthermore, this process has been found to be compatible with large-scale manufacturing of development candidates to support clinical trials in autoimmune diseases and cancer.

3011 Case study of Single use centrifuges for processing HEK lenti virus in both intensification and viral collection in bench and manufacturing scales

David Richardson
Carrbiosystems

CARR Biosystems™ manufactures three sizes of single-use centrifuges: UFMini®, UniFuge® Pilot, and U2k®. All three centrifuges provide versatility with capabilities to collect concentrate and wash HEK – 293 and Vero to collect both AAV, and Lentivirus. These systems achieve >90% recovery, are scalable, and they reduce filtration. CARR Biosystems single-use centrifuges are in licensed facilities for human therapeutics and have been in the manufacturing environment since 2010. This presentation will examine case study from a viral

vector clinical manufacturing facility. These HEK cell lines are very sticky and tend to clog filters, with our single-use centrifuge- we increase viral titer while reducing filtration.

3012 AAV-Mediated DUX4 Knockdown in Facioscapulohumeral Muscular Dystrophy: Therapeutic Benefits and Challenges for Long-Term Efficacy

Virginie Mariot[1], Solene Sohn[2], Sophie Reid[2], Maximilien Bowen[3], Canille Hudon[2], Emilio Corbex[2], Baptiste Morel-Prieur[3], Christophe Hourde[3], Julie Dumonceaux[1]
[1]*University College London*; [2]*UCL GOSH Institute of Child health*; [3]*Universite Savoie Mont Blanc*

Background:
Facioscapulohumeral muscular dystrophy (FSHD) is characterised by the aberrant expression of the toxic transcription factor DUX4 in skeletal muscle, leading to progressive muscle degeneration. Therapeutic strategies targeting DUX4 inhibition are promising, with AAV-mediated delivery emerging as a key approach. However, the regenerative nature of skeletal muscle poses a challenge to AAV-based therapies, as muscle fibre turnover can diminish AAV transduction efficiency and the persistence of therapeutic transgenes over time. Aims: This study aimed to evaluate the efficacy and durability of AAV-mediated DUX4 inhibition using an AAV vector carrying a short hairpin RNA targeting DUX4 (shDUX4) in a mouse model of FSHD. The goal was to assess this approach's short- and long-term therapeutic impact and identify potential limitations.

Methods:
The ACTA1-MCM; FLExDUX4/+ mouse model, which replicates key features of FSHD, was used. Mice received a single administration of AAV-shDUX4 (MyoAAV 2A capsid), and therapeutic efficacy was assessed one month and 10 months post-treatment. Outcomes included molecular analyses, histopathological evaluation, and functional assessments using force-velocity-endurance (FOvE) tests. The persistence of AAV genomes and DUX4 knockdown efficacy were also evaluated over time.

Results:
One month after AAV-shDUX4 administration, significant improvements were observed in DUX4-associated pathological features, including reduced molecular markers of toxicity, improved muscle histology, and enhanced functional FOvE parameters. However, by 10 months post-treatment, these therapeutic benefits had largely diminished. Most pathological markers remained uncorrected, and muscle force showed no sustained improvement. The decline in therapeutic effect is correlated with reduced DUX4 knockdown and a loss of AAV genomes, which is likely due to muscle fiber turnover and AAV genome dilution.

Conclusion:
AAV-mediated shDUX4 therapy offers significant short-term benefits for FSHD by effectively suppressing DUX4 expression. However, the long-term therapeutic efficacy is limited by muscle fibre regeneration and associated AAV genome loss. These findings underscore the need for strategies to enhance the durability of AAV-based therapies to achieve sustained benefits in FSHD treatment.

3013 Myostatin is a Marker of Disease Severity in Facioscapulohumeral Dystrophy

Virginie Mariot[1], Solene Sohn[2], Sandrine Arbogast[3], Dalila Laoudj-Chenivesse[3], **Julie Dumonceaux**[1]
[1]*University College London*, [2]*UCL GOSH Institute of Child health*,[3]*Universite of Montpellier*

Background:
Facioscapulohumeral dystrophy (FSHD) is a rare genetic disease with a prevalence of 4.5/100000 in Europe. The disease is characterised by weakness and atrophy of specific muscle groups. The likely cause of the disease is the aberrant expression of the double homeobox DUX4 transcription factor in skeletal muscles. Over the past five years, DUX4 has become a favourite target for pharmaceutical companies developing treatments for FSHD, and several approaches to mitigate DUX4's pathological role have been developed, including small molecules, antisense oligonucleotides, and gene therapy vectors, with 2 clinical trials currently underway. However, the clinical trials are complicated by the high variability in disease onset and progression in patients. Moreover, a significant challenge in

the FSHD field is the difficulty in measuring DUX4 expression in patient biopsies, which complicates disease monitoring and therapy development. While circulating biomarkers could provide a quantitative and robust measure of disease severity and therapeutic efficacy, none are currently available.

Aims
This study aimed to evaluate myostatin (MSTN) as a potential biomarker for FSHD disease severity.

Methods
We analysed serum MSTN levels in FSHD patients and healthy controls, followed by a larger analysis of serum from 51 FSHD patients using ELISA. The correlations between MSTN levels and clinical severity scores were evaluated. We then used a DUX4-expressing mouse model, which exhibits chronic and mosaic DUX4 expression and develops an FSHD-like pathology over time to measure Mstn levels at both the mRNA and protein levels in muscle biopsies and serum.

Results
In mice expressing DUX4, Mstn expression was significantly lower at both the mRNA and circulating protein levels than controls, with further decreases observed as the disease progressed. In FSHD patients, MSTN levels were approximately two-fold lower than in healthy controls. In the larger patient cohort, MSTN levels strongly inversely correlated with clinical score (pearson r=-0.74; $p = 9 \times 10^{-10}$).

Conclusion
Our findings suggest that MSTN could be a reliable biomarker of the severity of FSHD disease.

3014 Drug Discovery of Next-Generation Circular mRna Vaccine Platform Targeting Tumor Immune Escape Mechanism

Peng Huang, Tianyun Zhou, Kazuyo Igawa, Hiroyuki Michiue, Motoo Araki
Okayama University

Introduction & Objectives
Immunotherapy represents a novel therapeutic approach to cancer treatment in which the immune system's potential is harnessed to recognize and eliminate tumor cells. mRNA vaccines are regarded as a highly promising avenue for next-generation cancer immunotherapy. The purpose of this study is to create an innovative cancer treatment method that is new mRNA vaccines can cure even advanced prostate cancers that have invaded or metastasized.

Materials & Methods
Using benign prostatic hyperplasia, hormone-sensitive prostate cancer and Castration-Resistant Prostate Cancer tissues from the same patient, multiple tumor-specific mutant mRNAs were identified using a next-generation sequencing approach, candidate circRNA expression was validated by quantitative real- time PCR (RT- qPCR) using divergent primers. Furthermore, mutant mRNAs are delivered by existing nanocarriers, as a novel platform of mRNA vaccines.

Results and Conclusions
We identified multiple neoepitopes from mutant mRNAs that are upregulated in prostate cancer samples from clinical samples and verified with the MiOncoCirc database. Human leukocyte antigen binding affinity of open reading frames from potentially translatable circRNA was assessed using pVACtools. low-dose circRNA nanoparticles elicited potent immune responses in both young adult mice and aged mice, protected mice from target cell challenge, and mediated robust tumor immunotherapy.

In conclusion, this study will lay the foundation to develop circRNA as a novel platform of mRNA vaccines for wide application in the prophylaxis and treatment of cancer.

3015 First-in-human study of cord blood-derived NK cells generated by mRNA-LNP- for relapsed/refractory acute leukemia

Antonio Carrasco[1], **Sonia Macia Escalante**[2], Hassan Bennani[3]
[1]*Clinica Anglo Americana,* [2]*SMED Clinical Research*, [3]*Immunovacell*

Acute myeloid leukemia (AML) is an aggressive cancer in which an excess of myeloblasts is found in bone marrow and blood. AML is the most common type of acute leukemia in adults, accounting for 80% of acute leukemia cases in Western countries. The main cause of therapeutic failure is resistance to chemotherapy by abnormal pathways that allow blasts survive and relapsing even after attaining complete response. Although prognosis for relapsed/refractory (R/R) patients is particularly poor, a proportion can be efficaciously salvaged using chemotherapy-based therapies followed by allogeneic hematopoietic stem cell transplant. However, many AML patients are not considered candidates for front-line or salvage intensive chemotherapy-based strategies. Given the dismal prognosis and the absence of standard/satisfactory treatment options, patients with R/R AML continue to represent a challenging unmet medical need. Cellular immunotherapy is gathering increasing interest for cancer treatment, which can be deployed in different ways: lymphokine-activated killer (LAK) therapy, tumor-infiltrating lymphocyte (TIL) and, for better recognition and killing of tumor cells, modified immune cells expressing antigen-specific T cell receptors (TCRs) or chimeric antigen receptors (CARs).

CAR-NK cells have a potential for generating “off-the-shelf” products that could be readily available and safe for clinical use. CAR-NK cells can be generated from multiple sources, including NK92 cell lines, peripheral blood mononuclear cells, umbilical cord blood, and induced pluripotent stem cells. Their unique biological features include lower risk of on-target/off-tumor toxicity to normal tissues due to their limited lifespan in blood; potentially eliminate cancer cells in a CAR-independent manner, via both CAR-dependent and NK cell receptor-dependent mechanisms.

One of the major barriers for CAR-NK has been the lack of an efficient gene transfer method in the cultured NK cells. This has been overcome by using a lipid nano particle (LNP) for mRNA delivery into cocultured NK cells at very last state and expanded with IL-2 and IL-15for long lasting presence as circulated CAR-NK after infused.

Manufacture “off-the-shelf” CAR-NK products can be ready for clinical use, with less manufacturing time and lower cost, as it eliminates the manufacturing time and allows true point of care administration and can scale to much larger numbers.

This is an open label, Phase 1 study in adult patients with AML to determine the recommended Phase 2 dose (RP2D) of CAR-NK19. Secondary objectives include PK and preliminary anti-tumor activity. Dose escalation will follow an adaptive design, which would allow to optimize different treatment schedules and increase specific cohorts based on response rate.

3016 Unique Surface Anchoring of Cytokines Mediates Improved T-cell Subpopulation Expansion for Immunotherapy

Colleen O’Connor, Andres Campos, Jinchun Wang, Vanessa Garapola, Andries Zijlstra

StimulusBio

Existing cellular expansion technologies are greatly limited because they are unable to specifically expand target cells, require excessive material resources or synthetics, and lead to unintended or undesired phenotypes. This failure is in large part due to the inability of existing methods to recapitulate the full complement of cell signaling required to mediate target cell expansion. The rapid expansion of cell-based therapies and associated research requires effective expansion with reduced costs and improved scalability. A customizable and programmable cellular interface, sbPCI, was designed to promote selective cellular expansion by purposely creating an individualized T-cell cytokine dosing system to decrease cost and technician time while improving the final immunotherapeutic product. To demonstrate the utility of sbPCI, human RBCs were modified to mediate

stimulation of autologous and/or allogeneic T-cells; specifically in this project, to present activating co-stimulatory molecules, as well as cytokines, Interleukin-2 (IL-2) and Interleukin-21 (IL-21). The sbPCI platform presents biomolecules at a density and configuration optimized previously for T-cell specific activation, while the sbPCI is modified to display tethered cytokines. sbPCI bioactivity was demonstrated through a 21-day expansion assay benchmarking performance metrics against industry standards using exogenous human recombinant IL-2 and IL-21. Expanded T cells were enumerated, cryopreserved, and phenotyped weekly. Additional samples were collected daily and twice per week (24hrs post and at 7-day post stimulation) for gene expression analysis to determine immune-specific mRNA changes. Single cell analysis was also conducted to determine individual T-cell cytokine "feeding" patterns with respect to sbPCI co-culture at a 1:1 ratio. Data analyzed included expansion and genotypic changes.

Variations in the intentional mechanical stressors on the RBC as well as cytokine tethers triggered membrane alterations that resulted in cyclical sbPCI presentation over 5 to 7 days. Continuous cytokine cycling within the co-culture triggered nuanced phenotypic and genotypic T-cell differentiation. The sbPCI drove exponential T-cell expansion with a mean viability ≥ 90%. A 48-hour sbPCI/PBMC co-culture resulted in ≥ 60% of activated T-cell expansion as defined by elevated expression of Granzyme B and IFN-y. By day 7, the cultures were primarily composed of the desired $CD3^{+}CD8^{+}$ T cells. Gene expression was consistent with activation in response to biostimulatory molecule presentation, revealing exploitable T-cell variations accessible through selective programming. Irreversible cellular exhaustion was not observed with the use of sbPCI.

The current implementation of sbPCI emphasizes polyclonal expansion of cytotoxic T-cells. Furthermore, specific tuning of sbPCI expression will be leveraged in future programming to selectively expand variations that emulate the expansion of therapeutically active populations *in vivo*. In doing so, sbPCI can produce subtypes tailored to safely support and improve CAGT efficacy leading to a narrowed production window.

3017 Access to Curative Gene Therapies in Africa: A Syatematic Analysis of Barriers and Enablers

Tchofor Dick Nchang[1], Paul Ashigbie[2], Jonathan Spector[2]
[1]*St. Olaf College*, [2]*Novartis Institutes for BioMedical Research*

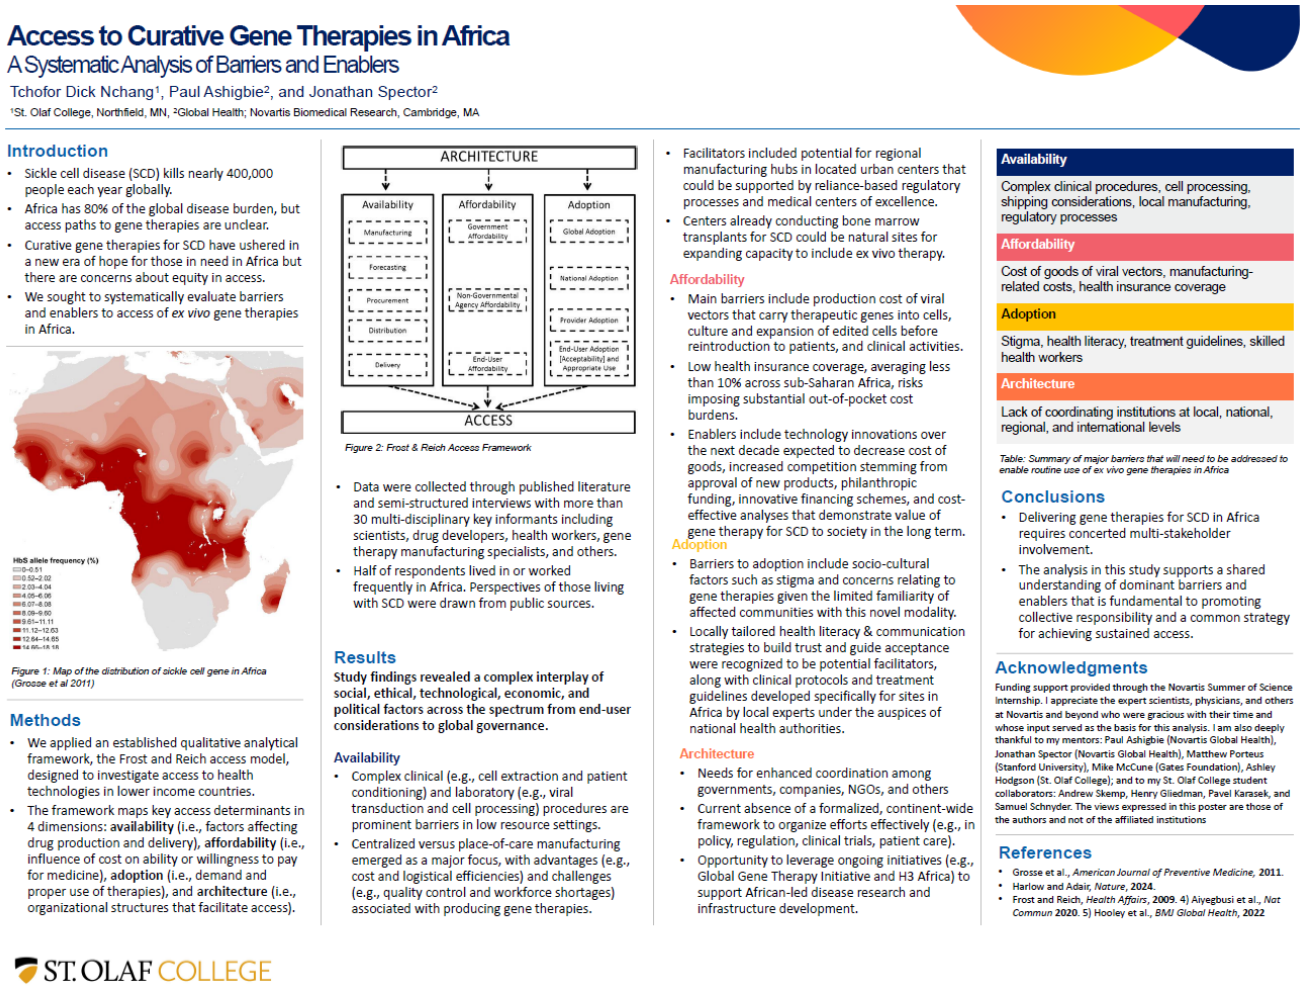
Background
The recent approval of curative gene therapies for sickle cell disease (SCD) is to be celebrated even as concerns have been voiced about equity in access to medicines in Africa, home to 80% of births affected by SCD. This study systematically evaluated barriers and enablers to ex vivo gene therapy distribution in Africa using an established qualitative analytical framework designed to investigate access to health technologies in lower-income countries.

Methods
The model used in this study maps key access determinants across four dimensions: availability (factors affecting drug production and delivery), affordability (cost influence on ability or willingness to pay), adoption (demand and proper use of therapies), and architecture (organizational structures facilitating access). Data were gathered through published literature and semi-structured interviews with over 30 multi-disciplinary experts including scientists, clinicians, and gene therapy specialists. More than half of respondents worked in Africa. Publicly available perspectives of individuals living with SCD were also included.

Findings
The study revealed a complex interplay of social, technological, economic, and political factors ranging from end-user aspects to global governance. Regarding availability, complex clinical (e.g., cell extraction) and laboratory (e.g., viral transduction) procedures were prominent recognized barriers, while the potential for regional manufacturing hubs in urban centers, supported by reliance-based regulatory processes, emerged as a facilitator. Affordability concerns are driven by high production costs and low health insurance coverage, which risks imposing substantial out-of-pocket expenses. Enablers include future technological innovations expected to lower costs, increased market competition, and innovative financing schemes. Adoption is hindered by socio-cultural factors including stigma and unfamiliarity with gene therapies and enabled by locally tailored health literacy programs and clinical protocols developed by African experts. Architecture challenges include the absence of a formalized,

continent-wide framework to coordinate efforts, although leveraging existing initiatives such as the Global Gene Therapy Initiative could help address this gap.

Conclusion
Delivering gene therapies for SCD in Africa will require concerted multi-stakeholder involvement. This analysis promotes a shared understanding of dominant barriers and enablers that is fundamental to encouraging collective responsibility and a common strategy for achieving sustained access.



3018 A "Transcriptional Repressor Substrate Reduction Strategy" for Tay-Sachs and Sandhoff diseases

Alessia Medugno[1], Rosa Maritato[1], Emanuela D'Andretta[1], Claudio Mussolino[2], Enrico Surace[1]
[1]*University of Naples Federico II,* [2]*Medical Center - University of Freiburg*

Tay-Sachs disease (TSD) and Sandhoff disease (SD) are lysosomal storage disorders caused by mutations in the HEXA and HEXB genes that result in the accumulation of GM2 ganglioside and progressive neurodegeneration. Current treatment options are limited and do not effectively target central nervous system involvement. To address this challenge, we are developing a gene therapy approach that uses transcriptional repressors to regulate genes involved in ganglioside biosynthesis, thereby reducing substrate accumulation. We initially mapped B4GALNT1

regulatory elements in cis by assessing the accessibility-occupancy of the proximal regulatory region of B4GALNT1 by bioinformatics analysis. We then generated constructs with deletions and site-specific modifications of B4GALNT1 regulatory elements and assessed their impact on B4GALNT1 expression by gene reporter assay. Once we identified the critical regions that functionally control B4GALNT1 expression, we validated their relevance by editing these cis-regulatory elements in the native B4GALNT1 locus by genome editing (CRISPR/Cas). In parallel, we are perturbing /interfering the expression of B4GALNT1 by targeting the identified cis targets in trans through (i) ectopic expression of endogenous transcription factors (TFs), (ii) synthetic transcription factors (TFs) and (iii) CRISPR inhibition systems (CRISPRi). We are currently implementing this transcriptional repression strategy also in fibroblasts from patients with Tay-Sachs and Sandhoff diseases.

3019 Engineered Polyclonal Anti-tumor Antibodies to Counteract Tumor Escape

Yarden Shor Nareznoy[1], Nataly Tarasenko[1], Nimrod Golan[1], Adva Levi Barda[2], Anastasiia Fruman[2], Omri Sulimani[2], Oded Raban[2], Ram Eitan[2], Eran Sadot[2], Shay Golan[3], Michal Besser[1], Gal Markel[1], Salomon Stemmer[1], **Alessio Nahmad**[1]
[1]*Samueli Integrative Cancer Pioneering Institute,* [2]*Rabin Medical Center,* [3]*Davidoff Cancer Center*

Counteracting tumor adaptation is a long-standing challenge in oncology. Targeted therapies are susceptible to escape following mutation, shedding, or downregulation of the tumor antigen. Polyclonal treatments targeting multiple antigens may improve outcomes by impeding tumor resistance. Tumor-Infiltrating Lymphocytes are polyclonal T cell therapies clinically approved for the treatment of selected solid tumors. However, these autologous medicines are complex to manufacture. To conceptualize a strategy to overcome tumor resistance, we turned to tumor-infiltrating antibody expressing lymphocytes. Tumor-infiltrating B cells are linked to favorable prognosis and were demonstrated to promote response to immune checkpoint blockade.

We harvest tumor-infiltrating B cells to produce a polyclonal, anti-tumor antibody therapy for multiple malignancies. We enrich, culture and differentiate tumor-infiltrating lymphocytes towards antibody-secreting cells. Polyclonal antibodies purified from tumor-infiltrating B cell cultures effectively bind patient-derived tumor cells and cell lines from similar tumor types.

Importantly, to elicit supraphysiological responses, we engineer tumor-infiltrating antibody-secreting cells. Specifically, we employ CRISPR-Cas9 RNP and AAV transductions to target the constant segments of the antibody coding genes to force the secretion of T cell engager molecules, without modifying the polyclonal variable domains. We achieve up to 23% engineering in patient derived samples. Antibodies purified from engineered tumor-infiltrating lymphocyte cultures engage T cells without significant impairment in tumor binding capacity.

Anti-tumor antibodies may also be extracted from tumor-associated fluids. Indeed, ascites-infiltrating antibody expressing cells are more frequent than in peripheral blood, enabling robust cell cultures from very large samples. Polyclonal antibodies derived from ascites fluids or from ascites infiltrating B cells cultures also display anti-tumor activity, but not antibodies derived from the sera of healthy donors or antibodies from the sera of patients with similar tumor types. Polyclonal antibodies derived from these strategies did not bind healthy cells, indicative of tumor specificity and facilitate tumor cell killing in co-cultures with effector cells.

Uniquely, our method produces engineered polyclonal anti-tumor antibodies for a wide variety of solid malignancies. This therapy is non-autologous and combining several sources of antibodies may produce a potent therapeutic with cross-tumor reactivity. We propose that polyclonal anti-tumor antibody therapy should be considered as a novel strategy to counteract tumor escape.

3020 Challenges and Advancements in GLP-Compliant Preclinical Toxicology Studies for ATMPs

Riccardo Bazzoni, Alice Busato, Giulia Speziali, Alessandro Casartelli, Francesca Martinetto, Dario Salerno, Barbara Vaccarini, Michela Pecoraro, Chiara Cazzin, Massimo Breda

Aptuit (Verona) Srl, an Evotec Company

Preclinical toxicology studies play a critical role in the drug development t ensuring their safety and effectiveness before entering clinical phases. These studies must comply with Good Laboratory Practice (GLP) principles, following international regulatory guidelines (FDA, OECD, EMA, and ICH). While these regulations are well-defined for traditional small-molecule drugs, their direct application to Advanced Therapy Medicinal Products (ATMPs) presents unique challenges. Unlike conventional pharmaceuticals, ATMPs often feature highly diverse and complex mechanisms of action, combining multiple therapeutic strategies, such as gene editing, cell therapy, and tissue engineering, within a single product, and therefore, their unique nature demands a product-specific preclinical development approach. A major hurdle in ensuring GLP compliance for ATMPs lies in addressing critical aspects such as Test Article characterization, manipulation, formulation analysis, stability testing, and the establishment of well-defined acceptance criteria. These challenges are further compounded by the need for specialized delivery techniques, including surgically based in situ administration, which requires meticulous planning, validation, and execution. Additionally, study protocol endpoints must be carefully defined and managed to ensure that the generated toxicology and biodistribution data are not only scientifically robust but also interpretable for regulatory submissions. Given the variability inherent to ATMPs, traditional GLP study designs often require modifications or refinements to accommodate the specific properties of these advanced therapies.

Over the past five years, Evotec's GLP Test Facility has played a pivotal role in refining processes to navigate these complexities, conducting a range of toxicology and biodistribution studies tailored to different ATMP modalities. These include gene therapies mediated by adeno-associated viruses (AAVs) and oncolytic viruses, as well as cell-based therapies utilizing diverse cell types with various administration routes and delivery platforms. In this work, implemented quality risk assessments and optimized processes adopted by Evotec GLP Testing Facility were described. In particular, proper definition of the Test Article characteristics, test article formulation analysis and stability, acceptance criteria, and various management approaches based on different ATMP products were explored. Thanks to this work, the facility has enhanced the reliability and reproducibility of preclinical data while maintaining full GLP compliance. This approach has strengthened the integrity of toxicology and biodistribution evaluations, ensuring that preclinical studies for ATMPs align with both scientific rigor and evolving regulatory expectations.

These advancements highlight the importance of an adaptive, science-driven approach in the preclinical development of ATMPs. By integrating regulatory compliance with innovative risk assessment strategies, research facilities can generate high-quality preclinical data that support the successful clinical translation of these groundbreaking therapies. The ongoing refinement of GLP methodologies specific to ATMPs will be crucial in overcoming current and future challenges, ultimately accelerating the safe and effective development of next-generation cell and gene therapies.

3021 An AAV GMP Manufacturing Solution for Large Clinical Demand Indications

Marina Goldfeld, Eric Lin, Noah Miller-Medzon, Christina Pelella, Elena Bianchetti, Aileen Rottinger, Ambryice Riggs, Alexandro Berumen, Eric Tompkins, Nene Kalu, Vincent Turula, Cathleen Santus; David Lin, Harris Shaikh, **Tim Fenn**, Manny Otero
Lexeo Therapeutics

The high cost of goods (COGs) and low yields of current AAV manufacturing processes preclude development pipelines from considering indications with large patient and/or dose demands due to the significant capital required to supply the clinic and to commercialize the drug product. The combination of costly manufacturing and small number of patients has driven up the price of AAV therapies to record-setting heights, further limiting patient access and under-serving many patient populations. We have developed a highly reproducible and scalable 200L GMP AAV production process using the Sf9-baculovirus system. The process is relatively simple – there is no need for costly plasmids, time-intensive generation of producer cell lines, intensification, or large-scale production of recombinant baculovirus, and purification is a straightforward 2-column process. The overall process delivers over 1E15 vg/L of purified AAVrh.10 product that contains less than 25% empty capsids. A 200L GMP batch can yield approximately thirty (30) 6E13 vg/kg doses for Lexeo's LX2020 PKP2 program. Produced this way, Lexeo's AAV

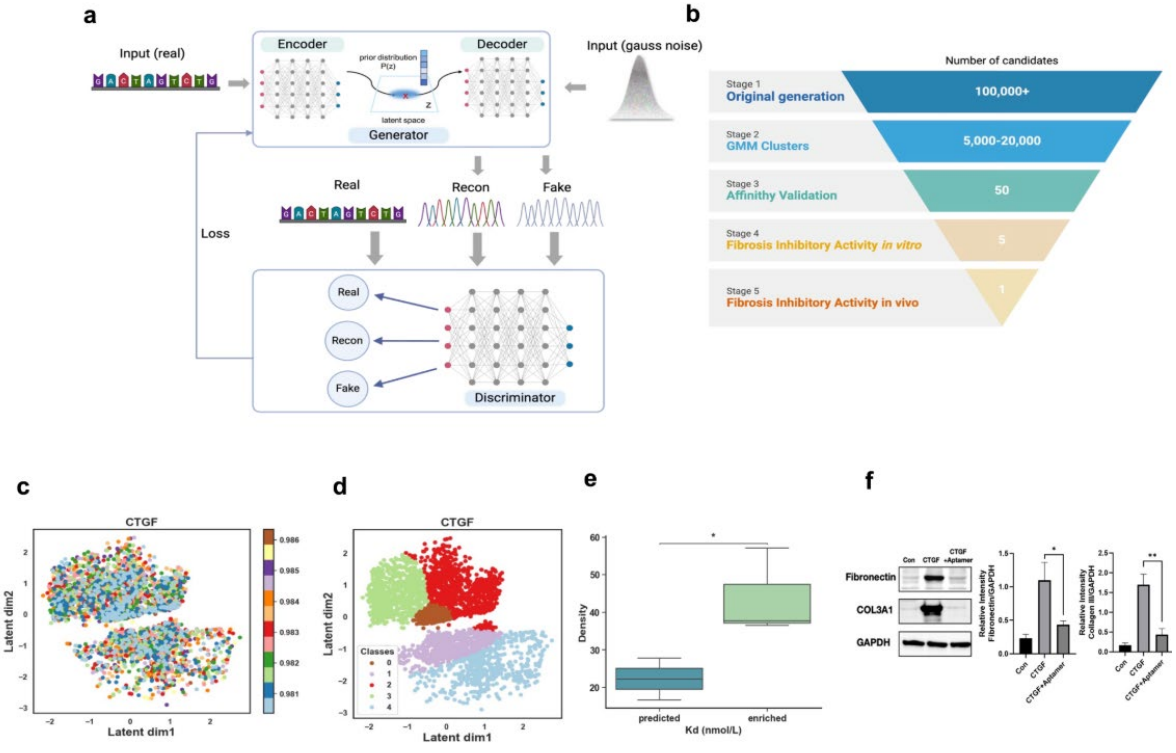
drug substance has shown consistent potency from *in vivo* and IND-enabling studies through GMP production of clinical-grade material and is currently supplying Lexeo's clinical-stage programs.

The current state of AAV manufacturing has significantly limited the progression of AAV gene therapy to successful commercial viability. The universal problem of high COGS and low yield has not allowed gene therapy to have the deep impact on healthcare that it has the potential to do. Lexeo's manufacturing process and overall CMC strategy can dramatically expand patient access and transform the gene therapy field.

3022 AI-powered therapeutic aptamer drug discovery: Targeting CTGF CT-domain for Duchenne muscular dystrophy

Xin Yang[1], Baoting Zhang[2] , Yuanyuan Yu[3] , Sifan Yu[3], Ge Zhang, Shanshan Yao[2], Meishen Ren[1], Huarui Zhang[2] Yufei Pan[4], Luyao Wang[1], Yuan Ma[1], Ding Shijian[1], Aiping Lu[1], Yixin He[5], Zongkang Zhang[2]
[1]*Hong Kong Baptist University*, [2]*The Chinese University of Hong Kong*, [3]*The Hong Kong Baptist University*, [4]*Peking University*, [5]*Aptacure Therapeutics Limited*

Following the clinical failure of the connective tissue growth factor (CTGF) VWC-domain specific antibody (FG-3019) in Duchenne muscular dystrophy (DMD), we identified the CT-domain as an optimal target than the VWC-domain by experimental validation. The inherent flexibility of the CTGF CT-domain presents a challenge for traditional small molecule approaches due to the absence of stable binding pockets, while monoclonal antibody strategies are primarily challenged by lengthy antigenic immune cycles and poor muscle tissue permeability. To address these limitations, we employed our generative AI method, AptGen, to rapidly discover a potent CTGF CT-domain specific aptamer within 42 days. This chemically modified aptamer could distribute and remain in muscle tissues for an extended period, whereas FG-3019 could not do so. Importantly, this aptamer demonstrated better fibrosis inhibitory activity in vitro and in mdx mice when compared to the FG-3019, with no detected lesions in the major organs. Within 10 months, we went from target domain discovery, aptamer drug discovery, and then obtained the orphan drug (DRU-2024-10138) and pediatric rare disease designation (RPD-2024-838) by US FDA.



3023 Adeno-associated Virus (AAV) Inverted Terminal Repeats (ITRs) Induce Toxicity in Breast Cancer Stem Cells

Trace McCall, Matthew Hirsch, Jacquelyn Bower
University of North Carolina at Chapel Hill

The adeno-associated virus (AAV) inverted terminal repeats (ITRs) are the only viral cis elements that remain in the recombinant AAV (rAAV) genomes currently used for gene therapy applications. These 145-nucleotide hairpin-like structures are required for rAAV production and flank both ends of the single-stranded (ss) AAV transgene cassette. Previous reports have suggested that the presence of the AAV-ITR alone, which elicits a cellular DNA damage response (DDR), exhibits significant anti-tumorigenic activity in a subset of cancer cells and cytotoxicity in certain stem and progenitor cells. Because cancer stem cells (CSCs) emerge upon activation of the epithelial to mesenchymal transition (EMT), a transcriptional program involved in the reversion of differentiated epithelial cells to a partially undifferentiated state that mimics the molecular and physiological traits of human embryonic stem cells (hESCs), it was posited that rAAV ITRs could be harnessed to induce selective cell death in CSCs. To investigate this hypothesis, a large and molecularly diverse panel of well-characterized breast cancer cell lines (BCCLs, N=11) were transduced with self-complementary (sc) AAV2 expressing a green fluorescent protein (GFP) reporter under the control of a cytomegalovirus (CMV) promoter (scAAV2-CMV-GFP). Growth rates, cell viability, CSC marker expression, transduction efficiencies, and viral entry were investigated. Cell viability assays completed eight days post-transduction resulted in variable reductions in cell viability across the panel; however, the most sensitive cell lines belonged to the "claudin-low" intrinsic molecular subtype class which is characterized by enrichment of EpCAM-/CD49f+ cell populations (CSCs) and EMT-associated transcriptional profiles. The EpCAM-/CD49f+ CSC population of the two most sensitive BCCLs (MDA-MB-436 and BT549) were further characterized via flow cytometry after treatment with either doxorubicin, a first-line chemotherapy reagent, or scAAV2-CMV-GFP. As expected, both cell lines demonstrated an increase in the percentage of CSCs (>80% of the remaining cells) following treatment with doxorubicin, confirming that the CSC population is chemoresistant. In contrast, three days post-transduction with scAAV2-CMV-GFP, the percentage of CSCs was reduced by up to 20%, suggesting that transduction resulted in CSC death. Data will also be presented to further define the mechanism of AAV-ITR2-associated cell death in CSCs, including the use of small molecule inhibitors of apoptosis and a comparison of ssAAV2-CMV-GFP vectors containing either a wild-type ITR2 (wtITR) or a mutant synthetic ITR (synITR), which has been shown to attenuate p53-dependent apoptosis in hESCs.

3024 In vitro and clinical assessments of muscle specific promoters in driving gene expression and long-term cardiac efficacy in Duchenne muscular dystrophy

Stephanie Salabarria, Benevides Ethan, Jakob Shoti, Denise Cloutier, Christina Cousins, Julie Berthy, Renata Shih, Faris Al-Mousily, Carmen Leon-Astudillo, Manuela Corti, Barry Byrne
University of Florida

BACKGROUND:
AAV derived gene therapy has been the primary approach for gene therapy in Duchenne muscular dystrophy (DMD). Three of these products include zildistrogene varoparvovec (SGT-001), an AAV9 vector containing a CK8 promoter, fordaditrogene movaparvovec (PF-06939926), an AAV9 vector containing an hCK promoter, and delandistrogene-moxeparvovec (SRP-9001, ElevidysÒ), an AAVrh74 vector containing a MHCK7 promoter. There is ongoing discussion surrounding the efficacy of these treatments to prevent or delay the cardiac manifestations of the disease. Here, we aim to demonstrate the effect of each muscle specific promoter from in-vitro and clinical data.

METHODS:
This is a two-part study looking at in-vitro and clinical data using 7 unique muscle specific promoters. Part 1 (In vitro): C2C12 cells underwent lipofectamine transfection of ITR plasmids encoding *Firefly* luciferase downstream of one of seven muscle specific promoters (Desmin, CK8, TNNT, MHCK7, hCK, TCK, SP-5-12). Co-transfection with an ITR plasmid encoding *Renilla* luciferase downstream of the constitutively active EF1α promoter enabled

normalization of luciferase luminescence. A positive control consisting of the constitutively active CBh promoter was included, as well as several negative controls. *Firefly* luminescence was measured at 590 nm while *Renilla* luciferase luminescence was measured at 460 nm. Part 2 (Clinical): Echocardiogram (ECHO) (N=13) and cardiac MRI (cMRI) (N=10) findings for subjects dosed in four DMD gene therapy clinical trials were analyzed (NCT03368742, NCT03362502, NCT03769116, NCT04626674). ECHO and cMRIs were collected at Baseline, Day 360, Day 730 and Years 3-6. cMRIs were only collected in subjects dosed with SGT-001 or PF-06939926. ECHO and cMRIs from baseline and yearly up to year 6 after dosing were included.

RESULTS: Part 1 (In vitro): All muscle promoter groups showed evidence of positive luminescence at both 590 nm and 460 nm. Negative control showed minimal luminescence at comparable levels (mean: 7.7 rlu at 590 nm; 8.3 rlu at 480 nm). The CBh positive control showed the highest normalized luminescence. Of the muscle specific promoters, Desmin showed the highest overall normalized luminescence (mean: 11.6) which was greater than all other promoters on one-way ANOVA ($p < 0.001$). Part 2 (Clinical): Thirteen subjects met criteria. Seven subjects received SGT-001, three received PF-06939926 and three received SRP-9001. Median age (range) at dosing was 7y (4-14). All were on a daily steroid regimen and under standard cardiac care. Left Ventricular Ejection fraction (LVEF) on ECHO analysis remained within normal range for subjects 2-13, median 66% (53-76) and on cMRI analysis for subjects 2-10, median 58.2% (52.5-64.3). The oldest subject (14y, Subject 1) exhibited a decreased EF via cMRI at Year 5 (39%) when compared to his pre-treatment EF (50.9%) however, had near normal left ventricle (LV) endo Global circumferential strain (GCS)% at Year 5 (–16.8).

CONCLUSION: This two-part study illustrated the Desmin promoter was superior to the others in transfecting skeletal muscle and cardiac function was preserved over time in patients treated with gene therapy. Further studies are needed to test efficacy of each promoter in human cardiomyocytes and additional long term follow up is needed to understand the effects of DMD gene therapy are sustained in cardiac muscle.

Figure 1. Echocardiogram (ECHO) Analysis for Subjects 1-13. Shaded areas denote natural history ranges for Left ventricular internal diameter at end-diastole (LVIDd) and Left ventricular ejection fraction (LVEF) of untreated DMD patients.

SGT-001: Circles indicate patients receiving the low dose (5E13 vg/kg), triangles indicate patients receiving the high dose of (2E14vg/kg). PF-06939926: Circles indicate patients receiving the low dose (1E14 vg/kg), triangles indicate patients receiving the intermediate dose (2E14 vg/kg). SRP-9001: Triangles indicate patients receiving 2E14 vg/kg and circles indicate patients receiving 1.33E14 vg/kg.

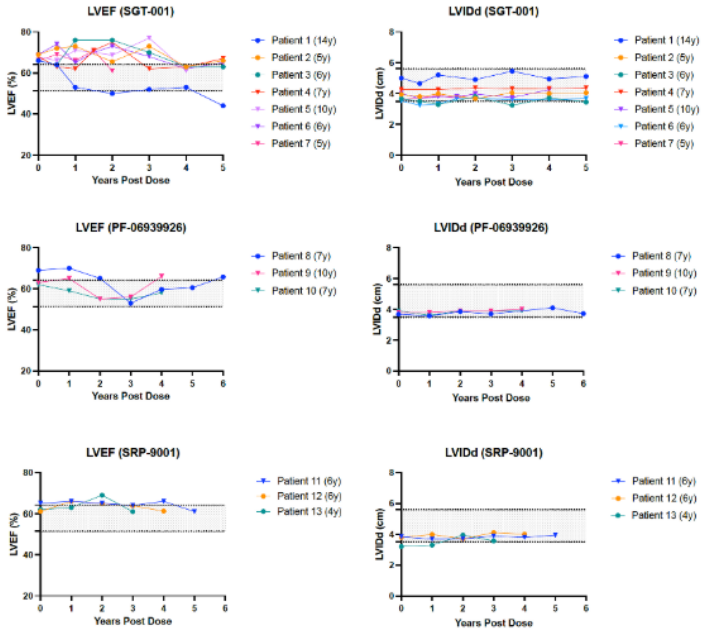


Figure 2. Luciferase luminescence results from transfection experiments using muscle-specific promoters in C2C12 cells. Data are presented as the ratio of *Firefly* to *Renilla* luminescence. One-way ANOVA revealed a significant main effect of promoter type on luminescence ($F(6,14) = 224$, $p < 0.0001$). Tukey's post-hoc test was performed to access pairwise comparisons. The desmin promoter showed significantly higher luminescence compared to all other promoters (* $p < 0.0001$). The hCK promoter showed significantly higher luminescence than all other promoters expect desmin (# $p < 0.05$). The remaining post-hoc comparisons are provided in the table below.

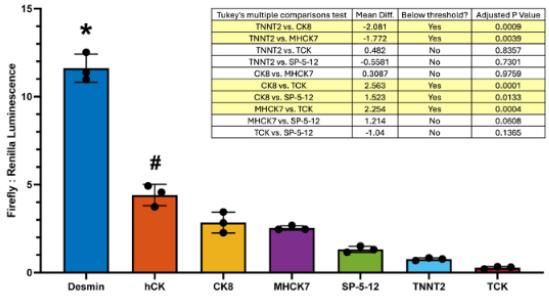

Tukey's multiple comparisons test	Mean Diff.	Below threshold?	Adjusted P Value
TNNT2 vs. CK8	-2.081	Yes	0.0009
TNNT2 vs. MHCK7	-1.772	Yes	0.0039
TNNT2 vs. TCK	0.482	No	0.8357
TNNT2 vs. SP-5-12	-0.5581	No	0.7301
CK8 vs. MHCK7	0.3087	No	0.9759
CK8 vs. TCK	2.563	Yes	0.0001
CK8 vs. SP-5-12	1.523	Yes	0.0133
MHCK7 vs. TCK	2.254	Yes	0.0004
MHCK7 vs. SP-5-12	1.214	No	0.0608
TCK vs. SP-5-12	-1.04	No	0.1365

3025 Leveraging Biobank Scale Data to Uncover Novel Actionable Genetic Variants

Evangelos Nizamis, Julianna Brutman, Tina Busald, Eli Kaufman, Paul Valdmanis
University of Washington

Alzheimer's disease (AD) is the most common form of dementia and has increasing prevalence in global populations. An *APOE-ε4/ε4* genotype is one of the strongest risk factors for AD, though this risk is diminished in individuals with African ancestry. Administration of *APOE* bearing protective variants such as the *APOE* Christchurch missense change represent powerful candidates for AD therapeutics. To uncover novel protective variants for AD and other conditions, we leveraged ~245,400 individuals with short-read whole genome sequencing information of which ~185,000 were unrelated and had matching electronic health record data (EHR) from the NIH *All of Us* dataset. Samples included roughly 32,500 African, 3,200 East Asian, 2,000 South Asian, 98,600 European, 28,200 Admixed American, and 650 individuals of Middle Eastern ancestry. We performed phenome-wide association studies (PheWAS) to identify which of 1,816 potential phenotypes is significantly associated with single nucleotide variants after adjusting for age, sex, and the first three principal components. We confirmed robust association with known variants enriched in African or European populations such as rs334 in sickle cell anemia ($p=1\times10^{-305}$) and rs113993960 in cystic fibrosis ($p=1.91\times10^{-123}$). The ApoE4 defining risk variant rs429358 was associated with AD, but primarily in individuals of European ancestry (OR 2.92; $p=7.31\times10^{-25}$) with less of an effect in individuals of African ancestry (OR 1.59; $p=0.07$). In individuals of African ancestry, we identified several variants that explained this reduced risk, which we confirmed in functional assays in HMC3 and SH-Sy5y cells. Interestingly, we identified several co-morbidities associated with APOE risk or protective variants including hyperlipidemia (OR 1.21; $p=1.1\times10^{-55}$) and hypercholesterolemia (OR 1.24; $p=3.3\times10^{-38}$). Understanding genotype-phenotype correlations is critical for assessing functional effect of therapeutics, especially in a population-specific manner. Addressing phenotypes at scale can help predict and proactively respond to side-effects or co-morbidities of therapy. Collectively, our tools create a powerful roadmap for identifying and acting on protective genetic variants in AD and other human diseases.

3026 Comparison of 8 DNA payloads for universal CAR-T engineering with multi-loci gene editing—cell tolerance, efficiency and accuracy

Lumeng Ye, *GenScript USA Inc.*

Universal CAR-T therapy engineered via non-viral CRISPR gene editing approach could empower CAR-T therapy with more advantages: as targeted precise CAR gene knock-in to ensure its location, copy number per cell and expression level, which make the safety and quality more under the control of engineering process; besides CAR gene knock-in, multiple gene knock-out can be managed simultaneously to eliminate the trigger of host immune

response. This one-step non-viral manufacture process could even further shorten the turn-around time and total cost for CAR-T therapy. Large fragment knock-in by CRISPR DSB (double-stranded break) and HDR (homology-directed repairing) based precise knock-in is widely used for cell therapy development. Managing the balance between editing efficiency and cell viability, the format and quality of DNA payloads is critical to achieve high proportion of CAR expressing cell and good cell fitness after gene editing and manufacture. To provide a thorough comparison of different DNA payloads, we adopted the GFP insertion at TRAC exon 1 in primary T cell via CRISPR gene knock-in, plus B2M and PDCD1 gene knock-out to abrogate surface expression of MHC-I and PD-1 as a multiple-genes editing allogenic universal CAR-T engineering model. Here we collected 8 types of different DNA payloads encoding the same GFP and 300bp homology arms flaking the DSB site of TRAC, to test their performance in the scenario of only TRAC gene knock-out and TRAC+B2M+PDCD1 triple gene knock-outs. For HDR template, we prepared 1) linear ssDNA, 2) classic 5'-ssCTS with annealing oligo, 3) 5'-ssCTS modified as hairpin structure, 4) circular single-stranded DNA, 5) open-ends linear dsDNA prepared by PCR amplification, 6) closed-ends linear dsDNA as GenWand dsDNA, 7) super-coiled circular dsDNA with minimized backbone as GenCircle, and 8) the classic DNA vector as pUC57 plasmid to compare.

For editing efficiency, overall, double-stranded DNA templates (~30%) have lower editing efficiency than single-stranded DNA payloads (40-60%), due to their cytotoxicity caused by trigger cGas-Sting pathway during electroporation. Linear dsDNA has slightly higher editing efficiency than circular dsDNA, but not significant. Single-stranded DNA either in linear or circular format show similar editing efficiency as well. Linear single-stranded DNA with CTS sequence modification at 5'-end has high editing efficiency (60%), due its low cytotoxicity, increase nucleus delivery and better stability with Cas9 RNP protects the 5'-end of linear ssDNA. To our surprise, when we replace the partial dsDNA structure of CTS as self-annealed hairpin structure than the annealing complex of ssDNA and oligo, the editing efficiency decreases, although we can prove the binding of RNP in vitro.

We also measured the editing accuracy by amplifying the insertion flanking region and long-reads nanopore sequencing. Among the three loci editing samples, GFP fragment insertion at other loci than TRAC, especially partial insertion at B2M and PD-1 gene were observed on sequencing reads. Among the 8 DNA payloads, circular ssDNA gives the highest 90% on-target editing accuracy, and ssCTS 88% with improved editing accuracy by RNP binding and guiding, while blunt-ends dsDNA shows multi-loci off-target insertion.

3027 Dynamic of DNA payloads for CRISPR-HDR editing on primary T cell via electroporation

Lumeng Ye, *GenScript USA Inc.*

During the protocol optimization of non-viral CRISPR gene editing for CAR-T engineering, the fact that different editing efficiency by different HDR DNA payload formats on the same editing design draw our attention. We assume this may due to the cytoplasm delivery efficiency of DNA payload via electroporation, and the consequence delivery efficiency into nucleus and cytoplasm stability. To solve this puzzle, we adopted the GFP insertion at TRAC exon 1 in primary T cell via CRISPR gene knock-in as testing model, and prepare 8 different DNA formats, to be delivered with eSpCas9 protein and sgRNA either targeting TRAC to mimic the condition of CRISPR-based knock-in (HDR group), or with sgRNA that targeting RAB11a locus, to measure the stability of DNA payloads under the condition of double-stranded breaking, but no intend gene knock-in via homology-directed repairing (no HDR group). T cell electroporation was done on Neon^{TM} platform 10 µL setting, 0.5 million 48h activated T cell for each run. All the single-stranded DNA payloads were delivered as 2 µg, theoretical calculation is about 4.4 million copy per cell; both of the linear dsDNA payloads were delivered as 0.5 µg due to its toxicity, theoretical calculation is about 0.5 million copy per cell, GenCircle and pUC57 vector were delivered as 1 µg, calculated as 0.88 and 0.43 million copy per cell, respectively. DNA payload stability was measured by harvesting the T cell after electroporation immediately (day 0), and day 3, day 5, day 7, and day 10. Then use qPCR to quantify the copy number of DNA payloads from the washed T cell lysate. Editing efficiency were measured at day 3, 5, 7, and 10 as well.

From the DNA payload copy number measurement on day 0 sample, circular ssDNA was detected as the highest with 0.2 million copy per cell, about 4.7% delivery by electroporation. The second is ssCTS with 0.18 million copy

per cell, about 4.0% delivery efficiency. By comparing the copy number detected at different days, circular ssDNA is observed with the slowest degrading rate, which may explain the toxicity and editing efficiency drop of the 2 μg group on editing results. The stability of ssCTS is higher than the linear ssDNA without CTS design, indicated the 5'-end protection and stability improvement by RNP binding, and its stability data correlates to the high editing efficiency.

In the no HDR group, all 8 DNA payloads continuously degrading. While in the HDR group, elevation of DNA copy number at day 5 compares day 3 observed for most of the DNA payloads with >30% editing efficiency. Another major difference is on the cells with two linear dsDNA payloads, although they have the same copy number at day 10. However, closed-ends dsDNA was detected with higher copy number from day 3 to day 7 in no HDR sample indicates the improved stability by closed-ends, but open-ends dsDNA sample has higher detected copy number from day 5 to day 7, but lower detected editing efficiency. Overall, circular ssDNA and ssCTS degrades the slowest, while GenCircle and pUC57 vector degrades the fastest. To our surprise, the residue of 2 μg cssDNA sample was detected lower than 0.5 μg sample, given the fact of decreased editing efficiency, we hypothesis that an extra DNA degradation event happened in the T cell electroporated with 2 μg cssDNA due to overdosing.

3028 Anti-HIV Function of duo CAR-T Cells is Enhanced by Treatment with an Immunotherapeutic Combining IL-15 Stimulation with TGF-β Inhibition

Sara Lamcaj[1], Erin Cole[1], Shrestha[2], Zhongyu Zhu[3], Ying Xiong[3], Gregory Sowd[3], Boro Dropulic[3], Hing Wong[2], Harris Goldstein[1]

[1]*Albert Einstein College of Medicine*, [2]*HCW Biologics,* [3]*Caring Cross*

Transforming growth factor-β (TGF-β) is a critical immunosuppressive cytokine that suppresses T cell cytotoxic function. Elevated levels of TGF-β are common in people with HIV (PWH) even if treated with antiretroviral therapy (ART) and is associated with systemic inflammation and immune suppression. We previously described a duoCAR-T cell therapy which targets two gp120 sites, the CD4 binding site with the CD4 D1 domain and the coreceptor binding site with a human VH based single domain antibody (sdAb) to target and eliminate HIV-infected cells while protecting the duoCAR-T cells from HIV infection. Despite its potent anti-HIV activity, the suppressive function of duoCAR-T cells may be inhibited by systemic inflammation and elevated TGF-β in PWH. We hypothesized that inhibiting TGF-β activity while stimulating IL-15 signaling using a bifunctional fusion molecule, HCW9218, may unleash a more potent anti-HIV immune response mediated by our duoCAR-T cells. HCW Biologics developed bifunctional immunomodulatory proteins including HCW9218, composed of TGF-βRII and IL-15/IL-15Rα. TGF-βRII acts as a TGF-β sink, effectively neutralizing its activity and the linked IL-15/IL-15Rα activates NK and CD8+ T cells. As controls, we used HCW9228, composed of TGF-βRII with IL-15/IL-15Rα mutated to reduce activity and HCW9238 with a functional IL-15/IL-15Rα but inactivated TGF-βRII. TGF-β neutralizing activity of HCW proteins were evaluated by treating duoCAR-Ts with HCW proteins and TGF-β, followed by quantifying TGF-β induced-phosphorylation of SMAD2/3 (Fig. 1A, B). IL-15 function was assessed by staining for IL-15 induced STAT5 phosphorylation in HCW protein treated T cells and measuring cell growth of duoCAR-Ts stimulated with HCWs and TGF-β after 5 days (Fig. 1C). Anti-HIV activity of duoCAR-Ts in the presence of TGF-β and the HCW proteins was evaluated by HIV viral suppression assays using autologous HIV-LucR-infected CD4+ T cells and cytotoxicity assays targeting 293T-gp120-Luc cells (Fig. 1D, E).

TGF-β-induced SMAD2/3 phosphorylation was inhibited by HCW9218 but not HCW9238 which lacks functional TGF-βRII. HCW9218 displayed robust IL-15 activity by phosphorylating STAT5 in isolated T cells and stimulating proliferation of an IL-15 dependent cell line and HCW9218 IL-15 activity stimulated significantly greater cell growth of duoCAR-Ts compared to HCW9228 treatment (Fig. 1C). duoCAR-Ts treated with TGF-β maintained cytotoxicity and HIV suppression (n=3 donors) in the presence of HCW9218 but not HCW9238 (Fig. 1D, E).

In summary, our findings demonstrate that HCW9218 neutralizes TGF-β activity and thereby prevents TGF-β-mediated inhibition of duoCAR-T cell proliferation, cytotoxicity, and HIV suppression. HCW9218 may serve as an adjunct therapeutic to contribute to a functional cure for HIV by increasing the anti-HIV activity of duoCAR-Ts in PLWH with elevated levels of TGF-β, thereby sustaining their anti-HIV immune responses to suppress the HIV-1 reservoir.

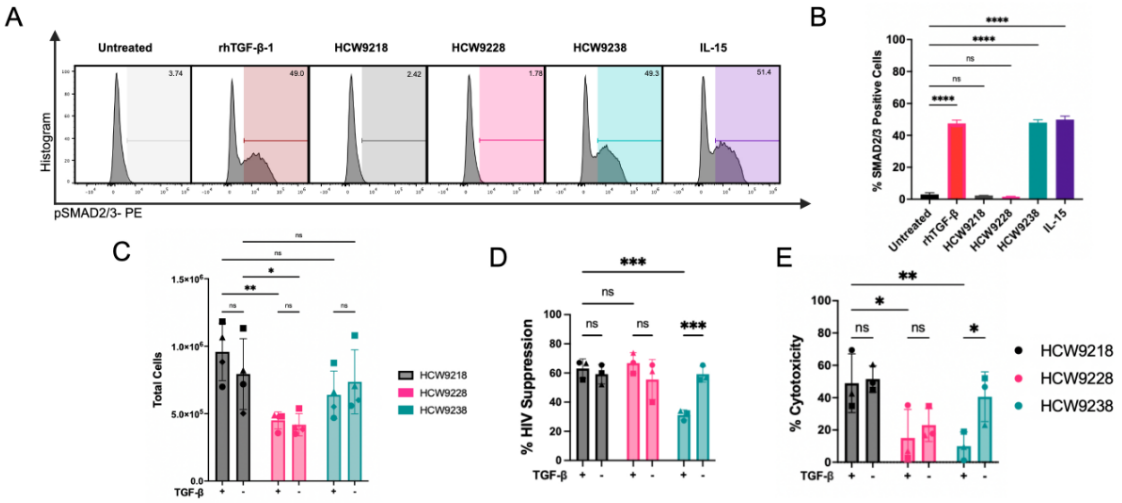

Figure 1. HCW9218 inhibits TGF-β induced suppression of duoCAR-Ts. (A) Representative histograms of flow cytometry analysis for pSMAD2/3 staining of duoCAR-T cells. **(B)** Bar graph showing % SMAD2/3 positive cells in duoCAR-T cells based off the flow cytometry plots. **(C)** CAR-T cells from 4 independent donors were cultured with 50 nM of HCW proteins, with or without 10 ng/mL TGF-β, for 5 days. **(D)** HIV suppression assay in healthy donors. CD8 CAR-T cells were generated and pre-treated with indicated HCW proteins and with and without TGF-β for 3 days. CAR-T cells were then cultured at an [E:T] of 1:60 with autologous HIV infected CD4 T cells with indicated HCW proteins or cytokines with and without TGF-β for 24 hours, n=3. **(E)** Luciferase cytotoxicity assay against 293T-gp120-Luc cells. CD4/CD8 duoCAR-T cells were generated from healthy donors and cultured at an E:T of 2:1 with 293T-gp120-Luc for 48 hours with and without 10ng/mL TGF-β supplemented in the media. Cytotoxicity was measured based on luciferase released in the supernatant upon lysis of cells, n=3. Data was analyzed by two-way ANOVA using multiple comparison. All statistical analysis was done in GraphPad Prism 9.5.0. For all significance values, * = p<0.05, ** = p<0.01, *** = p<0.001, **** = p<0.0001.

3029 AAV-Based Homeostatic Modulation for RHO-ADRP Gene Therapy

Transcriptional modulation is becoming increasingly important in various fields of gene therapy. In the context of transcriptional silencing, this can be achieved by cis-sequence mutagenesis using CRISPR/Cas9 or base editors (BE), or by trans-acting DNA-binding proteins tethered to repressor domains such as epigenetic modifiers (CRISPR inhibition, CRISPRi). In our quest for an effective treatment for rhodopsin autosomal dominant retinitis pigmentosa (RHO-ADRP) - a severe and currently untreatable retinal degeneration - we established a robust proof of principle using an unconventional approach. Specifically, we used a zinc finger (ZF) DNA-binding protein (ZF-RHO) to silence endogenous RHO expression independently of tethered repressor domains. This silencing strategy is combined with gene replacement by introducing a functional copy of RHO within the same AAV vector containing two expression cassettes. Here to ensure optimal transgene expression of both cassettes we exploited the intrinsic regulatory syntax of RHO expression itself. We recently identified a compact RHO regulatory unit (RRU) that controls RHO expression via a novel gene regulatory code (Rosa Maritato et al., 2024). The use of the regulatory lexicon of RHO enables to drive balanced expression of both the silencing (ZF6) and replacement (exogenous RHO) components. We achieved “homeostatic”, stable and therapeutically relevant gene expression levels with a well-distributed transgene expression profile across the retina, while maintaining low AAV vector doses. Our findings represent a significant advance in gene therapy for RHO-ADRP, paving the way for safer and more effective interventions for this and potentially other blinding diseases.
